where $F(u)$ and $G(v)$ are arbitrary functions. The above metric characterizes a surface which is called Liouville surface in the geometry textbooks. Therefore we have shown that a system is integrable in Class I only when the surface is a Liouville surface. The surfaces of constant curvature or the rotation surfaces are Liouville surfaces, but there are Liouville surfaces which have not constant curvature and they are not rotation surfaces.

The function $\beta(\xi, \eta)$ can be calculated from Eq. (6),

$$\frac{\partial \beta}{\partial \xi} = \frac{\partial g}{\partial \eta}, \quad \frac{\partial \beta}{\partial \eta} = \frac{\partial g}{\partial \xi},$$

then

$$\beta(\xi, \eta) = F(\xi + \eta) - G(\xi - \eta). \tag{12}$$

The potential $V(\xi, \eta)$ in Liouville coordinates is the solution of Eq. (10),

$$(F(\xi + \eta) + G(\xi - \eta))\left(\frac{\partial^2 V}{\partial \xi^2} - \frac{\partial^2 V}{\partial \eta^2}\right) + 2F'(\xi + \eta)\left(\frac{\partial V}{\partial \xi} - \frac{\partial V}{\partial \eta}\right) + 2G'(\xi - \eta)\left(\frac{\partial V}{\partial \xi} + \frac{\partial V}{\partial \eta}\right) = 0.$$

The general solution of the above equation in Liouville coordinates is

$$V(\xi, \eta) = \frac{f(\xi + \eta) + g(\xi - \eta)}{F(\xi + \eta) + G(\xi - \eta)}. \tag{13}$$

The functions $f(u)$ and $g(v)$ are arbitrary functions. The function $Q(\xi, \eta)$ is determined from Eqs. (9) and the solution is easily calculated,

$$Q(\xi, \eta) = 4\frac{f(\xi + \eta)G(\xi - \eta) - g(\xi - \eta)F(\xi + \eta)}{F(\xi + \eta) + G(\xi - \eta)}. \tag{14}$$

Usually it is more convenient to use the coordinates u, v, which are defined by

$$\xi = u + iv, \quad \eta = u - iv, \quad p_\xi = \frac{p_u - ip_v}{2}, \quad \text{and } p_\eta = \frac{p_u + ip_v}{2}.$$

The Hamiltonian H and the integral can be written as

$$H = \frac{{p_u}^2 + {p_v}^2 + 4(f(u) + g(v))}{4(F(u) + G(v))},$$

$$I = \frac{{p_u}^2 G(v) - {p_v}^2 F(u)}{F(u) + G(v)} + 4\frac{f(u)G(v) - g(v)F(u)}{F(u) + G(v)}.$$

The above formula has been investigated in a different context in Ref. 30. In these coordinates the action $S(u, v)$ satisfy the following equations:

$$E = H(u,v,p_u,p_v), \quad J = I(u,v,p_u,p_v),$$
$$p_u = \frac{\partial S}{\partial u}, \quad p_v = \frac{\partial S}{\partial v}, \tag{15}$$

and we can find the action $S(u,v)$ by separation of variables,

$$S = -Et + \int \sqrt{4EF(u) + J - 4f(u)}\,\mathrm{d}u + \int \sqrt{4EG(v) - J - 4g(v)}\,\mathrm{d}v.$$

CLass II: $B(y)=0$.

We can choose a new coordinate system

$$\xi = \int \frac{\mathrm{d}x}{\sqrt{A(x)}} \quad \text{and} \quad \eta = y$$

the associated momenta are

$$p_\xi = \sqrt{A(x)}p_x \quad \text{and} \quad p_\eta = p_y.$$

In this case the metric is written

$$\mathrm{d}s^2 = \hat{g}(\xi,\eta)\mathrm{d}\xi\,\mathrm{d}\eta, \quad \text{where } \hat{g}(\xi,\eta) = g(x,y)\sqrt{A(x)}.$$

We can easily show that the formulas are the same by replacing $x \to \xi$, $y \to \eta$ and fixing $A(x)=1$ and $B(y)=0$. For simplicity reasons we omit the hat on the metric $\hat{g}(\xi,\eta) \to g(\xi,\eta)$. Equations (2) and (3) are written

$$H = \frac{p_\xi p_\eta}{g(\xi,\eta)} + V(\xi,\eta),$$
$$I = p_\xi^2 - 2p_\xi p_\eta \frac{\beta(\xi,\eta)}{g(\xi,\eta)} + Q(\xi,\eta). \tag{16}$$

We call these specific coordinates (ξ,η) *Lie coordinates*. In Lie coordinates the Hamiltonian H *and* the integral I are written as it is given in the above equation (16). In Lie coordinates Eq. (18) is written

$$\frac{\partial^2 g}{\partial \xi^2} = 0.$$

The general solution is

$$g(\xi,\eta) = F(\eta)\xi + G(\eta),$$

where $F(\eta)$ and $G(\eta)$ are arbitrary functions. The above metric characterizes a surface which will be called Lie surface. Therefore we have shown that a system is integrable in Case 2 only when the surface is a Lie surface.

Equations (6) imply

$$\left.\begin{aligned} \frac{\partial \beta}{\partial \eta} &= \frac{\partial g}{\partial \xi} \\ \frac{\partial \beta}{\partial \xi} &= 0 \end{aligned}\right\} \Rightarrow \begin{cases} g(\xi,\eta) = F(\eta)\xi + G(\eta), \\ \beta(\xi,\eta) = \int F(\eta)\mathrm{d}\eta. \end{cases} \tag{17}$$

Equation (10) is written

$$(F(\eta)\xi + G(\eta))\frac{\partial^2 V}{\partial \xi^2} + 2F(\eta)\frac{\partial V}{\partial \xi} = 0$$

and the general solution of the above equation is

$$V(\xi,\eta) = \frac{f(\eta)\xi + g(\eta)}{F(\eta)\xi + G(\eta)}. \tag{18}$$

The functions $F(\eta)$, $G(\eta)$, $f(\eta)$, and $g(\eta)$ are arbitrary functions. In this case the solution of the system of equations (9) is given by

$$Q(\xi,\eta) = -2\frac{(f(\eta)\xi + g(\eta))\int F(\eta)\mathrm{d}\eta}{F(\eta)\xi + G(\eta)} + 2\int f(\eta)\mathrm{d}\eta. \tag{19}$$

The action integral in this case can be easily calculated,

$$S = \xi\sqrt{J - 2\left(\int f(\eta)\mathrm{d}\eta - E\int F(\eta)\mathrm{d}\eta\right)} - \int \mathrm{d}\eta \frac{g(\eta) - EG(\eta)}{\sqrt{J - 2(\int f(\eta)\mathrm{d}\eta - E\int F(\eta)\mathrm{d}\eta)}},$$

where

$$E = H(\xi,\eta,p_\xi,p_\eta), \quad J = I(\xi,\eta,p_\xi,p_\eta),$$

$$p_\xi = \frac{\partial S}{\partial \xi}, \quad p_\eta = \frac{\partial S}{\partial \eta}.$$

The integrable systems which belong in Classes I and II are well-known integrable systems (see Ref. 12) the supporting manifold is a Liouville or a Lie surface. We must notice that the Hamiltonian and the integral of an integrable system determine uniquely the Liouville (or Lie) coordinate system. Therefore the use of this privileged system is imposed by the notion of integrability. In the next sections we shall work in this special coordinate system, which is denoted exclusively by the coordinates ξ and η. In Class I integrable systems the system is separable, while in Class II systems there is no separation of variables in general.

III. POISSON ALGEBRA OF SUPERINTEGRABLE SYSTEMS WITH TWO QUADRATIC INTEGRALS OF MOTION

If a system is superintegrable on a two-dimensional manifold, that means that there are three functionally independent integrals of motion H, A, and B. In this section, we assume that these integrals of motion are quadratic functions of the momenta and there are no other integrals of motion, which are linear functions of the momenta. Regarding the Hamiltonian H and the first integral A, we can choose the Liouville coordinate system and in this system,

$$H = \frac{p_\xi p_\eta}{g(\xi,\eta)} + V(\xi,\eta).$$

As we have shown in the preceding section the system is integrable with a square integral of motion in two cases. The integral of motion A in the Liouville coordinate system is written.

$$A = p_\xi^2 + bp_\eta^2 - 2p_\xi p_\eta \frac{\sigma(\xi,\eta)}{g(\xi,\eta)} + \Theta(\xi,\eta),$$

where

$$b = \begin{cases} 1 & \text{in Class I,} \quad \text{where } g(\xi,\eta) = F(\xi+\eta) + G(\xi-\eta) \quad \text{(Liouville system)}, \\ 0 & \text{in Class II,} \quad \text{where } g(\xi,\eta) = F(\eta)\xi + G(\eta) \qquad \text{(Lie system)}. \end{cases}$$

The integral of motion B is assumed to be indeed a quadratic function of momenta, thus the general form in Liouville coordinates is

$$B = A(\xi)p_\xi^2 + B(\eta)p_\eta^2 - 2p_\xi p_\eta \frac{\beta(\xi,\eta)}{g(\xi,\eta)} + Q(\xi,\eta).$$

By definition the following relations are satisfied:

$$\{H,A\}_P = \{H,B\}_P = 0. \tag{20}$$

From the integrals of motion A and B, we can construct the integral of motion

$$C = \{A,B\}_P. \tag{21}$$

The integral of motion C is not a new independent integral of motion, which is a cubic function of the momenta. The integral C is not functionally independent from the integrals H, A, and B as it will be shown later. The fact that, the integral C is a cubic function of momenta, implies the impossibility of expressing C as a polynomial function of the other integrals, which are quadratic functions of momenta. We shall prove that the square of this cubic polynomial is indeed a cubic combination of the integrals. Starting from the integral of motion C, we can construct the (non-independent) integrals $\{A,C\}_P$ and $\{B,C\}_P$. These integrals are quartic functions of the momenta, i.e., functions of fourth order. In the Appendix we show that these integrals can be expressed as quadratic combinations of the integrals H,A, and B. Therefore the following relations are valid:

$$\{A,C\}_P = \alpha A^2 + \beta B^2 + 2\gamma AB + \delta A + \epsilon B + \zeta \tag{22}$$

and

$$\{B,C\}_P = aA^2 + bB^2 + 2cAB + \mathrm{d}A + eB + z. \tag{23}$$

By taking an appropriate rotation of the integrals A and B we can always consider the case $\beta = 0$.

The existence of the Poisson algebra (22) and (23) is not evident. The above form was assumed as obvious by several authors.[4–7,17–29] In Classical mechanics the Poisson algebra was not considered as an important point, but in quantum mechanics the existence of Poisson algebra permits the algebraic treatment of the superintegrable system.[20] In this paper we prove that the superintegrable systems can be classified using the properties of the Poisson algebra. The superintegrability is a global property of the system, and this fact is reflected in the Poisson algebra structure, which is indeed a global property. The mathematical proof of the existence of the algebra (22) and (23) for the two-dimensional superintegrable systems can be found in the Appendix.

The Jacobi equality for the Poisson brackets induces the relation

$$\{A,\{B,C\}_P\}_P = \{B,\{A,C\}_P\}_P.$$

The following relations:

$$b = -\gamma, \quad c = -\alpha, \quad \text{and } e = -\delta$$

must be satisfied.

The integrals A, B, and C satisfy the quadratic Poisson algebra,

$$\{A,B\}_P = C,$$

$$\{A,C\}_P = \alpha A^2 + 2\gamma AB + \delta A + \epsilon B + \zeta, \tag{24}$$

$$\{B,C\}_P = aA^2 - \gamma B^2 - 2\alpha AB + \mathrm{d}A - \delta B + z,$$

where α, γ, a are constants and

$$\delta = \delta(H) = \delta_0 + \delta_1 H,$$

$$\epsilon = \epsilon(H) = \epsilon_0 + \epsilon_1 H,$$

$$\zeta = \zeta(H) = \zeta_0 + \zeta_1 H + \zeta_2 H^2,$$

$$d = d(H) = d_0 + d_1 H,$$

$$z = z(H) = z_0 + z_1 H + z_2 H^2,$$

where δ_i, ϵ_i, ζ_i, d_i, and z_i are constants. The associative algebra, whose generators satisfy Eq. (24), is the general form of the closed Poisson algebra of the integrals of superintegrable systems with integrals quadratic in momenta.

The quadratic Poisson algebra (24) possess a Casimir which is a function of momenta of degree 6 and it is given by

$$K = C^2 - 2\alpha A^2 B - 2\gamma AB^2 - 2\delta AB - \epsilon B^2 - 2\zeta B + \tfrac{2}{3} aA^3 + \mathrm{d}A^2 + 2zA = k_0 + k_1 H + k_2 H^2 + k_3 H^3. \tag{25}$$

Obviously

$$\{K,A\}_P = \{K,B\}_P = \{K,C\}_P = 0.$$

Therefore the integrals of motion of a superintegrable two-dimensional system with quadratic integrals of motion close a constrained classical quadratic Poisson algebra (24), corresponding to a Casimir equal at most to a cubic function of the Hamiltonian (25)

In Ref. 5 the algebra (24) induced by the Casimir (25) can be equivalently formulated as the Poisson algebra generated by

$$C^2 = 2f(A,B,H), \quad C = \{A,B\}_P,$$

$$\{A,C\}_P = \frac{\partial f}{\partial B}, \quad \{C,B\}_P = \frac{\partial f}{\partial A},$$

where $f(A,B,H)$ is a cubic function of A, B, and H.

In the general case of a superintegrable system the integrals are not necessarily quadratic functions of the momenta, but rather polynomial functions of the momenta. The case of the systems with a quadratic and a cubic integral of motion are studied by Tsiganov.[31,32]

IV. CLASSES OF SUPERINTEGRABLE SYSTEMS ON A TWO-DIMENSIONAL MANIFOLD WITH QUADRATIC INTEGRALS OF MOTION

The main result of the preceding section is that the definition of the Casimir of the Poisson algebra, given by Eq. (25) determines uniquely the Poisson algebra. This Poisson algebra is specific for each superintegrable system, therefore it can be used for the classification of the possible superintegrable systems. Usually the proposed classifications of superintegrable systems assumed the definition of the manifold metric and the superintegrable systems were fixed for the given metric. In this paper we propose a classification which is based on the Poisson algebra. Let

us consider a superintegrable system, which is described by a Hamiltonian H and two integrals of motion A and B. The integrability of the system imposes several choices which are determined by two Classes I and II of integrable systems, as it has been shown in Sec. II. These classes of superintegrable systems are the following.

Class I: This class contains superintegrable systems, whose manifold metric and integrals of motion are written in a specific coordinate,

$$ds^2 = g(\xi,\eta)d\xi d\eta, \quad g(\xi,\eta) = F(\xi+\eta) + G(\xi-\eta), \tag{26}$$

$$H = \frac{p_\xi p_\eta}{F(\xi+\eta)+G(\xi-\eta)} + \frac{f(\xi+\eta)+g(\xi-\eta)}{F(\xi+\eta)+G(\xi-\eta)}, \tag{27}$$

and

$$A = p_\xi^2 + p_\eta^2 - 2p_\xi p_\eta \frac{F(\xi+\eta)-G(\xi-\eta)}{F(\xi+\eta)+G(\xi-\eta)} + 4\frac{f(\xi+\eta)G(\xi-\eta)-g(\xi-\eta)F(\xi+\eta)}{F(\xi+\eta)+G(\xi-\eta)}. \tag{28}$$

The second integral of motion has the general form

$$B = A(\xi)p_\xi^2 + B(\eta)p_\eta^2 - 2p_\xi p_\eta \frac{\beta(\xi,\eta)}{F(\xi+\eta)+G(\xi-\eta)} + Q(\xi,\eta), \tag{29}$$

where $A(\xi)$ and $B(\eta)$ are not zero.

Class II: This class contains superintegrable systems, whose manifold metric and integrals of motion are written in a specific coordinate,

$$ds^2 = g(\xi,\eta)d\xi d\eta, \quad g(\xi,\eta) = F(\eta)\xi + G(\eta), \tag{30}$$

$$H = \frac{p_\xi p_\eta}{F(\eta)\xi+G(\eta)} + \frac{f(\eta)\xi+g(\eta)}{F(\eta)\xi+G(\eta)}, \tag{31}$$

and

$$A = p_\xi^2 - 2p_\xi p_\eta \frac{\int F(\eta)d\eta}{F(\eta)\xi+G(\eta)} - 2\frac{(f(\eta)\xi+g(\eta))\int F(\eta)d\eta}{F(\eta)\xi+G(\eta)} + 2\int f(\eta)d\eta. \tag{32}$$

The second integral of motion has the general form

$$B = A(\xi)p_\xi^2 + B(\eta)p_\eta^2 - 2p_\xi p_\eta \frac{\beta(\xi,\eta)}{F(\eta)\xi+G(\eta)} + Q(\xi,\eta), \tag{33}$$

where $A(\xi)$ and $B(\eta)$ are not zero. The existence of a second integral of motion B implies that there is another Liouville coordinate system (X,Y) corresponding to the pair of integrals H and B. In this system there are analytic formulas for the second integral of motion. The analytic calculation of these formulas will be given in the following sections.

The Class I superintegrable system is described by the integrals of motion which are given by Eqs. (26)–(29). Correspondingly, the Class II superintegrable system is described by the integrals of motion which are given by Eqs. (30)–(33). These integrals of motion should satisfy the relation (25), which is an identity relation between polynomials of sixth degree for the momenta. The coefficients of p_ξ^6 and p_η^6 in (25) vanish and the following identities are true:

$$6(A'(\xi))^2 = 3\gamma A^2(\xi) + 3\alpha A(\xi) - a, \tag{34}$$

$$6(B'(\eta))^2 = 3\gamma B^2(\eta) + 3\alpha B(\eta) - a.$$

In Eq. (29), the coefficients of p_ξ^2 and p_η^2 in the integral B are determined by the solution of the above equations (34).

The superintegrable systems on a manifold can be classified by the possible solutions of Eqs. (34). The integral of motion A has a standard form, given by Eq. (28), this form is the Liouville form and the coefficients of p_x^2 and p_y^2 are equal to 1. The second integral of motion B can be replaced by any combination of the form

$$B \to qB + rH + sA,$$

where q,r,s are arbitrary constants. From this fact we can show that there are six subclasses of possible solutions of Eq. (34).

Subclass I_1: This class corresponds to

$$\gamma = 0, \quad \alpha = 0, \quad a \neq 0$$

if we choose $a=-6$, then

$$A(\xi) = \xi, \quad B(\eta) = \eta.$$

Subclass I_2: This class corresponds to

$$\gamma = 0, \quad \alpha \neq 0, \quad a = 0$$

if we choose $\alpha=8$, then

$$A(\xi) = \xi^2, \quad B(\eta) = \eta^2.$$

Subclass I_3: This class corresponds to

$$\gamma \neq 0, \quad \alpha = 0, \quad a \neq 0$$

if we choose $\gamma=2$, then we can show that all cases are equivalent to the choice

$$A(\xi) = (e^{\xi} + e^{-\xi})^2, \quad B(\eta) = (e^{\eta} + e^{-\eta})^2.$$

Subclass II_1: This class corresponds to

$$\gamma = 0, \quad \alpha = 0, \quad a = 0$$

then

$$A(\xi) = 1, \quad B(\eta) = 1.$$

Subclass II_2: This class corresponds to

$$\gamma = 0, \quad \alpha = 0, \quad a \neq 0$$

if we choose $a=-6$, then

$$A(\xi) = \xi, \quad B(\eta) = \eta.$$

Subclass II_3: This class corresponds to

$$\gamma = 0, \quad \alpha \neq 0, \quad a = 0$$

if we choose $\alpha=8$, then we can show that

$$A(\xi) = \xi^2, \quad B(\eta) = \eta^2.$$

These classes of solutions will be studied in detail in Sec. V.

A. Class I superintegrable systems

Starting from the definition of functions $A(\xi)$ and $B(\eta)$ we can solve Eqs. (6)–(10) and the superintegrable system is fully determined. This procedure will be sketched in detail in the next paragraphs.

Let us start by the known solutions $A(\xi)$, $B(\eta)$ of Eq. (34).

Equation (8) is written

$$(A''(\xi)-B''(\eta))(F(\xi+\eta)+G(\xi-\eta))+3A'(\xi)(F'(\xi+\eta)+G'(\xi-\eta))-3B'(\eta)(F'(\xi+\eta) - G'(\xi-\eta))+2(A(\xi)-B(\eta))(F''(\xi+\eta)+G''(\xi-\eta))=0. \tag{35}$$

In the next paragraphs we will show that, the above equation can be separated in two second order differential equations for the involved functions $F(u)$ and $G(v)$. The general solution of these equations are given by

$$\begin{aligned} F(u)&=\lambda_1F_1(u)+\lambda_2F_2(u)+\lambda_3F_3(u)+\lambda_4F_4(u),\\ G(v)&=\ell_1G_1(v)+\ell_2G_2(v)+\ell_3G_3(v)+\ell_4G_4(v), \end{aligned} \tag{36}$$

where $F_k(u)$ and $G_k(u)$ are functions which are not generally partial independent solutions of two second order differential equation (8). Between the eight parameters λ_k and ℓ_k for $k=1,2,3,4$ only four among them are independent.

After the calculation of the functions $F(u)$ and $G(v)$ we can calculate the function $\beta(x,y)$ from Eq. (6). The general form of the potential $V(\xi,\eta)$ is given by Eq. (13).

After some elementary (but rather lengthy) algebraic calculation we can show that Eq. (10) leads to a differential equation for the functions $f(u)$ and $g(v)$ which are involved in the definition (13) of the potential,

$$\begin{aligned} &f(\xi+\eta)\{-3B'(\eta)(F'(\xi+\eta)-G'(\xi-\eta))+3A'(\xi)(F'(\xi+\eta)+G'(\xi-\eta))+2(A(\xi)-B(\eta))(F''(\xi\\ &+\eta)+G''(\xi-\eta))\}+g(\xi-\eta)\{-3B'(\eta)(F'(\xi+\eta)-G'(\xi-\eta))+3A'(\xi)(F'(\xi+\eta)+G'(\xi\\ &-\eta))+2(A(\xi)-B(\eta))(F''(\xi+\eta)+G''(\xi-\eta))\}-(F(\xi+\eta)+G(\xi-\eta))\{-3B'(\eta)(f'(\xi+\eta)\\ &-g'(\xi-\eta))+3A'(\xi)(f'(\xi+\eta)+g'(\xi-\eta))+2(A(\xi)-B(\eta))(f''(\xi+\eta)+g''(\xi-\eta))\}=0. \end{aligned}$$

We can eliminate in the above equation the functions $F(u)$ and $G(v)$ which satisfy Eq. (35) and finally the functions involved in the definition of the potential satisfy the following equation:

$$(A''(\xi)-B''(\eta))(f(\xi+\eta)+g(\xi-\eta))+3A'(\xi)(g'(\xi+\eta)+g'(\xi-\eta))-3B'(\eta)(g'(\xi+\eta) - g'(\xi-\eta))+2(A(\xi)-B(\eta))(f''(\xi+\eta)+g''(\xi-\eta))=0. \tag{37}$$

This equation is indeed the same as (35) and the general solution has been given by Eq. (36). Then we have proved the following general proposition.

Proposition 1: The general form of the potential $V(\xi,\eta)$ in Liouville coordinates for a superintegrable system of Class I is given by the general formula:

$$V(\xi,\eta)=\frac{f(\xi+\eta)+g(\xi-\eta)}{F(\xi+\eta)+G(\xi-\eta)},$$

where both pairs of functions $f(u)$, $g(v)$ and $F(u)$, $G(v)$ satisfy the same differential equations (35) and (37).

Therefore the solutions of Eq. (37) are given by

$$f(u)=\rho_1F_1(u)+\rho_2F_2(u)+\rho_3F_3(u)+\rho_4F_4(u), \tag{38}$$

$$g(v) = r_1 G_1(v) + r_2 G_2(v) + r_3 G_3(v) + r_4 G_4(v).$$

The equations of motion do not depend on the shifts of the potential by one constant. This fact explains physically the identity of differential equations (35) and (37).

The calculation of the second integral of motion B is now straightforward. If the functions $A(x)$ and $B(y)$ are fixed as solutions of the characteristic equations (34) then we can introduce the new coordinates,

$$X = \int \frac{\mathrm{d}x}{\sqrt{A(x)}} \quad \text{and} \quad Y = \int \frac{\mathrm{d}y}{\sqrt{B(y)}}. \tag{39}$$

In these coordinates the metric of the manifold can be written

$$\mathrm{d}s^2 = g(x,y)\mathrm{d}x\,\mathrm{d}y = \tilde{g}(X,Y)\mathrm{d}X\,\mathrm{d}Y, \tag{40}$$

where

$$\tilde{g}(X,Y) = g(x,y)\sqrt{A(x)B(y)}$$

and

$$H = \frac{p_x p_y}{g(x,y)} + V(x,y) = \frac{p_X p_Y}{\tilde{g}(X,Y)} + \tilde{V}(X,Y).$$

The integrability of the above Hamiltonian implies

$$\tilde{g}(X,Y) = \tilde{F}(X+Y) + \tilde{G}(X-Y). \tag{41}$$

The above relation implies

$$\tilde{g}\left(\frac{U+V}{2}, \frac{U-V}{2}\right) = \tilde{F}(U) + \tilde{G}(V),$$

$$\tilde{g}\left(\frac{U+d}{2}, \frac{U-d}{2}\right) = \tilde{F}(U) + \tilde{G}(d),$$

$$\tilde{g}\left(\frac{c+V}{2}, \frac{c-V}{2}\right) = \tilde{F}(c) + \tilde{G}(V),$$

$$\tilde{g}\left(\frac{c+d}{2}, \frac{c-d}{2}\right) = \tilde{F}(c) + \tilde{G}(d),$$

where c and d are two arbitrary constants. Therefore the functions $\tilde{F}(U)$ and $\tilde{G}(V)$ are calculated up to one constant by

$$\begin{aligned} \tilde{F}(U) &= \tilde{g}\left(\frac{U+d}{2}, \frac{U-d}{2}\right) - \frac{1}{2}\tilde{g}\left(\frac{c+d}{2}, \frac{c-d}{2}\right) + \mu, \\ \tilde{G}(V) &= \tilde{g}\left(\frac{c+V}{2}, \frac{c-V}{2}\right) - \frac{1}{2}\tilde{g}\left(\frac{c+d}{2}, \frac{c-d}{2}\right) - \mu, \end{aligned} \tag{42}$$

where μ can be an arbitrary chosen constant. Starting from the well-known form of the potential

$$V(x,y)=\frac{w(x,y)}{g(x,y)},\quad w(x,y)=f(x+y)+g(x-y)$$

we can show that

$$V(x,y)=\tilde{V}(X,Y)=\frac{\tilde{w}(X,Y)}{\tilde{g}(X,Y)},$$
$$\tilde{w}(X,Y)=\tilde{f}(X+Y)+\tilde{g}(X-Y)=w(x,y)\sqrt{A(x)B(y)}. \tag{43}$$

The functions $\tilde{f}(U)$ and $\tilde{g}(V)$ are calculated by

$$\tilde{f}(U)=\tilde{w}\left(\frac{U+d}{2},\frac{U-d}{2}\right)-\frac{1}{2}\tilde{w}\left(\frac{c+d}{2},\frac{c-d}{2}\right),$$

$$\tilde{g}(V)=\tilde{w}\left(\frac{c+V}{2},\frac{c-V}{2}\right)-\frac{1}{2}\tilde{w}\left(\frac{c+d}{2},\frac{c-d}{2}\right).$$

Then the second integral of motion in the coordinates X,Y is

$$B=p_X^2+p_Y^2-2p_Xp_Y\frac{\tilde{F}(X+Y)-\tilde{G}(X-Y)}{\tilde{F}(X+Y)+\tilde{G}(X-Y)}+4\frac{\tilde{f}(X+Y)\tilde{G}(X-Y)-\tilde{g}(X-Y)\tilde{F}(X+Y)}{\tilde{F}(X+Y)+\tilde{G}(X-Y)}. \tag{44}$$

After calculating the above integral in the coordinates X,Y, we can compute analytically the second integral B in the original coordinates x,y.

B. Class II superintegrable systems

Equation (8) is written

$$(A''(x)-B''(y))(F(y)x+G(y))+3A'(x)F(y)-3B'(y)(F'(y)x+G'(y))$$
$$+2(A(x)-B(y))(F''(y)x+G''(y))=0. \tag{45}$$

The general solutions of Eq. (45) are given by

$$F(y)=\lambda_1F_1(y)+\lambda_2F_2(y)+\lambda_3F_3(y)+\lambda_4F_4(y),$$
$$G(y)=\ell_1G_1(y)+\ell_2G_2(y)+\ell_3G_3(y)+\ell_4G_4(y), \tag{46}$$

where $F_k(y)$ and $G_k(y)$ are partial independent solutions of two second order differential equations with several constant parameters. Between the eight parameters λ_k and ℓ_k for $k=1,2,3,4$ only four among them are linearly independent.

After the calculation of the functions $F(y)$ and $G(y)$ we can calculate the function $\beta(x,y)$ from Eq. (17). The general form of the potential $V(x,y)$ is given by Eq. (18). After some elementary (but rather complicated) algebraic calculation we can show that, Eq. (19) leads to a differential equation for the functions $f(y)$ and $g(y)$, which are involved in the definition (13) of the potential,

$$(A''(x)-B''(y))(f(y)x+g(y))+3A'(x)f(y)-3B'(y)(f'(y)x+g'(y))$$
$$+2(A(x)-B(y))(f''(y)x+g''(y))=0. \tag{47}$$

Then we have proved the following general proposition.

Proposition 2: The general form of the potential $V(\xi,\eta)$ in Liouville coordinates for a superintegrable system of Class II is given by the general formula

$$V(\xi,\eta)=\frac{f(\eta)\xi+g(\eta)}{F(\eta)\xi+G(\eta)},$$

where both the pairs of functions $f(u)$, $g(v)$ *and* $F(u)$, $G(v)$ *satisfy the same differential equations (45) and (47).*

Therefore the solutions of Eq. (47) are given by

$$\begin{aligned} f(y)&=\rho_1F_1(y)+\rho_2F_2(y)+\rho_3F_3(y)+\rho_4F_4(y),\\ g(y)&=r_1G_1(y)+r_2G_2(y)+r_3G_3(y)+r_4G_4(y). \end{aligned} \tag{48}$$

The equations of motion do not depend on the shifts of the potential by one constant. This fact explains physically the identity of differential equations (35) [or (45)] and (37) [or (47)].

The calculation of the second integral of motion B is now straightforward and we can use the same procedure of solution as it has been described by Eqs. (39)–(44).

V. CLASSIFICATION OF TWO-DIMENSIONAL SUPERINTEGRABLE SYSTEMS WITH TWO QUADRATIC INTEGRALS OF MOTION

In this section we give the analytical solutions for the different classes of superintegrable systems. As we have shown there are two general classes of superintegrable systems, each class has three subclasses.

A. Class I superintegrable systems

1. Subclass I_1 of superintegrable systems

We have

$$A(\xi)=\xi,\quad B(\eta)=\eta,$$

$$F(u)=4\lambda u^2+\kappa u+\nu/2,\quad G(v)=-\lambda v^2+\mu/v^2+\nu/2,$$

$$f(u)=4\ell u^2+ku+n/2,\quad g(v)=-\ell v^2+m/v^2+n/2$$

$$ds^2=(F(\xi+\eta)+G(\xi-\eta))d\xi\,d\eta,\quad H=\frac{p_\xi p_\eta+f(\xi+\eta)+g(\xi-\eta)}{F(\xi+\eta)+G(\xi-\eta)}. \tag{49}$$

The other integral of motion is

$$A=p_\xi^2+p_\eta^2-2p_\xi p_\eta\frac{F(\xi+\eta)-G(\xi-\eta)}{F(\xi+\eta)+G(\xi-\eta)}+4\frac{f(\xi+\eta)G(\xi-\eta)-g(\xi-\eta)F(\xi+\eta)}{F(\xi+\eta)+G(\xi-\eta)}.$$

We introduce the functions

$$\begin{aligned} \tilde F(u)&=\frac{\lambda u^6}{256}+\frac{\kappa u^4}{128}+\frac{\nu u^2}{16}-\frac{\mu}{u^2},\\ \tilde G(v)&=-\frac{\lambda v^6}{256}-\frac{\kappa v^4}{128}-\frac{\nu v^2}{16}+\frac{\mu}{v^2},\\ \tilde f(u)&=\frac{lu^6}{256}+\frac{ku^4}{128}+\frac{nu^2}{16}-\frac{m}{u^2}, \end{aligned} \tag{50}$$

$$\tilde{g}(v) = -\frac{lv^6}{256} - \frac{kv^4}{128} - \frac{nv^2}{16} + \frac{m}{v^2}.$$

The second integral of motion is

$$B = p_X^2 + p_Y^2 - 2p_X p_Y \frac{\tilde{F}(X+Y) - \tilde{G}(X-Y)}{\tilde{F}(X+Y) + \tilde{G}(X-Y)} + 4\frac{\tilde{f}(X+Y)\tilde{G}(X-Y) - \tilde{g}(X-Y)\tilde{F}(X+Y)}{\tilde{F}(X+Y) + \tilde{G}(X-Y)},$$

where

$$X = 2\sqrt{\xi}, \quad p_X = \sqrt{\xi}p_\xi, \quad Y = 2\sqrt{\eta}, \quad p_Y = \sqrt{\eta}p_\eta.$$

The constants of the Poisson algebra are

$$\alpha = 0, \quad \beta = 0, \quad \gamma = 0, \quad \delta = 16(\kappa H - k), \quad \epsilon = 256(\lambda H - \ell),$$

$$\zeta = -32(\kappa H - k)(\nu H - n), \quad a = -6, \quad d = 8(\nu H - n),$$

$$z = 8(\nu H - n)^2 - 128(\lambda H - \ell)(\mu H - m),$$

$$K = 32(\nu H - n)^3 + 512(\lambda H - \ell)(\mu H - m)(\nu H - n) - 64(\kappa H - k)^2(\mu H - m).$$

2. Subclass I_2 of superintegrable systems

We have

$$A(\xi) = \xi^2, \quad B(\eta) = \eta^2,$$

$$F(u) = \lambda u^2 + \frac{\kappa}{u^2} + \frac{\nu}{2}, \quad G(v) = -\lambda v^2 + \frac{\mu}{v^2} + \frac{\nu}{2},$$

$$f(u) = \ell u^2 + \frac{k}{u^2} + \frac{n}{2}, \quad g(v) = -\ell v^2 + \frac{m}{v^2} + \frac{n}{2},$$

$$\mathrm{d}s^2 = (F(\xi+\eta) + G(\xi-\eta))\mathrm{d}\xi\,\mathrm{d}\eta, \quad H = \frac{p_\xi p_\eta + f(\xi+\eta) + g(\xi-\eta)}{F(\xi+\eta) + G(\xi-\eta)}. \tag{51}$$

The other integral of motion is

$$A = p_\xi^2 + p_\eta^2 - 2p_\xi p_\eta \frac{F(\xi+\eta) - G(\xi-\eta)}{F(\xi+\eta) + G(\xi-\eta)} + 4\frac{f(\xi+\eta)G(\xi-\eta) - g(\xi-\eta)F(\xi+\eta)}{F(\xi+\eta) + G(\xi-\eta)}.$$

We introduce the functions

$$\tilde{F}(u) = 4\lambda e^{2u} + \nu e^u, \quad \tilde{G}(v) = \frac{\kappa e^v}{(1+e^v)^2} + \frac{\mu e^v}{(-1+e^v)^2},$$

$$\tilde{f}(u) = 4\ell e^{2u} + n e^u, \quad \tilde{g}(v) = \frac{k e^v}{(1+e^v)^2} + \frac{m e^v}{(-1+e^v)^2}. \tag{52}$$

The second integral of motion is

$$B = p_X^2 + p_Y^2 - 2p_X p_Y \frac{\tilde{F}(X+Y) - \tilde{G}(X-Y)}{\tilde{F}(X+Y) + \tilde{G}(X-Y)} + 4\frac{\tilde{f}(X+Y)\tilde{G}(X-Y) - \tilde{g}(X-Y)\tilde{F}(X+Y)}{\tilde{F}(X+Y) + \tilde{G}(X-Y)},$$

where

$$X = \ln \xi, \quad p_X = \xi p_\xi, \quad Y = \ln \eta, \quad p_Y = \eta p_\eta.$$

The constants of the Poisson algebra are

$$\alpha = 8, \quad \beta = 0, \quad \gamma = 0, \quad \delta = 0, \quad \epsilon = 256(\lambda H - \ell),$$

$$\zeta = -32(\nu H - n)^2 + 256(\lambda H - \ell)((\mu - \kappa)H - (m - k)),$$

$$a = 0, \quad d = 0, \quad z = 32((\kappa + \mu)H - (k + m))(\nu H - n),$$

$$K = 256(\lambda H - \ell)((\kappa + \mu)H - (k + m))^2 + 128((\kappa - \mu)H - (k - m))(\nu H - n)^2.$$

3. Subclass I_3 of superintegrable systems

We have

$$A(\xi) = (e^{\xi} + e^{-\xi})^2, \quad B(\eta) = (e^{\eta} + e^{-\eta})^2,$$

$$\begin{aligned} F(u) &= \frac{\kappa e^{2u}}{(-1 + e^{2u})^2} + \frac{\lambda e^u (1 + e^{2u})}{(-1 + e^{2u})^2}, \quad G(v) = \frac{\mu e^{2v}}{(-1 + e^{2v})^2} + \frac{\nu e^v (1 + e^{2v})}{(-1 + e^{2v})^2}, \\ f(u) &= \frac{k e^{2u}}{(-1 + e^{2u})^2} + \frac{\ell e^u (1 + e^{2u})}{(-1 + e^{2u})^2}, \quad g(v) = \frac{m e^{2v}}{(-1 + e^{2v})^2} + \frac{n e^v (1 + e^{2v})}{(-1 + e^{2v})^2}, \end{aligned} \tag{53}$$

$$\mathrm{d}s^2 = (F(\xi + \eta) + G(\xi - \eta))\mathrm{d}\xi\, \mathrm{d}\eta, \quad H = \frac{p_\xi p_\eta + f(\xi + \eta) + g(\xi - \eta)}{F(\xi + \eta) + G(\xi - \eta)}.$$

The other integral of motion is

$$A = p_\xi^2 + p_\eta^2 - 2p_\xi p_\eta \frac{F(\xi + \eta) - G(\xi - \eta)}{F(\xi + \eta) + G(\xi - \eta)} + 4\frac{f(\xi + \eta)G(\xi - \eta) - g(\xi - \eta)F(\xi + \eta)}{F(\xi + \eta) + G(\xi - \eta)}.$$

We introduce the functions

$$\begin{aligned} \tilde{F}(u) &= \frac{(\kappa + 2\lambda)}{4} \tan^2 u + \frac{2\nu - \mu}{4} \cot^2 u + \frac{\lambda + \nu}{2}, \\ \tilde{G}(v) &= \frac{(2\lambda - \kappa)}{4} \tan^2 v + \frac{\mu + 2\nu}{4} \cot^2 v + \frac{\lambda + \nu}{2}, \\ \tilde{f}(u) &= \frac{(k + 2\ell)}{4} \tan^2 u + \frac{2n - m}{4} \cot^2 u + \frac{\ell + n}{2}, \end{aligned} \tag{54}$$

$$\tilde{g}(v) = \frac{(2\ell - k)}{4} \tan^2 v + \frac{m + 2n}{4} \cot^2 v + \frac{\ell + n}{2}.$$

The second integral of motion is

$$B = p_X^2 + p_Y^2 - 2p_X p_Y \frac{\tilde{F}(X+Y) - \tilde{G}(X-Y)}{\tilde{F}(X+Y) + \tilde{G}(X-Y)} + 4\frac{\tilde{f}(X+Y)\tilde{G}(X-Y) - \tilde{g}(X-Y)\tilde{F}(X+Y)}{\tilde{F}(X+Y) + \tilde{G}(X-Y)},$$

where

$$X = \arctan(e^{\xi}), \quad p_X = (e^{\xi} + e^{-\xi})p_{\xi}, \quad Y = \arctan(e^{\eta}), \quad p_Y = (e^{\eta} + e^{-\eta})p_{\eta}.$$

The constants of the Poisson algebra are

$$\alpha = -32, \quad \beta = 0, \quad \gamma = 8, \quad \delta = 0, \quad \epsilon = 0, \quad \zeta = -32(\lambda H - \ell)(\nu H - n),$$

$$a = 0, \quad d = 64(k - m) - 64(\kappa - \mu)H,$$

$$z = 32((\lambda - \nu)H - (\ell - n))^2 - 32((\kappa H - k)(\mu H - m)\ ,$$

$$K = 64(\kappa H - k)(\nu H - n)^2 - 64(\lambda H - \ell)^2(\mu H - m).$$

B. Class II superintegrable systems

1. Subclass II_1 of superintegrable systems

We have

$$A(\xi) = 1, \quad B(\eta) = 1,$$

$$F(\eta) = \kappa\eta + \lambda, \quad G(\eta) = \mu\eta + \nu,$$

$$f(\eta) = k\eta + \ell, \quad g(\eta) = m\eta + n,$$

$$\mathrm{d}s^2 = g(\xi, \eta)\mathrm{d}\xi\,\mathrm{d}\eta, \quad g(\xi, \eta) = \xi F(\eta) + G(\eta),$$

$$H = \frac{p_{\xi}p_{\eta}}{g(\xi, \eta)} + V(\xi, \eta), \quad V(\xi, \eta) = \frac{w(\xi, \eta)}{g(\xi, \eta)}, \quad w(\xi, \eta) = \xi f(\eta) + g(\eta). \tag{55}$$

The other integral of motion is

$$A = p_{\xi}^2 - \frac{2p_{\xi}p_{\eta}\int F(\eta)\mathrm{d}\eta}{g(\xi, \eta)} - \frac{2(\xi f(\eta) + g(\eta))\int F(\eta)\mathrm{d}\eta}{g(\xi, \eta)} + 2\int f(\eta)\mathrm{d}\eta.$$

We introduce the functions

$$\tilde{F}(u) = \frac{\kappa u^2}{4} + \frac{(\lambda + \mu)u}{2} + \frac{\nu}{2},$$

$$\tilde{G}(v) = -\frac{\kappa v^2}{4} + \frac{(\lambda - \mu)v}{2} + \frac{\nu}{2},$$

$$\tilde{f}(u) = \frac{ku^2}{4} + \frac{(\ell + m)u}{2} + \frac{n}{2}, \tag{56}$$

$$\tilde{g}(v) = -\frac{kv^2}{4} + \frac{(\ell - m)v}{2} + \frac{n}{2}.$$

The second integral of motion is

$$B = p_\xi^2 + p_\eta^2 - 2p_\xi p_\eta \frac{\tilde{F}(\xi+\eta) - \tilde{G}(\xi-\eta)}{\tilde{F}(\xi+\eta) + \tilde{G}(\xi-\eta)} + 4\frac{\tilde{f}(\xi+\eta)\tilde{G}(\xi-\eta) - \tilde{g}(\xi-\eta)\tilde{F}(\xi+\eta)}{\tilde{F}(\xi+\eta) + \tilde{G}(\xi-\eta)}.$$

The constants of the Poisson algebra are

$$\alpha = 0, \quad \beta = 0, \quad \gamma = 0, \quad \delta = 8(k - \kappa H), \quad \epsilon = 0, \quad \zeta = 8(\lambda H - \ell)^2,$$

$$a = 0, \quad d = 16(k - \kappa H), \quad z = 8(\lambda H - \ell)^2 - (\mu H - m)^2,$$

$$K = 16(\nu H - n)^2(\kappa H - k) - 32(\lambda H - \ell)(\mu H - m)(\nu H - n).$$

2. Subclass $\mathbf{II_2}$ *of superintegrable systems*

We have

$$A(\xi) = \xi, \quad B(\eta) = \eta,$$

$$F(\eta) = \frac{\kappa}{\sqrt{\eta}} + \lambda, \quad G(\eta) = 3\kappa\sqrt{\eta} + \lambda\eta + \frac{\mu}{\sqrt{\eta}} + \nu,$$

$$f(\eta) = \frac{k}{\sqrt{\eta}} + \ell, \quad g(\eta) = 3k\sqrt{\eta} + \ell\eta + \frac{m}{\sqrt{\eta}} + n,$$

$$\mathrm{d}s^2 = g(\xi,\eta)\mathrm{d}\xi\,\mathrm{d}\eta, \quad g(\xi,\eta) = \xi F(\eta) + G(\eta),$$

$$H = \frac{p_\xi p_\eta}{g(\xi,\eta)} + V(\xi,\eta), \quad V(\xi,\eta) = \frac{w(\xi,\eta)}{g(\xi,\eta)}, \quad w(\xi,\eta) = \xi f(\eta) + g(\eta). \tag{57}$$

The other integral of motion is

$$A = p_\xi^2 - \frac{2p_\xi p_\eta \int F(\eta)\mathrm{d}\eta}{g(\xi,\eta)} - \frac{2(\xi f(\eta) + g(\eta)) \int F(\eta)\mathrm{d}\eta}{g(\xi,\eta)} + 2\int f(\eta)\mathrm{d}\eta.$$

We introduce the functions

$$\tilde{F}(u) = \frac{\lambda u^4}{128} + \frac{\kappa u^3}{16} + \frac{\nu u^2}{16} + \frac{\mu u}{4},$$

$$\widetilde{G}(v) = -\frac{\lambda v^4}{128} + \frac{\kappa v^3}{16} + \frac{\mu v}{4} - \frac{\nu v^2}{16},$$
$$\widetilde{f}(u) = \frac{\ell u^4}{128} + \frac{k u^3}{16} + \frac{n u^2}{16} + \frac{m u}{4}, \tag{58}$$
$$\widetilde{g}(v) = -\frac{\ell v^4}{128} + \frac{k v^3}{16} + \frac{m v}{4} - \frac{n v^2}{16}.$$

The second integral of motion is

$$B = p_X^2 + p_Y^2 - 2p_X p_Y \frac{\widetilde{F}(X+Y) - \widetilde{G}(X-Y)}{\widetilde{F}(X+Y) + \widetilde{G}(X-Y)} + 4\frac{\widetilde{f}(X+Y)\widetilde{G}(X-Y) - \widetilde{g}(X-Y)\widetilde{F}(X+Y)}{\widetilde{F}(X+Y) + \widetilde{G}(X-Y)},$$

where

$$X = 2\sqrt{\xi}, \quad p_X = \sqrt{\xi} p_\xi, \quad Y = 2\sqrt{\eta}, \quad p_Y = \sqrt{\eta} p_\eta.$$

The constants of the Poisson algebra are

$$\alpha = 0, \quad \beta = 0, \quad \gamma = 0, \quad \delta = 4(\ell - \lambda H), \quad \epsilon = 0, \quad \zeta = 8(\kappa H - k)^2,$$

$$a = -6, \quad d = 8(\nu H - n), \quad z = -8(\kappa H - k)(\mu H - m) - 2(\nu H - n)^2,$$

$$K = 8(\lambda H - \ell)(\mu H - m)^2 - 16(\kappa H - k)(\mu H - m)(\nu H - n).$$

3. Subclass II_3 of superintegrable systems

We have

$$A(\xi) = \xi^2, \quad B(\eta) = \eta^2,$$

$$F(\eta) = \lambda \eta + \frac{\kappa}{\eta^3}, \quad G(\eta) = \nu + \frac{\mu}{\eta^2},$$

$$f(\eta) = \ell \eta + \frac{k}{\eta^3}, \quad g(\eta) = n + \frac{m}{\eta^2},$$

$$\mathrm{d}s^2 = g(\xi, \eta)\mathrm{d}\xi\, \mathrm{d}\eta, \quad g(\xi, \eta) = \xi F(\eta) + G(\eta),$$

$$H = \frac{p_\xi p_\eta}{g(\xi, \eta)} + V(\xi, \eta), \quad V(\xi, \eta) = \frac{w(\xi, \eta)}{g(\xi, \eta)}, \quad w(\xi, \eta) = \xi f(\eta) + g(\eta). \tag{59}$$

The other integral of motion is

$$A = p_\xi^2 - \frac{2p_\xi p_\eta \int F(\eta)\mathrm{d}\eta}{g(\xi, \eta)} - \frac{2(\xi f(\eta) + g(\eta)) \int F(\eta)\mathrm{d}\eta}{g(\xi, \eta)} + 2\int f(\eta)\mathrm{d}\eta.$$

We introduce the functions

$$\widetilde{F}(u)=\lambda e^{2u}+\nu e^{u},\quad \widetilde{G}(v)=\kappa e^{2v}+\mu e^{v},$$
$$\widetilde{f}(u)=\ell e^{2u}+ne^{u},\quad \widetilde{g}(v)=ke^{2v}+me^{v}. \tag{60}$$

The second integral of motion is

$$B=p_X^2+p_Y^2-2p_Xp_Y\frac{\widetilde{F}(X+Y)-\widetilde{G}(X-Y)}{\widetilde{F}(X+Y)+\widetilde{G}(X-Y)}+4\frac{\widetilde{f}(X+Y)\widetilde{G}(X-Y)-\widetilde{g}(X-Y)\widetilde{F}(X+Y)}{\widetilde{F}(X+Y)+\widetilde{G}(X-Y)},$$

where

$$X=\ln\xi,\quad p_X=\xi p_\xi,\quad Y=\ln\eta,\quad p_Y=\eta p_\eta.$$

The constants of the Poisson algebra are

$$\alpha=8,\quad \beta=0,\quad \gamma=0,\quad \delta=0,\quad \epsilon=0,\quad \zeta=32(\kappa H-k)(\lambda H-\ell),$$

$$a=0,\quad d=0,\quad z=32(\mu H-m)(\nu H-n),$$

$$K=64(\lambda H-\ell)(\mu H-m)^2-64(\kappa H-k)(\nu H-n)^2.$$

All the above superintegrable systems generally are defined on manifolds which have neither constant curvature nor are they surfaces of revolution. All the known superintegrable systems are defined on manifolds of constant curvature or on surfaces of revolution. Therefore we have proved that there are new superintegrable systems, which have not yet been studied.

VI. SUPERINTEGRABLE SYSTEMS CORRESPONDING TO KOENIGS ESSENTIAL FORMS

Class I_1: Using the coordinate transformation

$$\xi=\frac{1}{2}x^2,\quad p_\xi=\frac{p_x}{x},\quad \eta=\frac{1}{2}y^2,\quad p_\eta=\frac{p_y}{y},$$

the metric of the Class I_2 superintegrable systems is reduced to the metric of the essential form VII.4 (Ref. 1, Vol. IV, p. 385), if

$$\kappa=16A_2,\quad \lambda=16A_3,\quad \mu=-A_0,\quad \nu=4A_1.$$

The corresponding superintegrable system (using the coordinates of Ref. 1) is given by the Hamiltonian,

$$H=\frac{p_xp_y+w(x,y)}{g(x,y)},$$

$$g(x,y)=A_0\left[\frac{1}{(x+y)^2}-\frac{1}{(x-y)^2}\right]+A_1[(x+y)^2-(x-y)^2]+A_2[(x+y)^4-(x-y)^4]$$
$$+A_3[(x+y)^6-(x-y)^6],$$

$$w(x,y)=a_0\left[\frac{1}{(x+y)^2}-\frac{1}{(x-y)^2}\right]+a_1[(x+y)^2-(x-y)^2]+a_2[(x+y)^4-(x-y)^4]$$
$$+a_3[(x+y)^6-(x-y)^6],$$

where only three of the constants a_0, a_1, a_2, a_3 are independent, i.e., we can set one among them

equal to zero. Using relations (50) we have that in x,y coordinates the other integral of motion is

$$A(x,y)=\frac{1}{2}p_x^2+\frac{1}{2}p_y^2-p_xp_y\frac{\tilde{\Phi}(x,y)-\tilde{\Psi}(x,y)}{\tilde{\Phi}(x,y)+\tilde{\Psi}(x,y)}+2\frac{\tilde{\phi}(x,y)\tilde{\Psi}(x,y)-\tilde{\psi}(x,y)\tilde{\Phi}(x,y)}{\tilde{\Phi}(x,y)+\tilde{\Psi}(x,y)},$$

where

$$\tilde{\Phi}(x,y)=A_0\frac{1}{(x+y)^2}+A_1(x+y)^2+A_2(x+y)^4+A_3(x+y)^6,$$

$$\tilde{\Psi}(x,y)=-A_0\frac{1}{(x-y)^2}-A_1(x-y)^2-A_2(x-y)^4-A_3(x-y)^6,$$

$$\tilde{\phi}(x,y)=a_0\frac{1}{(x+y)^2}+a_1(x+y)^2+a_2(x+y)^4+a_3(x+y)^6,$$

$$\tilde{\psi}(x,y)=-a_0\frac{1}{(x-y)^2}-a_1(x-y)^2-a_2(x-y)^4-a_3(x-y)^6,$$

while using relations (49) we have that in x,y coordinates the second integral of motion is

$$B(x,y)=\frac{1}{x^2}p_x^2+\frac{1}{y^2}p_y^2-2\frac{p_xp_y}{xy}\frac{\Phi(x,y)-\Psi(x,y)}{\Phi(x,y)+\Psi(x,y)}+4\frac{\phi(x,y)\Psi(x,y)-\psi(x,y)\Phi(x,y)}{xy\Phi(x,y)+\Psi(x,y)},$$

where

$$\begin{aligned}\Phi(x,y)=&\tfrac{1}{2}A_1[(x+y)^2-(x-y)^2]+A_2[(x+y)^4-(x-y)^4]+A_3([(x+y)^6-(x-y)^6]\\&+(x+y)^4(x-y)^2-(x+y)^2(x-y)^4),\end{aligned}$$

$$\begin{aligned}\Psi(x,y)=&A_0\left[\frac{1}{(x+y)^2}-\frac{1}{(x-y)^2}\right]+\frac{1}{2}A_1[(x+y)^2-(x-y)^2]-A_3((x+y)^4(x-y)^2\\&-(x+y)^2(x-y)^4),\end{aligned}$$

$$\begin{aligned}\phi(x,y)=&\frac{1}{2}a_1[(x+y)^2-(x-y)^2]+a_2[(x+y)^4-(x-y)^4]+a_3([(x+y)^6-(x-y)^6]\\&+(x+y)^4(x-y)^2-(x+y)^2(x-y)^4),\end{aligned}$$

$$\psi(x,y)=a_0\left[\frac{1}{(x+y)^2}-\frac{1}{(x-y)^2}\right]+\frac{1}{2}a_1[(x+y)^2-(x-y)^2]-a_3((x+y)^4(x-y)^2-(x+y)^2(x-y)^4).$$

Class I_2: Using the coordinate transformation

$$\xi=-\tfrac{1}{2}\cos(2x),\quad p_\xi=\frac{p_x}{\sin(2x)},\quad \eta=-\tfrac{1}{2}\cos(2y),\quad p_\eta=\frac{p_y}{\sin(2y)},$$

the metric of the Class I_2 superintegrable systems is reduced to the metric of the essential form VII.4 (Ref. 1, Vol. IV, p. 385), if

$$\kappa = A_1, \quad \lambda = -8A_3, \quad \mu = -A_0, \quad \nu = -2A_2.$$

The corresponding superintegrable system (using the coordinates of Ref. 1) is given by the Hamiltonian,

$$H = \frac{p_x p_y + w(x,y)}{g(x,y)},$$

where

$$g(x,y) = A_0\left[\frac{1}{\sin^2(x+y)} - \frac{1}{\sin^2(x-y)}\right] + A_1\left[\frac{1}{\cos^2(x+y)} - \frac{1}{\cos^2(x-y)}\right] + A_2[\cos 2(x+y) - \cos 2(x-y)] + A_3[\cos 4(x+y) - \cos 4(x-y)],$$

$$w(x,y) = a_0\left[\frac{1}{\sin^2(x+y)} - \frac{1}{\sin^2(x-y)}\right] + a_1\left[\frac{1}{\cos^2(x+y)} - \frac{1}{\cos^2(x-y)}\right] + a_2[\cos 2(x+y) - \cos 2(x-y)] + a_3[\cos 4(x+y) - \cos 4(x-y)],$$

where only three of the constants a_0, a_1, a_2, a_3 are independent, i.e., we can set one among them equal to zero. Using Relations (52) we have that in x, y coordinates the other integral of motion is

$$A(x,y) = \frac{1}{4}\cot^2(2x)p_x^2 + \frac{1}{4}\cot^2(2y)p_y^2 - \frac{p_x p_y}{2\tan(2x)\tan(2y)}\frac{\tilde{\Phi}(x,y) - \tilde{\Psi}(x,y)}{\tilde{\Phi}(x,y) + \tilde{\Psi}(x,y)} + \frac{1}{\tan(2x)\tan(2y)}\frac{\tilde{\phi}(x,y)\tilde{\Psi}(x,y) - \tilde{\psi}(x,y)\tilde{\Phi}(x,y)}{\tilde{\Phi}(x,y) + \tilde{\Psi}(x,y)},$$

where

$$\tilde{\Phi}(x,y) = A_2[\cos 2(x+y) - \cos 2(x-y)] + A_3[\cos 4(x+y) - \cos 4(x-y)],$$

$$\tilde{\Psi}(x,y) = A_0\left[\frac{1}{\sin^2(x+y)} - \frac{1}{\sin^2(x-y)}\right] + A_1\left[\frac{1}{\cos^2(x+y)} - \frac{1}{\cos^2(x-y)}\right],$$

$$\tilde{\phi}(x,y) = a_2[\cos 2(x+y) - \cos 2(x-y)] + a_3[\cos 4(x+y) - \cos 4(x-y)],$$

$$\tilde{\psi}(x,y) = a_0\left[\frac{1}{\sin^2(x+y)} - \frac{1}{\sin^2(x-y)}\right] + a_1\left[\frac{1}{\cos^2(x+y)} - \frac{1}{\cos^2(x-y)}\right]$$

while using relations (51) we have that in x, y coordinates the second integral of motion is

$$B(x,y) = \frac{1}{\sin^2(2x)}p_x^2 + \frac{1}{\sin^2(2y)}p_y^2 - 2\frac{p_x p_y}{2\sin(2x)\sin(2y)}\frac{\Phi(x,y) - \Psi(x,y)}{\Phi(x,y) + \Psi(x,y)} + 4\frac{1}{\sin(2x)\sin(2y)}\frac{\phi(x,y)\Psi(x,y) - \psi(x,y)\Phi(x,y)}{\Phi(x,y) + \Psi(x,y)},$$

where

$$\Phi(x,y) = A_1\left[\frac{1}{\cos^2(x+y)} - \frac{1}{\cos^2(x-y)}\right] + \frac{1}{2}A_2[\cos 2(x+y) - \cos 2(x-y)] + 4A_3\cos^2(x+y)\cos^2(x-y)[\cos 2(x+y) - \cos 2(x-y)],$$

$$\Psi(x,y) = A_0\left[\frac{1}{\sin^2(x+y)} - \frac{1}{\sin^2(x-y)}\right] + \frac{1}{2}A_2[\cos 2(x+y) - \cos 2(x-y)]$$
$$- 4A_3 \sin^2(x+y)\sin^2(x-y)[\cos 2(x+y) - \cos 2(x-y)],$$

$$\phi(x,y) = a_1\left[\frac{1}{\cos^2(x+y)} - \frac{1}{\cos^2(x-y)}\right] + \frac{1}{2}a_2[\cos 2(x+y) - \cos 2(x-y)]$$
$$+ 4a_3 \cos^2(x+y)\cos^2(x-y)[\cos 2(x+y) - \cos 2(x-y)],$$

$$\psi(x,y) = a_0\left[\frac{1}{\sin^2(x+y)} - \frac{1}{\sin^2(x-y)}\right] + \frac{1}{2}a_2[\cos 2(x+y) - \cos 2(x-y)]$$
$$- 4a_3 \sin^2(x+y)\sin^2(x-y)[\cos 2(x+y) - \cos 2(x-y)].$$

Class I_3: Using the coordinate transformation,

$$\xi = \ln\left(\frac{\frac{\wp(x)-\wp(\omega_1)}{\Delta} - 1}{\frac{\wp(x)-\wp(\omega_1)}{\Delta} + 1}\right) + \frac{1}{2}\ln\left(\frac{\frac{\wp(\omega_1)-\wp(\omega_2)}{\Delta} - 1}{\frac{\wp(\omega_1)-\wp(\omega_2)}{\Delta} + 1}\right), \quad p_\xi = \frac{\wp(2x)-\wp(\omega_1)}{2\Delta}p_x,$$

$$\eta = \ln\left(\frac{\frac{\wp(y)-\wp(\omega_1)}{\Delta} - 1}{\frac{\wp(xy)-\wp(\omega_1)}{\Delta} + 1}\right) + \frac{1}{2}\ln\left(\frac{\frac{\wp(\omega_1)-\wp(\omega_2)}{\Delta} - 1}{\frac{\wp(\omega_1)-\wp(\omega_2)}{\Delta} + 1}\right), \quad p_\eta = \frac{\wp(2y)-\wp(\omega_1)}{2\Delta}p_y,$$

where

$$\Delta^2 = (\wp(\omega_1) - \wp(\omega_2))(\wp(\omega_1) - \wp(\omega_3)),$$

the metric of the Class I_3 superintegrable systems is reduced to the metric of the essential form VII.1 (Ref. 1, Vol. IV, p. 385) if

$$\kappa = 2(A_2 + A_3), \quad \lambda = A_2 - A_3, \quad \mu = -2(A_0 + A_1), \quad \nu = -A_0 + A_1.$$

The corresponding superintegrable system (using the coordinates of Ref. 1) is given by the Hamiltonian,

$$H = \frac{p_x p_y + w(x,y)}{g(x,y)},$$

where

$$g(x,y) = A_0(\wp(x+y) - \wp(x-y)) + A_1(\wp(x+y+\omega_1) - \wp(x-y+\omega_1))$$
$$+ A_2(\wp(x+y+\omega_2) - \wp(x-y+\omega_2)) + A_3(\wp(x+y+\omega_3) - \wp(x-y+\omega_3)),$$

$$w(x,y) = a_0(\wp(x+y) - \wp(x-y)) + a_1(\wp(x+y+\omega_1) - \wp(x-y+\omega_1))$$
$$+ a_2(\wp(x+y+\omega_2) - \wp(x-y+\omega_2)) + a_3(\wp(x+y+\omega_3) - \wp(x-y+\omega_3)),$$

where only three of the constants a_0, a_1, a_2, a_3 are independent, i.e., we can set one among them equal to zero. Using relations (53) we have that in x, y coordinates the other integral of motion is

$$A(x,y)=\frac{1}{4\Delta^2}(\wp(2x)-\wp(\omega_1))p_x^2+\frac{1}{4\Delta^2}(\wp(2y)-\wp(\omega_1))p_y^2$$
$$-\frac{\sqrt{\wp(2x)-\wp(\omega_1)}\sqrt{\wp(2y)-\wp(\omega_1)}p_xp_y}{2\Delta^2}\frac{\Phi(x,y)-\Psi(x,y)}{\Phi(x,y)+\Psi(x,y)}$$
$$+\frac{\sqrt{\wp(2x)-\wp(\omega_1)}\sqrt{\wp(2y)-\wp(\omega_1)}}{\Delta^2}\frac{\phi(x,y)\Psi(x,y)-\psi(x,y)\Phi(x,y)}{\Phi(x,y)+\Psi(x,y)},$$

where

$$\Phi(x,y)=A_2(\wp(x+y+\omega_2)-\wp(x-y+\omega_2))+A_3(\wp(x+y+\omega_3)-\wp(x-y+\omega_3)),$$

$$\Psi(x,y)=A_0(\wp(x+y)-\wp(x-y))+A_1(\wp(x+y+\omega_1)-\wp(x-y+\omega_1)),$$

$$\phi(x,y)=a_2(\wp(x+y+\omega_2)-\wp(x-y+\omega_2))+a_3(\wp(x+y+\omega_3)-\wp(x-y+\omega_3)),$$

$$\psi(x,y)=a_0(\wp(x+y)-\wp(x-y))+a_1(\wp(x+y+\omega_1)-\wp(x-y+\omega_1))$$

while using relations (54) we have that in x, y coordinates the second integral of motion is

$$B(x,y)=\frac{1}{(\wp(\omega_3)-\wp(\omega_1))(\wp(\omega_2)-\wp(\omega_3))}(\wp(2x)-\wp(\omega_3))p_x^2$$
$$+\frac{1}{(\wp(\omega_3)-\wp(\omega_1))(\wp(\omega_2)-\wp(\omega_3))}(\wp(2y)-\wp(\omega_3))p_y^2$$
$$-2\frac{\sqrt{\wp(2x)-\wp(\omega_3)}\sqrt{\wp(2y)-\wp(\omega_3)}p_xp_y}{(\wp(\omega_3)-\wp(\omega_1))(\wp(\omega_2)-\wp(\omega_3))}\frac{\tilde{\Phi}(x,y)-\tilde{\Psi}(x,y)}{\tilde{\Phi}(x,y)+\tilde{\Psi}(x,y)}$$
$$+4\frac{\sqrt{\wp(2x)-\wp(\omega_3)}\sqrt{\wp(2y)-\wp(\omega_3)}}{(\wp(\omega_3)-\wp(\omega_1))(\wp(\omega_2)-\wp(\omega_3))}\frac{\tilde{\phi}(x,y)\tilde{\Psi}(x,y)-\tilde{\psi}(x,y)\Phi(x,y)}{\tilde{\Phi}(x,y)+\tilde{\Psi}(x,y)},$$

where

$$\tilde{\Phi}(x,y)=A_1(\wp(x+y+\omega_1)-\wp(x-y+\omega_1))+A_2(\wp(x+y+\omega_2)-\wp(x-y+\omega_2))$$
$$-\frac{1}{2}(A_0+A_1+A_2+A_3)\frac{\sqrt{\wp(2x)-\wp(\omega_3)}\sqrt{\wp(2y)-\wp(\omega_3)}}{(\wp(\omega_3)-\wp(\omega_1))(\wp(\omega_2)-\wp(\omega_3))},$$

$$\tilde{\Psi}(x,y)=A_0(\wp(x+y)-\wp(x-y))+A_3(\wp(x+y+\omega_3)-\wp(x-y+\omega_3))$$
$$+\frac{1}{2}(A_0+A_1+A_2+A_3)\frac{\sqrt{\wp(2x)-\wp(\omega_3)}\sqrt{\wp(2y)-\wp(\omega_3)}}{(\wp(\omega_3)-\wp(\omega_1))(\wp(\omega_2)-\wp(\omega_3))},$$

$$\tilde{\phi}(x,y)=a_1(\wp(x+y+\omega_1)-\wp(x-y+\omega_1))+a_2(\wp(x+y+\omega_2)-\wp(x-y+\omega_2))$$
$$-\frac{1}{2}(a_0+a_1+a_2+a_3)\frac{\sqrt{\wp(2x)-\wp(\omega_3)}\sqrt{\wp(2y)-\wp(\omega_3)}}{(\wp(\omega_3)-\wp(\omega_1))(\wp(\omega_2)-\wp(\omega_3))},$$

$$\tilde{\psi}(x,y) = a_0(\wp(x+y) - \wp(x-y)) + a_3(\wp(x+y+\omega_3) - \wp(x-y+\omega_3)) + \frac{1}{2}(a_0 + a_1 + a_2 + a_3)\frac{\sqrt{\wp(2x) - \wp(\omega_3)}\sqrt{\wp(2y) - \wp(\omega_3)}}{(\wp(\omega_3) - \wp(\omega_1))(\wp(\omega_2) - \wp(\omega_3))}.$$

Class II_1: This case is not covered by Table VII of Koenigs (Ref. 1, Vol. IV, p. 385). This class corresponds to the Kress[16] equivalence class [0,11] of the nondegenerate superintegrable systems E_{11}, E_{20} of Ref. 6.

The Hamiltonian is

$$H = \frac{p_\xi p_\eta + k\xi\eta + \ell\xi + m\eta + n}{\kappa\xi\eta + \lambda\xi + \mu\eta + \nu},$$

the integrals of motion are

$$A = p_\xi^2 - 2p_\xi p_\eta \frac{\frac{\kappa}{2}\eta^2 + \lambda\eta}{\kappa\xi\eta + \lambda\xi + \mu\eta + \nu} + 2\left(\frac{k\eta^2}{2} + \ell\eta\right) - 2\frac{\left(\frac{\kappa}{2}\eta^2 + \lambda\eta\right)(k\xi\eta + \ell\xi + m\eta + n)}{\kappa\xi\eta + \lambda\xi + \mu\eta + \nu},$$

$$B = p_\xi^2 + p_\eta^2 - 2p_\xi p_\eta \frac{\frac{\kappa}{2}(\xi^2 + \eta^2) + \lambda\eta + \mu\xi}{\kappa\xi\eta + \lambda\xi + \mu\eta + \nu} + 2\left(\frac{k}{2}(\xi^2 + \eta^2) + \ell\eta + m\xi\right) - 2\frac{\left(\frac{\kappa}{2}(\xi^2 + \eta^2) + \lambda\eta + \mu\xi\right)(k\xi\eta + \ell\xi + m\eta + n)}{\kappa\xi\eta + \lambda\xi + \mu\eta + \nu}.$$

The case VI_6 in Table VI (Ref. 1 Vol. IV, p. 384) of Koenigs studied separately the cases where $\kappa=0$ and $\kappa\neq 0$, $\lambda=\mu=0$.

Class II_2: Using the coordinate transformation,

$$\xi = \frac{1}{2}x^2, \quad p_\xi = \frac{p_x}{x}, \quad \eta = \frac{1}{2}y^2, \quad p_\eta = \frac{p_y}{y},$$

the metric of the Class II_2 superintegrable systems is reduced to the metric of the essential form VII.5 (Ref. 1 Vol. IV, p. 385) if

$$\kappa = 2\sqrt{2}A_1, \quad \lambda = 16A_0, \quad \mu = \sqrt{2}A_3, \quad \nu = 4A_2.$$

The corresponding superintegrable system (using the coordinates of Ref. 1) is given by the Hamiltonian

$$H = \frac{p_x p_y + w(x,y)}{g(x,y)},$$

where

$$g(x,y) = A_0[(x+y)^4 - (x-y)^4] + A_1[(x+y)^3 - (x-y)^3] + A_2[(x+y)^2 - (x-y)^2] + A_3[(x+y) - (x-y)],$$

$$w(x,y) = a_0[(x+y)^4 - (x-y)^4] + a_1[(x+y)^3 - (x-y)^3] + a_2[(x+y)^2 - (x-y)^2] + a_3[(x+y) - (x-y)],$$

where only three of the constants a_0, a_1, a_2, a_3 are independent, i.e., we can set one among them

equal to zero. Using relations (58) we have that in x, y coordinates the other integral of motion is

$$A(x,y)=\frac{1}{2}p_x^2+\frac{1}{2}p_y^2-p_xp_y\frac{\tilde{\Phi}(x,y)-\tilde{\Psi}(x,y)}{\tilde{\Phi}(x,y)+\tilde{\Psi}(x,y)}+2\frac{\tilde{\phi}(x,y)\tilde{\Psi}(x,y)-\tilde{\psi}\tilde{\Phi}(x,y)}{\tilde{\Phi}(x,y)+\tilde{\Psi}(x,y)},$$

where

$$\tilde{\Phi}(x,y)=A_0(x+y)^4+A_1(x+y)^3+A_2(x+y)^2+A_3(x+y),$$

$$\tilde{\Psi}(x,y)=-A_0(x-y)^4-A_1(x-y)^3-A_2(x-y)^2-A_3(x-y),$$

$$\tilde{\phi}(x,y)=a_0(x+y)^4+a_1(x+y)^3+a_2(x+y)^2+a_3(x+y),$$

$$\tilde{\psi}(x,y)=-a_0(x-y)^4-a_1(x-y)^3-a_2(x-y)^2-a_3(x-y),$$

while using relations (57) we have that in x, y coordinates the second integral of motion is

$$B(x,y)=\frac{1}{\sin^2(2y)}p_y^2-2\frac{p_xp_y}{g(x,y)}\int\Phi(x)\mathrm{d}x-2\frac{w(x,y)}{g(x,y)}\int\Phi(x)\mathrm{d}x+2\phi(x)\mathrm{d}x,$$

where

$$\Phi(x)=16A_0x+4A_1,\phi(x)=16a_0x+4a_1.$$

Class II$_3$: Using the coordinate transformation the metric of the Class II$_3$ superintegrable systems is reduced to the metric of the essential form VII.3 (Ref. 1, Vol. IV, p. 385), if

$$\kappa=2(A_1+iA_0),\quad \lambda=2(iA_0-A_1),\quad \mu=-\tfrac{1}{2}(A_3+iA_2),\quad \nu=\tfrac{1}{2}(A_3-iA_2),$$

where

$$\begin{aligned}g(x,y)=&A_0[\sin 4(x+y)-\sin 4(x-y)]+A_1[\cos 4(x+y)-\cos 4(x-y)]\\&+A_2[\sin 2(x+y)-\sin 2(x-y)]+A_3[\cos 2(x+y)-\sin 2(x-y)],\end{aligned}$$

$$\begin{aligned}w(x,y)=&a_0[\sin 4(x+y)-\sin 4(x-y)]+a_1[\cos 4(x+y)-\cos 4(x-y)]\\&+a_2[\sin 2(x+y)-\sin 2(x-y)]+a_3[\cos 2(x+y)-\sin 2(x-y)],\end{aligned}$$

where only three of the constants a_0, a_1, a_2, a_3 are independent, i.e., we can set one among them equal to zero. Using relations (60) we have that in x, y coordinates the other integral of motion is

$$\begin{aligned}A(x,y)=&-\frac{1}{4}p_x^2+\frac{1}{4}\cot^2(2y)p_y^2+\frac{p_xp_y}{2i\tan(2y)}\frac{\tilde{\Phi}(x,y)-\tilde{\Psi}(x,y)}{\tilde{\Phi}(x,y)+\tilde{\Psi}(x,y)}\\&-\frac{1}{2i\tan(2y)}\frac{\tilde{\phi}(x,y)\tilde{\Psi}(x,y)-\tilde{\psi}(x,y)\tilde{\Phi}(x,y)}{\tilde{\Phi}(x,y)+\tilde{\Psi}(x,y)},\end{aligned}$$

where

$$\tilde{\Phi}(x,y)=(A_0+iA_1)e^{4ix}\sin(4y)+(A_2+iA_3)e^{2ix}\sin(2y),$$

$$\tilde{\Psi}(x,y)=(A_0-iA_1)e^{-4ix}\sin(4y)+(A_2-iA_3)e^{-2ix}\sin(2y),$$

TABLE I. Essential forms of Table VII in Ref. 1 and equivalence classes of Ref. 16.

Class	κ	λ	μ	ν	Essential from Ref. 1	Classes from Ref. 16
I_1	$16A_2$	$16A_3$	$-A_0$	$4A_1$	VII.4	[3, 2]
I_2	A_1	$-8A_3$	$-A_0$	$-2A_2$	VII.2	[21, 2]
I_3	$2(A_2+A_3)$	A_2-A_3	$-2(A_0+A_1)$	$-A_0+A_1$	VII.1	[111, 1]
II_1						[0, 11]
II_2	$2\sqrt{2}A_1$	$16A_0$	$\sqrt{2}A_3$	$4A_2$	VII.5	[3, 11]
II_3	$2(A_1+iA_0)$	$2(iA_0-A_1)$	$-\frac{1}{2}(A_3+iA_2)$	$\frac{1}{2}(A_3-iA_2)$	VII.3	[21, 0]

$$\tilde{\phi}(x,y) = (a_0 + ia_1)e^{4ix}\sin(4y) + (a_2 + ia_3)e^{2ix}\sin(2y),$$

$$\tilde{\psi}(x,y) = (a_0 - ia_1)e^{-4ix}\sin(4y) + (a_2 - ia_3)e^{-2ix}\sin(2y),$$

while using relations (59) we have that in x, y coordinates the second integral of motion is

$$B(x,y) = \frac{1}{y^2}p_y^2 - 2\frac{p_x p_y}{g(x,y)}\int \Phi(x)\mathrm{d}x - 2\frac{w(x,y)}{g(x,y)}\int \Phi(x)dx + \int \phi(x)\mathrm{d}x,$$

where

$$\Phi(x,y) = -8A_0\cos(4x) + 8A_1\sin(4x),$$

$$\phi(x,y) = -8a_0\cos(4x) + 8a_1\sin(4x).$$

(Also see Table I.)

VII. SUPERINTEGRABLE POTENTIALS ON A SURFACE OF REVOLUTION WITH TWO QUADRATIC INTEGRALS OF MOTION

A manifold which is described by a metric of the form

$$\mathrm{d}s^2 = g(x+y)\mathrm{d}x\,\mathrm{d}y \quad \text{or } \mathrm{d}s^2 = g(x-y)\mathrm{d}x\,\mathrm{d}y$$

is called a surface of revolution.

The above condition is possible only for a specific choice of the parameters κ, λ, μ, and ν. In many cases the superintegrable systems can be calculated by using the general forms which are studied in Sec. V. The general forms of these systems by revolution in many instances are given by the formulas

$$H = \frac{p_\xi p_\eta + f(\xi+\eta) + g(\xi-\eta)}{F(\xi+\eta)} \quad \text{or } H = \frac{p_\xi p_\eta + f(\xi+\eta) + g(\xi-\eta)}{G(\xi-\eta)}$$

and

$$H = \frac{p_X p_Y + \tilde{f}(X+Y) + \tilde{g}(X-Y)}{\tilde{F}(X+Y)} \quad \text{or } H = \frac{p_X p_Y + \tilde{f}(X+Y) + \tilde{g}(X-Y)}{\tilde{G}(X-Y)}.$$

But we must notice that the Liouville or the Lie coordinates are not always the appropriate ones for concluding whether a surface is a surface by revolution. Among the parameters κ, λ, μ, and ν the surfaces of revolution are determined by two independent parameters. In Table II these special values of the parameters κ, λ, μ, and ν are shown. We notice the corresponding potentials given in Refs. 13 and 12. This classification scheme shows that there is the case R_{11} which is not given

TABLE II. Potentials by revolution with two quadratic integrals of motion, (u,v) and (ϕ,ω) are the coordinates, used Ref. 13.

	Class	κ	λ	μ	ν	Potentials from Ref. 13	Potentials from Ref. 12	ξ	η

R_{13}		$-\mu$	0		0	3[C]		$\frac{v-u}{\sqrt{uv}}$	$\frac{2}{\sqrt{uv}}$

in the above references and it is a new not known superintegrable system. A detailed description of the superintegrable systems R_1 R_{11}.

R_1: *Class* I_1 $\kappa=0$, $\lambda=0$: The form of the Hamiltonian in Liouville coordinates is given by

$$H=\frac{p_\eta p_\xi}{\nu+\dfrac{\mu}{(\xi-\eta)^2}}+\frac{k(\eta+\xi)+4\ell(\eta+\xi)^2-\ell(\xi-\eta)^2+\dfrac{m}{(\xi-\eta)^2}+n}{\nu+\dfrac{\mu}{(\xi-\eta)^2}}.$$

By the coordinate transformation

$$\xi=\frac{v+iu}{2},\quad \eta=\frac{v-iu}{2},\quad p_\xi=p_v-ip_u,\quad p_\eta=pv+ip_u$$

and setting $\mu=-1$, $\nu=1$, the Hamiltonian 2[A] of Ref. 13 is obtained

$$H=\frac{u^2}{u^2+1}\left(p_u^2+p_v^2+kv+4\ell\left(\frac{1}{4}u^2+v^2\right)-\frac{m+n}{u^2}\right)+n.$$

R_{11}: *Class* II_2 $\kappa=0$, $\mu=0$: The form of the Hamiltonian in Liouville coordinates is given by

$$H=\frac{p_\eta p_\xi}{\lambda(\eta+\xi)+\nu}+\frac{n+\dfrac{m+\ell\sqrt{\eta}(\eta+\xi)+k(3\eta+\xi)}{\sqrt{\eta}}}{\lambda(\eta+\xi)+\nu}$$

by the coordinate transformation

$$\xi = u + iv, \quad \eta = u - iv, \quad p_\xi = \tfrac{1}{2}(p_u - ip_v), \quad p_\eta = \tfrac{1}{2}(p_u + ip_v)$$

and setting $\lambda = \frac{1}{2}$, $\nu = 0$, we have

$$H = \frac{p_u^2 + p_v^2}{4u} + \frac{m + (n + 2\ell u)\sqrt{u - iv} + k(4u - 2iv)}{u\sqrt{u - iv}}.$$

For this Hamiltonian the additional integrals of motion have the form

$$A = -\frac{i}{2}X_1 - \frac{K^2}{2} - \frac{2\sqrt{u - iv}\left(\frac{m}{2} + \frac{n\sqrt{u - iv}}{2} - ikv\right)}{u},$$

$$B = X_2 - \frac{2v\left(m\left(iu + \frac{v}{2}\right) + v\left(\frac{n\sqrt{u - iv}}{2} - ikv\right)\right)}{u\sqrt{u - iv}},$$

where K, X_1, X_2 are the three integrals of the free motion of Ref. 12,

$$K = p_v, \quad X_1 = p_u p_v - \frac{v}{2u}(p_u^2 + p_v^2), \quad \text{and } X_2 = p_v(vp_u - up_v) - \frac{v^2}{4u}(p_u^2 + p_v^2).$$

This system was not included in Ref. 12. Therefore it is a new superintegrable system, which is studied here for the first time as far as we know.

VIII. SUPERINTEGRABLE POTENTIALS ON A MANIFOLD WITH CURVATURE ZERO

Let us consider the manifold corresponding to the metric in the Liouville coordinates;

$$ds^2 = g(\xi, \eta)d\xi\, d\eta,$$

the curvature is defined by

$$K = -\frac{1}{2g}\frac{\partial^2}{\partial\xi\partial\eta}\ln g = 0. \tag{61}$$

The above constraint imposes restrictions on the choice of the parameters κ, λ, μ, and ν. In Tables III and IV we can see the possible choices of the values of the above parameters.

In this category there are three families of potentials.

The potentials on the complex E plane corresponding to the Hamiltonian,

$$H = p_x^2 + p_y^2 + V(x,y);$$

these potentials are classified in Ref. 5 and finally the final list of potentials are given in Ref. 6. In this section we follow the enumeration of the potentials given by this exhaustive list.[6]

The Drach potentials corresponding to the Hamiltonian,

$$H = p_x p_y + V(x,y);$$

these potentials are classified in Ref. 8. In this section we follow the enumeration of this reference for the Drach potentials with quadratic integrals of motion.

The potentials on the real hyperbolic plane H_2 corresponding to the Hamiltonian,

$$H = p_x^2 - p_y^2 + V(x,y);$$

these potentials are classified in Ref. 9.

F_8	II_3	0	0			E_8	$x+iy$	$x-iy$
F_9		0	0			E_7	$\frac{1}{2}(x+iy)$	$\frac{x-iy-\sqrt{(x-iy)^2+16\mu\nu}}{4\nu}$
F_{10}				0	0	E_{17}	$2\sqrt{x-iy}$	$2\sqrt{x+iy}$
F_{11}				0	0	E_{19}	$2\sqrt{x+iy}$	$\sqrt{x-iy+\sqrt{(x-iy)^2-4}}$

Generally the condition (61) restricts the choices of the constants κ, λ, μ, and ν in one independent parameter. These values characterize the permitted metrics in the classification given in Sec. V.

IX. SUPERINTEGRABLE POTENTIALS ON A MANIFOLD WITH CONSTANT CURVATURE

Let us consider the manifold corresponding to the metric in the Liouville coordinates:

$$ds^2 = g(\xi,\eta)d\xi\, d\eta,$$

the curvature is defined by

$$K = -\frac{1}{2g}\frac{\partial^2}{\partial\xi\partial\eta}\ln g = \text{const}. \tag{62}$$

The above constraint imposes restrictions on the choice of the parameters κ, λ, μ, and ν. In Tables V and VI we can see the possible choices of the values of the above parameters.

X. SUPERINTEGRABLE SYSTEMS WITH A LINEAR AND A QUADRATIC INTEGRAL

In the case of a linear integral of motion and a quadratic integral of motion, there is a Liouville coordinate system where the Hamiltonian and the linear integral of motion are written as

$$I=(p_\xi+p_\eta)^2 \quad \text{or } A=(p_\xi-p_\eta)^2$$

and

$$H=\frac{p_\xi p_\eta}{G(\xi-\eta)}+\frac{g(\xi-\eta)}{G(\xi-\eta)} \quad \text{or } H=\frac{p_\xi p_\eta}{F(\xi+\eta)}+\frac{f(\xi+\eta)}{F(\xi+\eta)}.$$

From the forms of the integral of motion, which are given in Sec. V we can find all the possible subclasses corresponding to a linear and quadratic integral of motion in Liouville coordinates. In all the above cases we remark that the potential depends on two parameters among the k, ℓ, m, and n. In Table VII we give the possible cases of superintegrable systems with a linear and a quadratic integral of motion.

In Table VIII, the possible superintegrable systems which are defined on a surface of revolution with a linear and a quadratic integral of motion are listed.

In Table IX, the possible superintegrable systems which are defined on a surface of zero curvature with a linear and a quadratic integral of motion are listed.

In Table X, the possible superintegrable systems which are defined on a surface of constant curvature with a linear and a quadratic integral of motion are listed.

XI. DISCUSSION

The findings of this paper are summarized as follows:

(1) The superintegrable systems with quadratic integrals of motion can be classified in six subclasses. Each subclass depends on seven parameters. Four among these parameters (κ, λ, μ, and ν) determine the metric of the manifold, on which the system is determined. These parameters are characteristic of the system's "kinetic" energy. The remaining three parameters define the potential (the potential depends on four parameters k, ℓ, m, and n but only three among them are independent). For each subclass, the analytic explicit forms of the

manifold metric, the potential and the integrals of motion are calculated. Also the constants of the quadratic Poisson algebra of integrals of motion are given as functions of the energy and the eight parameters are given.

(2) All the known two-dimensional superintegrable systems are systems defined on surfaces of constant curvature or on surfaces of revolution. All these systems are classified in these six classes. Each class is characterized by the values of four parameters κ, λ, μ, and ν, which are determined by the form of the assumed manifold. If we fix the manifold, let us suppose that the manifold is a manifold with negative constant curvature, the possible values of the parameters κ, λ, μ, and ν are calculated for each subclass. Therefore we can "guess" the existence of the permitted superintegrable systems and to classify these systems in tables. Using this technique we can classify all the possible known superintegrable systems and to investigate the possible missing potentials. With this method a new superintegrable system was found for the class I superintegrable systems by revolution, given in Ref. 5.

(3) Generally for any values of the parameters κ, λ, μ, and ν the associated manifolds are neither surfaces of constant curvature nor surfaces of revolution. Therefore we have investigated superintegrable systems, which are not yet known. We believe that all the possible superintegrable systems with two quadratic integrals of motion are investigated.

(4) The two-dimensional nondegenerate[5] superintegrable systems are classified by the values of the constants of the Darboux equations[9,5] and the constants of the system. The relation of these constants with the constants of the quadratic Poisson algebra is explained.

(5) The six classes of superintegrable systems are the equivalence classes of Stäckel equivalent systems.

From the above discussion several open problems arise.

(i) The superintegrable systems for the case of cubic integrals of motion are under investigation.[8,31–36] The general structure of these systems is recently investigated[14] but the general form and their classification is not yet known for manifolds which carry integrable systems with one third order integral of motion.

(ii) The quantum counterparts of the general six subclasses of superintegrable systems with quadratic integrals of motion are not yet known. In Sec. II, the separation of variables of these systems has been explicitly written. The form of the separation of Schrödinger equation can be written in a Liouville coordinate system. The solutions of the quantum Schröedinger equation can be calculated. This work is under current investigation. The form of the Poisson algebra can be generalized in a quadratic associative algebra, whose energy eigenvalues are generally calculated by using deformed oscillator techniques.[18–22] From the form of the Poisson algebra, one can guess that the energy eigenvalues of these quantum systems are roots of cubic polynomials.

(iii) The general form of the three-dimensional superintegrable systems with quadratic integrals of motion is not yet known. The Poisson algebras and the associated quantum counterparts for the three-dimensional superintegrable systems are not yet fully studied. Recently[37,38] the quantum quadratic algebras have been written down, which are not generally closed as polynomial algebras. A systematic calculation of energy eigenvalues with algebraic methods has not been performed yet.

Kress for their valuable comments and for indicating the substantial Refs. 14–16, which treat the problem of the classification from the point of view of equivalence classes of Stäckel transform. This paper is part of a project supported by PYTHAGORAS II/80897.

APPENDIX: POLYNOMIAL COMBINATIONS OF INTEGRALS

Let consider a superintegrable system with two quadratic integrals of motion. The general forms of the Hamiltonian and the integrals of motion in Liouville coordinates are

$$H = \frac{p_\xi p_\eta}{g(\xi,\eta)} + V(\xi,\eta),$$

$$A = p_\xi^2 + k p_\eta^2 - 2c(\xi,\eta)\frac{p_\xi p_\eta}{g(\xi,\eta)} + q(\xi,\eta), \quad k = 0 \text{ or } 1, \tag{A1}$$

$$B = a^2(\xi)p_\xi^2 + b^2(\eta)p_\eta^2 - 2\beta(\xi,\eta)\frac{p_\xi p_\eta}{g(\xi,\eta)} + Q(\xi,\eta).$$

In this Appendix we consider that the system has quadratic integrals of motion. We assume that the system has not any linear integral of motion. That assumption excludes the system $H=p_x^2+p_y^2$, because it possesses two linear integrals of motion. In this Appendix, we shall prove the following proposition.

Proposition 3: Let M be an integral of motion, which is a polynomial function of the momenta of even order. We assume that this integral contains only monomials of momenta of even order, i.e.,

$$M = \sum_{k+\ell=even}^{2n} \alpha_{k,\ell}(\xi,\eta) p_\xi^k p_\eta^\ell. \tag{A2}$$

Then M is a polynomial of order n of the integrals H,A,B.

The existence of three integrals of motion implies that the integral M is functionally dependent integral, i.e., there is some smooth function Φ (nongenerally a polynomial one) such that

$$\Phi(M,A,B,H) = 0 \quad \text{or } M = f(A,B,H)$$

but the function $f(A,B,H)$ is not evident that it is a polynomial one. From (A1) we can see that

$$p_\xi^2 = \frac{\begin{vmatrix} A + 2cH - q - 2cV & k \\ B + 2\beta H - Q - 2\beta V & b^2(\xi,\eta) \end{vmatrix}}{\begin{vmatrix} 1 & k \\ a^2(\xi,\eta) & b^2(\xi,\eta) \end{vmatrix}},$$

$$p_\eta^2 = \frac{\begin{vmatrix} 1 & A + 2cH - q - 2cV \\ a^2(\xi,\eta) & B + 2\beta H - Q - 2\beta V \end{vmatrix}}{\begin{vmatrix} 1 & k \\ a^2(\xi,\eta) & b^2(\xi,\eta) \end{vmatrix}},$$

$$p_\xi p_\eta = gH - V.$$

The above equations imply that the momentum monomials $p_\xi^k p_\eta^\ell$ inside the sum sign in (A2) can be written as polynomials of the integrals A,B,H with coefficients, which depend on ξ and η. Therefore the integral of motion M is written

$$M = \sum_{0 \le i+j+k \le n} c_{ijk}(\xi,\eta) A^i B^j H^k.$$

Generally the coefficients c_{ijk} should be constants not depending on the variables ξ,η. If these functions are nonconstant functions $c_{ijk}(\xi,\eta)$ then we choose a fixed value of these parameters ξ_0,η_0. In general there is an infinity of trajectories passing through these position values ξ_0,η_0. Each trajectory is characterized by a special value of the integrals H,A,B, therefore M is a polynomial of fixed constants for an infinity of trajectories. For another pair of parameters ξ_1,η_1 we have another choice of the coefficients in (A2) therefore there is a relation of the form

$$\sum_{0 \le i+j+k \le n} (c_{ijk}(\xi_1,\eta_1) - c_{ijk}(\xi_0,\eta_0)) A^i B^j H^k = 0.$$

The above relations mean that the integrals of motion H,A,B are not functionally independent functions, that is a contradiction to assumption initial regarding the independence of the integrals. Therefore we have proved that the polynomial expansion (A2) of the integral M is indeed unique, when M is an even polynomial of the momenta.

A direct application of Proposition 3 is the following Proposition.

Proposition 4: Let a superintegrable two-dimensional system have even quadratic integrals of motion H,A,B. If we set $C=\{A,B\}$. The integrals $\{A,C\}$ and $\{B,C\}$ can written as quadratic polynomials of the integrals. The integral C^2 is a cubic polynomial of the integrals H,A,B.

The above proposition was taken as a conjecture in the previous work.[18–25] Here we prove that this assumption is indeed true. A generalization of Proposition 4 is indeed true for superintegrable two-dimensional systems with an integral, which is an odd cubic polynomial in momenta.[32,31] This Proposition means that the superintegrable two-dimensional systems with even quadratic integrals

correspond to a quadratic Poisson algebra, which is characteristic for the superintegrable system. The situation in three-dimensional superintegrable systems is not yet clear.[37,38] Recently this problem is studied in complex flat spaces.[39]

(Received 5 October 2005; accepted 15 March 2006; published online 28 April 2006)

This paper considers systems subject to nonholonomic constraints which are not uniform on the whole configuration manifold. When the constraints change, the system undergoes a transition in order to comply with the new imposed conditions. Building on previous work on the Hamiltonian theory of impact, we tackle the problem of mathematically describing the classes of transitions that can occur. We propose a comprehensive formulation of the transition principle that encompasses the various impulsive regimes of Hamiltonian systems. Our formulation is based on the partial symplectic formalism, which provides a suitable framework for the dynamics of nonholonomic systems. We pay special attention to mechanical systems and illustrate the results with several examples. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2192974]

I. INTRODUCTION

In this paper we consider the problem of mathematically describing impulsive motions (impacts, collisions, reflection, refractions) of Hamiltonian systems subject to nonholonomic constraints. An impulsive behavior takes place when one or more of the basic ingredients of the Hamiltonian dynamical picture undergoes a drastic change. As an example, one may consider the instant of time when the configuration space of the system collapses instantaneously because of an inelastic collision. Another example is given by a ray of light that splits into reflected and refracted rays when passing from one optical media to another, and so on. In situations like these, the phase trajectory of the system becomes discontinuous and the problem of how to describe this discontinuity arises.

The problem of describing impulsive motion has been extensively studied in classical books such as Refs. 2, 29, 31, 32, and 36. In these references, the emphasis is put on the analysis of mechanical systems subject to impulsive forces, and in particular, the study of rigid body collisions by means of Newton and Poisson laws of impact. Impulsive nonholonomic constraints (i.e., constraints whose reaction force is impulsive) are also considered in Refs. 14, 30, 36, and 42, and, from a geometric perspective, in more recent works such as Refs. 13, 20, 23, and 33. If impulsive constraints and impulsive forces are present at the same time, Newton and Poisson approaches have been revealed to be physically inconsistent in certain cases.[8,38] This surprising consequence of the impact laws is only present when the velocity along the impact surface stops or reverses during collision due to the friction. Energetically consistent hypothesis for rigid body collisions with slip and friction are proposed in Refs. 37 and 38. From a design point of view, the interest in systems subject to impulsive forces is linked to the emergence of nonsmooth and hybrid dynamical systems in control theory, i.e., systems where continuous and discrete dynamics coexist, see

Refs. 7–9 and 40 and references therein. Hybrid mechanical systems that locomote by switching between different constraint regimes and are subject to elastic impacts are studied in Ref. 10. Hyperimpulsive control of mechanical systems is analyzed in Ref. 19.

Here, we aim at a comprehensive analysis of the various situations which can occur concerning impulsive regimes of nonholonomic Hamiltonian systems. In particular, we focus on two different but complementary cases. The first one deals with a drastic change in the nonholonomic constraints imposed on the system. The second one concerns a drastic change of the Hamiltonian function and includes, in particular, collisions and impacts of nonholonomic systems. The proposed solution is given in terms of a generalized version of the *transition principle*. This principle, sketched for the first time in a series of lectures of the second author[6] for discontinuous Hamiltonians, was recently extended to other nonconstrained situations in Refs. 34 and 35 (see also Ref. 17 for a related discussion in an optimal control setting). By its very nature, the transition principle is a direct dynamic interpretation of the geometric data of the problem. This feature distinguishes it from other approaches. For instance, in classical mechanics, the velocity jumps caused by an impact are traditionally derived from some assumptions on the nature of the impulsive forces (see, for instance, Refs. 2 and 24). However, these assumptions are not logical consequences of the fundamental dynamical principles and therefore one should really consider them as additional principles for impulsive problems. The distinguishing feature of the transition principle is that it gives full credit to the geometry of the nonholonomic Hamiltonian system. This seems reasonable for the impulsive regime, keeping in mind the adequacy of the Hamiltonian description to the dynamical behavior of the system in the absence of impulsive motions. In addition, there are some noticeable advantages deriving from the transition principle. First of all, its application gives an exact and direct description of the post-impact state which is of immediate use for both theoretical and computational purposes. Second, it is still valid in some situations where standard methods can hardly be applied. In particular, this is the case of Hamiltonian systems describing the propagation of singularities of solutions of partial differential equations (consider, for instance, the example of geometrical optics).[26,27,41] Clearly, no variational or traditional approach can be applied to this very important class of systems.

A second contribution of this paper concerns the formulation of the dynamics of nonholonomic Hamiltonian systems. We make use of the notion of partial symplectic structures introduced in Ref. 6 and relate this framework with other modern approaches to nonholonomic systems (see Refs. 3–5, 15, 22, 18, 28, and 39 and references therein). One advantage of the partial symplectic formalism is that it allows us to draw clear analogies between the unconstrained and constrained situations. Another advantage is that the treatment of nonlinear constraints can be easily incorporated.

The paper is organized as follows. Section II introduces some geometric preliminaries on distributions, constraint submanifolds and partial symplectic structures. In Sec. III we show how any nonholonomic Hamiltonian system possesses an associated partial symplectic structure, and we use this fact to intrinsically formulate the dynamics. We also analyze systems with instantaneous nonholonomic constraints and systems exhibiting discontinuities. In Sec. IV, we develop a new formulation of the transition principle for systems with constraints. We present the novel notion of focusing points with respect to a constraint submanifold and we also introduce the concept of constrained characteristic. Decisive points are defined for each impulsive regime resorting to in, out, and trapping points. Section V presents a detailed study of the concepts introduced in the preceding sections in the case of mechanical systems. We compute the focusing points and the characteristic curves, and present various results concerning the decisive points. We also prove an appropriate version for generalized constraints of the classical Carnot's theorem for systems subject to impulsive forces: if the constraints are linear, we show that the transition principle always implies a loss of energy. We conclude this section by showing that if the constraints are integrable, then our formulation of the transition principle recovers the solution for completely inelastic collisions.[35] Section VI presents various examples of the application of the above-developed theory. Finally, Sec. VII presents our conclusions and directions for future research.

To ease the exposition, below we make use of the standard notation concerning differential geometry and the Hamiltonian formalism without making explicit reference to any work. In particular, we denote by Λ^i [respectively, $D(M)$] the $C^\infty(M)$-module of ith order differential forms (respectively, of vector fields) on a manifold M. We use $F^*(\varphi)$ to denote the pullback with respect to a smooth map F of a function or differential form φ. If x is a point of M, then the subscript x refers to the value of the corresponding geometric object at x. For instance, X_x stands for the vector field vector $X \in D(M)$ evaluated at x. The interested reader may consult classical books such as Refs. 1, 21, and 25 for further reference. We also assume smoothness of all the objects we are dealing with.

II. PRELIMINARIES

In this paper we deal with Hamiltonian systems defined on the cotangent bundle T^*M of an n-dimensional manifold M. In the particular case of a mechanical system, M and T^*M are, respectively, the configuration space and the phase space of the system. As usual, $\pi_M: T^*M \to M$ (or simply π) stands for the canonical projection from T^*M to M, $H \in C^\infty(T^*M)$ for the Hamiltonian function and $X_H \in D(M)$ for the corresponding Hamiltonian vector field. The canonical symplectic structure on T^*M is denoted by $\Omega = \Omega_M$. In canonical coordinates (q^a, p_a), $a = 1, \ldots, n$ of T^*M, the symplectic form reads $\Omega = \mathrm{d}q^a \wedge \mathrm{d}p_a$.

We say that the Hamiltonian system (M,H) *comes from a Lagrangian system* (M,L) *on* TM if $H = (\mathcal{L}_L^*)^{-1}(E_L)$, where $E_L \in C^\infty(TM)$ is the energy function corresponding to the (hyper-regular) Lagrangian function $L \in C^\infty(TM)$ and $\mathcal{L}_L: TM \to T^*M$ is the associated Legendre map.

If X is a vector field on T^*M, then the map $\alpha_X: T^*M \to TM$ defined by

$$\alpha_X(\theta) = d_\theta \pi(X_\theta) \in T_{\pi(\theta)}, \quad \theta \in T^*M,$$

denotes the *anti-Legendre map associated with* X. In standard coordinates, if $X = A^a(q,p)(\partial/\partial q^a) + B^a(q,p)(\partial/\partial p_a)$, then α_X reads $\alpha_X(q^a, p_a) = (q^a, A^a(q,p))$. For the Hamiltonian vector field $X = X_H$, we write α_H instead of α_{X_H}, so that

$$\alpha_H: (q,p) \mapsto \left(q, v = \frac{\partial H}{\partial p}\right).$$

It is not difficult to see that if the Hamiltonian system (M,H) comes from a Lagrangian system (M,L), then $\alpha_H = \mathcal{L}_L^{-1}$.

A. Distributions and codistributions

Recall that a *distribution* (respectively, *codistribution*) on a manifold M is a vector subbundle of TM (respectively, of T^*M). The *annihilator* of a distribution $\mathcal{D}$ on M is the codistribution $\mathrm{Ann}(\mathcal{D})$ defined by

$$\mathrm{Ann}(\mathcal{D})_x = \{\theta \in T_x^*M \,|\, \theta(\xi) = 0, \ \forall\ \xi \in \mathcal{D}_x\}, \quad x \in M.$$

If $\mathcal{D}$ is $(n-m)$-dimensional, the codistribution $\mathrm{Ann}(\mathcal{D})$ is m-dimensional. The *dual bundle* $\mathcal{D}^*$ *of* $\mathcal{D}$ is canonically identified with the cotangent bundle T^*M modulo $\mathrm{Ann}(\mathcal{D})$. We will also denote by $\mathcal{D}^\perp$ the orthogonal complement of a distribution $\mathcal{D}$ on T^*M with respect to the symplectic form Ω, i.e.,

$$\mathcal{D}_y^\perp = \{\xi \in T_y(T^*M) \,|\, \Omega_y(\xi, \eta) = 0, \ \forall\ \eta \in \mathcal{D}_y\}, \quad y \in T^*M.$$

A vector field $X \in D(M)$ *belongs* to $\mathcal{D}$ if $X_x \in \mathcal{D}_x$ for all $x \in M$. Vector fields belonging to $\mathcal{D}$ constitute a $C^\infty(M)$-module, denoted by $D_{\mathcal{D}}(M)$, which is a submodule of $D(M)$. In the partial symplectic formalism (see Sec. II C below), they are interpreted as "constrained" vector fields. Dually, denote by $\Lambda^1_{\mathcal{D}}(M)$ the $C^\infty(M)$-module of sections of the bundle $\mathcal{D}^*$ and by $\Lambda^i_{\mathcal{D}}(M)$ its ith

exterior product. These are interpreted as "constrained" differential i-forms. We denote the natural restriction map from $\Lambda^i(M)$ to $\Lambda^i_{\mathcal{D}}(M)$ by $r_{\mathcal{D}}$: $\Lambda^i(M)\to\Lambda^i_{\mathcal{D}}(M)$.

The geometric description of nonholonomic systems in the framework of the partial symplectic formalism[6] requires a slight "affine" generalization of these standard notions. Namely, an *affine distribution* on a manifold M is an affine subbundle Δ of TM. This means that the fiber Δ_x of Δ over $x\in M$ is an affine subspace in T_xM. Therefore, Δ_x can be represented in the form $\Delta_x=v+\Delta^0_x$ with $v\in T_xM$ and Δ^0_x being the vector subspace of T_xM canonically associated with Δ_x. In this representation, the *displacement vector* v is unique modulo Δ^0_x. The union $\cup_{x\in M}\Delta^0_x$ constitutes a linear distribution of the tangent bundle TM, denoted by Δ^0, canonically associated with Δ. It is not difficult to see that there always exist a vector field $Y\in D(M)$ such that Y_x is a displacement vector for Δ_x. Such vector fields are called *displacement vector fields of* Δ. Obviously, displacement vector fields differ by another vector field belonging to Δ. In coordinate terms, an $(n-m)$-dimensional affine codistribution is described by a system of linear equations $\Phi_i=0$ with respect to the variables p_a, i.e., $\Phi_i(q,p)=\Phi_{ia}(q)p_a+\Phi_{i0}(q)$, $i=1,\ldots,m$.

Similarly, an *affine codistribution* on M is an affine subbundle $C\subset T^*M$ of the cotangent bundle. As above, one has $C=\Upsilon+C^0$, where C^0 is the unique codistribution on M canonically associated with C, and $\Upsilon\in\Lambda^1(M)$ is a *displacement form*. Point-wisely this means that $C_x=\Upsilon_x+C^0_x$, for all $x\in M$.

1. Linear constraints

In the case of linear constraints, the analogy between free and constrained systems is particularly clear. In fact, it is natural to interpret an affine distribution (respectively, codistribution) on a manifold M as the "constrained" tangent (respectively, cotangent) bundle of M. A linearly constrained Hamiltonian system is then a triple (M,H,C), with $H\in C^\infty(T^*M)$ and C an affine codistribution on M. Similarly, a triple (M,L,Δ), with $L\in C^\infty(TM)$ and Δ an affine distribution on M, is a linearly constrained Lagrangian system. The anti-Legendre map allows one to pass from a constrained Hamiltonian system to the corresponding Lagrangian system and vice versa. More precisely, if (M,H,C) is a linearly constrained Hamiltonian system, the map α_H is linear and (M,H) comes from a Lagrangian system (M,L), then the corresponding linearly constrained Lagrangian system is (M,L,Δ), with $\Delta=\alpha_H(C)$. To go in the opposite direction, one must use the Legendre map $\mathcal{L}_L$ instead of α_H.

Throughout the paper, we distinguish the class of mechanical systems subject to linear constraints because of two reasons. First, classically they have been intensively studied. Second, one can extract from them the motivations for the basic constructions which will be discussed below.

2. Nonlinear constraints

In the Hamiltonian setting, the *nonholonomic constraints* are given by a submanifold (not necessarily a vector subbundle) $C\subset T^*M$. Similarly, *nonholonomic Lagrangian or kinematic constraints* are given by a submanifold $C'\subset TM$. If the Hamiltonian system (M,H) comes from a Lagrangian system (M,L), then $C=\mathcal{L}_L(C')$ if and only if $C'=\alpha_H(C)$. In mechanics, these two approaches correspond to two possible descriptions of nonholonomic constraints: either as limitations imposed on the momenta or as limitations imposed on the velocities, respectively. The fact that C (respectively, C') represents limitations imposed only on the momenta (respectively, velocities), but not on the configurations of the system, implies that the projection π must send C (respectively, C') surjectivity onto M. However, the assumption of "infinitesimal surjectivity" of $\pi|_C$ is more adequate in this context. This means that $\pi|_C$ is a *submersion*, i.e., $d_y(\pi|_C)$: $T_yC\to T_{\pi(y)}M$ is surjective for all $y\in C$. With this motivation, we adopt the following definition.

Definition 2.1: A set of nonholonomic constraints *imposed on a Hamiltonian system* (M,H) *is a submanifold* $C\subset T^*M$ *such that* $\pi|_C$ *is a submersion. The constrained Hamiltonian system is denoted by* (M,H,C).

Since C and $\alpha_H(C)$ are, respectively, interpreted as the constrained cotangent and tangent bundle of the system (M,H,C), we will always assume that they have equal dimensions. It is

worth stressing that the above definition also makes sense for manifolds with boundary. In such a case, the boundary of T^*M is $\pi^{-1}(\partial M)$ and the boundary of C is $\partial C = C \cap \pi^{-1}(\partial M)$.

Remark 2.2: Similarly, *nonholonomic Lagrangian constraints* are represented by submanifolds of TM that project regularly onto M.

In what follows, $\Phi_i(q,p)=0$, $i=1,\ldots,m$, will denote a set of local equations defining C. For a point $x \in M$, we denote by C_x the fiber of C at x,

$$C_x = C \cap T^*_x M = \{y \in C | \pi(y) = x\} = (\pi_{|C})^{-1}(x).$$

3. Instantaneous nonholonomic constraints

Let N be a hypersurface in M. Consider the induced hypersurface $T^*_N M = \pi^{-1}(N)$ of T^*M. Let $C \subset T^*M$ be a set of nonholonomic constraints on M. Instantaneous constraints may be thought as limitations on the momenta (respectively, velocities) of the system that are imposed only at the instant when a trajectory passes through a point of N. Therefore, they are represented by a submanifold C^{inst} of $C \cap T^*_N M$. These constraints are assumed to be additional to the ones already prescribed by C. In order to admit an adequate mechanical interpretation, we also assume that the projection π restricted to C^{inst} is a submersion onto N. From the Lagrangian point of view, instantaneous kinematic constraints are naturally interpreted as a submanifold $C^{\text{inst}'}$ of TN. Based on these considerations, we take the following definition.

Definition 2.3: Let (M,H,C) *be a constrained Hamiltonian system and let N be a hypersurface of M. A set of* instantaneous constraints along *N imposed on* (M,H,C) *is a submanifold* C^{inst} *of* $C \cap T^*_N M$ *such that* π *restricted to* C^{inst} *is a submersion onto N.*

It is worth stressing that, in some cases, a set of instantaneous constraints along N additionally verifies the condition $C^{\text{inst}} \subset \alpha_H^{-1}(TN)$ (here TN is thought to be naturally embedded into TM). In an inelastic scenario, where the nonholonomic motion in M is forced to take place in N after the impact, this latter condition formalizes the parity between the Hamiltonian and Lagrangian approaches: if the Hamiltonian system in question comes from a Lagrangian one, then $C^{\text{inst}} = \mathcal{L}_L(C^{\text{inst}'})$, with $C^{\text{inst}'}$ being the instantaneous kinematic constraints.

B. Dynamics of Hamiltonian systems

As is well known, in the absence of constraints, the dynamics of the Hamiltonian system (M,H) is given by the Hamiltonian vector field X_H, whose coordinate description is

$$\frac{\mathrm{d}q^a}{\mathrm{d}t} = \frac{\partial H}{\partial p_a}, \quad \frac{\mathrm{d}p_a}{\mathrm{d}t} = -\frac{\partial H}{\partial q^a}, \quad a = 1, \ldots, n.$$

In the presence of constraints, the "free" Hamiltonian vector field X_H must be modified along the constraint manifold C in order to become tangent to C. In the traditional approach this goal is achieved by adding to X_H another vector field along C, say, R, interpreted as the *reaction of constraints*. From a purely geometrical point of view, the choice of a vector field that makes X_H tangent to C is far from being unique. Therefore, a new principle must be invoked to select the one that merits being called the "reaction of constraints." The history of this problem (see, for instance, Ref. 30) shows that its solution is not straightforward. By applying, for instance, the Lagrange-d'Alembert principle (see Refs. 4, 15, and 30), one gets the following equations of motion:

$$\frac{\mathrm{d}q^a}{\mathrm{d}t} = \frac{\partial H}{\partial p_a}, \quad \frac{\mathrm{d}p_a}{\mathrm{d}t} = -\frac{\partial H}{\partial q^a} + \lambda_i \frac{\partial \Phi_i}{\partial p_a}, \quad \Phi_i(q^a, p_a) = 0,$$

$a=1,\ldots,n$, $i=1,\ldots,m$, where the "Lagrange multipliers" λ_i's are to be duly determined. Shortcomings of such an approach are that it is not manifestly intrinsic and does not reveal clearly the geometric background of the situation. This is why in our further exposition we shall follow a purely geometric approach, which does not require any discussion of reactions of constraints. It is

based on the concept of *partial symplectic formalism*, which also appears to be more concise from an algorithmic point of view.

C. Partial symplectic structures

The following elementary facts from linear algebra will be most useful. Let V be a vector space, $W\subset V$ a subspace and $b:V\times V\to\mathbb{R}$ a bilinear form on V. Denote by $W_b^\perp$ the b-orthogonal complement of W,

$$W_b^\perp=\{v\in V|b(v,w)=0,\ \forall\, w\in W\}.$$

Note that $W\cap W_b^\perp=0$ if and only if the restriction $b|_W$ of b to W is nondegenerate. The form b is said to be *nondegenerate* on an affine subspace U of V, $U=p_0+W$, $p_0\in V$, if it is nondegenerate on its associated vector space W. In such a case, U can be uniquely represented in the form $U=p_1+W$ with $p_1\in W_b^\perp$ due to the fact that $U\cap W_b^\perp=\{p_1\}$. The vector p_1 is called the *canonical displacement* of U with respect to b. Consider the associated map

$$\mathsf{T}_{W,b}:W\to W^*,\quad \mathsf{T}_{W,b}(w)=b(w,\cdot),\quad w\in W.$$

In other words, $\mathsf{T}_{W,b}(w)(w')=b(w,w')$, for all $w'\in W$. Obviously, $\mathsf{T}_{W,b}$ is an isomorphism if and only if $b|_W$ is nondegenerate.

If b is skew-symmetric and nondegenerate on V, and W is a subspace of V with codimension one, then the kernel of the restricted form $b|_W$, $\ker\, b|_W$ is a one-dimensional subspace, i.e., a *line* in V contained in W. Therefore, $\ker\, b|_W=W_b^\perp$.

Let now Δ be an affine distribution on a manifold Q. A form $\omega\in\Lambda^2(Q)$ is called *nondegenerate* on Δ if $b=\omega_x$ is nondegenerate on $U=\Delta_x$, for all $x\in Q$. In such a case, there exists a unique vector field $Y\in D(Q)$ such that Y_x is the canonical displacement of Δ_x with respect to ω_x, for all $x\in Q$. The vector field $Y=Y_{\Delta,\omega}$ is called the *canonical displacement* of Δ with respect to ω. If $\omega\in\Lambda^2(Q)$ is nondegenerate on Δ, then one has the isomorphism of vector bundles

$$\gamma=\gamma_{\Delta^0,\omega}:\Delta^{0*}\to\Delta^0,\quad \gamma_x=-(\mathsf{T}_{\Delta^0_x,\omega_x})^{-1}:\Delta^{0*}_x\to\Delta^0_x.$$

Passing to sections of these bundles, one gets the isomorphism of $C^\infty(Q)$-modules $\Gamma_{\Delta^0,\omega}:\Lambda^1_{\Delta^0}(Q)\to D_{\Delta^0}(Q)$ defined by

$$\Gamma=\Gamma_{\Delta^0,\omega}(\varrho)(x)=\gamma(\varrho(x)),\quad \varrho\in\Lambda^1_{\Delta^0}(Q). \tag{1}$$

Definition 2.4: A partial symplectic structure *on a manifold Q is a pair (Δ,ω) consisting of an affine distribution Δ on Q and a closed 2-form $\omega\in\Lambda^2(Q)$ which is nondegenerate on Δ.*

Given a partial symplectic structure $\Theta=(\Delta,\omega)$, we will use the subscript Θ to denote the associated objects: $\Delta_\Theta=\Delta$, $\omega_\Theta=\omega$, $Y_\Theta=Y_{\Delta,\omega}$, and Δ^0_Θ for the distribution canonically associated to Δ. We also write

$$r_\Theta=r_{\Delta^0_\Theta},\quad D_\Theta=D_{\Delta^0_\Theta}(Q),\quad \Lambda^1_\Theta=\Lambda^1_{\Delta^0_\Theta}(Q),\quad \Gamma_\Theta=\Gamma_{\Delta^0_\Theta,\omega}:\Lambda^1_\Theta\to D_\Theta.$$

In the partial symplectic formalism, the elements of $C^\infty(Q)$-modules D_Θ and Λ^1_Θ may be viewed as "constrained" vector fields and differential forms, respectively. The *constrained Hamiltonian vector field* associated with a Hamiltonian function $H\in C^\infty(Q)$ is defined as

$$X^\Theta_H=\Gamma_\Theta(r_\Theta(dH))+Y_\Theta. \tag{2}$$

The *almost-Poisson* bracket associated to the partial symplectic structure Θ is

$$\{f,g\}_\Theta=\Gamma_\Theta(r_\Theta(df))(g)=X^\Theta_f-Y_\Theta(g),\quad f,g\in C^\infty(Q).$$

The wording "almost" here refers to the fact that this bracket does not satisfy in general the Jacobi identity. However, it is still skew-symmetric and a bi-derivation.

Definition 2.5: Let $\Theta=(\Delta,\omega)$ *be a partial symplectic structure on a manifold* Q. *A hypersurface* $B\subset Q$ *is* transversal *to* Θ (*or to* Δ) *if the affine subspaces* T_yB *and* Δ_y *of* T_yQ *are transversal for any* $y\in C$.

If B is *transversal* to Θ, then $T_yB\cap\Delta_y$ is of codimension 1 in Δ_y. If Θ is a partial symplectic structure on $C\subset T^*M$, we shall extend this terminology by saying that Θ is *transversal* to a hypersurface $\tilde{B}$ in T^*M if $\tilde{B}$ is transversal to C, so that $B=\tilde{B}\cap C$ is a hypersurface in C, and B is transversal to Θ.

III. DYNAMICS OF NONHOLONOMIC HAMILTONIAN SYSTEMS

In this section, we formulate the dynamics of nonholonomic Hamiltonian systems using the partial symplectic formalism. We show how, under some technical conditions, any Hamiltonian system subject to nonholonomic constraints possesses an associated partial symplectic structure. Then, we analyze the cases of systems with instantaneous nonholonomic constraints, and systems exhibiting discontinuities.

A. The partial symplectic structure associated with a constrained Hamiltonian system

Let (M,H,C) be a constrained Hamiltonian system. Our goal is to associate with it a partial symplectic structure Θ on the "constrained" cotangent bundle C in such a way the corresponding constrained Hamiltonian field X_H^Θ gives the desired nonholonomic dynamics. With this purpose, consider the *constrained symplectic form* defined by the restriction of the "free" symplectic form Ω_M to C,

$$\omega_\Theta=j^*(\Omega_M), \tag{3}$$

with $j:C\hookrightarrow T^*M$ the canonical inclusion. The next step is to construct a suitable affine distribution Δ_Θ on C. A natural nonsingularity requirement on C is asking for the regularity of the map $\alpha_H|_C$. This is the reason why we assume that $\alpha_H|_C$ is an immersion, i.e., that the differential $d_y\alpha_H$ is nonsingular for any $y\in C$. Since $\alpha_H:T^*M\to TM$ is fibered, this assumption implies that the map $(\alpha_H)_x:C_x\to TM$ is an immersion for any $x\in M$ and vice versa.

Let $y\in C$ and $x=\pi(y)$. Let Π_y be the affine subspace of T_xM tangent to $\alpha_H(C_x)$ at $z=\alpha_H(y)$. Since by the above assumption $\alpha_H|_C$ is an immersion, $\dim\Pi_y=\dim C_x=n-m$. Consider the affine distribution Δ_Θ on C defined by

$$\Delta_{\Theta y}=\{\xi\in T_yC|d_y\pi(\xi)\in\Pi_y\}\subset T_yC. \tag{4}$$

Since $d_y(\pi|_C)$ is surjective, the codimension of Δ_{Θ_y} in T_yC is equal to the codimension of Π_y in T_xM, i.e., to m. Therefore, $\dim\Delta_{\Theta_y}=2(n-m)$. It is not difficult to see now that if the form ω_Θ is nondegenerate on the distribution Δ_Θ, then $\alpha_H|_C$ is an immersion.

Proposition 3.1: Let $S=(M,H,C)$ *be a constrained Hamiltonian system. Then,* $\alpha_H|_C$ *is an immersion if the pair* $(\Delta_\Theta,\omega_\Theta)$ *defined by Eqs. (3) and (4) is a partial symplectic structure*.

The converse, however, is in general not true. Since the partial symplectic structure associated with $S=(M,H,C)$ is determined by H and C, we will simply denote it by $\Theta(H,C)=(\Delta_{H,C},\omega_C)$.

For most Hamiltonian systems (including those coming from Mechanics), the anti-Legendre map α_H is regular not only when restricted to C, but on the whole space T^*M. If this is the case, and the Hamiltonian system comes from a Lagrangian system, one can indeed show that the condition of ω_Θ being nondegenerate on the distribution Δ_Θ is equivalent to the so-called *compatibility condition*.[3,18] Therefore, Proposition 3.1 establishes a link between the classical partial symplectic formalism introduced in Ref. 6 and more recent approaches as explained, for instance, in Ref. 15. Also note that the class of mechanical systems automatically verifies the compatibility condition, therefore admitting both formulations. Indeed, for mechanical systems, the conditions in Proposition 3.1 are equivalent.

Definition 3.2: A nonholonomic Hamiltonian system *on a manifold* M *is a constrained system*

(M,H,C), $H\in C^\infty(T^*M)$, $C\subset T^*M$ *such that* $\Theta(H,C)=(\Delta_{H,C},\omega_C)$ *is a partial symplectic structure*.

The dynamics of a nonholonomic Hamiltonian system is given by the constrained Hamiltonian vector field X_H^Θ with respect to the partial symplectic structure $\Theta=\Theta(H,C)$ [cf. Eq. (2)]. This vector field will be denoted by $X_{H,C}$. Under regularity of the map α_H, $X_{H,C}$ reads in canonical coordinates

$$X_{H,C}=\frac{\partial H}{\partial p_a}\frac{\partial}{\partial q^a}-\left(\frac{\partial H}{\partial q^a}+\mathcal{C}_{ij}\left(\frac{\partial H}{\partial p_b}\frac{\partial\Phi^j}{\partial q^b}-\frac{\partial H}{\partial q^b}\frac{\partial\Phi^j}{\partial p_b}\right)\frac{\partial\Phi^i}{\partial p_c}\mathcal{H}_{ca}\right)\frac{\partial}{\partial p_a},$$

where the matrices $(\mathcal{H}_{ab})$ and $(\mathcal{C}_{ij})$ are defined by

$$(\mathcal{H}_{ab})=\left(\frac{\partial^2 H}{\partial p_a\partial p_b}\right)^{-1},\quad (\mathcal{C}_{ij})=\left(\frac{\partial\Phi^i}{\partial p_a}\mathcal{H}_{ab}\frac{\partial\Phi^j}{\partial p_b}\right)^{-1}.$$

Observe that the *force of reaction of nonholonomic constraints* (see Sec. II B) in the partial symplectic framework is defined *a posteriori* as the difference between the constrained and the free Hamiltonian vector fields, $X_{H,C}-X_H$. Also, note that the almost-Poisson bracket associated with the partial symplectic structure $\Theta_{H,C}$ coincides with the so-called nonholonomic bracket.[15,11,39]

Transversality: It is convenient to adapt the terminology related to the notion of transversality discussed in Sec. II C to the context of nonholonomic Hamiltonian systems. First, we shall say that a nonholonomic Hamiltonian system $S=(M,H,C)$ is *transversal* to a hypersurface B in T^*M if the underlying partial symplectic structure $\Theta(H,C)$ is transversal to B. Second, if N is a hypersurface in M, we shall say that S is *transversal* to N if S is transversal to the hypersurface T^*_NM. The following result follows from the definition of the partial symplectic structure $\Theta(H,C)$.

Proposition 3.3: A nonholonomic Hamiltonian system (M,H,C) *is transversal to a hypersurface* $N\subset M$ *if and only if* $\Pi_y\subset T_{\pi(y)}M$, *the affine subspace of* $T_{\pi(y)}M$ *tangent to* $\alpha_H(C_{\pi(y)})$ *at* $z=\alpha_H(y)$, *is transversal to* $T_{\pi(y)}N\subset T_{\pi(y)}M$ *for all* $y\in C$.

B. Instantaneous partial symplectic structures

It is intuitive to think that when a trajectory of a Hamiltonian system (M,H,C) crosses a *critical* hypersurface N in the configuration manifold M, its phase space reduces to T^*N. Moreover, it could possibly be subject to additional instantaneous constraints along N. In the language of our approach, this idea is naturally expressed by saying that all such *critical* states constitute a nonholonomic Hamiltonian system on N. Since T^*N is not naturally embedded into T^*M, a realization of this idea is not completely straightforward. What one really needs is a partial symplectic structure on the manifold of instantaneous constraints C^{inst} which, by definition, is a submanifold of T^*M.

Namely, let C^{inst} be a set of instantaneous constraints along N imposed on (M,H,C) (cf. Definition 2.3). Take $y\in C^{\text{inst}}$. Let $x=\pi(y)$ and denote by Π_y^{inst} the affine subspace of $T_xN\subset T_xM$ tangent to $\alpha_H(C_x^{\text{inst}})$ at $\alpha_H(y)$. Consider the 2-form $\omega_{\Theta^{\text{inst}}}$ and the affine distribution $\Delta_{\Theta^{\text{inst}}}$ on C^{inst} defined by

$$\omega_{\Theta^{\text{inst}}}=j^*(\Omega_M),\quad \Delta_{\Theta^{\text{inst}}y}=\{\xi\in T_yC^{\text{inst}}\,|\,d_y\pi(\xi)\in\Pi_y^{\text{inst}}\}\subset T_yC^{\text{inst}},\tag{5}$$

with $j:C^{\text{inst}}\hookrightarrow T^*M$ the canonical inclusion. We then have the following definition.

Definition 3.4: Let (M,H,C) *be a nonholonomic Hamiltonian system and let* C^{inst} *be a set of instantaneous constraints along a hypersurface* $N\subset M$. *The pair* $(\Delta_{\Theta inst},\omega_{\Theta inst})$ *defined by (5) is called the* instantaneous partial symplectic structure along N *if* $\omega_{\Theta inst}$ *is not degenerate on* $\Delta_{\Theta inst}$. *If this is the case*, C^{inst} *is called a* regular *set of instantaneous constraints*.

Note that this structure is defined by H, C^{inst}, and N. To highlight this fact, we denote $\Theta^{\text{inst}}=\Theta^{\text{inst}}(H,C^{\text{inst}},N)$. Accordingly, we denote by $X_{(H,C^{\text{inst}},N)}$ the constrained Hamiltonian vector field $X_{H^{\text{inst}}}^{\Theta^{\text{inst}}}$, with $H^{\text{inst}}=H|_{C^{\text{inst}}}$.

In general, since $C^{\text{inst}} \subset C$ by definition, one has that $\alpha_H|_{C^{\text{inst}}}$ is an immersion. For mechanical systems, this implies that the 2-form $\omega_{\Theta^{\text{inst}}}$ is nondegenerate on $\Delta_{\Theta^{\text{inst}}}$, and therefore any set of instantaneous constraints is regular.

In what follows, we shall only deal with regular instantaneous nonholonomic constraints. A natural class of instantaneous structures arises in the following situation of particular interest. Assume that the nonholonomic Hamiltonian system $S=(M,H,C)$ is transversal to N and that α_H is regular. Then $\alpha_H^{-1}(TN)$ is transversal to C and, hence,

$$C_{(N,H)} = \alpha_H^{-1}(TN) \cap C$$

is a submanifold of codimension 2 in C. Note that $C_{(N,H)}$ is a set of instantaneous nonholonomic constraints on S along N. By construction, the codimension of $\Delta_{N_y} = \Delta_y \cap T_y(C_{(N,H)})$ in Δ_y is also 2 and Ω_y is nondegenerate when restricted to Δ_{N_y}. Therefore, the affine distribution Δ_N and the 2-form $\Omega|_N$ endow $C_{(N,H)}$ with a partial symplectic structure, which is an instantaneous partial symplectic structure along N. We call it the *trace of S on N* and denote it by $S_{(N,H)}$. In the special case $N=\partial M$, we call it the *boundary of S*, and denote it by ∂S, i.e., $\partial S = S_{(\partial M,H)}$. We will denote the constrained Hamiltonian vector field with respect to the trace (respectively, boundary) as $X^{\text{tr}} = X^{\text{tr}}_{(H,C,N)}$ (respectively, $X^{\partial} = X^{\partial}_{(H,C,\partial M)}$).

C. Discontinuous nonholonomic systems

An impulsive behavior of a Hamiltonian system occurs when its trajectory "tries" to go across a *critical* hypersurface N in the configuration space M. In such an instant, the system may be forced to drastically change its constraints, to pass under the control of another Hamiltonian and/or to be eventually subject to additional instantaneous constraints. Such situations may be interpreted as *discontinuities* on both the constraints and the Hamiltonian of the system. Below, we formalize these concepts properly via the notion of cutting-up.

Definition 3.5: Let $N \subset M$ be a hypersurface of M with $N \cap \partial M = \emptyset$. A pair $(\hat{M}, \varsigma)$, $\varsigma: \hat{M} \to M$, is called a cutting-up of M along N *if*

(i) $\hat{N} = \varsigma^{-1}(N) \subset \partial \hat{M}$,

(ii) ς *maps $\hat{M} \backslash \hat{N}$ diffeomorphically onto $M \backslash N$*,

(iii) $\varsigma|_{\hat{N}}: \hat{N} \to N$ *is a double covering of N.*

Note that, by definition, ς is a local diffeomorphism. Cuttings-up for a given N exist and are equivalent one to each other. If N divides M into two parts, say, M_+ and M_-, i.e., $M = M_+ \cup M_-$, $M_+ \cap M_- = N$, then $\hat{M}$ may be viewed as the disjoint union of M_+ and M_-, and ς as the map that matches them together along the common border N. Locally any cutting-up is of this form.

For our purposes, it is important to realize that, if $(\hat{M}, \varsigma)$ is a cutting-up of M along N, then $(T^*\hat{M}, T^*\varsigma)$ is a cutting-up of T^*M along the hypersurface $T^*_N M$. Here, $T^*\varsigma$ denotes the dual of the inverse of the isomorphism $d_z\varsigma: T_z\hat{M} \to T_{\varsigma(z)}M$, for all $z \in \hat{M}$. In the following definition, we introduce the class of Hamiltonian systems we shall be dealing with throughout this paper.

Definition 3.6: Let $N \subset M$ be a hypersurface of M with $N \cap \partial M = \emptyset$ and let $(\hat{M}, \varsigma)$ be a cutting-up of M along N. A nonholonomic Hamiltonian system discontinuous along N, *denoted $S = (M,H,C|N)$, is the direct image with respect to $T^*\varsigma$ of a nonholonomic Hamiltonian system $(\hat{M}, \hat{H}, \hat{C})$. Such system is called* regular *if $(\hat{M}, \hat{H}, \hat{C})$ is transversal to $\hat{N}$.*

A system of instantaneous nonholonomic constraints on S along N *is the direct image with respect to $T^*\varsigma$ of a set of instantaneous constraints $\hat{C}^{inst}$ along $\hat{N}$ on the associated system $\hat{S} = (\hat{M}, \hat{H}, \hat{C}|\hat{N})$. The* trace of S on N *is the direct image with respect to $T^*\varsigma$ of the trace of $\hat{S}$ along $\hat{N}$.*

According to Definition 3.6, $\hat{H}$ is a smooth function on $T^*\hat{M}$ and $\hat{C}$ is a submanifold of $T^*\hat{M}$.

Therefore, the *direct image* of $\hat{H}$ along the matching map $T^*\varsigma: T^*\hat{M} \to T^*M$ may be viewed as a function on T^*M, which is 1-valued and smooth outside of $T^*_N M$ and 2-valued and smooth on $T^*_N M$. We will continue to use the notation H for this function and will refer to it as a *discontinuous Hamiltonian along N*. Similarly, the direct image $C = T^*\varsigma(\hat{C})$ of $\hat{C}$ will be referred to as *discontinuous nonholonomic constraints along N*. Outside of $T^*_N M$, C is a "good" smooth submanifold of T^*M, whose boundary is an immersed submanifold of $T^*_N M$.

The previous discussion becomes particularly simple when N divides M into two parts, M_+ and M_-, as mentioned above. In such a case, $T^*_N M$ also divides T^*M into two parts, T^*M_+ and T^*M_-, whose common boundary is $T^*_N M$. Then, a discontinuous Hamiltonian H along N may be naturally seen as a pair of Hamiltonians, say, H_+ and H_-, defined on T^*M_+ and T^*M_-, respectively. Similarly, a set of discontinuous nonholonomic constraints along N is regarded as a pair of sets of nonholonomic constraints $C_\pm \subset T^*M_\pm$. Since N always divides M locally, this description constitutes a local picture of a discontinuous nonholonomic Hamiltonian system along N.

We will continue to use the notation C^{inst} (respectively, S^{tr}) for instantaneous nonholonomic constraints (respectively, the trace of S) in the case of discontinuous nonholonomic systems. As before, one may interpret C^{inst} as a 2-valued system of instantaneous nonholonomic constraints along N. In the case when N divides M into two parts, we will distinguish between the two branches using the notation $C^{\text{inst}}_\pm$, and write also $X_{(H,C^{\text{inst}}_\pm,N)}$ (respectively, $X^{\text{tr}}_{(H,C_\pm,N)}$).

Remark 3.7: The impulsive behavior of a Hamiltonian system is not necessarily related to some discontinuity. This type of phenomena occurs, for instance, each time that one of its trajectories "strikes" against the boundary ∂M of the configuration space M. Various kinds of collisions, impacts, etc., in mechanical systems are described in this way. Otherwise said, impulsive behavior is characteristic of Hamiltonian systems *with boundary*. Moreover, systems with boundary may be viewed as a "limit" case of discontinuous systems by dropping the requirement $N \cap \partial M = \emptyset$ and choosing $N = \partial M$, $M_- = \emptyset$, $M_+ = M$. This allows a unified approach to both situations.

IV. THE TRANSITION PRINCIPLE

In this section we discuss the formulation of the transition principle for systems subject to nonholonomic constraints. We first introduce the notions of focusing points, constrained characteristics, and in, out and decisive points. The transition principle builds on these elements to prescribe the behavior of the Hamiltonian system when one or more of its ingredients undergoes a drastic change.

A. Focusing points

The following simple linear result will be key for the subsequent discussion.

Lemma 4.1: Let $y \in T^*M$, *and let* W *be an affine subspace in* $T_y(T^*M)$ *such that* Ω_y *is nondegenerate on* W (*hence*, $\dim W = 2l$ *for certain* l) *and* $\dim d_y\pi(W) = l$. *Denote by* $W^0 \subset T_y(T^*M)$ *and* $d_y\pi(W)^0 = d_y\pi(W^0) \subset T_{\pi(y)}M$ *the linear subspaces associated with the affine spaces* W *and* $d_y\pi(W)$, *respectively. Then the affine subspaces* $W^\bullet = y + \text{Ann}(d_y\pi(W)^0)$ *and* $W_\bullet = y + W^0 \cap T_y(T^*_{\pi(y)}M)$ *in* $T^*_{\pi(y)}M$ *passing through* y *are transversal.*

Proof: Since, by hypothesis, $\dim d_y\pi(W) = l$, one has

$$\dim W^0 \cap T_y(T^*_{\pi(y)}M) = l \quad \text{and} \quad \dim d_y\pi(W)^0 = l.$$

Now, the dimension of $\text{Ann}(d_y\pi(W)^0) \subset T^*_{\pi(y)}M$ is $n-l$. Moreover, $W^0 \cap T_y(T^*_{\pi(y)}M)$ is transversal to $\text{Ann}(d_y\pi(W)^0)$ if one identifies the spaces $T^*_{\pi(y)}M$ and $T_y(T^*_{\pi(y)}M)$. The result now follows. ■

Consider now a nonholonomic Hamiltonian system (M, H, C). Let $y \in C$. Denote by $\Delta = \Delta_{(H,C)}$ be the affine distribution of the corresponding partial symplectic structure $\Theta(H, C)$ (cf. Sec. III A). By Definition 3.2, the affine subspace $W = \Delta_y$ satisfies the assumptions of Lemma 4.1 on W [observe that $d_y\pi(W)$ is precisely Π_y in Eq. (4)]. Therefore, the subspace $W^\bullet = \Delta^\bullet_y$ is well defined and we set

$$K_y = K_y(H,C) = \Delta_y^* \subset T^*_{\pi(y)}M.$$

Moreover, it is not difficult to see that the subspace $W_\bullet = (\Delta_y)_\bullet$ is identical to $T_y C_{\pi(y)}$. This shows that K_y is transversal to C at y, and that $\dim K_y = m$. The *crown of the nonholonomic Hamiltonian system* (M,H,C) is the map

$$\kappa = \kappa_{H,C}: C \to A_m(T^*M), \quad y \mapsto K_y,$$

where $A_k(T^*M)$ denotes the manifold whose elements are k-dimensional affine submanifolds contained in the fibers of the cotangent bundle T^*M. One can see that the graph of the crown κ,

$$\mathrm{Graph}(\kappa) = \{(y,v) \in C \times T^*M | v \in K_y\}$$

is a $2n$-dimensional smooth submanifold of $C \times T^*M$. Note that $\mathrm{Graph}(\kappa)$ is a fiber bundle over C with projection

$$p = p_{(H,C)}: \mathrm{Graph}(\kappa) \to C, \quad (y,v) \mapsto y.$$

The fiber over y of this bundle is precisely K_y. Since $y \in K_y$, the map

$$\sigma: C \to \mathrm{Graph}(\kappa), \quad y \mapsto (y,y),$$

is a section of $p_{(H,C)}$. Since the fibers of $p_{(H,C)}$ are affine spaces, the bundle $\mathrm{Graph}(\kappa) \to C$ has a natural vector bundle structure whose zero section is σ. Moreover, this vector bundle is canonically isomorphic to the normal bundle of C in T^*M. This is due to the fact that, for any $y \in C$, the fiber K_y is transversal to C at y. The same argument also guarantees that the map

$$\Xi = \Xi_{(H,C)}: \mathrm{Graph}(\kappa) \to T^*M, \quad (y,v) \mapsto v,$$

induces a diffeomorphism of a neighborhood of the "zero" section $\sigma(C)$ in $\mathrm{Graph}(\kappa)$ onto its image.

Definition 4.2: Let (M,H,C) *be a nonholonomic Hamiltonian system. Given a point* $u \in T^*M$, *its* (H,C)-focusing locus $F_{(H,C)}(u)$ *is the set of all points* $y \in C$ *such that* $u \in K_y$. *In other words*,

$$F_{(H,C)}(u) = p_{(H,C)}(\Xi^{-1}_{(H,C)}(u)) \subset C_{\pi(u)}.$$

A point in $F_{(H,C)}(u)$ *is called* focusing for u.

Standard arguments show that $\Xi_{(H,C)}$ is regular, i.e., of maximal rank $2n$ almost everywhere, that is, with the exception of a closed subset without interior points. Therefore, for a generic point $u \in T^*M$, the subset $\Xi^{-1}_{(H,C)}(u)$ is discrete, and so is $F_{(H,C)}(u)$ as well. Note also that if $u \in C$, then $u \in F_{(H,C)}(u)$.

Remark 4.3: Focusing points can be understood as *nonintegrable* analogs of the notion of *reducing points* considered in Ref. 35 in connection with the transition principle for inelastic collisions.

Remark 4.4: It is worth noticing that the concept of a focusing point also makes sense in the absence of constraints. Obviously, in this case $F_{(H,C)}(u) = \{u\}$. Therefore there is no need to distinguish between the constrained and nonconstrained cases in the statement of the transition principle.

If the constraints are linear, i.e., $C = \Upsilon + C^0$ with C^0 a linear codistribution and $\Upsilon \in \Lambda^1(M)$ (the displacement form), then for each $y \in T^*M$,

$$T^*_{\pi(y)}M = C^0_{\pi(y)} \oplus \mathrm{Ann}(d_y\pi(\Delta_y)),$$

where $\Delta=\Delta_{(H,C)}$. Denote the corresponding projectors by $\mathcal{P}:T^*_{\pi(y)}M \to C^o_{\pi(y)}$ and $\mathcal{Q}:T^*_{\pi(y)}M \to \mathrm{Ann}(d_y\pi(\Delta_y))$. Given $u \in T^*M$, one has that $z \in F_{(H,C)}(u)$ if and only if $z \in C$ and $\mathcal{P}(z)=\mathcal{P}(u)$. Since $z=\mathcal{P}(z)+\mathcal{Q}(z)=\mathcal{P}(u)+\mathcal{Q}(\Upsilon_y)$, one has the following result.

Proposition 4.5: Let (M,H,C) be a nonholonomic Hamiltonian system with linear constraints. Then, for $u \in T^*_yM$, there is a unique focusing point given by $F_{(H,C)}(u)=\{\mathcal{P}(u)+\mathcal{Q}(\Upsilon_y)\}$.

B. Instantaneous focusing points

We will also need an instantaneous version of the notion of a focusing point introduced in the preceding section. For this purpose, it is sufficient to apply the above construction to instantaneous constraints instead of to the "usual" ones. Namely, let C^{inst} be a system of regular instantaneous constraints along N (see Sec. II A 3) and $\Delta^{\mathrm{inst}}=\Delta_{\Theta^{\mathrm{inst}}}$ be the corresponding affine distribution (see Sec. III B). Following the same reasoning as above, the affine subspace $W=\Delta^{\mathrm{inst}}_y \subset T_y(T^*M)$ satisfies the assumptions of Lemma 4.1. Therefore, the affine subspace $K^{\mathrm{inst}}_y=(\Delta^{\mathrm{inst}})^\bullet$ of $T_y(T^*M)$ is well defined, and we have all the ingredients to define the notion of instantaneous crown and instantaneous focusing point of a system subject to instantaneous nonholonomic constraints. For completeness, we state the latter.

Definition 4.6: Let (M,H,C) be a nonholonomic Hamiltonian system and let C^{inst} be a set of instantaneous constraints along a hypersurface $N \subset M$. Given a point $u \in T^*_NM$, its (H,C^{inst},N)-instantaneous focusing locus $F_{(H,C^{\mathrm{inst}},N)}(u)$ *is the set of all points $y \in C^{\mathrm{inst}}$ such that $u \in K^{\mathrm{inst}}_y$. In other words*,

$$F_{(H,C^{\mathrm{inst}},N)}(u) = p_{(H,C^{\mathrm{inst}})}(\Xi^{-1}_{(H,C^{\mathrm{inst}},N)}(u)) \subset C^{\mathrm{inst}}_{\pi(u)}.$$

A point in $F_{(H,C^{\mathrm{inst}},N)}(u)$ is called instantaneous focusing for u.

As before, if the instantaneous nonholonomic constraints are linear $C^{\mathrm{inst}}=\Upsilon^{\mathrm{inst}}+C^{\mathrm{inst}^o}$, then for each $y \in T^*_NM$,

$$T^*_{\pi(y)}M = C^0_{\pi(y)} \oplus \mathrm{Ann}(d_y\pi(\Delta^{\mathrm{inst}}_y)),$$

where $\Delta^{\mathrm{inst}}=\Delta_{(H,C^{\mathrm{inst}},N)}$. Denoting the corresponding projectors by $\mathcal{P}^{\mathrm{inst}}:T^*_{\pi(y)}M \to C^{\mathrm{inst}^o}{}_{\pi(y)}$ and $\mathcal{Q}^{\mathrm{inst}}:T^*_{\pi(y)}M \to \mathrm{Ann}(d_y\pi(\Delta^{\mathrm{inst}}_y))$, one has the following result.

Proposition 4.7: Let (M,H,C) be a nonholonomic Hamiltonian system and let C^{inst} be a set of instantaneous affine constraints along a hypersurface $N \subset M$. Then, for $u \in T^*_yM$, there is a unique instantaneous focusing point given by $F_{(H,C^{\mathrm{inst}},N)}(u)=\{\mathcal{P}^{\mathrm{inst}}(u)+\mathcal{Q}^{\mathrm{inst}}(\Upsilon^{\mathrm{inst}}_y)\}$.

C. Constrained characteristics

Consider then a partial symplectic structure $\Theta=(\Delta,\omega)$ on a manifold C which is transversal to a hypersurface $B \subset C$ (cf. Definition 2.5). Let Δ^0 denote the linear distribution associated with Δ. For each $y \in B$, consider the linear space $V=\Delta^0_y$, the hyperplane $W=\Delta^0_y \cap T_yB$ of V and the nondegenerate skew-symmetric form $b=\omega_y|_{\Delta^0_y}$. The *characteristic direction at $y \in B$* is defined as

$$l_y = l_y(\Theta,B) = \ker\ b|_W = \ker(\omega_y|_{\Delta^0_y \cap T_yB}) \subset \Delta^0_y \cap T_yB.$$

The proof of the following result is straightforward.

Lemma 4.8: Given a partial symplectic structure $\Theta=(\Delta,\omega)$ on a manifold C and a hypersurface $B \subset C$ transversal to it, the distribution $y \mapsto l_y(\Theta,B)$ is one dimensional.

Definition 4.9: Given a partial symplectic structure $\Theta=(\Delta,\omega)$ on C and a hypersurface $B \subset C$ transversal to it, $y \mapsto l_y(\Theta,B)$ is called the characteristic distribution with respect to (Θ,B), *and its integral curves, denoted by ζ, are the* (Θ,B)-characteristics.

We are particularly interested in the case when we have a nonholonomic Hamiltonian system $S=(M,H,C)$, the partial symplectic structure Θ is $\Theta_{H,C}$, N is a hypersurface in M and $\widetilde{B}=T^*_N M$, $B=T^*_N M\cap C$. We will use the terminology $(S|N)$-or $(H,C|N)$-*characteristic* as a substitute for (Θ,B)-characteristic. It should be emphasized that $(H,C|N)$ characteristics are only defined when S is transversal to N (see Sec. III A).

In the absence of constraints, i.e., when $(C=T^*M,\ \omega=\Omega)$ is a symplectic manifold, and Δ is the trivial distribution $y\mapsto T_y C$ on C, the characteristic curves are precisely the characteristics introduced in Ref. 6. We will refer to *nonconstrained characteristics* and *constrained characteristics* when it is necessary to distinguish between the unconstrained and the constrained cases.

Remark 4.10: Just as nonconstrained characteristics play a key role in describing holonomic elastic collisions, and reflection and refraction phenomena of rays of light,[6,34] the constrained characteristics will be fundamental in describing the "elastic part" of nonholonomic impulsive phenomena. What is meant by "elastic part" will become clear in Sec. IV E when describing decisive points.

If the constraints C are affine, then the $(H,C|N)$-characteristics passing through a point $y\in C$, $\pi(y)\in N$, is described in a particularly simple way. Namely, following Proposition 3.3, it is not difficult to see that the $(H,C|N)$-characteristic passing through y is given by

$$\zeta_y = y + C^0_{\pi(y)} \cap \mathrm{Ann}(d_y\alpha_H(C^0)\cap T_{\pi(y)}N),$$

with C^0 being the linear codistribution associated to C. In particular, in the absence of constraints, $C=T^*M$ and the characteristics are straight lines in $T^*_x M$ parallel to $\mathrm{Ann}(T_x N)$, $x\in N$.

D. In, out and trapping points

Here, we first introduce some concepts concerning the behavior of a vector field in a neighborhood of the boundary of its supporting manifold. We then discuss the notions in, out and trapping points.

Let Q be a manifold with boundary and X a vector field on Q. A point $y\in\partial Q$ is called a jth *order in point for* X if there exists a trajectory of X, $\beta:[0,a]\to Q$, $a>0$ such that

$$y=\beta(0) \quad \text{and } \beta(t)\notin\partial Q \quad \text{for } 0<t\leqslant a,$$

and β is jth order tangent to ∂Q at y. A jth *order out point for* X is a jth order in point for $-X$. In the dynamical context we have in mind, in and out points of 0th order are the most important. It is easy to see that $y\in\partial Q$ is a 0th order in point (respectively, out point) for X if the vector X_y is transversal to ∂Q and directed inside (respectively, outside) of Q. A point that lies on a trajectory of X which is entirely contained in ∂Q is called a *trapping point for* X.

Let $\partial Q^j=\partial Q^j(X)$ denote the subset of all points of ∂Q where X is jth order tangent to ∂Q, and $\partial Q^j_>=\partial Q^j_>(X)$ [respectively, $\partial Q^j_<=\partial Q^j_<(X)$] the set of all jth order in points (respectively, out points) for X. Note that $\partial Q^j\supset\partial Q^{j+1}$ and

$$\partial Q^j\setminus(\partial Q^j_>\cup\partial Q^j_<)\subset\partial Q^{j+1}. \tag{6}$$

In a generic situation, ∂Q^j is a submanifold (with singularities) of codimension j in ∂Q, which is divided by ∂Q^{j+1} into two parts, $\partial Q^j_>\setminus\partial Q^{j+1}_>$ and $\partial Q^j_<\setminus\partial Q^{j+1}_<$. An analytical description of the previous discussion is obtained by choosing a smooth function f on Q with $f\geqslant 0$ and $d_z f\neq 0$, for all $z\in\partial Q$ such that $\partial Q=\{f=0\}$ (which always exists locally). Then

$$\partial Q^j=\{z\in Q|f(z)=0,X(f)(z)=0,\ldots,X^j(f)(z)=0\},$$

$$\partial Q^j_>\setminus\partial Q^{j+1}_>=\partial Q^j\cap\{z\in Q|X^{j+1}(f)(z)>0\},$$

$$\partial Q^j_<\setminus\partial Q^{j+1}_<=\partial Q^j\cap\{z\in Q|X^{j+1}(f)(z)<0\}.$$

The vector field X is said to be *regular with respect to* ∂Q when the inclusion in Eq. (6) is an equality for all $j \geqslant 0$. This is a generic property of vector fields. In such a case, the chain of inclusions

$$\partial Q = \partial Q^0 \supset \partial Q^1 \supset \cdots \supset \partial Q^j \supset \cdots \supset \partial Q^n$$

is a *stratification* of ∂Q whose strata are $\partial Q^j_> \setminus \partial Q^{j+1}_>$ and $\partial Q^j_< \setminus \partial Q^{j+1}_<$. Note also that the set of trapping points precisely corresponds to ∂Q^n.

Consider now a discontinuous nonholonomic Hamiltonian system $(M, H, C|N)$ and the corresponding cutting-up $(\hat{M}, \varsigma)$. Then we can resort to the previous discussion with the manifold $Q = \hat{C} \subset T^*\hat{M}$ and the vector field $X = X_{\hat{H},\hat{C}}$. Recall that $\hat{N} \subset \partial \hat{M}$ and $\partial \hat{C} = \hat{C} \cap T^*_{\partial \hat{M}} \hat{M}$.

Definition 4.11: Let $S = (M, H, C|N)$ *be a discontinuous nonholonomic system and denote by* $(\hat{M}, \varsigma)$ *the associated cutting-up. A point* $y \in T^*_N M$ *is called an* in point (*respectively, an* out point) *of* S *if there exists* $z \in T_{\hat{N}}\hat{M}$ *such that* $y = \varsigma(z)$ *and* z *is an in point (respectively, an out point) of* $X_{\hat{H},\hat{C}}$ *with respect to* $\partial \hat{C}$.

By definition, the map $T^*\varsigma$ restricted to $\partial \hat{C}$ is an immersion. A point in $T^*_N M$ may turn out to be an in and an out point at the same time. To resolve this ambiguity, the branch of $T^*\varsigma$ to which such a point belongs must be taken into consideration. This distinction is easily described in the case when N divides M into two parts. In fact, in this case the system $(M, H, C|N)$ may be viewed as a couple of nonholonomic Hamiltonian systems $(M_\pm, H_\pm, C_\pm)$, with the common boundary $\partial M_\pm = N$, and where $H_\pm \in C^\infty(M_\pm)$ and $C_\pm \subset M_\pm$ (cf. Sec. III C). An in (respectively, out, or trapping) point of the vector field X_{H_+,C_+} with respect to the boundary ∂C_+ is called a *plus-in* (respectively, *plus-out*, or *plus-trapping*) *point*. Analogous definitions are established for $\varepsilon = -$. In this way, the notions of plus-in point, minus-in point, etc., introduced in Ref. 6 for the unconstrained situation are generalized to the constrained case. Finally, we observe that N always divides M locally, and therefore the previous discussion is always valid locally.

E. Decisive points

At this point, we are ready to introduce the key notion of decisive point corresponding to an out point. The construction of decisive points depends on two elements: first, the mode (elastic or inelastic) in which the system passes through the critical state and, second, the continuity and differentiability properties of the Hamiltonian. Below, we will limit our discussion to the two most relevant situations, just to avoid not very instructive technicalities arising in the most general context. The first one is the case when the Hamiltonian is smooth and only the constraints are discontinuous along the critical hypersurface. The second one concerns discontinuous Hamiltonians and not necessarily discontinuous constraints. It is worth stressing that the first situation cannot be considered as a particular case of the second one, i.e., that the notion of a decisive point is not "continuous" in this sense. In what follows, $\varepsilon \in \{+, -\}$ and $\bar{\varepsilon}$ stands for the opposite sign to ε. Throughout the section, instantaneous constraints are assumed to be regular.

1. Elastic mode: change of constraints

Here, we deal with a discontinuous nonholonomic system $(M, H, C|N)$, where the Hamiltonian function is smooth, $H \in C^\infty(M)$.

Definition 4.12 (Decisive points for smooth Hamiltonians and discontinuous constraints): Let $(M, H, C|N)$ *be a regular discontinuous nonholonomic system, with* $H \in C^\infty(M)$ *and consider a set of instantaneous constraints* C^{inst} *along* N. *Let* y *be an* ε*-out point of the system. A sequence* (y_i, ε_i), $i = 0, 1, \ldots, k$, *with* $y_i \in C \cap T^*_N M$ *is called* (y, ε)-admissible*if it verifies the following conditions:*

(i) $(y_0,\varepsilon_0)=(y,\varepsilon)$,
(ii) *for all* $i<k$, y_{i+1} *is a focusing point for* y_i *with respect to either* $C^{inst}_{\varepsilon_{i+1}}$ *or, if instantaneous constraints are absent,* $C_{\varepsilon_{i+1}}$,
(iii) y_i *is an* ε_i*-out point for all* $i<k$ *and* y_k *is either an* ε_k*-in point or an* ε_k*-trapping point*,
(iv) *the sequence of signs* $\{\varepsilon_i\}$ *alternates, i.e.,* $\varepsilon_{i+1}=\bar{\varepsilon}_i$.

The endpoint of an (y,ε)*-admissible sequence,* (y_k,ε_k), *is called* (y,ε)-decisive *and the constrained Hamiltonian vector field* $X_{H,C_{\varepsilon_k}}$ *is referred to as the vector field* corresponding *to it*.

Remark 4.13: The above formal description of decisive points is equivalent to the following iterative procedure. Take, for instance, a plus-out point y. Then, according to Definition 4.12, all focusing with respect to $C^{\text{inst}}_{\bar{\varepsilon}}$ (respectively, to $C_{\bar{\varepsilon}}$) minus-in and minus-trapping points are decisive. On the other hand, the procedure continues by restarting from any of the remaining focusing points that are minus-out points, and so on. In some situations, this process may turn out to be infinite. At the present time, however, it is not clear whether that kind of phenomena can occur, say in propagation of singularities or similar processes.

2. Elastic mode: discontinuous Hamiltonians

In this case, decisive points are constructed on the basis of an iterative procedure whose single steps are either of *reflective* or of *refractive* type, as described below. Consider a regular discontinuous noholonomic system $S=(M,H,C|N)$, which might be subject to additional instantaneous constraints C^{inst} along N. Let $y\in C\cap T^*_NM$ be an ε-out point.

Reflective step:

First move: $y\Rightarrow z$, where z is a point in the constrained characteristic $\zeta_y(H_\varepsilon,C_\varepsilon)$ such that $H_\varepsilon(z)=H_\varepsilon(y)$.

Second move: $z\Rightarrow u$, where u is a focusing point for z with respect to either $C^{\text{inst}}_\varepsilon$ or, if ε-instantaneous constraints are absent, C_ε.

Refractive step:

First move: $y\Rightarrow z$, where z is a point of the constrained characteristic $\zeta_y(H_\varepsilon,C_\varepsilon)$ and such that $H_{\bar{\varepsilon}}(z)=H_\varepsilon(y)$.

Second move: $z\Rightarrow u$, where u is a focusing point for z with respect to either $C^{\text{inst}}_{\bar{\varepsilon}}$ or, if $\bar{\varepsilon}$-instantaneous constraints are absent, $C_{\bar{\varepsilon}}$.

With a slight abuse of language, we shall say that (y,ε) is the *initial point of the step* and (u,ε) [respectively, $(u,\bar{\varepsilon})$] is the *endpoint of the step* if the scenario is reflective (respectively, refractive).

Definition 4.14 (Decisive points for discontinuous Hamiltonians): Consider a regular discontinuous nonholonomic system $(M,H,C|N)$. *Let* C^{inst} *be a set of instantaneous constraints along* N. *Let* y *be an* ε*-out point. A sequence* (y_i,ε_i), $i=0,1,\ldots,k$, *is called* (y,ε)-admissible *if*

(i) $(y_0,\varepsilon_0)=(y,\varepsilon)$,
(ii) (y_i,ε_i) *and* $(y_{i+1},\varepsilon_{i+1})$ *are the initial and the endpoints of a step, respectively*,
(iii) y_i *is an* ε_i*-out point,* $0\leqslant i<k$, *and* y_k *is an* ε_k*-in point or an* ε_k*-trapping point*.

The endpoint (y_k,ε_k) *of an admissible sequence is called* (y,ε)*-decisive and the constrained Hamiltonian vector field* $X_{H,C_{\varepsilon_k}}$ *is referred to as the vector field* corresponding *to it*.

If the Hamiltonian is discontinuous and the constraints are linear, i.e., $C\subset T^*M$ is a smooth linear submanifold, and the instantaneous constraints are absent, the previous definition of decisive points becomes much simpler, as the following result shows.

Proposition 4.15: Let $(M,H,C|N)$ *be a regular discontinuous nonholonomic Hamiltonian system with smooth linear constraints. Let* y *be an* ε*-out point. The* (y,ε)-decisive *points are the in and the trapping points belonging to the intersection of the constrained characteristic* ζ_y *passing through* y *with the set* $\{z\in C|H_\pm(z)=H_\varepsilon(y)\}$.

Proof: Let y be an ε-out point and denote by $\{z_1,\ldots,z_s\}$ (respectively, $\{\bar{z}_1,\ldots,\bar{z}_{\bar{s}}\}$) the points belonging to the intersection of the constrained characteristic ζ_y passing through y with the set

$\{z \in C | H_\varepsilon(z) = H_\varepsilon(y)\}$ [respectively, with $\{z \in C | H_{\bar{\varepsilon}}(z) = H_\varepsilon(y)\}$]. Since the constraints are smooth, then $u = z$ in the second move of both a reflective and a refractive step. Now, for any $j \in \{1, \ldots, s\}$, the intersection of the constrained characteristic passing ζ_{z_j} through z_j with the set $\{z \in C | H_\varepsilon(z) = H_\varepsilon(z_j)\}$ (respectively, with $\{z \in C | H_{\bar{\varepsilon}}(z) = H_\varepsilon(y)\}$) is again $\{z_1, \ldots, z_s\}$ (respectively, $\{\bar{z}_1, \ldots, \bar{z}_{\bar{s}}\}$). The same observation holds for any $\bar{z}_j$, $j \in \{1, \ldots, \bar{s}\}$. The result now follows from Definition 4.14. ■

Remark 4.16: The introduced terminology remains valid for nonholonomic systems with boundary (cf. Remark 3.7). In such a case, one must formally set

$$M_- = \emptyset, \quad M_+ = M, \quad N = \partial M, \quad H_- = \infty, \quad H_+ = H.$$

This type of geometric data occurs in describing various collision phenomena.

3. Inelastic mode: change of constraints

As in the elastic case, we first deal with the case when the Hamiltonian H is smooth. We treat an inelastic behavior of the system as the passage under the control of either the instantaneous discontinuous nonholonomic system or, if instantaneous constraints are absent, the discontinuous boundary system. In this and subsequent sections, the following shorthand notation will be used (cf. Secs. III B and III C):

$$C_\varepsilon^{\mathrm{inst,tr}} = C_\varepsilon^{\mathrm{inst}} \cap \alpha_{H_\varepsilon}^{-1}(TN), \quad X_\varepsilon^{\mathrm{inst,tr}} = X_{(H_\varepsilon, C_\varepsilon^{\mathrm{inst,tr}}, N)},$$

$$C_\varepsilon^{\mathrm{tr}} = C_{\varepsilon(N,H_\varepsilon)}, \quad X_\varepsilon^{\mathrm{tr}} = X_{(H_\varepsilon, C_\varepsilon, N)}^{\mathrm{tr}}.$$

We also use this notation when the Hamiltonian H is smooth, i.e., $H_\pm = H$.

Definition 4.17 (Decisive points for smooth Hamiltonians and discontinuous constraints): Consider a regular discontinuous nonholonomic system $(M, H, C|N)$. Let C^{inst} be a set of instantaneous constraints along N. Let y be an ε-out point. An (y, ε)-decisive point *is a focusing point for y with respect to either $C_\varepsilon^{inst,tr}$ or, if the instantaneous constraints are absent, $C_{\bar{\varepsilon}}^{tr}$. The constrained Hamiltonian vector field $X_{\bar{\varepsilon}}^{inst,tr}$, respectively, $X_{\bar{\varepsilon}}^{tr}$ is referred to as the* corresponding *vector field.*

4. Inelastic mode: discontinuous Hamiltonians

As in the elastic case, decisive points are constructed on the basis of *reflective* or *refractive* steps, as we now describe.

Reflected falling step:

First move: $y \Rightarrow z$, where z is a point of the constrained characteristic $\zeta_y(H_\varepsilon, C_\varepsilon)$ such that $H_\varepsilon(z) = H_\varepsilon(y)$.

Second move: $z \Rightarrow u$, where u is a focusing point for z with respect to either $C_\varepsilon^{\mathrm{inst,tr}}$ or, if ε-instantaneous constraints are absent, $C_\varepsilon^{\mathrm{tr}}$.

Refracted falling step:

First move: $y \Rightarrow z$, where z is a point of the constrained characteristic $\zeta_y(H_\varepsilon, C_\varepsilon)$ such that $H_{\bar{\varepsilon}}(z) = H_\varepsilon(y)$.

Second move: $z \Rightarrow u$, where u is a focusing point for z with respect to $C_{\bar{\varepsilon}}^{\mathrm{inst,tr}}$ or, if $\bar{\varepsilon}$-instantaneous constraints are absent, $C_{\bar{\varepsilon}}^{\mathrm{tr}}$.

We shall refer to (u, ε) [respectively, $(u, \bar{\varepsilon})$] as a *reflected* (respectively, *refracted*) *falling point*.

Definition 4.18 (Decisive points for discontinuous Hamiltonians): Consider a regular discontinuous nonholonomic system $(M, H, C|N)$. Let C^{inst} be a set of instantaneous constraints along N. Let y be an ε-out point. An (y, ε)-decisive *point is a falling point for y. The vector field $X_\varepsilon^{inst,tr}$ (respectively, $X_\varepsilon^{\mathrm{tr}}$ if $C_\varepsilon^{inst} = \emptyset$) is called the vector field* corresponding *to a reflected falling point. The vector field $X_\varepsilon^{inst,tr}$ (respectively, $X_{\bar{\varepsilon}}^{tr}$ if $C_\varepsilon^{inst} = \emptyset$) is called the vector field* corresponding *to a refracted falling point*.

F. Transition principle

From a physical point of view, the transition principle formulated below is an explicit description of the discontinuity of a trajectory of a regular nonholonomic Hamiltonian system S that occurs when it traverses a *critical state*. Such a discontinuity is interpreted as an impact, collision, reflection, refraction, etc., depending on the physical situation modeled by the system S. From a mathematical point of view, the transition principle corresponds to the definition of the trajectory of a regular discontinuous nonholonomic Hamiltonian system.

The elastic or inelastic character of the impulsive motions of an specific physical system must be taken into account when defining the trajectories. Accordingly, there are two different versions of the transition principle that distinguish between the two situations. Let $S=(M,H,C|N)$ stand for a regular discontinuous nonholonomic system and let C^{inst} be eventual instantaneous constraints imposed on S along N. Let $(\hat{M},\varsigma)$ be the associated cutting-up of M along N (cf. Sec. III C). The *regular part of a trajectory of the system* $\hat{S}=(\hat{M},\hat{H},\hat{C})$ is the part of the trajectory of the Hamiltonian vector field $X_{\hat{H},\hat{C}}$ that lies outside $\partial\hat{M}$. The *regular part of a trajectory of* S is the image by ς of the regular part of the corresponding trajectory of $\hat{S}$. At least locally, the regular part may be viewed as a piece of the trajectory of the vector field $X_{H_\varepsilon,C_\varepsilon}$ that lies outside the hypersurface T^*_NM.

Transition principle: Let $S=(M,H,C|N)$ *be a regular discontinuous nonholonomic system and let* C^{inst} *be eventual instantaneous constraints on* S *along* N. *If a regular trajectory of the vector field* $X_{H_\varepsilon,C_\varepsilon}$, $\varepsilon=\pm$ *reaches the critical hypersurface* T_NM *at a point* y, *it then continues its motion from any* (y,ε)*-decisive point according to the chosen mode, elastic or inelastic, under the control of the corresponding constrained Hamiltonian vector field.*

Some features of the transition principle are worth mentioning. First of all, it prescribes a *splitting of the trajectory* when the number of decisive points is greater than one. Of course, it is difficult to imagine that a true mechanical system "goes into pieces" when reaching the critical hypersurface. But it may perfectly happen when a Hamiltonian system describes the propagation of singularities in a field or a continuum media. A classical example one finds in geometrical optics when a light ray passing from one optic medium to another splits into reflected and refracted rays (see, for instance, Ref. 34). The trajectory may also be *trapped* by the critical hypersurface. This happens when an "impact" state y possesses no y-decisive points.

V. MECHANICAL SYSTEMS

In this section, we particularize the preceding discussion to mechanical systems subject to affine constraints. Let g be a Riemannian metric on M and $V\in C^\infty(M)$, and consider the mechanical system whose kinetic energy and potential function are $T(q,v)=\frac{1}{2}g(v,v)$ and V, respectively. The corresponding Lagrangian function is $L(q,v)=T(q,v)-V(q)$ and the Hamiltonian one is

$$H(q,p)=\hat{T}(q,p)+V(q), \tag{7}$$

where $\hat{T}(q,p)=\frac{1}{2}\mathcal{G}(p,p)$, and $\mathcal{G}$ is the cometric, i.e., the metric on the cotangent bundle induced by g. In a local chart q^a on M, the local expressions of g and $\mathcal{G}$ are

$$g=g_{ab}\,\mathrm{d}q^a\otimes\mathrm{d}q^b,\quad \mathcal{G}=g^{ab}\frac{\partial}{\partial q^a}\otimes\frac{\partial}{\partial q^b}.$$

In the mechanical case, the Legendre transform $\mathcal{L}_L:TM\to T^*M$ is a linear bundle mapping whose local description is $\mathcal{L}_L(q^a,\dot{q}^a)=(q^a,g_{ab}\dot{q}^b)$.

Consider an affine distribution $C=C^0+Y$ in T^*M determining some nonholonomic constraints on the system (M,H). The linearity of $\alpha_H=\mathcal{L}_L^{-1}$ implies that the space $\alpha_H(C)=\alpha_H(C^0)+\alpha_H(Y)$ is a distribution of affine spaces on M, or otherwise said, that $\alpha_H(C^0)$ is a linear distribution on M. Throughout this section, we will often resort to the shorthand notation $\mathcal{D}=\alpha_H(C^0)$ and $\Upsilon=\alpha_H(Y)$. Now, it is easy to verify that $T^*_qM=C^0_q\oplus\mathrm{Ann}(\mathcal{D})_q$, with associated projectors

$$\mathcal{P}_q : T_q^*M \to C_q^0, \quad \mathcal{Q}_q : T_q^*M \to \mathrm{Ann}(\mathcal{D})_q, \quad q \in M.$$

Let $\mu_1 = \mu_{1\alpha}\,\mathrm{d}q^a, \ldots, \mu_m = \mu_{ma}\,\mathrm{d}q^a$ be 1-forms such that (locally) $\mathrm{Ann}(\mathcal{D}) = \mathrm{span}\{\mu_1, \ldots, \mu_m\}$. Define the local function $\mu_{i0} : M \to \mathbb{R}$ by $\mu_{i0}(q) = -\mu_i(\Upsilon(q))$. Then $\alpha_H(C)$ is locally defined by the equations

$$\mu_{ia}(q)\dot{q}^a + \mu_{i0}(q) = 0, \quad 1 \leqslant i \leqslant m.$$

Now, consider the matrices

$$G = (g_{ab}), \quad J = (\mu_{ia}), \quad \mathcal{B} = JG^{-1}J^t. \tag{8}$$

From the discussion after Proposition 3.1, recall that $(\Delta_{H,C}, \omega_C)$ is a partial symplectic structure if and only if $\alpha_H|_C$ is an immersion, or, equivalently, if the compatibility condition is verified. Following Ref. 12, the latter is equivalent to the matrix $\mathcal{B}$ being invertible. A direct computation gives the following local expression for the projectors $\mathcal{P}$ and $\mathcal{Q}$:

$$\mathcal{P}(x) = x - \mathcal{Q}(x), \quad \mathcal{Q}(x) = J^t\mathcal{B}^{-1}JG^{-1}x, \quad x \in T^*M.$$

Finally, let $N \subset M$ be a hypersurface and assume that the nonholonomic system $S = (M, H, C)$ is transversal to N. Consider also a set of instantaneous nonholonomic linear constraints $C^{\mathrm{inst}} = (C^{\mathrm{inst}^o}, \Upsilon_{C^{\mathrm{inst}}})$ imposed on S along N. Note that $T_q^*M = C_q^{\mathrm{inst}^o} \oplus \mathrm{Ann}(\mathcal{D}^{\mathrm{inst}})_q$, with associated projectors

$$\mathcal{P}_q^{\mathrm{inst}} : T_q^*M \to C_q^{\mathrm{inst}^o}, \quad \mathcal{Q}_q^{\mathrm{inst}} : T_q^*M \to \mathrm{Ann}(\mathcal{D}^{\mathrm{inst}})_q, \quad q \in N.$$

A. Focusing points

Since the mechanical system is subject to an affine distribution of constraints, Proposition 4.5 implies that for a given $u \in T^*M$, the focusing locus is $F_{(H,C)}(u) = \{\mathcal{P}(u) + \mathcal{Q}(\Upsilon)\}$. Regarding the instantaneous focusing points, according to Proposition 4.7 one has that $F_{(H,C^{\mathrm{inst}},N)}(u) = \{\mathcal{P}^{\mathrm{inst}}(u) + \mathcal{Q}^{\mathrm{inst}}(\Upsilon_{C^{\mathrm{inst}}})\}$.

B. Constrained characteristics

Here we give an explicit description of the characteristic curves. Let N be the critical hypersurface, and assume that (locally) $N = f^{-1}(0)$, with $f \in C^\infty(M)$ verifying that $d_q f \neq 0$ for all $q \in N$. Consider the convector field $\mathcal{P}(\mathrm{d}f)$ along N defined as $q \mapsto \mathcal{P}(\mathrm{d}f)_q = \mathcal{P}_q(d_q f)$, $q \in N$. The transversality assumption between C and N implies that $\mathcal{P}(\mathrm{d}f)_q \neq 0$, for all $q \in N$. Clearly $\mathcal{P}(\mathrm{d}f) \in C^0$. In addition, for $v \in \mathcal{D} \cap TN$,

$$\mathcal{P}(\mathrm{d}f)(v) = (\mathrm{d}f - \mathcal{Q}(\mathrm{d}f))(v) = \mathrm{d}f(v) = 0,$$

and one can conclude that $C^0 \cap \mathrm{Ann}(\mathcal{D} \cap TN) = \mathrm{span}\{\mathcal{P}(\mathrm{d}f)\}$. Therefore, we have the following result.

Lemma 5.1: The constrained characteristic of a mechanical system $(M, H, C|N)$ passing through $y \in C \cap T_N^*M$ is given by $\zeta_y = y + \mathrm{span}\{\mathcal{P}(d_{\pi(y)}f)\} \subset C \cap T_N^*M$.

Note that in the absence of constraints one recovers the standard nonconstrained characteristic $\zeta_y = y + \mathrm{span}\{d_{\pi(y)}f\}$ passing through y.

C. Decisive points: elastic mode

1. Change of constraints

Let $C_\pm \subset T^*M$ be two affine constraint submanifolds. Denote by $\mathcal{P}_\pm$ and $\mathcal{Q}_\pm$ the projectors corresponding to $C_\pm$ and the cometric $\mathcal{G}$. Let $y \in C_\varepsilon \cap T_N^*M$ be a ε-out point, $\varepsilon \in \{+, -\}$. Then,

according to Definition 4.12, an y-admissible sequence, (y_i,ε_i), $i=0,1,\ldots,k$, is necessarily of the form $y_{i+1}=\mathcal{P}_{\varepsilon_{i+1}}(y_i)+\mathcal{Q}_{\varepsilon_{i+1}}(\Upsilon_{C_{\varepsilon_{i+1}}})$. If instantaneous constraints are present, then one must use the projectors $\mathcal{P}_\varepsilon^{\text{inst}}$ and $\mathcal{Q}_\varepsilon^{\text{inst}}$ instead of $\mathcal{P}_\varepsilon$ and $\mathcal{Q}_\varepsilon$, respectively.

Remark 5.2: Mechanical systems subject to generalized constraints are also treated in Ref. 16 in a somehow different context. The approach taken there makes use of generalized (i.e., nonconstant rank) codistributions defining the nonholonomic constraints and a generalized version of Newton's second law. Under appropriate regularity conditions, it can be seen that the post-impact point in Ref. 16 is a decisive point of the Hamiltonian system according to Definition 4.12.

2. Discontinuous Hamiltonian systems

Let $C_\pm\subset T^*M$ be two affine constraint submanifolds. Let $g_\pm$ be a Riemannian metric on $M_\pm$ and $V_\pm\in C^\infty(M_\pm)$ such that

$$H_\pm(q,p)=\hat{T}_\pm(q,p)+V_\pm(q),\quad \hat{T}_\pm(q,p)=\tfrac{1}{2}\mathcal{G}_\pm(p,p). \tag{9}$$

For simplicity, we only treat the case $V_\pm=V|_{M_\pm}$, $V\in C^\infty(M)$. We denote by $\mathcal{P}_\pm$ and $\mathcal{Q}_\pm$ the projectors corresponding to $C_\pm$ and the cometric $\mathcal{G}_\pm$. Additionally, let $C_\pm^{\text{inst}}\subset T_N^*M$ be affine constraint submanifolds corresponding to some instantaneous constraints imposed along N. Denote by $\mathcal{P}_\pm^{\text{inst}}$ and $\mathcal{Q}_\pm^{\text{inst}}$ the projectors corresponding to $C_\pm^{\text{inst}}$ and the cometric $\mathcal{G}_\pm$.

Let $y\in C_\varepsilon\cap T_N^*M$ be an ε-out point. Following Definition 4.14, we first describe the reflective and refractive steps with initial point (y,ε). According to Lemma 5.1, we must look for points of the form

$$x=y+c\mathcal{P}_\varepsilon(d_qf),\quad q=\pi(y),$$

for some c, which in addition belong to the same H-energy level as y.

Reflective step: Concerning the first move, note that $y+c\mathcal{P}_\varepsilon(d_qf)$ and y belong to T_q^*M. Then, the equality $H_\varepsilon(y+c\mathcal{P}_\varepsilon(d_qf))=H_\varepsilon(y)$ implies that $\hat{T}_\varepsilon(y+c\mathcal{P}_\varepsilon(d_qf))=\hat{T}_\varepsilon(y)$. Now,

$$\hat{T}_\varepsilon(y+c\mathcal{P}_\varepsilon(d_qf))=\hat{T}_\varepsilon(y)+c\mathcal{G}_\varepsilon(y,\mathcal{P}_\varepsilon(d_qf))+\frac{c^2}{2}\mathcal{G}_\varepsilon(\mathcal{P}_\varepsilon(d_qf),\mathcal{P}_\varepsilon(d_qf)),$$

and, therefore, we have

$$c\left(\mathcal{G}_\varepsilon(y,\mathcal{P}_\varepsilon(d_qf))+\frac{c}{2}\mathcal{G}_\varepsilon(\mathcal{P}_\varepsilon(d_qf),\mathcal{P}_\varepsilon(d_qf))\right)=0,$$

with solutions

$$c_{\varepsilon,1}=0,\quad c_{\varepsilon,2}=-\frac{2\mathcal{G}_\varepsilon(y,\mathcal{P}_\varepsilon(d_qf))}{\mathcal{G}_\varepsilon(\mathcal{P}_\varepsilon(d_qf),\mathcal{P}_\varepsilon(d_qf))}. \tag{10}$$

An important property of these points is contained in the following lemma.

Lemma 5.3: Let $y\in C_\varepsilon\cap T_N^*M$ and $c_{\varepsilon,2}$ be the constant given by (10). *Then*,

$$\mathcal{G}_\varepsilon(y,d_qf)=\mathcal{G}_\varepsilon(\mathcal{P}_\varepsilon(y)+\mathcal{Q}_\varepsilon(\Upsilon_q),d_qf),$$

$$\mathcal{G}_\varepsilon(y+c_{\varepsilon,2}\mathcal{P}_\varepsilon(d_qf),d_qf)=\mathcal{G}_\varepsilon(-\mathcal{P}_\varepsilon(y)+\mathcal{Q}_\varepsilon(\Upsilon_q),d_qf).$$

Proof: The first statement follows by noting that if $y\in C_q$, then $y=\mathcal{P}_\varepsilon(y)+\mathcal{Q}_\varepsilon(\Upsilon_q)$. For the second one, notice that

$$\mathcal{G}_\varepsilon(y + c_{\varepsilon,2}\mathcal{P}_\varepsilon(d_q f), d_q f) = \mathcal{G}_\varepsilon(y, d_q f) + c_{\varepsilon,2}\mathcal{G}_\varepsilon(\mathcal{P}_\varepsilon(d_q f), \mathcal{P}_\varepsilon(d_q f)) = \mathcal{G}_\varepsilon(y, d_q f - 2\mathcal{P}_\varepsilon(d_q f))$$
$$= -\mathcal{G}_\varepsilon(\mathcal{P}_\varepsilon(y), \mathcal{P}_\varepsilon(d_q f)) + \mathcal{G}_\varepsilon(\mathcal{Q}_\varepsilon(y), d_q f) = \mathcal{G}_\varepsilon(-\mathcal{P}_\varepsilon(y) + \mathcal{Q}_\varepsilon(\Upsilon_q), d_q f),$$

which gives the desired result. ■

The second move simply consists of determining the focusing points for points (10) with respect to $C_\varepsilon^{\text{inst}}$ or, if ε instantaneous constraints are absent, with respect to C_ε. This is done in terms of the corresponding projectors, exactly as explained in Sec. V A above.

Refractive step: Concerning the first move, the equality $H_{\bar{\varepsilon}}(y + c\mathcal{P}_\varepsilon(d_q f)) = H_\varepsilon(y)$ implies $\hat{T}_{\bar{\varepsilon}}(y + c\mathcal{P}_\varepsilon(d_q f)) = \hat{T}_\varepsilon(y)$. Now,

$$\hat{T}_{\bar{\varepsilon}}(y + c\mathcal{P}_\varepsilon(d_q f)) = \hat{T}_{\bar{\varepsilon}}(y) + c\mathcal{G}_{\bar{\varepsilon}}(y, \mathcal{P}_\varepsilon(d_q f)) + \frac{c^2}{2}\mathcal{G}_{\bar{\varepsilon}}(\mathcal{P}_\varepsilon(d_q f), \mathcal{P}_\varepsilon(d_q f)).$$

Therefore, one has

$$c\left(\mathcal{G}_{\bar{\varepsilon}}(y, \mathcal{P}_\varepsilon(d_q f)) + \frac{c}{2}\mathcal{G}_{\bar{\varepsilon}}(\mathcal{P}_\varepsilon(d_q f), \mathcal{P}_\varepsilon(d_q f))\right) + \hat{T}_{\bar{\varepsilon}}(y) - \hat{T}_\varepsilon(y) = 0,$$

with solutions $i = 1, 2$,

$$c_{\bar{\varepsilon},i} = \frac{1}{\mathcal{G}_{\bar{\varepsilon}}(\mathcal{P}_\varepsilon(d_q f), \mathcal{P}_\varepsilon(d_q f))}(-\mathcal{G}_{\bar{\varepsilon}}(y, \mathcal{P}_\varepsilon(d_q f))$$
$$\pm \sqrt{\mathcal{G}_{\bar{\varepsilon}}(y, \mathcal{P}_\varepsilon(d_q f))^2 - 2\mathcal{G}_{\bar{\varepsilon}}(\mathcal{P}_\varepsilon(d_q f), \mathcal{P}_\varepsilon(d_q f))(\hat{T}_{\bar{\varepsilon}}(y) - \hat{T}_\varepsilon(y))}). \tag{11}$$

As before, the second move simply consists of computing the focusing points for the solutions (11) with regards to $C_{\bar{\varepsilon}}^{\text{inst}}$ or, if $\bar{\varepsilon}$-instantaneous constraints are absent, $C_{\bar{\varepsilon}}$. This is done in terms of the corresponding projectors according to Sec. V A.

Discontinuous Hamiltonian systems with smooth constraints: In this situation, there is a single constraint submanifold C, and a discontinuous Hamiltonian $H_\pm$ on T^*M. Denote by $\mathcal{P}_\pm$ and $\mathcal{Q}_\pm$ the projectors corresponding to C and the cometrics $\mathcal{G}_\pm$, respectively. According to Proposition 4.15, the decisive points for a given ε-out point $y \in C \cap T_N^*M$ are simply the in and trapping points belonging to the intersection of the constrained characteristic ζ_y passing through y with the set $\{z \in C \,|\, H_\pm(z) = H_\varepsilon(y)\}$. Therefore, as candidate ε-decisive points we have the solution corresponding to $c_{\varepsilon,2}$ in (10), and as candidate $\bar{\varepsilon}$-decisive points we have the solutions corresponding to $c_{\bar{\varepsilon},i}$, $i = 1, 2$, in (11).

Proposition 5.4: Let $y \in C_\varepsilon \cap T_N^*M$ be a ε-out point. If the constraints are linear, $C = C^0$, then the solution corresponding to $c_{\varepsilon,2}$ in (10) *is a ε-decisive point for y.*

Proof: The basic observation is the second order character of the dynamics, both in the presence and in the absence of nonholonomic constraints. This implies that for any $y \in T^*M$ and any distribution of affine constraints C, we have $X_H(f)(y) = X_{H,C}(f)(y)$, since f is only a function of the configurations. Note that if H is of mechanical type, then $X_H(f)(x) = \mathcal{G}(x, d_q f)$, for any $x \in T_q^*M$. Now, from Lemma 5.3, taking $H = H_\varepsilon$, one gets

$$\mathcal{G}_\varepsilon(y + c_2\mathcal{P}_\varepsilon(d_q f), d_q f) = -\mathcal{G}_\varepsilon(y, d_q f).$$

Since y is a ε-out point, then $\mathcal{G}_\varepsilon(y, d_q f) \neq 0$. Consequently, $X_{H_+}(f)(y + c_2\mathcal{P}_+(d_q f)) = -\mathcal{G}_+(d_q f, y)$ has the opposite sign, and hence it is an in point. ■

D. Decisive points: inelastic mode

1. Change of constraints

Let $C_\pm \subset T^*M$ be two affine constraint submanifolds and let C^{inst} be a set of instantaneous affine constraints. We denote by $\mathcal{P}_\pm^{\text{inst}}$ and $\mathcal{Q}_\pm^{\text{inst}}$ the projectors corresponding to $C_\pm^{\text{inst}}$ and the cometric $\mathcal{G}$. If the instantaneous constraints are absent, denote by $\mathcal{P}_\pm$ and $\mathcal{Q}_\pm$ the projectors

corresponding to $C^{\mathrm{tr}}_{\pm}$ and the cometric $\mathcal{G}$. Let $y \in C_\varepsilon \cap T^*_N M$ be a ε-out point, $\varepsilon \in \{+,-\}$. Then, according to Definition 4.17, the unique y-decisive point is $\mathcal{P}^{\mathrm{inst}}_{\bar{\varepsilon}}(y) + \mathcal{Q}^{\mathrm{inst}}_{\bar{\varepsilon}}(\Upsilon_{C_{\bar{\varepsilon}}})$ [or, if there are no instantaneous constraints, $\mathcal{P}_{\bar{\varepsilon}}(y) + \mathcal{Q}_{\bar{\varepsilon}}(\Upsilon_{C_{\bar{\varepsilon}}})$].

2. Discontinuous Hamiltonian systems

As in Sec. V C 2, let $C_\pm \subset T^*M$ be two affine constraint submanifolds, $g_\pm$ a Riemannian metric on $M_\pm$ and $V_\pm \in C^\infty(M_\pm)$ such that Eq. (9) is verified. For simplicity, we only treat the case $V_\pm = V|_{M_\pm}$, $V \in C^\infty(M)$. We denote by $\mathcal{P}_\pm$ and $\mathcal{Q}_\pm$ the projectors corresponding to $C_\pm$ and the cometric $\mathcal{G}_\pm$. Additionally, let $C^{\mathrm{inst}}_\pm \subset T^*_N M$ be affine constraint submanifolds corresponding to some instantaneous constraints imposed along N. We denote by $\mathcal{P}^{\mathrm{inst,tr}}_\varepsilon$ and $\mathcal{Q}^{\mathrm{inst,tr}}_\varepsilon$ the projectors associated with the submanifold $C^{\mathrm{inst,tr}}_\varepsilon$ and the cometric $\mathcal{G}_\varepsilon$. In the absence of instantaneous constraints, we denote by $\mathcal{P}^{\mathrm{tr}}_\varepsilon$ and $\mathcal{Q}^{\mathrm{tr}}_\varepsilon$ the projectors associated with the submanifold $C^{\mathrm{tr}}_\varepsilon$ and the cometric $\mathcal{G}_\varepsilon$. In case $N = \partial M$, we denote the latter with the superscript "∂" instead of "tr."

Let $y \in C_\varepsilon \cap T^*_N M$ be an ε-out point. The points associated with y resulting from the first moves in a reflected or a refracted falling step are given, respectively, by Eqs. (10) and (11). As before, the second move simply consists of computing the focusing points for these solutions with respect to $C^{\mathrm{inst,tr}}_\varepsilon$ for a reflected falling step (respectively, $C^{\mathrm{inst,tr}}_{\bar{\varepsilon}}$ for a refracted falling step) or, if the instantaneous constraints are absent, $C^{\mathrm{tr}}_\varepsilon$ (respectively, $C^{\mathrm{tr}}_{\bar{\varepsilon}}$). This is done in terms of the corresponding projectors according to Sec. V A. According to Definition 4.18, this gives all the y-decisive points.

Proposition 5.5: Let $y \in C_\varepsilon \cap T^*_N M$ be an ε-out point and assume that the constraints are linear. For $N = \partial M$, the unique y-reflected falling point is given by $\mathcal{P}^{inst,\partial}_\varepsilon(y)$ [or, in the absence of ε-instantaneous nonholonomic constraints, $\mathcal{P}^{\partial}_\varepsilon(y)$].

Proof: From the previous discussion, we know that the points in the constrained characteristic passing through y with the same H_ε-energy level are y itself and $y + c_{\varepsilon,2}\mathcal{P}_\varepsilon(d_q f)$, $q = \pi(y)$ [cf. Eq. (10)]. Now, note that $d_q f$ belongs to the $\mathcal{G}_\varepsilon$-orthogonal complement of $\alpha^{-1}_{H_\varepsilon}(T(\partial M))$, i.e.,

$$\mathcal{G}_\varepsilon(d_q f, \beta) = d_q f(\alpha_{H_\varepsilon}(\beta)) = 0, \quad \beta \in \alpha^{-1}_{H_\varepsilon}(T(\partial M)).$$

Using the equality $C^\partial_\varepsilon = C_\varepsilon \cap \alpha^{-1}_{H_\varepsilon}(T(\partial M))$, we have that $d_q f \in \alpha^{-1}_{H_\varepsilon}(T(\partial M))^{\perp_\varepsilon}$ implies $\mathcal{P}^{\mathrm{inst},\partial}_\varepsilon(\mathcal{P}_\varepsilon(d_q f)) = 0$ and $\mathcal{P}^{\partial}_\varepsilon(\mathcal{P}_\varepsilon(d_q f)) = 0$. The result is then a consequence of Definition 4.18. ■

E. Energy behavior

In this section, we discuss the consequences regarding the energy behavior of the system that result from the application of the transition principle.

Lemma 5.6: Given $y \in T^*_N M$, let $x = \mathcal{P}(y) + \mathcal{Q}(\Upsilon_q)$, $q = \pi(y)$, be the associated y-focusing point with respect to a submanifold $C \subset T^*M$. Then

$$\hat{T}(x) \leqslant \hat{T}(y) + \hat{T}(\mathcal{Q}(\Upsilon_q), \mathcal{Q}(\Upsilon_q)),$$

and the equality holds if and only if y belongs to C^0.

Proof: Note that

$$\begin{aligned}\mathcal{G}(\mathcal{P}(y) + \mathcal{Q}(\Upsilon_q), \mathcal{P}(y) + \mathcal{Q}(\Upsilon_q)) &= \mathcal{G}(\mathcal{P}(y), \mathcal{P}(y)) + \mathcal{G}\ (\mathcal{Q}(\Upsilon_q), \mathcal{Q}(\Upsilon_q))) \\ &\leqslant \mathcal{G}(\mathcal{P}(y), \mathcal{P}(y)) + \mathcal{G}(\mathcal{Q}(y), \mathcal{Q}(y)) + \mathcal{G}(\mathcal{Q}(\Upsilon_q), \mathcal{Q}(\Upsilon_q)) \\ &= \mathcal{G}(y, y) + \mathcal{G}(\mathcal{Q}(\Upsilon_q), \mathcal{Q}(\Upsilon_q)),\end{aligned}$$

where we have used that $\mathcal{G}$ is positive-definite, and the fact that C^0 and $\mathrm{Ann}(\mathcal{D})$ are orthogonal spaces with respect to the cometric $\mathcal{G}$. If the equality holds, then $\mathcal{G}(\mathcal{Q}(y), \mathcal{Q}(y)) = 0$, which is equivalent to $y \in C^0$. ■

As a consequence of this simple lemma we can conclude that in the case of linear constraints the transition principle always implies a loss of energy. This is a suitable generalization to constrained systems of the classical Carnot theorem for systems subject to impulsive forces.[36]

Theorem 5.7 (Carnot's theorem for generalized linear constraints): *Suppose that the Hamiltonian system is subject to nonholonomic constraints given by a linear distribution. Then the transition principle implies always a loss of energy as the result of an "impact."*

Proof: Under linear constraints, note that $\Upsilon=0$. From Lemma 5.6, we get $\hat{T}(x)\leqslant\hat{T}(y)$ with $F_{(H,C)}(y)=\{x\}$. The result now follows from the formulation of the transition principle and the definitions of decisive points in Sec. IV E (cf. Definitions 4.12–4.18). ■

Under linear constraints, the trajectory of the system maintains the same energy level after the application of the transition principle in the following cases:

(i) when the decisive points are determined according to Definitions 4.12 and 4.17 and the impact point $y\in T^*_NM$ belongs to $C_+\cap C_-$; and
(ii) when the constraints are smooth, and therefore the decisive points are determined according to Proposition 4.15.

If the decisive points are determined according to Definitions 4.14 and 4.18, then nothing can be said in general. The refractive steps will typically imply an energy decrease.

Remark 5.8: This type of energy arguments also allows to discard as follows the possibility of chattering when computing the y-decisive points if the constraints change (see Definition 4.12 and Remark 4.13 above). Let $N=\{y\in T^*M\,|\,f(y)=0\}$. Assume there is an infinite y-admissible sequence (y_i,ε_i), $i=0,\ldots,\infty$. For each i, we have that $y_i\neq y_{i+1}$, since otherwise

$$X^l_{H,C_{\varepsilon_i+1}}(f)(y_{i+1})=X^l_H(f)(y_{i+1})=X^l_{H,C_{\varepsilon_i}}(f)(y_i)\quad\text{for all } l,$$

which together with the fact that y_i is a ε_i-out point, implies that y_{i+1} is a ε_{i+1}-in point. The latter contradicts the definition of admissible sequence. As a consequence of Lemma 5.6, we then have

$$\hat{T}(y_0)>\hat{T}(y_1)>\hat{T}(y_2)>\cdots>\hat{T}(y_i)\geqslant 0.$$

The limit of this sequence is zero, which implies that the y-decisive point corresponding to such a sequence would be 0, that is, the trajectory would get stuck when reaching N.

F. Integrable constraints

The integrability of the constraints simplifies the application of the transition principle. Consider, for instance, the situation when the mechanical system is unconstrained on M_- and is subject to some generalized linear constraints $C=C^0$ on M_+ that turn out to be holonomic, i.e., $\alpha_H(C^0)=\mathcal{D}$ is integrable. Denote by $\{S_\alpha\}$, α being an m-dimensional parameter, the foliation of M_+ induced by $\mathcal{D}$. Locally this foliation is described by m functions $f_i\in C_\infty(M)$ such that

$$q\in S_\alpha\Leftrightarrow f_i(q)=\alpha_i,\quad 1\leqslant i\leqslant m.$$

A similar situation has been treated in Ref. 35 in the context of totally inelastic collisions (note, however, that in Ref. 35 the integrable distribution is defined only on N, whereas here $\mathcal{D}$ is defined on M_+). The integrable constraints imposed by $\mathcal{D}$ can be interpreted as an abrupt reduction of the phase space of the mechanical system.

By definition, one has that $\mathrm{Ann}(\mathcal{D})=\mathrm{span}\{\mathrm{d}f_1,\ldots,\mathrm{d}f_m\}$. The matrix J in (8) is then given by $J=(\partial f_i/\partial q^a)$ and the projector $\mathcal{P}$ is $\mathcal{P}(x)=(1-J^t\mathcal{B}^{-1}JG^{-1})x$. Let $y\in C_-\cap T^*_NM$ be the impact state of a trajectory $q(t)$ coming from M_-. From the discussion in Sec. V C, we obtain that the unique focusing point associated to y is $x=(1-J^t\mathcal{B}^{-1}JG^{-1})y$. The trajectory will continue its motion in M_+, M_- or N depending on the in/out/trapping character of the focusing point x. If it evolves in M_+ (more precisely, in $S_\alpha\subset M_+$ with α such that $x\in S_\alpha$), we call it the refraction of the original trajectory. If it evolves in M_-, we call it the reflection of the original trajectory.

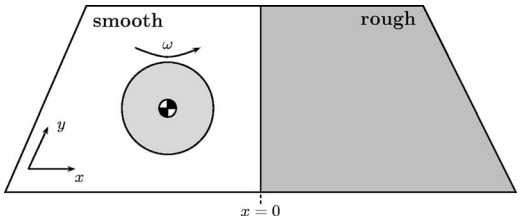

FIG. 1. The rolling sphere on a special surface.

VI. EXAMPLES

In this section we consider four examples to illustrate the theory exposed above. They all present the example of a rolling sphere considered in various constrained situations. The first one is taken from Ref. 16 and is treated here in order to provide a further comparison with previous approaches. The second one combines the presence of smooth nonholonomic constraints with discontinuous Hamiltonians and instantaneous constraints acting on the system along a hypersurface. The third one consists of a ball rolling on a rotating surface whose angular velocity is suddenly changed to a different value, and this is modeled via a discontinuous affine distribution of constraints. Finally, the fourth one presents a two-wheeled system with a rod of variable length and illustrates the application of the transition principle in both the elastic and the inelastic modes.

A. A rolling sphere

Consider a homogeneous sphere rolling on a plane. Assume it has unit mass ($m=1$) and let k^2 be its inertia about any axis. Let (x,y) denote the position of the center of the sphere and let (φ,θ,ψ) denote the Eulerian angles. The configuration space is therefore $Q=\mathbb{R}^2\times \mathrm{SO}(3)$. Assume that the plane is smooth if $x<0$ and absolutely rough if $x>0$ (see Fig. 1). On the smooth half-plane, the motion of the sphere is assumed free, that is, the sphere can slip. On the rough half-plane, the sphere should roll without slipping due to the constraints imposed by the roughness. We are interested in determining the eventual sudden changes in the trajectories of the sphere when it reaches the line separating the smooth and the rough half-planes.

The kinetic energy of the sphere is

$$T=\tfrac{1}{2}(\dot{x}^2+\dot{y}^2+k^2(\omega_x^2+\omega_y^2+\omega_z^2)), \tag{12}$$

where ω_x, ω_y, and ω_z are the angular velocities with respect to the inertial frame, given by

$$\omega_x=\dot{\theta}\cos\psi+\dot{\varphi}\sin\theta\sin\psi,\quad \omega_y=\dot{\theta}\sin\psi-\dot{\varphi}\sin\theta\cos\psi,\quad \omega_z=\dot{\varphi}\cos\theta+\dot{\psi}.$$

The condition of rolling without sliding of the sphere when $x>0$ implies that the point of contact of the sphere and the plane has zero velocity

$$\phi^1=\dot{x}-r\omega_y=0,\quad \phi^2=\dot{y}+r\omega_x=0,$$

where r is the radius of the sphere.

Following the classical procedure,[30] we introduce quasicoordinates q^1, q^2, and q^3 such that $\dot{q}^1=\omega_x$, $\dot{q}^2=\omega_y$, and $\dot{q}^3=\omega_z$. The latter merely have a symbolic meaning in the sense that in the present example, for instance, the partial derivative operators $\partial/\partial q^i$ should be interpreted as linear combinations of the partial derivatives with respect to Euler's angles. Also to the differential forms $\mathrm{d}q^i$ one should attach the appropriate meaning, i.e., they do not represent exact differentials but, instead, we should read them as $\mathrm{d}q^1=\cos\psi\,\mathrm{d}\theta+\sin\theta\sin\psi\,\mathrm{d}\varphi$, etc.

The singular hypersurface N is defined by $N=\{x=0\}$. In this case, the constraints are linear and the nonholonomic distribution $\alpha_H(C)=\mathcal{D}$ on M_+ is given by

$$\mathcal{D}_{(x,y,q^1,q^2,q^3)} = \operatorname{span}\left\{ r\frac{\partial}{\partial x} + \frac{\partial}{\partial q^2}, -r\frac{\partial}{\partial y} + \frac{\partial}{\partial q^1}, \frac{\partial}{\partial q^3} \right\}.$$

Here we are dealing with a single distribution which constrains the motion on M_+.

In the following we compute the decisive points for this example. Let $\lambda \in C_- \cap T^*M$ be a minus-out point. A direct computation shows that the expression of the projector $\mathcal{P}: T^*M \to C$ in local coordinates is

$$\mathcal{P} = \begin{pmatrix} \frac{r^2}{r^2+k^2} & 0 & 0 & \frac{r}{r^2+k^2} & 0 \\ 0 & \frac{r^2}{r^2+k^2} & -\frac{r}{r^2+k^2} & 0 & 0 \\ 0 & \frac{-rk^2}{r^2+k^2} & \frac{k^2}{r^2+k^2} & 0 & 0 \\ \frac{rk^2}{r^2+k^2} & 0 & 0 & \frac{k^2}{r^2+k^2} & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{13}$$

Therefore, the single focusing point for $\lambda \in T^*_N M$ is given by $x = \mathcal{P}(\lambda) \in C \cap T^*_N M$. If we denote $\lambda = (x_0, y_0, q^1_0, q^2_0, q^3_0, (p_x)_0, (p_y)_0, (p_1)_0, (p_2)_0, (p_3)_0)$ and $x = (x, y, q^1, q^2, q^3, p_x, p_y, p_1, p_2, p_3)$, we get

$$p_x = \frac{r^2(p_x)_0 + r(p_2)_0}{r^2+k^2},$$

$$p_y = \frac{r^2(p_y)_0 - r(p_1)_0}{r^2+k^2},$$

$$p_1 = \frac{rk^2(p_y)_0 + k^2(p_1)_0}{r^2+k^2},$$

$$p_2 = \frac{rk^2(p_x)_0 + k^2(p_2)_0}{r^2+k^2},$$

$$p_3 = (p_3)_0.$$

Note also that the focusing point with respect to $C_- = T^*M$ associated with x is x itself. Therefore, if x is a plus-out point, the only admissible sequence for λ is $\{(\lambda,-),(x,+),(x,-)\}$. If x is either a plus-in or a plus-trapping point, then the only admissible sequence for λ is $\{(\lambda,-),(x,+)\}$. The set of plus-trapping points for the dynamics X_{H,C_+} is $\partial(T^*M)^n = \{\mu \in T^*M \,|\, x=0, p_x=0\}$. Consequently, the trajectory is refracted, i.e., the sphere follows its motion on M_+ under the dynamics X_{H,C_+} (rolling without slipping) if $p_x \geqslant 0$. Otherwise (i.e., if $p_x < 0$), the trajectory is reflected by the "roughness" and continues in M_- under the dynamics X_H starting from x.

B. A rolling sphere hitting a wall

This is a classical example[13,20,30] that we treat here for the sake of completeness. Consider again a homogeneous sphere of radius r and unit mass. Assume that the sphere rolls without sliding on a horizontal table, and that at a certain instant of time it hits a wall determined by the plane $x = d > 0$ (cf. Fig. 2). When this happens, the following constraint is instantaneously imposed on the system:

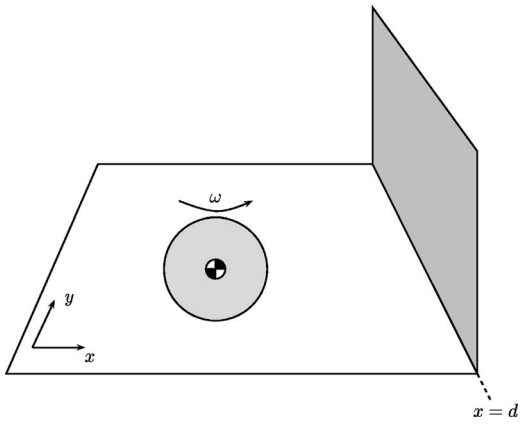

FIG. 2. A rolling sphere that eventually hits a wall.

$$\psi = \dot{y} - r\omega_z = 0.$$

Therefore, we are in the situation explained in Remark 4.16. The configuration space of the system is $M=M_+=\{x<d\}$, with the boundary $N=\{x=d\}$, and the linear constraint submanifold $C=C_+\subset T^*M$ is given by $\alpha_H(C)=\mathcal{D}$,

$$\mathcal{D} = \operatorname{span}\left\{ r\frac{\partial}{\partial x} + \frac{\partial}{\partial q^2}, -r\frac{\partial}{\partial y} + \frac{\partial}{\partial q^1}, \frac{\partial}{\partial q^3} \right\}.$$

The expression for the projector $\mathcal{P}: T^*M \to C$ is given by Eq. (13). The submanifold giving the instantaneous constraints along N is

$$C^{\text{inst}} = \{\lambda \in C | \psi(\alpha_H(\lambda)) = 0\}.$$

The projector $\mathcal{P}^{\text{inst}}=\mathcal{P}_+^{\text{inst}}: T^*M \to C^{\text{inst}}$ is

$$\mathcal{P}^{\text{inst}}(\lambda) = \frac{r\lambda_x + \lambda_2}{r^2 + k^2}(\eta\, dx + k^2\, dq^2) + \frac{-r\lambda_y + \lambda_1 - \lambda_3}{r^2 + 2k^2}(-\eta\, dy + k^2\, dq^1 - k^2\, dq^3). \tag{14}$$

Let $\lambda=(x_0,y_0,q_0^1,q_0^2,q_0^3,(p_x)_0,(p_y)_0,(p_1)_0,(p_2)_0,(p_3)_0) \in C_+ \cap T^*_N M \subset T^*M$ be a plus-out point, i.e., $\mathcal{G}(\lambda, dx) < 0$. We first consider an elastic impact. Since $H_-=\infty$, we only compute the outcome of a reflective step. According to (10), the points in the constrained characteristic passing through λ within the same H_+-energy level are

$$\lambda \quad \text{and } \lambda + c_{+,2}\mathcal{P}(dx), \quad \text{with } c_{+,2} = -2\frac{r^2 + k^2}{r^2}(p_x)_0.$$

The associated focusing points are given by

$$\mathcal{P}^{\text{inst}}(\lambda) \quad \text{and } \mathcal{P}^{\text{inst}}(\lambda) + c_{+,2}\mathcal{P}^{\text{inst}}(\mathcal{P}(dx)). \tag{15}$$

Note that $\mathcal{P}^{\text{inst}}(\mathcal{P}(dx))=\mathcal{P}^{\text{inst}}(dx)=\mathcal{P}(dx)$, and therefore the points in (15) belong to the same constrained characteristic and to the same H_+-energy level. Denoting the coordinates of the point $\mathcal{P}^{\text{inst}}(\lambda)$ by $(x,y,q^1,q^2,q^3,p_x,p_y,p_1,p_2,p_3)$, we get

$$p_x = (p_x)_0,$$

$$p_y = \frac{(r^2 + k^2)(p_y)_0 + r(p_3)_0}{r^2 + 2k^2},$$

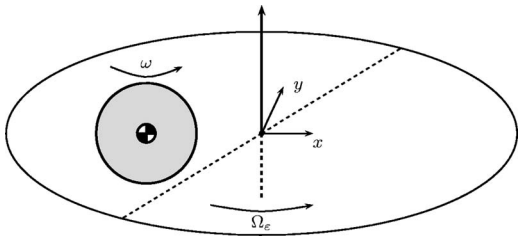

FIG. 3. A rolling sphere on a rotating table.

$$p_1 = -k^2 \frac{(r^2+k^2)(p_y)_0 + r(p_3)_0}{r(r^2+2k^2)},$$

$$p_2 = k^2 \frac{(p_x)_0}{r},$$

$$p_3 = k^2 \frac{(r^2+k^2)(p_y)_0 + r(p_3)_0}{r(r^2+2k^2)}.$$

Now, notice that $\mathcal{P}^{\text{inst}}(\lambda)$ is a plus-out point, because $\mathcal{G}(\mathcal{P}^{\text{inst}}(\lambda), \mathrm{d}x) = \mathcal{G}(\lambda, \mathrm{d}x) < 0$. Therefore, following Proposition 5.4, we conclude that the sequence $\{(\lambda, +), \mathcal{P}^{\text{inst}}(\lambda) + c_{+,2}\mathcal{P}^{\text{inst}}(\mathrm{d}x), +)\}$ is λ-admissible, and $\mathcal{P}^{\text{inst}}(\lambda) + c_{+,2}\mathcal{P}^{\text{inst}}(\mathrm{d}x)$ is a decisive point. The other possible λ-admissible sequence corresponds to

$$\{(\lambda, +), \mathcal{P}^{\text{inst}}(\lambda), \mathcal{P}^{\text{inst}}(\lambda) + c_{+,2}\mathcal{P}^{\text{inst}}(\mathrm{d}x), +)\},$$

but renders the same decisive point.

In the case of an inelastic impact, Proposition 5.5 yields that the unique λ-decisive point is $\mathcal{P}^{\text{inst},\partial}(\lambda)$. After the impact, the ball continues its motion along the wall under the dynamics specified by the vector field $X_+^{\text{inst},\partial}$.

C. A rolling sphere on a rotating table

Consider again a homogeneous sphere of radius r and unit mass. Assume that the sphere rolls without sliding on a horizontal table which is rotating with certain constant angular velocity about a vertical axis through one of its points (see Fig. 3). Let Ω_- and Ω_+ be two angular velocities. Here we consider the following situation: each time the sphere reaches the hypersurface $x=y$, an impulsive force is exerted on the table to put it spinning with a different angular velocity. That is, if the angular velocity of the table was Ω_-, the force applied on its rotation axis changes it to Ω_+ and vice versa. We assume that $\Omega_- < \Omega_+$. This can be modeled as thinking of a system which is subject to two different affine constraint distributions. In order for this model to be consistent, we also assume that the surface of the table is rough enough so that the sphere is rolling without slipping at all times.

The Lagrangian is again given by Eq. (12). The nonholonomic constraints are now affine in the velocities,

$$\dot{x} - r\omega_y = -\Omega y, \quad \dot{y} + r\omega_x = \Omega x.$$

The constraint space $\alpha_H(C)$ is then described by

$$\alpha_H(C) = \mathcal{D} + Y = \operatorname{span}\left\{ r\frac{\partial}{\partial x} + \frac{\partial}{\partial q^2}, -r\frac{\partial}{\partial y} + \frac{\partial}{\partial q^1}, \frac{\partial}{\partial q^3} \right\} + Y,$$

where Y is the vector field defined by

$$Y = -\Omega y\frac{\partial}{\partial x} + \Omega x\frac{\partial}{\partial y}.$$

Note that the projection of $\Upsilon = \mathcal{L}_L(Y)$ to $\mathrm{Ann}(\mathcal{D})$ is given by

$$\mathcal{Q}(\Upsilon) = \frac{\Omega k^2}{r^2 + k^2}(-y\,\mathrm{d}x + x\,\mathrm{d}y - xr\,\mathrm{d}q^1 - yr\,\mathrm{d}q^2).$$

Following the discussion for the case of affine constraints, given $y \in T^*M$, the focusing point with respect to $C_\pm$ is given by

$$x = \mathcal{P}(y) + \mathcal{Q}(\Upsilon_\pm),$$

where $\mathcal{P}$ is the projector in (13).

Assume that the sphere is rolling on the hyperplane $M_- = \{x < y\}$ and that the constant angular velocity of the table is Ω_-. Consider the case when the sphere "hits" the hypersurface $N = \{x = y\}$ with the impact state

$$\lambda = (x_0, y_0, q_0^1, q_0^2, q_0^3, (p_x)_0, (p_y)_0, (p_1)_0, (p_2)_0, (p_3)_0) \in C_- = C_-^0 + \Upsilon_-.$$

Denote the coordinates of the associated focusing point by

$$x = \mathcal{P}(\lambda) + \mathcal{Q}(\Upsilon_+) = (x, y, q^1, q^2, q^3, p_x, p_y, p_1, p_2, p_3).$$

Then

$$\mathcal{G}(\mathrm{d}f, x) = p_x - p_y = (p_x)_0 - (p_y)_0 + \frac{k^2}{r^2 + k^2}(x_0 + y_0)(\Omega_- - \Omega_+). \tag{16}$$

Given that λ is an minus-out point, we have that $\mathcal{G}(\mathrm{d}f, \lambda) = (p_x)_0 - (p_y)_0 > 0$. If $x_0 = y_0 < 0$, then the second term in (16) is also positive, and $\{(\lambda, -), (x, +)\}$ is the unique admissible sequence for λ. In this case, x is the λ-decisive point. On the contrary, for certain values of $x_0 = y_0 > 0$, it might happen that $\mathcal{G}(\mathrm{d}f, x)$ is negative, i.e., that x is a plus-out point. Now, note that the focusing point associated with x is λ itself, since

$$\mathcal{P}(x) + \mathcal{Q}(\Upsilon_-) = \mathcal{P}(\mathcal{P}(\lambda)) + \mathcal{Q}(\Upsilon_-) = \mathcal{P}(\lambda) + \mathcal{Q}(\Upsilon_-) = \lambda.$$

As a consequence, in this case there would not be any λ-decisive point. This problem stems from the fact the modeling of this example as a system subject to affine constraints does not take into account that the jump in the angular velocity of the table takes place *no matter what*. Therefore, after the impact, we should really regard C_+ as the new set of affine constraints acting on the whole configuration manifold. With this interpretation, x would obviously be a plus-in point (and hence decisive). In other words, the trajectory of the ball gets reflected back by the blow of the greater velocity Ω_+.

D. A two-wheeled system with a rod of variable length

Consider a system composed of two wheels of different radii, $r_1 < r_2$, connected by a massless rod of variable length ℓ (see Fig. 4). For simplicity, assume that the two-wheeled system moves along a line, and that both the masses and the momenta of inertia of the wheels are unitary. The wheels are subject to the standard constraints of nonslipping. Assume that the length ℓ of the rod is constrained between a minimum length a and a maximum length b. Here we consider the following two situations: (i) when the length ℓ of the rod becomes extreme, an elastic impact occurs; (ii) when the length ℓ of the rod becomes extreme, an arresting device fixes it, and therefore an inelastic impact occurs.

The Lagrangian of the system is given by the kinetic energy of the wheels

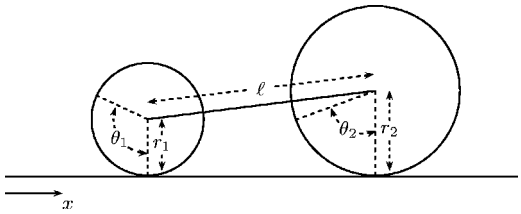

FIG. 4. A two-wheeled system with a rod of variable length.

$$L = \tfrac{1}{2}(\dot{\theta}_1^2 + \dot{\theta}_2^2 + \dot{x}_1^2 + \dot{x}_2^2).$$

The conditions of rolling without sliding are encoded in the constraints

$$\dot{x}_1 - r_1\dot{\theta}_1 = 0, \quad \dot{x}_2 - r_2\dot{\theta}_2 = 0,$$

which, since we are considering the motion of the two-wheeled system only along a line, turn out to be holonomic. The constraint on the length of the rod is given by

$$a \leqslant \ell = \sqrt{(r_2 - r_1)^2 + (x_2 - x_1)^2} \leqslant b.$$

Following Remark 4.16, we set $M_- = \emptyset$, $M_+ = M = \{(x_1, x_2, \theta_1, \theta_2) \in \mathbb{R}^2 \times \mathbb{S}^1 \times \mathbb{S}^1 \,|\, a \leqslant \ell(x_1, x_2, \theta_1, \theta_2) \leqslant b\}$, with boundary set $N = \partial M = \{(x_1, x_2, \theta_1, \theta_2) \in \mathbb{R}^2 \times \mathbb{S}^1 \times \mathbb{S}^1 \,|\, \ell(x_1, x_2, \theta_1, \theta_2) = a \text{ or } \ell(x_1, x_2, \theta_1, \theta_2) = b\}$, and linear constraint submanifold $C = C_+ \subset T^*M$ given by $\alpha_H(C) = \mathcal{D}$,

$$\mathcal{D} = \operatorname{span}\left\{ r_1\frac{\partial}{\partial x_1} + \frac{\partial}{\partial \theta_1}, r_2\frac{\partial}{\partial x_2} + \frac{\partial}{\partial \theta_2} \right\}.$$

The expression for the projector $\mathcal{P}: T^*M \to C$ in local coordinates is given by the following matrix:

$$\mathcal{P} = \begin{pmatrix} \frac{r_1^2}{1+r_1^2} & 0 & \frac{r_1}{1+r_1^2} & 0 \\ 0 & \frac{r_2^2}{1+r_2^2} & 0 & \frac{r_2}{1+r_2^2} \\ \frac{r_1}{1+r_1^2} & 0 & \frac{1}{1+r_1^2} & 0 \\ 0 & \frac{r_2}{1+r_2^2} & 0 & \frac{1}{1+r_2^2} \end{pmatrix}.$$

Let $\lambda \in T^*M_+$ be a plus-out point with $\ell(\lambda) = b$ and $\mathcal{G}(\lambda, \mathrm{d}\ell) > 0$. Since $H_- = \infty$, we only compute the outcome of a reflective step. Following Eq. (10), the points in the constrained characteristic passing through λ with the same H_+-energy level are λ and $\lambda + c_{+,2}\mathcal{P}(\mathrm{d}\ell)$, with

$$c_{+,2} = -\frac{2\mathcal{G}(\lambda, \mathcal{P}(\mathrm{d}\ell))}{\mathcal{G}(\mathcal{P}(\mathrm{d}\ell), \mathcal{P}(\mathrm{d}\ell))}. \tag{17}$$

According to Proposition 5.4, the point $\lambda + c_{+,2}\mathcal{P}(\mathrm{d}\ell)$ is $+$-decisive.

Consider now an inelastic impact, i.e., the case when the length ℓ of the rod becomes fixed after the impact. Since there are no additional instantaneous constraints imposed on the system at the impact state, we compute the decisive points with regards to the boundary of the constraint manifold,

$$C^{\partial} = C \cap \alpha_{H_+}^{-1}(T\partial M) = \{(x_1, x_2, \theta_1, \theta_2, p_{x_1}, p_{x_2}, p_{\theta_1}, p_{\theta_2}) \in T^*M | p_{x_1} = p_{x_2},\ p_{x_1} = r_1 p_{\theta_1},\ p_{x_2} = r_2 p_{\theta_2},\ \ell(x_1, x_2, \theta_1, \theta_2) = a \text{ or } \ell(x_1, x_2, \theta_1, \theta_2) = b\}.$$

As before, we only compute the outcome of a reflective step. Following Proposition 5.5, we deduce that the unique decisive point is $\mathcal{P}^{\partial}(\lambda)$. After the inelastic impact, the length of the rod is fixed forever after, the velocities of the two wheels of the system are reset according to $\mathcal{P}^{\partial}(\lambda)$ and evolve according to $X^{\partial}_{(H,C,N)}$.

VII. CONCLUSIONS

We have developed a generalization of the transition principle to deal with impulsive regimes in general nonholonomic systems, and particularized our discussion to the case of mechanical systems with affine constraints. We have also provided a geometric formulation of the dynamics of nonholonomic Hamiltonian systems via partial symplectic structures. Future work will be devoted to the development of a suitable version of the transition principle for optimal control problems, the comparison of quantitative and qualitative predictions made by the transition principle in specific examples, and the implementation of the results obtained here in numerical schemes for impulsive nonholonomic systems.

Flow acoustics and linearized equations for ideal barotropic fluid flows

Mikhail V. Deryabin[a] and Morten Willatzen[b]
The Mads Clausen Institute, The University of Southern Denmark, DK-6400 Sønderborg, Denmark

(Received 30 August 2005; accepted 15 March 2006; published online 28 April 2006)

In this paper we analyze the acoustic flow in periodic structures for general time-dependent problems. Mathematically, the acoustic problem reduces to analysis of the linearized Helmholtz equations of an ideal barotropic fluid in the neighbourhood of the stationary background flow. We show that in the linear approximation stationary flows are generally unstable. Explicit unbounded solutions are determined and, in some cases, expressions for the general solution of the acoustic problem are stated. © *2006 American Institute of Physics.*

I. INTRODUCTION

In periodic structures such as water-air mixtures, the following phenomenon has been observed: due to special arrangement of the two materials, the speed of sound in the mixed structure can drop drastically[17] allowing for several possible applications, see, e.g., Refs. 5, 10, and 13. In Ref. 19, the Bloch theory of acoustic wave propagation in periodically arranged materials has been extended to include the case where a fluid flows in one of the two constituent media. The fluid flow velocity has been assumed to be any function of the coordinates perpendicular to the direction of the flow, i.e., $\mathbf{v}_0=(0,0,v_0(x_1,x_2))$ in Cartesian coordinates x_1,x_2,x_3, while the acoustic materials have been arranged periodically perpendicular to the flow direction.

In this paper we analyze stability of acoustic flows in the general case of flow propagation with respect to the material periodicity and for general time-dependent problems. We consider two cases: when the acoustic materials are arranged perpendicular to the flow direction (homogeneity applies along the flow direction), and when the acoustic materials are arranged periodically also along the flow direction.

Mathematically, the acoustic problem reduces to analysis of the linearized Helmholtz equation of an ideal barotropic fluid (i.e., assuming fluid pressure to be a function of density only) in the neighborhood of the stationary background flow. There have been many works devoted to analysis of stability of stationary fluid flows and loss of smoothness of solutions for incompressible fluids, see, e.g., Refs. 11, 8, 14, 9, and 20, and references therein.

For the case, when the acoustic materials are arranged perpendicular to the flow direction, we study the so-called short-wave asymptotics of perturbations of stationary flows. It has been shown,[2] by studying the Jordan form of the equations, that for incompressible fluids the solutions to linearized equations can be unbounded. We find explicitly these unbounded solutions for our system, and we also expand these results for barotropic fluids: the stationary background flows under consideration are linearly unstable subject to (acoustic) disturbances. In particular, we find that whenever the frequency is an integer times the local flow velocity, unstable solutions to the periodic lattice problem exist in agreement with previous results.[19] In case when the acoustic

[a]Electronic mail: mikhail@mci.sdu.dk
[b]Electronic mail: Willatzen@mci.sdu.dk

materials are arranged periodically along the flow direction, we also find explicitly the unbounded solutions, and show that the absence of the so-called monofrequency solutions may lead to loss of smoothness of solutions.

In the present analysis, we consider small flows such that pressure drops are negligible, i.e., we consider the ideal case where all flow variables, to a good approximation, can be treated as periodic quantities. At higher flow values this assumption is, however, difficult to establish in practice due to the formation of viscous wakes behind objects.

The instability mechanism in our examples is advective in character, and the growth of solutions is linear (similar to Ref. 2). Usually, the linear growth of solutions to linearized equations is not enough to conclude instability in the nonlinear case. However, here the nonlinear system is also Lyapunov-unstable, and we demonstrate this in the Appendix.

II. MAIN EQUATIONS

Let an ideal compressible barotropic fluid flow on a manifold $M=\mathbb{R}^2\times S^1$, i.e., we assume that the flow velocity and density is periodic in one direction.

We consider the Euler equations in the Helmholtz, or vortex form, see, e.g., Ref. 12,

$$\frac{\partial\rho}{\partial t}+\operatorname{div}(\rho\mathbf{v})=0,\quad \frac{\partial\mathbf{w}}{\partial t}+[\mathbf{w},\mathbf{v}]=0, \tag{1}$$

where ρ is the fluid density, $\mathbf{v}$ is the velocity vector field, $\mathbf{w}=(1/\rho)\operatorname{curl}\mathbf{v}$ and $[\mathbf{w},\mathbf{v}]_i=w_j(\partial v_i/\partial x_j)-v_j(\partial w_i/\partial x_j)$ is the commutator of the vector fields.

We assume that the metric on the manifold M is flat. Let $x_1,x_2;x_3(\mathrm{mod}\,2\pi)$ be the (local) Cartesian coordinates on M, thus the volume element being $\mathrm{d}x_1\,\mathrm{d}x_2\,\mathrm{d}x_3$.

Let ρ_0, $\mathbf{v}_0$ be the stationary flow of the following type:

$$\mathbf{v}_0=(0,0,v_0(x_1,x_2)),\quad \rho_0=\rho_0(x_1,x_2). \tag{2}$$

Stationary flow (2) will be referred to as a *background flow*. Note that, as $\operatorname{div}\mathbf{v}_0\equiv 0$, the derivative $\partial\rho_0/\partial x_3=0$. The functions $v_0(x_1,x_2)$ and $\rho_0(x_1,x_2)$ can be chosen independently. In our coordinate system the vorticity vector equals

$$\mathbf{w}_0=\frac{1}{\rho_0}\operatorname{curl}\mathbf{v}_0=\frac{1}{\rho_0}\left(\frac{\partial v_0}{\partial x_2},-\frac{\partial v_0}{\partial x_1},0\right).$$

Remark: The Helmholtz equations (1) are not equivalent to the Euler equations

$$\rho\frac{\partial\mathbf{v}}{\partial t}+\rho(\mathbf{v},\nabla)\mathbf{v}=\nabla h(\rho),$$

as there are solutions to the Helmholtz equations that are not the solutions to the Euler equations (but, of course, all solutions to the Euler equation are also solutions to the Helmholtz equations), provided the pressure function $h(\rho)$ is given. For example, our stationary flow is the solution to the Euler equations either if $\rho_0=\mathrm{const}$, or if the pressure function $h(\rho)$ is a constant.

We now denote

$$\mathbf{s}=\mathbf{w}-\mathbf{w}_0,\quad r=\rho-\rho_0,$$

and write down the linearized system,

$$\frac{\partial r}{\partial t}+\operatorname{div}(r\mathbf{v}_0+\rho_0\operatorname{curl}^{-1}(r\mathbf{w}_0+\rho_0\mathbf{s}))=0,$$

$$\frac{\partial \mathbf{s}}{\partial t} + [\mathbf{s}, \mathbf{v}_0] + [\mathbf{w}_0, \mathrm{curl}^{-1}(r\mathbf{w}_0 + \rho_0 \mathbf{s})] = 0. \tag{3}$$

This is the general setup for the flow acoustic problem, see Ref. 19. In writing Eq. (3), we have implicitly assumed that $\mathrm{div}(r\mathbf{w}_0 + \rho_0 \mathbf{s}) = 0$ such that $\mathrm{curl}^{-1}(r\mathbf{w}_0 + \rho_0 \mathbf{s})$ is meaningful.

III. INSTABILITY OF LINEARIZED EQUATIONS

We first notice [see, e.g., Ref. 4, Chap. II, and the discussion following Eq. (9)] that, as $[\mathbf{s}, \mathbf{v}_0]$ is the "strongest" linear operator, comparing with the one containing curl^{-1}, it is reasonable to consider the "shortened" equation

$$\frac{\partial r}{\partial t} + \mathrm{div}(r\mathbf{v}_0) = 0, \quad \frac{\partial \mathbf{s}}{\partial t} + [\mathbf{s}, \mathbf{v}_0] = 0. \tag{4}$$

Proposition 1: For nonuniform background flows (i.e., for $v_0 \neq \mathrm{const}$*), almost all solutions to the shortened equation (4) grow linearly in time.*

Thus the stationary solution (2) is unstable in the linear approximation. Proposition 1 can be deduced from Proposition 5.2 in Ref. 4, Chap. II, if we assume the existence of the "action-angle" variables. We give an independent proof in the Appendix.

Theorem 1: *Let* $\mathbf{w}_0 \neq \mathrm{const}$ *or* $\rho_0 \neq \mathrm{const}$. *Then Eqs. (3) have a solution that grows linearly in time.*

Proof: We search for a solution in the following form:

$$\mathbf{u} = (c_1, c_2, u_3(x_1, x_2, t)), \quad r = r(x_1, x_2, t),$$

where $\mathbf{u} = \mathrm{curl}^{-1}(r\mathbf{w}_0 + \rho_0 \mathbf{s})$. Then

$$\mathbf{s} = \frac{1}{\rho_0} \mathrm{curl}\, \mathbf{u} - \frac{r}{\rho_0} \mathbf{w}_0. \tag{5}$$

From Eq. (3), we formally get that

$$s_1 = -\left(c_1 \frac{\partial w_1}{\partial x_1} + c_2 \frac{\partial w_1}{\partial x_2} \right) t, \quad s_2 = -\left(c_1 \frac{\partial w_2}{\partial x_1} + c_2 \frac{\partial w_2}{\partial x_2} \right) t, \quad s_3 = 0,$$

$$r = -\left(c_1 \frac{\partial \rho_0}{\partial x_1} + c_2 \frac{\partial \rho_0}{\partial x_2} \right) t,$$

where

$$w_1 = \frac{1}{\rho_0} \frac{\partial v_0}{\partial x_2}, \quad w_2 = -\frac{1}{\rho_0} \frac{\partial v_0}{\partial x_1}$$

are the components of the background vorticity. Thus we have found a solution that grows linearly in time, and is zero when $t = 0$. To complete the proof, it is enough to show that from relation (5) the value u_3 can be determined (which means that what we have is actually a solution). From (5) follows that

$$\mathrm{curl}\, \mathbf{u} = \rho_0 \mathbf{s} + r\mathbf{w}_0 = (\rho_0 s_1 + r w_1, \rho_0 s_2 + r w_2, 0).$$

One can verify directly that the divergence of the right-hand side is zero. □

In the Appendix we use the same construction as in Theorem 1 to find an unstable solution for the nonlinear (compressible) case, and to prove the (nonlinear) Lyapunov instability of shear flows on a 3-torus, considered in the linear approximation in Refs. 2 and 4.

Remark: Proposition 1 and Theorem 1 describe a known effect that acoustic waves change their frequency and magnitude while propagating through nonuniform flow, however, the effect is

limited to the area where the flow is really nonuniform, see, e.g., Refs. 6, 7, 15, and 16.

IV. SHORT-WAVE ASYMPTOTICS

We next return to the full set of Eqs. (3). Let us consider periodic solutions (being a subset of possible Bloch solutions for acoustic quantities in the linear approximation). Hence, we expand both $\mathbf{s}$ and r as Fourier series in x_3,

$$\mathbf{s} = \sum_m (A_m(x_1,x_2,t), B_m(x_1,x_2,t), C_m(x_1,x_2,t)) \exp imx_3,$$

$$r = \sum_m D_m(x_1,x_2,t) \exp imx_3. \tag{6}$$

The functions A_m, B_m, C_m, D_m cannot be arbitrary: the vector $r\mathbf{w}_0 + \rho_0\mathbf{s}$ should be divergence-free as mentioned above.

As we are interested in short-wave asymptotics, we take $m \neq 0$. The divergence of the mth term in the series representation of $r\mathbf{w}_0 + \rho_0\mathbf{s}$ is

$$\operatorname{div}\left(\left(\frac{1}{\rho_0} D_m \frac{\partial v_0}{\partial x_2} + \rho_0 A_m, -\frac{1}{\rho_0} D_m \frac{\partial v_0}{\partial x_1} + \rho_0 B_m, \rho_0 C_m\right) \exp imx_3\right) = 0,$$

as the mth term of $r\mathbf{w}_0 + \rho_0\mathbf{s}$ reads

$$r\mathbf{w}_0 + \rho_0\mathbf{s} = \left(D_m \frac{1}{\rho_0} \frac{\partial v_0}{\partial x_2} + \rho_0 A_m, -D_m \frac{1}{\rho_0} \frac{\partial v_0}{\partial x_1} + \rho_0 B_m, \rho_0 C_m\right).$$

Thus,

$$\frac{\partial D_m}{\partial x_1} \frac{1}{\rho_0} \frac{\partial v_0}{\partial x_2} + A_m \frac{\partial \rho_0}{\partial x_1} - D_m \frac{\partial \rho_0}{\partial x_1} \frac{1}{\rho_0^2} \frac{\partial v_0}{\partial x_2} + \rho_0 \frac{\partial A_m}{\partial x_1} + D_m \frac{1}{\rho_0} \frac{\partial^2 v_0}{\partial x_1 \partial x_2} - \frac{\partial D_m}{\partial x_2} \frac{1}{\rho_0} \frac{\partial v_0}{\partial x_1} + B_m \frac{\partial \rho_0}{\partial x_2}$$
$$+ D_m \frac{\partial \rho_0}{\partial x_2} \frac{1}{\rho_0^2} \frac{\partial v_0}{\partial x_1} + \rho_0 \frac{\partial B_m}{\partial x_2} - D_m \frac{1}{\rho_0} \frac{\partial^2 v_0}{\partial x_1 \partial x_2} + im\rho_0 C_m = 0. \tag{7}$$

Therefore one can express C_m as the function of A_m, B_m, and D_m

$$C_m = -\frac{i}{m\rho_0} \left(\frac{\partial D_m}{\partial x_1} \frac{1}{\rho_0} \frac{\partial v_0}{\partial x_2} + A_m \frac{\partial \rho_0}{\partial x_1} - D_m \frac{\partial \rho_0}{\partial x_1} \frac{1}{\rho_0^2} \frac{\partial v_0}{\partial x_2} + \rho_0 \frac{\partial A_m}{\partial x_1} - \frac{\partial D_m}{\partial x_2} \frac{1}{\rho_0} \frac{\partial v_0}{\partial x_1} \right.$$
$$\left. + B_m \frac{\partial \rho_0}{\partial x_2} + D_m \frac{\partial \rho_0}{\partial x_2} \frac{1}{\rho_0^2} \frac{\partial v_0}{\partial x_1} + \rho_0 \frac{\partial B_m}{\partial x_2} \right). \tag{8}$$

We next write a curl^{-1} operator in A_m, B_m, D_m coordinates.

Let $\operatorname{curl} \xi = r\mathbf{w}_0 + \rho_0\mathbf{s}$, and we also assume that

$$\xi = (\xi_1(x_1,x_2,t), \xi_2(x_1,x_2,t), \xi_3(x_1,x_2,t)) \exp imx_3.$$

Then

$$\operatorname{curl} \xi = \left(\frac{\partial \xi_3}{\partial x_2} - im\xi_2, -\frac{\partial \xi_3}{\partial x_1} + im\xi_1, \frac{\partial \xi_2}{\partial x_1} - \frac{\partial \xi_1}{\partial x_2}\right) \exp imx_3.$$

The operator curl^{-1} is defined up to a gradient of a function (the solution to the Euler equations is thus determined by the choice of the pressure function, the boundary conditions and initial conditions, which specify the unique form of the curl^{-1} operator). Here, for simplicity, we choose $\xi_3 \equiv 0$ (which is the correct choice for the incompressible case, as we will see later). In this case we get

$$\xi_1 = \frac{i}{m}\left(D_m \frac{1}{\rho_0}\frac{\partial v_0}{\partial x_1} - \rho_0 B_m\right), \quad \xi_2 = \frac{i}{m}\left(D_m \frac{1}{\rho_0}\frac{\partial v_0}{\partial x_2} + \rho_0 A_m\right). \tag{9}$$

Remark: The expression for curl^{-1} certifies our assumption that $[\mathbf{s}, \mathbf{v}_0]$ is the "strongest" linear operator, compared with the one that contains curl^{-1}: for large values of m the operator curl^{-1} is of order $1/m$, while $[\mathbf{s}, \mathbf{v}_0]$ is of order 1.

We can now write down the linear system for the Fourier coefficients [Eqs. (3)]

$$\frac{\partial D_m}{\partial t} + imv_0 D_m + \frac{\partial \rho_0}{\partial x_1}\xi_1 + \rho_0 \frac{\partial \xi_1}{\partial x_1} + \frac{\partial \rho_0}{\partial x_2}\xi_2 + \rho_0 \frac{\partial \xi_2}{\partial x_2} = 0,$$

$$\frac{\partial A_m}{\partial t} + imv_0 A_m + \frac{1}{\rho_0}\frac{\partial v_0}{\partial x_2}\frac{\partial \xi_1}{\partial x_1} - \frac{1}{\rho_0}\frac{\partial v_0}{\partial x_1}\frac{\partial \xi_1}{\partial x_2} - \xi_1 \frac{\partial}{\partial x_1}\left(\frac{1}{\rho_0}\frac{\partial v_0}{\partial x_2}\right) - \xi_2 \frac{\partial}{\partial x_2}\left(\frac{1}{\rho_0}\frac{\partial v_0}{\partial x_2}\right) = 0,$$

$$\frac{\partial B_m}{\partial t} + imv_0 B_m + \frac{1}{\rho_0}\frac{\partial v_0}{\partial x_2}\frac{\partial \xi_2}{\partial x_1} - \frac{1}{\rho_0}\frac{\partial v_0}{\partial x_1}\frac{\partial \xi_2}{\partial x_2} + \xi_1 \frac{\partial}{\partial x_1}\left(\frac{1}{\rho_0}\frac{\partial v_0}{\partial x_1}\right) + \xi_2 \frac{\partial}{\partial x_2}\left(\frac{1}{\rho_0}\frac{\partial v_0}{\partial x_1}\right) = 0. \tag{10}$$

As we have set $\xi_3 = 0$, the system of Eqs. (10) is a homogeneous linear system in A_m, B_m and D_m. These equations are the most interesting from an acoustic point of view.

We first assume that $\rho_0 = \text{const}$. Thus we can neglect the terms that contain partial derivatives $\partial\rho_0/\partial x$. One can check that Eq. (10) has an "incompressible" solution, $D_m = 0$,

$$A_m = \frac{\partial v_0}{\partial x_1} e^{-imv_0 t}, \quad B_m = \frac{\partial v_0}{\partial x_2} e^{-imv_0 t}.$$

Under our assumptions

$$C_m = \frac{i}{m}\left(\frac{\partial A_m}{\partial x_1} + \frac{\partial B_m}{\partial x_2}\right) = \left(\left(\frac{\partial v_0}{\partial x_1}\right)^2 t + \left(\frac{\partial v_0}{\partial x_2}\right)^2 t + \cdots\right) e^{-imv_0 t},$$

therefore our solution grows at least linearly in time. This solution is indeed incompressible under our choice of the operator curl^{-1}, as

$$\mathrm{div}\ \xi = \frac{i\rho_0}{m}\left(-\frac{\partial B_m}{\partial x_1} + \frac{\partial A_m}{\partial x_2}\right) e^{imx_3} \equiv 0.$$

This is an exact solution, that grows linearly in time, which existence was proved in Ref. 2 for a similar system, by studying the Jordan normal form.

Consider now the case when $v_0 = \text{const}$. Then Eqs. (10) becomes

$$\frac{\partial D_m}{\partial t} + imv_0 D_m + \frac{\partial \rho_0}{\partial x_1}\xi_1 + \rho_0 \frac{\partial \xi_1}{\partial x_1} + \frac{\partial \rho_0}{\partial x_2}\xi_2 + \rho_0 \frac{\partial \xi_2}{\partial x_2} = 0,$$

$$\frac{\partial A_m}{\partial t} + imv_0 A_m = 0, \quad \frac{\partial B_m}{\partial t} + imv_0 B_m = 0. \tag{11}$$

If we have chosen the operator curl^{-1} differently, then the last two equations in system (11) remain the same, but the first one acquires an extra term

$$\frac{\partial D_m}{\partial t} + imv_0 D_m + \frac{\partial \rho_0}{\partial x_1}\xi_1 + \rho_0 \frac{\partial \xi_1}{\partial x_1} + \frac{\partial \rho_0}{\partial x_2}\xi_2 + \rho_0 \frac{\partial \xi_2}{\partial x_2} + im\rho_0 \xi_3 = 0,$$

$$\frac{\partial A_m}{\partial t} + imv_0 A_m = 0, \quad \frac{\partial B_m}{\partial t} + imv_0 B_m = 0. \tag{12}$$

Proposition 2: For almost any choice of the operator curl^{-1}, the general solution to system (12) grows linearly in time.

Proof. All the equations in system (12) are ordinary differential equations, where the coordinates x_1 and x_2 serve as parameters. Instability of the general solution follows from the Jordan form of the system. □

At this point we note that our result giving unstable acoustic solutions whenever $m \neq 0$ is in perfect agreement with previous results obtained in Ref. 19, Eq. (17). In the latter case, it was shown that no stable acoustic solution exists if the wave-vector component m along the flow direction (which is β in the notation of Ref. 19) multiplied by the background flow v_0 equals the sound frequency ω. While the work in Ref. 19 gives emphasis to the small-flow case with large ultrasound frequencies where $|\beta v_0| \ll \omega$ such that acoustic instability is not an issue, the present work is dedicated to the study of acoustic instability in periodic media with background flows.

V. FLOW ACROSS THE PERIODIC STRUCTURE. LINEARIZED EQUATIONS

We consider next the case with flow along the periodic structure which consists of identical infinite cylindrical surfaces, arranged in a periodic rectangular lattice. We assume that both the background flow and the acoustic flow are two dimensional.

We will mostly consider the flows that respect the periodic structure in a sense that they are double periodic, or, formally saying, are invariant under the action of the group $\mathbb{Z}^2$. Thus we can restrict ourselves to studying acoustic flows on 2-tori $\mathbb{T}^2=\mathbb{R}^2/\mathbb{Z}^2$.

In two dimensions, the Helmholtz equation,

$$\frac{\partial \mathbf{w}}{\partial t} + [\mathbf{w}, \mathbf{v}] = 0,$$

reduces to one scalar equation for the *vorticity function* $\omega=\Delta\psi$ and

$$\mathbf{v} = (v_x, v_y) = \left(-\frac{\partial \psi}{\partial y}, \frac{\partial \psi}{\partial x} \right),$$

$$\frac{\partial \omega}{\partial t} + L_{\mathbf{v}}\omega = 0, \tag{13}$$

with $L_{\mathbf{v}}\omega=v_x(\partial\omega/\partial x)+v_y(\partial\omega/\partial y)$. Note that although the stream function ψ may not be defined *globally* on the torus, Eq. (13) is well defined.

We consider the classical case, when the background flow is potential. To construct such a flow one should solve the Laplace equation with certain boundary conditions. For a special shape of the base of the cylindrical surface this can be done explicitly, see the Appendix: there we give the analytic expression for the background flow in terms of the Weierstrass zeta functions (we first employ the vortex approximation to a flow of an ideal fluid on the 2-torus, and then construct the desired flow).

The flow pattern is shown in Fig. 1. The separatrices form a "Φ"-shape, turned by $\pi/2$. In the exterior of the "Φ" figure we get the background flow.

Let $\mathbf{v}_0$ denote the background potential flow. In our flow region, i.e., in the exterior of the "Φ" figure, curl $\mathbf{v}_0=0$, thus in the linear approximation the Helmholtz equation (13) becomes

$$\frac{\partial \omega}{\partial t} + L_{\mathbf{v}_0}\omega = 0. \tag{14}$$

But this means that the function ω is transported by the flow of the field $\mathbf{v}_0$ (or "frozen" in the flow), which implies that Eq. (14) can be integrated,

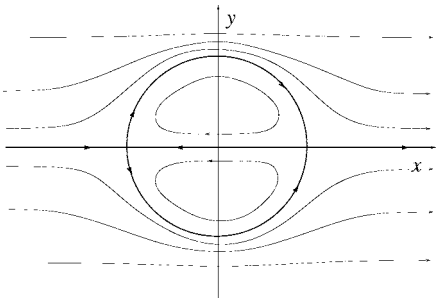

FIG. 1. Flow about the obstacle.

$$\omega(z,t) = \omega^*(g^{-t}_{\mathbf{v}_0} z), \tag{15}$$

where $\omega^*(z)$ is a function on the torus, and $g^t_{\mathbf{v}_0}$ is the phase flow of the vector field $\mathbf{v}_0$.

Let us denote $r=\rho-\rho_0$. We first note that the density function of the background flow ρ_0 is frozen in the flow just like ω. However, from physical considerations, it is natural to consider density as being time independent, as the background flow itself is stationary. Thus $\rho_0(z)$ is a first integral of the flow $g^t_{\mathbf{v}_0}$.

Remark: The operator curl^{-1} *on the plane* is defined for an arbitrary function. However this is not the case for the torus. The reason is that on the torus there are closed 2-forms, that are not exact. As the 2-form $\rho_0\omega^* \mathrm{d}x\wedge\mathrm{d}y$ should be exact (otherwise the d^{-1} operator on forms, that correspond to curl^{-1}, cannot be defined), the integral of the function $\rho_0\omega^*$ over the torus should equal zero—by virtue of the Stokes theorem.

Consider the equation that describes the evolution of r,

$$\frac{\partial r}{\partial t} + L_{\mathbf{v}_0} r + \mathrm{div}(\rho_0 \,\mathrm{curl}^{-1}(\rho_0\omega)) = 0. \tag{16}$$

We denote $\mathrm{div}(\rho_0 \,\mathrm{curl}^{-1}(\rho_0\omega))=f$ and note again that the function $f(z,t)$ should be double periodic in z.

Proposition 3: Let $\partial f/\partial t=0$. *The general solution to Eq. (16) is given by*

$$r(z,t) = r^*(g^{-s}_{\mathbf{v}_0} z) + \int_0^s f(z(\tau))\mathrm{d}\tau - sF(g^{-s}_{\mathbf{v}_0} z) + tF(g^{-s}_{\mathbf{v}_0} z),$$

where s is time passing in going along the phase curve $g^\tau_{\mathbf{v}_0} z$, *that passes through z, from z to the line* $x=0$ *(the integral is also taken along this phase curve), and*

$$F(y) = \int_0^{T(z)} f(z(\tau))\mathrm{d}\tau,$$

where $T(z)$ *is the period of motion along this phase curve.*

Proof: The proposition follows from the general theory of first-order partial differential equations, see, e.g., Ref. 3. The term $sF(g^{-s}_{\mathbf{v}_0} z)$ ensures that the function $\int_0^s f(z(\tau))\mathrm{d}\tau - sF(g^{-s}_{\mathbf{v}_0} z)$ is double periodic in z. □

In general, Eq. (16) has solutions that grow linearly in time. To see this, assume that ρ_0 $=$const and $\omega=0$, while

$$\mathrm{curl}^{-1}(\rho_0\omega) = (0, \cos y),$$

which means that the perturbed flow is potential, but not volume-preserving. The equation for r becomes

$$\frac{\partial r}{\partial t} + L_{\mathbf{v}_0} r - \sin y = 0. \tag{17}$$

For any point z (which does not lie on a separatrix), take a phase curve of the field $\mathbf{v}_0$, that passes through it. Now,

$$F(y) = \int_0^{T(z)} \sin y(\tau) \mathrm{d}\tau,$$

along this curve. The output function F is the function of y only, as the phase curves can be numerated by the y coordinate. Obviously F is not identically zero.

The general solution to Eq. (17) contains the term

$$tF(g_{\mathbf{v}_0}^{-s} z) \neq 0,$$

thus we have found an unbounded solution.

VI. MONOFREQUENCY SOLUTIONS

The usual form for partial solutions to acoustic equations is monofrequency solutions of the type $\omega = \omega(z) \exp i\lambda t$, where $\lambda = \text{const}$, see, e.g., Ref. 19.

Proposition 4: Equation (14) has no smooth (nonzero) monofrequency solutions given by a single-valued function on the torus.

Proof: Let us assume that $\omega = \omega(z) \exp i\lambda t$. Then $\omega(z)$ satisfies the following equation:

$$i\lambda\omega + L_{\mathbf{v}_0}\omega = 0. \tag{18}$$

This equation can be integrated,

$$\omega(z) = e^{i\lambda u(z)} \omega^*(g_{\mathbf{v}_0}^{-s} z), \tag{19}$$

where $\omega(0,x) = \omega^*(y)$, and $u(z)$ is a solution to equation

$$L_{\mathbf{v}_0} u = 1.$$

Solving the latter equation, we get that $u(z) = s$ is the time of the motion along the phase curve $g_{\mathbf{v}_0}^{\tau} z$ from the point z to the line $x = 0$.

If we are looking for a single-valued solution on the torus, we must demand that

$$e^{i\lambda u(2\pi, y)} = e^{i\lambda u(0,y)},$$

i.e., $\lambda u(2\pi, y) = \lambda u(0,y) + 2\pi n$, $n \in \mathbb{Z}$ which for any given point y, is wrong for almost all values of λ. Thus on the torus there are no monofrequency solutions. □

On the other hand, if we let λ depend on the space coordinates, *there may be solutions of the form* (19).

First we notice that if $\lambda = \lambda(z)$ is a first integral of the flow $g_{\mathbf{v}_0}^t$, then the formula (19) does give the solution to Eq. (18). We can now choose λ such that on each phase curve λ equals $1/T$, where T is the period. Then solution (19) is well defined on the torus.

Solutions containing terms of the form $\exp(i\lambda(z)t)$, may lose smoothness for $t \to \infty$: indeed, their *derivative* may contain the terms, linear in t (cf. Ref. 20), which, in our case, provides another source of instability in acoustic flows.

VII. CONCLUSIONS

In this paper we have analyzed the acoustic flow in the general situation, i.e., without assumptions on the monofrequency character of solutions. We have shown that monofrequency solutions, given by single-valued functions on the fluid flow domain, may not exist. We have proved that

general solutions to acoustic equations (that are linearized ideal barotropic fluid equations) usually grow linearly in time. We have found such unbounded solutions explicitly, and in some cases exact expression for the general solution of the acoustic problem were given.

APPENDIX

Proof of Proposition 1

We first write Eq. (4) in our local coordinates,

$$\frac{\partial r}{\partial t} + v_0 \frac{\partial r}{\partial x_3} = 0$$

$$\frac{\partial s_1}{\partial t} + v_0 \frac{\partial s_1}{\partial x_3} = 0, \quad \frac{\partial s_2}{\partial t} + v_0 \frac{\partial s_2}{\partial x_3} = 0,$$

$$\frac{\partial s_3}{\partial t} + v_0 \frac{\partial s_3}{\partial x_3} - s_1 \frac{\partial v_0}{\partial x_1} - s_2 \frac{\partial v_0}{\partial x_2} = 0, \tag{A1}$$

Equation system (A1) has a "wave"-like solution

$$r = \tilde{r}(x_3 - t v_0(x_1, x_2)),$$

$$s_1 = \tilde{s}_1(x_3 - t v_0(x_1, x_2)), \quad s_2 = \tilde{s}_2(x_3 - t v_0(x_1, x_2)),$$

$$s_3 = \tilde{s}_3(x_3 - t v_0(x_1, x_2)) + t\tilde{s}_1(x_3 - t v_0(x_1, x_2)) \frac{\partial v_0}{\partial x_1} + t\tilde{s}_2(x_3 - t v_0(x_1, x_2)) \frac{\partial v_0}{\partial x_2}, \tag{A2}$$

for arbitrary 2π-periodic functions $\tilde{r}(x), \tilde{s}_1(x), \tilde{s}_2(x), \tilde{s}_3(x)$. If we now assume that either $\tilde{s}_1 \partial v_0 / \partial x_1$ or $\tilde{s}_2 \partial v_0 / \partial x_2$ are not identically zero, we get that the function **s** grows linearly in time. Thus almost all solutions to the shortened Eq. (4) grow linearly in time. □

Nonlinear instability

We have shown in Sec. III, that the stationary flow under consideration is generally linearly unstable. In this Appendix, we prove the actual nonlinear instability.

Theorem 2: *Let* $\mathbf{v}_0 \neq const$. *Then the stationary solution (2) is Lyapunov-unstable.*

Proof: We search for a solution to the Helmholtz equations of the following form: $\mathbf{v} = (c_1, c_2, v_3(x_1, x_2, t))$, $\rho = \rho(x_1, x_2, t)$. One can see that for any values of the constants c_1 and c_2, the functions

$$\rho = \rho_0(x_1 - c_1 t, x_2 - c_2 t), \quad v_3 = v_0(x_1 - c_1 t, x_2 - c_2 t), \tag{A3}$$

provide a solution to Eqs. (1). In fact, one can take two arbitrary functions of two variables instead of ρ_0 and v_0. Indeed, the equation for the density reads

$$\frac{\partial \rho}{\partial t} + c_1 \frac{\partial \rho}{\partial x_1} + c_2 \frac{\partial \rho}{\partial x_2} = 0,$$

and it follows that any function $\rho(x_1 - c_1 t, x_2 - c_2 t)$ provides a solution. The same for the vorticity part of Eqs. (1), but now the vector $\mathbf{w}(x_1 - c_1 t, x_2 - c_2 t)$ cannot be arbitrary, as the condition div $\rho \mathbf{w} = 0$ should be satisfied. As this condition is satisfied for the stationary solution, we choose $\rho = \rho_0(x_1 - c_1 t, x_2 - c_2 t)$ and $\mathbf{w} = \mathbf{w}_0(x_1 - c_1 t, x_2 - c_2 t)$.

Now, for any $\epsilon > 0$, choose c_1 and c_2 such that $\|c\|^2 = c_1^2 + c_2^2 = \epsilon^2$. Then the solution (A3) is ϵ-close to the stationary solution (2) at $t = 0$, but then diverges from it for $t = 1/\epsilon$. □

The same result holds for flows on a 3-torus, i.e., when we assume that the velocity and density are periodic in three directions.

Remark: The partial solution we use can be regarded as a special case of solutions studied in Ref. 9 and 18 for incompressible flows. These are solutions that allow decomposition into the "horizontal" and "vertical" components, where both depend only on the "horizontal" coordinates; in our case the "horizontal" component is $(c_1,c_2,0)$, and the "vertical" component is $(0,0,v_3(x_1,x_2,t))$.

Finding a partial solution in the above form is a useful trick: it provides a simple proof for instability of the given stationary solution. As an example, we consider shear flows, studied in Ref. 2 in the linear approximation.

We assume that the flow is incompressible, the flow domain is a 3-torus $\mathbb{T}^3$, and that the stationary solution $\mathbf{v}_0$ is a non-Beltrami solution (the velocity is not proportional to the vorticity). Then both the velocity and vorticity lines lie on 2-tori. We suppose that the 3-torus $\mathbb{T}^3$ is foliated into these 2-tori, and one can choose (local) coordinates ϕ_1,ϕ_2,z, (mod 2π), such that the volume element on $\mathbb{T}^3$ is $\mathrm{d}\phi_1\,\mathrm{d}\phi_2\,\mathrm{d}z$, and

$$\mathbf{v}_0=(v_{1_0}(z),v_{2_0}(z),0).$$

Consider solution to the Euler equation, $\mathbf{v}=(v_1(z,t,\epsilon),v_2(z,t,\epsilon),\epsilon)$,

$$\frac{\partial v_i}{\partial t}+\epsilon\frac{\partial v_i}{\partial z}=0,\quad i=1,2,$$

such that $v_i(0,z)=v_{i_0}(z)$. Then

$$v_1=v_{1_0}(z-\epsilon t),\quad v_2=v_{2_0}(z-\epsilon t).$$

As above, *this solution escapes from the vicinity of the stationary solution, proving that the latter is Lyapunov-unstable*. Moreover, the following result is true.

Proposition 5: Let $\mathbf{v}_0\neq const$, *and let the ratio* v_{1_0}/v_{2_0} *be irrational for* $z=z_0$. *Then for almost all values of* ϵ, *there are trajectories of the vector field* $\mathbf{v}=(v_1(z-\epsilon t),v_2(z-\epsilon t),\epsilon)$, *that are everywhere dense on the torus* $\mathbb{T}^3$.

This proposition proves the nonlinear instability for shear flows in Ref. 2. Notice that the flow can no longer be decomposed into the "horizontal" and "vertical" components as in Ref. 9 and 20.

Proof: Indeed, the equations

$$\dot{\phi}_1=v_{1_0}(z-\epsilon t),\quad \dot{\phi}_2=v_{2_0}(z-\epsilon t),\quad \dot{z}=\epsilon$$

have a solution $z=z_0+\epsilon t$, $\phi_{1,2}=v_{1,2_0}(z_0)t$, which is everywhere dense for almost all ϵ. □

Thus, in general, the trajectories of the velocity field lie no longer on 2-tori. However, all the trajectories of the *vorticity* vector field for the perturbed velocity solution still lie on the same 2-tori, as the original ones ($z=const$), although for big t this field is not close to the vorticity of the stationary flow. Indeed, the z-component of the perturbed vorticity is identically zero: curl $\mathbf{v}=(-\partial v_2/\partial z,\partial v_1/\partial z,0)$.

The vortex approximation to a flow of an ideal fluid

Let $z=(x(\mathrm{mod}\,2\pi),y(\mathrm{mod}\,2\pi))$ be local coordinates on the torus. It is convenient to think of z as a complex number, the velocity $\mathbf{v}$ being a complex-valued function.

In the vortex approximation we assume that the vorticity function is a collection of the Dirac delta functions,

$$\omega(z) = \sum_{i=1}^{N} k_i \delta(z - z_i),$$

where z_i is the coordinate of the ith vortex. The position of the vortices at any given moment of time defines uniquely the fluid velocity field. Assume that the sum $\Sigma_i k_i = 0$. Then the (complex conjugate) velocity field of the fluid is given by a sum of the Weierstrass zeta functions,

$$\frac{d\bar{z}}{dt} = \frac{1}{2\pi i} \sum_{i=1}^{N} k_i \zeta(z - z_i) + C_N, \quad \frac{dz}{dt} = \mathbf{v}, \tag{A4}$$

where C_N does not depend on z, but may depend on instantaneous vortex configuration, see, e.g., Ref. 1, where the exact expression for this constant is provided. Note that although the Weierstrass zeta function is *quasiperiodic* [i.e., $\zeta(z+2\pi m+2\pi i n)=\zeta(z)+mp_1+np_2$, where the constants p_1 and p_2 do not depend on z], their sum is periodic—due to the condition $\Sigma_i k_i = 0$, thus the velocity is a well-defined function on the torus.

The dynamics of the vortices is given by the Hamilton equations

$$\frac{d\bar{z}_i}{dt} = \frac{1}{2\pi i} \sum_{j \neq i}^{N} k_j \zeta(z_i - z_j) + C_N.$$

Analytic expression for the background flow

Let us now consider the velocity field, created by two vortices with intensities $k_1 = -k_2 = k \neq 0$. We assume that the vortices are placed in the points $z_0 = (0, y_0)$ and $\bar{z}_0 = (0, -y_0)$, and that they do not move themselves. Using the expression for the fluid velocity Eq. (A4), we get

$$\frac{d\bar{z}}{dt} = \frac{k}{2\pi i} (\zeta(z - z_0) - \zeta(z + z_0) + \zeta(2z_0)). \tag{A5}$$

Note that there is no single-valued Hamilton function on the torus for our flow.

Remark: The two vortices that we have considered, move with a constant velocity, that equals $-k/2\pi i \zeta(2z_0) + C_N(z_0, \bar{z}_0)$. As we have subtracted this term, we change the coordinate system to the one that moves together with the vortices.

The elliptic function in Eq. (A5) is even ($\mathbf{v}(z) = \mathbf{v}(-z)$), thus if $z = z_1$ is zero of this function, then $z = -z_1$ is also a zero. The number of zero orders of an elliptic function equals the number of pole orders, see, e.g., Ref. 18. Our function $\mathbf{v}(z)$ has two first-order poles, thus it has two zeroes (one zero would be $z_1 = 0$, but one can check that this is not a solution).

We show now explicitly that if $\mathbf{v}(z_1) = 0$, then $\operatorname{Im} z_1 = 0$. Indeed, as $\bar{\zeta}(z) = \zeta(\bar{z})$, $\operatorname{Re} \zeta(iy) = 0$,

$$\frac{2\pi i}{k} \bar{\mathbf{v}}(z_1) = \zeta(x_1 + i(y_1 - y_0)) - \zeta(x_1 + i(y_1 + y_0)) + \zeta(2iy_0) = \bar{\zeta}(x_1 - i(y_1 - y_0)) - \bar{\zeta}(x_1 - i(y_1 + y_0))$$

$$- \bar{\zeta}(2iy_0) = -\bar{\zeta}(-x_1 + i(y_1 - y_0)) + \bar{\zeta}(-x_1 + i(y_1 + y_0)) - \bar{\zeta}(2iy_0) = -\frac{2\pi i}{k} \mathbf{v}(-\bar{z}_1) = 0.$$

Thus, if $\mathbf{v}(z_1) = 0$, then $\mathbf{v}(\bar{z}_1) = 0$. If $\operatorname{Im} z_1 \neq 0$, then we get four distinct points, where our elliptic function satisfies $\mathbf{v}(z) = 0$, which is impossible.

In a similar way as above, one can show that if $\operatorname{Im} z = 0$, then $\operatorname{Im} \mathbf{v}(z) = 0$. As the order of both zeroes of the function $\mathbf{v}(z)$ is one, these are nondegenerate stationary points. Similalry, one can show that if $\operatorname{Im} z = 0$, then $\operatorname{Im} \mathbf{v}(z) = 0$, thus two separatrices, that connect these points, are given by $y = 0$. Together with the to other separatrices, they form a characteristic "Φ"-shape, turned by $\pi/2$, see Fig. 1. In the exterior of the "Φ" figure we get the desired flow about the obstacle.

This way one can describe the potential fluid flow motion about a cylindrical surface. Note that the cross section of this surface is not a circle, still being an analytic curve.

We consider the long time behavior of the coupled Hamilton system of one-dimensional string and nonlinear oscillator, in contact with a heat bath modeled by the white noise. For any temperature the system converges to a statistical equilibrium described by the Boltzmann equilibrium measure. The convergence is caused by radiation provided by the nonlinear coupling. If the oscillator potential has more than one well and the temperature is small, the relaxation time is large, and the system goes through a sequence of metastable states located near local minima of the potential. If both, the temperature and the radiation rate are small, the metastable states are distributions among the minima of the potential. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2189198]

I. STRING COUPLED TO A NONLINEAR OSCILLATOR

We will consider a nonlinear oscillator coupled to a heat bath and to a one-dimensional (1D) string. The string is governed by the 1D wave equation

$$\mu\ddot{u}(x,t) = Tu''(x,t), \quad x \in \mathbb{R}\setminus\{0\}, \tag{1.1}$$

where $u(x,t)$ is the real function, $\mu>0$ is the string density, and $T>0$ is its tension. The oscillator is a particle of mass $m>0$ attached to the string at the point $x=0$, so

$$u(0,t) = q(t), \quad t \in \mathbb{R}, \tag{1.2}$$

where $q(t)$ is the deviation of the oscillator. The heat bath is modeled as white noise, so the oscillator is governed by the stochastic equation

$$m\ddot{q}(t) = F(q(t)) + T[u'(0+,t) - u'(0-,t)] + \sqrt{\sigma}\dot{W}(t); \quad q(t) \equiv u(0,t), \tag{1.3}$$

where $F(q)$ stands for the oscillator force function, $W(t)$ is the standard one-dimensional Wiener process, and $\sigma \geqslant 0$ is the temperature of the heat bath. The middle term on the right-hand side of (1.3) descibes the string-oscillator interaction. Roughly speaking, $Tu'(0+,t)$, respectively, $-Tu'(0+,t)$ is the "vertical projection" of the tension of the string to the right-handside, respectively, to the left-handside of the oscillator (see Fig. 1).

The system (1.1)–(1.3) is formally equivalent to a one-dimensional nonlinear wave equation with the nonlinear term concentrated at the single point $x=0$ and with a mass m concentrated at the same point,

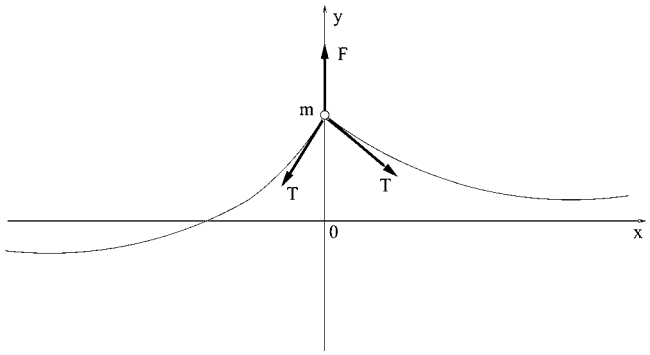

FIG. 1. String with the oscillator.

$$(\mu + m\delta(x))\ddot{u}(x,t) = Tu''(x,t) + \delta(x)[F(u(x,t)) + \sqrt{\sigma}\dot{W}(t)], \quad (x,t) \in \mathbb{R}^2. \tag{1.4}$$

Namely, the equation (1.1) follows from (1.4) with $x \neq 0$, while (1.3) follows by equating the coefficients at the delta function in both sides of (1.4).

For the linear oscillator when $F(q) = -\omega^2 q$ the system (1.1), (1.3) with $\sigma = 0$ was considered originally by Lamb.[11] For general nonlinear force function $F(q)$ and $\sigma = 0$ the system was analyzed in Refs. 8 and 9 (see also Ref. 10, pp. 26–37) where the convergence to stationary states has been proved for all finite energy solutions in the long-time limit $t \to \pm\infty$.

In the present paper we consider the long-time behavior of the Lamb system (1.1)–(1.3) with $\sigma > 0$ modeling the interaction with a heat bath of the temperature σ. We consider the Cauchy problem for the system (1.1)–(1.3) with the initial conditions

$$u|_{t=0} = u_0(x), \quad \dot{u}|_{t=0} = v_0(x), \quad \dot{q}|_{t=0} = p_0. \tag{1.5}$$

We assume that initial functions are compactly supported or decreasing fast enough at infinity. Then one can expect that, due to interplay between the energy dissipation caused by radiation and the incident energy flow from the heat bath, a stationary regime will be established in large time. If the potential $U(q) := -\int F(q)\mathrm{d}q$ has more than one well and the temperature σ is small, the relaxation time is large, and the system goes through a sequence of metastable states.

In generic situation, for a given time scale and an initial point, the system will be situated near certain local minimum of the potential. We consider also the situation when both, the temperature σ and the radiation rate (which can be characterized by the product of the string density and its tension), are small. An "additional stochasticity" appears in this case due to instability near the local maximums of potential. Therefore, even for generic potential, the metastable states are distributions among the minima of the potential. We calculate these limiting distributions.

II. NOTATIONS AND DYNAMICS

Write the Cauchy problem (1.4) and (1.5) in the form

$$\dot{Y}(t) = \mathbf{F}(Y(t),t), \quad t \in \mathbb{R}, \quad Y(0) = Y_0, \tag{2.1}$$

where $Y_0 = (u_0, v_0, p_0)$ and $Y(t) = (u(t), v(t), \dot{q}(t))$.

Let us introduce a phase space $\mathcal{E}$ of finite energy states for the system (1.1)–(1.3). Denote by $\|\cdot\|$, respectively, $\|\cdot\|_R$ the norm in the Hilbert space $L^2 := L^2(\mathbb{R})$, respectively, $L^2(-R,R)$.

Definition 2.1: (i) $\mathcal{E}$ *is the Hilbert space of the triples* $(u(x), v(x), p) \in C(\mathbb{R}) \oplus L^2 \oplus \mathbb{R}$ *with* $u'(x) \in L^2$ *and the* global energy norm

$$\|(u,v,p)\|_{\mathcal{E}} = \|u'\| + |u(0)| + \|v\| + |p|. \tag{2.2}$$

(ii) $\mathcal{E}_F$ *is the space* $\mathcal{E}$ *endowed with the Fréchet topology defined by the* local energy seminorms

$$\|(u,v,p)\|_{\mathcal{E},R} \equiv \|u'\|_R + |u(0)| + \|v\|_R + |p|, \quad R>0. \tag{2.3}$$

(iii) $Y_n \overset{\mathcal{E}_F}{\to} Y$ *iff* $\|Y_n - Y\|_{\mathcal{E},R} \to 0$, $\forall R>0$.

Remark 2.2: This convergence is equivalent to the convergence with respect to the metric

$$\rho(X,Y) = \sum_{R=1}^{\infty} 2^{-R} \frac{\|X-Y\|_{\mathcal{E},R}}{1+\|X-Y\|_{\mathcal{E},R}}, \quad X,Y \in \mathcal{E}. \tag{2.4}$$

We assume that

$$F(q) \in C^1(\mathbb{R}), \tag{2.5}$$

$$U(q) := -\int F(q)\mathrm{d}q \to +\infty, \quad |q| \to \infty. \tag{2.6}$$

Then the system (1.1)–(1.3) for $\sigma=0$ is formally Hamiltonian with the Hamilton functional

$$\mathcal{H}(u,v,p) = \frac{1}{2}\int [|v(x)|^2 + |u'(x)|^2]\mathrm{d}x + m\frac{|p|^2}{2} + U(u(0)) \tag{2.7}$$

for $(u,v,p) \in \mathcal{E}$. We consider solutions $u(x,t)$ such that $Y(t)=(u(\cdot,t),\dot{u}(\cdot,t),\dot{q}(t)) \in C(0,\infty;\mathcal{E})$.

Let us discuss the definition of the Cauchy problem (2.1) for the functions $Y(t) \in C(0,\infty;\mathcal{E})$. At first, $u(x,t) \in C(\mathbb{R}^2)$ due to $Y(t) \in C(0,\infty;\mathcal{E})$. Then the wave equation (1.1) is understood in the sense of distributions. This is equivalent to the d'Alembert decomposition

$$u(x,t) = f_{\pm}(x-at) + g_{\pm}(x+at), \quad \pm x>0, \tag{2.8}$$

where $a=\sqrt{T/\mu}>0$, and $f_- \in C(-\infty,0)$, $g_+ \in C(0,\infty)$, and $f_+, g_- \in C(-\infty,\infty)$. Therefore,

$$\dot{u}(x,t) = -f_{\pm}'(x-at) + g_{\pm}'(x+at), \quad u'(x,t) = f_{\pm}'(x-at) + g_{\pm}'(x+at) \text{ for } \pm x>0,\ t \in \mathbb{R}, \tag{2.9}$$

where all the derivatives are understood in the sense of distributions. The condition $Y(t) \in C(0,\infty;\mathcal{E})$ implies that

$$f_{\pm}', g_{\pm}' \in L^2_{\mathrm{loc}}(\mathbb{R}). \tag{2.10}$$

We now explain the second equation (1.3).

Definition 2.3: In the equation (1.3) *set*

$$u'(0\pm,t) \equiv f_{\pm}'(-at) + g_{\pm}'(at) \in L^2_{\mathrm{loc}}(0,\infty), \tag{2.11}$$

while the derivative $\ddot{q}(t)$ *of* $q(t) \equiv u(0,t) \in C[0,\infty)$ [*or of* $\dot{q}(t) \in L^2_{\mathrm{loc}}[0,\infty)$ *by* (2.10)] *is understood in the sense of distributions.*

Note that the functions $f_{\pm}$ and $g_{\pm}$ in (2.8) are unique up to an additive constant. Hence definition (2.11) is unambiguous.

Proposition 2.4: (*Ref.* 9) *Let the conditions* (2.5), (2.6) *be fulfilled, and* $W(t) \in C(0,\infty;\mathbb{R})$ *is a fixed function. Then*

(i) *For every* $Y_0 \in \mathcal{E}$ *the Cauchy problem* (2.1) *admits a unique solution* $Y(t) \in C(0,\infty;\mathcal{E})$.
(ii) *The map* $U(t): Y_0 \mapsto Y(t)$ *is continuous in* $\mathcal{E}$ *and* $\mathcal{E}_F$.

The proposition is proved in Ref. 9 for the case $W(t) \equiv 0$. The proof for the general case is very similar.

III. GLOBAL ATTRACTOR FOR ZERO TEMPERATURE

The stationary states $S=(s(x),0,0)\in\mathcal{E}$ for (1.1)–(1.3) with $\sigma=0$ are evidently determined. We define for every $c\in\mathbb{R}$ the constant function

$$s_c(x)=c,\quad x\in\mathbb{R}. \tag{3.1}$$

Then the set $\mathcal{S}$ of all stationary states $S\in\mathcal{E}$ is given by

$$\mathcal{S}=\{S_z=(s_z(\cdot),0,0):\ z\in Z\}, \tag{3.2}$$

where $Z=\{z\in\mathbb{R}:\ F(z)=0\}$.

The set S is a global attractor for the Lamb system (1.1)–(1.3) with $\sigma=0$.[9] Our main goal in this paper is to describe the convergence to the statistical equilibrium for the Lamb system with $\sigma>0$, and metastable rejimes for small $\sigma>0$ and $m>0$.

IV. REDUCED EQUATION FOR POSITIVE TEMPERATURE

The Lamb system (1.1)–(1.3) is equivalent to the following reduced equation:

$$m\ddot{q}(t)=F(q(t))-\frac{2T}{a}\dot{q}(t)+\frac{2}{a}\dot{w}_{\rm in}(t)+\sqrt{\sigma}\dot{W}(t),\quad t>0, \tag{4.1}$$

where $w_{\rm in}(t)\in C[0,\infty)$ is determined by the initial conditions (1.5) and the equation is understood in the sense of the corresponding integral equation (or distributions).[9,10]

For $|x|\geqslant at\geqslant 0$ at the solution of the system (1.1)–(1.3) is determined uniquely by the initial functions and is expressed by the d'Alembert formula

$$u(x,t)=\frac{u_0(x-at)+u_0(x+at)}{2}+\frac{1}{2}\int_{x-at}^{x+at}v_0(y)\mathrm{d}y,\quad |x|\geqslant at\geqslant 0. \tag{4.2}$$

For $|x|\leqslant at$ the solution cannot be expressed in the initial functions. Indeed, the waves $f_+(x-at)$, respectively, $g_-(x+at)$ [see (2.8)] in the regions $0<x<at$, respectively, $-at<x<0$ are the *reflected waves* and are not determined by the initial conditions. To determine both these two reflected waves we need two equations: first is the gluing equation $u(0+,t)=u(0-,t)$, and the second is the "jump equation" (1.3). Substituting the d'Alembert representations (2.8) to the equations, we get (see Ref. 9 or Ref. 10, Chap. 1, Lemma 4.6) the reduced equation (4.1), where $w_{\rm in}(t)$ is the sum of the *incident waves* $g_+(x+at)$ and $f_-(x-at)$ at the point $x=0$:

$$w_{\rm in}(t)=g_+(at)+f_-(-at),\quad t\geqslant 0. \tag{4.3}$$

For this function we have

$$\dot{w}_{\rm in}(t)\in L^2(0,\infty) \tag{4.4}$$

since the initial functions belong to the phase space of finite energy states. Moreover, we get the expressions [see Ref. 10, Chap. 1, (4.33)]

$$u(x,t)=\left\{\begin{array}{ll} q(t-x/a)+g_+(x+at)-g_+(at-x), & 0<x<at\\ q(t+x/a)+f_-(x-at)-f_-(-x-at), & -at<x<0\end{array}\right|,\quad t\geqslant 0. \tag{4.5}$$

It is important to note that this formula contains only the incident waves which are constant for large time if the initial functions are constant for large $|x|$. Namely, let us consider the initial functions in (1.5) with

$$u_0(x)=C_\pm,\quad v_0(x)=0,\quad \pm x>R_0. \tag{4.6}$$

Then $g_+(z)=c_+$ for $z>R_0$, and $f_-(z)=c_-$ for $z<-R_0$. Hence (4.3) implies that

$$w_{\text{in}}(t) = 0, \quad t > R_0/a. \tag{4.7}$$

Respectively, (4.1) becomes

$$m\ddot{q}(t) = F(q(t)) - \frac{2T}{a}\dot{q}(t) + \sqrt{\sigma}\dot{W}(t), \quad t > R_0/a, \tag{4.8}$$

and (4.5) implies that

$$u(x,t) = q(t - |x|/a), \quad |x| < R, \quad t \geqslant \frac{R + R_0}{a} \tag{4.9}$$

for every $R > 0$. Finally, take into account the value of a. Then (4.8) reads

$$m\ddot{q}(t) = F(q(t)) - 2\sqrt{\mu T}\dot{q}(t) + \sqrt{\sigma}\dot{W}(t), \quad t > R_0/a. \tag{4.10}$$

Our goal is to describe a long-time behavior of the solution for the cases

$$m \sim \sqrt{\mu T} \ll 1, \quad \sqrt{\sigma} \ll 1. \tag{4.11}$$

V. CONVERGENCE TO EQUILIBRIUM DISTRIBUTION

If the supports of the initial functions $u_0(x)$ and $v_0(x)$ belong to a finite interval $|x| < R_0 < \infty$, then, at least after time $t_0 = R_0/a$, no incident waves come to the origin. So the evolution of the oscillator can be described by Eq. (4.10) which is equivalent to the following system:

$$\begin{aligned} \dot{q}(t) &= p(t), \\ m\dot{p}(t) &= -U'(q(t)) - 2\sqrt{\mu T}p(t) + \sqrt{\sigma}\dot{W}(t), \quad t > t_0. \end{aligned} \tag{5.1}$$

The values $q(t_0)$ and $p(t_0)$ are defined by the initial condition and by the trajectory $W(t)$ for $0 \leqslant t \leqslant t_0$.

The stochastic process $(q(t), p(t))$ defined by (5.1) is a (degenerate) diffusion process governed by the differential operator

$$Lu(q,p) = p\frac{\partial u}{\partial q} - \frac{1}{m}[U'(q) + 2p\sqrt{\mu T}]\frac{\partial u}{\partial p} + \frac{\sigma}{2m^2}\frac{\partial^2 u}{\partial p^2}. \tag{5.2}$$

Solving the stationary Fokker-Planck (forward Kolmogorov) equation $L^* v(q,p) = 0$, we find the stationary Boltzman distribution

$$v(q,p) = \frac{1}{Z}\exp\left\{-\frac{4\sqrt{\mu T}}{\sigma}\left(\frac{mp^2}{2} + U(q)\right)\right\}, \tag{5.3}$$

where Z is a normalizing constant,

$$Z = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\exp\left\{-\frac{4\sqrt{\mu T}}{\sigma}\left(\frac{mp^2}{2} + U(q)\right)\right\}\mathrm{d}p\,\mathrm{d}q.$$

Assume that the following condition (*) is satisfied: for some $Q_0 > 0$,

$$U'(q)\,\operatorname{sign} q \geqslant \alpha > 0 \quad \text{for } |q| > Q_0\,. \,(*)$$

This condition, in particular, provides finiteness of the normalizing constant Z.

Proposition 5.1: Let condition (*) *be satisfied. Then*

(i) *There exists a unique stationary solution* $(\bar{q}(t), \bar{p}(t))$ *of system* (5.1). *For any* t, *the*

distribution of $(\bar{q}_t,\bar{p}_t)$ *is given by* (5.3).

(ii) *The solution* $(q(t),p(t))$ *of system* (5.1) *with any initial condition* $q(0)=q_0, p(0)=p_0$, *converges to* $(\bar{q}_t,\bar{p}_t)$ *as time tends to infinity, i.e.*

For every $A>0$, *the distribution of the random process* $(g(T+s),p(T+s)), 0\leqslant s\leqslant A$, *in* $C_{0,A}$ *converges weakly to the distribution of* $(\bar{q}_s,\bar{p}_s)$ *as* $T\to\infty$.

Proof: Without loss of generality, we can assume, that $m=2\sqrt{\mu T}=\sigma=1$. Then the function

$$v(q,p)=\frac{p^2}{2}+(q-\gamma\arctan q)p+v(q)+\int_0^q(s-\gamma\arctan s)\mathrm{d}s+k$$

for a suitable choice of parameters γ,k satisfies the conditions (see Ref. 7, Sec. 3.5) $v(q,p)\geqslant 0, Lv(q,p)<-\alpha<0$ for $|p|+|q|$ large enough, $\lim_{|p|+|q|\to\infty} v(q,p)=\infty$. Here L is defined in (5.2) and α is a positive constant from (*).

As we already mentioned, the Boltzman distribution is invariant for the equation (5.1). To prove uniqueness of the stationary distribution and convergence, one can use the standard construction which goes back to Ref. 7. Therefore we give just a sketch of the proof.

Let $\gamma_A, A>0$ be the boundary of the square $\{(q,p)\in\mathbb{R}^2: |q|<A, |p|<A\}, \Gamma_A=\gamma_{A+1}$. Consider a Markov chain Z_n with the state space γ_A which is defined as follows: Starting from any point $Z_0=(q_0,p_0)\in\gamma_A$, the trajectory of the process $X_t=(q_t,p_t)$ hits at some time Γ_A and then comes back to γ_A. Let τ be the first time when X_t comes to γ_A after hitting Γ_A. Existence of the function $v(q,p)$ constructed above implies that the random variable τ is finite with probability 1, and the expected value $E\tau<\infty$, at least, if A is large enough. Set $Z_1=X_\tau$, so that the chain Z_n in one step jumps from Z_0 to $Z_1=X_\tau$. The standard proof of uniqueness of the stationary distribution and convergence to it is given under nondegeneracy assumption of the operator L.

In our case L is degenerate. But it satisfies the Hörmander conditions, providing the existence of a positive density for X_t. Moreover, one can check that, due to the structure of the operator L, Doeblin conditions for the chain Z_n are satisfied (Ref. 2, Sec. 6.2). This implies that the chain Z_n on γ_A has a unique stationary distribution which is also the limiting distribution for Z_n.

The last property provides uniqueness of the stationary distribution for process (q_t,p_t) and convergence to this distribution (which is the Boltzman distribution) as $t\to\infty$. This implies existence and uniqueness of a stationary process $(\bar{q}_t,\bar{p}_t)$ satisfying equations (5.1) and the last statement of Proposition 5.1. The stationary process $(\bar{q}_t,\bar{p}_t)$ is the solution of (5.1) with the initial point distributed according to the Boltzman distribution.

Theorem 5.1: *Let* (*) *be satisfied, and the initial functions* (1.5) *have a compact support. Then, we have the following*:

(i) *There exists a unique random field* $\bar{u}(t,x)$, $t\in(-\infty,\infty)$, $x\in\mathbb{R}^1$, *such that* $\bar{u}(t,x)$ *is a solution of equation*

$$\mu\frac{\partial^2\bar{u}}{\partial t^2}=T\frac{\partial^2\bar{u}}{\partial x^2},\quad t\in(-\infty,\infty),\quad x\in\mathbb{R}^1\setminus\{0\};\tag{5.4}$$

at $x=0$ *the gluing conditions* (1.2) and (1.3) *are satisfied. The distribution of* $\bar{u}(t,x)$ *is invariant with respect to time shifts*: *for any* $h\in\mathbb{R}^1$, $\bar{u}(t+h,x)$ *and* $\bar{u}(t,x)$ *have the same distribution in the space of continuous functions* $\varphi(t,x)$, $t\in(-\infty,\infty), x\in\mathbb{R}^1$.

(ii) *This unique solution is given by the formula* [cf. (4.9)]

$$\bar{u}(t,x)=\bar{q}\left(t-\frac{|x|}{a}\right),\quad (x,t)\in\mathbb{R}^2,\tag{5.5}$$

where $a=\sqrt{T/\mu}$.

(iii) *For every initial condition with a compact support, the solution* $u(t,x)$ *of problem* (1.1)–(1.3) *converges to the stationary solution* $\bar{u}(t,x)$.

For any $A>0$, the random process $\tilde{u}_T(t,x)=u(T+t,x), 0\leqslant t\leqslant A, |x|\leqslant A$, converges weakly to $\bar{u}(t,x)$ as $T\to\infty$ in the space of continuous functions on $[0,A]\times[|x|\leqslant A]$ provided with uniform topology.

Proof: As it follows from Proposition 5.1, if condition (*) is satisfied, a unique stationary solution $(\bar{q}_t,\bar{p}_t)$ of problem (5.1) exists. Then the function (5.5) satisfies equation (5.4) and the gluing conditions at $x=0$. Since the stochastic process $\bar{q}_t$ is invariant with respect to the time shifts, so is the function $\bar{u}(t,x)$. If another time shift invariant solution $\bar{\bar{u}}(t,x)$ exists, then $\bar{\bar{u}}(t,0)$ should coincide in distribution with $\bar{q}_t$, since problem (5.1) has a unique stationary solution. Convergence of the solution of problem (1.1)–(1.3) with compactly supported initial functions to $\bar{u}(t,x)$ follows by the formula (4.9) from the convergence of $q(t)$ to $\bar{q}_t$.

VI. LOW TEMPERATURE LIMIT

Let us note that the Boltzman equilibrium distribution (5.3) corresponds to the temperature proportional to

$$\frac{\sigma}{\sqrt{\mu T}}. \tag{6.1}$$

Here we discuss low temperature behavior in the Lamb system (1.1)–(1.3), when $\sigma\to 0$ for fixed μ and T.

If the potential $U(q)$ has more than one well, and $\sigma\ll 1$, the convergence to the stationary regime will be slow, and the system will go through a sequence of metastable regimes, where it spends a long time before approaching the stationary solution described above.

The sequence of metastable regimes depends on the equilibrium state of equations (5.1) with $\sigma=0$, to which the system was brought by the initial conditions (1.5). Since we assume that the initial conditions have a compact support, say, they are equal to zero for $|x|>\theta$, no incident waves come to the origin $x=0$ after time $t_0=\theta/a$. Set $u(t_0,0)=q_0^*$, $\dot{u}(t_0,0)=p_0^*$.

Assume that, for system (5.1) with $\sigma=0$, the initial point (q_0^*,p_0^*) is attracted to the stable equilibrium $O_{k(q_0^*,p_0^*)}$. The point $O_{k(q_0^*,p_0^*)}$ in the phase space $\mathbb{R}^2$ has coordinates $(q_{k(q_0^*,p_0^*)},0)$; $q_{k(q_0^*,p_0^*)}$ is a local minimum of the potential $U(q)$.

If $\sigma=0$, then the solution of system (5.1) with initial point (q_0^*,p_0^*) will stay near $O_{k(q_0^*,p_0^*)}$ forever. In the case $0<\sigma\ll 1$, the trajectory (q_t^σ,p_t^σ) of system (5.1) will stay in a neighborhood of $O_{k(q_0^*,p_0^*)}$ a time of order $\exp\{\text{const}/\sigma\}$, and then will switch to another equilibrium of system (5.1) with $\sigma=0$. It will stay there a long time and then again switches to the basin of another equilibrium and so on. It is important to underline that, in the generic case, for each stable equilibrium O_k, there exists exactly one (nonrandom) equilibrium $O_{k'}$, such that, with probability close to 1 for σ small enough, the system switches from O_k to $O_{k'}$. Since we assume that there are just a finite number of minima of $U(q)$, the sequence of transitions, after some time, becomes periodic (see Refs. 3 and 4). Thus we will have a decomposition of the set of local minima of $U(q)$ in cycles of rank 1. Moreover, the transition time $T^\sigma_{k,k'}$ between the basins of O_k and $O_{k'}$ is a random variable, but its logarithmic asymptotics as $\sigma\downarrow 0$ is not random.[3] In time scale larger than transition time in first rank cycles, transitions between the 1-cycles begin. So that in larger time scale, cycles of rank 2 appear, then cycles of rank 3, and so on, until all stable equilibriums of the nonperturbed system will be involved in the transitions.

The cycles of higher rank, as well as the logarithmic asymptotics of transition times between them, are also not random. So that one can speak on quasideterministic approximation for the long-time behavior of a dynamical system perturbed by a small noise. This hierarchy of cycles in a rather general situation was described in Refs. 3 and 4. The construction based on the large deviation theory for dynamical system perturbed by a small noise.[6]

Denote by $\mathcal{E}(O_k,E)$, $E\geqslant U(O_k)$, the connected component of the set $\{q\in\mathbb{R}^1: U(q)\leqslant E\}$ con-

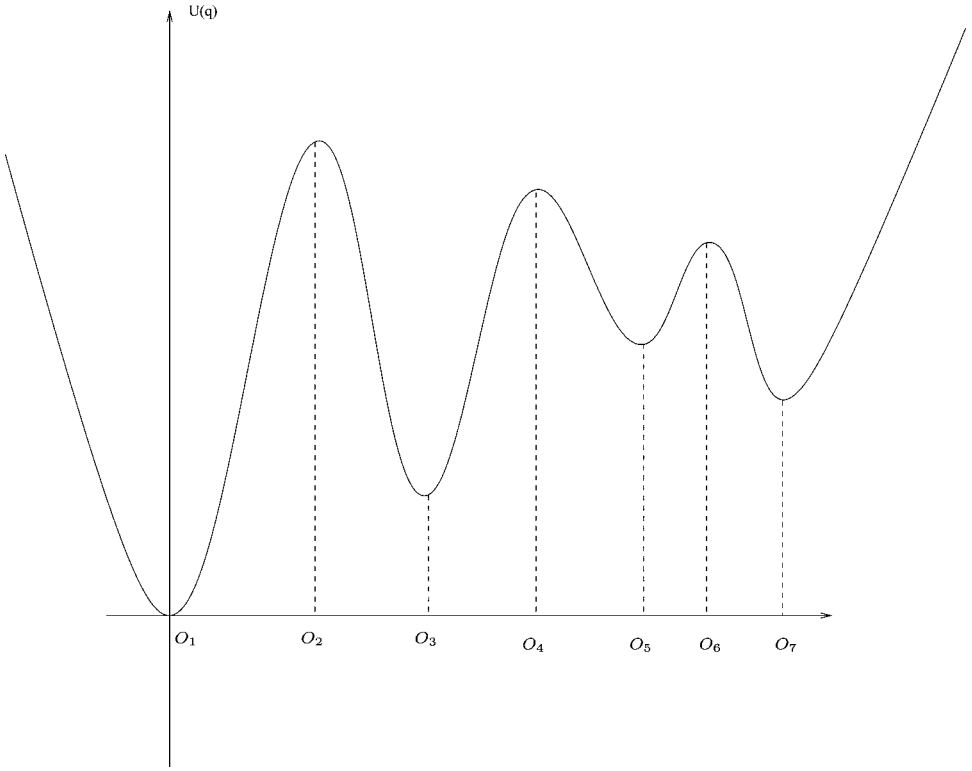

FIG. 2. Potential.

taining the stable equilibrium O_k. Let $O_{k^*(k,E)}$ be the point of $\mathcal{E}(O_k,E)$ such that $\min\{U(q):q \in \mathcal{E}(O_k,E)\}=U(O_{k^*(k,E)})$. We assume that the potential $U(q)$ is generic. Then the equilibrium $O_{k^*(k,E)}$ is defined in a unique way.

It is clear that for E close enough to $U(O_k)$, $O_{k^*(k,E)}=O_k$. If the potential is generic, and O_k is just a local, but not global, minimum of $U(q)$, then one can find E_1 such that $O_{k^*(k,E)}=O_k$ for $E \in (U(O_k),E_1)$, and $O_{k^*(k,E)} \neq O_k$ for $E>E_1$. In general, $E_1<E_2<\cdots<E_m$ exist such that $O_{k^*(k,E)}=O_{\bar{k}}$, $\bar{k}=\bar{k}(k,E_i,E_{i+1})=\text{const}$ for $E \in (E_i,E_{i+1})$, $i \in \{0,\ldots,m\}$, $E_0=U(O_k)$, $E_{m+1}=\infty$. Such an increasing sequence E_i can be defined for any stable equilibrium O_k. If $U(O_k)=\min\{U(q):q \in \mathbb{R}^1\}$, then set $E_1=\infty$.

For example, for the potential shown in Fig. 2 and $O_k=O_5$, $E_1=U(O_6)$, $E_2=U(O_4)$, $E_3=U(O_2)$, and $E_4=\infty$; $\bar{k}(5,U(O_5),E_1)=5$, $\bar{k}(5,E_1,E_2)=7$, $\bar{k}(5,E_2,E_3)=3$, $\bar{k}(5,E_3,E_4)=1$.

Set $\lambda_1=E_1-U(O_k)$, $\lambda_2=E_2-U(O_{\bar{k}(E_1,E_2)}),\ldots,\lambda_l=E_l-U(O_{\bar{k}(k,E_{l-1},E_l)}),\ldots,\lambda_m=E_m-U(O_{\bar{k}(k,E_{m-1},E_m)})$. It is easy to see that $\lambda_1<\lambda_2<\cdots<\lambda_m$.

It follows from Refs. 6 and 4 that in the time scale $T^\sigma \asymp e^{\lambda/\sigma}$, $\lambda_l<\lambda<\lambda_{l+1}$ (here "$\asymp$" is the sign of logarithmic equivalency as $\sigma \downarrow 0$), trajectory (q_t,p_t) of system (5.1) starting at a point from the basin of O_k spends most of the time as $a \downarrow 0$ in a small neighborhood of $O_{\bar{k}(E_l,E_{l+1})}$: For each $\delta>0$, the random variable,

$$\eta_\sigma^\delta=\frac{1}{T^\sigma}\wedge\{t \in [0,T^\sigma]:d((q_t,p_t),O_{\bar{k}(k,E_lE_{l+1})})>\delta\},$$

where $\wedge\{\cdot\}$ stands for the Lebesgue measure in $\mathbb{R}^1$, and $d(\cdot,\cdot)$ is Euclidian distance in $\mathbb{R}^2$, tends to zero in probability as $\sigma \downarrow 0$.

This and formula (4.9) imply the following result.

Theorem 6.1: *Let condition* (*) *be satisfied and the initial functions* (1.5) *have a compact*

support: $u_0(x)=v_0(x)=0$ *for* $|x|\geqslant R_0$. *Suppose the point* $(u(\theta/a,0),\dot{u}(\theta/a,0))$ *belongs to the basin of a stable equilibrium* O_k. *Let* $T^\sigma \asymp e^{-\lambda/\sigma}$, $\lambda \in (\lambda_l,\lambda_{l+1})$, $O^-_{k(k,E_l,E_{l+1})}=(q^-_{k(k,E_l,E_{l+1})},0)$. *Then, for every* $A>0$,

$$\int_{-A}^{A} \mathrm{d}x \int_0^A |u(tT^\sigma,x) - q^-_{k(k,E_l,E_{l+1})}|^2 \,\mathrm{d}t$$

tends to zero in probability as $\sigma \downarrow 0$.

VII. LOW TEMPERATURE AND RADIATION LIMIT

Consider now the case

$$m \ll 1, \quad 2m^{-1}\sqrt{T\mu} \sim 1, \quad k=\frac{\sigma}{m} \ll 1. \tag{7.1}$$

Then the Eq. (4.10) can be written as follows:

$$\ddot{q}(t) = -\frac{1}{m}U'(q(t)) - \dot{q}(t) + \sqrt{\frac{\kappa}{m}}\dot{W}_t. \tag{7.2}$$

Hence, the first two conditions in (7.1) mean that the Hamiltonian vector field is large with respect to the "radiative effects" described by the friction term in (7.2), so we can apply the averaging arguments. The last two conditions in (7.1) mean the low temperature limit $\sigma \to 0$, as above [see (6.1)].

In the preceding section, under certain conditions, we described metastable regimes of our system: For a given initial state and a time scale, the system spends most of the time near certain stationary state of the system without noise (zero temperature). Under conditions of this section, the metastable state, in general, is not a stationary state of the zero temperature system, but a certain distribution among such states. This distribution is determined by the initial conditions and the time scale.

To be specific, we assume that the potential has four minima. Then the Hamiltonian $H(p,q)=p^2/2m+U(q)$ has the wells as it is shown in Fig. 3. The case of general potential can be treated similarly.

The level set $C(z)=\{(q,p):H(q,p)=z\}$ consists, in general of several connected components $C_k(z):C(z)=\cup_{k=1}^N C_k(z)$. We denote by $G_k(z)$ the domain bounded by $C_k(z)$ (compare with Ref. 6, Chap. 8). Let Γ be the graph homeomorphic to the set of connected components of all level sets of the Hamiltonian $H(q,p)$ [Fig. 3(b)] provided with natural topology.

The connected component of the level set of a saddle point O_2, containing O_2, is an eight-shaped curve γ [Fig. 3(c) and 3(d)] consisting of two parts G_1 and G_2.

Equation (7.2) can be written as the system

$$\begin{aligned} \dot{q}^{m,\kappa}(t) &= \frac{1}{\sqrt{m}}p^{m,\kappa}(t), \\ \dot{p}^{m,\kappa}(t) &= -\frac{1}{\sqrt{m}}U'(q^{m,\kappa}(t)) - p^{m,\kappa}(t) + \sqrt{\kappa}\dot{W}(t). \end{aligned} \tag{7.3}$$

Let, first, $m \to 0$, then we are in the situation when the averaging principle should be applied. The fast component of the process $(q^{m,\kappa}(t),p^{m,\kappa}(t))$ is, roughly speaking, the motion along the trajectories of the Hamiltonian system with

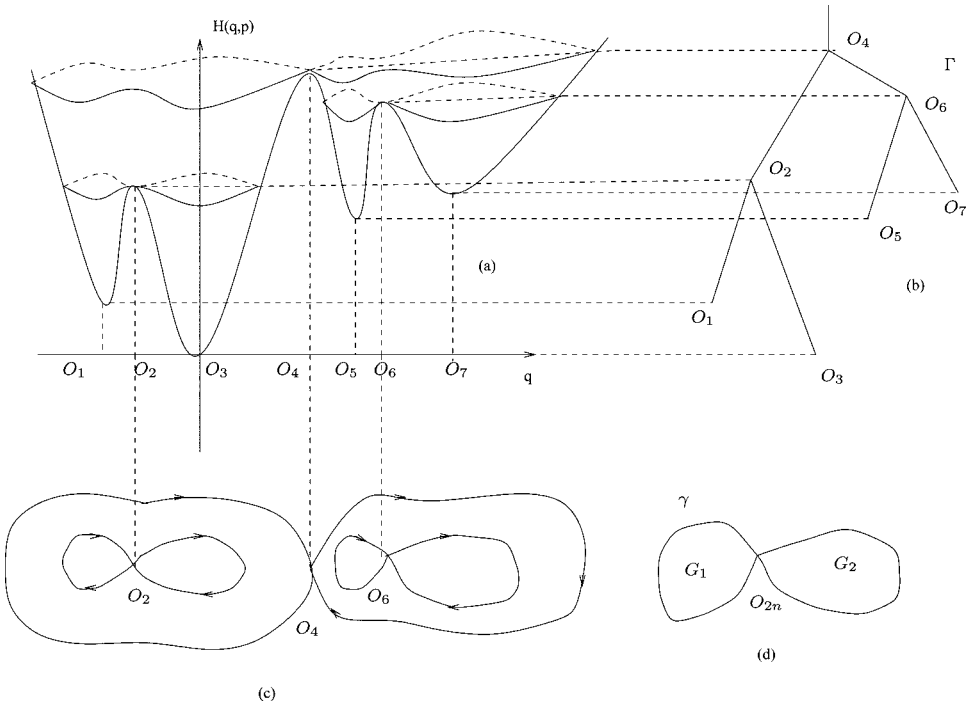

FIG. 3. Hamiltonian, graphs and level sets.

$$H = \frac{p^2}{2} + U(q),$$

and the slow component is the projection $Y(q^{m,\kappa}(t), p^{m,\kappa}(t))$ on the graph Γ: $Y(x)$ is the point of the graph corresponding to the connected component of $H(x)$-level set containing the point $x \in \mathbb{R}^2$.[5,6] It is shown in Ref. 5 that $Y(q^{m,\kappa}(t), p^{m,\kappa}(t))$ converges weakly (in the space of continuous functions on any finite time interval $[0, M]$ with the values in Γ) to a diffusion process $Y^\kappa(t)$ on Γ. The process $Y^\kappa(t)$ is defined by the family of second order operators L_k^κ, one on each edge of the graph, and by gluing conditions at the vertices.

The operator L_k^κ on the edge I_k has the form

$$L_k^\kappa(q,p)f(z) = \frac{\kappa}{2T_k(z)}\frac{d}{dz}\left(\bar{a}_k(z)\frac{df}{dz}\right) - \frac{\bar{\beta}_k(z)}{T_k(z)}\frac{df}{dz},$$

where $T_k(z)$ is the period of rotation along the level set component $C_k(z)$ corresponding to the point (z,k) of the graph: k is the number of the edge containing this point, and z is the corresponding value of the Hamiltonian $H(q,p)$ on the level set of component corresponding to the point of Γ.

Further, $T_k(z) = S'(z)$, where $S_k(z)$ is the area of the domain $G_k(z)$ bounded by $C_k(z)$, and

$$\bar{a}_k(z) = \bar{\beta}_k(z) = S_k(z).$$

To define the process $Y^\kappa(t)$ on Γ in a unique way one should add gluing conditions at the vertices. These conditions were calculated in Ref. 5, but we do not need their form, so we will not describe them here.

Now we want to take κ to zero in the process $Y^\kappa(t)$ on Γ. Then (see Ref. 1) $Y^\kappa(t)$ converges weakly as $\kappa \to 0$ to a process $Y(t)$ on Γ, which has the following structure. Inside an edge $I_k \subset \Gamma$, this is a nonrandom motion with the speed $-\bar{\beta}_k(z)/T_k(z) = -S_k(z)/S_k'(z)$. When a trajectory comes

to a vertex O corresponding to a saddle point (vertices O_2, O_4, and O_6 in Fig. 3), it proceeds without any delay at O in one of the edges below (in energy) of O with certain probabilities $P_1(O)$ and $P_2(O)$, $P_1(O)+P_2(O)=1$. To find these probabilities, one should consider the eight-shaped curve $\gamma(O)$ corresponding to the vertex O [see Fig. 3(d)]. It has two components $G_1(O)$ and $G_2(O)$. Then

$$P_i(O) = \frac{S(G_i)}{S(G_1) + S(G_2)}, \quad i = 1,2,$$

$S(G_i)$ being the area of G_i.

Assume that at time t_0 the oscillator has the energy H_0 greater than the level set of the highest saddle point [$H_0 > H(O_4)$ in Fig. 3]. Then because of "friction" (=radiation) it will lose the energy until it comes to the level $H(O_4)$; this will happen in a finite time. Then trajectory goes to the left (to the edge $[O_2, O_4]$) with probability

$$P_1(O_4) = \frac{S(G_1(O_4))}{S(G_1(O_4)) + S(G_2(O_4))},$$

and to the right (to $[O_4, O_6]$) with probability

$$P_2(O_4) = \frac{S(G_2(O_4))}{S(G_1(O_4)) + S(G_2(O_4))}.$$

Trajectory $Y(t)$ proceeds to go down until it meets the next saddle point (O_2 or O_6). It is scattered on those saddle points and eventually approaches one of the local minima of the potential. In a finite time for every $\delta > 0$ it approaches the δ neighborhood of one of the local minima and stays in the corresponding well a time of order $e^{C/\kappa}$, where

$$C = \min\{U(O_2) - U(O_1), U(O_2) - U(O_3), U(O_6) - U(O_5), U(O_6) - U(O_7)\}.$$

Thus if we observe $(q_t^{m,\kappa}, p_t^{m,\kappa})$ on the time interval $1 \ll t < T_E^\kappa = e^{E/\kappa}$ with $0 < E < C$, it is distributed among the local minima O_1, O_3, O_5, O_7 with probabilities, respectively, equal to

$$\begin{aligned}
m_1 &= \frac{S(G_1(O_4))}{S(G_1(O_4)) + S(G_2(O_4))} \cdot \frac{S(G_1(O_2))}{S(G_1(O_2)) + S(G_2(O_2))}, \\
m_3 &= \frac{S(G_1(O_4))}{S(G_1(O_4)) + S(G_2(O_4))} \cdot \frac{S(G_2(O_2))}{S(G_1(O_2)) + S(G_2(O_2))}, \\
m_5 &= \frac{S(G_2(O_4))}{S(G_1(O_4)) + S(G_2(O_4))} \cdot \frac{S(G_1(O_6))}{S(G_1(O_6)) + S(G_2(O_6))}, \\
m_7 &= \frac{S(G_2(O_4))}{S(G_1(O_4)) + S(G_2(O_4))} \cdot \frac{S(G_2(O_6))}{S(G_1(O_6)) + S(G_2(O_6))},
\end{aligned} \tag{7.4}$$

if, first, $m \downarrow 0$ and then $\kappa \downarrow 0$. This is metastable distribution in the time scale $T_E^\kappa = e^{E/\kappa}$ for $E < C$. In larger time scales, the support of this limiting distribution will become smaller and smaller. To be specific, assume that

$$U(O_6) - U(O_7) < U(O_6) - U(O_5) < U(O_4) - U(O_5) < U(O_2) - U(O_1) < U(O_2) - U(O_3). \tag{7.5}$$

Then if $U(O_6) - U(O_7) < E < U(O_6) - U(O_5)$, trajectory already have enough time to leave O_7 so that the metastable distribution among O_1, O_3, O_5, O_7 in this time scale is $(m_1, m_3, m_5 + m_7, 0)$. If $E \in (U(O_4) - U(O_5), U(O_2) - U(O_1))$, the metastable distribution is

$$\left(\frac{S(G_1(O_2))}{S(G_1(O_2))+S(G_2(O_2))},\frac{S(G_2(O_2))}{S(G_1(O_2))+S(G_2(O_2))},0,0\right).$$

Eventually, if $E>U(O_2)-U(O_1)$, then the distribution is concentrated at point O_3, which is the absolute minimum of the potential.

Together with the equality $u(t,x)=u^{m,\kappa}(t,x)=q^{m,\kappa}(t-|x|/a)$, $a=T/m$, which holds for any $x \in \mathbb{R}^1$ and t large enough, this implies the following result.

Theorem 7.1: Let condition (*) be satisfied, and initial functions (1.5) have a compact support belonging to $\{|x|<\theta\}\subset\mathbb{R}^1$. Let the Hamiltonian $H(p,q)=p^2/2+U(q)$ be as shown in Fig. 3. Let the energy of the oscillator with $\kappa=0$ be greater than $U(O_4)$ at time $t_0=\theta/a$:

$$\frac{m}{2}\left(\frac{\partial u^{m,0}(t_0,0)}{\partial t}\right)^2+U(u^{m,0}(t_0,0))>U(O_4).$$

Assume that inequalities (7.5) are satisfied. Then for any A, $E>0$ and $T_E^\kappa \asymp \exp\{E/\kappa\}$, the random function $u^{m,\kappa}(T_E^\kappa t,x)$, $t\in[0,A]$, $x\in[-A,A]$, converges weakly in $L^2_{[0,A]\times[-A,A]}$ to a random variable η_E as, first, $m\downarrow 0$ and then $\kappa\downarrow 0$.

The random variable η_E has values O_1,O_3,O_5,O_7 with probabilities m_1,m_3,m_5,m_7, respectively, if $0<E<C$, with probabilities $(m_1,m_3,m_5+m_7,0)$ if $E\in(U(O_6)-U(O_7),U(O_6),-U(O_5))$, with probabilities $m_1+m_3,m_5+m_7,0,0)$ if $E\in(U(O_4)-U(O_5),U(O_2)-U(O_1))$, and $P\{\eta_E=O_3\}=1$ if $E>U(O_2)-U(O_1)$.

(Received 20 April 2005; accepted 15 March 2006; published online 28 April 2006)

By following a strategy introduced in previous works, quantum extensions of the classical electron-phonon scattering operator are deduced from first principles. These quantum collision operators satisfy a quantum H-theorem and relax towards quantum equilibria. Then, under an assumption of dominant elastic interactions, a hierarchy of quantum spherical harmonic expansion (SHE) models is derived by a diffusive approximation of collisional Wigner equations. These models are proven entropic and their expansions into powers of the reduced Planck constant $\hbar$ are calculated, leading to $\hbar^2$ corrections for the classical SHE model. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2192968]

I. INTRODUCTION

The transport of charged particles in electronic devices is generally described by kinetic models such as Boltzmann-type equations or macroscopic models of hydrodynamic or diffusion type. Due to the ongoing miniaturization of these devices, reaching the nanometric scale, the reliability of these classical models becomes doubtful as quantum effects become important. Since, at an intermediate scale, collision phenomena remain significant, one of the most challenging areas of investigation in semiconductor modelling deals with the setting-up of quantum transport models which take into account scattering effects. Though many works are concerned with the numerical simulation of ballistic quantum transport models for semiconductors (see, e.g., Refs. 26, 37, 42, 25, 15, and 44), a quantum theory of collisions is still under development (among other works on the quantum theory of scattering, see, e.g., Refs. 3, 12, 24, 38, and 45 and, more recently, Refs. 4, 5, and 27). Furthermore, several attempts were made to adapt existing classical macroscopic models to quantum mechanics[1,2,30–33] but, generally, the link between the so-obtained models and a microscopic quantum description of the particle transport is to a large extent phenomenological.

Recently, a strategy for deriving quantum macroscopic models was introduced in Refs. 21 and 22. It relies on the notion of a quantum local equilibrium (called "quantum Maxwellian"), defined through a Gibbs principle as the minimizer of the quantum entropy under local moment constraints. This approach enabled to write prototypes of collision operators which decrease the quantum entropy and relax towards the quantum local equilibria. By introducing such collision operators in the Wigner equation and by performing formally a hydrodynamic (respectively, diffusive) limit, quantum hydrodynamic (respectively, quantum diffusive) models were derived in Refs. 21 and 19 (these two papers are reviewed in Ref. 20). As a by-product of the method, these

quantum macroscopic models display some interesting physical properties, such as the preservation of the positivity of the density or an entropy dissipation. The numerical resolution of the simplest of these models, the quantum drift-diffusion model, is investigated in Refs. 28 and 29.

The small size of current semiconductor devices raises another problem. In some regimes, the relevant time and length scales are too small for the cloud of electrons to reach a thermodynamical equilibrium. Therefore, an accurate description of these devices cannot be achieved by models which, like drift-diffusion or hydrodynamic models, rely on the assumption that the system has been driven to an equilibrium with a given profile (of Maxwellian or of Fermi-Dirac type). Intermediate models have been recently introduced, in a classical setting, to fill the gap between precise but numerically expensive models (kinetic models for instance) and numerically affordable but less accurate models such as drift-diffusion models: among others are the spherical harmonics expansion (SHE) models (see, Refs. 6 and 13 for a mathematical description and references). These models are diffusion models in the position-energy space. They have been applied to semiconductor physics,[34,10,11,7,8] neutronics,[35] gas discharge,[46] and plasma physics.[23] Numerical computations have established the relevance of the classical SHE models.[17,9] These models are also referred to as Fokker-Planck models. They consist of a mass balance equation (the continuity equation) for the energy distribution function, and of a constitutive law for the current of particles of given energy. The former governs the transport of the density and the latter describes the effects of the diffusion due to the particle scattering.

The goal of this paper is twofold. On the one hand, following the strategy, described above, which leads to deriving quantum versions of the hydrodynamic (HD), energy-transport (ET), and drift-diffusion (DD) models, we propose quantum SHE models. These models are expected to be better adapted than classical SHE models to situations where quantum phenomena are predominant. Moreover, as in the classical case where SHE models appear as intermediate models between kinetic and macroscopic equations, quantum SHE models fit systems far from Maxwellian-type equilibria better than quantum HD, ET, and DD models.

The derivation of quantum SHE models by a diffusion approximation procedure makes the introduction of quantum collision operators at the kinetic level necessary: this constitutes the second goal of this work. A quantum collision operator is built following ideas first introduced in Refs. 21, 22, and 19 and generalizing the classical electron-phonon scattering operator.[40] Then, in the regime of dominant elastic scattering, several other operators are proposed. All these operators are consistent with the elementary properties which are sought to describe collisions with phonons (conservations, equilibrium states, quantum entropy dissipation).

The paper is organized as follows. Section II recalls some well-known results about the derivation of classical SHE models and emphasizes the importance of the entropy dissipation of the collision operator to obtain an entropic structure for the macroscopic model. Classical features of the linearized electron-phonon collision operator are also recalled. Section III is a first step towards the derivation of a quantum SHE model: we consider the Wigner equation equipped with a classical collision operator and perform the derivation in this setting, which leads to the quasiquantum SHE model. This model does not account for quantum diffusion. Quantum collision operators are introduced in Sec. IV following a heuristic analogy: these operators must fulfill properties analogue to those satisfied by the classical operators given in Sec. II. For this sake, a quantum entropy is given and quantum thermodynamical equilibria are defined as minimizers of this entropy, allowing the introduction of quantum relaxation operators. Then the derivation of a fully quantum SHE model can be performed and this is achieved in Sec. V.

The quantum SHE and quasiquantum SHE models involve pseudodifferential operators and display a nonlocal character. In order to obtain models easier to handle, a formal expansion of these equations with respect to the reduced Planck constant $\hbar$ are given in Secs. III and V. As it was done in Ref. 19 for the quantum energy-transport and the quantum drift-diffusion models, by keeping only the terms up to second order in $\hbar$ in this expansion, we derive quantum correction terms for the classical SHE model.

II. CLASSICAL MODELLING OF ELECTRON-PHONON SCATTERING IN SEMICONDUCTOR DEVICES: A SHORT REVIEW

In this section, we review some well-known features concerning electron-phonon scattering in classical kinetic models. Indeed, having this review in mind will help understand our methodology for establishing quantum collision operators and deriving various quantum SHE models.

A. The Boltzmann equation

The evolution of electrons in semiconductor devices can be described at a microscopic level through classical kinetic equations of Boltzmann type as long as quantum effects are neglected. To that purpose, one introduces the distribution function $f(t,x,p)$ of the electrons. Then f is given as the solution of the initial value problem

$$\begin{gathered}\partial_t f + p\cdot\nabla_x f - \nabla_x V\cdot\nabla_p f = \mathcal{C}(f), \quad x\in\mathbb{R}^3, \quad p\in\mathbb{R}^3, \quad t>0,\\ f(0,x,p) = f_I(x,p),\end{gathered} \tag{2.1}$$

where $V=V(x)$ is a given potential and f_I an initial condition. The collision operator $\mathcal{C}$ models the interactions of the electrons with the medium. All the quantities that will be considered in the sequel are dimensionless. The equation is adimensioned and we set the temperature equal to 1 and the electron mass and elementary charge equal to 1 and -1, respectively. We will note

$$L = p\cdot\nabla_x - \nabla_x V\cdot\nabla_p$$

the classical transport (Liouville) operator. The classical relative entropy usually associated to this kind of equation is

$$H_C(f) = \int_{\mathbb{R}^6} f\left(\ln f - 1 + \frac{|p|^2}{2} + V(x)\right)\mathrm{d}x\,\mathrm{d}p = \int_{\mathbb{R}^6} f\left(\ln\frac{f}{\mathcal{M}} - 1\right)\mathrm{d}x\,\mathrm{d}p$$

where the global Maxwellian $\mathcal{M}$ is defined by

$$\mathcal{M}(x,p) = \exp\left(-\frac{|p|^2}{2} - V(x)\right). \tag{2.2}$$

When the context is clear, we will note as well $\mathcal{M}(x,\varepsilon)=\exp(-\varepsilon - V(x))$, where ε denotes the energy variable ($\varepsilon\geqslant 0$). The following lemma is a classical result on H_C. Its proof is straightforward.

Lemma 2.1: *Let* $\mathcal{C}$ *in* (2.1) *be such that, for any positive measurable function* g, *this inequality holds*,

$$-\int \mathcal{C}(g)\ln\left(\frac{g}{\mathcal{M}}\right)\mathrm{d}x\,\mathrm{d}p \geqslant 0. \tag{2.3}$$

Then, *if* f *is a positive solution of Eq.* (2.1), *the associated entropy satisfies*

$$\frac{\mathrm{d}H_C(f)}{\mathrm{d}t} \leqslant 0. \tag{2.4}$$

According to this lemma, the study of the entropic structure of equations of type (2.1) reduces to proving an inequality on the collision operator $\mathcal{C}$. In this section, several collision operators are introduced in order to model the scattering of electrons in semiconductors. The classical electron-phonon collision operator is introduced and some of its properties are recalled. The limit of a vanishing phonon energy is performed and yields an elastic collision operator. Then, the derivation of a classical SHE model is set out (following Refs. 6 and 13) and its entropic structure is emphasized.

Before achieving these tasks, we introduce the spherical coordinates in momentum space: $\omega = p/|p| \in \mathbb{S}^2$, $\varepsilon = |p|^2/2 > 0$, where $\mathbb{S}^2$ denotes the unit sphere in $\mathbb{R}^3$. For any function f, we note equally $f(p) = f(\varepsilon, \omega)$ and, when the context is unambiguous, $f = f(p)$ and $f' = f(p')$. The following formula holds for any integrable function f:

$$\int_{\mathbb{R}^3} f(p)\mathrm{d}p = \int_{(0,\infty)\times\mathbb{S}^2} f(\varepsilon,\omega)\sqrt{2\varepsilon}\mathrm{d}\varepsilon\,\mathrm{d}\omega$$

and we define

$$\int_{\mathbb{R}^3} f(p')\,\delta(|p'|^2/2-\varepsilon)\mathrm{d}p' = \int_{(0,\infty)\times\mathbb{S}^2} f(\varepsilon',\omega')\,\delta(\varepsilon'-\varepsilon)\sqrt{2\varepsilon'}\mathrm{d}\varepsilon'\,\mathrm{d}\omega := \sqrt{2\varepsilon}\int_{\mathbb{S}^2} f(\varepsilon,\omega')\mathrm{d}\omega'.$$

Let $L^2_{x,p} = L^2(\mathbb{R}^6)$ denote the space of square integrable functions on the phase space $\mathbb{R}^6$. The closed subspace of energy dependent functions will be of considerable interest in the remainder of the paper and is denoted by

$$\mathcal{E} = \{f \in L^2_{x,p} : f(x,p) = f(x,|p|) \text{a . e .}\}$$

and the space orthogonal to $\mathcal{E}$ in $L^2_{x,p}$ is denoted by $\mathcal{E}^\perp$. The projectors on $\mathcal{E}$ and on $\mathcal{E}^\perp$ are, respectively, denoted by $\mathcal{P}$ and $\mathcal{P}^\perp$ and, for any ϕ in $L^2_{x,p}$, they are given by

$$\mathcal{P}(\phi)(\varepsilon) = \frac{1}{N(\varepsilon)}\int_{\mathbb{R}^3} \phi(\varepsilon',\omega')\,\delta(\varepsilon'-\varepsilon)\mathrm{d}p', \quad \mathcal{P}^\perp\phi = (\mathrm{Id}-\mathcal{P})\phi,$$

where Id denotes the identity operator on $L^2_{x,p}$ and $N(\varepsilon)$, the density of state, is defined by

$$N(\varepsilon) = \int_{\mathbb{R}^3} \delta(|p'|^2/2-\varepsilon)\mathrm{d}p' = 4\pi\sqrt{2\varepsilon},$$

so that the projector $\mathcal{P}$ can be written equivalently as

$$\mathcal{P}(\phi)(\varepsilon) = \frac{1}{4\pi}\int_{\mathbb{S}^2} \phi(\varepsilon,\omega')\mathrm{d}\omega'.$$

Note that, for any f and ϕ, $\mathcal{P}(\phi f) = \phi\mathcal{P}(f)$ and $\mathcal{P}^\perp\phi = 0$ as soon as ϕ is a function of the energy ε only. Moreover, $\mathcal{E}^\perp$ is spanned by functions of null angular average.

B. The classical electron-phonon collision operator

We now focus on the expression of the collisions operator $\mathcal{C}(f)$. In semiconductors, electrons undergo mainly three types of collisions against ionized impurities, acoustic phonons, and optical phonons.[47] At large enough energies, optical phonon collisions are dominant and we shall discard the other types of collisions.

Classically (see Ref. 41 for instance), in a low density case, the electron-optical phonon collision operator is linear and can be written, after an appropriate scaling, according to

$$\mathcal{C}_{e\varphi}(f)(p) = \int \Sigma(p,p')\{[(N_0+1)\,\delta(\varepsilon-\varepsilon'+\beta)+N_0\delta(\varepsilon-\varepsilon-\beta)]f(p')$$

$$-[(N_0+1)\,\delta(\varepsilon'-\varepsilon+\beta)+N_0\delta(\varepsilon'-\varepsilon-\beta)]f(p)\mathrm{d}p'$$

with β the scaled phonon energy (which is a constant), $\Sigma(p,p')$ a symmetric function of the form

$$\Sigma(p,p') = C_{\text{opt}}\beta\begin{cases} \dfrac{1}{|p-p'|^2} & \text{(polar interactions)}, \\ 1 & \text{(nonpolar interactions)}, \end{cases} \tag{2.5}$$

where C_{opt} is an appropriate constant. The phonon occupation number N_0 for a lattice temperature $T=1$ is given by the Bose-Einstein statistics as

$$N_0 = \frac{1}{e^{\beta}-1}. \tag{2.6}$$

The collision operator can also be written

$$\mathcal{C}_{e\varphi}(f) = \int \mathcal{S}(p,p')[\delta(\varepsilon'-\varepsilon-\beta)+\delta(\varepsilon'-\varepsilon+\beta)]\left(\frac{f(p')}{M(\varepsilon')}-\frac{f(p)}{M(\varepsilon)}\right)\mathrm{d}p' \tag{2.7}$$

with $M=M(\varepsilon)=\exp(-\varepsilon)$ the Maxwellian and

$$\mathcal{S}(p,p') = \Sigma(p,p')N_0 e^{-(\varepsilon+\varepsilon')/2}e^{\beta/2},$$

which is a symmetric function. The following result can be found in Ref. 40.

Proposition 2.2: *The collision operator* $\mathcal{C}_{e\varphi}$ *defined by* (2.7) *satisfies the following properties*:

(i) *Mass conservation*: $\int \mathcal{C}_{e\varphi}(f)\mathrm{d}p=0$ *for any measurable function* f.

(ii) *Equilibrium states*: *for any measurable function* $f(x,p)$, *we have* $\mathcal{C}_{e\varphi}(f)=0$ *if and only if*

$$f(x,p) = M(|p|^2/2)F(x,|p|^2/2),$$

where F *is such that* $F(x,\varepsilon+\beta)=F(x,\varepsilon)$.

(iii) *Entropy dissipation*: $-\int \mathcal{C}_{e\varphi}(f)\ln(f/\mathcal{M})\mathrm{d}p \geqslant 0$ *for any positive integrable function* f.

Typically, the electron energy in a semiconductor device is of the same order of magnitude as the applied bias, i.e., of the order of 1 V. This is very large compared with the typical optical phonon energy, which is of the order of 10^{-2} V. Therefore, the scaled parameter $\beta \approx 10^{-2}$ is very small and it is meaningful to consider the elastic limit $\beta \to 0$ of the electron-phonon collision operator.

The following operator $\mathcal{C}_{\text{el}}$ can be obtained as the limit of $\mathcal{C}_{e\varphi}$ as $\beta \to 0$:

$$\mathcal{C}_{\text{el}}(f)(p) = N(|p|^2/2)\{\mathcal{P}(\widetilde{\mathcal{S}}(p,\cdot)f(\cdot)) - \mathcal{P}(\widetilde{\mathcal{S}}(p,\cdot))f(p)\}, \tag{2.8}$$

where

$$\widetilde{\mathcal{S}}(p,p') = 2C_{\text{opt}}\begin{cases} \dfrac{1}{|p-p'|^2} & \text{(polar interactions)}, \\ 1 & \text{(nonpolar interactions)}. \end{cases} \tag{2.9}$$

From now on, we drop the tildes. It is straightforward to prove the following.

Proposition 2.3: *The collision operator* $\mathcal{C}_{\text{el}}$ *defined by* (2.8) *satisfies the following properties*:

(i) *Mass conservation*: $\int \mathcal{C}_{\text{el}}(f)\mathrm{d}p=0$ *for any measurable function* f.

(ii) *Equilibrium states*: *for any function* f *in* $L^2_{x,p}$, *we have* $\mathcal{C}_{\text{el}}(f)=0$ *if and only if*

$$f(x,p) = F(x,|p|^2/2),$$

where F *lies in* $\mathcal{E}$.

(iii) *Entropy dissipation*: $-\int \mathcal{C}_{\text{el}}(f)\ln(f/\mathcal{M})\mathrm{d}p \geqslant 0$ *for any positive integrable function* f.

C. Derivation of the classical SHE model (CSHE)

Classical SHE models (CSHE) (also referred to as Fokker-Planck models) are obtained as asymptotic limits of the Boltzmann equation under the assumption of dominant elastic scattering, i.e., when the collision operator [of the type (2.8)] is supposed to be large, say of order $1/\alpha$ where α is a measure of the collision mean-free path in scaled units. We also need to observe the system over large periods of time, i.e., we must rescale the time variable $t \to t/\alpha$ in order to capture the significant dynamics, which is of diffusion type. In this new set of units, the classical Boltzmann equation becomes

$$\alpha \partial_t f^\alpha + (p \cdot \nabla_x - \nabla_x V \cdot \nabla_p) f^\alpha = \frac{1}{\alpha} \mathcal{C}_{\mathrm{el}}(f). \tag{2.10}$$

To ensure boundedness and positivity for the collision operator, we assume the following.

Assumption 2.4: *There exist two positive constants* K, K' *such that* $K < \mathcal{S} < K'$.

Under this assumption, operator $\mathcal{C}_{el}$ is an isomorphism from $\mathcal{E}^\perp$ onto $\mathcal{E}^\perp$ (see Ref. 6 for instance). Then, Eq. (2.10) has solutions according to the Hille-Yosida theorem.

Lemma 2.5: *Under regularity assumptions on the potential V and Assumption 2.4*, *Eq.* (2.10) *with initial datum* f_I *in* $\mathcal{D}(L) := \{f \in L^2_{x,p} : Lf \in L^2_{x,p}\}$ *has a unique solution* f^α in $C^1([0,T], L^2_{x,p}) \cap C^0([0,T], \mathcal{D}(L))$.

We do not enter into details regarding sufficient assumptions on V since the differential operator $\nabla_x V \cdot \nabla_p$ will not be used in this paper, but, instead, an L^2 bounded pseudodifferential operator. The (possibly not optimal) regularity required for V in the quantum case is stated in Assumption 3.2 below.

Proposition 2.6 summarizes some results on the derivation of the CSHE model (see Refs. 6 and 13 for this proposition as well as for precise regularity requirements on the potential V).

Proposition 2.6: *Assumption 2.4 is made and V is supposed regular enough.*

We consider Eq. (2.10) *with initial datum* f_I^α *such that the sequence* (f_I^α) *converges in* $L^2_{x,p}$ *to an element* F_{in} *of* $\mathcal{E}$ *as* $\alpha \to 0$. *By Lemma 2.5*, *this problem has a unique solution* f^α *for all* $\alpha > 0$.

The formal limit F of f^α *as* $\alpha \to 0$ *is the solution of the classical SHE (CSHE) model*,

$$N(\varepsilon)\partial_t F - \tilde{\nabla} \cdot (D \tilde{\nabla} F) = 0,$$

$$F(0,x,\varepsilon) = F_{in}(x,\varepsilon), \tag{2.11}$$

$$\tilde{\nabla} = \nabla_x - \nabla_x V \partial_\varepsilon,$$

$$D = \mathcal{P}(\mathcal{C}_{\mathrm{el}}^{-1}(p) \otimes p) = \frac{|p|^2}{4\pi} \int_{\mathrm{S}^2} \mathcal{C}_{\mathrm{el}}^{-1}(\omega) \otimes \omega \, \mathrm{d}\omega. \tag{2.12}$$

More precisely, *the sequence* $(f^\alpha)_\alpha$ *can be rigorously proved to converge weakly in* $L^\infty((0,T), L^2_{x,p})$ *to a limit* $F \in L^\infty((0,T), \mathcal{E})$ *which is a weak solution of* (2.11), *and* $F \geqslant 0$. *Moreover*, *the following expression*:

$$H_{\mathrm{CSHE}}(F) = \int F \left(\ln \frac{F}{\mathcal{M}} - 1 \right) N(\varepsilon) \mathrm{d}\varepsilon \, \mathrm{d}x$$

is a decreasing function of time.

Proof: The proof of the derivation itself can be found in Refs. 6 and 13 (formal proof) and Ref. 14, for a rigorous proof in the case of a null potential V. When the potential does not vanish, the proof can be adapted from Ref. 18 where the diffusion is driven by particle-wall scattering.□

An interesting case is when the collision kernel is isotropic: $\mathcal{S}(p,p')=\mathcal{S}(|p|,|p'|)$.Then, setting $\mathcal{S}(|p|,|p|)N(|p|^2/2)=\nu$, the collision operator reads

$$\mathcal{C}_{\mathrm{el}}(f)=\nu(\mathcal{P}f-f) \tag{2.13}$$

and the diffusion matrix is a scalar given by

$$D=\frac{4\pi}{3\nu}(2\varepsilon)^{3/2}. \tag{2.14}$$

Remark 2.7: The classical SHE model given by Eq. (2.11) is a degenerate parabolic equation. □

Remark 2.8: Note that, in the definition of this operator (2.13), the projection term $\mathcal{P}f$ can be obtained as the minimizer of the classical entropy $H_C(g)$ under the constraint $\mathcal{P}(g-f)=0$. The definition of a quantum analogue of this relaxation operator in Sec. IV B is inspired by this remark. □

III. CLASSICAL COLLISION OPERATORS AND QUASIQUANTUM SHE MODEL

As a first attempt to introduce quantum phenomenology in the SHE model, the Wigner equation can be substituted to the left-hand side of the Boltzmann equation (2.1). This is our goal in the present section. First, the Wigner-Boltzmann equation (i.e., the Wigner equation with a collisional source term) is introduced. Some notations and properties are given and the resolution of the Cauchy problem for this equation is recalled. Note that in this section, we will focus on the influence of the quantum transport operator. The scattering phenomena are still modeled by a classical collision operator. We emphasize that this approach lacks consistency, as we use a quantum model for transport and still a classical model for collisions. In order to remedy to this inconsistency, we introduce quantum collision operators in Sec. IV.

The so-called quasiquantum SHE (QQSHE) model is rigorously derived from the Wigner-Boltzmann equation in a diffusion asymptotics. As the Wigner equation, the QQSHE model depends on the Planck constant. The expansion of this model with respect to $\hbar$ is investigated and a focus is made on the QQSHE_2 model, that is, the expanded model up to second order terms in $\hbar$. This model is of interest since it introduces correction terms to the CSHE model and may lead to a cheap yet accurate way to introduce quantum corrections in classical SHE models.

A. The Wigner-Boltzmann equation

Let us introduce the Wigner transform and its properties. All the results of this section are given without proof (one can refer to Ref. 39 for instance). To any complex number z we associate its complex conjugate $\bar{z}$. We adopt the following conventions for the Fourier transform $\mathcal{F}$ and the inverse Fourier transform $\mathcal{F}^{-1}$ (in dimension 3):

$$\mathcal{F}(f)(\eta)=\int f(p)e^{-ip\cdot\eta/\hbar}\mathrm{d}p,\quad \mathcal{F}^{-1}(g)(p)=\int g(\eta)e^{ip\cdot\eta/\hbar}\frac{\mathrm{d}\eta}{(2\pi\hbar)^3},$$

where $\hbar$ is the reduced Planck constant. Let ρ denote a trace class non-negative Hermitian operator on $L^2(\mathbb{R}^3)$ and let $\rho(x,y)$ be its integral kernel. Then its Wigner transform is

$$W[\rho](x,p)=\int_{\mathbb{R}^3}\rho\left(x-\frac{\eta}{2},x+\frac{\eta}{2}\right)e^{i\eta\cdot p/\hbar}\,\mathrm{d}\eta,$$

whereas the Weyl quantization of any symbol $a(x,p)$ defines an operator $\mathrm{Op}(a)$,

$$\mathrm{Op}(a)\phi = (2\pi\hbar)^{-3}\int_{\mathbb{R}^6} a\left(\frac{x+y}{2}, p\right)\phi(y)e^{ip\cdot(x-y)/\hbar}\,\mathrm{d}p\,\mathrm{d}y.$$

Then Op and W are formally inverse operations to one another,

$$\mathrm{Op}(W[\rho]) = \rho, \quad W[\mathrm{Op}(a)] = a.$$

For any trace class operator ρ, we denote by $\mathrm{Tr}\,\rho$ its trace and by $\rho^\dagger$ its Hermitian adjoint. We summarize some classical properties of Op and W in the following lemma. We recall that an operator K is a Hilbert-Schmidt operator if there exists a kernel $k \in L^2_{x,p}$ such that, for any $\phi \in L^2_{x,p}$, $K(\phi)(y) = \int k(x,y)\phi(y)\mathrm{d}y$. We note $K \in \mathrm{HS}$.

Lemma 3.1: (Properties of W and Op)

(i) *The Weyl quantization Op(a) of a symbol a is a Hilbert-Schmidt operator if and only if a is in $L^2_{x,p}$. Moreover, Op is an isometry from $L^2_{x,p}$ onto HS.*

(ii) *An operator ρ is Hermitian if and only if $W[\rho]$ is real valued. The Wigner transform W, defined from HS onto $L^2_{x,p}$ is the inverse transform to the Weyl quantization.*

(iii) *For two Hilbert-Schmidt operators ρ and σ, the following formula is a consequence of Plancherel's identity*

$$\mathrm{Tr}\{\rho\sigma^\dagger\} = \frac{1}{(2\pi\hbar)^3}\int W[\rho]\overline{W[\sigma]}\mathrm{d}x\,\mathrm{d}p. \tag{3.1}$$

(iv) *Let $\mathcal{H} = -(\hbar^2/2)\Delta + V$ denote the particle Hamiltonian. Then, for any Hilbert-Schmidt operator ρ, we formally have*

$$\frac{i}{\hbar}W[\mathcal{H},\rho] = (p\cdot\nabla_x - \theta[V])(W[\rho]), \tag{3.2}$$

where $\theta[V]$ denotes the pseudodifferential operator associated with the potential $V(x)$,

$$\begin{aligned}\theta[V]f &= \mathcal{F}^{-1}\left(i\frac{V\left(x+\frac{\eta}{2}\right) - V\left(x-\frac{\eta}{2}\right)}{\hbar}\mathcal{F}(f)\right)\\ &= \frac{i}{(2\pi)^3}\int_{\mathbb{R}^6}\frac{V\left(x+\frac{\hbar}{2}\eta\right) - V\left(x-\frac{\hbar}{2}\eta\right)}{\hbar}f(t,x,p')e^{i(p-p')\cdot\eta}\,\mathrm{d}\eta\,\mathrm{d}p',\end{aligned} \tag{3.3}$$

and $[\rho,\sigma] = \rho\sigma - \sigma\rho$ is the commutator of two operators ρ and σ.

(v) *$Op(|p|^2) = -\hbar^2\Delta$ and, for any symbol s depending only on x, $Op(s)$ is the s-multiplication operator: $Op(s)\varphi: x \to s(x)\varphi(x)$.*

Now we recall the link between the Wigner and the von Neumann equations. The density matrix ρ satisfies the von Neumann equation

$$i\hbar\,\partial_t\rho = [\mathcal{H},\rho] \tag{3.4}$$

if and only if its Wigner transform $f = W[\rho]$ satisfies the Wigner equation

$$\partial_t f + p\cdot\nabla_x f - \theta[V]f = 0 \tag{3.5}$$

as can be seen thanks to Eq. (3.2). The function f cannot be easily interpreted as a distribution function (for instance, it is not necessarily positive), but the classical transport equation $\partial_t f + (p\cdot\nabla_x - \nabla_x V\cdot\nabla_p)f = 0$ can be obtained as the semiclassical limit of the Wigner equation as $\hbar$ tends to 0 (see Ref. 39).

Lemma 3.3 gives some information on the operator $\theta[V]$ if we assume the following.

Assumption 3.2: *The potential V lies in* $W^{2,\infty}(\mathbb{R}^3)$.

Lemma 3.3: *If the potential V satisfies Assumption 3.2, then*

(i) $\theta[V]$ *is a bounded skew-adjoint operator from* $L^2_{x,p}$ *to* $L^2_{x,p}$,
(ii) *for any function* $f \in W^{2,2}(\mathbb{R}^3_x; L^2(\mathbb{R}^3_p))$,

$$\theta[V](f) \in W^{2,2}(\mathbb{R}^3_x, L^2(\mathbb{R}^3_p)),$$

and, for $f \in W^{1,2}(\mathbb{R}^3_x; L^2(\mathbb{R}^3_p))$,

$$\nabla_x \theta[V] f = \theta[\nabla_x V](f) + \theta[V](\nabla_x f),$$

where $\theta[\nabla_x V](f)$ *and* $\theta[V](\nabla_x f)$ *denote, respectively, the two vectors of components* $\theta[\partial_{x_i} V](f)$ *and* $\theta[V](\partial_{x_i} f)$, *for* $i=1,2,3$,
(iii) *for any function* $f \in L^2_{x,p}$ *such that* $pf \in (L^2_{x,p})^3$, $p\theta[V](f)$ *is in* $L^2_{x,p}$,
(iv) *for any function* $F \in \mathcal{E}$, $\theta[V]F$ *belongs to* $\mathcal{E}^{\perp}$.

Equation (3.5) does not take collision phenomena into account. In the remainder of Sec. III it is assumed that the scattering can be modeled through a classical elastic collision operator. Therefore, the collision operator is still $\mathcal{C}_{\mathrm{el}}$, as defined in (2.8). This leads to the following Wigner-Boltzmann equation (after rescaling):

$$\alpha \partial_t f^\alpha + (p \cdot \nabla_x - \theta[V]) f^\alpha = \frac{1}{\alpha} \mathcal{C}_{\mathrm{el}}(f^\alpha). \tag{3.6}$$

We denote by Λ the Wigner operator of domain $\mathcal{D}(\Lambda) = \{g \in L^2_{x,p} : p \cdot \nabla_x g \in L^2_{x,p}\}$ and defined by

$$\Lambda : \mathcal{D}(\Lambda) \to L^2_{x,p},$$
$$g \to (p \cdot \nabla_x - \theta[V]) g.$$

Note that, since $\theta[V]$ is skew-adjoint on $L^2_{x,p}$, so is Λ on $\mathcal{D}(\Lambda)$.

Remark 3.4: It is not clear whether the Wigner-Boltzmann equation equipped with the classical relaxation operator $\mathcal{C}_{\mathrm{el}}$ preserves positivity. In this sense, it is not a consistent quantum model. □

For the study of the QQSHE model, we introduce the following functional spaces:

$$\mathcal{L}^2_{N^k} = \left\{ h(x,\varepsilon) - \text{measurable} : \int_{\mathbb{R}^3_x} \int_{\varepsilon > 0} |h(x,\varepsilon)|^2 (N(\varepsilon))^k \, \mathrm{d}\varepsilon \, \mathrm{d}x < \infty \right\}, \tag{3.7}$$

with $N(\varepsilon) = \sqrt{2\varepsilon}$ and $k \in \mathbb{Z}$. So $\mathcal{E} = \mathcal{L}^2_N$.

Now, we give an existence result for the Wigner-Boltzmann equation (3.6).

Lemma 3.5: *Suppose Assumptions 2.4 and 3.2 hold true.*

Then, for any value of the parameter $\alpha > 0$, *any initial condition* $f^\alpha_I \in \mathcal{D}(\Lambda)$ *and any time* $T > 0$, *there exists a unique solution* $f^\alpha \in C^1([0,T]; L^2_{x,p}) \cap C^0([0,T]; \mathcal{D}(\Lambda))$ *to the initial value problem* (3.6), $f(t=0,x,p) = f^\alpha_I$.

Proof: This is a straightforward consequence of the classical semigroup theory—see, e.g., Refs. 36 and 48. Indeed, Λ is a skew-adjoint operator and generates a unitary group by Stone's theorem. Since $\mathcal{C}_{\mathrm{el}}$ is a bounded perturbation of Λ, $\mathcal{C}_{el} + \Lambda$ with domain $\mathcal{D}(\Lambda)$ generates a group of operators. □

B. The quasiquantum SHE model (QQSHE)

This section is dedicated to the investigation of the limit $\alpha \to 0$ in (3.6). The collision phenomena are modeled by the collision operator $\mathcal{C}_{\mathrm{el}}$ defined by (2.13). For the sake of simplicity, we assume that the collision frequency ν is constant. The main result of this section is the following.

Theorem 3.6: *Assumptions 2.4 and 3.2 are supposed to hold true.*

Let $f^\alpha_I \in L^2_{x,p}$ *be a convergent sequence such that the limit* f_I *be in* $\mathcal{E}$. *We note* $F_I(x, |p|^2/2)$

$=f_I(x,p)$. *Therefore*, F_I *is in* $\mathcal{L}^2_N$. *We assume that the collision frequency* ν *is constant*.

Let f^α *denote the solution of* (3.6), *with initial condition* $f^\alpha(t=0,x,p)=f_I^\alpha(x,p)$, *and with the relaxation operator* $\mathcal{C}_{\mathrm{el}}(f)=\nu(\mathcal{P}(f)-f)$. *Then, as* $\alpha\to 0$, *the sequence* $(f^\alpha)_{\alpha>0}$ *converges* (*up to the extraction of a subsequence*) *weakly in* $L^2(0,T;L^2_{x,p})$ *to a limit* $f\in L^2(0,T;\mathcal{E})$. *We note* $F(t,x,|p|^2/2)=f(t,x,p)$, *so that* $F\in L^2(0,T;\mathcal{L}^2_N)$. *In addition*, F *is a weak solution of*

$$\partial_t F-\frac{1}{\nu}\mathcal{P}(\Lambda(\Lambda(F)))=0, \tag{3.8}$$

$$F(t=0,x,\varepsilon)=F_I(x,\varepsilon). \tag{3.9}$$

Remark 3.7: If the collisions are modeled by the more general collision operator (2.8), then one can prove that the limit equation satisfied by F is

$$\partial_t F-\mathcal{P}(\Lambda(\mathcal{C}_{\mathrm{el}}^{-1}(\Lambda(F))))=0, \tag{3.10}$$

under the condition that the following set of test functions is dense in $L^\infty(0,T;\mathcal{L}^2_N)$:

$$\mathbb{H}=\{\varphi\in W^{1,\infty}(0,T;C_c^\infty(\mathbb{R}^3\times\mathbb{R}^+)):\mathcal{P}(\Lambda(\mathcal{C}_{\mathrm{el}}^{-1}(\Lambda\varphi)))\in L^\infty(0,T;\mathcal{L}^2_N)\}.$$

This condition is obviously fulfilled when $\mathcal{C}_{\mathrm{el}}=\nu(\mathcal{P}f-f)$.

It is possible to insert the expression of Λ into (3.8) [or (3.10)], in order to get a more explicit form of the equation. However, this expression is quite complicated and not very illuminating. We shall derive an explicit expression after using an expansion of Λ in powers of $\hbar$ at Sec. III C. □

Remark 3.8: The quantum (Wigner) transport operator does not preserve the classical entropy. Therefore, there is no (obvious) classical entropy dissipation for the quasiquantum SHE model. Also, the classical relaxation operator $\mathcal{C}_{\mathrm{el}}$ does not decay the quantum entropy introduced below in Sec. IV. This leaves little hope to find a simple entropic structure for this model, at least in the framework presented in this paper.

We have to mention that, unlike the classical SHE model, the QQSHE model has not a clear parabolic (or even degenerate parabolic) structure. Indeed, the Wigner transport operator is a pseudodifferential operator, not a true partial differential operator.

Last, but not least, the quantum relevance of this model is weak since there is no indication whether it admits positive solutions (in the sense of operator positivity). □

Proof: We start from (3.6). We multiply by f^α and integrate with respect to t, x, and p. This yields

$$\|f^\alpha(t)\|^2_{L^2_{x,p}}+\frac{1}{\alpha^2}\int_0^t\|\mathcal{P}^\perp f^\alpha(s)\|^2_{L^2_{x,p}}\,\mathrm{d}s=\|f_I^\alpha\|^2_{L^2_{x,p}}. \tag{3.11}$$

Therefore, the sequence (f^α) is bounded in $L^2_{x,p}$ since (f_I^α) is bounded. There exists f in $L^\infty(0,T;L^2_{x,p})$ such that $f^\alpha\rightharpoonup f$ weakly * in $L^\infty(0,T;L^2_{x,p})$. Moreover, the same estimate (3.11) shows that $\mathcal{P}^\perp f^\alpha$ tends strongly to 0 as $\alpha\to 0$ in the same space. Consequently, the limit f belongs to $\mathcal{E}$ and we can note $F(t,x,|p|^2/2)=f(t,x,p)$.

The Wigner-Boltzmann equation can be written in a weak form, by introducing the following set of test functions:

$$\mathcal{S}=\{\varphi\in W^{1,\infty}(0,T;L^2_{x,p})\cap L^\infty(0,T;\mathcal{D}(\Lambda)):\quad \varphi(T,x,p)=0\}.$$

The weak solutions of (3.6) satisfy

$$\forall\,\varphi\in\mathcal{S}\quad \int_{[0,T]\times\mathbb{R}^6} f^\alpha\left(\partial_t\varphi+\frac{1}{\alpha}\Lambda\varphi+\frac{1}{\alpha^2}\mathcal{C}_{\mathrm{el}}\varphi\right)\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p=\int_{\mathbb{R}^6} f_I^\alpha\varphi(0,x,p)\mathrm{d}x\,\mathrm{d}p. \tag{3.12}$$

In order to prove that F is a weak solution of (3.8), let us introduce a test function $\Phi(t,x,\varepsilon)$ for this equation, in $W^{1,\infty}(0,T;C_c^\infty(\mathbb{R}^3\times\mathbb{R}^+))$. Obviously the function $\varphi_1(t,x,p)$ defined by $\varphi_1(t,x,p)=\Phi(t,x,|p|^2/2)$ belongs to $\mathcal{S}$ and can be taken as a test function in (3.12). We consider the asymptotic behavior of each term in (3.12) as $\alpha\to 0$, in this special case where the test function φ_1 is a function of $(t,x,|p|^2/2)$. The weak convergence of f^α implies

$$\int f^\alpha \partial_t \varphi_1(t,x,p)\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p \to \int N(\varepsilon)F(t,x,\varepsilon)\partial_t\Phi(t,x,\varepsilon)\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}\varepsilon$$

and

$$\int f_I^\alpha \varphi_1(0,x,p)\mathrm{d}x\,\mathrm{d}p \to \int N(\varepsilon)F_I(x,\varepsilon)\Phi(0,x,\varepsilon)\mathrm{d}x\,\mathrm{d}\varepsilon.$$

On the other hand, since $\varphi_1(t,\cdot,\cdot)\in\mathcal{E}$, necessarily $\int f^\alpha \mathcal{C}_{\mathrm{el}}\varphi_1\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p=0$.

Let us decompose f^α as follows:

$$f^\alpha = F^\alpha + \alpha g^\alpha,$$

with $F^\alpha=\mathcal{P}f^\alpha$ and $g^\alpha=\mathcal{P}^\perp f^\alpha/\alpha$. According to Lemma 3.3 (iv), $\Lambda\varphi_1$ lies in $\mathcal{E}^\perp$. Therefore, $\int F^\alpha\Lambda\varphi_1\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p=0$ since $F^\alpha\in\mathcal{E}$ and

$$\frac{1}{\alpha}\int f^\alpha\Lambda\varphi_1\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p = \int g^\alpha\Lambda\varphi_1\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p. \tag{3.13}$$

We are thus led to investigate the behavior of g^α as $\alpha\to 0$. According to Eq. (3.11), and using the definition of g^α, we have

$$\int_0^t \|g^\alpha(s)\|_{L^2_{x,p}}\,\mathrm{d}s \leqslant C.$$

Therefore, there exists g such that $g^\alpha \rightharpoonup g$ weakly * in $L^\infty(0,T;L^2_{x,p})$ and,

$$\frac{1}{\alpha}\int f^\alpha\Lambda\varphi_1\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p = \int g^\alpha\Lambda\varphi_1\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p \to \int g\Lambda\varphi_1\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p \tag{3.14}$$

as $\alpha\to 0$. It remains to relate the last integral in (3.14) to F.

To this aim, we come back to (3.12), that we write with another particular test function φ_2 (specified below). Equation (3.12) can be written in terms of g^α and F^α. Since the sequences F^α and g^α are bounded, keeping only the leading order terms in this equation leads to

$$\int g^\alpha\mathcal{C}_{\mathrm{el}}\varphi_2\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p = -\int F^\alpha\Lambda\varphi_2\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p + \mathcal{O}(\alpha),$$

or, letting $\alpha\to 0$,

$$\int g\mathcal{C}_{\mathrm{el}}\varphi_2\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p = -\int F\Lambda\varphi_2\,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p. \tag{3.15}$$

Now, by choosing

$$\varphi_2 = (\mathcal{C}_{\mathrm{el}})^{-1}(\Lambda\varphi_1),$$

we deduce that the last integral in (3.14) can be rewritten

$$\int g\Lambda\varphi_1 \,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p = \int g\mathcal{C}_{\mathrm{el}}\varphi_2 \,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p$$

and straightforward calculations lead to

$$\int g\Lambda\varphi_1 \,\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}p = -\int NF\mathcal{P}(\Lambda((\mathcal{C}_{\mathrm{el}})^{-1}(\Lambda\varphi_1)))\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}\varepsilon.$$

Finally, we get

$$\int NF(\partial_t\Phi - \mathcal{P}(\Lambda((\mathcal{C}_{\mathrm{el}})^{-1}(\Lambda\varphi_1))))\mathrm{d}t\,\mathrm{d}x\,\mathrm{d}\varepsilon = \int NF_I\Phi(0,x,\varepsilon)\mathrm{d}x\,\mathrm{d}\varepsilon \tag{3.16}$$

which is obviously the weak form of (3.10). It remains to check that this formal identification can be made rigorous. Namely, we must prove that, if $\Phi \in W^{1,\infty}(0,T;C_c^\infty(\mathbb{R}^3\times\mathbb{R}^+))$, then $\varphi_2 = (\mathcal{C}_{\mathrm{el}})^{-1}(\Lambda\varphi_1)$ is an admissible test function for (3.12). By Lemma 3.3 (under Assumption 3.2), it is an easy task, since we have

$$(\mathcal{C}_{\mathrm{el}})^{-1}(\Lambda\varphi_1) = -\frac{1}{\nu}\Lambda\varphi_1.$$

□

C. The QQSHE$_2$ model: quantum corrections to the classical SHE model

The explicit form of the diffusion term $\mathcal{P}(\Lambda(\Lambda F))N(\varepsilon)/\nu$ in (3.8) is not easy to handle. As in Ref. 19 we give the expansion of this model in $\hbar$, up to second order terms. This leads to the classical SHE model enriched with quantum correction terms.

In the remainder of this paper, when a function F depends on p through the energy $|p|^2/2$ only, we note equally $F(|p|^2/2)=F(p)$ when the context is clear.

The Wigner transport operator Λ depends on the reduced Planck constant. At usual macroscopic scales, this constant is negligible and the transport operator Λ can be expanded in powers of $\hbar$. Formally, one has

$$\Lambda = L + \hbar^2 L^{(2)} + \mathcal{O}(\hbar^4), \tag{3.17}$$

where $L=p\cdot\nabla_x - \nabla_x V\cdot\nabla_p$ is the classical transport operator and $L^{(2)}$ is a third order differential operator given by

$$L^{(2)} = \tfrac{1}{24}\nabla_x^{\otimes 3}V \vdots \nabla_p^{\otimes 3}.$$

Here the third order tensors are defined as $(\nabla_x^{\otimes 3})_{i,j,k}=\partial^3_{x_i,x_j,x_k}$ (and analogously for $\nabla_p^{\otimes 3}$) and $\vdots$ denotes the third order tensor product. Formula (3.17) gives the leading and second order terms of the so-called Wigner-Moyal expansion (see Ref. 43).

Then the diffusion term becomes

$$N(\varepsilon)\mathcal{P}(\Lambda(\Lambda F)) = N(\varepsilon)\mathcal{P}(L(LF)) + \hbar^2 N(\varepsilon)(\mathcal{P}(L^{(2)}(LF)) + \mathcal{P}(L(L^{(2)}F))) + \mathcal{O}(\hbar^4).$$

Note that $\mathcal{P}(L(LF))$ is the diffusion term that is involved in the CSHE model (2.11), (2.14). Indeed, when F is a function of the position and energy only $LF=p\cdot\tilde{\nabla}F$, where $\tilde{\nabla}$ is the "twisted" gradient operator defined at (2.12). Therefore, $L(LF)=p^{\otimes 2}:\tilde{\nabla}^{\otimes 2}F-\nabla_x V\cdot\tilde{\nabla}F$. Applying projector $\mathcal{P}$ yields

$$N(\varepsilon)\mathcal{P}(L(LF)) = 4\pi\frac{(2\varepsilon)^{3/2}}{3}\tilde{\nabla}\cdot\tilde{\nabla}F - 4\pi(2\varepsilon)^{1/2}\nabla_x V\cdot\tilde{\nabla}F$$

and one can check that the right-hand side of this equation can be written

$$4\pi\tilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{3/2}}{3}\tilde{\nabla}F\right)$$

which is the diffusion term in the classical SHE model.

For the computation of the other terms, we refer the reader to Appendix A. They are summarized in the following formal lemma.

Lemma 3.9: *We assume that the collision operator is given by* (2.13). *Up to second order terms in* $\hbar$, *the QQSHE model can be formally approached by the following* QQSHE_2 *model* (*in the case where* ν *is a constant independent of* ε):

$$N(\varepsilon)\partial_t F - \frac{4\pi}{\nu}\tilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{3/2}}{3}\tilde{\nabla}F\right) - \frac{4\pi\hbar^2}{24\nu}\left\{\frac{\partial^2}{\partial\varepsilon^2}\left(\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\cdot\partial_\varepsilon\tilde{\nabla}F\right)\right.$$
$$\left.+\frac{\partial}{\partial\varepsilon}\tilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\partial_\varepsilon^2 F\right)\right\}=0. \tag{3.18}$$

Remark 3.10: Compared with the CSHE model (2.11), additional terms involving fourth order derivatives appear. They are multiplied by factors involving third order derivatives of the potential, which is natural since these factors appear in the first correction to the classical limit in the Wigner-Moyal expansion.[43] Also, these fourth order derivatives of F involve cross-diffusion terms mixing space and energy derivatives. This is to be related with the cross-diffusion terms that appear in the Fokker-Planck equation used in Ref. 4. □

Given that the coefficients of the fourth order derivatives have no fixed sign, one can wonder about the stability and well-posedness of this model. As for the QQSHE model, there is no clear entropic structure for the QQSHE_2 model. Therefore, no clear indication is given why this model should be well-posed. A linearized stability analysis of this model is in progress to try to answer this question. If the model is found linearly stable, there is good hope that it can be used to efficiently simulate quantum semiconductor devices numerically. □

IV. QUANTUM COLLISION OPERATORS

All the results given in the following section are formal. In Sec. III, the SHE models are of a hybrid type since they are derived from a microscopic equation with a quantum transport term and a classical collision operator. To remedy to this inconsistency, we need to develop a notion of quantum collision operator which allows us to perform the program leading to SHE-type models.

An important property of the collision operators used in classical kinetic theory is the entropy dissipation. Therefore, a natural requirement of a quantum collision operator $\mathcal{Q}$ is that it dissipates quantum entropy and that a quantum kinetic equation such as the Wigner-Boltzmann equation

$$\partial_t f + p\cdot\nabla_x f - \theta[V]f = \mathcal{Q}(f) \tag{4.1}$$

satisfies a quantum analogue to Lemma 2.1.

The collision operator $\mathcal{Q}$ will be derived as a quantum counterpart of the classical electron-phonon collision operator (or its elastic approximation). Therefore, the equilibrium states of this quantum operator will be "quantum" Maxwellian, as the classical operator had ("classical") Maxwellian equilibria. Consequently, the quantum relative entropy associated with the von Neumann equation (3.4) is defined by $H_Q(\rho)=\mathrm{Tr}\{\rho(\ln\rho-1+\mathcal{H})\}$ where $\mathcal{H}=-(\hbar^2/2)\Delta+V$ is the particle Hamiltonian. Lemma 3.1 allows to deduce the expression of quantum entropy in the Wigner framework by

$$H_Q(f)=\frac{1}{(2\pi\hbar)^3}\int f\left(\mathcal{L}\mathrm{n}(f)+\frac{|p|^2}{2}+V-1\right)\mathrm{d}p\,\mathrm{d}x, \tag{4.2}$$

where the "quantum logarithm" $\mathcal{L}\mathrm{n}$ is defined by

$$\mathcal{L}\mathrm{n}(f) = W[\ln(\mathrm{Op}(f))],$$

assuming that $\mathrm{Op}(f) > 0$. Analogously, we define the "quantum exponential" and the quantum Maxwellian $\mathcal{M}\mathrm{ax}$, respectively, by

$$\mathcal{E}\mathrm{xp}(f) = W[\exp(\mathrm{Op}(f))],$$

$$\mathcal{M}\mathrm{ax}(x,p) = W\left[\exp\left(\mathrm{Op}\left(-\frac{|p|^2}{2} - V(x)\right)\right)\right] = \mathcal{E}\mathrm{xp}(-|p|^2/2 - V).$$

Note that $\mathcal{L}\mathrm{n}$ and $\mathcal{E}\mathrm{xp}$ are formal inverses and that $-|p|^2/2 - V = \mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}(x,p))$.

Then (4.2) is equivalently written [up to a constant multiplier $(2\pi\hbar)^2$]

$$H_Q(f) = \int f(\mathcal{L}\mathrm{n}(f) - \mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}) - 1)\mathrm{d}p\,\mathrm{d}x$$

and appears as the quantum relative entropy with respect to quantum Maxwellian steady states. The following lemma gives a criterion on $\mathcal{Q}$ for Eq. (4.1) to be consistent with the quantum entropy H_Q.

Lemma 4.1: *Let* $\mathcal{Q}$ *in* (4.1) *be such that, for any function* g, *we have*

$$-\int \mathcal{Q}(g)(\mathcal{L}\mathrm{n}(g) - \mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}))\mathrm{d}x\,\mathrm{d}p \geqslant 0. \tag{4.3}$$

Then, if f *is a solution of Eq.* (4.1), *the associated quantum entropy satisfies*

$$\frac{\mathrm{d}H_Q(f)}{\mathrm{d}t} \leqslant 0. \tag{4.4}$$

Proof: To begin with, we recall that H_Q is Gâteaux differentiable and its Gâteaux derivative at f in the direction δf is (see Ref. 21)

$$H_Q'(f)\,\delta f = (2\pi\hbar)^3\,\mathrm{Tr}\{(\ln \mathrm{Op}(f) + \mathcal{H})\mathrm{Op}(\delta f)\}$$

or,

$$H_Q'(f)\,\delta f = \int \left(\mathcal{L}\mathrm{n}\, f + \frac{|p|^2}{2} + V\right)\delta f\,\mathrm{d}p\,\mathrm{d}x.$$

Therefore, if f is a solution of (4.1),

$$\begin{aligned}\frac{\mathrm{d}H_Q(f)}{\mathrm{d}t} &= \int \left(\mathcal{L}\mathrm{n}\, f + \frac{|p|^2}{2} + V\right)\partial_t f\,\mathrm{d}p\,\mathrm{d}x = -\int \left(\mathcal{L}\mathrm{n}\, f + \frac{|p|^2}{2} + V\right)\Lambda f\,\mathrm{d}p\,\mathrm{d}x \\ &\quad - \int \left(\mathcal{L}\mathrm{n}\, f + \frac{|p|^2}{2} + V\right)\mathcal{Q}(f)\mathrm{d}p\,\mathrm{d}x \\ &= -\int \left((W[\ln(\mathrm{Op}(f))] + W[\mathcal{H}])\frac{i}{\hbar}W[\mathcal{H}\,\mathrm{Op}(f) - \mathrm{Op}(f)\mathcal{H}]\right)\mathrm{d}p\,\mathrm{d}x \\ &\quad - \int (\mathcal{L}\mathrm{n}(f) - \mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}))\,\mathcal{Q}(f)\mathrm{d}p\,\mathrm{d}x \end{aligned} \tag{4.5}$$

thanks to Lemma (3.1) (iv). Now, using (3.1) (iii), the first integral on the right-hand side can be written

$$(2\pi)^3 i\hbar^2 \operatorname{Tr}\{(\ln(\mathrm{Op}(f)) + \mathcal{H})[\mathcal{H}, \mathrm{Op}(f)]\}$$

or, using the cyclicity of the trace,

$$(2\pi)^3 i\hbar^2 \operatorname{Tr}\{[\mathrm{Op}(f), \ln(\mathrm{Op}(f))]\mathcal{H} + [\mathcal{H}, \mathcal{H}]\mathrm{Op}(f)\}$$

and this trace is obviously null. Finally, the second integral on the right-hand side of (4.5) is non-negative according to (4.3), which completes the proof. □

Consequently, after Ref. 22, what is meant in this paper by quantum collision operators is a class of collision operators $\mathcal{Q}$ that satisfy the following formal properties: for any function $f(x,p)$,

$$\textit{Mass conservation}: \int \mathcal{Q}(f)(p)\mathrm{d}x\,\mathrm{d}p = 0,$$

$$\textit{Entropy dissipation}: -\int \mathcal{Q}(f)(\mathcal{L}\mathrm{n}(f) - \mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}))\mathrm{d}x\,\mathrm{d}p \geqslant 0.$$

A. The quantum electron-phonon collision operator

In this section, quantum counterparts of the classical collision operator $\mathcal{C}_{e\varphi}$ and of its elastic approximation $\mathcal{C}_{\mathrm{el}}$ are introduced. They may lead to possibly interesting quantum models for electron-phonon scattering. Moreover, the derivation of a quantum SHE model in Sec. V is performed from a quantum kinetic equation with a relaxation collision operator which can be understood as a relaxation approximation of the operators studied in this section.

Keeping Lemma 4.1 in mind, we introduce the following quantum version of the electron-phonon collision operator $\mathcal{C}_{e\varphi}$ described in Sec. II B (we recall that β is the phonon energy in scaled variables):

$$\mathcal{Q}_{e\varphi}(f) = \int \mathcal{S}(p,p')[\delta(\varepsilon' - \varepsilon - \beta) + \delta(\varepsilon' - \varepsilon + \beta)]\left(\frac{\mathcal{A}(f)'}{M'} - \frac{\mathcal{A}(f)}{M}\right)\mathrm{d}p', \tag{4.6}$$

where

$$\mathcal{A}(f) = \exp W[\ln \mathrm{Op}(f)] = \exp \mathcal{L}\mathrm{n}\, f, \tag{4.7}$$

namely $\mathcal{L}\mathrm{n}\, f = \ln \mathcal{A}(f)$ where ln is the ordinary logarithm. Note that it is not clear what conditions f should satisfy for $\mathcal{A}(f)$ to be a well-defined function. Therefore, the definition of $\mathcal{Q}_{e\varphi}$ is purely formal at this point and all the results stated in this section are formal.

However, we claim that this operator is a natural extension of the classical phonon operator to quantum systems, and that it is consistent with quantum entropy relaxation. Indeed, we have the following.

Proposition 4.2: *The collision operator* $\mathcal{Q}_{e\varphi}$ *defined by* (4.6) *satisfies the following properties*:

(i) *Mass conservation*: $\int \mathcal{Q}_{e\varphi}(f)\mathrm{d}p = 0$ *for any measurable function* f.

(ii) *Equilibrium states*: *for any measurable function* $f(x,p)$, *we have* $\mathcal{Q}_{e\varphi}(f) = 0$ *if and only if*

$$f(x,p) = \mathcal{E}\mathrm{xp}\left(\frac{|\cdot|^2}{2} + \ln F\left(\frac{|\cdot|^2}{2}\right)\right)(x,p) = W\left[\exp\left(-\frac{\hbar^2}{2}\Delta + \mathrm{Op}(\ln F)\right)\right](x,p)$$

where $F = F(\varepsilon)$ *is such that* $F(\varepsilon+\beta) = F(\varepsilon)$.

(iii) *Entropy dissipation*: $-\int \mathcal{Q}_{e\varphi}(f)(\mathcal{L}\mathrm{n}(f) - \mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}))\mathrm{d}p \geqslant 0$ *for any function* f.

Proof: The mass conservation follows from the symmetry of $\mathcal{S}(p,p')$. The equilibria of operator $\mathcal{Q}_{e\varphi}$ can be easily deduced from those of operator $\mathcal{C}_{e\varphi}$ by remarking that $\mathcal{Q}_{e\varphi}(f) = \mathcal{C}_{e\varphi}(\mathcal{A}(f))$. On the other hand, it follows from the symmetry of $\mathcal{S}$ that

$$-\int \mathcal{Q}_{e\varphi}(f)(\mathcal{L}\mathrm{n}(f)-\mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}))\mathrm{d}p$$

$$=\frac{1}{2}\int \mathcal{S}(p,p')(\delta_+ + \delta_-)\left(\frac{\mathcal{A}(f)'}{M'}-\frac{\mathcal{A}(f)}{M}\right)\left(\ln\frac{\mathcal{A}(f)'}{M'}-\ln\frac{\mathcal{A}(f)}{M}\right)\mathrm{d}p\,\mathrm{d}p'\,\mathrm{d}x$$

which is non-negative since ln is an increasing function. □

Like in the case of the classical electron-phonon scattering, we are interested in the elastic limit $\beta\to 0$ of the operator $\mathcal{Q}_{e\varphi}$. More precisely, we let ω_0 tend to zero and get

$$\mathcal{Q}_{\mathrm{el}}(f)(p)=N(|p|^2/2)\{\mathcal{P}(\widetilde{\mathcal{S}}(p,\cdot)\mathcal{A}(f)(\cdot))-\mathcal{P}(\widetilde{\mathcal{S}}(p,\cdot))\mathcal{A}(f)(p)\}, \tag{4.8}$$

where $\widetilde{\mathcal{S}}$ is defined as in Sec. II B by formula (2.9). We drop the tildes in the remainder of the paper. This operator has the properties of a quantum collision operator.

Proposition 4.3: *The collision operator* $\mathcal{Q}_{\mathrm{el}}$ *defined by* (4.8) *satisfies the following properties*:

(i) *Mass conservation*: $\int \mathcal{Q}_{\mathrm{el}}(f)\mathrm{d}p=0$ *for any measurable function* f.

(ii) *Equilibrium states*: *for any measurable function* $f(x,p)$, *we have* $\mathcal{Q}_{\mathrm{el}}(f)=0$ *if and only if there exists a function* $\lambda(x,\varepsilon)$ *of position and energy only such that*

$$f(x,p)=\mathcal{E}\mathrm{xp}(\widetilde{\lambda})(x,p),$$

where $\widetilde{\lambda}(x,p)=\lambda(x,|p|^2/2)$.

(iii) *Entropy dissipation*: $-\int \mathcal{Q}_{\mathrm{el}}(f)(\mathcal{L}\mathrm{n}(f)-\mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}))\mathrm{d}p\geqslant 0$ *for any function* f.

Remark 4.4: Note that f, unlike λ, is *not* a function of the energy only in general. Indeed, it is not clear that the quantum exponential of a function of position and energy $(x,\varepsilon(p))$ remains a function of $(x,\varepsilon(p))$ [with $\varepsilon(p)=|p|^2/2$]. □

Proof: Mass conservation and entropy dissipation can be proven in the same way as for $\mathcal{Q}_{e\varphi}$. For (ii), we consider

$$-\int \mathcal{Q}_{\mathrm{el}}(f)(p)\mathcal{A}(f)(p)\mathrm{d}p=\frac{1}{2}\int \delta\left(\frac{|p'|^2}{2}-\frac{|p|^2}{2}\right)\mathcal{S}(p,p')(\mathcal{A}(f)(p')-\mathcal{A}(f)(p))^2\,\mathrm{d}p'\,\mathrm{d}p\geqslant 0,$$

where $\mathcal{A}$ is defined by (4.7).

Obviously, if $Q_{\mathrm{el}}(f)=0$, then one necessarily has $\mathcal{A}(f)(x,p)=\mathcal{A}(f)(x,p')$ whenever $|p|=|p'|$. Therefore, $\mathcal{A}(f)$ is a function of x and $|p|^2/2$ only. Consequently, $\ln\mathcal{A}(f)$ depends only on $|p|^2/2$ too and, finally, one can set $\lambda(\varepsilon)=\ln\mathcal{A}(f)=\mathcal{L}\mathrm{n}\,f$, or $f=\mathcal{E}\mathrm{xp}\,\lambda$. □

B. The quantum relaxation operator

In classical kinetic theory, an important class of collision operators is constituted by the relaxation operators. The mathematical study of these operators is simpler than for Boltzmann-type collision operators although they share many important properties with them, such as entropy dissipation, mass conservation and the expression of their equilibrium states.

The task in this section is to introduce a consistent notion of quantum relaxation operator that satisfies properties (i), (ii), and (iii) of Proposition 4.3. To this aim, we introduce the following minimization problem:

Given f, find $\mathcal{E}_f$ such that:

$$H_Q(\mathcal{E}_f) = \mathrm{Min}\{H_Q(g)/\mathcal{P}(f-g)=0\}. \tag{4.9}$$

Assuming that, for f in a suitable space, a solution $\mathcal{E}_f$ to this problem exists, we set

$$\mathcal{Q}_{\mathrm{rel}}(f) = \nu(\mathcal{E}_f - f), \tag{4.10}$$

where ν is assumed to be constant in the sequel.

It remains to prove that such an operator has the required properties. We have the following.

Proposition 4.5 The collision operator $\mathcal{Q}_{\mathrm{rel}}$ *defined by* (4.10) *satisfies the following properties:*

(i) *Mass conservation:* $\int \mathcal{Q}_{\mathrm{rel}}(f)\mathrm{d}p=0$ *for any measurable function* f.

(ii) *Equilibrium states: for any measurable function* $f(x,p)$, *we have* $\mathcal{Q}_{\mathrm{rel}}(f)=0$ *if and only if there exists a function* $\lambda(x,\varepsilon)$ *of* x *and the energy only such that*

$$f(x,p) = \mathcal{E}\mathrm{xp}(\tilde{\lambda})(x,p),$$

where $\tilde{\lambda}(x,p)=\lambda(x,|p|^2/2)$.

(iii) *Entropy dissipation:* $-\int \mathcal{Q}_{\mathrm{rel}}(f)(\mathcal{L}\mathrm{n}(f)-\mathcal{L}\mathrm{n}(\mathcal{M}\mathrm{ax}))\mathrm{d}p \geqslant 0$ *for any function* f.

Before proving Proposition 4.5, we state an important property of the solutions of the minimization problem (4.9).

Lemma 4.6: Let f *be a function such that a solution of the minimization problem* (4.9) *exists. We denote such a solution by* $\mathcal{E}_f$. *Then, there exists a function* $\lambda(x,\varepsilon)$ *such that*

$$\mathcal{E}_f(x,p) = \mathcal{E}\mathrm{xp}(\lambda)(x,p).$$

Proof: Since $\mathcal{E}_f$ is the minimizer of $H_Q(g)$ under the constraint $\mathcal{P}(f-g)=0$, there exists a Lagrange multiplier $\mu(x,\varepsilon)$ such that $H_Q'(f)g+\mu\mathcal{P}(g)=0$ for all g. This means that, for all g,

$$\int \left(\mathcal{L}\mathrm{n}(f) + \frac{|p|^2}{2} + V - \mu(x,|p|^2/2)\right) g(x,p)\mathrm{d}p\,\mathrm{d}x = 0,$$

that is $f=\mathcal{E}\mathrm{xp}(\lambda(x,\varepsilon))$ with $\lambda(x,\varepsilon)=\mu(x,\varepsilon)-\varepsilon-V(x)$. □

Proof of Proposition 4.5: Point (i) is obvious since the definition of $\mathcal{E}_f$ implies that $\mathcal{P}(f-\mathcal{E}_f)=0$. Point (ii) is a straightforward consequence of Lemma 4.6. The proof of point (iii) is inspired from Ref. 19. We introduce

$$\Gamma : \gamma \in [0,1] \to \int_{\mathbb{R}^6} \nu(x,\varepsilon) h((1-\gamma)\mathcal{E}_f + \gamma f)\mathrm{d}x\,\mathrm{d}p$$

with $h : f \to f(\mathcal{L}\mathrm{n}\, f - 1 + |p|^2/2 + V)$. Deriving Γ by a chain rule yields

$$\frac{\mathrm{d}\Gamma}{\mathrm{d}\gamma}(\gamma) = \int_{\mathbb{R}^6} \nu(x,\varepsilon_p)(f-\mathcal{E}_f)(\mathcal{L}\mathrm{n}((1-\gamma)\mathcal{E}_f + \gamma f) + |p|^2/2 + V)\mathrm{d}x\,\mathrm{d}p.$$

The convexity of h implies that Γ is also convex so that $(\mathrm{d}\Gamma/\mathrm{d}\gamma)(1) \geqslant \Gamma(1)-\Gamma(0)$, which in turn gives

$$-\int \mathcal{Q}_{\mathrm{rel}}(f)(\mathcal{L}\mathrm{n}(f) + |p|^2/2 + V)\mathrm{d}x\mathrm{d}p \geqslant \nu(H_Q(f) - H_Q(\mathcal{E}_f)) \geqslant 0$$

since $\mathcal{E}_f$ is a minimizer of H_Q and ν is a constant. □

Before turning to the derivation of a fully quantum SHE type model, it is important to underline that the collisional Wigner equation equipped with relaxation type operator $\mathcal{Q}_{\mathrm{rel}}$ is a consistent quantum model in the sense that it (formally) preserves positivity. Precisely, the following proposition holds true.

Proposition 4.7: Let the initial datum f_I be positive [in the sense of operators, i.e., *$\rho_I = \mathrm{Op}(f_I)$ is a positive operator]. If the following initial value problem,*

$$\partial_t f + \Lambda f = \mathcal{Q}_{\mathrm{rel}} f, \quad f(t=0,x,p) = f_I(x,p),$$

has a solution $f(t,x,p)$, then this solution is positive [i.e., *$\rho(t) = \mathrm{Op}(f)(t)$ is a positive operator*] *for all time*.

Proof: The proof is very close to the proof of Lemma 2.1 in Ref. 19. We just emphasize on the positivity of operator $\mathrm{Op}(\mathcal{E}_f)$. Indeed, according to Lemma 4.6, to any given function f there can be associated an energy dependent function λ_f such that

$$\mathcal{E}_f = \mathcal{E}\mathrm{xp}(\lambda_f).$$

Consequently, $\mathrm{Op}(\mathcal{E}_f) = \mathrm{Op}(W(\exp \mathrm{Op}(\lambda_f))) = \exp \mathrm{Op}(\lambda_f)$ which obviously is a positive operator.□

This quantum relaxation collision operator will be used for the derivation of the full quantum SHE model. Note that at this point, the existence of a minimizer for (4.9) is an open problem.

V. THE FULL QUANTUM SHE MODEL (QSHE)

In this section, we formally investigate the limit $\alpha \to 0$ in the following rescaled Wigner-Quantum relaxation equation:

$$\alpha \partial_t f^\alpha + \Lambda f^\alpha = \frac{1}{\alpha} \mathcal{Q}_{\mathrm{rel}}(f^\alpha), \tag{5.1}$$

where we recall that $\Lambda = p \cdot \nabla_x - \theta[V]$ is the Wigner operator. In the sequel, we assume the following.

Assumption 5.1: *For any given function f, there exists a solution $\mathcal{E}_f$ to the minimization problem* (4.9), *and this solution is unique*.

The following formal result holds.

Theorem 5.2: *If* (5.1) *admits a solution f^α for all α, and if the so-obtained sequence f^α admits a convergent subsequence, then the limit is denoted by $\mathcal{F}$ and there exists a function λ such that $\tilde{\lambda}: (t,x,p) \to \lambda(t,x,|p|^2/2)$ satisfies*

$$\begin{gathered} \mathcal{F}(t,x,p) = \mathcal{E}\mathrm{xp}(\tilde{\lambda})(t,x,p), \\ N(\varepsilon)\partial_t \mathcal{P}(\mathcal{E}\mathrm{xp}(\tilde{\lambda})) - N(\varepsilon)\mathcal{P}\left(\Lambda\left(\frac{1}{\nu}\Lambda(\mathcal{E}\mathrm{xp}(\tilde{\lambda}))\right)\right) = 0. \end{gathered} \tag{5.2}$$

Furthermore, the quantum entropy decreases with time,

$$\frac{d}{dt} H_{\mathrm{QSHE}}(\mathcal{F}) \leqslant 0, \quad H_{\mathrm{QSHE}}(\mathcal{F}) = \int \mathcal{P}(\mathcal{F})(\lambda + \varepsilon + V - 1) N(\varepsilon) d\varepsilon \, dx. \tag{5.3}$$

Remark 5.3: The main difference between the QQSHE and QSHE models is that the unknown F in the QQSHE model (which is a function of position and energy) is replaced by $\mathcal{E}\mathrm{xp}\,\tilde{\lambda}$ in the QSHE model, where λ is a function of position and energy. This is a true difference since $\mathcal{F} = \mathcal{E}\mathrm{xp}\,\tilde{\lambda}$ is in general *not* a function of position and energy only. This difference makes the QSHE model consistent with *quantum* entropy decay (5.3) rather than classical entropy decay. Again, we do not make this equation more explicit. Indeed, here, it is not possible to make the relation between $\mathcal{E}\mathrm{xp}\,\tilde{\lambda}$ and λ explicit because $\mathcal{E}\mathrm{xp}$ is a nonlinear nonlocal operator. □

Remark 5.4: Equation (5.2) is closed provided the minimization problem (4.9) is uniquely solvable. Indeed, in this case, there is a one to one correspondence between the intensive quantity λ and the extensive quantity $\mathcal{P}(\mathcal{E}\exp\lambda)$. □

Proof: First, letting $\alpha\to 0$ in Eq. (5.1) leads to $\mathcal{Q}_{\mathrm{rel}}(\mathcal{F})=0$ so that, according to Proposition 4.5, there exists $\lambda(x,\varepsilon)$ such that $\mathcal{F}=\mathcal{E}\exp\widetilde{\lambda}$. Now, the Chapman-Enskog expansion of f^α is written

$$f^\alpha=\mathcal{E}_{f^\alpha}+\alpha g^\alpha$$

since f^α is close to the equilibrium when α is small. We assume that $\mathcal{E}_{f^\alpha}$ and g^α are bounded with respect to α in a suitable topology (see Remark 5.5 below). Then, introducing this expansion in Eq. (5.1) yields, at first order in α,

$$\mathcal{P}(\partial_t\mathcal{E}_{f^\alpha}+\Lambda g^\alpha)=\mathcal{O}(\alpha) \tag{5.4}$$

and, at zeroth order in α,

$$\Lambda\mathcal{E}_{f^\alpha}=-\nu g^\alpha+\mathcal{O}(\alpha) \tag{5.5}$$

since $\mathcal{Q}_{\mathrm{rel}}(f^\alpha)=\nu(\mathcal{E}_{f^\alpha}-(\mathcal{E}_{f^\alpha}+\alpha g^\alpha))=-\alpha\nu g^\alpha$. According to (5.5), Eq. (5.4) becomes

$$\mathcal{P}\left(\partial_t\mathcal{E}_{f^\alpha}-\Lambda\left(\frac{1}{\nu}\Lambda\mathcal{E}_{f^\alpha}\right)\right)=\mathcal{O}(\alpha). \tag{5.6}$$

We recall that $\mathcal{E}_{f^\alpha}\to\mathcal{E}\exp\widetilde{\lambda}$ as $\alpha\to 0$. Letting $\alpha\to 0$ in (5.6) leads to (5.2). The entropy decay is obtained by taking the limit $\alpha\to 0$ in (4.4). □

Remark 5.5: At this stage of investigation, any rigorous convergence proof remains speculative. However, in simpler situations, if any, a reasonable proof would at least require that sequences $\mathcal{E}_{f^\alpha}$ and g^α be bounded with respect to α in a suitable topology (precisely the topology in which convergence of sequence f^α would be proven to hold). □

From now on, we drop the tildes and identify λ to $\widetilde{\lambda}$. As in the case of the quasiquantum SHE model, it is interesting to expand the quantum SHE model in powers of $\hbar$ up to second order terms. We recall that $\Lambda=L+\hbar^2L^{(2)}+\mathcal{O}(\hbar^4)$ where $L=p\cdot\nabla_x-\nabla_xV\cdot\nabla_p$ is the classical transport operator and $L^{(2)}=(1/24)\nabla_x^{\otimes 3}V\vdots\nabla_p^{\otimes 3}$. However, unlike in the case of the quasiquantum SHE model, here not only does Λ depend on $\hbar$, but also $\mathcal{E}\exp\lambda$. After Ref. 19, the quantum exponential of any function $f(x,p)$ can be written

$$\mathcal{E}\exp f=\exp f[1+\hbar^2\mathcal{T}f+\mathcal{O}(\hbar^4)], \tag{5.7}$$

$$\mathcal{T}f=\tfrac{1}{8}\left(\nabla_x^{\otimes 2}f:\nabla_p^{\otimes 2}f-\nabla_x\nabla_pf:\nabla_p\nabla_xf+\tfrac{1}{3}(\nabla_x^{\otimes 2}f:\nabla_pf\nabla_pf-2\nabla_x\nabla_pf:\nabla_pf\nabla_xf+\nabla_p^{\otimes 2}f:\nabla_xf\nabla_xf)\right). \tag{5.8}$$

Therefore, the QSHE model is formally approached, up to second order terms, by

$$\begin{aligned}&N(\varepsilon)\partial_tF-N(\varepsilon)\mathcal{P}\left(L\left(\frac{1}{\nu}L(F)\right)\right)+\hbar^2N(\varepsilon)\partial_t[\mathcal{P}(F\mathcal{T}(\ln F))]\\&\quad-\hbar^2N(\varepsilon)\mathcal{P}\left[\left(L\left(\frac{1}{\nu}L^{(2)}\right)+L^{(2)}\left(\frac{1}{\nu}L\right)\right)(F)-L\left(\frac{1}{\nu}L(F\mathcal{T}(\ln F))\right)\right]=0.\end{aligned} \tag{5.9}$$

where we have set $F=\exp\lambda$.

We recall that ν is a constant coefficient. Using the computations already performed to prove Lemma 3.9, we obtain

$$N(\varepsilon)\partial_tF-\frac{4\pi}{\nu}\widetilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{3/2}}{3}\widetilde{\nabla}F\right)$$

$$-\frac{4\pi\hbar^2}{24\nu}\left\{\frac{\partial^2}{\partial\varepsilon^2}\left(\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\cdot\partial_\varepsilon\widetilde{\nabla}F\right)+\frac{\partial}{\partial\varepsilon}\widetilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\partial_\varepsilon^2 F\right)\right\}$$

$$+\hbar^2 N(\varepsilon)\partial_t[\mathcal{P}(F\mathcal{T}(\ln F))]+\frac{\hbar^2 N(\varepsilon)}{\nu}\mathcal{P}[L(L(F\mathcal{T}(\ln F)))]=0.$$

Note that, in this equation, the two first lines correspond to the left-hand side of the QQSHE_2 equation (3.18). Other second order terms appear due to the expansion of the quantum exponential $\mathcal{E}\mathrm{xp}$ into powers of $\hbar$. Since λ is a function of the position and the energy only, after (5.8) $\mathcal{T}\lambda$ can be written as

$$\mathcal{T}\lambda=\tfrac{1}{8}\Big\{\Delta\lambda\partial_\varepsilon\lambda+p^{\otimes 2}{:}(\nabla_x^{\otimes 2}\lambda\partial_\varepsilon^2\lambda-\nabla_x(\partial_\varepsilon\lambda)\nabla_x(\partial_\varepsilon\lambda))+\tfrac{1}{3}[p^{\otimes 2}{:}(\nabla_x^{\otimes 2}\lambda(\partial_\varepsilon\lambda)^2-\partial_\varepsilon(\nabla_x\lambda\nabla_x\lambda)\partial_\varepsilon\lambda$$
$$+\nabla_x\lambda\nabla_x\lambda\partial_\varepsilon^2\lambda)+|\nabla_x\lambda|^2\partial_\varepsilon\lambda]\Big\}. \tag{5.10}$$

According to (5.10), $\mathcal{T}\lambda$ takes the following form:

$$\tfrac{1}{8}(\mathcal{I}_{[\lambda]}+p^{\otimes 2}{:}\mathcal{J}_{[\lambda]}), \tag{5.11}$$

where

$$\mathcal{I}_{[\lambda]}=\Delta\lambda\partial_\varepsilon\lambda+\tfrac{1}{3}|\nabla_x\lambda|^2\partial_\varepsilon\lambda, \tag{5.12}$$

$$\mathcal{J}_{[\lambda]}=\nabla_x^{\otimes 2}\lambda\partial_\varepsilon^2\lambda-\nabla_x(\partial_\varepsilon\lambda)\nabla_x(\partial_\varepsilon\lambda)+\tfrac{1}{3}[\nabla_x^{\otimes 2}\lambda(\partial_\varepsilon\lambda)^2-\partial_\varepsilon(\nabla_x\lambda\nabla_x\lambda)\partial_\varepsilon\lambda+\nabla_x\lambda\nabla_x\lambda\partial_\varepsilon^2\lambda]. \tag{5.13}$$

Therefore, the second order terms in the formal expansion of the QSHE model can be expressed in terms of $\mathcal{I}$ and $\mathcal{J}$.

Lemma 5.6: *We assume that the collision operator is given by* (4.10). *Up to second order terms in* $\hbar$, *the QSHE model can be formally approached by the following* QSHE_2 *model (in the case where* ν *is a constant)*:

$$N(\varepsilon)\partial_t F-\frac{4\pi}{\nu}\widetilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{3/2}}{3}\widetilde{\nabla}F\right)$$

$$-\frac{4\pi\hbar^2}{24\nu}\left\{\frac{\partial^2}{\partial\varepsilon^2}\left(\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\cdot\partial_\varepsilon\widetilde{\nabla}F\right)+\frac{\partial}{\partial\varepsilon}\widetilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\partial_\varepsilon^2 F\right)\right\}$$

$$+\frac{4\pi\hbar^2}{8}\left\{\partial_t\left[F\left(\sqrt{2\varepsilon}\mathcal{I}_{[\ln F]}+\frac{(2\varepsilon)^{2/3}}{3}\mathrm{Trace}\ \mathcal{J}_{[\ln F]}\right)\right]\right.$$

$$+\frac{1}{\nu}\left[\widetilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{3/2}}{3}\widetilde{\nabla}(F\mathcal{I}_{[\ln F]})\right)+2\widetilde{\nabla}^{\otimes 2}{:}\frac{(2\varepsilon)^{5/2}}{15}(F\mathcal{J}_{[\ln F]})\right.$$

$$\left.\left.\widetilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{5/2}}{3}\widetilde{\nabla}(F\ \mathrm{Trace}\ \mathcal{J}_{[\ln F]})\right)\right]\right\}=0,$$

where $\mathcal{I}$ *and* $\mathcal{J}$ *are given by* (5.12) and (5.13), *respectively*, *and* Trace $\mathcal{J}$ *denotes the trace of the second order tensor* $\mathcal{J}$, *namely*

$$\mathrm{Trace}\ \mathcal{J}=\Delta\lambda\ \partial_\varepsilon^2\lambda-|\nabla_x(\partial_\varepsilon\lambda)|^2+\tfrac{1}{3}(\Delta\lambda(\partial_\varepsilon\lambda)^2-\partial_\varepsilon(|\nabla_x\lambda|^2)\partial_\varepsilon\lambda+|\nabla_x\lambda|^2\partial_\varepsilon^2\lambda). \tag{5.14}$$

Remark 5.7: In this equation, we first find the terms involved in the QQSHE_2 model (3.18)

(the first two lines). Then, additional terms arise due to the nonlinear relation between F and $\mathcal{E}\mathrm{xp}\,\tilde{\lambda}$. They still are fourth order terms, but now they are nonlinear. They still involve crossed derivatives. The same stability questions as for the QQSHE_2 model can be posed for this model, completed by the fact that it is now a nonlinear model. The answer to the stability question is therefore even more complex. That this model can be effective for practical computations is not clear. Probably, a direct numerical resolution of the full QSHE model will be more efficient, as it is the case for drift diffusion models (see, e.g., Refs. 28, 29, and 16). □

VI. CONCLUSION

In this paper, we have investigated possible quantum extensions of classical SHE (or Fokker-Planck) models. After a review of the derivation of classical SHE models, two possible extensions have been given: one by using a classical operator at the right-hand side of a quantum Wigner equation, a second one, by using a quantum version of a relaxation operator. The first approach obviously lacks consistency but gives rise to a seemingly tractable equation. The second approach, although more consistent, gives rise to a rather complex model, the practical effectiveness of which is not clear. More work is required to settle the question of stability of these models and to try to find more tractable expressions of them.

APPENDIX A: THE QQSHE_2 MODEL

In the sequel, the following identities are needed (a denotes a fourth order tensor and Einstein's convention is used):

$$\mathcal{P}(1)=1,\quad \mathcal{P}(p)=0,\quad \mathcal{P}(p^{\otimes 2})(\varepsilon)=\frac{2\varepsilon}{3}\delta, \tag{A1}$$

$$(\mathcal{P}(p^{\otimes 4})::a)(\varepsilon)=\frac{(2\varepsilon)^2}{15}(a_{i,i,j,j}+a_{i,j,i,j}+a_{i,j,j,i}), \tag{A2}$$

where δ denotes the second order tensor the components of which are δ^i_j (δ^i_j is the Kronecker symbol). No confusion should arise with the Dirac measure δ. Moreover, :: denotes the fourth order tensor product, defined by

$$a::b=a_{i,j,k,l}b_{i,j,k,l},$$

for two fourth order tensors a and b.

The trace of any second order tensor $\mathcal{G}$ is denoted by $\mathrm{Trace}\,\mathcal{G}$. We recall that we note $\tilde{\nabla}=\nabla_x-\nabla_x V\partial_\varepsilon$.

We first compute the term $\mathcal{P}(L(L^{(2)}F))$, where F depends on p only through the kinetic energy $|p|^2/2$. Obviously then, $\nabla_p F=p\partial_\varepsilon F$. Then,

$$\begin{aligned}\nabla_p^{\otimes 3}F&=\nabla_p\otimes[\nabla_p\otimes(p\partial_\varepsilon F)]\\&=\nabla_p\otimes[\delta\partial_\varepsilon F+p\otimes p\partial_\varepsilon^2 F]\\&=(2\delta\otimes p+p\otimes\delta)\partial_\varepsilon^2 F+p^{\otimes 3}\partial_\varepsilon^3 F\end{aligned}$$

and, since $\nabla_x^{\otimes 3}V$ is a symmetric tensor, we have

$$\nabla_x^{\otimes 3}V\vdots\nabla_p^{\otimes 3}F=3\nabla_x^{\otimes 3}V\vdots p\otimes\delta\partial_\varepsilon^2 F+\nabla_x^{\otimes 3}V\vdots p^{\otimes 3}\partial_\varepsilon^3 F=3p\cdot\nabla_x(\Delta V)\partial_\varepsilon^2 F+\nabla_x^{\otimes 3}V\vdots p^{\otimes 3}\partial_\varepsilon^3 F \tag{A3}$$

since $\mathcal{G}:\delta=\mathrm{Trace}(\mathcal{G})$ for any second order tensor. Now, apply L to $\nabla_x^{\otimes 3}V\vdots\nabla_p^{\otimes 3}F$. First, by (A3),

$$p \cdot \nabla_x(\nabla_x^{\otimes 3} V \vdots \nabla_p^{\otimes 3} F) = 3p^{\otimes 2} : \nabla_x(\nabla_x(\Delta V)\partial_\varepsilon^2 F) + p^{\otimes 4} :: \nabla_x(\nabla_x^{\otimes 3} V \partial_\varepsilon^3 F) \tag{A4}$$

and, on the other hand,

$$\begin{aligned}\nabla_x V \cdot \nabla_p(\nabla_x^{\otimes 3} V \vdots \nabla_p^{\otimes 3} F) &= 3\nabla_x V \nabla_x(\Delta V) : \nabla_p(p\partial_\varepsilon^2 F) + \nabla_x V \nabla_x^{\otimes 3} V :: \nabla_p(p^{\otimes 3}\partial_\varepsilon^3 F) \\ &= 3\nabla_x V \nabla_x(\Delta V) : (\delta \partial_\varepsilon^2 F + p^{\otimes 2}\partial_\varepsilon^3 F) \\ &\quad + \nabla_x V \nabla_x^{\otimes 3} V :: [(\delta p^{\otimes 2} + 2p^{\otimes 2}\delta)\partial_\varepsilon^3 F + p^{\otimes 4}\partial_\varepsilon^4 F].\end{aligned} \tag{A5}$$

We recall that $N(\varepsilon) = 4\pi\sqrt{2\varepsilon}$ and that, for any function $f(p)$ and any function ϕ independent of p or depending on p only through the energy $|p|^2/2$, we have $\mathcal{P}(f\phi) = \mathcal{P}(f)\phi$. Based on this, the projection on $\mathcal{E}$ takes the form

$$\begin{aligned}&N(\varepsilon)\mathcal{P}(p \cdot \nabla_x(\nabla_x^{\otimes 3} V \vdots \nabla_p^{\otimes 3} F))(\varepsilon) \\ &\quad = N(\varepsilon)\mathcal{P}(3p^{\otimes 2}) : \nabla_x(\nabla_x(\Delta V)\partial_\varepsilon^2 F) + N(\varepsilon)\mathcal{P}(p^{\otimes 4}) :: \nabla_x(\nabla_x^{\otimes 3} V \partial_\varepsilon^3 F) \\ &\quad = 4\pi\left\{(2\varepsilon)^{3/2}\nabla_x \cdot (\nabla_x(\Delta V)\partial_\varepsilon^2 F) + \frac{(2\varepsilon)^{5/2}}{5}\nabla_x \cdot (\nabla_x(\Delta V)\partial_\varepsilon^3 F)\right\} \\ &\quad = 4\pi\frac{\partial}{\partial\varepsilon}\nabla_x \cdot \left\{\frac{(2\varepsilon)^{5/2}}{5}(\nabla_x(\Delta V)\partial_\varepsilon^2 F)\right\},\end{aligned}$$

according to (A4) [we have used (A1) and (A2)]. Following (A5), we deduce

$$\begin{aligned}&N(\varepsilon)\mathcal{P}(\nabla_x V \cdot \nabla_p(\nabla_x^{\otimes 3} V \vdots \nabla_p^{\otimes 3} F))(\varepsilon) \\ &\quad = N(\varepsilon)\left\{3\nabla_x V \nabla_x(\Delta V) : (\delta\partial_\varepsilon^2 F + \mathcal{P}(p^{\otimes 2})\partial_\varepsilon^3 F)\right. \\ &\qquad \left. + \nabla_x V \nabla_x^{\otimes 3} V :: [(\delta\mathcal{P}(p^{\otimes 2}) + 2\mathcal{P}(p^{\otimes 2})\delta)\partial_\varepsilon^3 F + \mathcal{P}(p^{\otimes 4})\partial_\varepsilon^4 F]\right. \\ &\quad = 4\pi\frac{\partial}{\partial\varepsilon}\left\{(2\varepsilon)^{3/2}\nabla_x V \cdot \nabla_x(\Delta V)\partial_\varepsilon^2 F + \frac{(2\varepsilon)^{5/2}}{5}\nabla_x V \cdot \nabla_x(\Delta V)\partial_\varepsilon^3 F\right\} \\ &\quad = 4\pi\frac{\partial}{\partial\varepsilon}\nabla_x V \cdot \frac{\partial}{\partial\varepsilon}\left\{\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\partial_\varepsilon^2 F\right\},\end{aligned}$$

where we have used (A1), (A2) and the symmetries of $\nabla_x^3 V$. Therefore,

$$N(\varepsilon)\mathcal{P}(L(L^{(2)}F))(\varepsilon) = \frac{4\pi}{24}\frac{\partial}{\partial\varepsilon}\tilde{\nabla} \cdot \left\{\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\partial_\varepsilon^2 F\right\}.$$

Let us turn to $\mathcal{P}(L^{(2)}(LF))$. First, note that, for any vector $\mathcal{G}(x,\varepsilon)$ depending only on the position and the energy (such as $\tilde{\nabla}F$ and its derivatives with respect to ε), one can write

$$\nabla_p(p \cdot \mathcal{G}) = \mathcal{G} + p(p \cdot \partial_\varepsilon \mathcal{G}). \tag{A6}$$

This will be useful in the following computations. We start from $LF = p \cdot \tilde{\nabla}F$ and apply $\nabla_p^{\otimes 3}$. Using (A6), this gives

$$\nabla_p^{\otimes 3}(p \cdot \tilde{\nabla}F) = \nabla_p^{\otimes 2}(\tilde{\nabla}F + p(p \cdot \partial_\varepsilon\tilde{\nabla}F))$$

$$= \nabla_p(p\partial_\varepsilon\tilde{\nabla}F) + \nabla_p(\delta(p \cdot \partial_\varepsilon\tilde{\nabla}F)) + \nabla_p(p\partial_\varepsilon\tilde{\nabla}F) + \nabla_p(p^{\otimes 2}(p \cdot \partial_\varepsilon^2\tilde{\nabla}F))$$

$$=3\delta\partial_\varepsilon\tilde{\nabla}F+3p^{\otimes 2}\partial_\varepsilon^2\tilde{\nabla}F+(2\delta p+p\delta)(p\cdot\partial_\varepsilon^2\tilde{\nabla}F)+p^{\otimes 3}(p\cdot\partial_\varepsilon^3\tilde{\nabla}F).$$

Using the symmetry of the third order tensor $\nabla_x^{\otimes 3}V$, we get

$$24L^{(2)}(LF)=3\partial_\varepsilon\tilde{\nabla}F\cdot\nabla_x(\Delta V)+3\nabla_x^{\otimes 3}V\vdots p^{\otimes 2}\partial_\varepsilon^2\tilde{\nabla}F$$

$$+3p^{\otimes 2}:\partial_\varepsilon^2\tilde{\nabla}F\nabla_x(\Delta V)+p^{\otimes 4}::\nabla_x^{\otimes 3}V\partial_\varepsilon^3\tilde{\nabla}F.$$

Reminding (A1) and (A2), we have

$$24\mathcal{P}(L^{(2)}(LF))=N(\varepsilon)(3\nabla_x(\Delta V)\cdot\partial_\varepsilon\tilde{\nabla}F)+3N(\varepsilon)\mathcal{P}(p^{\otimes 2}):(\partial_\varepsilon^2\tilde{\nabla}F\nabla_x(\Delta V))$$

$$+3N(\varepsilon)\mathcal{P}(p^{\otimes 2})\partial_\varepsilon^2\tilde{\nabla}F\vdots\nabla_x^{\otimes 3}V+N(\varepsilon)\mathcal{P}(p^{\otimes 4})::\partial_\varepsilon^3\tilde{\nabla}F\nabla_x^{\otimes 3}V$$

$$=4\pi\{3(2\varepsilon)^{1/2}\nabla_x(\Delta V)\cdot\partial_\varepsilon\tilde{\nabla}F+(2\varepsilon)^{3/2}(2\nabla_x(\Delta V)\cdot\partial_\varepsilon^2\tilde{\nabla}F)$$

$$+\frac{(2\varepsilon)^{5/2}}{5}(\tilde{\nabla}(\Delta V)\cdot\partial_\varepsilon^3\tilde{\nabla}F),$$

which finally gives

$$N(\varepsilon)\mathcal{P}(L^{(2)}(LF))(\varepsilon)=\frac{4\pi}{24}\frac{\partial^2}{\partial\varepsilon^2}\left\{\frac{(2\varepsilon)^{5/2}}{5}\nabla_x(\Delta V)\cdot\partial_\varepsilon\tilde{\nabla}F\right\}.$$

APPENDIX B: THE QSHE$_2$ MODEL

Let us note $\lambda=\ln F$ as in Theorem 5.2. The function λ is a function of x and ε only. We shall identify the functions $(x,p)\to\lambda(x,|p|^2/2)$ and λ when no confusion arises. We recall that, for $f(x,p)=\lambda(x,|p|^2/2)$, formula (5.8) can be rewritten as

$$\mathcal{T}\lambda(x,p)=\tfrac{1}{8}(\mathcal{I}+p^{\otimes 2}:\mathcal{J}),$$

where $\mathcal{I}$ and $\mathcal{J}$ are given by (5.12) and (5.13), respectively. The expression of the trace of the second order tensor $\mathcal{J}$ is given by (5.14).

The terms to compute are $\mathcal{P}(F\mathcal{T}(\ln F))$ and $\mathcal{P}(L(L(F\mathcal{T}(\ln F))))$. Since F is a function of the energy only, the first term is equal to $F\mathcal{P}(\mathcal{T}(\ln F))$.

1. Computation of $NF\mathcal{P}(\mathcal{T}(\ln F))$

Here, we only have to project Eq. (5.10). Using formulas (A1) and (A2), this equation becomes [we recall that $N(\varepsilon)=4\pi(2\varepsilon)^{1/2}$]:

$$N(\varepsilon)\mathcal{P}(\mathcal{T}\lambda)=\frac{4\pi}{8}\left(\sqrt{2\varepsilon}\mathcal{I}+\frac{(2\varepsilon)^{3/2}}{3}\text{Trace }\mathcal{J}\right),$$

where Trace $\mathcal{J}$ is explicited in (5.14).

2. Computation of $N\mathcal{P}(L(L(F\mathcal{T}(\ln F))))$

We first give some expressions valid for any function G and second order tensor $\mathcal{G}$ that depend only on the energy. It has been seen that $LG=p\cdot\tilde{\nabla}G$. Then a straightforward computation yields

$$L(LG) = L(p \cdot \tilde{\nabla} G) = p^{\otimes 2} : \tilde{\nabla}^{\otimes 2} G - \nabla_x V \cdot \tilde{\nabla} G,$$

where $L(p) = -\nabla_x V$ has been used. Recalling that $N(\varepsilon) = 4\pi\sqrt{2\varepsilon}$, formula (A1) gives

$$N(\varepsilon)\mathcal{P}(L(LG)) = 4\pi\left(\frac{(2\varepsilon)^{3/2}}{3}\tilde{\nabla} \cdot \tilde{\nabla}(G) - \sqrt{2\varepsilon}\nabla_x V \cdot \tilde{\nabla} G\right)$$

and, since $\tilde{\nabla}(2\varepsilon)^{(k+1)/2} = (k+1)(2\varepsilon)^{k/2}\nabla_x V$,

$$N(\varepsilon)\mathcal{P}(L(LG)) = 4\pi\tilde{\nabla} \cdot \left(\frac{(2\varepsilon)^{3/2}}{3}\tilde{\nabla} G\right). \tag{B1}$$

On the other hand, since L is a first order tensor, we have

$$L(L(p^{\otimes 2} : \mathcal{G})) = L(L(p^{\otimes 2})) : \mathcal{G} + 2L(p^{\otimes 2}) : L(\mathcal{G}) + p^{\otimes 2} : L(L(\mathcal{G})).$$

Obviously, $Lp = -\nabla_x V$ and $L(\nabla_x V) = p \cdot \nabla_x(\nabla_x V)$. Therefore,

$$\begin{aligned} L(L(p^{\otimes 2})) &= L(-\nabla_x V p - p\nabla_x V) \\ &= [-p \cdot \nabla_x(\nabla_x V)]p - p[p \cdot \nabla_x(\nabla_x V)] + 2\nabla_x V \nabla_x V. \end{aligned} \tag{B2}$$

Since $\mathcal{G}$ depends only on the energy, we have $L\mathcal{G} = p \cdot \tilde{\nabla}(\mathcal{G})$ and, consequently,

$$L(L(\mathcal{G})) = (p^{\otimes 2} : \tilde{\nabla}^{\otimes 2})\mathcal{G} - \nabla_x V \cdot \tilde{\nabla}(\mathcal{G}). \tag{B3}$$

Therefore, reminding that $L(p) = -\nabla_x V$, $L\mathcal{G} = p \cdot \tilde{\nabla}(\mathcal{G})$, that $\mathcal{G}$ is symmetric, and using (B2) and (B3), we obtain

$$\begin{aligned} L(L(p^{\otimes 2} : \mathcal{G})) = {} & [-(2p \cdot \nabla_x(\nabla_x V))p + 2\nabla_x V \nabla_x V] : \mathcal{G} \\ & + 4(-\nabla_x V)p : p \cdot \tilde{\nabla}(\mathcal{G}) + p^{\otimes 4} :: \tilde{\nabla}^{\otimes 2}\mathcal{G} - p^{\otimes 2} : \nabla_x V \cdot \tilde{\nabla}(\mathcal{G}), \end{aligned}$$

which, according to (A1) and (A2), yields

$$\begin{aligned} N(\varepsilon)\mathcal{P}[L(L(p^{\otimes 2} : \mathcal{G}))] = 4\pi\Bigg\{ & 2\left(-\frac{(2\varepsilon)^{3/2}}{3}\nabla_x^{\otimes 2} V + \sqrt{2\varepsilon}\nabla_x V \nabla_x V\right) : \mathcal{G} \\ & + 4\frac{(2\varepsilon)^{3/2}}{3}(-\nabla_x V \tilde{\nabla}) : \mathcal{G} + \frac{(2\varepsilon)^{5/2}}{15}(\tilde{\nabla} \cdot \tilde{\nabla}(\text{Trace } \mathcal{G}) + 2\tilde{\nabla}^{\otimes 2} : \mathcal{G}) \\ & - \frac{(2\varepsilon)^{3/2}}{3}\nabla_x V \cdot \tilde{\nabla}(\text{Trace } \mathcal{G})\Bigg\}. \end{aligned}$$

Finally, using again $\tilde{\nabla}(2\varepsilon)^{(k+1)/2} = (k+1)(2\varepsilon)^{k/2}\nabla_x V$, we have

$$N(\varepsilon)\mathcal{P}[L(L(p^{\otimes 2} : \mathcal{G}))] = 4\pi\left\{2\tilde{\nabla}^{\otimes 2} : \frac{(2\varepsilon)^{5/2}}{15}\mathcal{G} + \tilde{\nabla} \cdot \left(\frac{(2\varepsilon)^{5/2}}{3}\tilde{\nabla}\ \text{Trace } \mathcal{G}\right)\right\}. \tag{B4}$$

Let us go back to the computation of $N\mathcal{P}(L(L(F\mathcal{I}(\ln F))))$. Taking for G the function $F\mathcal{I}$ and, for $\mathcal{G}$, the second order tensor $F\mathcal{J}$, Eqs. (B1) and (B4) allow to conclude that

$$N\mathcal{P}(L(L(F\mathcal{I}(\ln F)))) = \frac{4\pi}{8}\left\{\tilde{\nabla} \cdot \left(\frac{(2\varepsilon)^{3/2}}{3}\tilde{\nabla}(F\mathcal{I})\right) + 2\tilde{\nabla}^{\otimes 2} : \frac{(2\varepsilon)^{5/2}}{15}(F\mathcal{J})\right.$$

$$+\tilde{\nabla}\cdot\left(\frac{(2\varepsilon)^{5/2}}{3}\tilde{\nabla}(F\ \mathrm{Trace}\ \mathcal{J})\right)\Bigg\},$$

since by (5.11) we have $F\mathcal{T}(\ln F)=F\mathcal{I}+p^{\otimes 2}:F\mathcal{J}$.

(Received 4 January 2006; accepted 14 February 2006; published online 7 April 2006)

In this paper, first, the ETM is applied to obtain variable separation solutions of (2+1)-dimensional systems. A common formula with some arbitrary functions is derived to describe suitable physical quantities for some (2+1)-dimensional models such as the generalized Nizhnik-Novikov-Veselov, Davey-Stewartson, Broer-Kaup-Kupershmidt, Boiti-Leon-Pempinelli, integrable Kortweg-de Vries (KdV), breaking soliton and Burgers models. The universal formula in Tang, Lou, and Zhang [Phys. Rev. E **66**, 046601 (2002)] can be simplified to the common formula in the present paper, which indicates that redundant process is included there since the easier variable separation form can be employed without loss of generality. Second, this method is successfully generalized to (1+1)-dimensional systems, such as coupled integrable dispersionless, long-wave–short-wave resonance interaction and negative KdV models, and obtain another common formula to describe suitable physical fields or potentials of these (1+1)-dimensional models, which is similar to the one in (2+1)-dimensional systems. Moreover, it also is extended to (3+1)-dimensional Burgers system, and find that the common formula in (2+1)-dimensional systems is also appropriate to describe the (3+1)-dimensional Burgers system. The only differences are that the function q is a solution of a constraint equation and p is an arbitrary function of three independent variables. Finally, based on the common formula for (2+1)-dimensional systems and by selecting appropriate multivalued functions, interactions among special dromion, special peakon and foldon are investigated. The interactions between two special dromions, and between two special peakons, both possess novel properties, that is, there exist a multivalued foldon in the process of their collision, which is different from the reported cases in previous literature. Furthermore, the explicit phase shifts for all the local excitations offered by the common formula have been given, and are applied to these novel interactions in detail. © *2006 American Institute of Physics.*

I. INTRODUCTION

In recent years, increasing attention has been paid to the study of the soliton theory in many natural sciences such as chemistry, biology, mathematics, communication, and particularly in almost all branches of physics like the fluid dynamics, plasma physics, field theory, nonlinear

[a)]Author to whom correspondence should be addressed. Electronic mail: jf_zhang@zjnu.cn

optics, and condensed matter physics, etc. How to derive possible exact solutions to a nonlinear model arising from the field of mathematical physics is a popular topic, but solving nonlinear physics problems is much more difficult than solving the linear ones.

In linear physics, it is generally recognized that both the Fourier transformation and the variable separation approach (VSA) are the most universal and powerful means for the study of linear partial differential equations (PDEs). The celebrated inverse scattering transformation, considered as an extension of the Fourier transformation in nonlinear physics, plays an important role in the nonlinear domain.[1] Meanwhile the extension of the variable separation approach to nonlinear field has been a highlight, and there come out some methods: the classical method,[2] the differential Stäckel matrix approach,[3] the ansatz-based method,[2–8] etc. To our excitement, three kinds of "variable separation" procedures have been presented recently. The first method is called the "formal variable separation approach" (FVSA),[4] or equivalently the symmetry constraints.[5] The second one is the procedure to seek for the functional separable solutions[6] and the derivative-dependent functional separable solutions[7] to a PDE via the generalized conditional symmetries.[8] The last one is now called the multilinear variable separation approach (MLVSA) established first in 1996 for the Davey-Stewartsen (DS) equation.[9]

Recently, the MLVSA is developed, and Tang *et al.*[10] presented a universal formula

$$U_1 \equiv \frac{2(a_1a_2 - a_0a_3)P_xQ_y}{(a_0 + a_1P + a_2Q + a_3PQ)^2}, \tag{1}$$

where $P \equiv P(x,t)$ is an arbitrary function of $\{x,t\}$, $Q \equiv Q(y,t)$ may be either an arbitrary function of $\{y,t\}$ for some models like the DS, generalized Nizhnik-Novikov-Veselov (GNNV) and 2DsG systems or an arbitrary solution of a Riccati equation for some other models such as the asymmetric NNV (ANNV), ADS, and the generalized $(N+M)$-component Ablowitz-Kaup-Newell-Segur (AKNS) system. In Ref. 10, a_0, a_1, a_2, and a_3 are taken as arbitrary constants. However, it is clear that a_0, a_1, a_2, and a_3 should satisfy $a_0a_3 \neq a_1a_2$, otherwise the quantity $U_1=0$. More recently, a differential-difference form of the universal formula (1) has also been given for a special differential-difference Toda system and the differential-difference ANNV system.[11] Moreover, The MLVSA is generalized to $(3+1)$-dimensional systems.[12,13] In the past several years, one thought that it is difficult to extend MLVSA to the $(1+1)$-dimensional nonlinear physics systems because the independent variables must be totally separated. However, there are some development recently. This extension of the MLVSA to $(1+1)$-dimensional nonlinear models was presented first by Xu and Zhang in Ref. 14. And then the method was developed to the $(1+1)$-dimensional long-wave–short-wave resonant interaction equation.[15] Shen *et al.* also successfully extended MLVSA to $(1+1)$-dimensional Boiti system[16] and $(N+M)$-component dispersionless system.[17]

In addition, many simple and effective direct methods are developed to solve the nonlinear evolution equations such as the tanh-function method,[18] the sech-function method and the Jacobian-function method,[19] the ETM (ETM) based on mapping method.[20] Now a natural and important issue is whether the variable separation solution based on the former MLVSA can be derived by the latter ETM, which is usually used to search for travelling wave solutions. The crucial question is how to obtain solutions with certain arbitrary functions. Recently, along with variable separation ideas, Zheng *et al.*[21,22] have realized variable separation for the Broer-Kaup-Kupershmidt (BKK) system and dispersive long-wave (DLW) equation by the ETM. However, they actually derived variable separation solutions only for the same kind of $(2+1)$-dimensional system, because the BKK system can be transformed to the DLW equation by using some suitable dependent and independent variable transformations. One finds that it is too difficult to generalize this ETM to obtain variable separation solutions for other $(2+1)$-dimensional systems in virtue of the complexity to solving the over-determined partial differential equations. Therefore, one thinks that this method is not an excellent approach to realize variable separation.

In this paper, we successfully generalize the ETM based on a mapping method to obtain

variable separation solutions of (1+1)-dimensional, (2+1)-dimensional, and (3+1)-dimensional mathematical physics models. Through careful analysis, we first find that there also exists a common formula in (2+1)-dimensional models via this method

$$U_2 \equiv \frac{2p_x q_y}{(p+q)^2}, \tag{2}$$

where $p \equiv p(x,t)$ is an arbitrary function of $\{x,t\}$, q is an arbitrary function of $\{y,t\}$ for some kinds of models like the GNNV and DS systems, or an arbitrary function of $\{y\}$ for the BKK, Boiti-Leon-Pempinelli (BLP) systems, or an arbitrary solution of a constraint equation for integrable Kortweg-de Vries (KdV), breaking soliton (BS) and Burgers models. For nonintegrable KdV equation, neither p or q is arbitrary function, and they must satisfy some constraint equations. Therefore, we can define the solvable models by the ETM: these kinds of models should not be less than an arbitrary function (p or q). The nonintegrable models are also not the solvable models by the ETM. Moreover, there exists also a common formula, which is similar to the formula (2), to describe suitable physical fields or potentials of some (1+1)-dimensional models. The universal formula (2) is also appropriate to describe the (3+1)-dimensional Burgers system. The only differences are that the function q is a solution of a constraint equation and p is an arbitrary function of three independent variables.

Because some arbitrary characteristics, lower dimensional functions (like p), have been included in the universal formula (2), by selecting them appropriately, abundant stable localized structures can be revealed for these models. If the boundary (or initial) conditions of the given localized excitations are considered, one can find that all the (2+1)-dimensional localized solutions of these models are caused by the suitable boundary (or initial) conditions. Namely, the richness of the localized excitations of the (2+1)-dimensional models results from the fact that arbitrary exotic behaviors can propagate along some special characteristics of the models. All rich localized coherent structures discussed by the quantities U_1 expressed by (1), such as nonpropagating solitons, dromion, peakon, compacton, foldon, instanton, ghoston, ring soliton, and the interaction between these solitons, can be rederived by the quantities U_2 expressed by (2).

In the real natural phenomena, there exist very complicated folded phenomena such as the folded protein,[23] folded brain, and skin surfaces, and many other kinds of folded biologic systems.[24] The simplest multivalued (folded) waves may be the bubbles on (or under) a fluid surface. Various ocean waves are really folded waves, too. In Ref. 25 and 26 the authors discussed some simpler cases of multiple-valued solitary waves (folded in all directions and semifoldon). However, nature is extremely colorful and may exhibit quite complicated structures. Of course, at the present stage, it is impossible to make satisfactory analytic descriptions for such complicated folded natural phenomena. But, it is still worth starting with some simpler cases. Dromion and peakon are the focus in the previous discussions. Usually, dromion solutions are driven by two or more nonparallel straight-line ghost solitons. Even more generalized dromion solutions have been found, which are driven by curved and straight line, or curved and curved soliton solutions for some types of (2+1)-dimensional nonlinear models.[9,27] The so-called peakon solution [$u = c\exp(-|x-ct|)$], which is discontinuous at its crest and refers to a weak solution of the celebrated (1+1)-dimensional Camassa-Holm equation, was first given by Camassa and Holm.[28] Within our knowledge, studying the interaction among dromion, peakon and foldon constructed by multivalued functions in higher dimensional physical models is still open. Here we mainly focus on some novel localized coherent structures about multivalued functions, i.e., special dromion, special peakon and foldon, and the interactions among them. The interactions between two special dromions, and between two special peakons, both posses novel properties, that is, there exist a multivalued foldon in the process of their collision, which is different from the reported cases in previous literature. The explicit phase shifts for all the local excitations offered by the common formula have been given, and are applied to these novel interactions in detail.

The paper is arranged as follows. In Sec. II, a remark to MLVSA and ETM is given. In Sec. III, we obtain the variable separation solutions of the GNNV system in detail via the ETM, and list

the known models that can be solved by this method. In Sec. IV, we generalize the ETM to (1 +1)-dimensional systems, and obtain a universal formula. By means of the ETM, variable separation solution of (3+1)-dimensional Burgers system is obtained in Sec. V. Three kind of coherent localized structures and interactions among them are discussed in Sec. VI. Finally, a short summary is presented.

II. REMARK TO MLVSA AND ETM

A. Comments on MLVSA

So far, the procedure of the MLVSA has been established: at first, one may obtain the Bäcklund transformation relation via standard Painlevé expansion. Second, change the model to a multilinear variant form with an arbitrary seed solution. Third, extend the Hirota's two-soliton solution to a general variable separation ansatz $f=a_0+a_1P+a_2Q+a_3PQ$ (see Ref. 10 in detail). Finally, by substituting the variable separation ansatz to the original model and selecting the seed solution appropriately, one may find some nontrivial variable separated solutions. All of the obtained results via MLVSA are remarkable, and it is a very effective method to construct rich localized coherent structures, including dromion,[9] peakon,[10] compacton,[29] foldon,[25] ghoston,[30] ring soliton,[10] and the interaction between these solitons.[10,25,26] Moreover, nonpropagating solitons,[31] chaotic, and fractal patterns,[10] periodic and quasi-periodic wave[32] can be obtained based on the universal formula (1).

In fact, the universal formula (1) obtained via MLVSA can be simplified to another equivalent and terse form

$$U_1 \equiv \frac{2\left(\frac{a_0+a_1P}{a_2+a_3P}\right)_x Q_y}{\left(\frac{a_0+a_1P}{a_2+a_3P}+Q\right)^2} \overset{\text{def}}{=} \frac{2p_xq_y}{(p+q)^2}, \tag{3}$$

where $p(x,t)\equiv(a_0+a_1P)/(a_2+a_3P)$, $q(y,t)\equiv Q$. Equation (3) implies that we can substitute the complicated variable separation forms $a_0+a_1P+a_2Q+a_3PQ$ in Ref. 10 as the simple and direct one $p+q$, which will greatly simplify the operation, and bring some terser constraint conditions than Ricatti equation to some models, such as (2+1)-dimensional DS system, LSRI system and so on. Moreover, the seed solution is very important in MLVSA, because Tang *et al.* employ a smart method to transfer the constraints about arbitrary functions p and q into the constraints about the seed solution in order to preserve the arbitrariness of the arbitrary functions (p or q) in some models. However, it is difficult to seek the seed solution at times. The difficulty can be taken over via ETM, by means of which the variable separation solutions can be derived without considering the seed solution.

B. Comments on ETM

The basic idea of the ETM is that for a given nonlinear partial differential equation (NPDE) with independent variables $x=(x_0=t,x_1,x_2,\ldots,x_m)$, and dependent variable u,

$$L(u,u_t,u_{x_i},u_{x_ix_j},\ldots)=0, \tag{4}$$

where L is in general a polynomial function of its argument, and the subscripts denote the partial derivatives. One assumes that Eq. (4) possesses the following ansatz:

$$u=u(\xi), \quad \xi=\sum_{i=0}^{m} K_ix_i \quad \text{or } \xi=R(x_i), \tag{5}$$

where K_i, $i=0,\ldots,m$ are all arbitrary constants. Substituting Eq. (5) into Eq. (4) yields an ordinary differential equation (ODE): $O(u(\xi),u(\xi)_\xi,u(\xi)_{\xi\xi},\ldots)=0$. Then $u(\xi)$ is expanded into a polynomial in $\phi(\xi)$,

$$u(\xi) = F(\phi(\xi)) = \sum_{j=0}^{n} a_j \phi(\xi)^j, \tag{6}$$

where a_j are constants or arbitrary functions of $\{x_i\}$ to be determined and n is fixed by balancing the linear term of the highest order with the nonlinear term in Eq. (4). If we suppose $\phi(\xi) = \tanh(\xi)$, $\phi(\xi) = \mathrm{sech}(\xi)$ and $\phi(\xi) = \mathrm{sn}(\xi)$ or $\phi(\xi) = \mathrm{cn}(\xi)$, respectively, then the corresponding approach is usually called the tanh-function method, the sech-function method, and the Jacobian-function method. Although the Jacobian elliptic function method is more improved than the tanh-function method and the sech-function method, the repeated calculations are often tedious since the different function $\phi(\xi)$ should be treated in a repeated way. However, this shortcoming is overcome by the ETM based on mapping method, whose virtue is that, without much complicated and repeated calculations, we circumvent integration to directly get solutions in a uniform way. The crucial idea of this ETM is that, $\phi(\xi)$ is not assumed to be a specific function, such as tanh, sech, sn, and cn, etc., but a solution of a mapping equation such as the Riccati equation

$$\frac{\mathrm{d}\phi}{\mathrm{d}R} = l_0 + \phi^2, \tag{7}$$

with its solutions

$$\phi = \begin{cases} -\sqrt{-l_0}\tanh(\sqrt{-l_0}R), & l_0 < 0, \\ -\sqrt{-l_0}\coth(\sqrt{-l_0}R), & l_0 < 0, \\ \sqrt{l_0}\tan(\sqrt{l_0}R), & l_0 > 0, \\ -\sqrt{l_0}\cot(\sqrt{l_0}R), & l_0 > 0, \\ -\dfrac{1}{R}, & l_0 = 0, \end{cases} \tag{8}$$

where l_0 is constant. By means of the mapping relation (7) and the solutions (8), one can obtain many explicit and exact travelling wave solutions or variable separation solutions of system (4).

Actually, these solutions in (8) are not all independent, which can be concluded from the variable separation solutions obtained by Zheng *et al.* for (2+1)-dimensional BKK,[21] DLW,[22] BLP,[33] GBK,[34] and so on. In these solutions of Ref. 21, 22, 33, and 34, only the solutions related to Eq. (2) is essentially effective, while other solutions related to tan, cot, tanh, and coth functions are special cases of Eq. (2). We take the solutions in Ref. 21, for example. Note that there is also some misprints in Ref. 21, and the solutions of the BKK system there should be

$$H_1 = -\frac{\chi_t + \chi_{xx}}{2\chi_x} + \chi_x\sqrt{-\sigma}\tanh(\sqrt{-a}(\chi+\varphi)), \tag{9}$$

$$v_1 = -\chi_x\varphi_y\sigma + \chi_x\varphi_y\sigma\tanh^2(\sqrt{-\sigma}(\chi+\varphi)), \tag{10}$$

$$H_2 = -\frac{\chi_t + \chi_{xx}}{2\chi_x} + \chi_x\sqrt{-\sigma}\coth(\sqrt{-\sigma}(\chi+\varphi)), \tag{11}$$

$$v_2 = -\chi_x\varphi_y\sigma + \chi_x\varphi_y\sigma\coth^2(\sqrt{-\sigma}(\chi+\varphi)), \tag{12}$$

$$H_3 = -\frac{\chi_t + \chi_{xx}}{2\chi_x} - \chi_x\sqrt{\sigma}\tan(\sqrt{\sigma}(\chi+\varphi)), \tag{13}$$

$$v_3 = -\chi_x\varphi_y\sigma - \chi_x\varphi_y\sigma\tan^2(\sqrt{\sigma}(\chi+\varphi)), \tag{14}$$

$$H_4 = -\frac{\chi_t + \chi_{xx}}{2\chi_x} + \chi_x\sqrt{\sigma}\cot(\sqrt{\sigma}(\chi+\varphi)), \tag{15}$$

$$v_4 = -\chi_x\varphi_y\sigma - \chi_x\varphi_y\sigma\cot^2(\sqrt{\sigma}(\chi+\varphi)), \tag{16}$$

$$H_5 = -\frac{\chi_t + \chi_{xx}}{2\chi_x} + \frac{\chi_x}{\chi+\varphi}, \tag{17}$$

$$v_5 = \frac{-\chi_x\varphi_y}{(\chi+\varphi)^2}, \tag{18}$$

with two arbitrary functions $\chi(x,t)$, $\varphi(y)$. The σ in solutions (9)–(18) is just l_0 in (8). By careful analysis, we find that when redefining $\chi=\exp\{-2\sqrt{-\sigma}\chi\}$, $\varphi=\exp\{2\sqrt{-\sigma}\varphi\}$ in solutions (17) and (18), solutions (9) and (10) can be obtained. Similarly, if taking $\chi=-\exp\{-2\sqrt{-\sigma}\chi\}$, $\varphi=\exp\{2\sqrt{-\sigma}\varphi\}$ in solutions (17) and (18), solutions (11) and (12) can be recovered. When considering $\chi=\exp\{-2i\sqrt{\sigma}\chi\}$, $\varphi=\exp\{2i\sqrt{\sigma}\varphi\}$ in solutions (17) and (18), solutions (13) and (14) can be obtained. If letting $\chi=-\exp\{-2i\sqrt{\sigma}\chi\}$, $\varphi=\exp\{2i\sqrt{\sigma}\varphi\}$ in solutions (17) and (18), solutions (15) and (16) can be recovered. Other results for DLW,[22] BLP,[33] and GBK[34] systems have similar relations.

By study, we find that ETM is an alternative approach to derive variable separation solutions without considering the seed solutions, and it is easier to handle than MLVSA to those readers unacquainted with MLVSA. In the following paper, via ETM, we also discuss the variable separation solutions for (1+1)-dimensional and (3+1)-dimensional mathematical physics models, besides (2+1)-dimensional systems.

III. VARIABLE SEPARATION SOLUTIONS FOR THE (2+1)-DIMENSIONAL SYSTEMS

A. (2+1)-dimensional generalized Nizhnik-Novikov-Veselov system

The (2+1)-dimensional generalized Nizhnik-Novikov-Veselov (NNV) equation reads

$$u_t + au_{xxx} + bu_{yyy} + cu_x + du_y - 3a(uv)_x - 3b(uw)_y = 0, \tag{19}$$

$$u_x = v_y, \quad u_y = w_x, \tag{20}$$

where a, b, c, and d are arbitrary constants. For $c=d=0$, the GNNV system will be degenerated to the usual two-dimensional NNV system, which is an isotropic Lax extension of the classical (1+1)-dimensional shallow water-wave KdV model. When $a=1$, $b=c=d=0$ in Eq. (19), we get the asymmetric NNV equation, which may be considered as a model for an incompressible fluid. Some types of the soliton solutions of the GNNV equation have been studied by many authors. For instance, Boiti *et al.*[35] solved the GNNV equation via the inverse scattering transformation. Zhang obtained many exact solution of this system based on an extended homogeneous balance approach.[36] Two new coherent structures for the GNNV equation are discussed in Ref. 37. Recently, a general solution including two arbitrary functions is first obtained for the generalized NNV equation by means of WTC truncation method.[38]

Along with the ETM, we assume that the (2+1)-dimensional NNV equation (19) and (20) possess the solutions of the following form:

$$u(x,y,t) = \sum_{i=0}^{l} a_i\phi^i(R), \quad v(x,y,t) = \sum_{j=0}^{m} b_j\phi^j(R), \quad w(x,y,t) = \sum_{k=0}^{n} c_k\phi^k(R), \tag{21}$$

where ϕ satisfies Eq. (7) with Eq. (8) and $R\equiv R(x,y,t)$, $a_i\equiv a_i(x,y,t)$, $(i=0,1,\ldots,l)$, $b_j\equiv b_j(x,y,t)$, $(j=0,1,\ldots,m)$, $c_k\equiv c_k(x,y,t)$, $(k=0,1,\ldots,n)$ and l_0 is an arbitrary real constant,

while $l=m=n=2$ is obtained by balancing the highest-order derivative terms with the nonlinear terms in Eqs. (19) and (20). Inserting Eqs. (21) and (7) with $l=m=n=2$ into Eqs. (19) and (20), selecting the variable separation ansatz,

$$R = p(x,t) + q(y,t), \tag{22}$$

and eliminating all the coefficients of polynomials of ϕ, one gets a set of partial differential equations

$$12a_2[ap_x(2p_x^2 - b_2) + bq_y(2q_y^2 - c_2)] = 0, \tag{23}$$

$$\begin{aligned}&[6bq_yq_{yy} - 2ap_xb_1 - a(b_1p_x + b_{2,x}) - 2bq_yc_1 + 6ap_xp_{xx} - b(c_1q_y + c_{2y})]a_2\\ &\quad + 2(ap_x^3 + bq_y^3 - 3ap_xb_2 - 3bq_yc_2)a_1 - aa_{2x}b_2 + 6aa_{2x}p_x^2 + 6ba_{2y}q_y^2 - ba_{2y}c_2 = 0,\end{aligned} \tag{24}$$

$$\begin{aligned}&-6(ab_2p_x + bc_2q_y)a_0 + 3(2ap_xp_{xx} - 2ab_1p_x - bc_{2y} - 2bc_1q_y - ab_{2x} + 2bq_yq_{yy})a_1\\ &\quad + (2p_y + 40bl_0q_y^3 + 2cp_x + 2q_t - 12ab_2l_0p_x - 6ap_xb_0 - 6bq_yc_0 + 40al_0p_x^3 - 12bc_2l_0q_y + 2dq_y\\ &\quad + 2bq_{yyy} - 3bc_{1y} + 2ap_{xxx} - 3ab_{1x})a_2 + 6ba_{2y}q_{yy} - 3bc_2a_{1y} + 6aa_{2xx}p_x + 6aa_{1x}p_x^2 - 3ab_1a_{2x}\\ &\quad - 3bc_1a_{2y} + 6aa_{2x}p_{xx} + 6ba_{1y}q_y^2 + 6ba_{2yy}q_y - 3ab_2a_{1x} = 0,\end{aligned} \tag{25}$$

$$2a_2p_x - 2b_2q_y = 0, \tag{26}$$

$$2a_2q_y - 2c_2p_x = 0, \tag{27}$$

$$\begin{aligned}&-3(bc_1q_y + bc_{2y} + ab_1p_x + ab_{2x})a_0 + (ap_{xxx} - 3bq_yc_0 - 9bc_2l_0q_y - 9ab_2l_0p_x - 3ab_{1x} + cp_x + 8al_0p_x^3\\ &\quad + dq_y - 3bc_{1y} - 3ap_xb_0 + bq_{yyy} + 8bl_0q_y^3 + p_t + q_t)a_1 - 3(ab_{0x} - 8bl_0q_yq_{yy} + bc_{0y} - 8al_0p_xp_{xx}\\ &\quad + 3ab_1l_0p_x + 3bc_1l_0q_y)a_2 + a_{2t} + 3ba_{1yy}q_y - 3ab_2a_{0x} + 24ba_{2y}l_0q_y^2 + 3aa_{1,x}p_{xx} + 24aa_{2x}l_0p_x^2\\ &\quad + 3ba_{1y}q_{yy} - 3ab_0a_{2x} - 3bc_0a_{2y} + da_{2y} + aa_{2xxx} + 3aa_{1xx}p_x - 3bc_1a_{1y} - 3ab_1a_{1x} - 3bc_2a_{0y}\\ &\quad + ba_{2yyy} + ca_{2x} = 0,\end{aligned} \tag{28}$$

$$a_{2x} - b_{2y} + a_1p_x - b_1q_y = 0, \tag{29}$$

$$a_{2y} - c_{2x} + a_1q_y - c_1p_x = 0, \tag{30}$$

$$\begin{aligned}&-3(2ab_2l_0p_x + ab_{1x} + bc_{1y} + 2bc_2l_0q_y)a_0 - 3(ab_{0x} + 2ab_1l_0p_x + bc_{0y} - 2al_0p_xp_{xx} - 2bl_0q_yq_{yy}\\ &\quad + 2bc_1l_0q_y)a_1 + 2(al_0p_{xxx} + bl_0q_{yyy} - 3bc_0l_0q_y + cl_0p_x + dl_0q_y - 3ab_0l_0p_x + 8bl_y^2q_y^3 + l_0p_t + l_0q_t\\ &\quad + 8al_0^2p_x^3)a_2 - 3ab_0a_{1x} + 6aa_{2x}l_0p_{xx} + 6aa_{2xx}l_0p_x + aa_{1xxx} + ba_{1yyy} + ca_{1x} + 6ba_{1y}l_0q_y^2\\ &\quad + 6aa_{1x}l_0p_x^2 - 3ab_1a_{0x} + 6ba_{2y}l_0q_{yy} + a_{1t} + 6ba_{2yy}l_0q_y + da_{1y} - 3bc_0a_{1y} - 3bc_1a_{0y} = 0,\end{aligned} \tag{31}$$

$$\begin{aligned}&-3(bc_1l_0q_y + ab_{0x} + bc_{0y} + ab_1l_0p_x)a_0 + (cl_0p_x + dl_0q_y + 2bl_0^2q_y^3 + bl_0q_{yyy} - 3bc_0l_0q_y + al_0p_{xxx}\\ &\quad + l_0q_t + l_0p_t - 3ab_0l_0p_x + 2al_0^2p_x^3)a_1 + 6(al_0^2p_xp_{xx} + bl_0^2q_yq_{yy})a_2 + da_{0y} + ca_{0,x} + aa_{0xxx}\\ &\quad + ba_{0yyy} + 3aa_{1x}l_0p_{xx} + a_{0t} + 6aa_{2x}l_0^2p_x^2 + 3aa_{1xx}l_0p_x + 3ba_{1yy}l_0q_y - 3ab_0a_{0x} + 3ba_{1y}l_0q_{yy}\\ &\quad + 6ba_{2y}l_0^2q_y^2 - 3bc_0a_{0y} = 0,\end{aligned} \tag{32}$$

$$a_{1y} - c_{1x} + 2a_2 l_0 q_y - 2c_2 l_0 p_x = 0, \tag{33}$$

$$a_{1x} - b_{1y} - 2b_2 l_0 q_y + 2a_2 l_0 p_x = 0, \tag{34}$$

$$a_{0x} - b_1 l_0 q_y + a_1 l_0 p_x - b_{0y} = 0, \tag{35}$$

$$a_{0y} - c_1 l_0 p_x + a_1 l_0 q_y - c_{0x} = 0. \tag{36}$$

It is very difficult to solve these prolix and complicated differential equations. Fortunately, by careful analysis and calculation, we derive the special solutions of Eqs. (23)–(36). Based on Eqs. (23), (26), and (27), we obtain

$$a_2 = 2p_x q_y, \quad b_2 = 2p_x^2, \quad c_2 = 2q_y^2. \tag{37}$$

Inserting Eq. (37) into Eqs. (24), (29), and (30) yields

$$a_1 = 0, \quad b_1 = 2p_{xx}, \quad c_1 = 2q_{yy}. \tag{38}$$

Substituting Eqs. (37) and (38) into other partial differential equations, we have

$$a_0 = 2l_0 p_x q_y, \quad b_0 = (3ap_x)^{-1}(p_t + ap_{xxx} + 2al_0 p_x^3 + cp_x), \quad c_0 = (3bq_y)^{-1}(q_t + bq_{yyy} + 2bl_0 q_y^3 + dq_y). \tag{39}$$

Therefore, from Eqs. (21), (8), and (37)–(39), the new types of variable separation solutions of the $(2+1)$-dimensional GNNV equation are of the following form:

Case 1: For $l_0 < 0$,

$$u_1 = 2l_0 p_x q_y - 2l_0 p_x q_y \tanh^2\{\sqrt{-l_0}(p+q)\},$$

$$v_1 = \frac{p_t + ap_{xxx} + cp_x + 2al_0 p_x^3}{3ap_x} - 2\sqrt{-l_0}p_{xx}\tanh\{\sqrt{-l_0}(p+q)\} - 2l_0 p_x^2 \tanh^2\{\sqrt{-l_0}(p+q)\},$$

$$w_1 = \frac{q_t + bq_{yyy} + dq_y + 2bl_0 q_y^3}{3bq_y} - 2\sqrt{-l_0}q_{yy}\tanh\{\sqrt{-l_0}(p+q)\} - 2l_0 q_y^2 \tanh^2\{\sqrt{-l_0}(p+q)\}, \tag{40}$$

$$u_2 = 2l_0 p_x q_y - 2l_0 p_x q_y \coth^2\{\sqrt{-l_0}(p+q)\},$$

$$v_2 = \frac{p_t + ap_{xxx} + cp_x + 2al_0 p_x^3}{3ap_x} - 2\sqrt{-l_0}p_{xx}\coth\{\sqrt{-l_0}(p+q)\} - 2l_0 p_x^2 \coth^2\{\sqrt{-l_0}(p+q)\},$$

$$w_2 = \frac{q_t + bq_{yyy} + dq_y + 2bl_0 q_y^3}{3bq_y} - 2\sqrt{-l_0}q_{yy}\coth\{\sqrt{-l_0}(p+q)\} - 2l_0 q_y^2 \coth^2\{\sqrt{-l_0}(p+q)\}. \tag{41}$$

Case 2: For $l_0 = 0$,

$$u_3 = U_2 = \frac{2p_x q_y}{(p+q)^2}, \tag{42}$$

$$v_3 = \frac{p_t + ap_{xxx} + cp_x}{3ap_x} - \frac{2p_{xx}}{p+q} + \frac{2p_x^2}{(p+q)^2},$$

$$w_3 = \frac{q_t + bq_{yyy} + dq_y}{3bq_y} - \frac{2q_{yy}}{p+q} + \frac{2q_y^2}{(p+q)^2}, \tag{43}$$

where p and q are arbitrary functions of $\{x,t\}$ and $\{y,t\}$, respectively. Here we omit the solutions as $l_0>0$, because they are of fewer significance in soliton theory. The solutions (42) and (43) is similar to the solution given by Darboux transformation in Ref. 39. According to the discussion in Sec. II B, the solutions (40) and (41) are the special examples of solutions (42) and (43). When redefining $p=\exp\{-2\sqrt{-l_0}p\}$, $q=\exp\{2\sqrt{-l_0}q\}$ in solutions (42) and (43), solution (40) can be obtained. Similarly, if taking $p=-\exp\{-2\sqrt{-l_0}p\}$, $q=\exp\{2\sqrt{-l_0}q\}$ in solutions (42) and (43), solution (41) can be recovered. Here we again prove the viewpoint in Sec. II B. Therefore, we only list the variable separation solutions for $l_0=0$ in the following mathematical physics models.

B. (2+1)-dimensional complex systems

(2+1)-dimensional Davey-Stewartson equation. The (2+1)-dimensional DS equation,

$$iU_t + \tfrac{1}{2}(U_{xx} + U_{yy}) - \alpha|U|^2U - UV = 0,$$

$$V_{xx} - V_{yy} - 2\alpha(|U|^2)_{xx} = 0, \tag{44}$$

can be derived from the plasma physics[40] and from the self-dual Yang-Mills field.[41] The DS system has also been proposed as a (2+1)-dimensional model for quantum field theory.[42] The DS equation is an isotropic Lax integrable extension of the well-known (1+1)-dimensional nonlinear Schrödinger equation, and it is IST and Painlevé integrable.

To find some exact solutions with some arbitrary functions of the DS equation, new coordinates X,Y are defined by

$$X = (x+y)/\sqrt{2}, \quad Y = (x-y)/\sqrt{2}, \tag{45}$$

and the transformed DS will be

$$iU_t + \tfrac{1}{2}(U_{XX} + U_{YY}) - \alpha|U|^2U - UV = 0,$$

$$2V_{XY} - \alpha(|U|^2)_{XX} - \alpha(|U|^2)_{YY} - 2\alpha(|U|^2)_{XY} = 0. \tag{46}$$

Introducing the transforms

$$U = u\exp[i(r+s)], \quad V = v, \tag{47}$$

then Eq. (46) changes into

$$-u(r_t + s_t) + \tfrac{1}{2}(u_{XX} + u_{YY}) - \tfrac{1}{2}u({r_X}^2 + {s_Y}^2) + \alpha u^3 - vu = 0,$$

$$u_t + u_X r_X + u_Y s_Y + \tfrac{1}{2}u(r_{XX} + s_{YY}) = 0,$$

$$v_{XY} - \alpha({u_X}^2 + uu_{XX} + {u_Y}^2 + uu_{YY} + 2u_Xu_Y + 2uu_{XY}) = 0, \tag{48}$$

where u, v are arbitrary function of $\{X,Y,t\}$, r and s are arbitrary functions of $\{X,t\}$ and $\{Y,t\}$, respectively.

Similar to the procedure to solve GNNV system, the special variable separation solution of system (46) has the form

$$U=\frac{\delta\sqrt{2\alpha^{-1}p_Xq_Y}}{p+q}\exp[i(r+s)],\quad \delta^2=1, \tag{49}$$

$$V=V_0(x,y,t)-\frac{p_{XX}q_{YY}}{p+q}+\frac{(p_Xq_Y)^2}{(p+q)^2}, \tag{50}$$

with

$$V_0(x,y,t)=\frac{p_{XXX}}{4p_X}+\frac{q_{YYY}}{4q_Y}-\frac{p_{XX}^2}{8p_X^2}-\frac{q_{YY}^2}{8q_Y^2}-r_t-s_t-\frac{1}{2}r_X^2-\frac{1}{2}s_Y^2, \tag{51}$$

and r, s satisfy

$$r_X=-\frac{p_t}{p_X},\quad s_Y=-\frac{q_t}{q_X}, \tag{52}$$

where p and q are arbitrary functions of $\{X,t\}$ and $\{Y,t\}$, respectively. Moreover, the real condition of solution (49) requires

$$2\alpha^{-1}p_Xq_Y\geqslant 0. \tag{53}$$

Especially, for the module square of the field U reads

$$|U|^2=\alpha^{-1}U_2=\frac{2\alpha^{-1}p_Xq_Y}{(p+q)^2}. \tag{54}$$

Clearly, the arbitrary constants $a_0\sim a_3$, which are introduced in MLVSA in Ref. 10, increase the complexity of the constraint conditions to r and s in DS model. However, the terse expressions of the constraint conditions to r and s in (52) make us easily obtain their concrete form.

(2+1)-dimensional long-wave–short-wave resonance interaction equation. The (2+1)-dimensional LSRI equation is of the form

$$i(S_t+S_y)-S_{xx}+LS=0,$$

$$L_t-2(|S|^2)_x=0, \tag{55}$$

where the fields S and L denote short surface wave packets and long interfacial waves, respectively. This system describe the long and short waves propagating at an angle to each other in a two-layer fluid. The above equation has recently been studied[43,44] and its position and one dromion solutions have been generated through the method of coalescence of eigenvalues or wave numbers.[45]

Similar to the procedure to solve DS equation, the special variable separation solution of system (55) reads

$$S=\frac{\delta\sqrt{p_xq_t}}{p+q}\exp[i(r_1+r_2)],\quad \delta^2=1,$$

$$L=\frac{4p_x^2(r_{1y}-r_{1x}^2)-p_{xx}^2+2p_xp_{xxx}}{4p_x^2}-\frac{2p_{xx}}{p+q}+\frac{2p_x^2}{(p+q)^2}, \tag{56}$$

where r_1 satisfies

$$r_{1x} = \frac{p_y + c_y}{2p_x}, \tag{57}$$

and $r_2 \equiv r_2(y-t)$, $q=F(y-t)+c(y)$, and p is an arbitrary function of $\{x,y\}$. Moreover, the real condition of solution (56) requires

$$p_x q_t \geqslant 0. \tag{58}$$

C. Other (2+1)-dimensional integrable systems

In this section, some known models which can be solved via the ETM are listed. With some suitable modifications, they possess a common quantity expressed as Eq. (2).

BKK system: The BKK system,

$$H_{ty} - H_{xxy} + 2(HH_x)_y + 2G_{xx} = 0,$$

$$G_t + G_{xx} + 2(HG)_x = 0, \tag{59}$$

may be derived from the inner parameter-dependent symmetry constraint of the Kadomtsev-Petviashvili (KP) equation.[46] Using some suitable dependent and independent variable transformations, Chen and Li[47] have proved that the (2+1)-dimensional BKKE can be transformed to the (2+1)-dimensional integrable dispersive long-wave equation (DLWE)

$$u_{ty} = -\eta_{xx} - \tfrac{1}{2}(u^2)_{xy},$$

$$\eta_t = -(u\eta + u + u_{xy})_x, \tag{60}$$

and the (2+1)-dimensional integrable Ablowitz-Kaup-Newell-Segur equation (AKNSE)

$$\psi_t = -\psi_{xx} + \psi u,$$

$$\phi_t = \phi_{xx} - \phi u,$$

$$u_y = \psi\phi. \tag{61}$$

When we take $y=x$, the (2+1)-dimensional BKKE is reduced to the usual (1+1)-dimensional BKKE, which can be used to describe the propagation of long wave in shallow water.[48]

For the BKK system, there are special variable solution in the form

$$H = -\frac{p_{xx} + p_t}{2p_x} + \frac{p_x}{p+q},$$

$$G = \frac{U_2}{2} = \frac{p_x q_y}{(p+q)^2}, \tag{62}$$

where p and q are arbitrary functions of $\{x,t\}$ and $\{y\}$, respectively.

Boiti-Leon-Pempinelli system: For the Boiti-Leon-Pempinelli system[49–51]

$$u_{ty} - (u^2 - u_x)_{xy} + 2v_{xxx} = 0,$$

$$v_t - v_{xx} + 2uv_x = 0, \tag{63}$$

special variable separation solutions read

$$u = -\frac{p_{xx} - p_t}{2p_x} + \frac{p_x}{p+q},$$

$$v = \frac{q_y}{p+q}, \tag{64}$$

where p and q are arbitrary functions of $\{x,t\}$ and $\{y\}$, respectively.

From solution (64), the potential v_x satisfies the universal formula, i.e.,

$$v_x = -\frac{U_2}{2} = -\frac{p_x q_y}{(p+q)^2}. \tag{65}$$

(2+1)-dimensional KdV equation: The (2+1)-dimensional KdV equation,

$$u_t + bu_{xxx} + 4b(uv)_x = 0,$$

$$v_y = u_x, \tag{66}$$

was first derived by Boiti *et al.*[35] using the idea of the weak Lax pair. Equation (69) can also be deduced from Jimbo and Miwa hierarchy of nonlinear partial differential equations.[52] The Painlevé property of (69) has been proved by Dorizzi *et al.*[53] The infinite-dimensional symmetries and Lie algebraic structure have been studied.[54]

The variable separation solutions of the (2+1)-dimensional KdV equation (69) possess the form

$$u = -\frac{3}{4}U_2 = -\frac{3p_x q_y}{2(p+q)^2}, \tag{67}$$

$$v = -\frac{p_t + bp_{xxx} + c_t}{4bp_x} + \frac{3p_{xx}}{2(p+q)} - \frac{3p_x^2}{2(p+q)^2}, \tag{68}$$

where p is an arbitrary functions of $\{x,t\}$, and $q(y,t)=F(y)+c(t)$.

(2+1)-dimensional breaking soliton equation: The (2+1)-dimensional BS equation[55–57]

$$u_t + bu_{xxx} + 4b(uv)_x = 0,$$

$$u_y = v_x, \tag{69}$$

have a special variable separation solution

$$u = -\frac{bp_{xxx} + cp_x}{4bp_x} + \frac{3p_{xx}}{2(p+q)} - \frac{3p_x^2}{2(p+q)^2}, \tag{70}$$

$$v = -\frac{3}{4}U_2 = -\frac{3p_x q_y}{2(p+q)^2}, \tag{71}$$

where p is an arbitrary function of $\{x,t\}$ and $q(y,t)=q(y+ct)$.

(2+1)-dimensional Burgers equation: The (2+1)-dimensional Burgers equation[58–60]

$$u_t = uu_y + avu_x + bu_{yy} + abu_{xx} = 0,$$

$$v_y = u_x, \tag{72}$$

have a special variable separation solution

$$u = -\frac{2bq_y}{p+q}, \tag{73}$$

$$v = -\frac{2bp_x}{p+q} + \frac{p_t - abp_{xx}}{ap_x}, \tag{74}$$

where p is an arbitrary function of $\{x,t\}$, and $q(y,t)$ satisfies $q_t = bq_{yy}$.

From solution (73), the potential u_x satisfies the universal formula, i.e.,

$$u_x = bU_2 = \frac{2bp_xq_y}{(p+q)^2}. \tag{75}$$

D. (2+1)-dimensional nonintegrable KdV system

The (2+1)-dimensional nonintegrable KdV equation,

$$u_t + u_{xxx} - auv_x - bvu_x = 0,$$

$$v_y = u_x, \tag{76}$$

is one of the extensions of a (1+1)-dimensional shallow water wave equation.[61] In the real physics problems, a and b in Eq. (76) may be arbitrary constant. This model is completely integrable only for $a=b$.[35]

The variable separation solutions of the (2+1)-dimensional nonintegrable KdV equation (76) possess the form

$$u = \frac{6}{a+b}U_2 = \frac{12p_xq_y}{(a+b)(p+q)^2}, \tag{77}$$

$$v = v_0(x,y,t) - \frac{12p_{xx}}{(a+b)(p+q)} + \frac{12p_x^2}{(a+b)(p+q)^2}, \tag{78}$$

with

$$v_0(x,y,t) = \frac{1}{bp_x}\left\{p_t + \frac{3(a-b)p_{xx}^2}{(a+b)p_x} - \frac{2(a-2b)(p_{xxx}) - K(t)}{a+b}\right\}, \tag{79}$$

where q satisfies

$$q_t = K(t), \tag{80}$$

and p satisfies

$$(a+b)(ap_xv_{0x} + av_0p_{xx} - p_{tx} - p_{xxxx}) - 2bl_0p_x^2p_{xx} = 0. \tag{81}$$

In conclusion, from the solutions (42), (62), (65), (67), (75), (54), and (77), we know that the field quantity satisfy the universal formula U_2 for the GNNV, BKK, integrable KdV, BS, and nonintegrable KdV models, while the potential satisfy the universal formula U_2 for BLP and Burgers models, or the module square of the field quantity satisfy the universal formula U_2 for DS model. For integrable models, such as GNNV, BKK, BLP, integrable KdV, BS, Burgers, DS, and LSRI models, there are not less than an arbitrary function (p or q), while some additional conditions must be introduced to reduce the arbitrariness of the arbitrary functions (both p and q) for the nonintegrable KdV model. Thus we can define the solvable models by the ETM: these kinds of models should not be less than an arbitrary function (p or q). The nonintegrable models are also not the solvable models by the ETM.

Now a subsequent intriguing issue is whether we can generalize the extended tanh-method to the lower $(1+1)$-dimensional and the higher $(3+1)$-dimensional systems? To answer this question, we take the $(1+1)$-dimensional CID, LSRI, negative KdV models and $(3+1)$-dimensional Burgers system as concrete examples.

IV. VARIABLE SEPARATION SOLUTIONS FOR THE (1+1)-DIMENSIONAL SYSTEMS

Coupled integrable dispersionless equations: The coupled integrable dispersionless (CID) equations have the form

$$u_{xt}+(vw)_x=0, \quad v_{xt}-2u_xv=0, \quad w_{xt}-2u_xw=0. \tag{82}$$

These equations were presented and solved by the inverse scattering method.[62] It is shown that the CID systems possess Painlevé property.[63] Starting from the Lagrangian of coupled integrable dispersionless equations, Kakuhata *et al.*[64] derived the Hamiltonian, and conserved quantities associated with the symmetries of the Lagrangian were obtained, which cannot be derived by the inverse scattering method. Alagesan *et al.*[65] investigated the singularity structure analysis of this system. The associated Bäcklund transformation was constructed and Hirota's bilinearization was also obtained through dependent variable transformations.

As in $(2+1)$-dimensional cases, by standard leading term analysis, the ansatz of CID systems is

$$u=a_0(x,t)+a_1(x,t)\phi(R), \quad v=b_0(x,t)+b_1(x,t)\phi(R), \quad w=c_0(x,t)+c_1(x,t)\phi(R), \tag{83}$$

where $\phi(R)$ satisfies Eq. (7) with $R=R(x,t)$. Inserting Eq. (83) with Eq. (7) into Eq. (82), yields a series of partial differential equations, from which we can obtain the variable separation solutions of the $(1+1)$-dimensional coupled integrable dispersionless equations (82),

$$u=-\frac{q_t}{p+q}+u_0(t), \tag{84}$$

$$v=\frac{aq_t}{p+q}-\frac{aq_{tt}}{2q_t}, \tag{85}$$

$$w=\frac{bq_t}{p+q}-\frac{bq_{tt}}{2q_t}, \tag{86}$$

where $q(t)$, $u_0(t)$ are the arbitrary functions of $\{t\}$, $p(x)$ is an arbitrary function of $\{x\}$ and $ab=-1$.

From the solutions (84)–(86), the potential function $G(=u_x=-v_x/a=-w_x/b)$

$$G=\frac{p_xq_t}{(p+q)^2}. \tag{87}$$

Long-wave–short-wave resonant interaction equation: The procedure for the long-wave–short-wave resonant interaction equation (LSRI) reads

$$iS_t+\beta S_{xx}=\gamma LS,$$

$$L_t+\alpha(SS^*)_x=0, \tag{88}$$

where L is the profile of the long wave and S is the envelope of the short wave. α, β, and γ are positive real model constant. Equations (88) were proposed for the time by Zakharov to describe the interaction of Langmuir oscillations with ionic sound in a plasma. The universal equations were obtained for waves on the water surface by Djordjevic and Redekopp[66] and for the model of

a molecular chain in the form of an α-helix by Davydov.[67] The equations were also derived in bubbly liquids by Akhatov and Khismatullin.[68] Reference 69 discussed the Cauahy problem and global solution for this equation.

A general excitation of LSRI system has the form

$$S(x,t) = \pm \frac{\sqrt{-2(\alpha\gamma)^{-1}\beta p_x q_t}}{p+q} \exp\left\{ i\left[c_0 + c_1 t - k \int (2\beta p_x)^{-1}\, \mathrm{d}x \right] \right\}, \tag{89}$$

$$L(x,t) = \frac{-2\beta p_{xx}}{\gamma(p+q)} + \frac{2\beta p_x^2}{\gamma(p+q)^2} + \frac{\beta^2(2p_{xxx}p_x - p_{xx}^2) - k^2}{4\gamma\beta p_x^2} - \gamma^{-1}c_1, \tag{90}$$

where k, c_0, c_1 are arbitrary real constants, p is the arbitrary function of $\{x\}$, and q can be expressed by $q_t = k$. Moreover, the real condition of solution (89) requires

$$-2(\alpha\gamma)^{-1}\beta p_x q_t \geqslant 0. \tag{91}$$

Especially, the module square of S can also be expressed as

$$G = |S|^2 = \frac{-2\beta p_x q_t}{\sigma\gamma(p+q)^2}. \tag{92}$$

Negative KdV model: The negative KdV hierarchy

$$\varphi_{xx} + u\varphi - \lambda\varphi = 0, \quad u_t = (\varphi^n)_x, \tag{93}$$

where $\varphi = \varphi(x,t)$, $u = u(x,t)$, λ and n are arbitrary constants. This model relates to Schrödinger equation[70,71] and has also been proved to relate to the sine-Gordon equation by Miura transformation.[72] By means of the Schrödinger operator, the negative KdV hierarchy can be rewritten to an equivalent differential equation system. As $n = 1, 2$, Eq. (93) is called KdV(−1) and KdV(−2) equations, respectively.

KdV(−1) *model:* As $n = 1$, Eq. (93) is simplified as

$$\varphi_{xx} + u\varphi - \lambda\varphi = 0, \quad u_t = \varphi_x. \tag{94}$$

The general excitation of system (94) has the form

$$\varphi(x,t) = \frac{-6p_x q_t}{(p+q)^2}, \tag{95}$$

$$u(x,t) = -\frac{6p_x^2}{(p+q)^2} + \frac{6p_{xx}}{p+q} - \frac{p_{xxx}}{p_x} + \lambda, \tag{96}$$

where p is the arbitrary function of $\{x\}$, and q is the arbitrary function of $\{t\}$.

KdV(−2) *model:* As $n = 2$, Eq. (93) is simplified as

$$\varphi_{xx} + u\varphi - \lambda\varphi = 0, \quad u_t = (\varphi^2)_x. \tag{97}$$

A special variable separation solution of system (97) reads

$$\varphi(x,t) = \pm \frac{\sqrt{-2p_x q_t}}{p+q}, \tag{98}$$

$$u(x,t) = -\frac{2p_x^2}{(p+q)^2} + \frac{2p_{xx}}{p+q} + \frac{p_{xx}^2 - 2p_{xxx}p_x}{4p_x^2} + \lambda, \tag{99}$$

where p is the arbitrary function of $\{x\}$, and q is the arbitrary function of $\{t\}$. From expression (98), because the real condition of φ,

$$-2p_x q_t \geqslant 0, \tag{100}$$

we must put a constraint on the selections of the functions p, q. In Ref. 14, another special variable separation solution was discussed in detail by MLVSA.

In short, we successfully generalize the ETM to $(1+1)$-dimensional systems. From the expressions (87), (92), (95), and (98), we find that there also exists a common formula

$$U_2' \equiv \frac{p_x q_t}{(p+q)^2}, \tag{101}$$

to describe suitable physical fields or potentials for some $(1+1)$-dimensional models. This formula is similar to the formula U_2 in $(2+1)$-dimensional models.

V. VARIABLE SEPARATION SOLUTION FOR THE (3+1)-DIMENSIONAL BURGERS SYSTEM

The ETM has been successfully generalized to $(1+1)$-dimensional systems, and whether it can be extended to $(3+1)$-dimensional systems? To answer this question, we take the $(3+1)$-dimensional Burgers system,

$$u_t = 2uu_y + 2vu_x + 2wu_x + u_{xx} + u_{yy} + u_{zz},$$

$$u_x = v_y,$$

$$u_z = w_y, \tag{102}$$

as a concrete example. If u is z independent (or $z=x$; $w=u$), (102) will be degenerated to the known $(2+1)$-dimensional Burgers equation (72). Furthermore, if u is both z independent and y independent (or $y=z=x$; $v=w=u$), Eq. (102) is just the well-known $(1+1)$-dimensional Burgers equation which is widely applied in many scientific fields. An alternative potential form of Eq. (102) is obtained from the invertible deformation of the heat conduction equation.[73] In Refs. 12 and 13, the authors extended the VSA to this system.

As in $(2+1)$-dimensional cases, by standard leading term analysis, the ansatz of Burgers system is

$$u = a_0(x,y,z,t) + a_1(x,y,z,t)\phi(R), \quad v = b_0(x,y,z,t) + b_1(x,y,z,t)\phi(R),$$

$$w = c_0(x,y,z,t) + c_1(x,y,z,t)\phi(R), \tag{103}$$

where $\phi(R)$ satisfies Eq. (7) with $R=R(x,y,z,t)$. Inserting Eq. (103) with Eq. (7) into Eq. (102), yields a series of partial differential equations, from which we can obtain the variable separation solution of the $(3+1)$-dimensional Burgers system (102) for $l_0=0$,

$$u = \frac{q_y}{p+q}, \tag{104}$$

$$v = \frac{p_x}{p+q} + \frac{p_t - p_{xx}}{2p_x}, \tag{105}$$

$$w = \frac{p_z}{p+q} - \frac{p_{zz}}{2p_z}, \tag{106}$$

where p is the arbitrary functions of $\{x,z,t\}$, q is an function of $\{y,t\}$ and satisfies $q_t = q_{yy}$.

One of the most important things may be that for the potential $G(=u_x=v_y)$, we have

$$G = -U_2 = -\frac{p_x q_y}{(p+q)^2}, \tag{107}$$

which satisfies the completely same form as the universal quantity (2) in (2+1)-dimensional systems.

VI. SPECIAL LOCALIZED COHERENT STRUCTURES FOR THE COMMON FORMULA (2)

In this section, we will discuss some special types of interesting localized structures for the quantities U_2 expressed by (2). From (2), we know that for general selections of p and q there may be some singularities for the quantity U_2. However, when the arbitrary functions p and q are selected appropriately to avoid the singularities, there may exist abundant excitations for U_2. All rich localized coherent structures discussed by the quantities U_1 expressed by (1), such as nonpropagating solitons, dromion, peakon, compacton, foldon, instanton, ghoston, ring soliton, and the interaction between these solitons, can be rederived by the quantities U_2 expressed by (2). Moreover, if p or q is considered to be a periodic function or a solution of a chaos system like the Lorenz chaos system, then solitons possess periodic or chaotic behaviors. It is well known that there are some lower-dimensional stochastic fractal functions, which may be used to construct higher-dimensional stochastic fractal dromion and lump excitations by the quantities U_2 expressed by (2). Since these similar situations have been widely discussed in some previous literature,[9,10,12–15,26,37,49] the related plots are neglected in our present paper. Here we focus on some novel localized coherent structures about multivalued functions and their interaction cases. For simplification in the following discussions, we merely analyze the expression U_2 without any constraints to p and q.

A. Special dromion, special peakon, and foldon

It is well known that in universal formula (2), dromion, peakon, and foldon can be obtained by selecting p or q single-valued function, piecewise function, and multivalued function, respectively. However, in fact, the single-valued structures, i.e., dromion and peakon can also be derived by selecting p or q multivalued function.[74] Based on the physical quantity (2), special dromion, special peakon, and foldon can be constructed if we select both p and q as the following relations:

$$p_x = \sum_{i=1}^{N} \kappa_i(\zeta - c_i t), \quad x = \zeta + \sum_{i=1}^{N} \chi_i(\zeta - c_i t), \tag{108}$$

$$q_y = \sum_{j=1}^{M} \vartheta_j(\eta - d_j t), \quad y = \eta + \sum_{j=1}^{M} \lambda_j(\eta - d_j t), \tag{109}$$

where $c_i(i=1,2,\ldots,N)$, $d_j(j=1,2,\ldots,M)$ are arbitrary constants, κ_i and χ_i, ϑ_j and λ_j are localized excitations with the properties $\kappa_i(\pm\infty)=0$, $\chi_i(\pm\infty)=\text{const}$, $\vartheta_j(\pm\infty)=0$, $\lambda_j(\pm\infty)=\text{const}$. From Eqs. (108) and (109), one can know that ζ (or η) may be a multivalued function in some suitable regions of x (or y) by choosing the functions χ_i (or λ_j) appropriately. Therefore, the function p_x (or q_y), which is obviously an interaction solution of N (or M) localized excitations due to the property $\zeta|_{x\to\infty}\to\infty$ (or $\eta|_{y\to\infty}\to\infty$), may be a multivalued function of x (or y) in these areas, though it is a single valued function of ζ (or η).

Concretely, p and q are chosen

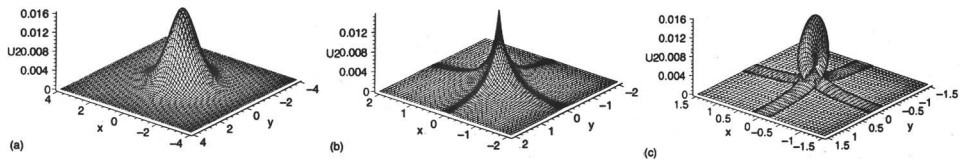

FIG. 1. Special dromion, special peakon and foldon structures for U_2 with conditions (110) and (112), (a) $A=C=0.05$, (b) $A=C=0.95$, (c) $A=C=1.5$ at $t=0$.

$$p_x = \operatorname{sech}^2(\zeta - t), \quad x = \zeta - A\tanh(\zeta), \tag{110}$$

$$q_y = \operatorname{sech}^2(\eta - t), \quad y = \eta - C\tanh(\eta), \tag{111}$$

where A and C are characteristic parameters, whose difference brings the different localized structures. When their values are chosen between 0 and 0.9, 0.9 and 1, and bigger than 1, special dromion, special peakon, and foldon can be derived. Figures 1(a)–1(c) describe three localized structures, special dromion, special peakon, and foldon with $A=C=0.05, 0.95, 1.5$, respectively.

B. Asymptotic behaviors of the localized excitations produced from the formula (2)

In order to discuss the interaction property of these localized excitations related to the physical quantity (2), we first study the asymptotic behaviors of the localized excitations produced from the formula (2) when $t\to\infty$.

In general, if the function p and q [considering Eqs. (108) and (109)] are selected as multilocalized solitonic excitations with ($z_i \equiv \zeta - c_i t$, $Z_j \equiv \eta - d_j t$)

$$p|_{t\to\mp\infty} = \sum_{i=1}^{N} p_i^{\mp}, p_i^{\mp}(z_i) \equiv p_i(\zeta - c_i t) \equiv \int \kappa_i \, \mathrm{d}x|_{z_i\to\mp\infty}, \tag{112}$$

$$q|_{t\to\mp\infty} = \sum_{j=1}^{N} q_j^{\mp}, q_j^{\mp}(Z_j) \equiv q_j(\eta - d_j t) \equiv \int \vartheta_j \, \mathrm{d}y|_{Z_j\to\mp\infty}, \tag{113}$$

where $\{p_i, q_j\}\forall\, i$ and j are localized functions, then the physical quantity expressed by Eq. (2) delivers $M\times N$ (2+1)-dimensional localized excitations with the asymptotic behavior,

$$U_2|_{t\to\mp\infty} \to \sum_{i=1}^{N}\sum_{j=1}^{M} \frac{p_{iz_i}^{\mp} q_{jZ_j}^{\mp}}{(1+\chi_{iz_i}^{\mp})(1+\lambda_{jZ_j}^{\mp})[(p_i^{\mp}(z_i)+\tilde{p}_i^{\mp}) + (q_j^{\mp}(Z_j)+\tilde{q}_j^{\mp})]^2} \equiv \sum_{i=1}^{N}\sum_{j=1}^{M} U_{2,ij}^{\mp}, \tag{114}$$

$$x|_{t\to\mp\infty} \to \zeta + \delta_i^{\mp} + \chi_i^{\mp}(z_i), \tag{115}$$

$$y|_{t\to\mp\infty} \to \eta + \Delta_j^{\mp} + \lambda_j^{\mp}(Z_i), \tag{116}$$

with

$$\tilde{p}_i^{\mp} = \sum_{j<i} p_j(\mp\infty) + \sum_{j>i} p_j(\mp\infty), \tag{117}$$

$$\tilde{q}_i^{\mp} = \sum_{j<i} q_j(\mp\infty) + \sum_{j>i} q_j(\pm\infty), \tag{118}$$

$$\delta_i^{\mp} = \sum_{j<i} \chi_j(\mp\infty) + \sum_{j>i} \chi_j(\pm\infty), \tag{119}$$

$$\Delta_j^{\mp} = \sum_{j<i} \lambda_j(\mp\infty) + \sum_{j>i} \lambda_j(\pm\infty). \tag{120}$$

In the above discussion, it has been assumed, without loss of generality, that $c_i > c_j$, $d_i > d_j$ if $i > j$. From the asymptotic result (114), we discover some important and interesting facts. (i) The ijth localized excitation $U_{2,ij}$ is a travelling wave moving with the velocity c_i along the positive ($c_i > 0$) or negative ($c_i < 0$) x direction, and d_j along the positive ($d_j > 0$) or negative ($d_j < 0$) y direction; (ii) the properties of the ijth localized excitation $U_{2,ij}$ is only determined by p_i of Eq. (112) and q_j of Eq. (113); (iii) the shape of the ijth localized excitation $U_{2,ij}$ will be changed (noncompletely elastic or completely inelastic interaction) if

$$\tilde{p}_i^{+} \neq \tilde{p}_i^{-}, \tag{121}$$

and (or)

$$\tilde{q}_j^{+} \neq \tilde{q}_j^{-}, \tag{122}$$

following the interaction. On the contrary, it will preserve its shape (completely elastic interaction) during the interaction if

$$\tilde{p}_i^{+} = \tilde{p}_i^{-}, \tag{123}$$

$$\tilde{q}_j^{+} = \tilde{q}_j^{-}. \tag{124}$$

(iv) The phase shift of the ijth localized excitation $U_{2,ij}$ reads

$$\delta_i^{+} - \delta_i^{-}, \tag{125}$$

in the x direction and

$$\Delta_j^{+} - \Delta_j^{-}. \tag{126}$$

in the y direction.

The above discussions indicate that localized solitonic excitations for the common quantity U_2 can be produced from the $(1+1)$-dimensional multivalued functions with the properties (112), (113), and (121)–(124). In general terms, if the functions p or q are taken as multiple localized excitations that possess the phase shifts of $(1+1)$-dimensional models then the $(2+1)$-dimensional localized excitations involving formula (2) inherit phase shifts structures.

C. Interaction between the localized coherent excitations produced by multivalued functions

Now we discuss some novel coherent structures for the physical quantity U_2, and focus our attention on interaction between the localized coherent excitations produced by multivalued functions. In Sec. VI A, we present three interesting coherent excitations, i.e., special dromion, special peakon, and foldon. Here we discuss some novel interactions between them. In order to discuss them expediently and reveal the phase shift more clearly and visually, it has proved convenient to fix the one possessing zero velocity. That is to say, if we take the concrete choice $N=2$, $M=1$, $c_1=0.25$, $c_2=0$, $d_1=0$ in Eqs. (112) and (113), one has

$$p_x = 0.5\,\mathrm{sech}^2(\zeta - 0.25t) + 0.8\,\mathrm{sech}^2(\zeta), \quad x = \zeta - A\tanh(\zeta - 0.25t) - B\tanh(\zeta), \tag{127}$$

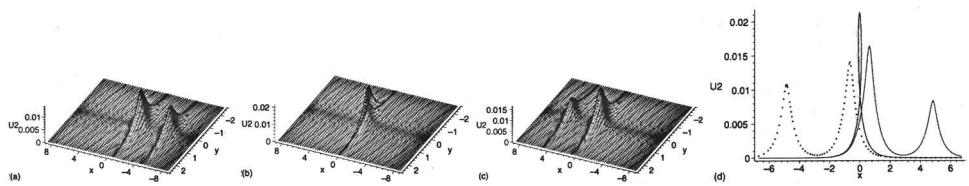

FIG. 2. Interaction between special dromions for U_2 with conditions (127) and (128) and $A=B=C=0.65$, (a) $t=-22$, (b) $t=0.04$, (c) $t=22$. (d) The corresponding sectional view at $y=0$ (dotted, solid, and dashed line denotes before, in, and after collision, respectively).

$$q_y = \mathrm{sech}^2(\eta), \quad y = \eta - C\tanh(\eta), \tag{128}$$

where A, B, and C are characteristic parameters, which determine the type of interactions.

1. Interaction between special dromions

If we take the concrete values $A=B=C=0.65$ in Eqs. (127) and (128), then we successfully construct interaction between special dromions that possess phase shifts for the physical quantity U_2 depicted in Fig. 2. From Fig. 2, we can see that the two special dromion localized excitations possess novel properties, that is, there exists a multivalued foldon in the process of their collision, which is different from the reported cases in previous literature.[75] Moreover, one can find that the interaction between them may exhibit a novel property, which is noncompletely elastic since their shapes are not completely preserved after interaction. Actually, the completely elastic interaction condition (123) and (124) is not satisfied for the common formula (2) with (127) and (128). For the static large dromion,

$$\tilde{p}_2^+ - \tilde{p}_2^- = p_1(+\infty) - p_1(-\infty) = \tfrac{17}{30} \neq 0. \tag{129}$$

For the moving small dromion,

$$\tilde{p}_1^+ - \tilde{p}_1^- = p_2(-\infty) - p_2(+\infty) = -\tfrac{68}{75} \neq 0. \tag{130}$$

The phase shift can also be observed. Prior to interaction, the large dromion has been set to be $\{v_{0x}=c_2=0,\ v_{0y}=0\}$, however, the position located by large dromion is still altered about from $x=-0.65$ to $x=0.65$, then stops at $x=0.65$ and preserves its initial velocities $\{v_x=v_{0x},\ v_y=v_{0y}\}$ after interaction. Therefore the phase shift of the static large dromion is $\delta_2^+ - \delta_2^- = \chi_1(-\infty) - \chi_1(+\infty) = 1.3$. The final velocities V_x and V_y of the moving small dromion also completely preserved its initial velocities $\{V_x=V_{0x}=c_1=0.25,\ V_y=V_{0y}=0\}$. The phase shift of the moving small dromion is $\delta_1^+ - \delta_1^- = \chi_2(+\infty) - \chi_2(-\infty) = -1.3$.

2. Interaction between special peakons

When we fix the concrete values $A=B=C=0.95$ in Eqs. (127) and (128), then we successfully construct interaction between special peakons that possess phase shifts for the physical quantity U_2 depicted in Fig. 3. From Fig. 3, we can see that the two special peakon localized excitations

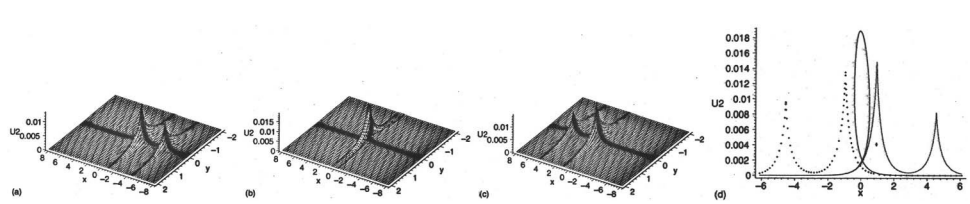

FIG. 3. Interaction between special peakons for U_2 with conditions (127) and (128) and $A=B=C=0.95$, (a) $t=-22$, (b) $t=0.5$, (c) $t=22$. (d) The corresponding sectional view at $y=0$ (dotted, solid, and dashed line denotes before, in, and after collision, respectively).

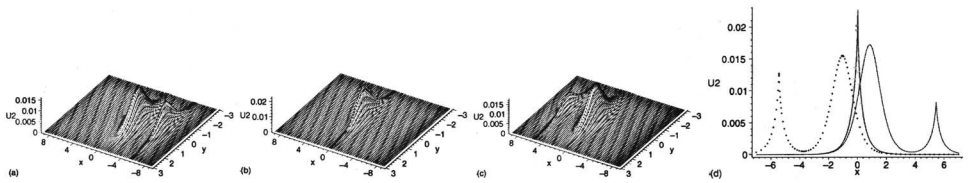

FIG. 4. Interaction between special dromion and peakon for U_2 with conditions (127) and (128) and $A=0.95$, $B=C=0.05$, (a) $t=-22$, (b) $t=0.1$, (c) $t=22$. (d) The corresponding sectional view at $y=0$ (dotted, solid, and dashed line denotes before, in, and after collision, respectively).

possess novel properties, that is, it is noncompletely elastic since their shapes are not completely preserved after interaction and there also exists a multivalued foldon in the process of their collision, which is different from the reported cases in previous literature.[10] The analytical analysis to noncompletely interaction is similar to the case in Sec. VI C 1. For the static large peakon, $\tilde{p}_2^+-\tilde{p}_2^-=\frac{2}{5}\neq 0$. For the moving small peakon, $\tilde{p}_1^+-\tilde{p}_1^-=-\frac{16}{25}\neq 0$. The phase shift can also be observed. Before interaction, the static large peakon is located at $x=-0.95$ and after the interaction, it is shifted to $x=0.95$. Then it stops at $x=0.95$ and preserves its initial velocities $\{v_x=v_{0x}=0, v_y=v_{0y}=0\}$ after interaction. Whereas the moving small peakon also completely preserved its initial velocities $\{V_x=V_{0x}=c_1=0.25, V_y=V_{0y}=0\}$. By careful analysis similar to Sec. VI C 1, we know that the phase shift of the static large peakon is 1.9, and the moving small peakon exists in the phase shift -1.9. These properties are analogous to the case in Sec. VI C 1.

3. Interactions among special dromion, special peakon, and foldon

Along the above ideas and performing a similar analysis, if $A=0.95$, $B=C=0.05$, or $A=1.5$, $B=C=0.05$, or $A=1.5$, $B=C=0.95$ in Eqs. (127) and (128), interactions between special dromion and special peakon, special dromion and foldon, special peakon and foldon can be constructed for the physical quantity U_2 depicted in Figs. 4–6, respectively. From these evolution profiles, one can know that they are all noncompletely elastic since their shapes are not completely preserved after interaction. Moreover, the phase shift can also be observed. In Fig. 4, the phase shift of the static dromion is $\delta_2^+-\delta_2^-=\chi_1(-\infty)-\chi_1(+\infty)=1.9$, and the moving peakon exists phase shift $\delta_1^+-\delta_1^-=\chi_2(+\infty)-\chi_2(-\infty)=-0.1$. In Fig. 5, the phase shift of the static dromion is 3, and the moving foldon exists of phase shift -0.1. In Fig. 6, the phase shift of the static peakon is 3, and the moving foldon exists of phase shift -1.9.

VII. SUMMARY AND DISCUSSION

In summary, the ETM is applied to obtain variable separation solutions of $(1+1)$-dimensional, $(2+1)$-dimensional, and $(3+1)$-dimensional systems. For some $(2+1)$-dimensional integrable models such as the GNNV, DS, BKK, BLP, integrable KdV, BS, and Burgers models, some lower dimensional arbitrary functions can be included in their exact solutions. A common variable separation formula is valid for all these models. For these integrable models, there are not less than an arbitrary function (p or q), whereas for nonintegrable KdV equation, neither p or q is an

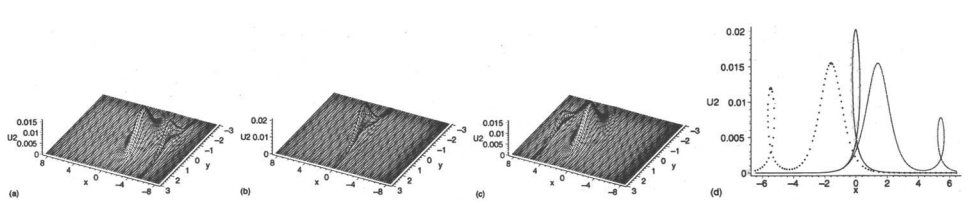

FIG. 5. Interaction between special dromion and foldon for U_2 with conditions (127) and (128) and $A=1.5$, $B=C=0.05$, (a) $t=-22$, (b) $t=0.1$, (c) $t=22$. (d) The corresponding sectional view at $y=0$ (dotted, solid, and dashed line denotes before, in, and after collision, respectively).

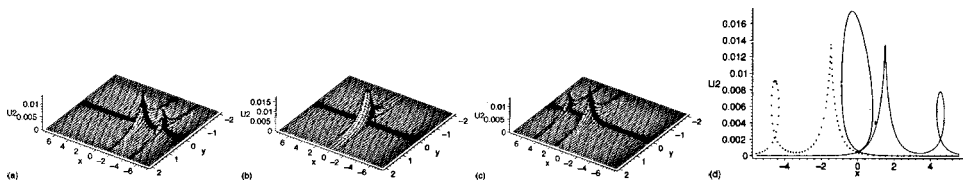

FIG. 6. Interaction between special peakon and foldon for U_2 with conditions (127) and (128) and $A=1.5$, $B=C=0.95$, (a) $t=-22$, (b) $t=-0.2$, (c) $t=22$. (d) The corresponding sectional view at $y=0$ (dotted, solid, and dashed line denotes before, in, and after collision, respectively).

arbitrary function, and they must satisfy some constraint equations. Therefore, we can define the solvable models by the ETM: these kinds of models should not be less than an arbitrary function (p or q). The nonintegrable models are also not the solvable models by the ETM. Moreover, there exists also a common formula, which is similar to the formula (2), to describe suitable physical fields or potentials of some $(1+1)$-dimensional models. The universal formula (2) is suitable to describe the $(3+1)$-dimensional Burgers. The only differences are that the function q is a solution of a constraint equation and p is an arbitrary function of three independent variables. In fact, the common formula (2) is a simplified form of the universal formula (4), i.e., through the transformation $p=(a_0+a_1P)/(a_2+a_3P)$, $q=Q$, we have $U_2=U_1$.

Starting from the common formula (2), all sorts of localized coherent structures discussed by the universal formula (1), such as nonpropagating solitons, dromion, peakon, compaction, foldon, instanton, ghoston, ring soliton, and the interaction between these solitons, can be rederived. Moreover, abundant local excitations with and without completely elastic interaction properties are constructed readily by suitable selecting the arbitrary multivalued functions according the asymptotic result (114). Especially, some novel interactions among special dromion, special peakon, and foldon are investigated both analytically and graphically. The interactions between two special dromions, and between two special peakons, both possess novel properties, that is, there exist a multivalued foldon in the process of their collision, which is different from the reported cases in previous literature. The explicit phase shifts for all the local excitations offered by the common formula have been given, and are applied to these novel interactions in detail.

What we have obtained is also further verification that the ETM is quite useful to generate abundant localized excitations for many models. Besides these systems listed in this paper, we can also obtain the variable separation solutions of $(2+1)$-dimensional Maccari system,[76] $(2+1)$-dimensional nonlinear Schrödinger equation,[77] $(2+1)$-dimensional generalized AKNS system,[78] $(2+1)$-dimensional generalized Burgers system,[79] and $(1+1)$-dimensional Boiti system,[16] and the like. For the limit of length, we do not list them here. It is also known that the DS and the KP equations are the reductions of the self-dual Yang-Mills (SDYM) equation. So both the KP and the SDYM equations may possess quite rich nonlinear excitations with some arbitrary characteristics. The KP equation and $(2+1)$-dimensional Boussinesq equation[80] are other types of important integrable models in the study of integrable models. However, we have not yet found its nontrivial variable separation solutions by ETM. The same cases happen in some known $(1+1)$-dimensional models such as nonlinear Schrödinger equation and KdV, etc. Therefore, how to find the variable separation solutions of these models is an open question. In our future work, we will devote to generalizing this method to these nonlinear systems, the differential-difference equations and other $(3+1)$-dimensional nonlinear systems.

(Received 23 December 2005; accepted 13 February 2006; published online 10 April 2006)

We present a new formulation of the maximum clique problem of a graph in complex space. We start observing that the adjacency matrix A of a graph can always be written in the form $A=B^2$ where B is a complex, symmetric matrix formed by vectors of zero length (null vectors) and the maximum clique problem can be transformed in a geometrical problem for these vectors. This problem, in turn, is translated in spinorial language and we show that each graph uniquely identifies a set of pure spinors, that is vectors of the endomorphism space of Clifford algebras, and the maximum clique problem is formalized in this setting so that, this much studied problem, may take advantage from recent progresses of pure spinor geometry. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2186256]

I. INTRODUCTION

In this paper we propose a new representation of the maximum clique problem in complex space. After a brief review of this famous NP-complete problem, we show how the adjacency matrix of a graph can be expressed as the square of a symmetric complex matrix. The vectors forming this matrix have zero length and Cartan has shown that this geometry can be treated elegantly with spinors. After a brief remind of spinor properties, we show that the adjacency matrix is better decomposed in the Witt basis of complex space. We finish with a formulation of the maximum clique problem in this formalism and show that each graph uniquely identifies a spinor whose properties surely deserve deeper studies.

II. THE MAXIMUM CLIQUE PROBLEM

A. A brief review

Given a graph of size n, a clique is a subgraph with pairwise adjacent vertices and the maximum clique (MC) problem is that of finding the *size k* of the largest clique. It is a well studied NP-complete problem and there are reviews with hundreds references (see, e.g., Refs. 4 and 16).

Given a graph let A be its $n\times n$ adjacency matrix with elements in $\{0,1\}$ and zero diagonal; we will consider only undirected graphs for which A is symmetric. Furthermore, since every undirected graph can be subdivided in connected graphs, we discuss only connected graphs that have irreducible adjacency matrices.

The quadratic form on A ($'$indicates transposition, bold characters, vectors) is bounded by

[a)]Electronic mail: mbh@ts.infn.it
[b)]Electronic mail: fit@ictp.trieste.it

$$0 \leqslant \mathbf{x}' A \mathbf{x} \leqslant 1 - \frac{1}{n} \quad \text{for } \mathbf{x} \in K_n,$$

where the simplex $K_n = \{\mathbf{x} \in \mathbb{R}^n : x_i \geqslant 0 \, \forall \, i \text{ and } \mathbf{e}'\mathbf{x} = 1\}$ and $\mathbf{e}' = (1, 1, \ldots, 1)$.

A subgraph with r vertices is uniquely determined by its characteristic vector that is an n dimensional vector whose ith component, by taking values $1/r$ or 0, indicates whether the ith element belongs or not to the subgraph. Characteristic vectors belong to K_n.

In 1965 Motzkin and Straus[14] proved the following.

Theorem 1: *If the MC of graph A has size k then*

$$\max_{\mathbf{x} \in K_n} \mathbf{x}' A \mathbf{x} = 1 - \frac{1}{k} \tag{1}$$

and if $\mathbf{x}_k$ *is the characteristic vector of a MC then* $\mathbf{x}_k' A \mathbf{x}_k = 1 - 1/k$.

Bomze[3] sharpened this result showing that, if $\mathbb{I}$ represents the identity matrix, $\max_{\mathbf{x} \in K_n} \mathbf{x}' (A + \frac{1}{2}\mathbb{I}) \mathbf{x} = 1 - 1/2k$ and moreover that this quadratic form reaches its maximum *if* and *only if* $\mathbf{x}$ is the characteristic vector of a MC.

With this formulation the, essentially combinatorial, MC problem is transposed to the search of the maximum of a quadratic function in a bounded region: a continuous optimization problem with linear constraints. Several authors[11,15,17] used this formulation to find approximate solutions to the MC problem.

B. Decomposition of the adjacency matrix

Any symmetric matrix like A may be expressed in the form (see Appendix for details)

$$A = B'B = BB = B^2, \tag{2}$$

where B is a complex, symmetric matrix that we can think as formed by n complex column vectors $\mathbf{z}_i \in \mathbb{C}^n$,

$$B = (\mathbf{z}_1, \mathbf{z}_2, \ldots, \mathbf{z}_n), \quad a_{jk} = (B'B)_{jk} = \mathbf{z}_j' \mathbf{z}_k \tag{3}$$

these vectors are called null vectors since they have zero length since $a_{jj} = \mathbf{z}_j^2 = 0$. Let n_0 be the number of zero eigenvalues of A, then rank A = rank $B = n - n_0$ and this is also the dimension of the space V spanned by the vectors $\mathbf{z}$. With B the quadratic form on A becomes

$$\mathbf{x}' A \mathbf{x} = \mathbf{x}' B' B \mathbf{x} = (B\mathbf{x})^2 := \mathbf{Z}^2,$$

where $\mathbf{Z} = B\mathbf{x} = \Sigma_i x_i \mathbf{z}_i \in \mathbb{C}^n$ is a complex vector with which the MC problem may be reformulated and (1) can be written

$$\max_{\mathbf{x} \in K_n} \mathbf{Z}^2 = 1 - \frac{1}{k}$$

this is the problem of finding the vector of maximum length that can be formed by a convex combination of the $\mathbf{z}$'s. In real space this is the problem of finding the point(s) of the convex hull of the $\mathbf{z}$'s with maximum distance from the origin. We remark that $\mathbf{Z}^2$ is real since x_i and $\mathbf{z}_j' \mathbf{z}_k = a_{jk}$ are all real.

C. Another formulation of the maximum clique problem

The MC problem is tightly connected to the problem of the maximum independent set that is the problem of finding the size of the largest subgraph whose vertices are pairwise nonadjacent. Let $\bar{A}$ represent the adjacency matrix of the complementary graph of A, i.e., the graph with the same vertices and complementary edges; if J is the matrix whose elements are all 1 then $\bar{A} = J - \mathbb{I} - A$. It is simple to verify that every subset of vertices of A that forms a clique form also an

independent set of $\bar{A}$ and vice versa. The cliques of A are thus in one to one correspondence to the independent sets of $\bar{A}$ and if $\mathbf{x}_k$ is the characteristic vector of a clique of A then it is also the characteristic vector of an independent set of $\bar{A}$ and $\mathbf{x}_k'\bar{A}\mathbf{x}_k=0$.

There are several ways to formulate the MC problem of A as the problem of the maximum independent set of $\bar{A}$.[13,16] Indicating $\overline{\mathbf{Z}}=\bar{B}\mathbf{x}$ (from now on we use overstriked symbols to indicate quantities relative to $\bar{A}$) a formulation with appealing properties is

$$\max_{\mathbf{x}\in\{\{0,1\}^n:\overline{\mathbf{Z}}^2=0\}} \mathbf{x}'\mathbf{x}=k. \tag{4}$$

This problem has the following geometrical interpretation: the null vectors $\overline{\mathbf{z}}$ span the space $V\subseteq\mathbb{C}^n$ and any couple of linearly independent vectors $\overline{\mathbf{z}}_j$ and $\overline{\mathbf{z}}_k$ span a two-dimensional space contained in V. If $\overline{\mathbf{z}}_j'\overline{\mathbf{z}}_k=\bar{a}_{jk}=0$ it is easy to verify that this space has the property that all of its elements are null vectors and are all mutually orthogonal: this space is called a totally null plane (TNP). If $\bar{A}$ contains at least one nondiagonal zero element, then V contains at least one two-dimensional TNP.

The solution of the MC problem provides the largest subset $\overline{\mathbf{z}}_{j_1},\overline{\mathbf{z}}_{j_2},\ldots,\overline{\mathbf{z}}_{j_k}$ of $\overline{\mathbf{z}}$'s which define a TNP contained in V. We note that, since for any two of them $\overline{\mathbf{z}}_{j_r}'\overline{\mathbf{z}}_{j_s}=\bar{a}_{j_r j_s}=0$, then not only $\Sigma_{l=1,k}\overline{\mathbf{z}}_{j_l}$, but any of their linear combinations

$$\overline{\mathbf{Z}}=\sum\nolimits_{l=1,k} x_{jl}\overline{\mathbf{z}}_{jl}$$

is a particular null vector that satisfy the constraint $\overline{\mathbf{Z}}^2=0$. Since $\mathbb{C}^n$ cannot contain a TNP of more than $n/2$ dimensions[9] this formulation have already been used to calculate an upper bound for the size of the MC.[5]

III. A BRIEF REVIEW OF SPINORS

It was Cartan who first has shown how the geometry of null vectors may be best dealt with in terms of spinors, nowadays defined as vectors of the representation space of Clifford algebras, whose components are equal (up to a sign) to the square root of linear combinations of null vector components (loosely speaking, spinors are square roots of null vectors). He furthermore has shown how Euclidean geometry may be derived from spinor geometry which then could be the fundamental geometry of space-time and of natural phenomena also because it has the property of linearizing tensor equations, like, for example, Dirac equation linearizes Klein-Gordon equation. It is then appropriate to attempt to reformulate the MC problem in spinorial form.

Following Chevalley[10] spinors may be dealt with in the frame of Clifford algebras.[1,7] Given a $2n$ dimensional complex space $\mathbb{C}^{2n}$, with Euclidean quadratic form and the corresponding Clifford algebra $\mathrm{Cl}(2n)$, let $\gamma_1,\gamma_2,\ldots,\gamma_{2n}$ be the generators of $\mathrm{Cl}(2n)$ with the property

$$[\gamma_j,\gamma_k]_+:=\gamma_j\gamma_k+\gamma_k\gamma_j=2\delta_{jk}\mathbb{I},\quad j,k=1,2,\ldots,2n.$$

$\mathrm{Cl}(2n)$ may be conceived as a direct sum of tensor spaces

$$\mathrm{Cl}(2n)=V^{(0)}\oplus V^{(1)}\oplus\cdots\oplus V^{(2n)}$$

and one can identify $V^{(1)}$ as the image of the vector space $\mathbb{C}^{2n}$ simply substituting the anticommutator with a scalar product and the γ_j with the unit vectors $\mathbf{e}_j$ of a standard orthonormal basis of $\mathbb{C}^{2n}$ with coordinates $(\mathbf{e}_j)_k=\delta_{jk}$.

A remark about notation: we indicated usual vectors in bold, so $\mathbf{v}$ represents a proper vector of $\mathbb{C}^{2n}$ while with v we represent the corresponding element of the Clifford algebra $\mathrm{Cl}(2n)$ belonging to tensor space $V^{(1)}$.

A spinor Φ is a vector belonging to the spaces S of endomorphism of $\mathrm{Cl}(2n)=\mathrm{End}\,S$ and is defined by the Cartan's equation,

$$v\Phi = \left(\sum_{j=1}^{2n} v_j \gamma_j\right)\Phi = 0, \tag{5}$$

where v_j are the orthonormal components of v (and also of $\mathbf{v} \in \mathbb{C}^{2n}$) and $v\Phi$ is a Clifford product $v\Phi = v\rfloor\Phi + v\wedge\Phi$.

A. The Witt basis of Cl(2*n*) and the Fock basis of the associated spinor Φ

Let us define the null, or Witt, basis Cl($2n$) as follows:

$$p_j = \tfrac{1}{2}(\gamma_{2j-1} + i\gamma_{2j}) \quad \text{and} \quad q_j = \tfrac{1}{2}(\gamma_{2j-1} - i\gamma_{2j}), \quad j = 1,2,\ldots,n \tag{6}$$

with the properties

$$[p_j,p_k]_+ = [q_j,q_k]_+ = 0 \quad \text{and} \quad [p_j,q_k]_+ = \delta_{jk}\mathbb{I}. \tag{7}$$

With this basis $\mathbb{C}^{2n}$ is easily seen as the direct sum of two maximal TNP P and Q spanned by null vectors $\{\mathbf{p}_j\}$ and $\{\mathbf{q}_j\}$, respectively,

$$\mathbb{C}^{2n} = P \oplus Q,$$

since $P \cap Q = \varnothing$ each vector $\mathbf{v} \in \mathbb{C}^{2n}$ may be expressed in the form $\mathbf{v} = \Sigma_{i=1}^{n}(\alpha_i\mathbf{p}_i + \beta_i\mathbf{q}_i)$ with α_i and β_i arbitrary complex numbers.

A spinor $\Phi \in S$, defined by Cartan equation (5), may be represented by minimal left ideals (MLI) of Cl($2n$).[10] Consider the 2^n MLI that form the Fock basis in spinor space[8]

$$\omega_0 = p_1 p_2 \ldots p_n,$$

$$\omega_1 = q_1\omega_0, \quad \omega_2 = q_2\omega_0, \quad \omega_4 = q_3\omega_0, \quad \ldots, \quad \omega_{2^{n-1}} = q_n\omega_0,$$

$$\omega_3 = q_1 q_2\omega_0, \quad \omega_5 = q_1 q_3\omega_0, \quad \ldots, \tag{8}$$

$$\ldots,$$

$$\omega_{2^n-1} = q_1 q_2 \ldots q_n\omega_0$$

in which the indexes of the q's always appear in ascending order and the interpretation of the 2^n values of the spinor index s of ω_s is immediate thinking of s as of a binary number of n digits where the jth digit from the right, taking the value 1 or 0, indicates wether q_j is present or not in ω_s. Any spinor Φ may be uniquely expressed in terms of the elements of the Fock basis (8),

$$\Phi = \sum_{s=0}^{2^n-1} \xi_s\omega_s, \tag{9}$$

where the ξ_s are the 2^n complex components of the spinor.

B. Cartan equation in the Fock basis

When we write the Cartan equation (5) in the basis, defined in (6) and (9), we get

$$v\Phi = \left(\sum_{i=1}^{n} \alpha_i p_i + \beta_i q_i\right)\left(\sum_{s=0}^{2^n-1} \xi_s \omega_s\right) = 0 \tag{10}$$

and this equation can be read in two ways depending on whether v or Φ plays the role of the unknown. For example, if $\Phi = \xi_0\omega_0$, i.e., $\Phi = (\xi_0, 0, \ldots, 0)$ (the spinor represented by the MLI ω_0 was named standard by Cartan) it becomes

$$\left(\sum_{i=1}^{n} \alpha_i p_i + \beta_i q_i\right)\xi_0\omega_0 = \left(\sum_{i=1}^{n} \alpha_i p_i + \beta_i q_i\right)\xi_0 p_1 p_2 \cdots p_n = 0$$

and, remembering that from (7) we have,

$$p_i p_i = 0 = q_i q_i, \quad p_i q_i = \mathbb{I} - q_i p_i, \tag{11}$$

one easily finds that the equation is satisfied, for $\xi \neq 0$, if, and only if, all the β_i are zero. Moreover the equation holds for every value taken by the α_i, i.e., for every point of the subspace $P = \mathrm{Span}(\mathbf{p}_1, \mathbf{p}_2, \ldots, \mathbf{p}_n)$. It is also simple to work this example the other way round, i.e., given a subspace whose generic vector has the form $\mathbf{v} = \Sigma_{i=1}^{n} x_i \mathbf{p}_i$ one finds that the spinor that satisfies (10) is of the form $\Phi = (\xi_0, 0, \ldots, 0) = \xi_0\omega_0 \ \forall\, \xi_0 \in \mathbb{C}$.

This shows explicitly the correspondence, set up by Cartan equation (10), between spinors and TNP's, in this example between ω_0 and the maximal TNP P of $\mathbb{C}^{2n}$. Similarly one can find that the TNP corresponding to ω_1 is $x_1 q_1 + \Sigma_{i=2}^{n} x_i p_i$ and so on. More generally left-multiplying (10) by v it becomes

$$v^2\Phi = 0$$

showing that v^2 is null for $\Phi \neq 0$ and Eqs. (5) and (10) are linearizations of this relation. Let v' be another solution of $v'\Phi = 0$ for the same Φ, left-multiplying (10) by v' we get

$$v'v\Phi = 0 \quad \text{and similarly} \quad vv'\Phi = 0$$

from which easily derives that

$$[v', v]_+ = 0$$

so v' and v, besides being null, are mutually orthogonal and thus form a TNP.

In general, given a spinor Φ, all the vectors v satisfying (10) are null and mutually orthogonal and define a TNP that we call $M_k(\Phi)$ where $k \leqslant n$ indicates its dimensions. If $k = n$, that is, the dimension of $M_k(\Phi)$ is maximal, the corresponding spinor was called *simple* by Cartan[9] and *pure* by Chevalley,[10] a name now prevailing in the literature. Each one of the 2^n spinors of the Fock basis (8) is pure.

Consequently, from now on, when we indicate with v the solution of $v\Phi = 0$ we actually refer to the entire subspace $M_k(\Phi)$ and not just to one of its vectors.

Pure spinors, as stressed by Cartan, are equivalent, up to a sign, to the corresponding maximal TNP whose null vectors may be bilinearly expressed in terms of them. This equivalence establishes a link between spinors and projective Euclidean geometry (of null vectors) which, being very simple and elegant, might have a crucial role for the explanation of several phenomena in physics. However there is a basic obstacle for setting in evidence this equivalence: while the dimensions of the TNP increase with n, that of the equivalent spinor increase with 2^n and consequently, for large n, their components will have to be subject to $O(2^n)$ constraint relations. In order to overcome this difficulty, Cartan, when discussing the elegant properties and proving the theorems of pure spinor geometry, introduced the concept of standard pure spinors with only one component and therefore not subject to constraint relations.

IV. SPINORIAL FORMULATION OF THE MAXIMUM CLIQUE PROBLEM

We are now ready to give a spinorial formulation of the MC problem and start by introducing the vectors $\overline{\mathbf{z}_i}$ of the matrix $\bar{B}$ defined above, in the Witt basis of $\mathrm{Cl}(2n)$ with the scalar product standing for an anticommutator,

$$\overline{\mathbf{z}_i} = \mathbf{p}_i + \sum_{j=1}^{n} \bar{a}_{ij}\mathbf{q}_j, \quad i = 1,2,\ldots,n.$$

These n vectors have the following properties (immediate to prove):

(i) belong to $\mathbb{C}^{2n}$ and are linearly independent (because of the $\mathbf{p}_i$);
(ii) are null, i.e. $\overline{\mathbf{z}_i}\overline{\mathbf{z}_i}=0$ since $\bar{a}_{ii}=0$;
(iii) satisfy (3) for the complementary matrix, i.e., $\overline{\mathbf{z}_i}\overline{\mathbf{z}_j}=\bar{a}_{ij}$.

In general they span an n dimensional subspace V, which will be partially null. Precisely each $\bar{a}_{ij}=0$ will imply the existence of a two-dimensional TNP in V. V will be totally null only if $\bar{a}_{ij}=0\ \forall ij$ in which case $\overline{\mathbf{z}_i}=\mathbf{p}_i$ and $V=P=\mathrm{Span}(\mathbf{p}_1,\mathbf{p}_2,\ldots,\mathbf{p}_n)$. Differently from (3) now $\bar{B}$ is a $2n\times n$ matrix formed by n linearly independent vectors such that $\bar{A}=\bar{B}'\bar{B}$.

To fully exploit the spinorial formulation we will consider the $\overline{\mathbf{z}_i}$ vectors as representative of the subspace they induce, i.e., $\mathrm{Span}(\mathbf{p}_i,\bar{a}_{i1}\mathbf{q}_1,\ldots,\bar{a}_{in}\mathbf{q}_n)$ of dimension $\Sigma_{j=1}^{n}\bar{a}_{ij}+1$. We do this introducing in the definition arbitrary coefficients α,

$$\overline{\mathbf{z}_i} = \alpha_i\mathbf{p}_i + \sum_{j=1}^{n} \bar{a}_{ij}\alpha_j\mathbf{q}_j, \quad i = 1,2,\ldots,n \tag{12}$$

and we can always get back the representative vectors setting all $\alpha=1$.

The equation $\overline{\mathbf{Z}}^2=0$, representing the constraints of the MC problem in (4), may be linearized formulating the problem in spinorial form:

$$\overline{\mathbf{Z}}\Phi = \bar{B}\mathbf{x}\Phi = \left(\sum_{i=1}^{n} x_i\overline{\mathbf{z}_i}\right)\Phi = 0 \tag{13}$$

or with $\overline{\mathbf{z}_i}$ from (12),

$$\left[\sum_{i=1}^{n} x_i\left(\alpha_i\overline{\mathbf{p}_i} + \sum_{j=1}^{n}\alpha_j\bar{a}_{ij}\mathbf{q}_j\right)\right]\Phi = 0 \tag{14}$$

of the form (10). In this equation, in general, x_i must be interpreted as complex variables, restricted to values in $\{0,1\}$ in the traditional formulation of the MC problem (4).

We thus have a set of n vectors $\overline{\mathbf{z}_i}$ defining an n-dimensional subspace of $\mathbb{C}^{2n}$ and we will look for the spinors Φ that satisfy (13).

A. Some properties of Cartan equation

Before analyzing in detail (14), devoted to graphs, we step back to the general form of Cartan equation (10) and derive some of its properties. First we study the case in which the TNP is not maximal.

Proposition 1: *Given a TNP of dimension $k\leqslant n$, the corresponding spinor Φ, solution of the Cartan equation* (10), *has at least 2^{n-k} nonzero coordinates in the Fock basis.*

Without loss of generality we take $\mathrm{Span}(\mathbf{p}_1,\mathbf{p}_2,\ldots,\mathbf{p}_k)$ as a TNP of dimension k, since given any TNP of dimension k it is always possible, by a proper choice of the basis, make it coincide with $\mathrm{Span}(\mathbf{p}_1,\mathbf{p}_2,\ldots,\mathbf{p}_k)$ (see, e.g, Ref. 8).

We will prove the proposition by induction: we already know that when the TNP is maximal, i.e., of dimension n as in the example in paragraph 3.2, the corresponding spinor can have one component (actually it may have at most two components, see proposition 5 in Ref. 8) and thus satisfies the proposition.

Let us suppose now that we have a TNP of dimension k and that the corresponding spinor Φ has m nonzero components: we will show that when reducing the dimension of the TNP to $k-1$ the new spinor has *at least* $2m$ components. So let us suppose that our spinor Φ has m nonzero components and satisfy

$$\left(\sum_{i=1}^{k} x_i p_i\right)\Phi = \left(\sum_{i=1}^{k-1} x_i p_i + x_k p_k\right)\Phi = 0.$$

Since this relation holds for any value of the x_i it must hold in particular for $x_k=0$ so that we have

$$\left(\sum_{i=1}^{k-1} x_i p_i\right)\Phi = 0$$

from which necessarily derives $p_k\Phi=0$. This implies that q_k does not appear in all the m ω's that are the nonzero components of Φ. Assuming the contrary we could write

$$x_k p_k \sum_s \xi_s \omega_s = x_k p_k \left(\sum_{s\in\{q_k\}} \xi_s \omega_s + \sum_{s\in\{\bar{q}_k\}} \xi_s \omega_s\right) = x_k p_k \sum_{s\in\{q_k\}} \xi_s \omega_s = 0,$$

where by $s\in\{q_k\}$ we indicate the subset of the m values of s such that the term q_k do appear in ω_s and by $s\in\{\bar{q}_k\}$ the complementary subset in which the term q_k do not appear; obviously this second sum vanish when left multiplied by p_k. The generic term of the surviving sum can be easily calculated with (11) and reduces to

$$x_k \sum_{s\in\{q_k\}} \xi_s (-1)^{l_s} (\mathbb{I} - q_k p_k)\omega_{s-2^k} = x_k \sum_{s\in\{q_k\}} \xi_s (-1)^{l_s} \omega_{s-2^k} = 0$$

when q_k is the l_sth of the q's present in ω_s. But this relation cannot hold because it would imply that the components of the Fock basis are linearly dependent (remark that ω_{s-2^k} are all different). Thus we proved that none of the m components of Φ can contain q_k.

Returning to our argument we observe that when we reduce the size of the TNP by 1, setting $x_k\equiv 0$, we have

$$\left(\sum_{i=1}^{k-1} x_i p_i\right)\Phi = 0$$

but also

$$\left(\sum_{i=1}^{k-1} x_i p_i\right)(\Phi + q_k\Phi) = 0$$

and since no component of Φ contains q_k all components of $q_k\Phi$ are different from those of Φ and the spinor $\Phi+q_k\Phi$ has $2m$ nonzero components. This concludes the induction argument proving the proposition. □

An immediate consequence of the arguments of the proof is that Φ relative to $\mathrm{Span}(\mathbf{p}_1,\mathbf{p}_2,\ldots,\mathbf{p}_k)$ cannot have components with any of the $\{q_1,q_2,\ldots,q_k\}$. This allows us to write Φ explicitly: its components are all and only the 2^{n-k} not containing any element of $\{q_1,q_2,\ldots,q_k\}$. This generalizes easily to the case of a TNP of size k of the more general form

$$\left(\sum_i x_i p_i + \sum_j x_j q_j\right)\Phi = 0$$

the corresponding spinor components are all and only the 2^{n-k} components not containing any element of $\{q_i\}$ and containing all of the elements of $\{q_j\}$.

We now consider the more general case of a TNP formed by the span of k null vectors v and show a way to express the corresponding spinor.

Proposition 2: *Given a TNP* $V=Span(v_1,\ldots,v_k)$, *of dimension* k, *the corresponding spinor* $\Phi(v_1,\ldots,v_k)$, *satisfying the Cartan equation* (10), *can be calculated with*

$$\Phi(v_1,\ldots,v_k) = v_1\cdots v_k\Phi(\mathbb{I}), \tag{15}$$

where with $\Phi(\mathbb{I})$ *we represent the most general spinor* (9) *expressed in the Fock basis.*

We start by proving the simpler case in which there is just one vector and moreover this vector coincides with one of the basis, i.e., $v=p_j$ and we prove that

$$\Phi(p_j) = p_j\Phi(\mathbb{I}).$$

To calculate $p_j\Phi(\mathbb{I})$, as in the previous proof, we split the sum over the Fock basis into two parts and get

$$p_j\Phi(\mathbb{I}) = p_j\sum_{s\in\{q_j\}}\xi_s\omega_s + p_j\sum_{s\in\{\bar{q}_j\}}\xi_s\omega_s = p_j\sum_{s\in\{q_j\}}\xi_s\omega_s$$

$$= \sum_{s\in\{q_j\}}\xi_s(-1)^{l_s}(\mathbb{I}-q_jp_j)\omega_{s-2^j} = \sum_{s\in\{q_j\}}\xi_s(-1)^{l_s}\omega_{s-2^j}$$

$$= \sum_{s\in\{\bar{q}_j\}}\xi_{s+2^j}(-1)^{l_{s+2^j}}\omega_s$$

that show that $p_j\Phi(\mathbb{I})$ obviously satisfy $p_j\Phi(p_j)=0$ and has for components the 2^{n-1} in which q_j do not appear in ω_s and thus, given the arbitrary values of the coefficients ξ_s, represents the most general expression for $\Phi(p_j)$, as shown in Proposition 1.

To prove the general proposition we proceed by induction and first extend the proof to a more general null vector $v_1=\Sigma_i\alpha_ip_i+\Sigma_j\beta_jq_j$,

$$\Phi(v_1) = v_1\Phi(\mathbb{I}) = \sum_i \alpha_i\Phi(p_i) + \sum_j \beta_j\Phi(q_j)$$

and

$$v_1\Phi(v_1) = v_1^2\Phi(\mathbb{I}) = 0$$

since, by hypothesis, v_1 is null. Now suppose that we already have

$$\Phi(v_1,\ldots,v_{j-1}) = v_1\cdots v_{j-1}\Phi(\mathbb{I})$$

and we add v_j that form a TNP with previous vectors, we have

$$\left(x_jv_j + \sum_{i=1}^{j-1} x_iv_i\right)v_j\Phi(v_1,\ldots,v_{j-1}) = -v_j\left(\sum_{i=1}^{j-1} x_iv_i\right)\Phi(v_1,\ldots,v_{j-1}) = 0,$$

where we have used the relations $v_j^2=0$ and $v_iv_j=-v_jv_i$ for $i<j$ deriving from the hypothesis that the v's form a TNP. This completes the proof showing also that the order of multiplication of v's in (15) is irrelevant since it can only affect the global sign of the sign of the spinor. □

We conclude with the general case.

Proposition 3: *Given* $V:=Span(v_1,\ldots,v_k)$, *there exists a spinor* Φ, *satisfying the Cartan equation for all values of the coefficients* $x_1,\ldots,x_k$,

$$\left(\sum_{i=1}^{k} x_i v_i\right)\Phi = 0$$

if, and only if, V is a TNP.

To prove it let us suppose the contrary, i.e., that there exists a non-null vector v and $\Phi \neq 0$ satisfying Cartan equation; left-multiplying by v we would get

$$v^2\Phi = 0$$

but since $v^2 \neq 0$ this implies $\Phi=0$ contradicting the initial hypothesis. On the other hand, for any null vector v the spinor $\Phi(v)=v\Phi(\mathbb{I})$ satisfies the Cartan equation since $v\Phi(v)=v^2\Phi(\mathbb{I})=0$. □

B. Back to the graph maximum clique problem

We get back to our form of Cartan equation (14) with an example: let us suppose that $\bar{a}_{12}=0$, this means that $\overline{\mathbf{z}}_1$ and $\overline{\mathbf{z}}_2$ form a TNP and, setting $x_3=x_4=\cdots=x_n=0$, with (12) and Proposition 2 we get

$$(x_1\overline{\mathbf{z}}_1 + x_2\overline{\mathbf{z}}_2)\Phi(\overline{\mathbf{z}}_1\overline{\mathbf{z}}_2) = (x_1\overline{\mathbf{z}}_1 + x_2\overline{\mathbf{z}}_2)\mathbf{p}_1\mathbf{p}_2\cdots\mathbf{q}_i\cdots\Phi(\mathbb{I}) = 0,$$

where with the notation $\cdots\mathbf{q}_i\cdots$ we indicate all different $\mathbf{q}_i$ that appear in $\overline{\mathbf{z}}_1$ and $\overline{\mathbf{z}}_2$. This example shows that it is simple to get particular solutions to (14) the real problem being to find the *set of all solutions*, for which we have the following.

Proposition 4: *The set of nonzero spinors that solve the Cartan equation* (14) *is isomorphic to the set of cliques of A.*

Given a solution of (14) with $\Phi \neq 0$ we will have corresponding values for the coefficients $x_1,\ldots,x_n$. For all $x_i \neq 0$ we can redefine the arbitrary α coefficients in (14) so that $x_i=1$ and the solution can be written in the form $x_i \in \{0,1\}$. The $\overline{\mathbf{z}}_i$ corresponding to $x_i=1$ form necessarily a clique since for any couple of them their scalar product is null. Vice versa given a clique $\overline{\mathbf{z}}_{i_1},\ldots,\overline{\mathbf{z}}_{i_k}$ the corresponding coefficients $x_i \in \{0,1\}$ and the corresponding spinor $\Phi(\overline{\mathbf{z}}_{i_1},\ldots,\overline{\mathbf{z}}_{i_k})$ satisfy the Cartan equation. □

We can now reformulate our initial MC problem (4): it will correspond to that solution of (14) with the maximum intersection with P, i.e.,

$$k = \max_{\Phi:\left(\sum_{i=1}^{n} x_i\bar{z}_i\right)\Phi=0} \dim(P \cap M(\Phi)). \tag{16}$$

This shows also that the problem of finding all possible spinor solutions of (14) is NP complete since, given the set of all solutions, one gets also the solution of the MC problem. With respect to the MC formulation (4) we remark two main differences: the first is that the demanding restriction $\mathbf{x} \in \{0,1\}^n$ can be relaxed since all solutions of (14) necessarily have binary x_i. The second is that the quadratic constraint $\overline{\mathbf{Z}}^2=0$ of (4) is linearized here to $\overline{\mathbf{Z}}\Phi=0$.

C. Definition of the spinor $\Psi(\bar{A})$ corresponding to graph *A*

Even if we cannot determine in general the set of all solutions to our problem (that would mean solving an NP-complete problem) we can try to better characterize the set of spinors satisfying (14). Let us define a null vector $\overline{\mathbf{Z}}_k$, sum of k vectors $\overline{\mathbf{z}}_i$,

$$\overline{\mathbf{Z}}_k = \overline{\mathbf{z}}_{j_1} + \overline{\mathbf{z}}_{j_2} + \cdots + \overline{\mathbf{z}}_{j_k} = \mathrm{Span}(\mathbf{p}_{j_1},\mathbf{p}_{j_2},\ldots,\mathbf{p}_{j_k},\ldots,\mathbf{q}_i\ldots).$$

as *saturated* if it is null and if no other $\overline{\mathbf{z}}_i$ can be added to it without destroying its nullness. In

other words $\overline{\mathbf{Z}}_k$ is saturated if, in its expression, appear exactly n of the $\mathbf{p}_i$ and $\mathbf{q}_i$ vectors all with different indexes. A clique is said to be *maximal* if no other vertex can be added obtaining a new clique (obviously a maximum clique is also maximal). We show that the concepts are identical.

Proposition 5: *The set of saturated vectors formed with the* $\overline{\mathbf{z}}_i$ *is isomorphic to that of the maximal cliques of the corresponding graph.*

Let us suppose that the null vector $\overline{\mathbf{Z}}_k$ is saturated, obviously the set of its $\mathbf{p}_{j_i}$ vectors uniquely identify a subgraph. From its nullness we have $\overline{\mathbf{z}}_{j_i}^{\dagger}\overline{\mathbf{z}}_{j_l}=\bar{a}_{j_i j_l}=0$ for every $j_i j_l$ and the identified subgraph is a clique. To prove that this clique is also maximal let us suppose the contrary, i.e., that the vertex j_{k+1} can be added to it obtaining a larger clique. Then we would necessarily have $\bar{a}_{j_i j_{k+1}}=0$ for all j_i that would mean that the vector $\mathbf{q}_{j_{k+1}}$ would be missing from $\overline{\mathbf{Z}}_k$ violating the hypothesis that $\overline{\mathbf{Z}}_k$ is saturated.

To prove the second part of the proposition let us suppose that we have a maximal clique identified by a vector $\mathbf{x}_k \in \{0,1\}^n$; the vector $\overline{\mathbf{Z}}_k=\bar{B}\mathbf{x}_k$ is null since $0=\bar{a}_{j_i j_l}=\overline{\mathbf{z}}_{j_i}^{\dagger}\overline{\mathbf{z}}_{j_l}$ for every $j_i j_l$. Also $n-k$ of the $\mathbf{q}_i$ appear in it otherwise, as in the preceding part, one can easily contradict the hypothesis that the starting clique is maximal. It follows that $\overline{\mathbf{Z}}_k$ is saturated. □

Each saturated vector $\overline{\mathbf{Z}}_k$, made up by k $\overline{\mathbf{z}}_i$'s, can be thought of as a k-dimensional TNP (remember $\overline{\mathbf{z}}_i$'s are linearly independent) but also, using the more general definition (12), one can use the $\mathbf{p}$'s and $\mathbf{q}$'s that appear in $\overline{\mathbf{Z}}_k$ to build a maximal TNP whose spinor is pure and given by

$$\Phi(\overline{\mathbf{Z}}_k)=\mathbf{p}_{j_1}\cdots\mathbf{p}_{j_k}\cdots\mathbf{q}\cdots\Phi(\mathbb{I}):=\omega_{\bar{Z}_k} \tag{17}$$

so that each saturated vector uniquely identifies one of the pure spinors of the Fock basis (8). Thus, in our formulation, every maximal clique corresponds to a saturated vector $\overline{\mathbf{Z}}_k$ which in turn identifies one of the components of the Fock basis (8).

We remark that the $M(\Phi(\bar{Z}_k))$ has dimension n and the set of the $\mathbf{p}_i$ of $\overline{\mathbf{Z}}_k$ always allow to indicate unambiguously the maximal clique associated with it. In other words, each maximal TNP $M(\Phi(\bar{Z}_k))$ contain one and only one of the saturated vectors and thus just one maximal clique.

We show now the equivalence of the formulation of the Cartan equation.

Proposition 6: *Given a set of* x_{j_i} *that give a solution of the Cartan equation* (14) *and calling* $\overline{\mathbf{Z}}_1,\ldots,\overline{\mathbf{Z}}_p$ *all the saturated vectors such that each of them contains all the* $\overline{\mathbf{z}}_{j_i}$ *we are considering, then*

$$\left(\sum_{i=1}^{k} x_{j_i}\overline{\mathbf{z}}_{j_i}\right)\left(\sum_{l=1}^{p}\Phi(\overline{\mathbf{Z}}_l)\right)=0.$$

First of all we observe that $p\geqslant 1$ since the set of $\overline{\mathbf{z}}_{j_i}$ form a TNP and are thus contained in at least one maximal clique how shown in the constructive proof of Proposition 7. By (17) all $\Phi(\overline{\mathbf{Z}}_l)$ contain all the $\overline{\mathbf{z}}_{j_i}$ of the first sum and the proposition is proved. □

Since, as we prove in the Appendix, each graph is uniquely identified by the set of its maximal cliques it is possible to define uniquely a spinor $\Psi(\bar{A})$ associated to a given graph A: the set of all its maximal cliques defines uniquely a set of saturated vectors $\{\overline{\mathbf{Z}}_l\}$. This set defines in turn a corresponding set $\{\omega_{\mathbf{Z}_l}\}$ in the Fock basis and therefore also a spinor $\Psi(\bar{A})$ of the form (9) uniquely defined by $\bar{A}$,

$$\Psi(\bar{A})=\sum_l \xi_l\Phi(\overline{\mathbf{Z}}_l)=\sum_l \xi_l\omega_{\overline{\mathbf{Z}}_l}. \tag{18}$$

We note that in this formulations not all components are different from zero for all the values of the x_i and we can render explicit this characteristic adding to each components a product of

Kronecker delta that set it to zero when one of the components having positive scalar products with one of the $\overline{\mathbf{Z}}_l$ is present so, calling Q_l the set of the indices of q_i appearing in $\overline{\mathbf{Z}}_l$, we get:

$$\Psi(\bar{A}) = \sum_l \xi_l \omega_{\overline{\mathbf{Z}}_l} \Delta(l, x_1, x_2, \ldots, x_n)$$

with

$$\Delta(l, x_1, x_2, \ldots, x_n) = \prod_{j \in Q_l} \delta_{x_j, 0}$$

and with this definition we can now rewrite (13) as

$$\left(\sum_{i=1}^{n} x_i \overline{\mathbf{z}}_i \right) \Psi(\bar{A}) = 0.$$

For example, if $\bar{A}=0$, $\Psi(\bar{A})=\omega_0$ while for $\bar{A}=J-\mathbb{I}$, $\Psi(\bar{A})=\xi_1\omega_1+\xi_2\omega_2+\xi_4\omega_4+\ldots+\xi_{2^{n-1}}\omega_{2^{n-1}}$. In general $\Psi(\bar{A})$ will have a number of nonzero components lower than 2^n but there exist graphs with an exponential number of maximal cliques.

While $\bar{A}$ uniquely determines $\Psi(\bar{A})$, not every spinor may be conceived as generated by a graph. As an example a spinor $\Psi(\bar{A})$ may not obviously contain components in $\{\omega_1, \omega_3, \omega_7, \ldots\}$. The spinors $\Psi(\bar{A})$ generated by graphs build up a subclass of spinors whose properties should be further analyzed and they will be certainly interesting also for other fields of application of pure spinor geometry, one can conjecture that they fall in the class of generalized spinors studied in Ref. 18.

V. CONCLUSIONS

Spinors were discovered by Cartan in 1913 and soon after introduced in physics for the representation of the electron (and fermions) by Dirac and Weyl. However the geometry of pure spinors was practically ignored after the publication of Chevalley book in 1954.[10] The main motivation is that general spinors are too difficult to deal with because of the exponentially many constraint relations, for large n.

However now, after 50 years, the scenario may change and pure spinors might attract the attention of both theoretical physicists and mathematicians. The main reason of this change is that theoretical physics, since several decades, is facing insormountable difficulties in some of its central sectors like the quantization of the gravitational field or the explanation of some aspects of elementary particles phenomenology (origin of charges, families, etc.). Recently, pure spinors have been discovered to allow to overcome, somehow miraculously, some of these difficulties[2] and to allow to shed some light on some aspects of the obscure phenomenology of elementary particles.[6]

As shown by Cartan the geometry of pure spinors is correlated to that of null vectors and totally null planes, and shares the elegance and simplicity of projective geometry. We have shown that null vectors and TNP are deeply connected to graphs and formulating the MC problem in spinorial language establishes a bridge between these two worlds that, we hope, will allow to cross-fertilize both the fields. If and when, the certainly rich and elegant geometry of the pure spinors will be better known, it might contribute also to the MC problem, once this is formulated in the frame of that geometry, as proposed here.

In this paper, establishing a correspondence between totally null planes and maximal cliques, we have been able to reformulate neatly (16) the maximum clique problem and to define spinors corresponding to graphs (18). Another interesting aspect, which emerges already in this preliminary approach, is that the pure spinor defined by graphs might belong to a subclass less prone to constraint relations.

APPENDIX

Any symmetric matrix like A may be expressed as $A=B^2$ where B is a complex symmetric matrix. Since A is symmetric its eigenvalues are real and it can be diagonalized $A=O'\Lambda O$ with $O'O=OO'=\mathbb{I}$ where Λ is the diagonal matrix of the eigenvalues λ_i and O' is the orthogonal, real, matrix of the eigenvectors. Then, as it is easy to verify, a possible definition of the "square root" of A is $B=O'\sqrt{\Lambda}O$ where $\sqrt{\Lambda}$ is the diagonal matrix whose elements are the square roots of the eigenvalues of A.[12]

We observe that, unless A is semipositive definite ($\lambda_i \geqslant 0$), B is complex and the choice of the signs of the diagonal elements of $\sqrt{\Lambda}$ is arbitrary so, in general, there are at least 2^n different possible B satisfying (2): Moreover when A has multiple eigenvalues, there are infinitely many possible choices of the corresponding eigenvectors, and there are, accordingly, infinitely many possible choices for B.

We conclude by proving the following.

Proposition 7: *Each graph is uniquely identified by the set of its maximal cliques.*

To prove this assertion we provide a constructive algorithm to build A from the set of its maximal cliques. One starts from $A=0$ and add to it (in a Boolean logic fashion) all the links of each maximal clique; it is sufficient to add only the links between the nodes of a maximal clique and these links are all known, since one knows the subset of vertices that forms a maximal clique. This procedure brings to the adjacency matrix of the graph since each link appears in at least one of the maximal cliques. This last statement is proved observing that each maximal clique can be built starting from any link, and the corresponding two nodes, and adding to them, one at the time, other fully connected nodes. This proves that any link must appear in at least one maximal clique and thus the proposition. □

A formula for the first eigenvalue of the Dirac operator on compact spin symmetric spaces

Jean-Louis Milhorat[a)]
Laboratoire Jean Leray, UMR CNRS 6629, Département de Mathématiques, Université de Nantes, 2, Rue de la Houssinière, BP 92208, F-44322 Nantes Cedex 03, France

(Received 5 September 2005; accepted 22 February 2006; published online 12 April 2006)

Let G/K be a simply connected spin compact inner irreducible symmetric space, endowed with the metric induced by the Killing form of G sign-changed. We give a formula for the square of the first eigenvalue of the Dirac operator in terms of a root system of G. As an example of application, we give the list of the first eigenvalues for the spin compact irreducible symmetric spaces endowed with a quaternion-Kähler structure. © *2006 American Institute of Physics.*

I. INTRODUCTION

Let G/K be a compact, simply connected, n-dimensional irreducible symmetric space with G compact and simply connected, endowed with the metric induced by the Killing form of G sign-changed. Assume that G and K have the same rank and that G/K has a spin structure. Let T be a common maximal torus of G and K, and let β_k, $k=1,\ldots,p$, be the K-dominant weights with respect to T, occurring in the decomposition into irreducible components of the spin representation under the action of K. In a previous paper, cf. Ref. 9, we proved that the first eigenvalue λ of the Dirac operator verifies

$$\lambda^2 = 2 \min_{1\leqslant k\leqslant p} \|\beta_k\|^2 + n/8, \tag{1}$$

where $\|\cdot\|$ is the norm associated to the scalar product induced by the Killing form of G sign-changed.

The proof was based on a lemma of Parthasarathy in Ref. 10 which allows to express the result in the following way.

Let Φ be the set of nonzero roots of G with respect to T. Let Φ_G^+ be the set of positive roots of G, Φ_K^+ be the set of positive roots of K, with respect to a fixed lexicographic ordering in Φ. Let δ_G (respectively, δ_K) be the half-sum of the positive roots of G (respectively, K). Then the square of the first eigenvalue of the Dirac operator is given by

$$\lambda^2 = 2\min_{w\in W}\|w\cdot\delta_G - \delta_K\|^2 + n/8, \tag{2}$$

where W is the subset of the Weyl group W_G defined by

$$W := \{w \in W_G; w\cdot\Phi_G^+ \supset \Phi_K^+\}. \tag{3}$$

In order to avoid the determination of the subset W for applications, we prove in the following that the square of the first eigenvalue of the Dirac operator is indeed given by

SU_{m+2}	$S(\mathrm{U}_m \times \mathrm{U}_2)$	Grassmannian $\mathrm{Gr}_2(\mathbb{C}^{m+2})$	$4m(m \geqslant 1)$	iff m even unique in that case
Spin_{m+4}	$\mathrm{Spin}_m\mathrm{Spin}_4$	Grassmannian $\widetilde{\mathrm{Gr}}_4(\mathbb{R}^{m+4})$	$4m(m \geqslant 3)$	iff m even, unique in that case
G_2	SO_4		8	Yes (unique)
F_4	$\mathrm{Sp}_3\mathrm{SU}_2$		28	No
E_6	$\mathrm{SU}_6\mathrm{SU}_2$		40	Yes (unique)
E_7	$\mathrm{Spin}_{12}\mathrm{SU}_2$		64	Yes (unique)
E_8	$E_7\mathrm{SU}_2$		112	Yes (unique)

$$\lambda^2 = 2 \min_{w \in W_G} \|w \cdot \delta_G - \delta_K\|^2 + n/8. \tag{4}$$

We then give a different expression to use the formula for explicit computations. We obtain

$$\lambda^2 = 2\|\delta_G - \delta_K\|^2 + 4 \sum_{\theta \in \Lambda} \langle \theta, \delta_K \rangle + n/8, \tag{5}$$

where Λ is the set

$$\Lambda := \{\theta \in \Phi_G^+; \langle \theta, \delta_K \rangle < 0\}.$$

As an example of application of the above formula, we obtain the list of the first eigenvalues of the Dirac operator for the spin compact irreducible symmetric spaces endowed with a quaternion-Kähler structure. By definition, a Riemannian manifold has a quaternion-Kähler structure if its holonomy group is contained in the group $\mathrm{Sp}_m\mathrm{Sp}_1$. In Ref. 13, Wolf gave the classification of compact quaternion-Kähler symmetric spaces (see Table I).

Note furthermore that all the symmetric spaces in Table I are "inner."

Endowing each symmetric space with the metric induced by the Killing form of G sign-changed, we obtain Table II.

The result was already known for quaternionic projective spaces $\mathbb{H}P^n$,[7] for the Grassmannians $\mathrm{Gr}_2(\mathbb{C}^{m+2})$,[8] and for the symmetric space G_2/SO_4.[11] To our knowledge, the other results are new.

TABLE II. First Eigenvalue of the Dirac Operator on Spin Compact Quaternion-Kähler Symmetric Spaces

G/K	Square of the first eigenvalue of D
$\mathbb{H}P^n = \mathrm{Sp}_{m+1}/(\mathrm{Sp}_m \times \mathrm{Sp}_1)$	$(m+3/m+2)(m/2) = (m+3/m+2)(\mathrm{Scal}/4)$
$\mathrm{Gr}_2(\mathbb{C}^{m+2}) = \mathrm{SU}_{m+2}/S(\mathrm{U}_m \times \mathrm{U}_2)$ (m even)	$(m+4/m+2)(m/2) = (m+4/m+2)(\mathrm{Scal}/4)$
$\widetilde{\mathrm{Gr}}_4(\mathbb{R}^{m+4}) = \mathrm{Spin}_{m+4}/\mathrm{Spin}_m\mathrm{Spin}_4$ (m even)	$[(m^2+6m-4)/m(m+2)](m/2) = [(m^2+6m-4)/m(m+2)](\mathrm{Scal}/4)$
G_2/SO_4	$3/2 = (3/2)(\mathrm{Scal}/4)$
$E_6/(\mathrm{SU}_6\mathrm{SU}_2)$	$41/6 = (41/30)(\mathrm{Scal}/4)$
$E_7/(\mathrm{Spin}_{12}\mathrm{SU}_2)$	$95/9 = (95/72)(\mathrm{Scal}/4)$
$E_8/(E_7\mathrm{SU}_2)$	$269/15 = (269/210)(\mathrm{Scal}/4)$

II. PROOF OF FORMULA (4)

With the notations of the introduction, and since the scalar product is W_G-invariant, one has for any $w \in W_G$,

$$\|w \cdot \delta_G - \delta_K\|^2 = \|\delta_G\|^2 + \|\delta_K\|^2 - 2\langle w \cdot \delta_G, \delta_K\rangle, \tag{6}$$

hence

$$\min_{w \in W} \|w \cdot \delta_G - \delta_K\|^2 = \|\delta_G\|^2 + \|\delta_K\|^2 - 2\max_{w \in W} \langle w \cdot \delta_G, \delta_K\rangle$$

and

$$\min_{w \in W_G} \|w \cdot \delta_G - \delta_K\|^2 = \|\delta_G\|^2 + \|\delta_K\|^2 - 2 \max_{w \in W_G} \langle w \cdot \delta_G, \delta_K\rangle.$$

So we must prove that

$$\max_{w \in W} \langle w \cdot \delta_G, \delta_K\rangle = \max_{w \in W_G} \langle w \cdot \delta_G, \delta_K\rangle. \tag{7}$$

Let

$$\Pi_G := \{\theta_1, \ldots, \theta_r\} \subset \Phi_G^+, \tag{8}$$

be the set of G-simple roots and let

$$\Pi_K := \{\theta'_1, \ldots, \theta'_l\} \subset \Phi_K^+, \tag{9}$$

be the set of K-simple roots.

Let $w_0 \in W_G$ such that

$$\langle w_0 \cdot \delta_G, \delta_K\rangle = \max_{w \in W_G} \langle w \cdot \delta_G, \delta_K\rangle. \tag{10}$$

Suppose that $w_0 \notin W$. Then we claim that there exists a K-simple root θ'_i such that $w_0^{-1} \cdot \theta'_i \notin \Phi_G^+$. Otherwise, if for any K-simple root θ'_i, $w_0^{-1} \cdot \theta'_i \in \Phi_G^+$, then since any K-positive root is a linear combination with non-negative coefficients of K-simple roots, we would have $\forall \theta' \in \Phi_K^+$, $w_0^{-1} \cdot \theta' \in \Phi_G^+$, contradicting the assumption made on w_0.

Now let σ'_i be the reflection across the hyperplane ${\theta'_i}^{\perp}$. Since $\sigma'_i \cdot \delta_K = \delta_K - \theta'_i$, (cf. for instance Corollary of Lemma B, Sec. 10.3 in Ref. 6), one gets by the W_G-invariance of the scalar product

$$\begin{aligned}\langle \sigma'_i w_0 \cdot \delta_G, \delta_K\rangle &= \langle w_0 \cdot \delta_G, \sigma'_i \cdot \delta_K\rangle = \langle w_0 \cdot \delta_G, \delta_K - \theta'_i\rangle \\ &= \langle w_0 \cdot \delta_G, \delta_K\rangle - \langle \delta_G, w_0^{-1} \cdot \theta'_i\rangle.\end{aligned}$$

But since $w_0^{-1} \cdot \theta'_i$ is a negative root of G, one has

$$w_0^{-1} \cdot \theta'_i = -\sum k_j \theta_j, \quad k_j \in \mathbb{N}.$$

Since for any G-simple root θ_j, $\sigma_j \cdot \delta_G = \delta_G - \theta_j$, where σ_j is the reflection across the hyperplane $\theta_j^{\perp}$, one has $\langle \theta_j, \delta_G\rangle = 2\langle \theta_j, \theta_j\rangle > 0$, so

$$-\langle \delta_G, w_0^{-1} \cdot \theta'_i\rangle = \sum k_j \langle \delta_G, \theta_j\rangle > 0,$$

hence

$$\langle \sigma'_i w_0 \cdot \delta_G, \delta_K\rangle > \langle w_0 \cdot \delta_G, \delta_K\rangle,$$

but that is in contradiction with the definition (10) of w_0, hence $w_0 \in W$ and

$$\max_{w\in W_G}\langle w\cdot\delta_G,\delta_K\rangle=\langle w_0\cdot\delta_G,\delta_K\rangle\leqslant\max_{w\in W}\langle w\cdot\delta_G,\delta_K\rangle\leqslant\max_{w\in W_G}\langle w\cdot\delta_G,\delta_K\rangle,$$

hence the result.

III. PROOF OF FORMULA (5)

In order to obtain the formula we will use the following result.

Lemma 3.1: *For any element w of the Weyl group* W_G,

$$w\cdot\delta_G=\delta_G-\sum_{\theta\in\Phi_G^+}k_\theta\theta,\quad k_\theta=0\ or\ 1.$$

Proof: Let $w\in W_G$. With the same notations as in the above proof, we write w in reduced form

$$w=\sigma_{i_1}\cdots\sigma_{i_k},\tag{11}$$

where σ_i is the reflection across the hyperplane $\theta_i^\perp$, $\theta_i\in\Pi_G$, and k is minimal.

Since $\sigma_{i_k}\cdot\delta_G=\delta_G-\theta_{i_k}$, one has

$$w\cdot\delta_G=\sigma_{i_1}\cdots\sigma_{i_{k-1}}(\sigma_{i_k}\cdot\delta_G)=\sigma_{i_1}\cdots\sigma_{i_{k-1}}(\delta_G)-\sigma_{i_1}\cdots\sigma_{i_{k-1}}(\theta_{i_k}).$$

Now, since the expression of w is reduced, $w(\theta_{i_k})$ is a negative root, cf. for instance corollary of Lemma C, Sec. 10.3 in Ref. 6. But $w(\theta_{i_k})=-\sigma_{i_1}\cdots\sigma_{i_{k-1}}(\theta_{i_k})$, hence $\sigma_{i_1}\cdots\sigma_{i_{k-1}}(\theta_{i_k})$ is a positive root.

Now the element $\sigma_{i_1}\cdots\sigma_{i_{k-1}}\in W_G$ is written in reduced form, otherwise the expression (11) of w would not be reduced. Hence we may conclude as above that

$$\sigma_{i_1}\cdots\sigma_{i_{k-1}}(\delta_G)=\sigma_{i_1}\cdots\sigma_{i_{k-2}}(\delta_G)-\sigma_{i_1}\cdots\sigma_{i_{k-2}}(\theta_{i_{k-1}}),$$

where $\sigma_{i_1}\cdots\sigma_{i_{k-2}}(\theta_{i_{k-1}})$ is a positive root.

Proceeding inductively we get

$$w\cdot\delta_G=\delta_G-\sum_{\theta\in\Phi_G^+}k_\theta\theta,\quad k_\theta\in\mathbb{N}.$$

In order to conclude, we must prove that if a G-positive root θ appears in the above sum, then it appears only once.

Suppose that a G-positive root appears at least twice in the above sum, then there exist two integers p and q, $1\leqslant p<q\leqslant k-1$ such that

$$\sigma_{i_1}\cdots\sigma_{i_p}(\theta_{i_{p+1}})=\sigma_{i_1}\cdots\sigma_{i_q}(\theta_{i_{q+1}})$$

applying $\sigma_{i_{p+1}}\sigma_{i_p}\cdots\sigma_{i_1}$ to the two members of the above equation, we get

$$-\theta_{i_{p+1}}=\sigma_{i_{p+2}}\cdots\sigma_{i_q}(\theta_{i_{q+1}})\quad\text{if } p+1<q,$$

$$-\theta_{i_q}=\theta_{i_{q+1}}\quad\text{if } p+1=q.$$

So we get a contradiction, even in the first case, since $\sigma_{i_{p+2}}\cdots\sigma_{i_q}\sigma_{i_{q+1}}\in W_G$ is expressed in reduced form [otherwise the expression (11) of w would not be reduced], hence $\sigma_{i_{p+2}}\cdots\sigma_{i_q}(\theta_{i_{q+1}})$ is a positive root. □

From the above result we deduce the following.

Lemma 3.2: *Let* Λ *be the set*

$$\Lambda:=\{\theta\in\Phi_G^+;\langle\theta,\delta_K\rangle<0\}.\tag{12}$$

One has

$$\max_{w \in W_G} \langle w \cdot \delta_G, \delta_K \rangle = \langle \delta_G, \delta_K \rangle - \sum_{\theta \in \Lambda} \langle \theta, \delta_K \rangle,$$

(setting $\Sigma_{\theta \in \Lambda} \langle \theta, \delta_K \rangle = 0$, *if* $\Lambda = \emptyset$*).*

Proof: Suppose $\Lambda \neq \emptyset$. We first prove that there exists $w_0 \in W_G$ such that

$$w_0 \cdot \delta_G = \delta_G - \sum_{\theta \in \Lambda} \theta.$$

Let

$$\Phi_n^+ := \Phi_G^+ \setminus \Phi_K^+.$$

We first remark that any root in Λ belongs to Φ_n^+. Otherwise, if there exists $\theta \in \Lambda \cap \Phi_K^+$, then since θ is a combination with non-negative coefficients of simple K-roots, and since $\langle \delta_K, \theta_i' \rangle > 0$, for any K-simple root θ_i', we would have $\langle \delta_K, \theta \rangle \geqslant 0$, contradicting the fact that $\theta \in \Lambda$.

Now, consider

$$\delta_n := \frac{1}{2} \sum_{\theta \in \Phi_n^+} \theta = \delta_G - \delta_K.$$

Then

$$\delta_G - \sum_{\theta \in \Lambda} \theta = \delta_K + \left(\delta_n - \sum_{\theta \in \Lambda} \theta \right).$$

But,

$$\beta := \delta_n - \sum_{\theta \in \Lambda} \theta,$$

is a weight of the decomposition of the spin representation under the action of K, cf. Sec. 2 in Ref. 10: the weights are just the elements of the form $\delta_n - \Sigma_{\theta \in \Upsilon} \theta$, where Υ is a subset of Φ_n^+.

In fact β is the highest weight of an irreducible component in the decomposition, otherwise we would have

$$\beta + \alpha = \delta_n - \sum_{\theta \in \Upsilon} \theta,$$

where α is a K-positive root and Υ is a subset of Φ_n^+.

Hence setting $\Lambda' := \Lambda \setminus \Upsilon$ and $\Upsilon' := \Upsilon \setminus \Lambda$, we would have

$$-\sum_{\theta \in \Lambda'} \theta + \alpha = -\sum_{\theta \in \Upsilon'} \theta.$$

But since $\Lambda' \subset \Lambda$ and α is a K-positive root,

$$\langle -\sum_{\theta \in \Lambda'} \theta + \alpha, \delta_K \rangle > 0,$$

whereas since $\Upsilon' \subset \Phi_n^+ \setminus \Lambda$,

$$\langle -\sum_{\theta \in \Upsilon'} \theta, \delta_K \rangle \leqslant 0,$$

hence a contradiction.

Now by the result of Lemma 2.2 in Ref. 10, any highest weight in the decomposition of the spin representation has the form

$$w \cdot \delta_G - \delta_K,$$

where w belongs to the subset W of W_G defined in (3). Hence there exists a $w_0 \in W$ such that

$$\beta = w_0 \cdot \delta_G - \delta_K,$$

hence

$$\delta_G - \sum_{\theta \in \Lambda} \theta = \delta_K + \beta = w_0 \cdot \delta_G,$$

hence the result.

Now let w be any element in W_G. By the above lemma,

$$w \cdot \delta_G = \delta_G - \sum_{\theta \in \Phi_G^+} k_\theta \theta, \quad k_\theta = 0 \text{ or } 1,$$

$$= \delta_G - \sum_{\theta \in \Lambda} k_\theta \theta - \sum_{\theta \in \Phi_G^+ \setminus \Lambda} k_\theta \theta.$$

Hence by the definition of Λ,

$$\langle w \cdot \delta_G, \delta_K \rangle \leqslant \langle \delta_G - \sum_{\theta \in \Lambda} k_\theta \theta, \delta_K \rangle \leqslant \langle \delta_G - \sum_{\theta \in \Lambda} \theta, \delta_K \rangle.$$

Thus

$$\max_{w \in W_G} \langle w \cdot \delta_G, \delta_K \rangle \leqslant \langle \delta_G, \delta_K \rangle - \sum_{\theta \in \Lambda} \langle \theta, \delta_K \rangle = \langle w_0 \cdot \delta_G, \delta_K \rangle$$

$$\leqslant \max_{w \in W_G} \langle w \cdot \delta_G, \delta_K \rangle,$$

hence the result. □

Now going back to formula (4), we get immediately from (6) the following.

Corollary 3.3: *The first eigenvalue* λ *of the Dirac operator verifies*

$$\lambda^2 = 2\|\delta_G - \delta_K\|^2 + 4 \sum_{\theta \in \Lambda} \langle \theta, \delta_K \rangle + n/8.$$

IV. PROOF OF THE RESULTS OF TABLE I

In the following, we note for any integer $n \geqslant 1$, $(e_1, \ldots, e_n)$, the standard basis of $\mathbb{K}^n$, $\mathbb{K} = \mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$, and by (E_{ij}), $1 \leqslant i, j \leqslant n$, the standard basis of the space $\mathrm{M}_n(\mathbb{K})$ of (n,n) matrices with coefficients in $\mathbb{K}$.

A. Quaternionic projective spaces $\mathbb{H}P^n$

Here $G = \mathrm{Sp}_{m+1}$ and $K = \mathrm{Sp}_m \times \mathrm{Sp}_1$, where Sp_{m+1} is the group of symplectic matrices acting on the left on $\mathbb{H}^{n+1}$, (viewed as a right vector space on $\mathbb{H}$), and $\mathrm{Sp}_m \times \mathrm{Sp}_1$ is the subgroup of G formed by matrices of the form $\left(\begin{smallmatrix} A & 0 \\ 0 & q \end{smallmatrix}\right)$, where A is a (n,n) symplectic matrix and q a unit quaternion.

The decomposition of the spin representation into irreducible components under the action of K is known (see Refs. 1 and 12 or 7), so we may conclude with formula (1). However the result may be also simply concluded with formula (5).

We consider the standard maximal torus T of G, which is a common maximal torus of G and K. We denote by $(x_1,\ldots,x_{m+1})$, the basis dual to the standard basis of the Lie algebra $\mathfrak{T}$ of T, and by $(\hat{x}_1,\ldots,\hat{x}_{m+1})$, the corresponding basis of $i\mathfrak{T}^*$. Any vector $\mu\in i\mathfrak{T}^*$ is simply denoted by the $(m+1)$-tuple of its components in this basis: $\mu=(\mu_1,\mu_2,\ldots,\mu_{m+1})$.

The restriction to $\mathfrak{T}$ of the Killing form B of G is given by

$$\forall X\in\mathfrak{T},\ \forall\, Y\in\mathfrak{T},\quad B(X,Y)=4(m+2)\Re(\mathrm{tr}(XY)).$$

Hence the scalar product on $i\mathfrak{T}^*$ induced by the Killing form sign-changed is given by

$$\begin{aligned}&\forall\,\mu=(\mu_1,\ldots,\mu_{m+1})\in i\mathfrak{T}^*,\\ &\forall\,\mu'=(\mu'_1,\ldots,\mu'_{m+1})\in i\mathfrak{T}^*,\end{aligned}\qquad \langle\mu,\mu'\rangle=\frac{1}{4(m+2)}\sum_{k=1}^{m+1}\mu_k\mu'_k. \tag{13}$$

Now, considering the root-spaces decomposition of the complexified Lie algebra of G under the action of T, we may choose as sets of positive roots,

$$\Phi_G^+=\left\{\begin{matrix}\hat{x}_i+\hat{x}_j,\\ \hat{x}_i-\hat{x}_j,\end{matrix}\quad 1\leqslant i\leqslant j\leqslant m+1;2\hat{x}_i,\ 1\leqslant i\leqslant m+1\right\},$$

and

$$\Phi_K^+=\left\{\begin{matrix}\hat{x}_i+\hat{x}_j,\\ \hat{x}_i-\hat{x}_j,\end{matrix}\quad 1\leqslant i\leqslant j\leqslant m;2\hat{x}_i,\ 1\leqslant i\leqslant m+1\right\}.$$

Then

$$\delta_G=\sum_{k=1}^{m+1}(m+2-k)\hat{x}_k=(m+1,m,\ldots,2,1)$$

and

$$\delta_K=\sum_{k=1}^{m}(m+1-k)\hat{x}_k+\hat{x}_{m+1}=(m,m-1,\ldots,1,1).$$

Hence $\delta_G-\delta_K=\Sigma_{k=1}^m\hat{x}_k=(1,1,\ldots,1,0)$, so $\|\delta_G-\delta_K\|^2=m/[4(m+2)]$.

On the other hand, it is easy to verify that the set $\Lambda:=\{\theta\in\Phi_G^+;\langle\theta,\delta_K\rangle<0\}$ is empty, hence by formula (5), the square of the first eigenvalue λ of the Dirac operator is given by

$$\lambda^2=\frac{m}{2(m+2)}+\frac{m}{2}=\frac{m+3}{m+2}\frac{m}{2}.$$

B. Grassmannians $\mathrm{Gr}_2(\mathbb{C}^{m+2})$, m even $\geqslant 2$

Here $G=\mathrm{SU}_{m+2}$ is the group of unitary matrices with determinant 1, and K is the subgroup $S(\mathrm{U}_m\times\mathrm{U}_2)$ formed by matrices of the form $\left(\begin{smallmatrix}A&0\\0&B\end{smallmatrix}\right)$, where A and B are unitary matrices with respective sizes (m,m) and $(2,2)$ such that $\det A\det B=1$.

Here again, the decomposition into irreducible components of the spin representation under the action of K is known,[8] hence the result may be obtained from formula (1). However the result may be also simply concluded with formula (5). The standard maximal torus T of SU_{m+2} is a common maximal torus of G and K. We denote by $(x_1,\ldots,x_{m+1})$, the basis dual to the basis of the Lie algebra $\mathfrak{T}$ of T defined by the vectors $i(E_{ii}-E_{m+2m+2})$, $1\leqslant i\leqslant m+1$, and by $(\hat{x}_1,\ldots,\hat{x}_{m+1})$, the corresponding basis of $i\mathfrak{T}^*$. Any vector $\mu\in i\mathfrak{T}^*$ is denoted by the $(m+1)$-tuple of its components in this basis: $\mu=(\mu_1,\mu_2,\ldots,\mu_{m+1})$.

The restriction to $\mathfrak{T}$ of the Killing form B of G is given by

$$\forall X \in \mathfrak{T}, \quad \forall Y \in \mathfrak{T}, \quad B(X,Y) = 2(m+2)\Re(\mathrm{tr}(XY)).$$

Hence the scalar product on $i\mathfrak{T}^*$ induced by the Killing form sign changed is given by

$$\forall \mu = (\mu_1, \ldots, \mu_{m+1}) \in i\mathfrak{T}^*, \quad \forall \mu' = (\mu'_1, \ldots, \mu'_{m+1}) \in i\mathfrak{T}^*,$$

$$\langle \mu, \mu' \rangle = \frac{1}{2(m+2)} \sum_{k=1}^{m+1} \mu_k \mu'_k - \frac{1}{2(m+2)^2} \left(\sum_{k=1}^{m+1} \mu_k \right) \left(\sum_{k=1}^{m+1} \mu'_k \right). \tag{14}$$

Now, considering the root-spaces decomposition of the complexified Lie algebra of G under the action of T, we may choose as sets of positive roots

$$\Phi_G^+ = \left\{ \hat{x}_i - \hat{x}_j, 1 \leqslant i \leqslant m+1; \hat{x}_i + \sum_{k=1}^{m+1} \hat{x}_k, 1 \leqslant i \leqslant m+1 \right\},$$

and

$$\Phi_K^+ = \left\{ \hat{x}_i - \hat{x}_j, 1 \leqslant i \leqslant m; \hat{x}_{m+1} + \sum_{k=1}^{m+1} \hat{x}_k \right\}.$$

Then

$$\delta_G = \sum_{k=1}^{m+1} (m+2-k)\hat{x}_k = (m+1, m, \ldots, 2, 1)$$

and

$$\delta_K = \frac{1}{2} \left(\sum_{k=1}^{m} (m+2-2k)\hat{x}_k + 2\hat{x}_{m+1} \right) = \frac{1}{2}(m, m-2, m-4, \ldots, 2-m, 2).$$

Hence $\delta_G - \delta_K = \frac{1}{2}(m+2)\Sigma_{k=1}^{m} \hat{x}_k = \frac{1}{2}(m+2)(1, 1, \ldots, 1, 0)$, so $\|\delta_G - \delta_K\|^2 = m/4$.

We now determine the set $\Lambda := \{\theta \in \Phi_G^+; \langle \theta, \delta_K \rangle < 0\}$. Recall that from the proof of Lemma 3.2, if Λ is nonempty, then any $\theta \in \Lambda$ belongs to $\Phi_G^+ \backslash \Phi_K^+$. It is then easy to verify that the elements of Λ are

$$\hat{x}_j - \hat{x}_{m+1}, \quad \frac{m}{2} + 1 \leqslant j \leqslant m, \quad \langle \hat{x}_j - \hat{x}_{m+1}, \delta_K \rangle = \frac{1}{2(m+2)} \left(\frac{m}{2} - j \right),$$

$$\hat{x}_j + \sum_{k=1}^{m+1} \hat{x}_k, \quad \frac{m}{2} + 2 \leqslant j \leqslant m, \quad \langle \hat{x}_j + \sum_{k=1}^{m+1} \hat{x}_k, \delta_K \rangle = \frac{1}{2(m+2)} \left(\frac{m}{2} + 1 - j \right).$$

So

$$\sum_{\theta \in \Lambda} \langle \theta, \delta_K \rangle = -\frac{m^2}{8(m+2)}.$$

Hence, by formula (5), the square of the first eigenvalue λ of the Dirac operator is given by

$$\lambda^2 = \frac{m}{2} - \frac{m^2}{2(m+2)} + \frac{m}{2} = \frac{m+4}{m+2}\frac{m}{2}.$$

C. Grassmannians $\widetilde{\mathrm{Gr}}_4(\mathbb{R}^{m+4})$, m even $\geqslant 4$

Here $G=\mathrm{Spin}_{m+4}$ and, identifying $\mathbb{R}^m$ with the subspace of $\mathbb{R}^{m+4}$ spanned by $e_1,\ldots,e_m$, and $\mathbb{R}^4$ with the subspace spanned by $e_{m+1},\ldots,e_{m+4}$, K is the subgroup of G defined by

$$\mathrm{Spin}_m\,\mathrm{Spin}_4 := \{\psi\in\mathrm{Spin}_{m+4};\psi=\varphi\phi,\varphi\in\mathrm{Spin}_m,\phi\in\mathrm{Spin}_4\}.$$

We consider the common maximal torus of G and K defined by

$$T=\left\{\sum_{k=1}^{(m/2)+2}(\cos(\beta_k)+\sin(\beta_k)e_{2k-1}\cdot e_{2k});\beta_1,\ldots,\beta_{(m/2)+2}\in\mathbb{R}\right\}.$$

We denote by $(x_1,\ldots,x_{(m/2)+2})$ the basis dual to the basis $(e_{2j-1}\cdot e_{2j})$, $1\leqslant j\leqslant(m/2)+2$, of the Lie algebra $\mathfrak{T}$ of T, and by $(\hat{x}_1,\ldots,\hat{x}_{(m/2)+2})$ the basis of $i\mathfrak{T}^*$ defined by

$$\hat{x}_k := 2ix_k,\quad k=1,\ldots,\frac{m}{2}+2.$$

Any vector $\mu\in i\mathfrak{T}^*$ is denoted by the $(m/2)+2$-tuple of its components in this basis, $\mu=(\mu_1,\mu_2,\ldots,\mu_{(m/2)+2})$.

The restriction to $\mathfrak{T}$ of the Killing form B of G is given by

$$B(e_{2k-1}\cdot e_{2k},e_{2l-1}\cdot e_{2l})=-8(m+2)\delta_{kl}.$$

Hence the scalar product on $i\mathfrak{T}^*$ induced by the Killing form sign-changed is given by

$$\begin{aligned}&\forall\mu=(\mu_1,\ldots,\mu_{\frac{m}{2}+2})\in i\mathfrak{T}^*,\\&\forall\mu'=(\mu'_1,\ldots,\mu'_{\frac{m}{2}+2})\in i\mathfrak{T}^*,\end{aligned}\quad\langle\mu,\mu'\rangle=\frac{1}{2(m+2)}\sum_{k=1}^{(m/2)+2}\mu_k\mu'_k.\tag{15}$$

Considering the root-spaces decomposition of the complexified Lie algebra of G under the action of T, we may choose as sets of positive roots

$$\Phi_G^+=\left\{\hat{x}_i+\hat{x}_j,\hat{x}_i-\hat{x}_j,1\leqslant i<j\leqslant\frac{m}{2}+2\right\},$$

and

$$\Phi_K^+=\left\{\hat{x}_i+\hat{x}_j,\hat{x}_i-\hat{x}_j,1\leqslant i<j\leqslant\frac{m}{2},\hat{x}_{(m/2)+1}+\hat{x}_{(m/2)+2},\hat{x}_{(m/2)+1}-\hat{x}_{(m/2)+2}\right\}.$$

Then

$$\delta_G=\sum_{k=1}^{(m/2)+2}\left(\frac{m}{2}+2-k\right)\hat{x}_k=\left(\frac{m}{2}+1,\frac{m}{2},\ldots,1,0\right)$$

and

$$\delta_K=\sum_{k=1}^{(m/2)}\left(\frac{m}{2}-k\right)\hat{x}_k+\hat{x}_{(m/2)+1}=\left(\frac{m}{2}-1,\frac{m}{2}-2,\ldots,1,0\right).$$

Hence $\delta_G-\delta_K=2\Sigma_{k=1}^{m/2}\hat{x}_k=2(1,1,\ldots,1,0,0)$, so $\|\delta_G-\delta_K\|^2=m/(m+2)$.

On the other hand, it is easy to verify that the set $\Lambda := \{\theta \in \Phi_G^+; \langle \theta, \delta_K \rangle < 0\}$ has only one element, namely

$$\hat{x}_{(m/2)} - \hat{x}_{(m/2)+1}, \quad \text{with } \langle \hat{x}_{(m/2)} - \hat{x}_{(m/2)+1}, \delta_K \rangle = -1.$$

Hence, by formula (5), the square of the first eigenvalue λ of the Dirac operator is given by

$$\lambda^2 = \frac{2m}{m+2} - \frac{2}{m+2} + \frac{m}{2} = \frac{m^2+6m-4}{2(m+2)}.$$

D. The four exceptional cases

Note first that since all the groups G we consider are simple, their roots system are irreducible so, up to a constant, there is only one W_G-invariant scalar product on the subspace generated by the set of roots, cf. for instance Remark (5.10), Sec. V in Ref. 3.

We use the description of root systems given in Ref. 2. Those root systems are expressed in the simple root basis (α_i). Note that the W_G-invariant scalar product $(,)$ used there is such that $(\alpha, \alpha) = 2$ for any long root α. In order to compare it with the scalar product $\langle , \rangle$ induced by the Killing form sign-changed, we use the "strange formula" of Freudenthal and de Vries, (cf. 47-11 in Ref. 5):

$$\langle \delta_G, \delta_G \rangle = \tfrac{1}{24} \dim G. \tag{16}$$

To determine the set of K-positive roots, we use Theorem 13, Theorem 14, and the proof of Theorem 18 in Ref. 4. By those results, the set Φ_K^+ may be defined as follows. Let $\theta = \Sigma m_i \alpha_i$ be the highest root. In all cases considered, there exists an index j such that $m_j = 2$. Then

$$\Phi_K^+ = \left\{ \sum n_i \alpha_i ; n_j \neq 1 \right\}.$$

1. The symmetric space G_2/SO_4

Using the results of pages 18 and 64 in Ref. 2, we get

$$\delta_G = 3\alpha_1 + 5\alpha_2.$$

By the expression of the Cartan matrix, the scalar product matrix is, in the basis (α_1, α_2), $\left(\begin{smallmatrix} 2 & -1 \\ -1 & 2/3 \end{smallmatrix}\right)$, hence $\|\delta_G\|_{(,)}^2 = \frac{14}{3}$. On the other hand, by the formula of Freudenthal and de Vries, $\|\delta_G\|_{\langle , \rangle}^2 = \frac{7}{12}$, so $\langle , \rangle = \frac{1}{8}(,)$.

The set of K-positive roots is $\Phi_K^+ = \{2\alpha_1 + 3\alpha_2, \alpha_2\}$, hence $\delta_K = \alpha_1 + 2\alpha_2$, so $\delta_G - \delta_K = 2\alpha_1 + 3\alpha_2$. Hence

$$\|\delta_G - \delta_K\|_{\langle , \rangle}^2 = \tfrac{1}{8}\|\delta_G - \delta_K\|_{(,)}^2 = \tfrac{1}{4}.$$

Finally, it is easy to verify that the set $\Lambda := \{\theta \in \Phi_G^+; \langle \theta, \delta_K \rangle < 0\}$ is empty, hence by formula (5), the square of the first eigenvalue λ of the Dirac operator is given by

$$\lambda^2 = \tfrac{1}{2} + 1 = \tfrac{3}{2}.$$

2. The symmetric space $E_6/(SU_6SU_2)$

Using the results of pages 14 and 60 in Ref. 2, we get

$$\delta_G = 8\alpha_1 + 15\alpha_2 + 21\alpha_3 + 15\alpha_4 + 8\alpha_5 + 11\alpha_6.$$

Since all roots have same length equal to 2, we may introduce the fundamental weight basis (ω_i) because $(\omega_i, \alpha_j) = \delta_{ij}$.

Since $\delta_G = \Sigma \omega_i$, we get $\|\delta_G\|^2_{(,)} = 78$, whereas by the formula of Freudenthal and de Vries, $\|\delta_G\|^2_{\langle,\rangle} = \frac{78}{24}$, so $\langle,\rangle = \frac{1}{24}(,)$.

The set of K-positive roots may be defined by $\Phi^+_K = \{\Sigma_{i=1}^6 n_i \alpha_i; n_6 \neq 1\}$.

Then $\delta_K = 3\alpha_1 + 5\alpha_2 + 6\alpha_3 + 5\alpha_4 + 3\alpha_5 + \alpha_6 = \omega_1 + \omega_2 + \omega_3 + \omega_4 + \omega_5 - 4\omega_6$.

Hence $\delta_G - \delta_K = 5\alpha_1 + 10\alpha_2 + 15\alpha_3 + 10\alpha_4 + 5\alpha_5 + 10\alpha_6 = 5\omega_6$. So

$$\|\delta_G - \delta_K\|^2_{\langle,\rangle} = \tfrac{1}{24}\|\delta_G - \delta_K\|^2_{(,)} = \tfrac{25}{12}.$$

On the other hand, it is easy to verify that the set $\Lambda := \{\theta \in \Phi^+_G; \langle \theta, \delta_K \rangle < 0\}$ has seven elements, and that

$$\sum_{\theta \in \Lambda} \langle \theta, \delta_K \rangle = \tfrac{1}{24} \sum_{\theta \in \Lambda} (\theta, \delta_K) = -\tfrac{7}{12}.$$

So by formula (5), the square of the first eigenvalue λ of the Dirac operator is given by

$$\lambda^2 = \tfrac{50}{12} - \tfrac{28}{12} + 5 = \tfrac{41}{6}.$$

3. The symmetric space $E_7/(\mathrm{Spin}_{12}\mathrm{SU}_2)$

By the results of pages 15 and 61 in Ref. 2, we get

$$\delta_G = \tfrac{1}{2}(34\alpha_1 + 66\alpha_2 + 96\alpha_3 + 75\alpha_4 + 52\alpha_5 + 27\alpha_6 + 49\alpha_7).$$

Here again, since all roots have the same length equal to 2, we may consider the fundamental weight basis (ω_i). We get $\|\delta_G\|^2_{(,)} = \frac{399}{2}$, whereas by the formula of Freudenthal and de Vries, $\|\delta_G\|^2_{\langle,\rangle} = \frac{133}{24}$, so $\langle,\rangle = \frac{1}{36}(,)$.

The set of K-positive roots may be defined by $\Phi^+_K = \{\Sigma_{i=1}^7 n_i \alpha_i; n_1 \neq 1\}$. Then

$$\delta_K = \tfrac{1}{2}(2\alpha_1 + 18\alpha_2 + 32\alpha_3 + 27\alpha_4 + 20\alpha_5 + 11\alpha_6 + 17\alpha_7)$$

$$= -7\omega_1 + \omega_2 + \omega_3 + \omega_4 + \omega_5 + \omega_6 + \omega_7.$$

Hence $\delta_G - \delta_K = 16\alpha_1 + 24\alpha_2 + 32\alpha_3 + 24\alpha_4 + 16\alpha_5 + 8\alpha_6 + 16\alpha_7 = 8\omega_6$. So

$$\|\delta_G - \delta_K\|^2_{\langle,\rangle} = \tfrac{1}{36}\|\delta_G - \delta_K\|^2_{(,)} = \tfrac{32}{9}.$$

On the other hand, it can be verified that the set $\Lambda := \{\theta \in \Phi^+_G; \langle \theta, \delta_K \rangle < 0\}$ has 13 elements, and that

$$\sum_{\theta \in \Lambda} \langle \theta, \delta_K \rangle = \frac{1}{36} \sum_{\theta \in \Lambda} (\theta, \delta_K) = -\frac{41}{36}.$$

So by formula (5), the square of the first eigenvalue λ of the Dirac operator is given by

$$\lambda^2 = \tfrac{64}{9} - \tfrac{41}{9} + 8 = \tfrac{95}{9}.$$

4. The symmetric space $E_8/(E_7\mathrm{SU}_2)$

By the results of pages 16, 62, and 63 in Ref. 2, we get

$$\delta_G = 29\alpha_1 + 57\alpha_2 + 84\alpha_3 + 110\alpha_4 + 135\alpha_5 + 91\alpha_6 + 46\alpha_7 + 68\alpha_8.$$

Here again, since all roots have the same length equal to 2, we may consider the fundamental weight basis (ω_i). We get $\|\delta_G\|^2_{(,)}=620$, whereas by the formula of Freudenthal and de Vries, $\|\delta_G\|^2_{\langle,\rangle}=\frac{31}{3}$, so $\langle,\rangle=\frac{1}{60}(,)$.

The set of K-positive roots may be defined by $\Phi_K^+=\{\Sigma_{i=1}^8 n_i\alpha_i; n_1 \neq 1\}$. Then

$$\delta_K = \alpha_1 + 15\ \alpha_2 + 28\alpha_3 + 40\alpha_4 + 51\alpha_5 + 35\alpha_6 + 18\alpha_7 + 26\alpha_8$$

$$= -13\omega_1 + \omega_2 + \omega_3 + \omega_4 + \omega_5 + \omega_6 + \omega_7 + \omega_8.$$

Hence

$$\delta_G - \delta_K = 28\alpha_1 + 42\alpha_2 + 56\alpha_3 + 70\alpha_4 + 84\alpha_5 + 56\alpha_6 + 28\alpha_7 + 42\alpha_8 = 14\omega_6.$$

So

$$\|\delta_G - \delta_K\|^2_{\langle,\rangle} = \tfrac{1}{60}\|\delta_G - \delta_K\|^2_{(,)} = \tfrac{98}{15}.$$

On the other hand, it can be verified that the set $\Lambda := \{\theta \in \Phi_G^+; \langle\theta, \delta_K\rangle < 0\}$ has 25 elements, and that

$$\sum_{\theta\in\Lambda} \langle\theta, \delta_K\rangle = \frac{1}{60}\sum_{\theta\in\Lambda} (\theta, \delta_K) = -\frac{137}{60}.$$

So by formula (5), the square of the first eigenvalue λ of the Dirac operator is given by

$$\lambda^2 = \tfrac{196}{15} - \tfrac{137}{15} + 14 = \tfrac{269}{15}.$$

Trace functions as Laplace transforms

Frank Hansen
Institute of Economics, University of Copenhagen, Studiestraede 6, DK-1455 Copenhagen K, Denmark

(Received 20 October 2005; accepted 21 February 2006; published online 14 April 2006)

We study trace functions on the form $t \to \mathrm{Tr}\, f(A+tB)$ where f is a real function defined on the positive half-line, and A and B are matrices such that A is positive definite and B is positive semidefinite. If f is non-negative and operator monotone decreasing, then such a trace function can be written as the Laplace transform of a positive measure. The question is related to the Bessis-Moussa-Villani conjecture. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2186925]

I. INTRODUCTION

The Gibbs density matrix of a system with Hamiltonian H in equilibrium and temperature $kT=1/\beta$ is given by $\exp(-\beta H)$. One would like to study perturbations $H_0+\lambda H_1$ of an exactly solvable Hamiltonian H_0 and see how the thermodynamical quantities are changed. This question was studied by Bessis, Moussa and Villani in Ref. 2 where it is noted that the Padé approximant to the partition function $Z(\beta)=\mathrm{Tr}\exp(-\beta(H_0+\lambda H_1))$ may be efficiently calculated, if the function

$$\lambda \to \mathrm{Tr}\exp(-\beta(H_0+\lambda H_1))$$

is the Laplace transform of a positive measure. The authors then noted that this is indeed true for a system of spinless particles with local interactions bounded from below. The statement also holds if H_0 and H_1 are commuting operators, or if they are just 2×2 matrices. These observations led to the formulation of the following conjecture:

Conjecture (BMV): Let A and B be $n\times n$ matrices for some natural number n, and suppose that A is self-adjoint and B is positive semidefinite. Then there is a positive measure μ with support in the closed positive half-axis such that

$$\mathrm{Tr}\exp(A-tB)=\int_0^\infty e^{-ts}\,d\mu(s)$$

for every $t\geqslant 0$.

The Bessis-Moussa-Villani (BMV) conjecture may be reformulated as an infinite series of inequalities.

Theorem (Bernstein): *Let f be a real C^∞-function defined on the positive half-axis. If f is completely monotone, that is*

$$(-1)^n f^{(n)}(t)\geqslant 0,\quad t>0,\ n=0,1,2,\ldots,$$

then there exists a positive measure μ on the positive half-axis such that

$$f(t)=\int_0^\infty e^{-st}\,\mathrm{d}\mu(s)$$

for every $t>0$.

The BMV conjecture is thus equivalent to saying that the function

$$f(t) = \mathrm{Tr}\exp(A - tB), \quad t > 0$$

is completely monotone. A proof of Bernstein's theorem can be found in Ref. 4.

Assuming the BMV conjecture one may derive a similar statement for free semicircularly distributed elements in a type II_1 von Neumann algebra with a faithful trace. This consequence of the conjecture has been proved by Fannes and Petz.[6] A hypergeometric approach by Drmota, Schachermayer, and Teichmann[5] gives a proof of the BMV-conjecture for some types of 3×3 matrices.

Equivalent formulations: The BMV conjecture can be stated in several equivalent forms.

Theorem 1.1: *The following conditions are equivalent*:

(i) *For arbitrary $n\times n$ matrices A and B such that A is self-adjoint and B is positive semidefinite the function $f(t)=\mathrm{Tr}\exp(A-tB)$, defined on the positive half-axis, is the Laplace transform of a positive measure supported in $[0,\infty)$.*

(ii) *For arbitrary $n\times n$ matrices A and B such that A is self-adjoint and B is positive semidefinite the function $g(t)=\mathrm{Tr}\exp(A+itB)$, defined on the positive half-axis, is of positive type.*

(iii) *For arbitrary positive definite $n\times n$* matrices A and B *the polynomial $P(t)=\mathrm{Tr}(A+tB)^p$ has non-negative coefficients for any $p=1,2,\ldots$.*

(iv) *For arbitrary positive definite $n\times n$ matrices A and B the function $\varphi(t)=\mathrm{Tr}\exp(A+tB)$ is m-positive on some open interval of the form $(-\alpha,\alpha)$.*

The first statement is the BMV-conjecture, and it readily implies the second statement by analytic continuation. The sufficiency of the second statement is essentially Bochner's theorem. The implication (iii)$\Rightarrow$(i) is obtained by applying Bernstein's theorem and approximation of the exponential function by its Taylor expansion. The implication (i)$\Rightarrow$(iii) was proved by Lieb and Seiringer.[15] A function $\varphi:(-\alpha,\alpha)\to\mathbf{R}$ is said to be m-positive, if for arbitrary self-adjoint $k\times k$ matrices X with non-negative entries and spectra contained in $(-\alpha,\alpha)$ the matrix $\varphi(X)$ has non-negative entries. The implication (iii)$\Rightarrow$(iv) follows by approximation, while the implication (iv)$\Rightarrow$(i) follows by Bernstein's theorem and Ref. 8. Theorem 3.3 which states that an m-positive function is real analytic with non-negative derivatives in zero.

II. PRELIMINARIES AND MAIN RESULT

Let f be a real function of one variable defined on a real interval I. We consider for each natural number n the associated matrix function $x\to f(x)$ defined on the set of self-adjoint matrices of order n with spectra in I. The matrix function is defined by setting

$$f(x) = \sum_{i=1}^{p} f(\lambda_i)P_i, \quad \text{where } x = \sum_{i=1}^{p}\lambda_i P_i$$

is the spectral resolution of x. The matrix function $x\to f(x)$ is Fréchet differentiable[7] if I is open and f is continuously differentiable.[3] The norm of the Fréchet differential $\mathrm{d}f(x)$ may be an unbounded function of the order n, cf. Refs. 19 and 18. If however f is assumed to be twice differentiable, then the norm of $\mathrm{d}f(x)$ is bounded independently of the order n for all self-adjoint matrices x with spectra contained in a fixed compact subset of I, cf. Ref. 9 Corollary 2.9 and Ref. 12. We consider in this paper the function

$$\varphi(x) = \mathrm{Tr}\, f(x)$$

defined on the set of self-adjoint matrices of order n with spectra in I. The Fréchet differential is given by $\mathrm{d}\varphi(x)=\mathrm{Tr}\,\mathrm{d}f(x)$, cf. Ref. 10.

The BMV property:

Definition 2.1: A function $f:\mathbf{R}_+\to\mathbf{R}$ is said to have the BMV property, if to each $n=1,2,\ldots$ and each pair of $n\times n$ matrices A and B, such that A is positive definite and B is positive semidefinite, there is a positive measure μ with support in $[0,\infty)$ such that

$$\operatorname{Tr} f(A+tB) = \int_0^\infty e^{-st}\, \mathrm{d}\mu(s)$$

for every $t>0$.

The BMV-conjecture is thus equivalent to the statement that the function $t \to \exp(-t)$ has the BMV property. The main contribution of this paper is the following result.

Main Theorem: *Every non-negative operator monotone decreasing function defined on the open positive half-line has the BMV property*.

III. DIFFERENTIAL ANALYSIS

A simple proof of the following result can be found in Ref. 12, Proposition 1.3.

Proposition 3.1: The Fréchet differential of the exponential operator function $x \to \exp(x)$ *is given by*

$$d\exp(x)h = \int_0^1 \exp(sx)h\exp((1-s)x)\mathrm{d}s = \int_0^1 A(s)\exp(x)\mathrm{d}s,$$

where $A(s)=\exp(sx)h\exp(-sx)$ *for* $s \in \mathbf{R}$.

This is only a small part of the Dyson formula which contains formalisms developed earlier by Tomonaga, Schwinger, and Feynman. The subject was given a rigorous mathematical treatment by Araki in terms of expansionals in Banach algebras. In particular Ref. 1, Theorem 3, the expansional

$$E_r(h;x) = \sum_{n=0}^{\infty} \int_0^1 \int_0^{s_1} \cdots \int_0^{s_{n-1}} A(s_n)A(s_{n-1})\cdots A(s_1)\mathrm{d}s_n\, \mathrm{d}s_{n-1}\cdots \mathrm{d}s_1$$

is absolutely convergent in the norm topology with limit

$$E_r(h;x) = \exp(x+h)\exp(-x).$$

We therefore obtain the pth Fréchet differential of the exponential operator function by the expression

$$d^p \exp(x)h^p = p! \int_0^1 \int_0^{s_1} \cdots \int_0^{s_{p-1}} A(s_p)A(s_{p-1})\cdots A(s_1)\exp(x)\mathrm{d}s_p\, \mathrm{d}s_{p-1}\cdots \mathrm{d}s_1.$$

Divided differences: The following representation of divided differences is due to Hermite,[13] confer also Refs. 17 and 16.

Proposition 3.2: Divided differences can be written in the following form:

$$[x_0,x_1]_f = \int_0^1 f'((1-t_1)x_0 + t_1x_1)\mathrm{d}t_1,$$

$$[x_0,x_1,x_2]_f = \int_0^1 \int_0^{t_1} f''((1-t_1)x_0 + (t_1-t_2)x_1 + t_2x_2)\mathrm{d}t_2\, \mathrm{d}t_1,$$

$$\vdots$$

$$[x_0,x_1,\ldots,x_n]_f = \int_0^1 \int_0^{t_1} \cdots \int_0^{t_{n-1}} f^{(n)}((1-t_1)x_0 + (t_1-t_2)x_1 + \cdots + (t_{n-1}-t_n)x_{n-1} + t_nx_n)\mathrm{d}t_n \cdots \mathrm{d}t_2\, \mathrm{d}t_1,$$

where f is an n-times continuously differential function defined on an open interval I, and $x_0, x_1, \dots, x_n$ are (not necessarily distinct) points in I.

Lemma 3.3: For $k=1,2,\dots$ and real numbers $\lambda_1, \dots, \lambda_k$ we have

$$\int_0^t e^{-\mu s}[s\lambda_1, \dots, s\lambda_k]_{\exp} s^{k-1}\, \mathrm{d}s = t^k e^{-\mu t}\,[t\lambda_1, \cdots, t\lambda_k, t\mu]_{\exp}$$

for any real μ and $t \geqslant 0$.

Proof: For $k=1$ we calculate

$$\int_0^t e^{-\mu s}[s\lambda_1]_{\exp}\, \mathrm{d}s = \int_0^t e^{s(\lambda_1-\mu)}\, \mathrm{d}s = t\, e^{-\mu t}\,[t\lambda_1, t\mu]_{\exp}.$$

Assuming the formula valid for k we obtain for $k+1$ the expression

$$\begin{aligned}
&\int_0^t e^{-\mu s}\,[s\lambda_1, \dots, s\lambda_{k+1}]_{\exp} s^k\, \mathrm{d}s \\
&\quad = \int_0^t e^{-\mu s} \frac{[s\lambda_1, \dots, s\lambda_k]_{\exp} - [s\lambda_2, \dots, s\lambda_{k+1}]_{\exp}}{s\lambda_1 - s\lambda_{k+1}} s^k\, \mathrm{d}s \\
&\quad = \frac{1}{\lambda_1 - \lambda_{k+1}} (t^k e^{-\mu t}\,[t\lambda_1, \dots, t\lambda_k, t\mu]_{\exp} - t^k e^{-\mu t}\,[t\lambda_2, \dots, t\lambda_{k+1}, t\mu]_{\exp}) \\
&\quad = t^{k+1} e^{-\mu t}\,[t\lambda_1, \dots, t\lambda_{k+1}, t\mu]_{\exp}
\end{aligned}$$

provided $\lambda_1 \neq \lambda_{k+1}$. The case $\lambda_1 = \lambda_{k+1}$ then follows by continuity, and the lemma is proved by induction. Q.E.D.

Theorem 3.4: *Let x and h be operators on a Hilbert space of finite dimension n written on the form*

$$x = \sum_{i=1}^n \lambda_i e_{ii} \quad \text{and } h = \sum_{i,j=1}^n h_{ij} e_{ij},$$

where $\{e_{ij}\}_{i,j=1}^n$ is a system of matrix units, and $\lambda_1, \dots, \lambda_n$ and $h_{i,j}$ for $i,j=1,\dots,n$ are complex numbers. Then the pth derivative

$$\frac{d^p}{\mathrm{d}t^p} \mathrm{Tr} \exp(x+th)\bigg|_{t=0} = p! \sum_{i_1=1}^n \cdots \sum_{i_p=1}^n h_{i_p i_{p-1}} \cdots h_{i_2 i_1} h_{i_1 i_p} [\lambda_{i_1}, \lambda_{i_2}, \dots, \lambda_{i_p}, \lambda_{i_p}]_{\exp},$$

where $[\lambda_{i_1}, \lambda_{i_2}, \dots, \lambda_{i_p}, \lambda_{i_p}]_{\exp}$ are divided differences of order $p+1$ of the exponential function.

Proof: We first prove the formulas

$$\begin{aligned}
I_k(s_0) &= \int_0^{s_0} \int_0^{s_1} \cdots \int_0^{s_{k-1}} A(s_k) A(s_{k-1}) \cdots A(s_1)\, \mathrm{d}s_k\, \mathrm{d}s_{k-1} \cdots \mathrm{d}s_1 \\
&= s_0^k \sum_{j=1}^n \sum_{i_1=1}^n \cdots \sum_{i_k=1}^n h_{i_k i_{k-1}} h_{i_{k-1} i_{k-2}} \cdots h_{i_2 i_1} h_{i_1 j}\, e^{-s_0 \lambda_j} [s_0\lambda_{i_1}, \dots, s_0\lambda_{i_k}, s_0\lambda_j]_{\exp}\, e_{i_k j} \qquad (1)
\end{aligned}$$

for natural numbers $k=1,\dots,p$ and real numbers $s_0 \geqslant 0$. For $k=1$ we calculate the integral

$$
\begin{aligned}
I_1(s_0) &= \int_0^{s_0} A(s_1)\mathrm{d}s_1 \\
&= \int_0^{s_0} \exp(s_1 x) h \exp(-s_1 x)\mathrm{d}s_1 \\
&= \sum_{i_1=1}^{n}\sum_{j=1}^{n} h_{i_1 j}\int_0^{s_0} \exp(s_1 x) e_{i_1 j} \exp(-s_1 x)\mathrm{d}s_1 \\
&= \sum_{i_1=1}^{n}\sum_{j=1}^{n} h_{i_1 j}\int_0^{s_0} \exp(s_1(\lambda_{i_1}-\lambda_j)) e_{i_1 j}\, \mathrm{d}s_1 \\
&= s_0 \sum_{j=1}^{n}\sum_{i_1=1}^{n} h_{i_1 j} e^{-s_0\lambda_j}[s_0\lambda_{i_1}, s_0\lambda_j]_{\exp}\, e_{i_1 j}
\end{aligned}
$$

in accordance with (1). For $k \geqslant 2$ and assuming the formulas (1) valid for $k-1$ we obtain the expression

$$
\begin{aligned}
I_k(s_0) &= \int_0^{s_0}\int_0^{s_1}\cdots\int_0^{s_{k-1}} A(s_k)A(s_{k-1})\cdots A(s_1)\mathrm{d}s_k\cdots \mathrm{d}s_2\, \mathrm{d}s_1 \\
&= \int_0^{s_0} I_{k-1}(s_1)A(s_1)\mathrm{d}s_1 \\
&= \int_0^{s_0} s_1^{k-1} \sum_{m,i_2,\cdots,i_k=1}^{n} h_{i_k i_{k-1}}\cdots h_{i_3 i_2} h_{i_2 m}\, e^{-s_1\lambda_m}[s_1\lambda_{i_2}, \ldots, s_1\lambda_{i_k}, s_1\lambda_m]_{\exp}\, e_{i_k m}\, A(s_1)\mathrm{d}s_1.
\end{aligned}
$$

We then insert

$$
A(s_1) = \sum_{i_1=1}^{n}\sum_{j=1}^{n} h_{i_1 j} \exp(s_1(\lambda_{i_1}-\lambda_j)) e_{i_1 j}
$$

and using $e_{i_k m} e_{i_1 j} = \delta(m, i_1) e_{i_k j}$ and the symmetry of the divided difference we obtain the expression

$$
\sum_{j,i_1,i_2,\ldots,i_k=1}^{n} h_{i_k i_{k-1}}\cdots h_{i_2 i_1} h_{i_1 j}\int_0^{s_0} e^{-s_1\lambda_j}[s_1\lambda_{i_1}, s_1\lambda_{i_2}, \ldots, s_1\lambda_{i_k}]_{\exp}\, s_1^{k-1}\, \mathrm{d}s_1\, e_{i_k j}
$$

for $I_k(s_0)$. Finally, using Lemma 3.3 we calculate

$$
I_k(s_0) = s_0^k \sum_{j,i_1,i_2,\ldots,i_k=1}^{n} h_{i_k i_{k-1}}\cdots h_{i_2 i_1} h_{i_1 j} e^{-s_0\lambda_j}\,[s_0\lambda_{i_1}, \ldots, s_0\lambda_{i_k}, s_0\lambda_j]_{\exp}\, e_{i_k j}
$$

which proves (1) by induction. We next observe that

$$
d^p \exp(x) h^p = p!\, I_p(1)\exp(x),
$$

where differentiation is with respect to x when nothing else is indicated. Finally, since

$$
\frac{d^p}{\mathrm{d}t^p}\exp(x+th) = d^p_{x+th}\exp(x+th)h^p
$$

we obtain

$$\frac{d^p}{dt^p}\mathrm{Tr}\exp(x+th)\bigg|_{t=0} = \mathrm{Tr}(d^p\exp(x)h^p) = p!\ \mathrm{Tr}(I_p(1)\exp(x))$$

$$= p!\ \mathrm{Tr}\left[\sum_{j,i_1,i_2,\ldots,i_p=1}^{n} h_{i_p i_{p-1}}\cdots h_{i_2 i_1}h_{i_1 j}e^{-\lambda_j}[\lambda_{i_1},\ldots,\lambda_{i_p},\lambda_j]_{\exp}\, e_{i_p j}\exp(x)\right]$$

$$= p!\sum_{i_1,i_2,\ldots,i_p=1}^{n} h_{i_p i_{p-1}}\cdots h_{i_2 i_1}h_{i_1 i_p}[\lambda_{i_1},\ldots,\lambda_{i_p},\lambda_{i_p}]_{\exp}$$

which is the statement of the theorem. Q.E.D.

Lemma 3.5: Let $f\in C_\infty(\mathbf{R})$, and let x and h be self-adjoint operators on a (possibly infinite dimensional) Hilbert space H. Then the operator function $x\to f(x)$ is infinitely Fréchet differentiable and the pth Fréchet differential is for $p\geqslant 1$ given by

$$d^p f(x)h^p = \int_{-\infty}^{\infty} d_x^p \exp(-isx)h^p\tilde{f}(s)\mathrm{d}s,$$

where d_x indicates differentiation with respect to x and

$$\tilde{f}(s) = \frac{1}{2\pi}\int_{-\infty}^{\infty}\exp(its)f(t)\mathrm{d}t$$

is the Fourier transform of f.

Proof: We note that the statement is true for $p=1$ by Ref. 12, Theorem 1.5 and assume the statement of the lemma to be valid for p. It follows from the definition of the Fréchet differential that the expression

$$d^p_{x+h}\exp(-is(x+h))h^p - d_x^p\exp(-isx)h^p - d_x(d_x^p\exp(-isx)h^p)h$$

even after division by $\|h\|$ tend to zero as $h\to 0$. We then multiply the above expression by the Fourier transform $\tilde{f}$ and integrate. By Lebesgues's theorem of dominated convergence we therefore obtain that also the expression

$$d^p_{x+h}f(x+h)h^p - d_x^p f(x)h^p - \int_{-\infty}^{\infty} d_x(d_x^p\exp(-isx)h^p)h\tilde{f}(s)\mathrm{d}s,$$

even after division by $\|h\|$, tend to zero as $h\to 0$. Hence

$$d_x^{p+1}f(x)h^{p+1} = \int_{-\infty}^{\infty} d_x^{p+1}\exp(-isx)h^{p+1}\tilde{f}(s)\mathrm{d}s$$

and the lemma is proved by induction. Q.E.D.

In the next corollary we need the identity,

$$t^{p-1}[t\lambda_1,\ldots,t\lambda_p]_f = [\lambda_1,\ldots,\lambda_p]_{f_t},\quad \text{where } f_t(s)=f(ts), \tag{2}$$

valid for p times continuously differentiable functions f. The statement is easily proved by induction after p.

Corollary 3.6: Let $f:I\to\mathbf{R}$ be a C^∞-function defined on an open and bounded interval I, and let x and h be self-adjoint operators on a Hilbert space of finite dimension n written in the forms

$$x=\sum_{i=1}^{n}\lambda_i e_{ii}\quad \textit{and}\ h=\sum_{i,j=1}^{n}h_{ij}e_{ij},$$

where $\{e_{ij}\}_{i,j=1}^n$ is a system of matrix units, and $\lambda_1,\ldots,\lambda_n$ are the eigenvalues of x counted with

multiplicity. If the spectrum of x is in I, then the trace function $t \to \mathrm{Tr}\, f(x+th)$ is infinitely differentiable in a neighborhood of zero and the pth derivative

$$\left.\frac{d^p}{dt^p}\mathrm{Tr}\, f(x+th)\right|_{t=0} = p! \sum_{i_1=1}^{n} \cdots \sum_{i_p=1}^{n} h_{i_1 i_2} h_{i_2 i_3} \cdots h_{i_{p-1} i_p} h_{i_p i_1} [\lambda_{i_1}, \lambda_{i_2}, \cdots, \lambda_{i_p}, \lambda_{i_1}]_f,$$

where $[\lambda_{i_1}, \lambda_{i_2}, \ldots, \lambda_{i_p}, \lambda_{i_1}]_f$ are divided differences of order $p+1$ of the function f.

Proof: Since the spectrum $\mathrm{Sp}(x)$ is compact, there is an open and bounded interval J such that

$$\mathrm{Sp}(x) \subset J \subset \bar{J} \subset I$$

and we may extend the restriction $f|_J$ to a function $g \in C_\infty(\mathbf{R})$. Since the spectrum $\mathrm{Sp}(x+th)$ is contained in J for small t we obtain

$$\begin{aligned}
\left.\frac{d^p}{dt^p}\mathrm{Tr}\, f(x+th)\right|_{t=0} &= \left.\frac{d^p}{dt^p}\mathrm{Tr}\, g(x+th)\right|_{t=0} \\
&= \int_{-\infty}^{\infty} \left.\frac{d^p}{dt^p}\mathrm{Tr}\exp(-isx-isth)\right|_{t=0} \tilde{g}(s)\,ds \\
&= \int_{-\infty}^{\infty} p! \sum_{i_1=1}^{n} \cdots \sum_{i_p=1}^{n} (-is)^p h_{i_p i_{p-1}} \cdots h_{i_2 i_1} h_{i_1 i_p} \\
&\quad \times [-is\lambda_{i_1}, \ldots, -is\lambda_{i_p}, -is\lambda_{i_p}]_{\exp}\, \tilde{g}(s)\,ds \\
&= p! \sum_{i_1=1}^{n} \cdots \sum_{i_p=1}^{n} h_{i_p i_{p-1}} \cdots h_{i_2 i_1} h_{i_1 i_p} \int_{-\infty}^{\infty} [\lambda_{i_1}, \ldots, \lambda_{i_p}, \lambda_{i_p}]_{\exp(-is\cdot)} \tilde{g}(s)\,ds \\
&= p! \sum_{i_1=1}^{n} \cdots \sum_{i_p=1}^{n} h_{i_p i_{p-1}} \cdots h_{i_2 i_1} h_{i_1 i_p} [\lambda_{i_1}, \ldots, \lambda_{i_p}, \lambda_{i_p}]_g\, ds,
\end{aligned}$$

where $\tilde{g}$ is the Fourier transform of g, and we used (2) and the linearity in g of arbitrary divided differences $[\lambda_1, \ldots, \lambda_p]_g$. The statement now follows by noting that $f=g$ in a neighborhood of the spectrum of x. Q.E.D.

IV. PROOF OF THE MAIN THEOREM

Proposition 4.1: Consider for a constant $c \geqslant 0$ the function

$$g(t) = \frac{1}{c+t}, \quad t > 0.$$

For arbitrary $n \times n$ matrices x and h such that x is positive definite and h is positive semidefinite we have

$$(-1)^p \left.\frac{d^p}{dt^p}\mathrm{Tr}\, g(x+th)\right|_{t=0} \geqslant 0$$

for $p=1,2,\ldots$.

Proof: We first note that the divided differences of g are of the form

$$[\lambda_1,\lambda_2,\ldots,\lambda_p]_g=(-1)^{p-1}g(\lambda_1)g(\lambda_2)\cdots g(\lambda_p),\quad p=1,2,\ldots \tag{3}$$

for arbitrary positive numbers $\lambda_1,\lambda_2,\ldots,\lambda_p$. There is nothing to prove for $p=1$. Assume the statement true for $p\geqslant 2$ and notice that

$$\frac{g(\lambda)-g(\mu)}{\lambda-\mu}=\frac{(c+\lambda)^{-1}-(c+\mu)^{-1}}{\lambda-\mu}=-g(\lambda)g(\mu)$$

for $\lambda\neq\mu$. Therefore

$$\begin{aligned}[\lambda_1,\ldots,\lambda_p,\lambda_{p+1}]_g&=\frac{[\lambda_1,\ldots,\lambda_p]_g-[\lambda_2,\ldots,\lambda_{p+1}]_g}{\lambda_1-\lambda_{p+1}}\\&=(-1)^{p-1}g(\lambda_2)\cdots g(\lambda_p)\frac{g(\lambda_1)-g(\lambda_{p+1})}{\lambda_1-\lambda_{p+1}}\\&=(-1)^p g(\lambda_1)\cdots g(\lambda_p)g(\lambda_{p+1})\end{aligned}$$

for $\lambda_1\neq\lambda_{p+1}$ and the general case follows by approximation. Next, applying Corollary 3.6 we obtain

$$\begin{aligned}&\frac{d^p}{dt^p}\mathrm{Tr}\,g(x+th)\bigg|_{t=0}\\&=p!\sum_{i_1=1}^n\cdots\sum_{i_p=1}^n h_{i_1i_2}h_{i_2i_3}\cdots h_{i_{p-1}i_p}h_{i_pi_1}[\lambda_{i_1},\lambda_{i_2},\ldots,\lambda_{i_p},\lambda_{i_1}]_g\\&=(-1)^p p!\sum_{i_1=1}^n\cdots\sum_{i_p=1}^n h_{i_1i_2}h_{i_2i_3}\cdots h_{i_{p-1}i_p}h_{i_pi_1}g(\lambda_{i_1})g(\lambda_{i_2})\cdots g(\lambda_{i_p})g(\lambda_{i_1}).\end{aligned}$$

Since h is positive semidefinite, it is of the form $h=aa^*$ for some matrix a and therefore

$$h_{ij}=\sum_{m=1}^n a_{im}a_{mj}^*=\sum_{m=1}^n a_{im}\bar{a}_{jm}=(a_i|a_j),\quad i,j=1,\ldots,n,$$

where

$$a_i=(a_{i1}\cdots a_{in})\in\mathbf{C}^n$$

is the ith row in the matrix a. We then set $\xi_i=g(\lambda_i)a_i$ and $b_i=g(\lambda_i)^{1/2}a_i$ for $i=1,\ldots,n$ and calculate

$$\begin{aligned}&\frac{(-1)^p}{p!}\frac{d^p}{dt^p}\mathrm{Tr}\,g(x+th)\bigg|_{t=0}\\&=\sum_{i_1=1}^n\cdots\sum_{i_p=1}^n h_{i_1i_2}h_{i_2i_3}\cdots h_{i_{p-1}i_p}h_{i_pi_1}g(\lambda_{i_1})g(\lambda_{i_2})\cdots g(\lambda_{i_p})g(\lambda_{i_1})\\&=\sum_{i_1=1}^n\cdots\sum_{i_p=1}^n(\xi_{i_1}|b_{i_2})(b_{i_2}|b_{i_3})\cdots(b_{i_{p-1}}|b_{i_p})(b_{i_p}|\xi_{i_1}).\end{aligned}$$

But any sum of the form

$$S=\sum_{i_2=1}^n\cdots\sum_{i_p=1}^n(\xi|b_{i_2})(b_{i_2}|b_{i_3})\cdots(b_{i_{p-1}}|b_{i_p})(b_{i_p}|\xi)$$

is non-negative. It is obvious for $p=2$ since then

$$S = \sum_{i_2=1}^{n} (\xi|b_{i_2})(b_{i_2}|\xi),$$

and for $p=3$ since then

$$\sum_{i_2=1}^{n}\sum_{i_3=1}^{n} (\xi|b_{i_2})(b_{i_2}|b_{i_3})(b_{i_3}|\xi) = \left(\sum_{i_2=1}^{n} (\xi|b_{i_2})b_{i_2}|\sum_{i_3=1}^{n} (\xi|b_{i_3})b_{i_3}\right).$$

For $p\geqslant 4$ we may therefore use induction over either the even or the odd natural numbers by noting that

$$\begin{aligned} S &= \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} (\xi|b_{i_2})(b_{i_2}|b_{i_3}) \cdots (b_{i_{p-1}}|b_{i_p})(b_{i_p}|\xi) \\ &= \sum_{i_3=1}^{n} \cdots \sum_{i_{p-1}=1}^{n} (\eta|b_{i_3})(b_{i_3}|b_{i_4}) \cdots (b_{i_{p-2}}|b_{i_{p-1}})(b_{i_{p-1}}|\eta), \end{aligned}$$

where the vector

$$\eta = \sum_{i=1}^{n} (\xi|b_i)b_i.$$

This concludes the proof of the statement. Q.E.D.

Proof of the main theorem: Consider again the function

$$g(t) = \frac{1}{c+t}, \quad t>0$$

for $c\geqslant 0$ and arbitrary $n\times n$ matrices x and h such that x is positive definite and h is positive semidefinite. We first note that

$$\left.\frac{d^p}{dt^p}\mathrm{Tr}\, g(x+th)\right|_{t=t_0} = \left.\frac{d^p}{d\varepsilon^p}\mathrm{Tr}\, g(x+t_0h+\varepsilon h)\right|_{\varepsilon=0}$$

for $p=1,2,\ldots$ and $t_0\geqslant 0$. The function $t\to \mathrm{Tr}\, g(x+th)$ is therefore completely monotone. Let now $f:\mathbf{R}_+\to\mathbf{R}$ be a non-negative operator monotone decreasing function. Any operator monotone decreasing function defined on the open positive half-line, thus in particular the function f, is necessarily of the form

$$f(t) = \alpha t + \beta + \int_0^\infty \left(\frac{1}{c+t} - \frac{c}{c^2+1}\right) d\nu(c), \tag{4}$$

where $\alpha\leqslant 0$ and ν is some positive Borel measure with support in $[0,\infty)$ such that the integral $\int (c^2+1)^{-1}\, d\nu(c)$ is finite, cf. Ref. 4 Chap. II, Theorem 1 and Lemma 2. Note that we may write

$$\int_0^\infty \left(\frac{1}{c+t} - \frac{c}{c^2+1}\right) d\nu(c) = \int_0^\infty \frac{1-ct}{c+t}\cdot (c^2+1)^{-1}\, d\nu(c),$$

where for each $t>0$ the function $c\to(1-ct)(c+t)^{-1}$ is decreasing and bounded between $-t$ and t^{-1}. Since f has a finite limit for $t\to\infty$ one may derive that $\alpha=0$, and by appealing to Lebesgues's theorem of monotone convergence we also obtain $\int c(c^2+1)^{-1}\, d\nu(c)<\infty$, hence f allows the representation

$$f(t) = \beta + \int_0^\infty \frac{1}{c+t} \mathrm{d}\nu(c),$$

where we have incorporated the constant contribution from the integral in (4) into β such that

$$\beta = \lim_{t\to\infty} f(t) \geqslant 0.$$

We conclude that the function $t \to \mathrm{Tr}\, f(x+th)$ is completely monotone and thus by Bernstein's theorem is the Laplace transform of a positive measure with support in $[0,\infty)$. Q.E.D.

Further analysis: One may try to use the Hermite expression in Proposition 3.2 to obtain a proof of the BMV conjecture. Applying Theorem 3.4 and calculating the third derivative of the trace function we obtain

$$\begin{aligned}\frac{-1}{3!}\frac{d^3}{\mathrm{d}t^3}\mathrm{Tr}\exp(x-th)\bigg|_{t=0} &= \sum_{p,i,j=1}^n (a_p|a_i)(a_i|a_j)(a_j|a_p)[\lambda_p\lambda_i\lambda_j\lambda_p]_{\exp} \\ &= \int_0^1\int_0^{t_1}\int_0^{t_2}\sum_{p,i,j=1}^n (a_p|a_i)(a_i|a_j)(a_j|a_p)\exp((1-(t_1-t_3))\lambda_p \\ &\quad + (t_1-t_2)\lambda_i + (t_2-t_3)\lambda_j)\mathrm{d}t_3\,\mathrm{d}t_2\,\mathrm{d}t_1,\end{aligned}$$

where $h=aa^*$ and a_i is the ith row in a. Assuming the BMV conjecture this integral should be non-negative, and this would obviously be the case if the integrand is a non-negative function.

Example 4.2: If we evaluate the above integrand in $t_1=t_2=1$ and $t_3=1/3$ we obtain

$$S = \sum_{p,i,j=1}^n (a_p|a_i)(a_i|a_j)(a_j|a_p)\exp\left(\frac{\lambda_p+2\lambda_j}{3}\right)\mathrm{d}t_3\,\mathrm{d}t_2\,\mathrm{d}t_1.$$

If we in addition set

$$a_1 = (1000,-10,1),$$

$$a_2 = (-10,10\,000,1000),$$

$$a_3 = (1,1000,202\,139)$$

and $(\lambda_1,\lambda_2,\lambda_3)=3\log 2\cdot(23,11,0)$, then the sum is an integer with value

$$S = -487\,062\,506\,352\,658\,941\,731\,358\,505\,750.$$

The values of S are extremely sensitive to the chosen figures, and they tend to be overwhelmingly positive. If for example, the third entry in a_3 is changed from 202 139 to 202 138, then

$$S = 376\,189\,230\,591\,238\,013\,538\,921\,396\,773.$$

The result is equally sensitive to changes in the values of $(\lambda_1,\lambda_2,\lambda_3)$.

The above example has not been found by simulation. In fact, millions of simulations with randomly chosen entries have been carried out, without ever hitting a negative value of S. Instead, the example has been obtained by the study and proper modification of an example in Ref. 14 of two positive definite 3×3 matrices A and B such that $\mathrm{Tr}(BABAAB)=-3164$.

Another way forward would be to examine the value of loops of the form

$$(a_1|a_2)(a_2|a_3)\cdots(a_{p-1}|a_p)(a_p|a_1)$$

since they, apart from an alternating sign, are the only possible negative factors in the expression of the derivatives of the trace functions. The value of a loop is a homogeneous function of degree

two in the norm of the vectors, so we only need to consider unit vectors. The value of such a loop is furthermore invariant under unitary transformations and thus takes the minimal value in any subspace of dimension p. By applying a variational principle the lower bound

$$-\cos^p\left(\frac{\pi}{p}\right) \leqslant (a_1|a_2)(a_2|a_3)\cdots(a_{p-1}|a_p)(a_p|a_1)$$

was established in Ref. 11. The lower bound converges very slowly to -1 as p tends to infinity, and it is attained essentially only when all the vectors form a "*fan*" in a two-dimensional subspace.

Remark 4.3: *If we only consider one-dimensional perturbations, that is if* $h=cP$ *for a constant* $c>0$ *and a one-dimensional projection* P, *then* h *is of the form* $h=(\xi_i\overline{\xi}_j)_{i,j=1,\ldots,n}$ *for some vector* $\xi=(\xi_1,\ldots,\xi_n)$ *and each loop*

$$h_{i_1i_2}h_{i_2i_3}\cdots h_{i_{p-1}i_p}h_{i_pi_1} = \|\xi_{i_1}\|^2\cdots\|\xi_{i_p}\|^2$$

is manifestly real and non-negative. This implies that the trace function

$$t \to \mathrm{Tr}\exp(-(x+th)),$$

for any self-adjoint $n\times n$ *matrix* x, *is the Laplace transform of a positive measure with support in* $[0,\infty)$. *The same statement holds, with* x *positive definite, for the trace function* $t\to\mathrm{Tr}\,f(x+th)$ *associated with an arbitrary completely monotone function* f.

Tri-Hamiltonian extensions of separable systems in the plane

Luca Degiovanni[a)]
Department of Mathematics, University of Torino, via Carlo Alberto 10, I-10123 Torino, Italy

(Received 16 December 2005; accepted 23 February 2006; published online 18 April 2006)

A method to construct tri-Hamiltonian extensions of a separable system is presented. The procedure is tested for systems, with a Hamiltonian quadratic in the momenta, separable in classical sense in any of the four sets of orthogonal separable coordinates on the Euclidean plane. Some explicit examples are constructed. Finally a conjecture on possible generalizations to other classes of systems is discussed: in particular, the method can be adapted to the 11 orthogonal separable coordinate sets of the Euclidean three-space. © *2006 American Institute of Physics.*

I. INTRODUCTION

Separation of variables for Hamilton-Jacobi equation is a very effective method to solve Hamiltonian systems. In recent years an increasing interest rose towards this classical topic in analytical mechanics, dated back to the pioneering works of Stäckel, Levi-Civita, and Eisenhart.[12] Starting from these foundations, a number of applications and new results, together with reinterpretations of old ones, have been constructed. A rich and coordinates-independent characterization of separation in the classical framework of cotangent bundles of a Riemannian manifold was developed (see Refs. 2, 9, and 8 and references therein), and some generalizations were proposed. In Ref. 11, Sklyanin presented a recipe to find a separable set of coordinates for systems admitting a Lax matrix with parameter and a corresponding spectral curve. Besides, in Ref. 6 the conditions under which a bi-Hamiltonian system is separable, in the so-called Darboux-Nijenhuis coordinates, are stated. In both these approaches the separation coordinates are general canonical coordinates $\{q^i, p_i\}$ on a $2n$-dimensional symplectic manifold, instead of the coordinates on a Riemannian manifold and their conjugate momenta, as in the classical approach. Moreover, the separability of a family of n Hamiltonians $\{h_k\}$ is characterized through the existence of n function W_i such that

$$W_1(q_1, p_1; \{h_k\}) = 0,$$

$$\cdots,$$

$$W_n(q_n, p_n; \{h_k\}) = 0. \tag{1}$$

The bi-Hamiltonian point of view inspires the results presented in Ref. 5. In this paper it is shown that, given three mutually compatible Poisson tensors P, Q, and R (a *tri-Hamiltonian structure*) with rank $2n$, such that the two Poisson pencils $Q-\lambda P$ and $R-\mu P$ admit a unique polynomial Casimir function $f(\lambda, \mu)$ common to both the pencils, it is possible to find a set of canonical coordinates $\{\lambda_i, \mu_i\}$ that satisfies the relationship

[a)]Electronic mail: degio@dm.unito.it

$$f(\lambda_i, \mu_i; \{h_k\}) = r_i(\lambda_i, \mu_i) \quad \forall\, i = 1, \ldots n, \tag{2}$$

where H_k are the coefficients of $f(\lambda, \mu)$ (restricted to a given symplectic leaf of P), and $r_i(\lambda, \mu)$ are constant functions. This implies that $\{\lambda_i, \mu_i\}$ are separation coordinates (in the generalized sense) for the Hamiltonians h_k, the functions W_i being strictly related to the common Casimir function $f(\lambda, \mu)$. In the same article[5] a class of systems is presented, admitting a Lax matrix with spectral parameter and such that the Casimir function $f(\lambda, \mu)$ is the polynomial defining the spectral curve of the system. This result links the multi-Hamiltonian approach to the Sklyanin one.

Another theory inspired by the bi-Hamiltonian point of view is reviewed in Ref. 3. In that paper the attention is drawn to separable systems in which any conjugate pair of separation coordinates consists of roots of a polynomial. The curve defined by this polynomial is called *separation curve*. A standard form (in separation coordinates) is found for this kind of system, and a pair of compatible Poisson tensors P and Q setting the coefficients of the polynomial in a Lenard recurrence relation are constructed. The standard form and the Poisson structures depend on the number and the position of the Casimir functions for P inside the recurrence relation between the coefficients: in *split type systems* the recurrence relation can be divided in different Lenard chains, otherwise one has *unsplit type systems*.

The aim of the present work is to introduce, in the simple case of the Euclidean plane, a recipe for constructing tri-Hamiltonian (and consequently bi-Hamiltonian) extensions of an orthogonally separable natural Hamiltonian. Although referred to a particular case, the results of the present paper give hints on more general issues.

First, the similarities between the two approaches presented in Refs. 3 and 5 raise a natural question about the relation between the separation curve and the common Casimir function of a tri-Hamiltonian structure. The present work shows a link between the two approaches: at least in the Euclidean plane, the separation curve can be obtained through a reduction procedure from the common Casimir function associated to a tri-Hamiltonian structure.

Second, starting from a tri-Hamiltonian extension of a separable system in the plane, it is possible to construct two different bi-Hamiltonian extensions, whose recursion relations are in a case of unsplit type, while in the other case of split type. This suggests the possibility to deal with both cases in a unified way.

Third, until now very few examples of tri-Hamiltonian systems are known: the recipe proposed in this paper can, in principle, produce a whole class of them, starting from any separable system. Moreover, if one of the questions answered in Ref. 5 was "how to construct separable coordinates for a tri-Hamiltonian system?," this paper gives a partial answer to the opposite question: "does any separable system admit a tri-Hamiltonian interpretation?"

Eventually, the properties of the tri-Hamiltonian systems obtained in this paper cast light on the general theory of tri-Hamiltonian separability: in fact only the Hamiltonians separable in asymmetric coordinate systems (parabolic and elliptic-hyperbolic) produce a tri-Hamiltonian structure admitting a unique common Casimir function such that (2) holds; but the explained procedure can be applied even to systems separable in symmetric coordinate systems (Cartesian and polar), and the tri-Hamiltonian structures obtained in these cases admit more Casimir functions. This indicates a possible generalization of the method to find separation coordinates for a tri-Hamiltonian system.

The main open question is the possibility of extending the partial results presented in the paper: although the method looks promising also for the separable coordinate systems of the Euclidean three-space, the extension of the procedure to any orthogonally separable system has still to be performed.

The paper is organized in the following way: in the second section the general separation theory in the classical framework is briefly reviewed. The four separable sets of coordinates on the Euclidean plane are presented together with the associated pairs of quadratic Hamiltonians. These systems are, in different coordinates, the four types of integrable systems in the plane with two quadratic first integrals listed in Ref. 10. In Sec. III the basic concepts of the bi-Hamiltonian and tri-Hamiltonian framework are summarized. The procedure for constructing a tri-Hamiltonian

extension is presented first for the two asymmetric coordinate systems, and then for the two symmetric ones. Finally, in Sec. IV some explicit examples are shown. In particular the one-Casimir extensions of Hénon-Heiles and Kepler systems presented in Ref. 3 is recovered from a tri-Hamiltonian point of view and it is shown, in the Kepler case, how multiple sets of separation coordinates lead to different tri-Hamiltonian extensions of the same Hamiltonian. The paper ends with an appendix that shows how to adapt to the extension method the Stäckel matrices for the sets of orthogonally separable coordinates in the Euclidean space.

II. ORTHOGONAL SEPARATION OF VARIABLES

A. General theory

Let (Q,g) be a n-dimensional Riemannian manifold with coordinates $q=\{q^1,\ldots q^n\}$, T^*Q is its cotangent bundle, with canonical coordinates given by $\{q^i\}$ and by the momenta $p=\{p_1,\ldots,p_n\}$. In this paper only Hamiltonian functions depending quadratically on the momenta are considered. The Hamiltonian functions constructed with the metric tensor

$$H(q,p)=\tfrac{1}{2}g^{ij}p_ip_j+V(q)=G(q,p)+V(q), \tag{3}$$

are particularly important and are called *natural*. The function G is called the *geodesic part* of the Hamiltonian. One should observe that a *point transformation of coordinates*,

$$Q^i=Q^i(q), \quad P_i=\frac{\partial q^j}{\partial Q^i}p_j$$

sends any natural Hamiltonian in a natural one. In this paper only this kind of transformation is considered.

In the following the basic facts about the classical theory of separation of variables are recalled. Proofs and a more systematic review can be found in Refs. 2 and 4.

A complete solution $W(q;\{a^i\})$ of the (time-independent) Hamilton-Jacobi equation

$$H\left(q,\frac{\partial W}{\partial q}\right)=E$$

associated to a natural Hamiltonian is called *separated* in the coordinates $\{q^i\}$ if $W=\Sigma_iW_i(q^i)$ where any function W_i depends only on the coordinate q^i. A *separated change of coordinates* (i.e., a transformation such that any new coordinate Q^i depends only on the old coordinate q^i) sends a separated solution of the Hamilton-Jacobi equation in another separated solution. Thus, instead of a coordinate system, it is more appropriate to consider the associated web, i.e., the n families of hypersurfaces given by the level set of the coordinates: webs, indeed, are invariant under separated change of variables.

The natural Hamiltonian (3) is separable in a given set of coordinates only if its geodesic part G is separable. Therefore it is possible to determine the sets of coordinates in which a certain Hamiltonian may be separated through the study of all separable coordinate systems associated to the metric g. If the separation is performed in an orthogonal set of coordinates, then it is called *orthogonal separation*, otherwise it is called *general separation*. Orthogonal separation is quite important not only because it is simpler, but even because general separation is always equivalent to orthogonal separation in a Riemannian manifold of constant curvature.

The keystone of the separability theory of Stäckel and Eisenhart[12] is the concept of Stäckel matrix: Stäckel proved that a geodetic Hamiltonian is separable in a set of orthogonal coordinates if and only if an invertible $n\times n$ matrix S exists, such that each element S_i^j belonging to the ith row of the matrix depends only on the coordinate q^i, and the diagonal controvariant components g^{ii} of the metric tensor form a row of the inverse of S,

$$g^{ii} = (S^{-1})^i_j \quad \text{for a fixed } j.$$

The existence of a Stäckel matrix is equivalent to the existence of a family of $n-1$ Killing tensors $K_{(l)}$ that together with the metric g have n common normal eigenvectors. The vector space spanned by g and this family is the *Killing-Stäckel algebra* associated to the orthogonal coordinate systems. Conversely, from a Killing-Stäckel algebra it is possible to reconstruct the Stäckel matrix of the coordinate system. Finally, also the separability of a natural Hamiltonian with potential, $H=G+V$, can be related to the Stäckel matrix: the Killing-Stäckel algebra allows to construct a family of $n-1$ potentials $V_{(l)}$ such that the Hamiltonians

$$H_{(l)} = K^{ij}_{(l)} p_i p_j + V_{(l)}$$

are in involution both mutually and with H. An alternative way to restate these results is the following: a family of n Hamiltonians H_i is orthogonally separable if and only if there exists a Stäckel matrix S and a set of n functions Φ_i, each depending only on the ith coordinate and its momentum and forming the so-called *Stäckel vector*, such that

$$S \begin{pmatrix} H_1 \\ \vdots \\ H_n \end{pmatrix} = \begin{pmatrix} \Phi_1(q_1,p_1) \\ \vdots \\ \Phi_n(q_n,p_n) \end{pmatrix}. \tag{4}$$

It is important to remark that, if a family of Hamiltonians is separable in a set of coordinates, then any their linear combination is separable in the same coordinates. Therefore the separability is a property related not just to a given metric tensor g, and to the associated natural Hamiltonian, but to the whole Killing-Stäckel algebra.

These classical results have been set in a more handy form in Ref. 1, where it has been proved that a natural Hamiltonian is orthogonally separable if and only if a Killing tensor K with n normal and simple eigenvalues exists such that $\mathrm{d}(K\,\mathrm{d}V)=0$. A stronger result can be proved if Q is also equipped with a *conformal Killing tensor* with vanishing *Nijenhuis torsion*, i.e., a tensor L of type (1,1) satisfying

$$[LX,LY] - L[LX,Y] - L[X,LY] + L^2[X,Y] = 0$$

for all vector fields X and Y on Q, and

$$\{L^{ij} p_i p_j, g^{ij} p_i p_j\} = c g^{ij} p_i p_j.$$

In this case, indeed, the whole Killing-Stäckel algebra can be generated by a recursion formula. This kind of systems are called *Benenti systems* or *L-systems*.

B. Orthogonal separable systems in the plane

It is well known that in the Euclidean plane only four systems of orthogonal coordinates exist, that allow the separation of the Hamilton-Jacobi equation associated to a natural Hamiltonian (see, for example, Ref. 4). If x and y denote the Cartesian coordinates then the other three coordinate systems are

(i) parabolic coordinates,

$$x = \frac{u+v}{2}, \quad u = x + \sqrt{x^2+y^2},$$

$$y = \sqrt{-uv}, \quad v = x - \sqrt{x^2+y^2}$$

with a web made up of two families of confocal parabolae with focus in the origin and symmetric with respect to the x axis;

(ii) elliptic-hyperbolic coordinates,

$$x = \frac{\mathrm{d}s}{2k}, \quad s = \sqrt{(x+k/2)^2 + y^2} + \sqrt{(x-k/2)^2 + y^2},$$

$$y = \frac{\sqrt{-(d^2-k^2)(s^2-k^2)}}{2k}, \quad d = \sqrt{(x+k/2)^2 + y^2} - \sqrt{(x-k/2)^2 + y^2}$$

with a web made up of a family of confocal hyperbolas and a family of confocal ellipses. The common foci of these conic sections lie on the x axis with coordinate $\pm k/2$;

(iii) polar coordinates,

$$x = r\cos\theta, \quad r = \sqrt{x^2 + y^2},$$

$$y = r\sin\theta, \quad \theta = \arctan(y/x),$$

centered at the origin.

A pair of Hamiltonian functions, H and K, can be constructed for each separable coordinate system (more precisely for each web underlying the coordinate system), through the associated Killing tensors.[4] These functions are in involution with respect to the canonical Poisson bracket on the contangent bundle of $\mathbb{R}^2$: hence they define four canonical types of completely integrable system. Both H and K are separable in the given coordinates, as it is ensured by the Stäckel relation.

1. Cartesian coordinates

Hamiltonian functions,

$$H = \tfrac{1}{2}p_x^2 + \phi_1(x),$$

$$K = \tfrac{1}{2}p_y^2 + \phi_2(y).$$

Stäckel relation,

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} H \\ K \end{pmatrix} = \begin{pmatrix} \frac{1}{2}p_x^2 + \phi_1(x) \\ \frac{1}{2}p_y^2 + \phi_2(y) \end{pmatrix}. \tag{5}$$

2. Parabolic coordinates

Hamiltonian functions,

$$H = \frac{\left(\frac{1}{2}p_u^2 + \phi_1(u)\right)u - \left(\frac{1}{2}p_v^2 + \phi_2(v)\right)v}{u - v},$$

$$K = \frac{\left(\frac{1}{2}p_v^2 - \frac{1}{2}p_u^2 + \phi_2(v) - \phi_1(u)\right)uv}{u - v}.$$

Stäckel relation,

$$\begin{pmatrix} 1 & \frac{1}{u} \\ 1 & \frac{1}{v} \end{pmatrix}\begin{pmatrix} H \\ K \end{pmatrix} = \begin{pmatrix} \frac{1}{2}p_u^2 + \phi_1(u) \\ \frac{1}{2}p_v^2 + \phi_2(v) \end{pmatrix}. \tag{6}$$

3. Elliptic-hyperbolic coordinates

Hamiltonian functions,

$$H = \frac{\left(\frac{1}{2}p_s^2 + \phi_1(s)\right)(s^2 - k^2) - \left(\frac{1}{2}p_d^2 + \phi_2(d)\right)(d^2 - k^2)}{s^2 - d^2},$$

$$K = \frac{\left(\frac{1}{2}p_d^2 - \frac{1}{2}p_s^2 + \phi_2(d) - \phi_1(s)\right)(s^2 - k^2)(d^2 - k^2)}{s^2 - d^2}.$$

Stäckel relation,

$$\begin{pmatrix} 1 & \frac{1}{s^2 - k^2} \\ 1 & \frac{1}{d^2 - k^2} \end{pmatrix} \begin{pmatrix} H \\ K \end{pmatrix} = \begin{pmatrix} \frac{1}{2}p_s^2 + \phi_1(s) \\ \frac{1}{2}p_d^2 + \phi_2(d) \end{pmatrix}. \tag{7}$$

4. Polar coordinates

Hamiltonian functions,

$$H = \frac{1}{2}p_r^2 + \phi_1(r) + \frac{1}{r^2}\left(\frac{1}{2}p_\theta^2 + \phi_2(\theta)\right),$$

$$K = -\frac{1}{2}p_\theta^2 - \phi_2(\theta).$$

Stäckel relation,

$$\begin{pmatrix} 1 & \frac{1}{r^2} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} H \\ K \end{pmatrix} = \begin{pmatrix} \frac{1}{2}p_r^2 + \phi_1(r) \\ -\frac{1}{2}p_\theta^2 - \phi_2(\theta) \end{pmatrix}. \tag{8}$$

In Cartesian coordinates, the two alternative Hamiltonian functions,

$$\hat{H} = \frac{1}{2}(p_x^2 + p_y^2) + \phi_1(x) + \phi_2(y),$$

$$\hat{K} = \frac{1}{2}p_y^2 + \phi_2(y),$$

with Stäckel matrix

$$S = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$$

are sometimes preferred. Indeed $\hat{H}$ is a natural Hamiltonian associated to the Euclidean metric, while H is not natural. The Hamiltonians H and K used in the present work are trivial recombinations of the Hamiltonians $\hat{H}$ and $\hat{K}$, hence they are still separable in Cartesian coordinates. The reason for choosing the two Hamiltonians H and K, instead of $\hat{H}$ and $\hat{K}$, is to put the Stäckel matrix in a form such that in the ith row only different powers of a suitable function of the coordinate q^i appear. In order to extend the procedure presented in this paper to more general cases, one of the key points is to characterize the class of Stäckel matrix that can be put in this form.

The method to construct a tri-Hamiltonian extension of the previous systems is slightly different for the asymmetric coordinate systems (parabolic and elliptic-hyperbolic) and for the sym-

metric ones (polar and Cartesian). This is due to the different form of the Stäckel matrix in the two cases, as it can be seen in the formulas from (5)–(8). In fact, for asymmetric coordinate systems all the rows of the Stäckel matrix have the same form, whereas for symmetric coordinate systems different rows of the Stäckel matrix have different forms. Therefore, the algorithm used in the asymmetric case needs to be adapted to each symmetric coordinate system in a specific way.

III. TRI-HAMILTONIAN EXTENSION

A. Separation of tri-Hamiltonian systems

The idea of a tri-Hamiltonian extension of separable systems is suggested by the construction of bi-Hamiltonian extension of Benenti systems presented in Ref. 7, and by some results about tri-Hamiltonian systems, briefly summarized in this section (see Ref. 5 for proofs). Let P, Q, and R be three Poisson structures mutually compatible, with rank $2n$, on a manifold of dimension $2n+k$. Let, moreover, f be a simultaneous Casimir function for the two Poisson pencils $Q-\lambda P$ and $R-\mu P$, and a polynomial in λ and μ. Then, it can be proved that all the coefficients h_k of this polynomial are functions mutually in involution with respect to all the three Poisson structures, and satisfy a recurrence scheme determined by the form of the polynomial f. Under some further hypotheses, it is possible to find out a set of coordinates $\{\lambda_i, \mu_i, c_\alpha\}$ with the following characteristics:

(1) c_α are k Casimir functions for P;
(2) λ_i, μ_i are $2n$ Darboux-Nijenhuis coordinates for both the Nijenhuis tensors obtained, through a deformation procedure, from the two Poisson pencils $Q-\lambda P$ and $R-\mu P$;
(3) λ_i, μ_i satisfy the n relations,

$$f(\lambda_i, \mu_i; \{h_k\}, c_\alpha) = r_i(\lambda_i, \mu_i) \tag{9}$$

in which the functions $r_i(\lambda, \mu)$ are constant functions on the manifold.

The relations (9) imply the separability, in the sense (1) of Sklyanin, of the Hamiltonians h_k. It is then natural to ask if it is possible, starting from a classical separable system, to obtain an adapted tri-Hamiltonian structure.

A special case is important for the next sections: set $n=2$ and consider the common Casimir function $f=h_1+\lambda h_2+\hat{f}(\lambda, \mu; \{c_\alpha\})$, where $\hat{f}$ is a polynomial in λ, μ and in the Casimir functions c_α, then the relations (9) become

$$\begin{aligned} h_1 + \lambda_1 h_2 + \hat{f}(\lambda_1, \mu_1; \{c_\alpha\}) &= r_1(\lambda_1, \mu_1), \\ h_1 + \lambda_2 h_2 + \hat{f}(\lambda_2, \mu_2; \{c_\alpha\}) &= r_2(\lambda_2, \mu_2). \end{aligned} \tag{10}$$

For any fixed value of the Casimir functions c_α the formula (10) gives a separation relation in the sense of (1).

B. Asymmetric coordinate systems

The separation relations encoded by the Stäckel matrix in asymmetric coordinate systems are very similar to relations (10). Indeed with the symplectic (and separated) transformations:

$$\lambda_1 = u, \quad \lambda_2 = v, \quad \mu_1 = p_u, \quad \mu_2 = p_v$$

for parabolic coordinates and

$$\lambda_1 = s^2 - k^2, \quad \lambda_2 = d^2 - k^2, \quad \mu_1 = \frac{p_s}{2s}, \quad \mu_2 = \frac{p_d}{2d}$$

for elliptic-hyperbolic coordinates, the relations extracted from Stäckel matrix become

$$\begin{pmatrix} \lambda_1 & 1 \\ \lambda_2 & 1 \end{pmatrix} \begin{pmatrix} H \\ K \end{pmatrix} = \begin{pmatrix} r_1(\lambda_1, \mu_1) \\ r_2(\lambda_1, \mu_1) \end{pmatrix},$$

that is

$$K + \lambda_i H = r_i(\lambda_i, \mu_i), \tag{11}$$

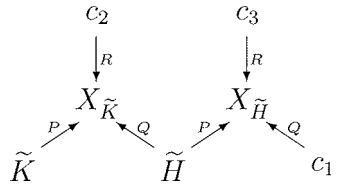
where the functions $r_i(\lambda, \mu)$ are, respectively, in the two coordinate systems,

$$r_i(\lambda, \mu) = \tfrac{1}{2}\lambda\mu^2 + \lambda\phi_i(\lambda), \tag{12}$$

$$r_i(\lambda, \mu) = 2\mu^2(\lambda^2 + \lambda k^2) + \lambda\phi_i(\sqrt{\lambda + k^2}). \tag{13}$$

Relations (10) and (11) differ only in the lack of the Casimir function c_α in (11). A set of Casimir functions are also necessary to construct a recurrence relation with a finite number of elements. In order to add Casimir functions and to obtain a set of relations analogous to (10), it is necessary to extend the phase space of the system $\mathbb{R}^4 = T^*\mathbb{R}^2$ to $\mathbb{R}^{4+k}$, with k extra coordinates c_α. Obviously the phase space $\mathbb{R}^4$ can be identified with the level surface $\mathcal{S} = \{c_\alpha = 0\}$ of the extended space. On $\mathbb{R}^{4+k}$, a Poisson structure P should be defined such that the new coordinates c_α are its Casimir functions, and the reduction of P on the symplectic leaf $\mathcal{S}$ gives the canonical Poisson bracket of $\mathbb{R}^4$. An extension of a given function g on $\mathbb{R}^2$ is any function $\tilde{g}$ on $\mathbb{R}^{4+k}$ such that $\tilde{g}|_{\mathcal{S}} = g$. In this framework the relations (11) can be thought of as a restriction of relations (10) on the symplectic leaf $\mathcal{S}$.

The simplest tri-Hamiltonian recursion relation involving two vector fields and compatible with the relations (11) is



(14)

where $\tilde{H}$ and $\tilde{K}$ are extensions of the Hamiltonians H and K and three extra coordinates are introduced. The recurrence scheme (14) corresponds to the common Casimir function.

$$f = \tilde{K} + \lambda\tilde{H} + c_1\lambda^2 + \mu c_2 + \lambda\mu c_3. \tag{15}$$

In the scheme (14), the notation $g \xrightarrow{P} X_g$ means that the vector field X_g is obtained from the differential of the function g, through the extended Poisson structure P given by

$$P = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{16}$$

The next step of the procedure is to require that λ_i, μ_i satisfy the two relations (10). This implies that $\tilde{H}$ and $\tilde{K}$ must solve the linear system

$$f(\lambda_i,\mu_i;\tilde{K},\tilde{H},c_\alpha)=r_i(\lambda_i,\mu_i).$$

Therefore the solution, using the function (15), is

$$\tilde{H}=\frac{r_2(\lambda_2,\mu_2)-r_1(\lambda_1,\mu_1)}{\lambda_2-\lambda_1}-(\lambda_1+\lambda_2)c_1+\frac{(\mu_2-\mu_1)}{\lambda_1-\lambda_2}c_2+\frac{(\mu_2\lambda_2-\mu_1\lambda_1)}{\lambda_1-\lambda_2}c_3, \tag{17}$$

$$\tilde{K}=\frac{\lambda_2 r_1(\lambda_1,\mu_1)-\lambda_1 r_2(\lambda_2,\mu_2)}{\lambda_2-\lambda_1}+\lambda_2\lambda_1 c_1+\frac{(\lambda_2\mu_1-\mu_2\lambda_1)}{\lambda_1-\lambda_2}c_2+\frac{\lambda_2\lambda_1(\mu_2-\mu_1)}{\lambda_2-\lambda_1}c_3, \tag{18}$$

where the two functions r_i are related to the two arbitrary functions ϕ_i by the expression (12) in the case of parabolic coordinates, and by the expression (13) in the case of elliptic-hyperbolic coordinates.

It is important to point out some aspects of the construction just presented. First, it is possible to reduce the number of new coordinates needed, by omitting the "vertical" part of the recurrence scheme and looking for a function in the form

$$f=\tilde{K}+\lambda\tilde{H}+\lambda^2 c_1.$$

This approach is followed in Refs. 7 and 3, but it allows to obtain only a bi-Hamiltonian recursion. This bi-Hamiltonian extension can be recovered in the tri-Hamiltonian approach through a reduction process.

Second, it is possible, both in the bi-Hamiltonian (as in Ref. 3) and in the tri-Hamiltonian case, to add to the function (15) a "redundant" Casimir function common to all the Poisson structures, by setting

$$\bar{f}=f+\lambda^n c_4 \quad \text{with } n>2.$$

In this way another pair of extended Hamiltonians $\tilde{H}$ and $\tilde{K}$ and a new tri-Hamiltonian structure are constructed. The new Hamiltonians and Poisson structures can be related to the old ones, through the reduction on the level set $c_4=0$.

Besides these digressions, the last step, in order to obtain the desired recursion scheme, is to construct two further Poisson structures. For this purpose a method similar to Ref. 5 is implemented. One starts by defining the two Poisson tensors represented by the 7×7 matrices

$$Q_d=\begin{pmatrix}0 & \Lambda & 0\\ -\Lambda & 0 & 0\\ 0 & 0 & 0\end{pmatrix},\quad R_d=\begin{pmatrix}0 & M & 0\\ -M & 0 & 0\\ 0 & 0 & 0\end{pmatrix},$$

where the null matrices have the appropriate dimensions and

$$\Lambda=\begin{pmatrix}\lambda_1 & 0\\ 0 & \lambda_2\end{pmatrix},\quad M=\begin{pmatrix}\mu_1 & 0\\ 0 & \mu_2\end{pmatrix}.$$

Then, one constructs the two vector fields,

$$X_Q=\sum_\alpha F_\alpha\frac{\partial}{\partial c_\alpha},\quad X_R=\sum_\alpha G_\alpha\frac{\partial}{\partial c_\alpha}, \tag{19}$$

where the functions F_α and G_α satisfy the relations $P\,\mathrm{d}F_\alpha=Q\,\mathrm{d}c_\alpha$ and $P\,\mathrm{d}G_\alpha=R\,\mathrm{d}c_\alpha$ in the recurrence scheme (14). Hence one has $F_1=\tilde{H}$, $F_2=F_3=0$ and $G_1=0$, $F_2=\tilde{K}$, $F_3=\tilde{H}$, and the two vector fields become

$$X_Q = \tilde{H}\frac{\partial}{\partial c_1}, \quad X_R = \tilde{K}\frac{\partial}{\partial c_2} + \tilde{H}\frac{\partial}{\partial c_3},$$

where the Hamiltonians $\tilde{H}$ and $\tilde{K}$ are already known by formulas (17) and (18).

Eventually, the two further tensors needed to realize the recursion scheme (14) are given by

$$Q = Q_d - L_{X_Q}P, \quad R = R_d - L_{X_R}P. \tag{20}$$

The surprising result of this complicated construction is the following fact, proved by direct computation.

Fact 1: The tensors Q and R, defined by (20), are compatible Poisson tensors independently of the choice of the functions $r_i(\lambda,\mu)$. *Moreover, the function f given by (15) is a common Casimir function for the two Poisson pencils* $Q-\lambda P$ *and* $R-\lambda P$, *thus realizing the recursion scheme (14).*

Since c_2 and c_3 are Casimir functions for both P and Q, these two Poisson structures can be reduced on the level surface $\{c_2=c_3=0\}$. On this surface the function (15) reduces to

$$\tilde{K} + \lambda\tilde{H} + \lambda^2 c_1$$

and the tri-Hamiltonian recursion scheme (14) becomes a simply bi-Hamiltonian one. Moreover, since the separation relations (10) for the reduced system become

$$\tilde{K} + \lambda_1\tilde{H} + \lambda_1^2 c_1 = r_1(\lambda_1,\mu_1),$$

$$\tilde{K} + \lambda_2\tilde{H} + \lambda_2^2 c_1 = r_2(\lambda_2,\mu_2),$$

if $\phi_1=\phi_2$ (and so $r_1=r_2=r$) then the function

$$\tilde{K} + \lambda\tilde{H} + \lambda^2 c_1 - r(\lambda,\mu)$$

defines an unsplitted separation curve in the sense of Ref. 3.

Conversely, a splitted bi-Hamiltonian recursion chain is obtained by reducing the function f and the Poisson structures P and R on the level surface $\{c_1=0\}$ of their common Casimir function c_1.

C. Symmetric coordinate systems

The procedure described above cannot be directly applied to Hamiltonians that are separable in a symmetric coordinate system, i.e., in polar or Cartesian coordinates. In these cases, actually, the rows of the Stäckel matrix are of different form, and therefore do not identify an unique polynomial, from whom to construct a Casimir function common to the two Poisson pencils $Q-\lambda P$ and $R-\lambda P$. This difficulty can be overcome by observing that a tri-Hamiltonian structure does not admit necessarily only one common Casimir function for the two Poisson pencils. Therefore, it will be sufficient to build a different common Casimir function for each of the different polynomial relations generated by the Stäckel matrix.

In the case of polar coordinates, through the symplectic transformations,

$$\lambda_1 = r^2, \quad \lambda_2 = \tan\theta, \quad \mu_1 = \frac{p_r}{2r}, \quad \mu_2 = \cos^2\theta p_\theta$$

the Stäckel relationships can be rewritten with the two equations

$$\begin{aligned} K + \lambda_1 H &= r_1(\lambda_1,\mu_1), \\ K &= r_2(\lambda_2,\mu_2), \end{aligned} \tag{21}$$

where the functions $r_i(\lambda,\mu)$ are

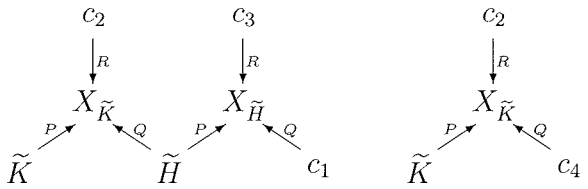
$$r_1(\lambda,\mu) = 2\mu^2\lambda^2 + \lambda\phi_1(\sqrt{\lambda}),$$

$$r_2(\lambda,\mu) = -\tfrac{1}{2}(1+\lambda^2)^2\mu^2 - \phi_2(\arctan\lambda).$$

Hence it is necessary to build two functions in the form

$$f_1 = \widetilde{K} + \lambda\widetilde{H} + \lambda^2 c_1 + \mu c_2 + \lambda\mu c_3,$$
$$f_2 = \widetilde{K} + \lambda c_4 + \mu c_2 \tag{22}$$

that realize the tri-Hamiltonian recursion scheme:



(23)

The expressions for $\widetilde{H}$ and $\widetilde{K}$ can be obtained solving the system

$$\widetilde{K} + \lambda_1\widetilde{H} + \lambda_1^2 c_1 + \mu_1 c_2 + \lambda_1\mu_1 c_3 = r_1(\lambda_1,\mu_1),$$

$$\widetilde{K} + \lambda_2 c_4 + \mu_2 c_2 = r_2(\lambda_2,\mu_2),$$

whose solution is

$$\widetilde{H} = \frac{r_1(\lambda_1,\mu_1) - r_2(\lambda_2,\mu_2)}{\lambda_1} - \lambda_1 c_1 + \frac{\mu_2-\mu_1}{\lambda_1}c_2 - \mu_1 c_3 + \frac{\lambda_2}{\lambda_1}c_4, \tag{24}$$

$$\widetilde{K} = r_2(\lambda_2,\mu_2) - \mu_2 c_2 - \lambda_2 c_4. \tag{25}$$

The Poisson tensor P used in this case is analogous to (16) but it has four Casimir functions. The structures Q and R are obtained, similarly to the asymmetric case

$$Q = Q_d - L_{X_Q}P, \quad R = R_d - L_{X_R}P, \tag{26}$$

where the vector fields X_Q and X_R are again constructed according to the formulas (19), but using the four functions $c_1,\ldots,c_4$. Hence from the recursion scheme (23) one obtains

$$X_Q = \widetilde{H}\frac{\partial}{\partial c_1} + \widetilde{K}\frac{\partial}{\partial c_4}, \quad X_R = \widetilde{K}\frac{\partial}{\partial c_2} + \widetilde{H}\frac{\partial}{\partial c_3}. \tag{27}$$

By direct computation the following fact can be proved:

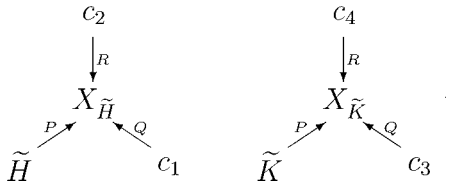
Fact 2: The tensors Q and R, defined by (26) with vector fields (27), are compatible Poisson tensors independently of the choice of the functions $r_i(\lambda,\mu)$. Moreover, the functions f_1 and f_2 given by (22) are two common Casimir functions for the two Poisson pencils $Q-\lambda P$ and $R-\lambda P$, thus realizing the recursion scheme (23).

Finally, in the case of Cartesian coordinates, the starting point is the construction of two functions of the form

$$f_1 = \widetilde{H} + c_1\lambda + \mu c_2,$$
(28)

$$f_2 = \tilde{K} + \lambda c_3 + \mu c_4,$$

that realize the tri-Hamiltonian recursion scheme,



(29)

By solving the linear system,

$$\tilde{H} + c_1\lambda_1 + \mu_1 c_2 = r_1(\lambda_1, \mu_1),$$

$$\tilde{K} + \lambda_2 c_3 + \mu_2 c_4 = r_2(\lambda_2, \mu_2),$$

one finds out the Hamiltonians

$$\tilde{H} = r_1(\lambda_1, \mu_1) - c_1\lambda_1 - \mu_1 c_2, \tag{30}$$

$$\tilde{K} = r_2(\lambda_2, \mu_2) - \lambda_2 c_3 - \mu_2 c_4, \tag{31}$$

where the arbitrary functions r_1, r_2 are linked to the functions ϕ_1, ϕ_2 in (5) by

$$r_1(\lambda_1(x), \mu_1(p_x, x)) = \tfrac{1}{2}p_x^2 + \phi_1(x),$$

$$r_2(\lambda_2(y), \mu_2(p_y, y)) = \tfrac{1}{2}p_y^2 + \phi_2(y).$$

The vector fields obtained from the recursion scheme (29) are the following:

$$X_Q = \tilde{H}\frac{\partial}{\partial c_1} + \tilde{K}\frac{\partial}{\partial c_3}, \quad X_R = \tilde{H}\frac{\partial}{\partial c_2} + \tilde{K}\frac{\partial}{\partial c_4}. \tag{32}$$

A result analogous to Fact 1 and Fact 2 is true also in this case, and it takes the following form.

Fact 3: The tensors Q and R, defined by (26) with vector fields (32), are compatible Poisson tensors independently of the choice of the functions $r_i(\lambda, \mu)$. Moreover, the functions f_1 and f_2 given by (28) are two common Casimir functions for the two Poisson pencils $Q - \lambda P$ and $R - \lambda P$, thus realizing the recursion scheme (29).

IV. EXAMPLES

A. Tri-Hamiltonian extension of Hénon-Heiles system

An application of the recipe presented above is given by the Hénon-Heiles system, already considered in Ref. 3. Its Hamiltonian expressed in natural coordinates is

$$H = \tfrac{1}{2}(p_1^2 + p_2^2) + V, \quad V = \tfrac{1}{2}q_1 q_2^2 + q_1^3. \tag{33}$$

This system is separable in the parabolic coordinate system given by

$$q_1 = \lambda_1 + \lambda_2, \quad q_2 = 2\sqrt{-\lambda_1\lambda_2},$$

$$p_1 = \frac{\lambda_1\mu_1 - \lambda_2\mu_2}{\lambda_1 - \lambda_2}, \quad p_2 = \sqrt{-\lambda_1\lambda_2}\frac{\mu_1 - \mu_2}{\lambda_1 - \lambda_2}.$$

If the Hénon-Heiles Hamiltonian (33) is compared with the general Hamiltonian (17), with $c_1=c_2=c_3=0$, one finds

$$V(\lambda_1,\lambda_2) = \frac{\lambda_2\phi(\lambda_2) - \lambda_1\phi(\lambda_1)}{\lambda_2 - \lambda_1}.$$

Any choice of the two functions ϕ_1 and ϕ_2 gives a separable potential and a suitable tri-Hamiltonian extension. On the contrary, a pair of functions ϕ_1, ϕ_2 is associated to any potential separable in the coordinates $\{\lambda_i, \mu_i\}$, also if the potential contains additional terms with respect to (33). Under the assumption that both $\phi_i(z)$ are continuous for $z=0$ one has

$$\phi_1(z) = V(z,0), \quad \phi_2(z) = V(0,z).$$

One should observe that the choice of the arbitrary functions is not unique: in fact, the pair $\phi_i(z)+(k/z)$ produce the same potential as the pair $\phi_i(z)$. The potential (33) is obtained by choosing

$$\phi_1(z) = \phi_2(z) = z^3.$$

The corresponding extended Hamiltonians are found by substituting in the general formulas (17) and (18):

$$\tilde{H} = \frac{1}{2}(p_1^2 + p_2^2) + \frac{1}{2}q_1q_2^2 + q_1^3 - q_1c_1 - 2\frac{p_2}{q_2}c_2 - p_1c_3,$$

$$\tilde{K} = \frac{1}{2}(q_2p_1p_2 - q_1p_2^2) + \frac{1}{4}q_1^2q_2^2 + \frac{1}{16}q_2^4 - \frac{1}{4}q_2^2c_1 + \left(2\frac{q_1p_2}{q_2} - p_1\right)c_2 - \frac{1}{2}q_2p_2c_3.$$

They are set in the recursion scheme (14) by the three Poisson structures,

$$P = \begin{pmatrix} 0_{2\times2} & 1_{2\times2} & 0_{2\times3} \\ -1_{2\times2} & 0_{2\times2} & 0_{2\times3} \\ 0_{3\times2} & 0_{3\times2} & 0_{3\times3} \end{pmatrix},$$

$$Q=\begin{pmatrix} 0 & 0 & q_1 & \frac{1}{2}q_2 & p_1-c_3 & 0 & 0 \\ 0 & 0 & \frac{1}{2}q_2 & 0 & p_2-2\frac{c_2}{q_2} & 0 & 0 \\ -q_1 & -\frac{1}{2}q_2 & 0 & \frac{1}{2}p_2 & c_1-3q_1^2-\frac{1}{2}q_2^2 & 0 & 0 \\ -\frac{1}{2}q_2 & 0 & -\frac{1}{2}p_2 & 0 & -q_1q_2-2\frac{p_2}{q_2^2}c_2 & 0 & 0 \\ c_3-p_1 & 2\frac{c_2}{q_2}-p_2 & 3q_1^2+\frac{1}{2}q_2^2-c_1 & q_1q_2+2\frac{p_2}{q_2^2}c_2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$R=\begin{pmatrix} 0 & 0 & p_1 & p_2 & 0 & Y_1 & X_1 \\ 0 & 0 & p_2 & p_1-2\frac{p_2q_1}{q_2} & 0 & Y_2 & X_2 \\ -p_1 & -p_2 & 0 & \frac{p_2^2}{q_2} & 0 & Y_3 & X_3 \\ -p_2 & 2\frac{q_1p_2}{q_2}-p_1 & -\frac{p_2^2}{q_2} & 0 & 0 & Y_4 & X_4 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -Y_1 & -Y_2 & -Y_3 & -Y_4 & 0 & 0 & 0 \\ -X_1 & -X_2 & -X_3 & -X_4 & 0 & 0 & 0 \end{pmatrix},$$

where $X=X_{\tilde{H}}=P\,\mathrm{d}\tilde{H}$ and $Y=X_{\tilde{K}}=P\,\mathrm{d}\tilde{K}$. It is worth to observe that both P and Q can be reduced by restriction on the level surface $c_2=c_3=0$ and the reduced Hamiltonians and Poisson structures are those considered in Ref. 3. On the contrary the structure R is not reducible, so the reduced system appears to be just a one-Casimir bi-Hamiltonian extension of the Hénon-Heiles system. An advantage of the knowledge of a tri-Hamiltonian extension of the system is the possibility to perform a reduction on the level set $c_1=0$, thus producing a different, two-Casimir bi-Hamiltonian extension of the system, whose Poisson structures are the reductions of P and R.

B. Tri-Hamiltonian extension of Kepler system in the plane

The Kepler system in the plane is separable in three different sets of coordinates: the parabolic, the elliptic-hyperbolic and the polar coordinate systems. A different second constant of motion (related to the Killing tensor of the coordinate system) and a different tri-Hamiltonian extension can be associated to each of these coordinate systems.

In the case of parabolic coordinates, the transformation between the natural and the $\{\lambda_i,\mu_i\}$ coordinates is given by

$$q_1=2\sqrt{-\lambda_1\lambda_2},\quad q_2=\lambda_1+\lambda_2,$$

$$p_1=\frac{\sqrt{-\lambda_1\lambda_2}(\mu_1-\mu_2)}{\lambda_1-\lambda_2},\quad p_2=\frac{\lambda_1\mu_1-\lambda_2\mu_2}{\lambda_1-\lambda_2}.$$

If one sets

$$\phi_1(z) = \frac{a}{2z}, \quad \phi_2(z) = -\frac{a}{2z},$$

the extended Hamiltonians (17) and (18) become

$$\widetilde{H} = \frac{1}{2}(p_1^2 - p_2^2) - \frac{a}{\sqrt{q_1^2 + q_2^2}} - q_2 c_1 - 2\frac{p_1}{q_1} c_2 - p_2 c_3,$$

$$\widetilde{K} = \frac{1}{2}(q_1 p_1 p_2 - q_2 p_1^2) + \frac{a q_2}{2\sqrt{q_1^2 + q_2^2}} - \frac{1}{4} q_1^2 c_1 + \frac{2q_2 p_1 - q_1 p_2}{q_1} c_2 - \frac{1}{2} q_1 p_1 c_3.$$

They are set in the recursion scheme (14) by the three Poisson structures,

$$P = \begin{pmatrix} 0_{2\times 2} & 1_{2\times 2} & 0_{2\times 3} \\ -1_{2\times 2} & 0_{2\times 2} & 0_{2\times 3} \\ 0_{3\times 2} & 0_{3\times 2} & 0_{3\times 3} \end{pmatrix},$$

$$Q = \begin{pmatrix} 0 & 0 & 0 & \frac{1}{2}q_1 & X_1 & 0 & 0 \\ 0 & 0 & \frac{1}{2}q_1 & q_2 & X_2 & 0 & 0 \\ 0 & -\frac{1}{2}q_1 & 0 & -\frac{1}{2}p_1 & X_3 & 0 & 0 \\ -\frac{1}{2}q_1 & -q_2 & \frac{1}{2}p_1 & 0 & X_4 & 0 & 0 \\ -X_1 & -X_2 & -X_3 & -X_4 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$R = \begin{pmatrix} 0 & 0 & p_2 - 2\frac{p_1 q_2}{q_1} & p_1 & 0 & Y_1 & X_1 \\ 0 & 0 & p_1 & p_2 & 0 & Y_2 & X_2 \\ 2\frac{p_1 q_2}{q_1} - p_2 & -p_1 & 0 & -\frac{p_1^2}{q_1} & 0 & Y_3 & X_3 \\ -p_1 & -p_2 & \frac{p_1^2}{q_1} & 0 & 0 & Y_4 & X_4 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -Y_1 & -Y_2 & -Y_3 & -Y_4 & 0 & 0 & 0 \\ -X_1 & -X_2 & -X_3 & -X_4 & 0 & 0 & 0 \end{pmatrix},$$

where $X = X_{\widetilde{H}} = P\,\mathrm{d}\widetilde{H}$ and $Y = X_{\widetilde{K}} = P\,\mathrm{d}\widetilde{K}$. As it can be easily seen, the one-Casimir extension considered in Ref. 3 is obtained by reducing the Poisson structures P and Q and the Hamiltonians on the level set $c_2 = c_3 = 0$. It is important to observe that the separation coordinates used do not seem to originate a unique "separation curve" because the two functions ϕ_1 and ϕ_2 are different.

In the case of the elliptic-hyperbolic coordinates, the transformation from the natural coordinates is

$$q_2 = \frac{\sqrt{-\lambda_1\lambda_2}}{k}, \quad q_1 = \frac{\sqrt{(\lambda_1 + k^2)(\lambda_2 + k^2)}}{k} + k,$$

$$p_1 = 2\frac{(\lambda_1\mu_1 - \lambda_2\mu_2)\sqrt{(\lambda_1 + k^2)(\lambda_2 + k^2)}}{k(\lambda_1 - \lambda_2)}, \quad p_2 = 2\frac{\mu_1(\lambda_1 + k^2) - \mu_2(\lambda_2 + k^2)}{k(\lambda_1 - \lambda_2)}\sqrt{-\lambda_1\lambda_2}$$

and the two arbitrary functions are

$$\phi_1(z) = \phi_2(z) = \frac{az}{k^2 - z^2}.$$

The two extended Hamiltonians (17) and (18) turn out to be

$$\tilde{H} = \frac{1}{2}(p_1^2 + p_2^2) - \frac{a}{\sqrt{q_1^2 + q_2^2}} - (q_1^2 + q_2^2 - 2q_1k)c_1 + \frac{1}{2k^2}\left(\frac{p_1}{(q_1 - k)} - \frac{p_2}{q_2}\right)c_2 - \frac{p_1}{2(q_1 - k)}c_3,$$

$$\tilde{K} = (q_1 - k)q_2p_1p_2 - \frac{1}{2}q_1(q_1 - 2k)p_2^2 - \frac{1}{2}q_2^2p_1^2 - \frac{akq_1}{\sqrt{q_1^2 + q_2^2}} - q_2^2k^2c_1 + \frac{1}{2k^2}\left(\frac{q_1^2 + q_2^2 - 2q_1k}{q_2}p_2 - \frac{(q_1 - k)^2 + q_2^2}{(q_1 - k)}p_1\right)c_2 + \frac{1}{2}\left(\frac{q_2^2p_1}{q_1 - k} - q_2p_2\right)c_3,$$

and the three Poisson structures are

$$P = \begin{pmatrix} 0_{2\times2} & 1_{2\times2} & 0_{2\times3} \\ -1_{2\times2} & 0_{2\times2} & 0_{2\times3} \\ 0_{3\times2} & 0_{3\times2} & 0_{3\times3} \end{pmatrix},$$

$$Q = \begin{pmatrix} 0 & 0 & q_1(q_1 - 2k) & (q_1 - k)q_2 & X_1 & 0 & 0 \\ 0 & 0 & (q_1 - k)q_2 & q_2^2 & X_2 & 0 & 0 \\ q_1(2k - q_1) & (k - q_1)q_2 & 0 & (q_1 - k)p_2 - q_2p_1 & X_3 & 0 & 0 \\ (k - q_1)q_2 & -q_2^2 & (k - q_1)p_2 + q_2p_1 & 0 & X_4 & 0 & 0 \\ -X_1 & -X_2 & -X_3 & -X_4 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$R = \begin{pmatrix} 0 & 0 & \frac{(q_2^2 + k^2)p_1}{2k^2(q_1 - k)} - \frac{q_2p_2}{2k^2} & \frac{(q_1 - k)p_2 - q_2p_1}{2k^2} & 0 & Y_1 & X_1 \\ 0 & 0 & -\frac{(q_1 - k)p_2 - q_2p_1}{2k^2} & \frac{(q_1 - k)p_1}{2k^2} - \frac{q_1(q_1 - 2k)p_2}{2q_2k^2} & 0 & Y_2 & X_2 \\ \frac{(q_2^2 + k^2)p_1}{2k^2(k - q_1)} + \frac{q_2p_2}{2k^2} & \frac{(k - q_1)p_2 + q_2p_1}{2k^2} & 0 & \frac{(q_1 - k)^2p_2^2 + p_1^2q_2^2}{2q_2k^2(q_1 - k)} - \frac{p_2p_1}{k^2} & 0 & Y_3 & X_3 \\ \frac{(k - q_1)p_2 + q_2p_1}{2k^2} & \frac{(k - q_1)p_1}{2k^2} + \frac{q_1(q_1 - 2k)p_2}{2q_2k^2} & \frac{(q_1 - k)^2p_2^2 + p_1^2q_2^2}{2k^2q_2(q_1 - k)} + \frac{p_2p_1}{k^2} & 0 & 0 & Y_4 & X_4 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -Y_1 & -Y_2 & -Y_3 & -Y_4 & 0 & 0 & 0 \\ -X_1 & -X_2 & -X_3 & -X_4 & 0 & 0 & 0 \end{pmatrix},$$

where $X = X_{\tilde{H}} = P\,\mathrm{d}\tilde{H}$ and $Y = X_{\tilde{K}} = P\,\mathrm{d}\tilde{K}$.

Finally, in the case of polar coordinates, the transformation between the natural and the $\{\lambda_i, \mu_i\}$ coordinates is given by

$$q_1 = \sqrt{\frac{\lambda_1}{1+\lambda_2^2}}, \quad q_2 = \lambda_2 \sqrt{\frac{\lambda_1}{1+\lambda_2^2}},$$

$$p_1 = \frac{2\mu_1\lambda_1 - \mu_2\lambda_2^3 - \lambda_2\mu_2}{\sqrt{\lambda_1(1+\lambda_2^2)}}, \quad p_2 = \frac{\mu_2\lambda_2^2 + 2\lambda_1\lambda_2\mu_1 + \mu_2}{\sqrt{\lambda_1(1+\lambda_2^2)}}.$$

With the choice

$$\phi_1(z) = -\frac{a}{z}, \quad \phi_2(z) = 0$$

the extended Hamiltonians (24) and (25) become

$$\widetilde{H} = \frac{1}{2}(p_1^2 + p_2^2) - \frac{a}{\sqrt{q_1^2+q_2^2}} - (q_1^2+q_2^2)c_1 - \frac{q_1p_1 + q_2p_2 - 2q_1^2(q_1p_2 - q_2p_1)}{2(q_1^2+q_2^2)^2}c_2 - \frac{q_1p_1+q_2p_2}{2(q_1^2+q_2^2)^2}c_3 + \frac{q_2c_4}{q_1(q_1^2+q_2^2)},$$

$$\widetilde{K} = q_1q_2p_1p_2 - \frac{1}{2}(q_2^2p_1^2 + q_1^2p_2^2) - q_1^2\frac{q_1p_2 - q_2p_1}{q_1^2+q_2^2}c_2 - \frac{q_2}{q_1}c_4.$$

They are set in the recursion scheme (23) by the three Poisson structures,

$$P = \begin{pmatrix} 0_{2\times2} & 1_{2\times2} & 0_{2\times4} \\ -1_{2\times2} & 0_{2\times2} & 0_{2\times4} \\ 0_{4\times2} & 0_{4\times2} & 0_{4\times4} \end{pmatrix},$$

$$Q = \begin{pmatrix} 0 & 0 & q_1^2 + \frac{q_2^3}{q_1(q_1^2+q_2^2)} & q_1q_2 - \frac{q_2^2}{q_1^2+q_2^2} & X_1 & 0 & 0 & Y_1 \\ 0 & 0 & q_1q_2 - \frac{q_2^2}{q_1^2+q_2^2} & q_2^2 + \frac{q_1q_2}{q_1^2+q_2^2} & X_2 & 0 & 0 & Y_2 \\ -q_1^2 - \frac{q_2^3}{q_1(q_1^2+q_2^2)} & \frac{q_2^2}{q_1^2+q_2^2} - q_1q_2 & 0 & q_1p_2 - q_2p_1 - \frac{q_2(q_1p_2-q_2p_1)}{q_1(q_1^2+q_2^2)} & X_3 & 0 & 0 & Y_3 \\ \frac{q_2^2}{q_1^2+q_2^2} - q_1q_2 & -q_2^2 - \frac{q_1q_2}{q_1^2+q_2^2} & q_2p_1 - q_1p_2 - \frac{q_2(q_2p_1-q_1p_2)}{q_1(q_1^2+q_2^2)} & 0 & X_4 & 0 & 0 & Y_4 \\ -X_1 & -X_2 & -X_3 & -X_4 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -Y_1 & -Y_2 & -Y_3 & -Y_4 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$R = \begin{pmatrix} 0 & 0 & A & B & 0 & Y_1 & X_1 & 0 \\ 0 & 0 & B & C & 0 & Y_2 & X_2 & 0 \\ -A & -B & 0 & D & 0 & Y_3 & X_3 & 0 \\ -B & -C & -D & 0 & 0 & Y_4 & X_4 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -Y_1 & -Y_2 & -Y_3 & -Y_4 & 0 & 0 & 0 & 0 \\ -X_1 & -X_2 & -X_3 & -X_4 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

where $X = X_{\widetilde{H}} = P\,\mathrm{d}\widetilde{H}$, $Y = X_{\widetilde{K}} = P\,\mathrm{d}\widetilde{K}$, and

$$A = q_1^2 \frac{q_1p_1 + q_2p_2 + 2q_2^2(q_1p_2 - q_2p_1)}{2(q_1^2 + q_2^2)^2},$$

$$B = q_1q_2 \frac{q_1p_1 + q_2p_2 - 2q_1^2(q_1p_2 - q_2p_1)}{2(q_1^2 + q_2^2)^2},$$

$$C = \frac{q_2^2(q_1p_1 + q_2p_2) + 2q_1^4(q_1p_2 - q_2p_1)}{2(q_1^2 + q_2^2)^2},$$

$$D = (q_1p_2 - q_2p_1) \frac{q_1p_1 + q_2p_2 - 2q_1^2(q_1p_2 - q_2p_1)}{2(q_1^2 + q_2^2)^2}.$$

V. FINAL REMARKS

In this paper a procedure to construct tri-Hamiltonian extensions of classical separable systems has been presented. This procedure has been tested in the particularly simple case of the Euclidean plane; however in principle it may be applied also to more general cases. It is articulated in the following steps:

(1) Write down the separation relations of a given system with n degree of freedom in the form involving the Stäckel matrix of the separation coordinates,

$$\begin{pmatrix} a_{11}(q_1) & \cdots & a_{1n}(q_1) \\ a_{21}(q_2) & \cdots & a_{2n}(q_2) \\ \vdots & & \vdots \\ a_{n1}(q_n) & \cdots & a_{nn}(q_n) \end{pmatrix} \begin{pmatrix} \hat{H}_1(\{p_i,q_i\}) \\ \hat{H}_2(\{p_i,q_i\}) \\ \vdots \\ \hat{H}_n(\{p_i,q_i\}) \end{pmatrix} = \begin{pmatrix} \Phi_1(p_1,q_1) \\ \Phi_2(p_2,q_2) \\ \vdots \\ \Phi_n(p_n,q_n) \end{pmatrix}.$$

(2) Transform, through a transformation to a suitable system of coordinates $\{\lambda_i, \mu_i\}$ (and in some case a linear combination of the Hamiltonians) the Stäckel relation in such a way that the ith row contains only different powers of λ_i. This is the most troublesome step: in fact it is not clear if all the Stäckel matrix can be put in this form. However this is possible for all the 11 orthogonal separable webs in $\mathbb{R}^3$, as it is shown in the Appendix.

(3) The separation relation encoded by the ith row of Stäckel matrix is now given by a polynomial in the coordinate λ_i: its coefficients are a set of Hamiltonians H_j obtained from the recombination of the $\hat{H}_j$. These polynomials can be grouped on the basis of their form: a polynomial function is associated to each different form, together with the corresponding tri-Hamiltonian recursion scheme between the H_j. In general there will be $m \leqslant n$ of such functions, labeled $f_1, \ldots, f_m$. The coefficients of the polynomial functions f_l are the extended Hamiltonians $\tilde{H}_j$ and a suitable number of Casimir functions.

(4) Solve the n equations (linear in the n extended Hamiltonians)

$$f_1(\lambda_1;\{\tilde{H}_j\}) = r_1(\lambda_1,\mu_1), \quad \cdots, \quad f_m(\lambda_n;\{\tilde{H}_j\}) = r_n(\lambda_n,\mu_n)$$

so that the explicit form of the extended Hamiltonians is obtained.

(5) The Poisson tensor P on the extended space is obtained in a trivial way from the canonical Poisson tensor. Moreover, from the extended Hamiltonian and the recursion scheme, it is possible to construct the two vector fields X_Q and X_R, and then the two tensors $Q = Q_d - L_{X_Q}P$ and $R = R_d - L_{X_R}P$.

The *conjecture* (proved in the Euclidean plane) suggested by this recipe is that the three tensors P, Q, and R are Poisson tensors mutually compatible; and that, moreover, the m functions

$f_l(\lambda,\mu)$ are common Casimir functions for the two Poisson pencils $Q-\lambda P$ and $R-\mu P$. As a consequence, the extended Hamiltonians $\tilde{H}_j$ satisfy the required tri-Hamiltonian recursion scheme.

APPENDIX: STÄCKEL MATRICES IN $\mathbb{R}^3$

The aim of this appendix is only to show how to set the Stäckel matrices, for the orthogonally separable coordinate systems in $\mathbb{R}^3$ with the Euclidean metric, in a form suitable for the application of the extension method. The existence of a tri-Hamiltonian extension will not be discussed. Actually, this issue is a particular case of the more general conjecture suggested by the results in the Euclidean plane. In the following list on the left-hand side there are the standard Stäckel matrix and separable Hamiltonians (derived, with minor modifications, from Ref. 4), while on the right-hand side there is the form adapted to the extension algorithm. The Stäckel vector is omitted. In most cases the transformations in the ith row of the Stäckel matrix is multiplied by a suitable function of the ith coordinate only, this operation preserves the separation relation.

Cartesian coordinates,

$$\begin{pmatrix} 1 & 1 & -1 \\ 1 & -1 & -1 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the new Hamiltonians are $H_1=\hat{H}_1+\hat{H}_2-\hat{H}_3$, $H_2=\hat{H}_1-\hat{H}_2-\hat{H}_3$, $H_3=\hat{H}_3$. The coordinates are just renamed.

Elliptic-hyperbolic cylindrical coordinates,

$$\begin{pmatrix} 1 & \dfrac{1}{d^2-k^2} & \dfrac{d^2+3k^2}{d^2-k^2} \\ 1 & \dfrac{1}{s^2-k^2} & \dfrac{s^2+3k^2}{s^2-k^2} \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1 & 1 & 0 \\ \lambda_2 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the new Hamiltonians are $H_1=\hat{H}_1+\hat{H}_3$, $H_2=\hat{H}_2+4k^2\hat{H}_3$, $H_3=\hat{H}_3$. It is also set $\lambda_1=d^2-k^2$, $\lambda_2=s^2-k^2$.

Circular cylindrical coordinates,

$$\begin{pmatrix} 1 & \dfrac{1}{r^2} & \dfrac{1+r^2}{r^2} \\ 1 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the new Hamiltonians are $H_1=\hat{H}_1+\hat{H}_3$, $H_2=\hat{H}_2+\hat{H}_3$, $H_3=\hat{H}_3$. It is also set $\lambda_1=r^2$.

Parabolic cylindrical coordinates,

$$\begin{pmatrix} 1 & \dfrac{1}{d_+} & 1 \\ 1 & \dfrac{1}{d_-} & 1 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1 & 1 & 0 \\ \lambda_2 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the new Hamiltonians are $H_1=\hat{H}_1+\hat{H}_3$, $H_2=\hat{H}_2$, $H_3=\hat{H}_3$. The coordinates are just renamed.

Prolate spheroidal coordinates,

$$\begin{pmatrix} \dfrac{d^2}{d^2-k^2} & \dfrac{1}{d^2-k^2} & \dfrac{1}{(d^2-k^2)^2} \\ \dfrac{s^2}{s^2-k^2} & \dfrac{1}{s^2-k^2} & \dfrac{1}{(s^2-k^2)^2} \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1^2 & \lambda_1 & 1 \\ \lambda_2^2 & \lambda_2 & 1 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the new Hamiltonians are $H_1=\hat{H}_1$, $H_2=\hat{H}_2+k^2\hat{H}_1$, $H_3=\hat{H}_3$. It is also set $\lambda_1=d^2-k^2$, $\lambda_2=s^2-k^2$.

Oblate spheroidal coordinates,

$$\begin{pmatrix} 1 & \dfrac{1}{d^2-k^2} & \dfrac{1}{d^2(d^2-k^2)} \\ 1 & \dfrac{1}{s^2-k^2} & \dfrac{1}{s^2(s^2-k^2)} \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix}$$

multiplying the first row by $d^2(d^2-k^2)$ and the second by $s^2(s^2-k^2)$, the Stäckel relation is equivalent to

$$\begin{pmatrix} d^4-k^2d^2 & d^2 & 1 \\ s^4-k^2s^2 & s^2 & 1 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1^2 & \lambda_1 & 1 \\ \lambda_2^2 & \lambda_2 & 1 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the new Hamiltonians are $H_1=\hat{H}_1$, $H_2=\hat{H}_2-k^2\hat{H}_1$, $H_3=\hat{H}_3$. It is also set $\lambda_1=d^2$, $\lambda_2=s^2$.

Spherical coordinates,

$$\begin{pmatrix} 1 & \dfrac{1}{r^2} & 0 \\ 0 & 1 & \dfrac{1}{\sin^2\theta} \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1 & 1 & 0 \\ 0 & 1 & \lambda_2 \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where it is set $\lambda_1=r^2$, $\lambda_2=\sin^2\theta$.

Parabolic coordinates,

$$\begin{pmatrix} 1 & \frac{1}{d_+} & \frac{1}{d_+^2} \\ 1 & \frac{1}{d_-} & \frac{1}{d_-^2} \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1 & 1 & 0 \\ \lambda_2 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the coordinates are just renamed.

Ellipsoidal coordinates,

$$\begin{pmatrix} \frac{u^2}{\Pi_i(u-a_i)} & \frac{u}{\Pi_i(u-a_i)} & \frac{1}{\Pi_i(u-a_i)} \\ \frac{v^2}{\Pi_i(v-a_i)} & \frac{v}{\Pi_i(v-a_i)} & \frac{1}{\Pi_i(v-a_i)} \\ \frac{w^2}{\Pi_i(w-a_i)} & \frac{w}{\Pi_i(w-a_i)} & \frac{1}{\Pi_i(w-a_i)} \end{pmatrix} \begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1^2 & \lambda_1 & 1 \\ \lambda_2^2 & \lambda_2 & 1 \\ \lambda_3^2 & \lambda_3 & 1 \end{pmatrix} \begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the coordinates are just renamed.

Paraboloidal coordinates,

$$\begin{pmatrix} \frac{u^2}{(u^2-k^2)} & \frac{u}{(u^2-k^2)} & \frac{1}{(u^2-k^2)} \\ \frac{v^2}{(v^2-k^2)} & \frac{v}{(v^2-k^2)} & \frac{1}{(v^2-k^2)} \\ \frac{w^2}{(w^2-k^2)} & \frac{w}{(w^2-k^2)} & \frac{1}{(w^2-k^2)} \end{pmatrix} \begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} \lambda_1^2 & \lambda_1 & 1 \\ \lambda_2^2 & \lambda_2 & 1 \\ \lambda_3^2 & \lambda_3 & 1 \end{pmatrix} \begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the coordinates are just renamed.

Spherical-conical coordinates,

$$\begin{pmatrix} 0 & \frac{u}{\Pi_i(u-a_i)} & \frac{1}{\Pi_i(u-a_i)} \\ 0 & \frac{v}{\Pi_i(v-a_i)} & \frac{1}{\Pi_i(v-a_i)} \\ \frac{1}{w} & \frac{1}{w^2} & 0 \end{pmatrix} \begin{pmatrix} \hat{H}_1 \\ \hat{H}_2 \\ \hat{H}_3 \end{pmatrix} \to \begin{pmatrix} 0 & \lambda_1 & 1 \\ 0 & \lambda_2 & 1 \\ \lambda_3 & 1 & 0 \end{pmatrix} \begin{pmatrix} H_1 \\ H_2 \\ H_3 \end{pmatrix},$$

where the coordinates are just renamed.

In this paper we analyze the resolvent, the heat kernel and the spectral zeta function of the operator $-d^2/dr^2-1/(4r^2)$ over the finite interval. The structural properties of these spectral functions depend strongly on the chosen self-adjoint realization of the operator, a choice being made necessary because of the singular potential present. Only for the Friedrichs realization standard properties are reproduced, for all other realizations highly nonstandard properties are observed. In particular, for $k \in \mathbb{N}$ we find terms like $(\log t)^{-k}$ in the small-t asymptotic expansion of the heat kernel. Furthermore, the zeta function has $s=0$ as a logarithmic branch point.

I. INTRODUCTION

A. Zeta functions and an unusual example

It is well known that the zeta function of a Laplacian over a smooth compact manifold, with or without boundary, defines a meromorphic function on $\mathbb{C}$ with simple poles at prescribed half-integer values depending on the dimension of the manifold.[21] (For a manifold with boundary, we put local boundary conditions, e.g., Dirichlet conditions.) These properties have far reaching applications in physics as well as mathematics, e.g., in the context of Casimir energies, effective actions and analytic torsion; see, for example, Refs. 12–14, 25, 28, and 41.

Surprisingly, there is a completely natural example of a zeta function for which the described properties break down and which has no meromorphic extension to $\mathbb{C}$. Let $\Omega \subset \mathbb{R}^2$ be any compact region and take polar coordinates $(x,y) \leftrightarrow (r,\theta)$ centered at any fixed point in Ω. Then in these coordinates, the standard Laplacian on $\mathbb{R}^2$ takes the form

$$\Delta_{\mathbb{R}^2} = -\partial_x^2 - \partial_y^2 = -\partial_r^2 - \frac{1}{r}\partial_r - \frac{1}{r^2}\partial_\theta^2,$$

and the measure transforms to $dx\,dy = r\,dr\,d\theta$. A short computation shows that

[a)]Electronic mail: klaus_Kirsten@baylor.edu
[b)]Electronic mail: paul@math.binghamton.edu
[c)]Electronic mail: jinsung@kias.re.kr

$$\Delta_{\mathbb{R}^2}\phi = \left(-\partial_r^2 - \frac{1}{r}\partial_r - \frac{1}{r^2}\partial_\theta^2\right)\phi = \mathcal{R}^{-1}\left(-\partial_r^2 + \frac{1}{r^2}\left(-\partial_\theta^2 - \frac{1}{4}\right)\right)\mathcal{R}\phi,$$

where $\mathcal{R}$ is the multiplication map by $r^{1/2}$, which is an isometry from $L^2(\Omega, r\,\mathrm{d}r\,\mathrm{d}\theta)$ to $L^2(\Omega, \mathrm{d}r\,\mathrm{d}\theta)$. Hence, the following two operators are equivalent under $\mathcal{R}$:

$$\Delta_{\mathbb{R}^2} \leftrightarrow -\partial_r^2 + \frac{1}{r^2}A, \quad \text{where } A = -\partial_\theta^2 - \frac{1}{4}.$$

In the zero eigenspace of $-\partial_\theta^2$, we obtain the operator of the form $-\partial_r^2 - (1/4r^2)$. Then this Laplace type operator has many different self-adjoint realizations parametrized by angles $\theta \in [0, \pi)$; the angle $\theta = \pi/2$ corresponds to the so-called Friedrichs realization. Each realization has a discrete spectrum.[35] Consider any one of the realizations, say Δ_θ, with $\theta \neq \pi/2$ and form the corresponding zeta function,

$$\zeta(s, \Delta_\theta) := \sum_{\lambda_j \neq 0} \frac{1}{\lambda_j^s},$$

where the λ_j's are the eigenvalues of Δ_θ. The shocking fact is that *every* such zeta function corresponding to an angle $\theta \in [0, \pi)$, except $\theta = \pi/2$, does not have a meromorphic extension to $\mathbb{C}$; in fact each such zeta function has a logarithmic branch cut with $s = 0$ as the branch point.

B. Self-adjoint realizations

The properties of the Laplace operator considered above boil down to the main object of consideration in this paper,

$$\Delta := -\frac{d^2}{\mathrm{d}r^2} - \frac{1}{4r^2} \quad \text{over } [0, R]. \tag{1.1}$$

In Sec. II we work out an explicit description of the maximal domain of Δ. In order to choose a self-adjoint realization of Δ, we first fix a boundary condition for Δ at $r = R$; it turns out that any such boundary condition for $\phi \in \mathcal{D}_{\max}(\Delta)$ must be of the form (see Sec. IV)

$$\cos\theta_2 \phi'(R) + \sin\theta_2 \phi(R) = 0. \tag{1.2}$$

In other words, the boundary conditions we can choose at $r = R$ are parametrized by angles $\theta_2 \in [0, \pi)$. Note that the Dirichlet condition is when $\theta_2 = \pi/2$ and the Neumann condition is when $\theta_2 = 0$. Let us henceforth *fix* an angle $\theta_2 \in [0, \pi)$ and consider Δ with the condition in (1.2). At $r = 0$, the operator Δ is singular and a limiting procedure $r \to 0$ must be used to define boundary conditions. As shown in Sec. III (see also Sec. IV), the self-adjoint realizations of Δ with the condition (1.2) are again parametrized by angles $\theta_1 \in [0, \pi)$; the paper by Kochubeĭ[31] is perhaps one of the earliest references to contain such a parametrization. It turns out that $\theta_1 = \pi/2$ corresponds to the Friedrichs realization.

As we will show in Theorem 2.1, $\phi \in \mathcal{D}_{\max}(\Delta)$ if and only if it can be written in the form

$$\phi = c_1(\phi) r^{1/2} + c_2(\phi) r^{1/2} \log r + \mathcal{O}(r^{3/2}),$$

where $c_1(\phi)$ and $c_2(\phi)$ are constants depending on ϕ. In terms of these constants, given angles $\theta_1, \theta_2 \in [0, \pi)$, we consider the operator

$$\Delta_L := \Delta : \mathcal{D}_L \to L^2([0, R]),$$

where

$$\mathcal{D}_L = \{\phi \in \mathcal{D}_{\max}(\Delta) | \cos\,\theta_1 c_1(\phi) + \sin\,\theta_1 c_2(\phi) = 0, \cos\,\theta_2 \phi'(R) + \sin\,\theta_2 \phi(R) = 0\}.$$

Here, the subscript "L" represents the two-dimensional subspace $L \subset \mathbb{C}^4$ defined by

$$L := \{(z_1, z_2, z_3, z_4) \in \mathbb{C}^4 | \cos\,\theta_1 z_1 + \sin\,\theta_1 z_2 = 0, \cos\,\theta_2 z_3 + \sin\,\theta_2 z_4 = 0\}.$$

This vector space is a Lagrangian subspace of $\mathbb{C}^4$ with respect to a natural Hermitian symplectic form intimately related to self-adjoint realizations of Δ; see Sec. III. For general references on this relation see; Refs. 23, 24, 27, and 31–34. For a study of adjoints of "cone operators" (in the sense of Schulze) see Ref. 19. For properties of resolvents of cone operators see, for example, Refs. 20 and 42.

C. The resolvent, heat kernel, and zeta function

When $\theta_1 = \pi/2$ (the Friedrichs realization), the following properties concerning the resolvent, heat kernel, and zeta function are well known; see for example, Brüning and Seeley,[7,8] Falomir *et al.*,[15] or Mooers.[38] With $\theta_1 = \pi/2$, the following properties hold.

Theorem 1.1 (cf. Refs. 8, 15, and 38): *Fixing a boundary condition* (1.2) *at* $r=R$, *let* Δ_L *denote the corresponding Friedrichs realization* (*that is, take* $\theta_1 = \pi/2$). *Then*

(1) *Let* $\Lambda \subset \mathbb{C}$ *be any sector (solid angle) not intersecting the positive real axis. Then as* $|\lambda| \to \infty$ *with* $\lambda \in \Lambda$, *we have*

$$\mathrm{Tr}(\Delta_L - \lambda)^{-1} \sim \sum_{k=1}^{\infty} a_k (-\lambda)^{-k/2}.$$

(2) *As* $t \to 0$, *we have*

$$\mathrm{Tr}(e^{-t\Delta_L}) \sim \sum_{k=0}^{\infty} \beta_k t^{(k-1)/2}.$$

(3) *The zeta function*

$$\zeta(s, \Delta_L) = \mathrm{Tr}(\Delta_L^{-s})$$

extends from $\Re s > 1/2$ *to a meromorphic function on* $\mathbb{C}$ *with poles at* $s = 1/2 - k$ *for* $k = 0, 1, 2, \ldots$.

These properties are "usual" in that they remain valid, with appropriate changes, to Laplace-type operators on compact manifolds (with or without boundary); see for example, Gilkey's book[21] for a thorough treatment. The first result of this paper shows that for *any* other realization, these properties are completely destroyed; see also Ref. 29.

Theorem 1.2: *With any boundary condition* (1.2) *fixed at* $r=R$, *choose a self-adjoint realization* Δ_L *of the resulting operator that is not the Friedrichs realization*. (*That is, take* $\theta_1 \neq \pi/2$). *Let* $\kappa = \log 2 - \gamma - \tan\,\theta_1$ *where* γ *is the Euler constant*. *Then the following properties hold*:

(1) *Let* $\Lambda \subset \mathbb{C}$ *be any sector (solid angle) not intersecting the positive real axis*. *Then as* $|\lambda| \to \infty$ *with* $\lambda \in \Lambda$, *we have*

$$\mathrm{Tr}(\Delta_L - \lambda)^{-1} \sim \frac{1}{(-\lambda)(\log(-\lambda) - 2\kappa)} + \sum_{k=1}^{\infty} b_k (-\lambda)^{-k/2}.$$

(2) *As* $t \to 0$, *we have* (*here* $\Im$ *denotes* "*imaginary part of*")

$$\mathrm{Tr}(e^{-t\Delta_L}) \sim \frac{1}{\pi} \Im \left(\int_1^{\infty} e^{-tx} \frac{1}{x(\log x + i\pi - 2\kappa)} dx \right) + \sum_{k=0}^{\infty} \beta_k t^{(k-1)/2}.$$

(3) *The zeta function* $\zeta(s,\Delta_L)$ *can be written in the form*

$$\zeta(s,\Delta_L) = -\frac{e^{-2s\kappa}\sin \pi s}{\pi}\log s + \zeta_L(s),$$

where $\zeta_L(s)$ *extends from* $\Re s > 1/2$ *to a holomorphic function on* $\mathbb{C}$ *with poles at* $s = 1/2 - k$ *for* $k = 0,1,2,\ldots$. *In particular,* $\zeta(s,\Delta_L)$ *has* $s=0$ *as a logarithmic branch point*

Remark 1.3: The authors have never seen a natural *geometric* differential operator with discrete spectrum on a compact manifold having a spectral zeta function with properties of the sort described in this theorem.

Remark 1.4: The first term in assertion (1) can be expanded further if needed. In the formulation of this theorem we leave it in this more useful compact form.

Remark 1.5: The same kind of remark holds for the first term in assertion (2). Expanding further we obtain the following expansion: As $t \to 0$, we have

$$\mathrm{Tr}(e^{-t\Delta_L}) \sim \sum_{k=1}^{\infty} \alpha_k (\log t)^{-k} + \sum_{k=0}^{\infty} \beta_k t^{(k-1)/2} \tag{1.3}$$

with the α_k's depending on κ via (here $\Im$ denotes "imaginary part of")

$$\alpha_k = -\frac{1}{k\pi}\Im\left(\int_1^{\infty} e^{-x}(\log x + i\pi - 2\kappa)^k \, \mathrm{d}x\right), \quad k = 1,2,3,\ldots .$$

The expansion (1.3) is misleading as written because for $k>1$, the terms $\beta_k t^{(k-1)/2}$ are subleading to any of the inverse log terms. However, we interpret the first sum in the expansion (1.3) to mean that for all N, we have

$$\frac{1}{\pi}\Im\left(\int_1^{\infty} e^{-tx}\frac{1}{x(\log x + i\pi - 2\kappa)}\mathrm{d}x\right) = \sum_{k=1}^{N} \alpha_k (\log t)^{-k} + \mathcal{O}((\log t)^{-N-1}).$$

D. Explicit formula for the zeta determinant

Our second result is an explicit formula for a regularized determinant. For concreteness, we shall impose the Dirichlet boundary condition at $r=R$. That is, given an angle $\theta \in [0,\pi)$ with $\theta \neq \pi/2$, we consider the operator

$$\Delta_\theta := \Delta : \mathcal{D}_\theta \to L^2([0,R]),$$

where

$$\mathcal{D}_\theta = \{\phi \in \mathcal{D}_{\max}(\Delta) \,|\, \cos\theta c_1(\phi) + \sin\theta c_2(\phi) = 0, \phi(R) = 0\}.$$

Then from Theorem 1.2, the zeta function $\zeta(s,\Delta_\theta)$ has the following form:

$$\zeta(s,\Delta_\theta) = -\frac{e^{-2s\kappa}\sin \pi s}{\pi}\log s + \zeta_\theta(s),$$

where $\zeta_\theta(s)$ extends from $\Re s > 1/2$ to a holomorphic function on $\mathbb{C}$ with poles at $s = 1/2 - k$ for $k = 0,1,2,\ldots$.

In particular, $\zeta(s,\Delta_\theta)$ has the form

$$\zeta(s,\Delta_\theta) \sim -s\log s + \mathcal{O}(s^2\log s) + \text{holomorphic} \quad \text{as } s\to 0. \tag{1.4}$$

In particular,

$$\zeta'(s,\Delta_\theta) \sim -\log s + \mathcal{O}(s\log s) + \text{holomorphic} \quad \text{as } s\to 0,$$

so the ζ-regularized determinant $\det(\Delta_\theta) := \exp(-\zeta'(0,\Delta_\theta))$ is *not* defined However, from (1.4), we see that

$$\zeta_{\text{reg}}(s,\Delta_\theta) := \zeta(s,\Delta_\theta) + s\log s$$

does have a well-defined derivative at $s=0$. For this reason, we define

$$\det{}_{\text{reg}}(\Delta_\theta) := \exp(-\zeta'_{\text{reg}}(0,\Delta_\theta)).$$

In the following theorem, we give a beautiful explicit formula for this regularized determinant.

Theorem 1.6: *For any* $\theta\in[0,\pi)$ *with* $\theta\neq\pi/2$, *we have*

$$\det{}_{\text{reg}}(\Delta_\theta) = \begin{cases} 2\sqrt{2\pi R}\,e^{\gamma}(\tan\theta - \log R), & \tan\theta \neq \log R, \\ \sqrt{\dfrac{\pi R}{2}}\,e^{\gamma}R^2, & \tan\theta = \log R. \end{cases}$$

We remark that when $\theta=\pi/2$, the zeta function $\zeta(s,\Delta_\theta)$ is regular at $s=0$ and we can also compute the (usual) ζ-regularized determinant: For $\theta=\pi/2$, we have

$$\det(\Delta_\theta) = \sqrt{2\pi R},$$

a well known result, see, e.g., Theorem 2.3 of Ref. 36, Proposition 5.2 of Ref. 37.

We now outline this article. In Secs. II–IV we study the self-adjoint realizations of our main operator using the Hermitian symplectic theory due to Gelfand (Ref. 39, p. 1); cf. also Refs. 15, 31–33, 37, 38, and 40. Although some of this material can be found piecemeal throughout the literature, we present all the details here in order to keep our paper elementary, self-contained, and "user-friendly." In Secs. V–VIII we prove Theorem 1.2 in the special case that the Dirichlet boundary condition is chosen at $r=R$ and in Sec. IX we prove Theorem 6, all using the contour integration method developed in Refs. 3–5. In Sec. X we prove Theorem 1.2 in full generality. Finally, in the Appendix, we explicitly calculate the resolvent of Δ_θ, which is needed at various places in our analysis.

II. THE MAXIMAL DOMAIN

Our first order of business is to characterize the self-adjoint realizations of the operator in (1.1); for general references on self-adjoint realizations and their applications to physics see, e.g., Refs. 2, 6, 10, 11, 16–18, 31–34, 40, and 44 To do so, we first need to determine the maximal domain of Δ:

$$\mathcal{D}_{\max}(\Delta) := \{\phi\in L^2([0,R]) \,|\, \Delta\phi\in L^2([0,R])\}.$$

For a quick review, $\Delta\phi$ is understood in the distributional sense; thus, $\Delta\phi$ is the functional on test functions $C_c^\infty((0,R))$ defined by

$$(\Delta\phi)(\xi) := \int_0^R \Delta\xi(r)\overline{\phi(r)}\mathrm{d}r \quad \text{for all } \xi\in C_c^\infty((0,R)).$$

Then $\Delta\phi\in L^2([0,R])$ means that the distribution $\Delta\phi: C_c^\infty((0,R))\to\mathbb{C}$ is represented by an L^2 function in the sense that there is a function $f\in L^2([0,R])$ such that

$$\int_0^R \Delta\xi(r)\overline{\phi(r)}\mathrm{d}r = \langle \xi, f\rangle \quad \text{for all } \xi \in C_c^\infty((0,R)),$$

where $\langle\cdot,\cdot\rangle$ denotes the L^2 inner product (conjugate linear in the second slot) on $L^2([0,R])$. The following theorem is inspired by Falomir *et al.* (Ref. 15, Lemma 2.1).

Theorem 2.1: *$\phi \in \mathcal{D}_{\max}(\Delta)$ if and only if ϕ can be written in the form*

$$\phi = c_1(\phi)r^{1/2} + c_2(\phi)r^{1/2}\log r + \tilde{\phi}, \tag{2.1}$$

where $c_1(\phi), c_2(\phi)$ are constants and $\tilde{\phi}$ is a continuously differentiable function on $[0,R]$ such that $\tilde{\phi}(r) = \mathcal{O}(r^{3/2})$, $\tilde{\phi}'(r) = \mathcal{O}(r^{1/2})$, and $\Delta\tilde{\phi} \in L^2([0,R])$.

Proof: Since

$$\Delta(c_1 r^{1/2} + c_2 r^{1/2}\log r) = 0,$$

it follows that any ϕ of the stated form is in $\mathcal{D}_{\max}(\Delta)$. Now let $\phi \in \mathcal{D}_{\max}(\Delta)$; then $\Delta\phi = f \in L^2([0,R])$. Let us define $\psi := r^{-1/2}\phi$ so that $\phi = r^{1/2}\psi$. Then

$$f = -\phi'' - \frac{1}{4r^2}\phi = \frac{1}{4}r^{-3/2}\psi - r^{-1/2}\psi' - r^{1/2}\psi'' - \frac{1}{4}r^{-3/2}\psi = -r^{-1/2}\psi' - r^{1/2}\psi''.$$

After multiplication by $r^{1/2}$, we get

$$\psi' + r\psi'' = -r^{1/2}f \Rightarrow (r\psi')' = -r^{1/2}f.$$

Since $r^{1/2}$ and f are in $L^2([0,R])$, by the Cauchy-Schwartz inequality, we know that $r^{1/2}f$ is in $L^1([0,R])$, therefore we can conclude that

$$\psi' = \frac{c_2}{r} - \frac{1}{r}\int_0^r t^{1/2}f(t)\mathrm{d}t. \tag{2.2}$$

Notice that by Cauchy-Schwartz,

$$\left|\int_0^r t^{1/2}f(t)\mathrm{d}t\right| \leqslant \sqrt{\int_0^r t\,\mathrm{d}t}\cdot\|f\|_2 = \frac{r}{\sqrt{2}}\|f\|_2. \tag{2.3}$$

Thus, the second term on the right-hand side in (2.2) is in $L^1([0,R])$. Therefore, from (2.2) we see that

$$\psi(r) = c_1 + c_2\log r - \int_0^r \frac{1}{x}\int_0^x t^{1/2}f(t)\mathrm{d}t\,\mathrm{d}x,$$

or, since $\phi = r^{1/2}\psi$, we get

$$\phi(r) = c_1 r^{1/2} + c_2 r^{1/2}\log r + \tilde{\phi}, \quad \tilde{\phi} := -r^{1/2}\int_0^r \frac{1}{x}\int_0^x t^{1/2}f(t)\mathrm{d}t\,\mathrm{d}x.$$

By (2.3), we have

$$\left|\int_0^r \frac{1}{x}\int_0^x t^{1/2}f(t)\mathrm{d}t\,\mathrm{d}x\right| \leqslant \int_0^r \frac{1}{\sqrt{2}}\|f\|_2\,\mathrm{d}x = \frac{r}{\sqrt{2}}\|f\|_2.$$

From this estimate, it follows that $\tilde{\phi}(r) = \mathcal{O}(r^{3/2})$ and $\tilde{\phi}'(r) = \mathcal{O}(r^{1/2})$. □

III. SELF-ADJOINT REALIZATIONS

Choosing a linear subspace $\mathcal{D}\subset\mathcal{D}_{\max}(\Delta)$, we say that

$$\Delta_{\mathcal{D}} := \Delta:\mathcal{D}\to L^2([0,R])$$

is *self-adjoint* (in which case $\Delta_{\mathcal{D}}$ is called a *self-adjoint realization* of Δ) if

$$\{\psi\in\mathcal{D}_{\max}(\Delta)|\langle\Delta\phi,\psi\rangle=\langle\phi,\Delta\psi\rangle \text{ for all } \phi\in\mathcal{D}\}=\mathcal{D};$$

in other words, Δ is symmetric on $\mathcal{D}$ and adding any elements to $\mathcal{D}$ will destroy this symmetry.

In order to determine if Δ has any self-adjoint realization, we need to analyze the quadratic form

$$\langle\phi,\Delta\psi\rangle-\langle\Delta\phi,\psi\rangle \quad \text{for } \phi,\psi\in\mathcal{D}_{\max}(\Delta).$$

It turns out that this difference is related to finite-dimensional symplectic linear algebra. Let us define

$$\omega:\mathbb{C}^4\times\mathbb{C}^4\to\mathbb{C}$$

by

$$\omega(v,w) := v_1\overline{w_2}-v_2\overline{w_1}+v_3\overline{w_4}-v_4\overline{w_3}. \tag{3.1}$$

The function ω is Hermitian antisymmetric and nondegenerate; for this reason, ω is called a *Hermitian symplectic form*.

Theorem 3.1: *Let* $\phi,\psi\in\mathcal{D}_{\max}(\Delta)$ *be written in the form* (2.1), *i.e.*,

$$\phi=c_1(\phi)r^{1/2}+c_2(\phi)r^{1/2}\log r+\tilde{\phi},$$

where $\tilde{\phi}$ *is continuously differentiable with* $\tilde{\phi}(r)=\mathcal{O}(r^{3/2})$, $\tilde{\phi}'(r)=\mathcal{O}(r^{1/2})$, *and* $\Delta\tilde{\phi}\in L^2([0,R])$, *and with a similar formula holding for* ψ. *Then*,

$$\langle\phi,\Delta\psi\rangle-\langle\Delta\phi,\psi\rangle=\omega(\vec{\phi},\vec{\psi}),$$

where ω *is the Hermitian symplectic form defined above and* $\vec{\phi},\vec{\psi}\in\mathbb{C}^4$ *are the vectors*

$$\vec{\phi} := (c_1(\phi),c_2(\phi),\phi'(R),\phi(R)), \quad \vec{\psi} := (c_1(\psi),c_2(\psi),\psi'(R),\psi(R)).$$

Proof: We have

$$\begin{aligned}\langle\phi,\Delta\psi\rangle-\langle\Delta\phi,\psi\rangle &= \lim_{\varepsilon\to0}\int_\varepsilon^R(\phi(r)\overline{\Delta\psi(r)}-\Delta\phi(r)\overline{\psi(r)})\mathrm{d}r=\lim_{\varepsilon\to0}\int_\varepsilon^R\frac{d}{\mathrm{d}r}(-\phi(r)\overline{\psi'(r)}+\phi'(r)\overline{\psi(r)})\mathrm{d}r\\ &=\lim_{\varepsilon\to0}(\phi(\varepsilon)\overline{\psi'(\varepsilon)}-\phi'(\varepsilon)\overline{\psi(\varepsilon)})+(\phi'(R)\overline{\psi(R)}-\phi(R)\overline{\psi'(R)}).\end{aligned} \tag{3.2}$$

Recall that

$$\phi=c_1(\phi)r^{1/2}+c_2(\phi)r^{1/2}\log r+\tilde{\phi}, \quad \psi=c_1(\psi)r^{1/2}+c_2(\psi)r^{1/2}\log r+\tilde{\psi},$$

where $\tilde{\phi}$ and $\tilde{\psi}$ are continuously differentiable functions on $[0,R]$ such that $\tilde{\phi}(r),\tilde{\psi}(r)=\mathcal{O}(r^{3/2})$, $\tilde{\phi}'(r),\tilde{\psi}'(r)=\mathcal{O}(r^{1/2})$. Taking derivatives, we get

$$\phi'=\frac{c_1(\phi)}{2}r^{-1/2}+\frac{c_2(\phi)}{2}r^{-1/2}(\log r+2)+\tilde{\phi}'$$

and similarly for ψ'. It follows that

$$\phi(\varepsilon)\overline{\psi'(\varepsilon)} = \frac{c_1(\phi)\overline{c_1(\psi)}}{2} + \frac{c_1(\phi)\overline{c_2(\psi)}}{2}(\log\varepsilon + 2) + \frac{c_2(\phi)\overline{c_1(\psi)}}{2}\log\varepsilon + \frac{c_2(\phi)\overline{c_2(\psi)}}{2}\log\varepsilon(\log\varepsilon + 2) + o(1)$$

and similarly for $\phi'(\varepsilon)\overline{\psi(\varepsilon)}$. Subtracting, we get

$$\phi(\varepsilon)\overline{\psi'(\varepsilon)} - \phi'(\varepsilon)\overline{\psi(\varepsilon)} = c_1(\phi)\overline{c_2(\psi)} - c_2(\phi)\overline{c_1(\psi)} + o(1).$$

Combining this with (3.2) proves our result. □

Recall that a subspace $L \subset \mathbb{C}^4$ is called *Lagrangian* if $L^{\perp_\omega} = L$ where $L^{\perp_\omega}$ is the orthogonal complement of L with respect to ω; explicitly, L is Lagrangian means

$$\{w \in \mathbb{C}^4 | \omega(v,w) = 0 \text{ for all } v \in L\} = L.$$

We now have our main result.

Theorem 3.2: *Self-adjoint realizations of* Δ *are in one-to-one correspondence with Lagrangian subspaces of* $\mathbb{C}^4$ *in the sense that given any Lagrangian subspace* $L \subset \mathbb{C}^4$, *defining*

$$\mathcal{D}_L := \{\phi \in \mathcal{D}_{\max}(\Delta) | \vec{\phi} \in L\}$$

the operator

$$\Delta_L := \Delta : \mathcal{D}_L \to L^2([0,R])$$

is self-adjoint and any self-adjoint realization of Δ *is of the form* $\mathcal{D}_L$ *for some Lagrangian* $L \subset \mathbb{C}^4$.

Proof: By definition,

$$\Delta_{\mathcal{D}} := \Delta : \mathcal{D} \to L^2([0,R])$$

is *self-adjoint* means

$$\{\psi \in \mathcal{D}_{\max}(\Delta) | \langle \Delta\phi, \psi\rangle = \langle \phi, \Delta\psi\rangle \text{ for all } \phi \in \mathcal{D}\} = \mathcal{D}.$$

By Theorem 3.1, we can write this as: $\Delta_{\mathcal{D}}$ is self-adjoint if and only if

$$\omega(\vec{\phi}, \vec{\psi}) = 0 \text{ for all } \phi \in \mathcal{D} \Leftrightarrow \psi \in \mathcal{D}. \tag{3.3}$$

Suppose that $\Delta_{\mathcal{D}}$ is self-adjoint and define $L := \{\vec{\phi} \in \mathbb{C}^4 | \phi \in \mathcal{D}\}$; we shall prove that L is Lagrangian. Let $w \in L$ and choose $\psi \in \mathcal{D}$ such that $\vec{\psi} = w$. Then by (3.3), $\omega(\vec{\phi}, w) = 0$ for all $\phi \in \mathcal{D}$. Therefore, $\omega(v, w) = 0$ for all $v \in L$. Conversely, let $w \in \mathbb{C}^4$ and assume that $\omega(v, w) = 0$ for all $v \in L$. Choose $\psi \in \mathcal{D}_{\max}(\Delta)$ such that $\vec{\psi} = w$; e.g., if $w = (w_1, w_2, w_3, w_4)$, then

$$\psi := w_1 r^{1/2} + w_2 r^{1/2}\log r + (w_3 - w_4)(r - R) + w_4 r \tag{3.4}$$

will do. Then $\omega(v, w) = 0$ for all $v \in L$ implies that $\omega(\vec{\phi}, \vec{\psi}) = 0$ for all $\phi \in \mathcal{D}$, which by (3.3), implies that $\psi \in \mathcal{D}$, which further implies that $w = \vec{\phi} \in L$.

Now let $L \subset \mathbb{C}^4$ be Lagrangian; we shall prove that Δ_L is self-adjoint, that is, (3.3) holds. Let $\psi \in \mathcal{D}_L$. Then, since L is Lagrangian, we automatically have $\omega(\vec{\phi}, \vec{\psi}) = 0$ for all $\phi \in \mathcal{D}_L$. Conversely, let $\psi \in \mathcal{D}_{\max}(\Delta)$ and assume that $\omega(\vec{\phi}, \vec{\psi}) = 0$ for all $\phi \in \mathcal{D}_L$. By the construction (3.4) given any $v \in L$ we can find a $\phi \in \mathcal{D}_{\max}(\Delta)$ such that $\vec{\phi} = v$. Therefore, $\omega(\vec{\phi}, \vec{\psi}) = 0$ for all $\phi \in \mathcal{D}_L$ implies that $\omega(v, \vec{\psi}) = 0$ for all $v \in L$, which by the Lagrangian condition on L, implies that $\vec{\psi} \in L$. This shows that $\psi \in \mathcal{D}_L$ and our proof is complete. □

IV. MORE ON LAGRANGIAN SUBSPACES

The symplectic form $\omega : \mathbb{C}^4 \times \mathbb{C}^4 \to \mathbb{C}$ defined in (3.1) is naturally separated into two parts:

$$\omega(v,w) = \omega_0((v_1,v_2),(w_1,w_2)) + \omega_0((v_3,v_4),(w_3,w_4)), \tag{4.1}$$

where

$$\omega_0{:}\mathbb{C}^2 \times \mathbb{C}^2 \to \mathbb{C} \text{ is defined by } \omega_0(v,w) = v_1\overline{w_2} - v_2\overline{w_1}.$$

The first ω_0 appearing in (4.1) corresponds to the singularity at $r=0$ and the second ω_0 in (4.1) corresponds to the boundary $r=R$. For this reason, it is natural to focus on Lagrangian subspaces $L\subset\mathbb{C}^4$ of the form $L=L_1\oplus L_2$ where $L_i\subset\mathbb{C}^2$ is Lagrangian with respect to ω_0. With this in mind, let us characterize all such Lagrangian subspaces of $\mathbb{C}^2$. First, we observe the following.

Lemma 4.1: We can write

$$\omega_0(v,w) = \langle Gv,w\rangle \text{ for all } v,w \in \mathbb{C}^2,$$

where $\langle,\rangle$ *denotes the inner product on* $\mathbb{C}^2$ *and* $G=\left(\begin{smallmatrix}0&-1\\1&0\end{smallmatrix}\right)$.

Recalling that $L\subset\mathbb{C}^2$ is Lagrangian means that

$$\{w \in \mathbb{C}^2 | \omega_0(v,w) = 0 \text{ for all } v \in L\} = L,$$

from this lemma, it is straightforward to show that

$$L \subset \mathbb{C}^2 \text{ is Lagrangian if and only if } GL^{\perp} = L,$$

where $L^{\perp}$ is the orthogonal complement of L with respect to the inner product $\langle,\rangle$. From this, one can easily prove the following main result in this section.

Theorem 4.2: *$L\subset\mathbb{C}^2$ is Lagrangian if and only if $L=L_\theta$ for some $\theta\in\mathbb{R}$ where*

$$L_\theta = \{(x,y) \in \mathbb{C}^2 | \cos\theta x + \sin\theta y = 0\}.$$

Notice that we can restrict to $0\leqslant\theta<\pi$ in Theorem 4.2. Let θ_1,θ_2 be two such angles and set $L:=L_{\theta_1}\oplus L_{\theta_2}$. As in (2.1), we write $\phi\in\mathcal{D}_{\max}(\Delta)$ as

$$\phi = c_1(\phi)r^{1/2} + c_2(\phi)r^{1/2}\log r + \tilde{\phi},$$

where $\tilde{\phi}$ is continuously differentiable with $\tilde{\phi}(r)=\mathcal{O}(r^{3/2})$, $\tilde{\phi}'(r)=\mathcal{O}(r^{1/2})$, and $\Delta\tilde{\phi}\in L^2([0,R])$. Then as a consequence of Theorem 3.2, we know that

$$\Delta_L := \Delta{:}\mathcal{D}_L \to L^2([0,R]) \tag{4.2}$$

is self-adjoint, where

$$\mathcal{D}_L = \{\phi \in \mathcal{D}_{\max}(\Delta) | \cos\theta_1 c_1(\phi) + \sin\theta_1 c_2(\phi) = 0, \cos\theta_2\phi'(R) + \sin\theta_2\phi(R) = 0\}.$$

When $\theta_1=\pi/2$, then we are requiring $c_2(\phi)$ vanish so that near $r=0$, we have

$$\phi = c_1(\phi)r^{1/2} + \tilde{\phi};$$

that is, no log terms; in Ref. 8, Brüning and Seeley prove that $\theta_1=\pi/2$ is the Friedrichs realization of the operator Δ acting on smooth functions supported away from $r=0$ with the boundary condition $\cos\theta_2\phi'(R)+\sin\theta_2\phi(R)=0$ at $r=R$. As seen in Theorem 1.1 in the Introduction, this self-adjoint realization gives rise to the "usual" resolvent, heat kernel, and zeta function properties. When $\theta_1\neq\pi/2$, we get very pathological properties as shown in Theorem 1.2. In the following sections we enter in the proof of Theorem 1.2.

V. EIGENVALUES WITH DIRICHLET CONDITIONS AT $r=R$

As shown in detail in Sec. X, the strange behaviors depicted in Theorem 1.2 do not depend on the choice of the Lagrangian L_2 (that is, the choice of boundary condition at $r=R$). For this reason, we shall use $\theta_2=0$ for the Lagrangian L_2 in (4.2); thus, we shall consider the self-adjoint operator $\Delta_\theta := \Delta : \mathcal{D}_\theta \to L^2([0,R])$, where $0 \leqslant \theta < \pi$ and $\theta \neq \pi/2$, and

$$\mathcal{D}_\theta = \{\phi \in \mathcal{D}_{\max}(\Delta) | \cos\theta c_1(\phi) + \sin\theta c_2(\phi) = 0, \phi(R) = 0\};$$

so we are simply imposing the Dirichlet condition at $r=R$.

We now find an explicit formula for the eigenfunctions and a transcendental equation, which determines the spectrum of Δ_θ. We begin with the following eigenvalue equation:

$$(\Delta_\theta - \mu^2)\phi = 0 \Leftrightarrow \phi'' + \frac{1}{4r^2}\phi + \mu^2\phi = 0.$$

We can turn this into a Bessel equation via the usual trick by setting $\phi = r^{1/2}\psi(\mu r)$. Then,

$$\phi'' = -\tfrac{1}{4}r^{-3/2}\psi(\mu r) + \mu r^{-1/2}\psi'(\mu r) + \mu^2 r^{1/2}\psi''(\mu r),$$

so

$$\phi'' + \frac{1}{4r^2}\phi + \mu^2\phi = 0 \Leftrightarrow \mu r^{-1/2}\psi'(\mu r) + \mu^2 r^{1/2}\psi''(\mu r) + \mu^2 r^{1/2}\psi(\mu r) = 0,$$

or

$$(\mu r)^2\psi''(\mu r) + (\mu r)\psi'(\mu r) + (\mu r)^2\psi(\mu r) = 0.$$

For fixed μ, the solutions to this equation are linear combinations of J_0 and Y_0 (with Y_0 the Bessel function of the second kind), so

$$\phi = C_1 r^{1/2} J_0(\mu r) + C_2 r^{1/2} Y_0(\mu r).$$

Using that (Ref. 1, p. 360)

$$\frac{\pi}{2}Y_0(z) := (\log z - \log 2 + \gamma)J_0(z) - \sum_{k=1}^{\infty} \frac{H_k\left(-\frac{1}{4}z^2\right)^k}{(k!)^2}, \tag{5.1}$$

where $H_k := 1 + \frac{1}{2} + \cdots + (1/k)$, the form (2.1) for $\phi \in \mathcal{D}_{\max}(\Delta)$ is obtained by choosing the constants C_1 and C_2 in such a way that

$$\phi = c_1(\phi) r^{1/2} J_0(\mu r) + c_2(\phi) r^{1/2}\left(\frac{\pi}{2}Y_0(\mu r) - (\log\mu - \log 2 + \gamma)J_0(\mu r)\right).$$

By definition of the Bessel function (Ref. 1, p. 360) we have as $z \to 0$,

$$J_v(z) = \frac{z^v}{2^v}\sum_{k=0}^{\infty} \frac{\left(-\frac{1}{4}z^2\right)^k}{k!\Gamma(v+k+1)} = \frac{z^v}{2^v\Gamma(1+v)}\left(1 - \frac{z^2}{4(1+v)} + \frac{z^4}{32(1+v)(2+v)} - + \cdots\right) \tag{5.2}$$

and by (5.1)), we see that

$$\phi = c_1(\phi)r^{1/2} + c_2(\phi)r^{1/2}\log r + \mathcal{O}((\mu r)^2),$$

where $\mathcal{O}((\mu r)^2)$ is a power series in $(\mu r)^2$ vanishing like $(\mu r)^2$ as $r\to 0$. Therefore, by definition of $\mathcal{D}_\theta$, we have

$$\cos\theta c_1(\phi) + \sin\theta c_2(\phi) = 0. \tag{5.3}$$

To satisfy the Dirichlet condition at $r=R$, we must have

$$c_1(\phi)J_0(\mu R) + c_2(\phi)\left(\frac{\pi}{2}Y_0(\mu R) - (\log\mu - \log 2 + \gamma)J_0(\mu R)\right) = 0.$$

It follows that

$$\det\begin{pmatrix} \cos\theta & \sin\theta \\ J_0(\mu R) & \dfrac{\pi}{2}Y_0(\mu R) - (\log\mu - \log 2 + \gamma)J_0(\mu R) \end{pmatrix} = 0,$$

or $(\pi/2)Y_0(\mu R) - (\log\mu - \log 2 + \gamma)J_0(\mu R) = \tan\theta J_0(\mu R)$. We summarize our findings in the following proposition.

Proposition 5.1: The transcendental equation,

$$F(\mu) := \frac{\pi}{2}Y_0(\mu R) - (\log\mu - \kappa)J_0(\mu R) = 0, \quad \kappa = \log 2 - \gamma - \tan\theta, \tag{5.4}$$

determines the eigenvalues of Δ_θ.

In the following theorem we state various properties of the eigenvalues of Δ_θ; note that in Ref. 15, p. 4572 it is stated that there are no negative eigenvalues; however, it turns out that, for example, when $\pi/2 < \theta < \pi$ and $R \geqslant 1$, there is *always* a negative eigenvalue.

Theorem 5.2: *For* $0 \leqslant \theta < \pi$ *with* $\theta \neq \pi/2$,

(1) Δ_θ *has a zero eigenvalue if and only if* $\log R = \tan\theta$.
(2) Δ_θ *has a unique negative eigenvalue if and only if* $\tan\theta < \log R$.

Proof: Using (5.1) and the expansion

$$J_0(z) = \sum_{k=0}^{\infty} \frac{\left(-\frac{1}{4}z^2\right)^k}{(k!)^2}, \tag{5.5}$$

the eigenvalue equation $(\pi/2)Y_0(\mu R) - (\log\mu - \log 2 + \gamma)J_0(\mu R) = \tan\theta J_0(\mu R)$ can be written as

$$-\sum_{k=1}^{\infty} \frac{H_k\left(-\frac{1}{4}\mu^2R^2\right)^k}{(k!)^2} = (-\log R + \tan\theta)\sum_{k=0}^{\infty} \frac{\left(-\frac{1}{4}\mu^2R^2\right)^k}{(k!)^2}. \tag{5.6}$$

Thus, $\mu = 0$ solves this equation if and only if $\log R = \tan\theta$.

Now Δ_θ has a negative eigenvalue means that $\mu = ix$ for x real solves (5.6):

$$-\sum_{k=1}^{\infty} \frac{H_k\left(\frac{1}{4}x^2R^2\right)^k}{(k!)^2} = (-\log R + \tan\theta)\sum_{k=0}^{\infty} \frac{\left(\frac{1}{4}x^2R^2\right)^k}{(k!)^2}. \tag{5.7}$$

If $(-\log R + \tan\theta) > 0$, then (5.7) has no solutions because the right-hand side of (5.7) will be strictly positive for all real x while the left-hand side of (5.7) is nonpositive. Thus, we may assume that $\alpha := \log R - \tan\theta > 0$. Then we can write (5.7) as

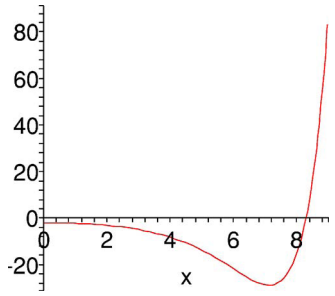

FIG. 1. (Color online) Graph of $f(x)$ when $R=1$ and $\tan\theta=-2$.

$$f(xR)=0 \quad \text{where } f(x)=\sum_{k=1}^{\infty}\frac{H_k x^{2k}}{4^k(k!)^2}-\sum_{k=0}^{\infty}\frac{\alpha x^{2k}}{4^k(k!)^2};$$

thus, we just have to prove that $f(x)=0$ has a unique solution. To prove this, observe that since the harmonic series $1+\frac{1}{2}+\frac{1}{3}+\cdots$ diverges, we can choose $N\in\mathbb{N}$ such that $H_N>\alpha>H_{N-1}$. We now write

$$f(x)=\sum_{k=N}^{\infty}\frac{(H_k-\alpha)x^{2k}}{4^k(k!)^2}-\left(\sum_{k=0}^{N-1}\frac{(\alpha-H_k)x^{2k}}{4^k(k!)^2}\right),$$

where $H_0:=0$, and note that $f(x)=0$ if and only if $g(x)=0$ where

$$g(x):=x^{-2N}f(x)=\sum_{k=N}^{\infty}\frac{(H_k-\alpha)x^{2(k-N)}}{4^k(k!)^2}-\left(\sum_{k=0}^{N-1}\frac{(\alpha-H_k)}{4^k(k!)^2x^{2(N-k)}}\right).$$

Because of the powers of x in the denominator the second sum on the right-hand side, we see that $g(0+)=-\infty$ while because of the first sum on the right-hand side, we see that $\lim_{x\to\infty}g(x)=\infty$. In particular, by the intermediate value theorem, $g(x)=0$ for some $0<x<\infty$. Since

$$g'(x)=\sum_{k=N+1}^{\infty}\frac{(H_k-\alpha)2(k-N)x^{2(k-N)-1}}{4^k(k!)^2}+\left(\sum_{k=0}^{N-1}\frac{2(N-k)(\alpha-H_k)}{4^k(k!)^2x^{2(N-k)+1}}\right)>0$$

the function g is strictly increasing, so there is only one $x>0$ such that $g(x)=0$. It follows that $f(x)=0$ for a unique $x>0$ and our proof is now complete. A graph of $f(x)$ for $R=1$ and $\tan\theta=-2$ is shown in Fig. 1. □

VI. THE ζ-FUNCTION WITH DIRICHLET CONDITIONS AT $r=R$

Let $0\leqslant\theta<\pi$ with $\theta\neq\pi/2$. We now analyze the zeta function using the contour integral techniques developed in Refs. 4, 5, 28, and 30.

In the Appendix, Theorem A.1, we have shown that

$$\mathrm{Tr}(\Delta_\theta-\mu^2)^{-1}=-\frac{1}{2\mu}\frac{d}{d\mu}\log F(\mu).$$

Therefore, for $\Re s>1/2$, by *definition* the zeta function is given by

$$\zeta(s,\Delta_\theta)=\frac{1}{2\pi i}\int_\gamma \mu^{-2s}\frac{d}{d\mu}\log F(\mu)d\mu=\frac{1}{2\pi i}\int_\gamma \mu^{-2s}\frac{F'(\mu)}{F(\mu)}d\mu, \tag{6.1}$$

where γ is a contour in the plane shown in Fig. 2.

To analyze properties of the zeta function, we need the following technical lemma.

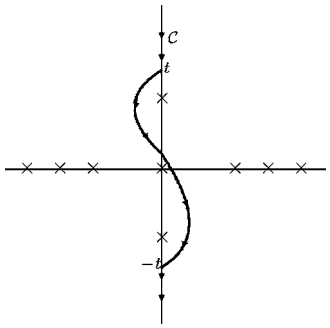

FIG. 2. The contour γ for the zeta function. The $\times$'s represent the zeros of $F(\mu)$. The squares of the $\times$'s on the imaginary axis represent the negative eigenvalues of Δ_θ. Here, t is on the imaginary axis and is larger in absolute value than the absolute value of the negative eigenvalue of Δ_θ (if one exists). The contour γ_t goes from t to $-t$.

Lemma 6.1: Let $0 \leqslant \theta < \pi$ *with* $\theta \neq \pi/2$ *and* $\Upsilon \subset \mathbb{C}$ *be a sector (closed angle) in the right-half plane. Then as* $|x| \to \infty$ *with* $x \in \Upsilon$, *we have*

$$F(ix) \sim -\frac{1}{\sqrt{2\pi}}(\log x - \kappa)(xR)^{-1/2}e^{xR}\left(1 + \frac{1}{8xR} + \frac{9}{2(8xR)^2} + \mathcal{O}(x^{-3})\right), \tag{6.2}$$

where $\mathcal{O}(x^{-3})$ *is a power series in* x^{-1} *starting from* x^{-3}, *and*

$$\frac{d}{dx}\log F(ix) \sim \frac{1}{x(\log x - \kappa)} + R - \frac{1}{2x} - \frac{1}{8x^2R} + \mathcal{O}(x^{-3}), \tag{6.3}$$

with the same meaning for $\mathcal{O}(x^{-3})$. *Finally,* $F(\mu)$ *is an even function of* μ, *and as* $\mu \to 0$, *we have*

$$F(\mu) \sim (\log R - \tan\theta) + \frac{1}{4}\mu^2R^2(1 + \tan\theta - \log R) + \mathcal{O}(\mu^4). \tag{6.4}$$

Proof: From (5.1), we have

$$\frac{\pi}{2}Y_0(ix) = (\log(ix) - \log 2 + \gamma)J_0(ix) - \sum_{k=1}^{\infty}\frac{H_k\left(-\frac{1}{4}(ix)^2\right)^k}{(k!)^2}$$

$$= \left(\log x + i\frac{\pi}{2} - \log 2 + \gamma\right)I_0(x) - \sum_{k=1}^{\infty}\frac{H_k\left(\frac{1}{4}x^2\right)^k}{(k!)^2} = i\frac{\pi}{2}I_0(x) - K_0(x),$$

where $I_0(x)$ is the modified Bessel function of the first kind, and

$$K_0(x) := -(\log x - \log 2 + \gamma)I_0(x) + \sum_{k=1}^{\infty}\frac{H_k\left(\frac{1}{4}x^2\right)^k}{(k!)^2}$$

is the modified Bessel function of the second kind. Therefore,

$$F(ix) = \frac{\pi}{2}Y_0(ixR) - (\log(ix) - \kappa)J_0(ixR) = i\frac{\pi}{2}I_0(xR) - K_0(xR) - \left(\log x + i\frac{\pi}{2} - \kappa\right)I_0(xR)$$

$$= -(\log x - \kappa)I_0(xR) - K_0(xR).$$

By Ref. 1, p. 377, as $|x| \to \infty$ for $x \in \Upsilon$, we have

$$I_0(x) \sim \frac{e^x}{\sqrt{2\pi x}}\left(1+\frac{1}{8x}+\frac{9}{2(8x)^2}+\mathcal{O}(x^{-3})\right),$$

where $\mathcal{O}(x^{-3})$ is a power series in x^{-1} starting with x^{-3}; furthermore (Ref. 1, p. 378), as $|x|\to\infty$ for $x\in\Upsilon$,

$$K_0(x) \sim \sqrt{\frac{2}{\pi x}}e^{-x}\left(1-\frac{1}{8x}+\frac{9}{2(8x)^2}+\mathcal{O}(x^{-3})\right).$$

Therefore, as $|x|\to\infty$ for $x\in\Upsilon$, we have

$$F(ix) \sim -(\log x-\kappa)I_0(xR) \sim -\frac{1}{\sqrt{2\pi}}(\log x-\kappa)(xR)^{-1/2}e^{xR}\left(1+\frac{1}{8xR}+\frac{9}{2(8xR)^2}+\mathcal{O}(x^{-3})\right),$$

which proves (6.2). Taking logarithms, we see that as $|x|\to\infty$ for $x\in\Upsilon$, we have

$$\log F(ix) \sim c+\log(\log x-\kappa)-\frac{1}{2}\log x+xR+\log\left(1+\frac{1}{8xR}+\frac{9}{2(8xR)^2}+\mathcal{O}(x^{-3})\right),$$

where c is a constant. Since $\log(1+z)=z-(z^2/2)+(z^3/3)-+\dots$, we have

$$\log F(ix) \sim c+\log(\log x-\kappa)-\frac{1}{2}\log x+xR+\frac{1}{8xR}+\mathcal{O}(x^{-2}).$$

Taking the derivative of this we get (6.3).

To determine the asymptotics as $\mu\to 0$, recalling that $\kappa=\log 2-\gamma-\tan\theta$, we see that

$$\begin{aligned}F(\mu) &= \frac{\pi}{2}Y_0(\mu R)-(\log\mu-\kappa)J_0(\mu R) = \frac{\pi}{2}Y_0(\mu R)-(\log\mu-\log 2+\gamma)J_0(\mu R)-\tan\theta J_0(\mu R)\\ &= \frac{1}{4}\mu^2R^2+(\log R-\tan\theta)+(\tan\theta-\log R)\cdot\frac{1}{4}\mu^2R^2+\mathcal{O}(\mu^4)\\ &= (\log R-\tan\theta)+\frac{1}{4}\mu^2R^2(1+\tan\theta-\log R)+\mathcal{O}(\mu^4),\end{aligned}$$

where we used (5.1) and (5.5) in passing from the second to the third line. In particular, the second line with (5.1) and (5.5) shows that $F(\mu)$ is an even function of μ. This completes our proof. □

We need one more lemma.

Lemma 6.2: We have

$$\int_{|t|}^{\infty}x^{-2s}\frac{1}{x(\log x-\kappa)}\mathrm{d}x = -e^{-2s\kappa}\log s-e^{-2s\kappa}(\gamma+\log(2(\log|t|-\kappa))+\mathcal{O}(s)),$$

where $\mathcal{O}(s)$ is an entire function of s that is $\mathcal{O}(s)$ at $s=0$.

Proof: In the integral we assume that $\log|t|>\kappa$ so that the integral is well defined. Now to analyze this integral we make the change of variables $u=\log x-\kappa$ or $x=e^{\kappa}e^{u}$, and obtain

$$\int_{|t|}^{\infty}x^{-2s}\frac{1}{x(\log x-\kappa)}\mathrm{d}x = e^{-2s\kappa}\int_{\log|t|-\kappa}^{\infty}e^{-2su}\frac{\mathrm{d}u}{u}.$$

Making the change of variables $y=2su$, we get

$$\int_{|t|}^{\infty}x^{-2s}\frac{1}{x(\log x-\kappa)}\mathrm{d}x = e^{-2s\kappa}\int_{2s(\log|t|-\kappa)}^{\infty}e^{-y}\frac{\mathrm{d}y}{y}.$$

Recall that the *exponential integral* is defined by (see Ref. 22, Sec. 8.2)

$$\mathrm{Ei}(z) := -\int_{-z}^{\infty} e^{-y}\frac{\mathrm{d}y}{y}.$$

Therefore,

$$\int_{|t|}^{\infty} x^{-2s}\frac{1}{x(\log x-\kappa)}\mathrm{d}x = -e^{-2s\kappa}\,\mathrm{Ei}(-2s(\log|t|-\kappa)).$$

Also from Ref. 22, p. 877, we have

$$\mathrm{Ei}(z) = \gamma + \log(-z) + \sum_{k=1}^{\infty}\frac{z^k}{k\cdot k!},$$

therefore

$$\begin{aligned}\int_{|t|}^{\infty} x^{-2s}\frac{1}{x(\log x-\kappa)}\mathrm{d}x &= -e^{-2s\kappa}(\gamma+\log(2s(\log|t|-\kappa))+\mathcal{O}(s))\\ &= -e^{-2s\kappa}\log s - e^{-2s\kappa}(\gamma+\log(2(\log|t|-\kappa))+\mathcal{O}(s)),\end{aligned} \tag{6.5}$$

where $\mathcal{O}(s)$ is an entire function of s that is $\mathcal{O}(s)$ at $s=0$. This completes our proof. □

We now determine the structure of the zeta function.

Proposition 6.3: The zeta function $\zeta(s,\Delta_\theta)$ can be written in the form

$$\zeta(s,\Delta_\theta) = -\frac{e^{-2s\kappa}\sin\pi s}{\pi}\log s + \zeta_\theta(s),$$

where $\kappa=\log 2-\gamma-\tan\theta$ and $\zeta_\theta(s)$ extends from $\Re s>1/2$ to a holomorphic function on $\mathbb{C}$ with poles at $s=1/2-k$ for $k=0,1,2,\ldots$. In particular, $\zeta(s,\Delta_\theta)$ has $s=0$ as a logarithmic branch point.

Proof: Recalling (6.1), we write

$$\int_{\gamma} = -\int_{t}^{0+i\infty} + \int_{-t}^{0-i\infty} + \int_{\gamma_t},$$

where γ_t is the part of γ from t to $-t$, and using that

$$i^{-2s} = (e^{i\pi/2})^{-2s} = e^{-i\pi s} \text{ and } (-i)^{-2s} = (e^{-i\pi/2})^{-2s} = e^{i\pi s},$$

we obtain the integral

$$\begin{aligned}\zeta(s,\Delta_\theta) &= \frac{1}{2\pi i}\int_{\gamma}\mu^{-2s}\frac{d}{\mathrm{d}\mu}\log F(\mu)\mathrm{d}\mu = \frac{1}{2\pi i}\left\{-\int_{|t|}^{\infty}(ix)^{-2s}\frac{d}{\mathrm{d}x}\log F(ix)\mathrm{d}x\right.\\ &\quad\left.+\int_{|t|}^{\infty}(-ix)^{-2s}\frac{d}{\mathrm{d}x}\log F(-ix)\mathrm{d}x\right\}+\frac{1}{2\pi i}\int_{\gamma_t}\mu^{-2s}\frac{F'(\mu)}{F(\mu)}\mathrm{d}\mu\\ &= \frac{1}{2\pi i}(-e^{-i\pi s}+e^{i\pi s})\int_{|t|}^{\infty}x^{-2s}\frac{d}{\mathrm{d}x}\log F(ix)\mathrm{d}x+\frac{1}{2\pi i}\int_{\gamma_t}\mu^{-2s}\frac{F'(\mu)}{F(\mu)}\mathrm{d}\mu,\end{aligned}$$

or,

$$\zeta(s,\Delta_\theta)=\frac{\sin \pi s}{\pi}\int_{|t|}^{\infty} x^{-2s}\frac{d}{dx}\log F(ix)dx+\frac{1}{2\pi i}\int_{\gamma_t}\mu^{-2s}\frac{F'(\mu)}{F(\mu)}d\mu, \tag{6.6}$$

a formula that will be analyzed in a moment. The second integral here is over a finite contour so an entire function of $s\in\mathbb{C}$, so we are left to analyze the analytic properties of the first integral. To do so, recall from (6.3) that for $x\to\infty$, we have

$$\frac{d}{dx}\log F(ix)\sim\frac{1}{x(\log x-\kappa)}+\sum_{k=0}^{\infty}\beta_k x^{-k},$$

for some constants β_k. Since

$$\frac{\sin \pi s}{\pi}\int_{|t|}^{\infty} x^{-2s-k}\,dx=\frac{\sin \pi s}{\pi}\left.\frac{x^{-2s-k+1}}{-2s-k+1}\right|_{x=|t|}^{\infty}=\frac{\sin \pi s}{\pi}\frac{|t|^{-2s-k+1}}{2s+k-1}$$

which has poles at $s=(1-k)/2$ for $s\notin\mathbb{Z}$, it follows that the expansion $\Sigma_{k=0}^{\infty}\beta_k x^{-k}$ will contribute to the function $\zeta_\theta(s)$ in the statement of this proposition where $\zeta_\theta(s)$ extends from $\Re s>1/2$ to a holomorphic function on $\mathbb{C}$ with poles at $s=1/2-k$ for $k=0,1,2,\ldots$. Lemma 6.2 applied to the integral

$$\frac{\sin \pi s}{\pi}\int_{|t|}^{\infty} x^{-2s}\frac{1}{x(\log x-\kappa)}dx$$

now completes our proof. □

Remark 6.4: The existence of the logarithmic branch point at $s=0$ has been missed in Ref. 15. *The error occurs in Eq. (A13) where certain antiderivatives [specifically $xY_1(x)$ and $x^2Y_1^2$] were accidentally set equal to zero at $s=0$.*

VII. TRACE OF THE RESOLVENT WITH DIRICHLET CONDITIONS AT *r=R*

Using the Theorem A.1, we can now prove Theorem 1.2 (1) for Δ_θ. We have chosen to present the results in a form where the first term has been expanded further; Theorem 1.2 (1) is contained in Eq. (7.1) of the proof and the explanation of the meaning of the expansion is similar to that found in Remark 1.5.

Proposition 7.1: Let $\theta\neq\pi/2$ and $\kappa=\log 2-\gamma-\tan\theta$, furthermore let $\Lambda\subset\mathbb{C}$ be any sector (solid angle) not intersecting the positive real axis. Then as $|\lambda|\to\infty$ with $\lambda\in\Lambda$, we have

$$\mathrm{Tr}(\Delta_\theta-\lambda)^{-1}\sim(-\lambda)^{-1}\sum_{k=0}^{\infty}a_k(\log(-\lambda))^{-k-1}+\sum_{k=1}^{\infty}b_k(-\lambda)^{-k/2},$$

where $a_k=(2\kappa)^k$ for $k=0,1,2,\ldots$ (in particular, $a_0=1\neq 0$).

Proof: Setting $\lambda=-x^2$ with $x\in\Upsilon\subset\mathbb{C}$ a sector in the right-half plane, it suffices to prove that as $|x|\to\infty$ with $x\in\Upsilon$, we have

$$\mathrm{Tr}(\Delta_\theta+x^2)^{-1}\sim x^{-2}\sum_{k=0}^{\infty}\frac{\kappa^k}{2}(\log x)^{-k-1}+x^{-1}\sum_{k=0}^{\infty}b_k x^{-k},$$

or after multiplication by $2x$, we just have to prove that

$$2x\,\mathrm{Tr}(\Delta_\theta+x^2)^{-1}\sim x^{-1}\sum_{k=1}^{\infty}\kappa^k(\log x)^{-k-1}+\sum_{k=0}^{\infty}\beta_k x^{-k}.$$

To prove this, we recall from Theorem A.1 that

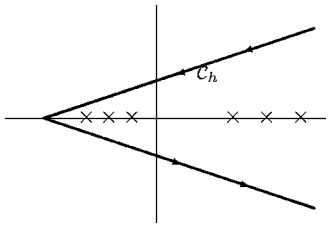

FIG. 3. The contour γ.

$$2x\,\mathrm{Tr}(\Delta_\theta + x^2)^{-1} = \frac{d}{dx}\log F(ix).$$

By Lemma 6.1 [see (6.3)] we know that as $|x|\to\infty$ for $x\in\Upsilon$,

$$\frac{d}{dx}\log F(ix) \sim \frac{1}{x(\log x - \kappa)} + \sum_{k=0}^{\infty}\beta_k x^{-k}. \tag{7.1}$$

Finally, the expansion

$$\frac{1}{x(\log x-\kappa)} = \frac{1}{x\log x}\cdot\frac{1}{(1-\kappa(\log x)^{-1})} = \frac{1}{x\log x}\sum_{k=0}^{\infty}\kappa^k(\log x)^{-k} = x^{-1}\sum_{k=0}^{\infty}\kappa^k(\log x)^{-k-1},$$

concludes our result. □

As shown in the proof, for $|x|\to\infty$ with $x\in\Upsilon$, where Υ is a sector in the right-half plane, we have

$$2x\,\mathrm{Tr}(\Delta_\theta + x^2)^{-1} = \frac{d}{dx}\log F(ix) \sim \frac{1}{x(\log x-\kappa)} + \sum_{k=0}^{\infty}\beta_k x^{-k}, \tag{7.2}$$

or with $\lambda=-x^2$, as $|\lambda|\to\infty$ with $\lambda\in\Lambda\subset\mathbb{C}$, a sector not intersecting the positive real axis, we have

$$\mathrm{Tr}(\Delta_\theta-\lambda)^{-1} \sim \frac{1}{(-\lambda)(\log(-\lambda)-2\kappa)} + \sum_{k=1}^{\infty} b_k(-\lambda)^{-k/2}. \tag{7.3}$$

This fact will be used in the next section.

VIII. THE HEAT TRACE WITH DIRICHLET CONDITIONS AT $r=R$

To determine the small-time heat asymptotics, we write

$$\mathrm{Tr}(e^{-t\Delta_\theta}) = \frac{i}{2\pi}\int_\gamma e^{-t\lambda}\,\mathrm{Tr}(\Delta_\theta-\lambda)^{-1}\,d\lambda,$$

where γ is a counter-clockwise contour in the plane surrounding the eigenvalues of Δ_θ; see Fig. 3. This is the starting point to show Theorem 1.2 (2) for Δ_θ. Again we have chosen to present the results in a form where the first term has been expanded further. This makes the actual structure of the small-t expansion more explicit; Theorem 1.2 (2) is contained in Eq. (8.2) of the proof.

Proposition 8.1: As $t\to 0$, we have

$$\mathrm{Tr}(e^{-t\Delta_\theta}) \sim \sum_{k=1}^{\infty}\alpha_k(\log t)^{-k} + \sum_{k=0}^{\infty}\beta_k t^{(k-1)/2}$$

with the *α_k's depending on κ via*

$$\alpha_k = -\frac{1}{k\pi}\Im\left(\int_0^\infty e^{-x}(\log x + i\pi - 2\kappa)^k \, dx\right).$$

Proof: The small-time asymptotics are determined by the large-spectral parameter asymptotics of the resolvent. Now recall from (7.3) that as $|\lambda|\to\infty$ with λ in a sector not intersecting the positive real axis, we have

$$\mathrm{Tr}(\Delta_\theta - \lambda)^{-1} \sim \frac{1}{(-\lambda)(\log(-\lambda) - 2\kappa)} + \sum_{k=1}^{\infty} b_k(-\lambda)^{-k/2}.$$

Since (making the change of variables $\lambda \mapsto t^{-1}\lambda$)

$$\int e^{-t\lambda}(-\lambda)^{-k/2}\, d\lambda = t^{-1+k/2}\int e^{-\lambda}(-\lambda)^{-k/2}\, d\lambda$$

the series $\Sigma_{k=1}^{\infty} b_k(-\lambda)^{-k/2}$ gives rise to a small time expansion

$$\sum_{k=1}^{\infty} \beta_k t^{-1+k/2}.$$

Therefore, we just have to analyze the behavior of

$$\frac{i}{2\pi}\int_\gamma e^{-t\lambda}\frac{1}{(-\lambda)(\log(-\lambda) - 2\kappa)}d\lambda.$$

Deforming γ to the real line, the integral here is, modulo a term that is a smooth function of t at $t=0$, equal to

$$-\int_1^\infty e^{-tx}\frac{1}{(-x)(\log(-(x+i0)) - 2\kappa)}dx + \int_1^\infty e^{-tx}\frac{1}{(-x)(\log(-(x-i0)) - 2\kappa)}dx,$$

or after simplification, this sum becomes

$$\int_1^\infty e^{-tx}\frac{1}{x(\log x - i\pi - 2\kappa)}dx - \int_1^\infty e^{-tx}\frac{1}{x(\log x + i\pi - 2\kappa)}dx.$$

(The reason we start at $x=1$ is that $1/(x[\log x \pm i\pi - 2\kappa])$ is not integrable near $x=0$.) Since for any complex number z, we have $i(\bar{z}-z)=2\Im z$, we see that modulo a term that is a smooth function of t at $t=0$,

$$\frac{i}{2\pi}\int_\gamma e^{-t\lambda}\frac{1}{(-\lambda)(\log(-\lambda) - 2\kappa)}d\lambda \equiv \frac{1}{\pi}\Im\left(\int_1^\infty e^{-tx}\frac{1}{x(\log x + i\pi - 2\kappa)}dx\right) = \frac{1}{\pi}\Im\ell(t), \quad (8.1)$$

where

$$\ell(t) := \int_1^\infty e^{-tx}\frac{1}{x(\log x + i\pi - 2\kappa)}dx.$$

In summary, we have proved that

$$\mathrm{Tr}(e^{-t\Delta_\theta}) \sim \frac{1}{\pi}\Im\ell(t) + \sum_{k=0}^{\infty}\beta_k t^{(k-1)/2}, \quad (8.2)$$

which is exactly the statement of Theorem 1.2 (2).

We shall compute the asymptotics of $\ell(t)$ as $t\to 0$. To do so, observe that

$$\ell'(t) := -\int_1^\infty e^{-tx}\frac{1}{(\log x + i\pi - 2\kappa)}\mathrm{d}x.$$

Now $1/\log x$ is integrable near $x=0$, so we can write

$$\ell'(t) = f(t) + g(t),$$

where

$$f(t) := -\int_0^\infty e^{-tx}\frac{1}{(\log x + i\pi - 2\kappa)}\mathrm{d}x, \quad g(t) := \int_0^1 e^{-tx}\frac{1}{(\log x + i\pi - 2\kappa)}\mathrm{d}x.$$

Note that $g(t)$ is smooth at $t=0$. We will now determine the asymptotics of $f(t)$ near $t=0$. To this end, we make the change of variables $x\mapsto t^{-1}x$,

$$f(t) = -t^{-1}\int_0^\infty e^{-x}\frac{1}{(\log(x/t) + i\pi - 2\kappa)}\mathrm{d}x = t^{-1}(\log t)^{-1}\int_0^\infty e^{-x}\frac{1}{1 - \dfrac{\log x + i\pi - 2\kappa}{\log t}}\mathrm{d}x.$$

Since $(1-r)^{-1} = \Sigma_{k=0}^{N} r^k + r^{N+1}(1-r)^{-1}$ for any $N \in \mathbb{N}$, we see that for any $N \in \mathbb{N}$,

$$f(t) = t^{-1}(\log t)^{-1}\sum_{k=0}^{N}(\log t)^{-k}\int_0^\infty e^{-x}(\log x + i\pi - 2\kappa)^k\,\mathrm{d}x$$
$$+ t^{-1}(\log t)^{-1}\cdot(\log t)^{-N-1}\int_0^\infty e^{-x}\frac{(\log x + i\pi - 2\kappa)^{N+1}}{1 - \dfrac{\log x + i\pi - 2\kappa}{\log t}}\mathrm{d}x.$$

The last integral here is bounded in t as $t\to 0$. Since N is arbitrary, it follows that

$$f(t) \sim t^{-1}\sum_{k=0}^{\infty}(\log t)^{-k-1}\int_0^\infty e^{-x}(\log x + i\pi - 2\kappa)^k\,\mathrm{d}x.$$

Therefore, since $\ell'(t) = f(t) + g(t)$, as $t\to 0$ we have

$$\ell'(t) \sim t^{-1}\sum_{k=0}^{\infty}(\log t)^{-k-1}\int_0^\infty e^{-x}(\log x + i\pi - 2\kappa)^k\,\mathrm{d}x + \sum_{k=0}^{\infty}\gamma_k t^k.$$

Integrating both sides, using that

$$\int t^{-1}(\log t)^{-1}\,\mathrm{d}t = \log|\log t|, \quad \int t^{-1}(\log t)^{-k-1}\,\mathrm{d}t = -\frac{1}{k}(\log t)^{-k} \quad \text{for } k > 0,$$

we get

$$\ell(t) \sim \log|\log t| - \sum_{k=1}^{\infty}\frac{1}{k}(\log t)^{-k}\int_0^\infty e^{-x}(\log x + i\pi - 2\kappa)^k\,\mathrm{d}x + \sum_{k=0}^{\infty}\delta_k t^k.$$

Finally, in view of (8.1), we see that as $t\to 0$,

$$\frac{i}{2\pi}\int_\gamma e^{-t\lambda}\frac{1}{(-\lambda)(\log(-\lambda)-2\kappa)}\mathrm{d}\lambda \sim \frac{1}{\pi}\mathfrak{I}\ell(t) \sim -\sum_{k=1}^{\infty}\frac{1}{k\pi}(\log t)^{-k}\mathfrak{I}\left(\int_0^\infty e^{-x}(\log x + i\pi - 2\kappa)^k\,\mathrm{d}x\right) + \sum_{k=0}^{\infty}\epsilon_k t^k.$$

□

IX. THE ZETA DETERMINANT

By Proposition 6.3, we have

$$\zeta(s,\Delta_\theta) = -\frac{e^{-2s\kappa}\sin\pi s}{\pi}\log s + \zeta_\theta(s),$$

where $\zeta_\theta(s)$ extends from $\Re s > 1/2$ to a holomorphic function on $\mathbb{C}$ with poles at $s = 1/2 - k$ for $k = 0,1,2,\ldots$. Since $e^{-2s\kappa}\sin\pi s/\pi = s + \mathcal{O}(s^2)$, it follows that

$$\zeta_{\mathrm{reg}}(s,\Delta_\theta) := \zeta(s,\Delta_\theta) + s\log s$$

has a derivative at $s=0$. Therefore, we can define

$$\det{}_{\mathrm{reg}}(\Delta_\theta) := \exp(-\zeta'_{\mathrm{reg}}(0,\Delta_\theta)),$$

which is computed in this section.

Recall that $0 \leqslant \theta < \pi$ with $\theta \neq \pi/2$. The idea here is to make the first term in

$$\zeta(s,\Delta_\theta) = \frac{\sin\pi s}{\pi}\int_{|t|}^\infty x^{-2s}\frac{d}{\mathrm{d}x}\log F(ix)\mathrm{d}x + \frac{1}{2\pi i}\int_{\gamma_t}\mu^{-2s}\frac{F'(\mu)}{F(\mu)}\mathrm{d}\mu$$

regular at $s=0$, as the second term (being entire) is already regular at $s=0$. In order to analytically continue the first term, we add and subtract off the leading asymptotics of $F(ix)$. Thus, recalling Lemma 6.1 [see (6.3)]

$$F(ix) \sim C_0(\log x - \kappa)x^{-1/2}e^{xR}\left(1 + \mathcal{O}\left(\frac{1}{x}\right)\right) \quad \text{as } x \to \infty,$$

where $C_0 = -1/\sqrt{2\pi R}$, we consider

$$\int_{|t|}^\infty x^{-2s}\frac{d}{\mathrm{d}x}\log F(ix)\mathrm{d}x = \int_{|t|}^\infty x^{-2s}\frac{d}{\mathrm{d}x}\log\left(\frac{F(ix)}{C_0(\log x-\kappa)x^{-1/2}e^{xR}}\right)\mathrm{d}x + \int_{|t|}^\infty x^{-2s}\frac{d}{\mathrm{d}x}\log(C_0(\log x - \kappa)x^{-1/2}e^{xR})\mathrm{d}x.$$

The second integral can be computed explicitly,

$$\int_{|t|}^\infty x^{-2s}\frac{d}{\mathrm{d}x}\log(C_0(\log x-\kappa)x^{-1/2}e^{xR})\mathrm{d}x = \int_{|t|}^\infty x^{-2s}\frac{1}{x(\log x-\kappa)}\mathrm{d}x - \frac{|t|^{-2s}}{4s} + \frac{|t|^{-2s+1}}{2s-1}R.$$

Therefore,

$$\zeta(s,\Delta_\theta)=\frac{\sin\pi s}{\pi}\int_{|t|}^{\infty}x^{-2s}\frac{d}{dx}\log\left(\frac{F(ix)}{C_0(\log x-\kappa)x^{-1/2}e^{xR}}\right)dx+\frac{\sin\pi s}{\pi}\int_{|t|}^{\infty}x^{-2s}\frac{1}{x(\log x-\kappa)}dx$$
$$-\frac{\sin\pi s}{\pi}\frac{|t|^{-2s}}{4s}+\frac{\sin\pi s}{\pi}\frac{|t|^{-2s+1}}{2s-1}R+\frac{1}{2\pi i}\int_{\gamma_t}\mu^{-2s}\frac{F'(\mu)}{F(\mu)}d\mu.$$

Hence, as $\zeta_{\mathrm{reg}}(s,\Delta_\theta)=\zeta(s,\Delta_\theta)+s\log s$, we see that

$$\zeta_{\mathrm{reg}}(s,\Delta_\theta)=\frac{\sin\pi s}{\pi}\int_{|t|}^{\infty}x^{-2s}\frac{d}{dx}\log\left(\frac{F(ix)}{C_0(\log x-\kappa)x^{-1/2}e^{xR}}\right)dx+\frac{\sin\pi s}{\pi}\int_{|t|}^{\infty}x^{-2s}\frac{1}{x(\log x-\kappa)}dx$$
$$+s\log s-\frac{\sin\pi s}{\pi}\frac{|t|^{-2s}}{4s}+\frac{\sin\pi s}{\pi}\frac{|t|^{-2s+1}}{2s-1}R+\frac{1}{2\pi i}\int_{\gamma_t}\mu^{-2s}\frac{F'(\mu)}{F(\mu)}d\mu.$$

By Lemma 6.2, we have

$$\frac{\sin\pi s}{\pi}\int_{|t|}^{\infty}x^{-2s}\frac{1}{x(\log x-\kappa)}dx=-\frac{e^{-2s\kappa}\sin\pi s}{\pi}\log s-\frac{e^{-2s\kappa}\sin\pi s}{\pi}(\gamma+\log(2(\log|t|-\kappa))+\mathcal{O}(s))$$
$$=-s\log s-s(\gamma+\log(2(\log|t|-\kappa))+\mathcal{O}(s\log s)).$$

Thus,

$$\zeta_{\mathrm{reg}}(s,\Delta_\theta)=\frac{\sin\pi s}{\pi}\int_{|t|}^{\infty}x^{-2s}\frac{d}{dx}\log\left(\frac{F(ix)}{C_0(\log x-\kappa)x^{-1/2}e^{xR}}\right)dx-s(\gamma+\log(2(\log|t|-\kappa))$$
$$+\mathcal{O}(s^2\log s))-\frac{\sin\pi s}{\pi}\frac{|t|^{-2s}}{4s}+\frac{\sin\pi s}{\pi}\frac{|t|^{-2s+1}}{2s-1}R+\frac{1}{2\pi i}\int_{\gamma_t}\mu^{-2s}\frac{F'(\mu)}{F(\mu)}d\mu.$$

The first integral on the right-hand side is regular at $s=0$ due to the asymptotics found in Lemma 6.1. Therefore, using that

$$\frac{\sin(\pi s)}{\pi}\bigg|_{s=0}=0,\quad \frac{d}{ds}\ \frac{\sin(\pi s)}{\pi}\bigg|_{s=0}=1,\qquad \frac{\sin(\pi s)}{\pi s}\bigg|_{s=0}=1,\quad \frac{d}{ds}\ \frac{\sin(\pi s)}{\pi s}\bigg|_{s=0}=0,$$

we see that

$$\zeta'_{\mathrm{reg}}(0,\Delta_\theta)=\int_{|t|}^{\infty}\frac{d}{dx}\log\left(\frac{F(ix)}{C_0(\log x-\kappa)x^{-1/2}e^{xR}}\right)dx-(\gamma+\log(2(\log|t|-\kappa))+\frac{1}{2}\log|t|-|t|R$$
$$-\frac{1}{\pi i}\int_{\gamma_t}\log\mu\frac{F'(\mu)}{F(\mu)}d\mu=-\log\left(\frac{F(i|t|)}{C_0}\right)-\gamma-\log 2-\frac{1}{\pi i}\int_{\gamma_t}\log\mu\frac{F'(\mu)}{F(\mu)}d\mu.$$

Therefore,

$$\det{}_{\mathrm{reg}}(\Delta_\theta)=2e^{\gamma}\frac{F(t)}{C_0}\cdot\exp\left(\frac{1}{\pi i}\int_{\gamma_t}\log\mu\frac{F'(\mu)}{F(\mu)}d\mu\right).\tag{9.1}$$

This formula is derived, *a priori*, when t is on the upper half of the imaginary axis. However, the right-hand side is a *holomorphic* function of $t\in\mathcal{D}$, where $\mathcal{D}$ is the set of complex numbers minus the negative real axis and the zeros of $F(\mu)$. Therefore (9.1) holds for all $t\in\mathcal{D}$. Here, we recall that γ_t is any curve in $\mathcal{D}$ from t to $-t$. As before, the trick now is to let $t\to 0$ in (9.1).

First, assume that $\log R-\tan\theta\neq 0$ so that Δ_θ has no zero eigenvalue by Theorem 5.2. We determine the limit as $t\to 0$ of the exponential $\exp(1/\pi i)\int_{\gamma_t}\log\mu[F'(\mu)/F(\mu)]d\mu)$. Let's take $t\to 0$ in $\mathcal{D}$ from the upper half plane as shown in Fig. 4. In view of Fig. 4, it follows that

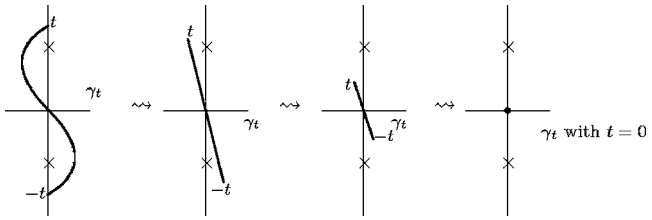

FIG. 4. The contour γ_t as we let $t \to 0$ in $\mathcal{D}$ from the upper half plane.

$$\exp\left(\frac{1}{\pi i}\int_{\gamma_t} \log \mu \frac{F'(\mu)}{F(\mu)} \mathrm{d}\mu\right) \to \exp(0) = 1.$$

Recalling (6.4), as $\mu \to 0$, we have

$$F(\mu) \sim (\log R - \tan\theta) + \tfrac{1}{4}\mu^2 R^2(1 + \tan\theta - \log R) + \mathcal{O}(\mu^4).$$

In this case $F(0) = \log R - \tan\theta$. In conclusion, taking $t \to 0$ in (9.1), we see that

$$\det_{\mathrm{reg}}(\Delta_\theta) = 2\sqrt{2\pi R}\, e^{\gamma}(\tan\theta - \log R). \tag{9.2}$$

Second, assume now that $\log R - \tan\theta = 0$ so that as $\mu \to 0$, we have

$$F(\mu) \sim \tfrac{1}{4}\mu^2 R^2(1 + \mathcal{O}(\mu^2)).$$

Let us set

$$\widetilde{F}(\mu) := \frac{F(\mu)}{\mu^2};$$

then $\widetilde{F}(\mu)$ is nonzero at $\mu = 0$ with value $R^2/4$, and

$$\zeta(s, \Delta_\theta) = \frac{\sin \pi s}{\pi}\int_{|t|}^{\infty} x^{-2s}\frac{d}{\mathrm{d}x}\log \widetilde{F}(ix)\mathrm{d}x + \frac{1}{2\pi i}\int_{\gamma_t} \mu^{-2s}\frac{\widetilde{F}'(\mu)}{\widetilde{F}(\mu)}\mathrm{d}\mu.$$

By Lemma 6.1 [see (6.2)], we have

$$\widetilde{F}(ix) \sim \frac{C_0(\log x - \kappa)x^{-1/2}e^{xR}}{-x^2} = \widetilde{C}_0(\log x - \kappa)x^{-5/2}e^{xR}, \quad \text{where } \widetilde{C}_0 = \frac{1}{\sqrt{2\pi R}}.$$

Now following the argument above used to prove (9.1), we can show

$$\det_{\mathrm{reg}}(\Delta_\theta) = 2e^{\gamma}\frac{\widetilde{F}(t)}{\widetilde{C}_0}\cdot \exp\left(\frac{1}{\pi i}\int_{\gamma_t} \log \mu \frac{\widetilde{F}'(\mu)}{\widetilde{F}(\mu)}\mathrm{d}\mu\right).$$

Finally, taking $t \to 0$ as we did before, yields in the $\tan\theta = \log R$ case, the result

$$\det_{\mathrm{reg}}(\Delta_\theta) = 2e^{\gamma}\frac{R^2}{4\widetilde{C}_0} = \frac{R^2}{2}e^{\gamma}\sqrt{2\pi R} = \sqrt{\frac{\pi R}{2}}e^{\gamma}R^2.$$

X. GENERAL BOUNDARY CONDITIONS AT $r = R$

We now prove Theorem 1.2. Let us briefly recall the setup. Let $0 \leqslant \theta_1, \theta_2 < \pi$ with $\theta_1 \neq \pi/2$ and set $L := L_{\theta_1} \oplus L_{\theta_2}$. Then as a consequence of Theorem 3.2, we know that

$$\Delta_L := \Delta : \mathcal{D}_L \to L^2([0,R])$$

is self-adjoint, where

$$\mathcal{D}_L = \{\phi \in \mathcal{D}_{\max}(\Delta) | \cos\theta_1 c_1(\phi) + \sin\theta_1 c_2(\phi) = 0, \cos\theta_2 \phi'(R) + \sin\theta_2 \phi(R) = 0\}.$$

The trick to proving Theorem 1.2 is to write the resolvent $(\Delta_L - \lambda)^{-1}$ in terms of $(\Delta_{\theta_1} - \lambda)^{-1}$ (same self-adjoint condition at $r=0$ but with the Dirichlet condition at $r=R$). To do so, let $\varrho(r) \in C^\infty((-\infty,\infty))$ be a nondecreasing function such that $\varrho(r)=0$ for $r \leqslant 1/4$ and $\varrho(r)=1$ for $r \geqslant 3/4$. Given any real numbers $\alpha < \beta$, we define

$$\varrho_{\alpha,\beta}(r) := \varrho((r-\alpha)/(\beta-\alpha)). \tag{10.1}$$

Then $\varrho_{\alpha,\beta}(r)=0$ on a neighborhood of $\{r \leqslant \alpha\}$ and $\varrho_{\alpha,\beta}(r)=1$ on a neighborhood of $\{r \geqslant \beta\}$. We define

$$\psi_1(r) = \varrho_{R/2,3R/4}(r), \quad \psi_2(r) = 1 - \psi_1(r),$$

$$\varphi_1(r) = \varrho_{R/4,R/2}(r), \quad \varphi_2(r) = 1 - \varrho_{3R/4,R}(r). \tag{10.2}$$

Let $\Delta' := -(d^2/dr^2) - (1/4r^2)$ over $[R/4,R]$ with the Dirichlet condition at $r=R/4$ and the condition $\cos\theta_2\phi'(R) + \sin\theta_2\phi(R)=0$ at $r=R$; note that since $r \geqslant R/4$ over $[R/4,R]$, the operator Δ' is a true smooth elliptic operator over this interval with no singularities. We define

$$Q(\lambda) := \varphi_1(\Delta' - \lambda)^{-1}\psi_1 + \varphi_2(\Delta_{\theta_1} - \lambda)^{-1}\psi_2. \tag{10.3}$$

It follows that $Q(\lambda)$ maps into the domain $\mathcal{D}_L$ of Δ_L, and

$$\begin{aligned}(\Delta_L - \lambda)Q(\lambda) &= (\Delta_L - \lambda)\varphi_1(\Delta' - \lambda)^{-1}\psi_1 + (\Delta_L - \lambda)\varphi_2(\Delta_{\theta_1} - \lambda)^{-1}\psi_2 \\ &= \varphi_1(\Delta' - \lambda)(\Delta' - \lambda)^{-1}\psi_1 + \varphi_2(\Delta_{\theta_1} - \lambda)(\Delta_{\theta_1} - \lambda)^{-1}\psi_2 + K_0(\lambda) \\ &= \psi_1 + \psi_2 + K_0(\lambda) = \mathrm{Id} + K_0(\lambda),\end{aligned}$$

where

$$K_0(\lambda) = [\Delta, \varphi_1](\Delta' - \lambda)^{-1}\psi_1 + [\Delta, \varphi_2](\Delta_{\theta_1} - \lambda)^{-1}\psi_2.$$

Because the supports of $[\Delta, \varphi_i]$ and ψ_i, where $i=1,2$, are disjoint, using the explicit formula (A3) for the resolvent $(\Delta_{\theta_1} - \lambda)^{-1}$ and the properties of the resolvent of $(\Delta' - \lambda)^{-1}$ found in the work of Seeley[43] it is straightforward to check that $K_0(\lambda)$ is trace-class operator that vanishes to infinite order as $|\lambda| \to \infty$ for λ in any sector Λ of $\mathbb{C}$ not intersecting the positive real axis; we shall fix such a sector Λ from now on. In particular, forming the Neumann series, it follows that $\mathrm{Id} + K_0(\lambda)$ is invertible for $|\lambda|$ large with $\lambda \in \Lambda$ with

$$(\mathrm{Id} + K_0(\lambda))^{-1} = \mathrm{Id} + K(\lambda),$$

where $K(\lambda)$ has the same properties as $K_0(\lambda)$. Thus, multiplying both sides of $(\Delta_L - \lambda)Q(\lambda) = \mathrm{Id} + K_0(\lambda)$ by $\mathrm{Id} + K(\lambda)$, we see that

$$(\Delta_L - \lambda)^{-1} = Q(\lambda) + Q(\lambda)K(\lambda).$$

Therefore, as $|\lambda| \to \infty$ for $\lambda \in \Lambda$, we see that Proposition 7.1 holds also for $\mathrm{Tr}(\Delta_L - \lambda)^{-1}$. Now using the resolvent asymptotics, we can proceed to copy the proofs of Proposition 8.1 and 6.3. The proof of Theorem 1.2 is now complete.

APPENDIX: THE RESOLVENT WITH DIRICHLET CONDITIONS AT $r=R$

In this Appendix, we compute the trace of the resolvent by explicitly finding the Schwartz kernel of the Bessel function. To do so, recall that the resolvent kernel of the differential operator $\Delta_\theta-\mu^2$ with given boundary conditions at $r=0$ and $r=R$ can be expressed as follows (see Lemma 4.1 in Ref. 9 or Ref. 26, Sec. 3.3 for an elementary account):

$$\frac{-1}{W(p,q)}\begin{cases} p(r,\mu)q(s,\mu) & \text{for } r\leqslant s,\\ p(s,\mu)q(r,\mu) & \text{for } r\geqslant s,\end{cases}$$

where $p(r,\mu)$ and $q(r,\mu)$ are solutions of $(\Delta_L-\mu^2)\phi=0$ satisfying the given boundary conditions at $r=0$ and $r=R$, respectively and where $W(p,q)$ is the Wronskian of (p,q). Recall that the general solution to $(\delta_L-\mu^2)\phi=0$ is

$$\phi=c_1(\phi)r^{1/2}J_0(\mu r)+c_2(\phi)r^{1/2}\left(\frac{\pi}{2}Y_0(\mu r)-(\log\mu-\log 2+\gamma)J_0(\mu r)\right).$$

To satisfy the boundary condition at $r=0$, we must have [see (5.3)]:

$$\cos\theta c_1(\phi)+\sin\theta c_2(\phi)=0.$$

Thus, we can take $c_2(\phi)=1$ and $c_1(\phi)=-\tan\theta$; this gives

$$p(r,\mu)=r^{1/2}\left(\frac{\pi}{2}Y_0(\mu r)-(\log\mu-\kappa)J_0(\mu r)\right), \tag{A1}$$

where $\kappa=\log 2-\gamma-\tan\theta$. To determine $q(r,\mu)$ we use the less fancy formulation of the general solution:

$$\phi=C_1r^{1/2}J_0(\mu r)+C_2r^{1/2}Y_0(\mu r).$$

To satisfy the Dirichlet condition at $r=R$, we therefore take

$$q(r,\mu)=r^{1/2}(Y_0(\mu R)J_0(\mu r)-J_0(\mu R)Y_0(\mu r)). \tag{A2}$$

The Wronskian is easily computed using that $W(r^{1/2}J_0(\mu r),r^{1/2}Y_0(\mu r))=2/\pi$ (see Ref. 45):

$$\begin{aligned}W(p,q)&=\frac{\pi}{2}Y_0(\mu R)W(r^{1/2}Y_0(\mu r),r^{1/2}J_0(\mu r))+(\log\mu-\kappa)J_0(\mu R)W(r^{1/2}J_0(\mu r),r^{1/2}Y_0(\mu r))\\&=-Y_0(\mu R)+\frac{2}{\pi}(\log\mu-\kappa)J_0(\mu R).\end{aligned}$$

Therefore,

$$(\Delta_\theta-\mu^2)^{-1}(r,s)=\frac{1}{F(\mu)}\begin{cases} p(r,\mu)q(s,\mu) & \text{for } r\leqslant s,\\ p(s,\mu)q(r,\mu) & \text{for } r\geqslant s,\end{cases} \tag{A3}$$

where p and q are given in (A1) and (A2), respectively, and where

$$F(\mu):=Y_0(\mu R)-\frac{2}{\pi}(\log\mu-\kappa)J_0(\mu R).$$

We now need to compute $\int_0^R p(r,\mu)q(r,\mu)\mathrm{d}r$; that is,

$$\int_0^R r\left(\frac{\pi}{2}Y_0(\mu r)-(\log\mu-\kappa)J_0(\mu r)\right)(Y_0(\mu R)J_0(\mu r)-J_0(\mu R)Y_0(\mu r))\mathrm{d}r$$
$$=\frac{\pi}{2}Y_0(\mu R)\int_0^R rY_0(\mu r)J_0(\mu r)\mathrm{d}r-\frac{\pi}{2}J_0(\mu R)\int_0^R rY_0(\mu r)^2\,\mathrm{d}r+(\log\mu$$
$$-\kappa)J_0(\mu R)\int_0^R rJ_0(\mu r)Y_0(\mu r)\mathrm{d}r-(\log\mu-\kappa)Y_0(\mu R)\int_0^R rJ_0(\mu r)^2\,\mathrm{d}r. \tag{A4}$$

We next use the indefinite integrals

$$\int rJ_0(\mu r)^2\,\mathrm{d}r=\frac{r^2}{2}(J_0(\mu r)^2+J_1(\mu r)^2),$$

$$\int rY_0(\mu r)^2\,\mathrm{d}r=\frac{r^2}{2}(Y_0(\mu r)^2+Y_1(\mu r)^2),$$

$$\int rY_0(\mu r)J_0(\mu r)\mathrm{d}r=\frac{r^2}{2}(Y_0(\mu r)J_0(\mu r)+Y_1(\mu r)J_1(\mu r)),$$

which we need to evaluate between $r=0$ and $r=R$. Recalling (5.2), $zJ_0(z)$ and $zJ_1(z)$ vanish at $z=0$. Also, by (5.1) $zY_0(z)$ also vanishes at $z=0$. However, it is a remarkable fact, which may be easily overlooked, that since

$$\frac{\pi}{2}Y_1(z)=-\frac{1}{z}J_0(z)+(\log z-\log 2+\gamma)J_1(z)-\frac{1}{2}z\sum_{k=1}^{\infty}\frac{kH_k\left(-\frac{1}{4}z^2\right)^{k-1}}{(k!)^2},$$

where we used that $Y_1(z)=-Y_0'(z)$ and $J_1(z)=-J_0'(z)$ from Ref. 1 p. 361, we have

$$(zY_1(z))|_{z=0}=-\frac{2}{\pi}\Rightarrow\ (z^2Y_1(z)^2)|_{z=0}=\frac{4}{\pi^2}.$$

Therefore,

$$\int_0^R rJ_0(\mu r)^2\,\mathrm{d}r=\frac{R^2}{2}(J_0(\mu R)^2+J_1(\mu R)^2)$$

$$\int_0^R rY_0(\mu r)^2\,\mathrm{d}r=\frac{R^2}{2}(Y_0(\mu R)^2+Y_1(\mu R)^2)-\frac{1}{2}\ \ (r^2Y_1(\mu r)^2)|_{r=0})$$
$$=\frac{R^2}{2}(Y_0(\mu R)^2+Y_1(\mu R)^2)-\frac{2}{\pi^2\mu^2}$$

$$\int_0^R rY_0(\mu r)J_0(\mu r)\mathrm{d}r=\frac{R^2}{2}(Y_0(\mu R)J_0(\mu R)+Y_1(\mu R)J_1(\mu R)).$$

Plugging these integrals into (A4) and using the identity (Ref. 1, p. 360)

$$J_1(z)Y_0(z) - J_0(z)Y_1(z) = \frac{2}{\pi z}$$

to simplify the expression obtained, we eventually arrive that

$$\int_0^R p(r,\mu)q(r,\mu)\mathrm{d}r = \frac{R}{2\mu}\left(Y_1(\mu R) - \frac{2}{\pi}(\log\mu - \kappa)J_1(\mu R)\right) + \frac{1}{\pi\mu^2}J_0(\mu R)$$

$$= \frac{R}{2\mu}\left(Y_1(\mu R) - \frac{2}{\pi}(\log\mu - \kappa)J_1(\mu R) + \frac{2}{\pi\mu R}J_0(\mu R)\right).$$

Using the fact that $J_0'(z) = -J_1(z)$ and $Y_0'(z) = -Y_1(z)$, we can write this as

$$\int_0^R p(r,\mu)q(r,\mu)\mathrm{d}r = -\frac{1}{2\mu}\frac{d}{\mathrm{d}\mu}\left(Y_0(\mu R) - \frac{2}{\pi}(\log\mu - \kappa)J_0(\mu R)\right) = -\frac{1}{2\mu}\frac{d}{\mathrm{d}\mu}F(\mu),$$

where we recall that

$$F(\mu) \coloneqq Y_0(\mu R) - \frac{2}{\pi}(\log\mu - \kappa)J_0(\mu R).$$

Since [see (A3)]

$$(\Delta_\theta - \mu^2)^{-1}(r,s) = \frac{1}{F(\mu)}\begin{cases} p(r,\mu)q(s,\mu) & \text{for } r \leqslant s, \\ p(s,\mu)q(r,\mu) & \text{for } r \geqslant s, \end{cases}$$

we have proved the following theorem.

Theorem A.1: *With* $F(\mu) \coloneqq Y_0(\mu R) - (2/\pi)(\log\mu - \kappa)J_0(\mu R)$, *we have*

$$\mathrm{Tr}(\Delta_\theta - \mu^2)^{-1} = -\frac{1}{2\mu}\frac{1}{F(\mu)}\frac{d}{\mathrm{d}\mu}F(\mu) = -\frac{1}{2\mu}\frac{d}{\mathrm{d}\mu}\log F(\mu).$$

This theorem has been used to analyze the zeta function, resolvent, and heat kernel of Δ_θ in Secs. VI–VIII.

(Received 21 October 2005; accepted 3 March 2006; published online 21 April 2006)

Cayley-Dickson doubling procedure is used to construct the root systems of some celebrated Lie algebras in terms of the integer elements of the division algebras of real numbers, complex numbers, quaternions, and octonions. Starting with the roots and weights of SU(2) expressed as the real numbers one can construct the root systems of the Lie algebras of SO(4), SP(2)$\approx$SO(5), SO(8), SO(9), F_4 and E_8 in terms of the discrete elements of the division algebras. The roots themselves display the groups structures besides the octonionic roots of E_8 which form a closed octonion algebra. The automorphism group Aut(F_4) of the Dynkin diagram of F_4 of order 2304, the largest crystallographic group in four-dimensional Euclidean space, is realized as the direct product of two binary octahedral group of quaternions preserving the quaternionic root system of F_4. The Weyl groups of many Lie algebras, such as, G_2, SO(7), SO(8), SO(9), SU(3)*X*SU(3), and SP(3)$\times$SU(2) have been constructed as the subgroups of Aut(F_4). We have also classified the other non-parabolic subgroups of Aut(F_4) which are not Weyl groups. Two subgroups of orders 192 with different conjugacy classes occur as maximal subgroups in the finite subgroups of the Lie group G_2 of orders 12096 and 1344 and proves to be useful in their constructions. The triality of SO(8) manifesting itself as the cyclic symmetry of the quaternionic imaginary units e_1, e_2, e_3 is used to show that SO(7) and SO(9) can be embedded, triply symmetric way in SO(8) and F_4 in respectively. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2190334]

I. INTRODUCTION

There are a few celebrated Lie algebras which seem to be playing important roles in understanding the underlying symmetries of the unified theory of all interactions. The most popular ones are the exceptional Lie groups G_2, F_4, E_6, E_7, and E_8 and the related groups.[1] The groups Spin7 and G_2 are proposed as the holonomy groups for the compactification of the M-theory from 11 to four dimensional space-time.[2] It is also well known that two orthogonal groups SO(8) and SO(9) are the little groups of the massless particles of string theories in 10-dimensions and the M-theory in 11-dimensions, respectively. The fact that SO(9) can be embedded in the exceptional Lie group F_4 in a triply symmetric way and the noncompact $F_{4(-25)}$ can be embedded in the Lorenz group SO(25,1) indicates the importance of the exceptional group F_4.[3] The largest exceptional group E_8 which had been suggested as the unified theory of the electroweak and strong interactions with three generations of lepton-quark families[4] naturally occurred as the gauge symmetry of the $E_8 \times E_8$ heterotic string theory.[5] It has many novel mathematical aspects[6] which has not been ex-

ploited in physics. It was known that a non-compact version of E_7 manifests itself as a global symmetry of the 11-dimensional supergravity.[7] Some of its maximal subgroups show themselves as local symmetries.[8] The E_6 has been suggested as a unified theory of electroweak and strong interactions.[9]

The Weyl groups of these groups are also important for the invariants of the Lie groups can be deduced using the related Weyl groups. The Weyl groups of the exceptional Lie groups F_4, E_6, E_7, and E_8 correspond to some finite subgroups of the Lie groups of O(4), O(6), O(7), and O(8), respectively.[10]

It has been shown in some details that the finite subgroups of O(4) can be classified as direct products of finite subgroups of quaternions,[11] isomorphic to the finite subgroups of SU(2), which is the double cover of SO(3). Therefore the relevant Weyl groups of the Lie groups F_4, SO(9), and SO(8) correspond to some finite subgroups of O(4).[12] Similarly, the Weyl groups of some rank-3 Lie algebras can be obtained from the finite subgroups of O(3). Interestingly enough, the relevant root systems can be represented as discrete quaternions and the Weyl groups can be realized as the left-right actions of the quaternions on the root systems. When one considers the finite subgroups of O(8) it is natural to encounter with the discrete octonions which represent the root system of E_8 where the root system of E_7 is described by imaginary octonions.[13] The automorphism group of octonionionic root system of E_7 turns out to be a finite subgroup of G_2 of order 12096.[14] In what follows we will restrict ourselves to the quaternionic root system of F_4, SO(9), SO(8), SO(7), SP(3) and construct explicitly their Weyl groups as finite subgroups of O(4). The largest group of interest here is the Aut(F_4) of order $2304=48\times 48$ which is the direct product of the binary octahedral group with itself.[15] We follow a chain of decomposition of Aut(F_4) into its relevant subgroups, some of which are maximal subgroups in the finite subgroups of G_2 of orders 12096 and 1344.[16]

The paper is organized as follows. In Sec. II we start with the scaled roots ± 1 0 and the weights $\pm\frac{1}{2}$ of SU(2) and using the Cayley-Dickson doubling procedure we construct the roots of SO(4) and SP(2)$\approx$SO(5) in terms of complex numbers. Further doubling of the roots of SP(2) $\approx$SO(5) leads to the quaternionic roots of SO(8).[13,16] The eight-dimensional vector and spinor representations of Spin-8 constitute the short roots of F_4. Doubling of two sets of quaternionic roots of F_4 leads to the octonionic roots of E_8. The triality of SO(8) is then coded in the cyclic symmetry of the quaternionic imaginary units. In Sec. III we introduce the finite subgroups of SU(2) in terms of quaternions and explain their geometric properties. We explain how to construct the Aut(F_4) and the Weyl groups of F_4, SO(9), and SO(8).[15]In Sec. IV we construct the root systems of SO(7) and G_2 by folding the Coxeter-Dynkin diagram of SO(8),[17] which displays the threefold embeddings of SO(7) into SO(8). The Weyl groups of SO(7), G_2, and SP(3) are constructed in terms of quaternions. In Sec. V we discuss the subgroup chains of Aut(F_4) and find out the explicit expressions of the groups down to the groups of order 192. A particular emphasis is given to two groups of orders 192 since they appear as the maximal subgroups in the finite subgroups of G_2 of orders 12096 and 1344. Finally in Sec. VI we further elaborate the geometric aspects of the symmetries discussed in the preceding sections.

II. ROOT SYSTEMS WITH THE CAYLEY-DICKSON DOUBLING PROCEDURE

The Cayley-Dickson doubling is a procedure to build the elements of division algebras starting with the real numbers. Let us denote by p, q, r, s the elements of a division algebra other than the octonions. Then the pairs (p,q) and (r,s) with the multiplication rule

$$(p,q)(r,s) = (pr - s\bar{q}, rq + \bar{p}s) \tag{1}$$

constitute the elements of a division algebra in higher dimension. The celebrated Hurwitz's theorem[18] states that there are only four division algebras, namely, real numbers, complex numbers, quaternions, and octonions. Starting with the complex numbers at every higher level of division algebras one introduces one complex number, say, e_1, e_2, and e_7 which anticommute with each other and satisfy the relation $e_1^2=e_2^2=e_7^2=-1$. Doubling of the real numbers constitutes the

complex numbers, two sets of complex numbers define the quaternions and finally a pair of quaternions defines the octonions under the definition (1). Let us revise the work of Ref. 13 by starting with the roots ±1 0 and the weights $\pm\frac{1}{2}$ of SU(2). A pair of set ±1 0 leads to the roots of SO(4):

$$(\pm 1,0) = \pm 1,(0,\pm 1) = \pm e_1(\text{we use } e_1 \text{ for the imaginary number } i). \tag{2}$$

The nonzero roots ± 1 $\pm e_1$ of SO(4) form a cyclic group of order 4. The weights of the spinor representation $(\underline{2},\underline{2})$ of SO(4) can be taken as

$$\left(\pm\tfrac{1}{2},\pm\tfrac{1}{2}\right) = \tfrac{1}{2}(\pm 1 \pm e_1). \tag{3}$$

The roots in (2) and the weights in (3) constitute the scaled roots of $\mathrm{SP}(2) \approx \mathrm{SO}(5)$,

$$\mathrm{SP}(2) \approx \mathrm{SO}(5): \pm 1, \pm e_1, \tfrac{1}{2}(\pm 1 \pm e_1). \tag{4}$$

When the short roots are scaled to the unit norm then the roots of SP(2) form a cyclic group of order 8. A nontrivial structure will arise when two sets of the roots of SP(2) are paired as $(\mathrm{SP}(2),\mathrm{SP}(2))$ where the long roots match with the zero roots while the short roots match with the short roots leading to the quaternionic roots of SO(8):

$$T:\left\{\pm 1, \pm e_1, \pm e_2, \pm e_3, \tfrac{1}{2}(\pm 1 \pm e_1 \pm e_2 \pm e_3)\right\}, \tag{5}$$

where we have used $e_3e_1=-e_1e_3=e_2$. If we include the pairing of the short roots with the zero roots we obtain

$$V_1':\left(\tfrac{1}{2}(\pm 1 \pm e_1),0\right) = \tfrac{1}{2}(\pm 1 \pm e_1),\left(0,\tfrac{1}{2}(\pm 1 \pm e_1)\right) = \tfrac{1}{2}(\pm e_2 \pm e_3). \tag{6}$$

These are the weights of the eight-dimensional representation of SO(8) and together with the roots in (5) they represent the roots of SO(9). The cyclic symmetry of the quaternionic imaginary units would lead to the weights of the two eight-dimensional spinor representations of SO(8) which represent the weights of the 16-dimensional spinor representation of SO(9):

$$\begin{aligned} V_2':&\left\{\tfrac{1}{2}(\pm 1 \pm e_2), \quad \tfrac{1}{2}(\pm e_3 \pm e_1)\right\}, \\ V_3':&\left\{\tfrac{1}{2}(\pm 1 \pm e_3), \quad \tfrac{1}{2}(\pm e_1 \pm e_2)\right\}. \end{aligned} \tag{7}$$

The set of quaternions in (5)–(7) constitutes the scaled roots of F_4. A further doubling the set of roots of F_4 will lead to the octonionic roots of E_8,[13]

$$\begin{aligned} &(T,0) = T, \quad (0,T) = e_7T, \\ &(V_1',V_1') = V_1' + e_7V_1', \\ &(V_2',V_3') = V_2' + e_7V_3', \\ &(V_3',V_2') = V_3' + e_7V_2', \end{aligned} \tag{8}$$

where one can define $e_4=e_7e_1$, $e_5=e_7e_2$, $e_6=e_7e_3$. We note that when the roots in (6) and (7) are multiplied by $\sqrt{2}$ to make the norm 1 then the 48 sets of quaternions are the elements of the binary octahedral group O of SU(2) where T represents the binary tetrahedral subgroup of order 24.

III. BINARY OCTAHEDRAL GROUP AND THE Aut(F_4)

Some of the material of this section have been discussed in Ref. 12. The finite subgroups of SO(3) are well known: icosahedral group of order 60, octahedral group of order 24, tetrahedral group of order 12, and dihedral and cyclic groups of various orders.[19] Their double covers are the

finite subgroups of quaternions which are related to the ADE series of the Lie algebras through the McKay correspondence.[20] Our interests here solely are constrained to the binary octahedral group whose direct product with itself is isomorphic to the Aut(F_4) which can be realized as the left and right actions of the quaternionic elements on the quaternionic roots of F_4. The root system of F_4 has very interesting geometrical structures which has not been discussed in the literature. We classify the elements of the binary octahedral group as sets of the hyperoctahedra in four dimensions,[21]

$$\begin{aligned} V_0 &= \{\pm 1, \pm e_1, \pm e_2, \pm e_3\} \\ T{:}V_+ &= \left\{\tfrac{1}{2} \pm 1 \pm e_1 \pm e_2 \pm e_3\right\}, \quad \text{even number of } (+) \text{ signs} \\ V_- &= \overline{V_+} = \left\{\tfrac{1}{2} \pm 1 \pm e_1 \pm e_2 \pm e_3\right\}, \quad \text{odd number of } (+) \text{ signs}, \end{aligned} \tag{9}$$

where $\overline{V_+}$ is the quaternionic conjugate of V_+.

$$\begin{aligned} V_1 &= \left\{\frac{1}{\sqrt{2}}(\pm 1 \pm e_1), \frac{1}{\sqrt{2}}(\pm e_2 \pm e_3)\right\} \\ T'{:}V_2 &= \left\{\frac{1}{\sqrt{2}}(\pm 1 \pm e_2), \frac{1}{\sqrt{2}}(\pm e_3 \pm e_1)\right\} \\ V_3 &= \left\{\frac{1}{\sqrt{2}}(\pm 1 \pm e_3), \frac{1}{\sqrt{2}}(\pm e_1 \pm e_2)\right\} \end{aligned} \tag{10}$$

$$O{:}T \oplus T'. \tag{11}$$

Here each of V_0, V_+, and V_- represents the vertices of a hyperoctahedron in four-dimensions and any two hyperoctahedra form a hypercube in four dimensions with 16 vertices. The set of quaternions T in (9) not only constitute the nonzero roots of SO(8) but also represent a polytope 3,4,5 called 24-cell.[21] The set of quaternions in T' are the duals of T; consequently any $V_i(i=1,2,3)$ is a hyperoctahedron and any two hyperoctahedra form the vertices of a hypercube. We give the multiplication table of these sets of quaternions in Table I to understand the structure of the binary octahedral group. Here V_0 is the quaternion group and forms an invariant subgroup both in T and O.

A general element of $\mathrm{O}(4) \approx \mathrm{SU}(2) \times \mathrm{SU}(2)$ can be defined as follows. Denote by p,q the quaternions of unit norm acting on an arbitrary quaternion $r=r_0+r_1e_1+r_2e_2+r_3e_3$,

$$^{[29]}r \to prq{:}[p,q], \tag{12}$$

$$r \to p\bar{r}q{:}[p,q]^*, \tag{13}$$

where $\bar{r}$ is the quaternion conjugate $\bar{r}=r_0-r_1e_1-r_2e_2-r_3e_3$. For arbitrary quaternions p,q with unit norm the elements $[p,q]$ and $[p,q]^*$ form a six parameter group leaving the norm $r\bar{r}=\bar{r}r$ invariant. When written in terms of matrices the group elements $[p,q]$ and $[p,q]^*$ have determinants +1 and

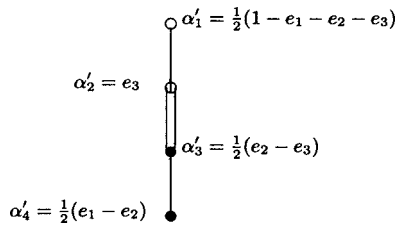

FIG. 1. The Coxeter-Dynkin diagram of F_4.

-1, respectively. Therefore the elements $[p,q]$ form a subgroup $\mathrm{SO}(4) \approx \mathrm{SU}(2) \times \mathrm{SU}(2)/Z_2$ of $\mathrm{O}(4)$. In Ref. 12 we have proven that the Weyl group $W(F_4)$ can be compactly written as the union of elements,

$$W(F_4) = [T,T] \oplus [T',T'] \oplus [T,T]^* \oplus [T',T']^*. \tag{14}$$

The automorphism group $\mathrm{Aut}(F_4)$ is the semidirect product of the Weyl group $W(F_4)$ with the Z_2 symmetry of the Coxeter-Dynkin diagram of F_4,

$$^{[30]}\mathrm{Aut}(F_4) \equiv (O,O) \oplus (O,O)^* \approx W(F_4){:}Z_2. \tag{15}$$

The generators of $\mathrm{Aut}(F_4)$ can be obtained from the Coxeter-Dynkin diagram of F_4 where the simple roots are given in terms of scaled quaternions (Fig. 1).

The regular simple roots α_i are related to α_i' by $\alpha_i = \sqrt{2}\alpha_i' (i=1,2,3,4)$. The $\mathrm{Aut}(F_4)$ is generated by the elements

$$[\alpha_1', -\alpha_1']^*, [\alpha_2', -\alpha_2']^*, [\alpha_3, -\alpha_3]^*, [\alpha_4, -\alpha_4]^*, \left[\frac{1}{\sqrt{2}}(e_2 + e_3), -e_2\right]. \tag{16}$$

The first four generators in (16) represent the reflections in the roots $\alpha_i (i=1,2,3,4)$ and generate the Weyl group $W(F_4)$ and the last term stands for the diagram symmetry of F_4 which transforms, by conjugation, $\alpha_1' \leftrightarrow \alpha_4'$ and $\alpha_2' \leftrightarrow \alpha_3'$. An extended Coxeter-Dynkin diagram of F_4 can be used to obtain the Coxeter-Dynkin diagrams of its maximal Lie algebras. We will discuss all starting with SO(9).

A. The parabolic subgroups of F_4

1. SO(9)

We have shown in Ref. 12 that the Weyl group $W(\mathrm{SO}(9))$ can be represented by the set of group elements

$$[V_0, V_0], [V_+, V_+], [V_-, V_-], [V_0, V_0]^*, [V_+, V_+]^*, [V_-, V_-]^*, \tag{17}$$

$$[V_1, V_1], [V_2, V_3], [V_3, V_2], [V_1, V_1]^*, [V_2, V_3]^*, [V_3, V_2]^*. \tag{18}$$

This is a group of order 384. The $W(\mathrm{SO}(9))$ can be embedded in the $W(F_4)$ triply symmetric way by permuting the quaternionic imaginary units e_1, e_2, e_3 in the cyclic order. It is an inner automorphism of $W(F_4)$ which replaces the elements in (18) by the corresponding elements where the indices 1,2,3 are permuted in the cyclic order. This permutation of the indices leaves the set of elements in (17) invariant as expected. Actually the set of elements in (17) constitute the elements of the Weyl group $W(\mathrm{SO}(8))$. The Weyl group $W(\mathrm{SO}(9))$ has a very interesting geometrical aspect; it is the largest symmetry preserving the four-dimensional hyperoctahedron. One can show that the group elements in (17) and (18) leave the set of elements in V_1 invariant which is one of those six hyperoctahedra of the 48 roots of F_4. This must be expected anyway because the set of roots $V_1/\sqrt{2}$ are the short roots of SO(9) and must be rotated to each other by the elements of $W(\mathrm{SO}(9))$.

FIG. 2. The Coxeter-Dynkin diagram of $SU(2)\times SP(3)$.

Since the weights of the 16-dimensional spinor representation are represented by the quaternions $(1/\sqrt{2})(V_2+V_3)$ corresponding to the vertices of a cube in four-dimensions they are also preserved by the elements of $W(SO(9))$ in (14). Embedding $W(SO(9))$ in $\mathrm{Aut}(F_4)$ can be made with a sixfold cyclic symmetry under the conjugation, say, by $[V_+,V_1]W(SO(9))[V_-,V_1]$ where $[V_+,V_1]^6=[V_0,V_0]$. This leads to six conjugate representations of $W(SO(9))$ in $\mathrm{Aut}(F_4)$ in each of which one of the six hyperoctahedra $V_0,V_\pm,V_i(i=1,2,3)$ is left invariant by $W(SO(9))$. There are other subgroups of $\mathrm{Aut}(F_4)$ of order 384 not isomorphic to the Weyl group $W(SO(9))$. We will discuss them in Sec. V. Now we discuss the Weyl group of the maximal subalgebra $SU(2)\times SP(3)$ of F_4.

2. SU(2)×SP(3)

The algebra $SU(2)\times SP(3)$ can be represented by the Coxeter-Dynkin diagram shown in Fig. 2.

The reflection generators on the simple roots are represented by

$$r_0=[1,-1]^*,\quad r_1=[e_3,-e_3]^*,\quad r_2=\left[\frac{1}{\sqrt{2}}(e_2-e_3),-\frac{1}{\sqrt{2}}(e_2-e_3)\right]^*,$$
$$r_3=\left[\frac{1}{\sqrt{2}}(e_1-e_2),-\frac{1}{\sqrt{2}}(e_1-e_2)\right]^* \tag{19}$$

and will generate the set of roots

$$\begin{array}{cc} \mathrm{SU}(2) & \mathrm{SP}(3) \\ \pm 1 & \pm e_1,\pm e_2,\pm e_3 \\ & \frac{1}{2}(\pm e_1\pm e_2) \\ & \frac{1}{2}(\pm e_2\pm e_3) \\ & \frac{1}{2}(\pm e_3\pm e_1). \end{array} \tag{20}$$

The long roots $\pm e_1$, $\pm e_2$, $\pm e_3$ of SP(3) form the vertices of an octahedron. Therefore the Weyl group $W(SP(3))$ is the symmetry of the octahedron in three-dimensions. Since the product of two reflections is a rotation around some axis the proper rotation subgroup of $W(SP(3))$ is generated by

$$R=r_1r_2=\left[\frac{1}{\sqrt{2}}(1-e_1),\frac{1}{\sqrt{2}}(1+e_1)\right],S=r_2r_3=[\bar{t},t] \tag{21}$$

with $t=\frac{1}{2}(1+e_1+e_2+e_3)$. Here the generators satisfy the generation relations of an octahedral group[23]

$$R^4=S^3=(RS)^2=[1,1]. \tag{22}$$

It is one of the finite subgroups of SO(3) isomorphic to the symmetric group S_4. Another generator $(r_1r_2r_3)^3=[1,1]^*$ commutes with the generators R and S so that the maximal group of the SP(3) roots is the group $W(SP(3))\approx S_4\times Z_2$, a group of order 48. The Z_2 group of $W(SU(2))$ is generated by $[1,-1]^*$ which commutes with the generators of $W(SP(3))$. Therefore the Weyl group $W(SU(2))\times W(SP(3))$ is isomorphic to the group $S_4\times Z_2^2$ of order 96. The group elements are represented by the pair of quaternions

$$[p,\pm\bar{p}],[p',\pm\bar{p}'],[p,\pm\bar{p}]^*,[p',\pm\bar{p}']^*;p\in T,p'\in T'. \tag{23}$$

FIG. 3. The Coxeter-Dynkin diagram of $SU(3)\times SU(3)$. Here $\bar{t}=\frac{1}{2}(1-e_1-e_2-e_3)$, $s_1'=\frac{1}{2}(e_1-e_2)$, and $s_2'=\frac{1}{2}(e_2-e_3)$.

Since the vertices of the octahedron are represented by the imaginary quaternions $\pm e_1, \pm e_2, \pm e_3$ one can naturally ask the question: what is the maximal group which preserves the quaternion algebra of the set of quaternions $\pm e_1, \pm e_2, \pm e_3$? It is well known that when p is the unit quaternion with nonzero real component then the transformation $e_i'=pe_i\bar{p}$ is the only transformation which preserves the quaternion algebra and is isomorphic to the group SO(3). This implies that the finite subgroup of SO(3) which preserves the set of quaternions $\pm e_1, \pm e_2, \pm e_3$ is the octahedral group represented by the elements $[p,\bar{p}],[p',\bar{p}]$ which is isomorphic to the symmetric group S_4.

3. SU(3)×SU(3)

From the extended Coxeter-Dynkin diagram of F_4 we obtain the Coxeter-Dynkin diagram of $SU(3)\times SU(3)$ (Fig. 3).

Note that one of the SU(3) is represented by the short roots. The nonzero roots of $SU(3)\times SU(3)$ are given by

$$\pm 1, \pm t, \pm \bar{t}, \pm s_1', \pm s_2', \pm s_3', \tag{24}$$

where $s_3'=\frac{1}{2}(e_3-e_1)$. Using the standard technique one can form the elements of $W(SU(3))\times W(SU(3))$ of order 36 which is the direct product of two symmetric groups S_3. A further symmetry is the diagram automorphism of $SU(3)\times SU(3)$ which can be made by an element $c=[1,(1/\sqrt{2})(e_1-e_2)]$ which permutes the simple roots and preserve the Cartan matrix of the algebra $SU(3)\times SU(3)$. An extension of the Weyl group $W(SU(3))\times W(SU(3))$ by the element $c=[1,(1/\sqrt{2})(e_1-e_2)]$ leads to, up to conjugation, the group $\mathrm{Aut}(SU(3)\times SU(3))\approx[W(SU(3))\times W(SU(3))]:Z_4$ (Ref. 24) where Z_4 is the cyclic group of order 4 generated by the element c. The set of elements can be represented by $[p,q]\oplus[p,q]^*$ where p,q take arbitrary values from the set of scaled roots $p,q\in\{\pm 1,\pm t,\pm\bar{t},\pm s_1,\pm s_2,\pm s_3\}$ where $s_i=\sqrt{2}s_i'(i=1,2,3)$.

IV. SO(8) AND ITS SUBGROUPS

The SO(8) algebra plays a special role when embedding in F_4 since the long roots of F_4 are the roots of SO(8). Its Coxeter-Dynkin diagram illustrates the triality in terms of the cyclic symmetry of the quaternionic imaginary units.

The Weyl group $W(SO(8))$ is represented by the set of elements (17) and the $\mathrm{Aut}(S(O(8))$ is isomorphic to the Weyl group $W(F_4)$. Since in Ref. 12 we have worked SO(8) in some detail here we will deal with its two special subgroups SO(7) and G_2 (Fig. 4).

A. SO(7)

The SO(7) diagram can be obtained from that of SO(8) by folding two branches and averaging the corresponding simple roots.[17]

Denote by the reflection generators r_1, r_2, r_3 of SO(7) (Fig. 5) corresponding to the simple roots e_1, $\bar{t}=\frac{1}{2}(1-e_1-e_2-e_3)$, $\frac{1}{2}(e_2+e_3)$, respectively, which can be expressed as

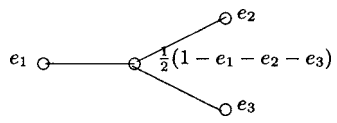

FIG. 4. The Coxeter-Dynkin diagram of SO(8).

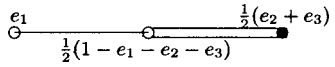

FIG. 5. The Coxeter-Dynkin diagram of SO(7).

$$r_1=[e_1,-e_1]^*,\quad r_2=[\bar{t},-\bar{t}]^*,\quad r_3=\left[\frac{1}{\sqrt{2}}(e_2+e_3),-\frac{1}{\sqrt{2}}(e_2+e_3)\right]^*. \tag{25}$$

One can also express r_3 in terms of the simple roots of SO(8) as the product of reflection generators corresponding to e_2 and e_3 rather than the one in (25). That would give us $r_3=[e_2,-e_2]^*[e_3,-e_3]^*=[e_1,-e_1]$ which gives the same result when acting on the roots of SO(7). If we define $d_1=(1/\sqrt{2})(e_2-e_3)$ then we can write the $W(\mathrm{SO}(7))$ generators as

$$r_1=[e_1,-d_1\bar{e}_1\bar{d}_1]^*,\quad r_2=[\bar{t},-d_1t\bar{d}_1]^*,\quad r_3=[e_1,-d_1\bar{e}_1\bar{d}_1]. \tag{26}$$

The generators $a=r_1r_2$ and $b=(r_1r_2r_3)^2$ satisfy the generation relation

$$a^3=b^3=(ab)^2=[1,1] \tag{27}$$

which is the generation relation of the tedrahedral group of order 12 isomorphic to the group A_4 of the even permutations of four letters.[23] The group elements can be written as

$$[p,d_1\bar{p}\bar{d}_1],p\in T. \tag{28}$$

One can check that the elements

$$[1,-1],[1,\pm 1]^* \tag{29}$$

preserve the simple roots by conjugation. This means that the tetrahedral group in (28) can be extended by the elements in (29) so that the whole set of elements will read

$$[p,\pm d_1\bar{p}\bar{d}_1],[p,\pm d_1\bar{p}\bar{d}_1]^*. \tag{30}$$

We note that the set of elements

$$[p,d_1\bar{p}\bar{d}_1],[p,d_1\bar{p}\bar{d}_1]^* \tag{31}$$

form a group isomorphic to the octahedral group S_4. The element $[1,-1]$ commutes with the elements of S_4 in (31). Therefore the set of elements represent a group isomorphic to the group $S_4\times Z_2$ which is the Weyl group $W(\mathrm{SO}(7))$ of order 48. This is the group isomorphic to $W(\mathrm{SP}(3))$ represented by (30) and (31). We could have different foldings of SO(8) diagram other than the one shown in Fig. 5. This would lead to replacing the quaternion d_1 in (30) by $d_2=\frac{1}{2}(e_3-e_1)$ and $d_3=\frac{1}{2}(e_1-e_2)$. By replacing d_1 by d_2 and d_3 in (30) we obtain three different embeddings of SO(7) in SO(8). When we stick to the representation of $W(\mathrm{SO}(7))$ in (30) we can show that the 24 nonzero roots of SO(8) can be decomposed as

$$\pm 1,\pm e_1,e_2,-e_3,\tfrac{1}{2}(\pm 1\pm e_1\pm(e_2+e_3)),\tfrac{1}{2}(\pm 1\pm e_1+(e_2-e_3)) \tag{32}$$

which represent 18 nonzero roots of SO(7) and the remaining ones are the six nonzero weights of the seven-dimensional representation of SO(7),

$$-e_2,e_3,\tfrac{1}{2}(\pm 1\pm e_1-(e_2-e_3)). \tag{33}$$

Three different embeddings of SO(7) in SO(8) can be realized by permuting the indices (1,2,3) in (32) and (33) in the cyclic order.

FIG. 6. The Coxeter-Dynkin diagram of G_2.

B. G_2

The Coxeter-Dynkin diagram of G_2 can be obtained from that of SO(8) by folding three branches and taking the average of the outer simple roots[17] (Fig. 6).

Let us denote by $I=(1/\sqrt{3})(e_1+e_2+e_3)$ with $I^2=-1$. The simple roots scaled by $\sqrt{2}$ are given by $\alpha_1=\frac{1}{2}(1-\sqrt{3}I)=e^{-(\pi/3)I}$, $\alpha_2=I/\sqrt{3}$ and the reflection generators read $r_1=[e^{-(\pi/3)I},-e^{-\pi I/3}]^*$, $r_2=[I,-I]^*$. The group $W(G_2)$ generated by r_1 and r_2 is the dihedral group D_6 of order 12. One can obtain the 12 nonzero roots of G_2 by acting the generators r_1 and r_2 on the simple roots. The weights of the seven-dimensional representation can be obtained from the highest weight $\sqrt{\frac{2}{3}}e^{(\pi/6)I}$.

A remark is in order. We can summarize the discussion in this section that the SO(7) can be embedded in SO(8) triply symmetric way and the G_2 takes place in the intersection of these three SO(7) in SO(8) (Fig. 7).[25]

V. NONPARABOLIC SUBGROUPS OF Aut(F_4)

So far we have discussed the parabolic subgroups of Aut(F_4) related with the Lie subalgebras of F_4. As we have mentioned before the Aut(F_4) is the largest crystallographic group in four dimensions and deserves further analysis regarding its chain decomposition through its maximal subgroups which could be useful for the crystallography in four dimensions. First we discuss the maximal subgroups of Aut(F_4). We will give the group elements in terms of quaternions and distinguish the groups by their orders and conjugacy classes. The group orders and conjugacy classes are not sufficient to understand the group structures. Since we will write down the group elements explicitly in terms of quaternions the distinguishing the groups of the same order will not create a problem. Nevertheless we will denote a group of interest with its order together with its conjugacy classes in a parentheses and display the group elements in terms of quaternions. For example, the group Aut(F_4), being of order 2304 with 29 conjugacy classes will be shortly denoted by 2304(29) and its quaternionic representation will follow the group notation. We know that this is not a proper group notation; it should rather have a decomposition involving invariant subgroups. Since we denote each group by their elements the order with the conjugacy classes would be sufficient.

A. Maximal subgroups of Aut(F_4)

We have three maximal subgroups of Aut(F_4) of order 1152.

1. $W(F_4)$ of order 1152(25)

It is a subgroup of O(4). We have discussed this group in details which was represented by the quaternions in (14),

$$W(F_4)=[T,T]\oplus[T',T']\oplus[T,T]^*\oplus[T',T']^*.$$

Note that the group $W(F_4)$ is invariant under the transformation $T\leftrightarrow T'$.

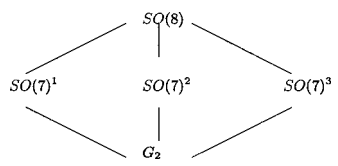

FIG. 7. Threefold embedding of SO(7) in SO(8).

2. The group 1152(19)

It is a subgroup of O(4) and its quaternionic structure can be written as follows:

$$[T,T] \oplus [T',T'] \oplus [T,T']^* \oplus [T',T]^*. \tag{34}$$

We know that the first two sets of elements form a subgroup of order 576. One can show that the set of elements in (30) is closed by noting that

$$[T,T']^*[T,T']^* = [T',T]^*[T',T]^* = [T,T], \quad [T,T']^*[T',T]^* = [T',T']. \tag{35}$$

It is clear that it is a maximal subgroup of $\mathrm{Aut}(F_4)$ and will be left invariant under the transformation $T \leftrightarrow T'$.

3. The group 1152(34)

This is the largest crystallographic group in four dimensions with proper rotations. That means it is a finite subgroup of SO(4). Naturally, it involves only nonstar elements of $\mathrm{Aut}(F_4)$

$$[T,T] \oplus [T',T'] \oplus [T,T'] \oplus [T',T]. \tag{36}$$

Its closure property is straightforward. Some of its subgroups of order 192 will be of our special interest for they appear as maximal subgroups in some of the finite subgroups of the Lie group G_2.[26] It is also invariant under the transformation $T \leftrightarrow T'$.

Now we discuss, in turn, the maximal subgroups classified under the subclasses A, B, C.

B. The maximal subgroups of $W(F_4)$

Its parabolic subgroups have been already discussed in Sec. IV. Besides those groups there are two maximal subgroups of order 576 with the conjugacy classes 20 and 23. The group 576(23) is the extension of the Weyl group $W(\mathrm{SO}(8))$ by a cyclic symmetry of the simple roots represented by imaginary quaternions. The group 576(20) is also a maximal subgroup of the groups 1152(19) and 1152(34).

1. The group 576(23)

It is the extension of the group $W(\mathrm{SO}(8))$ by a cyclic group of order 3 and its elements can be written as

$$[T,T] \oplus [T,T]^* \approx [T,T] \oplus [T',T']^*. \tag{37}$$

It can be shown that the group can be written as a semidirect product of the Weyl group of SO(8) and the cyclic group Z_3,

$$W(\mathrm{SO}(8)){:}Z_3,$$

where the cyclic symmetry permutes the outer simple roots of SO(8).

2. The group 576(20)

It has the structure

$$[T,T] \oplus [T',T']. \tag{38}$$

It is also a maximal subgroup in the crystallographic subgroup of SO(4) denoted by 1152(34) and the group 1152(19). No doubt that the elements in (38) closes under multiplication. We simply note the nontrivial case, namely,

$$[T',T']^2 = [T,T].$$

C. The maximal subgroups of the group 1152(19)

1. The group 576(20)

This group is just discussed in the above.

2. The group 192(17)

This group occurs also in the subgroup decomposition of the group 1152(34) and will be discussed in the following.

D. The maximal subgroups of the group 1152(34)

1. The group 576(29)

It has the structure

$$[T,T]\oplus[T,T']\approx[T,T]\oplus[T',T]. \tag{39}$$

Since the group 576(29) is an index 2 group in the group 1152(34) it should have two conjugates subgroups which is reflected in the isomorphism above.

2. The group 384(31)

We have the following structure of the group:

$$[V_0,T]\oplus[V_1,T]\oplus[V_0,T']\oplus[V_1,T']. \tag{40}$$

This is certainly a maximal subgroup of the group 1152(34) because $V_0\oplus V_1$ form a maximal subgroup of order 16 in the binary octahedral group $T\oplus T'$. It can be embedded in the group 1152(34) triply symmetric way by replacing V_1 by V_2 and V_3 in (40) in a similar manner where $W(\mathrm{SO}(9))$ is embedded in $W(F_4)$.

3. The group 288(24)

When we examine the parent group $[O,O]$ we know that the binary octahedral group O has many maximal subgroups, one of which is the dicyclic group (binary dihedral group) of order 12. It can be generated by two elements $a=\frac{1}{2}(1-e_1-e_2-e_3)$ and $b=(1/\sqrt{2})(e_1-e_2)$ where $a^6=b^4=1$ satisfying the generation relation $ba^n\bar{b}=\bar{a}^n(n=1,\ldots,6)$. The group can be denoted by $2D_3$ where D_3 is the dihedral group of order 6. When $2D_3$ acts on the left and the binary octahedral group acts on the right we obtain the group 288(24) which reads in our notation

$$[2D_3,O]. \tag{41}$$

We can further continue to determine the maximal subgroups of the groups discussed in the series A, B, and C.

4. The maximal subgroups of $W(\mathrm{SO}(8)):Z_3$

A1.1. The group 288(25):This is the group $[T,T]$ occurring in many groups discussed above.

A1.2. The group $192(13)\approx W(\mathrm{SO}(8))$: It has been discussed before and shown to be the Weyl group of SO(8)

$$[V_0,V_0]\oplus[V_+,V_+]\oplus[V_-,V_-]\oplus[V_0,V_0]^*\oplus[V_+,V_+]^*\oplus[V_-,V_-]^* \tag{42}$$

which is invariant under the cyclic symmetry Z_3. The action of the group elements on the hyperoctahedra V_0, V_+, V_- are as follows:

(i) $[V_0,V_0]$ leaves each hyperoctahedra invariant.
(ii) $[V_+,V_+]$ permutes the three octahedra in the cycylic order and $[V_-,V_-]$ does the same in the reverse order.

(iii) The element $[V_i,V_i]^*(i=0,+,-)$ leaves the hyperoctahedron V_i invariant but interchanges the other two. These properties indicate that the $[V_0,V_0]$ form an invariant subgroup where the factor group is the symmetric group of order 6,

$$\frac{W(\mathrm{SO}(8))}{[V_0,V_0]} \approx S_3.$$

The group 192(16): It can be represented in three equivalent ways and can be proven that they are the conjugate groups

(i) $[V_0,V_0]\oplus[V_+,V_-]\oplus[V_-,V_+]\oplus[V_0,V_0]^*\oplus[V_+,V_-]^*\oplus[V_-,V_+]^*$,
(ii) $[V_0,V_0]\oplus[V_+,V_-]\oplus[V_-,V_+]\oplus[V_+,V_+]^*\oplus[V_-,V_0]^*\oplus[V_0,V_-]^*$,
(iii) $[V_0,V_0]\oplus[V_+,V_-]\oplus[V_-,V_+]\oplus[V_-,V_-]^*\oplus[V_+,V_0]^*\oplus[V_0,V_+]^*$.

Interestingly enough that each of these conjugate groups leaves one of the hyperoctahedra invariant. One can easily show that the groups in (i), (ii), and (iii) leave V_0, V_+, and V_- invariant, respectively. Embedding of the group 192(16) in the group $W(\mathrm{SO}(8)):Z_3$ follows the cyclic symmetry of quaternionic units e_1,e_2,e_3.

5. The maximal subgroups of the group 576(20)

B1.1. The group 288(25): It has been discussed in Sec. Vd4a.

B1.2. The group 288(24): This group was discussed in Sec. Vd3a.

B1.3. The group 192′(13): It has the same order and the same number of conjugacy classes with $W(\mathrm{SO}(8))$ but not isomorphic to it. It has the structure

$$[V_0,V_0]\oplus[V_+,V_+]\oplus[V_-,V_-]\oplus[V_1,V_1]\oplus[V_2,V_3]\oplus[V_3,V_2]. \tag{43}$$

An important difference is that $W(\mathrm{SO}(8))$ is a subgroup of O(4) whereas this group is a subgroup of SO(4). The group 192′(13) has an index 6 in the group 1152(34). Its conjugate groups can be obtained by the conjugation of the element $[V_+,V_1]$ which permutes the six hyperoctahedra in the cyclic order $V_0\to V_3\to V_-\to V_1\to V_+\to V_2\to V_0$. This would yield the six conjugate representations of (43). This group turns out to be a maximal subgroup of the finite subgroup of G_2 of order 1344 preserving the octonion algebra of the set $\pm e_i(i=1,2,\ldots,7)$.[26]

6. Maximal subgroups of the group 576(29)

All its maximal subgroups which have not been discussed so far also occur as the maximal subgroups of the group 384(31) and will be discussed below.

7. Maximal subgroups of the group 384(31)

C2.1. The group 192(26): It has the structure

$$[V_0,T]\oplus[V_1,T]. \tag{44}$$

*C2.2. The group 192(23)*It can be represented by

$$[V_0,T]\oplus[V_0,T']. \tag{45}$$

C2.3. The group 192(20): This group has an interesting structure which can be written as

$$[a,T]\oplus[b,T'], \tag{46}$$

where the set of elements of a is generated by $(1/\sqrt{2})(1+e_1)$ and the set $b=e_3a$. The set $[a,T]$ forms an invariant subgroup of order 96. The set of elements a and b generate a dicyclic group of order 16 as we discussed before, however, as a and b are paired with different subsets of the binary octahedral group the dicyclic group is not a subgroup of the group 192(20). The set of elements of a and b are given by

$$a=\left\{\pm 1,\pm e_1,\frac{1}{\sqrt{2}}(\pm 1\pm e_1)\right\},\quad b=\left\{\pm e_2,\pm e_3,\frac{1}{\sqrt{2}}(\pm e_2\pm e_3)\right\}. \tag{47}$$

C2.4. The group 192(17): It can be represented by

$$[V_0,T]\oplus[V_1,T'] \tag{48}$$

which is also a subgroup of the group 576(20). It is one of the maximal subgroup of the finite subgroup of the Lie group of G_2 order 12096 which leaves the quaternion decomposition of the octonionic root system of the exceptional Lie algebra E_7 (Ref. 26) invariant.

VI. CONCLUSION

The automorphism group $\mathrm{Aut}(F_4)$ of the root system of the exceptional Lie algebra F_4 is the largest crystallographic group in four-dimensions which has not been discussed in the literature using quaternions. This work not only relates this crystallographic group to the Coxeter-Dynkin diagram of F_4 but also discusses its relevance to other Lie algebraic structures as well as to the four-dimensional Euclidean geometry. We have discussed the decomposition of $\mathrm{Aut}(F_4)$ down to the groups of order 192 and shown that a number of groups of order 192 have different structures related to different geometries. It is perhaps also interesting to continue the same decomposition to determine the groups acting in three-dimensions. In this context we have discussed only the Weyl groups $W(S(7))\approx W(\mathrm{SP}(3))$.

We have noted that two groups of order 192, namely, the groups $192'(13)$ and 192(17), occur as maximal subgroups in the finite subgroups of the Lie group G_2. The group $192'(13)$ is a maximal subgroup of a group $Z_2^3\cdot PSL_2(7)$ of order 1344 which is a finite subgroup of G_2 preserving the set of imaginary octonions $\pm e_i(i,1,2,\ldots,7)$.[16] Here $PSL_2(7)$ is the famous Klein's simple group of order 168 and $Z_2^3=Z_2\times Z_2\times Z_2$ is the elementary Abelian group of order 8. The group 192(17) is the maximal subgroup of the Chevalley group $G_2(2)$ of order 12096 which leaves the octonionic roots of the Lie algebra E_7 invariant.

The Weyl group $W(\mathrm{SO}(8))$ which is the group 192(13) is also a maximal subgroup of a group $Z_2^3{:}PSL_2(7)$ of order 1344 which is, in turn, a maximal subgroup of the simple group A_8, even permutations of eight letters. The group A_8 is related to the Weyl group $W(E_7)$ through $W(\mathrm{SU}(8))$ and is a maximal subgroup of the Chevalley group $\mathrm{SO}_7(2)$.[27] It is also interesting to note that some finite subgroups of SO(4) also occur in the phase transitions of the liquid helium ^{3}He.[28]

We believe that the group structures and their quaternionic representations will be useful in various fields of physics which may need the finite subgroups of O(4).[29,30]

JOURNAL OF MATHEMATICAL PHYSICS **47**, 043508 (2006)

BRST quantization of quasisymplectic manifolds and beyond

S. L. Lyakhovich[a] and A. A. Sharapov[b]
Department of Theoretical Physics, Physics Faculty, Tomsk State University, Lenin Av. 36, 634050 Tomsk, Russia

(Received 23 September 2005; accepted 6 March 2006; published online 24 April 2006)

We consider a class of *factorizable* Poisson brackets which includes almost all reasonable Poisson structures. A particular case of the factorizable brackets are those associated with symplectic Lie algebroids. The BRST theory is applied to describe the geometry underlying these brackets as well as to develop a deformation quantization procedure in this particular case. This can be viewed as an extension of the Fedosov deformation quantization to a wide class of *irregular* Poisson structures. In a more general case, the factorizable Poisson brackets are shown to be closely connected with the notion of n-algebroid. A simple description is suggested for the geometry underlying the factorizable Poisson brackets based on construction of an odd Poisson algebra bundle equipped with an Abelian connection. It is shown that the zero-curvature condition for this connection generates all the structure relations for the n-algebroid as well as a generalization of the Yang-Baxter equation for the symplectic structure. © *2006 American Institute of Physics.*

I. INTRODUCTION

The deformation quantization of a Poisson manifold $(M,\{\cdot,\cdot\})$ is the construction of a local one-parameter deformation of the commutative algebra of functions $C^\infty(M)$ respecting associativity.[1,2] The deformed product is usually denoted by $*$, and the deformation parameter is the Plank constant $\hbar$. In each order in $\hbar$ the $*$-product is given by a bidifferential operator (locality) and the skew-symmetric part of the first $\hbar$ order coincides with the Poisson bracket of functions (correspondence principle).

Very early it appeared that the complexity of the deformation quantization program essentially depends on whether a given Poisson manifold is regular or not. In the regular case, i.e., where the rank of the Poisson tensor is constant, one can introduce an affine symmetric connection respecting the Poisson structure (a Poisson connection). Clearly, in the irregular case such a connection cannot exist. The relevance of the Poisson connection for constructing $*$-products had been already discussed in Ref. 2, but in its full strength, the connection was first exploited by Fedosov in his seminal paper[3] on the deformation quantization of symplectic and regular Poisson manifolds (see also Ref. 4).

The existence of deformation quantization for general Poisson manifolds, not necessarily regular, was proved by Kontsevich[5] as a consequence of his Formality Theorem. An explicitly covariant version of the Kontsevich quantization has been given in Ref. 6 (see also Ref. 7, where both covariant and equivariant versions of the formality theorem have been presented). It should be noted that the Kontsevich quantization is based on completely different ideas and involves a

[a]Electronic mail: sll@phys.tsu.ru
[b]Electronic mail: sharapov@phys.tsu.ru

more complicated algebraic technique as compared to the Fedosov quantization. A nice "physical explanation" of the Kontsevich quantization formula was given in Ref. 8 by applying the BV quantization method[9] to the Poisson sigma model.

Recently, it was recognized that the method of Fedosov's quantization can further be extended to include a certain class of irregular Poisson manifolds even though no Poisson connection can exist in this case. To give an idea about the manifolds in question let us write the following expression describing the general structure of the corresponding Poisson brackets:

$$\{f,g\} = \omega^{ab}(X_a^\mu \partial_\mu f)(X_b^\nu \partial_\nu g), \quad \det(\omega^{ab}) \neq 0. \tag{1.1}$$

The matrices X and ω are subject to certain conditions ensuring the Jacobi identity. The geometric meaning of these conditions as well as the precise mathematical status of X and ω will be explained in the next section. Here we would like to mention that, no *a priori* assumption is made about the rank of the matrix X, so the Poisson brackets (1.1) may well be irregular.

In the case where the matrix X is the anchor of a Lie algebroid the manifolds under consideration are something intermediate between symplectic and general Poisson manifolds. For this reason, we refer to them as *quasisymplectic* Poisson manifolds (not to be confused with the quasi-Poisson manifolds introduced in Ref. 10). Being closely related with the notion of a dynamical r-matrix, these manifolds may be of immediate interest in the theory of integrable systems.

The generalization of the Fedosov deformation quantization to the case of symplectic Lie algebroids was first given by Nest and Tsygan.[11] They also proved corresponding classification theorems. Fedosov's quantization method was also described in the work[12] for the same class of manifolds in the language of symplectic ringed spaces. Particular classes of quasisymplectic manifolds have been quantized in Refs. 13–15 making use of various ideas, including BRST theory.

The aim of this work is twofold. In the first part of the paper we put the deformation quantization of quasisymplectic manifolds in the framework of BFV-BRST theory.[16–18] For the (constrained) Hamiltonian systems on symplectic manifolds, the relationship has been already established between the BFV-BRST and the Fedosov quantizations.[19,20] Here we reshape this technology to make it work in a more general case of quasisymplectic manifolds. The second part of the paper is devoted to a possible generalization of the notion of a quasisymplectic manifold to the case of n algebroids or, in other terminology, NQ manifolds.[21–24] This generalization essentially relaxes the restrictions on the structure functions X and ω, entering factorization (1.1), and covers almost all reasonable Poisson structures.

The paper is organized as follows. In Sec. II we give the definition of a quasisymplectic Poisson manifold and discuss some examples. Here we also construct a simple counterexample to existence of a quasisymplectic representation for any Poisson bracket. Section III deals with realization of quasisymplectic manifolds as coisotropic surfaces in the total space of vector bundles associated with symplectic Lie algebroids. In Sec. IV this realization is exploited to perform the BRST quantization of the resulting gauge system. We prove that the quantum multiplication in the algebra of physical observables induces an associative $*$-product on the initial quasisymplectic manifold. In Sec. V we generalize the notion of a quasisymplectic manifold to a wider class of factorizable Poisson brackets. Under reasonable restrictions this class of Poisson structures is proved to be closely connected with n algebroids. Using the 2-algebroid as an example, we show how the geometry underlying factorizable Poisson brackets can be described in terms of a supervector bundle equipped with a fiberwise odd Poisson structure and a compatible Abelian connection.

II. QUASISYMPLECTIC MANIFOLDS: DEFINITION AND EXAMPLES

The most concise and geometrically transparent way to define the quasisymplectic manifolds is to use the notion of a *Lie algebroid*.[25]

Definition: A Lie algebroid over a manifold M is a (real) vector bundle $\mathcal{E}\to M$ equipped with the following additional structures:

(1) There is a (real) Lie algebra structure on the linear space of sections $\Gamma(\mathcal{E})$.
(2) There is a bundle map $\rho:\mathcal{E}\to TM$ such that the Lie algebra and $C^\infty(M)$-module structures on $\Gamma(\mathcal{E})$ are compatible in the following sense:

$$[s_1,fs_2]=f[s_1,s_2]+(\rho_*(s_1)f)s_2,\quad \forall\, f\in C^\infty(M),\quad \forall\, s_1,s_2\in\Gamma(\mathcal{E}). \tag{2.1}$$

The map ρ is called the *anchor* of the Lie algebroid $\mathcal{E}\to M$.

The last relation can be viewed as the Leibniz rule for the Lie algebroid bracket. Using this relation and the Jacobi identity for the bracket it is not hard to see that the anchor map $\rho:\mathcal{E}\to TM$ defines a Lie algebra homomorphism on sections, i.e.,

$$\rho_*([s_1,s_2])=[\rho_*(s_1),\rho_*(s_2)],\quad \forall\, s_1,s_2\in\Gamma(\mathcal{E}), \tag{2.2}$$

where the brackets on the right-hand side (rhs) stand for the commutator of vector fields.

It is instructive to look at the local coordinate expression of the above relations. Let x^μ be a coordinate system on a trivializing chart $\mathcal{U}\subset M$ and let s_a be a frame of $\mathcal{E}|_{\mathcal{U}}$. By definition, we have

$$\begin{gathered}[s_a,s_b]=f_{ab}^c(x)s_c,\quad \rho_*(s_a)=X_a^\mu(x)\partial_\mu,\\ \mu=1,\ldots,\dim M,\quad a=1,\ldots,\operatorname{rank}\mathcal{E}.\end{gathered} \tag{2.3}$$

In view of Relations (2.2) and (2.1) the structure functions f_{ab}^c, $X_a^\mu\in C^\infty(U)$ meet the following conditions:

$$[X_a,X_b]^\nu:=X_a^\mu\partial_\mu X_b^\nu-X_b^\mu\partial_\mu X_a^\nu=f_{ab}^cX_c^\nu, \tag{2.4}$$

$$f_{ab}^df_{dc}^e-X_c^\mu\partial_\mu f_{ab}^e+\operatorname{cycle}(a,b,c)=0. \tag{2.5}$$

Notice that the second relation is automatically satisfied for any vector bundle $\mathcal{E}$ of rank 1 or 2, whereas in the case of rank $\mathcal{E}>2$ it becomes an actual restriction on the structure functions f_{ab}^c.

In general, $\rho(\mathcal{E})$ is not a smooth subbundle of TM as the rank of the distribution $\rho(\mathcal{E})$ may vary from point to point. Nonetheless, in view of (2.2), $\rho(\mathcal{E})$ generates a (singular) integrable distribution in the sense of Sussman:[26] for each $p\in M$ there is a smooth submanifold $\Sigma_p\subset M$ such that $p\in\Sigma_p$ and $T_q\Sigma_p=\rho(\mathcal{E}_q)$ for any $q\in\Sigma_p$. The corresponding foliation will be denoted by $F(M)$.

Example: Any tangent bundle TM may be viewed as a Lie algebroid with the Lie bracket given by the commutator of vector fields and the anchor $\rho=\mathrm{id}:TM\to TM$.

A. Differential geometry of Lie algebroids

One can regard the concept of a Lie algebroid as a tool for transferring all the usual differential-geometric constructions from a tangent bundle to an abstract vector bundle. In particular, it is possible to define the Lie-algebroid counterpart of the exterior calculus. Denote by $\Lambda(\mathcal{E})=\oplus\Lambda^p(\mathcal{E})$ the exterior algebra of sections $\Gamma(\wedge^\bullet\mathcal{E}^*)$, $\mathcal{E}^*$ being the bundle dual to $\mathcal{E}$. Consider the following nilpotent operator $d:\Lambda^p(\mathcal{E})\to\Lambda^{p+1}(\mathcal{E})$:

$$\mathrm{d}\alpha(s_0,\ldots,s_p)=\sum_{k=0}^{p}(-1)^k\rho_*(s_k)(\alpha(s_0,\ldots,\hat{s}_k,\ldots,s_p))$$
$$+\sum_{k<n=1}^{p}(-1)^{k+n}\alpha([s_k,s_n],s_0,\ldots,\hat{s}_k,\ldots,\hat{s}_n,\ldots,s_p), \tag{2.6}$$

for all $s_0,s_1,\ldots,s_p\in\Gamma(\mathcal{E})$. Since $d^2=0$, we have a generalization of the De Rham complex. We will refer to elements of $\Lambda^p(\mathcal{E})$ as $\mathcal{E}$-p-forms, or just p-forms when it cannot lead to confusion. Note that $\Lambda^0(\mathcal{E})$ is naturally identified with $C^\infty(M)$.

More generally, one may consider the tensor product $\mathcal{E}\otimes V$, where $V\to M$ is a vector bundle with connection ∇. Then, ∇ induces the covariant derivative $\nabla_\rho:\Lambda^p(\mathcal{E},V)\to\Lambda^{p+1}(\mathcal{E},V)$ on the space $\Lambda(M,\mathcal{E})=\Lambda(\mathcal{E})\otimes\Gamma(V)$ of $\Gamma(V)$-valued $\mathcal{E}$ forms,

$$\nabla_\rho\omega(s_0,\ldots,s_p)=\sum_{k=0}^{p}(-1)^k\nabla_{\rho_*(s_k)}(\omega(s_0,\ldots,\hat{s}_k,\ldots,s_p))$$
$$+\sum_{k<n=1}^{p}(-1)^{k+n}\alpha([s_k,s_n],s_0,\ldots,\hat{s}_k,\ldots,\hat{s}_n,\ldots,s_p). \tag{2.7}$$

The curvature of ∇_ρ is defined in the usual way,

$$R=\nabla_p^2:\Gamma(V)\to\Lambda^2(\mathcal{E},V). \tag{2.8}$$

One may verify that

$$R(fu)=fRu,\quad \forall f\in C^\infty(M),\quad \forall u\in\mathcal{E}, \tag{2.9}$$

so that in each coordinate chart the curvature R is given by a matrix-valued 2-form determining a $C^\infty(M)$-linear automorphism of $\Gamma(V)$. Like the curvature of the bundle connection ∇, R satisfies the *Bianchi identity*,

$$[\nabla_\rho,\nabla_\rho^2]=0\Leftrightarrow\nabla_\rho R=0. \tag{2.10}$$

(To write the last formula we extend the action of ∇ from V to the tensor product $V\otimes V^*$ by the usual formulas of differential geometry.)

In what follows we will mostly deal with the case $V=\mathcal{E}$. Then, in addition to the curvature, one more covariant of the connection can be introduced. The *torsion* T of a Lie algebroid connection ∇_ρ is an element of $\Lambda^2(\mathcal{E},\mathcal{E})$ defined by the rule

$$\Gamma(\mathcal{E})\ni T(u,v)=\nabla_{\rho_*(u)}v-\nabla_{\rho_*(v)}u-[u,v],\quad \forall u,v\in\Gamma(\mathcal{E}). \tag{2.11}$$

If $\Gamma^a_{\mu b}$ are coefficients of the connection ∇ with respect to local coordinates x^μ and a frame s_a, then the components of the torsion tensor read

$$T^c_{ab}=X^\mu_a\Gamma^c_{\mu b}-X^\mu_b\Gamma^c_{\mu a}-f^c_{ab}. \tag{2.12}$$

The components of the curvature tensor R are

$$R^d_{abc}=X^\mu_aX^\nu_bR^d_{\mu\nu c}, \tag{2.13}$$

where

$$R^d_{\mu\nu c}=\partial_\mu\Gamma^d_{\nu c}-\partial_\nu\Gamma^d_{\mu c}+\Gamma^d_{\mu a}\Gamma^a_{\nu c}-\Gamma^d_{\nu a}\Gamma^a_{\mu c} \tag{2.14}$$

is the curvature of ∇. There is a simple formula relating the exterior and covariant derivatives:

$$\mathrm{d}\alpha(s_0,\ldots,s_p)=\sum_{k=0}^{p}(-1)^k(\nabla_{\rho_*(s_k)}\alpha)(s_0,\ldots,\hat{s}_k,\ldots,s_p)$$
$$+\sum_{k<n=1}^{p}(-1)^{k+n}\alpha(T(s_k,s_n),s_0,\ldots,\hat{s}_k,\ldots,\hat{s}_n,\ldots,s_p); \tag{2.15}$$

here we use the isomorphism $\Lambda^p(\mathcal{E})\simeq\Lambda^0(\mathcal{E},\wedge^p\mathcal{E})$. A straightforward computation yields the *torsion Bianchi identity*

$$\nabla_c T^d_{ab}+R^d_{abc}+\mathrm{cycle}(a,b,c)=0, \tag{2.16}$$

where $\nabla_a:=\nabla_{\rho^*(s_a)}$.

In this paper we are interested in the Lie algebroids endowed with a closed and nondegenerate 2-form $\omega\in\Lambda^2(\mathcal{E})$. A 2-form ω is called nondegenerate if the equality

$$\omega(u,v)=0,\quad \forall\, u\in\Gamma(\mathcal{E}), \tag{2.17}$$

implies $v=0$. In terms of local coordinates the closedness condition $\mathrm{d}\omega=0$ reads

$$X^\mu_c\partial_\mu\omega_{ab}+\omega_{cd}f^d_{ab}+\mathrm{cycle}(a,b,c)=0, \tag{2.18}$$

where $\omega_{ab}:=\omega(s_a,s_b)$. Extending the analogy with classical differential geometry, we refer to ω as the *symplectic form* and call the triple $(\mathcal{E},\rho,\omega)$ the *symplectic Lie algebroid*. (This is a particular example of *triangular Lie bialgebroids* studied in Ref. 27.)

B. Quasisymplectic manifolds

It is well known that any symplectic structure on a Lie algebroid $\mathcal{E}\to M$ gives rise to a Poisson structure on the base manifold M. It is this Poisson structure we are going to quantize by the BFV-BRST method.

Proposition 2.1: Let $(\mathcal{E},\rho,\omega)$ be a symplectic Lie algebroid, then M is a Poisson manifold with respect to the following Poisson bracket:

$$\{f,g\}=\omega^{-1}(\mathrm{d}f,\mathrm{d}g),\quad \forall\, f,g\in C^\infty(M)\simeq\Lambda^0(\mathcal{E}); \tag{2.19}$$

here ω^{-1} is the bisection inverse to the symplectic form $\omega\in\Lambda^2(\mathcal{E})$ and $\mathrm{d}f$, $\mathrm{d}g\in\Lambda^1(\mathcal{E})$ are the differentials defined by (2.6).

Proof: In terms of local coordinates the Poisson bivector determining the bracket (2.19) has the form

$$\alpha=\omega^{ab}c_a\wedge X_b\in\wedge^2 TM,\quad \{f,g\}=\alpha^{\mu\nu}\partial_\mu f\partial_\nu g, \tag{2.20}$$

where $X_a:=X^\mu_a\partial_\mu$, $\omega^{ac}\omega_{cb}=\delta^a_b$, and $\alpha^{\mu\nu}=\omega^{ab}X^\mu_aX^\nu_b$. The Jacobi identity for α follows immediately from the Lie algebroid relations (2.4) and the closedness condition (2.18). Indeed, using the Leibniz rule for the Schouten bracket of α with itself, we get

$$\tfrac{1}{4}[\alpha,\alpha]=\omega^{ab}\omega^{cd}X_a\wedge[X_b,X_c]\wedge X_d+\omega^{ab}[X_b,\omega^{cd}]X_a\wedge X_c\wedge X_d$$
$$=(\omega^{am}f^b_{mn}\omega^{nc}+\omega^{am}X^u_m\partial_\mu\omega^{bc})X_a\wedge X_b\wedge X_c=(\mathrm{d}\omega)_{abc}X^a\wedge X^b\wedge X^c=0. \tag{2.21}$$

The indices are lowered and raised with the help of the symplectic form ω and its inverse.

Since the rank of the anchor distribution may vary through M, the induced Poisson structure (2.20) is irregular in general (though it involves a nondegenerate bivector $\omega^{-1}\in\wedge^2\mathcal{E}$). For this reason and following the terminology of Ref. 12 we refer to (M,α) as the *quasisymplectic manifold*. Accordingly, relation (2.19) is said to define a *quasisymplectic representation* for the Poisson bivector α.

Given a symplectic Lie algebroid, we have two (singular) foliations on M: the anchor foliation $F(M)$ and the symplectic foliation $S(M)$ associated with the induced Poisson structure (2.20). Clearly, the latter foliation is subordinated to the former one in the sense that any symplectic leaf belongs to a leaf of the anchor foliation.

Remark: A natural question to ask is as follows: Given a Poisson bivector (2.20), where ω_{ab} is some nondegenerate 2-form and X_a is an integrable distribution, are these data sufficient to define a symplectic Lie algebroid? In general, the answer is negative, since we do not require the local vector fields X_a to be linearly independent. Nonetheless, if X's are linearly independent on an everywhere dense domain in M, the answer is positive. In that case the structure equations (2.5) and (2.18) follow immediately from the Jacobi identities for the Schouten commutators of the local vector fields (2.4) and the Poisson bivector (2.20). We will discuss this question in more detail in Sec. V.

C. Symplectic connection and curvature

The deformation quantization of quasisymplectic Poisson manifolds to be developed in the next sections involves one more geometric ingredient, a *symplectic connection*. This is defined as a torsion-free Lie-algebroid connection respecting a symplectic 2-form, i.e.,

$$\nabla_\rho \omega = 0. \tag{2.22}$$

Here we consider ω as a section of $\Lambda^0(\mathcal{E}, \wedge^2\mathcal{E})$.

Proposition 2.2: Any symplectic Lie algebroid admits a symplectic connection.

Proof: We are looking for a symplectic connection of the form $\nabla + \Delta\Gamma$, where ∇ is an arbitrary connection and $\Delta\Gamma \in \Gamma(\mathcal{E}\otimes\mathcal{E}^*\otimes\mathcal{E}^*)$. In terms of local coordinates the compatibility condition (2.22) reads

$$\nabla_c \omega_{ab} = \Delta\Gamma_{cab} - \Delta\Gamma_{cba}, \tag{2.23}$$

where $\Delta\Gamma_{abc} = \Delta\Gamma^d_{ab}\omega_{dc}$. Obviously, these equations cannot have a unique solution: any tensor $\Delta\Gamma'_{abc}$, symmetric in bc, satisfies the homogeneous equation and therefore it can be added to a given solution $\Delta\Gamma_{abc}$ to produce another one. A particular solution to Eq. (2.23) is given by

$$\Delta\Gamma^c_{ab} = -\tfrac{1}{2}\omega^{cd}\nabla_a \omega_{db}. \tag{2.24}$$

Now let ∇_ρ be an arbitrary Lie-algebroid connection which respects ω and has torsion T. By making use of the aforementioned ambiguity, one can define the new connection $\nabla'_\rho = \nabla_\rho + \Delta\Gamma'$,

$$\Delta\Gamma'_{abc} = -\tfrac{1}{3}(T_{abc} + T_{acb}), \quad T_{abc} = T^d_{ab}\omega_{dc}, \tag{2.25}$$

which is also compatible with ω. By definition (2.12), we have

$$T'^c_{ab} = T^c_{ab} + \Delta\Gamma'^c_{ab} - \Delta\Gamma'^c_{ba}. \tag{2.26}$$

Substituting (2.25) into (2.26) and lowering the upper index with the help of ω we get

$$T'_{abc} = T_{acb} + \mathrm{cycle}(a,b,c) = 0. \tag{2.27}$$

The last equality follows immediately from (2.15) with ω in place of α. Thus, ∇'_ρ is a symplectic connection.

Let R^d_{abc} be the curvature of a symplectic connection. By analogy with Riemannian geometry we can define the *covariant curvature tensor* just lowering upper index with the help of the symplectic 2-form, $R_{abcd} = R^n_{abc}\omega_{nd}$. The following symmetry properties take place:

$$R_{abcd} = -R_{bacd}, \quad R_{abcd} = R_{abdc}, \quad R_{abcd} + R_{bcad} + R_{cabd} = 0. \tag{2.28}$$

The first equality is obvious, the second one follows from the definition (2.8) and the fact that ∇_ρ respects ω, the third equality is just the Bianchi identity (2.16).

D. Examples

Let us give some examples of symplectic Lie algebroids and the corresponding quasisymplectic Poisson brackets. More examples of Lie algebroids, with or without symplectic structure, can be found in Refs. 12 and 25.

Example 1: Any symplectic manifold (M,ω) gives rise to the symplectic Lie algebroid $(TM,$ id, $\omega)$. The quasisymplectic Poisson structure is given by

$$\alpha = (\omega^{-1})^{\mu\nu}\partial_\mu \wedge \partial_\nu. \tag{2.29}$$

To get a less trivial quasisymplectic representation for α consider an almost complex structure J compatible with ω. Recall that an almost complex structure is a smooth field of automorphisms $J:TM\to TM$ obeying conditions

$$J^2 = -\,\mathrm{id}, \quad \omega(JX,JY) = \omega(X,Y), \tag{2.30}$$

where X,Y are arbitrary vector fields. J being nondegenerate, we get a quasisymplectic representation for the Poisson bivector α associated with the symplectic Lie algebroid (TM,J,ω),

$$\alpha = (\omega^{-1})^{\mu\nu}J_\mu \wedge J_\nu. \tag{2.31}$$

Here $J=\mathrm{d}x^\mu J^\nu_\mu \partial_\nu$ and $J_\mu = J^\nu_\mu \partial_\nu$.

Example 2: Generalizing the previous example, consider a pair of Schouten-commuting bivectors β and ω, where the former is a Poisson one and the latter is nondegenerate. The triple (T^*M,β,ω) defines a symplectic Lie algebroid with the structure functions

$$[\beta(\mathrm{d}x^\mu),\beta(\mathrm{d}x^\nu)] = \partial_\lambda \beta^{\mu\nu}\beta(\mathrm{d}x^\lambda), \quad \beta(\mathrm{d}x^\mu) = \beta^{\mu\nu}\partial_\nu.$$

The induced Poisson structure on M is given by

$$\alpha = (\omega^{-1})_{\mu\nu}\beta^{\mu\gamma}\beta^{\nu\lambda}\partial_\gamma \wedge \partial_\lambda. \tag{2.32}$$

Example 3: Recall that a Lie algebra L is called *quasi-Frobenius*[28] if it admits a nondegenerate central extension L_c of the form

$$[p_a,p_b] = f^d_{ab}p_d + \omega_{ab}c, \quad [c,p_a] = 0, \quad \det(\omega_{ab}) \neq 0.$$

The Jacobi identity for L_c requires the nondegenerate matrix ω_{ab}, determining the central extension, to be a 2-cocycle of the Lie algebra $L \simeq L_c/c$.

Given an action $\rho: L\to \mathrm{Vect}(M)$ of the Lie algebra L on M by smooth vector fields $X_a = \rho(p_a)$, one can define a symplectic Lie algebroid associated with the trivial vector bundle $M \oplus L$, anchor ρ, and symplectic form ω_{ab}. The induced quasisymplectic structure on M reads

$$\alpha = \omega^{ab}X_a \wedge X_b, \quad \omega^{ac}\omega_{cd} = \delta^a_d. \tag{2.33}$$

A simple quantization procedure for such Poisson brackets has been proposed in Ref. 15.

Example 4: Let (M,α) be a two-dimensional Poisson manifold. We say that the bivector α is *quasihomogeneous* if there exist a volume form ω and a vector field Y such that the function $h = \omega(\alpha)$ obeys condition $Yh=h$.

It turns out that any quasihomogeneous Poisson manifold is also a quasisymplectic one. Namely, a simple computation yields

$$\alpha = X \wedge Y, \quad [X,Y] = (1 - \mathrm{div}_\omega Y)X. \tag{2.34}$$

Here X is the Hamiltonian vector field associated with the Hamiltonian h and the symplectic (volume) form ω. The structure equations (2.5) and (2.18) are automatically satisfied by the reason of dimension and we get a symplectic Lie algebroid associated with the trivial vector bundle $M \oplus \mathbb{R}^2$.

For instance, the following polynomial Poisson brackets on 2-plane,

$$\{x,y\} = x^m y^n + x^k y^l,$$
$$\delta = nk - lm \neq 0, \quad m,n,k,l \in \mathbb{N}, \tag{2.35}$$

are quasihomogeneous with respect to $\omega = \mathrm{d}x \wedge \mathrm{d}y$ and

$$Y = \delta^{-1}(n-l)x\partial_x + \delta^{-1}(k-m)y\partial_y,$$
$$X = (mx^{m-1}y^n + kx^{k-1}y^l)\partial_y - (nx^m y^{n-1} + lx^k y^{l-1})\partial_x. \tag{2.36}$$

In accordance with (2.34),

$$[Y,X] = (1 - \delta^{-1}(n+k-l-m))X, \tag{2.37}$$

and we arrive at the symplectic Lie algebroid associated with the two-dimensional quasi-Frobenius Lie algebra (2.37) (see the previous example).

E. Counterexample

As we have seen the quasisymplectic manifolds constitute a wide class of Poisson manifolds. Here is an example of a Poisson manifold that does not admit any quasisymplectic representation (even locally).

Proposition 2.3: The Lie-Poisson bracket on the dual of so(3) *algebra does not admit a quasisymplectic representation*.

Proof: The Poisson bracket in question is of the form

$$\{x^i,x^j\} = \sum_k \epsilon^{ijk}x^k, \tag{2.38}$$

where x^i are linear coordinates in $\mathbb{R}^3$ and ϵ^{ijk} is the Levi-Civita tensor. The only irregular point is $0 \in \mathbb{R}^3$, where the rank of the Poisson bracket is equal to zero; at the other points the rank equals 2. The leaves of the symplectic foliation $S(\mathbb{R}^3)$ are exactly the level sets of the Casimir function $(x^1)^2+(x^2)^2+(x^3)^2$, i.e., spheres centered at the origin.

Since any vector bundle $\mathcal{E}$ over $\mathbb{R}^3$ is trivial, we may look for an anchor being just an integrable vector distribution $X_a \in \mathrm{Vect}(\mathbb{R}^3)$. For the same reason, any symplectic 2-$\mathcal{E}$-form is given by an invertible skew-symmetric matrix $\omega_{ab}(x)$ on $\mathbb{R}^3$. Clearly, each sphere from $S(\mathbb{R}^3)$ is entirely contained in some leaf of the anchor foliation $F(\mathbb{R}^3)$; so, we write $S(\mathbb{R}^3) \subset F(\mathbb{R}^3)$. The existence of a quasisymplectic representation is expressed by the equality

$$X^i_a \omega^{ab} X^j_b = \sum_k \epsilon^{ijk}x^k. \tag{2.39}$$

The key to the analysis of this equation lies with the rank r of the vector distribution at the origin. *A priori*, r may take any value from 0 to 3. Let us show that any assumption about r leads to a contradiction.

The case $r=0$: This possibility is ruled out by comparing the order of zero on both sides of the equality (2.39). Indeed, since all X's must vanish at $x=0$, the order of zero on the left-hand side (lhs) is of at least 2, while the rhs tends to zero linearly.

The cases $r=1,2$: There is an integral leaf of dimension 1 or 2 passing through the origin and intersecting *transversally* at least one of the symplectic spheres. (Otherwise, this leaf would be entirely contained in one of the spheres, and thus, could not reach the origin.) But this contradicts to the inclusion $S(\mathbb{R}^3) \subset F(\mathbb{R}^3)$.

The case $r=3$: Passing, if necessary, to another basis we may assume that $X_a=(X_i,X_\alpha)$, where $X_i=\partial_i$ and $X_\alpha=0$. Then the matrix ω^{ab} takes the block form

$$\begin{pmatrix} \omega^{ij} & \omega^{i\beta} \\ \omega^{\alpha j} & \omega^{\alpha\beta} \end{pmatrix} \tag{2.40}$$

with $\omega^{ij}=\Sigma\epsilon^{ijk}x^k$. Among various equations on the matrix elements of (2.40), expressing the fact of closedness of ω, one can find the following one:

$$\omega^{\alpha k}\partial_k\omega^{ij}+\omega^{ik}\partial_k\omega^{j\alpha}-\omega^{jk}\partial_k\omega^{i\alpha}=0. \tag{2.41}$$

Since $\omega^{ij}(0)=0$ and $\partial_k\omega^{ij}(0)=\epsilon^{ijk}$, the last equation implies that $\omega^{\alpha i}(0)=0$, and hence the entire matrix (2.40) must degenerate at the origin. This contradiction concludes the proof.

III. POISSON DESCRIPTION OF SYMPLECTIC LIE ALGEBROIDS

In order to construct as well as physically interpret the deformation quantization of quasisymplectic manifolds it is convenient to think of (M,α) as the phase space of some (gauge invariant) mechanical system with zero Hamiltonian. In what follows we will use the standard terminology from the theory of constrained systems: first and second class constraints, gauge-fixing conditions, ghost variables, BRST charge, etc.[18] It should be noted that unlike the common practice we will consider Hamiltonian constraints that are defined by a *section* of some vector bundle $\mathcal{E}\to M$ rather than scalar functions on M. To provide the covariance of the quantization with respect to the bundle automorphisms an appropriate linear connection is needed, and that requires some modification of the conventional BRST formalism.[16–18] In particular, it will be convenient to use noncanonical commutation relations for ghost variables. The details will be explained below.

Now let us outline the basic steps of our approach. The main idea is to quantize a quasisymplectic manifold M by means of its suitable embedding into a certain supermanifold endowed with "a more simple" Poisson structure. The construction of such an embedding involves a quite standard machinery of the Hamiltonian BRST theory;[17,18,29] it can be subdivided into three steps. First, using the Lie algebroid structure, we represent (M,α) as a second-class constrained system on the vector bundle $\mathcal{E}^*$ dual to the Lie algebroid $\mathcal{E}$. As the next step, the second-class constrained system on $\mathcal{E}^*$ is converted into an equivalent gauge system on the direct sum of vector bundles $\mathcal{N}=\mathcal{E}^*\oplus\mathcal{E}$. The equivalence just means that the Poisson algebra of physical observables on $\mathcal{N}$ is isomorphic to the Poisson algebra of smooth functions on (M,α). Finally, the classical gauge system is covariantly quantized by the BFV-BRST method. The key point is that the space of physical observables on $\mathcal{N}$, being identified with a certain BFV-BRST cohomology in ghost number zero, carries a simple Poisson structure which can easily be quantized. By construction, the associative product on the algebra of quantum observables on $\mathcal{N}$ induces a $*$-product on the original quasisymplectic manifold (M,α).

For the case of symplectic manifolds, including second-class constrained system, such a program was first implemented in Refs. 19 and 20 establishing detailed correspondence between the key ingredients of the BRST theory and the Fedosov deformation quantization.

A. Symplectic embedding

We start with the description of a sympletic embedding of (M,α) into the dual bundle of the corresponding Lie algebroid. It is well known that $\mathcal{E}^*$ carries a natural Poisson structure, which is dual to the Lie algebroid structure.[25,30] A proper modification of this Poisson structure in the presence of a symplectic 2-form is offered by the next proposition.

Proposition 3.1: Let $(\mathcal{E},\rho,\omega)$ be a symplectic Lie algebroid corresponding to a quasisymplectic manifold (M,α). Then $C^\infty(\mathcal{E}^*)$ can be equipped with the following Poisson brackets:

$$\{x^\mu,x^\nu\}=0,\quad \{p_a,x^\mu\}=X_a^\mu,\quad \{p_a,p_b\}=f_{ab}^c p_c+\omega_{ab}. \tag{3.1}$$

Here x^μ are local coordinates on M and p_a are linear coordinates on the fibers of $\mathcal{E}^*$. The Poisson manifold (M,α) is symplectically imbedded into $\mathcal{E}^*$ as zero section.

Remark: Although the definition of the brackets on $\mathcal{E}^*$ involves local coordinates, the Poisson structure (3.1) is actually coordinate independent, so the relationship between the Lie algebroid

structure on $\mathcal{E}$ and the Poisson bivector on $\mathcal{E}^*$ is intrinsic. The Jacobi identity for (3.1) generates the full set of the Lie algebroid axioms as well as the closedness condition for the symplectic structure.

In terms of local coordinates (x^μ, p_a) one may identify the base manifold M with those points of $\mathcal{E}^*$ for which

$$p_a = 0. \tag{3.2}$$

Since

$$\det(\{p_a, p_b\})\big|_{p=0} = \det(\omega_{ab}) \neq 0, \tag{3.3}$$

the canonical imbedding $M \hookrightarrow \mathcal{E}^*$ defined by (3.2) is symplectic, and the induced Poisson structure on M reads

$$\{f, g\} = \omega^{ab}(X_a^\mu \partial_\mu f)(X_b^\nu \partial_\nu g), \quad \forall f, g \in C^\infty(M). \tag{3.4}$$

From the physical viewpoint, this bracket can be thought of as the Dirac bracket associated with the second-class constraints (3.2), where f and g are taken to be p-independent functions on $\mathcal{E}^*$.

B. Classical conversion

Choosing a symplectic connection ∇_ρ, one can extend the Poisson structure (3.1) on $\mathcal{E}^*$ to that on the direct sum $\mathcal{N}=\mathcal{E}\otimes\mathcal{E}^*$. Namely, if y^a are linear coordinates on the fibers of $\mathcal{E}$, then the corresponding Poisson brackets read

$$\begin{gathered}\{x^\mu, x^\nu\} = 0, \quad \{p_a, x^\mu\} = X_a^\mu(x), \\ \{x^\mu, y^a\} = 0, \quad \{p_a, y^b\} = -\Gamma_{ac}^b(x) y^c, \\ \{y^a, y^b\} = \omega^{ab}(x), \quad \{p_a, p_b\} = \omega_{ab}(x) + f_{ab}^c(x) p_c - \tfrac{1}{2} R_{abcd}(x) y^c y^d.\end{gathered} \tag{3.5}$$

Here Γ_{ab}^c are the coefficients of the connection ∇_ρ and R_{abcd} is the corresponding curvature tensor.

The brackets (3.5) are well defined and meet the Jacobi identity. Verifying the Jacobi identity, one gets the compatibility condition (2.22), the definition of the curvature tensor (2.13), the Bianchi identity (2.10), and the axioms of a symplectic Lie algebroid.

Now we aim to replace the second-class constrained system (3.1) and (3.2) on $\mathcal{E}^*$ with an equivalent gauge system on the extended Poisson manifold $\mathcal{N}$. In the Hamiltonian formalism a reparametrization invariant gauge system is completely specified by a set of first class constraints $T_a=0$ defining some coisotropic submanifold $\Sigma \subset \mathcal{N}$ (a constraint surface). The quotient of Σ by the Hamiltonian action of T's is assumed to be isomorphic to the quasisymplectic manifold (M, α) and this is the sense in which the equivalence will be established between the original Poisson manifold and the effective gauge theory. In fact, for the purposes of deformation quantization it is sufficient to work with a *formal gauge system* on $\mathcal{N}$ in the sense that the first class constraints T_a are allowed to be given by formal power series in y's. It is required, however, that the canonical projection of the formal coisotropic submanifold Σ onto $\mathcal{E}^*$ to coincide with the well-defined constraint surface (3.2), i.e., with M. This allows one to assign a precise meaning to the Hamiltonian reduction by the formal first class constraints.

Thus, we are looking for a set of Hamiltonian constraints $T_a(x, p, y)$ obeying conditions

$$\{T_a, T_b\} = U_{ab}^c T_c, \quad T_a(x,p,y)\big|_{\mathcal{E}} = T_a(x,p,0) = p_a, \tag{3.6}$$

where $U_{ab}^c(x, p, y)$ are some structure functions. Geometrically, one can think of T's as a section of the vector bundle $\pi: \mathcal{E}\oplus\mathcal{E}^* \to \mathcal{E}$ over the base $\mathcal{E}$, with π being the canonical projection onto the first factor.

Proposition 3.2: The equations (3.6) have a solution of the form

$$T_a = p_a + \sum_{n=1}^{\infty} T_a^n, \quad T_a^n = t_{ab_1\cdots b_n}(x) y^{b_1}\cdots y^{b_n}, \tag{3.7}$$

where the coefficients $t_{ab_1\cdots b_n}(x)$ *do not depend on* p's.

Remark: In the physical literature, the passage from a given second-class constrained system to an equivalent first-class one is known as the *conversion procedure*; accordingly, y's are called *conversion variables*. In the local setting, i.e., for a sufficiently small domain in the extended phase space, the existence of the conversion is ensured by a fairly general theorem.[29] Moreover, passing, if necessary, to an equivalent basis of second class constraints, it is possible to have a solution with $U_{ab}^c = 0$ (Abelian conversion). Here, however, we concern with account of global geometry that requires to consider a non-Abelian conversion in general.

Proof: Substituting the expansion (3.7) into the involution relations (3.6) and extracting contribution to zero order in y's, we find

$$(f_{ab}^c - U_{ab}^c) p_c + t_{an}\omega^{nm} t_{bm} + \omega_{ab} = 0. \tag{3.8}$$

A particular solution to this equation is obvious

$$U_{ab}^c = f_{ab}^c, \quad t_{ab} = -\omega_{ab}. \tag{3.9}$$

Taking this solution, one gets the following chain of equations for higher orders in y's:

$$F_{ab}^s := \partial_{[a} T_{b]}^{s+1} - B_{ab}^s = 0, \quad s \geqslant 1, \tag{3.10}$$

where

$$B_{ab}^1 = (X_{[a}^i \partial_i \omega_{b]c} + \omega_{d[a}\Gamma^d_{b]c} + f_{ab}^d \omega_{dc}) y^c,$$

$$B_{ab}^2 = \{p_{[a}, T_{b]}^2\} + f_{ab}^c T_c^2 - \tfrac{1}{2} R_{abcd} y^c y^d, \tag{3.11}$$

$$B_{ab}^s = \{p_{[a}, T_{b]}^s\} + f_{ab}^c T_c^s + \sum_{n=2}^{s} \{T_a^n, T_b^{s+2-n}\}, \quad s \geqslant 3.$$

Hereinafter the square brackets denote antisymmetrization of indices and ∂_a is the partial derivative with respect to y^a. The form of the equations (3.10) suggests to interpret T_a^s as the components of 1-form $T^s = T_a^s \, \mathrm{d}y^a$ defined on the linear space of y's. Thus, we can write

$$F^s = \mathrm{d}T^{s+1} - B^s = 0, \quad s \geqslant 1, \tag{3.12}$$

where d is the usual exterior differential with respect to y's, and B^s is a given 2-form provided the 1-forms $T^1, \ldots, T^s$ have been already determined. According to the Poincaré lemma, Eqs. (3.12) are consistent iff the 2-forms B^s are closed. In this case, the general solution to (3.10) reads

$$T_a^{s+1} = \frac{1}{s+2} y^b B_{ba}^s + \partial_a C^s, \tag{3.13}$$

C^s being an arbitrary monomial of degree $s+2$. The closedness of B's is now proved by induction in s. Consider the identity

$$\{\bar{T}_a^s, \bar{T}_b^s\} - f_{ab}^d \bar{T}_d^s = \sum_{n=0}^{s-1} F_{ab}^n + B_{ab}^s + \cdots, \tag{3.14}$$

where $\bar{T}_a^s = p_a + \Sigma_{n=1}^s T_a^n$ and dots stand for the terms of order higher than s. Taking the Poisson bracket of this relation with $\bar{T}_c^s$ and using the Jacobi identity

$$\{\{\bar{T}^s_a,\bar{T}^s_b\},\bar{T}^s_c\}+\mathrm{cycle}(a,b,c)=0, \tag{3.15}$$

we can write

$$(f^d_{ab}\{\bar{T}^s_c,\bar{T}^s_d\}+\{\bar{T}_c,f^d_{ab}\}\bar{T}_d)\mathrm{d}y^a\wedge\mathrm{d}y^b\wedge\mathrm{d}y^c=\left(\sum_{n=0}^{s-1}\{F^n_{ab},\bar{T}^s_c\}-\{B^s_{ab},\bar{T}^s_c\}+\cdots\right)\mathrm{d}y^a\wedge\mathrm{d}y^b\wedge\mathrm{d}y^c. \tag{3.16}$$

With account of (3.5) and the Lie algebroid relations (2.5), the contribution to the $(s-1)$th order of the last equation is given by

$$\mathrm{d}B^s=\left(f^d_{ab}F^{s-1}_{dc}+\sum_{n=0}^{s-1}\{F^n_{ab},T^{s-n+2}_c\}\right)\mathrm{d}y^a\wedge\mathrm{d}y^b\wedge\mathrm{d}y^c. \tag{3.17}$$

But the rhs of this relation vanishes by the induction hypothesis. Thus, B^s is a closed 2-form and the recurrent formula (3.13) gives the general solution for T_a.

Notice that the ambiguity concerning the choice of arbitrary functions C^s, entering the general solution for T_a, can be removed by imposing the y-transversality condition

$$y^aT^s_a=0,\quad s\geqslant 1. \tag{3.18}$$

Then it follows from Eq. (3.13) that

$$y^a\partial_aC^s(x,y)=(s+2)C^s(x,y)=0\Rightarrow C^s(x,y)=0.$$

Remark: For the case of symplectic manifolds, the convergence of the series (3.7) in a tubular neighborhood of M was proved in Ref. 31 under assumptions of analyticity and compactness. It seems that the same arguments are applicable to any quasisymplectic manifold provided all the structure functions are real-analytical and M is compact.

Now to see the equivalence of the constructed gauge system on $\mathcal{N}$ to the original Hamiltonian system on M it suffices to note that equations $\chi^a:=y^a=0$ are well-defined gauge-fixing conditions for the first class constraints $T_a=0$. Indeed,

$$\det\left.\begin{pmatrix}\{T_a,T_c\} & \{T_a,\chi^d\}\\ \{\chi^b,T_c\} & \{\chi^b,\chi^d\}\end{pmatrix}\right|_{T=\chi=0}=\det\begin{pmatrix}0 & -\delta^d_a\\ \delta^b_c & \omega^{bd}\end{pmatrix}=1. \tag{3.19}$$

Therefore, the reduced Poisson manifold (physical phase space) is isomorphic to the constraint surface $T_a=\chi^b=0$. The last equations are obviously equivalent to $p_a=y^a=0$, i.e., defines the canonical projection $\varphi:\mathcal{N}\to M$. The explicit description of the resulting Poisson structure on M can be obtained by introducing the Dirac bracket for the second-class constraints (T_a,χ^b). Identifying the space of smooth functions on M with the subspace of p- and y-independent functions on $\mathcal{N}$, it is easy to see that $\varphi:\mathcal{N}\to M$ is a Poisson map relating the Dirac bracket $\{\cdot,\cdot\}_D$ on $\mathcal{N}$ with the initial quasisymplectic bracket on M, i.e.,

$$\varphi_*(\{f,g\}_D)=\{\varphi_*(f),\varphi_*(g)\}_M. \tag{3.20}$$

IV. QUANTIZATION

Having realized the quasisymplectic manifold (M,α) as a formal gauge system on $\mathcal{N}$ we are ready to perform its BRST quantization. As usual, this implies further enlargement of the phase space of the system by ghost variables, constructing a nilpotent BRST charge, and identifying physical observables with certain BRST cohomology classes.

A. Ghost variables and the classical BRST charge

With each first class constraint T_a we associate the pair of anticommuting (Grassman odd) ghost variables $(\mathcal{C}^a,\mathcal{P}_b)$ subject to the canonical Poisson bracket relations

$$\{\mathcal{C}^a,\mathcal{P}_b\}=\delta^a_b,\quad \{\mathcal{C}^a,\mathcal{C}^b\}=\{\mathcal{P}_a,\mathcal{P}_b\}=0. \tag{4.1}$$

It is quite natural to treat $\mathcal{C}^a$ and $\mathcal{P}_b$ as linear coordinates on the fibers of the vector bundles $\Pi\mathcal{E}$ and $\Pi\mathcal{E}^*$, respectively. Here by Π we denote the parity reversion operation: being applied to a vector bundle it transforms the bundle into the supervector bundle with the same base manifold and transition functions, and the fibers being the Grassman odd vector spaces. Thus, the phase space of our gauge system is extended to the direct sum of (super-)vector bundles $\mathcal{M}=\mathcal{N}\oplus\Pi\mathcal{N}$. This geometric interpretation places the ghosts on equal footing with the conversion variables y's and suggests the following extension of the Poisson structure from $\mathcal{N}$ to $\mathcal{M}$:

$$\{p_a,\mathcal{C}^b\}=-\Gamma^b_{ac}(x)\mathcal{C}^c,\quad \{p_a,\mathcal{P}_b\}=\Gamma^c_{ab}(x)\mathcal{P}_c. \tag{4.2}$$

The brackets of the ghosts with x^μ and y^a are equal to zero. To meet the Jacobi identity one must modify the Poisson brackets of p's by ghost terms as follows:

$$\{p_a,p_b\}=\omega_{ab}(x)+f^c_{ab}(x)p_c-\tfrac{1}{2}R_{abcd}(x)y^cy^d-R^d_{abc}(x)\mathcal{C}^c\mathcal{P}_d. \tag{4.3}$$

The other Poisson brackets (3.5) remain intact.

Remark: At this point we slightly deviate from the usual line of the BRST scheme, where the ghost variables are assumed to Poisson commute with functions on the original phase space ($\mathcal{N}$ in our case) and, in particular, with the first class constraints. In principle, it is possible to work with the canonical Poisson brackets for ghosts, setting the rhs of (4.2) to zero and omitting the last term in (4.3), but this leads to nonlinear transformations of p_a under bundle automorphisms (p's are mixed with the ghost bilinears $\mathcal{C}^a\mathcal{P}_b$). We refer to Ref. 19 for the details of this construction in the case where M is a symplectic manifold (2.29). As we will see below, these noncanonical Poisson brackets of ghosts can be naturally incorporated into the BRST quantization procedure making it explicitly covariant.

Let $\mathcal{F}(M)$ denote the super-Poisson algebra of functions on the supermanifold $\mathcal{M}$; the elements of $\mathcal{F}(\mathcal{M})$ are superfunctions of the form (in what follows we omit the prefix "super" whenever possible)

$$A(x,p,y,\mathcal{C},\mathcal{P})=\sum A^{b_1\cdots b_m}_{a_1\cdots a_k d_1\cdots d_n}(x)y^{a_1}\cdots y^{a_k}\mathcal{C}^{d_1}\cdots\mathcal{C}^{d_n}\mathcal{P}_{b_1}\cdots\mathcal{P}_{b_m}, \tag{4.4}$$

where $A^{b_1\cdots b_m}_{a_1\cdots a_k d_1\cdots d_n}(x)$ are $\mathcal{E}$ tensors. In addition to the usual $\mathbb{Z}_2$ grading, associated with the Grassman parity,

$$\epsilon(\mathcal{C}^a)=\epsilon(\mathcal{P}_b)=1,\quad \epsilon(x^i)=\epsilon(p_a)=\epsilon(y^b)=0\pmod 2, \tag{4.5}$$

the space $\mathcal{F}(\mathcal{M})$ is endowed with an additional $\mathbb{Z}$ grading by prescribing the following *ghost numbers* to the local coordinates:

$$\mathrm{gh}(\mathcal{C}^a)=1,\quad \mathrm{gh}(\mathcal{P}_a)=-1,\quad \mathrm{gh}(x^i)=\mathrm{gh}(p_a)=\mathrm{gh}(y^a)=0. \tag{4.6}$$

The ghost number just counts the difference between powers of $\mathcal{C}$'s and $\mathcal{P}$'s, entering homogeneous elements of $\mathcal{F}(\mathcal{M})$, and is additive with respect to the Poisson algebra operations,

$$\mathrm{gh}(AB)=\mathrm{gh}(A)+\mathrm{gh}(B),\quad \mathrm{gh}(\{A,B\})=\mathrm{gh}(A)+\mathrm{gh}(B). \tag{4.7}$$

In particular, functions with zero ghost number form a subalgebra in the Poisson algebra $\mathcal{F}(\mathcal{M})$.

The classical BRST charge $Q\in\mathcal{F}(\mathcal{M})$ is defined as an odd function of ghost number 1 obeying the *classical master equation*

$$\{Q,Q\}=0, \tag{4.8}$$

and the standard boundary conditions

$$Q|_{\mathcal{P}=0}=\mathcal{C}^a T_a. \tag{4.9}$$

A function $A\in\mathcal{F}(\mathcal{M})$ is said to be BRST invariant if

$$DA:=\{Q,A\}=0, \quad \mathrm{gh}(A)=0. \tag{4.10}$$

Clearly, $D^2=0$. The space of *physical observables* is identified with the zero-ghost-number cohomology of the BRST operator D. The Poisson algebra structure on $\mathcal{F}(\mathcal{M})$ induces that on the space of physical observables.

According to general theorems of the BRST theory,[18] (i) Eq. (4.8) is always soluble, and (ii) the Poisson algebra of physical observables is isomorphic to that obtained by the Hamiltonian reduction by the first class constraints. In the case at hand, these statements can be refined as follows.

Proposition 4.1: The classical master equation (4.8) admits the following solution:

$$Q=\mathcal{C}^a T_a. \tag{4.11}$$

The Poisson algebra of physical observables on $\mathcal{M}$ is isomorphic to that on the quasisymplectic manifold (M,α). Each physical observable can be represented by a BRST invariant element from $\mathcal{F}(\mathcal{M})$ that does not depend on the ghost variables.

Proof: The first part of the proposition is easily verified by straightforward calculations. Notice that, unlike what one has in the standard BRST theory, the first class constraints T_a are no longer in involution as we have modified the Poisson brackets of p's by the ghost-dependent term (4.3). Luckily, this term does not contribute to the nilpotency condition due to the symmetry properties of the curvature tensor (2.28).

The rest of the proposition will follow from the classical limit of the analogous statement for the quantum BRST observables to be considered in the next section. Here we just show that each physical observable $A(x,p,y,\mathcal{C},\mathcal{P})$ on $\mathcal{M}$ is uniquely determined by its projection $A(x,0,0,0,0)$ on M. Speaking informally, this implies that the space of physical observables is not larger than $C^\infty(M)$. In order to see this, let us introduce the following *homotopy operator* $h:\mathcal{F}(\mathcal{M})\to\mathcal{F}(\mathcal{M})$:

$$h=\mathcal{P}_a\frac{\partial}{\partial\bar{p}_a}+y^a\frac{\partial}{\partial\mathcal{C}^a}, \tag{4.12}$$

where $\bar{p}_a:=p_a-\omega_{ab}y^b$. From the explicit expression for the BRST charge (4.11) it follows that

$$D=\bar{p}_a\frac{\partial}{\partial\mathcal{P}_a}+\mathcal{C}^a\frac{\partial}{\partial y^a}+\cdots. \tag{4.13}$$

Here the dots stand for the terms that increase the total degree when acting on monomials in y, $\mathcal{C}$, $\mathcal{P}$, and p. Then

$$Dh+hD=N, \tag{4.14}$$

where $N=N_0+\cdots$, and

$$N_0=y^a\frac{\partial}{\partial y^a}+\bar{p}_a\frac{\partial}{\partial\bar{p}_a}+\mathcal{C}^a\frac{\partial}{\partial\mathcal{C}^a}+\mathcal{P}_a\frac{\partial}{\partial\mathcal{P}_a}. \tag{4.15}$$

Obviously, $\ker N_0=C^\infty(M)\subset\mathcal{F}(\mathcal{M})$, and hence the operator N_0 is invertible on the subspace $\mathcal{F}_0=\mathcal{F}(\mathcal{M})\backslash C^\infty(M)$ and so is the operator N. This implies that the BRST cohomology is centered in the subspace $C^\infty(M)$; for any BRST invariant B from the complementary subspace $\mathcal{F}_0$ we have

$$B = DC, \quad C = h(N|_{\mathcal{F}_0})^{-1}B. \tag{4.16}$$

To conclude this section, let us depict the diagram of maps describing the path from the original quasisymplectic manifold (M,α) to the super-Poisson manifold $\mathcal{M}$,

$$\mathcal{M} = \mathcal{N} \oplus \Pi\mathcal{N} \to \mathcal{N} = \mathcal{E} \oplus \mathcal{E}^* \to \mathcal{E} \to M. \tag{4.17}$$

All the arrows are canonical projections.

B. Quantization of the super-Poisson manifold $\mathcal{M}$

In the general case, it is not easy to quantize the irregular Poisson brackets (3.5) and (4.1)–(4.3). Fortunately, for our purposes, it is sufficient to deal with a special Poisson subalgebra $\mathcal{A} \subset \mathcal{F}(\mathcal{M})$. This is given by functions of x^μ, y^a, $\mathcal{C}^a$ and $p := \mathcal{C}^a p_a$. Since $p^2 = 0$, the generic element of $\mathcal{A}$ has the form

$$A(x,y,p,\mathcal{C}) = a(x,y,\mathcal{C}) + b(x,y,\mathcal{C})p, \tag{4.18}$$

where a, b belong to the Poisson subalgebra $\mathcal{A}_0$ of p-independent elements of $\mathcal{A}$. The elements of $\mathcal{A}_0$ are given thus by formal power series in y's and $\mathcal{C}$'s with coefficients in $\Lambda(\mathcal{E}, S(\mathcal{E}))$, $S(\mathcal{E})$ being the space of symmetric tensor powers of $\mathcal{E}$. With this geometrical interpretation the basic Poisson bracket relations in $\mathcal{A}$ can be written as

$$\{p,p\} = R + \omega, \quad \{p,a\} = \nabla a, \quad \{a,b\} = \omega^{cd}\frac{\partial a}{\partial y^c}\frac{\partial b}{\partial y^d}, \quad a,b \in \mathcal{A}_0. \tag{4.19}$$

Here

$$\nabla a = \mathcal{C}^d \nabla_d a = \mathcal{C}^a \left(X^\mu_a \frac{\partial}{\partial x^\mu} - y^b \Gamma^d_{ab}\frac{\partial}{\partial y^d} - \mathcal{C}^b \Gamma^d_{ab}\frac{\partial}{\partial \mathcal{C}^d} \right) a \tag{4.20}$$

is the covariant derivative in $\mathcal{A}_0$ induced by the symplectic connection ∇_ρ on $\Lambda(\mathcal{E}, S(\mathcal{E}))$, and

$$R = -\tfrac{1}{2} R_{abcd}\mathcal{C}^a\mathcal{C}^b y^c y^d, \quad \omega = \omega_{ab}\mathcal{C}^a\mathcal{C}^b, \quad R,\omega \in \mathcal{A}_0, \tag{4.21}$$

are the covariant curvature tensor and the symplectic form written in the frame $(y^a, \mathcal{C}^a)$.

In view of Proposition (4.1), the algebra $\mathcal{A}$ contains the classical BRST charge (5.23) as well as all the physical observables of the effective gauge system. It is the reason why one can restrict consideration to the subalgebra $\mathcal{A}$ when the goal is to quantize the algebra of physical observables.

Proceeding to quantization, we introduce the formal deformation parameter $\hbar$ and extend the Poisson algebra $\mathcal{A}$ to the tensor product

$$\hat{\mathcal{A}} = \mathcal{A} \otimes [[\hbar]], \tag{4.22}$$

where $[[\hbar]]$ denotes the space of formal power series in $\hbar$ with coefficients in $\mathbb{C}$. Accordingly, denote by $\hat{\mathcal{A}}_0 := \mathcal{A}_0 \otimes [[\hbar]]$ the subalgebra of p-independent elements of $\hat{\mathcal{A}}$. There is an almost obvious quantum product giving rise to deformation quantization of the Poisson algebra $\hat{\mathcal{A}}$. For any two elements a, $b \in \hat{\mathcal{A}}_0$ we just use the Weyl-Moyal formula

$$(a \circ b)(x,y,\mathcal{C},\hbar) = \exp\left(-\frac{i\hbar}{2}\omega^{ab}\frac{\partial}{\partial y^a}\frac{\partial}{\partial z^b} \right) a(x,y,\mathcal{C},\hbar)\, b(x,z,\mathcal{C},\hbar)|_{y=z}, \tag{4.23}$$

and then extend this $\circ$-product to the whole algebra $\hat{\mathcal{A}}$ by associativity setting

$$p \circ a = pa - i\hbar\, \nabla a, \quad a \circ p = ap, \quad p \circ p = -i\hbar(R + \omega). \tag{4.24}$$

Clearly, the $\circ$-product respects both the Grassman and the ghost-number gradings.

As for any graded associative algebra, we can endow $\hat{\mathcal{A}}$ with the structure of super-Lie algebra with respect to the supercommutator

$$[A,B] = A \circ B - (-1)^{\epsilon(A)\epsilon(B)} B \circ A, \tag{4.25}$$

A, B being homogeneous elements of $\hat{\mathcal{A}}$.

For further purposes let us introduce one more useful grading on $\hat{\mathcal{A}}$ by prescribing the following degrees to the variables:

$$\deg(x^\mu) = \deg(\mathcal{C}^a) = 0, \quad \deg(y^a) = 1, \quad \deg(p) = \deg(\hbar) = 2. \tag{4.26}$$

Since this grading involves essentially the deformation parameter we will refer to it as *ħ-grading*.

C. Quantum BRST charge

This is defined as an element $\hat{Q} \subset \hat{\mathcal{A}}$ of ghost number 1 satisfying the *quantum master equation*

$$[\hat{Q},\hat{Q}] = 2\hat{Q} \circ \hat{Q} = 0 \tag{4.27}$$

with the boundary condition

$$\hat{Q}|_{\mathcal{P}=\hbar=0} = \mathcal{C}^a T_a. \tag{4.28}$$

The adjoint action of $\hat{Q}$ defines the nilpotent derivation $\hat{D}: \hat{\mathcal{A}} \to \hat{\mathcal{A}}$:

$$\hat{D}a = \frac{i}{\hbar}[\hat{Q},a], \quad a \in \hat{\mathcal{A}}. \tag{4.29}$$

The operator $\hat{D}$ increases the ghost number by 1 preserving the subalgebra $\hat{\mathcal{A}}_0$.

By definition, the space of *quantum physical observables* is identified with the zero-ghost-number cohomology of the operator $\hat{D}$.

Let us show the existence of a quantum BRST charge $\hat{Q}$ whose classical limit coincides with the classical BRST charge Q. Technically, instead of finding $\hbar$ corrections to Q, it is more convenient to build up $\hat{Q}$ using recursion on the total $\hbar$ degree (4.26). In order to do this we introduce the pair of Fedosov's operators changing the $\hbar$ degree by 1 unit. The first operator is given by

$$\delta a = \mathcal{C}^a \frac{\partial a}{\partial y^a}, \quad \delta^2 = 0 \tag{4.30}$$

for any $a \in \hat{\mathcal{A}}_0$. Since

$$\delta a = \frac{i}{\hbar}[\mathcal{C}^a \omega_{ab} y^b, a], \tag{4.31}$$

it is an internal derivation of $\hat{\mathcal{A}}_0$. The second operator is defined by its action on homogeneous functions,

$$\delta^* a_{mn} = \frac{1}{n+m} y^a \frac{\partial a}{\partial \mathcal{C}^a}, \quad n+m \neq 0,$$
$$\delta^* a_{00} = 0, \tag{4.32}$$

where $a_{nm} = a_{a_1 \cdots a_n, b_1 \cdots b_m}(x, \hbar) y^{a_1} \cdots y^{a_n} \mathcal{C}^{b_1} \cdots \mathcal{C}^{b_m}$. Like δ, the operator δ^* is nilpotent, though it is not a derivation of the $\circ$-product. One can regard δ^* as a homotopy operator:

$$a|_{\mathcal{C}=y=0} + \delta\delta^* a + \delta^* \delta a = a, \quad \forall\, a \in \hat{\mathcal{A}}_0. \tag{4.33}$$

The last relation resembles the usual Hodge-De Rham decomposition for the exterior algebra of differential forms.

Proposition 4.2: The quantum master equation (4.27) has a solution of the form

$$\hat{Q} = \sum_{r=1}^{\infty} Q_r, \quad \deg(Q_r) = r, \tag{4.34}$$

where

$$Q_1 = -\mathcal{C}^a \omega_{ab} y^b, \quad Q_2, = p, \quad \textit{and } Q_r \in \hat{\mathcal{A}}_0, \quad \forall\, r > 2, \tag{4.35}$$

which is unique if we require

$$\delta^* Q_r = 0, \quad \forall\, r > 2. \tag{4.36}$$

Proof: The first three terms in the expansion (4.34) coincide with those in the classical BRST charge (4.11), and this proves the validity of Eq. (4.27) in the lowest order in $\hbar$ degree. For $r \geqslant 4$ Eq. (4.27) implies

$$\delta Q_{r+1} = B_r, \tag{4.37}$$

where

$$B_r = -\frac{i}{2\hbar} \sum_{s=0}^{r-2} [Q_{r+2}, Q_{r-s}], \quad \deg(B_r) = r. \tag{4.38}$$

In view of the Hodge-De Rham decomposition (4.33), Eq. (4.37) is soluble iff $\delta B_r = 0$. In this case we have the unique solution

$$Q_{r+1} = \delta^* B_r \tag{4.39}$$

subject to the extra condition $\delta^* Q_{r+1} = 0$. So, it remains to show that $\delta B_r = 0$. Proceeding by induction, we assume that Eq. (4.27) is valid up to the sth order in $\hbar$ degree. Then, extracting the $(s+3)$-order in the Jacobi identity

$$[Q^s, [Q^s, Q^s]] = 0, \quad Q^s = \sum_{k=1}^{s} Q_k, \tag{4.40}$$

one gets $\delta B_s = 0$, that completes the proof.

Since $\mathrm{gh}(Q) = 1$, the ansatz (4.34) implies the following structure of the quantum BRST charge: $Q = \mathcal{C}^a \hat{T}_a(x, y, \hbar)$, where $\hat{T}_a$ are the "quantum" first class constraints. Then relation (4.36) is just another form of the y-transversality condition (3.18), which allows one to extract a unique solution both at the classical and quantum levels.

D. Quantum observables and star-product

In Sec. IV A we have shown that the space of physical observables of the classical gauge system on $\mathcal{N}$ is not larger than $C^\infty(M)$ in the sense that any physical observable is uniquely determined by its projection on M. In this section we prove the inverse: any physical observable on M has a unique BRST-invariant extension to a zero-ghost-number function from $\mathcal{A}_0$. Moreover, this picture takes place at the quantum level as well if we replace $C^\infty(M)\to C^\infty(M)\otimes[[\hbar]]$ and $\mathcal{A}_0\to\hat{\mathcal{A}}_0$. Therefore, it is sufficient to consider only the quantum case, the classical statement will follow from the classical limit.

Proposition 4.3: For any $a\in C^\infty(M)$ there is a unique $\hat{a}\in\hat{\mathcal{A}}_0$ obeying conditions

$$[\hat{Q},\hat{a}]=0,\quad \hat{a}|_{y=0}=a. \tag{4.41}$$

Proof: Consider the expansion of $\hat{a}\in\hat{\mathcal{A}}_0$ according to the $\hbar$ degree,

$$\hat{a}=\sum_{s=0}^{\infty}a_s,\quad \deg(a_s)=s. \tag{4.42}$$

The second condition in (4.41) says that $a_0=a(x)$. Substituting this expansion into the first equation, one gets

$$\delta a_{s+1}=B_s,\quad s>1, \tag{4.43}$$

where

$$B^s=\frac{i}{\hbar}\sum_{k=0}^{s-2}[Q^{k+2},a^{s-k}],\quad \deg(B^s)=s. \tag{4.44}$$

In view of the Hodge-De Rham decomposition (4.33) and the boundary condition (4.41), Eq. (4.43) has the unique solution

$$a^{s+1}=\delta^* B^s, \tag{4.45}$$

provided the rhs is δ-closed. The equality $\delta B^s=0$ follows by induction from the $(s+3)$-order of the identity

$$[\hat{Q},[\hat{Q},\hat{a}]]=0. \tag{4.46}$$

Corollary: There is a linear isomorphism between the spaces of quantum observables on M, i.e., $C^\infty(M)\otimes[[\hbar]]$, *and the zero-ghost-number cohomology of the BRST-differential $\hat{D}:\hat{\mathcal{A}}_0\to\hat{\mathcal{A}}_0$.*

Proof: Equation (4.41), being linear, has a unique solution even though we allow $\hat{a}|_{y=0}$ to depend formally on $\hbar$. Therefore, we can replace $C^\infty(M)$ with $C^\infty(M)\otimes[[\hbar]]$.

Clearly, the $\circ$-product on $\hat{\mathcal{A}}_0$ descends to the BRST cohomology and, in view of the corollary, induces an associative $*$-product on $C^\infty(M)\otimes[[\hbar]]$. Explicitly,

$$a*b=(\hat{a}\circ\hat{b})|_{y=0}=\sum_{n=1}^{\infty}\hbar^n D_n(a,b),\quad \forall\, a,b\in C^\infty(M)\otimes[[\hbar]], \tag{4.47}$$

where

$$D_0(a,b)=ab,\quad D_1(a,b)=-\frac{i}{2}\{a,b\}_M, \tag{4.48}$$

and the "hat" stands for the BRST-invariant lift from M to $\mathcal{M}$ (the existence and uniqueness of such a lift are ensured by Proposition 4.3). The higher orders in $\hbar$, being recurrently constructed by (4.39) and (4.45), involve also the symplectic connection and curvature.

Remark: By construction, the bidifferential operators D_n entering the $*$-product (4.47) have a rather peculiar structure. Namely, they are determined by repeated differentiations along the anchor distribution $\{X_a\}$,

$$D_n(a,b) = \sum_{k,l\leqslant n} D_n^{c_1\cdots c_k d_1\cdots d_l}(x)(X_{c_1}\cdots X_{c_k}a)(X_{d_1}\cdots X_{d_l}b). \tag{4.49}$$

Here the structure functions $D^{c_1\cdots c_k d_1\cdots d_l}(x)$ are *universally* expressed via the data of a symplectic Lie algebroid and a Lie algebroid connection. The differential operators of the form (4.49) are called the $\mathcal{E}$-differential operators; accordingly, the $*$-product (4.47) is called the $\mathcal{E}$-deformation of M. As was shown in Ref. 11, any $\mathcal{E}$ deformation of M can be induced by an $\mathcal{E}$ deformation of the commutative algebra of $\mathcal{E}$ jets. Conversely, the $\mathcal{E}$ deformation of M, given by the formula (4.47), admits a canonical extension to the space of $\mathcal{E}$ jets (by universality). In Ref. 15 such an extension was used to derive the universal deformation formula for triangular Lie bialgebras.

V. FACTORIZABLE POISSON BRACKETS BEYOND SYMPLECTIC LIE ALGEBROIDS

As we have seen, the concept of a symplectic Lie algebroid gives rise to an interesting class of Poisson brackets. Not any Poisson bracket comes in this way, but when it does, we have a simple quantization procedure generalizing the Fedosov quantization. In this section we would like to discuss, in a sense, an inverse problem: To what extent the factorization (2.20) of a Poisson bivector α defines a symplectic Lie algebroid?

The precise formulation of the problem is as follows. Let $\mathcal{E}\to M$ be a vector bundle over a smooth manifold M, ω a section of $\mathcal{E}\wedge\mathcal{E}$, and X a section of $\mathcal{E}^*\otimes TM$. By a slight abuse of notation, we will use the same letters ω and X to denote the corresponding bundle homomorphisms $\omega:\mathcal{E}^*\to\mathcal{E}$ and $X:\mathcal{E}\to TM$. Let us also suppose that the $\mathcal{E}$-bivector ω is nondegenerate (defines an isomorphism between $\mathcal{E}$ and its dual $\mathcal{E}^*$) and X is involutive. The latter means that in each trivializing coordinate chart $\mathcal{U}\subset M$ with frame $s_\alpha\in\Gamma(\mathcal{E}|_{\mathcal{U}})$, the local vector fields $X_\alpha = X_\alpha^i\partial_i \in \mathrm{Vect}(\mathcal{U})$ form an involutive distribution,

$$[X_\alpha, X_\beta] = f_{\alpha\beta}^\gamma X_\gamma, \tag{5.1}$$

$f_{\alpha\beta}^\gamma$ being smooth functions on $\mathcal{U}$. Clearly, the property of $\{X_\alpha\}$ to be involutive does not depend on a frame, and hence, $\{X_a\}$ generates a (singular) foliation $F(M)$. Suppose now that the bivector

$$\alpha = \omega^{\alpha\beta}X_\alpha\wedge X_\beta \in \wedge^2 TM \tag{5.2}$$

satisfies the Jacobi identity

$$[\alpha,\alpha] = 0. \tag{5.3}$$

Question: What is the most general geometric structure underlying Eqs. (5.1)–(5.3).

A particular solution to these equations is delivered by a symplectic Lie algebroid $\mathcal{E}\to M$ with anchor X and symplectic 2-form ω. In this case (M,α) is just a quasisymplectic manifold considered in the preceding sections.

Explicitly, the Jacobi identities for the local vector fields X_a and the Poisson bivector α read

$$(f_{\alpha\beta}^\delta f_{\delta\gamma}^\mu - X_\gamma f_{\alpha\beta}^\mu + \mathrm{cycle}(\alpha,\beta,\gamma))X_\mu = 0, \tag{5.4}$$

$$\begin{gathered}(\omega_{\gamma\delta}f_{\alpha\beta}^\delta - X_\gamma\omega_{\alpha\beta})X^\alpha\wedge X^\beta\wedge X^\gamma = 0,\\ X^\alpha = \omega^{\alpha\beta}X_\beta,\quad \omega_{\alpha\gamma}\omega^{\gamma\beta} = \delta_\alpha^\beta.\end{gathered} \tag{5.5}$$

If the map $X:\mathcal{E}\to TM$ is injective on an everywhere dense domain in M, the expressions in parentheses (5.5) must vanish by continuity, and we arrive at a symplectic Lie algebroid $(\mathcal{E},X,\omega)$. In the opposite case the lhs of Eqs. (5.4) and (5.5) cannot be "divided" by X_a so simply, and thus,

more general solutions for the structure functions $f^{\gamma}_{\alpha\beta}$, $\omega_{\alpha\beta}$, and X^i_α are possible. To further study these equations, we impose a certain regularity condition on X. In what follows we will assume that the space $\Gamma(TM)$, considered as a $C^\infty(M)$-module, admits a resolution of the form

$$0 \leftarrow TM \xleftarrow{d_1} \mathcal{E}_1 \xleftarrow{d_2} \mathcal{E}_2 \leftarrow \cdots \leftarrow \mathcal{E}_{n-1} \xleftarrow{d_n} \mathcal{E}_n \leftarrow 0, \tag{5.6}$$

where $\mathcal{E}_k \to M$ and d_k are sequences of vector bundles over M and their M-morphisms with $\mathcal{E}_1 = \mathcal{E}$ and $d_1 = X$. [A sequence of homomorphisms of modules (5.6) is called a resolution of the module $\Gamma(TM)$, if $\operatorname{im} d_{k+1} = \ker d_k$. In other words, the sequence (5.6) is just a cochain complex, which is exact, exclusive of maybe the first term.] Here we do not require the morphisms d_k to have constant ranks, but since $n < \infty$, their ranks must be constant on an open everywhere dense domain in M. In particular, the last structure map $d_k : \mathcal{E}_k \to \mathcal{E}_{k-1}$ should be injective on an everywhere dense domain in M. By analogy with ordinary Lie algebroids, we will refer to the first structure map $d_1 = X$ as anchor.

In order to clarify the meaning of the regularity condition, let us choose an open domain $\mathcal{U} \subset M$ such that for all $k = 1, \ldots, n$, $\mathcal{E}_k|_{\mathcal{U}}$ is a trivial vector bundle with frame s_{α_k}. Upon restriction on $\mathcal{U}$, the morphisms d_k are represented by matrices $d^{\alpha_{k-1}}_{\alpha_k}$, so that $d^{\alpha_{k-1}}_{\alpha_k} d^{\alpha_k}_{\alpha_{k+1}} = 0$. Since the complex (5.6) is exact starting with $\mathcal{E}_1$, the equality $f^{\alpha_k} d^{\alpha_{k-1}}_{\alpha_k} = 0$, f^{α_k} being a section of $\mathcal{E}_k$, implies that $f^{\alpha_k} = g^{\alpha_{k+1}} d^{\alpha_k}_{\alpha_{k+1}}$ for some section $g^{\alpha_{k+1}}$ of $\mathcal{E}_{k+1}$.

Example 0: Consider the adjoint representation of so(3). Identifying the carrier space so(3) with $\mathbb{R}^3$ we get a set of three linear vector fields on $\mathbb{R}^3$ generating the so(3)-algebra action:

$$\mathrm{ad}_i = \epsilon_{ijk} x_j \partial_k, \quad [\mathrm{ad}_i, \mathrm{ad}_j] = -\epsilon_{ijk}\, \mathrm{ad}_k. \tag{5.7}$$

Clearly, the rank of the anchor $\mathrm{ad} : \mathbb{R}^3 \times \mathrm{so}(3) \to T\mathbb{R}^3$ equals 2 in general position and vanishes at the origin $0 \in \mathbb{R}^3$. Since the equation $f^i(x)\mathrm{ad}_i = 0$ implies $f^i(x) = g(x)x^i$, for some smooth function g, while the equation $x^i h(x) = 0$ has the unique solution $h = 0$, we get the following resolution:

$$0 \leftarrow T\mathbb{R}^3 \xleftarrow{\mathrm{ad}} \mathbb{R}^3 \times \mathrm{so}(3) \xleftarrow{d_2} \mathcal{E}_2 \leftarrow 0, \tag{5.8}$$

were $\mathcal{E}_2$ is a linear bundle over $\mathbb{R}^3$ and $d_2 = (x^i)$.

Given an anchor X satisfying the regularity condition, one can solve the Jacobi identity (5.4) in the following form:

$$f^{\delta}_{\alpha\beta} f^{\mu}_{\delta\gamma} - X_\gamma f^{\mu}_{\alpha\beta} + \mathrm{cycle}(\alpha,\beta,\gamma) = f^{a}_{\alpha\beta\gamma} d^{\mu}_{a}, \tag{5.9}$$

where $f^{\alpha}_{\alpha\beta\gamma}$ are smooth functions on $\mathcal{U}$, skew-symmetric in $\alpha\beta\gamma$, and d^{α}_{a} is the matrix of the second structure map d_2 in (5.6). By definition, we have

$$d^{\gamma}_{a} X_\gamma = 0. \tag{5.10}$$

In order to solve the Jacobi identity for α, we assume the anchor foliation $F(M)$ to be regular (this technical restriction can be weakened), i.e., $\operatorname{im} X$ is an integrable subbundle of TM. Then

$$\omega_{\gamma\delta} f^{\delta}_{\alpha\beta} - X_\gamma \omega_{\alpha\beta} + \mathrm{cycle}(\alpha,\beta,\gamma) = W^{a}_{\alpha\beta} d_{a\gamma} + \mathrm{cycle}(\alpha,\beta,\gamma), \quad d_{a\gamma} = \omega_{\gamma\beta} d^{\beta}_{a}, \tag{5.11}$$

$W^{a}_{\alpha\beta} = -W^{a}_{\beta\alpha}$ being smooth functions on $\mathcal{U}$. Examining compatibility of these equations with the involution relations (5.1), one obtains an infinite set of higher structure functions and structure relations to be studied below.

Let us forget for a moment about the Poisson bivector α, focusing at the anchor distribution X. Commuting (5.10) with X_β, we find

$$X_\beta d^{\alpha}_{a} + f^{\alpha}_{\beta\gamma} d^{\gamma}_{a} = -f^{b}_{\beta a} d^{\alpha}_{b}, \tag{5.12}$$

f^{β}_{ba} being local functions. Contracting the last identity with d^{β}_{c} and symmetrizing in the indices ac, we get

$$d_c^\beta f_{\beta a}^b + d_a^\beta f_{\beta c}^d = f_{ca}^A d_A^b, \tag{5.13}$$

where d_A^b is the matrix of the third structure map in (5.6), so that $d_A^b d_b^\alpha = 0$. Proceeding in the same manner one can derive the other structure relations.

There is a nice way to generate all these relations systematically using the language of *NQ manifolds*. Let us recall the basic definitions.[21–24] An *N manifold* is a non-negatively integer graded supermanifold, whose *N* grading is compatible with the underlying $\mathbb{Z}_2$ grading (Grassman parity). In other words, an *N* manifold is just a supermanifold with a privileged class of atlases in which particular coordinates are assigned non-negative integer degrees (even coordinates have even degrees, while odd ones have odd degrees) so that the changes of coordinates respect these degrees. The highest degree of coordinates is called the *degree* of an *N* manifold. For example, if $\deg M = 0$, then *M* is just an ordinary manifold. Finally, an *NQ* manifold is an *N* manifold endowed with integrable vector field *Q* of degree 1, called a *homological vector field*. Since *Q* is odd, the integrability condition $[Q,Q] = 2Q^2 = 0$ is nontrivial. The classical example of an *NQ* manifold of degree 1 is the anticotangent bundle ΠTM (cotangent bundle with the reverse parity of fibers). The functions on ΠTM are just inhomogeneous differential forms on *M* and *Q* is the usual exterior differential. More generally, an *NQ* manifold of degree 1 is the same as Lie algebroid. For this reason it is natural to name the *NQ* manifolds of degree *n* as *n algebroids*.[24]

A general homological vector field looks like (all derivatives are assumed to be acting on the left)

$$Q = c^{\alpha_1} X_{\alpha_1}^i(x) \frac{\partial}{\partial x^i} + \sum_{k=1}^{\deg \mathcal{M}} c^{\alpha_{k+1}} d_{\alpha_{k+1}}^{\alpha_k}(x) \frac{\partial}{\partial c^{\alpha_k}} + \cdots, \tag{5.14}$$

where $\deg(x^i) = 0$, $\deg(c^{\alpha_k}) = k$, and dots stand for higher orders in the positively graded variables c^{α_k}. Evaluating the equation $Q^2 = 0$ at the first order in *c*'s one recovers the cochain complex axioms $d_{\alpha_m}^{\alpha_{m-1}} d_{\alpha_{m+1}}^{\alpha_m} = 0$, the second order in c^{α_1} reproduces the involution relations (5.1), relation (5.9) contributes to the cubic order, and so on. [Notice, that any *n* algebroid can also be viewed as an $(n+1)$-algebroid whose higher structure functions are just equal to zero.] Thus, we see that the resolution (5.6) for the involutive distribution $X: \mathcal{E} \to TM$ is just a regular *n* algebroid.

Although the language of *NQ* manifolds is quite convenient to describe the structure of *n* algebroids as such, it becomes unappropriated when one tries to incorporate the symplectic structure entering the factorization (2.20). Here we would like to present a new geometric framework providing a uniform description for both *n*-algebroid and symplectic structures underlying factorizable Poisson brackets. For the sake of simplicity we restrict our consideration to the case of 2-algebroids. The general construction will be developed elsewhere. Before going into details let us give two examples which are of interest by themselves.

Example 1: (Poisson-Lie algebras.) Consider an invariant Poisson bracket on a Lie group *G* associated with the bivector

$$\alpha = r^{ij}(L_i \wedge L_j - R_i \wedge R_j). \tag{5.15}$$

Here L_i, R_j are left and right invariant vector fields on *G*, and the matrix (r^{ij}) obeys the Yang-Baxter equation

$$f_{ml}^i (r^{jn} f_{ns}^l r^{sk} + \mathrm{cycle}(j,l,k)) + \mathrm{cycle}(i,j,k) = 0, \tag{5.16}$$

f_{ij}^k being the structure constants of the corresponding Lie algebra $L(G)$. If $\det(r^{ij}) \neq 0$, we have the Poisson bivector α associated with the symplectic structure r^{ij} and the 2-algebroid,

$$0 \leftarrow TG \xleftarrow{(L,R)} TG \oplus TG \xleftarrow{d_2} TG \leftarrow 0, \tag{5.17}$$

where $d_2 = (1, A)$, and *A* is the automorphism of the tangent bundle *TG* relating the left and right invariant vector fields, $L_i = A_i^j R_j$.

Example 2: (Universal factorization.) Any Poisson bivector $\alpha=\alpha^{ij}\partial_i\wedge\partial_j$ can be factorized in a skew-symmetric product of Hamiltonian and coordinate vector fields,

$$\alpha = P_i \wedge Q^i, \quad P_i = \partial_i, \quad Q^i = \alpha^{ij}\partial_j. \tag{5.18}$$

The local vector distribution (P_j, Q^j) is obviously transitive and hence involutive. Moreover, there is a one-parameter ambiguity in writing the involution relations,

$$[P_i, P_j] = 0,$$

$$[P_i, Q^j] = \partial_i\alpha^{jk}P_k, \tag{5.19}$$

$$[Q^i, Q^j] = t\partial_k\alpha^{ij}Q^k + (1-t)\partial_k\alpha^{ij}\alpha^{kn}P_n, \quad t\in\mathbb{R}.$$

This ambiguity is due to linear dependence of the local vector fields,

$$Q^i = \alpha^{ij}P_j. \tag{5.20}$$

The last equations are already independent and we arrive at the following cochain complex:

$$0 \leftarrow TM \xleftarrow{(P,Q)} TM\oplus T^*M \xleftarrow{(1,\alpha)} TM \leftarrow 0, \tag{5.21}$$

which is exact provided α is nondegenerate on an everywhere dense domain in M.

Consider now a general NQ-manifold $\mathcal{M}$ of degree 2. As for usual manifolds, the structure of $\mathcal{M}$ can be described in terms of coordinate charts and transition functions gluing together individual N-graded domains $U\in\mathcal{M}$. Without loss of generality we can assume that each U is given by a direct product $\mathcal{U}\times\mathbb{R}^n_1\times\mathbb{R}^m_2$, where $\mathcal{U}\in M$ is an open contractible domain on the base manifold with local coordinates x^i, $\mathbb{R}^n_1$ and $\mathbb{R}^m_2$ are vector spaces with linear coordinates c^α and c^a, respectively. We set $\deg(x^i)=0$, $\deg(c^\alpha)=1$, $\deg(c^a)=2$, so that x^i and c^a are commuting, while c^α are anticommuting coordinates on $U\in\mathcal{M}$. If now U and U' are two graded domains with nonempty intersection, then the most general form of transition functions, compatible with the N grading, is given by

$$x'^i = f^i(x), \quad c'^\alpha = A^\alpha_\beta(x)c^\beta, \quad c'^a = B^a_b(x)c^b + \tfrac{1}{2}F^a_{\alpha\beta}(x)c^\alpha c^\beta, \tag{5.22}$$

f^i, A^α_β, B^a_b and $F^a_{\alpha\beta}$ are smooth functions on $\mathcal{U}\cap\mathcal{U}'$. The first equation defines transformation of local coordinates on the base manifold M. Disregarding the F term, we see that the second and third equations are similar to those defining transition functions for (graded) vector bundles. Moreover, the matrix-valued functions A and B do really obey the standard cocycle conditions on overlaps of two and three coordinate charts, defining thus the direct sum $\mathcal{E}_1\oplus\mathcal{E}_2$ of two graded vector bundles.

In terms of local coordinates the most general homological vector field on $\mathcal{M}$ reads

$$Q = c^\alpha X^i_\alpha\frac{\partial}{\partial x^i} + c^a d^\alpha_a\frac{\partial}{\partial c^\alpha} + \frac{1}{2}c^\beta c^\alpha f^\gamma_{\alpha\beta}\frac{\partial}{\partial c^\gamma} + c^\alpha c^a f^b_{\alpha a}\frac{\partial}{\partial c^b} + c^\gamma c^\beta c^\alpha f^a_{\alpha\beta\gamma}\frac{\partial}{\partial c^a}. \tag{5.23}$$

Using relations (5.22) one can derive transformation properties for the structure functions X^i_α, d^γ_a, $f^\gamma_{\alpha\beta}$, $f^b_{a\beta}$, $f^a_{\alpha\beta\gamma}\in C^\infty(\mathcal{U})$ under coordinate changes. In particular, the F term induces the shift

$$f^\gamma_{\alpha\beta} \to f^\gamma_{\alpha\beta} + F^a_{\alpha\beta}d^\gamma_a, \tag{5.24}$$

which reflects an inherent ambiguity concerning the choice of the structure functions (5.1) whenever X_α are linearly dependent. Also, it is not hard to see that X^i_α and d^γ_a transform homogeneously, i.e., as sections of the associated vector bundles $\mathcal{E}^*_1\oplus TM$ and $\mathcal{E}^*_2\oplus\mathcal{E}_1$.

Now suppose that $\mathcal{M}$ defines a 2-algebroid factorizing a Poisson bivector α. Our aim is to give a unified description for both the 2-algebroid and the symplectic structure entering this

factorization. It turns out that all structure relations underlying the factorization (5.2) can be described in terms of an Abelian connection (covariant derivative) acting on a bundle of odd Poisson algebras over M. The construction goes as follows.

Let $E_0 \oplus E_1$ be a $\mathbb{Z}_2$-graded vector bundle over M defined by the aforementioned gluing cocycles A and $(B^{-1})^*$, that is $E_1 = \mathcal{E}_1$, $E_0 = \mathcal{E}_2^*$. If c^α and π_a are linear coordinates in the fibers of E_1 and E_0 over a trivializing domain $\mathcal{U} \in M$, we set $\epsilon(c^\alpha) = 1$, $\epsilon(\pi_a) = \epsilon(x^i) = 0$. It is convenient to think of this bundle as a formal supermanifold $\mathcal{N}$ with even coordinates x^i, π_a and odd coordinates c^α. The word "formal" reflects the fact that we allow the functions on $\mathcal{N}$ to be given by formal power series in π's. These functions form a supercommutative algebra $\mathcal{F}$ with the generic element

$$f(x,c,\pi) = \sum_{k,n} f^{a_1 \cdots a_k}_{\alpha_1 \cdots \alpha_n}(x)\, \pi_{a_1} \cdots \pi_{a_k} c^{\alpha_1} \cdots c^{\alpha_n}. \tag{5.25}$$

The algebra $\mathcal{F} = \oplus \mathcal{F}_{n,m}$ is naturally bigraded with respect to powers of c's and π's and is isomorphic to the tensor algebra of sections of the associated vector bundle $S^\bullet E_0^* \otimes \Lambda^\bullet E_1^*$.

The space $\mathcal{F}$ can also be endowed with the structure of odd Poisson algebra. To this end, we introduce the odd Laplacian $\Delta : \mathcal{F}_{m,n} \to \mathcal{F}_{m-1,n-1}$,

$$\Delta f = d_a^\alpha(x) \frac{\partial^2 f}{\partial c^\alpha \partial \pi_a}. \tag{5.26}$$

Clearly, $\Delta^2 = 0$. The odd Poisson bracket $(\cdot,\cdot) : \mathcal{F}_{n,m} \oplus \mathcal{F}_{k,l} \to \mathcal{F}_{n+k-1,m+l-1}$ is defined by the rule

$$(-1)^{\epsilon(f)}(f,g) = \Delta(f \cdot g) - \Delta f \cdot g - (-1)^{\epsilon(f)} f \cdot \Delta g. \tag{5.27}$$

It obeys the standard identities which may be taken as the axioms of an odd Poisson manifold,

$$\begin{gathered} \epsilon(f,g) = \epsilon(f) + \epsilon(g) + 1 \pmod 2, \\ (f,g) = -(g,f)(-1)^{(\epsilon(f)+1)(\epsilon(g)+1)} \quad \text{(symmetry)}, \\ (f,gh) = (f,g)h + (f,h)g(-1)^{\epsilon(g)\epsilon(h)} \quad \text{(Leibnitz rule)}, \\ (f,(g,h))(-1)^{(\epsilon(f)+1)(\epsilon(h)+1)} + \text{cycle}(f,g,h) = 0 \quad \text{(Jacobi identity)}. \end{gathered} \tag{5.28}$$

Notice that Δ respects the odd Poisson bracket (5.27) in the sense that

$$\Delta(f,g) = (\Delta f, g) + (-1)^{\epsilon(f)+1}(f, \Delta g). \tag{5.29}$$

The algebra $\mathcal{F}$ contains a special element $\omega = \frac{1}{2}\omega_{\alpha\beta} c^\alpha c^\beta \in \mathcal{F}_{2,0}$ associated with the symplectic structure. The adjoint action of ω gives rise to the nilpotent differentiation $\delta : \mathcal{F}_{n,m} \to \mathcal{F}_{n+1,m-1}$,

$$\delta f = (\omega, f) = -c^\alpha \omega_{\alpha\beta} d_a^\beta \frac{\partial f}{\partial \pi_a}, \quad \delta^2 = 0. \tag{5.30}$$

It is easy to see that the δ-cohomology is trivial when evaluated on $\mathcal{F}_{\bullet,k}$ with $k > 0$.

Now we would like to endow the bundle of odd Poisson algebras $\mathcal{F}$ with a sort of partial connection $\nabla : \mathcal{F}_{m,n} \to \mathcal{F}_{m+1,n}$ making possible parallel transport along the leaves of the anchor foliation $F(M)$. Treating ∇ as an odd vector field on $\mathcal{N}$, we set

$$\nabla a = c^\alpha \left(X^i_\alpha \frac{\partial}{\partial x^i} + \frac{1}{2} c^\beta f^\gamma_{\alpha\beta} \frac{\partial}{\partial c^\gamma} + \pi_a f^\alpha_{ab} \frac{\partial}{\partial \pi_b} \right) a + (W_1, a), \tag{5.31}$$

where the structure functions X^i_α, $f^\gamma_{\alpha\beta}$, $f^a_{\alpha b}$ are the same as in Eq. (5.23) and $W_1 = c^\alpha c^\beta W^a_{\alpha\beta} \pi_a \in \mathcal{F}_{2,1}$ is given by the rhs of Eq. (5.11). Using the definition of ∇, one can rewrite Eq. (5.11) as

$$\nabla\omega = 0 \tag{5.32}$$

or, equivalently,

$$\nabla\delta + \delta\nabla = 0. \tag{5.33}$$

The main property of the local vector field ∇ is that it respects the odd Poisson bracket, i.e.,

$$\nabla(f,g) = -(\nabla f,g) + (-1)^{\epsilon(f)+1}(f,\nabla g), \tag{5.34}$$

for any $f,g \in \mathcal{F}|_U$. Squaring ∇, we get an internal derivation of the odd Poisson algebra,

$$\nabla^2 f = (R,f), \tag{5.35}$$

where one can thought of the odd function $R = c^\gamma c^\beta c^\alpha f^a_{\alpha\beta\gamma}\pi_a \in \mathcal{F}_{3,1}$ as the curvature of ∇. Like a curvature, R obeys the Bianchi identity

$$\nabla R = 0. \tag{5.36}$$

Now we can extend ∇ from a local coordinate chart U to the whole $\mathcal{N}$. To this end, we choose a trivializing covering $\{\mathcal{U}_i\}$ of M together with local connections ∇_i on $(E_0 \oplus E_1)|_{\mathcal{U}_i}$. It follows from (5.32) that on each nonempty intersection $\mathcal{U}_i \cap \mathcal{U}_j$,

$$\nabla_i - \nabla_j = (\delta\phi_{ij}, \cdot), \tag{5.37}$$

for some $\phi_{ij} \in \mathcal{F}_{1,2}|_{\mathcal{U}_i\cap\mathcal{U}_j}$. Then, on each nonempty intersection $\mathcal{U}_i \cap \mathcal{U}_j \cap \mathcal{U}_k$ the functions ϕ_{ij} satisfy the relation

$$\delta(\phi_{ij} + \phi_{jk} + \phi_{ki}) = 0. \tag{5.38}$$

Since the δ-cohomology is trivial on $\mathcal{F}_{1,2}$ we conclude that

$$\phi_{ij} + \phi_{jk} + \phi_{ki} = \delta\psi_{ijk} \quad \text{on } \mathcal{U}_i \cap \mathcal{U}_j \cap \mathcal{U}_k, \tag{5.39}$$

for some $\chi_{ijk} \in \mathcal{F}_{0,3}|_{\mathcal{U}_i\cap\mathcal{U}_j\cap\mathcal{U}_k}$. Again, from the last equation it follows that on each nonempty intersection $\mathcal{U}_i \cap \mathcal{U}_j \cap \mathcal{U}_k \cap \mathcal{U}_l$ of four domains one has

$$\chi_{ijk} - \chi_{jkl} + \chi_{kli} - \chi_{lij} = 0. \tag{5.40}$$

Notice that Eq. (5.37) does not define ϕ_{ij} uniquely as we are free to add to them any δ-closed terms $\delta\psi_{ij} \in \mathcal{F}_{1,2}$. This modifies the rhs of Eq. (5.39) as follows:

$$\chi_{ijk} \to \chi_{ijk} - (\psi_{ij} + \psi_{jk} + \psi_{ki}). \tag{5.41}$$

Equations (5.40) and (5.41) imply that to any collection of local connections ∇_i we have associated an element χ of the second Čech cohomology group with coefficients in $\mathcal{F}_{0,3}$. Since this group is completely determined by the second De Rham's cohomology group of M we can think of χ as an element of $H^2(M)$.

Given a partition of unity $\{h^i\}$ subordinated to the covering $\{\mathcal{U}_i\}$, we set

$$\phi_i = \phi_{ij}h^j. \tag{5.42}$$

It is not hard to check, using relation (5.39), that the new local connections $\nabla'_i = \nabla_i - (\delta\phi_i, \cdot)$ already coincide on each intersection $\mathcal{U}_i \cap \mathcal{U}_j \neq \emptyset$. Thus, there are no topological obstructions to introducing a partial connection of the form (5.31) and we can regard $\chi \in H^2(M)$ as an invariant of ∇.

Combining now the action of ∇ with internal differentiations of the odd Poisson algebra $\mathcal{F}$, one can construct a more general connection $D: \mathcal{F}_{n,\bullet} \to \mathcal{F}_{n+1,\bullet}$,

$$Da = \delta a + \nabla a - (W,a) = \nabla a + (\omega - W,a), \tag{5.43}$$

W being an element of $\mathcal{F}_{2,\bullet}$, if $D^2=0$, we refer to D as an Abelian connection. The condition of D to be an Abelian connection is equivalent to the following equation:

$$\delta W = R + \nabla W + \tfrac{1}{2}(W,W). \tag{5.44}$$

The existence of an Abelian connection follows from the solubility of (5.44). Indeed, substituting expansion

$$W = \sum_{k=2}^{\infty} W_k, \quad W_k \in \mathcal{F}_{2,k}, \tag{5.45}$$

into (5.44) one gets

$$\begin{aligned} \delta W_2 &= R, \\ \delta W_{n+1} &= \nabla W_n + \frac{1}{2}\sum_{k=2}^{n} (W_{n-k+2}, W_k), \quad n \geqslant 2. \end{aligned} \tag{5.46}$$

Since the δ-cohomology is trivial when evaluated on $\mathcal{F}_{2,k}$ with $k>0$, the first equation is soluble provided $\delta R=0$. But the last condition immediately follows from the identities $0=\nabla^2\omega=(R,\omega)=-\delta R$. Proceeding by induction, one can see that the rhs of the $(n+1)$th equation is δ closed (and thus is δ exact) provided all the previous equations for $W_2,\ldots,W_n$ have been satisfied.

The main results of this section can be summarized as follows.

Proposition 5.1: Suppose we are given the following data:

(1) *a short exact sequence*

$$0 \to \mathcal{E}_2 \xrightarrow{d} \mathcal{E}_1 \xrightarrow{X} F \to 0,$$

where $\mathcal{E}_1 \to M$, $\mathcal{E}_2 \to M$ are vector bundles over a smooth manifold M, F is an integrable subbundle of the tangent bundle TM, and d, X are M-morphisms of the vector bundles (not necessarily of constant rank);

(2) *a nondegenerate, skew-symmetric, bilinear form ω on $\mathcal{E}_1$ inducing a Poisson bivector field on the base manifold*,

$$\alpha = \langle \omega, X \wedge X \rangle \in \wedge^2 TM, \quad [\alpha,\alpha] = 0.$$

(Here we identify $X:\mathcal{E}_1 \to F \subset TM$ with a section of $\mathcal{E}_1^* \otimes TM$.)

Then to each set of such data one can associate

(1) *an invariant χ taking value in the second group of De Rham's cohomology of M, and*
(2) *a bundle of odd Poisson algebras $\mathcal{F}$ over M together with an Abelian connection D differentiating $\mathcal{F}$ such that the condition $D^2=0$ generates all structure relations arising from the integrability of F and the Jacobi identity for α.*

The generating procedure stated above could be viewed as starting point for quantizing general factorizable brackets associated with symplectic 2-algebroids along the lines of Secs. III and IV.

(Received 25 October 2005; accepted 6 March 2006; published online 24 April 2006)

We expand a partial difference equation (PΔE) on multiple lattices and obtain the PΔE which governs its far field behavior. The perturbative-reductive approach is here performed on well-known nonlinear PΔEs, both integrable and nonintegrable. We study the cases of the lattice modified Korteweg-de Vries (mKdV) equation, the Hietarinta equation, the lattice Volterra-Kac-Van Moerbeke equation and a nonintegrable lattice KdV equation. Such reductions allow us to obtain many new PΔEs of the nonlinear Schrödinger type. © *2006 American Institute of Physics.*

I. INTRODUCTION

Problems involving the evolution of nonlinear phenomena, both continuous and discrete, have become of increasing interest in various branches of science and engineering. Nonlinear waves, without dissipation and dispersion give rise in a finite time to a discontinuity. A typical example of nonlinear wave is the shock wave produced by a supersonic object. Dissipation and dispersion play an important role in balancing the steepening due to nonlinearity, so that when these effects are present, a steep but smooth solitary wave may be formed and then propagates for all times. The solitary wave phenomenon has actually been observed for many years in the form of a surface wave in shallow water. A model equation of nonlinear dispersive phenomena may, in general, be very complicated. The soliton may appear only in the asymptotics, after a long transient period. Thus to be able to put in evidence the solitons, Taniuti and collaborators[11,12] introduced an asymptotic method which makes it possible to reduce general nonlinear evolution equations to some more tractable nonlinear equations. This method go under the denomination of *reductive perturbation technique*. Under the assumption that the amplitude of the waves are small, one is able to reduce the starting hyperbolic system to a few simple equations, such as the Burgers equation, the Korteweg-de Vries equation, the nonlinear Schrödinger equation and few others.

In the reductive perturbation method, the space and time coordinates are stretched in terms of a small expansion parameter and we introduce the concept of *far field*, as the field governing the asymptotic behavior of the reduced equation. To give a simple idea of the reasoning underlining this concept, let us consider, as an example, the familiar wave equation in two variables:

$$\phi_{,tt} - \phi_{,xx} = 0. \tag{1}$$

The general solution of Eq. (1) can be expressed as the superposition of waves moving to the right and to the left. In general these two waves are excited simultaneously by an arbitrary initial condition. However, if the initial condition is localized, after a certain finite time the disturbance separates in a progressive wave propagating to the right and one to the left, and they are solutions

[a)]Electronic mail: levi@fis.uniroma3.it
[b)]Electronic mail: petrera@fis.uniroma3.it

to a first order equation, i.e., an equation of one fewer degree of freedom:

$$\phi_{,x} \pm \phi_{,t} = 0.$$

We call the solutions of the first order equation the *far field solutions* of the original wave equation. The concept of far field came from the idea of finding properties of a given evolution equation which do not depend in a sensitive manner on the details of the initial conditions, but correspond to a wide class of initial conditions.

As an example of the simplification obtained by considering the reductive perturbation method, let us consider a Riemann wave,

$$\phi_{,t} + \lambda(\phi)\phi_{,x} = 0. \tag{2}$$

When the wave function is small we may find the solution ϕ by a perturbation calculation. Let ϵ be a small parameter and let us expand the solution around the constant solution $\phi^{(0)}$,

$$\phi = \phi^{(0)} + \epsilon\phi^{(1)} + O(\epsilon^2).$$

Expanding in powers of ϵ we get from Eq. (2) the following results:

$$\epsilon^0, \quad \phi^{(1)}_{,t} + \lambda_0 \phi^{(1)}_{,x} = 0,$$

$$\epsilon^1, \quad \phi^{(2)}_{,t} + \lambda_0 \phi^{(2)}_{,x} = -\lambda_{,\phi^{(0)}} \phi^{(1)} \phi^{(1)}_{,x},$$

with

$$\lambda_0 \doteq \lambda(\phi^{(0)}), \quad \lambda_{,\phi^{(0)}} \doteq \left(\frac{d\lambda}{d\phi}\right)_{\phi=\phi^{(0)}}.$$

Introducing the new variables $x' = x - \lambda_0 t$, $t' = \epsilon t$, we can rewrite Eq. (2), up to the second order in ϵ, as

$$\phi^{(1)}_{,t'} + \lambda_{,\phi^{(0)}} \phi^{(1)} \phi^{(1)}_{,x'} = 0. \tag{3}$$

If we consider a nonlinear dispersive system, like, for example, the Euler equation, instead of Eq. (3) we get

$$\phi_{,t'} = \phi_{,x'x'x'} + 6\phi\phi_{,x'}, \tag{4}$$

that is the Korteweg-de Vries (KdV) equation.

The nonlinear system at the lowest order approximation can admit a solution given by monocromatic wave packets, i.e., $\phi^{(0)} = A \exp[kx - \omega(k)t]$. Then it is reasonable to consider perturbations of such solution and to turn the nonlinear system into a set of equations for the complex envelope of these packets. The characteristic packet size and wavelength play the role of different scales for this system.

Let us consider, for example, the KdV equation (4) for a small amplitude field ϕ of order ϵ. The linear equations admits a monocromatic solution with dispersion relation $\omega(k) = -k^3$. Then the solution of the KdV equation can be written as

$$\phi = \sum_{n=-\infty}^{+\infty} \epsilon^{\alpha_{|n|}} v_n(x', t') e^{in(kx - \omega(k)t)}, \quad v_n^* = v_{-n},$$

with

$$x' = \epsilon(x + 3k^2 t), \quad t' = -6\epsilon^2 kt,$$

$$\alpha_0 = 1, \quad \alpha_n = n - 1, \quad n \geqslant 1,$$

and v_1 will satisfy the well-known integrable nonlinear Schrödinger (NLS) equation

$$v_{1,t'} + \tfrac{1}{2} v_{1,x'x'} - k^2 v_1 |v_1|^2 = 0. \tag{5}$$

It is important to notice that these multiscale expansions are structurally strong and can be applied to both integrable and nonintegrable systems. Zakharov and Kuznetsov in the introduction of their paper[14] say: *If the initial system is not integrable, the result can be both integrable and nonintegrable. But if we treat the integrable system properly, we again must get from it an integrable system.*

Calogero and Eckhaus[3] used similar ideas starting from generic hyperbolic systems to prove in 1987 the necessary conditions for the integrability of nonlinear partial differential equations (PDEs). Later Degasperis and Procesi[4] introduced the notion of *asymptotic integrability of order n* by requiring that the multiscale expansion be verified up to order n.

Also in the case of differential equations on a lattice, we would like to have a reliable reductive perturbative method which would produce reduced discrete systems. As the far field solution implies the introduction of a new variable which combines the continuous time with the discrete lattice, it is natural to get from a differential-difference equation by the reductive perturbation technique a continuous NLS equation (5). Leon and Manna[7] and later Levi and Heredero[9] proposed a set of tools which allows to perform multiscale analysis for a discrete evolution equation. These tools rely on the definition of a large grid scale via the comparison of the magnitude of related difference operators and on the introduction of a slow varying condition for functions defined on the lattice. Their results, however, are not very promising as the reduced models are neither simpler nor as integrable as the original ones. Starting from an integrable model, like the Toda lattice, Leon and Manna[7] produce a nonintegrable differential-difference equation of the discrete NLS type. Levi and Heredero[9] from the integrable differential-difference NLS equation obtain a nonintegrable system of differential-difference equations of KdV type.

In the present paper we consider the case of nonlinear partial difference equations (PΔEs). To be able to carry out the discrete reductive perturbation technique, in Sec. II we introduce multiple lattice variables and give a definition of slow varying functions on the lattice. Section III is devoted to the application of the perturbative expansions introduced to the case of a set of integrable and nonintegrable equations, i.e., the lattice modified Korteweg-de Vries (mKdV) equation, the Hietarinta equation, the lattice Volterra-Kac-Van Moerbeke (VKVM) equation and a nonintegrable lattice KdV equation. Section IV is devoted to some conclusive remarks.

II. MULTIPLE SCALES ON THE LATTICE AND FUNCTIONAL VARIATION ON THEM

The aim of this section is to fix the notation and to introduce the mathematical formulas necessary to reduce integrable and nonintegrable lattice equations in the framework of the perturbative-reductive approach. In doing so we will partly follow Ref. 8, trying to present a clearer and simpler derivation of all necessary formulas.

A. Slow varying variables on the lattice

Given a lattice defined by a constant lattice spacing h, we will denote by n the running index of the points separated by h. In correspondence with the lattice variable n, we can introduce the real variables $x = hn$.

We can define on the same lattice a set of slow varying variables by introducing a small parameter $\epsilon = N^{-1}$ and requiring that

$$n_j = \epsilon^j n. \tag{6}$$

This is equivalent to sampling points from the original variables which are situated at a distance of $N^j h$ between them and then setting them on a lattice of spacing h. The corresponding slowly varying real variables x_j are related to the variable x by the equation $x_j = \epsilon^j x$.

B. Expansion of slowly varying functions

Let us study the relation between functions living on the different lattices defined in Sec. II A. We consider a function $f \doteq f_n$ defined on the points of a lattice of index n. Let us assume that $f_n = g_{n_1,n_2,\ldots,n_K}$, i.e., f depends on a finite number K of slow varying lattice variables n_j $j=1,2,\ldots,K$ defined as in (6). We want to get explicit expressions for, say, f_{n+1} in terms of $g_{n_1,n_2,\ldots,n_K}$ evaluated on the points of the $n_1,n_2,\ldots,n_K$ lattices. At first let us consider the case, studied in Ref. 6, when we have only two different lattices, i.e., $K=1$. Using the results obtained in this case we will then consider the case corresponding to $K=2$. The general case will then be obvious.

(I) $K=1$ ($f_n = g_{n_1}$): In this case we use the following result presented in Ref. 6:

$$\Delta^k g_{n_1} \doteq \sum_{i=0}^{k} (-1)^{k-i} \binom{k}{i} g_{n_1+i} = \sum_{i=k}^{\infty} \frac{k!}{i!} P(i,k) \Delta^i f_n. \tag{7}$$

Here the coefficients $P(i,k)$ are given by

$$P(i,j) = \sum_{\alpha=j}^{i} \omega^{\alpha} S_i^{\alpha} \mathfrak{S}_{\alpha}^{j}, \tag{8}$$

where ω is the ratio of the increment in the lattice of variable n with respect to that of variable n_1. In this case, taking into account Eq. (6), $\omega = N$. The coefficients S_i^{α} and $\mathfrak{S}_{\alpha}^{j}$ are the Stirling numbers of the first and second kind, respectively.[2] Formula (7) allow us to express a difference of order k in the lattice of variable n_1 in terms of an infinite number of differences on the lattice of variable n. The result (7) can be inverted and we get

$$\Delta^k f_n = \sum_{i=k}^{\infty} \frac{k!}{i!} Q(i,k) \Delta^i g_{n_1}, \tag{9}$$

where the coefficients $Q(i,k)$ are given by (8) with $\omega = N^{-1} = \epsilon$.

To get from Eqs. (7) and (9) a finite approximation of the variation of $g_{n_1} \doteq f_n$ we need to truncate the expansion on the right-hand side (rhs) by requiring a slow varying condition for the function f_n. Let us introduce the following definition.

Definition: The function f_n is a slow varying function of order p iff $\Delta^{p+1} f_n = 0$.

From Sec. II A it follows that a slow varying function of order p is a polynomial of degree p in n. From Eqs. (7) and (9) we see that also the following statement holds.

Theorem: *f_n is a slow varying function of order p iff $\Delta^{p+1} g_{n_1} = 0$, namely g_{n_1}, is of order p.*

Equation (9) provides us with the formulas for f_{n+1} in terms of g_{n_1} and its neighboring points in the case of slow varying functions of any order. Let us write down explicitly these expressions in the case of g_{n_1} of order 1, 2, and 3.

(i) $p=1$. The formula (9) reduces to

$$\Delta f_n = \frac{1}{N} \Delta g_{n_1},$$

i.e., f_{n+1} reads

$$f_{n+1} = g_{n_1} + \frac{1}{N}(g_{n_1+1} - g_{n_1}) + O(N^{-2}).$$

(ii) $p=2$: From Eq. (9) we get

$$\Delta f_n = \frac{1}{N}\Delta g_{n_1} + \frac{1-N}{2N^2}\Delta^2 g_{n_1},$$

and thus f_{n+1} reads

$$f_{n+1} = g_{n_1} + \frac{1}{2N}(-g_{n_1+2} + 4g_{n_1+1} - 3g_{n_1}) + \frac{1}{2N^2}(g_{n_1+2} - 2g_{n_1+1} + g_{n_1}) + O(N^{-3}). \quad (10)$$

(iii) $p=3$: From Eq. (9) we get

$$\Delta f_n = \frac{1}{N}\Delta g_{n_1} + \frac{1-N}{2N^2}\Delta^2 g_{n_1} + \frac{(1-N)(1-2N)}{6N^3}\Delta^3 g_{n_1},$$

and thus f_{n+1} reads

$$f_{n+1} = g_{n_1} + \frac{1}{6N}(2g_{n_1+3} - 9g_{n_1+2} + 13g_{n_1+1} - 6g_{n_1}) + \frac{1}{2N^2}(-g_{n_1+3} + 4g_{n_1+2} - 5g_{n_1+1} + 2g_{n_1})$$
$$+ \frac{1}{6N^3}(g_{n_1+3} - 3g_{n_1+2} + 3g_{n_1+1} - g_{n_1}) + O(N^{-4}).$$

In the next sections we will consider mainly the reduction of integrable discrete equations and we will be interested in obtaining from them integrable discrete equations. It is known[13] that a scalar differential-difference equation can possess higher conservation laws and thus be integrable only if it depends symmetrically on the discrete variable, i.e., if the discrete equation is invariant with respect to the inversion of the lattice index. The results contained in (9) do not provide us with symmetric formulas. To get symmetric formulas we start from Eq. (7) and take into account the following remarks:

(1) Formula (7) holds also if h is negative;
(2) For a slow varying function of order p, we have $\Delta^p f_n = \Delta^p f_{n+\ell}$, for all $\ell \in \mathbb{Z}$.

When f_n is a slow varying function of odd order we are not able to construct completely symmetric derivatives using just an odd number of points centered around the n_1 point and thus $f_{n\pm1}$ can never be expressed in a symmetric form.

Using the above remarks we can construct the symmetric version of (10). From (7) we get

$$g_{n_1+1} = g_{n_1} + N\Delta f_n + \tfrac{1}{2}N(N-1)\Delta^2 f_n, \quad (11)$$

where $\Delta^2 f_n = f_{n+1} - 2f_n + f_{n-1}$ thanks to the remark 2. Using the remark 1 we can also write

$$g_{n_1-1} = g_{n_1} + N\Delta_{-1} f_n + \tfrac{1}{2}N(N-1)\Delta^2 f_n, \quad (12)$$

where $\Delta_{-1} f_n \doteq f_{n-1} - f_n$. From Eqs. (11) and (12) we obtain the following form for f_{n+1}:

$$f_{n+1} = g_{n_1} + \frac{1}{2N}(g_{n_1+1} - g_{n_1-1}) + \frac{1}{2N^2}(g_{n_1+1} - 2g_{n_1} + g_{n_1-1}) + O(N^{-3}). \quad (13)$$

(II) $K=2$ ($f_n = g_{n_1,n_2}$): The derivation of the formulas in this case is done in the same spirit as for the symmetric expansion presented above, see Eq. (13). Let us just consider the case when $p=2$, as this is the lowest value of p for which we can consider f_n as a function of the two scales n_1 and n_2. From Eq. (11) we get

$$g_{n_1+1,n_2} = g_{n_1,n_2} + N\Delta_1 f_{n,n} + \tfrac{1}{2}N(N-1)\Delta_1^2 f_{n,n}, \quad (14)$$

$$g_{n_1,n_2+1} = g_{n_1,n_2} + N^2\Delta_2 f_{n,n} + \tfrac{1}{2}N^2(N^2-1)\Delta_2^2 f_{n,n}. \tag{15}$$

Here the symbols Δ_1 and Δ_2 denote difference operators which acts on the first and, respectively, on the second index of the function $f_{n,n} \doteq g_{n_1,n_2}$, e.g., $\Delta_1 f_{n,n} \doteq f_{n+1,n} - f_{n,n}$ and $\Delta_2 f_{n,n} = f_{n,n+1} - f_{n,n}$.

Let us now consider a function g_{n_1,n_2} where one shifts both indices by 1. From Eq. (14), taking into account that, from Eq. (6), for example, $g_{n_1+1,n_2} = f_{n+N,n}$, one has

$$g_{n_1+1,n_2+1} = g_{n_1,n_2+1} + N\Delta_1 f_{n,n+N^2} + \tfrac{1}{2}N(N-1)\Delta_1^2 f_{n,n+N^2}, \tag{16}$$

and using the result (15) we can write Eq. (16) as

$$\begin{aligned} g_{n_1+1,n_2+1} &= g_{n_1,n_2} + N^2\Delta_2 f_{n,n} + \tfrac{1}{2}N^2(N^2-1)\Delta_2^2 f_{n,n} + N\Delta_1\left[f_{n,n} + N^2\Delta_2 f_{n,n} + \tfrac{1}{2}N^2(N^2-1)\Delta_2^2 f_{n,n}\right] \\ &\quad + \tfrac{1}{2}N(N-1)\Delta_1^2\left[f_{n,n} + N^2\Delta_2 f_{n,n} + \tfrac{1}{2}N^2(N^2-1)\Delta_2^2 f_{n,n}\right] \\ &= g_{n_1,n_2} + N^2\Delta_2 f_{n,n} + \tfrac{1}{2}N^2(N^2-1)\Delta_2^2 f_{n,n} + N\Delta_1 f_{n,n} + N^3\Delta_1\Delta_2 f_{n,n} + \tfrac{1}{2}N^3(N^2-1)\Delta_1\Delta_2^2 f_{n,n} \\ &\quad + \tfrac{1}{2}N(N-1)\Delta_1^2 f_{n,n} + N^3(N-1)\Delta_1^2\Delta_2 f_{n,n} + \tfrac{1}{4}N^3(N^2-1)(N-1)\Delta_1^2\Delta_2^2 f_{n,n}. \end{aligned} \tag{17}$$

As, using the second remark, the second difference of $f_{n,n}$ depends just on its nearest neighboring points, the right-hand side of Eq. (17) depends, apart from $f_{n,n} = g_{n_1,n_2}$, on $f_{n,n+1}$, $f_{n,n-1}$, $f_{n+1,n}$, $f_{n-1,n}$, $f_{n+1,n+1}$, $f_{n+1,n-1}$, $f_{n-1,n+1}$, and $f_{n-1,n-1}$, i.e., eight unknowns. Starting from Eqs. (14), (15), and (17) we can write down eight equations, using the first remark, which defines g_{n_1+1,n_2}, g_{n_1-1,n_2}, g_{n_1,n_2+1}, g_{n_1,n_2-1}, g_{n_1+1,n_2+1}, g_{n_1+1,n_2-1}, g_{n_1-1,n_2+1}, and g_{n_1-1,n_2-1} in terms of the functions $f_{n+i,n+j}$ with $(i,j) = 0, \pm 1$. Inverting this system of equations we get $f_{n\pm1}$ in term of g_{n_1,n_2} and its shifted values:

$$\begin{aligned} f_{n\pm1} &= g_{n_1,n_2} \pm \frac{1}{2N}(g_{n_1+1,n_2} - g_{n_1-1,n_2}) + \frac{1}{2N^2}(g_{n_1+1,n_2} - 2g_{n_1,n_2} + g_{n_1-1,n_2}) \pm \frac{1}{2N^2}(g_{n_1,n_1+1} - g_{n_1,n_2-1}) \\ &\quad + \frac{1}{4N^3}(g_{n_1+1,n_2+1} - g_{n_1-1,n_2+1} - g_{n_1+1,n_2-1} + g_{n_1-1,n_2-1}) + O(N^{-4}). \end{aligned} \tag{18}$$

It is worthwhile to notice that the two lowest order (in N^{-1}) terms of the expansion (18) are just the sum of the first symmetric differences of g_{n_1} and g_{n_2}. Thus in the continuous limit, when we divide by h and send h to zero in such a way that $x = hn$, $x_1 = hn_1$, and $x_2 = hn_2$ be finite, we will have

$$f_{,x} = \epsilon g_{x_1} + \epsilon^2 g_{x_2}.$$

Extra terms appear at the order N^{-3} and contain shifts in both n_1 and n_2.

When f_n is a slow varying function of order 2 in n_1 it can also be of order 1 in n_2. In such a case Eq. (15) is given by

$$g_{n_1,n_2+1} = g_{n_1,n_2} + N\Delta_2 f_{n,n}. \tag{19}$$

Starting from Eqs. (14) and (19) and a modified (17) we can get a set of eight equations which allows us to get $f_{n\pm1}$ in terms of g_{n_1,n_2} and its shifted values. In such a case $f_{n\pm1}$ reads

$$\begin{aligned} f_{n\pm1} &= g_{n_1,n_2} \pm \frac{1}{2N}(g_{n_1+1,n_2} - g_{n_1-1,n_2}) + \frac{1}{N^2}(g_{n_1,n_2\pm1} - g_{n_1,n_2}) + \frac{1}{2N^2}(g_{n_1+1,n_2} - 2g_{n_1,n_2} + g_{n_1-1,n_2}) \\ &\quad + O(N^{-3}). \end{aligned} \tag{20}$$

It is possible to introduce two parameters in the definition of n_1, n_2 in terms of n. Let us define

$$n_1 = \frac{nM_1}{N}, \quad n_2 = \frac{nM_2}{N^2},$$

where M_1 and M_2 are divisors of N and N^2 so that n_1 and n_2 are integers numbers. In such a case, Eq. (18) reads

$$f_{n\pm1} = g_{n_1,n_2} \pm \frac{M_1}{2N}(g_{n_1+1,n_2} - g_{n_1-1,n_2}) + \frac{M_1^2}{2N^2}(g_{n_1+1,n_2} - 2g_{n_1,n_2} + g_{n_1-1,n_2}) \pm \frac{M_2}{2N^2}(g_{n_1,n_2+1} - g_{n_1,n_2-1})$$
$$+ \frac{M_1M_2}{4N^3}(g_{n_1+1,n_2+1} - g_{n_1-1,n_2+1} - g_{n_1+1,n_2-1} + g_{n_1-1,n_2-1}) + O(N^{-4}) \tag{21}$$

and Eq. (20) accordingly.

When we consider partial difference equations we have more than one independent variable. Let us consider the case of two independent lattices and a function $f_{n,m}$ defined on them. As the two lattices are independent the formulas presented above apply independently on each of the lattice variables. So, for instance, the variation $f_{n+1,m}$ when the function $f_{n,m}$ is a slowly varying function of order 2 of a lattice variable n_1 reads

$$f_{n+1,m} = g_{n_1,m} + \frac{1}{2N}(g_{n_1+1,m} - g_{n_1-1,m}) + \frac{1}{2N^2}(g_{n_1+1,m} - 2g_{n_1,m} + g_{n_1-1,m}) + O(N^{-3}). \tag{22}$$

A slightly less obvious situation appears when we consider $f_{n+1,m+1}$, as new terms will appear. We consider here just the case we will need later when

$$n_1 = \frac{M_1 n}{N}, \quad m_1 = \frac{M_2 m}{N}, \quad m_2 = \frac{n}{N^2}. \tag{23}$$

If $f_{n,m}$ is a slow varying function of first order in m_2 and of second order in both n_1 and m_1, from Eqs. (21) and (22) the variation $f_{n+1,m+1}$ reads

$$f_{n+1,m+1} = g_{n_1,m_1,m_2} + \frac{M_1}{2N}(g_{n_1+1,m_1,m_2} - g_{n_1-1,m_1,m_2}) + \frac{M_2}{2N}(g_{n_1,m_1+1,m_2} - g_{n_1,m_1-1,m_2}) + \frac{M_1^2}{2N^2}(g_{n_1+1,m_1,m_2}$$
$$+ g_{n_1-1,m_1,m_2} - 2g_{n_1,m_1,m_2}) + \frac{M_2^2}{2N^2}(g_{n_1,m_1+1,m_2} + g_{n_1,m_1-1,m_2} - 2g_{n_1,m_1,m_2})$$
$$+ \frac{M_1M_2}{4N^2}(g_{n_1+1,m_1+1,m_2} + g_{n_1-1,m_1-1,m_2} - g_{n_1+1,m_1-1,m_2} - g_{n_1-1,m_1+1,m_2}) + \frac{1}{N^2}(g_{n_1,m_1,m_2+1}$$
$$- g_{n_1,m_1,m_2}) + O(N^{-3}).$$

III. MULTISCALE REDUCTION OF NONLINEAR PARTIAL DIFFERENCE EQUATIONS

In the following we will apply the formulas obtained in Sec. II to some well-known partial difference equations. Some of those are known to have a Lax pair and are associated to integrable partial differential equations. Others are concocted so as to have a real dispersion relation but with no particular reason why they should be integrable. The integrable equations we will consider here, the lattice modified KdV (mKdV), presented in Sec. III A, the Hietarinta equation, presented in Sec. III B and the lattice Volterra-Kac-Van Moerbeke (VKVM) equation, presented in Sec. III C, are defined on four lattice points and are PΔEs *consistent around a cube*.[5] From this property one can derive their Lax equation.

The lattice mKdV is an integrable equation of the same class of the lattice potential KdV and KdV (Ref. 3) and it possesses a Lax pair.[10] As from KdV we get by multiscale reduction the NLS,[14] the same we may expect here. To get an integrable discrete equation we expect a resulting

discrete equation which is somehow symmetric. At least when $h_t \to 0$ with $t=mh_t$ the differential difference equation we obtain must be symmetric in terms of the inversion of n_j, i.e., if it contains n_{j+k} it will contain also n_{j-k}.

The nonintegrable KdV equation presented in Sec. III D is obtained by a straightforward discretization using the symmetric representation of the derivatives so as to get a real dispersion relation.

In all the cases considered we will expand the solution of the nonlinear lattice equation around a wave solution of the linear part. In doing so we require that the wave solution be always bounded so that a perturbative expansion with slowly variable coefficients is meaningful. This can be always achieved if the dispersion relation is real. This is always true if the equation can be rewritten in terms of symmetric derivatives. Moreover to get a meaningful reduction we need to have a nontrivial nonlinear dispersion relation.

A. Reduction of the lattice mKdV

The discrete analogue of the modified Korteweg-de Vries (mKdV) equation is given by the following nonlinear PΔE:[10]

$$p(u_{n,m}u_{n,m+1} - u_{n+1,m}u_{n+1,m+1}) - q(u_{n,m}u_{n+1,m} - u_{n,m+1}u_{n+1,m+1}) = 0. \tag{24}$$

This equation involves just four points which lay on two orthogonal infinite lattices and are the vertices of an elementary square. In Eq. (24) $u_{n,m}$ is the dynamical field (real) variable at site $(m,n) \in \mathbb{Z}\times\mathbb{Z}$ and $p,q \in \mathbb{R}$ are the lattice parameters. These are assumed different from zero and will go to zero in the continuous limit so as to get the continuous mKdV.

Carrying out the change of variable $u_{n,m} \mapsto 1+u_{n,m}$, one can separate the linear and nonlinear parts of Eq. (24),

$$\begin{aligned} &p(u_{n,m} + u_{n,m+1} - u_{n+1,m} - u_{n+1,m+1}) - q(u_{n,m} + u_{n+1,m} - u_{n,m+1} - u_{n+1,m+1}) \\ &\quad = q(u_{n,m}u_{n+1,m} - u_{n,m+1}u_{n+1,m+1}) - p(u_{n,m}u_{n,m+1} - u_{n+1,m}u_{n+1,m+1}). \end{aligned} \tag{25}$$

Let us consider the linear part of Eq. (25), namely

$$p(u_{n,m} + u_{n,m+1} - u_{n+1,m} - u_{n+1,m+1}) - q(u_{n,m} + u_{n+1,m} - u_{n,m+1} - u_{n+1,m+1}) = 0. \tag{26}$$

Given any initial condition $u_{n,0}$ the general solution of Eq. (26) is given by

$$u_{n,m} = \frac{1}{2\pi i}\sum_{j=-\infty}^{\infty} u_{j,0} \oint_{|z|=1} \left[\frac{(p-q)-(p+q)z}{(p-q)z-(p+q)}\right]^m z^{n-j-1}\,\mathrm{d}z. \tag{27}$$

Equation (27) can be rewritten in a more natural way (from the continuous point of view) by defining

$$z \doteq e^{ik}, \quad \Omega \doteq e^{-i\omega} = \frac{(p-q)-(p+q)z}{(p-q)z-(p+q)}. \tag{28}$$

In such a case the solution (27) is written as a superposition of linear waves

$$E_{n,m} = e^{i[kn-\omega(k)m]} = z^n\Omega^m. \tag{29}$$

The dispersion relation for these linear waves is given by

$$\omega = -2\arctan\left[\frac{p}{q}\tan\left(\frac{k}{2}\right)\right], \tag{30}$$

the same as for the lattice potential KdV (pKdV) equation.[8] From Eqs. (28) and (30), by differentiation with respect to k, we get the group velocity $\omega_{,k}$,

$$\omega_{,k} = \frac{4pqz}{[(p-q)z-(p+q)][(p+q)z-(p-q)]} = \frac{2pq}{p^2+q^2-(p^2-q^2)\cos k}. \tag{31}$$

The linear part of the PΔE (25), i.e., Eq. (26), is solved in terms of harmonics (29) if ω is given by (30). The nonlinearity will couple the harmonics. This suggests to look for solutions of the PΔE (25) written as a combination of modulated waves,

$$u_{n,m} = \sum_{s=0}^{\infty} \epsilon^{\beta_s} \psi_{n,m}^{(s)} (E_{n,m})^s + \sum_{s=1}^{\infty} \epsilon^{\beta_s} \bar{\psi}_{n,m}^{(s)} (\bar{E}_{n,m})^s, \tag{32}$$

where the functions $\psi_{n,m}^{(s)}$ are slowly varying functions on the lattice, i.e., $\psi_{n,m}^{(s)} = \psi_{n_1,m_1,m_2}^{(s)}$ and $\epsilon^{\gamma} = N^{-1}$. By $\bar{b}$ we mean the complex conjugate of a complex quantity b so that, for example, $\bar{E}_{n,m} = (E_{n,m})^{-1}$. The positive numbers β_s are to be determined in such a way that

(1) $\beta_1 \leqslant \beta_s \ \forall s = 0, 2, 3, \ldots, \infty$. In general it is possible to set $\beta_1 = 1$.
(2) In the equation for $\psi_{n,m}^{(1)} = \psi_{n,m}$, we require that the lowest order nonlinear terms should match the slow time derivative of the linear part after having solved all linear equations. This will provide a relation between γ and the β_s.

The fact that the second summation in Eq. (32) starts from $s=1$ and contains the complex conjugates of the terms of the first summation is due to the reality condition for the solutions of the PΔE (24).

After introducing the expansion (32) in the PΔE (25) and analyzing the coefficients of the various harmonics $(E_{n,m})^s$ for $s=1$, $s=2$, and $s=0$ (as, assuming that β_s increases with s, the nonlinear terms will depend only on the lowest s terms) we came to the conclusion that we can choose

$$\gamma = 1, \quad \beta_0 = 2, \quad \beta_s = s, \quad s \geqslant 1. \tag{33}$$

The discrete slow varying variables n_1, m_1, and m_2 are defined in terms of n and m by Eq. (23).

Having fixed the constants β_s according to Eq. (33) we can introduce the ansatz (32) into Eq. (25) and get the determining equations.

For $s=1$ we get, at lowest order in ϵ,

$$\psi_{n_1,m_1,m_2}[(q-p)(1-z\Omega)-(p+q)(\Omega-z)] = 0,$$

which is identically solved by the dispersion relation (28).

At ϵ^2 we get the linear equation

$$M_1 z[(p-q)\Omega+(p+q)](\psi_{n_1+1,m_1,m_2} - \psi_{n_1-1,m_1,m_2}) + M_2\Omega[(p-q)z-(p+q)](\psi_{n_1,m_1+1,m_2} - \psi_{n_1,m_1-1,m_2}) = 0, \tag{34}$$

whose solution is given by

$$\psi_{n_1,m_1,m_2} = \phi_{n_2,m_2}, \quad n_2 = n_1 - m_1.$$

provided that the integers M_1 and M_2 are chosen as

$$M_1 = S\Omega[(p-q)z-(p+q)], \quad M_2 = Sz[(p-q)\Omega+(p+q)], \tag{35}$$

where $S \in \mathbb{C}$ is a constant; S cannot be completely arbitrary since M_1 and M_2 are to be integer numbers. We will show in Appendix A how it is possible to choose the complex constant S in such a way that M_1 and M_2 are in fact integer numbers as required by Eq. (23). Substituting the expression of Ω given in (28) into Eq. (35), we can rewrite M_1 and M_2 as

$$M_1 = -S[(p+q)z-(p-q)], \quad M_2 = \frac{4pqSz}{[(p+q)-z(p-q)]}. \tag{36}$$

From Eqs. (31) and (36) we get

$$\omega_{,k} = \frac{M_2}{M_1}, \tag{37}$$

i.e., the ratio M_2/M_1 is the group velocity. As M_1 and M_2 are integers, it follows that not all values of k are admissible as $\omega_{,k} \in \mathbb{Q}$. Let us notice that also $n_2 = n_1 + m_1$ solves Eq. (34) by an appropriate choice of M_1 and M_2.

At ϵ^3 we get a nonlinear equation for ϕ_{n_2,m_2} which depends on $\psi^{(2)}_{n_2,m_2}$,

$$\phi_{n_2,m_2+1} - \phi_{n_2,m_2} + c_1(\phi_{n_2+2,m_2} + \phi_{n_2-2,m_2} - 2\phi_{n_2,m_2}) + c_2(\phi_{n_2+1,m_2} + \phi_{n_2-1,m_2} - 2\phi_{n_2,m_2}) + c_3\psi^{(2)}_{n_2,m_2}\bar{\phi}_{n_2,m_2} = 0, \tag{38}$$

where

$$c_1 = pq(p-q)S^2z^2\frac{(p-q)-(p+q)z}{[(p-q)z-(p+q)]^2},$$

$$c_2 = 2pq(p-q)S^2z\frac{(p+q)(1+z^2)-2(p-q)z}{[(p-q)z-(p+q)]^2},$$

$$c_3 = \frac{2pq(p^2-q^2)(1-z^2)^3}{z[(p-q)z-(p+q)]^2[(p+q)z-(p-q)]^2}. \tag{39}$$

Using the form of the complex constant S obtained in Appendix A, the coefficients (39) read

$$c_1 = -\frac{M_2^2(p-q)}{16pq}[(p+q)(\cos k + i\sin k)-(p-q)],$$

$$c_2 = \frac{M_2^2(p-q)}{4pq}[(p+q)\cos k-(p-q)],$$

$$c_3 = i\frac{2pq(p^2-q^2)\sin^3 k}{[(p^2+q^2)-(p^2-q^2)\cos k]^2}. \tag{40}$$

The coefficients (40) depend on the integer constant M_2. The integer M_1 is then written out in terms of M_2 and reads

$$M_1 = M_2\frac{p^2+q^2-(p^2-q^2)\cos k}{2pq},$$

so that not all values of k are admissible as M_1 must be also an integer. See Appendix A for details.

The lowest order equations for the harmonic $s=2$ appear at ϵ^2 and give

$$\psi^{(2)}_{n_2,m_2} = \tfrac{1}{2}(\phi_{n_2,m_2})^2.$$

It is easy to see that the choice (33) implies that the coefficients of all other harmonics are expressed in terms of ϕ_{n_2,m_2} and $\bar{\phi}_{n_2,m_2}$.

Taking these results into account the nonlinear equation PΔE (38) for ϕ_{n_2,m_2} reads

$$i(\phi_{n_2,m_2+1}-\phi_{n_2,m_2})=C_1(\phi_{n_2+2,m_2}+\phi_{n_2-2,m_2}-2\phi_{n_2,m_2})+C_2(\phi_{n_2+1,m_2}+\phi_{n_2-1,m_2}-2\phi_{n_2,m_2})+C_3\phi_{n_2,m_2}|\phi_{n_2,m_2}|^2, \tag{41}$$

where $C_i=-ic_i$, $i=1,2$, $C_3=-ic_3/2$, and the coefficients c_i's are given by Eq. (40). It is easy to see that C_3 is a real coefficient.

The PΔE (41) is a *completely discrete and local* NLS equation depending on the first and second neighboring lattice points. At difference from the Ablowitz and Ladik[1] discrete NLS, the nonlinear term in (41) is completely local. The PΔE (41) has a natural semicontinuous limit when $m_2\to\infty$ as $H_2\to 0$ in such a way that $t_2=m_2\,H_2\in\mathbb{R}$ is finite. Setting $n_2\doteq n$ and $t_2\doteq t$ one gets the following nonlinear differential-difference equation:

$$i\frac{\partial\phi_n}{\partial t}=C_1(\phi_{n+2}+\phi_{n-2}-2\phi_n)+C_2(\phi_{n+1}+\phi_{n-1}-2\phi_n)+C_3\phi_n|\phi_n|^2. \tag{42}$$

The continuous limit of the PΔE (41) is obtained if we consider in Eq. (42) the limit $n\to\infty$ as $H_1\to 0$ in such a way that $x=nH_1\in\mathbb{R}$ is finite. The resulting NLS equation reads

$$i\phi_{,t}=(4C_1+C_2)\phi_{,xx}+C_3\phi|\phi|^2, \tag{43}$$

where

$$4C_1+C_2=-\frac{M_2^2(p^2-q^2)\sin k}{4pq}. \tag{44}$$

As the coefficient (44) is real, Eq. (43) is just the well-known integrable NLS equation.

B. Reduction of the Hietarinta equation

In Ref. 5 Hietarinta introduces a new *consistent around a cube* PΔE,

$$\frac{u_{n,m}+e_2}{u_{n,m}+e_1}\frac{u_{n+1,m+1}+o_2}{u_{n+1,m+1}+o_1}-\frac{u_{n+1,m}+e_2}{u_{n+1,m}+o_1}\frac{u_{n,m+1}+o_2}{u_{n,m+1}+e_1}=0, \tag{45}$$

where the four constants $e_i,o_i\in\mathbb{R}$, $1\leqslant i\leqslant 2$, are lattice parameters.

By a direct calculation one can separate the linear and the nonlinear parts of Eq. (45),

$$\begin{aligned}&o_1o_2(e_1-e_2)u_{n,m}+e_1e_2(o_1-o_2)u_{n+1,m+1}+e_1o_2(e_2-o_1)u_{n+1,m}+e_2o_1(o_2-e_1)u_{n,m+1}\\&=[(o_2-e_1)u_{n+1,m}+(e_2-o_1)u_{n,m+1}]u_{n,m}u_{n+1,m+1}+[(o_1-o_2)u_{n,m}+(e_1-e_2)u_{n+1,m+1}]u_{n+1,m}u_{n,m+1}\\&\quad+[o_1(e_2-o_2)u_{n,m+1}+o_2(o_1-e_1)u_{n+1,m}]u_{n,m}+[e_2(e_1-o_1)u_{n,m+1}+e_1(o_2-e_2)u_{n+1,m}]u_{n+1,m+1}\\&\quad+(o_2e_2-o_1e_1)(u_{n,m}u_{n+1,m+1}-u_{n+1,m}u_{n,m+1}).\end{aligned} \tag{46}$$

Let us now solve the linear part of the PΔE (46),

$$o_1o_2(e_1-e_2)u_{n,m}+e_1e_2(o_1-o_2)u_{n+1,m+1}+e_1o_1(e_2-o_2)u_{n+1,m}+e_2o_2(o_1-e_1)u_{n,m+1}=0. \tag{47}$$

Defining

$$z\doteq e^{ik},\quad \Omega\doteq e^{-i\omega}=\frac{o_2[e_1(e_2-o_1)z+o_1(e_1-e_2)]}{e_2[e_1(o_2-o_1)z+o_1(e_1-o_2)]},$$

the (complex) dispersion relation for these linear waves is given by

$$\omega = 2 \arctan\left\{ \frac{ie_1o_1(o_2 - e_2)\tan(k/2)}{[o_1o_2(e_1 - e_2) + e_1e_2(o_1 - o_2)]\tan(k/2) + ie_2o_2(e_1 - o_1)} \right\}.$$

The dispersion relation is a real function of k if the following condition holds:

$$o_1o_2(e_1 - e_2) + e_1e_2(o_1 - o_2) = 0. \tag{48}$$

To give a meaning to the expansion (32) we must require that the dispersion relation $\omega(k)$ be a real function for k real. From Eq. (48) we can write o_2 in terms of o_1, e_1, e_2, and get

$$\Omega \doteq e^{-i\omega} = \frac{e_1(e_2 - o_1)z + o_1(e_1 - e_2)}{o_1(e_1 - e_2)z + e_1(e_2 - o_1)}, \tag{49}$$

so that the real dispersion relation reads

$$\omega = 2 \arctan\left[\frac{e_2(e_1 + o_1) - 2e_1o_1}{e_2(o_1 - e_1)} \tan\left(\frac{k}{2}\right) \right]. \tag{50}$$

From Eq. (49), by differentiation with respect to k, we get the real group velocity $\omega_{,k}$,

$$\omega_{,k} = \frac{e_2(o_1 - e_1)[2e_1o_1 - e_2(e_1 + o_1)]z}{[e_1(o_1 - e_2)z + o_1(e_2 - e_1)][o_1(e_1 - e_2)z + e_1(e_2 - o_1)]}. \tag{51}$$

The PΔE (47) has a bounded wave solution given by Eq. (29), where Ω is given by Eq. (49). So we can look for solutions of the PΔE (46) in the form of a combination of modulated waves (32), where the functions $\psi^{(s)}_{n,m}$ are slowly varying functions on the lattice, i.e., $\psi^{(s)}_{n,m} = \psi^{(s)}_{n_1,m_1,m_2}$ and $\epsilon^\gamma = N^{-1}$.

Introducing the expansion (32) in the Hietarinta equation (46) and considering the equations for $s=1$, $s=2$, and $s=0$ harmonics we deduce that the choice (33) is still valid. Moreover, the discrete slow varying variables n_1, m_1 and m_2 are defined in terms of n and m by Eq. (23).

Having fixed the constants β_s we can now introduce the ansatz (32) into Eq. (46) and pick out the coefficients of the various harmonics $(E_{n,m})^s$ to get the determining equations.

For $s=1$, having defined $\psi^{(1)}_{n,m} \doteq \psi_{n,m}$, we obtain an equation at the first order in ϵ which is identically solved by the dispersion relation (50).

At ϵ^2 we get the linear equation

$$M_1 z[o_1(e_1 - e_2)\Omega + e_1(o_1 - e_2)](\psi_{n_1+1,m_1,m_2} - \psi_{n_1-1,m_1,m_2}) + M_2\Omega[o_1(e_1 - e_2)z - e_1(o_1 - e_2)] \times (\psi_{n_1,m_1+1,m_2} - \psi_{n_1,m_1-1,m_2}) = 0,$$

whose solution is given by

$$\psi_{n_1,m_1,m_2} = \phi_{n_2,m_2}, \quad n_2 = n_1 - m_1$$

provided that the integers M_1 and M_2 are chosen as

$$M_1 = S\Omega[o_1(e_1 - e_2)z - e_1(o_1 - e_2)], \quad M_2 = Sz[o_1(e_1 - e_2)\Omega + e_1(o_1 - e_2)], \tag{52}$$

where $S \in \mathbb{C}$ is a constant. Inserting Ω given by Eq. (49) in Eq. (52) we can show that the ratio M_2/M_1 coincides with the group velocity (51).

At ϵ^3 we get a nonlinear equation for ϕ_{n_2,m_2} which depends on $\psi^{(0)}_{n_2,m_2}$ and $\psi^{(2)}_{n_2,m_2}$. It reads

$$\phi_{n_2,m_2+1} - \phi_{n_2,m_2} + c_1(\phi_{n_2+2,m_2} + \phi_{n_2-2,m_2} - 2\phi_{n_2,m_2}) + c_2(\phi_{n_2+1,m_2} + \phi_{n_2-1,m_2} - 2\phi_{n_2,m_2}) + c_3\phi_{n_2,m_2}|\phi_{n_2,m_2}|^2 + c_4\psi^{(0)}_{n_2,m_2}\phi_{n_2,m_2} + c_5\psi^{(2)}_{n_2,m_2}\bar{\phi}_{n_2,m_2} = 0, \tag{53}$$

where the coefficients c_i, $1 \leqslant i \leqslant 5$, depend on z, S and the lattice parameters e_1, e_2, o_1 and are given in Appendix B as their expressions are rather complicated.

The functions $\psi^{(0)}_{n_2,m_2}$ and $\psi^{(2)}_{n_2,m_2}$ that appear in Eq. (53) are obtained by considering the equations for the harmonics $s=0$, at the third order in ϵ, and $s=2$ at the second one. From them we get

$$\psi^{(2)}_{n_2,m_2} = p_1(\phi_{n_2,m_2})^2, \tag{54}$$

$$\psi^{(0)}_{n_2+1,m_2} - \psi^{(0)}_{n_2-1,m_2} = p_2[\bar{\phi}_{n_2,m_2}(\phi_{n_2+1,m_2} - \phi_{n_2-1,m_2}) + \phi_{n_2,m_2}(\bar{\phi}_{n_2+1,m_2} - \bar{\phi}_{n_2-1,m_2})], \tag{55}$$

with

$$p_1 = \frac{e_1 z - o_1}{e_1 o_1 (z-1)}, \quad p_2 = \frac{e_1 + o_1}{e_1 o_1}.$$

From Eqs. (54) and (55) we evince that both $\psi^{(0)}_{n_2,m_2}$ and $\psi^{(2)}_{n_2,m_2}$ are expressed in term of ϕ_{n_2,m_2}. In particular, we notice that $\psi^{(2)}_{n_2,m_2}$ depends from ϕ_{n_2,m_2} in a local way while $\psi^{(0)}_{n_2,m_2}$ depends from ϕ_{n_2,m_2} in a nonlocal way through a summation, namely

$$\psi^{(0)}_{n_2,m_2} = (-1)^{n_2}\left[w_1 + p_2 \sum_{j=n_2}^{\infty} (-1)^j (\bar{\phi}_{j,m_2}\phi_{j+1,m_2} + \phi_{j,m_2}\bar{\phi}_{j+1,m_2}) \right] + w_2, \tag{56}$$

where w_1, w_2 are two arbitrary summation constants.

Inserting $\psi^{(2)}_{n_2,m_2}$ given by Eq. (54) in Eq. (53) we get

$$\phi_{n_2 m_2+1} - \phi_{n_2,m_2} + c_1(\phi_{n_2+2,m_2} + \phi_{n_2-2,m_2} - 2\phi_{n_2,m_2}) + c_2(\phi_{n_2+1,m_2} + \phi_{n_2-1,m_2} - 2\phi_{n_2,m_2}) + \hat{c}_3\phi_{n_2,m_2}|\phi_{n_2,m_2}|^2 + c_4\psi^{(0)}_{n_2,m_2}\phi_{n_2,m_2} = 0, \tag{57}$$

where, using the form of the complex constant S, see Appendix A, and the fact that $z \doteq e^{ik}$, the coefficients are

$$c_1 = \frac{P_2[P_1(\cos k + i \sin k) + P_2]}{4(P_2^2 - P_1^2)} M_2^2,$$

$$c_2 = \frac{P_2(P_1 \cos k + P_2)}{P_2^2 - P_1^2} M_2^2,$$

$$\hat{c}_3 = \frac{2(P_1 - P_2)[P_1(e_1 - e_2) + P_2(e_2 - o_1)](\cos k - 1)}{e_2(o_1 e_2 + P_2)(P_1^2 + P_2^2 + 2P_1 P_2 \cos k)},$$

$$c_4 = -\frac{2(P_1 - P_2)(P_1 - e_2^2 + o_1 e_2)(\cos k - 1)}{e_2(P_1^2 + P_2^2 + 2P_1 P_2 \cos k)},$$

with

$$P_1 = e_1(e_2 - o_1), \quad P_2 = o_1(e_1 - e_2).$$

Here M_2 is an arbitrary integer number, while M_1 is given by (see Appendix A)

$$M_1 = M_2 \frac{P_1^2 + P_2^2 + 2P_1P_2 \cos k}{P_2^2 - P_1^2}.$$

C. Reduction of the lattice VKVM equation

The completely discrete version of the Volterra-Kac-Van Moerbeke (VKVM) equation is given by the following PΔE:[10]

$$\frac{u_{n,m+1}}{u_{n+1,m}} = \frac{\alpha u_{n,m} - 1}{\alpha u_{n+1,m+1} - 1}. \tag{58}$$

Here α is a real lattice parameter and $u_{n,m}$ is a real field.

The dispersion relation of the linear part of Eq. (58) is trivial. So, we carry out the change of variable $u_{n,m} \mapsto 1 + u_{n,m}$. Then one can split Eq. (58) into the linear and nonlinear parts:

$$\alpha(u_{n+1,m+1} - u_{n,m}) + (1-\alpha)(u_{n+1,m} - u_{n,m+1}) = \alpha(u_{n,m}u_{n+1,m} - u_{n+1,m+1}u_{n,m+1}). \tag{59}$$

The dispersion relation for the linear waves is given by

$$\Omega = \frac{\alpha(z+1) - z}{\alpha(z+1) - 1}, \quad \omega = \arctan\left[\frac{(2\alpha - 1)\sin k}{(2\alpha^2 - 2\alpha + 1)\cos k + 2\alpha(\alpha - 1)}\right]. \tag{60}$$

From Eq. (60), by differentiation with respect to k, we get the group velocity $\omega_{,k}$,

$$\omega_{,k} = \frac{(2\alpha - 1)z}{[\alpha(z+1) - z][\alpha(z+1) - 1]} = \frac{(2\alpha - 1)}{2\alpha(\alpha - 1)(\cos k + 1) + 1}. \tag{61}$$

We now consider a solution of the PΔE (59) in the form of a combination of modulated waves, see Eq. (32), where $E_{n,m}$ is given by Eq. (29) with Ω as in Eq. (60). As in the previous cases the functions $\psi^{(s)}_{n,m}$ are to be slowly varying functions on the lattice, i.e., $\psi^{(s)}_{n,m} = \psi^{(s)}_{n_1,m_1,m_2}$ and $\epsilon^\gamma = N^{-1}$.

Introducing the expansion (32) in the lattice VKVM equation (59) and considering the equations for $s=1$, $s=2$, and $s=0$ we deduce that the choice (33) is still valid. The discrete slow varying variables n_1, m_1 and m_2 are defined in terms of n and m by the positions (23), where $M_1, M_2 \in \mathbb{Z}$.

For $s=1$ we obtain an equation at the first order in ϵ which is identically solved by the dispersion relation (60).

At ϵ^2 we get a linear equation

$$M_1 z[\alpha(\Omega - 1) + 1](\psi_{n_1+1,m_1,m_2} - \psi_{n_1-1,m_1,m_2}) + M_2 \Omega[\alpha(z+1) - 1](\psi_{n_1,m_1+1,m_2} - \psi_{n_1,m_1-1,m_2}) = 0,$$

whose solution is given by

$$\psi_{n_1,m_1,m_2} = \phi_{n_2,m_2}, \quad n_2 = n_1 - m_1$$

provided that the integers M_1 and M_2 are chosen as

$$M_1 = S\Omega[\alpha(z+1) - 1], \quad M_2 = Sz[\alpha(\Omega - 1) + 1], \tag{62}$$

where $S \in \mathbb{C}$ is a constant. Inserting Ω given by Eq. (60) in Eq. (62) we get that the ratio M_2/M_1 coincides with the group velocity (61). As shown in Appendix A it is possible to choose the complex constant S in such a way that M_1 and M_2 are in fact integer numbers.

At ϵ^3 we get a nonlinear equation for ϕ_{n_2,m_2} which depends on $\psi^{(0)}_{n_2,m_2}$ and $\psi^{(2)}_{n_2,m_2}$. It reads

$$\phi_{n_2,m_2+1} - \phi_{n_2,m_2} + c_1(\phi_{n_2+2,m_2} + \phi_{n_2-2,m_2} - 2\phi_{n_2,m_2}) + c_2(\phi_{n_2+1,m_2} + \phi_{n_2-1,m_2} - 2\phi_{n_2,m_2}) + c_3\psi^{(0)}_{n_2,m_2}\phi_{n_2,m_2} + c_4\psi^{(2)}_{n_2,m_2}\bar{\phi}_{n_2,m_2} = 0, \tag{63}$$

where the coefficients c_i, $1 \leqslant i \leqslant 4$, are

$$c_1 = \alpha S^2 z^2 \frac{(1-2\alpha)[\alpha(z+1)-z]}{4[\alpha(z+1)-1]^2},$$

$$c_2 = \alpha S^2 z \frac{(2\alpha-1)[\alpha(z+1)^2 - z^2 - 1]}{2[\alpha(z+1)-1]^2},$$

$$c_3 = \frac{\alpha(1-z^2)}{[\alpha(z+1)-z][\alpha(z+1)-1]},$$

$$c_4 = \frac{\alpha(1-z^2)(z^2-z+1)}{[\alpha(z+1)-z][\alpha(z+1)-1]z}.$$

The functions $\psi^{(0)}_{n_2,m_2}$ and $\psi^{(2)}_{n_2,m_2}$ that appear in Eq. (63) are obtained by considering the equations for the harmonics $s=0$, at the second order in ϵ, and $s=2$, at the third one. We get the following equations:

$$\psi^{(2)}_{n_2,m_2} = p_1(\phi_{n_2,m_2})^2, \tag{64}$$

$$\psi^{(0)}_{n_2+1,m_2} - \psi^{(0)}_{n_2-1,m_2} = p_2[\bar{\phi}_{n_2,m_2}(\phi_{n_2+1,m_2} - \phi_{n_2-1,m_2}) + \phi_{n_2,m_2}(\bar{\phi}_{n_2+1,m_2} - \bar{\phi}_{n_2-1,m_2})], \tag{65}$$

with

$$p_1 = \frac{(1-2\alpha)z}{\alpha(z+1)^2 - z^2 - 1}, \quad p_2 = \frac{2\alpha(1+z^2) - z^2 - 1}{(1-z^2)(\alpha-1)}.$$

From Eqs. (64) and (65) we evince that both $\psi^{(0)}_{n_2,m_2}$ and $\psi^{(2)}_{n_2,m_2}$ are expressed in term of ϕ_{n_2,m_2}. In particular $\psi^{(0)}_{n_2,m_2}$ admits a nonlocal expansion as in Eq. (56). Inserting $\psi^{(2)}_{n_2,m_2}$ given by Eq. (64) in Eq. (63) we get

$$\phi_{n_2,m_2+1} - \phi_{n_2,m_2} + c_1(\phi_{n_2+2,m_2} + \phi_{n_2-2,m_2} - 2\phi_{n_2,m_2}) + c_2(\phi_{n_2+1,m_2} + \phi_{n_2-1,m_2} - 2\phi_{n_2,m_2}) + c_3\psi^{(0)}_{n_2,m_2}\phi_{n_2,m_2} + \hat{c}_4\phi_{n_2,m_2}|\phi_{n_2,m_2}|^2 = 0, \tag{66}$$

where $\hat{c}_4 = c_4 p_1$.

Let us write the coefficients that appear in Eq. (66), i.e., $c_1, c_2, c_3, \hat{c}_4$, using the form of the complex constant S, see Appendix A, and the fact that $z \doteq e^{ik}$. We get

$$c_1 = -\alpha \frac{(\alpha-1)(\cos k + i \sin k) + \alpha}{4(2\alpha-1)} M_2^2,$$

$$c_2 = \alpha \frac{(\alpha-1)\cos k + \alpha}{2\alpha-1} M_2^2,$$

$$c_3 = -i \frac{2\alpha \sin k}{2\alpha(\alpha-1)(\cos k + 1) + 1},$$

$$\hat{c}_4 = i\frac{(2\cos k - 1)\sin k}{(\alpha - 1)(\cos k - 1)[2\alpha(\alpha - 1)(\cos k + 1) + 1]}.$$

As in the previous cases we can choose the integer number M_2, while M_1 is given by (see Appendix A)

$$M_1 = M_2\frac{2\alpha(\alpha - 1)(\cos k + 1) + 1}{2\alpha - 1}.$$

D. Reduction of a nonintegrable lattice KdV equation

Let us now consider the following nonintegrable lattice KdV equation:

$$u_{n,m+1} - u_{n,m-1} = \frac{\alpha}{4}(u_{n+3,m} - 3u_{n+1,m} + 3u_{n-1,m} - u_{n-3,m}) + \beta[(u_{n+1,m})^2 - (u_{n-1,m})^2], \tag{67}$$

where $\alpha, \beta \in \mathbb{R}$ are the lattice parameters and $u_{n,m}$ is a real field.

As we did for previous cases we apply the standard discrete Fourier transform procedure introducing $u_{n,m} = z^n\Omega^m$ into the linear part of the lattice equation (67). Here $z \doteq e^{ik}$ and $\Omega \doteq e^{-i\omega}$. We easily get

$$\Omega - \Omega^{-1} = \frac{\alpha}{4}(z - z^{-1})^3. \tag{68}$$

Hence the dispersion relation reads

$$\omega = \arcsin(\alpha \sin^3 k)$$

and the corresponding group velocity is

$$\omega_{,k} = -\frac{3}{4}\frac{\alpha\Omega}{1 + \Omega^2}\frac{(z^4 - 1)(z^2 - 1)}{z^3} = \frac{3\alpha\cos k \sin^2 k}{\sqrt{1 - \alpha^2 \sin^6 k}}. \tag{69}$$

Introducing the expansion (32) into the PΔE (67), where $E_{n,m}$ is given by Eq. (29) and taking into account that

$$f_{n\pm k} = g_{n_1} \pm \frac{k}{2N}(g_{n_1+1} - g_{n_1-1}) + \frac{k^2}{4N^2}(g_{n_1+1} + g_{n_1-1} - 2g_{n_1}) + O(N^{-3}),$$

we get the standard choice (33).

Let us consider now the equations for the harmonics $s = 1$. The equation at the order ϵ is identically satisfied by taking into account the dispersion relation (68). The equation at the order ϵ^2 is satisfied if we introduce the index $n_2 = n_1 - m_1$ when M_1 and M_2 are chosen as

$$M_1 = S\left(\Omega + \frac{1}{\Omega}\right), \quad M_2 = -\frac{3}{4}S\alpha\frac{(z^4 - 1)(z^2 - 1)}{z^3}. \tag{70}$$

We notice that the group velocity $\omega_{,k}$ (69) coincides again with the ratio M_2/M_1, as in Eq. (37). From Eq. (70), using the fact that $z \doteq e^{ik}$ and $\Omega \doteq e^{-i\omega}$, we obtain

$$M_1 = -2S\cos\omega, \quad M_2 = -6S\alpha\cos k \sin^2 k.$$

We can now fix the (real) constant S in such a way that M_1 is an integer number; M_2 will be an integer if the group velocity is a rational number. Hence not all values of k are admissible, but only those which make $\omega_{,k}$ (69) rational.

The equation at the order ϵ^3 is given by

$$\phi_{n_2 m_2+1} - \phi_{n_2,m_2} + c_1(\phi_{n_2+1,m_2} + \phi_{n_2-1,m_2} - 2\phi_{n_2,m_2}) + c_2(\phi_{n_2,m_2}\phi^{(0)}_{n_2,m_2} + \bar{\phi}_{n_2,m_2}\phi^{(2)}_{n_2,m_2}) = 0, \tag{71}$$

where $\phi_{n_2,m_2} = \psi_{n_1,m_1,m_2}$, $n_2 = n_1 - m_1$, and c_1, c_2 are known, easy to compute but too complicated to write down, complex coefficients depending on z and on the lattice parameter α. The functions $\psi^{(0)}_{n_2,m_2}$ and $\psi^{(2)}_{n_2,m_2}$ that appear in Eq. (71) are obtained by considering the equations for the harmonics $s=0$, at the third order in ϵ, and $s=2$, at the second one. We get the following equations:

$$\psi^{(2)}_{n_2,m_2} = p_1(\phi_{n_2,m_2})^2, \tag{72}$$

$$\psi^{(0)}_{n_2+1,m_2} - \psi^{(0)}_{n_2-1,m_2} = p_2[\bar{\phi}_{n_2,m_2}(\phi_{n_2+1,m_2} - \phi_{n_2-1,m_2}) + \phi_{n_2,m_2}(\bar{\phi}_{n_2+1,m_2} - \bar{\phi}_{n_2-1,m_2})], \tag{73}$$

where p_1, p_2 are known complex coefficients depending on z and on the lattice parameters. From Eqs. (72) and (73) we evince that both $\psi^{(0)}_{n_2,m_2}$ and $\psi^{(2)}_{n_2,m_2}$ are expressed in term of ϕ_{n_2,m_2}. As in the previous cases $\psi^{(0)}_{n_2,m_2}$ admits a nonlocal expansion as in Eq. (56). Hence the PΔE (71) is a well-defined lattice equation in the field variable ϕ_{n_2,m_2}.

IV. CONCLUSIVE REMARKS

In this paper we have shown that we can construct a well-defined procedure to carry out the reductive perturbation technique on the lattice. In this case, at difference with respect to the differential-difference case, we are able to solve all linear equations and thus can obtain a final nonlinear difference equation. To do so we had to apply some nontrivial but at the end obvious tricks which consist in the introduction of appropriate lattice variables so as to be able to perform the symmetric reduction of the linear discrete wave equation.

Applying the perturbative-reductive technique to some integrable and nonintegrable equations we obtain some new completely discrete NLS equations. As some of these equations (41), (57), and (66) come from the reduction of integrable equations we expect them to be also integrable. However they are very different from the Ablowitz-Ladik discrete-discrete NLS (Ref. 1) as all contains, apart from the nearest neighboring points, also the points $n\pm 2$ and either they are completely local or they have nonlocal completely irregular terms [depending on $(-1)^n$].

So we are at the moment, from one side extending our analysis to other well-known integrable equations, like the discrete time Toda lattice, the sine-Gordon and the Volterra equations and from the other using the integrability properties of the starting nonlinear equations (i.e., Lax pairs or generalized symmetries) to show the integrability of the derived equations. If our equation are integrable than we have presented a very important tool for obtaining new integrable equations and for analyzing the far field behavior of physical problems described by differential-difference or partial difference equations.

In the derivation we introduced the request that the far field expansion of a slow varying function on the lattice should depend on the discrete asymptotic variables in a symmetric way. As a consequence of this ansatz we find that the nonlocal resulting equation depends on $(-1)^n$. This may not be a necessary ansatz and work is in progress in this direction.

APPENDIX A

From Eqs. (35), (52), and (62) we get that the coefficients M_1 and M_2 can always be written in the following general form:

$$M_1 = S\Omega(Pz - Q), \quad M_2 = Sz(P\Omega + Q), \tag{A1}$$

where $S \in \mathbb{C}$ is a suitable constant such that $M_1, M_2 \in \mathbb{Z}$, $\Omega \doteq e^{-i\omega}$, $z \doteq e^{ik}$ and $P, Q \in \mathbb{R}$ are given by

$$P = p - q, \quad Q = p + q, \quad \text{lattice mKdV equation},$$

$$P = o_1(e_1 - e_2), \quad Q = e_1(o_1 - e_2), \quad \text{Hietarinta equation},$$

$$P = \alpha, \quad Q = 1 - \alpha, \quad \text{lattice VKVM equation}.$$

The (real) dispersion relation for the linear parts of the above lattice equations can be written in the form

$$\Omega = \frac{P - Qz}{Pz - Q}. \tag{A2}$$

Let us now define the complex constant S as $S \doteq \rho e^{i\theta}$, with $\rho \in \mathbb{R}_+$ and $-\pi \leqslant \theta < \pi$. From Eqs. (A1) and (A2) we get

$$\mathrm{Re}(M_1) = \rho[P\cos(\theta) - Q\cos(\theta + k)], \tag{A3}$$

$$\mathrm{Im}(M_1) = \rho[P\sin(\theta) - Q\sin(\theta + k)], \tag{A4}$$

$$\mathrm{Re}(M_2) = \frac{\rho(P^2 - Q^2)}{P^2 + Q^2 - 2PQ\cos k}[P\cos(\theta) - Q\cos(\theta + k)], \tag{A5}$$

$$\mathrm{Im}(M_2) = \frac{\rho(P^2 - Q^2)}{P^2 + Q^2 - 2PQ\cos k}[P\sin(\theta) - Q\sin(\theta + k)]. \tag{A6}$$

Since $M_1, M_2 \in \mathbb{Z}$ we must require that $\mathrm{Im}(M_1) = \mathrm{Im}(M_2) = 0$. From Eqs. (A4) and (A6) we obtain

$$\theta = -\arctan\left(\frac{Q\sin k}{Q\cos k - P}\right) + \ell\pi, \quad \ell \in \mathbb{Z}. \tag{A7}$$

We must now require that $M_1 = \mathrm{Re}(M_1)$, $M_2 = \mathrm{Re}(M_2) \in \mathbb{Z}$. According to Eqs. (A3), (A5), and (A7), we get

$$M_1 = (-1)^\ell \rho(P^2 + Q^2 - 2PQ\cos k)^{1/2}, \tag{A8}$$

$$M_2 = (-1)^\ell \rho \frac{(P^2 - Q^2)}{(P^2 + Q^2 - 2PQ\cos k)^{1/2}}. \tag{A9}$$

We can fix arbitrarily the integer number M_2 (or equivalently M_1) and express M_1 (or M_2) in terms of it,

$$M_1 = M_2 \frac{P^2 + Q^2 - 2PQ\cos k}{P^2 - Q^2}. \tag{A10}$$

From (A10) we can see that not all values of k are admissible since M_1 must be integer.

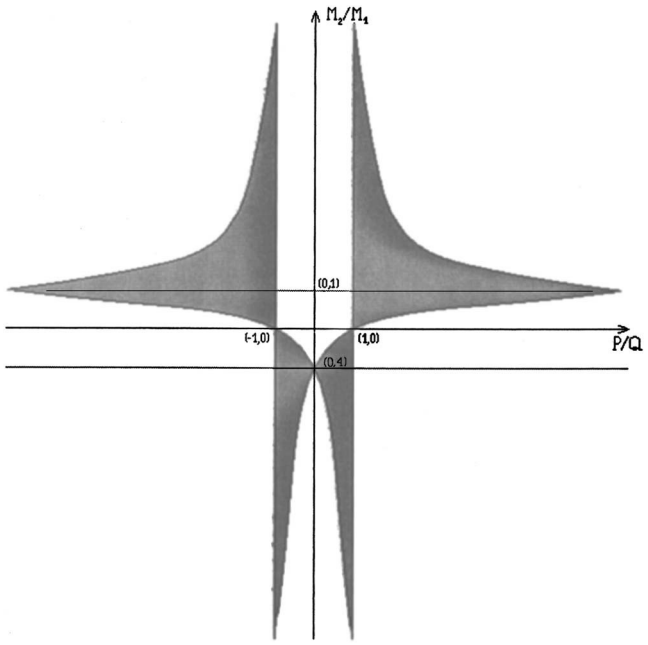

FIG. 1. The grey zones denote the allowed regions for the ratio M_2/M_1 in terms of the ratio P/Q.

Let us finally notice that the fact that Eq. (A10) contains $\cos(k)$ implies that the ratios M_2/M_1 and P/Q are constrained as $-1 \leqslant \cos(k) \leqslant 1$. We have the following cases (see Fig. 1):

$$P/Q \in (1,\infty) \Rightarrow M_2/M_1 \in [(P/Q-1)/(P/Q+1),(P/Q+1)/(P/Q-1)] \in \mathbb{Q},$$

$$P/Q \in (0,1) \Rightarrow M_2/M_1 \in [(P/Q+1)/(P/Q-1),(P/Q-1)/(P/Q+1)] \in \mathbb{Q},$$

$$P/Q \in (-1,0) \Rightarrow M_2/M_1 \in [(P/Q-1)/(P/Q+1),(P/Q+1)/(P/Q-1)] \in \mathbb{Q},$$

$$P/Q \in (-\infty,-1) \Rightarrow M_2/M_1 \in [(P/Q+1)/(P/Q-1),(P/Q-1)/(P/Q+1)] \in \mathbb{Q}.$$

APPENDIX B

The coefficients c_i, $1 \leqslant i \leqslant 5$ that appear in Eq. (53) are

$$c_1 = S^2 z^2 \frac{P_2(P_1^2 - P_2^2)(P_1 z + P_2)}{4(P_1 + P_2 z)^2},$$

$$c_2 = -S^2 z \frac{P_2(P_1^2 - P_2^2)[P_1(1+z^2) + 2P_2 z]}{2(P_1 + P_2 z)^2},$$

$$c_3 = \frac{(z-1)(P_1 - P_2)[Q_1 z^5 + Q_2 z^4 + Q_3 z^3 + Q_4 z^2 + Q_5 z + Q_6]}{e_2(P_1 - e_1 e_2)(P_1 + P_2 z)^2 (P_1 z + P_2)^2 z},$$

$$c_4 = \frac{(z-1)^2(P_1 - P_2)(e_2^2 - e_1 e_2 + P_2)}{e_2(P_2 z + P_1)(P_1 z + P_2)},$$

$$c_5 = \frac{(z-1)^2(P_1 - P_2)[R_1 z^4 + R_2 z^3 + R_3 z + R_4]}{e_2(P_1 + P_2 z)^2(P_1 z + P_2)^2 z},$$

with

$$P_1 = e_1(e_2 - o_1),$$

$$P_2 = o_1(e_1 - e_2),$$

$$Q_1 = P_1 P_2(P_1 e_1 + P_2 e_2),$$

$$Q_2 = P_1^3(e_1 - e_2) + P_2^3(e_2 - o_1) + P_1 P_2(P_2 e_1 + 2P_1 e_2 - P_1 o_1),$$

$$Q_3 = -P_1[P_1^2(e_1 - e_2) + P_2^2(e_1 + 4o_1 - 3e_2) + P_1 P_2(3e_2 - e_1)],$$

$$Q_4 = -P_2[P_1^2(4e_1 - 3e_2 + o_1) + P_2^2(o_1 - e_2) + P_1 P_2(3e_2 - o_1)],$$

$$Q_5 = -P_1^3(e_1 - e_2) - P_2^3(e_2 - o_1) - P_1 P_2(P_2 e_1 - 2P_1 e_2 - P_1 o_1),$$

$$Q_6 = P_1 P_2(P_1 e_2 + P_2 o_1),$$

$$R_1 = P_2[P_1^2 + P_2^2 + P_1 P_2 + P_2(e_2^2 - e_1 e_2)],$$

$$R_2 = P_2^3 + (e_2^2 - e_1 e_2)(P_2^2 - P_1^2) + P_1 P_2(e_2^2 - e_1 e_2 + P_1 + 3P_2),$$

$$R_3 = -P_2^3 - (e_2^2 - e_1 e_2)(P_2^2 - P_1^2) - P_1 P_2(e_2^2 - e_1 e_2 + P_1 + P_2),$$

$$R_4 = P_1(P_1 e_2^2 - P_2^2 - P_1 e_1 e_2).$$

(Received 9 January 2006; accepted 6 March 2006; published online 25 April 2006)

In this paper we reconsider the problem of the Euler parametrization for the unitary groups. After constructing the generic group element in terms of generalized angles, we compute the invariant measure on SU(N) and then we determine the full range of the parameters, using both topological and geometrical methods. In particular, we show that the given parametrization realizes the group SU($N+1$) as a fibration of U(N) over the complex projective space $\mathbb{CP}^n$. This justifies the interpretation of the parameters as generalized Euler angles. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2190898]

I. INTRODUCTION

The importance of group theory in all branches of physics is a well-known fact. Explicit realizations of group representations are often necessary technical tools. Often it is finite dimensional and compact Lie groups and then the knowledge of the associated algebra, which describes the group in a neighborhood of the identity, is enough for this purpose.

There are however cases where an explicit expression of the full global group structure is needed, as, for example, when nonperturbative computations come into play. In most of these cases, the main objectives are two: First, one would like to find a relative simple parametrization, making all the computations manageable. Second, one needs to determine the full range of the parameters, in order to be able to handle global questions.

If both such points can seem unnecessary at an abstract level, they become essential at a most concrete level, e.g., in instantonic calculus or in nonperturbative lattice gauge theory computations. The necessary computer memory for simulations is in fact drastically diminished.

The case of SU(N) was first considered and solved by Tilma and Sudarshan, in Ref. 1. There, they provide a parametrization, in terms of angular parameters, for the unitary groups. In particular, in the first paper they consider special groups, SU(N), together with some applications to qubit and qutrit configurations. In the second paper, they give an extension to U(N) groups, using the fibration structure of SU($N+1$) as U(N) fiber over the complex projective space $\mathbb{CP}^n$.

In this paper we reconsider the problem of finding a generalized Euler parametrization for special unitary groups. The intent is to provide a fully explicit and elementary (which does not mean short) proof of the beautiful results of Ref. 1. Our motivation is that the determination of the range of the parameters is a quite difficult task, so that disagreements are present in the literature

[a)]Electronic mail: bertiste@tiscalinet.it
[b)]Electronic mail: sergio.cacciatori@mi.infn.it
[c)]Electronic mail: blcerchiai@lbl.gov

even for SU(3) (for example, in Ref. 2). Therefore, we think that a careful deduction is necessary in order to corroborate the results of Tilma and Sudarshan. Also, all our proofs based essentially on inductive procedures, and they are explicit, in order to be easily accessible to anyone who needs them.

Our construction is quite different from Ref. 1, and as a result our parametrization differs slightly from theirs. However, this does not affect the final expression of the invariant measure.

To illustrate the spirit of our construction, let us start by taking a look at the Euler parametrization for SU(2).

Starting from the Pauli matrices

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{1.1}$$

it is known that the generic element of SU(2) can be written as

$$g = e^{i\phi\sigma_3} e^{i\theta\sigma_2} e^{i\psi\sigma_3}. \tag{1.2}$$

Here $\phi \in [0,\pi]$, $\theta \in [0,\pi/2]$, $\psi \in [0,2\pi]$ are the so-called Euler angles for SU(2). They are related to the well-known Euler angles traditionally used in classical mechanics to describe the motion of a spin. From the point of view of the structure of the representation, (1.2) is obtained starting from a one parameter subgroup $\exp(i\theta\sigma_2)$ and then acting on it both from the left and from the right with a maximal subgroup of SU(2) which does not contain the first subgroup. We can rewrite it in the schematic form $g=\mathrm{U}(1)\exp(i\theta\sigma_2)\mathrm{U}(1)$. On the other hand, the group SU(2) is topologically equivalent to the three-sphere S^3, and admits a Hopf fibration structure with fiber S^1 over the base $S^2 \simeq \mathbb{CP}^1$.

To recognize this fibration structure in (1.2), we can apply the methods used in Refs. 3 and 4. After introducing the metric $\langle A|B\rangle = \frac{1}{2}\mathrm{Tr}(AB)$ on the algebra, the metric on the group can be computed as $\mathrm{d}s^2 = \frac{1}{2}\,\mathrm{Tr}\, J\otimes J$, where $J=-ig^{-1}\,\mathrm{d}g$ are the left-invariant currents. Following Ref. 3, it is possible to separate the fiber from the base by writing $g=h\mathrm{U}(1)$, where $h=e^{i\phi\sigma_3}e^{i\theta\sigma_2}$ and $\mathrm{U}(1)=e^{i\psi\sigma_3}$. To find the metric on the fiber, let us fix the point on the base and compute the currents along the fiber, $J_F=-i\mathrm{U}(1)^{-1}d\mathrm{U}(1)=\mathrm{d}\psi\sigma_3$. The metric on the fiber is then simply given by $\mathrm{d}s_F^2=\mathrm{d}\psi^2$. To determine the metric on the base, we first must project out from the current $J_B=-ih^{-1}\,\mathrm{d}h$ the component along the fiber, in order to be left with the reduced current on the basis $\tilde{J}_B=\mathrm{d}\psi\sigma_2+\sin(2\psi)\mathrm{d}\psi\,\sigma_1$, which then in turn provides the metric

$$\mathrm{d}s_B^2 = \tfrac{1}{4}[d(2\psi)^2 + \sin^2(2\psi)d(2\phi)^2]. \tag{1.3}$$

This corresponds in fact with the metric of a sphere of radius $\frac{1}{2}$. It is easy to see that, introducing the complex coordinates $z=\tan\psi e^{i\phi}$ and their complex conjugates, the metric $\mathrm{d}s_B^2$ reduces to the standard Fubini-Study metric for $\mathbb{CP}^1$.

This shows that the Euler parametrization captures the Hopf fibration structure of SU(2), which is the starting point for our construction. Mimicking what we said about SU(2), let us write the generic element of SU($N+1$) as $g=\mathrm{U}(N)e(\theta)\mathrm{U}(N)$, where $e(\theta)$ is a one parameter subgroup not contained in U(N). The first difficulty we must face here is that this expression for a generic SU($N+1$) group has redundancies, which must be eliminated. After this problem is solved, we then must show that the parametrization respects the Hopf fibration structure of SU($N+1$).

II. THE SU(N) ALGEBRA

The generators of su(N) are all the $N\times N$ traceless Hermitian matrices. A convenient choice for a base are the generalized Gell-Mann matrices as explained in Ref. 1. Let us remind how they can be constructed using an inductive procedure. Let $\{\lambda_i\}_{i=1}^{N^2-1}$ be the Gell-Mann base for su(N): They are $N\times N$ matrices which can be embedded in su($N+1$) adding a null column and a null row

$$\tilde{\lambda}_i = \begin{pmatrix} \lambda_i & \vec{0} \\ \vec{0} & 0 \end{pmatrix}. \tag{2.1}$$

We will omit the tilde from now on. The dimension of SU(N) being $(N+1)^2-1$, we must add $2N+1$ matrices to obtain a Gell-Mann base for su($N+1$). This can be done as follows: Set

$$\begin{aligned} \{\lambda_{N^2+2a-2}\}_{\alpha\beta} &= \delta_{\alpha,a}\delta_{\beta,N+1} + \delta_{\alpha,N+1}\delta_{\beta,a}, \\ \{\lambda_{N^2+2a-1}\}_{\alpha\beta} &= i(-\delta_{\alpha,a}\delta_{\beta,N+1} + \delta_{\alpha,N+1}\delta_{\beta,a}), \end{aligned} \tag{2.2}$$

for $a=1,\ldots,N$. The last matrix we need is diagonal and traceless so that we can take $\lambda_{(N+1)^2-1} = \epsilon_{N+1}\,\mathrm{diag}\{1,\ldots,1,-N\}$.

One can easily verify that the base of matrices $\{\lambda_I\}_{I=1}^{(N+1)^2-1}$ so obtained satisfies the normalization condition $\mathrm{Trace}\{\lambda_I\lambda_J\}=2\delta_{IJ}$ if we choose $\epsilon_{N+1}=\sqrt{2/[(N+1)^2-(N+1)]}$.

These are exactly the matrices we need to generate the group elements.

III. THE EULER PARAMETRIZATION FOR SU($N+1$): INDUCTIVE CONSTRUCTION

It is a well-known fact that special unitary groups SU($N+1$) can be geometrically understood as U(N) fibration over the complex projective space $\mathbb{CP}^N$. Now U(N) is generated by the first N^2-1 generalized Gell-Mann matrices plus the last one $\lambda_{(N+1)^2-1}$. Using the fact that all the remaining generators of SU($N+1$) can be obtained from the commutators of these matrices with λ_{N^2+1}, one is tempted to write the general element of SU($N+1$) in the form

$$\mathrm{SU}(N+1) = \mathrm{U}(N)e^{ix\lambda_{N^2+1}}\mathrm{U}(N). \tag{3.1}$$

However to describe SU($N+1$) we need $(N+1)^2-1$ parameters, while in the rhs they are $2N^2+1$: There are $(N-1)^2$ redundancies. Inspired at first by dimensional arguments, we propose that an U($N-1$) subgroup can be subtracted from the left U(N) in the following way. Let us write U(N) in the form $\mathrm{U}(N)=\mathrm{SU}(N)e^{i\psi\lambda_{(N+1)^2-1}}$. Inductively, we can think that also SU(N) can be recovered from $\mathrm{U}(N-1)e^{i\phi\lambda_{(N-1)^2+1}}\,\mathrm{U}(N-1)$ eliminating the redundant parameters, so that it will have the form $\mathrm{SU}(N)=he^{i\phi\lambda_{(N-1)^2+1}}\,\mathrm{SU}(N-1)e^{i\theta\lambda_{N^2-1}}$. We then choose to eliminate the appearing SU($N-1$) together with the phase $e^{i\psi\lambda_{(N+1)^2-1}}$. In this way the SU($N+1$) group element can be written in the form $\mathrm{SU}(N+1)=he^{i\phi\lambda_{(N-1)^2+1}}e^{i\theta\lambda_{N^2-1}}e^{ix\lambda_{N^2+1}}\,\mathrm{U}(N)$. By induction, assuming $N\geqslant 2$ we arrive to the final form of our Ansatz about the parametrization of the general element $g \in \mathrm{SU}(N+1)$,

$$g = e^{i\theta_1\lambda_3}e^{i\phi_1\lambda_2}\prod_{a=2}^{N}[e^{i(\theta_a/\epsilon_a)\lambda_{a^2-1}}e^{i\phi_a\lambda_{a^2+1}}]\mathrm{U}(N)[\alpha_1,\ldots,\alpha_{N^2}], \tag{3.2}$$

where $\mathrm{U}(N)[\alpha_1,\ldots,\alpha_{N^2}]$ is a parametrization of U(N) which in turn can be obtained inductively using the fact

$$\mathrm{U}(N) = [\mathrm{SU}(N)\times\mathrm{U}(1)]/\mathbb{Z}_N. \tag{3.3}$$

The Ansatz (3.2) contains the correct number of parameters. However, we need to show that it is a good Ansatz, meaning that at least locally it must generate the whole tangent space to the identity. Using the Backer-Campbell-Hausdorff formula and some properties of the Gell-Mann matrices, (essentially the fact that the commutators of $\lambda_{(k-1)^2+1}$ with the first $(k-1)^2-1$ matrices generate all the remaining matrices of the su(k) algebra but the last one) it is easy to show that

$$e^{i\theta_1\lambda_1}e^{i\phi_1\lambda_3}\prod_{a=2}^{N}\left[e^{i(\theta_a/\epsilon_a)\lambda_{a^2-1}}e^{i\phi_a\lambda_{a^2+1}}\right]=e^{i\sum_{j=1}^{(N+1)^2-2}a_j\lambda_j}, \tag{3.4}$$

where a_j are all nonvanishing functions of the $2N$ parameters θ_a,ϕ_a. Thus in a change of coordinates (from the θ_a,ϕ_a to the a_j) only $2N$ of the a_j can be chosen as independent parameters. We could choose the last ones, corresponding to the coefficients of the matrices $\{\lambda_k\}_{k=N^2}^{N^2+2N-1}$. In this way, the N^2 free parameters for the remaining matrices come out exactly from the U(N) factors in (3.2).

We have not entered into details here because a second simple proof of the validity of this parametrization will be given by constructing a nonsingular invariant measure from our Ansatz.

IV. INVARIANT MEASURE AND THE RANGE OF THE PARAMETERS

A. The invariant measure

To construct the invariant measure for the group starting from (3.2), we will adopt the same method used in Ref. 3, with $U:=\mathrm{U}(N)$ as the fiber group. Let us then write (3.2) as

$$g=h\cdot U. \tag{4.1}$$

Starting from the computation of the left invariant currents $j_h=-ih^{-1}\,\mathrm{d}h$, we can define the one forms

$$e^l:=\tfrac{1}{2}\mathrm{Tr}[j_h\cdot\lambda_{N^2+l-1}],\quad l=1,\ldots,2N, \tag{4.2}$$

which turns out to give the Vielbein one forms of the base space of the fibration. If $\underline{e}$ denotes the corresponding Vielbein matrix, the invariant measure for SU($N+1$) will then take the form

$$\mathrm{d}\mu_{\mathrm{SU}(N+1)}=\det\underline{e}\cdot\mathrm{d}\mu_{U(N)}, \tag{4.3}$$

$\mathrm{d}\mu_{U(N)}$ being the invariant measure for U(N). Using (3.3) with $\mathrm{U}(1)=e^{i(\omega/\epsilon_{N+1})\lambda_{(N+1)^2-1}}$ we obtain the recursion relation (note that here ω is allowed to vary in the range $[0,2\pi/N]$)

$$\mathrm{d}\mu_{\mathrm{SU}(N+1)}=\det\underline{e}\cdot\mathrm{d}\mu_{\mathrm{SU}(N)}\frac{\mathrm{d}\omega}{\epsilon_{N+1}}. \tag{4.4}$$

Then we will concentrate on the $\det\underline{e}$ term. To this end let us write (3.2) in the form

$$g=h_{N+1}[\theta_a,\phi_a]\cdot U[\alpha_i]. \tag{4.5}$$

Here we will consider $N\geqslant 3$ so that the relation

$$h_{N+1}=h_N e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}e^{i\phi_N\lambda_{N^2+1}}, \tag{4.6}$$

is true. If we introduce the right currents $J_{h_{N+1}}=-ih_{N+1}^{-1}\,\mathrm{d}h_{N+1}$ then the Vielbein (4.2) takes the form

$$\begin{aligned}e_l^{\{N\}}&=\frac{1}{2}\mathrm{Tr}\{J_{h_{N+1}}\lambda_l\}=\mathrm{d}\phi_N\delta_{l,N^2+1}+\frac{1}{2\epsilon_N}\mathrm{d}\theta_N\,\mathrm{Tr}\{e^{-i\phi_N\lambda_{N^2+1}}\lambda_{N^2-1}e^{i\phi_N\lambda_{N^2+1}}\lambda_{N^2+l}\}\\&+\frac{1}{2}\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}}J_{h_N}e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}e^{i\phi_N\lambda_{N^2+1}}\lambda_{N^2+l}e^{-i\phi_N\lambda_{N^2+1}}\},\end{aligned} \tag{4.7}$$

and using the relations in Appendix A we find

$$\underline{e}^{\{N\}} = \begin{pmatrix} \mathrm{d}\phi_N & 0 & 0 \\ 0 & \sin\phi_N \cos\phi_N \,\mathrm{d}\theta_N & \sin\phi_N \cos\phi_N \frac{1}{2}\sum_{a=2}^{N} \mathrm{Tr}\left[\frac{1}{\alpha_a} J_{h_N} \lambda_{a^2-1}\right] \\ 0 & 0 & \frac{1}{2}\sin\phi_N \,\mathrm{Tr}[e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}} \underline{M}] \end{pmatrix}, \tag{4.8}$$

where we introduced the $\{N\}$ index to remember that this is a $2N\times 2N$ matrix associated to the group SU$(N+1)$. Here $\underline{M}$ is a column of matrices, $M_{2j-1}=\lambda_{j^2+1}$, $M_{2j}=\lambda_{j^2}$, $j=1,2,\ldots,N-1$. Formula (4.8) then reads as follows: J_{h_N} is a 1-form with components $J_{h_N,c}$, $c=1,2,\ldots,2n-2$, with respects to the coordinates X^c, defined as $X^{2j-1}=\theta_j$, $X^{2j}=\phi_j$. To find the component (r,c) of (4.8) one must then take the cth component of $J_{h_N,c}$ and the rth component of $\underline{M}$ before to compute the trace.

The invariant measure is then

$$\det \underline{e}^{\{N\}} = \mathrm{d}\phi_N \,\mathrm{d}\theta_N \cos\theta_N \sin^{2N-1}\phi_N \det\left(\frac{1}{2}\mathrm{Tr}[e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}} \underline{M}]\right). \tag{4.9}$$

We now use the recurrence relation

$$\begin{aligned} J_{h_N} = {} & \lambda_{(N-1)^2+1}\,\mathrm{d}\phi_{N-1} + \frac{1}{\epsilon_{N-1}} e^{-i\phi_{N-1}\lambda_{(N-1)^2+1}} \lambda_{(N-1)^2-1} e^{i\phi_{N-1}\lambda_{(N-1)^2+1}}\,\mathrm{d}\theta_{N-1} \\ & + e^{-i\phi_{N-1}\lambda_{(N-1)^2+1}} e^{-i(\theta_{N-1}/\epsilon_{N-1})\lambda_{(N-1)^2-1}} J_{h_{N-1}} e^{i(\theta_{N-1}/\epsilon_{N-1})\lambda_{(N-1)^2-1}} e^{i\phi_{N-1}\lambda_{(N-1)^2+1}}. \end{aligned} \tag{4.10}$$

Computing the traces different cases arise depending on whether $j=N-1$ or $j<N-1$; using again the relations in Appendix A it is not too difficult to show that the last determinant is equal to

$$\begin{aligned} & \det\begin{pmatrix} \mathrm{d}\phi_{N-1}\cos(N\theta_N) & -\frac{1}{2}\sin(N\theta_N)\sin(2\phi_{N-1})\mathrm{d}\theta_{N-1} \\ \mathrm{d}\phi_{N-1}\sin(N\theta_N) & \frac{1}{2}\cos(N\theta_N)\sin(2\phi_{N-1})\mathrm{d}\theta_{N-1} \end{pmatrix} \\ & \times \det\left(\frac{1}{2}\cos\phi_{N-1}\,\mathrm{Tr}[e^{-i(\theta_{N-1}/\epsilon_{N-1})\lambda_{(N-1)^2-1}} J_{h_{N-1}} e^{i(\theta_{N-1}/\epsilon_{N-1})\lambda_{(N-1)^2-1}} \underline{M}]\right), \end{aligned}$$

which set into (4.9) in turn yields the recurrence relation

$$\det \underline{e}^{\{N\}} = \mathrm{d}\phi_N \,\mathrm{d}\theta_N \frac{\sin^{2N-1}\phi_N}{\tan^{2N-4}\phi_{N-1}} \det \underline{e}^{\{N-1\}}, \tag{4.11}$$

which can be solved to give

$$\det \underline{e}^{\{N\}} = 2\,\mathrm{d}\theta_N \,\mathrm{d}\phi_N \cos\phi_N \sin^{2N-1}\phi_N \prod_{a=1}^{N-1} [\sin\phi_a \cos^{2a-1}\phi_a \,\mathrm{d}\theta_a \,\mathrm{d}\phi_a]. \tag{4.12}$$

This is the same result as found in Ref. 1.

B. The range of the parameters

At this point we are able to determine the range of the parameters in such a way as to cover the whole group. We will do this only for the base space: The remaining ranges for the fiber can be determined recursively, as discussed above, remembering in particular that the U(1) phase in U(k) can be taken in $[0,2\pi/k]$.

We then proceed as in Ref. 3. We first choose the ranges so as to generate a closed $[(N+1)^2-1]$-dimensional closed manifold which then must wrap around the group manifold of

SU($N+1$) an integer number of times. This can be done by looking at the measure (4.12) on the base manifold and noticing that it is nonsingular when $0<\phi_a<\pi/2$, whereas θ_a can take all the period values $\theta_a \in [0,2\pi]$, for all $a=1,\ldots,N$. However, note that the angles θ_1,ϕ_1,θ_2 generate the whole SU(2) group when $0\leqslant\theta_1\leqslant\pi$, $0<\phi_a<\pi/2$ and $0\leqslant\theta_2\leqslant 2\pi$. We can then restrict $\theta_1 \in [0,\pi]$. The rest of the variety is generated by the remaining U(N) part.

If we call V_{N+1} the manifold obtained this way we then find

$$\begin{aligned}\mathrm{Vol}(V_{N+1}/\mathrm{U}(N)) &= \int_0^{\pi} \mathrm{d}\theta \prod_{a=2}^{N} \int_0^{2\pi} \mathrm{d}\theta_a \prod_{b=1}^{N} \int_0^{\pi/2} \mathrm{d}\phi_b \left\{ \cos\phi_N \sin^{2N-1}\phi_N \prod_{c=1}^{N-1} [\sin\phi_c \cos^{2c-1}\phi_c] \right\} \\ &= \frac{\pi^N}{N!},\end{aligned} \tag{4.13}$$

or equivalently

$$\mathrm{Vol}(V_{N+1}) = \mathrm{Vol}(\mathrm{U}(N))\frac{\pi^N}{N!}. \tag{4.14}$$

This is exactly the recursion relation found in Appendix B. Therefore, it is the correct range of the parameters for every $N\geqslant 2$, if we have $V_3=\mathrm{SU}(3)$, as can be easily checked directly or by comparison with the results given in Appendix A of Ref. 2 (see also Appendix B of Ref. 4). The next step is to determine the parametrization of SU($N+1$) for every value of N. It is given by (3.2) with

$$\begin{gathered}0\leqslant\theta_1\leqslant\pi, \quad 0\leqslant\theta_a\leqslant 2\pi, a=2,\ldots,N, \\ 0\leqslant\omega\leqslant\frac{2\pi}{N}, \quad 0\leqslant\phi_a\leqslant\frac{\pi}{2}, a=1,\ldots,N,\end{gathered} \tag{4.15}$$

and the remaining parameters which cover SU(N) (determined inductively).

To prove that our parametrization is well defined we can do more: We are in fact able to show that the induced metric on the base manifold is exactly the Fubini-Study metric over $\mathbb{CP}^N$.

V. THE GEOMETRIC ANALYSIS OF THE FIBRATION

We will now show that the metric induced on the base space takes exactly the form of the Fubini-Study metric in trigonometric coordinates as given in Appendix C. To do so we will again use inductive arguments.

The metric on the base is $\mathrm{ds}_B^2=[\underline{e}^{\{N\}}]^T\otimes\underline{e}^{\{N\}}$, where T indicates transposition and $\underline{e}^{\{N\}}$ is given in (4.8). Using the relations in Appendix A and defining

$$X_N = \frac{1}{2}\sum_{a=2}^{N} \mathrm{Tr}[J_{h_N}\epsilon_a\lambda_{a^2-1}] \tag{5.1}$$

the metric takes the form

$$\begin{aligned}\mathrm{ds}_B^2 = d^2\phi_N + \sin^2\phi_N \Bigg\{ [\mathrm{d}\theta_N + X_N]^2 + \sum_{j=1}^{N-1} \left[\frac{1}{2}\mathrm{Tr}(e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}) \lambda_{j^2} \right]^2 \\ + \sum_{j=1}^{N-1} \left[\frac{1}{2}\mathrm{Tr}(e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}) \lambda_{j^2+1} \right]^2 \Bigg\} - \sin^4\phi_N [\mathrm{d}\theta_N + X_N]^2.\end{aligned} \tag{5.2}$$

This is an encouraging form, which upon comparison with (C3) suggests the identification $\xi=\phi_N$. With this identification in mind, let us first remark that the following recursion relation holds:

$$X_N = \cos^2 \phi_{N-1}(\mathrm{d}\theta_{N-1} + X_{N-1}), \tag{5.3}$$

which can be shown by inserting (4.10) in (5.1) and then applying (A6) and (A11). A direct computation yields

$$X_3 = \cos^2 \phi_2(\mathrm{d}\theta_2 + \cos(2\phi_1)\mathrm{d}\theta_1), \tag{5.4}$$

from which, through repeated application of the recurrence relation (5.3), we obtain

$$X_N = \sum_{k=1}^{N-3} \left[\prod_{i=1}^{k} \cos^2 \phi_{N-i} \right] \mathrm{d}\theta_{N-k} + \left[\prod_{i=1}^{N-2} \cos^2 \phi_{N-i} \right] (\mathrm{d}\theta_2 + \cos(2\phi_1)\mathrm{d}\theta_1). \tag{5.5}$$

At this point we must to compare $\mathrm{d}\theta_N + X_N$ with the coefficient of $\sin^4 \xi$ in (C3). In fact, to bring $\mathrm{d}\theta_N + X_N$ to the desired form $\Sigma_{i=1}^{N} (\widetilde{R}^i)^2 \, \mathrm{d}\psi_i$, one is tempted to just set $\theta_i = \psi_i$ and $\phi_\mu = \omega_\mu$. However, this cannot be the case because the $\widetilde{R}^i$ does not satisfy the condition $\Sigma(\widetilde{R}^i)^2 = 1$.

These observations, together with explicit calculations for the case $N=4$ and $N=5$, suggest that we should simply take some linear combination $\psi_i = \psi_i(\theta_j)$. This can be done as follows: Let us introduce new variables $\widetilde{\theta}_K$, $k=1, \ldots, N$, such that

$$\begin{gathered} \widetilde{\theta}_N = \theta_N, \quad \theta_{N-k} = \widetilde{\theta}_{N-k} - \widetilde{\theta}_{N-k+1}, \quad k = 1, \ldots, N-3, \\ \theta_1 + \theta_2 = \widetilde{\theta}_1 - \widetilde{\theta}_3, \quad \theta_1 - \theta_2 = \widetilde{\theta}_3 - \widetilde{\theta}_2. \end{gathered} \tag{5.6}$$

In this way $\mathrm{d}\theta_N + X_N$ takes the desired form

$$\mathrm{d}\theta_N + X_N = \sum_{i=1}^{N} (R^i(\omega_\mu))^2 \, \mathrm{d}\psi_i \tag{5.7}$$

with $\omega_\mu = \phi_\mu$, $\mu = 1, \ldots N-1$, $\psi_i = \widetilde{\theta}_{N-i+1}$, $i=1, \ldots, N$ and

$$\begin{gathered} R_1 = \sin \phi_{N-1}, \quad R_k = \sin \phi_{N-k} \prod_{i=1}^{k-1} \cos \phi_{N-i}, \quad k = 2, \ldots, N-1, \\ R_N = \prod_{i=1}^{N-1} \cos \phi_{N-i}. \end{gathered} \tag{5.8}$$

These formulas agree with the expressions in Appendix C. As the last step, in Appendix D we finally show that, after performing the change of variables described above, the coefficients of $\sin^2 \xi$ and $\sin^2 \phi_N$ also agree. This proves that the metric induced on the base $\mathbb{CP}^N$ of the U(N) fibration by the invariant metric on SU($N+1$) is nothing else but the natural Fubini-Study metric in trigonometric coordinates.

We can now use this result as a different method to fix the range of the parameters. In fact, $(R^1, \ldots, R^N)$ parametrize the positive orthant of a sphere, if $0 < \phi_i < \pi/2$, $i=1, \ldots, N-1$. Moreover, the identification of ϕ_N with ξ yields $\phi \in [0, \pi/2]$. Finally, it is easy to show that the conditions $\widetilde{\theta}_i \in [0, 2\pi]$ are equivalent to $\theta_1 \in [0, \pi]$ and $\theta_i \in [0, 2\pi]$, $i=2, \ldots, N$. These are the same results obtained in (4.15).

VI. CONCLUSIONS

In this paper, we have reconsidered the problem of constructing a generalized Euler parametrization for SU(N). The parametrization we find differs slightly from the one described by Tilma and Sudarshan. In fact, comparing our results with the expression (18) in Ref. 1, it is possible to

see that we have chosen $\lambda_{(k-1)^2-1}$ instead of λ_3. Furthermore, we have computed the corresponding invariant measure, which turns out to coincide with the result in Ref. 1, despite the slight differences in the choice of the parametrization.

To determine the range of the parameters, we have used two distinct methods, both yielding the same result. To better motivate the name "Euler angles," we have carefully shown that the parametrization captures the Hopf fibration structure of the SU(N) groups. In particular the change of coordinate we found to evidentiate the fibrations, gives an explicit map between the Euler coordinates introduced starting from the generalized Gell-Mann matrices, and the ones introduced in Ref. 5 using geometrical considerations.

We have given a quite explicit proof of every assertion. Apart from corroborating the results of Tilma and Sudarshan, we think that our work is providing a complete toolbox of computation techniques useful in applied theoretical physics as well as for experimental physicists.

APPENDIX A: SOME COMMUTATORS

Using the explicit form of the generalized Gell-Mann matrices constructed with the conventions of Sec. II, we find the useful commutators

$$\begin{aligned}[\lambda_{N^2+1},\lambda_{N^2+2j}] &= -i\lambda_{j^2},\\ [\lambda_{N^2+1},\lambda_{N^2+2j+1}] &= i\lambda_{j^2+1},\end{aligned} \tag{A1}$$

when $j=1,\ldots,N-1$.

Others interesting relations easy to check are

$$\begin{aligned}[\lambda_{N^2+1},\lambda_{N^2}] &= -i(N+1)\epsilon_{N+1}\lambda_{(N+1)^2-1} - i\sum_{a=2}^{N}\epsilon_a\lambda_{a^2-1},\\ [\lambda_{N^2+1},\lambda_{a^2-1}] &= i\epsilon_a\lambda_{N^2},\\ [\lambda_{N^2+1},\lambda_{(N+1)^2-1}] &= i(N+1)\epsilon_{N+1}\lambda_{N^2},\end{aligned} \tag{A2}$$

where $a=1,\ldots,N$, from which remembering that $\epsilon_k=\sqrt{2/k(k-1)}$, one also finds

$$[\lambda_{N^2+1},[\lambda_{N^2+1},\lambda_{N^2}]] = 4\lambda_{N^2}. \tag{A3}$$

From the first two commutators we find the very useful relations

$$e^{ix\lambda_{N^2+1}}\lambda_{j^2+1}e^{-ix\lambda_{N^2+1}} = \frac{1}{\sin x}\lambda_{N^2+2j+1} - \frac{1}{\tan x}e^{ix\lambda_{N^2+1}}\lambda_{N^2+2j+1}e^{-ix\lambda_{N^2+1}},$$

$$e^{ix\lambda_{N^2+1}}\lambda_{j^2}e^{-ix\lambda_{N^2+1}} = -\frac{1}{\sin x}\lambda_{N^2+2j} + \frac{1}{\tan x}e^{ix\lambda_{N^2+1}}\lambda_{N^2+2j}e^{-ix\lambda_{N^2+1}}, \tag{A4}$$

when $j=1,\ldots,N-1$.

Other useful relations easy to prove using the previous relations are

$$\sum_{a=2}^{N}\epsilon_a^2 + (N+1)^2\epsilon_{N+1}^2 = 4, \tag{A5}$$

$$\sum_{a=2}^{N}\epsilon_a^2 + (N+1)\epsilon_{N+1}^2 = 2, \tag{A6}$$

$$\mathrm{Tr}[e^{-ix\lambda_{N^2+1}}\lambda_{N^2-1}e^{ix\lambda_{N^2+1}}\lambda_{N^2+I}] = \epsilon_N\delta_{I0}\sin(2x), \tag{A7}$$

$$\frac{1}{2}\mathrm{Tr}[\lambda_a e^{ix\lambda_{N^2+1}}\lambda_{N^2+2i}e^{-ix\lambda_{N^2+1}}] = \delta_{a,i^2}\sin x,\ a \leqslant N^2-1,\ i=1,\ldots,N-1, \tag{A8}$$

$$\frac{1}{2}\mathrm{Tr}[\lambda_a e^{ix\lambda_{N^2+1}}\lambda_{N^2+2i-1}e^{-ix\lambda_{N^2+1}}] = -\delta_{a,i^2+1}\sin x,\ a \leqslant N^2-1,\ i=1,\ldots,N-1, \tag{A9}$$

$$\frac{1}{2}\mathrm{Tr}\left[e^{ix\lambda_{N^2+1}}\lambda_{N^2}e^{-ix\lambda_{N^2+1}}\sum_{a=1}^{N^2-1}C^a\lambda_a\right] = \sin(2x)\frac{1}{2}\sum_{b=2}^{N}\mathrm{Tr}[C^{b^2-1}\epsilon_{b^2-1}], \tag{A10}$$

$$\sum_{a=2}^{N}\mathrm{Tr}[Ae^{ix\lambda_{(N-1)^2+1}}\lambda_{a^2-1}e^{-ix\lambda_{(N-1)^2+1}}] = \cos^2 x\sum_{a=2}^{N}\mathrm{Tr}[A\epsilon_a\lambda_{a^2-1}], \tag{A11}$$

$$e^{ix\lambda_{N^2-1}}\lambda_{(N-1)^2}e^{-ix\lambda_{N^2-1}} = \cos(N\epsilon_N x)\lambda_{(N-1)^2} - \sin(N\epsilon_N x)\lambda_{(N-1)^2+1}, \tag{A12}$$

$$e^{ix\lambda_{N^2-1}}\lambda_{(N-1)^2+1}e^{-ix\lambda_{N^2-1}} = \cos(N\epsilon_N x)\lambda_{(N-1)^2+1} + \sin(N\epsilon_N x)\lambda_{(N-1)^2}, \tag{A13}$$

where we used $A := \Sigma_{i=1}^{(N-1)^2-1}A^i\lambda_i$.

APPENDIX B: THE TOTAL VOLUME OF SU(*k*)

The total volume for the groups SU(k) can be found following Macdonald in Ref. 6. First remember that, in the sense of rational cohomology, SU(k) is equivalent to the product of odd dimensional spheres

$$\mathrm{SU}(k+1) \sim \prod_{j=1}^{k} S^{2i+1}, \tag{B1}$$

where we choosen $k+1$ to obtain recursive relations. The total volume of the group is then uniquely determined when a metric is established on the Lie algebra. We chose the metric induced by the scalar product $(A|B)=\frac{1}{2}\mathrm{Tr}(AB)$, for $A,B\in\mathrm{su}(k+1)$. In this way the Gell-Mann generators are orthonormal. The formula for the total volume is (Ref. 6)

$$\mathrm{Vol}(\mathrm{SU}(k+1)) = \prod_{j=1}^{k} \mathrm{Vol}(S^{2i+1}) \cdot \mathrm{Vol}(\mathbb{T}_k) \prod_{\alpha>0} |\alpha^\vee|^2, \tag{B2}$$

where $\alpha^\vee$ are the coroots associated to positive roots and $\mathrm{Vol}(\mathbb{T}_k)$ is the volume of the torus generated by the simple coroots.

For su$(k+1)$ the simple coroots are $s_i = L_i - L_{i+1}$, $i=1,\ldots,k$ where L_i is the diagonal matrix with the only nonvanishing entry $\{L_i\}_{ii}=1$. After writing s_i in terms of λ_j, as

$$s_i = \sum_{a=1}^{k} \frac{1}{2} \mathrm{Tr}\{s_i \lambda_{(a+1)^2-1}\} \lambda_{(a+1)^2-1}, \tag{B3}$$

it is easy to prove the recursive relation

$$\mathrm{Vol}(\mathbb{T}_k) = \sqrt{\frac{k+1}{2k}} \mathrm{Vol}(\mathbb{T}_{k-1}). \tag{B4}$$

From this we find

$$\mathrm{Vol}(\mathrm{SU}(k+1)) = \mathrm{Vol}(\mathrm{SU}(k)) 2 \frac{\pi^{k+1}}{k!} \sqrt{\frac{k+1}{2k}}, \tag{B5}$$

where we used the fact that all the positive coroots have unitary length. If we note that the phase $e^{i(\theta_k/\epsilon_k)\lambda_{(k+1)^2-1}}$ generates a U(1) group of volume $2\pi\sqrt{k(k+1)/2}$ and that $\mathrm{U}(k) = [\mathrm{SU}(k) \times \mathrm{U}(1)]/Z_k$, we can finally write

$$\mathrm{Vol}(\mathrm{SU}(k+1)) = \mathrm{Vol}(\mathrm{U}(k)) \frac{\pi^k}{k!}, \tag{B6}$$

APPENDIX C: THE FUBINI-STUDY METRIC FOR $\mathbb{CP}^N$

$\mathbb{CP}^N$ is a Kähler manifold of complex dimension N. In a local chart, which uses holomorphic inhomogeneous coordinates $\{z^i\}_{i=1}^N \in \mathbb{C}$, the Kähler potential is $K(z^i, \overline{z^j}) = k/2 \log(1+\Sigma_{i=1}^N |z^i|^2)$ with k a constant. The associated Kähler metric $g_{i\bar{j}} = \partial^2 K / \partial z^i \partial \overline{z^j}$ is then

$$\mathrm{d}s^2_{\mathbb{CP}^N} = k \left(\frac{\sum_{i=1}^N \mathrm{d}z^i \, \mathrm{d}\overline{z^i}}{1+\sum_{i=1}^N |z^i|^2} - \frac{\sum_{i,j=1}^N z^i \, \mathrm{d}\overline{z^i} \, \overline{z^j} \, \mathrm{d}z^j}{(1+\sum_{i=1}^N |z^i|^2)^2} \right). \tag{C1}$$

Notice that obviously it is not possible to cover the whole space with a single chart, but the set of points which cannot be covered has vanishing measure. For our purpose it is therefore enough to consider a single chart.

Let us now search for a trigonometric coordinatization. To this aim let us introduce the new real coordinates ξ, ω_μ, ψ_i, $\mu=1,\ldots,N-1$, $i=1,\ldots,N$, such that

$$z^i = \tan \xi R^i(\omega_\mu) e^{i\psi_i}. \tag{C2}$$

Here $R^i(\omega_\mu)$ is a parametrization of the unit sphere S^{n-1}, construced as an immersion in $\mathbb{R}^N$, where $\Sigma_{i=1}^N (R^i)^2 = 1$ and ω_μ are the angles of the sphere. However, notice that we are restricted to the positive orthant only: $R_i > 0$. If ω_μ are the standard angles (starting, for example, with the azimuthal one ω_1), then $\omega_\mu \in [0, \pi/2]$, $\xi \in [0, \pi/2]$, and $\psi_i \in [0, 2\pi]$. This choice of coordinates finally gives

$$ds^2_{\mathbb{C}P^N} = d\xi^2 + \sin^2\xi\left[\sum_{i=1}^{N} dR^i\, dR^i + \sum_{i=1}^{N} (R^i)^2 d^2\psi_i\right] - \sin^4\xi\left[\sum_{i=1}^{N} (R^i)^2\, d\psi_i\right]^2. \tag{C3}$$

In particular notice that the coefficient of $\sin^2\xi$ yields a metric for (the positive orthant of) the sphere S^{N-1}.

APPENDIX D: FINAL CHECKS

Here we verify that the change of variables introduced in Sec. V transforms the terms

$$[d\theta_N + X_N]^2 + \sum_{j=1}^{N-1}\left[\frac{1}{2}\mathrm{Tr}(e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}})\lambda_{j^2}\right]^2 + \sum_{j=1}^{N-1}\left[\frac{1}{2}\mathrm{Tr}(e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}})\lambda_{j^2+1}\right]^2, \tag{D1}$$

into the coefficient of $\sin^2\xi$ in (C3).

First, using (4.10) and the relations in Appendix A, it is possible to show that

$$\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}\lambda_{j^2}\} = \cos\phi_{N-1}\,\mathrm{Tr}\{e^{-i(\theta_{N-1}/\epsilon_{N-1})\lambda_{(N-1)^2-1}} J_{h_{N-1}} e^{i(\theta_{N-1}/\epsilon_{N-1})\lambda_{(N^2-1)-1}}\lambda_{j^2}\}, \quad j < N-1,$$

$$\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}\lambda_{j^2+1}\} = \cos\phi_{N-1}\mathrm{Tr}\{e^{-i(\theta_{N-1}/\epsilon_{N-1})\lambda_{(N-1)^2-1}} J_{h_{N-1}} e^{i(\theta_{N-1}/\epsilon_{N-1})\lambda_{(N-1)^2-1}}\lambda_{j^2+1}\}, \quad j < N-1,$$

$$\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}\lambda_{(N-1)^2}\} = \sin(2\phi_{N-1})\cos(N\theta_N)[d\theta_{N-1} + X_{N-1}] - 2\sin(N\theta_N)d\phi_{N-1},$$

$$\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}\lambda_{(N-1)^2+1}\} = \sin(2\phi_{N-1})\sin(N\theta_N)[d\theta_{N-1} + X_{N-1}] + 2\cos(N\theta_N)d\phi_{N-1}. \tag{D2}$$

Note that these are true for $N \geqslant 3$, if we define $X_2 := \cos(2\phi_1)d\theta_1$. From these relations we find

$$\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}\lambda_{j^2}\} = \left[\prod_{k=j+1}^{N-1}\cos\phi_k\right][\sin(2\phi_j)\cos[(j+1)\theta_{j+1}](d\theta_j + X_j) - 2\sin[(j+1)\theta_{j+1}]d\phi_j],$$

$$\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}\lambda_{j^2+1}\} = \left[\prod_{k=j+1}^{N-1}\cos\phi_k\right][\sin(2\phi_j)\sin[(j+1)\theta_{j+1}](d\theta_j + X_j) + 2\cos[(j+1)\theta_{j+1}]d\phi_j],$$

with $j = 2, \ldots, N-1$. For $j = 1$,

$$\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}} J_{h_N} e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}\lambda_1\} = \left[\prod_{k=2}^{N-1}\cos\phi_k\right][\sin(2\phi_1)\cos(2\theta_2)d\theta_1 - \sin(2\theta_2)d\phi_1],$$

$$\mathrm{Tr}\{e^{-i(\theta_N/\epsilon_N)\lambda_{N^2-1}}J_{h_N}e^{i(\theta_N/\epsilon_N)\lambda_{N^2-1}}\lambda_2\} = \left[\prod_{k=2}^{N-1}\cos\phi_k\right][\sin(2\phi_1)\sin(2\theta_2)\mathrm{d}\theta_1 + \cos(2\theta_2)\mathrm{d}\phi_1].$$

Thus we see that (D2) takes the form $S_N + U_N$, where

$$S_N = \mathrm{d}\phi_{N-1}^2 + \sum_{j=1}^{N-2}\left[\prod_{k=j+1}^{N-1}\cos^2\phi_k\right]\mathrm{d}\phi_j^2, \tag{D3}$$

$$U_N = (\mathrm{d}\theta_N + X_N)^2 + \sum_{j=2}^{N-1}\sin^2\phi_j\left[\prod_{k=j}^{N-1}\cos^2\phi_k\right](\mathrm{d}\theta_j + X_j)^2 + \prod_{k=2}^{N-1}\cos^2\phi_k\sin^2(2\phi_1)\mathrm{d}\theta_1^2. \tag{D4}$$

First, we show that

$$S_N = \sum_{j=1}^{N}\mathrm{d}R^j\mathrm{d}R^j, \tag{D5}$$

with R^j as in (5.8). To this aim let us define the N-dimensional vector $\vec{R}_N = (R^1, \ldots, R^N)$. Such a vector has unit length, and satisfies the recurrence relation $\vec{R}_N = (\sin\phi_{N-1}, \cos\phi_{N-1}\vec{R}_{N-1})$, from which we find

$$\mathrm{d}\vec{R}_N \cdot \mathrm{d}\vec{R}_N = \mathrm{d}\phi_{N-1}^2 + \cos^2\phi_{N-1}\,\mathrm{d}\vec{R}_{N-1}\cdot\mathrm{d}\vec{R}_{N-1}. \tag{D6}$$

Here the dot indicates the scalar product in N dimensions. Now, from (D3), we also have

$$S_N = \mathrm{d}\phi_{N-1}^2 + \cos^2\phi_{N-1}S_{N-1}. \tag{D7}$$

As S_N and $\mathrm{d}\vec{R}_N\cdot\mathrm{d}\vec{R}_N$ both satisfy the same recurrence relation, the thesis follows because of $S_2 = \mathrm{d}\vec{R}_2\cdot\mathrm{d}\vec{R}_2$.

The second and last step of our proof consists in showing that after the change of coordinates (5.6) the Eq. (D4) takes the form

$$U_N = \sum_{i=1}^{N}(R^i)^2\mathrm{d}\psi_i^2. \tag{D8}$$

The structure of (D4) suggests that it is convenient to make the change of variables starting from θ_N and θ_{N-1} step by step. Note that X_{N-1} is invariant under this transformation, so that we have

$$(\mathrm{d}\theta_N + X_N)^2 + \sin^2\phi_{N-1}\cos^2\phi_{N-1}(\mathrm{d}\theta_{N-1} + X_{N-1})^2 = \sin^2\phi_{N-1}\mathrm{d}\tilde{\theta}_N^2 + \cos^2\phi_{N-1}(\mathrm{d}\tilde{\theta}_{N-1} + X_{N-1})^2. \tag{D9}$$

Here we have used (5.3) to express X_N in terms of X_{N-1}. Then U_N takes the form

$$U_N = \sin^2\phi_{N-1}\mathrm{d}\tilde{\theta}_N^2 + \cos^2\phi_{N-1}[(\mathrm{d}\tilde{\theta}_{N-1} + X_{N-1})^2 + \sin^2\phi_{N-2}\cos^2\phi_{N-2}(\mathrm{d}\theta_{N-2} + X_{N-2})^2] + \cdots. \tag{D10}$$

Now it is possible to use (D9) with $N-1$ in place of N in order to write θ_{N-2} in terms of $\tilde{\theta}_{N-2}$. In fact, this relation can be applied recursively up to $\mathrm{d}\theta_3$, obtaining

$$U_N = \sin^2\phi_{N-1}\,\mathrm{d}\tilde{\theta}_N^2 + \sum_{j=2}^{N-4}\sin^2\phi_{N-j}\left[\prod_{l=N-j+1}^{N-1}\cos^2\phi_l\right]\mathrm{d}\tilde{\theta}_{N-j+1}^2 + \left[\prod_{l=3}^{N-1}\cos^2\phi_l\right](\mathrm{d}\tilde{\theta}_3 + X_3)^2$$
$$+ \sin^2\phi_2\left[\prod_{k=2}^{N-1}\cos^2\phi_k\right](\mathrm{d}\theta_2 + \cos(2\phi_1)\mathrm{d}\theta_1)^2 + \left[\prod_{k=2}^{N-1}\cos^2\phi_k\right]\sin^2(2\phi_1)\theta_1^2. \tag{D11}$$

At this point we can perform the last two changes of coordinates in (5.6), to show that

$$\mathrm{d}\tilde{\theta}_3 + X_3 = \sin^2\phi_2\,\mathrm{d}\tilde{\theta}_3 + \cos^2\phi_2(\sin^2\phi_1\tilde{\theta}_2 + \cos^2\phi_1\,d\tilde{\theta}_1), \tag{D12}$$

and this completes the proof.

(Received 7 February 2006; accepted 13 February 2006; published online 25 April 2006)

A class of two-dimensional superintegrable systems on a constant curvature surface is considered as the natural generalization of some well known one-dimensional factorized systems. By using standard methods to find the shape-invariant intertwining operators we arrive at a so(6) dynamical algebra and its Hamiltonian hierarchies. We pay attention to those associated to certain unitary irreducible representations that can be displayed by means of three-dimensional polyhedral lattices. We also discuss the role of superpotentials in this new context. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2191360]

I. INTRODUCTION

This work deals with a class of superintegrable Hamiltonian systems, in the framework of the Schrödinger equation of quantum mechanics, and its connections with the factorization method. We will restrict ourselves to a particular case where the underlying symmetry is the Lie algebra u(3), but its main features can be directly implemented to higher dimensional systems.

The main objective of this study is to show a natural extension to higher dimensional spaces of the intertwining (or Darboux) transformations from a well known class of one-dimensional factorized systems. In fact, we want to set the higher rank u(n) systems corresponding to those having as dynamical algebra the Lie algebra u(2). We will show in detail that the application of procedures familiar in one dimension to a concrete two-dimensional system will lead us to a wide set of operators closing a dynamical Lie algebra. We also consider discrete symmetry operators quite important to perform equivalences. All these operators connect eigenstates that can be drawn as points in a three-dimensional lattice giving rise to polyhedrons representing degenerate series of u(3) irreducible representations. Each of these series corresponds to the same energy and can be embedded in just one representation of the Lie algebra so(6).

The notion of superpotential will also be re-examined inside the higher rank formalism. Thus, the usual procedure to look for solutions with separable variables can be better appreciated under this point of view.

Thus, we try to implement the program of generalization of the factorizable one-dimensional systems involving Lie algebras of rank one as dynamical algebras, as can be seen, for instance, in the classical paper by Infeld and Hull.[1] We also hope that this work will be useful when dealing with other integrable systems, but not necessarily maximally integrable, for instance not enjoing so many factorizations, or even not having a system of separable variables, but still allowing for algebraic methods.[2–7]

The organization of this article is as follows. In Sec. II we will introduce a two-dimensional superintegrable system and find some separable solutions by standard procedures. Although these polynomial solutions are known and can be found in other references, this will serve us to recall some aspects of the usual factorization technique and to specify the operators of the Lie algebra u(2) related with the Lie algebra so(4), and their support spaces. Next, in Sec. III, we will look for other sets of intertwining operators, corresponding to the Lie algebras u(3) and so(6), taking also into account discrete symmetries. We characterize the eigenfunctions belonging to irreducible representations that will be depicted as the points on octahedrons and the interpretation of some of its planar sections. The analog of the superpotentials and their relation with certain types of solutions will be considered in Sec. IV. Some conclusions and perspective for future work will close the article.

II. A SUPERINTEGRABLE u(3)-HAMILTONIAN SYSTEM

We will fix our attention on a superintegrable Hamiltonian system defined inside a three-dimensional Euclidean ambient space.[8–11] In fact, our system lives on the two-sphere $\mathcal{S}$

$$\mathcal{S} \equiv (s_0)^2 + (s_1)^2 + (s_2)^2 = 1, \quad (s_0, s_1, s_2) \in \mathbb{R}^3.$$

In the frame of the Schrödinger equation, this Hamiltonian takes the form

$$H = -(J_0^2 + J_1^2 + J_2^2) + \frac{l_0^2 - 1/4}{(s_0)^2} + \frac{l_1^2 - 1/4}{(s_1)^2} + \frac{l_2^2 - 1/4}{(s_2)^2}, \tag{2.1}$$

where $(l_0, l_1, l_2) \in \mathbb{R}^3$, and $J_i = -\epsilon_{ijk} s_j \partial_k$ [note that the J_i's operators generate the rotation Lie algebra so(3)]. We can parameterize $\mathcal{S}$ by means of spherical coordinates (ϕ_1, ϕ_2) around the s_2 axis given by

$$s_0 = \cos\phi_2 \cos\phi_1, \quad s_1 = \cos\phi_2 \sin\phi_1, \quad s_2 = \sin\phi_2. \tag{2.2}$$

Then, the eigenvalue problem

$$H\Phi = E\Phi$$

after substituting the coordinates (2.2), takes the form of a separable differential equation

$$\left[-\partial_{\phi_2}^2 + \tan\phi_2 \partial_{\phi_2} + \frac{l_2^2 - 1/4}{\sin^2\phi_2} + \frac{1}{\cos^2\phi_2} \left[-\partial_{\phi_1}^2 + \frac{l_0^2 - 1/4}{\cos^2\phi_1} + \frac{l_1^2 - 1/4}{\sin^2\phi_1} \right] \right] \Phi = E\Phi. \tag{2.3}$$

The solutions separated in the variables ϕ_1 and ϕ_2, i.e.

$$\mathbf{\Phi}(\phi_1, \phi_2) = f(\phi_1) g(\phi_2)$$

after replacing in (2.3) originate the equations

$$\left[-\partial_{\phi_1}^2 + \frac{l_0^2 - 1/4}{\cos^2\phi_1} + \frac{l_1^2 - 1/4}{\sin^2\phi_1} \right] f(\phi_1) = \alpha f(\phi_1), \tag{2.4}$$

$$\left[-\partial_{\phi_2}^2 + \tan\phi_2 \partial_{\phi_2} + \frac{\alpha}{\cos^2\phi_2} + \frac{l_2^2 - 1/4}{\sin^2\phi_2} \right] g(\phi_2) = E g(\phi_2), \tag{2.5}$$

where α is a separating constant. Next we will solve each of these two equations through standard factorizations giving rise to polynomials. The key point is that the results obtained for the first equation will match in a certain way with those of the second one originating degenerate levels.

A. The ϕ_1 factorization

The one-dimensional Hamiltonian (2.4) in the variable ϕ_1 is a well known example in the theory of factorizations.[1] So, in the following we will restrict ourselves to give a list of the relevant results. We will see later, in Sec. III, how to make use of these considerations in a broader context.

The second order operator at the left-hand side of Eq. (2.4) can be cast as a product of first order operators

$$H^{\phi_1}_{(0)} = A^+_0 A^-_0 + \lambda_0$$

being

$$A^\pm_0 = \pm \partial_{\phi_1} - (l_0 + 1/2)\tan\phi_1 + (l_1 + 1/2)\cot\phi_1, \quad \lambda_0 = (l_0 + l_1 + 1)^2.$$

These elements are part of a family of operators $\{A^+_m, A^-_m, \lambda_m, H^{\phi_1}_{(m)}\}$, $m \in \mathbb{Z}$, where

$$A^\pm_m = \pm \partial_{\phi_1} - (l_0 + m + 1/2)\tan\phi_1 + (l_1 + m + 1/2)\cot\phi_1, \tag{2.6}$$

$$\lambda_m = (l_0 + l_1 + 2m + 1)^2,$$

$$H^{\phi_1}_{(m)} = -\partial^2_{\phi_1} + \frac{(l_0 + m)^2 - 1/4}{\cos^2\phi_1} + \frac{(l_1 + m)^2 - 1/4}{\sin^2\phi_1}. \tag{2.7}$$

They originate the one-dimensional Hamiltonian hierarchy (2.7), starting from $H^{\phi_1}_{(0)}$. The Hamiltonians $H^{\phi_1}_{(m)}$ satisfy the fundamental relation

$$H^{\phi_1}_{(m)} = A^+_m A^-_m + \lambda_m = A^-_{m-1} A^+_{m-1} + \lambda_{m-1} \tag{2.8}$$

so that $A^\pm_m$ are shape invariant intertwining operators, i.e.,

$$A^-_m H^{\phi_1}_{(m)} = H^{\phi_1}_{(m+1)} A^-_m, \quad A^+_m H^{\phi_1}_{(m+1)} = H^{\phi_1}_{(m)} A^+_m. \tag{2.9}$$

Hence, from a formal point of view, the operators $A^\pm_m$ acting on a Hamiltonian eigenfunction will give another eigenfunction of a consecutive Hamiltonian in the hierarchy with the same eigenvalue. If we design the eigenfunction spaces of $H^{\phi_1}_{(m)}$ (as differential operators) by $\mathcal{H}^{\phi_1}_m$, then we have

$$A^-_m : \mathcal{H}^{\phi_1}_m \to \mathcal{H}^{\phi_1}_{m+1}, \quad A^+_m : \mathcal{H}^{\phi_1}_{m+1} \to \mathcal{H}^{\phi_1}_m.$$

In principle, the discrete spectrum and the physical eigenstates of $H^{\phi_1}_{(0)}$ could be obtained from the fundamental states $f^0_{(m)}$ and their eigenvalues of all the Hamiltonians in the hierarchy $\{H^{\phi_1}_{(m)}\}$. These fundamental states are determined by $A^-_m f^0_{(m)} = 0$, giving the solutions (up to a normalization constant)

$$f^0_{(m)}(\phi_1) = \cos^{l_0+m+1/2}\phi_1 \, \sin^{l_1+m+1/2}\phi_1$$

with eigenvalues $\lambda_m = (l_0 + l_1 + 2m + 1)^2$. Often the intertwining operators (2.6) are written in the form

$$A^\pm_m = \pm \partial_{\phi_1} + \omega_m(\phi_1), \quad \omega_m(\phi_1) = \frac{\partial_{\phi_1} f^0_{(m)}(\phi_1)}{f^0_{(m)}(\phi_1)}, \tag{2.10}$$

where $\omega_m(\phi_1)$ is called superpotential function.

In order to go from the ground eigenstate, $f^0_{(m)}$ of $H^{\phi_1}_{(m)}$, up to the excited eigenfunction, $f^m_{(0)}$ of $H^{\phi_1}_{(0)}$, with the same eigenvalue, we apply consecutive operators A^+

$$f^m_{(0)} = A^+_0 A^+_1 \cdots A^+_{m-1} f^0_{(m)} \tag{2.11}$$

obtaining explicitly

$$f^m_{(0)} = N \sin^{l_1+1/2} \phi_1 \cos^{l_0+1/2} \phi_1 P^{(l_1,l_0)}_m(\cos(2\phi_1)), \tag{2.12}$$

where $P^{(a,b)}_n(x)$ are Jacobi polynomials and N is a normalization constant. Therefore, the spectrum of the first separating Hamiltonian (2.4) is given by

$$\alpha = \lambda_m = (l_0 + l_1 + 2m + 1)^2, \quad m \in \mathbb{Z}^+. \tag{2.13}$$

The following two subsections are devoted to characterize the Lie algebras of shape invariant intertwining operators for the one-dimensional Hamiltonian hierarchies. They will constitute a useful pattern for the two-dimensional Hamiltonians of Sec. III.

B. The dynamical algebra u(2)

Starting from the operators $A^\pm_m$ let us define free-index operators $A^\pm$ acting inside the total space $\oplus_m \mathcal{H}_m$, in the following way:[12,13]

$$\begin{aligned} A^+ f_{(m+1)} &:= \tfrac{1}{2} A^+_m f_{(m+1)} \propto \tilde{f}_{(m)}, \\ A^- f_{(m)} &:= \tfrac{1}{2} A^-_m f_{(m)} \propto \tilde{f}_{(m+1)}, \\ A f_{(m)} &:= -\tfrac{1}{2}(l_0 + l_1 + 2m) f_{(m)} \propto f_{(m)}, \end{aligned} \tag{2.14}$$

where $f_{(m)}$ (or $\tilde{f}_{(m)}$) denotes an eigenfunction of $H_{(m)}$. This action can be extended to linear combinations of eigenfunctions by linearity. With this convention we can rewrite (2.8) and (2.14) simply as the commutators

$$[A, A^\pm] = \pm A^\pm, \quad [A^-, A^+] = -2A \tag{2.15}$$

assuming that the action is on any (linear combination of) $f_{(m)}$. The commutators (2.15) close the Lie algebra su(2), whose Casimir element is given by $\mathcal{C} = A^+A^- + A(A-1)$. The eigenvalues of $\mathcal{C}$, labeling the irreducible unitary representations (IUR), are $j(j+1)$, where $2j \in \mathbb{Z}^+$. The dimension of the support spaces of these IURs is, obviously, $2j+1$. We make use of the standard notation $|j,s\rangle$ for an A eigenvector with eigenvalue s, inside the "j-representation."

Now, we can identify the eigenstates of the Hamiltonians $H^{\phi_1}_{(m)}$ in terms of representation vectors $|j,s\rangle$. First, let us consider the ground states $f^0_{(m)}$ characterized by

$$A^- f^0_{(m)} = 0, \quad A f^0_{(m)} = -[(l_0 + l_1 + 2m)/2] f^0_{(m)} \tag{2.16}$$

following notation (2.14). These relations suggest the identification (up to a normalization constant)

$$f^0_{(m)} = |j_m, -j_m\rangle, \quad j_m = (l_0 + l_1 + 2m)/2.$$

To see that indeed this is the case we need to define the whole representation space as well as an inner product. Thus, consider the space $\mathcal{L}^2[0, \pi/2]$ of square integrable functions in the interval $[0, \pi/2]$. Then, the wave functions obtained from the ground state $f^0_{(m)}$ by the consecutive action of the operator A^+ will span the representation space of a j_m representation, with $j_m = (l_0 + l_1 + 2m)/2$, provided that both $l_0 + m$ and $l_1 + m$ belong to $\mathbb{Z}^+$. The wave functions of the space so

generated vanish at the end points, and the hermiticity relations $(A^-)^\dagger = A^+$, $A^\dagger = A$ are implemented in all the space. Hence, under these conditions, $(A^+)^k f^0_{(m)}$ can be identified, up to normalization, with the vector state $|j_m, -j_m + k\rangle$.

As a consequence, the excited states obtained in this way for any Hamiltonian in a factorization hierarchy where l_0 and l_1 are positive integers, correspond to IUR-vector states. For instance, the eigenstate of the kth excited level of $H^{\phi_1}_{(0)}$ is

$$f^k_{(0)} \equiv |j_k + k, -j_k + k\rangle, \quad j_k = (l_0 + l_1 + 2k)/2, \quad k = 0, 1, 2, \ldots,$$

and $H^{\phi_1}_{(0)}$ (as well as any $H^{\phi_1}_{(m)}$) can be expressed in terms of the su(2)-Casimir $\mathcal{C}$ acting on such representations

$$H^{\phi_1}_{(0)} = 4(\mathcal{C} + 1/4).$$

Therefore, the eigenvalue equation for any of the excited states can be written as follows

$$H^{\phi_1}_{(0)} f^k_{(0)} \equiv 4(\mathcal{C} + 1/4)|j_0 + k, -j_0 + k\rangle = 4(j_0 + k + 1/2)^2 |j_0 + k, -j_0 + k\rangle = (l_0 + l_1 + 2k + 1)^2 f^k_{(0)}$$

with $k = 0, 1, 2, \ldots$.

It will be convenient to consider a new diagonal operator D, to be added to the generators of su(2) (2.14), defined by

$$D f_{(m)} := (l_0 - l_1) f_{(m)}.$$

It is immediate to see that D commutes with any other operator of su(2) giving rise to the Lie algebra u(2). In this way any eigenstate in the Hamiltonian hierarchy can be characterized completely by an eigenfunction of an u(2)-IUR. Without D we would have an ambiguity due to the fact that different fundamental states with values of l_0 and l_1 giving the same $j_0 = (l_0 + l_1)/2$ would lead to the same j representation of su(2).

It is worth noting that when l_0 or l_1 are not in $\mathbb{Z}^+$ the eigenfunctions and spectrum of the Hamiltonian hierarchies are still given by (2.12) and (2.13), but these states belong to nonunitary representations of u(2).

C. The dynamical algebra so(4)

As we have just seen in the previous subsection the eigenstates sharing the same energy of the one-dimensional Hamiltonian hierarchies in the variable ϕ_1 are given in terms of IURs of the dynamical algebra u(2). However, in this respect, there is a point not quite satisfactory: different u(2) IURs may correspond to states with the same energy. We would prefer a larger dynamical algebra with a simpler correspondence, i.e., such that only one of its IURs gives all the eigenstates with the same energy in the hierarchy.

In order to build up a dynamical algebra having these properties, let us introduce the two-dimensional parameter space (l_0, l_1). Any operator with one subindex defined in Secs. II A and II B will change to a two-subindex notation in the following way.

(1) The one-dimensional Hamiltonian (2.4) will be denoted by $H_{(l_0,l_1)}$

$$H^{\phi_1}_{(l_0,l_1)} = -\partial^2_{\phi_1} + \frac{l_0^2 - 1/4}{\cos^2 \phi_1} + \frac{l_1^2 - 1/4}{\sin^2 \phi_1}.$$

Its eigenfunctions will be designed by $f_{(l_0,l_1)}$.

(2) The factor operators $A^\pm_0$ in (2.6) will be rewritten as $A^\pm_{(l_0,l_1)}$

$$A^\pm_{(l_0,l_1)} = \pm \partial_{\phi_1} - (l_0 + 1/2)\tan \phi_1 + (l_1 + 1/2)\cot \phi_1, \quad A_{(l_0,l_1)} = -\tfrac{1}{2}(l_0 + l_1).$$

Now, in this way, relations (2.9) can be expressed as

$$A^-_{(l_0,l_1)}H^{\phi_1}_{(l_0,l_1)} = H^{\phi_1}_{(l_0+1,l_1+1)}A^-_{(l_0,l_1)}, \quad A^+_{(l_0,l_1)}H^{\phi_1}_{(l_0+1,l_1+1)} = H^{\phi_1}_{(l_0,l_1)}A^+_{(l_0,l_1)}. \tag{2.17}$$

With this convention we can also define the free-subindex operators $A^{\pm}$, A, D as in (2.14).

On the other hand, notice that each two-parameter Hamiltonian $H^{\phi_1}_{(l_0,l_1)}$ is invariant under the reflections

$$I_0 := (l_0,l_1) \to (-l_0,l_1), \quad I_1:(l_0,l_1) \to (l_0,-l_1).$$

This property gives rise to a second factorization (see also Refs. 14–16) via conjugation of the operators of the first factorization by the reflection operators

$$I_0A^{\pm}I_0 = \widetilde{A}^{\pm}, \quad I_0AI_0 = \widetilde{A}, \quad I_0DI_0 = \widetilde{D},$$

$$\widetilde{I}_1A^{\pm}I_1 = \widetilde{A}^{\mp}, \quad I_1AI_1 = -\widetilde{A}, \quad I_1DI_1 = -\widetilde{D}.$$

Explicitly

$$\widetilde{A}^{\pm}_{(l_0,l_1)} = \pm\partial_{\phi_1} + (l_0 - 1/2)\tan\phi_1 + (l_1 + 1/2)\cot\phi_1, \quad \widetilde{A}_{(l_0,l_1)} = -\tfrac{1}{2}(-l_0 + l_1). \tag{2.18}$$

The above-mentioned operators $\{\widetilde{A},\widetilde{A}^{\pm}\}$ generate a Lie algebra isomorphic to su(2) denoted by $\widetilde{\mathrm{su}}(2)$. Since su(2) and $\widetilde{\mathrm{su}}(2)$ commute and, essentially, D and $\widetilde{D}$ coincide with $\widetilde{A}$ and A, respectively, the complete dynamical algebra has the structure of a direct sum $\mathrm{su}(2)\oplus\widetilde{\mathrm{su}}(2)\approx\mathrm{so}(4)$.

If we allow to act with the so(4) generators on an Hamiltonian $H_{(l_0,l_1)}$ we will get a two-dimensional parameter lattice of Hamiltonians which constitute a so(4) hierarchy fixed by the initial values (l_0,l_1): $\{H_{l_0-n+m,l_1+n+m}\}$, $m, n \in \mathbb{Z}$. Each energy level of this Hamiltonian hierarchy is degenerated and the eigenstates belong to so(4) representations.

Let us concentrate on the hierarchies associated to IURs of so(4). Now, these so(4) IURs are fixed by the fundamental (or lowest weight) states satisfying

$$A^-_{(l_0,l_1)}f^0_{(l_0,l_1)} = \widetilde{A}^-_{(l_0,l_1)}f^0_{(l_0,l_1)} = 0. \tag{2.19}$$

These are realized, up to a constant, by the wave functions

$$f^0_{(0,n)} = \cos^{1/2}\phi_1 \sin^{n+1/2}\phi_1, \quad n \in \mathbb{Z}^+, \tag{2.20}$$

where we have taken $l_0=0$ and $l_1=n$. We see also that the state (2.20) is stable under I_0 (i.e., $I_0f^0_{(l_0,l_1)}=f^0_{(l_0,l_1)}$), and comes into the other fundamental state (annihilated by A^+ and $\widetilde{A}^+$: the highest weight) of the same representation. Hence, these representations will be invariant under I_0 and I_1. Therefore, the so(4) IURs obtained from (2.20) are symmetric tensor products that can be denoted by

$$j \otimes j, \quad j = l_1/2 = n/2, \quad n \in \mathbb{Z}^{\geqslant 0},$$

where "j" stands for a j representation of su(2). In this way the degenerancy of the nth energy level is $(n+1)\times(n+1)$, which is composed of $n+1$ IURs of u(2) each of them of dimension $n+1$.

The Hamiltonians in this hierarchy can be expressed in terms of any of the su(2) [or $\widetilde{\mathrm{su}}(2)$] Casimir operators $H_{(l_0,l_1)}=4(\mathcal{C}+1/4)=4(\widetilde{\mathcal{C}}+1/4)$. With the help of all the discrete reflections we get directly its expression also in terms of the so(4) Casimir

$$\begin{aligned} H_{(l_0,l_1)} &= (\mathcal{C}+1/4) + I_0(\mathcal{C}+1/4)I_0 + I_1(\mathcal{C}+1/4)I_1 + I_0I_1(\mathcal{C}+1/4)I_0I_1 \\ &= \{A^+,A^-\} + 2A^2 + \{\widetilde{A}^+,\widetilde{A}^-\} + 2\widetilde{A}^2 + 1 = \{A^+,A^-\} + \{\widetilde{A}^+,\widetilde{A}^-\} + {L_0}^2 + {L_1}^2 + 1, \end{aligned}$$

where the diagonal operators L_0 and L_1 are defined by

$$L_0 f_{(l_0,l_1)} = l_0 f_{(l_0,l_1)}, \quad L_1 f_{(l_0,l_1)} = l_1 f_{(l_0,l_1)}.$$

Certainly, some so(4) hierarchies (those corresponding to the IURs previously described) may have Hamiltonians whose explicit expressions coincide

$$H_{(l_0,l_1)} = H_{(-l_0,l_1)} = H_{(l_0,-l_1)}$$

and the same happens with their corresponding eigenstates. But we cannot get rid of this multiplicity unless we enlarge the ambient space.

Another natural question is whether there are other intertwining shape-invariant operators inside the so(4) hierarchy. We can build, for instance, other pairs of operators through the composition of those already known

$$\mathcal{X}^{\pm} = A^{\pm}\tilde{A}^{\pm}, \quad \mathcal{Y}^{\pm} = A^{\pm}\tilde{A}^{\mp}.$$

These kinds of shape-invariant operators change two units, either the parameter l_0 or l_1 (but not both at the same time). When we restrict to $l_0=0$ or $l_1=0$ there are also first order intertwining operators changing one unit the nonvanishing parameter. This feature is not so special; it is also shared by the "radial oscillator" hierarchies[17] (which are closely related to the ones presented here).

For other Hamiltonian so(4) hierarchies the physical eigenstates are described by nonunitary representations that are not invariant under both reflections. In this respect, their description becomes more involved, so that one must be very careful in these cases.

D. The ϕ_2 factorization

Now, let us return to the separation process started in Sec. II A. The second equation (2.5) obtained from the initial separation of variables can be dealt with along the same lines, substituting the eigenvalues obtained from the previous factorization, $\alpha=\lambda_m=(l_0+l_1+2m)^2$. The most relevant fact, here, is that the new factorization leads to a degeneration of the energy levels which suggest that the underlying dynamical symmetry could be larger, as it will be confirmed in the next section. Thus, substituting in (2.5), we have

$$\begin{aligned} H^{\phi_2}_{(0)} &= -\partial^2_{\phi_2} + \tan(\phi_2)\partial_{\phi_2} + \frac{(l_0+l_1+2m+1)^2}{\cos^2(\phi_2)} + \frac{(l_2^2-1/4)}{\sin^2(\phi_2)} \\ &= \{\partial_{\phi_2} - (l_0+l_1+2(m+1))\tan(\phi_2) + (l_2+1/2)\cot(\phi_2)\} \\ &\quad \times \{-\partial_{\phi_2} - (l_0+l_1+2m+1)\tan(\phi_2) + (l_2+1/2)\cot(\phi_2)\} \\ &\quad + (l_2+l_0+l_1+2m+3/2)(l_2+l_0+l_1+2m+5/2) \\ &\equiv M_0^+ M_0^- + \mu_0. \end{aligned} \tag{2.21}$$

This is the first one of the Hamiltonian hierarchy $H^{\phi_2}_{(n)}$ in the variable ϕ_2,

$$H^{\phi_2}_{(n)} = M_n^+ M_n^- + \mu_n = M_{n-1}^- M_{n-1}^+ + \mu_{n-1},$$

where

$$M_n^{\pm} = \pm\partial_{\phi_2} - (l_0+l_1+2(m+1)+n)\tan(\phi_2) + (l_2+n+1/2)\cot(\phi_2),$$

$$\mu_n = (l_1+l_0+l_2+2n+2m+3/2)(l_2+l_1+l_0+2n+2m+5/2).$$

Now, the values for the energy (closely following the same arguments in Sec. II A) are given by

$$E = \mu_n = (l_1 + l_0 + l_2 + 2n + 2m + 3/2)(l_2 + l_1 + l_0 + 2n + 2m + 5/2). \tag{2.22}$$

The fundamental states $g^0_{(n)}$ for this factorization are

$$g^0_{(n)}(\phi_2) = N \cos^{l_1+l_0+2m+1} \phi_2 \sin^{l_2+n+1/2} \phi_2$$

and the eigenfunctions $g^n_{(0)}$ of the initial Hamiltonian (2.21) can be written in the form

$$g^n_{(0)}(\phi_2) = \cos^{l_1+l_0+2m+1} \phi_2 \sin^{l_2+1/2} \phi_2 P_n^{(l_2+1/2, l_1+l_0+2m+1)}(\cos 2\phi_2). \tag{2.23}$$

The commutation relation for the relevant free-index operators $M^{\pm}$, defined in a similar way as $A^{\pm}$ in (2.14), is again that of su(2),

$$[M^-, M^+] = -4(l_1 + l_0 + l_2 + 2m + 2n + 1) \equiv -2M.$$

Eigenfunctions (2.23) are square integrable, but the representations are unitary provided that, besides the previous conditions on l_0 and l_1, the parameter l_2 be also a positive integer number.

In summary, if we finally join the results of both factorizations, the square integrable eigenfunctions of Hamiltonian (2.3) in the separable variables (ϕ_1, ϕ_2) are given by the products

$$\Phi_{m,n}(\phi_1, \phi_2) = f^m_{(0)}(\phi_1) g^n_{(0)}(\phi_2), \quad m, n \in \mathbb{Z}^+, \tag{2.24}$$

where the components have the polynomial expressions (2.12) and (2.23). The corresponding eigenvalues given in (2.22) are degenerated for those values of m and n whose sum $m+n$ keeps constant (see also, for instance, Ref. 11).

III. DYNAMICAL SYMMETRIES

The spectrum obtained by the methods of Sec. II suggests the existence of a bigger dynamical algebra of the Hamiltonian hierarchy. This is the point that we want to address here developing exhaustively the concept of intertwining (shape invariant) operators for this kind of Hamiltonians. Such operators will supply us with a more consistent picture of the spectrum and eigenfunctions. Thus, based on the considerations of Secs. II B and II C, we will introduce three sets of intertwining operators closing the Lie algebra u(3). Then, in the following subsection, we will enlarge this algebra to so(6) by means of the relevant reflections.

A. The Hamiltonian u(3) hierarchies

1. The set $\{A^+, A^-, A\}$

As we will use some properties of Sec. II in a different direction, it is convenient to introduce another notation more appropriate to rewrite some previous results. The Hamiltonian (2.1) characterized by the parameters $\ell \equiv (l_0, l_1, l_2)$ will be referred to as $H_{(l_0,l_1,l_2)}$, and the operators defined by (2.6) will be taken henceforth with a threefold subindex

$$A^{\pm}_{(l_0,l_1,l_2)} = \pm \partial_{\phi_1} - (l_0 + 1/2)\tan \phi_1 + (l_1 + 1/2)\cot \phi_1. \tag{3.1}$$

As differential operators (2.6) and (3.1) depend only on the variable ϕ_1, they do not affect the part in the total Hamiltonian (2.1) depending on the second separable variable ϕ_2. So that, in the same way as (2.17) we have the intertwining relations

$$A^-_{(l_0,l_1,l_2)} H_{(l_0,l_1,l_2)} = H_{(l_0+1,l_1+1,l_2)} A^-_{(l_0,l_1,l_2)},$$

$$A^{+}_{(l_0,l_1,l_2)}H_{(l_0+1,l_1+1,l_2)} = H_{(l_0,l_1,l_2)}A^{+}_{(l_0,l_1,l_2)}.$$

This means that now $A^{-}_{(l_0,l_1,l_2)}$ is acting on eigenstates of $H_{(l_0,l_1,l_2)}$ leading to eigenstates of $H_{(l_0+1,l_1+1,l_2)}$ whereas $A^{+}_{(l_0,l_1,l_2)}$ does it in the opposite way (later we will comment on the square-integrability conditions through unitary representations).

If we include the normalizing constant just as in (2.14), and define global operators acting on eigenfunctions of this class of Hamiltonians in the forms

$$A^{+}\Phi_{(l_0+1,l_1+1,l_2)} := \tfrac{1}{2}A^{+}_{(l_0,l_1,l_2)}\Phi_{(l_0+1,l_1+1,l_2)} \propto \tilde{\Phi}_{(l_0,l_1,l_2)},$$

$$A^{-}\Phi_{(l_0,l_1,l_2)} := \tfrac{1}{2}A^{-}_{(l_0,l_1,l_2)}\Phi_{(l_0,l_1,l_2)} \propto \tilde{\Phi}_{(l_0+1,l_1+1,l_2)},$$

$$A\Phi_{(l_0,l_1,l_2)} := -\tfrac{1}{2}(l_0+l_1)\Phi_{(l_0,l_1,l_2)},$$

we are led to the standard su(2) commutators (2.15). Here, we want to stress again that now these operators are acting on the total wave function of complete Hamiltonians like $H_{(l_0,l_1,l_2)}$, not just on a factor function in only one variable.

In order to introduce other sets of operators we will use the fact that the Hamiltonian (2.1) can be separated in other coordinate systems. Since the axes (s_0,s_1,s_2) play a symmetric role in the Hamiltonian, we will take their cyclic rotations to get two other sets of coordinates and, hence, new sets of intertwining operators.

2. The set $\{B^{+},B^{-},B\}$

We will take the spherical coordinates choosing as third axis not s_2, but s_1, i.e.,

$$s_2 = \cos\xi_2\cos\xi_1, \quad s_0 = \cos\xi_2\sin\xi_1, \quad s_1 = \sin\xi_2. \tag{3.2}$$

Then, the initial Hamiltonian is also separated in the coordinates (ξ_1,ξ_2). In particular, we can build the operators $B^{\pm}_{(l_0,l_1,l_2)}$ in a similar way as $A^{\pm}_{(l_0,l_1,l_2)}$. From coordinate systems (2.2) and (3.2) we easily arrive at the following expressions for the new set in terms of the initial coordinates (ϕ_1,ϕ_2):

$$B^{\pm}_{(l_0,l_1,l_2)} = \pm(\sin\phi_1\tan\phi_2\partial_{\phi_1} + \cos\phi_1\partial_{\phi_2}) - (l_2+1/2)\cos\phi_1\cot\phi_2 + (l_0+1/2)\sec\phi_1\tan\phi_2. \tag{3.3}$$

These operators intertwine the pair of Hamiltonians

$$B^{-}_{(l_0,l_1,l_2)}H_{(l_0,l_1,l_2)} = H_{(l_0+1,l_1,l_2+1)}B^{-}_{(l_0,l_1,l_2)},$$

$$B^{+}_{(l_0,l_1,l_2)}H_{(l_0+1,l_1,l_2+1)} = H_{(l_0,l_1,l_2)}B^{+}_{(l_0,l_1,l_2)}.$$

The "global" operators, defined by

$$B^{+}\Phi_{(l_0+1,l_1,l_2+1)} := \tfrac{1}{2}B^{+}_{(l_0,l_1,l_2)}\Phi_{(l_0+1,l_1,l_2+1)} \propto \tilde{\Phi}_{(l_0,l_1,l_2)},$$

$$B^{-}\Phi_{(l_0,l_1,l_2)} := \tfrac{1}{2}B^{-}_{(l_0,l_1,l_2)}\Phi_{(l_0,l_1,l_2)} \propto \tilde{\Phi}_{(l_0+1,l_1,l_2+1)},$$

$$B\Phi_{(l_0,l_1,l_2)} := -\tfrac{1}{2}(l_0+l_2)\Phi_{(l_0,l_1,l_2)},$$

also close a new su(2).

3. The set $\{C^+, C^-, C\}$

Finally, taking the spherical coordinates around the s_0 axis,

$$s_1 = \cos\theta_2 \cos\theta_1, \quad s_2 = \cos\theta_2 \sin\theta_1, \quad s_0 = \sin\theta_2$$

the Hamiltonian is also separated in the variables $\{\theta_1, \theta_2\}$ and we get a new pair of operators, that written in terms of the initial ϕ_1 and ϕ_2 variable, take the expression

$$C^{\pm}_{(l_0,l_1,l_2)} = \pm(\cos\phi_1 \tan\phi_2 \partial_{\phi_1} - \sin\phi_1 \partial_{\phi_2}) + (l_1 - 1/2)\csc\phi_1 \tan\phi_2 + (l_2 + 1/2)\sin\phi_1 \cot\phi_2. \tag{3.4}$$

These operators act as intertwiners of the Hamiltonians in the following way:

$$C^-_{(l_0,l_1,l_2)} H_{(l_0,l_1,l_2)} = H_{(l_0,l_1-1,l_2+1)} C^-_{(l_0,l_1,l_2)},$$

$$C^+_{(l_0,l_1,l_2)} H_{(l_0,l_1-1,l_2+1)} = H_{(l_0,l_1,l_2)} C^+_{(l_0,l_1,l_2)}.$$

The global operators are defined by

$$C^+\Phi_{(l_0,l_1-1,l_2+1)} := \tfrac{1}{2} C^+_{(l_0,l_1,l_2)} \Phi_{(l_0,l_1-1,l_2+1)} \propto \tilde{\Phi}_{(l_0,l_1,l_2)},$$

$$C^-\Phi_{(l_0,l_1,l_2)} := \tfrac{1}{2} C^-_{(l_0,l_1,l_2)} \Phi_{(l_0,l_1,l_2)} \propto \tilde{\Phi}_{(l_0,l_1-1,l_2+1)},$$

$$C\Phi_{(l_0,l_1,l_2)} := -\tfrac{1}{2}(-l_1 + l_2)\Phi_{(l_0,l_1,l_2)},$$

closing the third algebra su(2). Notice that $C = B - A$.

In fact, as we saw in Sec. II, each separable system gives rise to two sets of intertwining operators (in that section distinguished by means of the tilde). However, here we have made a "good" choice of the previous three sets that will close a Lie algebra (on this point see Sec. III B).

4. The complete algebra u(3)

Now, we can join all the above-defined transformations, $A^{\pm}$, A, $B^{\pm}$, B, $C^{\pm}$, C, and commute any two of them to check that indeed they close a Lie algebra su(3). The nonvanishing commutators are

$$[A^3, A^{\pm}] = \pm A^{\pm}, \quad [A^-, A^+] = 2A, \quad [A^+, B^-] = C^-, \quad [A^+, B] = -A^+/2,$$

$$[A^+, C^+] = -B^+, \quad [A^+, C] = A^+/2, \quad [A^-, B^+] = -C^+, \quad [A^-, B] = A^-/2,$$

$$[A^+, C^+] = B^-, \quad [A^-, C] = -A^-/2, \quad [A, B^+] = B^+/2, \quad [A, C^+] = -C^+/2,$$

$$[A, C^-] = C^-/2, \quad [B, B^{\pm}] = \pm B^{\pm}, \quad [B^-, B^+] = 2B, \quad [B^+, C^-] = -A^+,$$

$$[B^+, C] = -B^+/2, \quad [B^-, C^+] = C^+/2, \quad [B^-, C] = B^-/2, \quad [B, C^+] = C^+/2,$$

$$[B, C^-] = C^-/2, \quad [C, C^{\pm}] = \pm C^{\pm}, \quad [C^+, C^-] = 2C, \quad [A^-, C^-] = B^-.$$

The Casimir operator is given by

$$\mathcal{C} = A^+A^- + B^+B^- + C^+C^- + \tfrac{2}{3}A(A-3/2) + \tfrac{2}{3}B(B-3/2) + \tfrac{2}{3}C(C-3/2). \tag{3.5}$$

In order to complete an algebra u(3) we can add a diagonal operator D commuting with all the above-mentioned transformations. It is a central operator, i.e.,

$$D := l_0 - l_1 - l_2, \quad [D, \cdot\,] = 0.$$

We can also adopt the global operator convention H for the Hamiltonians in the hierarchy by defining its action on the eigenfunctions $\Phi_{(l_1,l_2,l_3)}$ of $H_{(l_1,l_2,l_3)}$ by

$$H\Phi_{(l_1,l_2,l_3)} := H_{(l_1,l_2,l_3)}\Phi_{(l_1,l_2,l_3)}.$$

In this way we can express the Hamiltonian H in terms of both operators $\mathcal{C}$ and D

$$H = 4\mathcal{C} - \tfrac{1}{3}D^2 + \tfrac{15}{4}. \tag{3.6}$$

In the case of one-dimensional systems, one (first order) intertwining set $\{A^\pm\}$ for the Hamiltonian gives rise to its factorization. However, for Hamiltonians with more degrees of freedom (more components, or in more dimensions) the relationship of H with these operators, in general, turns out to be more complex. In our case the set $\{A^\pm, B^\pm, C^\pm\}$ according to expressions (3.5) and (3.6) is enough to express the Hamiltonian as a certain quadratic function $H=h(A^+A^-, B^+B^-, C^+C^-)$ generalizing the usual factorization.

In summary, we have built an algebra u(3) of intertwining operators that, once fixed the initial Hamiltonian with parameter values (l_0, l_1, l_2), gives rise to a two-parameter Hamiltonian hierarchy

$$\{H_{(l_0+m, l_1+m-n, l_2+n)}\}, \quad m,n \in \mathbb{Z}$$

where the points (l_0+m, l_1+m-n, l_2+n) lie on a certain plane $D=d_0$. In this subsection we will consider this special hierarchy, together with its eigenstates, connected to the IURs of u(3). The states of such representations are square integrable and, therefore, should take part of the physical eigenfunctions whose energy eigenvalues belong to the spectrum.

In order to build an IUR we start from a fundamental state Φ annihilated by A^- and C^- [two simple roots of su(3)]

$$A^-_\ell \Phi_\ell = C^-_\ell \Phi_\ell = 0 \tag{3.7}$$

with $\ell=(l_0, l_1, l_2)$. Such states exist only when $l_1=0$, taking the explicit form

$$\Phi_\ell(\phi_1, \phi_2) = N \cos^{l_0+1/2}\phi_1 \sin^{1/2}\phi_1 \cos^{l_0+1}\phi_2 \sin^{l_2+1/2}\phi_2, \tag{3.8}$$

where N is a normalizing constant. The diagonal operators A and C act on Φ_ℓ as

$$A\Phi_\ell = -l_0/2\Phi_\ell, \quad l_0 = m, \quad l_1 = 0, \quad m = 0,1,2,\ldots,$$

$$C\Phi_\ell = -l_2/2\Phi_\ell, \quad l_2 = n, \quad n = 0,1,2,\ldots. \tag{3.9}$$

This means that Φ_ℓ is a fundamental state of the representations $j_1=m/2$ of the subalgebra su(2) generated by $\{A^\pm, A\}$, and $j_2=n/2$ of the corresponding su(2) determined by $\{C^\pm, C\}$. Such a representation of su(3) will be denoted (m,n) with $m,n \in \mathbb{Z}^+$. The points labeling the states of this representation obtained from Φ_ℓ lie on the plane $D=m-n$ inside the ℓ-parameter space.

The energy for the states of the IURs determined by the fundamental state (3.9) with the parameters $(l_0, 0, l_2)$, according to (3.6) is given by

$$E = (l_0 + l_2 + 3/2)(l_0 + l_2 + 5/2) = (m + n + 3/2)(m + n + 5/2). \tag{3.10}$$

Therefore, the IURs fixed by (m,n) with the same value $m+n$ will lead to states with the same energy. We call such IURs an isoenergy series and they will be examined under the light of the algebra so(6) in the following section. The values for the energy (3.10) coincide with the ones

computed by the method of variable separation of Sec. II, as can be seen from (2.22) once the replacement $l_1=1/2$ is performed. We can also check that in this case the ground state (2.24) coincides with those fixing an IUR (3.8).

B. The so(6) hierarchy

Following the pattern and motivation of Sec. II C, we will consider the relevant discrete symmetries in order to find a larger dynamical algebra.

It is obvious that the Hamiltonian $H_{(l_0,l_1,l_2)}$ is invariant under reflections in the parameter space $\{(l_0,l_1,l_2)\}$

$$I_0{:}(l_0,l_1,l_2)\to(-l_0,l_1,l_2),\quad I_1{:}(l_0,l_1,l_2)\to(l_0,-l_1,l_2),\quad I_2{:}(l_0,l_1,l_2)\to(l_0,l_1,-l_2).$$

Each of these symmetries can be directly implemented in the eigenfunction space, leading through conjugation to another set of intertwining operators that close a Lie algebra isomorphic to u(3) and denoted by ${}_i\mathrm{u}(3)$

$${}_iX=I_iXI_i,\quad X\in\mathrm{u}(3),\quad {}_iX\in{}_i\mathrm{u}(3),\quad i=0,1,2.$$

The intertwining operators of ${}_i\mathrm{u}(3)$ connect eigenstates of Hamiltonians whose parameters (l_0,l_1,l_2) belong to the planes ${}_iD=k_i$, k_i being certain real constants. We will choose the following convention for the resulting generators

$$\{A^{\pm},B^{\pm},C^{\pm}\}\xrightarrow{I_0}\{\tilde{A}^{\mp},\tilde{B}^{\mp},C^{\pm}\},$$

$$\{A^{\pm},B^{\pm},C^{\pm}\}\xrightarrow{I_1}\{\tilde{A}^{\pm},B^{\pm},\tilde{C}^{\pm}\},$$

$$\{A^{\pm},B^{\pm},C^{\pm}\}\xrightarrow{I_2}\{A^{\pm},\tilde{B}^{\pm},\tilde{C}^{\mp}\},$$

where, for instance, the sets $\{A^{\pm},A\}$ and $\{\tilde{A}^{\pm},\tilde{A}\}$ close the two commuting Lie algebras su(2) of Sec. II. The explicit expression for the new operators (labeled with a tilde) can be easily obtained in the same way as it was done in (2.18). The set of all the generators obtained in this process close the Lie algebra of rank 3, so(6). In the eigenfunction space it is enough to consider three independent diagonal operators $\{L_0,L_1,L_2\}$ defined by

$$L_i\Phi_{(l_0,l_1,l_2)}=l_i\Phi_{(l_0,l_1,l_2)}.$$

The Hamiltonian can be expressed in terms of the so(6)-Casimir operator by means of the "symmetrization" of the u(3) Hamiltonian (3.6)

$$\begin{aligned}H_{\mathrm{so}(6)}&=\tfrac{1}{8}\Big(H_{\mathrm{u}(3)}+\sum_j I_jH_{\mathrm{u}(3)}I_j+\sum_{j\neq k}I_jI_kH_{\mathrm{u}(3)}I_jI_k+I_0I_1I_2H_{\mathrm{u}(3)}I_0I_1I_2\Big)\\&=\{A^+,A^-\}+\{B^+,B^-\}+\{C^+,C^-\}+\{\tilde{A}^+,\tilde{A}^-\}+\{\tilde{B}^+,\tilde{B}^-\}+\{\tilde{C}^+,\tilde{C}^-\}+{L_0}^2+{L_1}^2+{L_2}^2+\tfrac{41}{12}.\end{aligned}$$

Henceforth we remove the subindex so(6) of the Hamiltonian.

The intertwining generators of so(6) give rise to larger three-dimensional Hamiltonian hierarchies

$$\{H_{(l_0+m+p,l_1+m-n-p,l_2+n)}\},\quad m,n,p\in\mathbb{Z},$$

each one including a class of the previous ones coming from u(3). The eigenstates of these Hamiltonian hierarchies can be classified in terms of so(6) representations. Let us fix our attention in those determined by the so(6) IURs. These IURs are built from the fundamental states annihilated by the simple roots $A^-,C^-,\tilde{A}^-$

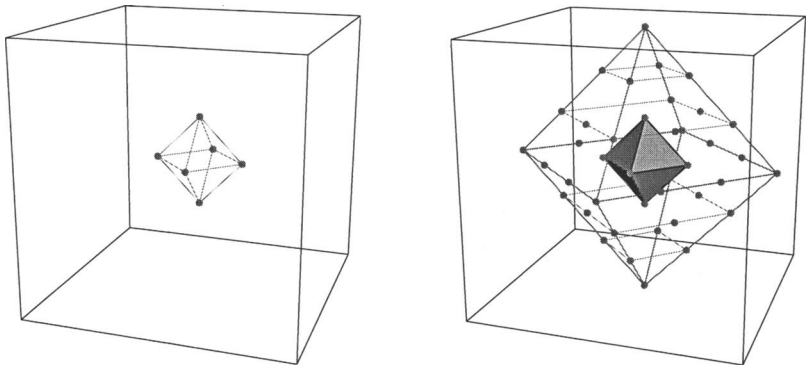

FIG. 1. Plot of the points representing the states of two odd IURs with (left) $q=1$ and (right) $q=3$. The 6 ($q=1$) eigenstates share the energy $E=\frac{5}{2}\cdot\frac{3}{2}$. The 50 ($q=3$) eigenstates share the energy $E=\frac{7}{2}\cdot\frac{5}{2}$ (the points corresponding to $q=3$ include those of $q=1$, of the inner octahedron, which are doubly degenerated).

$$A^-\Phi_\ell^{(0)} = C^-\Phi_\ell^{(0)} = \tilde{A}^-\Phi_\ell^{(0)} = 0.$$

The equations for the operators A^- and C^- have been used in (3.7), whereas the one for $\tilde{A}^-$ were already applied in (2.19). Therefore, the wave functions of the highest weight vectors take the form

$$\Phi_\ell^{(0)}(\phi_1,\phi_2) = N\cos^{1/2}\phi_1 \sin^{1/2}\phi_1 \cos\phi_2 \sin^{l_2+1/2}\phi_2$$

characterized by the eigenvalues of the diagonal operators,

$$L_0\Phi_\ell = L_1\Phi_\ell = 0, \quad L_2\Phi_\ell = n\Phi_\ell, \quad n \in \mathbb{Z}^+.$$

This fundamental state is invariant under the inversions I_0 and I_1, and the representation, so obtained, is also invariant under I_2. Thus, in this way we arrive at two classes of symmetric IURs of so(6)

(a) $(l_0=0,\ l_1=0,\ l_2=0)$; $\{H_{(m+p,m-n-p,n)}\}$, $n,\ m,\ p \in \mathbb{Z}$ (even IURs) and
(b) $(l_0=0,\ l_1=0,\ l_2=1)$; $\{H_{(m+p,m-n-p,1+n)}\}$, $n,\ m,\ p \in \mathbb{Z}$ (odd IURs).

Each of these IURs is described in the parameter space by an octahedral lattice of points such that it will include an isoenergy su(3) [or ${}_i$su(3)] series of representations, quoted in the previous subsection, which correspond to parallel exterior faces of the octahedron and some of its sections. Such sections are determined by the values of the diagonal operator D (or ${}_iD$) whose values fix the corresponding u(3) representations.

For instance, the so(6) representation labeled by $q=1$, corresponding to the odd hierarchy, includes the first su(3) series, (1, 0) and (0, 1) described by the opposite faces of an elemental octahedron. The so(6) representation of the even hierarchy fixed by $q=2$ includes the su(3) series made of (2, 0), (1, 1), and (0, 2). Those associated to (2, 0) and (0, 2) correspond to opposite triangular faces, whereas (1, 1) is described by the parallel hexagonal section through the origin. These features can be better appreciated in Figs. 1 and 2.

In general, the so(6) IURs fixed by the parameter q will include the isoenergy series of the su(3) representations labeled by (m,n) with $m+n=q$. This is the degeneration explained by the larger algebra so(6). A similar discussion can be done with respect to the representations of the su(2) $\oplus$ $\tilde{\text{su}}$(2) subalgebra. They can be identified with square sections of the octahedron.

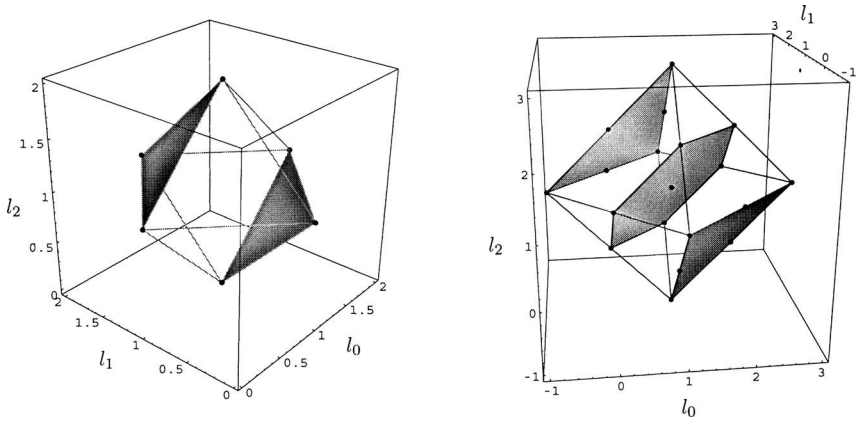

FIG. 2. (Left) $q=1$ IUR of so(6) where the triangular opposite faces correspond to two IURs of su(3). (Right) Points of a $q=3$ IUR of so(6). The three sections describe three IURs of su(3).

IV. EIGENSTATES AND FACTORIZATIONS

Let H_ℓ and $H_{\ell'}$ be two Hamiltonians related by means of a differential operator X in the following form

$$XH_\ell = H_{\ell'}X \Rightarrow X^\dagger H_{\ell'} = H_\ell X^\dagger, \tag{4.1}$$

where the dagger denotes adjoint differential operators. Then, it is said that X is an intertwining operator connecting H_ℓ with $H_{\ell'}$.

In a formal way, the eigenfunctions of H_ℓ are transformed by X into eigenfunctions of $H_{\ell'}$, but one must be careful about the behavior of some properties, such as square-integrability, singularities, or boundary conditions, which might be altered by X. The intertwining problem just as introduced in (4.1), which applies to the u(3) system of Sec. III, takes into account shape invariance, in the sense that the partner Hamiltonian $H_{\ell'}$ differs from the initial H_ℓ simply by changing the values of the parameters: $\ell \to \ell'$. In general, shape invariance leads to an algebraic structure of the intertwining operators as it happens in our present case.

Now, we will discuss in this section the form of the su(3) intertwining operators of Sec. III and its relation to certain eigenstates [similar considerations also apply to so(6)]. First of all, note that we can write such operators [see expressions (3.1), (3.3), and (3.4)] as

$$A_\ell^\pm = a^\pm + \alpha_\ell, \quad B_\ell^\pm = b^\pm + \beta_\ell, \quad C_\ell^\pm = c^\pm + \gamma_\ell \tag{4.2}$$

where $a^\pm$, $b^\pm$, and $c^\pm$ stand for vector fields (expressed, for instance, in the variables ϕ_1, ϕ_2) defined on the sphere and α_ℓ, β_ℓ, γ_ℓ design functions also defined on the sphere. Notice that

$$a^+ = (a^-)^\dagger = J_2, \quad b^+ = (b^-)^\dagger = J_1, \quad c^+ = (c^-)^\dagger = J_0$$

where J_0, J_1, and J_2 close the rotation algebra so(3). Moreover, taking the hermitian conjugate we have made use of the invariant measure on the sphere. If we write the Hamiltonians in the hierarchy displaying the kinetic (or free) part and the potential as

$$H_\ell = H^{(\mathrm{kin})} + V_\ell$$

we see that the vector fields originate the kinetic term, i.e.,

$$H^{(\mathrm{kin})} = a^+a^- + b^+b^- + c^+c^-$$

and the components α_ℓ, β_ℓ, and γ_ℓ (defined on the sphere) give rise to the potential $V_\ell(\phi_1, \phi_2)$, labeled by the parameters $\ell \equiv (l_0, l_1, l_2)$. Substituting (4.2) into Hamiltonian (3.6) and taking into account (3.5), we get the expression

$$V_\ell(\phi_1,\phi_2) = (a_\ell)^2 + (a^+\alpha_\ell) + (\beta_\ell)^2 + (b^+\beta_\ell) + (\gamma_\ell)^2 + (c^+\gamma_\ell) + \lambda_\ell, \tag{4.3}$$

where γ_ℓ is a number depending on l_0, l_1, l_2. Equation (4.3) can be considered as a nonlinear partial differential equation linking the unknowns $\{\alpha_\ell,\beta_\ell,\gamma_\ell\}$ with the potential, in a quite similar way to the Riccati equation for the superpotential ω in the one-dimensional Schrödinger equation. For this reason, we sometimes will refer to $\{\alpha_\ell,\beta_\ell,\gamma_\ell\}$ as superpotential functions. This is in agreement with a more general result[2,3] where the first order intertwining is built by dressing the symmetries of the Laplacian operator with certain functions.

The basic property of the one-dimensional superpotential ω was that it could be considered as the logarithmic derivative of a Hamiltonian eigenstate [see (2.10)]. Here, we have something similar with respect to the superpotentials $\{\alpha_\ell,\beta_\ell,\gamma_\ell\}$ but first we want to settle this problem in general terms. If we know an intertwining operator X satisfying (4.1) it can help us in computing certain eigenfunctions of H_ℓ. Notice that if we define the kernel, $\mathcal{K}_X$, of X as the linear manifold of wave-functions annihilated by X,

$$X\psi = 0, \quad \forall\ \psi \in \mathcal{K}_X$$

then, such a space is invariant under the Hamiltonian operator H_ℓ. Thus, we can look for eigenfunctions inside $\mathcal{K}_X$, in general a much simpler problem. But, in the case of X being a partial differential operator, its kernel includes certain arbitrary functions, so it is still an infinite dimensional space. This is in sharp contrast with ordinary first order differential operators where the kernel is one-dimensional.

Another option we have at hand is the following. The intertwining relation (4.1) implies the commutation

$$X^\dagger X H_\ell = H_\ell X^\dagger X.$$

This means that we can look for eigenfunctions of H_ℓ inside any eigenfunction space of $X^\dagger X$, not necessarily that one annihilated by X, as was the case just considered previously. In this case, however, a similar expression to (2.10) in terms of such eigenfunctions is no longer valid for ω. When we know several intertwining operators, as in the present case, we can apply them in different ways according to the above-mentioned comments.

(i) *Superpotentials associated to a global fundamental eigenstate of* $\{A^-,B^-,C^-\}$. We consider the intersection of the kernels of all the intertwining operators. Assuming that this subspace is one-dimensional we have just one eigenstate (up to a factor) Φ_0 annihilated by all the lowering operators $\{A^-,B^-,C^-\}$, so that we obtain the following expressions quite similar to (2.10)

$$\alpha_\ell = -\frac{(a^-\Phi_0)}{\Phi_0}, \quad \beta_\ell = -\frac{(b^-\Phi_0)}{\Phi_0}, \quad \gamma_\ell = -\frac{(c^-\Phi_0)}{\Phi_0}. \tag{4.4}$$

This mechanism corresponds to the IURs characterized in Sec. III.

(ii) *Superpotentials associated to a partial fundamental eigenstate*. If the previous subspace is the trivial null space, we can still restrict ourselves to the kernel subspace of anyone of the intertwining operators, for example A^-. Thus, let Φ be an eigenfunction of H_ℓ with $\Phi \in \mathcal{K}_{A^-}$, i.e., $A^-\Phi = 0$. This allows us to set

$$\alpha_\ell = -(a^-\Phi)/\Phi.$$

From this equation we can also separate variables in Φ, so that the eigenfunction equation $H\Phi = E\Phi$ leads to a second order ordinary differential equation whose solution can be easily obtained.

However, we must outline that in this case the remaining superpotential functions β_ℓ, γ_ℓ

have not a simultaneous expression (4.4) in terms of the same Φ, they need different eigenfunctions. Under this point of view, Sec. II constitutes an illustration of how this option leads to eigenfunctions separated in the variables ϕ_1, ϕ_2.

(iii) *Other excited eigenstates*. The second option is to solve, for instance, the eigenvalue problem $A^+A^-\Phi=\alpha\Phi$, requiring at the same time Φ to be also a Hamiltonian eigenfunction. In terms of the ambient coordinates s_0, s_1, s_2 this equation is (see also Ref. 11)

$$\left\{-\left(s_1\frac{\partial}{\partial s_0}-s_0\frac{\partial}{\partial s_1}\right)^2+(l_0-1/4)\frac{s_0^2+s_1^2}{s_0^2}+(l_1-1/4)\frac{s_0^2+s_1^2}{s_1^2}\right\}\Phi=\alpha\Phi.$$

The same procedure can be applied with other more general sets of operators commuting with the Hamiltonian. For instance, we can diagonalize H inside the subspace

$$(e_2A^+A^-+e_1B^+B^-+e_0C^+C^-)\Phi=\alpha\Phi$$

where the e_i's are constant coefficients. This leads to eigenfunctions separated in elliptic coordinates, that we do not consider here.[11]

V. CONCLUSIONS

We have shown how to deal with the u(3) [and the general u(n) case[9,18] follows the same pattern[19]] analog of a class of factorizable one-dimensional potentials with underlying dynamical algebra u(2). The higher rank systems in consideration are well known inside the class of superintegrable Hamiltonians and, of course, our objective was not to compute original eigenfunctions. Our interest was to apply a different point of view to understand some properties in a new context. For instance, the classification of the irreducible representations of su(3) in series corresponding to so(6) octahedrons, and the relations involved in this framework is a nontrivial result that could be best appreciated inside the intertwining technique. The relation of the unitary representations with a special form of the superpotential functions, or the separable eigensolutions determined in terms of intertwining operators clarifies some of the known procedures.

We have seen how the elements of one-dimensional factorizations must be adapted to the new context. For example, the relation of superpotentials and a whole class of eigenfunctions (not just one), the expression of the Hamiltonian operator is not just a simple factorization, the lattice of states must be drawn in a three-dimensional space, etc.

There are several problems that can be addressed using the present procedure. The systems underlying noncompact algebras u(p,q), inhomogeneous Lie algebras $iu(p,q)$ and contracted algebras[20] are among the first applications that we expect to report in a near future. But, in general, other integrable Hamiltonian systems could also allow for this treatment, with or without variable separation. This application would be of most interest.

Discrete and continuous sine transform generalized to semisimple Lie groups of rank two

J. Patera[a] and A. Zaratsyan[b]
Centre de Recherches Mathématiques, Université de Montréal, C. P. 6128 succ. Centre-ville, Montréal, Québec, H3C 3J7 Canada

(Received 30 January 2006; accepted 21 February 2006; published online 26 April 2006)

A new continuous group transform, together with its discretization over a lattice of any density and admissible symmetry, is defined and described for the four compact semisimple Lie groups of rank 2. In the case of rank 1, the discrete version is the sine transform. Properties of the expansion functions of the transform, called *S*-functions, are studied. Digital data processing is our motivating application.
 [DOI: 10.1063/1.2191361]

I. INTRODUCTION

The present paper is the concluding but independent part of a series of three articles.[1,2] Previous papers, which also include Refs. 3–7, dealt with properties of *C*-functions [see Eq. (3.2)]. General comments and motivation to our study are found in those papers. Originally the *C*-functions of this paper were called "orbit functions" or "orbit sums."[8]

Our subject in this paper are analogous properties of *S*-functions [see Eq. (3.1)]. Both types of functions are based on compact semisimple Lie groups. The rank of the group is the number of continuous variables of the *C*- and *S*-functions. Since our main motivation are two-dimensional applications, we are focused on Lie groups of rank 2, although most of the properties of *S*-functions described in Sec. III are general as to the type and rank of semisimple compact Lie group.

The *S*-functions are known in Lie theory mainly from the Weyl character formula, where an irreducible character of a representation labeled by its highest weight λ, is written as the ratio of two *S*-functions, say $S_{\lambda+\rho}$ and S_ρ, where ρ is the half-sum of positive roots of the Lie group. In this article we make use of the *S*-functions in a very different way. Apparently, no group transforms based on *S*-functions, either continuous or discrete, have been considered elsewhere in the literature (except in Ref. 9).

Let us point out that recently a third type of generalization of one-dimensional group transforms was introduced.[9] The expansion functions in that case, called *E*-functions, are multidimensional generalizations of the exponential function. Their properties will be studied elsewhere.[10]

Among the possible applications, the most interesting to us in this paper, is decomposition of class functions on a compact semisimple Lie group. Such a decomposition takes place on the fundamental region *F* of the Lie group where each conjugacy class of the group is represented by precisely one point. It is a basic problem of Fourier analysis which in theory is solved by decomposition of the functions into series of irreducible characters of the group. In practice that is hardly ever done even in one dimension for a number of reasons. Let us point out at least two of them.

First, characters are complicated functions. Their complexity rapidly increases without limits, the higher is the underlying irreducible representation. They are built either as a ratio of polyno-

[a]Electronic mail: patera@crm.umontreal.ca
[b]Electronic mail: zaratsyan@crm.umontreal.ca

mials of ever increasing degree, or as integer linear combination of *C*-functions.[7] Coefficients of the linear combinations are the multiplicities of dominant weights. Finding the coefficients is a laborious computational task. Look-up tables[11] offer only limited help.

Our second objection is related to the behavior of irreducible characters (and also *C*-functions) at the boundary ∂F of F. Both are symmetric with respect to reflection in any side of F of maximal dimension, i.e., $n-1$. Thus both being continuous functions, their normal derivative at ∂F must be zero (Neumann conditions). Clearly functions on F which have a different behavior at ∂F cannot be satisfactorily decomposed either into series of irreducible characters or *C*-functions. The *S*-functions are antisymmetric with respect to reflections in the sides of F. Therefore, being continuous, they go through zero at ∂F.

In two dimensions there are four families of *C*-functions and four families of *S*-functions. The families are determined by compact semisimple Lie groups.

There are three compact simple Lie groups of rank 2, namely the following: SU(3), O(5) or Sp(4), and G(2). There is only one nonsimple but semisimple compact Lie group: $\mathrm{SU}(2)\times\mathrm{SU}(2)$. In this article, we use the notation more familiar in Lie algebra theory:

$$\mathrm{A}_1 \leftrightarrow \mathrm{SU}(2),$$

and

$$\mathrm{A}_1 \times \mathrm{A}_1 \leftrightarrow \mathrm{SU}(2) \times \mathrm{SU}(2), \quad \mathrm{A}_2 \leftrightarrow \mathrm{SU}(3),$$

$$\mathrm{C}_2 \leftrightarrow \mathrm{O}(5) \text{ or } \mathrm{Sp}(4), \quad \mathrm{G}_2 \leftrightarrow \mathrm{G}(2).$$

In principle, one could also consider the compact Lie groups of rank 2 $\mathrm{U}(1)\times\mathrm{U}(1)$ and $\mathrm{U}(1)\times\mathrm{SU}(2)$, which are not semisimple, and which only lead to the traditional Fourier decompositions. Here we disregard those cases.

Two and two of the four groups of rank 2 are related by their root and weight lattices. Specifically, for $\mathrm{A}_1\times\mathrm{A}_1$ and C_2 the lattices are rectangular, whereas they are triangular for A_2 and G_2.

Discrete expansions of functions given on the fundamental region of a compact semisimple Lie group in terms of *S*-functions are described here for the first time. It turns out that the discretization of *C*-function expansions laid out in Ref. 8 is valid also for *S*-functions with only minimal modifications. In the one-dimensional case the transforms are known and are called cosine and sine transforms, respectively.[12]

The main goal of this article is to describe properties of the *S*-functions, and their exploitation for continuous and discrete expansions of class functions of the corresponding Lie group of rank 2, into a series of *S*-functions. We provide such a description in an explicit ready-to-use form. Apparently such expansions have not been considered in the literature. Crucial property for the expansions is the orthogonality of *S*-functions, both continuous and discrete. For rank 2 that is shown by direct computation. In general, for compact semisimple Lie groups of any rank $n<\infty$, it is proven elsewhere.[13]

In one dimension the underlying group is the group A_1. Expansion functions in this case are the familiar ones:

$$C\text{-functions of } \mathrm{A}_1\text{:} \quad C_m(z) \overset{\text{def}}{=} 2\cos(\pi m z), \quad m \in \mathbb{Z}^{\geqslant 0}, z \in \mathbb{R},$$

$$S\text{-functions of } \mathrm{A}_1\text{:} \quad S_m(z) \overset{\text{def}}{=} 2i\sin(\pi m z), \quad m \in \mathbb{N}, z \in \mathbb{R}.$$

In higher dimensions, *C*-functions generalize cosines, whereas the *S*-functions generalize sines. From that we take the terms *C*- and *S*-functions.

An observation, important for the generalization, is that in 1-dimension the functions inside of either family are orthogonal not only when integrated over $0 \leqslant z \leqslant 2$, but already when they are integrated over $0 \leqslant z \leqslant 1$. That range of z is the fundamental region F of A_1.

Let us point out properties of the (continuous) C- and S-functions which they have in common and where they differ.

(a) Minimal domains of their orthogonality coincide. It is the fundamental region F of the corresponding Lie group.
(b) C- and S-functions with the same dominant weight have the same number of exponential constituents.
(c) The symmetry properties of C- and S-functions with respect of the affine Weyl group coincide up to a sign.
(d) C- and S- functions are eigenfunctions of the same Laplace operators. Their eigenvalues are up to a constant equal to the square length of their dominant weights.
(e) Discretizations of both families is made on identically defined grids in F.
(f) Products of any two C-functions decompose into a sum of C-functions with positive integer coefficients. Products of any C- and S-function decomposes into a sum of S-functions with positive integer coefficients. Products of any two S-functions decompose into a sum of C-functions with integer coefficients. Only the highest and the lowest terms in such decompositions are easily determined. Efficient and general algorithms for the decompositions are yet to be found.
(g) Dominant weights labeling C-functions are in the positive Weyl chamber P^+ of the weight lattice P. Dominant weights labeling S-functions are restricted to the interior P^{++} of P^+. More precisely, S-functions with dominant weight at the boundary of P^+ turn out to be zero. One has $P^{++} \subset P^+ \subset P$.

Let us underline some notations used throughout the article. The symbols $\mathbb{C}$, $\mathbb{R}$, $\mathbb{Z}$, and $\mathbb{N}$ denote complex, real, integer, and positive integer numbers, respectively. In a real Euclidean space $\mathbb{R}^2$ of dimension two the form $\langle a|b\rangle$ denotes the scalar product of $a,b \in \mathbb{R}^2$, whereas in the complex space of functions, it denotes a Hermitian form.

In Sec. II we present a brief introduction to one-dimensional S-functions and an overview of the one-dimensional S-function transform; Sec. III describes the S-functions in the general case, whereas the cases for the four compact semisimple groups of rank two are described in Sec. IV; polynomials derived from C- and S-functions are briefly presented in Sec. V; Sec. VI contains the discretization of the S-function transforms for all the two-dimensional cases; some comparative examples are given in Sec. VII; and, finally, the concluding remarks are found in Sec. VIII.

II. THE GROUP A_1

The rank 1 case is transparent without reference to the underlying simple Lie group A_1.

A. The continuous case

The S-functions of A_1 happen to be the familiar periodic functions

$$S_m(z) = 2i \sin(\pi m z), \quad m \in \mathbb{N}, \quad z \in \mathbb{R}. \tag{2.1}$$

In particular

$$S_m(0) = S_m(1) = \cdots = S_m(k) = 0, \quad \forall\, k \in \mathbb{Z}.$$

Note that $m=0$ is excluded from consideration in Eq. (2.1). The functions are pairwise orthogonal. Indeed, the Hermitian form of two S-functions

$$\langle S_m(z)|S_{m'}(z)\rangle \overset{\text{def}}{=} \int_0^1 S_m(z)\overline{S_{m'}(z)}\mathrm{d}z = \int_0^1 4\sin(\pi m z)\sin(\pi m' z)\mathrm{d}z \sim \delta_{m,m'}.$$

Consequently, the continuous sine transform is the expansion of functions over $0 \leqslant z \leqslant 1$ and its inversion,

$$f(z) = \sum_{m=1}^{\infty} d_m S_m(z),$$

where the expansion coefficients d_m are obtained from

$$d_m \sim \langle f(z)|S_m(z)\rangle = \int_0^1 f(z)\cdot(-2i\sin(\pi m z))\mathrm{d}z.$$

Somewhat more generally, the expansion and its inversion would hold for any $a \leqslant z \leqslant a+1$ with $a \in \mathbb{R}$.

We refrain from recalling well known properties of S-functions in this case even if they become rather non-trivial in subsequent generalizations.

B. Discretization in one dimension

Fixing $M \in \mathbb{N}$, determines an equidistant grid of $M+1$ points F_M

$$F_M \overset{\text{def}}{=} \left\{ s = \frac{s_1}{M} \mid s_0 + s_1 = M > 0, s_0, \quad s_1 \in \mathbb{Z}^{\geqslant 0} \right\}$$

by running the values of nonnegative integers s_0 and s_1 through their admissible values. Thus we have explicitly

$$F_M = \left\{ 0, \frac{1}{M}, \frac{2}{M}, \frac{3}{M}, \ldots, \frac{M-1}{M}, 1 \right\}.$$

The values of S-functions on the points of the grid F_M are thus

$$S_m(s) = 2i\sin(\pi m s), \quad s \in F_M, \quad m \in \mathbb{N}.$$

Since the values of the S-functions are always equal to 0 on the points $k\pi$, $k \in \mathbb{Z}$, it makes sense to exclude such points from F_M. Thus we obtain a grid of $M-1$ points which we define by F_M^-

$$F_M^- \overset{\text{def}}{=} \left\{ s = \frac{s_1}{M} \mid s_0 + s_1 = M, \quad s_0, s_1 \in \mathbb{N} \right\} = F_M \setminus \partial F.$$

Discrete orthogonality for $0 < m, m' < M$ is defined on F_M^- using a discrete version of the Hermitian form

$$\langle S_m|S_{m'}\rangle_M \overset{\text{def}}{=} \sum_{s \in F_M^-} S_m(s)\overline{S_{m'}(s)} = 2M\delta_{m,m'}.$$

Our aim in developing the formalism so far, is to use it for expansion of functions $f(s)$, given by its values on the grid F_M^-.

We have the discrete sine transform of A_1,

$$f(s) = \sum_{m=1}^{M-1} a_m S_m(s), \quad a_m = \frac{1}{2M}\sum_{s \in F_M^-} f(s)\overline{S_m(s)}, \tag{2.2}$$

and its continuous extension

$$f(z) = \sum_{m=1}^{M-1} a_m S_m(z), \quad \text{for } z \in \mathbb{R}. \tag{2.3}$$

A remarkable property of the continuous extension [Eq. (2.3)] is how smoothly it interpolates the values of $f(s)$ between the points of the grid F_M^-. Analogous property of continuous extension of cosine transform was established in Refs. 3, 14, and 15, see also Refs. 1 and 2.

III. HIGHER RANK CASES IN GENERAL

Most of the tools and properties we need can be presented in a uniform way for any dimension $n < \infty$. In this section we recall to some of the facts brought forward in the first two parts of the series.[1,2]

Such are α- and ω-bases, the bases of simple roots and fundamental weights, respectively, their duals, whenever those are different, corresponding root and weight lattices, Q and P, respectively, the positive chamber $P^+ \subset P$; the finite Weyl groups W and their orbits W_λ, the infinite affine Weyl groups W^{aff} and its fundamental region F (colloquially called also the fundamental region of the Lie group).

A. Definition of *S*-functions (Ref. 9)

The definitions of S- and C-function, $S_\lambda(z)$ and $C_\lambda(z)$, respectively, involve both $\lambda \in P^+$ and $z \in \mathbb{R}^n$. It requires also the W-orbit W_λ of λ. The compact semisimple Lie group enters only through its Weyl group and through the fact that the functions are formed as sums of exponential functions, constituents of irreducible characters. One has,

$$S_{\lambda+\rho}(z) \overset{\text{def}}{=} \sum_{\mu \in W_{\lambda+\rho}} (-1)^{p(\mu)} e^{2\pi i \langle \mu | z \rangle}, \tag{3.1}$$

$$C_\lambda(z) \overset{\text{def}}{=} \sum_{\mu \in W_\lambda} e^{2\pi i \langle \mu | z \rangle}, \quad \lambda \in P^+, \quad z \in \mathbb{R}^n. \tag{3.2}$$

Here $p(\mu)$ is the number of elementary reflections of W one needs to transform $\lambda+\rho$ to μ. The symbol ρ is the half-sum of positive roots of the Lie group. Relative to the ω-basis, it happens to be the vector

$$\rho = \sum_{k=1}^{n} \omega_k = (1,1,\ldots,1)$$

for every semisimple Lie group of rank $1 \leqslant n < \infty$.

The number of summands in Eqs. (3.1) and (3.2) is finite. It is equal to the number of weights in the corresponding Weyl group orbit. That number varies for C-functions (it is always one of the divisors of the order of the Weyl group). More precisely, the number of terms in W_λ is equal to the ratio

$$|W_\lambda| = \frac{|W|}{|\text{Stab}_W \lambda|}.$$

However, for S-functions, the number of summands in Eq. (3.1) always coincides with the order of the Weyl group because the stabilizer of $\lambda+\rho$ is always 1. That is, a weight $\lambda+\rho$, with $\lambda \in P^+$, has only the trivial stabilizer in W.

B. Orthogonality of *S*- and *C*-functions

Suppose that the S- and C-functions belong to the same Weyl group (equivalently to the same compact semisimple Lie group). Then we have the orthogonality relations:

$$\langle S_{\lambda+\rho}(z)|S_{\lambda'+\rho}(z)\rangle \overset{\text{def}}{=} \int_F S_{\lambda+\rho}(z)\overline{S_{\lambda'+\rho}(z)}\mathrm{d}z \sim \delta_{\lambda,\lambda'},$$

$$\langle C_{\lambda}(z)|C_{\lambda'}(z)\rangle \overset{\text{def}}{=} \int_F C_{\lambda}(z)\overline{C_{\lambda'}(z)}\mathrm{d}z \sim \delta_{\lambda,\lambda'},$$

where the overbar denotes complex conjugation.

C. Decomposition of functions on *F*

Continuous *S*-transform of a function $f(z)$ on F, is the decomposition

$$f(z) = \sum_{\lambda \in P^+} b_\lambda S_{\lambda+\rho}(z) = \sum_{\lambda \in P^{++}} b_\lambda S_{\lambda+\rho}(z), \quad \text{for } z \in F$$

and its inversion

$$b_\lambda = \frac{1}{\langle S_{\lambda+\rho}|S_{\lambda+\rho}\rangle}\int_F f(z)\overline{S_{\lambda+\rho}(z)}\mathrm{d}F.$$

Since $S_{\lambda+\rho}(z)=0$ when z is at the boundary ∂F of F, the *S*-transform is appropriate for functions $f(z)$ having zero values at ∂F.

D. Weyl group antisymmetries of *S*-functions

Important antisymmetry properties of *S*-functions are the following three:

$$S_{\lambda+\rho}(r_k z) = -S_{\lambda+\rho}(z), \quad k = 1,2,\ldots,n,$$

$$S_{\lambda+\rho}(r_j r_k z) = S_{\lambda+\rho}(z), \quad j,k = 1,2,\ldots,n,$$

$$S_{\lambda+\rho}(R_{\xi_h} z) = -S_{\lambda+\rho}(z),$$

where r_k, $k=1,2,\ldots,n$ are the Weyl group reflections and R_{ξ_h} is the affine reflection with respect to the highest root ξ_h, see Refs. 1 and 2.

E. Laplace operator

The *C*- and *S*-functions are eigenfunctions of the same Laplace operator. Moreover, the eigenvalues of $C_\mu(z)$ and $S_{\lambda+\rho}(z)$, coincide if $\mu=\lambda+\rho$. They are determined, up to a constant, by the square length of the weight of the Weyl group orbit.

Special cases of type A_2 (in our notation) are found in the literature, see Refs. 16–19.

Consider the application of the following operator on *S*-functions:

$$LS_{\lambda+\rho}(z) = \left(\sum_{k=1}^{n} \alpha_k \partial_k\right)^2 S_{\lambda+\rho}(z) = \sum_{j=1}^{n}\sum_{k=1}^{n} \langle \alpha_j|\alpha_k\rangle \partial_j\partial_k S_{\lambda+\rho}(z) = -4\pi^2\langle \lambda+\rho|\lambda+\rho\rangle S_{\lambda+\rho}(z).$$

Here we take ∂_k as acting on the kth coordinates of z in $\check{\omega}$-basis.

On the boundary ∂F of F one has

$$S_{\lambda+\rho}(z) = 0, \quad z \in \partial F.$$

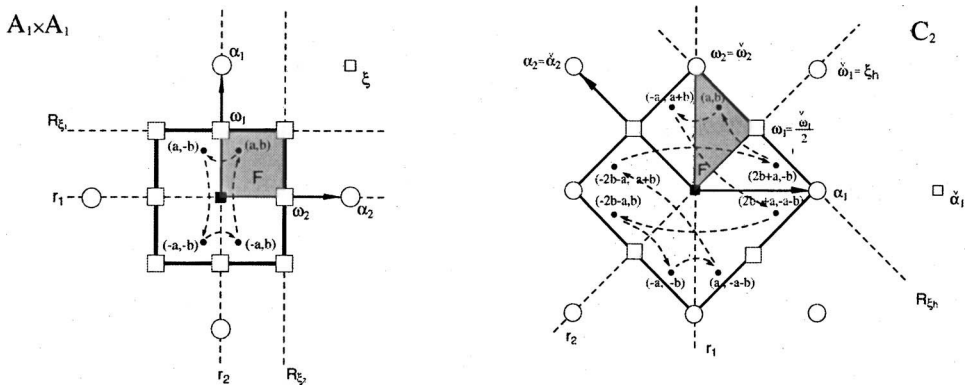

FIG. 1. The simple roots, the fundamental weights, along with their duals, and the fundamental region for the cases $A_1 \times A_1$ and C_2. The thick line square encloses the proximity cell to origin of the dual root lattice in each case. The dots are points of a generic Weyl group orbit for a, b not integers.

F. Decomposition of products of *S*- and *C*-functions

Products of *S*- and *C*-functions referring to the same Lie group and for the same z are completely decomposable into their linear combination. More precisely, products of *S*- and *C*-functions decompose into finite sums of *S*-functions,

$$S_{\lambda+\rho}C_{\lambda'} = S_{\lambda+\lambda'+\rho} + \cdots$$

It is a computational problem to find the remaining terms of the sum and their multiplicities in each case.

Products of two *S*-functions decompose into finite linear combinations of *C*-functions with integer coefficients of both signs, in general.

$$S_{\lambda+\rho}S_{\lambda'+\rho} = C_{\lambda+\lambda'+2\rho} + \cdots$$

We have seen in Refs. 1 and 2 that also products of *C*-functions decompose into sums of *C*-functions

$$C_{\lambda}C_{\lambda'} = C_{\lambda+\lambda'} + \cdots$$

with positive integer coefficients.

IV. THE TWO-DIMENSIONAL CONTINUOUS CASES

A. The group $A_1 \times A_1$

This is a straightforward concatenation of two A_1 cases of Sec. II.

Lengths and angles of the simple roots are given by the scalar products

$$\langle \alpha_1 | \alpha_2 \rangle = 0, \quad \langle \alpha_1 | \alpha_1 \rangle = \langle \alpha_2 | \alpha_2 \rangle = 2.$$

The Cartan matrix and its inverse are

$$C = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}, \quad C^{-1} = \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & \frac{1}{2} \end{pmatrix}.$$

Consequently, $\alpha_1 = 2\omega_1$ and $\alpha_2 = 2\omega_2$. Also $\check{\alpha}_j = \alpha_j$ and $\check{\omega}_j = \omega_j$ for $j = 1, 2$. Further, the root system $\Delta = \{\pm\alpha_1, \pm\alpha_2\}$ geometrically represents vertices of a square, see Fig. 1. The fundamental region F is the Cartesian product of two fundamental regions of A_1, namely, the square $[0,1] \times [0,1]$.

The *S*-functions are defined for W_λ-orbits with only a trivial stabilizer in W, i.e., such that $\lambda = a\omega_1 + b\omega_2 \in P^{++} \subset P^+$, where $a, b \in \mathbb{N}$. Then the Weyl group orbit W_λ is given by

$$W_\lambda \equiv W_{(a,b)} = \{\pm(a,b), \pm(a,-b)\}.$$

The S-functions of $A_1 \times A_1$, with $\lambda = a\omega_1 + b\omega_2$ and $z = x\omega_1 + y\omega_2$ are products of two S-functions of A_1

$$S_{(a,b)}(x,y) = S_a(x)S_b(y) = -4\sin(\pi a x)\sin(\pi b y), \quad a,b \in \mathbb{N} \text{ and } x,y \in \mathbb{R}.$$

The orthogonality relation of the S-functions of $A_1 \times A_1$ is expressed by the following:

$$\int_F S_{(a,b)}(x,y)S_{(c,d)}(x,y)\mathrm{d}F = \int_0^1 \mathrm{d}x \int_0^1 \mathrm{d}y S_{(a,b)}(x,y)S_{(c,d)}(x,y) = 4\delta_{a,c}\delta_{b,d}.$$

B. The group C_2

First we recall standard information about α- and ω-bases in this case. Lengths and angles of the simple roots are given by

$$\langle \alpha_1 | \alpha_2 \rangle = -1, \quad \langle \alpha_1 | \alpha_1 \rangle = 1, \quad \langle \alpha_2 | \alpha_2 \rangle = 2.$$

The Cartan matrix and its inverse are

$$C = \begin{pmatrix} 2 & -1 \\ -2 & 2 \end{pmatrix}, \quad C^{-1} = \begin{pmatrix} 1 & \frac{1}{2} \\ 1 & 1 \end{pmatrix}.$$

Consequently,

$$\begin{aligned} \alpha_1 &= 2\omega_1 - \omega_2, & \omega_1 &= \alpha_1 + \tfrac{1}{2}\alpha_2, & \check{\omega}_1 &= 2\omega_1, \\ \alpha_2 &= -2\omega_2 + 2\omega_2, & \omega_2 &= \alpha_1 + \alpha_2, & \check{\omega}_2 &= \omega_2. \end{aligned}$$

The root system $\Delta = \{\pm(2\alpha_1 + \alpha_2), \pm(\alpha_1 + \alpha_2), \pm\alpha_1, \pm\alpha_2\}$ geometrically represents vertices and midpoints of a square. The highest root is $\xi_h = 2\alpha_1 + \alpha_2$.

Put $\lambda = a\omega_1 + b\omega_2 \in P^{++}$. Then the Weyl group orbit W_λ consists of the following eight points:

$$W_\lambda \equiv W_{(a,b)} = \{\pm(a,b), \pm(-a,a+b), \pm(a+2b,-b), \pm(a+2b,-a-b)\}.$$

The S-functions of C_2, with $\lambda = a\omega_1 + b\omega_2$ and $z = x\check{\omega}_1 + y\check{\omega}_2$, are all real-valued, namely the following:

$$\begin{aligned} S_{(a,b)}(x,y) = {} & 2\cos(\pi(2(a+b)x + (a+2b)y)) - 2\cos(\pi(2(a+b)x) + ay) \\ & - 2\cos(\pi(2bx + (a+2b)y)) + 2\cos(\pi(-2bx + ay)), \end{aligned}$$

where $a,b \in \mathbb{N}$ and $x,y \in \mathbb{R}$.

The fundamental region $F(C_2)$ is described by

$$F(C_2) = \{x\check{\omega}_1 + y\check{\omega}_2 \mid 0 \leqslant x,y;\ 1 \geqslant 2x + y\}.$$

The orthogonality relation of the S-functions of C_2 is expressed by the following:

$$\int_F S_{(a,b)}(x,y)S_{(c,d)}(x,y)\mathrm{d}F = \int_0^{1/2} dx \int_0^{1-2x} S_{(a,b)}(x,y)S_{(c,d)}(x,y)\mathrm{d}y = 2\delta_{a,c}\delta_{b,d}.$$

C. The group A_2

Lengths and angles of the simple roots are given by

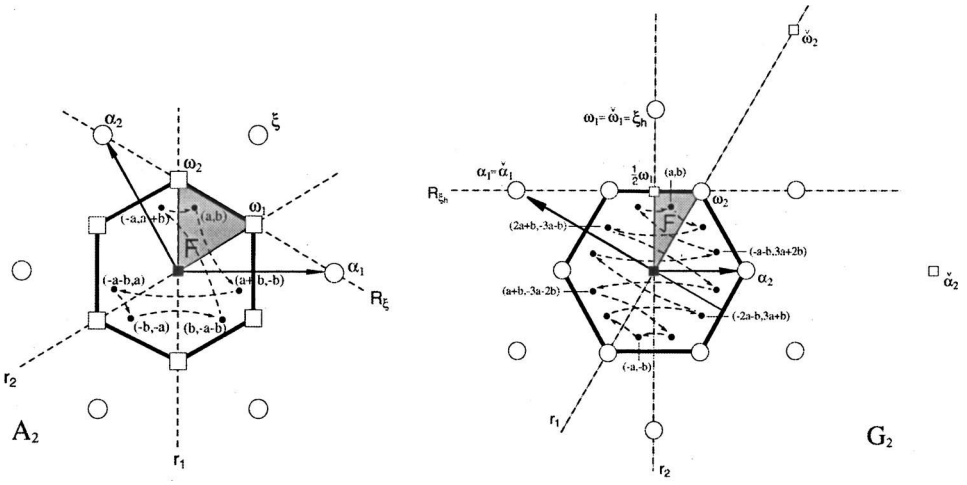

FIG. 2. The simple roots, the fundamental weights, along with their duals, and the fundamental region for the cases A_2 and G_2. The thick line hexagon encloses the proximity cell to origin of the dual root lattice in each case. The dots are points of a generic Weyl group orbit for a, b not integers.

$$\langle \alpha_1 | \alpha_2 \rangle = -1, \quad \langle \alpha_1 | \alpha_1 \rangle = \langle \alpha_2 | \alpha_2 \rangle = 2.$$

The Cartan matrix and its inverse are

$$C = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \quad C^{-1} = \tfrac{1}{3}\begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}.$$

Consequently,

$$\alpha_1 = 2\omega_1 - \omega_2, \quad \omega_1 = \tfrac{1}{3}(2\alpha_1 + \alpha_2),$$

$$\alpha_2 = -\omega_2 + 2\omega_2, \quad \omega_2 = \tfrac{1}{3}(\alpha_1 + 2\alpha_2).$$

Also $\check{\alpha}_j = \alpha_j$ and $\check{\omega}_j = \omega_j$ for $j = 1, 2$.

The root system $\Delta = \{\pm(\alpha_1 + \alpha_2), \pm\alpha_1, \pm\alpha_2\}$ geometrically represents vertices of a regular hexagon, see Fig. 2.

Put $\lambda = a\omega_1 + b\omega_2 \in P^{++}$. Then the Weyl group orbit W_λ consists of the points given here in ω-basis

$$W_\lambda \equiv W_{(a,b)} = \{(a,b),(-a,a+b),(a+b,-b),(-b,-a),(b,-a-b),(-a-b,a)\}.$$

The S-functions of A_2 are then defined

$$\begin{aligned} S_{(a,b)}(x,y) = {} & e^{(2\pi i/3)((2a+b)x+(a+2b)y)} - e^{(2\pi i/3)((-a+b)x+(a+2b)y)} \\ & - e^{(2\pi i/3)((2a+b)x+(a-b)y)} + e^{-(2\pi i/3)((a-b)x+(2a+b)y)} \\ & + e^{-(2\pi i/3)((a+2b)x+(b-a)y)} - e^{-(2\pi i/3)((2b+a)x+(b+2a)y)}, \end{aligned}$$

$$S_{(a,a)}(x,y) = -2i(\sin(2\pi a y) + \sin(2\pi a y) - 2\sin(2\pi a(x+y))),$$

where $a, b \in \mathbb{N}$ and $x, y \in \mathbb{R}$.

The fundamental region $F(A_2)$ is described by

$$F(A_2) = \{x\omega_1 + y\omega_2 \mid 0 \leqslant x, y; \quad 1 \geqslant x + y\}.$$

The orthogonality relation of the S-functions of A_2 is expressed by

$$\int_F S_{(a,b)}(x,y)\overline{S_{(c,d)}(x,y)}\mathrm{d}x\mathrm{d}y = \frac{1}{\sqrt{3}}\int_0^1 \mathrm{d}x \int_0^{1-x} S_{(a,b)}(x,y)\overline{S_{(c,d)}(x,y)}\mathrm{d}y = \sqrt{3}\,\delta_{a,c}\delta_{b,d}.$$

Recall that for A_2 complex conjugation, denoted here by overbar, is also achieved by interchange of the subscripts, $S_{(a,b)}(x,y)=\overline{S_{(b,a)}(x,y)}$.

D. The group G_2

Lengths and angles of the simple roots are given by

$$\langle\alpha_1|\alpha_2\rangle = -1, \quad \langle\alpha_1|\alpha_1\rangle = 2, \quad \langle\alpha_2|\alpha_2\rangle = \tfrac{2}{3}.$$

The Cartan matrix and its inverse are

$$C = \begin{pmatrix} 2 & -3 \\ -1 & 2 \end{pmatrix}, \quad C^{-1} = \begin{pmatrix} 2 & 3 \\ 1 & 2 \end{pmatrix}.$$

Consequently,

$$\alpha_1 = 2\omega_1 - 3\omega_2, \quad \omega_1 = 2\alpha_1 + 3\alpha_2, \quad \check{\omega}_1 = \omega_1, \quad \check{\alpha}_1 = \alpha_1,$$

$$\alpha_2 = -\omega_2 + 2\omega_2, \quad \omega_2 = \alpha_1 + 2\alpha_2, \quad \check{\omega}_2 = 3\omega_2, \quad \check{\alpha}_2 = 3\alpha_2.$$

Note that in this case, $\alpha_1,\ \alpha_2 \in P$. Hence the root and weight lattices coincide.

The root system

$$\Delta = \{\pm(2\alpha_1 + 3\alpha_2), \pm(\alpha_1 + 3\alpha_2), \pm(\alpha_1 + 2\alpha_2), \pm(\alpha_1 + \alpha_2), \pm\alpha_1, \pm\alpha_2\}$$

geometrically represents the twelve vertices of a regular hexagonal star, see Fig. 2.

Let $\lambda = a\omega_1 + b\omega_2 \in P^{++}$. Then the Weyl group orbit W_λ is given by

$$W_\lambda \equiv W_{(a,b)} = \{\pm(a,b), \pm(-a,3a+b), \pm(a+b,-b),$$
$$\pm(2a+b,-3a-b), \pm(-a-b,-3a+2b), \pm(2a+b,-3a-2b)\}.$$

The S-functions of G_2, with $\lambda = a\omega_1 + b\omega_2$ and $z = x\check{\omega}_1 + y\check{\omega}_2$, are all real:

$$\begin{aligned} S_{(a,b)}(x,y) = {} & 2\cos(2\pi((a+b)x+by)) + 2\cos(2\pi((2a+b)x+(3a+2b)y)) \\ & - 2\cos(2\pi(ax-by)) - 2\cos(2\pi((a+b)x+(3a+2b)y)) \\ & - 2\cos(2\pi((2a+b)x+(3a+b)y)) + 2\cos(2\pi(ax+(3a+b)y)), \end{aligned}$$

where $a,b \in \mathbb{N}$ and $x,y \in \mathbb{R}$.

The fundamental region $F(G_2)$ is described by

$$F(G_2) = \{x\check{\omega}_1 + y\check{\omega}_2 \mid 0 \leqslant x,y;\ 1 \geqslant 2x+3y\}.$$

The orthogonality relation of the S-functions of G_2 is expressed by the following:

$$\int_F S_{(a,b)}(x,y)S_{(c,d)}(x,y)\mathrm{d}F = \sqrt{3}\int_0^{1/2} dx \int_0^{2/3-(1/2)x} S_{(a,b)}(x,y)S_{(c,d)}(x,y)\mathrm{d}y = \sqrt{3}\,\delta_{a,c}\delta_{b,d}.$$

V. *C*- AND *S*-POLYNOMIALS IN TWO VARIABLES

The *C*- and *S*-functions can be viewed also as polynomials.[1,2,7] From a narrow perspective of our functions, variables of such polynomials take values on an n-dimensional torus. However, it is natural to enlarge one's perspective and consider the variables as taking any complex values.

In general, properties of the polynomials arising from the *C*-, *S*-, and *E*-functions[9,10] will be studied elsewhere. In here we just point out the structure of these polynomials and their relation to semisimple Lie groups. For a more general approach, see Refs. 20 and 21.

A. *S*-polynomials

Assuming that $a,b \in \mathbb{N}$, and after a suitable substitution of variables, the *S*-functions are converted to polynomials, say in X and Y. Thus, for example, the substitutions

$$X = e^{(2\pi i/3)(2x+y)}, \quad Y = e^{(2\pi i/3)(x+2y)}, \quad \text{for } x,y \in \mathbb{R},$$

convert the generic *S*-function of A_2 into the corresponding polynomial.

The *S*-polynomials $S_{(a,b)}(X,Y)$ of compact semisimple Lie groups of rank two are the following ones.

$$\begin{aligned}
\mathrm{A}_1 \times \mathrm{A}_1\colon\ & X^aY^b - X^{-a}Y^b - X^aY^{-b} + X^{-a}Y^{-b},\\
\mathrm{A}_2\colon\ & X^aY^b - X^{-a}Y^{a+b} - X^{a+b}Y^{-b} + X^bY^{-a-b}\\
& + X^{-a-b}Y^a - X^{-b}Y^{-a},\\
\mathrm{C}_2\colon\ & X^aY^b - X^{-a}Y^{a+b} - X^{a+2b}Y^{-b}\\
& + X^{a+2b}Y^{-a-b} + X^{-a-2b}Y^{a+b}\\
& - X^{-a-2b}Y^b - X^aY^{-a-b} + X^{-a}Y^{-b},\\
\mathrm{G}_2\colon\ & X^aY^b - X^{-a}Y^{3a+b} - X^{a+b}Y^{-b} + X^{2a+b}Y^{-3a-b}\\
& + X^{a-b}Y^{3a+2b} - X^{-2a-b}Y^{3a+2b} - X^{-2a-b}Y^{3a+b}\\
& + X^{-a+b}Y^{-3a-b} + X^{2a+b}Y^{-3a-2b} - X^{-a-b}Y^b\\
& - X^aY^{-3a-b} + X^{-a}Y^{-b}.
\end{aligned}$$

Although the *S*-functions are defined for a and b strictly positive, one sees from the above polynomials that they turn to zero whenever either $a=0$ or $b=0$.

B. *C*-polynomials

A *C*-polynomial $C_\lambda(z)$ differs from an *S*-polynomial $S_\lambda(z)$ for the same group of rank 2, in two ways. Both are formed by the same monomials, but in the case of $C_\lambda(z)$ all signs are positive. Second, $C_\lambda(z)$ is also different from zero for $\lambda=(0,b)$, $(a,0)$, and $(0,0)$.

VI. DISCRETIZATION OF 2-DIMENSIONAL TRANSFORMS

We recall the essentials of the discretization in the case of *S*-functions even if it closely parallels that of *C*-functions.[1,2] In fact it is noticeably simpler. That is related to $S_\lambda(z)$ being equal to zero when $z \in \partial F$. Therefore points z at the boundary of F do not contribute to the value of a scalar product (or Hermitian form if the values are complex) of two *S*-functions.

A. Equidistant grids of points in the fundamental region

The fundamental region F can be used to tile the entire plane $\mathbb{R}^2$ by reflecting it repeatedly in its sides. A grid F_M of discrete points in F of any density is fixed by a positive integer M. One requires that the grid extends to a lattice during the tiling of $\mathbb{R}^2$ by copies of F.

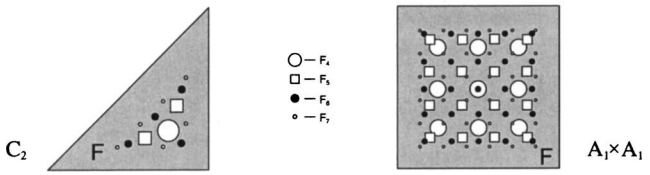

FIG. 3. The lattice points of F_4^-, F_5^-, F_6^-, and F_7^- in the fundamental region F for the cases $A_1 \times A_1$ and C_2.

The points $z_s \in F_M$ are conveniently described in barycentric coordinates. That is, by fixing nonnegative integers, s_0, s_1, and s_2 such that

$$F_M \overset{\text{def}}{=} \left\{ \left(\frac{s_1}{M}, \frac{s_2}{M} \right) \mid s_0, s_1, s_2 \in \mathbb{Z}^{\geqslant 0}, \quad s_0 + q_1 s_1 + q_2 s_2 = M > 0 \right\},$$

where $z_s = (s_1/M, s_2/M) = (s_1/M)\check{\omega}_1 + (s_2/M)\check{\omega}_2$. The constants q_1 and q_2 are given by the highest root $\xi_h = q_1\alpha_1 + q_2\alpha_2$ of the group. Specifically,

$$A_2: \quad q_1 = q_2 = 1,$$

$$C_2: \quad q_1 = 2, \quad q_2 = 1,$$

$$G_2: \quad q_1 = 2, \quad q_2 = 3.$$

Since the S-functions are always equal to 0 on the boundary ∂F of the fundamental region F, it makes sense to exclude those points from F_M. Thus we obtain a subgrid of points which we define by F_M^-

$$F_M^- \overset{\text{def}}{=} \left\{ \left(\frac{s_1}{M}, \frac{s_2}{M} \right) \mid s_0, s_1, s_2 \in \mathbb{N}, \; s_0 + q_1 s_1 + q_2 s_2 = M \right\} = \{ s \in F_M, \text{ where } s \notin \partial F \}. \tag{6.1}$$

See Figs. 3 and 4 for examples of such grids.

B. Sesquilinear form on F_M

Given the set of points F_M in the fundamental region, and two functions $f(s)$ and $h(s)$ given by their values at the points $s \in F_M$. One defines a Hermitian form as follows.

$$\langle f | h \rangle_M \overset{\text{def}}{=} \sum_{s \in F_M} c_s f(s) \overline{h(s)}.$$

The overbar stands for complex conjugation. The coefficients c_s are positive integers specific for each Lie group. They are listed in Refs. 1 and 2 for the groups of rank 2. They do not intervene in this article because they are all equal on F_M^- to the order of the Weyl group,

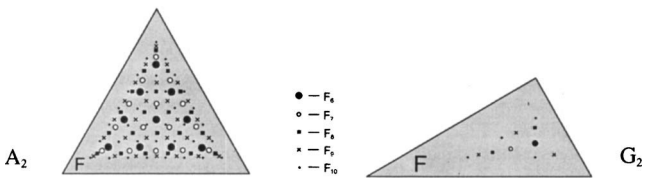

FIG. 4. The lattice points of F_6^-, F_7^-, F_8^-, F_9^-, and F_{10}^- in the fundamental region F for the cases A_2 and G_2.

$$c_s \equiv c, \quad s \in F_M^-,$$

hence would influence only the normalization of the form.

Besides, since S_λ are always 0 on the boundary ∂F of F, therefore, for the purpose of discretization in this paper, we can freely use

$$\langle f|h\rangle_M = c \sum_{s\in F_M^-} f(s)\overline{h(s)}$$

for any functions f and h.

C. Discrete orthogonality of *S*-functions

For a fixed value of $M \in \mathbb{N}$, the crucial property of S-functions is their discrete orthogonality on $F_M^- \subset F$:

$$\langle S_{(a,b)}|S_{(a',b')}\rangle_M = c \sum_{s\in F_M^-} S_{(a,b)}(s)\overline{S_{(a',b')}(s)} = \delta_{a,a'}\delta_{b,b'}\langle S_{(a,b)}|S_{(a,b)}\rangle_M. \tag{6.2}$$

It holds for (a,b), (a',b') from a finite subset S_M^- of S-functions. One has $S_{a,b} \in S_M^-$, provided a and b satisfy the inequality

$$a,b \in \mathbb{N}, \quad aq_2 + bq_1 < M \Leftrightarrow S_{(a,b)} \in S_M^-,$$

The numbers $\langle S_{(a,b)}|S_{(a,b)}\rangle_M$ in Eq. (6.2) take only integer multiples of M^2 for each M. Subsequently we provide them for all of the cases considered in this article and for all $0<a,b<\infty$.

D. Discretization in the case of $A_1 \times A_1$

This is a simple combination of two A_1-discretizations already described in Sec. II, in two orthogonal directions.

In the general case, the density of points $s \in F_{M,M'}^-$ is chosen by fixing positive integers M and M'. A rectangular lattice $F_{M,M'}^-$, of orders M in the ω_1-direction and M' in the ω_2-direction, is built on F the following way:

$$F_{M,M'}^-(A_1 \times A_1) = \left\{ \frac{s_1}{M}\omega_1 + \frac{s_1'}{M'}\omega_2 \mid s_0 + s_1 = M,\ s_0' + s_1' = M',\ s_0,s_1,s_0',s_1' \in \mathbb{N} \right\}.$$

In this case the coefficient $c=4$.

The S-functions are discretely orthogonal, i.e., for $S_{(a,b)}, S_{(a',b')} \in S_{M,M'}^-(A_1\times A_1) = \{S_{(a,b)}|a,b\in\mathbb{N}, a<M, b<M'\}$:

$$\langle S_{(a,b)}|S_{(a',b')}\rangle_{M,M'} = 4 \sum_{s\in F_{M,M'}^-} S_{(a,b)}(s)S_{(a',b')}(s) = \begin{cases} 0 & \text{if } a \neq a' \text{ or } b \neq b' \\ 16MM' & \text{otherwise,} \end{cases}$$

with the higher S-functions repeating the values of the functions in $S_{M,M'}^-$.

For simplicity, we choose $M=M'$ in our examples, and for simplicity, in such cases we denote the $F_{M,M'}^-$ by only F_M^- and $S_{M,M'}^-$ by S_M^-.

Examples: $F_4^-(A_1\times A_1)$ is a square grid with $M=M'=4$ that consists of the nine points (see Fig. 3) given as $[s_0,s_1],[s_0',s_1'] = (s_1/4, s_1'/4)$:

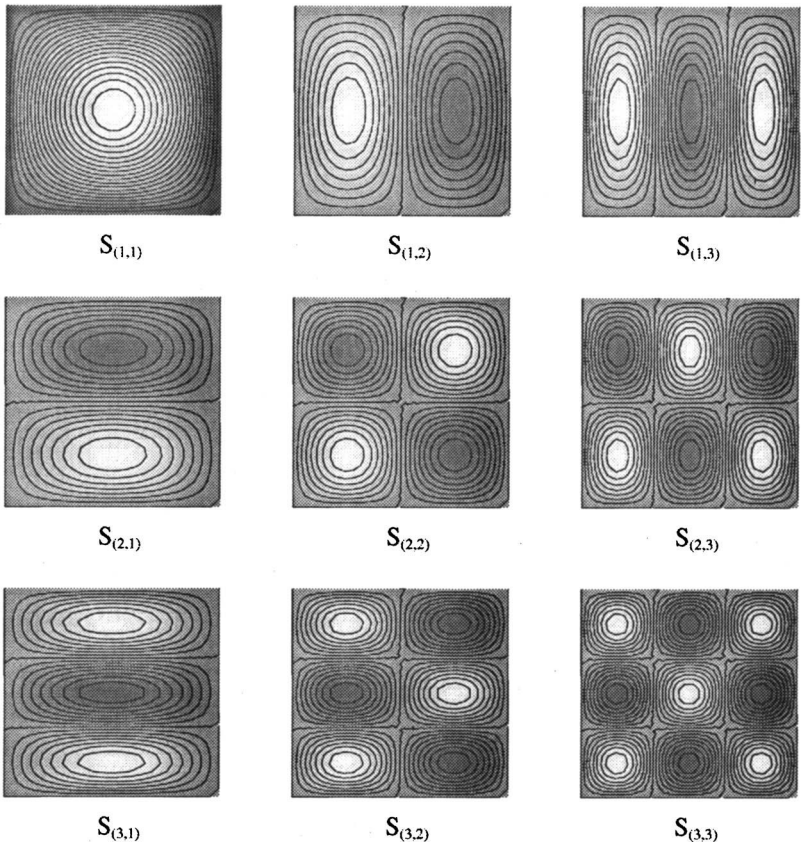

FIG. 5. The set of nine lowest pairwise orthogonal S-functions of $A_1 \times A_1$ for the grid $F_4^-(A_1 \times A_1)$.

$$
\begin{aligned}
&[3,1],[3,1]=\left(\tfrac{1}{4},\tfrac{1}{4}\right), \quad [3,1],[2,2]=\left(\tfrac{1}{4},\tfrac{1}{2}\right), \quad [3,1],[1,3]=\left(\tfrac{1}{4},\tfrac{3}{4}\right),\\
&[2,2],[3,1]=\left(\tfrac{1}{2},\tfrac{1}{4}\right), \quad [2,2],[2,2]=\left(\tfrac{1}{2},\tfrac{1}{2}\right), \quad [2,2],[1,3]=\left(\tfrac{1}{2},\tfrac{3}{4}\right),\\
&[1,3],[3,1]=\left(\tfrac{3}{4},\tfrac{1}{4}\right), \quad [1,3],[2,2]=\left(\tfrac{3}{4},\tfrac{1}{2}\right), \quad [1,3],[1,3]=\left(\tfrac{3}{4},\tfrac{3}{4}\right),
\end{aligned}
$$

whereas $F_3^-(A_1 \times A_1)$ has only four points:

$$
[2,1],[2,1]=\left(\tfrac{1}{3},\tfrac{1}{3}\right), \quad [1,2],[2,1]=\left(\tfrac{2}{3},\tfrac{1}{3}\right), \quad [2,1],[1,2]=\left(\tfrac{1}{3},\tfrac{2}{3}\right), \quad [1,2],[1,2]=\left(\tfrac{2}{3},\tfrac{2}{3}\right).
$$

See Fig. 5 for examples of S-functions of $A_1 \times A_1$.

E. Discretization in the case of A_2

Individual points $s \in F_M^-$ are given by triplets $s=[s_0,s_1,s_2] \equiv (s_1/M, s_2/M)$ of positive integers that satisfy the following A_2 sum rule:

$$
s_0 + s_1 + s_2 = M, \quad s_0,s_1,s_2 \in \mathbb{N}. \tag{6.3}
$$

All points of $F_M^- \subset F$ are obtained by letting the three positive integers run through all the values compatible with Eq. (6.3). Equivalently,

$$
F_M^-(A_2) = \left\{ \frac{s_1}{M}\omega_1 + \frac{s_2}{M}\omega_2 \mid s_0,s_1,s_2 \in \mathbb{N}, s_0+s_1+s_2=M \right\}.
$$

In this case the coefficient $c=6$.

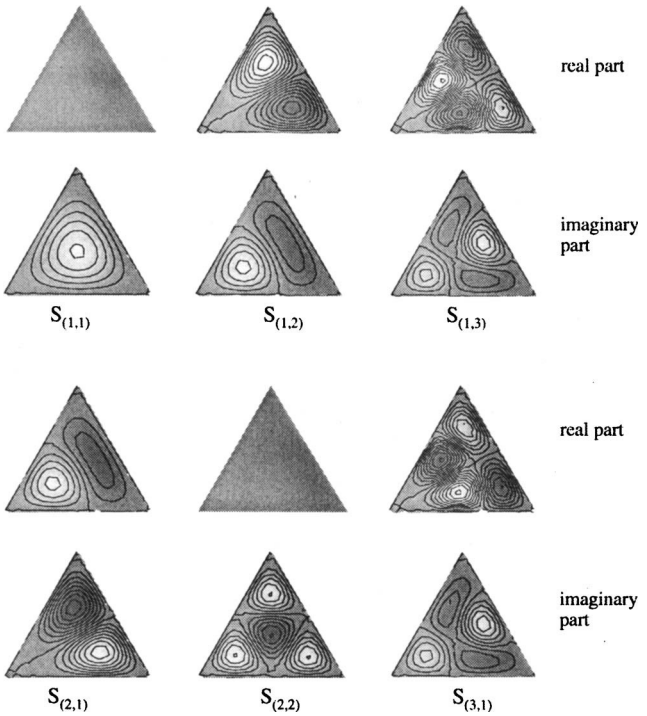

FIG. 6. The set of six lowest S-functions of A_2 which are pairwise orthogonal on the grid $F_5^-(A_2)$.

The S-functions are discretely orthogonal, i.e., for $S_{(a,b)}, S_{(a',b')} \in S_M^-(A_2) = \{S_{(a,b)} | a,b \in \mathbb{N}, a+b < M\}$:

$$\langle S_{(a,b)} | S_{(a',b')} \rangle_M = \begin{cases} 0 & \text{if } a \neq a' \text{ or } b \neq b' \\ 18M^2 & \text{otherwise,} \end{cases}$$

with the higher S-functions repeating the values of the functions in S_M^-.

Examples: $F_5^-(A_2)$ consists of the following six points (see Fig. 4) given as $[s_0, s_1, s_2] \equiv (s_1/M, s_2/M)$:

TABLE I. Values of several S-functions of A_2 at the six points of $F_5^-(A_2)$. Notation: $\kappa = 2i(-2\sin(2\pi/5) + \sin(\pi/5))$, $\zeta = -2i(\sin(2\pi/5) + 2\sin(\pi/5))$, and $\eta = e^{2\pi i/6}$.

$S_{(3,4)}(z_s)$	ζ	$\kappa\eta^5$	$\zeta\eta^4$	$\kappa\eta$	$\kappa\eta^3$	$\zeta\eta^2$
$S_{(4,4)}(z_s)$	κ	ζ	κ	ζ	ζ	κ

$$[1,1,3]=\left(\tfrac{1}{5},\tfrac{3}{5}\right),\quad [1,2,2]=\left(\tfrac{2}{5},\tfrac{2}{5}\right),\quad [1,3,1]=\left(\tfrac{3}{5},\tfrac{1}{5}\right),$$
$$[2,1,2]=\left(\tfrac{1}{5},\tfrac{2}{5}\right),\quad [2,2,1]=\left(\tfrac{2}{5},\tfrac{1}{5}\right),\quad [3,1,1]=\left(\tfrac{1}{5},\tfrac{1}{5}\right).$$

In Table I several S-functions are found along with their values at the points of $F_5^-(\mathrm{A}_2)$. The first six belong to $S_5^-(\mathrm{A}_2)$. However, a closer inspection reveals presence of another orthogonal set obtained from $S_5^-(\mathrm{A}_2)$ by affine reflection $R_{(5,5)}$ applied to all its elements.

Using the entries of Table I, where $\kappa=2i(-2\sin(2\pi/5)+\sin(\pi/5))$, $\zeta=-2i(\sin(2\pi/5)+2\sin(\pi/5))$, and $\eta=e^{2\pi i/6}$, let us calculate the products:

$$\begin{aligned}\langle S_{1,1}|S_{1,2}\rangle_5 &= 6(\kappa\cdot\bar{\zeta}+\zeta\cdot\overline{\kappa\eta^5}+\kappa\cdot\overline{\zeta\eta^4}+\zeta\cdot\overline{\kappa\eta}+\zeta\cdot\overline{\kappa\eta^3}+\kappa\cdot\overline{\zeta\eta^2})\\ &= 6(\kappa\bar{\zeta}\cdot(\overline{1+\eta^2+\eta^4})+\zeta\bar{\kappa}\cdot(\overline{\eta+\eta^3+\eta^5}))=0;\end{aligned}$$

$$\begin{aligned}\langle S_{1,2}|S_{1,2}\rangle_5 &= 6(\zeta\cdot\bar{\zeta}+\kappa\eta^5\cdot\overline{\kappa\eta^5}+\zeta\eta^4\cdot\overline{\zeta\eta^4}+\kappa\eta\cdot\overline{\kappa\eta}+\kappa\eta^3\cdot\overline{\kappa\eta^3}+\zeta\eta^2\cdot\overline{\zeta\eta^2})\\ &= 6.3(\kappa\bar{\kappa}+\zeta\bar{\zeta})=18(20(\sin(2\pi/5))^2+20(\sin(\pi/5))^2)\\ &= 18\cdot 25=450.\end{aligned}$$

See Fig. 6 for examples of S-functions of A_2.

F. Discretization in the case of C_2

The highest root of C_2 is $\xi_h,=2\alpha_1+2\alpha_2$, therefore the individual points $s\in F_M^-$ are given by triplets $s=[s_0,s_1,s_2]=(s_1/M,s_2/M)$ of positive integers that satisfy the following C_2 sum rule:

$$s_0+2s_1+s_2=M,\quad s_0,s_1,s_2\in\mathbb{N}. \tag{6.4}$$

All points of $F_M^-\subset F$ are obtained by letting the three positive integers run through all the values compatible with Eq. (6.4). Equivalently,

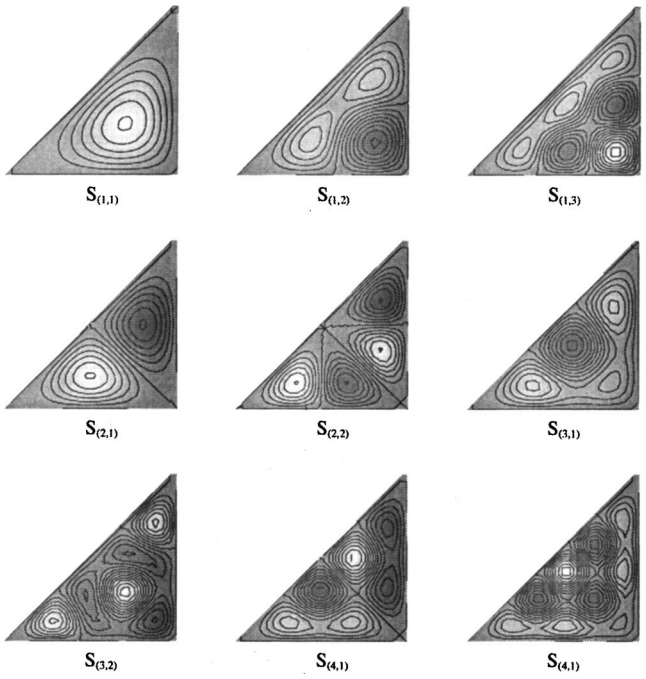

FIG. 7. The set of nine lowest S-functions of C_2 which are pairwise orthogonal on the grid $F_8^-(\mathrm{C}_2)$.

$$F_M^-(\mathrm{C}_2) = \left\{ \frac{s_1}{M}\check{\omega}_1 + \frac{s_2}{M}\check{\omega}_2 \mid s_0, s_1, s_2 \in \mathbb{N}, \quad s_0 + 2s_1 + s_2 = M \right\}.$$

In this case the coefficient $c=8$.

The S-functions are discretely orthogonal, i.e., for $S_{(a,b)}, S_{(a',b')} \in S_M^-(\mathrm{C}_2) = \{S_{(a,b)} | a, b \in \mathbb{N}, a + 2b < M\}$:

$$\langle S_{(a,b)} | S_{(a',b')} \rangle_M = \begin{cases} 0 & \text{if } a \neq a' \text{ or } b \neq b' \\ 16M^2 & \text{otherwise,} \end{cases}$$

with the higher S-functions repeating the values of the functions in S_M^-.

Examples: $F_7^-(\mathrm{C}_2)$ consists of the following six points given as $[s_0, s_1, s_2] \equiv (s_1/M, s_2/M)$:

$$[1,1,4] = \left(\tfrac{1}{7}, \tfrac{4}{7}\right), \quad [1,2,2] = \left(\tfrac{2}{7}, \tfrac{2}{7}\right), \quad [2,1,3] = \left(\tfrac{1}{7}, \tfrac{3}{7}\right),$$
$$[2,2,1] = \left(\tfrac{2}{7}, \tfrac{1}{7}\right), \quad [3,1,2] = \left(\tfrac{1}{7}, \tfrac{2}{7}\right), \quad [4,1,1] = \left(\tfrac{1}{7}, \tfrac{1}{7}\right).$$

See Fig. 7 for examples of S-functions of C_2.

G. Discretization in the case of G_2

As before, the value of M fixes the grid of discretization. The highest root of G_2 is $\xi_h = 2\alpha_1 + 3\alpha_2$, therefore the individual points $s \in F_M^-$ are given by triplets $s = [s_0, s_1, s_2] \equiv (s_1/M, s_2/M)$ of positive integers that satisfy the following G_2 sum rule:

$$s_0 + 2s_1 + 3s_2 = M, \quad s_0, s_1, s_2, \in \mathbb{N}. \tag{6.5}$$

All points of $F_M^- \subset F$ are obtained by letting the three positive integers run through all the values compatible with Eq. (6.5). Equivalently,

$$F_M^-(\mathrm{G}_2) = \left\{ \frac{s_1}{M}\check{\omega}_1 + \frac{s_2}{M}\check{\omega}_2 \mid s_0, s_1, s_2 \in \mathbb{N}, \quad s_0 + 2s_1 + 3s_2 = M \right\}.$$

In this case the coefficient c is equal to 12.

The S-functions are discretely orthogonal, i.e., for $S_{(a,b)}, S_{(a',b')}, \in S_M^-(\mathrm{G}_2) = \{S_{(a,b)} | a, b \in \mathbb{N}, 3a + 2b < M\}$:

$$\langle S_{(a,b)} | S_{(a',b')} \rangle_M = \begin{cases} 0 & \text{if } a \neq a' \text{ or } b \neq b' \\ 12M^2 & \text{otherwise,} \end{cases}$$

with the higher S-functions repeating the values of the functions in S_M^-.

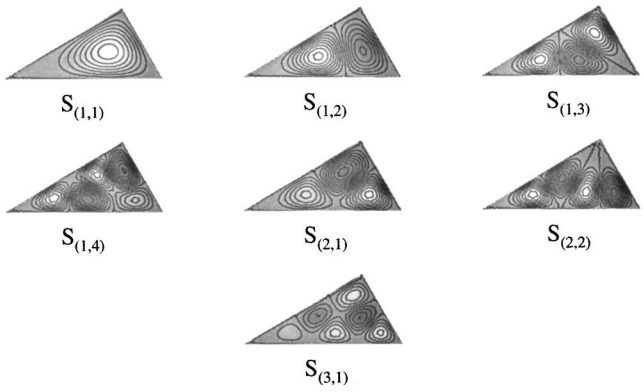

FIG. 8. The set of seven lowest S-functions of G_2 which are pairwise orthogonal on the grid $F_{12}^-(\mathrm{G}_2)$.

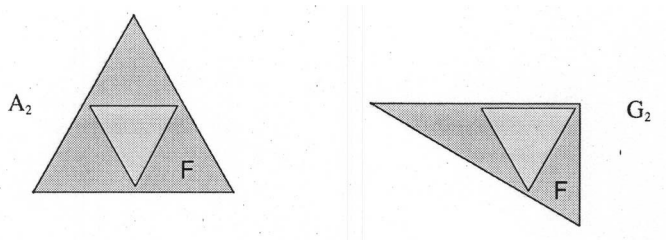

FIG. 9. The triangular step function [Eq. (7.2)] placed in the fundamental regions of A_2 and G_2.

Examples: $F_{14}^{-}(G_2)$ consists of the following ten points given as $[s_0,s_1,s_2]\equiv(s_1/M,s_2/M)$:

$$[1,2,3]=\left(\tfrac{1}{7},\tfrac{3}{14}\right),\quad [1,5,1]=\left(\tfrac{5}{14},\tfrac{1}{14}\right),\quad [2,3,2]=\left(\tfrac{3}{14},\tfrac{1}{7}\right),\quad [3,1,3]=\left(\tfrac{1}{14},\tfrac{3}{14}\right),$$
$$[3,4,1]=\left(\tfrac{2}{7},\tfrac{1}{14}\right),\quad [4,2,2]=\left(\tfrac{1}{7},\tfrac{1}{7}\right),\quad [5,3,1]=\left(\tfrac{3}{14},\tfrac{1}{14}\right),\quad [6,1,2]=\left(\tfrac{1}{14},\tfrac{1}{7}\right),$$
$$[7,2,1]=\left(\tfrac{1}{7},\tfrac{1}{14}\right),\quad [9,1,1]=\left(\tfrac{1}{14},\tfrac{1}{14}\right).$$

See Fig. 8 for examples of *S*—functions of G_2.

VII. MOTIVATING EXAMPLES

Comparison of expansions of class functions into series of *S*-functions of all groups considered here will require further study. Related results/questions are illustrated by the following examples.

There are two examples shown in this section, involving decomposition of the square function $f_{sq}(x,y)$ and a triangular function $f_{tr}(x,y)$ into series of *S*-functions of $A_1\times A_1$ and C_2, and A_2 and G_2, respectively. The goal of the examples is: (i) to illustrate discrete decomposition of a given function followed by the continuous extension and (ii) to compare the continuous extensions in both cases at compatible densities of the grids.

In order to make the comparison, for the cases $A_1\times A_1$ and C_2 we set up the vertices of the two fundamental regions as follows (relative to an orthonormal basis),

$$F(A_1\times A_1)=\{(0,0),(0,1),(1,1),(1,0)\},$$

$$F(C_2)=\{(0,0),(1,1),(1,0)\}.$$

Thus, the area of $F(A_1\times A_1)$ is exactly half of the area of $F(C_2)$.

We choose for $f_{sq}(x,y)$ a square step function with sharp edges with vertices in $(0,0),\left(0,\frac{1}{2}\right)$, $\left(\frac{1}{2},\frac{1}{2}\right)$, and $\left(\frac{1}{2},0\right)$:

$$f_{sq}(x,y)=\begin{cases}1 & \text{for } (x,y)\in\left\{(0,0),\left(0,\frac{1}{2}\right),\left(\frac{1}{2},\frac{1}{2}\right),\left(\frac{1}{2},0\right)\right\}\\ 0 & \text{elsewhere in } F.\end{cases}\tag{7.1}$$

For the cases A_2 and G_2, we set up the vertices of the two fundamental regions as follows (relative to an orthonormal basis):

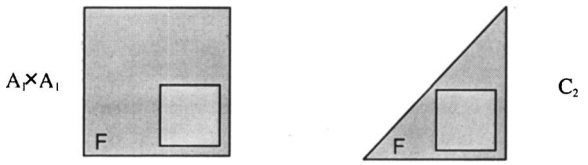

FIG. 10. The square step function [Eq. (7.1)] placed in the fundamental regions of $A_1\times A_1$ and C_2.

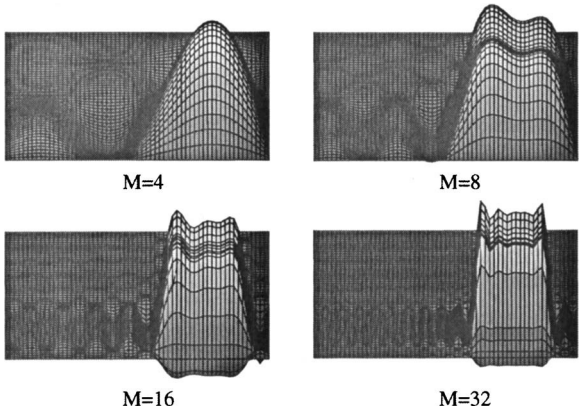

FIG. 11. Decomposition and continuous extension of a square step function placed in the fundamental region of $A_1 \times A_1$ on the grids of orders $M=4$, 8, 16, and 32.

$$F(A_2) = \left\{(0,0),(1,0),\left(\tfrac{1}{2},\tfrac{\sqrt{3}}{2}\right)\right\}$$

$$F(G_2) = \left\{\left(-\tfrac{1}{4},\tfrac{\sqrt{3}}{4}\right),\left(\tfrac{3}{4},\tfrac{\sqrt{3}}{4}\right),\left(\tfrac{3}{4},\tfrac{\sqrt{3}-2}{4}\right)\right\}$$

Thus, the area of $F(G_2)$ is also exactly half of the area of $F(A_2)$.

Here, we choose for $f_{\mathrm{tr}}(x,y)$ a triangular step function with sharp edges with vertices in $\left(\frac{1}{4},\frac{\sqrt{3}}{4}\right)$, $\left(\frac{3}{4},\frac{\sqrt{3}}{4}\right)$, and $\left(\frac{1}{2},0\right)$:

$$f_{\mathrm{tr}}(x,y) = \begin{cases} 1 & \text{for } (x,y) \in \left\{\left(\frac{1}{4},\frac{\sqrt{3}}{4}\right),\left(\frac{3}{4},\frac{\sqrt{3}}{4}\right),\left(\frac{1}{2},0\right)\right\} \\ 0 & \text{elsewhere in } F. \end{cases} \tag{7.2}$$

Chosen as such, $f_{\mathrm{tr}}(x,y)$ and $f_{\mathrm{sq}}(x,y)$ fit into the fundamental regions F of the four groups as shown in Figs. 9 and 10. Further, in order to have the same density of grid points, the orders of the grids are taken with the ratio $M_{A_1\times A_1}=M_{C_2}$ and $M_{G_2}=2M_{A_2}$. Figures 3 and 4 demonstrate the difference of densities of the grids of the same order for the four cases. It also helps to demonstrate the reason of the choice of the example functions and their placement into the fundamental regions in order to ensure a fair comparison of the cases.

Figures 11–14 contain results of our two examples. The values of the two functions $f_{\mathrm{sq}}(x,y)$ and $f_{\mathrm{tr}}(x,y)$ are sampled at the points s of the grids F_M^- 6.1 and taken as our digital data $f_{\mathrm{sq}}(s)$ and $f_{\mathrm{tr}}(x,y)$. Then the functions are expanded 2.2 into S-functions on the corresponding grids F_M^-, i.e.,

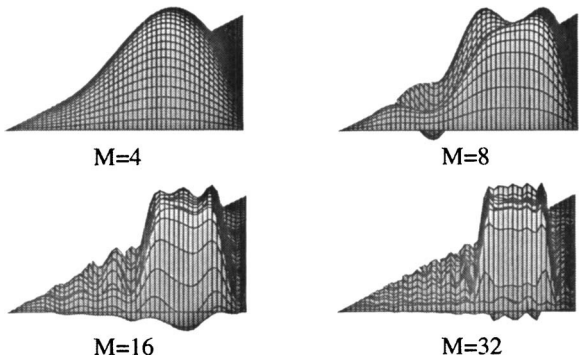

FIG. 12. Decomposition and continuous extension of a triangular step function placed in the fundamental region of C_2 on the grids of orders $M=4$, 8, 16, and 32.

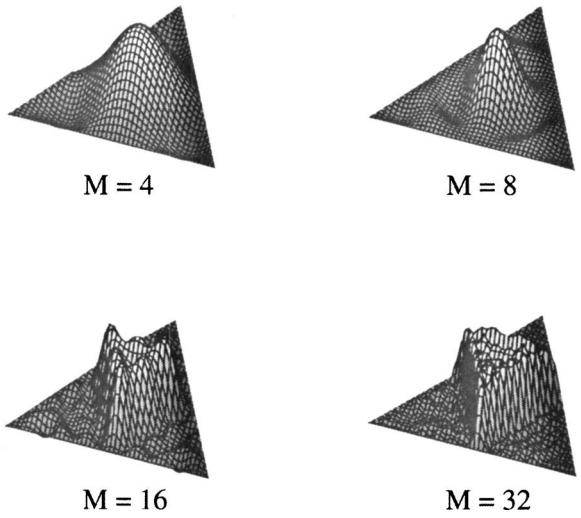

FIG. 13. Decomposition and continuous extension of a triangular step function placed in the fundamental region of A_2 on the grids of orders $M=4$, 8, 16, and 32.

expansion coefficients are calculated. After that, continuous extensions of the discrete expansions of $f_{\mathrm{sq}}(s)$ and $f_{\mathrm{tr}}(x,y)$ are made 2.3 by replacing the S-functions of the discrete argument s in the expansions by the same functions of the continuous argument, while keeping the expansion coefficients unchanged. Figures 11–14 show the functions $f_{\mathrm{sq\ cont}}(x,y)$ and $f_{\mathrm{tr\ cont}}(x,y)$ resulting from the continuous extension of discrete expansions. More precisely, four different continuous extensions are shown. They differ by the densities of the grid F_M^-, namely $M_{\mathrm{A}_1\times\mathrm{A}_1}=4$, 8, 16, 32, $M_{\mathrm{C}_2}=4$, 8, 16, 32, $M_{\mathrm{A}_2}=4$, 8, 16, 32, and $M_{\mathrm{G}_2}=8$, 16, 32, 64, from which the continuous extension is made. For these values the densities of grid points in the sample function are the same. The points of the grids are not shown in Figs. 11–14.

Inspecting and comparing the results, one readily observes the following:

1. As in Ref. 1, increasing density of the grid, i.e., increasing the value M, makes the continuous extension to match more closely the given model functions $f_{\mathrm{sq}}(x,y)$ of Eq. (7.1) and $f_{\mathrm{tr}}(x,y)$ of Eq. (7.2).
2. Quality of the extension, i.e., the match between the continuous extensions $f_{\mathrm{sq\ cont}}(x,y)$, $f_{\mathrm{tr\ cont}}(x,y)$, and the original functions $f_{\mathrm{sq}}(x,y)$, $f_{\mathrm{tr}}(x,y)$, is comparable for the same density of the grid in both cases, though C_2 and G_2 expansion may be slightly superior, as noticeable by comparing the two at the highest values of M in Figs. 11–14.

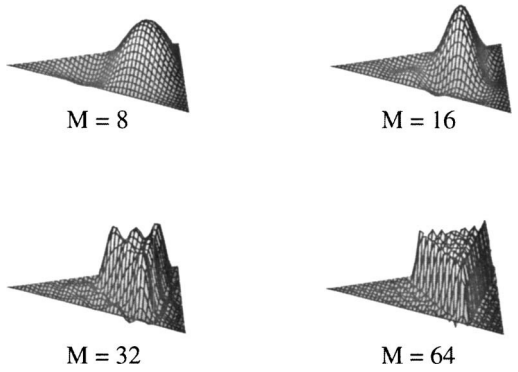

FIG. 14. Decomposition and continuous extension of a triangular step function placed in the fundamental region of G_2 on the grids of orders $M=8$, 16, 32 and 64.

3. The calculations of complex-valued functions in the case of A_2 took much longer time compared to the other cases, which gives them an obvious advantage in the discretization of real-valued functions, whereas A_2 is more useful for processing complex-valued information.

VIII. CONCLUDING COMMENTS

Comparison of the properties of *C*-functions of Refs. 1 and 2 with the properties of *S*-functions in this article reveals a far going parallel. Both families were described in the special case of two dimensions only, but both generalize to any finite dimension through the underlying compact semisimple Lie group *G*. The number of variables/dimension equals the rank of *G*.

Discretization in both families coincide: Identical grids are defined in the fundamental region *F* of *G*. Their symmetry is determined by the choice of *G*, their density is fixed by the positive integer *M*. Extended by the action of the affine Weyl group into the entire space, the grids automatically form a lattice because the points of F_M can also be interpreted[22] as representative of conjugacy classes of an Abelian subgroup of the maximal torus of *G* generated by the elements of order *M*.

The difference between the two families stems from their behavior under the action of the Weyl group *W* of *G*. Although *C*-functions are symmetric with respect to the reflections *r*, generating *W*, the *S*-functions are antisymmetric. Geometrically it is equivalent to the behavior of the functions with respect to their reflections in any side of *F*. Flipping $C_\lambda(z)$ values for $z \in F$ to its adjacent copy of *F*, flips also their values, $C_\lambda(rz)=C_\lambda(z)$, $r \in W$. Under the same operations the *S*-functions are antisymmetric, $S_\lambda(rz)=-S_\lambda(z)$. Thus, one is justified taking *C*- and *S*-functions as multidimensional generalizations of cosine and sine, respectively. A natural question of what then would be the multidimensional generalization of the exponential function has been answered in Ref. 9. Properties of *E*-functions of compact semisimple Lie groups will be studied elsewhere.[10]

Since our motivating application has been the decomposition of functions on *F* into a series of *C*- and/or *S*-functions, practically important for us is the behavior of the functions on the boundary of *F*. The *C*-transform requires that the normal derivatives at ∂F are zero, whereas the *S* transforms apply to functions that take zero value at ∂F.

Comparison of various decompositions of functions of two variables, using *C*- and *S*-functions of different groups is evidently of practical interest. In order to get an idea of the efficiency of the decomposition, we choose to consider continuous extension of model functions with sharp edges, more precisely cylinders, with zero value in the neighborhood of the boundary ∂F of *F*. Thus the value of the model function and its normal derivatives are both zero at ∂F. Sampling the functions at grids of comparable densities yields digital model data to work with. Continuous extension of such model data can then be visually inspected and compared.

Comparison of the functions plotted on Figs. 5 and 6 of Ref. 1 and Figs. 9 and 10 here, as well as the functions on Figs. 6 and 7 of Ref. 2 with Figs. 13 and 14 here, leads one to a qualitative conclusion that for the same grids (same value of *M*) the *C*- and *S*-functions are equally appropriate and, more importantly, that the interpolation of the digital data in both cases is equally good.

Similarly as with common discrete Fourier expansions one has continuous expansions (Fourier integral), it would be interesting to explore integral expansions based on *C*- or *S*-functions, where the variable λ takes continuous values from the *n* dimensional space rather than from an *n* dimensional lattice.

We construct all finite irreducible modules over Lie conformal superalgebras of type *W* and *S*. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2191788]

I. INTRODUCTION

Lie conformal superalgebras encode the singular part of the operator product expansion of chiral fields in two-dimensional quantum field theory.[8] On the other hand, they are closely connected to the notion of formal distribution Lie superalgebra $(\mathfrak{g},\mathcal{F})$, that is a Lie superalgebra $\mathfrak{g}$ spanned by the coefficients of a family $\mathcal{F}$ of mutually local formal distributions. Namely, to a Lie conformal superalgebra R one can associate a formal distribution Lie superalgebra (Lie R,R) which establishes an equivalence between the category of Lie conformal superalgebras and the category of equivalence classes of formal distribution Lie superalgebras obtained as quotients of Lie R by irregular ideals.[8]

Finite simple Lie conformal algebras were classified in Ref. 6 and all their finite irreducible representations were constructed in Ref. 4. According to Ref. 6, any finite simple Lie conformal algebra is isomorphic either to the current Lie conformal algebra Cur$\mathfrak{g}$, where $\mathfrak{g}$ is a simple finite-dimensional Lie algebra, or to the Virasoro conformal algebra.

However, the list of finite simple Lie conformal superalgebras is much richer, mainly due to existence of several series of super extensions of the Virasoro conformal algebra. The complete classification of finite simple Lie conformal superalgebras was obtained in Ref. 7. The list consists of current Lie conformal superalgebras Cur$\mathfrak{g}$, where $\mathfrak{g}$ is a simple finite-dimensional Lie superalgebra, four series of "Virasoro like" Lie conformal superalgebras W_n $(n\geqslant 0)$, $S_{n,b}$ and $\widetilde{S}_n$ $(n\geqslant 2, b\in\mathbb{C})$, K_n $(n\geqslant 0)$, and the exceptional Lie conformal superalgebra CK_6.

All finite irreducible representations of the simple Lie conformal superalgebras Cur$\mathfrak{g}$, K_0 = Vir and K_1 were constructed in Ref. 4 and those of $S_{2,0}$, $W_1=K_2$, K_3, K_4 in Ref. 5.

The main result of the present paper is the construction of all finite irreducible modules over the Lie conformal superalgebras W_n, $S_{n,b}$, and $\widetilde{S}_n$. The proof relies on the method developed in Ref. 4, that is, the observation that representation theory of Lie conformal superalgebras is controlled by the representation theory of the (extended) annihilation superalgebra, and a lemma from Ref. 1. In our cases, this reduces to the study of certain representations of the Lie superalgebra $W(1,n)_+$

[a)]Electronic mail: boyallia@mate.uncor.edu

of all vector fields on a superline (an affine superspace of dimension $(1|n)$) and the Lie superalgebra $S(1,n)_+$ of such vector fields with zero divergence. As in Refs. 9 and 10, we follow the approach developed for representations of infinite-dimensional simple linearly compact Lie algebras by A.R. in Ref. 11. The problem reduces to the description of the so-called degenerate modules, and for the latter we have to study singular vectors.

The paper is organized as follows. In Sec. II, we recall the notions and some basic facts on formal distributions, Lie conformal superalgebras, and their modules. In Sec. III, we recall some simple facts of the representation theory of infinite-dimensional simple linearly compact Lie superalgebras. In Sec. IV, we describe the conformal Lie superalgebra W_n and we classify its finite irreducible conformal modules by studying the corresponding singular vectors. In Sec. V, we obtain similar results for the Lie conformal superalgebra $S_n = S_{n,0}$. Finally, in Sec. VI, we complete the cases $S_{n,b}$ and $\widetilde{S}_n$. In all cases (as in Ref. 11) the answer has a geometric meaning: all finite irreducible modules are either "nondegenerate" tensor modules, or occur as cokernels of the differential in the conformal de Rham complex, or are duals of the latter.

Note that similar results for arbitrary non-super Lie pseudoalgebras of types W and S have been obtained in Ref. 2.

The remaining cases of the Lie conformal superalgebras K_n and CK_6 will be worked out in the subsequent publication.

II. FORMAL DISTRIBUTIONS, LIE CONFORMAL SUPERALGEBRAS, AND THEIR MODULES

First we introduce the basic definitions and notations, see Refs. 8 and 6. Let $\mathfrak{g}$ be a Lie superalgebra. A $\mathfrak{g}$-valued *formal distribution* in one indeterminate z is a series in the indeterminate z,

$$a(z) = \sum_{n \in \mathbb{Z}} a_n z^{-n-1}, \quad a_n \in \mathfrak{g}.$$

The vector superspace of all formal distributions, $\mathfrak{g}[[z,z^{-1}]]$, has a natural structure of a $\mathbb{C}[\partial_z]$-module. We define

$$\mathrm{Res}_z a(z) = a_0.$$

Let $a(z), b(z)$ be two $\mathfrak{g}$-valued formal distributions. They are called *local* if

$$(z-w)^N [a(z), b(w)] = 0 \quad \text{for } N \gg 0.$$

Let $\mathfrak{g}$ be a Lie superalgebra, a family $\mathcal{F}$ of $\mathfrak{g}$-valued formal distributions is called a *local family* if all pairs of formal distributions from $\mathcal{F}$ are local. Then, the pair $(\mathfrak{g}, \mathcal{F})$ is called a *formal distribution Lie superalgebra* if $\mathcal{F}$ is a local family of $\mathfrak{g}$-valued formal distributions and $\mathfrak{g}$ is spanned by the coefficients of all formal distributions in $\mathcal{F}$. We define the *formal δ-function* by

$$\delta(z-w) = z^{-1} \sum_{n \in \mathbb{Z}} \left(\frac{w}{z} \right)^n.$$

Then it is easy to show (Ref. 8, Corollary 2.2), that two local formal distributions are local if and only if the bracket can be represented as a finite sum of the form

$$[a(z), b(w)] = \sum_j [a(z)_{(j)} b(w)] \partial_w^j \delta(z-w)/j!,$$

where $[a(z)_{(j)} b(w)] = \mathrm{Res}_z (z-w)^j [a(z), b(w)]$. This is called the *operator product expansion*. Then we obtain a family of operations $_{(n)}$, $n \in \mathbb{Z}_+$, on the space of formal distributions. By taking the generating series of these operations, we define the λ-bracket:

$$[a_\lambda b] = \sum_{n \in \mathbb{Z}_+} \frac{\lambda^n}{n!} [a_{(n)} b].$$

The properties of the λ-bracket motivate the following definition:

Definition 2.1: A *Lie conformal superalgebra* R is a left $\mathbb{Z}/2\mathbb{Z}$-graded $\mathbb{C}[\partial]$-module endowed with a $\mathbb{C}$-linear map,

$$R \otimes R \to \mathbb{C}[\lambda] \otimes R, \quad a \otimes b \mapsto [a_\lambda b]$$

called the λ-bracket, and satisfying the following axioms $(a, b, c \in R)$,

Conformal sesquilinearity	$[\partial a_\lambda b] = -\lambda [a_\lambda b], \quad [a_\lambda \partial b] = (\lambda + \partial)[a_\lambda b],$
Skew-symmetry	$[a_\lambda b] = -(-1)^{p(a)p(b)} [b_{-\lambda-\partial} a],$
Jacobi identity	$[a_\lambda [b_\mu c]] = [[a_\lambda b]_{\lambda+\mu} c] + (-1)^{p(a)p(b)} [b_\mu [a_\lambda c]].$

Here and further $p(a) \in \mathbb{Z}/2\mathbb{Z}$ is the parity of a.

A Lie conformal superalgebra is called *finite* if it has finite rank as a $\mathbb{C}[\partial]$-module. The notions of homomorphism, ideal and subalgebras of a Lie conformal superalgebra are defined in the usual way. A Lie conformal superalgebra R is *simple* if $[R_\lambda R] \neq 0$ and contains no ideals except for zero and itself.

Given a formal distribution Lie superalgebra $(\mathfrak{g}, \mathcal{F})$ denote by $\bar{\mathcal{F}}$ the minimal subspace of $\mathfrak{g}[[z, z^{-1}]]$ which contains $\mathcal{F}$ and is closed under all jth products and invariant under ∂_z. Due to Dong's lemma, we know that $\bar{\mathcal{F}}$ is a local family as well. Then $\mathrm{Conf}(\mathfrak{g}, \mathcal{F}) := \bar{\mathcal{F}}$ is the Lie conformal superalgebra associated to the formal distribution Lie superalgebra $(\mathfrak{g}, \mathcal{F})$.

In order to give the (more or less) reverse functorial construction, we need the notion of *affinization* $\widetilde{R}$ of a conformal algebra R (which is a generalization of that for vertex algebras[3]). We let $\widetilde{R} = R[t, t^{-1}]$ with $\widetilde{\partial} = \partial + \partial_t$ and the λ-bracket:[8]

$$[af(t)_\lambda bg(t)] = [a_{\lambda+\partial_t} b] f(t) g(t') \big|_{t'=t}. \tag{2.1}$$

The 0-th product is

$$[at^n_{(0)} bt^m] = \sum_{j \in \mathbb{Z}_+} \binom{m}{j} [a_j b] t^{m+n-j}. \tag{2.2}$$

Observe that $\widetilde{\partial}\widetilde{R}$ is an ideal of $\widetilde{R}$ with respect to the 0-th product. We let $\mathrm{Alg}R = \widetilde{R}/\widetilde{\partial}\widetilde{R}$ with the 0-th product and let

$$\mathcal{R} = \left\{ \sum_{n \in \mathbb{Z}} (at^n) z^{-n-1} = a\delta(t - z) \,|\, a \in R \right\}.$$

Then $(\mathrm{Alg}R, \mathcal{R})$ is a formal distribution Lie superalgebra. Note that Alg is a functor from the category of Lie conformal superalgebras to the category of formal distribution Lie superalgebras. One has[8]

$$\mathrm{Conf}(\mathrm{Alg}R) = R, \quad \mathrm{Alg}(\mathrm{Conf}(\mathfrak{g}, \mathcal{F})) = (\mathrm{Alg}\bar{\mathcal{F}}, \bar{\mathcal{F}}).$$

Note also that $(\mathrm{Alg}R, \mathcal{R})$ is the *maximal formal distribution superalgebra* associated to the conformal superalgebra R, in the sense that all formal distribution Lie superalgebras $(\mathfrak{g}, \mathcal{F})$ with $\mathrm{Conf}(\mathfrak{g}, \mathcal{F}) = R$ are quotients of $(\mathrm{Alg}R, \mathcal{R})$ by irregular ideals (that is, an ideal I in $\mathfrak{g}$ with no nonzero $b(z) \in \mathcal{R}$ such that $b_n \in I$). Such formal distribution Lie superalgebras are called *equivalent*.

We thus have an equivalence of categories of conformal Lie superalgebras and equivalence classes of formal distribution Lie superalgebras. So the study of formal distribution Lie superalgebras reduces to the study of conformal Lie superalgebras.

An important tool for the study of Lie conformal superalgebras and their modules is the (extended) annihilation algebra. The *annihilation algebra* of a Lie conformal superalgebra R is the subalgebra $\mathcal{A}(R)$ (also denoted by $(\mathrm{Alg}R)_+$) of the Lie superalgebra Alg$R$ spanned by all elements at^n, where $a \in R, n \in \mathbb{Z}_+$. It is clear from (2.2) that this is a subalgebra, which is invariant with respect to the derivation $\partial = -\partial_t$ of Alg$R$. The *extended annihilation algebra* is defined as

$$\mathcal{A}(R)^e = (\mathrm{Alg}R)^+ := \mathbb{C}\,\partial \ltimes (\mathrm{Alg}R)_+.$$

Introducing the generating series

$$a_\lambda = \sum_{j \in \mathbb{Z}_+} \frac{\lambda^j}{j!}(at^j), \tag{2.3}$$

we obtain from (2.2):

$$[a_\lambda, b_\mu] = [a_\lambda b]_{\lambda+\mu}, \quad \partial(a_\lambda) = (\partial a_\lambda) = \lambda(a_\lambda). \tag{2.4}$$

Now let $\mathfrak{g}$ be a Lie superalgebra, and let V be a $\mathfrak{g}$-module. Given a $\mathfrak{g}$-valued formal distribution $a(z)$ and a V-valued formal distribution $v(z)$ we may consider the formal distribution $a(z)v(w)$ and the pair $(a(z), v(z))$ is called *local* if $(z-w)^N(a(z)v(w)) = 0$ for $N \gg 0$. As before, we have an expansion of the form:

$$a(z)v(w) = \sum_j (a(z)_{(j)}v(w))\partial_w^j \delta(z-w)/j\,!\,,$$

where $a(w)_{(j)}v(w) = \mathrm{Res}_z (z-w)^j a(z)v(w)$ and the sum is finite. By taking the generating series of these operations, we define the λ-*action of* $\mathfrak{g}$ *on* V:

$$a(w)_\lambda v(w) = \sum_{n \in \mathbb{Z}_+} \frac{\lambda^n}{n!}(a(w)_{(n)}v(w)) \quad \text{(finite sum)}.$$

It has the following properties:

$$\partial_z a(z)_\lambda v(z) = -\lambda a(z)_\lambda v(z), \quad a(z)_\lambda \partial_z v(z) = (\partial_z + \lambda)(a(z)_\lambda v(z)),$$

and

$$[a(z)_\lambda, b(z)_\mu]v(z) = [a(z)_\lambda b(z)]_{\lambda+\mu} v(z).$$

This motivates the following definition:

Definition 2.2: A *module* M over a Lie conformal superalgebra R is a $\mathbb{Z}/2\mathbb{Z}$-graded $\mathbb{C}[\partial]$-module endowed with a $\mathbb{C}$-linear map $R \otimes M \to \mathbb{C}[\lambda] \otimes M$, $a \otimes v \mapsto a_\lambda^M v$, satisfying the following axioms $(a, b \in M;\ v \in M)$,

$$(\mathrm{M1})_\lambda \qquad (\partial a)_\lambda^M v = [\partial^M, a_\lambda^M]v = -\lambda a_\lambda^M v,$$
$$(\mathrm{M2})_\lambda \qquad [a_\lambda^M, b_\mu^M]v = [a_\lambda b]_{\lambda+\mu}^M v.$$

An R-module M is called *finite* if it is finitely generated over $\mathbb{C}[\partial]$. An R-module M is called *irreducible* if it contains no nontrivial submodule, where the notion of submodule is the usual one.

As before, if $\mathcal{F} \subset \mathfrak{g}[[z, z^{-1}]]$ is a local family and $\mathcal{E} \subset V[[z, z^{-1}]]$ is such that all pairs $(a(z), v(z))$, where $a(z) \in \mathcal{F}$ and $v(z) \in \mathcal{E}$, are local, let $\bar{\mathcal{E}}$ be the minimal subspace of $V[[z, z^{-1}]]$ which contains E and all $a(z)_{(j)}v(z)$ for $a(z) \in \mathcal{F}$ and $v(z) \in \mathcal{E}$, and is ∂_z-invariant. Then it is easy to show that all pairs $(a(z), v(z))$, where $a(z) \in \bar{\mathcal{F}}$ and $v(z) \in \bar{\mathcal{E}}$, are local and $a(z)_{(j)}(\bar{\mathcal{E}}) \subset \bar{\mathcal{E}}$ for all $a(z) \in \bar{\mathcal{F}}$.

Let $\mathcal{F}$ be a local family that spans $\mathfrak{g}$ and let $\mathcal{E} \subset V[[z, z^{-1}]]$ be a family that span V. Then $(V, \mathcal{E})$ is called a *formal distribution module* over the formal distribution Lie superalgebra $(\mathfrak{g}, \mathcal{F})$ if all pairs $(a(z), v(z))$, where $a(z) \in \mathcal{F}$ and $v(z) \in \mathcal{E}$, are local. It follows that a formal distribution

module $(V,\mathcal{E})$ over a formal distribution Lie superalgebra $(\mathfrak{g},\mathcal{F})$ gives rise to a module $\mathrm{Conf}(V,\mathcal{E}):=\bar{\mathcal{E}}$ over the conformal Lie superalgebra $\mathrm{Conf}(\mathfrak{g},\mathcal{F})$.

In the same way as above, we have an equivalence of categories of modules over a Lie conformal superalgebra R and equivalence classes of formal distribution modules over the Lie superalgebra Alg$R$. Namely, given an R-module M, one defines its *affinization* $\tilde{M}=M[t,t^{-1}]$ as an $\tilde{R}$-module with $\tilde{\partial}=\partial+\partial_t$ and the λ-action similar to (2.1):

$$af(t)_\lambda vg(t)=(a_{\lambda+\partial_t^{(t)}}v)f(t)g(t')\big|_{t'=t}. \tag{2.5}$$

The 0-th action is

$$at^n_{(0)}vt^m=\sum_{j\in\mathbb{Z}_+}\binom{m}{j}(a_jv)t^{m+n-j}. \tag{2.6}$$

Observe that $\tilde{\partial}\tilde{M}$ is invariant with respect to the 0-th action and $(\tilde{\partial}\tilde{R})_{(0)}\tilde{M}=0$, hence the 0-th action of $\tilde{R}$ on $\tilde{M}$ induces a representation of the Lie superalgebra $\mathrm{Alg}R=\tilde{R}/\tilde{\partial}\tilde{R}$ on $V(M):=\tilde{M}/\tilde{\partial}\tilde{M}$. Let $\mathcal{M}=\{v\,\delta(z-t)\,|\,v\in M\}$. Then $(V(M),\mathcal{M})$ is a formal distribution module over the formal distribution Lie superalgebra $(\mathrm{Alg}R,\mathcal{R})$, which is maximal in the sense that all conformal $(\mathrm{Alg}R,\mathcal{R})$ modules $(V,\mathcal{E})$ such that $\bar{\mathcal{E}}\simeq M$ as R-modules are quotients of $(V(M),\mathcal{M})$ by irregular submodules. Such formal distribution modules are called equivalent, and we get an equivalence of categories of R-modules and equivalence classes of formal distribution $(\mathrm{Alg}R,\mathcal{R})$-modules.

Formula (2.4) implies the following important proposition relating modules over a Lie conformal superalgebra R to continuous modules over the corresponding extended annihilation Lie superalgebra $(\mathrm{Alg}R)^+$.

Proposition 2.3: (Ref. 4) A module over a Lie conformal superalgebra R is the same as a continuous module over the Lie superalgebra $(\mathrm{Alg}R)^+$, *i.e. it is an* $(\mathrm{Alg}R)^+$*-module satisfying the property*

$$a_\lambda m\in\mathbb{C}[\lambda]\otimes M\quad \textit{for any } a\in R,m\in M. \tag{2.7}$$

(*One just views the action of the generating series* a_λ *of* $(\mathrm{Alg}R)^+$ *as the* λ*-action of* $a\in R$).

Denote by $V(M)_+$ the span of elements $\{vt^n\,|\,v\in M,n\in\mathbb{Z}_+\}$ in $V(M)$. It is clear from (2.5) that $V(M)^+$ is an $(\mathrm{Alg}R)^+$ submodule, hence an R -module by Proposition 2.3. We denote by $V(M)_+^*$ the restricted dual of $V(M)_+$, i.e., the space of all linear functions on $V(M)_+$ which vanish on all but finite number of subspaces Mt^n, with $n\in\mathbb{Z}_+$. This is an $(\mathrm{Alg}R)^+$-module and hence an R-module as well. The *conformal dual* M^* to an R-module M is defined as

$$M^*=\{f_\lambda:M\to\mathbb{C}[\lambda]\,|\,f_\lambda(\partial m)=\lambda f_\lambda(m)\},$$

with the structure of $\mathbb{C}[\partial]$-module $(\partial f)_\lambda(m)=-\lambda f_\lambda(m)$, with the following λ-action of R:

$$(a_\lambda f)_\mu(m)=-(-1)^{p(a)(p(f)+1)}f_{\mu-\lambda}(a_\lambda m),\quad a\in R,m\in M.$$

Given a homomorphism of conformal R-modules $T:M\to N$, we define the transpose homomorphism $T^*:N^*\to M^*$ by

$$[T^*(f)]_\lambda(m)=-f_\lambda(T(m)).$$

Proposition 2.4: Let $T:M\to N$ *be an injective homomorphism of R-modules such that* $N/\mathrm{Im}\,T$ *is finitely generated torsion-free* $\mathbb{C}[\partial]$*-module. Then* T^* *is surjective*.

Proof: Since $L=N/\mathrm{Im}\,T$ is finitely generated torsion-free, then it is free and therefore a projective $\mathbb{C}[\partial]$-module. Hence, the short exact sequence $0\to\mathrm{Im}\,T\to N\to N/\mathrm{Im}\,T\to 0$ is split and $N=\mathrm{Im}\,T\oplus L$ as $\mathbb{C}[\partial]$-module. Now, given $\alpha\in M^*$, we define $\beta\in N^*$ as follows:

$$\beta_\lambda(T(m)) = \alpha_\lambda(m), \quad m \in M, \quad \beta_\lambda(l) = 0, \quad l \in L.$$

Then β is well-defined since T is injective and β belongs to N^* since L is a complementary $\mathbb{C}[\partial]$-submodule, finishing the proof. □

Remark 2.5: Observe that the injectivity is not enough (cf. Remark 4.12). Namely, let $R = \mathrm{Vir} = \mathbb{C}[\partial]L$ be the Virasoro conformal algebra with λ-bracket $[L_\lambda L] = (2\lambda + \partial)L$. Consider the following Vir-modules:

$$\Omega_0 = \mathbb{C}[\partial]m, \quad \text{with } L_\lambda m = (\lambda + \partial)m, \quad \Omega_1 = \mathbb{C}[\partial]n \quad \text{with } L_\lambda n = \partial n.$$

Then it is easy to see that the map $d: \Omega_0 \to \Omega_1$ given by $d(m) = \partial n$ is an injective homomorphism of R-modules, but the dual map $d^*: \Omega_1^* \to \Omega_0^*$ given by $d^*(m^*) = \partial n^*$ is not surjective.

Proposition 2.6: Let $T: M \to N$ be a homomorphism of R-modules such that $N/\mathrm{Im}\, T$ is finitely generated torsion-free $\mathbb{C}[\partial]$-module. Then the standard map $\psi: N^*/\mathrm{Ker}\, T^* \to (M/\mathrm{Ker}\, T)^*$, given by $[\psi(\bar{f})]_\lambda(\bar{m}) = f_\lambda(T(m))$ (where by the bar we denote the corresponding class in the quotient) is an isomorphism of R-modules.

Proof: Using Proposition 2.4 the proof follows by standard arguments. □

Proposition 2.7: If M is an R-module finitely generated (over $\mathbb{C}[\partial]$), then $M^{**} \simeq M$.

Proof: Let $M = \oplus \mathbb{C}[\partial]m_i$ (finite sum), with $a_\lambda m_j = \Sigma_k P_{jk}(\lambda, \partial)m_k$. Then $M^* = \oplus \mathbb{C}[\partial]m_i^*$, with $(m_i^*)_\lambda(m_k) = \delta_{i,k}$ and

$$(a_\lambda m_i^*)_\mu(m_j) = -(m_i^*)_{\mu-\lambda}(a_\lambda m_j) = -\sum_k (m_i^*)_{\mu-\lambda}(P_{jk}(\lambda, \partial)m_k) = P_{ji}(\lambda, \mu - \lambda).$$

Therefore,

$$(a_\lambda m_i^*) = -\sum_j P_{ji}(\lambda, -\partial - \lambda)m_j^*,$$

and the last formula shows that by taking the dual again we obtain

$$(a_\lambda m_i^{**}) = \sum_j P_{ij}(\lambda, \partial)m_j^{**}.$$

Hence the map $m_i \mapsto m_i^{**}$ gives us the isomorphism between M and M^{**}. □

Proposition 2.8: (*a*) *The map $M \to V(M)/V(M)_+$ given by $v \mapsto vt^{-1}$ mod $V(M)_+$ is an isomorphism of* $(\mathrm{Alg}R)^+$- (*and R-*)*modules.*

(*b*) *The map $V(M)_+^* \to M^*$ defined by $f \mapsto f_\lambda$, where*

$$f_\lambda(m) = \sum_{j \in \mathbb{Z}_+} \frac{(-\lambda)^j}{j!} f(mt^j),$$

is an isomorphism of $(\mathrm{Alg}R)^+$- (*and R-*)*modules.*

Proof: A direct verification. □

Assuming that R is finite, choose a finite set of generators of this $\mathbb{C}[\partial]$-module: $\{a^i \mid i \in I\}$, and for each $m \in \mathbb{Z}_+$, denote by $(\mathrm{Alg}R)^+_{(m)}$ the $\mathbb{C}$-span of all elements $a^i t^j, i \in I, j \geqslant m$ of $(\mathrm{Alg}R)^+$. This defines a descending filtration of $(\mathrm{Alg}R)^+$ by subspaces of finite codimension:

$$(\mathrm{Alg}R)^+ \supset (\mathrm{Alg}R)_+ = (\mathrm{Alg}R)_{(0)} \supset (\mathrm{Alg}R)_{(1)} \supset \dots . \tag{2.8}$$

It is easy to see from (2.2) that there exists $s \in \mathbb{Z}_+$ such that for all $k, r \in \mathbb{Z}_+$ one has

$$[(\mathrm{Alg}R)_{(k)}, (\mathrm{Alg}R)_{(r)}] \subset (\mathrm{Alg}R)_{(k+r-s)}. \tag{2.9}$$

In particular, $(\mathrm{Alg}R)_r := (\mathrm{Alg}R)_{(r+s)}$ is a filtration of $(\mathrm{Alg}R)^+$ by subalgebras of finite codimension.

Given an R-module M, it is an $(\mathrm{Alg}R)^+$-module (by Proposition 2.3), and we let for $j \in \mathbb{Z}_+$:

$$M_{(j)} = \{v \in M | (\mathrm{Alg}R)_{(j)} v = 0\}. \tag{2.10}$$

The subspaces $M_{(j)}$ form an ascending filtration of M by $(\mathrm{Alg}R)_0$-invariant subspaces. The following proposition is a special case of Lemma 14.4 from Ref. 1.

Proposition 2.9: Let R be a finite Lie conformal superalgebra and let M be a finite R-module such that

$$M^R = \{m \in M | R_\lambda m = 0\} (= M_{(0)})$$

is finite dimensional (over $\mathbb{C}$). Then all subspaces $M_{(j)}$ are finite-dimensional. In particular M is locally finite as an $(\mathrm{Alg}R)_0$-module, meaning that any $m \in M$ is contained in a finite-dimensional $(\mathrm{Alg}R)_0$-invariant subspace.

This Proposition together with the results of the following section will provide a characterization of all finite irreducible modules over a finite Lie conformal superalgebra in terms of certain (quotients of) induced modules over the extended annihilation algebra.

III. GENERAL REMARKS ON REPRESENTATIONS OF LINEARLY COMPACT LIE SUPERALGEBRAS

We follow the approach developed for representations of infinite-dimensional simple linearly compact Lie algebras by A.R. in Ref. 11. In this section we will follow Ref. 9.

We shall consider continuous representations in spaces with discrete topology. The continuity of a representation of a linearly compact Lie superalgebra L in a vector space V with discrete topology means that the stabilizer $L_v = \{g \in L | gv = 0\}$ of any $v \in V$ is an open (hence of finite codimension) subalgebra of L.

Let L be a simple linearly compact Lie superalgebra. In some cases (the examples studied in the following sections), L has a $\mathbb{Z}$-gradation of the form

$$L = \oplus_{m \geqslant -1} L_m, \tag{3.1}$$

this gives a triangular decomposition

$$L = L_- \oplus L_0 \oplus L_+ \quad \text{with } L_\pm = \oplus_{\pm m > 0} L_m. \tag{3.2}$$

Let $L_{\geqslant 0} = L_{>0} \oplus L_0$. Denote by $P(L, L_{\geqslant 0})$ the category of all continuous L-modules V, where V is a vector space with discrete topology, that are $L_{\geqslant 0}$-locally finite, that is any $v \in V$ is contained in a finite-dimensional $L_{\geqslant 0}$-invariant subspace. When talking about representations of L, we shall always mean modules from $P(L, L_{\geqslant 0})$. Modules in this category are called *finite continuous L-modules*.

In most cases of simple L, for example if L is of W or S type, by taking $L_{\geqslant 0}$ certain maximal open subalgebra, one can choose L_- to be a subalgebra. Taking an ordered basis of L_-, we denote by $U(L_-)$ the span of all PBW monomials in this basis. We have $U(L) = U(L_-) \otimes U(L_{\geqslant 0})$, as vector spaces (here and in the following $U(L)$ stands for the universal enveloping algebra of the Lie superalgebra L). It follows that any irreducible L-module V in the category $P(L, L_{\geqslant 0})$ is finitely generated over $U(L_-)$:

$$V = U(L_-)E$$

for some finite-dimensional subspace E. This property is very important in the theory of conformal modules.[4]

Given an $L_{\geqslant 0}$-module F, we may consider the associated induced L-module

$$M(F) = \mathrm{Ind}_{L_{\geqslant 0}}^{L} F = U(L) \otimes_{U(L_{\geqslant 0})} F,$$

called the *generalized Verma module* associated to F. Sometimes, we shall omit L and $L_{\geqslant 0}$, and simply denote it as $\mathrm{Ind}\, F$.

Let V be an L-module. The elements of the subspace

$$\mathrm{Sing}(V) := \{v \in V | L_{>0} v = 0\}$$

are called *singular vectors*. For us the most important case is when $V=M(F)$. The $L_{\geqslant 0}$-module F is canonically an $L_{\geqslant 0}$-submodule of $M(F)$, and $\mathrm{Sing}(F)$ is a subspace of $\mathrm{Sing}(M(F))$, called the *subspace of trivial singular vectors*. Observe that $M(F)=F\oplus F_+$, where $F_+=U_+(L_-)\otimes F$ and $U_+(L_-)$ is the augmentation ideal in the symmetric algebra $U(L_-)$. Then

$$\mathrm{Sing}_+(M(F)) := \mathrm{Sing}(M(F)) \cap F_+$$

are called the *nontrivial singular vectors*.

Theorem 3.1: (Refs. 9 and 11) (*a*) *If F is a finite-dimensional $L_{\geqslant 0}$-module, then $M(F)$ is in $P(L,L_{\geqslant 0})$.*

(*b*) *In any irreducible finite-dimensional $L_{\geqslant 0}$-module F the subalgebra L_+ acts trivially.*

(*c*) *If F is an irreducible finite-dimensional $L_{\geqslant 0}$-module, then $M(F)$ has a unique maximal submodule.*

(*d*) *Denote by $I(F)$ the quotient by the unique maximal submodule of $M(F)$. Then the map $F\mapsto I(F)$ defines a bijective correspondence between irreducible finite-dimensional L_0-modules and irreducible L-modules in $P(L,L_{\geqslant 0})$, the inverse map being $V\mapsto Sing(V)$.*

(*e*) *An L-module $M(F)$ is irreducible if and only if the L_0-module F is irreducible and $M(F)$ has no nontrivial singular vectors.*

Remark 3.2: The correspondence defined in Theorem 3.1(d) provides the classification of irreducible modules of the category $P(L,L_{\geqslant 0})$. Also, we would like to remark that in general $\mathrm{Sing}_+(M(F))$ generates a proper submodule in the L-module $M(F)$, but the factor by this submodule is not necessarily irreducible, there could appear new nontrivial singular vectors. However this happens very rarely (see Ref. 10 for an example and cf. Remark 4.8) and in most cases it can be proven that the factor module will be irreducible.

IV. LIE CONFORMAL SUPERALGEBRA W_n AND ITS FINITE IRREDUCIBLE MODULES

A. Definition of W_n and the induced modules

According to Ref. 6, any finite simple Lie conformal algebra is isomorphic either to $\mathrm{Cur}\mathfrak{g}$, where $\mathfrak{g}$ is a simple finite-dimensional Lie algebra, or to the Virasoro conformal algebra.

However, the list of finite simple Lie conformal superalgebras is much richer, mainly due to existence of several series of super extensions of the Virasoro conformal algebra, see Ref. 7.

The first series is associated to the Lie superalgebra $W(1,n)$ $(n\geqslant 1)$. More precisely, let $\Lambda(n)$ be the Grassmann superalgebra in the n odd indeterminates $\xi_1,\xi_2,\ldots,\xi_n$. Set $\Lambda(1,n)=\mathbb{C}[t,t^{-1}]\otimes\Lambda(n)$, then

$$W(1,n)=\left\{ a\partial_t+\sum_{i=1}^{n} a_i\partial_i | a,a_i \in \Lambda(1,n) \right\}, \tag{4.1}$$

where $\partial_i=\partial/\partial\xi_i$ and $\partial_t=\partial/\partial t$ are odd and even derivations, respectively. Then $W(1,n)$ is a formal distribution Lie superalgebra with spanning family of (pairwise local) formal distributions:

$$\mathcal{F}=\{\delta(t-z)a | a\in W(n)\}\cup\{\delta(t-z)f\partial_t | f\in\Lambda(n)\},$$

where $W(n)=\{\Sigma_{i=1}^{n} a_i\partial_i \,|\, a_i\in\Lambda(n)\}$ is the (finite-dimensional) Lie superalgebra of all derivations of $\Lambda(n)$. The associated Lie conformal superalgebra W_n is defined as

$$W_n=\mathbb{C}[\partial]\otimes(W(n)\oplus\Lambda(n)). \tag{4.2}$$

The λ-bracket is defined as follows $(a,b\in W(n);f,g\in\Lambda(n))$:

$$[a_\lambda b]=[a,b],\quad [a_\lambda f]=a(f)-(-1)^{p(a)p(f)}\lambda fa,\quad [f_\lambda g]=-(\partial+2\lambda)fg. \tag{4.3}$$

The Lie conformal algebra W_n is simple for $n\geqslant 0$ and has rank $(n+1)2^n$.

The annihilation subalgebra is

$$\mathcal{A}(W_n) = W(1,n)_+ = \left\{ a\partial_t + \sum_{i=1}^{n} a_i\partial_i | a, a_i \in \Lambda(1,n)_+ \right\}, \tag{4.4}$$

where $\Lambda(1,n)_+ = \mathbb{C}[t] \otimes \Lambda(n)$. The extended annihilation subalgebra is

$$\mathcal{A}(W_n)^e = W(1,n)^+ = \mathbb{C}\partial_t \ltimes W(1,n)_+,$$

and therefore it is isomorphic to the direct sum of $W(1,n)_+$ and a commutative one-dimensional Lie algebra.

The $\mathbb{Z}$-gradation in (3.1) is obtained by letting

$$\deg t = \deg \xi_i = 1 = -\deg \partial_t = -\deg \partial_i.$$

If $L = W(1,n)_+$, then $L_{-1} = \langle \partial_t, \partial_1, \ldots, \partial_n \rangle$, where ∂_t is an even element and $\partial_1, \ldots, \partial_n$ are odd elements of a basis in L_{-1}. Note also that $L_0 \simeq gl(1|n)$.

From now on, we shall use the notation $\partial_0 = \partial_t$. Explicitly, we have

$$L_0 = \langle \{ t\partial_i, \xi_i\partial_j : 0 \leqslant i, j \leqslant n \} \rangle.$$

In order to write explicitly weights for vectors in $W(1,n)_+$-modules, we would consider the basis

$$t\partial_0; t\partial_0 + \xi_1\partial_1, \ldots, t\partial_0 + \xi_n\partial_n$$

for the Cartan subalgebra H in $W(1,n)_+$, and we write the weight of an eigenvector for the Cartan subalgebra H as a tuple

$$\bar{\mu} = (\mu; \lambda_1, \ldots, \lambda_n)$$

for the corresponding eigenvalues of the basis.

B. Modules of Laurent differential forms

1. Restricted dual

Our algebra $L = W(1,n)_+$, and in the last section $S(1,n)_+$, are $\mathbb{Z}$-graded (super)algebras and the modules we intend to study are graded modules, i.e., an L-module V is a direct sum $V = \oplus_{m \in \mathbb{Z}} V_m$ of finite-dimensional subspaces V_m, and $L_k \cdot V_m \subset V_{k+m}$. For a graded module V we define the *restricted dual module* $V^\#$ as

$$V^\# = \oplus_{m \in \mathbb{Z}} (V_m)^*.$$

Hence $V^\#$ is a subspace of V^* and it is invariant with respect to the contragradient action, so it defines an L-module structure. Observe that $(V^\#)^\# = V$.

In our situation, we have $L_{-1} = \langle \partial_0, \partial_1, \ldots, \partial_n \rangle$, then any L-module becomes a $\mathbb{C}[\partial_0, \partial_1, \ldots, \partial_n]$-module. Hence, a module V is a free $\mathbb{C}[\partial_0, \partial_1, \ldots, \partial_n]$-module if and only if $V^\#$ is a cofree module, i.e., it is isomorphic to a direct sum of copies of the standard module $\mathbb{C}[z, \rho_1, \ldots, \rho_n]$, with $\partial_0 \cdot f = (\partial/\partial z) f$, and $\partial_i \cdot f = (\partial/\partial \rho_i) f$.

An induced module $\mathrm{Ind}_{L_{\geqslant 0}}^{L} F$ is by definition a free $\mathbb{C}[\partial_0, \partial_1, \ldots, \partial_n]$-module, so the co-induced (or produced) module

$$\mathrm{Cnd} F^\# = (\mathrm{Ind} F)^\#$$

will be cofree.

2. Differential forms modules

In order to define the differential forms one considers an odd variable dt and even variables $d\xi_1,\dots,d\xi_n$ and defines the differential forms to be the (super)commutative algebra freely generated by these variables over $\Lambda(1,n)_+=\mathbb{C}[t]\otimes\Lambda(n)$, or

$$\Omega_+=\Lambda(1,n)_+[d\xi_1,\dots,d\xi_n]\otimes\Lambda[dt].$$

Generally speaking Ω_+ is just a polynomial (super)algebra over a big set of variables

$$t,\xi_1,\dots,\xi_n,dt,d\xi_1,\dots,d\xi_n,$$

where the parity is

$$p(t)=0,\quad p(\xi_i)=1,\quad p(dt)=1,\quad p(d\xi_i)=0.$$

These are called (*polynomial*) *differential forms*, and we define the *Laurent differential forms* to be the same algebra over $\Lambda(1,n)=\mathbb{C}[t,t^{-1}]\otimes\Lambda(n)$:

$$\Omega=\Lambda(1,n)[d\xi_1,\dots,d\xi_n]\otimes\Lambda[dt].$$

We would like to consider a fixed complementary subspace Ω_- to Ω_+ in Ω chosen as follows:

$$\Omega_-=t^{-1}\mathbb{C}[t^{-1}]\otimes\Lambda(n)\otimes\mathbb{C}[d\xi_1,\dots,d\xi_n]\otimes\Lambda[dt].$$

For the differential forms we need the usual differential degree that measure only the involvement of the differential variables $dt,d\xi_1,\dots,d\xi_n$, that is

$$\deg t=0,\quad \deg\xi_i=0,\quad \deg dt=1,\quad \deg d\xi_i=1.$$

As a result, the degree of a function is zero and it gives us the *standard* $\mathbb{Z}$*-gradation* both on Ω and $\Omega_\pm$. As usual, we denote by $\Omega^k,\Omega^k_\pm$ the corresponding graded components.

We denote by Ω^k_c the special subspace of differential forms with constant coefficients in Ω_k.

The operator d is defined on Ω as usual by the rules $d\cdot t=dt,d\cdot\xi_i=d\xi_i,d\cdot d\xi_i=0$, and the identity

$$d(fg)=(df)g+(-1)^{p(f)}fdg.$$

Observe that d maps both Ω_+ and Ω_- into themselves.

As usual, we extend the natural action of $W(1,n)_+$ on $\Lambda(1,n)$ to the whole Ω by imposing the property

$$D\cdot d=(-1)^{p(D)}d\cdot D,\quad D\in W(1,n)_+,$$

that is, D (super)commutes with d. It is clear that Ω_+ and all the subspaces Ω^k are invariant. Hence Ω^k_+ and Ω^k are $W(1,n)_+$-modules, which are called the *natural representations* of $W(1,n)_+$ in differential forms.

We define the action of $W(1,n)_+$ on Ω_- via the isomorphism of Ω_- with the factor of Ω by Ω_+. Practically this means that in order to compute $D\cdot f$, where $f\in\Omega_-$, we apply D to f and "disregard terms with non-negative powers of t."

The operator d restricted to $\Omega^k_\pm$ defines an odd morphism between the corresponding representations. Clearly the image and the kernel of such a morphism are submodules in $\Omega^k_\pm$.

Let $\Theta^k_c=(\Omega^k_c)^\#$ and $\Theta^k_+=(\Omega^k_+)^\#$. In the rest of this section, we consider $L=W(1,n)_+$.

Proposition 4.1: For $L=W(1,n)_+$ *we have*:

(1) *The* L_0*-module* $\Theta^k_c,k\geqslant 0$ *is irreducible with highest weight*

$$(0;0,\dots,0,-k),\quad k\geqslant 0.$$

(2) *The L-module* Θ^k_+, $k\geqslant 0$ *contains* Θ^k_c *and this inclusion induces the isomorphism*

$$\Theta_+^k = \mathrm{Ind}\,\Theta_c^k.$$

(3) *The dual maps* $d^{\#}: \Theta_+^{k+1} \to \Theta_+^k$ *are morphisms of L-modules. The kernel of one of them is equal to the image of the next one and it is a nontrivial proper submodule in* Θ_+^k.

Proof: (1) It is well known that Ω_c^k are irreducible and thus Θ_+^k are also irreducible. Observe that the lowest vector in Ω_c^k is $(d\xi_n)^k$ and it has the weight $(0;0,\ldots,0,k)$. Now the sign changes as we go to the dual module and so we get the highest weight of Θ_c^k.

(2) By the definition of the restricted dual, it is the sum of the dual of all the graded components of the initial module. In our case Ω_c^k is the component of the minimal degree in Ω_+^k, so Θ_c^k becomes the component of the maximal degree in Θ_+^k. This implies that $L_{>0}$ acts trivially on Θ_c^k, so the morphism $\mathrm{Ind}\,\Theta_c^k \to \Theta_+^k$ is defined. Clearly Ω_+^k is isomorphic to

$$\Omega_c^k \otimes \mathbb{C}[t,\xi_1,\ldots,\xi_n],$$

so it is a cofree module. Then the module Θ_+^k is a free $\mathbb{C}[\partial_0,\partial_1,\ldots,\partial_n]$-module and the morphism

$$\mathrm{Ind}\,\Theta_c^k \to \Theta_+^k$$

is therefore an isomorphism.

(3) This statement follows immediately from the fact that d commutes with the action of vector fields. □

Corollary 4.2: The $W(1,n)_+$*-modules* Ω_+^k *of differential forms are isomorphic to the coinduced modules*

$$\Omega_+^k = \mathrm{Cnd}\,\Omega_c^k.$$

Let us now study the $L=W(1,n)_+$-modules Ω_-^k. First, notice that these modules are free as $\mathbb{C}[\partial_0,\partial_1,\ldots,\partial_n]$-modules. Let

$$\xi_* = \xi_1 \cdots \xi_n, \quad \text{and} \quad \bar{\Omega}_c^k = t^{-1}\xi_* \Omega_c^k \subset \Omega_-^k. \tag{4.5}$$

Proposition 4.3: For $L=W(1,n)_+$*, we have:*

(1) $\bar{\Omega}_c^k$ *is an irreducible* L_0*-submodule in* Ω_-^k *with highest weight*

$$\begin{aligned} &(-1;0,0,\ldots,0) && \text{for } k=0,\\ &(0;k,1,\ldots,1) && \text{for } k>0, \end{aligned}$$

and $L_{>0}$ *acts trivially on* $\bar{\Omega}_c^k$.

(2) *There is an isomorphism* $\Omega_-^k = \mathrm{Ind}_{L_{\geqslant 0}}^{L} \bar{\Omega}_c^k$.

(3) *The differential d gives us L-module morphisms on* Ω_-^k *and the kernel and image of d are L-submodules in* Ω_-^k.

(4) *The kernel of d and image of d in* Ω_-^k *for* $k \geqslant 2$ *coincide, in* Ω_-^1 *we have* $\mathrm{Ker}\,d = \mathbb{C}(t^{-1}dt) + \mathrm{Im}\,d$*, and in* Ω_-^0*, we have* $\mathrm{Ker}\,d = 0$ (*and the image does not exist*).

Proof: (1) First of all, $\bar{\Omega}_c^k$ is the maximum total degree component in Ω_-^k, so any element from $L_{>0}$ moves it to zero. Also, as L_0-module $\bar{\Omega}_c^k$ is isomorphic to Ω_c^k multiplied by the one-dimensional module $\langle t^{-1}\xi_* \rangle$. This permits us to see that its highest vectors are

$$\begin{aligned} &\langle t^{-1}\xi_* \rangle && \text{for } k=0,\\ &\langle t^{-1}\xi_* dt \rangle && \text{for } k=1,\\ &\langle t^{-1}\xi_* dt (d\xi_1)^{k-1} \rangle && \text{for } k>1. \end{aligned}$$

The values of the highest weights are easy to compute.

(2) It is straightforward to see that Ω_-^0 is a free rank 1 $\mathbb{C}[\partial_0,\partial_1,\ldots,\partial_n]$-module. Now, the action of $\partial_0,\partial_1,\ldots,\partial_n$ on Ω_-^k is coefficient-wise and the fact that Ω_-^k is a free

$\mathbb{C}[\partial_0,\partial_1,\ldots,\partial_n]$-module follows. This gives us the isomorphism $\Omega^k_-=\mathrm{Ind}^L_{L_{\geqslant 0}}\bar{\Omega}^k_c$. Parts (3) and (4) are left to the reader. □

The above statement shows us that there are nontrivial submodules in $\Omega^k_\pm$ and Θ^k_+. In fact, these are "almost all" proper submodules and the respective factors are irreducible. These results are discussed in Sec. IV D. In order to get this result we need to study singular vectors.

C. Singular vectors of W_n-modules

Having in mind the results of Sec. III, we introduce the following modules. Given a $gl(1|n)$-module V, we have the associated tensor field $W(1,n)$-module $\mathbb{C}[t,t^{-1}]\otimes\Lambda(n)\otimes V$, which is a formal distribution module spanned by a collection of fields $E=\{\delta(t-z)fv\,|\,f\in\Lambda(n),v\in V\}$. The associated conformal W_n-module is

$$\mathrm{Tens}(V)=\mathbb{C}[\partial]\otimes(\Lambda(n)\otimes V) \tag{4.6}$$

with the following λ-action:

$$a_\lambda(g\otimes v)=a(g)\otimes v+(-1)^{p(a)}\sum_{i,j=1}^n(\partial_i f_j)g\otimes(E_{ij}-\delta_{ij})(v)-\lambda(-1)^{p(g)}\sum_{j=1}^n f_j g\otimes E_{0j}(v), \tag{4.7}$$

$$f_\lambda(g\otimes v)=(-\partial)(fg\otimes v)+(-1)^{p(fg)}\sum_{i=1}^n(\partial_i f)g\otimes E_{i0}(v)+\lambda(fg\otimes E_{00}(v)), \tag{4.8}$$

where $a=\Sigma_{i=1}^n f_i\partial_i\in W(n),f,g\in\Lambda(n),v\in V$, and $E_{ij}\in gl(1|n)$ are matrix units (they correspond to the level 0 elements $\xi_i\partial_j$ with the notation $\xi_0=t$ and $\partial_0=\partial_t$).

In this case, the modules $M(F)=\mathrm{Ind}^L_{L_{\geqslant 0}}F$ defined in Sec. III, correspond to the W_n-module $\mathrm{Tens}(F)$, with F a finite-dimensional (irreducible) $gl(1|n)$-module. When we discuss the highest weight of vectors and singular vectors, we always mean with respect to the upper Borel subalgebra in $L=W(1,n)_+$ generated by $L_{>0}$ and the elements of L_0:

$$t\partial_i,\quad \xi_i\partial_j\ i<j. \tag{4.9}$$

Therefore, in the module $M(V)$, viewed as a module over the annihilation algebra $W(1,n)_+$ (see Proposition 2.3), a vector $m\in M(V)$ is a singular vector if and only if the following conditions are satisfied ($g=\xi_{i_1}\cdots\xi_{i_s}\in\Lambda(n)$, and $\partial_0=\partial_t$)

$$\begin{aligned}&\text{(s1) } t^n g\partial_i\cdot m=0 \quad \text{for } n>1,\\ &\text{(s2) } t^1 g\partial_i\cdot m=0 \quad \text{except for } g=1 \text{ and } i=0,\\ &\text{(s3) } t^0 g\partial_j\cdot m=0 \quad \text{for } s>1 \text{ or } g=\xi_i \text{ with } i<j.\end{aligned} \tag{4.10}$$

We shall frequently use the notation

$$\xi_I=\xi_{i_1}\cdots\xi_{i_s}\in\Lambda(n),\quad \text{with } I=\{i_1,\ldots,i_s\}. \tag{4.11}$$

Therefore, these conditions on a singular vector $m\in\mathrm{Tens}(V)$ translate in terms of the λ-action to (cf. (2.3)):

(S1) $d^2/d\lambda^2(f_\lambda m)=0$ for all $f\in\Lambda(n)$,
(S2) $d/d\lambda(a_\lambda m)=0$ for all $a\in W(n)$,
(S3) $d/d\lambda(f_\lambda m)|_{\lambda=0}=0$ for all $f\in\Lambda(n)$ with $f\neq 1$,
(S4) $(a_\lambda m)|_{\lambda=0}=0$ for all $a=\xi_I\partial_j\in W(n)$ with $|I|>1$ or $a=\xi_i\partial_j$ with $i<j$,
(S5) $(f_\lambda m)|_{\lambda=0}=0$ for all $f=\xi_I\in\Lambda(n)$ with $|I|>1$.

In order to classify the finite irreducible W_n-modules we should solve these equations (S1–5) to obtain the singular vectors.

Let $m \in \mathrm{Tens}(V) = \mathbb{C}[\partial] \otimes \Lambda(n) \otimes V$, then

$$m = \sum_{k=0}^{N} \sum_{I} \partial^k (\xi_I \otimes v_{I,k}) \quad \text{with } v_{I,k} \in V. \tag{4.12}$$

In order to obtain the singular vectors, we need some reduction lemmas:

Lemma 4.4: If $m \in \mathrm{Tens}(V)$ is a singular vector, then the degree of m in ∂ is at most 1.

Proof: Using (4.7), we have for $a = \sum_{i=1}^{n} f_i \partial_i$ that

$$\frac{d}{d\lambda}(a_\lambda m) = \sum_{k=1}^{N} \sum_{I} k(\lambda + \partial)^{k-1} [a(\xi_I) \otimes v_{I,k} + (-1)^{p(a)} \sum_{i,j=1}^{n} (\partial_i f_j) \xi_I \otimes (E_{ij} - \delta_{ij})(v_{I,k}) - \lambda (-1)^{|I|} \sum_{j=1}^{n} f_j \xi_I \otimes E_{0j}(v_{I,k})] - \sum_{k=0}^{N} \sum_{I} (\lambda + \partial)^k (-1)^{|I|} \sum_{j=1}^{N} f_j \xi_I \otimes E_{0j}(v_{I,k}). \tag{4.13}$$

Taking $a = \partial_j$, condition (S2) becomes

$$0 = \sum_{k=1}^{N} \sum_{I | j \in I} k(\lambda + \partial)^{k-1} (\xi_{i_1} \cdots \hat{\xi}_j \cdots \xi_{i_s} \otimes v_{I,k}) - \lambda \sum_{k=1}^{n} \sum_{I} (-1)^{|I|} k(\lambda + \partial)^{k-1} (\xi_I \otimes E_{0j}(v_{I,k})) - \sum_{k=0}^{N} \sum_{I} (\lambda + \partial)^k (-1)^{|I|} (\xi_I \otimes E_{0j}(v_{I,k})). \tag{4.14}$$

Now, viewed as a polynomial in λ, we obtain

$$E_{0j}(v_{I,k}) = 0, \quad \forall\, I, k = 1, \ldots, N, \quad \text{and } j = 1, \ldots, n. \tag{4.15}$$

Using it in (4.14) and taking the coefficients in $\lambda + \partial$, we get

$$v_{I,k} = 0 \quad \text{for all } I \neq \emptyset, \text{ and } k \geqslant 2.$$

Hence, $m = \sum_{k=0}^{1} \sum_{I} \partial^k (\xi_I \otimes v_{I,k}) + \sum_{k=2}^{N} \partial^k (1 \otimes v_{\emptyset,k})$.

Using (4.8) and condition (S1) for $f = 1$, we have

$$0 = \frac{d^2}{d\lambda^2}(f_\lambda m) = 2 \sum_{I} (\xi_I \otimes E_{00}(v_{I,1})) - \sum_{k=2}^{N} (k-1)k(\lambda + \partial)^{k-2}\, \partial\, (1 \otimes v_{\emptyset,k}) + \sum_{k=2}^{N} (2k(\lambda + \partial)^{k-1} + \lambda k(k-1)(\lambda + \partial)^{k-2})(1 \otimes E_{00}(v_{\emptyset,k})). \tag{4.16}$$

Then, viewed as a polynomial in λ, we have $E_{00}(v_{\emptyset,k}) = 0$ for all $k \geqslant 2$. Hence the last term in (4.16) is 0. Now, viewed as a polynomial in $(\lambda + \partial)$, we obtain $v_{\emptyset,k} = 0$ for all $k \geqslant 2$, finishing the proof. □

Observe that the coefficient in $(\lambda + \partial)^0$ in (4.16), gives us the following useful identity:

$$E_{00}(v_{I,1}) = 0 \quad \text{for all } I. \tag{4.17}$$

We will use the following notation: $[1, n] = \{1, \ldots, n\}$.

Lemma 4.5: If m is a singular vector, then

$$m = \partial(\xi_{[1,n]} \otimes w) + \sum_{l=1}^{n} (\xi_{[1,n]-\{l\}} \otimes v_l) + \xi_{[1,n]} \otimes v_0.$$

Proof: By the previous lemma, we have

$$m = \sum_{I} [\partial(\xi_I \otimes v_{I,1}) + (\xi_I \otimes v_{I,0})].$$

Now (S5) gives us

$$0=(f_\lambda m)_{|_{\lambda=0}}=\sum_I((-\partial)(f\xi_I\otimes v_{I,0})-(-1)^{|I|}\sum_{i=1}^n(\partial_i f)\xi_I\otimes E_{i0}(v_{I,0}))$$
$$+\sum_I((-\partial^2)(f\xi_I\otimes v_{I,1})-(-1)^{|I|}\sum_{i=1}^n\partial((\partial_i f)\xi_I\otimes E_{i0}(v_{I,1}))) \tag{4.18}$$

for any $f=\xi_J$ with $|J|>1$. Considering the coefficient of ∂^2 and taking $f=\xi_l\xi_k$, we obtain $v_{I,1}=0$ for all I with $|I|\leqslant n-2$. Using this and considering the coefficient of ∂ with $f=\xi_l\xi_k\xi_s$, we obtain $v_{I,0}=0$ for all I with $|I|\leqslant n-3$. With this reduction, the coefficient of ∂ with $f=\xi_i\xi_j$ $(i\neq j)$ is

$$0=-(\xi_{[1,n]}\otimes v_{[1,n]-\{i,j\},0})+(-1)^{n-1}(\xi_{[1,n]}\otimes E_{i0}(v_{[1,n]-\{j\},1})),$$

obtaining

$$E_{i0}(v_{[1,n]-\{j\},1})=(-1)^{n-1}v_{[1,n]-\{i,j\},0}\quad\text{for all } i\neq j. \tag{4.19}$$

Computing (S3), we have

$$0=\frac{d}{d\lambda}(f_\lambda m)_{|_{\lambda=0}}=\sum_{|I|\geqslant n-1}((-\partial)(f\xi_I\otimes v_{I,1})-(-1)^{|I|}\sum_{i=1}^n(\partial_i f)\xi_I\otimes E_{i0}(v_{I,1}))$$
$$+\partial\sum_{|I|\geqslant n-1}f\xi_I\otimes E_{00}(v_{I,1})+\sum_{|I|\geqslant n-2}f\xi_I\otimes E_{00}(v_{I,0}).$$

Now, taking $f=\xi_i$, using (4.17), and considering the coefficient in ∂, we have

$$v_{I,1}=0\quad\text{for all } |I|=n-1,$$

and using it in (4.19), we have

$$v_{I,0}=0\quad\text{for all } |I|=n-2,$$

finishing the proof. □

Let $\xi_*:=\xi_{[1,n]}$ and $\xi^l:=\xi_{[1,n]-\{l\}}$. Due to the previous lemma, any singular vector has the form

$$m=\partial(\xi_*\otimes w)+\sum_{l=1}^n(\xi^l\otimes v_l)+\xi_*\otimes v_0.$$

Then, it is easy to see that conditions (s1–3) are equivalent to the following list

(s1):

$$E_{00}(w)=0, \tag{4.20}$$

$$E_{0i}(w)=0,\quad i=1,\ldots,n. \tag{4.21}$$

(s2):

$$E_{ji}(w)+E_{0i}(v_j)=0,\quad i,j=1,\ldots,n, \tag{4.22}$$

$$E_{0i}(v_0)=0,\quad i=1,\ldots,n, \tag{4.23}$$

$$E_{0i}(v_j)=0,\quad i,j=1,\ldots,n,\quad i\neq j, \tag{4.24}$$

$$E_{0j}(v_j)=-w,\quad j=1,\ldots,n. \tag{4.25}$$

$$E_{i0}(w)=E_{00}(v_i),\quad i=1,\ldots,n. \tag{4.26}$$

(s3):

$$E_{i0}(v_j) = E_{j0}(v_i), \quad i,j = 1, \ldots, n, \quad i \neq j. \tag{4.27}$$

$$E_{ij}(v_l) = E_{lj}(v_i), \quad i,j,l = 1, \ldots, n, \quad i \neq l. \tag{4.28}$$

$$E_{ij}(w) = 0, \quad i,j = 1, \ldots, n, \quad i < j, \tag{4.29}$$

$$E_{ij}(v_0) = 0, \quad i,j = 1, \ldots, n, \quad i < j, \tag{4.30}$$

$$E_{ij}(v_l) = 0, \quad i,j,l = 1, \ldots, n, \quad i < j, l \neq j, \tag{4.31}$$

$$E_{ij}(v_j) = v_i, \quad i,j = 1, \ldots, n, \quad i < j. \tag{4.32}$$

Now replacing (4.24) and (4.25) on (4.22), we obtain

$$E_{ij}(w) = \delta_{ij} w, \quad i,j = 1, \ldots, n. \tag{4.33}$$

Recall that we are considering the basis $(\partial_0 = \partial_t)$

$$t\partial_0; t\partial_0 + \xi_1\partial_1, \ldots, t\partial_0 + \xi_n\partial_n$$

for the Cartan subalgebra H in $W(1,n)_+$, and we write the weight of an eigenvector for the Cartan subalgebra H as a tuple

$$\bar{\mu} = (\mu; \lambda_1, \ldots, \lambda_n) \tag{4.34}$$

for the corresponding eigenvalues of the basis.

Using the above conditions, we can prove the following:

Proposition 4.6: Let $n \geqslant 2$ *and* m *be a nontrivial singular vector in* Tens V *with weight* $\bar{\mu}_m$, *then we have one of the following:*

(*a*) $m = \xi^n \otimes v_n$, $\bar{\mu}_m = (0; 0, \ldots, 0, -k)$ *with* $k \geqslant 0$, v_n *is a highest weight vector in* V *with weight* $(0; 0, \ldots, 0, -k-1)$, *and* m *is uniquely defined by* v_n.

(*b*) $m = \Sigma_{l=1}^n \xi^l \otimes v_l$, $\bar{\mu}_m = (0; k, 1, \ldots, 1)$ *with* $k \geqslant 2$, v_1 *is a highest weight vector in* V *with weight* $(0; k-1, 1, \ldots, 1)$, *and* m *is uniquely defined by* v_1.

(*c*) $m = \partial(\xi_* \otimes w) + \Sigma_{l=1}^n \xi^l \otimes v_l$, $\bar{\mu}_m = (-1; 0, \ldots, 0)$, w *is a highest weight vector in* V *with weight* $(0; 1, \ldots, 1)$, *and* m *is uniquely defined by* w.

Proof: By computing $E_{00} \cdot m = (t\partial) \cdot m$ and using (4.20) and (4.26) on it, we obtain the following conditions:

If $w = 0$, then

$$E_{00} \cdot m = 0 \quad \text{and} \quad E_{00}(v_0) = 0. \tag{4.35}$$

If $w \neq 0$, then

$$E_{00} \cdot m = -m, \tag{4.36}$$

$$E_{00}(v_l) = -v_l, \quad l = 0, \ldots, n, \tag{4.37}$$

and using (4.26), in this case $(w \neq 0)$ we have

$$E_{i0}(w) = -v_i, \quad i = 1, \ldots, n. \tag{4.38}$$

Similarly, observe that $E_{ii} \cdot m = (\xi_i \partial_i) \cdot m$. Now this action can be easily computed, and using (4.33) on it, we have the following:

If $w \neq 0$, then

$$E_{ii}\cdot m = m, \quad i = 1, \ldots, n,$$

$$\begin{aligned} E_{ii}(v_l) &= v_l, \quad l, i = 1, \ldots, n, l \neq i, \\ E_{ii}(v_i) &= 2v_i, \quad i = 1, \ldots, n, \end{aligned} \tag{4.39}$$

$$E_{ii}(v_0) = v_0, \quad i = 1, \ldots, n.$$

Using this and Eqs. (4.36), (4.20), and (4.33), we obtain for the case $w \neq 0$, that the corresponding weights are

$$\bar{\mu}_m = (-1; 0, \ldots, 0) \quad \text{and} \quad \bar{\mu}_w = (0; 1, \ldots, 1).$$

This result together with (4.38) give us the proof of case (c) in the proposition.

For the rest of the proof, we assume $w=0$, let us show that the only possible cases are (a) and (b).

Observe that replacing (4.32) in (4.28), we get

$$E_{jj}(v_i) = v_i \quad \forall\, i < j. \tag{4.40}$$

Now, Eq. (4.32) shows that if $v_l=0$ for some l with $1 \leqslant l \leqslant n$, then $v_j=0$ for all $j<l$. In order to finish the proof, we should show that only the two extreme cases are possible, that is $v_l \neq 0$ for all l or $v_l=0$ except for $l=n$.

Now, suppose that there exist $l>1$ such that $v_j=0$ for all $j<l$ and $v_l \neq 0$, then using (4.28) we have that

$$E_{ii}(v_k) = 0, \quad i < l \leqslant k. \tag{4.41}$$

Then by (4.41) and (4.40), we obtain that

$$E_{ii}\cdot m = \alpha m \quad \text{with } \alpha = 0 \text{ or } 1, \quad \text{if } i < l \text{ or } i > l, \text{ respectively.}$$

Therefore, using this and (4.35) we get

$$\bar{\mu}_m = (0; 0, \ldots, 0, k, 1, \ldots, 1)$$

where $E_{ll}\cdot m = km$. But the space V, from which we are inducing is finite-dimensional and a singular vector generates a finite-dimensional L_0-submodule, then (recall notation (4.34))

$$\lambda_1 \geqslant \lambda_2 \geqslant \cdots \geqslant \lambda_n$$

is a highest weight, and because of that only two extreme positions of k are possible (recall that $n>1$). This gives us the cases (a) and (b). In order to finish the proof we need to complete the computation of weights in each case.

If $v_1 \neq 0$, then using (4.26) and (4.40) we obtain

$$\bar{\mu}_m = (0; k, 1, \ldots, 1) \quad \text{and} \quad \bar{\mu}_{v_1} = (0; k-1, 1, \ldots, 1) \quad \text{with } k \geqslant 1,$$

getting case (b).

If $v_l=0$ except for $l=n$, then using (4.26) and (4.41) we obtain

$$\bar{\mu}_m = (0; 0, \ldots, 0, k) \quad \text{and} \quad \bar{\mu}_{v_n} = (0; 0, \ldots, 0, k-1) \quad \text{with } k \leqslant 0$$

obtaining case (c). Case (d) is immediate. □

D. Irreducible induced $W(1,n)_+$-modules

In this section we consider $L=W(1,n)_+$, with $n\geqslant 2$. Now, we have the following:

Theorem 4.7: *Let $n\geqslant 2$ and F be an irreducible L_0-module with highest weight $\bar{\mu}_*$. Then the L-modules $\mathrm{Ind}_{L_{\geqslant 0}}^{L} F$ are irreducible finite continuous modules except for the following cases*:

(*a*) $\bar{\mu}_*=(0;\bar{0},\ldots,0,-m), m\geqslant 0$, *where* $\mathrm{Ind}_{L_{\geqslant 0}}^{L} F=\Theta_+^m$ *and the image* $d^{\#}\Theta_+^{m+1}$ *is the only nontrivial proper submodule.*

(*b*) $\bar{\mu}_*=(0;k,1,\ldots,1), k\geqslant 1$, *where* $\mathrm{Ind}_{L_{\geqslant 0}}^{L} F=\Omega_-^k$. *For* $k\geqslant 2$ *the image* $d\Omega_-^{k-1}$ *is the only nontrivial proper submodule. For* $k=1$, *both* $\mathrm{Im}(d)$ *and* $\mathrm{Ker}(d)$ *are proper submodules*. $\mathrm{Ker}(d)$ *is a maximal submodule.*

Remark 4.8: Let F be an irreducible L_0-module with highest weight $\bar{\mu}_*=(-1;0,\ldots,0)$. Then $\mathrm{Ind}_{L_{\geqslant 0}}^{L} F=\Omega_-^0$ is an irreducible L-module. Note that the image of $d:\Omega_-^0\to\Omega_-^1$ is the submodule in Ω_-^1 generated by the singular vector corresponding to the case (c) in Proposition 4.6, but it is not a maximal submodule (see Proposition 4.3 (4)).

Proof: We know from Theorem 3.1 that in order for $\mathrm{Ind}_{L_{\geqslant 0}}^{L} F$ to be reducible it has to have nontrivial singular vectors and the possible highest weights of F in this situation are listed in Proposition 4.6 above.

The fact that the induced modules are actually reducible in those cases is known because we have got nice realizations for these induced modules in Propositions 4.1 and 4.3 together with morphisms defined by $d, d^{\#}$, so kernels and images of these morphisms become submodules.

The subtle thing is to prove that a submodule is really a maximal one. We notice that in each case the factor is isomorphic to a submodule in another induced module so it is enough to show that the submodule is irreducible. This can be proved as follows, a submodule in the induced module is irreducible if it is generated by any highest singular vector that it contains. We see from our list of nontrivial singular vectors that there is at most one such vector for each case and the images and kernels in question are exactly generated by those vectors, hence they are irreducible. □

Corollary 4.9: The theorem gives us a description of finite continuous irreducible $W(1,n)_+$-modules for $n\geqslant 2$. Such a module is either $\mathrm{Ind}_{L_{\geqslant 0}}^{L} F$ for an irreducible finite-dimensional L_0-module F where the highest weight of F does not belong to the types listed in (a), (b) of the theorem or the factor of an induced module from (a), (b) by its submodule $Ker(d)$.

E. Finite irreducible W_n-modules

In order to give an explicit construction and classification, we need the following notation. Recall that $W(1,n)$ acts by derivations on the algebra of differential forms $\Omega=\Omega(1,n)$, and note that this is a conformal module by taking the family of formal distributions

$$E=\{\delta(z-t)\omega \quad \text{and} \quad \delta(z-t)\omega dt \,|\, \omega\in\Omega(n)\}.$$

Translating this and all other attributes of differential forms, like de Rham differential, etc., into the conformal algebra language, we arrive at the following definitions.

Recall that given an algebra A, the associated current formal distribution algebra is $A[t,t^{-1}]$ with the local family $F=\{a(z)=\Sigma_{n\in\mathbb{Z}}(at^n)z^{-n-1}=a\delta(z-t)\}_{a\in A}$. The associated conformal algebra is $\mathrm{Cur}A=\mathbb{C}[\partial]\otimes A$ with multiplication defined by $a_\lambda b=ab$ for $a,b\in A$ and extended using sesquilinearity. This is called the *current conformal algebra*, see Ref. 8 for details.

The conformal algebra of differential forms Ω_n is the current algebra over the commutative associative superalgebra $\Omega(n)+\Omega(n)dt$ with the obvious multiplication and parity, subject to the relation $(dt)^2=0$:

$$\Omega_n=\mathrm{Cur}(\Omega(n)+\Omega(n)dt).$$

The de Rham differential $\tilde{d}$ of Ω_n (we use the tilde in order to distinguish it from the de Rham differential d on $\Omega(n)$) is a derivation of the conformal algebra Ω_n such that

$$\widetilde{d}(\omega_1 + \omega_2 dt) = d\omega_1 + d\omega_2 dt - (-1)^{p(\omega_1)}\,\partial\,(\omega_1 dt). \tag{4.42}$$

Here and further $\omega_i \in \Omega(n)$.

The standard $\mathbb{Z}_+$-gradation $\Omega(n) = \oplus_{j\in\mathbb{Z}_+}\Omega(n)^j$ of the superalgebra of differential forms by their degree induces a $\mathbb{Z}_+$-gradation

$$\Omega_n = \oplus_{j\in\mathbb{Z}_+}\Omega_n^j, \quad \text{where } \Omega_n^j = \mathbb{C}[\partial]\otimes(\Omega(n)^j + \Omega(n)^{j-1}dt),$$

so that $\widetilde{d}:\Omega_n^j \to \Omega_n^{j+1}$.

The contraction ι_D for $D = a + f \in W_n$ is a conformal derivation of Ω_n such that:

$$(i_a + f)_\lambda \quad (\omega_1 + \omega_2 dt) = i_a\omega_1 + (-1)^{p(f)} f\omega_2.$$

Here and further, as before, $a \in W(n)$, $f \in \Lambda(n)$. The Lie derivative $\widetilde{L}_D$ for $D \in W_n$ is a conformal derivation of Ω_n such that:

$$(\widetilde{L}_a)_\lambda(\omega_1 + \omega_2 dt) = L_a\omega_1 + (L_a\omega_2)dt,$$

$$(\widetilde{L}_f)_\lambda\omega = -(\partial + \lambda)(f\omega), \tag{4.43}$$

$$(\widetilde{L}_f)_\lambda(\omega dt) = (-1)^{p(f)+p(\omega)}(df)\omega - \partial(f\omega dt).$$

The properties of $\Omega(1,n)$ imply the corresponding properties of Ω_n given by the following proposition.

Proposition 4.10:

(a) $\widetilde{d}^2 = 0$.

(b) *The complex* $(\Omega_n, \widetilde{d}) = \{0 \to \Omega_n^0 \to \cdots \to \Omega_n^j \to \cdots\}$ *is exact at all terms* Ω_n^j, *except for* $j = 1$. *One has*: $\operatorname{Ker}\widetilde{d}_{|\Omega_n^1} = \widetilde{d}\Omega_n^0 \oplus \mathbb{C}dt$.

(c) $\iota_{D_1}\iota_{D_2} + p(D_1, D_2)\iota_{D_2}\iota_{D_1} = 0$.

(d) $\widetilde{L}_D\widetilde{d} = (-1)^{p(D)}\widetilde{d}\widetilde{L}_D$.

(e) $\widetilde{L}_D = \widetilde{d}\iota_D + (-1)^{p(D)}\iota_D\widetilde{d}$.

(f) *The map* $D \mapsto \widetilde{L}_D$ *defines a* W_n*-module structures on* Ω_n, *preserving the* $\mathbb{Z}_+$*-gradation and commuting with* $\widetilde{d}$.

Proof: Only the proof of (b) requires a comment. Following Proposition 3.2.2 of Ref. 8, we construct $\mathbb{C}[\partial]$-linear maps $K:\Omega_n \to \Omega_n$ (a homotopy operator) and $\epsilon:\Omega_n \to \Omega_n$ by the formulas ($\omega \in \Omega(n) + \Omega(n)dt$):

$$K(d\xi_n\omega) = \xi_n\omega, \quad K(\omega) = 0 \quad \text{if } \omega \text{ does not involve } d\xi_n,$$

$$\epsilon(d\xi_n\omega) = \epsilon(\xi_n\omega) = 0, \quad \epsilon(\omega) = \omega \quad \text{if } \omega \text{ does not involve both } d\xi_n \text{ and } \xi_n.$$

One checks directly that

$$K\widetilde{d} + \widetilde{d}K = 1 - \epsilon.$$

Therefore, if $\omega \in \Omega_n$ is a closed form, we get $\omega = \widetilde{d}(K\omega) + \epsilon(\omega)$. It follows by induction on n that $\omega = \widetilde{d}\omega_1 + P(\partial)dt$ for some $\omega_1 \in \Omega_n$ and a polynomial $P(\partial)$. But it is clear from (4.42) that $P(\partial)dt$ is always closed, and it is exact iff $P(\partial)$ is divisible by ∂. □

Since the extended annihilation algebra $W(1,n)^+$ is a direct sum of $W(1,n)_+$ and a one-dimensional Lie algebra $\mathbb{C}a$, any irreducible $W(1,n)^+$-module is obtained from a $W(1,n)_+$-module M by extending to $W(1,n)^+$, letting $a \mapsto -\alpha$, where $\alpha \in \mathbb{C}$. Translating into the conformal language

(see Proposition 2.3), we see that all W_n-modules are obtained from conformal $W(1,n)_+$-modules by taking for the action of ∂ the action of $-\partial_t+\alpha I, \alpha\in\mathbb{C}$. We denote by $\mathrm{Tens}_\alpha V$ and $\Omega_{k,\alpha}, \alpha\in\mathbb{C}$, the W_n-modules obtained from Tens V and Ω_k by replacing in (4.7) and (4.8), respectively, ∂ by $\partial+\alpha$.

Now, Theorem 4.7 and Corollary 4.9, along with Sec. III and Propositions 2.3, 2.8, 2.6, and 2.9 give us a complete description of finite irreducible W_n-modules.

Theorem 4.11: *The following is a complete list of nontrivial finite irreducible W_n-modules* $(n\geqslant 2, \alpha\in\mathbb{C})$:

(a) $\mathrm{Tens}_\alpha V$, *where V is a finite-dimensional irreducible $gl(1|n)$-module different from* $\Lambda^k(\mathbb{C}^{1|n})^*$, $k=1,2,\ldots$ *and* $\bar{\Omega}^k_c$ (*see* (4.5)), $k=1,2,\ldots$,
(b) $\Omega^*_{k,\alpha}/\mathrm{Ker}\,\tilde{d}^*, k=1,2,\ldots$, *and the same modules with reversed parity*,
(c) W_n*-modules dual to* (*b*), *with* $k>1$.

Remark 4.12: (a) Using Proposition 4.3, we have that the kernel of $\tilde{d}$ and the image of $\tilde{d}$ coincide in Ω_k for $k\geqslant 2$. Now, since Ω_{k+2} is a free $\mathbb{C}[\partial]$-module of finite rank and $\Omega_{k+1}/\mathrm{Im}\,\tilde{d}=\Omega_{k+1}/\mathrm{Ker}\,\tilde{d}\simeq \mathrm{Im}\,\tilde{d}\subset\Omega_{k+2}$, we obtain that $\Omega_{k+1}/\mathrm{Im}\,\tilde{d}$ is a finitely generated free $\mathbb{C}[\partial]$-module. Therefore, we can apply Proposition 2.6, and we have that

$$\Omega^*_{k+1,\alpha}/\mathrm{Ker}\,\tilde{d}^*\simeq(\Omega_{k,\alpha}/\mathrm{Ker}\,\tilde{d})^*. \tag{4.44}$$

for $k\geqslant 1$.

(b) Observe that we cannot apply the previous argument for $k=0$ since, by Proposition 4.3, the image of $\tilde{d}$ has codimension one (over $\mathbb{C}$) in $\mathrm{Ker}\,\tilde{d}$. In fact, (4.44) is not true for $k=0$. For example, this can be easily seen for $W_0=\mathrm{Vir}$ using the differential map which is explicitly written in Remark 2.5.

(c) Observe that $\Omega_{0,\alpha}$ is an irreducible tensor module ($\mathrm{Ker}\,\tilde{d}=0$, cf. Proposition 4.3), that is why this module is included in case (a) of Theorem 4.11.

(d) Since for a finite rank module M over a Lie conformal superalgebra we have $M^{**}=M$ (see Proposition 2.7), the W_n-modules in case (c) of Theorem 4.11 are isomorphic to $\Omega_{k,\alpha}/ker\tilde{d}$, $k=2,3,\ldots$.

(e) Observe that $(\mathrm{Tens}\,V)^*$ is not isomorphic to Tens V^*. For example, consider the case of W_1. We have, using the notation below, that $M(a,b)=\mathrm{Tens}V_{a,b}$. It is easy to see that for the case $a+b\neq 0$, $(\mathrm{Tens}V_{a,b})^*=\mathrm{Tens}V_{-a,-b}$, but $(V_{a,b})^*=V_{1-a,-b-1}$.

Now we will present the case $n=1$ in detail and we shall see that our result agrees with the classification given in Ref. 5 for $K_2\simeq W_1$. Let us fix some notations. We have

$$W_1=\mathbb{C}[\partial]\otimes(\Lambda(1)\oplus W(1))=\mathbb{C}[\partial]\{1,\xi,\partial_1,\xi\partial_1\}.$$

In Ref. 5, the conformal Lie superalgebra K_2 is presented as the freely generated module over $\mathbb{C}[\partial]$ by $\{L,J,G^\pm\}$. An isomorphism between K_2 and W_1 is explicitly given by

$$L\mapsto -1+\frac{1}{2}\,\partial\,\xi\partial_1,\quad J\mapsto\xi\partial_1,\quad G^+\mapsto 2\xi,\quad G^-\mapsto-\partial_1. \tag{4.45}$$

The irreducible modules of W_1 are parametrized by finite-dimensional irreducible representations of $gl(1,1)$ (and the additional twist by alpha that, for simplicity, shall be omitted in the formulas to follow). The irreducible representations of $gl(1,1)$, denoted by $V_{a,b}$, are parametrized by a and b, the corresponding eigenvalues of e_{11} and e_{22} on the highest weight vector.

If both parameters are equal to zero, the representation is trivial one-dimensional. Otherwise, either $a+b=0$, the dimension of the $gl(1,1)$-representation is 1, and the corresponding representation of W_1 is one of the tensor modules of rank 2. Or else $a+b$ is nonzero, the dimension of the $gl(1,1)$-representation is 2, and the corresponding tensor module has rank 4.

Explicitly, consider the set of $\mathbb{C}[\partial]$-generators of $W_1\{1,\xi,\partial_1,\xi\partial_1\}$. Let a and b such that $a+b\neq 0$. Let $V_{a,b}=\mathbb{C}-\text{span}\{v_0,v_1\}$, where v_0 is a highest weight vector. Let $M(a,b)=M(V_{a,b})=\mathbb{C}[\partial]\{v_0,v_1,w_1=\partial_1 v_0,w_0=\partial_1 v_1\}$ be the tensor W_1-module and denote by $L(a,b)$ the irreducible quotient. The action of W_1 in $M(a,b)$ is given explicitly by the following formulas:

$$\begin{gathered}
1_\lambda v_0=(a\lambda-\partial)v_0,\quad 1_\lambda v_1=((a-1)\lambda-\partial)v_1,\\
1_\lambda w_1=(a\lambda-\partial)w_1,\quad 1_\lambda w_0=((a-1)\lambda-\partial)w_0,\\
\xi_\lambda v_0=v_1,\quad \xi_\lambda v_1=0,\\
\xi_\lambda w_1=(a\lambda-\partial)v_0-w_0,\quad \xi_\lambda w_0=((a-1)\lambda-\partial)v_1,\\
\partial_{1\lambda}v_0=w_1,\quad \partial_{1\lambda}v_1=(a+b)\lambda v_0+w_0,\\
\partial_{1\lambda}w_1=0,\quad \partial_{1\lambda}w_0=-(a+b)\lambda w_1\\
\xi\partial_{1\lambda}v_0=bv_0,\quad \xi\partial_{1\lambda}v_1=(b+1)v_1,\\
\xi\partial_{1\lambda}w_1=(b-1)w_1,\quad \xi\partial_{1\lambda}w_0=-(a+b)\lambda v_0+bw_0.
\end{gathered}\tag{4.46}$$

If $a+b\neq 0$ and $a\neq 0$, then $M(a,b)$ is irreducible of rank 4, and the explicit action is given by (4.45). The proof of this statement is in the following way (the proof of the other statements below are much simpler): Take $v=p(\partial)v_0+q(\partial)w_0+r(\partial)v_1+s(\partial)w_1$ in a submodule of $M(a,b)$. Denote by w the coefficient of the highest power in λ of $\xi_\lambda v$ and by y the coefficient of the highest power in λ of $\xi_\lambda w$.

If $a\neq 1$ then $y=v_1$ (up to a constant factor), therefore v_1 lies in the submodule. If $a=1$, then by taking the coefficient of the highest power in λ of $\xi\partial_{1\lambda}y$ and using that in this case $b\neq -1$, we also obtain that v_1 lies in the submodule.

Therefore, in any case we have that v_1 lies in any submodule, and by the formulas for the actions on v_1 it is immediate that the other generators also belong to any submodule, proving that $M(a,b)$ is irreducible in this case.

If $a+b\neq 0$ but $a=0$, it is easy to show as above that $N=\mathbb{C}[\partial]w_1\oplus\mathbb{C}[\partial](\partial v_0+w_0)$ is a submodule of $M(0,b)$. The irreducible quotient of $M(0,b)$ by N is $L(0,b)=\mathbb{C}[\partial]v_0\oplus\mathbb{C}[\partial]v_1$, of rank 2, and the action here is explicitly, as follows:

$$\begin{gathered}
1_\lambda v_0=(-\partial)v_0,\quad 1_\lambda v_1=(-\lambda-\partial)v_1,\\
\xi_\lambda v_0=v_1,\quad \xi_\lambda v_1=0,\\
\partial_{1\lambda}v_0=0,\quad \partial_{1\lambda}v_1=(b\lambda-\partial)v_0,\\
\xi\partial_{1\lambda}v_0=bv_0,\quad \xi\partial_{1\lambda}v_1=(b+1)v_1.
\end{gathered}\tag{4.47}$$

If $a+b=0$, but $a\neq 0$, it is easy to show as above that $M(a,-a)=C[\partial]\{v_0,w_1\}$ is irreducible of rank 2 and the action of W_1 here is given by

$$\begin{gathered}
1_\lambda v_0=(a\lambda-\partial)v_0,\quad 1_\lambda w_1=(a\lambda-\partial)w_1,\\
\xi_\lambda v_0=0,\quad \xi_\lambda w_1=(a\lambda-\partial)v_0,\\
\partial_{1\lambda}v_0=w_1,\quad \partial_{1\lambda}w_1=0,\\
\xi\partial_{1\lambda}v_0=-av_0,\quad \xi\partial_{1\lambda}w_1=(-a-1)w_1.
\end{gathered}\tag{4.48}$$

Thus we obtain

Corollary 4.13: *The W_1-module $L(a,b)$ as a $\mathbb{C}[\partial]$-module has rank*: 4 *if* $a+b\neq 0$ *and* $a\neq 0$, 2 *if* $a+b\neq 0$ *and* $a=0$, 2 *if* $a+b=0$ *and* $a\neq 0$, 0 *if* $a=b=0$. *These are all nontrivial finite irreducible W_1-modules*.

Remark 4.14: In Ref. 5, the irreducible representations of K_2 are classified in terms of parameters Λ and Δ. Using the isomorphism between K_2 and W_1 in (4.45), these parameters are related to ours as follows:

$$a=-\Delta-\frac{\Lambda}{2},\quad b=\Lambda.$$

Then it can be easily checked that the above corollary corresponds to Theorem 4.1 in Ref. 5, and explicit formulas for the λ-action given at the end of Sec. IV in Ref. 5, corresponds to ours in each case.

V. LIE CONFORMAL SUPERALGEBRA S_n AND ITS FINITE IRREDUCIBLE MODULES

Recall that the *divergence* of a differential operator $D=\Sigma_{i=0}^{n}a_i\partial_i\in W(1,n)$, with $a_i\in\Lambda(1,n)$ and $\partial_0=\partial_t$ is defined by the formula

$$\operatorname{div} D=\partial_0 a_0+\sum_{i=1}^{n}(-1)^{p(a_i)}\partial_i a_i.$$

The basic property of the divergence is ($D_1,D_2\in W(1,n)$)

$$\operatorname{div}[D_1,D_2]=D_1(\operatorname{div} D_2)-(-1)^{p(D_1)p(D_2)}D_2(\operatorname{div} D_1).$$

It follows that

$$S(1,n)=\{D\in W(1,n):\operatorname{div} D=0\}$$

is a subalgebra of the Lie superalgebra $W(1,n)$. Similarly,

$$S(1,n)_+=\{D\in W(1,n)_+:\operatorname{div} D=0\}$$

is a subalgebra of $W(1,n)_+$. We have

$$S(1,n)\ (\text{respectively, } S(1,n)_+)=S(1,n)'\ (\text{respectively, } S(1,n)'_+)\oplus\mathbb{C}\xi_1\cdots\xi_n\partial_0,\qquad(5.1)$$

where $S(1,n)'$ (respectively, $S(1,n)'_+$) denotes the derived subalgebra. It is easy to see that $S(1,n)'$ is a formal distribution Lie superalgebra, see Ref. 7, Example 3.5.

In order to describe the associated Lie conformal superalgebra, we need to translate the notion of divergence to the "conformal" language as follows. It is a $\mathbb{C}[\partial]$-module map $\operatorname{div}: W_n\to\operatorname{Cur}\Lambda(n)$, given by

$$\operatorname{div} a=\sum_{i=1}^{n}(-1)^{p(f_i)}\partial_i f_i,\quad \operatorname{div} f=-\partial\otimes f,$$

where $a=\Sigma_{i=1}^{n}f_i\partial_i\in W(n)$ and $f\in\Lambda(n)$. The following identity holds in $\mathbb{C}[\partial]\otimes\Lambda(n)$, where $D_1,D_2\in W_n$:

$$\operatorname{div}[D_{1\lambda}D_2]=(D_1)_\lambda(\operatorname{div} D_2)-(-1)^{p(D_1)p(D_2)}(D_2)_{-\lambda-\partial}(\operatorname{div} D_1).\qquad(5.2)$$

Therefore,

$$S_n=\{D\in W_n:\operatorname{div} D=0\}$$

is a subalgebra of the Lie conformal superalgebra W_n. It is known that S_n is simple for $n\geqslant 2$, and finite of rank $n2^n$. Furthermore, it is the Lie conformal superalgebra associated to the formal

distribution Lie superalgebra $S(1,n)'$. The annihilation algebra and the extended annihilation algebra is given by

$$\mathcal{A}(S_n) = S(1,n)'_+ \quad \text{and} \quad \mathcal{A}(S_n)^e = \mathbb{C}ad(\partial_0) \ltimes S(1,n)'_+.$$

Now, we have to study representations of $S(1,n)_+$ and of its derived algebra $S(1,n)'_+$ which has codimension 1. Observe that $S(1,n)_+$ inherits the $\mathbb{Z}$-gradation in $W(1,n)_+$, and denoting by $L=S(1,n)_+$ (for the rest of this section), we have that $L_{-1}=\langle \partial_0, \ldots, \partial_n \rangle$ as in $W(1,n)_+$ but the other graded components are strictly smaller than these of $W(1,n)_+$. Observe that $L_0=sl(1|n)$.

In order to consider weights of vectors in $S(1,n)_+$-modules, we take the basis

$$t\partial_0 + \xi_1\partial_1, \ldots, t\partial_0 + \xi_n\partial_n$$

for the Cartan subalgebra. And the weights are written as $\bar{\lambda}=(\lambda_1, \ldots, \lambda_n)$ for the corresponding eigenvalues.

Propositions 4.1 and 4.3, and Corollary 4.2 hold for $L=S(1,n)_+$ with the following minor modification: all highest weights are the same as in the W case, except for the first coordinate that should be removed.

Similarly, if V is an $sl(1|n)$-module, then formulas (4.7) and (4.8) define an S_n-module structure in Tens(V). Indeed, elements $(-1)^{p(f)}\partial(f\partial_i)+\partial_i f$, with $f \in \Lambda(n)$ generate S_n as a $\mathbb{C}[\partial]$-module, and it is easy to see that for the action of these elements defined by (4.7) and (4.8), one needs only $E_{ij}(v)$ for $i \neq j$ and $(E_{00}+E_{ii})(v)$ for $i>0$.

As in the W-case, the classification is reduced to the study of singular vectors in Tens(V), where V is an $sl(1|n)$-module. Observe that the reduction Lemma 4.4 hold in this case, and the proof is basically the same. Therefore, analogous computations give as the following

Proposition 5.1: *Let $n \geqslant 2$ and V an irreducible finite-dimensional $sl(1|n)$-module. If m is a nontrivial singular vector in the $S(1,n)_+$-module* Tens V *with weight $\bar{\lambda}_m$, then we have one of the following*:

(*a*) $m=\xi^n \otimes v_n$, $\bar{\lambda}_m=(0, \ldots, 0, -k)$ *with* $k \geqslant 0$, v_n *is a highest weight vector in* V *with weight* $(0, \ldots, 0, -k-1)$, *and* m *is uniquely defined by* v_n.

(*b*) $m=\sum_{l=1}^n \xi^l \otimes v_l$, $\bar{\lambda}_m=(k, 1, \ldots, 1)$ *with* $k \geqslant 2$, v_1 *is a highest weight vector in* V *with weight* $(k-1, 1, \ldots, 1)$, *and* m *is uniquely defined by* v_1.

(*c*) $m=\partial(\xi_* \otimes w)+\sum_{l=1}^n \xi^l \otimes v_l$, $\bar{\lambda}_m=(0, \ldots, 0)$, w *is a highest weight vector in* V *with weight* $(1, \ldots, 1)$, *and* m *is uniquely defined by* w.

(*d*) $m=\partial(\xi^n \otimes w)+\sum_{l=1}^{n-1} \xi_{[l,n]-\{l,n\}} \otimes v_l + \xi^n \otimes v_n$, $\bar{\lambda}_m=(0, \ldots, 0, -1)$, w *is a highest weight vector in* V *with weight* $(1, \ldots, 1)$, *and* m *is uniquely defined by* w.

Using the above proposition, we have

Theorem 5.2: *Let $L=S(1,n)_+$ $(n \geqslant 2)$ and F be an irreducible L_0-module with highest weight $\bar{\lambda}_*$. Then the L-modules* $\mathrm{Ind}_{L_{\geqslant 0}}^L F$ *are irreducible finite continuous modules except for the following cases*:

(*a*) $\bar{\lambda}_*=(0, \ldots, 0, -p), p \geqslant 0$, *where* $\mathrm{Ind}_{L_{\geqslant 0}}^L F=\Theta_+^p$ *and the image* $d^{\#}\Theta_+^{p+1}$ *is the only nontrivial proper submodule*.

(*b*) $\bar{\lambda}_*=(q, 1, \ldots, 1), q \geqslant 1$, *where* $\mathrm{Ind}_{L_{\geqslant 0}}^L F=\Omega_-^q$. *For* $q \geqslant 2$ *the image* $d\Omega_-^{q-1}$ *is the only nontrivial proper submodule. For* $q=1$, *the proper submodules are* $\mathrm{Im}(d)$, $\mathrm{Ker}(d)$ *and* $\mathrm{Im}(\alpha)$, *where* α *is the composition*

$$\alpha: \Theta_+^1 \xrightarrow{d^{\#}} \Theta_+^0 \simeq \Omega_-^0 \xrightarrow{d} \Omega_-^1,$$

and $\mathrm{Ker}(d)$ *is the maximal proper submodule*.

Proof: Similar to the case of $W(1,n)_+$, the modules $\mathrm{Ind}_{L_{\geqslant 0}}^L F$ are irreducible except when they have a singular vector and the highest weights of such F, when it could happen, are listed in (a), (b), (c), and (d) of the above Proposition 5.1. The weight $(1, \ldots, 1)$ is special here because it is

relevant to (b), (c), and (d). There are three types of singular vectors possible in this case. The corresponding module $\mathrm{Ind}(F)=\Omega^1_-$ has three different submodules and all three vectors are present. The same argument as for $W(1,n)_+$-modules allows us easily to conclude that the listed submodules are the only ones and the factors are irreducible. □

Corollary 5.3: *The theorem gives us a description of finite continuous irreducible* $S(1,n)_+$*-modules when* $n\geqslant 2$. *Such a module is either* $\mathrm{Ind}^L_{L_{\geqslant 0}}F$ *for an irreducible finite-dimensional* L_0*-module* F *where the highest weight of* F *does not belong to the types listed in* (*a*), (*b*) *of the theorem or the factor of an induced module from* (*a*), (*b*) *by the submodule* $\mathrm{Ker}(d)$.

Corollary 5.4: *The Lie superalgebras* $S(1,n)_+$ *and* $S(1,n)'_+$ *have the same finite continuous irreducible modules*, *and they are described by the previous corollary*.

Proof: In order to see that Theorem 5.2 also holds for $S(1,n)'_+$, it is basically enough to see that Proposition 5.1 holds in this case. But, if we check the proof in the classification of singular vectors, we see that the element $\xi_1\cdots\xi_n\partial_0$ (cf. (5.1)) appears only in the condition (s3) in (4.10) in the special case $g=\xi_1\cdots\xi_n$ and $j=0$. If we track the details of the proof, we see that this special constraint only produces Eq. (4.27) for $n=2$, but in any case, this equation is not used in the rest of the proof. Therefore, the singular vectors are the same for both Lie superalgebras $S(1,n)'_+$ and $S(1,n)_+$, finishing the proof. □

Now, as in the W_n case, Theorem 5.2 and Corollary 5.4, along with Sec. III and Propositions 2.3, 2.8, and 2.9 give us a complete description of finite irreducible S_n-modules ($n\geqslant 2$): it is given by Theorem 4.11 in which W_n is replaced by S_n and $gl(1|n)$ is replaced by $sl(1|n)$.

Remark 5.5: Under the standard isomorphism between S_2 and small $N=4$ conformal superalgebra it is easy to see that our result agrees with the classification given in Ref. 5. Indeed, in Ref. 5 (Theorem 6.1) the classification of irreducible modules was given in terms of parameters Λ and Δ, and these parameters are related to ours as follows:

$$\lambda_1=-\Delta+\frac{\Lambda}{2}, \tag{5.3}$$

$$\lambda_2=-\Delta-\frac{\Lambda}{2}. \tag{5.4}$$

Therefore, the case $2\Delta-\Lambda=0$ ($\Lambda\in\mathbb{Z}_+$) corresponds to the family $\Omega^*_{\Lambda,\alpha}/\mathrm{Ker}\,\tilde{d}^*$ of rank 4Λ, and the case $2\Delta+\Lambda+2=0$ ($\Lambda\in\mathbb{Z}_+$) corresponds to $\Omega_{\Lambda+1,\alpha}/\mathrm{Ker}\,\tilde{d}$ of rank $4\Lambda+8$. Therefore, we have one module of rank 4 that corresponds to $\Omega^*_1/\mathrm{Ker}\,\tilde{d}^*$, and by Remark 4.12, the dual of this module is Ω_0 (Ker is trivial in this case) and (using Proposition 4.3) Ω_0 is the tensor module $\mathrm{Tens}(V)$ where V is the trivial representation, therefore it is reducible with a maximal submodule of codimension 1 (over $\mathbb{C}$).

VI. LIE CONFORMAL SUPERALGEBRAS $S_{n,b}$ AND $\tilde{S}_n$, AND THEIR FINITE IRREDUCIBLE MODULES

Case $S_{n,b}$:

For any $b\in\mathbb{C}$, $b\neq 0$, we take

$$S(1,n,b)=\{D\in W(1,n)\,|\,\mathrm{div}(e^{bx}D)=0\}.$$

This is a formal distribution subalgebra of $W(1,n)$. The associated Lie conformal superalgebra is constructed explicitly as follows. Let $D=\sum_{i=1}^n P_i(\partial,\xi)\partial_i+f(\partial,\xi)$ be an element of W_n. We define the deformed divergence as

$$\mathrm{div}_b D=\mathrm{div}\,D+bf.$$

It still satisfies Eq. (5.2), therefore

$$S_{n,b} = \{D \in W_n | \mathrm{div}_b D = 0\}$$

is a subalgebra of W_n, which is simple for $n \geqslant 2$ and has rank $n2^n$. Since $S_{n,0} = S_n$ has been discussed in the previous section, we can (and will) assume that $b \neq 0$.

If $b \neq 0$, the extended annihilation algebra is given by

$$(\mathrm{Alg}(S_{n,b}))^+ = \mathbb{C}ad\left(\partial_0 - b\sum_{i=1}^{n} \xi_i \partial_i\right) \ltimes S(1,n)_+ \simeq CS(1,n)'_+$$

where $CS(1,n)'_+$ is obtained from $S(1,n)'_+$ by enlarging $sl(1,n)$ to $gl(1,n)$ in the 0-th-component.

Therefore, the construction of all finite irreducible modules over $S_{n,b}$ is the same as that for W_n, but without twisting by α. Hence, using Theorem 4.11, we have

Theorem 6.1: *The following is a complete list of finite irreducible $S_{n,b}$-modules* ($n \geqslant 2, b \in \mathbb{C}, b \neq 0$):

(a) $\mathrm{Tens}\, V$, *where V is a finite-dimensional irreducible $gl(1|n)$-module different from* $\Lambda^k(\mathbb{C}^{1|n})^*$, $k=1,2,\ldots$ *and* $\Lambda^k(\mathbb{C}^{1|n})$, $k=0,1,2,\ldots$,

(b) $\Omega_k^*/\mathrm{Ker}\, \tilde{d}^*$, $k=1,2,\ldots$, *and the same modules with reversed parity*,

(c) *$S_{n,b}$-modules dual to* (*b*), *with* $k>1$.

Case $\widetilde{S}_n$:

Let $n \in \mathbb{Z}_+$ be an even integer. We take

$$\widetilde{S}(1,n) = \{D \in W(1,n) | \mathrm{div}((1+\xi_1 \ldots \xi_n)D) = 0\}.$$

This is a formal distribution subalgebra of $W(1,n)$. The associated Lie conformal superalgebra $\widetilde{S}_n$ is constructed explicitly as follows:

$$\widetilde{S}_n = \{D \in W_n | \mathrm{div}((1+\xi_1 \ldots \xi_n)D) = 0\} = (1-\xi_1 \ldots \xi_n)S_n.$$

The Lie conformal superalgebra $\widetilde{S}_n$ is simple for $n \geqslant 2$ and has rank $n2^n$.

The extended annihilation algebra is given by

$$(\mathrm{Alg}(\widetilde{S}_n))^+ = \mathbb{C}ad(\partial_0 - \xi_1 \ldots \xi_n \partial_0) \ltimes S(1,n)'_+ \simeq S(1,n)_+.$$

Therefore, the construction of all finite irreducible modules over $\widetilde{S}_n$ is the same as that for S_n, but without the twist by α.

This article is one of a series that lays the groundwork for a structure and classification theory of second order superintegrable systems, both classical and quantum, in conformally flat spaces. In the first part of the article we study the Stäckel transform (or coupling constant metamorphosis) as an invertible mapping between classical superintegrable systems on different three-dimensional spaces. We show first that all superintegrable systems with nondegenerate potentials are multiseparable and then that each such system on any conformally flat space is Stäckel equivalent to a system on a constant curvature space. In the second part of the article we classify all the superintegrable systems that admit separation in generic coordinates. We find that there are eight families of these systems. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2191789]

I. INTRODUCTION

This is a continuation of the series[1–3] whose purpose is to lay the groundwork for a structure and classification theory of second order superintegrable systems, both classical and quantum, in complex conformally flat spaces. Real spaces are considered as restrictions of these to the various real forms. In Refs. 1 and 3 we have given examples in two and three dimensions, described the background as well as the interest and importance of these systems in mathematical physics and given many applications relevant to such systems on conformally flat spaces. Observed features of the systems are multiseparability, closure of the quadratic algebra of second order symmetries at order 6, use of representation theory of the quadratic algebra to derive spectral properties of the quantum Schrödinger operator, and a close relationship with exactly solvable and quasiexactly solvable problems. Our approach is, rather than focus on particular spaces and systems, to use a general theoretical method based on integrability conditions to derive structure common to all systems. In distinction to the two-dimensional (2D) case, there are relatively few papers considering superintegrability on spaces of dimension $\geqslant 3$. A few exceptions are Refs. 4–13. Except for our own work, no one appears to have studied the detailed structure and classification theory for these higher dimensional systems.

In the first part of this article we study the Stäckel transform, or coupling constant metamorphosis,[14,15] for three-dimensional (3D) classical superintegrable systems. Recall that for a classical 3D system on a conformally flat space we can always choose local coordinates x, y, z, not unique, such that the Hamiltonian takes the form $H=(p_1^2+p_2^2+p_3^2)/\lambda(x,y,z)+V(x,y,z)$. This

[a)]Electronic mail: j.kress@unsw.edu.au

system is *second order superintegrable with nondegenerate* potential $V=V(x,y,z,\alpha,\beta,\gamma,\delta)$ if it admits five functionally independent quadratic constants of the motion (i.e., generalized symmetries) $S_k=\Sigma_{ij}a^{ij}_{(k)}p_ip_j+W_{(k)}(x,y,\alpha,\beta,\gamma)$. As described in Ref. 3, the potential V is *nondegenerate* if it satisfies a system of coupled partial differential equations of the form

$$V_{22}=V_{11}+A^{22}V_1+B^{22}V_2+C^{22}V_3,\quad V_{33}=V_{11}+A^{33}V_1+B^{33}V_2+C^{33}V_3,$$

$$V_{12}=A^{12}V_1+B^{12}V_2+C^{12}V_3,\quad V_{13}=A^{13}V_1+B^{13}V_2+C^{13}V_3, \tag{1}$$

$$V_{23}=A^{23}V_1+B^{23}V_2+C^{23}V_3,$$

whose integrability conditions are satisfied identically. The analytic functions A^{ij},B^{ij},C^{ij} are determined uniquely from the Bertrand-Darboux equations for the five constants of the motion and are analytic except for a finite number of poles. At any regular point $\mathbf{x}_0=(x_0,y_0,z_0)$, i.e., a point where the A^{ij}, B^{ij}, and C^{ij} are defined and analytic and the constants of the motion are functionally independent, we can prescribe the values of $V(\mathbf{x}_0),V_1(\mathbf{x}_0),V_2(\mathbf{x}_0),V_3(\mathbf{x}_0),V_{11}(\mathbf{x}_0)$ arbitrarily and obtain a unique solution of (1). Here, $V_1=\partial V/\partial x$, $V_2=\partial V/\partial y$, etc. The four parameters for a nondegenerate potential (in addition to the usual additive constant) are the maximum number of parameters that can appear in a superintegrable system. If the number of parameters is fewer than four, we say that the superintegrable potential is *degenerate*.

The 3D Stäckel transform is a conformal transformation of a superintegrable system on one conformally flat 3D space to a superintegrable system on another such space. We discuss some of the properties of this transform for a classical system and then prove two fundamental results: (1) We show that every superintegrable system with nondegenerate potential is multiseparable. This result uses the structure theory for such systems that we worked out in Ref. 3. (2) We prove that all nondegenerate 3D superintegrable systems are Stäckel transforms of constant curvature systems. Thus, to obtain all nondegenerate conformally flat superintegrable systems, it is sufficient to classify those of constant curvature. The proofs of these fundamental results rest on results obtained in Ref. 3, and the careful reader of this article will need to keep Ref. 3 at hand.

In the second part of the article we use the results of the first part and our explicit knowledge of all separable coordinate systems on 3D constant curvature spaces to make a major advance in the classification of all separable systems with nondegenerate potential on a conformally flat space. Among the separable systems for 3D complex Euclidean space there are seven that are "generic." We give a precise definition later, but, essentially this means that the coordinates belong to a multiparameter family. The ultimate generic coordinates are the Jacobi elliptic coordinates from which all others can be obtained by limiting processes.[16,17] We show that each of the generic separable systems uniquely determines a nondegenerate superintegrable system that contains it. We obtain a similar result for the five generic separable systems on the complex three-sphere. However, four of these turn out to be Stäckel transforms of Euclidean generic systems. Thus we find eight Stäckel inequivalent generic systems on constant curvature spaces and all generic systems on 3D conformally flat spaces must be Stäckel equivalent to one of these. (In addition there are two nondegenerate superintegrable systems in Euclidean space that are only weakly functionally independent and these give rise to similar systems on a variety of conformally flat spaces.) Thus we exhibit ten families of superintegrable systems in conformally flat spaces. This does not solve the classification problem completely, but it is a major advance. Any remaining nondegenerate superintegrable systems must be multiseparable but separate *only* in degenerate separable coordinates. This remaining problem is still complicated, but much less so than the original problem. This is a technically detailed proof, but the results are quite explicit and easy to grasp. We derive and give a simple characterization of eight families of separable systems whose Stäckel transforms yield nondegenerate superintegrable systems on a variety of conformally flat spaces.

The next article in this series will extend all of our classical 2D and 3D results to the quantum case. This is very easy in the 2D case but requires some machinery in 3D.

Second order conformal Killing tensors: There is a close relationship between the second-order Killing tensors of a conformally flat space in 3D and the second order conformal Killing tensors of flat space. A second order conformal Killing tensor for a space M_3 with metric $ds^2=\lambda(x_1,x_2,x_3)(dx_1^2+dx_2^2+dx_3^2)$ and free Hamiltonian $\mathcal{H}=(p_1^2+p_2^2+p_3^2)/\lambda$ is a quadratic form $\mathcal{S}=\Sigma a^{ij}(x_1,x_2,x_3)p_ip_j$ such that $\{\mathcal{H},\mathcal{S}\}=f(x_1,x_2,x_3)\mathcal{H}$, for some function f. Since f is arbitrary, it is easy to see that $\mathcal{S}$ is a conformal Killing tensor for M_3 if and only if it is a conformal Killing tensor for flat space $dx_1^2+dx_2^2+dx_3^2$. The conformal Killing tensors for flat space are very well known, e.g., Ref. 18. The space of conformal Killing tensors is infinite dimensional.[19] It is spanned by products of the conformal Killing vectors

$$p_1,\quad p_2,\quad p_3,\quad x_3p_2-x_2p_3,\quad x_1p_3-x_3p_1,\quad x_2p_1-x_1p_2,\quad x_1p_1+x_2p_2+x_3p_3,$$

$$(x_1^2-x_2^2-x_3^2)p_1+2x_1x_3p_3+2x_1x_2p_2,\quad (x_2^2-x_1^2-x_3^2)p_2+2x_2x_3p_3+2x_2x_1p_1,$$

$$(x_3^2-x_1^2-x_2^2)p_3+2x_3x_1p_1+2x_3x_2p_2,$$

and terms $g(x_1,x_2,x_3)(p_1^2+p_2^2+p_3^2)$, where g is an arbitrary function. Since every Killing tensor is also a conformal Killing tensor, we see that every second-order Killing tensor for M_3 can be expressed as a linear combination of these second-order generating elements though, of course, the space of Killing tensors is only finite dimensional. This shows in particular that every a^{ij} and every $a^{ii}-a^{jj}$ with $i\neq j$ is a polynomial of order at most four in x_1, x_2, x_3, no matter what is the choice of λ.

A straightforward, though tedious, computation from the above-mentioned results yields the expressions

$$\begin{aligned}
a_{11}^{12}&=-a_{22}^{12}=\alpha_3(x_1^2-x_2^2)+(\delta_1+\gamma_2)x_1x_2-\alpha_1x_1x_3-\alpha_2x_2x_3+\phi_3x_1+\xi_3x_2+\mu_3x_3+\nu_3,\\
a_{11}^{13}&=-a_{33}^{13}=\alpha_2(x_1^2-x_3^2)-\alpha_1x_1x_2+\gamma_2x_1x_3-\alpha_3x_2x_3+\phi_2x_1+\xi_2x_2+\mu_2x_3+\nu_2,\\
\alpha_{33}^{23}&=-a_{22}^{23}=\alpha_1(x_2^2-x_3^2)-\alpha_2x_1x_2+\alpha_3x_1x_3+\delta_1x_2x_3+\phi_1x_1+\xi_1x_2+\mu_1x_3+\nu_1,
\end{aligned}\tag{2}$$

where α_j, δ_j, γ_j, ϕ_j, ξ_j, μ_j, and ν_j are constants. Further $(a^{ii}-a^{jj})_i=2a_j^{ij}$ for $i\neq j$, and $a_3^{12}+a_2^{13}+a_1^{23}=0$.

It is useful to pass to new variables a^{11}, a^{24}, a^{34}, a^{12}, a^{13}, a^{23} for the Killing tensor, where $a^{24}=a^{22}-a^{11}$, $a^{34}=a^{33}-a^{11}$. Then we see that a^{24}, a^{34}, a^{12}, a^{13}, a^{23} are polynomials of order $\leqslant 4$. The remaining conditions can be expressed in the form

$$\begin{aligned}
(a^{11}\lambda)_1&=-\lambda_2a^{12}-\lambda_3a^{13},\quad (a^{11}\lambda)_2=-\lambda_1a^{12}-(a^{24}\lambda)_2-\lambda_3a^{23},\\
(a^{11}\lambda)_3&=-\lambda_1a^{13}-\lambda_2a^{23}-(a^{34}\lambda)_3.
\end{aligned}\tag{3}$$

Theorem 1: *Necessary and sufficient conditions that the quadratic form* $\mathcal{S}=\Sigma_{ij}a^{ij}p_ip_j+W$ *be a second order constant of the motion for the space with metric* $ds^2=\lambda(dx_1^2+dx_2^2+dx_3^2)$ *and potential V are*

(1) $\Sigma_{ij}a^{ij}p_ip_j$ *is a conformal Killing tensor on the flat space with metric* $dx_1^2+dx_2^2+dx_3^2$.
(2) *The integrability conditions for (3) hold:*

$$\begin{aligned}
(\lambda_2a^{12}+\lambda_3a^{13})_2&=(\lambda_1a^{12}+(a^{24}\lambda)_2+\lambda_3a^{23})_1,\\
(\lambda_2a^{12}+\lambda_3a^{13})_3&=(\lambda_1a^{13}+\lambda_2a^{23}+(a^{34}\lambda)_3)_1,\\
(\lambda_1a^{12}+(a^{24}\lambda)_2+\lambda_3a^{23})_3&=(\lambda_1a^{13}+\lambda_2a^{23}+(a^{34}\lambda)_3)_2.
\end{aligned}\tag{4}$$

(3) *The Bertrand-Darboux conditions for the potential hold:*

$$\sum_{s=1}^{3} [V_{sj}\lambda a^{s\ell} - V_{s\ell}\lambda a^{sj} + V_s((\lambda a^{s\ell})_j - (\lambda a^{sj})_\ell)] = 0. \tag{5}$$

These are just the conditions $\partial_{x_\ell} W_j = \partial_{x_j} W_\ell$ *for* $j \neq \ell$.

II. THE STÄCKEL TRANSFORM FOR 3D SYSTEMS

The Stäckel transform[14] or coupling constant metamorphosis[15] plays a fundamental role in relating superintegrable systems on different manifolds. Suppose we have a superintegrable system

$$H = \frac{p_1^2 + p_2^2 + p_3^2}{\lambda(x,y,z)} + V(x,y,z) \tag{6}$$

in local orthogonal coordinates, with nondegenerate potential $V(x,y,z)$:

$$V_{33} = V_{11} + A^{33}V_1 + B^{33}V_2 + C^{33}V_3, \quad V_{22} = V_{11} + A^{22}V_1 + B^{22}V_2 + C^{22}V_3,$$

$$V_{23} = A^{23}V_1 + B^{23}V_2 + C^{23}V_3, \quad V_{13} = A^{13}V_1 + B^{13}V_2 + C^{13}V_3, \tag{7}$$

$$V_{12} = A^{12}V_1 + B^{12}V_2 + C^{12}V_3$$

and suppose $U(x,y,z)$ is a particular solution of Eqs. (7), nonzero in an open set. Then the transformed system $\tilde{H} = (p_1^2 + p_2^2 + p_3^2)/\tilde{\lambda} + \tilde{V}$ with nondegenerate potential $\tilde{V}(x,y,z)$:

$$\tilde{V}_{33} = \tilde{V}_{11} + \tilde{A}^{33}\tilde{V}_1 + \tilde{B}^{33}\tilde{V}_2 + \tilde{C}^{33}\tilde{V}_3, \quad \tilde{V}_{22} = \tilde{V}_{11} + \tilde{A}^{22}\tilde{V}_1 + \tilde{B}^{22}\tilde{V}_2 + \tilde{C}^{22}\tilde{V}_3,$$

$$\tilde{V}_{23} = \tilde{A}^{23}\tilde{V}_1 + \tilde{B}^{23}\tilde{V}_2 + \tilde{C}^{23}\tilde{V}_3, \quad \tilde{V}_{13} = \tilde{A}^{13}\tilde{V}_1 + \tilde{B}^{13}\tilde{V}_2 + \tilde{C}^{13}\tilde{V}_3, \tag{8}$$

$$\tilde{V}_{12} = \tilde{A}^{12}\tilde{V}_1 + \tilde{B}^{12}\tilde{V}_2 + \tilde{C}^{12}\tilde{V}_3,$$

is also superintegrable, where

$$\tilde{\lambda} = \lambda U, \quad \tilde{V} = \frac{V}{U}, \quad \tilde{A}^{33} = A^{33} + 2\frac{U_1}{U}, \quad \tilde{C}^{33} = C^{33} - 2\frac{U_3}{U},$$

$$\tilde{A}^{22} = A^{22} + 2\frac{U_1}{U}, \quad \tilde{B}^{22} = B^{22} - 2\frac{U_2}{U}, \quad \tilde{B}^{23} = B^{23} - \frac{U_3}{U}, \quad \tilde{C}^{23} = C^{23} - \frac{U_2}{U},$$

$$\tilde{A}^{13} = A^{13} - \frac{U_3}{U}, \quad \tilde{C}^{13} = C^{13} - \frac{U_1}{U}, \quad \tilde{A}^{12} = A^{12} - \frac{U_2}{U}, \quad \tilde{B}^{12} = B^{12} - \frac{U_1}{U},$$

and $\tilde{A}^{23} = A^{23}$, $\tilde{B}^{33} = B^{33}$, $\tilde{B}^{13} = B^{13}$, $\tilde{C}^{22} = C^{22}4$, $\tilde{C}^{12} = C^{12}$. Let $S = \Sigma a^{ij}p_ip_j + W = S_0 + W$ be a second order symmetry of H and $S_U = \Sigma a^{ij}p_ip_j + W_U = S_0 + W_U$ be the special case that is in involution with $(p_1^2 + p_2^2 + p_3^2)/\lambda + U$. Then $\tilde{S} = S_0 - (W_U/U)H + (1/U)H$ is the corresponding symmetry of $\tilde{H}$. Since one can always add a constant to a nondegenerate potential, it follows that $1/U$ defines an inverse Stäckel transform of $\tilde{H}$ to H. See Ref. 14 for many examples of this transform.

III. MULTISEPARABILITY AND STÄCKEL EQUIVALENCE

From the general theory of variable separation for Hamilton-Jacobi equations, e.g., Refs. 20 and 21 we know that second order symmetries L_1, L_2 define a separable system for the equation

$$H = \frac{p_x^2 + p_y^2 + p_z^2}{\lambda(x,y,z)} + V(x,y,z) = E$$

if and only if (1) the symmetries H, L_1, L_2 form a linearly independent set as quadratic forms, (2) $\{L_1, L_2\}=0$, and, (3) the three quadratic forms have a common eigenbasis of differential forms. This last requirement means that, expressed in coordinates x, y, and z, at least one of the matrices $\mathcal{A}_{(j)}(\mathbf{x})$ (of the quadratic form associated with L_j) can be diagonalized by conjugacy transforms in a neighborhood of a regular point and that $[\mathcal{A}_{(2)}(\mathbf{x}), \mathcal{A}_{(1)}(\mathbf{x})]=0$. However, for nondegenerate superintegrable potentials in a conformally flat space we see that $\{L_1, L_2\}=0 \leftrightarrow [\mathcal{A}_{(2)}(\mathbf{x}_0), \mathcal{A}_{(1)} \times(\mathbf{x}_0)]=0$, $\mathcal{F}(\mathbf{x}_0)=0$ at a single regular point $\mathbf{x}_0$, see Sec. V of Ref. 3, so that the intrinsic conditions for the existence of a separable coordinate system are simplified.

Let $\mathcal{A}=\Sigma_{i\leqslant j} a^{ij}\mathcal{A}^{ij}$, $\mathcal{B}=\Sigma_{i\leqslant j} b^{ij}\mathcal{A}^{ij}$, be the matrices of two symmetries at the point $\mathbf{x}_0$. Here, $\mathcal{A}^{ij}=\frac{1}{2}(\mathcal{E}^{ij}+\mathcal{E}^{ji})$ where $\mathcal{E}^{ij}$ is the 3×3 matrix with matrix element 1 in row i, column j, and 0 everywhere else. From the table in Sec. V of Ref. 3 we see that the corresponding symmetries are in involution if and only if the matrices $\mathcal{A}, \mathcal{B}$ commute and the additional condition

$$\begin{aligned}
&(a^{12}b^{11} - b^{12}a^{11})(C^{33} - B^{23} - A^{13}) + (a^{22}b^{12} - a^{12}b^{22})(C^{33} - 2B^{23}) \\
&\quad + (a^{13}b^{11} - a^{11}b^{13})(B^{33} + 2A^{12} - B^{22}) + (a^{33}b^{13} - a^{13}b^{33})(2B^{33} + 2A^{12} - B^{22}) \\
&\quad + (a^{23}b^{22} - a^{22}b^{23})(-2B^{12} - A^{33}) + (a^{33}b^{23} - b^{33}a^{23})(-2B^{12} + A^{22} - 2A^{33}) \\
&\quad + 2(a^{11}b^{22} - a^{22}b^{11} + a^{33}b^{11} - a^{11}b^{33} + a^{22}b^{33} - a^{33}b^{22})A^{23} + (a^{23}b^{11} - a^{11}b^{23})(A^{22} - A^{33}) \\
&\quad + (a^{33}b^{12} - a^{12}b^{33})(B^{23} - A^{13}) + (a^{13}b^{22} - a^{22}b^{13})B^{33} = 0
\end{aligned} \tag{9}$$

holds. Note that the metric G does not appear in these conditions.

Theorem 2: *Let V be a superintegrable nondegenerate potential in a 3D conformally flat space. Then V defines a multiseparable system.*

Proof: From (9) we see that the second order symmetries with matrices $\mathcal{A}^{(33)}$ and $\alpha\mathcal{A}^{(11)} + \beta\mathcal{A}^{(12)}$ will be in involution if and only if $2\alpha A^{23} + \beta(B^{23} - A^{13}) = 0$ at the regular point $\mathbf{x}_0$. If $A^{23}(\mathbf{x}_0)=0$ we can set $\alpha=1$, $\beta=0$ and the symmetries $\mathcal{A}^{(33)}$, $\mathcal{A}^{11}$ will define a separable system. If $A^{23}(\mathbf{x}_0)\neq 0$ we can set $\alpha=-(B^{23}-A^{13})/2A^{23}$, $\beta=1$. Then the symmetries with nonzero matrices $\mathcal{A}^{(33)}$ and $\alpha\mathcal{A}^{(11)}+\beta\mathcal{A}^{(12)}$ will be in involution. The second case must occur for some regular point $\mathbf{x}_0$ unless $A^{23}(\mathbf{x})=0$ for all $\mathbf{x}$. In this last eventuality we can perform a suitable Euclidean rotation (with arbitrarily small complex rotation angle) so that A^{23} does not vanish identically in the rotated coordinate system. It is a straightforward exercise to show that this transformation is not possible if and only if

$$B^{33} = C^{22} = 0, \quad A^{13} = B^{23}, \quad A^{12} = C^{23}, \quad A^{22} = A^{33}. \tag{10}$$

In this eventuality, we can set $\alpha=0$, $\beta=1$ and find a solution. Thus we can always find a linear combination of these matrices, corresponding to $\beta=1$ and with three distinct eigenvalues, so they will determine separable coordinates. We could have carried through this same construction for the second order symmetries with matrices $\mathcal{A}^{(22)}$ and $\gamma\mathcal{A}^{(11)}+\delta\mathcal{A}^{(13)}$ and for the second order symmetries with matrices $\mathcal{A}^{(11)}$ and $\mu\mathcal{A}^{(22)}+\xi\mathcal{A}^{(23)}$ and shown that we could always find solutions with $\delta=\xi=1$. Thus the system is multiseparable (in at least three coordinate systems). Q.E.D.

Corollary 1: Let V be a superintegrable nondegenerate potential in a 3D conformally flat space. Then there is a continuous one-parameter (or multiparameter) family of separable systems for V, spanning at least a five-dimensional subspace of symmetries.

Proof: We follow the method of proof of the theorem.

Case I: Suppose $A^{23}(\mathbf{x}_0)\neq 0$. From (9) we can verify that the symmetries with matrices

$$\mathcal{A}=\begin{pmatrix}0 & 0 & 0\\ 0 & f^2 & -f\\ 0 & -f & 1\end{pmatrix},\quad \mathcal{B}=\begin{pmatrix}g & 1/2 & f/2\\ 1/2 & 0 & 0\\ f/2 & 0 & 0\end{pmatrix}, \tag{11}$$

are in involution provided

$$-4f^2B^{23}+2f^2C^{33}+3fB^{33}+4fA^{12}-2fB^{22}+fB^{23}-4f^2gA^{23}-4fgA^{22}$$
$$+4fgA^{33}+4gA^{23}+2B^{23}-2A^{13}-2f^3B^{33}=0.$$

As $A^{23}(\mathbf{x}_0)\neq 0$ this equation can be solved for g as a function of f for f in some open set. The resulting symmetries $\mathcal{A},\mathcal{B}$ are in involution and have eigenvalues $(0,0,f^2+1)$ and $\left(0,\frac{1}{2}[g+\sqrt{f^2+g^2+1}],\frac{1}{2}[g-\sqrt{f^2+g^2+1}]\right)$, respectively. Thus they determine a one-parameter family of separable coordinates. Moreover, as f varies in an open set, the space spanned by the symmetries (including the Hamiltonian) has dimension six.

Case II: If $A^{23}(\mathbf{x}_0)=0$, we can assume that Eq. (10) holds. Then the problem breaks up into a series of special cases. Suppose first that $C^{33}-2A^{13}=\ell\neq 0$. Then we can verify that the symmetries with matrices

$$\mathcal{A}=\begin{pmatrix}0 & 2gk/K & 0\\ 2gk/K & 1 & -g/K\\ 0 & -g/K & g^2/K\end{pmatrix},\quad \mathcal{B}=\begin{pmatrix}f & g/2 & 1/2\\ g/2 & 0 & 0\\ 1/2 & 0 & k\end{pmatrix}, \tag{12}$$

are in involution provided $K=1-4fk\neq 0$ and g satisfies

$$-g(2A^{12}-B^{22})+2k(A^{22}+2B^{12})=\ell.$$

If $2A^{12}-B^{22}\neq 0$ then there is a nonzero solution expression g as a function of k. Since f,k are essentially arbitrary, they determine a five-dimensional space spanned by the symmetries and a two-parameter family of separable coordinates. If $2A^{12}-B^{22}=0$, $A^{22}+2B^{12}\neq 0$ then k is a nonzero constant and f,g are essentially arbitrary, so they again determine a five-dimensional space spanned by the symmetries and a two-parameter family of separable coordinates. If $2A^{12}-B^{22}=0$, $A^{22}+2B^{12}=0$, then the symmetries with matrices

$$\mathcal{A}=\begin{pmatrix}0 & H/K & 0\\ H/K & 1 & 0\\ 0 & 0 & L/K\end{pmatrix},\quad \mathcal{B}=\begin{pmatrix}f & g/2 & 1/2\\ g/2 & 0 & h/2\\ 1/2 & h/2 & k\end{pmatrix}, \tag{13}$$

where $K=1-4fk-h^2-2hgf\neq 0$, and

$$H=-h+2gk+hg^2,\quad G=-g+2fh+gh^2,\quad L=g^2-h^2+2hg(k-f),$$

are in involution provided $f=(g/2h-h/2g)$. (This implies $G=0$ and $L=Hh$.) They determine a six-dimensional space spanned by the symmetries and a three-parameter family of separable coordinates. This covers all cases where $\ell\neq 0$.

Now suppose $\ell=0$, i.e., $C^{33}=2A^{13}$. Then the symmetries with matrices (13) are in involution provided

$$(2A^{12}-B^{22})(h^2-g^2+2hgf-2hkg)+(A^{22}+2B^{12})(-h+2kg+hg^2)=0.$$

If $2A^{12}-B^{22}\neq 0$ then we can solve this equation to express f as a nonzero function of g,h,k. This yields at least a five-dimensional space spanned by the symmetries and a three-parameter family of separable coordinates. Finally, suppose in addition that $2A^{12}-B^{22}=0$. Then we can verify that the symmetries with matrices

$$\mathcal{A}=\begin{pmatrix}0 & 0 & 0\\ 0 & f^2 & -f\\ 0 & -f & 1\end{pmatrix},\quad \mathcal{B}=\begin{pmatrix}g & 1/2 & f/2\\ 1/2 & 0 & 0\\ f/2 & 0 & 0\end{pmatrix}, \tag{14}$$

are in involution with no conditions on f,g. Again, as f,g vary in an open set, the space spanned by the symmetries (including the Hamiltonian) has dimension six. Q.E.D.

In Ref. 17 the following result was obtained.

Theorem 3: *Let u_1,u_2,u_3 be an orthogonal separable coordinate system for a 3D conformally flat space with metric $\mathrm{d}\tilde{s}^2$. Then there is a function f such that $f\mathrm{d}\tilde{s}^2=\mathrm{d}s^2$ where $\mathrm{d}s^2$ is a constant curvature space metric and $\mathrm{d}s^2$ is orthogonally separable in exactly these same coordinates u_1,u_2,u_3. The function f is called a Stäckel multiplier with respect to this coordinate system.*

Thus the possible separable coordinate systems for a conformally flat space are all obtained, modulo a Stäckel multiplier, from separable systems on 3D flat space or on the three sphere.

Theorem 4: *Every superintegrable system with nondegenerate potential on a 3D conformally flat space is Stäckel equivalent to a superintegrable system on either 3D flat space or the three sphere.*

Proof: Suppose we have a superintegrable system with nondegenerate potential on a conformally flat space. Then by Corollary 1 this system separates in a one- or multiparameter family of coordinate systems spanning a five-dimensional subspace of symmetries. By Theorem 3 each of these three systems is conformal to a separable system in flat space or on the three sphere. Thus from Ref. 19, p. 85, the metric for the space in standard Cartesian-like coordinates x, y, z is simultaneously conformal to three systems corresponding to the following possible choices for the metric function $\lambda(x,y,z)$, namely

$$1,\quad 1/(x+iy)^2,\quad 1/r^4\quad \text{(flatspace)};\quad 1/x^2,\quad 1/(1+r^2/4)^2\quad \text{(three sphere)}; \tag{15}$$

in the same coordinates, and each of the conformal factors is a Stäckel multiplier with respect to the corresponding separable coordinates. From the Corollary we see that we can find two separable systems such that the factor (15) is the same, i.e., the metric must take the form $\mathrm{d}\tilde{s}^2=f\mathrm{d}s^2$, where $\mathrm{d}s^2$ is the metric on a single constant curvature space, either 3D flat space or the three sphere, and the constant curvature space separates in these same two coordinate systems. Further the space of symmetries spanned by the two sets is at least five dimensional.

Then we have $(\tilde{\mathcal{H}}+\tilde{V})/f=\mathcal{H}+V$, where $\tilde{\mathcal{H}}+\tilde{V}$ is the original superintegrable system, $\mathcal{H}$ is the Hamiltonian on a constant curvature space, and V is the induced multiparameter potential. Under the transform f each of the commuting second order symmetries $\mathcal{S}$ of the original system that defines a coordinate separation transforms to a symmetry of the form $\mathcal{S}+g_S\mathcal{H}$ for g_S a function. There are at least five such functionally linearly independent symmetries arising from separation in two coordinate systems, so the constant curvature space system admits five functionally linearly independent symmetries. Thus the potential V must satisfy the Bertrand–Darboux equations for these symmetries. It follows that V is nondegenerate and by Theorem 2 of Ref. 3 that the system $\mathcal{H}+V$ is itself superintegrable with nondegenerate potential. The function f is simultaneously a Stäckel multiplier with respect to the two coordinate systems whose symmetries completely characterize the superintegrable system $\mathcal{H}+V$. That is, f satisfies the Bertrand–Darboux equations for five functionally linearly independent symmetries. Hence f itself satisfies the equations that determine the nondegenerate potential V. This means that the system $\tilde{\mathcal{H}}+\tilde{V}$ is Stäckel equivalent to the constant curvature space superintegrable system. Q.E.D.

IV. CLASSIFICATION OF NONDEGENERATE SYSTEMS

A. Separable systems in complex Euclidean space

It is a difficult task to list all 3D conformally flat superintegrable systems with nondegenerate potential and to show that the classification is complete. However, we now have tools to simplify the problem. First, as every such system is Stäckel equivalent to a system on Euclidean space or the complex sphere, we can restrict ourselves to those two spaces. Second, since every such

system is multiseparable, we can bring to bear our knowledge of all orthogonal separable coordinates on these spaces. These results can be gleaned from the books[20,16] and many papers of the authors, e.g., Ref. 17. Thus in principle, we have enough information to accomplish our task, though the details are formidably complicated.

We begin by summarizing the full list of orthogonal separable systems in complex Euclidean space and the associated symmetry operators. Here, a "natural" basis for first order symmetries is given by $p_1 \equiv p_x$, $p_2 \equiv p_y$, $p_3 \equiv p_z$, $J_1 = yp_z - zp_y$, $J_2 = zp_x - xp_z$, $J_3 = xp_y - yp_x$ in the classical case and $p_1 = \partial_x$, $p_2 = \partial_y$, $p_3 = \partial_z$, $J_1 = y\partial_z - z\partial_y$, $J_2 = z\partial_x - x\partial_z$, $J_3 = x\partial_y - y\partial_x$ in the quantum case. (In the operator characterizations for the quantum case, the classical product of two constants of the motion is replaced by the symmetrized product of the corresponding operator symmetries.) The Hamiltonian is $H = p_1^2 + p_2^2 + p_3^2$. In each case below we list the coordinates followed by the constants of the motion that characterize them.

Note: The bracket notation used to describe generic coordinates in three-dimensional Euclidean space is due to Bôcher and is an adaptation of the notation used to describe the elementary divisors of two quadratic forms one of which is the quadratic form associated with Euclidean space and the second with the quadratic form of the coordinate curves describing the coordinate system. In order to do this in three dimensions and also deal with separable solutions of Laplace's equation we use the symbol $[p_0, p_1, \ldots, p_r]$ where $\Sigma_{i=0}^{r} p_i = 5$ and $p_0 \geqslant 2$. (See Ref. 16 for further details). This determines a coordinate system whose infinitesimal distance is of the form

$$\mathrm{d}s^2 = \frac{1}{(u-v)(u-w)} P(u) p_u^2 + \frac{1}{(v-u)(v-w)} P(v) p_v^2 + \frac{1}{(w-v)(w-u)} P(w) p_w^2,$$

where $P(\lambda) = (\lambda - e_1)^{p_1} \cdots (\lambda - e_r)^{p_r}$. The index p_0 is associated with ∞.

$$[2111] \quad x^2 = c^2 \frac{(u-e_1)(v-e_1)(w-e_1)}{(e_1-e_2)(e_1-e_3)}, \quad y^2 = c^2 \frac{(u-e_2)(v-e_2)(w-e_2)}{(e_2-e_1)(e_2-e_3)},$$

$$z^2 = c^2 \frac{(u-e_3)(v-e_3)(w-e_3)}{(e_3-e_1)(e_3-e_2)},$$

$$L_1 = J_1^2 + J_2^2 + J_3^2 + c^2((e_1+e_2)p_3^2 + (e_1+e_3)p_2^2 + (e_3+e_2)p_1^2),$$

$$L_2 = e_1 J_1^2 + e_2 J_2^2 + e_3 J_3^2 + c^2(e_1 e_2 p_3^2 + e_1 e_3 p_2^2 + e_3 e_2 p_1^2).$$

$$[211] \quad x^2 + y^2 = -c^2 \left[\frac{(u-e_1)(v-e_1)(w-e_1)}{(e_1-e_2)^2} \right] - \frac{c^2}{e_1-e_2}[(u-e_1)(v-e_1) + (u-e_1)(w-e_1) + (v-e_1)(w-e_1)],$$

$$(x-iy)^2 = c^2 \frac{(u-e_1)(v-e_1)(w-e_1)}{e_1-e_2}, \quad z^2 = c^2 \frac{(u-e_2)(v-e_2)(w-e_2)}{(e_2-e_1)^2}.$$

$$L_1 = J_1^2 + J_2^2 + J_3^2 + c^2((e_1-e_2)(p_1+ip_2)^2 + 2e_2 p_3^2 + (e_1+e_2)(p_1^2+p_2^2)),$$

$$L_2 = e_2(J_1^2 + J_2^2) + (e_2-e_1)(J_1+iJ_2)^2 + e_1 J_3^2 + c^2((e_1 e_2(p_1^2+p_2^2) + e_1(e_1-e_2)(p_1+ip_2)^2 + e_2^2 p_3^2)).$$

$$[23] \quad x - iy = \frac{1}{2} c \left(\frac{u^2+v^2+w^2}{uvw} - \frac{1}{2} \frac{u^2v^2 + u^2w^2 + v^2w^2}{u^3v^3w^3} \right),$$

$$z=\frac{1}{2}c\left(\frac{uv}{w}+\frac{uw}{v}+\frac{vw}{u}\right),\quad x+iy=cuvw.$$

$$L_1=J_1^2+J_2^2+J_3^2+2c^2(p_1+ip_2)p_3,\quad L_2=-2J_3(J_1+iJ_2)+c^2(p_1+ip_2)^2.$$

$$[311]\quad x=\frac{c}{4}\left(u^2+v^2+w^2+\frac{1}{u^2}+\frac{1}{v^2}+\frac{1}{w^2}\right)+\frac{3}{2}c,$$

$$y=-\frac{c}{4}\frac{(u^2-1)(v^2-1)(w^2-1)}{uvw},\quad z=i\frac{c}{4}\frac{(u^2+1)(v^2+1)(w^2+1)}{uvw}.$$

$$L_1=c(J_3p_2-J_2p_3)+c^2(p_1^2-p_2^2),\quad L_2=-\frac{1}{4}J_1^2-cJ_2p_3-c^2p_3^2.$$

$$[32]\quad x+iy=uvw,\quad x-iy=-\left(\frac{uv}{w}+\frac{uw}{v}+\frac{vw}{u}\right),\quad z=\frac{1}{2}(u^2+v^2+w^2).$$

$$L_1=-c(J_2+iJ_1)(p_1+ip_2)-c(J_2-iJ_1)(p_1-ip_2)-c^2(p_1+ip_2)^2,$$

$$L_2=J_3^2-2c(J_2-iJ_1)(p_1+ip_2).$$

$$[41]\quad x+iy=u^2v^2+u^2w^2+v^2w^2-\tfrac{1}{2}(u^4+v^4+w^4),\quad x-iy=c^2(u^2+v^2+w^2),\quad z=2icuvw.$$

The symmetries that describe this system are

$$L_1=-iJ_3(p_1-ip_2)+(J_2+iJ_1)p_3+\tfrac{1}{4}c^4(p_1+ip_2)^2,\quad L_2=-(J_1-iJ_2)^2-2ic^4(J_1+iJ_2)p_3.$$

$$[5]\quad x+iy=c(u+v+w),\quad x-iy=\frac{c}{4}(u-v-w)(u+v-w)(u+w-v),$$

$$z=-\frac{c}{4}(u^2+v^2+w^2-2(uv+uw+vw)).$$

$$L_1=iJ_3(p_1+ip_2)+(J_2-iJ_1)p_3+cp_3(p_1-ip_2),$$

$$L_2=\frac{1}{4}(J_2-iJ_1)^2-c(2(J_2+iJ_1i(p_1+ip_2)+i(p_1-ip_2)(J_1+iJ_2))+\frac{c^2}{4}(p_1-ip_2)^2.$$

We summarize the remaining degenerate separable coordinates:

Euclidean coordinates: All of these have one symmetry in common: $L_1=p_3^2$. The seven systems are, polar, Cartesian, light cone, elliptic, parabolic, hyperbolic, and semihyperbolic.

Complex sphere coordinates: These all have the symmetry $L_1=J_1^2+J_2^2+J_3^2$ in common. The five systems are spherical, horospherical, elliptical, hyperbolic, and semicircular parabolic.

Rotational types of coordinates: There are three of these systems, each of which is characterized by the fact that one defining symmetry is a perfect square.

Nonorthogonal heat type coordinates: Each of these nonorthogonal systems corresponds to one first order symmetry. Hence it cannot arise for systems with nondegenerate potentials.

Note that the first seven separable systems are generic, i.e., they occur in one-, two- or three-parameter families, whereas the remaining systems are special limiting cases of the generic ones. We shall show that each of the generic separable systems uniquely determines a nondegenerate superintegrable system.

B. Generic 3D Euclidean superintegrable systems

Each of the seven generic Euclidean separable systems depends on a scaling parameter c and up to three parameters e_1, e_2, e_3. For each such set of coordinates we shall show that there is exactly one nondegenerate superintegrable system that admits separation in these coordinates *simultaneously for all values of the parameters* c, e_j.

Consider the system in Ref. 23, for example. If a nondegenerate superintegrable system separates in these coordinates for all values of the parameter c, then the space of second order symmetries must contain the five symmetries

$$\mathcal{H} = p_x^2 + p_y^2 + p_z^2 + V, \quad \mathcal{S}_1 = J_1^2 + J_2^2 + J_3^2 + f_1, \quad \mathcal{S}_2 = J_3(J_1 + iJ_2) + f_2,$$

$$\mathcal{S}_3 = (p_x + ip_y)^2 + f_3, \quad \mathcal{S}_4 = p_z(p_x + ip_y) + f_4.$$

It is straightforward to check that the 12×5 matrix of coefficients of the second derivative terms in the twelve Bertrand-Darboux equations associated with symmetries $\mathcal{S}_1, \ldots, \mathcal{S}_4$ has rank five in general. Thus, there is at most one nondegenerate superintegrable system admitting these symmetries. Solving the Bertrand-Darboux equations for the potential we find the unique solution

$$V(\mathbf{x}) := \alpha(x^2 + y^2 + z^2) + \frac{\beta}{(x+iy)^2} + \frac{\gamma z}{(x+iy)^3} + \frac{\delta(x^2 + y^2 - 3z^2)}{(x+iy)^4}.$$

Finally, we can use the symmetry conditions for this potential to obtain the full six-dimensional space of second order symmetries. This is the superintegrable system III on the following table. The other six cases yield corresponding results.

Theorem 5: *Each of the seven generic Euclidean separable systems determines a unique nondegenerate superintegrable system that permits separation simultaneously for all values of the scaling parameter c and any other defining parameters* e_j. *For each of these systems there is a basis of five (strongly) functionally independent and six linearly independent second order symmetries. The corresponding nondegenerate potentials and basis of symmetries are (the* f_j *are functions of* x_1, x_2, x_3):

$$\text{I } [2111] \quad V = \frac{\alpha_1}{x^2} + \frac{\alpha_2}{y^2} + \frac{\alpha_3}{z^2} + \delta(x^2 + y^2 + z^2), \tag{16}$$

$$\mathcal{P}_i = \partial_{x_i}^2 + \delta x_i^2 + \frac{\alpha_i}{x_i^2}, \quad \mathcal{J}_{ij} = (x_i p_{x_j} - x_j p_{x_i})^2 + \alpha_i^2 \frac{x_j^2}{x_i^2} + \alpha_j^2 \frac{x_i^2}{x_j^2}, \quad i \geqslant j.$$

$$\text{II } [221] \quad V = \alpha(x^2 + y^2 + z^2) + \beta\frac{x - iy}{(x+iy)^3} + \frac{\gamma}{(x+iy)^2} + \frac{\delta}{z^2}, \tag{17}$$

$$\mathcal{S}_1 = J \cdot J + f_1, \quad \mathcal{S}_2 = p_z^2 + f_2, \quad \mathcal{S}_3 = J_3^2 + f_3,$$

$$\mathcal{S}_4 = (p_x + ip_y)^2 + f_4, \quad L_5 = (J_2 - iJ_1)^2 + f_5.$$

$$\text{III [23]} \quad V=\alpha(x^2+y^2+z^2)+\frac{\beta}{(x+iy)^2}+\frac{\gamma z}{(x+iy)^3}+\frac{\delta(x^2+y^2-3z^2)}{(x+iy)^4}, \tag{18}$$

$$\mathcal{S}_1=J\cdot J+f_1,\quad \mathcal{S}_2=(J_2-iJ_1)^2+f_2,\quad \mathcal{S}_3=J_3(J_2-iJ_1)+f_3,$$

$$\mathcal{S}_4=(p_x+ip_y)^2+f_4,\quad \mathcal{S}_5=p_z(p_x+ip_y)+f_5.$$

$$\text{IV [311]} \quad V=\alpha(4x^2+y^2+z^2)+\beta x+\frac{\gamma}{y^2}+\frac{\delta}{z^2}, \tag{19}$$

$$\mathcal{S}_1=p_x^2+f_1,\quad \mathcal{S}_2=p_y^2+f_2,\quad \mathcal{S}_3=p_zJ_2+f_3,$$

$$\mathcal{S}_4=p_yJ_3+f_4,\quad \mathcal{S}_5=J_1^2+f_5.$$

$$\text{V [32]} \quad V=\alpha(4x^2+y^2+z^2)+\beta x+\frac{\gamma}{(y+iz)^2}+\frac{\delta(y-iz)}{(y+iz)^3}, \tag{20}$$

$$\mathcal{S}_1=p_x^2+f_1,\quad \mathcal{S}_2=J_1^2+f_2,\quad \mathcal{S}_3=(p_z-ip_y)(J_2+iJ_3)+f_3,$$

$$\mathcal{S}_4=p_zJ_2-p_yJ_3+f_4,\quad \mathcal{S}_5=(p_z-ip_y)^2+f_5.$$

$$\text{VI [41]} \quad V=\alpha(z^2-2(x-iy)^3+4(x^2+y^2))+\beta(2(x+iy)-3(x-iy)^2)+\gamma(x-iy)+\frac{\delta}{z^2}, \tag{21}$$

$$\mathcal{S}_1=(p_x-ip_y)^2+f_1,\quad \mathcal{S}_2=p_z^2+f_2,\quad \mathcal{S}_3=p_z(J_2+iJ_1)+f_3,$$

$$\mathcal{S}_4=J_3(p_x-ip_y)-\frac{i}{4}(p_x+ip_y)^2+f_4,\quad \mathcal{S}_5=(J_2+iJ_1)^2+4ip_zJ_1+f_5.$$

$$\begin{aligned}\text{VII [5]} \quad V=&\alpha(x+iy)+\beta\left(\tfrac{3}{4}(x+iy)^2+\tfrac{1}{4}z\right)+\gamma\left((x+iy)^3+\tfrac{1}{16}(x-iy)+\tfrac{3}{4}(x+iy)z\right)\\&+\delta\left(\tfrac{5}{16}(x+iy)^4+\tfrac{1}{16}(x^2+y^2+z^2)+\tfrac{3}{8}(x+iy)^2z\right),\end{aligned} \tag{22}$$

$$\mathcal{S}_1=(J_1+iJ_2)^2+2iJ_1(p_x+ip_y)-J_2(p_x+ip_y)+\tfrac{1}{4}(p_y^2-p_z^2)-iJ_3p_z+f_1,$$

$$\mathcal{S}_2=J_2p_z-J_3p_y+i(J_3p_x-J_1p_z)-\frac{i}{2}p_yp_z+f_2,\quad \mathcal{S}_3=(p_x+ip_y)^2+f_4,$$

$$\mathcal{S}_4=J_3p_z+iJ_1p_y+iJ_2p_x+2J_1p_x+\frac{i}{4}p_z^2+f_3,\quad \mathcal{S}_5=p_z(p_x+ip_y)+f_5.$$

Note that in the complete list of orthogonal separable coordinate systems for complex 3D Euclidean space there are some other systems besides the first seven that have parameter depen-

dence, e.g., cylindrical elliptic coordinates $L_1=p_3^2$, $L_2=J_3^2+c^2p_1^2$. However, for all of these other coordinates the corresponding Bertrand-Darboux equations have only rank four, hence they do not uniquely determine a possible superintegrable system.

C. Interbasis expansions for Euclidean systems

To proceed with the classification of nondegenerate Euclidean superintegrable systems we need to look more closely at the relationship between a standard basis of symmetries for such a system and the natural basis written in terms of the linear and angular momentum generators p_k, J_k, $k=1,\ldots,3$.

Let us denote our preferred Cartesian coordinate system by $\mathbf{x}=(u,v,w)$ and let $\mathbf{x}_0=(x,y,z)$, be a fixed regular point. We define the translated Cartesian coordinates (X,Y,Z) by $u=x+X$, $v=y+Y$, $w=z+Z$. Then, near the regular point (x,y,z) we have a basis of "natural symmetries" $p_1=p_X$, $p_2=p_Y$, $p_3=p_Z$, $J_1=Yp_z-Zp_Y$, $J_2=Zp_X-Xp_Z$, $J_3=Xp_Y-Yp_X$. Now suppose we have a Euclidean superintegrable system with nondegenerate potential. Then there will exist fifteen rational functions $A^{ij}(x,y,z)$, $B^{ij}(x,y,z)$, $C^{ij}(x,y,z)$, that completely characterize the superintegrable system. In particular, only 10 of these are linearly independent [see relations (A2)],

$$A^{22},\ A^{33},\ B^{22},\ B^{33},\ C^{33},\ A^{12},\ B^{12},\ A^{13},\ A^{23},\ B^{23}, \tag{23}$$

and they are subject to the five quadratic conditions (A3) with $G\equiv 0$. These functions are related to the symmetries $\mathcal{S}=\Sigma a^{ij}p_ip_j+W$ via the conditions (A1). Recall that the second order basis symmetries at the regular point $\mathcal{S}^{(\ell m)}_{\mathbf{x}_0}(\mathbf{x})=\Sigma a^{ij}_{(\ell m)}(\mathbf{x})p_ip_j+f_{(\ell m)}$ take the form $\mathcal{S}^{(\ell m)}_{\mathbf{x}_0}(\mathbf{x}_0)=p_ip_j+f_{(\ell m)}(\mathbf{x}_0)$ when evaluated at the point. Thus we can expand each standard basis symmetry in terms of the natural basis at the point via

$$\begin{aligned}\mathcal{S}^{(\ell m)}_{\mathbf{x}_0}=&\,p_\ell p_m+\alpha_3^{(\ell m)}J_1^2+\alpha_4^{(\ell m)}J_2^2+\alpha_5^{(\ell m)}J_3^2+\alpha_6^{(\ell m)}p_1J_1+\alpha_7^{(\ell m)}p_2J_2+\alpha_8^{(\ell m)}p_1J_2+\alpha_9^{(\ell m)}p_1J_3\\&+\alpha_{10}^{(\ell m)}p_2J_1+\alpha_{11}^{(\ell m)}p_2J_3+\alpha_{12}^{(\ell m)}p_3J_1+\alpha_{13}^{(\ell m)}p_3J_2+\alpha_{14}^{(\ell m)}J_1J_2+\alpha_{15}^{(\ell m)}J_1J_3\\&+\alpha_{16}^{(\ell m)}J_2J_3+W^{(\ell m)}(\mathbf{x}),\end{aligned} \tag{24}$$

where the $\alpha_k^{(\ell m)}$ are constants in X,Y,Z but rational functions of the parameters x, y, z of the regular point. [This notation for the expansion coefficients α_s is not completely logical, but since all of our software programs use the same notation we continue to use it to avoid (our) confusion.]

We conclude that all of the expansion constants $\alpha_k^{(\ell m)}$ can be expressed in terms of the ten numbers (23). However, we shall not embark on this straightforward task but instead restrict ourselves to expanding the two symmetries

$$\begin{aligned}\mathcal{S}^{(12)}_{\mathbf{x}_0}=&\,p_1p_2+\alpha_3J_1^2+\alpha_4J_2^2+\alpha_5J_3^2+\alpha_6p_1J_1+\alpha_7p_2J_2+\alpha_8p_1J_2+\alpha_9p_1J_3+\alpha_{10}p_2J_1+\alpha_{11}p_2J_3\\&+\alpha_{12}p_3J_1+\alpha_{13}p_3J_2+\alpha_{14}J_1J_2+\alpha_{15}J_1J_3+\alpha_{16}J_2J_3+W^{(12)}(\mathbf{x}),\end{aligned} \tag{25}$$

$$\begin{aligned}\mathcal{S}^{(13)}_{\mathbf{x}_0}=&\,p_1p_3+\alpha'_3J_1^2+\alpha'_4J_2^2+\alpha'_5J_3^2+\alpha'_6p_1J_1+\alpha'_7p_2J_2+\alpha'_8p_1J_2+\alpha'_9p_1J_3+\alpha'_{10}p_2J_1+\alpha'_{11}p_2J_3\\&+\alpha'_{12}p_3J_1+\alpha'_{13}p_3J_2+\alpha'_{14}J_1J_2+\alpha'_{15}J_1J_3+\alpha'_{16}J_2J_3+W^{(13)}(\mathbf{x}).\end{aligned} \tag{26}$$

(Here, $\alpha_s=\alpha_s^{(12)}$, $\alpha'_s=\alpha_s^{(13)}$.) Indeed it is easy to verify that the six Bertrand-Darboux equations for these two symmetries have rank five (an illustration of Lemma 1 of Ref. 3). Thus these two symmetries completely determine the A^{ij}, B^{ij}, C^{ij}, hence the superintegrable system.

If $a^{ij}(\mathbf{x})$ is the quadratic form associated with $\mathcal{S}^{(12)}(\mathbf{x})$ it is straightforward to verify that

$$a_1^{11}(\mathbf{x}_0)=0,\quad a_2^{11}(\mathbf{x}_0)=-\alpha_9,\quad a_3^{11}(\mathbf{x}_0)=\alpha_8,$$

$$a_1^{22}(\mathbf{x}_0)=\alpha_{11},\quad a_2^{22}(\mathbf{x}_0)=0,\quad a_3^{22}(\mathbf{x}_0)=-\alpha_{10},$$

$$
\begin{gathered}
a_1^{33}(\mathbf{x}_0) = -\alpha_{13}, \quad a_2^{33}(\mathbf{x}_0) = \alpha_{12}, \quad a_3^{33}(\mathbf{x}_0) = 0, \\
a_1^{12}(\mathbf{x}_0) = \tfrac{1}{2}\alpha_9, \quad a_2^{12}(\mathbf{x}_0) = -\tfrac{1}{2}\alpha_{11}, \quad a_3^{12}(\mathbf{x}_0) = \tfrac{1}{2}(\alpha_7 - \alpha_6), \\
a_1^{13}(\mathbf{x}_0) = -\tfrac{1}{2}\alpha_8, \quad a_2^{13}(\mathbf{x}_0) = \tfrac{1}{2}\alpha_6, \quad a_3^{13}(\mathbf{x}_0) = \tfrac{1}{2}\alpha_{13}, \\
a_1^{23}(\mathbf{x}_0) = -\tfrac{1}{2}\alpha_7, \quad a_2^{23}(\mathbf{x}_0) = \tfrac{1}{2}\alpha_{10}, \quad a_3^{23}(\mathbf{x}_0) = -\tfrac{1}{2}\alpha_{12},
\end{gathered}
\tag{27}
$$

where $a_k^{ij}(\mathbf{x}_0) = \partial_k a^{ij}(\mathbf{x})|_{\mathbf{x}_0}$. There are identical relations for the other symmetries $\mathcal{S}^{(\ell m)}(\mathbf{x})$. Using (27) and the identities (A2) and (A1) we can express the expansion coefficients $\alpha_6, \ldots, \alpha_{13}$ in terms of the ten numbers (23) at $\mathbf{x}_0$:

$$
\begin{gathered}
\alpha_6 = \tfrac{1}{3}(2A^{13} - B^{23}), \quad \alpha_7 = \tfrac{1}{3}(A^{13} - 2B^{23}), \quad \alpha_8 = -\tfrac{1}{3}A^{23}, \\
\alpha_9 = \tfrac{1}{3}A^{22}, \quad \alpha_{10} = \tfrac{1}{3}A^{23}, \quad \alpha_{11} = \tfrac{1}{3}B^{22}, \\
\alpha_{12} = \tfrac{1}{3}(B^{12} - A^{22} + A^{33}), \quad \alpha_{13} = -\tfrac{1}{3}(B^{33} + A^{12}).
\end{gathered}
\tag{28}
$$

The corresponding results for the expansion coefficients $\alpha'_6, \ldots, \alpha'_{13}$ of $\mathcal{S}^{(13)}$ are

$$
\begin{gathered}
\alpha'_6 = -\tfrac{1}{3}(2A^{12} + B^{33}), \quad \alpha'_7 = -\tfrac{1}{3}(A^{12} + 2B^{23}), \quad \alpha'_8 = -\tfrac{1}{3}A^{33}, \\
\alpha'_9 = \tfrac{1}{3}A^{23}, \quad \alpha'_{10} = -\tfrac{1}{3}B^{12}, \quad \alpha'_{11} = \tfrac{1}{3}B^{23}, \\
\alpha'_{12} = -\tfrac{1}{3}A^{23}, \quad \alpha'_{13} = -\tfrac{1}{3}C^{33}.
\end{gathered}
\tag{29}
$$

The expansion coefficients of the terms of the form $J_\ell J_m$, i.e., $\alpha_3, \alpha_4, \alpha_5, \alpha_{14}, \alpha_{15}, \alpha_{16}$ can be expressed in terms of second derivatives of the associated quadratic form, evaluated at the regular point $\mathbf{x}_0$. For example, $\alpha_{14} = 2a_{23}^{13}(\mathbf{x}_0) = -a_{33}^{12}(\mathbf{x}_0) = -a_{12}^{33}(\mathbf{x}_0)$. For a superintegrable system the integrability conditions for the symmetry relations (A1) are satisfied identically, so these equations can be differentiated to compute the second derivatives $a_{k\ell}^{ij}(\mathbf{x}_0)$ as a quadratic expression in the ten basic constants [subject to the five quadratic identities (A3)]. Though straightforward, these computations are tedious. The only relations that we will use here are those for the expansion coefficients $\alpha_{14}^{(\ell m)}$. We have

$$
\begin{gathered}
\alpha_{14}^{(11)} = \tfrac{1}{9}(4A^{23}(B^{33} - B^{22}) - 4B^{23}(A^{23} - A^{22}) - 2A^{13}B^{12} + 2A^{12}A^{23}), \\
\alpha_{14}^{(22)} = \tfrac{1}{9}(4A^{12}A^{23} + 2B^{12}B^{23} + 2A^{23}B^{33} - 2A^{13}B^{12} - 2B^{23}A^{33} + 2B^{23}A^{22} - 4B^{12}B^{23}), \\
\alpha_{14}^{(33)} = \tfrac{1}{9}(2B^{23}(A^{22} - A^{33} + B^{12}) - 4A^{13}B^{12} + 2A^{23}(A^{12} - 2B^{22} + B^{33})), \\
\begin{aligned}
\alpha_{14}^{(12)} = \tfrac{1}{9}((2B^{23} - A^{13})(B^{33} - B^{22}) - 2(B^{33} + A^{12} - B^{22})B^{23} \\
- A^{23}B^{12} + (2B^{23} + A^{13})A^{12} + 2B^{33}A^{13} - A^{23}A^{33}),
\end{aligned}
\end{gathered}
\tag{30}
$$

$$
\begin{aligned}
\alpha_{14}^{(13)} = \tfrac{1}{18}(7(B^{33})^2 + (A^{33})^2 - 2A^{22}B^{12} - (A^{23})^2 + 4A^{12}B^{33} - A^{13}C^{33} - 3(A^{12})^2 - 5(B^{12})^2 - 4A^{33}B^{12} \\
- 7B^{22}B^{33} - 7B^{23}C^{33} + 2A^{13}B^{23} + 7(B^{23})^2 - A^{22}A^{33}),
\end{aligned}
$$

$$\alpha_{14}^{(23)} = \tfrac{1}{9}(A^{23}(-B^{23}+C^{33}) + (A^{23}-A^{22}+B^{12})(A^{12}+B^{22}-B^{33})).$$

Note that since the Hamiltonian is $\mathcal{S}^{(11)}+\mathcal{S}^{(22)}+\mathcal{S}^{(33)}$ and the coefficient of J_1J_2 in the Hamiltonian is 0, we must have $\alpha_{14}^{(11)}+\alpha_{14}^{(22)}+\alpha_{14}^{(33)}=0$, which can be verified directly from the above-mentioned expressions.

As a result of the previous discussion we have the result

Theorem 6: *For a nondegenerate superintegrable system the expansion coefficients* $\alpha_k^{(\ell m)}$ *expressing the standard basis* $\mathcal{S}^{\ell m}$ *in terms of the natural basis* p_hp_k, p_hJ_k, J_hJ_k *are explicit linear and quadratic expressions in the ten terms (23).*

D. The significance of generic Euclidean systems

Suppose we have a nondegenerate Euclidean superintegrable system with potential V that is separable with respect to some orthogonal coordinates. (Since every superintegrable system is multiseparable, we know that such coordinates exist.) By performing an Euclidean transformation, if necessary, we can assume that the separable coordinates are in a standard form determined by two constants of the motion in involution,

$$L_1 = \sum a^{ij}p_ip_j + f_1, \quad L_2 = \sum b^{ij}p_ip_j + f_2.$$

Clearly, L_1 and L_2 lie in the six-dimensional space of second order symmetries for the superintegrable system. Thus, the quadratic form a^{ij}, for example, satisfies the three Bertrand-Darboux equations for potential V. Since V is nondegenerate we can express the second derivatives $V_{jj}-V_{kk}$ and V_{jk} with $j\neq k$ in the Bertrand-Darboux equations as linear combinations of the first derivatives V_h. Equating coefficients of V_1, V_2, V_3 separately in each of the three equations, we end up with nine linear conditions for the ten constants $A^{22},\ldots,B^{23}$ at each regular point. A typical example of one of these conditions is

$$A^{13}(3a^{11}-3a^{33}) + B^{23}(0) + A^{23}(-3a^{12}) + A^{22}(0) + B^{22}(0) + B^{12}(0) + A^{33}(-3a^{13}) + B^{33}(0) + A^{12}(-3a^{23}) + C^{33}(0) = -a_1^{13} + a_3^{11}.$$

Here, $B^{23}(0)=0$, etc. For the second symmetry there will be nine more linear conditions with a^{ij} replaced by b^{ij}. Thus we will have eighteen linear equations (not linearly independent) for the ten quantities $A^{22},\ldots,B^{23}$. Another source of conditions is obtained by writing the symmetry L_1 in terms of the standard basis:

$$a^{ij}(\mathbf{x}) = \sum_{\ell\leq m} a^{\ell m}(\mathbf{x}_0)\mathcal{A}^{ij}_{(\ell,m)}(\mathbf{x}),$$

where $\mathcal{A}^{ij}_{(\ell,m)}$ is the quadratic form associated with the standard basis symmetry $\mathcal{S}^{(\ell,m)}$ at $\mathbf{x}_0$. Expanding both sides of this equation in terms of the natural basis we obtain linear and quadratic conditions on the ten basic quantities. For example if we equate coefficients of the natural basis element J_1J_2 we find the quadratic conditions for L_1 and L_2:

$$2a_{23}^{13}(\mathbf{x}_0) = \sum_{\ell\leq m} a^{\ell m}(\mathbf{x}_0)\alpha_{14}^{(\ell m)}, \quad 2b_{23}^{13}(\mathbf{x}_0) = \sum_{\ell\leq m} b^{\ell m}(\mathbf{x}_0)\alpha_{14}^{(\ell m)}. \tag{31}$$

Though there are many other quadratic conditions for L_1, L_2 to belong to the symmetry algebra, we shall use only these two and the five fundamental quadratic identities (A3) that hold independent of any choice of L_1, L_2. Note that by equating coefficients of natural basis elements of the form p_iJ_k we could obtain linear identities. However, these are equivalent to the linear conditions for a^{ij}, b^{ij} already discussed previously.

We give an example to show how this works. Suppose we have a nondegenerate superintegrable system that admits separation for some special choice of ellipsoidal coordinates [2111]. (Here we do *not* assume that the system separates for all values of the parameters c, e_1, e_2, e_3, but only for one value.) By performing an Euclidean transformation and a change of scale we can

assume that the coordinates are in the standard form [2111] in our table and that $c=1$, $e_1=0$, $e_2=1$, and $e_3=a$ where a is any fixed complex number such that $a(a-1)\neq 0$. It follows that

$$a^{11}=y^2+z^2+a+1,\quad a^{22}=x^2+z^2+a,\quad a^{33}=x^2+y^2+1,$$

$$a^{12}=-xy,\quad a^{13}=-xz,\quad a^{23}=-yz,\quad b^{11}=ay^2+z^2+a,$$

$$b^{22}=ax^2,\quad b^{33}=x^2,\quad b^{12}=-axy,\quad b^{13}=-xz,\quad b^{23}=0,$$

at any regular point with coordinates (x,y,z). Substituting these expressions into the 18 linear conditions discussed previously, with the help of the computer algebra system MAPLE, we find that there are exactly seven independent linear conditions. Thus the ten quantities $A^{22},\ldots,B^{23}$ can be expressed linearly in terms of three of these quantities. Substituting this result into the five fundamental quadratic identities (A3) we find that these identities yield a single *linear* relation for the remaining three unknowns. Finally we substitute our expressions in terms of the three unknowns and (30) into (50) and obtain (with the help of MAPLE) two more independent linear conditions. Thus we end up with ten independent linear conditions for our ten unknowns, and we obtain the unique solution

$$A^{12}=B^{12}=A^{23}=B^{23}=A^{13}=B^{33}=0,\quad A^{33}=A^{22}=\frac{3}{x},\quad C^{33}=-\frac{3}{z},\quad B^{22}=-\frac{3}{y},$$

which corresponds to the nondegenerate potential [I],

$$V=\frac{\alpha}{x^2}+\frac{\beta}{y^2}+\frac{\gamma}{z^2}+\delta(x^2+y^2+z^2).$$

Note that it was obvious that our conditions would have solutions, since we already knew that system [I] separated simultaneously for all choices of the parameters c, e_1, e_2, e_3. What was far from obvious is the fact that *no other* nondegenerate superintegrable system separates for *any* special case of ellipsoidal coordinates.

Theorem 7: *A 3D Euclidean nondegenerate superintegrable system admits separation in a special case of the generic coordinates [2111], [221], [23], [311], [32], [41], or [5], respectively, if and only if it is equivalent via a Euclidean transformation to system [I], [II], [III], [IV], [V], [VI], or [VII], respectively.*

The proof (complicated but straightforward) proceeds exactly as the case [2111] described previously. For each case [221]–[5] we use the symmetries a^{ij}, b^{ij} listed. The eighteen linear conditions discussed previously reduce to exactly seven independent linear conditions. Thus always the ten quantities $A^{22},\ldots,B^{23}$ can be expressed linearly in terms of three of these quantities. Substituting into the five fundamental quadratic identities (A3) we find that these identities yield a single *linear* relation for the remaining three unknowns. Substituting our expressions in terms of the three unknowns and (30) into (50) we obtain two more independent linear conditions. Thus we end up with ten independent linear conditions for our ten unknowns, and a unique solution, the corresponding generic superintegrable system.

This does not settle the problem of classifying all 3D nondegenerate superintegrable systems in complex Euclidean space, for we have not excluded the possibility of such systems that separate only in degenerate separable coordinates. In fact we have already studied two such systems in:[3]

$$[O]\quad V(x,y,z)=\alpha x+\beta y+\gamma z+\delta(x^2+y^2+z^2),$$

$$[OO]\quad V(x,y,z)=\frac{\alpha}{2}\left(x^2+y^2+\frac{1}{4}z^2\right)+\beta x+\gamma y+\frac{\delta}{z^2}. \tag{32}$$

However, both of these nondegenerate superintegrable systems are only weakly functionally independent, in contrast to systems [I]–[VII]. Thus we consider $[O]$ and $[OO]$ as associate members of the superintegrable family, not regular members. An investigation of other possible Euclidean systems is in progress.

E. Generic superintegrable systems on the three sphere

An important task remaining is to classify the possible systems on the three sphere (particularly those three-sphere systems not Stäckel equivalent to a flat space system). We choose a standardized Cartesian-like coordinate system $\{x,y,z\}$ on the three sphere such that the metric and Hamiltonian are

$$\mathrm{d}s^2=\frac{1}{\left(1+\frac{r^2}{4}\right)^2}(\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2),\quad \mathcal{H}=\left(1+\frac{r^2}{4}\right)^2(p_x^2+p_y^2+p_z^2)+V, \tag{33}$$

where $r^2=x^2+y^2+z^2$. These coordinates can be related to the standard realization of the sphere via complex coordinates $\mathbf{s}=(s_1,s_2,s_3,s_4)$ such that $\Sigma_{j=1}^4 s_j^2=1$ and $\mathrm{d}s^2=\Sigma_j \mathrm{d}s_j^2$ via

$$s_1=\frac{4x}{4+r^2},\quad s_2=\frac{4y}{4+r^2},\quad s_3=\frac{4z}{4+r^2},\quad s_4=\frac{4-r^2}{4+r^2} \tag{34}$$

with inverse $x=2s_1/(1+s_4)$, $y=2s_2/(1+s_4)$, $z=2s_3/(1+s_4)$. Here x,y,z are local coordinates in a neighborhood of the pole $\mathbf{P}=(0,0,0,1)$ on the three sphere. A basis of Killing vectors for the zero potential system is J_h, K_h, $h=1,2,3$ where

$$J_1=yp_z-zp_y,\quad J_2=zp_x-xp_z,\quad J_3=xp_y-yp_x,$$

$$K_1=\left(1+\frac{x^2-y^2-z^2}{4}\right)p_x+\frac{xy}{2}p_y+\frac{xz}{2}p_z,\quad K_2=\left(1+\frac{y^2-x^2-z^2}{4}\right)p_y+\frac{xy}{2}p_x+\frac{yz}{2}p_z, \tag{35}$$

$$K_3=\left(1+\frac{z^2-x^2-y^2}{4}\right)p_z+\frac{xz}{2}p_x+\frac{yz}{2}p_y.$$

The commutation relations are

$$\{J_1,J_2\}=J_3,\quad \{K_1,K_2\}=J_3,\quad \{K_1,J_2\}=K_3 \tag{36}$$

and their cyclic permutations. The relation between this basis and the standard basis of rotation generators on the sphere $I_{\ell m}=s_\ell p_m-s_m p_\ell=-I_{m\ell}$ is

$$J_1=I_{23},\quad J_2=I_{31},\quad J_3=I_{12},\quad K_1=I_{41},\quad K_2=I_{42},\quad K_3=I_{43}. \tag{37}$$

We shall use the x,y,z coordinates as standard but we also need to see how these coordinates relate to analogous Cartesian-like coordinates centered at any point $\mathbf{T}$ on the sphere. We can always find a complex orthogonal matrix O, not unique, such that $\mathbf{T}=O\mathbf{P}$. If X,Y,Z, (34), define local Cartesian-like coordinates near $\mathbf{P}$ then via $\mathbf{t}=Os(X,Y,Z)$ they also define local coordinates in a neighborhood of $\mathbf{T}=(T_1,T_2,T_3,T_4)$. Moreover, since O is orthogonal we have

$$\mathrm{d}s^2=\mathrm{d}\mathbf{t}\cdot\mathrm{d}\mathbf{t}=\mathrm{d}O\mathbf{s}\cdot\mathrm{d}O\mathbf{s}=\mathrm{d}\mathbf{s}\cdot\mathrm{d}\mathbf{s}=\frac{1}{\left(1+\frac{R^2}{4}\right)^2}(\mathrm{d}X^2+\mathrm{d}Y^2+\mathrm{d}Z^2),$$

so we can consider X,Y,Z as Cartesian-like coordinates in a neighborhood of $\mathbf{T}$. We can also require that the coordinate axes line up so that differentiation of $\mathbf{s}$ by X,Y,Z, respectively, at $\mathbf{P}$ corresponds to (normalized) differentiation of $\mathbf{t}$ by x,y,z, respectively, at $\mathbf{T}$, i.e., so that p_X corresponds to $(1+r^2/4)p_x$, etc. Thus,

$$\left(\frac{2}{1+t_4}\partial_x \mathbf{t}\right)\Big|_{\mathbf{t}=\mathbf{T}} = O\begin{pmatrix}1\\0\\0\\0\end{pmatrix}, \quad \left(\frac{2}{1+t_4}\partial_y \mathbf{t}\right)\Big|_{\mathbf{t}=T} = O\begin{pmatrix}0\\1\\0\\0\end{pmatrix},$$

$$\left(\frac{2}{1+t_4}\partial_z \mathbf{t}\right)\Big|_{\mathbf{t}=T} = O\begin{pmatrix}0\\0\\1\\0\end{pmatrix}, \quad \mathbf{T} = O\begin{pmatrix}0\\0\\0\\1\end{pmatrix}.$$

This determines O uniquely, since the column vectors on the left-hand sides of these expressions are mutually orthogonal unit vectors. We find

$$O_T = \begin{pmatrix} -\frac{T_1^2 - T_4 - 1}{T_4+1} & -\frac{T_2 T_1}{T_4+1} & -\frac{T_3 T_1}{T_4+1} & T_1 \\ -\frac{T_1 T_2}{T_4+1} & -\frac{T_2^2 - T_4 - 1}{T_4+1} & -\frac{T_3 T_2}{T_4+1} & T_2 \\ -\frac{T_1 T_3}{T_4+1} & -\frac{T_2 T_3}{T_4+1} & -\frac{T_3^2 - T_4 - 1}{T_4+1} & T_3 \\ -T_1 & -T_2 & -T_3 & T_4 \end{pmatrix}. \tag{38}$$

In the **P**-based coordinate system the coordinates of **t** are u, v, w where $u=2t_1/(1+t_4)$, $v=2t_2/(1+t_4)$, $w=2t_3/(1+t_4)$. From the equation $\mathbf{t}=O_T\mathbf{s}$ we can solve for u, v, w to obtain

$$u = \frac{4[r^2 X - 2x(xX+yY+zZ) + 4(x+X) - xR^2]}{16 - 8(xX+yY+zZ) + r^2R^2},$$

$$v = \frac{4[r^2 Y - 2y(xX+yY+zZ) + 4(y+Y) - yR^2]}{16 - 8(xX+yY+zZ) + r^2R^2}, \tag{39}$$

$$w = \frac{4[r^2 Z - 2z(xX+yY+zZ) + 4(z+Z) - zR^2]}{16 - 8(xX+yY+zZ) + r^2R^2}.$$

To recapitulate: **t** is a point on the complex unit sphere, (x,y,z) are the coordinates of **T** in the **P**-based system, (u,v,w) are the coordinates of **t** in the **P**-based system, and (X,Y,Z) are the coordinates of **t** in the **T**-based system. Thus, for fixed **T**, Eq. (39) defines the coordinate transformation between (u,v,w) and (X,Y,Z). We can write Eq. (39) in a simpler form by introducing the supplementary variables

$$U = \frac{u-x}{1+\frac{r^2}{4}}, \quad V = \frac{v-y}{1+\frac{r^2}{4}}, \quad W = \frac{v-z}{1+\frac{r^2}{4}}, \quad Q^2 = U^2 + V^2 + W^2.$$

Then

$$U = \frac{1 - \frac{1}{2}xX}{1 - \frac{1}{2}(xX+yY+zZ) + \frac{r^2R^2}{16}},$$

$$V=\frac{1-\frac{1}{2}yY}{1-\frac{1}{2}(xX+yY+zZ)+\frac{r^2R^2}{16}},\quad W=\frac{1-\frac{1}{2}zZ}{1-\frac{1}{2}(xX+yY+zZ)+\frac{r^2R^2}{16}},\tag{40}$$

with inverse

$$X=\frac{U+\frac{x}{4}Q^2}{1+\frac{1}{2}(xU+yV+zW)+\frac{r^2Q^2}{16}},$$

$$Y=\frac{V+\frac{y}{4}Q^2}{1+\frac{1}{2}(xU+yV+zW)+\frac{r^2Q^2}{16}},\quad Z=\frac{W+\frac{z}{4}Q^2}{1+\frac{1}{2}(xU+yV+zW)+\frac{r^2Q^2}{16}}.\tag{41}$$

In Ref. 22 we have determined all orthogonal separable coordinate systems on the complex unit three sphere. Of the 21 systems listed those that are generic, in the sense we used for Euclidean separable systems, are given as follows with coordinates followed by defining constants of the motion. (Here we take the Hamiltonian as $\mathcal{L}_0=I_{12}^2+I_{13}^2+I_{14}^2+I_{23}^2+I_{24}^2+I_{34}^2$, and we recall the identity $I_{23}I_{41}+I_{31}I_{42}+I_{12}I_{43}=0$.)

[1111] (system (17) in Ref. [22])

$$s_1^2=\frac{(x_1-e_1)(x_2-e_1)(x_3-e_1)}{(e_1-e_2)(e_1-e_3)(e_1-e_4)},\quad s_2^2=\frac{(x_1-e_2)(x_2-e_2)(x_3-e_2)}{(e_2-e_1)(e_2-e_3)(e_2-e_4)},$$

$$s_3^2=\frac{(x_1-e_3)(x_2-e_3)(x_3-e_3)}{(e_3-e_1)(e_3-e_2)(e_3-e_4)},\quad s_4^2=\frac{(x_1-e_4)(x_2-e_4)(x_3-e_4)}{(e_4-e_2)(e_4-e_3)(e_4-e_1)},$$

$$\mathcal{L}_1=(e_1+e_2)I_{12}^2+(e_1+e_3)I_{13}^2+(e_1+e_4)I_{14}^2+(e_2+e_3)I_{23}^2+(e_2+e_4)I_{24}^2+(e_3+e_4)I_{34}^2,$$

$$\mathcal{L}_2=e_1e_2I_{12}^2+e_1e_3I_{13}^2+e_1e_4I_{14}^2+e_2e_3I_{23}^2+e_2e_4I_{24}^2+e_3e_4I_{34}^2.$$

[211] (system (18) in Ref. [22])

$$(is_1+s_2)^2=-2\frac{(x_1-e_1)(x_2-e_1)(x_3-e_1)}{(e_1-e_3)(e_1-e_4)},$$

$$s_1^2+s_2^2=-\partial_{e_1}\left(\frac{(x_1-e_1)(x_2-e_1)(x_3-e_1)}{(e_1-e_3)(e_1-e_4)}\right),$$

$$s_3^2=-\frac{(x_1-e_3)(x_2-e_3)(x_3-e_3)}{(e_3-e_1)^2(e_3-e_4)},\quad s_4^2=-\frac{(x_1-e_4)(x_2-e_4)(x_3-e_4)}{(e_4-e_1)^2(e_4-e_3)};$$

$$\mathcal{L}_1=(I_{14}+iI_{24})^2+(I_{13}+iI_{23})^2+2e_1(2I_{12}^2+I_{14}^2+I_{24}^2+I_{13}^2+I_{23}^2)+2e_3(I_{34}^2+I_{13}^2+I_{23}^2)$$
$$+2e_4(I_{14}^2+I_{24}^2+I_{34}^2),$$

$$\mathcal{L}_2=e_1^2I_{12}^2+e_1e_3(I_{13}^2+I_{23}^2)+e_1e_4(I_{14}^2+I_{24}^2)+e_3e_4I_{34}^2+\frac{e_3}{2}(I_{13}+iI_{23})^2+\frac{e_4}{2}(I_{14}+iI_{24})^2.$$

[22] (system (19) in Ref. [22])

$$(s_3+is_4)^2=-2\frac{(x_1-e_3)(x_2-e_3)(x_3-e_3)}{(e_1-e_3)^2},\quad s_1^2+s_2^2=-\frac{\partial}{\partial e_1}\left(\frac{(x_1-e_1)(x_2-e_1)(x_3-e_1)}{(e_1-e_3)^2}\right);$$

$$\mathcal{L}_1=-I_{24}^2+I_{13}^2+iI_{13}I_{23}+iI_{14}I_{24}+iI_{23}I_{24}+iI_{13}I_{14}+(e_1-e_3)[I_{12}^2-I_{34}^2]+e_2,$$

$$\mathcal{L}_2=e_1^2I_{12}^2+e_3^2I_{34}^2+e_1e_3[I_{13}^2+I_{24}^2+I_{14}^2+I_{23}^2]+\frac{1}{4}[I_{13}^2+I_{24}^2-I_{14}^2-I_{23}^2+2iI_{13}I_{23}+2iI_{13}I_{14}-2iI_{14}I_{24}$$
$$-2iI_{23}I_{24}-4I_{13}I_{24}-2I_{12}I_{34}]+\frac{e_1}{2}[I_{13}^2-I_{24}^2-I_{14}^2+I_{23}^2+2iI_{13}I_{14}+2iI_{23}I_{24}]+\frac{e_3}{2}[-I_{24}^2+I_{13}^2+I_{14}^2$$
$$-I_{23}^2+2iI_{13}I_{23}+2iI_{14}I_{24}].$$

[31] (system (20) in Ref. in [22])

$$(s_1+is_2)^2=-2\frac{(x_1-e_1)(x_2-e_1)(x_3-e_1)}{(e_1-e_4)},\quad s_4^2=-\frac{(x_1-e_4)(x_2-e_4)(x_3-e_4)}{(e_4-e_1)^3},$$

$$\sqrt{2}s_3(s_1+is_2)=-\frac{\partial}{\partial e_1}\left(\frac{(x_1-e_1)(x_2-e_1)(x_3-e_1)}{(e_1-e_4)}\right),$$

$$s_1^2+s_2^2+s_3^2=-\frac{1}{2}\frac{\partial^2}{\partial e_1^2}\frac{(x_1-e_1)(x_2-e_1)(x_3-e_1)}{(e_1-e_4)};$$

$$\mathcal{L}_1=\sqrt{2}(I_{14}I_{34}-I_{12}I_{23}+iI_{24}I_{34}+iI_{12}I_{13})+e_1(I_{12}^2+I_{13}^2+I_{23}^2)+e_4(I_{34}^2+I_{14}^2+I_{24}^2),$$

$$\mathcal{L}_2=-\frac{1}{2}I_{13}^2+\frac{1}{2}I_{23}^2-iI_{13}I_{23}+e_1e_4(I_{34}^2+I_{14}^2+I_{24}^2)=e_1^2(I_{12}^2+I_{13}^2+I_{23}^2)-\frac{e_1}{\sqrt{2}}(-2iI_{12}I_{13}+2I_{12}I_{23})$$
$$+\sqrt{2}e_4(I_{14}I_{34}+iI_{24}I_{34}).$$

[4] (system (21) in [22])

$$(s_1+is_2)^2=-2(x_1-e_1)(x_2-e_2)(x_3-e_3),$$

$$(s_1+is_2)(s_3+is_4)=-\frac{\partial}{\partial e_1}((x_1-e_1)(x_2-e_1)(x_3-e_1)),$$

$$2(s_1+is_2)(s_3-is_4)+(s_3+is_4)^2=-\frac{\partial^2}{\partial e_1^2}((x_1-e_1)(x_2-e_1)(x_3-e_1));$$

$$\mathcal{L}_1=\frac{1}{2}(2I_{34}I_{14}+2I_{12}I_{14}-2I_{23}I_{34}-2I_{12}I_{23}-I_{24}^2+I_{23}^2-I_{14}^2+I_{13}^2+2iI_{13}I_{14}+2iI_{23}I_{24}+2iI_{12}I_{24}$$
$$+2iI_{13}I_{34}+2iI_{24}I_{34}+2iI_{12}I_{13}),$$

$$\mathcal{L}_2 = -I_{14}^2 - I_{23}I_{34} - \frac{1}{4}I_{24}^2 + \frac{1}{4}I_{23}^2 + \frac{1}{4}I_{14}^2 - \frac{1}{4}I_{13}^2 - \frac{i}{2}I_{13}I_{23} - \frac{i}{2}I_{23}I_{24}\frac{i}{2}I_{14}I_{24} + \frac{i}{2}I_{13}I_{14} - iI_{24}I_{34} + iI_{13}I_{34}$$
$$- \frac{1}{2}I_{13}I_{34} - \frac{1}{2}I_{14}I_{23}.$$

We now show that each generic separable system on the three sphere uniquely determines a superintegrable system with nondegenerate potential. The proof is, in most part, analogous to that for the Euclidean case. Consider system (1111). If we have a superintegrable system that admits the symmetries $\mathcal{L}_1$, $\mathcal{L}_2$ for all values of the parameters $e_1, \ldots, e_4$ then it must have the basis of symmetries

$$\text{VIII} \quad \mathcal{S}_0 = I_{12}^2 + f_0, \quad \mathcal{S}_1 = I_{13}^2 + f_1, \quad \mathcal{S}_2 = I_{14}^2 + f_2, \quad \mathcal{S}_3 = I_{32}^2 + f_3,$$

$$\mathcal{S}_4 = I_{24}^2 + f_4, \quad \mathcal{S}_5 = I_{34}^2 + f_5.$$

The system of Bertrand-Darboux equations associated with these symmetries has rank five so the potential is uniquely determined. Solving the Bertrand-Darboux equations we obtain the nondegenerate potential on the three sphere

$$V(s) = \frac{\alpha}{s_1^2} + \frac{\beta}{s_2^2} + \frac{\gamma}{s_3^2} + \frac{\delta}{s_4^2}. \tag{42}$$

This potential is not Stäckel equivalent to a potential on Euclidean space.

Three of the four remaining systems can be obtained in the same way. However there is an alternative approach which enables us to obtain systems 2, 3, and 4 from 1 via well defined limiting processes. These are discussed elsewhere, e.g., Refs. 16 and 17, but we content ourselves with an example of how to obtain [211] from [1111]. If we make the transformations

$$s_1 \to \frac{1}{\sqrt{-\epsilon}}y_1, \quad s_2 \to \frac{1}{\sqrt{\epsilon}}(y_1 + \epsilon y_2), \quad \alpha \to -\sqrt{\beta}2\epsilon^2, \quad \beta \to \frac{\alpha}{\epsilon} - \frac{\beta}{2\epsilon^2}$$

then we deduce the relations

$$y_1^2 = -\frac{(u-e_1)(v-e_1)(w-e_1)}{(e_1-e_2)(e_1-e_3)}, \quad 2y_1y_2 = \frac{\partial}{\partial e_1}y_1^2.$$

The coordinates on the sphere can be represented using the identifications $y_1=(s_1+is_2)/\sqrt{2}$, $y_2=(s_1-is_2)/\sqrt{2}$, $y_3=s_3$, $y_4=s_4$ where $2y_1y_2+y_3^2+y_4^2=s_1^2+s_2^2+s_3^2+s_4^2=1$. We then transform the potential according to $\alpha/s_1^2+\beta/s_2^2+\gamma/s_3^2+\delta/s_4^2 \to \alpha/y_1^2+\beta y_2/y_1^3+\gamma/y_3^2+\delta/y_4^2$.

An exactly similar approach leads to the coordinates, constants of the motion and nondegenerate potential for the system [22]. Here the limit is taken in the form $e_2=e_1+\epsilon$, $e_4=e_3+\epsilon'$ where $\epsilon, \epsilon' \to 0$. For the system [31] we set $e_2=e_1+\epsilon$, $e_3=e_1+\epsilon'$ and allow $\epsilon, \epsilon' \to 0$, whereas for system [4] we set $e_2=e_1+\epsilon$, $e_3=e_1+\epsilon_1$, $e_4=e_1+\epsilon_2$ and allow $\epsilon, \epsilon_1, \epsilon_2 \to 0$. In all cases except [4] the requirement that we have separation for all values of the parameters e_j yields a set of six linearly independent second-order constants of the motion that can be verified to correspond to a nondegenerate superintegrable system. In the case [4] the constants of the motion do not depend on e_1 and we have only three independent symmetries. However, there is a unique potential that is obtained as the limit of the nondegenerate potential for case [1111]. By writing down the Bertrand-Darboux equations for this limit potential we can directly verify that it admits six linearly independent symmetries and is nondegenerate.

Theorem 8: *Each of the five generic three-sphere separable systems determines a unique nondegenerate superintegrable system that permits separation simultaneously for all values of the parameters e_j. For each of these systems there is a basis of five (strongly) functionally independent and six linearly independent second order symmetries. In addition to system [VIII] above there are*

the following superintegrable systems (nondegenerate potential, followed by a basis of constants of the motion):

I′ [211] (Stäckel equivalent to the Euclidean superintegrable system [I])

$$V=\frac{\alpha_1}{(s_1+is_2)^2}+\frac{\alpha_2(s_1-is_2)}{(s_1+is_2)^3}+\frac{\alpha_3}{s_3^2}+\frac{\alpha_4}{s_4^2};$$

$$\mathcal{S}_0=I_{12}^2+f_0,\quad \mathcal{S}_1=I_{34}^2+f_1,\quad \mathcal{S}_2=I_{13}^2+I_{23}^2+f_2, \tag{43}$$

$$\mathcal{S}_3=I_{14}^2+I_{24}^2+f_3,\quad \mathcal{S}_4=I_{13}(I_{13}+iI_{23})+f_4,\quad \mathcal{S}_5=I_{14}(I_{14}+iI_{24})+f_5.$$

II′ [22] (Stäckel equivalent to the Euclidean superintegrable system [II])

$$V=\frac{\alpha_1}{(s_1+is_2)^2}+\frac{\alpha_2(s_1-is_2)}{(s_1+is_2)^3}+\frac{\alpha_3}{(s_3+is_4)^2}+\frac{\alpha_4(s_3-is_4)}{(s_3+is_4)^3};$$

$$\begin{gathered}\mathcal{S}_0=I_{12}^2+f_0,\quad \mathcal{S}_1=I_{34}^2+f_1,\quad \mathcal{S}_2=I_{13}^2+I_{14}^2+I_{23}^2+I_{24}^2+f_2,\\ \mathcal{S}_3=I_{13}^2+I_{14}^2+i(I_{13}I_{23}+I_{14}I_{24})+f_3,\quad \mathcal{S}_4=I_{13}^2+I_{23}^2+i(I_{13}I_{14}+I_{23}I_{24})+f_4,\end{gathered} \tag{44}$$

$$\mathcal{S}_5=I_{13}^2+I_{24}^2+i(I_{13}I_{14}+I_{13}I_{23}-I_{14}I_{24}-I_{23}I_{24})-2I_{13}I_{24}-I_{12}I_{34}+f_5.$$

IV′ [31] (Stäckel equivalent to the Euclidean superintegrable system [IV])

$$V=\frac{\alpha_1}{(s_1+is_2)^2}+\frac{\alpha_2 s_3}{(s_1+is_2)^3}+\frac{\alpha_3(s_1^2+s_2^2-3s_3^2)}{(s_1+is_2)^4}+\frac{\alpha_4}{s_4^2};$$

$$\begin{gathered}\mathcal{S}_0=I_{12}^2+I_{13}^2+I_{23}^2+f_0,\quad \mathcal{S}_1=I_{14}^2+I_{24}^2+I_{34}^2+f_1,\quad \mathcal{S}_2=(I_{23}-iI_{13})^2+f_2,\\ \mathcal{S}_3=I_{12}(I_{23}-iI_{13})+f_3,\quad \mathcal{S}_4=I_{34}(I_{14}+iI_{24})+f_4,\end{gathered} \tag{45}$$

$$\mathcal{S}_5=I_{14}I_{34}-I_{12}I_{23}+i(I_{24}I_{34}+I_{12}I_{13})+f_5.$$

VI′ [4] (Stäckel equivalent to the Euclidean superintegrable system [VI])

$$\begin{aligned}V=&\frac{\alpha_1}{(s_1+is_2)^2}+\frac{\alpha_2(s_3+is_4)}{(s_1+is_2)^3}+\frac{\alpha_3\left[(s_1+is_2)(s_3-is_4)-\frac{3}{2}(s_3+is_4)^2\right]}{(s_1+is_2)^4}\\&+\frac{\alpha_4\left[(s_1+is_2)\left(s_1^2+s_2^2-\frac{3}{2}(s_3^2+s_4^2)+(s_3+is_4)^3\right]\right.}{(s_1+is_2)^5};\end{aligned}$$

$$\mathcal{S}_0=I_{12}^2+I_{13}^2+I_{14}^2+I_{23}^2+I_{24}^2+I_{34}^2+V,$$

$$\mathcal{S}_1=(I_{13}-I_{24}+iI_{23}+iI_{14})^2+f_1,$$

$$\begin{aligned}\mathcal{S}_2=&4(I_{23}I_{34}+I_{14}I_{34}+I_{13}I_{24})+4i(I_{24}I_{34}-I_{13}I_{34})+2i(I_{13}I_{23}-I_{14}I_{24}-I_{13}I_{14}+I_{23}I_{24})-2I_{12}I_{34}+I_{13}^2\\&+I_{24}^2-I_{14}^2-I_{23}^2+f_2,\end{aligned}$$

$$\mathcal{S}_3 = 2(I_{12}I_{23} + I_{23}I_{34} - I_{12}I_{14} - I_{14}I_{34}) - 2i(I_{23}I_{24} + I_{13}I_{14} + I_{13}I_{34} + I_{24}I_{34} + I_{12}I_{24} + I_{12}I_{13}) - I_{13}^2 + I_{24}^2 + I_{14}^2 - I_{23}^2 + f_3,$$

$$\mathcal{S}_4 = (I_{13} - I_{24} + iI_{23} + iI_{14})(I_{13} + I_{24} + iI_{23} - iI_{14}) + f_4,$$

$$\mathcal{S}_5 = (I_{13} - I_{24} + iI_{23} + iI_{14})(I_{34} - I_{12}) + f_5. \tag{46}$$

We also mention that the nongeneric superintegrable system on the three sphere with potential

$$\mathbf{00'} \quad V = \frac{\alpha}{(s_1 + is_2)^2} + \frac{\beta s_3}{(s_1 + is_2)^3} + \frac{\gamma s_4}{(s_1 + is_2)^3} + \frac{\delta(1 - 4s_3^2 - 4s_4^2)}{(s_1 + is_2)^4}$$

is Stäckel equivalent to the Euclidean superintegrable system [00].

F. Interbasis expansions for three-sphere systems

In analogy with our treatment of Euclidean systems, to proceed with the classification of nondegenerate superintegrable systems on the three sphere we need to look more closely at the relationship between a standard basis of symmetries and the natural basis written in terms of the angular momentum generators J_ℓ, K_ℓ $\ell = 1, \ldots, 3$. Then, near the regular point $\mathbf{T}$, i.e., (x, y, z), we have a basis of "natural symmetries" $J_1 = Yp_Z - Zp_Y$, $J_2 = Zp_X - Xp_Z$, $J_3 = Xp_Y - Yp_X$, $K_1 = K_X$, $K_2 = K_Y$, $K_3 = K_Z$. At the point itself we have $(1 + r^2/4)p_u = p_X$, $(1 + r^2/4)p_v = p_Y$, $(1 + r^2/4)p_w = p_Z$. Now suppose we have a three-sphere superintegrable system with nondegenerate potential. Then there will exist fifteen rational functions $A^{ij}[x, y, z]$, $B^{ij}[x, y, z]$, $C^{ij}[x, y, z]$, [with respect to the (X, Y, Z) coordinates and restricted to the point $(X, Y, Z) = (0, 0, 0)$, that completely characterize the superintegrable system]. In particular, only ten of these, (23), are linearly independent, see relations (A2), and they are subject to the five quadratic conditions (A3) with $G(X, Y, Z) = \ln \lambda = -2 \ln(1 + R^2/4)$. These functions are related to the symmetries $\mathcal{S} = \Sigma a^{ij} p_i p_j + W$ via the conditions (A1). The second order basis symmetries at the regular point $\mathcal{S}_{\mathbf{x}_0}^{(\ell m)}(\mathbf{X}) = \Sigma a_{(\ell m)}^{ij}(\mathbf{X}) p_i p_j + f_{(\ell m)}(\mathbf{X})$ take the form $\mathcal{S}_{\mathbf{x}_0}^{(\ell m)}(0, 0, 0) = p_i p_j + f_{(\ell m)}(0, 0, 0)$ when evaluated at the point. Thus we can expand each standard basis symmetry in a neighborhood of the point (x, y, z) in terms of the natural basis at the point via

$$\begin{aligned}\mathcal{S}_{\mathbf{x}_0}^{(\ell m)} = {} & K_\ell K_m + \alpha_3^{(\ell m)} J_1^2 + \alpha_4^{(\ell m)} J_2^2 + \alpha_5^{(\ell m)} J_3^2 + \alpha_6^{(\ell m)} K_1 J_1 + \alpha_7^{(\ell m)} K_2 J_2 + \alpha_8^{(\ell m)} K_1 J_2 + \alpha_9^{(\ell m)} K_1 J_3 \\ & + \alpha_{10}^{(\ell m)} K_2 J_1 + \alpha_{11}^{(\ell m)} K_2 J_3 + \alpha_{12}^{(\ell m)} K_3 J_1 + \alpha_{13}^{(\ell m)} K_3 J_2 + \alpha_{14}^{(\ell m)} J_1 J_2 + \alpha_{15}^{(\ell m)} J_1 J_3 \\ & + \alpha_{16}^{(\ell m)} J_2 J_3 + W^{(\ell m)}(\mathbf{X}),\end{aligned} \tag{47}$$

where the $\alpha_k^{(\ell m)}$ are constants in X, Y, Z but rational functions of the parameters x, y, z of the regular point. Here we are taking into account the identity $\Sigma_{h=1}^3 K_h J_h = 0$ and the fact that $K_h = p_h$ at the point $(X, Y, Z) = (0, 0, 0)$. Again, nondegenerate superintegrable system is uniquely determined by the ten numbers (23), and these numbers themselves are subject to five quadratic identities (A3). (Note that G and all of its first and second derivatives vanish when $X = Y = Z = 0$, except that $G_{ii} = -1$, $i = 1, 2, 3$. Further, we can use relations (40) to express the derivatives of V at the regular point with respect to the (X, Y, Z) coordinates in terms of derivatives with respect to (u, v, w). Thus the numbers (23) can be expressed as linear combinations of the corresponding numbers with respect to the (u, v, w) coordinates.)

Although all of the expansion constants $\alpha_k^{(\ell m)}$ can be expressed in terms of these ten numbers, we shall restrict ourselves to expanding the two symmetries

$$\begin{aligned}\mathcal{S}_{\mathbf{x}_0}^{(12)} = {} & K_1 K_2 + \alpha_3 J_1^2 + \alpha_4 J_2^2 + \alpha_5 J_3^2 + \alpha_6 K_1 J_1 + \alpha_7 K_2 J_2 + \alpha_8 K_1 J_2 + \alpha_9 K_1 J_3 + \alpha_{10} K_2 J_1 + \alpha_{11} K_2 J_3 \\ & + \alpha_{12} K_3 J_1 + \alpha_{13} K_3 J_2 + \alpha_{14} J_1 J_2 + \alpha_{15} J_1 J_3 + \alpha_{16} J_2 J_3 + W^{(12)}(\mathbf{X}),\end{aligned} \tag{48}$$

$$\mathcal{S}^{(13)}_{\mathbf{x}_0} = K_1K_3 + \alpha'_3J_1^2 + \alpha'_4J_2^2 + \alpha'_5J_3^2 + \alpha'_6K_1J_1 + \alpha'_7K_2J_2 + \alpha'_8K_1J_2 + \alpha'_9K_1J_3 + \alpha'_{10}K_2J_1 + \alpha'_{11}K_2J_3$$
$$+ \alpha'_{12}K_3J_1 + \alpha'_{13}K_3J_2 + \alpha'_{14}J_1J_2 + \alpha'_{15}J_1J_3 + \alpha'_{16}J_2J_3 + W^{(13)}(\mathbf{X}). \tag{49}$$

(Here, $\alpha_s=\alpha_s^{(12)}$, $\alpha'_s=\alpha_s^{(13)}$.) Since the six Bertrand-Darboux equations for these two symmetries have rank five, the symmetries completely determine the A^{ij}, B^{ij}, C^{ij}, hence the superintegrable system.

From (39)–(41) we have (with $J_w=up_v-vp_u$ and cyclic permutations)

$$J_1 = \frac{1}{1+\frac{r^2}{4}}\left(\left(1+\frac{x^2}{4}-\frac{y^2}{4}-\frac{z^2}{4}\right)J_u + \frac{zx}{2}J_w + \frac{yx}{2}J_v - yK_w + zK_v\right),$$

$$J_2 = \frac{1}{1+\frac{r^2}{4}}\left(\left(1-\frac{x^2}{4}+\frac{y^2}{4}-\frac{z^2}{4}\right)J_v + \frac{xy}{2}J_u + \frac{zy}{2}J_w - zK_u + xK_w\right),$$

$$J_3 = \frac{1}{1+\frac{r^2}{4}}\left(\left(1-\frac{x^2}{4}-\frac{y^2}{4}+\frac{z^2}{4}\right)J_w + \frac{yz}{2}J_v + \frac{xz}{2}J_u - xK_v + yK_u\right),$$

$$K_1 = \frac{1}{1+\frac{r^2}{4}}\left(\left(1+\frac{x^2}{4}-\frac{y^2}{4}-\frac{z^2}{4}\right)K_u + \frac{yx}{2}K_v + \frac{zx}{2}K_w - yJ_w + zJ_v\right),$$

$$K_2 = \frac{1}{1+\frac{r^2}{4}}\left(\left(1-\frac{x^2}{4}+\frac{y^2}{4}-\frac{z^2}{4}\right)K_v + \frac{xy}{2}K_u + \frac{zy}{2}K_w - zJ_u + xJ_w\right),$$

$$K_3 = \frac{1}{1+\frac{r^2}{4}}\left(\left(1-\frac{x^2}{4}-\frac{y^2}{4}+\frac{z^2}{4}\right)K_w + \frac{xz}{2}K_u + \frac{yz}{2}K_v - xJ_v + yJ_u\right).$$

The inverse of these relations takes almost exactly the same form. Now, suppose we have a nondegenerate three-sphere superintegrable system with potential V, that is separable with respect to some orthogonal coordinates. (As every superintegrable system is multiseparable, we know that such coordinates exist.) By performing an Euclidean transformation, if necessary, we can assume that the separable coordinates are in some standard form determined by two constants of the motion in involution, $L_1=\Sigma a^{ij}p_ip_j+f_1$, $L_2=\Sigma b^{ij}p_ip_j+f_2$. Clearly, L_1 and L_2 lie in the six-dimensional space of second order symmetries for the superintegrable system. Thus, the quadratic form a^{ij}, for example, satisfies the three Bertrand-Darboux equations for potential V. Since V is nondegenerate we can express the second derivatives $V_{jj}-V_{kk}$ and V_{jk} with $j\neq k$ in the Bertrand-Darboux equations as linear combinations of the first derivatives V_h. Equating coefficients of V_1, V_2, V_3 separately in each of the three equations, we end up with nine linear conditions for the ten constants $A^{22},\ldots,B^{23}$ at each regular point. If we choose the Cartesian-like coordinates X, Y, Z that vanish at the regular point, then we obtain the same 18 conditions as in the Euclidean case. Indeed, the first derivatives G_i all vanish at the regular point.

For the second symmetry there will be nine more such linear conditions with a^{ij} replaced by b^{ij}. Thus we will have eighteen linear equations (not linearly independent) for the ten quantities $A^{22},\ldots,B^{23}$.

The five fundamental quadratic identities (A3) are identical to those for the Euclidean case. This is because the only nonzero terms in the metric for the three sphere are $G_{ii}=-1$ and all such terms occur in the form $G_{ii}-G_{jj}=0$ in the five quadratic conditions.

Another source of conditions is obtained by writing the symmetry L_1 in terms of the standard basis: $a^{ij}(\mathbf{x})=\Sigma_{\ell\leqslant m}a^{\ell m}(\mathbf{x}_0)\mathcal{A}^{ij}_{(\ell,m)}(\mathbf{x})$, where $\mathcal{A}^{ij}_{(\ell,m)}$ is the quadratic form associated with the standard basis symmetry $\mathcal{S}^{(\ell,m)}$ at $\mathbf{x}_0$. Expanding both sides of this equation in terms of the natural

basis we obtain linear and quadratic conditions on the ten basic quantities. In this case there is a difference between the Euclidean and three-sphere expressions. For example if we equate coefficients of the natural basis element J_1J_2 we find the quadratic conditions for L_1 and L_2

$$-a_{12}^{33}(\mathbf{x}_0)=\sum_{\ell\leqslant m}a^{\ell m}(\mathbf{x}_0)\alpha_{14}^{(\ell m)},\quad -b_{12}^{33}(\mathbf{x}_0)=\sum_{\ell\leqslant m}b^{\ell m}(\mathbf{x}_0)\alpha_{14}^{(\ell m)}. \tag{50}$$

It is no longer true that $-a_{12}^{33}=2a_{23}^{13}$ as in the Euclidean case. The expressions for the terms $\alpha_{14}^{(\ell m)}$ can be computed from the basic formulas (A1). They involve the terms G_{ii} and differ from the Euclidean case. For example, from (A1) and formulas for the derivatives $\partial_i A^{jk}$, $\partial_i B^{jk}$, $\partial_i C^{jk}$ we can calculate $-a_{12}^{33}(\mathbf{x}_0)$ corresponding to the basis symmetry $\mathcal{S}^{(12)}$ and obtain

$$\begin{aligned}-3\alpha_{14}^{(12)}=&\tfrac{1}{3}B^{22}C^{23}-\tfrac{2}{3}(C^{13})^2-\tfrac{2}{3}C^{13}A^{22}+\tfrac{1}{6}(A^{23})^2+\tfrac{1}{3}C^{33}\left(\tfrac{7}{2}B^{23}-2C^{22}\right)+\tfrac{3}{2}-\tfrac{1}{2}(B^{33})^2+\tfrac{5}{6}B^{33}B^{22}\\&+\tfrac{5}{6}(B^{12})^2+A^{33}B^{12}-\tfrac{1}{2}(B^{23})^2+\tfrac{1}{6}(A^{12})^2-\tfrac{1}{3}B^{33}A^{12}-\tfrac{1}{6}A^{22}A^{33}+\tfrac{1}{6}(A^{33})^2-\tfrac{1}{6}C^{33}A^{13}.\end{aligned}$$

Though there are many other quadratic conditions for L_1, L_2 to belong to the symmetry algebra, we shall use only these two.

G. Significance of generic three-sphere systems

Suppose we have a nondegenerate superintegrable system that admits separation for some special choice of ellipsoidal coordinates [1111]. (Here we do *not* assume that the system separates for all values of the parameters c, e_1, e_2, e_3, e_4, but only for one value.) By performing an Euclidean transformation and a change of scale we can assume that the coordinates are in the standard form [1111] in our table and that $e_1=0$, $e_2=1$, $e_3=a$, and $e_4=b$ where a, b are any fixed complex numbers such that $ab(a-1)(b-1)(b-a)\neq 0$. We follow the same method given before in the Euclidean case. We evaluate the a^{ij}, b^{ij} at any regular point with coordinates (x, y, z). Substituting these expressions into the eighteen linear conditions, with the help of MAPLE, we find that there are exactly seven independent linear conditions. Thus the ten quantities $A^{22}, \ldots, B^{23}$ can be expressed linearly in terms of three of these quantities. Substituting this result into the five fundamental quadratic identities (A3) we find that these identities yield exactly two solutions. Finally we substitute each of these solutions into (50) and find conditions that rule out one of these solutions. Thus only one solution exists and it must be the one that we already knew: System [VIII] that separates simultaneously for all choices of the parameters $e_1, \ldots, e_4$. What was far from obvious is the fact that *no other* nondegenerate superintegrable system separates for *any* special case of ellipsoidal coordinates on the three sphere.

Theorem 9: *A three-sphere nondegenerate superintegrable system admits separation in a special case of the generic coordinates [1111], [211], [22], [31], or [4], respectively, if and only if it is equivalent via a complex rotation to system [VII],* [*I′*], [*II′*], [*IV′*], *or* [*VI′*], *respectively*.

We have indicated the proof for coordinates [1111]. The other generic coordinates are Stäckel transforms of generic coordinates in Euclidean space so the proof for them follows immediately from Theorem 7.

APPENDIX

This is a list of some important results from Ref. 3. Using the nondegenerate potential condition and the Bertrand-Darboux equations we can solve for all of the first partial derivatives a_i^{jk} of a quadratic symmetry to obtain the defining conditions [with $\lambda=\exp(G)$]

$$a_1^{11}=-G_1a^{11}-G_2a^{12}-G_3a^{13},$$

$$a_2^{22}=-G_1a^{12}-G_2a^{22}-G_3a^{23},$$

$$a_3^{33}=-G_1a^{13}-G_2a^{23}-G_3a^{33},$$

$$3a_1^{12} = a^{12}A^{22} - (a^{22} - a^{11})A^{12} - a^{23}A^{13} + a^{13}A^{23} + G_2a^{11} - 2G_1a^{12} - G_2a^{22} - G_3a^{23},$$

$$3a_2^{11} = -2a^{12}A^{22} + 2(a^{22} - a^{11})A^{12} + 2a^{23}A^{13} - 2a^{13}A^{23} - 2G_2a^{11} + G_1a^{12} - G_2a^{22} - G_3a^{23},$$

$$3a_3^{13} = -a^{12}C^{23} + (a^{33} - a^{11})C^{13} + a^{23}C^{12} - a^{13}C^{33} - G_1a^{11} - G_2a^{12} - 2G_3a^{13} + G_1a^{33},$$

$$3a_1^{33} = 2a^{12}C^{23} - 2(a^{33} - a^{11})C^{13} - 2a^{23}C^{12} + 2a^{13}C^{33} - G_1a^{11} - G_2a^{12} + G_3a^{13} - 2G_1a^{33},$$

$$3a_2^{23} = a^{23}(B^{33} - B^{22}) - (a^{33} - a^{22})B^{23} - a^{13}B^{12} + a^{12}B^{13} - G_1a^{13} - 2G_2a^{23} - G_3a^{33} + G_3a^{22},$$

$$3a_3^{22} = -2a^{23}(B^{33} - B^{22}) + 2(a^{33} - a^{22})B^{23} + 2a^{13}B^{12} - 2a^{12}B^{13} - G_1a^{13} + G_2a^{23} - G_3a^{33} - 2G_3a^{22},$$

$$3a_1^{13} = -a^{23}A^{12} + (a^{11} - a^{33})A^{13} + a^{13}A^{33} + a^{12}A^{23} - 2G_1a^{13} - G_2a^{23} - G_3a^{33} + G_3a^{11},$$

$$3a_3^{11} = 2a^{23}A^{12} + 2(a^{33} - a^{11})A^{13} - 2a^{13}A^{33} - 2a^{12}A^{23} + G_1a^{13} - G_2a^{23} - G_3a^{33} - 2G_3a^{11},$$

$$3a_2^{33} = -2a^{13}C^{12} + 2(a^{22} - a^{33})C^{23} + 2a^{12}C^{13} - 2a^{23}(C^{22} - C^{33}) - G_1a^{12} - G_2a^{22} + G_3a^{23} - 2G_2a^{33},$$

$$3a_3^{23} = a^{13}C^{12} - (a^{22} - a^{33})C^{23} - a^{12}C^{13} - a^{23}(C^{33} - C^{22}) - G_1a^{12} - G_2a^{22} - 2G_3a^{23} + G_2a^{33},$$

$$3a_2^{12} = -a^{13}B^{23} + (a^{22} - a^{11})B^{12} - a^{12}B^{22} + a^{23}B^{13} - G_1a^{11} - 2G_2a^{12} - G_3a^{13} + G_1a^{22},$$

$$3a_1^{22} = 2a^{13}B^{23} - 2(a^{22} - a^{11})B^{12} + 2a^{12}B^{22} - 2a^{23}B^{13} - G_1a^{11} + G_2a^{12} - G_3a^{13} - 2G_1a^{22},$$

$$3a_1^{23} = a^{12}(B^{23} + C^{22}) + a^{11}(B^{13} + C^{12}) - a^{22}C^{12} - a^{33}B^{13} + a^{13}(B^{33} + C^{23}) - a^{23}(C^{13} + B^{12}) - 2G_1a^{23} + G_2a^{13} + G_3a^{12}.$$

$$3a_3^{12} = a^{12}(-2B^{23} + C^{22}) + a^{11}(C^{12} - 2B^{13}) - a^{22}C^{12} + 2a^{33}B^{13} + a^{13}(-2B^{33} + C^{23}) + a^{23}(-C^{13} + 2B^{12}) - 2G_3a^{12} + G_2a^{13} + G_1a^{23}.$$

$$3a_2^{13} = a^{12}(B^{23} - 2C^{22}) + a^{11}(B^{13} - 2C^{12}) + 2a^{22}C^{12} - a^{33}B^{13} + a^{13}(B^{33} - 2C^{23}) + a^{23}(2C^{13} - B^{12}) - 2G_2a^{13} + G_1a^{23} + G_3a^{12}, \tag{A1}$$

plus the linear relations

$$A^{23} = B^{13} = C^{12}, \quad B^{23} - A^{31} - C^{22} = 0,$$
$$B^{12} - A^{22} + A^{33} - C^{13} = 0, \quad B^{33} + A^{12} - C^{23} = 0. \tag{A2}$$

Using the linear relations we can express C^{12}, C^{13}, C^{22}, C^{23}, and B^{13} in terms of the remaining ten functions. Finally, requiring that the integrability conditions for (A1) hold identically, we obtain exactly five quadratic identities for the ten independent functions:

$$-A^{23}B^{23} - A^{12}A^{23} + A^{13}B^{12} + B^{22}A^{23} + B^{23}A^{33} + \frac{1}{2}A^{22}G_3 - \frac{1}{2}A^{33}G_3 - \frac{1}{2}B^{12}G_3 - \frac{1}{2}G_1G_3 - \frac{1}{2}A^{13}G_1 + \frac{3}{2}G_{13} - \frac{1}{2}A^{23}G_2 - A^{22}B^{23} = 0, \tag{A3a}$$

$$(A^{33})^2 + B^{12}A^{33} - A^{33}A^{22} - B^{33}A^{12} - C^{33}A^{13} + B^{22}A^{12} - B^{12}A^{22} + A^{13}B^{23} - (A^{12})^2 + \frac{3}{2}G_{22} - \frac{1}{2}G_y^2$$
$$- \frac{3}{2}G_{33} + \frac{1}{2}A^{13}G_3 + \frac{1}{2}B^{33}G_2 - \frac{1}{2}A^{22}G_1 + \frac{1}{2}A^{33}G_1 - \frac{1}{2}B^{23}G_3 - \frac{1}{2}B^{22}G_2 + \frac{1}{2}C^{33}G_3 + \frac{1}{2}(G_3)^2 = 0, \tag{A3b}$$

$$- (B^{33})^2 - B^{33}A^{12} + B^{33}B^{22} + B^{12}A^{33} + B^{23}C^{33} - (B^{23})^2 + (B^{12})^2 + \frac{1}{2}(G_1)^2 - \frac{3}{2}G_{11} + \frac{3}{2}G_{33}$$
$$- \frac{1}{2}B^{33}G_2 - \frac{1}{2}A^{33}G_1 - \frac{1}{2}(G_3)^2 - \frac{1}{2}C^{33}G_3 = 0, \tag{A3c}$$

$$- B^{12}A^{23} - A^{33}A^{23} + A^{13}B^{33} + A^{12}B^{23} + \frac{3}{2}G_{23} - \frac{1}{2}A^{23}G_1 - \frac{1}{2}A^{12}G_3 - \frac{1}{2}B^{23}G_2 - \frac{1}{2}G_2G_3$$
$$- \frac{1}{2}B^{33}G_3 = 0, \tag{A3d}$$

$$A^{12}B^{12} + C^{33}A^{23} - A^{23}B^{23} + B^{33}A^{22} - B^{33}A^{33} + \frac{3}{2}G_{12} - \frac{1}{2}G_1G_2 - \frac{1}{2}A^{12}G_1 - \frac{1}{2}B^{12}G_2 - \frac{1}{2}A^{23}G_3 = 0. \tag{A3e}$$

The performance of the OSRC method for concentric penetrable circular cylinder

Bülent Yılmaz[a)]
Department of Mathematics, Faculty of Sciences and Letters, Marmara University Göztepe Kampüsü, 34722, Kadiköy, Istanbul, Turkey

(Received 15 August 2005; accepted 21 February 2006; published online 28 April 2006)

In this paper we consider the scattering of a wave by concentric penetrable circular cylinder to examine the performance of higher order SRCs up to the L_4 operator in two dimensions. We assume that in the rectangular Cartesian axes, (x,y,z), the z axis coincides with the axis of a cylinder and an incident wave propagates in a direction perpendicular to the cylinder. All the field quantities are then independent of z. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2186923]

I. INTRODUCTION

Approximate techniques have been introduced to study the scattering of waves by obstacles. The aim of these methods is to reduce the labor involved in solving an integral equation or any appropriate formulation of the problem. The on-surface radiation condition (OSRC) method, has been devised by Kriegsmann, Taflove, and Umashankar, to investigate electromagnetic scattering problems involving cylindrical convex objects. The main concept in this method is the application of a radiation condition, connecting the field and its normal derivative, directly onto the surface of the scatterer to determine approximately the surface field or its derivative in terms of the given field. The calculation of the scattered field is then reduced to quadratures. As is demonstrated in references for a wide variety of two-dimensional obstacles, results are in confirmity with exact analysis or numerical methods over a wide range of frequencies. The approach has been employed to derive radiation boundary conditions (RBCs). The method is based on the idea of killing the terms of the expansion of the scattering field satisfying the Helmholtz equation and Sommerfeld radiation condition. An nth order RBC operator which annihilates the first n terms in the expansion is obtained either on a large circular cylinder enclosing a cylindrical convex object, or on a large sphere enclosing a finite convex object, depending on the geometrical dimensions of the problem. These RBCs can be generalized so that they can be used in the OSRC method for constructing the approximate solution of a scattering problem involving an arbitrary convex object. Until now, only the first and second order RBCs have been generalized and used in conjunction with the OSRC method.[1–9] It seems that the main obstacle to such a generalization is the difficulty in interpreting the terms properly.

In this work we apply the higher-order SRCs to scattering plane waves by a concentric penetrable circular cylinder. The results are compared with those of second- and fourth-order SRCs.

This paper is organized as follows. The formulation of the problem is described in Sec. II. In Sec. III the exact and approximate solutions of these equations with OSRC method are presented and calculated and the Appendix has some concluding remarks. In the Appendix the higher order radiation conditions are found.

II. FORMULATION

Elliptic boundary value problems governed by the Helmholtz equation in exterior regions arise in many branches of continuum physics. An example is the scattering of a time harmonic acoustic wave u^i by an obstacle occupying the region $\mathcal{B}_2$ with a boundary surface Σ_1. Let us denote the region outside Σ_1 by $\mathcal{B}_1$. We assume that $\mathcal{B}_1$ is a homogeneous isotropic medium with sound speed c_1 and constant density ρ_1.

The scattering of plane waves by a two-layered penetrable circular cylinder is examined. The concentric case is considered. We denote the outer and inner layers by $\mathcal{B}_2$ with sound speed c_2 and constant density ρ_2 and $\mathcal{B}_3$ with sound speed c_3 and constant density ρ_3, respectively. The interface between them is the circular cylinder Σ_2 of radius r_2. The radius of the circular cylinder between the exterior region $\mathcal{B}_1$ and the region $\mathcal{B}_2$ is r_1, i.e., $\mathcal{B}_1=\{r>r_1\}$, $\mathcal{B}_2=\{r_1<r<r_2\}$, $\mathcal{B}_3=\{r<r_3\}$. A plane wave incident in the direction of the positive x axis can be written as $u^i=e^{-ik_1 r\cos\theta}=\sum_{n=-\infty}^{\infty}J_n(k_1r)e^{in[\theta-(\pi/2)]}$.

The scattering problem for a two layered cylinder is described by the following equations and boundary conditions:

$$\nabla^2 u_l + k_l^2 u_l = 0, \quad \mathbf{x}\in\mathcal{B}_l \quad \text{for } k_l=\frac{w}{c_l}, \quad l=1,2,3, \tag{2.1}$$

$$u_1+u^i=u_2 \quad \text{and} \quad \frac{\partial}{\partial r}(u_1+u^i)=\xi_1\frac{\partial u_2}{\partial r} \quad \text{on } \Sigma_1, \tag{2.2}$$

$$u_2=u_3 \quad \text{and} \quad \frac{\partial u_2}{\partial r}=\xi_2\frac{\partial u_3}{\partial r} \quad \text{on } \Sigma_2, \tag{2.3}$$

where $\zeta_1=\rho_1/\rho_2$, $\zeta_2=\rho_2/\rho_3$. In addition, at infinity the scattered field u_1 must have the form of a radiating wave, i.e., the following Sommerfeld radiation condition must be satisfied:

$$\lim_{r\to\infty} r^{1/2}\left(\frac{\partial u_1}{\partial r}+ik_1u_1\right)=0. \tag{2.4}$$

The solutions for u_1, u_2, and u_3 are defined as follows:

$$u_1=\sum_{n=-\infty}^{\infty}a_nH_n(k_1r)e^{in[\theta-(\pi/2)]}, \tag{2.5}$$

$$u_2=\sum_{n=-\infty}^{\infty}[b_nJ_n(k_2r)+c_nH_n(k_2r)]e^{in[\theta-(\pi/2)]}, \tag{2.6}$$

$$u_3=\sum_{n=-\infty}^{\infty}d_nJ_n(k_3r)e^{in[\theta-(\pi/2)]}. \tag{2.7}$$

Using boundary conditions (2.2) and (2.3) the coefficients a_n, b_n, c_n, and d_n are found to be

$$J_n(k_1r_1)+a_nH_n(k_1r_1)=b_nJ_n(k_2r_1)+c_nH_n(k_2r_1), \tag{2.8}$$

$$k_1J_n'(k_1r_1)+a_nk_1H_n'(k_1r_1)=\xi_1k_2b_nJ_n'(k_2r_1)+\xi_1k_2c_nH_n'(k_2r_1), \tag{2.9}$$

$$b_nJ_n(k_2r_2)+c_nH_n(k_2r_2)=d_nJ_n(k_3r_2), \tag{2.10}$$

$$k_2 b_n J_n'(k_2 r_2) + k_2 c_n H_n'(k_2 r_2) = \xi_2 k_3 d_n J_n'(k_3 r_2), \tag{2.11}$$

$$a_n = \frac{\Delta_1}{\Delta}, \quad b_n = \frac{\Delta_2}{\Delta}, \quad c_n = \frac{\Delta_3}{\Delta}, \quad d_n = \frac{\Delta_4}{\Delta}, \tag{2.12}$$

where

$$\begin{aligned}\Delta = {} & [\xi_1 k_2 H_n(k_1 r_1) J_n'(k_2 r_1) - k_1 H_n'(k_1 r_1) J_n(k_2 r_1)][\xi_2 k_3 H_n(k_2 r_2) J_n'(k_3 r_2) - k_2 H_n'(k_2 r_2) J_n(k_3 r_2)] \\ & - [\xi_1 k_2 H_n(k_1 r_1) H_n'(k_2 r_1) - k_1 H_n'(k_1 r_1) H_n(k_2 r_1)][\xi_2 k_3 J_n(k_2 r_2) J_n'(k_3 r_2) - k_2 J_n'(k_2 r_2) J_n(k_3 r_2)],\end{aligned} \tag{2.13}$$

$$\begin{aligned}\Delta_1 = {} & [\xi_1 k_2 J_n(k_1 r_1) H_n'(k_2 r_1) - k_1 J_n'(k_1 r_1) H_n(k_2 r_1)][\xi_2 k_3 J_n(k_2 r_2) J_n'(k_3 r_2) - k_2 J_n'(k_2 r_2) J_n(k_3 r_2)] \\ & - [\xi_1 k_2 J_n(k_1 r_1) J_n'(k_2 r_1) - k_1 J_n'(k_1 r_1) J_n(k_2 r_1)][\xi_2 k_3 H_n(k_2 r_2) J_n'(k_3 r_2) - k_2 H_n'(k_2 r_2) J_n(k_3 r_2)],\end{aligned} \tag{2.14}$$

$$\Delta_2 = \frac{2i}{\pi r_1}[\xi_2 k_3 H_n(k_2 r_2) J_n'(k_3 r_2) - k_2 H_n'(k_2 r_2) J_n(k_3 r_2)],$$

$$\Delta_3 = \frac{-2i}{\pi r_1}[\xi_2 k_3 J_n(k_2 r_2) J_n'(k_3 r_2) - k_2 J_n'(k_2 r_2) J_n(k_3 r_2)], \tag{2.15}$$

$$\Delta_4 = \frac{-4}{\pi^2 r_1 r_2}.$$

The radiation boundary conditions have been derived at the phase fronts and on these surfaces establish approximate (asymptotic) between the derivative of u in the direction of the normal to u and their tangential derivatives. Hence these relations will be valid wherever there is a wave front. Kriegsmann, Taflove, and Umashankar[3] assume that these expressions are also valid on Σ_1 and replace $\partial/\partial n$ with $\partial/\partial s$ at $L_1 u$ and $L_2 u$. Therefore at the representation in two dimensions of the radiation boundary conditions given replacing $\partial/\partial s$ by $\partial/\partial n$ and writing $u = u_1$, the following relation is given between the normal derivative of scattering field and tangential derivative on Σ_1.

The relation

$$\frac{\partial u_1}{\partial n} = \Lambda^{(m)} u_1, \quad m = 2,3,4 \tag{2.16}$$

based on behavior local to a wave front is derived where $\Lambda^{(m)} u_1$ denotes all terms out of $\partial u/\partial s$ at radiation boundary conditions. Boundary condition on Σ_1 from (2.4) is

$$u_1 = u_2 - u^i, \quad \frac{\partial u_1}{\partial n} = \zeta \frac{\partial u_2}{\partial n} - \frac{\partial u^i}{\partial n}.$$

Then the relation is obtained as follows:

$$\zeta \frac{\partial u_2}{\partial n} - \Lambda^{(m)} u_2 = \frac{\partial u^i}{\partial n} - \Lambda^{(m)} u^i. \tag{2.17}$$

$\nabla^2 u_2 + k_2^2 u_2 = 0$ and (2.17) defines an interior problem for u_2. This condition and

$$u_2 = u_3, \quad \frac{\partial u_2}{\partial n} = \zeta_2 \frac{\partial u_3}{\partial n}, \quad \text{on } r = r_1$$

conditions constitute an interior elliptic boundary value problem with

$$\nabla^2 u_l + k_l^2 u_l = 0, \quad \mathbf{x} \in \mathcal{B}_l, \quad l = 2,3$$

equations. Defining $v_2(\theta) = u_2(a, \theta)$ and $w_2(\theta) = (1/k_2)(\partial u_2/\partial r)$ the boundary conditions (2.2) can be written as

$$v_1 + v^i = v_2 \quad \text{and} \quad k_1(w_1 + w^i) = k_2 \zeta w_2. \tag{2.18}$$

Using these equations, v_1 and w_1 can be eliminated from the SRCs given in the Appendix by (A13) to obtain

$$\alpha_1^{(m)} \frac{d^4 v_2}{\mathrm{d}\theta^4} + \alpha_2^{(m)} \frac{d^2 v_2}{\mathrm{d}\theta^2} + \alpha_3^{(m)} v_2 - \frac{k_2}{k_1} \zeta \left\{ \alpha_4^{(m)} \frac{d^2 w_2}{\mathrm{d}\theta^2} + \alpha_5^{(m)} w_2 \right\}$$

$$= \alpha_1^{(m)} \frac{d^4 v^i}{\mathrm{d}\theta^4} + \alpha_2^{(m)} \frac{d^2 v^i}{\mathrm{d}\theta^2} + \alpha_3^{(m)} v^i - \frac{k_2}{k_1} \zeta \left\{ \alpha_4^{(m)} \frac{d^2 w^i}{\mathrm{d}\theta^2} + \alpha_5^{(m)} w^i \right\}. \tag{2.19}$$

The use of SRCs (A13) together with (2.18) yields the impedance conditions (2.19) with $\zeta = \xi_1$. The impedance condition (2.19) together with

$$\nabla^2 u_l + k_l^2 u_l = 0, \quad \mathbf{x} \in \mathcal{B}_l, \quad l = 2,3, \tag{2.20}$$

$$u_2 = u_3 \quad \text{and} \quad \frac{\partial u_2}{\partial r} = \xi_2 \frac{\partial u_3}{\partial r}. \tag{2.21}$$

constitute an interior boundary value problem for u_2 and u_3,

$$u_2 = \sum_{n=-\infty}^{\infty} [B_n J_n(k_2 r) + C_n H_n(k_2 r)] e^{in[\theta - (\pi/2)]}, \tag{2.22}$$

$$u_3 = \sum_{n=-\infty}^{\infty} D_n J_n(k_3 r) e^{in[\theta - (\pi/2)]}. \tag{2.23}$$

Once u_2 and u_3 have been determined, v_1 and w_1 are found from (2.18). If we use boundary conditions (2.2) and (2.3) the coefficients B_n, C_n, and D_n are found.

For the approximate solution, the coeffcients B_n, C_n, and D_n are found using (2.17) and (2.19) ($\varepsilon = k_1 r_1$),

$$\Theta^{(l)}(\varepsilon)\{B_n J_n(k_2 r_1) + C_n H_n(k_2 r_1)\} - \frac{k_2}{k_1} \xi_1 \{B_n J_n'(k_2 r_1) + C_n H_n'(k_2 r_1)\}$$

$$= \Theta^{(l)}(\varepsilon) J_n(\varepsilon) - J_n'(\varepsilon), \tag{2.24}$$

$$B_n J_n(k_2 r_2) + k_2 C_n H_n(k_2 r_2) = D_n J_n(k_3 r_2), \tag{2.25}$$

$$k_2 B_n J_n'(k_2 r_2) + k_2 C_n H_n'(k_2 r_2) = \xi_2 k_3 D_n J_n'(k_3 r_2), \tag{2.26}$$

$$B_n = \frac{\tilde{\Delta}_2}{\tilde{\Delta}}, \quad C_n = \frac{\tilde{\Delta}_3}{\tilde{\Delta}}, \quad D_n = \frac{\tilde{\Delta}_4}{\tilde{\Delta}}, \tag{2.27}$$

where

$$\tilde{\Delta} = [\xi_1 k_2 J_n'(k_2 r_1) - k_1 \Theta^{(l)}(\varepsilon) J_n(k_2 r_1)][\xi_2 k_3 H_n(k_2 r_2) J_n'(k_3 r_2) - k_2 H_n'(k_2 r_2) J_n(k_3 r_2)] - [\xi_1 k_2 H_n'(k_2 r_1) - k_1 \Theta^{(l)}(\varepsilon) H_n(k_2 r_1)][\xi_2 k_3 J_n(k_2 r_2) J_n'(k_3 r_2) - k_2 J_n'(k_2 r_2) J_n(k_3 r_2)], \tag{2.28}$$

$$\tilde{\Delta}_2 = -k_1[\Theta^{(l)}(\varepsilon) J_n(\varepsilon) - J_n'(\varepsilon)][\xi_2 k_3 H_n(k_2 r_2) J_n'(k_3 r_2) - k_2 H_n'(k_2 r_2) J_n(k_3 r_2)], \tag{2.29}$$

$$\tilde{\Delta}_3 = k_1[\Theta^{(l)}(\varepsilon) J_n(\varepsilon) - J_n'(\varepsilon)][\xi_2 k_3 J_n(k_2 r_2) J_n'(k_3 r_2) - k_2 J_n'(k_2 r_2) J_n(k_3 r_2)] \tag{2.30}$$

$$\tilde{\Delta}_4 = k_1 k_2[\Theta^{(l)}(\varepsilon) J_n(\varepsilon) - J_n'(\varepsilon)][J_n(k_2 r_2) H_n'(k_2 r_2) - J_n'(k_2 r_2) J_n(k_2 r_2)], \tag{2.31}$$

and

$$\Theta^{(m)}(\varepsilon) = -\frac{n^4 \alpha_1^{(m)} - n^2 \alpha_2^{(m)} + \alpha_3^{(m)}}{n^2 \alpha_4^{(m)} - \alpha_5^{(m)}}. \tag{2.32}$$

III. COMPARISON

It is observed that the replacement of $\Theta^{(m)}(\varepsilon)$ by $H_n'(\varepsilon)/H_n(\varepsilon)$ in the approximate solutions and using $H_n(z)J_n'(z) - H_n'(z)J_n(z) = 2i/\pi z$ the Wronskian relation also yields the exact ones. It is shown that the expressions $\tilde{\Delta}$, $\tilde{\Delta}_2$, $\tilde{\Delta}_3$, $\tilde{\Delta}_4$, are transformed to Δ, Δ_2, Δ_3, Δ_4. Thus, for the problem under consideration the SRC method is equivalent to introducing the approximation

$$\frac{H_n'(\varepsilon)}{H_n(\varepsilon)} \approx \Theta^{(m)}(\varepsilon) \tag{3.1}$$

and therefore, this result is independent of the boundary conditions prescribed on the surface of the circular cylinder Σ_1. Hence, the accuracy of the method for the cylinder problems will depend on the accuracy of the approximation in (3.1). Hence, the accuracy of the method for the cylinder problems will depend on the accuracy of the approximation in (3.1).

Comparisons were made between the exact answer of the problem and the SRC solutions. It is observed that introductions of higher-order radiation conditions improve the approximation considerably in comparison to results obtained by the use of a second-order radiation condition, especially in cases which creeping waves are less pervasive.

The characterization of the region and the wave within this region given in Fig. 1 and graphs (a) and (b) for $\varepsilon = 1, 10$, respectively, are as follows: $k_3 = (c_1/c_3)k_1$, $k_2 = (c_1/c_2)k_1$, $\xi_1 = \rho_1/\rho_2$, $\xi_2 = \rho_2/\rho_3$,

$$\rho_1 = 1.2, \quad c_1 = 340, \quad \rho_2 = 1000, \quad c_2 = 1480, \quad \rho_3 = 1200, \quad c_3 = 1600. \tag{3.2}$$

Whenever the regions are, respectively, air, water, and a region denser than water from outside to inside the results of the second and fourth order SRCs for the parameters in (3.2) are depicted together with the exact curve for $\varepsilon = 1, 10$. It can be seen that the performance of the higher-order SRCs give better results than the second-order SRC. Note that the existence of dissipation improves the results to a certain extent. It should be noted that in the cases given in the graphs the concentric penetrable cylinder behaves nearly as a hard cylinder.[10]

The characterization of the region and the wave within this region given in Fig. 2 and graphs (a) and (b) for $\varepsilon = 1, 10$, respectively, are as follows:

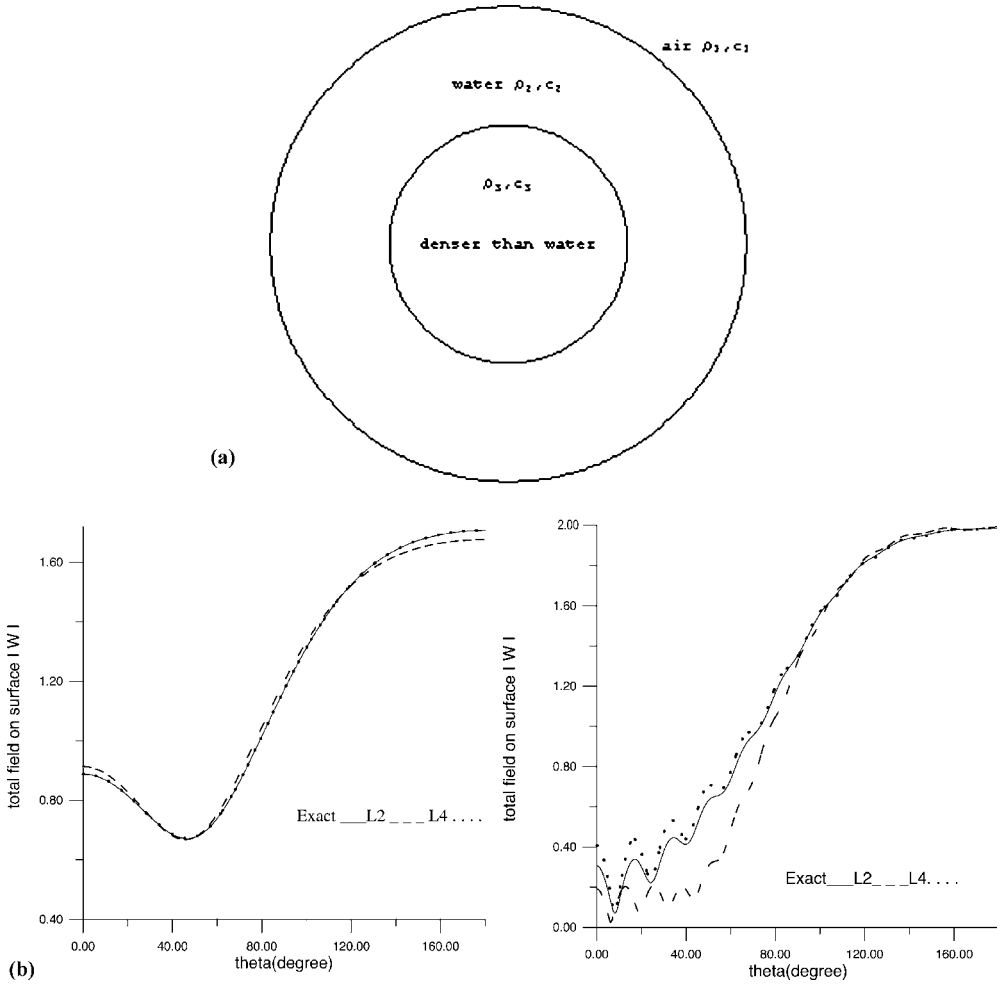

FIG. 1.

$$\rho_1 = 1000, \quad c_1 = 1480, \quad \rho_2 = 1.2, \quad c_2 = 340, \quad \rho_3 = 1.0, \quad c_3 = 280. \tag{3.3}$$

Figure 2 shows the results of the second- and fourth-order SRCs for the parameters in (3.3) for $\varepsilon = 1, 10$. It can be seen that for $\varepsilon = 1, 10$ the performance of the fourth-order SRCs are perfect, and they offer an improvement, although in these cases the second-order SRCs also produce quite good results. It should be noted that in the cases given in the graphs, the concentric penetrable cylinder behaves nearly as a soft cylinder.[11]

In a different manner from Figs. 1 and 2 whenever the densities of the first two regions are similar and the density of the smaller third region is greater than those, the case specific parameters and graphs (a) and (b) of Figure 3 for $\varepsilon = 1, 10$, respectively, are as follows:

$$\rho_1 = 1,2, \quad c_1 = 340, \quad \rho_2 = 1.4, \quad c_2 = 400, \quad \rho_3 = 1000, \quad c_3 = 1480. \tag{3.4}$$

As opposed to Fig. 3, whenever the densities of the first two regions are similar between them and lower than the third region the case specific parameters and graphs (a) and (b) of Figure 4 for $\varepsilon = 1, 10$, respectively, are as follows:

$$\rho_1 = 1200, \quad c_1 = 1600, \quad \rho_2 = 1000, \quad c_2 = 1480, \quad \rho_3 = 1.2, \quad c_3 = 340. \tag{3.5}$$

In Figs. 3 and 4 we see almost the same results of the problem according to the parameters in (3.4) and (3.5) as in (3.2) and (3.3), respectively.

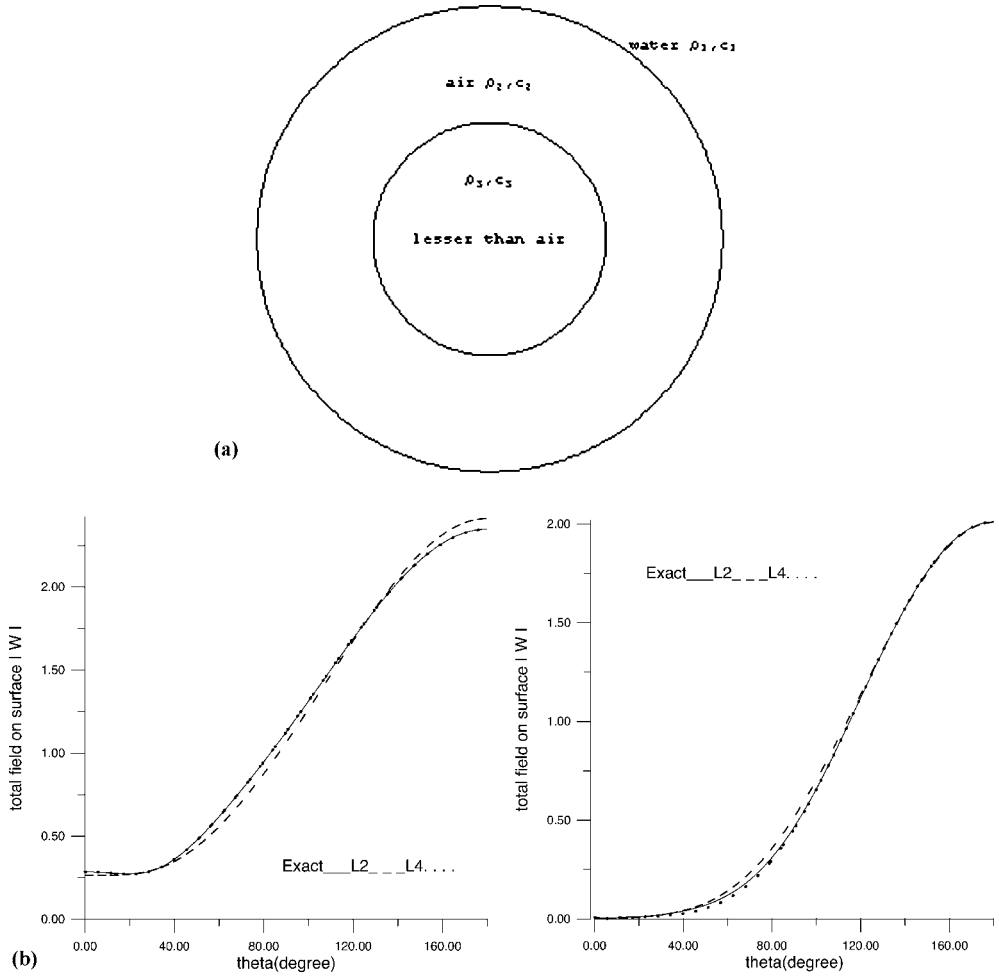

FIG. 2.

From all the graphics related to Figs. 1–4 it can be seen that the fourth-order SRC produces the most accurate results for all of the frequencies. It is known that the creeping waves are less pervasive for the case in Fig. 1 objects and therefore the results are more accurate in the high-frequency range. Nevertheless the fourth-order SRC improves the SRC approximation considerably for both Figs. 1 and 2 and also for all frequencies.

APPENDIX

It is well known that the solution of the Helmholtz equation satisfying the Sommerfeld radiation condition can be represented by the series which is convergent in $\mathcal{B}_1$ and is

$$u = H_0^{(2)}(kr)\sum_{n=0}^{\infty}\frac{F_n(\theta)}{r^n} + H_1^{(2)}(kr)\sum_{n=0}^{\infty}\frac{G_n(\theta)}{r^n}. \tag{A1}$$

For large values, the asymptotic expansion for u is

$$u \approx \sqrt{\frac{2}{\pi kr}}e^{-i(kr-\pi/4)}\sum_{n=0}^{\infty}\frac{f_n(\theta)}{r^n}. \tag{A2}$$

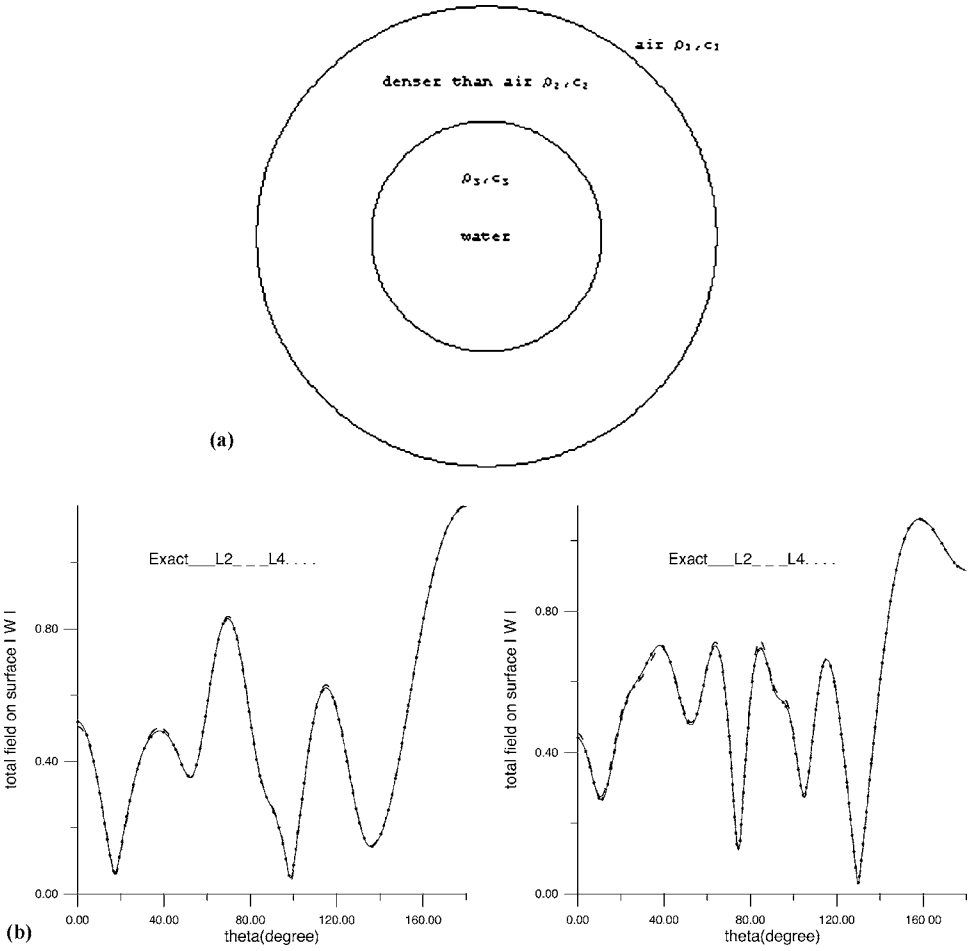

FIG. 3.

If we want to solve the problem numerically by direct methods; we must first make the region $\mathcal{B}_1$ finite. This can be done by means of a Σ_2 curve which includes Σ_1 curve and whose center is in $\mathcal{B}_2$ and has radius r_1. With these assumptions the problem is reduced to finding the solution of the Helmholtz equation on the region bounded by Σ_1 and Σ_2 the solution must satisfy the empedance condition on Σ_1 and the boundary condition must be satisfied on Σ_2 which will play the role of the Sommerfeld radiation condition. How ever this condition is as yet unknown and the first thing that comes to mind is to carry the Sommerfeld condition over to Σ_2. That is,

$$\left(\frac{\partial u}{\partial r} + iku\right)_{r=r_1} = 0. \tag{A3}$$

Howewer, this is a wrong approach. It can be immediately seen that even for the first term of expansion (A2), (A3) is not definite,

$$\left(\frac{\partial}{\partial r} + ik\right)\sqrt{\frac{2}{\pi kr}}e^{-i(kr-\pi/4)}f_0(\theta) = \vartheta(r^{-3/2}). \tag{A4}$$

If the operator $L_1 = (\partial/\partial r) + ik + (1/2r)$ is used instead of $[(\partial/\partial r) + ik]$

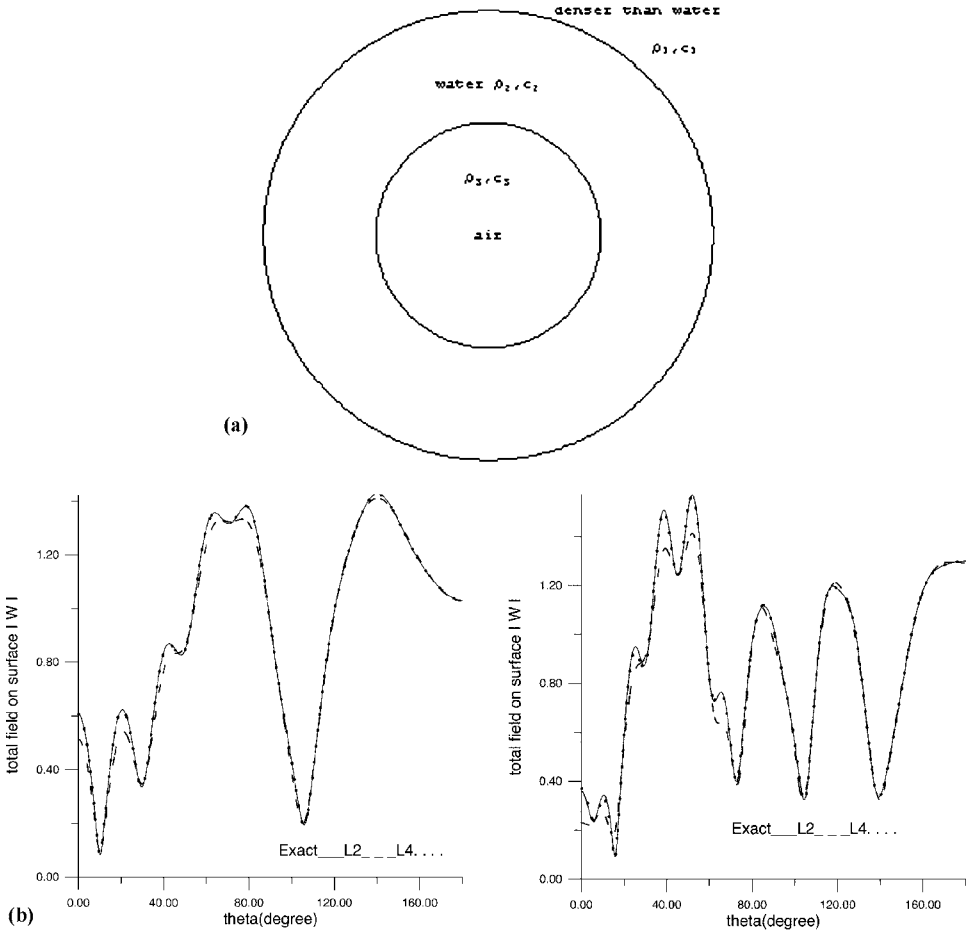

FIG. 4.

$$L_1\left(\sqrt{\frac{2}{\pi kr}}e^{-i(kr-\pi/4)}f_0(\theta)\right)=0 \tag{A5}$$

will be found. This result will be true for

$$\frac{e^{-i(kr)}}{\sqrt{kr}}F(\theta), \tag{A6}$$

where $F(\theta)$ is an arbitrary function and for (A2) the following will be valid:

$$(L_1u)_{r=r_1}=\vartheta(r^{-5/2}) \tag{A7}$$

That is when L_1 is applied to u, a result less erroneous then the Sommerfeld radiation condition is obtained. Similarly, higher order boundary condition operators can be obtained from Ref. 6 and are given by

$$L_m=\left(\frac{\partial}{\partial r}+ik+\frac{4m-3}{2r}\right)L_{m-1}. \tag{A8}$$

The first four operators in polar coordinates for the Helmholtz equations, which are used in this paper, are

$$L_1 u = \frac{\partial u}{\partial r} + iku + \frac{u}{2r}, \tag{A9}$$

$$L_2 u = 2\left(\frac{1}{r} + ik\right)\frac{\partial u}{\partial r} - \left(2k^2 + \frac{3}{4r^2} + \frac{3ik}{r}\right)u - \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2}, \tag{A10}$$

$$L_3 u = \left(\frac{23}{4r^2} + \frac{12ik}{r} - 4k^2\right)\frac{\partial u}{\partial r} + \left(\frac{15}{8r^3} + \frac{45ik}{4r^2} - \frac{14k^2}{r} - 4ik^3\right)u + \left(\frac{-9}{2r^3} - \frac{3ik}{r^2}\right)\frac{\partial^2 u}{\partial \theta^2} - \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2}\left(\frac{\partial u}{\partial r}\right), \tag{A11}$$

and

$$\begin{aligned} L_4 u = {} & \left(\frac{22}{r^3} + \frac{71ik}{r^2} - \frac{48k^2}{r} - 8ik^3\right)\frac{\partial u}{\partial r} + \left(\frac{105}{16r^4} + \frac{105ik}{2r^3} - \frac{94k^2}{r^2} - \frac{52ik^3}{r} + 8k^4\right)u \\ & + \left(\frac{-43}{2r^4} - \frac{30ik}{r^3} + \frac{8k^2}{r^2}\right)\frac{\partial^2 u}{\partial \theta^2} + \left(\frac{-8}{r^3} - \frac{4ik}{r^2}\right)\frac{\partial^2}{\partial \theta^2}\left(\frac{\partial u}{\partial r}\right) + \frac{1}{r^4}\frac{\partial^4 u}{\partial \theta^4}, \end{aligned} \tag{A12}$$

respectively.

For a cylinder the second-, third-, and fourth-order radiation conditions are found to be

$$\alpha_1^{(m)}\frac{d^4 v_1}{d\theta^4} + \alpha_2^{(m)}\frac{d^2 v_1}{d\theta^2} + \alpha_3^{(m)} v_1 = \alpha_4^{(m)}\frac{d^2 w_1}{d\theta^2} + \alpha_5^{(m)} w_1, \quad m = 2,3,4, \tag{A13}$$

where

$$v_1(\theta) = u_1(a,\theta) \quad \text{and} \quad w_1(\theta) = \frac{1}{k_1}\frac{\partial u_1}{\partial r}(a,\theta) \tag{A14}$$

and $\alpha_q^{(m)}$ are functions of $\varepsilon = k_1 a$. In (A13) the superscript m denotes the order. $\alpha_q^{(m)}$ are defined as

$$\alpha_1^{(2)} = 0, \quad \alpha_2^{(2)} = 1, \quad \alpha_3^{(2)} = -\frac{3}{4} - 3i\epsilon + 2\epsilon^2, \quad \alpha_4^{(2)} = 0, \quad \alpha_5^{(2)} = 2\epsilon(1 + i\epsilon),$$

$$\alpha_1^{(3)} = 0, \quad \alpha_2^{(3)} = -3i\epsilon - \frac{9}{2}, \quad \alpha_3^{(3)} = \frac{15}{8} + \frac{45}{4}i\epsilon - 14\epsilon^2 - 4i\epsilon^3,$$

$$\alpha_4^{(3)} = \epsilon, \quad \alpha_5^{(3)} = -\epsilon\left(\frac{23}{4} + 12i\epsilon - 4\epsilon^2\right), \tag{A15}$$

$$\alpha_1^{(4)} = 1, \quad \alpha_2^{(4)} = -\frac{43}{2} - 30i\epsilon + 8\epsilon^2, \quad \alpha_3^{(4)} = \frac{105}{16} + \frac{105i\epsilon}{2} - 94\epsilon^2 - 52i\epsilon^3 + 8\epsilon^4,$$

$$\alpha_4^{(4)} = 4\epsilon(2 + i\epsilon), \quad \alpha_5^{(4)} = -\epsilon(22 + 71i\epsilon - 48\epsilon^2 - 8i\epsilon^3).$$

Quantum entanglement and geometry of determinantal varieties

Hao Chen[a)]
Department of Computing and Information Technology, Fudan University, Shanghai 200433, People's Republic of China

(Received 24 November 2005; accepted 15 March 2006; published online 3 May 2006)

Quantum entanglement was first recognized as a feature of quantum mechanics in the famous paper of Einstein, Podolsky, and Rosen. Recently it has been realized that quantum entanglement is a key ingredient in quantum computation, quantum communication, and quantum cryptography. In this paper, we introduce algebraic sets, which are determinantal varieties in the complex projective spaces or the products of complex projective spaces, for the mixed states on bipartite or multipartite quantum systems as their invariants under local unitary transformations. These invariants are naturally arised from the physical consideration of measuring mixed states by separable pure states. Our construction has applications in the following important topics in quantum information theory: (1) separability criterion, it is proved that the algebraic sets must be a union of the linear subspaces if the mixed states are separable; (2) simulation of Hamiltonians, it is proved that the simulation of semipositive Hamiltonians of the same rank implies the projective isomorphisms of the corresponding algebraic sets; (3) construction of bound entangled mixed states, examples of the entangled mixed states which are invariant under partial transpositions (thus PPT bound entanglement) are constructed systematically from our new separability criterion. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2194629]

I. INTRODUCTION

A bipartite pure quantum state $|\psi\rangle \in H=H_A^m \otimes H_B^n$, where H_A^m, H_B^n are finite dimensional Hilbert spaces of dimensions m and n, and the tensor inner product is used on H, is called entangled if it cannot be written as $|\psi\rangle=|\psi_A\rangle \otimes |\psi_B\rangle$ for some $|\psi_A\rangle \in H_A^m$ and $|\psi_B\rangle \in H_B^n$. A mixed state (or a density matrix) ρ, which is a semipositive definite operator on H with trace 1, is called entangled if it cannot be written as

$$\rho = \Sigma_i p_i P_{|\psi_i^A\rangle} \otimes P_{|\psi_i^B\rangle}, \tag{1}$$

for some set of states $|\psi_i^A\rangle \in H_A^m$, $|\psi_i^B\rangle \in H_B^n$, and $p_i \geqslant 0$. Here P_v for a state (unit vector) v means the (rank 1) projection operator to the vector v. If the mixed state ρ can be written in the form of (1), it is called separable (see Refs. 28, 39, and 41).

For the mixed state ρ on $H=H_A^m \otimes H_B^n$, we have the following partial transposition ρ^{PT} and the partial trace $\mathrm{tr}_B(\rho)$ on H_A^m [$\mathrm{tr}_A(\rho)$ on H_B^n can be defined similarly] defined as follows:

$$\langle ij|\rho^{\mathrm{PT}}|kl\rangle = \langle il|\rho|kj\rangle,$$

a)Electronic mail: chenhao@fudan.edu.cn

$$\langle i|\mathrm{tr}_B(\rho)|k\rangle = \Sigma_j \langle ij|\rho|kj\rangle, \tag{2}$$

where $\{|1\rangle,\ldots,|m\rangle\}$, $\{|1\rangle,\ldots,|n\rangle\}$, $\{|11\rangle,\ldots|1n\rangle,\ldots|m1\rangle,\ldots,|mn\rangle\}$ are orthogonal bases of $H'_A H^n_B$ and H, respectively. We observe that the partial transposition of a separable mixed state is again a separable mixed state, this implies that the partial transposition of a separable mixed state is semi positive definite. This is the famous Peres PPT criterion of separability (see Ref. 38).

For multipartite quantum systems, there are similar definitions of entangled and separable mixed states (see Refs. 28, 39, and 41). We restrict ourselves to the tripartite case. Let ρ be a mixed state on $H=H^m_A\otimes H^n_B\otimes H^l_C$. ρ is called separable if it can be written as

$$\rho = \Sigma_i p_i P_{|\psi^A_i\rangle}\otimes P_{|\psi^B_i\rangle}\otimes P_{|\psi^C_i\rangle}, \tag{3}$$

for some set of states $|\psi^A_i\rangle\in H^m_A$, $|\psi^B_i\rangle\in H^n_B, |\psi^C_i\rangle\in H^l_C$, and $p_i\geqslant 0$. If the mixed state ρ cannot be written in the form of (3), it is called entangled. Sometimes we also consider the separability relative to the cut $A:BC$ ($B:AC$, etc.), that means ρ is considered as a mixed state on the bipartite quantum system $H=H^m_A\otimes(H^n_B\otimes H^l_C)$.

For a n-party quantum system $H=H^{m_1}_{A_1}\otimes\cdots\otimes H^{m_n}_{A_n}$, local unitary transformations (acting on a mixed state ρ by $U\rho U^\dagger$, where $\dagger$ is the adjoint) are those unitary transformations of the form $U=U_{A_1}\otimes\cdots\otimes U_{A_n}$, where U_{A_i} is a unitary transformation on $H^{m_i}_{A_i}$ for $i=1,\ldots,n$. We can check that all eigenvalues (spectra) of ρ (global spectra) and, $\mathrm{tr}_{A_{i_1}\cdots A_{i_l}}(\rho)$ of mixed states ρ, where $i_1,\ldots,i_l\in\{1,\ldots,n\}$, (local spectra) are invariant under local unitary transformations, and the invariants in the examples of Refs. 33 and 34 are more or less spectra-involved. It is clear that separability (or being entangled) is an invariant property under local unitary transformations. For a mixed state ρ, to judge whether it is entangled or separable and decide its entangled class (i.e., the equivalent class of all entangled (or separable) mixed states which are equivalent to ρ by local unitary transformations) is a fundamental problem in the study of quantum entanglement.[28,41] Thus for the purpose to quantify entanglement, any good measure of entanglement must be invariant under local transformations.[33,34,28,41] Another important concept is the distillable mixed state, which means that some singlets can be extracted from it by local operations and classical communication (LOCC) (see Ref. 28). A mixed state ρ on H is distillable if and only if for some t, there exists projections $P_A:H^{\otimes t}_A\to H^2$ and $P_B:H^{\otimes t}_B\to H^2$, where H^2 is a two-dimensional Hilbert space, such that the mixed state $(P_A\otimes P_B)\rho^{\otimes t}(P_A\otimes P_B)^\dagger$ is an entangled state in $H^2\otimes H^2$ (see Ref. 28). A mixed state which cannot be distilled is called bound entangled mixed state.

The phonomenon of quantum entanglement lies at the heart of quantum mechanics since the famous Einstein, Podolsky, and Rosen[16] paper (see Refs. 8, 28, and 39). Its importance lies not only in philosophical consideration of the nature of quantum theory, but also in applications where it has emerged recently that quantum entanglement is the key ingredient in quantum computation[20] and communication[4] and plays an important role in cryptography (Ref. 19). These new applications of quantum entanglement have stimulated tremendous studies of quantum entanglements of both pure and mixed states from both theoretical and experimental view, for surveys we refer to Refs. 8, 28, 32, 39, and 41.

To find good necessary conditions of separability (separability criterion) is a fundamental problem in the study of quantum entanglement.[28,41] Bell-type inequalities[28] and entropy criterion[28] are well-known numerical criterion of separable states. In 1996, Peres[38] gave a striking simple criterion which asserts that a separable mixed state ρ necessarily has (semi) positive definite partial transposition (PPT), which has been proved by Horodeckis[25] also a sufficient condition of separability in 2×2 and 2×3 systems. The significance of PPT property is also reflected in the facts that PPT mixed states satisfy Bell inequalities[44] and cannot be distilled,[28,26] thus the first several examples of the PPT entangled mixed states[24] indicated the new phenomenon that there is bound entanglement in nature.[26] These examples were constructed from the so-called range criterion of Horodecki (see Refs. 24 and 28). However, constructing PPT entangled mixed states (thus bound entanglement) is an exceedingly difficult task,[6] and the only known systematic way of such construction is the context of unextendible product base (UPB) in Ref. 6, which works in both the

bipartite and multipartite case and is also based on Horodecki's range criterion. The most recent disorder criterion of separability in Ref. 37, which is stronger than entropy criterion, was proved by the mathematics of majorization.

It has been realized that the entanglement of tripartite pure quantum states is not a trivial extension of the entanglement of bipartite pure quantum states.[21] Recently Bennett *et al.*,[5] studied the exact and asymptotic entanglement measure of multipartite pure states, which showed essential difference to that of bipartite pure states. On the other hand Carteret *et al.*,[12] proved a generalization of Schmidt decomposition for pure multipartite states. Basically, the understanding of multipartite quantum entanglement for both pure and mixed states, is much less advanced.

It is clear that any separability criterion for bipartite mixed states, such as Peres PPT criterion[38] and Horodecki range criterion,[24,28] can be applied to multipartite mixed states for their separability under various cuts. For example, from Peres PPT criterion, a separable multipartite mixed state necessarily has all its partial transpositions semipositive. In Ref. 27, Horodeckis studied the separability criterion of multipartite mixed states by linear maps. Classification of triqubit mixed states was studied in Ref. 2.

There have been many interesting works (Refs. 10, 11, 30, 35, and 43) for understanding quantum entanglement and related problems from the view of representation theory and topology.

The physical motivation of this paper is as follows. We consider the following situation. Alice and Bob share a bipartite quantum system $H_A^m \otimes H_B^n$, and they have a mixed state ρ. Now they want to understand the entanglement properties of ρ. It is certain that they can prepare any separable pure state $|\phi_1\rangle \otimes |\phi_2\rangle$ separately. Now they measure ρ with this separable pure state, the expectation value is $\langle \phi_1 \otimes \phi_2 | \rho | \phi_1 \otimes \phi_2 \rangle$. If Alice's pure state $|\phi_1\rangle$ is fixed, then $\langle \phi_1 \otimes \phi_2 | \rho | \phi_1 \otimes \phi_2 \rangle$ is a Hermitian bilinear form on Bob's pure states (i.e., on H_B^n). We denote this bilinear form by $\langle \phi_1 | \rho | \phi_1 \rangle$. Intuitively the *degenerating locus* $V_A^k(\rho) = \{|\phi_1\rangle \in P(H_A^m) : \mathrm{rank}(\langle \phi_1 | \rho | \phi_1 \rangle) \leqslant k\}$, where $P(H_A^m)$ is the projective space of all pure states in H_A^m, should contain the physical information of ρ and it is almost obvious that these *degenerating locus* are invariant under local unitary transformations. For a multipartite quantum system, a similar consideration leads to some Hermitian bilinear forms on some of its parts and similarly we can consider the *degenerating locus* of these Hermitian bilinear forms. We prove that these *degenerating locus* are algebraic sets, which are determinantal varieties, for the mixed states on both bipartite and multipartite quantum systems. They have the following properties.

(1) When we apply local unitary transformations on the mixed state the corresponding algebraic sets are changed by local (unitary) linear transformations, and thus these invariants can be used to distinguish inequivalent mixed states under local unitary transformations.

(2) The algebraic sets must be linear (a union of some linear subspaces) if the mixed state is separable, and thus we give a new separability criterion.

(3) The algebraic sets are independent of eigenvalues and only measure the positions of eigenvectors of the mixed states.

(4) These algebraic sets can be calculated easily.

From our construction here, we establish a connection between quantum entanglement and algebraic geometry. Actually from our results below, we can see that if the Fubini-Study metric of the projective complex space is used, the metric properties of these algebraic sets are also preserved when local unitary transformations are applied on the mixed state. Hence we establish a connection between quantum entanglement and both the algebraic geometry and complex differential geometry. Any algebraic geometric or complex differential geometric invariant of the algebraic set of the mixed state is an invariant of the mixed state under local unitary transformations.

The determinantal varieties (Ref. 23 Lecture 9 and Ref. 3 Chap. II) have been studied from different motivations such as geometry of curves,[3,18] geometry of determinantal varieties,[17] Hodge theory,[22] commutative algebra,[15] and even combinatorics.[1] It is interesting to see that it can be useful even in quantum information theory. We refer to Refs. 23 and 3 for the standard facts about determinantal varieties.

The paper is organized as follows. We define the algebraic sets of the mixed states and prove their basic properties including the separability criteria based on these algebraic sets in Sec. II. In

Sec. III, we indicate briefly how numerical invariants of the bipartite or multipartite mixed states under local unitary transformations can be derived from these algebraic sets. As an easiest example, Schmidt rank of a pure state on bipartite quantum systems, a classical concept in quantum entanglement, is shown to be the codimension of the algebraic set. Many examples of entangled mixed states corresponding to the famous determinantal varieties in algebraic geometry, such as Segre varieties, rational normal scrolls and generic determinantal varieties are constructed in Sec. IV. We also show that a well-known theorem of Eisenbud[17] can help us to construct many entangled bipartite mixed states of low ranks. In Sec. V we introduce a family of the generalized Smolin states, which is a natural extension of Smolin's physical construction[40] from algebraic-geometric view. In Secs. VI and VII, it is proved that these algebraic sets are nonempty for low rank mixed states, and indicate how a *finer* result with the same idea (Theorem 9′) can be potentially used to treat the entanglement properties of high rank mixed states. Based on the algebraic sets introduced in Sec. II, a necessary condition about the simulating Hamiltonians efficiently using local unitary transformations is given in Sec. VIII. In Sec. IX, we give a continuous family of bipartite mixed states, tripartite pure states, and bipartite Hamiltonians with the property that the eigenvalues (spectra) of them and their partial traces are constant, however, their entanglement properties are distinct. This offers strong evidence that it is hopeless to characterize the entanglement properties by only using eigenvalue spectra. In Sec. X, we illustrate by an explicit example that our separability criterion can be used to construct PPT entangled mixed states (thus bound entanglement) systematically.

II. INVARIANTS AND SEPARABILITY CRITERIA

Now we define the invariants and give the coordinate form. Let $H=H_A^m\otimes H_B^n$, $\{|ij\rangle\}$, where $i=1,\ldots,m$ and $j=1,\ldots,n$, be an orthogonal base and ρ be a mixed state on H. We represent the matrix of ρ in the bases $\{|11\rangle,\ldots|1n\rangle,\ldots,|m1\rangle,\ldots,|mn\rangle\}$, and consider ρ as a blocked matrix $\rho=(\rho_{ij})_{1\leqslant i\leqslant m,1\leqslant j\leqslant m}$ with each block ρ_{ij} a $n\times n$ matrix corresponding to the $|i1\rangle,\ldots,|in\rangle$ rows and the $|j1\rangle,\ldots,|jn\rangle$ columns. For any pure state $|\phi_1\rangle=r_1|1\rangle+\cdots+r_m|m\rangle\in P(H_A^m)$ the matrix of the Hermitian linear form $\langle\phi_1|\rho|\phi_1\rangle$ with the basis $|1\rangle,\ldots,|n\rangle$ is $\Sigma_{i,j}r_ir_j^*\rho_{ij}$. Thus the *degenerating locus* are as follows.

Definition 1: We define

$$V_A^k(\rho)=\{|\phi_1\rangle\in P(H_A^m):\mathrm{rank}(\langle\phi_1|\rho|\phi_1\rangle)\leqslant k\}=\{(r_1,\ldots,r_m)\in CP^{m-1}:\mathrm{rank}(\Sigma_{i,j}r_ir_j^*\rho_{ij})\leqslant k\},\tag{4}$$

where $k=0,1,\ldots,n-1$. *Similarly* $V_B^k(\rho)\subseteq CP^{n-1}$, *where* $k=0,1,\ldots,m-1$, *can be defined.*

Example 1: Let $\rho=(1/mn)I_{mn}$ be the maximally mixed state, we easily have $V_A^k(\rho)=\{(r_1,\ldots,r_m):\mathrm{rank}(\Sigma r_ir_i^*I_n)\leqslant k\}=\varnothing$ for $k=0,1,\ldots,n-1$, where $*$ is the complex conjugate.

Example 2: Let $H=H_A^2\otimes H_B^n$, T_1,T_2 be 2 $n\times n$ matrices of rank $n-1$ such that the $n\times(2n)$ matrix (T_1,T_2) has rank n. Let T' be a $2n\times 2n$ matrix with 11 block T_1, 22 block T_2, 12 and 21 blocks 0. Its rows correspond to the orthogonal base $|11\rangle,\ldots,|1n\rangle,|21\rangle,\ldots,|2n\rangle$ of H. Let $\rho=(1/D)TT^\dagger$ (where D is a normalizing constant) be a mixed state on H. It is easy to check that ρ is of rank $2n-2$ and $V_A^{n-1}(\rho)=\{(r_1,r_2):r_1r_2=0\}$.

Let $H=H_A^m\otimes H_B^n\otimes H_C^l$. Take an orthogonal base of H, $|ijk\rangle$, where, $i=1,\ldots,m$, $j=1,\ldots,n$, and $k=1,\ldots,l$, and ρ is a mixed state on H. We represent the matrix of ρ in the base $\{|111\rangle,\ldots|11l\rangle,\ldots,|mn1\rangle,\ldots,|mnl\rangle\}$ as $\rho=(\rho_{ij,i'j'})_{1\leqslant i,i'\leqslant m,1\leqslant j,j'\leqslant n}$, and $\rho_{ij,i'j'}$ is a $l\times l$ matrix. Consider H as a bipartite system as $H=(H_A^m\otimes H_B^n)\otimes H_C^l$, then we have $V_{AB}^k(\rho)=\{(r_{11},\ldots,r_{mn})\in CP^{mn-1}:\mathrm{rank}(\Sigma r_{ij}r_{i'j'}^\dagger\rho_{ij,i'j'})\leqslant k\}$ defined as above. This set is actually the *degenerating locus* of the Hermitian bilinear form $\langle\phi_{12}|\rho|\phi_{12}\rangle$ on H_C^l for the given pure state $|\phi_{12}\rangle=\Sigma_{i,j}^{m,n}r_{ij}|ij\rangle\in P(H_A^m\otimes H_B^n)$. When the finer cut $A:B:C$ is considered, it is natural to take $|\phi_{12}\rangle$ as a separable pure state $|\phi_{12}\rangle=|\phi_1\rangle\otimes|\phi_2\rangle$, i.e., there exist $|\phi_1\rangle=\Sigma_ir_i^1|i\rangle\in P(H_A^m)$ and $|\phi_2\rangle=\Sigma_jr_j^2|j\rangle\in P(H_B^n)$ such that $r_{ij}=r_i^1r_j^2$. In this way the tripartite mixed state ρ is measured by tripartite separable pure states $|\phi_1\rangle\otimes|\phi_2\rangle\otimes|\phi_3\rangle$. Thus it is natural that we define $V_{A:B}^k(\rho)$ as follows. It is the *degenerating locus* of the bilinear form $\langle\phi_1\otimes\phi_2|\rho|\phi_1\otimes\phi_2\rangle$ on H_C^l.

Definition 2: Let $\phi: CP^{m-1} \times CP^{n-1} \to CP^{mn-1}$ *be the mapping defined by*

$$\phi(r_1^1, \ldots r_m^1, r_1^2, \ldots, r_n^2) = (r_1^1 r_1^2, \ldots, r_i^1 r_j^2, \ldots r_m^1 r_n^2) \tag{5}$$

(i.e., $r_{ij} = r_i^1 r_j^2$ *is introduced).*

Then $V_{A:B}^k(\rho)$ *is defined as the preimage* $\phi^{-1}(V_{AB}^k(\rho))$.

Similarly $V_{B:C}^k(\rho), V_{A:C}^k(\rho)$ can be defined. In the following statement we just state the result for $V_{A:B}^k(\rho)$. The conclusion holds similarly for other V's.

For the mixed state ρ on the multipartite system $H = H_{A_1}^{m_1} \otimes \cdots \otimes H_{A_k}^{m_k}$, we want to study the entanglement under the cut $A_{i_1}: A_{i_2}: \cdots : A_{i_l} : (A_{j_1} \cdots A_{j_{k-l}})$, where $\{i_1, \ldots, i_l\} \cup \{j_1, \ldots, j_{k-l}\} = \{1, \ldots, k\}$. We can define the set $V_{A_{i_1}: \cdots : A_{i_l}}^k(\rho)$ similarly.

It is obvious we have the following results about the "invariance" under local unitary transformations.

Theorem 1: *Let* $T = U_A \otimes U_B$, *where* U_A *and* U_B *are the unitary transformations on* H_A^m *and* H_B^n, *respectively. Then* $V_A^k(T(\rho)) = U_A^{-1}(V_A^k(\rho))$, *that is* $V_A^k(\rho)$ [*respectively,* $V_B^k(\rho)$] *is an "invariant" up to a linear transformation of* CP^{m-1} *of the mixed state* ρ *under local unitary transformations.*

Theorem 1′: *Let* $T = U_A \otimes U_B \otimes U_C$, *where* U_A, U_B, *and* U_C *are unitary transformations on* H_A^m, H_B^n, *and* H_C^l, *respectively. Then* $V_{A:B}^k(T(\rho)) = U_A^{-1} \times U_B^{-1}(V_{A:B}^k(\rho))$, *that is* $V_{A:B}^k(\rho)$ *is an "invariant" up to a linear transformation of* $CP^{m-1} \times CP^{n-1}$ *of the mixed state* ρ *under local unitary transformations.*

Theorem 1″: *Let* $T = U_{A_{i_1}} \otimes \cdots \otimes U_{A_{i_l}} \otimes U_{j_1 \cdots j_{k-l}}$, *where* $U_{A_{i_1}}, \ldots, U_{A_{i_l}}, U_{j_1 \cdots j_{k-l}}$ *are unitary transformations on* $H_{A_{i_1}}^{m_{i_1}}, \ldots, H_{A_{i_l}}^{m_{i_l}}$ *and* $(H_{A_{j_1}}^{m_{j_1}} \otimes \cdots \otimes H_{A_{j_{k-l}}}^{m_{j_{k-l}}})$, *respectively. Then* $V_{A_{i_1}: \cdots : A_{i_l}}^k(T(\rho)) = U_{A_{i_1}}^{-1} \times \cdots \times U_{A_{i_l}}^{-1}(V_{A_{i_1}: \cdots : A_{i_l}}^k(\rho))$.

Remark 1: Since $U_{A_{i_1}}^{-1} \times \cdots \times U_{A_{i_l}}^{-1}$ certainly preserves the standard Euclid metric of complex linear space and hence the (product) Fubini-Study metric of the product of projective complex spaces, all metric properties of $V_{A_{i_1}: \cdots : A_{i_l}}^k(\rho)$ are preserved when the local unitary transformations are applied to the mixed state ρ.

Moreover from the proof it is easy to see that all algebraic-geometric properties [since $V_A^k(\rho)$, $V_B^k(\rho)$ are algebraic sets as proved in Theorem 2] of $V_A^k(\rho)$ [respectively, $V_B^k(\rho)$] are preserved even under local linear inversible transformations (i.e., $T = T_A \otimes T_B$ where T_A, T_B are just linear inversible operators of H_A^m, H_B^n)

We observe $V_A^k(\rho^{\mathrm{PT}}) = (V_A^k(\rho))^*$, here * is the conjugate mapping of CP^{m-1} defined by $(r_1, \ldots, r_m)^* = (r_1^*, \ldots, r_m^*)$. It is clear that this property holds for other V's invariants.

Theorem 2: $V_A^k(\rho)$ [*respectively*, $V_B^k(\rho)$] *is an algebraic set in* CP^{m-1} (*respectively*, CP^{n-1}).

From Definition 2 and Theorem 2 we immediately have the following result.

Theorem 2′: $V_{A:B}^k(\rho)$ *is an algebraic set in* $CP^{m-1} \times CP^{n-1}$.

The general result can be stated as follows.

Theorem 2″: $V_{A_{i_1}: \cdots : A_{i_l}}^k(\rho)$ *is an algebraic set in* $CP^{m_{i_1}-1} \times \cdots \times CP^{m_{i_l}-1}$.

It is easy to see from Definitions that we just need to prove Theorem 2.

Theorem 3: *If* ρ *is a separable mixed state,* $V_A^k(\rho)$ [*respectively*, $V_B^k(\rho)$] *is a linear subset in* CP^{m-1} (*respectively*, CP^{n-1}), *i.e., it is a union of the linear subspaces.*

In the following statement we give the separability criterion of the mixed state ρ under the cut $A:B:C$. The "linear subspace of $CP^{m-1} \times CP^{n-1}$" means the product of a linear subspace in CP^{m-1} and a linear subspace in CP^{n-1}.

Theorem 3′: *If* ρ *is a separable mixed state on* $H = H_A^m \otimes H_B^n \otimes H_C^l$ *under the cut* $A:B:C$, $V_{A:B}^k(\rho)$ *is a linear subset in* $CP^{m-1} \times CP^{n-1}$, *i.e., it is a union of the linear subspaces.*

The general result can be stated as follows.

Theorem 3″: *If* ρ *is a separable mixed state on* $H = H_{A_1}^{m_1} \otimes \cdots \otimes H_{A_k}^{m_k}$ *under the cut* $A_{i_1}: A_{i_2}: \cdots : A_{i_l} : (A_{j_1} \cdots A_{j_{k-l}})$, $V_{A_{i_1}: \cdots : A_{i_l}}^k(\rho)$ *is a linear subset in* $CP^{m_{i_1}-1} \times \cdots \times CP^{m_{i_l}-1}$, *i.e., it is a union of the linear subspaces.*

We just proved Theorem 3 and Theorem 3′. The proof of Theorem 3″ is similar.

For the purpose to prove Theorems 2 and 3 we need the following lemmas.

Lemma 1: Let $\{e_1,\ldots,e_h\}$ *be an orthogonal base of a h dimension Hilbert space H,* $\rho=\Sigma_{l=1}^{t}p_lP_{v_l}$, *where* v_l *is unit vector in H for* $l=1,\ldots,t$, $v_l=\Sigma_{k=1}^{h}a_{kl}e_k$, *and* $A=(a_{kl})_{1\leqslant k\leqslant h,1\leqslant l\leqslant t}$ *is the* $h\times t$ *matrix. Then the matrix of* ρ *with the base* $\{e_1,\ldots,e_h\}$ *is* $APA^{\dagger}$, *where P is the diagonal matrix with diagonal entries* $p_1,\ldots,p_t$.

Proof: We note that the matrix of P_{v_l} with the basis is $\alpha_l\alpha_l^{\dagger}$ where $\alpha_l=(a_{1l},\ldots,a_{hl})^{\tau}$ is just the expansion of v_l with the basis. The conclusion follows immediately.

The following conclusion is a direct matrix computation from Lemma 1 or see Ref. 24.

Corollary 1: Suppose $p_i>0$, *then the image of* ρ *is the linear span of vectors* $v_1,\ldots,v_t$.

From Corollary 1 it is clear that the ranges of the separable mixed states and its partial transposition are the linear span of separable pure states. This is the so-called range criterion of Horodecki (see Refs. 24 and 28).

Now let H be the $H_A^m\otimes H_B^n$, $\{e_1,\ldots,e_{mn}\}$ be a orthogonal bases $\{|11\rangle,\ldots,|1n\rangle,\ldots,|m1\rangle,\ldots,|mn\rangle\}$ and $\rho=\Sigma_{l=1}^{t}p_lP_{v_l}$ with positive p_l's be a mixed state on H. We may consider the $mn\times t$ matrix A as a $m\times 1$ blocked matrix with each block A_w, where $w=1,\ldots,m$, a $n\times t$ matrix corresponding to $\{|w1\rangle,\ldots,|wn\rangle\}$. Then it is easy to see $\rho_{ij}=A_iPA_j^{\dagger}$, where $i=1,\ldots,m$, $j=1,\ldots,m$. Thus

$$\Sigma r_ir_j^{*}\rho_{ij}=(\Sigma r_iA_i)P(\Sigma r_iA_i)^{\dagger}. \tag{6}$$

Lemma 2: $\Sigma r_ir_j^{*}\rho_{ij}$ *is a (semi) positive definite* $n\times n$ *matrix. Its rank equals the rank of* (Σr_iA_i).

Proof: The first conclusion is clear. The matrix $\Sigma r_ir_j^{*}\rho_{ij}$ is of rank k if and only if there exist $n-k$ linear independent vectors $c^j=(c_1^j,\ldots,c_n^j)$ with the property,

$$c^j(\Sigma_{ij}r_ir_j^{*}\rho_{ij})(c^j)^{*}=(\Sigma_i r_ic^jA_i)P(\Sigma_i r_ic^jA_i)^{\dagger}=0. \tag{7}$$

Since P is a strictly positive definite matrix, our conclusion follows immediately.

Proof of Theorem 2: From Lemma 1, we know that $V_A^k(\rho)$ is the zero locus of all determinants of $(k+1)\times(k+1)$ submatrices of (Σr_iA_i). The conclusion is proved.

Because the determinants of all $(k+1)\times(k+1)$ submatrices of (Σr_iA_i) are homogeneous polynomials of degree $k+1$, thus $V_A^k(\rho)$ [respectively, $V_B^k(\rho)$] is an algebraic subset (called determinantal varieties in algebraic geometry[16,17]) in CP^{m-1} [respectively, CP^{n-1}].

The point here is for different representations of ρ as $\rho=\Sigma_j p_jP_{v_j}$ with p_j's positive real numbers, the determinantal varieties from their corresponding $\Sigma_i r_iA_i$'s are the same.

Now suppose that the mixed state ρ is separable, i.e., there are unit product vectors $a_1\otimes b_1,\ldots,a_s\otimes b_s$ such that $\rho=\Sigma_{l=1}^{s}q_lP_{a_l\otimes b_l}$, where $q_1,\ldots,q_s$ are positive real numbers. Suppose $a_u=a_u^1|1\rangle+\cdots+a_u^m|m\rangle$, $b_u=b_u^1|1\rangle+\cdots+b_u^n|n\rangle$ for $u=1,\ldots,s$. Hence the vector representation of $a_u\otimes b_u$ with the standard basis is $a_u\otimes b_u=\Sigma_{ij}a_u^ib_u^j|ij\rangle$. Consider the corresponding $mn\times s$ matrix C of $a_1\otimes b_1,\ldots,a_s\otimes b_s$ as in Lemma 1, we have $\rho=CQC^{\dagger}$, where Q is diagonal matrix with diagonal entries $q_1,\ldots,q_s$. As before we consider C as $m\times 1$ blocked matrix with blocks C_w, $w=1,\ldots,m$. Here C_w is a $n\times s$ matrix of the form $C_w=(a_j^wb_j^i)_{1\leqslant i\leqslant n,1\leqslant j\leqslant s}=BT_w$, where $B=(b_j^i)_{1\leqslant i\leqslant n,1\leqslant j\leqslant s}$ is a $n\times s$ matrix and T_w is a diagonal matrix with diagonal entries $a_1^w,\ldots,a_s^w$. Thus from Lemma 1, we have $\rho_{ij}=C_iQC_j^{\dagger}=B(T_iQT_j^{\dagger})B^{\dagger}=BT_{ij}B^{\dagger}$, where T_{ij} is a diagonal matrix with diagonal entries $q_1a_1^i(a_1^j)^{\dagger},\ldots,q_sa_s^i(a_s^j)^{\dagger}$.

Proof of Theorem 3: As in the proof of Theorem 2, we have

$$\Sigma r_ir_j^{\dagger}\rho_{ij}=\Sigma r_ir_j^{\dagger}BT_{ij}B^{\dagger}=B(\Sigma r_ir_j^{\dagger}T_{ij})B^{\dagger}. \tag{8}$$

Here we note $\Sigma r_ir_j^{\dagger}T_{ij}$ is a diagonal matrix with diagonal entries $q_1(\Sigma r_ia_1^i)\times(\Sigma r_ia_1^i)^{\dagger},\ldots,q_s(\Sigma r_ia_s^i)(\Sigma r_ia_s^i)^{\dagger}$. Thus $\Sigma r_ir_j^{*}\rho_{ij}=BGQG^{\dagger}B^{\dagger}$, where G is a diagonal matrix with diagonal entries $\Sigma r_ia_1^i,\ldots,\Sigma r_ia_s^i$. Because Q is a strictly positive definite matrix, from Lemma 1 we know that $\Sigma r_ir_j^{\dagger}\rho_{ij}$ is of rank smaller than $k+1$ if and only if the rank of BG is strictly smaller than $k+1$. Note that BG is just the multiplication of s diagonal entries of G (which are linear forms

of $r_1,\ldots,r_m$) on the s columns of B, thus the determinants of all $(k+1)\times(k+1)$ submatrices of BG (in the case $s\geqslant k+1$, otherwise automatically linear) are the multiplications of a constant (possibly zero) and $k+1$ linear forms of $r_1,\ldots,r_m$. Thus the conclusion is proved.

From Lemma 1 and the proof of Theorems 2 and 3, $\Sigma_i r_i A_i$ play a key role. If we take the standard $\rho=\Sigma_{j=1}^{r} p_j P_{\varphi_j}$, where $p_j,\varphi_j, j=1,\ldots,r$ are eigenvalues and eigenvectors, the corresponding $\Sigma_i r_i A_i$ measures the *geometric positions* of eigenvectors in $H_A^m\otimes H_B^n$. It is obvious from the proof of Theorem 2, the invariants defined in Definition 1 are independent of $p_1,\ldots,p_r$, the global eigenvalue spectra of the mixed states.

Proof of Theorem 3′: We first consider the separability of ρ under the cut $AB:C$, i.e., $\rho=\Sigma_{f=1}^{g} p_f P_{a_f\otimes c_f}$, where $a_f\in H_A^m\otimes H_B^n$ and $c_f\in H_C^l$ for $f=1,\ldots,g$. Consider the separability of ρ under the cut $A:B:C$, we have $a_f=a_f'\otimes a_f''$, $a_f'\in C_A^m, a_f''\in C_B^m$. Let $a_f=(a_f^1,\ldots,a_f^{mn})$, $a_f'=(a_f'^1,\ldots,a_f'^m)$, and $a_f''=(a_f''^1,\ldots,a_f''^n)$ be the coordinate forms with the standard orthogonal basis $\{|ij\rangle\}$, $\{|i\rangle\}$, and $\{|j\rangle\}$, respectively, we have that $a_f^{ij}=a_f'^i a_f''^j$. Recall the proof of Theorem 3, the diagonal entries of G in the proof of Theorem 3 are

$$\Sigma_{ij} r_{ij} a_f^{ij}=\Sigma_{ij} r_i^1 a_f'^i r_j^2 a_f''^j=(\Sigma_i r_i^1 a_f'^i)(\Sigma_j r_j^1 a_f''^j). \tag{9}$$

Thus as argued in the proof of Theorem 3, $V_{A:B}^k(\rho)$ must be the zero locus of the multiplications of the linear forms in (9). The conclusion is proved.

III. NUMERICAL INVARIANTS

It is a standard fact in algebraic geometry that V's defined in Sec. II are the sum of irreducible algebraic varieties (components). Suppose $V_A^k(\rho)=V_1\cup\cdots\cup V_t$. From Theorem 1 and Remark 1, we know that t is a numerical invariant of ρ when local linear inversible transformations are applied to ρ. Actually, since there are a lot of numerical algebraic-geometric invariants of these components, e.g., dimensions, cohomology classes [represented by V_i's in $H^*(CP^{m-1})$], cohomology rings of V_i's, etc. We can get many numerical invariants of the mixed state when local linear inversible transformations are applied to them. In this way, we get a very powerful tool of numerical invariants to distinguish the entangled classes of the mixed states in composite quantum systems.

On the other hand, if local unitary transformations are applied to the mixed states, it is known that even the metric properties of V's (the metric on V is from the standard Fubini-Study metric of projective spaces) are invariant. Thus any complex differential geometric quantity, such as the volumes of V_i's, the integrations (over the whole component) of some curvature functions of V_i's, are the invariants of the mixed states under local unitary transformations.

For any given pure state $|v\rangle$ on a bipartite quantum system, $|v\rangle\in H_A^m\otimes H_B^n$, there exist orthogonal basis $|\phi_1\rangle,\ldots,|\phi_m\rangle$ of H_A^m and orthogonal basis $|\psi_1\rangle,\ldots,|\psi_n\rangle$ of H_B^n, such that $|v\rangle=\lambda_1|\phi_1\rangle\otimes|\psi_1\rangle+\cdots+\lambda_d|\phi_d\rangle\otimes|\psi_d\rangle$, where $d\leqslant\min\{m,n\}$. This is Schmidt decomposition (see Ref. 39). It is clear that d is an invariant under local unitary transformations. This number is called the Schmidt rank of the pure state $|v\rangle$. It is clear that $|v\rangle$ is separable if and only if its Schmidt rank is 1. Schmidt rank of pure states on a bipartite quantum system is a classical concept in the theory of quantum entanglement, it is actually the codimension of the invariant $V_A^0(\rho)$ for the pure state $\rho=P_{|v\rangle}$.

Let $\rho=P_{|v\rangle}$ be a pure state on $H_A^m\otimes H_B^n$ with $m\leqslant n$. From Theorem 1 about the invariance of $V_A^0(\rho)$, we can compute it from its Schmidt decomposition $|v\rangle=\Sigma_{i=1}^{d}\lambda_i|\phi_i\rangle\otimes|\psi_i\rangle$. It is clear that $V_A^0(\rho)=\{(r_1,\ldots,r_m)\in CP^{m-1}:(\lambda_1 r_1,\ldots,\lambda_d r_d,0,\ldots,0)^\tau=0\}$.

Proposition 1: For the pure state $\rho=P_{|v\rangle}$, $d=m$ *if and only if* $V_A^0(\rho)=\varnothing$ *and* $d=m-1-dim(V_A^0(\rho))=n-1-dim(V_B^0(\rho))$ *if* $d\leqslant m-1$.

In this way we show that the Schmidt rank of a pure state is just the codimension of the algebraic set, and thus it seems interesting to study the quantity $m-1-\dim(V_A^k(\rho))$ for mixed states, since it is nonlocal invariant and the generalization of the classical concept of Schmidt rank of pure states.[14,42]

IV. EXAMPLES

Now we give some examples to show how to use Theorems 1, 2, and 3 to construct and distinguish the entangled classes of the mixed states.

Example 3: Let $H=H_A^m\otimes H_B^n$ and $\rho_{a_1,\ldots,a_n}=(1/n)(\Sigma_{i=1}^n P_{a_i\otimes|i\rangle})$, where a_i, $i=1,\ldots,n$, are unit vectors in H_A^m. This is a rank n separable mixed state. Suppose $a_i=(a_i^1,\ldots,a_i^m)$, $i=1,\ldots,n$, the expansion with respect to the standard basis $|1\rangle,\ldots,|m\rangle$ of H_A^m. Let $l_i(r_1,\ldots,r_m)=a_i^1r_1+\cdots+a_i^mr_m$ for $i=1,\ldots,n$ be n linear forms. It is easy to check that $V_A^{n-1}(\rho)=\{(r_1,\ldots,r_m):l_1\cdots l_n=0\}$.

Proposition 2: The mixed states $\rho_{a_1,\ldots,a_n}$ and $\rho_{b_1,\ldots,b_n}$ are equivalent under the local unitary transformations if and only if there exists a unitary transformation U_A on H_A^m such that the n vectors $b_1,\ldots,b_n$ are exactly $U_A(a_1),\ldots,U_A(a_n)$, i.e., $b_i=U_A(a_{i_j})$, where $\{i_1,\ldots,i_n\}=\{1,\ldots,n\}$.

Proof: The "if" part is clear. Let $l_i'(r_1,\ldots,r_m)=b_i^1r_1+\cdots+b_i^mr_m$ for $i=1,\ldots,n$. Then $V_A^{n-1}(\rho_{a_1,\ldots,a_n})$ [respectively, $V_A^{n-1}(\rho_{b_1,\ldots,b_n})$] are the union of n hyperplanes defined by $l_i=0$ (respectively $l_i'=0$) for $i=1,\ldots,n$. It should be noted here that these hyperplanes are counted with multiplicities. From Theorem 1 we get the conclusion.

Segre variety $\Sigma_{n,m}$, which is the image of the following map, $\sigma:CP^n\times CP^m\to CP^{(n+1)(m+1)-1}$ where $\sigma([X_0,\ldots,X_n],[Y_0,\ldots,Y_m])=[\ldots,X_iY_j,\ldots]$, is a famous determinantal variety (see Ref. 23, pp. 25 and 26). It is clear that Segre variety is irreducible and not a linear subvariety. We consider the Segre variety $\Sigma_{1,m}$ in the case $n=1$, actually $\Sigma_{1,m}=\{(r_1,\ldots,r_{2n}):\mathrm{rank}(M)\leqslant 1\}$ where M is the following matrix:

$$\begin{pmatrix} r_1 & r_2 & \cdots & r_n \\ r_{n+1} & r_{n+2} & \cdots & r_{2n} \end{pmatrix}. \tag{10}$$

Example 4 (entangled mixed state from Segre variety): Let $H=H_A^{2m}\otimes H_B^2$, $|\phi_i\rangle=(1/\sqrt{2})(|i1\rangle+|(m+i)2\rangle)$ for $i=1,\ldots,m$ and $\rho=(1/m)(P_{|\phi_1\rangle}+\cdots+P_{|\phi_m\rangle})$. This is a mixed state of rank m. By computing $\Sigma_i r_iA_i$ as in the proof of Theorem 2, we get $V_A^1(\rho)=\Sigma_{1,m}$. Thus ρ is an entangled mixed state.

The rank 1 locus $X_{l,n-l-1}=\{\mathrm{rank}(R)\leqslant 1\}$ of the following $2\times(n-1)$ matrix R:

$$\begin{pmatrix} r_0 & \ldots & r_{l-1} & r_{l+1} & \ldots & r_{n-1} \\ r_1 & \ldots & r_l & r_{l+2} & \ldots & r_n \end{pmatrix}$$

is the rational normal scroll (see p. 106 of Ref. 23). The mixed states corresponding to them are as follows.

Example 5 (entangled mixed state from rational normal scroll): Let $H=H_A^{n+1}\otimes H_B^2$ and $|\phi_1\rangle=(1/\sqrt{2})(|01\rangle+|12\rangle),\ldots,|\phi_i\rangle=(1/\sqrt{2})(|(i-1)1\rangle+|i2\rangle),\ldots,|\phi_l\rangle=(1/\sqrt{2})(|(l-1)1\rangle+|l2\rangle),|\phi_{l+1}\rangle=(1/\sqrt{2})(|(l+1)1\rangle+|(l+2)2\rangle),\ldots,|\phi_j\rangle=(1/\sqrt{2})(|j1\rangle+|(j+1)2\rangle),\ldots,|\phi_{n-1}\rangle=(1/\sqrt{2})(|(n-1)1\rangle+|n2\rangle)$. We consider the mixed state $\rho_l=[1/(n-1)](P_{|\phi_1\rangle}+\cdots+P_{|\phi_{n-1}\rangle})$ of rank $n-1$ on H. It is clear from Sec. II that $V_A^1(\rho)=X_{l,n-l-1}\subset CP^n$. From the well-known fact in algebraic geometry (see pp. 92 and 93 of Ref. 23) we have the following result.

Proposition 3. The mixed states $\rho_l, l=1,\ldots,[(n-1)/2]$ are entangled and ρ_l and $\rho_{l'}$ for $l\neq l'$ are not equivalent under local unitary transformations.

We need to recall a well-known result in the theory of determinantal varieties (see Proposition on p. 67 of Ref. 8). Let $M(m,n)=\{(x_{ij}):1\leqslant i\leqslant m,1\leqslant j\leqslant n\}$ (isomorphic to CP^{mn-1}) be the projective space of all $m\times n$ matrices. For an integer $0\leqslant k\leqslant min\{m,n\}$, $M(m,n)_k$ is defined as the locus $\{A=(x_{ij})\in M(m,n):\mathrm{rank}(A)\leqslant k\}$. $M(m,n)_k$ is called generic determinantal varieties.

Proposition 4: $M(m,n)_k$ is an irreducible algebriac subvariety of M of codimension $(m-k)\times(n-k)$.

Suppose $m\leqslant n$, we now construct a mixed state ρ with $V_A^{m-1}(\rho)=M(m,n)_{(m-1)}$.

Example 6 (generic entangled mixed state): Let $H=H_A^{mn}\otimes H_B^m$, where $m\leqslant n$, and A_{ij}, $i=1,\ldots,m$, $j=1,\ldots n$ be $m\times n$ matrix with only nonzero entry at ij position equal to 1. Let A be a blocked $mn\times 1$ matrix with ij block A_{ij}. Here the kth row of A_{ij} in A corresponds to the vector $|(ij)k\rangle$ in the standard basis of H. Hence A is a size $m^2n\times n$ matrix. Let $\rho=(1/D)AA^\dagger$ be a mixed

state on H. (Here D is a normalizing constant.) It is a rank n mixed state.

It is easy to compute $\Sigma_{ij} r_{ij} A_{ij} = (r_{ij})_{1 \leqslant i \leqslant m, 1 \leqslant j \leqslant n}$ (up to a constant). Thus we have $V_A^{m-1}(\rho) = M(m,n)_{(m-1)}$. From Proposition 4 and Theorem 3, ρ is an entangled mixed state.

Example 7: Let $H = H_A^m \otimes H_B^n \otimes H_C^m$, $|\phi_l\rangle = (1/m)\Sigma_{i=1}^m |ili\rangle$ for $l = 1, \ldots, n$ and $\rho = (1/n)(P_{|\phi_1\rangle} + \cdots + P_{|\phi_n\rangle})$ be a rank n mixed state on H. It is clear that under the cut $B:AC$, ρ is separable. However, under the cut $AB:C$, we can check that ρ is just the mixed state in Example 6 and thus entangled. Similarly under the cut $A:BC$, ρ is also the mixed state in Example 6 and thus entangled. Hence this is a mixed state on tripartite quantum system with the property that it is separable under $B:AC$ cut and entangled under $AB:C$ and $A:BC$ cuts.

Example 8 (entangled mixed states from Eisenbud theorem (Ref. 17): Let $H = H_A^h \otimes H_B^m$, where $h \geqslant nm - m + 2$ and $n \geqslant m$ are positive integers, A_i, $i = 1, \ldots, h$ be $m \times n$ matrix with the property: the space M of linear forms (of $r_1, \ldots, r_h$) span by the entries of $T(r_1, \ldots, r_h) = \Sigma_i r_i A_i$ is of dimension h. Let A be the $hm \times n$ matrix with ith block A_i. Here the kth row of A_i in A corresponds to the vector $|ik\rangle$ in the standard basis of H. Let $\rho = (1/D)AA^\dagger$ (D is a normalizing constant) be a (rank n) mixed state on H. From the proof of Theorem 2 we have $V_A^{m-1}(\rho) = \{(r_1, \ldots, r_h) : \mathrm{rank}(T(r_1, \ldots, r_h)) \leqslant m-1\}$. We observe that when $h = mn$ it is just the mixed state in Example 6.

Theorem 6: *ρ is an entangled mixed state.*

Proof: It is clear that $M(m,n)$ is 1-generic (see Ref. 17, p. 548). We can see that the space M has codimension [in $M(m,n)$] smaller or equal to $m-1$ (here $v = n$, $w = m$, $k = m-1$ as referred to Theorem 2.1 on p. 552 of Ref. 17). From definition it is clear that $V_A(\rho)$ is just M_{m-1}, which is reduced and irreducible and of codimension $n-m+1$ in $M(m,n)$ from Theorem 2.1 of Ref. 17. The conclusion is proved.

Eisenbud theorem (Theorem 2.1 in Ref. 17 and thus Theorem 6 here) gives us a general method to construct many entangled states of low ranks, since the condition about M is not a very strong restriction.

Example 9 (Bennett-DiVincenzo-Mor-Shor-Smolin-Terhal mixed state from UPB (Ref. 7)): Let $H = H_A^2 \otimes H_B^2 \otimes H_C^2$, $|\phi_+\rangle = (1/\sqrt{2})(|1\rangle + |2\rangle)$, $|\phi_-\rangle = (1/\sqrt{2})(|1\rangle - |2\rangle)$. Consider the linear subspace T spaned by the following four vectors $|1\rangle \otimes |2\rangle \otimes |\phi_+\rangle$, $|2\rangle \otimes |\phi_+\rangle \otimes |1\rangle$, $|\phi_+\rangle \otimes |1\rangle \otimes |2\rangle$, $|\phi_-\rangle \otimes |\phi_-\rangle \otimes |\phi_-\rangle$. Now P is the projection to the complementary space $T^\perp$ of T and $\rho = (1/D)P$ is a rank 4 PPT mixed state on H for any bipartite cut (see Ref. 7). It is proved in Ref. 7 that ρ is entangled under the cut $A:B:C$ (thus bound entanglement), however, it is separable under the cuts $A:BC, B:AC, C:AB$. Now we can compute its invariants $V_{AB}^1(\rho)$ and $V_{A:B}^1(\rho)$. It is easy to see from Theorem 3 that $V_{AB}^1(\rho)$ should be linear, however we can see that $V_{A:B}^1(\rho)$ is also linear from our computation below, though it is entangled under the cut $A:B:C$.

It is easy to check that the following four vectors $|010\rangle - |011\rangle$, $|100\rangle - |110\rangle$, $|001\rangle - |101\rangle$, $|000\rangle - |111\rangle$ are the base of $T^\perp$. Thus the matrix A is of the following form (with rows corresponding to $|000\rangle$, $|001\rangle$, $|010\rangle$, $|011\rangle$, $|100\rangle$, $|101\rangle$, $|110\rangle$, $|111\rangle$):

$$\begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix} \tag{11}$$

and $\Sigma_{ij} r_{ij} A_{ij}$ is of the following form:

$$\begin{pmatrix} r_{01} & r_{10} - r_{11} & 0 & r_{00} \\ -r_{01} & 0 & r_{00} - r_{10} & -r_{11} \end{pmatrix}. \tag{12}$$

Thus $V^1_{AB}(\rho)$ is the union of the following three points (1:1:0:0), (0:1:0:1), (0:0:1:0) in CP^3 and $V^1_{A:B}(\rho)$ is union of $CP^1\times(1:0)$, $(0:1)\times CP^1$, and $(1:0)\times(0:1)$ in $CP^1\times CP^1$.

V. GENERALIZED SMOLIN STATE

Smolin[40] introduced a rank 4 mixed state $\rho=\frac{1}{4}(P_{|v_1\rangle}+P_{|v_2\rangle}+P_{|v_3\rangle}+P_{|v_4\rangle})$ on 4-party quantum system $H^2_A\otimes H^2_B\otimes H^3_C\otimes H^2_D$, where

$$|v_1\rangle=\tfrac{1}{2}(|0000\rangle+|0011\rangle+|1100\rangle+|1111\rangle),$$

$$|v_2\rangle=\tfrac{1}{2}(|0000\rangle-|0011\rangle-|1100\rangle+|1111\rangle),$$

$$|v_3\rangle=\tfrac{1}{2}(|0101\rangle+|0110\rangle+|1001\rangle+|1010\rangle),$$

$$|v_4\rangle=\tfrac{1}{2}(|0101\rangle-|0110\rangle-|1001\rangle+|1010\rangle).$$

This mixed state ρ is a bound entangled state when four parties A,B,C,D are isolated.

The following example, which is a continuous family (depending on eight parameters) of mixed state on the four-party quantum system $H^2_A\otimes H^2_B\otimes H^2_C\otimes H^2_D$ separable for any 2:2 cut but entangled for any 1:3 cut (thus bound entangled mixed state when A,B,C,D are isolated), can be thought of as a generalization of Smolin's mixed state in Ref. 40. We prove that the generic members in this family of mixed states are not equivalent under local unitary transformations (Theorem 7 below).

Example 10: Let $H=H^2_A\otimes H^2_B\otimes H^2_C\otimes H^2_D$ and h_1,h_2,h_3,h_4 (understood as row vectors) be four mutually orthogonal unit vectors in C^4 and $a_1,a_2,a_3,a_4,a_5,a_6,a_7,a_8$ be eight nonzero real parameters satisfying $a_1a_8=a_2a_7=a_3a_6=a_5a_4$. Consider the 16×4 matrix T with 16 rows as $T=(a_1h_1^\tau,0,0,a_2h_2^\tau,0,a_3h_3^\tau,a_4h_4^\tau,0,0,a_5h_4^\tau,a_6h_3^\tau,0,a_7h_2^\tau,0,0,a_8h_1^\tau)^\tau$. Let $|\phi_1'\rangle$, $|\phi_2'\rangle$, $|\phi_3'\rangle$, $|\phi_4'\rangle$ be four vectors in H whose expansions with the basis $|0000\rangle$, $|0001\rangle$, $|0010\rangle$, $|0011\rangle$, $|0100\rangle$, $|0101\rangle$, $|0110\rangle$, $|0111\rangle$, $|1000\rangle$, $|1001\rangle$, $|1010\rangle$, $|1011\rangle$, $|1100\rangle$, $|1101\rangle$, $|1110\rangle$, $|1111\rangle$ are exactly the four columns of the matrix T. Let $\rho=(1/D)TT^\dagger$ (D is a normalizing constant) be the mixed states (matrix with respect to the standard base of H as above).

It is easy to check that when $h_1=(1/\sqrt{2})(1,1,0,0)$, $h_2=(1/\sqrt{2})(1,-1,0,0)$, $h_3=(1/\sqrt{2})\times(0,0,1,1)$, $h_4=(1/\sqrt{2})(0,0,1,-1)$ and all a_i's are 1, it is just the Smolin's mixed state in Ref. 40.

Now we prove that ρ is invariant under the partial transposes of the cuts $AB:CD,AC:BD,AD:BC$.

Let the "representation" matrix $T=(b^t_{ijkl})_{i=0,1,j=0,1,k=0,1,l=0,1,t=1,2,3,4}$ be the matrix with columns corresponding the expansions of $\phi_1,\phi_2,\phi_3,\phi_4$. Then we can consider that $T=(T_1,T_2,T_3,T_4)^\tau$ as a blocked matrix of size 4×1 with each block $T_{ij}=(b^t_{kl})_{k=0,1,l=0,1,=1,2,3,4}$ a 4×4 matrix, where $ij=00,01,10,11$. Because h_1,h_2,h_3,h_4 are mutually orthogonal unit vectors we can easily check that $T_{ij}T^\dagger_{i'j'}=T_{i'j'}T^\dagger_{ij}$ from the condition $a_1a_8=a_2a_7=a_3a_6=a_5a_4$. Thus it is invariant when the partial transpose of the cut $AB:CD$ is applied.

With the same methods we can check that ρ is invariant when the partial transposes of the cuts $AC:BD$, $AD:BC$ are applied. Hence ρ is PPT under the cuts $AB:CD$, $AC:BD$, $AD:BC$. Thus from a result in Ref. 31 which claims that the PPT mixed states on $H^m_T\otimes H^n_S$ with their ranks not bigger than $\max\{m,n\}$ are separable, we know ρ is separable under these cuts $AB:CD$, $AC:BD$, $AD:BC$.

Now we want to prove ρ is entangled under the cut $A:BCD$ by computing $V^1_{BCD}(\rho)$. From the previous arguments, we can check that $V^1_{BCD}(\rho)$ is the locus of the condition: $a_1h_1r_{000}+a_2h_2r_{011}+a_3h_3r_{101}+a_4h_4r_{110}$ and $a_7h_1r_{100}+a_8h_2r_{111}+a_5h_3r_{001}+a_6h_4r_{010}$ are linear dependent. This is equivalent to the condition that the matrix (8) is of rank 1,

$$\begin{pmatrix} a_7r_{100} & a_8r_{111} & a_5r_{001} & a_6r_{010}\\ a_1r_{000} & a_2r_{011} & a_3r_{101} & a_4r_{110}\end{pmatrix}.$$

From Ref. 23, pp. 25 and 26 we can check that $V^1_{BCD}(\rho)$ is exactly the famous Segre variety in algebraic geometry. It is irreducible and thus cannot be linear. From Theorem 3, ρ is entangled under the cut $A:BCD$. Similarly we can prove that ρ is entangled under the cuts $B:ACD$, $C:ABD$, $D:ABC$.

Now we compute $V^3_{A:B}(\rho)$. From the previous arguments and Definition 2, it is just the locus of the condition that the vectors $h_1(a_1r^1_0r^2_0+a_7r^1_1r^2_1)$, $h_3(a_3r^1_0r^2_1+a_5r^1_1r^2_0)$, $h_4(a_4r^1_0r^2_1+a_6r^1_1r^2_0)$, $h_2(a_2r^1_0r^2_0+a_8r^1_1r^2_1)$ are linear dependent. Since h_1,h_2,h_3,h_4 are mutually orthogonal unit vectors, we have

$$V^3_{A:B}(\rho)=\{(r^1_0,r^1_1,r^2_0,r^2_1)\in CP^1\times CP^1:\\ (a_1r^1_0r^2_0+a_7r^1_1r^2_1)(a_3r^1_0r^2_1+a_5r^1_1r^2_0)(a_4r^1_0r^2_1+a_6r^1_1r^2_0)(a_2r^1_0r^2_0+a_8r^1_1r^2_1)=0\}.$$

Set $\lambda_1=a_1/a_7=a_2/a_8$ and $\lambda_2=a_3/a_5=a_4/a_6$, we know that $V^3_{A:B}(\rho)$ is the union of V_1 and V_2 with multiplicity 2, where

$$V_1=\{(r^1_0,r^1_1,r^2_0,r^2_1)\in CP^1\times CP^1:r^1_0r^2_0-\lambda_1r^1_1r^2_1=0\},$$

$$V_2=\{(r^1_0,r^1_1,r^2_0,r^2_1)\in CP^1\times CP^1:r^1_0r^2_1-\lambda_2r^1_1r^2_0=0\}.$$

From Theorem 3 we know that ρ is entangled for the cut $A:B:CD$, $A:C:BD$, and $A:D:BC$ for generic parameters, since $r^1_0r^2_0+\lambda_1r^1_1r^2_1$, etc., cannot be factorized to two linear forms for generic λ_1. This provides another proof that the mixed state is entangled if the four parties are isolated.

Theorem 7: *The generic members in this continuous family of mixed states are inequivalent under the local unitary transformations on* $H=H^2_A\otimes H^2_B\otimes H^2_C\otimes H^2_D$.

Proof: From the above computation, $V^3_{A:B}(\rho_{\lambda_{1,2}})$ is the union of V_1 and V_2 with multiplicity 2. From Theorem 1′, if $\rho_{\lambda_{1,2}}$ and $\rho\lambda'_{1,2}$ are equivalent by a local operation, there must exist two fractional linear transformations T_1,T_2 of CP^1 such that $T=T_1\times T_2$ (acting on $CP^1\times CP^1$) transforms the two varieties V_1,V_2 of $\rho_{\lambda_{1,2}}$ to the two varieties V'_1,V'_2 of $\rho\lambda'_{1,2}$, i.e., $T(V_i)=V'_j$.

Introduce the inhomogeneous coordinates $x_1=r^1_0/r^1_1$, $x_2=r^2_0/r^2_1$. Suppose $T(V_i)=V'_i$ $i=1,2$ without loss of generality. Then we have $\lambda_1\lambda_2=1$. This means that there are some algebraic relations of parameters if the T exists. This implies that there are some algebraic relations on parameters if $\rho_{\lambda_{1,2}}$ and $\rho\lambda'_{1,2}$ are equivalent by local unitary transformations. Hence our conclusion follows immediately.

VI. NONEMPTY THEOREM

In this section, we prove that the algebraic set invariants introduced in Sec. II are not empty for low rank mixed states.

Theorem 8: *Let* $H=H^m_A\otimes H^n_B$ *be a bipartite quantum system and* ρ *is a rank* r *mixed state on* H *with* $r\leqslant m+n-2$. *Then* $V^{n-1}_A(\rho)$ *and* $V^{m-1}_B(\rho)$ *are not empty.*

Proof: We take "the standard representation" $\rho=\Sigma^r_{i=1}p_iP_{v_i}$, where $p_1,\ldots,p_r$, $v_1,\ldots,v_r$ are eigenvalues and eigenvectors of ρ and $r=\mathrm{rank}(\rho)$. Recall the proof of Theorem 2, $V^{n-1}_A(\rho)$ is the locus of the condition that $\Sigma_ir_tA_i$ (a $n\times r$ matrix) has its rank smaller than n. From Proposition 4 the variety of *generic* $n\times r$ matrices of rank less than or equal to $n-1$ has its codimension smaller or equal to $(n-(n-1))(r-(n-1))=r-n+1$, we know that the codimension of $V^{n-1}_A(\rho)$ in CP^{m-1} is smaller or equal to $r-n+1$. Hence $\dim(V_A(\rho))\geqslant m-1-r+n-1\geqslant 0$ and $V^{n-1}_A(\rho)$ is not empty. The conclusion for $V^{m-1}_B(\rho)$ can be proved similarly.

VII. A RELATION OF DETERMINANTS

As indicated in Sec. II, we can have the following statement from Lemma 2.

Theorem 9: *Let* $H=H^m_A\otimes H^n_B$ *be a bipartite quantum system and* $\rho=\Sigma^t_{l=1}p_lP_{v_l}=\Sigma^s_{l=1}q_lP_{v'_l}$ *be a mixed state with two "representations" as convex combinations of projections with* $p_1,\ldots,p_t,q_1,\ldots,q_s>0$. *Let* A *(respectively,* A'*) be the* $mn\times t$ *(respectively,* $mn\times s$*) matrix of*

vectors $v_1,\ldots,v_t$ *(respectively,* $v_1',\ldots,v_s'$*) in the standard basis* $|11\rangle,\ldots,|1n\rangle,\ldots,|m1\rangle,\ldots,|mn\rangle$ *as in Lemma 1. We represent A (respectively,* A'*) as* $m\times 1$ *blocked matrix with blocks* $A_1,\ldots,A_m$ *(respectively,* $A_1',\ldots,A_m'$*). Then the determinantal varieties defined by the conditions that the ranks of* $R=\Sigma_i r_i A_i$ *and* $R'=\Sigma_i r_i A_i'$ *are smaller than* $k,k=0,1,\ldots,n-1$*, are the same.*

Actually we can get more information about the determinants of $n\times n$ submatrices of $\Sigma_i r_i A_i$ and $\Sigma_i r_i A_i'$ from the proof of Theorems 2 and 3. This relation seems to be helpful to extract information of ρ's one unknown "representation" from its another known "representation," as in the proof of Theorem 3.

Theorem 9′: *Let* $H,\rho,p_1,\ldots p_t,q_1,\ldots,q_s,A,A',R,R'$ *be as above and* $R_{i_1,\ldots i_n}$ *(respectively,* $R'_{i_1'},\ldots,i_n'$*) be the* $n\times n$ *submatrix of R (respectively,* R'*) consisting of* $i_1<\cdots<i_n$ *(respectively,* $i_1'<\cdots<i_n'$)th *columns, where* $i_1,\ldots,i_n\in\{1,\ldots t\}$ *and* $i_1',\ldots,i_n'\in\{1,\ldots,s\}$ *are distinct indices. Then we have*

$$\Sigma_{i_1<\cdots<i_n} p_{i_1}\cdots p_{i_n}|R_{i_1,\ldots,i_n}|^2=\Sigma_{i_1'<\cdots<i_n'} q_{i_1'}\cdots q_{i_n'}|R'_{i_1',\ldots,i_n'}|^2. \tag{13}$$

The above result follows from the following lemma immediately, since both sides of the equality are just $\det(\Sigma_{ij} r_i r_j^\dagger \rho_{ij})$.

Lemma 3 (Binet-Cauchy formula): Let B be a $n\times t$ *matrix with* $t>n$ *and* $B_{i_1,\ldots,i_n}$ *be the* $n\times n$ *submatrix of B consisting of* $i_1<\cdots<i_n$-th *columns. Then* $\det(BB^\dagger)=\Sigma_{i_1<\cdots<i_n}|\det B_{i_1,\ldots,i_n}|^2$.

It is clear that Theorems 2 and 3 follow from Theorem 8′ here immediately.

The following result was previously known in Refs. 29 and 31.

Proposition 5: Let $H=H_A^n\otimes H_B^n$, $\rho=(1/n)\Sigma_{i=1}^n p_i P_{a_i\otimes b_i}$ *where* $a_1,\ldots,a_n$ *(respectively,* $b_1,\ldots,b_n$*) are linearly independent unit vectors in* H_A^n *(respectively,* H_B^n*). Suppose that* $\rho=(1/t)\Sigma_{i=1}^t q_i P_{c_i\otimes d_i}$ *is another representation of* ρ *as a convex combination with* q_i*'s positive, then actually we have* $t=n$ *and* $\{a_1\otimes b_1,\ldots,a_n\otimes b_n\}=\{c_1\otimes d_1,\ldots,c_n\otimes d_n\}$.

Proof: We apply Theorem 9′ to the 2 "representations" here. First of all, we know that $\det(\Sigma_{ij} r_i r_j^\dagger \rho_{ij})$ is (up to a nonzero constant) the square of the absolute value of a multiplication of linear forms $b_i(r_1,\ldots,r_n)=\Sigma_j b_1^j r_j$, where $b_i=\Sigma_j b_i^j|j\rangle$ is the coordinate form of b_i for $i=1,\ldots,n$, from one known "representation." Thus we know from Theorem 8′ that there are at least n vectors in $\{d_1,\ldots,d_t\}$, without loss of generality, suppose they are $d_1,\ldots,d_n$, are just $b_1,\ldots,b_n$. Using Theorem 9′ for the second factor and consider the first through nth columns of R', this implies that the multiplication of the linear forms $c_1(r_1,\ldots,r_n),\ldots,c_n(r_1,\ldots,r_n)$ are just the multiplication of the linear forms $a_1(r_1,\ldots,r_n),\ldots,a_n(r_1,\ldots,r_n)$. Hence we know that the set $\{c_1,\ldots,c_n\}$ are just the set $\{a_1,\ldots,a_n\}$.

On the other hand, it is easy to see that $a_i\otimes b_j$ with $i\neq j$ is not in the linear span of $a_1\otimes b_1,\ldots,a_n\otimes b_n$, since $a_1,\ldots,a_n$ (respectively, $b_1,\ldots,b_n$) are linear independent. Thus $c_i=a_i$ from Corollary 1.

Applying Theorem 9′ to other columns of R and R' by a similar argument, we have $c_j\in\{a_1,\ldots,a_n\}$ and $d_j\in\{b_1,\ldots,b_n\}$. Since $a_i\otimes b_j$ with $i\neq j$ cannot be in the image of ρ, $c_j\otimes d_j$ must be the form $a_{i_j}\otimes b_{i_j}$. The conclusion is proved.

Remark 2: If we compute $V_A^{n-1}(\rho)$ from the representation of ρ's standard form, i.e., linear sum of projections to its eigenvectors, it can be seen that our invariants defined in Sec. II are independent of eigenvalues ($p_1,\ldots,p_t$ in Sec. II). However the information of $p_1,\ldots,p_t$ or eigenvalues is certainly reflected in Theorem 9′ here. Thus Theorem 9′ might be more useful in determining whether a given mixed state is entangled or not, provided that we know how to extract sufficient information from Theorem 9′.

Remark 3: As shown in Example 1, our invariants might be an empty set for high rank mixed states, however it seems that Theorem 9′ is still useful in determining whether a given high rank mixed state is entangled or not in this case, provided that we know how to extract information from Theorem 9′.

VIII. SIMULATION OF HAMILTONIANS

Historically, the idea of simulating Hamiltonian (self-adjoint operators on the Hilbert space corresponding to the quantum system, see Ref. 39) time evolutions was the first motivation for quantum computation because of the famous paper of Feynman. Recently the ability of nonlocal Hamiltonians to simulate one another is a popular topic, which has applications in quantum control theory, quantum computation, and the task of generating entanglement. For the general treatment of this topic and the references, we refer to Ref. 5.

We say, for two bipartite Hamiltonians H and H' on $H_A^m \otimes H_B^n$, H' can be efficiently simulated by H with local unitary operations, write as $H' \prec_{LU} H$, if H' can be written as a convex combination of conjugates of H by local unitary operations, $H' = p_1(U_1 \otimes V_1)H(U_1 \otimes V_1)^\dagger + \cdots + p_s(U_s \otimes V_s)H(U_s \otimes V_s)^\dagger$, where $p_1, \ldots, p_s$ are positive real numbers such that $p_1 + \cdots + p_s = 1$, $U_1, \ldots, U_s$, and $V_1, \ldots, V_s$ are unitary operations on H_A^m and H_B^n, respectively. Here we use $\dagger$ for the adjoint. This is equivalent to the notion "infinitesimal simulation" in Ref. 5. In Ref. 5 it is shown that "local terms" like $I \otimes K_B$ and $K_A \otimes I$ are irrelevant to the simulation problem up to the second order, thus they considered the simulation problem for Hamiltonians without local terms' effect. Our definition here is more restricted without neglecting the local terms.

We can have the following necessary conditions about the simulation of semipositive Hamiltonians based on the algebraic set invariants introduced in Sec. II.

Theorem 10: *Let H and H' be two semipositive Hamiltonians on the bipartite quantum system $H_A^m \otimes H_B^n$. Suppose $H' \prec_{LU} H$, that is, H' can be simulated by H efficiently by using local unitary transformations. Then there are projective isomorphisms U_1 of CP^{m-1} and V_1 of CP^{n-1} such that $U_1(V_A^k(H')) \subset V_A^k(H)$ for $k = 0, \ldots, n-1$ and $V_1(V_B^k(H')) \subset V_B^k(H)$ for $k = 0, \ldots, m-1$.*

The following observation about the computation of $V_A^k(\rho)$ is the key point of the proof of Theorem 10 and Corollary 3. From Corollary 1 if $\rho = \Sigma_i^t p_i P_{v_i}$ with p_i's positive real numbers, the range of ρ is the linear span of vectors $v_1, \ldots, v_t$. We take some vectors in the set $\{v_1, \ldots, v_t\}$, say they are $v_1, \ldots, v_s$. Let B be the $mn \times s$ matrix with columns corresponding to the s vectors $v_1, \ldots, v_s$'s coordinates in the standard basis of $H_A^m \otimes H_B^n$. We consider B as $m \times 1$ blocked matrix with blocks $B_1, \ldots, B_m$ $n \times s$ matrix as in Sec. II. It is clear that $V_A^k(\rho)$ is an algebraic subset of the zero locus of the determinants of all $(k+1) \times (k+1)$ submatrices of $\Sigma_i^m r_i B_i$, since $\Sigma_i^m r_i B_i$ is a submatrix of $\Sigma_i^m r_i A_i$. On the other hand, if $v_1, \ldots, v_s$ are linear independent and $s = \dim(\text{range}(\rho))$, $V_A^k(\rho)$ is just the zero locus of the determinants of all $(k+1) \times (k+1)$ submatrices of $\Sigma_i^m r_i B_i$, since any column in $\Sigma_i r_i A_i$ is a linear combination of columns in $\Sigma_i r_i B_i$ [$\text{rank}(\Sigma_i r_i A_i) \leqslant k$ is equivalent to $\text{rank}(\Sigma_i r_i B_i) \leqslant k$].

Proof of Theorem 10: Suppose $H' \prec_{LU} H$, then there exist positive numbers $p_1, \ldots, p_s$ and local unitary transformations $U_1 \otimes V_1, \ldots, U_s \otimes V_s$, such that $\Sigma_i p_i U_i \otimes V_i H(U_i \otimes V_i)^\dagger = H'$. Let $H = \Sigma_i^s q_i P_{\psi_i}$, where $s = \dim(\text{range}(H))$, $q_1, \ldots, q_s$ are eigenvalues of H and $\psi_1, \ldots, \psi_s$ are eigenvectors of H. Then it is clear that $(U_i \otimes V_i)H(U_i \otimes V_i)^\dagger = \Sigma_j^s q_j P_{(U_i \otimes V_i)\psi_j}$ and thus $H' = \Sigma_{i,j} p_i q_j P_{(U_i \otimes V_i)\psi_j}$. This is a representation of H' as a convex combination of projections. From our above observation $V_A^k(H')$ is an algebraic subset in $V_A^k((U_1 \times V_1)H)$ [which can be computed from vectors $(U_1 \otimes V_1)\psi_1, \ldots, (U_1 \otimes V_1)\psi_s$]. Thus the conclusion follows from Theorem 1.

Corollary 3 (see Ref. 13): Let H and H' be two semipositive Hamiltonians on the bipartite quantum system $H_A^m \otimes H_B^n$ of the same rank, i.e., $\dim(\text{range}(H)) = \dim(\text{range}(H'))$. Suppose $H' \prec_{LU} H$, that is, H' can be simulated by H efficiently by using local unitary transformations. Then $V_A^k(H') = V_A^k(H)$ for $k = 0, \ldots, n-1$ and $V_B^k(H') = V_B^k(H)$ for $k = 0, \ldots, m-1$. Here the equality of the algebraic sets means they are isomorphic via projective linear transformations of complex projective spaces.

Proof: Suppose $H' \prec_{LU} H$, then there exist positive numbers $p_1, \ldots, p_s$ and local unitary transformations $U_1 \otimes V_1, \ldots, U_s \otimes V_s$, such that, $\Sigma_i p_i U_i \otimes V_i H(U_i \otimes V_i)^\dagger = H'$. Let $H = \Sigma_i^s q_i P_{\psi_i}$, where $s = \dim(\text{range}(H))$, $q_1, \ldots, q_s$ are eigenvalues of H and $\psi_1, \ldots, \psi_s$ are eigenvectors of H. Then it is clear that $(U_i \otimes V_i)H(U_i \otimes V_i)^\dagger = \Sigma_j^s q_j P_{(U_i \otimes V_i)\psi_j}$ and thus $H' = \Sigma_{i,j} p_i q_j P_{(U_i \otimes V_i)\psi_j}$. This is a representation of H' as a convex combination of projections. From our above observation $V_A^k(H')$ can be computed from vectors $(U_1 \otimes V_1)\psi_1, \ldots, (U_1 \otimes V_1)\psi_s$, since they are linear independent and s

$=\dim(\mathrm{range}(H'))$. Hence $V_A^k(H')=V_A^k((U_1\otimes V_1)H)$ from the definition. Thus the conclusion follows from Theorem 1.

Let S be the swap operator on the bipartite system $H_A^n\otimes H_B^n$ defined by $S|ij\rangle=|ji\rangle$. For any Hamiltonian H, $S(H)=SHS^\dagger$ corresponds to the Hamiltonian evolution of H with A and B interchanged. It is very interesting to consider the problem if H can be simulated by $S(H)$ efficiently. This led to some important consequences in the discussion VII of Ref. 5. For example it was shown there are examples that H and $S(H)$ cannot be simulated efficiently with one another in higher dimensions ($n\geqslant 3$). Thus in higher dimensions nonlocal degrees of freedom of Hamiltonians cannot be characterized by quantities that are symmetric with respect to A and B, such as eigenvalues. This conclusion is also obtained from our example and Corollary 5 in the next section. From Corollary 3 we have the following necessary condition about $H\prec_{LU}S(H)$.

Corollary 4: Let H be a semipositive Hamiltonian on $H_A^n\otimes H_B^n$. *Suppose* $H\prec_{LU}S(H)$. *Then* $V_A^k(H)=V_B^k(H)$ *for* $k=0,\ldots,n-1$.

The following is a Hamiltonian H on 3×3 system for which H cannot be simulated efficiently by $S(H)$.

Example 11: $H=P_{|\phi_1\rangle}+P_{|\phi_2\rangle}+P_{|\phi_3\rangle}$, where

$$|\phi_1\rangle=\frac{1}{\sqrt{3}}(|11\rangle+|21\rangle+|32\rangle),$$

$$|\phi_2\rangle=\frac{1}{\sqrt{1+|v|^2}}(|12\rangle+v|22\rangle), \tag{14}$$

$$|\phi_3\rangle=\frac{1}{\sqrt{1+|\lambda|^2}}(|13\rangle+\lambda|23\rangle).$$

Then it is easy to compute that $V_A^2(H)$ is the sum of three lines in CP^2 defined by $r_1+r_2=0$, $r_1+vr_2=0$, and $r_1+\lambda r_2=0$ for $v\neq\lambda$ and both v,λ are not 1, and $V_B^2(H)$ is the sum of 2 lines in CP^2 defined by $r_2=0$ and $r_3=0$. Thus we cannot have $H\prec_{LU}S(H)$.

IX. A CONTINUOUS FAMILY OF STATES AND HAMILTONIANS RELATED TO ELLIPTIC CURVES

From a physical point of view, it is very interesting to have isospectral [i.e., eigenvalues of $\rho,\mathrm{tr}_A(\rho),\mathrm{tr}_B(\rho)$ are the same] mixed states, but they are not equivalent under local unitary transformations. This phenomenon indicates that we cannot obtain a complete understanding of a bipartite quantum system by just studying the local and global properties of the spectra of the system. Some examples of such mixed states have been found by several authors (see Nielsen and Kempe[37] and references therein). Their result would imply the existence of continuously many isospectral no-local-equivalent mixed states. Here we give a continuous family of such mixed states by the theory of elliptic curves.[9]

Let $H=H_A^3\otimes H_B^3$ and $\rho_{\eta_1,\eta_2,\eta_3}=\frac{1}{3}(P_{|v_1\rangle}+P_{|v_2\rangle}+P_{|v_3\rangle})$ (η_1,η_2,η_3 are real parameters), a continuous family of mixed states on H, where

$$|v_1\rangle=\frac{1}{\sqrt{3}}(e^{i\eta_1}|11\rangle+|22\rangle+|33\rangle),$$

$$|v_2\rangle=\frac{1}{\sqrt{3}}(e^{i\eta_2}|12\rangle+|23\rangle+|31\rangle), \tag{15}$$

$$|v_3\rangle=\frac{1}{\sqrt{3}}(e^{i\eta_3}|13\rangle+|21\rangle+|32\rangle).$$

It is easy to calculate that Σr_iA_i (up to a constant) is the following 3×3 matrix:

$$\begin{pmatrix} e^{i\eta_1}r_1 & r_3 & r_2 \\ r_2 & e^{i\eta_2}r_1 & r_3 \\ r_3 & r_2 & e^{i\eta_3}r_1 \end{pmatrix}.$$

Thus $V_A^2(\rho_{\eta_1,\eta_2,\eta_3})$ is defined by $e^{i(\eta_1+\eta_2+\eta_3)}r_1^3+r_2^3+r_3^3-(e^{i\eta_1}+e^{i\eta_2}+e^{i\eta_3})r_1r_2r_3=0$ in CP^2. With $e^{i(\eta_1+\eta_2+\eta_3)/3}r_1=r_1'$ we have $r_1'^3+r_2^3+r_3^3-[(e^{i\eta_1}+e^{i\eta_2}+e^{i\eta_3})/(e^{i(\eta_1+\eta_2+\eta_3)/3})]r_1'r_2r_3=0$. This is a family of elliptic curves.

It is easy to check that three nonzero eigenvalues of $\rho_{\eta_1,\eta_2,\eta_3}, \mathrm{tr}_A(\rho_{\eta_1,\eta_2,\eta_3}), \mathrm{tr}_B(\rho_{\eta_1,\eta_2,\eta_3})$ are all the same value $\frac{1}{3}$ for different parameters. In this case we have a family of isospectral (both global and local) mixed states $\rho_{\eta_1,\eta_2,\eta_3}$. Set $g(\eta_1,\eta_2,\eta_3)=(e^{i\eta_1}+e^{i\eta_2}+e^{i\eta_3})/(e^{i(\eta_1+\eta_2+\eta_3)/3})$.

Theorem 11: *$\rho_{\eta_1,\eta_2,\eta_3}$ is entangled mixed state when $(g(\eta_1,\eta_2,\eta_3))^3\neq 27$. Moreover $\rho_{\eta_1,\eta_2,\eta_3}$ and $\rho_{\eta_1',\eta_2',\eta_3'}$ are not equivalent under local unitary transformations if $k(g(\eta_1,\eta_2,\eta_3))\neq k(g(\eta_1',\eta_2',\eta_3'))$, where $k(x)=x^3(x^3+216)^3/(-x^3+27)^3$ is the moduli function of elliptic curves.*

Proof: The conclusion follows from Theorem 3, Theorem 1 and the well-known fact about elliptic curves (see Ref. 9).

In Ref. 36 Nielsen gave a beautiful necessary and sufficient condition for the bipartite pure state $|\psi\rangle$ that can be transformed to the pure state $|\phi\rangle$ by local operations and classical communication (LOCC) based on the majorization between the eigenvalue vectors of the partial traces of $|\psi\rangle$ and $|\phi\rangle$. In Ref. 7 an example was given, from which we know that Nielsen's criterion cannot be generalized to multipartite case, **3EPR** and **2GHZ** are understood as pure states in a $4\times4\times4$ quantum system, they have the same eigenvalue vectors when traced over any subsystem. However it is proved that they are LOCC incomparable in Ref. 7.

In the following example, a continuous family $|\{\phi\}_{\eta_1,\eta_2,\eta_3}\rangle$ of pure states in tripartite quantum system $H_{A_1}^3\otimes H_{A_2}^3\otimes H_{A_3}^3$ is given, the eigenvalue vectors of $\mathrm{tr}_{A_i}(P_{|\phi_{\eta_1,\eta_2,\eta_3}\rangle}), \mathrm{tr}_{A_iA_j}(P_{|\phi_{\eta_1,\eta_2,\eta_3}\rangle})$ are independent of parameters η_1,η_2,η_3. However, the *generic* pure states in this family are entangled and LOCC incomparable. This gives stronger evidence that it is hopeless to characterize the entanglement properties of multipartite pure states by only using the eigenvalue spectra of their partial traces.

Let $H=H_{A_1}^3\otimes H_{A_2}^3\otimes H_{A_3}^3$ be a tripartite quantum system and $|\phi_{\eta_1,\eta_2,\eta_3}\rangle=(1/\sqrt{3})(|v_1\rangle\otimes|1\rangle+|v_2\rangle\otimes|2\rangle+|v_3\rangle\otimes|3\rangle)$, where $|v_1\rangle,|v_2\rangle,|v_3\rangle$ are as in (15). This is a continuous family of pure states in H parametrized by three real parameters. We can check that the eigenvalue vector of any partial trace of $P_{|\phi_{\eta_1,\eta_2,\eta_3}\rangle}$ is a constant vector. On the other hand, it is clear that $\mathrm{tr}_{A_3}(P_{|\phi_{\eta_1,\eta_2,\eta_3}\rangle})=\frac{1}{3}(P_{|v_1\rangle}+P_{|v_2\rangle}+P_{|v_3\rangle})$ is a rank 3 mixed state in $H_{A_1}^3\otimes H_{A_2}^3$. $|\phi_{\eta_1,\eta_2,\eta_3}\rangle$ and $|\phi_{\eta_1',\eta_2',\eta_3'}\rangle$ are not equivalent under local unitary transformations if $k(g(\eta_1,\eta_2,\eta_3))\neq k(g(\eta_1',\eta_2',\eta_3'))$, since their corresponding traces over A_3 are not equivalent under local unitary transformations of $H_{A_1}^3\otimes H_{A_2}^3$ from Theorem 11. Hence the *generic* members of this family of pure states in tripartite quantum system H are entangled and LOCC incomparable from Theorem 1 in Ref. 7.

We can also consider the following continuous family of semipositive Hamiltonians depending on three real parameters, $H_{\eta_1,\eta_2,\eta_3}=P_{|v_1\rangle}+P_{|v_2\rangle}+P_{|v_3\rangle}$, where v_1,v_2,v_3 are as in (15). As calculated above, $V_A^2(H_{\eta_1,\eta_2,\eta_3})$ is just the elliptic curve in CP^2 defined by $r_1^3+r_2^3+r_3^3-[(e^{i\eta_1}+e^{i\eta_2}+e^{i\eta_3})/(e^{i(\eta_1+\eta_2+\eta_3)/3})]r_1r_2r_3=0$. The elliptic curve $V_A^2(H_{\eta_1,\eta_2,\eta_3})$ is not isomorphic to the elliptic curve $V_A^2(H_{\eta_1',\eta_2',\eta_3'})$ if $k(g(\eta_1,\eta_2,\eta_3))\neq k(g(\eta_1',\eta_2',\eta_3'))$. Thus we have the following Corollary of Theorem 9.

Corollary 5: $H_{\eta_1',\eta_2',\eta_3'}$ cannot be simulated by H_{η_1,η_2,η_3} efficiently by using local unitary transformations, i.e., we cannot have $H_{\eta_1',\eta_2',\eta_3'}\prec_{LU}H_{\eta_1,\eta_2,\eta_3}$, if $k(g(\eta_1,\eta_2,\eta_3))\neq k(g(\eta_1',\eta_2',\eta_3'))$, though the three nonzero eigenvalues of H_{η_1,η_2,η_3}, $H_{\eta_1',\eta_2',\eta_3'}$ and their partial traces are all 1.

X. CONSTRUCTING ENTANGLED PPT MIXED STATES

As mentioned in the Introduction, the first several entangled PPT mixed states were constructed in Ref. 24 based on Horodecki's range criterion of separable states, which asserts that a separable mixed state must include sufficiently many *separable pure states* in its own range (see Refs. 24 and 28). This range criterion of separable mixed states was also the base to construct PPT entangled mixed states in the context of unextendible product base (UPB) studied by Bennett, DiVincenzo, Mor, Shor, Smolin, and Terhal in Ref. 6. (We should mention that unextendible product bases also have other physical significance *nonlocality without entanglement*, see Refs. 6 and 28.) It is always interesting and important to have more methods to construct entangled PPT mixed states. In this section, we give an example to show how our separability criterion Theorem 3 can be used to construct entangled mixed states which are invariant under partial transposition (thus PPT and bound entanglement) systematically.

In the following example we construct a family of rank 7 mixed states $\{\rho_{e_1,e_2,e_3}\}$ (e_1,e_2,e_3 are real parameters) with $\rho_{e_1,e_2,e_3}=\rho^{\mathrm{PT}}_{e_1,e_2,e_3}$ (hence PPT automatically) on $H=H_A^4\otimes H_B^6$. We prove that they are entangled by Theorem 3 (thus bound entanglement) for generic parameters e_1,e_2,e_3 and parameters $(e_1,e_2,e_3)=(0,0,1)$. This family and the method used here can be easily generalized to construct entangled mixed states with $\rho=\rho^{\mathrm{PT}}$ systematically.

Consider the following four 6×7 matrices:

$$A_1=\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 1 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 1 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 2 & 0 & 0 & 1\\ 0 & 0 & 0 & 0 & 2 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 2 & 0 \end{pmatrix},$$

$$A_2=\begin{pmatrix} 0 & 1 & 1 & -1 & 0 & 0 & 1\\ 1 & 0 & 1 & 0 & 0 & 0 & 0\\ 1 & 1 & 0 & 0 & 0 & 0 & 0\\ -1 & 0 & 0 & 0 & 1 & 1 & 0\\ 0 & 0 & 0 & 1 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 & 1 & 0 & 0 \end{pmatrix},$$

$$A_3=\begin{pmatrix} e_2+e_3 & e_1 & 0 & 0 & 0 & 0 & 0\\ e_1 & e_2 & e_3 & 0 & 0 & 0 & 0\\ 0 & e_3 & e_1+e_2 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & e_2+e_3 & e_1 & 0 & 0\\ 0 & 0 & 0 & e_1 & e_2 & e_3 & 0\\ 0 & 0 & 0 & 0 & e_3 & e_1+e_2 & 0 \end{pmatrix},$$

where e_1,e_2,e_3 are real parameters, and $A_4=(I_6,0)$, where I_6 is the 6×6 unit matrix.

Let A be a 24×7 matrix with four blocks A_1,A_2,A_3,A_4 where the 24 rows correspond to the standard basis $\{|11\rangle,\ldots,|16\rangle,\ldots,|41\rangle,\ldots,|46\rangle\}$. Let ρ_{e_1,e_2,e_3} be $(1/D)AA^\dagger$ (where D is a normalizing constant), a mixed state on H. It is easy to check that $A_iA_j^\dagger=A_jA_i^\dagger$, hence ρ_{e_1,e_2,e_3} is invariant under partial transposition and thus PPT.

Let $|\psi_1\rangle,\ldots,|\psi_7\rangle\in H_A^4\otimes H_B^6$ be seven vectors corresponding to seven columns of the matrix A. It is clear that the range of ρ_{e_1,e_2,e_3} is the linear span of $|\psi_1\rangle,\ldots,|\psi_7\rangle$. When $e_1=e_2=0$, $e_3=1$,

$|\psi_2\rangle - |\psi_3\rangle = (|1\rangle + |4\rangle - |2\rangle) \otimes (|2\rangle - |3\rangle)$. Thus there are some separable pure states in the range of $\rho_{0,0,1}$. We will show that $\rho_{0,0,1}$ and ρ_{e_1,e_2,e_3} for generic parameters e_1, e_2, e_3 are entangled by our separability criterion Theorem 3.

As in the proof of Theorem 2 it is easy to compute $F = r_1A_1 + r_2A_2 + r_3A_3 + r_4A_4$,

$$\begin{pmatrix} u_1 & r_2+e_1r_3 & r_2 & -r_2 & 0 & 0 & r_2 \\ r_2+e_1r_3 & u_1' & r_2+e_3r_3 & 0 & 0 & 0 & 0 \\ r_2 & r_2+e_3r_3 & u_1'' & 0 & 0 & 0 & 0 \\ -r_2 & 0 & 0 & u_2 & r_2+e_1r_3 & r_2 & r_1 \\ 0 & 0 & 0 & r_2+e_1r_3 & u_2' & r_2+e_3r_3 & 0 \\ 0 & 0 & 0 & r_2 & r_2+e_3r_3 & u_2'' & 0 \end{pmatrix} \tag{16}$$

where $u_1 = r_1 + r_4 + (e_2+e_3)r_3$, $u_1' = r_1 + r_4 + e_2r_3$, $u_1'' = r_1 + r_4 + (e_1+e_2)r_3$ and $u_2 = 2r_1 + r_4 + (e_2+e_3)r_3$, $u_2' = 2r_1 + r_4 + e_2r_3$, $u_2'' = 2r_1 + r_4 + (e_1+e_2)r_3$.

We consider the following matrix F' which is obtained by adding the seventh column of F to the fourth column of F and adding r_2/r_1 of the seventh column to the first column,

$$\begin{pmatrix} v_1 & r_2+e_1r_3 & r_2 & 0 & 0 & 0 & r_2 \\ r_2+e_1r_3 & u_1' & r_2+e_3r_3 & 0 & 0 & 0 & 0 \\ r_2 & r_2+e_3r_3 & u_1'' & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & v_2 & r_2+e_1r_3 & r_2 & r_1 \\ 0 & 0 & 0 & r_2+e_1r_3 & u_2' & r_2+e_3r_3 & 0 \\ 0 & 0 & 0 & r_2 & r_2+e_3r_3 & u_2'' & 0 \end{pmatrix}, \tag{17}$$

where $v_1 = r_1 + r_4 + (e_2+e_3)r_3 + (r_2^2/r_1)$, $v_2 = 3r_1 + r_4 + (e_2+e_3)r_3$.

It is clear that the determinantal varieties defined by F and F' are the same in the affine chart C^3 defined by $r_1 \neq 0$. Consider the zero locus Z_1 defined by the condition that the determinants of the two diagonal 3×3 submatrices of the first 6×6 submatrix in (17) are zero, locus Z_2 defined by the condition that the first three rows in (17) are linear dependent and the locus Z_3 defined by the condition that the last three rows in (17) are linear dependent, it is clear that $V_A^5(\rho_{e_1,e_2,e_3}) \cap C^3$ is the sum of Z_1, Z_2, Z_3. We can use the affine coordinates $r_2' = r_2/r_1$, $r_3' = r_3/r_1$, $r_4' = r_4/r_1$ on the affine chart C^3 of CP^3 defined by $r_1 \neq 0$. In this affine coordinate system all r_2, r_3, r_4 should be replaced by r_2', r_3', r_4' and r_1 should be replaced by 1 in (17). Now we analyze $V_A^5(\rho_{0,0,1})$. It is clear that the following two planes $H_1 = \{(r_2', r_3', r_4') : r_2' = r_4' + 1\}$, $H_2 = \{(r_2', r_3', r_4') : r_2' = r_4' + 2\}$ are in $V_A^5(\rho_{0,0,1}) \cap C^3$, since in the case $r_2' = r_4' + 1$ the second and the third rows of (17) are linearly dependent and in the case $r_2' = r_4' + 2$ the fifth and sixth rows of (17) are linearly dependent. The determinants of two 3×3 diagonal submatrices of the first 6×6 submatrix of (17) are

$$(r_2' - r_4' - 1)((r_2')^3 + (r_2')^2 r_4' - (r_2')^2 + (r_4')^2 + r_2'r_3' + r_2'r_4' + r_3'r_4' + r_2' + r_3' + 2r_4' + 1)$$

and

$$(r_2' - r_4' - 2)((r_4')^2 - 2(r_2')^2 + r_2'r_3' + r_2'r_4' + r_3'r_4' + 3r_2' + 2r_3' + 5r_4' + 6).$$

Let X_1 and X_2 be the zero locus of the second factors of the above two determinants. It is obvious that $X_1 \cap X_2$ is in $V_A^5(\rho_{0,0,1}) \cap C^3$, we want to show that $X_1 \cap X_2 \backslash H_1 \cup H_2$ is a curve, not a line. Take the point $P = (0, 2, -1) \in X_1 \cap X_2 \cap H_1$, the tangent plane H_3 of X_2 at P is defined by $4r_2' + r_3' + 5r_4' = -3$. If $X_1 \cap X_2$ is a line around the point P, this line is contained in $H_3 \cap X_2$. However we can easily find that $H_3 \cap X_2$ is defined by $3(r_2')^2 + 2(r_4')^2 + 4r_2'r_4' + 4r_4' = 0$. This polynomial is irreducible and thus $H_3 \cap X_2$ is a curve around the point P. Thus $X_1 \cap X_2$ is a curve around the point P. It is easy to check that $X_1 \cap X_2$ is not contained in H_1 around the point P. This implies that $V_A^5(\rho_{e_1,e_2,e_3}) \cap C^3$ (actually the locus Z_1) contains a curve (not a line) for generic parameters e_1, e_2, e_3 (including parameters 0,0,1) from algebraic geometry. Thus if $V_A^5(\rho_{e_1,e_2,e_3}) \cap C^3$ is the sum

of (affine) linear subspaces, it must contain a dimension 2 affine linear subspace H_4 other than H_1 and H_2 of the affine chart C^3. Thus the determinants of all 6×6 submatrices of (17) must contain a (fixed) affine linear form (i.e., a degree one polynomial of r_2, r_3, r_4 which may contain a constant term) other than r_2-r_4-1 and r_2-r_4-1 as one of their factors. This affine linear form defines that dimension 2 linear affine subspace H_4 of C^3. However it is easy to check that this is impossible for generic parameters e_1, e_2, e_3 (including parameters 0,0,1). We know that $V_A^5(\rho_{e_1,e_2,e_3})\cap C^3$ cannot be the sum of (affine) linear subspaces of C^3 for generic e_1, e_2, e_3 (including parameters 0,0,1). Thus from Theorem 3, ρ_{e_1,e_2,e_3} is entangled for generic parameters e_1, e_2, e_3 (including parameters 0,0,1).

Theorem 12: *The mixed states* ρ_{e_1,e_2,e_3}*'s, which are invariant under partial transposition, are entangled for generic parameters and* $(e_1, e_2, e_3)=(0,0,1)$.

Remark 4: $\rho_{0,0,1}$ is the first example of PPT entangled mixed state (thus bound entanglement) with some separable pure states in its range.

From the construction in this example we can see if $A_1, \ldots, A_m$ are $mn\times t$ matrices satisfying $A_iA_j^\dagger = A_jA_i^\dagger$, A is the $m\times 1$ matrix with ith block A_i and the rows of A correspond to the basis $|11\rangle, \ldots, |1n\rangle, \ldots, |m1\rangle, \ldots, |mn\rangle$ of $H_A^m\otimes H_B^n$, then the mixed state $\rho=(1/D)AA^\dagger$, where D is a normalized constant, is invariant under partial transpose. It is not very difficult to find such matrices. For the purpose that the constructed mixed state ρ is entangled (thus a bound entangled mixed state), we just need that the determinantal variety $\{(r_1, \ldots, r_m): \mathrm{rank}(\Sigma r_iA_i)\leqslant n-1\}$ is not linear. We know from algebraic geometry, it is not very hard to find such matrices $A_1, \ldots, A_m$. However, as illustrated in this Example we do need some explicit calculation to prove this point. Thus our separability criterion and the method used in this Example offer a new systematic way to construct PPT bound entangled mixed states.

(Received 5 August 2005; accepted 21 March 2006; published online 15 May 2006)

In this paper we construct quantum mechanical observables of a single free particle that lives on the surface of the two-sphere $\mathbb{S}^2$ by implementing the Fedosov $*$-formalism. The Fedosov $*$ is a generalization of the Moyal star product on an arbitrary symplectic manifold. After their construction we show that they obey the standard angular momentum commutation relations in ordinary nonrelativistic quantum mechanics. The purpose of this paper is threefold. One is to find an exact, nonperturbative solution of these observables. The other is to verify that the commutation relations of these observables correspond to angular momentum commutation relations. The last is to show a more general computation of the observables in Fedosov $*$-formalism; essentially an undeformation of Fedosov's algorithm. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2195529]

I. INTRODUCTION

The Moyal star product formalism is an equivalent way to do quantum mechanics.[1] The idea is that instead of using abstract linear operators on a Hilbert space such as position $\hat{x}$ and momentum $\hat{p}$, we may use classical variables x and p however we change the product so that the commutation relations are the same as in the Hilbert space formalism. Namely,

$$[\hat{x}^a,\hat{p}_b]=i\hbar\,\delta^a_b,\quad [\hat{x}^a,\hat{x}^b]=0=[\hat{p}_a,\hat{p}_b],$$

become

$$[x^a,p_b]_*=i\hbar\,\delta^a_b,\quad [x^a,x^b]_*=0=[p_a,p_b]_*$$

we use the convention that the lower case indices run from $1,\ldots,n$ and capital ones run from $1,\ldots,2n$ and

$$[f,g]_*=f*g-g*f,$$

where f and g are any 2 functions of x and p.

We note that the limit $\hbar\to 0^+$ gives the ordinary product of functions.

The definition of the Moyal star for $\mathbb{R}^{2n}$ explicitly is

a)Electronic mail: phil.tillman@gmail.com
b)Electronic mail: sparling@twistor.org

$$f * g = f e^{(i\hbar/2)\omega^{AB}\overleftarrow{\partial}_A\overrightarrow{\partial}_B} g = fg + \frac{i\hbar}{2}\omega^{AB}(\partial_A f)(\partial_B g) - \frac{\hbar^2}{8}\omega^{CE}\omega^{AB}(\partial_C\partial_A f)(\partial_E\partial_B g) + \cdots ,$$

where $\partial_A = (\partial/\partial x^a, \partial/\partial p_a)$ and the arrow determines the direction that the derivative acts and the operator $\omega^{AB}\overleftarrow{\partial}_A\overrightarrow{\partial}_B$ is called the Poisson bracket.

There is an invertible map called the Weyl transform $\mathcal{W}$ that translates from the Hilbert space formalism to the Moyal formalism. The main property of this transform is that an arbitrary Taylor series operator on the Hilbert space (note that this is effectively an arbitrary operator since we can use the commutators to rearrange each term so that the x's are to the left and the p's are to the right):

$$\hat{A} = \sum_{m,n} A_{a_1\cdots a_m}{}^{b_1\cdots b_n}\hat{x}^{a_1}\cdots\hat{x}^{a_m}\hat{p}_{b_1}\cdots\hat{p}_{b_n}$$

becomes by applying the Weyl transform

$$\mathcal{W}(\hat{A}) = A = \sum_{m,n} A_{a_1\cdots a_m}{}^{b_1\cdots b_n}x^{a_1} * \cdots * x^{a_m} * p_{b_1} * \cdots * p_{b_n}$$

in a mechanical way by simply replacing each $\hat{x}$ with x, $\hat{p}$ with p and placing stars between each of them as is done above.[1]

The trace over an operator of compact support goes to

$$\mathrm{Tr}(\hat{A}) \overset{\mathcal{W}}{\leftrightarrow} \mathrm{Tr}_*(A) := \frac{1}{(2\pi\hbar)^n}\int \frac{\omega^n}{n!}A.$$

So if we are given the Hamiltonian $\hat{H}$ and the density matrix $\hat{\rho}$ we may map

$$\hat{H} \overset{\mathcal{W}}{\leftrightarrow} H, \quad \hat{\rho} \overset{\mathcal{W}}{\leftrightarrow} \rho.$$

We thus can get the time-independent Schrödinger equation by mapping

$$\hat{H}\hat{\rho}_n = E_n\hat{\rho}_n, \quad [\hat{H},\hat{\rho}_n] = 0$$

to

$$H * \rho_n = E_n\rho_n, \quad [H,\rho_n]_* = 0,$$

where ρ_n are called the Wigner functions. This also works with the time-dependent Schrödinger equation. (See Fedosov for clarification.[2])

Also expectation values become

$$\mathrm{Tr}(\hat{\rho}\hat{A}) \leftrightarrow \mathrm{Tr}_*(\rho * A).$$

The Moyal $*$ has been generalized to an arbitrary smooth symplectic manifold $(\mathcal{N},\omega,D)$ endowed with a preserved two-form ω (called the symplectic form) and a phase-space connection D by Fedosov[2] (an excellent summary is Ref. 3). For any such manifold $(\mathcal{N},\omega,D)$ he gives a perturbative expansion for his $*$-product. However, the convergence issues of the Fedosov $*$, in general, remain unknown.

The properties of the Fedosov $*$ are

(i) It is an associative (but not commutative) map $*: C^\infty(\mathcal{N})\times C^\infty(\mathcal{N}) \to C^\infty(\mathcal{N})$.
(ii) Invariant under *all* smooth coordinate transformations of the phase-space variables x and p.
(iii) No assumed Hamiltonian.
(iv) The Fedosov $*$ is given perturbatively given any symplectic manifold $(\mathcal{N},\omega,D)$.
(v) In the limit $\hbar \to 0^+$, $*$ becomes the ordinary pointwise multiplication of functions on $\mathcal{N}$.
(vi) To first order in $\hbar$ the commutator is the Poisson bracket $[f,g]_* = i\hbar\{f,g\} + \mathcal{O}(\hbar^2)$.

(vii) When $\mathcal{N}=T^*\mathbb{E}^n$ (i.e., the phase space or the cotangent bundle of $\mathbb{E}^n$) (here $\mathbb{E}^n$ stands for Euclidean n-dimensional space) we get the Moyal $*$.

In this paper we restrict $\mathcal{N}$ to be the cotangent bundle of a manifold with metric g $(\mathcal{M},g)$ denoted $T^*\mathcal{M}$. (The cotangent bundle of any manifold is known to be a symplectic manifold.) The reason to do this is that the cotangent bundle of a manifold is the phase space of that manifold (i.e., the space of all coordinates x and momentum p). In quantum mechanics using the Moyal $*$ the phase space is the arena for quantization by giving proper $*$-commutation relations between the x's and p's. The importance of the Fedosov $*$-formalism is that it is a coordinate invariant way of constructing these commutation relations on general $T^*\mathcal{M}$ in such a way that they patch consistently to any coordinate map of the cotangent bundle. Also another important point is that it can be constructed at least perturbatively for any cotangent bundle.

However unlike Fedosov who defines a formulation based on the deformation of covectors (i.e., covectors equipped with a Moyal-type product between them) we will not. We will introduce a Heisenberg algebra generated by $\tilde{s}$ and $\tilde{k}$ ($[\tilde{s}^i,\tilde{s}^j]=[\tilde{k}_i,\tilde{k}_j]=0$, $[\tilde{s}^i,\tilde{k}_j]=i\hbar\delta^i_j$ where i and j run from 1 through $2n$) at every point of our phase-space $T^*\mathcal{M}$. The motivation to do this instead of Fedosov's way is to make a more direct connection between ordinary quantum mechanics involving Heisenberg algebras and the state spaces that the algebra acts on called Hilbert spaces. We then define this algebra to be linear operators on a Hilbert space which, of course, will eventually contain our states. This new construction will still preserve all of the essential properties of the original Fedosov $*$ albeit reformulated so as to apply to different objects. It will be a quantization procedure, i.e., a map of the variables on the phase-space x and p to the observables $\hat{x}$ and $\hat{p}$ which are linear operators on the Hilbert space.

The properties of the Fedosov $*$-quantization in our construction are

(i) $\hat{x}$ and $\hat{p}$ form an associative but noncommutative algebra.
(ii) The map from $(x,p)\rightarrow(\hat{x},\hat{p})$ is invariant under *all* smooth canonical coordinate transformations of the phase-space variables x and p.
(iii) No assumed Hamiltonian.
(iv) We can construct the $\hat{x}$ and $\hat{p}$ perturbatively given any $(T^*\mathcal{M},\omega,D)$.
(v) In the limit $\hbar\rightarrow 0^+$, $\hat{x}$ and $\hat{p}$ become x and p, respectively, i.e., the ordinary variables on $T^*\mathcal{M}$.
(vi) To first order in $\hbar$ the commutator is the Poisson bracket $[\hat{f},\hat{g}]=i\hbar\{\hat{f},\hat{g}\}+\mathcal{O}(\hbar^2)$.
(vii) When $\mathcal{M}=\mathbb{R}^n$ we get the ordinary quantum mechanics.

In the present work we take as our symplectic manifold $T^*\mathbb{S}^2$, the phase space of a single particle on the 2-sphere, $\mathbb{S}^2$. For this space we construct the Fedosov observables nonperturbatively. The advantage of choosing $\mathbb{S}^2$ is that we had suspected previous to the calculation that the commutators are the same as the usual angular momentum commutators in nonrelativistic quantum mechanics. Saying in fact that the theory of angular momentum is the quantization of the two-sphere without the need for it to be embedded in $\mathbb{R}^3$.

Outline: We will follow the basic scheme of keeping derivations sufficiently general so as to apply to a completely general manifold with metric $(\mathcal{M},g)$ and then state results from our specific case of the sphere.

In Sec. II we introduce the phase-space connection. We introduce the basis of covectors of matrices/operators $\hat{y}^A$ on the cotangent bundle in Sec. III. In Sec. IV we attempt to motivate and solve for a new derivation $\hat{D}$. Also we talk a bit about $\hat{D}$'s ambiguities. Moving into Sec. V we explicitly compute the quantities $\hat{x}$ and $\hat{p}$. In Sec. VI we compute the commutators $[\hat{x}^a,\hat{x}^b]$, $[\hat{x}^a,\hat{p}_b]$, and $[\hat{p}_a,\hat{p}_b]$ using the explicit forms of the operators. Section VII explains how one would construct states of angular momentum on $T^*\mathbb{S}^2$ by finally introducing the standard Hamiltonian in ordinary nonrelativistic quantum mechanics. Up until this point no Hamiltonian was assumed.

II. THE PHASE-SPACE CONNECTION FOR $T^*\mathbb{S}^2$

Before we begin, we note the use of the convention that the lower case are the indices of $\mathcal{M}$ (these run from $1,\ldots,n$) and capital ones are the indices of the phase-space $T^*\mathcal{M}$ (these run from $1,\ldots,2n$).

We start with the phase space of a single classical particle confined to a general manifold $(\mathcal{M},g)$. The objects needed are the phase space, $T^*\mathcal{M}$ which is the cotangent bundle of $\mathcal{M}$, an affine connection on the phase space D and the symplectic form ω of $T^*\mathcal{M}$.

A phase-space connection's action on all functions $f(x,p)\in T^*\mathcal{M}$ and a basis of covectors $\Theta^A\in T^*T^*\mathcal{M}$ are

$$Df = \mathrm{d}f = \frac{\partial f}{\partial x^a}\mathrm{d}x^a + \frac{\partial f}{\partial p_a}\mathrm{d}p_a,$$

$$D\otimes\Theta^A = \Gamma^A_B\otimes\Theta^B = \Gamma^A_{BC}\Theta^C\otimes\Theta^B$$

in such a way as to preserve the symplectic form $\omega=\mathrm{d}p_a\wedge\mathrm{d}x^a$ on $T^*\mathbb{S}^2$ $(D\otimes\omega=0)$ where $D=\Theta^C D_C$, $D_C\Theta^A=\Gamma^A_{BC}\Theta^B$ and Γ^A_{BC} is the Christoffel symbol in this basis.

Additionally we impose that D be torsion-free $(D^2f=0)$ and that it corresponds to the Levi-Civita connection on $\mathcal{M}$ when it acts on functions of x and $\mathrm{d}x$. Of course we extend to vectors and higher tensors by the Leibnitz rule.

In the specific case of $\mathbb{S}^2$ $(T^*\mathbb{S}^2)$ we employ the convention that the lower/upper-case indices be of the embedding space $\mathbb{E}^3$ $(T^*\mathbb{E}^3)$ running from 1, 2, 3 (1,…,6) instead of 1, 2 (1,…,4). We note before continuing that the calculation of the Fedosov observables is *inherently* two space-time dimensional. The third coordinate is merely for convenience. We see this fact manifest itself by the two conditions (e.g., $\underline{x}\cdot\underline{x}=1$ and $\underline{x}\cdot\underline{p}=0$) on the three coordinates every step of the way.

The natural objects and quantities on $T^*\mathbb{S}^2$ are

(i) The induced $\mathbb{S}^2$ metric g by the $\mathbb{E}^3$ embedding metric δ.
(ii) The induced $T^*\mathbb{S}^2$ symplectic form ω by the $T^*\mathbb{E}^3$ embedding symplectic form.
(iii) Also the equations defining $T^*\mathbb{S}^2$ inside of $T^*\mathbb{E}^3$, $\underline{x}\cdot\underline{x}=\delta_{ab}x^ax^b=1$ and $\underline{x}\cdot\underline{p}=x^ap_a=0$.
(iv) A torsion-free phase-space connection $D=\Theta^AD_A$ on $T^*\mathbb{S}^2$ that preserves all of the above conditions along with the symplectic form ω and there subsequent derivatives. In other words,

$$D^l\otimes g = D^l\otimes\omega = D^l(\delta_{ab}x^ax^b) = D^l(x^ap_a) = 0$$

for all positive integers l where $g=g_{ab}\,\mathrm{d}x^a\vee\mathrm{d}x^b$, $\omega=\omega_{AB}\Theta^A\wedge\Theta^B$, where Θ^A is basis of forms and $\vee$, $\wedge$ are the symmetric, antisymmetric tensor products, respectively, that we will omit because it will be clear when we mean the one or the other.

We define a basis of covectors or forms by

$$\Theta^A = (\theta^a,\alpha_a),$$

where the θ's are the first three Θ's and the α's are the last three Θ's. θ and α are defined to be

$$\underline{\alpha} := \underline{x}\times\mathrm{d}\underline{p},$$

$$\underline{\theta} := \underline{x}\times\mathrm{d}\underline{x}.$$

The metric on $\mathbb{S}^2$ is

$$g = \underline{\theta}\cdot\underline{\theta}.$$

The phase-space connection we use for $T^*\mathbb{S}^2$ is

$$D\underline{x} := \mathrm{d}\underline{x} = \underline{\theta} \times \underline{x},$$

$$D\underline{p} := \mathrm{d}\underline{p} = \underline{\alpha} \times \underline{x} - \underline{p} \times \underline{\theta},$$

$$D \otimes \underline{\theta} = \underline{\theta} \otimes_{\times} \underline{\theta}, \quad (D\theta)$$

$$D \otimes \underline{\alpha} = \underline{\theta} \otimes_{\times} \underline{\alpha} - \tfrac{2}{3}(\underline{\theta} \times \underline{x}) \otimes (\underline{p} \cdot \underline{\theta}) + \tfrac{1}{3}(\underline{p} \cdot \underline{\theta}) \otimes (\underline{\theta} \times \underline{x}), \quad (D\alpha)$$

and its corresponding curvature

$$D^2\underline{x} := 0,$$

$$D^2\underline{p} := 0,$$

$$D^2 \otimes \underline{\theta} = \tilde{\omega} \otimes (\underline{x} \times \underline{\theta}), \quad (D^2\theta)$$

$$D^2 \otimes \underline{\alpha} = \tilde{\omega} \otimes (\underline{x} \times \underline{\alpha}) + \tfrac{1}{3}(\underline{\alpha}(\underline{\theta} \otimes_{\cdot} \underline{\theta}) - \underline{\theta}(\underline{\alpha} \otimes_{\cdot} \underline{\theta}) - 2\omega \otimes \underline{\theta}). \quad (D^2\alpha)$$

III. INTRODUCING THE $\hat{y}$'s

Following Fedosov, we are going to introduce some machinery namely the operators $\hat{y}$'s to calculate the observables on general manifold $\mathcal{M}$. However, unlike Fedosov who defines these $\hat{y}$'s as covectors equipped with a Moyal-type product between them we choose a different starting point. We define the $\hat{y}$'s at fixed point to be a Heisenberg algebra $[\hat{y}^A, \hat{y}^B] = i\hbar\omega^{AB}$ where ω^{AB} is the inverse of ω_{AB} with $\omega^{AB}\omega_{BC} = \delta^A_C$. More explicitly $\hat{y}$'s are huge (infinite dimensional) matrices that act on a Hilbert space

$$\hat{y}^A = \begin{pmatrix} y^A_{11}(x,p) & y^A_{12}(x,p) & \cdots \\ y^A_{21}(x,p) & y^A_{22}(x,p) & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix},$$

where for each A, j, and k $y^A_{jk} \in C^\infty(T^*\mathcal{M})$.

To make a connection with a more familiar form of the Heisenberg algebra we use Darboux's theorem. Darboux's theorem says that in the neighborhood of each point of $q \in T^*\mathcal{M}$ there exist $2n$ local coordinates $(\tilde{x}^1, \ldots, \tilde{x}^n, \tilde{p}_1, \ldots, \tilde{p}_n)$ [note that these $2n$ coordinates are different from the $2n+2$ embedding coordinates (x^μ, p_μ)], called canonical or Darboux coordinates, such that the symplectic form ω may be written by means of these coordinates as $\omega = \mathrm{d}\tilde{p}_1\,\mathrm{d}\tilde{x}^1 + \cdots + \mathrm{d}\tilde{p}_n\,\mathrm{d}\tilde{x}^n$. Thus in this coordinate system at q the $\hat{y}$'s are expressed as $2n$ operators $(\tilde{s}^1, \ldots, \tilde{s}^n, \tilde{k}_1, \ldots, \tilde{k}_n)$ which have the commutators $[\tilde{s}^i, \tilde{s}^j] = [\tilde{k}_i, \tilde{k}_j] = 0$, $[\tilde{s}^i, \tilde{k}_j] = i\hbar\delta^i_j$ where i and j run from 1 through $2n$. And so at each point the $\hat{y}$'s establish a Heisenberg algebra which acts on a Hilbert space.

Important note: Fedosov actually begins with the $\hat{y}$'s as being an arbitrary basis of ordinary covectors with a Moyal-type product between themselves.[1] We take the point of view that the specific form of the product is irrelevant. All that matters is that we have an algebra with the same commutation relations and the action of the connection is the same on the $\hat{y}$'s.

Defining properties of $\hat{y}$,

$$[\hat{y}^A, \hat{y}^B] = i\hbar\omega^{AB},$$

$$D\hat{y}^A = \Gamma^A{}_B\hat{y}^B = \Gamma^A{}_{BC}\Theta^C\hat{y}^B, \quad \Theta^A = (\theta^a, \alpha_a).$$

The $\hat{y}$'s commute with the set of quantities $\{x, p, \mathrm{d}x, \mathrm{d}p, g, \omega, \hbar, i\}$ where i is the complex unit.

Note: The action of the phase-space connection on $\hat{y}$ is the same as the one on Θ ($D\otimes\Theta^A=\Gamma^A_{BC}\Theta^C\otimes\Theta^B$) and so we regard it as a basis of operator or matrix-valued covectors. [One may be tempted to quantize the manifold by mapping $(x^1,x^2,x^3,p_1,p_2,p_3)$ to the matrices $(\hat{y}^1,\hat{y}^2,\hat{y}^3,\hat{y}^4,\hat{y}^5,\hat{y}^6)$, but we want a coordinate independent formalism and, in general, this is not coordinate independent.] This tells us how to parallel transport the Heisenberg algebra (the $\hat{y}$'s) at one point to the Heisenberg algebra of every other point in a consistent way.

Introducing terminology: In this paper when we say f is a function/form we define it to be a complex Taylor series in its variables. (The set of all of these type of functions is sometimes called the enveloping algebra of its arguments.) Explicitly,

$$f(u,\ldots,v)=\sum_{l,j\text{'s}} f_{j_1\cdots j_l}u^{j_1}\cdots v^{j_l}\quad (j\text{ 's are powers not indices}),$$

where $f_{j_1\cdots j_l}$ are constants while u and v could be any of the set $\{x,p,\mathrm{d}x,\mathrm{d}p,\omega,\hbar,i\}$.

So if f is a function/form of some subset or all of the quantities x, p, $\mathrm{d}x$, $\mathrm{d}p$, ω, $\hbar$, and i it then commutes with the $\hat{y}$'s and will be called a complex-valued function/form. On the contrary a matrix-valued function/form is a complex Taylor series in $\hat{y}$ and possibly some subset or all of the quantities x, p, $\mathrm{d}x$, $\mathrm{d}p$, ω, $\hbar$, and i.

So if $f\,(x,p,\mathrm{d}x,\mathrm{d}p,\omega,\hbar,i)$ is a complex-valued function/form it then commutes with the $\hat{y}$'s. More explicitly with the matrix indices written

$$(\hat{y}^A\hat{y}^B)_{jk}=\Sigma_l\hat{y}^A_{jl}\hat{y}^B_{lk},$$

$$([\hat{y}^A,f])_{jk}:=\hat{y}^A_{jk}f-f\hat{y}^A_{jk}=0.$$

On the contrary a matrix-valued function/form does not. From now on we will not write the matrix indices explicitly.

The end goal: The idea for Fedosov's introduction of the $\hat{y}$'s is to associate to each $f(x,p)\in C^\infty(T^*\mathcal{M})$ a unique observable $\hat{f}(x,p,\hat{y})$,

$$\hat{f}(x,p,\hat{y})=\sum_l f_{A_1\cdots A_l}\hat{y}^{A_1}\cdots\hat{y}^{A_l},\quad (\hat{f})$$

where $f_{A_1\cdots A_l}$ are some unknown functions of x and p to be determined.

Important note: Most of the rest of the sections will be dedicated to finding a solution for $\hat{f}$ (i.e., the coefficients functions $f_{A_1\cdots A_l}$) for each $f(x,p)\in C^\infty(T^*\mathbb{S}^2)$ up to some "reasonable" ambiguity (discussed in Secs. IV and V).

$T^*\mathbb{S}^2$ *explicitly:* Specifically for $T^*\mathbb{S}^2$ we have the induced symplectic form ω of $T^*\mathbb{R}^3$ onto $T^*\mathbb{S}^2$ being

$$\omega=\underline{\alpha}\cdot\underline{\theta}=(\delta^a_b-x^ax_b)\alpha_a\theta^b.$$

We make the convention

$$\hat{y}^A=(s^a,k_a),$$

where the s's are the first three $\hat{y}$'s and the k's are the last three $\hat{y}$'s. [Note that the indices go from 1 to $2n+2$ and are different from the $2n$ operators defined above by $(\tilde{s}^1,\ldots,\tilde{s}^n,\tilde{k}_1,\ldots,\tilde{k}_n)$. The difference between them is the same as the difference between the embedding coordinates $(x^1,\ldots,x^{n+1},p_1,\ldots,p_{n+1})$ and $(\tilde{x}^1,\ldots,\tilde{x}^n,\tilde{p}_1,\ldots,\tilde{p}_n)$.] Using the above formulas we then write the commutation relations

$$[s^a,s^b]=0=[k_a,k_b],\quad [s^a,k_b]=i\hbar(\delta^a_b-x^ax_b).$$

We may assume that $\underline{x}\cdot\underline{s}=\underline{x}\cdot\underline{k}=0$ because we observe that the only part of s and k that affect the commutators are the parts that are perpendicular to x. The irrelevance of the part of s and k

parallel to x stems from the above relations because $[x_a s^a, k_b]=0$ and $[s^a, k_b x^b]=0$ and so we could always subtract off the part of s and k parallel to x and get the same commutators. Since $\underline{x}\cdot\underline{s}=\underline{x}\cdot\underline{k}=0$ we have four independent operators which are required (one for each direction on $T^*\mathbb{S}^2$).

The action of the connection and curvature acting on $\underline{s}$ and $\underline{k}$ is written down directly from the equations $(D\theta)$, $(D\alpha)$, $(D^2\theta)$, and $(D^2\alpha)$,

$$D\underline{s} = \underline{\theta}\times\underline{s},$$

$$D\underline{k} = \underline{\theta}\times\underline{k} - \tfrac{2}{3}\underline{\theta}\times\underline{x}(\underline{p}\cdot\underline{s}) + \tfrac{1}{3}(\underline{p}\cdot\underline{\theta})(\underline{s}\times\underline{x}),$$

$$D^2\underline{s} = \tilde{\omega}(\underline{x}\times\underline{s}),$$

$$D^2\underline{k} = \tilde{\omega}(\underline{x}\times\underline{k}) + \tfrac{1}{3}(\underline{\alpha}(\underline{s}\cdot\underline{\theta}) + (\underline{s}\cdot\underline{\alpha})\underline{\theta} - 2\omega\underline{s}).$$

IV. CONSTRUCTING THE GLOBAL DERIVATION $\hat{D}$

Following Fedosov, we now introduce a global derivation as a matrix commutator $\hat{D}=[\hat{Q},\cdot]$ which is central to constructing the coefficients $f_{A_1\cdots A_l}$ in equation $(\hat{f})$ for each $f(x,p)\in C^\infty(T^*\mathcal{M})$. One possible physical motivation for $\hat{D}$ is that in the next section we will require that all observables $\hat{f}$ must satisfy the equation $(D-\hat{D})\hat{f}(x,p,\hat{y})=0$. We see that on $\hat{f}$ $\hat{D}$ is an infinitesimal translation matrix operator equivalent to D. We then reason that matrix operators corresponding to infinitesimal translations on the cotangent bundle should exist, i.e., $\hat{D}$. The reason that we require that they must exist is because we are constructing the set of *all* physical matrix operators on states and certainly infinitesimal translations are in this set. If this reasoning is correct then the equation $(D-\hat{D})\hat{f}=0$ must be satisfied for all observables $\hat{f}$. Also the case of $T^*\mathbb{R}^n$ may provide some insight since it is the overlap of this formalism and quantum mechanics using the Moyal $*$ (see Appendix D for the example of $T^*\mathbb{R}^n$).

Define the derivation $\hat{D}$ by the graded commutator [graded commutators have the property that $[\hat{Q}_A\Theta^A,w]=[\hat{Q}_A,w]\Theta^A=(\hat{Q}_A w - w\hat{Q}_A)\Theta^A$ where w is an l-form with coefficients $w_{A_1\cdots A_l}$ which are complex-valued functions of the variables x, p, and $\hat{y}$.]

$$\hat{D}=[\hat{Q},\cdot]=[\hat{Q}_A\Theta^A,\cdot], \quad (\hat{D})$$

$$\hat{Q}_A=\sum_l Q_{AA_1\cdots A_l}\hat{y}^{A_1}\cdots\hat{y}^{A_l},$$

where $\Theta^A=(\theta^a,\alpha_a)$ and $Q_{AA_1\cdots A_l}$ are complex-valued functions of x and p that need to be determined. We reiterate that complex-valued functions are not matrices hence they commute with the $\hat{y}$'s.

Again following Fedosov, we can partially determine the functions $Q_{AA_1\cdots A_l}$ by the mysterious equation

$$(D-\hat{D})^2\hat{y}^A=0. \quad (\text{cond } \hat{D})$$

[Fedosov adds an additional condition that makes his $\hat{D}$ unique from a fixed D being $\hat{d}^{-1}r_0=0$ where $\hat{d}^{-1}$ is what he calls δ^{-1} (an operator used in a de Rham decomposition) and r_0 is the first term in the recursive solution. We regard this choice as being artificial and thus omit it from the paper.]

The physical motivation for this equation is still unclear and may lurk in the work of Fedosov. One reason for the above requirement is that in the next section we want to solve the equation $(D-\hat{D})\hat{f}=0$ for $\hat{f}$ and the above is an integrability condition for the solvability of this equation.

We now let $\hat{Q}$ be the sum of two parts the first being the solution in the case of $T^*\mathbb{R}^n$ (Christoffels$=\Gamma=0$),

$$\hat{Q}_A\Theta^A = \omega_{AB}\hat{y}^A\Theta^B + r, \quad (\hat{Q})$$

where

$$r = \sum_l r_{AA_1\cdots A_l}\Theta^A\hat{y}^{A_1}\cdots\hat{y}^{A_l},$$

and $r_{AA_1\cdots A_l}$ are complex-valued functions of x and p that need to be determined. In general, we assume that r has terms that are cubic or higher powers in the $\hat{y}$'s (see Appendix B and Fedosov[2] for clarification).

We rewrite the condition (cond $\hat{D}$) as

$$(D-\hat{D})^2\hat{y}^A = [\Omega - Dr + \hat{\mathrm{d}}r + r^2, \hat{y}^A] = 0,$$

where $\Omega := (1/2i\hbar)\omega_{FN}R^F_{BCE}\Theta^C\Theta^E\hat{y}^N\hat{y}^B$ is the phase-space curvature $(D^2\otimes\Theta^A = R^A_{BCE}\Theta^C\Theta^E\otimes\Theta^B)$ as a commutator and $\hat{\mathrm{d}}h = (1/i\hbar)[\omega_{AB}\hat{y}^A\Theta^B, h]$ where h is a matrix-valued function of x p, dx dp, and $\hat{y}$ (see Appendix A for the proof).

From now on we let

$$\Omega - Dr + \hat{\mathrm{d}}r + r^2 = 0, \quad (r)$$

and keep it in the back of our minds that we could add something that commutes with all $\hat{y}$'s to $\Omega - Dr + \hat{\mathrm{d}}r + r^2$.

Important: To emphasize the importance of this equation the reader should note that the whole Fedosov $*$-formalism hinges on this r existing. We know solutions exists perturbatively in general [Fedosov has the recursive solution for it (Ref. 2, p. 144)], however convergence issues still remain unresolved. On a technical note we have found that solving for r to be the hardest point of the computation of the Fedosov observables because of the need for the right ansatz and the nonlinear equation (r) above that it must solve.

Specifically for the case of $T^*\mathbb{S}^2$ the solution for the curvature as a commutator Ω is

$$\Omega := \tfrac{1}{3}((\underline{s}\cdot\underline{\alpha})(\underline{s}\cdot\underline{\theta}) - s^2\omega) + (\underline{x}\times\underline{k})\cdot\underline{s}\widetilde{\omega}.$$

We then verify that it gives the curvature as commutators,

$$[\Omega, \underline{s}] = [-\underline{k}\cdot(\underline{x}\times\underline{s})\widetilde{\omega}, \underline{s}] = \widetilde{\omega}(\underline{x}\times\underline{s}),$$

$$[\Omega, \underline{k}] = \tfrac{1}{3}(\underline{\alpha}(\underline{s}\cdot\underline{\theta}) + (\underline{s}\cdot\underline{\alpha})\underline{\theta} - 2\omega\underline{s}) + (\underline{x}\times\underline{k})\widetilde{\omega}.$$

To simplify the calculations we set $i\hbar = 1$ which we will eventually put back in the end.

Fedosov at this point would implement an algorithm to construct r perturbatively, however rather than do this we will make an ansatz for r by exploiting the rotational symmetry of the sphere. This will give us an exact solution for r. (On a technical note: we ran the Fedosov algorithm a few times to help us see what form the ansatz should take. Also remember that we require $\Omega - Dr + \hat{\mathrm{d}}r + r^2 = 0$ modulo terms that commute with the $\hat{y}$'s.)

Our ansatz for r is

$$r = r_0 + f(s^2)\underline{z}\cdot\underline{s}(\underline{x}\times\underline{s})\cdot\underline{\theta} + g(s^2)\underline{z}\cdot(\underline{x}\times\underline{s})\underline{s}\cdot\underline{\theta} + h(s^2)\underline{s}\cdot\underline{\theta}, \quad (r \text{ ansatz})$$

where $\underline{z}=\underline{p}-\underline{x}\times\underline{k}$ and $r_0=\frac{1}{3}((\underline{k}\cdot\underline{\theta})s^2-\underline{k}\cdot\underline{s}(\underline{s}\cdot\underline{\theta}))$.

We will now state the results of our calculations because the calculations are just too space consuming and yet at the same time straightforward. Given the formulas for r and Ω and performing lengthy calculations eventually we get

$$Dr = \left(\frac{1}{9}-\frac{2g}{3}+\frac{f}{3}\right)s^2\underline{p}\cdot\underline{s}\tilde{\omega} + f\underline{\alpha}\cdot(\underline{x}\times\underline{s})(\underline{x}\times\underline{s})\cdot\underline{\theta} - g(\underline{s}\cdot\underline{\alpha})\underline{s}\cdot\underline{\theta},$$

$$\hat{\mathrm{d}}r = -\Omega + (2f's^2+3f+g)\underline{z}\cdot\underline{s}\tilde{\omega} - g(\underline{s}\cdot\underline{\alpha})\underline{s}\cdot\underline{\theta} + f\underline{\alpha}\cdot(\underline{x}\times\underline{s})(\underline{x}\times\underline{s})\cdot\underline{\theta},$$

$$r^2 = \left(\frac{1}{9}-\frac{2g}{3}+\frac{f}{3}\right)s^2\underline{p}\cdot\underline{s}\tilde{\omega} + \left(2gf's^2+gf-f^2-\frac{2f}{3}+\frac{g}{3}-\frac{1}{9}\right)s^2\underline{z}\cdot\underline{s}\tilde{\omega},$$

where $f'=\partial f/\partial(s^2)$ for all functions.

Putting these into the equation (r) we obtain a condition for g,

$$g = \frac{s^2\left(\left(f+\frac{1}{3}\right)^2-2f'\right)-3f}{s^2\left(\left(f+\frac{1}{3}\right)+2s^2f'\right)+1}$$

while f and h are left arbitrary as long as g is well defined. This is a necessary and sufficient condition for the equation (r) to hold.

We note that $f=-\frac{1}{3}$, $g=1$ and $f=-\frac{1}{12}$, $g=\frac{1}{4}$ are the only solutions where f and g are constant. We will choose to work with the $f=-\frac{1}{3}$ $g=1$, $h=0$ solution from now on. We choose this solution for the sake of clarity because it turns out to be the easiest to use in the next few sections. However, the reader should note that we calculated the commutators for the general solutions for g, f, and h and obtained the same result for all of them. See Sec. VI for the exact result of the commutators for the particular solution $f=-\frac{1}{3}$, $g=1$, $h=0$ (and hence the solution for the general solutions for g f, and h).

The solution for r for $f=-\frac{1}{3}$, $g=1$, $h=0$ is

$$r = -\tfrac{1}{3}(\underline{p}\cdot\underline{s})((\underline{x}\times\underline{s})\cdot\underline{\theta}) + \underline{z}\cdot(\underline{x}\times\underline{s})\underline{s}\cdot\underline{\theta}. \quad (r \text{ soln})$$

Ambiguities in r: It is worth while to note that the condition (cond $\hat{D}$) does not uniquely define $\hat{D}$ given a fixed D. [Fedosov adds an additional condition that makes his $\hat{D}$ unique from a fixed D being $\hat{d}^{-1}r_0=0$ where $\hat{d}^{-1}$ is what he calls δ^{-1} (an operator used in a de Rham decomposition) and r_0 is the first term in the recursive solution. We regard this choice as being artificial and thus omit it from the paper.]

It appears however that most of the ambiguities in constructing $\hat{D}$ when given a fixed phase space connection D can be absorbed by a basis change (in other words a gauge transformation). It is easy to see this in a Darboux chart because the connection may be expressed as a commutator,

$$\tilde{D}\hat{y}^A = [\tilde{Q},\hat{y}^A],$$

where $\tilde{D}=D-\hat{D}$, $\tilde{Q}=Q-\hat{Q}$, and $D=[Q,\cdot]$. The gauge transformation takes the form

$$\hat{y}^A \to \hat{y}^A_{\text{new}} := U\hat{y}^AU^{-1}, \quad \tilde{D}\hat{y}^A \to \tilde{D}_{\text{new}}\hat{y}^A_{\text{new}} := [U\tilde{Q}U^{-1},U\hat{y}^AU^{-1}] = U(\tilde{D}\hat{y}^A)U^{-1},$$

where U is some invertible function of the x's, p's, and $\hat{y}$'s. Thus the physical content of this theory is independent of U because the commutators remain unchanged.

This can be seen as follows:

$$r \to r + r',$$

where r is a solution to the equation (r) and r' is some unknown series,

$$r' = \sum_l r'_{AA_1\cdots A_l} \Theta^A \hat{y}^{A_1} \cdots \hat{y}^{A_l}.$$

Setting $r \to r+r'$ into (r) we obtain

$$\Omega - D(r+r') + [\underline{s}\cdot\underline{\alpha} - \underline{k}\cdot\underline{\theta}, (r+r')] + (r+r')^2 = 0$$

modulo the equation (r) to get

$$-Dr' + [\underline{s}\cdot\underline{\alpha} - \underline{k}\cdot\underline{\theta}, r'] + (r')^2 + [r,r'] = 0 \Rightarrow \tilde{D}r' - (r')^2 = 0.$$

This tells us that if r' is of the form

$$r' = (\tilde{D}U)U^{-1}$$

for any U which corresponds to a gauge transformation in the enveloping algebra then the resulting $r_{\text{new}} = r + r'$ will solve equation (r). In other words once we have one solution we have actually have huge class of equivalent solutions. We suspect this class of equivalent solutions are all of the solutions for a simply connected manifold.

Note: There is another source of ambiguity namely the ambiguity in the phase-space connection D. Given a connection D we may add to it a tensor Δ^A_{BC} where if we lower by $\Delta_{ABC} = \omega_{AE}\Delta^E_{BC}$ it is symmetric in all three indices. The new connection still preserves the symplectic form ω. Our curvature becomes

$$(D+\Delta)^2 = D^2 + D(\Delta) + \Delta^2.$$

It is unclear what this ambiguity means so we will leave it for a future discussion.

V. COMPUTING $\hat{x}$ AND $\hat{p}$

At this point in Fedosov's algorithm we have all the tools in place to associate an observable $\hat{f}$ to every $f \in C^\infty(T^*\mathcal{M})$. Following Fedosov we require that every observable $\hat{f}(x,p,\hat{y})$ must satisfy the equation

$$(D - \hat{D})\hat{f}(x,p,\hat{y}) = 0,$$

where $f_{A_1\cdots A_l}$ are some unknown functions of x and p such that

$$\ell o(\hat{f}(x,p,\hat{y})) = f(x,p)$$

ℓo (short for leading order in $\hat{y}$ and $\hbar$) picks out the term which has no $\hat{y}$'s and no $\hbar$'s in it. Explicitly,

$$\hat{f}(x,p,\hat{y}) = f(x,p) + \mathcal{O}(\hat{y},\hbar),$$

where f has no $\hbar$'s in it.

And so the condition to solve (we believe unique up to unitary transformations) for an observable $\hat{f}$ for every $f \in C^\infty(T^*\mathcal{M})$ is

$$(D - \hat{D})\hat{f}(x,p,\hat{y}) = 0, \quad \ell o(\hat{f}(x,p,\hat{y})) = f(x,p). \quad (\text{cond } \hat{f})$$

If we have determined our D and $\hat{D}$ we can find solutions for the operators $\hat{x}^a$ and $\hat{p}_a$ (i.e., their coefficients $b^a_{A_1\cdots A_l}$ and $c_{aA_1\cdots A_l}$),

$$\hat{x}^a = \sum_l b^a_{A_1\cdots A_l}\hat{y}^{A_1}\cdots\hat{y}^{A_l}, \quad (\hat{x})$$

$$\hat{p}_a = \sum_l c_{aA_1\cdots A_l}\hat{y}^{A_1}\cdots\hat{y}^{A_l}, \quad (\hat{p})$$

where $b^a_{A_1\cdots A_l}$ and $c_{aA_1\cdots A_l}$ are complex-valued functions of x and p [which are the coefficients $f_{A_1\cdots A_l}$ in equation $(\hat{f})$ where the first terms in the series is $f=b^a=x^a$ or $f=c_a=p_a$, respectively] and will be determined by the equations:

$$(D-\hat{D})\hat{x}^a = 0, \quad \ell o(\hat{x}^a) = x^a, \quad (\text{cond } \hat{x})$$

$$(D-\hat{D})\hat{p}_a = 0, \quad \ell o(\hat{p}_a) = p_a\,. \quad (\text{cond } \hat{p})$$

Again see the example in Appendix D for solutions to $\hat{x}$ and $\hat{p}$ in the case of $T^*\mathbb{R}^n$ where $D=d$.

If we invert the equations $(\hat{x})$ and $\hat{p})$ once we have solved for the coefficients $b^a_{A_1\cdots A_l}$ and $c^a_{A_1\cdots A_l}$ to get $\hat{y}$ as matrix-valued function of x, p, $\hat{x}$, and $\hat{p}$ [i.e., $\hat{y}^A=\hat{y}^A(x,p,\hat{x},\hat{p})$] and then substitute it into the equation for an arbitrary observable $(\hat{f})$ and get

$$\hat{f}(\hat{x},\hat{p}) = \sum_{lm} f^{b_1\cdots b_m}_{a_1\cdots a_l}\hat{x}^{a_1}\cdots\hat{x}^{a_l}\hat{p}_{b_1}\cdots\hat{p}_{b_m}, \quad (\hat{f}\text{ soln})$$

where $f^{b_1\cdots b_m}_{a_1\cdots a_l}$ are constant coefficients. (To prove this act $D-\hat{D}$ on this equation.)

However, once we have our $\hat{x}$ and $\hat{p}$ there is the ambiguity of how to order each variable when you map a function $f(x,p)$ to $\hat{f}(\hat{x},\hat{p})$. For example, does the function $f(x,p)=x^1p_1$ go to $\hat{x}^1\hat{p}_1$, $\hat{p}_1\hat{x}^1$ or some linear combination of the two? We should expect this in any well-defined quantization procedure because such ordering ambiguities arise in quantum mechanics. We will, for now, regard the ordering of each $\hat{f}$ to be undetermined. (Fedosov chooses Weyl ordering.)

$T^*\mathbb{S}^2$ explicitly: Fedosov at this point would implement an algorithm to construct $\hat{x}$ and $\hat{p}$ perturbatively (Ref. 2, p. 146) for our specific case of $T^*\mathbb{S}^2$. We instead try to find exact solutions to them. (We, again, ran the Fedosov algorithm a few times to help us see what for the ansatz we should take.) Specifically for the case of $T^*\mathbb{S}^2$ we have the ansatz for both $\hat{x}$ and $\hat{p}$ as

$$\hat{\underline{x}} = v(s^2)\underline{x} + w(s^2)\underline{x}\times\underline{s} + y(s^2)\underline{s},$$

$$\hat{\underline{p}} = (\underline{z}\cdot\underline{s}t(s^2) + \underline{z}\cdot(\underline{x}\times\underline{s})q(s^2))\underline{x} + \underline{z}n(s^2) + \underline{z}\times\underline{x}u(s^2)$$

with some functions v, w, y, t, q, n, and u to be determined and the requirements that $\ell o(\hat{\underline{x}})=\underline{x}$ and $\ell o(\hat{\underline{p}})=\underline{p}$.

The conditions (cond $\hat{x}$) and (cond $\hat{p}$) become the following equations:

$$\begin{aligned}0 = (D-\hat{D})\hat{\underline{x}} &= ((-2v'(s^2+1)+w)(\underline{s}\cdot\underline{\theta}) - y(\underline{x}\times\underline{s})\cdot\underline{\theta})\underline{x}\\ &+\left(\left(-\frac{v}{s^2}-2w'(s^2+1)-w\left(1+\frac{1}{s^2}\right)\right)(\underline{s}\cdot\underline{\theta}) - y\frac{1}{s^2}(\underline{x}\times\underline{s})\cdot\underline{\theta}\right)\underline{x}\times\underline{s}\\ &+\left(\left(\frac{v}{s^2}+w\frac{1}{s^2}\right)(\underline{x}\times\underline{s})\cdot\underline{\theta} + \left(-2y'(s^2+1)-y\left(1+\frac{1}{s^2}\right)\right)(\underline{s}\cdot\underline{\theta})\right)\underline{s}\end{aligned}$$

and

$$
0=(D-\hat{D})\underline{\hat{p}}=\left(\begin{array}{c}\left(\begin{array}{c}-2\underline{z}\cdot\underline{s}t'(s^2+1)-(\underline{z}\cdot\underline{s})\dfrac{1}{s^2}t-2\underline{z}\cdot(\underline{x}\times\underline{s})q'(s^2+1)\\ +\underline{z}\cdot(\underline{x}\times\underline{s})\left(1-\dfrac{1}{s^2}\right)q-(\underline{z}\cdot\underline{s})\dfrac{1}{s^2}u+\underline{z}\cdot(\underline{x}\times\underline{s})\dfrac{1}{s^2}n\end{array}\right)(\underline{s}\cdot\underline{\theta})\\ \left(\begin{array}{c}-\left(\underline{z}\cdot(\underline{x}\times\underline{s})\left(1+\dfrac{1}{s^2}\right)\right)t+(\underline{z}\cdot\underline{s})\dfrac{1}{s^2}q\\ +\underline{x}\cdot(\underline{z}\times\underline{s})\dfrac{1}{s^2}u-(\underline{z}\cdot\underline{s})\dfrac{1}{s^2}n\end{array}\right)(\underline{x}\times\underline{s})\cdot\underline{\theta}\end{array}\right)\underline{x}
$$

$$
+\left(\begin{array}{c}\left(\begin{array}{c}-\underline{z}\cdot\underline{s}t-\underline{z}\cdot(\underline{x}\times\underline{s})q+2\underline{z}\cdot(\underline{x}\times\underline{s})n\\ -(\underline{z}\cdot\underline{s})u+2(\underline{z}\cdot\underline{s})(s^2+1)u'-2(\underline{z}\times\underline{x})\cdot\underline{s}(s^2+1)n'\end{array}\right)(\underline{s}\cdot\underline{\theta})\\ +\underline{z}\cdot(\underline{x}\times\underline{s})(\underline{x}\times\underline{s})\cdot\underline{\theta}u\end{array}\right)\frac{1}{s^2}\underline{x}\times\underline{s}
$$

$$
+\left(\begin{array}{c}\left(\begin{array}{c}2\underline{z}\cdot(\underline{x}\times\underline{s})u+(\underline{z}\cdot\underline{s})n\\ -2(\underline{z}\cdot\underline{s})(s^2+1)n'-2((\underline{z}\times\underline{x})\cdot\underline{s})(s^2+1)u'\end{array}\right)\underline{s}\cdot\underline{\theta}\\ +(\underline{z}\cdot\underline{s}t+\underline{z}\cdot(\underline{x}\times\underline{s})q-\underline{z}\cdot(\underline{x}\times\underline{s})n)(\underline{x}\times\underline{s})\cdot\underline{\theta}\end{array}\right)\frac{1}{s^2}\underline{s}.
$$

So the conditions that $\tilde{D}\underline{\hat{x}}=0$ and $\tilde{D}\underline{\hat{p}}=0$ becomes 6+6 equations because $(\underline{s}\cdot\underline{\theta})^2=0=((\underline{x}\times\underline{s})\cdot\underline{\theta})^2$ and $(\underline{s}\cdot\underline{\theta})(\underline{x}\times\underline{s})\cdot\underline{\theta}=\tilde{\omega}$ where $\tilde{\omega}_{ab}$ is invertible. We then solve the subsequent differential equations for the functions v,w,y,t,q,n, and u along with requiring that they have the correct term with no $\hat{y}$'s [$\ell o(\underline{\hat{x}})=\underline{x}$ and $\ell o(\underline{\hat{p}})=\underline{p}$] in the Taylor expansion to obtain the solutions

$$
\underline{\hat{x}}=(\underline{x}-\underline{x}\times\underline{s})(s^2+1)^{-1/2},\quad(\hat{x}\text{ soln})
$$

$$
\underline{\hat{p}}=(\underline{z}\cdot(\underline{x}\times\underline{s})\underline{x}+\underline{z})(s^2+1)^{1/2},\quad(\hat{p}\text{ soln})
$$

where $\underline{z}=\underline{p}-\underline{x}\times\underline{k}$ with the following conditions holding:

$$
\begin{array}{l}\ell o(\underline{\hat{x}})=\underline{x},\ \ell o(\underline{\hat{p}})=\underline{p},\\ \underline{\hat{p}}\cdot\underline{\hat{x}}=\underline{\hat{x}}\cdot\underline{\hat{p}}-2i\hbar=0.\end{array}\quad(\hat{x}\hat{p}\text{ conds})
$$

We note at this point that there is not much insight looking at these formulas except for what we get for the commutators in the next section.

VI. THE COMMUTATORS $[\hat{x}^a,\hat{x}^b]$, $[\hat{x}^a,\hat{p}_b]$, AND $[\hat{p}_a,\hat{p}_b]$

Once we have $\hat{x}^a$ and $\hat{p}_a$, i.e., the coefficients $b^a_{A_1\cdots A_l}$ and $c^a_{A_1\cdots A_l}$ we work out the commutation relations $[\hat{x}^a,\hat{x}^b]$, $[\hat{x}^a,\hat{p}_b]$, and $[\hat{p}_a,\hat{p}_b]$ using the formulas $(\hat{x})$ and $(\hat{p})$ in the previous section in a brute force calculation. Remember that the $*$-commutators is the Poisson bracket on $T^*\mathcal{M}$ to first order in $\hbar$,

$$
[\hat{f}(\hat{x},\hat{p}),\hat{g}(\hat{x},\hat{p})]=\hat{h}(\hat{x},\hat{p})
$$

$$
[f_*(x,p),g_*(x,p)]_*=h_*(x,p)=i\hbar\{f,g\}_{\mathcal{M}}+\mathcal{O}(\hbar^2)\quad(*\text{-comm})
$$

where $\hat{f},\hat{g},\hat{h}$ and f_*,g_*,h_* are functions defined by:

$$
\hat{f}(\hat{x},\hat{p})=\sum_{Im}f^{b_1\cdots b_m}_{ja_1\cdots a_l}\hbar^j\hat{x}^{a_1}\cdots\hat{x}^{a_1}\hat{p}_{b_1}\cdots\hat{p}_{b_m}
$$

$$f_*(x,p) = \sum_{Im} f_{ja_1\cdots a_l}^{b_1\cdots b_m} \hbar^j x^{n_1} * \cdots * x^{a_1} * p_{b_1} * \cdots * p_{b_m}$$

where $f_{ja_1\cdots a_l}^{b_1\cdots b_m}$ are constants.

These two sets, one of all f_*'s $\{f_*\}$ and one of all $\hat{f}$'s $\{\hat{f}\}$ defined above are isomorphic.

$T^*\mathbb{S}^2$ explicitly: In our case of $T^*\mathbb{S}^2$ we find

$$[\hat{x}^a,\hat{x}^b] = 0,$$

$$[\hat{x}^a,\hat{p}_b] = i\hbar(\delta_b^a - \hat{x}^a\hat{x}_b),$$

$$[\hat{p}_a,\hat{p}_b] = 2i\hbar\hat{x}_{[b}\,\hat{p}_{a]},$$

$$\underline{\hat{x}}\cdot\underline{\hat{x}} = 1, \quad \underline{\hat{p}}\cdot\underline{\hat{x}} = \underline{\hat{x}}\cdot\underline{\hat{p}} - 2i\hbar = 0.$$

We now define $\underline{\hat{L}}$ because we argue below that it is a more "natural" momentum,

$$\underline{\hat{L}} := -\underline{\hat{p}}\times\underline{\hat{x}} = \underline{\hat{x}}\times\underline{\hat{p}} = \underline{x}\times\underline{z} + (\underline{z}\cdot\underline{s})\underline{x} - \underline{z}\cdot(\underline{x}\times\underline{s})\underline{s}$$

again with the computed conditions

$$\underline{\hat{L}}\cdot\underline{\hat{x}} = \underline{\hat{x}}\cdot\underline{\hat{L}} = 0, \quad \underline{\hat{x}}\cdot\underline{\hat{x}} = 1,$$

$$\ell o(\underline{\hat{L}}) = \underline{L} = \underline{x}\times\underline{p}.$$

We easily recognize that $\underline{\hat{L}}$ is the more "natural" variable compared to $\underline{\hat{p}}$. This is because $\underline{\hat{p}}\cdot\underline{\hat{x}}=0$ and $\underline{\hat{x}}\cdot\underline{\hat{p}}=2i\hbar$ are very "unnatural" conditions since there is no physical reason why it should not be $\underline{\hat{x}}\cdot\underline{\hat{p}}=0$ and $\underline{\hat{p}}\cdot\underline{\hat{x}}=-2i\hbar$. We could define $\underline{\hat{p}}_{\text{new}}=\underline{\hat{p}}+A\underline{\hat{x}}$ where A is an arbitrary constant and obtain the same commutators. On the other hand, the symmetry between $\underline{\hat{L}}\cdot\underline{\hat{x}}=\underline{\hat{x}}\cdot\underline{\hat{L}}=0$ seems to suggest that $\underline{\hat{L}}$ should be the preferred quantity over $\underline{\hat{p}}$. In other words, the relevant component of $\underline{\hat{p}}$ is the one perpendicular to $\underline{\hat{x}}$ which is precisely what $\underline{\hat{L}}$ is.

Therefore the part of $\hat{p}$ parallel to $\hat{x}$ is irrelevant,

$$\underline{\hat{x}} = (\underline{x} - \underline{x}\times\underline{s})(s^2+1)^{-1/2}, \quad (\hat{x}\text{ soln})$$

$$\underline{\hat{L}} = \underline{x}\times\underline{z} + (\underline{z}\cdot\underline{s})\underline{x} - \underline{z}\cdot(\underline{x}\times\underline{s})\underline{s}, \quad (\hat{L}\text{ soln})$$

where $\underline{z}=\underline{p}-\underline{x}\times\underline{k}$ with conditions

$$\underline{\hat{L}}\cdot\underline{\hat{x}} = \underline{\hat{x}}\cdot\underline{\hat{L}} = 0, \quad \underline{\hat{x}}\cdot\underline{\hat{x}} = 1\,. \quad (\hat{x}\hat{L}\text{ conds})$$

Again we note at this point that there is not much insight looking at these formulas except for what we get for the commutators in the remainder of this section.

We compute the commutators,

$$[\hat{x}^a,\hat{x}^b] = 0, \quad (xx)$$

$$[\hat{x}^a,\hat{L}_b] = i\hbar\varepsilon^a{}_{bc}\hat{x}^c, \quad (xL)$$

$$[\hat{L}_a, \hat{L}_b] = i\hbar \varepsilon^c{}_{ab} \hat{L}_c, \quad (LL)$$

along with

$$\underline{\hat{x}} \cdot \underline{\hat{x}} = 1, \underline{\hat{L}} \cdot \underline{\hat{x}} = \underline{\hat{x}} \cdot \underline{\hat{L}} = 0 . \quad (\text{cond } xL)$$

Once we know these relations we know the whole algebra of functions since the algebra is associative. And thus we are done.

And so in the case of $T^*\mathbb{S}^2$ a general element $\hat{f}$ [the function $(\hat{f})$ we were looking for and the specific form of the solution ($\hat{f}$ soln)] in the space of all observables of $\hat{x}$ and $\hat{L}$ is

$$\hat{f}(\hat{x}, \hat{L}) = \sum_{lm} f^{b_1 \cdots b_m}_{a_1 \cdots a_l} \hat{x}^{a_1} \cdots \hat{x}^{a_l} \hat{L}_{b_1} \cdots \hat{L}_{b_m},$$

where $f^{b_1 \cdots b_m}_{a_1 \cdots a_l}$ are constants. This is the enveloping algebra of the operators of angular momentum and position on a Hilbert space.

Clearly we see that the $\hat{L}$'s generate the standard angular momentum algebra and the $\hat{x}$'s transform properly under rotations. However both the $\hat{x}$'s and the $\hat{L}$'s form a constrained version of the standard $\mathbb{R}^3$ Euclid algebra with invariant constraints given by the last equations.

VII. ANGULAR MOMENTUM STATES

Since we now have the algebra of observables we can ask about Hamiltonians and states. The free single quantum particle Hamiltonian in ordinary quantum mechanics is $\hat{H} = \hat{p}^2/2m = (\hat{p}_r^2/2m) + (\hat{\underline{L}} \cdot \hat{\underline{L}}/mr^2)$ where $\hat{p}_r$ is the radial component of momentum and $\hat{\underline{L}}$ is the angular momentum. In other words, the natural choice for the Hamiltonian on our $\mathbb{S}^2$ (which we are free to choose) is $\hat{H} = \hat{\underline{L}} \cdot \hat{\underline{L}}$, $r=1, m=1$ because it is just the restricted version of the $\mathbb{E}^3$ free particle Hamiltonian onto $\mathbb{S}^2$. We then construct our angular momentum states in the usual way by solving the eigenvalue equation

$$\hat{H}|\phi\rangle = E|\phi\rangle, \quad (\text{Schrödinger})$$

where $E \in \mathbb{R}$.

We will not do it because it is standard physics that one is able to do as an undergraduate physics student.

VIII. CONCLUSIONS

We have explicitly constructed an exact nonperturbative solutions to the observables in the Fedosov $*$-formalism on $T^*\mathbb{S}^2$ and showed that they obeyed the angular momentum commutation relations. In other words, we took the phase space of a single classical particle confined to a sphere, quantized it and got the quantum angular momentum algebra (which we expected). This is done by starting with a chosen phase-space connection D and constructing an explicit formula for $\hat{D}$. Via the equation $(D - \hat{D})\hat{f} = 0$ that defines the algebra, i.e., the algebra of all $\hat{f}$'s we then explicitly constructed $\underline{\hat{x}}$ and $\underline{\hat{p}}$ (the operator analogues of $\underline{x}$ and $\underline{p}$) and computed their commutators. We realized (by defining $\hat{\underline{L}} = \underline{\hat{x}} \times \underline{\hat{p}}$) that the enveloping algebra of all $\underline{\hat{x}}$'s and $\underline{\hat{p}}$'s gives the angular momentum algebra.

Subsequently we defined a Hamiltonian $\hat{\underline{L}} \cdot \hat{\underline{L}}$ that would have eigenstates of angular momentum, however we did not explicitly construct it because it is standard physics.

Another main point was that most of the ambiguity given a fixed phase-space connection D of the construction of $\hat{D}$, it seemed, stemmed from the freedom of a change of basis $(\hat{f} \to U\hat{f}U^{-1})$ given by the argument in Sec. IV. Finally the matrix form of the $\hat{y}$'s did not change anything from a Moyal-type object as is done in deformation quantization.

We conclude that we would arrive at the same answer given any algebraic object $\hat{y}$ that had the same commutators along with the same action of the connection on them. We then view the Fedosov $*$-formalism as a general algebraic construction and less tied to the deformation aspect of its original formulation. Thus our formulation using Heisenberg algebras and their subsequent representation spaces (Hilbert spaces) makes a more direct connection to the standard formulation of ordinary quantum mechanics.[4–12]

APPENDIX A

We now show that the equation $(D-\hat{D})^2\hat{y}^A=0$ is equivalent to $[\Omega-Dr+\hat{\mathrm{d}}r+r^2,\hat{y}^A]=0$.

Proof:

$$(D-\hat{D})^2\hat{y}^A=(D^2-D\hat{D}-\hat{D}D+\hat{D}^2)\hat{y}^A,$$

$$(D\hat{D}+\hat{D}D)\hat{y}^A=[D(\omega_{AB}\hat{y}^A\Theta^B+r),\hat{y}^A]=[Dr,\hat{y}^A],$$

$$\begin{aligned}\hat{D}^2\hat{y}^A=[\hat{Q},[\hat{Q},\hat{y}^A]]=\hat{Q}(\hat{Q}\hat{y}^A-\hat{y}^A\hat{Q})+(\hat{Q}\hat{y}^A-\hat{y}^A\hat{Q})\hat{Q}=[\hat{Q}^2,\hat{y}^A]_-=[(\omega_{AB}\hat{y}^A\Theta^B+r)^2,\hat{y}^A]_-\\=[(\omega_{AB}\hat{y}^A\Theta^B)^2+[\omega_{AB}\hat{y}^A\Theta^B,r]+r^2,\hat{y}^A]_-,\end{aligned}$$

$$\begin{aligned}2(\omega_{AB}\hat{y}^A\Theta^B)^2=[\omega_{AB}\hat{y}^A\Theta^B,\omega_{CE}\hat{y}^C\Theta^E]=[\hat{y}^A,\hat{y}^C]\omega_{AB}\Theta^B\omega_{CE}\Theta^E=\omega_{AB}\Theta^A\Theta^B\\\Rightarrow\hat{D}^2\hat{y}^A=[[\omega_{AB}\hat{y}^A\Theta^B,r]+r^2,\hat{y}^A]_-,\end{aligned}$$

where $[A,B]_-=AB-BA$ for any A and B.

The curvature D^2 acting on Θ^A is

$$D^2\otimes\Theta^A=R_B{}^A\otimes\Theta^B.$$

Thus the curvature D^2 acting on $\hat{y}^A$ is

$$D^2\hat{y}^A=R_B{}^A\hat{y}^B.$$

Knowing this we define Ω as the curvature D^2 acting on $\hat{y}^A$ as a commutator, namely,

$$\frac{1}{i\hbar}[\Omega,\hat{y}^A]=R_B{}^A\hat{y}^B,$$

we can immediately write a solution for Ω knowing $[\hat{y}^A,\hat{y}^B]=i\hbar\omega^{AB}$, $\omega^{AB}\omega_{BC}=\delta^A_C$ and using the symmetries of the curvature tensor,

$$\Omega:=-\tfrac{1}{2}\omega_{AC}R_B{}^A\hat{y}^B\hat{y}^C.$$

Thus we may rewrite the condition $(D-\hat{D})^2\hat{y}^A=0$ as

$$(D-\hat{D})^2\hat{y}^A=[\Omega-Dr+\hat{\mathrm{d}}r+r^2,\hat{y}^A]=0.$$

APPENDIX B

Here we present an argument as to why r only has terms that are cubic or higher powers in the $\hat{y}$'s. Given

$$\hat{D} = [\hat{Q}, \cdot\,] = [\hat{Q}_A \Theta^A, \cdot\,],$$

$$\hat{Q}_A = \sum_l Q_{AA_1\cdots A_l} \hat{y}^{A_1} \cdots \hat{y}^{A_l},$$

we require

$$(D - \hat{D})^2 \hat{y}^A = 0.$$

If we let

$$\hat{Q}_A \Theta^A = \omega_{AB} \hat{y}^A \Theta^B + r,$$

$$r = \sum_l r_{AA_1\cdots A_l} \Theta^A \hat{y}^{A_1} \cdots \hat{y}^{A_l}.$$

If we want r to be globally defined for *all* manifolds we must define it out of nondegenerate tensors namely the metric, the symplectic form and the curvature. This is because Ω is degree 2 in the $\hat{y}$'s (i.e., $\Omega := -\frac{1}{2}\omega_{AC} R^A_{BDE} \hat{y}^B \hat{y}^C$ has 2 $\hat{y}$'s). The degree is defined by

$$\deg(a) = (\text{number of } \hat{y}\text{'s}) + 2(\text{number of } \hbar\text{'s}).$$

A linear r would yield

$$\underbrace{\Omega}_{2} - \underbrace{Dr}_{1} + \underbrace{\hat{d}r}_{0} + \underbrace{r^2}_{1}$$

and this cannot be zero for $\Omega \neq 0$. This means that r must have a quadratic term in it.

If r is quadratic ($r = \Sigma_{l=0}^{2} r_{AA_1\cdots A_l} \Theta^A \hat{y}^{A_1} \cdots \hat{y}^{A_l}$), in general, there is no way to construct the degree 2 coefficient $r_{AA_1A_2}$ out of invariant tensors. Thus we require that r has terms that are cubic or higher powers in the $\hat{y}$'s. Fedosov mentions this fact also.[2]

For a specific manifold there might be an r that is quadratic. The argument above is meant for an r in a *general* construction for a *general* manifold and so we give a counterexample in the case when the manifold $\mathcal{M}$ is $\mathbb{E}^n$.

There is always the trivial solution to r,

$$r = -\tfrac{1}{2}\omega_{CB} \Gamma^C{}_A \hat{y}^A \hat{y}^B,$$

where $\Gamma^C_A = \Gamma^C_{BA} \Theta^B$ are the Christoffel symbols associated to D. One can easily observe that this is a solution knowing $[\hat{y}^A, \hat{y}^B] = i\hbar\omega^{AB}$, $\omega^{AB}\omega_{BC} = \delta^A_C$ and using the symmetries of the Christoffel symbols. However, the Γ's are not necessarily globally defined and if we find an r in one coordinate patch on $T^*\mathcal{M}$ there is no guarantee that it will be well defined in another. However if $\mathcal{M} = \mathbb{E}^n$ then this is a global r.

APPENDIX C

Useful identities,

$$\mathrm{d}\underline{p} = \underline{\alpha} \times \underline{x} - \underline{p} \times \underline{\theta},$$

$$\theta^a \theta^b = \tilde{\omega} \varepsilon^{abc} x_c,$$

$$\underline{z} \times \underline{x} = \underline{p} \times \underline{x} - \underline{k},$$

$$\underline{z} = \underline{p} - \underline{x} \times \underline{k},$$

$$\theta^a \theta^b = \theta^{[a}\ \theta^{b]} = \tfrac{1}{2}\varepsilon^{abc}(\underline{\theta} \times \underline{\theta})_c = \tilde{\omega}\varepsilon^{abc}x_c,$$

$$(\underline{v} \times \underline{w}) \times \underline{u} = \delta_{ab}v^a \underline{w} u^b - \underline{v}(\underline{w} \cdot \underline{u}),$$

$$\underline{v} \times (\underline{w} \times \underline{u}) = \delta_{ab}v^a \underline{w} u^b - (\underline{v} \cdot \underline{w})\underline{u},$$

for all 3D vectors assuming nothing about $[v_a, w_b]$, $[v_a, u_b]$ or $[w_a, u_b]$,

$$(\underline{v} \cdot \underline{\theta})(\underline{x} \times \underline{w}) \cdot \underline{\theta} = \tilde{\omega}(\underline{v} \cdot \underline{w})$$

for all 3D vectors assuming $[\theta^a, v_b] = [\theta^a, w_b] = 0$ and assuming nothing about $[v_a, w_b]$. For two vectors such that $\underline{v} \cdot \underline{x} = \underline{w} \cdot \underline{x} = 0$ we have the identities

$$\underline{v} \times \underline{w} = ((\underline{v} \times \underline{w}) \cdot \underline{x})\underline{x} \sim \underline{x},$$

$$\underline{z} \cdot (\underline{x} \times \underline{s}) = \underline{p} \cdot (\underline{x} \times \underline{s}) - t,$$

$$[s^2, (\underline{x} \times \underline{k}) \cdot \underline{s}] = 0,$$

$$s_a f(\underline{k} \cdot \underline{s}) = f(\underline{k} \cdot \underline{s} + 1)s_a,$$

$$[r_0, \underline{s}] = \tfrac{1}{3}((\underline{s} \cdot \underline{\theta})\underline{s} - s^2 \underline{\theta}),$$

$$[r_0, (\underline{s} \cdot \underline{\theta})] = 0,$$

$$[r_0, s^2] = 0 = [\underline{z} \cdot \underline{s}, s^2],$$

$$[r_0, \underline{k}] = \tfrac{1}{3}(2\underline{s}(\underline{k} \cdot \underline{\theta}) - \underline{\theta} t - (\underline{s} \cdot \underline{\theta})\underline{k}),$$

$$[r_0, \underline{z}] = \tfrac{1}{3}((\underline{s} \cdot \underline{\theta})\underline{x} \times \underline{k} - \underline{\theta} \times \underline{x} t - 2\underline{x} \times \underline{s}(\underline{k} \cdot \underline{\theta})),$$

$$\tilde{D}\underline{s} = \underline{\theta} \times \underline{s} - \left(1 + \frac{1}{s^2}\right)(\underline{s} \cdot \underline{\theta})\underline{s} - \frac{1}{s^2}((\underline{x} \times \underline{s}) \cdot \underline{\theta})\underline{x} \times \underline{s},$$

$$\tilde{D}\underline{x} = D\underline{x} = \underline{\theta} \times \underline{x} = \frac{1}{s^2}((\underline{x} \times \underline{s}) \cdot \underline{\theta})\underline{s} - (\underline{s} \cdot \underline{\theta})\underline{x} \times \underline{s},$$

$$\tilde{D}\underline{z} = \underline{\theta} \times \underline{z} + ((\underline{z} \cdot \underline{s})(\underline{s} \cdot \underline{\theta}) - \underline{z} \cdot (\underline{x} \times \underline{s})((\underline{x} \times \underline{s}) \cdot \underline{\theta}))\frac{1}{s^2}\underline{s} + 2\underline{z} \cdot (\underline{x} \times \underline{s})(\underline{s} \cdot \underline{\theta})\frac{1}{s^2}\underline{x} \times \underline{s}.$$

APPENDIX D: $T^*\mathbb{R}^n$

In the case of $T^*\mathbb{R}^n$ we solve equation (r) above for r when $D \otimes \Theta^A = 0$ therefore $D\hat{y}^A = 0$ and hence $\Omega = 0$ and get the solution $r = 0$. This gives us $\hat{D}$ by the formulas $(\hat{D})$ and $(\hat{Q})$,

$$\hat{D} = \frac{1}{i\hbar}[\omega_{AB}\hat{y}^A\Theta^B, \cdot\,] = \frac{1}{i\hbar}[\underline{s}\cdot \mathrm{d}\underline{p} - \underline{k}\cdot \mathrm{d}\underline{x}, \cdot\,] = \frac{1}{i\hbar}[(\underline{x}+\underline{s})\cdot \mathrm{d}\underline{p} - (\underline{p}+\underline{k})\cdot \mathrm{d}\underline{x}, \cdot\,],$$

where s and k are the first n $\hat{y}$'s and the last n $\hat{y}$'s, respectively [i.e., $\hat{y}^A=(s^a,k_a)$] also we have $[s^a,s^b]=0=[k_a,k_b],[s^a,k_b]=i\hbar\,\delta^a_b$, and $Ds^a=0=Dk_a$.

All operators are required to satisfy

$$\frac{\partial \hat{f}}{\partial x^a}\mathrm{d}x^a + \frac{\partial \hat{f}}{\partial p_a}\mathrm{d}p_a - \hat{D}\hat{f} = 0$$

$$\Rightarrow \frac{\partial \hat{f}}{\partial x^a}\mathrm{d}x^a + \frac{\partial \hat{f}}{\partial p_a}\mathrm{d}p_a = \frac{1}{i\hbar}[(\underline{x}+\underline{s})\cdot \mathrm{d}\underline{p} - (\underline{p}+\underline{k})\cdot \mathrm{d}\underline{x}, \hat{f}].$$

This equation is the specific case of the equation (cond $\hat{f}$) for $T^*\mathbb{R}^n$ introduced in Sec. II. The above equation tells us that $\hat{f}$ is a function of $\hat{x}^a=x^a+s^a$ and $\hat{p}_a=p_a+k_a$ $[\hat{f}=\hat{f}(\hat{x},\hat{p})]$ which are solutions to the equation (cond $\hat{f}$), i.e., the coefficients $b^a_{A_1\ldots A_l}$ and $c_{aA_1\ldots A_l}$ in the case of $T^*\mathbb{R}^n$ introduced in Sec. II when $\ell o(\hat{f})=x^a$ and $\ell o(\hat{f})=p_a$, respectively. The equation above implies that $(1/i\hbar)[\cdot,\hat{p}_a]$ generates the translation on the cotangent bundle in the x^a direction and $(1/i\hbar)\times[\hat{x}^a,\cdot\,]$ generates the translation on the cotangent bundle in the p_a direction on all observables $\hat{f}$. See Fedosov for more details on motivating the need for $\hat{D}$.[2] □

(Received 2 March 2006; accepted 30 March 2006; published online 17 May 2006)

We show that the time evolved Wigner function of a quantum particle under the action of a smooth potential can be formally expanded in powers of $\hbar$, where each term of the expansion can be computed in terms of the corresponding classical flow. Moreover the solution can be approximated by the N-order truncation with an error $O(\hbar^{N+1})$. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2200143]

I. INTRODUCTION

WKB methods (see, e.g., Refs. 6–8, and references quoted therein) provide an asymptotic expansion of the solutions to the Schrödinger equation:

$$i\varepsilon\partial_t\Psi = -\frac{\varepsilon^2}{2}\Delta\Psi + U\Psi, \tag{1.1}$$

in powers of $\varepsilon=\hbar$, $\hbar=h/2\pi$, h being the Planck constant. Here we consider a quantum system whose corresponding classical Hamiltonian is

$$H(x,p) = \frac{p^2}{2} + U(x), \tag{1.2}$$

where $x \in \mathbb{R}^d$ is a configuration of the system. The initial state is usually assumed of the form:

$$\Psi(x) = a(x)e^{iS(x)/\varepsilon} \tag{1.3}$$

where a and S are real functions of the configurational space.

The main disadvantage of the WKB methods is that they easily work for a short time, while extensions to arbitrary times require significant technical efforts. In fact assuming the solution to the problem (1.1) of the form

$$\Psi(x,t) = a(x,t)e^{iS(x,t)/\varepsilon}, \tag{1.4}$$

we find, at zero order in ε, the following equations for a and S:

$$\partial_t a + \tfrac{1}{2}a\,\mathrm{div}(\nabla S) + \nabla S\cdot\nabla a = 0, \tag{1.5}$$

$$\partial_t S + \tfrac{1}{2}|\nabla S|^2 + U = 0. \tag{1.6}$$

Setting $u=\nabla S$ and $n=a^2$, from (1.5) and (1.6) we obtain the pressureless Euler equations:

$$\partial_t n + \mathrm{div}(un) = 0, \tag{1.7}$$

$$\partial_t u + u\cdot\nabla u + \nabla U = 0. \tag{1.8}$$

a)Electronic mail: pulvirenti@mat.uniromal.it

It is well known that Eqs. (1.7) and (1.8) deliver, in general, singularities in a finite time, therefore we find difficulties in justifying Eq. (1.4) globally in time, even at zero order in ε.

On the other hand we can introduce the Wigner transform (see Ref. 11) of a quantum state described by the integral kernel $\rho=\rho(x;y)$. It is a function in the classical phase space defined by

$$f_\rho(x,v)=\left(\frac{1}{2\pi}\right)^d\int \mathrm{d}y e^{iv\cdot y}\rho\left(x-\frac{\varepsilon}{2}y;x+\frac{\varepsilon}{2}y\right) \tag{1.9}$$

reducing to

$$f_\Psi(x,v)=\left(\frac{1}{2\pi}\right)^d\int \mathrm{d}y e^{iv\cdot y}\Psi\left(x-\frac{\varepsilon}{2}y\right)\bar{\Psi}\left(x+\frac{\varepsilon}{2}y\right) \tag{1.10}$$

whenever $\rho(x;y)=\bar{\Psi}(x)\Psi(y)$, that is the quantum state is pure and described by the wave function Ψ. The quantum evolution usually given in terms of the Heisenberg (or the Schrödinger) equation is equivalently described by the so-called Wigner-Liouville equation which we shall introduce later on. At zero order in ε such an equation reduces to the classical Liouville equation

$$(\partial_t+v\cdot\nabla_x)f+F\cdot\nabla_v f=0, \tag{1.11}$$

where $F=-\nabla U$ is the force field.

The Wigner transform of the initial state (1.3) is, at zero order in ε,

$$f(x,v)=n(x)\delta(v-u(x)), \tag{1.12}$$

where $u=\nabla S$ and $n=a^2$. Now, by using the characteristics of the Hamiltonian flow generated by the Hamiltonian (1.2), we can construct a global solution to Eq. (1.11), with initial state (1.12), provided that U is sufficiently smooth. Therefore, at least at zero order in ε, the Wigner formalism works globally in time. As a consequence it seems natural to go further, namely to find an asymptotic expansion for the solution to the Wigner-Liouville equation, which is expected to work globally. However, in doing this we have to pay a price: we cannot pretend to recover the WKB wave function globally in time. Indeed the solution to Eq. (1.11) has the hydrodynamical representation

$$f(x,v;t)=n(x,t)\delta(v-u(x,t)) \tag{1.13}$$

only locally in time because Eq. (1.13) holds if and only if the pair n,u solves the problem (1.7) and (1.8) which, as we said, has unique smooth solution for a short time only. This is well known and has been pointed out in recent works (see, e.g., Ref. 9, and references quoted therein).

On the other side the loss of a clear wave function picture is compensated by the fact that we can compute, at least in principle, the asymptotic expansion of the physical observables, which are moments of the Wigner measure. For instance the current and the current density are given by

$$n(x)=|\psi(x)|^2=\int f(x,v)\mathrm{d}v, \tag{1.14}$$

$$\varepsilon\ \mathrm{Im}\ \bar{\psi}\nabla\ \psi(x)=J(x)=\int vf(x,v)\mathrm{d}v, \tag{1.15}$$

respectively.

The formal expansion we present here (see Sec. II) is not new. It corresponds to the well-known Egorov theorem and has been previously used by different authors (see, e.g., Refs. 2, 5, and 10 and also Ref. 1 for a geometrical description of the propagator of the time evolved Wigner function). However it is somehow surprising that a rigorous analysis of the semiclassical expansion of the Wigner function is apparently absent, as far as we know, from the current literature. The main purpose of the present paper is to fill this gap.

We mention that Wigner function approaches have been invoked in connection with compactness methods also to weaken the usual regularity assumptions (see, e.g., Refs. 3 and 4). Here we use a different and complementary point of view: we assume smoothness on the potential and analyze the coefficients of the formal expansion in power of ε of the solution. Then we control the remainder showing that it is $O(\varepsilon^{N+1})$ if N is the order of approximation.

We point out that the present method works for a large class of initial states including WKB and coherent states.

Our regularity assumptions are severe. We believe that they can be relaxed, however we prefer to privilege the simplicity in this context.

II. THE FORMAL EXPANSION

The Wigner-Liouville equation for our quantum system described by the Wigner function $f(x,v)$ on the classical phase space, reads as

$$(\partial_t + v \cdot \nabla_x) f = Tf, \tag{2.1}$$

where

$$Tf(x,v) = \frac{i}{\varepsilon} \sum_{\sigma=\pm 1} \sigma \int \mathrm{d}k \hat{U}(k) e^{ik\cdot x} f\left(x, v + \frac{\sigma}{2}\varepsilon k\right). \tag{2.2}$$

We find it convenient to express T in the following equivalent divergence form, namely,

$$T = i \int_{-1/2}^{1/2} \mathrm{d}\lambda \int \mathrm{d}k \hat{U}(k) e^{ik\cdot x} k \cdot \nabla_v f(x, v + \varepsilon\lambda k). \tag{2.3}$$

By using the Taylor formula:

$$f(x,v+\varepsilon\lambda k) = \sum_{n=0}^{N} (k\cdot\nabla_v)^n f(x,v) \frac{(\varepsilon\lambda)^n}{n!} + \frac{(\varepsilon)^{N+1}}{N!} \int_0^{\lambda} \mathrm{d}\mu (k\cdot\nabla_v)^{N+1} f(x, v+\varepsilon\mu k) \mu^N, \tag{2.4}$$

we expand T in the formal power series in ε,

$$T = T_0 + \varepsilon T_1 + \varepsilon^2 T_2 + \cdots, \tag{2.5}$$

where

$$T_{2n} = i\left(\frac{1}{2}\right)^{2n} \frac{1}{(2n+1)!} \int \mathrm{d}k \hat{U}(k) e^{ik\cdot x} (k\cdot\nabla_v)^{2n+1} f(x,v), \quad n = 0,1\ldots \tag{2.6}$$

and

$$T_{2n+1} = 0, \quad n = 0,1\ldots. \tag{2.7}$$

Note that odd powers vanish and that:

$$T_0 = \nabla_x U \cdot \nabla_v f \tag{2.8}$$

is the classical interaction part of the Liouville operator.

Now let f_0 be the initial state. We assume that f_0 has the following formal power expansion:

$$f_0 = f_0^{(0)} + \varepsilon f_0^{(1)} + \varepsilon^2 f_0^{(2)} + \cdots. \tag{2.9}$$

We expand also the solution $f(t)$ to Eq. (2.1) accordingly

$$f(t) = f^{(0)}(t) + \varepsilon f^{(1)}(t) + \varepsilon^2 f^{(2)}(t) + \cdots \tag{2.10}$$

and, using (2.5) in (2.1), we find at zero order:

$$(\partial_t + v \cdot \nabla_x) f^{(0)} = T_0 f^{(0)}, \tag{2.11}$$

that is the classical Liouville equation with initial condition $f_0^{(0)}$. More generally at order ε^n we have

$$(\partial_t + v \cdot \nabla_x) f^{(n)} = T_0 f^{(n)} + \sum_{k=1}^{n} T_k f^{(n-k)}, \tag{2.12}$$

with initial condition $f_0^{(n)}$.

Equation (2.11) has the solution expressed in terms of the classical Hamiltonian flow $\phi^t(x,v)$ generated by the Hamiltonian (1.2), namely $\phi^t(x,v)=(x(t),v(t))$ where

$$\dot{x}(t) = v(t), \quad \dot{v}(t) = -\nabla_x U(x(t)), \tag{2.13}$$

with initial condition $x(0)=x$, $v(0)=v$. Then the solution to (2.11) is

$$f^{(0)}(x,v;t) = f_0^{(0)}(\phi^{-t}(x,v)). \tag{2.14}$$

Equation (2.12) can be solved for $n>0$ by recurrence. In fact the Duhamel formula gives us

$$f^{(n)}(x,v;t) = f_0^{(n)}(\phi^{-t}(x,v)) + \int_0^t \mathrm{d}\tau S_n(\phi^{-(t-\tau)},\tau), \tag{2.15}$$

where

$$S_n = \sum_{k=1}^{n} T_k f^{(n-k)} \tag{2.16}$$

is known by the previous steps.

It is remarkable that each term of the expansion can be computed in terms of the classical flow $\phi^t(x,v)$ and its derivative with respect to the initial velocities.

The formal algebra we present in this section corresponds to the semiclassical Egorov theorem (see, e.g., Ref. 8). It gives the formal expansion, in power of ε, of the symbol of the time evolution of a quantum observable. In other words the Weyl quantization formula (see Eq. (4.1)) of Eq. (2.10) yields the power expansion of the time evolved quantum density matrix.

III. INITIAL STATES

The expansions introduced in the previous section are formal and presumably diverging as a power series in ε. For a rigorous analysis we truncate the series and estimate the remainder. To do this, however, we first want to see which reasonable hypotheses we have to do on the expansion at time zero. If it is given by a wave function Ψ not depending on ε, the Wigner transform $f_0 = f_\Psi$ given by Eq. (1.10) is gently varying with ε and has a series expansion

$$f_0 = f_0^{(0)} + \varepsilon f_0^{(1)} + \varepsilon^2 f_0^{(2)} + \cdots \tag{3.1}$$

in which all the coefficients $f_0^{(k)}$ are smooth. These initial data, however, do not exhaust all cases of physical interest. For instance WKB states have a quickly oscillating phase. Let us compute the coefficient of the expansion (3.1) starting with the simplest case, namely the one in which the phase is a linear function of the configuration:

$$S(x) = p \cdot x, \quad p \in \mathbb{R}^d. \tag{3.2}$$

Then the Wigner transform of the wave function (1.3) is

$$f_0(x,v) = \left(\frac{1}{2\pi}\right)^d \int \mathrm{d}y e^{i(v-p)\cdot y} a\left(x - \frac{\varepsilon}{2}y\right) a\left(x + \frac{\varepsilon}{2}y\right) \tag{3.3}$$

(assuming a real). Inserting in (3.3) the Taylor expansion

$$a\left(x \pm \frac{\varepsilon}{2}y\right) = \sum_{n\geqslant 0} (y\cdot\nabla_x)^n a(x) \frac{(\pm 1)^n}{n!}\left(\frac{\varepsilon}{2}\right)^n \tag{3.4}$$

we find

$$f_0(x,v) = \sum_{n\geqslant 0}\left(\frac{\varepsilon}{2}\right)^n \sum_{k\leqslant n} \frac{(-1)^k}{k!}\frac{1}{(n-k)!} \times \sum_{j_1\ldots j_n=1}^{\mathrm{d}} \frac{\partial^k}{\partial_{x_{j_1}}\ldots\partial_{x_{j_k}}} a(x) \frac{\partial^{n-k}}{\partial_{x_{j_{k+1}}}\ldots\partial_{x_{j_n}}} a(x) \int \mathrm{d}y y_{j_1}\ldots y_{j_n} e^{i(v-p)\cdot y}. \tag{3.5}$$

Therefore the coefficients, which are explicitly given by

$$f_0^{(n)}(x,v) = \left(\frac{-i}{2}\right)^n \sum_{k=0}^{n} \frac{1}{k!}\frac{1}{(n-k)!}(-1)^k \sum_{j_1\ldots j_n} \frac{\partial^k}{\partial_{x_{j_1}}\ldots\partial_{x_{j_k}}} a(x) \frac{\partial^{n-k}}{\partial_{x_{j_{k+1}}}\ldots\partial_{x_{j_n}}} a(x) \frac{\partial^n}{\partial_{v_{j_1}}\ldots\partial_{v_{j_n}}} \delta(v-p), \tag{3.6}$$

are distributions in v, no matter how a is assumed smooth.

When S is not a linear function of x, we can proceed analogously by expanding also the exponential of the oscillating phase. The calculations are slightly more involved but again the coefficients are smooth as regards the x dependence and derivatives of δ functions as regards the v dependence. The explicit form of the coefficients is not particularly relevant in the present context and hence we omit the details.

Let us now analyze the case of a coherent state of the form:

$$\Psi(x) = \left(\frac{1}{\pi\varepsilon}\right)^{d/4} e^{(i/\epsilon)v_0\cdot x} \exp\left(\frac{(x-x_0)^2}{2\varepsilon}\right) \tag{3.7}$$

whose Wigner transform is

$$f_\Psi(x,v) = \left(\frac{1}{\pi\varepsilon}\right)^d \exp\left(-\frac{(x-x_0)^2}{2\varepsilon}\right)\exp\left(-\frac{(v-v_0)^2}{2\varepsilon}\right). \tag{3.8}$$

Given a test function $\varphi(x,v)$, setting $z=(x,v)$ and $z_0=(x_0,v_0)$, we obtain

$$\langle f_\Psi,\varphi\rangle = \left(\frac{1}{\pi}\right)^d \int_{\mathbb{R}^{2d}} \mathrm{d}z e^{-z^2}\varphi(z_0+\sqrt{\varepsilon}z) = \left(\frac{1}{\pi}\right)^d \sum_{n\geqslant 0}\frac{1}{(2n)!}\varepsilon^n \int_{\mathbb{R}^{2d}} \mathrm{d}z e^{-z^2}(z\cdot\nabla_z)^{2n}\varphi(z_0). \tag{3.9}$$

Hence:

$$f_\Psi(x,v) = \delta(x-x_0)\delta(v-v_0) + \varepsilon\sum_{i=1}^{d}\left(\frac{\partial^2}{\partial x_i^2} + \frac{\partial^2}{\partial v_i^2}\right)\delta(x-x_0)\delta(v-v_0) + \cdots. \tag{3.10}$$

Thus the expansion at order n of the Wigner function of a coherent state involved derivatives of order $2n$ of δ functions. On the other hand a mixture of coherent states by means of a smooth probability density on (x_0,v_0) can be expanded in terms of smooth coefficients. Therefore we are led to consider initial expansions (2.9) with smooth and distributional coefficients.

IV. H_s ESTIMATES FOR THE WIGNER FUNCTION

We start by reviewing some well-known facts concerning the solution to the Wigner-Liouville Eq. (2.1).

Equation (1.9) can be inverted, namely we have

$$\rho(x,y)=\left(\frac{1}{2\pi}\right)^d\int \mathrm{d}v e^{i(v/\varepsilon)(x-y)}f\left(\frac{x+y}{2};v\right). \tag{4.1}$$

Actually the operator $\hat{\rho}$, whose integral kernel is given by (4.1), is the Weyl quantization of the classical observable f defined on the phase space.

Consider now the Hamiltonian $H=-(\varepsilon^2/2)\Delta+U$. Under a suitable assumption on U (for instance $U\in L_\infty$) H is self-adjoint on a suitable domain and $V(t)=\exp(it/\varepsilon)H$ is a strongly continuous group of unitaries in $L_2(\mathbb{R}^d)$. The time evolution of $\hat{\rho}$ is $\hat{\rho}(t)=V(t)\hat{\rho}V(-t)$. Therefore, given $f\in L_2(x,v)$ we can define the time evolution mapping $f\to f(t)$ by means of the following steps:

$$f\to\hat{\rho}\to\hat{\rho}(t)\to f(t)\equiv\Omega(t)f$$

where the above actions are the Weyl quantization (4.1), the quantum time evolution and the Wigner transform, respectively. The family of transformations $\Omega(t)$ is a one-parameter group of unitaries whose generator extends $-v\cdot\nabla+T$ as an anti-self-adjoint operator. Therefore Eq. (2.1) may be seen as an equation in $L_2(x,v)$.

Remark: Here f is considered as a classical observable and $\hat{\rho}$ a quantum observable obtained by means of the Weyl quantization. Of course a probability density f does not correspond necessarily to a physical admissible state. Conversely the Wigner transform of a quantum state is not, in general, a probability density.

Now we look for further regularity. Let $f=f(x,v;t)$ be the solution to the Wigner-Liouville equation, with initial datum $f_0\in H_s(x,v)$, where $H_s(x,v)$ is the Sobolev space of order s and s is a positive integer. In this section we show that $f(t)\in H_s(x,v)$, provided that the potential energy U is sufficiently smooth. In proving this we exploit the antisymmetry of the operators $v\cdot\nabla_x$ and T using straightforward L_2 estimates.

For any multi-index $\alpha=\{\alpha_1\ldots\alpha_d\}$, we introduce the standard notation:

$$D_x^\alpha=\frac{\partial^{|\alpha|}}{\partial^{\alpha_1}x_1\ldots\partial^{\alpha_d}x_d}, \tag{4.2}$$

where $|\alpha|=\Sigma_j\alpha_j$. Analogously we set:

$$D_v^\alpha=\frac{\partial^{|\alpha|}}{\partial^{\alpha_1}v_1\ldots\partial^{\alpha_d}v_d}, \tag{4.3}$$

and define the scalar product:

$$(f,g)_n=\sum_{\substack{\alpha,\beta:\\ |\alpha|+|\beta|\le n}}(D_v^\alpha D_x^\beta f,D_v^\alpha D_x^\beta g)_{L_2(x,v)}, \tag{4.4}$$

and the associated norm $\|f\|_n=\sqrt{(f,f)_n}$. The Hilbert space equipped with the scalar product (4.4) is denoted by H_n.

In order to estimate $\|f(t)\|_n$ we compute $\partial_t D_v^\alpha D_x^\beta f$ with $|\alpha|+|\beta|\le n$. We have

$$\partial_t D_v^\alpha D_x^\beta f = D_v^\alpha D_x^\beta(-v\cdot\nabla_x + T)f = (-v\cdot\nabla_x + T)D_v^\alpha D_x^\beta f + \sum_{\substack{\alpha'<\alpha:\\ |\alpha'|=1}} C_{\alpha,\alpha'} D_v^{\alpha'} v\cdot\nabla_x D_v^{\alpha-\alpha'} D_x^\beta f$$

$$+ i\sum_{\substack{\beta'<\beta:\\ |\beta'|>0}} C_{\beta,\beta'} \int_{-1/2}^{1/2} \mathrm{d}\lambda \int \mathrm{d}k \hat{U}(k) D_x^{\beta'} e^{ik\cdot x}(k\cdot\nabla_v) D_v^\alpha D_x^{\beta-\beta'} f(x, v+\varepsilon\lambda k), \tag{4.5}$$

where $C_{\alpha,\alpha'}$ is a suitable combinatorial coefficient and $\alpha'<\alpha$ means $\alpha'_j \leqslant \alpha_j$ with $|\alpha'|<|\alpha|$. Finally $\beta-\beta' = \{\beta_j - \beta'_j\}_{j=1}^d$.

Note that the second term on the right-hand side of (4.5) is absent when $|\alpha|=0$.

We have now that

$$(g, v\cdot\nabla_x g)_{L_2(x,v)} = (g, Tg)_{L_2(x,v)} = 0 \tag{4.6}$$

for any g smooth enough. Then, for f real:

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}(D_v^\alpha D_x^\beta f, D_v^\alpha D_x^\beta f)_{L_2(x,v)} = (D_v^\alpha D_x^\beta f, D_v^\alpha D_x^\beta f \partial_t f)_{L_2(x,v)}. \tag{4.7}$$

Inserting (4.5) in (4.7) we realize that, by virtue of (4.6), the first term on the right-hand side of (4.5) (namely that with higher order derivatives) does not give any contribution. By the Schwarz inequality, for $|\alpha|\geqslant 1$:

$$(D_v^\alpha D_x^\beta f, D_v^{\alpha'} v\cdot\nabla_x D_v^{\alpha-\alpha'} D_x^\beta f)_{L_2} \leqslant C\|f\|_n^2, \tag{4.8}$$

because $|\alpha|-|\alpha'|+|\beta|+1\leqslant n$. Analogously the last term on the right-hand side of (4.5) is bounded in the L_2 norm, by

$$\int \mathrm{d}k |\hat{U}(k)||k|^{(|\beta'|+1)} \|\nabla_v D_v^\alpha D_x^{\beta-\beta'} f\|_{L_2} \leqslant C\|f\|_n \tag{4.9}$$

because $|\alpha|+|\beta|-|\beta'|+1\leqslant n$. In conclusion,

$$\frac{\mathrm{d}}{\mathrm{d}t}\|f\|_n^2 \leqslant C\|f\|_n^2, \tag{4.10}$$

provided that

$$\int \mathrm{d}k |\hat{U}(k)||k|^n \leqslant C < +\infty. \tag{4.11}$$

Summarizing we proved the following.

Theorem 4.1: Let $f=f(t)$ be the solution to Eq. (2.1) with initial datum $f_0 \in H_n(x,v)$ with $n \geqslant 0$ and suppose that the potential U satisfies condition (4.11). Then $f(t) \in H_n(x,v)$ and

$$\|f(t)\|_n \leqslant \|f_0\|_n e^{Ct},$$

where the constant C (which depends on n) is independent of ε. For $n=0$ we have $C=1$, namely the L_2 norm is conserved.

V. CONTROLLING THE REMAINDER

In this section we present the main results of this paper. We show that the formal expansion (2.10) can be truncated at an arbitrary order N and the error we make is $O(\varepsilon^{N+1})$.

The discussion in Sec. III on the initial data suggests to consider separately the case of smooth and distributional coefficients (for instance when dealing with a suitable mixture of coherent states and WKB or coherent pure states, respectively). We need first to establish a few preliminary estimates. We introduce the operator $\mathcal{T}_N$ by

$$\mathcal{T}_N = T - \sum_{j=0}^{N} T_j \varepsilon^j = i\varepsilon^{N+1} \int \mathrm{d}k \hat{U}(k) e^{ik\cdot x} \int_{-1/2}^{1/2} \mathrm{d}\lambda \int_0^{\lambda} \mathrm{d}\mu \frac{\mu^N}{N!} (k\cdot\nabla_v)^{N+2} f(x, v+\mu\varepsilon k) \tag{5.1}$$

and set:

$$u(n) = \int \mathrm{d}k |\hat{U}(k)| (1+|k|)^n. \tag{5.2}$$

Then if $g \in H_{N+s+2}(x,v)$ and if U is sufficiently smooth, from (5.1) we get

$$\|\mathcal{T}_N g\|_s \leqslant C\varepsilon^{N+1} u(s+N+2) \|g\|_{N+s+2}. \tag{5.3}$$

Here and in the sequel C denotes any positive constant depending on N, the Sobolev indices $n, s, \ldots$ and time, but not on ε. Estimate (5.3) follows easily by the definition. In the same way we obtain

$$\|T_n g\|_s \leqslant C u(s+n+1) \|g\|_{n+s+1}. \tag{5.4}$$

Finally setting

$$\widetilde{\mathcal{D}} = \bigcap_{s\in\mathbb{N}^+} H_s(x,v), \tag{5.5}$$

we can prove the following:

Theorem 5.1: Consider $f(t)$ the solution to the initial value problem (2.1) with initial condition

$$f_0 = \sum_{n=0}^{N} \varepsilon^n f_0^{(n)} + R_N(0), \tag{5.6}$$

for some integer $N \geqslant 1$. Assume that $f_0^{(n)} \in \widetilde{\mathcal{D}}$ for all $n \geqslant 0 \ldots N$ and that $R_N(0) \in \widetilde{\mathcal{D}}$ with the bound

$$\|R_N(0)\|_s \leqslant C\varepsilon^{N+1}, \quad s = 0, 1, \ldots . \tag{5.7}$$

If $u(n) < C_n < +\infty$ for any $n \geqslant 1$, then

$$f(t) = \sum_{n=0}^{N} \varepsilon^n f^{(n)}(t) + R_N(t) \tag{5.8}$$

with $f^{(n)}(t)$ given by (2.14). Furthermore the following bound on the remainder holds:

$$\|R_N(t)\|_s \leqslant C\varepsilon^{N+1} \tag{5.9}$$

for any $s \geqslant 0$.

Proof: By Eq. (2.1), assuming for the solution the representation (5.8), we have

$$(\partial_t + v\cdot\nabla_x)\sum_{n=0}^{N}\varepsilon^n f^{(n)} + (\partial_t + v\cdot\nabla_x)R_N = \sum_{n=0}^{N}\varepsilon^n T f^{(n)} + TR_N = \sum_{\substack{s,n=0:\\ s+n\leqslant N}}^{N}\varepsilon^{n+s}T_s f^{(n)} + \sum_{n=0}^{N}\varepsilon^n \mathcal{T}_N f^{(n)} + \sum_{\substack{s,n=0:\\ s+n>N}}^{N}\varepsilon^{n+s}T_s f^{(n)} + TR_N. \tag{5.10}$$

By construction the first terms on the left- and right-hand sides of (5.10) compensate, so that the equation for the remainder $R_N(t)$ is

$$(\partial_t + v\cdot\nabla_x)R_N(t) = TR_N(t) + S_N^R(t), \tag{5.11}$$

where

$$S_N^R = \sum_{n=0}^{N}\varepsilon^n \mathcal{T}_N f^{(n)} + \sum_{\substack{s,n=0:\\ s+n>N}}^{N}\varepsilon^{n+s}T_s f^{(n)}. \tag{5.12}$$

By Eq. (2.15) and Theorem 4.1 we have, for any $s\geqslant 0$,

$$\|f^{(n)}(t)\|_s \leqslant C\|f_0^{(n)}\|_s + C\int_0^t \mathrm{d}\tau \|S_n(\tau)\|_s. \tag{5.13}$$

Moreover, by (2.16) and (5.4):

$$\|S_n(\tau)\|_s = \sum_{k=1}^{n}\|T_k f^{(n-k)}(\tau)\|_s \leqslant C\sum_{k=1}^{n}\|f^{(n-k)}(\tau)\|_{s+k+1}. \tag{5.14}$$

Therefore $\sup_{t\leqslant t_0}\|f^{(n)}(t)\|_s \leqslant C$ for all $s\geqslant 0$ provided that the same estimate holds for $0,1,\ldots n-1$. By Theorem 4.1 if $f_0^{(0)}\in\widetilde{\mathcal{D}}$ then $\sup_{t\leqslant t_0}\|f^{(0)}(t)\|_s \leqslant C$ for all $s\geqslant 0$. Therefore we can inductively conclude that

$$\sup_{t\leqslant t_0}\|f^{(n)}(t)\|_s \leqslant C$$

for all s and n.

By (5.11) and the Duhamel formula:

$$R_N(t) = \Omega(t)R_N(0) + \int_0^t \mathrm{d}\tau\,\Omega(t-\tau)S_N^R(\tau). \tag{5.15}$$

By Theorem 4.1 we have

$$\|R_N(t)\|_s \leqslant C\|R_N(0)\|_s + C\int_0^t \mathrm{d}\tau\|S_N^R(\tau)\|_s \tag{5.16}$$

and finally, by (5.12), (5.3), and (5.4):

$$\|S_N^R(\tau)\|_s \leqslant \sum_{n=0}^{N}\varepsilon^n\|\mathcal{T}_N f^{(n)}(\tau)\|_s + \sum_{\substack{s,n=0:\\ s+n>N}}^{N}\varepsilon^{n+s}\|T_s f^{(n)}(\tau)\|_s \leqslant C\varepsilon^{N+1}. \tag{5.17}$$

This concludes the proof. ■

We remark that the hypotheses under which we proved Theorem 5.1 could be considerably relaxed. Indeed if N is not arbitrary but given, we can prove (5.9) with $s=0$, provided that $f_0^{(n)} \in H_{N+1}$ for all $n \leqslant N$ and $u(N+1) < C$.

We now rephrase Theorem 5.1 for Sobolev spaces with negative indices to include WKB or coherent states.

We start by observing that H_{-s} solutions to Eq. (2.1), for initial condition $f_0 \in H_{-s}$, can be defined by duality:

$$(g, f(t)) = (\Omega(-t)g, f_0) \tag{5.18}$$

for all $g \in H_s$. Theorem 4.1 makes the above definition meaningful and provides the bound

$$\|f(t)\|_{-s} \leqslant C\|f_0\|_{-s}. \tag{5.19}$$

We can also extend estimates (5.3) and (5.4) by duality:

$$\|\mathcal{T}_N g\|_{-s} \leqslant C\varepsilon^{N+1} u(s+N+2)\|g\|_{-(s-N-2)}, \tag{5.20}$$

$$\|T_n g\|_s \leqslant Cu(s+n+1)\|g\|_{-(s-n-1)}. \tag{5.21}$$

Obviously Eqs. (5.20) and (5.21) make sense provided that $g \in H_{-(s-N-2)}$ and $g \in H_{-(s-n-1)}$, respectively.

Theorem 5.2: Let $f(t)$ be the solution to the initial value problem (2.1) with initial condition

$$f_0 = \sum_{n=0}^{N} \varepsilon^n f_0^{(n)} + R_N(0), \tag{5.22}$$

for some integer $N \geqslant 1$. Assume that $f_0^{(n)} \in H_{-(r+2n)}$, for some $r \geqslant 0$ and all $n \geqslant 0 \ldots N$ and that $R_N(0) \in H_{-(r+4N)}$ with the bound

$$\|R_N(0)\|_{-(r+4N)} \leqslant C\varepsilon^{N+1}. \tag{5.23}$$

If $u(r+4N+2) < C < +\infty$, then

$$f(t) = \sum_{n=0}^{N} \varepsilon^n f^{(n)}(t) + R_N(t) \tag{5.24}$$

with $f^{(n)}(t)$ given by (2.15). Furthermore:

$$\|R_N(t)\|_{-(r+4N)} \leqslant C\varepsilon^{N+1}. \tag{5.25}$$

Proof: We proceed as in the proof of Theorem 5.1. By (2.15) and (5.22), for fixed arbitrary t_0, if $t \leqslant t_0$:

$$\|f^{(n)}(t)\|_{-(r+2n)} \leqslant C\|f_0^{(n)}\|_{-(r+2n)} + C \sup_{\tau < t_0} \|S_n(\tau)\|_{-(r+2n)}. \tag{5.26}$$

Moreover, by (2.16) and (5.21):

$$\|S_n(\tau)\|_{-(r+2n)} \leqslant \sum_{k=1}^{n} \|T_k f^{(n-k)}(\tau)\|_{-(r+2n)} \leqslant C \sum_{k=1}^{n} \|f^{(n-k)}(\tau)\|_{-(r+2n-k-1)}. \tag{5.27}$$

Assuming, by inductive hypothesis, that for all $k < n$,

$$\sup_{t<t_0}\|f^{(k)}(t)\|_{-(r+2k)} = C \tag{5.28}$$

[note that Eq. (5.28) is known to hold for $k=0$ by (5.19)] then, using (5.28) in (5.27), we conclude that

$$\|S_n(\tau)\|_{-(r+2n)} \leqslant C\sum_{k=1}^{n} \|f^{(n-k)}(\tau)\|_{-(r+2(n-k))} \leqslant C \tag{5.29}$$

and hence (5.28) holds for any $k \leqslant N$.

Furthermore by (5.15), (5.11), and (5.12):

$$\|R_N(t)\|_{-(r+4N)} \leqslant C\|R_N(0)\|_{-(r+4N)} + C\sup_{t<t_0}\|S_N^R(\tau)\|_{-(r+4N)}, \tag{5.30}$$

$$\begin{aligned}\|S_N^R(\tau)\|_{-(r+4N)} &\leqslant \sum_{n=0}^{N} \varepsilon^n \|\mathcal{T}_N f^{(n)}(\tau)\|_{-(r+4N)} + \sum_{\substack{s,n=0:\\ s+n>N}}^{N} \varepsilon^{n+s}\|T_s f^{(n)}(\tau)\|_{-(r+4N)} \\ &\leqslant \varepsilon^{N+1}\sum_{s,n=0}^{N} \|f^{(n)}(\tau)\|_{-(r+2n)} \leqslant \varepsilon^{N+1}.\end{aligned} \tag{5.31}$$

This concludes the proof. ■

To comment on the result we note that if A is a quantum observable with kernel $A(x,y)$ and symbol $a(x,v)$, then:

$$(\Psi, A\Psi)_{L_2(x)} = (f_\Psi, a)_{L_2(x,v)} \tag{5.32}$$

where

$$a(x,v) = \left(\frac{\varepsilon}{2\pi}\right)^3 \int \mathrm{d}y e^{iv\cdot y} A\left(x+\varepsilon\frac{y}{2}; x-\varepsilon\frac{y}{2}\right), \tag{5.33}$$

where a is the symbol of A (which is its Weyl quantization). For many fundamental observables (like momentum, energy, angular momentum, etc.) the symbol a is independent of ε. In this case $(\Psi, A\Psi)_{L_2(x)}$ can be easily expanded:

$$(\Psi, A\Psi)_{L_2(x)} = \sum_n A_n(t)\varepsilon^n, \tag{5.34}$$

where

$$A_n(t) = \int \mathrm{d}x \int \mathrm{d}v a(x,v) f_\Psi^{(n)}(x,v;t). \tag{5.35}$$

For instance for the current density we have

$$J(x,t) = \sum_n J_n(x,t)\varepsilon^n,$$

where

$$J_n(x,t) = \int \mathrm{d}v v f_\Psi^{(n)}(x,v;t).$$

However, in principle, other observables A can have symbols which depend on ε. In this case we have to combine the semiclassical expansion of the symbol:

$$a(x,v,\varepsilon) = \sum_n a_n(x,v)\varepsilon^n$$

with the expansion (2.10) for f_Ψ, namely we have to replace (5.35) by

$$A_n(t) = \sum_{k=0}^{n} \int dx \int dv a_k(x,v) f_\Psi^{(n-k)}(x,v;t). \tag{5.36}$$

(Received 21 October 2005; accepted 2 March 2006; published online 26 May 2006)

The spreading of the quantum-mechanical probability distribution density of *D*-dimensional hydrogenic orbitals is quantitatively determined by means of the local information-theoretic quantity of Fisher in both position and momentum spaces. The Fisher information is found in closed form in terms of the quantum numbers of the orbital. © *2006 American Institute of Physics.*

I. INTRODUCTION

The Fisher information, originally introduced by R. A. Fisher in the theory of statistical estimation,[1,2] is the main theoretic tool of the extreme physical information principle, a general variational principle which allows one to derive numerous fundamental equations of physics:[3–5] Maxwell equations, the Einstein field equations, the Dirac and Klein-Gordon equations, various laws of statistical physics and some laws governing nearly incompressible turbulent fluid flows. Applications to a large variety of problems in theoretical physics have received a strong impulse when it was realized that the spatial distribution of the single-particle probability density $\rho(\vec{r})$ of a many-particle system, which is the basic variable of the density functional theory,[6,7] can be quantitatively measured by its translationally invariant Fisher information in a different and complementary manner as the Shannon entropy. Both quantities characterize the information-theoretic content of the density $\rho(\vec{r})$ which describes the physical state under consideration. The Shannon entropy[8,9] is a logarithmic functional of the density, so that it is a global measure of disorder or smoothness of $\rho(\vec{r})$. The Fisher information is the gradient functional of the density

$$I_\rho = \int_{\mathbb{R}^3} \frac{[\vec{\nabla}\rho(\vec{r})]^2}{\rho(\vec{r})} d\vec{r}, \tag{1}$$

so it has a property of locality because it is sensitive to local rearrangements of the position variable $\vec{r}$.[3,10] The higher this quantity is, the more concentrated the single-particle density, the smaller the uncertainty and the higher the accuracy is in predicting the localization for the particle.[3,11]

The Fisher information I_ρ has been shown to be closely connected with other density functionals which characterize a number of macroscopic properties of fundamental character as well as physical observables;[3,7,12,13] in particular, it represents, a constant apart, the Weiszäcker energy functional of the many-particle system.[7,13] Moreover, it has been used (i) to build up uncertainty relations stronger than the variance-based Heisenberg principle (e.g., the Cramer-Rao

[a]Electronic mail: dehesa@ugr.es

relation),[3,11,14] (ii) to analyze the correlation problem of the many-electron systems,[15] and (iii) to identify the most distinctive nonlinear spectral phenomena (the avoided crossings) of electronic systems in external fields.[16]

However, the analytical determination of the Fisher information from first principles has not been undertaken yet, even for single-particle systems. In this paper we shall calculate the Fisher information of a D-dimensional hydrogenic system in terms of D quantum numbers which characterize its orbitals not only in the position but also in the momentum representation. Emphasis will be on momentum hydrogenic orbitals, i.e., the solution to the nonrelativistic, time-independent Schrödinger equation in momentum space describing the quantum-mechanics for the motion of an electron in the Coulomb field of a nucleus with charge $+Ze$. This is not only because the momentum orbitals have usually been avoided in favor of the position orbitals but also because of (i) their conceptual importance, (ii) the distribution of momenta for real ($D=3$) atomic systems and specifically for hydrogen atom[17–19] is nowadays experimentally accessible in atomic, molecular, and nuclear experiments, especially since the advent of the modern spectroscopy (e,e'),[19] (iii) the scattering phenomena are most conveniently viewed in numerical simulations by means of momentum orbitals (see, e.g., Ref. 20), and (iv) they play a very relevant role in numerous other physical processes with atoms and molecules which are governed by simple functions of the momentum transfer.[21,22] Moreover, the D-dimensional hydrogenic orbitals are of interest as many-electron Sturmians.[23,24] For further details and motivation see Refs. 25–38.

The position and momentum hydrogenic orbitals in D-dimensions in polar coordinates are known to be composed of an angular part and a radial part.[25,39–42] The angular part, which is common to both position and momentum cases, corresponds to hyperspherical harmonics because of the radially symmetric character of the Coulomb potential. The radial part is controlled by the Laguerre and Gegenbauer polynomials in the position and momentum representations, respectively. This is not accidental; it is associated with the well-known $O(3)$ and $O(4)$ symmetries of the hydrogen atom.[43–46]

The paper is structured as follows. First in Sec. II the known position and momentum wave functions of the hydrogenic system in D dimensions are described in detail, and the corresponding probability densities are explicitly shown. Then in Secs. III and IV we find closed expressions for the Fisher information of the hydrogenic orbitals in terms of the D quantum numbers which characterize them in position and momentum spaces, respectively. Finally, some concluding remarks are given.

II. THE HYDROGENIC PROBLEM IN *D* DIMENSIONS

In the following we fix our notation and we describe in hyperspherical polar coordinates the wave functions of the D-dimensional hydrogenic orbitals (i.e., the solutions to the nonrelativistic, time-independent Schrödinger equation in D dimensions describing the quantum mechanics for the motion of an electron in the Coulomb field of a nucleus with charge $+Ze$) in the configuration (or position) and momentum spaces, as well as the associated probability densities.

A. *D*-dimensional position orbitals

The position hydrogenic orbitals $\Psi(\vec{r})$ are the solutions of the Schrödinger equation

$$\left(-\frac{\hbar^2}{2\mu}\vec{\nabla}_D^2-\frac{Ze^2}{r}\right)\Psi(\vec{r})=E\Psi(\vec{r}), \tag{2}$$

where μ is the reduced mass, the position vector $\vec{r}=(x_1,x_2,\ldots,x_D)$, and $\vec{\nabla}_D^2$ is the Laplacian operator in the D-dimensional space, $D\geqslant 2$. By use of the polar coordinates $(r,\theta_1,\theta_2,\ldots,\theta_{D-2},\varphi)$ defined by

$$x_1=r\sin\theta_1\sin\theta_2\ldots\sin\theta_{D-2}\cos\varphi,$$

$$x_2 = r \sin\theta_1 \sin\theta_2 \ldots \sin\theta_{D-2} \sin\varphi,$$

$$x_3 = r \sin\theta_1 \sin\theta_2 \ldots \cos\theta_{D-2},$$

$$\vdots$$

$$x_{D-1} = r \sin\theta_1 \cos\theta_2,$$

$$x_D = r \cos\theta_1,$$

with $0 \leqslant \theta_j \leqslant \pi$, $j=1,\ldots,D-2$, and $0 \leqslant \varphi \leqslant 2\pi$, one has that Eq. (2) transforms as

$$\left[-\frac{\hbar^2}{2\mu_e}\left(\frac{\mathrm{d}^2}{\mathrm{d}r^2} + \frac{D-1}{r}\frac{\mathrm{d}}{\mathrm{d}r} - \frac{\Lambda^2}{r^2} \right) - \frac{Ze^2}{r} \right] \Psi(\vec{r}) = E\Psi(\vec{r}),$$

where Λ^2 is the D-dimensional generalization of the square of the angular momentum operator[26,40,47] which only depends on the $D-1$ angular coordinates $\theta_1, \theta_2, \ldots, \theta_{D-2}$, and φ of a D-dimensional sphere. The technique of separation of variables is known to provide the bound state solutions $\{E, \Psi(\vec{r})\}$ for this problem. The energies are given (see, e.g., Ref. 36) by

$$E = -\frac{Z^2e^2}{a_\mu}\frac{1}{2\eta^2} = -\frac{Z^2e^2}{a_0}\frac{\mu}{m_e}\frac{1}{2\eta^2}, \tag{3}$$

where $a_\mu = \hbar^2/\mu e^2 = (m_e/\mu)a_0$, and $a_0 = \hbar^2/m_e e^2$ is the Bohr radius, and

$$\eta = n + \frac{D-3}{2}, \quad n = 1,2,3,\ldots . \tag{4}$$

The associated eigenfunctions $\Psi(\vec{r})$ have a radial part $R(r)$ and an angular part $Y(\Omega_{D-1})$ so that

$$\Psi(\vec{r}) = R(r)Y(\Omega_{D-1}), \tag{5}$$

where $Y(\Omega_{D-1})$ are the hyperspherical harmonics, i.e., the eigenfunctions of the nonradial part of the Hamiltonian, Λ^2, i.e.,

$$\Lambda^2 Y_{l,\{\mu\}}(\Omega_{D-1}) = l(l+D-2)Y_{l,\{\mu\}}(\Omega_{D-1}), \quad l = 0,1,2,\ldots .$$

Each hyperspherical harmonic is determined by the $D-1$ quantum numbers $(l \equiv \mu_1, \mu_2, \ldots, \mu_{D-1}) \equiv (l, \{\mu\})$, which may have all values consistent with the inequalities $l \equiv \mu_1 \geqslant \mu_2 \geqslant \ldots \geqslant \mu_{D-1} \equiv |m| \geqslant 0$. These functions have the form

$$Y_{l,\{\mu\}}(\Omega_{D-1}) = \frac{1}{\sqrt{2\pi}} A_{l,\{\mu\}} e^{im\varphi} \prod_{j=1}^{D-2} C_{\mu_j-\mu_{j+1}}^{\alpha_j+\mu_{j+1}}(\cos\theta_j)(\sin\theta_j)^{\mu_{j+1}} \equiv \frac{1}{\sqrt{2\pi}} e^{im\varphi} \prod_{j=1}^{D-2} Y_{\mu_j,\mu_{j+1}}^{(j)}(\theta_j), \tag{6}$$

with the normalization constant

$$|A_{l,\{\mu\}}|^2 = \prod_{j=1}^{D-2} \frac{(\alpha_j+\mu_j)(\mu_j-\mu_{j+1})![\Gamma(\alpha_j+\mu_{j+1})]^2}{\pi 2^{1-2\alpha_j-2\mu_{j+1}}\Gamma(2\alpha_j+\mu_j+\mu_{j+1})} \equiv \prod_{j=1}^{D-2} A_{\mu_j,\mu_{j+1}}^{(j)}, \tag{7}$$

where $2\alpha_j = D-j-1$ and $C_k^\lambda(t)$ is the Gegenbauer polynomial of degree k and parameter λ. In addition, we have used the notation

$$Y^{(j)}_{\mu_j,\mu_{j+1}}(\theta_j) = A^{(j)}_{\mu_j,\mu_{j+1}} C^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}}(\cos\theta_j)(\sin\theta_j)^{\mu_j+1}.$$

Remark that for $D=2$ there are no products, so that the corresponding spherical harmonic is just $e^{im\varphi}/(2\pi)$. The spherical harmonics satisfy the orthonormalization condition

$$\int_{-1}^{1} \mathrm{d}\Omega_{D-1} Y_{l',\{\mu'\}}(\Omega_{D-1}) Y_{l,\{\mu\}}(\Omega_{D-1}) = \delta_{ll'}\delta_{\{\mu\}\{\mu'\}}. \tag{8}$$

The radial eigenfunctions $R(r)$, i.e., the solutions of the radial Schrödinger equation

$$\left[-\frac{\hbar^2}{2\mu}\left(\frac{\mathrm{d}^2}{\mathrm{d}r^2} + \frac{D-1}{r}\frac{\mathrm{d}}{\mathrm{d}r} - \frac{l(l+D-2)}{r^2}\right) - \frac{Ze^2}{r}\right] R(r) = ER(r), \tag{9}$$

have the form

$$R_{\eta,L}(r) = N_{\eta,L}\left[\frac{\omega_{2L+1}(\tilde{r})}{\tilde{r}^{D-2}}\right]^{1/2} L^{2L+1}_{\eta-L-1}(\tilde{r}), \tag{10}$$

where the grand orbital angular momentum quantum number L and the adimensional parameter $\tilde{r}$ are

$$L = l + \frac{D-3}{2}, \quad l = 0,1,2,\ldots,$$

$$\tilde{r} = \frac{r}{\lambda} \quad \text{with } \lambda = \frac{\eta\hbar^2}{2Z\mu e^2} = \frac{\eta a_\mu}{2Z},$$

and $\omega_\alpha(\tilde{r}) = \tilde{r}^\alpha e^{-\tilde{r}}$ denotes the weight function with respect to which the Laguerre polynomials $L^\alpha_k(\tilde{r})$ are orthogonal on the interval $[0,\infty)$. And the normalization constant is given by

$$N_{\eta,L} = \lambda^{-D/2}\left\{\frac{(\eta-L-1)!}{2\eta[(\eta+L)!]^3}\right\}^{1/2} = \left\{\left(\frac{2Z}{a_\mu\left(n+\frac{D-3}{2}\right)}\right)^D \frac{(n-l-1)!}{2\left(n+\frac{D-3}{2}\right)[(n+l+D-3)!]^3}\right\}^{1/2} \equiv N_{n,l}.$$

Then, the complete energy eigenfunctions of the D-dimensional hydrogen atom are

$$\Psi_{\eta,L,\{\mu\}}(\vec{r}) = R_{\eta,L}(r) Y_{L,\{\mu\}}(\Omega_{D-1}) = N_{\eta,L}\left[\frac{\omega_{2L+1}(\tilde{r})}{\tilde{r}^{D-2}}\right]^{1/2} L^{2L+1}_{\eta-L-1}(\tilde{r}) Y_{L,\{\mu\}}(\Omega_{D-1}),$$

or, also the form

$$\Psi_{n,l,\{\mu\}}(\vec{r}) = R_{n,l}(r) Y_{l,\{\mu\}}(\Omega_{D-1}) = N_{n,l}\left(\frac{r}{\lambda}\right)^l e^{-(r/2\lambda)} L^{2l+D-2}_{n-l-1}\left(\frac{r}{\lambda}\right) Y_{l,\{\mu\}}(\Omega_{D-1}). \tag{11}$$

So, the probability density of the system in the configuration space $\rho(\vec{r}) = |\Psi(\vec{r})|^2$ has the form

$$\begin{aligned}\rho(\vec{r}) &= R^2_{nl}|Y_{l,\{\mu\}}(\Omega_{D-1})|^2 = N^2_{\eta,L}\left[\frac{\omega_{2L+1}(\tilde{r})}{\tilde{r}^{D-2}}\right][L^{2L+1}_{\eta-L-1}(\tilde{r})]^2 |Y_{L,\{\mu\}}(\Omega_{D-1})|^2 \\ &= N^2_{n,l}\tilde{r}^{2l}e^{-\tilde{r}}[L^{2l+D-2}_{n-l-1}(\tilde{r})]^2 |Y_{l,\{\mu\}}(\Omega_{D-1})|^2,\end{aligned} \tag{12}$$

where Eqs. (5), (10), and (11) were taken into account, and the notation $\tilde{r} = r/\lambda$ given by Eq. (9) has been used. It is worth noticing that this expression reduces to the well-known position eigenfunctions for the three-dimensional hydrogenic atom when $D=3$.

B. *D*-dimensional momentum orbitals

By means of a generalization of the Fock method[48] (see also Refs. 40–42 and 49) to *D*-dimensional hydrogenic atoms or, alternatively, by computing the *D*-dimensional Fourier transform of the configuration eigenfunction $\Psi_{nl\{\mu\}}(\vec{r})$[25,50,51] it is obtained that the *D*-dimensional hydrogen eigenfunction in momentum space $\Psi_{nl\{\mu\}}(\vec{p})$ has the form

$$\Psi_{nl\{\mu\}}(\vec{p}) = M_{\eta,L}(p) Y_{l\{\mu\}}(\Omega_{D-1}), \tag{13}$$

when

$$M_{\eta,l}(p) = K_{\eta,L} \frac{(\eta p)^l}{(1+\eta^2 p^2)^{L+2}} C_{\eta-L-1}^{L+1}\left(\frac{1-\eta^2 p^2}{1+\eta^2 p^2}\right). \tag{14}$$

Here the electron momentum p is assumed to be expressed in units of Zp_μ, where $p_\mu=(\mu/m)p_0$, with the atomic momentum unit $p_0=\hbar/a_0$. And the normalization constant

$$K_{\eta,L} = \left(\frac{(\eta-L-1)!}{2\pi(\eta+L)!}\right)^{1/2} 2^{2L+3}\Gamma(L+1)\,\eta^{(D+1)/2}. \tag{15}$$

Then, the corresponding probability density in momentum space $\gamma(\vec{p})=|\Psi_{nl\{\mu\}}(\vec{p})|^2$ is expressed as

$$\gamma(\vec{p}) = K_{nl}^2 \frac{(\eta p)^{2l}}{(1+\eta^2 p^2)^{2l+D+1}} \left[C_{n-l-1}^{l+(D-1)/2}\left(\frac{1-\eta^2 p^2}{1+\eta^2 p^2}\right)\right]^2 |Y_{l\{\mu\}}(\Omega_D)|^2.$$

Here again, for $D=3$ this expression reduces to the corresponding momentum density of the three-dimensional hydrogenic atom.[52]

III. THE FISHER INFORMATION IN POSITION SPACE

In this section we compute the Fisher information of the *D*-dimensional hydrogenic orbital in configuration space, characterized by the quantum numbers $(n,l,\mu_2,\ldots,\mu_{D-1})\equiv(n,l,\{\mu\})$, i.e.,

$$I_\rho(D) := \int_{\mathbb{R}^D} \frac{[\vec{\nabla}_D \rho(\vec{r})]^2}{\rho(\vec{r})} \mathrm{d}^D r, \tag{16}$$

where $\rho(\vec{r})$ is the position probability density of the orbital as given by Eq. (12), $\vec{\nabla}_D$ denotes the *D*-dimensional gradient operator given by

$$\vec{\nabla}_D = \frac{\partial}{\partial r}\hat{r} + \frac{1}{r}\sum_{i=1}^{D-2} \frac{1}{\prod_{k=1}^{i-1} \sin\theta_k} \frac{\partial}{\partial\theta_i}\theta_i + \frac{1}{r\prod_{i=1}^{D-2}\sin\theta_i}\frac{\partial}{\partial\varphi}\hat{\varphi}, \tag{17}$$

in the polar coordinates $(r,\theta_1,\theta_2,\ldots,\theta_{D-2},\varphi)$, and the volume element in the *D*-dimensional space is

$$\mathrm{d}\vec{r} = r^{D-1}\mathrm{d}r\mathrm{d}\Omega_{D-1}; \mathrm{d}\Omega_{D-1} = \left(\prod_{j=1}^{D-2}(\sin\theta_j)^{2\alpha_j}\mathrm{d}\theta_j\right)\mathrm{d}\varphi.$$

Taking into account that

$$\rho(\vec{r}) = |\Psi_{n,l,\{\mu\}}(r,\theta_1,\theta_2,\ldots,\theta_{D-2},\varphi)|^2 = |\Psi_{n,l,\{\mu\}}(r,\theta_1,\theta_2,\ldots,\theta_{D-2},0)|^2,$$

one has that

$$I_\rho(D) = 4\int_{\Re^D} [\vec{\nabla}_D \Psi_{n,l,\{\mu\}}(r,\theta_1,\theta_2,\ldots,\theta_{D-2},0)]^2 \mathrm{d}^D r. \tag{18}$$

The use of Eqs. (11) and (17) into this expression allows us to write that

$$\begin{aligned} I_\rho(D) &= 4\int_0^\infty \left[\frac{\partial}{\partial r} R_{nl}(r)\right]^2 r^{D-1}\mathrm{d}r + 4\int_0^\infty r^{-2} R_{nl}^2(r) r^{D-1}\mathrm{d}r \\ &\times \sum_{i=1}^{D-2} \int_{\Omega_{D-1}} \left[\frac{1}{\prod_{k=1}^{i-1} \sin\theta_k} \frac{\partial}{\partial\theta_i} Y_{l,\{\mu\}}(\theta_1,\theta_2,\ldots,\theta_{D-2},0)\right]^2 \mathrm{d}\Omega_{D-1} \\ &\equiv I_R(D) + \langle r^{-2}\rangle \sum_{i=1}^{D-2} I_{\theta_i}(D), \end{aligned} \tag{19}$$

where we have used the orthonormalization condition (8) of the hyperspherical harmonics in the first equality, and the expectation value

$$\langle f(r)\rangle = \int_{\Re^D} f(r)\rho(\vec{r})\mathrm{d}^D r = \int_0^\infty f(r) R_{nl}^2(r) r^{D-1}\mathrm{d}r, \tag{20}$$

for $f(r)=r^{-2}$ in the second equality. As well we have used the notations

$$I_R(D) \equiv 4\int_0^\infty \left[\frac{\mathrm{d}}{\mathrm{d}r} R_{nl}(r)\right]^2 r^{D-1}\mathrm{d}r, \tag{21}$$

for the radial component of the Fisher information $I_\rho(D)$, and

$$I_{\theta_i}(D) \equiv 4\int_{\Omega_{D-1}} \left[\frac{1}{\prod_{k=1}^{i-1} \sin\theta_k} \frac{\partial}{\partial\theta_i} Y_{l,\{\mu\}}(\theta_1,\theta_2,\ldots,\theta_{D-2},0)\right]^2 \mathrm{d}\Omega_{D-1}, \tag{22}$$

for the ith part of the angular component.

In the following we are going to show that the radial integral $I_R(D)$ has the value

$$I_R(D) = \frac{4Z^2}{a_\mu^2 \eta^3}\left[\eta - 2\frac{l(l+D-2)}{2l+D-2}\right] = \frac{4Z^2}{a_\mu^2\eta^3}\left\{\eta - \frac{2}{2L+1}\left[L(L+1) - \frac{1}{4}(D-1)(D-3)\right]\right\}, \tag{23}$$

where we have used that $l(l+D-2)=L(L+1)-\frac{1}{4}(D-1)(D-3)$, and that the angular component $I_{\theta_i}(D)$ is given by

$$I_{\theta_i}(D) = 4\left[\mu_i(\mu_i+D-i-1) - \mu_{i+1}(\mu_{i+1}+D-i-2)\frac{2\mu_i+D-i-1}{2\mu_{i+1}+D-i-2}\right] \times \prod_{k=1}^{i-1} \frac{2\mu_k+D-k-1}{2\mu_{k+1}+D-k-2}. \tag{24}$$

Taking into account that the product

$$\prod_{k=1}^{i-1} \frac{2\mu_k+D-k-1}{2\mu_{k+1}+D-k-2} = \frac{2\mu_1+D-2}{2\mu_i+D-i-1}, \tag{25}$$

one has that Eq. (24) reduces as

$$I_{\theta_i}(D) = 4\left[\mu_i(\mu_i + D - i - 1) - \mu_{i+1}(\mu_{i+1} + D - i - 2)\frac{2\mu_i + D - i - 1}{2\mu_{i+1} + D - i - 2}\right] \times \frac{2\mu_1 + D - 2}{2\mu_i + D - i - 1}. \tag{26}$$

Consideration of Eqs. (19), (23), and (26), and that the expectation value

$$\langle r^{-2}\rangle = \frac{2Z^2}{a_\mu^2 \eta^3}\frac{1}{2l + D - 2} = \frac{2Z^2}{a_\mu^2 \eta^3}\frac{1}{2L + 1}, \tag{27}$$

we have found the following value for the Fisher information of the D-dimensional hydrogenic orbital in the configuration space:

$$I_\rho(D) = \frac{4Z^2}{a_\mu^2 \eta^3}\left\{\eta - \frac{2}{2L+1}\left[L(L+1) - \frac{1}{4}(D-1)(D-3) - \sum_{i=1}^{D-2}\left(\mu_i(\mu_i + D - i - 1) - \frac{\mu_{i+1}(\mu_{i+1} + D - i - 2)(2\mu_i + D - i - 1)}{2\mu_{i+1} + D - i - 2}\right) \times \frac{2\mu_1 + D - 2}{2\mu_i + D - i - 1}\right]\right\}. \tag{28}$$

Straightforward algebraic manipulations lead to the following simple expression for the D-dimensional position Fisher information

$$I_\rho(D) = \frac{4Z^2}{a_\mu^2 \eta^3}[\eta - \mu_{D-1}], \tag{29}$$

valid for $D \geqslant 2$. Remark that for $D=2$, the summation is empty, so that it does not contribute.

It is observed that the Fisher information, as the ionization energy [see Eq. (3)], behaves as η^{-2} with respect to the generalized principal quantum number η [see Eq. (4)]. Remark that the Fisher information depends on the grand principal quantum number η and the grand magnetic quantum number $\mu_{D-1} = |m|$. It is worth noticing that for $D=3$ this expression boils down to

$$I_\rho(D=3) = \frac{4Z^2}{a_\mu^2}\frac{n - |m|}{n^3},$$

recently obtained by other means.[53,54] One observes that the Fisher information of the real hydrogenic system, as well as the level energy, does not depend on the familiar orbital quantum number, but it does depend on the magnetic quantum number m.

Let us first compute the radial integral $I_R(D)$ given by Eq. (21). The integration by parts leads us to the expression

$$I_R(D) = 4\int_0^\infty r^{D-1}R'\,\mathrm{d}R = -4(D-1)\int_0^\infty r^{D-2}RR'\,\mathrm{d}r - 4\int_0^\infty r^{D-1}RR''\,\mathrm{d}r.$$

The use of the radial Schrödinger equation (9) expressed as

$$R''(r) = a_1(r)R'(r) + a_2(r)R(r), \tag{30}$$

with

$$a_1(r) = \frac{1-D}{r}, \tag{31}$$

$$a_2(r) = \frac{2Z}{a_\mu r} + \frac{2E}{a_\mu e^2} - \frac{l(l+D-2)}{r^2}, \tag{32}$$

allows us to write

$$\begin{aligned} I_R(D) &= -4(D-1)\int_0^\infty r^{D-2} RR' \mathrm{d}r - 4\int_0^\infty r^{D-1} R[a_1(r)R' + a_2(r)R]\mathrm{d}r \\ &= -4\int_0^\infty [(D-1)r^{D-2} + a_1(r)r^{D-1}]RR' \mathrm{d}r - 4\int_0^\infty a_2(r)R^2 r^{D-1}\mathrm{d}r \\ &= -2\int_0^\infty [(D-1)r^{D-2} + a_1(r)r^{D-1}]\mathrm{d}R^2 - 4\int_0^\infty a_2(r)R^2 r^{D-1}\mathrm{d}r. \end{aligned}$$

And the integration by parts in the first integral gives rise to

$$\begin{aligned} I_R(D) &= \int_0^\infty \left\{ 2(D-1)\left[(D-2)r^{-2} + \frac{a_1(r)}{r} \right] + 2a_1'(r) - 4a_2(r) \right\} R^2 r^{D-1}\mathrm{d}r \\ &= \left\langle 2(D-1)\left[(D-2)r^{-2} + \frac{a_1(r)}{r} \right] + 2a_1'(r) - 4a_2(r) \right\rangle \\ &= 2(D-1)\left[(D-2)\langle r^{-2}\rangle + \left\langle \frac{a_1(r)}{r} \right\rangle \right] + 2\langle a_1'(r)\rangle - 4\langle a_2(r)\rangle, \end{aligned} \tag{33}$$

where we have used of the expectation value of $f(r)$ given by Eq. (20).

The use of Eqs. (31) and (32) allows us to write

$$\left\langle \frac{a_1(r)}{r} \right\rangle = (1-D)\langle r^{-2}\rangle, \quad \langle a_1'(r)\rangle = (D-1)\langle r^{-2}\rangle \langle a_2(r)\rangle = \frac{2Z}{a_\mu}\langle r^{-1}\rangle + \frac{2E}{a_\mu e^2} - l(l+D-2)\langle r^{-2}\rangle,$$

so that the radial integral $I_R(D)$ is equal to

$$I_R(D) = \frac{8Z}{a_\mu}\langle r^{-1}\rangle + \frac{8E}{a_\mu e^2} - 4l(l+D-2)\langle r^{-2}\rangle.$$

And taking into account the virial theorem

$$E = -\frac{Ze^2}{2}\langle r^{-1}\rangle,$$

one has that

$$I_R(D) = \frac{8Z}{2a_\mu}\langle r^{-1}\rangle - 4l(l+D-2)\langle r^{-2}\rangle. \tag{34}$$

Then, since $\langle r^{-1}\rangle = Z/a_\mu \eta^2$ and $\langle r^{-2}\rangle$ has the value (27), it is straightforward to obtain the searched expression (23) for the radical position Fisher information of the hydrogenic orbital.

Let us now compute the angular integral $I_{\theta_i}(D)$ given by Eq. (22). To do that, according to Eq. (6) we express the involved hyperspherical harmonics as

$$Y_{l,\{\mu\}}(\theta_1, \theta_2, \ldots, \theta_{D-2}, 0) = \frac{1}{2\pi}\prod_{j=1}^{D-2} Y^{(j)}_{\mu_j,\mu_{j+1}}(\theta_j),$$

where

$$Y^{(j)}_{\mu_j,\mu_{j+1}}(\theta_j) \equiv A^{(j)}_{\mu_j,\mu_{j+1}} C^{\alpha_j+\mu_{j+1}}_{\mu_j-\mu_{j+1}}(\cos\,\theta_j)(\sin\,\theta_j)^{\mu_j+1},$$

where the constant $A^{(j)}_{\mu_j,\mu_{j+1}}$ was defined by Eq. (7).

These functions satisfy the following properties: the normalization condition

$$\int_0^\pi [Y^{(j)}_{\mu_j,\mu_{j+1}}(\theta_j)]^2(\sin\,\theta_j)^{D-j-1}\mathrm{d}\theta_j = 1,$$

and the differential equation (see, e.g., Ref 26):

$$\frac{\partial}{\partial\theta_j}\left[(\sin\,\theta_j)^{D-j-1}\frac{\partial}{\partial\theta_j}Y^{(j)}_{\mu_j,\mu_{j+1}}(\theta_j)\right]$$
$$= -(\sin\,\theta_j)^{D-j-1}\left[\mu_j(\mu_j+D-j-1) - \frac{\mu_{j+1}(\mu_{j+1}+D-j-2)}{\sin^2\,\theta_j}\right]Y^{(j)}_{\mu_j,\mu_{j+1}}(\theta_j).$$

Use of these considerations into Eq. (22) allows us to write

$$I_{\theta_i}(D) = I^{(1)}_{\theta_i}(D)\cdot\prod_{k=1}^{i-1}\int_0^\pi [Y^{(k)}_{\mu_k,\mu_{k+1}}(\theta_k)]^2(\sin\,\theta_k)^{D-k-3}\mathrm{d}\theta_k$$

where

$$I^{(1)}_{\theta_i}(D) = \int_0^\pi\left[\frac{\partial}{\partial\theta_i}Y^{(i)}_{\mu_i,\mu_{i+1}}(\theta_i)\right]^2(\sin\,\theta_i)^{D-i-1}\mathrm{d}\theta_i = -\int_0^\pi\frac{\partial}{\partial\theta_i}\left[(\sin\,\theta_i)^{D-i-1}\frac{\partial}{\partial\theta_i}Y^{(i)}_{\mu_i,\mu_{i+1}}(\theta_i)\right]Y^i_{l,\{\mu\}}\mathrm{d}\theta_i$$
$$= \mu_i(\mu_i+D-i-1)\int_0^\pi [Y^{(i)}_{\mu_i,\mu_{i+1}}(\theta_i)]^2(\sin\,\theta_i)^{D-i-1}\mathrm{d}\theta_i$$
$$-\mu_{i+1}(\mu_{i+1}+D-i-2)\int_0^\pi [Y^{(i)}_{\mu_i,\mu_{i+1}}(\theta_i)]^2(\sin\,\theta_i)^{D-i-3}\mathrm{d}\theta_i,$$

where an integration by parts has been performed in the second equality, and the orthogonalization condition of the harmonics $Y^{(i)}_{\mu_i,\mu_{i+1}}(\theta_i)$ were taken into account in the second equality. The normalization of these functions and the value of the integral

$$\int_0^\pi [Y^{(i)}_{\mu_i,\mu_{i+1}}(\theta_i)]^2(\sin\,\theta_i)^{D-i-3}\mathrm{d}\theta_i = \frac{2\mu_i+D-i-1}{2\mu_{i+1}+D-i-2}, \tag{35}$$

has allowed us to find the value given by Eq. (24) for the searched angular integral $I_{\theta_i}(D)$. The integral (35) can be obtained by the use of the relation between the involved spherical harmonics and the associated Legendre function $P^m_n(x)$, together with the expression

$$\int_{-1}^{+1}(1-x^2)^{-1}[p^m_n(x)]^2\mathrm{d}x = \frac{(n+m)!}{m(n-m)!}.$$

IV. THE FISHER INFORMATION IN MOMENTUM SPACE

Here we calculate the Fisher information of D-dimensional hydrogenic orbital in momentum space given by

$$I_\gamma(D) \coloneqq \int_{\Re^D} \frac{|\vec{\nabla}_D \gamma(\vec{p})|^2}{\gamma(\vec{p})} \mathrm{d}^D p, \tag{36}$$

where

$$\gamma(\vec{p}) = |\Psi_{\eta,l,\{\mu\}}(\vec{p})|^2 = |\Psi_{\eta,l,\{\mu\}}(p,\theta_1,\theta_2,\ldots,\theta_{D-1})|^2 = [\Psi_{\eta,l,\{\mu\}}(p,\theta_1,\theta_2,\ldots,\theta_{D-2},0)]^2,$$

so that, after an integration by parts, one has

$$I_\gamma(D) = 4\int_{\Re^D} [\vec{\nabla}_D \Psi_{\eta,l,\{\mu\}}(p,\theta_1,\theta_2,\ldots,\theta_{D-2},0)]^2 \mathrm{d}^D p.$$

Remark that the spherical polar angles of the momentum vector $\vec{p}$ are denoted with the same symbols as in the position vector. The D-dimensional gradient operator in momentum space has the same formal expression as given by Eq. (17) with the only change $r \leftrightarrow p$, so that

$$\begin{aligned} I_\gamma(D) &= 4\int_0^\infty \left[\frac{\mathrm{d}}{\mathrm{d}p} M_{\eta,L}(p)\right]^2 p^{D-1}\mathrm{d}p + 4\int_0^\infty p^{-2} M_{\eta,L}^2(p) p^{D-1}\mathrm{d}p \\ &\quad \times \sum_{i=1}^{D-2} \int_{\Omega_{D-1}} \left[\frac{1}{\prod_{k=1}^{i-1} \sin\theta_k} \frac{\partial}{\partial\theta_i} Y_{l,\{\mu\}}(\theta_1,\theta_2,\ldots,\theta_{D-2},0)\right]^2 \mathrm{d}\Omega_{D-1} \\ &\equiv 4J_R(D) + 4\langle p^{-2}\rangle \sum_{i=1}^{D-2} I_{\theta_i}(D), \end{aligned} \tag{37}$$

where the angular integral $I_{\theta_i}(D)$ has been shown to have the value (26) in the previous section and the expectation value $\langle p^{-2}\rangle$ is given by

$$\langle p^{-2}\rangle = \int_0^\infty p^{-2} M_{\eta,L}^2(p) p^{D-1}\mathrm{d}p = \eta^2 \frac{8\eta - 6L - 3}{(2L+1)}. \tag{38}$$

Let us now compute the radial integral $J_R(D)$ given by

$$J_R(D) = \int_0^\infty \left[\frac{\mathrm{d}}{\mathrm{d}p} M_{\eta,L}(p)\right]^2 p^{D-1}\mathrm{d}p = \left(\frac{1}{\eta}\right)^{D-2} \int_0^\infty \left[\frac{\mathrm{d}M_{\eta,L}(x)}{\mathrm{d}x}\right]^2 x^{D-1}\mathrm{d}x,$$

where $x = \eta p$, and

$$M_{\eta,L}(x) = K_{n,l} \frac{x^l}{(1+x^2)^{L+2}} C_{\eta-L-1}^{L+1}\left(\frac{1-x^2}{1+x^2}\right).$$

The change of the variable $x \to y : y = (1-x^2)/(1+x^2)$, so that $\mathrm{d}x = (1-y)^{-3/2}(1+y)^{-1/2}\mathrm{d}y$, allows us to write

$$J_R(D) = \left(\frac{1}{\eta}\right)^{D-2} \int_{-1}^{+1} \left[\frac{\mathrm{d}M_{\eta,L}(y)}{\mathrm{d}y}\right]^2 (1+y)^{D/2}(1-y)^{-(D-4)/2}\mathrm{d}y, \tag{39}$$

where

$$M_{\eta,L}(y) = \frac{K_{\eta,L}}{2^{L+2}} (1+y)^{L/2-(D-3)/4} (1-y)^{L/2+(D-5)/4} C_{\eta-L-1}^{L+1}(y). \tag{40}$$

This integral can be decomposed into a sum of functionals of Gegenbauer polynomials whose members can be calculated following a modus operandi similar to that described in Ref. 51. This is done in the Appendix. We have found the value

$$J_R(D) = \eta^2 \frac{[(2L-D+3)(2L+D-1)(6L-8\eta+3)]}{4(2L+1)} + \frac{\eta^2}{2}(1+5\eta^2-3L(L+1)). \tag{41}$$

Gathering together in Eq. (37) the values for the radial integral $J_R(D)$, the expectation value $\langle p^{-2}\rangle$ and the angular integral $I_{\theta_i}(D)$ given by Eqs. (41), (38), and (26), respectively, one finally obtains the following expression for the Fisher information of a D-dimensional hydrogenic orbital in momentum space [see Eq. (36)]:

$$I_\gamma(D) = \eta^2 \Bigg\{ \frac{[(2L-D+3)(2L+D-1)(6L-8\eta+3)]}{(2L+1)} + 2(1+5\eta^2-3L(L+1)) + 4\frac{8\eta-6L-3}{2L+1} \cdot \times \sum_{i=1}^{D-2} \left[\mu_i(\mu_i+D-i-1) - \mu_{i+1}(\mu_{i+1}+D-i-2)\frac{2\mu_i+D-i-1}{2\mu_{i+1}+D-i-2} \right] \times \frac{2\mu_1+D-2}{2\mu_i+D-i-1} \Bigg\}. \tag{42}$$

A straightforward algrebraic manipulation leads to the more compact expression

$$I_\gamma(D) = 2\eta^2[5\eta^2 - 3L(L+1) - (8\eta-6L-3)\mu_{D-1}],$$

valid for $D \geqslant 2$. Here again for $D=2$ the term containing the summation does not contribute since the sum is empty. In the case $D=3$ this expression reduces as

$$I_\gamma(D=3) = 2n^2[5n^2+1-3l(l+1)+3(2l+1)|m| - 8n|m|],$$

which provides the Fisher information of the momentum distribution of a hydrogenic state characterized by the quantum numbers (n,l,m), already found by other means.[54]

V. CONCLUDING REMARKS

The translationally invariant Fisher information for D-dimensional hydrogenic systems, which is an information-theoretic measure of the localization of the quantum-mechanical distribution density of these systems all over the space, has been determined in a closed and compact form for both position and momentum spaces in terms of the dimension parameter D, the nuclear charge Z and the quantum numbers η, L and $\mu_{D-1}=|m|$ of the physical state under consideration.

Finally, let us point out that this information-theoretic quantity remains to be calculated for multidimensional hydrogenic Sturmians of nonspherical character (e.g., parabolic, elliptic)[55–57] in the two complementary spaces. This work is presently being done by the authors.

APPENDIX: CALCULATION OF THE MOMENTUM RADIAL INTEGRAL $J_R(D)$

Here we shall prove that the radial integral $J_R(D)$ given by Eqs. (39) and (40) has the value given by Eq. (41). From Eqs. (39) and (40) one has that $J_R(D)$ can be decomposed into six different integrals as

$$J_R(D) = J_{R_1} + J_{R_2} + J_{R_3} + J_{R_4} + J_{R_5} + J_{R_6}. \tag{A1}$$

With the notation $\omega_{L+1}(y)=(1-y^2)^{L+1/2}$ for the weight function of the Gegenbauer polynomials $C_m^{L+1}(y)$, these integrals have the following values:

$$J_{R_1}=\frac{K_{\eta,L}^2}{2^{2L+4}}\left(\frac{1}{\eta}\right)^{D-2}(2L-D+3)^2\int_{-1}^{+1}[C_{\eta-L-1}^{L+1}(y)]^2\omega_{L+1}(y)(1+y)^{-1}\mathrm{d}y=\frac{2\eta^3(2L-D+3)^2}{2L+1},$$

$$J_{R_2}=\frac{K_{\eta,L}^2}{2^{2L+4}}\left(\frac{1}{\eta}\right)^{D-2}\left[\frac{(D+1)^2}{4}-(2L-D+3)^2\right]\int_{-1}^{+1}[C_{\eta-L-1}^{L+1}(y)]^2\omega_{L+1}(y)\mathrm{d}y$$
$$=\eta^2\left[\frac{(D+1)^2}{4}-(2L-D+3)^2\right],$$

$$J_{R_3}=\frac{K_{\eta,L}^2}{2^{2L+4}}\left(\frac{1}{\eta}\right)^{D-2}[L(D-3L-11)+2D-10]\times\int_{-1}^{+1}[C_{\eta-L-1}^{L+1}(y)]^2\omega_{L+1}(y)y^2\mathrm{d}y$$
$$=\frac{\eta^2}{2}[L(D-3L-11)+2D-10]\frac{\eta^2-1-L(L+1)}{\eta^2-1},$$

$$J_{R_4}=\frac{K_{\eta,L}^2}{2^{2L+2}}\left(\frac{1}{\eta}\right)^{D-2}(L+1)^2\int_{-1}^{+1}[C_{\eta-L-2}^{L+2}(y)]^2\omega_{L+2}(y)(1-y)^3\mathrm{d}y$$
$$=\eta^2[\eta^2-(L+1)^2]\left[1+\frac{3}{2}\frac{\eta^2-3-L(L+3)}{\eta^2-1}\right],$$

$$J_{R_5}=-8\frac{K_{\eta,L}^2}{2^{2L+4}}\left(\frac{1}{\eta}\right)^{D-2}(2L-D+3)(L+1)\int_{-1}^{+1}[C_{\eta-L-1}^{L+1}(y)][C_{\eta-L-2}^{L+2}(y)]\omega_{L+1}(y)y\mathrm{d}y$$
$$=-4\eta^2(2L-D+3)(\eta-L-1),$$

and

$$J_{R_6}=2\frac{K_{\eta,L}^2}{2^{2L+4}}\left(\frac{1}{\eta}\right)^{D-2}(6L-D+11)(L+1)\int_{-1}^{+1}[C_{\eta-L-1}^{L+1}(y)][C_{\eta-L-2}^{L+2}(y)]\omega_{L+2}(y)y\mathrm{d}y$$
$$=\frac{\eta^2}{2}(6L-D+11)(L+1)\frac{\eta^2-(L+1)^2}{\eta^2-1}.$$

To compute the integrals included in the six expressions considered above, we have made an intensive use of the special properties which characterize the Gegenbauer polynomials (e.g., the three-term recurrence relation, the orthogonality relation, etc.).

Gathering all these J-expressions together in Eq. (A1), one obtains the searched value given by Eq. (41) for $J_R(D)$; namely,

$$J_R(D)=\eta^2\frac{[(2L-D+3)(2L+D-1)(6L-8\eta+3)]}{4(2L+1)}+\frac{\eta^2}{2}(1+5\eta^2-3L(L+1)).$$

(Received 20 October 2006; accepted 21 March 2006; published online 5 May 2006)

We use a coproduct on the time-ordered algebra of field operators to derive simple relations between complete, connected and 1-particle irreducible *n*-point functions. Compared to traditional functional methods our approach is much more intrinsic and leads to efficient algorithms suitable for concrete computations. It may also be used to efficiently perform tree level computations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2196239]

I. INTRODUCTION

It may be said that time-ordered *n*-point functions are at the heart of (perturbative) quantum field theory. These determine the S-matrix that in turn allows to calculate experimentally observable scattering cross sections. Besides the complete *n*-point functions which are expectation values of time-ordered products of field operators, a key role is played by connected and by 1-particle irreducible (1PI) *n*-point functions. In particular, the latter play a prominent role in the process of renormalization, as it is enough to renormalize 1PI *n*-point functions. Furthermore, they are intimately related to the effective action. The different classes of *n*-point functions correspond directly to different sums over Feynman graphs, namely all graphs (excluding vacuum graphs), connected graphs and 1PI graphs.

The relations between these different classes of *n*-point functions (and thus sums over Feynman graphs) are traditionally expressed by using functional methods. While having an undeniable elegance, a disadvantage of these methods is the need for auxiliary sources and associated generating functions. These, as well as functional derivatives used in the process are often purely formal and have no rigorous mathematical existence. Consequently, they are only indirectly related to concrete calculations of *n*-point functions one may wish to perform.

In the present paper we describe the relation between these classes of *n*-point functions directly on the level of the algebra of time-ordered field operators. The key structure we will make use of is the natural *coproduct* on this algebra, making it into a *Hopf algebra*. Ensembles of time-ordered *n*-point functions are simply linear forms on this algebra. We show that the convolution product (induced by the coproduct) provides an extremely concise and elegant way of relating complete and connected *n*-point functions. Indeed, this relation is simply given by the convolution exponential (or, conversely, the logarithm).

Our second (and perhaps main) result concerns the relation of connected and 1PI *n*-point functions. As is well known, the former are expressible in terms of the latter as the sum over all tree graphs with 1PI vertices. We present a simple recursion formula using the coproduct, which generates exactly all tree diagrams. Moreover, the result takes an algebraic form which can be directly evaluated on 1PI functions so as to yield the connected functions. We proceed to derive an alternative recursion formula which relates directly components of connected *n*-point functions

[a]Electronic mail: mestre@matmor.unam.mx
[b]Electronic mail: robert@matmor.unam.mx

ordered by vertex number. Moreover, these same formulas can be alternatively applied to calculate the tree level contribution to the connected n-point functions, using the interaction terms of the Lagrangian.

A key feature of our results is their close relation to algorithmic descriptions of the computations involved. Indeed, it is easy to read off from our recursion relations not only algorithms to perform the computations, but even data structures relevant for an implementation. Our algorithm for generating trees also seems to be particular efficient as it allows to impose a lower bound on the number of legs per vertex from the outset.

The present paper may be seen as part of a program laid out in Ref. 1 and rooted in Ref. 2–4, with the aim of formulating and understanding the key structures of quantum field theory and their combinatorics in terms of the Hopf algebra of field operators. The focus of Ref. 1 were the different products of field operators (normal product, canonical product, and time-ordered product), uncovering their relation through Drinfeld twists via certain 2-cocycles in Hopf algebra cohomology. At the same time the relation between products and associated n-point functions was elucidated, again using Hopf algebra cohomology. The present paper complements this by investigating with the same means the relation between different classes of n-point functions that correspond to different classes of Feynman diagrams.

While Hopf algebras and coproducts have a long history in combinatorics, their use in combinatorial problems in quantum field theory is rather recent. The first instance probably was Kreimer's Hopf algebraic explanation of the Bogoliubov formula of renormalization and of Zimmermann's solution,[5] subsequently developed together with Connes.[6] We caution the reader, however, that the Hopf algebras used by Kreimer and Connes, while also being related to Feynman graphs, are quite distinct from the Hopf algebra of field operators used here.

Section II starts with recalling the different classes of n-point functions and their relation to Feynman graphs. Then, the basic algebraic formalism used in this paper is introduced, in particular the coproduct. Section III deals with the relation between complete and connected n-point function, Sec. IV with that between connected and 1PI n-point functions. An alternative recursion formula for the latter is derived in Sec. V. In Sec. VI various generalizations (e.g., tree level calculations) and related issues are discussed. Some Conclusions are offered in Sec. VII. The appendix shows all tree graphs with up to seven vertices with weight factors computed according to Sec. IV.

No knowledge of Hopf algebras is required to read this paper.

II. BASIC DEFINITIONS

We shall be concerned in the following with a generic perturbative quantum field theory. We denote the basic field operators by $\phi(x)$, where x represents a label that completely determines the operator. In a position representation x would specify a point in Minkowski space, possibly together with internal indices. While our notation suggests a field theory with a single scalar field, this is just a convenience. Although our results are general, we limit ourselves in the following exposition to a purely bosonic theory for simplicity. We return in Sec. VI D to a discussion of the general case, including fermionic fields.

A. Feynman graphs and *n*-point functions

We review here essentials about (classes of) Feynman graphs and n-point functions. For more information on these and the standard functional approach used to manipulate them we refer the reader to standard textbooks such as Ref. 7.

Definition 1: *A graph is a finite collection of* vertices *and* edges (*also called* legs), *such that any end of an edge may be connected to a vertex. Edges that are connected to vertices at both ends are called* internal, *while edges with at least one free end are called* external. *The* valence *of a vertex is the number of ends of edges connected to the vertex. A* tree *(graph) is a connected graph that has no cycles.*

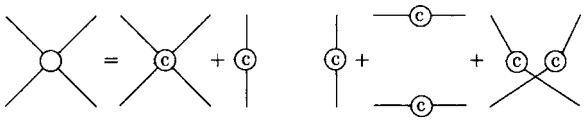

FIG. 1. Decomposition of the complete 4-point function in terms of connected functions.

Feynman graphs are graphs that carry certain labels on vertices and edges. The former correspond to the interaction terms of the Lagrangian while the latter may correspond to momenta and internal indices (usually indicated by different styles of lines, e.g., straight for fermions, wiggly for bosons, etc.). We shall only consider labels attached to (open ends) of external legs, assuming internal labels to be summed or integrated over.

Definition 2: *A* labeled *graph is a graph whose (ends of) external legs are labeled by field operator labels.*

In the following we shall consider only such labeled graphs, i.e., from now on *graph* really means *labeled graph*. A Feynman graph has a (usually complex) value as a function of the labels on the external legs.

We denote by $G^{(n)}(x_1,\ldots,x_n)$ the *complete* n-point function. This is the vacuum expectation value of the time-ordered product of n field operators, i.e.,

$$G^{(n)}(x_1,\ldots,x_n)=\langle 0|T\phi(x_1)\cdots\phi(x_n)|0\rangle.$$

In terms of Feynman graphs it is the sum of the values of all graphs with external legs labeled by $x_1,\ldots,x_n$. Let us denote by Γ^n the set of all Feynman graphs of the given theory with n legs (with vacuum graphs, i.e., graphs containing pieces not connected to any external leg already excluded). [Whether one considers the bare or renormalized (including counter terms) theory does not matter to us here. Of course, in the former case quantities might be infinite and manipulations therefore formal.] For a given graph $\gamma\in\Gamma^n$ we denote by $\gamma(x_1,\ldots,x_n)$ its value for the given labelings. Then,

$$G^{(n)}(x_1,\ldots,x_n)=\sum_{\gamma\in\Gamma^n}\gamma(x_1,\ldots,x_n). \tag{1}$$

Of particular importance is the Feynman propagator $G_F(x,y)$ which is the value of the graph that consists of an edge only, its two ends labeled by x and y, respectively. Note that the Feynman propagator is symmetric in its arguments $G_F(x,y)=G_F(y,x)$ as suggested by the corresponding symmetry of the graph. We also define its inverse G_F^{-1} which is determined by the equation

$$\int \mathrm{d}y G_F(x,y)G_F^{-1}(y,z)=\delta(x,z). \tag{2}$$

(Here as in the following we use a notation that suggests merely an integration over space–time. However, appropriate summations over internal indices are also implied, but not written explicitly.)

Consider the restricted class Γ_c of Feynman graphs that are connected. The n-point functions $G_c^{(n)}$ defined by the corresponding restriction of (1) are called the *connected* n-point functions. The relation between complete and connected n-point functions can be described in a simple way. Partition the set of external legs of the complete n-point function in all possible ways. The sum over the product of connected functions for each partition yields the complete n-point function,

$$G^{(n)}(x_1,\ldots,x_n)=\sum_{k=1}^{n}\sum_{I_1\cup\cdots\cup I_k=\{x_1,\ldots,x_n\}}\prod_{j=1}^{k}G_c(I_j). \tag{3}$$

Here $I_1,\ldots,I_k$ denote nonempty subsets of $\{x_1,\ldots,x_n\}$ forming a partition. Note also that the partitions are *unordered*, i.e., the subsets $I_1,\ldots,I_k$ are not distinguished. As an example, Fig. 1

FIG. 2. Decomposition of the connected propagator in terms of 1PI functions. Only part of the infinite sum is shown.

shows the decomposition of the complete 4-point function in terms of connected functions. The former is indicated by an empty circle, while the latter are indicated by circles carrying the letter "c."

We turn to consider the restriction of the class of connected Feynman graphs to that of *1-particle irreducible (1PI)* Feynman graphs, denoted by $\Gamma_{1\mathrm{PI}}$. These are Feynman graphs which are connected and remain connected when any one of their internal edges is cut. We define $G_{1\mathrm{PI}}$ in analogy to (1) for this restricted class. The relation between 1PI functions and connected ones may now be described as follows. The connected n-point function is the sum over all tree graphs with the given external legs, where the value of each vertex is given by $G_{1\mathrm{PI}}$. Since the latter carry Feynman propagators on all their legs, internal edges connecting two vertices need to carry the inverse Feynman propagator G_F^{-1} to cancel one superfluous Feynman propagator. As an example, Fig. 2 shows the infinite decomposition of the connected 2-point function (propagator) in terms of 1PI ones. The 1PI vertices are drawn as shaded discs.

One variant of the 1PI functions is of interest. Namely, replace the Feynman propagator G_F on the external legs of a 1PI function by the connected propagator $G_c^{(2)}$. We denote these modified 1PI functions by $\hat{G}_{1\mathrm{PI}}$. The relation between G_c and $\hat{G}_{1\mathrm{PI}}$ is the same as that between G_c and $G_{1\mathrm{PI}}$ described above, except that internal edges now carry the inverse $(G_c^{(2)})^{-1}$ of the connected propagator [defined analogous to (2)]. A crucial property of the modified 1PI functions is that the 2-point function $\hat{G}_{1\mathrm{PI}}^{(2)}$ vanishes by definition. This means that only trees with vertices that have valence at least three can occur in the sum. In particular, this makes the sum over trees finite for any given set of external legs. Figure 3 shows the decomposition of the connected 4-point function in terms of modified 1PI functions. The fact that the legs now carry the connected propagator is indicated with little circles.

Note that we assume all 1-point functions to vanish.

B. Field operator algebra and coproduct

We turn to introduce the basic algebraic definitions and elementary formalism employed in this paper. While our basic setup is largely the same as that in Ref. 1 we give an adapted and self-contained description here.

Let V be the vector space of linear combinations of elementary field operators $\phi(x)$. That is, elements of V take the form $\lambda_1\phi(x_1)+\lambda_2\phi(x_2)+\cdots+\lambda_n\phi(x_n)$, where λ_i are complex numbers and x_i denote field operator labels. Consider now the commutative algebra $\mathsf{S}(V)$ generated by those field operators with the *time-ordered* product. In Ref. 1 the same algebra was considered, but with the *normal ordered* product. This makes no difference to its structure. It is just more convenient in the present context to start immediately with time-ordered product. A general element in $\mathsf{S}(V)$ takes the form

$$\lambda_1\phi(x_{1,1})\phi(x_{1,2})\cdots\phi(x_{1,k_1})+\lambda_2\phi(x_{2,1})\phi(x_{2,2})\cdots\phi(x_{2,k_2})+\cdots.$$

Note that we do not explicitly indicate the time-ordering prescription, but it is always understood. Let us denote by V^k the vector space of k-fold products of field operator. Then, $\mathsf{S}(V)$ is the direct sum of the spaces V^k, i.e., $\mathsf{S}(V)=\oplus_{k=0}^{\infty}V^k$. We denote the identity operator spanning V^0 by $\mathbf{1}$.

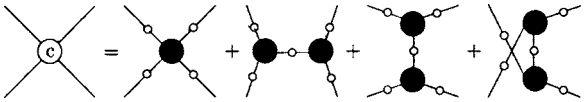

FIG. 3. Decomposition of the complete 4-point function in terms of modified 1PI functions.

In mathematical terms, $\mathsf{S}(V)$ is called the *symmetric algebra* over V. In our current notation a time-ordered n-point function is a linear map $V^n \to \mathbb{C}$. Thus, the ensemble of time-ordered n-point functions (of a given type) determines a linear map $\mathsf{S}(V) \to \mathbb{C}$. Recalling the various types of n-point functions introduced in the preceding section we denote the corresponding linear maps $\mathsf{S}(V) \to \mathbb{C}$ as follows:

$$\rho(\phi(x_1)\cdots\phi(x_n)) := G^{(n)}(x_1,\ldots,x_n),$$

$$\sigma(\phi(x_1)\cdots\phi(x_n)) := G_c^{(n)}(x_1,\ldots,x_n),$$

$$\tau(\phi(x_1)\cdots\phi(x_n)) := G_{1\mathrm{PI}}^{(n)}(x_1,\ldots,x_n),$$

$$\hat{\tau}(\phi(x_1)\cdots\phi(x_n)) := \hat{G}_{1\mathrm{PI}}^{(n)}(x_1,\ldots,x_n).$$

The assumption that all 1-point functions vanish means that $\rho(\phi(x))=\sigma(\phi(x))=\tau(\phi(x))=\hat{\tau}(\phi(x))=0$. For completeness, we also need to define 0-point functions. Since $\rho(\mathbf{1})=\langle 0|0\rangle$ we need to set $\rho(\mathbf{1})=1$. We shall see that the consistent choice for the other 0-point functions is $\sigma(\mathbf{1})=\tau(\mathbf{1})=\hat{\tau}(\mathbf{1})=0$. Also, the 2-point function $\hat{\tau}(\phi(x)\phi(y))$ vanishes by construction.

$\mathsf{S}(V)$ is not only an algebra, but also a *coalgebra* in a natural way. This means that there exists a linear *coproduct* map $\Delta:\mathsf{S}(V)\to\mathsf{S}(V)\otimes\mathsf{S}(V)$ with certain properties. One way to think about this coproduct map is as a way to split a product of field operators into two parts in all possible ways. For example,

$$\Delta(\mathbf{1}) = \mathbf{1}\otimes\mathbf{1}, \tag{4}$$

$$\Delta(\phi(x)) = \phi(x)\otimes\mathbf{1} + \mathbf{1}\otimes\phi(x), \tag{5}$$

$$\Delta(\phi(x)\phi(y)) = \phi(x)\phi(y)\otimes\mathbf{1} + \phi(x)\otimes\phi(y) + \phi(y)\otimes\phi(x) + \mathbf{1}\otimes\phi(x)\phi(y). \tag{6}$$

The general formula for the coproduct is

$$\Delta(\phi(x_1)\cdots\phi(x_n)) = \sum_{I_1\cup I_2=\{\phi(x_1),\ldots,\phi(x_n)\}} T(I_1)\otimes T(I_2). \tag{7}$$

Here the sum runs over partitions of the set of field operators $\{\phi(x_1),\ldots,\phi(x_n)\}$ into two sets I_1 and I_2. T denotes the time-ordered product of the field operators in the corresponding partition.

The coproduct has the property that it is an algebra map. This means that $\Delta(\phi(x_1)\cdots\phi(x_n))=\Delta(\phi(x_1)\cdots\phi(x_k))\cdot\Delta(\phi(x_{k+1})\cdots\phi(x_n))$. Here, the product in $\mathsf{S}(V)$ is extended to a product in $\mathsf{S}(V)\otimes\mathsf{S}(V)$ in the obvious way. The property of the coproduct to be an algebra map together with (4) and (5) completely determines it. Formula (7) can be derived from these properties.

Another important structure is the *counit* $\epsilon:\mathsf{S}(V)\to\mathbb{C}$. It is defined by $\epsilon(\mathbf{1})=1$ and $\epsilon(\phi(x_1)\cdots\phi(x_n))=0$ for $n>0$. The characterizing property of the counit is the equality $(\epsilon\otimes\mathrm{id})\circ\Delta=\mathrm{id}=(\mathrm{id}\otimes\epsilon)\circ\Delta$. The algebra $\mathsf{S}(V)$ together with unit, counit, coproduct, and antipode (which is another map that we do not need here) forms a *Hopf algebra*, see Ref. 1.

We shall also need iterated coproducts. First note that the coproduct satisfies the equality $(\Delta\otimes\mathrm{id})\circ\Delta=(\mathrm{id}\otimes\Delta)\circ\Delta$. That is, after applying the coproduct once, a second application either on the first or on the second component yield the same result. This is called *coassociativity*. We define the map $\Delta^k:\mathsf{S}(V)\to\mathsf{S}(V)^{\otimes k+1}$ as the k-fold application of the coproduct. Here, $\mathsf{S}(V)^{\otimes k+1}$ denotes the $(k+1)$-fold tensor product of $\mathsf{S}(V)$. Thus, $\Delta^0=\mathrm{id}$ and $\Delta^{k+1}=(\Delta\otimes\mathrm{id}^{\otimes k})\circ\Delta^k$. Here, the latter equation could be written in $k+1$ different ways (corresponding to different positions of the application of the coproduct) which are all equivalent due to coassociativity. The map Δ^k generalizes (7) as follows:

$$\Delta^k(\phi(x_1)\cdots\phi(x_n)) = \sum_{I_1\cup\cdots\cup I_{k+1}=\{\phi(x_1),\ldots,\phi(x_n)\}} T(I_1)\otimes\cdots\otimes T(I_{k+1}). \tag{8}$$

The difference to the single coproduct is that the set of field operators is now split into $k+1$ partitions. Note also that the partitions are *ordered*, i.e., the sets $I_1\ldots I_{k+1}$ are distinguishable.

A further definition we will require is the following. Given linear maps $\alpha:\mathsf{S}(V)\to\mathbb{C}$ and $\beta:\mathsf{S}(V)\to\mathbb{C}$ their *convolution product* is the map $\alpha\star\beta:\mathsf{S}(V)\to\mathbb{C}$ defined by $(\alpha\otimes\beta)\circ\Delta$. That is, we apply the coproduct followed by the application of α to its first and β to its second component. Note that the coassociativity of the coproduct implies associativity of the convolution product. Thus, we can write multiple convolution products without needing to specify brackets. In particular, we may write an iterated convolution product using the iterated coproduct,

$$\alpha_1\star\cdots\star\alpha_k = (\alpha_1\otimes\cdots\otimes\alpha_k)\circ\Delta^{k-1}. \tag{9}$$

The convolution product makes $(\mathsf{S}(V))^*$, the space of complex linear functions on $\mathsf{S}(V)$, into an algebra. This algebra has a unit which is given by the counit ϵ of $\mathsf{S}(V)$. Furthermore, any element α which satisfies $\alpha(\mathbf{1})\neq 0$ is invertible in this algebra, i.e., has an inverse with respect to the convolution product.

III. COMPLETE AND CONNECTED *n*-POINT FUNCTIONS

The first instance where we shall apply the Hopf algebraic approach to capture the combinatorics of quantum field theory is in the relation between the complete and the connected n-point functions.

As the (iterated) coproduct (8) is intimately related to partitions it seems predestined to express the relation between complete and connected n-point functions (3). Indeed, the relation between the two is very compactly and elegantly expressed using the convolution product (and thus implicitly the coproduct).

Proposition 3: *The complete n-point functions may be expressed in terms of the connected ones through the convolution exponential,* $\rho=\exp_\star\sigma$. *The convolution exponential is defined in terms of its power series expansion.*

Proof: We explicitly perform the power series expansion on a given argument in the subspace $V^n\subset\mathsf{S}(V)(n>0)$,

$$(\exp_\star(\sigma))(\phi(x_1)\cdots\phi(x_n)) = \sum_{k=0}^{\infty}\frac{1}{k!}\sigma^{\star k}(\phi(x_1)\cdots\phi(x_n))$$

$$=\sum_{k=1}^{\infty}\frac{1}{k!}(\sigma\otimes\cdots\otimes\sigma)\circ\Delta^{k-1}(\phi(x_1)\cdots\phi(x_n))$$

$$=\sum_{k=1}^{n}\frac{1}{k!}\sum_{I_1\cup\cdots\cup I_k=\{\phi(x_1),\ldots,\phi(x_n)\}}\prod_{j=1}^{k}\sigma(T(I_j)).$$

Here, $\sigma^{\star k}$ denotes the k-fold convolution product of σ with itself. In particular, $\sigma^{\star 0}=\epsilon$ by definition. Since $\epsilon(\phi(x_1)\cdots\phi(x_n))=0$ the first summand is zero in the first line and we may omit it. In going from the second to the third line we insert the definition of the iterated coproduct (8). Note that by definition $\sigma(\mathbf{1})=0$. This implies that all partitions where at least one partitioning set I_j is empty do not contribute. In particular, all summands of the outer sum with $k>n$ must vanish. The only difference to the partitioning in (3) is that the latter are unordered. However, the number of occurrences of each unordered partition in the set of ordered ones is exactly $k!$. Thus, the factor $1/k!$ establishes equality with $\rho(\phi(x_1)\cdots\phi(x_n))$. To complete the proof, note that $\rho(\mathbf{1})=\sigma^{\star 0}(\mathbf{1})=\epsilon(\mathbf{1})=1$ since $\sigma(\mathbf{1})=0$ and thus $\sigma^{\star k}(\mathbf{1})=0$ for $k>0$. □

Let us emphasize that although the power series defining the exponential is formally infinite, on any given element of $\mathsf{S}(V)$ it is truncated to a finite and thus well defined sum as shown in the proof above. Thus, the relation $\rho=\exp_\star \sigma$ is completely well-defined algebraically. Indeed, we may even invert it.

Corollary 4: *The connected n-point functions may be expressed in terms of the complete ones through the convolution logarithm,* $\sigma=\log_\star 0$. *The convolution logarithm is defined in terms of its power series expansion in* $\rho-\epsilon$.

Proof: By definition

$$\log_\star \rho = \sum_{k=0}^{\infty} (-1)^k \frac{1}{k} (\rho - \epsilon)^{\star k}.$$

Note that $(\rho-\epsilon)(\mathbf{1})=0$. This implies as in the proof of Proposition 3 that the sum truncates to a finite sum on any given element in $\mathsf{S}(V)$. One may show that the operations $\exp_\star$ and $\log_\star$ are mutually inverse by inserting one power series into the other. Since the procedure and result is exactly the same as in the usual arithmetic of complex numbers (say) we do not perform it explicitly here. However, it is crucial that the truncation of the power series for any given argument in $\mathsf{S}(V)$ makes it algebraically well defined in the present context. □

The attentive reader will notice that the present method of relating the complete and connected *n*-point functions shows certain similarities to the conventional one. Namely, in the conventional method one also finds that the relation is given by the exponential and the logarithm respectively, see e.g., Ref. 7. The difference is of course that the conventional method uses sources while the present one uses the coproduct to define exponential and logarithm.

IV. CONNECTED AND 1PI *n*-POINT FUNCTIONS

We now turn to the relation between connected and 1PI *n*-point functions. To state our Hopf algebraic formulation of this relation we need to define a few auxiliary structures first.

Define the formal element $R \in \mathsf{S}(V) \otimes \mathsf{S}(V)$ using the inverse Feynman propagator (2) as follows [R is formal insofar as it really lives in a completion of the tensor product $\mathsf{S}(V) \otimes \mathsf{S}(V)$. However, this fact is largely irrelevant for our purposes]:

$$R := \int \mathrm{d}x\, \mathrm{d}y\, G_F^{-1}(x,y)(\phi(x) \otimes \phi(y)). \tag{10}$$

Using the product in $\mathsf{S}(V) \otimes \mathsf{S}(V)$ we may view R as an operator acting on this space by multiplication. Define now the map $Q: \mathsf{S}(V) \to \mathsf{S}(V) \otimes \mathsf{S}(V)$ as the composition of R with the coproduct together with a factor of $1/2$:

$$Q := \tfrac{1}{2} R \circ \Delta. \tag{11}$$

We generalize Q to maps $Q_i: \mathsf{S}(V)^{\otimes k} \to \mathsf{S}(V)^{\otimes k+1}$. Namely, let Q_i be the application of Q on the ith component only, i.e.,

$$Q_i := \mathrm{id}^{\otimes i-1} \otimes Q \otimes \mathrm{id}^{\otimes k-i}.$$

Finally, we define maps $\Lambda^k: \mathsf{S}(V) \to \mathsf{S}(V)^{\otimes k+1}$ for $k \in \mathbb{N}_0$ recursively as follows:

$$\Lambda^0 := \mathrm{id},$$

$$\Lambda^k := \frac{1}{k} \sum_{i=1}^{k} Q_i \circ \Lambda^{k-1}. \tag{12}$$

We are now ready to state our main result.

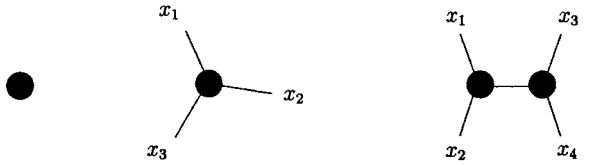

FIG. 4. Examples for the correspondence of graphs with elements of $\mathsf{S}(V)^{\otimes k}$.

Theorem 5: *The connected n-point functions may be expressed in terms of the 1PI ones through the formula*

$$\sigma = \sum_{k=1}^{\infty} \sigma^k, \text{ with } \sigma^k := \tau^{\otimes k} \circ \Lambda^{k-1}. \tag{13}$$

The remainder of this section will be devoted to the proof of this result.

Recall from the description in Sec. II A that the connected n-point functions are expressible as the sum over all tree graphs with 1PI n-point functions as vertices. Since the latter are represented by τ we see that the sum in formula (13) must correspond to the sum over the number of such vertices k. In turn, the map Λ^k must contain the information about all tree graphs with k vertices. We proceed to explain this.

We first generalize the definition of R given in (10) to an element (or operator) $R_{i,j} \in \mathsf{S}(V)^{\otimes k}$ with $1 \leqslant i < j \leqslant k$ via

$$R_{i,j} := \int \mathrm{d}x\, \mathrm{d}y\, G_F^{-1}(x,y)(\mathbf{1}^{\otimes i-1} \otimes \phi(x) \otimes \mathbf{1}^{\otimes j-i-1} \otimes \phi(y) \otimes \mathbf{1}^{\otimes k-j}). \tag{14}$$

In other words, the field operators $\phi(x)$ and $\phi(y)$ are inserted at the ith and jth position, respectively.

We proceed to establish a correspondence between graphs with k vertices and certain elements of $\mathsf{S}(V)^{\otimes k}$. Each tensor factor of $\mathsf{S}(V)^{\otimes k}$ corresponds to one vertex. A product $\phi(x_1)\cdots\phi(x_n)$ in a given tensor factor corresponds to external legs labeled by $x_1, \ldots, x_n$. The element $R_{i,j} \in \mathsf{S}(V)^{\otimes k}$ corresponds to an internal edge connecting the ith vertex with the jth vertex. Combining several internal edges and external legs by multiplying the respective expressions in $\mathsf{S}(V)^{\otimes k}$ allows to build arbitrary graphs with k vertices. Figure 4 shows some examples. Applying $\tau^{\otimes k}$ to the resulting expression obviously yields the value of the respective graph with the vertices being 1PI functions. Thus, the graphs we just discussed are exactly those that are to enter into expressing the connected functions in terms of the 1PI ones.

The ordering of the tensor factors of $\mathsf{S}(V)^{\otimes k}$ induces an ordering of the vertices of the graph, i.e., we may think of them as labeled with numbers $1, \ldots, k$. However, when applying $\tau^{\otimes k}$ the ordering is "forgotten." Indeed, it is not relevant for the interpretation of graphs, but only plays a role at the level of their algebraic representation here. For short, we call a graph *ordered* if its vertices are ordered. In the following, we will encounter elements of $\mathsf{S}(V)^{\otimes k}$ that are linear combinations of expressions corresponding to ordered graphs. Alternatively, we might think of such elements as linear combinations of unordered graphs by considering different ordered graphs that correspond to the same unordered graph as the same. We call *weight* of the graph the scalar multiplying the expression for a given graph. Clearly, the weight of an unordered graph is the sum of the weights of all corresponding ordered graphs.

We see now what is required to prove Theorem 5. Namely, we need to show that $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n)) \in \mathsf{S}(V)^{\otimes k}$ corresponds exactly to the sum over all tree graphs with k (unordered) vertices and external legs labeled by $x_1, \ldots, x_n$, each with weight one. Actually, we need to

show something slightly weaker, namely, the statement needs to apply only to graphs where all of the vertices have valence at least two. This is because the 0-point and 1-point 1PI functions are zero. Indeed, we will see in the process that the more general statement is false.

Consider the coproduct applied to the ith component of $\mathsf{S}(V)^{\otimes k}$, i,e., $\Delta_i := \mathrm{id}^{\otimes i-1} \otimes \Delta \otimes \mathrm{id}^{\otimes k-i}$ as a map $\mathsf{S}(V)^{\otimes k} \to \mathsf{S}(V)^{\otimes k+1}$. Recalling the formula (7) we see that Δ_i converts a graph with k vertices into a sum over graphs with $k+1$ vertices by *splitting* the ith vertex into two in all possible ways. That is, the ith vertex is replaced by two vertices (numbered i and $i+1$) and its legs (considered as distinguishable) are distributed between the two new vertices in all possible ways. Note that the two new vertices are distinguished due to the ordering of the tensor factors. Thus, to obtain the corresponding operation for unordered graphs we need to divide by a factor of 2. This factor corresponds to the two different relative orderings of the new vertices with which each unordered configuration occurs. The only exception to this is the case when the split vertex has no legs at all. No overcounting happens in this case. The meaning of the map Q_i given by (11) becomes clear now in terms of graphs. Namely, it splits the ith vertex into two and subsequently reconnects the two new vertices with an edge. Dividing by 2 compensates for the double counting as described above if we are interested in unordered graphs (assuming the set of legs of the split vertex is not empty).

Lemma 6: *Fix integers $k \geqslant 1$ and $n \geqslant 0$ as well as field operator labels $x_1, \ldots, x_n$. (a) $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))$ corresponds in the manner described above to a sum of weighted graph with k vertices and n external legs labeled by $x_1, \ldots, x_n$. (b) Each of these graphs is connected. (c) Each of these graphs is a tree graph. (d) Any free graph with k unlabeled vertices and the given external legs occurs in $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))$ with some positive weight.*

Proof: First, it is clear that $\Lambda^0(\phi(x_1)\cdots\phi(x_n))$ corresponds to the graph with one vertex and the external legs labeled by $x_1, \ldots, x_n$. Second, $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))$ is generated from this by sums of multiple applications of maps Q_i and scalar factors. But Q_i converts a term corresponding to a graph to a sum over terms corresponding to graphs. Thus, $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))$ is a sum of terms each of which corresponds to a graph (with some weight). This completes the proof of (a).

Given a connected graphs, splitting a vertex produces at most two disconnected pieces. Reconnecting the new vertices with an edge yields again a connected graph. Thus, Q_i produces connected graphs from connected ones. Evidently, $\Lambda^0(\phi(x_1)\cdots\phi(x_n))$ corresponds to a connected graph. This proves (b).

Splitting a vertex of a tree graph necessarily yields two disconnected graphs. Reconnecting the new vertices with an edge thus cannot introduce a cycle. Therefore, Q_i produces tree graphs from tree graphs. Evidently, $\Lambda^0(\phi(x_1)\cdots\phi(x_n))$ corresponds to a tree graph. This proves (c).

To prove (d) we use a recursive argument. Evidently, for $k=1$ the statement is true. Now assume that any tree graph with $k-1$ unlabeled vertices and the given external legs occurs in $\Lambda^{k-2}(\phi(x_1)\cdots\phi(x_n))$ with positive weight. Consider a tree graph with k unlabeled vertices and the given external legs. Choose an arbitrary internal edge. Shrinking this edge and fusing the vertices it connects yields a tree graph that corresponds by assumption to a term in $\Lambda^{k-2}(\phi(x_1)\cdots\phi(x_n))$. Say, the fused vertex has position i. Applying Q_i to this term will yield a sum over terms one of which will correspond to the original tree graph. By the recursive definition of $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))$ it thus contains this term with positive weight. This completes the proof. □

What remains in order to prove Theorem 5 is to show that the term corresponding to each tree graph (with all vertices of valence at least two) has weight exactly 1. We start with a more restricted result.

Lemma 7: *Fix integers $k \geqslant 1$ and $n \geqslant k$ and field operator labels $x_1, \ldots, x_n$. Consider a tree with k vertices, external legs labeled by $x_1, \ldots, x_n$ and the property that each vertex has at least one external leg. Then, the term in $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))$ corresponding to that tree has weight 1.*

Proof: We proceed by induction on the number of vertices. Clearly, the statement is true for $k=1$. Now assume that $\Lambda^{k-2}(\phi(x_1)\cdots\phi(x_n))$ contains each tree graph with $k-1$ vertices and external legs labeled by $x_1, \ldots, x_n$ and the property that each vertex carries at least one external leg with weight exactly 1. (Of course it may in addition contain terms corresponding to other graphs.) Consider a tree graph γ with k vertices, external legs labeled by $x_1, \ldots, x_n$ and the property that

each vertex carries at least one external leg. We proceed to show that it occurs with weight exactly 1 in $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))$. To this end we check from which graphs with $k-1$ vertices γ is generated by the recursion formula (12) and in how many ways. Translated into the language of graphs, the formula prescribes that a given graph is split and reconnected at every of its vertices. The resulting terms are summed over and multiplied by $1/k$. Conversely, this implies that γ is generated from all the graphs that are obtained by shrinking one of its internal edges. Since there are k edges these are a priori k graphs. These graphs are indeed all distinct, since the external legs attached to each vertex force them to be distinguishable. Furthermore, each of these graphs generates γ in only one way, i.e., as one resulting graph in the splitting and reconnecting of only one of its vertices (again due to the forced distinguishability of the vertices). Since by assumption each generating graph has weight one, the multiplicity k cancels exactly with the factor $1/k$ in (12) to produce weight 1 for γ. This completes the proof. □

To describe the weight of arbitrary tree graphs we will need to consider symmetries of graphs.

Definition 8: *Consider a tree graph γ with ordered vertices*. A symmetry *of γ is a permutation of the ordering of its vertices that yields the (topologically) same ordered graph. The number of symmetries, i.e., order of the group of permutations leaving the graph invariant, is called the* symmetry factor *of the graph*.

Since the symmetry factor is the same for any ordering of the vertices of a graph the concept makes sense for unordered graphs as well.

We also need the following property of Λ^k.

Lemma 9: *Fix integers $k,n\geqslant 0$ and operator labels $x_1,\ldots,x_n$. Then, Λ^k satisfies the factorization property*

$$\Lambda^k(\phi(x_1)\cdots\phi(x_n)) = \Lambda^k(\mathbf{1})\cdot\Delta^k(\phi(x_1)\cdots\phi(x_n)).$$

Proof: This follows immediately from the multiplicativity of the coproduct and the recursive definition (12). □

We can now state the generalization of Lemma 7.

Lemma 10: *Fix integers $k\geqslant 1$ and $n\geqslant 0$ and field operator labels $x_1,\ldots,x_n$. Consider a tree γ with k vertices and external legs labeled by $x_1,\ldots,x_n$. Let s be the symmetry factor of γ. Then, the term in $\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))$ corresponding to that tree has weight $1/s$.*

Proof: If γ has external legs attached to every of its vertices we simply recall Lemma 7 and note that a graph with this property has no nontrivial symmetries. Thus, we may now assume that γ has m vertices to which no external leg is attached. Consider a graph γ' which is constructed from γ by attaching an external leg to every vertex without external legs, choosing arbitrary but fixed labels $y_1,\ldots,y_m$ for the legs in the process. By Lemma 9 and the multiplicativity of Δ and thus Δ^j we have

$$\Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n)\phi(y_1)\cdots\phi(y_m)) = \Lambda^{k-1}(\phi(x_1)\cdots\phi(x_n))\cdot\Delta^{k-1}(\phi(y_1)\cdots\phi(y_m)).$$

By Lemma 7, the graph γ' occurs in the term on left-hand side with weight 1. By Lemma 6, the graph γ occurs in the first factor on the right-hand side with some nonzero weight, say α. Every summand of $\Delta^{k-1}(\phi(y_1)\cdots\phi(y_m))$ [recall the formula (8)] which places the external legs at the designated vertices of γ to produce γ' contributes to the weight of γ' in terms of that of γ. Any different ways this can happen define a symmetry of γ. Furthermore, γ can have no more than these symmetries, since its vertices that already carry external legs are distinguishable and thus held fixed under any symmetry. Therefore, we obtain the formula $1=\alpha\cdot s$ for the weights, or $\alpha=1/s$. This completes the proof. □

The appendix shows the result of computing all tree graphs without external legs as weighted contributions to $\Lambda^{k-1}(\mathbf{1})$, for vertex number $k\leqslant 7$.

The proof of Theorem 5 is completed with the following lemma.

Lemma 11: *Consider a tree graph γ, all of whose vertices have valence at least two. Then, γ has no nontrivial, symmetries*.

Proof: Consider a vertex v of γ. We show that any symmetry must leave v invariant. If v

carries an external leg it must be invariant since it is distinguishable. Thus, assume v carries no external leg. Choose one internal edge e connected to v. Cut γ into two by removing e. This yields two tree graphs γ_1 and γ_2. Each of these must have at least one external leg to satisfy the valence requirement. Say e_1 is an external leg of γ_1 and e_2 an external leg of γ_2. Since γ is a tree there is exactly one path to connect e_1 with e_2. Since the vertices connected with e_1 and e_2 are held fixed under any symmetry so is the whole chain of vertices formed by the path. However, v is part of this chain by construction and thus held fixed by any symmetry. □

V. FURTHER RECURSION RELATIONS

We may extend the results of the preceding section to obtain further interesting recursion relations. Recall from (13) the decomposition of σ into components σ^k according to vertex number k.

Proposition 12: *σ^k may be determined recursively via $\sigma^1=\tau$ and with the recursion equation for $k>1$,*

$$\sigma^k = \frac{1}{k-1}\sum_{i=1}^{k-1} (\sigma^i \otimes \sigma^{k-i}) \circ Q.$$

Given the definition of σ^k in (13) Proposition 12 is implied by the following lemma.

Lemma 13:

$$\Lambda^{k-1} = \frac{1}{k-1}\sum_{i=1}^{k-1} (\Lambda^{i-1} \otimes \Lambda^{k-i-1}) \circ Q \quad \forall\, k>1.$$

Proof: As a first step to the proof, we "commute" the R-operator contained in Q through the tensor product $\Lambda^{i-1}\otimes\Lambda^{k-i-1}$. To this end, recall the multiplicativity of the (iterated coproduct) together with the factorization property of Λ (Lemma 9). We obtain the equivalent expression

$$\begin{aligned}\Lambda^{k-1} &= \frac{1}{2(k-1)}\sum_{i=1}^{k-1} ((\Delta^{i-1} \otimes \Delta^{k-i-1})R) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-i-1}) \circ \Delta \\ &= \frac{1}{2(k-1)}\sum_{i=1}^{k-1} \left(\sum_{a=1}^{i}\sum_{b=i+1}^{k} R_{a,b}\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-i-1}) \circ \Delta. \end{aligned} \tag{15}$$

Before proceeding with the proof we note that this formula has a straight forward interpretation in terms of sums over weighted tree diagrams following the correspondence of Sec. IV. Namely, the formula states that the weighted sum over trees with k vertices is given by summing over all ordered pairs of weighted trees with total number of vertices equal to k, connecting them in all possible ways with an edge and dividing by $2(k-1)$. [Indeed, it would be possible to base the proof of Lemma 7 on the recursion formula for Λ given here instead of (12). The argument would then roughly proceed by considering all $k-1$ ways to cut a tree with k vertices into two by removing an internal edge. The factor 2 accounts for the relative ordering of the two subtrees.]

The equation (15) is proved by induction. We verify it for $k=2$,

$$\Lambda^1 = \frac{1}{2}R \cdot (\Lambda^0 \otimes \Lambda^0) \circ \Delta = \frac{1}{2}R \cdot \Delta,$$

and assume it hold for general order k. Then, (12) yields

$$
\begin{aligned}
\Lambda^k &= \frac{1}{k}\left(\sum_{j=1}^{k} Q_j\right) \circ \Lambda^{k-1} \\
&= \frac{1}{k}\left(\sum_{j=1}^{k} Q_j\right) \frac{1}{2(k-1)} \left(\sum_{i=1}^{k-1} \left(\sum_{a=1}^{i} \sum_{b=i+1}^{k} R_{a,b}\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-i-1})\right) \circ \Delta \\
&= \frac{1}{2k(k-1)} \sum_{i=1}^{k-1} \left(\left(\sum_{j=1}^{i} Q_j\right)\left(\left(\sum_{a=1}^{i} \sum_{b=i+1}^{k} R_{a,b}\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-1-i})\right)\right. \\
&\quad \left. + \left(\sum_{j=i+1}^{k} Q_j\right)\left(\left(\sum_{a=1}^{i} \sum_{b=i+1}^{k} R_{a,b}\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-1-i})\right)\right) \circ \Delta \\
&= \frac{1}{2k(k-1)} \sum_{i=1}^{k-1} \left(\sum_{j=1}^{i} \left(\left(\Delta_j \sum_{a=1}^{i} \sum_{b=i+1}^{k} R_{a,b}\right) \cdot Q_j\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-1-i})\right. \\
&\quad \left. + \sum_{j=i+1}^{k} \left(\left(\Delta_j \sum_{a=1}^{i} \sum_{b=i+1}^{k} R_{a,b}\right) \cdot Q_j\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-1-i})\right) \circ \Delta \\
&= \frac{1}{2k(k-1)} \sum_{i=1}^{k-1} \left(i\left(\sum_{a=1}^{i+1} \sum_{b=i+2}^{k+1} R_{a,b}\right) \cdot (\Lambda^{i} \otimes \Lambda^{k-1-i})\right. \\
&\quad \left. + (k-i)\left(\sum_{a=1}^{i} \sum_{b=i+1}^{k+1} R_{a,b}\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-i})\right) \circ \Delta \\
&= \frac{1}{2k}\left(\left(\sum_{a=1}^{k} R_{a,k+1}\right) \cdot (\Lambda^{k-1} \otimes \Lambda^{0}) + \sum_{i=2}^{k-1} \left(\sum_{a=1}^{i} \sum_{b=i+1}^{k+1} R_{a,b}\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-i})\right. \\
&\quad \left. + \left(\sum_{b=2}^{k+1} R_{1,b}\right) \cdot (\Lambda^{0} \otimes \Lambda^{k-1})\right) \circ \Delta \\
&= \frac{1}{2k} \sum_{i=1}^{k} \left(\sum_{a=1}^{i} \sum_{b=i+1}^{k+1} R_{a,b}\right) \cdot (\Lambda^{i-1} \otimes \Lambda^{k-i}) \circ \Delta .
\end{aligned}
$$

□

VI. EXTENSIONS AND APPLICATIONS

A. Modified 1PI functions

In Sec. II A we have discussed two versions of 1PI functions, the standard one, denoted $G_{1\mathrm{PI}}$, and a modified one, denoted $\hat{G}_{1\mathrm{PI}}$. Recall that the connected n-point functions G_c are expressible in terms of $G_{1\mathrm{PI}}$ and of $\hat{G}_{1\mathrm{PI}}$ essentially in the same way, as a sum over all tree graphs, the difference being that for $\hat{G}_{1\mathrm{PI}}$ the (inverse) Feynman propagator G_F is replaced by the (inverse) connected propagator $G_c^{(2)}$ for all edges. Thus, the results of Secs. IV and V immediately carry over to the relation between connected functions and modified 1PI functions. We only need to modify the definition of R by replacing G_F^{-1} with $G_c^{(2)-1}$ in (10); call the new version $\hat{R}$. We denote the induced modifications of Q and Λ by $\hat{Q}$ and $\hat{\Lambda}$, respectively.

Corollary 14: *The connected n-point functions may be expressed in terms of the modified 1PI ones through the formula*

$$
\sigma = \sum_{k=1}^{\infty} \hat{\sigma}^k, \quad \textit{with} \quad \hat{\sigma}^k := \hat{\tau}^{\otimes k} \circ \hat{\Lambda}^{k-1}. \tag{16}
$$

Corollary 15: *$\hat{\sigma}^k$ may be determined recursively via $\hat{\sigma}^1=\hat{\tau}$ and with the recursion equation for $k>1$,*

$$\hat{\sigma}^k=\frac{1}{k-1}\sum_{i=1}^{k-1}(\hat{\sigma}^i\otimes\hat{\sigma}^{k-i})\circ\hat{Q}.$$

Recall that for the modified 1PI functions not only 0- and 1-point functions vanish, but also 2-point functions. This implies that only trees contribute which have the property that all their vertices have valence at least three. For a given number of external legs, there are only finitely many such trees. Thus, in contrast to (13) the sum in (16) is finite for each given set of external legs, i.e., for each element of $\mathsf{S}(V)$ to which it is applied.

B. Tree level contributions

Another context in quantum field theory, where we sum over all tree diagrams is of course when we wish to evaluate merely the tree level contribution to an *n*-point function. Let us indicate the tree level contribution by a lower index "*T*." Thus, the tree level contributions to the algebraic *n*-point functions are denoted ρ_T,σ_T, and τ_T for the complete, connected and 1PI *n*-point functions, respectively. Of course, the latter are now nothing but the interaction terms of the Lagrangian. The results of Sec. III carry over immediately.

Corollary 16: *$\rho_T=\exp_\star\sigma_T$, where the convolution exponential is defined in terms of its power series expansion.*

Corollary 17: *$\sigma_T=\log_\star\rho_T$, where the convolution logarithm is defined in terms of its power series expansion in $\rho_T-\epsilon$.*

The results of Secs. IV and V take the following form.

Corollary 18: *The tree level connected n-point functions may be expressed in terms of the interaction vertices through the formula*

$$\sigma_T=\sum_{k=1}^{\infty}\sigma_T^k\quad\text{with }\sigma_T^k:=\tau_T^{\otimes k}\circ\Lambda^{k-1}. \tag{17}$$

Corollary 19: *σ_T^k may be determined recursively via $\sigma_T^1=\tau_T$ and with the recursion equation for $k>1$,*

$$\sigma_T^k=\frac{1}{k-1}\sum_{i=1}^{k-1}(\sigma_T^i\otimes\sigma_T^{k-i})\circ Q.$$

Not only the 0- and 1-point, but also the 2-point contribution to τ_T vanishes by definition. Thus, as in the case of the modified 1PI functions, only finitely many tree graphs with given external legs contribute and the sum (17) is finite on any given element of $\mathsf{S}(V)$.

C. Algorithmic considerations

A key feature of the Hopf algebraic approach to *n*-point functions presented here is the close relation of the obtained algebraic relations to concrete algorithms. In Sec. IV the recursive definition (12) mirrors an algorithm to construct all tree graphs. Tree graphs with $k+1$ vertices are created from those with k vertices by taking each graph in turn and applying the following procedure: Take every vertex of the graph in turn and split it into two vertices, distributing the legs in all possible ways and reconnecting the two new vertices.

Of course, the actual algorithm is slightly more complicated as symmetries have to be taken into account and the correct weights must be obtained. However, the recursion relation (12) even suggests an implementation of data structures. For example, we may represent $\mathsf{S}(V)^{\otimes n}$ by an array, each element of which corresponds to a graph in the sense of Sec. IV. Such an element would contain a rational scalar (the weight) and an array, each element of which would correspond to one

tensor factor in $\mathsf{S}(V)^{\otimes n}$ or equivalently to one vertex. In turn each element would be a set of symbolic elements representing external or internal legs. The coproduct and the R-operator are then very simple operations distributing or adding pairs of symbolic elements.

In this context a certain property of the recursion algorithm represented by (12) is rather interesting. Namely, it is easy to see that a graph containing at least one vertex with valence 1 will in a recursion step only generate graphs that contain at least one vertex with valence 1. Conversely, this means that if we are not interested in such graphs we may exclude them at each recursion step without losing any relevant graphs. What is more, we may implement this removal of "irrelevant" graphs through a *truncated coproduct*. Recall from (7) that the coproduct restricted to the subspace $V^n \subset \mathsf{S}(V)$ is a map $V^n \to \oplus_{i=0}^n V^i \otimes V^{n-i}$. Removing those components of the direct sum where at least one of the target tensor factors is V^0 we obtain a map $V^n \to \oplus_{i=0}^{n-1} V^i \otimes V^{n-i}$. We call this the truncated coproduct $\Delta_{\geqslant 1}$. For example,

$$\Delta_{\geqslant 1}(\mathbf{1}) = 0, \quad \Delta_{\geqslant 1}(\phi(x)) = 0,$$

$$\Delta_{\geqslant 1}(\phi(x)\phi(y)) = \phi(x) \otimes \phi(y) + \phi(y) \otimes \phi(x).$$

In the recursion process (12) the number of legs of a vertex changes when the Q-operator is applied to it. The only terms corresponding to 1-point vertices arise from those terms in the coproduct where one of the new vertices receives no legs at all and has thus, after reconnecting with R, only one leg. Thus, replacing the coproduct Δ by the truncated coproduct $\Delta_{\geqslant 1}$ exactly eliminates the irrelevant trees with 1-point vertices.

If we limit the allowed valence of vertices even more, we can push the truncation prescription even further. Assume we are interested only in trees with vertices of valence at least three (as in the case of modified 1PI functions or tree level calculations). By extension of the above discussion it is clear that the removal of all irrelevant trees is achieved by a further truncation of the coproduct. Namely, remove from the coproduct map $V^n \to \oplus_{i=0}^n V^i \otimes V^{n-i}$ the components with tensor factors V^0 and V^1. We denote the truncated coproduct defined in this way by $\Delta_{\geqslant 2}$. It is then obvious that using this truncated coproduct to define Q and in turn Λ produces only trees all of whose vertices have valence at least three. In particular, this means that for given external legs the algorithm sketched above for calculating all trees terminates after finitely many steps. As in the above case, it never creates a tree that would need to be discarded later. Note that this procedure may be extended to any lower bound n on the valence of vertices by using the corresponding $(n-1)$-truncated coproduct $\Delta_{\geqslant n-1}$ defined in the obvious way.

D. Fermions

Recall that we have limited ourselves above to a purely bosonic theory. However, as already mentioned, this limitation is purely one of convenience and simplicity. Indeed, all of our arguments and results apply equally to fermionic fields. However, the underlying formalism becomes slightly more complicated. The vector space V will in general be a $\mathbb{Z}_2$-*graded* vector space, a direct sum of a bosonic and a fermionic part. In turn, the algebra $\mathsf{S}(V)$ is the $\mathbb{Z}_2$-*graded* symmetric algebra over V. As special cases, if V is completely bosonic we recover the usual commutative symmetric algebra (as above); if V is completely fermionic we recover the usual anticommutative exterior algebra. As a Hopf algebra $\mathsf{S}(V)$ is in general a $\mathbb{Z}_2$-*graded* or *super*-Hopf algebra. In particular, the coproduct becomes graded. This simply means that a minus sign appears as soon as odd elements are commuted, e.g.,

$$\Delta(ab) = ab \otimes \mathbf{1} + \mathbf{1} \otimes ab + a \otimes b + (-1)^{|a||b|} b \otimes a.$$

Here, $|a|$ is defined to be 0 or 1 depending on whether a is bosonic or fermionic. We refer to Ref. 1 for more details on the structure of $\mathsf{S}(V)$ in general.

However, all formulas appearing in Theorems, Propositions, and Corollaries generalize completely unchanged. The graded structure is completely implicit there. The only explicitly changing formulas are indeed those that involve explicit evaluations of the coproduct such as (6)–(8). The

underlying reason is that our constructions are completely "functorial" and could indeed be generalized to arbitrary (reasonable) symmetric categories. (For a generalization of certain *n*-point functions to nonsymmetric categories see Ref. 4.)

VII. CONCLUSIONS

Functional methods used to handle the combinatorics of quantum field theory, while having a certain elegance, have some serious drawbacks. While appearing to be analytic, they are really formal as the mathematical objects involved usually do not actually exist. In particular, the source terms appearing in functional expressions are usually merely a book keeping device, rather than actual mathematical (or physical) entities. We hope to have convinced the reader that at least certain combinatorial aspects of quantum field theory can be handled in a much more intrinsic and (we think) at least as elegant language. Indeed, our main object is nothing but the rather concrete time-ordered algebra of field operators. Its coproduct, while perhaps an unusual structure for quantum field theorists, is well known to mathematicians. It is thus natural to use it instead of more indirect and formal functional methods.

Another advantage of our algebraic approach over a functional one is its closeness to algorithmic descriptions of the processes involved. Recall from Sec. VI C how easy it is to translate the recursion relation underlying the correspondence between connected and 1PI *n*-point functions into an algorithm, which moreover appears to be rather efficient.

As mentioned in the introduction, the present paper shares a common program with Ref. 1, namely to employ the full Hopf algebraic structure of the algebra of field operators in describing and understanding quantum field theory. Thus, it is natural to combine the results of the present paper with those of Ref. 1. Indeed, the functorial nature of the Drinfeld twist employed in Ref. 1 to relate different products and their (complete) *n*-point functions should make it possible to induce the corresponding transformation on the corresponding connected or 1PI *n*-point functions using the results presented here. This, of course, goes beyond the scope of the present paper.

We study soliton solutions of the Nicole model—a non-linear four-dimensional field theory consisting of the CP^1 Lagrangian density to the non-integer power $\frac{3}{2}$—using an ansatz within toroidal coordinates, which is indicated by the conformal symmetry of the static equations of motion. We calculate the soliton energies numerically and find that they grow linearly with the topological charge (Hopf index). Further we prove this behavior to hold exactly for the ansatz. On the other hand, for the full three-dimensional system without symmetry reduction we prove a sublinear upper bound, analogously to the case of the Faddeev–Niemi model. It follows that symmetric solitons cannot be true minimizers of the energy for sufficiently large Hopf index, again in analogy to the Faddeev–Niemi model. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2199089]

I. INTRODUCTION

In the last few years there has been rising interest in non-linear field theories which allow for the existence of ringlike, or, more generally, knotlike solitons. On the one hand, this interest is due to the fact that there may exist physical applications for such models, as is the case, for instance, for the Faddeev–Niemi model, which finds some applications both as a candidate for a low-energy effective theory for Yang-Mills theory and in condensed matter physics. On the other hand, the rising interest is related to the advance of more powerful computer facilities which allow for reliable numerical calculations of those solitons in cases when an analytical solution is not available (which happens quite often). In addition, there is some intrinsical mathematical interest in theories with knot solitons.

In the simplest case the field of the theory describes a map from one-point compactified three-dimensional space $\mathbb{R}^3_0$ to the two-sphere S^2. $\mathbb{R}^3_0$ is topologically equivalent to the three-sphere S^3, therefore such maps are characterized by the third homotopy group of the target space S^2, which is nontrivial, $\pi_3(S^2)=\mathbb{Z}$. As a consequence, fields which describe maps $\mathbb{R}^3_0 \to S^2$ fall into different homotopy classes, and a soliton is a field configuration which minimizes a given energy functional within a fixed homotopy class. The topological index characterizing the homotopy class is called Hopf index, the corresponding map is called a Hopf map, and the minimizers are sometimes called Hopf solitons. For details on the Hopf map we refer to Appendix A.

The probably best-known theory which allows for Hopf solitons is the Faddeev–Niemi model[1,2] with Lagrangian density

$$\mathcal{L}_{\mathrm{FN}} = \mathcal{L}_2 - \lambda \mathcal{L}_4, \tag{1}$$

where λ is a dimensionful coupling constant, $\mathcal{L}_2$ is

$$\mathcal{L}_2 = 4\frac{\partial_\mu u \partial^\mu \overline{u}}{(1+u\overline{u})^2}, \tag{2}$$

and $\mathcal{L}_4$ is

$$\mathcal{L}_4 = 4\frac{(\partial^\mu u \partial_\mu \overline{u})^2 - (\partial^\mu u \partial_\mu u)(\partial^\nu \overline{u} \partial_\nu \overline{u})}{(1+u\overline{u})^4}. \tag{3}$$

Further, u is a complex field which parametrizes the stereographic projection of the target S^2, see Appendix A. The Faddeev–Niemi model is the S^2 restriction of Skyrme theory and so circumvents Derrick's theorem, because it consists of two terms such that their corresponding energies behave oppositely under a scale transformation. The existence of (static) soliton solutions for the lowest Hopf indices has been confirmed by numerical calculations.[3–6]

There are two more models which can be constructed from the two Lagrangian densities $\mathcal{L}_2$ and $\mathcal{L}_4$ separately by choosing appropriate (non-integer) powers of these Lagrangians such that the corresponding energies are scale invariant. For $\mathcal{L}_4$ the appropriate choice is

$$\mathcal{L}_{\mathrm{AFZ}} = -(\mathcal{L}_4)^{3/4} \tag{4}$$

and for this model infinitely many analytic soliton solutions were found by Aratyn, Ferreira, and Zimerman (AFZ) by using an ansatz with toroidal coordinates.[7,8] We shall, therefore, refer to this model as the AFZ model in the sequel. The analysis of the AFZ model was carried further in Ref. 9, where, among other results, all the space-time and (geometric) target space symmetries of the AFZ model were determined, and, further, the use of the ansatz with toroidal coordinates was related to the conformal symmetry of the model (more precisely, of the static equations of motion). It turns out that the AFZ model has infinitely many target space symmetries and, moreover, realizes the notion of classical integrability in a rather strict sense, because the static equations of motion (e.o.m.) resulting from the ansatz with toroidal coordinates may be solved by simple integration. Let us also mention here that the model with Lagrangian $\mathcal{L}_4$ has the same (infinitely many) target space symmetries and, in addition, a scale invariant action, leading thereby to analytic time-dependent solutions[10].

The other model is

$$\mathcal{L}_{\mathrm{Ni}} = (\mathcal{L}_2)^{3/2}. \tag{5}$$

This model was first proposed by Nicole,[11] and it was shown in the same paper that the simplest Hopf map with Hopf index 1 is a soliton solution for this model. We, therefore, call this model the Nicole (Ni) model in this paper. This model is, in fact, the restriction to S^2 target space of a nonpolynomial SU(2) model which was studied first in Ref. 12 as a possible candidate for a pion model. The Nicole model shares the conformal symmetry with the AFZ model, therefore, again the ansatz with toroidal coordinates may be used to simplify the static e.o.m. (to reduce them to an ordinary differential equation). However, the Nicole model only has the obvious symmetries—the conformal base space symmetries (in the static case) and the modular target space symmetries, see Ref. 13. Consequently, the e.o.m. are no longer integrable, and the solutions are no longer available in closed, analytic form (except for the simplest case with Hopf index one—exact solitons with higher Hopf index have been found in modified Nicole models[14]). It is the main purpose of this paper to analyze these soliton solutions with higher Hopf index by developing the analytical treatment as far as possible and by performing numerical calculations where it is necessary.

The AFZ and Nicole models currently do not have direct physical applications, but they can serve as useful test labors for the understanding of generic features of models with knot solitons. This is all the more true as analytic results—already for solitons, but even more so for time-

dependent problems like soliton scattering—are notoriously difficult to obtain for realistic models like the Faddeev–Niemi model. Both the AFZ and the Nicole model are much easier to treat, and for time-dependent problems the Nicole model even has one advantage over the AFZ model. The infinitely many symmetries of the former—which provide its integrability on the one hand—imply that the moduli space for multi-soliton configurations is infinite dimensional. This most likely makes an adiabatic treatment of soliton scattering problematic. On the other hand, that problem is absent for the Nicole model which may, therefore, probably serve as a natural test labor for an adiabatic study of the scattering of knot-like solitons. A further issue which may be useful for the study of time-dependent problems is provided by the observation that all field configurations within the toroidal ansatz belong to an integrable subsector of the Nicole model (i.e., to a sector with infinitely many conservad currents), see Sec. III.

The paper is organized as follows. In Sec. II we provide the static e.o.m. of the Nicole model as well as the non-linear ODE resulting from the ansatz with toroidal coordinates. Then we analyze the latter equation in detail, establishing some properties analytically. In a next step we calculate the energies of the corresponding solitons numerically with high precision. We provide all energies for solitons with sufficiently small Hopf index. Further, we calculate some energies for larger Hopf index in order to establish some generic behavior. We prove that this generic behavior is in accordance with exact energy estimates for the ansatz in toroidal coordinates.

In Sec. III we show that for all the solutions of Sec. II there exist infinitely many conserved currents, that is to say, all these field configurations belong to an integrable subsector of the Nicole model.

In Sec. IV A we prove an upper bound for the energies of field configurations with given Hopf index, of the type $E_Q \leqslant C_2 Q^{3/4}$, and provide an explicit value for the constant C_2. In Sec. IV B we derive an analogous bound for the AFZ and Faddeev–Niemi model, which is easily achieved with the help of the results of Sec. IV A. The discussion of the possibility to find a corresponding lower bound $E_Q \geqslant C_1 Q^{3/4}$ for the Nicole model, analogous to the Vakulenko-Kapitansky bound for the Faddeev–Niemi model, is presented in Appendix C. We show where a Vakulenko-Kapitansky type proof needs to be refined for the Nicole (and also for the AFZ) model and leave this lower bound as a conjecture for the moment.

Section V contains our conclusions, where we comment on the relevance of our results for issues like stability, and on the relation to the corresponding results for the other two models (Faddeev–Niemi and AFZ). In Appendix A we collect useful results and facts about Hopf maps which we use throughout the paper. Appendix B contains some proofs which we need in the main sections. In Appendix C we discuss the lower energy bound.

II. SOLITONS IN THE NICOLE MODEL

A. Equation of motion

The static e.o.m. for the Nicole model (5) is

$$\frac{1}{2}(u_{jk}\overline{u_j}u_k + \overline{u_{jk}}u_j u_k) + u_j\overline{u_j}u_{kk} - \frac{u_j\overline{u_j}}{1+u\overline{u}}(u_k\overline{u_k}u + 3u_k u_k\overline{u}) = 0, \tag{6}$$

where $u_k \equiv \partial_\mu u$, etc., and the Einstein summation convention is understood. We now introduce toroidal coordinates (η, ξ, φ) via

$$\begin{gathered} x = q^{-1}\sinh\eta\cos\varphi, \quad y = q^{-1}\sinh\eta\sin\varphi, \\ z = q^{-1}\sin\xi, \quad q = \cosh\eta - \cos\xi. \end{gathered} \tag{7}$$

Further, we choose for u the ansatz

$$u = f(\eta)e^{im\varphi+in\xi}, \quad m,n \in \mathbb{Z}, \tag{8}$$

which is compatible with the e.o.m. for the Nicole model as well as for the AFZ model. The reason for this ansatz may, in fact, be understood from the symmetries of the model. More precisely, the presence of the conformal symmetry on base space implies that the ansatz (8) is an "educated guess" for a solution to Eq. (6) in the sense of the Lie theory of symmetry. That is to say, if we choose a rotation about the z axis and a certain combination of proper conformal transformation along the z axis and translation along the z axis as a maximal set of two commuting base space transformations, then the corresponding infinitesimal symmetry generators (vectors $\mathbf{v}^i$) are precisely given by the tangent vectors along φ and ξ, $\mathbf{v}^1=\partial_\varphi$, and $\mathbf{v}^2=\partial_\xi$. The ansatz (8) is invariant under a combination of these base space transformations and phase transformations of the target space variable u, i.e., under the action of the vector fields $\tilde{\mathbf{v}}^1=\partial_\varphi - imu\partial_u$ and $\tilde{\mathbf{v}}^2=\partial_\xi - inu\partial_u$, which provides precisely the educated guess according to Lie. A concise discussion of these points can be found in Ref. 9, where the symmetries of the AFZ model are discussed in great detail.

We need the gradient in toroidal coordinates

$$\nabla = (\nabla\eta)\partial_\eta + (\nabla\xi)\partial_\xi + (\nabla\varphi)\partial_\varphi = q\left(\hat{e}_\eta\partial_\eta + \hat{e}_\xi\partial_\xi + \frac{1}{\sinh\,\eta}\hat{e}_\varphi\partial_\varphi\right), \tag{9}$$

where $(\hat{e}_\eta,\hat{e}_\xi,\hat{e}_\varphi)$ form an orthonormal frame in $\mathbb{R}^3$. Further we need the relations

$$\nabla\cdot\hat{e}_\eta = -\sinh\,\eta + \frac{1-\cosh\,\eta\cos\,\xi}{\sinh\,\eta}, \quad \nabla\cdot\hat{e}_\xi = -2\sin\,\xi, \quad \nabla\cdot\hat{e}_\varphi = 0. \tag{10}$$

Inserting now the ansatz (8) into the static e.o.m. (6) we find, after a straight-forward calculation, that the ansatz is indeed compatible with the static e.o.m. and that f has to obey the non-linear ODE

$$\begin{aligned} &2f''f'^2 + f''f^2\left(n^2+\frac{m^2}{\sinh^2\,\eta}\right) + (f'^3 + n^2f'f^2)\frac{\cosh\,\eta}{\sinh\,\eta} - f^3\left(n^2+\frac{m^2}{\sinh^2\,\eta}\right)^2 \\ &\quad - f\frac{f'^2 + f^2\left(n^2+\frac{m^2}{\sinh^2\,\eta}\right)}{1+f^2}\left(4f'^2 - 2f^2\left(n^2+\frac{m^2}{\sinh^2\,\eta}\right)\right) = 0, \end{aligned} \tag{11}$$

where $f' \equiv \partial_\eta f$, etc. It may be checked without difficulty that the simplest Hopf map

$$u = \sinh\,\eta e^{i\xi+i\varphi} \Rightarrow f = \sinh\,\eta, \quad m=n=1 \tag{12}$$

indeed solves the above equation.

For technical reasons it is preferable to introduce the new variable

$$t \equiv \sinh\,\eta \tag{13}$$

in terms of which the above-noted e.o.m. can be expressed as a pure polynomial in the independent and dependent variables t, f, f_t, f_{tt},

$$\begin{aligned} F(t,f,f_t,f_{tt}) \equiv\ & t^2(1+t^2)(1+f^2)(2t^2(1+t^2)f_t^2 + (n^2t^2+m^2)f^2)f_{tt} - 4t^4(1+t^2)^2ff_t^4 + t^3(1 \\ & + 3t^2)(1+t^2)(1+f^2)f_t^3 - 2t^2(1+t^2)(n^2t^2+m^2)f^3f_t^2 \\ & + t^3(m^2+n^2(1+2t^2))(1+f^2)f^2f_t - (n^2t^2+m^2)^2f^3(1-f^2) = 0 \end{aligned} \tag{14}$$

where $f_t \equiv \partial_t f$, etc. Further, we need the energy functional $E[f]$ which results for the ansatz (8) after the integration with respect to the variables ξ,φ. With

$$dV \equiv d^3r = q^{-3}\sinh\,\eta\,d\eta\,d\xi\,d\varphi \tag{15}$$

we find

$$E[f] = 32\pi^2 \int_0^\infty d\eta \sinh\eta \frac{\left(f_\eta^2 + f^2\left(n^2 + \frac{m^2}{\sinh^2\eta}\right)\right)^{3/2}}{(1+f^2)^3}$$

$$= 32\pi^2 \int_0^\infty dt\, t(1+t^2) \frac{\left(f_t^2 + \left(n^2 + \frac{m^2}{t^2}\right)\frac{f^2}{1+t^2}\right)^{3/2}}{(1+f^2)^3}. \tag{16}$$

For $n=m=1$ for the solution $f(t)=t$ the energy may be calculated analytically,

$$E = 32\pi^2 2^{3/2} \int_0^\infty \frac{dtt}{(1+t^2)^2} = 32\pi^2\sqrt{2}. \tag{17}$$

If we calculate the energy for the field configuration $f(t)=ct$ instead, we find

$$E = 32\pi^2\sqrt{2}\frac{1}{2}\left(c + \frac{1}{c}\right), \tag{18}$$

which certainly has a minimum at $c=1$ but also shows clearly that the one-soliton sector is indeed separated from the trivial sector (with Hopf index zero) by an infinite energy barrier.

Next we have to fix the boundary conditions which f has to obey. The u of Eq. (8) has to take values in the whole target space $\mathbb{C}_0$ in order to be a Hopf map. This implies that f has to take values in the whole positive real numbers, including zero, i.e., in the whole $\mathbb{R}_{+0}$. It follows that the possible boundary conditions on f are restricted to one of the two following options. Either $f(0)=0$, $f(\infty)=\infty$ or $f(0)=\infty$, $f(\infty)=0$. The reason for this is that the values $f=0$ and $f=\infty$ correspond to the north and south pole of the target space S^2, respectively. Consequently, their preimages in the base space $\mathbb{R}_0^3$ must be one-dimensional objects (closed lines). But the only two values $\eta=\eta_0=$const (or $t=t_0=$const) which correspond to lines rather than surfaces (tori) are the values $\eta=0$ ($t=0$) and $\eta=\infty$ ($t=\infty$). Therefore we assume

$$f(\eta=0) = f(t=0) = 0, \quad f(\eta=\infty) = f(t=\infty) = \infty, \tag{19}$$

which is general, because the other option is related to this one by a symmetry transformation.

B. Asymptotic behavior and numerical evaluation

In a next step we want to determine the asymptotic behavior of the function $f(t)$ for small and large values of t from the differential equation (14). For small t we assume that $f(t) \sim t^\alpha + o(t^\beta)$ where $\beta > \alpha > 0$. From Eq. (14) we get

$$F(t,f,f_t,f_{tt}) \sim (2\alpha^4 - \alpha^3 + \alpha^2 m^2 - \alpha m^2 - m^4)t^{3\alpha} + o(t^{3\alpha+2}) + o(t^{3\beta}) \equiv 0. \tag{20}$$

The condition that the leading (i.e., smallest) order $t^{3\alpha}$ is absent therefore leads to

$$2\alpha^4 - \alpha^3 + \alpha^2 m^2 - \alpha m^2 - m^4 = 0, \tag{21}$$

which has four solutions for α of which only one is acceptable (real and positive), namely

$$\alpha_m \equiv \tfrac{1}{4}(1 + \sqrt{8m^2+1}). \tag{22}$$

In the same fashion we may determine the subleading (higher order) contributions to f for small t in an iterative manner. We find

$$f = t^{\alpha_m} P^{(0)}(t, t^{\alpha_m}) \quad \text{for } t \ll 1, \tag{23}$$

where $P^{(0)}(t,t^{\alpha_m})$ is a polynomial of its arguments, which is determined up to a multiplicative constant,

$$P^{(0)}(t,t^{\alpha_m}) = \sum_{k,l=0}^{\infty} c_{kl}^{(0)} t^k t^{l\alpha_m}. \tag{24}$$

Here it is possible to determine the higher coefficients $c_{kl}^{(0)}$ in terms of m, n, and $c_{00}^{(0)}$. Unfortunately, it is not possible to determine $c_{00}^{(0)}$, i.e., an overall constant remains undetermined by this asymptotic analysis.

We repeat the same asymptotic analysis for large values of t. We assume that $f(t) \sim t^{\alpha} + o(t^{\beta})$ where now $\alpha > \beta > 0$ and find

$$F(t,f,f_t,f_{tt}) \sim (2\alpha^4 - \alpha^3 + \alpha^2 n^2 - \alpha n^2 - n^4) t^{5\alpha+4} + o(t^{5\alpha+2}) + o(t^{5\beta+4}) \equiv 0 \tag{25}$$

and therefore the same condition for α like for small t with the only replacement $m \to n$. We may again determine f asymptotically up to an overall constant,

$$f = t^{\alpha_n} P^{(\infty)}(t^{-1}, t^{-\alpha_n}) \quad \text{for } t \gg 1, \tag{26}$$

where

$$P^{(\infty)}(t^{-1}, t^{-\alpha_n}) = \sum_{k,l=0}^{\infty} c_{kl}^{(\infty)} t^{-k} t^{-l\alpha_n} \tag{27}$$

and again the higher coefficients $c_{kl}^{(\infty)}$ are determined in terms of m, n, and $c_{00}^{(\infty)}$. Again, $c_{00}^{(\infty)}$ remains undetermined.

Next we turn to the numerical evaluation of the soliton energies for general m, n. For this purpose it is preferable to minimize the energy functional (16). The problem is that standard evolution procedures for the differential equation (14) cannot be used because of the singular nature of this equation at $t=0$. We proceed as follows with the minimization. We first factorize the leading behavior, e.g., we choose

$$f(t) \equiv t^{\alpha_m} (1+t^2)^{(\alpha_n - \alpha_m)/2} g(t), \tag{28}$$

where g obeys

$$g > 0 \; \forall \; t, \quad g(0) = g_0, \quad g(\infty) = g_{\infty}. \tag{29}$$

Then we make a finite parameter ansatz for g of the form

$$g(t) = \frac{g_0 + g_{\infty} t^2}{1+t^2} \frac{1 + \sum_{i=1}^{k} a_i t^{2i} + t^{k+2}}{1 + \sum_{j=1}^{k} b_j t^{2j} + t^{k+2}}, \tag{30}$$

where g_0, g_{∞}, a_i, and b_j are the parameters with respect to which we minimize the energy functional (16). For each value of m, n we increase the number of parameters (i.e., the integer number k), until we reach stability (i.e., until the energies do not change further with the increase of the number of parameters). We do not choose a full numerical minimization of the energy functional for the following reason. It turns out that the leading behavior (i.e., $g(t)=\text{const}$), already provides rather good results for the corresponding energies. This implies that the energy functional, when viewed as a functional of g, is rather shallow. As a consequence, a full numerical minimization which implements the derivatives numerically has the tendency to produce false minima unless the numerical minimization grid is chosen very finely (and consumes a lot of computer time). On the other hand, within our finite parameter ansatz we are able to perform the derivatives analytically, and therefore this problem is absent.

We show our numerical results in Table I for all $(m,n)=(1,1),\ldots,(5,5)$ as well as for some higher values. Further we plot the energies versus the Hopf index $Q=mn$ in Fig. 1. From our results it is obvious that the energies grow linearly in Q to a very good accuracy. More precisely, the energies for $m=n$ lie on a straight line in Fig. 1 almost exactly. The energies for $m \neq n$ lie

TABLE I. The rescaled energies $E^*=(32\pi^2)^{-1}E$ of solutions for selected values of m and n.

slightly above, whereas no energy lies below this line. It is in fact possible to prove the linear growth of energies with the Hopf charge for solutions of the ansatz (8). This we show for the simplest case $m=n$ in the next section.

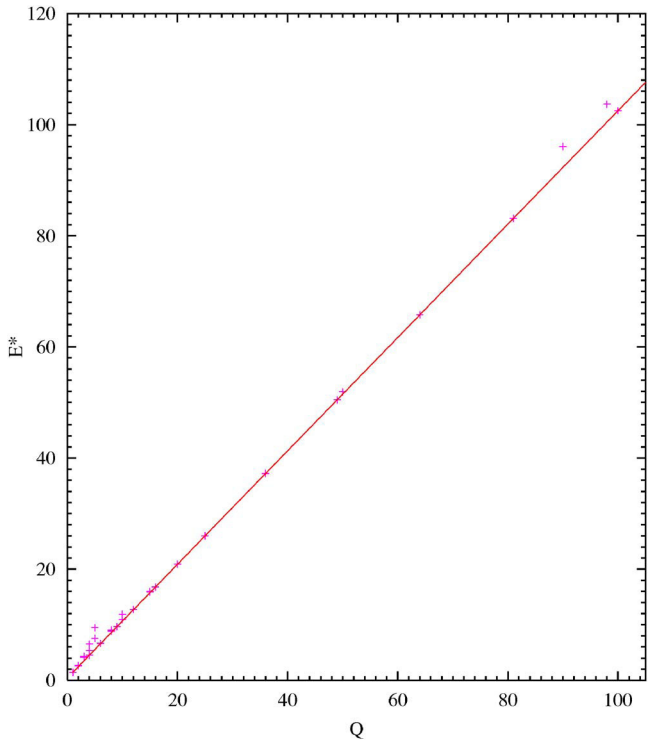

FIG. 1. (Color online) The rescaled energies $E^*=(32\pi^2)^{-1}E$ (vertical axis) are plotted vs the Hopf index $Q=mn$. The straight line connects energies for $m=n$. The energies for $m\neq n$ lie slightly above this line.

On the other hand, for the full model the sublinear upper bound $E \leqslant C_2 Q^{3/4}$ holds, which we prove in Sec. IV. It follows that the solutions we found for the symmetric ansatz (8) *cannot* be true solitons, i.e., global minima of topological sectors with fixed Q for sufficiently large values of Q. This is akin to the situation in the Faddeev–Niemi model and differs from the situation in the AFZ model (see our discussion in Sec. V).

C. Upper and lower bounds for the torus ansatz

In this section we prove the bounds $c_1 Q \leqslant E[f_{m,n}]$ and, for the special case $m=n$, $E[f_{m,m}] \leqslant c_2 m^2$ (with explicit values for the constants c_1 and c_2) in order to further support our numerical results. Here $E[f]$ is the energy functional (16) and $f_{m,n}$ is the corresponding solution of the equation of motion. We first prove the lower bound. We use the inequality

$$(a+b)^{3/2} \geqslant \frac{3\sqrt{3}}{2} a^{1/2} b \quad \text{for } a,b \geqslant 0, \tag{31}$$

which we prove in Appendix B (here $3\sqrt{3}/2$ is an optimal value). We choose $a=f_t^2$ and $b=(n^2+m^2/t^2)f^2/(1+t^2)$ and introduce

$$Q = mn, \quad \mu = \frac{m}{n} \tag{32}$$

to get

$$\begin{aligned} E[f] &= 32\pi^2 \int_0^\infty dt t(1+t^2) \frac{\left(f_t^2 + Q\left(\frac{1}{\mu} + \frac{\mu}{t^2}\right)\frac{f^2}{1+t^2}\right)^{3/2}}{(1+f^2)^3} \\ &\geqslant 32\pi^2 Q \frac{3\sqrt{3}}{2} \int_0^\infty dt \left(\frac{t}{\mu} + \frac{\mu}{t}\right) |f_t| \frac{f^2}{(1+f^2)^3} \\ &\geqslant 32\pi^2 Q 3\sqrt{3} \int_0^\infty dt f_t \frac{f^2}{(1+f^2)^3} \equiv \tilde{E}[f], \end{aligned} \tag{33}$$

where we used $(t/\mu+\mu/t) \geqslant 2$. Up to now we have in fact used inequalities for the energy densities, i.e., these inequalities hold for given, fixed functions f. However, if we evaluate the last expression for its minimizer $f_{\min}$ then the inequality holds for arbitrary f and, consequently, for the solutions $f_{m,n}$. The minimization of the last expression is simplified by the observation that it is a total derivative. Therefore it is minimized for all f which obey the required boundary conditions $f(0)=0$ and $f(\infty)=\infty$. Explicitly we get

$$\tilde{E}[f] = 32\pi^2 Q 3\sqrt{3} \left[-\frac{f}{4(1+f^2)^2} + \frac{f}{8(1+f^2)} + \frac{1}{8} \arctan f \right]_{f=0}^{f=\infty} = 32\pi^2 Q 3\sqrt{3} \frac{\pi}{16} = 1.02 \times 32\pi^2 Q. \tag{34}$$

Comparing with Table I, we see that for larger values of m, n our lower bound gets very close to the numerical values, especially for $m=n$ (e.g., better than 1% for $m=n=10$ or $m=n=20$). This demonstrates the very good accuracy of our numerical results.

For the derivation of an upper bound we restrict to the simpler case $m=n$. We simply insert a trial function $f_{m,m}^{\mathrm{tr}}$ into the energy functional $E[f]$. Concretely we choose $f_{m,m}^{\mathrm{tr}} = t^m$ and get

$$E[t^m] = 32\pi^2 \int_0^\infty dt t(1+t^2) \frac{m^3 t^{3m-3} 2^{3/2}}{(1+t^{2m})^3} \tag{35}$$

and, with the substitution $u=t^m$,

$$E[t^m] = 32\pi^2 m^2 2^{3/2} \int_0^\infty du(u^{1/m} + u^{-1/m}) \frac{u^2}{(1+u^2)^3} = 32\pi^2 m^2 2^{3/2} \frac{1}{8} \left(1 - \frac{1}{m^2}\right) \frac{\pi}{\cos \frac{\pi}{2m}}. \quad (36)$$

The function $(1-1/m^2)/(\cos(\pi/2m))$ is a monotonously decreasing function in m and may, therefore, be estimated by its value at $m=2$ for the range $m \geqslant 2$. With

$$\left(1 - \frac{1}{4}\right) \frac{1}{\cos \frac{\pi}{4}} = \frac{3}{4}\sqrt{2} \quad (37)$$

we therefore get

$$E[t^m] \leqslant 32\pi^2 m^2 \frac{3\pi}{8} = 1.18 \times 32\pi^2 m^2 \quad \text{for } m \geqslant 2 \quad (38)$$

which, for large m, is about 15% above the numerical value. By using Eq. (36) instead of the order m^2 estimate (38), we get slightly better results which, for large m, are less than 10% above the numerical values.

In short, we established the bounds $c_1 m^2 \leqslant E[f_{m,m}] \leqslant c_2 m^2$ with $c_1 = 1.02 \times 32\pi^2$ and $c_2 = 1.18 \times 32\pi^2$, as announced.

III. INFINITELY MANY CONSERVED CURRENTS

In this section we want to demonstrate that the ansatz (8) belongs to a subsector of the Nicole model with infinitely many conserved currents for arbitrary profile function $f(\eta)$. The integrability condition defining this subsector exists for a wide class of models, and discussing it for the whole class does not complicate matters (for a more detailed discussion, and especially for the geometric meaning of the integrability condition, we refer to Ref. 15; the concept of higher dimensional integrability, which is at the basis of these discussions, was introduced in Ref. 16). Therefore, we start with the general class of Lagrangian densities

$$\mathcal{L}(u, \overline{u}, u_\mu, \overline{u_\mu}) = F(a,b,c), \quad (39)$$

where

$$a = u\overline{u}, \quad b = u_\mu \overline{u^\mu}, \quad c = (u_\mu \overline{u^\mu})^2 - u_\mu^2 \overline{u_\nu^2} \quad (40)$$

and F is an arbitrary real function of its arguments. Obviously, the Nicole model belongs to this class, $\mathcal{L}_{\mathrm{Ni}} = [4(1+a)^{-1}b]^{3/2}$.

Further, we define the currents

$$K^\mu = h(a)\overline{\Pi}^\mu, \quad (41)$$

where h is an arbitrary given real function of its argument, and Π^μ and $\overline{\Pi}^\mu$ are the conjugate four-momenta of u and $\overline{u}$, i.e.,

$$\Pi_\mu \equiv \mathcal{L}_{u^\mu} = \overline{u}^\mu F_b + 2(u^\lambda \overline{u}_\lambda \overline{u}_\mu - \overline{u}_\lambda^2 u_\mu) F_c. \quad (42)$$

Finally, we define the infinitely many Noether currents

$$J_\mu^G = i(G_u K_\mu - G_{\overline{u}} \overline{K}_\mu), \quad (43)$$

where G is an arbitrary real function of u and $\overline{u}$, and $G_u \equiv \partial_u G$.

Now we want to study the conditions which one has to impose in order to make the divergence $\partial^\mu J_\mu^G$ vanish. A simple calculation reveals

$$\partial^\mu J^G_\mu = ih\left(\left[\left(\frac{h'}{h}\overline{u}G_u + G_{uu}\right)u_\mu^2 - \left(\frac{h'}{h}uG_{\overline{u}} + G_{\overline{uu}}\right)\overline{u}_\mu^2\right]F_b + (uG_u - \overline{u}G_{\overline{u}})\left[\frac{h'}{h}(bF_b + 2cF_c) + F_a\right]\right), \tag{44}$$

where the prime denotes the derivative with respect to a.

The second term at the right-hand side of Eq. (44) certainly vanishes if

$$uG_u - \overline{u}G_{\overline{u}} = 0 \tag{45}$$

with the general solution

$$G(u,\overline{u}) = \widetilde{G}(u\overline{u}) \equiv \widetilde{G}(a). \tag{46}$$

Without taking condition (46) into account, the first term on the right-hand side of Eq. (44) vanishes for the integrability condition

$$u_\mu^2 = 0, \tag{47}$$

i.e., the complex eikonal equation (it also vanishes for some more complicated integrability conditions which we do not discuss here, see Refs. 17 and 18). However, by using condition (46) we may re-express the first term like

$$(h'G' + hG'')F_b[\overline{u}^2 u_\mu^2 - u^2\overline{u}_\mu^2] \tag{48}$$

and, therefore, we find, instead of the complex eikonal equation, the weaker integrability condition

$$\overline{u}^2 u_\mu^2 - u^2\overline{u}_\mu^2 = 0. \tag{49}$$

The meaning of this condition becomes especially transparent when we re-express u in terms of its modulus and phase like

$$u = \exp(\Sigma + i\Lambda). \tag{50}$$

Then the complex eikonal equation is equivalent to the two real equations

$$\Sigma_\mu^2 = \Lambda_\mu^2 \tag{51}$$

and

$$\Sigma^\mu \Lambda_\mu = 0 \tag{52}$$

whereas the weaker condition (49) becomes Eq. (52) alone or, for time-independent u,

$$(\nabla\Sigma)\cdot(\nabla\Lambda) = 0. \tag{53}$$

Remark: The condition $G(u,\overline{u}) = \widetilde{G}(u\overline{u})$, Eq. (46), restricts the space of allowed G to a subspace which is still infinite-dimensional, therefore the integrability condition (49) really defines a subsector with infinitely many conserved currents.

Remark: The ansatz (8) obeys the integrability condition (53) for arbitrary profile function $f(\eta)$, as is obvious from the orthonormality of the basis vectors $(\hat{e}_\eta, \hat{e}_\xi, \hat{e}_\varphi)$. Therefore, all our solutions of Sec. II really belong to the subsector of the Nicole model defined by condition (49) with infinitely many conserved currents. This is in contrast to the complex eikonal equation (47), which leads to a non-linear ODE for the profile function which is not compatible with the Nicole model field equation except for the simplest Hopf map $m=n=1$, see Ref. 19.

Remark: Both condition (46) and the integrability condition (49) do not restrict the Lagrangian density, therefore the corresponding integrable subsectors with infinitely many conservation laws exist for all Lagrangians of the type (39). So they may be of interest for other models like, e.g., the Faddeev–Niemi model.

IV. ENERGY ESTIMATES FOR THE FULL MODEL

In this section we study upper bounds on the energies of solitons with a given Hopf index, of the type $E_Q \leqslant C_2 Q^{3/4}$. In Sec. IV A we prove the upper bound $E_Q \leqslant C_2 Q^{3/4}$ by following the method used in Ref. 20 for the Faddeev–Niemi model. Further, we provide an explicit value for the constant C_2. In Sec. IV B, we briefly derive the analogous upper bounds for the AFZ and the Faddeev–Niemi models, again with explicit values for the constants C_2. They easily follow from our results from Sec. IV A. The issue of a lower bound $C_1 Q^{3/4} \leqslant E_Q$ is discussed in Appendix C. There we show where a naive Vakulenko-Kapitansky type proof does not work and needs some refinement in our case, leaving open for the moment the problem of rigorously establishing such a lower bound.

A. The estimate $E_Q \leqslant C_2 Q^{3/4}$

In this section we use the unit vector $\vec{n}$ to denote Hopf maps, because this has some technical advantages (components of the vector $\vec{n}$ can be easily estimated, whereas the complex function u may take arbitrary values). In our proof we will closely follow the method used in Ref. 20 for the proof of an analogous result for the Faddeev–Niemi model. However, we will use explicit expressions for certain functions instead of using just their existence, which enables us to provide an explicit value for the constant C_2 in our estimate.

For a Hopf index which is a square, $Q=l^2$, a Hopf map is constructed in Ref. 20 which is a composition of a Hopf map $\vec{n}(\vec{r})$ with Hopf index 1 and a map $\vec{N}(\vec{n}):S^2 \to S^2$ with winding number $w=l$. The Hopf map $\vec{n}(\vec{r})$ is constructed such that it varies smoothly from $\vec{n}=(0,0,1)$ at $\vec{r}=0$ to $\vec{n}=(0,0,-1)$ at $|\vec{r}|=R$ and remains at this value for $r>R$. This implies, by Eq. (A20), that it has indeed Hopf index 1. Further, the gradient $|\nabla^{\mathbb{R}^3}\vec{n}|$ may be estimated like $|\nabla^{\mathbb{R}^3}\vec{n}| \leqslant c/R$ for $r \leqslant R$ and by $|\nabla^{\mathbb{R}^3}\vec{n}|=0$ for $r>R$ (here and below c denotes an unspecified constant). The map $\vec{N}(\vec{n}):S^2 \to S^2$ is constructed such that $\vec{N}$ varies smoothly over l nonintersecting geodesic discs covering the base S^2, where $\vec{N}=(0,0,1)$ in the center of each disc and $\vec{N}=(0,0,-1)$ at the boundary of each disc and between the discs. Each disc contributes a winding number 1 for the map $\vec{N}(\vec{n})$, therefore the total winding number is l. Further, the geodesic radius of each disc can be chosen (not larger than) $R_g=cl^{-1/2}$ in order to be able to put l nonintersecting discs on one unit S^2. The gradient may be again estimated by the inverse (geodesic) radius, $|\nabla^{S^2}\vec{N}(\vec{n})| \leqslant cl^{1/2}$, and with the help of the chain rule one finds for the gradient of $\vec{N}$ that $|\nabla^{\mathbb{R}^3_0}\vec{N}(\vec{n}(\vec{r}))| \leqslant cR^{-1}l^{1/2}$ and for the energy density $\mathcal{E}_{\mathrm{Ni}}(\vec{r}) \sim |\nabla^{\mathbb{R}^3_0}\vec{N}|^3 \leqslant cR^{-3}l^{3/2}$. The energy E_{Ni}, which is the integral over all space of $\mathcal{E}_{\mathrm{Ni}}(\vec{r})$, may in the case at hand be calculated by integrating over the ball B^R of radius R with the result that $E_{\mathrm{Ni}} \leqslant cl^{3/2} \equiv cQ^{3/4}$ which is the announced estimate for $Q=l^2$.

Before rederiving this result in more detail and with explicit choices for the above described maps, it may be useful to have a geometric picture of the above-noted composition of maps. In fact, the map $\vec{N}(\vec{n}(\vec{r}))$ describes l nonintersecting, full tori confined to the ball B^R, where, in addition, each full torus is linked with all other tori. In the center of each torus there is a closed line along which $\vec{N}$ takes the value $\vec{N}=(0,0,1)$. From the center to the surface of each full torus, $\vec{N}$ varies smoothly from $\vec{N}=(0,0,1)$ to $\vec{N}=(0,0,-1)$. At the surface of each full torus (which has the topology of the two-torus T^2) as well as in the space between the tori and outside the ball B^R, $\vec{N}$ remains at the value $\vec{N}=(0,0,-1)$.

Now for the detailed derivation, where we still assume $Q=l^2$ for the moment. For the map $\vec{n}(\vec{r})=(\sin\vartheta\cos\phi, \sin\vartheta\sin\phi, \cos\vartheta)$ with Hopf index 1 we assume that it has cylindrical symmetry, as in Eq. (A24). For the profile function $\rho(r)$ we want to find a choice which varies as smoothly as possible from 0 to π as r varies from 0 to R, in order to be able to estimate it with a number as small as possible. The smoothest choice $\rho=\pi r/R$ for $r \leqslant R$ and $\rho=\pi$ for $r>R$ does not have a continuous first derivative at $r=R$, which we need for the energy density, but there is a simple generalization which does have one. We choose

$$\rho_\epsilon(r) = \pi F_\epsilon(x), \quad x \equiv \frac{r}{R}, \tag{54}$$

where

$$F_\epsilon(x) = F_\epsilon^<(x) \equiv \frac{2}{2-\epsilon}x \quad \text{for } 0 \leqslant x \leqslant 1-\epsilon,$$

$$F_\epsilon(x) = F_\epsilon^>(x) \equiv 1 - \frac{1}{\epsilon(2-\epsilon)}(x-1)^2 \quad \text{for } 1-\epsilon < x \leqslant 1, \tag{55}$$

$$F_\epsilon(x) = 1 \quad \text{for } x > 1,$$

and ϵ is a sufficiently small, positive nonzero parameter. It may be checked easily that $\rho_\epsilon(r)$ is continuous and has continuous first derivatives everywhere. Further, the following estimates hold:

$$|F_\epsilon(x)| \leqslant k(\epsilon)x \quad \text{for } 0 \leqslant x \leqslant 1,$$

$$|F_\epsilon(x)| \leqslant k(\epsilon) \quad \text{for } 1 < x < \infty, \tag{56}$$

$$|F'_\epsilon(x)| \leqslant k(\epsilon) \quad \text{for } 0 \leqslant x < \infty,$$

where

$$k(\epsilon) \equiv \frac{2}{2-\epsilon} > 0. \tag{57}$$

For the map $\vec{N}(\vec{n})$ with winding number l we choose l nonintersecting geodesic discs on the base S^2 such that $\vec{N}$ varies smoothly from $\vec{N}=(0,0,1)$ in the center of each disc to $\vec{N}=(0,0,-1)$ at the boundary of each disc and remains at this value in between the discs. The geodesic radius ϑ_0 of these geodesic discs has to be chosen sufficiently small so that it is possible to put l nonintersecting discs with this geodesic radius on the base S^2. We prove in Appendix B that the choice

$$\vartheta_0 = \frac{\pi}{4\sqrt{l}} \tag{58}$$

is sufficient. Next we give an explicit expression for the map $\vec{N}$ for one geodesic disc which is chosen symmetric about the north pole. With

$$\vec{N} = (\sin\chi\cos\sigma, \sin\chi\sin\sigma, \cos\chi) \tag{59}$$

and

$$\vec{n} = (\sin\vartheta\cos\phi, \sin\vartheta\sin\phi, \cos\vartheta) \tag{60}$$

we get

$$\chi(\vartheta) = \pi F_\epsilon(\tilde{\vartheta}), \quad \tilde{\vartheta} \equiv \frac{\vartheta}{\vartheta_0} \tag{61}$$

and

$$\sigma = \phi, \tag{62}$$

where $F_\epsilon(\cdot)$ is defined in (55) (with the additional restriction that here $\tilde{\vartheta} \leqslant 4\sqrt{l}$ because $\vartheta \leqslant \pi$). The above-defined $\vec{N}$ has winding number 1, and to reach winding number l we have to require that it is nonconstant over $l-1$ further geodesic discs. We do not need, however, explicit expressions for the contribution of these further discs to $\vec{N}$, because their gradients on S^2, $|\nabla^{S^2}\vec{N}|$ can be estimated by the same majorants as the above explicit expression. The reason for this is that the above-noted symmetrically chosen disc is related to an arbitrary disc with the same geodesic radius by a rotation of the base space S^2, and the gradient $|\nabla^{S^2}\vec{N}|$ is invariant under such rotations. All that changes is that more regions of the base S^2 provide nonzero contributions to the gradient.

Next we want to estimate the energy density $\mathcal{E}_{\mathrm{Ni}}(\vec{r}) \sim |\nabla\vec{N}|^3$. Here we first estimate (Einstein summation convention is understood, $k, a = 1, \ldots, 3$)

$$|\nabla\vec{N}|^2 = (\nabla_k N^a)^2 = \chi_\vartheta^2 (\nabla_k \vartheta)^2 + \sin^2\chi (\nabla_k \sigma)^2, \tag{63}$$

where we used (59), and $\chi_\vartheta \equiv \partial_\vartheta \chi$. The first term may be estimated by

$$\chi_\vartheta^2 \leqslant \left(\frac{\pi}{\vartheta_0}\right)^2 k(\epsilon)^2 \tag{64}$$

and, with the help of spherical polar coordinates, by

$$(\nabla_k\vartheta)^2 = \vartheta_r^2 + \frac{1}{r^2}\vartheta_\theta^2 = \frac{4\rho_r^2 \cos^2\rho \sin^2\theta}{1-\sin^2\rho\sin^2\theta} + \frac{\sin^2\rho}{r^2}\frac{4\cos^2\theta}{1-\sin^2\rho\sin^2\theta} \leqslant 4\rho_r^2 + 4\frac{\rho^2}{r^2} \leqslant 8\pi^2\frac{k(\epsilon)^2}{R^2}, \tag{65}$$

where we used

$$\frac{\cos^2\alpha}{1-\sin^2\alpha\sin^2\beta} \leqslant 1, \quad \sin\alpha \leqslant \alpha \tag{66}$$

as well as Eqs. (54) and (56). For the second term we find

$$\sin^2\chi \leqslant \sin^2\left(\pi k(\epsilon)\frac{\vartheta}{\vartheta_0}\right) \leqslant \left(\frac{\pi k(\epsilon)}{\vartheta_0}\right)^2 \sin^2\vartheta, \tag{67}$$

where we used

$$\sin ax \leqslant a \sin x \quad \text{for } a \geqslant 1, \quad x \in \left[0, \frac{\pi}{2}\right] \tag{68}$$

which we prove in Appendix B. Further we find, using $\sigma = \phi$ and the expression for ϕ in Eq. (A24)

$$\sin^2\vartheta(\nabla_k\phi)^2 = 4\sin^2\rho\sin^2\theta(1-\sin^2\rho\sin^2\theta) \tag{69}$$

$$\cdot\left(\frac{1}{r^2\sin^2\theta} + \frac{\rho_r^2\cos^2\theta + (1/r^2)\cos^2\rho\sin^2\rho\sin^2\theta}{(1-\sin^2\rho\sin^2\theta)^2}\right) \tag{70}$$

$$= 4\frac{\sin^2\rho}{r^2}(1-\sin^2\rho\sin^2\theta) \tag{71}$$

$$+ 4\sin^2\rho\sin^2\theta\rho_r^2\frac{\cos^2\theta}{1-\sin^2\rho\sin^2\theta} \tag{72}$$

$$+4\sin^2\rho\sin^4\theta\frac{\sin^2\rho}{r^2}\frac{\cos^2\rho}{1-\sin^2\rho\sin^2\theta} \tag{73}$$

$$\leqslant 4\left(\frac{\pi k(\epsilon)}{R}\right)^2+4\left(\frac{\pi k(\epsilon)}{R}\right)^2+4\left(\frac{\pi k(\epsilon)}{R}\right)^2=12\left(\frac{\pi k(\epsilon)}{R}\right)^2. \tag{74}$$

Putting everything together, we therefore find

$$|\nabla\vec{N}|^2\leqslant 20\left(\frac{\pi^2 k(\epsilon)^2}{\vartheta_0 R}\right)^2=20l\left(\frac{4\pi k(\epsilon)^2}{R}\right)^2. \tag{75}$$

Taking the power of $\frac{3}{2}$ and integrating over the ball B^R we estimate the energy by

$$E_{\mathrm{Ni}}=\int d^3r|\nabla\vec{N}|^3\leqslant\int_{B^R}d^3r5^{3/2}l^{3/2}\left(\frac{8\pi k(\epsilon)^2}{R}\right)^3=\frac{4\pi}{3}5^{3/2}l^{3/2}(8\pi k(\epsilon)^2)^3. \tag{76}$$

Finally, for the estimate it is sufficient if the estimating field configuration is a distribution. Therefore we may now perform the limit $\lim_{\epsilon\to 0}k(\epsilon)=1$ and get, for $Q=l^2$,

$$E_{\mathrm{Ni}}\leqslant\frac{4\pi}{3}(8\pi)^3 5^{3/2}l^{3/2}. \tag{77}$$

In the cases when the Hopf index Q is not a square, we shall find a slightly weaker bound (i.e., a slightly larger value for the constant C_2). Again following Ref. 20, we write Q as

$$Q=l^2+m,\quad m\in[1,2l] \tag{78}$$

and estimate the energy by the following Hopf map. It maps the ball B^R with radius R about the origin to the two-sphere with a contribution of l^2 to the Hopf index in exactly the way constructed above for the case $Q=l^2$. Further, it maps m balls B_i^1, $i=1,\ldots,m$ with unit radius to the S^2 such that each ball contributes one unit to the Hopf index. Here the m unit balls are chosen such that they intersect neither each other nor the ball B^R. The map from B^R contributes exactly the above-calculated expression (77) to the energy, whereas the m maps from the B_i^1 contribute the energy of a unit Hopf map each. One might think to take just the energy (77) with $l=1$ for each energy contribution, but we can do better. The reason is that we were forced to choose ϑ_0 rather small in Eq. (58) to ensure that we can put l geodesic discs on one S^2. But here we are only interested in a map with winding number one, therefore we can choose the "geodesic disc" equal to the full S^2, i.e., $\vartheta_0=\pi$. This leads to the following energy estimate:

$$E_{\mathrm{Ni}}\leqslant\frac{4\pi}{3}(8\pi)^3 5^{3/2}l^{3/2}+\frac{4\pi}{3}(2\pi)^3 5^{3/2}m, \tag{79}$$

which we want to estimate in terms of Q again, i.e.,

$$c_2 l^{3/2}+c_3 m\leqslant c_4(l^2+m)^{3/4}. \tag{80}$$

Here the left-hand side grows linearly in m, whereas the right-hand side grows sublinearly, therefore the inequality certainly holds for all $m\in[1,2l]$ if it holds for the maximum value $m=2l$, i.e.,

$$c_2 l^{3/2}+2c_3 l\leqslant c_4(l^2+2l)^{3/4}. \tag{81}$$

With the help of the inequality

$$c_2 + 2c_3 l^{-1/2} \leqslant c_2 + 2c_3 \leqslant (c_2 + 2c_3)\left(1 + \frac{2}{l}\right)^{3/4} \tag{82}$$

we see that the above-noted inequality certainly holds for $c_4 = c_2 + 2c_3$. Inserting the concrete numbers from (79) we therefore get

$$E_{\mathrm{Ni}} \leqslant \frac{4\pi}{3}(2\pi)^3(4^3+2)5^{3/2}Q^{3/4} \tag{83}$$

as our final estimate for general Q.

B. Upper bounds for the AFZ and Faddeev–Niemi models

We may use our result to obtain upper bounds for the energies of the AFZ and Faddeev–Niemi models, as well. For the bound on the AFZ model we use the simple inequality for the energy densities

$$\mathcal{E}_4 \leqslant \tfrac{1}{2}\mathcal{E}_2^2, \tag{84}$$

which is obvious from the (ϑ, ϕ) parametrization, see Eqs. (A25) and (A26). It follows immediately that $E_{\mathrm{AFZ}} \leqslant (\frac{1}{2})^{3/4} E_{\mathrm{Ni}}$ and, therefore,

$$E_{\mathrm{AFZ}} \leqslant \left(\frac{1}{2}\right)^{3/4}\frac{4\pi}{3}(2\pi)^3(4^3+2)5^{3/2}Q^{3/4}. \tag{85}$$

For the Faddeev–Niemi model with energy density $\mathcal{E}_{\mathrm{FN}} = \mathcal{E}_2 + \lambda\mathcal{E}_4$ we consider the case $Q = l^2$ of a square Hopf index first. We use Eq. (75) for the density $\mathcal{E}_2$ and the inequality (84) and find

$$\begin{aligned} E_{\mathrm{FN}} &= \int_{B^R} d^3r(\mathcal{E}_2 + \lambda\mathcal{E}_4) \leqslant \int_{B^R} d^3r\left(20l\left(\frac{4\pi}{R}\right)^2 + \frac{\lambda}{2}(20l)^2\left(\frac{4\pi}{R}\right)^4\right) \\ &= \frac{4\pi}{3}R^3\left(20l\left(\frac{4\pi}{R}\right)^2 + \frac{\lambda}{2}(20l)^2\left(\frac{4\pi}{R}\right)^4\right) \end{aligned} \tag{86}$$

and, with the choice

$$R = R_0\sqrt{l}, \tag{87}$$

we get

$$E_{\mathrm{FN}} \leqslant 20\frac{4\pi}{3}(4\pi)^2 l^{3/2}\left(R_0 + 10(4\pi)^2\frac{\lambda}{R_0}\right). \tag{88}$$

For a neat estimate we now minimize the expression in brackets with respect to R_0 which leads to

$$R_0 = 4\pi\sqrt{10\lambda} \tag{89}$$

and to

$$E_{\mathrm{FN}} \leqslant 40\frac{4\pi}{3}(4\pi)^3\sqrt{10\lambda}\, l^{3/2}. \tag{90}$$

Here we have separated a factor $(4\pi)^3$ because it can be replaced by π^3 for winding number one, exactly as in the estimate for the Nicole model, which we need for general Q. Again we write $Q = l^2 + m$ and estimate

$$E_{\mathrm{FN}} \leqslant 40\frac{4\pi}{3}(4\pi)^3\sqrt{10\lambda}l^{3/2} + 40\frac{4\pi}{3}\pi^3\sqrt{10\lambda}m \tag{91}$$

and finally by

$$E_{\mathrm{FN}} \leqslant 40\frac{4\pi}{3}\pi^3\sqrt{10\lambda}(4^3+2)Q^{3/4} \tag{92}$$

in complete analogy to the Nicole model.

Note added: after finishing this paper we became aware of Ref. 21, where an analogous bound $E_{\mathrm{FN}} \leqslant C_2 Q^{3/4}$ was derived for the Faddeev–Niemi model. There the authors found a better (i.e., lower) value for C_2 by a combination of analytical and numerical methods.

V. CONCLUSIONS

Combining numerical and analytical techniques, we found the energies for static solutions of the Nicole model within the symmetric ansatz (8) for a wide (in principle arbitrary) range of the integers m and n. It turns out that the energies of these symmetric solutions grow linearly with the Hopf index $Q=mn$ within a very good accuracy. Together with the sublinear growth inequality of Sec. IV, $E \leqslant C_2 Q^{3/4}$ this implies that, for sufficiently large values of Q, the symmetric solutions we found cannot be global minima within their respective topological sectors with fixed Hopf index Q. It is of some interest to compare this result with the corresponding results for the AFZ and Faddeev–Niemi models.

For the AFZ model all solutions for the symmetric ansatz (8) and their corresponding energies can be calculated exactly.[8] The energies are

$$E_{\mathrm{AFZ}} = 8\sqrt{2}\pi^2\sqrt{|m||n|(|m|+|n|)} = 8\sqrt{2}\pi^2 Q^{3/4}\sqrt{\mu+\frac{1}{\mu}}, \quad \mu^2 \equiv \left|\frac{m}{n}\right| \tag{93}$$

and, for $m=n$ ($\mu=1$) perfectly fit within the upper bound $E_{\mathrm{AFZ}} \leqslant C_2 Q^{3/4}$ which holds also for the AFZ model (see Sec. IV). It is, therefore, plausible to conjecture that these solutions might be true minima for $m=n$ (and, maybe, even for $m \neq n$ provided that m and n do not differ too much).

For the Faddeev–Niemi model the ansatz (8) is not compatible with the equations of motion (due to the lack of conformal symmetry of the latter), but the cylindrically symmetric ansatz

$$u = f(\eta,\xi)e^{im\varphi} \tag{94}$$

for complex f is compatible and leads to an equation in the two independent variables η and ξ. Numerical investigation of the full e.o.m. in three variables shows that the solutions for the ansatz (94) are true minima only for the lowest values $Q=1,2$ of the Hopf index.[4] In this respect, therefore, the Nicole model bears more similarity with the Faddeev–Niemi model than with the AFZ model. It is tempting to speculate at this instant that the different behavior of the AFZ model—i.e., the possibility that the symmetric solutions (93) are true minima for arbitrary Q—is related to the integrability properties of the latter. But at the moment this is, of course, only speculation which deserves further investigation.

APPENDIX A: FACTS ABOUT HOPF MAPS

A Hopf map is a map from the three-sphere S^3 to the two-sphere S^2. The third homotopy group of the two-sphere is nontrivial, $\Pi_3(S^2)=\mathbb{Z}$, therefore Hopf maps are characterized by an integer topological index, the so-called Hopf index Q. The three-sphere is topologically equivalent to one-point compactified three-dimensional Euclidean space $\mathbb{R}^3_0$, therefore, for each Hopf map $S^3\to S^2$ there exists a corresponding map $\mathbb{R}^3_0\to S^2$, which we shall call Hopf map, as well, and which has the same Hopf index (due to the metric independence of a topological index). Explicitly, a Hopf map $\mathbb{R}^3_0\to S^2$ may be given by a three-component unit vector field

$$\vec{n}(\vec{r}):\mathbb{R}^3_0\to S^2,\quad \vec{n}^2=1,\quad \lim_{\vec{r}\to\infty}=\vec{n}_0=\text{const}, \tag{A1}$$

where the tip of the unit vector field spans the unit two-sphere, or via stereographic projection

$$\vec{n}=\frac{1}{1+|u|^2}(u+\overline{u},-i(u-\overline{u}),1-u\overline{u}),\quad u=\frac{n_1+in_2}{1+n_3} \tag{A2}$$

by a complex field

$$u(\vec{r}):\mathbb{R}^3_0\to\mathbb{C}_0,\quad \lim_{\vec{r}\to\infty}=u_0=\text{const}, \tag{A3}$$

where our conventions are such that the projection is from the south pole to the equatorial plane of the two-sphere. Further, $\mathbb{C}_0$ is the one-point compactified complex plane. A third possibility to parametrize a Hopf map is by the spherical angles $\phi\in[0,2\pi]$, $\vartheta\in[0,\pi]$, which are related to the unit vector $\vec{n}$ and complex field u via

$$u=\tan\frac{\vartheta}{2}e^{i\phi},\quad \vec{n}=(\sin\vartheta\cos\phi,\sin\vartheta\sin\phi,\cos\vartheta). \tag{A4}$$

The geometry behind the Hopf map may be visualized as follows. The pre-images under the inverse of the Hopf map u of points in the target space S^2 (or, equivalently, $\mathbb{C}_0$) are closed curves in $\mathbb{R}^3_0$ (in general, knots), where each two curves corresponding to two different points in target space are linked exactly Q times. An analytic expression for the Hopf index Q is

$$Q=\frac{1}{16\pi^2}\int d^3r\vec{\mathcal{A}}\cdot\vec{\mathcal{B}}, \tag{A5}$$

where $\vec{\mathcal{B}}$ is the Hopf curvature

$$\vec{\mathcal{B}}=\frac{2}{i}\frac{\nabla u\times\nabla\overline{u}}{(1+u\overline{u})^2}=-\frac{1}{2}\epsilon^{abc}n^a\nabla n^b\times\nabla n^c=-\sin\vartheta\nabla\vartheta\times\nabla\phi \tag{A6}$$

and $\vec{\mathcal{A}}$ is the gauge potential for the "magnetic field" $\vec{\mathcal{B}}$, $\vec{\mathcal{B}}=\nabla\times\vec{\mathcal{A}}$. There is no local expression for $\vec{\mathcal{A}}$ in terms of the Hopf map u alone (however, there certainly exist nonlocal expressions for certain gauges, as is obvious from the analogy with electrodynamics, by choosing, e.g., the Coulomb gauge $\nabla\cdot\vec{\mathcal{A}}=0$ which implies $\vec{\mathcal{A}}=\nabla\times\int d^3r'\Delta^{-1}(\vec{r}-\vec{r}')\vec{\mathcal{B}}(\vec{r}')$).

Geometrically, $\vec{\mathcal{B}}$ is the Hodge dual of the pullback of the area two-form on S^2 under the Hopf map u, i.e.,

$$\mathcal{B}\equiv\mathcal{B}_k dr^k=*\mathcal{F}, \tag{A7}$$

$$\mathcal{F}\equiv\tfrac{1}{2}\mathcal{F}_{jk}dr^j dr^k,\quad \mathcal{B}_k=\varepsilon_{klm}\mathcal{F}_{lm}, \tag{A8}$$

where

$$\mathcal{F} = u^*(\Omega), \quad \Omega = \frac{2}{i}\frac{d\zeta d\bar{\zeta}}{(1+\zeta\bar{\zeta})^2}, \quad \int_{S^2} \Omega = 4\pi. \tag{A9}$$

The second cohomology group of the three-sphere is trivial, $H_2(S^3)=0$, therefore the closed two-form $\mathcal{F}$ must be exact, $\mathcal{F}=d\mathcal{A}$. It follows that the gauge potential $\vec{\mathcal{A}}$ is globally well-defined for appropriately chosen gauges (e.g., in the Couloumb gauge).

The simplest Hopf map with Hopf index 1 is

$$u = i\frac{2(x+iy)}{2z+i(r^2-1)} \tag{A10}$$

(the irrelevant factor i has been introduced to be in exact agreement with the simplest Hopf map of Eq. (12)). Its level curves (i.e., the pre-images of points $u=$const) are circles which lie on tori, and each two different circles are linked precisely once.

There are different ways to construct Hopf maps explicitly. One method which we shall need is to compose a given Hopf map with a map $S^2 \to S^2$,

$$\vec{N}(\vec{n}(\vec{r})):\mathbb{R}^3_0 \xrightarrow{\vec{n}(\vec{r})} S^2 \xrightarrow{\vec{N}(\vec{n})} S^2. \tag{A11}$$

If the Hopf map $\vec{n}(\vec{r})$ has Hopf index Q and the map $\vec{N}(\vec{n})$ has winding number w, then the composition map $\vec{N}(\vec{n}(\vec{r}))$ has Hopf index $Q'=w^2Q$.

A method to construct all possible Hopf maps starts from maps $S^3 \to S^3$ (or, equivalently, maps $\mathbb{R}^3_0 \to S^3$). The third homotopy group of S^3 is nontrivial, $\Pi_3(S^3)=\mathbb{Z}$, therefore such maps are classified by a topological index, the winding number W. It is possible to construct Hopf maps $\mathbb{R}^3_0 \to S^2$ from maps $\mathbb{R}^3_0 \to S^3$ such that the Hopf index equals the winding number. Explicitly a map $\mathbb{R}^3_0 \to S^3$ may be given by a four component unit vector field

$$(e_1(\vec{r}),e_2(\vec{r}),e_3(\vec{r}),e_4(\vec{r})):\mathbb{R}^3_0 \to S^3, \quad e_\alpha e_\alpha = 1, \quad \alpha = 1,\ldots,4 \tag{A12}$$

$$\lim_{\vec{r}\to\infty} e_\alpha = e^0_\alpha = \text{const} \tag{A13}$$

then the corresponding Hopf map is given in terms of u as

$$u = \frac{e_1+ie_2}{e_3+ie_4} \tag{A14}$$

or in terms of $\vec{n}$ as

$$\vec{n} = (2e_1e_3+2e_2e_4, -2e_1e_4+2e_2e_3, e_3^2+e_4^2-e_1^2-e_2^2). \tag{A15}$$

Further, it is now possible to give an explicit, local expression for the gauge potential $\vec{\mathcal{A}}$, in terms of the e_α, as

$$\vec{\mathcal{A}} = \frac{2}{i}[(e_1-ie_2)\,\nabla\,(e_1+ie_2)+(e_3-ie_4)\,\nabla\,(e_3+ie_4)]. \tag{A16}$$

It may be checked without difficulty that indeed $\nabla\times\vec{\mathcal{A}}=\vec{\mathcal{B}}$ where $\vec{\mathcal{B}}$ is the Hopf curvature (A6).

As the group manifold of SU(2) is equivalent to the three-sphere S^3, we may use maps $\mathbb{R}^3_0 \to \mathrm{SU}(2)$ instead. Indeed, with the group element

$$U = e_4 - i\vec{e}\cdot\vec{\sigma} \equiv \exp[-i\rho\vec{k}\cdot\vec{\sigma}], \quad \lim_{\vec{r}\to\infty} U = U_0 = \text{const} \tag{A17}$$

$$e_4 = \cos\rho, \quad \vec{e} = \sin\rho\vec{k}, \quad \vec{k}^2 = 1 \tag{A18}$$

(where $\vec{e}=(e_1,e_2,e_3)$ and $\vec{\sigma}$ are the Pauli matrices) the Hopf map (A15) may be expressed like

$$\vec{n} = \tfrac{1}{2}\mathrm{tr}\sigma_3 U^\dagger \vec{\sigma} U. \tag{A19}$$

This latter representation may be used to produce ansaetze for Hopf maps with cylindrical symmetry from maps $\mathbb{R}^3_0 \to \mathrm{SU}(2)$ with rotational symmetry. Indeed, for

$$\vec{k} = \hat{r} \equiv \vec{r}/r, \quad \rho = \rho(r), \quad \rho(0) = 0, \quad \lim_{r\to\infty} \rho = \pi W, \quad W \in \mathbb{Z} \tag{A20}$$

(the conditions on $\rho(r)$ are to ensure a well-defined U on all $\mathbb{R}^3_0$, and they provide, at the same time, a winding number equal to W for the corresponding map $\mathbb{R}^3_0 \to S^3$ or $\mathbb{R}^3_0 \to \mathrm{SU}(2)$), the resulting group element $U(\rho(r),\hat{r})$ is rotationally invariant in the sense that any rotation in $\mathbb{R}^3_0$ can be compensated by a SU(2) transformation,

$$U(\rho(r),O\hat{r}) \equiv \cos\rho(r) - i\sin(\rho(r)\vec{\sigma}\cdot(O\hat{r}) = V^\dagger U(\rho(r),\hat{r})V, \tag{A21}$$

where O is a rotation matrix acting on $\hat{r}$ and V is the SU(2) matrix corresponding to the rotation O. Within this ansatz, and using spherical polar coordinates $\hat{r}=(\sin\theta\cos\varphi, \sin\theta\sin\varphi, \cos\theta)$, we get for the complex field u

$$u = \frac{\sin\rho\sin\theta e^{i\varphi}}{\sin\rho\cos\theta + i\cos\rho}, \tag{A22}$$

which has cylindrical symmetry in the sense that any rotation $\varphi \to \varphi+\varphi_0$ can be compensated by a phase transformation $u \to e^{i\varphi_0}u$. Further, u is a Hopf map with Hopf index equal to the winding number W. For technical reasons we prefer to use a u which is multiplied by $-i$ in our main calculation, i.e.,

$$u = -i\frac{e_1+ie_2}{e_3+ie_4} = \frac{\sin\rho\sin\theta}{\sqrt{\sin^2\rho\cos^2\theta+\cos^2\rho}} e^{i\varphi + i\arctan[\tan\rho\cos\theta]}. \tag{A23}$$

With $u=\tan(\vartheta/2)e^{i\phi}$ this leads to

$$\sin\vartheta = 2\sin\rho\sin\theta\sqrt{1-\sin^2\rho\sin^2\theta}, \quad \phi = \varphi + \arctan[\tan\rho\cos\theta]. \tag{A24}$$

Finally, we display the energy densities of the Nicole and AFZ models in the three different parametrizations, $\mathcal{E}_{\mathrm{Ni}}=\mathcal{E}_2^{3/2}$ with

$$\mathcal{E}_2 = |\nabla\vec{n}|^2 \equiv |\nabla_k n^a|^2 = 4\frac{\nabla u\cdot\nabla\overline{u}}{(1+u\overline{u})^2} = (\nabla\vartheta)^2 + \sin^2\vartheta(\nabla\phi)^2 \tag{A25}$$

and $\mathcal{E}_{\mathrm{AFZ}}=\mathcal{E}_4^{3/4}$ with

$$\begin{aligned}\mathcal{E}_4 = \vec{\mathcal{B}}^2 &= \frac{1}{2}((\nabla n^b\cdot\nabla n^b)^2 - (\nabla n^b\cdot\nabla n^c)^2) \\ &= 4\frac{(\nabla u\cdot\nabla\overline{u})^2 - (\nabla u)^2(\nabla\overline{u})^2}{(1+u\overline{u})^4} = \sin^2\vartheta((\nabla\vartheta)^2(\nabla\phi)^2 - (\nabla\vartheta\cdot\nabla\phi)^2).\end{aligned} \tag{A26}$$

APPENDIX B

Proof that

$$(a+b)^{3/2} \geqslant ca^{1/2}b \quad \text{for } a,b \geqslant 0, \quad c \leqslant \sqrt{3}\frac{3}{2}. \tag{B1}$$

By squaring the above expression and subtracting the right-hand side we get

$$a^3 + 3a^2b + 3(1-d^2)ab^2 + b^3 \geqslant 0, \quad d^2 \equiv \frac{c^2}{3} \tag{B2}$$

or, by introducing the variable $x=a/b$,

$$h(x) \equiv x^3 + 3x^2 + 3(1-d^2)x + 1 \geqslant 0 \quad \text{for } x \geqslant 0. \tag{B3}$$

This problem we solve by first calculating the minimum $x_{\min}$ of $h(x)$ for $x \geqslant 0$, and by then requiring that $h(x_{\min})=0$. The minimum is at

$$h'(x) = 3(x^2 + 2x + (1-d^2)) \equiv 0 \Rightarrow x_{\min} = d - 1 \tag{B4}$$

and the condition $h(x_{\min})=0$ finally leads to

$$h(x_{\min}) = d^2(3-2d) \equiv 0 \wedge d \geqslant 1 \Rightarrow d = \tfrac{3}{2} \tag{B5}$$

which implies (B1). QED

Proof that one may cover the unit sphere with l nonintersecting discs with geodesic radius $\vartheta_0 = \pi/4\sqrt{l}$. First we study the case where l is a square, $l=k^2$. We divide the northern hemisphere of the two-sphere into segments by circles which are concentric about the north pole and are given by

$$\vartheta = \frac{m\pi}{2k}, \quad m = 1, \ldots, k. \tag{B6}$$

This divides the northern hemisphere into one disc with geodesic radius $\pi/2k$ about the north pole (on which one geodesic disc with geodesic radius $\vartheta_0 = \pi/4k$ certainly does fit) and into sphere segments such that the boundary circles have a geodesic distance of $\pi/2k$. Therefore discs with geodesic diameter $2\vartheta_0 = \pi/2k$ exactly fit in between. Further, $2m+1$ geodesic discs fit on the segment between the circles at $\vartheta = m\pi/2k$ and at $\vartheta = [(m+1)\pi]/2k$. This is because the central circle of the segment has a circumference which is bigger than the sum of $m+1$ diameters of the geodesic discs, i.e.,

$$2\pi \sin\left(\left(m+\frac{1}{2}\right)\frac{\pi}{2k}\right) \geqslant 2\pi\frac{2}{\pi}\left(\left(m+\frac{1}{2}\right)\frac{\pi}{2k}\right) = (2m+1)\frac{\pi}{k} \geqslant (2m+1)\frac{\pi}{2k}, \tag{B7}$$

where we used

$$\sin x \geqslant \frac{2}{\pi}x \quad \text{for } x \in \left[0, \frac{\pi}{2}\right]. \tag{B8}$$

Finally, summing over all discs on all segments (including the first disc at the segment which is itself a disc) we find

$$\sum_{m=0}^{k-1} (2m+1) = \sum_{m=1}^{k} (2m-1) = k^2, \tag{B9}$$

therefore we may indeed distribute k^2 nonintersecting geodesic discs with geodesic radius $\vartheta_0 = \pi/4k$ on the northern hemisphere.

It remains to study the case where l is not a square. Then we write $l=k^2+j$. We distribute the k^2 discs on the northern hemisphere as just described. Further, we distribute the remaining j discs on the southern hemisphere. This is obviously possible as long as $k^2 \geqslant j$. So we cover all cases except the case $l=3$. This latter case may be proven easily with the help of elementary geometry. QED

Proof that

$$\sin ax \leqslant a \sin x \quad \text{for } a \geqslant 1, \quad x \in \left[0, \frac{\pi}{2}\right]. \tag{B10}$$

We introduce $a \equiv 1+\epsilon$, $\epsilon \geqslant 0$ and write

$$\sin((1+\epsilon)x) = \sin x \cos \epsilon x + \cos x \sin \epsilon x \leqslant \sin x + \epsilon x \cos x \leqslant \sin x + \epsilon \sin x \equiv a \sin x, \tag{B11}$$

where we used $\cos x \leqslant 1$, $\sin x \leqslant x$ for $x \geqslant 0$, and

$$x \cos x \leqslant \sin x \Rightarrow \tan x \geqslant x \quad \text{for } x \in \left[0, \frac{\pi}{2}\right] \tag{B12}$$

which is obviously true. QED

APPENDIX C: ON THE POSSIBILITY OF A LOWER BOUND $C_1 Q^{3/4} \leqslant E_Q$

It may be useful to briefly comment on the problem of deriving a lower bound for the energy of the type $C_1 Q^{3/4} \leqslant E_Q$, analogously to the case of the Faddeev–Niemi model, where this bound can be proven (Vakulenko-Kapitansky bound, see, e.g., Refs. 22–24). In the case of the Faddeev–Niemi model, the first step in the proof is Hoelder's inequality (we use the conventions of Ref. 25, where all inequalities of this appendix can be found; further, we assume that $\vec{\mathcal{A}}$ and $\vec{\mathcal{B}}$ belong to the appropriate Sobolev spaces such that all integrals below exist)

$$16\pi^2 Q \equiv \int d^3r \vec{\mathcal{A}} \cdot \vec{\mathcal{B}} \leqslant \left(\int d^3r |\vec{\mathcal{A}}|^p\right)^{1/p} \left(\int d^3r |\vec{\mathcal{B}}|^q\right)^{1/q} \tag{C1}$$

$$\frac{1}{p} + \frac{1}{q} = 1. \tag{C2}$$

For the Faddeev–Niemi model one has to choose $p=6$, $q=\frac{6}{5}$ and may estimate the first term with the help of the Gagliardo-Nirenberg-Sobolev (GNS) inequality,

$$\left(\int d^3r |\vec{\mathcal{A}}|^6\right)^{1/6} \leqslant c \left(\int d^3r |\nabla |\vec{\mathcal{A}}||^2\right)^{1/2} \tag{C3}$$

(here and below c is an unspecified constant) and, when the Couloumb gauge condition $\nabla \cdot \vec{\mathcal{A}} = 0$ is imposed, the integrand can be reexpressed like

$$|\nabla |\vec{\mathcal{A}}||^2 \leqslant c \left|\sum_{jk} \partial_j \mathcal{A}_k\right|^2 = c(|\nabla \times \vec{\mathcal{A}}|^2 + \nabla \cdot \vec{\Lambda}), \tag{C4}$$

where

$$\Lambda_1 = (\mathcal{A}_2 \partial_2 + \mathcal{A}_3 \partial_3)\mathcal{A}_1 - \mathcal{A}_1(\partial_2 \mathcal{A}_2 + \partial_3 \mathcal{A}_3) \tag{C5}$$

and Λ_2, Λ_3 follow by permutation. Therefore, the integrand is the sum of $\vec{\mathcal{B}}^2$ and a total divergence which does not contribute to the integral (for $\vec{\mathcal{A}}$ which decay sufficiently fast in the limit $|\vec{r}| \to \infty$; this is automatically satisfied by the class of $\vec{\mathcal{A}}$ we consider). The proof continues with the interpolation inequality

$$\left(\int d^3r|\vec{\mathcal{B}}|^{6/5}\right)^{5/6} \leqslant \left(\int d^3r|\vec{\mathcal{B}}|\right)^{2/3}\left(\int d^3r|\vec{\mathcal{B}}|^2\right)^{1/6} \tag{C6}$$

for the second term. This leads to

$$16\pi^2 Q \leqslant c\left(\int d^3r|\vec{\mathcal{B}}|^2\right)^{2/3}\left(\int d^3r|\vec{\mathcal{B}}|\right)^{2/3} \tag{C7}$$

and, together with $|\vec{\mathcal{B}}|^2=\mathcal{E}_4$ and $|\vec{\mathcal{B}}|\leqslant(1/\sqrt{2})\mathcal{E}_2$, to

$$16\pi^2 Q \leqslant c\lambda^{-2/3}\left[\left(\lambda\int d^3r\mathcal{E}_4\right)^{1/2}\left(\int d^3r\mathcal{E}_2\right)^{1/2}\right]^{4/3} \leqslant c\lambda^{-2/3}\left[\lambda\int d^3r\mathcal{E}_4+\int d^3r\mathcal{E}_2\right]^{4/3}, \tag{C8}$$

where we used Cauchy's inequality in the last step. The Vakulenko–Kapitansky bound follows immediately by taking the above inequality to the power $\frac{3}{4}$.

Now let us point out where the analogous proof fails for the AFZ and Nicole models. One again starts with Hoelder's inequality (C1), but now one would have to choose $p=3$ and $q=\frac{3}{2}$. With the GNS inequality one can again estimate the first term

$$\left(\int d^3r|\vec{\mathcal{A}}|^3\right)^{1/3} \leqslant c\left(\int d^3r|\nabla|\vec{\mathcal{A}}||^{3/2}\right)^{2/3} \tag{C9}$$

but now the integrand is

$$|\nabla|\vec{\mathcal{A}}||^{3/2} \leqslant c\left|\sum_{jk}\partial_j\mathcal{A}_k\right|^{3/2} = c(|\nabla\times\vec{\mathcal{A}}|^2+\nabla\cdot\vec{\Lambda})^{3/4} \tag{C10}$$

and therefore no longer a total derivative, and we cannot express the integrand in terms of the Hopf curvature alone. We have not been able to overcome this difficulty. For our main results, however, the upper bound is more important, which shows that for sufficiently high Hopf index our solutions of Sec. II cannot be true minimizers of the energy.

We study the $(\lambda/4!)\varphi^4$ massless scalar field theory in a four-dimensional Euclidean space, where all but one of the coordinates are unbounded. We are considering Dirichlet boundary conditions in two hyperplanes, breaking the translation invariance of the system. We show how to implement the perturbative renormalization up to two-loop level of the theory. First, analyzing the full two and four-point functions at the one-loop level, we show that the bulk counterterms are sufficient to render the theory finite. Meanwhile, at the two-loop level, we must also introduce surface counterterms in the bare Lagrangian in order to make finite the full two and also four-point Schwinger functions. © *2006 American Institute of Physics.*

I. INTRODUCTION

In this paper we are interested to show how to implement the renormalization procedure up to two-loop level in the massless $(\lambda/4!)\varphi^4$ scalar field theory, defined in a four-dimensional Euclidean space with one compactified dimension. Our aim is to shed light on the renormalization procedure in a system defined in a domain where translational symmetry is broken, which must be done, for example, in the high temperature dimensional reduced quantum chromodynamics (QCD), defined in a finite region.

Quantum chromodynamics is a non-Abelian Yang-Mills theory with gauge group SU(3). Since it is assumed that the fermions of the theory transform according to the fundamental representation of the gauge group, each flavor of quark is a triplet of the color group SU(3). Gauge bosons transform according to the adjoint representation. The interaction between the quarks is mediated by the gluons. Due to the non-Abelian structure of the theory, the gluons couple not only with the quarks but have also cubic and quartic self-interaction. The self-interaction of the gluons provides the antiscreening of the color charge in QCD. This is responsible for asymptotic freedom and presumably confinement.

The confinement-deconfinement phase transition in QCD may occur in usual matter at sufficiently high temperature or if it is strongly compressed.[1–3] In ultrarelativistic heavy ion collisions, we expect that the plasma of quarks and gluons can be produced. We would like to stress that, although nonequilibrium processes occur in the quark-gluon plasma in the heavy ion collisions, for

[a)]Electronic mail: aparicio@cbpf.br

[c)]Electronic mail: nfuxsvai@cbpf.br

simplicity in a first approximation we can assume a static situation. Just after the collision hot and compressed nuclear matter is confined in a small region of the space and in such circumstances the volume and surface effects become very important.

In the above described physical situation there are two important points: the first one is that the thermodynamic limit of the infinite volume system cannot be used and therefore finite volume effects should be investigated and taken into account. The second point is that the quark-gluon plasma exists in a situation of high temperature, where using the Matsubara formalism to describe high temperature QCD, dimensional reduction must occur.[4–7] Dimensional reduction is based on the Appelquist-Carrazone decoupling theorem.[8] From a more fundamental theory, the effective Lagrangian density of this theory can be obtained as some low-energy limit of the fundamental theory where the heavy modes have been removed. There are some interesting physical situations where the decoupling theorem can be used. First, for scalar fields without spontaneous symmetry breaking. Second, in quantum electrodynamics, where a derivative expansion of the photon effective action can be obtained by integrating out the fermionic fields. Also in QCD at least in lowest order in perturbation theory the decoupling theorem works. The decoupling theorem is not valid, for example, in spontaneous broken gauge theories. It is important to stress that the nonvalidity of the decoupling theorem means that low-energy experiments can provide information about the high energy physics.

Going back to the heavy-ions collision situation, we can assume that the following scenario appears: in the situation where dimensional reduction occurs, we have an effective theory for the gluons field and also finite size effects for these bosonic fields. To shed light on the renormalization procedure in systems defined in domain where translational symmetry is broken, as for example, the high temperature dimensional reduced QCD, in this paper we are interested to investigate scalar models, impose classical boundary condition over the fields. We hope that this study will give us some insight over the most interesting and also more complicated situation as the one mentioned above. Therefore, in this paper we analyze how to implement the perturbative renormalization up to two-loop level of $(\lambda/4!)\varphi^4$ massless scalar field model defined in a four-dimensional Euclidean space with one compactified dimension.

Finite size effects and the presence of macroscopic structures in different field theory models have been extensively studied in the literature. The critical behavior of the O(N) model in the presence of a surface was a target of intense investigations.[9] The same O(N) model was studied in two different geometries: the periodic cube and the cylinder along one dimension (the time) and finite and periodic in the $(d-1)$ remaining dimensions by Brezin and Zinn-Justin.[10] Finite size effects in QCD[11] and also in different field theory models have also been extensively studied in the literature. Assuming periodic or antiperiodic boundary conditions for bosonic and fermionic models, respectively, the translation symmetry is maintained, and surface effects are avoided. Therefore, to avoid surface effects, quantum fields defined in manifolds with periodic or anti-periodic boundary conditions in the spatial section were preferred by many authors.[12] Nevertheless, the case of boundaries conditions that break the translational symmetry deserves our attention.

In the case of hard boundary conditions as, for example, Dirichlet-Dirichlet (DD) or Neumann-Neumann (NN), the translational invariance is lacking. This fact makes the Feynman diagrams harder to compute than in an unbounded space. Moreover the renormalization program is implemented in a different way from unbounded or translational invariance systems since some surface divergence appears.[13] For translational invariant systems, one can use the momentum space representation, which is a more convenient framework to analyze the ultraviolet divergences of a theory. Translational invariance is preserved for momentum conservation conditions. For nontranslational invariant systems a more convenient representation for the n-point Schwinger functions is a mixed momentum coordinate space.

Fosco and Svaiter considered the anisotropic scalar model in a d-dimensional Euclidean space, where all but one of the coordinates are unbounded. Translational invariance along the bounded coordinate which lies in the interval $[0,L]$ is broken because the choice of boundary condition chosen for the hyperplanes at $z=0$ and $z=L$. Two different possibilities of boundary conditions were considered: (DD) and also (NN), and the renormalization of the two-point func-

tion was achieved in the one-loop approximation.[14] Further, the renormalization of the four-point function was achieved in the one-loop approximation by Caicedo and Svaiter.[15] Finally Svaiter[16] studied the renormalization of the $(\lambda/4!)\varphi^4$ massless scalar field model in the one-loop approximation in finite size systems assuming that the system is in thermal equilibrium with a reservoir. Also, still studying surface, edge, and corners effects, Rodrigues and Svaiter[17] analyzed first the renormalized vacuum fluctuations associated with a massless real scalar field, confined in the interior or a rectangular infinitely long waveguide. A closed form of the analytic continuation of the local zeta function in the interior of the waveguide was obtained and a detailed study of the surface and edge divergences was presented. Next, these authors[18] studied the renormalized stress tensor associated with an electromagnetic field in the interior of a rectangular infinitely long waveguide.

In this paper we will consider an interacting massless scalar model, in a four-dimensional Euclidean space, where the first three coordinates are unbounded and the last one lies in the interval $[0,L]$. We analyze only DD boundary conditions. First, we present an algebraic expression in coordinate space for the free propagator which let us identify the divergences of the *n*-point Schwinger functions for the interacting theory. This algebraic expression agrees with the result obtained by Lukosz.[19] We would like to stress that instead of assuming hard boundary conditions, some authors assumed soft boundary conditions and also treated the boundary as a quantum mechanical object.[20] Here, we prefer to keep hard classical boundary conditions.

The organization of the paper is as follows: In Sec. II we discuss the slab configurations, obtaining some important expressions for the free propagator in order to understand some procedures in the divergence identification. In Sec. III the regularization program is implemented in the one-loop approximation. In Sec. IV the regularization program is implemented in the two-loop approximation. Section V contains our conclusions. In the Appendix, an expression for the free propagator is introduced. Throughout this paper we use $\hbar=c=1$.

II. CLASSICAL BOUNDARY CONDITIONS AND SOME PROPERTIES OF THE FREE PROPAGATOR

Let us consider a neutral scalar field with a $(\lambda\varphi^4)$ self-interaction, defined in a *d*-dimensional Minkowski space-time. The vacuum persistence functional is the generating functional of all vacuum expectation value of time-ordered products of the theory. The Euclidean field theory can be obtained by analytic continuation to imaginary time allowed by the positive energy condition for the relativistic field theory. In the Euclidean field theory, we have the Euclidean counterpart for the vacuum persistence functional, that is, the generating functional of complete Schwinger functions. The $(\lambda\varphi^4)_d$ Euclidean theory is defined by these Euclidean Green's functions. The Euclidean generating functional $Z(h)$ is formally defined by the following functional integral:

$$Z(h)=\int [\mathrm{d}\varphi]\exp\left(-S_0-S_I+\int d^dx h(x)\varphi(x)\right), \tag{1}$$

where the action that describes a free scalar field is

$$S_0(\varphi)=\int d^dx\left(\frac{1}{2}(\partial\varphi)^2+\frac{1}{2}m_0^2\varphi^2(x)\right), \tag{2}$$

and the interacting part, defined by the non-Gaussian contribution, is

$$S_I(\varphi)=\int d^dx\frac{\lambda}{4!}\varphi^4(x). \tag{3}$$

In Eq. (1), $|\mathrm{d}\varphi|$ is a translational invariant measure, formally given by $|\mathrm{d}\varphi|=\Pi_x \mathrm{d}\varphi(x)$. The terms λ and m_0^2 are, respectively, the bare coupling constant and mass squared of the model.

Finally, $h(x)$ is a smooth function that we introduce to generate the Schwinger functions of the theory by means of functional derivatives. Note that we are using the same notation for functionals and functions, for example, $Z(h)$ instead of the usual notation $Z[h]$.

In the weak-coupling perturbative expansion, we perform a formal perturbative expansion with respect to the non-Gaussian terms of the action. As a consequence of this formal expansion, all the n-point unrenormalized Schwinger functions are expressed in a power series of the bare coupling constant g_0. Let us summarize how to perform the weak-coupling perturbative expansion in the $(\lambda\varphi^4)_d$ theory. The Gaussian functional integral $Z_0(h)$ associated with the Euclidean generating functional $Z(h)$ is

$$Z_0(h) = \mathcal{N} \int [\mathrm{d}\varphi] \exp\left(-\frac{1}{2}\varphi K \varphi + h\varphi\right). \tag{4}$$

We are using a compact notation and the first term on the right-hand side of Eq. (4) is given by

$$\varphi K \varphi = \int d^d x \int d^d y \varphi(x) K(m_0; x, y) \varphi(y). \tag{5}$$

The term that couples linearly the field with the external source is

$$h\varphi = \int d^d x \varphi(x) h(x). \tag{6}$$

As usual $\mathcal{N}$ is a normalization factor and the symmetric kernel $K(m_0; x, y)$ is defined by

$$K(m_0; x, y) = (-\Delta + m_0^2)\delta^d(x - y), \tag{7}$$

where Δ denotes the Laplacian in the Euclidean space R^d. As usual, the normalization factor is defined using the condition $Z_0(h)|_{h=0} = 1$. Therefore $\mathcal{N} = (\det(-\Delta + m_0^2))^{1/2}$ but, in the following, we are absorbing this normalization factor in the functional measure. It is convenient to introduce the inverse kernel, i.e., the free two-point Schwinger function $G_0(m_0; x-y)$ which satisfies the identity

$$\int d^d z G_0(m_0; x - z) K(m_0; z - y) = \delta^d(x - y). \tag{8}$$

Since Eq. (4) is a Gaussian functional integral, simple manipulations, performing only Gaussian integrals, gives

$$\int [\mathrm{d}\varphi] e^{-S_0 + \int d^d x h(x)\varphi(x)} = \exp\left[\frac{1}{2}\int d^d x \int d^d y h(x) G_0^{(2)}(m_0; x - y) h(y)\right]. \tag{9}$$

Therefore, we have an expression for $Z_0(h)$ in terms of the inverse kernel $G_0^{(2)}(m_0; x-y)$, i.e., in terms of the free two-point Schwinger function. This construction is fundamental to perform the weak-coupling perturbative expansion with the Feynman diagramatic representation of the perturbative series. The non-Gaussian contribution in a perturbation with regard to the remaining terms of the action. It is important to point out that the weak-coupling perturbative expansion can be defined in arbitrary geometries, and classical boundary conditions must be implemented in the two-point Schwinger function. Another way is to restrict the space of functions that appear in the functional integral.

We are interested in studying finite size systems, where the translational invariance is broken. In this situation, we are analyzing the perturbative renormalization for the $(\lambda/4!)\varphi^4$ massless scalar field model, in the two-loop approximation. Therefore, let us assume boundary conditions over the plates for the massless field $\varphi(x)$. For simplicity we are assuming Dirichlet-Dirichlet boundary conditions, i.e.,

$$\varphi(\vec{r},z)\big|_{z=0} = \varphi(\vec{r},z)\big|_{z=L} = 0, \tag{10}$$

for the free field. Since the translational invariance is not preserved, let us use a Fourier expansion of the fields in the following form:

$$\varphi(\vec{r},z) = \frac{1}{(2\pi)^{(d-1)/2}} \int d^{d-1}p \sum_n \phi_n(\vec{p}) e^{i\vec{p},\vec{r}} u_n(z), \tag{11}$$

where the set $u_n(z)$ are the orthonormalized eigenfunctions associated to the operator $-d^2/\mathrm{d}z^2$, $[-d/\mathrm{d}z^2 u_n(z) = k_n^2 u_n(z)]$, and $k_n = n\pi/L$, $n = 1,2,\ldots$. The orthonormal set corresponding to the eigenfunctions of the Hermitian operator $-d^2/\mathrm{d}z^2$ defined on a finite interval is given by

$$u_n(z) = \sqrt{\frac{2}{L}} \sin\left(\frac{n\pi z}{L}\right), \; n = 1,2,\ldots \; . \tag{12}$$

These eigenfunctions satisfy the completeness and orthonormality relations, i.e.,

$$\sum_n u_n(z) u_n^*(z') = \delta(z - z') \tag{13}$$

and

$$\int_0^L \mathrm{d}z \, u_n(z) u_{n'}^*(z) = \delta_{n,n'}. \tag{14}$$

Since we are interested in performing the weak coupling expansion, let us first write the free two-point Schwinger function. This free two-point Schwinger function can be expressed in the following form:

$$G_0^{(2)}(\vec{r},z,z') = \frac{1}{(2\pi)^{d-1}} \int d^{d-1}p \sum_n e^{i\vec{p}.\vec{r}} u_n(z) u_n^*(z') G_{0,n}(\vec{p}), \tag{15}$$

where $G_{0,n}(\vec{p})$ is given by

$$G_{0,n}(\vec{p}) = (\vec{p}^2 + k_n^2 + m^2)^{-1}. \tag{16}$$

Next, we will present some properties of the two-point free Schwinger function in order to understand the behavior of the interacting field theory in the presence of macroscopic structures. Therefore, in order to understand some procedures used in the identification of the divergences in the Schwinger functions that will appear in the next section, let us analyze some properties of the free two-point Schwinger function. Substituting Eq. (12) and Eq. (16) in Eq. (15) we get that the free propagator $G_0^{(2)}(\vec{r}_1 - \vec{r}_2, z_1, z_2)$ can be written as

$$G_0^{(2)}(\vec{r}_1 - \vec{r}_2, z_1, z_2) = \frac{2}{L} \sum_{n=1}^{\infty} \sin\left(\frac{n\pi z_1}{L}\right) \sin\left(\frac{n\pi z_2}{L}\right) \int \frac{d^{d-1}p}{(2\pi)^{d-1}} \frac{e^{i\vec{p}.(\vec{r}_1 - \vec{r}_2)}}{\left(\vec{p}^2 + \left(\frac{n\pi}{L}\right)^2 + m^2\right)}. \tag{17}$$

The next step is to show that the two-point free Schwinger function can be written in terms of the variables: r_{12}, z_{12}^- and finally z_{12}^+, where $r_{12} = (|\vec{r}_1 - \vec{r}_2|)/L$, $z_{12}^- = (z_1 - z_2)/L$, and $z_{12}^+ = (z_1 + z_2)/L$, respectively. Working in the four-dimensional case and also in the massless situation, a straightforward calculation (see the Appendix) gives us that $G_0^{(2)}(\vec{r}_1 - \vec{r}_2, z_1, z_2)$ can be written as

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{1}{16\pi^2L^2}\sum_{k=-\infty}^{\infty}\left\{\frac{1}{\left(k-\frac{|z_{12}^-|}{2}\right)^2+\left(\frac{r_{12}}{2}\right)^2}-\frac{1}{\left(k-\frac{|z_{12}^+|}{2}\right)^2+\left(\frac{r_{12}}{2}\right)^2}\right\}. \tag{18}$$

The former expression for the two-point Schwinger function was obtained also by Lukosz[19] using the image method. Performing the summations in Eq. (18) (see the Appendix), it is possible to find a closed expression for $G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)$. We get

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{\sinh(\pi r_{12})}{16\pi L^2 r_{12}}\left\{\frac{\sin\left(\frac{\pi z_1}{L}\right)\sin\left(\frac{\pi z_2}{L}\right)}{\left[\sinh^2\left(\frac{\pi r_{12}}{2}\right)+\sin^2\left(\frac{\pi z_{12}^-}{2}\right)\right]\left[\sinh^2\left(\frac{\pi r_{12}}{2}\right)+\sin^2\left(\frac{\pi z_{12}^+}{2}\right)\right]}\right\}. \tag{19}$$

It is not difficult to show that the two-point Schwinger function $G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)$ satisfies the following properties:

(i) The free two-point Schwinger function is not negative, i.e., $G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)\geqslant 0$, for $z_1,z_2\in[0,L]$ and $\vec{r}_1$, $\vec{r}_2\in\mathcal{R}^3$, since we are working in a Euclidean space.

(ii) The free two-point Schwinger function is zero when one of its points are evaluated on the boundaries

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,0,z_2)=G_0^{(2)}(\vec{r}_1-\vec{r}_2,L,z_2)=G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,0)=G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,L)=0,$$

since we are assuming Dirichlet boundary conditions.

(iii) The free two-point Schwinger function contain the usual bulk divergences, i.e., when $(\vec{r}_1,z_1)=(\vec{r}_2,z_2)$, it is singular. From Eq. (18) we can identify three singular terms. Splitting the free two-point Schwinger function in the singular and regular terms we have

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{1}{4\pi^2L^2}\left\{\frac{1}{(z_{12}^-)^2+r_{12}^2}-\frac{1}{(z_{12}^+)^2+r_{12}^2}-\frac{1}{(2-z_{12}^+)^2+r_{12}^2}\right\}$$

$$+\frac{1}{4\pi^2L^2}\left\{\sum_{\substack{k=-\infty\\k\neq 0}}^{\infty}\frac{1}{(2k-|z_{12}^-|)^2+r_{12}^2}-\sum_{\substack{k=-\infty\\k\neq 0}}^{\infty}\frac{1}{(2k-|z_{12}^+|)^2+r_{12}^2}\right\}. \tag{20}$$

The first term on the right-side of the last equation, is singular only when $\vec{r}_1=\vec{r}_2$ and $z_1=z_2$. This is the term that carries the usual bulk divergences. The second term is singular only when $z_1=z_2=0$ and $\vec{r}_1=\vec{r}_2$. The third term is singular only when $z_1=z_2=L$ and $\vec{r}_1=\vec{r}_2$. These two terms mentioned previously carries surface divergences. Finally the two last terms do not have singularities.

(iv) When $|\vec{r}_1-\vec{r}_2|/L\gg 1$ the free propagator behaves like

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)\sim\frac{1}{2\pi L^2}\frac{e^{-\pi r_{12}}}{r_{12}}\sin\left(\frac{\pi z_1}{L}\right)\sin\left(\frac{\pi z_2}{L}\right), \tag{21}$$

which shows an exponential convergence behavior.

(v) The integral of the variable $\{\vec{r},z\}$ on a neighborhood around $\{\vec{r}',z'\}$ of the free propagator is finite, i.e., $\int_R d^3r\,\mathrm{d}_z\,G_0^{(2)}(\vec{r}-\vec{r}',z,z')<\infty$. See Fig. 1.

Property (v) allows us to show that the external legs of the Feynman diagrams do not create divergences. Let us suppose we have the integral corresponding to some Feynman diagram,

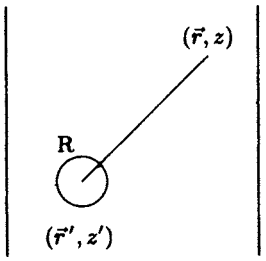

FIG. 1. The integral of the variable $\{\vec{r},z\}$ on a neighborhood around $\{\vec{r}';z'\}$.

$$\int_R d^3r\, \mathrm{dz}\, G_0^{(2)}(\vec{r}-\vec{r}',z,z')F(\vec{r}',z'), \tag{22}$$

where $G_0^{(2)}(\vec{r}-\vec{r}',z,z')$ is some external leg and $F(\vec{r}',z')$ describes the remainder part of the diagram. Now in order to proceed we must use the following statement: for two continuous and positives functions $f(\vec{x})$ and $g(\vec{x})$ defined in a finite region R with the exception of the point $\vec{x}_1$ where $f(\vec{x})$ diverges, then the integral $I=\int_R d^dx f(\vec{x})g(\vec{x})$ is finite, if and only if $I'=\int_V d^dx f(\vec{x})$ is finite on some neighborhoods V of the point $\vec{x}_1$. With the property (v) and the statement before we can see that external legs from the Feynman diagrams do not generate divergences.

III. REGULARIZED TWO- AND FOUR-POINT SCHWINGER FUNCTIONS AT ONE-LOOP ORDER

In this section we identify the divergent contribution in the two- and four-point Schwinger function at one-loop level. Essentially we use Eq. (20) in the 1PI diagrams of the Green functions considering their external legs, and the integrations in the coordinate space. We write Eq. (20) as

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{1}{4\pi^2L^2}\left[\frac{1}{(z_{12}^-)^2+r_{12}^2}-\frac{1}{(z_{12}^+)^2+r_{12}^2}-\frac{1}{(2-z_{12}^+)^2+r_{12}^2}+h(r_{12},z_1,z_2)\right], \tag{23}$$

where $h(r_{12},z_1,z_2)$ is given by

$$h(r_{12},z_1,z_2)=\frac{1}{4}\sum_{\substack{k=-\infty\\k\neq 0}}^{\infty}\frac{1}{\left(k-\frac{|z_{12}^-|}{2}\right)^2+\left(\frac{r_{12}2}{2}\right)}-\frac{1}{4}\sum_{\substack{k=-\infty\\k\neq 0,1}}^{\infty}\frac{1}{\left(k-\frac{z_{12}^+}{2}\right)^2+\left(\frac{r_{12}2}{2}\right)}. \tag{24}$$

From the property (iii) we see that the three first contributions on the right-hand side of Eq. (23) have singularities. Otherwise, the last term is finite in the whole domain where we defined the model. After this brief introduction, we are able to study the interacting theory. Let us start analyzing the tadpole diagram, displayed in Fig. 2, from which we can write the expression for the

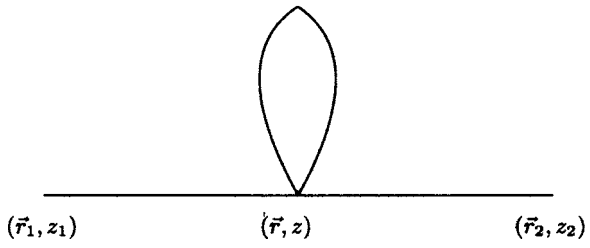

FIG. 2. The two-point function at one-loop level.

one-loop two-point Schwinger function $G_1^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)$. We have that

$$G_1^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{\lambda}{2}\int d^3r\,\mathrm{d}z\,G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)G_0^{(2)}(0,z,z)G_0^{(2)}(\vec{r}_2-\vec{r},z_2,z). \tag{25}$$

In the following we are generalizing the results obtained by Fosco and Svaiter.[14] Let us begin studying the quantity $G_0^{(2)}(0,z,z)$ that appears in the tadpole defined in Eq. (25). From Eq. (20) we get that $G_0^{(2)}(0,z,z)$ can be written as

$$G_0^{(2)}=(0,z,z)=\frac{1}{4\pi^2L^2}\left[A-\frac{1}{(2z/L)^2}-\frac{1}{(2-2z/L)^2}+\sum_{\substack{k=-\infty\\k\neq 0}}^{\infty}\frac{1}{(2k)^2}-\sum_{\substack{k=-\infty\\k\neq 0,1}}^{\infty}\frac{1}{(2k-2z/L)^2}\right], \tag{26}$$

where A is given by

$$A=\lim_{(z_1,\vec{r}_1)\to(z_2,\vec{r}_2)}\frac{L^2}{(z_1-z_2)^2+|\vec{r}_1-\vec{r}_2|^2}$$

$$=\lim_{\Lambda\to\infty}\frac{L^2S_4}{8\pi^2}\Lambda^2, \tag{27}$$

$S_d=[2\pi^{d/2}/\Gamma(d/2)]$ and Λ is an ultraviolet cutoff. In the same way, from Eq. (26) by performing the summations, we-get for $G_0^{(2)}(0,z,z)$,

$$G_0^{(2)}(0,z,z)=\frac{1}{4\pi^2L^2}\left[A+\frac{\pi^2}{12}-\frac{\pi^2}{4}\frac{1}{\sin^2(\pi z/L)}\right]. \tag{28}$$

Substituting Eq. (27) in Eq. (28) we obtain

$$G_0^{(2)}(0,z,z)=\lim_{\Lambda\to\infty}\frac{S_4}{32\pi^4}\Lambda^2+\frac{1}{48L^2}-\frac{1}{16L^2}\frac{1}{\sin^2(\pi z/L)}. \tag{29}$$

The first term in Eq. (29) is a bulk divergence. Substituting Eq. (29) in Eq. (25) we get

$$\begin{aligned}G_1^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=&\lim_{\Lambda\to\infty}\frac{\lambda S_4}{64\pi^4}\Lambda^2\int_R d^3r\,\mathrm{d}z\,G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)G_0^{(2)}(\vec{r}_2-\vec{r},z_2,z)\\&+\frac{\lambda}{96L^2}\int_R d^3r\,\mathrm{d}z\,G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)G_0^{(2)}(\vec{r}_2-\vec{r},z_2,z)\\&-\frac{\lambda}{32L^2}\int_R d^3r\,\mathrm{d}z\frac{G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)G_0^{(2)}(\vec{r}_2-\vec{r},z_2,z)}{\sin^2(\pi z/L)}\end{aligned} \tag{30}$$

The first term on the right-hand side carries a bulk divergence. The second term is finite. To see this we analyze the integral by sectors. Therefore we have

$$\int_R d^3r\,\mathrm{d}z\,G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)G_0^{(2)}(\vec{r}_2-\vec{r},z_2,z)=\int_{R_1}+\int_{R_2}+\int_{R_3}+\int_{R_4}+\int_{R_5}, \tag{31}$$

where each integral is defined in different regions displayed in Fig. 3, where the points $(\vec{r}_1,z_1)$ and $(\vec{r}_2,z_2)$ are the centers of the regions R_1 and R_2, respectively. Using the property (v) we have that the integrals on R_1 and R_2 are finite. Since the free propagators $G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)$ and $G_0^{(2)}(\vec{r}_2-\vec{r},z_2,z)$ presented in Eq. (31) do not have divergences on R_3 and this region is compact, then the integral on R_3 is finite. The integrals defined in regions R_4 and R_5 also are finite since from the property (iv) the propagator decreases exponentially when one of its points becomes far from the

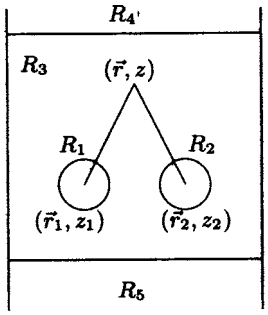

FIG. 3. Regions of integration R_i.

other. Thus the integral defined by Eq. (31) is finite. Finally we must study the third integral on the right-hand side of Eq. (30). Note that the term $1/\sin^2(\pi z/L)$ diverges when z is evaluated on the boundaries.

Nevertheless this integral is convergent, because the products of $G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)$ and $G_0^{(2)}\times(\vec{r}_2-\vec{r},z_2,z)$ take away the divergence. Using Eq. (19), we have that the third integral on the right-hand side of Eq. (30) is finite. Therefore the one-loop two-point Schwinger function only has bulk divergence.

Our next step is to analyze the four-point Schwinger function in the one-loop level (see Fig. 4). Since the free propagator only has singularities when its two points are equal or also when the two points joined are evaluated at the boundaries, we continue our analysis of the integrals only in the domains where the two external points of the free propagators take the same values. The complete four-point function at one-loop level is given by

$$G_1^{(4)}(\vec{r}_1,z_1,\vec{r}_2,z_2,\vec{r}_3,z_3,\vec{r}_4,z_4)=\frac{\lambda^2}{2}\int d^{d-1}r\int d^{d-1}r'\int_0^L \mathrm{d}z\int_0^L \mathrm{d}z'\; G_0^{(2)}(\vec{r}_1-\vec{r},z_1,z)G_0^{(2)}(\vec{r}_2-\vec{r},z_2,z)$$
$$\times\left[G_0^{(2)}(\vec{r}-\vec{r}',z,z')\right]^2 G_0^{(2)}(\vec{r}_3-\vec{r}',z_3,z')G_0^{(2)}(\vec{r}_4-\vec{r}',z_4,z'). \qquad (32)$$

For simplicity, in Fig. 5 we define three different regions between the boundaries. The first one, R_1 is concerned when $\{\vec{r}',z'\}$ is close to $\{\vec{r},z\}$. In this region the contribution coming from $[G_0^{(2)}(\vec{r}-\vec{r}',z,z')]^2$ is singular. Nevertheless, we still must analyze if this divergent behavior will appear in the integral defined by Eq. (32). We will show that the singularities will appear only as bulk divergences. In the region R_2 ($z,z'\to 0$ and $\vec{r}'\to\vec{r}$) the term $[G_0^{(2)}(\vec{r}-\vec{r}',z,z')]^2$ is also divergent. As we will see, this divergent behavior disappears when we compute the complete four-point function at one-loop order, defined by Eq. (32). In the region R_3 ($z,z'\to L$ and $\vec{r}'\to\vec{r}$) the situation is identical as in the region R_2. Using the same argument that we used before to analyze the convergence of the integral denned by Eq. (22), we can study the convergence of the integral defined by Eq. (32) with the amputated external legs. Therefore we must study Eq. (32) with the external legs amputated. Therefore we must study the quantity $\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'[G_0^{(2)}(\vec{r}'-\vec{r},z',z)]^2$. Substituting Eq. (23) in the former equation we get

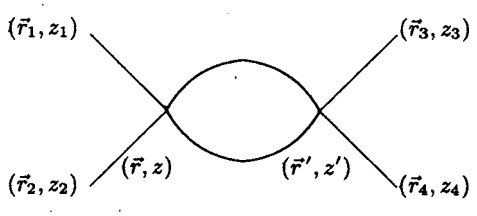

FIG. 4. The four-point function at one loop.

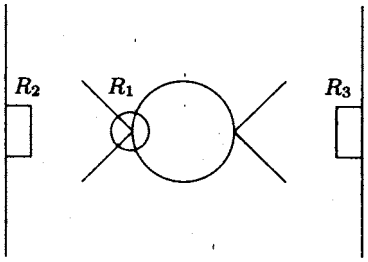

FIG. 5. Regions of integration for the four-point function.

$$\int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \left[G_0^{(2)}(\vec{r}'-\vec{r},z',z)\right]^2 = \frac{1}{(4\pi^2L^2)^2}\left(I_1+I_2+I_3+I_4+I_5\right) + \text{finite part}, \tag{33}$$

where the integrals $I_i, i=1,2,\ldots,$ are given by

$$I_1 = \int d^3r'\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \frac{1}{\left[(z_{12}^-)^2+r_{12}^2\right]^2}, \tag{34}$$

$$I_2 = \int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \left[-\frac{1}{\left[(z_{12}^+)^2+r_{12}^2\right]^2} + \frac{1}{\left[(2-z_{12}^+)^2+r_{12}^2\right]^2}\right], \tag{35}$$

$$I_3 = \int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \left[-\frac{2}{\left[(z_{12}^-)^2+r_{12}^2\right]\left[(z_{12}^+)^2+r_{12}^2\right]} - \frac{2}{\left[(z_{12}^-)^2+r_{12}^2\right]\left[(2-z_{12}^+)^2+r_{12}^2\right]}\right] \tag{36}$$

$$I_4 = \int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \frac{2}{\left[(z_{12}^+)^2+r_{12}^2\right]\left[(2-z_{12}^+)^2+r_{12}^2\right]}, \tag{37}$$

$$I_5 = \int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \left[\frac{1}{(z_{12}^-)^2+r_{12}^2} - \frac{1}{(z_{12}^+)^2+r_{12}^2} - \frac{1}{(2-z_{12}^+)+r_{12}^2}\right] h(r_{12},z_1,z_2). \tag{38}$$

Let us investigate each term of Eq. (33). The integral I_1 must be analyzed only in the region R_1. For this purpose we need an auxiliary result. We can prove that a continuous and positive function $f(x)$ which does not have singularities except for $x=0$, and $M=\int_{-\vec{\epsilon}}^{\vec{\epsilon}} d^dx f(w^2)$ where $w^2=|\vec{w}|^2$, then there exist ϵ' such that $M=S_d\int_0^{\epsilon'} \mathrm{d}w\, w^{d-1} f(w^2)$ where $\epsilon<\epsilon'<\sqrt{d}\epsilon$. Then we get

$$I_1 = \int_{R_1} d^3r'\, \mathrm{d}z' \frac{1}{[(z_{12}^-)^2+r_{12}^2]^2} = \int_{\vec{r}-\vec{\epsilon}}^{\vec{r}+\vec{\epsilon}} d^3r' \int_{z-\epsilon}^{z+\epsilon} \mathrm{d}z' \frac{1}{[(z-z')^2+|\vec{r}-\vec{r}'|^2]^2}$$

$$= \int_{-\vec{\epsilon}}^{\vec{\epsilon}} \frac{d^4w}{w^4} = S_4 \int_0^{\epsilon'} \mathrm{d}w \frac{w^3}{w^4} = S_4 \ln w \Big|_0^{\epsilon'}. \tag{39}$$

Therefore I_1 contributes with a bulk divergence of the type as the one that appears in the theory without boundaries. In the usual renormalization procedure, the contribution coming from I_1 can be eliminated by the usual counterterms. Concerning the contribution coming from I_2 we have that the first term $1/[(z_{12}^+)^2+r_{12}^2]^2$ is not singular in the region R_1. In the region R_2, using the same auxiliary result that we used before, we can obtain an upper bound to the contribution coming from this term. We get

$$\int_{R_2} d^3r\, dz\, d^3r\, dz' \frac{1}{[(z+z')^2+|\vec{r}-\vec{r}'|^2]^2} < \int d^3r \int_{\vec{r}-\vec{\epsilon}}^{\vec{r}+\vec{\epsilon}} d^3r' \int_0^{\epsilon}\int_0^{\epsilon} dz\, dz' \frac{1}{[z^2+z'^2+|\vec{r}-\vec{r}'|^2]^2}$$

$$< \frac{1}{4}\int d^3r \int_{-\vec{\epsilon}}^{\vec{\epsilon}} d^5w \frac{1}{w^2} = \frac{1}{12} S_5 \epsilon'^3 \int_{R'} d^3r. \tag{40}$$

Since the region $R' \subset R_2$ is finite this integral is convergent. Next, let us analyze the term $1/[(2-z_{12}^+)^2+r_{12}^2]^2$ of I_2 in the region R_3. Since the behavior of the field in each plates (for $z=0$ and $z=L$) is the same, then the analysis follows the same lines as previous ones and therefore this contribution is also finite. To study I_3, we consider first the term $2/[(z_{12}^-)^2+r_{12}^2][(z_{12}^+)^2+r_{12}^2]$. This expression must be studied in the regions R_1 and R_2, respectively. In R_1 we can see that the convergence of

$$\int_{R_1} d^3r dz d^3r' dz' \frac{1}{[(z-z')^2+|\vec{r}-\vec{r}'|^2]\underbrace{[(z+z')^2+|\vec{r}-\vec{r}'|^2]}_{\text{finite in } R_1}}, \tag{41}$$

depends on the convergence of

$$\int_{R_1} d^3r\, dz\, d^3r'\, dz' \frac{1}{(z-z')^2+|\vec{r}-\vec{r}'|^2}. \tag{42}$$

From the above arguments we have that Eq. (42) can be written as

$$\int_{-\vec{\epsilon}}^{\vec{\epsilon}} \frac{d^4w}{w^2} = S_4 \int_0^{\epsilon'} dw\, w = \frac{S_4 \epsilon'^2}{2}, \tag{43}$$

thus Eq. (42) gives a finite contribution. Now we consider the first term of I_3 in the region R_2. For this purpose we will use the following property. Let us take a continuous and positive function $f(x)$ which does not have singularities except for $x=0$, and $N=\int_0^{\vec{\epsilon}}\int_0^{\vec{\epsilon}} d^l y d^m z f(y^2+z^2)$ then there exist ϵ' in such a way that $N=(S_{l+m+2}/S_{l+1}S_{m+1})\int_0^{\epsilon'} dw\, w^{l+m+1} f(w^2)$ where $\epsilon'>0$. Using this property, we have for the first term of Eq. (35), in the region R_2, that

$$\int d^3r \int_0^{\epsilon} dz \int_z^{z+\epsilon} dz' \int_{\vec{r}-\vec{\epsilon}}^{\vec{r}+\vec{\epsilon}} d^3r' \frac{1}{[(z-z')^2+|\vec{r}-\vec{r}'|^2][(z+z')^2+|\vec{r}-\vec{r}'|^2]}$$

$$< \int d^3r \int_0^{\epsilon} dz \int_0^{\epsilon} du \int_{-\vec{\epsilon}}^{\vec{\epsilon}} d^3v \frac{1}{(u^2+v^2)(z^2+u^2+v^2)}$$

$$< \frac{1}{4} S_4 \int d^3r \int_0^{\epsilon} dz \int_0^{\epsilon'} dw \frac{w}{(z^2+w^2)} = \frac{S_3 S_4}{2 S_1 S_2} \epsilon''. \tag{44}$$

Therefore the first term of I_3 is also finite in R_2. The second term $2/[((z_{12}^-)^2+r_{12}^2)((2-z_{12}^+)^2+r_{12}^2)]$ in I_3 must be analyzed also in the regions R_1 and R_3. This analysis follows the same lines as the last case, therefore the contribution coming from this term is also finite.

We have now to study the term I_4. Note that $2/[((z_{12}^+)^2+r_{12}^2)((2-z_{12}^+)^2+r_{12}^2)]$ must be analyzed in the regions R_2 and R_3, respectively. Let us start with the region R_2. Using previous arguments we have that the convergence of I_4 depends on the convergence of the following expression:

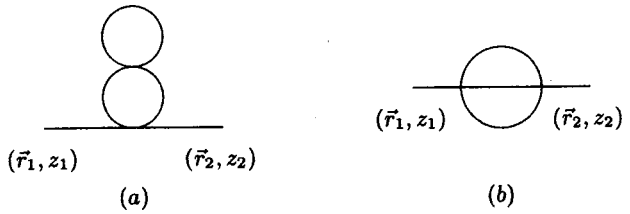

FIG. 6. Two-point Schwinger functions at two-loop level.

$$\int_0^\epsilon \int_0^\epsilon \mathrm{d}z\, \mathrm{d}z' \int_{\vec{r}-\vec{\epsilon}}^{\vec{r}+\vec{\epsilon}} d^3r' \frac{1}{z^2+z'^2+|\vec{r}-\vec{r}'|^2} = \frac{S_5}{4}\int_0^{\epsilon'} \mathrm{d}w \frac{w^4}{w^2} = \frac{S_5}{12}\epsilon'^3, \tag{45}$$

which is finite. In the region R_3 our analysis follows the same lines as in the region R_2, thus the integral in the region. R_3 is also finite.

Using the same argument that we used before, it is not difficult to show that the contribution coming from I_5 is also finite. We conclude that the integrals given by Eq. (32) only have bulk divergences. In this way we can conclude that at the one-loop level the bulk counterterms are sufficient to render the complete connected Schwinger functions finite. In the next section we will identify the divergent contribution in the connected two-point Schwinger functions at the two-loop order.

IV. THE DIVERGENCES IN THE TWO-POINT SCHWINGER FUNCTIONS AT TWO-LOOP LEVEL

In this section we will generalize some results obtained by Fosco and Svaiter[14] and also by Caicedo and Svaiter.[15] We will identify the divergent contribution in the connected two-point Schwinger functions at the two-loop order. The diagrams that we are interested to analyze are displayed in Fig. 6. The expression that corresponds to Fig. 6(a) is given by

$$\frac{\lambda^2}{4}\int d^3r'\, \mathrm{d}z'\, d^3r\, \mathrm{d}z\, G_0^{(2)}(\vec{r}_1-\vec{r}',z_1,z')\left[G_0^{(2)}(\vec{r}'-\vec{r},z',z)\right]^2 G_0^{(2)}(0,z,z) G_0^{(2)}(\vec{r}_2-\vec{r}',z_2,z'). \tag{46}$$

Since the external legs in Eq. (46) do not contribute to generate divergences, let us consider only the following integral:

$$\int d^3r\, \mathrm{d}z [G_0^{(2)}(\vec{r}'-\vec{r},z',z)]^2 G_0^{(2)}(0,z,z). \tag{47}$$

Replacing Eq. (29) in Eq. (47) we get

$$\begin{aligned}\int d^3r\, \mathrm{d}z [G_0^{(2)}(\vec{r}'-\vec{r},z',z)]^2 G_0^{(2)}(0,z,z) = \lim_{\Lambda\to\infty} \frac{S_4}{32\pi^4}\Lambda^2 \int d^3r\, \mathrm{d}z [G_0^{(2)}(\vec{r}'-\vec{r},z',z)]^2 \\ + \frac{1}{48L^2}\int d^3r\, \mathrm{d}z [G_0^{(2)}(\vec{r}'-\vec{r},z',z)]^2 \\ - \frac{1}{16L^2}\int d^3r\, \mathrm{d}z [G_0^{(2)}(\vec{r}'-\vec{r},z',z)]^2 \frac{1}{\sin^2(\pi z/L)}.\end{aligned} \tag{48}$$

The first term and the second one in Eq. (48) can be renormalized introducing only bulk counterterms. The most interesting behavior appears in the last term of this equation. Note that this unrenormalized quantity contains only bulk divercences, since the contribution coming from

$[G_0^{(2)}(\vec{r}'-\overline{r},z',z)]^2$ cancels the surface divergent behavior generated by the $1/\sin^2(\pi z/L)$ term. Nevertheless, after the introduction of a bulk counterterm to render the contribution $[G_0^{(2)}(\vec{r}'-\vec{r},z',z)]^2$ finite between the plates, surface divergences appear. Thus this surface divergence must be renormalized. After the introduction of surface and bulk counterterms, the finite contribution coming from the last term of Eq. (48), up to a finite renormalization constant, is given by

$$\frac{1}{16L^2}\int d^3r\,\mathrm{d}z\left[(G_0^{(2)}(\vec{r}'-\vec{r},z',z))^2-\frac{1}{(4\pi^2L^2)^2}\frac{1}{[(z_{12}^-)^2+r_{12}^2]^2}\right]\left[\frac{1}{\sin^2(\pi z/L)}-\frac{L^2}{(\pi z)^2}-\frac{L^2}{\pi^2(L-z)^2}\right]. \tag{49}$$

Therefore this term contains an overlapping between bulk and surface counterterms.

We still must analyze the sunset diagram. The expression corresponding to Fig. 6(b) is given by

$$\frac{\lambda^2}{6}\int d^3r'\,\mathrm{d}z'\,d^3r\,\mathrm{d}z\,G_0^{(2)}(\vec{r_1}-\vec{r}',z_1z')\left[G_0^{(2)}(\vec{r}'-\vec{r},z',z)\right]^3G_0^{(2)}(\vec{r}_2-\vec{r}',z_2,z'). \tag{50}$$

Again, the external legs do not contribute to generate divergences, and therefore let us study the amputated diagram, i.e., without external legs. We have

$$\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'[G_0^{(2)}(\vec{r}'-\vec{r},z',z)]^3=\frac{1}{(4\pi^2L^2)^3}(I_1+I_2+\cdots+I_{12})+\text{finite part}, \tag{51}$$

where

$$I_1=\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'\frac{1}{[(z_{12}^-)^2+r_{12}^2]^3}, \tag{52}$$

$$I_2=\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'\,\frac{1}{[(z_{12}^+)^2+r_{12}^2]^3}, \tag{53}$$

$$I_3=\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'\frac{1}{[(2-z_{12}^+)^2+r_{12}^2]^3}, \tag{54}$$

$$I_4=\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'\frac{2}{[(z_{12}^-)^2+r_{12}^2]^2[(z_{12}^+)^2+r_{12}^2]}, \tag{55}$$

$$I_5=\int d^3r\,\mathrm{d}z\,d^3r'\mathrm{d}z'\,\frac{2}{[(z_{12}^-)^2+r_{12}^2]^2[(2-z_{12}^+)^2+r_{12}^2]}, \tag{56}$$

$$I_6=\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'\frac{2}{[(z_{12}^-)^2+r_{12}^2][(z_{12}^+)^2+r_{12}^2]^2}, \tag{57}$$

$$I_7=\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'\frac{2}{[(z_{12}^-)^2+r_{12}^2][(2-z_{12}^+)^2+r_{12}^2]^2}, \tag{58}$$

$$I_8=\int d^3r\,\mathrm{d}z\,d^3r'\,\mathrm{d}z'\frac{2}{[(z_{12}^+)^2+r_{12}^2]^2[(2-z_{12}^+)^2+r_{12}^2]}, \tag{59}$$

$$I_9 = \int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \frac{2}{[(z_{12}^+)^2 + r_{12}^2][(2 - z_{12}^+)^2 + r_{12}^2]^2}, \tag{60}$$

$$I_{10} = \int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \frac{6}{[(z_{12}^-)^2 + r_{12}^2][(z_{12}^+)^2 + r_{12}^2][(2 - z_{12}^+)^2 + r_{12}^2]}, \tag{61}$$

$$I_{11} = \int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \left[\frac{1}{(z_{12}^-)^2 + r_{12}^2} - \frac{1}{(z_{12}^+)^2 + r_{12}^2} - \frac{1}{(2 - z_{12}^+)^2 + r_{12}^2} \right]^2 h(r_{12}, z_1, z_2), \tag{62}$$

$$I_{12} = \int d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \left[\frac{1}{(z_{12}^-)^2 + r_{12}^2} - \frac{1}{(z_{12}^+)^2 + r_{12}^2} - \frac{1}{(2 - z_{12}^+)^2 + r_{12}^2} \right] h^2(r_{12}, z_1, z_2), \tag{63}$$

Let us analyze each contribution coming from each term of Eq. (51). The first integral I_1 given by Eq. (52) is divergent in R_1. In general we can show that

$$\int_{R_1} d^3r'\, \mathrm{d}z' \frac{1}{[(z_{12}^-)^2 + r_{12}^2]^n} = \begin{cases} \text{finite}, & n < 2, \\ \infty, & n \geqslant 2. \end{cases} \tag{64}$$

Using the above result we can see that the integrals I_3, I_4 and the first integral of I_{11} are divergent. These integrals contain bulk divergences which must be removed introducing bulk counterterms. Next let us analyze the contribution coming from the integral I_2 in the region R_2. Using previous arguments and considering the external legs we get

$$\int_{R_2} d^3r\, \mathrm{d}z\, \mathrm{d}^3r'\, \mathrm{d}z' \frac{zz'}{[(z_{12}^+)^2 + r_{12}^2]^3} < \int d^3r \int_{-\vec{\epsilon}}^{\vec{\epsilon}} \int_0^{\epsilon} \int_0^{\epsilon} d^3u\, \mathrm{d}z\, \mathrm{d}z' \frac{zz'}{(z^2 + z'^2 + w^2)^3} < \frac{S_7}{S_2^2} \epsilon' \int d^3r. \tag{65}$$

Therefore this term gives a finite contribution to Eq. (50). The contribution from the integral I_6 to the integral must be studied in region R_2. In this case we must consider the external legs, and the property: let us take a function $f(x,y)$ positive which does not have singularities except for $(x,y)=(0,0), I=\int_0^{\epsilon}\int_0^{\epsilon} \mathrm{d}x\, \mathrm{d}y\, f(x,y)$ then, $I < \int_0^{\epsilon} \mathrm{d}x \int_x^{x+\epsilon} \mathrm{d}y\, f(x,y) + \int_0^{\epsilon} \mathrm{d}y \int_y^{y+\epsilon} \mathrm{d}y f(x,y)$, we get

$$\int_{R_2} d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \frac{zz'}{[(z_{12}^-)^2 + r_{12}^2][(z_{12}^+)^2 + r_{12}^2]^2} < 2 \int d^3r \int_{-\vec{\epsilon}}^{\vec{\epsilon}} d^3w \int_0^{\epsilon} \mathrm{d}z \int_0^{\epsilon} \mathrm{d}u \frac{z(z+u)}{(u^2 + w^2)(u^2 + z^2 + w^2)^2}. \tag{66}$$

From the above arguments we have that the contribution from the integral I_6 is smaller than

$$S_4 \int d^3r \int_0^{\epsilon} \mathrm{d}z \int_0^{\epsilon'} \mathrm{d}s \frac{z^2 s}{(s^2 + z^2)^2} + 2S_3 \int d^3r \int_0^{\epsilon} \mathrm{d}z \int_0^{\epsilon} \mathrm{d}u \int_0^{\epsilon'} \mathrm{d}s \frac{zus^2}{(u^2 + s^2)(u^2 + s^2 + z^2)^2}$$

$$< \frac{S_4 S_5}{S_2 S_3}\epsilon'' \int d^3r + 2\frac{(S_5)^2}{(S_2)^2 S_3}\int d^3r \int_0^{\epsilon'''} \mathrm{d}w \frac{w^4}{w^4} < \left(\frac{S_4 S_5}{S_2 S_3}\epsilon'' + 2\frac{(S_5)^2}{(S_2)^2 S_3}\epsilon'''\right)\int d^3r. \tag{67}$$

We conclude that the integral I_6 is finite. Also integrating the contribution coming from the term I_8 on R_2 we get

$$\int_{R_2} d^3r dz d^3r' dz' \frac{1}{[(z_{12}^+)^2 + r_{12}^2]^2 \underbrace{[(2 - z_{12}^+)^2 + r_{12}^2]}_{\text{finite}}}. \tag{68}$$

Using the fact that the integral $\int_{R_2} d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z'\, 1/[(z_{12}^+)^2 + r_{12}^2]^2$ is finite, we have that this integral also is convergent in R_2. The contribution from the term I_{10} on R_2 is given by

$$\int_{R_2} d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \frac{1}{[(z_{12}^-)^2 + r_{12}^2][(z_{12}^+)^2 + r_{12}^2]\underbrace{[(2 - z_{12}^+)^2 + r_{12}^2]}_{\text{finite}}}. \tag{69}$$

Since the integral $\int_{R_2} d^3r\, \mathrm{d}z\, d^3r'\, \mathrm{d}z' \frac{1}{[(z_{12}^-)^2 + r_{12}^2][(x_{12}^+) + r_{12}^2]}$ is finite, then the integral defined by Eq. (69) is convergent in R_2. The contribution coming from the terms I_{11} contain only a bulk divergence. Otherwise, the contributions coming from the terms I_{12} are finite. We conclude that we need only bulk counterterms to render the integral defined by Eq. (50) finite. The same analysis can be done for the four-point Schwinger function in the two-loop approximation. We obtained that only bulk divergences appear in the full four-point function.

V. CONCLUSIONS

In this paper we are interested to show how to implement the renormalization procedure in systems where the translational invariance is broken by the presence of macroscopic structures. For the sake of simplicity we are studying the self-interacting massless scalar field theory in a four-dimensional Euclidean space. We impose that one coordinate is defined in a compact domain, introducing two parallel mirrors where we are assuming Dirichlet-Dirichlet boundary conditions. Note that although that there are some similarities with the finite temperature field theory using the Matsubara formalism, in thermal systems there appears only bulk divergences, as for example, in the case of the system where we assume periodic boundary conditions. In nontranslational invariant systems, in general, to render the theory finite it is necessary to introduce surface counterterms.

In this work we generalize some results obtained by Fosco and Svaiter[14] and also by Caicedo and Svaiter.[15] We identify the divergences of the Schwinger functions in the massless self-interacting scalar field theory up to the two-loop approximation. First, analyzing the full two- and four-point Schwinger functions at the one-loop level, we show that the bulk counterterms are sufficient to render the theory finite. Second, at the two-loop level, we must introduce surface counterterms in the bare Lagrangian in order to make finite the full two- and also four-point Schwinger functions. The most interesting behavior appears in the "double scoop" diagram given by Eq. (46). The amputated diagram is given by Eq. (47) and we are interested in the last term of Eq. (48). This unrenormalized quantity contains only bulk divergences. Nevertheless, after the introduction of a bulk counterterm to render the contribution finite between the plates, surface divergences appear. Thus this surface divergence must be renormalized. Therefore this term contains an overlapping between bulk and surface counterterms. This procedure can be generalized to the n-loop level. The inclusion of the counterterm in the Lagrangian up to two-loop level with the full renormalized action and the general algorithm to identify the surface and bulk conterterms in the n-loop level will be left to future work.

APPENDIX

In this Appendix we will derive a useful representation for the free two-point Schwinger function. Starting from Eq. (17), we have that $G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)$ is given by

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{2}{(2\pi)^{d-1}L}\sum_{n=1}^{\infty}\int d^{d-1}p\,\sin\left(\frac{n\pi z_1}{L}\right)\sin\left(\frac{n\pi z_2}{L}\right)\frac{e^{i\vec{p}\cdot(\vec{r}_1-\vec{r}_2)}}{\left[\vec{p}^2+\left(\frac{n\pi}{L}\right)^2+m^2\right]}. \tag{A1}$$

Using the variables $u=(z_1-z_2)/L$ and $v=(z_1+z_2)/L$ defined, respectively, in the region $u\in[-1,1]$ and $v\in[0,2]$, and also making use of a trigonometric identity and performing the sum that appears in Eq. (A1) we obtain[21]

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{1}{2}\int\frac{d^{d-1}p}{(2\pi)^{d-1}}\frac{e^{i\vec{p}}\cdot(\vec{r}_1-\vec{r}_2)}{(\vec{p}^2+m^2)^{1/2}}\left[\frac{\cosh(L(1-|u|)(\vec{p}^2+m^2)^{1/2})}{\sinh(L(\vec{p}^2+m^2)^{1/2})}-\frac{\cosh(L(1-v)(\vec{p}^2+m^2)^{1/2})}{\sinh(L(\vec{p}^2+m^2)^{1/2})}\right]. \tag{A2}$$

Taking $m=0,d=4$, and integrating the angular part, it is possible to show that $G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)$ can be written as

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{-i}{2(2\pi)^2r'L^2}\int_0^{\infty}dx(e^{ixr'}-e^{-ixr'})\left[\frac{\cosh((1-|u|)x)}{\sinh x}-\frac{\cosh((1-v)x)}{\sinh x}\right], \tag{A3}$$

where the variable r' is defined by $r'\equiv(|\vec{r}_1-\vec{r}_2|)/L$. Making use of the following integral representation of the product between the gamma function and the Riemann zeta function[21]

$$\int_0^{\infty}dx\frac{x^{z-1}e^{-\beta x}}{e^{px}-1}=\frac{\Gamma(z)}{p^z}\zeta\left(z,\frac{\beta}{p}+1\right), \tag{A4}$$

where $\mathrm{Re}(z)>1,\mathrm{Re}(\beta/p)>-1$ and the Riemann zeta function $\zeta(z,q)$ is defined by

$$\zeta(z,q)=\sum_{k=0}^{\infty}\frac{1}{(k+q)^z},\quad q\neq 0,-1,-2,\ldots, \tag{A5}$$

then, it is possible to write $G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)$ as

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2)=\frac{1}{16\pi^2L^2}\left[\sum_{k=-\infty}^{\infty}\frac{1}{\left(k-\frac{|u|}{2}\right)^2+\left(\frac{r'}{2}\right)^2}-\sum_{k=-\infty}^{\infty}\frac{1}{\left(k-\frac{v}{2}\right)^2+\left(\frac{r'}{2}\right)^2}\right]. \tag{A6}$$

Finally, using the following identity:

$$\sum_{k=-\infty}^{\infty} \frac{1}{(k-z)^2+r^2} = \frac{\pi}{2r}\frac{\sinh(2\pi r)}{\sinh^2(\pi r)+\sin^2(\pi z)}, \tag{A7}$$

we obtain the expression for the two-point Schwinger function that we need to proceed in our analysis. Using the above equation in Eq. (A6) we get

$$G_0^{(2)}(\vec{r}_1-\vec{r}_2,z_1,z_2) = \frac{\sinh(\pi r')}{16\pi L^2 r'}\left[\frac{\sin\left(\frac{\pi z_1}{L}\right)\sin\left(\frac{\pi z_2}{L}\right)}{\left[\sinh^2\left(\frac{\pi r'}{2}\right)+\sin^2\left(\frac{\pi u}{2}\right)\right]\left[\sinh^2\left(\frac{\pi r'}{2}\right)+\sin^2\left(\frac{\pi v}{2}\right)\right]}\right]. \tag{A8}$$

(Received 2 March 2006; accepted 6 April 2006; published online 23 May 2006)

This paper revisits the quantum mechanics for one photon from the modern viewpoint and by the geometrical method. Especially, besides the ordinary (rectangular) momentum representation, we provide an explicit derivation for the other two important representations, called the cylindrically symmetrical representation and the spherically symmetrical representation, respectively. These other two representations are relevant to some current photon experiments in quantum optics. In addition, the latter is useful for us to extract the information on the quantized black holes. The framework and approach presented here are also applicable to other particles with arbitrary mass and spin, such as the particle with spin $\frac{1}{2}$. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2200572]

I. INTRODUCTION

From the modern viewpoint, relativistic quantum mechanics originates from the natural marriage of special relativity and quantum theory: The Hilbert space for one particle quantum wave functions forms the unitary representation of the Poincare group, which is the isometric transformation group of the Minkowski spacetime. Especially, as realized on the Minkowski spacetime, the quantum wave functions need to satisfy the field equation of motion.[1–5] Not only does it provide a basis for relativistic quantum field, i.e., the quantum field operator is just defined on the Fock space associated with the Hilbert space of one particle states, but relativistic quantum mechanics itself is of significance in those cases which do not involve particle creation and annihilation, such as free propagations for in states before interaction and out states after interaction. It is here that relativistic quantum mechanics demonstrates its most striking properties such as quantum superposition and quantum entanglement, and thus acquires many invaluable applications such as quantum information and quantum computation.[6] Moreover, the information on the interaction can be extracted by comparing out states with in states.

Obviously, light occupies a special position in our attempts to understand nature both relativistically and quantum mechanically. It was light that initiated the great birth of both special relativity and quantum theory. Furthermore, the quantum mechanics on the photon and its interaction with matters has been developed into an individual discipline with wide applications, now called quantum optics.[7] By the geometric method, this paper is mainly intended to revisit the quantum mechanics for one photon from the modern viewpoint mentioned in the beginning. In particular, besides the momentum representation, we explicitly provide the other two important

[a)]Electronic mail: yphu@mail.bnu.edu.cn
[b)]Electronic mail: wgqiu@hutc.zj.cn
[c)]Electronic mail: hbzhang@pkuaa.edu.cn

representations, i.e., the cylindrically symmetrical representation and the spherically symmetrical one. These other two representations are very relevant to some of the current research in quantum optics.[8–11] Especially, the latter is significant to the multi-pole radiation and electro-magnetic scattering around such a central potential as the Schwarzschild black hole. Furthermore, based on Hod's corresponding principle, it acquires a new application in the quantized black holes.[12]

It is worth noting that although all the three representations are known, they are treated here in a uniform framework and on an equal footing. (The first and third can be found in many of advanced textbooks such as Ref. 13, but the second was obtained for the first time in Ref. 14.) Especially, for the derivation of the later two representations, our method is obviously different from that used before.[13,14] We here employ the spin weighted harmonics functions and the corresponding spin weighted raising(lowering) operators, which have advantage of providing a straightforward and unified formalism applicable to particles of any spin.

The paper is organized as follows. In the next section, we construct the Hilbert space for one photon states from the solutions to the Maxwell equation. Based on the Killing field realization of the Poincare Lie algebra, Sec. III well defines the relevant conserved observables on the Hilbert space for one photon states, which is thus indicated to form the unitary representation of the Poincare group. The three representations are presented in Sec. IV, where the explicit derivation is given. We conclude with some implications and extensions in Sec. V.

Our notation and conventions follow those in Ref. 3. In particular, the index is raised or lowered by the Minkowski metric η_{ab}. We denote the covariant derivative and volume element compatible with the metric by ∇_a and ϵ_{abcd}, respectively. The d'Alembertian is defined as $\Box = \nabla_a \nabla^a$. The Lorentz coordinate system is specially denoted by $\{x^\mu | \mu = 0,1,2,3\}$, and the spatial vectors are indicated by letters in boldface.

II. THE HILBERT SPACE FOR ONE PHOTON STATES

Start with the source free Maxwell equation on the Minkowski spacetime

$$\nabla_{[a} F_{bc]} = 0, \qquad \nabla^a F_{ab} = 0, \tag{1}$$

where F_{ab} is a skew tensor field, called field strength. It is obvious that the solutions to the Maxwell equation form a complex vector space, denoted by H. (More precisely, we define H to be the complex vector space of solutions which vanish rapidly at spatial infinity.) To introduce an inner product on our complex vector space, we first define a conserved current as

$$j_a[A,A'] = i[\overline{F}_{ab} A'^b - \overline{A}^b F'_{ab}], \tag{2}$$

where A_a is the vector potential, satisfying

$$F_{ab} = 2\nabla_{[a} A_{b]}. \tag{3}$$

Whence the inner product can be defined as

$$(F,F') = (A,A') = \int_\Sigma j^a[A,A'] \epsilon_{abcd}. \tag{4}$$

Note that the conservation of $j_a[A,A']$ implies that this inner product is independent of choice of the Cauchy surface Σ. (This point also implies the unitarity of the evolution of source free fields.) Thus, for later convenience, we choose the surface of constant x^0 as Σ once and for all. Moreover, Eq. (4) can be written as

$$(F,F') = (A,A') = \int_{\Sigma} \left(\frac{\partial}{\partial x^0}\right)^a j_a[A,A']\tilde{\epsilon}_{bcd}, \tag{5}$$

where $\tilde{\epsilon}_{bcd} = (\partial/\partial x^0)^a \epsilon_{abcd}$ is the induced spatial volume element on Σ.

In addition, by Eq. (2), Eq. (5), and the second part of Eq. (1), the Stokes theorem shows that the inner product is invariant under gauge transformations

$$\begin{aligned} A_a &\to A_a + \nabla_a \Lambda, \\ A'_a &\to A'_a + \nabla_a \Lambda', \end{aligned} \tag{6}$$

where Λ and Λ' are both arbitrary scalar fields. However, this inner product is not always non-negative on our whole complex vector space. We next restrict H to its subvector space which guarantees the non-negativity of the above inner product. We denote this subvector space by H^+, which is just the Hilbert space for one photon states.

III. CONSERVED OBSERVABLES FROM THE POINCARE LIE ALGEBRA

As is well known, the Poincare Lie algebra can be realized by the Killing vector fields on the Minkowski spacetime as follows:

$$\begin{aligned} P_\mu &= i\left(\frac{\partial}{\partial x^\mu}\right)^a, \\ M_{\mu\nu} &= i\left[x_\mu\left(\frac{\partial}{\partial x^\nu}\right)^a - x_\nu\left(\frac{\partial}{\partial x^\mu}\right)^a\right]. \end{aligned} \tag{7}$$

According to the fact that the covariant derivative commutes with the Lie derivatives via Killing vector fields, the operators from the Poincare Lie algebra, i.e.,

$$\begin{aligned} \hat{P}^\mu F_{ab} &= \mathcal{L}_{P^\mu} F_{ab}, \\ \hat{M}_{\mu\nu} F_{ab} &= \mathcal{L}_{M_{\mu\nu}} F_{ab}, \end{aligned} \tag{8}$$

are well defined on H. Moreover, it can also be shown that they are well defined on the Hilbert space for one photon states indeed. (It seems easier to prove in the rectangular momentum representation.) Later, employing the Leibnitz rule, the conservation of $j_a[A,A']$, and the Stokes theorem, we find that the above operators are Hermitian with respect to the inner product (5). In addition, since the inner product (5) is independent of the choice of Σ, the above-noted operators are also conserved observables. Furthermore, taking into account $[\mathcal{L}_u, \mathcal{L}_v] = \mathcal{L}_{[u,v]}$ with u and v arbitrary vector fields, we can obtain

$$[\hat{P}_\mu, \hat{P}_\nu] = 0, \tag{9}$$

$$[\hat{P}_\mu, \hat{M}_{\rho\sigma}] = 2i\,\eta_{\mu[\rho}\hat{P}_{\sigma]}, \tag{10}$$

$$[\hat{M}_{\mu\nu}, \hat{M}_{\rho\sigma}] = 2i(\eta_{\mu[\rho}\hat{M}_{\sigma]\nu} - \eta_{\nu[\rho}\hat{M}_{\sigma]\mu}). \tag{11}$$

Here, $\hat{P}^\mu$ is the four-momentum operator. By Eq. (1), we have

$$\hat{P}_\mu \hat{P}^\mu = -\ \Box\ = 0, \tag{12}$$

which shows that the eigenvalue of the four-momentum operator is null. Furthermore, $\{\hat{L}_1 \equiv \hat{M}_{23}, \hat{L}_2 \equiv \hat{M}_{31}, \hat{L}_3 \equiv \hat{M}_{12}\}$ are the total angular momentum operators.

We next introduce the Pauli-Lubanski spin vector operator

$$\hat{S}_\mu = \tfrac{1}{2}\epsilon_{\mu\nu\rho\sigma}\hat{P}^\nu \hat{M}^{\rho\sigma}. \tag{13}$$

Resorting to Eq. (1) and after a straightforward calculation, we can obtain (the reader is suggested to follow the steps described in Ref. 15)

$$\hat{S}_\mu = \hat{P}_\mu \hat{S}, \tag{14}$$

where $\hat{S}$ is the helicity operator, defined by

$$\hat{S}F_{ab} = (-i)^* F_{ab} = -\frac{i}{2}\epsilon_{abcd}F^{cd}. \tag{15}$$

Based on the fact that the Lie derivatives via Killing vector fields annihilate the volume element, $\hat{S}$ commutes with both $\hat{P}_\mu$ and $\hat{M}_{\mu\nu}$. Furthermore, we have

$$\hat{S}^2 = 1, \tag{16}$$

which implies that the possible eigenvalue of the helicity operator takes ± 1.

IV. THREE REPRESENTATIONS IN THE COULOMB GAUGE

In this section, we shall employ the vector potential in the Coulomb gauge. In terms of the vector potential, the Maxwell equation can be written as

$$\Box A_a = 0, \tag{17}$$

where the Coulomb gauge

$$\begin{aligned} \nabla^a A_a &= 0, \\ \left(\frac{\partial}{\partial x^0}\right)^a A_a &= 0, \end{aligned} \tag{18}$$

has been employed. In this case, the inner product (5) is equivalent to

$$(F,F') = (A,A') = \int_\Sigma \left(\frac{\partial}{\partial x^0}\right)^a j'_a[A,A']\tilde{\epsilon}_{bcd}, \tag{19}$$

where the conserved current

$$j'_a[A,A'] = i[\nabla_a \overline{A_b})A'^b - \overline{A^b}\nabla_a A'_b]. \tag{20}$$

Later, according to the commutation relations in the last section, we can choose $\{\hat{P}^1, \hat{P}^2, \hat{P}^3, \hat{S}\}$ as a complete observable set, which forms the ordinary rectangular momentum representation. Similarly, the complete observable set $\{\hat{P}^0, \hat{P}^3, \hat{L}_3, \hat{S}\}$ forms the cylindrically symmetrical representation, and $\{\hat{P}^0, \hat{\mathbf{L}}^2, \hat{L}_3, \hat{S}\}$ forms the spherically symmetrical representation.

A. The rectangular momentum representation

Since the details of the rectangular momentum representation have appeared in the literature, we will only recall the main results without entering into the explicit derivations. First, according to Eqs. (17) and (18), any vector potential can be written as

$$A_a(x) = \frac{1}{\sqrt{(2\pi)^3}}\left\{\int_{p^0>0}\frac{d^3\mathbf{p}}{p^0}[\acute{A}_+(\mathbf{p})(\varepsilon^+)_a(\mathbf{p}) + \acute{A}_-(\mathbf{p})(\varepsilon^-)_a(\mathbf{p})]e^{-ip_bx^b} + \int_{p^0<0}\frac{d^3\mathbf{p}}{p^0}[\grave{A}_+(\mathbf{p})(\varepsilon^+)_a(\mathbf{p}) + \grave{A}_-(\mathbf{p})(\varepsilon^-)_a(\mathbf{p})]e^{-ip_bx^b}\right\}. \tag{21}$$

Here $p^a = p^u(\partial/\partial x^\mu)^a$ is a constant real null vector field, and $x^a = x^\mu(\partial/\partial x^\mu)^a$ is the position vector field. In addition, $(\varepsilon^\pm)_a(\mathbf{p})$ are constant null fields and complex conjugate with each other, satisfying

$$p^a(\varepsilon^\pm)_a(\mathbf{p}) = 0,$$

$$\left(\frac{\partial}{\partial x^0}\right)^a(\varepsilon^\pm)_a(\mathbf{p}) = 0, \tag{22}$$

$$\epsilon_{abcd} = -\frac{i}{p^0}(dx^0)_a \wedge p_b \wedge (\varepsilon^+)_c(\mathbf{p}) \wedge (\varepsilon^-)_d(\mathbf{p}).$$

Later, substituting Eq. (21) into Eq. (19), we have

$$(F,F') = (A,A') = \int d^3\mathbf{x}\left(\frac{\partial}{\partial x^0}\right)aj'_a[A,A'] = 2\left\{\int_{p^0>0}\frac{d^3\mathbf{p}}{p^0}[\overline{\acute{A}}_+(\mathbf{p})\acute{A}'_+(\mathbf{p}) + \overline{\acute{A}}_-(\mathbf{p})\acute{A}'_-(\mathbf{p})] + \int_{p^0<0}\frac{d^3\mathbf{p}}{p^0}[\overline{\grave{A}}_+(\mathbf{p})\grave{A}'_+(\mathbf{p}) + \overline{\grave{A}}_-(\mathbf{p})\grave{A}'_-(\mathbf{p})]\right\}. \tag{23}$$

Whence H^+ is just the positive energy solutions to the Maxwell equation, as is also what we expect. Therefore, we shall restrict ourselves to the case of $p^0>0$ in all of the following discussions. Furthermore, the orthonormal basis for H^+ in the rectangular momentum representation is given by

$$|\mathbf{p},s = \pm 1\rangle = \frac{1}{\sqrt{(2\pi)^3}}\frac{1}{\sqrt{2p^0}}(\varepsilon^\pm)_a(\mathbf{p})e^{-ip_bx^b}, \tag{24}$$

where $\mathbf{p}$ is the eigenvalue of three-momentum operator, and s is the eigenvalue of the helicity operator.

B. The cylindrically symmetrical representation

It is convenient to provide the cylindrically symmetrical representation in the cylindrical coordinate system, i.e.,

$$x^0 = t,$$

$$x^1 = \varrho\cos\phi,$$

$$x^2 = \varrho \sin \phi,$$

$$x^3 = z. \tag{25}$$

Whence the Minkowski metric reads

$$ds^2 = dt^2 - dz^2 - d\varrho^2 - \varrho^2 d\phi^2, \tag{26}$$

and

$$P^0 = i\left(\frac{\partial}{\partial t}\right)^a,$$

$$P^3 = -i\left(\frac{\partial}{\partial z}\right)^a, \tag{27}$$

$$L_3 = -i\left(\frac{\partial}{\partial \phi}\right)^a.$$

Define a pair of null covariant vector fields as

$$(\varepsilon^{\mp})_a = \frac{1}{\sqrt{2}}[(d\varrho)_a \pm i\varrho(d\phi)_a], \tag{28}$$

then according to the second part in Eq. (18), any vector potential can be written as

$$A_a = A_z(dz)_a + A_-(\varepsilon^-)_a + A_+(\varepsilon^+)_a, \tag{29}$$

where, A_z has spin weight 0, A_- with spin weight -1, and A_+ with spin weight 1.[16] From

$$\nabla_a(dz)_b = 0,$$

$$\nabla_a(\varepsilon^-)_b = \frac{1}{\sqrt{2}\varrho}[(\varepsilon^+)_a - (\varepsilon^-)_a](\varepsilon^-)_b, \tag{30}$$

$$\nabla_a(\varepsilon^+)_b = \frac{1}{\sqrt{2}\varrho}[(\varepsilon^-)_a - (\varepsilon^+)_a](\varepsilon^+)_b,$$

it can be shown that the Maxwell equation reads

$$\begin{aligned}\Box A_a = &\left(-\bar{\eth}\,\eth A_z + \frac{\partial^2 A_z}{\partial t^2} - \frac{\partial^2 A_z}{\partial z^2}\right)(dz)_a \\ &+ \left(-\bar{\eth}\,\eth A_- + \frac{\partial^2 A_-}{\partial t^2} - \frac{\partial^2 A_-}{\partial z^2}\right)(\varepsilon^-)_a + \left(-\bar{\eth}\,\eth A_+ + \frac{\partial^2 A_+}{\partial t^2} - \frac{\partial^2 A_+}{\partial z^2}\right)(\varepsilon^+)_a = 0,\end{aligned} \tag{31}$$

together with

$$\nabla^a A_a = -\frac{\partial A_z}{\partial z} + \frac{1}{\sqrt{2}}(\eth A_- + \bar{\eth} A_+) = 0. \tag{32}$$

Here $\eth, \bar{\eth}$ are operators acting on a quantity f with spin weight n, i.e.,

$$\eth f = -\left(\frac{\partial}{\partial \varrho} + \frac{i}{\varrho}\frac{\partial}{\partial \phi} - \frac{n}{\varrho}\right)f,$$

$$\bar{\eth} f = -\left(\frac{\partial}{\partial \varrho} - \frac{i}{\varrho}\frac{\partial}{\partial \phi} + \frac{n}{\varrho}\right) f. \tag{33}$$

Then, $\eth f$ and $\overline{\eth f}$ have spin weight $n+1$ and $n-1$, respectively.[16] Later, it is easy to check that the Lie derivatives of $\{(dz)_a, (\varepsilon^{\mp})_a\}$ via $\{P^0, P^3, L_3\}$ all vanish, thus the simultaneous eigensolutions of $\{\hat{P}^0, \hat{P}^3, \hat{L}_3\}$ to Eq. (31) with the corresponding eigenvalue $\{p^0, p^3, m\}$ must take the form

$$\begin{aligned} A_z &= a_{00} Z_{\alpha m}(\varrho, \phi) e^{-i(p_0 t + p_3 z)}, \\ A_- &= a_{--1} Z_{\alpha m}(\varrho, \phi) e^{-i(p_0 t + p_3 z)}, \\ A_+ &= a_{+1} Z_{\alpha m}(\varrho, \phi) e^{-i(p_0 t + p_3 z)}, \end{aligned} \tag{34}$$

where a_0, a_-, and a_+ are all constant coefficients; ${}_nZ_{\alpha m}$ is the spin-weighted cylindrical harmonics with spin weight n such that[16]

$$\begin{aligned} \eth {}_nZ_{\alpha m} &= \alpha_{n+1} Z_{\alpha m}, \\ \bar{\eth} {}_nZ_{\alpha m} &= -\alpha_{n-1} Z_{\alpha m}, \\ \hat{L}_{3n} Z_{\alpha m} &= m_n Z_{\alpha m} \end{aligned} \tag{35}$$

with $\alpha = \sqrt{p_0^2 - p_3^2}$. Moreover, by the boundary condition, here p_3 is a real constant, and

$${}_nZ_{\alpha m} = J_{m+n}(\alpha \varrho) e^{im\phi}, \tag{36}$$

where J_{m+n} is the first kind of Bessel function of order $m+n$ with $\alpha \geq 0$ and m an integer.

Substituting Eq. (34) into Eq. (32), we have

$$ip_3 a_0 + \frac{\alpha}{\sqrt{2}}(a_- - a_+) = 0. \tag{37}$$

Next combine it with the eigenequations of the helicity operator, i.e.,

$$\begin{aligned} ip_0 a_0 - s\frac{\alpha}{\sqrt{2}}(a_- + a_+) &= 0, \\ i(p_0 - sp_3) a_+ + s\frac{\alpha}{\sqrt{2}} a_0 &= 0, \\ i(p_0 + sp_3) a_- + s\frac{\alpha}{\sqrt{2}} a_0 &= 0, \end{aligned} \tag{38}$$

where $s = \pm 1$ is the eigenvalue of the helicity operator. Thus we have

$$\begin{aligned} a_- &= \frac{isa_0}{\sqrt{2}\alpha}(p_0 - sp_3), \\ a_+ &= \frac{isa_0}{\sqrt{2}\alpha}(p_0 + sp_3). \end{aligned} \tag{39}$$

Furthermore, note

$$\int_0^\infty \mathrm{d}\varrho\,\varrho J_m(\alpha\varrho)J_m(\alpha'\varrho) = \frac{1}{\alpha}\delta(\alpha-\alpha') \tag{40}$$

with $\alpha \leq \alpha'$.[20] Then it follows that the orthonormal basis with respect to the inner product (19) in the cylindrically symmetrical representation reads

$$|p^0,p^3,m,s\rangle = \frac{\alpha}{4\pi p_0}\Bigg\{ J_m(\alpha\varrho)e^{im\phi}e^{-i(p_0t+p_3z)}(\mathrm{dz})_a + \frac{i}{\sqrt{2}\alpha}[(sp_0-p_3)J_{m-1}(\alpha\varrho)e^{im\phi}e^{-i(p_0t+p_3z)}(\varepsilon^-)_a + (sp_0+p_3)J_{m+1}(\alpha\varrho)e^{im\phi}e^{-i(p_0t+p_3z)}(\varepsilon^+)_a]\Bigg\}, \tag{41}$$

which satisfies

$$\langle p^0,p^3,m,s|p'^0,p'^3,m',s'\rangle = \delta(p^0-p'^0)\delta(p^3-p'^3)\delta_{mm'}\delta_{ss'}. \tag{42}$$

Finally, we would like to point out that $|p^0,p^3,m,s\rangle$ vanishes for $m \neq \pm 1$ in the case of $\alpha=0$.

C. The spherically symmetrical representation

To provide the spherically symmetrical representation, we would like to use the spherical coordinate system, i.e.,

$$\begin{aligned} x^0 &= t, \\ x^1 &= r\sin\theta\cos\varphi, \\ x^2 &= r\sin\theta\sin\varphi, \\ x^3 &= r\cos\theta. \end{aligned} \tag{43}$$

In this case, the Minkowski metric takes the form

$$\mathrm{d}s^2 = \mathrm{d}t^2 - \mathrm{d}r^2 - r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\varphi^2), \tag{44}$$

and

$$\begin{aligned} P^0 &= i\left(\frac{\partial}{\partial t}\right)^a, \\ L_\pm &\equiv L_1 \pm iL_2 = \pm e^{\pm i\varphi}\left[\left(\frac{\partial}{\partial\theta}\right)^a \pm i\cot\theta\left(\frac{\partial}{\partial\varphi}\right)^a\right], \\ L_3 &= -i\left(\frac{\partial}{\partial\varphi}\right)^a. \end{aligned} \tag{45}$$

Define a pair of null covariant vector fields as

$$(\varepsilon^\mp)_a = \frac{r}{\sqrt{2}}[(\mathrm{d}\theta)_a \pm i\sin\theta(\mathrm{d}\varphi)_a], \tag{46}$$

then from the second part in Eq. (18), any vector potential reads

$$A_a = A_r(\mathrm{d}r)_a + A_-(\varepsilon^-)_a + A_+(\varepsilon^+)_a, \tag{47}$$

where A_r has spin weight 0, A_- with -1, and A_+ with 1.[17–19] Using

$$\nabla_a(\mathrm{d}r)_b = \frac{1}{r}[(\varepsilon^-)_a(\varepsilon^+)_b + (\varepsilon^+)_a(\varepsilon^-)_b],$$

$$\nabla_a(\varepsilon^-)_b = \frac{1}{r}\left\{\frac{\cot\theta}{\sqrt{2}}[(\varepsilon^+)_a - (\varepsilon^-)_a](\varepsilon^-)_b - (\varepsilon^-)_a(\mathrm{d}r)_b\right\}, \tag{48}$$

$$\nabla_a(\varepsilon^+)_b = \frac{1}{r}\left\{\frac{\cot\theta}{\sqrt{2}}[(\varepsilon^-)_a - (\varepsilon^+)_a](\varepsilon^+)_b - (\varepsilon^+)_a(\mathrm{d}r)_b\right\},$$

it follows that

$$\begin{aligned}\Box A_a = &\left[\frac{-1}{2r^2}(\eth\bar{\eth} + \bar{\eth}\,\eth)A_r + \frac{\partial^2 A_r}{\partial t^2} - \left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r} - \frac{2}{r^2}\right)A_r - \frac{\sqrt{2}}{r^2}(\eth A_- + \bar{\eth}A_+)\right](\mathrm{d}r)_a \\ &+ \left[\frac{-1}{2r^2}(\eth\bar{\eth} + \bar{\eth}\,\eth)A_- + \frac{\partial^2 A_-}{\partial t^2} - \left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r} - \frac{1}{r^2}\right)A_- + \frac{\sqrt{2}}{r^2}\bar{\eth}A_r\right](\varepsilon^-)_a \\ &+ \left[\frac{-1}{2r^2}(\eth\bar{\eth} + \bar{\eth}\,\eth)A_+ + \frac{\partial^2 A_+}{\partial t^2} - \left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r} - \frac{1}{r^2}\right)A_+ + \frac{\sqrt{2}}{r^2}\eth A_r\right](\varepsilon^+)_a = 0,\end{aligned} \tag{49}$$

and

$$\nabla_a A^a = -\left(\frac{\partial}{\partial r} + \frac{2}{r}\right)A_r + \frac{1}{\sqrt{2}r}(\eth A_- + \bar{\eth}A_+) = 0. \tag{50}$$

Here $\eth, \bar{\eth}$ are operators acting on a quantity f with spin weight n, i.e.,

$$\begin{aligned}\eth f &= -\left(\frac{\partial}{\partial\theta} + i\csc\theta\frac{\partial}{\partial\varphi} - n\cot\theta\right)f, \\ \bar{\eth}f &= -\left(\frac{\partial}{\partial\theta} - i\csc\theta\frac{\partial}{\partial\varphi} + n\cot\theta\right)f.\end{aligned} \tag{51}$$

Then, $\eth f$ and $\bar{\eth}f$ have spin weight $n+1$ and $n-1$, respectively.[19]

On the other hand, we have

$$\hat{L}_\pm(\mathrm{d}r)_a = L_\pm^b\partial_b(\mathrm{d}r)_a + (\mathrm{d}r)_b\partial_a L_\pm^b = 0,$$

$$\hat{L}_\pm(\varepsilon^-)_a = L_\pm^b\partial_b(\varepsilon^-)_a + (\varepsilon^-)_b\partial_a L_\pm^b = e^{\pm i\varphi}(\varepsilon^-)_a, \tag{52}$$

$$\hat{L}_\pm(\varepsilon^+)_a = L_\pm^b\partial_b(\varepsilon^+)_a + (\varepsilon^+)_b\partial_a L_\pm^b = -e^{\pm i\varphi}(e^+)_a,$$

where ∂_a is the ordinary derivative associated with the spherical coordinate system. Thus

$$\hat{L}_\pm A_a = (\hat{L}_\pm A_r)(\mathrm{d}r)_a + (\hat{L}_\pm A_- + e^{\pm i\varphi}\csc\theta A_-)(\varepsilon^-)_a + (\hat{L}_\pm A_+ - e^{\pm i\varphi}\csc\theta A_+)(\varepsilon^+)_a. \tag{53}$$

Similar, it is easy to check that the Lie derivatives of $\{(\mathrm{d}r)_a, (\varepsilon^\pm)_a\}$ via $\{P^0, L_3\}$ all vanish. Whence the simultaneous eigensolutions of $\{\hat{P}^0, \hat{\mathbf{L}}^2, \hat{L}_3\}$ to Eq. (49) with the corresponding eigenvalue $\{p^0, l(l+1), m\}$ must satisfy

$$A_r = R_0(r)_0 Y_{lm}(\theta,\varphi)e^{-ip_0 t},$$

$$A_- = R_-(r)_{-1}Y_{lm}(\theta,\varphi)e^{-ip_0t},$$

$$A_+ = R_+(r)_1Y_{lm}(\theta,\varphi)e^{-ip_0t}. \tag{54}$$

Here ${}_nY_{lm}$ is the spin weighted spherical harmonics with l non-negative integers and $m=-l,-l+1,\ldots,l$, such that

$${}_0Y_{lm} = Y_{lm},$$

$$\eth_nY_{lm} = \sqrt{(l-n)(l+n+1)}{}_{n+1}Y_{lm},$$

$$\bar{\eth}_nY_{lm} = -\sqrt{(l+n)(l-n+1)}{}_{n-1}Y_{lm}, \tag{55}$$

$$(\hat{L}_\pm - ne^{\pm i\varphi}\csc\theta){}_nY_{lm} = \sqrt{(l\mp m)(l\pm m+1)}{}_nY_{lm\pm1},$$

$$\hat{L}_{3n}Y_{lm} = m_nY_{lm},$$

where Y_{lm} is the ordinary spherical harmonics, and ${}_nY_{lm}$ with $l<|n|$ vanishes.[19]

We next substitute Eq. (54) into Eq. (49) to obtain the radial equations

$$\left(\frac{d^2}{dr^2}+\frac{2}{r}\frac{d}{dr}-\frac{2}{r^2}\right)R_0 + p_0^2R_0 - \frac{l(l+1)}{r^2}R_0 + \frac{\sqrt{2l(l+1)}}{r^2}(R_- - R_+) = 0,$$

$$\left(\frac{d^2}{dr^2}+\frac{2}{r}\frac{d}{dr}\right)R_- + p_0^2R_- - \frac{l(l+1)}{r^2}R_- + \frac{\sqrt{2l(l+1)}}{r^2}R_0 = 0, \tag{56}$$

$$\left(\frac{d^2}{dr^2}+\frac{2}{r}\frac{d}{dr}\right)R_+ + p_0^2R_+ - \frac{l(l+1)}{r^2}R_+ - \frac{\sqrt{2l(l+1)}}{r^2}R_0 = 0.$$

Furthermore, Eq. (50) requires

$$-\left(\frac{d}{dr}+\frac{2}{r}\right)R_0 + \frac{\sqrt{l(l+1)}}{\sqrt{2}r}(R_- - R_+) = 0. \tag{57}$$

It can be shown that Eqs. (56) and (57) are equivalent to

$$\left(\frac{d^2}{dr^2}+\frac{2}{r}\frac{d}{dr}\right)(R_- + R_+) + p_0^2(R_- + R_+) - \frac{l(l+1)}{r^2}(R_- + R_+) = 0,$$

$$\left(\frac{d^2}{dr^2}+\frac{4}{r}\frac{d}{dr}+\frac{2}{r^2}\right)R_0 + p_0^2R_0 - \frac{l(l+1)}{r^2}R_0 = 0, \tag{58}$$

$$R_- - R_+ - \frac{\sqrt{2}r}{\sqrt{l(l+1)}}\left(\frac{d}{dr}+\frac{2}{r}\right)R_0 = 0.$$

By the boundary condition, the solutions to Eq. (58) are given by

$$R_- + R_+ = b\frac{j_{l+1/2}(p_0 r)}{\sqrt{p_0 r}},$$

$$R_0 = b_0\frac{j_{l+1/2}(p_0 r)}{(\sqrt{p_0 r})^3},$$

$$R_- - R_+ = b_0\frac{\sqrt{2}}{\sqrt{l(l+1)}}\left[\frac{J_{l-1/2}(p_0 r)}{\sqrt{p_0 r}} - l\frac{J_{l+1/2}(p_0 r)}{(\sqrt{p_0 r})^3}\right], \tag{59}$$

where b and b_0 are both constant coefficients; $J_{l\pm1/2}$ is the first kind of Bessel function of order $l\pm 1/2$.[20]

Substituting Eq. (59) into the eigenequations of the helicity operator with the eigenvalue $s = \pm 1$, i.e.,

$$ip_0 R_0 - s\frac{\sqrt{l(l+1)}}{\sqrt{2}r}(R_- + R_+) = 0,$$

$$ip_0 R_- + s\frac{\sqrt{l(l+1)}}{\sqrt{2}r}R_0 - s\left(\frac{\mathrm{d}}{\mathrm{d}r} + \frac{1}{r}\right)R_- = 0, \tag{60}$$

$$ip_0 R_+ + s\frac{\sqrt{l(l+1)}}{\sqrt{2}r}R_0 + s\left(\frac{\mathrm{d}}{\mathrm{d}r} + \frac{1}{r}\right)R_+ = 0.$$

We obtain

$$b = isb_0\frac{\sqrt{2}}{\sqrt{l(l+1)}}. \tag{61}$$

Note

$$\int_{4\pi} d\varphi d\theta \sin\theta_n \overline{Y}_{lmn} Y_{l'm'} = \delta_{ll'}\delta_{mm'} \tag{62}$$

with $l \geq |n|$,[19] and

$$\int_0^\infty \mathrm{d}r r J_{l+1/2}(p_0 r) J_{l+1/2}(p_0' r) = \frac{1}{p_0}\delta(p_0 - p_0'),$$

$$\int_0^\infty \mathrm{d}r \frac{1}{r} J_{l+1/2}(p_0 r) J_{l+1/2}(p_0' r) = \frac{1}{2l+1}\left(\frac{p_0}{p_0'}\right)^{l+1/2},$$

$$\int_0^\infty \mathrm{d}r J_{l-1/2}(p_0 r) J_{l+1/2}(p_0' r) = \frac{1}{p_0}\left(\frac{p_0}{p_0'}\right)^{l+1/2}, \tag{63}$$

$$\int_0^\infty \mathrm{d}r J_{l-1/2}(p_0' r) J_{l+1/2}(p_0 r) = 0,$$

$$\int_0^\infty \mathrm{d}r J_{l-1/2}(p_0 r) J_{l+1/2}(p_0 r) = \frac{1}{2p_0}$$

with $p_0 \leq p_0'$.[20] Thus it follows that the orthonormal basis with respect to the inner product (19) in the spherical symmetrical representation reads

$$\begin{aligned}|p^0,l,m,s\rangle = \frac{\sqrt{l(l+1)}}{2\sqrt{r}}\Bigg\{ & \frac{J_{l+1/2}(p_0 r)}{p_0 r}{}_0Y_{lm}(\theta,\varphi)e^{-ip_0 t}(\mathrm{d}r)_a \\ & + \frac{1}{\sqrt{2l(l+1)}}\Bigg[\left(\frac{isp_0 r - l}{p_0 r}J_{l+\frac{1}{2}}(p_0 r) + J_{l-\frac{1}{2}}(p_0 r)\right){}_{-1}Y_{lm}(\theta,\varphi)e^{ip_0 t}(\varepsilon^-)_a \\ & + \left(\frac{isp_0 r + l}{p_0 r}J_{l+\frac{1}{2}}(p_0 r) - J_{l-\frac{1}{2}}(p_0 r)\right){}_1Y_{lm}(\theta,\varphi)e^{-ip_0 t}(\varepsilon^+)_a\Bigg]\Bigg\},\end{aligned} \tag{64}$$

which satisfies

$$\langle p^0,l,m,s|p'^0,l',m',s'\rangle = \delta(p^0 - p'^0)\delta_{ll'}\delta_{mm'}\delta_{ss'}. \tag{65}$$

It is obvious that $|p^0,l,m,s\rangle$ vanishes in the case of $l=0$, which implies that the angular quantum number l of one photon only takes positive integers.

V. DISCUSSIONS

We would like to stress that the framework and method presented here are also applicable to other particles with arbitrary mass and spin such as neutrino and electron. In addition, after a simple modification, our results obtained here are easy to be generalized to those cavities with the suitable boundaries, which is important not only to the investigation of the Casimir effect, but also to understanding the relationship between the holographic entropy bound and local quantum field theory.[21]

ACKNOWLEDGMENTS

We are particularly grateful to Professor R. P. Geroch for his interesting exchanges of ideas and unpublished lecture notes, which directly stimulates our investigation of this project. In addition, we also thank Professor G. F. Torres del Castillo for private communications on spin weighted harmonics functions. Y. H. and H. Z. would like to acknowledge the colleagues from Gravitational Group at BNU for their endless encouragements, especially Professor S. Pei and Dr. B. Zhou for their helpful discussions. H. Z. owes much gratitude to Professor H. Guo for his instructive criticisms and suggestions. Y. H. and H. Z.'s work was supported in part by NSFC(Grant Nos. 10205002, 10373003, and 10533010). Noncommutative geometry and the standard model vacuum

John W. Barrett[a] and Rachel A. Dawe Martins[b]
School of Mathematical Sciences, University of Nottingham, University Park, Nottingham NG7 2RD, United Kingdom

(Received 25 March 2006; accepted 7 April 2006; published online 25 May 2006)

The space of Dirac operators for the Connes-Chamseddine spectral action for the standard model of particle physics coupled to gravity is studied. The model is extended by including right-handed neutrino states, and the S^0-reality axiom is not assumed. The possibility of allowing more general fluctuations than the inner fluctuations of the vacuum is proposed. The maximal case of all possible fluctuations is studied by considering the equations of motion for the vacuum. While there are interesting nontrivial vacua with Majorana-type mass terms for the leptons, the conclusion is that the equations are too restrictive to allow solutions with the standard model mass matrix. © *2006 American Institute of Physics.*

I. INTRODUCTION

A. The noncommutative geometry of the standard model

Connes discovered a geometric principle which unifies the metric tensor of general relativity with the classical fields of particle physics—both bosons and fermions—in one geometric structure.[1] The principle is similar to the Kaluza and Klein idea of extending Einstein's space–time geometry to incorporate an internal space at each point in space–time so that the geometry of the extra dimensions is determined by the matter fields of particle physics.[2] Connes' principle is both a generalization of this idea and a simplification. It is more general because the internal space is allowed to be a noncommutative space, whereas it is at the same time simpler because the internal space is 0-dimensional. This is possible because in the noncommutative world 0-dimensional spaces have a much richer structure than in the commutative world of Kaluza and Klein, for whom a 0-dimensional space would have been merely an uninteresting discrete set of points. A noncommutative 0-dimensional space is characterized by a finite-dimensional matrix algebra, which turns out to be just what is required to produce non-Abelian gauge fields.

In fact, noncommutative geometry explains the geometrical structure of the standard model of particle physics.[3] One of the most striking features of this is the discovery that the Higgs field and the gauge bosons are both part of a connection on the total geometry—space–time plus internal space. The Higgs field is the part of the connection in the internal space directions. These directions are actually discrete, so one can think of the Higgs field as providing the parallel transport for hops from left-to right-handed particles, and vice-versa. This geometrical picture extends to a unified formula for the particle physics action, the famous quartic "mexican hat" potential for the Higgs being nothing other than part of the (quartic) Yang-Mills action for the connection on the total geometry. Another striking feature is the extension of the Yang-Mills gauge group to a matrix algebra. For example, SU(3) becomes $M_3(\mathbb{C})$, the algebra of all 3×3 matrices, which contains SU(3), but has a more restricted representation theory. The fact that the fermions fall into representations of the matrix algebra provides a deep explanation of the ad hoc pattern of charges which

[a]Electronic mail: john.barrett@nottingham.ac.uk
[b]Electronic mail: rachel.dawe@maths.nottingham.ac.uk

appears in the usual formulation of the standard model. These insights are very striking and suggest that noncommutative geometry is an important part of particle physics.

Connes' spectral triple formulation of a noncommutative geometry contains the following elements: A Hilbert space $\mathcal{H}$ with an involution γ and an antilinear involution J, a real *-algebra $\mathcal{A}$ of bounded operators in $\mathcal{H}$, and a Dirac operator D. Here we would like to give a brief description of these for the standard model; more details are given below in Sec. II.

The Hilbert space $\mathcal{H}$ is the space of classical fermion fields on the space–time manifold M. This is a finite number of Dirac spinors, one for each elementary fermion (left-handed leptons and quarks, right-handed leptons and quarks, and their antiparticles). Thus $\mathcal{H}=\mathcal{H}_M\otimes\mathcal{H}_F$, where $\mathcal{H}_M$ is the Hilbert space of Dirac spinors on M and $\mathcal{H}_F$ is the finite-dimensional Hilbert space with the basis of the elementary fermions.

The algebra $\mathcal{A}=\mathcal{A}_M\otimes\mathcal{A}_F$ is the algebra of coordinates on the total space, the product of the space–time with the internal space. While the functions on space–time $\mathcal{A}_M$ commute as usual, the internal space is noncommutative, so that its algebra of coordinates $\mathcal{A}_F$ is a matrix algebra. The operator J is charge conjugation, while γ is the chirality operator. Finally the Dirac operator contains all the bosonic fields (metric, gauge fields and Higgs), as well as the parameters for the fermion masses and their mixing angles.

In Ref. 4, Connes and Chamseddine formulated a very simple formula for the action for this data, called the spectral action. The action is

$$\mathrm{Tr}(\chi(D^2)) + (\psi, D\psi) \tag{1}$$

with $\psi\in\mathcal{H}$ the fermion field and χ a cutoff function on the spectrum of D^2 which interpolates between 1 below a very high-energy cutoff scale (possibly the Planck scale), and 0 above it. Amazingly, there is a class of Dirac operators for which this unpacks to give the very long formula for the full standard model Lagrangian coupled to gravity.

Impressive as this is, there are a number of issues that need to be resolved before it can have a greater impact in particle physics. In the Lagrangian of Ref. 4.

(1) The space–time metric has Euclidean signature.
(2) The fermions are quadrupled. For example, there are separate Dirac spinors for the left-handed electron, right-handed electron and their antiparticles, whereas physically there should be only one.[5,6]
(3) The bare Weinberg angle is predicted as $\sin^2\theta=\frac{3}{8}$. In Ref. 4 this is assumed to be the high energy value, which changes under renormalization. However renormalization does not give the correct experimental value.[7]
(4) The neutrinos are massless. While this is correct for the standard model, observational evidence shows that neutrinos have mass, and so the noncommutative geometry should be extended to account for neutrino masses.

In addition to this, there are some further theoretical puzzles about seemingly ad hoc features of the action. In contrast to the above, these points do not indicate problems with the physics of the model, but raise questions about the mathematical formulation and about the understanding of the standard model in terms of noncommutative geometry.

(5) To obtain the standard model, it is necessary to remove a U(1) gauge field in D by the unimodularity constraint.[1,8,9] It is known that this is equivalent to the requirement that the resulting quantum field theory is anomaly free,[10,11] but the reason for this equivalence is mysterious.
(6) To obtain the standard model, a particular vacuum Dirac operator D_0 is chosen. Are there any theoretical constraints on this choice, or are there many other (nonphysical) variants of the standard model?
(7) Is there an intrinsic definition (in terms of noncommutative geometry) of the set of Dirac operators that the action (1) applies to?

B. Sets of Dirac operators

Our main observation is that the theoretical puzzles are all questions about which is the set of Dirac operators to which the spectral action should be applied. Our contribution is to study what happens when the set of Dirac operators is enlarged to the maximum extent allowed by the axioms.

Accordingly, we first explain the class of Dirac operators which appears in Connes' standard model. In Connes' construction, given a metric (and spin structure) g on M, a vacuum geometry is defined by the Dirac operator on $\mathcal{H}=\mathcal{H}_M\otimes\mathcal{H}_F$,

$$D_0 = D_M \otimes I + \gamma_M \otimes D_F, \tag{2}$$

where D_M is the usual Dirac first-order differential operator of g with the Levi-Civita connection, γ_M is the chirality operator on (M,g) (often denoted γ_5) and D_F is a certain matrix which encodes the vacuum Higgs fields and the fermion mass matrix. The details of D_F are explained below in Sec. II. Then the gauge and Higgs fields for this metric are obtained by the process of internal fluctuations determined by the 1-forms $A=A^*=\Sigma_i a_i[D_0,b_i]$ given a finite set of elements $a_i,b_i \in \mathcal{A}$. The result is the set of Dirac operators

$$\mathcal{D}^g = \{D_0 + A + JAJ^{-1}\}. \tag{3}$$

Note: in an arbitrary dimension the correct formula is $D_0+A+\epsilon' JAJ^{-1}$, where $\epsilon'=\pm 1$ is determined by $JDJ^{-1}=\epsilon' D$; $\epsilon'=1$ in all even dimensions. However the unimodular condition must be taken account of. This restricts to a smaller set of Dirac operators $\mathcal{D}'^g \subset \mathcal{D}^g$ obtained by removing a U(1) gauge field that has charge +1 for all quarks, 0 for leptons, and −1 for antiquarks. Finally, the set of all Dirac operators for the Connes-Chamseddine spectral action is the union of these for all metrics and spin structures,

$$\mathcal{D}_{\mathrm{CC}} = \bigcup_g \mathcal{D}'^g.$$

It appears that a similar construction could be carried out starting with any matrix D_F. The only difficulty would be deciding exactly how the unimodularity condition generalizes; the most physical generalization would be a condition that guarantees the absence of anomalies in the corresponding perturbative quantum field theory.

An answer to question (6) is provided by the observation that the vacuum Dirac operator should be a stationary point for the spectral action. Therefore there are equations which restrict D_0. These equations require that the Higgs fields in D_F are actually at a stationary point of the Higgs potential. There are no constraints on the parameters of the fermion mass matrix.

From the point of view of noncommutative geometry, the Connes-Chamseddine class of Dirac operators is very strange, as its description uses the underlying commutative description of the fields and requires an unexplained choice of D_F which is rather special. From the point of view of physics one can describe this by saying that the Connes-Chamseddine class of Dirac operators treats the gravitational and the bosonic matter degrees of freedom differently; for the bosons the internal fluctuations are used but for the gravitational degrees of freedom, all possible fluctuations of the Dirac operator are used, the internal fluctuations being trivial. This undermines the idea of a geometric unification of matter and gravity.

A much more natural class of operators (alluded to in Ref. 1) is the set $\mathcal{D}$ of all Dirac operators for the standard model $\mathcal{A}$ and $\mathcal{H}$. From a physical point of view, this class is almost certainly too big; however understanding the consequences of choosing $\mathcal{D}$ for the spectral action is a necessary first step towards investigating whether there is a natural class which is larger than $\mathcal{D}_{\mathrm{CC}}$ but smaller than $\mathcal{D}$.

Enlarging the set of Dirac operators for the action has two effects. First, some of the parameters in D_0 which were previously constants now become variables. Second, there are an equal number of new equations of motion which, in the generic situation, will therefore fix the vacuum values of this number of constants. So, for example, taking the extreme case where the set of Dirac

operators is just one Dirac operator, $\{D_0\}$, then there are no equations of motion and so no constraints on any of the parameters in D_F. Then enlarging the class of Dirac operators to the set $\mathcal{D}^g$ given by the internal fluctuations of a vacuum D_0, results in promoting the Higgs vacuum parameters to fields. The corresponding new equations of motion, as noted above, demand that the vacuum values of these parameters lie at the stationary points of the Higgs potential, which is a significant constraint. The gauge fields have equations of motion of course, but these are all compatible with the vacuum values zero, and the unimodularity constraint does not affect the vacuum either. Looking at the class $\mathcal{D}_{\mathrm{CC}}$, one has in addition the Einstein equations for the variation of the metric g.

Enlarging the class further brings the prospect of further Higgs fields and further constraint equations. The danger is that the additional equations may rule out the standard model vacuum, or provide additional fields which contradict phenomenology. However if these dangers do not materialize, there is the major benefit that further equations will provide previously unknown relations between the parameters of the standard model in the fermion mass matrix, and in models which are extended to allow neutrino masses, may have predictive power in constraining the form of the neutrino sector.

In this paper we consider the set $\mathcal{D}$ of all Dirac operators for the given $\mathcal{H}$ and $\mathcal{A}$ for the standard model, and also for the model where $\mathcal{H}$ is enlarged to allow a right-handed neutrino. This approach contrasts with that of Ref. 12, where enlarging the set of Dirac operators was considered by enlarging the algebra $\mathcal{A}$ but staying with the class of inner fluctuations. We assume the vacuum is of the form (2), with g a flat metric. Thus we are essentially ignoring the Einstein equations, which of course would be important on a macroscopic scale (e.g., in cosmology), but not microscopically. We calculate the equations of motion for D_F by requiring that it is stationary for all variations of the action in this class and classify the possible vacua under some simplifying assumptions. Finally the physical relevance of the equations and the vacua we have found is addressed in the concluding remarks.

II. DETAILS OF THE STANDARD MODEL

The internal Hilbert space is

$$\mathcal{H}_F = \mathcal{H}_L \oplus \mathcal{H}_R \oplus \mathcal{H}_L^c \oplus \mathcal{H}_R^c, \tag{4}$$

where

$$\mathcal{H}_L = (\mathbb{C}^2 \otimes \mathbb{C}^n \otimes \mathbb{C}^3) \oplus (\mathbb{C}^2 \otimes \mathbb{C}^n),$$

$$\mathcal{H}_R = ((\mathbb{C} \oplus \mathbb{C}) \otimes \mathbb{C}^n \otimes \mathbb{C}^3) \oplus (\mathbb{C} \otimes \mathbb{C}^n).$$

A basis of $\mathcal{H}_F$ is labelled by the elementary fermions and their antiparticles. The symbol c is used to indicate the subspace represented by the antiparticles, which duplicates the particle space. In either case of $\mathcal{H}_L$ and $\mathcal{H}_R$, the first direct summand is the quarks and the second, the leptons. The first factor in the tensor product is the down/up (or electron/neutrino) doublet, the second factor is the space of n generations, and the third factor, for quarks, is color.

Since the fermions are left or right handed, $\mathcal{H}_F$ is $\mathbb{Z}/2$ graded by the chirality operator $\gamma_F = \mathrm{diag}(1,-1,1,-1)$, using the decomposition (4). The right-handed neutrino ν_R does not occur in the standard model, but we include it as an extension of the standard model which allows neutrino masses. Results for models without the right-handed neutrino can be easily obtained by setting the relevant matrix entries in D_F to zero and dropping the equations obtained by varying them. In the following, explicit matrices are written and so we need a convention for the order of the rows and columns: the quark basis is (d_L, u_L, d_R, u_R), each of which is reproduced in three colors, and a similar basis of singlets for the leptons (e_L, ν_L, e_R, ν_R). The antiparticle bases are correspondingly $(d_L^c, u_L^c, d_R^c, u_R^c)$ and $(e_L^c, \nu_L^c, e_R^c, \nu_R^c)$.

The standard model algebra is

$$\mathcal{A}_F = \mathbb{H} \oplus \mathbb{C} \oplus M_3(\mathbb{C}),$$

where $\mathbb{H}$ are the quaternions. The action of an element (q, λ, m) of $\mathcal{A}_F$ is

$$\rho = \begin{pmatrix} \rho_L & 0 & 0 & 0 \\ 0 & \rho_R & 0 & 0 \\ 0 & 0 & \rho_L^c & 0 \\ 0 & 0 & 0 & \rho_R^c \end{pmatrix}, \tag{5}$$

where $\rho_L = q$ acting on isospin, $\rho_R = \Lambda = \begin{pmatrix} \overline{\lambda} 0 \\ 0 \lambda \end{pmatrix}$ acting on the two isospin scalars, (d_R, u_R) or (e_R, ν_R). The action on the antiparticles is $\rho_L^c = \rho_R^c = m$ acting on the color index for quarks, and $\rho_L^c = \rho_R^c = \lambda$ for leptons. The action is the same for each generation, and we refer to the analogs of the down, up, electron and neutrino in the other generations by the same names.

A real spectral triple possesses a real structure given by an operator J that takes particles into antiparticles and charge conjugation,

$$J \begin{pmatrix} \psi_1 \\ \psi_2^c \end{pmatrix} = \begin{pmatrix} \overline{\psi_2^c} \\ \overline{\psi_1} \end{pmatrix} \in \mathcal{H}.$$

It turns the Hilbert space into a bimodule,

$$a \psi b = a J b^* J^{-1} \psi. \tag{6}$$

Note that

$$[a, J b^* J^{-1}] = 0. \tag{7}$$

Also, J commutes with $\gamma = \gamma_M \otimes \gamma_F$.

This data satisfies an axiom called Poincaré duality, which is the generalization of the familiar Poincaré duality of manifolds to noncommutative geometry. While this axiom is a natural generalization from the mathematical point of view, its physical meaning for the internal space is unclear. Applied to the internal geometry, the axiom is satified for the standard model but not if there is the same number of left- and right-handed neutrinos.[13] However it is satisfied if one of the generations does not have a right-handed neutrino but the other two do. In the following we do not require that the Poincaré duality axiom holds.

So far, we have explained some of the axioms relating to the Hilbert space and the algebra for the standard model finite triple. The final ingredient is the Dirac operator. A Dirac operator must satisfy the first order condition:

$$[[D, a], J b^* J^{-1}] = 0 \tag{8}$$

for all $a, b \in \mathcal{A}$ in order that D be a first order differential operator.[14] Note that due to (7), this implies that also $[[D, J b^* J^{-1}], a] = 0$.

The choice made for D_F in Ref. 4 in order that the spectral action principle reproduces the standard model is

$$D_F = \begin{pmatrix} 0 & M^* & 0 & 0 \\ M & 0 & 0 & 0 \\ 0 & 0 & 0 & M^T \\ 0 & 0 & \overline{M} & 0 \end{pmatrix}, \tag{9}$$

where $M = Q \otimes 1_3 \oplus L$

$$Q^* = \begin{pmatrix} k_d\phi_1 & k_u\overline{\phi}_2 \\ k_d\phi_2 & -k_u\overline{\phi}_1 \end{pmatrix},$$

$$L^* = \begin{pmatrix} k_e\phi_1 & 0 \\ k_e\phi_2 & 0 \end{pmatrix},$$

with

$$k_u = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_c & 0 \\ 0 & 0 & m_t \end{pmatrix}, \quad k_d = V_{\mathrm{CKM}} \begin{pmatrix} m_d & 0 & 0 \\ 0 & m_s & 0 \\ 0 & 0 & m_b \end{pmatrix},$$

$$k_e = \begin{pmatrix} m_e & 0 & 0 \\ 0 & m_\mu & 0 \\ 0 & 0 & m_\tau \end{pmatrix}.$$

M^T denotes the transpose, M^* denotes Hermitian conjugate, $\overline{M}$ denotes the complex conjugate matrix, m_x are the Yukawa couplings of the elementary fermions, V_{CKM} is the Cabibbo-Kobayashi-Maskawa generation mixing matrix, and (ϕ_1, ϕ_2) is the Higgs scalar doublet.

III. THE GENERAL D_F

The problem of finding the vacua reduces in essence to considering a single point of space–time. We simplify the action formula (1) by removing all terms involving the space–time curvature, and all kinetic terms, and set the gauge fields to zero. This is equivalent to varying the Dirac operator over all operators of the form (2), with a fixed D_M. By inspecting the heat expansion detailed in Ref. 15 we find that the action we are looking for is

$$S = \mathrm{Tr}(D_F^4 - 2D_F^2). \tag{10}$$

This formula gives the Higgs potential for internal fluctuations of the standard model vacuum. However it applies to the wider class of operators $\mathcal{D}$.

In order to find the most general D_F for the standard model internal space, we employ the constraints given by the axioms for a 0-dimensional noncommutative space. Only the axioms involving the Dirac operator are listed here.

(i) Self-adjointness, $D_F = D_F^*$.

(ii) Reality, $[D_F, J] = 0$.
These first two imply that, splitting the Dirac operator into four blocks corresponding to the particle/antiparticle split of the basis,

$$D_F = \begin{pmatrix} Y & Z \\ \overline{Z} & \overline{Y} \end{pmatrix}, \tag{11}$$

where $Y = Y^*$ and $Z = Z^T$.

(iii) Orientability, $D_F\gamma_F + \gamma_F D_F = 0$, implies that

$$D_F = \begin{pmatrix} Y & Z \\ \overline{Z} & \overline{Y} \end{pmatrix} = \begin{pmatrix} 0 & M^* & 0 & G \\ M & 0 & G^T & 0 \\ 0 & \overline{G} & 0 & M^T \\ G^* & 0 & \overline{M} & 0 \end{pmatrix} \tag{12}$$

using a further split of each block into the left/right subspaces. In this formula M and G are general matrices with complex coefficients, M giving a generalization of the mass matrix of the standard model and G having the interpretation of Majorana mass terms and other interactions.

If the vacuum Dirac operator generates Majorana masses then the model is no longer the standard model but a modification of it. In this modified model, the generation of Majorana masses involves symmetry breaking with new scalar fields, in addition to the Higgs fields. This introduction of new fields is not necessarily undesirable because any new physics of fermion masses must necessarily go beyond the standard model.

The remaining axiom is the following.

(iv) First order condition, $[[D_F, a], Jb^*J^{-1}]=0$. The effect of applying the first order condition to (12) is to determine which elements of M and G are nonzero.

In Ref. 16, Krajewski shows that for any finite dimensional spectral triple, the Dirac operator solves the first order condition uniquely in the form of the sum, $D_F=D_L+D_R$ where D_R commutes with any element $b^o=Jb^*J^{-1}$ in the opposite algebra and D_L commutes with any element in the algebra. See also Ref. 17. Using these formulas

$$D_L a - aD_L = 0, \quad D_R b^o - b^o D_R = 0 \tag{13}$$

and using the representation as given above (5) we find that

$$D_L = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & G^T & 0 \\ 0 & \overline{G} & 0 & M^T \\ 0 & 0 & \overline{M} & 0 \end{pmatrix} \tag{14}$$

and

$$D_R = \begin{pmatrix} 0 & M^* & 0 & G \\ M & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ G^* & 0 & 0 & 0 \end{pmatrix} \tag{15}$$

with $M=Q\otimes 1_3 \oplus L$, a direct sum of a quark matrix Q which commutes with color, and a lepton matrix L. Both Q and L are arbitrary 4×4 complex matrices (for one generation). For three generations, these become arbitrary 12×12 matrices. The other matrix is in block form

$$G = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & U & 0 & N \end{pmatrix}, \tag{16}$$

using the basis explained in Sec. II, i.e., a map $(d_R^c, u_R^c, e_R^c, \nu_R^c) \mapsto (d_L, u_L, e_L, \nu_L)$. The nonzero entries are the blocks U and N. These are maps

$$U: u_R^c \mapsto (e_L, \nu_L)$$

and

$$N: \nu_R^c \mapsto (e_L, \nu_L).$$

Their appearance results from the fact that u_R^c, ν_R^c, and e_L and ν_L are all in the same representation of the opposite algebra $\mathcal{A}^o$, multiplication by the complex number λ. The other entries of G are zero because they are intertwining inequivalent representations. Note that the matrix $\overline{G}$ gives maps $u_R \mapsto (e_L^c, \nu_L^c)$ and $\nu_R \mapsto (e_L^c, \nu_L^c)$.

Explicitly, for one generation we use the matrices

$$Q = \begin{pmatrix} d & c \\ b & a \end{pmatrix}, \quad L = \begin{pmatrix} q & r \\ s & t \end{pmatrix}, \tag{17}$$

$$U = \begin{pmatrix} x & u & g \\ y & v & h \end{pmatrix}, \quad N = \begin{pmatrix} j \\ l \end{pmatrix}, \tag{18}$$

(x,u,g), (y,v,h) are three-dimensional color vectors and j, l are color singlets.

It is also convenient to split Q and L into smaller blocks corresponding to the gauge-invariant split of the right-handed fermions into down/up or electron/neutrino:

$$Q = \begin{pmatrix} Q_d \\ Q_u \end{pmatrix}, \quad L = \begin{pmatrix} L_e \\ L_\nu \end{pmatrix}. \tag{19}$$

For example, for one generation this means that $L_e = (q\ r)$, etc.

The nonzero entries give rise to terms in the fermionic part of the action (1) given, for one generation, by

$$(\psi_L^c, \overline{G}\psi_R) = (e_L^c, (\overline{x,u,g}) \cdot u_R) + (\nu_L^c, (\overline{y,v,h}) \cdot u_R) + (e_L^c, \overline{j}\nu_R) + (\nu_L^c, \overline{l}\nu_R),$$

$$(\psi_R^c, G^*\psi_L) = (\nu_R^c, \overline{j}e_L) + (\nu_R^c, \overline{l}\nu_L) + (u_R^c, (\overline{x,u,g})e_L) + (u_R^c, (\overline{y,v,h})\nu_L),$$

plus the Hermitian conjugate of each term, which are $(\psi_R, G^T\psi_L^c)$ and $(\psi_L, G\psi_R^c)$, respectively. Thus the action contains, for example,

$$(\nu_R^c, \overline{l}\nu_L) + (\nu_L^c, \overline{l}\nu_R) + (\nu_L, l\nu_R^c) + (\nu_R, l\nu_L^c).$$

This action is plausibly the Euclidean analog of a Majorana mass term; but note that significant differences between the Euclidean and Minkowskian formulation mean that this is somewhat heuristic. The fields U have been studied before in the context of the noncommutative standard model and are called leptoquarks,[18] while the N are new fields which are of course absent if the right-handed neutrino is not included in the model.

Relatively recently there has been new experimental evidence for neutrinos being massive. There are two possibilities for theoretical neutrino mass generation, the Dirac mass and the Majorana mass term. For a particle to have a Dirac mass, both chiralities must be present, so this would require ν_R and thus a modification of the standard model. To justify existence of the ν_R, there must be an explanation as to why it remains undetected; it must either be extremely massive or sterile (not interacting). A Majorana mass term is possible without ν_R, but it requires an SU(2) Higgs triplet; many models include ν_R and a combination of Majorana and Dirac mass terms to render ν_R very heavy while leaving ν_L relatively light.

IV. EQUATIONS OF MOTION

The overall aim is to see if the standard model vacuum D_F can be found as a solution of the internal space equations without making any assumptions other than the axioms themselves, instead of making the choice (9) motivated from laboratory evidence. To this end, we need to vary *all* the degrees of freedom of D_F which means that the Yukawa couplings, and generation mixing

angles (plus all the other fluctuations) are no longer viewed as constants but as dynamical variables. In other words, we let $\mathcal{D}=\{D_F\}$ form the configuration space of the theory and calculate the internal space equations of motion.

To calculate the internal space equations of motion, we minimize the action (10) with respect to the degrees of freedom of both M and G. The action is

$$\begin{aligned} S &= \mathrm{Tr}(-2D_F^2 + (D_F)^4) \\ &= \mathrm{Tr}(-2(G^*G + M^*M) + (M^*M)^2 + (G^*G)^2 + 2(M^*MGG^* + MM^*G^T\overline{G} + MG\overline{MG})) \\ &= \mathrm{Tr}\Big(-(LL^* + 3QQ^* + UU^* + NN^*) + \tfrac{1}{2}((L^*L)^2 + 3(Q^*Q)^2 + (UU^* + NN^*)^2) \\ &\quad + L^*L(UU^* + NN^*) + L_\nu L_\nu^* N^T\overline{N} + (Q_u Q_u^* \otimes I_3)U^T\overline{U}\Big). \end{aligned} \tag{20}$$

The results for varying with respect to Q, L, U, and N are, respectively,

$$Q^*\left(-3I + 3QQ^* + \begin{pmatrix} 0 & 0 \\ 0 & \mathrm{Tr}_{\mathrm{col}}(U^T\overline{U}) \end{pmatrix}\right) = 0, \tag{21}$$

$$-L^* + L^*LL^* + (UU^* + NN^*)L^* + (0\ L_\nu^* N^T\overline{N}) + (0\ N\overline{L_\nu}\,\overline{N}) = 0, \tag{22}$$

$$U^*(-I + UU^* + NN^* + L^*L) + (\overline{Q_u}Q_u^T \otimes I_3)U^* = 0, \tag{23}$$

$$-N^* + N^*UU^* + N^*NN^* + N^*L^*L + \overline{L_\nu}L_\nu^T N^* + \overline{L_\nu}\,\overline{N}L_\nu = 0. \tag{24}$$

In Eq. (21), the matrix is split into blocks according to the down/up split of the basis, and $\mathrm{Tr}_{\mathrm{col}}$ denotes the trace over color degrees of freedom. Thus each matrix block has size $n\times n$, where n is the number of generations.

In the following we analyze the solutions of these equation in various special cases, and then make some remarks about the general case.

V. SOLUTIONS WITH $G=0$

With $U=0$ and $N=0$, the equations of motion reduce to

$$Q^*(QQ^* - I) = 0, \tag{25}$$

$$L^*(LL^* - I) = 0. \tag{26}$$

By multiplying (25) on the left by Q, we see that QQ^* is a self-adjoint projection, and by multiplying the conjugate on the left by Q^* that Q^*Q is also a projector. Therefore, by definition, $Q \in M_n(\mathbb{C})$ is a partial isometry. Another characterization of a partial isometry is that it is a projector multiplied by a unitary matrix. Obviously the same conclusion applies for L.

These equations are the same as the ones obtained from assuming the additional S^0-reality axiom,[3] which has the effect that U and N are equal to zero in the action.

The standard model vacuum (9) is clearly not a solution of our equations. To see this, we write down MM^*,

$$\begin{pmatrix} k_d^* k_d(|\phi_1|^2+|\phi_2|^2) & 0 & 0 \\ 0 & k_u^* k_u(|\phi_1|^2+|\phi_2|^2) & 0 \\ 0 & 0 & k_e^* k_e(|\phi_1|^2+|\phi_2|^2) \\ 0 & 0 & 0 \end{pmatrix} \tag{27}$$

so the vacua satisfying our equations of motion have degenerate fermion masses that are either 0 or 1 (times a constant, which has been omitted from the action). We note that in the case in which ν_R is absent, the left-handed neutrino is necessarily massless. This is a consequence of the fact that L is not a square matrix in that case.

The impact of the following sections is to explore the way in which lifting the assumption of S^0-reality allows further vacua with U or N not equal to zero.

VI. SOLUTIONS WITH $G \neq 0$

A. General

Throughout we assume that the quark mass matrix Q is nondegenerate. This means that Q^* can be cancelled from (21) to give

$$-3I + 3QQ^* + \begin{pmatrix} 0 & 0 \\ 0 & \mathrm{Tr}_{\mathrm{col}}(U^T\overline{U}) \end{pmatrix} = 0. \tag{28}$$

This equation can be solved for QQ^*, and thus for Q, up to multiplication on the right-hand side by a unitary operator, which is a symmetry. One very important feature (not always shared by the degenerate case) is that QQ^* is block diagonal. This is an important feature of the standard model vacuum. Indeed, using the split (19), the equation becomes the three equations

$$Q_d Q_d^* = I,$$

$$Q_d Q_u^* = 0,$$

$$Q_u Q_u^* = I - \tfrac{1}{3}\mathrm{Tr}_{\mathrm{col}}(U^T\overline{U})$$

which shows that the down-quark masses are all equal to 1, the block-diagonal feature, and that the up-quark masses are split by a nonzero U. It is worth noting that the condition $Q_d Q_u^* = 0$ fixes the form of Q_u in the standard model vacuum (9) if Q_d is given the correct form. However there is no equation which constrains Q_d to have the special form of (9).

B. One generation

For one generation of fermions, we use the explicit matrices of (17) and (18). The equations of motion are written out in the appendix. Equation (21) becomes (A1)–(A4) and (22) becomes (A5)–(A8) and (23) becomes (A9)–(A14) and (24) becomes (A15) and (A16).

The equation (28) becomes the following:

$$|c|^2 + |d|^2 - 1 = 0, \tag{29}$$

$$a\overline{c} + \overline{b}d = 0, \tag{30}$$

$$3|a|^2 + 3|b|^2 + |g|^2 + |u|^2 + |x|^2 + |h|^2 + |v|^2 + |y|^2 - 3 = 0. \tag{31}$$

As above, (30) implies that QQ^* is a diagonal matrix.

1. Solutions with $U=0$, $N\neq 0$

In this case, Q decouples from the other fields and its equation reduces to (25). Thus Q is a unitary matrix and the quark masses are all equal to 1. To present the solutions to these equations we have used the symmetry afforded by a 2×2 unitary matrix acting on e_L and ν_L to simplify one of the vectors (q,r), (s,t) or (j,l).

The possible solutions are all equivalent to

(i) $q=1$, $s=t=r=0$, $j=0$, $|l|=1$,
(ii) $q=r=s=0$, $|t|^2+|j|^2=1$, $l=0$,
(iii) $q=1$, $s=r=0$, $|t|=1/2$, $j=0$, $|l|=1/2$,
(iv) $q=0$, $s=r=0$, $|t|=1/2$, $j=0$,$|l|=1/2$,
(v) $r=s=t=0$, $|q|^2+|j|^2=1$, $l=0$.

The proof that these are the only solutions is to consider combining the equations $N^*(22)-(24)L^*$. This leads to a set of algebraic conditions which reduce to the given solutions when substituted into the full equations of motion.

2. Solutions with $U\neq 0$

We have been unable to find any explicit one-generation solutions with nonzero leptoquarks U. For the case where the quark and electron masses in the mass matrix M are nonzero, we can prove that there are no such solutions. This has the corollary that there are no solutions where the matrix M takes the form of a one-generation version of the standard model vacuum (9).

The argument is as follows. Using a symmetry as above, we may assume that $r=0$ and $q\neq 0$. Combining (A6), (A5), and (A9) shows that $g=0$, since $|a|^2+|b|^2\neq 0$. Similarly, $u=x=0$. Then (A10) and (31) imply either $h=0$ or $\frac{2}{3}(|v|^2+|h|^2+|y|^2)+|l|^2+|t|^2=0$, which also implies $h=0$. A similar argument shows $v=y=0$. Hence $U=0$.

If additionally, $N=0$, then the same conclusion also holds if the electron mass $q=0$ (see Sec. VI C below).

It is worth noting that the solutions considered here in the case that $L_\nu=0$ are the same as for the system obtained by omitting the right-handed neutrino ν_R from the action.

C. Three generations

For three generations we do not have complete results but note that the equations are of course solved by aggregating three one-generation solutions. In addition we outline some general features of the solutions. We continue to assume that the quark masses are all nonzero; thus the remarks of Sec. VI A continue to hold. A general feature of the solutions to the equations can be found by taking the combination of equations $U^*(22)-(23)L^*$. This gives the equation

$$L_e U=0.$$

In the case where $N=0$, it also shows that

$$L_\nu U=0$$

and Eq. (23) reduces to

$$\left(U^*U-\tfrac{1}{3}\mathrm{Tr}_{\mathrm{col}}(U^*U)\otimes I_3\right)U^*=0$$

from which follows that

$$U^*U=C\otimes I_3$$

for some 3×3 matrix C. Since the rank of U^*U is at most 6, C has rank at most 2. As a consequence, only two out of the three up quarks, charm and top are given different masses from that of the three down-family quarks.

The corresponding argument for one generation shows that the rank of U^*U is at most 2, and hence C must be zero. This agrees with the result found explicitly in the preceding section, and holds even if $q=0$.

VII. CONCLUSIONS

We have attempted to understand the standard model vacuum from a fundamental point of view involving noncommutative geometry. In particular, the question is: why does nature pick one particular vacuum geometry, i.e., one particular set of parameters in the fermion mass matrix? To attack this question, we investigated the simplest possible Ansatz for the set of Dirac operators in the action which is to promote all the degrees of freedom of the internal geometry, including the mass parameters, to be dynamical fields. This gives additional equations of motion which complement the usual Einstein and matter equations. The conclusion is that these equations exclude the standard model vacuum. Therefore there is something unexplained about either the physics of the standard model or the geometry of spectral triples. This is our overall conclusion.

The main problem is that the simplest solutions involve an unwanted degeneracy in the masses of the fermions. However there are some quite complicated vacua in which this problem is partially alleviated. Allowing an extension of the model to include a right-handed neutrino lifts the degeneracy of the lepton Dirac masses via Eq. (22) in some solutions. The potential occurence of leptoquark fields lifts the degeneracy of the up-quark Dirac masses to some extent, but the degeneracy of the down quarks remains. In practice it seems to be hard to find vacua with nonzero values of the leptoquark field. With one generation and reasonable assumptions, the leptoquarks are always equal to zero. This is in a sense reassuring because the leptoquarks would break color symmetry, but it does not help with the problem of quark mass degeneracy. With three generations, leptoquark fields are possible but we have found solutions affecting at most two out of the three generations, thus giving some sort of consistency with the one-generation result.

Some features of the very special standard model vacuum are automatically incorporated, whereas others are not. In particular there are typically many Higgs fields and there appears to be no constraint which forces the Higgs for the leptons and the quarks to be the same field. One can see this in our results for one generation. Since it is not possible to diagonalize both Q and L with a single unitary transformation, the parameters q, r, a, and b are independent, providing two Higgs doublets.

The extension to include the right-handed neutrino also introduces potential Majorana mass terms for the leptons. The explicit solutions we found allow (i) a Dirac mass for the electron and a Majorana mass for the neutrino, (ii) a Dirac mass for the neutrino and a mixing between ν_R and e_L, (iii) a Dirac mass for the electron and a neutrino with both Dirac and Majorana mass terms, (iv) a massless electron with a neutrino with both Dirac and Majorana mass terms, and (v) a Dirac mass for the electron and a massless neutrino with a mixing between ν_R and e_L. Further calculations show that in each case the Majorana term is such that the eigenvalues of D always remain 0 or $+/-1$. However it is worth emphasizing that there are differences between the Euclidean and Lorenzian formulations for fermions which make it difficult to draw conclusions from this for the physical Lorentzian case. In spite of this our overall conclusion that the masses are too degenerate stands, and this points to the need for modifications to the formalism if the overall objectives are to be retained. In the future this could possibly be carried out by adding more constraints to the space of Dirac operators or by additional terms to the spectral action.

(Received 24 January 2006; accepted 15 March 2006; published online 8 May 2006)

Path and path deviation equations for charged, spinning and spinning charged objects in different versions of Kaluza-Klein (KK) theory using a modified Bazanski Lagrangian have been derived. The significance of motion in five dimensions, especially for a charged spinning object, has been examined. We have also extended the modified Bazanski approach to derive the path and path deviation equations of a test particle in a version of non-symmetric KK theory. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2196749]

I. INTRODUCTION

In an attempt to unify gravity and electromagnetism Kaluza (1921) introduced a fifth dimension to describe electromagnetism. Klein (1926) added a stringent cylindrical condition, which keeps the extra dimension compact.[1] Following the scheme of compactification many theories have developed Kaluza-Klein (KK) ideas and extended the process of compactification to include higher dimensions as a way to unify many fields.[2] However, Wesson *et al.*[3] have considered unification of geometry with matter by dropping the cylindrical condition, and introducing non-compact theories of higher dimensions based geometrically on the Campbell-Magaard theorem. This approach has been emerged into two classes of non-compact theories: brane theories[4] and space-time-matter theories.[5]

From this perspective, path and path deviation equations play a vital part to interpret the behavior of any particle describing any of the above-mentioned theories. These equations offer a way to test the new physics coming from the introduction of extra dimensions.[6] The behavior of test particles and extended objects could be used for examining additional phenomena embedded in higher dimensions. Accordingly, we present a study of path and path deviation equations for charged, spinning, and spinning charged objects using different theories of KK. The path and path deviation equations could also be used to detect the cosmological variation of spin, and to study the evolution of the angular momentum of galaxies, pulsars, and high energy primordial objects[7] using a gyroscopic motion in five dimensions. KK theories have been extended to include different types of non-symmetric theory of gravity. One such trial has been done by Kalinowski to unify gravity and gauge fields using a multidimensional manifold in the Jordan-Thirry manner.[8]

The aim of the present work is to extend the Bazanski approach[9] into five dimensions (5D) in order to derive some versions of path and path deviation equations in multidimensional space for different objects such as charged, spinning, and spinning charged particles, with taking the status of extra dimension as either compact or non-compact. The paper is organized into the following steps:

(1) Describing path equations and their corresponding path deviation equations in four dimensions (4D).
(2) Extending these equations into 5D.

II. MOTION IN 4D

A. Path and path deviation equations in Riemannian geometry

Geodesic and geodesic deviation equations can be obtained simultaneously by applying the action principle on the Bazanski Lagrangian:[9]

$$L = g_{\alpha\beta} U^{\alpha} \frac{D\Psi^{\beta}}{Ds}, \tag{1}$$

where D/Ds is the covariant derivative. This can be done if one takes the variation with respect to the deviation vector Ψ^{ρ} in order to derive the geodesic equation:

$$\frac{dU^{\alpha}}{ds} + \left\{ \begin{matrix} \alpha \\ \mu\nu \end{matrix} \right\} U^{\mu} U^{\nu} = 0, \tag{2}$$

where $\left\{ \begin{matrix} \alpha \\ \mu\nu \end{matrix} \right\}$ is the Christoffel symbol. If one takes the variation with respect to the unit tangent vector U^{ρ}, one derives the geodesic deviation equation:

$$\frac{D^2\Psi^{\alpha}}{Ds^2} = R^{\alpha}_{.\beta\gamma\delta} U^{\beta} U^{\gamma} \Psi^{\delta}, \tag{3}$$

where $R^{\alpha}_{\beta\gamma\delta}$ is the Riemann-Christoffel curvature tensor. It is worth mentioning that the Bazanski approach has been successfully applied in geometries different from the Riemannian.[10,11] Now, Lagrangian (1) can be amended to describe path and path deviation equations of charged, spinning, and spinning charged particles if we introduce the following Lagrangian:

$$L = g_{\alpha\beta} U^{\alpha} \frac{D\Psi^{\beta}}{Ds} + f_{\beta} \Psi^{\beta} \tag{4}$$

such that

$$f_{\beta} = a_1 F_{\alpha\beta} U^{\beta} + a_2 R_{\alpha\beta\gamma\delta} S^{\gamma\delta} U^{\alpha},$$

where a_1 and a_2 are parameters that may take the values e/m and $1/2m$, respectively, $F^{\mu}_{.\nu}$ is an electromagnetic tensor and $S^{\gamma\delta}$ is the spin tensor. These parameters have to be adjusted with their counterparts in the original Lorentz force equation,[12] the Papapetrou equation,[13] and the Dixon equation.[14]

Applying the Bazanski approach for obtaining path and path deviation equations on Lagrangian (4) we get the following.

(i) The Lorentz charged equation (for $a_1 = e/m$ and $a_2 = 0$),

$$\frac{\mathrm{d}U^{\alpha}}{ds} + \left\{ \begin{matrix} \alpha \\ \mu\nu \end{matrix} \right\} U^{\mu} U^{\nu} = \frac{e}{m} F^{\mu}_{.\nu} U^{\nu}, \tag{5}$$

and the charged deviation equation:[15]

$$\frac{D^2\Psi^{\alpha}}{Ds^2} = R^{\alpha}_{.\mu\nu\rho} U^{\mu} U^{\nu} \Psi^{\rho} + \frac{e}{m} \left(F^{\alpha}_{.\nu} \frac{D\Psi^{\nu}}{Ds} + F^{\alpha}_{.\nu;\rho} U^{\nu} \Psi^{\rho} \right). \tag{6}$$

(ii) The Papapetrou equation for spinning objects (for $a_1 = 0$ and $a_2 = 1/2m$)

$$\frac{\mathrm{d}U^{\alpha}}{\mathrm{d}s} + \left\{ \begin{matrix} \alpha \\ \mu\nu \end{matrix} \right\} U^{\mu} U^{\nu} = \frac{1}{2m} R^{\alpha}_{.\mu\nu\rho} S^{\nu\rho} U^{\mu}. \tag{7}$$

The spinning deviation equation becomes[16]

$$\frac{D^2\Psi^\alpha}{Ds^2} = R^\alpha_{.\mu\nu\rho}U^\mu U^\nu\Psi^\rho + \frac{1}{2m}\left(R^\alpha_{.\mu\nu\rho}S^{\nu\rho}\frac{D\Psi^\mu}{Ds} + R^\alpha_{\mu\nu\lambda}S^{\nu\lambda}_{\ \ :\rho}U^\mu\Psi^\rho + R^\alpha_{\mu\nu\lambda;\rho}S^{\nu\lambda}U^\mu\Psi^\rho\right). \tag{8}$$

(iii) The Dixon equation for spinning charged objects (for $a_1=e/m$ and $a_2=1/2m$)[14]

$$\frac{\mathrm{d}U^\alpha}{\mathrm{d}s} + \left\{\begin{matrix}\alpha\\ \mu\nu\end{matrix}\right\}U^\mu U^\nu = \frac{e}{m}F^\mu_{\ .\nu}U^\nu + \frac{1}{2m}R^\alpha_{.\mu\nu\rho}S^{\nu\rho}U^\mu, \tag{9}$$

and its spinning charged deviation equation becomes

$$\frac{D^2\Psi^\alpha}{Ds^2} = R^\alpha_{.\mu\nu\rho}U^\mu U^\nu\Psi^\rho + \frac{e}{m}\left(F^\mu_{\ .\nu}\frac{D\Psi^\nu}{Ds} + F^\mu_{\ .\nu;\rho}U^\nu\Psi^\rho\right)$$
$$+ \frac{1}{2m}\left(R^\alpha_{.\mu\nu\rho}S^{\nu\rho}\frac{D\Psi^\mu}{Ds} + R^\alpha_{.\mu\nu\lambda;\rho}S^{\nu\lambda}U^\mu\Psi^\rho + R^\alpha_{.\mu\nu\lambda}S^{\nu\lambda}_{\ \ ;\rho}U^\mu\Psi^\rho\right). \tag{10}$$

Papapetrou[17] has derived an equation describing a spinning object which is able to precess:

$$\frac{D}{Ds}\left(mU^\alpha + U_\rho\frac{DS^{\alpha\rho}}{Ds}\right) = \frac{1}{2}R^\alpha_{.\mu\nu\rho}S^{\nu\rho}U^\mu. \tag{11}$$

Using the Bazanski approach, we can suggest the following Lagrangian:

$$L = g_{\alpha\beta}\left(mU^\alpha + U_\rho\frac{DS^{\alpha\rho}}{Ds}\right)\frac{D\Psi^\beta}{Ds} + R_{\alpha\beta\gamma\delta}S^{\gamma\delta}U^\beta\Psi^\alpha, \tag{12}$$

which can be used to derive Eq. (11) and to obtain its corresponding deviation equation in the following way:

$$\frac{D^2\Psi^\alpha}{Ds^2} = R^\alpha_{.\mu\nu\rho}U^\mu\left(mU^\nu + U_\beta\frac{DS^{\nu\beta}}{Ds}\right)\Psi^\rho + g^{\alpha\sigma}g_{\nu\lambda}\left(mU^\lambda + U_\beta\frac{DS^{\lambda\beta}}{Ds}\right)_{;\sigma}\frac{D\Psi^\nu}{Ds} + R^\alpha_{.\mu\nu\rho}S^{\nu\rho}\frac{D\Psi^\mu}{Ds}$$
$$+ R^\alpha_{\mu\nu\lambda}S^{\nu\lambda}_{\ \ :\rho}U^\mu\Psi^\rho + R^\alpha_{\mu\nu\lambda;\rho}S^{\nu\lambda}U^\mu\Psi^\rho. \tag{13}$$

B. Path and path deviation equations in non-symmetric geometries

Path equations in one of the versions of non-symmetric geometries, e.g., Legaré and Moffat, have been derived from following Lagrangian:[18]

$$L = g_{(\mu\nu)}U^\mu U^\nu + \lambda\hat{A}_\nu U^\nu, \tag{14}$$

by taking the variation with respect to U^σ to give

$$\frac{dU^\alpha}{ds} + \left\{\begin{matrix}\alpha\\ \mu\nu\end{matrix}\right\}U^\mu U^\nu = \lambda g^{(\alpha\mu)}f_{[\mu\nu]}U^\nu, \tag{15}$$

where $g_{(\mu\nu)}$ is the symmetric part of the gravitational potential tensor, λ is a parameter and, $f_{[\mu\nu]}=\hat{A}_{\mu,\nu}-\hat{A}_{\nu,\mu}$ is a skew symmetric tensor related to the Yukawa force.

Applying the Bazanski approach, we can derive (15) from the following Lagrangian:

$$L = g_{(\alpha\beta)}U^\alpha\frac{D\Psi^\beta}{Ds} + \lambda f_{\nu\rho}\Psi^\nu U^\rho. \tag{16}$$

Using the same approach, we can show its corresponding deviation equation to be

$$\frac{D^2\Psi^\alpha}{Ds^2} = R^\alpha_{.\mu\nu\rho}U^\mu U^\nu\Psi^\rho + \lambda\left(f^\alpha_{\ .\nu}\frac{D\Psi^\nu}{Ds} + f^\alpha_{\ .\nu;\rho}U^\nu\Psi^\rho\right). \tag{17}$$

But, if we consider the following Lagrangian:

$$L = \mathbf{g}_{\mu\nu} U^{\mu} \frac{D\Psi^{\nu}}{D\tau} + \lambda f_{\nu\rho} \Psi^{\nu} U^{\rho}, \tag{18}$$

where $\mathbf{g}_{\mu\nu} = g_{(\mu\nu)} + g_{[\mu\nu]}$, and follow the Bazanski approach to get the path and path deviation equations related to this type of geometry by taking the variation with respect to Ψ^{σ} and U^{σ}, respectively, we can obtain:

$$\frac{\mathrm{d}U^{\alpha}}{\mathrm{d}s} + \left\{ \begin{matrix} \alpha \\ \mu\nu \end{matrix} \right\} U^{\mu} U^{\nu} = \lambda \mathbf{g}^{\alpha\mu} f_{[\mu\nu]} U^{\nu} + \mathbf{g}^{\alpha\sigma} g_{[\nu\sigma];\rho} U^{\nu} U^{\rho}, \tag{19}$$

and the path deviation equation becomes

$$\frac{D^2\Psi^{\alpha}}{Ds^2} = R^{\alpha}_{\cdot\mu\nu\rho} U^{\mu} U^{\nu} \Psi^{\rho} + 2\mathbf{g}^{\sigma\alpha} (g_{[\nu[\sigma];\rho]}) \frac{D\Psi^{\nu}}{Ds} U^{\rho} + \lambda \left(f^{\alpha}_{\cdot\nu} \frac{D\Psi^{\nu}}{Ds} + f^{\alpha}_{\cdot\nu;\rho} U^{\nu} \Psi^{\rho} \right). \tag{20}$$

It is clear that the difference between (15) and (19) is related to absence of the spin of the source in (15). Thus, from (19) it is possible to find an interaction between the spin of the source and the skew field.[19] Kalinowski[20] has extended Moffat's version[21] which is described in Einstin-Cartan geometry, to establish a relation between the mass and fermion current curve space-time while the spin of the source is twisting it.

Moreover, Wanas and Kahil have extended the Bazanski approach, applying it in Einstein non-symmetric geometries[22] to reach the conclusion that paths in these geometries are naturally quantized (in the Planck sense of quantization).[10] This type of natural quantization of paths exists in absolute parallelism geometries as well.[11]

III. MOTION IN 5D

The problem of motion in higher dimensions is an intriguing problem. The significance of motion in higher dimensions may yield some indications with regards to the principles that should be followed when describing motion in 4D, i.e., an equation which governs the motion in $4D$[6]. In the present work, we will examine the effect of non gravitational forces on the current motion, i.e., should this motion be absorbed into the extra dimension or remain unchanged from the usual equation of motion in 4D space apart from increasing the dimensions?

A. The Bazanski approach in five dimensions

In an attempt to derive path and path deviation equations in five dimensions, we extend the Bazanski Lagrangian to 5D:

$$L = g_{AB} U^{A} \frac{D\Psi^{B}}{DS} \tag{21}$$

where $(A=1,2,3,4,5)$. By taking the variation with respect to the deviation vector Ψ^{C} and the tangent vector U^{C}, we obtain the geodesic and geodesic deviation equations, respectively,

$$\frac{dU^{C}}{dS} + \left\{ \begin{matrix} C \\ AB \end{matrix} \right\} U^{A} U^{B} = 0, \tag{22}$$

and

$$\frac{D^2\Psi^{C}}{DS^2} = R^{C}_{\cdot ABD} \Psi^{D} U^{A} U^{B}. \tag{23}$$

B. Compact spaces

The process to unify electromagnetism (gauge fields) and gravity depends on extra component(s) of the metric using the cylinder condition.[1] Some authors believe that compact dimensions can be tested, for example, by examining the rate of energy released as a result of gravitational waves from binary pulsars.[23]

In our study, we derive the same geodesic and geodesic deviation equations given by Kerner *et al.*[15] using the Bazanski approach:

$$\frac{dU^{\mu}}{dS}+\left\{\begin{matrix}\mu\\ \nu\lambda\end{matrix}\right\}U^{\nu}U^{\lambda}+\left(\frac{dx^{5}}{dS}+A_{\nu}\frac{dx^{\nu}}{dS}\right)F^{\mu}_{\cdot\lambda}U^{\lambda}=0, \tag{24}$$

$$\frac{d}{dS}\left(\frac{dx^{5}}{dS}+A_{\mu}\frac{dx^{\mu}}{dS}\right)=0. \tag{25}$$

where $Q\equiv dx^{5}/dS+A_{\mu}dx^{\mu}/dS$ is constant along the 5D geodesics, i.e.,

$$\frac{q}{m}=\frac{dx^{5}}{dS}+A_{\mu}\frac{dx^{\mu}}{dS}.$$

Consequently, (24) becomes

$$\frac{dU^{\mu}}{dS}+\left\{\begin{matrix}\mu\\ \nu\lambda\end{matrix}\right\}U^{\nu}U^{\lambda}+\frac{q}{m}F^{\mu}_{\cdot\lambda}U^{\mu}=0, \tag{26}$$

with $ds^{2}=(1-Q^{2})dS^{2}$ and its corresponding path deviation equation becomes:

$$\frac{D^{2}\Psi^{\mu}}{DS^{2}}=R^{\mu}_{\cdot\rho\nu\lambda}U^{\rho}U^{\nu}\Psi^{\lambda}+\frac{q}{m}\left(F^{\mu}_{\cdot\nu;\rho}U^{\nu}\Psi^{\rho}+F^{\mu}_{\cdot\nu}\frac{D\Psi^{\nu}}{DS}\right)+F^{\mu}_{\cdot\lambda}U^{\lambda}\left(\frac{d}{dS}(A_{\lambda}\Psi^{\lambda}+\Psi^{5})+F_{\nu\rho}U^{\nu}\Psi^{\rho}\right) \tag{27}$$

and

$$\frac{d}{dS}((\Psi^{5}+A_{\lambda}\Psi^{\lambda})+F_{\lambda\rho}U^{\rho}\Psi^{\lambda})=0 \tag{28}$$

A charged particle whose behavior is described by the Lorentz equation in 4D behaves as a test particle moving on a geodesic in 5D. This result is obtained from the usual Basanski method in 5D rather than its modified method in 4D.

C. Noncompact spaces

In an attempt to unify geometry and matter, Wesson and his collaborators[3] have assumed that $g_{AB,5}\neq 0$, which is applied in the brane world models[4] and space-time-matter theories.[5] The idea of non-compact spaces is based upon the Campbell-Maagard theorem.[24] Using this approach, Wesson[25] has found that: (1) Massive particles traveling on a time-like geodesic in 4D can be regarded as traveling on a null-geodesic in 5D. This is obvious as an implication of the behavior of wave-like particles in a double slits experiment.

(2) Massive particles traveling on any path may exhibit changes their rest mass because there is a direct contact with the fifth force. In this case, the path equation will be a generalization of the problem of moving particles having variable mass in classical mechanics.

It is well known that the path equation of a charged object described in non-compact space[26] is given by

$$\frac{dU^{\alpha}}{dS}+\left\{\begin{matrix}\alpha\\ \mu\nu\end{matrix}\right\}U^{\mu}U^{\nu}=nF^{\alpha}_{\mu}U^{\nu}U^{\nu}+\epsilon n^{2}\frac{\Phi^{;\alpha}}{\Phi^{3}}-A^{\alpha}\frac{dn}{dS}-g^{\alpha\lambda}\frac{dx^{5}}{dS}\left(nA_{\lambda,5}+g_{\lambda\mu,5}\frac{dx^{\mu}}{dS}\right) \tag{29}$$

and

$$\frac{d}{dS}\epsilon\Phi^{2}\left(\frac{dx^{5}}{dS}+A_{\mu}\frac{dx^{\mu}}{dS}\right)=0, \tag{30}$$

where $n=\epsilon\Phi^{2}(dx^{5}/dS+A_{\mu}U^{\mu})$, Φ is a scalar potential, and $\epsilon=\pm 1$ depending on whether the extra dimension is space-like or time-like, respectively. This leads to $q/m=\epsilon\Phi^{2}(dx^{5}/dS+A_{\mu}U^{\mu})$ in which its scalar field affects the ratio of charge to mass.

However, the above equation has two main defects: *it is not gauge invariant*, and *the additional extra force from an extra dimension is parallel to the four vector velocity* i.e., $f_{\mu}U^{\mu}\neq 0$.

Ponce de Leon[26] has dealt with these two defects by using various types of transformations in order to make (29) and (30) like the geodesic equation in its usual form:

$$\frac{d^{2}\xi^{A}}{dS^{2}}+\left\{\begin{matrix}A\\ BC\end{matrix}\right\}\frac{d\xi^{B}}{dS}\frac{d\xi^{C}}{dS}=0, \tag{31}$$

where ξ^{A} is the projected 5D velocity. This allows us to introduce its corresponding Bazanski Lagrangian:

$$L=g_{AB}\frac{d\xi^{A}}{dS}\frac{D\Psi^{B}}{DS} \tag{32}$$

which gives its geodesic deviation equation as

$$\frac{D^{2}\Psi^{A}}{DS^{2}}=0 \tag{33}$$

D. Path and path deviation equations of nonsymmetric geometries in 5D

We now consider the following Lagrangian:

$$L=\mathbf{g}_{AB}U^{A}\frac{D\Psi^{B}}{DS}+\lambda f_{CE}\Psi^{C}U^{E}, \tag{34}$$

Applying the Bazanski approach to derive the path and path deviation equations by taking the variation with respect to Ψ^{D} and U^{D}, respectively, we obtain:

$$\frac{dU^{A}}{dS}+\left\{\begin{matrix}A\\ BC\end{matrix}\right\}U^{B}U^{C}=\lambda\mathbf{g}^{AD}f_{[DC]}U^{C}+\mathbf{g}^{AD}g_{[CD];M}U^{C}U^{M}, \tag{35}$$

and

$$\frac{D^{2}\Psi^{A}}{DS^{2}}=R^{A}_{.BCD}U^{B}U^{C}\Psi^{D}+2\mathbf{g}^{DA}(g_{[A[D];M]})\frac{D\Psi^{C}}{DS}U^{M}+\lambda\mathbf{g}^{DA}\left(f_{A_{.C}}\frac{D\Psi^{C}}{Ds}+f_{AC;M}U^{C}\Psi^{M}\right). \tag{36}$$

In one version of KK Non-symmetric theory of gravity, Kalinowski[8] has summarized the role of the extra dimension in the following matter: mass and fermion current curve the four dimensions, the spin of the source and the electromagnetic potential twist the fifth dimension.

IV. ROTATION IN 5D

The concept of rotation in higher dimensions is related to obtaining the governing equation of the current spinning object.[27] For a spinning gyroscope it is well known that the fifth equation is testing the rate of precession.[28] Some authors believe that the study of two nearby free-falling gyroscopes could be used to examine the question of the existence of gravitational waves.[16]

We may apply the Bazanski approach on the following Lagrangian:

$$L = g_{AB}U^A\frac{D\Psi^B}{DS} + \frac{1}{2m}R_{ABCD}S^{CD}U^B\Psi^A \tag{37}$$

to derive the path equation of a spinning object in 5D:

$$\frac{\mathrm{d}U^C}{\mathrm{d}S} + \begin{Bmatrix} C \\ AB \end{Bmatrix} U^A U^B = \frac{1}{2m}R^C_{.ABD}S^{BD}U^A. \tag{38}$$

The above equation describes spinning objects in compact spaces which satisfy the cylinder condition, i.e., $g_{AB,5}=0$. This is identical to the Dixon equation if we project it into four dimensions. The fifth coordinate will contribute the electromagnetic tensor, which has already appeared in the Dixon equation.

Also, the original Papapetrou equation in 5D will be as follows:

$$\frac{D}{DS}\left(mU^A + U_E\frac{DS^{AE}}{DS}\right) = \frac{1}{2}R^A_{.BCD}S^{CD}U^B \tag{39}$$

and its corresponding deviation equation will take the following form:

$$\frac{D^2\Psi^A}{DS^2} = R^A_{.BCD}U^B\left(mU^C + U_E\frac{DS^{CE}}{DS}\right)\Psi^D + g^{AC}g_{BE}\left(mU^E + U_O\frac{DS^{EO}}{DS}\right)_{;C}\frac{D\Psi^B}{DS} + R^A_{.BCD}S^{CD}\frac{D\Psi^B}{DS} + R^A_{BCE}S^{CE}_{.;D}U^B\Psi^D + R^A_{BCE;D}S^{CE}U^B\Psi^D. \tag{40}$$

These equations could be used to study the behavior of spinning charged objects that exhibit precession, e.g., neutron stars, compact objects, etc.

In non-compact spaces with $R_{ABCD}=0$, it is found that a spinning particle is moving on a geodesic in 5D rather than the Papapetrou equation.[29] This leads us to suggest that in non-compact spaces, satisfying the Campbell-Magaard theorem, spinning particles and spinning charged particles as well as test particles are moving along geodesics in 5D. But if we consider the original Papapetrou equation in 5D, we can find out that it is different from the usual geodesic equation, i.e.,

$$\frac{D}{DS}\left(mU^A + U_B\frac{DS^{AB}}{DS}\right) = 0. \tag{41}$$

On the contrary, its corresponding deviation equation is identical to (33).

V. DISCUSSION AND CONCLUSION

The Lagrangian required to derive the path and path deviation equations in higher dimensions becomes the conventional Bazanski Lagrangian if the extra fields are described in the fifth (higher) dimension. Path equations of different particles in 4D can be considered as the projection of the geodesic equation in 5D on 4D. But if the extra effect, non-gravitational force, is not totally absorbed in the higher dimensional equations then the Bazanski Lagrangian should be amended like their counterparts in four-dimension, which is seen in the 5D Papapertrou's equation (38).

It has been shown in this paper that the effect of the compactness of the extra dimension(s) can be clearly perceived on moving objects. Also, we find that the effect of precession may distinguish between tops and test particles moving in a background whose 5D curvature has vanished.

In our study we have shown that the apparent Papapetrou equation in 5D is merely the projection of the Dixon equation in 4D. But if the space does not include electromagnetism as an extra dimension, the Papapetrou equation in 4D remains the same in 5D unless the extra dimension space is not compact satisfying the Campbell-Magaard theorem. Also, as can be seen from (25) and (30) the path equations in compact and non-compact spaces display a contradictory aspect: the ratio of charge to mass is constant in the case of compact space, while it is variable depending on the scalar field in case of non-compact spaces, which can be explored due to the effect of the cylinder condition on higher dimensions.

It was shown that in 4D, the Bazanski Lagrangian can be modified to describe path equations for charged, spinning, and spinning charged particles, as well as for spinning objects with precession and their corresponding path deviation equation. In an attempt to find the path and path deviation equations of the above-mentioned particles in 5D, we have found that the Bazanski Lagrangian could remain unmodified if the non-gravitational force could be absorbed into the higher dimension. Otherwise, the Bazanski Lagrangian must be amended.

In our study, we have also found that in non-compact spaces, spinning objects and the non-precessing ones are not following the same trajectory, although their path deviation equations are the same.

We have applied the Bazanski approach to determine path and path deviation equations of one version of the Einstein non-symmetric theories of gravity in 5D. This work could be extended to study the effect of compactness on the path equations in our future work.

ACKNOWLEDGMENTS

(Received 7 September 2005; accepted 30 March 2006; published online 11 May 2006)

The electric and the magnetic part of the Weyl tensor, as well as the invariants obtained from them, are calculated for the Bondi vacuum metric. One of the invariants vanishes identically and the other only exhibits contributions from terms of the Weyl tensor containing the static part of the field. It is shown that the necessary and sufficient condition for the spacetime to be purely electric is that such spacetime be static. It is also shown that the vanishing of the electric part implies Minkowski spacetime. Unlike the electric part, the magnetic part does not contain contributions from the static field. Finally a speculation about the link between the vorticity of world lines of observers at rest in a Bondi frame, and gravitational radiation, is presented. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2199027]

I. INTRODUCTION

The study of the electric $E_{\alpha\beta}$ and magnetic $H_{\alpha\beta}$ parts of Weyl tensor has attracted the attention of researchers for many years (see Refs. 1–19, and references therein).

Particularly intriguing is the eventual relationship of the magnetic part of the Weyl tensor, with rotation[2,9] and with gravitational radiation.[1,5,8,10–12]

On the other hand, the link has been established between gravitational radiation and vorticity of world lines of observers at rest in a Bondi spacetime.[20,21] Specifically, it has been shown that the leading term in the vorticity (in an expansion of powers of $1/r$) is expressed through the news function in such a way that it will vanish if and only if there is no news (no radiation). This suggests the possibility of detecting gravitational waves by means of gyroscopes.[20,22]

In order to delve deeper into these issues, we shall calculate in this work the electric and the magnetic part of the Weyl tensor, as well as the two invariants obtained from them, in the field of gravitational radiation.

From the obtained expressions, it follows that the vanishing of the magnetic part, implies the vanishing of the news function and also the vanishing of nonradiative but time-dependent field, except for a very peculiar class of solutions, called by Bondi "non-natural, non-radiative moving systems." This result, together with the known fact[6] that static Weyl metrics are purely electric,

[a)]Electronic mail: laherrera@movistar.net.ve
[b)]Electronic mail: nos@cbpf.br; santos@ccr.jussieu.fr
[c)]Electronic mail: jcarot@uib.es

implies, if we exclude by physical reasons the class of solutions mentioned before, that the necessary and sufficient condition for a Bondi spacetime to be purely electric is that such spacetime be static.

The vanishing of the electric part of the Weyl tensor is shown to imply that the spacetime is Minkowski. Thus there is no purely magnetic vacuum Bondi spacetimes, in agreement with the conjecture that purely magnetic vacuum spacetimes do no exist.[6,7,9,18,19]

It is also obtained that one of the invariants ($Q \equiv E^{\alpha\beta}H_{\alpha\beta}$) vanishes identically whereas the other ($L \equiv E^{\alpha\beta}E_{\alpha\beta} - H^{\alpha\beta}H_{\alpha\beta}$) has a leading term with contributions only from the coefficients in the expansion of the Weyl tensor which contain the static part of the field. Coefficients containing purely radiative and/or nonradiative but time-dependent part of the field, do not enter in L.

Finally, we shall speculate that the fact that gravitational radiation produces vorticity of a time-like congruence might be explained by a mechanism similar to the one suggested to explain the vorticity of a time-like congruence in the field of a charged static magnetic dipole.[23]

We shall carry out our calculations using the Bondi's formalism[24] which has, among other things, the virtue of providing a clear and precise criterion for the existence of gravitational radiation (see also Ref. 25). Namely, if the news function is zero over a time interval, then there is no radiation during that interval.

The formalism has as its main drawback[26] the fact that it is based on a series expansion which could not give closed solutions and which raises unanswered questions about convergence and appropriateness of the expansion.

However we shall restrain ourselves to a region sufficiently far from the source, so that we shall need in our calculations only the leading terms in the expansion of metric functions. Furthermore, since the source is assumed to radiate during a finite interval, then no problem of convergence appears.[27]

A brief resume of Bondi's formalism is given in the next section, together with the expression of the vorticity of a time-like congruence of observers at rest in a Bondi frame. In Sec. III we present the result of the calculations of the electric and a magnetic part as well as the invariants Q and L, and in the last section results are discussed.

II. BONDI'S FORMALISM

The general form of an axially and reflection symmetric asymptotically flat metric given by Bondi is[24]

$$ds^2 = \left(\frac{V}{r}e^{2\beta} - U^2r^2e^{2\gamma}\right)du^2 + 2e^{2\beta}du dr + 2Ur^2e^{2\gamma}du d\theta - r^2(e^{2\gamma}d\theta^2 + e^{-2\gamma}\sin^2\theta d\phi^2), \quad (1)$$

where V, β, U, and γ are functions of u, r, and θ.

We number the coordinates $x^{0,1,2,3} = u, r, \theta, \phi$, respectively. u is a timelike coordinate such that $u = constant$ defines a null surface. In flat spacetime this surface coincides with the null light cone open to the future. r is a null coordinate ($g_{rr} = 0$) and θ and ϕ are two angle coordinates (see Ref. 24 for details).

Regularity conditions in the neighborhood of the polar axis ($\sin\theta = 0$), imply that as $\sin\theta -> 0$,

$$V, \beta, U/\sin\theta, \gamma/\sin^2\theta, \quad (2)$$

each equals a function of $\cos\theta$ regular on the polar axis.

The four metric functions are assumed to be expanded in series of $1/r$, then using the field equations Bondi gets

$$\gamma = cr^{-1} + \left(C - \tfrac{1}{6}c^3\right)r^{-3} + \cdots, \quad (3)$$

$$U = -(c_\theta + 2c\cot\theta)r^{-2} + [2N + 3cc_\theta + 4c^2\cot\theta]r^{-3}\cdots, \tag{4}$$

$$V = r - 2M - \left(N_\theta + N\cot\theta - c_\theta^2 - 4cc_\theta\cot\theta - \tfrac{1}{2}c^2(1 + 8\cot^2\theta)\right)r^{-1} + \cdots, \tag{5}$$

$$\beta = -\tfrac{1}{4}c^2r^{-2} + \cdots, \tag{6}$$

where c, C, N, and M are functions of u and θ, letters as subscripts denote derivatives, and

$$4C_u = 2c^2c_u + 2cM + N\cot\theta - N_\theta. \tag{7}$$

The three functions c, M, and N are further related by the supplementary conditions

$$M_u = -c_u^2 + \tfrac{1}{2}(c_{\theta\theta} + 3c_\theta\cot\theta - 2c)_u, \tag{8}$$

$$-3N_u = M_\theta + 3cc_{u\theta} + 4cc_u\cot\theta + c_uc_\theta. \tag{9}$$

In the static case M equals the mass of the system whereas N and C are closely related to the dipole and quadrupole moment, respectively.

Next, Bondi defines the mass $m(u)$ of the system as

$$m(u) = \frac{1}{2}\int_0^\pi M\sin\theta d\theta \tag{10}$$

which by virtue of (8) and (2) yields

$$m_u = -\frac{1}{2}\int_0^\pi c_u^2\sin\theta d\theta. \tag{11}$$

Let us now recall the main conclusions emerging from Bondi's approach.

1. If γ, M, and N are known for some $u=a$ (constant) and c_u (the news function) is known for all u in the interval $a \leqslant u \leqslant b$, then the system is fully determined in that interval. In other words, whatever happens at the source, leading to changes in the field, it can only do so by affecting c_u and vice versa. In the light of this comment the relationship between news function and the occurrence of radiation becomes clear.
2. As it follows from (11), the mass of a system is constant if and only if there are no news.

Now, for an observer at rest in the frame of (1), the four-velocity vector has components

$$u^\alpha = \left(\frac{1}{A}, 0, 0, 0\right) \tag{12}$$

with

$$A \equiv \left(\frac{V}{r}e^{2\beta} - U^2r^2e^{2\gamma}\right)^{1/2}. \tag{13}$$

Then, it can be shown that for such an observer the vorticity vector may be written as (see Ref. 20 for details)

$$\omega^\alpha = (0, 0, 0, \omega^\phi) \tag{14}$$

with

$$\omega^{\phi} = -\frac{e^{-2\beta}}{2r^2 \sin\theta}\left[2\beta_{\theta}e^{2\beta} - \frac{2e^{2\beta}A_{\theta}}{A} - (Ur^2e^{2\gamma})_r + \frac{2Ur^2e^{2\gamma}}{A}A_r + \frac{e^{2\beta}(Ur^2e^{2\gamma})_u}{A^2} - \frac{Ur^2e^{2\gamma}}{A^2}2\beta_u e^{2\beta}\right] \tag{15}$$

and for the absolute value of ω^{α} we get

$$\Omega \equiv (-\omega_{\alpha}\omega^{\alpha})^{1/2} = \frac{e^{-2\beta-\gamma}}{2r}\left[2\beta_{\theta}e^{2\beta} - 2e^{2\beta}\frac{A_{\theta}}{A} - (Ur^2e^{2\gamma})_r + 2Ur^2e^{2\gamma}\frac{A_r}{A} + \frac{e^{2\beta}}{A^2}(Ur^2e^{2\gamma})_u - 2\beta_u\frac{e^{2\beta}}{A^2}Ur^2e^{2\gamma}\right]. \tag{16}$$

Feeding back (3)–(6) into (16) and keeping only the two leading terms, we obtain

$$\Omega = -\frac{1}{2r}(c_{u\theta} + 2c_u\cot\theta) + \frac{1}{r^2}[M_{\theta} - M(c_{u\theta} + 2c_u\cot\theta) - cc_{u\theta} + 6cc_u\cot\theta + 2c_uc_{\theta}]. \tag{17}$$

Therefore, up to order $1/r$, a gyroscope at rest in (1) will precess as long as the system radiates ($c_u \neq 0$). Observe that if

$$c_{u\theta} + 2c_u\cot\theta = 0 \tag{18}$$

then

$$c_u = \frac{F(u)}{\sin^2\theta}, \tag{19}$$

which implies

$$F(u) = 0 \Rightarrow c_u = 0 \tag{20}$$

in order to ensure regularity conditions, mentioned earlier, in the neighborhood of the polar axis ($\sin\theta = 0$). Thus the leading term in (17) will vanish if and only if $c_u = 0$.

The order $1/r^2$ contains, beside the terms involving c_u, a term not involving news, namely M_{θ}. This last term represents the class of nonradiative motions discussed by Bondi[24] and may be thought of as corresponding to the tail of the wave, appearing after the radiation process.[26]

Let us now assume that initially (before some $u = u_0 = \text{constant}$) the system is static, in which case

$$N_u = c_u = 0 \tag{21}$$

which implies, because of (9),

$$M_{\theta} = 0 \tag{22}$$

and $\Omega = 0$ (actually, in this case $\Omega = 0$ at any order) as expected for a static field (for the electrovacuum case however, this may change[23]). Then let us suppose that at $u = u_0$ the system starts to radiate ($c_u \neq 0$) until $u = u_f$, when the news vanish again. For $u > u_f$ the system is not radiating although (in general) $M_{\theta} \neq 0$ implying (see for example (9)) time dependence of metric functions (nonradiative motions[24]).

For $u > u_f$ there is a vorticity term of order $1/r^2$ describing the effect of the tail of the wave. This in turn provides "observational" evidence for the violation of the Huygens's principle, a problem largely discussed in the literature (see, for example Refs. 24 and 26, and references therein).

III. THE ELECTRIC AND MAGNETIC PARTS OF WEYL TENSOR

The electric and magnetic parts of Weyl tensor, $E_{\alpha\beta}$ and $H_{\alpha\beta}$, respectively, are formed from the Weyl tensor $C_{\alpha\beta\gamma\delta}$ and its dual $\tilde{C}_{\alpha\beta\gamma\delta}$ by contraction with the four velocity vector given by (12):[28]

$$E_{\alpha\beta} = C_{\alpha\gamma\beta\delta} u^{\gamma} u^{\delta}, \tag{23}$$

$$H_{\alpha\beta} = \tilde{C}_{\alpha\gamma\beta\delta} u^{\gamma} u^{\delta} = \tfrac{1}{2} \epsilon_{\alpha\gamma\epsilon\delta} C^{\epsilon\delta}_{\beta\rho} u^{\gamma} u^{\rho}, \quad \epsilon_{\alpha\beta\gamma\delta} \equiv \sqrt{-g}\, \eta_{\alpha\beta\gamma\delta}, \tag{24}$$

where $\eta_{\alpha\beta\gamma\delta} = +1$ for $\alpha, \beta, \gamma, \delta$ in even order, -1 for $\alpha, \beta, \gamma, \delta$ in odd order, and 0 otherwise. Also note that

$$\sqrt{-g} = r^2 \sin\theta e^{2\beta} \approx r^2 \sin\theta \exp\left(-\frac{c^2}{2r^2}\right) \approx r^2 \sin\theta + O(1).$$

Since the obtained expressions are fairly long, in order to check our results we have calculated the magnetic and electric parts in two different ways and then compared results, excluding thereby any possible error. On the one hand we have calculated with MAPLE the components of Weyl tensor and from them, "by hand" its electric and magnetic part from (23) and (24). We do not include here the detailed expressions of Weyl components, but they are available upon request. The only nonvanishing components of Weyl tensor are

$$C_{0101}, C_{0102}, C_{0112}, C_{0202}, C_{0212}, C_{0303},$$

$$C_{0313}, C_{0323}, C_{1212}, C_{1313}, C_{1323}, C_{2323}.$$

However they are not independent, since the following relations between them exist:

$$\frac{r^4 \sin^2\theta}{e^{2\beta}} C_{1010} = e^{2\gamma}(V - r^4 e^{2\gamma - 2\beta}) C_{1313} - 2r^2 e^{2\gamma} C_{0313}, \tag{25}$$

$$\frac{r^2 \sin^2\theta}{e^{2\gamma}} C_{0112} = e^{2\beta} C_{1323} - r^2 e^{2\gamma} C_{1313}, \tag{26}$$

$$\frac{2r^2 \sin^2\theta}{e^{2\gamma}} C_{0212} = e^{2\beta} C_{2323} - r e^{2\gamma} C_{1313}, \tag{27}$$

$$\sin^2\theta C_{1212} = -e^{4\gamma} C_{1313}. \tag{28}$$

On the other hand, we have calculated the magnetic and electric part using GRTENSOR. Thus, one has for the components of the magnetic Weyl tensor, up to the order $1/r^3$:

$$H^0_0 = H^0_1 = H^0_2 = H^1_0 = H^1_1 = H^1_2 = H^2_0 = H^2_1 = H^2_2 = H^3_0 = H^3_3 = 0, \tag{29}$$

$$\begin{aligned} H^0_3 = &-\frac{1}{r}(2c_u \cos\theta + c_{\theta u} \sin\theta) \\ &+ \frac{1}{r^2}\left\{ 4c_u(c - M)\cos\theta + \left[\frac{3}{2}(N_u + M_\theta + c_u c_\theta) + \frac{7}{2} c c_{\theta u} - 2M c_{\theta u} \right] \sin\theta \right\} \\ &+ \frac{1}{r^3}\left\{ -\frac{N}{\sin\theta}(1 + 2c_u) + \left[8M c_u (c - M) + N_\theta (1 - 2c_u) + \frac{5}{2} c^2 c_u - N c_{\theta u} - P_u - 4Mc \right] \right. \end{aligned}$$

$$\times\cos\theta+\left[2(N-Mc_\theta)-c_{\theta u}\left(7Mc-4M^2-N_\theta-\frac{7}{4}c^2\right)+3M(N_u+M_\theta)\right.$$
$$\left.-\frac{1}{2}P_{\theta u}-3cM_\theta+N_{\theta\theta}+c_u\left(8N+3Mc_\theta+\frac{5}{2}cc_\theta\right)\right]\sin\theta\Bigg\}, \tag{30}$$

$$H_3^1=\frac{1}{r}[(c_\theta c_{uu}+c_{\theta u})\sin\theta+2(cc_{uu}+c_u)\cos\theta]+\frac{1}{r^2}\Bigg\{\frac{4cc_u\cos\theta}{\sin^2\theta}+\frac{2c_uc_\theta-cc_{\theta u}}{\sin\theta}$$
$$+\left[-\frac{1}{2}c_\theta c_{\theta\theta u}+(2M-3c)c_\theta c_{uu}-\frac{5}{2}(cc_{\theta u}+c_uc_\theta)-2Nc_{uu}-\frac{3}{2}(N_u+M_\theta)\right]$$
$$\times\sin\theta+\left[-6cc_u+4c(M-c)c_{uu}-\frac{1}{2}c_\theta c_{\theta u}-cc_{\theta\theta u}\right]\cos\theta\Bigg\}$$
$$+\frac{1}{r^3}\Bigg\{\frac{8cc_u(M-c)\cos\theta}{\sin^2\theta}+\frac{1}{\sin\theta}[c_uc_\theta(4M-3c)+N-2cN_u+2Ncc_{uu}$$
$$+cc_{\theta u}(7c-2M)-4c_uN-cM_\theta]+\left[\frac{1}{2}P_{\theta u}-N_{\theta\theta}-2N+4cM_\theta-4c_uN+2cN_u\right.$$
$$+c_uc_\theta\left(-\frac{9}{2}c-M+cc_u+\frac{1}{2}c_{\theta\theta}\right)+c_\theta\left(2M-cM_u+P_{uu}+N_{\theta u}+\frac{1}{2}M_{\theta\theta}\right)$$
$$+c_{\theta u}\left(-\frac{19}{4}c^2+2c_\theta^2+2Mc\right)+c_{\theta\theta u}(N+3cc_\theta-Mc_\theta)$$
$$\left.+c_\theta c_{uu}\left(-6Mc+\frac{1}{2}c^2+N_\theta+4M^2\right)-2Nc_{uu}(c+2M)\right]\sin\theta$$
$$+\left[2c\left(2M+N_{\theta u}+P_{uu}-cM_u+\frac{1}{2}M_{\theta\theta}\right)+c_u\left(-2Mc-\frac{3}{2}c^2+2c^2c_u+\frac{3}{2}c_\theta^2+cc_{\theta\theta}\right)\right.$$
$$+c_{\theta u}(N-Mc_\theta+8cc_\theta)+c_{uu}(c^3+2cN_\theta+Nc_\theta-8Mc^2+8M^2c)$$
$$\left.+cc_{\theta\theta u}(5c-2M)-c_\theta\left(\frac{1}{2}M_\theta+N_u\right)+P_u-N_\theta\right]\cos\theta\Bigg\}, \tag{31}$$

$$H_3^2=\frac{1}{r}(\sin\theta c_{uu})+\frac{1}{r^2}\left\{\frac{2c_u}{\sin\theta}-\frac{1}{2}c_{\theta u}\cos\theta+\left[2c_{uu}(M-c)-c_u-\frac{1}{2}c_{\theta\theta u}\right]\sin\theta\right\}$$
$$+\frac{1}{r^3}\Bigg\{4c_u\frac{M-c}{\sin\theta}+\left[\frac{3}{2}c_uc_\theta-N_u-\frac{1}{2}M_\theta+Nc_{uu}+\left(\frac{7}{2}c-M\right)c_{\theta u}\right]\cos\theta$$
$$+\left[\left(\frac{5}{2}c-M\right)c_{\theta\theta u}+\left(\frac{1}{2}c_{\theta\theta}-M\right)c_u+2c_\theta c_{\theta u}+c_{uu}\right.$$
$$\left.\times(2c^2+4M^2-4Mc+N_\theta)+\frac{1}{2}M_{\theta\theta}-cM_u+N_{\theta u}+P_{uu}+cc_u^2\right]\sin\theta\Bigg\}, \tag{32}$$

$$H_1^3=\frac{1}{r^3}\frac{2c_u\cos\theta+c_{\theta u}\sin\theta}{\sin^2\theta}, \tag{33}$$

$$H_2^3=\frac{1}{r\sin\theta}\frac{c_{uu}}{}+\frac{1}{r^2\sin\theta}\Bigg[2c_{uu}(c+M)-c_u-\frac{1}{2}c_{\theta\theta u}-\frac{1}{2}\cot\theta c_{\theta u}+2\frac{c_u}{\sin^2\theta}\Bigg]$$
$$+\frac{1}{r^3\sin\theta}\Bigg\{\frac{4Mc_u}{\sin^2\theta}+\cot\theta\Bigg[-N_u+Nc_{uu}-\frac{1}{2}c_uc_\theta-\left(\frac{1}{2}c+M\right)c_{\theta u}-\frac{1}{2}M_\theta\Bigg]$$
$$+c_{uu}(N_\theta+4Mc+4M^2+2c^2)+cc_u^2+\left(\frac{1}{2}c_{\theta\theta}-M\right)c_u+\left(\frac{1}{2}c-M\right)c_{\theta\theta u}$$
$$+P_{uu}+\frac{1}{2}M_{\theta\theta}+c_\theta c_{\theta u}-cM_u+N_{\theta u}\Bigg\}. \tag{34}$$

Regarding the electric part, one gets, up to the order $1/r^3$:

$$E_0^0=E_3^0=E_0^1=E_3^1=E_0^2=E_3^2=E_0^3=E_1^3=E_2^3=0, \tag{35}$$

$$E_1^0=\frac{2(cc_u+M)}{r^3}, \tag{36}$$

$$E_2^0=\frac{2c_u\cos\theta+c_{\theta u}\sin\theta}{r\sin\theta}+\frac{1}{2\sin\theta r^2}$$
$$\times\{8Mc_u\cos\theta+[c_{\theta u}(4M-3c)-3(M_\theta+c_uc_\theta+N_u)]\sin\theta\}$$
$$+\frac{1}{4r^3}\Bigg\{(1+2c_u)\frac{4N}{\sin^2\theta}+\cot\theta[4(Nc_{\theta u}+P_u-N_\theta)+c_u(32M^2+8N_\theta-42c^2)]$$
$$+4(N-3cN_u-N_{\theta\theta})-12M(M_\theta+N_u)+c_{\theta u}(4N_\theta+16M^2-13c^2-12Mc)$$
$$-c_u(30cc_\theta+12Mc_\theta+32N)+2P_{\theta u}\Bigg\}, \tag{37}$$

$$E_1^1=-\frac{2cc_u(1+\cos^2\theta)+(c_\theta c_{\theta u}+2M)\sin^2\theta+2\sin\theta\cos\theta(c_uc_\theta+cc_{\theta u})}{r^3\sin^2\theta}, \tag{38}$$

$$E_2^1=-\frac{2(cc_{uu}+c_u)\cos\theta+(c_\theta c_{uu}+c_{\theta u})\sin\theta}{r\sin\theta}+\frac{1}{2r^2}$$
$$\times\Bigg\{3(N_u+M_\theta)+c_{uu}(2cc_\theta-4Mc_\theta+4N)+5c_\theta c_u+c_\theta c_{\theta\theta u}+cc_{\theta u}$$
$$+\cot\theta[2c(c_{\theta\theta u}+2c_u-4Mc_{uu})+c_\theta c_{\theta u}]+\frac{2}{\sin^2\theta}(cc_{\theta u}-2c_\theta c_u)-\frac{8}{\sin^3\theta}cc_u\cos\theta\Bigg\}$$
$$-\frac{1}{r^3}\Bigg\{8cc_u(M-c)\frac{\cos\theta}{\sin^3\theta}+\frac{1}{\sin^2\theta}\Big[(4M-7c)c_uc_\theta-4c_uN+2Ncc_{uu}$$
$$+(c^2-2Mc)c_{\theta u}+N-c(M_\theta+2N_u)\Big]+\cot\theta\Bigg[c_u\left(-\frac{1}{2}c_\theta^2-2Mc+cc_{\theta\theta}+2c^2c_u-\frac{15}{2}c^2\right)$$
$$+c_\theta\left(c_{uu}N+(3c-M)c_{\theta u}-N_u-\frac{1}{2}M_\theta\right)+cc_{uu}(8M^2-3c^2+2N_\theta)$$
$$+cc_{\theta\theta u}(3c-2M)+c_{\theta u}N+cM_{\theta\theta}+P_u-N_\theta+2c(P_{uu}+N_{\theta u}-M-cM_u)\Bigg]$$
$$+c_{uu}\Bigg[c_\theta\left(-\frac{7}{2}c^2+N_\theta-2Mc+4M^2\right)-6Nc-4MN\Bigg]$$

$$+c_u\left[c_\theta\left(\frac{1}{2}c_{\theta\theta}-\frac{9}{2}c-M+cc_u\right)-4N\right]+c_{\theta u}\left(c_\theta^2+2Mc-\frac{15}{4}c^2\right)+c_{\theta\theta u}(N-Mc_\theta+2cc_\theta)$$
$$+c_\theta\left(\frac{1}{2}M_{\theta\theta}-M+N_{\theta u}+P_{uu}-M_uc\right)-N_{\theta\theta}+\frac{1}{2}P_{\theta u}-cN_u+N+cM_\theta\Bigg\}, \tag{39}$$

$$E_1^2=-\frac{2c_u\cos\theta+c_{\theta u}\sin\theta}{r^3\sin\theta}, \tag{40}$$

$$E_2^2=-\frac{c_{uu}}{r}+\frac{1}{2r^2}\left(c_{\theta\theta u}-4Mc_{uu}+2c_u+\cot\theta c_{\theta u}-\frac{4c_u}{\sin^2\theta}\right)$$
$$+\frac{1}{r^3}\Bigg\{M_uc-\frac{1}{2}M_{\theta\theta}+M-N_{\theta u}-P_{uu}+\cot\theta\left[Mc_{\theta u}+\frac{1}{2}M_\theta+N_u-\frac{1}{2}cc_{\theta u}+\frac{1}{2}c_\theta c_u-Nc_{uu}\right]$$
$$+c_u\left[\frac{4(c-M)}{\sin^2\theta}+M-c-cc_u-\frac{1}{2}c_{\theta\theta}\right]-c_{uu}(4M^2+N_\theta)-c_\theta c_{\theta u}+c_{\theta\theta u}\left(M-\frac{3}{2}c\right)\Bigg\}, \tag{41}$$

$$E_3^3=\frac{c_{uu}}{r}-\frac{1}{2r^2}\left(c_{\theta\theta u}-4Mc_{uu}+2c_u+\cot\theta c_{\theta u}-\frac{4c_u}{\sin^2\theta}\right)$$
$$+\frac{1}{r^3}\Bigg\{M+N_{\theta u}+P_{uu}+\frac{1}{2}M_{\theta\theta}-cM_u+\cot\theta\left[\frac{5}{2}cc_{\theta u}-\frac{1}{2}M_\theta-N_u+Nc_{uu}-Mc_{\theta u}+\frac{3}{2}c_uc_\theta\right]$$
$$+c_u\left[\frac{4M}{\sin^2\theta}+cc_u-M+\frac{1}{2}c_{\theta\theta}-c\right]+c_{uu}(4M^2+N_\theta)+2c_\theta c_{\theta u}+\left(\frac{3}{2}c-M\right)c_{\theta\theta u}\Bigg\}, \tag{42}$$

where

$$P\equiv C-\frac{c^3}{6}. \tag{43}$$

We shall now provide expressions for the two algebraic invariants associated to the electric and magnetic parts of the Weyl tensor, namely

$$Q=H^\alpha_\beta E^\beta_\alpha,\quad L=E^\alpha_\beta E^\beta_\alpha-H^\alpha_\beta H^\beta_\alpha. \tag{44}$$

As it turns out, the invariant Q vanishes identically, i.e.,

$$Q=0, \tag{45}$$

whereas the first nonvanishing order in L is $1/r^6$ and one then has

$$L=\frac{2}{r^6}\left[3(cc_u+M)^2+(c^3+6P)c_{uu}+6N(c_{\theta u}+2c_u\cot\theta)\right]+O(1/r^7). \tag{46}$$

IV. DISCUSSION

We are now ready to try to answer the main questions which motivated this work, in the context of the Bondi metric, namely:

- What consequences emerge from the vanishing of the magnetic part of the Weyl tensor?
- What consequences emerge from the vanishing of the electric part of the Weyl tensor?
- How do different types of fields (radiative, nonradiative but time dependent, and static) enter into the electric and magnetic part of the Weyl tensor, and into the corresponding invariants?

- Why does gravitational radiation produce vorticity?

Let us start with the first question. If we put $H^{\alpha}_{\beta}=0$ then it follows from the coefficient of $1/r$ in (30) that

$$c_{\theta u}\sin\theta+2c_u\cos\theta=0, \tag{47}$$

which according to (19) and (20) implies

$$c_u=0. \tag{48}$$

Thus the field is nonradiative. Next, the vanishing of the coefficient $1/r^2$ in (30) implies in turn that

$$M_{\theta}=N_u=0, \tag{49}$$

where we have used (9).

Finally from the vanishing of the coefficient of the $1/r^3$ in (30) it follows that

$$N_{\theta\theta}\sin^2\theta+N_{\theta}\sin\theta\cos\theta-N\cos 2\,\theta-(2cM\sin^2\theta)_{\theta}=0 \tag{50}$$

whose general solution is

$$N=\left(\int\frac{2cM}{\sin\theta}d\theta+\sigma\right)\sin\theta \tag{51}$$

where σ is a constant.

Feeding back (51) into (7) and using (48), it follows that

$$C_u=0. \tag{52}$$

It can be easily checked that no further information can be obtained from (31) and (34). Therefore up to order $1/r^3$ in γ, the metric is static, and the mass, the "dipole" (N), and the "quadrupole" (C) moments correspond to a static situation. However, the time dependence might enter through coefficients of higher order in γ, giving rise to what Bondi calls "non-natural non-radiative moving system" (nnnrms). In this later case, the system keeps the three first moments independent of time, but allows for time dependence of higher moments. As unlikely as this situation may be from the physical point of view, we were not able not rule it out mathematically. On the other hand it is known that static spacetimes are purely electric. Accordingly, we conclude that, excluding nnnrms, the necessary and sufficient condition for a Bondi metric to be purely electric is to be static.

The second question has a simple answer. Indeed assuming $E^{\alpha}_{\beta}=0$ and using regularity conditions, we find from the coefficient of order $1/r$ in (37)

$$c_u=0, \tag{53}$$

then it follows at once from (36) that $M=0$. If we exclude the possibility of negative masses, then the spacetime must be Minkowski, giving further support to the conjecture that there are no purely magnetic vacuum spacetimes.[9]

The third question also has a simple answer. The electric part contains all kinds of contributions, radiative, nonradiative but time dependent (nrtd), and static. At order $1/r$ only radiative contributions appear, whereas nrtd terms appear at order $1/r^2$, and higher and contributions from the static field enter in the $1/r^3$ order, and higher. However the magnetic part does not contain contribution from the static field. Only radiative (at order $1/r$ and higher) and nrtd terms (at order $1/r^2$ and higher) appear.[28]

On the other hand, the only nonvanishing invariant (L) has a leading term of order $1/r^6$ implying that purely radiative and nrtd terms in the Weyl tensor do not contribute to L. This is in agreement with the fact that for purely radiative spacetimes, both invariants Q and L vanish.[8]

Finally, let us consider the last question. With this purpose in mind, it is worth recalling a result obtained by Bonnor[23] concerning the dragging of inertial frames by a charged magnetic dipole. To explain the appearance of vorticity in such spacetimes, Bonnor notices that the corresponding electromagnetic Poynting vector has a nonvanishing component, describing a flow of electromagnetic energy round in circles where frame-dragging occurs.[29] He then suggests that such a flow of energy affects inertial frames by producing vorticity of congruences of particles, relative to the compass of inertia.

One could speculate about a similar mechanism in our case, i.e., a flow of gravitational radiation in the ϕ direction. However for testing such a conjecture we should have available a unique expression for a "gravitational" Poynting vector, which is still an open question in general relativity.

Thus for example, the super-Poynting vector based on the Bel–Robinson tensor, as defined in Ref. 15, is

$$P_\alpha = \epsilon_{\alpha\beta\gamma\delta} E^\beta_\rho H^{\gamma\rho} u^\delta \tag{54}$$

giving in our case $P^\phi = 0$. However, besides the ambiguity problem in the definition of energy, this negative result may be caused by the reflection symmetry of the Bondi metric, which intuitively seems to be incompatible with the presence of a circular flow of energy in the ϕ direction. In order to clarify this situation, P^ϕ should be calculated for the general radiative metric without reflection symmetry,[30] but this of course is out of the scope of the present work.

We prove the local existence of solutions of nonlinear Dirac and Dirac-Klein-Gordon equations in Kerr metric with regular Cauchy initial datas. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2196240]

I. INTRODUCTION

This paper deals with the Cauchy problem for nonlinear Dirac and Dirac-Klein-Gordon equations in Kerr space–time. This curved space–time is one of physical relevant space–time solution of Einstein equations in vacuum. More precisely in Boyer-Lindquist coordinates on $\mathcal{M}:=\mathbb{R}_t \times \mathbb{R}_r \times S^2_\omega$, we have

$$g_{\mu\nu}\,\mathrm{d}x^\mu\,\mathrm{d}x^\nu = \left(1-\frac{2Mr}{\rho^2}\right)\mathrm{d}t^2 + \frac{4aMr\sin^2\theta}{\rho^2}\mathrm{d}t\,\mathrm{d}\varphi - \frac{\rho^2}{\Delta}\mathrm{d}r^2 - \rho^2\,\mathrm{d}\theta^2 - \frac{\sigma^2}{\rho^2}\sin^2\theta\,\mathrm{d}\varphi^2,$$

$$\sigma^2 := (r^2+a^2)\rho^2 + 2Mra^2\sin^2\theta, \quad \Delta := r^2 - 2Mr + a^2,$$

$$\rho^2 := r^2 + a^2\cos^2\theta. \tag{1}$$

The manifold $(\mathcal{M},g)$ describes a rotating uncharged black hole where M is its mass and a is its angular momentum per unit mass. Briefly, we remark that we have two types of singularities: a true curvature singularity, the space of points $\{\rho;\rho^2=0\}$, and the coordinates singularities, the sphere(s) where Δ vanishes. This last property defines the horizon of the black-hole. Roughly speaking the sphere-horizon are the regions for which an observer does not cross and comes back them without a speed greater than the light. Finally the number of real roots of Δ ($\leqslant 2$) define three types of Kerr black hole:

(i) Δ has no real root, i.e., for $|a|>M$, there are no horizon and the ring $\{\rho;\rho^2=0\}$ is a naked singularity.
(ii) Δ has double root, i.e., for $|a|=M$, $\{r=M\}$ is the only horizon, this is the extreme Kerr space–time.
(iii) For $0<|a|<M$, Δ has two real roots,

$$r_\pm = M \pm \sqrt{M^2-a^2}, \tag{2}$$

so there are two horizons $\{r=r_-\}$ and $\{r=r_+\}$. This is the slow Kerr space–time.

In the sequel we consider this last type of Kerr black-hole. Hence the two horizons define three regions of the space–time. The block III ($\mathcal{B}_{\mathrm{III}}$), $\{r<r_-\}$ contains the ring singularity and a time machine. The block II ($\mathcal{B}_{\mathrm{II}}$), $\{r_-<r<r_+\}$, is a dynamic region where an inertial observer is dragged toward the horizon $\{r=r_-\}$. The block I ($\mathcal{B}_{\mathrm{I}}$), $\{r>r_+\}$ is the exterior of the black-hole.

[a)]Electronic mail: fabrice.melnyk@math.u-bordeaux1.fr

Moreover, $\mathcal{B}_{\mathrm{I}}$ is not stationary, i.e., the killing vector field $K:=\partial/\partial t$ is not timelike in all block I. The region $\mathcal{E}\subset\mathcal{B}_{\mathrm{I}}$ where K is spacelike in $\mathcal{B}_{\mathrm{I}}$ ($g_{tt}<0$) is called the ergosphere,

$$\mathcal{E} := \{(t,r,\theta,\varphi): r_+ < r < M + \sqrt{M^2 - a^2\cos^2\theta}\}.$$

We study on $(\mathcal{B}_{\mathrm{I}},g)$ the solutions of the nonlinear Dirac equation (NLD):

$$i\gamma^\mu\nabla_\mu\Psi - m_d\Psi = k(\Psi^*\mathcal{V}_1\Psi)\Psi, \tag{3}$$

where $m_d>0$ is the mass of the spin-1/2 field, $\mathcal{V}_1$ a matrix and $k\in L^\infty(\mathcal{B}_{\mathrm{I}})$. γ^μ are the Dirac matrices. We also study the Dirac-Klein-Gordon system (DKG),

$$i\gamma^\mu\nabla_\mu\Psi - m_d\Psi = \Phi\mathcal{V}_2\Psi,$$

$$\Box_g\Phi + m_{kg}^2\Phi = \Psi^*\mathcal{V}_3\Psi, \tag{4}$$

where $m_{kg}>0$ is the mass of the spin-0 field, $\mathcal{V}_2$, $\mathcal{V}_3$ two matrices and $\Box_g$ the Laplacian for the Lorentzian metric g.

The difficulties of these studies on this type of space–time are principally due to the fact that we must work with a curved manifold with less symmetries than flat space–time. Moreover in $\mathcal{B}_{\mathrm{I}}$ of Kerr black-hole and for the spin-0 fields (wave, Klein-Gordon equations) the phenomenon of the super-radiance takes place. It is a consequence of the absence of globally defined timelike Killing vector field that implies the nonexistence of positive-definite conserved quantities useful to define a functional framework to study the field equation. The super-radiance is the analogue for spin-0 fields of the Penrose experience of extraction of energy from the ergosphere. On the other hand, the spin-1/2 field always possess a conserved current inducing a positive-definite inner product. Therefore the super-radiance seems not to be a real problem to prove the existence of the solutions of (3) unlike of (4) since the system consists in the Klein-Gordon field of spin-0.

The first paper about Cauchy problem for a nonlinear field equation in the black-hole background concerns the Klein-Gordon equation.[32] Later, the author extended in Ref. 34 his first work for the nonlinear Klein-Gordon equation in Schwarzschild metric [$a=0$ in (1)] to the Kerr metric. To overcome the problem of the super-radiance, he used the geometrical 3+1 decomposition (ADM) of the Block I. It consists in adopt the coordinates of fixed observer with the respect to infinity. Indeed, we recall that the exterior of the black-hole $\mathcal{B}_{\mathrm{I}}$ is dynamic, i.e., an inertial observer turns with the black hole. Using the ADM decomposition we have outside the black hole

$$\mathcal{B}_{\mathrm{I}} = \mathbb{R}_\tau\times\Sigma, \quad g = N^2\,\mathrm{d}\tau^2 - h(\tau), \tag{5}$$

where N is called the lapse function and h is the spacelike metric. We prove that $N\to 0$ at the horizon and that $h(\tau)$ is equivalent uniform in space and locally uniform in time to the euclidean metric outside a unit closed ball in $\mathbb{R}^3$ ($\Sigma\cong\mathbb{R}^3\backslash\bar{B}(0,1)$). In this framework the Klein-Gordon equation [but also our equations (3) and (4)] have the form of an evolution problem on natural Hilbert space. The norm of this Hilbert space is not *a priori* conserved but it is controlled by an energy estimate. The author of Ref. 34 proves the global existence and the uniqueness for weakly regular initial data (energy data $H^1\oplus L^2$). Indeed this regularity is sufficient to give sense of an equivalent integral formulation of the nonlinear Cauchy problem since we have a cubic nonlinearity and the Sobolev embedding $H^1\hookrightarrow L^6$. Moreover the globalization is obtained thanks to an energy estimate.

For our problems, the charge spaces are L^2 for (NLD) and $L^2\oplus H^1\oplus L^2$ for (DKG). These regularities do not allow us to control the nonlinear terms of the equations. Hence, we take the more regular data for our study: H^2 for (NLD) and $H^2\oplus H^2\oplus H^1$ for (DKG). The important property that $h(t)$ is equivalent to the euclidean metric outside a unit closed ball gives, thanks to the flat Sobolev embedding in $\mathbb{R}^3, H^2\hookrightarrow L^\infty$, the same embedding for the curved space. This allows us to control the nonlinear terms. The global existence is much more difficult since for our equations, we do not have the conservation or control of the norm H^2 for (NLD) or $H^2\oplus H^2$

$\oplus H^1$ for (DKG). Usually for (3) and (4) in the flat space-time, we obtain the global existence for the sufficiently small initial data in often using the sharper estimations. See this as well as possible exhaustive list of papers: For Dirac semilinear equation, Refs. 35, 36, and 19. For nonlinear Dirac equation, Refs. 30, 27, 28, 37, 31, 15, 4, 5, 27, 16, 17, 14, 13, 12, and 11. For Dirac-Klein-Gordon, Refs. 20, 29, 26, 8, 7, 6, 40, 18, 3, 2, 1, 39, 38, 10, and 9. Obviously the sharp estimates in curved space–time (like Strichartz) are a problem of great complexity, and in ours case there are not proved.

The paper is organized as follows. The second section concerns the $3+1$ decomposition. In the third and fourth we treat, respectively, of Cauchy problem for Dirac and Dirac-Klein-Gordon equation.

II. THE ADM 3+1 DECOMPOSITION OF THE KERR BLOCK I

Usually, to describe the Kerr space-time we adopt the Boyer-Lindquist coordinates $(t,r,\omega) \in \mathbb{R}_t \times \mathbb{R}_r^+ \times S_\omega^2$. We have a time function t globally defined in Block I, i.e., ∇t is a timelike future oriented vector field in $\mathcal{B}_\mathrm{I}$. This function provides a foliation $\{\Sigma_t\}_{t\in\mathbb{R}}$ of $\mathcal{B}_\mathrm{I}$ by its level Cauchy hypersurfaces. Moreover, $K=a\,.\,\partial/\partial t$, $a\in\mathbb{R}$, is the only Killing vector field timelike near spacelike infinity. It fixes the product structure $\mathcal{B}_\mathrm{I}:=\mathbb{R}_t\times\Sigma$, i.e., the identification of points of Σ_t along the integral lines of K. We remark that $\partial/\partial t$ is not timelike everywhere in $\mathcal{B}_\mathrm{I}$. Indeed, $g_{tt}\leqslant 0$ if $(t,r,\omega)\in\mathcal{E}$ and $g_{tt}\geqslant 0$ if $(t,r,\omega)\in\mathcal{B}_\mathrm{I}\backslash\mathcal{E}$. Hence, there exists no global timelike Killing vector field in $\mathcal{B}_\mathrm{I}$. Therefore, this space–time is not stationary. We know that the function t of the Boyer-Lindquist coordinates is a time function. Hence t can be used as time parameter in an evolution equation on $\mathcal{B}_\mathrm{I}=\mathbb{R}_t\times\Sigma$,

$$\Sigma = \,]\, r_+, +\infty[\, \times S_\omega^2. \tag{6}$$

Since the metric g is time independent in the Boyer Lindquist coordinates ($\partial/\partial t$ is a Killing vector field), then the coefficients of the field equation are also time independent.

Now, we point out the difficulties linked to the Boyer-Lindquist coordinates to study a Cauchy problem for equations (3) and (4). These difficulties are mainly due to the nonglobally timelike definition of the Killing vector field $\partial/\partial t$. Indeed, we consider $T_{\mu\nu}$ the stress-energy-momentum tensor for the following scalar field u such that

$$\Box_g u + m^2 u = 0, \quad \nabla^\mu T_{\mu\nu} = 0. \tag{7}$$

Since $\partial/\partial t$ is a Killing vector then the 1-form $T_{\mu 0}\,\mathrm{d}x^\mu$ is closed. Now, we denote by $\mathbf{T}$ the unit future oriented vector field which is normal to Σ_t such that

$$\mathbf{T}^\mu \frac{\partial}{\partial x^\mu} = \sqrt{\frac{\sigma^2}{\Delta\rho^2}}\left(\frac{\partial}{\partial t} + \frac{2aMr}{\sigma^2}\frac{\partial}{\partial\varphi}\right). \tag{8}$$

Then the energy of the field measured by an observer (static at infinity) whose 4-velocity vector is $\partial/\partial t$ is given by

$$E(u,t) := \int_{\Sigma_t} \mathbf{T}^\mu T_{\mu 0}\mathrm{dVol}, \quad \mathrm{dVol} = \sqrt{\frac{\rho^2\sigma^2}{\Delta}}\mathrm{d}r\,\mathrm{d}\omega \tag{9}$$

where dVol is the volume measure on Σ. Hence,

$$E(u,t) = \int_\Sigma \left(|\partial_t u(t)|^2 + \frac{\Delta^2}{\sigma^2}|\partial_r u(t)|^2 + \frac{\Delta}{\sigma^2}|\partial_\theta u(t)|^2 + \frac{\rho^2-2Mr}{\sigma^2\sin^2\theta}|\partial_\varphi u(t)|^2 + \frac{\Delta\rho^2 m^2}{\sigma^2}|u(t)|^2\right)\frac{\sigma^2}{\Delta}\mathrm{d}r\,\mathrm{d}\omega. \tag{10}$$

Clearly, the fourth term is positive outside the ergosphere and negative inside. Hence the energy is not positive definite in all $\mathcal{B}_\mathrm{I}$. This property allows superradiance to take place outside the black

hole. Hence we do not choose this energy space to study the Cauchy problem with a system which contains a spin-0 field as (4). Then, the study is more difficult but not impossible, see, for example, the strategy used in Ref. 24. Roughly speaking, it consists in finding a new energy norm positive definite such that its growth is controlled by an energy estimate. Finally in the sequel, we adopt this approach but the choice of the new energy space is naturally given by the geometry thanks to the $3+1$ decomposition. Although in the case of the spin-$1/2$ the phenomenon of superradiance does not take place, we show in the following paragraph that the $3+1$ decomposition is nevertheless useful for this field.

The space–time $(\mathcal{B}_{\mathrm{I}}, g)$ is globally hyperbolic. This means that there exists a time function t globally defined on $\mathcal{B}_{\mathrm{I}}$ (providing of foliation of $\mathcal{B}_{\mathrm{I}}$ by the hypersurfaces Σ_t) and that any points of $\mathcal{B}_{\mathrm{I}}$ can be reached from Σ_{t_0} along a nonspacelike curve (see Geroch[22]). Each Σ_t are homeomorphic to a given 3-manifold Σ. Now, we choose $\mathbf{T}$ the unit timelike oriented vector normal to Σ_t defined in (8) to fixed the product structure $\mathcal{B}_{\mathrm{I}}=\mathbb{R}\times\Sigma$, i.e., the points on different hypersurfaces Σ_t are identified along the integral lines of $\mathbf{T}$. This construction induces an explicit system of coordinates that is referred to as the point of view of locally non rotating observers:

$$\tau = t, \quad R = r, \quad \Theta = \theta, \quad \Phi = \varphi - t\alpha, \quad \alpha := -\frac{g_{t\varphi}}{g_{\phi\phi}} = \frac{2aMr}{\sigma^2}. \tag{11}$$

Now, we decompose the metric g as the sum of its orthogonal projection along $\mathbf{T}$ and $(\mathbf{T})^{\perp} = T_p\Sigma_t$,

$$g_{\mu\nu}\,\mathrm{d}x^{\mu}\,\mathrm{d}x^{\nu} = N^2\,\mathrm{d}\tau^2 - h(\tau), \quad N := \sqrt{g_{tt} - \frac{g_{t\varphi}^2}{g_{\varphi\varphi}}} = \sqrt{\frac{\Delta\rho^2}{\sigma^2}}, \tag{12}$$

where N is the lapse function, and

$$h(\tau) = -g_{rr}\,\mathrm{d}R^2 - g_{\theta\theta}\,\mathrm{d}\Theta^2 - g_{\varphi\varphi}\left(\mathrm{d}\Phi + \tau\frac{\partial\alpha}{\partial R}\mathrm{d}R + \tau\frac{\partial\alpha}{\partial\Theta}\mathrm{d}\Theta\right)^2. \tag{13}$$

The definition of g in these new coordinates leads to simple form of hyperbolic evolution equation without crossed terms depending on t and φ since $g_{t\varphi}=0$ (unlike to the Boyer-Lindquist coordinates form for g). This is the main motivation to use the $3+1$ decomposition for spin-$1/2$ fields. But we remark that the metric is not time independent anymore. Henceforth, the evolution equation is defined with the help of time-dependent Hamiltonian. The following proposition state that the dependence on t is rather nice (see Ref. 33.)

Proposition 2.1:

(i) $\Sigma_\tau=(\Sigma, h(\tau))$ *is a* C^∞*-Riemannian manifold for all* $\tau\in\mathbb{R}$ *with smooth boundary* $\partial\Sigma=\{r_+\}\times S^2_\omega$.

(ii) *The lapse function* N *is strictly positive on* Σ, *vanishes on* $\partial\Sigma$, *is independent of* τ, C^∞ *and uniformly bounded on* $\bar{\Sigma}$ *as well as all its derivatives*.

(iii) $h_{\mu\nu}\in C^\infty(\mathbb{R}_\tau; C_b^\infty(\Sigma; T_{\mu\nu}\mathcal{M}))$, $h^{\mu\nu}\in C^\infty(\mathbb{R}_\tau; C_b^\infty(\Sigma; T^{\mu\nu}\mathcal{M}))$. *All slice* Σ_τ *have the same geometry (*g *is independent of* t *in Boyer-Lindquist coordinates) and* $h(\tau)$ *is obtained from* $h(0)$ *by a rotation around the axis of the black hole whose angle is* $\tau\alpha$ *with* α *defined in (11).*

$$h(0) = \frac{\rho^2}{R^2}\mathrm{d}u^2 + \frac{\rho^2}{(1+u)^2}(1+u)^2\,\mathrm{d}\Theta^2 + \frac{(R^2+a^2)\rho^2 + 2MRa^2\sin^2\Theta}{\rho^2(1+u)^2}(1+u)^2\sin^2\Theta\,\mathrm{d}\Phi^2 \tag{14}$$

with u *the h-distance to the horizon such that*

$$u:\left[r_+,+\infty\right[_R \mapsto \mathbb{R}, \quad u(R) := \int_{r_+}^{R} \frac{s}{\sqrt{\Delta}} \mathrm{d}s. \tag{15}$$

Hence, we remark that $h(\tau)$ is equivalent to the Euclidian metric on $\mathbb{R}^3 \backslash \bar{B}(0,1)$,

$$\mathrm{d}u^2 + (1+u)^2\, \mathrm{d}\Theta^2 + (1+u)^2 \sin^2\Theta\, \mathrm{d}\Phi^2. \tag{16}$$

(iv) *$|h|$, the determinant of the metric $h(\tau)$, is independent of τ and $|g| := |\det g| = -N^2|h|$.*

III. LOCAL CAUCHY PROBLEM FOR NONLINEAR DIRAC EQUATION OUTSIDE A KERR BLACK HOLE

In this section we study the local Cauchy problem for the nonlinear Dirac equation (3). We use the 3+1 decomposition to defined an evolution problem in $\mathcal{B}_{\mathrm{I}}$. A result of Nicolas[33] gives the existence of a propagator for a solution of the linear part of (3). For the nonlinear equation, a Duhamel formula and a Sobolev embedding $H^2 \hookrightarrow L^\infty$ are useful to obtain the result.

We describe more precisely the Dirac equation in 3+1 decomposition framework. Since $(\mathcal{B}_{\mathrm{I}}, g)$ is a globally hyperbolic spacetime then it admits a spin structure (Refs. 21 and 23). We denote by $\mathbb{S}$ the bundle over $\mathcal{B}_{\mathrm{I}}$ of negative spinors and by $\bar{\mathbb{S}}$ the bundle of positive spinors i.e., the complex structure in $\mathbb{S}$ simply replaced by its opposite. We also, respectively, denote by the $\mathbb{S}^*$ and $\bar{\mathbb{S}}^*$ the dual of $\mathbb{S}$ and $\bar{\mathbb{S}}$. Finally the complexified tangent bundle to $\mathcal{B}_{\mathrm{I}}$ is recovered as the tensor product of $\mathbb{S}$ and $\bar{\mathbb{S}}$,

$$T\mathcal{B}_{\mathrm{I}} \otimes \mathbb{C} = \mathbb{S} \otimes \bar{\mathbb{S}}, \quad T^*\mathcal{B}_{\mathrm{I}} \otimes \mathbb{C} = \mathbb{S}^* \otimes \bar{\mathbb{S}}^*. \tag{17}$$

We define the Dirac equation on the block I. The bundle of Dirac spinors on $\mathcal{B}_{\mathrm{I}}$ is described as

$$\mathbb{S}_D := \mathbb{S}^* \oplus \bar{\mathbb{S}}. \tag{18}$$

On space–time $\mathcal{B}_{\mathrm{I}}$, we choose a local orthogonal Lorentz frame $\{e_0, e_1, e_2, e_3\}$ such that

$$g(e_0, e_0) = 1, \quad g(e_a, e_a) = -1, \quad a = 1,2,3, \quad g(e_a, e_b) = 0, \quad a \neq b. \tag{19}$$

Obviously in the 3+1 decomposition framework, we choose for the basis $\{e_0, e_1, e_2, e_3\}$

$$e_0{}^a := \frac{1}{\sqrt{2}} T^a, \quad e_1, e_2, e_3 \in T\Sigma_t. \tag{20}$$

Hence, we define the Dirac operator on $\mathcal{B}_{\mathrm{I}}$ by

$$\mathbf{D} := \sum_{a=0}^{3} e_a \,.\, \nabla_{e_a} \tag{21}$$

where ∇_{e_a} is the directional convariante derivative along e_a and e_a. The Clifford product by the vector e_a. More presicely by a choice of spin-frame or Newman-Penrose tetrad, the Clifford multiplication of a Dirac spinor $\Psi \in \mathbb{S}_D$ by e_a is described as the multiplication by a Dirac matrices γ^a satisfying the following relation:

$$\gamma^\mu \gamma^\nu + \gamma^\nu \gamma^\mu = 2g^{\mu\nu}\mathbf{1}_4, \quad \mu, \nu = 0,1,2,3,4. \tag{22}$$

The Dirac equation for a spin-1/2 particle with mass $m_d > 0$ takes the following form with Einstein notation:

$$i\gamma^\mu \nabla_{e_\mu} \Psi - m_d \Psi = (\mathbf{D} - m_d)\Psi = 0. \tag{23}$$

From (20) and (23), we write the Dirac equation as an evolution system

$$ie_0 \,.\, \nabla_{e_0}\Psi = -i\sum_{a=1}^{3} e_a \,.\, \nabla_{e_a}\Psi + m_d\Psi \tag{24}$$

or

$$\nabla_{e_0}\Psi = -\sum_{a=1}^{3} e_0 \,.\, e_a \,.\, \nabla_{e_a}\Psi - im_d\Psi. \tag{25}$$

We introduce the Dirac-Witten operator $\mathbf{D}_w(\tau)$ on Σ_τ (extrinsic geometry) such that

$$\mathbf{D}_w(\tau) = \sum_{a=1}^{3} e_a \,.\, \nabla_{e_a}. \tag{26}$$

We also define $\mathbf{D}_\Sigma(\tau)$ the Dirac operator associated to the Levi-Civita connection on $(\Sigma_\tau, h(\tau))$ such that

$$\mathbf{D}_w(\tau) = \mathbf{D}_\Sigma(\tau) + \frac{1}{2\sqrt{2}}Ke_0, \tag{27}$$

where K is the $\sqrt{2}$ times the trace of the extrinsic curvature. This operator is symmetric on $C_0^\infty(\Sigma_t, \mathbb{S}_D)$ for the inner product

$$\langle \Psi, \Phi \rangle_{L^2_{\Sigma_\tau}} := \int_\Sigma \langle \Psi, \Phi \rangle \mathrm{dVol}_{h_\tau}, \tag{28}$$

where

$$\langle \Psi, \Phi \rangle := \Psi_1\bar{\Phi}_1 + \Psi_2\bar{\Phi}_2 + \Psi_3\bar{\Phi}_3 + \Psi_4\bar{\Phi}_4 \tag{29}$$

when we choose a spin-frames adapted to the foliation Σ_τ. According to Proposition 2.1, this inner product is in fact τ-independent since the determinent of g is also τ-independent. Finally, we write the Dirac equation in the following form, i.e., as a first order symmetric hyperbolic system on Σ,

$$\nabla_{e_0}\Psi = -e_0 \cdot \mathbf{D}_\Sigma(\tau)\Psi - \frac{1}{2\sqrt{2}}K\Psi - im_d\Psi, \tag{30}$$

and the operator

$$\mathbf{D}_D := e_0 \cdot \mathbf{D}_\Sigma(\tau), \quad e_0 = \frac{1}{\sqrt{2}}\mathbf{T}^\mu\partial_\mu \tag{31}$$

being formally skew-adjoint on $L^2(\Sigma; \mathbb{S}_D)$. By choosing a adapted Newman-Penrose tetrad (a spin frame adapted to foliation Σ_τ) equation (30) becomes (see Appendix A in Ref. 33)

$$\frac{\partial\Psi}{\partial\tau} = \mathcal{A}_D(\tau)\Psi, \quad \mathcal{A}_D(\tau) := -\frac{N}{\sqrt{2}}\left(\mathbf{D}_\Sigma(\tau) + \frac{1}{2\sqrt{2}}K + im_d\gamma^0 + B(\tau)\right), \tag{32}$$

where B is a matrix containing the connections terms of ∇_{a_0}, N the lapse function and

$$\gamma^0 = i\begin{pmatrix} 0 & \mathbf{1}_2 \\ -\mathbf{1}_2 & 0 \end{pmatrix}. \tag{33}$$

We introduce the functional framework. On Σ_τ we define the Sobolev space $H_0^k(\Sigma_\tau; \mathbb{S}_D)$ as the completion of $C_0^\infty(\Sigma; \mathbb{S}_D)$ for the norm

$$\|\Psi\|_{H_0^k(\Sigma_\tau)} = \left(\sum_{p=0}^{k} \int_\Sigma \langle (D_\tau)^p \Psi, (D_\tau)^p \Psi \rangle \mathrm{dVol}_h \right)^{1/2}, \tag{34}$$

where D_τ is the Levi-Civita connection on $(\Sigma, h(\tau))$. According Proposition 2.1, we remark that for all $\tau \in \mathbb{R}$, $\mathrm{dVol}_h = \mathrm{dVol}_{h(\tau)}$ and the norms in $H_0^k(\Sigma_\tau; \mathbb{S}_D)$ and $H_0^k(\Sigma_{\tau_0}; \mathbb{S}_D)$ are locally uniformly in time equivalent (the constants in the norms estimates are time dependent and locally bounded in time). Hence, we simply denote by $H_0^k(\Sigma, \mathbb{S}_D)$ the Sobolev space associated with the norm

$$\left\| \cdot \right\|_{(k)} := \left\| \cdot \right\|_{H_0^k(\Sigma_{\tau_0})}$$

and the metric $h(\tau_0)$.

Proposition 3.1:

We define the following norm for all $\tau \in \mathbb{R}$:

$$\|\Psi\|_{k,\tau} := \left(\sum_{p=0}^{k} \int_\Sigma \langle (\mathbf{D}_\Sigma)^p(\tau)\Psi, (\mathbf{D}_\Sigma)^p(\tau)\Psi \rangle \mathrm{dVol}_h \right)^{1/2}, \quad \forall\, \Psi \in H_0^k(\Sigma; \mathbb{S}_D). \tag{35}$$

Then the norm $\|\cdot\|_{(k)}$ *and* $\|\cdot\|_{k,\tau}$ *are locally uniformly in time equivalent on* $H_0^k(\Sigma; \mathbb{S}_D)$.

This proposition is a consequence of Proposition 2.1 and the Bochner-Lichnerowicz-Weitzenböck formula

$$(\mathbf{D}_\Sigma(\tau))^* \mathbf{D}_\Sigma(\tau) = (\mathbf{D}_\Sigma)^2 = D_\tau^* D_\tau + \tfrac{1}{4} R_{h(\tau)} = -\Delta_{h(\tau)} + \tfrac{1}{4} R_{h(\tau)}, \tag{36}$$

where $R_{h(\tau)}$ is the scalar curvature of $(\Sigma, h(\tau))$. The following theorem concerns the Cauchy problem on Block I for the linear equation (32) (see Ref. 33).

Theorem 3.1: *For any initial data* $\Psi_0 \in H_0^k(\Sigma; \mathbb{S}_D)$, $k \in \mathbb{N}$, *the system (32) has a unique solution* Ψ *satisfying*

$$\Psi \in \bigcap_{l=0}^{k} C^l(\mathbb{R}_\tau; H_0^{k-l}(\Sigma; \mathbb{S}_D)). \tag{37}$$

Moreover, there exits a propagator $\mathcal{U}_D$ *such that*

(i) $\mathcal{U}_D(\tau, \tau_0) : \Psi_0 \mapsto \Psi(\tau)$.

(ii) $\forall t, s \mathbb{R}$, $\mathcal{U}_D(t,s) \in \mathcal{L}(H_0^k(\Sigma; \mathbb{S}_D))$, $\mathcal{U}_D$ *is strongly continuous on* $\mathbb{R}^2_{ts}$ *to* $\mathcal{L}(H_0^k(\Sigma; \mathbb{S}_D))$.

(iii) $\mathcal{U}_D(t,t) = \mathrm{Id}$, $\mathcal{U}_D(t,s) = \mathcal{U}_D(t,r)\mathcal{U}_D(r,s)$ *for all* $t, s, r \in \mathbb{R}$.

(iv) *we have in the sense of distributions on* $\mathbb{R} \times \Sigma$,

$$\frac{\partial}{\partial \tau} \mathcal{U}_D(\tau, \tau_0)\Psi_0 = \mathcal{A}_D(\tau)\mathcal{U}_D(\tau, \tau_0)\Psi_0, \tag{38}$$

$$\frac{\partial}{\partial \tau_0} \mathcal{U}_D(\tau, \tau_0)\Psi_0 = -\mathcal{U}_D(\tau, \tau_0)\mathcal{A}_D(\tau_0)\Psi_0, \tag{39}$$

(v) *We have also the unitary evolution in* $L^2(\Sigma; \mathbb{S}_D)$,

$$\|\Psi(\tau)\|_{L^2(\Sigma; \mathbb{S}_D)} = \|\Psi_0\|_{L^2(\Sigma; \mathbb{S}_D)}. \tag{40}$$

(vi) *There exists a continuous, strictly positive function* α_k *such that*

$$\|\Psi(\tau)\|_{k,\tau} \leqslant \alpha_k(\tau, \tau_0)\|\Psi_0\|_{k,\tau_0}, \quad \alpha_k(\tau, \tau) = 1, \tag{41}$$

and a continuous, strictly positive function κ *such that*

$$\|\Psi(\tau)\|_{(k)} \leqslant \kappa_k(\tau,\tau_0)\|\Psi_0\|_{(k)}, \quad \kappa_k(\tau,\tau)=1, \tag{42}$$

According to the 3+1 decomposition, we consider the nonlinear problem (3) in the new equivalent form

$$\frac{\partial\Psi}{\partial\tau}=\mathcal{A}_D(\tau)\Psi+\mathcal{J}_D(\Psi), \quad \mathcal{J}_D(\Psi):=i\frac{N}{\sqrt{2}}k(\Psi^*\gamma^0\Psi)\gamma^0\Psi. \tag{43}$$

In the sequel, we present a proof of the local Cauchy problem for the previous nonlinear equation with $H_0^2(\Sigma;\mathbb{S}_D)$ initial data. First, we prove the following lemma.

Lemma 3.1: There exists a constant $C\geqslant 0$ such that,

$$\|\mathcal{J}_D(\Psi)\|_{(2)} \leqslant C\|\Psi\|_{(2)}^3, \quad \Psi,\Phi\in H_0^2(\Sigma;\mathbb{S}_D), \tag{44}$$

$$\|\mathcal{J}_D(\Psi)-\mathcal{J}_D(\Phi)\|_{(2)} \leqslant C(\|\Psi\|_{(2)}^2+\|\Phi\|_{(2)}^2)\|\Psi-\Phi\|_{(2)}, \tag{45}$$

Proof: We only prove (45), since (44) is (45) with $\Phi\equiv 0$. We have

$$\begin{aligned}\mathcal{J}_D(\Psi)-\mathcal{J}_D(\Phi)=\frac{N}{\sqrt{2}}k[&(\Psi^*\gamma^0\Psi)\gamma^0\Psi-(\Phi^*\gamma^0\Psi)\gamma^0\Psi+(\Phi^*\gamma^0\Psi)\gamma^0\Psi+(\Phi^*\gamma^0\Phi)\gamma^0\Psi\\&-(\Phi^*\gamma^0\Phi)\gamma^0\Psi-(\Phi^*\gamma^0\Phi)\gamma^0\Phi],\end{aligned}$$

$$=\frac{N}{\sqrt{2}}k[([\Psi^*-\Psi^*]\gamma^0\Psi)\gamma^0\Psi+(\Phi^*\gamma^0[\Psi-\Phi])\gamma^0\Psi+(\Phi^*\gamma^0\Phi)\gamma^0[\Psi-\Phi]]. \tag{46}$$

Now, we remark that $H^2(\mathbb{R}^3)\hookrightarrow L^\infty(\mathbb{R}^3)$. Then, since $h(\tau)$ is equivalent to the Euclidian metric on $\mathbb{R}^3\backslash\bar{B}(0,1)$, we have for $\Psi\in H_0^2(\Sigma;\mathbb{S}_D)$

$$\|\Psi\|_{L^\infty(\Sigma;\mathbb{S}_D)} \leqslant C_1\|\Psi\|_{(2)}, \quad C_1>0. \tag{47}$$

Therefore, according to (46) and (47), since $N,k\in L^\infty$, we have

$$\begin{aligned}\|\mathcal{J}_D(\Psi)-\mathcal{J}_D(\Phi)\|_{(2)} &\leqslant C_3(\|\Psi\|_{L^\infty(\Sigma;\mathbb{S}_D)}^2+\|\Psi\|_{L^\infty(\Sigma;\mathbb{S}_D)}\|\Phi\|_{L^\infty(\Sigma;\mathbb{S}_D)}+\|\Phi\|_{L^\infty(\Sigma;\mathbb{S}_D)}^2)\|\Psi-\Phi\|_{(2)}\\&\leqslant C(\|\Psi\|_{(2)}^2+\|\Phi\|_{(2)}^2)\|\Psi-\Phi\|_{(2)}, \quad C_3,C>0.\end{aligned} \tag{48}$$

■

Now, we study the following problem:

$$\Psi(\tau)=S(\Psi)(\tau),$$

$$S(\Psi)(\tau):=\mathcal{U}_D(\tau,\tau_0)\Psi_0+\int_{\tau_0}^{\tau}\mathcal{U}_D(\tau,s)\mathcal{J}_D(\Psi(s))\mathrm{d}s, \quad \Psi\in C^0([\tau_0,\tau_0+T[_\tau,H_0^2(\Sigma;\mathbb{S}_D)). \tag{49}$$

to solve the local Cauchy problem

$$\begin{aligned}&\frac{\partial\Psi}{\partial\tau}=\mathcal{A}_D(\tau)\Psi+\mathcal{J}_D(\Psi),\\&\Psi(\tau_0)=\Psi_0\in H_0^2(\Sigma;\mathbb{S}_D), \quad \Psi\in C^0([\tau_0,\tau_0+T[_\tau,H_0^2(\Sigma;\mathbb{S}_D)).\end{aligned} \tag{50}$$

Theorem 3.2: *For* $\Psi_0 \in H_0^2(\Sigma;\mathbb{S}_D)$, *there exists* $T(\|\Psi_0\|_{(2)})>0$ *such that (43) admits a unique solution* Ψ *such that*

$$\Psi(\tau_0)=\Psi_0 \in H_0^2(\Sigma;\mathbb{S}_D), \quad \Psi \in C^0([\tau_0,\tau_0+T[_\tau,H_0^2(\Sigma;\mathbb{S}_D)). \tag{51}$$

Proof: The operator S in (49) is well defined if $\Psi_0 \in H_0^2(\Sigma;\mathbb{S}_D)$. Indeed, if $\Psi_0 \in H_0^2(\Sigma;\mathbb{S}_D)$ then $\mathcal{U}_D(\tau,\tau_0)\Psi_0 \in H_0^2(\Sigma;\mathbb{S}_D)$ by (42) and

$$\|\mathcal{U}_D(\tau,s+h)\mathcal{J}_D(\Psi(s+h))-\mathcal{U}_D(\tau,s)\mathcal{J}_D(\Psi(s))\|_{(2)}, \quad K:=\max\{\kappa_2(\sigma,\tau),\sigma,\tau\in[\tau_0,\tau_0+T]\},$$

$$\leqslant \|\mathcal{U}_D(\tau,s+h)(\mathcal{J}_D(\Psi(s+h))-\mathcal{J}_D(\Psi(s)))\|_{(2)}+\|(\mathcal{U}_D(\tau,s+h)-\mathcal{U}_D(\tau,s))\mathcal{J}_D\ (\Psi(s)))\|_{(2)}$$
$$\leqslant K\|\mathcal{J}_D(\Psi(s+h))-\mathcal{J}_D(\Psi(s))\|_{(2)}+K\|(\mathcal{U}_D(s,s+h)-1)\mathcal{J}_D(\Psi(s))\|_{(2)}.$$

Hence $s\mapsto\mathcal{U}_D(\tau,s)\mathcal{J}_D(\Psi(s))$ is continuous on $H_0^2(\Sigma;\mathbb{S}_D)$, thanks to (44) and (45) and since $\mathcal{U}_D$ is strongly continuous on $H_0^2(\Sigma;\mathbb{S}_D)$.

Moreover, $C^0([\tau_0,\tau_0+T[_\tau,H_0^2(\Sigma;\mathbb{S}_D))$ is stable by S,

$$\|S(\Psi)(\tau+h)-S(\Psi)(\tau)\|_{(2)}\leqslant\|\mathcal{U}_D(\tau+h,\tau_0)\Psi_0-\mathcal{U}_D(\tau,\tau_0)\Psi_0\|_{(2)}+\int_{\tau_0}^{\tau}\|\mathcal{U}_D(\tau+h,s)\mathcal{J}_D(\Psi(s))$$
$$-\mathcal{U}_D(\tau,s)\mathcal{J}_D(\Psi(s))\|_{(2)}\,\mathrm{d}s+\int_{\tau+h}^{\tau}\|\mathcal{U}_D(\tau+h,s)\mathcal{J}_D(\Psi(s))\|_{(2)}\,\mathrm{d}s \tag{52}$$

This norm vanishes as $h\to 0$, since $\mathcal{U}$ is strongly continuous on $H_0^2(\Sigma;\mathbb{S}_D)$ for the first term on right on side, thanks to the same property, the Lebesgue theorem and (45) for the second. The last is bounded by $Kh\sup_{s\in[\tau,\tau+h]}\|\Psi(s)\|^3_{H_0^2(\Sigma;\mathbb{S}_D)}$, $K:=\max\{\kappa_2(\sigma,\tau),\sigma,\tau\in[\tau_0,\tau_0+T]\}$ thanks to (44).

Now, we define the convex closed of $C^0([\tau_0,\tau_0+T[_\tau,H_0^2(\Sigma;\mathbb{S}_D))$,

$$V_{T,\Psi_0}:=\{\Psi\in C^0([\tau_0,\tau_0+T[_\tau,H_0^2(\Sigma;\mathbb{S}_D));\Psi(\tau_0)=\Psi_0,\ \|\Psi\|_T\leqslant 2K\|\Psi_0\|_{(2)}\}, \tag{53}$$

$$K:=\max\{\kappa_2(\sigma,\tau),\sigma,\tau\in[s,s+T]\}, \tag{54}$$

with

$$\|\Psi\|_T=\sup_{[\tau_0,\tau_0+T[_\tau}\|\Psi\|_{(2)}. \tag{55}$$

For T small $S(V_{T,\Psi_0})\subset V_{T,\Psi_0}$. Indeed, according to (45) and (53), we have

$$\|S(\Psi)\|_T\leqslant K(1+8TCK^2\|\Psi_0\|^2_{(2)})\|\Psi_0\|_{(2)}, \quad \Psi\in V_{T,\Psi_0}, \tag{56}$$

and we choose

$$T<(8CK^2\|\Psi_0\|^2_{(2)})^{-1}. \tag{57}$$

Moreover, we obtain with (45).

$$\|S(\Psi)-S(\Phi)\|_T\leqslant TK\|\mathcal{J}_D(\Psi)-\mathcal{J}_D(\Phi)\|_T\leqslant 4TK^2C\|\Psi_0\|^2_{(2)}\|\Psi-\Phi\|_T, \quad \Psi,\Phi\in V_{T,\Psi_0}. \tag{58}$$

Then, if we choose

$$T<\min(8CK^2\|\Psi_0\|^2_{(2)})^{-1}, \quad (4TK^2C\|\Psi_0\|^2_{(2)})^{-1}) \tag{59}$$

by the Banach fixed point theorem there exists a solution of (49).

Now we study the uniqueness of this problem. Given $T>0$, $\Psi_0 \in H_0^2(\Sigma;\mathbb{S}_D)$ and two solutions $\Psi_1, \Psi_2 \in C^0([\tau_0, \tau_0+T[_\tau, H_0^2(\Sigma;\mathbb{S}_D))$ associated to Ψ_0, then with $K := \max\{\kappa_2(\sigma,\tau), \sigma, \tau \in [\tau_0, \tau_0+T]\}$

$$\|\Psi_1(\tau)-\Psi_2(\tau)\|_{(2)} \leqslant K\int_{\tau_0}^{\tau} \|\mathcal{J}_D(\Psi_1(s))-\mathcal{J}_D(\Psi_2(s))\|_{(2)}\,\mathrm{d}s \leqslant K(\|\Psi\|_T^2+\|\Phi\|_T^2) \times \int_{\tau_0}^{\tau} \|\Psi_1(s)-\Psi_2(s)\|_{(2)}\,\mathrm{d}s. \tag{60}$$

Then by Gronwall lemma we have $\Psi_1=\Psi_2$.

First, we prove that the problems (49) and (50) are equivalent. If Ψ is solution of (49) then Ψ, satisfies equation (50). Indeed, according to the properties of $\mathcal{U}_D$ we have

$$\frac{\partial\Psi}{\partial\tau}(\tau) = \mathcal{A}_D(\tau)\mathcal{U}_D(\tau,\tau_0)\Psi + \int_{\tau_0}^{\tau} \mathcal{A}_D(\tau)\mathcal{U}_D(\tau,s)\mathcal{J}_D(\Psi(s))\mathrm{d}s + \mathcal{J}_D(i(\tau)) = \mathcal{A}_D(\tau)\Psi(\tau) + \mathcal{J}_D(\Psi(\tau))$$

since $s \mapsto \mathcal{A}_D(\tau)\mathcal{U}_D(\tau,s)\mathcal{J}_D(\Psi(s))$ is bounded on $H_0^2(\Sigma;\mathbb{S}_D)$ by (44) and (42) and also $\mathcal{A}_D(\tau)$ is closed for each τ. The inverse is straightforward. The uniqueness follows from the Gronwall lemma. ■

Remark 3.1:

(1) *Theorem 3.2 is in fact valid for* $\Psi_0 \in H_0^s(\Sigma;\mathbb{S}_D)$, $s \geqslant 2$. *Indeed, it is easy to prove thanks to the Sobolev embedding* $H^s(\mathbb{R}^3) \hookrightarrow L^\infty(\mathbb{R}^3)$ *an equivalent lemma of Lemma 3.1 for* $H_0^s(\Sigma;\mathbb{S}_D)$. *The proof of the theorem with* $\Psi_0 \in H_0^s(\Sigma;\mathbb{S}_D)$ *is essentially the same.*

(2) *Theorem 3.2 is still valid with the following non linearity,*

$$\mathcal{J}_D^p(\Psi) := i\frac{N}{\sqrt{2}}k|(\Psi^*\gamma^0\Psi)|^{(p-1)/2}\gamma^0\Psi, \quad p \geqslant 3. \tag{61}$$

Then, we obtain the following estimates:

$$\|\mathcal{J}_D^p(\Psi)\|_{(s)} \leqslant C\|\Psi\|_{(s)}^p, \quad \Psi,\Phi \in H_0^s(\Sigma;\mathbb{S}_D), \tag{62}$$

$$\|\mathcal{J}_D^p(\Psi)-\mathcal{J}_D^p(\Phi)\|_{(s)} \leqslant C(\|\Psi\|_{(s)}^{p-1}+\|\Phi\|_{(s)}^{p-1})\|\Psi-\Phi\|_{(s)}. \tag{63}$$

As above, the proof with this nonlinearity remains essentially the same.

IV. LOCAL CAUCHY PROBLEM FOR THE DIRAC-KLEIN-GORDON EQUATION OUTSIDE A KERR BLACK HOLE

In this section we study the local Cauchy problem for the Dirac-Klein-Gordon equation (4). As above, we use the 3+1 decomposition to defined an evolution problem in $\mathcal{B}_I$. To prove the existence of local solutions, we use a Duhamel formula and a Sobolev embedding $H^s(\mathbb{R}^3) \hookrightarrow L^\infty(\mathbb{R}^3)$, $s \geqslant 2$.

According to the 3+1 decomposition, the preceding section and the following definition:

$$\Box_g = \frac{1}{\sqrt{|g|}}\frac{\partial}{\partial x^\mu}\left(\sqrt{|g|}g^{\mu\nu}\frac{\partial}{\partial x^\nu}\right), \tag{64}$$

Eq. (4) is equivalent to

$$\frac{\partial\Psi}{\partial\tau} = \mathcal{A}_D(\tau)\Psi + i\frac{N}{\sqrt{2}}\Phi\gamma^0\mathcal{V}_2\Psi, \tag{65}$$

$$\frac{\partial^2\Phi}{\partial\tau^2} = \mathcal{A}_{\mathrm{KG}}(\tau)\Phi + N^2\Psi^*\mathcal{V}_3\Psi, \quad \mathcal{A}_{\mathrm{KG}}(\tau) := N^2\Delta_h - N^2 m_{kg}^2, \tag{66}$$

where

$$\Delta_h := \frac{1}{N\sqrt{|h|}}\frac{\partial}{\partial x^a}\left(N\sqrt{|h|}h^{ab}\frac{\partial}{\partial x^b}\right) \tag{67}$$

and $\mathcal{A}_D(\tau)$ defined in (32). Now we put this equation in Hamiltonian form such that

$$\frac{\partial U}{\partial\tau} = \mathcal{A}_{\mathrm{DKG}}(\tau)U + \mathcal{J}_{\mathrm{DKG}}(U), \quad U={}^t(\Psi,\Phi,\partial_\tau\Phi), \tag{68}$$

where

$$\mathcal{A}_{\mathrm{DKG}}(\tau) := \begin{pmatrix} \mathcal{A}_D(\tau) & 0 & 0 \\ 0 & 0 & 1 \\ 0 & \mathcal{A}_{\mathrm{KG}}(\tau) & 0 \end{pmatrix}, \quad \mathcal{J}_{\mathrm{DKG}}(U) := \begin{pmatrix} i\frac{N}{\sqrt{2}}\Phi\gamma^0\mathcal{V}_2\Psi \\ 0 \\ N^2\Psi^*\mathcal{V}_3\Psi \end{pmatrix}. \tag{69}$$

First, we remark some properties for the linear part of the equation (66) (i.e., $\mathcal{V}_3=0$). According to a result due to Leray,[25] we have for this linear equation.

Theorem 4.1: *For initial data $\Phi_0,\Phi_1\in C_0^\infty(\Sigma)$ in $\tau_0\in\mathbb{R}$, the equation (66) with $V_3=0$ has a solution $\Phi\in C^\infty(\mathbb{R}_\tau,C_0^\infty(\Sigma))$ satisfying $\Phi(\tau_0)=\Phi_0$ and $\partial_\tau\Phi(\tau_0)=\Phi_1$.*

The proof of the following proposition consists in multiplying the equation by $\partial_\tau\Phi$ and integrating by part on $[\tau_0,\tau]\times\Sigma$:

Proposition 4.1: There exists a continuous, strictly positive function ξ such that $\xi(\tau,\tau)=1$ and for each $\Phi\in C^\infty(\mathbb{R}_\tau,C_0^\infty(\Sigma))$ solution of the equation (68) with $V_3=0$, we have for any $\tau,\tau_0\in\mathbb{R}$

$$E_{3+1}(\Phi,\tau) \leqslant \xi(\tau,\tau_0)E_{3+1}(\Phi,\tau_0) \tag{70}$$

with

$$E_{3+1}(\Phi,\tau) := \int_{\Sigma_\tau}(|\partial_t\Phi|^2 + N^2h^{ab}\partial_a\Phi\partial_b\bar{\Phi} + N^2m_{kg}^2|\Phi|^2)\frac{1}{N}\mathrm{dVol}. \tag{71}$$

According to Proposition 2.1, we consider $\eta=h(0)$ on $\bar{\Sigma}$ and we introduce the Hilbert space $\mathcal{H}_0^{1,0}(\Sigma)$ as the completion of $C_0^\infty(\Sigma)\oplus C_0^\infty(\Sigma)$ for the norm

$$\|(u,v)\|_{[1,0]}^2 := \int_\Sigma(|v|^2 - \mathcal{A}_{\mathrm{KG}}u\bar{u})\frac{1}{N}\mathrm{dVol} = \int_\Sigma(|v|^2 + N^2|\nabla u|^2 + N^2m_{kg}^2|u|^2)\frac{1}{N}\mathrm{dVol},$$
$$|\nabla u|^2 = \eta^{ab}\partial_a u\partial_b\bar{u}. \tag{72}$$

With these two last results, we deduce the following.

Proposition 4.2: For any initial data $U_0 := {}^t(\Phi_0, \Phi_1) \in \mathcal{H}_0^{1,0}(\Sigma)$ *in* $\tau_0 \in \mathbb{R}$, *the equation (66) with* $V_3 = 0$ *has an unique solution* $U \in C^0(\mathbb{R}_\tau, \mathcal{H}_0^{1,0}(\Sigma))$ *satisfying* $U(\tau_0) = {}^t(\Phi_0, \Phi_1)$. *Moreover, we have the existence of a propagator* $\mathcal{U}_{\mathrm{KG}}$ *such that:*

(i) *For all* $\tau, \sigma \in \mathbb{R}$, $\mathcal{U}_{\mathrm{KG}}(\tau, \sigma) \in \mathcal{L}(\mathcal{H}_0^{1,0})$, $\|\mathcal{U}_{\mathrm{KG}}(\tau, \sigma)\|_{\mathcal{L}(\mathcal{H}_0^{1,0}(\Sigma))} \leqslant \xi(\sigma, \tau)$ *where* ξ *is the function defined in (70).*

(ii) $\mathcal{U}_{\mathrm{KG}}(\tau, \tau) = 1$, $\mathcal{U}_{\mathrm{KG}}(\tau, s) = \mathcal{U}_{\mathrm{KG}}(t, r)\mathcal{U}_{\mathrm{KG}}(r, s)$ *for all* $t, s, r \in \mathbb{R}$.

(iii) *We have in the sense of distributions on* $\mathbb{R} \times \Sigma$,

$$\frac{\partial}{\partial \tau}\mathcal{U}_{\mathrm{KG}}(\tau, \tau_0)U_0 = \mathcal{M}_{\mathcal{A}_{\mathrm{KG}}}(\tau)\mathcal{U}_{\mathrm{KG}}(\tau, \tau_0)U_0, \quad \mathcal{M}_{\mathcal{A}_{\mathrm{KG}}} = \begin{pmatrix} 0 & 1 \\ \mathcal{A}_{\mathrm{KG}} & 0 \end{pmatrix}, \tag{73}$$

$$\frac{\partial}{\partial \tau_0}\mathcal{U}_{\mathrm{KG}}(\tau, \tau_0)U_0 = -\mathcal{U}_{\mathrm{KG}}(\tau, \tau_0)\mathcal{M}_{\mathcal{A}_{\mathrm{KG}}}(\tau_0)U_0. \tag{74}$$

We introduce $\tilde{\mathcal{A}}_{\mathrm{KG}}$ such that

$$\tilde{\mathcal{A}}_{\mathrm{KG}} := N^2\Delta_\eta - 1. \tag{75}$$

Now, we define $\mathcal{H}_0^{2,1}(\Sigma)$ as the completion of $C_0^\infty(\Sigma) \oplus C_0^\infty(\Sigma)$ for the norm

$$\|(u, v)\|_{[2,1]}^2 := \int_\Sigma (|\tilde{\mathcal{A}}_{\mathrm{KG}}u|^2 - \mathcal{A}_{\mathrm{KG}}u\bar{u} - \mathcal{A}_{\mathrm{KG}}v\bar{v})\frac{1}{N}\mathrm{dVol},$$

$$= \int_\Sigma (N^2|\nabla v|^2 + N^2 m_{kg}^2|v|^2 + |N^2\Delta_\eta u - u|^2 + N^2|\nabla u|^2 + N^2 m_{kg}^2|u|^2)\frac{1}{N}\mathrm{dVol} = \int_\Sigma (N^2|\nabla v|^2 + N^2 m_{kg}^2|v|^2$$

$$+ N^4|\Delta_\eta u|^2 + (1 + m_{kg}^2)N^2|\nabla u|^2 + (m_{kg}^2 N^2 + 1)|u|^2)\frac{1}{N}\mathrm{dVol}.$$

But, for a regular solution U^{KG} of (66) with $V_3 = 0$ associated to the initial data $U_0^{\mathrm{KG}} \in C_0^\infty(\Sigma) \oplus C_0^\infty(\Sigma)$, we have

$$\partial_\tau(\mathcal{M}_{\tilde{\mathcal{A}}_{\mathrm{KG}}}(\tau)U^{\mathrm{KG}}(\tau)) = \mathcal{M}_{\mathcal{A}_{\mathrm{KG}}}(\tau)(\mathcal{M}_{\tilde{\mathcal{A}}_{\mathrm{KG}}}(\tau)U^{\mathrm{KG}}(\tau)) + ((\partial_\tau\mathcal{M}_{\mathcal{A}_{\mathrm{KG}}}(\tau)) + [\mathcal{M}_{\mathcal{A}_{\mathrm{KG}}}(\tau), \mathcal{M}_{\tilde{\mathcal{A}}_{\mathrm{KG}}}(\tau)])U^{\mathrm{KG}}(\tau)$$

where

$$[\mathcal{M}_{\mathcal{A}_{\mathrm{KG}}}(\tau), \mathcal{M}_{\tilde{\mathcal{A}}_{\mathrm{KG}}}(\tau)] = \begin{pmatrix} \tilde{\mathcal{A}}_{\mathrm{KG}} - \mathcal{A}_{\mathrm{KG}} & 0 \\ 0 & \mathcal{A}_{\mathrm{KG}} - \tilde{\mathcal{A}}_{\mathrm{KG}}, \end{pmatrix} = (N^2 - 1)\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{76}$$

Hence, we obtain the integral formula

$$\mathcal{M}_{\tilde{\mathcal{A}}_{\mathrm{KG}}}(\tau)U^{\mathrm{KG}}(\tau) = \mathcal{U}_{\mathrm{KG}}(\tau, \tau_0)(\mathcal{M}_{\tilde{\mathcal{A}}_{\mathrm{KG}}}(au_0)U^{\mathrm{KG}}(\tau_0)) + \int_{\tau_0}^{\tau} \mathcal{U}_{\mathrm{KG}}(\tau, \sigma)G(\sigma)\mathrm{d}\sigma, \tag{77}$$

with

$$G(\sigma) := ((\partial_\tau\mathcal{M}_{\mathcal{A}_{\mathrm{KG}}}(\sigma)) + [\mathcal{M}_{\mathcal{A}_{\mathrm{KG}}}(\tau), \mathcal{M}_{\tilde{\mathcal{A}}_{\mathrm{KG}}}(\tau)])U^{\mathrm{KG}}(\sigma). \tag{78}$$

But thanks to Proposition 2.1 we have

$$\|G(\sigma)\|_{[1,0]} \leqslant C(\sigma)\|U^{\mathrm{KG}}(\sigma)\|_{[2,1]}, \tag{79}$$

where C is a continuous positive function on $\mathbb{R}$ independent of U^{KG}. Hence, by formula (77) and the Gronwall lemma we obtain the estimate

$$\|U^{\mathrm{KG}}(\tau)\|_{[2,1]} \leqslant C'(\tau,\tau_0)\|U_0^{\mathrm{KG}}\|_{[2,1]}, \tag{80}$$

where C' is a continuous function such that $C'(\tau,\tau)=1$. Now, we introduce $H_0^{2,1}(\Sigma)$ as the completion of $C_0^\infty(\Sigma)\oplus C_0^\infty(\Sigma)$ for the norm

$$\|(u,v)\|_{(2,1)}^2 := \int_\Sigma (N^2|\nabla v|^2 + |v|^2 + N^4|\Delta_\eta u|^2 + N^2|\nabla u|^2 + |u|^2)\frac{1}{N}\mathrm{dVol}. \tag{81}$$

This space, smaller than $\mathcal{H}_0^{2,1}(\Sigma)$ allow us to use the Sobolev embedding. Clearly $H_0^{2,1}(\Sigma)\hookrightarrow\mathcal{H}_0^{2,1}(\Sigma)$. Moreover, if we consider the initial data $U_0^{\mathrm{KG}}\in C_0^\infty(\Sigma)\oplus C_0^\infty(\Sigma)$ in some initial time $\tau_0\in\mathbb{R}$, we have $U^{\mathrm{KG}}\in C^\infty(\mathbb{R}_\tau; C_0^\infty(\Sigma)\oplus C_0^\infty(\Sigma))$ and

$$\|U^{\mathrm{KG}}(\tau)\|_{(2,1)} \leqslant C_1(\|U^{\mathrm{KG}}(\tau)\|_{[2,1]} + \|\Phi(\tau)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})} + \|\partial_\tau\Phi(\tau)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})}), \quad C_1>0. \tag{82}$$

But

$$\|\Phi(\tau)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})} \leqslant \|\Phi(\tau_0)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})} + \int_{\tau_0}^{\tau}\|\partial_\tau\Phi(\sigma)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})}\mathrm{d}\sigma \tag{83}$$

$$\leqslant \|U^{\mathrm{KG}}(\tau_0)\|_{(2,1)} + \int_{\tau_0}^{\tau}\|U^{\mathrm{KG}}(\sigma)\|_{(2,1)}\,\mathrm{d}\sigma \tag{84}$$

and

$$\|\partial_\tau\Phi(\tau)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})} \leqslant \|\partial_\tau\Phi(\tau_0)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})} + \int_{\tau_0}^{\tau}\|\partial_\tau^2\Phi(\sigma)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})}\mathrm{d}\sigma \tag{85}$$

$$\leqslant \|U^{\mathrm{KG}}(\tau_0)\|_{(2,1)} + \int_{\tau_0}^{\tau}\|\mathcal{A}_{\mathrm{KG}}\Phi(\sigma)\|_{L^2(\Sigma;N^{-1}\,\mathrm{dVol})}\mathrm{d}\sigma \tag{86}$$

$$\leqslant \|U^{\mathrm{KG}}(\tau_0)\|_{(2,1)} + \int_{\tau_0}^{\tau}\|U^{\mathrm{KG}}(\sigma)\|_{(2,1)}\mathrm{d}\sigma. \tag{87}$$

Hence, thanks to (80) and the two previous estimates, we deduce with (82) that

$$\|U^{\mathrm{KG}}(\tau)\|_{(2,1)} \leqslant C'(\tau,\tau_0)\|U^{\mathrm{KG}}(\tau_0)\|_{(2,1)} + C_2\|U^{\mathrm{KG}}(\tau_0)\|_{(2,1)} + C_2\int_{\tau_0}^{\tau}\|U^{\mathrm{KG}}(\sigma)\|_{(2,1)}\mathrm{d}\sigma, \quad C_2>0 \tag{88}$$

and by the Gronwall lemma

$$\|U^{\mathrm{KG}}(\tau)\|_{(2,1)} \leqslant C''(\tau,\tau_0)\|U_0^{\mathrm{KG}}\|_{(2,1)}, \tag{89}$$

with C'' a continuous positive function on $\mathbb{R}$ independent of U^{KG}. This last estimate allows us to extend $\mathcal{U}_{\mathrm{KG}}$ as a propagator on $H_0^{2,1}(\Sigma)$. Hence, with the Theorem 3.1 and the preview result we deduce the existence of a progator for the linear part of equation (68) on $H_0^2(\Sigma;\mathbb{S}_D)\oplus H_0^{2,1}(\Sigma)$:

Proposition 4.3: For any initial data $U_0\in H_0^2(\Sigma;\mathbb{S}_D)\oplus H_0^{2,1}(\Sigma)$, *the system (68) with* $\mathcal{J}_{\mathrm{DKG}}$

$=0$ *has a unique solution* U *satisfying*

$$U \in C^0(\mathbb{R}_\tau; H_0^2(\Sigma;\mathbb{S}_D) \oplus H_0^{2,1}(\Sigma)). \tag{90}$$

Moreover, there exits a propagator $\mathcal{U}_{\mathrm{DKG}}$ *such that*

(i) $\mathcal{U}_{\mathrm{DKG}}(\tau,\tau_0): U_0 \mapsto U(\tau)$, $\mathcal{U}_{\mathrm{DKG}} := {}^t(\mathcal{U}_D, \mathcal{U}_{\mathrm{KG}})$.
(ii) $\forall t,s \in \mathbb{R}$, $\mathcal{U}_{\mathrm{DKG}}(t,s) \in \mathcal{L}(H_0^2(\Sigma;\mathbb{S}_D) \oplus H_0^{2,1}(\Sigma))$.
(iii) $\mathcal{U}_{\mathrm{DKG}}$ *is strongly continuous on* $\mathbb{R}^2_{ts}$ *to* $\mathcal{L}(H_0^2(\Sigma;\mathbb{S}_D) \oplus H_0^{2,1}(\Sigma))$.
(iv) $\mathcal{U}_{\mathrm{DKG}}(t,t) = \mathrm{Id}$, $\mathcal{U}_{\mathrm{DKG}}(t,s) = \mathcal{U}_{\mathrm{DKG}}(t,r)\mathcal{U}_{\mathrm{DKG}}(r,s)$ *for all* $t,s,r \in \mathbb{R}$.
(iv) *There exists a continuous, strictly positive function* κ_{DKG} *such that*

$$\|U(\tau)\|_{(2,2,1)} := \|\Psi(\tau)\|_{(2)} + \|(\Phi(\tau), \partial_\tau \Phi(\tau))\|_{(2,1)} \leqslant \kappa_{\mathrm{DKG}}(\tau,\tau_0)\|U_0\|_{(2,2,1)}, \quad \kappa_{\mathrm{DKG}}(\tau,\tau) = 1. \tag{91}$$

To study the nonlinear Cauchy problem for (DKG), we establish the following lemma about the continuity of $\mathcal{J}_{\mathrm{DKG}}$ on $H_0^2(\Sigma;\mathbb{S}_D) \oplus H_0^{2,1}(\Sigma)$.

Lemma 4.1: There exists a constant $C \geqslant 0$ *such that,* $U_i = (\Psi_i, V_i) = (\Psi_i, \Phi_i, \partial_\tau \Phi_i) \in H_0^2(\Sigma;\mathbb{S}_D) \oplus H_0^{2,1}(\Sigma)$ *and* $\cup_i \mathrm{supp}(\Phi_i) \subset [R,+\infty] \times S_\omega$, $R > 0$,

$$\|\mathcal{J}_{\mathrm{DKG}}(U_1)\|_{(2,2,1)} \leqslant C\|U_1\|^2_{(2,2,1)}, \tag{92}$$

$$\|\mathcal{J}_{\mathrm{DKG}}(U_1) - \mathcal{J}_{\mathrm{DKG}}(U_2)\|_{(2,2,1)} \leqslant C(\|U_1\|_{(2,2,1)} + \|U_2\|_{(2,2,1)})\|U_1 - U_2\|_{(2,2,1)}. \tag{93}$$

Proof: We prove (93), indeed (92) is (93) with $U_2 \equiv 0$. We have

$$\mathcal{J}_{\mathrm{DKG}}(U_1) - \mathcal{J}_{\mathrm{DKG}}(U_2) = \begin{pmatrix} i\dfrac{N}{\sqrt{2}}(\Phi_2 \gamma^0 \mathcal{V}_2(\Psi_1 - \Psi_2) + (\Phi_1 - \Phi_2)\gamma^0 \mathcal{V}_2 \Psi_1) \\ 0 \\ N^2(\Psi_2^* \mathcal{V}_3(\Psi_1 - \Psi_2) + (\Psi_1^* - \Psi_2^*)\mathcal{V}_3 \Psi_1) \end{pmatrix}. \tag{94}$$

We estimate the first component of the previous difference. We introduce $H_0^2(\Sigma)$ as the completion of $C_0^\infty(\Sigma)$ in the norm

$$\|\Phi\|_{H^2(\Sigma)} := \int_\Sigma |\Phi|^2 + |\nabla\Phi|^2 + |\underline{\Delta}_\eta|^2 \, \mathrm{dVol}, \quad \underline{\Delta}_\eta := \frac{1}{\sqrt{|\eta|}} \frac{\partial}{\partial x^a}\left(\sqrt{|\eta|}\,\eta^{ab}\frac{\partial}{\partial x^b}\right). \tag{95}$$

Since $H^2(\mathbb{R}^3) \hookrightarrow L^\infty(\mathbb{R}^3)$ and $h(\tau)$ is equivalent to the Euclidian metric on $\mathbb{R}^3 \backslash \bar{B}(0,1)$, we obtain as in Lemma 3.1,

$$\|\Phi\|_{L^\infty(\Sigma)} \leqslant C_1\|\Phi\|_{H^2(\Sigma)}, \quad C_1 > 0, \quad \Phi \in H_0^2(\Sigma). \tag{96}$$

Moreover, for $\Phi \in C_0^\infty(\Sigma)$,

$$N\Delta_\eta \Phi = N\underline{\Delta}_\eta \Phi + \nabla N \,.\, \nabla\Phi \tag{97}$$

and

$$\underline{\Delta}_\eta(N\Phi) = N\underline{\Delta}_\eta\Phi + 2\,\nabla N \,.\, \nabla\Phi + (\underline{\Delta}_\eta N)\Phi. \tag{98}$$

Therefore, for $V = {}^t(\Phi, \partial_\tau\Phi) \in H_0^{2,1}(\Sigma)$ with $\mathrm{supp}(\Phi) \subset [R,+\infty[\times S_\omega, R > 0$ and since on $\mathrm{supp}(\Phi)$ there exists $C_i > 0$ such that $C_1 \leqslant N \leqslant C_2$, we have

$$\|N\Phi\|_{L^\infty(\Sigma)} \leqslant C_2\|V\|_{(2,1)}, \quad C_2 > 0, \quad V = {}^t(\Phi, \partial_\tau\Phi) \in H_0^{2,1}(\Sigma). \tag{99}$$

Hence

$$\left\| i\frac{N}{\sqrt{2}}(\Phi_2\mathcal{V}_2(\Psi_1-\Psi_2)+(\Phi_1-\Phi_2)\mathcal{V}_2\Psi_1)\right\|_{(2)} \leqslant C_2(\|V_2\|_{(2,1)}\|\Psi_1-\Psi_2\|_{(2)}+\|V_1-V_2\|_{(2,1)}\|\Psi_1\|_{(2)})$$
$$\leqslant C_2(\|U_1\|_{(2,2,1)}+\|U_2\|_{(2,2,1)})\|U_1-U_2\|_{(2,2,1)}. \tag{100}$$

Moreover with (47), we have

$$\|(0,N^2(\Psi_2^*\gamma^0\mathcal{V}_3(\Psi_1-\Psi_2)+(\Psi_1^*-\Psi_2^*)\gamma^0\mathcal{V}_3\Psi_1))\|_{(2,1)} \leqslant C_3(\|U_1\|_{(2,2,1)}+\|U_2\|_{(2,2,1)})\|U_1-U_2\|_{(2,2,1)}, \tag{101}$$

$$C_3>0$$

and with (100) we deduce the result. ■

According to Theorem 4.3, $\mathcal{U}_{\mathrm{DKG}}\in\mathcal{L}(H_0^2(\Sigma;\mathbb{S}_D)\oplus H_0^{2,1}(\Sigma))$ and satisfies (91). Moreover, for $U_0:=(\Psi_0,\Phi_0,\Phi_1)\in H_0^2(\Sigma;\mathbb{S}_D)\oplus H_0^{2,1}(\Sigma)$ at $\tau_0>0$ and $\cup_i \mathrm{supp}(\Phi_i)\subset[R,+\infty[\times S_\omega$, $R>0$, we have $\mathrm{supp}(\mathcal{U}(\tau,\tau_0)U_0)\subset[R'(R,\tau,\tau_0),+\infty[\times S_\omega$, $R'(R,\tau,\tau_0)<R$ since the system (68) with $\mathcal{J}_{\mathrm{DKG}}=0$ is hyperbolic. Hence, in the integral formulation of the Cauchy problem, we can apply Lemma 4.1 for $\mathcal{U}(\tau,\tau_0)U_0$. By an identical proof of Theorem 3.2, we have the following theorem.

Theorem 4.2: *For* $U_0:=(\Psi_0,\Phi_0,\Phi_1)\in H_0^2(\Sigma;\mathbb{S}_D)\oplus H_0^{2,1}(\Sigma)$ *at* $\tau_0>0$ *and* $\cup_i \mathrm{supp}(\Phi_i)\subset[R,+\infty[\times S_\omega$, $R>0$, *there exists* $T(\|U_0\|_{(2,2,1)})>0$ *such that system (68) admits a unique solution* U *such that*

$$U(\tau_0)=U_0\in H_0^2(\Sigma;\mathbb{S}_D)\oplus H_0^{2,1}(\Sigma),\quad U\in C^0([\tau_0,\tau_0+T[_\tau,H_0^2(\Sigma;\mathbb{S}_D)\oplus H_0^{2,1}(\Sigma)). \tag{102}$$

(Received 16 November 2005; accepted 15 March 2006; published online 26 May 2006)

We continue our analysis of the polynomial invariants of the Riemann tensor in a four-dimensional Lorentzian space. We concentrate on the mixed invariants of even degree in the Ricci spinor $\Phi_{AB\dot{A}\dot{B}}$ and show how, using constructive graph-theoretic methods, arbitrary scalar contractions between copies of the Weyl spinor Ψ_{ABCD}, its conjugate $\bar{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}$ and an even number of Ricci spinors can be expressed in terms of paired contractions between these spinors. This leads to an algorithm for the explicit expression of dependent invariants as polynomials of members of the complete set. Finally, we rigorously prove that the complete set as given by Sneddon [J. Math. Phys. **39**, 1659–1679 (1998)] for this case is both complete and minimal.

I. INTRODUCTION

This paper continues our recent work on the classic problem of determining a complete set of polynomial invariants of the Riemann tensor in a four-dimensional Lorentzian space.[1] Recall that a set, $I=\{I_1,I_2,\ldots I_n\}$, of invariants is said to be a complete set in the usual classical sense if any polynomial invariant can be expressed as a *polynomial* in $I_1,I_2,\ldots I_n$, and no invariant in the set can be so expressed in terms of the remaining I_i. It then seems natural to ask the following questions:

(i) How does one find a complete set of invariants for the Riemann tensor, and prove that this set is both complete and minimal?
(ii) How does one construct the polynomial syzygies[2] relating any other invariant to the members of this set?

The first question has received a significant amount of attention recently.[3–11] However, none of the existing work fully solves the problem without introducing additional restrictions.

It will be convenient to partition the set of Riemann tensor invariants into two subsets. The set $\mathcal{E}$ consists of invariants that are even in polynomial degree in the Ricci spinor, and the set $\mathcal{O}$ consists of invariants that are odd in polynomial degree in the Ricci spinor. We shall refer to members of $\mathcal{E}$ and $\mathcal{O}$ as "even invariants" and "odd invariants," respectively. The pure Weyl invariants, $\mathcal{W}$, and the even-degree pure Ricci invariants are subsets of $\mathcal{E}$, whereas the odd-degree pure Ricci invariants form a subset of $\mathcal{O}$.

Bonanos investigated the subset of even invariants formed by contractions between arbitrary products of Ψ_{ABCD} and the Weyl-type square of the Ricci spinor, $\Phi_{(AB}{}^{\dot{C}\dot{D}}\Phi_{CD)\dot{C}\dot{D}}$, with the additional requirement that all contractions involve pairs of indices.[11] All such invariants could be expressed in terms of traces of products of two symmetric matrices, and the problem was reduced to finding a complete set for these traces. Bonanos also conjectured that scalars formed via different types of spinor index contractions between Ψ_{ABCD} and $\Phi_{(AB}{}^{\dot{C}\dot{D}}\Phi_{CD)\dot{C}\dot{D}}$ can be expressed in terms of these traces.[12]

Sneddon's work on the even invariants was also similarly restricted to scalars formed solely via paired index contractions between Ψ_{ABCD}, $\Phi_{AB\dot{A}\dot{B}}\Phi_{CD}{}^{\dot{A}\dot{B}}$, $\Phi_{AB\dot{A}\dot{B}}\bar{\Psi}^{\dot{A}\dot{B}}{}_{\dot{C}\dot{D}}\Phi_{CD}{}^{\dot{C}\dot{D}}$, $\Phi_{AB\dot{A}\dot{B}}\bar{\Psi}^{\dot{A}\dot{B}}{}_{\dot{C}\dot{D}}\bar{\Psi}^{\dot{C}\dot{D}}{}_{\dot{E}\dot{F}}\Phi_{CD}{}^{\dot{E}\dot{F}}$ and their complex conjugates.[7,8] The problem of expressing even invariants formed via different types of spinor index contractions in terms of this subset was not explicitly addressed. In a subsequent work, Sneddon argued that the odd invariants are expressible in terms of the restricted even invariants and a subset of the odd invariants. This subset of odd invariants contains invariants which have exactly one factor of ϵ^{ABC} and exactly one factor of $\epsilon^{\dot{A}\dot{B}\dot{C}}$, where A, B, and C are rotor (bivector) indices that run from 1 to 3.[9] It is still unclear how to construct the functions relating arbitrary invariants to these subsets.

The *algebraically complete* set of Carminati and Zakhary is complete in a less restrictive sense: no invariant in their set can be expressed in an algebraic, as opposed to polynomial, relation with the remaining elements of the set.[3–5]

The second question has hardly been addressed at all in the literature. With the exception of Bonanos,[11] these existing results established completeness using nonconstructive methods and therefore provide no insight on how to relate invariants outside the complete sets to those within these sets.

In the first part of this series, which will be referred to throughout this paper as "paper I," we introduced a correspondence between directed multigraphs and pure Weyl and pure Ricci invariants.[1] This correspondence allowed the development of a graph-theoretic algorithm for the construction of syzygies relating *any* pure invariant in terms of members of their complete sets. A constructive proof of Bonanos' conjecture for the special case of the pure Weyl invariants is a corollary of these results.[1]

In this paper, we extend the graphical representation of invariants to cover mixed invariants, and investigate the completeness problem for mixed invariants which are of even degree in the Ricci spinor. Unless otherwise stated, the notation and terminology used is that of our previous paper.[1]

II. GRAPHICAL REPRESENTATION OF MIXED INVARIANTS

In the case of the mixed invariants, we need to uniquely associate the invariants with directed multigraphs possessing three distinct classes of vertices corresponding to the Ricci spinor, the Weyl spinor and the conjugate Weyl spinor. We accomplish this using the following definition:

Definition 1: The directed multigraph G_N uniquely associated with each invariant N consists of the following:

(i) *A vertex set $V=\{v_1,v_2,\ldots,v_n\}$, where each element of V is uniquely associated with each spinor contracted to form N.*

(ii) *A vertex characteristic function $\varphi: V\rightarrow\{4,4i,2+2i\}$ such that*

$$\varphi(v_j)=\begin{cases}2+2i, & \text{iff } v_j \text{ is a Ricci spinor}\\ 4, & \text{iff } v_j \text{ is a Weyl spinor}\\ 4i, & \text{iff } v_j \text{ is a conjugate Weyl spinor},\end{cases}$$

(iii) *An arc set $E=V\times V$, and*

(iv) *Two multiplicity functions, $m^S: V\times V\rightarrow\{0,1,2,3,4\}$, and $m^D: V\times V\rightarrow\{0,1,2,3,4\}$, such that each arc $(v_j,v_k)\in E$ is associated with two multiplicities: the number of contractions between lower undotted indices on the spinor v_j and upper undotted indices on the spinor v_k is $m^S(v_j,v_k)$, whereas the number of contractions between lower dotted indices on the spinor v_j and upper dotted indices on the spinor v_k is $m^D(v_j,v_k)$.*

In the figures, vertices of characteristic 4, $4i$ and $2+2i$ are depicted using the symbols Ψ, $\bar{\Psi}$, and Φ, respectively. Recall that we use two types of arcs to depict the two multiplicity functions: contractions between undotted indices are represented by solid arcs, and contractions between dotted indices are represented by dashed arcs. For example, the invariants I_1

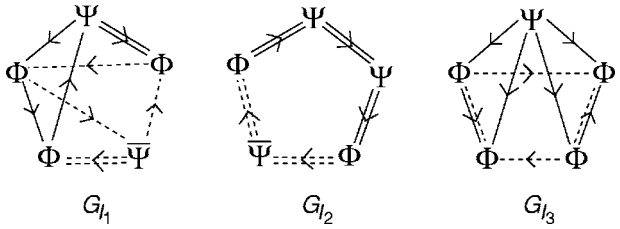

FIG. 1. Directed multigraphs associated with the invariants I_1, I_2, and I_3.

$=\Psi_{A\dot{A}DE}\Phi^{DE\dot{A}\dot{B}}\bar{\Psi}_{\dot{B}\dot{D}\dot{E}}\Phi_{B}{}^{C\dot{D}\dot{E}}\Phi_{C\dot{C}}{}^{A\dot{A}}$, $I_2=\Psi^{AB}{}_{CD}\Psi^{CD}{}_{EF}\Phi^{EF}{}_{\dot{E}\dot{F}}\bar{\Psi}^{\dot{E}\dot{F}}{}_{\dot{C}\dot{D}}\Phi_{AB}{}^{\dot{C}\dot{D}}$, and $I_3=\Psi_{ABCD}\Phi^{AE\dot{A}\dot{B}}\Phi^{B}{}_{E\dot{A}\dot{C}}\Phi^{CF\dot{C}\dot{D}}\Phi^{D}{}_{F\dot{D}\dot{B}}$ are associated with the graphs G_{I_1}, G_{I_2}, and G_{I_3}, respectively, in Fig. 1.

Adopting vertex orderings as given in the contraction sequences of I_1, I_2, and I_3 in the preceding paragraph, we can represent these graphs as their adjacency matrices, where the entry in row j and column k is the total multiplicity of the arcs from vertex j to vertex k. The generalized definition of total multiplicity given in paper I is applicable to the mixed invariants.[1]

$$A(G_N)=[a_{jk}],$$

$$a_{jk}=m(v_j,v_k)=m^S(v_j,v_k)+im^D(v_j,v_k),\quad j,k=1,2,\ldots,n, \tag{1}$$

$$A(G_{I_1})=\begin{bmatrix}0&2&0&0&1\\0&0&0&0&i\\0&i&0&2i&0\\1&0&0&0&0\\0&0&i&1&0\end{bmatrix},$$

$$A(G_{I_2})=\begin{bmatrix}0&2&0&0&0\\0&0&2&0&0\\0&0&0&2i&0\\0&0&0&0&2i\\2&0&0&0&0\end{bmatrix},$$

$$A(G_{I_3})=\begin{bmatrix}0&1&1&1&1\\0&0&0&0&0\\0&1+i&0&i&0\\0&0&0&0&0\\0&i&0&1+i&0\end{bmatrix}.$$

We can assume without loss of generality that no loops are present in these graphs, i.e., for all $v_j\in V(G_N), a_{jj}=m(v_j,v_j)=0$, because self-contracted Weyl and Ricci spinors are identically zero. Using the convention introduced in our previous paper, the sum of the outdegrees and the indegrees at each vertex depends on whether it is associated with a Ricci spinor, Weyl spinor, or conjugate Weyl spinor. The following condition holds for the sum of outdegrees and indegrees at v_j:

$$\sum_{k=1}^{n}(a_{jk}+a_{kj})=\varphi(v_j),\quad j=1,2,\ldots,n. \tag{2}$$

Equivalently, the degrees of the vertices of the underlying undirected graph, U_N, of G_N are equal to their respective characteristics.

As per our previous paper, we associate each invariant N with its oriented form N' by reorienting arcs in G_N to form $G_{N'}$, which satisfies the condition $m(v_j,v_k)=0$ whenever $m(v_k,v_j)\neq 0$ for all $j\neq k$. N' is equivalent to N up to a sign, depending on whether the number of arcs reoriented to form $G_{N'}$ from G_N is even or odd.

We say that the graph G_N, which possesses two types of arcs, is connected iff at least one path exists between any pair of vertices when the types and the directions of the arcs are both disregarded. We can now describe an invariant N as being connected iff G_N is a connected graph.

By directly extending Definition 1 in an obvious manner, we can use graphs to represent spinors with free indices, up to a sign. While the directions of contractions between pairs of indices are specified, we note that the correspondence in Definition 1 would not provide any information on the covariant or contravariant nature of the free indices. It is possible to augment the correspondence to account for the nature of these indices. However, we shall not do so here as this is not required in any of the subsequent discussion in this paper.

Unlike the graphs associated with the invariants, the graph G_ξ associated with the p-spinor ξ possesses *deficient vertices*, which are associated with the component spinors of ξ that possess free indices. Assuming ξ is formed via contractions between the Weyl, conjugate Weyl and Ricci spinors, we may associate with each vertex of G_ξ a vertex deficiency, $\mathcal{D}:V\rightarrow\{0,1,2,3,4,i,2i,3i,4i,1+i,1+2i,2+i,2+2i\}$, where

$$\mathcal{D}(v_j)=\varphi(v_j)-\sum_{k=1}^{n}(a_{jk}+a_{kj}),\quad j=1,2,\ldots,n.$$

$\mathrm{Re}(\mathcal{D}(v_j))$ and $\mathrm{Im}(\mathcal{D}(v_j))$ are the number of free undotted and dotted indices on the spinor associated with v_j, respectively. It immediately follows that

$$\sum_{j=1}^{n}[\mathrm{Re}(\mathcal{D}(v_j))+\mathrm{Im}(\mathcal{D}(v_j))]=p.$$

We are now in a position to state that ξ is *connected* iff G_ξ is connected. A disconnected spinor may be expressed as a product of connected spinors and invariants, where each factor corresponds to a connected subgraph of G_ξ. For example, $\Psi_{ABEF}\Psi_{CGH}{}^{E}\Psi_{D}{}^{FGH}$ is connected, whereas $\Psi_{AEFG}\Phi_{BH\dot{B}\dot{H}}\Psi_{C}{}^{EFG}\Phi_{D}{}^{H\dot{B}\dot{H}}$ is disconnected, and is the product of two connected spinors, $\Psi_{AEFG}\Psi_{C}{}^{EFG}$ and $\Phi_{BH\dot{B}\dot{H}}\Phi_{D}{}^{H\dot{B}\dot{H}}$.

The following result holds for oriented graphs associated with any mixed invariant.

Lemma 1: The total number of odd-multiplicity arcs of a given type which are incident with each vertex of $G_{N'}$ is even (or zero).

Proof: Each vertex of $G_{N'}$ is incident with an even number of (or zero) arcs of either type. It immediately follows that any vertex of $G_{N'}$ cannot be incident with an odd number of odd-multiplicity arcs of either type. ■

We introduced unpaired subgraphs in paper I when discussing the construction of syzygies involving the pure Weyl invariants.[1] The concept is readily extendable to the mixed case: consider the subgraphs, $S^S_{N'}$ and $S^D_{N'}$, of the oriented directed graph, $G_{N'}$ where $m_{S^S_{N'}}(v_j,v_k)=1$ iff $\mathrm{Re}(m_{G_{N'}}(v_j,v_k))$ is odd, and $m_{S^S_{N'}}(v_j,v_k)=0$ otherwise; while $m_{S^D_{N'}}(v_j,v_k)=i$ iff $\mathrm{Im}(m_{G_{N'}}(v_j,v_k))$ is odd, and $m_{S^D_{N'}}(v_j,v_k)=0$ otherwise. Thus, the oriented graph $G_{N'}$ associated with a mixed invariant may be considered to be the union of three edge-disjoint subgraphs: $G_{N'}=S^S_{N'}\cup S^D_{N'}\cup G^S_{N'}$, where the subgraph $G^S_{N'}$ consists solely of solid and dashed arcs of even multiplicity. The adjacency matrices of these subgraphs satisfy the following conditions:

$$A(S^S_{N'})=[\mathrm{Re}(a'_{jk})\bmod 2],$$

$$A(S^D_{N'}) = [i(\mathrm{Im}(a'_{jk}) \bmod 2)], \tag{3}$$

$$A(G^S_{N'}) = A(G_{N'}) - (A(S^S_{N'}) + A(S^D_{N'})),$$

and the subgraphs $S^S_{N'}$ and $S^D_{N'}$ satisfy the following property.

Lemma 2: The arcs in $S^S_{N'}$ and $S^D_{N'}$ may be reoriented to form $S^S_{N''}$ and $S^D_{N''}$ respectively, such that each connected component of $S^S_{N''}$ and $S^D_{N''}$ has a directed Euler circuit.

Proof: This immediately follows from Lemma 1, which implies that the degrees of every vertex of $S^S_{N'}$ and $S^D_{N'}$ are divisible by two. ■

III. PROPERTIES OF EVEN AND ODD INVARIANTS

Consider the sets $\mathcal{E}^c \subset \mathcal{E}$ and $\mathcal{O}^c \subset \mathcal{O}$, which are the connected invariants within $\mathcal{E}$ and $\mathcal{O}$, respectively. We observe that an invariant $N \in \mathcal{E}$ either belongs to $\mathcal{E}^c$ or is the product of elements of $\mathcal{E}^c$ and/or an even number of elements of $\mathcal{O}^c$, whereas an invariant $N \in \mathcal{O}$ either belongs to $\mathcal{O}^c$ or is the product of an element of $\mathcal{O}^c$ and an element of $\mathcal{E}$.

Lemma 3: When $N \in \mathcal{E}$, G_N possesses an even number of solid arcs and an even number of dashed arcs. Furthermore, the number of distinct odd-multiplicity arcs of each type in $G_{N'}$ is either zero, or even and greater than or equal to four.

Proof: N has the general form $\Psi^n \Phi^{2m} \bar{\Psi}^p$. The sum of the degrees of all vertices in the underlying undirected graph, U_N, of G_N is $4n+2m(2+2i)+(4p)i$. It follows that the sums of all solid arc multiplicities, and of all dashed arc multiplicities in G_N are even, being $2(n+m)$ and $2(m+p)$, respectively. Hence, there must be an even number of (or zero) odd-multiplicity arcs of each type in G_N. Suppose we had some $G_{N'}$ possessing only two odd-multiplicity arcs of a given type. By Lemma 2, it follows that both these arcs must connect one pair of vertices v_j and v_k, where both $m(v_j, v_k)$ and $m(v_k, v_j)$ are odd. This contradicts the fact that $G_{N'}$ is oriented. Thus, if the number of distinct odd-multiplicity arcs of a given type in $G_{N'}$ is nonzero, the minimum number of such odd-multiplicity arcs is four. ■

Lemma 4: When $N \in \mathcal{O}$, G_N possesses an odd number of solid arcs and an odd number of dashed arcs. Furthermore, the number of distinct odd-multiplicity arcs of each type in $G_{N'}$ is odd and greater than or equal to three.

Proof: N has the form $\Psi^n \Phi^{2m+1} \bar{\Psi}^p$. The sum of the degrees of all vertices in the underlying undirected graph, U_N, of G_N is $4n+(2m+1)(2+2i)+(4p)i$. It follows that the number of solid and dashed arcs in G_N are $2(n+m)+1$ and $2(m+p)+1$, respectively. Hence, there must be an odd number of odd-multiplicity arcs of each type in G_N. Suppose we had some $G_{N'}$ possessing exactly one odd-multiplicity arc of a given type. By Lemma 2, it follows that this arc forms a loop at a single vertex, which implies that $N \equiv 0$. Thus, the minimum number of such odd-multiplicity arcs in $G_{N'}$ is three. ■

We shall concentrate on finding a complete set of invariants for $\mathcal{E}$ in this paper, and address the determination of a complete set for $\mathcal{O}$ in a subsequent presentation. We define the set $\hat{\mathcal{E}} \subset \mathcal{E}$ such that an even invariant N belongs to $\hat{\mathcal{E}}$ iff all contractions in N are *even*, i.e., all contractions between spinors in N occur pairwise, and the contractions belonging to each pair have the same direction. This is equivalent to saying that every arc in G_N possesses multiplicities that are divisible by 2. The invariant I_2 represented in Fig. 1 is a member of this set.

The set $\hat{\mathcal{E}}^c \subset \hat{\mathcal{E}}$ consists of the connected invariants within $\hat{\mathcal{E}}$. We note that $\hat{\mathcal{W}} \subset \hat{\mathcal{E}}$, and $\hat{\mathcal{W}}^c \subset \hat{\mathcal{E}}^c$. The even-degree pure Ricci invariants belonging to $\hat{\mathcal{E}}^c$ are associated with "polygon-shaped" graphs with alternating solid and dashed arcs of multiplicity two.

Lemma 5: An invariant $N \in \hat{\mathcal{E}}$ either belongs to $\hat{\mathcal{E}}^c$, or is expressible as a product of elements of $\hat{\mathcal{E}}^c$.

Proof: Suppose $N \in \hat{\mathcal{E}}$. If G_N is connected, then $N \in \hat{\mathcal{E}}^c$. Suppose G_N is disconnected and it possesses a connected subgraph, S_{odd} containing an odd number of vertices of vertex characteristic

$2+2i$. It follows from Lemma 4 that S_{odd} possesses an odd number of arcs of either arc type. Hence the multiplicity of every arc in G_N is not divisible by 2, contradicting the fact that $N \in \hat{\mathcal{E}}$. Thus, if G_N is disconnected, each of its connected components must possess an even number of vertices of characteristic $2+2i$, and given that the multiplicity of every arc in G_N must be divisible by 2, it follows that each connected component is associated with a member of $\hat{\mathcal{E}}^c$. ■

We are now in a position to state the main result of this section. Following the convention introduced in Paper I, we use the symbol $\oplus$ in the graphical representation to denote addition of the associated invariants of two graphs.[1,13]

Theorem 1: *For any invariant $N \in \mathcal{E}$, $S^S_{N'}$ and $S^D_{N'}$ are expressible, using the identity, as a finite sum of graphs, $\tilde{S}^S_j$ and $\tilde{S}^D_l$, consisting only of even-multiplicity arcs which are solid and dashed, respectively,*

$$S^S_{N'} \equiv \mathop{\oplus}_{j=1}^{n} b_j \tilde{S}^S_j, \tag{4}$$

$$S^D_{N'} \equiv \mathop{\oplus}_{l=1}^{m} c_l \tilde{S}^D_l, \tag{5}$$

where the coefficients b_j and c_l are rational numbers.

The graph $G_{N'}$ may then be expressed as

$$G_{N'} \equiv \mathop{\oplus}_{j=1}^{n} \mathop{\oplus}_{l=1}^{m} b_j c_l G_{X_{jl}}, \tag{6}$$

where

$$G_{X_{jl}} = G^S_{N'} \cup \tilde{S}^S_j \cup \tilde{S}^D_l. \tag{7}$$

The invariant N' then obeys the following identity:

$$N' = \sum_{j=1}^{n} \sum_{l=1}^{m} b_j c_l X_{jl}, \tag{8}$$

where $X_{jl} \in \hat{\mathcal{E}}$, $j=1,2,\ldots,n$; $l=1,2,\ldots,m$.

Proof: By Lemma 2, the unpaired subgraphs $S^S_{N'}$ and $S^D_{N'}$ are reorientable to $S^S_{N''}$ and $S^D_{N''}$ where each connected component of $S^S_{N''}$ and $S^D_{N''}$ are Euler circuits. $S^S_{N''}$ and $S^D_{N''}$ are equivalent to $S^S_{N'}$ and $S^D_{N'}$, respectively, up to a sign modulo union with $G^S_{N'}$ in the graphical representation, depending on whether the total number of arcs reoriented is even or odd. Lemma 3 requires that the sums of lengths of the solid circuits in $S^S_{N''}$ and of the dashed circuits in $S^D_{N''}$ must both be even.

Case 1: Both $S^S_{N''}$ and $S^D_{N''}$ are connected.

Let $S^S_{N''}$ be a single solid k-circuit, and $S^D_{N''}$ be a single dashed k^*-circuit, where both k and k^* are even. Following the argument presented in Case 1 of the proof of Theorem 1 in Paper I,[1] and incorporating a sign change if an odd number of arcs were reoriented to form $S^S_{N''}$ from $S^S_{N'}$, it is possible to reexpress $S^S_{N''}$ as written in Eq. (4). A direct extension of this method to dashed arcs yields Eq. (5). Each individual term, $G_{X_{jl}}$ in the graphical decomposition of $G_{N'}$ [Eq. (6)] is constructed by forming the union of $G^S_{N'}$ with $\tilde{S}^S_j$ and $\tilde{S}^D_l$, as shown in Eq. (7). The equivalent expression in spinor form expresses N' as a polynomial of members of $\hat{\mathcal{E}}$ [Eq. (8)].

Case 2: At least one of $S^S_{N''}$ or $S^D_{N''}$ is not connected.

When $S^S_{N''}$ is not connected, it is reducible to the connected case using the procedure described in Case 2 of the proof of Theorem 1 in Paper I.[1] The extension towards the reduction of $S^D_{N''}$ to the connected case is trivial. ■

Bonanos' full conjecture[11] is a corollary of this result. We note that Theorem 1 holds for both connected and disconnected members of $\mathcal{E}$, and applying the decomposition process outlined in the proof to disconnected members of $\mathcal{E}$ yields *algebraic* syzygies involving connected invariants. Sneddon has suggested that squares of odd invariants, and products of any two odd invariants, will be expressible as polynomials of even invariants.[8] In fact, this will be true for any product containing an even number of odd invariants. We have now provided a means of explicitly constructing such syzygies, and an example is provided in Appendix A. Polynomial syzygies relating odd invariants to members of $\hat{\mathcal{O}}^c$ and $\hat{\mathcal{E}}^c$ will be explored in detail in the next part of this series.

IV. DETERMINATION OF THE BASIS ELEMENTS OF $\hat{\mathcal{E}}^c$

Lemma 5 and Theorem 1 reduce the problem of finding a polynomial basis for $\mathcal{E}$ to that of finding one for $\hat{\mathcal{E}}^c$. Ultimately, we also wish to explicitly construct the syzygies relating any member of $\mathcal{E}$ to the basis. To achieve these objectives, we construct spinorial objects that constitute fundamental building blocks for the elements of $\hat{\mathcal{E}}^c$, and examine the structures of these elements in terms of the building blocks. We make the following definition.

Definition 2: A Υ*-spinor is any connected 4-indexed spinor* Υ_{ABCD} *which may be formed solely from even dotted contractions between copies of the Weyl, conjugate Weyl and Ricci spinors.*

Apart from the trivial Υ-spinor, Ψ_{ABCD}, the Υ-spinors can only be formed using the conjugate Weyl and Ricci spinors. All of the available dotted indices must be completely exhausted using even dotted contractions. Furthermore, a Υ-spinor must have four free undotted indices, and not contain any undotted contractions. Therefore, all nontrivial Υ-spinors contain exactly two copies of the Ricci spinor, and can be described as a contiguous sequence of even dotted contractions beginning with a Ricci spinor, continuing with an arbitrary number of conjugate Weyl spinors, and ending with another Ricci spinor: $\Phi\bar{\Psi}^p\Phi$. It will be convenient to describe the Υ-spinors as having two types of symmetries: index-pair symmetry $\Upsilon_{ABCD}=\Upsilon_{BACD}=\Upsilon_{ABDC}$, and block symmetry $\Upsilon_{ABCD}=\Upsilon_{CDAB}$.

Every Υ-spinor has a dyad expansion of the following form:

$$
\begin{aligned}
{}^j\Upsilon_{ABCD} = {}&{}^j\Upsilon_{00}\iota_A\iota_B\iota_C\iota_D - 4{}^j\Upsilon_{01}\iota_{(A}\iota_B\iota_C o_{D)} + {}^j\Upsilon_{02}(o_A o_B\iota_C\iota_D + o_C o_D\iota_A\iota_B) + {}^j\Upsilon_{11}(o_A o_C\iota_B\iota_D + o_A o_D\iota_B\iota_C \\
&+ o_B o_C\iota_A\iota_D + o_B o_D\iota_A\iota_C) - 4{}^j\Upsilon_{12}o_{(A}o_B o_C\iota_{D)} + {}^j\Upsilon_{22}o_A o_B o_C o_D,
\end{aligned}
$$

where

$$
\begin{aligned}
{}^j\Upsilon_{00} &= {}^j\Upsilon_{0000}, \\
{}^j\Upsilon_{01} &= {}^j\Upsilon_{0001} = {}^j\Upsilon_{0010} = {}^j\Upsilon_{0100} = {}^j\Upsilon_{1000}, \\
{}^j\Upsilon_{02} &= {}^j\Upsilon_{0011} = {}^j\Upsilon_{1100}, \\
{}^j\Upsilon_{11} &= {}^j\Upsilon_{1010} = {}^j\Upsilon_{1001} = {}^j\Upsilon_{0110} = {}^j\Upsilon_{0101}, \\
{}^j\Upsilon_{12} &= {}^j\Upsilon_{0111} = {}^j\Upsilon_{1011} = {}^j\Upsilon_{1101} = {}^j\Upsilon_{1110}, \\
{}^j\Upsilon_{22} &= {}^j\Upsilon_{1111},
\end{aligned}
\tag{9}
$$

and the prefix j distinguishes distinct Υ-spinors.

Taking the conjugates of the Υ-spinors yield the $\bar{\Upsilon}$-spinors. Apart from the trivial $\bar{\Upsilon}$-spinor, $\bar{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}$, all $\bar{\Upsilon}$-spinors have the form of a contiguous sequence of even undotted contractions beginning with a Ricci spinor, continuing with an arbitrary number of Weyl spinors, and ending with another Ricci spinor: $\Phi\Psi^{p}\Phi$.

We now establish that the Υ-spinors and the $\bar{\Upsilon}$-spinors constitute fundamental building blocks for the invariants belonging to $\hat{\mathcal{E}}^{c}$.

Lemma 6: A connected invariant N belongs to $\hat{\mathcal{E}}^{c}$ iff it is expressible in at least one of the following ways:

(i) *solely as even contractions between copies of* Υ*-spinors, or*
(ii) *solely as even contractions between copies of* $\bar{\Upsilon}$*-spinors.*

Proof: The graph G_N associated with any such N only possesses arcs of even multiplicity. The lemma is trivially true for the quadratic invariants: $\Psi_{ABCD}\Psi^{ABCD}$, $\bar{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}\bar{\Psi}^{\dot{A}\dot{B}\dot{C}\dot{D}}$, and $\Phi_{AB\dot{A}\dot{B}}\Phi^{AB\dot{A}\dot{B}}$. Hence we can assume without loss of generality that each spinor in N is evenly contracted to exactly two other distinct spinors. It is then clear from the structure of G_N that N is a cyclic sequence of such even contractions. Suppose contractions between pairs of undotted indices are present. These undotted contractions can be viewed to separate this cyclic sequence of even contractions into connected 4-indexed compound spinors formed solely from even dotted contractions. Thus, we obtain a contractive partitioning of N into copies of Υ-spinors. Similarly, contractions between pairs of dotted indices yield a contractive partitioning of N into copies of $\bar{\Upsilon}$-spinors. The converse follows immediately from the fact that besides Ψ_{ABCD} and $\bar{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}$, every Υ-spinor and $\bar{\Upsilon}$-spinor contain exactly two copies of the Ricci spinor. ■

For example, the invariant $\Psi_{ABCD}\Phi^{CD\dot{C}\dot{D}}\bar{\Psi}_{\dot{C}\dot{D}\dot{E}\dot{F}}\Phi^{AB\dot{E}\dot{F}}$ can be formed by even undotted contractions between the Υ-spinors Ψ_{ABCD} and $\Phi_{CD\dot{C}\dot{D}}\bar{\Psi}^{\dot{C}\dot{D}\dot{E}\dot{F}}\Phi_{AB\dot{E}\dot{F}}$, or by even dotted contractions between the $\bar{\Upsilon}$-spinors $\bar{\Psi}_{\dot{C}\dot{D}\dot{E}\dot{F}}$ and $\Phi_{AB\dot{E}\dot{F}}\Psi^{ABCD}\Phi_{CD\dot{C}\dot{D}}$. The pure Weyl invariants belonging to $\hat{\mathcal{W}}^{c}$ and their conjugates both form subsets of $\hat{\mathcal{E}}^{c}$. The former is expressible only in terms of Υ-spinors, and the latter only in terms of $\bar{\Upsilon}$-spinors. However, all other invariants belonging to $\hat{\mathcal{E}}^{c}$ possess both undotted and dotted contractions. Thus for these invariants we can obtain both a Υ-*structure* and a $\bar{\Upsilon}$-*structure*. This existence of two distinct structures of the mixed invariants belonging to $\hat{\mathcal{E}}^{c}$ will play a significant role in the subsequent basis determination.

It will be useful to define the Γ-spinors to be connected 4-spinors formed by sequential pairwise undotted contractions between copies of Υ-spinors, and $\bar{\Gamma}$-spinors to be the conjugates of Γ-spinors. All Γ-spinors possess index-pair symmetry, but a Γ-spinor will not possess block symmetry unless it is formed from a palindromic sequence of Υ-spinors. Every Γ-spinor has a dyad expansion of the following form:

$$
\begin{aligned}
{}^{j}\Gamma_{ABCD} = {}&{}^{j}\Gamma_{00}\iota_A\iota_B\iota_C\iota_D - 2{}^{j}\Gamma_{10}\iota_C\iota_D\iota_{(A}o_{B)} - 2{}^{j}\Gamma_{01}\iota_A\iota_B\iota_{(C}o_{D)} + {}^{j}\Gamma_{20}o_Ao_B\iota_C\iota_D + {}^{j}\Gamma_{02}o_Co_D\iota_A\iota_B \\
&+ {}^{j}\Gamma_{11}(o_Ao_C\iota_B\iota_D + o_Ao_D\iota_B\iota_C + o_Bo_C\iota_A\iota_D + o_Bo_D\iota_A\iota_C) - 2{}^{j}\Gamma_{12}o_Co_Do_{(A}\iota_{B)} \\
&- 2{}^{j}\Gamma_{21}o_Ao_Bo_{(C}\iota_{D)} + {}^{j}\Gamma_{22}o_Ao_Bo_Co_D,
\end{aligned}
$$

where

$$
{}^{j}\Gamma_{00} = {}^{j}\Gamma_{0000},
$$

$$
{}^{j}\Gamma_{01} = {}^{j}\Gamma_{0001} = {}^{j}\Gamma_{0010},
$$

$$
{}^{j}\Gamma_{10} = {}^{j}\Gamma_{0100} = {}^{j}\Gamma_{1000},
$$

$$
\begin{aligned}
{}^{j}\Gamma_{02} &= {}^{j}\Gamma_{0011},\\
{}^{j}\Gamma_{20} &= {}^{j}\Gamma_{1100},\\
{}^{j}\Gamma_{11} &= {}^{j}\Gamma_{1010} = {}^{j}\Gamma_{1001} = {}^{j}\Gamma_{0110} = {}^{j}\Gamma_{0101},\\
{}^{j}\Gamma_{12} &= {}^{j}\Gamma_{0111} = {}^{j}\Gamma_{1011},\\
{}^{j}\Gamma_{21} &= {}^{j}\Gamma_{1101} = {}^{j}\Gamma_{1110},\\
{}^{j}\Gamma_{22} &= {}^{j}\Gamma_{1111},
\end{aligned}
\tag{10}
$$

and the prefix j distinguishes distinct Γ-spinors.

Lemma 6 implies that all scalars constructed from evenly contracting Γ-spinors belong to $\hat{\mathcal{E}}^c$. We shall specify these scalars as a list, $[j_1,j_2,j_3,\ldots]$, of the prefixes of the sequence of Γ-spinors evenly contracted in a cyclic manner to form the scalar. For example, the scalar ${}^{1}\Gamma_{ABCD}\,{}^{3}\Gamma^{CD}{}_{EF}\,{}^{3}\Gamma^{EF}{}_{GH}\,{}^{4}\Gamma^{GHAB}$ would be denoted as [1, 2, 3, 4]. Obviously, the scalar denoted by $[j_1,j_2,j_3,\ldots,j_n]$ is equivalent to the scalars represented by any cyclic permutation of that list. In the special case where all of the spinors denoted by $j_1,j_2,j_3,\ldots,j_n$ are Υ-spinors, the scalar denoted by $[j_1,j_2,j_3,\ldots,j_n]$ is also equivalent to the scalars represented by any cyclic permutation of the reversal of that list, $[j_n,\ldots,j_3,j_2,j_1]$. For convenience, we shall drop the commas whenever this will not create any ambiguities and rewrite $[A,B,C,D]$ as $[ABCD]$. Additionally, we will further simplify the representation by indicating a contiguous, evenly contracted sequence of n copies of ${}^{j}\Gamma$ as j^n within the square brackets. For example, we will write $[AAAB]$ and $[AABB]$ as $[A^3B]$ and $[A^2B^2]$, respectively.

One can verify the following scalar identity using Eq. (10):

$$
\begin{aligned}
&[ABCD]+[ABDC]+[ACBD]+[ACDB]+[ADBC]+[ADCB]\\
&\quad-[A][BCD]-[A][BDC]-[B][ACD]-[B][ADC]-[C][ABD]\\
&\quad-[C][ADB]-[D][ABC]-[D][ACB]-[AB][CD]-[AC][BD]\\
&\quad-[AD][BC]+[AB][C][D]+[AC][B][D]+[AD][B][C]\\
&\quad+[BC][A][D]+[BD][A][C]+[CD][A][B]-[A][B][C][D]\equiv 0.
\end{aligned}
\tag{11}
$$

Equation (11), which obviously also holds when A, B, C, and D are all $\bar{\Gamma}$-spinors, is a polynomial identity relating invariants of the form $[ABCD]$ to other members of $\hat{\mathcal{E}}^c$. The form of this equation is readily justified by associating each Γ-spinor, Γ_{ABCD}, with a 3×3 complex matrix, $\Gamma_{\alpha\beta}$, which transforms under the $\mathrm{SO}(3,\mathbb{C})$ representation. The elements of $\Gamma_{\alpha\beta}$ are the components of Γ_{ABCD} with respect to the orthonormal basis,[14]

$$
\begin{aligned}
{}^{1}\delta_{AB} &= -\frac{i}{\sqrt{2}}(o_A o_B - \iota_A \iota_B),\\
{}^{2}\delta_{AB} &= \frac{1}{\sqrt{2}}(o_A o_B + \iota_A \iota_B),\\
{}^{3}\delta_{AB} &= \frac{i}{\sqrt{2}}(o_A \iota_B + \iota_A o_B),
\end{aligned}
$$

such that

$$\Gamma_{\alpha\beta} = \Gamma^{ABCD} \overset{\alpha}{\delta}_{AB} \overset{\beta}{\delta}_{CD}.$$

In terms of the dyad components of Γ_{ABCD}, the matrix $\Gamma_{\alpha\beta}$ has the following form:

$$\Gamma_{\alpha\beta} = \begin{bmatrix} \frac{1}{2}(\Gamma_{02}+\Gamma_{20}-\Gamma_{00}-\Gamma_{22}) & \frac{i}{2}(\Gamma_{20}+\Gamma_{22}-\Gamma_{00}-\Gamma_{02}) & \Gamma_{01}-\Gamma_{21} \\ \frac{i}{2}(\Gamma_{02}+\Gamma_{22}-\Gamma_{00}-\Gamma_{20}) & \frac{1}{2}(\Gamma_{00}+\Gamma_{02}+\Gamma_{20}+\Gamma_{22}) & (\Gamma_{01}+\Gamma_{21})i \\ \Gamma_{10}-\Gamma_{12} & (\Gamma_{10}+\Gamma_{12})i & -2\Gamma_{11} \end{bmatrix},$$

and performing a similar calculation on Υ_{ABCD} yields the analogous matrix $\Upsilon_{\alpha\beta}$,

$$\Upsilon_{\alpha\beta} = \begin{bmatrix} \Upsilon_{02}-\frac{1}{2}(\Upsilon_{00}+\Upsilon_{22}) & \frac{i}{2}(\Upsilon_{22}-\Upsilon_{00}) & \Upsilon_{01}-\Upsilon_{12} \\ \frac{i}{2}(\Upsilon_{22}-\Upsilon_{00}) & \Upsilon_{02}+\frac{1}{2}(\Upsilon_{00}+\Upsilon_{22}) & (\Upsilon_{01}+\Upsilon_{12})i \\ \Upsilon_{01}-\Upsilon_{12} & (\Upsilon_{01}+\Upsilon_{12})i & -2\Upsilon_{11} \end{bmatrix}.$$

Equtation (11) is equivalent to the statement that antisymmetrizing over four indices annihilates any product of 3×3 matrices, $\Gamma^{[\alpha}{}_{\beta}\Gamma^{\beta}{}_{\gamma}\Gamma^{\gamma}{}_{\delta}\Gamma^{\delta]}{}_{\alpha} \equiv 0$. The derivation of the corresponding matrix identity from the Cayley-Hamilton theorem has been reported by Spencer and Rivlin, who subsequently used various versions of this identity to construct bases for matrix polynomials in up to five 3×3 matrices.[15–17]

Setting $D=A$ and $D=C=A$ in Eq. (11) gives the special cases Eqs. (12) and (13), respectively,

$$\begin{aligned} &2[A^2BC]+2[A^2CB]+2[ABAC]-2[A][ABC]-2[A][ACB]-2[B][A^2C]-2[C][A^2B]-[A^2][BC] \\ &-2[AB][AC]+[A^2][B][C]+2[AB][A][C]+2[AC][A][B]+[BC][A]^2-[A]^2[B][C]\equiv 0, \end{aligned} \tag{12}$$

$$6[A^3B]-6[A][A^2B]-2[B][A^3]-3[A^2][AB]+3[A^2][A][B]+3[AB][A]^2-[A]^3[B]\equiv 0. \tag{13}$$

Given that Υ-spinors are a specialized form of Γ-spinors, it is immediately obvious that Eqs. (11)–(13) also hold when A, B, C, and D are all Υ-spinors, or all $\bar{\Upsilon}$-spinors. Equation (13) states that whenever three or more identical Υ-spinors are contracted sequentially within the Υ-structure of an invariant, this invariant is then expressible as a polynomial function of lower-degree invariants. We define an invariant $N \in \hat{\mathcal{E}}^c$ to be Υ-*irreducible* if it does not possess a Υ-structure or if its Υ-structure is not expressible as a function of lower-degree invariants modulo Eq. (13). Simliarly, if N does not possess a $\bar{\Upsilon}$-structure or if its $\bar{\Upsilon}$-structure is not expressible as a function of lower-degree invariants modulo Eq. (13), then N is said to be $\bar{\Upsilon}$-*irreducible*. We shall make use of this result, which follows immediately from Eq. (13).

Lemma 7: An invariant $N \in \hat{\mathcal{E}}^c$ is either Υ-irreducible or expressible as a polynomial function of Υ-irreducible elements of $\hat{\mathcal{E}}^c$. Furthermore, N is either $\bar{\Upsilon}$-irreducible or expressible as a polynomial function of $\bar{\Upsilon}$-irreducible elements of $\hat{\mathcal{E}}^c$.

We are now in a position to introduce the following specific Υ-spinors:

$${}^1\Upsilon_{ABCD} = \Psi_{ABCD},$$

$${}^2\Upsilon_{ABCD} = \Phi_{AB\dot{A}\dot{B}}\Phi_{CD}{}^{\dot{A}\dot{B}},$$

$$^{3}\Upsilon_{ABCD} = \Phi_{AB\dot{A}\dot{B}}\bar{\Psi}^{\dot{A}\dot{B}}{}_{\dot{C}\dot{D}}\Phi_{CD}{}^{\dot{C}\dot{D}},$$

$$^{4}\Upsilon_{ABCD} = \Phi_{AB\dot{A}\dot{B}}\bar{\Psi}^{\dot{A}\dot{B}}{}_{\dot{C}\dot{D}}\bar{\Psi}^{\dot{C}\dot{D}}{}_{\dot{E}\dot{F}}\Phi_{CD}{}^{\dot{E}\dot{F}},$$

which are the four lowest-degree Υ-spinors, and the respective spinorial counterparts of the matrices A, B, C, and D in Sneddon's paper.[8] The dyad components of $^{1}\Upsilon$, $^{2}\Upsilon$, $^{3}\Upsilon$, and $^{4}\Upsilon$ are presented in Appendix B. From this point onwards, we shall follow Sneddon's notation and use the symbols A, B, C, and D to represent the symmetric 3×3 matrix representations of $^{1}\Upsilon$, $^{2}\Upsilon$, $^{3}\Upsilon$, and $^{4}\Upsilon$, respectively, and the list notation to denote the traces of matrix products. For example, the scalar invariant $\Psi_{AB}{}^{CD}\Psi_{CD}{}^{EF}\Phi_{EF}{}^{\dot{E}\dot{F}}\Phi^{AB}{}_{\dot{E}\dot{F}}$ is equivalent to the trace of the matrix product A^2B, and shall be denoted as $[A^2B]$. Sneddon has suggested that any even invariant is expressible in terms of traces of products of the matrices A, B, C, and D, and their conjugates.[8] The following result, in conjunction with Theorem 1, formally justifies a stronger version of this claim.

Theorem 2: *Any invariant $N\in\hat{\mathcal{E}}^{c}$ is expressible as a polynomial function of $\overline{[A^2]}$, $\overline{[A^3]}$ and traces of products of the matrices A, B, C, and D.*

Proof: Theorem 1 in paper I[1] immediately implies that this statement is true for all pure Weyl and conjugate-Weyl invariants. Hence, without loss of generality, we only consider the remaining invariants belonging to $\hat{\mathcal{E}}^{c}$. Consider any such $N\in\hat{\mathcal{E}}^{c}$. It possesses both a Υ-structure and a $\bar{\Upsilon}$-structure. There are two cases.

Case 1: N is $\bar{\Upsilon}$-irreducible.

Here, N will never contain contiguous, evenly contracted sequences of more than two copies of the conjugate Weyl spinor. Thus, Lemma 6 implies that its Υ-structure will contain only copies of $^{1}\Upsilon$, $^{2}\Upsilon$, $^{3}\Upsilon$, and $^{4}\Upsilon$; and the theorem is established in this case.

Case 2: N is $\bar{\Upsilon}$-reducible.

Here, N is a polynomial function of $\bar{\Upsilon}$-irreducible elements of $\hat{\mathcal{E}}^{c}$, by Lemma 7. Apart from the pure conjugate Weyl invariants $\overline{[A^2]}$ and $\overline{[A^3]}$, every other $\bar{\Upsilon}$-irreducible invariant possesses a Υ-structure, and the problem is reduced to Case 1. ■

The concept of reducibility modulo Eq. (13) thus reduces the general problem to one of determining the basis of the set of all product traces of four symmetric 3×3 complex matrices, $^{1}\Upsilon$, $^{2}\Upsilon$, $^{3}\Upsilon$, $^{4}\Upsilon$. Spencer and Rivlin have derived the following basis, which we shall call $\mathcal{S}$, for product traces of four arbitrary symmetric 3×3 matrices, A, B, C, and D, under the orthogonal transformation group.[15–17]

Degree 1: $[A],[B],[C],[D]$.
Degree 2: $[A^2],[AB],[AC],[AD],[B^2],[BC],[BD],[C^2],[CD],[D^2]$.
Degree 3: $[A^3],[A^2B],[A^2C],[A^2D],[AB^2],[ABC],[ABD],[AC^2],[ACD],[AD^2],[B^3]$,
$[B^2C],[B^2D],[BC^2],[BCD],[BD^2],[C^3],[C^2D],[CD^2],[D^3]$.
Degree 4: $[A^2B^2],[A^2BC],[A^2BD],[A^2C^2],[A^2CD],[A^2D^2],[AB^2C],[AB^2D]$,
$[ABC^2],[ABCD],[ABDC],[ABD^2],[AC^2D],[ACD^2],[B^2C^2],[B^2CD]$,
$[B^2D^2],[BC^2D],[BCD^2],[C^2D^2]$
Degree 5: $[A^2B^2C],[A^2B^2D],[A^2BC^2],[A^2BCD],[A^2BDC],[A^2BD^2]$,
$[A^2C^2D],[A^2CD^2],[AB^2C^2],[AB^2CD],[AB^2D^2],[ABC^2D]$,
$[ABCD^2],[ABDC^2],[ACB^2D],[ACBD^2],[AC^2D^2],[B^2C^2D]$,
$[B^2CD^2],[BC^2D^2]$.
Degree 6: $[A^2BACD],[A^2B^2CD],[A^2CBD^2],[A^2C^2BD],[AB^2CBD]$,
$[ABC^2DC],[ABC^2D^2],[ACB^2D^2],[AC^2B^2D],[ADBCD^2]$

The proofs of Lemmas 1–3 and Theorem 1 in Ref. 15 and Sec. V in Ref. 16 are able to be implemented as an algorithm that allows the trace of any product of A, B, C, and D to be systematically expressed in terms of $\mathcal{S}$ using only variations of Eq. (11).[18]

In our case, $[A] \equiv 0$ owing to the trace-free character of ${}^{1}\Upsilon$. Furthermore, the matrices A, B, C, D are not independent, and the complete set for $\mathcal{E}$ will be a proper subset of $\mathcal{S}$. We say that an element of $\hat{\mathcal{E}}^c$ is minimal with respect to the Υ-structure, or Υ-*minimal* iff it does not possess a Υ-structure or its Υ-structure corresponds to an element in $\mathcal{S}$. With the exception of $[A^2]$ and $[A^3]$, the remaining Υ-minimal elements also possess $\bar{\Upsilon}$-structures. It can be easily verified that their $\bar{\Upsilon}$-structures contain only $\overline{{}^{1}\Upsilon}$, $\overline{{}^{2}\Upsilon}$, $\overline{{}^{3}\Upsilon}$, and $\overline{{}^{4}\Upsilon}$; therefore these invariants also belong in the space of product traces of $\bar{A}$, $\bar{B}$, $\bar{C}$, and $\bar{D}$. It immediately follows that the set $\bar{\mathcal{S}}$ of conjugates of the elements of $\mathcal{S}$ form the basis of this space, and an element of $\hat{\mathcal{E}}^c$ is $\bar{\Upsilon}$-*minimal* iff it does not possess a $\bar{\Upsilon}$-structure or its $\bar{\Upsilon}$-structure corresponds to an element in $\bar{\mathcal{S}}$.

For example, the invariant $N = \Psi_{ABCD}\Phi^{CD\dot{C}\dot{D}}\Phi_{EF\dot{C}\dot{D}}\Phi^{EF\dot{E}\dot{F}}\Phi_{AB}{}^{\dot{E}\dot{F}}$ possesses the Υ-structure $[AB^2]$ and the $\bar{\Upsilon}$-structure $\overline{[BC]}$. Therefore N is both Υ-minimal and $\bar{\Upsilon}$-minimal. On the other hand, the Υ-minimal invariant $[CD]$ possesses the $\bar{\Upsilon}$-structure $\overline{[A^2BAB]}$, and can be expressed in terms of $\bar{\Upsilon}$-minimal invariants as follows:

$$\overline{[A^2BAB]} = \tfrac{1}{6}(\overline{[A^3]}[B]^2 - \overline{[A^3]}\overline{[B^2]}) + \overline{[AB]}\overline{[A^2B]}.$$

In accordance with Theorem 2, we can rewrite $\overline{[A^2BAB]}$, $\overline{[B]}$, $\overline{[B^2]}$, $\overline{[AB]}$, and $\overline{[A^2B]}$ in terms of their Υ-structures to give

$$[CD] = \tfrac{1}{6}(\overline{[A^3]}[B]^2 - \overline{[A^3]}[B^2]) + [C][D].$$

It is straightforward to verify that every invariant on the right-hand side is both Υ-minimal and $\bar{\Upsilon}$-minimal. Analyzing every member of $\mathcal{S}$ in this manner yields the set of even invariants which are both Υ-minimal and $\bar{\Upsilon}$-minimal, $\mathcal{J}_{\mathcal{E}} = \{[A^2], [A^3], \overline{[A^2]}, \overline{[A^3]}, [B], [B^2], [B^3], [C], [D], [AB], [AC], [AD], [BC], [BD], [A^2B], [A^2C], [A^2D], [AB^2], [ABC], [ABD], [A^2B^2], [A^2BC], [A^2BD], [AB^2C], [AB^2D], [A^2B^2C], [A^2B^2D], [A^2BACD]\}$.

An even invariant belonging to the complete set for $\mathcal{E}$ is necessarily a member of $\mathcal{J}_{\mathcal{E}}$ and it remains to be established whether every member of $\mathcal{J}_{\mathcal{E}}$ belongs to the complete set for $\mathcal{E}$. Sneddon has previously specialized the set $\mathcal{S}$ towards the determination of a complete set, $\mathcal{J}$, for the even invariants,[8] and the set $\mathcal{J}_{\mathcal{E}}$ is identical to his complete set $\mathcal{J}$. In Sec. VI of his subsequent paper concerning the odd invariants, Sneddon examined new syzygies that arose from multiplying syzygies of the odd invariants with other odd invariants.[9] These results led him to argue that $\mathcal{J}_{\mathcal{E}}$ is a minimal basis for $\mathcal{E}$. Now, every four-dimensional Lorentzian manifold belongs to one of 15 different possible Segre types. Therefore, we may explicitly demonstrate the minimality of $\mathcal{J}_{\mathcal{E}}$, without needing to consider the odd invariants, by showing that each invariant is necessary as a basis element for at least one of the 15 different Segre types.

For each Segre type, a canonical frame[4,5] was selected and the members of $\mathcal{J}_{\mathcal{E}}$ were expressed in terms of the Newman-Penrose curvature components. Trial polynomial syzygies of the form $I_n = \Sigma a_j P_j$ were then constructed, where P_j were all products of invariants within $\mathcal{J}_{\mathcal{E}} - \{I_n\}$ of the same polynomial degree in Ψ_{ABCD}, $\bar{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}$, and $\Phi_{AB\dot{A}\dot{B}}$ as I_n. Attempts were then made to solve for the coefficients a_j. If no solution existed for a particular I_n in a given Segre type, then I_n is necessarily a member of the complete set for that particular Segre type. The complete sets and polynomial syzygies within $\mathcal{J}_{\mathcal{E}}$ for all 15 Segre types are given in Appendix C, and it is apparent that *no member of* $\mathcal{J}_{\mathcal{E}}$ *is a polynomial function of the remaining members of* $\mathcal{J}_{\mathcal{E}}$ *for every Segre type*. Hence, every member of $\mathcal{J}_{\mathcal{E}}$ belongs to the complete set for $\mathcal{E}$, and it follows that $\mathcal{J}_{\mathcal{E}}$ is a minimal complete set for $\mathcal{E}$.

The 10 real and 18 complex members of $\mathcal{J}_{\mathcal{E}}$ are depicted graphically in Figs. 2 and 3, respectively. Sneddon worked exclusively in the space of 3×3 complex matrices in his derivation of his complete set $\mathcal{J}$.[8] To the best of our knowledge, there is no explicit justification in the literature for the assertion that *every* even invariant is expressible as polynomials of traces of 3×3 complex matrix products. Furthermore, a general method to construct polynomial syzygies expressing the dependent invariants in terms of $\mathcal{J}$ is not available. We have provided a rigorous

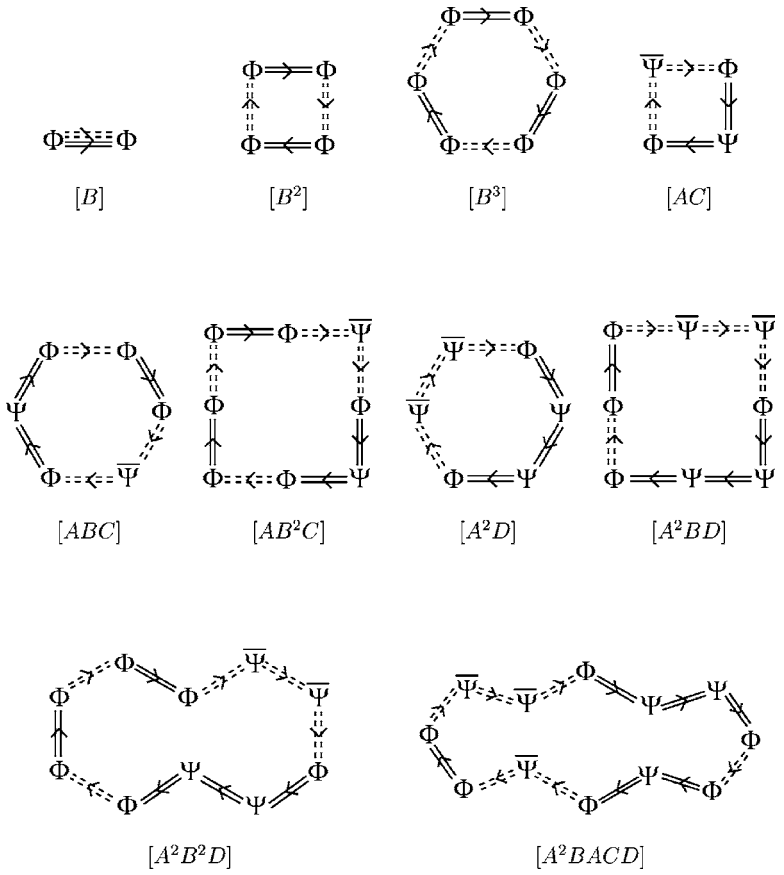

FIG. 2. Real invariants belonging to $\mathcal{J}_{\mathcal{E}}$.

derivation of a complete set for the even invariants in a manner that resolves the aforementioned problems, and we can now explicitly construct the syzygies expressing any even invariant as a polynomial function of the elements in $\mathcal{J}_{\mathcal{E}}$.

V. SYZYGY CONSTRUCTION

The proof of Theorem 1 provides a general algorithm for constructing the polynomial syzygies relating any even invariant $N \notin \hat{\mathcal{E}}^c$ in terms of elements of $\hat{\mathcal{E}}^c$, given N in the form of its associated oriented matrix $A(G_{N'})$. The characteristics of each vertex in the ordering defined by $A(G_{N'})$ are provided by Eq. (2). $A(G_{N'})$ is partitioned into $A(G^S_{N'})$, $A(S^S_{N'})$, and $A(S^D_{N'})$ using the conditions of Eq. (3). The subgraphs $S^S_{N'}$ and $S^D_{N'}$ can be decomposed separately into the forms specified by Eqs. (4) and (5) via the method of permutations of vertex sequences described in Sec. V of paper I.[1] The adjacency matrices $A(G_{X_{jl}})$ associated with each component of the syzygy are obtained by adapting Eq. (3),

$$A(G_{X_{jl}}) = A(G^S_{N'}) + A(\tilde{S}^S_j) + A(\tilde{S}^D_l).$$

It is then straightforward to obtain X_{jl} and construct the first syzygy expressing N in terms of elements of $\hat{\mathcal{E}}^c$ according to Eq. (8).

Lemma 7 guarantees that we can use Eq. (13) to express any invariant belonging to $\hat{\mathcal{E}}^c$ as a polynomial function of Υ-irreducible invariants, or of $\bar{\Upsilon}$-irreducible invariants; and we then make

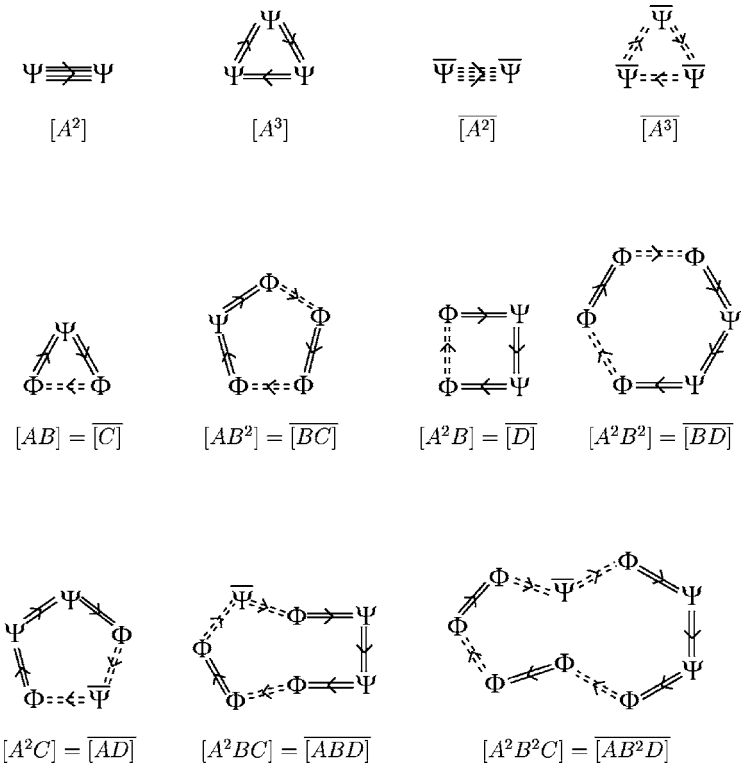

FIG. 3. Complex invariants belonging to $\mathcal{J}_\mathcal{E}$.

use of the fact that every $\bar{\Upsilon}$-irreducible invariant other than $\overline{[A^2]}$ and $\overline{[A^3]}$ is expressible in terms of Υ-irreducible invariants to express N in the manner specified by Theorem 2.

An implementation[18] of the Spencer and Rivlin solution of the basis problem for four symmetric 3×3 matrices, is then used to express N in terms of $\overline{[A^2]}$, $\overline{[A^3]}$ and the elements of $\mathcal{S}$. N is now expressed entirely in terms of Υ-minimal invariants. Each individual term is examined and decomposed further into $\bar{\Upsilon}$-minimal invariants if it is not already $\bar{\Upsilon}$-minimal. Each new term is reexamined for Υ-minimality and reduced if necessary. This alternate checking for Υ-minimality and $\bar{\Upsilon}$-minimality is repeated until every term is both Υ-minimal and $\bar{\Upsilon}$-minimal. We then have the polynomial syzygy expressing N in terms of the elements of $\mathcal{J}_\mathcal{E}$. This algorithm is guaranteed to terminate because in each step, invariants which are not Υ-minimal or $\bar{\Upsilon}$-minimal are reexpressed in terms of invariants of lower polynomial degree in the Weyl, conjugate Weyl and Ricci spinors.

We now give an example of this decomposition process applied to an even invariant for $N' = \bar{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}\Phi_{AB}{}^{\dot{A}\dot{B}}\Phi^{A}{}_{C}{}^{\dot{C}}{}_{\dot{E}}\Phi^{B}{}_{D}{}^{\dot{E}}{}_{\dot{F}}\Psi^{CD}{}_{EF}\Phi^{EF}{}_{\dot{G}\dot{H}}\Phi_{GH}{}^{\dot{G}\dot{H}}\Phi^{GHD\dot{F}}$. The graph $G_{N'}$ is drawn and its vertices labeled as shown in Fig. 4.

Partitioning the arc set of $G_{N'}$ using Eq. (3) yields the subgraphs $S^S_{N'}$ and $S^D_{N'}$, which are then decomposed separately as described earlier in this section. The graphical representations of Eqs. (4) and (5) for this particular example are depicted in Fig. 5.

Constructing the double sum described in Eqs. (7) and (8) yields a syzygy of nine terms which simplifies to the following expression:

$$N' = \tfrac{1}{4}([B][ABC] - 2[ABCB]),$$

$[ABCB]$ is not Υ-minimal, and is rewritten using a relation with the form of Eq. (12) to give

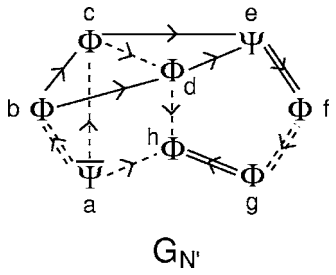

FIG. 4. The graph $G_{N'}$ associated with the example invariant N'.

$$N' = [AB^2C] + \tfrac{1}{4}([B]^2[AC] - [AC][B^2] + 2[B][C][AB] - 2[AB][BC] - 2[C][AB^2] - 3[B][ABC]).$$

It is easily verified that every invariant on the right-hand side is both Υ-minimal and $\bar{\Upsilon}$-minimal, and hence N' is expressed as a polynomial function of elements of $\mathcal{J}_{\mathcal{E}}$.

VI. CONCLUDING REMARKS

We have extended our work in paper I and provided a graph-theoretic algorithm that constructs the polynomial syzygies relating any even invariant to the even invariants formed solely via paired spinor index contractions. This fills in a significant gap in previous work by others. In our determination of the basis for this subset of even invariants, we have confirmed Sneddon's earlier insights and placed them on a rigorous footing.

This concludes the complete analysis of the polynomial syzygies of the even invariants. The solution of the complete problem requires a similar study of the odd invariants and their relationships with the even invariants. We have managed to derive a graph-theoretic algorithm to express odd invariants in terms of restricted subsets and work is currently underway to determine the basis of these subsets. This work will appear in a forthcoming presentation.

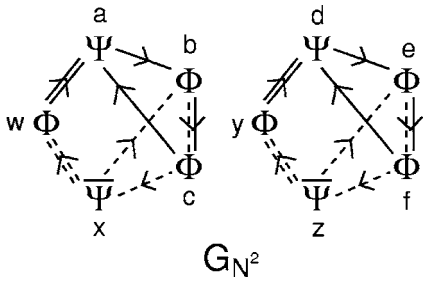

FIG. 6. The graph G_{N^2} associated with the example invariant N^2.

APPENDIX A: GENERATION OF AN ALGEBRAIC SYZYGY

We shall apply the results of this paper to construct an algebraic syzygy relating the square of the odd invariant $N=\bar{\Psi}_{\dot{A}\dot{B}\dot{D}}{}^{\dot{E}}\Phi_{AB}{}^{\dot{A}\dot{B}}\Psi^{AB}{}_{C}{}^{E}\Phi^{C}{}_{D\dot{C}}{}^{\dot{D}}\Phi_{E}{}^{D\dot{C}}{}_{\dot{E}}$ to members of the set $\mathcal{J}_{\mathcal{E}}$. The graph G_{N^2} associated with the quantity N^2 is shown in Fig. 6. The solid unpaired subgraph $S^S_{N^2}$ consists of two disjoint 3-circuits, and is rewritten as the difference between two 6-circuits using the procedure described in Case 2 of the proof of Theorem 1 in Paper I.[1] Subsequent application of the arc-pairing procedure (Case 1) yields 15 terms, each consisting solely of paired arcs, for each 6-circuit. After collecting like terms, $S^S_{N^2}$ is equivalently rewritten as the six terms shown in Fig. 7. The dashed unpaired subgraph $S^D_{N^2}$ is rewritten as a combination of six paired-arc terms in a very similar manner.

Constructing the double sum in Eq. (6) yields a 36-term expression for N^2 in terms of members of $\hat{\mathcal{E}}^c$. After collecting like terms, this simplifies to

$$N^2=[B][AC]^2-2[AC][ABC]+[A^2CBC]-[B][A^2C^2]+[ABAC^2]+[AB^2AD]$$
$$-[B][ABAD]+\frac{[A^2D]}{2}([B]^2-[B^2]).$$

The procedure outlined in Sec. V is used to rewrite nonminimal invariants in terms of invariants that are both Υ-minimal and $\bar{\Upsilon}$-minimal, resulting in the final algebraic syzygy relating N to elements of $\mathcal{J}_{\mathcal{E}}$,

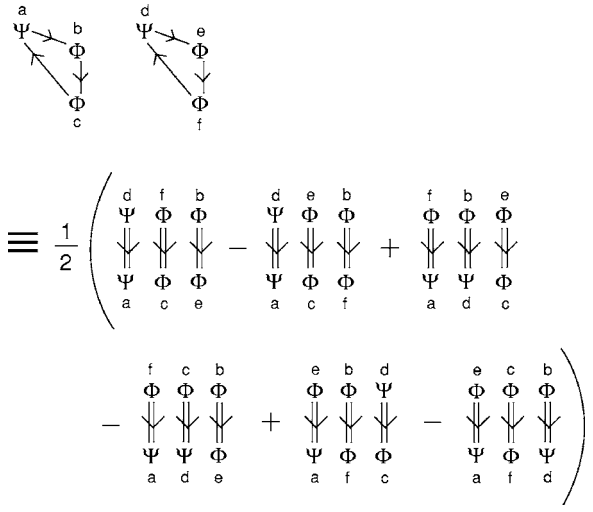

FIG. 7. Decomposition of $S^S_{N^2}$.

$$

& + \frac{\overline{[A^2]}}{2}([AB^2][AB] + [B][A^2B^2] - [B][AB]^2).
\end{aligned}
$$

APPENDIX B: DYAD COMPONENTS OF $^1\Upsilon$, $^2\Upsilon$, $^3\Upsilon$, AND $^4\Upsilon$

Below are the dyad components of the Υ-spinors $^1\Upsilon$, $^2\Upsilon$, $^3\Upsilon$ and $^4\Upsilon$ when they are written in the form of Eq. (9).

$$^1\Upsilon_{00} = \Psi_0,$$

$$^1\Upsilon_{01} = {}^1\Upsilon_{10} = \Psi_1,$$

$$^1\Upsilon_{02} = {}^1\Upsilon_{20} = {}^1\Upsilon_{11} = \Psi_2,$$

$$^1\Upsilon_{12} = {}^1\Upsilon_{21} = \Psi_3,$$

$$^1\Upsilon_{22} = \Psi_4,$$

$$^2\Upsilon_{00} = 2\Phi_{00}\Phi_{02} - 2\Phi_{01}^2,$$

$$^2\Upsilon_{01} = {}^2\Upsilon_{10} = \Phi_{10}\Phi_{02} + \Phi_{12}\Phi_{00} - 2\Phi_{11}\Phi_{01},$$

$$^2\Upsilon_{02} = {}^2\Upsilon_{20} = \Phi_{22}\Phi_{00} + \Phi_{20}\Phi_{02} - 2\Phi_{01}\Phi_{21},$$

$$^2\Upsilon_{11} = 2\Phi_{10}\Phi_{12} - 2\Phi_{11}^2,$$

$$^2\Upsilon_{12} = {}^2\Upsilon_{21} = \Phi_{10}\Phi_{22} + \Phi_{12}\Phi_{20} - 2\Phi_{21}\Phi_{11},$$

$$^2\Upsilon_{22} = 2\Phi_{20}\Phi_{22} - 2\Phi_{21}^2,$$

$$^3\Upsilon_{00} = 4\bar{\Psi}_2\Phi_{01}^2 + \bar{\Psi}_0\Phi_{02}^2 + \bar{\Psi}_4\Phi_{00}^2 + 2\bar{\Psi}_2\Phi_{00}\Phi_{02} - 4\bar{\Psi}_3\Phi_{00}\Phi_{01} - 4\bar{\Psi}_1\Phi_{01}\Phi_{02},$$

$$
\begin{aligned}
^3\Upsilon_{01} = {}^3\Upsilon_{10} = {} & \bar{\Psi}_0\Phi_{12}\Phi_{02} - 2\bar{\Psi}_3\Phi_{00}\Phi_{11} + \bar{\Psi}_2\Phi_{10}\Phi_{02} + \bar{\Psi}_2\Phi_{00}\Phi_{12} - 2\bar{\Psi}_1\Phi_{12}\Phi_{01} + \bar{\Psi}_4\Phi_{00}\Phi_{10} \\
& + 4\bar{\Psi}_2\Phi_{11}\Phi_{01} - 2\bar{\Psi}_1\Phi_{11}\Phi_{02} - 2\bar{\Psi}_3\Phi_{01}\Phi_{10},
\end{aligned}
$$

$$
\begin{aligned}
^3\Upsilon_{02} = {}^3\Upsilon_{20} = {} & 4\bar{\Psi}_2\Phi_{21}\Phi_{01} - 2\bar{\Psi}_3\Phi_{00}\Phi_{21} + \bar{\Psi}_0\Phi_{02}\Phi_{22} + \bar{\Psi}_4\Phi_{20}\Phi_{00} + \bar{\Psi}_2\Phi_{20}\Phi_{02} - 2\bar{\Psi}_3\Phi_{01}\Phi_{20} \\
& + \bar{\Psi}_2\Phi_{00}\Phi_{22} - 2\bar{\Psi}_1\Phi_{01}\Phi_{22} - 2\bar{\Psi}_1\Phi_{21}\Phi_{02},
\end{aligned}
$$

$$
{}^{3}\Upsilon_{11} = 4\bar{\Psi}_2\Phi_{11}^2 - 4\bar{\Psi}_1\Phi_{11}\Phi_{12} + \bar{\Psi}_4\Phi_{10}^2 - 4\bar{\Psi}_3\Phi_{10}\Phi_{11} + \bar{\Psi}_0\Phi_{12}^2 + 2\bar{\Psi}_2\Phi_{10}\Phi_{12},
$$

(Received 4 November 2005; accepted 5 April 2006; published online 18 May 2006)

This paper discusses the long time behavior of solutions for a two-dimensional (2D) nonautonomous incompressible non-Newtonian fluid in 2D bounded domains. When the external force $g_0(x,t)$ is locally uniform integrable (see Definition 1.1) in $L^2_{\mathrm{loc}}(\mathbf{R};H)$, the authors obtain the existence and structure of uniform attractors in space V for the family of processes associated with the fluid. Moreover, when $\|g_0\|_{L^2_b}$ is properly small, they provide some interesting corollaries. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2200145]

I. INTRODUCTION

In the past decades there was considerable progress in the research of infinite dimensional dynamical systems. There arose some well-known works in this area (see e.g., Refs. 7, 10, 20, 21, 24, and 25). In Ref. 21, Temam studied systematically the notation of global attractor, as well as many concrete autonomous equations arising in mathematical physics. Later on, Chepyzhov and Vishik[7] presented a general theory that is well valid to deal with nonautonomous equations. When one studies the uniform attractor for some nonautonomous equations, the construction of the skew-product flow plays the main role in this theory which makes it possible to reduce the problem to the study of an attractor of some semigroup acting in an extended function phase space.[9,17] Moreover, this theory reveals that the uniform attractor could be represented as the union of kernel sections of the family of processes. Generally speaking, one can obtain the strongly compact uniform attractor for some systems with symbols of strongly compact hull, in other words, to obtain the strongly compact uniform attractor, one usually assumes that the symbol $g_0(x,t)=g_0(t)$ of the addressed equations is translation compact (tr.c.) in some Banach space, i.e., the strong closure of the set $\{g_0(t+h):h\in\mathbf{R}\}$ is compact in the Banach space. Recently, Lu *et al.*,[15] used the definition of measure of noncompactness and uniformly ω-limit compactness to discuss the two-dimensional (2D) Navier-Stokes equations and obtained some new result, which showed that it is possible to obtain the strongly compact uniform attractor for the system with symbols of weakly compact hull (see later for definitions).

In the present paper, we will develop the idea of Ref. 15 to obtain the uniform attractors and to reveal their structure for the family of processes corresponding to the following 2D nonautonomous incompressible fluid:

[a)]Author to whom correspondence should be addressed; electronic mail: sfzhou@mail.shu.edu.cn

$$\frac{\partial u}{\partial t} + (u \cdot \nabla)u + \nabla p = \nabla \cdot \tau(e(u)) + g(x,t), \quad x = (x_1,x_2) \in \Omega, \quad t \in \mathbf{R}, \tag{1.1}$$

$$\nabla \cdot u = 0, \tag{1.2}$$

where Ω is a smooth bounded subset of $\mathbf{R}^2$, the unknown function $u=u(x,t)=(u_1,u_2)$ represents the velocity of the fluid, $g(x,t)=g(t)=(g_1,g_2)$ is the time-dependent external force, and the scalar function p is the pressure. Equation (1.1) describes the motion of an isothermal, incompressible viscous fluid, where $\tau(e(u))=(\tau_{ij}(e(u)))_{2\times 2}$, which is usually called the extra stress tensor for the fluid, is a matrix of order 2×2 in which

$$\begin{aligned} &\tau_{ij}(e(u)) = 2\mu_0(\varepsilon + |e|^2)^{-\alpha/2}e_{ij} - 2\mu_1\Delta e_{ij}, \quad i,j = 1,2, \\ &\text{and} \quad e_{ij} = e_{ij}(u) = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right), \quad |e|^2 = \sum_{i,j=1}^{2} |e_{ij}|^2, \end{aligned} \tag{1.3}$$

and $\mu_0, \mu_1, \alpha, \varepsilon$ are parameters which generally depend on the temperature and pressure. In this paper we assume that $\mu_0, \mu_1, \varepsilon$ are positive constants and $0<\alpha<1$. In (1.3) if the dependence of $\tau_{ij}(e(u))$ on $e(u)$ is linear then we say systems (1.1) and (1.2) satisfy the Stokes law and the corresponding fluid is called a Newtonian one. Incompressible fluid whose extra stress tensor cannot be adequately described by the Stokes law is usually called non-Newtonian fluid (see, Ref. 16). We refer to Refs. 3–5, 13, 16, and 18 and references therein for detailed background. Obviously, if $\alpha=\mu_1=0$, (1.1) and (1.2) turn into the famous Navier-Stokes equations; if $\mu_1=\mu_0=0$, (1.1) and (1.2) reduce to the well-known Euler equations.

We consider the initial boundary value problem of (1.1) and (1.3) as follows:

$$\frac{\partial u}{\partial t} + (u \cdot \nabla)u + \nabla p = \nabla \cdot (2\mu_0(\varepsilon + |e|^2)^{-\alpha/2}e - 2\mu_1\Delta e) + g(x,t), \quad x \in \Omega, \quad t > \tau, \tag{1.4}$$

$$\nabla \cdot u = 0, \tag{1.5}$$

$$u|_{\partial\Omega} = 0, \tag{1.6}$$

$$u|_{t=\tau} = u_\tau, \quad \tau \in \mathbf{R}. \tag{1.7}$$

There are many works concerning the unique existence, regularity, and long time behavior of solutions to Eqs. (1.4)–(1.7) or its associated version (see, e.g., Refs. 2, 6, 8, 11, 26, and 27). The main objective of the present paper is to construct the uniform attractors and to reveal their structure for the family of processes corresponding to Eqs. (1.4)–(1.7). We consider the classical mathematical setting of problem (1.4)–(1.7). Set

$$\mathcal{V} = \{\varphi = (\varphi_1,\varphi_2) \in C_0^\infty(\bar{\Omega}) \times C_0^\infty(\bar{\Omega}), \nabla \cdot \varphi = 0\},$$

$$H = \text{the closure of } \mathcal{V} \text{ in } L^2(\Omega) \times L^2(\Omega),$$

$$V = \text{the closure of } \mathcal{V} \text{ in } H^2(\Omega) \times H^2(\Omega).$$

We use H' and V' to denote the dual space of H and V, respectively. If one identifies H' with H itself, then $V \hookrightarrow H = H' \hookrightarrow V'$. Also $(\cdot,\cdot)$ and $\langle\cdot,\cdot\rangle$ represent the inner product in H and the dual pairing between V' and V, respectively. Moreover we have (see Ref. 22) $(f,u)=\langle f,u\rangle, \forall f \in H, u \in V$. Eliminating the pressure p, we can express problem (1.4)–(1.7) as follows (see Refs. 5 and 26):

$$\frac{\partial u}{\partial t} + 2\mu_1 Au + B(u) + N(u) = g(x,t), \quad t > \tau, \tag{1.8}$$

$$u|_{t=\tau} = u_\tau, \quad \tau \in \mathbf{R}. \tag{1.9}$$

The definitions of the operators $A, B(\cdot)$ and $N(\cdot)$ will be introduced in Sec. II. The time-dependent external force $g(\cdot,t)$ will be taken as the time symbol of the equation.

To state our main result clearly, we introduce some notations. Let E be some Banach space. A function $g(t) \in L^2_{\mathrm{loc}}(\mathbf{R};E)$ is said to be translation bounded (tr.b.) in $L^2_{\mathrm{loc}}(\mathbf{R};E)$ if

$$\|g\|^2_{L^2_b(\mathbf{R};E)} = \|g\|^2_{L^2_b} = \sup_{t\in\mathbf{R}} \int_t^{t+1} \|g(s)\|^2_E \mathrm{d}s < +\infty.$$

We denote by $L^2_b(\mathbf{R};E)$ the union of tr.b. functions in $L^2_{\mathrm{loc}}(\mathbf{R};E)$. We say that a function $g(t) \in L^2_{\mathrm{loc}}(\mathbf{R};E)$ is tr.c. in $L^2_{\mathrm{loc}}(\mathbf{R};E)$ if $\mathcal{H}_s(g)$ is compact in $L^2_{\mathrm{loc}}(\mathbf{R};E)$, where $\mathcal{H}_s(g)$ refers that the set $\mathcal{H}_0(g)=\{g(t+h): h\in\mathbf{R}\}$ takes closure with respect to (w.r.t.) the strong topology of $L^2_{\mathrm{loc}}(\mathbf{R};E)$. The collection of tr.c. functions in $L^2_{\mathrm{loc}}(\mathbf{R};E)$ is denoted by $L^2_c(\mathbf{R};E)$.

Definition 1.1: A function $g(t) \in L^2_{\mathrm{loc}}(\mathbf{R};E)$ is said to be locally uniform integrable, if for any $\epsilon>0$ there exists $\eta=\eta(\epsilon)>0$ such that

$$\sup_{t\in\mathbf{R}} \int_t^{t+\eta} \|g(s)\|^2_E \mathrm{d}s \leqslant \epsilon. \tag{1.10}$$

We use $L^2_{\mathrm{lui}}(\mathbf{R};E)$ to denote the union of locally uniform integrable functions in $L^2_{\mathrm{loc}}(\mathbf{R};E)$. We remark that Definition (1.1) originates from Ref. 15, which pointed out that $L^2_c(\mathbf{R};E) \subset L^2_{\mathrm{lui}}(\mathbf{R};E) \subset L^2_b(\mathbf{R};E)$. In this paper, we assume some fixed external force $g_0(t)$ that is locally uniform integrable in $L^2_{\mathrm{loc}}(\mathbf{R};H)$ and take the symbol space $\Sigma=\mathcal{H}_w(g_0)$, where $\mathcal{H}_w(g_0)$ refers that the set $\mathcal{H}_0(g_0)=\{g_0(t+h): h\in\mathbf{R}\}$ takes closure w.r.t. the weak topology of $L^2_{\mathrm{loc}}(\mathbf{R};E)$. Obviously, $\mathcal{H}_w(g_0)$ is weakly compact in $L^2_{\mathrm{loc}}(\mathbf{R};H)$.

Our main result reads as follows.

Theorem 1.1: *If the external force $g_0(t)$ of Eq. (1.8) is locally uniform integrable in $L^2_{\mathrm{loc}}(\mathbf{R};H)$. Then the family of processes $\{U_g(t,\tau)\}, g\in\mathcal{H}_w(g_0)$, corresponding to Eqs. (1.8) and (1.9) has a compact uniform (w.r.t. $g\in\mathcal{H}_w(g_0)$) attractor $\mathcal{A}_{\mathcal{H}_w(g_0)}$ in space V, which uniformly (w.r.t. $g\in\mathcal{H}_w(g_0)$) attracts any bounded sets of H in norm of V. Also the process $\{U_{g_0}(t,\tau)\}$, the family of processes $\{U_g(t,\tau)\}, g\in\mathcal{H}_0(g_0)$, corresponding to Eqs. (1.8) and (1.9) possesses, respectively, the compact uniform (w.r.t. $\tau\in\mathbf{R}$, w.r.t. $g\in\mathcal{H}_0(g_0)$, respectively) attractor $\mathcal{A}_0$ and $\mathcal{A}_{\mathcal{H}_0(g_0)}$. Moreover,*

$$\mathcal{A}_0 = \mathcal{A}_{\mathcal{H}_0(g_0)} = \mathcal{A}_{\mathcal{H}_w(g_0)} = \bigcup_{g\in\mathcal{H}_w(g_0)} \mathcal{K}_g(0) = \omega_{0,\mathcal{H}_w(g_0)}(B_1), \tag{1.11}$$

where $\mathcal{K}_g(0)$ is the kernel section at time moment $t=0$, $\mathcal{K}_g$ is the kernel of the process $\{U_g(t,\tau)\}$, and $\mathcal{K}_g$ is nonempty for all $g\in\mathcal{H}_w(g_0)$; B_1 is the bounded uniformly (w.r.t. $g\in\mathcal{H}_w(g_0)$) absorbing set defined by (2.30) and $\omega_{0,\mathcal{H}_w(g_0)}(B_1)$ is its uniform (w.r.t. $g\in\mathcal{H}_w(g_0)$) ω-limit set.

This result shows that we can obtain the strongly compact uniform attractor for the family of processes corresponding to the incompressible non-Newtonian fluid with weakly compact hull. This is essentially caused by the particular extra stress tensor $\tau(e(u))$ in the equation of the fluid.

We arrange the paper as follows. In Sec. II we introduce some definitions and show the unique existence and some estimations of the solutions. In Sec. III, we first prove the uniform (w.r.t. $g\in\mathcal{H}_w(g_0)$) ω-limit compactness and $(V\times\mathcal{H}_w(g_0), V)$ weak continuity for the associated family of processes. Then we prove Theorem 1.1 and provide some interesting corollaries.

In this paper we use the stand norms of vector-valued functional spaces (see Ref. 1). If no confusion arises, we denote by $X=X\times X$, and $\|\cdot\|_X$ stands for the norm of the Banach space $X\times X$. For instance, $L^2(\Omega)=L^2(\Omega)\times L^2(\Omega)$, $\|\cdot\|_{L^2(\Omega)}$ denotes the norm of $L^2(\Omega)\times L^2(\Omega)$; especially,

$\|\cdot\|=\|\cdot\|_{L^2(\Omega)}$. In addition, $\mathrm{dist}_{\mathcal{M}}(X,Y)=\sup_{x\in X}\inf_{y\in Y}\mathrm{dist}(x,y)$ denotes the semidistance from $X\subset\mathcal{M}$ to $Y\subset\mathcal{M}$ in the metric space $\mathcal{M}$. "$\rightharpoonup$" denotes the convergence in weak topology. The summation convention of repeated indices is used in the whole paper.

II. *A PRIORI* ESTIMATES AND BOUNDED UNIFORMLY ABSORBING SET

In this section, we first introduce the definitions of the operators A, $B(\cdot)$, $N(\cdot)$ and show some properties of them. Then we prove the unique existence and some estimations of the solutions to Eqs. (1.8) and (1.9). Lastly we use these estimations to construct the bounded uniformly (w.r.t. $g\in\mathcal{H}_w(g_0)$) absorbing set in V.

Set

$$a(u,v)=\sum_{i,j,k=1}^{2}\left(\frac{\partial e_{ij}(u)}{\partial x_k},\frac{\partial e_{ij}(v)}{\partial x_k}\right)=\sum_{i,j,k=1}^{2}\int_\Omega\frac{\partial e_{ij}(u)}{\partial x_k}\frac{\partial e_{ij}(v)}{\partial x_k}\mathrm{d}x,\quad u,v\in V. \tag{2.1}$$

Lemma 2.1: (Bloom and Hao[5]) *There exists a positive constant C_1 that depends only on Ω such that*

$$C_1\|u\|_V^2\leqslant a(u,u)\leqslant\|u\|_V^2,\quad \forall\, u\in V. \tag{2.2}$$

Lemma 2.1 implies that $a(\cdot,\cdot)$ defines a positive definite symmetric bilinear form on V. As a consequence of the Lax-Milgram Lemma we obtain an isometric operator $A\in\mathcal{L}(V,V')$, via

$$\langle Au,v\rangle=a(u,v),\quad \forall\, u,v\in V.$$

Let $D(A)=\{\varphi\in V:A\varphi\in H\}$, then $D(A)$ is a Hilbert space and A is also a positive and self-adjoint operator from $D(A)=V\cap H^4(\Omega)$ to H. In fact, $A=P\Delta^2$, where P is the Leray projector from $L^2(\Omega)$ into H. Moreover, for any $u\in D(A)$ we have

$$C_1\|u\|_V\leqslant\|Au\|, \tag{2.3}$$

hereafter C_1 is the constant from Lemma 2.1. In fact, for any $u\in D(A)$, we have by using Lemma 2.1 that

$$C_1\|u\|_V^2\leqslant a(u,u)=\langle Au,u\rangle=(Au,u)\leqslant\|Au\|\|u\|\leqslant\|Au\|\|u\|_V.$$

Thus we obtain (2.3).

Now we define a continuous trilinear form on $H_0^1(\Omega)$ as follows.

$$b(u,v,w)=\sum_{i,j=1}^{2}\int_\Omega u_i\frac{\partial v_j}{\partial x_i}w_j\mathrm{d}x,\quad u,v,w\in H_0^1(\Omega). \tag{2.4}$$

In fact, one can easily check

$$b(u,v,w)=-b(u,w,v),\quad \forall\, u,v,w\in H_0^1(\Omega), \tag{2.5}$$

$$b(u,v,v)=0,\quad \forall\, u,v\in H_0^1(\Omega). \tag{2.6}$$

Since $V\subset H_0^1(\Omega)$, $b(u,v,w)$ is also continuous on V. Moreover, for any $u\in V$,

$$\langle B(u),w\rangle=b(u,u,w),\quad \forall\, w\in V, \tag{2.7}$$

defines a continuous functional $B(u)$ from $V\times V$ to V'. For further details on the operator $B(u)$ one can refer to Refs. 7 and 21–23.

Lastly we introduce the operator $N(\cdot)$ acting on V. For $u\in V$, we set

$$\mu(u) = 2\mu_0(\varepsilon + |e(u)|^2)^{-\alpha/2}$$

and define $N(u)$ by

$$\langle N(u), v\rangle = \sum_{i,j=1}^{2} \int_\Omega \mu(u) e_{ij}(u) e_{ij}(v) \mathrm{d}x, \quad \forall\, v \in V. \tag{2.8}$$

Then the functional $N(u)$ is continuous from V to V'. Moreover, when $u \in D(A)$, $N(u)$ can be extended to H via $\langle N(u), v\rangle = -\int_\Omega \{\nabla \cdot [\mu(u)e(u)]\} \cdot v \mathrm{d}x$, $\forall v \in H$.

With the above definitions, we can formulate the weak form of problem (1.4)–(1.7) as (1.8) and (1.9) in the sense of distributions (see Refs. 5, 14, and 23).

We now begin to show the unique existence and some estimations of the solutions to Eqs. (1.8) and (1.9).

Lemma 2.2: (*i*) *Suppose* $g(x,t) \in L_b^2(\mathbf{R}; H)$, *then for any* $\tau \in \mathbf{R}$ *and* $u_\tau \in H$ *Eqs. (1.8) and (1.9) possess a unique solution* $u(t)$ *satisfying*

$$u \in C([\tau, +\infty); H) \cap L^2_{\mathrm{loc}}([\tau, +\infty); V), \quad u_t \in L^2_{\mathrm{loc}}([\tau, +\infty); V'). \tag{2.9}$$

Moreover,

$$\|u(t)\|^2 \leqslant \|u_\tau\|^2 e^{-\delta(t-\tau)} + \frac{2}{\delta}\left(1 + \frac{1}{\delta}\right)\|g\|^2_{L_b^2}, \tag{2.10}$$

$$\|u(t)\|^2 + C_1\mu_1 \int_\tau^t \|u(s)\|_V^2 \mathrm{d}s \leqslant \|u_\tau\|^2 + \frac{2}{C_1\mu_1}\int_\tau^t \|g(s)\|^2 \mathrm{d}s, \tag{2.11}$$

where the positive constant δ *essentially depends only on* Ω *and* μ_1.

(*ii*) *Suppose* $g(x,t) \in L_b^2(\mathbf{R}; H)$, *then for any* $\tau \in \mathbf{R}$ *and* $u_\tau \in V$ *Eqs. (1.8) and (1.9) possess a unique solution* $u(t)$ *satisfying*

$$u \in C([\tau, +\infty); V) \cap L^2_{\mathrm{loc}}([\tau, +\infty); D(A)), \quad u_t \in L^2_{\mathrm{loc}}([\tau, +\infty); H). \tag{2.12}$$

Moreover,

$$(t-\tau)\|u(t)\|_V^2 \leqslant Q_1\left(t-\tau, \|u_\tau\|^2, \int_\tau^t \|g(s)\|^2 \mathrm{d}s\right), \quad t \geqslant \tau, \quad \tau \in \mathbf{R}, \tag{2.13}$$

where $Q_1(z_1, z_2, z_3)$ *is a monotone continuous function of* $z_1 = t-\tau$, z_2 *and* z_3.

Proof of (i): One can use the Galerkin method to prove the unique existence and regularity of solutions to Eqs. (1.8) and (1.9). Since the method is classical and the proof is essentially the same as that in Ref. 5, we omit it and here we only prove the estimations (2.10) and (2.11). Let $u(t)$ be the unique solution corresponding to initial data $u_\tau \in H$. Using $u(t)$ to multiply Eq. (1.8), we obtain, using (2.6) and the positive definiteness of the term $\langle N(u), u\rangle$,

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|u(t)\|^2 + 2C_1\mu_1\|u(t)\|_V^2 \leqslant \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|u(t)\|^2 + 2\mu_1 a(u,u) + \langle N(u), u\rangle = (g(t), u(t)). \tag{2.14}$$

Now from the definition of norm for Sobolev space we see $\|u\|^2 \leqslant \|u\|_V^2$ holds for any $u \in V$. Thus by (2.14) we get

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|u(t)\|^2 + 2C_1\mu_1\|u(t)\|^2 \leqslant (g(t), u(t)) \leqslant \frac{\|g(t)\|^2}{C_1\mu_1} + \frac{3C_1\mu_1}{2}\|u(t)\|^2,$$

i.e.,

$$\frac{\mathrm{d}}{\mathrm{d}t}\|u(t)\|^2 + C_1\mu_1\|u(t)\|^2 \leqslant \frac{2\|g(t)\|^2}{C_1\mu_1}. \tag{2.15}$$

Applying Gronwall inequality to (2.15) and taking some transformation in the integral, we have

$$\|u(t)\|^2 \leqslant \|u_\tau\|^2 e^{-\delta(t-\tau)} + \frac{2}{\delta}\int_\tau^t e^{-\delta(t-s)}\|g(s)\|^2\mathrm{d}s \leqslant \|u_\tau\|^2 e^{-\delta(t-\tau)} + \frac{2}{\delta}\Bigg[\int_{t-1}^t e^{-\delta(t-s)}\|g(s)\|^2\mathrm{d}s + \int_{t-2}^{t-1} e^{-\delta(t-s)}$$
$$\times\|g(s)\|^2\mathrm{d}s + \cdots\Bigg] \leqslant \|u_\tau\|^2 e^{-\delta(t-\tau)} + \frac{2}{\delta}\Bigg[\int_{t-1}^t \|g(s)\|^2\mathrm{d}s + e^{-\delta}\int_{t-2}^{t-1}\|g(s)\|^2\mathrm{d}s$$
$$+ e^{-2\delta}\int_{t-3}^{t-2}\|g(s)\|^2\mathrm{d}s + \cdots\Bigg] \leqslant \|u_\tau\|^2 e^{-\delta(t-\tau)} + \frac{2}{\delta}[1 + e^{-\delta} + e^{-2\delta} + \cdots]\|g\|_{L_b^2}^2 \leqslant \|u_\tau\|^2 e^{-\delta(t-\tau)}$$
$$+ \frac{2}{\delta}(1 - e^{-\delta})^{-1}\|g\|_{L_b^2}^2 \leqslant \|u_\tau\|^2 e^{-\delta(t-\tau)} + \frac{2}{\delta}\left(1 + \frac{1}{\delta}\right)\|g\|_{L_b^2}^2,$$

where $\delta = C_1\mu_1 > 0$. Obviously, δ depends essentially only on Ω and μ_1. Thus (2.10) holds. Now from (2.14) we easily have

$$\frac{\mathrm{d}}{\mathrm{d}t}\|u(t)\|^2 + C_1\mu_1\|u(t)\|_V^2 \leqslant \frac{2\|g(t)\|^2}{C_1\mu_1}. \tag{2.16}$$

Equation (2.11) follows directly from (2.16) by integrating it over $[\tau, t]$. The proof of (i) is completed.

In the sequel, we use C to denote a generic constant that maybe depends on Ω, μ_0, μ_1, α, ε, and C_1, also maybe depend on the Sobolev embedding coefficient between spaces (and thus essentially depends on Ω), but is independent of u. We allow C to take different value in different place.

Proof of (ii): Similar to the proof of (i), we only establish the estimation (2.13). For the sake of brevity, we set $\tau = 0$ and thus $t \geqslant 0$. Multiplying Eq. (1.8) by tAu, we obtain

$$\left(\frac{\partial u}{\partial t}, tAu\right) + 2\mu_1 t(Au, Au) + \langle B(u), tAu\rangle + \langle N(u), tAu\rangle = \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}[ta(u,u)] - \frac{1}{2}a(u,u) + 2\mu_1 t\|Au\|^2$$
$$+ t\langle B(u), Au\rangle + t\langle N(u), Au\rangle = t(g(t), Au) \leqslant \frac{1}{2}\mu_1 t\|Au\|^2 + \frac{2t}{\mu_1}\|g(t)\|^2. \tag{2.17}$$

At the same time, using Hölder inequality, Gagliardo-Nirenberg inequality, and (2.3), we obtain

$$t\langle B(u), Au\rangle \leqslant t\|B(u)\|\|Au\| \leqslant Ct\|u\|_{L^4(\Omega)}\|\nabla u\|_{L^4(\Omega)}\|Au\| \leqslant Ct\|u\|_V^{1/2}\|u\|_{H^1(\Omega)}\|u\|^{1/2}\|Au\|$$
$$\leqslant Ct\|Au\|^{3/2}\|u\|^{1/2}\|u\|_{H^1(\Omega)} \leqslant \tfrac{1}{2}\mu_1 t\|Au\|^2 + Ct\|u\|^2\|u\|_{H^1(\Omega)}^4, \tag{2.18}$$

where C is a positive constant independent of u. Also we have

$$t\langle N(u), Au\rangle = -t\int_\Omega \{\nabla\cdot[\mu(u)e(u)]\}\cdot Au\,\mathrm{d}x. \tag{2.19}$$

To estimate (2.19), we set

$$F(s) = (\varepsilon + |s|^2)^{-\alpha/2}s, \quad \text{where } s = \begin{pmatrix} s_1 & s_2 \\ s_3 & s_4 \end{pmatrix}, \quad s_i \in \mathbf{R},\ i = 1,2,3,4.$$

By computation we see that the first-order Frechét derivative of $F(s)$ satisfies

$$\|DF(s)\| \leqslant \sqrt{4+\frac{12}{\varepsilon}}\varepsilon^{-\alpha/2} \leqslant C\varepsilon^{-\alpha/2}, \quad \forall\, s_i \in \mathbf{R},\ i=1,2,3,4. \tag{2.20}$$

Using (2.20), we deduce from (2.19) that

$$\begin{aligned} t\langle N(u),Au\rangle &\leqslant 2\mu_0 Ct\sqrt{4+\frac{12}{\varepsilon}}\varepsilon^{-\alpha/2}\|\nabla u\|\|Au\| + 2\mu_0 Ct\varepsilon^{-\alpha/2}\|\Delta u\|\|Au\| \\ &\leqslant Ct\|u\|_{H^1(\Omega)}\|Au\| + Ct\|u\|_V\|Au\| \\ &\leqslant \frac{\mu_1 t}{2}\|Au\|^2 + Ct\|u\|^2_{H^1(\Omega)} + Ct\|u\|^2_V. \end{aligned} \tag{2.21}$$

Combining (2.17), (2.18), and (2.21), we obtain by using Lemma 2.1 and (2.3) that

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}t}[ta(u,u)] + \mu_1 t\|Au\|^2 &\leqslant a(u,u) + \frac{4t}{\mu_1}\|g(t)\|^2 + Ct\|u\|^2\|u\|^4_{H^1(\Omega)} + Ct\|u\|^2_{H^1(\Omega)} + Ct\|u\|^2_V \\ &\leqslant a(u,u) + \frac{4t}{\mu_1}\|g(t)\|^2 + Ct\|u\|^2\|u\|^4_V + Ct\|u\|^2_V \\ &\leqslant a(u,u) + \frac{4t}{\mu_1}\|g(t)\|^2 + ta(u,u)[Ca(u,u)\|u\|^2 + C]. \end{aligned}$$

Therefore, we get

$$\frac{\mathrm{d}}{\mathrm{d}t}H(t) \leqslant K(t)H(t) + I(t), \tag{2.22}$$

where

$$H(t) = ta(u(t),u(t)), \quad K(t) = Ca(u(t),u(t))\|u(t)\|^2 + C, \quad I(t) = a(u(t),u(t)) + \frac{4t}{\mu_1}\|g(t)\|^2.$$

Applying Gronwall inequality to (2.22), we obtain

$$H(t) \leqslant \left[H(0) + \int_0^t I(s)\mathrm{d}s\right]\exp\left\{\int_0^t K(s)\mathrm{d}s\right\} = \int_0^t I(s)\mathrm{d}s\,\exp\left\{\int_0^t K(s)\mathrm{d}s\right\}. \tag{2.23}$$

Now using Lemma 2.1 and estimation (2.11), we have

$$\begin{aligned} \int_0^t I(s)\mathrm{d}s = \int_0^t\left[a(u(s),u(s)) + \frac{4s}{\mu_1}\|g(s)\|^2\right]\mathrm{d}s &\leqslant \int_0^t\|u(t)\|^2_V\mathrm{d}s + \frac{4t}{\mu_1}\int_0^t\|g(s)\|^2\mathrm{d}s \leqslant \frac{1}{C_1\mu_1}\|u(0)\|^2 \\ + \left[\frac{2}{C_1^2\mu_1^2} + \frac{4t}{\mu_1}\right]\int_0^t\|g(s)\|^2\mathrm{d}s &\leqslant C\left(\|u(0)\|^2 + (1+t)\int_0^t\|g(s)\|^2\mathrm{d}s\right), \end{aligned} \tag{2.24}$$

where

$$C = \max\left\{\frac{1}{C_1\mu_1}, \frac{2}{C_1^2\mu_1^2}, \frac{4}{\mu_1}\right\}.$$

Similarly, using (2.10) and (2.11), we get

$$\int_0^t K(s)\mathrm{d}s = \int_0^t [Ca(u(s),u(s))\|u(s)\|^2 + C]\mathrm{d}s \leqslant C\int_0^t \|u(t)\|_V^2\|u(s)\|^2\mathrm{d}s + Ct$$
$$\leqslant C\left\{\left(\|u(0)\|^2 + \int_0^t \|g(s)\|^2\mathrm{d}s\right)^2 + t\right\}. \tag{2.25}$$

Equations (2.3) and (2.23)–(2.25) imply

$$t\|u(t)\|_V^2 \leqslant C\left(\|u(0)\|^2 + (1+t)\int_0^t \|g(s)\|^2\mathrm{d}s\right) \times \exp\left\{C\left[\left(\|u(0)\|^2 + \int_0^t \|g(s)\|^2\mathrm{d}s\right)^2 + t\right]\right\}$$
$$\doteq Q_1\left(t, \|u(0)\|^2, \int_0^t \|g(s)\|^2\mathrm{d}s\right), \tag{2.26}$$

where $Q_1(z_1,z_2,z_3)=C[z_2+(1+z_1)z_3]\exp\{C[(z_2+z_3)^2+z_1]\}$. We complete the proof (*ii*) of this lemma.

The proof of Lemma 2.2 is completed. □

Obviously, if $g_0 \in L_b^2(\mathbf{R};H)$, then

$$\|g\|_{L_b^2}^2 \leqslant \|g_0\|_{L_b^2}^2 < +\infty, \quad \forall\, g \in \mathcal{H}_w(g_0). \tag{2.27}$$

In other words, $g_0 \in L_b^2(\mathbf{R};H)$ implies $g \in L_b^2(\mathbf{R};H)$ for all $g \in \mathcal{H}_w(g_0)$. Thus, according to Lemma 2.2(*ii*), we can define the process $\{U_{g_0}(t,\tau)\}: U_{g_0}(t,\tau)V \mapsto V$, $U_{g_0}(t,\tau)u_\tau = u(t)$, where $u(t)$ is the solution of Eqs. (1.8) and (1.9) with symbol g_0 and initial condition $u_\tau \in V$. Similarly, the family of processes $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$, and $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_0(g_0)$, can be defined on V, respectively.

Lemma 2.3: Suppose $g_0(x,t) \in L_b^2(\mathbf{R};H)$, then the family of processes $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$, corresponding to Eqs. (1.8) and (1.9) has a bounded uniformly (w.r.t. $g \in \mathcal{H}_w(g_0)$) absorbing set $B_1 \subset V$, which uniformly (w.r.t. $g \in \mathcal{H}_w(g_0)$) absorbs any bounded sets of H in norm of V.

Proof. By (2.10) and (2.27), we see that the set

$$B_0 = \left\{u \in H: \|u\|^2 \leqslant \frac{4}{\delta}\left(1 + \frac{1}{\delta}\right)\|g_0\|_{L_b^2}^2 \doteq R_0^2\right\} \tag{2.28}$$

is a bounded uniformly (w.r.t. $g \in \mathcal{H}_w(g_0)$) absorbing set in H, that is, for any bounded sets B of H, there exists $t_0 = t_0(\tau,B) \geqslant \tau$ such that

$$\bigcup_{g\in\mathcal{H}_w(g_0)} U_g(t,\tau)B \subset B_0, \quad \forall\, t \geqslant t_0(\tau,B). \tag{2.29}$$

Now set

$$B_1 = \bigcup_{g\in\mathcal{H}_w(g_0)} U_g(\tau+1,\tau)B_0. \tag{2.30}$$

Then we can derive from (2.13), (2.27), and (2.28) that B_1 is bounded in V. Precisely, we have

$$\|u\|_V^2 \leqslant Q_1(1,R_0^2,\|g_0\|_{L_b^2}^2) \doteq R_1^2, \quad \forall\, u \in B_1. \tag{2.31}$$

Clearly, $B_1 \subset V$ is the bounded uniformly (w.r.t. $g \in \mathcal{H}_w(g_0)$) absorbing set of the family of processes $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$, which uniformly (w.r.t. $g \in \mathcal{H}_w(g_0)$) absorbs any bounded sets of H in norm of V. The proof is completed. □

III. UNIFORM ω-LIMIT COMPACTNESS AND WEAK CONTINUITY

In this section we prove that the family of processes $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$ is uniformly (w.r.t. $g \in \mathcal{H}_w(g_0)$) ω-limit compact and is $(V \times \mathcal{H}_w(g_0), V)$ weakly continuous. Then we briefly establish Theorem 1.1.

Let E be a Banach space and $\mathcal{B}(E)$ be the union of all bounded sets of E. Also let Σ be the symbol space of some family of processes $\{U_\sigma(t,\tau\}$, $\sigma\in\Sigma$, defined on E. For the sake of brevity, we set

$$B_t=\bigcup_{\sigma\in\Sigma}\bigcup_{s\geqslant t}U_\sigma(s,\tau)B.$$

Definition 3.1: The set $\omega_{\tau,\Sigma}(B)=\cap_{t\geqslant\tau}\bar{B}_t$ *is called the uniform (w.r.t.* $\sigma\in\Sigma$*)* ω*-limit set of* $B\subset E$*. A family of processes* $\{U_\sigma(t,\tau)\}$, $\sigma\in\Sigma$, *is said to be uniformly (w.r.t.* $\sigma\in\Sigma$*)* ω*-limit compact if for any* $\tau\in\mathbf{R}$ *and any* $B\in\mathcal{B}(E)$*, the set* B_t *is bounded and* $\lim_{t\to+\infty}\alpha(B_t)=0$*, where* $\alpha(B)$ *denotes the Kuratowski measure of noncompactness which is defined by*

$$\alpha(B)=\inf\{\gamma>0\text{: }B\text{ admits a finite cover by sets of diameters}\leqslant\gamma\}.$$

Lemma 3.1: Let $g_0\in L^2_{\mathrm{lui}}(\mathbf{R};H)$*, then for any* $\tau\in\mathbf{R}$*, there holds*

$$\lim_{\lambda\to+\infty}\sup_{t\geqslant\tau}\int_\tau^t e^{-\lambda(t-\tau)}\|g(s)\|^2\mathrm{d}s=0 \tag{3.1}$$

uniformly w.r.t. $g\in\mathcal{H}_w(g_0)$.

This lemma is a directly corollary of Lemma 3.1 in Ref. 15.

Lemma 3.2: Let $g_0\in L^2_{\mathrm{lui}}(\mathbf{R};H)$*. Then the family of processes* $\{U_g(t,\tau)\}$, $g\in\mathcal{H}(g_0)$*, corresponding to Eqs. (1.8) and (1.9) is uniformly (w.r.t.* $g\in\mathcal{H}(g_0)$*)* ω*-limit compact in* V.

Proof: According to Theorem 2.3 in Ref. 15, we only need to prove the following assertion: for any fixed $\tau\in\mathbf{R}$, any $B\in\mathcal{B}(V)$ and any $\epsilon>0$, there exist $t_1=t_1(\tau,B,\epsilon)$ and a finite dimensional subspace V_m of V such that

$$P\Big(\bigcup_{g\in\mathcal{H}_w(g_0)}\bigcup_{t\geqslant t_1}U_g(t,\tau)B\Big)\text{ is bounded in }V, \tag{3.2}$$

$$\text{and }\Big\|(I-P)\Big(\bigcup_{g\in\mathcal{H}_w(g_0)}\bigcup_{t\geqslant t_1}U_g(t,\tau)x\Big)\Big\|_V\leqslant\epsilon,\quad\forall\,x\in B, \tag{3.3}$$

where I is the identity operator and P is a bounded projector from V into V_m.

In fact, by the classical spectral theory of elliptic operators (see e.g., Ref. 16), there exist a sequence $\{\lambda_n\}_{n=1}^\infty$ satisfying

$$0<\lambda_1\leqslant\lambda_2\leqslant\cdots\leqslant\lambda_n\leqslant\cdots,\quad\lambda_n\to+\infty\text{ as }n\to+\infty, \tag{3.4}$$

and a family of elements $\{w_n\}_{n=1}^\infty\subset D(A)$, which form a basis of V and are orthonormal in H, such that

$$Aw_n=\lambda_n w_n,\quad\forall\,n\in\mathbf{N}. \tag{3.5}$$

Let $V_m=\mathrm{span}\{w_1,\ldots,w_m\}$, then V_m is a finite dimensional subspace of V. Denote by P_m the orthogonal projector from V into V_m and we obviously have $\|P_m\|\leqslant1$ for each $m\in\mathbf{N}$. Now for any $u\in D(A)\subset V$, we set

$$u=P_mu+(I-P_m)u\doteq u_1+u_2.$$

Using Au_2 to take inner product with (1.8) in H, we obtain

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}a(u_2,u_2)+2\mu_1(Au_2,Au_2)+\langle B(u),Au_2\rangle+\langle N(u),Au_2\rangle=(g,Au_2). \tag{3.6}$$

Now using the definition of $B(\cdot)$, Hölder inequality and Gagliardo-Nirenberg inequality, we have

$$|\langle B(u),Au_2\rangle| \leqslant \|u\|_{L^4(\Omega)}\|\nabla u\|_{L^4(\Omega)}\|Au_2\| \leqslant C\|u\|^{1/2}\|\nabla u\|^{1/2}\|u\|^{1/4}\|\Delta u\|^{3/4}\|Au_2\|$$
$$\leqslant C\|u\|^{3/4}\|u\|^{1/2}_{H^1(\Omega)}\|u\|^{3/4}_V\|Au_2\| \leqslant \frac{3}{8}\mu_1\|Au_2\|^2 + \frac{8C}{3\mu_1}\|u\|^{3/2}\|u\|_{H^1(\Omega)}\|u\|^{3/2}_V$$
$$\leqslant \frac{3}{8}\mu_1\|Au_2\|^2 + \frac{C}{\mu_1}\|u\|^{3/2}\|u\|^{5/2}_V, \tag{3.7}$$

here and in the following C denotes the generic constant that has been mentioned in Sec. II. Also we have by using (2.20) and Hölder inequality that

$$|\langle N(u),Au_2\rangle| = \left|-\int_\Omega \{\nabla\cdot[\mu(u)e(u)]\}\cdot Au_2 \mathrm{d}x\right| \leqslant 2C\mu_0\varepsilon^{-\alpha/2}\sqrt{4+\frac{12}{\varepsilon}}\|\nabla u\|\|Au_2\| + 2C\mu_0\varepsilon^{-\alpha/2}\|\Delta u\|$$
$$\times\|Au_2\| \leqslant \frac{C}{\mu_1}\|u\|^2_{H^1(\Omega)} + \frac{3}{4}\mu_1\|Au_2\|^2 + \frac{C}{\mu_1}\|u\|^2_V \leqslant \frac{3}{4}\mu_1\|Au_2\|^2 + \frac{C}{\mu_1}\|u\|^2_V. \tag{3.8}$$

It is clear that

$$(g,Au_2) \leqslant \|Au_2\|\|g\| \leqslant \frac{3}{8}\mu_1\|Au_2\|^2 + \frac{8}{3\mu_1}\|g\|^2. \tag{3.9}$$

Taking (3.6)–(3.9) into account, we obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}a(u_2,u_2) + \mu_1(Au_2,Au_2) \leqslant \frac{C}{\mu_1}\|u\|^{3/2}\|u\|^{5/2}_V + \frac{C}{\mu_1}\|u\|^2_V + \frac{16}{3\mu_1}\|g\|^2. \tag{3.10}$$

Now (3.4) and (3.5) and Lemma 2.1 imply

$$\|Au_2\|^2 \geqslant \lambda_{m+1}\|u_2\|^2_V \geqslant \lambda_{m+1}a(u_2,u_2). \tag{3.11}$$

Combining (3.10) and (3.11) and Lemma 2.3, we see that $t \geqslant t_0+1$ implies

$$\frac{\mathrm{d}}{\mathrm{d}t}a(u_2(t),u_2(t)) + \mu_1\lambda_{m+1}a(u_2(t),u_2(t)) \leqslant \frac{C}{\mu_1}R_0^{3/2}R_1^{5/2} + \frac{C}{\mu_1}R_1^2 + \frac{16}{3\mu_1}\|g\|^2, \tag{3.12}$$

where t_0 is the constant from Lemma 2.3. Applying Gronwall inequality to (3.12), we obtain

$$a(u_2(t),u_2(t)) \leqslant a(u_2(t_0+1),u_2(t_0+1))e^{-\mu_1\lambda_{m+1}(t-t_0-1)} + \frac{C}{\mu_1^2\lambda_{m+1}}(R_0^{3/2}R_1^{5/2}+R_1^2)$$
$$+ \frac{C}{\mu_1^2\lambda_{m+1}}\int_{t_0+1}^t e^{-\mu_1\lambda_{m+1}(s-t_0-1)}\|g(s)\|^2\mathrm{d}s, \quad \forall\, t \geqslant t_0+1. \tag{3.13}$$

By (3.4) and Lemma 3.1, we derive that for any $\epsilon>0$, there exists $m_0\in\mathbf{N}$ such that

$$\frac{C}{\mu_1^2\lambda_{m+1}}(R_0^{3/2}R_1^{5/2}+R_1^2) \leqslant \frac{C_1\epsilon}{3}, \quad m \geqslant m_0, \tag{3.14}$$

$$\frac{C}{\mu_1^2\lambda_{m+1}}\int_{t_0+1}^t e^{-\mu_1\lambda_{m+1}(s-t_0-1)}\|g(s)\|^2\mathrm{d}s \leqslant \frac{C_1\epsilon}{3}, \quad m \geqslant m_0, \quad \forall\, g\in\mathcal{H}_w(g_0). \tag{3.15}$$

Now we set

$$\tilde{t} = \tilde{t}(\tau, B, \epsilon) = t_0 + 1 + \frac{1}{\mu_1 \lambda_{m+1}} \ln\left(\frac{3R_1^2}{C_1 \epsilon}\right),$$

then

$$a(u_2(t_0+1), u_2(t_0+1)) e^{-\mu_1 \lambda_{m+1}(t-t_0-1)} \leqslant \frac{C_1 \epsilon}{3}, \quad \forall\, t \geqslant \tilde{t}. \tag{3.16}$$

Choose $t_1 = t_1(\tau, B, \epsilon) = \max\{\tilde{t}, t_0+1\}$ and we combine Lemma 2.1 and (3.13)–(3.16) to obtain (when $m \geqslant m_0$)

$$\|u_2(t)\|_V^2 \leqslant \frac{1}{C_1} a(u_2(t), u_2(t)) \leqslant \frac{1}{C_1}\left(\frac{C_1\epsilon}{3} + \frac{C_1\epsilon}{3} + \frac{C_1\epsilon}{3}\right) = \epsilon, \quad \forall\, t \geqslant t_1, \quad \forall\, g \in \mathcal{H}_w(g_0).$$

Therefore, we have established the assertion formulated in the beginning of the proof. The proof of this lemma is completed. □

Lemma 3.3: Let $g_0 \in L^2_{\mathrm{lui}}(\mathbf{R}; H)$. Then the family of processes $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$, corresponding to Eqs. (1.8) and (1.9) is $(V \times \mathcal{H}_w(g_0), V)$ weakly continuous, i.e., for any $t \geqslant \tau$, $\tau \in \mathbf{R}$, the mapping $U_g(t,\tau): (u,g) \mapsto U_g(t,\tau)u$ is weakly continuous from $V \times \mathcal{H}_w(g_0)$ to V.

Proof: Let $u_0^{(n)} \rightharpoonup u_0$ in V and $g_n \rightharpoonup g_0$ in $L^2_{\mathrm{loc}}(\mathbf{R}; H)$. For any $\tau \in \mathbf{R}$, we set $u^{(n)}(t) = U_{g_n}(t,\tau)u_0^{(n)}$ and $u(t) = U_{g_0}(t,\tau)u_0$. Analogous with Lemma 2.2(*ii*), we can prove that $\{u^{(n)}\}$ is bounded in $C([\tau, +\infty); V) \cap L^2_{\mathrm{loc}}([\tau, +\infty); D(A))$ and $\{u_t^{(n)}\}$ is bounded in $L^2_{\mathrm{loc}}([\tau, +\infty); H)$. The rest is essentially the same as the proof of Lemma 2.2 in Ref. 12 or of Lemma 2.1 in Ref. 19. So we omit it here. □

Proof of Theorem 1.1; Since $g_0 \in L^2_{\mathrm{lui}}(\mathbf{R}; H) \subset L^2_b(\mathbf{R}; H)$, $\mathcal{H}_w(g_0)$ is weakly compact in $L^2_{\mathrm{loc}}(\mathbf{R}; H)$. At the same time, Lemma 3.3 shows that the family of processes $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$, corresponding to Eqs. (1.8) and (1.9) is $(V \times \mathcal{H}_w(g_0), V)$ weakly continuous. Moreover, Lemma 2.3 shows that $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$, has a bounded uniformly (w.r.t. $g \in \mathcal{H}_w(g_0)$) absorbing set in V and Lemma 3.2 implies that $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$, is uniformly (w.r.t. $g \in \mathcal{H}_w(g_0)$) ω-limit compact. It is clear that for any $h \geqslant 0$, we have $T(h)\mathcal{H}_w(g_0) = \mathcal{H}_w(g_0)$ and $U_{T(h)g}(t,\tau) = U_g(t+h, \tau+h)$, $\forall t \geqslant \tau$, $\tau \in \mathbf{R}$, $g \in \mathcal{H}_w(g_0)$, where $\{T(h)\}_{h \geqslant 0}$ is the natural translation semigroup (see Ref. 7 for details). These results show that the family of processes $\{U_g(t,\tau)\}$, $g \in \mathcal{H}_w(g_0)$, satisfies all conditions of Theorem 2.6 in Ref. 15 and thus we obtain Theorem 1.1. The proof is completed. □

In Ref. 28 the authors of the present paper assumed that the external force g_0 is tr.c in $L^2_{\mathrm{loc}}(\mathbf{R}; H)$ and obtained the existence and structure of the uniform attractor in space H for the family of processes corresponding to Eqs. (1.8) and (1.9). The result of this paper extends that of Ref. 28. The following corollaries could be proved essentially in the same way as that in Ref. 28. Here we only list them out and omit the proofs.

Corollary 3.1: Assume $g_0 \in L^2_{\mathrm{lui}}(\mathbf{R}; H)$ and $\|g_0\|^2_{L^2_b} < \hat{C}$, where $\hat{C}$ depends only on Ω and μ_1. Then for all $g \in \mathcal{H}_w(g_0)$ Eqs. (1.8) and (1.9) possess a unique bounded solution $\hat{u}(t) \in V$, $t \in \mathbf{R}$, which is asymptotically stable in H, that is,

$$\|\hat{u}(t) - u(t)\|^2 \leqslant \|\hat{u}(\tau) - u_\tau\|^2 K_0 e^{-\beta(t-\tau)}, \quad t \geqslant \tau, \quad \tau \in \mathbf{R},$$

where $u_\tau \in H$ is arbitrary and $u(t)$ is the corresponding solution; the positive constants K_0 and β are both independent of u_τ.

Corollary 3.2: Let g_0 satisfy the conditions of Corollary 3.1. If g_0 is a periodic function, then $\hat{u}(t)$ is also a periodic function with the same period.

Corollary 3.3: Let the conditions of Corollary 3.1 be satisfied and let $\hat{u}(t)$, $t \in \mathbf{R}$, be the bounded solution of Eqs. (1.8) and (1.9) with symbol g_0. Then

$$\mathcal{A}_0 = \mathcal{A}_{\mathcal{H}_w(g_0)} = \mathcal{A}_{\mathcal{H}_0(g_0)} = \{\hat{u}(t) : t \in \mathbf{R}\} = [\{\hat{u}(t) : t \in \mathbf{R}\}]_V,$$

where $[\cdot]_V$ *denotes taking closure w.r.t. strong topology of* V.

Corollary 3.4: If $g_0 \in L^2_{\mathrm{lui}}(\mathbf{R};H)$, *then*

$$\mathcal{A}_0 = \mathcal{A}_{\mathcal{H}_w(g_0)} = \mathcal{A}_{\mathcal{H}_0(g_0)} \subseteq B_{R_1}(0),$$

where $B_{R_1}(0)$ *is the ball in* V *centered at* 0 *with radius* R_1 *defined in (2.31).*

Remark 3.1: When $g_0 \in L^2_c(\mathbf{R};H)$,[28] constructed the uniform attractor $\mathcal{A}_{\mathcal{H}_s(g_0)} \subset H$ for the family of processes corresponding to the non-Newtonian fluid. Indeed, if $g_0 \in L^2_c(\mathbf{R};H)$, then Theorem 1.1 also holds true and we can deduce from Theorem 1.1 and Theorem 3.1 in Ref. 28 that $\mathcal{A}_{\mathcal{H}_s(g_0)} \subset \mathcal{A}_{\mathcal{H}_w(g_0)} \subset V$, which implies the regularity of uniform attractors and thus reveals the asymptotic smoothing effect of solutions in the sense that the solutions become eventually more regular than the initial data.

A new energy method for the Boltzmann equation

Tong Yang[a)]

Hui-Jiang Zhao[b)]
School of Mathematics and Statistics, Wuhan University, Wuhan 430072, China

(Received 31 May 2005; accepted 21 March 2006; published online 4 May 2006)

An energy method for the Boltzmann equation was proposed by Liu, Yang, and Yu [Physica D **188**, 178–192 (2004)] based on the decomposition of the Boltzmann equation and its solution around the local Maxwellian. The main idea is to rewrite the Boltzmann equation as a fluid-type dynamics system with the nonfluid component appearing in the source terms, coupled with an equation for the time evolution of the nonfluid component. In this paper, we will elaborate this method and our main observation is that the microscopic projection of the local Maxwellian with respect to a given global Maxwellian is not linear but quadratic. Based on this and by analyzing the fluid-type system using the analytic techniques for the system of conservation laws, we can indeed control the conserved quantities $\rho, \rho u$, and $\rho(\frac{1}{2}u^2+\mathcal{E})$ of the Boltzmann equation by the microscopic projection of the solution of the Boltzmann equation with respect to the global Maxwellian, which is sufficient to deduce the energy estimates for the solution of the Boltzmann equation. The main purpose here is to show that there is no need to perform two sets of energy estimates with respect to the local and a global Maxwellian as in the previous works. In fact, one set of energy estimates with respect to the global Maxwellian is sufficient for closing the energy estimates. Therefore, it not only simplifies the analysis in the previous works, but also shed some light on the stability analysis in some complicated systems, such as the Vlasov-Poisson-Boltzmann and Vlasov-Maxwell-Boltzmann systems. © *2006 American Institute of Physics.*

I. INTRODUCTION

Consider the Boltzmann equation

$$f_t + \xi \cdot \nabla_x f = \frac{1}{\kappa} Q(f,f), \quad (f,t,x,\xi) \in \mathbf{R}^+ \times \mathbf{R}^+ \times \mathbf{R}^3 \times \mathbf{R}^3, \tag{1.1}$$

where $f=f(t,x,\xi)$ represents the distributional density of particles at space–time (x,t) with velocity ξ, κ is the Knudsen number proportional to the mean free path, and $Q(f,f)$ is the collision operator given by the following bilinear form, cf. Ref. 1,

[a)]Electronic mail: matyang@math.cityu.edu.hk. Research supported by the RGC Competitive Earmarked Research Grant, CityU 103004.
[b)]Electronic mail: hhjjzhao@hotmail.com. Research supported by the National Natural Science Foundation of China under Contracts Nos. 10329101 and 10431060, respectively.

$$Q(f,g)(\xi)=\int_{\mathbf{R}^3}\int_{\mathbf{S}^2_+}(f(\xi')g(\xi'_*)+f(\xi'_*)g(\xi')-f(\xi)g(\xi_*)-f(\xi_*)g(\xi))B(|\xi-\xi_*|,\theta)\mathrm{d}\xi_*\,\mathrm{d}\Omega,$$

with θ being the angle between the relative velocity and the unit vector Ω, i.e., $\cos\theta=(\xi-\xi_*)\cdot\Omega/|\xi-\xi_*|$. Here $\mathbf{S}^2_+=\{\Omega\in\mathbf{S}^2:(\xi-\xi_*)\cdot\Omega\geqslant 0\}$. The conservation of momentum and energy gives the following relation between velocities before and after collision:

$$\xi'=\xi-[(\xi-\xi_*)\cdot\Omega]\Omega,\quad \xi'_*=\xi_*+[(\xi-\xi_*)\cdot\Omega]\Omega.$$

Throughout this paper, the collision kernel $B(|V|,\theta)$ is assumed to satisfy the following two conditions:

(A1) There is $0\leqslant\delta_1<1$ such that

$$0\leqslant B(|V|,\theta)\leqslant C_1(|V|+|V|^{-\delta_1})|\cos\theta|. \tag{1.2}$$

(A2) There are constants $0<\beta\leqslant 1$ such that

$$C_2(1+|\xi|)^{\beta}\leqslant\nu(\xi)\leqslant C_3(1+|\xi|)^{\beta}, \tag{1.3}$$

where $C_i>0(i=1,2,3)$ are positive constants and $\nu(\xi)$ is the collision frequency defined by (cf. Ref. 6)

$$\nu(\xi)=\int_{\mathbf{R}^3}\int_{\mathbf{S}^2}\mathbf{M}(\xi)B(|\xi-\xi_*|,\theta)\mathrm{d}\xi_*\,\mathrm{d}\Omega. \tag{1.4}$$

Notice that both the hard sphere model and the hard potential model with angular cutoff satisfy the above two conditions (A1) and (A2).

In this paper, we consider the Boltzmann equation (1.1) in the whole space with its initial data given by

$$f(0,x,\xi)=f_0(x,\xi). \tag{1.5}$$

Here $f_0(x,\xi)$ is assumed to be a small perturbation of a given global Maxwellian $\overline{\mathbf{M}}=\mathbf{M}_{[\bar\rho,\bar u,\bar\theta]}$ for any given constant $\bar\rho>0$, $\bar u\in\mathbf{R}^3$, $\bar\theta>0$. Without loss of generality, we can let $\bar u=0$ in the rest of this paper.

For a solution around a global Maxwellian or a nontrivial solution profile, the solution spaces for the Boltzmann equation can be in $L^\infty_{x,\xi}$, $L^1_{x,\xi}$, and $H^s_x(L^2_\xi)$, respectively. The solution in $L^\infty_{x,\xi}$ is proved based on the spectral analysis and the bootstrapping argument from Grad[6] to Ukai.[21] The important contribution of DiPerna and Lions[4] is the establishment of the renormalized solutions in $L^1_{x,\xi}$ space using the Boltzmann's celebrated **H** theorem and the averaging lemma. Recently, the existence of solutions in the $H^s_x(L^2_\xi)$ space was proved by energy method for the study on the stability of solution profiles and the large time behavior of the solutions related to fluid dynamics. For this, the decomposition of the solution and the equation around a global Maxwellian was introduced in Ref. 17 for the stability analysis of the shock profiles. And it was also used in the study on the space periodic solutions.[7,8] For the study of the nontrivial solution profiles, a decomposition of the solution into the local Maxwellian and the nonfluid component was used in Ref. 15 so that the Boltzmann equation can be rewritten as a new fluid-type system and an equation for the nonfluid component. So far, the stability of each basic wave pattern, i.e., shock wave, rarefaction wave and contact discontinuity, and the solution profiles for Boltzmann equation with external force and the Vlasov-Poisson-Boltzmann system have been investigated by the energy method through the above decomposition on both the solution and the Boltzmann equation, cf. Refs. 11, 12, 15–17, and 22–24.

However, in all the above analysis through the decomposition around the local Maxwellian, two sets of energy estimates are used. One is with respect to the local Maxwellian and another with respect to a global Maxwellian chosen appropriately. The reason to use two sets of energy

estimates is that the collision frequency is of the order of $(1+|\xi|)^{\beta}$ with $\beta \leqslant 1$ for $|\xi|$ large, while the differentiation on the local Maxwellian may generate a factor as a polynomial of ξ of order greater than 1. And the set of the energy estimates with respect to the global Maxwellian is to absorb the polynomial in ξ, while the energy estimates with respect to the local Maxwellian $\mathbf{M}$ is used by applying the orthogonality of $\mathbf{P}_0^{\mathbf{M}} f$ and $L_{\mathbf{M}}(\mathbf{P}_1^{\mathbf{M}} f)$ with respect to the local Maxwellian $\mathbf{M}$.

The main purpose of this paper is to give a new way of obtaining energy estimates so that only one set of energy estimates is needed. Our main observation is that the microscopic projection of the local Maxwellian $\mathbf{M}$ with respect to the global Maxwellian $\overline{\mathbf{M}}$ is not linearly but quadratic. Based on this and by analyzing the fluid-type system (2.13) using the analytic techniques for the system of conservation laws, we can indeed control the conserved quantities ρ, ρu, and $\rho\left(\frac{1}{2}u^2+\mathcal{E}\right)$ of the Boltzmann equation (1.1) by $\mathbf{P}_1^{\bar{M}} f$ besides the initial data, which is the microscopic projection of the solution $f(t,x,\xi)$ to the Boltzmann equation (1.1) with respect to the global Maxwellian $\overline{\mathbf{M}}$. Hence, it is sufficient to close the energy estimates for the solution of the Boltzmann equation (1.1) by performing the energy estimates on the original equation (1.1) with respect to the global Maxwellian $\overline{\mathbf{M}}$. Therefore, it indeed provides a clear energy method for the study of Boltzmann equation not only simplifies all the previous works in the direction, but also give a clear-cut relation of the Boltzmann equation with the corresponding fluid dynamics. Moreover, in some cases, it gives the optimal results.

The relation of the Boltzmann equation for rarefied gas with the systems of the fluid dynamics is well known since Boltzmann's derivation of this fundamental equation from statistics physics. In fact, the Hilbert expansion in 1912 gives the system of the compressible Euler equations as the first order approximation, while the Chapman-Enskog expansion in 1916–1917 yields the system of the compressible Navier-Stokes equations in the second order approximation, cf. Refs. 3 and 10. By using the decomposition around the local Maxwellian,[15] the derived system of fluid-type equations is not an approximation but an exact system for the time evolution of the fluid components in the solution with a source in terms of the nonfluid component. Moreover, even though the decomposition of the solution into the local Maxwellian and the nonfluid component is known since Maxwell,[19] the analysis on its time evolution and the solution behavior becomes much clearer until recently.[9,11,12,15–17,22–24]

The rest of the paper will be organized as follows. In the next section, we will review the decomposition and rewrite Boltzmann equation as in Ref. 15. In Sec. III, the new energy method is given by the estimation on the fluid component through the fluid-type system and the original equation for the nonfluid component where a basic estimate on the projection of the local Maxwellian with respect to the global Maxwellian is crucially used.

II. REFORMULATION

For completeness and the convenience of the readers, in this section, we give reformulation of the Boltzmann equation through the decomposition introduced in Ref. 15.

Let $f(t,x,\xi)$ be the solution to the Boltzmann equation, we decompose it into the macroscopic, fluid part, the local Mawellian $\mathbf{M}=\mathbf{M}(x,t,\xi)=\mathbf{M}_{[\rho,u,\theta]}(\xi)$, and the microscopic, nonfluid part $\mathbf{G}=\mathbf{G}(x,t,\xi)$,

$$f(t,x,\xi)=\mathbf{M}(t,x,\xi)+\mathbf{G}(t,x,\xi). \tag{2.1}$$

Here, $\mathbf{M}(t,x,\xi)$ is defined by the five conserved quantities, the mass density $\rho(t,x)$, momentum $m(t,x)=\rho(t,x)u(t,x)$ and energy density $\mathcal{E}(t,x)+|u(t,x)|^2/2$,

$$\rho(t,x) \equiv \int_{\mathbf{R}^3} f(t,x,\xi)\mathrm{d}\xi,$$

$$m^i(t,x) \equiv \int_{\mathbf{R}^3} \psi_i(\xi) f(t,x,\xi) \mathrm{d}\xi, \quad i = 1,2,3,$$

$$\left[\rho\left(\mathcal{E} + \tfrac{1}{2}|u|^2\right)\right](t,x) \equiv \int_{\mathbf{R}^3} \psi_4(\xi) f(t,x,\xi) \mathrm{d}\xi, \tag{2.2}$$

in the form of

$$\mathbf{M} \equiv \mathbf{M}_{[\rho,u,\theta]}(\xi) \equiv \frac{\rho}{\sqrt{(2\pi R\theta)^3}} \exp\left(-\frac{|\xi - u|^2}{2R\theta}\right). \tag{2.3}$$

Here $\theta(t,x)$ is the temperature which is related to the internal energy $\varepsilon(t,x)$ through the gas constant R, $\mathcal{E} = \frac{3}{2}R\theta$, and $u(t,x) = (u^1(t,x), u^2(t,x), u^3(t,x))$ is the fluid velocity. Also $\psi_\alpha(\xi)$, $\alpha = 0,1,\ldots,4$, are the five collision invariants,[1]

$$\psi_0(\xi) \equiv 1,$$

$$\psi_i(\xi) \equiv \xi^i, \quad i = 1,2,3, \tag{2.4}$$

$$\psi_4(\xi) \equiv \tfrac{1}{2}|\xi|^2.$$

For any given Maxwellian $\tilde{\mathbf{M}} = \tilde{\mathbf{M}}_{[\tilde{\rho},\tilde{u},\tilde{\theta}]}$, we define an inner product in $\xi \in \mathbf{R}^3$ as

$$\langle h, g \rangle_{\tilde{\mathbf{M}}} \equiv \int_{\mathbf{R}^3} \frac{h(\xi) g(\xi)}{\tilde{\mathbf{M}}} \mathrm{d}\xi,$$

for functions h and g of ξ such that the integral is well defined. Using this inner product with respect to this Maxwellian, the subspace spanned by the collision invariants has the following set of orthogonal basis:

$$\begin{aligned}
\chi_0^{\tilde{\mathbf{M}}} &= \chi_0(\xi;\tilde{\rho},\tilde{u},\tilde{\theta}) \equiv \frac{1}{\sqrt{\tilde{\rho}}}\tilde{\mathbf{M}}, \\
\chi_i^{\tilde{\mathbf{M}}} &= \chi_i(\xi;\tilde{\rho},\tilde{u},\tilde{\theta}) \equiv \frac{\xi^i - \tilde{u}^i}{\sqrt{R\tilde{\theta}\tilde{\rho}}}\tilde{\mathbf{M}}, \quad i = 1,2,3, \\
\chi_4^{\tilde{\mathbf{M}}} &= \chi_4(\xi;\tilde{\rho},\tilde{u},\tilde{\theta}) \equiv \frac{1}{\sqrt{6\tilde{\rho}}}\left(\frac{|\xi - \tilde{u}|^2}{R\theta} - 3\right)\tilde{\mathbf{M}},
\end{aligned} \tag{2.5}$$

$$\langle \chi_\alpha^{\tilde{\mathbf{M}}}, \chi_\beta^{\tilde{\mathbf{M}}} \rangle_{\tilde{\mathbf{M}}} = \delta_{\alpha\beta}, \quad \text{for } \alpha,\beta = 0,1,2,3,4.$$

With this basis, we can define the macroscopic projection $\mathbf{P}_0^{\tilde{\mathbf{M}}}$ and microscopic projection $\mathbf{P}_1^{\tilde{\mathbf{M}}}$ by

$$\mathbf{P}_0^{\tilde{\mathbf{M}}} h \equiv \sum_{\alpha=0}^{4} \langle h, \chi_\alpha^{\tilde{\mathbf{M}}} \rangle_{\tilde{\mathbf{M}}} \chi_\alpha^{\tilde{\mathbf{M}}},$$

$$\mathbf{P}_1^{\tilde{\mathbf{M}}} h \equiv h - \mathbf{P}_0^{\tilde{\mathbf{M}}} h.$$

Notice that the operators $\mathbf{P}_0^{\tilde{\mathbf{M}}}$ and $\mathbf{P}_1^{\tilde{\mathbf{M}}}$ are projections, that is,

$$\mathbf{P}_0^{\tilde{\mathbf{M}}}\mathbf{P}_0^{\tilde{\mathbf{M}}} = \mathbf{P}_0^{\tilde{\mathbf{M}}}, \quad \mathbf{P}_1^{\tilde{\mathbf{M}}}\mathbf{P}_1^{\tilde{\mathbf{M}}} = \mathbf{P}_1^{\tilde{\mathbf{M}}}, \quad \mathbf{P}_0^{\tilde{\mathbf{M}}}\mathbf{P}_1^{\tilde{\mathbf{M}}} = \mathbf{P}_1^{\tilde{\mathbf{M}}}\mathbf{P}_0^{\tilde{\mathbf{M}}} = 0.$$

Now, the system of conservation laws

$$\int_{\mathbf{R}^3} \psi_\alpha (f_t + \xi \cdot \nabla_x f) \mathrm{d}\xi = 0, \quad \alpha = 0,1,\ldots,4, \tag{2.6}$$

takes the following form:

$$\rho_t + \mathrm{div}_x\, m = 0,$$

$$m_t^i + \left(\sum_{j=1}^3 u^j m^i \right)_{x^j} + p_{x^i} + \int_{\mathbf{R}^3} \psi_i(\xi)(\xi \cdot \nabla_x \mathbf{G}) \mathrm{d}\xi = 0, \quad i = 1,2,3, \tag{2.7}$$

$$\left[\rho \left(\frac{|u|^2}{2} + \mathcal{E} \right) \right]_t + \sum_{j=1}^3 \left\{ u^j \left[\rho \left(\frac{|u|^2}{2} + \mathcal{E} \right) + p \right] \right\}_{x^j} + \int_{\mathbf{R}^3} \psi_4(\xi)(\xi \cdot \nabla_x \mathbf{G}) \mathrm{d}\xi = 0.$$

The equation of the state is that for the monatomic gas, with the gas constant R chosen to be $\frac{3}{2}$ without loss of generality, cf. Ref. 16,

$$p = \tfrac{2}{3}\rho e.$$

And the macroscopic entropy S is given by

$$S = -\tfrac{2}{3} \ln \rho + \ln\left(\tfrac{4}{3}\pi\theta\right) + 1.$$

The microscopic equation is obtained by applying the microscopic projection $\mathbf{P}_1^{\mathbf{M}}$ to the Boltzmann equation (1.1):

$$\mathbf{G}_t + \mathbf{P}_1^{\mathbf{M}}(\xi \cdot \nabla_x \mathbf{G} + \xi \cdot \nabla_x \mathbf{M}) = \frac{1}{\kappa} L_{\mathbf{M}} \mathbf{G} + \frac{1}{\kappa} Q(\mathbf{G}, \mathbf{G}), \tag{2.8}$$

where $L_{\mathbf{M}}$ is the linearized collision operator defined by

$$L_{\mathbf{M}} g = L_{\mathbf{M}_{[\rho,u,\theta]}} g \equiv Q(\mathbf{M}_{[\rho,u,\theta]} + g, \mathbf{M}_{[\rho,u,\theta]} + g) - Q(g,g). \tag{2.9}$$

From (2.8) we have

$$\mathbf{G} = \kappa L_{\mathbf{M}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi \cdot \nabla_x \mathbf{M})) + L_{\mathbf{M}}^{-1}(\kappa(\partial_t \mathbf{G} + \mathbf{P}_1^{\mathbf{M}} \xi \cdot (\nabla_x \mathbf{G})) - Q(\mathbf{G}, \mathbf{G})) = \kappa L_{\mathbf{M}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi \cdot \nabla_x \mathbf{M})) + \Theta. \tag{2.10}$$

By substituting (2.10) into (2.7) yields the following fluid-type system for the macroscopic components:

$$\rho_t + \mathrm{div}_x\, m = 0,$$

$$m_t^i + \left(\sum_{j=1}^3 u^j m^i \right)_{x^j} + p_{x^i} + \kappa \int_{\mathbf{R}^3} \psi_i(\xi)(\xi \cdot \nabla_x L_{\mathbf{M}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi \cdot \nabla_x \mathbf{M}))) \mathrm{d}\xi$$

$$+ \int_{\mathbf{R}^3} \psi_i(\xi)(\xi \cdot \nabla_x \Theta) \mathrm{d}\xi = 0, \quad i = 1,2,3,$$

$$\left[\rho\left(\frac{|u|^2}{2}+\mathcal{E}\right)\right]_t+\sum_{j=1}^{3}\left\{u^j\left[\rho\left(\frac{|u|^2}{2}+\mathcal{E}\right)+p\right]\right\}_{x^j}+\kappa\int_{\mathbf{R}^3}\psi_4(\xi)(\xi\cdot\nabla_x L_{\mathbf{M}}^{-1}(\mathrm{P}_1^{\mathbf{M}}(\xi\cdot\nabla_x\mathbf{M})))\mathrm{d}\xi$$
$$+\int_{\mathbf{R}^3}\psi_4(\xi)(\xi\cdot\nabla_x\Theta)\mathrm{d}\xi=0. \tag{2.11}$$

Notice also that in the above system, the terms

$$-\kappa\int_{\mathbf{R}^3}\psi_i(\xi)(\xi\cdot\nabla_x L_{\mathbf{M}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi\cdot\nabla_x\mathbf{M})))\mathrm{d}\xi$$

$$=-\kappa\int_{\mathbf{R}^3}\psi_i(\xi)(\xi\cdot\nabla_x L_{\mathbf{M}_{[\rho,u,\theta]}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi\cdot\nabla_x\mathbf{M}_{[\rho,u,\theta]})))\mathrm{d}\xi$$

$$=-\kappa\int_{\mathbf{R}^3}\psi_i(\xi)(\xi\cdot\nabla_x L_{\mathbf{M}_{[1,u,\theta]}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi\cdot\nabla_x\mathbf{M}_{[1,u,\theta]})))\mathrm{d}\xi,\quad i=1,2,3,$$

$$-\kappa\int_{\mathbf{R}^3}\psi_4(\xi)(\xi\cdot\nabla_x L_{\mathbf{M}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi\cdot\nabla_x\mathbf{M})))\mathrm{d}\xi$$

$$=-\kappa\int_{\mathbf{R}^3}\psi_4(\xi)(\xi\cdot\nabla_x L_{\mathbf{M}_{[\rho,u,\theta]}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi\cdot\nabla_x\mathbf{M}_{[\rho,u,\theta]})))\mathrm{d}\xi$$

$$=-\kappa\int_{\mathbf{R}^3}\psi_4(\xi)(\xi\cdot\nabla_x L_{\mathbf{M}_{[1,u,\theta]}}^{-1}(\mathbf{P}_1^{\mathbf{M}}(\xi\cdot\nabla_x\mathbf{M}_{[1,u,\theta]})))\mathrm{d}\xi$$

are the viscosity and heat conductivity terms which are the same as those in the compressible Navier-Stokes equations; and they are independent of the density gradient $\nabla_x\rho$. In fact, with the Burnett functions A and B, the viscosity coefficient $\mu(\theta)$ and heat conductivity coefficient $\kappa(\theta)$ can be represented by

$$A_j(\xi)=\frac{|\xi|^2-5}{2}\xi^j,\quad j=1,2,3,$$

$$B_{ij}(\xi)=\xi^i\xi^j-\tfrac{1}{3}\delta_{ij}|\xi|^2,\quad i,j=1,2,3,$$
$$\mu(\theta)=-\kappa R\theta\int_{\mathbf{R}^3}B_{ij}\left(\frac{\xi}{\sqrt{R\theta}}\right)L_{\mathbf{M}_{[1,u,\theta]}}^{-1}\left(B_{ij}\left(\frac{\xi}{\sqrt{R\theta}}\right)\mathbf{M}_{[1,u,\theta]}\right)\mathrm{d}\xi>0,\quad i\neq j, \tag{2.12}$$

$$\kappa(\theta)=-\kappa R^2\theta\int_{\mathbf{R}^3}A_l\left(\frac{\xi}{\sqrt{R\theta}}\right)L_{\mathbf{M}_{[1,u,\theta]}}^{-1}\left(A_l\left(\frac{\xi}{\sqrt{R\theta}}\right)\mathbf{M}_{[1,u,\theta]}\right)\mathrm{d}\xi>0,$$

and the fluid-type system (2.11) can be rewritten as

$$\rho_t+\mathrm{div}_x\, m=0,$$

$$m_t^i+\sum_{j=1}^{3}(u^j m^i)_{x^j}+p_{x^i}=\sum_{j=1}^{3}\left[\mu(\theta)\left(u^i_{x^j}+u^j_{x^i}-\tfrac{2}{3}\delta_{ij}\,\mathrm{div}_x\, u\right)\right]_{x^j}-\int_{\mathbf{R}^3}\psi_i(\xi)(\xi\cdot\nabla_x\Theta)\mathrm{d}\xi,\quad i=1,2,3,$$

$$\left[\rho\left(\tfrac{1}{2}|u|^2+\mathcal{E}\right)\right]_t+\sum_{j=1}^{3}\left(u^j\left(\rho\left(\tfrac{1}{2}|u|^2+\mathcal{E}\right)+p\right)\right)_{x^j}=\sum_{i,j=1}^{3}\left\{\mu(\theta)u^i\left(u^i_{x^j}+u^j_{x^i}-\tfrac{2}{3}\delta_{ij}\,\mathrm{div}_x\,u\right)\right\}_{x^j}$$
$$+\sum_{j=1}^{3}\left(\kappa(\theta)\theta_{x^j}\right)_{x^j}-\int_{\mathbf{R}^3}\psi_4(\xi)(\xi\cdot\nabla_x\Theta)\mathrm{d}\xi. \tag{2.13}$$

From this fluid-type system, one can easily see the structure of the compressible Euler and the compressible Navier-Stokes equations. For instance, when the Knudsen number κ is set zero, the system (2.13) becomes the compressible Euler equations. On the other hand, when Θ is set to be zero in (2.13), it becomes the compressible Navier-Stokes equations. These fluid equations as derived through the Hilbert and Chapman-Enskog expansions are approximations to the Boltzmann equation.[3] However, the above system is part of the Boltzmann equation. Nevertheless, this reformulation is consistent in spirit with these expansions in that the higher order terms beyond first order in the expansions must be microscopic. The above analysis also indicates that if we deduce the compressible Navier-Stokes equations from the Boltzmann equation, the viscosity coefficient $\mu(\theta)>0$ and the heat conductivity coefficient $\kappa(\theta)>0$ are smooth functions of the temperature θ.

III. ENERGY METHOD

This section is devoted to the energy method for the Boltzmann equation (1.1). For simplicity, we assume from now on that the Knudsen number $\kappa=1$.

We first state some basic inequalities for later use. The first lemma is concerned with some inequalities of Sobolev type.

Lemma 3.1: For $g(x)\in H^1(\mathbf{R}^3)$, we have

$$\|g(x)\|_{L^6(\mathbf{R}^3)}\leqslant C_0\|\nabla_x g(x)\|, \tag{3.1}$$

where C_0 is a positive constant independent of $g(x)$. Consequently, for $g(x)\in H^2(\mathbf{R}^3)$, there exists a positive constant C_1 independent of $g(x)$ such that

$$\|g(x)\|_{L^\infty(\mathbf{R}^3)}\leqslant C_1\|\nabla_x g(x)\|_1,$$
$$\|g(x)\|_{L^4(\mathbf{R}^3)}\leqslant C_1\|\nabla_x g(x)\|^{\frac{3}{4}}\|g(x)\|^{\frac{1}{4}}. \tag{3.2}$$

Here and in the sequel, $\|\cdot\|$ and $\|\cdot\|_s$ denote the standard $L^2(\mathbf{R}^3)$-norm and $H^s(\mathbf{R}^3)$-norm, respectively.

In the following, we will give some inequalities on the nonlinear and linearized collision operators $Q(f,f)$ and $L_{\mathbf{M}}\mathbf{G}$. The first lemma is from Ref. 5.

Lemma 3.2: Suppose that $B(|\xi-\xi_*|,\theta)$ satisfies (A1) and (A2), then there exists a positive constant $C_2>0$ such that

$$\int_{\mathbf{R}^3}\frac{\nu(\xi)^{-1}Q(f,g)^2}{\tilde{\mathbf{M}}}\mathrm{d}\xi\leqslant C_2\left\{\int_{\mathbf{R}^3}\frac{\nu(\xi)f^2}{\tilde{\mathbf{M}}}\mathrm{d}\xi\cdot\int_{\mathbf{R}^3}\frac{g^2}{\tilde{\mathbf{M}}}\mathrm{d}\xi+\int_{\mathbf{R}^3}\frac{f^2}{\tilde{\mathbf{M}}}\mathrm{d}\xi\cdot\int_{\mathbf{R}^3}\frac{\nu(\xi)g^2}{\tilde{\mathbf{M}}}\mathrm{d}\xi\right\}, \tag{3.3}$$

where $\tilde{\mathbf{M}}$ is any Maxwellian such that the above integrals are well defined.

As pointed out before, to perform the energy estimates for the Boltzmann equation (1.1), for $\mathbf{P}_1^{\mathbf{M}_0}f$, the microscopic projection of its solution $f(t,x,\xi)$ with respect to a given Maxwellian $\mathbf{M}_0$, the dissipative effect through the microscopic **H** theorem should be used. In short, the microscopic **H** theorem states that the linearized collision operator $L_{\mathbf{M}_0}$ around a fixed Maxwellian state $\mathbf{M}_0$ is negative definite on the nonfluid element $\mathbf{P}_1^{\mathbf{M}_0}f$,[2] i.e.,

$$-\int_{\mathbf{R}^3}\frac{\mathbf{P}_1^{\mathbf{M}_0} f L_{\mathbf{M}_0}(\mathbf{P}_1^{\mathbf{M}_0} f)}{\mathbf{M}_0}\mathrm{d}\xi \geqslant \sigma\int_{\mathbf{R}^3}\frac{\nu(\xi)|\mathbf{P}_1^{\mathbf{M}_0} f|^2}{\mathbf{M}_0}\mathrm{d}\xi,$$

for a positive constant σ. Furthermore, one can vary the background for linearization and the weight function. That is, we also have the following result whose proof is based on Lemma 3.2, cf. Ref. 16.

Lemma 3.3: If $\theta/2<\widetilde{\theta}$ and the assumptions in Lemma 3.2 are satisfied, then there exist two positive constants $\bar{\sigma}=\bar{\sigma}(u,\theta;\widetilde{u},\widetilde{\theta})$ and $\eta_0=\eta_0(u,\theta;\widetilde{u},\widetilde{\theta})$ such that if $|u-\widetilde{u}|+|\theta-\widetilde{\theta}|<\eta_0$, we have for $h(\xi)\in\mathcal{N}^{\perp}$,

$$-\int_{\mathbf{R}^3}\frac{hL_{\mathbf{M}}h}{\widetilde{\mathbf{M}}}\mathrm{d}\xi \geqslant \bar{\sigma}\int_{\mathbf{R}^3}\frac{\nu(\xi)h^2}{\widetilde{\mathbf{M}}}\mathrm{d}\xi. \tag{3.4}$$

Here $\mathbf{M}\equiv\mathbf{M}_{[\rho,u,\theta]}(\xi)$, $\widetilde{\mathbf{M}}=\widetilde{\mathbf{M}}_{[\widetilde{\rho},\widetilde{u},\widetilde{\theta}]}(\xi)$ and

$$\mathcal{N}^{\perp}=\left\{f(\xi):\quad \int_{\mathbf{R}^3}\psi_j(\xi)f(\xi)\mathrm{d}\xi=0,\quad j=0,1,2,3,4\right\}.$$

Remark 3.1: The constant η_0 is some positive constant depending on the first nonzero eigenvalue of the linearized operator $L_{\mathbf{M}}$. Note that η_0 is not necessary to be small, cf. Ref. 16.

A direct consequence of Lemma 3.3 and the Cauchy inequality is the following corollary, cf. Ref. 16.

Corollary 3.1: Under the assumptions in Lemma 3.3, we have for $h(\xi)\in\mathcal{N}^{\perp}$,

$$\int_{\mathbf{R}^3}\frac{\nu(\xi)}{\widetilde{\mathbf{M}}}|L_{\mathbf{M}}^{-1}h|^2\,\mathrm{d}\xi \leqslant \bar{\sigma}^{-2}\int_{\mathbf{R}^3}\frac{\nu(\xi)^{-1}h^2(\xi)}{\widetilde{\mathbf{M}}}\mathrm{d}\xi. \tag{3.5}$$

Before performing the energy estimates for the Boltzmann equation (1.1), we first give the function space for the solutions considered in this paper

$$\mathbf{H}_{x,\xi}^N([0,T])=\left\{g(t,x,\xi)\;\middle|\;\begin{array}{c}\dfrac{\partial_t^\beta\partial_x^\alpha g(t,x,\xi)}{\sqrt{\overline{\mathbf{M}}(\xi)}}\in\mathbf{BC}_t([0,T],L^2_{x,\xi}(\mathbf{R}^3\times\mathbf{R}^3))\\ \dfrac{\sqrt{\nu(\xi)}\partial_t^\beta\partial_x^\alpha g(t,x,\xi)}{\sqrt{\overline{\mathbf{M}}(\xi)}}\in L^2_{t,x,\xi}([0,T]\times\mathbf{R}^3\times\mathbf{R}^3),\quad \text{for } |\alpha|+|\beta|>0\\ 0\leqslant t\leqslant T,\quad |\alpha|+|\beta|\leqslant N\end{array}\right\}.$$

Here $g(t,x,\xi)=f(t,x,\xi)-\overline{\mathbf{M}}(\xi)$.

Now we deduce an estimate on the conserved quantities $\rho(t,x)$, $m(t,x)\equiv\rho(t,x)u(t,x)$, $\rho(t,x)\left(\frac{1}{2}u^2(t,x)+\mathcal{E}(t,x)\right)$ by using the analytic techniques for the systems of conservation laws, cf. Refs. 13, 15, and 18, based on the following *a priori* assumption:

$$\begin{aligned}N(t)^2\equiv&\sup_{0\leqslant\tau\leqslant t}\sum_{|\alpha|+|\beta|\leqslant 4}\int_{\mathbf{R}^3}|\partial_x^\alpha\partial_t^\beta(\rho(\tau,x)-\bar{\rho},u(\tau,x),\theta(\tau,x)-\bar{\theta})|^2\,\mathrm{d}x\\&+\sup_{0\leqslant\tau\leqslant t}\sum_{|\alpha|+|\beta|\leqslant 4}\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta(f(\tau,x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\\&+\sum_{1\leqslant|\alpha|+|\beta|\leqslant 4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|\partial_x^\alpha\partial_t^\beta(f(\tau,x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\leqslant\varepsilon^2.\end{aligned}\tag{3.6}$$

Here, the small parameter $\varepsilon>0$ will be given in terms of the strength of the initial data $f_0(x,\xi)$,

and the discussion is in $\mathbf{H}^4_{x,\xi}([0,T])$ space which can be readily generalized to the $\mathbf{H}^s_{x,\xi}([0,T])$ space for $s>4$.

It is easy to see from (3.6), the conservation laws (2.7) and Sobolev's inequality that

$$N(0) \leqslant O(1)\mathcal{E}(f_0) \quad \text{with } \mathcal{E}(f_0)^2 \equiv \sum_{|\alpha|+|\beta|\leqslant 4} \int_{\mathbf{R}^3}\int_{\mathbf{R}^3} \frac{|\partial_x^\alpha \partial_t^\beta (f_0(x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi\, \mathrm{d}x \tag{3.7}$$

and

$$\begin{aligned} &\sup_{0\leqslant\tau\leqslant t, x\in\mathbf{R}^3}\left(\sum_{|\alpha|+|\beta|\leqslant 2} |\partial_x^\alpha \partial_t^\beta(\rho(\tau,x)-\bar{\rho}, u(\tau,x), \theta(\tau,x)-\bar{\theta})|^2\right) \\ &\quad + \sup_{0\leqslant\tau\leqslant t, x\in\mathbf{R}^3}\left(\sum_{|\alpha|+|\beta|\leqslant 2}\int_{\mathbf{R}^3} \frac{|\partial_x^\alpha \partial_t^\beta (f(\tau,x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\right) \leqslant O(1)\varepsilon^2. \end{aligned} \tag{3.8}$$

Here and in the sequel, we will use $O(1)$ to denote a generic positive constant independent of t and x.

Let $\mathbf{m}=(m^0,m,m^4)^t=(m^0,m^1,m^2,m^3,m^4)=\left(\rho,m,\rho\left(\frac{1}{2}u^2+\mathcal{E}\right)\right)^t$, as in Ref. 15, we construct a convex entropy-entropy flux pair (η,q) around the global Maxwellian $\overline{\mathbf{M}}$ as follows:

$$\begin{aligned} \eta &= \tfrac{3}{2}\left\{\rho\theta - \bar{\theta}\rho S + \rho\left[\left(\bar{S}-\tfrac{5}{3}\right)\bar{\theta}+\frac{|u|^2}{2}\right]+\tfrac{2}{3}\bar{\rho}\bar{\theta}\right\}, \\ q_j &= u_j\eta + u_j(\rho\theta-\bar{\rho}\bar{\theta}), \quad j=1,2,3. \end{aligned} \tag{3.9}$$

Notice that for $\mathbf{m}$ in any closed bounded region $\mathcal{D}\subset\Sigma=\{\mathbf{m}:\rho>0,\theta>0\}$, there exists a positive constant C_3 depending on $\mathcal{D}$ such that the entropy-entropy flux thus constructed satisfies (cf. Refs. 15 and 16)

$$c_3^{-1}|\mathbf{m}-\overline{\mathbf{m}}|^2 \leqslant \eta \leqslant C_3|\mathbf{m}-\overline{\mathbf{m}}|^2. \tag{3.10}$$

The (η,q_1,q_2,q_3) solves the following partial differential equation:

$$\begin{aligned} \eta_t + \mathrm{div}_x\, q &= \sum_{i,j=1}^3 \eta_{m^i}(\mathbf{m})\left[\mu(\theta)\left(u^i_{x^j}+u^j_{x^i}-\tfrac{2}{3}\delta_{ij}\,\mathrm{div}_x\, u\right)\right]_{x^j} \\ &\quad + \sum_{i,j=1}^3 \eta_{m^4}(\mathbf{m})\left[\mu(\theta)u^i\left(u^i_{x^j}+u^j_{x^i}-\tfrac{2}{3}\delta_{ij}\,\mathrm{div}_x\, u\right)\right]_{x^j} + \sum_{j=1}^3 \eta_{m^4}(\mathbf{m})(\kappa(\theta)\theta_{x^j})_{x^j} \\ &\quad - \int_{\mathbf{R}^3} \nabla_{\mathbf{m}}\eta(\mathbf{m})\cdot(0,\psi_1(\xi),\psi_2(\xi),\psi_3(\xi),\psi_4(\xi))(\xi\cdot\nabla_x\Theta)\mathrm{d}\xi. \end{aligned} \tag{3.11}$$

Since

$$\nabla_{\mathbf{m}}\eta(\mathbf{m}) = -\frac{3}{2}\bar{\theta}\left(S+\frac{|u|^2}{2\theta}-\bar{S}, -\frac{u^1}{\theta}, -\frac{u^2}{\theta}, -\frac{u^3}{\theta}, -\frac{\theta-\bar{\theta}}{\theta\bar{\theta}}\right), \tag{3.12}$$

we have by integrating (3.11) with respect to t and x over $[0,t]\times\mathbf{R}^3$, and using the Cauchy-Schwarz inequality and (3.10) that

$$\|(\rho-\bar{\rho},u,\theta-\bar{\theta})\|^2(t) + \int_0^t \|\nabla_x(u,\theta)\|^2(\tau)\mathrm{d}\tau$$

$$\leqslant O(1)\|(\rho_0(x)-\bar{\rho},u_0(x),\theta_0(x)-\bar{\theta})\|^2+O(1)\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}|\xi|^4|\Theta|^2\,\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau. \tag{3.13}$$

If we choose ε sufficiently small such that

$$\varepsilon<\min\left\{\frac{\eta_0}{2},\bar{\theta}\right\}, \tag{3.14}$$

then for any θ_- satisfying

$$\bar{\theta}<\theta_-<\bar{\theta}+\varepsilon, \tag{3.15}$$

we have

$$\begin{gathered}\theta\leqslant\bar{\theta}+|\theta-\bar{\theta}|<\bar{\theta}+\varepsilon<2\bar{\theta}<2\theta_-,\\ |u|+|\theta-\theta_-|\leqslant(|u|+|\theta-\bar{\theta}|)+\theta_--\bar{\theta}<2\varepsilon<\eta_0.\end{gathered} \tag{3.16}$$

Denote $\mathbf{M}_-=\mathbf{M}_{[\bar{\rho},0,\theta_-]}$, we have from Lemma 3.2, Corollary 3.1, (1.3), (2.10), (3.6), (3.8), and (3.16) that

$$\begin{aligned}\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}|\xi|^4|\Theta|^2\,\mathrm{d}\xi\,\mathrm{d}x&\leqslant O(1)\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|L_{\mathbf{M}}^{-1}(\mathbf{G}_t\mathbf{P}_1^{\mathbf{M}}(\xi\cdot\nabla_x\mathbf{G})-Q(\mathbf{G},\mathbf{G}))|^2}{\mathbf{M}_-}\mathrm{d}\xi\,\mathrm{d}x\\ &\leqslant O(1)\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)^{-1}(|\mathbf{G}_t|^2|\xi|^2|\nabla_x\mathbf{G}|^2+|Q(\mathbf{G},\mathbf{G})|^2)}{\mathbf{M}_-}\mathrm{d}\xi\,\mathrm{d}x\\ &\leqslant O(1)\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{(|\mathbf{G}_t|^2+|\nabla_x\mathbf{G}|^2)}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\\ &\quad+O(1)\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)\mathbf{G}^2}{\mathbf{M}_-}\mathrm{d}\xi\int_{\mathbf{R}^3}\frac{\mathbf{G}^2}{\mathbf{M}_-}\mathrm{d}\xi\,\mathrm{d}x\\ &\leqslant O(1)\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{1}{\underline{\underline{\mathbf{M}}}}(\mathbf{G}_t^2+|\nabla_x\mathbf{G}|^2+\varepsilon^2\mathbf{G}^2)\mathrm{d}\xi\,\mathrm{d}x.\end{aligned} \tag{3.17}$$

Setting (3.13) and (3.17) together gives

$$\begin{aligned}&\|(\rho-\bar{\rho},u,\theta-\bar{\theta})\|^2(t)+\int_0^t\|\nabla_x(u,\theta)\|^2(\tau)\mathrm{d}\tau\\ &\leqslant O(1)\|(\rho_0(x)-\bar{\rho},u_0(x),\theta_0(x)-\bar{\theta})\|^2\\ &\quad+O(1)\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{1}{\underline{\underline{\mathbf{M}}}}(\mathbf{G}_t^2+|\nabla_x\mathbf{G}|^2+\varepsilon^2\mathbf{G}^2)\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau.\end{aligned} \tag{3.18}$$

To obtain the higher order estimates on the conserved quantities, we first note that the system (2.13) can be rewritten as

$$\rho_t=-(\rho-\bar{\rho})\mathrm{div}_x\,u-\nabla_x(\rho-\bar{\rho})\cdot u-\bar{\rho}\,\mathrm{div}_x\,u, \tag{3.19a}$$

$$u_t^i + \sum_{j=1}^{3} u^j u_{x^j}^i + \frac{2}{3\rho}(\rho\theta - \bar{\rho}\bar{\theta})_{x^i} = -\int_{\mathbf{R}^3} \frac{\psi_i(\xi\cdot\nabla_x\Theta)}{\rho}\mathrm{d}\xi + \frac{1}{\rho}\sum_{j=1}^{3}\left\{\mu(\theta)\left(u_{x^j}^i + u_{x^i}^j - \frac{2}{3}\delta_{ij}\mathrm{div}_x u\right)\right\}_{x^j}, \tag{3.19b}$$

$$i = 1,2,3,$$

$$\theta_t + \sum_{j=1}^{3}\left(u^j\theta_{x^j} + \frac{2}{3}\theta u_{x^j}^j\right) = -\int_{\mathbf{R}^3}\frac{\psi_4 - \xi\cdot u}{\rho}(\xi\cdot\nabla_x\Theta)\mathrm{d}\xi + \frac{1}{\rho}\left\{\sum_{j=1}^{3}(\kappa(\theta)\theta_{x^j})_{x^j} + \frac{1}{2}\mu(\theta)\sum_{i,j=1}^{3}(u_{x^j}^i + u_{x^i}^j)^2 - \frac{2}{3}\mu(\theta)(\mathrm{div}_x u)^2\right\}. \tag{3.19c}$$

Similar to the analysis in Ref. 18, 14, and 20 for the compressible Navier-Stokes equations, we have by applying $\partial^\gamma(1\leqslant|\gamma|\leqslant 3)$ to (3.19b) and (3.19c), multiplying the resulting identities by $\rho\partial^\gamma u_i$ and $\bar{\rho}/\theta\partial^\gamma\theta$, taking the summation with respect to i from 1 to 3, and integrating the resulting equations with respect to t and x over $[0,t]\times\mathbf{R}^3$ that, for $j=1,2,3$,

$$\begin{aligned}
&\sum_{|\alpha|+|\beta|=j}\int_{\mathbf{R}^3}|\partial_x^\alpha\partial_t^\beta(\rho-\bar{\rho},u,\theta)|^2\,\mathrm{d}x + \sum_{|\alpha|+|\beta|=j}\int_0^t\int_{\mathbf{R}^3}|\nabla_x\partial_x^\alpha\partial_t^\beta(u,\theta)|^2\,\mathrm{d}x\,\mathrm{d}\tau\\
&\leqslant O(1)\varepsilon(f_0)^2 + O(1)\sum_{|\gamma|=j}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{(|\partial_x^\alpha\partial_t^\beta\mathbf{G}_t|^2 + |\nabla_x\partial_x^\alpha\partial_t^\beta\mathbf{G}|^2)}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\
&\quad + O(1)\varepsilon\sum_{1\leqslant|\alpha|+|\beta|\leqslant j+1}\int_0^t\int_{\mathbf{R}^3}|\partial_x^\alpha\partial_t^\beta(\rho-\bar{\rho},u,\theta)|^2\,\mathrm{d}x\,\mathrm{d}\tau\\
&\quad + O(1)\varepsilon\sum_{|\alpha|+|\beta|\leqslant j}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta\mathbf{G}|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau.
\end{aligned} \tag{3.20}$$

It is worthy to point out that, compared with those estimates in Ref. 18, the only difference is that we need to deal with the terms containing Θ. This can be estimated suitably as in the proof of (3.17) by using Lemma 3.2, Corollary 3.1, (1.3), (2.10), (3.6), (3.8), and (3.16) and the following basic estimate on the collision operator $Q(f,g)$ (cf. Corollary 3.1 of Ref. 22),

$$\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)^{-1}|\partial_x^\alpha\partial_t^\beta Q(\mathbf{G},\mathbf{G})|^2}{\mathbf{M}_-}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau \leqslant O(1)\varepsilon\sum_{|\alpha'|+|\beta'|\leqslant 4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^{\alpha'}\partial_t^{\beta'}\mathbf{G}|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau.$$

Here $|\alpha|+|\beta|\leqslant 4$.

To get the $L^2_{t,x}$ estimates on $\partial_x^\alpha\partial_t^\beta(\rho-\bar{\rho})$ for $1\leqslant|\alpha|+|\beta|\leqslant 4$, we use the conservation laws (2.13) as in Refs. 13 and 15 to deduce that

$$\sum_{|\alpha|+|\beta|=j+1}\int_0^t\int_{\mathbf{R}^3}|\partial_x^\alpha\partial_t^\beta(\rho-\bar{\rho})|^2\,\mathrm{d}x\,\mathrm{d}\tau \tag{3.21}$$

$$\leqslant O(1)\varepsilon(f_0)^2 + O(1)\int_{\mathbf{R}^3}\left(\sum_{|\alpha|+|\beta|=j+1}|\partial_x^\alpha\partial_t^\beta(\rho-\bar{\rho})|^2 + \sum_{|\alpha|+|\beta|=j}|\partial_x^\alpha\partial_t^\beta u|^2\right)\mathrm{d}x$$
$$+ O(1)\sum_{1\leqslant|\alpha|+|\beta|\leqslant j+1}\int_0^t\int_{\mathbf{R}^3}|\partial_x^\alpha\partial_t^\beta(u-\theta)|^2\,\mathrm{d}x\,\mathrm{d}\tau$$
$$+ O(1)\varepsilon\sum_{1\leqslant|\alpha|+|\beta|\leqslant j}\int_0^t\int_{\mathbf{R}^3}|\partial_x^\alpha\partial_t^\beta(\rho-\bar{\rho})|^2\,\mathrm{d}x\,\mathrm{d}\tau$$
$$+ O(1)\sum_{|\alpha|+|\beta|\leqslant j+1}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta\mathrm{G}|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau,\quad j=0,1,2,3.$$

A suitable linear combination of (3.18), (3.20), and (3.21) yields an estimate on the conserved quantities, $\rho, m, \rho\frac{1}{2}|u|^2+\varepsilon$ which is controlled by $\mathbf{G}$ besides the initial data, the microscopic projection of the solution $f(t,x,\xi)$ of the Boltzmann equation (1.1) with respect to the local Maxwellian $\mathbf{M}$.

Lemma 3.4: Under the a priori assumption (3.6) *we have*

$$\sum_{|\alpha|+|\beta|\leqslant 3}\|\partial_x^\alpha\partial_t^\beta(\rho-\bar{\rho},u,\theta-\bar{\theta})\|^2(t) + \sum_{1\leqslant|\alpha|+|\beta|\leqslant 4}\int_0^t\|\partial_x^\alpha\partial_t^\beta(\rho,u,\theta)\|^2(\tau)\mathrm{d}\tau$$
$$\leqslant O(1)\varepsilon(f_0)^2 + O(1)\sum_{|\alpha|+|\beta|\leqslant 4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta\mathbf{G}|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau. \tag{3.22}$$

Since we want to close the energy estimates for the solution $f(t,x,\xi)$ of the Boltzmann equation (1.1) by performing the energy estimates on the original equation (1.1) with respect to the global Maxwellian $\overline{\mathbf{M}}$, we need to transform the estimates on $\mathbf{G}$, the microscopic projection of $f(t,x,\xi)$ with respect to the local Maxwellian $\mathbf{M}$ into $\mathbf{P}_1^{\overline{\mathbf{M}}}f$, the microscopic projection of $f(t,x,\xi)$ with respect to the global Maxwellian $\overline{\mathbf{M}}$. For this purpose, by noticing

$$\mathbf{P}_1^{\overline{\mathbf{M}}}\mathbf{G} = \mathbf{G},\quad \mathbf{P}_1^{\overline{\mathbf{M}}}f = \mathbf{G} + \mathbf{P}_1^{\overline{\mathbf{M}}}\mathbf{M}, \tag{3.23}$$

we only need to obtain an estimate on $\mathbf{P}_1^{\overline{\mathbf{M}}}\mathbf{M}$ which is presented in the following lemma.

Lemma 3.5: Under the assumptions of Lemma 3.4, we can deduce

$$\int_{\mathbf{R}^3}\frac{\nu(\xi)^k|\mathbf{P}_1^{\overline{\mathbf{M}}}\mathbf{M}|^2}{\mathbf{M}_0}\mathrm{d}\xi \leqslant O(1)|(\rho-\bar{\rho},u,\theta-\bar{\theta})|^4. \tag{3.24}$$

Here $k>0$ *is any positive constant and* $\mathbf{M}_0=\mathbf{M}_{[\rho_0,u_0,\theta_0]}$ *can be any Maxwellian satisfying* $\theta_0 > \frac{1}{2}\max\{\theta,\bar{\theta}\}$.

Consequently, we have for all $|\alpha|+|\beta|\leqslant 4$ *that*

$$\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta\mathbf{G}|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau \leqslant \int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}f|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau$$
$$+ O(1)\varepsilon\sum_{1\leqslant|\alpha|+|\beta|\leqslant 4}\int_0^t\|\partial_x^\alpha\partial_t^\beta(\rho,u,\theta)\|^2(\tau)\mathrm{d}\tau. \tag{3.25}$$

Proof: We only prove (3.24) since (3.25) follows immediately from (3.23), (3.24), Lemma 3.1 and the *a priori* assumption (3.6).

To prove (3.24), first notice that $\mathbf{P}_1^{\overline{\mathbf{M}}}\mathbf{M}$ is a smooth function of ρ, u, θ, and

$$\nabla_{(\rho,u,\theta)}\mathbf{P}_1^{\overline{\mathbf{M}}}\mathbf{M} = \mathbf{P}_1^{\overline{\mathbf{M}}}(\nabla_{(\rho,u,\theta)}\mathbf{M}).$$

Since

$$\mathbf{P}_1^{\overline{\mathbf{M}}}(\nabla_{(\rho,u,\theta)}\mathbf{M})|_{(\rho,u,\theta)=(\bar{\rho},0,\bar{\theta})} = 0,$$

we can easily deduce that $\mathbf{P}_1^{\overline{\mathbf{M}}}\mathbf{M}$ is quadratic with respect to $(\rho-\bar{\rho},u,\theta-\bar{\theta})$ and (3.24) follows immediately. This completes the proof of Lemma 3.5.

The following corollary is a direct consequence of Lemma 3.4 and Lemma 3.5.

Corollary 3.2: Under the assumptions in Lemma 3.3, we have

$$\sum_{|\alpha|+|\beta|\leqslant 3}\|\partial_x^\alpha\partial_t^\beta(\rho-\bar{\rho},u,\theta-\bar{\theta})\|^2(t) + \sum_{1\leqslant|\alpha|+|\beta|\leqslant 4}\int_0^t\|\partial_x^\alpha\partial_t^\beta(\rho,u,\theta)\|^2(\tau)\mathrm{d}\tau$$

$$\leqslant O(1)\varepsilon(f_0)^2 + O(1)\sum_{|\alpha|+|\beta|\leqslant 4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}f|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau. \tag{3.26}$$

Now we can finalize the energy estimates on the solutions $f(t,x,\xi)$ of the Boltzmann equation (1.1). To this end, since $g(t,x,\xi)=f(t,x,\xi)-\overline{\mathbf{M}}(\xi)$ solves

$$g_t + \xi\cdot\nabla_x g = L_{\overline{\mathbf{M}}}(\mathbf{P}_1^{\overline{\mathbf{M}}}g) + Q(\mathbf{P}_1^{\overline{\mathbf{M}}}g,\mathbf{P}_1^{\overline{\mathbf{M}}}g) + 2Q(\mathbf{P}_1^{\overline{\mathbf{M}}}g,\mathbf{P}_0^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}})) + Q(\mathbf{P}_1^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}}),\mathbf{P}_0^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}})), \tag{3.27}$$

we have by applying $\partial_x^\alpha\partial_t^\beta(|\alpha|+|\beta|\leqslant 4)$ to (3.27) and integrating its product with $\partial_x^\alpha\partial_t^\beta g/\overline{\mathbf{M}}$ over $[0,t]\times\mathbf{R}\times\mathbf{R}^3$ that

$$\begin{aligned}\frac{1}{2}\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\Bigg|_0^t &= \int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\partial_x^\alpha\partial_t^\beta g\cdot\partial_x^\alpha\partial_t^\beta L_{\overline{\mathbf{M}}}(\mathbf{P}_1^{\overline{\mathbf{M}}}g)}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\ &+\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\partial_x^\alpha\partial_t^\beta g\,.\,\partial_x^\alpha\partial_t^\beta Q(\mathbf{P}_1^{\overline{\mathbf{M}}}g,\mathbf{P}_1^{\overline{\mathbf{M}}}g)}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\ &+2\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\partial_x^\alpha\partial_t^\beta g\,.\,\partial_x^\alpha\partial_t^\beta Q(\mathbf{P}_1^{\overline{\mathbf{M}}}g,\mathbf{P}_0^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}}))}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\ &+\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\partial_x^\alpha\partial_t^\beta g\,.\,\partial_x^\alpha\partial_t^\beta Q(\mathbf{P}_1^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}}),\mathbf{P}_0^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}}))}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau.\\ &:=\sum_{j=1}^4 I_j.\end{aligned} \tag{3.28}$$

Here $I_i(i=1,2,3,4)$ are the corresponding terms in the above equation without any ambiguity.

Since $\overline{\mathbf{M}}$ is independent of t and x, we have

$$\begin{aligned}\mathbf{P}_1^{\overline{\mathbf{M}}}(\partial_x^\alpha\partial_t^\beta g) &= \partial_x^\alpha\partial_t^\beta g\mathbf{P}_1^{\overline{\mathbf{M}}}g,\\ \partial_x^\alpha\partial_t^\beta L_{\overline{\mathbf{M}}}(\mathbf{P}_1^{\overline{\mathbf{M}}}g) &= L_{\overline{\mathbf{M}}}(\partial_x^\alpha\partial_t^\beta g\mathbf{P}_1^{\overline{\mathbf{M}}}g).\end{aligned} \tag{3.29}$$

Thus from Lemma 3.2, Lemma 3.3, and (3.6), I_1 and I_2 can be estimated as follows:

$$I_1=\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}g\cdot L_{\overline{\mathbf{M}}}(\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}g)}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\leqslant-\sigma\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau,\tag{3.30}$$

$$\begin{aligned}I_2&=\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}g\cdot\partial_x^\alpha\partial_t^\beta Q(\mathbf{P}_1^{\overline{\mathbf{M}}}g,\mathbf{P}_1^{\overline{\mathbf{M}}}g)}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\&\leqslant\frac{\sigma}{4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau+O(1)\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)^{-1}|\partial_x^\alpha\partial_t^\beta Q(\mathbf{P}_1^{\overline{\mathbf{M}}}g,\mathbf{P}_1^{\overline{\mathbf{M}}}g)|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\&\leqslant\frac{\sigma}{4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\&\quad+O(1)\varepsilon\sum_{|\alpha|+|\beta'|\leqslant4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)^{-1}|\partial_x^{\alpha'}\partial_t^{\beta'}\mathbf{P}_1^{\overline{\mathbf{M}}}g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau.\end{aligned}\tag{3.31}$$

Here we have used the inequality

$$\begin{aligned}&\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)^{-1}|\partial_x^\alpha\partial_t^\beta Q(\mathbf{P}_1^{\overline{\mathbf{M}}}g,\mathbf{P}_1^{\overline{\mathbf{M}}}g)|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\&\qquad\leqslant O(1)\varepsilon\sum_{|\alpha|+|\beta'|\leqslant4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|\partial_x^{\alpha'}\partial_t^{\beta'}\mathbf{P}_1^{\overline{\mathbf{M}}}g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau,\end{aligned}\tag{3.32}$$

which follows similarly to the Corollary 3.1 of Ref. 22.

For I_3 and I_4, we want to prove the following estimates;

$$\begin{aligned}I_3&\leqslant\frac{\sigma}{4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\&\quad+O(1)\varepsilon\sum_{|\alpha'|+|\beta'|\leqslant4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|\partial_x^{\alpha'}\partial_t^{\beta'}\mathbf{P}_1^{\overline{\mathbf{M}}}g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau\\&\quad+O(1)\varepsilon\sum_{1\leqslant|\alpha'|+|\beta'|\leqslant4}\int_0^t\int_{\mathbf{R}^3}|\partial_x^{\alpha'}\partial_t^{\beta'}(\rho,u,\theta)|^2\mathrm{d}x\,\mathrm{d}\tau.\end{aligned}\tag{3.33}$$

and

$$I_4\leqslant\frac{\sigma}{4}\int_0^t\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{\nu(\xi)|\partial_x^\alpha\partial_t^\beta\mathbf{P}_1^{\overline{\mathbf{M}}}g|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\,\mathrm{d}\tau+O(1)\varepsilon\sum_{1\leqslant|\alpha'|+|\beta'|\leqslant4}\int_0^t\int_{\mathbf{R}^3}|\partial_x^{\alpha'}\partial_t^{\beta'}(\rho,u,\theta)|^2\mathrm{d}x\,\mathrm{d}\tau.\tag{3.34}$$

For illustration, we only prove (3.34) because similar argument holds for (3.33). For this, we have from Lemma 3.2, (3.6), (3.8), and (3.29) that

$$
\begin{aligned}
I_4 = & \sum_{(\alpha',\beta')\leqslant(\alpha,\beta)} C_{\alpha,\beta}^{\alpha',\beta'} \int_0^t \int_{\mathbf{R}^3} \int_{\mathbf{R}^3} \\
& \times \frac{\partial_x^\alpha \partial_t^\beta \mathbf{P}_1^{\overline{\mathbf{M}}} g \cdot Q(\partial_x^{\alpha'} \partial_t^{\beta'} \mathbf{P}_1^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}}), \partial_x^{\alpha-\alpha'} \partial_t^{\beta-\beta'} \mathbf{P}_0^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}}))}{\overline{\mathbf{M}}} \mathrm{d}\xi \, \mathrm{d}x \, \mathrm{d}\tau \\
\leqslant & \frac{\sigma}{4} \int_0^t \int_{\mathbf{R}^3} \int_{\mathbf{R}^3} \frac{\nu(\xi) |\partial_x^\alpha \partial_t^\beta \mathbf{P}_1^{\overline{\mathbf{M}}} g|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi \, \mathrm{d}x \, \mathrm{d}\tau \\
& + O(1) \sum_{(\alpha',\beta')\leqslant(\alpha,\beta)} \int_0^t \int_{\mathbf{R}^3} \int_{\mathbf{R}^3} \frac{\nu(\xi)^{-1} |Q(\partial_x^{\alpha'} \partial_t^{\beta'} \mathbf{P}_1^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}}), \partial_x^{\alpha-\alpha'} \partial_t^{\beta-\beta'} \mathbf{P}_0^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}}))|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi \, \mathrm{d}x \, \mathrm{d}\tau \\
\leqslant & \frac{\sigma}{4} \int_0^t \int_{\mathbf{R}^3} \int_{\mathbf{R}^3} \frac{\nu(\xi) |\partial_x^\alpha \partial_t^\beta \mathbf{P}_1^{\overline{\mathbf{M}}} g|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi \, \mathrm{d}x \, \mathrm{d}\tau \\
& + O(1) \sum_{(\alpha',\beta')\leqslant(\alpha,\beta)} \int_0^t \int_{\mathbf{R}^3} \left(\int_{\mathbf{R}^3} \frac{\nu(\xi)^{-1} |\partial_x^{\alpha'} \partial_t^{\beta'} \mathbf{P}_1^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}})|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi \right. \\
& \left. \cdot \int_{\mathbf{R}^3} \frac{|\partial_x^{\alpha-\alpha'} \partial_t^{\beta-\beta'} \mathbf{P}_0^{\overline{\mathbf{M}}}(\mathbf{M}-\overline{\mathbf{M}})|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi \right) \mathrm{d}x \, \mathrm{d}\tau \\
\leqslant & \frac{\sigma}{4} \int_0^t \int_{\mathbf{R}^3} \int_{\mathbf{R}^3} \frac{\nu(\xi) |\partial_x^\alpha \partial_t^\beta \mathbf{P}_1^{\overline{\mathbf{M}}} g|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi \, \mathrm{d}x \, \mathrm{d}\tau \\
& + O(1)\varepsilon \sum_{1\leqslant|\alpha'|+|\beta'|\leqslant 4} \int_0^t \int_{\mathbf{R}^3} |\partial_x^{\alpha'} \partial_t^{\beta'}(\rho,u,\theta)|^2 \, \mathrm{d}x \, \mathrm{d}\tau \\
& + O(1) \sum_{(\alpha',\beta')\leqslant(\alpha,\beta)} \int_0^t \int_{\mathbf{R}^3} |\partial_x^{\alpha'} \partial_t^{\beta'}(\rho,u,\theta)|^2 |\partial_x^{\alpha-\alpha'} \partial_t^{\beta-\beta'}(\rho,u,\theta)|^2 \mathrm{d}x \, \mathrm{d}\tau. \qquad (3.35)
\end{aligned}
$$

Denote

$$
I_{\alpha,\beta}^{\alpha',\beta'} = \int_0^t \int_{\mathbf{R}^3} |\partial_x^{\alpha'} \partial_t^{\beta'}(\rho,u,\theta)|^2 |\partial_x^{\alpha-\alpha'} \partial_t^{\beta-\beta'}(\rho,u,\theta)|^2 \mathrm{d}x \, \mathrm{d}\tau. \qquad (3.36)
$$

We estimate $I_{\alpha,\beta}^{\alpha',\beta'}$ by considering the following three cases.

Case 1: $(\alpha',\beta')=(\alpha,\beta)=(0,0)$.

For this case, we have from Lemma 3.1 and the *a priori* assumption (3.6) that

$$
\begin{aligned}
I_{0,0}^{0,0} = & \int_0^t \int_{\mathbf{R}^3} |(\rho-\bar{\rho},u,\theta-\bar{\theta})|^4 \mathrm{d}x \, \mathrm{d}\tau \\
\leqslant & O(1) \int_0^t \|(\rho-\bar{\rho},u,\theta-\bar{\theta})\| \|\nabla_x(\rho-\bar{\rho},u,\theta-\bar{\theta})\|^3 \mathrm{d}\tau \\
\leqslant & O(1)\varepsilon \int_0^t \|\nabla_x(\rho-\bar{\rho},u,\theta-\bar{\theta})\|^2 \mathrm{d}\tau. \qquad (3.37)
\end{aligned}
$$

Case 2: $0\leqslant|\alpha'|+|\beta'|\leqslant 2$, $(\alpha',\beta')<(\alpha,\beta)$.

In this case, we have from (3.8) that

$$I_{\alpha,\beta}^{\alpha',\beta'} \leqslant O(1)\varepsilon \int_0^t \int_{\mathbf{R}^3} |\partial_x^{\alpha-\alpha'} \partial_t^{\beta-\beta'}(\rho,u,\theta)|^2 \mathrm{d}x\, \mathrm{d}\tau. \tag{3.38}$$

Case 3: $2<|\alpha'|+|\beta'|\leqslant 4$.

In this case, we have $|\alpha-\alpha'|+|\beta-\beta'|\leqslant 1$ because $|\alpha|+|\beta|\leqslant 4$. Similar to Case 2, we have

$$I_{\alpha,\beta}^{\alpha',\beta'} \leqslant O(1)\varepsilon \int_0^t \int_{\mathbf{R}^3} |\partial_x^{\alpha'} \partial_t^{\beta'}(\rho,u,\theta)|^2 \mathrm{d}x\, \mathrm{d}\tau. \tag{3.39}$$

Setting (3.37), (3.38), and (3.39) together yields

$$I_{\alpha,\beta}^{\alpha',\beta'} \leqslant O(1)\varepsilon \sum_{1\leqslant|\alpha'|+|\beta'|\leqslant 4} \int_0^t \int_{\mathbf{R}^3} |\partial_x^{\alpha'} \partial_t^{\beta'}(\rho,u,\theta)|^2 \mathrm{d}x\, \mathrm{d}\tau. \tag{3.40}$$

Plugging (3.40) into (3.35) gives (3.34) immediately. This completes the proof of (3.33) and (3.34).

Now substituting (3.30), (3.31), (3.33), and (3.34) into (3.28) yields

$$\begin{aligned}
&\int_{\mathbf{R}^3}\int_{\mathbf{R}^3} \frac{|\partial_x^\alpha \partial_t^\beta g|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi\, \mathrm{d}x + \int_0^t \int_{\mathbf{R}^3}\int_{\mathbf{R}^3} \frac{\nu(\xi)|\partial_x^\alpha \partial_t^\beta \mathbf{P}_1^{\overline{\mathbf{M}}} g|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi\, \mathrm{d}\tau \\
&\quad \leqslant O(1)\varepsilon (f_0)^2 + O(1)\varepsilon \sum_{|\alpha'|+|\beta'|\leqslant 4} \int_0^t \int_{\mathbf{R}^3}\int_{\mathbf{R}^3} \frac{\nu(\xi)|\partial_x^{\alpha'} \partial_t^{\beta'} \mathbf{P}_1^{\overline{\mathbf{M}}} g|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi\, \mathrm{d}x\, \mathrm{d}\tau \\
&\quad + O(1)\varepsilon \sum_{1\leqslant|\alpha'|+|\beta'|\leqslant 4} \int_0^t \int_{\mathbf{R}^3} |\partial_x^{\alpha'} \partial_t^{\beta'}(\rho,u,\theta)|^2\, \mathrm{d}x\, \mathrm{d}\tau.
\end{aligned} \tag{3.41}$$

Thus

$$\begin{aligned}
&\sum_{|\alpha|+|\beta|\leqslant 4} \int_{\mathbf{R}^3}\int_{\mathbf{R}^3} \frac{|\partial_x^\alpha \partial_t^\beta g|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi\, \mathrm{d}x + \sum_{|\alpha|+|\beta|\leqslant 4} \int_0^4 \int_{\mathbf{R}^3}\int_{\mathbf{R}^3} \frac{\nu(\xi)|\partial_x^\alpha \partial_t^\beta \mathbf{P}_1^{\overline{\mathbf{M}}} g|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi\, \mathrm{d}x\, \mathrm{d}\tau \\
&\quad \leqslant O(1)\varepsilon (f_0)^2 + O(1)\varepsilon \sum_{1\leqslant|\alpha|+|\beta|\leqslant 4} \int_0^t \int_{\mathbf{R}^3} |\partial_x^\alpha \partial_t^\beta(\rho,u,\theta)|^2\, \mathrm{d}x\, \mathrm{d}\tau.
\end{aligned} \tag{3.42}$$

Multiplying (3.42) by a suitably large positive constant C_4 and adding the result to (3.26) yields

$$\begin{aligned}
&\sum_{|\alpha|+|\beta|\leqslant 4} \int_{\mathbf{R}^3}\int_{\mathbf{R}^3} \frac{|\partial_x^\alpha \partial_t^\beta (f-\overline{\mathbf{M}})|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi\, \mathrm{d}x + \sum_{|\alpha|+|\beta|\leqslant 4} \int_{\mathbf{R}^3} |\partial_x^\alpha \partial_t^\beta(\rho-\bar{\rho},u,\theta-\bar{\theta})|^2\, \mathrm{d}x \\
&\quad + \sum_{|\alpha|+|\beta|\leqslant 4} \int_0^t \int_{\mathbf{R}^3}\int_{\mathbf{R}^3} \frac{\nu(\xi)|\partial_x^\alpha \partial_t^\beta \mathbf{P}_1^{\overline{\mathbf{M}}} f|^2}{\overline{\mathbf{M}}} \mathrm{d}\xi\, \mathrm{d}x\, \mathrm{d}\tau + \sum_{1\leqslant|\alpha|+|\beta|\leqslant 4} \int_0^t \int_{\mathbf{R}^3} |\delta_x^\alpha \delta_t^\beta(\rho,u,\theta)|^2 \mathrm{d}x\, \mathrm{d}\tau \\
&\quad \leqslant O(1)\varepsilon (f_0)^2.
\end{aligned} \tag{3.43}$$

This closes the *a priori* assumption (3.6) provided that we choose $\delta_0>0$ sufficiently small such that

$$\begin{aligned}
&\varepsilon(f_0) < \delta_0, \\
&O(1)\delta_0^2 < \varepsilon^2.
\end{aligned} \tag{3.44}$$

The above analysis yields the following energy estimates for the solution $f(t,x,\xi)$ of the Boltzmann equation (1.1) with initial data $f_0(x,\xi)$.

Lemma 3.6 (Energy estimates): Assume that $f(t,x,\xi)\in \mathbf{H}^4_{x,\xi}([0,T])$ *is a solution of the Cauchy problem* (1.1) and (1.5) *for some constant* $T>0$. *Then there exist two sufficiently small positive constants* ε, δ_0 *such that if* $\varepsilon(f_0)<\delta_0$ *we have*

$$N(T)<\varepsilon. \tag{3.45}$$

In order to use the above energy estimates and the continuity argument to get the global existence result for the Cauchy problem (1.1) and (1.5), we need the local existence result in $\mathbf{H}^4_{x,\xi}([0,T])$ from Refs. 9 and 22.

Lemma 3.7 (Local existence result): For any sufficiently small constant $M>0$, *there exists a positive constant* $T^*(M)>0$ *such that if* $\varepsilon(f_0)\leqslant M$, *then the Cauchy problem* (1.1) and (1.5) *admits a unique classical solution* $f(t,x,\xi)\in \mathbf{H}^4_{x,\xi}([0,T^*(M)))$ *on* $[0,T^*(M))\times\mathbf{R}^3\times\mathbf{R}^3$ *such that* $f(t,x,\xi)\geqslant 0$ *and*

$$\sup_{0\leqslant t\leqslant T^*(M)}\sum_{|\alpha|+|\beta|\leqslant 4}\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta(f(t,x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\overline{\mathbf{M}}(\xi)}\mathrm{d}\xi\,\mathrm{d}x\leqslant C_5M, \tag{3.46}$$

for some positive constant C_5.

Remark 3.2: Notice that even for the local existence, the smallness of the initial data $g_0(x,\xi)=f_0(x,\xi)-\overline{\mathbf{M}}(\xi)$ *is needed.*

By combining Lemma 3.6 with Lemma 3.7, the main result in this paper can be stated as in the following theorem.

Theorem 3.1: Let $N\geqslant 4$ *be an integer and* $\overline{\mathbf{M}}(\xi)$ *be any given global Maxwellian, then there exist two sufficiently small positive constants* δ_0 *and* ε *such that if*

$$\varepsilon(f_0)\equiv\sum_{|\alpha|+|\beta|\leqslant N}\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta(f_0(x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x<\delta_0, \tag{3.47}$$

the Cauchy problem (1.1) and (1.5) *admits a unique global classical solution* $f(t,x,\xi)\in\mathbf{H}^N_{x,\xi}(\mathbf{R}^+)$ *satisfying* $f(t,x,\xi)\geqslant 0$ *and*

$$\begin{aligned}&\sum_{|\alpha|+|\beta|\leqslant N}\sup_{t\in\mathbf{R}^+}\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta(f(t,x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\overline{\mathbf{M}}}\mathrm{d}\xi\,\mathrm{d}x\leqslant\varepsilon,\\ &\lim_{t\to\infty}\sup_{x\in\mathbf{R}^3}\sum_{|\alpha|+|\beta|\leqslant N-3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta(f(t,x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\overline{\mathbf{M}}(\xi)}\mathrm{d}\xi=0.\end{aligned} \tag{3.48}$$

Remark 3.3: The above analysis only shows that Theorem 3.1 *holds for* $N=4$. *But the case* $s>4$ *can be discussed similarly. It is worthy to point out that the assumption* $N\geqslant 4$ *is to guarantee that* $H^N_{x,\xi}([0,T])$ *is a Banach algebra.*

Before concluding this paper, we point out the main difference of this work from the previous ones on the stability analysis. The nonlinear stability of the global Maxwellian $\overline{\mathbf{M}}$ is studied in Ref. 15 based on the decomposition of the Boltzmann equation (1.1) and its solution $f(t,x,\xi)$ around the local Maxwellian $\mathbf{M}(t,x,\xi)$. The fluid component $\mathbf{P}_0^{\mathbf{M}}f$ and nonfluid component $\mathbf{P}_1^{\mathbf{M}}f$ are estimated separately. The energy estimates are closed with respect to some suitably chosen global Maxwellian $\mathbf{M}_-=\mathbf{M}_{[\rho_-,u_-,\theta_-]}$. Because of the technicality, it requires, among others, that

$$\theta_-<\bar{\theta},$$

and the initial data $f_0(x,\xi)$ satisfies

$$\sum_{|\alpha|+|\beta|\leqslant N}\int_{\mathbf{R}^3}\int_{\mathbf{R}^3}\frac{|\partial_x^\alpha\partial_t^\beta(f_0(x,\xi)-\overline{\mathbf{M}}(\xi))|^2}{\mathbf{M}_-}\mathrm{d}\xi\,\mathrm{d}x<\delta_0,$$

for some sufficiently small positive constant δ_0. Hence, it is easy to see that the assumptions imposed on the initial data in Ref. 15 is stronger than those in this paper.

On the other hand, the energy estimate is also closed with respect to the global Maxwellian $\overline{\mathbf{M}}$ in Ref. 9 and the key point there is to use the positivity of the linearized collision operator $L_{\overline{\mathbf{M}}}$ for the solution $f(t,x,\xi)$ with small amplitude to the Boltzmann equation (1.1). Precisely, based on the macroscopic projection

$$\mathbf{P}_0^{\overline{\mathbf{M}}}f=\left(a(t,x)+\sum_{j=1}^{3}b^j(t,x)\xi^j+c(t,x)|\xi|^2\right)\overline{\mathbf{M}},$$

the author in Ref. 9 gave a set of equations for the macroscopic quantities $a(t,x),b^j(t,x)(j=1,2,3)$ and $c(t,x)$. And the proof of the positivity of $L_{\overline{\mathbf{M}}}$ for the solution $f(t,x,\xi)$ with small amplitude to the Boltzmann equation (1.1) is then obtained by some delicate estimates on the macroscopic quantities $a(t,x),b^j(t,x)(j=1,2,3)$, and $c(t,x)$. However, the time evolution of the conserved quantities $\rho,m,\rho\frac{1}{2}|u|^2+\varepsilon$ is not clearly presented by just analyzing the macroscopic quantities $a(t,x),b^j(t,x)(j=1,2,3)$, and $c(t,x)$ as in Ref. 9.

The main observation in this paper is to close the energy estimates with respect to the global Maxwellian $\overline{\mathbf{M}}$ by estimating the conserved quantities $\rho,\rho u,\rho\frac{1}{2}|u|^2+\varepsilon$ governed by the well-known compressible Navier–Stokes equations with the nonfluid component $\mathbf{P}_1^{\mathbf{M}}f$ appearing in the source terms. Hence, the analytic techniques for the system of the compressible Navier–Stokes equations can be used to deduce the desired estimates on the conserved quantities. Therefore, it not only simplifies the analysis in the previous works, but also sheds some light on the stability analysis in some complicated systems, such as the Vlasov-Poisson-Boltzmann and Vlasov-Maxwell-Boltzmann systems.

(Received 5 December 2005; accepted 17 March 2006; published online 3 May 2006)

A relation between semidirect sums of Lie algebras and integrable couplings of lattice equations is established, and a practicable way to construct integrable couplings is further proposed. An application of the resulting general theory to the generalized Toda spectral problem yields two classes of integrable couplings for the generalized Toda hierarchy of lattice equations. The construction of integrable couplings using semidirect sums of Lie algebras provides a good source of information on complete classification of integrable lattice equations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2194630]

I. INTRODUCTION

Integrable couplings have been receiving growing attention recently. A few ways to construct integrable couplings are presented by using perturbations,[1–3] enlarging spectral problems,[4,5] and creating new loop Lie algebras.[6,7]

The problem of integrable couplings can be expressed as follows:[2] *For a given integrable system, how can we construct a nontrivial system of differential equations which is still integrable and includes the original integrable system as a subsystem?* Obviously, a change of orders of equations in a system does not lose integrability of the system. Therefore, up to a permutation, an integrable coupling of a given integrable system $u_t=K(u)$ is given by a bigger and triangular system:

$$u_t = K(u), \quad v_t = S(u,v).$$

The vector-valued function S should satisfy the nontriviality condition $\partial S/\partial[u]\neq 0$, where $[u]=(u,D_x u,D_x^2 u,\ldots)$ and $D_x^n u$ denotes a vector consisting of all derivatives of u of order n with respect to the space variable x. The above nontriviality condition means that the second subsystem involves the dependent variables of the first subsystem (i.e., the original system), and thus it guarantees that trivial diagonal systems with $S(u,v)=S(v)$ are not within our discussion.

A basic integrable coupling of an integrable system $u_t=K(u)$ is given by

[a)]Electronic mail: mawx@math.usf.edu; Tel: (813)974-9563, Fax: (813)974-2700
[b)]Electronic mail: xu_xixiang@sohu.com
[c)]Electronic mail: zhang_yfshandong@163.com

$$u_t = K(u), \quad v_t = K'(u)[v], \tag{1.1}$$

which can be generated by a perturbation around a solution of the system $u_t = K(u)$.[1] In the above system and elsewhere throughout this paper, $P'(u)[v]$ denotes the Gateaux derivative of $P(u) \equiv P(u, D_x u, \ldots)$ with respect to u in a direction v, i.e.,

$$P'(u)[v] = \frac{\partial}{\partial \varepsilon} P(u + \varepsilon v)|_{\varepsilon=0} = \frac{\partial}{\partial \varepsilon} P(u + \varepsilon v, D_x u + \varepsilon D_x v, \ldots)|_{\varepsilon=0}.$$

Obviously, the second subsystem $v_t = K'(u)[v]$ in the above integrable coupling (1.1) is linear with respect to v. Moreover, a symmetry $S(u)$ of the system $u_t = K(u)$ leads to a solution $(u, S(u))$ to the integrable coupling (1.1). However, the second component v of a solution (u, v) to the integrable coupling (1.1) is generally not a symmetry of the system $u_t = K(u)$. This is because v satisfies the linearized system $v_t = K'(u)[v]$ only for one solution, not for all solutions of the system $u_t = K(u)$. Therefore, the simple integrable coupling (1.1) is already a generalization of the symmetry problem. Another basic integrable coupling of an integrable system $u_t = K(u)$ reads as

$$u_t = K(u), \quad v_t = K'(u)[v] + K(u). \tag{1.2}$$

This system has a set of hereditary recursion operators[2]

$$\Phi(\beta_1, \beta_2) = \begin{pmatrix} \beta_1 \Phi(u) & 0 \\ \beta_1 \Phi'(u)[v] + \beta_2 \Phi(u) & \beta_1 \Phi(u) \end{pmatrix}$$

with two arbitrary constants β_1 and β_2, if the original system $u_t = K(u)$ has a hereditary recursion operator $\Phi(u)$. Therefore, integrable couplings possess richer integrable structures than the original integrable systems.

The study of integrable couplings provides clues towards complete classification of integrable systems. Let us first observe classification of square matrix spectral problems through the Jordan blocks under similar transformations of matrices. Each triangular Jordan block corresponds to an undecomposable subsystem in a given integrable system. Now, note that an arbitrary Lie algebra has a semidirect sum structure of a solvable Lie algebra and a semisimple Lie algebra,[8] and we will see that semidirect sums of Lie algebras can result in integrable couplings. These imply that the study of integrable couplings through semidirect sums of Lie algebras is an inevitable step towards complete classification of integrable systems with an arbitrary number of components, from a point of view of Lie algebras.

The study of integrable couplings also generates interesting mathematical structures such as Lax pairs with several spectral parameters,[9,10,2] integrable constrained flows with higher multiplicity,[11,12] local bi-Hamiltonian structures in higher dimensions[13] and hereditary recursion operators of higher order.[2,14] Very recently, we have proposed a relation between semidirect sums of Lie algebras and integrable couplings of continuous soliton equations, which provides an interesting and systematic approach to integrable couplings of continuous soliton equations.[15] In this paper, we would like to discuss the problem of discrete integrable couplings and develop a theory for constructing discrete integrable couplings by use of semidirect sums of Lie algebras.

Throughout our discussion, we denote by E the shift operator, write

$$(E^m x)(n) = x^{(m)}(n) = x(m+n), \quad \text{where } x: \mathbb{Z} \to \mathbb{R}, \ m, n \in \mathbb{Z}, \tag{1.3}$$

and adopt an inverse of the difference operator $E-1$ as follows:

$$(E-1)^{-1} = \frac{1}{2}\left(\sum_{k=-\infty}^{-1} - \sum_{k=0}^{\infty} \right) E^k. \tag{1.4}$$

Let G be a matrix Lie algebra with the standard Lie bracket $[A, B] = AB - BA$, and closed under matrix multiplication: $AB \in G$ for all $A, B \in G$. We assume that an integrable lattice equation (or system) of evolution type

$$u_t = K(u) = K(u, Eu, E^{-1}u, \dots) \tag{1.5}$$

is associated with G, where $u=u(n,t)$ is a dependent variable. More precisely, there is a pair of square matrices U and V in G, called a Lax pair, so that the discrete spatial matrix spectral problem

$$E\phi = U\phi = U(u,\lambda)\phi \tag{1.6}$$

and the associated discrete temporal matrix spectral problem

$$\phi_t = V\phi = V(u, Eu, E^{-1}u, \dots; \lambda)\phi, \tag{1.7}$$

where λ is a spectral parameter and ϕ is an eigenfunction, generate[16,17] the integrable lattice equation (1.5) through their isospectral (i.e., $\lambda_t=0$) compatibility condition

$$U_t = (EV)U - UV, \tag{1.8}$$

which is called a discrete zero curvature equation. In other words, we have

$$U'(u)[K] = (EV)U - UV, \tag{1.9}$$

where $U'(u)[K]$ denotes the Gateaux derivative as above. In a nonisospectral case, e.g., $\lambda_t=f(\lambda)$, then we have

$$U'(u)[K] + fU_\lambda = (EV)U - UV, \tag{1.10}$$

where U_λ is a partial derivative of U with respect to λ. Based on (1.6) and (1.7), the lattice equation (1.5) can often be solved by the inverse scattering transform (for example, see Ref. 18). There are also a few interesting Lie algebraic structures hidden behind the equation (1.10) (see Ref. 17 for more information). An integrable hierarchy and its master symmetry hierarchy usually correspond to the isospectral case and the nonisospectral case $\lambda_t=\lambda^n$, $n\geqslant 0$, respectively. These two hierarchies constitute a semidirect sum of Lie algebras, each of which consists of symmetries in one hierarchy. The spatial matrix spectral problem (1.6) is our starting point in constructing discrete integrable couplings. The closure property of the Lie algebra G under matrix multiplication guarantees that $(EV)U-UV$ is still in G so that the discrete zero curvature equation (1.8) makes sense.

In what follows, we are going to establish a relation between semidirect sums of Lie algebras and integrable couplings of lattice equations and a technically practicable way to generate integrable couplings through semidirect sums of Lie algebras. The resulting general theory will be used to generate two classes of integrable couplings for the generalized Toda hierarchy presented in Ref. 19. It will also be indicated that the construction of integrable couplings using semidirect sums of Lie algebras provides a good source of information about classification of integrable lattice equations. A few concluding remarks will be given in the last section.

II. CONSTRUCTING INTEGRABLE COUPLINGS USING SEMIDIRECT SUMS OF LIE ALGEBRAS

A. Generating scheme

Assume that the lattice equation (1.5) has a Lax pair (U,V) in a matrix Lie algebra G closed under matrix multiplication.

To construct an integrable coupling of the lattice equation (1.5), we use semidirect sums of Lie algebras to enlarge the original Lie algebra G. Take another matrix Lie algebra G_c closed under matrix multiplication and then form a semidirect sum $\overline{G}$ of G and G_c:

$$\overline{G} = G \dotplus G_c. \tag{2.1}$$

The notion of semidirect sums means that G and G_c satisfy

$$[G, G_c] \subseteq G_c, \tag{2.2}$$

where $[G, G_c] = \{[A, B] | A \in G, B \in G_c\}$. Obviously, G_c is an ideal Lie subalgebra of $\overline{G}$. The subscript c here indicates a contribution to the construction of couplings. We also require that the closure property between G and G_c under matrix multiplication,

$$GG_c, G_cG \subseteq G_c, \tag{2.3}$$

where $G_1G_2 = \{AB | A \in G_1, B \in G_2\}$, to guarantee that a Lax pair from the semidirect sum $\overline{G}$ can generate a coupling system. Note that the two different binary operations were used in the above closure properties in (2.2) and (2.3).

Now choose a pair of new Lax matrices in the semidirect sum $\overline{G}$ of Lie algebras:

$$\overline{U} = U + U_c, \quad \overline{V} = V + V_c, \quad U_c, V_c \in G_c, \tag{2.4}$$

and make a pair of enlarged discrete spatial matrix spectral problems

$$\begin{aligned} E\overline{\phi} &= \overline{U}\overline{\phi} = \overline{U}(\overline{u}, \lambda)\overline{\phi}, \\ \overline{\phi}_t &= \overline{V}\overline{\phi} = \overline{V}(\overline{u}, E\overline{u}, E^{-1}\overline{u}, \ldots; \lambda)\overline{\phi}, \end{aligned} \tag{2.5}$$

where the matrix U_c in $\overline{U}$ introduces additional dependent variables and $\overline{u}$ consists of both the original dependent variables and the additional dependent variables. In addition, the matrix U_c could depend on the spectral parameter λ, and the matrix V_c in $\overline{V}$ really does almost in all cases. Based on the closure properties of G, G_c and between G and G_c, it is easy to see that

$$\begin{aligned} (E\overline{V})\overline{U} - \overline{UV} &= [(EV)U - UV] + \{[(EV)U_c - U_cV] + [(EV_c)U - UV_c] + [(EV_c)U_c - U_cV_c]\} \\ &\in G \oplus G_c. \end{aligned}$$

Therefore, under $u_t = K(u)$, the corresponding enlarged discrete zero curvature equation

$$\overline{U}_t = (E\overline{V})\overline{U} - \overline{UV} \tag{2.6}$$

precisely presents

$$\begin{aligned} U_t &= (EV)U - UV, \\ U_{c,t} &= [(EV)U_c - U_cV] + [(EV_c)U - UV_c] + [(EV_c)U_c - U_cV_c]. \end{aligned} \tag{2.7}$$

The first equation above is equivalent to the lattice equation (1.5), and hence, this is a coupling system for the lattice equation (1.5).

The whole construction process above shows that semidirect sums of a given Lie algebra G with new Lie algebras provide a great choice of candidates of integrable couplings for the lattice equation (1.5) generated from the Lie algebra G.

B. Realizations by particular semi-direct sums

To shed light on the above general scheme of constructing coupling systems, let us introduce the following particular class of semidirect sums of Lie algebras:

$$\bar{G} = G \oplus G_c, \quad G = \{\mathrm{diag}(\underbrace{A, \ldots, A}_{\mu}, \underbrace{0, \ldots, 0}_{\nu-\mu+1})\},$$

$$G_c = \left\{ \begin{pmatrix} 0 & & & & \\ & \ddots & & B_{ij} & \\ & & 0 & & \\ & & & B_{\mu+1,\mu+1} & \\ & 0 & & & \ddots \\ & & & & & B_{\nu+1,\nu+1} \end{pmatrix} \right\}, \tag{2.8}$$

where A, B_{ii} are arbitrary square matrices, A is of the same order as U and the partitions of matrices in G and G_c are the same. Obviously, $B_{ij}, j \leqslant \mu$, are square but $B_{ij}, j \geqslant \mu+1$, may not; and all closure conditions of G, G_c and between G and G_c under matrix multiplication are satisfied.

Define

$$U_G := \operatorname{diag}(\underbrace{U, \ldots, U}_{\mu}, \underbrace{0, \ldots, 0}_{\nu-\mu+1}), \quad V_G := \operatorname{diag}(\underbrace{V, \ldots, V}_{\mu}, \underbrace{0, \ldots, 0}_{\nu-\mu+1}).$$

Note that U_G and V_G in G generate the same lattice equation as U and V, and thus for integrable couplings, the corresponding enlarged spectral matrices $\overline{U}$ and $\overline{V}$ in the semidirect sum $G \dotplus G_c$ can be chosen as

$$\overline{U} = U_G + U_{G,c} := \begin{pmatrix} U & & & & \\ & \ddots & & U_{ij} & \\ & & U & & \\ & & & U_{\mu+1,\mu+1} & \\ & 0 & & & \ddots \\ & & & & & U_{\nu+1,\nu+1} \end{pmatrix}$$

$$\overline{V} = V_G + V_{G,c} := \begin{pmatrix} V & & & & \\ & \ddots & & V_{ij} & \\ & & V & & \\ & & & V_{\mu+1,\mu+1} & \\ & 0 & & & \ddots \\ & & & & & V_{\nu+1,\nu+1} \end{pmatrix},$$

where the first two matrices U_G and V_G play the (U,V)-part and the second two matrices $U_{G,c}$ and $V_{G,c}$ play the (U_c, V_c)-part in the pair of $\overline{U}$ and $\overline{V}$ defined in (2.4). It is not difficult to see that the resulting coupling system (2.7) becomes

$$U_t = (EV)U - UV,$$

$$(U_{i+1,i+1})_t = (EV_{i+1,i+1})U_{i+1,i+1} - U_{i+1,i+1}V_{i+1,i+1}, \quad \mu \leqslant i \leqslant \nu, \tag{2.9}$$

$$U_{ij,t} = \sum_{k=i}^{j} [(EV_{ik})U_{kj} - U_{ik}V_{kj}], \quad 1 \leqslant i < j \leqslant \nu + 1,$$

where $U_{ii} = U$ and $V_{ii} = V$, $1 \leqslant i \leqslant \mu$.

In particular, first, if we take

$$\overline{U}=\begin{pmatrix} U & U_{12} & \cdots & U_{1,\mu+1} \\ & \ddots & \ddots & \vdots \\ & & U & U_{\mu,\mu+1} \\ 0 & & & 0 \end{pmatrix}, \quad \overline{V}=\begin{pmatrix} V & V_{12} & \cdots & V_{1,\mu+1} \\ & \ddots & \ddots & \vdots \\ & & V & V_{\mu,\mu+1} \\ 0 & & & 0 \end{pmatrix},$$

then the coupling system (2.9) becomes

$$\begin{aligned} U_t &= (EV)U - UV, \\ U_{ij,t} &= \sum_{k=i}^{j} [(EV_{ik})U_{kj} - U_{ik}V_{kj}], \quad 1 \leqslant i < j \leqslant \mu+1, \end{aligned} \tag{2.10}$$

where $U_{ii}=U$, $V_{ii}=V$, $1 \leqslant i \leqslant \mu$, and $U_{ii}=V_{ii}=0$, $i=\mu+1$. Second, if we take

$$\overline{U}=\begin{pmatrix} U & U_{a_1} & \cdots & U_{a_\nu} \\ & U & \ddots & \vdots \\ & & \ddots & U_{a_1} \\ 0 & & & U \end{pmatrix}, \quad \overline{V}=\begin{pmatrix} V & V_{a_1} & \cdots & V_{a_\nu} \\ & V & \ddots & \vdots \\ & & \ddots & V_{a_1} \\ 0 & & & V \end{pmatrix},$$

then the coupling system (2.9) becomes

$$\begin{aligned} U_t &= (EV)U - UV, \\ U_{a_i,t} &= \sum_{k+l=i,k,l\geqslant 0} [(EV_{a_k})U_{a_l} - U_{a_l}V_{a_k}], \quad 1 \leqslant i \leqslant \nu, \end{aligned} \tag{2.11}$$

where $U_{a_0}=U$ and $V_{a_0}=V$.

We remark that here we have just presented one class of semidirect sums of Lie algebras, together with two specific examples. It is interesting to construct other possible realizations, especially those which could carry essential information for keeping integrable properties of the original lattice equations.

C. Linearly dependent case on the spectral parameter

Let us now assume that the spatial spectral matrix U depends linearly on the spectral parameter λ (see, for example, Refs. 17 and 19–21):

$$U = U(u,\lambda) = \lambda U_0 + U_1, \quad \frac{\partial U_0}{\partial \lambda} = \frac{\partial U_1}{\partial \lambda} = 0. \tag{2.12}$$

Consider two specific examples of the enlarged spatial spectral matrices introduced in the last section,

$$\overline{U_1}=\begin{pmatrix} U & U_a \\ 0 & 0 \end{pmatrix}, \quad \overline{U_2}=\begin{pmatrix} U & U_a \\ 0 & U \end{pmatrix}, \quad \frac{\partial U_a}{\partial \lambda} = 0. \tag{2.13}$$

Note that the submatrices U_a in the above two enlarged spatial spectral matrices could be of different sizes. As in the continuous cases,[4,15] suppose that

$$\overline{W_1}=\begin{pmatrix} W & W_a \\ 0 & 0 \end{pmatrix}, \quad \overline{W_2}=\begin{pmatrix} W & W_a \\ 0 & W \end{pmatrix}$$

with

$$W=\sum_{i\geqslant 0} W_i\lambda^{-i},\quad W_a=\sum_{i\geqslant -n_0} W_{a,i}\lambda^{-i},\quad \frac{\partial W_i}{\partial\lambda}=0,\quad \frac{\partial W_{a,i}}{\partial\lambda}=0, \tag{2.14}$$

where $n_0\geqslant 0$ is a proper integer, solve the corresponding enlarged discrete stationary zero curvature equations

$$(E\overline{W}_i)\overline{U}_i-\overline{U}_i\overline{W}_i=0,\quad i=1,2, \tag{2.15}$$

respectively.

Then for each $m\geqslant 0$, choose

$$\overline{V}_1^{[m]}=\begin{pmatrix} V^{[m]} & V_a^{[m]}\\ 0 & 0\end{pmatrix}=(\lambda^m\overline{W}_1)_+ +\overline{\Delta}_m,\quad \overline{\Delta}_m=\begin{pmatrix}\Delta_m & \Delta_{m,a}\\ 0 & 0\end{pmatrix},$$

where Δ_m and $\Delta_{m,a}$ do not depend on λ and satisfy

$$(E\Delta_m)U_0-U_0\Delta_m=0,\quad U_0\Delta_{m,a}=0, \tag{2.16}$$

and choose

$$\overline{V}_2^{[m]}=\begin{pmatrix} V^{[m]} & V_a^{[m]}\\ 0 & V^{[m]}\end{pmatrix}=(\lambda^m\overline{W}_2)_+ +\overline{\Delta}_m,\quad \overline{\Delta}_m=\begin{pmatrix}\Delta_m & \Delta_{m,a}\\ 0 & \Delta_m\end{pmatrix},$$

where Δ_m and $\Delta_{m,a}$ do not depend on λ and satisfy

$$(E\Delta_m)U_0-U_0\Delta_m=0,\quad (E\Delta_{m,a})U_0-U_0\Delta_{m,a}=0. \tag{2.17}$$

The subscript $+$ above denotes to select the polynomial part in λ. Based on (2.10) and (2.11) and using (2.15), we can directly show that the enlarged discrete zero curvature equations

$$\overline{U}_{i,t_m}=(E\overline{V}_i^{[m]})\overline{U}_i-\overline{U}_i\overline{V}_i^{[m]},\quad i=1,2,$$

namely,

$$U_{t_m}=(EV^{[m]})U-UV^{[m]},$$

$$U_{a,t_m}=(EV^{[m]})U_a-UV_a^{[m]},$$

and

$$U_{t_m}=(EV^{[m]})U-UV^{[m]},$$

$$U_{a,t_m}=(EV^{[m]})U_a+(EV_a^{[m]})U-UV_a^{[m]}-U_aV^{[m]},$$

present

$$\begin{aligned} U_{t_m}&=(\Delta_m)_x+[U_0,W_{m+1}]-[U_1,\Delta_m],\\ U_{a,t_m}&=U_0W_{a,m+1}+(E\Delta_m)U_a-U_1\Delta_{m,a},\end{aligned} \tag{2.18}$$

and

$$U_{t_m}=(\Delta_m)_x+[U_0,W_{m+1}]-[U_1,\Delta_m], \tag{2.19a}$$

$$U_{a,t_m} = U_0 W_{a,m+1} - (EW_{a,m+1})U_0 + (E\Delta_m)U_a - U_a\Delta_m + (E\Delta_{m,a})U_1 - U_1\Delta_{m,a}, \qquad (2.19b)$$

respectively.

We remark that these two enlarged hierarchies in (2.18) and (2.19) share the enlarged discrete spectral problems

$$E\overline{\phi} = \overline{U}_1\overline{\phi}, \quad E\overline{\phi} = \overline{U}_2\overline{\phi},$$

respectively. Thus, all lattice equations in each of the two enlarged hierarchies can possess infinitely many common conserved densities except the original ones (see Refs. 22–24 for a few concrete examples). Moreover, one can construct a specific nondegenerate bilinear form on $\overline{G}$ with the invariance property, to present Hamiltonian structures of the enlarged lattice equations by a generalized trace identity. The detailed analysis on those integrable properties will be left to a future presentation.

To sum up, each system of lattice equations in the hierarchy (2.18) or (2.19) can provide an integrable coupling for its first subsystem of lattice equations. In the next section, we will only discuss two examples of constructing enlarged lattice hierarchies, in the generalized Toda case presented in Ref. 19.

III. INTEGRABLE COUPLINGS OF THE GENERALIZED TODA HIERARCHY

A. The generalized Toda equations

Let us here recall the generalized Toda hierarchy.[19] The corresponding discrete spatial spectral problem reads

$$E\phi = U(u,\lambda)\phi, U(u,\lambda) = \begin{pmatrix} 0 & 1 \\ (\alpha\lambda+\beta)r & \lambda+s \end{pmatrix}, \quad u = \begin{pmatrix} r \\ s \end{pmatrix}, \qquad (3.1)$$

where λ is a spectral parameter, and α and β are two arbitrary constants satisfying $\alpha^2+\beta^2 \neq 0$. When $\alpha=0$ and $\beta=-1$, (3.1) becomes the Toda spectral problem.[16]

Its stationary discrete zero curvature equation

$$(EW)U - UW = 0 \qquad (3.2)$$

has the solution

$$W = \begin{pmatrix} a & b \\ (\alpha\lambda+\beta)c & -a \end{pmatrix}, \qquad (3.3)$$

with

$$a = \sum_{i\geqslant 0} a_i\lambda^{-i}, \quad b = \sum_{i\geqslant 0} b_i\lambda^{-i}, \quad c = \sum_{i\geqslant 0} c_i\lambda^{-i},$$

where the coefficients are defined by the initial conditions

$$a_0 = -\tfrac{1}{2}, \quad b_0 = 0, \quad c_0 = 0,$$

and the recursion relation

$$c_{i+1} - rb_{i+1}^{(1)} = 0, \quad i \geqslant 0, \qquad (3.4a)$$

$$b_{i+1}^{(1)} + sb_i^{(1)} + (a_i^{(1)} + a_i) = 0, \quad i \geqslant 0, \qquad (3.4b)$$

$$(a_{i+1}^{(1)} - a_{i+1}) + s(a_i^{(1)} - a_i) + \alpha(rb_{i+1} - c_{i+1}^{(1)}) + \beta(rb_i - c_i^{(1)}) = 0, \quad i \geqslant 0, \tag{3.4c}$$

which are all difference polynomials in u with respect to the lattice variable n. Under the initial-value conditions

$$a_1|_{u=0} = c_1|_{u=0} = 0, \quad a_i|_{u=0} = b_i|_{u=0} = c_i|_{u=0} = 0, \quad i \geqslant 2,$$

the recursion relation (3.4) uniquely determines the lattice functions a_i, b_i, and c_i, $i \geqslant 1$. The first few lattice functions are

$$a_1 = \alpha r, \quad b_1 = 1, \quad c_1 = r,$$

$$a_2 = -\alpha^2 r^{(1)} r - \alpha^2 r^2 - \alpha^2 r r^{(-1)} - \alpha r s - \alpha r s^{(-1)} + \beta r,$$

$$b_2 = -\alpha r - \alpha r^{(-1)} - s^{(-1)}, \quad c_2 = -rs - \alpha r^2 - \alpha r r^{(1)}.$$

As usual, choose that

$$V_m = \begin{pmatrix} (\lambda^m a)_+ & (\lambda^m b)_+ \\ (\alpha\lambda + \beta)(\lambda^m c)_+ & -(\lambda^m a)_+ \end{pmatrix}, \quad m \geqslant 0. \tag{3.5}$$

Then it follows from (3.4) that

$$(EV_m)U - UV_m = \begin{pmatrix} 0 & -b_{m+1}^{(1)} \\ (\alpha\lambda + \beta)c_{m+1} & \beta(c_m^{(1)} - rb_m) - s(a_m^{(1)} - a_m) \end{pmatrix}.$$

Take a modification

$$\Delta_m = \begin{pmatrix} b_{m+1} & 0 \\ 0 & 0 \end{pmatrix},$$

and define the temporal spectral matrices

$$V^{[m]} = V_m + \Delta_m, \quad m \geqslant 0. \tag{3.6}$$

Then, a direct calculation leads to the following matrix:

$$(EV^{[m]})U - UV^{[m]} = \begin{pmatrix} 0 & 0 \\ (\alpha\lambda + \beta)(c_{m+1} - rb_{m+1}) & \beta(c_m^{(1)} - rb_m) - s(a_m^{(1)} - a_m) \end{pmatrix}.$$

This is consistent with U_{t_m}, and thus, making the evolution laws

$$\phi_{t_m} = V^{[m]}\phi, \quad m \geqslant 0, \tag{3.7}$$

the compatibility conditions

$$U_{t_m} = (EV^{[m]})U - UV^{[m]}, \quad m \geqslant 0,$$

of the discrete spatial spectral problem (3.1) and the associated discrete temporal spectral problems (3.7) give rise to the following hierarchy of lattice equations:

$$\begin{aligned} r_{t_m} &= c_{m+1} - rb_{m+1}, \\ s_{t_m} &= -\alpha(c_{m+1}^{(1)} - rb_{m+1}) + (a_{m+1}^{(1)} - a_{m+1}), \end{aligned} \quad m \geqslant 0. \tag{3.8}$$

This generalized Toda hierarchy is Liouville integrable,[19] and its Hamiltonian structure leads to infinitely many conservation laws and symmetries for every system in the hierarchy.

Obviously, the first nonlinear lattice equation in the hierarchy is

$$r_{t_1} = r(s^{(-1)} - s) + \alpha r(r^{(-1)} - r^{(1)}),$$
$$s_{t_1} = \alpha s(r - r^{(1)}) + \beta(r^{(1)} - r). \tag{3.9}$$

When $\alpha=0$ and $\beta=-1$, (3.9) becomes the Toda lattice equation,[25]

$$r_{t_1} = r(s^{(-1)} - s), \quad s_{t_1} = r - r^{(1)}, \tag{3.10}$$

and when $\alpha=1$ and $\beta=0$, (3.9) becomes the following lattice equation presented in Ref. 26:

$$r_{t_1} = r(s^{(-1)} - s) + r(r^{(-1)} - r^{(1)}), \quad s_{t_1} = s(r - r^{(1)}). \tag{3.11}$$

The lattice equation (3.11) is linearly independent of the Toda lattice equation (3.10). There exist a voluminous literature on the Toda lattice equation, and its generalizations and solution structures (for example, see Refs. 27–32).

B. Integrable couplings from specific semidirect sums

The generalized Toda spectral problem (3.1) linearly depends on the spectral parameter λ, and thus we can write

$$U = \begin{pmatrix} 0 & 1 \\ (\alpha\lambda + \beta)r & \lambda + s \end{pmatrix} = U_0\lambda + U_1, \quad U_0 = \begin{pmatrix} 0 & 0 \\ \alpha r & 1 \end{pmatrix}, \quad U_1 = \begin{pmatrix} 0 & 1 \\ \beta r & s \end{pmatrix}. \tag{3.12}$$

We will also see that there is a difference between the two cases of $\alpha=0$ and $\alpha\neq 0$ in computing integrable couplings.

Let us first consider the semidirect sum of Lie algebras of 3×3 matrices,

$$G \dot{+} G_c, \quad G = \left\{ \begin{pmatrix} A & 0 \\ 0 & 0 \end{pmatrix} | A \in \mathbb{C}[\lambda,\lambda^{-1}] \otimes M_{2\times 2} \right\}, \quad G_c = \left\{ \begin{pmatrix} 0 & B \\ 0 & 0 \end{pmatrix} | B \in \mathbb{C}[\lambda,\lambda^{-1}] \otimes M_{2\times 1} \right\},$$

where $\mathbb{C}[\lambda,\lambda^{-1}]\otimes M_{m\times n} = \mathrm{span}\{\lambda^k A | k \in \mathbb{Z}, A \in M_{m\times n}\}$. In this case, G_c is an Abelian ideal of $G \dot{+} G_c$. We define the corresponding enlarged spatial spectral matrix as

$$\overline{U} = \overline{U}(\overline{u},\lambda) = \begin{pmatrix} U & U_a \\ 0 & 0 \end{pmatrix} \in G \dot{+} G_c, \quad U_a = U_a(v) = \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}, \tag{3.13}$$

where v_1 and v_2 are new dependent variables and

$$v = (v_1, v_2)^T, \quad \overline{u} = (u^T, v^T)^T = (r, s, v_1, v_2)^T.$$

Upon setting

$$\overline{W} = \begin{pmatrix} W & W_a \\ 0 & 0 \end{pmatrix}, \quad W_a = W_a(\overline{u},\lambda) = \begin{pmatrix} e \\ f \end{pmatrix},$$

where W is a solution to $(EW)U - UW = 0$, defined by (3.3), the corresponding enlarged discrete stationary zero curvature equation $(E\overline{W})\overline{U} - \overline{UW} = 0$ becomes

$$(EW)U_a - UW_a = 0, \tag{3.14}$$

which is equivalent to

$$W_a = WU^{-1}U_a,$$

namely,

$$f = a^{(1)}v_1 + b^{(1)}v_2, \tag{3.15a}$$

$$(\alpha\lambda+\beta)re=(\alpha\lambda+\beta)c^{(1)}v_1-a^{(1)}v_2-(\lambda+s)f. \tag{3.15b}$$

This system determines a solution for e and f as follows:

$$e=\sum_{i\geqslant -n_0} e_i\lambda^{-i},\quad f=\sum_{i\geqslant 0} f_i\lambda^i,$$

where $n_0=1$ if $\alpha=0$ and $n_0=0$ if $\alpha\neq 0$ [see (2.14) for introduction of n_0]. Now define the enlarged temporal spectral matrix as

$$\overline{V}^{[m]}=\begin{pmatrix} V^{[m]} & V_a^{[m]} \\ 0 & 0 \end{pmatrix},\quad V_a^{[m]}=(\lambda^m W_a)_+ +\Delta_{m,a},\quad m\geqslant 0, \tag{3.16}$$

where $V^{[m]}$ is defined as in (3.6). To satisfy (2.16), choose $\Delta_{m,a}$ as

$$\Delta_{m,a}=\begin{pmatrix} h_m \\ -\alpha r h_m \end{pmatrix},\quad h_m-\text{arbitrary},\quad m\geqslant 0. \tag{3.17}$$

Then based on (3.15), we can compute that

$$\begin{aligned}(EV^{[m]})U_a-UV_a^{[m]}&=(EV_m)U_a-U(\lambda^m W_a)_+ +(E\Delta_m)U_a-U_1\Delta_{m,a}=\begin{pmatrix} 0 \\ -\alpha c_{m+1}^{(1)}v_1+\alpha r e_{m+1}+f_{m+1}\end{pmatrix}\\ &\quad+\begin{pmatrix} b_{m+1}^{(1)}v_1 \\ 0\end{pmatrix}-\begin{pmatrix} -\alpha r h_m \\ \beta r h_m-\alpha r s h_m\end{pmatrix}\\ &=\begin{pmatrix} b_{m+1}^{(1)}v_1+\alpha r h_m \\ -\alpha c_{m+1}^{(1)}v_1+\alpha r e_{m+1}+f_{m+1}-\beta r h_m+\alpha r s h_m\end{pmatrix},\quad m\geqslant 0.\end{aligned}$$

Therefore, the mth enlarged discrete zero curvature equation

$$\overline{U}_{t_m}=(E\overline{V}^{[m]})\overline{U}-\overline{U}\overline{V}^{[m]}$$

leads to

$$v_{t_m}=\begin{pmatrix} v_1 \\ v_2\end{pmatrix}_{t_m}=S_m(u,v)=\begin{pmatrix} b_{m+1}^{(1)}v_1+\alpha r h_m \\ -\alpha c_{m+1}^{(1)}v_1+\alpha r e_{m+1}+f_{m+1}-\beta r h_m+\alpha r s h_m\end{pmatrix}, \tag{3.18}$$

together with the mth generalized Toda equation in (3.8). Therefore, we obtain a hierarchy of coupling systems defined by (2.18),

$$\overline{u}_{t_m}=\begin{pmatrix} u \\ v\end{pmatrix}_{t_m}=\overline{K}_m(u)=\begin{pmatrix} K_m(u) \\ S_m(u,v)\end{pmatrix},\quad m\geqslant 0 \tag{3.19}$$

for the generalized Toda hierarchy (3.8).

Let us second consider the semidirect sum of Lie algebras of 4×4 matrices,

$$G\oplus G_c,\quad G=\left\{\begin{pmatrix} A & 0 \\ 0 & A\end{pmatrix}|A\in\mathbb{C}[\lambda,\lambda^{-1}]\otimes M_{2\times 2}\right\},\quad G_c=\left\{\begin{pmatrix} 0 & B \\ 0 & 0\end{pmatrix}|B\in\mathbb{C}[\lambda,\lambda^{-1}]\otimes M_{2\times 2}\right\}.$$

In this case, G_c is an Abelian ideal of $G\oplus G_c$, too. We define the corresponding enlarged spatial spectral matrix as

$$\overline{U}=\overline{U}(\overline{u},\lambda)=\begin{pmatrix} U & U_a \\ 0 & U\end{pmatrix}\in G\oplus G_c,\quad U_a=U_a(v)=\begin{pmatrix} v_1 & v_2 \\ v_3 & v_4\end{pmatrix}, \tag{3.20}$$

where v_i, $1\leqslant i\leqslant 4$, are new dependent variables and

$$v=(v_1,v_2,v_3,v_4)^T,\quad \overline{u}=(u^T,v^T)^T=(r,s,v_1,v_2,v_3,v_4)^T.$$

If we set

$$\overline{W}=\begin{pmatrix} W & W_a \\ 0 & W \end{pmatrix},\quad W_a=W_a(\overline{u},\lambda)=\begin{pmatrix} e & f \\ g & -e \end{pmatrix},$$

where W is a solution to $(EW)U-UW=0$, defined by (3.3), then the corresponding enlarged discrete stationary zero curvature equation $(E\overline{W})\overline{U}-\overline{UW}=0$ becomes

$$(EW)U_a+(EW_a)U-UW_a-U_aW=0, \tag{3.21}$$

which is equivalent to

$$\begin{aligned}
&(e^{(1)}+e)+(\lambda+s)f^{(1)}+(a^{(1)}+a)v_2+b^{(1)}v_4-bv_1=0,\\
&-(\alpha\lambda+\beta)r(e^{(1)}+e)-(\lambda+s)g+(\alpha\lambda+\beta)(c^{(1)}v_1-cv_4)-(a^{(1)}+a)v_3=0,\\
&g^{(1)}-(\lambda+s)(e^{(1)}-e)-(\alpha\lambda+\beta)(rf-c^{(1)}v_2)-(a^{(1)}-a)v_4-bv_3=0.
\end{aligned} \tag{3.22}$$

This system can determine a solution for e, f, and g as follows:

$$e=\sum_{i\geqslant 0}e_i\lambda^{-i},\quad f=\sum_{i\geqslant 0}f_i\lambda^{-i},\quad g=\sum_{i\geqslant 0}g_i\lambda^{-i}.$$

Now, we define the enlarged temporal spectral matrix as

$$\overline{V}^{[m]}=\begin{pmatrix} V^{[m]} & V_a^{[m]} \\ 0 & V^{[m]} \end{pmatrix},\quad V_a^{[m]}=(\lambda^mW_a)_+ +\Delta_{m,a},\quad m\geqslant 0, \tag{3.23}$$

where $V^{[m]}$ is defined as in (3.6). To satisfy (2.17), choose $\Delta_{m,a}$ as

$$\Delta_{m,a}=\begin{pmatrix} h_m & 0 \\ -\alpha rh_m & 0 \end{pmatrix},\quad h_m-\text{arbitrary},\quad m\geqslant 0. \tag{3.24}$$

Then based on (3.22), we can compute that

$$\begin{aligned}
&(EV^{[m]})U_a+(EV_a^{[m]})U-UV_a^{[m]}-U_aV^{[m]}\\
&\quad=[(EV_m)U_a+(E(\lambda^mW_a)_+)U-U(\lambda^mW_a)_+-U_aV_m]\\
&\qquad+[(E\Delta_m)U_a-U_a\Delta_m]+[(E\Delta_{m,a})U_1-U_1\Delta_{m,a}]\\
&\quad=\begin{pmatrix} -\alpha c_{m+1}v_2+\alpha rf_{m+1}^{(1)} & f_{m+1}^{(1)} \\ \alpha c_{m+1}^{(1)}v_1-\alpha c_{m+1}v_4-\alpha r(e_{m+1}^{(1)}+e_{m+1})-g_{m+1} & \alpha c_{m+1}^{(1)}v_2-\alpha rf_{m+1}-(e_{m+1}^{(1)}-e_{m+1}) \end{pmatrix}\\
&\qquad+\begin{pmatrix} (b_{m+1}^{(1)}-b_{m+1})v_1 & b_{m+1}^{(1)}v_2 \\ -b_{m+1}v_3 & 0 \end{pmatrix}+\begin{pmatrix} \alpha rh_m & h_m^{(1)} \\ r(\alpha s-\beta)h_m & -\alpha r^{(1)}h_m^{(1)} \end{pmatrix}\\
&\quad=\begin{pmatrix} -\alpha c_{m+1}v_2+\alpha rf_{m+1}^{(1)}+(b_{m+1}^{(1)}-b_{m+1})v_1+\alpha rh_m, \\ \alpha c_{m+1}^{(1)}v_1-\alpha c_{m+1}v_4-\alpha r(e_{m+1}^{(1)}+e_{m+1})-g_{m+1}-b_{m+1}v_3+r(\alpha s-\beta)h_m, \\ f_{m+1}^{(1)}+b_{m+1}^{(1)}v_2+h_m^{(1)} \\ \alpha c_{m+1}^{(1)}v_2-\alpha rf_{m+1}-(e_{m+1}^{(1)}-e_{m+1})-\alpha r^{(1)}h_m^{(1)} \end{pmatrix}.
\end{aligned}$$

Then the mth enlarged discrete zero curvature equation

$$\overline{U}_{t_m} = (E\overline{V}^{[m]})\overline{U} - \overline{U}\overline{V}^{[m]}$$

leads to

$$v_{t_m} = (v_1, v_2, v_3, v_4)^T_{t_m} = T_m(u,v)$$
$$= \begin{pmatrix} -\alpha c_{m+1} v_2 + \alpha r f^{(1)}_{m+1} + (b^{(1)}_{m+1} - b_{m+1}) v_1 + \alpha r h_m \\ f^{(1)}_{m+1} + b^{(1)}_{m+1} v_2 + h^{(1)}_m \\ \alpha c^{(1)}_{m+1} v_1 - \alpha c_{m+1} v_4 - \alpha r (e^{(1)}_{m+1} + e_{m+1}) - g_{m+1} - b_{m+1} v_3 + r(\alpha s - \beta) h_m \\ \alpha c^{(1)}_{m+1} v_2 - \alpha r f_{m+1} - (e^{(1)}_{m+1} - e_{m+1}) - \alpha r^{(1)} h^{(1)}_m \end{pmatrix}, \quad (3.25)$$

together with the mth generalized Toda equation in (3.8). Therefore, we obtain a hierarchy of coupling systems defined by (2.19),

$$\overline{u}_{t_m} = \begin{pmatrix} u \\ v \end{pmatrix}_{t_m} = \overline{K}_m(u) = \begin{pmatrix} K_m(u) \\ T_m(u,v) \end{pmatrix}, \quad m \geqslant 0 \quad (3.26)$$

for the generalized Toda hierarchy (3.8).

C. Illustrative examples

We now work out two concrete examples as follows, one in each of the two above cases.

Case of $\alpha=1$ and $\beta=0$: Let us first compute an example of the hierarchy (3.19). Assume that $\alpha=1$ and $\beta=0$ for convenience, which corresponds to the lattice hierarchy presented in Ref. 26. In this case, we have $n_0=0$ in (2.14).

It directly follows from (3.15) that

$$f_i = a^{(1)}_i v_1 + b^{(1)}_i v_2,$$

$$re_{i+1} = c^{(1)}_{i+1} v_1 - a^{(1)}_i v_2 - f_{i+1} - s f_i,$$

where $i \geqslant 0$ and $re_0 = c^{(1)}_0 v_1 - f_0$. We can then obtain that

$$f_0 = -\tfrac{1}{2} v_1, \quad f_1 = r^{(1)} v_1 + v_2,$$

$$f_2 = -[r^{(2)} r^{(1)} + (r^{(1)})^2 + r^{(1)} r + r^{(1)} s^{(1)} + r^{(1)} s] v_1 - (r^{(1)} + r + s) v_2;$$

$$re_0 = \tfrac{1}{2} v_1, \quad re_1 = \tfrac{1}{2} s v_1 - \tfrac{1}{2} v_2, \quad re_2 = r^{(1)} r v_1 + r v_2.$$

If we choose

$$h_1 = 2\xi f_0 f_1 = -\xi v_1 (r^{(1)} v_1 + v_2), \quad \xi = \text{const},$$

then the vector-valued function S_1 defined by (3.18) becomes

$$S_1(u,v) = \begin{pmatrix} -(r^{(1)} + r + s) v_1 - \xi r v_1 (r^{(1)} v_1 + v_2) \\ -r^{(1)} s v_1 - (r^{(1)} + s) v_2 - \xi r s v_1 (r^{(1)} v_1 + v_2) \end{pmatrix}.$$

Therefore, the integrable coupling of the generalized Toda lattice equation (3.11), defined by (3.19), reads as

$$r_{t_1} = r(s^{(-1)} - s) + r(r^{(-1)} - r^{(1)}),$$

$$
\begin{aligned}
s_{t_1} &= s(r - r^{(1)}),\\
v_{1,t_1} &= -(r^{(1)} + r + s)v_1 - \xi r v_1 (r^{(1)} v_1 + v_2),\\
v_{2,t_1} &= -r^{(1)} s v_1 - (r^{(1)} + s)v_2 - \xi r s v_1 (r^{(1)} v_1 + v_2),
\end{aligned}
\tag{3.27}
$$

the second subsystem of which is nonlinear with respect to both subsets of dependent variables when $\xi \neq 0$.

Case of $\alpha=0$ and $\beta=1$: Let us second compute an example of the hierarchy (3.26). Assume that $\alpha=0$ and $\beta=1$ for convenience, which corresponds to the Toda lattice hierarchy. In this case, we have $n_0=1$ in (2.14).

We take the initial set of functions as follows:

$$f_0 = g_0 = 0, \quad e_0 = -\tfrac{1}{2}.$$

Obviously from (3.22), we can have

$$f_{i+1}^{(1)} = -s f_i^{(1)} - (e_i^{(1)} + e_i) - (a_i^{(1)} + a_i)v_2 - b_i^{(1)} v_4 + b_i v_1,$$

$$g_{i+1} = -s g_i - r(e_i^{(1)} + e_i) - (a_i^{(1)} + a_i)v_3 + c_i^{(1)} v_1 - c_i v_4,$$

$$e_{i+1}^{(1)} - e_{i+1} = -s(e_i^{(1)} - e_i) + g_i^{(1)} - r f_i - (a_i^{(1)} - a_i)v_4 + c_i^{(1)} v_2 - b_i v_3,$$

where $i \geqslant 0$. It then follows that

$$f_1 = 1 + v_2^{(-1)}, \quad g_1 = r + v_3, \quad e_1 = v_3 + r(1 + v_2^{(-1)}),$$

$$f_2 = -(s^{(-1)} + r)(1 + v_2^{(-1)}) - v_3 - v_3^{(-1)} - r^{(-1)}(1 + v_2^{(-2)}) - v_4^{(-1)} + v_1^{(-1)},$$

$$g_2 = -s(r + v_3) - r[v_3^{(1)} + v_3 + r^{(1)}(1 + v_2) + r(1 + v_2^{(-1)})] + r^{(1)} v_1 - r v_4,$$

$$e_2^{(1)} - e_2 = (1 - s)(r^{(1)} - r + v_3^{(1)} - v_3 + r^{(1)} v_2 - r v_2^{(-1)}).$$

We can use the inverse formula (1.4) to compute e_2 here, but as we will see, this is not necessary for computing the corresponding integrable coupling.

Now if we choose

$$h_1 = \eta v_1 e_1 = \eta v_1 [v_3 + r(1 + v_2^{(-1)})], \quad \eta = \text{const},$$

then the vector-valued function T_1 defined by (3.25) becomes

$$
T_1(u,v) = \begin{pmatrix}
-(s - s^{(-1)})v_1,\\
-s v_2 - (s + r^{(1)})(1 + v_2) - r(1 + v_2^{(-1)}) + v_1 - v_3^{(1)}\\
-v_3 - v_4 + \eta v_1^{(1)}[v_3^{(1)} + r^{(1)}(1 + v_2)],\\
(s^{(-1)} + s)v_3 + rs + r[v_3^{(1)} + v_3 + r^{(1)}(1 + v_2) + r(1 + v_2^{(-1)})]\\
-r^{(1)} v_1 + r v_4 - \eta r v_1 [v_3 + r(1 + v_2^{(-1)})],\\
(s - 1)(r^{(1)} - r + v_3^{(1)} - v_3 + r^{(1)} v_2 - r v_2^{(-1)})
\end{pmatrix}.
$$

Therefore, the integrable coupling of the Toda lattice equation (3.10), defined by (3.26), reads as

$$r_{t_1} = r(s^{(-1)} - s), \quad s_{t_1} = r^{(1)} - r,$$

$$v_{1,t_1} = -(s - s^{(-1)})v_1,$$

$$\begin{aligned} v_{2,t_1} &= -sv_2 - (s + r^{(1)})(1 + v_2) - r(1 + v_2^{(-1)}) + v_1 - v_3^{(1)} - v_3 - v_4 + \eta v_1^{(1)}[v_3^{(1)} + r^{(1)}(1 + v_2)], \\ v_{3,t_1} &= (s^{(-1)} + s)v_3 + rs + r[v_3^{(1)} + v_3 + r^{(1)}(1 + v_2) + r(1 + v_2^{(-1)})] \\ &\quad - r^{(1)}v_1 + rv_4 - \eta r v_1[v_3 + r(1 + v_2^{(-1)})], \end{aligned} \tag{3.28}$$

$$v_{4,t_1} = (s - 1)(r^{(1)} - r + v_3^{(1)} - v_3 + r^{(1)}v_2 - rv_2^{(-1)}),$$

the second subsystem of which is nonlinear with respect to both subsets of dependent variables when $\eta \neq 0$.

IV. CONCLUSIONS AND REMARKS

A feasible approach to construct integrable couplings of discrete soliton equations has been proposed by taking advantage of semidirect sums of Lie algebras, and the resulting theory has been applied to the generalized Toda hierarchy of lattice equations to generate integrable couplings for the hierarchy. The key point in our generating scheme is to establish a relation between semidirect sums of Lie algebras and integrable couplings of discrete soliton equations. The underlying discrete matrix spectral problems are generated from semidirect sums of Lie algebras, and the discrete Lax spectral matrices associated with given soliton equations play the nonideal part in the semidirect sums.
