where $\boldsymbol{\theta}=(\theta^1,\dots,\theta^n)$, $\Phi^i(\boldsymbol{\theta},\mathbf{U})$ are smooth functions 2π-periodic with respect to each θ^α, $\mathbf{k}(\mathbf{U})=(k^1(\mathbf{U}),\dots,k^m(\mathbf{U}))$, $\boldsymbol{\omega}(\mathbf{U})=(\omega^1(\mathbf{U}),\dots,\omega^m(\mathbf{U}))$ are "wave numbers" and "frequencies" of the solution, $\mathbf{U}=(U^1,\dots,U^N)$ are parameters of the solution, and $\boldsymbol{\theta}_0=(\theta_0^1,\dots,\theta_0^m)$ are arbitrary initial phases.

The functions $\boldsymbol{\Phi}(\boldsymbol{\theta},\mathbf{U})$ satisfy the nonlinear system

$$F^i(\boldsymbol{\Phi},\omega^\alpha(\mathbf{U})\boldsymbol{\Phi}_{\theta^\alpha},k^\beta(\mathbf{U})\boldsymbol{\Phi}_{\theta^\beta},\omega^\gamma(\mathbf{U})\omega^\delta(\mathbf{U})\boldsymbol{\Phi}_{\theta^\gamma\theta^\delta},\dots)=0. \tag{1.3}$$

We can introduce the families $\Lambda_{\mathbf{k},\boldsymbol{\omega}}$ and the full family $\Lambda=\cup\Lambda_{\mathbf{k},\boldsymbol{\omega}}$ of the functions $\boldsymbol{\Phi}(\boldsymbol{\theta},\mathbf{U})$ satisfying the system (1.3) in the space of 2π-periodic with respect to each θ^α function. Let us choose (in a smooth way) at every $(U^1,\dots,U^N)$ some function $\boldsymbol{\Phi}(\boldsymbol{\theta},\mathbf{U})$ as having "zero initial phase shifts" and represent the full family of m-phase solutions of system (1.1) in the form (1.2).

In Whitham method we make a rescaling $X=\epsilon x$, $T=\epsilon t$ $(\epsilon\to 0)$ of both variables x and t and try to find a function

$$\mathbf{S}(X,T)=(S^1(X,T),\dots,S^m(X,T)) \tag{1.4}$$

and 2π-periodic functions

[a)]Electronic mail: maltsev@itp.ac.ru

$$\Psi^i(\boldsymbol{\theta},X,T,\epsilon)=\sum_{k\geqslant 0}\Psi^i_{(k)}(\boldsymbol{\theta},X,T)\epsilon^k \tag{1.5}$$

such that the functions

$$\phi^i(\boldsymbol{\theta},X,T,\epsilon)=\Psi^i\left(\frac{\mathbf{S}(X,T)}{\epsilon}+\boldsymbol{\theta},X,T,\epsilon\right) \tag{1.6}$$

satisfy the system

$$F^i(\phi,\epsilon\phi_T,\epsilon\phi_X,\epsilon^2\phi_{TT},\dots)=0 \tag{1.7}$$

at every X, T, and $\boldsymbol{\theta}$.

It is easy to see that the function $\boldsymbol{\Psi}_{(0)}(\boldsymbol{\theta},X,T)$ satisfies the system (1.3) at every X and T with

$$k^\alpha=S^\alpha_X,\quad \omega^\alpha=S^\alpha_T$$

and so belongs at every (X,T) to the family Λ. We can write then

$$\Psi^i_{(0)}(\boldsymbol{\theta},X,T)=\Phi^i(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T),\mathbf{U}(X,T))$$

and introduce the functions $U^\nu(X,T)$, $\theta^\alpha_0(X,T)$ as the parameters characterizing the main term in (1.5) which should satisfy the condition

$$[k^\alpha(\mathbf{U})]_T=[\omega^\alpha(\mathbf{U})]_X. \tag{1.8}$$

The functions $\Psi^i_{(1)}(\boldsymbol{\theta},X,T)$ are defined from the linear system

$$\hat{L}^i_j\Psi^j_{(1)}(\boldsymbol{\theta},X,T)=f^i_{(1)}(\boldsymbol{\theta},X,T) \tag{1.9}$$

where

$$\begin{aligned}\hat{L}^i_j=\hat{L}^i_{(X,T)j}=&\frac{\partial F^i}{\partial\varphi^j}(\boldsymbol{\Psi}_{(0)}(\boldsymbol{\theta},X,T),\dots)+\frac{\partial F^i}{\partial\varphi^j_t}(\boldsymbol{\Psi}_{(0)}(\boldsymbol{\theta},X,T),\dots)\omega^\alpha(X,T)\frac{\partial}{\partial\theta^\alpha}\\&+\frac{\partial F^i}{\partial\varphi^j_x}(\boldsymbol{\Psi}_{(0)}(\boldsymbol{\theta},X,T),\dots)k^\beta(X,T)\frac{\partial}{\partial\theta^\beta}+\cdots\end{aligned} \tag{1.10}$$

is the linearization of system (1.3) and $\mathbf{f}_{(1)}(\boldsymbol{\theta},X,T)$ is discrepancy given by

$$\begin{aligned}f^i_{(1)}(\boldsymbol{\theta},X,T)=&-\frac{\partial F^i}{\partial\varphi^j_t}(\boldsymbol{\Psi}_{(0)}(\boldsymbol{\theta},X,T),\dots)\Psi^j_{(0)T}(\boldsymbol{\theta},X,T)-\frac{\partial F^i}{\partial\varphi^j_x}(\boldsymbol{\Psi}_{(0)}(\boldsymbol{\theta},X,T),\dots)\Psi^j_{(0)X}(\boldsymbol{\theta},X,T)\\&-\frac{\partial F^i}{\partial\varphi^j_{tt}}(\boldsymbol{\Psi}_{(0)}(\boldsymbol{\theta},X,T),\dots)(2\omega^\alpha(X,T)\Psi^j_{(0)\theta^\alpha T}+\omega^\beta_T(X,T)\Psi^j_{(0)\theta^\beta})-\dots.\end{aligned} \tag{1.11}$$

We have here

$$\frac{\partial}{\partial T}=U^\nu_T\frac{\partial}{\partial U^\nu}+\theta^\alpha_{(0)T}\frac{\partial}{\partial\theta^\alpha},\quad \frac{\partial}{\partial X}=U^\nu_X\frac{\partial}{\partial U^\nu}+\theta^\alpha_{(0)X}\frac{\partial}{\partial\theta^\alpha}$$

for the functions

$$\Psi^i_{(0)}(\boldsymbol{\theta},X,T)=\Phi^i(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T),\mathbf{U}(X,T)).$$

We will assume that k^α and ω^α can be considered (locally) as the independent parameters on the family Λ and the total family of solutions of (1.3) depends (for generic k^α, ω^α) on $N=2m+s$, $(s\geqslant 0)$ parameters U^ν and m initial phases θ^α_0.

It is easy to see that the functions $\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T),\mathbf{U}(X,T))$ and $\nabla_{\boldsymbol{\xi}}\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T),\mathbf{U}(X,T))$ where $\boldsymbol{\xi}$ is any vector in the space of parameters U^ν tangential to the surface $\mathbf{k}=\text{const}$, $\boldsymbol{\omega}=\text{const}$ belong to the kernel of the operator $\hat{L}^i_{(X,T)j}$.

Let us put now some "regularity" conditions on the family (1.2) of quasiperiodic solutions of (1.1)

Definition 1.1: We call the family (1.2) the full regular family of m-phase solutions of (1.1) if:

(1) The functions $\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{U})$, $\mathbf{\Phi}_{U^\nu}(\boldsymbol{\theta},\mathbf{U})$ *are linearly independent (almost everywhere) on the set* Λ;

(2) The $m+s$ *linearly independent functions* $\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{U})$, $\nabla_{\boldsymbol{\xi}}\mathbf{\Phi}(\boldsymbol{\theta},\mathbf{U})$ $(\nabla_{\boldsymbol{\xi}}\mathbf{k}=0,\nabla_{\boldsymbol{\xi}}\boldsymbol{\omega}=0)$ *give the full kernel of the operator* $\hat{L}^i_{[\mathbf{U}]j}$ *(here* $\boldsymbol{\theta}_0=0$*) for generic* $\mathbf{k}$ *and* $\boldsymbol{\omega}$.

(3) There are exactly $m+s$ *linearly independent "left eigen-vectors"* $\boldsymbol{\kappa}^{(q)}_{[\mathbf{U}]}(\boldsymbol{\theta})$, $q=1,\dots,m+s$ *of the operator* $\hat{L}^i_{[\mathbf{U}]j}$ *(for generic* $\mathbf{k}$ *and* $\boldsymbol{\omega}$*) corresponding to zero eigenvalues, i.e.,*

$$\int_0^{2\pi}\dots\int_0^{2\pi}\kappa^{(q)}_{[\mathbf{U}]i}(\boldsymbol{\theta})\hat{L}^i_{[\mathbf{U}]j}\psi^j(\boldsymbol{\theta})\frac{d^m\theta}{(2\pi)^m}\equiv 0$$

for any periodic $\psi^j(\boldsymbol{\theta})$.

It is not difficult to see that the Definition 1.1 is connected with the regularity properties of the submanifold Λ given by the set of functions $\mathbf{\Phi}(\boldsymbol{\theta},\mathbf{U})$ in the space of 2π-periodic functions. In fact, for our purposes we can use also the weaker definition of the full regular family of m-phase solutions of (1.1). Namely, let us represent the space of parameters $\mathbf{U}$ in the form $\mathbf{U}=(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ where $\mathbf{k}$ are the wave numbers, $\boldsymbol{\omega}$ are the frequencies of m-phase solutions, and $\mathbf{n}=(n^1,\dots,n^s)$ are some additional parameters (if they exist). Let us give now the "weak" definition of the full regular family of m-phase solutions in the form:

Definition 1.1′: We call the family Λ *the full regular family of m-phase solutions of (1.1) if*

(1) The functions $\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$, $\mathbf{\Phi}_{n^l}(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ *are linearly independent and give (for generic* $\mathbf{k}$ *and* $\boldsymbol{\omega}$*) the full basis in the kernel of the operator* $\hat{L}^i_{j[\boldsymbol{\theta}_0,\mathbf{k},\boldsymbol{\omega},\mathbf{n}]}$;

(2) The operator $\hat{L}^i_{j[\boldsymbol{\theta}_0,\mathbf{k},\boldsymbol{\omega},\mathbf{n}]}$ *has (for generic* $\mathbf{k}$ *and* $\boldsymbol{\omega}$*) exactly* $m+s$ *linearly independent "left eigenvectors"*

$$\boldsymbol{\kappa}^{(q)}_{[\mathbf{U}]}(\boldsymbol{\theta}+\boldsymbol{\theta}_0)=\boldsymbol{\kappa}^{(q)}_{[\mathbf{k},\boldsymbol{\omega},\mathbf{n}]}(\boldsymbol{\theta}+\boldsymbol{\theta}_0)$$

depending on the parameters $\mathbf{U}$ *in a smooth way and corresponding to zero eigenvalues.*

We will assume now that the system (1.1) has a full regular family of quasiperiodic m-phase solutions in strong or weak sense in all our considerations.

To find the function $\mathbf{\Psi}_{(1)}(\boldsymbol{\theta},X,T)$ we have to put now the $m+s$ conditions of orthogonality of the discrepancy $\mathbf{f}_{(1)}(\boldsymbol{\theta},X,T)$ to the functions $\boldsymbol{\kappa}^{(q)}_{[\mathbf{U}(X,T)]}(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T))$

$$\int_0^{2\pi}\dots\int_0^{2\pi}\kappa^{(q)}_{[\mathbf{U}(X,T)]i}(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T))f^i_{(1)}(\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m}=0. \tag{1.12}$$

The system (1.12) together with (1.8) gives $m+(m+s)=2m+s=N$ conditions at each X and T on the parameters of zero approximation $\mathbf{\Psi}_{(0)}(\boldsymbol{\theta},X,T)$ necessary for the construction of the first $\boldsymbol{\epsilon}$-term in the solution (1.5).

Let us prove now the following Lemma about the orthogonality conditions (1.12):

Lemma 1.1: Under all the assumptions of regularity formulated above the orthogonality conditions (1.12) do not contain the functions $\theta^\alpha_0(X,T)$ *and give just the restrictions on the functions* $U^\nu(X,T)$ *having the form*

$$C^{(q)}_\nu(\mathbf{U})U^\nu_T-D^{(q)}_\nu(\mathbf{U})U^\nu_X=0 \tag{1.13}$$

(with some functions $C^{(q)}_\nu(\mathbf{U})$, $D^{(q)}_\nu(\mathbf{U})$*).*

Proof: Let us write down the part $\mathbf{f}'_{(1)}$ of the function $\mathbf{f}_{(1)}$ which contains the derivatives $\theta^\beta_{0T}(X,T)$ and $\theta^\beta_{0X}(X,T)$. We have from (1.11)

$$f'^{\,i}_{(1)}(\boldsymbol{\theta},X,T) = -\frac{\partial F^i}{\partial \varphi^j_t}(\boldsymbol{\Psi}_{(0)},\dots)\Psi^j_{(0)\theta^\beta}\theta^\beta_{0T} - \frac{\partial F^i}{\partial \varphi^j_x}(\boldsymbol{\Psi}_{(0)},\dots)\Psi^j_{(0)\theta^\beta}\theta^\beta_{0X}$$
$$-\frac{\partial F^i}{\partial \varphi^j_{tt}}(\boldsymbol{\Psi}_{(0)},\dots)2\omega^\alpha(X,T)\Psi^j_{(0)\theta^\alpha\theta^\beta}\theta^\beta_{0T} - \frac{\partial F^i}{\partial \varphi^j_{xx}}(\boldsymbol{\Psi}_{(0)},\dots)2k^\alpha(X,T)\Psi^j_{(0)\theta^\alpha\theta^\beta}\theta^\beta_{0X} - \dots .$$

Let us choose again the set of parameters $\mathbf{U}$ in the form

$$\mathbf{U} = (k^1,\dots,k^m,\omega^1,\dots,\omega^m,n^1,\dots,n^s),$$

where k^α are the wave numbers, ω^α are the frequencies of m-phase solutions, and $(n^1,\dots,n^s)$ are additional parameters (except the initial phases).

We can write then

$$f'^{\,i}_{(1)}(\boldsymbol{\theta},X,T) = \left[-\frac{\partial}{\partial\boldsymbol{\omega}^\beta}F^i(\boldsymbol{\Phi}(\boldsymbol{\theta}+\boldsymbol{\theta}_0,\mathbf{U}),\dots) + \hat{L}^i_j\frac{\partial}{\partial\boldsymbol{\omega}^\beta}\Phi^j(\boldsymbol{\theta}+\boldsymbol{\theta}_0,\mathbf{U})\right]\theta^\beta_{0T}$$
$$+\left[-\frac{\partial}{\partial k^\beta}F^i(\boldsymbol{\Phi}(\boldsymbol{\theta}+\boldsymbol{\theta}_0,\mathbf{U}),\dots) + \hat{L}^i_j\frac{\partial}{\partial k^\beta}\Phi^j(\boldsymbol{\theta}+\boldsymbol{\theta}_0,\mathbf{U})\right]\theta^\beta_{0X}.$$

The derivatives $\partial F^i/\partial\omega^\beta$ and $\partial F^i/\partial k^\beta$ are identically zero on Λ according to (1.3). We have then

$$\int_0^{2\pi}\dots\int_0^{2\pi}\kappa^{(q)}_{[\mathbf{U}(X,T)]i}(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T))f'^{\,i}_{(1)}(\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m}\equiv 0$$

since all $\boldsymbol{\kappa}^{(q)}(\boldsymbol{\theta},X,T)$ are the left eigenvectors of $\hat{L}$ with zero eigenvalues.

It is easy to see also that all $\boldsymbol{\theta}_0(X,T)$ in the arguments of $\boldsymbol{\Phi}$ and $\boldsymbol{\kappa}^{(q)}$ will disappear after the integration with respect to $\boldsymbol{\theta}$ so we get the statement of the Lemma.

Lemma 1.1 is proved.

The system

$$\frac{\partial k^\alpha}{\partial U^\nu}U^\nu_T = \frac{\partial\omega^\alpha}{\partial U^\nu}U^\nu_X,\quad \alpha=1,\dots,m,$$
$$C^{(q)}_\nu(\mathbf{U})U^\nu_T = D^{(q)}_\nu(\mathbf{U})U^\nu_X,\quad q=1,\dots,m+s \tag{1.14}$$

is called the Whitham system for the m-phase solutions of system (1.1).

Let us note that we have rank $\|\partial k^\alpha/\partial U^\nu\| = m$ according to our assumption above. In the generic case the derivatives U^ν_T can be expressed through U^μ_X and the Whitham system (1.14) can be written in the form

$$U^\nu_T = V^\nu_\mu(\mathbf{U})U^\mu_X,\quad \nu,\mu=1,\dots,N, \tag{1.15}$$

where $V^\nu_\mu(U)$ is some $N\times N$ matrix depending on the variables $U^1,\dots,U^N$.

Let us say that quite often the system (1.1) can be written in the evolution form

$$\varphi^i_t = Q^i(\boldsymbol{\varphi},\boldsymbol{\varphi}_x,\boldsymbol{\varphi}_{xx},\dots). \tag{1.16}$$

For systems (1.16) the form (1.15) of the corresponding Whitham system has then a natural motivation.

We will assume here that if the conditions (1.14) are satisfied then the system (1.9) is resolvable on the space of 2π-periodic with respect to each θ^α function. The solution $\boldsymbol{\Psi}_{(1)}(\boldsymbol{\theta},X,T)$ is

defined then modulo a linear combination of the "right eigenfunctions" of $\hat{L}^i_{(X,T)j}$ $(\boldsymbol{\Psi}_{(0)\theta^\alpha}, \boldsymbol{\Psi}_{(0)n^l})$ introduced above. According to common approach[4,12] we can try to use the corresponding coefficients to make the systems analogous to (1.9) resolvable in the next orders and try to find recursively all the terms of series (1.5).

Different aspects and numerous applications of the Whitham method were studied in many different works[1–51] (we apologize for the impossibility to give here the full list of numerous works on the Whitham method) and the Whitham method is considered now as one of the classical methods of investigation of nonlinear systems.

It was pointed out by G. Whitham[1–3] that the Whitham system (1.14) has a local Lagrangian structure in case when the initial system has a local Lagrangian structure

$$\delta \int \int \mathcal{L}(\boldsymbol{\varphi}, \boldsymbol{\varphi}_t, \boldsymbol{\varphi}_x, \ldots)\mathrm{d}x\, \mathrm{d}t = 0$$

on the space $\{\boldsymbol{\varphi}(x,t)\}$.

The procedure of construction of Lagrangian formalism for the Whitham system (1.14) is given by the averaging of the Lagrangian function $\mathcal{L}$ on the family of m-phase solutions of system (1.1).[1–3] Let us note also that in the case of the presence of additional parameters n^l the additional method of Whitham pseudophases should be used.

The important procedure of averaging of local field-theoretical Hamiltonian structures was suggested by B. A. Dubrovin and S. P. Novikov.[14,18,28,32] The Dubrovin-Novikov procedure gives the local field-theoretical Hamiltonian formalism for the Whitham system (1.15) in the case when the initial system (1.16) has a local Hamiltonian formalism of general type. The Dubrovin-Novikov bracket for the Whitham system has a general form

$$\{U^\nu(X), U^\mu(Y)\} = g^{\nu\mu}(\mathbf{U})\delta'(X-Y) + b^{\nu\mu}_\lambda(\mathbf{U})U^\lambda_X\delta(X-Y) \tag{1.17}$$

and was called the local Poisson bracket of hydrodynamic type. The theory of the brackets (1.17) is closely related with differential geometry[14,28,32] and is connected with different coordinate systems in the (pseudo) Euclidean spaces. Let us say also that during the last years the important weakly nonlocal generalizations of Dubrovin-Novikov brackets (Mokhov-Ferapontov bracket and Ferapontov brackets) were introduced and studied.[53–59]

The Hamiltonian structure (1.17) for the systems (1.15) has a direct relation to the integrability of the systems of this class. Thus it was conjectured by S. P. Novikov that any diagonalizable system (1.15) Hamiltonian with respect to the bracket of hydrodynamic type is integrable. The conjecture of S. P. Novikov was proved by S. P. Tsarev,[52] who suggested the "generalized Hodograph method" for solving the diagonal Hamiltonian systems (1.15). Let us say that the Tsarev method has become especially important for the Whitham systems corresponding to integrable hierarchies and provided a lot of very important solutions for such systems in different cases. We note here that the Whitham systems of integrable hierarchies can usually be written in diagonal form[3,11,25] and admit the (multi-) Hamiltonian structures given by the averaging of the Lagrangian or the field-theoretical Hamiltonian structures of the initial system.

During the last years the theory of compatible Poisson brackets (1.17) and their deformations in connection with Quantum Field Theory was intensively developed.[60–72] Namely, the theory of compatible Poisson brackets (1.17) plays the main role in the theory of "Frobenius manifolds" constructed by B. A. Dubrovin and connected with the classification of the topological quantum field theories (based on the Witten-Dijkgraaf-Verlinde-Verlinde equation). Every "Frobenius manifold" is connected also with the integrable hierarchy of hydrodynamic type

$$U^\nu_{t_s} = V^\nu_{(s)\mu}(\mathbf{U})U^\mu_X \tag{1.18}$$

having the bi-Hamiltonian structure in Dubrovin-Novikov sense with a pair of Poisson brackets (1.17). [The hierarchy (1.18) and the corresponding pair of Poisson brackets also possess some additional properties (the existence of "unit vector field," Euler field, τ-symmetry, etc.)]

The "ϵ-deformations" of the integrable hierarchies and the Poisson brackets (1.17) are connected with the "higher" corrections in the quantum field theories and are being intensively investigated now.[64–72] According to B. A. Dubrovin and Y. Zhang the ϵ-deformation of Frobenius manifold is given by the infinite series polynomial with respect to derivatives $\mathbf{U}_X, \mathbf{U}_{XX}, \mathbf{U}_{XXX}, \ldots$ and representing the "small dispersion" deformation of the hierarchy (1.18) and the corresponding bi-Hamiltonian structure of hydrodynamic type. The deformed hierarchy and bi-Hamiltonian structure should possess also the additional properties of Frobenius manifolds ("unit vector field," Euler field, τ-symmetry etc.,…) and give then the "deformation" of the corresponding Frobenius manifold.[64,66,68] The general problem of classification of deformations of bi-Hamiltonian hierarchies (1.18) is being also intensively studied by now and very important results were obtained recently in this area.[67–72]

The dispersive corrections to the Whitham systems were first considered by M. Y. Ablowitz and D. J. Benney (see Ref. 5, also Refs. 6 and 7) where the first consideration of multiphase Whitham method was also made. As was shown in Ref. 5 the dispersive corrections to Whitham systems can naturally arise and, besides that, can be generalized to the multiphase situation.

In this paper we will consider the deformations of the Whitham systems (1.15) having Dubrovin-Zhang form, i.e., the dispersive corrections to (1.15) containing the higher X-derivatives of the parameters $\mathbf{U}$. The problem in this form is connected with the problem set by B. A. Dubrovin, which is formulated as the problem of deformations of Frobenius manifolds corresponding to the Whitham systems of integrable hierarchies. B. A. Dubrovin problem contains both the problem of deformation of Whitham systems (1.15) and the corresponding bi-Hamiltonian structures of hydrodynamic type giving the dispersive corrections to these structures.

We will consider here the first part of the B. A. Dubrovin problem and suggest a general scheme of recursive construction of terms of the deformation of the Whitham system (1.15) using the initial system (1.1) or (1.16). The second part of the B. A. Dubrovin problem will then be considered in the next paper. We will not require, however, the "integrability" of the system (1.15) and all the considerations below can be applicable for both integrable and nonintegrable systems (1.1) and (1.16). Thus, we do not require also the bi-Hamiltonian property of the Whitham system (1.15).

In the next section we will make more detailed investigation of the asymptotic series (1.5) and describe the construction of the deformation procedure for general Whitham systems.

II. THE DEFORMATION OF THE WHITHAM SYSTEMS

Let us start again with the description of the construction of asymptotic series (1.5) connected with the Whitham method. We will assume that we have the initial system having the general form (1.1) which has an N-parametric (modulo the initial phases θ_0^α) family of m-phase solutions

$$\varphi^i(x,t) = \Phi^i(\mathbf{k}(\mathbf{U})x + \boldsymbol{\omega}(\mathbf{U})t + \boldsymbol{\theta}_0, \mathbf{U}) \tag{2.1}$$

with the functions $\boldsymbol{\Phi}(\boldsymbol{\theta}, \mathbf{U})$ satisfying the system

$$F^i(\boldsymbol{\Phi}, \omega^\alpha(\mathbf{U})\boldsymbol{\Phi}_{\theta^\alpha}, k^\beta(\mathbf{U})\boldsymbol{\Phi}_{\theta\beta}, \omega^\gamma(\mathbf{U})\omega^\delta(\mathbf{U})\boldsymbol{\Phi}_{\theta\gamma\theta\delta}, \ldots) = 0 \tag{2.2}$$

(and 2π-periodic with respect to all θ^α).

The choice of the functions $\Phi^i(\boldsymbol{\theta}, \mathbf{U})$ at each $\mathbf{U}$ is defined modulo the initial phase $\boldsymbol{\theta}_0$ and the full family of solutions of (2.2) is given by all the functions $\boldsymbol{\Phi}(\boldsymbol{\theta}+\boldsymbol{\theta}_0, \mathbf{U})$ with arbitrary $\boldsymbol{\theta}_0 = (\theta_0^1, \ldots, \theta_0^m)$. We will just assume here that the choice of $\Phi^i(\boldsymbol{\theta}, \mathbf{U})$ is smooth on the family of m-phase solutions Λ.

We will assume also that the parameters $(\mathbf{k}, \boldsymbol{\omega})$ are independent on the family Λ such that $N \geqslant 2m$. It will be convenient to use the parameters $(k^1, \ldots, k^m, \omega^1, \ldots, \omega^m, n^1, \ldots, n^s)$ on the family Λ where k^α are the "wave numbers," ω^α are frequencies, and $(n^1, \ldots, n^s)$ are additional parameters (if they present). The linearly independent solutions of the linearized system (2.2) will then be given by $m+s$ functions $\boldsymbol{\Phi}_{\theta^\alpha}(\boldsymbol{\theta}, \mathbf{U})$, $\boldsymbol{\Phi}_{n^l}(\boldsymbol{\theta}, \mathbf{U})$.

As we already said above we assume that the family Λ represents the "full regular family" of m-phase solutions of (2.3) such that the requirements formulated in Definition 1.1 or Definition 1.1′ are satisfied. We thus have exactly $m+s$ functions $\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{U})$, $\mathbf{\Phi}_{n^l}(\boldsymbol{\theta},\mathbf{U})$ giving the basis in the kernel of linearized system (2.2) and exactly $m+s$ linearly independent functions $\boldsymbol{\kappa}^{(q)}_{[\mathbf{U}]}(\boldsymbol{\theta}+\boldsymbol{\theta}_0)$ giving the basis in the kernel of the adjoint operator (for generic $\mathbf{k}$, $\boldsymbol{\omega}$) and depending in a smooth way on the parameters $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$.

As we mentioned already we make a rescaling of coordinates $X=\epsilon x$, $T=\epsilon t$ and try to find the solutions of system

$$F^i(\boldsymbol{\varphi},\epsilon\boldsymbol{\varphi}_T,\epsilon\boldsymbol{\varphi}_X,\epsilon^2\boldsymbol{\varphi}_{TT},\epsilon^2\boldsymbol{\varphi}_{XT},\epsilon^2\boldsymbol{\varphi}_{XX},\dots)=0,\quad i=1,\dots,n \tag{2.3}$$

having the form

$$\phi^i(\boldsymbol{\theta},X,T,\epsilon)=\Psi^i\left(\frac{\mathbf{S}(X,T)}{\epsilon}+\boldsymbol{\theta},X,T,\epsilon\right), \tag{2.4}$$

$$\Psi^i(\boldsymbol{\theta},X,T,\epsilon)=\sum_{k\geqslant 0}\Psi^i_{(k)}(\boldsymbol{\theta},X,T)\epsilon^k. \tag{2.5}$$

The function $\mathbf{\Psi}_{(0)}(\boldsymbol{\theta},X,T)$ belongs to the family Λ at every fixed X and T,

$$\Psi^i_{(0)}(\boldsymbol{\theta},X,T)=\Phi^i(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T),\mathbf{k}(X,T),\boldsymbol{\omega}(X,T),\mathbf{n}(X,T)), \tag{2.6}$$

and the compatibility conditions (1.12) for the system

$$\hat{L}^i_j\Psi^j_{(1)}(\boldsymbol{\theta},X,T)=f^i_{(1)}(\boldsymbol{\theta},X,T) \tag{2.7}$$

give the Whitham system (1.13) on the parameters $\mathbf{U}(X,T)$ of the zero approximation. The function $\mathbf{\Psi}_{(1)}(\boldsymbol{\theta},X,T)$ is defined from the system (2.7) modulo the linear combination of functions $\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{U})$, $\mathbf{\Phi}_{n^l}(\boldsymbol{\theta},\mathbf{U})$ at every X and T.

All the other approximations $\mathbf{\Psi}_{(k)}(\boldsymbol{\theta},X,T)$ satisfy the linear systems

$$\hat{L}^i_j\Psi^j_{(k)}(\boldsymbol{\theta},X,T)=f^i_{(k)}(\boldsymbol{\theta},X,T), \tag{2.8}$$

where the functions $\mathbf{f}_{(k)}(\boldsymbol{\theta},X,T)$ represent the higher order discrepancies given by system (2.3).

The compatibility conditions of the systems (2.8) ($k\geqslant 2$) give the restrictions on the "initial phases" θ^α_0 of the zero approximation and on the previous corrections $\mathbf{\Psi}_{(k')}(\boldsymbol{\theta},X,T)$.

Let us make now one more general assumption about the systems (2.7) and (2.8). Namely we omit here the special investigation of the solvability of systems (2.7) and (2.8) on the space of 2π-periodic functions and assume that the orthogonality conditions

$$\int_0^{2\pi}\dots\int_0^{2\pi}\kappa^{(q)}_{[\mathbf{U}(X,T)]_i}(\boldsymbol{\theta}+\boldsymbol{\theta}_0(X,T))f^i_{(k)}(\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m}=0 \tag{2.9}$$

give the necessary and sufficient conditions of solvability of these systems. So, we will assume that under the conditions (2.9) we can always find a smooth 2π-periodic solution of (2.7) and (2.8) defined modulo the linear combination

$$\sum_{\alpha=1}^{m}c^\alpha_{(k)}(X,T)\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta},X,T)+\sum_{l=1}^{s}d^l_{(k)}(X,T)\mathbf{\Phi}_{n^l}(\boldsymbol{\theta},X,T). \tag{2.10}$$

Let us consider now the construction of the asymptotic series (2.5). We note first that the solution $\mathbf{\Psi}_{(k)}(\boldsymbol{\theta},X,T)$ is defined from the system (2.8) modulo the linear combination (2.10) which is equivalent in the main order to the addition of the values $\epsilon^{k+1}c^\alpha_{(k)}(X,T)$ to the phases $S^\alpha(X,T)$ of

the zero approximation $\mathbf{\Psi}_{(0)}(\boldsymbol{\theta},X,T)$ and to the addition of the values $\epsilon^k d^l_{(k)}(X,T)$ to the parameters $n^l(X,T)$ of $\mathbf{\Psi}_{(0)}(\boldsymbol{\theta},X,T)$ according to the formulas (2.4) and (2.5). It is easy to see also that we can add the values $\epsilon^{k+1}c^\alpha_{(k)X}(X,T)$ and $\epsilon^{k+1}c^\alpha_{(k)T}(X,T)$ to the parameters k^α and ω^α in the **U**-dependence of $\mathbf{\Psi}_{(0)}(\boldsymbol{\theta},X,T)$ which does not affect the kth order of ϵ in the series (2.5).

Let us change now the procedure of construction of series (2.5) in the following way:

(1) At every step k we choose the solution $\mathbf{\Psi}_{(k)}(\boldsymbol{\theta},X,T)$ in arbitrary way;

(2) We allow the regular ϵ-dependence

$$S^\alpha(X,T,\epsilon)=\sum_{k\geqslant 0} S^\alpha_{(k)}(X,T)\epsilon^k,$$

$$n^l(X,T,\epsilon)=\sum_{k\geqslant 0} n^l_{(k)}(X,T)\epsilon^k$$

of the phases S^α and the parameters $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ of the zero approximation $\mathbf{\Psi}_{(0)}(\boldsymbol{\theta},X,T)$ such that

$$k^\alpha(X,T,\epsilon)=S^\alpha_X(X,T,\epsilon),\quad \omega^\alpha(X,T,\epsilon)=S^\alpha_T(X,T,\epsilon)$$

(3) We use the higher orders $S^\alpha_{(k)}$, $n^l_{(k)}$ of the functions $S^\alpha(X,T,\epsilon)$, $n^l(X,T,\epsilon)$ to provide the orthogonality conditions (2.9) for the systems (2.8).

We can now write the asymptotic solution of (2.3) in the form

$$\phi^i(\boldsymbol{\theta},X,T,\epsilon)=\Phi^i\left(\frac{\mathbf{S}(X,T,\epsilon)}{\epsilon}+\boldsymbol{\theta},\mathbf{S}_X(X,T,\epsilon),\mathbf{S}_T(X,T,\epsilon),\mathbf{n}(X,T,\epsilon)\right)+\sum_{k\geqslant 1}\tilde{\Psi}^i_{(k)}\left(\frac{\mathbf{S}(X,T,\epsilon)}{\epsilon}+\boldsymbol{\theta},X,T\right)\epsilon^k. \tag{2.11}$$

Let us note that the phase shift $\boldsymbol{\theta}_0(X,T)$ of the initial approximation now becomes the ϵ-term in ϵ-expansion of the function $\mathbf{S}(X,T,\epsilon)$.

It is not difficult to see that the series (2.11) can be always represented in the form (2.4) and (2.5) and give the same set of the asymptotic solutions of system (2.3). However, the series (2.11) contains a big "renormalization freedom" since we can change in arbitrary way the higher orders corrections $\mathbf{S}_{(2)}(X,T)$, $\mathbf{S}_{(3)}(X,T),\ldots$, $\mathbf{n}_{(1)}(X,T)$, $\mathbf{n}_{(2)}(X,T),\ldots$ and then adjust the functions $\tilde{\mathbf{\Psi}}_{(k)}$ in the appropriate way.

Let us now "fix the normalization" of the solution (2.11) in the following way.

We require that the first term

$$\Phi^i\left(\frac{\mathbf{S}(X,T,\epsilon)}{\epsilon}+\boldsymbol{\theta},\mathbf{S}_X(X,T,\epsilon),\mathbf{S}_T(X,T,\epsilon),\mathbf{n}(X,T,\epsilon)\right)$$

of (2.11) gives "the best approximation" of the asymptotic solution (2.11) by the modulated m-phase solution of (1.1). To be more precise, we require that the rest of the series (2.11) is orthogonal (at every X and T) to the vectors $\mathbf{\Phi}_{\theta^\alpha}(\boldsymbol{\theta},X,T)$, $\mathbf{\Phi}_{n^l}(\boldsymbol{\theta},X,T)$ "tangent" to Λ at the "point" $[\mathbf{S}(X,T,\epsilon),\mathbf{n}(X,T,\epsilon)]$.

Thus we will now put the conditions

$$\int_0^{2\pi}\cdots\int_0^{2\pi}\sum_{i=1}^n \Phi^i_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{S}_X,\mathbf{S}_T,\mathbf{n})\left[\sum_{k=1}^\infty \tilde{\Psi}^i_{(k)}(\boldsymbol{\theta},X,T)\epsilon^k\right]\frac{d^m\theta}{(2\pi)^m}=0, \tag{2.12}$$

$$\int_0^{2\pi}\cdots\int_0^{2\pi}\sum_{i=1}^n \Phi^i_{n^l}(\boldsymbol{\theta},\mathbf{S}_X,\mathbf{S}_T,\mathbf{n})\left[\sum_{k=1}^\infty \tilde{\Psi}^i_{(k)}(\boldsymbol{\theta},X,T)\epsilon^k\right]\frac{d^m\theta}{(2\pi)^m}=0 \tag{2.13}$$

(for all ϵ).

The representation (2.6) defines in fact the first correction $\mathbf{S}_{(1)}=\boldsymbol{\theta}_{(0)}(X,T)$. As we saw above, the functions $\tilde{\boldsymbol{\Psi}}_{(k)}(\boldsymbol{\theta},X,T)$ are defined modulo the linear combinations of the functions $\boldsymbol{\Phi}_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})$, $\boldsymbol{\Phi}_{n^l}(\boldsymbol{\theta},\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})$ which are linearly independent for the full regular family of m-phase solutions of (1.1). Using this fact it is not difficult to prove that the conditions (2.12) and (2.13) fix uniquely all the terms $\mathbf{S}_{(k+1)}$, $\mathbf{n}_{(k)}$, and $\tilde{\boldsymbol{\Psi}}_{(k)}(\boldsymbol{\theta},X,T)$ $(k\geqslant 1)$ for a given solution (2.4) and (2.5) which gives then the representation (2.11).

Let us say now that the choice of the normalization (2.12) and (2.13) is not unique. In particular, it depends on the choice of the variables $\varphi^i(x,t)$ for the "vector" $(i>1)$ systems (1.1). We will speak about the normalization (2.12) and (2.13) as about one possible way to fix the functions $\tilde{\boldsymbol{\Psi}}_{(k)}(\boldsymbol{\theta},X,T)$.

The solution $\phi(\boldsymbol{\theta},X,T)$ can now be defined as the asymptotic solution of the system (2.3) having the form (2.11) which satisfies the conditions

$$\int_0^{2\pi}\cdots\int_0^{2\pi}\sum_{i=1}^{n}\Phi^i_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{S}_X,\mathbf{S}_T,\mathbf{n})\phi^i\left(\boldsymbol{\theta}-\frac{\mathbf{S}}{\epsilon},X,T,\epsilon\right)\frac{d^m\theta}{(2\pi)^m}=0,$$

$$\int_0^{2\pi}\cdots\int_0^{2\pi}\sum_{i=1}^{n}\Phi^i_{n^l}(\boldsymbol{\theta},\mathbf{S}_X,\mathbf{S}_T,\mathbf{n})\left[\phi^i\left(\boldsymbol{\theta}-\frac{\mathbf{S}}{\epsilon},X,T,\epsilon\right)-\Phi^i(\boldsymbol{\theta},\mathbf{S}_X,\mathbf{S}_T,\mathbf{n})\right]\frac{d^m\theta}{(2\pi)^m}=0$$

(for all ϵ).

To find a solution in the form (2.11) we substitute the series (2.11) in the system (2.3) and try to find the functions $\tilde{\Psi}^i_{(k)}(\boldsymbol{\theta},X,T)$ from the linear systems

$$\hat{L}^i_{j[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]}\tilde{\Psi}^j_{(k)}(\boldsymbol{\theta},X,T)=\tilde{f}^i_{(k)}(\theta,X,T) \tag{2.14}$$

analogous to (2.8).

The functions $\tilde{f}^i_{(k)}(\boldsymbol{\theta},X,T)$ are different from the functions $f^i_{(k)}(\boldsymbol{\theta},X,T)$ since we included "a part of ϵ-dependence" in the first term of (2.11). The functions $\tilde{\mathbf{f}}_{(k)}(\boldsymbol{\theta},X,T)$ should be orthogonal to the functions $\kappa^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]}(\boldsymbol{\theta},X,T)$, $q=1,\ldots,m+s$ and we use the conditions (2.12) and (2.13) for the recurrent determination of $\tilde{\boldsymbol{\Psi}}_{(k)}(\boldsymbol{\theta},X,T)$. The functions $S^\alpha_{(k)}(X,T)$, $n^l_{(k)}(X,T)$ are used now to provide the resolvability of the systems (2.14) in all orders of ϵ.

Let us investigate now the systems arising on the functions $\mathbf{S}_{(0)}(X,T)$, $\mathbf{S}_{(1)}(X,T),\ldots$, $\mathbf{n}_{(0)}(X,T)$, $\mathbf{n}_{(1)}(X,T),\ldots$. Let us note that we have in our notations $\mathbf{S}(X,T)=\mathbf{S}_{(0)}(X,T)$, $\boldsymbol{\theta}_0(X,T)=\mathbf{S}_{(1)}(X,T)$. We saw in Lemma 1.1 that the function $\boldsymbol{\theta}_0(X,T)$ does not appear in the solvability conditions of the system (1.9). For the asymptotic solution written in the form (2.11) with the normalization conditions (2.12) and (2.13) we can prove here even stronger statement.

Lemma 2.1: The functions $S^\alpha_{(k)}(X,T)$, $n^l_{(k)}(X,T)$ do not appear in the expression for the discrepancy $\tilde{\mathbf{f}}_{(k)}(\boldsymbol{\theta},X,T)$ and do not affect the solution $\tilde{\boldsymbol{\Psi}}_{(k)}(\boldsymbol{\theta},X,T)$.

Proof: The way we get the discrepancy $\tilde{\mathbf{f}}_{(k)}(\boldsymbol{\theta},X,T)$ can be described as follows:

(1) We substitute the solution (2.11) in the system (2.3);

(2) After "making all differentiations" we can omit the argument shift $\mathbf{S}(X,T,\epsilon)/\epsilon$ in all functions depending on $\boldsymbol{\theta}$;

(3) Then collecting together all the terms of order ϵ^k we get the system (2.14).

It is not difficult to see that in this approach the kth order of ϵ containing the functions $\mathbf{S}_{(k)}(X,T)$ or $\mathbf{n}_{(k)}(X,T)$ have the form

$$\frac{\mathrm{d}F^i}{\mathrm{d}k^\alpha}S^\alpha_{(k)X},\quad \frac{\mathrm{d}F^i}{\mathrm{d}\omega^\alpha}S^\alpha_{(k)T}\quad \frac{\mathrm{d}F^i}{\mathrm{d}n^l}n^l_{(k)},$$

where F^i are the constraints (2.2) defining the m-phase solutions of (1.1). The derivatives $\mathrm{d}/\mathrm{d}k^\alpha$, $\mathrm{d}/\mathrm{d}\omega^\alpha$, $\mathrm{d}/\mathrm{d}n^l$ here are the total derivatives including the dependence of the functions $\Phi^i(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ on the corresponding parameters view the form of (2.11). However, all these derivatives are identically equal to zero on the family Λ, so we get the first part of the Lemma. To finish the proof we have to note also that the values $\mathbf{S}_{(k)}(X,T)$, $\mathbf{n}_{(k)}(X,T)$ do not appear in the kth order of $\boldsymbol{\epsilon}$ of the normalization conditions (2.12) and (2.13) either.

Lemma 2.1 is proved.

We can now formulate the procedure in the following form:

We try to solve the systems (2.14) recursively in all orders and find the functions $\widetilde{\boldsymbol{\Psi}}_{(k)}(\boldsymbol{\theta},X,T)$ satisfying the conditions (2.12) and (2.13). At each kth step of our procedure we get a system on the functions $\mathbf{S}_{(k-1)}(X,T)$, $\mathbf{n}_{(k-1)}(X,T)$ from the solvability conditions of (2.14). The full set of Whitham solutions will then be parametrized by the set of all functions $\{\mathbf{S}_{(k)}(X,T),\mathbf{n}_{(k)}(X,T)\}$, $k\geqslant 0$ satisfying the conditions of solvability of systems (2.14).

Now let us investigate the systems arising on the functions $\mathbf{S}_{(k-1)}(X,T)$, $\mathbf{n}_{(k-1)}(X,T)$ from the solvability conditions of (2.14)

$$\int_0^{2\pi}\cdots\int_0^{2\pi}\kappa^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]i}(\boldsymbol{\theta},X,T)\widetilde{f}^i_{(k)}(\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m}\equiv 0,\quad q=1,\ldots,m+s \tag{2.15}$$

in the kth order of $\boldsymbol{\epsilon}$. We note first that the solvability conditions of (2.14) for $k=1$ give a nonlinear system on the functions $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$. It is not difficult to prove the following Lemma:

Lemma 2.2: The system arising for $k=1$ coincides with the Whitham system for the functions $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$.

Proof: Indeed, using Lemma 2.1 it is not difficult to see that the discrepancy $\mathbf{f}_{(1)}(\boldsymbol{\theta},X,T)$ differs from $\widetilde{\mathbf{f}}_{(1)}(\boldsymbol{\theta},X,T)$ just by the terms containing derivatives $\boldsymbol{\theta}_{0X}$ and $\boldsymbol{\theta}_{0T}$. However, according to Lemma 1.1 these terms do not affect the orthogonality conditions (1.12) which then coincide with orthogonality conditions for $\widetilde{\mathbf{f}}_{(1)}(\boldsymbol{\theta},X,T)$.

Lemma 2.2 is proved.

The Whitham system (orthogonality conditions) for the functions $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$ can be written in the following general form:

$$\begin{aligned}
W^{(q)}[\mathbf{S}_{(0)},\mathbf{n}_{(0)}](X,T) &\equiv \langle\boldsymbol{\kappa}^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]}\cdot\widetilde{\mathbf{f}}_{(1)}[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]\rangle(X,T)\\
&=\int_0^{2\pi}\cdots\int_0^{2\pi}\kappa^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]i}(\boldsymbol{\theta},X,T)\widetilde{f}^i_{(1)}[\mathbf{S}_{(0)},\mathbf{n}_{(0)}](\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m}\\
&=A^{(q)}_\alpha(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})S^\alpha_{(0)TT}\\
&\quad+B^{(q)}_\alpha(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})S^\alpha_{(0)XT}+C^{(q)}_\alpha(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})S^\alpha_{(0)XX}\\
&\quad+G^{(q)}_l(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})n^l_{(0)T}+H^{(q)}_l(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})n^l_{(0)X}=0
\end{aligned}\tag{2.16}$$

with some functions $A^{(q)}_\alpha$, $B^{(q)}_\alpha$, $C^{(q)}_\alpha$, $G^{(q)}_l$, $H^{(q)}_l$, $q=1,\ldots,m+s$, $\alpha=1,\ldots,m$, $l=1,\ldots,s$.

Let us prove now the following Lemma about the systems on $\mathbf{S}_{(k)}$, $\mathbf{n}_{(k)}$, $k\geqslant 1$.

Lemma 2.3: The orthogonality conditions of $\widetilde{\mathbf{f}}_{(k+1)}(\boldsymbol{\theta},X,T)$ to the functions $\boldsymbol{\kappa}^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]}$ give the following linear systems for the functions $\mathbf{S}_{(k)}(X,T)$, $\mathbf{n}_{(k)}(X,T)$, $k\geqslant 1$:

$$\int\int \frac{\delta W^{(q)}(X,T)}{\delta S^{\alpha}_{(0)}(X',T')} S^{\alpha}_{(k)}(X',T')dX'dT' + \int\int \frac{\delta W^{(q)}(X,T)}{\delta n^{l}_{(0)}(X',T')} n^{l}_{(k)}(X',T')\mathrm{d}X'\mathrm{d}T'$$
$$= V^{(q)}_{(k)}[\mathbf{S}_{(0)},\ldots,\mathbf{S}_{(k-1)},\mathbf{n}_{(0)},\ldots,\mathbf{n}_{(k-1)}](X,T),$$

where

$$\frac{\delta W^{(q)}(X,T)}{\delta S^{\alpha}_{(0)}(X',T')} = \frac{\partial W^{(q)}}{\partial S^{\alpha}_{(0)T}}\delta'(T-T')\delta(X-X') + \frac{\partial W^{(q)}}{\partial S^{\alpha}_{(0)X}}\delta(T-T')\delta'(X-X')$$
$$+ \frac{\partial W^{(q)}}{\partial S^{\alpha}_{(0)TT}}\delta''(T-T')\delta(X-X') + \frac{\partial W^{(q)}}{\partial S^{\alpha}_{(0)XT}}\delta'(T-T')\delta'(X-X') + \frac{\partial W^{(q)}}{\partial S^{\alpha}_{(0)XX}}\delta(T-T')\delta''(X-X'),$$

$$\frac{\delta W^{(q)}(X,T)}{\delta n^{l}_{(0)}(X',T')} = \frac{\partial W^{(q)}}{\partial n^{l}_{(0)}}\delta(T-T')\delta(X-X') + \frac{\partial W^{(q)}}{\partial n^{l}_{(0)T}}\delta'(T-T')\delta(X-X') + \frac{\partial W^{(q)}}{\partial n^{l}_{(0)X}}\delta(T-T')\delta'(X-X').$$

In other words, the functions $\mathbf{S}_{(k)}(X,T)$, $\mathbf{n}_{(k)}(X,T)$ satisfy the linearized Whitham system on the functions $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$ with additional right-hand part depending on the functions $\mathbf{S}_{(0)},\ldots,\mathbf{S}_{(k-1)}$, $\mathbf{n}_{(0)},\ldots,\mathbf{n}_{(k-1)}$.

Proof: Let us look at the terms in $\widetilde{\mathbf{f}}_{(k+1)}(\boldsymbol{\theta},X,T)$ which contain the functions $\mathbf{S}_{(k)}(X,T)$, $\mathbf{n}_{(k)}(X,T)$:

(1) As we proved in Lemma 2.1 the functions $\widetilde{f}^{i}_{(1)}(\boldsymbol{\theta},X,T)$ contain only the terms depending on $\mathbf{S}_{(0)}$, $\mathbf{n}_{(0)}$. It is easy to see that the functions $\widetilde{f}^{i}_{(k+1)}(\boldsymbol{\theta},X,T)$ will then contain the terms

$$\int\int \frac{\delta\widetilde{f}^{i}_{(1)}(\boldsymbol{\theta},X,T)}{\delta S^{\alpha}_{(0)}(X',T')} S^{\alpha}_{(k)}(X',T')\mathrm{d}X'\,\mathrm{d}T' + \int\int \frac{\delta\widetilde{f}^{i}_{(1)}(\boldsymbol{\theta},X,T)}{\delta n^{l}_{(0)}(X',T')} n^{l}_{(k)}(X',T')\mathrm{d}X'\,\mathrm{d}T'$$

according to the form of the first term in (2.11).

(2) There are terms containing the functions $\mathbf{S}_{(k)}$, $\mathbf{n}_{(k)}$ and the function $\widetilde{\boldsymbol{\Psi}}_{(1)}(\boldsymbol{\theta},X,T)$. All such terms can be written in the form:

$$-\int\int\left[S^{\alpha}_{(k)}(X',T')\frac{\delta\hat{L}^{i}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]j}(X,T)}{\delta S^{\alpha}_{(0)}(X',T')} + n^{l}_{(k)}(X',T')\frac{\delta\hat{L}^{i}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]j}(X,T)}{\delta n^{l}_{(0)}(X',T')}\right]\widetilde{\Psi}^{j}_{(1)}(\boldsymbol{\theta},X,T)\mathrm{d}X'\,\mathrm{d}T',$$

where $\hat{L}^{i}_{j[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]}$ is the linear operator (1.10) given by the linearization of the system (2.2) on the family of m-phase solutions.

(3) There are terms of the form

$$-\int\ldots\int\frac{\delta^{2}F^{i}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]}(\boldsymbol{\theta},X,T)}{\delta S^{\alpha}_{(0)}(X',T')\,\delta S^{\beta}_{(0)}(X'',T'')} S^{\alpha}_{(k)}(X',T')S^{\beta}_{(1)}(X'',T'')\mathrm{d}X'\,\mathrm{d}T'\,\mathrm{d}X''\,\mathrm{d}T'' - \cdots,$$

where $F^{i}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]}(\boldsymbol{\theta},X,T)$ is the left-hand part of the system (2.2).

However, the sum of all such terms is equal to zero since they all correspond to the expansion of the "shift of parameters" $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$ on the family Λ where we have $F^{i}(\boldsymbol{\theta},X,T)\equiv 0$ identically.

Let us look now at the terms in the orthogonality conditions

$$\int_{0}^{2\pi}\ldots\int_{0}^{2\pi}\kappa^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]i}(\boldsymbol{\theta},X,T)\widetilde{f}^{i}_{(k+1)}(\boldsymbol{\theta},X,T)\frac{d^{m}\theta}{(2\pi)^{m}} = 0 \tag{2.17}$$

containing the terms (1) and (2).

We have identically

$$\int_0^{2\pi} \cdots \int_0^{2\pi} \kappa^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]i}(\boldsymbol{\theta},X,T) L^i_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]j}(\boldsymbol{\theta},\boldsymbol{\theta}',X,T)\frac{d^m\theta}{(2\pi)^m} \equiv 0 \tag{2.18}$$

on Λ (where $L^i_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]j}(\boldsymbol{\theta},\boldsymbol{\theta}',X,T)$ is the "core" of the operator $\hat{L}^i_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]j}(X,T)$).

It is easy to see then that the inner product of $\boldsymbol{\kappa}^{(q)}$ with the terms (2) is equal to

$$\int_0^{2\pi} \cdots \int_0^{2\pi} \int\int \left[S^\alpha_{(k)}(X',T')\frac{\delta\kappa^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]i}(\boldsymbol{\theta},X,T)}{\delta S^\alpha_{(0)}(X',T')} + n^l_{(k)}(X',T')\frac{\delta\kappa^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]i}(\boldsymbol{\theta},X,T)}{\delta n^l_{(0)}(X',T')}\right] \mathrm{d}X'\,\mathrm{d}T'$$

$$\times \hat{L}^i_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]j}(X,T)\tilde{\Psi}^j_{(1)}(\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m}.$$

It is not difficult to see now that the terms of orthogonality conditions containing the terms (1) and (2) can be written together in the form

$$\int\int S^\alpha_{(k)}(X',T')\frac{\delta}{\delta S^\alpha_{(0)}(X',T')}\langle \boldsymbol{\kappa}^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]} \cdot \tilde{\mathbf{f}}_{(1)}[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]\rangle(X,T)\mathrm{d}X'\,\mathrm{d}T'$$

$$+ \int\int n^l_{(k)}(X',T')\frac{\delta}{\delta n^l_{(0)}(X',T')}\langle \boldsymbol{\kappa}^{(q)}_{[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]} \cdot \tilde{\mathbf{f}}_{(1)}[\mathbf{S}_{(0)},\mathbf{n}_{(0)}]\rangle(X,T)\mathrm{d}X'\,\mathrm{d}T'$$

(where $\langle\cdots\cdots\rangle$ is the inner product of $\boldsymbol{\kappa}^{(q)}$ and $\tilde{\mathbf{f}}_{(1)}$).

All the other terms in the orthogonality conditions (2.17) are the smooth functionals of $\mathbf{S}_{(0)},\ldots,\mathbf{S}_{(k-1)}$, $\mathbf{n}_{(0)},\ldots,\mathbf{n}_{(k-1)}$, so we get the statement of the Lemma.

Lemma 2.3 is proved.

Let us consider now the systems (1.1) satisfying the special nondegeneracy conditions. Namely, we will assume that the corresponding Whitham system (2.16) can be resolved with respect to the highest T derivatives of the functions $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$ and written in the "evolution" form:

$$S^\alpha_{(0)TT} = M^\alpha_{(0)\beta}(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})S^\beta_{(0)XX} + N^\alpha_{(0)\beta}(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})S^\beta_{(0)TX} + P^\alpha_{(0)p}(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})n^p_{(0)X},$$

$$\alpha = 1,\ldots,m, \tag{2.19}$$

$$n^l_{(0)T} = T^l_{(0)\beta}(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})S^\beta_{(0)XX} + L^l_{(0)\beta}(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})S^\beta_{(0)TX} + R^l_{(0)p}(\mathbf{S}_{(0)X},\mathbf{S}_{(0)T},\mathbf{n}_{(0)})n^p_{(0)X},$$

$$l = 1,\ldots,s. \tag{2.20}$$

After the introduction of the variables $k^\alpha_{(0)} = S^\alpha_{(0)X}$, $\omega^\alpha_{(0)} = S^\alpha_{(0)T}$ we can write the system (2.19) and (2.20) in the form

$$k^\alpha_{(0)T} = \omega^\alpha_{(0)X},$$

$$\omega^\alpha_{(0)T} = M^\alpha_{(0)\beta}(\mathbf{k}_{(0)},\boldsymbol{\omega}_{(0)},\mathbf{n}_{(0)})k^\beta_{(0)X} + N^\alpha_{(0)\beta}(\mathbf{k}_{(0)},\boldsymbol{\omega}_{(0)},\mathbf{n}_{(0)})\omega^\beta_{(0)X} + P^\alpha_{(0)p}(\mathbf{k}_{(0)},\boldsymbol{\omega}_{(0)},\mathbf{n}_{(0)})n^p_{(0)X},$$

$$n^l_{(0)T} = T^l_{(0)\beta}(\mathbf{k}_{(0)},\boldsymbol{\omega}_{(0)},\mathbf{n}_{(0)})k^\beta_{(0)X} + L^l_{(0)\beta}(\mathbf{k}_{(0)},\boldsymbol{\omega}_{(0)},\mathbf{n}_{(0)})\omega^\beta_{(0)X} + R^l_{(0)p}(\mathbf{k}_{(0)},\boldsymbol{\omega}_{(0)},\mathbf{n}_{(0)})n^p_{(0)X}, \tag{2.21}$$

i.e., in the form (1.15).

We will consider now the hyperbolic systems (2.21), i.e., such that the matrix

$$V_{\mu}^{\nu}(\mathbf{k}_{(0)},\boldsymbol{\omega}_{(0)},\mathbf{n}_{(0)})=\begin{pmatrix}0 & I_m & 0\\ M_{(0)} & N_{(0)} & P_{(0)}\\ T_{(0)} & L_{(0)} & R_{(0)}\end{pmatrix}$$

has exactly $N=2m+s$ real eigenvalues with N linearly independent real eigenvectors. For hyperbolic systems (2.21) it is natural to consider the Cauchy problem with the smooth initial data $\mathbf{k}_{(0)}(X,0)$, $\boldsymbol{\omega}_{(0)}(X,0)$, $\mathbf{n}_{(0)}(X,0)$ (or $\mathbf{S}_{(0)}(X,0)$, $\mathbf{S}_{(0)T}(X,0)$, $\mathbf{n}_{(0)}(X,0)$). The smooth solution of (2.21) exists in general up to some finite time T_0 until the breakdown occurs. So we can write the zero (global in X) approximation for the solution (2.11) just in the time interval where we have a smooth solution of the Whitham system. Using Lemma 2.3 it is not difficult to prove then the following Lemma:

Lemma 2.4: For nondegenerate hyperbolic Whitham system (2.21) and the global solution $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$ *defined on the interval* $[0,T_0]$ *the higher orders approximations in (2.11) are all defined for all* X *and* $T\in[0,T_0)$ *and are parametrized by the initial values* $\mathbf{S}_{(k)}(X,0)$, $\mathbf{S}_{(k)T}(X,0)$, $\mathbf{n}_{(k)}(X,0)$. [Let us recall that we assume that all systems (2.14) are solvable if the corresponding orthogonality conditions are satisfied.]

Proof: Indeed, as follows from Lemma 2.3 the functions $\mathbf{S}_{(k)}(X,T)$, $\mathbf{n}_{(k)}(X,T)$ are defined by the initial values $\mathbf{S}_{(k)}(X,0)$, $\mathbf{S}_{(k)T}(X,0)$, $\mathbf{n}_{(k)}(X,0)$ and can be found from the linear system using the characteristic directions of (2.21) (defined by $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$) provided that all the smooth solutions $\mathbf{S}_{(0)}(X,T),\dots,\mathbf{S}_{(k-1)}(X,T)$, $\mathbf{n}_{(0)}(X,T)\dots,\mathbf{n}_{(k-1)}(X,T)$ and $\tilde{\boldsymbol{\Psi}}_{(1)}(\boldsymbol{\theta},X,T),\dots,\tilde{\boldsymbol{\Psi}}_{(k-2)}(\boldsymbol{\theta},X,T)$ exist on the interval $[0,T_0)$. According to Lemma 2.1 and Lemma 2.3 we can find then the functions $\tilde{\Psi}^{i}_{(k-1)}(\boldsymbol{\theta},X,T)$ which are the local expressions (in X and T) of $\mathbf{S}_{(0)}(X,T),\dots,\mathbf{S}_{(k-1)}(X,T)$, $\mathbf{n}_{(0)}(X,T)\dots,\mathbf{n}_{(k-1)}(X,T)$ and their derivatives. Using the induction we then finish the proof of the Lemma.

Lemma 2.4 is proved.

According to Lemma 2.4 we can formulate now the following statement:

For the initial system (1.1) having the nondegenerate hyperbolic Whitham system (2.21) the corresponding Whitham solutions (2.11) (or (2.4) and (2.5)) are defined by the initial values $\mathbf{S}(X,0,\epsilon)$, $\mathbf{S}_T(X,0,\epsilon)$, $\mathbf{n}(X,0,\epsilon)$ and exist in the time interval $[0,T_0)$ defined by the Whitham system (2.21) and the initial data $\mathbf{S}_{(0)}(X,0)=\mathbf{S}(X,0,0)$, $\mathbf{S}_{(0)T}(X,0)=\mathbf{S}_T(X,0,0)$, and $\mathbf{n}_{(0)}(X,0)=\mathbf{n}(X,0,0)$.

The deformation procedure: Let us note now that the series (2.11) (or (2.4) and (2.5)) give in fact the one-parametric formal solutions of (1.1) with a parameter ϵ. Let us rewrite now the solutions (2.11) in the form which gives the concrete (formal) solution of (1.1) and is not connected with the additional one-parametric ϵ-family including this given solution. We omit now the ϵ-dependence of functions $\mathbf{S}(X,T,\epsilon)$, $\mathbf{n}(X,T,\epsilon)$ (or put formally $\epsilon=1$) and say that the Whitham solution is defined now by functions $\mathbf{S}(X,T)$, $\mathbf{n}(X,T)$ determined by the initial values $\mathbf{S}(X,0)$, $\mathbf{S}_T(X,0)$, and $\mathbf{n}(X,0)$. (Let us keep here the notations X and T for the spatial and time coordinates just to emphasize that we consider the "slow" functions $\mathbf{S}_X(X,T)$, $\mathbf{S}_T(X,T)$, $\mathbf{n}(X,T)$.)

Thus, we define now the Whitham solution as the solution of the system

$$F^{i}(\boldsymbol{\varphi},\boldsymbol{\varphi}_T,\boldsymbol{\varphi}_X,\boldsymbol{\varphi}_{TT},\boldsymbol{\varphi}_{XT},\boldsymbol{\varphi}_{XX},\dots)=0,\quad i=1,\dots,n \tag{2.22}$$

having the form

$$\phi^{i}(\boldsymbol{\theta},X,T)=\Phi^{i}(\mathbf{S}(X,T)+\boldsymbol{\theta},\mathbf{S}_X(X,T),\mathbf{S}_T(X,T),\mathbf{n}(X,T))+\sum_{k\geqslant 1}\Phi^{i}_{(k)}(\mathbf{S}(X,T)+\boldsymbol{\theta},X,T) \tag{2.23}$$

where the functions $\Phi^{i}_{(k)}$:

(1) Are 2π-periodic with respect to each θ^{α};

(2) Have degree k (introduced below);

(3) Satisfy the normalization conditions (2.12) and (2.13) which will be written now in the form:

$$\int_0^{2\pi} \dots \int_0^{2\pi} \sum_{i=1}^{n} \Phi^i_{\theta^\alpha}(\boldsymbol{\theta},\mathbf{S}_X,\mathbf{S}_T,\mathbf{n})\Phi^i_{(k)}(\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m} = 0, \tag{2.24}$$

$$\int_0^{2\pi} \dots \int_0^{2\pi} \sum_{i=1}^{n} \Phi^i_{n^l}(\boldsymbol{\theta},\mathbf{S}_X,\mathbf{S}_T,\mathbf{n})\Phi^i_{(k)}(\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m} = 0 \tag{2.25}$$

$k \geqslant 1$, $(\alpha = 1, \dots, m,\ l = 1, \dots, s)$.

Let us introduce now the gradation used for the formal expansion (2.23). Namely, for the systems (1.1) having the nondegenerate hyperbolic Whitham system (2.21) we put the following gradation on the functions $\mathbf{S}_X(X,T)$, $\mathbf{S}_T(X,T)$, $\mathbf{n}(X,T)$ and their derivatives:

(1) The functions $k^\alpha(X,T) = S^\alpha_X(X,T)$, $\omega^\alpha(X,T) = S^\alpha_T(X,T)$, and $n^l(X,T)$ have degree 0;

(2) Every differentiation with respect to X adds 1 to the degree of the function;

(3) The degree of the product of two functions having certain degrees is equal to the sum of their degrees.

In other words, for the parameters $\mathbf{U} = (\mathbf{k}, \boldsymbol{\omega}, \mathbf{n})$ we have the gradation rule of Dubrovin-Zhang type, i.e.,

All the functions $f(\mathbf{U})$ have degree 0;

The derivatives U^ν_{kX} have degree k;

The degree of the product of functions having certain degrees is equal to the sum of their degrees.

We put now the evolution conditions to the functions $\mathbf{S}(X,T)$, $\mathbf{n}(X,T)$ having the form:

$$S^\alpha_{TT} = \sum_{k\geqslant 1} \sigma^\alpha_{(k)}(\mathbf{k},\boldsymbol{\omega},\mathbf{n},\mathbf{k}_X,\boldsymbol{\omega}_X,\mathbf{n}_X,\dots), \tag{2.26}$$

$$n^l_T = \sum_{k\geqslant 1} \eta^l_{(k)}(\mathbf{k},\boldsymbol{\omega},\mathbf{n},\mathbf{k}_X,\boldsymbol{\omega}_X,\mathbf{n}_X,\dots), \tag{2.27}$$

where $\sigma^\alpha_{(k)}$, $\eta^l_{(k)}$ are general polynomials in derivatives $\mathbf{k}_X, \boldsymbol{\omega}_X, \mathbf{n}_X, \mathbf{k}_{XX}, \boldsymbol{\omega}_{XX}, \mathbf{n}_{XX}, \dots$ (with coefficients depending on $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$) having degree k.

We now substitute the expansion (2.23) in the system (2.22) and use the relations (2.26) and (2.27) to remove all the time derivatives of parameters $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$. After that we can divide the system (2.22) into the terms of certain degrees and try to find recursively all the terms $\boldsymbol{\Phi}_{(k)}(\boldsymbol{\theta},X,T)$ for $k = 1,2,\dots$.

It is easy to see again that for any $\boldsymbol{\Phi}_{(k)}(\boldsymbol{\theta},X,T)$ we will have the linear system analogous to (2.8) and (2.14), i.e.,

$$\hat{L}^i_{[\mathbf{S}(X,T),\mathbf{n}(X,T)]j}\Phi^i_{(k)}(\boldsymbol{\theta},X,T) = \hat{f}^i_{(k)}(\boldsymbol{\theta},X,T), \tag{2.28}$$

where $\hat{\mathbf{f}}_{(k)}(\boldsymbol{\theta},X,T)$ is the discrepancy having degree k according to the definition above.

We have to put again the orthogonality conditions

$$\int_0^{2\pi} \dots \int_0^{2\pi} \kappa^{(q)}_{[\mathbf{S},\mathbf{n}]i}(\boldsymbol{\theta},X,T)\hat{f}^i_{(k)}(\boldsymbol{\theta},X,T)\frac{d^m\theta}{(2\pi)^m} \equiv 0 \tag{2.29}$$

on the functions $\hat{f}^i_{(k)}(\boldsymbol{\theta},X,T)$ and then find the unique $\boldsymbol{\Phi}_{(k)}(\boldsymbol{\theta},X,T)$ satisfying the normalization conditions (2.24) and (2.25).

It is not difficult to prove the following Lemma:

Lemma 2.5: (1) For any system (1.1) having the nondegenerate hyperbolic Whitham system

(2.21) the functions $\sigma^{\alpha}_{(k)}$, $\eta^{l}_{(k)}$ *are uniquely determined by the orthogonality conditions (2.29) in the order k.*

(2) The functions $\sigma^{\alpha}_{(1)}$, $\eta^{l}_{(1)}$ *give the Whitham system (2.19) and (2.20) for the functions* $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$. [In fact, the functions $\mathbf{S}(X,T,\epsilon)$, $\mathbf{n}(X,T,\epsilon)$ introduced previously satisfy the full system (2.26) and (2.27).]

Proof: Indeed, using Lemma 2.1 it is easy to see that the functions $\hat{f}^{i}_{(1)}(\boldsymbol{\theta},X,T)$ coincide with the functions $\tilde{f}^{i}_{(1)}(\boldsymbol{\theta},X,T)$ introduced in (2.14) after the replacement of functions $\mathbf{S}_{(0)}(X,T)$, $\mathbf{n}_{(0)}(X,T)$ by $\mathbf{S}(X,T)$, $\mathbf{n}(X,T)$. Comparing then the orthogonality conditions (2.29) with (2.15) we get the second part of the Lemma.

To prove the first part we just note that all $\sigma^{\alpha}_{(k)}$, $\eta^{l}_{(k)}$ arise in the kth order of system (2.22) "in the same way." We can conclude then that the orthogonality conditions (2.29) in the kth order always contain the functions $\sigma^{\alpha}_{(k)}$, $\eta^{l}_{(k)}$ in one particular way which coincides with the appearance of $\sigma^{\alpha}_{(1)}$, $\eta^{l}_{(1)}$ in the Whitham system arising for $k=1$. From the definition of the nondegenerate Whitham system we now obtain the first part of the Lemma.

Lemma 2.5 is proved.

Definition 2.1: We call the system (2.26) and (2.27) or the equivalent system

$$k^{\alpha}_{T}=\omega^{\alpha}_{X},$$

$$\omega^{\alpha}_{T}=\sum_{k\geqslant 1}\sigma^{\alpha}_{(k)}(\mathbf{k},\boldsymbol{\omega},\mathbf{n},\mathbf{k}_{X},\boldsymbol{\omega}_{X},\mathbf{n}_{X},\dots),$$

$$n^{l}_{T}=\sum_{k\geqslant 1}\eta^{l}_{(k)}(\mathbf{k},\boldsymbol{\omega},\mathbf{n},\mathbf{k}_{X},\boldsymbol{\omega}_{X},\mathbf{n}_{X},\dots) \tag{2.30}$$

the deformation of the Whitham system (2.19) and (2.20) (or (2.21)).

The functions $k^{\alpha}(X,T)$, $\omega^{\alpha}(X,T)$, $n^{l}(X,T)$ are the "slow" functions of the variables x and t and the system (2.30) gives the analog of the "low-dispersion" expansion in our case. The asymptotic solutions (2.23) of the initial system (2.22) are parametrized by the asymptotic solutions $k^{\alpha}(X,T)$, $\omega^{\alpha}(X,T)$, $n^{l}(X,T)$ of the system (2.30) and arbitrary (constant) initial phases θ^{α}_{0}. As follows from our considerations above the solutions (2.23) give all the "particular solutions" (2.4) and (2.5), however, they do not contain the additional information about the one-parametric ϵ-family given by (2.4) and (2.5)

Remark 1: Let us note that the full set of parameters of m-phase solutions of (1.1) is given by $\mathbf{k}$, $\boldsymbol{\omega}$, $\mathbf{n}$, and $\boldsymbol{\theta}_{0}$. However the functions $\boldsymbol{\theta}_{0}(X,T)$ do not present as the parameters of solutions (2.23) in this approach. This shows in fact that the introduction of the functions $\theta^{\alpha}_{0}(X,T)$ does not give "new" formal solutions of (1.1) and is responsible for the additional ϵ-dependence of one-parametric families (2.4) and (2.5). Here they are "absorbed" by the total phase $\mathbf{S}(X,T)$ connected with the "particular" formal solution of (1.1).

Remark 2: In our consideration we fixed some functions $\Phi^{i}(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ on the family Λ (for each $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$) as having zero initial phases. However, the choice of the functions $\Phi^{i}(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ is not unique. In particular, the natural change of the functions $\boldsymbol{\Phi}^{i}(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ on Λ can be written in the form

$$\boldsymbol{\Phi}'(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})=\boldsymbol{\Phi}(\boldsymbol{\theta}+\boldsymbol{\theta}_{0}(\mathbf{k},\boldsymbol{\omega},\mathbf{n}),\mathbf{k},\boldsymbol{\omega},\mathbf{n}), \tag{2.31}$$

where $\theta^{\alpha}_{0}(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ are arbitrary smooth functions.

It is not difficult to see also that the system (2.30) depends on the choice of the functions $\Phi^{i}(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ in the high $(k\geqslant 2)$ orders.

Let us give here the definition given by B. A. Dubrovin and Y. Zhang[64,66] and connected with the "equivalence" of different infinite (or finite) systems.

Definition 2.2 (B. A. Dubrovin, Y. Zhang): *Consider the system of the form*

$$U_T^\nu = \sum_{k\geqslant 1} V_{(k)}^\nu(\mathbf{U}, \mathbf{U}_X, \mathbf{U}_{XX}, \dots), \quad \nu = 1, \dots, N \tag{2.32}$$

for arbitrary parameters U^ν where all $V_{(k)}^\nu$ are smooth functions polynomial in $\mathbf{U}_X, \mathbf{U}_{XX}, \dots$ and having degree k. We say that two systems (2.32) are connected by the triviality transformation (or equivalent) if they are connected by the formal substitution

$$\widetilde{U}^\nu = \sum_{k\geqslant 0} \widetilde{U}_{(k)}^\nu(\mathbf{U}, \mathbf{U}_X, \mathbf{U}_{XX}, \dots),$$

where all $\widetilde{U}_{(k)}^\nu$ are smooth functions polynomial in $\mathbf{U}_X, \mathbf{U}_{XX}, \dots$ and having degree k.

Let us say actually that the definition of B. A. Dubrovin and Y. Zhang is applied usually to the whole integrable hierarchies and plays the important role in the classification of integrable hierarchies having the form (2.32). We will prove here the following Lemma:

Lemma 2.6: The deformations of the Whitham system (2.30) written for the initial functions $\mathbf{\Phi}(\boldsymbol{\theta}, \mathbf{k}, \boldsymbol{\omega}, \mathbf{n})$ and $\mathbf{\Phi}'(\boldsymbol{\theta}, \mathbf{k}, \boldsymbol{\omega}, \mathbf{n})$ connected by the transformation (2.31) are equivalent in Dubrovin-Zhang sense.

Proof: Let us prove first the following statement:

For any transformation (2.31) there exists a unique change of functions $S^\alpha(X)$, $n^l(X)$:

$$S'^\alpha = S^\alpha - \theta_0^\alpha(\mathbf{k}, \boldsymbol{\omega}, \mathbf{n}) + \sum_{k\geqslant 1} S_{(k)}^\alpha(\mathbf{k}, \boldsymbol{\omega}, \mathbf{n}, \mathbf{k}_X, \dots),$$

$$n'^l = n^l + \sum_{k\geqslant 1} n_{(k)}^l(\mathbf{k}, \boldsymbol{\omega}, \mathbf{n}, \mathbf{k}_X, \dots) \tag{2.33}$$

such that:

(1) All $\mathbf{S}_{(k)}$, $\mathbf{n}_{(k)}$ are polynomial in derivatives of $(\mathbf{k}, \boldsymbol{\omega}, \mathbf{n})$ and have degree k;

(2) For any solution (2.23) $(\phi_{[\mathbf{S},\mathbf{n}]}(\boldsymbol{\theta}, X, T))$ of (2.22) the functions $\Phi'^i(\mathbf{S}'(X,T) + \boldsymbol{\theta}, \mathbf{S}'_X, \mathbf{S}'_T, \mathbf{n}')$ satisfy the normalization conditions

$$\int_0^{2\pi} \dots \int_0^{2\pi} \sum_{i=1}^n \Phi'^i_{\theta^\alpha}(\mathbf{S}' + \boldsymbol{\theta}, \mathbf{S}'_X, \mathbf{S}'_T, \mathbf{n}') \phi^i_{[\mathbf{S},\mathbf{n}]}(\boldsymbol{\theta}, X, T) \frac{d^m\theta}{(2\pi)^m} \equiv 0, \tag{2.34}$$

$$\int_0^{2\pi} \dots \int_0^{2\pi} \sum_{i=1}^n \Phi'^i_{n'^l}(\mathbf{S}' + \boldsymbol{\theta}, \mathbf{S}'_X, \mathbf{S}'_T, \mathbf{n}')[\phi^i_{[\mathbf{S},\mathbf{n}]}(\boldsymbol{\theta}, X, T) - \Phi'^i(\mathbf{S}' + \boldsymbol{\theta}, \mathbf{S}'_X, \mathbf{S}'_T, \mathbf{n}')] \frac{d^m\theta}{(2\pi)^m} \equiv 0. \tag{2.35}$$

For the proof of this statement let us note first that we can always express all the time derivatives of $\mathbf{k}$, $\boldsymbol{\omega}$, and $\mathbf{n}$ using the system (2.30) in terms of X-derivatives of these functions. Using this procedure we try to find the transformation (2.33) recursively in all degrees by substitution of (2.33) in (2.34) and (2.35). It is not difficult to check then that the functions $S_{(k)}^\alpha$, $n_{(k)}^l$ are defined in the kth order of (2.34) and (2.35) from a linear system. The matrix of this linear system coincides with the Gram matrix of functions Φ_{θ^α}, Φ_{n^l} at every X and T. Thus, for the full nondegenerate family of m-phase solutions of (1.1) this system has a unique solution at every degree k. The transformation (2.33) is evidently invertible in sense of the infinite series (polynomial with respect to derivatives of $(\mathbf{k}, \boldsymbol{\omega}, \mathbf{n})$) so we can also express the functions $(\mathbf{S}, \mathbf{n})$ in terms of $(\mathbf{S}', \mathbf{n}')$.

We can now try to use the functions $\Phi'^i(\mathbf{S}' + \boldsymbol{\theta}, \mathbf{S}'_X, \mathbf{S}'_T, \mathbf{n}')$ as the zero approximation in the $(\mathbf{S}', \mathbf{n}')$-expansion of the corresponding solution (2.23). It is not difficult to see that the difference

$$\Phi'^{i}(\mathbf{S}'+\theta,\mathbf{S}'_X,\mathbf{S}'_T,\mathbf{n}')-\phi^i_{[\mathbf{S},\mathbf{n}]}(\boldsymbol{\theta},X,T)$$

can be represented as the infinite series polynomial with respect to derivatives of $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ and starting with the terms of degree 1. After the expression of the functions $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ in terms of $(\mathbf{k}',\boldsymbol{\omega}',\mathbf{n}')$ in this difference we get finally the $(\mathbf{S}',\mathbf{n}')$-expansion of the solution $\phi^i_{[\mathbf{S},\mathbf{n}]}(\boldsymbol{\theta},X,T)$.

The functions $(\mathbf{S}',\mathbf{n}')$ now satisfy the new deformed Whitham system (2.26) and (2.27) corresponding to the choice of the functions $\boldsymbol{\Phi}'(\boldsymbol{\theta},\mathbf{k}',\boldsymbol{\omega}',\mathbf{n}')$ as the functions of zero approximation.

It is easy to see also that the transformation (2.33) remains polynomial in X-derivatives of $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ after the expression of time derivatives of $(\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ using the system (2.30).

We obtain then that the transformation (2.33) gives a "triviality" connection between the systems (2.30) written for the initial functions $\boldsymbol{\Phi}(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$ and $\boldsymbol{\Phi}'(\boldsymbol{\theta},\mathbf{k},\boldsymbol{\omega},\mathbf{n})$.

Lemma 2.6 is proved.

At the end let us note again that Lemma 2.6 is important in fact for the integrable hierarchies rather than for the one particular system (1.1) according to Dubrovin-Zhang approach to classification of integrable systems.

ACKNOWLEDGMENT

I wish to thank Professor B. A. Dubrovin, who suggested the problem, for the interest in this work and many fruitful discussions.

Valence two Killing tensors in the Euclidean and Minkowski planes are classified under the action of the group which preserves the type of the corresponding Killing web. The classification is based on an analysis of the system of determining partial differential equations for the group invariants and is entirely algebraic. The approach allows one to classify both characteristic and noncharacteristic Killing tensors. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2217649]

I. INTRODUCTION AND BASIC PROPERTIES

A. Killing tensors and separable webs

A Killing tensor (KT) on a pseudo-Riemannian space $(M,\mathbf{g})$ is a tensor $\mathbf{K}$ of type $(0,k)$ which satisfies

$$\nabla_{(j} K_{i_1\ldots i_k)} = 0, \tag{1}$$

where ∇ denotes the covariant derivative defined by the Levi-Civita connection of the pseudo-Riemannian metric $\mathbf{g}$ and where the parentheses signify symmetrization of the enclosed indices. It was shown by Eisenhart[5] that such tensors arise naturally from first integrals of the geodesic flow on $(M,\mathbf{g})$ in the form

$$I = K_{i_1\ldots i_k}\frac{\mathrm{d}q^{i_1}}{\mathrm{d}s}\cdots\frac{\mathrm{d}q^{i_k}}{\mathrm{d}s}.$$

The function I, defined on the tangent bundle TM, is a first integral of the geodesic equations (i.e., it is constant along each geodesic) if and only if the Killing tensor equation (1) holds. Killing tensors may also be characterized in contravariant form by means of the following function defined on the cotangent bundle T^*M:

$$I^* = K^{i_1\ldots i_k}p_{i_1}\ldots p_{i_k},$$

where (q^i,p_i) denote canonical coordinates on T^*M. Condition (1) is then equivalent to

$$\{I^*,H\} = 0,$$

where $\{\cdot,\cdot\}$ denotes the Poisson bracket and

$$H = \tfrac{1}{2}g^{ij}p_ip_j,$$

the geodesic Hamiltonian.

a)Electronic mail: luca.degiovanni@gmail.com

The set of all Killing tensors of valence k, on an n-dimensional manifold M, is a real vector space which we denote by $\mathcal{K}^k(M)$. Its dimension d satisfies the Delong-Takeuchi-Thompson inequality[4,15,16]

$$d \leqslant \frac{1}{n}\binom{n+k}{k+1}\binom{n+k-1}{k}.$$

Equality is achieved for manifolds of constant curvature. Moreover, in this case the Killing tensors of valence k are sums of symmetrized products of the Killing vectors of the manifold. In manifolds with isometry groups of less than the maximal dimension there may exist Killing tensors which are not expressible in this way. For example, such a situation occurs in the Kerr space-time.[3]

Killing tensors of type (0, 2) which we call Killing 2-tensors, are particularly important. Indeed, if the eigenvalues of a Killing 2-tensor are real and simple and the eigenvectors are normal (orthogonally integrable), then the Killing tensor defines an orthogonally separable web on M, that is n foliations of mutually orthogonal $(n-1)$-dimensional hypersurfaces. To the separable web are associated systems of coordinates with respect to which the Hamilton-Jacobi equation for the geodesic flow is solvable by separation of variables (see Benenti[1]). Killing 2-tensors with the above properties are called characteristic Killing tensors (CKTs).

It is well known that in the Euclidean plane there exist four types of orthogonally separable webs (see, for example, Miller[11]). Nevertheless, it is not a trivial task to determine which type of web is defined by a given characteristic Killing tensor. The converse problem of characterizing the Killing tensors which define the same separable web is also challenging. This problem becomes even more difficult in dimension greater than two where the preliminary problem of identifying the characteristic Killing tensors is itself a daunting task. It is thus clear that finding an effective method of classifying Killing tensors would be very useful indeed.

The classification of separable coordinates in two- and three-dimensional Euclidean space by Killing tensors dates back to the work of Eisenhart.[5] A similar classification for two- and three-dimensional Minkowski space was undertaken by Kalnins,[8] who classified the symmetric second-order differential operators that commute with the wave operator and solved the Eisenhart integrability conditions[5] to obtain the metric in the two-dimensional case. A classification of KTs in the Euclidean and Minkowski planes based on an analysis of their singular sets (i.e., the points where the eigenvalues of the Killing tensors are not real and simple) is given by Benenti and Rastelli[2] and Rastelli.[13] Recently remarkable progress in the classification problem was achieved by McLenaghan, Smirnov, Horwood, The, and Yue by means of the invariant theory of Killing tensors on spaces of constant curvature.[7,9,10,14] In this theory Killing tensors are classified modulo the group which consists of the transformations on $\mathcal{K}^2(M)$ induced by the isometries of the underlying pseudo-Riemannian manifold $(M,\mathbf{g})$ and the transformation which maps any Killing tensor $\mathbf{K}$ into $\mathbf{K}+b\mathbf{g}$, where b is any real number. More specifically to any isometry ϕ on M is associated the transformation on $\mathbf{K}\mapsto\hat{\mathbf{K}}$ on $\mathcal{K}^2(M)$ defined with respect to a system of local coordinates (q^i) by

$$\hat{K}^{ij}(q) = J^i_k(\Phi^{-1}(q))J^j_l(\Phi^{-1}(q))K^{kl}(\Phi^{-1}(q)), \tag{2}$$

where $J^i_j(q)=\partial\Phi^i/\partial q^j$ is the Jacobian of the transformation Φ. Two Killing tensors are considered equivalent if one can be obtained from the other in this way. Clearly all CKTs in the same equivalence class define the same orthogonal web. The classification is based on set of algebraic invariants of $\mathcal{K}^2(M)$ under the action of the group, from which a classification scheme for the type of the separable web can be constructed in the cases considered, namely, $\mathbb{E}_2$, $\mathbb{M}_2$, and $\mathbb{E}_3$.

The approach presented in this paper is related but somewhat different than that developed by McLenaghan *et al.* It is based on two observations: (i) the transformations on $\mathcal{K}^2(M)$ induced by the isometries are not the only ones which preserve the type of web defined by a given CKT. Indeed, any transformation of the form $\mathbf{K}\mapsto a\mathbf{K}+b\mathbf{g}$ also preserves the web (in Refs. 9 and 10, $a=1$ was assumed); (ii) two webs of the same type are not necessarily isometric. For example two elliptic-hyperbolic in the Euclidean plane webs with different interfocal distances are of the same

type but are not isometric but are rather related by a dilatation transformation. In the following we do not focus on the transformations of the manifold M, but directly on the transformations of $\mathcal{K}^2(M)$ that preserve the type of separable web defined by a given characteristic Killing tensor. In the Euclidean and Minkowski planes these transformations are well known and generate a Lie group with dimension equal to that of $\mathcal{K}^2(M)$. This further fact allows the determination of the equivalence classes in a purely algebraic way which is described in the sequel.

There are both advantages and disadvantages to the extension of the group of transformation used in our classification scheme. On the positive side is the very natural way in which the classes of KTs which define the distinct types of separable webs are obtained. Restriction of the transformations of KTs to those that preserve the web has the result that the CKTs which define the same type of web are scattered through many classes. The method also leaves open the possibility of classifying noncharacteristic KTs. On the negative side, while the isometry group of pseudo-Riemannian manifold is known in many cases, it is not easy to identify the additional transformations of $\mathcal{K}^2(M)$ that preserve the type of a Killing web. This makes it very difficult to extend the method to higher dimensions and to spaces with nonvanishing curvature.

The plan of the paper is as follows: in Sec. I B we outline the necessary theory of Lie transformation groups to be applied later in the paper. In Sec. II we perform the classification in the Euclidean plane. The classification in the Minkowski plane is undertaken in Sec. III. Section IV contains the conclusion.

B. Orbit of Lie group actions

Let $\Psi: G\times\mathcal{K}\to\mathcal{K}$ be a linear action of a finite-dimensional Lie group G on the vector space $\mathcal{K}$. According to the notation of Ref. 12, the infinitesimal generators of the action form a finitely generated and involutive distribution Δ of nonconstant rank (isomorphic to the Lie algebra of G).

Proposition 1:[6,12] *A distribution on a manifold is integrable if and only if it is involutive and rank-invariant. Finitely generated involutive distributions are always rank-invariant and so integrable.*

By this generalized Frobenius theorem the distribution Δ is integrable, and for the rank-invariance property it is tangent to any of the sets

$$r_j = \{x \in \mathcal{K}: \operatorname{rank}(\Delta)|_x = j\},$$

which are unions of maximal connected integral submanifolds S_x of Δ, but in general not (immersed) submanifolds.

All the connected components of the Lie group G are diffeomorphic to the normal subgroup G_0 which is the connected component containing the identity. Then $G=\cup_{g\in Z} gG_0$ where Z is a set of cosets representatives.

The orbit $\mathcal{O}_x$ of the action Ψ can be obtained as union of maximal integral manifolds of Δ mapped one into the other by the diffeomorphisms Ψ_g with $g\in Z$,

$$\mathcal{O}_x = \bigcup_{g\in Z} \Psi_g(S_x) = \bigcup_{g\in Z} S_{g\cdot x}.$$

Lemma 2: If r_j is a submanifold of dimension j then for any $x\in r_j$ S_x is the connected component of r_j containing x and the orbit $\mathcal{O}_x$ is the union of the connected components of r_j which are images of S_x through the action of the elements of Z.

If $\dim G=\dim \mathcal{K}=n$ then we are able to determine the orbits where the distribution Δ has maximal rank by looking for the connected components of r_n and gluing the ones mapped into the others by the elements of Z. Moreover the other orbits are contained in the sets where the rank of Δ change and, if the condition $\dim r_j=j$ still holds, they can all be determined in an algebraic way.

Some tools useful to detect the components connected by arcs (equal to topological connected components in our case) of a subset of $\mathbb{R}^n$ are now introduced. Let us consider a set $A\subset\mathbb{R}^n$ and let $\{A_i\}_{i\in I}$ be its partition in connected components. We consider the natural decomposition $\mathbb{R}^n\to\mathbb{R}^m\times\mathbb{R}^{n-m}$, so that any point of $P\in\mathbb{R}^n$ can be labeled as $P=(v,p)$ with $v\in\mathbb{R}^m$ and

$p \in R^{n-m}$. In this way we get a partition $\{V^v\}_{v \in \mathbb{R}^m}$ of $\mathbb{R}^n$ in parallel hyperplanes of dimension $n-m$, where $V^v = \{P \in \mathbb{R}^n : P = (v,p), p \in \mathbb{R}^{n-m}\}$. We call $A^v = A \cap V^v$ the section of A determined by the hyperplane V^v and construct its partition in connected components

$$A^v = \bigcup_{\alpha \in I^v} A^v_\alpha.$$

On the family $\{A^v_\alpha\}_{\alpha \in I^v, v \in \mathbb{R}^m}$ of the connected components of the sections of A we define the relation

$$A^v_\alpha \sim A^w_\beta \Leftrightarrow \exists\, !i \in I : A^v_\alpha \subseteq A_i \text{ and } A^w_\beta \subseteq A_i$$

It's easy to check that the following Lemma holds:

Lemma 3: The relation $\sim$ is an equivalence relation. There is a one-to-one correspondence between the equivalence classes $[A^v_\alpha]$ and the (arc)-connected components A_i of A. If there exists a continuous arc $f : [0,1] \to \mathbb{R}^m \times \mathbb{R}^{n-m}$ such that $f([0,1]) \subseteq A$, $f(0) = (v,p)$, $f(1) = (w,q)$ with $p \in A^v_\alpha$, $q \in A^w_\beta$ then $A^v_\alpha \sim A^w_\beta$.

Hence, the study of the connected components of A can be reduced to the study of connected components of all sections A^v (of lower dimension) under the equivalence relation.

II. KILLING TENSORS IN THE EUCLIDEAN PLANE

In the Euclidean plane $\mathbb{E}_2$, with Cartesian coordinates (x,y) and the standard metric $\mathbf{g}$, the general Killing 2-tensor $\mathbf{K}$ has the following contravariant form:

$$\|K^{ij}\| = \begin{pmatrix} A + 2\alpha y + \gamma y^2 & C - \alpha x - \beta y - \gamma xy \\ C - \alpha x - \beta y - \gamma xy & B + 2\beta x + \gamma x^2 \end{pmatrix}.$$

We denote by $\mathcal{K}(\mathbb{E}_2)$ the vector space of KTs on the Euclidean plane. On this space there exist six kinds of transformation preserving the type of the web associated to each KT: three of them correspond to isometries, a fourth corresponds to the dilatation of $\mathbb{E}_2$. The last two are not associated with any coordinate transformation in the plane but act directly on the tensor $\mathbf{K}$ and correspond to the addition of a multiple of the metric tensor ($\mathbf{K} \mapsto \mathbf{K} + \tau\mathbf{g}$) and to the multiplication of the tensor for a nonvanishing constant ($\mathbf{K} \mapsto \lambda\mathbf{K}$). The infinitesimal generators of these transformations are easily calculated (see Ref. 9 for the generators corresponding to isometries and addition of a multiple of the metric). With respect to the basis of the vector fields on $\mathcal{K}(\mathbb{E}_2)$ given by $(\partial_A, \partial_B, \partial_C, \partial_\alpha, \partial_\beta, \partial_\gamma)$ the infinitesimal generators are spanned by:

Translations

$$V_1 = (0, -2\beta, \alpha, 0, -\gamma, 0),$$

$$V_2 = (-2\alpha, 0, \beta, -\gamma, 0, 0).$$

Rotation

$$V_3 = (-2C, 2C, A - B, \beta, -\alpha, 0).$$

Dilatation of $\mathbb{E}_2$,

$$V_4 = (2A, 2B, 2C, \alpha, \beta, 0).$$

Addition of the metric

$$V_5 = (1, 1, 0, 0, 0, 0).$$

Scalar multiplication

$$V_6 = (A, B, C, \alpha, \beta, \gamma).$$

These vector fields form a Lie algebra and therefore generate an integrable distribution, denoted by Δ_E. In order to study the rank of Δ_E we gather the components of the V_i in the matrix

$$M = \begin{pmatrix} 0 & -2\beta & \alpha & 0 & -\gamma & 0 \\ -2\alpha & 0 & \beta & -\gamma & 0 & 0 \\ -2C & 2C & A-B & \beta & -\alpha & 0 \\ 2A & 2B & 2C & \alpha & \beta & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 \\ A & B & C & \alpha & \beta & \gamma \end{pmatrix} \tag{3}$$

with determinant $\det M = -2\gamma[(\alpha^2-\beta^2-\gamma(A-B))^2+4(\alpha\beta+\gamma C)^2]$. We are led naturally to consider the two surfaces where $\det M = 0$,

$$S_1: \quad \gamma = 0 \quad \dim S_1 = 5, \tag{4}$$

$$S_2: \quad \begin{cases} \alpha^2 - \beta^2 = \gamma(A-B) \\ \alpha\beta = -\gamma C \end{cases} \qquad \dim S_2 = 4, \tag{5}$$

whose intersection is the vector subspace $\alpha=\beta=\gamma=0$. The sections of S_1, obtained using as parameters A, B, and C, are always planes; on the other hand the sections of S_2 are curves described by the following lemma:

Lemma 4: If the parameters A, B, and C have the values $C=0$ and $A=B$ then the section of S_2 is given by the axis γ, for other values of the parameters the section is given by two parabolas contained in two orthogonal planes, with vertex in the origin and foci on the γ axis symmetric with respect to the origin.

Proof: When $C \neq 0$ Eq. (5) become

$$(\alpha^2 - \beta^2)C + \alpha\beta(A-B) = 0,$$

$$\alpha\beta = -\gamma C.$$

The first equation can be factorized as $C(\alpha - k_+\beta)(\alpha - k_-\beta)$ where

$$k_\pm = \frac{B - A \pm \sqrt{(A-B)^2 + 4C^2}}{2C}.$$

Thus the section of S_2 is the union of the two parabolas

$$\begin{cases} \alpha = k_+\beta \\ \gamma = -\dfrac{k_+}{C}\beta^2 \end{cases} \cup \begin{cases} \alpha = k_-\beta \\ \gamma = -\dfrac{k_-}{C}\beta^2 \end{cases}.$$

We observe that $k_+k_- = -1$ thus the two parabolas are contained in two orthogonal planes. Their foci lie on the γ axis with

$$\gamma = \pm\tfrac{1}{4}\sqrt{(A-B)^2 + 4C^2};$$

being $k_+/C > 0$ the first parabola is always downward, while the second one is always upward. For $C=0$ the second equation in (5) becomes $\alpha\beta = 0$. Then when $A \neq B$ we have the two parabolas

$$\begin{cases} \alpha = 0 \\ \gamma = -\dfrac{\beta^2}{B-A} \end{cases} \cup \begin{cases} \beta = 0 \\ \gamma = \dfrac{\alpha^2}{A-B} \end{cases}$$

for which the previous considerations on foci hold. Finally when $A=B$ we have $\alpha=\beta=0$ and then the two parabolas degenerate in the γ axis.

We remark that the functions $\delta=(\alpha^2-\beta^2-\gamma(A-B))^2+4(\alpha\beta+\gamma C)^2$ and γ, defining the surfaces S_1 and S_2, are the fundamental invariant of $\mathcal{K}_2(\mathbb{R}^2)$ determined by McLenaghan *et al.*[9] under the action of the group induced by the isometries and the addition of a multiple of the metric.

Proposition 5: Outside of the union of the surfaces S_1 and S_2, the distribution Δ_E has rank 6 and the space $\mathcal{K}(\mathbb{E}_2)-(S_1\cup S_2)$ is an orbit of the action.

Proof: The distribution has maximal rank outside of $S_1\cup S_2$ because the determinant of the matrix (3) vanishes only on that set. Since $\mathcal{K}(\mathbb{E}_2)-(S_1\cup S_{2\,1})$ has the same dimension of the distribution, each connected component is an orbit of the action generated by the vector fields V_i. The connected components are two: one for $\gamma>0$ and the other for $\gamma<0$. However, the two components are linked together by the finite transformation that change the sign of the KT and so they form a unique orbit with respect to the disconnected group generated by the vector fields and this transformation.

Proposition 6: On S_1-S_2 the rank of Δ_E is 5 and this space is an orbit of the action.

Proof: In order to determine the rank of Δ_E on S_1 we set $\gamma=0$ in the matrix M: all the nonvanishing 5×5 minors contain the factor $\alpha^2+\beta^2$, and one of them is $2(\alpha^2+\beta^2)^2$. Thus the rank of M is lesser than 5 if and only if $\alpha=\beta=0$, that is on $S_1\cap S_2$. Because S_1-S_2 is connected and has dimension five it is an orbit of the action.

Proposition 7: On S_2-S_1 the rank of Δ_E is 4 and this space is an orbit of the action.

Proof: Assume $\gamma\neq0$, from Eq. (5) we obtain the relation

$$B = A - \frac{\alpha^2-\beta^2}{\gamma}, \quad C = -\frac{\alpha\beta}{\gamma},$$

which substituted in adj(M) make it identically zero. Then on S_2-S_1 the rank of the distribution is at most 4, but one 4×4 minor is $\gamma^3\neq0$. Thus outside of $S_1\cap S_2$ the rank is exactly 4. From Lemma 4 it follows that for any fixed values of $A-B$ and C (not both vanishing) the section of S_2-S_1 is formed by four disjoint parabola's arcs. But it is always possible to find a continuous deformation of the parameter A,B,C gluing together the two upward and downward arcs, respectively. Indeed with the change in the space of parameters $A-B=\rho\cos\theta$, $2C=\rho\sin\theta$ we have that the directions of the two planes containing the parabolas depends only on θ, while the amplitude of the two parabolas is inversely proportional to ρ, thus letting ρ go to zero with a fixed value of θ has the effect to glue together the arcs of the two parabolas along the γ axis. Hence, S_2-S_1 has two connected components only, which can be connected using the change of sign of the KT.

Finally we study the intersection $S_1\cap S_2$ which is the three-dimensional vector space with coordinates A, B, and C. On $S_1\cap S_2$ the only independent vector fields among the V_i are V_3, V_5, and V_6, whose components, with respect to $(\partial_A,\partial_B,\partial_C)$, form the matrix

$$\tilde{M} = \begin{pmatrix} -2C & 2C & A-B \\ A & B & C \\ 1 & 1 & 0 \end{pmatrix}. \tag{6}$$

Introducing the one-dimensional line

$$S_3: \begin{cases} \alpha=\beta=\gamma=0 \\ C=0 \\ A=B \end{cases} \qquad \dim S_3 = 1 \tag{7}$$

we are able to individuate the last two orbits.

Proposition 8: The rank of Δ_E *on* $(S_1 \cap S_2) - S_3$ *is* 3 *and then this space is an orbit of the action.*

Proof: The determinant of the matrix (6) is $\det \tilde{M} = 4C^2 + (A-B)^2$, then it vanishes only on S_3. Because $(S_1 \cap S_2) - S_3$ is connected it is an orbit. □

Proposition 9: The rank of Δ_E *on* S_3 *is* 1 *and then this space is an orbit of the action, containing the (noncharacteristic) tensors of the form* $\tau \mathbf{g}$.

Proof: The only independent vector field on S_3 is the constant vector V_5, generated by the addition of a multiple of the metric. □

We remark that the discrete transformation $(A \leftrightarrow B, \alpha \leftrightarrow \beta)$ induced by the discrete isometry of the Euclidean plane $(\{\overline{x}=y, \overline{y}=x\})$ does not allow one to glue together the above found orbits.

In conclusion five orbits of the action of the web preserving group are found.

E1) The set $\mathcal{K}(\mathbb{E}_2) - (S_1 \cup S_2)$, the tensors on this orbit generate elliptic-hyperbolic coordinates. A tensor of this type is

$$\begin{pmatrix} y^2 & 1-xy \\ 1-xy & x^2 \end{pmatrix}.$$

E2) The set $S_1 - S_2$, the tensors on this orbit generate parabolic coordinates. Two tensors of this type are

$$\begin{pmatrix} 2y & -x \\ -x & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & -y \\ -y & 2x \end{pmatrix}.$$

E3) The set $S_2 - S_1$, the tensors on this orbit generate polar coordinates. A tensor of this type is

$$\begin{pmatrix} y^2 & -xy \\ -xy & x^2 \end{pmatrix}.$$

E4) The set $(S_1 \cap S_2) - S_3$, the tensors on this orbit generate Cartesian coordinates. Three tensors of this type are

$$\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

E5) The line S_3, the tensors on this orbit are multiples of the metric.

This classification coincides with that given by McLenaghan *et al.*[9] where the four types of separable webs in $\mathbb{E}_2$ are characterized by the vanishing or not of the fundamental invariants γ and δ. The orbits are strictly related to the set of singular points discussed by Benenti and Rastelli.[2] Indeed, the discriminant of the characteristic polynomial of $\mathbf{K}$ vanishes on points satisfying

$$\gamma xy + \alpha x + \beta y - C = 0,$$

$$\gamma(y^2 - x^2) + 2(\alpha y - \beta x) + A - B = 0. \tag{8}$$

If $\gamma \neq 0$ (i.e., outside S_1), Eq. (8) describes two hyperbolas both centered in $(-\beta/\gamma, -\alpha/\gamma)$. For tensors belonging to $S_2 - S_1$ both conics degenerate into two couples of lines through the center (polar web). Otherwise, they have two points in common (elliptic-hyperbolic web). For tensor belonging to S_1 $(\gamma = 0)$ the system (8) is linear: if $\mathbf{K} \in S_1 - S_2$, it represents the intersection of two orthogonal lines (parabolic web); if $\mathbf{K} \in (S_1 \cap S_2) - S_3$ the system has no solution (Cartesian web), while for $\mathbf{K} \in S_3$ all points are singular.

III. KILLING TENSORS IN THE MINKOWSKI PLANE

On the Minkowski plane $\mathbb{M}_2$ with pseudo-Cartesian coordinates (t,x) and metric $\mathbf{g}$ with contravariant components

$$\|g^{ij}\| = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

the general Killing tensor $\mathbf{K}$ has contravariant components:

$$\|K^{ij}\| = \begin{pmatrix} A + 2\alpha x + \gamma x^2 & C + \alpha t + \beta x + \gamma t x \\ C + \alpha t + \beta x + \gamma t x & B + 2\beta t + \gamma t^2 \end{pmatrix}.$$

We denote by $\mathcal{K}(\mathbb{M}_2)$ the vector space of all the KTs on $\mathbb{M}_2$. On this space six kinds of transformation are defined, which preserve the type of the web associated to the KT: three are induced by the isometries of the Minkowski plane and a fourth by its dilatation; the last two do not depend on any transformation of $\mathbb{M}_2$ and are defined directly on $\mathcal{K}(\mathbb{M}_2)$: adding a multiple of the metric tensor ($\mathbf{K} \mapsto \mathbf{K} + \tau\mathbf{g}$) and multiplying the tensor for a nonvanishing constant ($\mathbf{K} \mapsto \lambda\mathbf{K}$). With respect to the basis of the vector fields on $\mathcal{K}(\mathbb{M}_2)$ given by $(\partial_A, \partial_B, \partial_C, \partial_\alpha, \partial_\beta, \partial_\gamma)$ the infinitesimal generators are spanned by:

Translation:

$$V_1 = (0, -2\beta, -\alpha, 0, -\gamma, 0),$$

$$V_2 = (-2\alpha, 0, -\beta, -\gamma, 0, 0).$$

Boost (hyperbolic rotation):

$$V_3 = (2C, 2C, A + B, \beta, \alpha, 0).$$

Dilatation of $\mathbb{M}_2$:

$$V_4 = (2A, 2B, 2C, \alpha, \beta, 0).$$

Addition of the metric:

$$V_5 = (1, -1, 0, 0, 0, 0).$$

Scalar multiplication:

$$V_6 = (A, B, C, \alpha, \beta, \gamma)$$

(see Ref. 10 for the computation of V_1, V_2, V_3, and V_5).

Moreover, similar to the Euclidean case, there are the following discrete transformations which are analyzed in detail in Sec. III B: the first is the change in sign of the Killing tensor

$$R_0 : K \to -K.$$

The others are induced from the discrete isometries of $\mathbb{M}_2\{\bar{t} = t, \bar{x} = -x\}$ and $\{\bar{t} = -t, \bar{x} = x\}$, they are

$$R_1 : C \to -C, \alpha \to -\alpha,$$

$$R_2 : C \to -C, \beta \to -\beta,$$

In Refs. 8 and 10 the transformations used are R_1 together with

$$\hat{R}_2: A \leftrightarrow B, \alpha \leftrightarrow \beta,$$

which arises from a change of signature of the metric. We prefer transformation R_2 instead of $\hat{R}_2$ because it preserves the interior (and exterior) of the null cone in $\mathbb{M}_2$.

A. Study of the distribution rank

The vector fields V_i form a Lie algebra and therefore generate an integrable distribution, denoted by Δ_M. In to order to study the rank of Δ_M we gather the components of the V_i in the matrix

$$M = \begin{pmatrix} 0 & -2\beta & -\alpha & 0 & -\gamma & 0 \\ -2\alpha & 0 & -\beta & -\gamma & 0 & 0 \\ 2C & 2C & A+B & \beta & \alpha & 0 \\ 2A & 2B & 2C & \alpha & \beta & 0 \\ 1 & -1 & 0 & 0 & 0 & 0 \\ A & B & C & \alpha & \beta & \gamma \end{pmatrix} \tag{9}$$

with determinant:

$$\det M = 2\gamma[\gamma(A+B-2C)-(\alpha-\beta)^2][\gamma(A+B+2C)-(\alpha+\beta)^2].$$

Thus we consider the two surfaces

$$S_1: \gamma = 0, \quad \dim S_1 = 5, \tag{10}$$

$$S_2: [\gamma(A+B-2C)-(\alpha-\beta)^2][\gamma(A+B+2C)-(\alpha+\beta)^2] = 0, \quad \dim S_2 = 5. \tag{11}$$

We remark that the functions

$$f_1 = \gamma, \quad f_2 = [\gamma(A+B-2C)-(\alpha-\beta)^2][\gamma(A+B+2C)-(\alpha+\beta)^2],$$

coincide with the two fundamental algebraic invariants of $\mathcal{K}(\mathbb{M}_2)$ under the action of the isometry group augmented by addition of a multiple of the metric given in Ref. 10.

The surface S_2 is formed by two branches B_1 and B_2 given, respectively, by the equations $\gamma(A+B-2C)=(\alpha-\beta)^2$ and $\gamma(A+B+2C)=(\alpha+\beta)^2$. Nevertheless these two branches are mapped one in the other by the transformation R_1 and thus it is appropriate to consider them as a unique object. The intersection of B_1 and B_2 is the surface

$$B_1 \cap B_2 = S_3: \begin{cases} \gamma(A+B) = \alpha^2 + \beta^2 \\ \gamma C = \alpha\beta \end{cases} \qquad \dim S_3 = 4 \tag{12}$$

The intersection of S_1 and S_2 is described by the equations $\gamma=0$ and $\alpha^2=\beta^2$, while $S_1 \cap S_3$ has equations $\alpha=\beta=\gamma=0$.

The surfaces in Fig. 1 represent all the possible (generic) sections of S_2 in the space α, β, γ. These sections can be grouped in four kinds, corresponding to the following open sets in the space of parameters $A+B$ and C:

$$\text{region I}: \{A+B-2C>0, A+B+2C>0\},$$

$$\text{region II}: \{A+B-2C<0, A+B+2C>0\},$$

$$\text{region III}: \{A+B-2C<0, A+B+2C<0\},$$

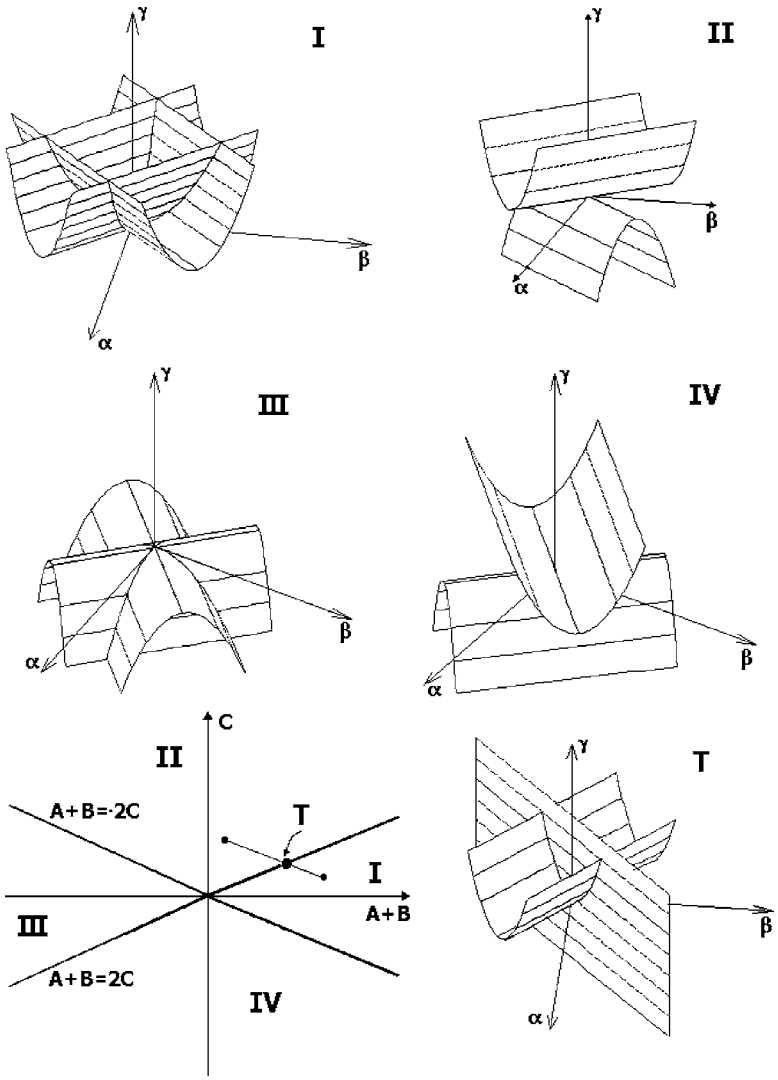

FIG. 1. The sections of surface S_2.

$$\text{region IV:}\{A+B-2C>0, A+B+2C<0\}.$$

Moreover, there are some nongeneric sections corresponding to the boundaries of the above regions, where at least one of the functions $A+B\pm 2C$ vanishes; in these cases the corresponding paraboloid becomes a plane (an example is given by the section T). Figure 2 describes the relation between the surfaces S_1, S_2, and S_3 for parameters belonging to region I.

Proposition 10: The rank of Δ_M *is* 6 *on* $\mathcal{K}(\mathbb{M}_2)-(S_1\cup S_2)$.

Proof: Since the determinant of the matrix (9) vanishes only on $S_1\cup S_2$, outside of this set the rank of Δ_M is maximal.

Proposition 11: The rank of Δ_M *on* S_1-S_2 *is* 5.

Proof: In order to study the rank of Δ_M on S_1 we set $\gamma=0$ in the matrix M: all the nonvanishing 5×5 minors contain the factor $\alpha^2-\beta^2$, and one of them is $2(\alpha^2-\beta^2)^2$. Thus the rank is lesser than 5 only when $\alpha^2=\beta^2$ that is on $S_1\cap S_2$. □

Proposition 12: The rank of Δ_M *on* $S_2-(S_1\cup S_3)$ *is* 5.

Proof: Let us study now the rank of the distribution on S_2 without its intersection with S_1: using the condition $\gamma\neq 0$ Eq. (11) of the two branches of S_2 becomes

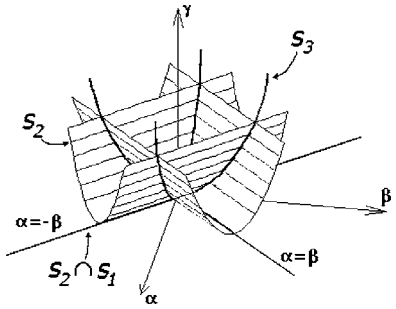

FIG. 2. The section of S_1, S_2, S_3 in region I.

$$B = \frac{(\alpha-\beta)^2}{\gamma} - A + 2C \quad \text{on the branch } B_1,$$

$$B = \frac{(\alpha+\beta)^2}{\gamma} - A - 2C \quad \text{on the branch } B_2.$$

Substituting them in the matrix M (9) and calculating the adjoint we obtain that in both cases all the nonvanishing 5×5 minors contain the factor $\alpha\beta-\gamma C$ and one of them is $\gamma^2(\alpha\beta-\gamma C)$. Then the rank is 5 except when $\gamma C=\alpha\beta$, that is outside of $S_3=B_1\cap B_2$. □

The surface $S_2-(S_1\cup S_3)$ is formed by several connected components: in Sec. III B we will study which of these components are mapped one in the other by the discrete transformations and then generate the same type of coordinates system.

Proposition 13: The rank of Δ_M on S_3-S_1 is 4.

Proof: From the previous proposition the rank of Δ_M on S_3-S_1 is at most 4 and it is lesser if all the 4×4 minors of M vanish. Outside of the intersection with S_1 (i.e., for $\gamma\neq0$) Eq. (12) of S_3 is

$$B = \frac{\alpha^2+\beta^2}{\gamma}, \quad C = \frac{\alpha\beta}{\gamma}$$

and substituting them in M one of the 4×4 minors is $\gamma^3\neq0$. Hence, the rank of Δ_M on S_3-S_1 is always 4. □

Let us now analyze the intersection between S_1 and S_2: $S_1\cap S_2$ is formed by two branches isomorphic to $\mathbb{R}^4$ intersecting in the three-dimensional vector space $\alpha=\beta=\gamma=0$. The first branch is described by the equations $\gamma=0$ and $\alpha=\beta$, while the second by the equations $\gamma=0$ and $\alpha=-\beta$. Inside $S_1\cap S_2$ we point out the surface (union of two branches, named, respectively, C_1 and C_2)

$$S_4:\begin{cases}\gamma=0\\ \alpha=\beta\\ A+B=2C\end{cases}\cup\begin{cases}\gamma=0\\ \alpha=-\beta\\ A+B=-2C\end{cases}\qquad \dim S_4=3. \tag{13}$$

We observe that the branches C_1 and C_2 are both isomorphic to $\mathbb{R}^4$ and their intersection (belonging entirely to $S_1\cap S_3$) is the line

$$C_1\cap C_2=S_5:\begin{cases}\alpha=\beta=\gamma=0\\ B=-A\\ C=0\end{cases}\qquad \dim S_5=1. \tag{14}$$

Proposition 14: The rank of Δ_M on $(S_1\cap S_2)-(S_3\cup S_4)$ is 4.

Proof: We study the rank of Δ_M on the two branches of $S_1\cap S_2$ separately. Moreover we work

outside of the intersection with S_3 (α and β both different from zero). On the first branch, where $\gamma=0$ and $\alpha=\beta$, we get that all the nonvanishing 4×4 minors contain the factor $\alpha^2(2C-B-A)$; on the other branch, where $\gamma=0$ and $\alpha=-\beta$, all the nonvanishing minors contain the factor $\alpha^2(B+A+2C)$. Then the rank is 4 outside S_4. □

Proposition 15: The rank of Δ_M on S_4-S_3 is 3.

Proof: We study the rank of the distribution on the two branches C_1 and C_2 of S_4. On C_1, where $\beta=\alpha$ and $2C=A+B$ it is straightforward that

$$V_2 = V_1 - 2\alpha V_5,$$

$$V_4 = V_3 + (A-B)V_5,$$

$$2V_6 = V_3 + V_4 + \frac{A+B}{2\alpha}(V_1+V_2)$$

and so outside of $S_4\cap S_3$, where $\alpha=0$. In a similar way, on $C_2\beta=-\alpha$ and $2C=-A-B$ hold, hence

$$V_2 = -V_1 - 2\alpha V_5,$$

$$V_4 = -V_3 + (A-B)V_5,$$

$$2V_6 = -V_3 + V_4 + \frac{A+B}{2\alpha}(V_2-V_1).$$

In both cases, the independent vector fields are V_1, V_3, and V_5 only. All the nonvanishing 3×3 minors of the two matrices constructed with these three vectors (restricted on C_1 and C_2, respectively) are real multiples of α^2, thus outside of $S_4\cap S_3$ the rank is 3. □

The rank of the distribution on $S_1\cap S_3$ remains to be evaluated. The space $S_1\cap S_3$ (see Fig. 4) is a three-dimensional vector space described by the equations $\alpha=\beta=\gamma=0$, with coordinates A, B, and C. We recall that $S_3\cap S_4\subset S_3\cap S_1$. On $S_3\cap S_1$ the only independent V_i are V_3, V_5, and V_6 and their components, with respect to $(\partial_A,\partial_B,\partial_C)$ can be collected in the matrix

$$\tilde{M} = \begin{pmatrix} 2C & 2C & A+B \\ 1 & -1 & 0 \\ A & B & C \end{pmatrix}. \tag{15}$$

Proposition 16: The rank of Δ_M on $(S_3\cap S_1)-S_4$ is 3.

Proof: The determinant of the matrix (15) is $\det\tilde{M}=(A+B+2C)(2C-A-B)$ and it vanishes only on the intersection with S_4. □

Proposition 17: The rank of Δ_M on $(S_3\cap S_4)-S_5$ is 2.

Proof: Evaluating the matrix $\tilde{M}$ on the two branches of $S_3\cap S_4$ we get in both cases that all the nonvanishing 2×2 minors contain the factor $A+B$, and one of them is exactly $-(A+B)$, then the rank is lesser than 2 only on the intersection of the branches given by $B=-A$, that is on the line S_5. □

Proposition 18: The rank of Δ_M on S_5 is 1.

Proof: On S_5 the only independent vector field is the constant vector V_5. □

B. Discrete transformations

As we already mentioned besides the continuous transformations associated with the vector fields V_i we have to consider also some discrete transformation leaving unchanged the web associated with a given Killing tensor: the first one is the change of the sign of the tensor

$$R_0{:}K \to -K$$

and the others are induced from the discrete isometries of the Minkowski plane $\{\overline{t}=t,\overline{x}=-x\}$ and $\{\overline{t}=-t,\overline{x}=x\}$, they are

$$R_1{:}C \to -C, \alpha \to -\alpha,$$

$$R_2{:}C \to -C, \beta \to -\beta.$$

Now we have to study the connected components of the sets determined in the Sec. III A and which of them are linked through one of the above discrete transformations. Since some of these sets have a quite high dimension we use the sectioning technique presented in Sec. I B.

In order to study the open set $\mathcal{K}(\mathbb{M}_2)-S_1-S_2$ we observe that it is the set where the three functions

$$\gamma,$$

$$Z_+ = \gamma(A+B-2C) - (\alpha-\beta)^2,$$

$$Z_- = \gamma(A+B+2C) - (\alpha+\beta)^2$$

are all different from zero, where the notation of Ref. 10 has been used. Then, the continuous function $\mathcal{K}(\mathbb{M}_2) \to \mathbb{R}^3$ given by $\Phi=(\gamma,Z_+,Z_-)$ maps $\mathcal{K}(\mathbb{M}_2)-S_1-S_2$ in the eight connected components of $\mathbb{R}^3$ without the coordinate planes. We introduce the eight (not empty) sets $\Gamma_1,\ldots,\Gamma_8$ such that

$$\Phi(\Gamma_1)=(+,+,+), \quad \Phi(\Gamma_5)=(-,+,+),$$

$$\Phi(\Gamma_2)=(+,+,-), \quad \Phi(\Gamma_6)=(-,+,-),$$

$$\Phi(\Gamma_3)=(+,-,+), \quad \Phi(\Gamma_7)=(-,-,+),$$

$$\Phi(\Gamma_4)=(+,-,-), \quad \Phi(\Gamma_8)=(-,-,-).$$

The sets $\Gamma_1,\ldots,\Gamma_8$ form a partition of $\mathcal{K}(\mathbb{M}_2)-S_1-S_2$.

Proposition 19: All the sets $\Gamma_1,\ldots,\Gamma_8$ *are connected and then the set* $\mathcal{K}(\mathbb{M}_2)-(S_1\cup S_2)$ *has* 8 *connected components. We have three orbits of the action:* $\Gamma_1\cup\Gamma_5$, $\Gamma_4\cup\Gamma_8$ (*both linked by the transformation* R_0) *and* $\Gamma_2\cup\Gamma_3\cup\Gamma_6\cup\Gamma_7$ (*linked by* R_0 *and* R_1).

Proof: We prove that all the sets $\Gamma_1,\ldots,\Gamma_8$ are connected by showing that all the connected components of their sections are equivalent in the sense of Lemma 3. First of all we remark that for any two sections with parameter belonging to same region of Fig. 1, the corresponding connected components (of any Γ_i) are trivially equivalent. Hence the sets Γ_1 and Γ_5 are connected because their sections are nonempty only for parameters in regions I and III, respectively. For any of the other Γ_i there exists a region of the parameter space in which the corresponding section has a unique connected component. On the other hand it is possible to construct a continuous path connecting a point of any connected components of the section of a given Γ_i to a point in the one with a unique connected component. For instance moving the parameters along the path shown in Fig. 1 (with $A+B+2C=$const) and leaving α, β, and γ fixed we link any point in one of the two connected components of Γ_3 obtained for parameter in region I, to a point in the unique connected component of the section of Γ_3, obtained for parameters in region II. We conclude, by applying Lemma 3, that the sets Γ_i are all connected. From the definition of transformation R_0 and R_1 we get that Γ_1 is in the same orbit of Γ_5, Γ_4 is in the same orbit of Γ_8, and all the other Γ_i are in the same orbit. Moreover, because all the transformations R_i maps any of the sets $\Gamma_1\cup\Gamma_5$, $\Gamma_4\cup\Gamma_8$, $\Gamma_2\cup\Gamma_3\cup\Gamma_6\cup\Gamma_7$ into themselves, they form distinct orbits. □

In order to study the set $S_2-(S_1\cup S_3)$ we introduce the eight (not empty) sets $\Theta_1,\dots,\Theta_8$ such that

$$\Phi(\Theta_1)=(+,0,+),\quad \Phi(\Theta_5)=(-,0,+),$$

$$\Phi(\Theta_2)=(+,0,-),\quad \Phi(\Theta_6)=(-,0,-),$$

$$\Phi(\Theta_3)=(+,+,0),\quad \Phi(\Theta_7)=(-,+,0),$$

$$\Phi(\Theta_4)=(+,-,0),\quad \Phi(\Theta_8)=(-,-,0).$$

The sets $\Theta_1,\dots,\Theta_8$ form a partition of $S_2-(S_1\cup S_3)$.

Proposition 20: All the sets $\Theta_1,\dots,\Theta_8$ are connected and then the set $S_2-(S_1\cup S_3)$ has 8 connected components. We have two orbits of the action: $\Theta_1\cup\Theta_3\cup\Theta_5\cup\Theta_7$ and $\Theta_2\cup\Theta_4\cup\Theta_6\cup\Theta_8$ (both linked by the transformations R_0 and R_1).

Proof: As in the previous proposition we prove that all the sets $\Theta_1,\dots,\Theta_8$ are connected by showing that all the connected components of their sections are equivalent in the sense of Lemma 3. Also in this case for any two sections with parameter belonging to same region of Fig. 1, the corresponding connected components (of any Θ_i) are trivially equivalent. We observe that because the plane $\gamma=0$ is removed all the paraboloids that form the sections of the sets Θ_i consist of at least two disconnected parts. For any Θ_i a section with a unique connected component exists. For instance in the section labeled T, in Fig. 1, the sets Θ_1 and Θ_5 have a connected section. Moreover it is possible to construct a continuous path connecting a point of any connected components of the section of a given Θ_i to a point in the one with a unique connected component. We conclude, by applying Lemma 3, that the sets Θ_i are all connected. From the definition of transformation R_0 and R_1 we get that Θ_1, Θ_3, Θ_5, and Θ_7 are mapped one into the other and then are in the same orbit, as well Θ_2, Θ_4, Θ_6, and Θ_8. Moreover, because all the transformations R_i maps the two sets $\Theta_1\cup\Theta_3\cup\Theta_5\cup\Theta_7$ and $\Theta_2\cup\Theta_4\cup\Theta_6\cup\Theta_8$ into themselves, they form distinct orbits. □

Proposition 21: The set S_3-S_1 has two connected components mapped one in the other by R_0, and so it forms a unique orbit of the action.

Proof: A section of the set S_3-S_1 is not empty only if its parameters (A,B,C) belong to the closure of regions I and III, referring to the notation of Fig. 1. All sections with parameters belonging to the interior of I (respectively, III) have four connected components which are equivalent to the positive part of the axis γ (respectively, the negative part) in the sections with parameters $A+B=C=0$. The sections with parameters on the boundary of I (respectively, III) and $C\neq 0$ have two connected components, also equivalent to the positive part of the axis γ (respectively, the negative part) in the sections with parameters $A+B=C=0$. Hence just two different equivalence classes of sections exist, corresponding to two connected components of S_3-S_1: one corresponds to positive values of γ, while the other to negative ones. Since the transformation R_0 maps the positive part of the γ axis in the negative one, these two connected components form a unique orbit. □

Proposition 22: The set S_1-S_2 is formed by 4 connected components. Each pair of components symmetric with respect to the origin are linked by R_0, thus two orbit of the action are present.

Proof: S_1 is homeomorphic to $\mathbb{R}^5$, then it is divided in four connected parts by the two four-dimensional hyperplanes that form $S_1\cap S_2$. The transformation R_0 represents a central symmetry and links together components symmetric with respect to the origin. The two transformations R_1 and R_2 on S_1-S_2 are symmetries with respect to the α and β axes, hence they map the two orbits into themselves. □

Proposition 23: The set $(S_1\cap S_2)-(S_3\cup S_4)$ contains eight connected components. They can be linked together using the three discrete transformation R_0, R_1, and R_2 and so they form a unique orbit of the action.

Proof: Each of the two branches of $S_1\cap S_2$ is homeomorphic to $\mathbb{R}^4$. Cutting out from the first

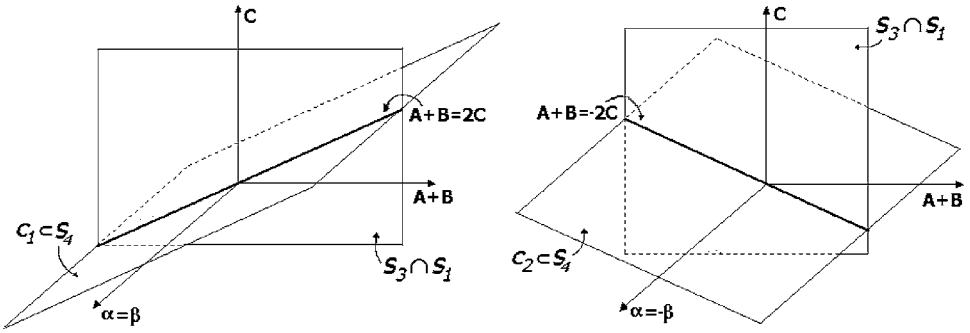

FIG. 3. The two branches of S_4 in $S_1 \cap S_2$.

one the two three-dimensional hyperplanes $S_3 \cap S_1$ and C_1, and from the second one $S_3 \cap S_1$ and C_2, respectively, we obtain four connected components in each case. In order to prove that all the components form a unique orbit, we can consider just the branch defined by $\alpha=\beta$, because R_1 (or equivalently R_2) maps each branch into the other. The transformation R_0 maps one in the other the components symmetric with respect to the origin (see Fig. 3), while the transformation $R_1 \circ R_2$ (corresponding in this branch to the inversion of the $\alpha=\beta$ axis) maps one in the other the components symmetric with respect to the hyperplane $S_3 \cap S_1$. Therefore all the eight connected components form a unique orbit. □

Proposition 24: The set $S_4 - S_3$ contains four connected components. They can be linked together using R_0 and one between R_1 and R_2 and so they form a unique orbit of the action.

Proof: Each of the two branches C_1 and C_2 of S_4 is homeomorphic to $\mathbb{R}^3$. Cutting out from the first one the two two-dimensional hyperplane $S_3 \cap S_4$, we obtain two connected components in each case. Each of the transformations R_1 or R_2 maps C_1 in C_2 and R_0 links the two connected components of C_2. Thus we have a unique orbit. □

Proposition 25: The space $(S_3 \cap S_1) - S_4$ has four connected components. The two pairs of components symmetric with respect to the origin (linked by R_0) form two different orbits of the action.

Proof: As shown in Fig. 4, in the space of coordinates A, B, and C, the set $(S_3 \cap S_1) - S_4$ is composed by the four dihedra determined by the two planes $A+B=2C$ and $A+B=-2C$. Hence it has four connected components. The transformation R_0 links together the two dihedra containing the plane $C=0$ as well as the other pair of dihedra. Unfortunately neither R_1 nor R_2 is able to connect together these two pairs of dihedra. Hence in $(S_3 \cap S_1) - S_4$ we have two different orbits: indeed, the KTs belonging to the pair that contains the plane $C=0$ define pseudo-Cartesian coordinates, while the ones belonging to the other pair are not characteristic tensors, with everywhere imaginary eigenvalues. □

Proposition 26: The space $(S_3 \cap S_4) - S_5$ has four connected components. They are mapped one into the other by the two discrete transformations R_0 and R_1, hence they form a unique orbit of the action.

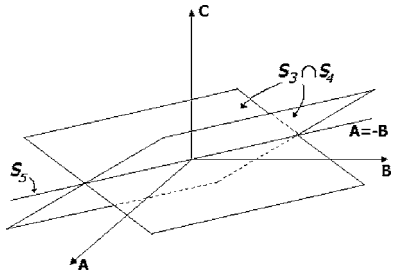

FIG. 4. The space $S_3 \cap S_1$.

Proof: As shown in Fig. 4, in the space of coordinates A, B, and C, the set $(S_3 \cap S_4) - S_5$ is formed by two planes intersecting on the line $A+B=0$, $C=0$ (S_5) without their intersection. Hence it has four connected components. The transformation R_0 maps an half of each plane in the other; moreover, the transformation R_1 maps each plane into the other. □

Proposition 27: The line S_5 formed by the (noncharacteristic) tensors of the kind $\tau \mathbf{g}$ is a connected orbit of the action.

The following list contains all orbits of the action of the group generated by the vector fields V_i, extended with the three finite transformations. For each orbit a representative tensor is given. Orbits of characteristic Killing tensors are labeled according both to Refs. 10 and 8 and the associated *complete* web is plotted. In each picture the set of singular points and the two distinct foliations of the web are emphasized completing the partial representation given in Refs. 10 and 8: the leaves belonging to the two foliations are plotted dashed and continuous, respectively, the grey lines represent the boundaries of the singular set of the web.

M1) The set $\Gamma_1 \cup \Gamma_5$, contained in $\mathcal{K}(\mathbb{M}_2) - (S_1 \cup S_2)$, where $Z_+ > 0$ and $Z_- > 0$: SC9, elliptic coordinates of type I. A tensor of this type is

$$\begin{pmatrix} x^2 & xt \\ xt & t^2+1 \end{pmatrix}.$$

M2) The set $\Gamma_2 \cup \Gamma_3 \cup \Gamma_6 \cup \Gamma_7$, contained in $\mathcal{K}(\mathbb{M}_2) - (S_1 \cup S_2)$, where Z_+ and Z_- have different sign: SC8, hyperbolic coordinates of type I. A tensor of this type is

$$\begin{pmatrix} x^2 & 1+xt \\ 1+xt & t^2 \end{pmatrix}.$$

M3) The set $\Gamma_4 \cup \Gamma_8$, contained in $\mathcal{K}(\mathbb{M}_2) - (S_1 \cup S_2)$, where $Z_+ < 0$ and $Z_- < 0$: SC5 and SC10, elliptic coordinates of type II. A tensor of this type is

$$\begin{pmatrix} x^2 & xt \\ xt & t^2-1 \end{pmatrix}.$$

M4) The set $\Theta_1 \cup \Theta_3 \cup \Theta_5 \cup \Theta_7$ contained in $S_2 - (S_1 \cup S_3)$, where the nonvanishing one of the two functions $Z_\pm$ is positive: SC6, hyperbolic coordinates of type II. Two tensors of this type are

$$\begin{pmatrix} x^2+1 & xt+1 \\ xt+1 & t^2+1 \end{pmatrix}, \quad \begin{pmatrix} x^2+1 & xt-1 \\ xt-1 & t^2+1 \end{pmatrix}.$$

M5) The set $\Theta_2 \cup \Theta_4 \cup \Theta_6 \cup \Theta_8$ contained in $S_2 - (S_1 \cup S_3)$, where the nonvanishing one of the two functions $Z_\pm$ is negative: SC7, hyperbolic coordinates of type III. Two tensors of this type are

$$\begin{pmatrix} x^2-1 & xt-1 \\ xt-1 & t^2-1 \end{pmatrix}, \quad \begin{pmatrix} x^2-1 & xt+1 \\ xt+1 & t^2-1 \end{pmatrix}.$$

M6) The set $S_3 - S_1$: SC2, polar coordinates. A tensor of this type is

$$\begin{pmatrix} x^2 & xt \\ xt & t^2 \end{pmatrix}.$$

M7) The subset of $S_1 - S_2$ containing the α axis: first web for SC4, parabolic coordinate of type I. A tensor of this type is

$$\begin{pmatrix} 2x & t \\ t & 0 \end{pmatrix}.$$

M8) The subset of S_1-S_2 containing the β axis: second web for SC4, parabolic coordinate of type I. A tensor of this type is

$$\begin{pmatrix} 0 & x \\ x & 2t \end{pmatrix}.$$

M9) The set $(S_1 \cap S_2)-(S_3 \cup S_4)$: SC3, parabolic coordinate of type II. Two tensors of this type are

$$\begin{pmatrix} 1+2x & x+t \\ x+t & 1+2t \end{pmatrix}, \quad \begin{pmatrix} 2x+1 & x+t-1 \\ x+t-1 & 2t+1 \end{pmatrix}.$$

M10) The set S_4-S_3: no characteristic tensors. A tensor of this type is

$$\begin{pmatrix} 2x & x+t \\ x+t & 2t \end{pmatrix}.$$

M11) The subset of $(S_1 \cap S_3)-S_4$ containing the plane $C=0$, that is where $\alpha=\beta=\gamma=0$ and $|A+B|>2|C|$: SC1, Cartesian coordinates. A tensor of this type is

$$\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

M12) The subset of $(S_1 \cap S_3)-S_4$ not containing the plane $C=0$, that is where $\alpha=\beta=\gamma=0$ and $|A+B|<2|C|$: no characteristic tensors. A tensor of this type is

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

M13) The set $(S_3 \cap S_4)-S_5$, that is where $\alpha=\beta=\gamma=0$ and $|A+B|=2|C|$: no characteristic tensors. A tensor of this type is

$$\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}.$$

M14) The line S_5, containing tensors multiple of the metric.

As in the Euclidean case, our classification is closely related to the one of Rastelli[13] based on the analysis of the singular set of the tensors. The discriminant of the characteristic polynomial of the general KT of the Minkowski plane is

$$\Delta = (\gamma(x+t)^2 + 2(\alpha+\beta)(x+t) + A + B + 2C)(\gamma(x-t)^2 + 2(\alpha-\beta)(x-t) + A + B - 2C).$$

For $\gamma \neq 0$ (i.e., outside of S_1), we rewrite Δ as

$$\gamma^2\left(\left(x+t+\frac{\alpha+\beta}{\gamma}\right)^2 + \frac{1}{\gamma^2}Z_+\right)\left(\left(x-t+\frac{\alpha-\beta}{\gamma}\right)^2 + \frac{1}{\gamma^2}Z_-\right).$$

In this case the set $\Delta=0$ is made of two couples of lines parallel to $x=t$ and $x=-t$, respectively. It is immediate to see that the lines of the first (second) pair are real and distinct, real and coinciding, imaginary according to the fact that Z_+ (Z_-) is negative, zero, or positive. So the singular set is empty when both $Z_\pm$ are positive (SC9); a strip when $Z_+Z_-<0$ (SC8); two intersecting strips without their intersection when $Z_\pm$ are negative (SC5,SC10); a line when one of $Z_\pm$ vanishes and the other is positive (SC6); a strip and a line orthogonal to it when one of $Z_\pm$ vanishes and the other is positive (SC7); two orthogonal lines if both $Z_\pm$ vanish.

On S_1 we have $\gamma=0$ and the discriminant reduces to

$$(2(\alpha+\beta)(x+t)+A+B+2C)(2(\alpha-\beta)(x-t)+A+B-2C).$$

On S_4 the discriminant identically vanishes, so the singular set is all the plane and the corresponding tensors are not characteristic tensors. Outside of S_4, if the discriminant is not constant (i.e., outside of $S_1\cap S_3$), then $\Delta=0$ is a pair of orthogonal lines or a single line and the singular set is made of two opposite quadrants (the two webs corresponding to SC4) or of a half-plane (SC3). If Δ is a positive constant, the singular set is empty (SC1), while if it is negative all points are singular and the tensor is not characteristic ($(S_1\cap S_3)-S_4$ not containing the plane $C=0$). The classification given here can also be compared with that given in Table III of Ref. 10, where the type of any separable web in $\mathbb{M}_2$ is characterized in terms gamma and $I_\pm=\mathrm{sgn}(Z_\pm)$. Note that in Ref. 10 (as in Ref. 8) the discrete transformation $\hat{R}_2$ is used, with the consequence that the number of distinct types of separable webs is reduced from the ten described in the present paper to nine. IV. CONCLUSION

We have classified Killing tensors of valence two in the Euclidean and Minkowski planes under the action of a group that preserves the type of the Killing web. The method is based on a detailed analysis of the rank of the determining system of partial differential equations for the group invariants and depends crucially on the fact the generic rank of the system is six, which equals the dimension of the space of Killing two-tensors. This result is dimensionally dependent. It is thus unclear whether the method or a modification thereof can be extended to flat spaces of higher dimension or to spaces of nonzero constant curvature. Nonetheless for the cases where the method is applicable it provides a very elegant algebraic classification for the type of the Killing web defined by a characteristic Killing tensor. This classification is equivalent to the classification of quadratic symmetric operators in the generators of the isometries of $\mathbb{M}_2$, given in Ref. 8 and to the classification given in Ref. 10 in terms of Killing tensor invariants, up to the exchange between space and time: since we do not allow a change in signature of the metric, the coordinates of type SC4 (parabolic of type I in Ref. 8) splits into the classes M7 and M8. Our classification, not being restricted to characteristic Killing tensors, extends the classification given in Ref. 10 through the invariant theory of Killing tensors.

We use the method of stochastic quantization in a topological field theory defined in an Euclidean space, assuming a Langevin equation with a memory kernel. We show that our procedure for the Abelian Chern-Simons theory converges regardless of the nature of the Chern-Simons coefficient. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2219158]

I. INTRODUCTION

In the Euclidean version of field theory, we are interested in computing the Schwinger functions of a theory. In order to obtain these functions, Parisi and Wu introduced the stochastic quantization.[1] This formalism was introduced as an alternative quantization scheme, different from the usual canonical and the path integral field quantization, based in the Hamiltonian and the Lagrangian, respectively. The method starts from a classical equation of motion, but not from Hamiltonian or Lagrangian, and consequently can be used to quantize dynamical systems without canonical formalism and therefore it is useful in situations where the other methods lead to difficult problems.

The main idea of the stochastic quantization is that a d-dimensional quantum system is equivalent to a $(d+1)$-dimensional classical system that undergoes random fluctuations. Some of the most important papers in the subject can be found in Ref. 2. A brief introduction to the stochastic quantization can be found in Ref. 3 and Ref. 4. See also Ref. 5.

In a previous paper,[6] we studied the stochastic quantization of a self-interacting scalar field theory, assuming a non-Markovian process, modifying the Langevin equation by introducing a memory kernel.[7–9] We have shown that although a system with a stationary, Gaussian, non-Markovian Langevin equation with a memory kernel and a colored noise converges in the asymptotic limit of the Markov parameter τ to the equilibrium, we obtain a nonregularized theory.

In this paper we would like to continue to investigate the virtues of this non-Markovian stochastic quantization method, now employed in the case of a topological field theory. One of the peculiar features within this kind of theory is the appearance of a factor of i in front of the topological action in Euclidean space. Since the topological theory does not depend on the metric of space-time, the path integral measure weighing remains to be e^{iS}, even after the Wick rotation. Another feature of a topological action is that it is the integral of a density that is not bounded from below in Euclidean space. So, if one attempts to use a Markovian Langevin equation with a white noise to quantize this theory, one will find serious problems if the factor of i is ignored. This Langevin equation will not tend to any equilibrium in the large τ limit. So, in this sense, the use of a Langevin equation with a complex action[10] becomes essential for stochastically quantizing a topological action.[11–13]

There is, in the literature, an approach to solve the above mentioned convergence problem. Studying the purely topological Chern-Simons theory, Ferrari *et al.* introduced a nontrivial kernel

[a]Electronic mail: gsm@cbpf.br
[b]Electronic mail: nfuxsvai@cbpf.br

in the Langevin equation.[14] On the other way, Wu *et al.*[15] showed that the Langevin equation for a Maxwell-Chern-Simons theory converges to the usual equilibrium result without the need to introduce such a kernel. Their method, however, only works in the case where the Chern-Simons coefficient is real.

We show in this paper that, if one uses a non-Markovian Langevin equation with a colored random noise, this convergence problem may be solved in a different way. We will apply this approach to three-dimensional Abelian Chern-Simons theory and prove that we obtain convergence toward equilibrium, even with an imaginary Chern-Simons coefficient. To simplify the calculations we assume the units to be such that $\hbar=c=1$.

II. STOCHASTIC QUANTIZATION OF ABELIAN CHERN-SIMONS THEORY

Let us consider the following action for the three-dimensional Maxwell-Chern-Simons theory, in Euclidean space:

$$S=\int d^3x\left(\frac{1}{4\epsilon^2}A_\mu(x)(-\Delta\delta_{\mu\nu}+\partial_\mu\partial_\nu)A_\nu(x)-i\frac{\kappa}{8\pi}\epsilon_{\mu\nu\rho}A_\mu(x)\partial_\nu A_\rho(x)\right), \tag{1}$$

where Δ is the three-dimensional Laplace operator. At the end of our calculations we set $\epsilon\to\infty$ to obtain the results for the purely topological theory, as discussed in Ref. 15. Notice the factor of i in front of the topological term, as mentioned before. In order to obtain the Schwinger functions of the theory, let us use the stochastic quantization method. Let us introduce a non-Markovian Langevin equation given by

$$\frac{\partial}{\partial\tau}A_\mu(\tau,x)=-\int_0^\tau ds\, M_\Lambda(\tau-s)\frac{\delta S}{\delta A_\mu(x)}\Big|_{A_\mu(x)=A_\mu(s,x)}+\eta_\mu(\tau,x), \tag{2}$$

where $M_\Lambda(\tau-s)$ is a memory kernel and Λ is a arbitrary parameter. We will have, from Eqs. (1) and (2), in momentum space:

$$\frac{\partial}{\partial\tau}A_\mu(\tau,k)=-\frac{k^2}{\epsilon^2}\left(\delta_{\mu\nu}-\frac{k_\mu k_\nu}{k^2}\right)\int_0^\tau ds\, M_\Lambda(\tau-s)A_\nu(s,k)-\frac{\kappa}{4\pi}\epsilon_{\mu\nu\rho}k_\rho\int_0^\tau ds\, M_\Lambda(\tau-s)A_\nu(s,k)$$
$$+\eta_\mu(\tau,k), \tag{3}$$

where the stochastic field $\eta_\mu(\tau,k)$ satisfies the modified Einstein relations:

$$\langle\eta_\mu(\tau,k)\rangle_\eta=0, \tag{4}$$

and also

$$\langle\eta_\mu(\tau,k)\,\eta_\nu(\tau',k')\rangle_\eta=2\,\delta_{\mu\nu}M_\Lambda(|\tau-\tau'|)\,\delta^d(k+k'). \tag{5}$$

For the initial condition $A_\mu(\tau,k)|_{\tau=0}=0$, it is easy to see that the solution of Eq. (3) is given by

$$A_\mu(\tau,k)=\int_0^\infty d\tau'\, G_{\mu\nu}(k;\tau-\tau')\,\eta_\nu(\tau',k), \tag{6}$$

where we introduced the retarded Green's function $G_{\mu\nu}(k,r)$, which satisfies

$$\frac{\partial}{\partial\tau}G_{\mu\nu}(k,\tau)=-\frac{k^2}{\epsilon^2}\left(\delta_{\mu\rho}-\frac{k_\mu k_\rho}{k^2}\right)\int_0^\tau ds\, M_\Lambda(\tau-s)G_{\rho\nu}(k,s)-\frac{\kappa}{4\pi}\epsilon_{\mu\rho\sigma}k_\sigma\int_0^\tau ds\, M_\Lambda(\tau-s)G_{\rho\nu}(k,s)$$
$$+\delta_{\mu\nu}\delta(\tau), \tag{7}$$

for $\tau>0$ and $G_{\mu\nu}(k,\tau)=0$ for $\tau<0$.

To proceed the calculations, let us introduce the Laplace transform of Eq. (7):

$$zG_{\mu\nu}(k,z) = -\frac{k^2}{\epsilon^2}\left(\delta_{\mu\rho} - \frac{k_\mu k_\rho}{k^2}\right)M_\Lambda(z)G_{\rho\nu}(k,z) - \frac{\kappa}{4\pi}\epsilon_{\mu\rho\sigma}k_\sigma M_\Lambda(z)G_{\rho\nu}(k,z) + \delta_{\mu\nu}, \tag{8}$$

where

$$M_\Lambda(z) = \int_0^\infty d\tau\, M_\Lambda(\tau)e^{-z\tau}. \tag{9}$$

For the result without memory [or, formally, when $M_\Lambda(\tau) \to \delta(\tau)$], we have, from Eq. (7),

$$\frac{\partial}{\partial\tau}G_{\mu\nu}(k,\tau) = -\frac{k^2}{\epsilon^2}\left(\delta_{\mu\rho} - \frac{k_\mu k_\rho}{k^2}\right)G_{\rho\nu}(k,\tau) - \frac{\kappa}{4\pi}\epsilon_{\mu\rho\sigma}k_\sigma G_{\rho\nu}(k,\tau) + \delta_{\mu\nu}\delta(\tau), \tag{10}$$

whose Laplace transform reads as

$$zG_{\mu\nu}(k,z) = -\frac{k^2}{\epsilon^2}\left(\delta_{\mu\rho} - \frac{k_\mu k_\rho}{k^2}\right)G_{\rho\nu}(k,z) - \frac{\kappa}{4\pi}\epsilon_{\mu\rho\sigma}k_\sigma G_{\rho\nu}(k,z) + \delta_{\mu\nu}. \tag{11}$$

Note the similarity between Eqs. (8) and (11). The solution to Eq. (10) is given by[15]

$$G_{\mu\nu}(k,\tau) = \frac{k_\mu k_\nu}{k^2} + \left(\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right)\cos\left(\frac{\kappa}{4\pi}k\tau\right) \quad - \epsilon_{\mu\nu\sigma}\frac{k_\sigma}{k}\sin\left(\frac{\kappa}{4\pi}k\tau\right)\right)\exp\left(\frac{-k^2}{\epsilon^2}\tau\right), \tag{12}$$

whose Laplace transform is

$$G_{\mu\nu}(k,z) = \frac{k_\mu k_\nu}{k^2}\frac{1}{z} + \frac{\left(\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right)z - \epsilon_{\mu\nu\sigma}k_\sigma\left(\frac{\kappa}{4\pi}\right)\right)}{\left(z + \frac{k^2}{\epsilon^2}\right)^2 + \left(\frac{\kappa}{4\pi}\right)^2 k^2}. \tag{13}$$

Comparing Eqs. (8) and (11), it is trivial to obtain the analog of Eq. (13) with memory:

$$G_{\mu\nu}(k,z) = \frac{k_\mu k_\nu}{k^2}\frac{1}{z} + \frac{\left(\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right)z - \epsilon_{\mu\nu\sigma}k_\sigma\left(\frac{\kappa'}{4\pi}\right)\right)}{\left(z + \frac{k^2}{\epsilon'^2}\right)^2 + \left(\frac{\kappa'}{4\pi}\right)^2 k^2}, \tag{14}$$

where

$$\frac{1}{\epsilon'^2} \equiv \frac{M_\Lambda(z)}{\epsilon^2} \tag{15}$$

and

$$\kappa' \equiv \kappa M_\Lambda(z). \tag{16}$$

In the Appendix , we derive in detail the inverse Laplace transform of Eq. (14). It is given by

$$G_{\mu\nu}(k,\tau) = \left(\frac{k_\mu k_\nu}{k^2} + g_{\mu\nu}G_1(k,\tau) + \tilde{g}_{\mu\nu}G_2(k,\tau)\right)\theta(\tau), \tag{17}$$

where the quantities $G_i(k,\tau)$, $i=1,2$, $g_{\mu\nu}$ and $\tilde{g}_{\mu\nu}$ are defined in the Appendix . We see that our $G_{\mu\nu}(k,\tau)$ does not approach zero as $\tau\to\infty$. The reason for such behavior is the presence of the longitudinal term $k_\mu k_\nu/k^2$, which is common in the stochastic quantization of all gauge theories without gauge fixing and can be eliminated by a suitable stochastic gauge fixing. In spite of this, the presence of this term will not give any contribution to gauge invariant quantities.

After this discussion, we are able to present the two-point correlation function. We have that $D_{\mu\nu}(k;\tau,\tau')$ is given by

$$\begin{aligned} D_{\mu\nu}(k,\tau,\tau') &\equiv \langle A_\mu(\tau,k)A_\nu(\tau' k')\rangle_\eta \\ &= \delta^d(k+k')\int_0^\infty ds\int_0^\infty ds'\, G_{\mu\kappa}(k,\tau-s)G_{\lambda\nu}(k,\tau'-s')\langle \eta_k(s,k)\,\eta_\lambda(s',k')\rangle_\eta \\ &= 2\delta^d(k+k')\int_0^\infty ds\int_0^\infty ds'\, G_{\mu\lambda}(k,\tau-s)G_{\lambda\nu}(k,\tau'-s')M_\Lambda(|s-s'|). \end{aligned} \tag{18}$$

So, inserting Eq. (17) in the above equation and splitting the result in five different contributions yields

$$D_{\mu\nu}(k;\tau,\tau') = 2\delta^d(k+k')(J_1+J_2+J_3+J_4+J_5) \tag{19}$$

where:

$$J_1 \equiv \int_0^\tau ds\int_0^{\tau'} ds'\frac{k_\mu k_\nu}{k^2}M_\Lambda(|s-s'|), \tag{20}$$

$$J_2 \equiv \int_0^\tau ds\int_0^{\tau'} ds'\, g_{\mu\lambda}g_{\lambda\nu}G_1(k;\tau-s)G_1(k;\tau'-s')M_\Lambda(|s-s'|), \tag{21}$$

$$J_3 \equiv \int_0^\tau ds\int_0^{\tau'} ds'\, \tilde{g}_{\mu\lambda}\tilde{g}_{\lambda\nu}G_2(k;\tau-s)G_2(k;\tau'-s')M_\Lambda(|s-s'|), \tag{22}$$

$$J_4 \equiv \int_0^\tau ds\int_0^{\tau'} ds'\, g_{\mu\lambda}\tilde{g}_{\lambda\nu}G_1(k;\tau-s)G_2(k;\tau'-s')M_\Lambda(|s-s'|), \tag{23}$$

and, finally,

$$J_5 \equiv \int_0^\tau ds\int_0^{\tau'} ds'\, \tilde{g}_{\mu\lambda}g_{\lambda\nu}G_2(k;\tau-s)G_1(k;\tau'-s')M_\Lambda(|s-s'|). \tag{24}$$

We can solve these equations by ordering the fictitious times s and s', $s>s'$ for instance, and solving the integrals in s (s') in the interval $[0,t]$ ($[0,s]$). We obtain for J_1, in the limit $\tau\to\infty$,

$$J_1 = \frac{1}{2}\frac{k_\mu k_\nu}{k^2}\left(\tau-\frac{1}{\Lambda^2}\right). \tag{25}$$

The integrals J_2 and J_3 can be solved by analogy with the scalar case.[6] Making the following replacements:

$$(k^2+m^2)_1 \to \frac{\alpha}{\Lambda^2}(1-\Lambda^4)+\Lambda^2 y_1+\frac{(\alpha^2-y_1^2)}{\Lambda^2}, \tag{26}$$

$$(k^2+m^2)_2 \to \frac{\alpha}{\Lambda^2}(1+\Lambda^4)-\Lambda^2 y_1-\frac{(\alpha^2-y_1^2)}{\Lambda^2}, \tag{27}$$

where the subscript 1 (2) stands for the G_1 (G_2) case (see the Appendix), we will have, in the asymptotic limit $\tau\to\infty$, that

$$J_2 = \left(\frac{\alpha}{\Lambda^2}(1-\Lambda^4) + \Lambda^2 y_1 + \frac{(\alpha^2 - y_1^2)}{\Lambda^2}\right)^{-1}\left[\frac{\Lambda^2}{(\sigma\gamma)^2}\left(\frac{\Lambda^4}{4} + \frac{(\sigma+\gamma)^2}{4}\right)\left(\frac{\kappa}{4\pi}\right)\epsilon_{\mu\nu\rho}k_\rho\right.$$
$$\left. + (\sigma\gamma)^{-2}\left(\left(\frac{\Lambda^4}{4} + \frac{(\sigma+\gamma)^2}{4}\right)^2 - \frac{\Lambda^4}{4}k^2\left(\frac{\kappa}{4\pi}\right)^2\right)\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right)\right], \tag{28}$$

and

$$J_3 = \left(\frac{\alpha}{\Lambda^2}(1+\Lambda^4) - \Lambda^2 y_1 - \frac{(\alpha^2 - y_1^2)}{\Lambda^2}\right)^{-1}\left[-\frac{\Lambda^2}{(\sigma\gamma)^2}\left(\frac{\Lambda^4}{4} + \frac{(\sigma-\gamma)^2}{4}\right)\left(\frac{\kappa}{4\pi}\right)\epsilon_{\mu\nu\rho}k_\rho\right.$$
$$\left. + (\sigma\gamma)^{-2}\left(\left(\frac{\Lambda^4}{4} + \frac{(\sigma-\gamma)^2}{4}\right)^2 - \frac{\Lambda^4}{4}k^2\left(\frac{\kappa}{4\pi}\right)^2\right)\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right)\right]. \tag{29}$$

The remaining integrals J_4 and J_5 can be solved without any further complications.[16] Again, in the asymptotic limit $\tau\to\infty$, we obtain

$$J_4 + J_5 = \frac{f(\Lambda,\sigma,\gamma)}{g(\Lambda,\sigma,\gamma)}\left[-\frac{\Lambda^2}{(2\sigma\gamma)}\left(\frac{\kappa}{4\pi}\right)\epsilon_{\mu\nu\rho}k_\rho \quad + (\sigma\gamma)^{-2}\left(\left(\frac{\Lambda^4}{4} + \frac{(\sigma+\gamma)^2}{4}\right)\left(\frac{\Lambda^4}{4} + \frac{(\sigma-\gamma)^2}{4}\right)\right.\right.$$
$$\left.\left. + \frac{\Lambda^4}{4}k^2\left(\frac{\kappa}{4\pi}\right)^2\right)\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right)\right], \tag{30}$$

where

$$f(\Lambda,\sigma,\gamma) \equiv 153\Lambda^{14} + \Lambda^{10}[18(\sigma+\gamma)^2 + 17(\sigma-\gamma)^2 + 9\sigma\gamma] + \Lambda^6\left[(\sigma+\gamma)^4 + (\sigma-\gamma)^4\right.$$
$$\left. + \frac{\sigma\gamma}{2}((\sigma+\gamma)^2 + (\sigma-\gamma)^2) - \frac{9}{2}\sigma\gamma((\sigma+\gamma)^2 - \sigma\gamma(1-2\sigma\gamma))\right]$$
$$+ \Lambda^2\sigma\gamma\left[\frac{(\sigma+\gamma)^2}{2} - \sigma\gamma(\sigma+\gamma)^2 - \frac{1}{2}(\sigma+\gamma)^2(\sigma-\gamma)^2\right], \tag{31}$$

and

$$g(\Lambda,\sigma,\gamma) \equiv (9\Lambda^4 + (\sigma-\gamma)^2)(9\Lambda^4 + (\sigma+\gamma)^2)(\Lambda^4 + \sigma^2)(\Lambda^4 + \gamma^2). \tag{32}$$

As mentioned before, the linearly divergent longitudinal term, found in Eq. (25), can be eliminated by stochastic gauge fixing. Now, taking the limit $\epsilon\to\infty$, it is easy to see that the contribution $J_2 + J_3$ vanishes identically. Then, finally, we obtain, for the purely topological two-point correlation function:

$$D_{\mu\nu}(k;\tau,\tau') = 2\delta^{ij}(k+k')\left[\frac{1}{2}\frac{k_\mu k_\nu}{k^2}\left(\tau - \frac{1}{\Lambda^2}\right) + \frac{f'(\Lambda,\sigma,\gamma)}{g'(\Lambda,\sigma,\gamma)}\left(-\frac{\Lambda^2}{2Q(y_1')}\left(\frac{\kappa}{4\pi}\right)\epsilon_{\mu\nu\rho}k_\rho\right.\right.$$
$$\left.\left. + \left(\frac{\beta'}{Q^2(y_1')} - 1\right)\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right)\right)\right], \tag{33}$$

where $\beta' = \beta|_{\epsilon\to\infty} = (\Lambda^4/4)k^2(\kappa/4\pi)$, $y_1' = y_1|_{\varepsilon\to\infty}$, and

$$f'(\Lambda,\sigma,\gamma) = f\Big|_{\varepsilon\to\infty} = 120\Lambda^{14} + \frac{19}{2}\Lambda^{10}Q(y_1') + 9\Lambda^6Q^2(y_1') - \frac{\Lambda^6}{2}Q(y_1') + \frac{9}{2}\Lambda^4Q(y_1') + \Lambda^2Q^2(y_1')$$
$$- 18Q^2(y_1') + \frac{9}{2}Q(y_1'), \tag{34}$$

$$g'(\Lambda,\sigma,\gamma) = g|_{\epsilon\to\infty} = 64\Lambda^8 Q^2(y_1') + 32\Lambda^4 Q^3(y_1') + 4Q^4(y_1'), \tag{35}$$

$$Q(y_1') \equiv (\Lambda^4 y_1' - (y_1')^2)^{1/2}. \tag{36}$$

We see that in our last expression for the propagator remained a term proportional to the Maxwell transversal propagator. This is a anomalous situation, since the Maxwell contribution is absent in the usual purely topological Chern-Simons theory. The origin of this anomalous situation is the use of a non-Markovian Langevin equation. To circumvent this problem and recover the usual result, we have to make the following choice:

$$\beta' = Q^2(y_1'), \tag{37}$$

which leads us to

$$y_1' = \frac{\Lambda}{2} \pm \frac{(\Lambda^8 - 4\beta')^{1/2}}{2}. \tag{38}$$

So, if we choose

$$y_1 = \frac{\Lambda}{2} \pm \frac{(\Lambda^8 - 4\beta')^{1/2}}{2} + \frac{C}{\varepsilon^n}, \tag{39}$$

where C is a real constant and n is an arbitrarily large integer number. Inserting this latter equation in Eq. (A23), we will get a cubic equation in C. From the usual Galois theory of radical solutions for polynomials,[16–18] we can always choose a real root from the three possible ones. So, in other words, we can always choose a real constant such that the two-point correlation function converges to a "purely topological" term, with some minor differences from the usual one. We notice as well that our approach still works when κ is purely imaginary [which is mathematically analogous to writing $A_\mu = A'_\mu + iA'_\mu$, where A'_μ is real, and taking the real part of the Langevin Eq. (3) in coordinate space].

III. CONCLUSIONS

In this paper we discussed the stochastic quantization for Maxwell Chern-Simons theory using a non-Markovian Langevin equation and examined the field theory that appears in the asymptotic limit of this non-Markovian process.

This paper is the second one of a program where the possibility that the Parisi-Wu quantization method can be extended is investigated, assuming a Langevin equation with a memory kernel with the modified Einstein relations. To make sure that this modification can be used, one must first check that the system evolves to the equilibrium in the asymptotic limit. Second, we have to show that it converges to the correct equilibrium distribution. We proved that although the system evolves to equilibrium, in the propagator remained a term proportional to the Maxwell transversal propagator. This is an anomalous situation, since the Maxwell contribution is absent in the usual purely topological Chern-Simons theory. To circumvent this problem and recover the usual result, we have imposed a constraint in the parameters of our theory.

APPENDIX: DERIVATION OF THE RETARDED GREEN'S FUNCTION FOR THE DIFFUSION PROBLEM

In this Appendix, we derive the retarded Green's function for the diffusion problem $G_{\mu\nu}(k,\tau)$. Expanding the denominator in Eq. (A1), given by

$$G_{\mu\nu}(k,z)=\frac{k_\mu k_\nu}{k^2}\frac{1}{z}+\frac{\left(\left(\delta_{\mu\nu}-\frac{k_\mu k_\nu}{k^2}\right)z-\epsilon_{\mu\nu\sigma}k_\sigma\left(\frac{\kappa'}{4\pi}\right)\right)}{\left(z+\frac{k^2}{\epsilon'^2}\right)^2+\left(\frac{\kappa'}{4\pi}\right)^2k^2}, \tag{A1}$$

we have

$$G_{\mu\nu}(k,z)=\frac{k_\mu k_\nu}{k^2}\frac{1}{z}+\left(\delta_{\mu\nu}-\frac{k_\mu k_\nu}{k^2}\right)I_1(z)-\epsilon_{\mu\nu\sigma}k_\sigma\left(\frac{\kappa}{4\pi}\right)I_2(z), \tag{A2}$$

where

$$I_1(z)\equiv\frac{z}{P(z)}, \tag{A3}$$

$$I_2(z)\equiv\frac{M_\Lambda(z)}{P(z)}, \tag{A4}$$

and

$$P(z)\equiv z^2+2\frac{k^2}{\varepsilon^2}M_\Lambda(z)z+\frac{k^4}{\varepsilon^4}M_\Lambda^2(z)+\left(\frac{\kappa}{4\pi}\right)^2k^2M_\Lambda^2(z). \tag{A5}$$

Using the following exponential representation for the memory kernel $M_\Lambda(\tau)$:

$$M_\Lambda^n(\tau)=\frac{1}{2n!}\Lambda^2(\Lambda^2|\tau|)^n\exp(-\Lambda^2|\tau|), \tag{A6}$$

where Λ is a parameter, we will have, for the case $n=0$,

$$I_1(z)=\frac{z^3+2\Lambda^2z^2+\Lambda^4z}{\Omega(z)}, \tag{A7}$$

$$I_2(z)=\frac{\frac{\Lambda^2}{2}z+\frac{\Lambda^4}{2}}{\Omega(z)}, \tag{A8}$$

and

$$\Omega(z)\equiv z^4+2\Lambda^2z^3+(\Lambda^4+\alpha)z^2+\alpha\Lambda^2z+\beta, \tag{A9}$$

where

$$\alpha\equiv\frac{k^2\Lambda^2}{\varepsilon^2}, \tag{A10}$$

and

$$\beta\equiv\left(\frac{k^4}{\varepsilon^4}+\left(\frac{\kappa}{4\pi}\right)^2k^2\right)\frac{\Lambda^4}{4}. \tag{A11}$$

In order to get the inverse Laplace transform of Eq. (A2), we must seek for the solutions of the quartic equation $\Omega(z)=0$. As it is well known, a general quartic equation is a fourth-order polynomial equation of the form:

$$z^4 + a_3 z^3 + a_2 z^2 + a_1 z + a_0 = 0. \tag{A12}$$

Using the familiar algebraic technique developed by Ferrari and Cardano,[19] it is easy to show that the roots of Eq. (A12) are given by

$$z_1 = -\frac{1}{4}a_3 + \frac{1}{2}R + \frac{1}{2}D, \tag{A13}$$

$$z_2 = -\frac{1}{4}a_3 + \frac{1}{2}R - \frac{1}{2}D, \tag{A14}$$

$$z_3 = -\frac{1}{4}a_3 - \frac{1}{2}R + \frac{1}{2}E, \tag{A15}$$

$$z_4 = -\frac{1}{4}a_3 - \frac{1}{2}R - \frac{1}{2}E, \tag{A16}$$

where

$$R \equiv \left(\frac{1}{4}a_3^2 - a_2 + y_1\right)^{1/2}, \tag{A17}$$

$$D \equiv \begin{cases} (F(R)+G)^{1/2}, & \text{for } R \neq 0, \\ (F(0)+H)^{1/2}, & \text{for } R = 0, \end{cases} \tag{A18}$$

$$E \equiv \begin{cases} (F(R)-G)^{1/2}, & \text{for } R \neq 0, \\ (F(0)-H)^{1/2}, & \text{for } R = 0, \end{cases} \tag{A19}$$

$$F(R) \equiv \frac{3}{4}a_3^2 - R^2 - 2a_2, \tag{A20}$$

$$H \equiv 2(y_1^2 - 4a_0)^{1/2}, \tag{A21}$$

$$G \equiv \frac{1}{4}(4a_3a_2 - 8a_1 - a_3^3)R^{-1}, \tag{A22}$$

and y_1 is a real root of the following cubic equation:

$$y^3 - a_2 y^2 + (a_1 a_3 - 4a_0)y + (4a_2 a_0 - a_1^2 - a_3^2 a_0) = 0. \tag{A23}$$

Therefore, the inverse Laplace transform of $I_1(z)$ and $I_2(z)$ reads

$$I_1(\tau) = \frac{z_1^3 + 2\Lambda^2 z_1^2 + \Lambda^4 z_1}{(z_1 - z_2)(z_1 - z_3)(z_1 - z_4)} e^{z_1\tau} + \frac{z_2^3 + 2\Lambda^2 z_2^2 + \Lambda^4 z_2}{(z_2 - z_1)(z_2 - z_3)(z_2 - z_4)} e^{z_2\tau} + \frac{z_3^3 + 2\Lambda^2 z_3^2 + \Lambda^4 z_3}{(z_3 - z_1)(z_3 - z_2)(z_3 - z_4)} e^{z_3\tau} + \frac{z_4^3 + 2\Lambda^2 z_4^2 + \Lambda^4 z_4}{(z_4 - z_1)(z_4 - z_2)(z_4 - z_3)} e^{z_4\tau}, \tag{A24}$$

and

$$I_2(\tau) = \frac{\frac{\Lambda^2}{2} z_1 + \frac{\Lambda^4}{2}}{(z_1 - z_2)(z_1 - z_3)(z_1 - z_4)} e^{z_1\tau} + \frac{\frac{\Lambda^2}{2} z_2 + \frac{\Lambda^4}{2}}{(z_2 - z_1)(z_2 - z_3)(z_2 - z_4)} e^{z_2\tau} + \frac{\frac{\Lambda^2}{2} z_3 + \frac{\Lambda^4}{2}}{(z_3 - z_1)(z_3 - z_2)(z_3 - z_4)} e^{z_3\tau} + \frac{\frac{\Lambda^2}{2} z_4 + \frac{\Lambda^4}{2}}{(z_4 - z_1)(z_4 - z_2)(z_4 - z_3)} e^{z_4\tau}. \tag{A25}$$

Now, let us study a simple convergence criterion in order that $G_{\mu\nu}(k,\tau) \to 0$ as the Markov parameter goes to infinity, i.e., $\tau \to \infty$. In this situation, the system converges to an equilibrium. Comparing the polynomial $\Omega(z)$ with expression Eq. (A12), it is trivial to make the following identifications: $a_0 = \beta$, $a_1 = \alpha\Lambda^2$, $a_2 = \alpha + \Lambda^4$ and, finally, $a_3 = 2\Lambda^2$.

For convenience, let us assume that R, defined by Eq. (A17), does not vanish. To proceed with the calculations, let us introduce the following real quantities σ and γ defined, respectively, by

$$\sigma \equiv \left(a_2 - \frac{1}{4} a_3^2 - y_1 \right)^{1/2} = (\alpha - y_1)^{1/2} \tag{A26}$$

and

$$\gamma \equiv \left(a_2 + y_1 - \frac{1}{2} a_3^2 \right)^{1/2} = (\alpha + y_1 - \Lambda^4)^{1/2}, \tag{A27}$$

where we used the identifications $a_2 = \alpha + \Lambda^4$ and $a_3 = 2\Lambda^2$. Then, we shall have

$$R = i\sigma \tag{A28}$$

and

$$E = i\gamma. \tag{A29}$$

So, with the above identifications, it is easy to see to prove that G, defined by Eq. (A22), vanishes identically. Therefore, we will have, from Eq. (A18) and Eq. (A19), that $D = E$. We also see that

$$\sigma^2 + \gamma^2 = 2\alpha - \Lambda^4 > 0, \tag{A30}$$

which implies

$$k^2 > \frac{\varepsilon^2 \Lambda^2}{2}, \tag{A31}$$

where we used Eq. (A10), which is a convergence criterion similar to the massless scalar field case.[6]

Thus, from Eqs. (A13)–(A16), Eq. (A28), and Eq. (A29), we obtain the following solutions to $\Omega(z) = 0$:

$$z_1 = -\frac{\Lambda^2}{2} + \frac{1}{2} i\sigma + \frac{1}{2} i\gamma, \tag{A32}$$

$$z_2 = -\frac{\Lambda^2}{2} + \frac{1}{2}i\sigma - \frac{1}{2}i\gamma, \tag{A33}$$

$$z_3 = -\frac{\Lambda^2}{2} - \frac{1}{2}i\sigma + \frac{1}{2}i\gamma, \tag{A34}$$

$$z_4 = -\frac{\Lambda^2}{2} - \frac{1}{2}i\sigma - \frac{1}{2}i\gamma. \tag{A35}$$

So, from these last results, we will have, finally, for $G_{\mu\nu}(k,\tau)$,

$$G_{\mu\nu}(k,\tau) = \left(\frac{k_\mu k_\nu}{k^2} + g_{\mu\nu}G_1(k,\tau) + \tilde{g}_{\mu\nu}G_2(k,\tau)\right)\theta(\tau), \tag{A36}$$

where:

$$G_1(k,\tau) \equiv \left(\frac{\Lambda^2}{(\sigma+\gamma)}\sin\left(\frac{(\sigma+\gamma)}{2}\tau\right) + \cos\left(\frac{(\sigma+\gamma)}{2}\tau\right)\right)e^{-(\Lambda^2/2)\tau}, \tag{A37}$$

$$G_2(k,\tau) \equiv \left(\frac{\Lambda^2}{(\sigma-\gamma)}\sin\left(\frac{(\sigma-\gamma)}{2}\tau\right) + \cos\left(\frac{(\sigma-\gamma)}{2}\tau\right)\right)e^{-(\Lambda^2/2)\tau}, \tag{A38}$$

and $g_{\mu\nu}$ and $\tilde{g}_{\mu\nu}$ appearing in Eq. (A36) are defined by

$$g_{\mu\nu} \equiv \Pi_{\mu\nu} - h_{\mu\nu}, \tag{A39}$$

$$\tilde{g}_{\mu\nu} \equiv h_{\mu\nu} - \tilde{\Pi}_{\mu\nu}, \tag{A40}$$

with

$$h_{\mu\nu} \equiv -\frac{\Lambda^2}{2\gamma\sigma}\epsilon_{\mu\nu\rho}k_\rho\left(\frac{\kappa}{4\pi}\right), \tag{A41}$$

$$\Pi_{\mu\nu} \equiv \frac{1}{\gamma\sigma}\left(\frac{\Lambda^4}{4} + \frac{(\sigma+\gamma)^2}{4}\right)\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right), \tag{A42}$$

and

$$\tilde{\Pi}_{\mu\nu} \equiv -\frac{1}{\gamma\sigma}\left(\frac{\Lambda^4}{4} + \frac{(\sigma-\gamma)^2}{4}\right)\left(\delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2}\right). \tag{A43}$$

In this paper, we study the symmetry of quantum torus with the concept of crossed product algebra. As a classical counterpart, we consider the orbifold of classical torus with complex structure and investigate the transformation property of classical theta function. An invariant function under the group action is constructed as a variant of the classical theta function. Then our main issue, the crossed product algebra representation of a quantum torus with complex structure under the symplectic group, is analyzed as a quantum version of orbifolding. We perform this analysis with Manin's so-called model II quantum theta function approach. The symplectic group $Sp(2n,\mathbb{Z})$ satisfies the consistency condition of a crossed product algebra representation of quantum torus times the algebra of functions on the Siegel space. However, only a subgroup of $Sp(2n,\mathbb{Z})$ satisfies the consistency condition for orbifolding of the quantum torus. © *2006 American Institute of Physics.*

I. INTRODUCTION

Classical theta functions[1] can be regarded as state functions on classical tori, and have played an important role in the string loop calculation.[2,3] Recently, Manin[4–6] introduced the concept of quantum theta function as a quantum counterpart of classical theta function. In our previous work,[7] we clarified the relationship between Manin's quantum theta function and the theta vector[8–10] that Schwarz introduced earlier. In Ref. 7 we showed the connection between the classical theta function and the so-called *kq* representation that appeared in the physics literature.[11,12] Then we showed that the Manin's quantum theta function corresponds to the quantum version of the *kq* representation. In the physics literature, quantum theta functions are related with noncommutative solitons[13] whose solutions are given in terms of projection operators.[13–15] Under the lattice translation, quantum theta function maintains the transformation property of a classical theta function. Manin's construction of quantum theta function[5,6] is based on the algebra valued inner product of the theta vector, and this construction is a generalization of Boca's construction of projection operators on the $\mathbb{Z}_4$ orbifold of a noncommutative two torus.[16]

In the algebra valued inner product one can make the inner product of the dual algebra, the representation of the perpendicular lattice space, be invertible or proportional to the identity operator. This makes the algebra valued inner product be a projection operator.[17] In Boca's work,[16] the projection operators on the $\mathbb{Z}_4$ orbifold of the noncommutative two torus were constructed based on the algebra valued inner product that Rieffel[17] used in his classic work on projective modules over noncommutative tori.

One can consider a symmetry group defining an orbifold from the view point of the crossed product algebra of the original algebra with the given symmetry group.[13,18,19] Therefore in order to

[a)]Electronic mail: cylee@sejong.ac.kr
[b)]Electronic mail: hikim@knu.ac.kr

find a representation of an orbifold algebra, one has to find a representation of the group compatible to that of the original algebra. In Boca's work, the action of the $\mathbb{Z}_4$ quotient was represented as the Fourier transformation, and the algebra valued inner product was evaluated with the eigenstates of Fourier transformation.[16]

When the consistency conditions for the representation of crossed product algebra are fulfilled, the group of the crossed product algebra behaves as a symmetry group of the original algebra. The consistency conditions for crossed product algebra are basically having compatible actions of the group acting on the original algebra and on the module.

For quantum tori, there are two types of symmetries. One is a symmetry under a group action, and the other is a symmetry under deformation of the algebra, the so-called Morita equivalence.[20] Here, we restrict our discussion to the symmetry under a group action that is not related to the Morita equivalence.

In this paper, we first consider classical functions under orbifolding of torus and try to find an invariant function under the symplectic group $Sp(2n,\mathbb{Z})$. We then look into the representation of crossed product algebra as a way of orbifolding in the quantum (noncommutative) case.

The organization of the paper is as follows. In Sec. II, we review orbifolding of the classical torus and construct an invariant function under the action of $Sp(2n,\mathbb{Z})$. In Sec. III, we first review the crossed product algebra and its consistency conditions. Then, we check the consistency conditions of our crossed product algebra with the group $Sp(2n,\mathbb{Z})$ via the approach of Manin's model II quantum theta function. In Sec. IV, we conclude with a discussion.

II. ORBIFOLDING AND CLASSICAL THETA FUNCTION

In this section, we first consider orbifolding under a group action. A classical function f on an orbifold $X=M/G$ should satisfy

$$f(g\cdot x)=f(x), \quad {}^{\forall}g\in G, \quad x\in M. \tag{1}$$

Now, we consider the case in which M is a complex torus. Let $M=\mathbb{C}^n/\Lambda$ ($\Lambda\cong\mathbb{Z}^{2n}$) be a complex torus. If M can be embedded in a projective space $\mathbb{C}P^N$ for some N, then it is called an Abelian variety. For M to be an Abelian variety, there must exist a polarization, a positive line bundle on M. A positive line bundle L on M should satisfy that $\int_C c_1(L)>0$, for any curve C in M, where $c_1(L)$ is the first Chern class of L as an element of $H^2(M,\mathbb{Z})\cap H^{1,1}(M,\mathbb{R})$. Explicitly, $c_1(L)=\Sigma\delta_\alpha dx_\alpha\wedge dy_\alpha=\Sigma q_\beta dz_\beta\wedge d\overline{z_\beta}$, $\delta_\alpha\in\mathbb{Z}$, and q_β is pure imaginary. In particular, if $\delta_\alpha=1$, for all α, then the Abelian variety is called *principally polarized*.[21] The moduli space $\mathfrak{M}$ of principally Polarized abelian varieties is the collection of the pair $\{(M,L)\,|\,M=\mathbb{C}^n/\Lambda;\ L$ is a principally polarized line bundle$\}$. Let $\mathbb{H}_n=\{T\,|\,T\in M_n(\mathbb{C}), T^t=T, \mathrm{Im}\,T>0\}$ on which $Sp(2n,\mathbb{Z})$ acts as follows:

$$g\cdot T=(AT+B)(CT+D)^{-1}, \quad \text{for } g=\begin{pmatrix} A & B \\ C & D\end{pmatrix}\in Sp(2n,\mathbb{Z}).$$

Then, $\mathfrak{M}=Sp(2n,\mathbb{Z})\backslash\mathbb{H}_n$.

Now, we consider an action of a group G on M. In other words, a map from $G\times M$ to M, such that for every $g\in G$, g is an automorphism of M preserving complex structure T and the group structure. Then, g induces a linear map from $\mathbb{C}^n$ to $\mathbb{C}^n$, sending Λ to Λ. It means that g belongs to $GL(n,\mathbb{C})$ and also $GL(2n,\mathbb{Z})$, which is given in terms of the basis of $\Lambda(\cong\mathbb{Z}^{2n})$, whose determinant is ±1. Additionally, if we impose that g preserves L, then g preserves $c_1(L)$, so that

$$c_1(L)=\sum dx_\alpha\wedge dy_\alpha=g^*(c_1(L))=\sum d(g^*x_\alpha)\wedge d(g^*y_\alpha).$$

It implies that $g\in Sp(2n,\mathbb{Z})$. Then we can define an orbifold M/G with the preserved polarization L.

If $g\in GL(n,\mathbb{C})$ and $g\in Sp(2n,\mathbb{Z})$, then $T'=g\cdot T=T$, as we see later. Hence, only a subgroup of $Sp(2n,\mathbb{Z})$, namely $GL(n,\mathbb{C})\cap Sp(2n,\mathbb{Z})$, acts as a symmetry group for orbifolding.

For $g\in Sp(2n,\mathbb{Z})$, it acts on the basis as follows:

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}\begin{pmatrix} T \\ I \end{pmatrix} = \begin{pmatrix} AT+B \\ CT+D \end{pmatrix} \sim \begin{pmatrix} (AT+B)(CT+D)^{-1} \\ I \end{pmatrix} = \begin{pmatrix} T' \\ I \end{pmatrix}.$$

On the other hand, for $g \in GL(n,\mathbb{C})$ it acts as follows:

$$\begin{pmatrix} T \\ I \end{pmatrix} \cdot g^t = \begin{pmatrix} T \cdot g^t \\ I \cdot g^t \end{pmatrix} \sim \begin{pmatrix} T \cdot g^t \cdot g^{-t} \\ I \end{pmatrix} = \begin{pmatrix} T \\ I \end{pmatrix}.$$

Since the two actions should yield the same result, we get to the result that $T' = g \cdot T = T$.

We now consider whether the classical theta function θ is well defined on the above mentioned orbifold. The classical theta function θ is a complex valued function on $\mathbb{C}^n$ satisfying the following relation.

$$\theta(z+\lambda') = \theta(z), \quad \text{for } z \in \mathbb{C}^n, \quad \lambda' \in \Lambda', \tag{2}$$

$$\theta(z+\lambda) = c(\lambda)e^{q(\lambda,z)}\theta(z), \quad \text{for } \lambda \in \Lambda, \tag{3}$$

where $\Lambda' \oplus \Lambda \subset \mathbb{C}^n$ is a discrete sublattice of rank $2n$ split into the sum of two sublattices of rank n, isomorphic to $\mathbb{Z}^n$, and $c:\Lambda \to \mathbb{C}$ is a map and $q:\Lambda \times \mathbb{C} \to \mathbb{C}$ is a biadditive pairing linear in z.

The above property reflects the fact that the classical theta function lives on $\mathbb{C}^n$, not on $\mathbb{T}^{2n}$. The function $\theta(z,T)$ satisfying (2) and (3) can be defined as

$$\theta(z,T) = \sum_{k \in \mathbb{Z}^n} e^{\pi i(k^t T k + 2k^t z)}, \tag{4}$$

where $T \in \mathbb{H}_n$. With the above definition, $c(\lambda)$ and $q(\lambda,z)$ in (3) are given explicitly by $c(\lambda) = e^{-\pi i m^t T m}$ and $q(\lambda,z) = -2\pi i m^t z$ when $\lambda = Tm$, $m \in \mathbb{Z}^n$. Also, $z \in \mathbb{C}^n$ transforms as

$$g \cdot z = z' = (CT+D)^{-t}z, \quad \text{for } g = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in Sp(2n,\mathbb{Z}), \tag{5}$$

where "$-t$" denotes the transposed inverse. Under this modular transformation, the classical theta function transforms as follows:

$$g \cdot \theta(z,T) = \theta(z',T') = \xi_g \det(CT+D)^{1/2} e^{\pi i\{z^t(CT+D)^{-1}Cz\}}\theta(z,T), \quad {}^\forall g \in Sp(2n,\mathbb{Z}), \tag{6}$$

where ξ_g is an eighth root of unity depending on the group element g.[1]

Now, we like to find a compatible function on the orbifold in which the complex structure is preserved, $g \cdot T = T$. For this, we first try to construct a new function that has the symmetry properties of the classical theta function, (2) and (3). We define a new function as a linear combination of the classical theta functions under the group action

$$\Theta_1(z,T) = \sum_{g \in G} g \cdot \theta(z,T). \tag{7}$$

Clearly the above function is invariant under the group action,

$$h \cdot \Theta_1(z,T) = \sum_{g \in G} h \cdot g \cdot \theta(z,T) = \sum_{g' \in G} g' \cdot \theta(z,T) = \Theta_1(z,T), \quad {}^\forall h \in G. \tag{8}$$

However, this function does not possess the symmetry properties of the classical theta function (2) and (3). This is because the condition (2) is not satisfied by $\Theta_1(z,T)$, since

$$g \cdot \theta(z+\lambda',T) = \theta(g \cdot (z+\lambda'), g \cdot T) = \theta(g \cdot z + g \cdot \lambda', T) \neq \theta(g \cdot z, T), \tag{9}$$

where $g \cdot \lambda' \in \Lambda + \Lambda'$ for some $\lambda' \in \Lambda'$ due to the modular transformation $g \cdot \lambda' = (CT+D)^{-t}\lambda'$. For the condition (3), each $g \cdot \theta$ in $\Theta_1(z,T)$ in (7) gets a different factor for a lattice shift in Λ:

$$g \cdot \theta(z+\lambda,T) = \theta(g\cdot(z+\lambda), g\cdot T) = \theta(g\cdot z + g\cdot\lambda, T) \neq \theta(g\cdot z+\lambda,T), \quad \text{for } \lambda \in \Lambda, \tag{10}$$

since again $g\cdot\lambda=(CT+D)^{-t}\lambda \neq \lambda$ and belongs to $\Lambda+\Lambda'$ in general. Thus the function $\Theta_1(z,T)$ fails to preserve the transformation properties of the classical theta function, (2) and (3), though it is a well defined function on the orbifold.

In (4), the above result was due to the product $k^t z$ in the exponent. So we need to find a new combination of this type of product under the modular transformation that preserves the complex structure. Since a symplectic product preserves the complex structures, we modify the classical theta function as follows:

$$\tilde{\Theta}(z,T) = \sum_{\underline{k}} \exp(-\pi H_T(\underline{k},\underline{k}) + 2\pi i \,\mathrm{Im}[H_T(\underline{k},z)]), \tag{11}$$

where

$$H_T(s,z) \equiv s^t(\mathrm{Im}\, T)^{-1} z^*, \quad \text{for } s,z \in \mathbb{C}^n. \tag{12}$$

Here, T is the complex structure given before, and $\underline{k}$ denotes the lattice point given by $\underline{k}=Tk_1+k_2$ with $k_1,k_2\in\mathbb{Z}^n$, and $z\in\mathbb{C}^n$ is given as usual with $z=Tx_1+x_2$ with $x_1,x_2\in\mathbb{R}^n$. Here, we notice that $\mathrm{Im}[H_T(\underline{k},z)]=\mathrm{Im}[\underline{k}^t(\mathrm{Im}\,T)^{-1}z^*]=k_1^t x_2 - k_2^t x_1$. If we denote $\underline{x}$ as $z=Tx_1+x_2\equiv\underline{x}$ and the same for $\underline{y}=Ty_1+y_2$ with $y_1,y_2\in\mathbb{R}^n$, then $H_T(\underline{x},\underline{y})=\underline{x}^t(\mathrm{Im}\,T)^{-1}\underline{y}^*$ is an invariant combination under the modular transformation, $T'=(AT+B)(CT+D)^{-1}$, $\underline{x}'=(CT+D)^{-t}\underline{x}$ and the same for $\underline{y}$, for any

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix} \in Sp(2n,\mathbb{Z}).$$

One can check that the above transformation of the complex coordinate $\underline{x}$ is compatible with the following coordinate transformation in the real basis:

$$\begin{pmatrix} x_1' \\ x_2' \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}^{-t} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}. \tag{13}$$

The first term in the exponent in (11) is invariant under the modular transformation as we shall see in the next section, and the second term is also invariant since it is a symplectic product that preserves the complex structure. Thus, our modified theta function $\tilde{\Theta}$ is invariant under the modular transformation, and it is a well defined function on the above orbifold.

In fact, we can view this as follows. The classical theta function θ in (4) is summed over only one of the two $\mathbb{Z}^n$ lattices Λ,Λ' in the $2n$-torus. Our modified theta function $\tilde{\Theta}$ is summed over both lattices, and its property under lattice translation is changed from that of the classical theta function. The new function $\tilde{\Theta}$ is invariant under the lattice translation in both directions, Λ and Λ'. And this property is preserved under the group action.

In general, for a manifold M on which a group G is acting, one can define invariant functions on M under the action of the group G as the functions on the orbifold M/G. In the next section, we will do a quantum counterpart of the above analysis with crossed product algebra.

III. QUANTUM TORUS WITH CROSSED PRODUCT ALGEBRA

In order to consider an orbifolding of a quantum torus, we have to express the group action in terms of the representation of the crossed product algebra. So, in this section we first review briefly about the crossed product algebra and its representation, then we will investigate the representation of crossed product algebra for orbifolding.

A. Crossed product algebra

We now consider the crossed product algebra and its representation.[13,18]

Let G, a group, act on an algebra $\mathcal{A}$. More explicitly, there is a group homomorphism,

$$\varepsilon: G \to \mathrm{Aut}(\mathcal{A}).$$

Then we define the crossed product algebra $\mathcal{B}=\mathcal{A}\rtimes_{\varepsilon}G$, which is $\mathcal{A}[G]=\{b|\, b: G\to\mathcal{A}\}$ as a set. And we formally express $b\in\mathcal{B}$ as $\Sigma_{g\in G}b_g g$, where $b_g=b(g)\in\mathcal{A}$. Here, the addition and scalar product are defined naturally. To define multiplication we require the following relation:

$$g\cdot b_{g'}g^{-1}=\varepsilon(g)(b_{g'}),\quad g,g'\in G,\quad b_{g'}\in\mathcal{A}. \tag{14}$$

For $b,c,d\in\mathcal{B}$ with $b=\Sigma_{g\in G}b_g g$, $c=\Sigma_{g'\in G}c_{g'}g'$, $d=\Sigma_{h\in G}d_h h$, we can express the multiplication $b*_{\varepsilon}c=d$ as

$$b*_{\varepsilon}c=\sum_g b_g g\cdot\sum_{g'}c_{g'}g'=\sum_{g,g'}b_g g\cdot c_{g'}g'=\sum_{g,h}b_g\varepsilon(g)(c_{g^{-1}h})h=\sum_h d_h h=d, \tag{15}$$

where we set $g'=g^{-1}h$, $d_h=b_g\varepsilon(g)(c_{g^{-1}h})$, and used the relation (14).

If there are representations π, u that are a representation of $\mathcal{A}$ and a representation of the group G, respectively, on a module $\mathcal{H}$,

$$\pi:\mathcal{A}\to\mathrm{End}(\mathcal{H}),\quad u: G\to\mathrm{Aut}(\mathcal{H}),$$

then (14) leads to the following condition for any representation of the crossed product algebra that should satisfy

$$u(g)\pi(a)u(g^{-1})=\pi(\varepsilon(g)(a)),\quad {}^{\forall}a\in\mathcal{A},\quad {}^{\forall}g\in G. \tag{16}$$

With the above condition, we can define a representation π_u of $\mathcal{B}$ on $\mathcal{H}$ as follows:

$$\pi_u\left(\sum_g b_g g\right)=\sum_g \pi(b_g)u(g),\quad \text{for } b_g\in\mathcal{A},\quad {}^{\forall}g\in G. \tag{17}$$

When the condition (16) is satisfied, G is called a symmetry group for the algebra representation π. Furthermore, if there exists an $\mathcal{A}$ valued inner product ${}_{\mathcal{A}}\langle\langle,\rangle\rangle$ on $\mathcal{H}$, then the following should be also satisfied for consistency:[18]

$$\varepsilon(g)({}_{\mathcal{A}}\langle\langle\xi,\eta\rangle\rangle)={}_{\mathcal{A}}\langle\langle u(g)\xi,u(g)\eta\rangle\rangle,\quad \text{for } g\in G,\quad \xi,\eta\in\mathcal{H}. \tag{18}$$

Here, ${}_{\mathcal{A}}\langle\langle\xi,\eta\rangle\rangle$ denotes the $\mathcal{A}$-algebra valued inner product to be defined below, which belongs to $\mathcal{A}$. We changed the notation for the algebra valued inner product from the single bracket in our previous work[7] to the double bracket to distinguish it from the usual scalar product that we will denote with the single bracket below.

B. Symmetry transformation

In Ref. 6, Manin constructed the quantum theta function in two ways that he called model I and model II. The model I basically follows the Rieffel's way of constructing projective modules over noncommutative tori. Thus, in model I, one deals with Schwartz functions on $\mathbb{R}^n$ a for complex n-torus. And the scalar product is defined as

$$\langle\xi,\eta\rangle=\int\xi(x_1)\overline{\eta(x_1)}d\mu(x_1),\quad x_1\in\mathbb{R}^n \tag{19}$$

where $\overline{\eta(x_1)}$ denotes the complex conjugation of $\eta(x_1)$, and $d\mu(x_1)$ denotes the Haar measure in which $\mathbb{Z}^n$ has covolume 1.

In model II, one deals with holomorphic functions on $\mathbb{C}^n$, and the scalar product is defined as

$$\langle \xi, \eta \rangle_T = \int_{\mathbb{C}^n} \xi(\underline{x}) \overline{\eta(\underline{x})} e^{-\pi H_T(\underline{x},\underline{x})} \, d\nu \tag{20}$$

where $d\nu$ is the translation invariant measure making $\mathbb{Z}^{2n}$ a lattice of covolume 1 in $\mathbb{R}^{2n}$. Here, $\underline{x}=Tx_1+x_2$ with $x_1,x_2 \in \mathbb{R}^n$. The complex structure T is given by an $n \times n$ complex valued matrix, and $H_T(\underline{x},\underline{x})=\underline{x}^t(\mathrm{Im}\, T)^{-1}\underline{x}^*$ as in (12).

Now, we do the analysis with model II quantum theta function. For consistency of the representation of a crossed product algebra $\mathcal{B}=\mathcal{A} \rtimes G$, we need to define the following as explained in Sec. III A:

(I) $\pi: \mathcal{A} \to \mathrm{End}(\mathcal{H})$
(II) $u: G \to \mathrm{Aut}(\mathcal{H})$
(III) $\varepsilon: G \to \mathrm{Aut}(\mathcal{A})$, such that $u(g)\pi(a)u(g^{-1})=\pi(\varepsilon(g)(a))$
(IV) $\langle\langle , \rangle\rangle$: $\mathcal{H} \times \mathcal{H} \to \mathcal{A}$, such that $\varepsilon(g)\langle\langle f,h\rangle\rangle=\langle\langle u(g)f, u(g)h\rangle\rangle$.

Let M be any locally compact Abelian group and $\hat{M}$ be its dual group and define $\mathcal{G} \equiv M \times \hat{M}$. And, let π be a representation of $\mathcal{G}$ on $L^2(M)$ such that

$$\pi_x \pi_y = \alpha(x,y)\pi_{x+y} = \alpha(x,y)\overline{\alpha}(y,x)\pi_y \pi_x, \quad \text{for } x,y \in \mathcal{G}, \tag{21}$$

where α is a map $\alpha: \mathcal{G} \times \mathcal{G} \to \mathbb{C}^*$ satisfying

$$\alpha(x,y) = \alpha(y,x)^{-1}, \quad \alpha(x_1+x_2,y) = \alpha(x_1,y)\alpha(x_2,y).$$

We also define $S(D)$ as the space of Schwartz functions on D that we take as a discrete subgroup of $\mathcal{G}$. For $\Phi \in S(D)$, it can be expressed as $\Phi=\Sigma_{w \in D}\Phi(w)e_{D,\alpha}(w)$, where $e_{D,\alpha}(w)$ is a delta function with support at w and obeys the following relation:

$$e_{D,\alpha}(w_1)e_{D,\alpha}(w_2) = \alpha(w_1,w_2)e_{D,\alpha}(w_1+w_2). \tag{22}$$

From now on, we take M as $\mathbb{R}^n$. Let $\mathcal{A}$ be $S(D)$ valued functions on the Siegel space, $\mathbb{H}_n$. More explicitly,

$$\mathcal{A} = S(D) \otimes \mathcal{F}(\mathbb{H}_n) = \{a | a: \mathbb{H}_n \to S(D)\}, \tag{23}$$

where $\mathcal{F}(\mathbb{H}_n)$ is an algebra of smooth complex functions on $\mathbb{H}_n$. Then $a(T)=\Sigma_{w \in D}a_{T,w}e(w)$, where $a_{T,w} \in \mathbb{C}$. Let $\mathcal{H}$ be given as follows:

$$\mathcal{H} = \left\{ f | f: \mathbb{R}^n \times \hat{\mathbb{R}}^n \times \mathbb{H}_n \to \mathbb{C}, \ \langle f(x,T), f(x,T)\rangle_T = \int |f(x,T)|^2 e^{-\pi H_T(x,x)} \, dx < \infty, {}^{\forall}T \right\}, \tag{24}$$

where $x \in \mathbb{R}^n \times \hat{\mathbb{R}}^n$, $T \in \mathbb{H}_n$ and from here on $H_T(x,y)$ that we used above denotes $H_T(\underline{x},\underline{y})$ defined in the Sec. II for notational convenience. In other words, $\mathcal{H}$ are global sections of $\bar{\mathbb{H}}$, a vector bundle over $\mathbb{H}_n$, where the fiber over T is

$$\mathbb{H}_T = \{\xi | \xi: \mathbb{R}^n \times \hat{\mathbb{R}}^n \to \mathbb{C}, \ \langle \xi, \xi \rangle_T < \infty\}. \tag{25}$$

Let the group G be $Sp(2n,\mathbb{Z})$ and we now carry out steps (I)–(IV) that we listed previously.
(I) Before we define π, we need to define a map π_0 from $S(D)$ to $\mathrm{End}(\mathcal{H})$:

$$\pi_0: e(w) \to \pi_w, \quad \text{for } w \in D$$

where

$$(\pi_w f)(x,T) = e^{-\pi H_T(x,w)-(\pi/2)H_T(w,w)} f(x+w,T). \tag{26}$$

Let $a \in \mathcal{A}$, where $a(T)=\Sigma_w a_{T,w}e(w)$. Now, we define π as follows:

$$(\pi(a)f)(x,T) = [\pi_0(a(T))f](x,T). \tag{27}$$

(II) We define u as follows:

$$(u(g)f)(x,T) = f(g\cdot x, g\cdot T), \tag{28}$$

where

$$g = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in Sp(2n,\mathbb{Z}), \quad g\cdot x = \begin{pmatrix} A & B \\ C & D \end{pmatrix}^{-t} x,$$

and $g\cdot T=(AT+B)(CT+D)^{-1}$.

For the remaining steps we need to use the following two lemmas.

Lemma 1:

$$H_T(x,y) = H_{g\cdot T}(g\cdot x, g\cdot y). \tag{29}$$

Lemma 2:

$$\langle f,h\rangle_{g\cdot T} = \langle u(g)f, u(g)h\rangle_T. \tag{30}$$

Proof of Lemma 1: We first want to show that

$$\mathrm{Im}(g\cdot T) = \mathrm{Im}((AT+B)(CT+D)^{-1}) = (C\overline{T}+D)^{-t}\,\mathrm{Im}(T)(CT+D)^{-1}. \tag{31}$$

Then the proof of Lemma 1 is given by the following steps:

$$\begin{aligned} H_{g\cdot T}(g\cdot x, g\cdot y) &= ((CT+D)^{-t}\underline{x})^t(\mathrm{Im}(g\cdot T))^{-1}((CT+D)^{-t}\underline{y})^* \\ &= \underline{x}^t(CT+D)^{-1}(CT+D)(\mathrm{Im}(T))^{-1}(C\overline{T}+D)^t(C\overline{T}+D)^{-t}\underline{y}^* \\ &= \underline{x}^t(\mathrm{Im}(T))^{-1}\underline{y}^* = H_T(x,y). \end{aligned}$$

Thus, we only have to show (31). We can prove it with the three generators of $Sp(2n,\mathbb{Z})$:[1]

$$(i)\ g = \begin{pmatrix} A & 0 \\ 0 & A^{-t} \end{pmatrix}, \quad A \in GL(n,\mathbb{Z}) \tag{32}$$

$$(ii)\ g = \begin{pmatrix} I & B \\ 0 & I \end{pmatrix}, \quad B^t = B, \quad B \in gl(n, \quad \mathbb{Z}) \tag{33}$$

$$(iii)\ g = \begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix}. \tag{34}$$

For the first two cases, (31) can be shown trivially. For case (iii), we need to show the following:

$$\mathrm{Im}\ T' = \overline{T}^{-t}(\mathrm{Im}\ T)T^{-1} = \overline{T}^{-1}(\mathrm{Im}\ T)T^{-1}, \tag{35}$$

where $T'=g\cdot T=-T^{-1}$.

Now, we prove (35).

Let $T=T_1+iT_2$ and $T'=T_1'+iT_2'$. Then from $T'T=-I$, we get $T_1'T_1-T_2'T_2=-I$ and $T_2'T_1+T_1'T_2=0$. Then the statement we want to prove becomes $T_2'=\overline{T}^{-1}T_2T^{-1}$, or equivalently,

$$\overline{T}T_2'T = T_2. \tag{36}$$

The left hand side of (36) is

$$\text{lhs} = (T_1 - iT_2)T_2'(T_1 + iT_2) = (T_1T_2'T_1 + T_2T_2'T_2) + i(-T_2T_2'T_1 + T_1T_2'T_2).$$

Using $T_1'T_1 - T_2'T_2 = -I$ and $T_2'T_1 + T_1'T_2 = 0$ together with the property that T_i, T_i' are symmetric, then we can easily show that

$$\text{lhs} = T_2 = \text{rhs}.$$

Proof of Lemma 2: The left hand side of (30) is

$$\text{lhs} = \langle f,h\rangle_{g\cdot T} = \int f(x,g\cdot T)\overline{h(x,g\cdot T)}e^{-\pi H_{g\cdot T}(x,x)}\,dx,$$

and the right hand side of (30) is

$$\text{rhs} = \langle u(g)f,u(g)h\rangle_T = \int f(g\cdot x,g\cdot T)\overline{h(g\cdot x,g\cdot T)}e^{-\pi H_T(x,x)}\,dx$$

$$= \int f(x,g\cdot T)\overline{h(x,g\cdot T)}e^{-\pi H_{g\cdot T}(x,x)}\,dx,$$

where we used Lemma 1 in the final step.

(III) We define $\varepsilon: G \to \text{Aut}(\mathcal{A})$ such that $u(g)\pi(a)u(g^{-1}) = \pi(\varepsilon(g)(a))$.

Let $a(T)$ be $\Sigma a_{T,w}e(w)$. The left hand side can be evaluated as follows:

$$(u(g)\pi(a)u(g^{-1})f)(x,T) = (\pi(a)u(g^{-1})f)(g\cdot x,g\cdot T)$$

$$= \sum_w a_{g\cdot T,w}e^{-\pi H_{g\cdot T}(g\cdot x,w)-(\pi/2)H_{g\cdot T}(w,w)}f(x+g^{-1}\cdot w,T).$$

If we define $\varepsilon(g)(a)(T) = \Sigma_w a_{g\cdot T,w}e(g^{-1}\cdot w)$, then the right hand side is given by

$$\pi(\varepsilon(g)(a)f)(x,T) = \sum_w a_{g\cdot T,w}\pi(g^{-1}\cdot w)f(x,T) = \sum_w a_{g\cdot T,w}e^{-\pi H_{g\cdot T}(g\cdot x,w)-(\pi/2)H_{g\cdot T}(w,w)}f(x+g^{-1}\cdot w,T).$$

In the last equality we used Lemma 1. So those two sides are equal. Using Lemma 1, one can also show the following:

$$u(g)\pi_w u(g^{-1}) = \varepsilon(g)\pi_w = \pi_{g^{-1}\cdot w}. \tag{37}$$

(IV) We define an $\mathcal{A}$-valued inner product on $\mathcal{H}$ as follows:

$$\langle\langle f,h\rangle\rangle(T) = \sum_w \langle f,\pi_w h\rangle_T e(w), \tag{38}$$

where $\langle f,\pi_w(h)\rangle_T = \langle f(x,T),\pi_w h(x,T)\rangle_T$.

In other words, if $a = \langle\langle f,h\rangle\rangle$ then $a_{T,w} = \langle f,\pi_w h\rangle_T$.

Now, we want to check that $\varepsilon(g)\langle\langle f,h\rangle\rangle = \langle\langle u(g)f,u(g)h\rangle\rangle$ holds.

Recall that

$$\varepsilon(g)(a)(T) = \sum_w a_{g\cdot T,w}e(g^{-1}\cdot w).$$

The left hand side is given by

$$(\varepsilon(g)(\langle\langle f,h\rangle\rangle))(T) = \sum_w \langle f,\pi_w h\rangle_{g\cdot T}e(g^{-1}\cdot w) = \sum_w \langle f,\pi_{g\cdot w}h\rangle_{g\cdot T}e(w).$$

The right hand side is given by

$$\langle\langle u(g)f,u(g)h\rangle\rangle_T=\sum_w \langle u(g)f,\pi_w u(g)h\rangle_T e(w)=\sum_w \langle f,u(g)^{-1}\pi_w u(g)h\rangle_{g\cdot T}e(w)=\sum_w \langle f,\pi_{g\cdot w}h\rangle_{g\cdot T}e(w),$$

where we used Lemma 2 and (37).

C. Orbifolding quantum torus

We consider an orbifolding of quantum torus with a polarized complex structure T. The symmetry group preserving the polarized complex structure is the subgroup $G_T=\{g \in Sp(2n,\mathbb{Z})|g\cdot T=T\}$ of $Sp(2n,\mathbb{Z})$. Orbifolding the quantum torus with a complex structure T corresponds to the crossed product algebra discussed in the previous section with fixed T.

Let $A_T=S(D)$ and $\mathbb{H}_T=\{f_T|f_T:\mathbb{R}^n\times\mathbb{R}^n\to\mathbb{C},\|f_T\|^2=\int|f_T(x)|^2e^{-\pi H_T(x,x)}dx<\infty\}$. Now, we can define the crossed product algebra, $A_T\rtimes G_T$, naturally from the construction in Sec. III B:

(1) $\pi_T:A_T\to \mathrm{End}(\mathbb{H}_T)$
(2) $u_T:G_T\to \mathrm{Aut}(\mathbb{H}_T)$
(3) $\varepsilon_T:G_T\to \mathrm{Aut}(A_T)$, such that $u_T(g)\pi_T(a)u_T(g^{-1})=\pi_T(\varepsilon_T(g)(a))$
(4) $\langle\langle,\rangle\rangle_T:\mathbb{H}_T\times\mathbb{H}_T\to A_T$ such that $\varepsilon_T(g)\langle\langle f_T,h_T\rangle\rangle_T=\langle\langle u_T(g)f_T,u_T(g)h_T\rangle\rangle_T$.

Here, π_T, u_T, ε_T, $\langle\langle,\rangle\rangle_T$, f_T satisfy the following relations:

$$(\pi_T(a(T))f_T)(x)=(\pi(a)f)(x,T),$$

$$(u_T(g)f_T)(x)=(u(g)f)(x,T),$$

$$(\varepsilon(g)(a))(T)=\varepsilon_T(g)(a(T)),$$

$$\langle\langle f_T,h_T\rangle\rangle_T=\langle\langle f,h\rangle\rangle(T),$$

where $f_T(x)=f(x,T)$, $a\in S(D)\otimes\mathcal{F}(\mathbb{H}_n)$, and $g\in G_T$. If we choose $f(x,T)=1$, then $\varepsilon(g)\langle\langle 1,1\rangle\rangle=\langle\langle u(g)1,u(g)1\rangle\rangle=\langle\langle 1,1\rangle\rangle$, and thus $\langle\langle 1,1\rangle\rangle$, which belongs to the algebra $\mathcal{A}$ is $Sp(2n,\mathbb{Z})$ invariant. Since $\langle\langle 1,1\rangle\rangle(T)=\Sigma_{w\in D}e^{-(\pi/2)H_T(w,w)}e(w)$ is Manin's model II quantum theta function; this also tells us that the model II quantum theta function is well defined on the orbifolds of a quantum complex torus. We further notice that Boca's projection operator[16] on the $\mathbb{Z}/4\mathbb{Z}$ orbifold of a quantum 2-torus with $T=i$ corresponds to a special case of this construction.

IV. CONCLUSION

In this paper, we investigate the symmetry of quantum torus with the group $Sp(2n,\mathbb{Z})$.

First, we investigate the orbifolding of the classical complex torus. It turns out that the orbifold group for a complex n torus leaving the complex structure and its polarization intact is a subgroup of $Sp(2n,\mathbb{Z})$. Also, the classical theta function is not invariant under the $Sp(2n,\mathbb{Z})$ transformation, and we construct a variant of the classical theta function as an invariant function under the transformation of $Sp(2n,\mathbb{Z})$. Then, as a quantum counterpart, we investigate the representation of crossed product algebra of quatum torus with $Sp(2n,\mathbb{Z})$ via Manin's model II quantum theta function approach.

In Manin's model I approach, the dimension of the Hilbert space variable x_1, which is n for quantum $\mathbb{T}^{2n}$, does not match the dimension of the fundamental representation of $Sp(2n,\mathbb{Z})$, which is $2n$. On the other hand, in the model II case the dimension of the Hilbert space variable $x=(x_1,x_2)$ exactly matches that of the group. Therefore in the model I case the group action cannot act directly on the variables of the Hilbert space. Thus, one has to devise a transformation such as Fourier transformation as in the Boca's work,[16] where $\mathbb{Z}_4$ acts directly on the functions as a Fourier transformation, not on the variables of the functions. This type of difficulty comes from the fact that in the model I case the number of variables of the functions is half that of the phase space, as

is typical in the conventional quantization. In the model II approach, the above mentioned difficulty does not arise. The group action can be defined nicely on the module as it acts on the variables.

In conclusion, in the model II case $Sp(2n,\mathbb{Z})$ turns out to be the symmetry group for the quantum torus times $\mathbb{H}_n$. The orbifolding of quantum torus with a complex structure corresponds to the crossed product algebra, $S(D)\rtimes G_T$, where G_T is the subgroup of $Sp(2n,\mathbb{Z})$ fixing the complex structure, $g\cdot T=T$ for $g\in Sp(2n,\mathbb{Z})$. And Manin's model II quantum theta function turns out to be a well defined function over the above orbifold of the quantum torus.

The Gell-Mann-Okubo and Coleman-Glashow relations for octet and decuplet baryons in the $SU_q(3)$ quantum algebra

Antonio E. Cárcamo Hernández[a)]
Departamento de Física, Universidad Nacional de Colombia, Bogotá, Colombia

(Received 14 November 2005; accepted 5 June 2006; published online 31 July 2006)

The q-deformed Clebsch-Gordan coefficients corresponding to the $\{3\}\times\{21\}$ reduction of the $SU_q(3)$ quantum algebra are computed. From these results and using the quantum Clebsch-Gordan coefficients for the $\{21\}\times\{21\}$ reduction found by Z. Q. Ma, the q-deformed Gell-Mann-Okubo mass relations for octet and decuplet baryons are determined by generalizing the procedure used for the SU(3) algebra. We also determine the Coleman-Glashow relations for octet and decuplet baryons in the $SU_q(3)$ algebra. Finally, by using the experimental particle masses of the octet and decuplet baryons, two values of the q-parameter are found and adjusted for the predicted expressions of the masses (one for the Gell-Mann-Okubo mass relations and the other for the Coleman-Glashow relations) and a possible physical interpretation is given. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2218672]

I. INTRODUCTION

The q-deformed algebras extend the domain of classical group theory and constitute a new and growing field of mathematics with a vast potential for applications in physics.[1–6] The quantum algebra $SU_q(3)$, as a generalization of the SU(3) algebra, has been studied by several authors[7–11] with several applications in particle physics, conformal field theory, statistical mechanics, quantum optics, condensed matter, molecular, atomic and nuclear spectroscopy.[1,3,7,12] In these applications either an existing model is identified with a quantum algebraic structure or a standard model is deformed to show a underlying quantum algebraic structure which reveals new features.[3]

Applications of quantum algebras in particle physics have been explored in several works.[12] In hadronic phenomenology q-deformed mass relations between particle families in the octet and decuplet baryons have been determined from the computation of the mass operator's expectation value. In these works, the mass operator has been defined in terms of generators of $SU_q(4)$ and $SU_q(5)$ and its expectation value has been computed from the determination of their matrix elements.

Our aim in this article is to determine the q-deformed Gell-Mann-Okubo and Coleman-Glashow relations for octet and decuplet baryons in the $SU_q(3)$ quantum algebra. First, we develop the $SU_q(3)$ quantum algebra and use it to compute the q-deformed Clebsch-Gordan coefficients corresponding to the $\{3\}\times\{21\}$ reduction. Second, to derive the q-deformed Gell-Mann-Okubo mass relations for octet and decuplet baryons in the $SU_q(3)$ quantum algebra we generalize the traditional procedure for the SU(3) algebra[13] and use the previous results together with the quantum Clebsch-Gordan coefficients corresponding to the $\{21\}\times\{21\}$ reduction.[8] After that, we obtain the q-deformed Coleman-Glashow relations for octet and decuplet baryons by following the same procedure used for the SU(3) algebra.[14] Finally, by using the experimental particle masses of the

[a)]Present address: Cra 30 No. 45-03, Ed 405, Ciudad Universitaria, Departamento de Física, Universidad Nacional de Colombia, Bogotá, Colombia. Electronic mail: aecarcamoh@unal.edu.co

octet and decuplet baryons, two values of the q-parameter are found and adjusted for the Gell-Mann-Okubo and Coleman-Glashow mass relations and a possible physical interpretation is given.

II. THE $SU_q(3)$ QUANTUM ALGEBRA

The quantum algebra $SU_q(3)$ is generated by the operators $\hat{I}$, $\hat{h}_1$, $\hat{h}_2$, $\hat{X}_1^{\pm}$, $\hat{X}_2^{\pm}$, which satisfy the following commutation relations[10]:

$$[\hat{h}_i,\hat{h}_j]=0, \quad [\hat{h}_i,\hat{X}_j^{\pm}]=\pm a_{ij}\hat{X}_j^{\pm}, \tag{1}$$

$$[\hat{X}_i^{+},\hat{X}_j^{-}]=\delta_{ij}[\hat{h}_i]_q=\delta_{ij}\frac{q^{\hat{h}_i}-q^{-\hat{h}_i}}{q-q^{-1}}, \quad i,j=1,2 \tag{2}$$

together with

$$(\hat{X}_i^{\pm})^2\hat{X}_j^{\pm}+\hat{X}_j^{\pm}(\hat{X}_i^{\pm})^2-[2]_q\hat{X}_i^{\pm}\hat{X}_j^{\pm}\hat{X}_i^{\pm}=0, \quad i\neq j, \tag{3}$$

where a_{ij} is the Cartan matrix given by

$$a_{ij}=\begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}. \tag{4}$$

Additional generators $\hat{X}_3^{\pm}$ are introduced by[9]:

$$\hat{X}_3^{+}=q^{1/2}[\hat{X}_1^{+},\hat{X}_2^{+}]_{q^{-1}}, \quad \hat{X}_3^{-}=-q^{-1/2}[\hat{X}_2^{-},\hat{X}_1^{-}]_q, \tag{5}$$

where

$$\hat{X}_1^{\pm}=\hat{T}_{\pm}, \quad \hat{X}_2^{\pm}=\hat{U}_{\pm}, \quad \hat{h}_1=2\hat{T}_3, \tag{6}$$

$$\hat{h}_2=-\hat{T}_3+\tfrac{3}{2}\hat{Y}, \quad [\hat{A},\hat{B}]_q=\hat{A}\hat{B}-q\hat{B}\hat{A}. \tag{7}$$

From the previous expressions, we obtain

$$[\hat{X}_3^{+},\hat{X}_3^{-}]=-\frac{q^{\widehat{h_3}}-q^{-\widehat{h_3}}}{q-q^{-1}}=-[\hat{h}_3]_q, \tag{8}$$

$$[\hat{h}_i,\hat{X}_3^{\pm}]=\pm\hat{X}_3^{\pm} \quad \text{with} \quad \hat{h}_3=\hat{h}_1+\hat{h}_2=\hat{T}_3+\tfrac{3}{2}\hat{Y}. \tag{9}$$

According to the standard coproduct definition at $SU_q(3)$, the following expressions are obtained[7]:

$$\Delta\hat{T}_{\pm}=\hat{T}_{\pm}\otimes q^{\hat{T}_3}+q^{-\hat{T}_3}\otimes\hat{T}_{\pm}, \tag{10}$$

$$\Delta\hat{U}_{\pm}=\hat{U}_{\pm}\otimes q^{(3\hat{Y}-2\hat{T}_3)/4}+q^{-(3\hat{Y}-2\hat{T}_3)/4}\otimes\hat{U}_{\pm}. \tag{11}$$

Hence, the coproduct of two $SU_q(3)$ irreps is defined as[7]:

$$\hat{T}_{\pm}(\psi_{\eta}^{\{\lambda_1,\lambda_2\}}\psi_{\beta}^{\{\mu_1,\mu_2\}})=(q^{-\hat{T}_3}\psi_{\eta}^{\{\lambda_1,\lambda_2\}})(\hat{T}_{\pm}\psi_{\beta}^{\{\mu_1,\mu_2\}})+(\hat{T}_{\pm}\psi_{\eta}^{\{\lambda_1,\lambda_2\}})(q^{\hat{T}_3}\psi_{\beta}^{\{\mu_1,\mu_2\}}),$$

$$\hat{U}_{\pm}(\psi_{\eta}^{\{\lambda_1,\lambda_2\}}\psi_{\beta}^{\{\mu_1,\mu_2\}}) = (\hat{U}_{\pm}\psi_{\eta}^{\{\lambda_1,\lambda_2\}})(q^{(3\hat{Y}-2\hat{T}_3)/4}\psi_{\beta}^{\{\mu_1,\mu_2\}}) + (q^{-(3\hat{Y}-2\hat{T}_3)/4}\psi_{\eta}^{\{\lambda_1,\lambda_2\}})(\hat{U}_{\pm}\psi_{\beta}^{\{\mu_1,\mu_2\}}),$$

where $\psi_{\alpha}^{\{\nu\}}$, with $\alpha=1,2,\ldots,\dim(\{\nu\})$, is the state with eigenvalues t_{α}, $t_{3\alpha}$, and y_{α}, which belongs to the $SU_q(3)$ representation $\{\nu\}=\{\nu_1,\nu_2\}$. (In this article, we consider $q\in R$ following the Quesne's prescription.)

III. THE *q*-DEFORMED GELL-MANN-OKUBO MASS RELATIONS FOR OCTET AND DECUPLET BARYONS

In order to get expressions of the masses corresponding to the octet and decuplet baryons, we introduce the following mass operator:

$$\hat{M} = \hat{M}_S + \hat{M}_T, \tag{12}$$

where $\hat{M}_S$ is a $SU_q(3)$ invariant and $\hat{M}_T$ is an isospin escalar.

By computing the expectation value of the mass operator in a $|\psi_{\alpha}^{\{\lambda\}}\rangle$ state belonging to a $\{\lambda\}$ representation, we obtain that the mass of the particle corresponding to this state is given by

$$m(\{\lambda\},\{\mu\}) = \langle\psi_{\alpha}^{\{\lambda\}}|\hat{M}_S|\psi_{\alpha}^{\{\lambda\}}\rangle + \langle\psi_{\alpha}^{\{\lambda\}}|\hat{M}_T|\psi_{\alpha}^{\{\lambda\}}\rangle \tag{13}$$

with

$$|\psi_{\alpha}^{\{\lambda\}}\rangle = |\{\lambda\},\{\mu\}\rangle = |\{\lambda\},y,t,t_z\rangle, \quad \{\mu\}=\{y,t,t_z\}, \tag{14}$$

where in order to simplify the notation we have taken $y=y_{\alpha}$, $t=t_{\alpha}$, and $t_z=t_{3\alpha}$ with y, t, and t_z being the hypercharge, the isospin, and the z isospin component, respectively.

As $\hat{M}_S$ is a $SU_q(3)$ scalar, its expectation value is the same for all members of the multiplet corresponding to a $\{\lambda\}$ representation. Therefore, according to the previous, we obtain

$$\langle\psi_{\alpha}^{\{\lambda\}}|\hat{M}_S|\psi_{\alpha}^{\{\lambda\}}\rangle = m_S(\{\lambda\}). \tag{15}$$

We also note that the $\hat{M}_T$ operator can be written as an expansion of irreducible tensor operators of $SU_q(3)$, according to

$$\hat{M}_T = \sum_{\mu\nu} \hat{T}_{\mu}^{\{\nu\}}. \tag{16}$$

Then, by taking into account that $[\hat{M}_T,\hat{Y}]=[\hat{M}_T,\hat{T}]=0$, from the previous expression we obtain that the irreducible tensor operators $\hat{T}_{\mu}^{\{\lambda\}}$ should satisfy the following conditions:

$$[\hat{T}_{\mu}^{\{\nu\}},\hat{Y}] = 0, \quad [\hat{T}_{\mu}^{\{\nu\}},\hat{T}] = 0. \tag{17}$$

On the other hand, according to the Wigner-Eckart theorem for the quantum group $SU_q(3)$, we have that the matrix element of the irreducible tensor operator $\hat{T}_{\mu_2}^{\{\lambda_2\}}$ is given by[15]

$$\langle\{\lambda_3\},y_3,t_3,t_{3z}|\hat{T}_{\mu_2}^{\{\lambda_2\}}|\{\lambda_1\},y_1,t_1,t_{1z}\rangle = \sum_{\gamma} \begin{pmatrix} \lambda_1 & \lambda_2 & \lambda_{3\gamma} \\ \mu_1 & \mu_2 & \mu_3 \end{pmatrix}_q \langle\{\lambda_3\}||\hat{T}^{\{\lambda_2\}}||\{\lambda_1\}\rangle_{\gamma}, \tag{18}$$

where the reduced matrix element $\langle\{\lambda_3\}||\hat{T}^{\{\lambda_2\}}||\{\lambda_1\}\rangle_{\gamma}$ only depends on the representations involved and the sum is performed over γ, being γ the index which labels the copies of the $\{\lambda_3\}$ representation in the $\{\lambda_1\}\otimes\{\lambda_2\}$ reduction. We also have that the coupling factor in the expression (18) corresponds to the q-deformed Clebsch-Gordan Coefficient of $SU_q(3)$.[15]

Moreover, in the $|\psi_{\alpha}^{\{\lambda\}}\rangle=|\{\lambda\},y,t,t_z\rangle$ basis, we have

$$\langle\{\lambda\}y't't_z'|\hat{T}_{\mu}^{\{\nu\}}|\{\lambda\}ytt_z\rangle = \delta_y^{y'}\delta_t^{t'}\delta_{t_z}^{t_z'}\langle\{\lambda\}||\hat{T}_{\mu}^{\{\nu\}}||\{\lambda\}\rangle. \tag{19}$$

Therefore, by comparing the previous result with the corresponding one to the q-deformed Wigner-Eckart theorem, we obtain that μ should be $(ytt_z)=(000)$.

Then, according to the previous we have that the $\hat{M}_T$ operator is given by

$$\hat{M}_T=\sum_{\nu}\hat{T}^{\{\nu\}}_{000}, \tag{20}$$

where the sum is performed over all physically allowed $SU_q(3)$ representations. Hence, we have $\{\nu\}=\{0\},\{21\},\{42\},\ldots$.

Therefore, the particle mass corresponding to a $|\psi^{\{\lambda\}}_{\alpha}\rangle=|\{\lambda\},y,t,t_z\rangle$ state of a multiplet belonging to a $\{\lambda\}$ representation of $SU_q(3)$ is given by

$$m(\{\lambda\},y,t,t_z)=m_S(\{\lambda\})+\sum_{\nu}\langle\{\lambda\},y,t,t_z|\hat{T}^{\{\nu\}}_{000}|\{\lambda\},y,t,t_z\rangle. \tag{21}$$

It is important to point out that the $\langle\psi^{\{\lambda\}}_{\alpha}|\hat{T}^{\{0\}}_{000}|\psi^{\{\lambda\}}_{\alpha}\rangle$ term remains absorbed in the $m_S(\{\lambda\})$ term, which is a $SU_q(3)$ scalar. We also have that the dominant contribution comes from the $\hat{T}^{\{21\}}_{000}$ component of the octet tensor operator. Hence, according to the previous we obtain[7]

$$m(\{\lambda\},y,t,t_z)=m_S(\{\lambda\})+\langle\{\lambda\},y,t,t_z|\hat{T}^{\{21\}}_{000}|\{\lambda\},y,t,t_z\rangle. \tag{22}$$

On the other hand, it is well known that the product of the $SU_q(3)$ representations $\{21\}$ and $\{21\}$ is given by

$$\{21\}\times\{21\}=\{42\}+\{3\}+\{3^2\}+\{21\}_S+\{21\}_A+\{0\}, \tag{23}$$

where $\{42\}$, $\{3\}$, $\{3^2\}$, $\{21\}$, and $\{0\}$ are representations with dimensions equal to 27, 10, 10, 8, and 1, respectively. Moreover, $\{21\}_S$ and $\{21\}_A$ are symmetric and antisymmetric representations with the same transformation properties under the quantum group $SU_q(3)$.

We also have that the $\{21\}$ representation corresponding to the octet baryon exhibits the following descomposition under the subgroup $U(1)_Y\times SU_q(2)_T$:

$$\{21\}\downarrow\{3\}\times\{1\}+\{0\}\times\{2\}+\{0\}\times\{0\}+\{\overline{3}\}\times\{1\}, \tag{24}$$

where the products $\{3\}\times\{1\}$, $\{0\}\times\{2\}$, $\{0\}\times\{0\}$, and $\{\overline{3}\}\times\{1\}$ represent 2, 3, 1, and 2 states corresponding to the N, Σ, Λ, and Ξ particles of the octet baryon.[16]

Then, by applying the q-deformed Wigner-Eckart theorem to the second term of expression (22) taking into account that in the $\{21\}\times\{21\}$ reduction, the $\{3\}\times\{1\}$, $\{0\}\times\{2\}$, $\{0\}\times\{0\}$, and $\{\overline{3}\}\times\{1\}$ states of the first $\{21\}$ representation are coupled to the $\{0\}\times\{0\}$ state of the second one $\{21\}$, where the coupling coefficients are the q-deformed isoscalar factors, we obtain the following expressions corresponding to the masses of the particle families in the octet baryon[7]:

$$\begin{aligned}m_N=m_S(\{21\})&+\begin{pmatrix}\{21\} & \{21\} & \| & \{21\}_S\\ \frac{1}{2}1 & 00 & \| & \frac{1}{2}1\end{pmatrix}_q\langle\{21\}||\hat{T}^{\{21\}}||\{21\}\rangle_S\\&+\begin{pmatrix}\{21\} & \{21\} & \| & \{21\}_A\\ \frac{1}{2}1 & 00 & \| & \frac{1}{2}1\end{pmatrix}_q\langle\{21\}||\hat{T}^{\{21\}}||\{21\}\rangle_A,\end{aligned} \tag{25}$$

$$\begin{aligned}m_\Sigma=m_S(\{21\})&+\begin{pmatrix}\{21\} & \{21\} & \| & \{21\}_S\\ 10 & 00 & \| & 10\end{pmatrix}_q\langle\{21\}||\hat{T}^{\{21\}}||\{21\}\rangle_S\\&+\begin{pmatrix}\{21\} & \{21\} & \| & \{21\}_A\\ 10 & 00 & \| & 10\end{pmatrix}_q\langle\{21\}||\hat{T}^{\{21\}}||\{21\}\rangle_A,\end{aligned} \tag{26}$$

$$m_{\Lambda} = m_S(\{21\}) + \begin{pmatrix} \{21\} & \{21\} & \| & \{21\}_S \\ 00 & 00 & \| & 00 \end{pmatrix}_q \langle\{21\}||\hat{T}^{\{21\}}||\{21\}\rangle_S + \begin{pmatrix} \{21\} & \{21\} & \| & \{21\}_A \\ 00 & 00 & \| & 00 \end{pmatrix}_q \langle\{21\}||\hat{T}^{\{21\}}||\{21\}\rangle_A, \tag{27}$$

$$m_{\Xi} = m_S(\{21\}) + \begin{pmatrix} \{21\} & \{21\} & \| & \{21\}_S \\ \frac{1}{2}-1 & 00 & \| & \frac{1}{2}-1 \end{pmatrix}_q \langle\{21\}||\hat{T}^{\{21\}}||\{21\}\rangle_S + \begin{pmatrix} \{21\} & \{21\} & \| & \{21\}_A \\ \frac{1}{2}-1 & 00 & \| & \frac{1}{2}-1 \end{pmatrix}_q \langle\{21\}||\hat{T}^{\{21\}}||\{21\}\rangle_A. \tag{28}$$

We also have that according to Racah's factorization lemma, the q-deformed isoscalar factors for the $SU_q(3)$ quantum algebra are given by[11]

$$\begin{pmatrix} \lambda_1 & \lambda_2 & \| & \lambda_{3\gamma} \\ t_1 y_1 & t_2 y_2 & \| & ty \end{pmatrix}_q = \frac{\begin{pmatrix} \lambda_1 & \lambda_2 & | & \lambda_{3\gamma} \\ \mu_1 & \mu_2 & | & \mu_3 \end{pmatrix}_q}{{}_qC^{t_1 t_2 t}_{t_{1z} t_{2z} t_z}} = \frac{{}_qC^{\{\lambda_1\}\times\{\lambda_2\}}_{(\alpha_1\alpha_2)\{\lambda_3\}(\alpha_3)}}{{}_qC^{t_1 t_2 t}_{t_{1z} t_{2z} t_z}}, \tag{29}$$

where ${}_qC^{t_1 t_2 t}_{t_{1z} t_{2z} t_z}$ is the q-deformed Clebsch-Gordan coefficient for $SU_q(2)$. For this case, we have[1,7]

$${}_qC^{1/2\ 0\ 1/2}_{1/2\ 0\ 1/2} = {}_qC^{101}_{101} = {}_qC^{000}_{000} = 1. \tag{30}$$

Then, for the octet baryon we get

$$\begin{pmatrix} \{21\} & \{21\} & \| & \{21\}_{S,A} \\ ty & 00 & \| & ty \end{pmatrix}_q = {}_qC^{\{21\}\times\{21\}}_{(\alpha 5)\{21\}_{S,A}(\alpha)}. \tag{31}$$

Therefore, by combining expressions (25)–(28) and using the quantum Clebsch-Gordan coefficients corresponding to the $\{21\}\times\{21\}$ reduction obtained in Ref. 8, the following q-deformed mass relation for octet baryons is obtained[7]:

$$[3]_q \sqrt{\frac{[3]_q+[2]_q}{[4]_q+1}} m_{\Lambda} + m_{\Sigma}(C(q)-E(q)-D(q)) = m_N \left\{ q^{-2}E(q) + \frac{q^2}{2}\left(A(q) + \frac{\left(\left[\frac{3}{2}\right]_q\right)^2 \sqrt{[5]_q}}{[3]_q \left[\frac{1}{2}\right]_q \left[\frac{5}{2}\right]_q} B(q) \right) \right\} + m_{\Xi} \left\{ q^2 E(q) + \frac{q^3}{2}\left(A(q) - \frac{\left(\left[\frac{3}{2}\right]_q\right)^2 \sqrt{[5]_q}}{[3]_q \left[\frac{1}{2}\right]_q \left[\frac{5}{2}\right]_q} B(q) \right) \right\}, \tag{32}$$

where $A(q)$, $B(q)$, $C(q)$, and $D(q)$ are functions of the q-real parameter given by

$$A(q) = 1 - q^{-1} + q^{-2} + q^{-3} - q^{-4} + q^{-5}, \quad B(q) = 1 + q^{-1} + q^{-2} - q^{-3} - q^{-4} - q^{-5},$$

$$E(q) = \sqrt{\frac{[3]_q+[2]_q}{[4]_q+1}},$$

$$C(q) = \frac{q^{5/2}([2]_q+1)(q^{3/2}+q^{-3/2})}{2[3]_q} A(q), \quad D(q) = \frac{q^{5/2}([2]_q-1)(q^{3/2}-q^{-3/2})\left(\left[\frac{3}{2}\right]_q\right)^2 \sqrt{[5]_q}}{2([3]_q)^2 \left[\frac{1}{2}\right]_q \left[\frac{5}{2}\right]_q} B(q). \tag{33}$$

By replacing the average multiplet masses[17] in the expression (32) and performing a program in C that finds the roots of this expression, we obtain (In this article we choose between the roots of the mass relations which satisfy $0 \leqslant q \leqslant 1$.)

$$q_1 = 0.9870 \pm 0.0002. \tag{34}$$

Throughout this article, the errors of the q-parameters were obtained by applying the formula:

$$\Delta q = \sqrt{\sum_{i=1}^{N} \left(\frac{\partial q}{\partial m_i} \right)^2 (\Delta m_i)^2}, \tag{35}$$

where N is the number of particles under consideration, Δm_i is the error of their masses and $\partial q/\partial m_\Lambda$, $\partial q/\partial m_\Sigma$, $\partial q/\partial m_N$, $\partial q/\partial m_\Xi$, obtained by performing an implicit differentiation of expression (32) are respectively given by

$$\frac{\partial q}{\partial m_\Lambda} = \frac{-F(q)}{m_\Lambda \frac{dF(q)}{dq} + m_\Sigma \frac{dG(q)}{dq} - m_N \frac{dH(q)}{dq} - m_\Xi \frac{dI(q)}{dq}},$$

$$\frac{\partial q}{\partial m_\Sigma} = \frac{-G(q)}{m_\Lambda \frac{dF(q)}{dq} + m_\Sigma \frac{dG(q)}{dq} - m_N \frac{dH(q)}{dq} - m_\Xi \frac{dI(q)}{dq}}$$

$$\frac{\partial q}{\partial m_N} = \frac{H(q)}{m_\Lambda \frac{dF(q)}{dq} + m_\Sigma \frac{dG(q)}{dq} - m_N \frac{dH(q)}{dq} - m_\Xi \frac{dI(q)}{dq}},$$

$$\frac{\partial q}{\partial m_\Xi} = \frac{I(q)}{m_\Lambda \frac{dF(q)}{dq} + m_\Sigma \frac{dG(q)}{dq} - m_N \frac{dH(q)}{dq} - m_\Xi \frac{dI(q)}{dq}}.$$

With the functions $F(q)$, $G(q)$, $H(q)$, and $I(q)$ given by

$$F(q) = [3]_q \sqrt{\frac{[3]_q + [2]_q}{[4]_q + 1}},$$

$$G(q) = C(q) - E(q) - D(q),$$

$$H(q) = q^{-2}E(q) + \frac{q^2}{2}\left(A(q) + \frac{\left(\left[\frac{3}{2} \right]_q \right)^2 \sqrt{[5]_q}}{[3]_q \left[\frac{1}{2} \right]_q \left[\frac{5}{2} \right]_q} B(q) \right),$$

$$I(q) = q^2 E(q) + \frac{q^3}{2}\left(A(q) - \frac{\left(\left[\frac{3}{2} \right]_q \right)^2 \sqrt{[5]_q}}{[3]_q \left[\frac{1}{2} \right]_q \left[\frac{5}{2} \right]_q} B(q) \right).$$

To determine the q-deformed mass relations for the decuplet baryon, we follow the same procedure used for the octet baryon, taking into account that when the q-deformed Wigner-Eckart theorem is applied to the second term of expression (22), the $\{3\} \times \{3\}$, $\{0\} \times \{2\}$, $\{\bar{3}\} \times \{1\}$, and

$\{\overline{6}\}\times\{0\}$ states of the $\{3\}$ representation (which represent 4, 3, 2, and 1 states respectively, corresponding to the Δ, Σ, Ξ, and Ω particles of the decuplet baryon) are coupled to the $\{0\}\times\{0\}$ state of the $\{21\}$ representation, where the coupling coefficients are the q-deformed isoscalar factors. Hence, according to the previous, we obtain the following expressions corresponding to the masses of the particle families in the decuplet baryon[7]:

$$m_{\Delta} = m_S(\{3\}) + \begin{pmatrix} \{3\} & \{21\} & \| & \{3\} \\ \frac{3}{2}1 & 00 & \| & \frac{3}{2}1 \end{pmatrix}_q \langle\{3\}||\hat{T}^{\{21\}}||\{3\}\rangle, \tag{36}$$

$$m_{\Sigma} = m_S(\{3\}) + \begin{pmatrix} \{3\} & \{21\} & \| & \{3\} \\ 10 & 00 & \| & 10 \end{pmatrix}_q \langle\{3\}||\hat{T}^{\{21\}}||\{3\}\rangle, \tag{37}$$

$$m_{\Xi} = m_S(\{3\}) + \begin{pmatrix} \{3\} & \{21\} & \| & \{3\} \\ \frac{1}{2}-1 & 00 & \| & \frac{1}{2}-1 \end{pmatrix}_q \langle\{3\}||\hat{T}^{\{21\}}||\{3\}\rangle, \tag{38}$$

$$m_{\Omega} = m_S(\{3\}) + \begin{pmatrix} \{3\} & \{21\} & \| & \{3\} \\ 0-2 & 00 & \| & 0-2 \end{pmatrix}_q \langle\{3\}||\hat{T}^{\{21\}}||\{3\}\rangle. \tag{39}$$

Where for this case, we have[1,7]

$${}_qC^{3/2\ 0\ 3/2}_{3/2\ 0\ 3/2} = {}_qC^{101}_{101} = {}_qC^{1/2\ 0\ 1/2}_{1/2\ 0\ 1/2} = 1. \tag{40}$$

Then, for the decuplet baryon we have

$$\begin{pmatrix} \{3\} & \{21\} & \| & \{3\} \\ ty & 00 & \| & ty \end{pmatrix}_q = {}_qC^{\{3\}\times\{21\}}_{(\alpha 5)\{3\}(\alpha)} \tag{41}$$

Therefore, by combining expressions (36)–(39) and using the q-deformed Clebsch-Gordan coefficients corresponding to the $\{3\}\times\{21\}$ reduction given in the Appendix, the following q-deformed mass relations for decuplet baryons is obtained[7]:

$$m_{\Sigma^*} - m_{\Omega} = \frac{1+q}{[2]_q}(m_{\Delta} - m_{\Xi^*}), \tag{42}$$

$$m_{\Xi^*} - m_{\Omega} = \frac{q^3}{1+q}(m_{\Sigma^*} - m_{\Omega}), \tag{43}$$

$$m_{\Omega} - m_{\Xi^*} = \frac{q^3}{1+q-q^3}(m_{\Xi^*} - m_{\Sigma^*}), \tag{44}$$

where the q-deformation parameter, according to expression (42) is given by

$$q = \frac{m_{\Delta} - m_{\Xi^*} \pm \sqrt{(m_{\Delta} - m_{\Xi^*})^2 - 4(m_{\Sigma^*} - m_{\Omega})(m_{\Sigma^*} + m_{\Xi^*} - m_{\Omega} - m_{\Delta})}}{2(m_{\Sigma^*} + m_{\Xi^*} - m_{\Omega} - m_{\Delta})}. \tag{45}$$

As in the case of the octet baryons, we replace the average multiplet masses obtaining the following values for the q-parameter:

$$q_2 = 0.917 \pm 0.012, \quad q_3 = 0.986 \pm 0.003, \quad q_4 = 0.985 \pm 0.002. \tag{46}$$

With the aim to determine a unique q-parameter for the q-deformed Gell-Mann-Okubo mass relations for octet and decuplet baryons, we perform a χ^2 adjustment given by the fitted function:

TABLE I. Error percentages of the Gell-Mann-Okubo mass relations for the $SU_q(3)$ and SU(3) algebras.

Mass relation	q	$\frac{\lvert\text{rhs}-\text{lhs}\rvert}{\text{rhs}}\%$
(32)	0.970	0.33
(32)	1.000	0.58
(42)	0.970	2.99
(42)	1.000	4.49
(43)	0.970	4.26
(43)	1.000	3.40
(44)	0.970	7.95
(44)	1.000	8.23

$$\chi^2 = \sum_{i=1}^{4} \frac{(q_i - q)^2}{q^2}. \tag{47}$$

By minimizing the χ^2 function, we obtain the fitted q-parameter given by

$$q = 0.970 \pm 0.003. \tag{48}$$

Besides that, by comparing the generalization of the Gell-Mann-Okubo mass formula for pseudoscalar meson with its q-deformed version, the following relation is obtained:[12]

$$\frac{f_K^2}{f_\pi^2} = \frac{[2]_q}{2([2]_q - [3]_q)}, \tag{49}$$

where f_K and f_π are the decay constants for the K and π mesons, respectively.

Moreover, the ratio f_K/f_π can be expressed in terms of the Cabbibo angle as follows[12]:

$$\tan^2\theta_C = \frac{\frac{m_\pi^2}{m_K^2}}{\frac{f_K}{f_\pi} - \frac{m_\pi^2}{m_K^2}}. \tag{50}$$

From expressions (49) and (50), a connection between the q-deformation parameter and the Cabbibo angle is observed.[12]

On the other hand, as we have chosen before that $0 \leqslant q \leqslant 1$, we can introduce a new τ parameter according to:

$$q = \cos\tau. \tag{51}$$

Then, from expressions (48) and (51) we get:

$$\tau = (0.246 \pm 0.012)\text{rad}. \tag{52}$$

As the Cabbibo angle is equal to $\theta_C = (0.226 \pm 0.002)\text{rad}$,[17] expression (52) implies:

$$\tau = (1.085 \pm 0.063)\,\theta_C. \tag{53}$$

Hence, according to the previous result, it is possible to interpret the q-deformation parameter with the cosine of the Cabbibo angle.

By replacing the q-deformation parameter obtained by the χ^2 fitting in the Gell-Mann-Okubo mass relations and comparing with the $q=1$ case, we obtain Table I. In Table I we can see that for the q-deformed Gell-Mann-Okubo mass relations for the octet and decuplet baryons, a better

agreement with the experimental masses than the predicted by the SU(3) algebra is obtained, except for expression (43) corresponding to the decuplet baryon, where the difference between the error percentages is only 0.86%.

IV. THE *q*-DEFORMED COLEMAN-GLASHOW RELATIONS FOR OCTET AND DECUPLET BARYONS

The center of the octet baryon is degenerate and so the U eigenfunctions differ from isoespin eigenfunctions. The $U=1$ and $U=0$ eigenfuntions are

$$|\Sigma_U^0\rangle = \frac{\sqrt{[3]_q}}{[2]_q}|\Lambda^0\rangle - \frac{1}{[2]_q}|\Sigma^0\rangle, \tag{54}$$

$$|\Lambda_U^0\rangle = \frac{\sqrt{[3]_q}}{[2]_q}|\Lambda^0\rangle + \frac{1}{[2]_q}|\Sigma^0\rangle. \tag{55}$$

For this case, we consider the following expression for the mass operator:

$$\hat{M} = \hat{M}_S + \hat{M}_T + \hat{M}_U, \tag{56}$$

where the operators $\hat{M}_S$, $\hat{M}_T$, and $\hat{M}_U$ are $\mathrm{SU}_q(3)$ scalar, isospin scalar and U spin scalar, respectively.

The mass operators $\hat{M}_T$ and $\hat{M}_U$ have matrix elements related by

$$m_T(n) = m_T(p), \quad m_T(\Sigma^+) = m_T(\Sigma^0), \quad m_U(n) = m_U(\Sigma_U^0), \quad m_U(p) = m_U(\Sigma_U^+),$$

$$m_T(\Sigma^-) = m_T(\Sigma^0), \quad m_T(\Xi^-) = m_T(\Xi^0), \quad m_U(\Sigma^-) = m_U(\Xi^-), \quad m_U(\Xi^0) = m_U(\Sigma_U^0). \tag{57}$$

Moreover, by taking into account that

$$m_U(\Sigma_U^0) = \langle\Sigma_U^0|\hat{M}_U|\Sigma_U^0\rangle \quad \langle\Sigma_U^0|\hat{M}_U|\Lambda_U^0\rangle = 0,$$

$$m(\Sigma^0\Lambda^0) = \langle\Sigma^0|\hat{M}|\Lambda^0\rangle = \langle\Sigma^0|\hat{M}_U|\Lambda^0\rangle = m_U(\Sigma^0\Lambda^0)$$

and using the expressions corresponding to the $|\Sigma_U^0\rangle$, $|\Lambda_U^0\rangle$ states, we get:

$$m_U(\Sigma_U^0) = \frac{[3]_q m_U(\Lambda^0) + m_U(\Sigma^0) - 2\sqrt{[3]_q}m_U(\Sigma^0\Lambda^0)}{([2]_q)^2}, \tag{58}$$

$$m_U(\Lambda^0) - m_U(\Sigma^0) = -\frac{[4]_q}{[2]_q\sqrt{[3]_q}}m(\Sigma^0\Lambda^0). \tag{59}$$

Then, from expressions (56)–(58), we find

$$m(n) - m(p) + m(\Sigma^+) - m(\Sigma^0) = \frac{[3]_q}{([2]_q)^2}(m_U(\Lambda^0) - m_U(\Sigma^0)) - \frac{2\sqrt{[3]_q}}{([2]_q)^2}m_U(\Sigma^0\Lambda^0), \tag{60}$$

$$m(\Xi^-) - m(\Xi^0) + m(\Sigma^0) - m(\Sigma^-) = \frac{2\sqrt{[3]_q}}{([2]_q)^2}m_U(\Sigma^0\Lambda^0) + \frac{[3]_q}{([2]_q)^2}(m_U(\Sigma^0) - m_U(\Lambda^0)). \tag{61}$$

Therefore, by replacing (59) in expressions (60) and (61), the following relations are obtained:

$$m_n - m_p + m_{\Sigma^+} - m_{\Sigma^0} = -\sqrt{[3]_q} m_{\Sigma^0\Lambda^0}, \tag{62}$$

$$m_{\Xi^-} - m_{\Xi^0} + m_{\Sigma^0} - m_{\Sigma^-} = \sqrt{[3]_q} m_{\Sigma^0\Lambda^0}. \tag{63}$$

From the linear combinations of the previous relations we find

$$m_{\Xi^-} - m_{\Xi^0} = m_{\Sigma^-} - m_{\Sigma^+} + m_p - m_n. \tag{64}$$

Hence, the Colemann-Glashow relation for the octet baryon is independent of q.

On the other hand, it is known that when the electromagnetic interactions are neglected, we have that the mass operator for hadron multiplets is given by

$$\hat{M} = \hat{M}_S + \hat{M}_T, \tag{65}$$

where $\hat{M}_S$ is a $\mathrm{SU}_q(3)$ invariant whereas $\hat{M}_T$ is an operator corresponding to the $\mathrm{SU}_q(3)$ symmetry breaking.

We also have that under $\mathrm{SU}_q(2)_U \times \mathrm{U}(1)_Q$ the $\hat{M}_T$ operator in expression (65) transforms as the sum of a U vector spin and a U scalar.[14] Applying the $\mathrm{SU}_q(2)$ Wigner-Eckart theorem to this subgroup, we have

$$M(U,U_3) = A + C(U,q) q^{-U_3} U_3, \tag{66}$$

where $C(U,q)$ is given by[11]

$$C(U,q) = \frac{q^{U+1/2}}{[2U+1]_q} \langle \alpha U || \hat{M}_U || \alpha U \rangle. \tag{67}$$

From expressions (66) and (67) we get

$$m(U,U_3) - m(U,U_3-1) = C(U,q) q^{-U_3+1} + C(U,q) q^{-U_3} (1-q) U_3. \tag{68}$$

By applying the previous formula to the octet baryon, we find that

$$m(n) - m(\Sigma_U^0) = C(1,q) q^{-1},$$

$$m(\Sigma_U^0) - m(\Xi^0) = C(1,q) q.$$

Then, the following relation holds:

TABLE II. Error percentages of the Coleman-Glashow relations for the $\mathrm{SU}_q(3)$ and SU(3) algebras.

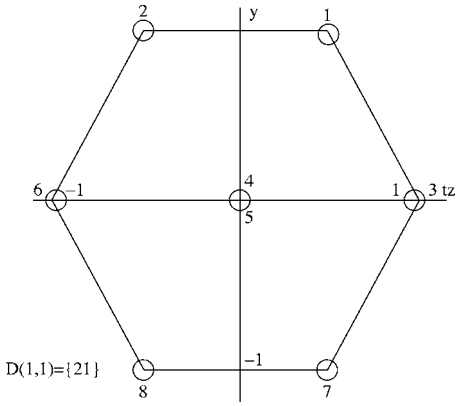

FIG. 1. Representation {21} of $SU_q(3)$ (Ref. 7).

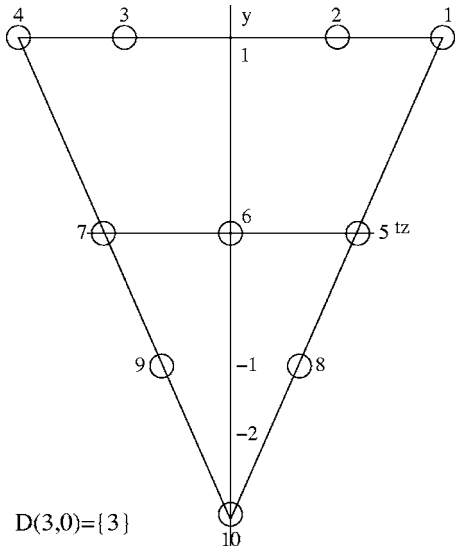

FIG. 2. Representation {3} of $SU_q(3)$ (Ref. 7).

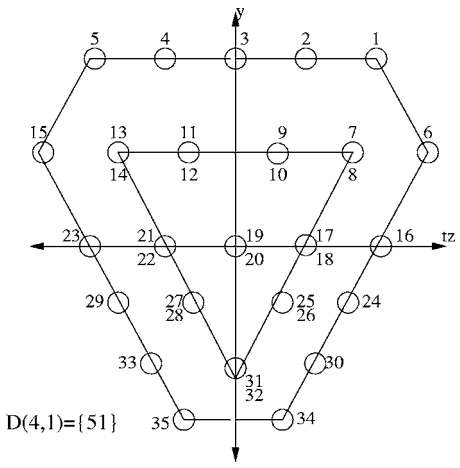

FIG. 3. Representation {51} of $SU_q(3)$ (Ref. 7).

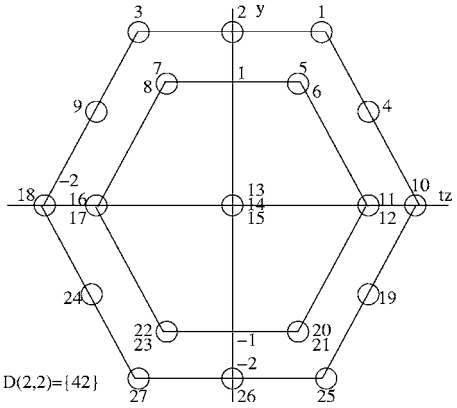

FIG. 4. Representation {42} of $SU_q(3)$ (Ref. 7).

$$q(m_n - m_{\Sigma_U^0}) = q^{-1}(m_{\Sigma_U^0} - m_{\Xi^0}). \tag{69}$$

Hence, by using (58), (59), and (69) we obtain a q deformed mass relation for the particles in the octet baryon:

$$q^2 m_n + m_p + q^{-2} m_{\Xi^0} + m_{\Xi^-} = [3]_q m_{\Lambda^0} + m_{\Sigma^+} + m_{\Sigma^-} - m_{\Sigma^0} \tag{70}$$

with the q deformation parameter given by

$$q = \pm \sqrt{\frac{s \pm \sqrt{s^2 - 4(m_n - m_{\Lambda^0})(m_{\Xi^0} - m_{\Lambda^0})}}{2(m_n - m_{\Lambda^0})}} \tag{71}$$

where the s parameter has been introduced according to

$$s = m_{\Sigma^+} + m_{\Sigma^-} + m_{\Lambda^0} - m_p - m_{\Xi^-} - m_{\Sigma^0}. \tag{72}$$

By replacing the experimental octet particle masses in expression (71), we obtain

$$q_1 = 0.965 \pm 0.001. \tag{73}$$

On the other hand, when formula (68) is applied to the decuplet baryon, we get the following expressions:

$$m_{\Delta^-} - m_{\Sigma^{*-}} = \tfrac{1}{2} C\left(\tfrac{3}{2}, q\right) q^{-3/2}(3 - q),$$

$$m_{\Sigma^{*-}} - m_{\Xi^{*-}} = \tfrac{1}{2} C\left(\tfrac{3}{2}, q\right) q^{-1/2}(1 + q),$$

$$m_{\Xi^{*-}} - m_{\Omega^-} = \tfrac{1}{2} C\left(\tfrac{3}{2}, q\right) q^{1/2}(3q - 1),$$

$$m_{\Delta^0} - m_{\Sigma^{*0}} = C(1, q) q^{-1},$$

$$m_{\Sigma^{*0}} - m_{\Xi^{*0}} = C(1, q) q.$$

Hence, for the decuplet baryons we obtain:

$$\frac{q^{3/2}(m_{\Delta^-} - m_{\Sigma^{*-}})}{3 - q^{-1}} = \frac{q^{1/2}(m_{\Sigma^{*-}} - m_{\Xi^{*-}})}{1 + q} = \frac{q^{-1/2}(m_{\Xi^{*-}} - m_{\Omega^-})}{3q - 1}, \tag{74}$$

$$q(m_{\Delta^0} - m_{\Sigma^{*0}}) = q^{-1}(m_{\Sigma^{*0}} - m_{\Xi^{*0}}). \tag{75}$$

Then, from expressions (74) and (75) and using the experimental decuplet particle masses we obtain:

$$q_2 = 0.976 \pm 0.007, \quad q_3 = 0.965 \pm 0.004, \tag{76}$$

$$q_4 = 0.970 \pm 0.003, \quad q_5 = 0.988 \pm 0.008. \tag{77}$$

Up to this point we have obtained five different values for the q-deformation parameter from the q-deformed Coleman-Glashow relations for octet and decuplet baryons. In order to obtain a unique q-parameter we perform a χ^2 adjustment obtaining

$$q = 0.973 \pm 0.002. \tag{78}$$

For this case, we have obtained the τ parameter given by

$$\tau = (0.233 \pm 0.010)\text{rad} = (1.030 \pm 0.053)\,\theta_C, \tag{79}$$

which implies that the q-deformation parameter can be interpreted with the cosine of the Cabbibo angle.

By replacing the q-deformation parameter obtained by the χ^2 adjustment in the Coleman-Glashow relations and comparing with the predicted by the SU(3) algebra, we obtain the Table II. From Table II, a better agreement of the q-deformed Coleman-Glashow relations with the experiment than the predicted by the SU(3) algebra is obtained in all cases except in the last [relation (75)], where the difference between the error percentages is only 0.46%.

V. CONCLUSIONS

The quantum group $SU_q(3)$ provides a good tool to solve problems in particle physics, especially when one needs to describe the mass splitting for particles from isomultiplets within octet and decuplet baryons.

The q-deformed Clebsch-Gordan coefficients corresponding to the $\{3\}\times\{21\}$ reduction of the $SU_q(3)$ algebra were computed. The q-deformed mass relations for octet and decuplet baryons have been explicity obtained from the quantum Clebsch-Gordan coefficients corresponding to the $\{21\}\times\{21\}$ and $\{3\}\times\{21\}$ reductions. The Coleman-Glashow relations for octet and decuplet baryons have been found in the $SU_q(3)$ quantum algebra. From the Coleman-Glashow relation for the octet baryon, a q-deformed mass relation between its particles has been obtained.

By performing an adjustment of the q-deformation parameter in the q-deformed Gell-Mann-Okubo and Coleman-Glashow relations for octet and decuplet baryons, we obtain that the corresponding values for this parameter are $q=0.970\pm0.003$ and $q=0.973\pm0.002$, respectively. These values are directly connected with the cosine of the Cabbibo angle. That is, a unique relation between the q-deformation parameter and the Cabbibo angle has been found, which differs with the results given in Ref. 12 in the fact that in this reference two different relations, $q=e^{2i\theta_C}$ and $q=e^{i\theta_C}$, between these parameters have been obtained for the octet and decuplet baryons, respectively, exhibiting error percentages of approximately 0.07% and 0.53% when these relations are replaced in the q deformed masses expressions.

In spite of the fact that the error percentages of the q-deformed mass relations obtained in Ref. 12 are lower than those obtained in this article, it is important to point out that we have shown that when two approximately equivalent values of the q-deformation parameter are used, the q-deformed Gell-Mann-Okubo and Coleman-Glashow relations for octet and decuplet baryons exhibit a very good agreement with the experimental results, in most cases better than the predicted by the SU(3) algebra. The error percentages of the q-deformed Gell-Mann-Okubo and Coleman-Glashow relations are lower than 7.95% and 2.97%, respectively.

ACKNOWLEDGMENTS

The author thanks professor Richard W Haase for introducing him to this field, for reviewing the calculations, and for carefully reading the manuscript. The author also thanks Professor R. Hurtado and Professor M. Di Sanctis for reading the manuscript and giving their suggestions and comments. Moreover, the author is grateful to Mateo Restrepo for facilitating useful references.

APPENDIX: QUANTUM CLEBSCH-GORDAN COEFFICIENTS FOR THE {3}×{21} REDUCTION

The product of the $SU_q(3)$ representations {3} and {21} is given by

$$\{3\} \times \{21\} = \{51\} + \{42\} + \{3\} + \{21\}, \tag{A1}$$

where {51}, {42}, {3}, and {21} are representations with dimensions equal to 35, 27, 10, and 8, respectively. These representations are shown in Figs. 1–4.

Through a straightforward calculation in which the angular momentum addition rules are taken into account together with the requirements of orthogonality, the q-deformed Clebsch-Gordan coefficients corresponding to the {3}×{21} reduction are determined and shown in the Table III. In this case, we have that χ_i, $i=1,2,\ldots,8$ and ξ_j, $j=1,2,\ldots,10$ are the wave functions which describe the octet and decuplet baryons states corresponding to the {21} and {3} representations.

I. INTRODUCTION

The first *correct* phase-integral connection formula for a real, single-hump potential barrier was published by Fröman and Fröman in 1965 for the first-order approximation,[1] and in 1970 for an arbitrary-order approximation, but a particular choice of the base function.[2] The formula is valid also for underdense barriers, if the energy does not lie too high above the top of the barrier. The corresponding connection formula for a possibly complex potential barrier, when the phase-integral appoximation of arbitrary order generated from an unspecified base function (which is described in Sec. 1.3.1 of Ref. 3 and in Sec. 2.2 of Ref. 4) is used, was derived by Fröman *et al.* in Chap. 5 of Ref. 3 by means of comparison equation technique and by Fröman and Fröman[4] by initially using the fact that the wave function is single valued and then, only finally, comparison equation technique; see Sec. 3.44 in Ref. 4. The previously mentioned connection formula for a real, single-hump potential barrier was derived and presented in an alternative way in Ref. 4; see their Secs. 2.5 and 3.45. It is valid for a barrier of arbitrary thickness with approximately parabolic top, when an arbitrary order of the phase-integral approximation is used. The purpose of the present article is to verify the correctness of this connection formula for a particular parabolic barrier, for the symmetric Eckart-Epstein barrier, and for the inverted Morse potential, when the first order of the phase-integral approximation is used. For the background we refer to Sec. 1.3.1 in Ref. 3 or to Sec. 2.2 in Ref. 4.

II. FIRST-ORDER PHASE-INTEGRAL CONNECTION FORMULA FOR A REAL, SINGLE-HUMP BARRIER

For a real, single-hump potential barrier of arbitrary thickness with the turning points t' and t'' (where $t'<t''$ if the barrier is superdense), we write in the first order of the phase-integral approximation generated from an unspecified base function $Q(z)$ the wave function on the real axis as

$$\Psi(x')=\tilde{A}'(x')|Q^{-1/2}(x')|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x'}Q(z)dz\right|\right]+\tilde{B}'(x')|Q^{-1/2}(x')|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x'}Q(z)dz\right|\right], \tag{2.1}$$

with x' lying to the left of the barrier, and

$$\Psi(x'') = \tilde{A}''(x'')|Q^{-1/2}(x'')|\exp\left[i \left| \mathrm{Re} \int_{t''}^{x''} Q(z)dz \right| \right] + \tilde{B}''(x'')|Q^{-1/2}(x'')|\exp\left[-i \left| \mathrm{Re} \int_{t''}^{x''} Q(z)dz \right| \right], \tag{2.2}$$

with x'' lying to the right of the barrier.

The coefficients $\tilde{A}'(x')$, $\tilde{B}'(x')$, and $\tilde{A}''(x'')$, $\tilde{B}''(x'')$ in (2.1) and (2.2) are related to each other according to Eq. (3.45.8) in Ref. 4, i.e.,

$$\begin{pmatrix} \tilde{A}''(x'') \\ \tilde{B}''(x'') \end{pmatrix} = \tilde{\mathbf{M}} \begin{pmatrix} \tilde{A}'(x') \\ \tilde{B}'(x') \end{pmatrix}, \tag{2.3}$$

with the connection matrix $\tilde{\mathbf{M}}$ given by approximate formula (3.45.9a) in Ref. 4, i.e., in the first-order approximation

$$\tilde{\mathbf{M}} = \begin{pmatrix} -i\exp(K_0) & [\exp(2K_0)+1]^{1/2}\exp(i\tilde{\varnothing}) \\ [\exp(2K_0)+1]^{1/2}\exp(-i\tilde{\varnothing}) & i\exp(K_0) \end{pmatrix}, \tag{2.4}$$

where K_0 is the first-order phase integral with t' and t'' as limits of integration, i.e.,

$$K_0 = -\mathrm{i}\int_{t'}^{t''} Q(z)dz, \tag{2.5}$$

with the phase of $Q(z)$ chosen such that K_0 is positive when the barrier is superdense but negative when the barrier is underdense, and $\tilde{\varnothing}$ is the parabolic phase correction given by Eqs. (2.5.11) and (2.5.13a-c) in Ref. 4, i.e., in the first order of the phase-integral approximation,

$$\tilde{\varnothing} = \arg\Gamma(1/2 + i\overline{K_0}) - \overline{K_0}\ln|\overline{K_0}| + \overline{K_0}, \quad \overline{K_0} = K_0/\pi. \tag{2.6}$$

The matrix (2.4) has the property that

$$\tilde{\mathbf{M}}^{-1} = \tilde{\mathbf{M}}, \tag{2.7}$$

and therefore it follows from (2.3) that

$$\begin{pmatrix} \tilde{A}'(x') \\ \tilde{B}'(x') \end{pmatrix} = \tilde{\mathbf{M}} \begin{pmatrix} \tilde{A}''(x'') \\ \tilde{B}''(x'') \end{pmatrix}. \tag{2.8}$$

Formulas (2.3) and (2.8) along with (2.4) and (2.6) are valid under the assumptions that the coefficient function in the Schrödinger equation is in some sense large and that the top of the barrier is approximately parabolic. One can express the first assumption more precisely by saying that the quantity ϵ_0, defined by Eq. (2.2.1) in Ref. 4, be small compared to unity in the relevant region of the complex x plane. The second assumption means that the distance from the two transition points of the barrier to the transition points that are not associated with the barrier is much larger than the distance between the transition points of the barrier.

III. CONNECTION FORMULA FOR A REAL PARABOLIC BARRIER, OBTAINED FROM EXACT SOLUTIONS

The time-independent Schrödinger equation for a particular parabolic barrier can be written as

$$\frac{d^2\Psi}{dx^2} + R(x)\Psi = 0, \tag{3.1}$$

with

$$R(x) = \tfrac{1}{4}x^2 - a, \tag{3.2}$$

where a is a real constant.

According to Secs. 19.21.1 and 19.17.10 in Ref. 5, differential equation (3.1) along with (3.2) has a solution $E(a,x)$ such that

$$E(a,x) \sim \left(\frac{2}{x}\right)^{1/2} \exp\left\{ i\left[\frac{1}{4}x^2 - a\ln x + \frac{1}{2}\arg\Gamma(1/2+ia) + \frac{\pi}{4}\right]\right\}, \quad x \to +\infty. \tag{3.3}$$

Using Secs. 19.17.9, 19.21.1, 19.17.10, 19.21.4, 19.21.5, 19.21.6, and 19.18.3 in Ref. 5, and noting that $\arg\Gamma(1/2+ia)$ is a real quantity, one finds that the behavior of $E(a,x)$ as $x \to -\infty$ is

$$\begin{aligned} E(a,x) \sim{}& \left(\frac{2}{|x|}\right)^{1/2} \exp\left\{ \pi a + i\left[\frac{1}{4}x^2 - a\ln|x| + \frac{1}{2}\arg\Gamma(1/2+ia) - \frac{\pi}{4}\right]\right\} \\ &+ [\exp(2\pi a)+1]^{1/2}\left(\frac{2}{|x|}\right)^{1/2} \exp\left\{ -i\left[\frac{1}{4}x^2 - a\ln|x| + \frac{1}{2}\arg\Gamma(1/2+ia) - \frac{\pi}{4}\right]\right\}, \\ & x \to -\infty. \end{aligned} \tag{3.4}$$

By expressing the right-hand sides of (3.3) and (3.4) in terms of phase-integral quantities we shall derive the connection formula described in Sec II.

Choosing

$$Q(x) = R^{1/2}(x) \tag{3.5}$$

with the phase of $R^{1/2}(x)$ in agreement with what is said following (2.5), and denoting the zeros of $Q^2(x)$ by t' and t'', where $t' < t''$ if the barrier is superdense, we obtain from (2.5), with the use of (3.2),

$$K_0 = -\,\mathrm{i}\int_{t'}^{t''} Q(x)dx = \int_{t'}^{t''} \left(a - \frac{1}{4}x^2\right)^{1/2} dx = \pi a = \pi\overline{K}_0, \tag{3.6}$$

where

$$\overline{K}_0 = K_0/\pi = a. \tag{3.7}$$

With the use of (3.2) and (3.5) we obtain

$$\left|\mathrm{Re}\int_{t''}^{x} Q(z)dz\right| = \mathrm{Re}\int_{2\sqrt{a}}^{x}\left(\frac{1}{4}z^2 - a\right)^{1/2} dz = \frac{1}{4}x(x^2-4a)^{1/2} - a\ln[(x^2-4a)^{1/2}+x] + a\ln(2\sqrt{|a|}), \tag{3.8}$$

with x lying to the right of the barrier, and hence, by neglecting terms of the order $O(x^{-2})$,

$$\left|\mathrm{Re}\int_{t''}^{x} Q(z)dz\right| \sim \frac{1}{4}x^2 - a\ln x + \frac{1}{2}a(\ln|a| - 1), \quad x \to +\infty. \tag{3.9}$$

Because of the symmetry of $Q^2(x)$ we obtain from (3.8)

$$\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right| = \left|\mathrm{Re}\int_{t''}^{|x|} Q(z)dz\right| = \frac{1}{4}|x|(x^2-4a)^{1/2} - a\ln[(x^2-4a)^{1/2}+|x|] + a\ln(2\sqrt{|a|}), \tag{3.10}$$

with x lying to the left of the barrier, and hence, by neglecting terms of the order $O(x^{-2})$,

$$\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right| \sim \frac{1}{4}x^2 - a\ln|x| + \frac{1}{2}a(\ln|a| - 1), \quad x \to -\infty. \tag{3.11}$$

Recalling (3.2), (3.5), (3.7), (3.9), and (3.11), one can write (3.3) and (3.4) as

$$E(a,x) \sim |Q^{-1/2}(x)|\exp\left\{ i\left[\left|\mathrm{Re}\int_{t''}^{x} Q(z)dz\right| + \frac{\tilde{\varnothing}}{2} + \frac{\pi}{4}\right]\right\}, \quad x \to +\infty, \tag{3.12}$$

$$\begin{aligned} E(a,x) \sim{}& |Q^{-1/2}(x)|\exp\left\{ K_0 + i\left[\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right| + \frac{\tilde{\varnothing}}{2} - \frac{\pi}{4}\right]\right\} \\ &+ [\exp(2K_0) + 1]^{1/2}|Q^{-1/2}(x)|\exp\left\{ - i\left[\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right| + \frac{\tilde{\varnothing}}{2} - \frac{\pi}{4}\right]\right\}, \\ & x \to -\infty, \end{aligned} \tag{3.13}$$

with

$$\tilde{\varnothing} = \arg\Gamma(1/2 + i\overline{K_0}) - \overline{K_0}\ln|\overline{K_0}| + \overline{K_0}. \tag{3.14}$$

From (3.12) and (3.13) one finds that the function

$$\Psi_1(x) = \exp\left[- i\left(\frac{\tilde{\varnothing}}{2} + \frac{\pi}{4}\right)\right]E(a,x) \tag{3.15}$$

for sufficiently large positive and negative values of x is given by

$$\Psi_1(x) \sim |Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t''}^{x} Q(z)dz\right|\right], \quad x \to +\infty, \tag{3.16}$$

$$\Psi_1(x) \sim b_1|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right] + b_2|Q^{-1/2}(x)|\exp\left[- i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right], \quad x \to -\infty, \tag{3.17}$$

where

$$b_1 = -i\exp(K_0), \tag{3.18}$$

$$b_2 = [\exp(2K_0) + 1]^{1/2}\exp(-i\tilde{\varnothing}). \tag{3.19}$$

The function

$$\Psi_2(x) = \Psi_1^*(x) \tag{3.20}$$

is another approximate solution of (3.1) along with (3.2). It behaves for large positive and negative values of x as

$$\Psi_2(x) \sim |Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t''}^{x} Q(z)dz\right|\right], \quad x \to +\infty, \tag{3.21}$$

$$\Psi_2(x) \sim b_2^*|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right] + b_1^*|Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right], \quad x \to -\infty. \tag{3.22}$$

As $x \to +\infty$ the general solution is according to (3.16) and (3.21)

$$\Psi(x) \sim \tilde{A}''|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t''}^{x} Q(z)dz\right|\right] + \tilde{B}''|Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t''}^{x} Q(z)dz\right|\right], \quad x \to +\infty, \tag{3.23}$$

where $\tilde{A}''$ and $\tilde{B}''$ are arbitrary constants. When $x \to -\infty$ this solution behaves according to (3.17) and (3.22) as

$$\begin{aligned}\Psi(x) \sim{}& \tilde{A}''\left\{b_1|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right] + b_2|Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right]\right\} \\ &+ \tilde{B}''\left\{b_2^*|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right] + b_1^*|Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right]\right\} \\ ={}& \tilde{A}'|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right] + \tilde{B}'|Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x} Q(z)dz\right|\right], \quad x \to -\infty,\end{aligned} \tag{3.24}$$

where

$$\tilde{A}' = b_1\tilde{A}'' + b_2^*\tilde{B}'', \tag{3.25}$$

$$\tilde{B}' = b_2\tilde{A}'' + b_1^*\tilde{B}'', \tag{3.26}$$

i.e.,

$$\begin{pmatrix}\tilde{A}' \\ \tilde{B}'\end{pmatrix} = \tilde{\mathbf{M}}\begin{pmatrix}\tilde{A}'' \\ \tilde{B}''\end{pmatrix}, \tag{3.27}$$

with

$$\tilde{\mathbf{M}} = \begin{pmatrix}b_1 & b_2^* \\ b_2 & b_1^*\end{pmatrix}. \tag{3.28}$$

Inserting (3.18) and (3.19) into (3.28) one obtains

$$\tilde{\mathbf{M}} = \begin{pmatrix}-i\exp(K_0) & [\exp(2K_0)+1]^{1/2}\exp(i\tilde{\varnothing}) \\ [\exp(2K_0)+1]^{1/2}\exp(-i\tilde{\varnothing}) & i\exp(K_0)\end{pmatrix}. \tag{3.29}$$

It is seen that (3.27) along with (3.29) and (3.14) agrees with the first-order phase-integral result given by (2.8) along with (2.4) and (2.6). This is true for any real value of the constant a in (3.2). According to (3.6) $K_0 = \pi a$, so the barrier can therefore be of arbitrary thickness (overdense or underdense).

Of the conditions stated following (2.8) for the validity of the general connection formula for a real barrier described in Sec. II the second condition is automatically fulfilled for the particular barrier now considered. Further, in the present section we did not use the first condition, i.e., the requirement that the absolute value of ϵ_0 be much smaller than unity in the relevant region of the complex plane. The reason for this is that the Schrödinger equation with a parabolic barrier was used as comparison equation in the derivation of the general connection formula presented in Sec. III, and therefore the condition in question is not needed here.

IV. CONNECTION FORMULA FOR THE REAL, SYMMETRIC ECKART-EPSTEIN BARRIER, OBTAINED FROM EXACT SOLUTIONS

Consider the real, symmetric Eckart-Epstein potential barrier

$$V(x) = \frac{4V_0 \exp(x/x_0)}{[\exp(x/x_0) + 1]^2}, \tag{4.1}$$

where x_0 is a positive constant with the dimension of length, and V_0 is a positive constant, which has the dimension of energy and is equal to the height of the barrier. With obvious notations the time-independent Schrödinger equation for a quantal particle in the potential (4.1) is

$$\frac{d^2\Psi}{dx^2} + R(x)\Psi = 0, \tag{4.2}$$

where

$$R(x) = \frac{2m}{\hbar^2}\left\{E - \frac{4V_0 \exp(x/x_0)}{[\exp(x/x_0) + 1]^2}\right\}. \tag{4.3}$$

From Eckart's[6] paper one finds that there is a solution $\Psi(x)$ of (4.2) along with (4.3) that for large positive and negative values of x behaves as

$$\Psi(x) \sim \left(\frac{\alpha}{x_0}\right)^{-1/2} \exp(i\alpha x/x_0), \quad x \to +\infty, \tag{4.4}$$

$$\begin{aligned}\Psi(x) \sim{}& \frac{\Gamma(-2i\alpha)\Gamma(1-2i\alpha)}{\Gamma(1/2 + i(\beta - 2\alpha))\Gamma(1/2 - i(\beta + 2\alpha))}\left(\frac{\alpha}{x_0}\right)^{-1/2} \exp(i\alpha x/x_0) \\ &+ \frac{\Gamma(2i\alpha)\Gamma(1-2i\alpha)}{\Gamma(1/2 + i\beta)\Gamma(1/2 - i\beta)}\left(\frac{\alpha}{x_0}\right)^{-1/2} \exp(-i\alpha x/x_0), \quad x \to -\infty,\end{aligned} \tag{4.5}$$

where

$$\alpha = \left(\frac{2mEx_0^2}{\hbar^2}\right)^{1/2} \tag{4.6}$$

is a dimensionless, positive parameter. By expressing the right-hand sides of (4.4) and (4.5) in terms of phase-integral quantities we shall in the following derive the phase-integral connection formula for a real barrier described in Sec. II.

When x lies sufficiently close to an arbitrary pole x_p of $R(x)$ one has the formula

$$\frac{\exp(x/x_0)}{4x_0^2[\exp(x/x_0) + 1]^2} \approx -\frac{1}{4(x - x_p)^2}. \tag{4.7}$$

Referring to Sec. 2.2 in Ref. 4, we therefore choose

$$Q^2(x) = R(x) + \frac{\exp(x/x_0)}{4x_0^2[\exp(x/x_0)+1]^2} \tag{4.8}$$

and hence, with the use of (4.3),

$$Q^2(x) = \frac{\alpha^2[\exp(x/x_0)+1]^2 - \beta^2\exp(x/x_0)}{x_0^2[\exp(x/x_0)+1]^2} \tag{4.9}$$

$$= \frac{\alpha^2[\exp(2x/x_0) - (\gamma^2-2)\exp(x/x_0)+1]}{x_0^2[\exp(x/x_0)+1]^2} \tag{4.10}$$

where α (dimensionless and positive) is defined by (4.6), and

$$\beta = \left(\frac{8mV_0x_0^2}{\hbar^2} - \frac{1}{4}\right)^{1/2}, \tag{4.11}$$

$$\gamma = \frac{\beta}{\alpha}, \tag{4.12}$$

are other dimensionless parameters, which are also assumed to be positive.

One finds from (4.10) that the turning points t' and t'' (where $t' < t''$ when the barrier is superdense), i.e., the zeros of $Q^2(x)$ on the real axis, are obtained from

$$-t' = t'' = x_0 \ln\frac{\gamma^2 - 2 + \gamma(\gamma^2-4)^{1/2}}{2} = x_0 \ln\frac{[\gamma+(\gamma^2-4)^{1/2}]^2}{4} = x_0 \ln\frac{\gamma+(\gamma^2-4)^{1/2}}{\gamma-(\gamma^2-4)^{1/2}}$$
$$= x_0 \ln\frac{1+(1-4/\gamma^2)^{1/2}}{1-(1-4/\gamma^2)^{1/2}},$$

i.e.,

$$-t' = t'' = x_0 \ln\frac{1+(1-4/\gamma^2)^{1/2}}{1-(1-4/\gamma^2)^{1/2}}. \tag{4.13}$$

According to (2.5) one has

$$K_0 = -\mathrm{i}\int_{t'}^{t''} Q(z)dz = \int_{t'}^{t''} [-Q^2(z)]^{1/2}dz, \tag{4.14}$$

where the phase of the integrand is to be chosen appropriately. In Appendices A and B it is shown that by inserting the expression for $Q(z)$ obtained from (4.9) into (4.14) and evaluating the integral one obtains

$$K_0 = \pi(\beta - 2\alpha), \tag{4.15}$$

where α and β are given by (4.6) and (4.11), respectively.

One finds with the use of (4.10) that

$$\lim_{x\to-\infty}|Q^{-1/2}(x)| = \lim_{x\to+\infty}|Q^{-1/2}(x)| = \left(\frac{\alpha}{x_0}\right)^{-1/2}, \tag{4.16}$$

and according to (C3) and (C4) in Appendix C one has

$$\lim_{x\to+\infty}\left[\left|\mathrm{Re}\int_{t''}^{x}Q(z)dz\right|-\frac{\alpha}{x_0}x\right]=\lim_{x\to-\infty}\left[\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|+\frac{\alpha}{x_0}x\right]=2\alpha\ln(2\alpha)-\frac{\beta+2\alpha}{2}\ln(\beta+2\alpha)$$
$$+\frac{\beta-2\alpha}{2}\ln|\beta-2\alpha|. \tag{4.17}$$

With the use of (4.4), (4.5), (4.16), and (4.17) one finds that the function

$$\Psi_1(x)=\exp\left\{i\left[2\alpha\ln(2\alpha)-\frac{\beta+2\alpha}{2}\ln(\beta+2\alpha)+\frac{\beta-2\alpha}{2}\ln|\beta-2\alpha|\right]\right\}\Psi(x) \tag{4.18}$$

has the following behavior for large positive and negative values of x

$$\Psi_1(x)\sim|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t''}^{x}Q(z)dz\right|\right],\quad x\to+\infty, \tag{4.19}$$

$$\Psi_1(x)\sim b_1|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|\right]+b_2|Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|\right],\quad x\to-\infty, \tag{4.20}$$

where

$$b_1=\frac{\Gamma(2i\alpha)\Gamma(1-2i\alpha)}{\Gamma(1/2+i\beta)\Gamma(1/2-i\beta)}, \tag{4.21}$$

$$b_2=\exp\left\{2i\left[2\alpha\ln(2\alpha)-\frac{\beta+2\alpha}{2}\ln(\beta+2\alpha)+\frac{\beta-2\alpha}{2}\ln|\beta-2\alpha|\right]\right\}$$
$$\times\frac{\Gamma(-2i\alpha)\Gamma(1-2i\alpha)}{\Gamma(1/2+i(\beta-2\alpha))\Gamma(1/2-i(\beta+2\alpha))}. \tag{4.22}$$

Using the formulas in Secs. 6.1.17 and 6.1.30 of Ref. 5 and (4.15), one can write (4.21) as

$$b_1=\frac{\cosh(\pi\beta)}{\sin(2i\pi\alpha)}=-i\frac{\exp(\pi\beta)+\exp(-\pi\beta)}{\exp(2\pi\alpha)-\exp(-2\pi\alpha)}=-i\exp[\pi(\beta-2\alpha)]\frac{1+\exp(-2\pi\beta)}{1-\exp(-4\pi\alpha)}$$
$$=-i\exp(K_0)\frac{1+\exp(-2\pi\beta)}{1-\exp(-4\pi\alpha)}, \tag{4.23}$$

and with the use of the formulas in Secs. 6.1.15, 6.1.29, and 6.1.30 of Ref. 5 one obtains from (4.22)

$$|b_2|=\left|\frac{\Gamma(-2i\alpha)\Gamma(1-2i\alpha)}{\Gamma(1/2+i(\beta-2\alpha))\Gamma(1/2-i(\beta+2\alpha))}\right|=\left|\frac{-2i\alpha[\Gamma(-2i\alpha)]^2}{\Gamma(1/2+i(\beta-2\alpha))\Gamma(1/2-i(\beta+2\alpha))}\right|$$
$$=\frac{2\alpha|\Gamma(-2i\alpha)|^2}{[|\Gamma(1/2+i(\beta-2\alpha))|^2|\Gamma(1/2-i(\beta+2\alpha))|^2]^{1/2}}=\frac{\cosh^{1/2}[\pi(\beta-2\alpha)]\cosh^{1/2}[\pi(\beta+2\alpha)]}{\sinh(2\pi\alpha)}$$
$$=\frac{\{1+\exp[-2\pi(\beta+2\alpha)]\}^{1/2}\{\exp[2\pi(\beta-2\alpha)]+1\}^{1/2}}{1-\exp(-2\pi\alpha)}. \tag{4.24}$$

The conditions under which the phase-integral connection formula given by (2.3) or (2.8) together with (2.4) and (2.6) is valid are stated following (2.8). They require that ϵ_0, defined by Eq. (2.2.1) in Ref. 4, be small compared to unity in the relevant region of the complex plane, and

that the distance from the two transition points of the barrier to the transition points not associated with the barrier be much larger than the distance between the transition points of the barrier.

The requirement that the distance between the transition points of the barrier, obtained from (4.13), be small compared to their distance from the other transition points yields

$$2x_0 \ln\left|\frac{1+(1-4/\gamma^2)^{1/2}}{1-(1-4/\gamma^2)^{1/2}}\right| \ll \pi x_0, \tag{4.25}$$

and this requirement is fulfilled when $|(1-4/\gamma^2)^{1/2}| \ll \pi/4$, i.e., when $|\gamma-2|^{1/2} \ll \pi/4$, which is the case when

$$|\gamma-2|^{1/2} \ll 1. \tag{4.26}$$

In order for the phase-integral approximation to be valid, one requires the absolute value of ϵ_0 to be small compared to unity in the relevant region of the complex plane. According to (4.8), (4.10), and (4.26) and definition (2.2.1) in Ref. 4 of ϵ_0 this is the case when α is sufficiently large. For the moment we do not know how large α must be, and therefore we now impose only the condition

$$\alpha \gg 1 \tag{4.27}$$

without specifiying for the moment how large α must be. From (4.12), (4.26), and (4.27) it follows that

$$\beta \approx 2\alpha \gg 1, \tag{4.28}$$

and hence (4.23) gives

$$b_1 \approx -i\exp(K_0)[1+\exp(-4\pi\alpha)+\exp(-2\pi\beta)]. \tag{4.29}$$

Having already obtained formula (4.24) for $|b_2|$, one needs a formula for $\arg b_2$ in order to obtain b_2. To derive it one recalls (4.22), (4.27), and (4.28), and starts by making, with the use of asymptotic expansion (5) in Luke (Ref. 7, p. 32), i.e.,

$$\ln\Gamma(1/2+z) \sim z\ln z - z + \ln(2\pi)^{1/2} - \frac{1}{24z}, \quad z\to\infty, \quad |\arg z| < \pi-\epsilon, \quad \epsilon>0, \tag{4.30}$$

the following calculation:

$$\begin{aligned}
\ln\frac{\Gamma(-2i\alpha)\Gamma(1-2i\alpha)}{\Gamma(1/2-i(\beta+2\alpha))} &= \ln\frac{-2i\alpha[\Gamma(-2i\alpha)]^2}{\Gamma(1/2-i(\beta+2\alpha))} = \ln(-2i\alpha)+2\ln\Gamma(-2i\alpha)-\ln\Gamma(1/2-i(\beta+2\alpha)) \\
&= \ln(-2i\alpha)+2\ln\Gamma(1/2-(1/2+2i\alpha))-\ln\Gamma(1/2-i(\beta+2\alpha)) \\
&\sim \ln(2\alpha)-i\frac{\pi}{2}+2\left\{\ln(2\pi)^{1/2}+(-1/2-2i\alpha)[\ln(-1/2-2i\alpha)-1]\right. \\
&\quad \left.-\frac{1}{24(-1/2-2i\alpha)}\right\}-\left\{\ln(2\pi)^{1/2}-i(\beta+2\alpha)\{\ln[-i(\beta+2\alpha)]-1\}\right. \\
&\quad \left.-\frac{1}{24[-i(\beta+2\alpha)]}\right\} \approx \ln(2\alpha)-i\frac{\pi}{2}+2\left\{\ln(2\pi)^{1/2}-(1/2+2i\alpha)\right. \\
&\quad \left.\times\left[\ln(4\alpha^2+1/4)^{1/2}-i\left(\frac{\pi}{2}+\frac{1}{4\alpha}\right)-1\right]-\frac{i}{48\alpha}\right\}-\left\{\ln(2\pi)^{1/2}-i(\beta+2\alpha)\right. \\
&\quad \left.\times\left[\ln(\beta+2\alpha)-i\frac{\pi}{2}-1\right]-\frac{i}{24(\beta+2\alpha)}\right\} \approx \ln(2\pi)^{1/2}+(\beta-2\alpha)\frac{\pi}{2}
\end{aligned}$$

$$-\frac{1}{32\alpha^2}+i\Bigg[(\beta+2\alpha)\ln(\beta+2\alpha)-4\alpha\ln(2\alpha)-(\beta-2\alpha)+\frac{1}{12\alpha}+\frac{1}{24(\beta+2\alpha)}\Bigg]. \tag{4.31}$$

From (4.22) and (4.31) one obtains

$$\ln b_2 \approx \ln(2\pi)^{1/2}+(\beta-2\alpha)\frac{\pi}{2}-\frac{1}{32\alpha^2}-\ln\Gamma(1/2+i(\beta-2\alpha))+i\Bigg[(\beta-2\alpha)\ln|\beta-2\alpha|-(\beta-2\alpha)+\frac{1}{12\alpha}+\frac{1}{24(\beta+2\alpha)}\Bigg]. \tag{4.32}$$

With the use of the formula in Sec. 6.1.30 of Ref. 5 together with (4.27) and (4.28) one can confirm that (4.32) is in approximate agreement with the exact formula (4.24). From (4.32) one obtains

$$\arg b_2 = \operatorname{Im}\ln b_2 \approx (\beta-2\alpha)\ln|\beta-2\alpha|-(\beta-2\alpha)+\frac{1}{12\alpha}+\frac{1}{24(\alpha+2\beta)}-\arg\Gamma(1/2+i(\beta-2\alpha)). \tag{4.33}$$

With the use of (4.15) and (4.28) one obtains from (4.24) and (4.33)

$$b_2 \approx [\exp(2K_0)+1]^{1/2}\Bigg\{1+\exp(-2\pi\alpha)+\frac{1}{2}\exp[-2\pi(\beta+2\alpha)]\Bigg\}\times\exp\Bigg\{-i\Bigg[\tilde{\varnothing}-\frac{1}{12\alpha}-\frac{1}{24(\alpha+2\beta)}\Bigg]\Bigg\}, \tag{4.34}$$

where

$$\tilde{\varnothing} = \arg\Gamma(1/2+i\overline{K_0})-\overline{K_0}\ln|\overline{K_0}|+\overline{K_0} \tag{4.35}$$

with

$$\overline{K_0} = K_0/\pi. \tag{4.36}$$

We have thus found that the solution $\Psi_1(x)$ behaves for large positive and negative values of x according to (4.19) and (4.20), where b_1 and b_2 are given by (4.29) and (4.34).

Putting

$$\Psi_2(x) = \Psi_1^*(x), \tag{4.37}$$

one obtains with the use of (4.19) and (4.20)

$$\Psi_2(x) \sim |Q^{-1/2}(x)|\exp\Bigg[-i\Bigg|\operatorname{Re}\int_{t''}^{x}Q(z)dz\Bigg|\Bigg], \quad x\to+\infty, \tag{4.38}$$

$$\Psi_2(x) \sim b_2^*|Q^{-1/2}(x)|\exp\Bigg[i\Bigg|\operatorname{Re}\int_{t'}^{x}Q(z)dz\Bigg|\Bigg]+b_1^*|Q^{-1/2}(x)|\exp\Bigg[-i\Bigg|\operatorname{Re}\int_{t'}^{x}Q(z)dz\Bigg|\Bigg], \quad x\to-\infty. \tag{4.39}$$

When $x\to+\infty$ the general solution $\tilde{A}''\Psi_1(x)+\tilde{B}''\Psi_2(x)$, where $\tilde{A}''$ and $\tilde{B}''$ are arbitrary constants, behaves according to (4.19) and (4.38) as

$$\tilde{A}''\Psi_1(x)+\tilde{B}''\Psi_2(x)\sim\tilde{A}''|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t''}^{x}Q(z)dz\right|\right]$$
$$+\tilde{B}''|Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t''}^{x}Q(z)dz\right|\right],\quad x\to+\infty. \tag{4.40}$$

When $x\to-\infty$ this solution behaves according to (4.20) and (4.39) as

$$\begin{aligned}\tilde{A}''\Psi_1(x)+\tilde{B}''\Psi_2(x)\sim{}&\tilde{A}''\Bigg\{b_1|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|\right]+b_2|Q^{-1/2}(x)|\\&\times\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|\right]\Bigg\}+\tilde{B}''\Bigg\{b_2^{*}|Q^{-1/2}(x)|\\&\times\exp\left[i\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|\right]+b_1^{*}|Q^{-1/2}(x)|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|\right]\Bigg\}\\={}&\tilde{A}'|Q^{-1/2}(x)|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|\right]+\tilde{B}'|Q^{-1/2}(x)|\\&\times\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x}Q(z)dz\right|\right],\quad x\to-\infty,\end{aligned} \tag{4.41}$$

where

$$\tilde{A}'=b_1\tilde{A}''+b_2^{*}\tilde{B}'', \tag{4.42}$$

$$\tilde{B}'=b_2\tilde{A}''+b_1^{*}\tilde{B}'', \tag{4.43}$$

i.e.,

$$\begin{pmatrix}\tilde{A}'\\ \tilde{B}'\end{pmatrix}=\tilde{\mathbf{M}}\begin{pmatrix}\tilde{A}''\\ \tilde{B}''\end{pmatrix}, \tag{4.44}$$

with

$$\tilde{\mathbf{M}}=\begin{pmatrix}b_1 & b_2^{*}\\ b_2 & b_1^{*}\end{pmatrix}. \tag{4.45}$$

Inserting (4.29) and (4.34) into (4.45) and recalling (4.28), one obtains, when 12α is much larger than unity,

$$\tilde{\mathbf{M}}\approx\begin{pmatrix}-i\exp(K_0) & [\exp(2K_0)+1]^{1/2}\exp(i\tilde{\varnothing})\\ [\exp(2K_0)+1]^{1/2}\exp(-i\tilde{\varnothing}) & i\exp(K_0)\end{pmatrix}. \tag{4.46}$$

It is seen that (4.44) along with (4.46) and (4.35) agrees with the first-order phase-integral connection formula given by (2.8) along with (2.4) and (2.6). This result is obtained under the conditions (4.26), which with the use of (4.12), (4.15), and (4.36) can be written as $|\overline{K_0}/\alpha|^{1/2}\ll 1$, and (4.27), or more precisely $12\alpha\gg 1$ according to what is said immediately prior to (4.46). For any value of K_0 (positive or negative) it is possible to find values of α such that these conditions are fulfilled. The barrier may thus be of arbitrary thickness.

V. CONNECTION FORMULA FOR THE INVERTED, REAL MORSE POTENTIAL BARRIER, OBTAINED FROM EXACT SOLUTIONS

The present section concerns the inverted Morse potential

$$V(x) = V_0[2\exp(-x/b) - \exp(-2x/b)], \quad V_0 > 0, \quad b > 0. \tag{5.1}$$

When the energy E is positive, the Schrödinger equation associated with this potential describes a quantal particle subject to the influence of a single-hump potential barrier with the top at $x=0$ and $V(0)=V_0$, where V_0 is the height of the barrier. Lundborg[8] has treated the connection problem for a barrier given by (5.1) with the use of exact solutions of the Schrödinger equation. According to Eqs. (4) and (3a–c) in Ref. 8 the time-independent Schrödinger equation in question can be written as

$$\frac{d^2\Psi}{dz^2} + R(z)\Psi = 0 \tag{5.2}$$

with

$$R(z) = G^2[p^2 - 2\exp(-z) + \exp(-2z)] \tag{5.3}$$

where, with obvious notations,

$$z = x/b, \tag{5.4}$$

$$G = b\left(\frac{2mV_0}{\hbar^2}\right)^{1/2} > 0, \tag{5.5}$$

$$p = \left(\frac{E}{V_0}\right)^{1/2} > 0. \tag{5.6}$$

Lundborg[8] relates the exact solution to the phase-integral approximation generated from an unspecified base function and chooses the square of the base function to be

$$Q^2(z) = R(z). \tag{5.7}$$

The barrier is superdense for $0<p<1$ but underdense for $p>1$. The transition zeros, i.e., the zeros of $Q^2(z)$, obtained from (5.7) and (5.3), are $t'+2\pi ki$ and $t''+2\pi ki$, $k=0,\pm1,\pm2,\ldots$, with

$$t' = \ln\frac{1-(1-p^2)^{1/2}}{p^2}, \tag{5.8}$$

$$t'' = \ln\frac{1+(1-p^2)^{1/2}}{p^2}, \tag{5.9}$$

t' and t'' being the zeros of $Q^2(z)$ associated with the barrier. From (5.8) and (5.9) one obtains

$$t''-t' = \ln\frac{1+(1-p^2)^{1/2}}{1-(1-p^2)^{1/2}}. \tag{5.10}$$

According to what is said following (2.8), the phase-integral expression (2.4) for the connection matrix $\tilde{\mathbf{M}}$ is valid when the quantity ϵ_0, defined in Eq. (2.2.1) in Ref. 4, is much smaller than unity in the relevant region of the complex plane, and the distances from t' and t'' to the transition points not associated with the barrier are much larger than $|t''-t'|$. Recalling (5.3) and (5.7) one sees that the first of these conditions is fulfilled when G is sufficiently large. With the use of (5.10) the second condition can be written as

$$\ln\left|\frac{1+(1-p^2)^{1/2}}{1-(1-p^2)^{1/2}}\right| \ll 2\pi, \tag{5.11}$$

and this condition is undoubtedly fulfilled when

$$|1-p|^{1/2} \ll 1. \tag{5.12}$$

According to Ref. 8 (p. 466) the functions f_1 and f_2 are the same in Lundborg[8] as in Fröman and Fröman.[2] According to Eqs. (16a,b), (17a,b), and (9a,b) in the latter paper one therefore has in the first order of the phase-integral approximation and with the notation of the present paper

$$f_1(x') = |Q^{-1/2}(x')|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x'} Q(z)dz\right|\right], \tag{5.13}$$

with x' lying to the left of the barrier,

$$f_2(x') = |Q^{-1/2}(x')|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x'} Q(z)dz\right|\right], \tag{5.14}$$

with x' lying to the left of the barrier, and

$$f_1(x'') = |Q^{-1/2}(x'')|\exp\left[+K_0 - i\left|\mathrm{Re}\int_{t''}^{x''} Q(z)dz\right| + i\pi/2\right], \tag{5.15}$$

with x'' lying to the right of the barrier,

$$f_2(x'') = |Q^{-1/2}(x'')|\exp\left[-K_0 + i\left|\mathrm{Re}\int_{t''}^{x''} Q(z)dz\right| - i\pi/2\right], \tag{5.16}$$

with x'' lying to the right of the barrier, where x' and x'' are points in the classically allowed regions to the left and to the right, respectively, of the barrier. According to Eq. (24a) in Lundborg[8] the first-order quantity K_0 in (5.15) and (5.16) is given by

$$K_0 = \pi\overline{K_0} = \pi G(1-p). \tag{5.17}$$

With the use of Eq. (18) in Ref. 2, i.e.,

$$\Psi(z) = a_1(z)f_1(z) + a_2(z)f_2(z), \tag{5.18}$$

together with (5.13)–(5.16) in the present paper one obtains

$$\Psi(x') = \tilde{A}'|Q^{-1/2}(x')|\exp\left[i\left|\mathrm{Re}\int_{t'}^{x'} Q(z)dz\right|\right] + \tilde{B}'|Q^{-1/2}(x')|\exp\left[-i\left|\mathrm{Re}\int_{t'}^{x'} Q(z)dz\right|\right], \tag{5.19}$$

where

$$\tilde{A}' = a_2(x'), \tag{5.20}$$

$$\tilde{B}' = a_1(x'), \tag{5.21}$$

and

$$\Psi(x'') = \tilde{A}''|Q^{-1/2}(x'')|\exp\left[i \left| \mathrm{Re} \int_{t''}^{x''} Q(z)dz \right| \right] + \tilde{B}''|Q^{-1/2}(x'')|\exp\left[-i \left| \mathrm{Re} \int_{t''}^{x''} Q(z)dz \right| \right], \tag{5.22}$$

where

$$\tilde{A}'' = i \exp(-K_0) a_2(x''), \tag{5.23}$$

$$\tilde{B}'' = i \exp(K_0) a_1(x''). \tag{5.24}$$

With the use of the formula (30) for $\mathbf{F}(-\infty, +\infty)$ in Lundborg,[8] and (5.20), (5.21), (5.23), and (5.24) in the present paper one can write Eq. (19) in Ref. 2, i.e.,

$$\begin{pmatrix} a_1(x') \\ a_2(x') \end{pmatrix} = \mathbf{F}(x', x'') \begin{pmatrix} a_1(x'') \\ a_2(x'') \end{pmatrix} \tag{5.25}$$

in the first order of the phase-integral approximation and in the limit when $x' \to -\infty$ and $x'' \to +\infty$ as

$$\begin{pmatrix} \tilde{A}' \\ \tilde{B}' \end{pmatrix} = \tilde{\mathbf{M}} \begin{pmatrix} \tilde{A}'' \\ \tilde{B}'' \end{pmatrix} \tag{5.26}$$

where

$$\tilde{M}_{11} = \tilde{M}_{22}^* = -i|F_{22}|\exp(K_0 + i \arg F_{22}) \tag{5.27}$$

$$\tilde{M}_{12} = \tilde{M}_{21}^* = |F_{12}|\exp(K_0 - 2i\sigma), \tag{5.28}$$

Lundborg's notation σ being related to our notation $\tilde{\varphi}$ according to the formula

$$\tilde{\varphi} = -2\sigma. \tag{5.29}$$

Using (5.29) and Lundborg's[8] formulas (32a,b) for $|F_{12}|$ and $|F_{22}|$ in the first-order approximation, one can write (5.27) and (5.28) as

$$\tilde{M}_{11} = \tilde{M}_{22}^* = -i\left[\frac{1 + \exp[-2\pi G(1+p)]}{1 - \exp(-4\pi G p)} \right]^{1/2} \exp(K_0 + i \arg F_{22}), \tag{5.30}$$

$$\tilde{M}_{12} = \tilde{M}_{21}^* = \left[\frac{\exp(2K_0) + 1}{1 - \exp(-4\pi G p)} \right]^{1/2} \exp(i\tilde{\varphi}). \tag{5.31}$$

For the first-order phase-integral approximation one obtains from (5.29) and Lundborg's[8] Eq. (33a)

$$\tilde{\varphi} = \arg \Gamma(1/2 + i\overline{K_0}) - \overline{K_0} \ln|\overline{K_0}| + \overline{K_0} + \mathrm{Im} \ln \Gamma(2iGp) - 2Gp[\ln(2Gp) - 1] + \pi/4, \tag{5.32}$$

and from Lundborg's[8] Eq. (34a), after correction by addition of a term $-\pi/4$ on the right-hand side,

$$\arg F_{22} = \operatorname{Im} \ln \Gamma(1/2 + iG(1+p)) - G(1+p)\{\ln[G(1+p)] - 1\} - \operatorname{Im} \ln \Gamma(2iGp) + 2Gp[\ln(2Gp) - 1] - \pi/4. \tag{5.33}$$

The logarithms of the gamma functions $\Gamma(2iGp)$ and $\Gamma(1/2+iG(1+p))$ in (5.32) and (5.33) are expanded for large arguments by the use of the asymptotic expansion (4.30), yielding

$$\operatorname{Im} \ln \Gamma(2iGp) \sim 2Gp[\ln(2Gp) - 1] - \frac{\pi}{4} - \frac{1}{24Gp}, \tag{5.34}$$

$$\operatorname{Im} \ln \Gamma(1/2 + iG(1+p)) \sim G(1+p)\{\ln(G(1+p)) - 1\} + \frac{1}{24G(1+p)}, \tag{5.35}$$

Inserting (5.34) and (5.35) into (5.32) and (5.33) we obtain

$$\tilde{\varnothing} \sim \arg \Gamma(1/2 + i\overline{K_0}) - \overline{K_0} \ln|\overline{K_0}| + \overline{K_0} - \frac{1}{24Gp}, \tag{5.36}$$

$$\arg F_{22} \sim \frac{1}{24G(1+p)} + \frac{1}{24Gp}. \tag{5.37}$$

Recalling condition (5.12) and assuming that $24G \gg 1$, one can in (5.36) and (5.37) neglect the terms containing G. Inserting the resulting formulas for $\tilde{\varnothing}$ and $\arg F_{22}$ into (5.30) and (5.31), where the terms containing G can also be neglected, one obtains (2.4) along with (2.6). With the use of (5.17) condition (5.12) can be written as $|\overline{K_0}/G|^{1/2} \ll 1$. For any value of $\overline{K_0}$ (positive or negative) it is possible to find values of G such that the condition $24G \gg 1$ and $|\overline{K_0}/G|^{1/2} \ll 1$ are fulfilled. The barrier may thus be of arbitrary thickness.

APPENDIX A: PREPARATION FOR THE DERIVATIONS OF (4.15) and (4.17)

With the use of (4.9) and (4.12) one obtains

$$\begin{aligned}[\pm Q^2(x)]^{1/2} &= \frac{\alpha\{\pm[\exp(x/x_0)+1]^2 \mp \gamma^2 \exp(x/x_0)\}^{1/2}}{x_0[\exp(x/x_0)+1]} \\ &= \frac{\alpha\{\pm[\exp(x/x_0)+1]^2 \mp \gamma^2 \exp(x/x_0)\}}{x_0[\exp(x/x_0)+1]\{\pm[\exp(x/x_0)+1]^2 \mp \gamma^2 \exp(x/x_0)\}^{1/2}} \\ &= \frac{\alpha\{\pm[\exp(x/x_0)+1] \mp \gamma^2 \exp(x/x_0)/[\exp(x/x_0)+1]\}}{x_0\{\pm[\exp(x/x_0)+1]^2 \mp \gamma^2 \exp(x/x_0)\}^{1/2}}.\end{aligned} \tag{A1}$$

Using (A1) one gets

$$\begin{aligned}\int [\pm Q^2(x)]^{1/2} dx = &\pm \frac{\alpha}{x_0} \int \{\pm[\exp(x/x_0)+1]^2 \mp \gamma^2 \exp(x/x_0)\}^{-1/2} \exp(x/x_0) dx \\ &\pm \frac{\alpha}{x_0} \int \{\pm[\exp(x/x_0)+1]^2 \mp \gamma^2 \exp(x/x_0)\}^{-1/2} dx \\ &\mp \frac{\alpha\gamma^2}{x_0} \int \{\pm[\exp(x/x_0)+1]^2 \mp \gamma^2 \exp(x/x_0)\}^{-1/2} \frac{\exp(x/x_0)}{[\exp(x/x_0)+1]} dx.\end{aligned} \tag{A2}$$

Here one introduces instead of the integration variable x in the first integral

$$y_1 = y_1(x) = \frac{2\exp(x/x_0) + 2 - \gamma^2}{\gamma(\gamma^2 - 4)^{1/2}}, \tag{A3}$$

in the second integral

$$y_2 = y_2(x) = \frac{\gamma^2 - 2 - 2\exp(-x/x_0)}{\gamma(\gamma^2 - 4)^{1/2}}, \tag{A4}$$

and in the third integral

$$y_3 = y_3(x) = \frac{2\gamma}{(\gamma^2 - 4)^{1/2}}\left[\frac{1}{2} - \frac{1}{\exp(x/x_0) + 1}\right], \tag{A5}$$

the functions $y_1(x)$, $y_2(x)$, and $y_3(x)$ being equal to -1 and $+1$ at the turning points t' and t'', respectively. With the aid of (A2)–(A5) one obtains

$$\int [\pm Q^2(x)]^{1/2} dx = \pm\alpha \int \frac{dy_1}{[\pm(y_1^2 - 1)]^{1/2}} \pm \alpha \int \frac{dy_2}{[\pm(y_2^2 - 1)]^{1/2}} \mp \alpha\gamma \int \frac{dy_3}{[\pm(y_3^2 - 1)]^{1/2}}. \tag{A6}$$

APPENDIX B: DERIVATION OF (4.15)

Inserting (A6) with the lower signs into (4.14), one obtains

$$K_0 = -\alpha \int_{-1}^{1} \frac{dy_1}{(1 - y_1^2)^{1/2}} - \alpha \int_{-1}^{1} \frac{dy_2}{(1 - y_2^2)^{1/2}} + \alpha\gamma \int_{-1}^{1} \frac{dy_3}{(1 - y_3^2)^{1/2}} = (\alpha\gamma - 2\alpha) \int_{-1}^{1} \frac{dy}{(1 - y^2)^{1/2}}$$
$$= \pi(\alpha\gamma - 2\alpha) = \pi(\beta - 2\alpha), \tag{B1}$$

where the last equality has been obtained with the use of (4.12).

APPENDIX C: DERIVATION OF (4.17)

Using (A6) with the upper signs, and recalling that $y_1(t'') = y_2(t'') = y_3(t'') = +1$, one obtains when x is real and lies to the right of the barrier

$$\left| \mathrm{Re} \int_{t''}^{x} Q(z)dz \right| = \mathrm{Re} \int_{t''}^{x} [Q^2(z)]^{1/2} dz = \alpha\, \mathrm{Re} \int_{+1}^{y_1(x)} \frac{dy_1}{(y_1^2 - 1)^{1/2}} + \alpha\, \mathrm{Re} \int_{+1}^{y_2(x)} \frac{dy_2}{(y_2^2 - 1)^{1/2}}$$
$$- \alpha\gamma\, \mathrm{Re} \int_{+1}^{y_3(x)} \frac{dy_3}{(y_3^2 - 1)^{1/2}}, \tag{C1}$$

and after evaluation of the integrals

$$\left| \mathrm{Re} \int_{t''}^{x} Q(z)dz \right| = \alpha\, \mathrm{Re}\ln\{y_1(x) + [y_1^2(x) - 1]^{1/2}\} + \alpha\, \mathrm{Re}\ln\{y_2(x) + [y_2^2(x) - 1]^{1/2}\}$$
$$- \alpha\gamma\, \mathrm{Re}\ln\{y_3(x) + [y_3^2(x) - 1]^{1/2}\}. \tag{C2}$$

From this formula one obtains with the aid of (A3)–(A5) and (4.12)

$$\lim_{x\to+\infty}\left[\left|\operatorname{Re}\int_{t''}^{x}Q(z)dz\right|-\frac{\alpha}{x_0}x\right]=\alpha\operatorname{Re}\ln\frac{4}{\gamma(\gamma^2-4)^{1/2}}+\alpha\operatorname{Re}\ln\frac{\gamma}{(\gamma^2-4)^{1/2}}-\alpha\gamma\operatorname{Re}\ln\frac{\gamma+2}{(\gamma^2-4)^{1/2}}$$

$$=\alpha\operatorname{Re}\left[\ln\frac{4}{\gamma^2-4}-\frac{\gamma}{2}\ln\frac{\gamma+2}{\gamma-2}\right]=2\alpha\ln(2\alpha)-\frac{\beta+2\alpha}{2}\ln(\beta+2\alpha)$$

$$+\frac{\beta-2\alpha}{2}\operatorname{Re}\ln(\beta-2\alpha)=2\alpha\ln(2\alpha)-\frac{\beta+2\alpha}{2}\ln(\beta+2\alpha)$$

$$+\frac{\beta-2\alpha}{2}\ln|\beta-2\alpha|. \tag{C3}$$

As the barrier is symmetric, one obtains with the use of (C3)

$$\lim_{x\to-\infty}\left[\left|\operatorname{Re}\int_{t'}^{x}Q(z)dz\right|+\frac{\alpha}{x_0}x\right]=\lim_{x\to+\infty}\left[\left|\operatorname{Re}\int_{t''}^{x}Q(z)dz\right|-\frac{\alpha}{x_0}x\right]=2\alpha\ln(2\alpha)-\frac{\beta+2\alpha}{2}\ln(\beta+2\alpha)$$

$$+\frac{\beta-2\alpha}{2}\ln|\beta-2\alpha|. \tag{C4}$$

Coherent states expectation values as semiclassical trajectories

N. C. Dias,[a] A. Miković,[b] and J. N. Prata[c]
Departamento de Matemática, Universidade Lusófona de Humanidades e Tecnologias, Av. do Campo Grande, 376, 1749-024 Lisboa, Portugal

(Received 9 February 2006; accepted 8 June 2006; published online 1 August 2006)

We study the time evolution of the expectation value of the anharmonic oscillator coordinate in a coherent state as a toy model for understanding the semiclassical solutions in quantum field theory. By using the deformation quantization techniques, we show that the coherent state expectation value can be expanded in powers of $\hbar$ such that the zeroth-order term is a classical solution while the first-order correction is given as a phase-space Laplacian acting on the classical solution. This is then compared to the effective action solution for the one-dimensional ϕ^4 perturbative quantum field theory. We find an agreement up to the order $\lambda\hbar$, where λ is the coupling constant, while at the order $\lambda^2\hbar$ there is a disagreement. Hence the coherent state expectation values define an alternative semiclassical dynamics to that of the effective action. The coherent state semiclassical trajectories are exactly computable and they can coincide with the effective action trajectories in the case of two-dimensional integrable field theories. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2227259]

I. INTRODUCTION

The notion of a semiclassical trajectory as a quantum corrected classical trajectory is a very useful idea in various areas of physics. In the case of field theories, the classical trajectory represents a classical field configuration, and the semiclassical field configurations are usually calculated from the effective action,[2,3] i.e., by solving the corresponding equations of motion. However, the semiclassical dynamics depends on the initial quantum state, so that one can have in principle many different semiclassical dynamics (for a review see Ref. 1).

In the effective action approach the initial state is the in-vacuum state. (This state can be described as a vacuum state of the Hamiltonian coupled to a source with appropriate boundary conditions.[4]) Since the effective action approach was tailor-made for the problems of scattering of the elementary particles, one is not calculating the expectation value of an appropriate operator, but a matrix element between the "in" and the "out" vacuum. This means that the obtained values can be complex and this is a problem in the context of quantum gravity and quantum cosmology applications because the field operator is a metric, and the effective metric has to be real. This problem can be resolved by using the effective action formalism where the field variable is a true expectation value.[5,6] However, in order to obtain a semiclassical trajectory, one needs to solve the corresponding effective equation of motion, which is often a difficult task.

These types of problems were encountered in the context of two-dimensional dilaton gravity models of quantum black holes, where the effective metric gives the information about the back-reaction of the black hole evaporation (for a review and references see Ref. 7). These models are exactly integrable two-dimensional field theories, and in the case of the CGHS model,[8] it was

[a]Electronic mail: ncdias@mail.telepac.pt
[b]Electronic mail: amikovic@ulusofona.pt
[c]Electronic mail: joao.prata@ulusofona.pt

demonstrated in Ref. 9 that a relevant one-loop ($O(\hbar)$) solution could be obtained as an expectation value of the metric operator in the coherent state corresponding to the initial matter distribution. Furthermore, a two-loop ($O(\hbar^2)$) solution was found by using this approach,[10] which was otherwise impossible to do by solving the corresponding two-loop effective action equations.

These results suggest an approach to constructing semiclassical trajectories for field theories via expectation values of the appropriate operators in the coherent states. A coherent state (and a related squeezed state) is the best possible description of a classical phase-space point, since they saturate the Heisenberg uncertainty relations. In quantum mechanics one can prove that for a general quadratic Hamiltonian, a coherent state wave packet follows the classical trajectory, while in the case of interactions, the wave packet is well approximated by the coherent state during the Ehrenfest time.[11–14] In the case of field theories one then expects that the coherent state trajectories should be the same as the effective action trajectories in the case of free-field theories, while in the case of interactions one expects that the coherent state trajectories should be a good approximation for the effective action ones.

The effective action quantum dynamics can be studied via the anharmonic oscillator (AHO) toy model.[15,16] One can then study the time evolution of the coherent states for the AHO and compare it to the effective action trajectories. However, the effective action trajectories were obtained only in the effective potential approximation. It is possible to improve this approximation by including more relevant terms in the effective action,[15] but there is no simple expression for the complete one-loop contribution, i.e., the $\hbar$ correction. On the other hand, it has been known from the deformation quantization applications to quantum optics how to evaluate the coherent states expectation values.[17] Hence one can apply these techniques to the case of the AHO and calculate the complete $\hbar$ contribution for the coherent states. The result can then be expanded perturbatively in the coupling constant and compared to the corresponding effective action expansion.

Given that it is easier to obtain semiclassical trajectories from the coherent states expectation values than from solving the equations of motion of the effective action, a natural question is to what extent one can approximate the effective action trajectories by the coherent states trajectories. In this paper we explore this and related issues by studying the example of the anharmonic oscilator. We calculate the coherent states trajectories by using the deformation quantization techniques, while for the effective action trajectories we use the Feynman diagram techniques and the results are compared order by order in the perturbative expansion. In Sec. II we introduce the basic concepts of deformation quantization (DQ) and derive a new formula for the expectation value (EV) of a generic dynamical variable in an arbitrary state. We then use this result in Sec. III to derive the $O(\hbar)$ contribution to the coherent state EV of a generic dynamical variable. We then derive the corresponding quantum equation of motion for the coordinate EV and in Sec. IV we specialize to the case of an AHO. In Sec. V we derive the perturbative quantum equations of motion for an AHO coming from the effective action formalism and compare the results of the two approaches. In Sec. VI we present our conclusions and in the Appendix we describe how to solve the perturbative equations of motion.

II. EXPECTATION VALUES

Let us consider an N-dimensional system with coordinates $q=(q_1,\ldots,q_N)$ and canonical momenta $p=(p_1,\ldots,p_N)$. We shall assume a flat phase space $T^*M\simeq\mathbb{R}^{2N}$ with symplectic form $\sigma(z,z')=q\cdot p'-p\cdot q'$, where $z=(p,q)$, $z'=(p',q')$.

In the context of deformation quantization[17–34]one computes the expectation value of a generic operator $\hat{A}(\hat{z},t)$ from the algebra of observables at time t in a state $\psi\in L^2(\mathbb{R}^N,dq)$ as

$$A(t)\equiv\langle\psi|\hat{A}(\hat{z},t)|\psi\rangle=\int \mathrm{d}z\, F_W(z)A_W(z,t), \tag{1}$$

where $F_W(z)$ is the Wigner function[19] associated with ψ,

$$F_W(p,q) = \frac{1}{(\pi\hbar)^N} \int \mathrm{d}y\, e^{-2ip\cdot y/\hbar} \psi^*(q-y)\psi(q+y). \tag{2}$$

$A_W(z,t)$ is the Weyl symbol[18] associated with $\hat{A}(\hat{z},t)$ given by

$$A_W(z,t) = \left(\frac{\hbar}{2\pi}\right)^N \int \mathrm{d}\xi\, \mathrm{Tr}\{\hat{A}(\hat{z},t)e^{i\xi\cdot\hat{z}}\}e^{-i\xi\cdot z}. \tag{3}$$

The Weyl symbol defines a noncommutative twisted product,[20]

$$(\hat{A}\cdot\hat{B})_W \equiv \; A_W \star_W B_W = \exp\left[\frac{i\hbar}{2}\sigma\left(\frac{\partial}{\partial z_1},\frac{\partial}{\partial z}\right)\right] A_W(z_1)B_W(z)\Big|_{z_1=z} = A_W(z)B_W(z) + \mathcal{O}(\hbar), \tag{4}$$

where $\partial/\partial z = (\partial/\partial p, \partial/\partial q)$. Likewise, one may define a bracket—the Moyal bracket—according to[21]

$$[A_W,B_W]_W \equiv \left(\frac{1}{i\hbar}[\hat{A},\hat{B}]\right)_W = \frac{1}{i\hbar}(A_W\star_W B_W - B_W\star_W A_W) = \; \frac{2}{\hbar}\sin\left[\frac{\hbar}{2}\sigma\left(\frac{\partial}{\partial z_1},\frac{\partial}{\partial z}\right)\right] A_W(z_1)B_W(z)\Big|_{z_1=z}$$
$$= \{A_W(z),B_W(z)\} + O(\hbar^2). \tag{5}$$

These algebraic operations are formal deformations of the usual product and of the Poisson bracket with deformation parameter $\hbar$.

The dynamics is governed by the Moyal equation

$$\dot{A}_W(z,t) = [H_W(z),A_W(z,t)]_W = \{H_W(z),A_W(z,t)\} + O(\hbar^2), \tag{6}$$

where H_W is the Weyl symbol of the quantum Hamiltonian.

The following remark is important for the sequel. If the Hamiltonian is of the form

$$H = \frac{p^2}{2m} + U(q), \tag{7}$$

then there are no ordering ambiguities and we conclude that Eq. (6) only yields corrections of even order in $\hbar$ to the classical solution $A_{\mathrm{cl}}(z,t)$ so that

$$A_W(z,t) = A_{\mathrm{cl}}(z,t) + O(\hbar^2). \tag{8}$$

The Wigner function being a square integrable function admits a Fourier transform:

$$\widetilde{F}_W(a) = \int dz F_W(z)e^{ia\cdot z} = \int \mathrm{d}x\, e^{iv\cdot x}\psi^*\left(x - \frac{\hbar u}{2}\right)\psi\left(x + \frac{\hbar u}{2}\right), \tag{9}$$

with the inverse

$$F_W(z) = \frac{1}{(2\pi)^{2N}} \int \mathrm{d}a\, \widetilde{F}_W(a)e^{-ia\cdot z}. \tag{10}$$

Here $a=(u,v)$ lives in the dual of the phase space. The function $\widetilde{F}(\tilde{a})$, with $\tilde{a}=(u,-v)$, is known as the symplectic Fourier transform or chord function and finds many applications in the context of deformation quantization and decoherence.[32–34]

If we substitute (10) into (1), we obtain

$$A(t) = \widetilde{F}_W\left(\frac{1}{i}\frac{\partial}{\partial z}\right)A_W(z,t)\Big|_{z=0}. \tag{11}$$

Equation (11) has a nice interpretation in the context of deformation quantization. In Eq. (1) the objects appearing on the right-hand side are defined up to an isomorphism, in the following sense. The Weyl symbol stems from a correspondence rule according to which operators are first written in a fully symmetric form—the Weyl order—before they are "dequantized." Alternatively, one may choose other ordering prescriptions for the operators (e.g., normal ordering). The price to pay is that one also needs to change the corresponding quasidistribution, in order to leave the expectation value (1) unchanged. This ambiguity has been systematized by Cohen.[31] Each correspondence rule is associated with an analytic so-called Cohen function $f(\xi)$, such that $f(0)=1$, which allows us to define a new f-symbol[17]

$$A_f(z,t) = f\left(\frac{1}{i}\frac{\partial}{\partial z}\right)A_W(z,t), \tag{12}$$

and the corresponding quasidistribution

$$F_f(z) = f^{-1}\left(i\frac{\partial}{\partial z}\right)F_W(z). \tag{13}$$

Likewise one naturally defines a $\star_f$-product and an f-bracket

$$A_f\star_f B_f = f\left(\frac{1}{i}\frac{\partial}{\partial z}\right)A_W\star_W B_W, \quad [A_f,B_f]_f = f\left(\frac{1}{i}\frac{\partial}{\partial z}\right)[A_W,B_W]_W. \tag{14}$$

The dynamics is then dictated by

$$\dot{A}_f(z,t) = [H_f(z),A_f(z,t)]_f. \tag{15}$$

Equation (11) can thus be interpreted in the following terms. If we regard $\widetilde{F}_W$ as one of Cohen's functions, then $A_{\tilde{F}}(z,t)\equiv\widetilde{F}_W((1/i)(\partial/\partial z))A_W(z,t)$ is just the $\widetilde{F}_W$ symbol associated with the operator $\hat{A}$. The only difference is that one eventually sets $z=0$. The symbol $A_{\tilde{F}}(t)$ is a solution of Eq. (15).

Note that Eq. (11) remains valid even if F_W is the Wigner function of a mixed state given by a density matrix ρ. However, in this paper we will be concerned with the pure states only.

III. COHERENT STATES

Equation (11) derived in Sec. II simplifies drastically if we choose the state ψ to be the coherent state

$$\psi_{\alpha_0}(q) = \left(\frac{m\omega}{\pi\hbar}\right)^{N/4}\exp\left[-\frac{m\omega}{2\hbar}(q-q_0)^2 + \frac{ip_0}{\hbar}\cdot\left(q-\frac{q_0}{2}\right)\right], \tag{16}$$

where in the standard notation

$$\alpha_0 \equiv \sqrt{\frac{m\omega}{2\hbar}}q_0 + \frac{ip_0}{\sqrt{2m\omega\hbar}}. \tag{17}$$

From (9) we have

$$\widetilde{F}_W(u,v) = \exp\left[-\frac{m\omega\hbar u^2}{4} - \frac{\hbar v^2}{4m\omega} + iu\cdot p_0 + iv\cdot q_0\right]. \tag{18}$$

Substituting into (11), we obtain

$$A_{\alpha_0}(t) = \exp\left[\frac{\hbar}{4m\omega}\frac{\partial^2}{\partial q^2} + \frac{\hbar m\omega}{4}\frac{\partial^2}{\partial p^2}\right] A_W(p+p_0, q+q_0, t)\Big|_{q=p=0}$$
$$= \exp\left[\frac{\hbar}{4m\omega}\frac{\partial^2}{\partial q_0^2} + \frac{\hbar m\omega}{4}\frac{\partial^2}{\partial p_0^2}\right] A_W(p_0, q_0, t). \tag{19}$$

The last expression is well known to be the phase space symbol stemming from normal ordering.[17] Now, this equation is particularly well suited for semiclassical expansions in powers of $\hbar$. Following the remark after Eq. (6), we conclude that if the Hamiltonian is of the form (7), then we get at the order $\hbar$ (cf. (8), (19)),

$$A_{\alpha_0}(t) = A_{\mathrm{cl}}(p_0, q_0, t) + \left[\frac{\hbar}{4m\omega}\frac{\partial^2}{\partial q_0^2} + \frac{\hbar m\omega}{4}\frac{\partial^2}{\partial p_0^2}\right] A_{\mathrm{cl}}(p_0, q_0, t) + O(\hbar^2). \tag{20}$$

Expression (20) is valid for any trace-class operator $\hat{A}$ and any Hamiltonian of the form (7) provided the wave function is the coherent state (16).

In fact these semiclassical expansions can be performed for other states, by using (11), as long as the chord function admits a regular expansion in powers of $\hbar$,

$$\tilde{F}_W(a) = \sum_{n=0}^{\infty} \rho_n(a)\hbar^n. \tag{21}$$

In most applications one is interested in the case $\hat{A} = \hat{q}$. For simplicity, we shall henceforth consider a one-dimensional system. Let us define $Q(p_0, q_0, t) \equiv \langle \psi_{\alpha_0} | \hat{q} | \psi_{\alpha_0} \rangle$ and $q_{\mathrm{cl}}(p_0, q_0, t) \equiv q(p_0, q_0, t)$. In order to compare to the effective action approach, let us derive the equations of motion to order $\hbar$ for $Q(p_0, q_0, t)$. From (20) we have

$$m\ddot{Q} = m\ddot{q} + \frac{\hbar}{4\omega}\frac{\partial^2}{\partial q_0^2}\ddot{q} + \frac{\hbar m^2\omega}{4}\frac{\partial^2}{\partial p_0^2}\ddot{q} + O(\hbar^2) = -U'(q) - \frac{\hbar}{4m\omega}\frac{\partial^2}{\partial q_0^2}U'(q) - \frac{\hbar m\omega}{4}\frac{\partial^2}{\partial p_0^2}U'(q) + O(\hbar^2). \tag{22}$$

Notice that $U(q)$ depends on p_0, q_0 only through $q(p_0, q_0, t)$. Consequently

$$m\ddot{Q} = -U'(q) - \frac{\hbar}{4m\omega}\left[U'''(q)\left(\frac{\partial q}{\partial q_0}\right)^2 + U''(q)\frac{\partial^2 q}{\partial q_0^2}\right] - \frac{\hbar m\omega}{4}\left[U'''(q)\left(\frac{\partial q}{\partial p_0}\right)^2 + U''(q)\frac{\partial^2 q}{\partial p_0^2}\right] + O(\hbar^2). \tag{23}$$

We then obtain

$$U'(q) = U'(Q) - U''(q)\left[\frac{\hbar}{4m\omega}\frac{\partial^2 q}{\partial q_0^2} + \frac{\hbar m\omega}{4}\frac{\partial^2 q}{\partial p_0^2}\right] + O(\hbar^2). \tag{24}$$

By substituting (24) into (23), we finally obtain

$$m\ddot{Q} = -U'(Q) - \frac{\hbar}{4}U'''(Q)\left[\frac{1}{m\omega}\left(\frac{\partial Q}{\partial q_0}\right)^2 + m\omega\left(\frac{\partial Q}{\partial p_0}\right)^2\right] + O(\hbar^2). \tag{25}$$

This is a partial differential equation for $Q(p_0, q_0, t)$ where (p_0, q_0) play a double role. They are variables, but also the initial conditions

$$Q(p_0, q_0, t)|_{t=0} = q_0, \qquad \dot{Q}(p_0, q_0, t)|_{t=0} = \frac{p_0}{m}. \tag{26}$$

One may instead derive an ordinary differential equation for Q and its time derivatives which is more suited for comparison with the effective action formalism. In order to do this let us consider the solution for q of the classical equations of motion given by

$$t = \pm \int_{q_0}^{q} \mathrm{d}x \left[\frac{2}{m}(E - U(x)) \right]^{-1/2}, \tag{27}$$

where

$$E = \frac{p_0^2}{2m} + U(q_0) = \frac{1}{2}m\dot{q}^2 + U(q) \tag{28}$$

is the total energy of the classical system. Taking into account that E and q depend on p_0 and q_0, and applying the implicit function theorem we obtain

$$\frac{\partial q}{\partial q_0} = \frac{m}{p_0}\dot{q} + \frac{\dot{q}U'(q_0)}{2}\sqrt{\frac{m}{2}}f(q,p_0,q_0), \quad \frac{\partial q}{\partial p_0} = \frac{p_0\dot{q}}{2\sqrt{2m}}f(q,p_0,q_0), \tag{29}$$

where

$$f(q,p_0,q_0) \equiv \int_{q_0}^{q} \mathrm{d}x[E - U(x)]^{-3/2}. \tag{30}$$

In Eq. (25) it is immaterial whether we write q or Q in the terms proportional to $\hbar$. From (29) we then obtain

$$m\ddot{Q} = -U'(Q) - \frac{\hbar}{4}\dot{Q}^2U'''(Q)\left\{ \frac{m}{\omega p_0^2} + \frac{U'(q_0)}{\omega p_0}\sqrt{\frac{m}{2}}f(Q,p_0,q_0) + \left[\frac{(U'(q_0))^2}{8\omega} + \frac{\omega p_0^2}{8} \right] f^2(Q,p_0,q_0) \right\} + O(\hbar^2). \tag{31}$$

If we neglect the $O(\hbar^2)$ terms in (31) we obtain a second-order nonlinear ordinary differential equation for $Q(t)$ with the initial conditions (26).

IV. THE ANHARMONIC OSCILLATOR

As an application we consider the quartic anharmonic oscillator

$$H = \frac{p^2}{2m} + \frac{1}{2}m\omega^2q^2 + \frac{\lambda}{4!}q^4, \tag{32}$$

where λ is a positive coupling constant. Let us define $\Lambda = \lambda/4!$ and

$$\alpha^2 \equiv \frac{\sqrt{m^2\omega^4 + 16E\Lambda} - m\omega^2}{4\Lambda}, \quad \beta^2 \equiv \frac{\sqrt{m^2\omega^4 + 16E\Lambda} + m\omega^2}{4\Lambda}. \tag{33}$$

By substituting

$$x = \frac{\alpha\beta \sin\varphi}{\sqrt{\beta^2 + \alpha^2\cos^2\varphi}} \tag{34}$$

into (30) we obtain

$$f(q,p_0,q_0)=\frac{1}{[\Lambda(\alpha^2+\beta^2)]^{3/2}}\left\{\frac{1}{\beta^2}E(\varphi(q)|n)+\frac{1}{\alpha^2}[\tan\varphi(q)\sqrt{1-n\sin^2\varphi(q)}+F(\varphi(q)|n)\right.$$
$$\left.-E(\varphi(q)|n)]-(q\leftrightarrow q_0)\right\}, \tag{35}$$

where $\{h(q)-(q\leftrightarrow q_0)\}=\{h(q)-h(q_0)\}$,

$$\varphi(q)\equiv\arcsin\sqrt{\frac{q^2}{n(q^2+\alpha^2)}},\quad n\equiv\frac{\alpha^2}{\alpha^2+\beta^2},\quad 0\leqslant n\leqslant 1, \tag{36}$$

and

$$F(\phi|m)\equiv\int_0^\phi \mathrm{d}\theta\frac{1}{\sqrt{1-m\sin^2\theta}},\quad E(\phi|m)\equiv\int_0^\phi \mathrm{d}\theta\sqrt{1-m\sin^2\theta} \tag{37}$$

are the incomplete elliptic integrals of the first and second kind, respectively.[35]

In order to compare this with the equations of motion stemming from the effective action, let us expand the right-hand side of (31) in powers of λ,

$$\ddot{Q}=-\omega^2Q-\frac{\lambda}{6m}Q^3-\hbar\lambda\frac{k_t^2x_t}{4m^2}\left\{\frac{1}{\omega p_0^2}+\frac{m\omega q_0}{p_0\sqrt{2m}}f_0(x_t,p_0,q_0)+\frac{\omega E_0}{4}f_0^2(x_t,p_0,q_0)\right\}+O(\hbar\lambda^2), \tag{38}$$

where x_t and k_t are the classical harmonic oscillator (HO) solutions for the coordinate and the momentum

$$x_t=q_0\cos(\omega t)+\frac{p_0}{m\omega}\sin(\omega t),\quad k_t=p_0\cos(\omega t)-m\omega q_0\sin(\omega t), \tag{39}$$

with the energy

$$E_0=\frac{p_0^2}{2m}+\frac{1}{2}m\omega^2q_0^2. \tag{40}$$

Moreover

$$f_0(x_t,p_0,q_0)=\int_{q_0}^{x_t}\mathrm{d}x\left(E_0-\frac{1}{2}m\omega^2x^2\right)^{-3/2}=\frac{\sqrt{2m}}{E_0}\left(\frac{x_t}{k_t}-\frac{q_0}{p_0}\right). \tag{41}$$

The terms proportional to $\hbar\lambda$ in (38) yield $-\hbar\lambda x_t/4m^2\omega$ and up to order $\hbar\lambda$ we may replace x_t by Q in the terms proportional to $\hbar\lambda$. By neglecting the $O(\hbar\lambda^2)$ terms we obtain

$$\ddot{Q}+\left(\omega^2+\frac{\hbar\lambda}{4m^2\omega}\right)Q+\frac{\lambda}{6m}Q^3=0, \tag{42}$$

as a semiclassical equation of motion.

V. THE EFFECTIVE ACTION RESULTS

Let us consider a D-dimensional scalar field theory given by the action

$$S[\phi]=\int\mathrm{d}^Dx\left[\frac{1}{2}(\partial_\mu\phi)^2-\frac{1}{2}M^2\phi^2-V(\phi)\right], \tag{43}$$

where $V(\phi)$ is polynomial in ϕ. The corresponding effective action can be written as[36]

$$\Gamma[\phi] = \sum_{n=2}^{\infty} \int \mathrm{d}^D x_1 \cdots \int \mathrm{d}^D x_1 \frac{1}{n!} \Gamma^{(n)}(x_1, \ldots, x_n) \phi(x_1) \cdots \phi(x_n), \tag{44}$$

where

$$\Gamma^{(n)}(x_1, \ldots, x_n) = \int \mathrm{d}^D p_1 \cdots \int \mathrm{d}^D p_n e^{i(p_1 x_1 + \cdots + p_n x_n)} (\Gamma^{(n)}(p_1, \ldots, p_n))^{\epsilon_n}. \tag{45}$$

The $\Gamma^{(n)}(p)$ are the momentum space n-particle irreducible Greens functions whose external legs are amputated for $n>2$ and $\epsilon_n=-1$ for $n=2$ and $\epsilon_n=1$ for $n>2$. These objects can be calculated perturbatively via the Feynman diagrams and for $V=\lambda\phi^4/4!$ the perturbative expansion can be organized in powers of λ (number of the vertices) and in powers of $\hbar$ (number of the loops), so that

$$\Gamma^{(n)}(p) = \sum_{v,l} \lambda^v \hbar^l \Gamma^{(n)}_{v,l}(p). \tag{46}$$

Up to the order of $\lambda\hbar$ only the tadpole diagram contributes,[36] so that in the case of $D=1$ field theory, i.e., quantum mechanics (QM), one obtains

$$\Gamma^{(2)}_E(p) = \frac{1}{p^2+M^2} - \frac{\lambda\hbar/2}{(p^2+M^2)^2} \int_{-\infty}^{\infty} \frac{\mathrm{d}q}{2\pi} \frac{1}{q^2+M^2} + O(\lambda^2\hbar) = \frac{1}{p^2+M^2} - \frac{\lambda\hbar}{2(p^2+M^2)^2} \frac{1}{2M} + O(\lambda^2\hbar), \tag{47}$$

where Γ_E is the Euclidean propagator. The physical (Minkowski) propagator is given by $\Gamma^{(2)}(p) = -\Gamma^{(2)}_E(ip)$, and the position space vertex function is given by

$$\Gamma^{(2)}(x_1,x_2) = 2\pi \int \frac{\mathrm{d}p_1}{2\pi} \int \frac{\mathrm{d}p_2}{2\pi} \delta(p_1+p_2)(\Gamma^{(2)}(p_1))^{-1} e^{i(p_1x_1+p_2x_2)}. \tag{48}$$

This gives

$$\Gamma[\phi] = S[\phi] + \frac{\lambda\hbar}{8M} \int_{x_1}^{x_2} \mathrm{d}x\, \phi^2(x) + O(\lambda^2\hbar). \tag{49}$$

Passing to the anharmonic oscillator parameters $(M\to\omega, \lambda\to\lambda/m^2)$ gives

$$\Gamma[q] = S[q] + \frac{\lambda\hbar}{8m^2\omega} \int_{t_1}^{t_2} \mathrm{d}t\, q^2(t) + O(\lambda^2\hbar). \tag{50}$$

Up to order $O(\hbar\lambda)$ this action gives the same equation of motion as (42).

When going to higher orders in perturbation theory, one obtains the nonlocal terms in the effective action. For example, at the order $\lambda^2\hbar$ one has to include four $\Gamma^{(4)}$ diagrams (one three-diagram plus three one-loop diagrams[36]) so that

$$\Gamma^{(4)}_E(p) = -\lambda + \lambda^2\hbar \int_{-\infty}^{\infty} \frac{\mathrm{d}q}{2\pi} \frac{1}{q^2+M^2} \frac{1}{(p_1+p_2-q)^2+M^2} + \lambda^2\hbar \int_{-\infty}^{\infty} \frac{\mathrm{d}q}{2\pi} \frac{1}{q^2+M^2} \frac{1}{(p_1-p_3+q)^2+M^2} + \lambda^2\hbar \int_{-\infty}^{\infty} \frac{\mathrm{d}q}{2\pi} \frac{1}{q^2+M^2} \frac{1}{(p_1-p_4+q)^2+M^2}. \tag{51}$$

This gives

$$\Gamma^{(4)}_E(p) = -\lambda + \frac{\lambda^2\hbar}{M} \left[-\frac{1}{(p_1+p_2)^2+4M^2} + \frac{1}{(p_1-p_3)^2+4M^2} + \frac{1}{(p_1-p_4)^2+4M^2} \right]. \tag{52}$$

The physical vertex function is given by $\Gamma^{(4)}(p)=\Gamma_E^{(4)}(ip)$, and the position space vertex function is given by

$$\Gamma^{(4)}(x_1,\ldots,x_4)=2\pi\int\frac{dp_1}{2\pi}\cdots\int\frac{dp_4}{2\pi}\delta(p_1+\cdots+p_4)\Gamma^{(4)}(p_1,\ldots,p_4)e^{i(p_1x_1+\cdots+p_4x_4)}. \tag{53}$$

One then obtains the effective action contribution

$$\int dx\left[-\frac{\lambda}{4!}\phi^4-\frac{\lambda^2\hbar}{4!\,M}\int dy\,G_{2M}(x-y)\phi^2(x)\phi^2(y)\right], \tag{54}$$

where

$$G_\mu(x)=Re\int\frac{dp}{2\pi}\frac{e^{ipx}}{p^2-\mu^2+i\epsilon}=\frac{1}{2\mu}\sin(\mu x)[\theta(-x)-\theta(x)] \tag{55}$$

is the real part of the $D=1$ Feynman propagator and $\theta(x)=1$ for $x>0$ and $\theta(x)=0$ for $x\leqslant 0$.

By going to the QM parameters via $\lambda\to\lambda/m^2$, $M\to\omega$, and $\phi\to\sqrt{m}q$, one obtains the following effective equations of motion:

$$0=\ddot{q}+\omega^2q+\frac{\lambda}{6m}q^3+\frac{\lambda\hbar}{4m^2\omega}q+\frac{\lambda^2\hbar}{6m^3\omega}q\int_{-\infty}^{\infty}d\tau\,G_{2\omega}(t-\tau)q^2(\tau)+O(\lambda^3\hbar). \tag{56}$$

This effective equation of motion can be solved perturbatively as

$$q(t)=q_{0,0}(t)+\sum_{m\geqslant 1,n\geqslant 0}\lambda^m\hbar^nq_{n,m}(t), \tag{57}$$

where $q_{0,0}(t)$ is the classical HO solution. The first and the second quantum correction will satisfy

$$\ddot{q}_{1,1}+\omega^2q_{1,1}=-\frac{1}{4m^2\omega}q_{0,0}, \tag{58}$$

$$\ddot{q}_{1,2}+\omega^2q_{1,2}=-\frac{1}{2m}q_{0,0}^2q_{1,1}-\frac{1}{4m^2\omega}q_{0,1}-\frac{1}{6m^3\omega}q_{0,0}\int_{-\infty}^{\infty}d\tau\,G_{2\omega}(t-\tau)q_{0,0}^2(\tau). \tag{59}$$

The solution (57) has a classical part given by

$$q_c=q_{0,0}+\lambda q_{0,1}+\lambda^2q_{0,2}+\cdots. \tag{60}$$

Up to the order of λ^2 the classical solution is given by

$$q_{0,0}=a\cos\omega t+b\sin\omega t, \tag{61}$$

$$q_{0,1}=a_1\cos 3\omega t+b_1\sin 3\omega t+(c_1t+e_1)\cos\omega t+(d_1t+f_1)\sin\omega t, \tag{62}$$

$$\begin{aligned}q_{0,2}=&\,a_2\cos 5\omega t+b_2\sin 5\omega t+(c_2t+c_2')\cos 3\omega t+(d_2t+d_2')\sin 3\omega t+(e_2t^2+e_2't+g_2)\cos\omega t\\&+(f_2t^2+f_2't+h_2)\sin\omega t,\end{aligned} \tag{63}$$

where $a=q_0$, $b=p_0/m\omega$ and the coefficients $a_k,b_k,\ldots$ are the homogeneous polynomials of a and b of the order $2k+1$, see Eqs. (A4) and (A5).

From (61) and (58) it follows that

$$q_{1,1} = \frac{t}{8m^2\omega^2}(b\cos\omega t - a\sin\omega t) - \frac{b}{8m^2\omega^3}\sin\omega t, \tag{64}$$

which coincides with the coherent state result

$$Q_{1,1} = \frac{1}{4m\omega}\left(\frac{\partial^2}{\partial a^2} + \frac{\partial^2}{\partial b^2}\right)q_{0,1}. \tag{65}$$

This is an expected result since the equations of motion coincide up to this order.

In order to solve the equation for $q_{1,2}$ we need to evaluate

$$\begin{aligned} I(t) &= \int_{-\infty}^{\infty} \mathrm{d}\tau G_{2\omega}(t-\tau)[a\cos(\omega\tau) + b\sin(\omega\tau)]^2 \\ &= \frac{\xi}{32\omega^2}[(b^2-a^2)\cos(2\omega t) - 2ab\sin(2\omega t) - 4(a^2+b^2)], \end{aligned} \tag{66}$$

where $\xi = \int_0^\infty \mathrm{d}x \sin x$. The divergent integral can be regularized by the formula

$$\int_0^\infty \mathrm{d}x\, e^{-\epsilon x + ix} = (\epsilon - i)^{-1}, \quad \epsilon > 0, \tag{67}$$

which in the $\epsilon \to 0$ limit gives $\xi = 1$. The solution will then have the form

$$q_{1,2} = (\gamma_2 t + \gamma_2')\cos 3\omega t + (\delta_2 t + \delta_2')\sin 3\omega t + (\epsilon_2 t^2 + \epsilon_2' t + \kappa_2)\cos\omega t + (\phi_2 t^2 + \phi_2' t + \chi_2)\sin\omega t, \tag{68}$$

see Eq. (A7).

The coherent state expectation value will give the correction of the form

$$\begin{aligned} Q_{1,2} = \frac{1}{4m\omega}\left(\frac{\partial^2}{\partial a^2} + \frac{\partial^2}{\partial b^2}\right)q_{0,2} &= (\tilde{c}_2 t + \tilde{c}_2')\cos 3\omega t + (\tilde{d}_2 t + \tilde{d}_2')\sin 3\omega t + (\tilde{e}_2 t^2 + \tilde{e}_2' t + \tilde{g}_2)\cos\omega t \\ &+ (\tilde{f}_2 t^2 + \tilde{f}_2' t + \tilde{h}_2)\sin\omega t, \end{aligned} \tag{69}$$

see Eq. (A6), which could in principle coincide with (68) if the corresponding coefficients were identical. However, by comparing (A6) to (A7) one can see that $q_{1,2} \neq Q_{1,2}$, and therefore there is a discrepancy at the order $\lambda^2\hbar$.

One can also try to obtain a nonperturbative in λ effective action equations of motion, which amounts to summing all the diagrams with different powers of λ at a fixed order in $\hbar$. This can be achieved by using the saddle point approximation in the path-integral formalism, see Ref. 36. This then boils down to evaluating the traces of D-dimensional differential operators. The drawback of this approach is that one can only obtain certain terms at a fixed order of $\hbar$, i.e., not the complete correction. The standard approximation is

$$\Gamma[\phi] \approx \int \mathrm{d}^D x\left[\frac{1}{2}(1+Z(\phi))(\partial_\mu\phi)^2 - \frac{1}{2}M^2\phi^2 - V_{\mathrm{eff}}(\phi)\right], \tag{70}$$

where V_{eff} is the effective potential. In the $D=1$ case one obtains at $O(\hbar)$,[15]

$$V_{\mathrm{eff}}(q) = V(q) + \frac{\hbar\omega}{2}\left(\sqrt{1 + \frac{V''(q)}{m\omega^2}} - 1\right), \quad Z(q) = \frac{\hbar}{32m^3}\frac{(V'''(q))^2}{\left(\omega^2 + \frac{V''(q)}{m}\right)^{5/2}}, \tag{71}$$

so that

$$\Gamma[q] \approx \int_{t_1}^{t_2} \mathrm{d}t \left[\frac{1}{2} m(1+Z(q))(\dot{q})^2 - \frac{1}{2} m\omega^2 q^2 - V_{\mathrm{eff}}(q) \right]. \tag{72}$$

The equations of motion coming from (72) are given by

$$0 = (1+Z)\ddot{q} + \frac{1}{2} Z'(q)(\dot{q})^2 + \omega^2 q + V'_{\mathrm{eff}}(q). \tag{73}$$

By using

$$V_{\mathrm{eff}}(q) = \lambda \frac{q^4}{4!} + \hbar\, \lambda \frac{q^2}{8m\omega} - \hbar\, \lambda^2 \frac{q^4}{64 m^2 \omega^3} + O(\lambda^3 \hbar), \tag{74}$$

$$Z(q) = \hbar\, \lambda^2 \frac{q^2}{32 m^3 \omega^5} + O(\lambda^3 \hbar), \tag{75}$$

(73) can be expanded in powers of λ and one can see that (73) agrees with (56) up to $O(\lambda\hbar)$. At $O(\lambda^2\hbar)$ there is a disagreement, reflecting the fact that there are other terms contributing at $O(\hbar)$ which we have not included in the approximation (72) (for example, $\int \mathrm{d}t\, A(q)(\dot{q})^4$ or nonlocal terms).

One can also compare the perturbative solutions, and it can be shown by using the techniques from the Appendix that the $O(\hbar\lambda^2)$ perturbative solution of (73) has a form

$$\tilde{q}_{1,2} = \tilde{\gamma}'_2 \cos 3\omega t + \tilde{\delta}'_2 \sin 3\omega t + (\tilde{\epsilon}_2 t^2 + \tilde{\epsilon}'_2 t + \tilde{\kappa}_2)\cos \omega t + (\tilde{\phi}_2 t^2 + \tilde{\phi}'_2 t + \tilde{\chi}_2)\sin \omega t, \tag{76}$$

which differs from the coherent state and the perturbative effective action results by the absence of the $t \cos 3\omega t$ and $t \sin 3\omega t$ terms.

VI. CONCLUSIONS

Comparing the effective action equations of motion (56) and (73) to the coherent state expectation value equation of motion (38) gives an agreement up to $O(\lambda\hbar)$. For the higher orders it is simpler to compare the solutions and we find that at $O(\lambda^2\hbar)$ there are discrepancies between all three approaches. Although all three solutions (68), (69), and (76) are linear combinations of $t^n \cos(2k+1)\omega t$ and $t^n \sin(2k+1)\omega t$ functions, the corresponding coefficients differ.

Note that the effective action perturbative solution (68) depends on a regularization dependent parameter ξ. However, the ξ-independent coefficients are different from the corresponding expectation value solution coefficients, see the Appendix. Hence the discrepancy cannot be explained as a regularization scheme artifact. Therefore the state whose EV gives the effective action trajectory is not the coherent state in the AHO case. This agrees with the assumption made in Ref. 16, where the effective action state was taken to be the ground state of the AHO with a source. The arguments for this state were first presented in Ref. 4.

The discrepancy between the perturbative effective action solution (68) and the perturbative effective potential solution (76) is simply due to the fact that the effective potential method is an approximation which did not take into account all possible terms which could contribute at a given order.

Although the formula (20) is valid for the coherent states, it can be used as an approximation for the field expectation value coming from the effective action. We expect that the expansion (20) can give the same result as the effective action in the case of two-dimensional integrable field theories. This happens in the case of the CGHS dilaton gravity model and the rationale is that the two-dimensional integrable field theories are closely related to the free-field theories, and for these the effective action and the coherent state expectation values give the same dynamics. In order to use formula (20) in the field theory case, one would have to extend the DQ formalism to the field theory case, see Ref. 37.

Our results imply that the coherent state expectation values define in general an alternative semiclassical dynamics to that coming from the effective action. The reason is that the effective action initial state is different from the coherent state in the case when the interactions are present. The coherent states expectation values could then be used as an approximation for the effective action trajectories, or one can obtain the exact trajectories in the situations where the system is prepared to be in the initial coherent state. The advantage of studying the semiclassical dynamics of coherent states is that one can obtain directly a semiclassical trajectory through computable $\hbar^n$ corrections to the classical one. In contrast, in the effective action case one has to obtain first the $\hbar^n$ corrections to the classical equations of motion, which can be only done approximately. Furthermore, the corresponding effective action equations of motion are nonlocal and difficult to solve nonperturbatively in the coupling constant.

APPENDIX

The classical AHO equation of motion can be solved perturbatively via the expansion (60). One then obtains

$$Lq_{0,1} = -\frac{q_{0,0}^3}{6m}, \quad Lq_{0,2} = -\frac{q_{0,0}^2 q_{0,1}}{2m}, \ldots, \tag{A1}$$

where $L = \mathrm{d}^2/\mathrm{d}t^2 + \omega^2$. These equations can be solved by the method of undetermined coefficients for the forced HO equation of motion $Lq = f(t)$.

In order to solve the first two equations in (A1) we will need a particular solution for

$$f(t) = (At + A')\cos \Omega t + (Bt + B')\sin \Omega t.$$

It is given by

$$q(t) = \left(\frac{At + A'}{\omega^2 - \Omega^2} - \frac{2B\Omega}{(\omega^2 - \Omega^2)^2}\right)\cos \Omega t + \left(\frac{Bt + B'}{\omega^2 - \Omega^2} + \frac{2A\Omega}{(\omega^2 - \Omega^2)^2}\right)\sin \Omega t, \tag{A2}$$

for $\Omega \neq \omega$ and by

$$q(t) = \frac{1}{4\omega}\left(-Bt - 2B' + \frac{A}{\omega}\right)t \cos \omega t + \frac{1}{4\omega}\left(At + 2A' + \frac{B}{\omega}\right)t \sin \omega t, \tag{A3}$$

for $\Omega = \omega$.

By using formulas (A2) and (A3) we obtain (62) and (63). The initial conditions

$$q(0) = a, \quad \dot{q}(0) = \omega b$$

are imposed by requiring

$$q_{n,m}(0) = 0, \quad \dot{q}_{n,m}(0) = 0,$$

for $(n,m) \neq (0,0)$. These conditions determine the coefficients of the HO terms as

$$e_1 = -a_1, \quad f_1 = -\frac{c_1}{\omega}, \quad g_2 = -a_2 - c_2', \quad h_2 = -5b_2 - \frac{c_2 + e_2'}{\omega},$$

etc.

One then obtains

$$q_{0,1} = \frac{1}{192m\omega^2}\{a(a^2-3b^2)\cos 3\omega t - b(b^2-3a^2)\sin 3\omega t + [-a^3+3ab^2+12b(a^2+b^2)\omega t]\cos \omega t + [21a^2b+9b^3+4a(a^2+b^2)\omega t]\sin \omega t\}, \tag{A4}$$

and

$$q_{0,2} = \frac{1}{36\,864m^2\omega^4}\{(a^5-10a^3b^2+5ab^4)\cos 5\omega t - 12[2a^5-15a^3b^2-(9a^4b+6a^2b^3-3b^5)\omega t]\cos 3\omega t + [23a^5-170a^3b^2-113ab^4-48b(7a^4+19a^2b^2+8b^4)\omega t - 72a(a^2+b^2)^2\omega^2t^2]\cos \omega t + (b^5-10a^2b^3+5a^4b)\sin 5\omega t + [132a^4b+12a^2b^3+48b^5-(36a^5-72a^3b^2-108ab^4)\omega t]\sin 3\omega t + [599a^4b+854a^2b^3+271b^5+(96a^5+528a^3b^2+240ab^4)\omega t + (72a^4b-144a^2b^3-72b^5)\omega^2t^2]\sin \omega t\}. \tag{A5}$$

The coherent state expectation value is then obtained from (20). This gives (64) and

$$Q_{1,2} = \frac{1}{6144m^3\omega^5}\{[24(3a^2b-b^3)\omega t+99ab^2-5a^3]\cos 3\omega t - [63a^2b-41b^3+24(a^3-3ab^2)\omega t]\sin 3\omega t + [5a^3-99ab^2-396b(a^2+b^2)\omega t - 72a(a^2+b^2)\omega^2t^2]\cos \omega t + [27b(19a^2+11b^2)+4a(31a^2+63b^2)\omega t - 72b(a^2+b^2)\omega^2t^2]\sin \omega t\}. \tag{A6}$$

The $O(\hbar\lambda^2)$ correction from the effective action equation of motion (56) can be obtained by solving

$$Lq_{1,2} = -\frac{1}{2m}q_{0,0}^2q_{1,1} - \frac{1}{4m\omega^2}q_{0,1} + \frac{\xi}{96m^3\omega^2}\left(2a^2+2b^2+\frac{a^2-b^2}{2}\cos 2\omega t + ab\sin \omega t\right)q_{0,0},$$

where ξ is a regularization dependent constant. The Cauchy problem solution will have the form (68), and the ξ independent coefficients are γ_2, δ_2, ϵ_2, and ϕ_2. For $\xi=1$ one obtains

$$q_{1,2} = \frac{1}{3072m^3\omega^5}\{[27ab^2-5a^3+6(3a^2b-b^3)\omega t]\cos 3\omega t + [11b^3-21a^2b+6(3ab^2-a^3)]\sin 3\omega t + [5a^3-27ab^2-6b(21a^2+25b^2)\omega t - 24a(a^2+b^2)\omega^2t^2]\cos \omega t + [3b(57a^2+41b^2)+2a(31a^2+51b^2)\omega t - 24b(a^2+b^2)\omega^2t^2]\sin \omega t\}. \tag{A7}$$

We have checked the results (A4)–(A7) by using the MATHEMATICA program.[38]

(Received 22 August 2005; accepted 19 June 2006; published online 3 August 2006)

In a previous paper we have presented a general scheme for the implementation of symmetric generalized measurements (POVMs) on a quantum computer. This scheme is based on representation theory of groups and methods to decompose matrices that intertwine two representations. We extend this scheme in such a way that the measurement is minimally disturbing, i.e., it changes the state vector $|\Psi\rangle$ of the system to $\sqrt{\Pi}|\Psi\rangle$ where Π is the positive operator corresponding to the measured result. Using this method, we construct quantum circuits for measurements with Heisenberg–Weyl symmetry. A continuous generalization leads to a scheme for optimal simultaneous measurements of position and momentum of a Schrödinger particle moving in one dimension such that the outcomes satisfy $\Delta x \Delta p \geqslant \hbar$. The particle to be measured collides with two probe particles, one for the position and the other for the momentum measurement. The position and momentum resolution can be tuned by the entangled joint state of the probe particles which is also generated by a collision with hard-core potential. The parameters of the POVM can then be controlled by the initial widths of the wave functions of the probe particles. We point out some formal similarities and differences to simultaneous measurements of quadrature amplitudes in quantum optics. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2222080]

I. INTRODUCTION

The question of how to implement quantum measurements is an important issue of quantum information theory. Even though the standard model of quantum computers uses only 1 qubit measurements in the computational basis at the end or during the computation,[1] other measurements are also relevant for quantum information for several reasons.

In quantum computing, models have been proposed where collective measurements on more than 1 qubit are necessary.[2] In Ref. 3 a quantum algorithm is described which uses even more general measurements than the usual von Neumann measurements, i.e., they are not described by a family of mutually orthogonal projections but by a so-called positive operator-valued measure (POVM).

In noncomputing applications of quantum information theory, like future nanoscience, it may, for instance, be useful to implement approximative simultaneous measurements of observables which are actually incompatible when measured accurately. An important example would be the position and the momentum of a Schrödinger particle.

The implementation of generalized measurements is not trivial since this is also true for the smaller class of von Neumann measurements.[4] Even though it is known that it is in principle possible to reduce every POVM measurement to a von Neumann measurement on an extended

[a]Electronic mail: janzing@ira.uka.de

quantum system it is little known so far about how to realize the required transformation by physical processes, particularly when the implementation should disturb the quantum state in a minimal way. In Refs. 5 and 6 the class of POVMs is described which can be measured using linear optics. Some special POVM measurements on low-dimensional spaces are described in Refs. 7–12.

In Ref. 13 we have described a general design principle to implement symmetric POVMs on a quantum register where universal quantum computation capabilities are available. However, these implementations are not minimally disturbing.

Here we describe an extension of the theory of Ref. 13 such that the symmetric measurements disturb the state in a minimal way and apply it to the Heisenberg–Weyl group in finite dimensions. Since the latter actually defines a *family* of groups it is desirable to have an implementation which is efficient in the sense that its running time scales polynomially in the logarithm of the dimension, i.e., with the number of qubits. We show that this can indeed be achieved for Heisenberg–Weyl groups with a power of 2 as dimension.

We then adapt the implementation scheme to the continuous situation. The corresponding POVM provides a good example for a measurement where the feature of minimal disturbance makes sense: Given the motivation to measure position and momentum of a particle in order to monitor its motion one would clearly try to avoid disturbance as far as possible.

The general idea of the paper is to show that the finite dimensional circuits provide a paradigm for the continuous variable implementation. By replacing the finite dimensional gates with appropriate analogs, we also obtain a possible measurement scheme even though it is not *a priori* clear how the required "gates" could be implemented physically. However, we show that a modification of the gate sequence could in principle be realized by three hard-core scattering processes. This kind of idealized scattering is not unphysical since hard-core potential can be a useful approximation in many real collision processes.

We proceed as follows. In Sec. II we recapitulate the definition of POVMs and recall a general scheme for the implementation of general measurements by orthogonal measurements. In Sec. III we define the symmetry of POVMs and present a method for designing measurement algorithms for symmetric POVMs. In Sec. IV we consider the implementation for two special classes of POVMs to illustrate the latter. Explicitly, we consider POVMs on qubits with cyclic symmetry groups and POVMs on d-dimensional quantum systems with Heisenberg–Weyl symmetry. In Sec. V we convert the implementation to quantum systems with Hilbert spaces of infinite dimension and describe a potential realization by scattering processes on an abstract level. In Sec. VI we compare this scheme to a quantum optical implementation of simultaneous measurements for the quadrature amplitudes.

II. MINIMALLY DISTURBING IMPLEMENTATION BY VON NEUMANN MEASUREMENTS

In this section we briefly outline a general scheme[1] for the minimally disturbing implementation of a POVM. Consider a quantum system with Hilbert space $\mathbb{C}^d$. A POVM consists of n operators $\Pi_j \in \mathbb{C}^{d\times d}$ with $\Pi_j \geqslant 0$ and $\Sigma_j \Pi_j = I_d$, where I_d denotes the identity matrix of size $d\times d$. A definition for POVMs on infinite dimensional quantum systems and an infinite number of results can be found in Ref. 14. In Sec. V we use this more general definition but here we start with finite POVMs since we consider implementation schemes on *quantum computers* at first. Following Refs. 15 and 16 we define:

Definition 1 (Minimally disturbing measurement): Let (Π_j) *be a POVM. Then a measurement is called minimally disturbing if it changes the state vector according to*

$$|\Psi\rangle \mapsto \frac{\sqrt{\Pi_j}|\Psi\rangle}{\|\sqrt{\Pi_j}|\Psi\rangle\|},$$

given that the measurement result is j.

The motivation for this definition is given by a theorem in Ref. 15 stating that the above type of measurements maximizes the average fidelity between the input and the output state if the input is drawn from a uniformly distributed ensemble of pure states.

The following lemma[1] reduces the implementation of this kind of measurements to von Neumann measurements (with Lüder's projection postulate) in the standard basis.

Lemma 2 (Reduction of a POVM to a von Neumann measurement): Let P be a POVM with the n operators $\Pi_j \in \mathbb{C}^{d\times d}$. *Furthermore, let* $\mathbb{C}^n$ *be the Hilbert space of an ancilla that is initialized with* $|0\rangle$. *Then, a minimally disturbing measurement of P can be achieved by a measurement in the standard basis of the ancilla after the implementation of a unitary* $U \in \mathbb{C}^{dn\times dn}$ *satisfying the equation*

$$U(|0\rangle \otimes |\Psi\rangle) = \sum_{j=0}^{n-1} |j\rangle \otimes \sqrt{\Pi_j}|\Psi\rangle. \tag{1}$$

Equation (1) states that U is a unitary extension of the matrix

$$M := \sum_j |j\rangle \otimes \sqrt{\Pi_j} = (\sqrt{\Pi_1}, \sqrt{\Pi_2}, \ldots, \sqrt{\Pi_n})^T \in \mathbb{C}^{dn\times d}, \tag{2}$$

which is defined by P. In the following section we consider this extension for symmetric POVMs. In some cases, the following observations help to show that a unitary U implements a POVM in a minimally disturbing way:

Lemma 3 (Linear assignment of Kraus operators): Let $U \in \mathbb{C}^{dn\times dn}$ *be a unitary operating on a bipartite system which is initialized with* $|\Phi\rangle \otimes |\Psi\rangle$ *where* $|\Phi\rangle \in \mathbb{C}^n$ *and* $|\Psi\rangle \in \mathbb{C}^d$. *Let the first component be measured in the standard basis after the joint system has been subjected to the unitary U*. *Then the conditional postmeasurement state is pure*.

Let $A_{U,\Phi,j}$ *be the Kraus operator describing the corresponding state change*

$$|\Psi\rangle \mapsto \frac{A_{U,\Phi,j}|\Psi\rangle}{\|A_{U,\Phi,j}|\Psi\rangle\|},$$

where j is the measurement result. For each U and *j*, *the mapping* $|\Phi\rangle \mapsto A_{U,\Phi,j}$ *is linear*.

The proof is straightforward since the projected state of the composed system is a product state and the map given by the partial trace is linear. We find:

Corollary 4 (Minimally disturbing Kraus operators): *Let P be a POVM with operators* Π_j. *Furthermore, let U*, $|\Phi\rangle$, *and* $A_{U,\Phi,j}$ *be as defined in Lemma 3. If the equation*

$$A_{U,\Phi,j} = \sqrt{\Pi_j}$$

holds for all j then U gives rise to a minimally disturbing measurement of P. *In other words*, *whenever* $A_{U,\Phi,j}$ *is positive for each j*, *it defines a minimally disturbing measurement for the POVM given by*

$$\Pi_j := A_{U,\Phi,j}^2.$$

III. IMPLEMENTATION OF SYMMETRIC POVMS

In this section we analyze how the symmetry of a POVM can be used for the implementation scheme of Lemma 2. Here, we follow the approach of Ref. 13 where we have obtained a general implementation scheme for POVMs without consideration of the disturbance of the measurement process. This implementation scheme also relies on the unitary extension of a matrix that is defined by the POVM operators. It turned out that the symmetry of the POVM leads to a symmetry of the matrix which can be exploited for the extension. In this section we show that a similar construction is possible for the minimally disturbing implementation of POVMs.

To begin with, we define the symmetry of POVMs:

Definition 5 (Symmetric POVMs): Let $\sigma: G \to \mathbb{C}^{d\times d}$ *be a unitary representation of a finite group* G. *A POVM with operators* $\Pi_0, \ldots, \Pi_{n-1}$ *is called* (σ, π) *symmetric if there is a permutation representation* $\pi: G \to S_n$ *of the indices such that*

$$\sigma(g)\Pi_j\sigma(g)^\dagger = \Pi_{\pi(g)j}.$$

Here, S_n *denotes the symmetric group consisting of all permutations of n objects.*

As mentioned above, the symmetry of a matrix is a useful tool for the implementation of POVMs. Here we define the symmetry of a matrix as in Refs. 17–19.

Definition 6 (Matrices with symmetry and intertwining spaces): Let G *be a finite group and* $\sigma: G \to \mathbb{C}^{m\times m}$ *as well as* $\tau: G \to \mathbb{C}^{n\times n}$ *be unitary representations. A matrix* $A \in \mathbb{C}^{m\times n}$ *is* (σ, τ) *symmetric if it satisfies*

$$\sigma(g)A = A\tau(g)$$

for all $g \in G$. *We also write* $\sigma M = M\tau$ *for the* (σ, τ) *symmetry. We call the set*

$$\mathrm{Int}(\sigma, \tau) = \{A \in \mathbb{C}^{m\times n} : \sigma A = A\tau\}$$

of all such matrices the intertwining space of σ *and* τ.

The structure of the intertwining space of two representations can be easily specified if both representations are decomposed into a direct sum of irreducible representations of the group as the following lemma[19] shows:

Lemma 7 (Structure of intertwining space): Let σ *and* τ *be decomposed into the direct sums*

$$\sigma = \bigoplus_j (I_{m_j} \otimes \kappa_j) \text{ and } \tau = \bigoplus_j (I_{n_j} \otimes \kappa_j)$$

of different irreducible representations κ_j *of the group* G. *Then*

$$\mathrm{Int}(\sigma, \tau) = \bigoplus_j (\mathbb{C}^{m_j\times n_j} \otimes I_{\deg(\kappa_j)})$$

where $\deg(\kappa_j)$ *denotes the degree of* κ_j. *For* $m_j = 0$ *and* $n_j = 0$ *we insert* $n_j \deg(\kappa_j)$ *zero columns or* $m_j \deg(\kappa_j)$ *zero rows, respectively.*

The key observation used for the extension of the matrix M from Eq. (2) to a unitary is that the symmetry of a POVM leads to a matrix M with symmetry. This is summarized in the following lemma which can be proved by direct calculation:

Lemma 8 (Symmetry of a POVM and its matrix): If the POVM with operators $\Pi_1, \ldots, \Pi_n$ *is* (σ, π) *symmetric then the corresponding matrix* M *is* $(\sigma_\pi \otimes \sigma, \sigma)$ *symmetric with the permutation matrix representation* $\sigma_\pi(g) = \Sigma_j |\pi(g)j\rangle\langle j|$.

The following theorem explicitly shows how the $(\sigma_\pi \otimes \sigma, \sigma)$ symmetry of M can be extended to a $(\sigma_\pi \otimes \sigma, \sigma \oplus \widetilde{B}^\dagger \sigma' \widetilde{B})$ symmetry of U where σ' is an appropriate representation and $\widetilde{B}$ a unitary.

Theorem 9 (Implementation of symmetric POVMs): Let M *be the matrix of Eq. (2) for a* (σ, π) *symmetric POVM with symmetry group* G. *Let* A *and* B *be transformations that decompose* $\sigma_\pi \otimes \sigma$ *and* σ *into irreducible representations, respectively. Then there is a representation* σ' *of* G *such that* $B\sigma B^\dagger \oplus \sigma'$ *is equal to* $A(\sigma_\pi \otimes \sigma)A^\dagger$ *up to a permutation of the irreducible components. Furthermore, there is a transformation* $W \in \mathrm{Int}[A(\sigma_\pi \otimes \sigma)A^\dagger, B\sigma B^\dagger \oplus \sigma']$ *which is a unitary extension of* $AMB^\dagger$. *Then*

$$U := A^\dagger W(B \oplus \widetilde{B})$$

implements the POVM for every unitary $\widetilde{B}$. *The unitary* U *is* $(\sigma_\pi \otimes \sigma, \sigma \oplus \widetilde{B}\sigma'\widetilde{B}^\dagger)$ *symmetric.*

Proof: We decompose $\sigma_\pi \otimes \sigma$ and σ with the unitaries $A \in \mathbb{C}^{dn\times dn}$ and $B \in \mathbb{C}^{d\times d}$, i.e., we obtain the equations

$$A(\sigma_\pi \otimes \sigma)A^\dagger = \bigoplus_j (I_{m_j} \otimes \kappa_j) \quad \text{and} \quad B\sigma B^\dagger = \bigoplus_j (I_{n_j} \otimes \kappa_j).$$

Therefore, the equation

$$\left[\bigoplus_j (I_{m_j} \otimes \kappa_j)\right] AMB^\dagger = AMB^\dagger \left[\bigoplus_j (I_{n_j} \otimes \kappa_j)\right]$$

holds. Following Lemma 7 the matrix $N := AMB^\dagger$ has the decomposition

$$N = \bigoplus_j (A_j \otimes I_{d_j})$$

with $A_j \in \mathbb{C}^{m_j \times n_j}$ and $d_j := \deg(\kappa_j)$. From Theorem 5 of Ref. 13 it follows that $B\sigma B^\dagger$ can be extended to $A(\sigma_\pi \otimes \sigma)A^\dagger$, i.e., the representations $A(\sigma_\pi \otimes \sigma)A^\dagger$ and $B\sigma B^\dagger \oplus \sigma'$ with

$$\sigma' = \bigoplus_j (I_{m_j - n_j} \otimes \kappa_j)$$

are equal up to a permutation of the irreducible components. We choose a unitary extension $W \in \mathrm{Int}[A(\sigma_\pi \otimes \sigma)A^\dagger, B\sigma\widetilde{B} \oplus \sigma']$ of N. This extension can be achieved by appending appropriate columns to the right side of N since the matrix N has orthogonal columns. We can write $W = (N|\widetilde{N})$ for this extension if we denote the new columns by $\widetilde{N}$. With this matrix we obtain for an arbitrary unitary $\widetilde{B} \in \mathbb{C}^{n(d-1)\times n(d-1)}$ the unitary extension

$$A^\dagger(N|\widetilde{N})(B \oplus \widetilde{B}) = (M|A^\dagger \widetilde{N}\widetilde{B})$$

of M. □

As shown in the following section, the unitary W of Theorem 9 can be chosen to be sparse for some POVMs. Within the standard model of quantum computing, this can be used for obtaining efficient decompositions into elementary gates for the cases discussed in the next section. Furthermore, there are methods known to decompose the transformations A and $B \oplus \widetilde{B}$ into products of simpler matrices.[17–19]

IV. EXAMPLES

In this section we explicitly construct quantum circuits and implementation schemes for the minimally disturbing implementation of two families of symmetric POVMs. First, we introduce the following notations: For $m \in \mathbb{N}$ define $\omega_m := \exp(-2\pi i/m)$ and let

$$X_m := \sum_{j=0}^{m-1} |(j+1) \bmod m\rangle\langle j| \in \mathbb{C}^{m\times m}$$

be the cyclic shift of the basis vectors of an m-dimensional space. Furthermore, define the diagonal phase matrix

$$Z_m := \sum_{j=0}^{m-1} \omega_m^j |j\rangle\langle j| \in \mathbb{C}^{m\times m}$$

and the Fourier transform

$$F_m := \sqrt{\frac{1}{m}} \sum_{j,k=0}^{m-1} \omega_m^{jk} |j\rangle\langle k| \in \mathbb{C}^{m\times m}.$$

We obtain the equalities $F_m X_m F_m^\dagger = Z_m$ and $Z_m X_m = \omega_m X_m Z_m$ which we will use in the following without proof.

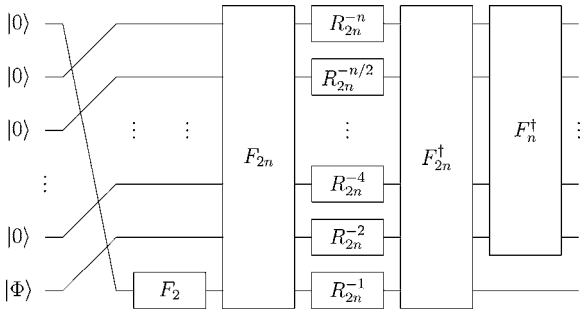

FIG. 1. Circuit for the implementation of POVMs with cyclic symmetry group C_{2^m} on a qubit. The circuit operates on $m+1$ qubits. On the right side the upper m qubits are measured in the standard basis.

A. Cyclic groups

Simple examples for our implementation scheme are POVMs operating on a qubit with a cyclic symmetry. Measurements with cyclic symmetry can, for instance, provide an estimation of time when applied to a dynamical quantum system. The reason for this is that the time evolution of a quantum system with energy eigenvalues being rational multiples of each other is periodic and the dynamics is therefore a unitary representation of SO(2). This leads naturally to the finite cyclic groups after discretization.

Fix $n \geqslant 2$. We consider the cyclic group $C_n = \langle r : r^n = 1 \rangle$ with n elements, the unitary matrix representation $\sigma : C_n \to \mathbb{C}^{2\times 2}$ with $\sigma(j) = R_n^j$ for

$$R_n := \begin{pmatrix} 1 & 0 \\ 0 & \omega_n \end{pmatrix} \in \mathbb{C}^{2\times 2}, \tag{3}$$

and the orbit of the vector $\sqrt{1/n}(1,1)^T \in \mathbb{C}^2$ with respect to this representation of C_n. We have the POVM operators

$$\Pi_j := \frac{1}{n}\begin{pmatrix} 1 & 0 \\ 0 & \omega_n^j \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & \omega_n^{-j} \end{pmatrix} = \frac{1}{n}\begin{pmatrix} 1 & \omega_n^{-j} \\ \omega_n^j & 1 \end{pmatrix} \tag{4}$$

for $j \in \{0, \ldots, n-1\}$.

Applying the methods discussed in Sec. III we obtain the following unitary for the minimally disturbing implementation of the POVM with cyclic symmetry:

Theorem 10 (Implementation of POVMs with cyclic symmetry): *The POVM with the operators of Eq. (4) can be implemented by the unitary*

$$U := (F_n^{\dagger} \otimes I_2) X_{2n}^{\dagger} (I_n \otimes F_2) K^{\dagger} \in \mathbb{C}^{2n\times 2n}$$

where K denotes the permutation matrix which is defined by

$$K|2j\rangle = |j\rangle \quad \text{and} \quad K|2j+1\rangle = |n+j\rangle.$$

The rather technical proof can be found in the Appendix. The idea is as follows: The transformation A must diagonalize the cyclic shift $X_n \otimes I_2$. This can be achieved by $F_n^{\dagger} \otimes I_2$. Furthermore, we need the cyclic shift $X_{2n}^{\dagger}$ to obtain the correct order of the irreducible representations. The transformation B is trivial since σ is already diagonal. The remaining transformation $(I_n \otimes F_2)K^{\dagger}$ is the sparse matrix in the intertwining space.

If n is a power of 2 the ancilla system can be a qubit register and the unitary of Theorem 10 can be implemented efficiently as the following corollary states.

Corollary 11 (Circuits for cyclic POVM): For $n = 2^m$, $m \geqslant 1$, the unitary U of Theorem 10 can be implemented efficiently with the circuit of Fig. 1.

Proof: Since Fourier transforms can be implemented with a polynomial number[1,20] of elemen-

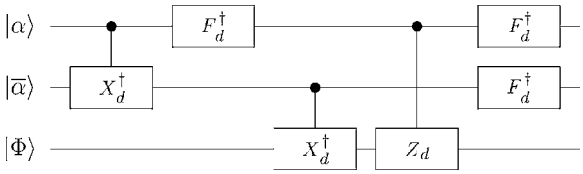

FIG. 2. Schematic circuit for the POVM with Heisenberg–Weyl symmetry. The basis state $|j\rangle$ of the control wire causes the implementation of the jth power of the controlled operation. On the right side of the circuit the two upper systems are measured in the standard basis.

tary gates, i.e., 1 and 2 qubit gates, $F_n^\dagger \otimes I_2$ can be implemented efficiently. Furthermore, the cyclic shift $X_{2n}^\dagger$ can be written as $X_{2n}^\dagger = F_{2n}^\dagger Z_{2n}^\dagger F_{2n}$ with

$$Z_{2n}^\dagger = R_{2n}^{-n} \otimes R_{2n}^{-n/2} \otimes \ \ldots \ \otimes R_{2n}^{-1}.$$

The unitary K is only a cyclic shift of qubits. □

B. Heisenberg–Weyl groups

The operators X_d and Z_d are discrete analogs of translations in position and momentum space. If $\mathbb{C}^d$ denotes the d possible positions of a particle on a cyclic chain, the eigenvectors of Z_d can be interpreted as positions eigenstates and the eigenvectors of X_d as eigenvectors of crystal momentum.[21] As for continuous quantum systems these observables are incompatible and it can be desirable to have approximative simultaneous measurements such that the result can be interpreted as a point in $2d$-dimensional "phase space." In Sec. V we discuss the continuous analog.

The basis of simultaneous measurements of position and momentum are POVMs with Heisenberg–Weyl symmetry. For all $d \geqslant 2$, the Heisenberg–Weyl group is given by $G = \langle X_d, Z_d \rangle$ and has order d^3. For a positive operator μ with $\mathrm{tr}(\mu) = 1/d$ we consider the POVM with the d^2 operators

$$Z_d^k X_d^j \mu X_d^{-j} Z_d^{-k} \quad \text{for } k,j = 0, \ldots, d-1. \tag{5}$$

The following theorem shows how to implement this type of POVMs:

Theorem 12 (POVMs with Heisenberg–Weyl symmetry): *Given the Heisenberg–Weyl POVM P with the d^2 operators from Eq. (5) with $\mu := |\alpha\rangle\langle\alpha|/d$ for some state vector $|\alpha\rangle$. Then P can be implemented by the circuit in Fig. 2 where the inputs of the ancillas are given by $|\alpha\rangle \otimes |\overline{\alpha}\rangle$ with the complex conjugated wave function $\overline{\alpha}$. For general μ the ancilla input has to be replaced with the state vector*

$$|\gamma\rangle := \sqrt{d} \sum_{j,k=0}^{d-1} \sqrt{\mu}_{jk} |j\rangle \otimes |k\rangle \in \mathbb{C}^{d^2},$$

where $\sqrt{\mu}_{jk}$ denotes the entry of $\sqrt{\mu}$ in the jth row and kth column.

The proof of the theorem can be found in the Appendix. In the following we briefly sketch the main points of the proof. For the decomposition of $\sigma_\pi \otimes \sigma$ we observe that the permutation π given by the action of the Heisenberg–Weyl group on the operators is a translation in the finite plane $(\mathbb{Z}/d\mathbb{Z})^2$. This translation is diagonalized by the inverse Fourier transform $F_d^\dagger \otimes F_d^\dagger \otimes I_d$ at the end of the circuit in Fig. 2. This transformation already block diagonalizes $\sigma_\pi \otimes \sigma$. However, the irreducible components are only equivalent, but not equal, to σ. We apply the controlled Z and controlled $X^\dagger$ operations to obtain equality. Hence, these operations correspond to the matrix A. The matrix B is trivial since σ is an irreducible representation. The unitary extension W used in Theorem 12 is decomposed into two components. One component is given by the first two gates of the circuit in Fig. 2, the other is absorbed into the preparation procedure for the initial state.

As already stated, we can efficiently implement F_d by elementary gates on a qubit register. We also obtain efficient implementations of controlled X and Z gates by concatenations of controlled

R_d gates as defined in Eq. (3). Hence, we can implement the POVM with initial operator $\mu = |\alpha\rangle\langle\alpha|/d$ efficiently if the same is true for the preparation of the states $|\alpha\rangle$ and $|\bar{\alpha}\rangle$.

V. CONTINUOUS MEASUREMENTS

Here we want to address how to implement Heisenberg–Weyl symmetric POVMs for continuous quantum systems such that we have also minimal disturbance. For a detailed mathematical description of such POVMs we refer also to Refs. 22 and 23.

The continuous degree of freedom can either be a Schrödinger wave of a quantum particle moving on a line (where the Heisenberg–Weyl group formalizes translations in position and momentum space) or a quantum optical light mode (where the translations shift the quadrature amplitudes). The most natural representation of the Hilbert space of a particle in one dimension is $\mathcal{H} := L^2(\mathbb{R})$, the space of square integrable functions over the real line. For a light mode, it is often more appropriate to choose the isomorphic Hilbert space $l^2(\mathbb{N}_0)$ of square-summable sequences. In this section, we will focus on Schrödinger particles since simultaneous measurements of quadrature amplitudes in quantum optics have already been implemented.[24] We will compare our implementation to the latter in the next section.

We first describe the continuous analogs of the "gates" in Fig. 2 and show that their concatenation leads indeed to a correct implementation. Later we will discuss a modification of the scheme which can be implemented by hard-core scattering processes. The description below refers to the Schrödinger representation where the position operator X, defined on a dense subspace of $\mathcal{H}$, is the multiplication operator

$$X\psi(x) := x\psi(x).$$

The momentum operator is

$$P\psi(x) := -i\frac{d}{dx}\psi(x),$$

where we have chosen the units such that $\hbar = 1$. Following Sec. 3.4 of Ref. 14 (with a slight modification of the sign) we introduce a family $(U_{s,t})$ of unitaries

$$(U_{s,t}\psi)(x) := e^{-ixs}\psi(x-t),$$

which formalize shifts in momentum and position space. These unitaries define a measurement by the positive operators

$$\Pi_{s,t} := \frac{1}{2\pi}U_{s,t}|\alpha\rangle\langle\alpha|U_{s,t}^{\dagger},$$

where $|\alpha\rangle \in \mathcal{H}$ is a wave function which is sufficiently localized in momentum and position space. The probability density for the result (s,t) is $\mathrm{tr}(\rho\Pi_{s,t})$ if the system state is described by the density operator ρ. The outcome (s,t) is interpreted as momentum s and position t of the particle in a "coarse grained phase space." We can clearly generalize the POVM above by replacing $|\alpha\rangle\langle\alpha|/(2\pi)$ with any operator μ having trace $1/(2\pi)$.

In agreement with the discussions of finite POVMs in the preceding sections we want to implement the POVM in such a way that the state changes according to

$$\rho \mapsto \frac{\sqrt{\Pi_{s,t}}\rho\sqrt{\Pi_{s,t}}}{\mathrm{tr}(\Pi_{s,t}\rho)},$$

given that the measurement outcome is (s,t).

Now we describe how to find a continuous analog of the circuit in Fig. 2. The system Hilbert space $(\mathbb{C}^d)^{\otimes 3}$ is replaced by $\mathcal{H}^{\otimes 3}$, i.e., in additional to the particle to be measured one uses two

particles in one dimension as an ancilla system. The final von Neumann measurement is a position measurement on both ancillas. (One could also use the remaining two dimensions of a particle in three dimensions as an ancilla system.)

The continuous analogs of the required gates are as follows. The discrete Fourier transform (whose inverse is occurring three times in Fig. 2) is replaced with the continuous unitary Fourier transform

$$(F\psi)(x) = \sqrt{\frac{1}{2\pi}}\int_{-\infty}^{\infty} e^{-ixy}\psi(y)\mathrm{d}y. \tag{6}$$

The controlled cyclic shift is replaced by a unitary Y describing controlled translations on the real line. It acts on the wave function ψ of two particles according to

$$(Y\psi)(x,y) = \psi(x,y-x), \tag{7}$$

since this transformation would correspond to the transformation

$$|x\rangle \otimes |y\rangle \mapsto |x\rangle \otimes |x+y\rangle,$$

if such position eigenstates $|x\rangle$ and $|y\rangle$ existed. Conjugating Y with the Fourier transform on the second tensor component makes it more apparent that it is indeed a unitary map since we obtain then the multiplication operator

$$V := [(I\otimes F)Y(I\otimes F^{\dagger})\psi](x,y) = e^{-ixy}\psi(x,y). \tag{8}$$

Here I denotes the identity operator on $\mathcal{H}$. The unitary in Eq. (8) is the straightforward generalization of the controlled phase-shift operation that is the fourth gate in Fig. 2. The following theorem shows that the above described replacements provide in fact the desired measurement procedure:

Theorem 13: *Replace the gates in Fig. 2 with their continuous analogs as follows:*

(1) *Set the inverse of the continuous unitary Fourier transform given by Eq. (6) instead of* $F_d^{\dagger}$;
(2) *Set the inverse of Y given in Eq. (7) instead of the controlled* $X_d^{\dagger}$ *gate*; and
(3) *Set V as given by Eq. (8) instead of the controlled* Z_d *gate*.

Let μ *be an arbitrary positive operator with* $\mathrm{tr}(\mu)=1/(2\pi)$ *and the two ancilla systems be in the state* γ *with*

$$|\gamma\rangle := \sum_{j=0}^{\infty} \sqrt{\lambda_j}|\alpha_j\rangle \otimes |\bar{\alpha}_j\rangle, \tag{9}$$

where $|\alpha_j\rangle$ *is an eigenvector basis of* μ *such that*

$$2\pi\mu = \sum_j \lambda_j |\alpha_j\rangle\langle\alpha_j|.$$

Then the resulting transformation on $\mathcal{H}^{\otimes 3}$ *implements a minimally disturbing measurement for the POVM*

$$\Pi_{s,t} := U_{s,t}\mu U_{s,t}^{\dagger},$$

when followed by position measurements on both ancillas at the end and interpreting the position of the first particle in Fig. 2 as t and the position of the second as s.

Proof: Due to Lemma 3 and its corollary it is sufficient to restrict the attention to rank-one operators $\mu := |\alpha\rangle\langle\alpha|/(2\pi)$ and show that the unnormalized output state coincides with the desired state. The linearity argument holds also if μ is an infinite series since one can check that the map

$$\Phi \mapsto A_{U,\Phi,j}$$

is continuous with respect to the topologies induced by the Hilbert space norm and the operator norm, respectively. This is seen from

$$\|\Phi\|^2 = \mathrm{tr}(A^\dagger_{U,\Phi,j} A_{U,\Phi,j}) \leqslant \|A^\dagger_{U,\phi,j} A_{U,\Phi,j}\| = \|A_{U,\Phi,j}\|^2.$$

The whole "circuit" creates some wave function $\tilde{\Psi} \in \mathcal{H}^{\otimes 3}$. After measuring t and s we obtain an unnormalized conditional state vector given by the wave function

$$z \mapsto \tilde{\Psi}(t,s,z) := \tilde{\Psi}_{t,s}(z).$$

We want to show that it satisfies

$$|\tilde{\Psi}_{t,s}\rangle = \sqrt{\Pi_{s,t}}|\Psi\rangle = \sqrt{\frac{1}{2\pi}} U_{s,t}|\alpha\rangle\langle\alpha|U^\dagger_{s,t}\Psi\rangle.$$

This means explicitly that

$$\tilde{\Psi}_{t,s}(z) = \sqrt{\frac{1}{2\pi}} e^{-izs}\alpha(z-t)\int_{-\infty}^{\infty} \bar{\alpha}(u-t)e^{ius}\Psi(u)\mathrm{d}u. \tag{10}$$

Now we calculate the effect of the circuit starting with the joint state

$$\alpha(x)\bar{\alpha}(y)\Psi(z),$$

where Ψ is the wave function of the measured particle. First, we apply the controlled inverse translation and obtain

$$\alpha(x)\bar{\alpha}(y+x)\Psi(z).$$

The inverse Fourier transform changes this state to

$$\sqrt{\frac{1}{2\pi}}\int_{-\infty}^{\infty} e^{iux}\alpha(u)\bar{\alpha}(y+u)\Psi(z)\mathrm{d}u.$$

The second controlled inverse shift followed by the controlled phase yields

$$\sqrt{\frac{1}{2\pi}}\int_{-\infty}^{\infty} e^{iux}\alpha(u)\bar{\alpha}(y+u)e^{-ixz}\Psi(z+y)\mathrm{d}u.$$

After applying the inverse Fourier transform to both ancilla registers we obtain

$$\sqrt{\frac{1}{8\pi^3}}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{iyw}e^{ixv}e^{iuv}\alpha(u)\bar{\alpha}(w+u)e^{-ivz}\Psi(z+w)\mathrm{d}u\,\mathrm{d}v\,\mathrm{d}w.$$

We simplify this term into

$$\sqrt{\frac{1}{8\pi^3}}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{iyw}e^{i(x-z+u)v}\alpha(u)\bar{\alpha}(w+u)\Psi(z+w)\mathrm{d}u\,\mathrm{d}v\,\mathrm{d}w.$$

The integral over v is only nonvanishing for $x-z+u=0$. Hence, we obtain

$$\sqrt{\frac{1}{2\pi}}\int_{-\infty}^{\infty} e^{iyw}\alpha(z-x)\bar{\alpha}(z+w-x)\Psi(z+w)\mathrm{d}w.$$

With the substitution $u := z+w$ we get

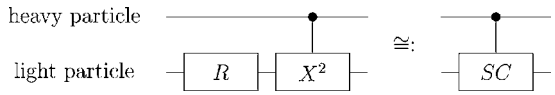

FIG. 3. Correspondence between gates and a scattering of two particles with extreme mass ratio. The scattering is called controlled SC gate.

$$\sqrt{\frac{1}{2\pi}}e^{-iyz}\alpha(z-x)\int_{-\infty}^{\infty}e^{iyu}\bar{\alpha}(u-x)\Psi(u)\mathrm{d}u.$$

The conditional state given that we obtain the result $x=t$ and $y=s$ coincides with Eq. (10). □

In order to realize the transformation in Theorem 13 by a physical process we first observe that scattering processes realize quantum gates which are close to the controlled phase shift in Eq. (7): Consider two particles interacting with hard-core potential, i.e., the interaction energy is zero whenever their distance is larger than some $a>0$ and infinite if the distance is smaller than a. In Ref. 25 we have discussed the state change caused by such a scattering provided that the considered time scale is small compared to the time scale on which the width of wave packets grows by dispersion. We will first explain the scattering process in momentum space since the change of momenta of classical particles provide a good intuition about the quantum case. The momentum p_2 of the light particle obtains a sign change since it is reflected. Due to the conservation of total momentum, the heavy particle acquires an additional momentum $2p_2$. The vector of momenta of both particles is therefore changed according to a linear transformation N given by

$$N\begin{pmatrix}p_1\\p_2\end{pmatrix}=\begin{pmatrix}p_1+2p_2\\-p_2\end{pmatrix}.$$

Neglecting irrelevant translations in position space, the corresponding linear transformation M in position space is already given by the requirement that the 4×4 matrix transformation $M\oplus N$ acting on the two positions and the two momenta has to be symplectic. We have therefore $M=(N^T)^{-1}$ and obtain in agreement with Ref. 25

$$M=\begin{pmatrix}1&0\\2&-1\end{pmatrix}.$$

The scattering process S acts therefore on the wave function in position space by multiplying the coordinate vector with M, i.e.,

$$(S\psi)(\mathbf{x}):=\psi(M\mathbf{x}),\quad \mathbf{x}\in\mathbb{R}^2.$$

We obtain

$$(S\psi)(x,y)=\psi(x,-y+2x).$$

In order to understand the relation to the gates in Theorem 13, we may represent this operation by the circuit in Fig. 3. The "reflection" gate R corresponds to a change of the wave function according to

$$(R\psi)(x):=\psi(-x).$$

Elementary calculations show that Fig. 2 is equivalent to the circuit in Fig. 4 where we have absorbed the Fourier transform on the wire in the middle by replacing an X measurement with a P measurement.

After we have converted the desired circuit into the equivalent one that avoids controlled phase gates in Fig. 4 we still have the problem that it requires controlled X gates and its inverse instead of a controlled X^2 gate which implements the shift twice. However, we observe that we may convert these gates into each other by conjugating them with the unitary squeezing operator

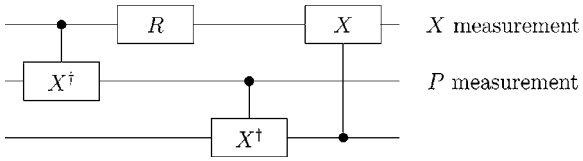

FIG. 4. Circuit equivalent to the circuit in Fig. 2.

$$S_2|x\rangle := |2x\rangle$$

combined with reflections when needed. (Note that the described reduction of controlled SC to controlled X is also possible in finite dimensions d. The definition $R|x\rangle := |-x\rangle$ is always possible and $|x\rangle \mapsto |2x \bmod d\rangle$ is bijective if d is odd. Then the ring $\mathbb{Z}/d\mathbb{Z}$ allows division by 2.) We will see later that we do not have to worry about the physical realization of S_2 since we need this gate and its inverse only at the end or at the beginning of the first or the second wire. Hence, they can either be absorbed into the preparation procedure or into the measurement by reinterpreting the result.

We will furthermore modify the entangling operation on ancilla 1 and 2, i.e., the first gate of the circuit in Fig. 4 for the following reason. An important feature of the circuits in Figs. 2 and 4 is that the POVM consists of rank-one operators if the input ancilla state is the product state $|\alpha\rangle \otimes |\bar{\alpha}\rangle$ and entangled inputs lead to POVM operators of higher rank. The preparation of these entangled states was not considered in Subsection IV B. Here we also want to describe *how to entangle* ancilla 1 and 2 when POVMs of higher rank are desired. The goal is therefore to change the operation on ancilla 1 and 2 preceding the interaction with the system to be measured such that a family of *product* input states allows the implementation of POVMs of higher rank. In other words, we want to tune the achieved information and the caused disturbance of the measurements by plugging different product states into the circuit.

After subsequently replacing the gates in Fig. 4 with scattering processes combined with squeezing operations and reflections and modifying the entangling operation between the ancillas, we found that an interesting class of POVMs can indeed be implemented by three scattering processes as depicted in Fig. 5 when the initial ancilla states are Gaussian wave packets.

To understand the effect of the "circuit" in Fig. 5 we shall compute a 3×3 matrix that describes the effect of the whole circuit on the three position coordinates. For doing so, we recall (see Fig. 5) that the masses of the particles satisfy

$$m_1 \ll m_3 \ll m_2.$$

First, we implement a collision between particles 1 and 2. Here, the position of particle 2 controls the position of particle 1. In analogy to the remarks above we describe the scattering and reflection by matrices that act on the vector of position coordinates of the three particles. The scattering processes with the pairs (2,1), (2,3), and (3,1) correspond to the matrices

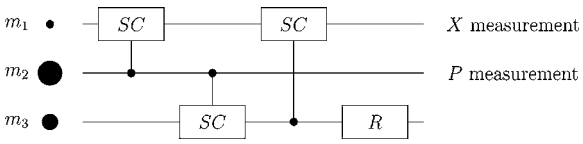

FIG. 5. Implementation of minimally disturbing simultaneous measurement of position and momentum by three scattering processes and one reflection. The masses m_1 and m_2 of the two ancilla particles are extremely small or extremely large compared to the mass m_3 of the particle to be measured.

$$S_{21} := \begin{pmatrix} -1 & 2 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad S_{23} := \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 2 & -1 \end{pmatrix}, \quad S_{31} := \begin{pmatrix} -1 & 0 & 2 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

The scatterings are followed by a reflection of the z coordinate (the R gate). Taking into account that we have to concatenate the effect on the coordinates from the left to the right, the complete transformations in position coordinate space is given by

$$A := S_{31}S_{23}S_{21}R_3 = \begin{pmatrix} 1 & 2 & 2 \\ 0 & 1 & 0 \\ 0 & 2 & 1 \end{pmatrix}.$$

Let the initial state of the three particles be given by the wave function

$$\alpha(x)\beta(y)\psi(z).$$

After subjecting the arguments to A we obtain

$$\alpha(x+2y+2z)\beta(y)\psi(2y+z). \tag{11}$$

In order to reduce a momentum measurement on the second wire to a position measurement we apply a Fourier transform to the state (11) and obtain

$$\sqrt{\frac{1}{2\pi}}\int_{-\infty}^{\infty} \alpha(x+2\tilde{w}+2z)\beta(\tilde{w})\psi(2\tilde{w}+z)e^{-i\tilde{w}y}\,\mathrm{d}\tilde{w}.$$

With $w := 2\tilde{w}+z$ we get

$$\sqrt{\frac{1}{8\pi}}\int_{-\infty}^{\infty} \alpha(x+w+z)\beta[(w-z)/2]\psi(w)e^{i(-y/2)(w-z)}\,\mathrm{d}w.$$

We define the integral kernel

$$k_{x,y}(z,w) := \sqrt{\frac{1}{8\pi}}\alpha(x+w+z)\beta[(w-z)/2]e^{i(-y/2)(w-z)}.$$

It defines for fixed x,y an operator $K_{x,y}$ on $\mathcal{H}$ by

$$(K_{x,y}\psi)(z) := \int_{-\infty}^{\infty} k_{x,y}(z,w)\psi(w)\mathrm{d}w.$$

Note that the Kraus operators $K_{x,y}$ describe the unnormalized output state $K_{x,y}|\psi\rangle$ of particle 3 given that we have measured x and y on the first and second particle, respectively (in straightforward analogy to the Kraus operators in Lemma 3 for the discrete setting).

Now we show that $K_{x,y}$ can be obtained by subjecting $K_{0,0}$ to the Heisenberg–Weyl group elements by

$$K_{x,y} = U_{-x/2,-y}K_{0,0}U^{\dagger}_{-x/2,-y}.$$

To see this, we observe that the translation by $-x/2$ in position space changes the integral kernel $k_{0,0}(z,w)$ into $k_{0,0}(z+x/2,w+x/2)$ and the additional translation in momentum space by $-y/2$ changes it into

$$k_{0,0}(z+x,w+x)e^{i(-y/2)(w-z)} = k_{x,y}(z,w).$$

This shows that the process in Fig. 5 implements a measurement for the POVM

$$\Pi_{s,t} := U_{s,t} K_{0,0}^{\dagger} K_{0,0} U_{s,t},$$

when reinterpreting the measurement outcomes x,y on particles 1 and 2 as $t=-x/2$ and $s=-y$, respectively. In order to obtain a minimally disturbing implementation, we have to ensure that $K_{0,0}$ is positive (in straightforward generalization of Corollary 4 to the continuous setting) because it can then be interpreted as $\sqrt{\mu}$. If α and β are real and β is an even function, i.e., $\beta(-y)=\beta(y)$, $K_{0,0}$ is self-adjoint due to

$$k_{0,0}(z,w) = \overline{k_{0,0}(w,z)}.$$

The integral kernel of $K_{0,0}$ is explicitly given by

$$k_{0,0}(z,w) = \frac{1}{\sqrt{2\pi}} \alpha(w+z)\beta[(w-z)/2].$$

Now we assume that α and β are both real Gaussian wave functions with widths σ_1 and σ_2, respectively, i.e.,

$$\alpha(x) := \frac{1}{\sqrt{\sigma_1}\pi^{1/4}} \exp\left(-\frac{x^2}{2\sigma_1^2}\right) \quad \text{and } \beta(y) := \frac{1}{\sqrt{\sigma_1}\pi^{1/4}} \exp\left(-\frac{y^2}{2\sigma_2^2}\right).$$

Under these conditions, $k_{0,0}$ defines a positive operator whenever $\sigma_1 \geqslant 2\sigma_2$. This follows from the following lemma after replacing a and b with $1/(2\sigma_1^2)$ and $1/(8\sigma_2^2)$, respectively.

Lemma 14: The operator given by the integral kernel

$$k(x,y) := de^{-a(x+y)^2 - b(x-y)^2}$$

with $d>0$ is for all $b>a\geqslant 0$ positive.

Proof: Rewrite the kernel as

$$k(x,y) = \mathrm{d}e^{-2ax^2} e^{-(b-a)(x-y)^2} e^{-2ay^2}. \tag{12}$$

It is known that the integral kernel

$$\tilde{k}(x,y) := \mathrm{d}e^{-c(x-y)^2}$$

defines for all positive c,d a positive operator[26] which we shall denote by $\tilde{K}$. Then the operator K given by the kernel (12) can be written as $K=D\tilde{K}D$ where D is the multiplication operator

$$(D\psi)(x) := e^{-2ax^2}\psi(x).$$

Hence, K is also positive. □

Since we have now described sufficient conditions for which $K_{0,0}$ is positive, we would like to better understand the POVM operator $\mu=K_{0,0}^2$. As simple computations show, it is (up to the normalization factor 2π) given by the reduced state of one particle in a two-particle system, if the latter is described by the wave function

$$\phi(x,y) := \sqrt{2\pi}k_{0,0} = \alpha(x+y)\beta[(x-y)/2]. \tag{13}$$

It can be obtained from the state $|\alpha\rangle\otimes|\beta\rangle$ by a linear mapping of the wave function arguments according to

$$\begin{pmatrix} x \\ y \end{pmatrix} \mapsto \begin{pmatrix} 1 & 1 \\ 1/2 & -1/2 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} =: G \begin{pmatrix} x \\ y \end{pmatrix}.$$

Such a linear operation transforms the initial Gaussian state into an entangled Gaussian state. Since Gaussian states are completely determined by their covariance matrix,[27] we will compute the latter for the state in Eq. (13).

For doing so, we must describe the linear transformation corresponding to G that acts on the arguments of the wave function in momentum space. According to the remarks at the beginning of this section, it is given by the transposed inverse:

$$\begin{pmatrix} p_x \\ p_y \end{pmatrix} \mapsto (G^T)^{-1} \begin{pmatrix} p_x \\ p_y \end{pmatrix}.$$

The covariance matrix of a two-particle state ρ consists of the entries

$$\mathrm{tr}(\rho X_i X_j) - \mathrm{tr}(\rho X_i)\mathrm{tr}(\rho X_j) \quad \text{with } i,j = 1, \ldots, 4$$

where X_1, X_2 denote the position operators and X_3, X_4 the momentum operators of particles 1 and 2, respectively. For the state $|\alpha\rangle \otimes |\beta\rangle$ it is given by (see Ref. 27)

$$\sigma = \begin{pmatrix} \sigma_1^2/2 & 0 & 0 & 0 \\ 0 & \sigma_2^2/2 & 0 & 0 \\ 0 & 0 & 1/(2\sigma_1^2) & 0 \\ 0 & 0 & 0 & 1/(2\sigma_2^2) \end{pmatrix}.$$

If the coordinate vector in the position wave function is subjected to some area-preserving linear map G and the coordinates of the momentum wave function to $(G^T)^{-1}$, the covariance matrix transforms in the following way:

$$\sigma' := \begin{pmatrix} G^{-1} & 0 \\ 0 & G^T \end{pmatrix} \sigma \begin{pmatrix} (G^T)^{-1} & 0 \\ 0 & G \end{pmatrix} = \frac{1}{8} \begin{pmatrix} \sigma_1^2 + 4\sigma_2^2 & \sigma_1^2 - 4\sigma_2^2 & 0 & 0 \\ \sigma_1^2 - 4\sigma_2^2 & \sigma_1^2 + 4\sigma_2^2 & 0 & 0 \\ 0 & 0 & \dfrac{4}{\sigma_1^2} + \dfrac{1}{\sigma_2^2} & \dfrac{4}{\sigma_1^2} - \dfrac{1}{\sigma_2^2} \\ 0 & 0 & \dfrac{4}{\sigma_1^2} - \dfrac{1}{\sigma_2^2} & \dfrac{4}{\sigma_1^2} + \dfrac{1}{\sigma_2^2} \end{pmatrix},$$

as simple computations show. The covariance matrix of the reduced state of each particle is given by the 2×2 submatrices that refer to its position and momentum. Due to the symmetry of our state, it is for both particles given by

$$\frac{1}{8} \begin{pmatrix} \sigma_1^2 + 4\sigma_2^2 & 0 \\ 0 & \dfrac{4}{\sigma_1^2} + \dfrac{1}{\sigma_2^2} \end{pmatrix}. \tag{14}$$

It is known[27] that such a state is pure if and only if the determinant is $\frac{1}{4}$. This is given for $\sigma_1 = 2\sigma_2$. One can rewrite a Gaussian state of a single mode having diagonal covariance matrix as a thermal state of a harmonic oscillator with frequency ω, mass m, and average phonon number N. (In quantum optics, one would also need squeezing transformations to obtain a general diagonal Gaussian state. But here the product of frequency and mass of the oscillator provides an additional free parameter.) It is explicitly given by

$$\rho_{N,\nu} = (1 - e^{-1/N}) \sum_{n=0}^{\infty} e^{-n/N} |n\rangle\langle n|,$$

where $|n\rangle$ with $n \in \mathbb{N}_0$ denotes the nth energy eigenstate of the oscillator. We will first use dimensionless position and momentum variables

$$X' := \frac{1}{\sqrt{2}}(a + a^\dagger) = \sqrt{m\omega} X \tag{15}$$

and

$$P' := \frac{1}{i\sqrt{2}}(a - a^\dagger) = \frac{1}{\sqrt{m\omega}} P, \tag{16}$$

with creation operator $a^\dagger$ and annihilation operator a. In these coordinates, the covariance matrix of the thermal state with average phonon number N is the identity matrix times $(N+1)/2$. This follows, e.g., from Eqs. (2.16) in Ref. 27. In natural units, we therefore have the covariance matrix

$$\frac{N+1}{2} \begin{pmatrix} \frac{1}{m\omega} & 0 \\ 0 & m\omega \end{pmatrix}. \tag{17}$$

Comparing Eq. (14) to Eq. (17) we obtain

$$(m\omega)^2 = \frac{4/\sigma_1^2 + 1/\sigma_2^2}{\sigma_1^2 + 4\sigma_2^2}$$

and

$$(N+1)^2 = \frac{1}{4}(\sigma_1^2 + 4\sigma_2^2)\left(\frac{1}{\sigma_1^2} + \frac{1}{4\sigma_2^2}\right).$$

Hence

$$N = \frac{1}{2}\sqrt{2 + \frac{4\sigma_2^2}{\sigma_1^2} + \frac{\sigma_1^2}{4\sigma_2^2}} - 1.$$

For $\sigma_1 = 2\sigma_2$ one obtains $N=0$, i.e., the ground state of the oscillator that corresponds to a rank-one operator μ. We rephrase the findings implied by the above discussion as a theorem:

Theorem 15: *Given three particles such that their masses satisfy*

$$m_1 \ll m_3 \ll m_2.$$

Let the first and the second particle be in Gaussian states with real wave functions such that their widths satisfy $\sigma_1 \geq 2\sigma_2$. *Then the sequence of scattering processes depicted in Fig. 5 implements the Heisenberg–Weyl POVM* $(U_{s,t}\mu U_{s,t}^\dagger)_{s,t}$ *in a minimally disturbing way when the position of particle 1 and the momentum of particle 2 is measured and the result* (x,y) *is interpreted as* $t=-x/2$ *and* $s=-y$. *The initial operator* μ *of the POVM is given by*

$$\mu = \frac{1}{2\pi}\rho_{N,m\omega},$$

where $\rho_{N,m\omega}$ *is the thermal equilibrium state of a harmonic oscillator with mass m and frequency* ω *when the temperature is chosen such that the average phonon number is N. The parameters N and* $m\omega$ *are determined by the widths* σ_1 and σ_2 *according to*

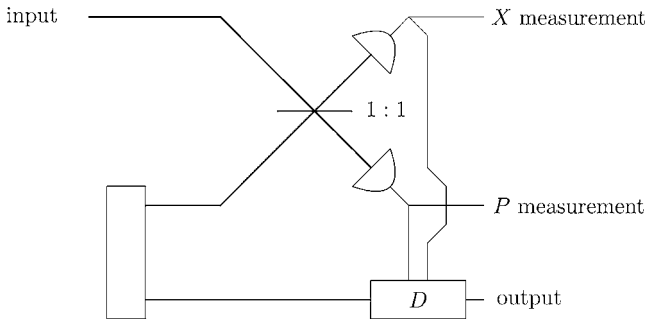

FIG. 6. Measurement scheme of Ref. 24. The box at the beginning of mode 2 and 3 indicate the entangled input on these two modes. The entanglement tunes the POVM. In the limit of infinite entanglement the output coincides with the input state and no information is gained. If mode 2 and 3 start in a product state, a rank-one POVM is implemented. The input interferes with mode 2 in a balanced beam splitter where one output mode is subjected to a position measurement and the other to a momentum measurement. The results determine the displacements in position and momentum the output is subjected to.

$$(m\omega)^2 = \frac{4/\sigma_1^2 + 1/\sigma_2^2}{\sigma_1^2 + 4\sigma_2^2},$$

and

$$N = \frac{1}{2}\sqrt{2 + \frac{4\sigma_2^2}{\sigma_1^2} + \frac{\sigma_1^2}{4\sigma_2^2}} - 1.$$

We want to briefly explain qualitatively how the measured POVM is tuned by the parameters σ_1 and σ_2. The ratio of both determine the purity of μ, for $\sigma_1 = 2\sigma_2$ we obtain a rank-one measurement. By increasing or decreasing both we can achieve a better resolution in momentum space or in position space: Small values σ_1, σ_2 lead to good position measurements for the cost of having large errors in the momentum measurement. If $\sigma_1 \gg 2\sigma_2$ both position and momentum measurements are bad and we obtain a measurement with small disturbance.

For detailed discussions on the disturbance and accuracy of the measurements we also refer to Refs. 22 and 23. It is shown that the outcomes for position and momentum in POVMs of the above type satisfy the inequality $\Delta x \Delta p \geqslant \hbar$ in contrast to the Heisenberg uncertainty relation $\Delta x \Delta p \geqslant \hbar/2$.

VI. Comparison to quantum optics implementations

Meanwhile there are several methods known to measure the quadrature amplitudes of a light mode simultaneously (see Ref. 24). We will consider the scheme shown in Fig. 6 which has some nice similarities to the continuous analog of our circuit in Fig. 2. In the following, we will use the dimensionless formal position and momentum operators as given in Eqs. (15) and (16) which generate the momentum and position translations in the Heisenberg–Weyl group and furthermore define implicitly a Schrödinger representation of a single mode state as wave function $\psi \in L^2(\mathbb{R})$ in position state.

The method in Fig. 6 also uses two ancilla modes. As in our proposal, the entanglement of the two modes tunes the POVM operator. One part of an entangled two-mode state (wires 2 and 3 in Fig. 6) interferes with the input state (wire 1) in a beam splitter. One of its output modes is subjected to a position measurement, the other to a momentum measurement. The results of the measurement determine furthermore displacements performed on the second component of the entangled input. The idea behind the scheme is to perform a teleportation using a nonmaximally entangled bipartite state (a maximally entangled state does not exist anyway in continuous variables) as a resource. Then the transfer of quantum information is not perfect but the measurements

performed during the "bad" teleportation provide some information on the input state. Similar to our scheme, the more entangled the joint state, the less information provides the measurement and the less disturbance on the output state will be observed.

One technical difference to our scheme is that the input and output are not on the same wire. The main difference is, however, that the interaction between input and entangled ancilla is given by a beam splitter, whereas we use scattering processes. This is geometrically the difference between a rotation or a shear in coordinate space (for details see Ref. 25). Note, however, that the effect of the controlled displacements of Fig. 6 could be mimicked by a controlled-X gate from wire 1 to 3 and a controlled-Z gate from wire 2 to 3 if the latter gate is conjugated by a Fourier transform on wire 2. The reason is that it does not make a difference whether the controlled operation is performed before the measurement or afterward. The scheme therefore contains elements quite similar to ours.

In Ref. 24 we did not find an explicit remark stating that their implementation scheme is minimally disturbing in the sense considered here since the authors use the term "minimally disturbing" in a different sense. Furthermore, the attention was restricted to Gaussian states for both the input as well as for the ancilla states. We have observed that the implementation is also applicable for non-Gaussian states and non-Gaussian POVM operators:

Theorem 16: *The scheme of Ref. 6 can in principle be used for a minimally disturbing implementation of any Heisenberg–Weyl symmetric POVM*

$$U_{s,t}\mu U_{s,t}^{\dagger}$$

by preparing the ancilla state

$$\sum_j \sqrt{\lambda_j}|\alpha_j\rangle \otimes |\overline{\alpha_j}\rangle,$$

where the $|\alpha_j\rangle$ *denote the eigenvector basis for* μ *and* $\lambda_j/(2\pi)$ *the corresponding eigenvalues.*

Proof: Due to the linearity argument in Lemma 3 we may prove our statement for the case where the two ancillas are in a product state. The initial three mode wave function is then given by

$$\phi(x,y,z) = \psi(x)\alpha(y)\beta(z),$$

where ψ is the wave function of the mode to be measured. The beam splitter transfers it to the wave function

$$\psi[(x+y)/\sqrt{2}]\alpha[(x-y)/\sqrt{2}]\beta(z).$$

We simulate the momentum measurement by an inverse Fourier transform followed by a position measurement. Conditioned on the measurement result (x,y) we therefore obtain a one-mode wave function (having z as argument) which is given by

$$\sqrt{\frac{1}{2\pi}}\left\{\int_{-\infty}^{\infty}\psi[(x+w)/\sqrt{2}]\alpha[(-x+w)/\sqrt{2}]e^{iwy}dw\right\}\beta(z).$$

After obtaining the measurement results x and y on wires 1 and 2, respectively, the conditioned displacement of position and momentum by $\sqrt{2}x$ and $\sqrt{2}y$, respectively, leads to

$$\sqrt{\frac{1}{2\pi}}\left\{\int_{-\infty}^{\infty}\psi[(x+w)/\sqrt{2}]\alpha[(-x+w)/\sqrt{2}]e^{iwy}dw\right\}\beta(z-\sqrt{2}x)e^{-iz\sqrt{2}y}$$
$$=\sqrt{\frac{1}{2\pi}}\left[\int\psi(w)\alpha(-\sqrt{2}x+w)e^{iw\sqrt{2}y}dw\right]\beta(z-\sqrt{2}x)e^{-iz\sqrt{2}y}.$$

This shows that the unnormalized state vector of the third particle, given that x,y was measured, reads

$$U_{\sqrt{2}y,\sqrt{2}x}|\beta\rangle\langle\bar{\alpha}|U^{\dagger}_{\sqrt{2}y,\sqrt{2}x}|\psi\rangle.$$

After taking into account that the quantum optics convention for position and momentum differs from the canonical definition of Eqs. (15) and (16) by the factor $\sqrt{2}$ (see Ref. 27), this is exactly the desired output state.

By choosing the input $|\bar{\alpha}\rangle\otimes\langle\alpha|$ we therefore have $\mu=|\alpha\rangle\langle\alpha|=\sqrt{\mu}$. Similarly we can obtain operators μ with higher rank by choosing entangled input states. □

Note that the calculations which show that the scheme does indeed implement a minimally disturbing POVM is very similar to the calculations in Sec. V which show the close formal analogy of both methods.

VII. CONCLUSIONS

We have presented a general scheme to implement minimally disturbing symmetric measurements by quantum circuits. By applying it to the Heisenberg–Weyl group, we obtain circuits for simultaneous measurements of position and momentum of a particle moving on a discrete cyclic chain. We show that an infinite dimensional generalization of this circuit leads to a well-defined measurement process on a Schrödinger particle moving on the real line using two probe particles. The "circuit" for this continuous variable quantum system can, in principle, be obtained by particle collisions with hard-core potential. The whole measurement process on the three particles shows some analogies but also differences to simultaneous measurements of the quadrature amplitudes in quantum optics using two ancilla modes.

APPENDIX

1. Proof of Theorem 10

The $(2n\times 2)$ matrix M of Eq. (2) has the $(\sigma_\pi\otimes\sigma,\sigma)$ symmetry that is defined by

$$(X_n\otimes R_n)M=MR_n,$$

as straightforward computation shows, i.e., we have $(\sigma_\pi\otimes\sigma)(j)=X_n^j\otimes R_n^j$ and $\sigma(j)=R_n^j$. To find the diagonalizing operations A and B of Theorem 9 we observe that σ is already decomposed into irreducible representations and B is therefore trivial. To decompose $\sigma_\pi\otimes\sigma$ we diagonalize σ_π by the Fourier transform F_n. The eigenvalues of $(F_nX_nF^\dagger)\otimes R_n$ are in the order $1,\omega_n,\omega_n,\omega_n^2,\omega_n^2,\ldots,\omega_n^{n-1},\omega_n^{n-1},1$. We apply the cyclic shift X_{2n} to group them into a sequence of pairs (ω_n^j,ω_n^j) as in Lemma 7. Therefore, we have $A=X_{2n}(F_n\otimes I_2)$. Following Theorem 9 we only have to find $W\in\mathrm{Int}[A(\sigma_\pi\otimes\sigma)A^\dagger,B\sigma B^\dagger\oplus\sigma']$ which is a unitary extension of $N:=A^\dagger MB$. Hence, we can choose

$$W := \sqrt{\frac{1}{2}} \begin{pmatrix} 1 & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ 1 & 0 & \cdots & 0 & -1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 & 0 & 1 & \cdots & 0 \\ 0 & 1 & \cdots & 0 & 0 & -1 & \cdots & 0 \\ \vdots & \vdots & & \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 1 & 0 & 0 & \cdots & 1 \\ 0 & 0 & \cdots & 1 & 0 & 0 & \cdots & -1 \end{pmatrix},$$

since the first two columns of this matrix coincide with N. This is verified by straightforward computations, too. One can also easily check that W can be written as $W=(I_n \otimes F_2)K^\dagger$ where K is defined in Theorem 10.

2. Proof of Theorem 12

To define M as in Eq. (2) we have to define a correspondence between ancilla basis states and POVM operators. Since our ancilla system is a tensor product of two d-dimensional systems, this correspondence is canonical and we obtain

$$M = \sum_{j,k=0}^{d-1} |j\rangle \otimes |k\rangle \otimes Z_d^k X_d^j \sqrt{\mu} X_d^{-j} Z_d^{-k} \in \mathbb{C}^{d^3 \times d}. \tag{A1}$$

The symmetry $(\sigma_\pi \otimes \sigma)M = M\sigma$ of M is defined by

$$(I_d \otimes X_d \otimes Z_d)M = MZ_d \quad \text{and} \quad (X_d \otimes I_d \otimes X_d)M = MX_d,$$

as straightforward computations show. Following Theorem 9 we decompose the representation on the left side into a direct sum of irreducible representations. First of all, we diagonalize the shifts X_d in the first and second tensor components by the Fourier transform. We obtain

$$(I_d \otimes Z_d \otimes Z_d)(F_d \otimes F_d \otimes I_d)M = (F_d \otimes F_d \otimes I_d)MZ_d$$

and

$$(Z_d \otimes I_d \otimes X_d)(F_d \otimes F_d \otimes I_d)M = (F_d \otimes F_d \otimes I_d)MX_d.$$

The matrices on the left side can be written as

$$(I_d \otimes Z_d \otimes Z_d) = \bigoplus_{j=0}^{d^2-1} \omega_d^{j \bmod d} Z_d \quad \text{and} \quad (Z_d \otimes I_d \otimes X_d) = \bigoplus_{j=0}^{d^2-1} \omega_d^{j \operatorname{div} d} X_d.$$

Therefore, the representation is decomposed into a direct sum of representations that are equal to σ up to phase factors. We now eliminate these factors. To simplify notation we define the block diagonal matrices

$$X_{\mathrm{mod}} := \bigoplus_{j=0}^{d^2-1} X_d^{j \bmod d} \quad \text{and} \quad Z_{\mathrm{div}} := \bigoplus_{j=0}^{d^2-1} Z_d^{j \operatorname{div} d}.$$

Using $Z_d^\dagger X_d Z_d = \omega_d^{-1} X_d$ and $X_d Z_d X_d^\dagger = \omega_d^{-1} Z_d$ we obtain

$$X_{\mathrm{mod}} \left(\bigoplus_{j=0}^{d^2-1} \omega_d^{j \bmod d} Z_d \right) X_{\mathrm{mod}}^\dagger = \bigoplus_{j=0}^{d^2-1} Z_d$$

and

$$Z_{\mathrm{div}}^{\dagger}\left(\bigoplus_{j=0}^{d^2-1}\omega_d^{j\ \mathrm{div}\ d}X_d\right)Z_{\mathrm{div}}=\bigoplus_{j=0}^{d^2-1}X_d.$$

Using both equations we can write

$$X_{\mathrm{mod}}Z_{\mathrm{div}}^{\dagger}(I_d\otimes Z_d\otimes Z_d)Z_{\mathrm{div}}X_{\mathrm{mod}}^{\dagger}=(I_d\otimes I_d\otimes Z_d)$$

and

$$X_{\mathrm{mod}}Z_{\mathrm{div}}^{\dagger}(Z_d\otimes I_d\otimes X_d)Z_{\mathrm{div}}X_{\mathrm{mod}}^{\dagger}=(I_d\otimes I_d\otimes X_d),$$

where we have no phase factors. Consequently, we obtain

$$(I_d\otimes I_d\otimes Z_d)X_{\mathrm{mod}}Z_{\mathrm{div}}^{\dagger}(F_d\otimes F_d\otimes I_d)M=X_{\mathrm{mod}}Z_{\mathrm{div}}^{\dagger}(F_d\otimes F_d\otimes I_d)MZ_d$$

and

$$(I_d\otimes I_d\otimes X_d)X_{\mathrm{mod}}Z_{\mathrm{div}}^{\dagger}(F_d\otimes F_d\otimes I_d)M=X_{\mathrm{mod}}Z_{\mathrm{div}}^{\dagger}(F_d\otimes F_d\otimes I_d)MX_d.$$

We can rewrite this as

$$(I_d\otimes I_d\otimes\sigma)N=N\sigma \tag{A2}$$

with $N=X_{\mathrm{mod}}Z_{\mathrm{div}}^{\dagger}(F_d\otimes F_d\otimes I_d)M$. Hence, using the notation of Theorem 9 we have

$$A:=X_{\mathrm{mod}}Z_{\mathrm{div}}^{\dagger}(F_d\otimes F_d\otimes I_d)\quad\text{and}\quad B=I_d$$

since σ is an irreducible representation. The matrix N is an element of the intertwining space $\mathrm{Int}(\oplus_{j=0}^{d^2-1}\sigma,\sigma)$. Following Lemma 7 it has the decomposition

$$N=|\Phi_1\rangle\otimes I_d\in\mathbb{C}^{d^3\times d}$$

with $|\Phi_1\rangle\in\mathbb{C}^{d^2}$. Elementary but cumbersome computations (write $\sqrt{\mu}=\Sigma_{j=0}^{d-1}X_d^j\Delta_j$ with appropriate diagonal matrices Δ_j and powers of the shift X_d) show

$$|\Phi_1\rangle=(F_d^{\dagger}\otimes I_d)\left(\sum_{q=0}^{d-1}|q\rangle\langle q|\otimes X_d^{-q}\right)\left(\sqrt{d}\sum_{j,k=0}^{d-1}\sqrt{\mu}_{jk}|j\rangle\otimes|k\rangle\right). \tag{A3}$$

We extend the representation σ on the right side of Eq. (A2) to the direct sum of d^2 copies of σ. The matrix W of the resulting intertwining space has the decomposition $C\otimes I_d$ with $C\in\mathbb{C}^{d^2\times d^2}$. Therefore, we extend $\{|\Phi_1\rangle\}$ to an orthonormal basis $\{|\Phi_1\rangle,|\Phi_2\rangle,\ldots,|\Phi_{d^2}\rangle\}$ of $\mathbb{C}^{d^2}$. We can define the unitary

$$U:=A^{\dagger}W(B\oplus\tilde{B})=A^{\dagger}[(|\Phi_1\rangle|\Phi_2\rangle\ldots|\Phi_{d^2}\rangle)\otimes I_d]$$

that extends M with $\tilde{B}:=I_{(n-1)d}$. Now we show how to simplify the implementation by preparing an appropriate ancilla state. We have

$$U(|0\rangle\otimes|\Psi\rangle)=A^{\dagger}[(|\Phi_1\rangle|\Phi_2\rangle\ldots|\Phi_{d^2}\rangle)\otimes I_d](|0\rangle\otimes|\Psi\rangle)=A^{\dagger}(|\Phi_1\rangle\otimes|\Psi\rangle).$$

Hence, we can omit the implementation of W if we initialize the ancilla with $|\Phi_1\rangle$ of Eq. (A3). In summary, we have to implement the unitary

$$(F_d^{\dagger}\otimes F_d^{\dagger}\otimes I_d)Z_{\mathrm{div}}X_{\mathrm{mod}}^{\dagger}(F_d^{\dagger}\otimes I_d\otimes I_d)\left(\sum_{q=0}^{d-1}|q\rangle\langle q|\otimes X_d^{-q}\otimes I_d\right)$$

after we have initialized the ancillas with the state vector

$$|\gamma\rangle := \sqrt{d}\sum_{j,k=0}^{d-1}\sqrt{\mu}_{jk}|j\rangle\otimes|k\rangle \in \mathbb{C}^{d^2}. \tag{A4}$$

As a special case consider the initial operator $\mu=|\alpha\rangle\langle\alpha|/d$ with $|\alpha\rangle\in\mathbb{C}^d$ and $\langle\alpha|\alpha\rangle=1$. In this case we have $\sqrt{\mu}=|\alpha\rangle\langle\alpha|/\sqrt{d}$. Furthermore, we have

$$|\gamma\rangle = |\alpha\rangle\otimes|\bar{\alpha}\rangle.$$

Zero energy resonance and the logarithmically slow decay of unstable multilevel systems

Manabu Miyamoto[a)]
Department of Physics, Waseda University, 3-4-1 Okubo, Shinjuku-ku, Tokyo 169-8555, Japan

(Received 23 February 2006; accepted 8 June 2006; published online 10 August 2006)

The long time behavior of the reduced time evolution operator for unstable multilevel systems is studied based on the *N*-level Friedrichs model in the presence of a zero energy resonance. The latter means the divergence of the resolvent at zero energy. Resorting to the technique developed by Jensen and Kato [Duke Math. J. **46**, 583 (1979)], the zero energy resonance of this model is characterized by the zero energy eigenstate that does not belong to the Hilbert space. It is then shown that for some kinds of the rational form factors the logarithmically slow decay proportional to $(\log t)^{-1}$ of the reduced time evolution operator can be realized. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2227260]

I. INTRODUCTION

The exponential decay of unstable systems has been a well-known law since the early days of quantum theory. The quantum description of those systems, however, allows deviation from exponential decay both at shorter and longer times[1] than those times over which the exponential decay law dominates.[2,3] The short time deviation was actually found in a quantum tunneling experiment,[4] while the long time deviation seems still not to have been detected in any quantum system.[5] The main cause that hinders the detection is considered as the smallness of the deviation at such long times.[6]

In a recent study, a method enhancing the long time deviation was proposed.[7] The decay of the unstable systems is theoretically modeled in the time evolution of the survival probability of unstable initial state. The survival probability is just the probability of finding the initial state in the state at a later time t. Since it is rewritten in a Fourier integral of the spectral function, its behavior at long times is determined by that of the spectral function near the threshold of the energy continuum.[2,3] The essential aspect of the method is then distorting the spectral function from the Breit-Wigner form and dislocating its peak toward the threshold energy. Mathematically, this causes a divergence of the spectral function, i.e., the resolvent at the threshold. Then, it is expected that the exponential decay period disappears and the survival probability at long times is increased. A similar idea was also considered in a related context.[5,8] In addition, in the analysis of the Friedrichs model[9,10] that is often used for the study on the decays of the unstable systems, the survival probability at long times sometimes exhibits a power decay law slower than that in cases of no divergence.[11–13]

These facts remind the author of the zero energy resonance proposed by Jensen and Kato.[14] According to them, such zero energy singularities are classified by the zero energy eigenstates of the total Hamiltonian that either belong to or do not belong to the Hilbert space. The cases where such eigenstates exist are called the exceptional cases; otherwise they are referred to as the regular case. The result in Ref. 14 is concerned with the three-dimensional system of the one particle in short-range potentials, and they proved that the time evolution operator asymptotically decreases as $O(t^{-1/2})$ for the exceptional cases, which is slower than $O(t^{-3/2})$ for the regular case. However,

a)Electronic mail: miyamo@hep.phys.waseda.ac.jp

to the author's knowledge, the zero energy resonance for the Friedrichs model seems not to have been examined in the previous studies including Refs. 7 and 11–13, in spite of the wide applicability of the model to the various physical systems.[8,11,13,15,16]

In the present paper, we examine the zero energy singularities of the resolvent at the threshold energy for the Friedrichs model from the viewpoint of the zero energy resonance,[14] and clarify how the asymptotic behavior of the survival probability at long times is affected. The Friedrichs model[9,10] describes the system of the finite discrete levels coupled with the continuous spectrum, in which the former can be interpreted as the unstable excited levels of atoms and the latter as the environmental electromagnetic fields.[11,15,16] We emphasize that the model is not restricted to the single level case[7–13,15,16] but, rather, the N-level case.[10,17–21] In addition, we assume that the square modulus of the form factors vanishes at zero energy with an integer power,[15,16,22] however it is treated without restriction to a specific form to some extent. Furthermore, since we only consider the initial state spanned by the discrete states, it is sufficient for us to see the reduced resolvent $\widetilde{R}(z)$ that is just the restriction of the resolvent to the subspace spanned by the discrete states. Then, the Fourier integral of $\widetilde{R}(z)$ that we call the reduced time evolution operator $\widetilde{U}(t)$ enables us to calculate the survival probability. In fact it is expressed by the square modulus of the expectation value of$\widetilde{U}(t)$ in a given initial state. We first study the zero energy eigenstates of the model which either belong to or do not belong to the Hilbert space. It is then possible to estimate correctly the asymptotic behavior of $\widetilde{R}(z)$ at small energies both in the regular case and the exceptional cases. The latter cases are examined in detail only for the first kind, where only the zero energy eigenstate not belonging to the Hilbert space exists. On the basis of this analysis, we can derive the long-time asymptotic formula for $\widetilde{U}(t)$ in those cases. In particular, the logarithmic decay proportional to $(\log t)^{-1}$ of $\widetilde{U}(t)$ is shown to occur in the exceptional case of the first kind for our form factors, which is extremely slower than the power decays in the regular case and in the exceptional case for another type of form factor.[11–13] These results are shown in Theorems VII.1 and VII.2.

The organization of the paper is as follows. We first explain in Sec. II the N-level Friedrichs model with an appropriate Hilbert space, and then in Sec. III we introduce the reduced resolvent $\widetilde{R}(z)$. Section IV is devoted to the identification of zero energy eigenstates in this model. It is then possible to obtain the asymptotic expansion of $\widetilde{R}(z)$ at small energies in Sec. V, where we examine the regular and the exceptional case of the first kind. By making sure of the relation between $\widetilde{R}(z)$ and $\widetilde{U}(t)$ in Sec. VI, the asymptotic formula for $\widetilde{U}(t)$ in the regular and the exceptional case of the first kind are derived in Sec. VII. Concluding remarks are given in Sec. VIII.

II. HILBERT SPACE AND THE *N*-LEVEL FRIEDRICHS MODEL

We shall use bracket notation; however it can be understood in a standard treatment based on functional analysis as in Refs. 10 and 17. The Hilbert space describing the unstable multilevel systems is here defined by

$$\mathcal{H} := \mathbb{C}^N \oplus L^2((0,\infty)). \tag{1}$$

A vector $|c\rangle \in \mathbb{C}^N$ is expressed by $|c\rangle = \Sigma_{n=1}^N c_n |n\rangle$, where $|n\rangle$'s are the orthonormal basis of $\mathbb{C}^N$, so that $\langle n|n'\rangle = \delta_{nn'}$, where $\delta_{nn'}$ is Kronecker's delta. $L^2((0,\infty))$ is the Hilbert space of the square-integrable complex function $|f\rangle$ of the variable ω defined on $(0,\infty)$, i.e.,

$$|f\rangle \in L^2((0,\infty)) \Leftrightarrow \int_0^\infty |f(\omega)|^2 \mathrm{d}\omega < \infty\,. \tag{2}$$

In a standard notation using the (generalized) eigenstate $|\omega\rangle$ of the multiplication operator by ω, $|f\rangle$ is nothing more than

$$|f\rangle = \int_0^\infty f(\omega)|\omega\rangle \mathrm{d}\omega, \tag{3}$$

where $\langle\omega|\omega'\rangle = \delta(\omega-\omega')$ and $\delta(\omega-\omega')$ is Dirac's delta. Then, an arbitrary vector $|\Psi\rangle \in \mathcal{H}$ composed of $|c\rangle \in \mathbb{C}^N$ and $|f\rangle \in L^2((0,\infty))$ is denoted by

$$|\Psi\rangle := |c\rangle + |f\rangle, \tag{4}$$

and the inner product between any two vectors $|\Psi\rangle$ and $|\Phi\rangle \in \mathcal{H}$ is defined by[23]

$$\langle\Phi|\Psi\rangle := \langle \mathrm{d}|c\rangle + \langle g|f\rangle = \sum_{n=1}^{N} \mathrm{d}_n^* c_n + \int_0^\infty g^*(\omega) f(\omega) \mathrm{d}\omega, \tag{5}$$

where $(^*)$ denotes the complex conjugate and $|\Phi\rangle = |\mathrm{d}\rangle + |g\rangle$ with $|\mathrm{d}\rangle \in \mathbb{C}^N$ and $|g\rangle \in L^2((0,\infty))$. In particular, the associated norm of $|\Psi\rangle$ is $\|\Psi\| := \sqrt{\langle\Psi|\Psi\rangle}$, which is ensured to be finite for all $|\Psi\rangle \in \mathcal{H}$.

Let us now introduce the N-level Friedrichs model for a description of the decay of the unstable multilevel systems. The Hamiltonian H of this model is defined by

$$H := H_0 + \lambda V, \tag{6}$$

where H_0 is the free part and V the interaction part of H, respectively, and $\lambda \in \mathbb{R}$ is the coupling constant. H_0 is defined by

$$H_0 := \sum_{n=1}^{N} \omega_n |n\rangle\langle n| + \int_0^\infty \omega|\omega\rangle\langle\omega| \mathrm{d}\omega, \tag{7}$$

where $\omega_n \in \mathbb{R}$ with $\omega_1 \leqslant \omega_2 \leqslant \cdots \leqslant \omega_N$, and its action is prescribed by $H_0|\Psi\rangle = \Sigma_{n=1}^N \omega_n c_n |n\rangle + \omega|f\rangle$ for any $|\Psi\rangle = |c\rangle + |f\rangle \in D(H_0)$. $D(H_0)$ is the domain of H_0 defined by $D(H_0) := \{|\Psi\rangle \in \mathcal{H} \,|\, \int_0^\infty |\omega f(\omega)|^2 \mathrm{d}\omega < \infty\}$, and then the self-adjointness of H_0 is guaranteed. The interaction part V is defined by

$$V := \sum_{n=1}^{N} \int_0^\infty [v_n^*(\omega)|n\rangle\langle\omega| + v_n(\omega)|\omega\rangle\langle n|] \mathrm{d}\omega, \tag{8}$$

where we assumed that $|v_n\rangle \in L^2((0,\infty))$.[24] We call the L^2-functions $v_n(\omega)$ the form factors of the system under consideration. The action of V is then given by $V|\Psi\rangle = \Sigma_{n=1}^N \langle v_n|f\rangle |n\rangle + \Sigma_{n=1}^N c_n |v_n\rangle$ for any $|\Psi\rangle \in \mathcal{H}$. Note that since $D(V) = \mathcal{H}$ and V is a bounded self-adjoint operator, H is self-adjoint with the domain $D(H) = D(H_0) \cap D(V) = D(H_0)$.

In the whole of the paper, we will restrict ourselves to the special kind of the form factor: Suppose that the product $v_m^*(\omega)v_n(\omega)$ between an arbitrary pair of $v_m^*(\omega)$ and $v_n(\omega)$ is written in a rational function, i.e., it is expressed by

$$v_m^*(\omega)v_n(\omega) = \frac{\pi_{mn}(\omega)}{\rho_{mn}(\omega)}, \tag{9}$$

where $\pi_{mn}(\omega)$ and $\rho_{mn}(\omega)$ are the polynomials of the degree M_{mn} and N_{nm}, respectively, and we assume that $\rho_{mn}(\omega)$ has no zeros in $[0,\infty)$. It is also assumed that $M_{mn}+2 \leqslant N_{mn}$ and $\pi_{mn}(0) = 0$. The former condition ensures that $v_m^*(\omega)v_n(\omega)$ is integrable in $[0,\infty)$ and $\lim_{\omega\to\infty} v_m^*(\omega)v_n(\omega) = 0$, while the latter condition implies that the rational function $v_m^*(\omega)v_n(\omega) = O(\omega)$ as $\omega \to +0$. The form factors with such properties are often found in actual systems involving the process of the spontaneous emission of photons from the hydrogen atom,[15,22] and quantum dots.[16] We do not treat the algebraic form factor that behaves as $O(\omega^{1/2})$ as $\omega \to +0$ instead, associated with the photodetachment of electrons from the negative ion[8,12,13,25] and the spontaneous emission from the

atoms in the photonic crystals;[11] however, the discussion developed in the following could be easily extended to such a case.

III. REDUCED RESOLVENT FOR THE *N*-LEVEL FRIEDRICHS MODEL

In the following, we introduce the reduced resolvent that is simply the restriction of the resolvent of H to the N dimensional subspace $\mathbb{C}^N \oplus \{0\}$. Since we only consider the initial state belonging to this subspace, this restriction is sufficient for our study. In a technical sense, this treatment corresponds to the appropriate choice of a weighted Sobolev space.[14,30] In the later sections, we do not distinguish the vector in $\mathbb{C}^N$ from that in $\mathbb{C}^N \oplus \{0\}$. After introducing the reduced resolvent, we see the existence of the boundary values of the reduced resolvent on the positive real line. The large-energy behavior of the reduced resolvent is also examined, which is necessary for a rigorous estimation of the long time behavior of the reduced time evolution operator.

A. Reduced resolvent

The resolvent of H_0 and that of H are defined by $R_0(z)=(H_0-z)^{-1}$ and $R(z)=(H-z)^{-1}$, respectively, where we assume that $z \in \mathbb{C}\backslash(\sigma(H_0) \cup \sigma(H))$. $\sigma(H_0)$ (or $\sigma(H)$) is the spectrum of H_0 (or H), i.e., the set of the singular points of $R_0(z)$ (or R(z)). Then, we have

$$R(z) - R_0(z) = -R_0(z)VR(z) \tag{10}$$

$$= -R_0(z)VR_0(z) + R_0(z)VR_0(z)VR(z). \tag{11}$$

From Eq. (10), one obtains the equation $R(z)=(1+R_0(z)V)^{-1}R_0(z)$, which is the starting point of the asymptotic expansion of $R(z)$ for the short-range potential systems.[14] On the other hand, we instead start from Eq. (11) to obtain

$$[H_0 - z - VR_0(z)V]R(z) = 1 - VR_0(z). \tag{12}$$

This equation can be solved for our model if we confine ourselves to the state subspace $\mathbb{C}^N \oplus \{0\}$.[10] In fact, from the fact that $\langle n|VR_0(z)|n'\rangle = 0$ for any $|n\rangle$ and $|n'\rangle \in \mathbb{C}^N \oplus \{0\}$, Eq. (12) reads

$$\sum_{m=1}^{N} [(\omega_n - z)\delta_{nm} - \lambda^2 S_{nm}(z)]\tilde{R}_{mn'}(z) = \delta_{nn'}, \tag{13}$$

where $S(z)$ and $\tilde{R}(z)$ are the $N \times N$ matrix defined with the matrix components

$$S_{mn}(z) := \langle m|VR_0(z)V|n\rangle = \int_0^\infty \frac{v_m^*(\omega)v_n(\omega)}{\omega - z} d\omega, \quad \tilde{R}_{mn}(z) := \langle m|R(z)|n\rangle. \tag{14}$$

We call $S(z)$ and $\tilde{R}(z)$ the *self energy* and the *reduced resolvent*, respectively. Note that $S(z)$ can be analytically defined for all $z \in \mathbb{C}\backslash[0,\infty)$. For a later convenience, we also introduce the matrix K_0 and $K(z)$ by

$$K_{0mn} := \langle m|H_0|n\rangle = \omega_n \delta_{mn}, \quad K_{mn}(z) := [K_0 - \lambda^2 S(z)]_{mn}, \tag{15}$$

respectively. Then, Eq. (13) is equivalent to

$$[K(z) - z]\tilde{R}(z) = 1, \quad \forall z \in \mathbb{C}\backslash(\sigma(H_0) \cup \sigma(H)), \tag{16}$$

which implies that $\det[K(z)-z]\det[\tilde{R}(z)]=1$, so that $\det[K(z)-z] \neq 0$ and $\det[\tilde{R}(z)] \neq 0$ for all $z \in \mathbb{C}\backslash(\sigma(H_0) \cup \sigma(H))$. Thus, the inverse of $K(z)-z$ exists, and we have

$$\tilde{R}(z) = [K(z) - z]^{-1}, \quad \forall z \in \mathbb{C}\backslash(\sigma(H_0) \cup \sigma(H)). \tag{17}$$

B. The boundary values of $\tilde{R}(z)$ and its large energy behavior

From the assumption on the form factors, every $v_m^*(\omega)v_n(\omega)$ is continued to the whole complex plane as a meromorphic function which we merely denote as $v_m^*(z)v_n(z)$. It may have a finite number of poles. Then, it follows from Lemma A.1 that $S(z)$ can be reduced to the form

$$S(z) = S(0) + A(z) - (\log(-z))\Gamma(z), \tag{18}$$

where we choose $\arg(-z)=\arg(z)-\pi$ and $0<\arg(z)<2\pi$. The matrix $\Gamma(z)$ is defined with the components

$$\Gamma_{mn}(z) := v_m^*(z)v_n(z), \tag{19}$$

and satisfies $\Gamma(z)\to 0$ as $z\to 0$ in $\mathbb{C}$. $S(0)$ is the limit of $S(z)$ as $z\to 0$ in $\mathbb{C}\backslash[0,\infty)$, which turns out to be unique. Indeed, as we see from the Appendix in Ref. 21, $S_{mn}(0)=\int_0^\infty v_m^*(\omega)v_n(\omega)/\omega \mathrm{d}\omega$. $A(z)$ is then defined through Eq. (18) and becomes a Hermitian matrix for real ω, whose components are the rational functions of z without any singularity on $[0,\infty)$. By definition, $A(z)$ satisfies $A(z)\to 0$ as $z\to 0$. One sees that the boundary values of $S(z)$ at the half line $(0,\infty)$ exist and satisfy[10]

$$\lim_{\epsilon\to+0} S(\omega \pm i\epsilon) = D(\omega) \pm \pi i\Gamma(\omega), \tag{20}$$

where

$$D(\omega) := S(0) + A(\omega) - (\log \omega)\Gamma(\omega). \tag{21}$$

The matrix $D(\omega)$ is just of the components

$$D_{mn}(\omega) := P\int_0^\infty \frac{v_m^*(\omega')v_n(\omega')}{\omega'-\omega}\mathrm{d}\omega', \tag{22}$$

where P denotes the principal value of the integral. Note that both $D(\omega)$ and $\Gamma(\omega)$ are Hermitian matrices and $\Gamma(\omega)\geqslant 0$.

In all the discussion developed in the following, we assume that

$$\det[K^\pm(\omega)-\omega]\neq 0, \quad \forall\ \omega>0, \tag{23}$$

where we introduced

$$K^\pm(\omega) := \lim_{\epsilon\to+0} K(\omega\pm i\epsilon) = K_0 - \lambda^2 D(\omega) \mp \lambda^2\pi i\Gamma(\omega), \quad \forall\ \omega>0. \tag{24}$$

It is worth noting that condition (23) is equivalent to the requirement of no positive eigenvalues of H_0, whose eigenstates are normalizable. Indeed, if $\det[K^\pm(\omega)-\omega]=0$ for some $\omega>0$, there is a nonzero vector $|\eta\rangle=\Sigma_{n=1}^N \eta_n|n\rangle\in\mathbb{C}^N$ such that $[K^\pm(\omega)-\omega]|\eta\rangle=0$. Since both $D(\omega)$ and $\Gamma(\omega)$ are Hermitian matrices, the latter equation implies that

$$\langle\eta|[K_0-\omega-\lambda^2 D(\omega)]|\eta\rangle = 0, \quad \langle\eta|\Gamma(\omega)|\eta\rangle = \left|\sum_{n=1}^N v_n(\omega)\eta_n\right|^2 = 0. \tag{25}$$

Note that the latter relation means that $\Gamma(\omega)|\eta\rangle=0$ because $\Gamma(\omega)\geqslant 0$. Thus, Eq. (25) implies that $\Gamma(\omega)|\eta\rangle=0$ and $[K_0-\lambda^2 D(\omega)]|\eta\rangle=\omega|\eta\rangle$, i.e.,

$$\sum_{n=1}^N v_n(\omega)\eta_n = 0, \quad \sum_{n=1}^N [\omega_m\delta_{mn}-\lambda^2 D_{mn}(\omega)]\eta_n = \omega\eta_m, \tag{26}$$

for all $m=1,\ldots,N$. This is merely the condition for the existence of a positive eigenvalue ω of H.[21]

Lemma III.1: *Under the assumption* (23), *it holds that* $\tilde{R}^{\pm}(\omega) := \lim_{\epsilon \to +0} \tilde{R}(\omega \pm i\epsilon)$ *exists for all* $\omega > 0$ *and* $\tilde{R}^{\pm}(\omega) = [K^{\pm}(\omega) - \omega]^{-1}$.

Proof: Under the assumption (23), $[K^{\pm}(\omega) - \omega]^{-1}$ exists. Then

$$\begin{aligned} &\| [K^{\pm}(\omega) - \omega]^{-1} - \tilde{R}(\omega \pm i\epsilon) \| \\ &\quad \leqslant \| [K^{\pm}(\omega) - \omega]^{-1} \| \, \| \pm i\epsilon + \lambda^2 S(\omega \pm i\epsilon) - \lambda^2 D(\omega) \mp \lambda^2 \pi i \Gamma(\omega) \| \, \| \tilde{R}(\omega \pm i\epsilon) \|. \end{aligned} \tag{27}$$

Note that for any nonzero $|y\rangle \in \mathbb{C}^N$ $(\neq 0)$ there is a nonzero $|x\rangle \in \mathbb{C}^N$ such that $|y\rangle = [K(\omega \pm i\epsilon) - \omega \mp i\epsilon]|x\rangle$. We then obtain

$$\begin{aligned} \frac{\| \tilde{R}(\omega \pm i\epsilon)|y\rangle \|}{\|y\|} &\leqslant \frac{\|x\|}{\| \| [K^{\pm}(\omega) - \omega]|x\rangle \| - \| [\pm i\epsilon + \lambda^2 S(\omega \pm i\epsilon) - \lambda^2 D(\omega) \mp \lambda^2 \pi i \Gamma(\omega)]|x\rangle \|} \\ &\leqslant \left[\inf_{|x\rangle \neq 0, |x\rangle \in \mathbb{C}^N} \frac{\| [K^{\pm}(\omega) - \omega] \|}{\|x\|} - \| \pm i\epsilon + \lambda^2 S(\omega \pm i\epsilon) - \lambda^2 D(\omega) \mp \lambda^2 \pi i \Gamma(\omega) \| \right]^{-1}, \end{aligned} \tag{28}$$

which implies that

$$\overline{\lim_{\epsilon \to +0}} \| \tilde{R}(\omega \pm i\epsilon) \| \leqslant \left[\inf_{|x\rangle \neq 0, |x\rangle \in \mathbb{C}^N} \frac{\| K^{\pm}(\omega) - \omega \|}{\|x\|} \right]^{-1} < \infty, \tag{29}$$

where the norm of an $N \times N$ matrix A is defined by $\|A\| = \sup_{|x\rangle \neq 0, |x\rangle \in \mathbb{C}^N} \|A|x\rangle\| / \|x\|$. In Eq. (28), we used the fact that there is some $\epsilon_0 > 0$ such that for any positive $\epsilon < \epsilon_0$ and for any nonzero $|x\rangle \in \mathbb{C}^N$,

$$\begin{aligned} \frac{\| [K^{\pm}(\omega) - \omega]|x\rangle \|}{\|x\|} &\geqslant \inf_{|x\rangle \neq 0, |x\rangle \in \mathbb{C}^N} \frac{\| [K^{\pm}(\omega) - \omega]|x\rangle \|}{\|x\|} > \| \pm i\epsilon + \lambda^2 S(\omega \pm i\epsilon) - \lambda^2 D(\omega) \mp \lambda^2 \pi i \Gamma(\omega) \| \\ &\geqslant \frac{\| [\pm i\epsilon + \lambda^2 S(\omega \pm i\epsilon) - \lambda^2 D(\omega) \mp \lambda^2 \pi i \Gamma(\omega)]|x\rangle \|}{\|x\|}, \end{aligned} \tag{30}$$

where the assumption (23) is taken into account. Thus, by using Eq. (29), Eq. (27) leads us to

$$\lim_{\epsilon \to +0} \| [K^{\pm}(\omega) - \omega]^{-1} - \tilde{R}(\omega \pm i\epsilon) \| = 0, \tag{31}$$

which completes the proof of the lemma. □

Lemma III.2: *Under the assumption* (23), $\tilde{R}^{\pm}(\omega)$ *is r-times differentiable in* $\omega \in (0, \infty)$, *and it behaves as*

$$\frac{\mathrm{d}^r \tilde{R}^{\pm}(\omega)}{\mathrm{d}\omega^r} = O(\omega^{-r-1}) \text{ as } \omega \to \infty. \tag{32}$$

Proof: We first show the statement for $r = 0$. From the assumption on the form factors and Lemma A.1, one sees that

$$\lim_{\omega \to \infty} D(\omega) = 0, \quad \lim_{\omega \to \infty} \Gamma(\omega) = 0. \tag{33}$$

Since from the assumption (23) $K^{\pm}(\omega) - \omega$ is invertible for all $\omega > 0$, it holds that there is some positive $\bar{\omega} > \omega_N$ such that for any $\omega > \bar{\omega}$,

$$\frac{\| \tilde{R}^{\pm}(\omega)|y\rangle \|}{\|y\|} \leqslant \frac{\|x\|}{\| (K_0 - \omega)|x\rangle \| - \lambda^2 \| [D(\omega) \pm \pi i \Gamma(\omega)]|x\rangle \|} \tag{34}$$

$$\leqslant \frac{1}{\omega - \omega_N - \lambda^2 \|D(\omega) \pm \pi i \Gamma(\omega)\|} = O(\omega^{-1}), \tag{35}$$

where the last inequality is obtained as follows: we can choose some positive $\bar{\omega} > \omega_N$ such that for any $\omega > \bar{\omega}$,

$$\frac{\|[K_0 - \omega]|x\rangle\|}{\|x\|} \geqslant \min_n\{\omega - \omega_n\} = \omega - \omega_N > \lambda^2 \|D(\omega) \pm \pi i \Gamma(\omega)\| \geqslant \lambda^2 \frac{\|[D(\omega) \pm \lambda^2 \pi i \Gamma(\omega)]|x\rangle\|}{\|x\|}, \tag{36}$$

where Eq. (33) was used. Thus Eq. (35) reads just as Eq. (32) does for $r=0$. In the case of $r \geqslant 1$, we first note that from our assumptions on the form factors and Lemma A.1 again, $A(\omega)$ and $\Gamma(\omega)$, which are connected through $D(\omega)=S_0+A(\omega)-\log \omega\Gamma(\omega)$, also satisfy

$$\frac{\mathrm{d}^r A(\omega)}{\mathrm{d}\omega^r} = O(\omega^{-1-r}), \quad \frac{\mathrm{d}^r \log \omega\Gamma(\omega)}{\mathrm{d}\omega^r} = O(\omega^{-1-r}\log \omega), \tag{37}$$

as $\omega \to \infty$, where we used the estimation that $\mathrm{d}^r\Gamma(\omega)/\mathrm{d}\omega^r = O(\omega^{-1-r})$. Thus, for $r=1$, we have

$$\frac{\mathrm{d}\tilde{R}^{\pm}(\omega)}{\mathrm{d}\omega} = \tilde{R}^{\pm}(\omega)\frac{\mathrm{d}}{\mathrm{d}\omega}[\omega + \lambda^2 D(\omega) \pm \lambda^2 \pi i \Gamma(\omega)]\tilde{R}^{\pm}(\omega) = O(\omega^{-2}), \tag{38}$$

as $\omega \to \infty$, where Eq. (32) for $r=0$ was used. For $r \geqslant 1$, we obtain

$$\frac{\mathrm{d}^r \tilde{R}^{\pm}(\omega)}{\mathrm{d}\omega^r} = \sum_{j=1}^{r} {\sum_{\{s_i\}_{i=1}^j}}' a^{(r)}(\{s_i\}_{i=1}^j) \left\{ \prod_{i=1}^{j} \tilde{R}^{\pm}(\omega) \frac{\mathrm{d}^{s_i}}{\mathrm{d}\omega^{s_i}}[\omega + \lambda^2 D(\omega) \pm \lambda^2 \pi i \Gamma(\omega)] \right\} \tilde{R}^{\pm}(\omega), \tag{39}$$

where $a^{(r)}(\{s_i\}_{i=1}^j)$ is an appropriate positive integer. Note that the symbol $(')$ means that the summation over $\{s_i\}_{i=1}^j$ is taken under the condition that $s_i \geqslant 1$ for all i and $\Sigma_{i=1}^j s_i = r$. If $r=1$, Eq. (39) reproduces Eq. (38) with $a^{(1)}(\{s_i\}_{i=1}^1)=1$. In the general case, if Eq. (39) holds for $r=k$, then its derivative is made up of a linear combination of

$$\left\{ \prod_{i=1}^{j+1} \tilde{R}^{\pm}(\omega) \frac{\mathrm{d}^{s_i}}{\mathrm{d}\omega^{s_i}}[\omega + \lambda^2 D(\omega) \pm \lambda^2 \pi i \Gamma(\omega)] \right\} \tilde{R}^{\pm}(\omega), \tag{40}$$

where $\Sigma_{i=1}^{j+1} s_i = k+1$ for $1 \leqslant j \leqslant k$, and

$$\left\{ \prod_{i=1}^{j+1} \tilde{R}^{\pm}(\omega) \frac{\mathrm{d}^{s_i}}{\mathrm{d}\omega^{s_i}}[\omega + \lambda^2 D(\omega) \pm \lambda^2 \pi i \Gamma(\omega)] \right\} \tilde{R}^{\pm}(\omega), \tag{41}$$

where $\Sigma_{i=1}^{j} s_i = k+1$ for $1 \leqslant j \leqslant k$. On the other hand, they are actually included in the right-hand side (rhs) of Eq. (39) for $r=k+1$. Thus Eq. (39) is valid for all integer $r \geqslant 1$. Let us now evaluate the asymptotic behavior of $\mathrm{d}^r\tilde{R}^{\pm}(\omega)/\mathrm{d}\omega^r$ for large ω. One can see that the summand for $j=r$ in Eq. (39), where all $s_i=1$, contributes $O(\omega^{-r-1})$ to $\mathrm{d}^r\tilde{R}^{\pm}(\omega)/\mathrm{d}\omega^r$, while the other summands for $j<r$ specified by $\{s_i\}_{i=1}^j$ contribute $O(\omega^{-r-1-2s_0}(\log \omega)^{s_0}))$ at most, where s_0 is a number of s_i satisfying $s_i \geqslant 2$ and never vanishes for $j<r$. Therefore, the summand dominating for large ω is that for $j=r$. Since we recursively show $a^{(r)}(\{s_1\}_{i=1}^r)=r!$, which never vanishes, the statement is proved. □

IV. CLASSIFICATION OF THE ZERO-ENERGY SINGULARITY OF $\tilde{R}^{\pm}(\omega)$

In order to prescribe the zero energy resonance in the N-level Friedrichs model, we should identify the zero energy eigenstates in this model which either belong to or do not belong to $\mathcal{H}$. In

the case of the short-range potential systems,[14] this task needs some elaborate examination with an appropriately extended Hilbert space. On the other hand, in our case, it is rather easily performed, as is seen in the following.

Let us first see whether the eigenvector $|\psi\rangle \in \mathbb{C}^N$ of $K_0 - \lambda^2 S(0)$, belonging to the zero eigenvalue, can be actually extended to the eigenvector of H belonging to the zero eigenvalue of H. If $|\Psi\rangle = |\psi\rangle + |f\rangle \in D(H) \subset \mathcal{H}$ is a zero eigenvector of H, it should satisfy $H|\Psi\rangle = 0$, or equivalently[21]

$$\omega_n \psi_n + \lambda \langle v_n | f \rangle = 0 \text{ for } n = 1, \ldots, N, \quad \omega f(\omega) + \lambda \sum_{n=1}^{N} \psi_n v_n(\omega) = 0. \tag{42}$$

The latter equation of Eq. (42) is immediately solved as

$$f(\omega) = -\lambda \frac{\sum_{n=1}^{N} \psi_n v_n(\omega)}{\omega}, \tag{43}$$

which should be square integrable because we intend to find $|\Psi\rangle$ in $\mathcal{H}$. If this is the case, $\omega f(\omega) \in L^2((0,\infty))$, i.e., $|\Psi\rangle \in D(H)$ is ensured, and the substitution of Eq. (43) into $\langle v_n | f \rangle$ is safely done. Then, we find that the former equation of Eq. (42) is nothing more than

$$(K_0 - \lambda^2 S(0))|\psi\rangle = K(0)|\psi\rangle = 0, \tag{44}$$

where $K(0) := K^{\pm}(0) = K_0 - \lambda^2 S(0)$. However, it is noted that such an $f(\omega)$ associated with $|\psi\rangle$ is not necessarily square integrable. Hence, we shall decompose the zero eigenspace of $K(0)$, denoted by $M = \{|\psi\rangle \in \mathbb{C}^N | K(0)|\psi\rangle = 0\}$, into two kinds of subspaces: $M_1 = (M_0 \oplus M_2)^{\perp}$ and $M_2 = \{|\psi\rangle \in M | f(\omega) \in L^2((0,\infty))\}$. Here $M_0 = M^{\perp}$, and $D^{\perp}$ denotes the orthogonal complement of the subspace D. In short we have $\mathbb{C}^N = M_0 \oplus M_1 \oplus M_2$. Then, as is expected from the definition, we have

$$M_1 \subset \{|\psi\rangle \in M | f(\omega) \notin L^2((0,\infty))\}. \tag{45}$$

Note that in general the subset on the rhs of the above is not a subspace. We call 0 the *zero energy resonance* (or merely *zero resonance*) of H if M_1 is not empty. We also introduce the projection operators Q_0, Q_1, and Q_2, associated with M_0, M_1, and M_2, respectively. What we next do is to introduce the terminology following the study of Jensen and Kato.[14]

Definition IV.1: We call the system a *regular* case if it holds that $0 \notin \sigma(K(0))$, i.e.,

$$\det[K(0)] \neq 0. \tag{46}$$

In this case, 0 is said to be a *regular* point for H.

Definition IV.2: We call the system the *exceptional* case if, instead of Eq. (46), it holds that $0 \in \sigma(K(0))$, i.e.,

$$\det[K(0)] = 0. \tag{47}$$

In particular, if 0 is a resonance but not an eigenvalue ($Q_1 \neq 0$, $Q_2 = 0$), 0 is said to be an *exceptional* point for H of the *first kind*. If 0 is not a resonance, but an eigenvalue ($Q_1 = 0$, $Q_2 \neq 0$), 0 is said to be an exceptional point of the *second kind*. If 0 is both a resonance and an eigenvalue ($Q_1 \neq 0$, $Q_2 \neq 0$), 0 is said to be an exceptional point of the *third kind*.

We here remark that in general a nontrivial solution of Eq. (44) does not exist, however we can find a special case where such a solution surely exists. Suppose that N_+ eigenvalues ω_n of H_0 are positive, and all form factors $v_n(\omega)$ satisfying the assumption (9) are linearly independent. Then increasing λ gradually from 0 to ∞, we can find some critical values of λ for which $K(0)$ has the zero eigenvalue. Let us denote the nth eigenvalue of $K(0)$ by $\kappa_n(0)$ where $\kappa_1(0) \leqslant \kappa_2(0) \leqslant \cdots \leqslant \kappa_N(0)$. Then, $\kappa_n(0)$ turns out to satisfy the inequality

$$\omega_n - \lambda^2\sigma_N(0) \leqslant \kappa_n(0) \leqslant \omega_n - \lambda^2\sigma_1(0), \tag{48}$$

where both of $\sigma_1(0)$ and $\sigma_N(0)$ are positive constants and ensured not to vanish.[21] Thus, for a sufficiently small $|\lambda|$ $\kappa_n(0)$ for each $n \geqslant N-N_+ +1$ should be positive, while for a sufficiently large $|\lambda|$ they should be negative. Furthermore, one easily sees that all $\kappa_n(0)$ are continuous functions of λ^2. Therefore, we conclude from the intermediate value theorem that there is at least one critical value of λ to make $\kappa_n(0)=0$ for each $n \geqslant N-N_+ +1$. We can actually find such special values of λ in Fig. 1 depicted in Ref. 21. The example mentioned here could be treated in a more general way with resort to the analytic Fredholm theorem,[26,27] which tells us at most a finite number of the critical values exists.

It is also worth remarking that the existence of the zero energy eigenstates that either belong to or not to the Hilbert space necessarily prescribes the small energy behavior of the form factors in the following way. Remember that under the assumption on the form factors, $\Gamma(\omega)$ defined by Eq. (19) has an asymptotic form like

$$\Gamma(\omega) = \sum_{n=1}^{N} \omega^n \Gamma_n + O(\omega^{N+1}), \tag{49}$$

as $\omega \to +0$. Then, if $|\psi\rangle \in M_1$ exists, it should satisfy

$$\langle\psi|\Gamma_1|\psi\rangle \neq 0. \tag{50}$$

In fact, if $\langle\psi|\Gamma_1|\psi\rangle=0$, we see that $f(\omega)$ in Eq. (43) has to satisfy $|f(\omega)|^2=\lambda^2\langle\psi|\Gamma(\omega)|\psi\rangle/\omega^2 = O(1)$ as $\omega \to +0$, however which concludes that $f(\omega)$ is square integrable. This contradicts the assumption that $|\psi\rangle \in M_1$. In order to make the condition (50) be satisfied, at least Γ_1 should not vanish identically. We can find such form factors in the physical systems for the spontaneous emission process of photons from the hydrogen atom[15,22] and the quantum dot.[16] On the other hand, the discussion mentioned here immediately implies the fact that if $|\psi\rangle \in M_2$ exists, this time it should satisfy

$$\langle\psi|\Gamma_1|\psi\rangle = 0, \tag{51}$$

which just ensures the requirement that $f(\omega) \in L^2((0,\infty))$. However, note that Eq. (51) does not imply $\Gamma_1=0$ identically and only requires $\Gamma_1=0$ on the subspace M_2.

A. The small-energy behavior of $\tilde{R}^{\pm}(\omega)$ in the regular case

In this case, the same as in Eq. (31), we can show that $\tilde{R}^{\pm}(0)=(K(0))^{-1}$. Furthermore, we can choose some positive $\omega_0>0$ such that

$$\|(K(0))^{-1}\|\,\|[\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega) - \lambda^2 S(0)]\| < 1, \tag{52}$$

for all positive $\omega<\omega_0$. Then, $\tilde{R}^{\pm}(\omega)$ is expanded as a Neumann series,

$$\tilde{R}^{\pm}(\omega) = \{K(0)[1-(K(0))^{-1}[\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega) - \lambda^2 S(0)]]\}^{-1} = \lim_{N\to\infty} S_N(\omega), \tag{53}$$

where

$$S_N(\omega) = \sum_{j=0}^{N} \{(K(0))^{-1}[\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega) - \lambda^2 S(0)]\}^j (K(0))^{-1}, \tag{54}$$

for all positive $\omega<\omega_0$ with $\{(K(0))^{-1}[\omega+\lambda^2 D(\omega)\pm\lambda^2\pi i\Gamma(\omega)-\lambda^2 S(0)]\}^0=1$. Under our assumptions on the form factors, $A(\omega)$ defined in Eq. (21) is asymptotically expanded as

$$A(\omega) = \sum_{n=1}^{N} \omega^n A_n + O(\omega^{N+1}), \tag{55}$$

as $\omega \to 0$. By using Eqs. (49) and (55), it also follows that

$$D(\omega) = S(0) - \omega \log \omega \Gamma_1 + \omega A_1 + O(\omega^2 \log \omega), \tag{56}$$

as $\omega \to +0$. Then, Eq. (53) tells us the dominant asymptotic behavior of $\tilde{R}^{\pm}(\omega)$ becomes

$$\tilde{R}^{\pm}(\omega) = (K(0))^{-1} + O(\omega \log \omega), \tag{57}$$

as $\omega \to +0$, where $(K(0))^{-1}$ never vanishes in the regular case.

B. The small-energy behavior of $\tilde{R}(z)$ in the exceptional case of the first kind

In the exceptional case of the first kind, from the definition, $Q_1 \neq 0$ while $Q_2 = 0$, so that $Q_0 + Q_1 = 1$. Then, $\tilde{R}(z)$ is divided into the following four terms,

$$\tilde{R}(z) = Q_0 \tilde{R}(z) Q_1 + Q_0 \tilde{R}(z) Q_0 + Q_1 \tilde{R}(z) Q_0 + Q_1 \tilde{R}(z) Q_1. \tag{58}$$

We now introduce the four matrices:

$$E_{kl}(z) = Q_k [K(z) - z] Q_l = Q_k [K_0 - z - \lambda^2 [S(0) + A(z) - (\log z)\Gamma(z) + i\pi\Gamma(z)]] Q_l, \tag{59}$$

where $k, l = 0, 1$, and $\log(-z) - \log z = -i\pi$ is used. From the relation that $[K(z) - z]\tilde{R}(z) = 1$, they satisfy

$$E_{k0} Q_0 \tilde{R} Q_l + E_{k1} Q_1 \tilde{R} Q_l = Q_k \delta_{kl}, \tag{60}$$

for $k, l = 0, 1$. To solve the above equations we need to check whether E_{11} and E_{00} are invertible in the subspaces M_1 and M_0, respectively. By using Eq. (49), $E_{11}(z)$ is rewritten as

$$E_{11}(z) = \lambda^2 z (\log z) Q_1 \Gamma_1 Q_1 - z Q_1 - \lambda^2 Q_1 \{A(z) - (\log z)[\Gamma(z)] - z\Gamma_1] + i\pi\Gamma(z)\} Q_1, \tag{61}$$

where $Q_1 K(0) Q_1 = 0$ is used. Note that $A(z) = O(z)$ and $\Gamma(z) - z\Gamma_1 = O(z^2)$ for our form factors, so that all terms excepting the first one of the rhs of Eq. (61) are of the order of $O(z)$. Furthermore, the exceptional case of the first kind imposes the fact that $Q_1 \Gamma_1 Q_1 \neq 0$ [see Eq. (50)], and $Q_1 \Gamma_1 Q_1$ is positive definite in M_1 and thus invertible in M_1. Hence, $E_{11}(\omega)$ is invertible for sufficiently small $|z| > 0$, and the inverse can be expanded by the Neumann series as

$$E_{11}^{-1}(z) = \sum_{j=0}^{\infty} (\tilde{E}_{11}(z))^j \frac{1}{\lambda^2 z \log z} (Q_1 \Gamma_1 Q_1)^{-1} \tag{62}$$

$$= \frac{1}{\lambda^2 z \log z} (Q_1 \Gamma_1 Q_1)^{-1} + O(z^{-1} (\log z)^{-2}) = O(z^{-1} (\log z)^{-1}), \tag{63}$$

for small $|z|$, where we define

$$\tilde{E}_{11}(z) := \frac{1}{\lambda^2 z \log z} (Q_1 \Gamma_1 Q_1)^{-1} \{z Q_1 + \lambda^2 Q_1 \{A(z) - (\log z)[\Gamma(z) - z\Gamma_1] + \pi i \Gamma(z)\} Q_1\}, \tag{64}$$

which behaves as $1/\log z$ as $z \to 0$. For E_{00} we have

$$E_{00}(z) = Q_0K(0)Q_0 - Q_0[z + \lambda^2[A(z) - (\log z)\Gamma(z) + i\pi\Gamma(z)]]Q_0, \tag{65}$$

where the first term of the above is invertible in M_0, and the last term vanishes as $z \to 0$. Hence, $E_{00}(z)$ is invertible in M_0 for sufficiently small $|z| > 0$ and is expanded as

$$E_{00}^{-1}(z) = -\sum_{j=0}^{\infty} \{[Q_0K(0)Q_0]^{-1}[z + \lambda^2[A(z) - (\log z)\Gamma(z) + i\pi\Gamma(z)]]Q_0\}^j[Q_0K(0)Q_0]^{-1} = O(1), \tag{66}$$

for small $|z|$. Furthermore, we obtain

$$E_{kl}(z) = -\lambda^2 Q_k[A(z) - (\log z)\Gamma(z) + \pi i\Gamma(z)]Q_l = O(z \log z), \tag{67}$$

for $k \neq l$ as $z \to 0$, because $Q_0K(0)Q_1 = Q_1K(0)Q_0 = 0$. Solving Eq. (60), we obtain[28]

$$Q_0\tilde{R}Q_0 = (E_{00} - E_{01}E_{11}^{-1}E_{10})^{-1} = O(1), \tag{68}$$

$$Q_0\tilde{R}Q_1 = -E_{00}^{-1}E_{01}Q_1\tilde{R}Q_1 = -E_{00}^{-1}E_{01}(E_{11} - E_{10}E_{00}^{-1}E_{01})^{-1} = O(1), \tag{69}$$

$$Q_1\tilde{R}Q_0 = -Q_1\tilde{R}Q_1E_{10}E_{00}^{-1} = -(E_{11} - E_{10}E_{00}^{-1}E_{01})^{-1}E_{10}E_{00}^{-1} = O(1), \tag{70}$$

$$Q_1\tilde{R}Q_1 = (E_{11} - E_{10}E_{00}^{-1}E_{01})^{-1} = O(z^{-1}(\log z)^{-1}). \tag{71}$$

It is worth noting that since the relation $[K(z) - z]\tilde{R}(z) = 1$ is analytically continued to the second Riemann sheet through the cut $[0, \infty)$, the above-mentioned results are also valid for such a continued region and the estimations obtained here can be applied without any corrections.

When we consider the small energy behavior of $\tilde{R}^-(\omega)$, it is convenient to expand E_{11}, differently from Eq. (61), as

$$E_{11}(z) = \lambda^2 z(\log z - 2\pi i)Q_1\Gamma_1Q_1 - zQ_1 - \lambda^2 Q_1\{A(z) - (\log z - 2\pi i)[\Gamma(z) - z\Gamma_1] - i\pi\Gamma(z)\}Q_1. \tag{72}$$

All the above-obtained results are only changed by replacing the term $\log z$ with $\log z - 2\pi i$. Then, we can obtain from Eq. (61)

$$E_{11}^+(\omega) = \lim_{\epsilon \to +0} E_{11}(\omega + i\epsilon) = \lambda^2(\log \omega)Q_1\Gamma(\omega)Q_1 - \omega Q_1 - \lambda^2 Q_1[A(\omega) - i\pi\Gamma(\omega)]Q_1, \tag{73}$$

while from Eq. (72)

$$E_{11}^-(\omega) = \lim_{\epsilon \to +0} E_{11}(\omega - i\epsilon) = \lambda^2(\log \omega)Q_1\Gamma(\omega)Q_1 - \omega Q_1 - \lambda^2 Q_1[A(\omega) + i\pi\Gamma(\omega)]Q_1. \tag{74}$$

C. The small-energy behavior of $\tilde{R}(z)$ in the exceptional case of the second kind

In the exceptional case of the second kind, it follows that $Q_1 = 0$, $Q_2 \neq 0$, and $Q_0 + Q_2 = 1$. Let us consider the asymptotic behavior of the reduced resolvent at small energies, which is written in the following form, $\tilde{R}(z) = \Sigma_{k,l=0,2}Q_k\tilde{R}(z)Q_l$. We now introduce the four matrices again,

$$E_{kl}(z) = Q_k[K(z) - z]Q_l, \tag{75}$$

where $k, l = 0, 2$. From the relation that $[K(z) - z]\tilde{R}(z) = 1$, they satisfy that

$$E_{k0}Q_0\tilde{R}Q_l + E_{k2}Q_2\tilde{R}Q_l = Q_k\delta_{kl}, \tag{76}$$

for $k,l=0,2$. This time, E_{22} and E_{00} are invertible in M_2 and M_0, respectively. In fact, from Eqs. (49) and (55) we have

$$E_{22}(z) = -zQ_2(1+\lambda^2 A_1)Q_2 - \lambda^2 Q_2[A(z) - zA_1 - (\log z)\Gamma(z) + i\pi\Gamma(z)]Q_2, \tag{77}$$

where $Q_2K(0)Q_2=0$ was used. Note that since $A(z)-zA_1=O(z^2)$ and $Q_2\Gamma_1Q_2=0$ [see Eq. (51)], the second term of the rhs of Eq. (77) is of the order of $O(z^2\log z)$. Furthermore, since $Q_2A_1Q_2\geqslant 0$ from $Q_2\Gamma_1Q_2=0$ and Lemma A.2, $Q_2(1+\lambda^2A_1)Q_2>0$ and invertible in M_2. These facts bring us the fact that $E_{22}(z)$ is invertible in M_2 for sufficiently small $z>0$, that is

$$E_{22}^{-1}(z) = -\sum_{j=0}^{\infty}(-\tilde{E}_{22}(z))^j\frac{1}{z}[Q_2(1+\lambda^2A_1)Q_2]^{-1} \tag{78}$$

$$= \frac{1}{z}[Q_2(1+\lambda^2A_1)]Q_2{}^{-1} + O(\log z) = O(z^{-1}), \tag{79}$$

where

$$\tilde{E}_{22}(z) := \frac{1}{z}[Q_2(1+\lambda^2A_1)Q_2]^{-1}\lambda^2Q_2[A(z) - zA_1 - (\log z)\Gamma(z) + i\pi\Gamma(z)]Q_2. \tag{80}$$

For E_{00}, we next have

$$E_{00}(z) = Q_0K(0)Q_0 - Q_0[z + \lambda^2[A(z) - (\log z)\Gamma(z) + i\pi\Gamma(z)]]Q_0, \tag{81}$$

where the first term of the above is invertible in M_0, and the last term vanishes as $|z|\to 0$. Hence, $E_{00}(z)$ is invertible in M_0 for sufficiently small $|z|>0$, and the inverse is obtained as a Neumann series. On the other hand, E_{20} and E_{02} behave as

$$E_{kl}(z) = Q_k[-z(1+\lambda^2A_1) - \lambda^2[A(z) - zA_1 - (\log z)\Gamma(z) + \pi i\Gamma(z)]]Q_l = O(z), \tag{82}$$

for small $|z|$ where $k\neq l$. Solving Eq. (76) as in Eqs. (68)–(71), one sees that $Q_0\tilde{R}Q_0=O(1)$, for $k,l=0,2$, except

$$Q_2\tilde{R}Q_2 = (E_{22} - E_{20}E_{00}^{-1}E_{02})^{-1} = O(z^{-1}), \tag{83}$$

as $z\to 0$. In particular, the last equation is expanded as

$$Q_2\tilde{R}(z)Q_2 = \sum_{j=0}^{\infty}[E_{22}^{-1}E_{20}E_{00}^{-1}E_{02}]^jE_{22}^{-1} = -\frac{1}{z}[Q_2(1+\lambda^2A_1)Q_2]^{-1} + O(\log z), \tag{84}$$

for small $|z|$, where we used Eq. (79).

We now remark that the zero energy eigenspace of H denoted by $\mathcal{N}_0$ is completely characterized by M_2. That is, there is a bijection from $M_2\oplus\{0\}$ to $\mathcal{N}_0$. From the discussion concerning Eqs. (42)–(44), for any $|\Psi\rangle\in\mathcal{M}_0$, there is a vector $|\psi\rangle\in M_2\oplus\{0\}$ such that

$$|\Psi\rangle = |\psi\rangle - \lambda\int_0^{\infty}\frac{\sum_{n=1}^{N}v_n(\omega)\psi_n}{\omega}|\omega\rangle d\omega = [1-\lambda R_0(0)V]|\psi\rangle, \tag{85}$$

where V is restricted to $\mathbb{C}^N\oplus\{0\}$ and $R_0(0)$ is the (unbounded) multiplication operator of $1/\omega$ in $L^2((0,\infty))$. Then we see $V|\psi\rangle\in D(R_0(0))$ because $|\psi\rangle\in M_2\oplus\{0\}$. Thus $1-\lambda R_0(0)V$ is well defined as an operator from $M_2\oplus\{0\}$ to $\mathcal{H}$. Now, Eq. (85) tells us that $1-\lambda R_0(0)V$ is a surjection from $M_2\oplus\{0\}$ to $\mathcal{N}_0$. On the other hand, for any $|\Psi\rangle\in\mathcal{N}_0$,if $|\Psi\rangle=0$, i.e., $0=\langle\Psi|\Psi\rangle$, Eq. (85) implies

that $0=\langle\Psi|\Psi\rangle \geqslant \langle\psi|\psi\rangle$. Therefore, $1-\lambda R_0(0)V$ is also an injection from $M_2 \oplus \{0\}$ to $\mathcal{N}_0$, and the proof is completed.

D. The small-energy behavior of $\tilde{R}^{\pm}(\omega)$ in the exceptional case of the third kind

In the exceptional case of the third kind, from the definition, $Q_1 \neq 0$, $Q_2 \neq 0$, and $Q_0+Q_1+Q_2=1$. The reduced resolvent is written in the form, $\tilde{R}^{\pm}(\omega)=\Sigma_{k,l=0}^{2} Q_k \tilde{R}^{\pm}(\omega) Q_l$. This time, we need nine matrices,

$$E_{kl}^{\pm}(\omega) = Q_k[K^{\pm}(\omega) - \omega]Q_l, \tag{86}$$

for $k,l=0,1,2$. From the relation that $[K^{\pm}(\omega)-\omega]\tilde{R}^{\pm}(\omega)=1$, they satisfy that

$$E_{k0}^{\pm} Q_0 \tilde{R}^{\pm} Q_l + E_{k1}^{\pm} Q_1 \tilde{R}^{\pm} Q_l + E_{k2}^{\pm} Q_2 \tilde{R}^{\pm} Q_l = Q_k \delta_{kl}, \tag{87}$$

for $k,l=0,1,2$. The asymptotic behaviors of $E_{kl}^{\pm}(\omega)$ are essentially examined in the preceding subsections, except for $E_{12}^{\pm}(\omega)$ and $E_{21}^{\pm}(\omega)$. Then, $E_{12}^{\pm}(\omega)$ becomes

$$E_{12}^{\pm}(\omega) = -\omega\lambda^2 Q_1 A_1 Q_2 - \lambda^2 Q_1[A(\omega) - \omega A_1 - (\log\omega)[\Gamma(\omega) - \omega\Gamma_1] \pm \pi i[\Gamma(\omega) - \omega\Gamma_1]]Q_2 \tag{88}$$

$$= -\omega\lambda^2 Q_1 A_1 Q_2 + O(\omega^2 \log\omega), \tag{89}$$

where $Q_1 K(0) Q_2=0$, $Q_1 Q_2=0$, and $\Gamma_1 Q_2=0$ are used. The last relation follows from the fact that $Q_2\Gamma_1 Q_2=0$ and $\Gamma_1 \geqslant 0$. In addition, since $Q_1\Gamma(\omega)Q_2=O(\omega^2)$, we see that $Q_1 A_1 Q_2 = \int_0^\infty Q_1\Gamma(\omega)Q_2\omega^{-2}\mathrm{d}\omega$. By the same way, we also see that

$$E_{21}^{\pm}(\omega) = -\omega\lambda^2 Q_1 A_1 Q_2 + O(\omega^2 \log\omega). \tag{90}$$

To solve Eq. (87), let us now put the $N\times N$ matrix $\mathbf{E}$ as

$$\mathbf{E} = \begin{bmatrix} E_{00} & E_{01} & E_{02} \\ E_{10} & E_{11} & E_{12} \\ E_{20} & E_{21} & E_{22} \end{bmatrix}, \tag{91}$$

and partition it into $\mathbf{A}=\begin{bmatrix} E_{00} & E_{01} \\ E_{10} & E_{11} \end{bmatrix}$, $\mathbf{B}=\begin{bmatrix} E_{02} \\ E_{12} \end{bmatrix}$, $\mathbf{C}=[E_{20} \;\; E_{21}]$, $\mathbf{D}=[E_{22}]$. Then, from the inverse matrix formula again, $\mathbf{E}^{-1}$ $(=\tilde{R})$ is expressed as[28]

$$\mathbf{E}^{-1} = \begin{bmatrix} [\mathbf{A}-\mathbf{B}\mathbf{D}^{-1}\mathbf{C}]^{-1} & -\mathbf{A}^{-1}\mathbf{B}[\mathbf{D}-\mathbf{C}\mathbf{A}^{-1}\mathbf{B}]^{-1} \\ -[\mathbf{D}-\mathbf{C}\mathbf{A}^{-1}\mathbf{B}]^{-1}\mathbf{C}\mathbf{A}^{-1} & [\mathbf{D}-\mathbf{C}\mathbf{A}^{-1}\mathbf{B}]^{-1} \end{bmatrix}. \tag{92}$$

The validities of $\mathbf{A}^{-1}$ and $\mathbf{D}^{-1}$ are already ensured in the exceptional cases of the first and second kinds, respectively. Then, one sees that since $\mathbf{A}^{-1}=O(\omega^{-1}(\log\omega)^{-1})$, $\mathbf{B}=O(\omega)$, $\mathbf{C}=O(\omega)$, and $\mathbf{D}^{-1}=O(\omega^{-1})$, it holds that $\mathbf{A}^{-1}\mathbf{B}\mathbf{D}^{-1}\mathbf{C}=O((\log\omega)^{-1})$. Thus, $[\mathbf{A}-\mathbf{B}\mathbf{D}^{-1}\mathbf{C}]^{-1}$ exists for small ω and $[\mathbf{A}-\mathbf{B}\mathbf{D}^{-1}\mathbf{C}]^{-1}=O(\omega^{-1}(\log\omega)^{-1})$. We also show that $[\mathbf{D}-\mathbf{C}\mathbf{A}^{-1}\mathbf{B}]^{-1}$ exists for small ω and $[\mathbf{D}-\mathbf{C}\mathbf{A}^{-1}\mathbf{B}]^{-1}=O(\omega^{-1})$. To obtain the asymptotic forms of the matrix components of $\mathbf{E}^{-1}$ explicitly, some redundant calculation is required; however, it could be achieved by a manner as similar to that used in the preceding subsections.

V. ASYMPTOTIC EXPANSION OF THE REDUCED RESOLVENT AT SMALL *z*

We examine the small-energy behavior of the reduced resolvent only for the regular case and the exceptional case of the first kind. This analysis is crucial for determining the asymptotic behavior of the reduced time evolution operator at long times.

A. The regular case

Here, we introduce $\tilde{A}(\omega) := \omega/\lambda^2 + A(\omega)$ and suppose that $\tilde{A}(\omega)$ and $\Gamma(\omega)$ behave as

$$\tilde{A}(\omega) := \frac{1}{\lambda^2}\omega + A(\omega) = \sum_{n=n_a}^{n_a+N} \omega^n \tilde{A}_n + O(\omega^{n_a+N+1}), \quad \Gamma(\omega) = \sum_{n=n_b}^{n_b+N} \omega^n \Gamma_n + O(\omega^{n_b+N+1}), \tag{93}$$

as $\omega \to 0$, respectively, that is, $\tilde{A}_n = 0$ for all $n < n_a$ and $\Gamma_{n_b} = 0$ for all $n < n_b$, while $\tilde{A}_{n_a} \neq 0$ and $\Gamma_{n_b} \neq 0$. Then, we obtain

$$\frac{1}{\lambda^2}\omega + D(\omega) = S(0) + \tilde{A}(\omega) - (\log \omega)\Gamma(\omega) = S(0) - \omega^{n_b} \log \omega \Gamma_{n_b} + \omega^{n_a}\tilde{A}_{n_a} + O(\omega h(\omega)), \tag{94}$$

as $\omega \to +0$, where

$$h(\omega) = \begin{cases} \omega^{n_b} \log \omega & (n_b \leqslant n_a) \\ \omega^{n_a} & (n_b > n_a) \end{cases} \tag{95}$$

It is important to note that the values of two parameters n_a and n_b are not determined independently. We shall here consider n_b as a controllable one. We first note that if $n_b \geqslant 2$ then $n_a = 1$ should be concluded, because from Lemma A.2 we have $A_1 > 0$, so that $\tilde{A}_1 = 1/\lambda^2 + A_1 > 0$ holds. Therefore, the conditions $n_b \leqslant n_a$ and $n_b > n_a$ can be realized only in the situations

$$n_b = 1 \text{ and } n_a \geqslant 1, \quad n_b \geqslant 2 \text{ and } n_a = 1, \tag{96}$$

respectively.

Lemma V.1: *Assume that* 0 *is a regular point for H. Then the rth derivative of* $\tilde{R}^{\pm}(\omega)$ *asymptotically behaves as*

$$\frac{d^r \tilde{R}^{\pm}(\omega)}{d\omega^r} = \begin{cases} O(1) & (r=0) \\ O(\omega^{1-r}(\log \omega)^{\theta(1-r)}) & (r \geqslant 1) \end{cases}, \quad or \quad \begin{cases} O(1) & (r=0) \\ O(\omega^{[1-r]^+}) & (1 \leqslant r < n_b) \\ O(\omega^{n_b-r}(\log \omega)^{\theta(n_b-r)}) & (n_b \leqslant r \leqslant 2n_b), \end{cases} \tag{97}$$

for $n_b = 1$, *or* $n_b \geqslant 2$, *respectively, as* $\omega \to 0$, *where* $[x]^+ = \max\{x, 0\}$ *and* $\theta(x) = 1$ *for* $x \geqslant 0$ *or* 0 *for* $x < 0$. *In addition, the rth derivative of* $\tilde{R}^{\pm}(\omega)$ *is approximated by that of a finite series*

$$(K(0))^{-1} + (K(0))^{-1}[-\omega^{n_b}(\log \omega)\lambda^2\Gamma_{n_b} + \omega^{n_a}\lambda^2\tilde{A}_{n_a} \pm \lambda^2 \pi i \omega^{n_b}\Gamma_{n_b}](K(0))^{-1}, \tag{98}$$

that is, it is shown that

$$\left\| \frac{d^r}{d\omega^r}\{\tilde{R}^{\pm}(\omega) - (K(0))^{-1} - (K(0))^{-1}[-\omega^{n_b}(\log \omega)\lambda^2\Gamma_{n_b} + \omega^{n_a}\lambda^2\tilde{A}_{n_a} \pm \lambda^2 \pi i \omega^{n_b}\Gamma_{n_b}](K(0))^{-1}\} \right\|$$

$$= O(\omega^{2-r}(\log \omega)^{1+\theta(2-r)}) \ (r \geqslant 0)$$

$$or \begin{cases} O(\omega^{[2-r]^+}) & (0 \leqslant r \leqslant n_b) \\ O(\omega^{n_b+1-r}(\log \omega)^{\theta(n_b+1-r)}) & (n_b + 1 \leqslant r \leqslant 2n_b) \end{cases}, \tag{99}$$

for $n_b = 1$, *or* $n_b \geqslant 2$, *respectively, as* $\omega \to 0$. *Here,* n_a *is restricted to the condition* (96).

Proof: The left-hand side (lhs) of Eq. (99) is written as follows:

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\{\widetilde{R}^{\pm}(\omega) - (K(0))^{-1} - (K(0))^{-1}[-\omega^{n_b}(\log\omega)\lambda^2\Gamma_{n_b} + \omega^{n_a}\lambda^2\widetilde{A}_{n_a} \pm \lambda^2\pi i\omega^{n_b}\Gamma_{n_b}](K(0))^{-1}\} \right\|$$

$$\leqslant \left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\{\widetilde{R}^{\pm}(\omega) - S_1(\omega)\} \right\| + \left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\{S_1(\omega) - (K(0))^{-1} - (K(0))^{-1}[-\omega^{n_b}(\log\omega)\lambda^2\Gamma_{n_b} + \omega^{n_a}\lambda^2\widetilde{A}_{n_a} \pm \lambda^2\pi i\omega^{n_b}\Gamma_{n_b}](K(0))^{-1}\} \right\| \tag{100}$$

where $S_N(\omega)$ is defined by Eq. (54). When $r=0$, the first term on the rhs of Eq. (100) is estimated from the special case of Eq. (101) for $N=1$,

$$\|\widetilde{R}^{\pm}(\omega) - S_N(\omega)\| \leqslant \frac{\|\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega) - \lambda^2 S(0)\|^{N+1}\|(K(0))^{-1}\|^{N+2}}{1 - \|(K(0))^{-1}\|\,\|[\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega) - \lambda^2 S(0)]\|} = O(h(\omega)^{N+1}), \tag{101}$$

as $\omega \to 0$. When $r \geqslant 1$, instead we have

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\{\widetilde{R}^{\pm}(\omega) - S_1(\omega)\} \right\|$$

$$\leqslant \left\| \sum_{j=2}^{r} {\sum_{\{s_i\}_{i=1}^{j}}}' a^{(r)}(\{s_i\}_{i=1}^{j}) \left\{ \prod_{i=1}^{j} \widetilde{R}^{\pm}(\omega) \frac{\mathrm{d}^{s_i}}{\mathrm{d}\omega^{s_i}}[\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega)] \right\} \widetilde{R}^{\pm}(\omega) \right\|$$

$$+ \left\| \widetilde{R}^{\pm}(\omega) \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}[\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega)]\widetilde{R}^{\pm}(\omega) - \frac{\mathrm{d}^r}{\mathrm{d}\omega^r} S_1(\omega) \right\|, \tag{102}$$

where Eq. (39) is used, and here $s_i \geqslant 1$ and $\Sigma_{i=1}^{j} s_i = r$ should be satisfied. Note that the first term on the rhs of Eq. (102) in the following appears only for $r \geqslant 2$, which is estimated in the following. In the following estimations, we temporarily forget the restriction (96) and consider the two general cases: $n_b \leqslant n_a$ and $n_b > n_a$. In the case of $n_b \leqslant n_a$, we can obtain for $r \geqslant 2$,

$$\left\| \sum_{j=2}^{r} {\sum_{\{s_i\}_{i=1}^{j}}}' a^{(r)}(\{s_i\}_{i=1}^{j}) \left\{ \prod_{i=1}^{j} \widetilde{R}^{\pm}(\omega) \frac{\mathrm{d}^{s_i}}{\mathrm{d}\omega^{s_i}}[\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega)] \right\} \widetilde{R}^{\pm}(\omega) \right\|$$

$$\leqslant \sum_{j=2}^{r} {\sum_{\{s_i\}_{i=1}^{j}}}' a^{(r)}(\{s_i\}_{i=1}^{j}) \|\widetilde{R}^{\pm}(\omega)\|^{j+1} O(\omega^{jn_b - r}) \prod_{i=1}^{j} O((\log\omega)^{\theta(n_b - s_i)})$$

$$= O(\omega^{2n_b - r}(\log\omega)^{\theta(n_b + 1 - r) + \theta(2n_b + 1 - r)}), \tag{103}$$

as $\omega \to 0$. For $n_a < n_b$,

$$\left\| \sum_{j=2}^{r} {\sum_{\{s_i\}_{i=1}^{j}}}' a^{(r)}(\{s_i\}_{i=1}^{j}) \widetilde{R}^{\pm}(\omega) \prod_{i=1}^{j} \left\{ \frac{\mathrm{d}^{s_i}}{\mathrm{d}\omega^{s_i}}[\omega + \lambda^2 D(\omega) \pm \lambda^2\pi i\Gamma(\omega)]\widetilde{R}^{\pm}(\omega) \right\} \right\|$$

$$= \begin{cases} O(\omega^{[2n_a - r]^+}) & (2 \leqslant r \leqslant n_a + n_b - 1) \\ O(\omega^{n_a + n_b - r}(\log\omega)^{\theta(n_a + n_b - r)}) & (n_a + n_b \leqslant r \leqslant 2n_b), \end{cases} \tag{104}$$

as $\omega \to 0$. We here used that

$$\frac{\mathrm{d}^r}{\mathrm{d}\omega^r}[\omega+\lambda^2 D(\omega)\pm\lambda^2\pi i\Gamma(\omega)-\lambda^2 S(0)]$$

$$=O(\omega^{n_b-r}(\log\omega)^{\theta(n_b-r)}),\quad \text{or}\quad \begin{cases} O(\omega^{[n_a-r]^+}) & (0\leqslant r<n_b)\\ O(\omega^{n_b-r}(\log\omega)^{\theta(n_b-r)}) & (r\geqslant n_b)\end{cases}, \tag{105}$$

for $n_b\leqslant n_a$, or $n_a<n_b$, respectively, as $\omega\to 0$. Equation (105) follows from

$$\frac{\mathrm{d}^r\widetilde{A}(\omega)}{\mathrm{d}\omega^r}=O(\omega^{[n_a-r]^+}),\frac{\mathrm{d}^r\Gamma(\omega)}{\mathrm{d}\omega^r}=O(\omega^{[n_b-r]^+}),\quad \frac{\mathrm{d}^r(\log\omega)\Gamma(\omega)}{\mathrm{d}\omega^r}=O(\omega^{n_b-r}(\log\omega)^{\theta(n_b-r)}), \tag{106}$$

as $\omega\to 0$. Incorporating Eqs. (103)–(105), with

$$\left\|\frac{\mathrm{d}^r\widetilde{R}^{\pm}(\omega)}{\mathrm{d}\omega^r}\right\|\leqslant\left\|\sum_{j=2}^{r}{\sum_{\{s_i\}_{i=1}^{j}}}'a^{(r)}(\{s_i\}_{i=1}^{j})\left\{\widetilde{R}^{\pm}(\omega)\prod_{i=1}^{j}\frac{\mathrm{d}^{s_i}}{\mathrm{d}\omega^{s_i}}[\omega+\lambda^2 D(\omega)\pm\lambda^2\pi i\Gamma(\omega)]\right\}\widetilde{R}^{\pm}(\omega)\right\|$$
$$+\left\|\widetilde{R}^{\pm}(\omega)\frac{\mathrm{d}^r}{\mathrm{d}\omega^r}[\omega+\lambda^2 D(\omega)\pm\lambda^2\pi i\Gamma(\omega)]\widetilde{R}^{\pm}(\omega)\right\|, \tag{107}$$

we have

$$\left\|\frac{\mathrm{d}^r\widetilde{R}^{\pm}(\omega)}{\mathrm{d}\omega^r}\right\|$$

$$=\begin{cases} O(1) & (r=0)\\ O(\omega^{n_b-r}(\log\omega)^{\theta(n_b-r)}) & (r\geqslant 1)\end{cases}\quad or\quad \begin{cases} O(1) & (r=0)\\ O(\omega^{[n_a-r]^+}) & (1\leqslant r<n_b)\\ O(\omega^{n_b-r}(\log\omega)^{\theta(n_b-r)}) & (n_b\leqslant r\leqslant 2n_b)\end{cases}, \tag{108}$$

for $n_b\leqslant n_a$, or $n_a<n_b$, respectively, as $\omega\to 0$. Then, the first part of the statement can be shown under the restriction (96). Let us next examine the second term on the rhs of Eq. (102), which reads for $r\geqslant 1$,

$$\left\|\widetilde{R}^{\pm}(\omega)\frac{\mathrm{d}^r}{\mathrm{d}\omega^r}[\omega+\lambda^2 D(\omega)\pm\lambda^2\pi i\Gamma(\omega)]\widetilde{R}^{\pm}(\omega)-\frac{\mathrm{d}^r}{\mathrm{d}\omega^r}S_1(\omega)\right\|$$

$$\leqslant 2\|\widetilde{R}^{\pm}(\omega)-(K(0))^{-1}\|\left\|\frac{\mathrm{d}^r}{\mathrm{d}\omega^r}[\omega+\lambda^2 D(\omega)\pm\lambda^2\pi i\Gamma(\omega)]\right\|\|\widetilde{R}^{\pm}(\omega)\|$$

$$=O(\omega^{2n_b-r}(\log\omega)^{1+\theta(n_b-r)}),\quad or\quad \begin{cases} O(\omega^{n_a+[n_a-r]^+}) & (r<n_b)\\ O(\omega^{n_a+n_b-r}(\log\omega)^{\theta(n_b-r)}) & (r\geqslant n_b),\end{cases} \tag{109}$$

for $n_b\leqslant n_a$ or $n_b>n_a$, respectively, as $\omega\to 0$. We here used Eq. (101) with $N=0$. Therefore, substituting Eqs. (103), (104), and (109) into Eq. (102), one has for $r\geqslant 1$,

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\{\widetilde{R}^{\pm}(\omega) - S_1(\omega)\} \right\|$$

$$= O(\omega^{2n_b - r}(\log \omega)^{1+\theta(n_b+1-r)}), \quad \text{or} \quad \begin{cases} O(\omega^{[2n_a - r]^+}) & (r \leqslant n_a + n_b - 1) \\ O(\omega^{n_a+n_b-r}(\log \omega)^{\theta(n_a+n_b-r)}) & (n_a + n_b \leqslant r \leqslant 2n_b) \end{cases} \tag{110}$$

for $n_b \leqslant n_a$ or $n_b > n_a$, respectively, as $\omega \to 0$. Note that this estimation is also valid for $r=0$ because it reproduces Eq. (101) for $N=1$.

Let us now evaluate the last term in Eq. (100). For $r \geqslant 0$, we have

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\left\{S_1(\omega) - (K(0))^{-1} - (K(0))^{-1}[-\omega^{n_b}(\log \omega)\lambda^2\Gamma_{n_b} + \omega^{n_a}\lambda^2\widetilde{A}_{n_a} \pm \lambda^2\pi i\omega^{n_b}\Gamma_{n_b}](K(0))^{-1}\right\} \right\|$$

$$\leqslant \|(K(0))^{-1}\|^2 \left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}[-(\log \omega)\lambda^2(\Gamma(\omega) - \omega^{n_b}\Gamma_{n_b}) + \lambda^2(\widetilde{A}(\omega) - \omega^{n_a}\widetilde{A}_{n_a})) \pm \lambda^2\pi i(\Gamma(\omega) - \omega^{n_b}\Gamma_{n_b})] \right\|$$

$$= O(\omega^{n_b+1-r}(\log \omega)^{\theta(n_b+1-r)}), \quad \text{or} \quad \begin{cases} O(\omega^{[n_a+1-r]^+}) & (0 \leqslant r \leqslant n_b) \\ O(\omega^{n_b+1-r}(\log \omega)^{\theta(n_b+1-r)}) & (r \geqslant n_b + 1) \end{cases}, \tag{111}$$

for $n_b \leqslant n_a$ or $n_b > n_a$, respectively, as $\omega \to 0$ for any $r \geqslant 0$. We here used that for $r \geqslant 0$,

$$\frac{\mathrm{d}^r(\Gamma(\omega) - \omega^{n_b}\Gamma_{n_b})}{\mathrm{d}\omega^r} = O(\omega^{[n_b+1-r]^+}), \quad \frac{\mathrm{d}^r(\log \omega)(\Gamma(\omega) - \omega^{n_b}\Gamma_{n_b})}{\mathrm{d}\omega^r} = O(\omega^{n_b+1-r}(\log \omega)^{\theta(n_b+1-r)}) \tag{112}$$

as $\omega \to 0$, and so forth. Thus, setting Eqs. (110) and (111) into Eq. (100), we conclude that

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\{\widetilde{R}^{\pm}(\omega) - (K(0))^{-1} - (K(0))^{-1}[-\omega^{n_b}(\log \omega)\lambda^2\Gamma_{n_b} + \omega^{n_a}\lambda^2\widetilde{A}_{n_a} \pm \lambda^2\pi i\omega^{n_b}\Gamma_{n_b}](K(0))^{-1}\} \right\|$$

$$= \begin{cases} O(\omega^{2n_b-r}(\log \omega)^{1+\theta(n_b+1-r)}) & (r \geqslant 0, n_b = 1) \\ O(\omega^{n_b+1-r}(\log \omega)^{\theta(n_b+1-r)}) & (r \geqslant 0, n_b \geqslant 2), \end{cases}$$

$$\text{or} \begin{cases} O(\omega^{[n_a+1-r]^+}) & (0 \leqslant r \leqslant n_b) \\ O(\omega^{n_b+1-r}(\log \omega)^{\theta(n_b+1-r)}) & (n_b + 1 \leqslant r \leqslant 2n_b), \end{cases} \tag{113}$$

for $n_b \leqslant n_a$ or $n_b > n_a$, respectively, as $\omega \to 0$. By taking into account the restriction (96), we can show the last part of the lemma. □

To estimate the long time behavior of the reduced time evolution operator, the above-mentioned lemma seems not precisely appropriate because the reduced time evolution operator is obtained from the Fourier transform of the imaginary part of $\widetilde{R}^+(\omega)$, not from $\widetilde{R}^+(\omega)$ itself, which is explained in the next section. Hence, the following lemma is more appropriate for our purpose.

Lemma V.2: *Assume that* 0 *is a regular point for H. Then the rth derivative of* $\mathrm{Im}\,\widetilde{R}^+(\omega) := (\widetilde{R}^+(\omega) - \widetilde{R}^-(\omega))/2i$ *is approximated by that of*

$$(K(0))^{-1}\lambda^2\pi\omega^{n_b}(\Gamma_{n_b} + \omega\Gamma_{n_b+1} + \omega^2\Gamma_{n_b+2})(K(0))^{-1}, \tag{114}$$

in the sense that for $0 \leqslant r \leqslant n_b + 1$ *the remainder is estimated as*

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\{\mathrm{Im}\,\tilde{R}^+(\omega) - (K(0))^{-1}\lambda^2\pi\omega^{n_b}(\Gamma_{n_b} + \omega\Gamma_{n_b+1} + \omega^2\Gamma_{n_b+2})(K(0))^{-1}\} \right\|$$

$$= O(\omega^{2-r}\log\omega) \quad \text{or} \quad O(\omega^{1+n_b-r}), \tag{115}$$

for $n_b=1$, *or* $n_b\geqslant 2$, *respectively*, *as* $\omega\to 0$. *For* $r=n_b+2$, *the estimation is replaced by* $O(\omega^{-1})$ *for* $n_b=1$, $O(\log\omega)$ *for* $n_b=2$, *or* $O(1)$ *for* $n_b\geqslant 3$, *respectively*, *as* $\omega\to 0$.

Proof: Since $\mathrm{Im}\,\tilde{R}^+(\omega)=\lambda^2\pi\tilde{R}^+(\omega)\Gamma(\omega)\tilde{R}^-(\omega)$, one has

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}\omega^r}\{\mathrm{Im}\,\tilde{R}^+(\omega) - (K(0))^{-1}\lambda^2\pi\omega^{n_b}(\Gamma_{n_b} + \omega\Gamma_{n_b+1} + \omega^2\Gamma_{n_b+2})(K(0))^{-1}\} \right\| \tag{116}$$

$$\leqslant \lambda^2\pi \sum_{\substack{s\geqslant 0,t\geqslant 0,u\geqslant 0,\\ (s+t+u=r)}}^{r} [F_1(s,t,u) + F_2(s,t,u) + F_3(s,t,u)], \tag{117}$$

with

$$F_1(s,t,u) = C_{stu}\left\| \frac{\mathrm{d}^s\tilde{R}^+(\omega)}{\mathrm{d}\omega^s} \right\| \left\| \frac{\mathrm{d}^t\Gamma(\omega)}{\mathrm{d}\omega^t} \right\| \left\| \frac{\mathrm{d}^u}{\mathrm{d}\omega^u}\{\tilde{R}^-(\omega) - (K(0))^{-1}\} \right\|, \tag{118}$$

$$F_2(s,t,u) = C_{stu}\left\| \frac{\mathrm{d}^s\tilde{R}^+(\omega)}{\mathrm{d}\omega^s} \right\| \left\| \frac{\mathrm{d}^t}{\mathrm{d}\omega^t}\{\Gamma(\omega) - \omega^{n_b}(\Gamma_{n_b} + \omega\Gamma_{n_b+1} + \omega^2\Gamma_{n_b+2})\} \right\| \left\| \frac{\mathrm{d}^u(K(0))^{-1}}{\mathrm{d}\omega^u} \right\|, \tag{119}$$

$$F_3(s,t,u) = C_{stu}\left\| \frac{\mathrm{d}^s}{\mathrm{d}\omega^s}\{\tilde{R}^+(\omega) - (K(0))^{-1}\} \right\| \left\| \frac{\mathrm{d}^t}{\mathrm{d}\omega^t}\omega^{n_b}(\Gamma_{n_b} + \omega\Gamma_{n_b+1} + \omega^2\Gamma_{n_b+2}) \right\| \left\| \frac{\mathrm{d}^u(K(0))^{-1}}{\mathrm{d}\omega^u} \right\|, \tag{120}$$

where C_{stu}'s are appropriate constants. For $1\leqslant r\leqslant n_b+1$, the summation of the first summand in Eq. (117) can be estimated as

$$\sum_{\substack{s\geqslant 0,t\geqslant 0,u\geqslant 0,\\ (s+t+u=r)}}^{r} F_1(s,t,u) = F_1(0,r,0) + \sum_{t\geqslant 0,u\geqslant 1}^{r} F_1(0,t,u) + \sum_{s\geqslant 1,t\geqslant 0}^{r} F_1(s,t,0) + \sum_{\min\{s,u\}\geqslant 1}^{r} F_1(s,t,u)$$

$$= O(F_1(0,r-1,1)) = O(\omega^{2n_b-r}\log\omega) \qquad \text{or} \quad O(\omega^{n_a+n_b-r}), \tag{121}$$

for $n_b\leqslant n_a$ or $n_b>n_a$, respectively, as $\omega\to 0$. Note that from Eq. (101) for $N=0$ this estimation is valid for $r=0$ too. For $r=n_b+2$, it is estimated as

$$\begin{cases} O(\omega^{n_b-1}\log\omega) & (n_b\geqslant 2) \\ O((\log\omega)^2) & (n_b=1) \end{cases} \quad \text{or } O(\omega^{n_a-1}), \tag{122}$$

for $n_b\leqslant n_a$ or $n_b>n_a$, respectively, as $\omega\to 0$. The summation of the second summand in Eq. (117) for $0\leqslant r\leqslant n_b+3$ is also estimated as

$$\lambda^2\pi \sum_{\substack{s\geqslant 0,t\geqslant 0,u\geqslant 0,\\ (s+t+u=r)}}^{r} F_2(s,t,u) = \sum_{(s+t=r)}^{r} F_2(s,t,0) = O(F_2(0,r,0)) = O(\omega^{n_b+3-r}), \tag{123}$$

both for $n_b \leqslant n_a$ and for $n_b > n_a$, as $\omega \to 0$. The summation of the last summand in Eq. (117) for $0 \leqslant r \leqslant n_b+1$ is estimated as

$$\lambda^2\pi \sum_{\substack{s\geqslant 0,t\geqslant 0,u\geqslant 0,\\ (s+t+u=r)}}^{r} F_3(s,t,0) = \sum_{(s+t=r)}^{r} F_3(s,t,0) = O(F_3(1,r-1,0))$$

$$= O(\omega^{2n_b-r}\log\omega), \quad \text{or} \quad O(\omega^{n_a+n_b-r}), \tag{124}$$

for $n_b \leqslant n_a$ or $n_a < n_b$, respectively, as $\omega \to 0$. For $r = n_b+2$, the estimation is replaced by

$$O(\omega^{n_b-2}(\log\omega)^{\theta(n_b-2)}), \quad \text{or} \quad \begin{cases} O(\omega^{[n_a-2]^+}) & (n_b \geqslant 3) \\ O(\log\omega) & (n_b = 2), \end{cases} \tag{125}$$

for $n_b \leqslant n_a$ or $n_a < n_b$, respectively, as $\omega \to 0$. Then, by summarizing the above-noted estimations from Eqs. (121) and (125), and by taking into account the restriction (96) again, the proof of the lemma is completed. □

B. The exceptional case of the first kind

In this case, we first remember that from the discussion around Eq. (50) it necessarily holds that $\Gamma_1 \neq 0$, i.e., $n_b = 1$ in Eq. (93).

Lemma V.3: *Assume that* 0 *is an exceptional point of the first kind for H. the* 0*th and the first derivative of* $\tilde{R}(z)$ *are approximated by those of a finite series*

$$\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} + \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1Q_1)(Q_1\Gamma_1Q_1)^{-1}, \tag{126}$$

that is, it is shown that

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}z^r}\left[\tilde{R}(z) - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} - \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1Q_1) \right.\right.$$
$$\left.\left. \times(Q_1\Gamma_1Q_1)^{-1} \right] \right\| = O(z^{-1}(\log z)^{-3}) \quad \textit{for} \quad r=0, \quad \textit{or } O(z^{-2}(\log z)^{-3}) \quad \textit{for} \quad r=1, \tag{127}$$

as $z \to 0$.

Proof: Let us first consider the quantity that

$$\left\| \frac{\mathrm{d}^r}{\mathrm{d}z^r}\left[\tilde{R}(z) - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} - \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1Q_1) \right.\right.$$
$$\left.\left. \times(Q_1\Gamma_1Q_1)^{-1} \right] \right\| \leqslant \left\| \frac{\mathrm{d}^r}{\mathrm{d}z^r}[\tilde{R}(z) - Q_1\tilde{R}(z)Q_1] \right\| + \left\| \frac{\mathrm{d}^r}{\mathrm{d}z^r}\left[Q_1\tilde{R}(z)Q_1 - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} \right.\right.$$
$$\left.\left. - \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1Q_1)(Q_1\Gamma_1Q_1)^{-1} \right] \right\|. \tag{128}$$

For $r=0$, the first term on the rhs of Eq. (128) is estimated as follows:

$$\|\tilde{R}(z) - Q_1\tilde{R}(z)Q_1\| \leqslant \|Q_0\tilde{R}(z)Q_0\| + \|Q_0\tilde{R}(z)Q_1\| + \|Q_1\tilde{R}(z)Q_0\| = O(1), \tag{129}$$

as $z \to 0$, where Eqs. (68)–(70) are used. For $r=1$, one obtains

$$\left\| \frac{\mathrm{d}\tilde{R}(z)}{\mathrm{d}z} - \frac{\mathrm{d}Q_1\tilde{R}(z)Q_1}{\mathrm{d}z} \right\| \leqslant \left\| \frac{\mathrm{d}Q_0\tilde{R}(z)Q_0}{\mathrm{d}z} \right\| + \left\| \frac{\mathrm{d}Q_0\tilde{R}(z)Q_1}{\mathrm{d}z} \right\| + \left\| \frac{\mathrm{d}Q_1\tilde{R}(z)Q_0}{\mathrm{d}z} \right\| = O(z^{-1}). \tag{130}$$

In fact, by using expression (68) the first term on the rhs of Eq. (130) is estimated as follows:

$$\frac{\mathrm{d}Q_0\tilde{R}(z)Q_0}{\mathrm{d}z} = -Q_0\tilde{R}(z)Q_0\left(\frac{\mathrm{d}E_{00}}{\mathrm{d}z} - \frac{\mathrm{d}E_{01}}{\mathrm{d}z}E_{11}^{-1}E_{10} - E_{01}\frac{\mathrm{d}E_{11}^{-1}}{\mathrm{d}z}E_{10} - E_{01}E_{11}^{-1}\frac{\mathrm{d}E_{10}}{\mathrm{d}z} \right) Q_0\tilde{R}(z)Q_0 \tag{131}$$

$$= O(\log z). \tag{132}$$

Four derivatives in Eq. (131) have the same order, which can be shown from the use of Eqs. (61), (63), (65), and (67): We here note that

$$\frac{\mathrm{d}E_{00}}{\mathrm{d}z} = O(\log z), \quad \frac{\mathrm{d}E_{01}}{\mathrm{d}z} = O(\log z), \quad \frac{\mathrm{d}E_{10}}{\mathrm{d}z} = O(\log z), \tag{133}$$

and from Eqs. (61) and (63)

$$\frac{\mathrm{d}E_{11}^{-1}}{\mathrm{d}z} = E_{11}^{-1}\left\{ \frac{\mathrm{d}}{\mathrm{d}z}Q_1\{z + \lambda^2[A(z) - \log z\Gamma(z) + \pi i\Gamma(z)]\}Q_1 \right\}E_{11}^{-1} \tag{134}$$

$$= E_{11}^{-1}Q_1\left\{ 1 + \lambda^2\left[\frac{\mathrm{d}A(z)}{\mathrm{d}z} - \Gamma(z)/z - \log z\frac{\mathrm{d}\Gamma(z)}{\mathrm{d}z} + \pi i\frac{\mathrm{d}\Gamma(z)}{\mathrm{d}z} \right] \right\}Q_1E_{11}^{-1} \tag{135}$$

$$= O(z^{-2}(\log z)^{-1}). \tag{136}$$

In the same way, the second term in the rhs of Eq. (130) is also estimated as follows:

$$\frac{\mathrm{d}Q_0\tilde{R}(z)Q_1}{\mathrm{d}z} = -\left(\frac{\mathrm{d}E_{00}^{-1}}{\mathrm{d}z}E_{01} + E_{00}^{-1}\frac{\mathrm{d}E_{01}}{\mathrm{d}z} \right)Q_1\tilde{R}Q_1 + E_{00}^{-1}E_{01}Q_1\tilde{R}Q_1\left(\frac{\mathrm{d}E_{11}}{\mathrm{d}z} - \frac{\mathrm{d}E_{10}}{\mathrm{d}z}E_{00}^{-1}E_{01} - E_{10}\frac{\mathrm{d}E_{00}^{-1}}{\mathrm{d}z}E_{01} - E_{10}E_{00}^{-1}\frac{\mathrm{d}E_{01}}{\mathrm{d}z} \right)Q_1\tilde{R}Q_1 \tag{137}$$

$$= O(z^{-1}), \tag{138}$$

where we used Eq. (69) and the fact that

$$\frac{\mathrm{d}E_{00}^{-1}}{\mathrm{d}z} = O(\log z), \quad \frac{\mathrm{d}E_{11}}{\mathrm{d}z} = O(\log z). \tag{139}$$

In a similar manner, we can also show

$$\frac{\mathrm{d}Q_1\tilde{R}(z)Q_0}{\mathrm{d}z} = O(z^{-1}). \tag{140}$$

Let us next consider the last term in Eq. (128). For $r=0$, it reads

$$\left\| Q_1\tilde{R}(z)Q_1 - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} - \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1Q_1) \times(Q_1\Gamma_1Q_1)^{-1}\right\| \tag{141}$$

$$\leqslant \left\| E_{11}^{-1} - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} - \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1Q_1) \times(Q_1\Gamma_1Q_1)^{-1}\right\| + \left\|(Q_{11}-E_{11}^{-1}E_{10}E_{00}^{-1}E_{01})^{-1}E_{11}^{-1}-E_{11}^{-1}\right\| \tag{142}$$

$$\leqslant \left\| \tilde{E}_{11}(z)\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} - \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1Q_1) \times(Q_1\Gamma_1Q_1)^{-1}\right\| + \left\|\sum_{j=2}^{\infty}(\tilde{E}_{11}(z))^j\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1}\right\| + O(1) \tag{143}$$

$$= O(z^{-1}(\log z)^{-3}), \tag{144}$$

where in the second inequality we used Eq. (62) and that

$$\left\|(Q_{11}-E_{11}^{-1}E_{10}E_{00}^{-1}E_{01})^{-1}E_{11}^{-1}-E_{11}^{-1}\right\| \leqslant \frac{\left\|E_{11}^{-1}E_{10}E_{00}^{-1}E_{01}\right\|\left\|E_{11}^{-1}\right\|}{1-\left\|E_{11}^{-1}E_{10}E_{00}^{-1}E_{01}\right\|} = O(1), \tag{145}$$

as $z\to 0$. Substituting Eqs. (129) and (144) into Eq. (128), we can obtain the estimation (127) for $r=0$.

For $r=1$, we can obtain

$$\left\| \frac{\mathrm{d}}{\mathrm{d}z}\left[Q_1\tilde{R}(z)Q_1 - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} - \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1Q_1) \times(Q_1\Gamma_1Q_1)^{-1}\right]\right\| \tag{146}$$

$$\leqslant \left\| \frac{\mathrm{d}}{\mathrm{d}z}\left[E_{11}^{-1} - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1Q_1)^{-1} - \frac{1}{\lambda^4 z(\log z)^2}(Q_1\Gamma_1Q_1)^{-1}(Q_1+\lambda^2Q_1A_1Q_1 + \lambda^2\pi i Q_1\Gamma_1Q_1)(Q_1\Gamma_1Q_1)^{-1}\right]\right\| + \left\| \frac{\mathrm{d}}{\mathrm{d}z}\left\{(Q_{11}-E_{11}^{-1}E_{10}E_{00}^{-1}E_{01})^{-1}E_{11}^{-1}-E_{11}^{-1}\right\}\right\| \tag{147}$$

$$\leqslant \left\| E_{11}^{-1}\left\{ \frac{\mathrm{d}}{\mathrm{d}z} Q_1\{z+\lambda^2[A(z)+\pi i\Gamma(z)]\}Q_1 \right\} E_{11}^{-1} - \frac{1}{\lambda^4 z^2 (\log z)^2}(Q_1\Gamma_1 Q_1)^{-1}(Q_1 \right.$$
$$\left. + \lambda^2 Q_1 A_1 Q_1 + \lambda^2 \pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1} \right\| + \left\| - E_{11}^{-1}\left\{ \frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z) Q_1\Gamma(z)Q_1 \right\} E_{11}^{-1} \right.$$
$$- \frac{\mathrm{d}}{\mathrm{d}z}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1} - z\left\{ \frac{\mathrm{d}}{\mathrm{d}z}\frac{1}{\lambda^4 z^2(\log z)^2} \right\}(Q_1\Gamma_1 Q_1)^{-1}(Q_1 + \lambda^2 Q_1 A_1 Q_1$$
$$\left. + \lambda^2 \pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1} \right\| + \left\| \{(Q_{11} - E_{11}^{-1}E_{10}E_{00}^{-1}E_{01})^{-1} - Q_{11}\}\frac{\mathrm{d}E_{11}^{-1}}{\mathrm{d}z} \right\|$$
$$+ \left\| \left\{ \frac{\mathrm{d}}{\mathrm{d}z}(Q_{11} - E_{11}^{-1}E_{10}E_{00}^{-1}E_{01})^{-1} \right\} E_{11}^{-1} \right\| \tag{148}$$

$$= O(z^{-2}(\log z)^{-3}), \tag{149}$$

where we used the expression for $\mathrm{d}E_{11}^{-1}/\mathrm{d}z$ in Eq. (134). Actually, the first term in Eq. (148) is estimated as

$$\left\| E_{11}^{-1}\left\{ \frac{\mathrm{d}}{\mathrm{d}z} Q_1\{z+\lambda^2[A(z)+\pi i\Gamma(z)]\}Q_1 \right\} E_{11}^{-1} - \frac{1}{\lambda^4 z^2(\log z)^2}(Q_1\Gamma_1 Q_1)^{-1}(Q_1 + \lambda^2 Q_1 A_1 Q_1 \right.$$
$$\left. + \lambda^2 \pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1} \right\| \leqslant \left\| E_{11}^{-1} - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1} \right\| \left\| \frac{\mathrm{d}}{\mathrm{d}z} Q_1\{z+\lambda^2[A(z) \right.$$
$$\left. + \pi i\Gamma(z)]\}Q_1 \right\| \|E_{11}^{-1}\| + \frac{\|(Q_1\Gamma_1 Q_1)^{-1}\|}{\lambda^2|z\log z|} \left\| \frac{\mathrm{d}}{\mathrm{d}z} Q_1\{z+\lambda^2[A(z)+\pi i\Gamma(z)]\}Q_1 \right\| \left\| E_{11}^{-1} \right\|$$
$$\left. - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1} \right\| + \frac{\|(Q_1\Gamma_1 Q_1)^{-1}\|^2}{\lambda^4 z^2(\log z)^2} \left\| \frac{\mathrm{d}}{\mathrm{d}z} Q_1\{z+\lambda^2[A(z)+\pi i\Gamma(z)]\}Q_1 - Q_1(1+\lambda^2 A_1 \right.$$
$$\left. + \lambda^2 \pi i\Gamma_1)Q_1 \right\| \tag{150}$$

$$= O(z^{-2}(\log z)^{-3}), \tag{151}$$

as $z \to 0$. On the other hand, the second term in Eq. (148) is slightly complicated to evaluate:

$$\left\| - E_{11}^{-1}\left\{ \frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z) Q_1\Gamma(z)Q_1 \right\} E_{11}^{-1} - \frac{\mathrm{d}}{\mathrm{d}z}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1} \right.$$
$$\left. - z\left\{ \frac{\mathrm{d}}{\mathrm{d}z}\frac{1}{\lambda^4 z^2(\log z)^2} \right\}(Q_1\Gamma_1 Q_1)^{-1}(Q_1 + \lambda^2 Q_1 A_1 Q_1 + \lambda^2 \pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1} \right\| \tag{152}$$

$$\leqslant \left\| - \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{ \frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z) Q_1\Gamma(z)Q_1 \right\} \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1} - \frac{\mathrm{d}}{\mathrm{d}z}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1} \right.$$
$$- \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{ \frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z) Q_1\Gamma(z)Q_1 \right\} \widetilde{E}_{11}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}$$
$$\left. - \widetilde{E}_{11}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{ \frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z) Q_1\Gamma(z)Q_1 \right\} \frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1} \right.$$

$$+ z\frac{2}{(\lambda^2 z\log z)^3}\left(\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2 z\log z\right)(Q_1\Gamma_1 Q_1)^{-1}(Q_1+\lambda^2 Q_1 A_1 Q_1+\lambda^2\pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1}\Big\|$$

$$+\left\|\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}\sum_{j=2}^{\infty}\tilde{E}_{11}^{j}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\right\| \tag{153}$$

$$+\left\|\tilde{E}_{11}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}\sum_{j=1}^{\infty}\tilde{E}_{11}^{j}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\right\|$$

$$+\left\|\sum_{j=2}^{\infty}\tilde{E}_{11}^{j}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}E_{11}^{-1}\right\|$$

$$\begin{aligned}\leqslant&\left\|-\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2\log z Q_1\Gamma(z)Q_1\right\}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\right.\\&\left.-\frac{\mathrm{d}}{\mathrm{d}z}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\right\|\\&+\left\|-\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}\tilde{E}_{11}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\right.\\&\left.+z\frac{1}{(\lambda^2 z\log z)^3}\left(\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2 z\log z\right)(Q_1\Gamma_1 Q_1)^{-1}z(Q_1+\lambda^2 Q_1 A_1 Q_1+\lambda^2\pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1}\right\|\\&+\left\|-\tilde{E}_{11}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\right.\\&\left.+z\frac{1}{(\lambda^2 z\log z)^3}\left(\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2 z\log z\right)(Q_1\Gamma_1 Q_1)^{-1}(Q_1+\lambda^2 Q_1 A_1 Q_1+\lambda^2\pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1}\right\|\\&+O(z^{-2}(\log z)^{-3})\end{aligned} \tag{154}$$

$$=O(z^{-2}(\log z)^{-3}). \tag{155}$$

In fact, the first term in Eq. (154) reads

$$\begin{aligned}&\left\|-\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2\log z Q_1\Gamma(z)Q_1\right\}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}-\frac{\mathrm{d}}{\mathrm{d}z}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\right\|\\&\quad\leqslant\left\|-(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}+\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2 z(\log z)Q_1\right\|\frac{\|(Q_1\Gamma_1 Q_1)^{-1}\|}{(\lambda^2 z\log z)^2}\end{aligned} \tag{156}$$

$$\begin{aligned}\leqslant&\lambda^2\left\{\left\|-(Q_1\Gamma_1 Q_1)^{-1}Q_1\frac{\Gamma(z)}{z}Q_1+Q_1\right\|+\left\|-(Q_1\Gamma_1 Q_1)^{-1}Q_1\frac{\mathrm{d}\Gamma(z)}{\mathrm{d}z}Q_1+Q_1\right\|(\log z)\right\}\\&\times\|(Q_1\Gamma_1 Q_1)^{-1}\|\frac{1}{\lambda^2 z\log z}\end{aligned} \tag{157}$$

$$=O((z\log z)^{-1}). \tag{158}$$

The second term in Eq. (154) also reads

$$\left\| -\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}\tilde{E}_{11}\frac{1}{\lambda^2 z\log z}(Q_1\Gamma_1 Q_1)^{-1}\right.$$
$$\left. +z\frac{1}{(\lambda^2 z\log z)^3}\left(\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2 z\log z\right)(Q_1\Gamma_1 Q_1)^{-1}(Q_1+\lambda^2 Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1}\right\|$$
$$\leqslant \|(Q_1\Gamma_1 Q_1)^{-1}\|\left\|-\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}(Q_1\Gamma_1 Q_1)^{-1}\{zQ_1+\lambda^2 Q_1\{A(z)-\log z[\Gamma(z)-z\Gamma_1]\right.\right.$$
$$\left.\left. +\pi i\Gamma(z)\}Q_1\}+z\left(\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2 z\log z\right)(Q_1+\lambda^2 Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1 Q_1)\right\|\frac{\|(Q_1\Gamma_1 Q_1)^{-1}\|}{(\lambda^2 z\log z)^3} \tag{159}$$

$$\leqslant \|(Q_1\Gamma_1 Q_1)^{-1}\|\left\|\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}(Q_1\Gamma_1 Q_1)^{-1}\right\|\left\|-\{zQ_1+\lambda^2 Q_1\{A(z)-\log z[\Gamma(z)-z\Gamma_1]\right.\right.$$
$$\left.\left. +\pi i\Gamma(z)\}Q_1\}+z(Q_1+\lambda^2 Q_1A_1Q_1+\lambda^2\pi i Q_1\Gamma_1 Q_1)\right\|\frac{\|(Q_1\Gamma_1 Q_1)^{-1}\|}{(\lambda^2 z\log z)^3}+\|(Q_1\Gamma_1 Q_1)^{-1}\|$$
$$\times\left\|-\left\{\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2(\log z)Q_1\Gamma(z)Q_1\right\}(Q_1\Gamma_1 Q_1)^{-1}+\left(\frac{\mathrm{d}}{\mathrm{d}z}\lambda^2 z\log z\right)Q_1\right\|\left\|z(Q_1+\lambda^2 Q_1A_1Q_1\right.$$
$$\left.+\lambda^2\pi i Q_1\Gamma_1 Q_1)\right\|\frac{\|(Q_1\Gamma_1 Q_1)^{-1}\|}{(\lambda^2 z\log z)^3} \tag{160}$$

$$=O((z\log z)^{-1}), \tag{161}$$

as $z\to 0$. The third term gives the same contribution to the order as the second one does. Furthermore, the last term in Eq. (154) comes from the estimations of the second, third, and last terms in Eq. (153), where each contributes the same order as $O(z^{-2}(\log z)^{-3})$. Therefore, Eq. (155) is proved.

On the other hand, the third term in Eq. (148) reads

$$\left\|\{(Q_{11}-E_{11}^{-1}E_{10}E_{00}^{-1}E_{01})^{-1}-Q_{11}\}\frac{\mathrm{d}E_{11}^{-1}}{\mathrm{d}z}\right\|\leqslant\frac{\left\|E_{11}^{-1}E_{10}E_{00}^{-1}E_{01}\right\|}{1-\left\|E_{11}^{-1}E_{10}E_{00}^{-1}E_{01}\right\|}\left\|\frac{\mathrm{d}E_{11}^{-1}}{\mathrm{d}z}\right\|=O(z^{-1}), \tag{162}$$

as $z\to 0$, where Eqs. (63), (65), (67), and (136) are used. In the same way, the last term in Eq. (148) reads

$$\left\|E_{11}^{-1}\frac{\mathrm{d}}{\mathrm{d}z}(Q_{11}-E_{11}^{-1}E_{10}E_{00}^{-1}E_{01})^{-1}\right\|\leqslant\|E_{11}^{-1}\|\|(Q_{11}-E_{11}^{-1}E_{10}E_{00}^{-1}E_{01})^{-1}\|^2\left[\left\|\frac{\mathrm{d}E_{11}^{-1}}{\mathrm{d}z}E_{10}E_{00}^{-1}E_{01}\right\|\right.$$
$$\left.+\left\|E_{11}^{-1}\frac{\mathrm{d}E_{10}}{\mathrm{d}z}E_{00}^{-1}E_{01}\right\|+\left\|E_{11}^{-1}E_{10}E_{00}^{-1}\frac{\mathrm{d}E_{01}}{\mathrm{d}z}\right\|+\left\|E_{11}^{-1}E_{10}\frac{\mathrm{d}E_{00}^{-1}}{\mathrm{d}z}E_{01}\right\|\right] \tag{163}$$

$$=O(z^{-1}\log z), \tag{164}$$

as $z\to 0$. By substituting Eqs. (151), (155), (162), and (164) into Eq. (148), one finally obtains Eq. (149). We can now show Eq. (127) for $r=1$ by setting Eqs. (130) and (149) into Eq. (128). □

If we start with expression (72), we obtain the following lemma instead of Lemma V.3.

Lemma V.4: *Assume that* 0 *is an exceptional point of the first kind for* H. *Then the* 0*th and the first derivative* of $\tilde{R}(z)$ *are approximated by those of a finite series*

$$\frac{1}{\lambda^2 z(\log z - 2\pi i)}(Q_1\Gamma_1 Q_1)^{-1} + \frac{1}{\lambda^4 z(\log z - 2\pi i)^2}(Q_1\Gamma_1 Q_1)^{-1}(Q_1 + \lambda^2 Q_1 A_1 Q_1 - \lambda^2 \pi i Q_1\Gamma_1 Q_1) \times (Q_1\Gamma_1 Q_1)^{-1}, \tag{165}$$

that is, it is shown that

$$\left\| \frac{d^r}{dz^r}\left[\tilde{R}(z) - \frac{1}{\lambda^2 z(\log z - 2\pi i)}(Q_1\Gamma_1 Q_1)^{-1} - \frac{1}{\lambda^4 z(\log z - 2\pi i)^2}(Q_1\Gamma_1 Q_1)^{-1}(Q_1 + \lambda^2 Q_1 A_1 Q_1 - \lambda^2 \pi i Q_1\Gamma_1 Q_1)(Q_1\Gamma_1 Q_1)^{-1} \right] \right\| = O(z^{-1}(\log z - 2\pi i)^{-3}) \quad for \quad r = 0, \ or \ O(z^{-2}(\log z - 2\pi i)^{-3}) \quad for \ r = 1, \tag{166}$$

as $z \to 0$.

VI. THE REDUCED TIME EVOLUTION OPERATOR

In this section, we show that the reduced time evolution operator is expressed by the Fourier transform of the imaginary part of the reduced resolvent both in the regular case and the exceptional case of the first kind. We here define the reduced time evolution operator by the $N \times N$ matrix $\tilde{U}(t)$ of the components $\tilde{U}_{mn}(t) := \langle m | Pe^{-itH}P | n \rangle$, where $P = E((0,\infty))$ and $\{E(B) | B \in \mathbb{B}\}$ is the spectral measure of H, which is a family of the projection operator. $\mathbb{B}$ is the Borel field of $\mathbb{R}$.

Lemma VI.1: *We assume that Eq.* (23) *holds so that there is no positive eigenvalue. Then, for the system with the rational form-factor* (9), *it holds that*

$$\tilde{U}(t) = \frac{1}{\pi}\int_{(0,\infty)} e^{-it\omega} \mathrm{Im}\, \tilde{R}^+(\omega) d\omega = \lim_{r \to +0} \frac{1}{\pi}\int_r^\infty e^{-it\omega} \mathrm{Im}\, \tilde{R}^+(\omega) d\omega, \tag{167}$$

both in the regular case and the exceptional case of the first kind, where

$$\mathrm{Im}\, \tilde{R}^+(\omega) := \frac{1}{2i}[\tilde{R}^+(\omega) - \tilde{R}^-(\omega)], \tag{168}$$

which is sometimes called the spectral density.

Proof: Let us remember that the matrix $\tilde{U}(t)$ is expressed by the spectral measure as

$$\tilde{U}_{mn}(t) = \int_{(0,\infty)} e^{-it\lambda} d\langle m | E(\lambda) | n \rangle = \int_{(0,\infty)} e^{-it\lambda} d\tilde{E}_{mn}(\lambda), \tag{169}$$

where $\tilde{E}(B)$ is the matrix of the components $\langle m | E(B) | n \rangle$. Therefore, what we first should do is to clarify the relation between $\mathrm{Im}\, \tilde{R}^+(\omega)$ and $\tilde{E}(\lambda)$. Resorting to Stone's formula between $E(B)$ and $R(z)$, we clearly see

$$\frac{1}{2}[\tilde{E}([a,b]) + \tilde{E}((a,b))] = \lim_{\epsilon \to +0} \frac{1}{2\pi i}\int_a^b [\tilde{R}(\omega + i\epsilon) - \tilde{R}(\omega - i\epsilon)] d\omega, \tag{170}$$

for $a, b \in \mathbb{R}$ with $a < b$. Under the assumption (23), Lebesgue's dominated convergence theorem and the proof of Lemma III.1 tell us that the exchange between the limit and the integration in Eq. (170) is allowed for $[a,b] \subset (0,\infty)$. If $[a,b] \subset (-\infty, 0) \setminus \sigma(H)$, then $\tilde{R}^\pm(\omega) = \tilde{R}(\omega)$, and thus $\tilde{E}([a,b]) = \tilde{E}((a,b)) = 0$. In addition, by the continuity of $\tilde{R}^\pm(\omega)$, Eq. (170) tells us that $\tilde{E}(\{a\}) = 0$ for all $a > 0$, which leads to

$$\widetilde{E}((a,b)) = \widetilde{E}([a,b]) = \frac{1}{\pi}\int_a^b \mathrm{Im}\,\widetilde{R}^+(\omega)\mathrm{d}\omega, \tag{171}$$

for all a,b with $b>a>0$.

Let us now consider the regular case and in particular the validity of the expression (171) for the interval including the origin. In this case, $\widetilde{R}^{\pm}(0) \coloneqq \lim_{\omega\to+0}\widetilde{R}^{\pm}(\omega)$ exists to be finite. Furthermore, $\lim_{\omega\to\infty}\widetilde{R}^{\pm}(\omega)=0$ from Lemma III.2. Thus, $\widetilde{R}^{\pm}(\omega)$ is uniformly continuous on $(0,\infty)$. Therefore, we can take the limit of Eq. (171) as $a\to+0$ to obtain $\lim_{a\to+0}E([a,b])=E((0,b])$. We next see that all components of $\mathrm{Im}\,\widetilde{R}^+(\omega)$ are integrable, i.e., belong to $L^1((0,\infty))$. Suppose that $|\psi\rangle \in \mathbb{C}^N$,then $\langle\psi|\widetilde{E}((0,\lambda))|\psi\rangle$ is positive and a monotonically increasing function of λ, and it is also differentiable in this case. Thus Eq. (171) tells us that $\langle\psi|\mathrm{Im}\,\widetilde{R}^+(\omega)|\psi\rangle \geqslant 0$. In addition,

$$\|\psi\|^2 \geqslant \lim_{\lambda\to\infty}\langle\psi|\widetilde{E}((0,\lambda))|\psi\rangle = \lim_{\lambda\to\infty}\frac{1}{\pi}\int_0^\lambda \langle\psi|\mathrm{Im}\,\widetilde{R}^+(\omega)|\psi\rangle\mathrm{d}\omega = \frac{1}{\pi}\int_0^\infty \langle\psi|\mathrm{Im}\,\widetilde{R}^+(\omega)|\psi\rangle\mathrm{d}\omega. \tag{172}$$

Hence, from the monotonic convergence theorem, we see that $\langle\psi|\mathrm{Im}\,\widetilde{R}^+(\omega)|\psi\rangle \in L^1((0,\infty))$. From this fact and the use of the polarization identity, we can prove that all components of the matrix $\mathrm{Im}\,\widetilde{R}^+(\omega)$ are integrable. Thus, extending the rhs of Eq. (171) to arbitrary $B\in\{B \in \mathbb{B}|B\subset(0,\infty)\}$, $\int_B \mathrm{Im}\,\widetilde{R}^+(\omega)\mathrm{d}\omega$ defines a measure. We can now see from Eq. (171) and from E. Hopf's extension theorem that

$$\widetilde{E}(B) = \frac{1}{\pi}\int_B \mathrm{Im}\,\widetilde{R}^+(\omega)\mathrm{d}\omega \tag{173}$$

holds for all $B\in\{B\in\mathbb{B}|B\subset(0,\infty)\}$. Note that this expression means that the restriction of $\widetilde{E}_{mn}(B)$ to $\{B\in\mathbb{B}|B\subset(0,\infty)\}$ is absolutely continuous. Therefore, rewriting of $\widetilde{U}(t)$ in Eq. (169) into (167) is straightforward.

In the exceptional case of the first kind, from the assumption (23), $\widetilde{R}^{\pm}(\omega)$ is continuous on $(0,\infty)$, while $\widetilde{R}^{\pm}(\omega)=O((\omega\log\omega)^{-1})$ as $\omega\to+0$, so that it is not integrable around 0. See, Eq. (71). However, $\mathrm{Im}\,\widetilde{R}^+(\omega)$ is of the order $O(\omega^{-1}(\log\omega)^{-2})$ from Lemmas V.3 and V.4, and thus it is integrable around 0. Hence, Eq. (173) holds again, and Eq. (167) is valid for this exceptional case. □

We remark that in the case of no negative eigenvalues (point spectrum) of H,[21] the restriction of $\widetilde{U}(t)$ to the continuous energy spectrum is removed because in such a case $P=I$ the identity. Furthermore, the connection between $\widetilde{U}(t)$ and the observables is easily found, e.g., $|\langle\psi|\widetilde{U}(t)|\psi\rangle|^2/\|P|\psi\rangle\|^4$ for $|\psi\rangle\in\mathbb{C}^N$ (or $\mathbb{C}^N\oplus\{0\}$) is the survival probability of $P|\psi\rangle$ which is the probability of finding the system in the state $P|\psi\rangle$ at the later time t, where $P|\psi\rangle$ is just the decaying component of the initial state$|\psi\rangle$.

VII. THE ASYMPTOTIC EXPANSION OF THE REDUCED TIME EVOLUTION OPERATOR

We can finally show the asymptotic formula for $\widetilde{U}(t)$ at long times for the rational form factors satisfying our assumptions. In the following, we assume that Eq. (23) holds, i.e., there is no positive eigenvalue. However, this is not explicitly mentioned in the statements of the theorems. Let us first consider the regular case. For this purpose, according to Lemma V.2, we introduce the remainder $F(\omega)$ in the following way:

$$\frac{1}{\pi}\mathrm{Im}\,\widetilde{R}^{+}(\omega)=\lambda^{2}(K(0))^{-1}\omega^{n_b}(\Gamma_{n_b}+\omega\Gamma_{n_b+1}+\omega^{2}\Gamma_{n_b+2})(K(0))^{-1}+F(\omega), \tag{174}$$

for $\omega>0$.

Theorem VII.1: *Assume that* 0 *is a regular point for H. For a system with the rational form factor* (9) *characterized by the positive integers* n_a *and* n_b *that satisfy that* $n_b\geqslant 2$ *and* $n_a=1$, *the reduced time evolution operator* $\widetilde{U}(t)$ *behaves asymptotically as*

$$\widetilde{U}(t)=\lambda^{2}\frac{\Gamma(1+n_b)}{(it)^{n_b+1}}(K(0))^{-1}\Gamma_{n_b}(K(0))^{-1}+O(t^{-n_b-2}), \tag{175}$$

as $t\to\infty$. *When* $n_b=1$ *and* $n_a\geqslant 1$, *the error term is replaced by* $O(t^{-3}\log t)$.

Proof: We first summarize the several properties of $\mathrm{Im}\,\widetilde{R}^{+}(\omega)$. By Lemma V.2, we see that the remainder $F(\omega)$ in Eq. (174) is arbitrary-times differentiable. Particularly it holds that $\lim_{\omega\to 0}\mathrm{d}^{r}F(\omega)/\mathrm{d}\omega^{r}=0$ for all $r\leqslant n_b$, and

$$\left\|\frac{\mathrm{d}^{n_b+1}F(\omega)}{\mathrm{d}\omega^{n_b+1}}\right\|=O(\log\omega),\quad \text{or } O(1), \tag{176}$$

for $n_b=1$ and $n_a\geqslant 1$, or $n_b\geqslant 2$ and $n_a=1$, respectively, and

$$\left\|\frac{\mathrm{d}^{n_b+2}F(\omega)}{\mathrm{d}\omega^{n_b+2}}\right\|=O(\omega^{-1}),\quad \text{or}\begin{cases} O(1) & (n_b\geqslant 3)\\ O(\log\omega) & (n_b=2)\end{cases}, \tag{177}$$

for $n_b=1$ and $n_a\geqslant 1$, or $n_b\geqslant 2$ and $n_a=1$, respectively, as $\omega\to 0$. On the other hand, we see from Lemma III.2 that $(\mathrm{d}/\mathrm{d}\omega)^{r}\mathrm{Im}\,\widetilde{R}^{+}(\omega)=O(\omega^{-r-1})$ as $\omega\to\infty$. In particular, if $m\geqslant 1$, $(\mathrm{d}/\mathrm{d}\omega)^{m}\mathrm{Im}\,\widetilde{R}^{+}(\omega)$ is integrable on $[\delta,\infty)$ for an arbitrary $\delta>0$.

Let us now split the integral in Eq. (167) into two parts by writing

$$\mathrm{Im}\,\widetilde{R}^{+}(\omega)=\phi(\omega)\mathrm{Im}\,\widetilde{R}^{+}(\omega)+(1-\phi(\omega))\mathrm{Im}\,\widetilde{R}^{+}(\omega), \tag{178}$$

where $\phi\in C_0^{\infty}([0,\infty))$ and satisfies $\phi(\omega)=1$ in a neighborhood of $\omega=0$. Such a function is realized by $f(\omega)=1-\int_0^{\omega}g(x)\mathrm{d}x$, where $g(x)=h(x)/\int_{\mathbf{R}}h(x)\mathrm{d}x$ and $h(x)=\exp(-1/[a^2-(x-\mathrm{d})^2])$ $(|x-\mathrm{d}|<a)$ or 0 $(|x-\mathrm{d}|\geqslant a)$ with $\mathrm{d}>a>0$.

From Lemma 10.1 in Ref. 14 and the above-mentioned discussion, we see that $(1-\phi(\omega))\mathrm{Im}\,\widetilde{R}^{+}(\omega)$ has a contribution of $O(t^{-m})$ to $\widetilde{U}(t)$ for an arbitrary $m\geqslant 1$, i.e., this term decays faster than any negative power of t.

On the other hand, the contribution of $\phi(\omega)\mathrm{Im}\,\widetilde{R}^{+}(\omega)$ to $\widetilde{U}(t)$ gives the main part of the asymptotic expansion. Then, the coefficient of Γ_{n_b}, Γ_{n_b+1}, and Γ_{n_b+2} is given by the form[29]

$$\int_0^{\infty}\phi(\omega)\omega^{q}e^{-it\omega}\mathrm{d}\omega=\sum_{k=0}^{N-1}\frac{1}{(it)^{k+1}}\left.\frac{\mathrm{d}^{k}\omega^{q}\phi(\omega)}{\mathrm{d}\omega^{k}}\right|_{\omega=0}+R_N(t)=\frac{\Gamma(1+q)}{(it)^{1+q}}+R_N(t), \tag{179}$$

for all $N\geqslant 1+q$, where q takes the value n_b, n_b+1, or n_b+2. We here used that

$$\left.\frac{\mathrm{d}^{k}\omega^{q}\phi(\omega)}{\mathrm{d}\omega^{k}}\right|_{\omega=0}=\sum_{j=0}^{\min\{k,q\}}\binom{k}{j}\left.\frac{\mathrm{d}^{j}\omega^{q}}{\mathrm{d}\omega^{j}}\right|_{\omega=0}\left.\frac{\mathrm{d}^{k-j}\phi(\omega)}{\mathrm{d}\omega^{k-j}}\right|_{\omega=0}=\Gamma(1+q)\delta_{kq}, \tag{180}$$

where $\Gamma(1+n)=\int_0^{\infty}x^{n}e^{-x}\mathrm{d}x$ is the gamma function. In addition, the remainder $R_N(t)$ is bounded above by

$$|R_N(t)| \leqslant \frac{1}{t^N}\left|\int_0^\infty \frac{\mathrm{d}^N\omega^q\phi(\omega)}{\mathrm{d}\omega^N}e^{-i\omega t}\mathrm{d}\omega\right| = o(t^{-N}). \tag{181}$$

Note that since all derivatives of $\phi(\omega)$ vanish in the neighborhood of $\omega=0$, Eq. (179) is valid for all $N\geqslant q+1$ and thus $R_N(t)$ decays faster than any negative power of t. Furthermore, we understand, by applying Eq. (B1) in Lemma B.1 directly to $\phi(\omega)F(\omega)$ with the discussion in the first part of this section, that the contribution of the Fourier transform of the remainder $\phi(\omega)F(\omega)$ to $\widetilde{U}(t)$ is

$$O(t^{-3}\log t) \quad \text{or } (t^{-n_b-2}), \tag{182}$$

for $n_b=1$ and $n_a\geqslant 1$, or $n_b\geqslant 2$ and $n_a=1$, respectively, as $\omega\to 0$, where we used the formula of the indefinite integral that $\int(\log\omega)^2\mathrm{d}\omega=\omega[(\log\omega)^2-2\log\omega+2]$. Summarizing the above-noted results, we finally obtain that

$$\left\|\widetilde{U}(t)-\lambda^2(K(0))^{-1}\left[\frac{\Gamma(1+n_b)}{(it)^{n_b+1}}\Gamma_{n_b}+\frac{\Gamma(2+n_b)}{(it)^{n_b+2}}\Gamma_{n_b+1}+\frac{\Gamma(3+n_b)}{(it)^{n_b+3}}\Gamma_{n_b+2}\right](K(0))^{-1}\right\| \leqslant \left\|\frac{1}{\pi}\int_0^\infty(1-\phi(\omega))\mathrm{Im}\,\widetilde{R}^+(\omega)e^{-it\omega}\mathrm{d}\omega\right\| + \left\|\frac{1}{\pi}\int_0^\infty\phi(\omega)F(\omega)e^{-it\omega}\mathrm{d}\omega\right\| + O(t^{-N}) = O(t^{-3}\log t) \text{ or } O(t^{-n_b-2}), \tag{183}$$

for $n_b=1$ and $n_a\geqslant 1$, or $n_b\geqslant 2$ and $n_a=1$, respectively, as $t\to\infty$, where $O(t^{-N})$ is due to the contribution from $R_N(t)$. This is just the asymptotic expansion of $\widetilde{U}(t)$ in the statement. □

It is worth noting that if we resort to Lemma V.1, instead of Eqs. (176) and (177), we have

$$\frac{\mathrm{d}^rF(\omega)}{\mathrm{d}\omega^r} = O(\omega^{2-r}(\log\omega)^{1+\theta(2-r)}), \quad \text{or} \begin{cases} O(\omega^{[2-r]^+}) & (0\leqslant r\leqslant n_b) \\ O(\omega^{n_b+1-r}(\log\omega)^{\theta(n_b+1-r)}) & (r\geqslant n_b+1), \end{cases} \tag{184}$$

for $n_b=1$ and $n_a\geqslant 1$, or $n_b\geqslant 2$ and $n_a=1$, respectively. However, in the latter case, we see that the Fourier transform of $\phi(\omega)F(\omega)$ gives the contribution of the order $O(t^{-n_b-1})$, which is just the same order as that coming from the dominant one. Hence, we can only obtain a useless estimation.

We next show the asymptotic formula for $\widetilde{U}(t)$ at long times for a system with an exceptional point of the first kind. To this end, we write $\mathrm{Im}\,\widetilde{R}^+(\omega)$ with the remainder $F(\omega)$ again as follows:

$$\frac{1}{\pi}\mathrm{Im}\,\widetilde{R}^+(\omega) = \frac{1}{\lambda^2\omega(\log\omega)^2}(Q_1\Gamma_1Q_1)^{-1}+F(\omega). \tag{185}$$

Theorem VII.2: *Assume that* 0 *is an exceptional point of the first kind for H, which necessarily imposes that* $n_b=1$. *Then, the reduced time evolution operator* $\widetilde{U}(t)$ *for the rational form factor* (9) *behaves asymptotically as*

$$\widetilde{U}(t) = \frac{1}{\lambda^2\log t}(Q_1\Gamma_1Q_1)^{-1}+O((\log t)^{-2}), \tag{186}$$

as $t\to\infty$.

Proof: Let us first look over some properties of $\mathrm{Im}\,\widetilde{R}^+(\omega)$ again. By Lemmas V.3 and V.4, we see that the remainder $F(\omega)$ in Eq. (185) is arbitrary-times differentiable, satisfies that $F(\omega)=O(\omega^{-1}(\log\omega)^{-3})$, and $\mathrm{d}F(\omega)/\mathrm{d}\omega=O(\omega^{-2}(\log\omega)^{-3})$, as $\omega\to+0$. On the other hand, we see from Lemma III.2 that $(\mathrm{d}/\mathrm{d}\omega)^r\mathrm{Im}\,\widetilde{R}^+(\omega)=O(\omega^{-r-1})$ as $\omega\to\infty$. In particular, if $m\geqslant 1$, $(\mathrm{d}/\mathrm{d}\omega)^m\mathrm{Im}\,\widetilde{R}^+(\omega)$ is integrable on $[\delta,\infty)$ for an arbitrary $\delta>0$.

We now split the integral in Eq. (167) into two parts as in Eq. (178) again using the C_0^∞-function $\phi(\omega)$. From Lemma 10.1 in Ref. 14 and the above-mentioned discussion, $(1-\phi(\omega))\mathrm{Im}\,\widetilde{R}^+(\omega)$ has a contribution of $O(t^{-m})$ to $\widetilde{U}(t)$ for an arbitrary $m \geqslant 1$. On the other hand, the contribution of $\phi(\omega)\mathrm{Im}\,\widetilde{R}^+(\omega)$ to $\widetilde{U}(t)$ gives the dominant part of the asymptotic expansion. Then, the dominant time dependence of the asymptote of $\widetilde{U}(t)$ follows from Lemma B.2, that is,

$$\int_0^\infty \phi(\omega)(\omega(\log\omega)^2)^{-1}e^{-it\omega}\mathrm{d}\omega = (\log t)^{-1} + O((\log t)^{-2}). \tag{187}$$

Furthermore, the contribution of the Fourier transform of the remainder $\phi(\omega)F(\omega)$ to $\widetilde{U}(t)$ can be estimated by a similar manner to Lemma B.2, rather than Lemma B.1. By setting $\sigma(\omega) = F(\omega)e^{-it\omega}$ instead in the proof of Lemma B.1 of inverse-lagarithmic-fourier-integral, we can apply it to this case, and we have

$$\int_0^\infty F(\omega)\phi(\omega)e^{-it\omega}\mathrm{d}\omega = -\lim_{\omega\to+0}(\hat{I}\sigma)(\omega) + (-1)^N\int_0^\infty (\hat{I}^N\sigma)(\omega)\frac{\mathrm{d}^N\phi(\omega)}{\mathrm{d}\omega^N}\mathrm{d}\omega. \tag{188}$$

Then, corresponding to Eq. (B10), we have

$$\|(\hat{I}\sigma)(\omega)\| \leqslant \left\| ie^{-it\omega}\int_0^\infty F(\omega - i\eta)e^{-t\eta}\mathrm{d}\eta \right\| + E(t) \leqslant C\int_0^\infty |(\omega - i\eta)^{-1}[\log(\omega - i\eta)]^{-3}|e^{-t\eta}\mathrm{d}\eta + E(t), \tag{189}$$

with an appropriate constant C. Note that in this procedure, $\widetilde{R}^+(\omega)$ is analytically continued to the lower plane of the second Riemann sheet, while $\widetilde{R}^-(\omega)$ still remains in the lower plane of the first Riemann sheet. Then, both are ensured to contribute the remainders of the same order to $F(\omega - i\eta)$ in the above integral from Lemmas V.3 and V.4. The remainder term $E(t)$ in Eq. (189) that gives the order of $O(e^{-\gamma t})$ for some $\gamma > 0$ is responsible for the possible poles of $\widetilde{R}^+(\omega)$ continued to the second Riemann sheet, the number of which are guaranteed to be finite from the analytic Fredholm theorem[26] and Lemma III.2 for the continued $\widetilde{R}^+(\omega)$. Thus, it follows from Lemma B.2 that $\lim_{\omega\to+0}\|(\hat{I}\sigma)(\omega)\| = O((\log t)^{-2})$. By the same argument as in Lemma B.2, one also sees that the remainder term in Eq. (188) is of the order of $O(t^{-N+1})$. Summarizing these arguments, we can finish the proof of the theorem. □

VIII. CONCLUDING REMARKS

We have rigorously derived the asymptotic formula of the reduced time evolution operator for the N-level Friedrichs model in the context of the zero energy resonance[14] both for the regular case and the exceptional case of the first kind. Then, in the latter case, the logarithmically slow decay proportional to $(\log t)^{-1}$ has been found, and the expansion coefficient has been explicitly presented by the projection operator associated with the zero energy eigenstates of the total Hamiltonian, which is an extended state not belonging to the Hilbert space. We note that the decay involving the logarithmic function expressed by $t^{-j}(\log t)^k$ ($j=1,2,\ldots$ and $k=0,\pm1,\ldots$) can occur in the short range potential systems in the even dimensional space.[30] It should be noted that a realization of the exceptional cases requires the parameters, e.g., the coupling constant λ, to take such special values that the matrix $K(0)$ in Eq. (44) has a zero eigenvalue. In addition, some of the form factors $v_n(\omega)$ have to behave as $|v_n(\omega)|^2 \sim c_n\omega$ around $\omega=0$. In other words, if all of them behave as $|v_n(\omega)|^2 \sim c_n\omega^{q_n}$ with $q_n \geqslant 2$, the exceptional case of the first kind never occurs though that of the second kind could happen. These circumstances explain how the exceptional cases are surely exceptional. The presented results also enable us to calculate the asymptotic formula for the survival probability of an arbitrary initial state $|\psi\rangle$ localized over the N discrete levels. If we choose the special initial state to satisfy $\Gamma_{n_b}(K(0))^{-1}|\psi\rangle = 0$ in Eq. (175) or $(Q_1\Gamma_1Q_1)^{-1}|\psi\rangle = 0$ in

Eq. (186)), our estimations are useless and other decay laws could appear.[20] The long time behavior of the reduced time evolution operator for the exceptional case of the second and the third kind are not examined. As is expected, in the former case, the nondecaying component associated with the localized zero energy eigenstate will appear due to the divergent behavior of $Q_2\tilde{R}(z)Q_2 = O(z^{-1})$ in Eq. (83). The latter case can occur in the N-level cases of the model only for $N \geqslant 3$, which yields a more complicated situation. In the whole of the paper, we assumed that there is no bound eigenstate with a positive eigenenergy. This situation is actually realized in the weak coupling cases.[17,21]However, its compatibility with the existence of the extended zero energy eigenstate is still not clear in the multilevel cases (except the single level case). The emergence of the logarithmic decay $(\log t)^{-1}$ is just due to the logarithmic energy dependence of the self energy $S(\omega)$ and it comes from the assumption (9) where $|v_n(\omega)|^2 \sim c_n\omega^{q_n}$ with a positive integer q_n is required. Therefore, if we choose another type of form factor, it is not necessary for such a slow decay to occur even in the exceptional case.[11–13] However, we stress that our assumption is often satisfied by actual systems.[15,16] The experimental realization of the exceptional case requires the setup of parameters like $\omega_1 \simeq \lambda^2\Lambda$, where Λ is a typical cutoff constant. This seems to be naturally satisfied in a strong coupling region,[7,31] and hence it could be suggested to invoke the artificial quantum structures for a realization.

APPENDIX A: CHARACTERISTICS OF SELF ENERGY FOR THE RATIONAL FORM FACTOR

Lemma A.1: *Suppose that* $\eta(\omega)$ *is a rational function*, *i.e.*, *it is expressed by* $\eta(\omega) = \pi(\omega)/\rho(\omega)$, *where* $\pi(\omega)$ *and* $\rho(\omega)$ *are the polynomials of the degree m and n*, *respectively*. *Furthermore*, *we assume that* $n \geqslant m+1$ *and* $\rho(z)$ *has no zeros in* $[0,\infty)$. *Then*

$$\int_0^\infty \frac{\eta(\omega)}{\omega-\zeta}\mathrm{d}\omega = \frac{P_{n-1}(\zeta) - \pi(\zeta)\log(-\zeta)}{\rho(\zeta)}, \tag{A1}$$

for all $\zeta \in \mathbb{C}\backslash([0,\infty)\cup\{a_k\}_{k=1}^N)$, *where* a_k *is a pole of* m_k*-th order of* $\eta(z)$, N *is the number of such poles*, *and* $P_n(\zeta)$ *is a polynomial of* ζ *of the degree not greater than n. For* $\zeta = |\zeta|e^{i\theta}$ *with* $0 \leqslant \theta \leqslant 2\pi$, *we define* $-\zeta = |\zeta|e^{i\phi}$ *with* $-\pi \leqslant \phi \leqslant \pi$.

Proof: From the fundamental theorems for the complex functions, it holds that

$$\int_0^\infty \frac{\eta(\omega)}{\omega-\zeta}\mathrm{d}\omega = -\sum_{k=1}^{N+1}\mathrm{Res}\left(\frac{\eta(z)}{z-\zeta}\log(-z), z=a_k\right), \tag{A2}$$

where $a_{N+1} = \zeta$. Then the residue at $z = a_k$ for $k \leqslant N$ is deduced to explicitly

$$\frac{1}{(m_k-1)!}\sum_{j=0}^{m_k-1}\binom{m_k-1}{j}\left[\left(\frac{\mathrm{d}^{m_k-1-j}}{\mathrm{d}z^{m_k-1-j}}(z-a_k)^{m_k}\frac{\eta(z)}{z-\zeta}\right)\left(\frac{\mathrm{d}^j}{\mathrm{d}z^j}\log(-z)\right)\right]_{z=a_k}$$
$$=-\sum_{j=1}^{m_k-1}\frac{P_{m_k-1-j}(\zeta)}{(a_k-\zeta)^{m_k-j}}-\frac{P_{m_k-1}(\zeta)}{(a_k-\zeta)^{m_k}}\log(-a_k). \tag{A3}$$

For $z=\zeta$, which is a simple pole, the residue becomes

$$\mathrm{Res}\left(\frac{\eta(z)}{z-\zeta}\log(-z),z=\zeta\right)=\eta(\zeta)\log(-\zeta). \tag{A4}$$

Therefore, by setting Eqs. (A3) and (A4) into Eq. (A2), one obtains Eq. (A1), and the proof is completed. □

Lemma A.2: *Suppose that the function* $\eta(\omega)$ *belonging to* $L^1([0,\infty))$ *is of the form*

$$\eta(\omega):=\omega^p r(\omega), \tag{A5}$$

where $p>1$ *and* $r(\omega)$ *is a* C^1*-function defined in* $[0,\infty)$. *Then it holds that both* $\eta(\omega)/\omega$ *and* $\eta(\omega)/\omega^2\in L^1([0,\infty))$, *and*

$$\lim_{E\to+0}\frac{1}{E}\left[P\int_0^\infty\frac{\eta(\omega)}{\omega-E}\mathrm{d}\omega-\int_0^\infty\frac{\eta(\omega)}{\omega}\mathrm{d}\omega\right]=\int_0^\infty\frac{\eta(\omega)}{\omega^2}\mathrm{d}\omega. \tag{A6}$$

Proof: From the proof of Proposition 3.2.2 in Ref. 10, the principal value of the integral on the rhs is written by the absolutely integrable function as follows:

$$P\int_0^\infty\frac{\eta(\omega)}{\omega-E}\mathrm{d}\omega=\int_0^\infty\frac{\eta(\omega)-\eta(E)\varphi_\delta(\omega-E)}{\omega-E}\mathrm{d}\omega, \tag{A7}$$

for all $E>0$, where $\varphi_\delta(\omega)$ is a C_0^∞-function with support $[-\delta,\delta]$ $(0<\delta<E)$, even with respect to the origin, and such that $\varphi_\delta(0)=1$. In the following, we choose such that $\varphi_\delta(\omega)=\exp[1-1/(1-(\omega/\delta)^2)]$ for $\omega\in(-\delta,\delta)$ or 0 otherwise, and $\delta=E/2$. Then, the proof of Eq. (A6) is equivalent to that of

$$\lim_{E\to+0}\int_0^\infty\left\{\frac{1}{E}\left[\frac{\eta(\omega)}{\omega}-\frac{\eta(\omega)-\eta(E)\varphi_\delta(\omega-E)}{\omega-E}\right]+\frac{\eta(\omega)}{\omega^2}\right\}\mathrm{d}\omega=0, \tag{A8}$$

which will be shown in the following. We note that the above-mentioned integrand can be rewritten as

$$-E\frac{\eta(\omega)}{\omega^2(\omega-E)}+\frac{\eta(E)\varphi_\delta(\omega-E)}{E(\omega-E)} \tag{A9}$$

$$=\frac{\eta(E)\varphi_\delta(\omega-E)}{E\omega}-\frac{E\eta(\omega)-\omega\eta(E)\varphi_\delta(\omega-E)}{\omega^2(\omega-E)}. \tag{A10}$$

We also put $I_1=(0,E/2]$, $I_2=(E/2,3E/2)$, and $I_3=[3E/2,\infty)$.

Let us first consider the case that $\omega\in I_1\cup I_3$. Then, since $\varphi_\delta(\omega-E)=0$, we can use Eq. (A9) to estimate the integrand in Eq. (A8), which reads

$$\left|E\frac{\eta(\omega)}{\omega^2(\omega-E)}\right|\leqslant 2\left|\frac{\eta(\omega)}{\omega^2}\right|, \tag{A11}$$

where the rhs is absolutely integrable and independent of E. Furthermore, it follows that $\lim_{E\to+0}E\chi_{I_1\cup I_3}(\omega)\eta(\omega)/[\omega(\omega-E)]=0$ for every $\omega\in(0,\infty)$, where $\chi_{I_1\cup I_3}(\omega)=1$ $(\omega\in I_1\cup I_3)$ or 0

($\omega \in I_2$), being the characteristic function. Thus, by the dominated convergence theorem, we can see that

$$\lim_{E\to+0}\int_{I_1\cup I_3} E\frac{\eta(\omega)}{\omega^2(\omega-E)}\mathrm{d}\omega = \lim_{E\to+0}\int_0^\infty E\chi_{I_1\cup I_3}(\omega)\frac{\eta(\omega)}{\omega^2(\omega-E)}\mathrm{d}\omega = 0. \tag{A12}$$

Next, for $\omega \in I_2$, we can use Eq. (A10). The integration of the first term of Eq. (A10) is estimated by

$$\left|\int_{I_2}\frac{\eta(E)\varphi_\delta(\omega-E)}{E\omega}\mathrm{d}\omega\right| \leqslant \frac{\eta(E)}{E^2/2}\int_{I_2}\varphi_\delta(\omega-E)\mathrm{d}\omega = \frac{\eta(E)}{E}\int_{-1}^{1}\varphi_1(x)\mathrm{d}x \to 0, \tag{A13}$$

as $E\to+0$, because $\eta(\omega)=O(\omega^p)$ where $p>1$. The second term of Eq. (A10) is also estimated with the decomposition

$$|E\eta(\omega)-\omega\eta(E)\varphi_\delta(\omega-E)| \leqslant |(E-\omega)\eta(\omega)| + |\omega(\eta(\omega)-\eta(E))| + |\omega\eta(E)||1-\varphi_\delta(\omega-E)|. \tag{A14}$$

The integral corresponding to the first term on the rhs of Eq. (A14) is evaluated as

$$\int_{I_2}\frac{|(E-\omega)\eta(\omega)|}{\omega^2|\omega-E|}\mathrm{d}\omega \to 0, \tag{A15}$$

as $E\to+0$, because of the fact $\eta(\omega)/\omega^2 \in L^1([0,\infty))$. The integral corresponding to the second term is also evaluated as

$$\int_{I_2}\frac{\omega|\eta(\omega)-\eta(E)|}{\omega^2|\omega-E|}\mathrm{d}\omega \leqslant (\ln 3)\sup_{\omega\in I_2}|\eta'(\omega)| \to 0, \tag{A16}$$

as $E\to+0$, because of the assumption on $\eta(\omega)$, where $\eta'(\omega)$ is the derivative of $\eta(\omega)$. The integral corresponding the last term on the rhs of Eq. (A14) is also estimated as

$$\int_{I_2}\frac{\omega|\eta(E)||1-\varphi_\delta(\omega-E)|}{\omega^2|\omega-E|}\mathrm{d}\omega \leqslant (\ln 3)\frac{|\eta(E)|}{\delta}\sup_{|x|\leqslant 1}|\varphi_1'(x)| \to 0, \tag{A17}$$

as $E\to+0$. Thus, we see from Eqs. (A15)–(A17),

$$\lim_{E\to+0}\int_{I_2}\frac{E\eta(\omega)-\omega\eta(E)\varphi_\delta(\omega-E)}{\omega^2(\omega-E)}\mathrm{d}\omega = 0. \tag{A18}$$

Equations (A12), (A13), and (A18) mean the completion of the proof of Eq. (A8). □

APPENDIX B: ASYMPTOTIC EXPANSION OF THE FOURIER INTEGRALS

We have to estimate the integrals of the form $U(t)=\int_0^\infty e^{-it\lambda}F(\lambda)\mathrm{d}\lambda$ in which $F(\lambda)=0$ identically either for small $\lambda>0$ or for large λ where F is supposed to take values in an arbitrary Banach space **B**. The following lemma is essentially the same as Lemma 10.2 in Ref. 14.

Lemma B.1: *Suppose that* $F(\lambda)=0$ *for* $\lambda>a>0$, $(F\in C^{k+1}(\delta,\infty;\mathbf{B}))$, $F^{(k+1)}\in L^1(\delta,\infty;\mathbf{B})$ *for any* $\delta>0$ *and for an integer* $k\geqslant 0$, *and that* $F^{(j)}(0)=0$ *for* $j\leqslant k-1$. *Then*

$$\|U(t)\| \leqslant \frac{1}{t^k}\left(\int_0^{2\pi/t}\|F^{(k)}(\lambda)\|\mathrm{d}\lambda + \frac{\pi}{2t}\int_{\pi/t}^{a}\sup_{\mu\in[\lambda,\lambda+\pi/t]}\|F^{(k+1)}(\mu)\|\mathrm{d}\lambda\right), \tag{B1}$$

for all $t>\pi/a$. *Here* $F^{(k)}(\lambda)$ *denotes the kth derivative of* $F(\lambda)$ *and so forth*.

Proof: By extending F by $F(\lambda)=0$ to $\lambda<0$, we obtain a function F on $(-\infty,\infty)$ with $F^{(k)}\in L^1(-\infty,\infty;\mathbf{B})$. Then we have that

$$\int_{-\infty}^{\infty} \|F^{(k)}(\lambda+h)-F^{(k)}(\lambda)\|\mathrm{d}\lambda = \left(\int_{-\infty}^{h} + \int_{h}^{a}\right)\|F^{(k)}(\lambda+h)-F^{(k)}(\lambda)\|\mathrm{d}\lambda \tag{B2}$$

$$\leqslant 2\int_{0}^{2h} \|F^{(k)}(\lambda)\|\mathrm{d}\lambda + \int_{h}^{a}\mathrm{d}\lambda\int_{\lambda}^{\lambda+h}\|F^{(k+1)}(\mu)\|\mathrm{d}\mu \tag{B3}$$

$$\leqslant 2\int_{0}^{2h} \|F^{(k)}(\lambda)\|\mathrm{d}\lambda + h\int_{h}^{a}\sup_{\mu\in[\lambda,\lambda+h]}\|F^{(k+1)}(\mu)\|\mathrm{d}\lambda. \tag{B4}$$

By noting that $e^{-it\lambda}=-e^{-it(\lambda-\pi/t)}$, one sees that the lhs of Eq. (B2) is just an upper bound of the Fourier transform of $2F^{(k)}$. Remember that the Fourier transform of $F^{(k)}$ is equal to $(it)^k U(t)$ under the assumption of the lemma, i.e., $F^{(j)}(0)=0$ for $j\leqslant k-1$, then the desired result follows. □

Lemma B.2: *Suppose that* $\phi\in C_0^{\infty}([0,\infty))$ *and satisfies* $\phi(\omega)=1$ *in a neighborhood of* $\omega=0$. *It then holds that for any positive integer* $q\geqslant 2$ *and* $N\geqslant 1$,

$$\int_{0}^{\infty}\omega^{-1}(\log\omega)^{-q}\phi(\omega)e^{-it\omega}\mathrm{d}\omega = \frac{(-1)^q}{q-1}\sum_{j=0}^{N-1}\binom{q+j-2}{j}(\log t)^{1-q-j}\left(\frac{\mathrm{d}}{\mathrm{d}\nu}-\frac{\pi}{2}i\right)^{j}\Gamma(\nu)\big|_{\nu=1} + O((\log t)^{1-q-N}) \tag{B5}$$

as $t\to\infty$.

Proof: We first put $\sigma(\omega)=\omega^{-1}(\log\omega)^{-q}e^{-it\omega}$ and introduce the indefinite integral operator $\hat{I}$ as[29]

$$(\hat{I}\sigma)(\omega) = \int_{c}^{\omega} s^{-1}(\log s)^{-q}e^{-its}\mathrm{d}s, \tag{B6}$$

where c is an arbitrary complex number. We can also recursively show

$$(\hat{I}^k\sigma)(\omega) = \frac{1}{(k-1)!}\int_{c}^{\omega}(\omega-s)^{k-1}s^{-1}(\log s)^{-q}e^{-its}\mathrm{d}s. \tag{B7}$$

Then, repeating the partial integration, we obtain

$$\int_{0}^{\infty}\omega^{-1}(\log\omega)^{-q}\phi(\omega)e^{-it\omega}\mathrm{d}\omega = -(\hat{I}\sigma)(\omega)\phi(\omega)\big|_{\omega=0} + R_N(t), \tag{B8}$$

for all $N\geqslant 1$ with

$$R_N(t) = (-1)^N\int_{0}^{\infty}(\hat{I}^N\sigma)(\omega)\mathrm{d}^N\phi(\omega)/\mathrm{d}\omega^N\mathrm{d}\omega, \tag{B9}$$

where we used the fact that $\mathrm{d}^k\phi(\omega)/\mathrm{d}\omega^k=\delta_{k0}$ at $\omega=0$ for any $k\geqslant 0$, and $\mathrm{d}^k\phi(\omega)/\mathrm{d}\omega^k=0$ at $\omega=\infty$ for any $k\geqslant 0$. We now choose $c=\omega-i\infty$ and change the variable as $s:=\omega-i\eta$, which leads to

$$(\hat{I}\sigma)(\omega) = ie^{-it\omega}\int_{0}^{\infty}(\omega-i\eta)^{-1}[\log(\omega-i\eta)]^{-q}e^{-t\eta}\mathrm{d}\eta. \tag{B10}$$

Then, we can use the dominated convergence theorem to obtain

$$\lim_{\omega\to+0}(\hat{I}\sigma)(\omega)=i\int_0^\infty(-i\eta)^{-1}[\log(-i\eta)]^{-q}e^{-t\eta}\mathrm{d}\eta. \tag{B11}$$

Here we used the fact that there is a positive number $\omega_0<1/(e^q\sqrt{2})$ such that

$$\begin{aligned}|(\omega-i\eta)^{-1}[\log(\omega-i\eta)]^{-q}e^{-t\eta}| &\leqslant \begin{cases}\eta^{-1}|\log\eta|^{-q}e^{-t\eta} & (0<\eta<\omega_0)\\ Ce^{-t\eta} & (\omega_0\leqslant\eta)\end{cases}\\ &\leqslant[\chi_{\eta\leqslant\omega_0}(\eta)\eta^{-1}|\log\eta|^{-q}+C]e^{-t\eta},\end{aligned} \tag{B12}$$

for all $0<\omega\leqslant\omega_0$ and all $0<\eta<\infty$, where $\chi_{\eta\leqslant\omega_0}(\eta)=1$ for $\eta\leqslant\omega_0$ or 0 otherwise, and C is an appropriate constant. The existence of such a C is ensured by the fact that $\log(\omega-i\eta)$ has no zeros in the rectangular region $\{\omega-i\eta|0<\omega\leqslant\omega_0,\omega_0\leqslant\eta<\infty\}$, and its modulus diverges as $\eta\to\infty$. The function on the rhs of Eq. (B12) is integrable, so that the use of the dominated convergence theorem is valid. To evaluate the asymptotic behavior of Eq. (B11), putting $\epsilon=(\log t)^{-1}$ and $t\eta=\xi$, one obtains

$$\lim_{\omega\to+0}(\hat{I}\sigma)(\omega)=i(-\epsilon)^q\int_0^\infty\frac{-i\epsilon^{-1}}{1-q}\left(\frac{\mathrm{d}}{\mathrm{d}\xi}[1-\epsilon\log(-i\xi)]^{1-q}\right)e^{-\xi}\mathrm{d}\xi \tag{B13}$$

$$=-\frac{(-\epsilon)^{q-1}}{1-q}\int_0^\infty[1-\epsilon\log(-i\xi)]^{1-q}e^{-\xi}\mathrm{d}\xi \tag{B14}$$

$$\begin{aligned}=&-\frac{(-\epsilon)^{q-1}}{1-q}\left\{\sum_{j=0}^{N-1}\binom{q+j-2}{j}\epsilon^j\left(\frac{\mathrm{d}}{\mathrm{d}\nu}-\frac{\pi}{2}i\right)^j\Gamma(\nu)\big|_{\nu=1}\right.\\ &\left.+\epsilon^N N\binom{q+N-2}{N}\int_0^\infty\left[\int_0^1\frac{(1-u)^{N-1}}{[1-\epsilon u\log(-i\xi)]^{q+N}}\mathrm{d}u\right][\log(-i\xi)]^N e^{-\xi}\mathrm{d}\xi\right\},\end{aligned} \tag{B15}$$

where we used the formulas that $f(\epsilon)=\sum_{j=0}^{N-1}\epsilon^j f^{(j)}(0)/j!+[\epsilon^N/(N-1)!]\int_0^1(1-u)^{N-1}f^{(N)}(\epsilon u)\mathrm{d}u$ with $f(\epsilon)=[1-\epsilon\log(-i\xi)]^{1-q}$, and $\int_0^\infty x^{\nu-1}e^{-\mu x}(\log x)^j\mathrm{d}x=\partial^j[\mu^{-\nu}\Gamma(\nu)]/\partial\nu^j$. The last integral in Eq. (B15) turns out to be finite because we have

$$\left|\int_0^\infty\left[\int_0^1\frac{(1-u)^{N-1}}{[1-\epsilon u\log(-i\xi)]^{q+N}}\mathrm{d}u\right][\log(-i\xi)]^N e^{-\xi}\mathrm{d}\xi\right|\leqslant\int_0^\infty\frac{[(\pi/2)^2+(\log\xi)^2]^{q/2+N}}{(\pi/2)^{q+N}}e^{-\xi}\mathrm{d}\xi, \tag{B16}$$

where we used that

$$|1-\epsilon u\log(-i\xi)|^2=(1-\epsilon u\log\xi)^2+(\epsilon u\pi/2)^2\geqslant\frac{(\pi/2)^2}{(\pi/2)^2+(\log\xi)^2}. \tag{B17}$$

Let us now evaluate the upperbound of $|(\hat{I}^N\sigma)(\omega)|$. Using the estimation (B12), we have

$$|(\hat{I}^N\sigma)(\omega)|=\frac{1}{(N-1)!}\left|\int_0^\infty(i\eta)^{N-1}(\omega-i\eta)^{-1}[\log(\omega-i\eta)]^{-q}e^{-t\eta}\mathrm{d}\eta\right| \tag{B18}$$

$$\leqslant\frac{1}{(N-1)!}\int_0^\infty[\eta^{N-2}|\log\omega_0|^{-q}+C\eta^{N-1}]e^{-t\eta}\mathrm{d}\eta=O(t^{-N+1}). \tag{B19}$$

Substituting this result into the error term $R_N(t)$ in Eq. (B9), we see that $R_N(t)=O(t^{-N+1})$ for any integer $N\geqslant2$. This proves the statement of the lemma. □

Some physical applications of fractional Schrödinger equation

Xiaoyi Guo[a] and Mingyu Xu[b]
School of Mathematics & System Sciences, Shandong University, Jinan 250100, China

(Received 11 May 2006; accepted 28 June 2006; published online 14 August 2006)

The fractional Schrödinger equation is solved for a free particle and for an infinite square potential well. The fundamental solution of the Cauchy problem for a free particle, the energy levels and the normalized wave functions of a particle in a potential well are obtained. In the barrier penetration problem, the reflection coefficient and transmission coefficient of a particle from a rectangular potential wall is determined. In the quantum scattering problem, according to the fractional Schrödinger equation, the Green's function of the Lippmann-Schwinger integral equation is given. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2235026]

I. INTRODUCTION

The Schrödinger equation is the fundamental equation of physics for describing nonrelativistic quantum mechanical behavior. It is also often called the Schrödinger wave equation, and is a partial differential equation that describes how the wave function of a physical system evolves over time. The time-dependent one-dimensional Schrödinger equation is given by

$$i\hbar\frac{\partial\psi(x,t)}{\partial t}=-\frac{\hbar^2}{2m}\frac{\partial^2\psi(x,t)}{\partial x^2}+V(x,t)\psi(x,t), \tag{1}$$

where i is the imaginary unit, $\psi(x,t)$ is the time-dependent wave function, $\hbar$ is Planck's constant (strictly speaking, is Plank's constant divided by 2π; this is Dirac's notation), $V(x,t)$ is the potential.

It is well known that Feynman and Hibbs[1] used path integrals over Brownian paths to derive the standard (nonfractional) Schrödinger equation. In quantum physics, the Feynman path integral approach to quantum mechanics was the first successful attempt applying the fractality concept that was first introduced by Mandelbrot.[2] Recently, Laskin[3–6] extended the fractality concept and formulated fractional quantum mechanics as a path integral over the Lévy flights paths. Through introducing the quantum Riesz fractional derivative

$$(-\hbar^2\Delta)^{\alpha/2}\psi(x,t)=\frac{1}{2\pi\hbar}\int_{-\infty}^{+\infty}e^{ipx/\hbar}|p|^{\alpha}\varphi(p,t)\mathrm{d}p, \tag{2}$$

$1<\alpha\leqslant 2$, they constructed the space fractional Schrödinger equation

$$i\hbar\frac{\partial\psi}{\partial t}=D_{\alpha}(-\hbar^2\Delta)^{\alpha/2}\psi+V(x,t)\psi \tag{3}$$

(here $\Delta=\partial^2/\partial x^2$ is the Laplacian). Laskin showed the Hermiticity of the fractional Hamilton operator and established the parity conservation law. Energy spectra of a hydrogenlike atom and of

[a]Electronic mail: xyguosdu@hotmail.com
[b]Electronic mail: xumingyu@sdu.edu.cn

a fractional oscillator were also computed. Afterwards, Naber[7] considered the Schrödinger equation with the first-order time derivative changed to a Caputo fractional detivative, the time fractional Schrödinger equation, and discussed the solutions of this kind of equation for a free particle and for a potential well.

In this paper, some other physical applications of the space fractional Schrödinger equation are considered, which are organized as follows. In Sec. II we solve the time-dependent fractional Schrödinger equation for a free particle and give the fundamental solution of the Cauchy problem, using the properties of Fox's H function. In Sec. III the energy levels and the normalized wave functions of a particle in an infinite square potential well are discussed. In Sec. IV according to the time-independent fractional Schrödinger equation we calculate the reflection coefficient and transmission coefficient of a particle from a rectangular potential wall. The quantum scattering problem is the basis of the quantum mechanics. Lippmann-Schwinger equation as the fundamental equation of quantum scattering theory obtains the widespread application in the three-dimensional quantum scattering.[8,9] In Sec. V the Lippmann-Schwinger equation equivalent to the fractional time-independent Schrödinger equation is considered, and the Green's function of it is determined in terms of Fox's H function. Finally, the paper is concluded with a discussion and summary.

II. FREE PARTICLE SOLUTION

The fractional Schrödinger equation for a free particle is given by

$$i\hbar\frac{\partial\psi}{\partial t}=D_\alpha(-\hbar^2\Delta)^{\alpha/2}\psi. \tag{4}$$

Taking into account the definitions of the Fourier transforms on the spatial coordinate

$$\varphi(p,t)=\int_{-\infty}^{+\infty}e^{-ipx/\hbar}\psi(x,t)\mathrm{d}x \tag{5}$$

and the quantum Riesz fractional derivative (2), we have

$$i\hbar\frac{\partial\varphi(p,t)}{\partial t}=D_\alpha|p|^\alpha\varphi(p,t), \tag{6}$$

and

$$\varphi(p,t)=C\exp\{-iD_\alpha|p|^\alpha t/\hbar\}, \tag{7}$$

where C is a constant. Inverse Fourier transforming gives the final solution

$$\psi(x,t)=\frac{C}{2\pi\hbar}\int_{-\infty}^{+\infty}e^{ipx/\hbar}\exp\{-iD_\alpha|p|^\alpha t/\hbar\}\mathrm{d}p, \tag{8}$$

which also can be expressed in terms of Fox's H functions

$$\psi(x,t)=\frac{C}{\alpha|x|}H_{2,2}^{1,1}\left[\frac{1}{\hbar}\left(\frac{\hbar}{iD_\alpha t}\right)^{1/\alpha}|x|\,\middle|\begin{matrix}(1,1/\alpha),(1,1/2)\\(1,1),(1,1/2)\end{matrix}\right], \tag{9}$$

by using the identical formula and the formula of the Fourier cosine transform of Fox's H function.[10,11] When $C=1$, Eq. (9) is the fundamental solution of the Cauchy problem, i.e., the solution to Eq. (4) with the initial condition $\psi(x,0)=\delta(x)$.

III. POTENTIAL WELL SOLUTION

Now consider a particle in a potential well

$$V(x) = \begin{cases} 0 & \text{for } |x| < a \\ \infty & \text{for } |x| > a. \end{cases} \tag{10}$$

We need to solve Eq. (4) for $|x|<a$, with the condition $\psi(x,t)=0$, *for* $|x|\geqslant a$.

By separation of variables $\psi=f(t)\phi(x)$, we get

$$f(t) = e^{-(iE/\hbar)t} \tag{11}$$

(let $f(t=0)=1$),

$$D_\alpha(-\hbar^2\Delta)^{\alpha/2}\phi = E\phi, \tag{12}$$

in which E is the energy of the particle.

Let

$$k^\alpha = \frac{E}{D_\alpha \hbar^\alpha}. \tag{13}$$

Then considering

$$(-\hbar^2\Delta)^{\alpha/2} \exp\left\{ i\frac{px}{\hbar} \right\} = |p|^\alpha \exp\left\{ i\frac{px}{\hbar} \right\}, \tag{14}$$

and $E=D_\alpha|p|^\alpha$, the solution of Eq. (12) is

$$\phi(x) = e^{\pm ikx}, \tag{15}$$

or

$$\phi(x) = A\sin(kx) + B\cos(kx). \tag{16}$$

The boundary conditions $\phi(-a)=\phi(a)=0$ give

$$\begin{aligned} A\sin(ka) &= 0, \\ B\cos(ka) &= 0. \end{aligned} \tag{17}$$

So the solutions fall into two classes: those with $A=0$ and those with $B=0$.

The odd solutions have $B=0$, so $ka=n\pi/2$, for $n=2,4,6,\ldots$,

$$E_n^{(o)} = D_\alpha\left(\frac{\hbar n\pi}{2a} \right)^\alpha, \tag{18}$$

$$\phi_n^{(o)}(x) = \begin{cases} A\sin\left(\dfrac{n\pi}{2a}x \right) & \text{for } |x| < a \\ 0 & \text{for } |x| \geqslant a. \end{cases} \tag{19}$$

The even solutions have $A=0$, so $ka=n\pi/2$, for $n=1,3,5,\ldots$,

$$E_n^{(e)} = D_\alpha\left(\frac{\hbar n\pi}{2a} \right)^\alpha, \tag{20}$$

$$\phi_n^{(e)}(x) = \begin{cases} B\cos\left(\dfrac{n\pi}{2a}x\right) & \text{for } |x| < a \\ 0 & \text{for } |x| \geqslant a. \end{cases} \tag{21}$$

Combining even and odd solutions gives the energy levels

$$E_n = D_\alpha\left(\frac{\hbar n\pi}{2a}\right)^\alpha, \tag{22}$$

$$\phi_n(x) = \begin{cases} C_0 \sin\dfrac{n\pi}{2a}(x+a) & \text{for } |x| < a \\ 0 & \text{for } |x| \geqslant a, \end{cases} \tag{23}$$

for $n=1,2,3,\ldots$. Normalizing gives $\int_{-\infty}^{+\infty}|\phi(x)|^2 \mathrm{d}x=1$, so $C_0=1/\sqrt{a}$.

Thus the time-dependent wave functions of a particle in a one-dimensional infinite square potential well are

$$\psi_n(x,t) = e^{-(i/\hbar)E_n t}\phi_n(x) = C_0 e^{-(i/\hbar)E_n t}\sin\frac{n\pi}{2a}(x+a), \tag{24}$$

for $n=1,2,3,\ldots$ and $|x|<a$, which also can be expressed in terms of exponential function

$$\psi_n(x,t) = C_1 e^{i/\hbar(n\pi\hbar x/2a - E_n t)} + C_2 e^{i/\hbar(n\pi\hbar x/2a + E_n t)}, \tag{25}$$

where C_1 and C_2 are constants.

It should be noted that the results [Eqs. (22) and (23)] are equivalent to those given by Laskin.[6]

IV. BARRIER PENETRATION

Let us consider the motion of particles in a rectangular potential barrier

$$V(x) = \begin{cases} V_0, & 0 < x < a \\ 0, & x < 0, x > a. \end{cases} \tag{26}$$

According to classical physics, a particle of energy E less than the height V_0 of a barrier could not penetrate the region inside the barrier. But the wave function associated with a free particle must be continuous at the barrier and will show an exponential decay inside the barrier. The wave function must also be continuous on the far side of the barrier, so there is a finite probability that the particle will tunnel through the barrier.

First we suppose that the energy of the particle satisfies $E>V_0$ and the incident particle is moving from the left of the potential wall to the right. Then for $x<0$ or $x>a$, the time-independent fractional Schrodinger equation is Eq. (12). Its solution is (15), with (13). For $0<x<a$, the time-independent fractional Schrödinger equation is

$$D_\alpha(-\hbar^2\Delta)^{\alpha/2}\phi(x) + V_0\phi(x) = E\phi(x). \tag{27}$$

Solving this equation yields

$$\phi(x) = e^{\pm i\kappa x}, \tag{28}$$

in which

$$\kappa = \left(\frac{E - V_0}{D_\alpha \hbar^\alpha} \right)^{1/\alpha}. \tag{29}$$

Then we have for the time-independent wave function ϕ in the different regions expressions of the form

$$\text{for } x < 0, \quad \phi = e^{ikx} + Re^{-ikx}, \tag{30}$$

$$\text{for } 0 < x < a, \quad \phi = Ae^{i\kappa x} + Be^{-i\kappa x}, \tag{31}$$

$$\text{for } x > a, \quad \phi = Se^{ikx}. \tag{32}$$

In (30), the first term corresponds to a particle incident on the barrier (we suppose ϕ normalized so that the coefficient of this term is unity); the second term represents a particle reflected from the barrier. In (32), the wave function describes a particle, which has passed "above the wall" and is moving in the positive direction of x. The fractional probability current density in the incident wave is (see Ref. 5)

$$j_i(x) = \frac{D_\alpha \hbar}{i} \left[\phi^*(x)(-\hbar^2\Delta)^{\alpha/2-1} \frac{\partial}{\partial x} \phi(x) - \phi(x)(-\hbar^2\Delta)^{\alpha/2-1} \frac{\partial}{\partial x} \phi^*(x) \right]. \tag{33}$$

Then we have

$$j_i(x) = \frac{D_\alpha \hbar}{i} \left[e^{-ikx}(-\hbar^2\Delta)^{\alpha/2-1} \frac{\partial}{\partial x} e^{ikx} - e^{ikx}(-\hbar^2\Delta)^{\alpha/2-1} \frac{\partial}{\partial x}\ e^{-ikx}] \right] = 2D_\alpha (k\hbar)^{\alpha-1}. \tag{34}$$

Similarly, the fractional probability current density in the reflected wave is $2D_\alpha(k\hbar)^{\alpha-1}|R|^2$, in the transmitted wave $2D_\alpha(k\hbar)^{\alpha-1}|S|^2$. Then the transmission coefficient T of the particle as the ratio of the probability current density in the transmitted wave to that in the incident wave is $|S|^2$, and the reflection coefficient of the particle as the ratio of the probability current density in the reflected wave to that in the incident wave is $|R|^2$. The constants R and S are determined from the conditions that ϕ and $(-\hbar^2\Delta)^{\alpha/2-1}\phi$ are continuous at $x=0$:

$$1 + R = A + B, \tag{35}$$

$$(ik)^{\alpha-1} + (-ik)^{\alpha-1} R = (i\kappa)^{\alpha-1} A + (-i\kappa)^{\alpha-1} B, \tag{36}$$

at $x=a$:

$$Ae^{i\kappa a} + Be^{-i\kappa a} = Se^{ika}, \tag{37}$$

$$(i\kappa)^{\alpha-1} Ae^{i\kappa a} + (-i\kappa)^{\alpha-1} Be^{-i\kappa a} = (ik)^{\alpha-1} Se^{ika}. \tag{38}$$

Combining (35) and (36) gives

$$A = \frac{1}{1 + (-1)^\alpha} \left\{ \left[1 - \left(\frac{k}{-\kappa} \right)^{\alpha-1} \right] + R \left[1 - \left(\frac{k}{\kappa} \right)^{\alpha-1} \right] \right\},$$

$$B = \frac{1}{1 + (-1)^\alpha} \left\{ \left[1 - \left(\frac{k}{\kappa} \right)^{\alpha-1} \right] + R \left[1 - \left(\frac{k}{-\kappa} \right)^{\alpha-1} \right] \right\}.$$

Combining (37) and (38) gives

$$A = \frac{S}{1 + (-1)^\alpha} \left[1 - \left(\frac{k}{-\kappa} \right)^{\alpha-1} \right] e^{i(ka+\kappa a)},$$

$$B = \frac{S}{1+(-1)^{\alpha}}\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]e^{i(ka-\kappa a)}.$$

Then we have

$$\frac{1}{1+(-1)^{\alpha}}\left\{\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]+R\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]\right\} = \frac{S}{1+(-1)^{\alpha}}\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]e^{i(ka+\kappa a)},$$

$$\frac{1}{1+(-1)^{\alpha}}\left\{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]+R\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]\right\} = \frac{S}{1+(-1)^{\alpha}}\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]e^{i(ka-\kappa a)}.$$

Hence

$$Se^{ika} = \frac{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2-\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2}{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2 e^{i\kappa a}-\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2 e^{-i\kappa a}}, \tag{39}$$

$$R = \frac{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right](e^{-i\kappa a}-e^{i\kappa a})}{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2 e^{i\kappa a}-\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2 e^{-i\kappa a}}. \tag{40}$$

Finally the transmission coefficient T is given by

$$T = |S|^2 = \frac{\left\{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2-\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2\right\}^2}{\left\{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2-\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2\right\}^2+4\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2\sin^2\kappa a},$$

$$T = \left\{1+\frac{4\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2\sin^2\kappa a}{\left\{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2-\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2\right\}^2}\right\}^{-1}, \tag{41}$$

and the reflection coefficient is

$$|R|^2 = \frac{4\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2\sin^2\kappa a}{\left\{\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2-\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2\right\}^2+4\left[1-\left(\frac{k}{\kappa}\right)^{\alpha-1}\right]^2\left[1-\left(\frac{k}{-\kappa}\right)^{\alpha-1}\right]^2\sin^2\kappa a}. \tag{42}$$

Obviously $|R|^2+|S|^2=1$.

For $E<V_0$, the corresponding expressions for T and $|R|^2$ are also obtained by replacing κ by k', where $k'=(-1)^{1/\alpha}((V_0-E)/D_{\alpha}\hbar^{\alpha})^{1/\alpha}$.

When the particle is passing over a rectangular potential well instead of a potential barrier, i.e.,

$$V(x)=\begin{cases}-V_0, & 0<x<a\\ 0, & x<0, x>a\end{cases}$$

($V_0>0$), the above theory still holds, in which $\kappa=((E+V_0)/D_\alpha\hbar^\alpha)^{1/\alpha}\geqslant k=(E/D_\alpha\hbar^\alpha)^{1/\alpha}$. In that case, it is interesting to note that $T=1$ ($|R|^2=0$), if $\sin^2\kappa a=0$, i.e., $a\kappa=n\pi$, thus $E=E_n=-V_0+D_\alpha(n\pi\hbar/a)^\alpha$, for $n=1,2,3,\ldots$. This phenomenon is called resonance transmission, and E_n is resonance energy levels.

V. THE GREEN'S FUNCTION IN QUAUTUM SCATTERING

Consider the incident particles with $E=D_\alpha|p|^\alpha$ are scattered by potential field $V(x)$. This problem sums up for solving the one-dimensional fractional Schrödinger equation

$$[-D_\alpha(-\hbar^2\Delta)^{\alpha/2}+E]\phi(x)=V(x)\phi(x). \tag{43}$$

According to the theory of Green's function of a fractional differential equation,[12] the solution of Eq. (43) can be expressed by

$$\phi(x)=\phi^0(x)+\int_{-\infty}^{+\infty}G(x,x')V(x')\phi(x')\mathrm{d}x', \tag{44}$$

in which $G(x,x')$ is the Green's function, satisfying

$$[-D_\alpha(-\hbar^2\Delta)^{\alpha/2}+E]G(x,x')=\delta(x-x'), \tag{45}$$

and $\phi^0(x)$ is an arbitrary solution of the homogeneous equation

$$[-D_\alpha(-\hbar^2\Delta)^{\alpha/2}+E]\phi(x)=0. \tag{46}$$

Supposing the incident wave $\phi_i(x)=e^{ikx}$, with $k^\alpha=E/D_\alpha\hbar^\alpha$, then the quantum scattering problem sums up for solving the generalized Lippmann-Schwinger integral equation equivalent to Eq. (43) as follows:

$$\phi(x)=e^{ikx}+\int_{-\infty}^{+\infty}G(x,x')V(x')\phi(x')\mathrm{d}x'. \tag{47}$$

In the following we calculate the Green's function. From Eq. (45), using Fourier transform we have

$$G(x,x')=G(x-x')=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\frac{1}{E-D_\alpha\hbar^\alpha|q|^\alpha}e^{iq(x-x')}\mathrm{d}q=\frac{1}{\pi}\int_0^\infty\frac{1}{E-D_\alpha\hbar^\alpha q^\alpha}\cos q(x-x')\mathrm{d}q$$
$$=\frac{1}{\pi E}\int_0^\infty\frac{1}{1-\dfrac{D_\alpha\hbar^\alpha}{E}q^\alpha}\cos q(x-x')\mathrm{d}q.$$

Considering the identical formula

$$\frac{z^\beta}{1+az^\alpha}=a^{-\beta/\alpha}H_{1,1}^{1,1}\left[az^\alpha\middle|\begin{matrix}(\beta/\alpha,1)\\(\beta/\alpha,1)\end{matrix}\right],$$

the properties of Fox's H function and the formula of the Fourier cosine transform of Fox's H functions,[11] we get

$$G(x-x') = \frac{1}{\pi E}\int_0^\infty H_{1,1}^{1,1}\left[\left(-\frac{D_\alpha \hbar^\alpha}{E}\right)q^\alpha \middle| \begin{matrix}(0,1)\\(0,1)\end{matrix}\right] \cos q(x-x')\mathrm{d}q$$

$$= \frac{1}{\alpha E|x-x'|}H_{2,3}^{2,1}\left[\frac{|x-x'|}{\left(-\frac{D_\alpha \hbar^\alpha}{E}\right)^{1/\alpha}} \middle| \begin{matrix}(1,1/\alpha) & (1,1/2)\\(1,1) & (1,1/\alpha)(1,1/2)\end{matrix}\right]$$

$$= \frac{-1}{\alpha D_\alpha \hbar^\alpha}\left(-\frac{D_\alpha \hbar^\alpha}{E}\right)^{1-1/\alpha} H_{2,3}^{2,1}\left[\frac{|x-x'|}{\left(-\frac{D_\alpha \hbar^\alpha}{E}\right)^{1/\alpha}} \middle| \begin{matrix}(1-1/\alpha,1/\alpha) & (1/2,1/2)\\(0,1) & (1-1/\alpha,1/\alpha)\quad (1/2,1/2)\end{matrix}\right]. \tag{48}$$

VI. CONCLUSION

Some physical applications of the fractional Schrödinger equation have been studied. The time-dependent free particle fractional Schrödinger equation was solved, using method of integral transform. The fundamental solution of the Cauchy problem was obtained in term of Fox's H function, which can be used for calculating boundary value problem in quantum mechanics. The motion of a particle in an infinite square potential well was discussed. We outlined the energy levels and wave functions. Also the reflection and transmission coefficient of a particle from a potential barrier or a potential well was derived. Last we gave the Green's function of the generalized Lippmann-Schwinger equation equivalent to time-independent fractional Schrödinger equation in quantum scattering processes. Equations (9), (22), (25), (41), (42), and (48) include the well-known equations as their special cases at $\alpha=2$.

On the other hand, we also can show that Eq. (48) is consistent with more general three-dimensional Green's function Eq. (47) obtained by Laskin.[13] According to his ideas, the one-dimensional fixed-energy kernel, i.e., the one-dimensional Green's function can be given by (using the expressions in Ref. 13)

$$k_L^{(0)}(x_2x_1;E) = \int_{t_1}^\infty \mathrm{d}t_2 e^{(i/\hbar)E(t_2-t_1)}K_L^{(0)}(x_2t_2|x_1t_1),$$

where

$$K_L^{(0)}(x_2t_2|x_1t_1) = \frac{1}{\alpha|x_2-x_1|}H_{2,2}^{1,1}\left[\frac{1}{\hbar}\left(\frac{\hbar}{iD_\alpha(t_2-t_1)}\right)^{1/\alpha}|x_2-x_1| \middle| \begin{matrix}(1,1/\alpha),(1,1/2)\\(1,1),(1,1/2)\end{matrix}\right].$$

Then we get the one-dimensional Green's function

$$k_L^{(0)}(x_2x_1;E) = \frac{i\hbar}{\alpha E|x_2-x_1|}H_{2,3}^{2,1}\left[\frac{|x_2-x_1|}{\left(-\frac{D_\alpha \hbar^\alpha}{E}\right)^{1/\alpha}} \middle| \begin{matrix}(1,1/\alpha)(1,1/2)\\(1,1)(1,1/\alpha)(1,1/2)\end{matrix}\right].$$

So we can see that Eq. (48) in this paper is a particular case of the more general Laskin's Eq. (47) in Ref. 13.

Thin layer quantization in higher dimensions and codimensions

Alexey V. Golovnev[a)]
Saint-Petersburg State University, Saint-Petersburg, Russia

(Received 7 November 2005; accepted 19 May 2006; published online 18 August 2006)

We consider the thin layer quantization with use of only the most elementary notions of differential geometry. We consider this method in higher dimensions and get an explicit formula for quantum potential. For codimension 1 surfaces the quantum potential is presented in terms of principal curvatures, and equivalence with Prokhorov quantization method is proved. It is shown that, in contrast with original da Costa method, Prokhorov quantization can be generalized directly to higher codimensions. © *2006 American Institute of Physics.*

I. INTRODUCTION

We consider free particle motion on a curved surface. Probably, the first quantum theory of it was proposed by Podolsky in Ref. 1; he postulated that the Hamiltonian operator is $\hat{H}=-(\hbar^2/2)\Delta_{\mathrm{LB}}$ with Δ_{LB} being the Laplace-Beltrami operator on the surface. One may try to get the Podolsky theory by some quantization procedure. Different methods of quantization yield various results which usually have the following general form:

$$\hat{H}=-\frac{\hbar^2}{2}\Delta_{\mathrm{LB}}+V_q(x), \tag{1}$$

the function $V_q(x)$ is commonly called "quantum potential." The Dirac canonical quantization[2] and the Abelian conversion method[3,4] were discussed in our previous work[5] for surfaces of codimension 1 in $\mathbb{R}^n$. (The codimension is the difference between the bulk space dimension and the dimension of the submanifold. In particular, codimension 1 surfaces can be defined by one equation and have one-dimensional normal space at each point. For these surfaces all notions of classical differential geometry are valid after obvious generalizations in the number of coordinates. For example, in the next section we would use the principal curvatures[6] of codimension 1 surfaces. At the same time, higher-codimensional surfaces present certain difficulties, and we encounter some of them in Sec. VI). This paper is devoted to another theory: the thin layer quantization. In this approach the particle moves between two equidistant infinite potential walls[7] or it is subject to some potential force which in a proper limit makes it moving strictly along the surface.[8]

The thin layer method seems to be natural for description of low dimensional motions in nanoelectronics. Recent progress in nanotechnology caused a great activity in the field. Free particle energy spectrum was investigated for thin layers around cylinders,[9] tori,[10] and arbitrary surfaces of revolution.[11] In this paper we clarify the general properties of the thin layer method and establish its equivalence with Prokhorov quantization procedure[12,13] for codimension 1 surfaces. For a vast majority of higher codimensional cases the thin layer method fails to yield meaningful results,[14] at least of the general form (1), while the Prokhorov quantization can be generalized directly as we show in Sec. VI.

[a)]Electronic mail: alex@amber.ff.phys.spbu.ru

In Sec. II we describe the thin layer quantization method in a geometrically clear manner which allows us to deal with any codimension 1 surface in $\mathbb{R}^n$ without any complications in comparison with two-dimensional surfaces in $\mathbb{R}^3$. In contrast with Ref. 8 we use only the most elementary notions of differential geometry. In Sec. III we establish the equivalence of the thin layer approach with Prokhorov quantization method[12,13]. In Sec. IV a method of quantization with Hermitian momenta recently proposed by Encinosa[15] is analyzed. In Secs. V and VI we consider surfaces of codimension greater than 1.

II. QUANTIZATION FOR CODIMENSION 1 SURFACES

We consider $(n-1)$-dimensional smooth surface in $\mathbb{R}^n$ and two infinite potential walls at the distance $\delta\to 0$ from the surface. Free quantum particle moves in the thin layer of width 2δ between these potential walls. We introduce a curvilinear coordinate system in which $|x_n|$ equals the distance from the surface to the given point, and the coordinate lines of $x_1,\ldots,x_{n-1}$ are orthogonal to coordinate lines of x_n. We have the boundary condition $\Psi|_{x_n=\delta}=\Psi|_{x_n=-\delta}=0$ and Hamiltonian $\widetilde{H}=-(\hbar^2/2)\widetilde{\Delta}$ with $\widetilde{\Delta}$ being the Laplace operator in $\mathbb{R}^n$,

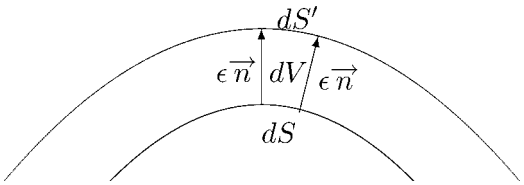
$$\widetilde{\Delta}=\sum_{i=1}^{n}\sum_{k=1}^{n}\tilde{g}^{-1/2}\partial_i\tilde{g}^{1/2}\tilde{g}^{ik}\partial_k=\partial_n^2+(\tilde{g}^{-1/2}\partial_n\tilde{g}^{1/2})\partial_n+\Delta_{\mathrm{LB}},$$

$$\tilde{g}_{ik}=\begin{pmatrix} g_{ab} & 0\\ 0 & 1\end{pmatrix},$$

where Δ_{LB} is the Laplace-Beltrami operator on the surface $x_n=\mathrm{const}$. One can prove[5] that $\tilde{g}^{-1/2}\partial_n\tilde{g}^{1/2}=\mathrm{div}\,\vec{n}$ with $\vec{n}$ being a unit normal vector to the surface, hence

$$\widetilde{\Delta}=\partial_n^2+\mathrm{div}(\vec{n})\cdot\partial_n+\Delta_{\mathrm{LB}}. \tag{2}$$

Indeed, let us consider two surfaces, $x_n=0$ and $x_n=\epsilon$. Suppose we have an infinitesimal area $\mathrm{d}S$ at the surface $x_n=0$. We denote the corresponding area element on $x_n=\epsilon$ surface by $\mathrm{d}S'$:



We have $\mathrm{div}(\vec{n})=[(\mathrm{d}S'-\mathrm{d}S)/\mathrm{d}V]+\mathcal{O}(\epsilon)=[(\mathrm{d}S'-\mathrm{d}S)/\epsilon\mathrm{d}S]+\mathcal{O}(\epsilon)$, so $\tilde{g}^{-1/2}\partial_n\tilde{g}^{1/2}=\mathrm{div}(\vec{n})$.

Now, let us take some point at the surface and consider another coordinate system $y_1,\ldots,y_n$. We choose it to be Cartesian and such that at the given point the tangent paraboloid of the surface is presented in its canonical form: $y_n=\frac{1}{2}\Sigma_{a=1}^{n-1}k_a y_a^2$. So, in the vicinity of the chosen point ($\vec{y}=0$) the equation of surface is $y_n=\frac{1}{2}\Sigma_{a=1}^{n-1}k_a y_a^2+\mathcal{O}(y_a^3)$, k_a's are the principal curvatures. The unit normal is

$$n_a=\frac{k_a y_a}{\sqrt{1+\sum_{a=1}^{n-1}k_a^2 y_a^2}}+\mathcal{O}(y_a^2)=k_a y_a+\mathcal{O}(y_a^2),\quad n_n=-1+\mathcal{O}(y_a^2)$$

and

$$\mathrm{div}\,\vec{n}=\sum_{a=1}^{n-1}k_a+\mathcal{O}(y_a). \tag{3}$$

The surface $x_n=\epsilon$ can be obtained by $\vec{y}\to\vec{y}'=\vec{y}+\epsilon\vec{n}$, and $\mathrm{d}y_a'=\mathrm{d}y_a(1+\epsilon k_a+\mathcal{O}(y_a))$. It yields

$$\frac{dS'}{dS} = \frac{\prod_{a=1}^{n-1}(1+\mathcal{O}(y_a'2))dy_a'}{\prod_{a=1}^{n-1}(1+\mathcal{O}(y_a^2))dy_a} = \prod_{a=1}^{n-1}(1+\epsilon k_a) + \mathcal{O}(y_a)$$

near the point $\vec{y}=0$. At the line $y_a=0\ \forall a=1,\ldots,n-1$ one has

$$\frac{dS'}{dS} = 1 + \epsilon\sum_{a=1}^{n-1} k_a + \frac{1}{2}\epsilon^2\left(\left(\sum_{a=1}^{n-1} k_a\right)^2 - \sum_{a=1}^{n-1} k_a^2\right) + \mathcal{O}(\epsilon^3). \tag{4}$$

The relation (4) is valid at every point of the surface provided that one takes the principal curvatures at the same point.

Following Refs. 7 and 8 we introduce a wave function

$$\chi(x) = \Psi(x)\sqrt{\frac{dS'}{dS}}.$$

It is natural because

$$\int_{|x_n|\le\delta} dV|\Psi(x)|^2 = \int_{-\delta}^{\delta} dx_n \int dS|\chi(x)|^2,$$

so that the normal and tangential coordinates are completely separated. For the lowest energy solutions the normal motion is restricted only to the factor of $\cos(\pi x_n/2\delta)$, and the integration over x_n yields just the constant number. It means that the conservation of norm for $\chi(x)$ is satisfied. From (2)–(4) one gets

$$\tilde{\Delta}\Psi(x) = \tilde{\Delta}\frac{\chi(x)}{\sqrt{\frac{dS'}{dS}}} = \Delta_{\mathrm{LB}}\frac{\chi(x)}{\sqrt{\frac{dS'}{dS}}} + \frac{\partial_n^2\chi(x)}{\sqrt{\frac{dS'}{dS}}} + \chi(x)\partial_n^2\frac{1}{\sqrt{\frac{dS'}{dS}}} + 2\partial_n\chi(x)\partial_n\frac{1}{\sqrt{\frac{dS'}{dS}}} + \mathrm{div}\,\vec{n}\cdot\frac{\partial_n\chi(x)}{\sqrt{\frac{dS'}{dS}}}$$

$$+ \mathrm{div}\,\vec{n}\cdot\chi(x)\partial_n\frac{1}{\sqrt{\frac{dS'}{dS}}} = \Delta_{\mathrm{LB}}\chi(x) + \partial_n^2\chi(x) + \left(\frac{1}{2}\sum_{a=1}^{n-1} k_a^2 - \frac{1}{4}\left(\sum_{a=1}^{n-1} k_a\right)^2\right)\chi(x) + \mathcal{O}(x_n).$$

For the lowest energy levels we have

$$\chi(x_1,\ldots,x_n) = f(x_1,\ldots,x_{n-1})\cos\frac{\pi x_n}{2\delta} \tag{5}$$

and, after taking $\delta\to 0$ limit and subtracting an infinite (proportional to $1/\delta^2$) energy, the Hamiltonian

$$\hat{H} = -\frac{\hbar^2}{2}\Delta_{\mathrm{LB}} + \frac{\hbar^2}{8}\left(\left(\sum_{a=1}^{n-1} k_a\right)^2 - 2\sum_{a=1}^{n-1} k_a^2\right) \tag{6}$$

is obtained. In simple cases the factorization (5) works very good even for not so small values of δ.[11]

What was presented before (infinite potential walls) is rather the approach of Ref. 7 than of Ref. 8. But the difference is not very important. One could use an appropriate confining potential instead of infinite walls. It would lead to the lowest energy level function of the potential $V_{\mathrm{conf}}(x_n/\delta)$ instead of $\cos(\pi x_n/2\delta)$ and to another infinite energy.

Hamiltonian (6) contains quantum potential

$$V_q = \frac{\hbar^2}{8}\left(\left(\sum_{a=1}^{n-1} k_a\right)^2 - 2\sum_{a=1}^{n-1} k_a^2\right).$$

For two-dimensional surfaces in $\mathbb{R}^3$ we get the result of da Costa:[8] $V_q=-(\hbar^2/8)(k_1-k_2)^2$. For a sphere $k_a=1/R$ and the potential is $V_q=\hbar^2(n-1)(n-3)/8R^2$.

Physically this quantization can describe lower dimensional motions in nanoelectronics provided that the restricting potential makes a layer of uniform effective width. Of course, it would be still a severe problem to check this potential experimentally due to the great energy proportional to the width of layer powered by −2. (Actually, it is not so great in comparison with the kinetic energy of chaotic motion at ordinary temperatures. It means that the method would not work well due to excitation of higher energy levels of the transverse motion. So, a cryogenic experiment is needed.) This energy is constant on the physical surface if the potential depends only on a distance from the surface. For more complex potentials the results may differ. One can get different infinite energies in different parts of the surface. It would mean infinite tangential forces, of course. But if variation of width becomes smaller and smaller while $\delta\to 0$ it is obviously possible to obtain some finite additional potential.

III. EQUIVALENCE WITH PROKHOROV QUANTIZATION

We should mention that there is one more method of quantization proposed by Prokhorov.[12] The motion of a particle is considered as a system with two second class constraints but the only one condition is imposed on the physical sector: $\hat{P}_n\Psi_{\text{phys}}(x)=0$ with $\hat{P}_n=-i\hbar\,(1/\tilde{g}^{1/4})(\partial/\partial x_n)\tilde{g}^{1/4}$. It means that

$$\partial_n\left(\sqrt{\frac{dS'}{dS}}\Psi_{\text{phys}}(x)\right)=0. \tag{7}$$

Having solved some task by this method, one should set $x_n=0$ in the results *after* all the differentiations over x_n are performed. Due to (7) the probability to find a particle at the distance $|x_n|$ from the surface *does not depend* on the value of x_n, and we choose one value we need. For Prokhorov's view see Refs. 12 and 13.

From (7) and (4) we conclude that

$$\partial_n\Psi_{\text{phys}}(x) = -\frac{\Psi_{\text{phys}}(x)}{\sqrt{\frac{dS'}{dS}}}\partial_n\sqrt{\frac{dS'}{dS}} = -\Psi_{\text{phys}}(x)\left(\frac{1}{2}\sum_{a=1}^{n-1} k_a - \frac{1}{2}x_n\sum_{a=1}^{n-1} k_a^2 + \mathcal{O}(x_n^2)\right),$$

$$\partial_n^2\Psi_{\text{phys}}(x) = \Psi_{\text{phys}}(x)\left(\frac{1}{4}\left(\sum_{a=1}^{n-1} k_a\right)^2 + \frac{1}{2}\sum_{a=1}^{n-1} k_a^2 + \mathcal{O}(x_n)\right).$$

Now (2) and (3) yield

$$-\frac{\hbar^2}{2}\tilde{\Delta}\Psi_{\text{phys}}(x) = -\frac{\hbar^2}{2}\Delta_{\text{LB}}\Psi_{\text{phys}}(x) + \frac{\hbar^2}{8}\left(\left(\sum_{a=1}^{n-1} k_a\right)^2 - 2\sum_{a=1}^{n-1} k_a^2\right)\Psi_{\text{phys}}(x).$$

So, the quantum potential coincides with the one obtained by the thin layer method. The reason is clear. The lowest energy level wave functions (in the model with two infinite potential walls) have nodes at $x_n=\pm\delta$ and the bunch at $x_n=0$: $\partial_n\chi=0$ or, equivalently, $\hat{P}_n\Psi=0$. The methods of da Costa and Prokhorov are equivalent (disregarding the infinite energy of the thin layer quantization).

Actually, one could use the calculation of $\tilde{\Delta}\Psi(x)$ from Sec. II and set $\partial_n\chi\equiv 0$ (but note that in Prokhorov method one uses Ψ as a wave function, not χ).

IV. ON HERMITIAN MOMENTA OF ENCINOSA

Recently Encinosa[15] proposed one more quantization method for a constrained free motion. The starting point is the Hamiltonian in curvilinear coordinates x_i,

$$H=\frac{1}{2}\left(\sum_{i-1}^{n-1}\frac{p_i^2}{h_i(x)}+p_n^2\right),$$

and the recipe is simple, $p_i\to\hat{p}_i=-i\hbar\tilde{g}^{-1/4}\partial_i\tilde{g}^{1/4}$ followed by the thin layer method. According to these rules we have in our notations

$$\hat{H}\frac{f(x_1,\ldots,x_{n-1})\cos\dfrac{\pi x_n}{2\delta}}{\sqrt{\dfrac{\mathrm{d}S'}{\mathrm{d}S}}}=\frac{1}{2}\sum_{i-1}^{n-1}\frac{\hat{p}_i^2}{h_i(x)}\frac{f(x_1,\ldots,x_{n-1})\cos\dfrac{\pi x_n}{2\delta}}{\sqrt{\dfrac{\mathrm{d}S'}{\mathrm{d}S}}}-\frac{1}{2}\frac{\hbar^2 f(x_1,\ldots,x_{n-1})}{\sqrt{\dfrac{\mathrm{d}S'}{\mathrm{d}S}}}\partial_n^2\cos\frac{\pi x_n}{2\delta}.$$

Effectively this result may be considered as zero quantum potential (geometric potential in the terminology of Ref. 15). We should make two important comments on this point.

(a) Quantization in curvilinear coordinates is dangerous, because the results usually depend on the choice of coordinate system. Nevertheless, the meaning of the method considered could be clear if momenta operators were self-adjoint, but it is not the case even for spherical coordinates on the sphere.

(b) Strictly speaking, the recipe is not defined correctly, because the operator ordering problem in $\hat{p}_i^2/h_i(x)$ terms is not solved. It is not difficult to deduce the correct ordering for the zero potential theory from the relation

$$-\hbar^2\tilde{\Delta}=-\hbar^2\sum_{i=1}^{n}\sum_{k=1}^{n}\tilde{g}^{-1/2}\partial_i\tilde{g}^{1/2}\tilde{g}^{ik}\partial_k=\sum_{i=1}^{n}\tilde{g}^{-1/4}\hat{p}_i\tilde{g}^{1/4}\tilde{g}^{ii}\hat{p}_i$$

in any orthogonal coordinate system. But this particular ordering is not natural *a priori*. Let us turn to the case of $\mathcal{S}^2$ with stereographic coordinates $x_1=2(R+x_3)\cot(\vartheta/2)\cos\varphi$ and $x_2=2(R+x_3)\cot(\vartheta/2)\sin\varphi$. In Ref. 16 it was shown that in these coordinates the Laplace-Beltrami operator on the sphere of radius $R+x_3$ equals

$$-\frac{\hbar^2}{2}\Delta_{\mathrm{LB}}=\left(1+\frac{x_1^2+x_2^2}{4(R+x_3)^2}\right)\frac{(\hat{p}_1^2+\hat{p}_2^2)}{2}\left(1+\frac{x_1^2+x_2^2}{4(R+x_3)^2}\right).$$

Even less natural it would seem for $\mathcal{S}^n$ in $\mathbb{R}^{n+1}$,

$$-\frac{\hbar^2}{2}\Delta_{\mathrm{LB}}=\frac{1}{2}\left(1+\frac{x_1^2+\cdots+x_n^2}{4(R+x_{n+1})^2}\right)^{n/2}\times\sum_{i=1}^{n}\left(\hat{p}_i\left(1+\frac{x_1^2+\cdots+x_n^2}{4(R+x_{n+1})^2}\right)^{2-n}\hat{p}_i\right)\left(1+\frac{x_1^2+\cdots+x_n^2}{4(R+x_{n+1})^2}\right)^{n/2}.$$

And, of course, for coordinates of Sec. 5 in Ref. 16 the situation would not be better.

V. ELEMENTARY CASES OF CODIMENSION >1

In general let us consider m-dimensional smooth surface in $\mathbb{R}^n$ represented by its tangent paraboloid at some point,

$$y_\alpha=\frac{1}{2}\sum_{a=1}^{m}\sum_{b=1}^{m}k_{ab}^{(\alpha)}y_a y_b+\mathcal{O}(y_a^3),\tag{8}$$

$\alpha=m+1,\ldots,n$, $k_{ab}^{(\alpha)}=k_{ba}^{(\alpha)}$. In general $n-m$ curvature forms $k^{(\alpha)}$ cannot be diagonalized simultaneously and the notion of principal curvatures does not exist, but in this section we treat the simplest cases for which the diagonalization can be performed.

First of all, for one-dimensional manifolds (curves) curvature forms $k^{(\alpha)}$ are just real numbers. In this case by a rotation in the space of y_α one can get $y_2=\frac{1}{2}ky_1^2+\mathcal{O}(y_1^3)$, $y_3,\ldots,y_n=\mathcal{O}(y_1^3)$. The unit normal vectors are $n_1^{(2)}=ky_1+\mathcal{O}(y_1^2)$, $n_2^{(2)}=-1+\mathcal{O}(y_1^2)$, $n_3^{(2)}=\cdots=n_n^{(2)}=\mathcal{O}(y_1^2)$; $n_i^{(\alpha)}=-\delta_{i\alpha}+\mathcal{O}(y_1^2)$ for $\alpha\geq 3$. We have $\vec{n}^{(\alpha)}\vec{n}^{(\beta)}=\delta_{\alpha\beta}+\mathcal{O}(y_1^2)$ and after the transformation $\vec{y}\to\vec{y}'=\vec{y}+\Sigma_{\alpha=2}^n\epsilon_\alpha\vec{n}^{(\alpha)}$ one gets $dy_1'=(1+\epsilon_2 k+\mathcal{O}(y_1))dy_1$, $dy_\alpha'=(1+\mathcal{O}(y_1))dy_\alpha$.

Now we consider a smooth family of such coordinate systems and normals along the curve. We introduce a curvilinear coordinate system in which x_1 is just the length along the curve while $x_\alpha=\vec{n}^{(\alpha)}\cdot\vec{r}$ where $\vec{r}$ is the minimal norm radius vector from the curve to a given point and $\vec{n}^{(\alpha)}$ is taken at the same point on the curve as $\vec{r}$. In this coordinate system we have

$$\tilde{g}_{ik}=\begin{pmatrix}(1+x_2k)^2 & 0\\ 0 & I\end{pmatrix}$$

and

$$\tilde{\Delta}=\Delta_c+\Delta_n+\left(\frac{1}{1+x_2k}\partial_2(1+x_2k)\right)\partial_2=\Delta_c+\Delta_n+\frac{k}{1+x_2k}\partial_2,$$

where Δ_c is Laplace-Beltrami operator on a curve $x_\alpha=\text{const}$ and $\Delta_n=\Sigma_{\alpha=2}^n\partial_\alpha^2$ is the Laplace operator in a hyperplane $x_1=\text{const}$.

To proceed with the thin layer quantization we introduce a thin layer $\Sigma_{\alpha=2}^n x_\alpha^2=\delta^2$ around the curve and a wave function $\chi(x)=\sqrt{1+x_2k}\,\Psi(x)$ such that $\int dx_1\int dS_{\text{normal}}|\chi(x)|^2=\int dV|\Psi(x)|^2$:

$$\tilde{\Delta}\Psi(x)=\tilde{\Delta}\frac{\chi(x)}{\sqrt{1+x_2k}}=\Delta_c\chi(x)+\Delta_n\chi(x)+\frac{k^2}{4}\chi(x)+\mathcal{O}(x_\alpha).$$

After subtracting an infinite energy due to $\Delta_n\chi(x)$ it yields the quantum potential $V_q=-(\hbar^2/8)k^2$ as in Ref. 8.

We should mention that it is very important for this result that the thin layer is spherical at every point of the curve. Indeed, suppose we have a straight line in $\mathbb{R}^3$. We can first embed a cylinder of any radius R into $\mathbb{R}^3$ and after that, with much more thin layer, we embed a line into the cylinder. The first embedding results in $V_q=-\hbar^2/8R^2$ and the second one changes nothing because the line is geodesic in the cylinder. Note that it is possible to generalize our considerations to the case of embedding into non-Euclidean spaces in a sense that, if one has a free particle Hamiltonian (probably, with some quantum potential) in a Riemannian manifold, he may consider a thin layer of constant width around any codimension 1 submanifold. For a cylinder it would literally reproduce the demonstrations of Sec. II because in intrinsic geometry the cylinder is flat.

As another simple example we consider two-dimensional flat torus isometrically embedded in $\mathbb{R}^4$,

$$x_1^2+x_2^2=R_1^2,$$

$$x_3^2+x_4^2=R_2^2.$$

We use the following coordinate system:

$$\phi_1=\arctan\frac{x_2}{x_1},$$

$$\phi_2=\arctan\frac{x_4}{x_3},$$

$$r_1 = \sqrt{x_1^2 + x_2^2} - R_1,$$

$$r_2 = \sqrt{x_3^2 + x_4^2} - R_2$$

with

$$\tilde{g}_{ik} = \begin{pmatrix} (r_1+R_1)^2 & 0 & 0 & 0 \\ 0 & (r_1+R_1)^2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

and $\tilde{\Delta} = \Delta_t + \Delta_n + [1/(r_1+R_1)]\partial_{r_1} + [1/(r_2+R_2)]\partial_{r_2}$ where Δ_t is the Laplace-Beltrami operator on the torus $r_1 = \text{const}$, $r_2 = \text{const}$. We have the volume element $dV = (r_1+R_1)(r_2+R_2)dr_1\, dr_2\, d\phi_1\, d\phi_2$, the wave function $\chi = \sqrt{[1+(r_1/R_1)][1+(r_2/R_2)]}\Psi$ and the quantum potential $V_q = -(\hbar^2/8)(k_1^2+k_2^2)$ with $k_a = 1/R_a$.

VI. GENERAL THEORY

In general the geometric construction is very similar to that of the one-dimensional case. The unit normals to the surface (8) at $\vec{y}=0$ are $n_\beta^{(\alpha)} = \delta_{\alpha\beta}(-1+\mathcal{O}(y_a^2))$, $n_a^{(\alpha)} = \sum_{b=1}^m k_{ab}^{(\alpha)} y_b + \mathcal{O}(y_a^2)$, $\alpha, \beta = m+1, \ldots, n$, $a, b = 1, \ldots, m$, and after the replacement $\vec{y} \to \vec{y}' = \vec{y} + \sum_{\alpha=m+1}^n \epsilon_\alpha \vec{n}^{(\alpha)}$ one gets

$$dy_a' = \sum_{b=1}^m \left(\delta_{ab} + \sum_{\alpha=m+1}^n \epsilon_\alpha k_{ab}^{(\alpha)} + \mathcal{O}(y_c) \right) dy_b,$$

$dy_\alpha' = (1+\mathcal{O}(y_c))dy_\alpha$. It means that in curvilinear coordinate system

$$g_{ab}(x_1, \ldots, x_n) = \sum_{c=1}^m \left(\delta_{ca} + \sum_{\alpha=m+1}^n x_\alpha k_{ca}^{(\alpha)} \right) \times \left(\delta_{cb} + \sum_{\beta=m+1}^n x_\beta k_{cb}^{(\beta)} \right) f_{ab}(x_1, \ldots, x_m)$$

with $x_\alpha = \vec{n}^{(\alpha)} \cdot \vec{r}$ as in the preceding section and $f_{ab}(x_1, \ldots, x_m) = g_{ab}(x_1, \ldots, x_m, 0, \ldots, 0)$. In this system if some point has coordinates $(x_1, \ldots, x_n)$ then its position can be found by adding the vector $\sum_{\alpha=m+1}^n x_\alpha \vec{n}^{(\alpha)}$ to the radius vector of the initial surface point with coordinates $(x_1, \ldots, x_m)$. If we choose $x_a = y_a$ at the surface $x_\alpha = 0$, then at the $x_a = 0$ hyperplane $f_{ab} = \delta_{ab}$, $x_\alpha = \epsilon_\alpha$, and $g_{ab} = \delta_{ab} + 2\sum_\alpha \epsilon_\alpha k_{ab}^{(\alpha)} + \sum_{\alpha,\beta,c} \epsilon_\alpha \epsilon_\beta k_{ac}^{(\alpha)} k_{bc}^{(\beta)}$. An easy computation yields

$$g = 1 + 2\sum_{\alpha,a} \epsilon_\alpha k_{aa}^{(\alpha)} + 2 \sum_{\alpha,\beta,a,b} \epsilon_\alpha \epsilon_\beta k_{aa}^{(\alpha)} k_{bb}^{(\beta)} - 2 \sum_{\alpha,\beta,a} \epsilon_\alpha \epsilon_\beta k_{aa}^{(\alpha)} k_{aa}^{(\beta)} + 3\sum_{a,b} \left(\sum_\alpha \epsilon_\alpha k_{ab}^{(\alpha)} \right)^2 - 2\sum_a \left(\sum_\alpha \epsilon_\alpha k_{aa}^{(\alpha)} \right)^2 + \mathcal{O}(\epsilon^3).$$

The problem is that the coordinates x_i are not orthogonal. Parallel translations of the surface along one of the normals breaks its orthogonality to other normals. Indeed, we have $\partial n_b^{(\alpha)} / \partial y_a = k_{ab}^{(\alpha)} + \mathcal{O}(y_c)$ and $\partial n_\beta^{(\alpha)} / \partial y_a = \mathcal{O}(y_c)$. We suppose that all normals have unit length, hence

$$0 = \frac{\partial \vec{n}^{(\alpha)}}{\partial y_a} \cdot \vec{n}^{(\alpha)} = \sum_{b,c} k_{bc}^{(\alpha)} y_c k_{ab}^{(\alpha)} - \frac{\partial n_\alpha^{(\alpha)}}{\partial y_a} + \mathcal{O}(y_c^2)$$

and

$$\frac{\partial n_\alpha^{(\alpha)}}{\partial y_a} = \sum_{b,c} k_{ab}^{(\alpha)} k_{bc}^{(\alpha)} y_c + \mathcal{O}(y_c^2).$$

Now we see that parallel translations lead to violation of orthogonality condition because

$$\frac{\partial \vec{n}^{(\beta)}}{\partial y_a} \cdot \vec{n}^{(\alpha)} = \sum_{b,c} (k_{ab}^{(\beta)} - k_{ab}^{(\alpha)}) k_{bc}^{(\alpha)} y_c + \mathcal{O}(y_c^2) \neq 0.$$

We introduce a notation $f_{\alpha a}^{(\beta)} = f_{a\alpha}^{(\beta)} = \Sigma_{b,c}(k_{ab}^{(\beta)} - k_{ab}^{(\alpha)}) k_{bc}^{(\alpha)} y_c$ and find the metric tensor

$$\tilde{g}_{ik} = \begin{pmatrix} g_{ab} & \sum_\gamma f_{a\beta}^{(\gamma)} \epsilon_\gamma + \mathcal{O}(\epsilon^2) \\ \sum_\gamma f_{\beta a}^{(\gamma)} \epsilon_\gamma + \mathcal{O}(\epsilon^2) & \delta_{\alpha\beta} \end{pmatrix},$$

its determinant $\tilde{g} = g + \mathcal{O}(\epsilon^2)$ and the reciprocal tensor

$$\tilde{g}^{ik} = \begin{pmatrix} g^{ab} & -\sum_{c,\gamma} g^{ac} f_{c\beta}^{(\gamma)} \epsilon_\gamma + \mathcal{O}(\epsilon^2) \\ -\sum_{c,\gamma} f_{\alpha c}^{(\gamma)} g^{cb} \epsilon_\gamma + \mathcal{O}(\epsilon^2) & \delta_{\alpha\beta} \end{pmatrix}.$$

Da Costa concluded[14] that the thin layer quantization would not work well in this situation because $\tilde{\Delta}$ contains terms with both derivatives ∂_a and ∂_α.

The situation is quite different for the method proposed in Ref. 12. All new terms in $\tilde{\Delta}$ have coefficients of order $\mathcal{O}(\epsilon)$; the only suspicious term,

$$\sum_{a,\alpha} (\partial_\alpha g^{a\alpha}) \partial_a = \left(- \sum_{a,c,\alpha,\beta} g^{ac} f_{c\alpha}^{(\beta)} \delta_{\alpha\beta} + \mathcal{O}(\epsilon) \right) \partial_a = \mathcal{O}(\epsilon) \partial_a,$$

is not dangerous because $f_{c\alpha}^{(\alpha)} = 0$. In Prokhorov quantization method the condition $\partial_\alpha (g^{1/4} \Psi_{\text{phys}}) = 0$, $\forall \alpha = m+1, \ldots, n$ is imposed. For a function $\chi(x) = (g/f)^{1/4} \Psi(x)$ it means $\partial_\alpha \chi = 0$, and we get

$$\tilde{\Delta} \frac{\chi(x)}{\left(\frac{g}{f}\right)^{1/4}} = \Delta_{\text{LB}} \frac{\chi(x)}{\left(\frac{g}{f}\right)^{1/4}} + \chi(x) \Delta_n \frac{1}{\left(\frac{g}{f}\right)^{1/4}} + \chi(x) \sum_{\alpha=m+1}^{n} \left(\frac{1}{\sqrt{g}} \partial_\alpha \sqrt{g} \right) \partial_\alpha \frac{1}{\left(\frac{g}{f}\right)^{1/4}} + \mathcal{O}(x_\alpha),$$

$\Delta_n \equiv \Sigma_{\alpha=m+1}^n \partial_\alpha^2$. It is easy to see that $(1/\sqrt{g}) \partial_\alpha \sqrt{g} = -2 g^{1/4} \partial_\alpha g^{-1/4}$, and the Hamiltonian is $\hat{H} = -(\hbar^2/2) \Delta_{\text{LB}} + V_q(x)$,

$$V_q = -\frac{\hbar^2}{2} \left(g^{1/4} \Delta_n g^{-1/4} - 2 \sum_{\alpha=m+1}^{n} (g^{1/4} \partial_\alpha g^{-1/4})^2 \right) \Bigg|_{x_\alpha = 0}.$$

One more (not too difficult) calculation yields

$$V_q = \frac{\hbar^2}{8} \sum_{\alpha=m+1}^{n} \left(\left(\sum_{a=1}^{m} k_{aa}^{(\alpha)} \right)^2 + 6 \sum_{a=1}^{m} \sum_{b=1}^{m} (k_{ab}^{(\alpha)})^2 - 8 \sum_{a=1}^{m} (k_{aa}^{(\alpha)})^2 \right). \tag{9}$$

The thin layer method would not give this answer because in this method we have $\partial_\alpha \chi = 0$ only at the original surface and generally $\partial_\alpha \chi \sim 1/\delta$, so that terms with $\partial_\alpha \chi$ are not negligible and factorization similar to (5) is not a good approximation of the exact thin layer solution. It is not surprising. Let us take a small element of the surface and its δ-neighborhood, $\delta \to 0$. The well-known theorem states that $\int \mathrm{d}V \, \Delta\Psi = \int \mathrm{d}\vec{S} \cdot \vec{\nabla} \Psi$. We have $\Delta\Psi \approx \int \mathrm{d}\vec{S} \cdot \vec{\nabla} \Psi / V$ and in the codimension 1 case the normal projection of $\vec{\nabla} \Psi$ leads to $1/\delta^2$ term in $\Delta\Psi$ (because $\partial_n \Psi \sim 1/\delta$ and $V \sim \delta$). Tangential components of $\vec{\nabla} \Psi$ result in finite values of $\Delta\Psi$ due to $\mathrm{d}S_\perp \sim \delta$. In the general case $V \sim \delta^{n-m}$ and $\mathrm{d}S \sim \delta^{n-m}$, hence the tangential components of $\vec{\nabla} \Psi$ yield finite terms in $\Delta\Psi$ again; but normal projections gain some components orthogonal to transverse hyperplanes (x_a

=const). The corresponding angles are of order δ but $\partial_\alpha \Psi \sim 1/\delta$. It results in finite terms in $\Delta\Psi$. So, normal components of $\vec{\nabla}\Psi$ influence the tangential dynamics. Hence, the thin layer method of Refs. 7, 8, and 14 *does not* yield the result of the general form (1). It means that the Prokhorov method in such cases *does not* correspond to the motion in the uniform thin layer but it turns out to be more powerful as an abstract quantization method for second class constrained systems. One could find, of course, some orthogonal coordinate system in the whole vicinity of the surface with normals depending on x_α and, maybe, one would be able to determine a geometry of the thin layer for which some factorization similar to (5) would be a good approximation. Quantum potential in this approach is likely to coincide with (9) at least with a certain realization of it, but generally the layer would not have constant width and the setup of the quantization would not be as easy and clear as the original one.

(Received 6 April 2006; accepted 13 June 2006; published online 21 August 2006)

By using the recent mathematical tools developed in quaternionic differential operator theory, we solve the Schrödinger equation in the presence of a quaternionic step potential. The analytic solution for the stationary states allows one to explicitly show the qualitative and quantitative differences between this quaternionic quantum dynamical system and its complex counterpart. A brief discussion on reflected and transmitted times, performed by using the stationary phase method, and its implication on the experimental evidence for deviations of standard quantum mechanics is also presented. The analytic solution given in this paper represents a fundamental mathematical tool to find an analytic approximation to the quaternionic barrier problem (up to now solved by numerical method). © *2006 American Institute of Physics.* [DOI: 10.1063/1.2227635]

I. INTRODUCTION

Since a quaternionic equation can be equivalently written as a two-component complex equation, it is natural to ask whether the quaternionic Schrödinger equation is simply another way of rewriting complex quantum mechanics. The answer to this question is given in the famous book[1] by Adler. Probabilities in quaternionic dynamical system are different from those of standard complex theory. In the first papers on the quaternionic Schrödinger equation, deviations from complex quantum mechanics were studied by considering quaternionic perturbation potentials.[2,3] Recent progress on the solution of quaternionic differential equations[4–6] has improved the physical discussion on quaternionic tunneling phenomena[7] and bound states.[8]

In this paper, an interesting simple quaternionic quantum mechanical system is *analytically* solved. This allows one to discuss both qualitative and quantitative differences between quaternionic and complex quantum mechanics. The explicit stationary wave solution for the quaternionic potential step shows some important results which could be very useful in looking for deviations from the standard quantum theory. For example, the quaternionic step diffusion is characterized by reflected and transmitted waves which are *not* instantaneous. The analytic solution is also very useful to understand the effect that quaternionic potentials play on the phase of stationary waves. The advantage to analytically solve a quaternionic problem is surely represented by the possibility to deeply study the quaternionic solution and understand where and if deviations from complex quantum theory could be seen.

II. FQUATERNIONIC SCHRÖDINGER EQUATION

In the quaternionic formulation of nonrelativistic quantum mechanics, the dynamics of a particle without spin subject to the influence of the anti-Hermitian scalar potential,

$$iV_1(\boldsymbol{r},t)+jV_2(\boldsymbol{r},t)+kV_3(\boldsymbol{r},t),$$

is described by

$$\hbar\,\partial_t\Psi(\boldsymbol{r},t)=\left[i\frac{\hbar^2}{2m}\nabla^2-iV_1(\boldsymbol{r},t)-jV_2(\boldsymbol{r},t)-kV_3(\boldsymbol{r},t)\right]\Psi(\boldsymbol{r},t), \tag{1}$$

with

$$V_{1,2,3}:\quad (\mathbb{R}^3,\mathbb{R})\to\mathbb{R}\quad\text{and}\quad \Psi:(\mathbb{R}^3,\mathbb{R})\to\mathbb{H}.$$

Equation (1) is known as the Schrödinger equation for quaternionic quantum mechanics.[1] It is natural to try to relate the new results coming from this quaternionic formulation with the well-known phenomena discussed in the standard textbooks of (complex) quantum mechanics.[9–11] In this spirit, the complex limit, i.e., $V_{2,3}\to 0$, surely represents a useful mathematical tool to test quaternionic calculations and to understand, by explicitly showing the difference between the quaternionic and complex formulation, if and where quaternionic deviations from standard quantum mechanics could be seen and investigated.

The linearity in ∂_t of the evolution time operator in Eq. (1) guarantees to obtain a positive probability density

$$\rho(\boldsymbol{r},t)=\overline{\Psi}(\boldsymbol{r},t)\Psi(\boldsymbol{r},t), \tag{2}$$

together with a continuity equation

$$\partial_t\rho(\boldsymbol{r},t)+\boldsymbol{\nabla}\cdot\boldsymbol{J}(\boldsymbol{r},t)=0. \tag{3}$$

To find the explicit form of the current density $\boldsymbol{J}(\boldsymbol{r},t)$, let us first derive the Schrödinger equation for $\overline{\Psi}(\boldsymbol{r},t)$ [the quaternionic conjugate of $\Psi(\boldsymbol{r},t)$, i.e., $(i,j,k)\to-(i,j,k)$],

$$\hbar\,\partial_t\overline{\Psi}(\boldsymbol{r},t)=-\frac{\hbar^2}{2m}\nabla^2\overline{\Psi}(\boldsymbol{r},t)i+\overline{\Psi}(\boldsymbol{r},t)[iV_1(\boldsymbol{r},t)+jV_2(\boldsymbol{r},t)+kV_3(\boldsymbol{r},t)]. \tag{4}$$

Combining Eq. (1) [multiplied from the left by $\overline{\Psi}(\boldsymbol{r},t)$] and Eq. (4) [multiplied from the right by $\Psi(\boldsymbol{r},t)$], we obtain

$$\partial_t[\overline{\Psi}(\boldsymbol{r},t)\Psi(\boldsymbol{r},t)]+\frac{\hbar}{2m}\{[\nabla^2\overline{\Psi}(\boldsymbol{r},t)]i\Psi(\boldsymbol{r},t)-\overline{\Psi}(\boldsymbol{r},t)i\nabla^2\Psi(\boldsymbol{r},t)\}=0.$$

Consequently, the density current in quaternionic quantum mechanics is formally equal to that one of the usual complex theory, i.e.,

$$\boldsymbol{J}(\boldsymbol{r},t)=\frac{\hbar}{2m}\{[\nabla\overline{\Psi}(\boldsymbol{r},t)]i\Psi(\boldsymbol{r},t)-\overline{\Psi}(\boldsymbol{r},t)i\,\nabla\,\Psi(\boldsymbol{r},t)\}. \tag{5}$$

It is worth pointing out that, due to the noncommutativity nature of quaternions, the position of the imaginary unit i is not a choice but it is imposed by the anti-Hermiticity of evolution time operator in Eq. (1).

A. Time independent potentials

In this paper, we are going to be concerned with a particle in a time independent potential. In complex quantum mechanics, the rapid spatial variations of a square potential introduce purely

quantum effects in the motion of the particle. The same is valid for perturbative quaternionic potentials. Before beginning our investigation, we shall discuss some important mathematical properties of the quaternionic Schrödinger equation in the presence of time independent potentials,

$$\hbar\,\partial_t\Psi(\boldsymbol{r},t)=\left[i\frac{\hbar^2}{2m}\nabla^2-iV_1(\boldsymbol{r})-jV_2(\boldsymbol{r})-kV_3(\boldsymbol{r})\right]\Psi(\boldsymbol{r},t). \tag{6}$$

Taking into account that $\Psi(\boldsymbol{r},t)$ is a quaternionic function, we apply the method of separation of variables with the time dependent function appearing on the right-hand side,[4]

$$\Psi(\boldsymbol{r},t)=\Phi(\boldsymbol{r})\exp\left[-\frac{i}{\hbar}Et\right], \tag{7}$$

with

$$\Phi:\quad \mathbb{R}^3\rightarrow\mathbb{H}.$$

This stationary solution of the Schrödinger equation leads to a time-independent probability density $\rho(\boldsymbol{r})$. Consequently, the current density satisfies

$$\boldsymbol{\nabla}\cdot\{[\nabla\overline{\Phi}(\boldsymbol{r})]i\Phi(\boldsymbol{r})-\overline{\Phi}(\boldsymbol{r})i\,\nabla\,\Phi(\boldsymbol{r})\}=0. \tag{8}$$

By using the separation of variable (7), Eq. (6) reduces to the following quaternionic (right) eigenvalue problem:[12,13]

$$\left[i\frac{\hbar^2}{2m}\nabla^2-iV_1(\boldsymbol{r})-jV_2(\boldsymbol{r})-kV_3(\boldsymbol{r})\right]\Phi(\boldsymbol{r})+\Phi(\boldsymbol{r})iE=0. \tag{9}$$

B. Time reversal invariance

From Eq. (6), we can immediately obtain the time-reversed Schrödinger equation

$$\hbar\,\partial_t\Psi_T(\boldsymbol{r},-t)=-\left[i\frac{\hbar^2}{2m}\nabla^2-iV_1(\boldsymbol{r})-jV_2(\boldsymbol{r})-kV_3(\boldsymbol{r})\right]\Psi_T(\boldsymbol{r},-t). \tag{10}$$

In complex quantum mechanics the *-conjugation yields a time-reversed version of the original Schrödinger equation. In quaternionic quantum mechanics there does *not* exist a universal time reversal operator.[1] Only a *restricted* class of time-independent quaternionic potentials $[V_2(\boldsymbol{r})\propto V_3(\boldsymbol{r})]$, i.e.,

$$W(\boldsymbol{r})=V_2(\boldsymbol{r})-iV_3(\boldsymbol{r})=|W(\boldsymbol{r})|\exp[i\theta]\quad(\theta=\text{const}),$$

is time reversal invariant. For these potentials,

$$\Psi_T(\boldsymbol{r},-t)=u\Psi(\boldsymbol{r},t)\overline{u},\quad u=k\exp[i\theta]. \tag{11}$$

In the standard quantum mechanics limit, due to the complex nature of the wave function $\Psi_{\mathbb{C}}(\boldsymbol{r},t)$, we recover the well-known result

$$\Psi_{\mathbb{C},T}(\boldsymbol{r},-t)=\Psi^*_{\mathbb{C}}(\boldsymbol{r},t).$$

C. One-dimensional square potentials

Let us consider one-dimensional potentials. In the case of square shapes, the potential is a quaternionic constant in certain regions of space. In such regions, the stationary wave function $\Phi(x)$ is obtained by solving the following second-order differential equation with (left) constant quaternionic coefficients,

$$\left[i\frac{\hbar^2}{2m}\Phi''(x) - iV_1 - jV_2 - kV_3 \right]\Phi(x) = -\Phi(x)iE. \tag{12}$$

It is not our purpose here to discuss the theory of quaternionic differential equations and we refer the interested reader to the papers cited in Refs. 4–6 where a detailed exposition of the subject is found. The solution of Eq. (12) is

$$\Phi(x) = (1+jw)\{\exp[\nu_- x]c_1 + \exp[-\nu_- x]c_2\} + (z+j)\{\exp[\nu_+ x]c_3 + \exp[-\nu_+ x]c_4\}, \tag{13}$$

where $c_{1,\ldots,4}$ are complex coefficients to be determined by the boundary conditions and

$$\nu_\pm = \sqrt{2m(V_1 \pm \sqrt{E^2 - V_2^2 - V_3^2})}/\hbar\ ,$$

$$z = i(V_2 + iV_3)/(E + \sqrt{E^2 - V_2^2 - V_3^2}),$$

$$w = -i(V_2 - iV_3)/(E + \sqrt{E^2 - V_2^2 - V_3^2}) \in \mathbb{C}(1,i).$$

In the free potential region ($V_{1,2,3}=0$) the previous solution reduces to

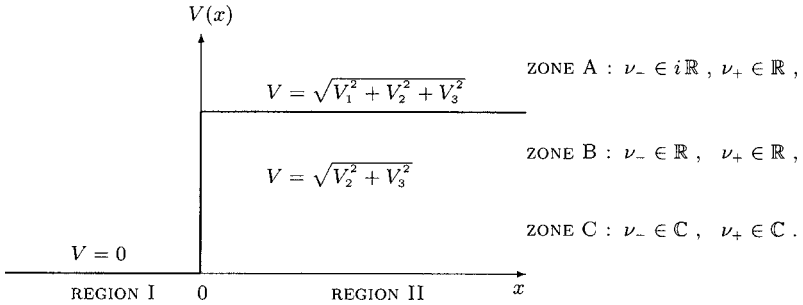
$$\Phi(x) = \exp[i\epsilon x]c_1 + \exp[-i\epsilon x]c_2 + j\{\exp[\epsilon x]c_3 + \exp[-\epsilon x]c_4\}, \tag{14}$$

where

$$\epsilon = \sqrt{2mE}/\hbar\ \in \mathbb{R}.$$

III. BOUNDED SOLUTIONS AND CURRENT DENSITY

Let us now calculate the stationary states in the case of a quaternionic step potential. The procedure follows the standard one. We use Eq. (13) in the region where the potential is a constant and Eq. (14) in the free region. We then impose that such solutions remain bounded and, finally, we match these functions by requiring the continuity of $\Phi(x)$ and its derivative in $x=0$. Before proceeding with our calculations, the only point deserving further discussion concerns the classification of the energy zones in the potential region (in order to distinguish between partial and total reflection). To do this, we have to analyze the complex exponential factors $\nu_\pm$. The possible cases are sketched in the following figure



To avoid any confusion between real and imaginary coefficients and to facilitate the reading of this paper, in the sequel, we shall adopt the following notation:

zone A:	$\nu_- = i\rho_-$,	ν_+,
zone B:	ν_-,	ν_+,
zone C:	$\nu_- = \sigma_+ - i\sigma_-$,	$\nu_+ = \sigma_+ + i\sigma_-$,

where

$$\rho_- = \sqrt{\frac{2m}{\hbar^2}(\sqrt{E^2 - V_2^2 - V_3^2} - V_1)}, \quad \sigma_\pm = \sqrt{\frac{m}{\hbar^2}(\sqrt{V_1^2 + V_2^2 + V_3^2 - E^2} \pm V_1)} \in \mathbb{R}.$$

A. Region I

For the solution to remain bounded when $x \to -\infty$, it is necessary to have $c_4=0$ in Eq. (14). So, the solution in region I becomes

$$\Phi_{\mathrm{I}}(x) = e^{i\epsilon x} + re^{-i\epsilon x} + j\tilde{r}e^{\epsilon x}, \tag{15}$$

where $c_2=r$ and $c_3=\tilde{r}$ represent the reflection coefficients to be determined by the matching conditions. From Eq. (8), we immediately find the constant value of the current density in this region, i.e.,

$$J_{\mathrm{I}} = (1 - |r|^2)\,\hbar\,\epsilon/m. \tag{16}$$

B. Region II - zone A: Partial reflection

The condition on the boundedness of the solution implies that $c_3=0$ in Eq. (13). Since the incident particle is coming from $x=-\infty$, we also have to impose $c_2=0$. The stationary wave function, in zone A, is then given by

$$\Phi_{\mathrm{II,A}}(x) = (1 + jw)te^{i\rho_- x} + (z + j)\tilde{t}e^{-\rho_+ x}, \tag{17}$$

where $c_1=t$ and $c_4=\tilde{t}$ represent the transmission coefficients to be determined by the matching conditions. In this region the current density is

$$J_{\mathrm{II,A}} = (1 - |w|^2)|t|^2\,\hbar\,\rho_-/m. \tag{18}$$

This means a non-null transmission probability and consequently partial reflection in region I.

C. Region II - zone B: Total reflection

For the solution to remain bounded when $x \to +\infty$, it is necessary that $c_2=c_4=0$ in Eq. (13). Thus, the solution in zone B is

$$\Phi_{\mathrm{II,B}}(x) = (1 + jw)te^{-\nu_- x} + (z + j)\tilde{t}e^{-\nu_+ x}. \tag{19}$$

In this zone, the current density is null

$$J_{\mathrm{II,B}} = 0. \tag{20}$$

This characterizes a total reflection in region I.

D. Region II - zone C: Total reflection

The boundedness condition of the solution implies that $c_1=c_3=0$ in Eq. (13). Thus, we have

$$\Phi_{\mathrm{II,C}}(x) = [(1 + jw)te^{i\sigma_- x} + (z + j)\tilde{t}e^{-i\sigma_- x}]e^{-\sigma_+ x}, \tag{21}$$

with

$$w = -i\frac{V_2 - iV_3}{\sqrt{V_2^2 + V_3^2}}e^{-i\varphi}, \quad z = i\frac{V_2 + iV_3}{\sqrt{V_2^2 + V_3^2}}e^{-i\varphi}, \quad \varphi = \arctan\left[\frac{\sqrt{V_2^2 + V_3^2 - E^2}}{E}\right].$$

As in the previous zone, the current density is null

$$J_{\mathrm{II,C}} = 0. \tag{22}$$

This implies total reflection in region I.

E. Relation between reflection and transmission coefficients

The stationary wave solution of the Schrödinger equation in the presence of a quaternionic step potential can then be expressed in terms of complex reflection $(r,\tilde{r})$ and transmission $(t,\tilde{t})$ coefficients:

$$\Phi_{\mathrm{I}}(x) = e^{i\epsilon x} + re^{-i\epsilon x} + j\tilde{r}e^{\epsilon x}, \tag{23}$$

$$\Phi_{\mathrm{II}}(x) = \begin{cases} (1+jw)te^{i\rho_- x} + (z+j)\tilde{t}e^{-\nu_+ x} & \text{zone A} \\ (1+jw)te^{-\nu_- x} + (z+j)\tilde{t}e^{-\nu_+ x} & \text{zone B} \\ [(1+jw)te^{i\sigma_- x} + (z+j)\tilde{t}e^{-i\sigma_- x}]e^{-\sigma_+ x} & \text{zone C}. \end{cases} \tag{24}$$

As we saw, the current density assumes a constant value. This value has been calculated in the free potential region and in each of the three different zones of region II. The continuity of $\Phi(x)$ and its derivative in $x=0$ implies the continuity of the current density, i.e., $J_{\mathrm{I}}=J_{\mathrm{II}}$. This gives an immediate relation between reflection and transmission coefficients,

$$R + T = 1, \tag{25}$$

with

$$R = |r|^2 \quad \text{and} \quad T = \frac{\rho_-}{\epsilon}(1-|w|^2)|t|^2 \quad \text{for } E > \sqrt{V_1^2+V_2^2+V_3^2},$$

$$R = |r|^2 \quad \text{and} \quad T = 0 \quad \text{for } E < \sqrt{V_1^2+V_2^2+V_3^2}.$$

Observe that both in complex and quaternionic quantum mechanics, to find the relation between R and T we do not have the necessity to find the explicit value of plane wave coefficients r and t.

IV. EXPLICIT PLANE WAVE SOLUTIONS

The usual method for determining the stationary states in a square potential requires the continuity of $\Phi(x)$ and its derivative at the point where the potential is discontinuous (in this case $x=0$). Then, we impose that

$$\begin{aligned} \Phi_{\mathrm{I}}(0) &= \Phi_{\mathrm{II}}(0), \\ \Phi_{\mathrm{I}}'(0) &= \Phi_{\mathrm{II}}'(0). \end{aligned} \tag{26}$$

A. Region II - zone A: Continuity

Matching the conditions at $x=0$, we get

$$1 + r + j\tilde{r} = (1+jw)t + (z+j)\tilde{t},$$

$$i\epsilon(1-r) + j\epsilon\tilde{r} = (1+jw)i\rho_- t - (z+j)\nu_+\tilde{t}.$$

After separating the complex from the pure quaternionic part, we find

$$1 + r = t + z\tilde{t},$$

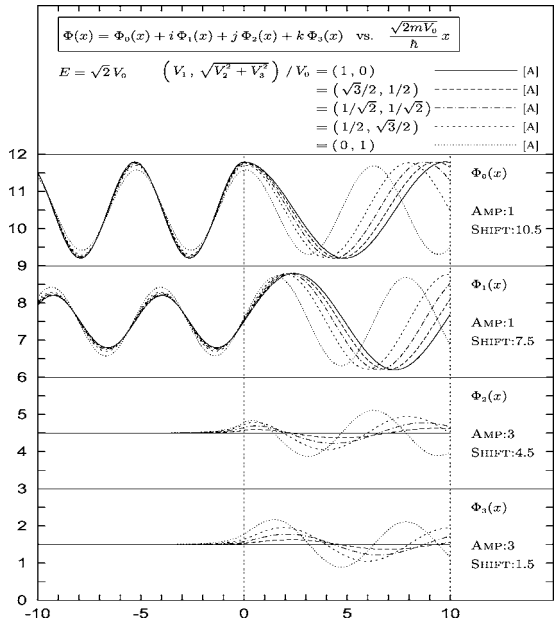


FIG. 1. Space is divided into region I ($x<0$) and region II ($x>0$). There is a constant quaternionic potential ($iV_1+jV_2+kV_3$) in region II whereas in region I there is no potential. The space dependence of the quaternionic stationary wave function $\Phi(x)$ is plotted for the energy zone A ($E>V_0=\sqrt{V_1^2+V_2^2+V_3^2}$) and for different complex/pure quaternionic potential ratios. The plots for the complex part of $\Phi(x)$ exhibit an oscillatory behavior both for region I and region II. The pure quaternionic part is practically absent in the free potential region.

$$\tilde{r} = wt + \tilde{t},$$

$$1 - r = \frac{\rho_-}{\epsilon}t + i\frac{\nu_+}{\epsilon}\tilde{zt},$$

$$\tilde{r} = i\frac{\rho_-}{\epsilon}wt - \frac{\nu_+}{\epsilon}\tilde{t},$$

which gives

$$\begin{aligned}
t &= \frac{2\epsilon}{\epsilon+\rho_-}\left[1 - zw\frac{\epsilon+i\nu_+}{\epsilon+\nu_+}\frac{\epsilon-i\rho_-}{\epsilon+\rho_-}\right]^{-1},\\
r &= \frac{\epsilon-\rho_-}{2\epsilon}\left[1 - zw\frac{\epsilon-i\nu_+}{\epsilon+\nu_+}\frac{\epsilon-i\rho_-}{\epsilon-\rho_-}\right]t,\\
\tilde{t} &= -\frac{\epsilon-i\rho_-}{\epsilon+\nu_+}wt,\\
\tilde{r} &= \frac{\nu_+ + i\rho_-}{\epsilon+\nu_+}wt.
\end{aligned} \tag{27}$$

We have determined the stationary states of a particle in the presence of a quaternionic step potential for plane waves of energy $E>V_0=\sqrt{V_1^2+V_2^2+V_3^2}$. In Fig. 1, we plot, for different ratios of the complex and pure quaternionic potential $(V_1/\sqrt{V_2^2+V_3^2}\,)$, the four real component of $\Phi(x)$

versus the adimensional space variable $\sqrt{2mV_0}x/\hbar$. In region I, only the complex part of $\Phi(x)$ presents an oscillatory behavior. The pure quaternionic part decreases exponentially due to the presence of the evanescent wave $e^{\epsilon x}$. In region II, we have a new oscillatory pure quaternionic wave. It is also important to note here that increasing the value of pure quaternionic potential, we smooth the phase changes expected in the potential region by standard quantum mechanics. Thus, we can conclude that this change in the phase is caused by the complex part of the quaternionic potential.

These plane waves do not represent a physical state for a localized incoming particle. They have to be linearly superposed to form wave packets. It is not our purpose to introduce the wave packet treatment for quaternionic wave functions in this paper. This topic deserves a deeper analysis and is, currently, under investigation. Nevertheless, a simple discussion can done at this stage. By using the stationary phase method,[9] we can follow the maximum of the reflected and transmitted wave packets. The use of a real modulation function $g(\epsilon)$ implies that the incident wave packets reach the point $x=0$ at $t=0$. Any phase in the reflected and/or transmitted waves will introduce a shift in time. To clarify this point, it can be useful to rewrite the reflection and transmission coefficients in terms of their modulus and phases. By simple algebraic manipulations, we find

$$\begin{aligned} r &= \frac{(\epsilon-\rho_-)(\epsilon+\nu_+)-zw(\epsilon^2-\rho_-\nu_+)+izw\epsilon(\rho_-+\nu_+)}{(\epsilon+\rho_-)(\epsilon+\nu_+)-zw(\epsilon^2+\rho_-\nu_+)+izw\epsilon(\rho_--\nu_+)} \\ &= \sqrt{\frac{[(\epsilon-\rho_-)(\epsilon+\nu_+)-zw(\epsilon^2-\rho_-\nu_+)]^2+z^2w^2\epsilon^2(\rho_-+\nu_+)^2}{[(\epsilon+\rho_-)(\epsilon+\nu_+)-zw(\epsilon^2+\rho_-\nu_+)]^2+z^2w^2\epsilon^2(\rho_--\nu_+)^2}}\exp[i(\theta_n-\theta_d)] \end{aligned} \tag{28}$$

and

$$\begin{aligned} t &= \frac{2\epsilon}{\epsilon+\rho_-}\left[\frac{(\epsilon+\rho_-)(\epsilon+\nu_+)}{(\epsilon+\rho_-)(\epsilon+\nu_+)-zw(\epsilon-i\rho_-)(\epsilon+i\nu_+)}\right] \\ &= \frac{2\epsilon(\epsilon+\nu_+)}{\sqrt{[(\epsilon+\rho_-)(\epsilon+\nu_+)-zw(\epsilon^2-\rho_-\nu_+)]^2+z^2w^2\epsilon^2(\rho_-+\nu_+)^2}}\exp[-i\theta_d], \end{aligned} \tag{29}$$

where

$$\theta_n = \arctan\left[\frac{zw\epsilon(\rho_-+\nu_+)}{(\epsilon-\rho_-)(\epsilon+\nu_+)-zw(\epsilon^2-\rho_-\nu_+)}\right], \tag{30}$$

$$\theta_d = \arctan\left[\frac{zw\epsilon(\rho_--\nu_+)}{(\epsilon+\rho_-)(\epsilon+\nu_+)-zw(\epsilon^2+\rho_-\nu_+)}\right]. \tag{31}$$

The phases of the reflected and transmitted waves are then given by

$$\begin{aligned} \theta_r(\epsilon;x,t) &= \theta_n(\epsilon)-\theta_d(\epsilon)-\epsilon x-\frac{\hbar\epsilon^2}{2m}t, \\ \theta_t(\epsilon;x,t) &= -\theta_d(\epsilon)+\rho_-(\epsilon)x-\frac{\hbar\epsilon^2}{2m}t. \end{aligned} \tag{32}$$

The stationary phase method suggests that the maximum of the reflected and transmitted waves is found at the point $x=0$ for the following time values:

$$\tau_r = \frac{m}{\hbar}\frac{\theta_n'(\epsilon_0)-\theta_d'(\epsilon_0)}{\epsilon_0},$$

$$\tau_t = -\frac{m}{\hbar}\frac{\theta_d'(\epsilon_0)}{\epsilon_0}, \tag{33}$$

where ϵ_0 is the maximum of the modulation function $g(\epsilon)$. In this energy zone ($E > V_0$), an immediate *qualitative* difference between complex and quaternionic quantum mechanics is found. For quaternionic potential the reflection and transmission are *not* instantaneous. We shall come back to this point later.

B. Region II - zone A: Complex limit

Performing the complex limit, $V_{2,3} \to 0$, we obtain

$$\nu_+ \to \sqrt{2m(E+V_1)}/\hbar\ ,$$

$$\rho_- \to \sqrt{2m(E-V_1)}/\hbar\ ,$$

$$z, w \to 0.$$

From Eq. (27), we find the reflection and transmission coefficient of standard (complex) quantum mechanics

$$t_{\mathrm{C}} = 2\sqrt{E}/(\sqrt{E}+\sqrt{E-V_1}),$$

$$r_{\mathrm{C}} = (\sqrt{E}-\sqrt{E-V_1})/(\sqrt{E}+\sqrt{E-V_1}),$$

$$\tilde{r}_{\mathrm{C}}, \tilde{t}_{\mathrm{C}} = 0.$$

Due to the real nature of r_{C} and t_{C}, we find instantaneous reflection and transmission. This means that at time zero, the maximum of the incident, reflected and transmitted waves are at $x=0$.

C. Region II - zone B: Continuity

Matching the continuity conditions at $x=0$, we obtain

$$t = \frac{2\epsilon}{\epsilon + i\nu_-}\left[1 - zw\frac{\epsilon+\nu_-}{\epsilon+i\nu_-}\frac{\epsilon+i\nu_+}{\epsilon+\nu_+}\right]^{-1},$$

$$r = \frac{\epsilon - i\nu_-}{2\epsilon}\left[1 - zw\frac{\epsilon+\nu_-}{\epsilon-i\nu_-}\frac{\epsilon-i\nu_+}{\epsilon+\nu_+}\right]t, \tag{34}$$

$$\tilde{t} = -\frac{\epsilon+\nu_-}{\epsilon+\nu_+}wt,$$

$$\tilde{r} = \frac{\nu_+ - \nu_-}{\epsilon+\nu_+}wt.$$

In Fig. 2, we plot the four real component of $\Phi(x)$ versus the adimensional space variable $\sqrt{2mV_0}x/\hbar$. Zone B is characterized by $\sqrt{V_2^2+V_3^2} < E < V_0$. In Fig. 2, we have considered the case $E = V_0/\sqrt{2}$. Consequently, the behavior of the stationary waves in this zone is given by the plots corresponding to $\sqrt{V_2^2+V_3^2}/V_0 < 1/\sqrt{2}$. In this zone, due to the presence of evanescent exponentials in the transmitted waves, we find a nonzero probability to find the particle in the region of space where x is positive only for short times. The stationary phase method can be applied to the reflected wave. The coefficient r can be rewritten as follows

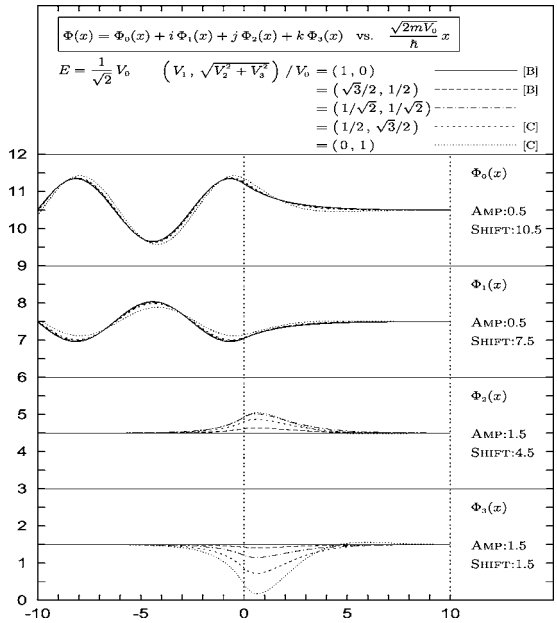

FIG. 2. The space dependence of the quaternionic stationary wave function $\Phi(x)$ is plotted for the energy zone B ($\sqrt{V_2^2+V_3^2}<E<V_0$) and C ($E<\sqrt{V_2^2+V_3^2}$), and for different complex/pure quaternionic potential ratios. The plots for the complex part of $\Phi(x)$ exhibit an evanescent behavior in region II. The pure quaternionic part is practically zero far from the discontinuity point. An interesting oscillatory behavior smoothed by the evanescent waves is also present in region II for energy values in zone C. This remembers the Klein zone in the Dirac equation.

$$r = \frac{\epsilon[(\epsilon+\nu_+) - zw(\epsilon+\nu_-)] + i[zw\nu_+(\epsilon+\nu_-) - \nu_-(\epsilon+\nu_+)]}{\epsilon[(\epsilon+\nu_+) - zw(\epsilon+\nu_-)] - i[zw\nu_+(\epsilon+\nu_-) - \nu_-(\epsilon+\nu_+)]} = \exp[2i\theta], \tag{35}$$

where

$$\theta = \arctan\left[\frac{zw\nu_+(\epsilon+\nu_-) - \nu_-(\epsilon+\nu_+)}{\epsilon(\epsilon+\nu_+) - zw\epsilon(\epsilon+\nu_-)}\right].$$

The phase of the reflected wave is then given by

$$\theta_r(\epsilon;x,t) = 2\theta(\epsilon) - \epsilon x - \frac{\hbar\epsilon^2}{2m}t. \tag{36}$$

It is important to observe that here we have a *quantitative* difference between complex and quaternionic quantum mechanics. Indeed, also for the standard quantum theory the reflection is not instantaneous. The reflect wave reaches $x=0$ at time

$$\tau_r = 2\frac{m}{\hbar}\frac{\theta'(\epsilon_0)}{\epsilon_0}. \tag{37}$$

D. Region II - zone B: Complex limit

Performing the complex limit, $V_{2,3}\to 0$, we obtain

$$t \to t_C = 2\sqrt{E}/(\sqrt{E} + i\sqrt{V_1 - E}),$$

$$r \to r_C = (\sqrt{E} - i\sqrt{V_1 - E})/(\sqrt{E} + i\sqrt{V_1 - E}),$$

$$\tilde{r},\tilde{t}\to 0.$$

The presence of the phase

$$\theta_{\mathrm{C}}=\arctan\left(-\sqrt{\frac{V_1-E}{E}}\right)$$

in r_{C} shows that the reflection is not instantaneous. The delay time[9] is

$$\tau_{r,\mathrm{C}}=2\frac{m}{\hbar}\frac{\theta_{\mathrm{C}}'(\epsilon_0)}{\epsilon_0}=\frac{\hbar}{E_0}\sqrt{\frac{E_0}{V_1-E_0}}. \tag{38}$$

E. Region II - zone C: Continuity

The last zone is characterized by $E<\sqrt{V_2^2+V_3^2}$. Continuity conditions give

$$\begin{aligned}
t&=\frac{2\epsilon}{\epsilon+\sigma_-+i\sigma_+}\left[1-zw\frac{\epsilon+\sigma_+-i\sigma_-}{\epsilon+\sigma_-+i\sigma_+}\frac{\epsilon-\sigma_-+i\sigma_+}{\epsilon+\sigma_++i\sigma_-}\right]^{-1},\\
r&=\frac{\epsilon-\sigma_--i\sigma_+}{2\epsilon}\left[1-zw\frac{\epsilon+\sigma_+-i\sigma_-}{\epsilon-\sigma_--i\sigma_+}\frac{\epsilon+\sigma_--i\sigma_+}{\epsilon+\sigma_++i\sigma_-}\right]t,\\
\tilde{t}&=-\frac{\epsilon+\sigma_+-i\sigma_-}{\epsilon+\sigma_++i\sigma_-}wt,\\
\tilde{r}&=\frac{2i\sigma_-}{\epsilon+\sigma_++i\sigma_-}wt.
\end{aligned} \tag{39}$$

The stationary waves corresponding to this case are also shown in Fig. 2, see the plots with $\sqrt{V_2^2+V_3^2}/V_0>1/\sqrt{2}$. To discuss the time reflection, we rewrite r in terms of its modulus and phase,

$$r=\frac{(\epsilon-\sigma_--i\sigma_+)(\epsilon+\sigma_++i\sigma_-)e^{i\varphi}-(\epsilon+\sigma_+-i\sigma_-)(\epsilon+\sigma_--i\sigma_+)e^{-i\varphi}}{(\epsilon+\sigma_++i\sigma_-)(\epsilon+\sigma_-+i\sigma_+)e^{i\varphi}-(\epsilon+\sigma_+-i\sigma_-)(\epsilon-\sigma_-+i\sigma_+)e^{-i\varphi}}=\exp[2i\theta] \tag{40}$$

where

$$\theta=\arctan\left[\frac{\epsilon(\epsilon+\sigma_+)\tan\varphi+\epsilon\sigma_-}{\epsilon\sigma_--(\epsilon\sigma_++\sigma_-^2+\sigma_+^2)\tan\varphi}\right].$$

In this zone, we do not have a complex limit case. It is important to observe that a *new* phenomenon appears. The oscillatory behavior of the particle in region II is damped due to the presence of the evanescent wave $e^{-\sigma_+x}$. Thus, a nonzero probability to find the particle in the potential region only exists for short times.

V. RELATIONSHIPS BETWEEN COMPLEX AND QUATERNIONIC QUANTUM MECHANICS

In the last several years, the Schrödinger equation in the presence of quaternionic (constant) potentials has been a matter of study and discussion in the literature. This is justified in view of a possible understanding of the role that a quaternionic quantum theory could play in the real physical world. As remarked by Adler[1] all known physical phenomena appear to be very well described by complex quantum mechanics. Nevertheless, to see if quaternionic quantum mechanics represents a possible way to describe the nature or if it is only an interesting mathematical exercise, we have to use and test this formalism in simple quantum mechanical systems. With

respect to previous works regarding potential barrier diffusion[2,3,7] and potential well bound states,[8] in this paper, we have preferred to go back in our analysis of nonrelativistic quaternionic quantum mechanics by studying the potential step.

The study presented in this paper can be seen as an attempt to understand, by starting from an *analytic* solution of a simple quantum mechanical system, where and if differences between standard quantum mechanics and theoretical solutions obtained by solving the Schrödinger equation in the presence of a quaternionic step perturbation can be observed. The main difficulty in obtaining quaternionic solutions of a physical problem is due to the fact that, in general, the standard mathematical methods of resolution break down. Nevertheless, the recent progress in quaternionic differential theory[4–6] and linear algebra[12,13] gives the possibility to use "new" quaternionic mathematical tools. As a direct consequence of this, we have been able to find an analytic solution for the stationary states in the presence of a quaternionic potential step. This means that we have now (for the first time) the possibility of describing in detail *qualitative* differences between complex and quaternionic quantum mechanics.

A. Experimental proposals in quaternionic quantum mechanics

The earliest experimental proposals to test quaternionic deviations from complex quantum mechanics[14] suggested that the noncommutativity of quaternionic phases could be observed in Bragg scattering by crystal made of three different atoms, in neutron interferometry and in meson regeneration. In 1984, the neutron interferometric experiment was realized by Kaiser, George, and Werner.[15] The neutron wave function traversing slabs of two dissimilar materials (titanium and aluminum) should experience the noncommutativity of the phase shifts when the order in which the barriers are traversed is reversed. The experimental result showed that the phase shifts commute to better than one part in 3×10^4. To explain this null result, Klein postulated[16] that quaternionic potentials act only for some of the fundamental forces and proposed an experiment for testing possible violations of the Schrödinger equation by permuting the order in which nuclear, magnetic, and gravitational potentials act on neutrons in an interferometer.

The first theoretical analysis of two quaternionic potential barriers was developed by Davies and McKellar.[3] In their paper, by translating the quaternionic Schrödinger equation into a pair of coupled complex equations and solving the corresponding complex system by numerical methods, Davies and McKellar showed that, notwithstanding the presence of complex *instead* of quaternionic phases, the predictions of quaternionic quantum mechanics differ from those of the usual theory. In particular, they pointed out that different from the complex quantum mechanics prediction, where the left and right transmission amplitudes, t_L and t_R, are equal in magnitude and in phase, in the quaternionic quantum mechanics only the magnitudes $|t_L|$ and $|t_R|$ are equal. So, the measurement of a phase shift should be an indicator of quaternionic effects *and* of space dependent phase potentials. However, this conclusion leads to the embarrassing question of why there was no phase change in the experiment proposed by Peres[14] and realized by Kaiser, George, and Werner.[15] To reconcile the theoretical predictions with the experimental observations, Davies and McKellar reiterated the Klein conclusion and suggested to subject the neutron beam to different interactions in permuted order.

In the final chapter of the Adler book,[1] we find an intriguing question. Do the Kayser and colleagues'[1] experiment, and the elaborations on it proposed by Klein actually test for residual quaternionic effects? According to the nonrelativistic quaternionic scattering theory developed by Adler[1] the answer is clearly *no*. Experiments to detect a phase shift are equivalent to detect *time reversal violation*, which so far has not been detectable in neutron-optical experiments.

B. Quaternionic potential step, CP violation, and kaons system

Based on the previous considerations, experimental proposals to test quaternionic deviations from standard quantum mechanics should involve CP violation dynamical systems. A natural candidate to such an investigation could be the system of K-mesons.[17,18] The quaternionic time reversal violation potential (see Sec. II)

$$W(\mathbf{r}) = |W(\mathbf{r})|\exp[i\theta(\mathbf{r})]$$

should be directly responsible for CP violation effects. The experimental results on $K_{S,L}$ (a K_L meson decays more often to $\pi^- e^+ \overline{\nu_e}$ than to $\pi^+ e^- \nu_e$ Ref. 19) could be useful to estimate the modulus and phase of the pure quaternionic part of this "effective" potential.

Once determined the magnitude of the quaternionic perturbation, by using the analytic solution obtained in this paper, could be possible (through a stationary phase analysis) to explicitly calculate the reflection and transmission times of a K-meson particle scattered by a complex potential step in the presence of a quaternionic (CP violating) perturbation. In the case of an above-potential incident particle the diffusion from a pure complex potential (standard quantum mechanics) happens instantaneously, i.e.,

$$\tau_{r,\mathbb{C}} = \tau_{t,\mathbb{C}} = 0.$$

The possibility to *analytically* solve the corresponding quaternionic problem gives us the chance to see an immediate *qualitative* difference between complex and quaternionic quantum mechanics. The presence of a quaternionic potential surprisingly modifies the reflection and transmission times which are now nonzero,

$$\tau_r = \frac{m}{\hbar}\frac{\theta_n'(\epsilon_0) - \theta_d'(\epsilon_0)}{\epsilon_0}, \quad \tau_t = -\frac{m}{\hbar}\frac{\theta_d'(\epsilon_0)}{\epsilon_0},$$

where ϵ_0 is the maximum of the wave packet modulation function.

With this paper, we would have liked to close the debate on the role that quaternionic potentials could play in quantum mechanics, but more realistically, we simply contribute to the general discussion. Physical interpretations of quaternionic solutions still represent a *delicate* question and before proposing a detailed experimental test, we think that more mathematical questions should be addressed and deeply investigated.

C. Complex and quaternionic geometries

To give a satisfactory probability interpretation, amplitudes of probability must be defined in *associative division algebras*.[1] Amplitudes of probabilities defined in nondivision algebras fail to satisfy the requirement that in the absence of quantum interference effects, probability amplitude superposition should reduce to probability superposition. The associative law of multiplication (which fails for the octonions) is needed to satisfy the completeness formula and to guarantee that the Schrödinger anti-self-adjoint operator leaves invariant the inner product.

At first glance it appears that we cannot formulate quantum theories by using wave functions defined in nondivision or nonassociative algebras. This is an erroneous conclusion because the constraint concerns the inner product and *not* the kind of Hilbert space in which we define our wave functions. Amplitudes of probability have to be given in $\mathbb{C}$ or $\mathbb{H}$ (complex or quaternionic geometry) but vectors in the Hilbert space have no limitation. We can formulate a consistent complexified quaternionic[20–24] or octonionic[25,26] quantum mechanics by adopting complex inner products. The use of complex inner product represents a fundamental tool in applying a Clifford algebraic formalism to physics and plays a fundamental role in looking for geometric interpretation of the algebraic structures in relativistic equations and gauge theories.[27–31] The choice of quaternionic inner product seems to be best adapted to investigate deviations from the standard complex theory in quantum mechanics[32,33] and field theory.[34,35]

D. Conclusions and outlooks

We conclude this paper by listing the most interesting features of our analysis and future investigations suggested by our results.

(1) An *analytic* solution for a simple quantum mechanical system (quaternionic potential step) has been given (previous studies on the quaternionic Schrödinger equation have been performed by numerical calculations).

(2) Our plane wave analysis immediately show *qualitative* differences between complex and quaternionic quantum mechanics (see, for example, the reflection and transmission times for above-potential diffusion and the oscillatory behavior in the new region below the potential).

(3) A plane wave analysis for a quaternionic barrier can be now developed by using an analytic *two step approach*.

(4) The plane wave results (valid in the physical situation of complete interference) should be revised by introducing a quaternionic *wave packet* formalism (particle viewpoint). This should confirm and explain the reflection and transmission times obtained by the stationary phase method.

(5) In the quaternionic barrier analysis, we expect *qualitative* differences between complex and quaternionic quantum dynamical system.

(5.1) For above-potential diffusion, the quaternionic wave packets will be characterized by *new* reflection and transmission times with respect to the standard (complex) case.[36,37]

(5.2) In the tunneling zone, the quaternionic *Hartman* effect has to be investigated and confronted with the standard one which predicts (for a long barrier) instantaneous transmission.[38–40]

(5.3) In the *new* below-potential region, a *Klein-like* phenomenon[41,42] appears and it should be interpreted within a nonrelativistic context.

(6) The natural candidate to quaternionic experimental proposals seems to be the system of *K*-mesons. The above-suggested investigations should give a more clear idea about the possibility to *really* perform an experiment involving nonrelativistic oscillating particles and CP violating potential barriers. This probably should close the debate on the use of a quaternionic mathematical formalism in quantum theories.

(Received 17 January 2006; accepted 15 June 2006; published online 22 August 2006)

We determine the structure of the spectrum and obtain nonpropagation estimates for a class of Toeplitz operators acting on a subset of the lattice $\mathbb{Z}^N$. This class contains the Hamiltonian of the one-dimensional Heisenberg model. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2222083]

I. INTRODUCTION

Spectral theory of Toeplitz operators and its connection with C^*-algebras is a vast topic. We only indicate Ref. 6 as a textbook systematization of part of the early theory. Since the appearance of Douglas' book, the theory has evolved by extension and abstraction in many directions. The works closest to the present paper are the ones relating Toeplitz operators and Toeplitz algebras to ordered groups.[11,13,20,21]

Our interest in the topic has been aroused by the remark[15,16,14] that the one-dimensional Heisenberg Hamiltonian H of ferromagnetism can be written as a direct sum $H=\oplus_{N\in\mathbb{N}}H_N$, where H_N can be interpreted as the Laplace operator on the subgraph

$$\mathbb{Z}^N_< := \{(x_1, \ldots, x_N) \in \mathbb{Z}^N : x_1 < x_2 < \cdots < x_N\}$$

of the standard (Cayley) graph $\mathbb{Z}^N$. In Sec. II we show that H_N (when suitably restricted to $\mathbb{Z}^N_<$) is equal to the sum of a Toeplitz operator and a multiplicative potential, both belonging to the Toeplitz-like C^*-algebra $\mathcal{T}^<(\mathbb{Z}^N)$ generated by the unilateral shifts on $\mathbb{Z}^N_<$.

Although $\mathcal{T}^<(\mathbb{Z}^N)$ is of none of the types thoroughly studied in the literature, its structure is simple enough to suggest spectral results for the operators it contains (see Sec. III). Since the elements of $\mathcal{T}^<(\mathbb{Z}^N)$ can be written as direct integrals over a torus, we are mainly concerned with spectral properties of the fibers (this presents a particular interest in the case of the one-dimensional Heisenberg model (see Refs. 14 and 22)). In Sec. IV we express the essential spectrum of the fibers as a union of spectra of a family of subhamiltonians, improving part of the statements of Zholondek,[23] which concerns a larger class of operators but imposes an unnecessary exponential decay condition. We consider that our formalism and proofs are much more simple and natural than those of Zholondek.[23] In Sec. V we show the following type of result concerning the whole Hamiltonian H_N. If κ is a continuous real function with suitable support, then there exists a natural family of multiplication operators $\{\chi_n\}_{n\in\mathbb{N}}$ for which $\|\chi_n\kappa(H_N)\|$ is arbitrarily small if n is large enough. This can be reformulated in terms of the evolution group $\{e^{-itH_N}\}_{t\in\mathbb{R}}$: at

a)Electronic mail: mondher.damak@fss.rnu.tn
b)Electronic mail: marius.mantoiu@imar.ro
c)Electronic mail: rafael.tiedra@math.u-psud.fr

energies belonging to $\mathrm{supp}(\kappa)$, the system governed by H_N stays "out of $\mathrm{supp}(\chi_n)$" uniformly in time. Practically, $\mathrm{supp}(\kappa)$ must not intersect the spectrum of a certain subhamiltonian associated to some ideal of $\mathcal{T}^<(\mathbb{Z}^N)$. For the Heisenberg model we put into evidence a nice interpretation involving cluster properties of N-magnon states. The related issue of determining a Plancherel formula for the one-dimensional Heisenberg model has been discussed in Refs. 17 and 4 in the isotropic case and in Ref. 3 for the *XXZ* model.

We think that the structure of $\mathcal{T}^<(\mathbb{Z}^N)$ may also be crucial for proving finer spectral and scattering properties. The attainment of a Mourre estimate, which is a first step in this direction, is a problem under review.

Actually the setting generalizes from $\mathbb{Z}^N$ to $(\mathbb{Z}^m_{\mathrm{lex}})^N$, where $\mathbb{Z}^m_{\mathrm{lex}}$ is the group $\mathbb{Z}^m$ ordered lexicographically. This relies on rather deep results of Murphy[13] on Toeplitz algebras associated to certain ordered groups. The statements of the present paper can be pushed to this more general case; they just require more involved notations. Unfortunately, this is *not* the right framework to study the m-dimensional Heisenberg model (another type of Toeplitz algebra is needed), so we refrained from giving explicit detailed results in this situation; see however Remark 4.3.

Let us finally mention that our treatment has few direct connections with previous work on the spectral theory of Toeplitz operators. We were actually guided by the C^*-algebra approach to spectral analysis for Schrödinger operators, as in Refs. 1, 5, 8, 9, and 2.

II. THE ONE-DIMENSIONAL HEISENBERG MODEL

In order to justify the class of operators we study, we present here briefly and rather formally the one-dimensional Heisenberg model. Further details may be found in Refs. 14–17.

We consider the one-dimensional lattice $\mathbb{Z}$ with a spin-$\frac{1}{2}$ attached at each vertex. Let

$$\mathbb{F}(\mathbb{Z}) := \{\alpha : \mathbb{Z} \to \{0,1\} : \mathrm{supp}(\alpha) \text{ is finite}\},$$

and write $\{e^0, e^1\} := \{(0,1),(1,0)\}$ for the canonical basis of the spin-$\frac{1}{2}$ Hilbert space $\mathbb{C}^2$. For any $\alpha \in \mathbb{F}(\mathbb{Z})$ we denote by e^α the element $\{e^{\alpha(x)}\}_{x\in\mathbb{Z}}$ of the direct product $\Pi_{x\in\mathbb{Z}}\mathbb{C}^2_x$. We distinguish the vector e^{α_0}; where $\alpha_0(x) := 0$ for all $x \in \mathbb{Z}$. Each element e^α is interpreted as a pure state of the system of spins, and e^{α_0} as its ground state with all spins pointing down. The Hilbert space $\mathcal{L}$ of the system (which is spanned by the states with all but finitely many spins pointing down) is the incomplete tensor product Ref. 15, Sec. II, and Ref. 16, Sec. II)

$$\mathcal{L} := \bigotimes_{x\in\mathbb{Z}}^{\alpha_0} \mathbb{C}^2_x \equiv \text{closed span}\{e^\alpha : \alpha \in \mathbb{F}(\mathbb{Z})\}.$$

The dynamics of the spins is given by the nearest-neighbor Heisenberg Hamiltonian

$$L := -\frac{1}{2}\sum_{|x-y|=1}[a(\sigma_1^{(x)}\sigma_1^{(y)} + \sigma_2^{(x)}\sigma_2^{(y)}) + b(\sigma_3^{(x)}\sigma_3^{(y)} - 1)].$$

The operator $\sigma_j^{(x)}$ acts in $\mathcal{L}$ as the identity operator on each factor $\mathbb{C}^2_y$, except on the component $\mathbb{C}^2_x$ where it acts as the Pauli matrix σ_j. The scalars $a, b \in \mathbb{R}$ prescribe the anisotropy of the system. The case $a \neq b$ corresponds to the *XXZ* model, whereas the standard Heisenberg model is obtained for $a = b$.

Let $\mathcal{H} := \ell^2[\mathbb{F}(\mathbb{Z})]$. Then the Hilbert spaces $\mathcal{L}$ and $\mathcal{H}$ are isomorphic due to the unitarity of the mapping $\mathfrak{s} : \mathcal{L} \to \mathcal{H}$ sending e^α onto $\chi_{\{\alpha\}}$ for all α ($\chi_{\{\alpha\}}$ stands for the characteristic function of the singleton α). In particular, the set $\mathbb{F}(\mathbb{Z})$ may be considered as the configuration space for the system of spins. The Hamiltonian L is unitarily equivalent to a difference operator in $\mathcal{H}$. Given $\alpha \in \mathbb{F}(\mathbb{Z})$ and $x \in \mathrm{supp}(\alpha), y \notin \mathrm{supp}(\alpha)$, we write α_x^y for the function of $\mathbb{F}(\mathbb{Z})$ such that $\mathrm{supp}(\alpha_x^y) = \mathrm{supp}(\alpha) \sqcup \{y\} \setminus \{x\}$.

Lemma 2.1: For any $f \in \mathcal{H}$, $\alpha \in \mathbb{F}(\mathbb{Z})$, one has the equality

$$(\varsigma L\varsigma^{-1}f)(\alpha) = -2\sum_{|x-y|=1}\alpha(x)[1-\alpha(y)][af(\alpha_x^y)-bf(\alpha)].$$

Proof: The claim follows from a direct calculation using the properties of the Pauli matrices.□

For $N\in\mathbb{N}$, let $\mathbb{F}_N(\mathbb{Z}):=\{\alpha\in\mathbb{F}(\mathbb{Z}):\mathrm{supp}(\alpha)$ has N elements$\}$ and set $\mathcal{H}_N:=\ell^2[\mathbb{F}_N(\mathbb{Z})]$. Lemma 2.1 shows that the subspace $\mathcal{H}_N$ of $\mathcal{H}$ is left invariant by $\varsigma L\varsigma^{-1}$. This is due to the fact that the Hamiltonian L commutes with the (magnon) number operator $\frac{1}{2}\Sigma_{x\in X}(\sigma_3^{(x)}+1)$. Moreover it is straightforward to show that the restriction $H_N:=(\varsigma L\varsigma^{-1})\restriction\mathcal{H}_N$ is bounded and symmetric.

The operator H_N has a more convenient form in another representation, which deserves the introduction of some notations. Elements of $\mathbb{Z}^N$ are denoted generically by $\xi\equiv(x_1,\ldots,x_N)$, $\eta\equiv(y_1,\ldots,y_N)$, or $\zeta\equiv(z_1,\ldots,z_N)$, and $P^<$ stands for the multiplication operator in $\ell^2(\mathbb{Z}^N)$ by the characteristic function $\chi_{\mathbb{Z}^N_<}$. We shall often interpret this projection as an operator from $\ell^2(\mathbb{Z}^N)$ to $\ell^2(\mathbb{Z}^N_<)$. For each $\eta\in\mathbb{Z}^N$ we define the unitary "bilateral shift" u_η in $\ell^2(\mathbb{Z}^N)$by

$$(u_\eta f)(\xi):=f(\xi-\eta),\quad f\in\ell^2(\mathbb{Z}^N),\quad \xi\in\mathbb{Z}^N.$$

We also define the "unilateral shift" $v_\eta^<:=P^<u_\eta\restriction\ell^2(\mathbb{Z}^N_<)$, which is a partial isometry in $\ell^2(\mathbb{Z}^N_<)$. Thus, for any $\varphi\in\ell^1(\mathbb{Z}^N)$, one can consider the convolution operator

$$C_\varphi:=\sum_{\eta\in\mathbb{Z}^N}\varphi(\eta)u_\eta$$

in $\ell^2(\mathbb{Z}^N)$, and the Toeplitz operator

$$T_\varphi^<:=\sum_{\eta\in\mathbb{Z}^N}\varphi(\eta)v_\eta^<$$

in $\ell^2(\mathbb{Z}^N_<)$. These operators are related by the formula $T_\varphi^<=P^<C_\varphi\restriction\ell^2(\mathbb{Z}^N_<)$. Let us also consider the projections $q_\eta^<:=v_\eta^<(v_\eta^<)^*$ on the range of the partial isometries $v_\eta^<$. One sees easily that $q_\eta^<$ is the multiplication operator by the characteristic function of the set $\mathbb{Z}^N_<\cap(\mathbb{Z}^N_<+\eta)$. Finally, among the multiplication operators in $\ell^2(\mathbb{Z}^N_<)$, we distinguish those of the form

$$V_\varphi^<:=\sum_{\eta\in\mathbb{Z}^N}\varphi(\eta)q_\eta^<,\quad \varphi\in\ell^1(\mathbb{Z}^N).$$

We identify now the Heisenberg Hamiltonian as an operator of the form above. The set S stands for the collection of vectors $\{s_i^\pm\}_{i=1}^N\subset\mathbb{Z}^N$ with components $(s_i^\pm)_j:=\pm\delta_{ij}$. Notice that S is a symmetric family of generators for the group $\mathbb{Z}^N$.

Proposition 2.2: The Hamiltonian H_N is unitarily equivalent to the operator $T_\varphi^<+V_\psi^<$, where $\varphi:=-2a\chi_S$ and $\psi:=2b\chi_S$.

Proof: Let $\phi:\mathbb{Z}^N_<\to\mathbb{F}_N(\mathbb{Z})$ be the one-to-one map $\xi\mapsto\chi_{\{x_1,\ldots,x_N\}}$. Let $\Phi:\mathcal{H}_N\to\ell^2(\mathbb{Z}^N_<)$ be the unitary operator given by $\Phi(f):=f\circ\phi$ for any $f\in\mathcal{H}_N$. Then one has for $g\in\ell^2(\mathbb{Z}^N_<)$, $\xi\in\mathbb{Z}^N_<$

$$(\Phi H\Phi^{-1}g)(\xi)=-2\sum_{j=1}^N\sum_{\substack{y=x_j\pm1\\ y\notin\{x_1,\ldots,x_N\}}}\{ag[\phi^{-1}(\chi_{\{x_1,\ldots,x_{j-1},y,x_{j+1},\ldots,x_N\}})]-bg(\xi)\}.$$

On the other hand

$$\phi^{-1}(\alpha)=[\min\alpha,\ \min(\alpha\setminus\{\min\alpha\}),\ \ldots]$$

for any $\alpha\in\mathbb{F}_N(\mathbb{Z})$. Thus

$$\Phi^{-1}(\chi_{\{x_1,\ldots,x_{j-1},y,x_{j+1},\ldots,x_N\}})=(x_1,\ldots,x_{j-1},y,x_{j+1},\ldots,x_N)$$

if $y=x_j\pm1$, $y\notin\{x_1,\ldots,x_N\}$ and $x_1<\cdots<x_N$. This implies that

$$(\Phi H \Phi^{-1} g)(\xi) = -2 \sum_{s \in S} \chi_{\mathbb{Z}^N_<}(\xi - s)[ag(\xi - s) - bg(\xi)]$$

$$= -2 \sum_{s \in S} [(av_s^< - bq_s^<)g](\xi) = [(T_\varphi^< + V_\psi^<)g](\xi).$$

□

Proposition 2.2 is one of the motivations to study operators of the form $T_\varphi^< + V_\psi^<$ for general functions $\varphi, \psi \in \ell^1(\mathbb{Z}^N)$. Actually, we can even indicate a larger class of operators $T_\varphi^< + V_\psi^<$ which have an interpretation on their own, outside the Toeplitz theory. If $M \subset \mathbb{Z}^N$ is a finite subset such that $\eta \in M$ implies $-\eta \in M$, then one can associate to it a Cayley graph having $\mathbb{Z}^N$ as a set of vertices by declaring that η and ζ are connected iff $\eta - \zeta \in M$. The Laplace operator Δ^M of this Cayley graph is a convolution operator in $\ell^2(\mathbb{Z}^N)$, easy to understand when applying a Fourier transformation. On the other hand Laplacians Δ_E^M on subgraphs E of this Cayley graph could be complicated objects. However it easy to show the identity $\Delta^M_{\mathbb{Z}^N_<} = T^<_{\chi_M} + V^<_{-\chi_M}$, which essentially applies to the Heisenberg model in the case $M = S$. Thus the Laplacians $\Delta^M_{\mathbb{Z}^N_<}$ are subject of the spectral results that follow below.

III. TOEPLITZ ALGEBRAS

In this section we collect some results on the Toeplitz-like algebra $\mathcal{T}^<(\mathbb{Z}^N)$. We first introduce the appropriate abstract setting.

Let X be a (discrete) Abelian group and E be a nonvoid subset of X. The projection $P^E: \ell^2(X) \to \ell^2(E)$ is defined in $\ell^2(X)$ as the multiplication operator by the characteristic function χ_E. As before we introduce the unitary translation operators $\{u_\eta\}_{\eta \in X}$ in $\ell^2(X)$ and the partial isometries $\{v_\eta^E := P^E u_\eta \restriction \ell^2(E)\}_{\eta \in X}$ in $\ell^2(E)$. Once again, for $\varphi \in \ell^1(X)$, the "Toeplitz operator"

$$T_\varphi^E := \sum_{\eta \in X} \varphi(\eta) v_\eta^E$$

and the "potential"

$$V_\varphi^E := \sum_{\eta \in X} \varphi(\eta) q_\eta^E \equiv \sum_{\eta \in X} \varphi(\eta) v_\eta^E (v_\eta^E)^*$$

are available as operators in $\ell^2(E)$.

Definition 3.1: The C^*-algebra $\mathcal{T}^E(X) \subset \mathcal{B}[\ell^2(E)]$ generated by the family $\{v_\eta^E\}_{\eta \in X}$ is called the Toeplitz algebra of the group X with respect to the subset E.

Obviously $\mathcal{T}^E(X)$ contains all the operators of the form $T_\varphi^E + V_\psi^E$, $\varphi, \psi \in \ell^1(\mathbb{Z}^N)$ (and many others). In fact $\mathcal{T}^E(X)$ is also generated by the family $\{T_\varphi^E : \varphi \in \ell^1(X)\}$ as in the case of usual Toeplitz algebras. If $E = X$, $\mathcal{T}^E(X)$ is equal to $C_r^*(X)$, the reduced group C^*-algebra of X. Since X is Abelian, we may identify it with $C^*(X)$, the enveloping C^*-algebra of the convolution Banach $*$-algebra $\ell^1(X)$. The identification puts into correspondence u_η with $\delta_\eta := \chi_{\{\eta\}}$. Due to the Fourier transform, $C^*(X)$ is isomorphic to the C^*-algebra $C(\hat{X})$ of continuous complex functions on $\hat{X}$, where $\hat{X}$ is the (compact, Abelian) dual group of X. The conventions "in dimension zero" are clear: The group is $X = \{0\}$, with subset $E = \{0\}$, all functions are scalars, and for $\varphi \in \mathbb{C}$ one sets $T_\varphi = V_\varphi := \varphi 1$ in $\ell^2(X) \equiv \mathbb{C}$.

The algebras $\mathcal{T}^E(X)$ were mainly studied for X an ordered group and E its positive cone.[11,13,20,21] The standard case is the "classical" Toeplitz algebra $\mathcal{T}^{\mathbb{N}}(\mathbb{Z}) \equiv \mathcal{T}$ (Ref. 6) associated with the unilateral shift on $\ell^2(\mathbb{N})$ (often presented in a Fourier transformed realization). In our proofs the isomorphic algebra $\mathcal{T}^* := \mathcal{T}^{\mathbb{N}^*}(\mathbb{Z})$, $\mathbb{N}^* := \{1, 2, \ldots\}$, will appear more naturally. The case $X = \mathbb{Z}^2$, $E = \mathbb{N}^2$ is studied in Ref. 7. The most relevant Toeplitz algebra for us is $\mathcal{T}^<(\mathbb{Z}^N) := \mathcal{T}^{\mathbb{Z}^N_<}(\mathbb{Z}^N)$, which is *not* of ordered type. We shall point out its structure, which will be the main tool in analyzing the operators $T_\varphi^< + V_\psi^<$.

The key facts are as follows:

(A) If $\theta: X \to X'$ is a group isomorphism sending E onto E', then $\mathcal{T}^E(X)$ and $\mathcal{T}^{E'}(X')$ are naturally isomorphic, the element v_η^E of $\mathcal{T}^E(X)$ being sent onto $v_{\theta(\eta)}^{E'} \in \mathcal{T}^{E'}(X')$.

(B) If E_j is a subset of a group X_j, $j=1,\ldots,m$, then $\mathcal{T}^{E_1\times\cdots\times E_m}(X_1\times\cdots\times X_m)$ can be identified with the spatial tensor product C^*-algebra $\otimes_{j=1}^m \mathcal{T}^{E_j}(X_j)$, $v^E_{(\eta_1,\ldots,\eta_m)}$ being identified with $\otimes_{j=1}^m v^{E_j}_{\eta_j}$.

Both isomorphisms are unitarily implemented, but this will not be used explicitly in the sequel.

Let $\theta: \mathbb{Z}^N \to \mathbb{Z}^N$ be the group automorphism defined by

$$\theta(y_1,\ldots,y_N) := (y_1, y_2 - y_1, \ldots, y_N - y_{N-1}),$$

with inverse

$$\theta^{-1}(z_1,\ldots,z_N) = (z_1, z_1+z_2, \ldots, z_1+\cdots+z_N).$$

Obviously, $\mathcal{E} := \theta(\mathbb{Z}^N_<) = \mathbb{Z}\times(\mathbb{N}^*)^{N-1}$. Thus, by (A), $\mathcal{T}^<(\mathbb{Z}^N)$ and $\mathcal{T}^{\mathcal{E}}(\mathbb{Z}^N)$ are isomorphic, $v_\eta^<$ being sent onto $v^{\mathcal{E}}_{\theta(\eta)}$ for any $\eta\in\mathbb{Z}^N$. Consequently, this isomorphism sends $T_\varphi^<$ onto $T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}$ and $V_\psi^<$ onto $V^{\mathcal{E}}_{\psi\circ\theta^{-1}}$. In the next few lines we only consider the case of $T_\varphi^<$.

By applying (B), one gets an isomorphism between $\mathcal{T}^{\mathcal{E}}(\mathbb{Z}^N)$ and $\mathcal{T}^{\mathbb{Z}}(\mathbb{Z})\otimes[\mathcal{T}^{\mathbb{N}^*}(\mathbb{Z})]^{\otimes(N-1)} \equiv C^*(\mathbb{Z})\otimes(\mathcal{T}^*)^{\otimes(N-1)}$, under which $T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}$ is transformed into

$$\sum_{(z_1,\ldots,z_N)\in\mathbb{Z}^N} (\varphi\circ\theta^{-1})(z_1,\ldots,z_N)\,\delta_{z_1}\otimes v_{z_2}^{\mathbb{N}^*}\otimes\cdots\otimes v_{z_N}^{\mathbb{N}^*}. \tag{3.1}$$

Now we apply the partial Fourier transform on the first variable. It maps $\delta_{z_1}\in C^*(\mathbb{Z})$ onto $\mathrm{e}_{z_1}\in C(\mathbb{T})$, where $\mathbb{T}$ is equal to the interval $[0,1]$ (with 0 identified to 1) and $\mathrm{e}_z(\tau) := \mathrm{e}^{-2\pi i z\tau}$ for all $z\in\mathbb{Z}$, $\tau\in\mathbb{T}$. Namely we use $\mathcal{F}_1 := \mathcal{F}\otimes 1$, where $(\mathcal{F}f)(\tau) := \Sigma_{z\in\mathbb{Z}}\mathrm{e}_z(\tau)f(z)$ for all $\tau\in\mathbb{T}$, $f\in\ell^1(\mathbb{Z})$. When performing the sum over z_1, the operator (3.1) becomes

$$\sum_{(z_2,\ldots,z_N)\in\mathbb{Z}^{N-1}} [\mathcal{F}_1(\varphi\circ\theta^{-1})](\cdot,z_2,\ldots,z_N)\,v_{z_2}^{\mathbb{N}^*}\otimes\cdots\otimes v_{z_N}^{\mathbb{N}^*},$$

which will be regarded as an element of $C(\mathbb{T})\otimes\mathcal{T}^{\otimes(N-1)} \equiv C[\mathbb{T};\mathcal{T}^{\otimes(N-1)}]$. Similar arguments can be carried on for $V_\psi^<$. When summing up we get the following lemma. For any $\rho\in\ell^1(\mathbb{Z}^N)$ and $\tau\in\mathbb{T}$ we define $\mu(\tau)\rho\in\ell^1(\mathbb{Z}^{N-1})$ by

$$[\mu(\tau)\rho](z_2,\ldots,z_N) := [\mathcal{F}_1(\rho\circ\theta^{-1})](\tau,z_2,\ldots,z_N).$$

Lemma 3.2: The C^*-algebras $\mathcal{T}^<(\mathbb{Z}^N)$ and $C(\mathbb{T})\otimes\mathcal{T}^{\otimes(N-1)}$ are naturally isomorphic. The isomorphism sends $T_\varphi^<+V_\psi^<$ onto the direct integral

$$\int_{\mathbb{T}}^{\oplus} \mathrm{d}\tau\,(T^{N-1}_{\mu(\tau)\varphi} + V^{N-1}_{\mu(0)\psi}),$$

where the exponent of the Toeplitz operators refers to the subset $(\mathbb{N}^*)^{N-1}$ of the group $\mathbb{Z}^{N-1}$.

The presence of a direct integral is connected to the invariance of our operators under a natural action of $\mathbb{Z}$ on $\mathbb{Z}^N_<$ by translations. For the Heisenberg model, this can be traced back to any of the earlier representations of the Hamiltonian.

As a rule, the spectral results will be stated only for operators of the form $T_\varphi^<+V_\psi^<$. By introducing suitable notations, they could be extended to all the elements of $\mathcal{T}^<(\mathbb{Z}^N)$.

Corollary 3.3: For any real functions $\varphi,\psi\in\ell^1(\mathbb{Z}^N)$, one has

$$\sigma_{\mathrm{ess}}(T_\varphi^<+V_\psi^<) = \sigma(T_\varphi^<+V_\psi^<) = \bigcup_{\tau\in\mathbb{T}} \sigma(T^{N-1}_{\mu(\tau)\varphi} + V^{N-1}_{\mu(0)\psi}). \tag{3.2}$$

Proof: The essential spectrum of an element A of a C^*-algebra $\mathcal{C}$ composed of bounded

operators in a Hilbert space $\mathcal{G}$ coincides with the spectrum of its image in the quotient $\mathcal{C}/[\mathcal{C}\cap\mathcal{K}(\mathcal{G})]$, where $\mathcal{K}(\mathcal{G})$ denotes the compact operators in $\mathcal{G}$. Thus the first equality follows from the obvious fact that there is no nontrivial compact operator in $C(\mathbb{T})\otimes\mathcal{T}^{\otimes(N-1)}$. For the second equality, we apply Lemma 3.2 and the discussion in Ref. 1, Sec. 8.2.4 on the spectrum of observables defined by a continuous family of selfadjoint operators. Note that the union on the right-hand side (r.h.s.) is automatically closed. □

If $N=1$, then $T_{\varphi}^{<}$ is the convolution operator C_{φ} and $V_{\psi}^{<}$ is the multiplication operator by $\Sigma_{z\in\mathbb{Z}}\psi(z)=(\mathcal{F}\psi)(0)\in\mathbb{R}$. Thus the spectrum (3.2) reduces to

$$\sigma(T_{\varphi}^{<}+V_{\psi}^{<})=(\mathcal{F}\varphi)(\mathbb{T})+(\mathcal{F}\psi)(0)=[\min(\mathcal{F}\varphi),\max(\mathcal{F}\varphi)]+(\mathcal{F}\psi)(0)$$

as it should be.

IV. THE ESSENTIAL SPECTRUM OF THE FIBER HAMILTONIANS

The fiber Hamiltonians $H(\tau):=T_{\mu(\tau)\varphi}^{N-1}+V_{\mu(0)\psi}^{N-1}$ can be interpreted physically as "energy operators at fixed quasi-momentum τ." We now study their essential spectrum. We again use the well known fact that, given a Hilbert space $\mathcal{G}$, the essential spectrum of an operator $A\in\mathcal{B}(\mathcal{G})$ coincides with the spectrum of its image in the Calkin algebra $\mathcal{B}(\mathcal{G})/\mathcal{K}(\mathcal{G})$, where $\mathcal{K}(\mathcal{G})$ is the ideal of compact operators.

The fibers $H(\tau)$ act in $\ell^2[(\mathbb{N}^*)^{N-1}]\simeq\ell^2(\mathbb{N}^*)^{\otimes(N-1)}$ and belong to the C^*-algebra $(\mathcal{T}^*)^{\otimes(N-1)}$. So we are faced with the problem of understanding the quotient of $(\mathcal{T}^*)^{\otimes(N-1)}$ by $\mathcal{K}[\ell^2(\mathbb{N}^*)^{\otimes(N-1)}]$, the latter being identified as $(\mathcal{K}^*)^{\otimes(N-1)}$, where $\mathcal{K}^*:=\mathcal{K}[\ell^2(\mathbb{N}^*)]$. The discussion in Ref. 7 is relevant here, especially in the case $N=2$. We start by proving a result in a more abstract setting (see Ref. 8, Theorem 2.3 for an alternate proof).

Lemma 4.1: Let $\mathcal{I}_j$ be an ideal of a nuclear C^*-algebra $\mathcal{C}_j$, $j=1,2$. Let $\pi_j:\mathcal{C}_j\to\mathcal{C}_j/\mathcal{I}_j$ be the canonical $*$-morphism. Then the mapping

$$\bar{\pi}:\mathcal{C}_1\otimes\mathcal{C}_2\to[(\mathcal{C}_1/\mathcal{I}_1)\otimes\mathcal{C}_2]\oplus[\mathcal{C}_1\otimes(\mathcal{C}_2/\mathcal{I}_2)]$$

$$A\mapsto\{(\pi_1\otimes 1)(A),(1\otimes\pi_2)(A)\}$$

is a $*$-morphism, and $\ker(\bar{\pi})=\mathcal{I}_1\otimes\mathcal{I}_2$.

Proof: Since $\mathcal{C}_1$ and $\mathcal{C}_2$ are nuclear, the mappings $\pi_1\otimes 1$ and $1\otimes\pi_2$ are (surjective) $*$-morphisms with $\ker(\pi_1\otimes 1)=\mathcal{I}_1\otimes\mathcal{C}_2$ and $\ker(1\otimes\pi_2)=\mathcal{C}_1\otimes\mathcal{I}_2$ (Ref. 12, Theorem 6.5.2). From this it follows that $\bar{\pi}$ is a $*$-morphism with $\ker(\bar{\pi})=(\mathcal{I}_1\otimes\mathcal{C}_2)\cap(\mathcal{C}_1\otimes\mathcal{I}_2)$. Since ideals in nuclear C^*-algebras are nuclear, the triple $(\mathcal{I}_1,\mathcal{C}_2,\mathcal{I}_2)$ verifies the (right) slice map conjecture (Ref. 19, Proposition 10). Thus one gets the equality $\ker(\bar{\pi})=\mathcal{I}_1\otimes\mathcal{I}_2$ by an easy adaptation of the proof of (Ref. 18, Corollary 5). □

We need two more notations. For any $j\in\{2,\ldots,N\}$, $\varrho\in\ell^1(\mathbb{Z}^{N-1})$ and $\tau\in\mathbb{T}$, we define $\nu_j(\tau)\varrho\in\ell^1(\mathbb{Z}^{N-2})$ by

$$[\nu_j(\tau)\varrho](z_2,\ldots,z_{j-1},z_{j+1},\ldots,z_N):=(\mathcal{F}_j\varrho)(z_2,\ldots,z_{j-1},\tau,z_{j+1},\ldots,z_N),$$

$\mathcal{F}_j$ being the Fourier transformation in the jth variable. Furthermore we denote by $\Sigma_j(\tau,\tau')$ the spectrum of the Toeplitz operator (relative to the pair $\{\mathbb{Z}^{N-2},(\mathbb{N}^*)^{N-2}\}$)

$$T_{\nu_j(\tau')\mu(\tau)\varphi}^{N-2}+V_{\nu_j(0)\mu(0)\psi}^{N-2}$$

acting in $\ell^2[(\mathbb{N}^*)^{N-2}]$.

Theorem 4.2: *Let $\varphi,\psi\in\ell^1(\mathbb{Z}^N)$ be real functions and $\tau\in\mathbb{T}$. Then one has*

$$\sigma_{\mathrm{ess}}(T_{\mu(\tau)\varphi}^{N-1}+V_{\mu(0)\psi}^{N-1})=\bigcup_{j=2}^{N}\bigcup_{\tau'\in\mathbb{T}}\Sigma_j(\tau,\tau').$$

Proof: By analogy to (the Fourier transformed version of) the isomorphism $\mathcal{T}/\mathcal{K}[\ell^2(\mathbb{N})] \simeq C(\mathbb{T})$ (Ref. 6, Theorem 7.23) one has a canonical isomorphism $\mathcal{T}^*/\mathcal{K}^* \simeq C(\mathbb{T})$, uniquely defined by the fact that for any $z \in \mathbb{Z}$ the operator $v_z^{\mathbb{N}^*} \in \mathcal{T}^*$ is sent onto the function $\mathrm{e}_z \in C(\mathbb{T})$. Therefore the class of operators $T_f^{\mathbb{N}^*} \in \mathcal{T}^*$, $f \in \ell^1(\mathbb{Z})$, must be sent onto the class of functions $\mathcal{F}f \in C(\mathbb{T})$.

The Toeplitz algebra $\mathcal{T}^*$ is nuclear, since it is the extension of the Abelian quotient $\mathcal{T}^*/\mathcal{K}^* \simeq C(\mathbb{T})$ by the nuclear ideal $\mathcal{K}^*$. So we may use the analog of Lemma 4.1 for the $N-1$ factors $\mathcal{C}_2=\cdots=\mathcal{C}_N=\mathcal{T}^*$ and $\mathcal{I}_2=\cdots=\mathcal{I}_N=\mathcal{K}^*$. We get an injective $*$-morphism

$$(\mathcal{T}^*)^{\otimes(N-1)}/(\mathcal{K}^*)^{\otimes(N-1)} \hookrightarrow \oplus_{j=2}^N(\mathcal{T}_*^{\otimes(j-2)} \otimes C(\mathbb{T}) \otimes \mathcal{T}_*^{\otimes(N-j)})$$

$$\simeq \oplus_{j=2}^N(C(\mathbb{T}) \otimes \mathcal{T}_*^{\otimes(N-2)}),$$

sending $T_{\mu(\tau)\varphi}+V_{\mu(0)\psi}$ onto the collection

$$\left\{\int_{\mathbb{T}}^{\oplus} \mathrm{d}\tau'(T^{N-2}_{\nu_j(\tau')\mu(\tau)\varphi} + V^{N-2}_{\nu_j(0)\mu(0)\psi})\right\}_{j=2,\ldots,N}.$$

One concludes by using Ref. 1, Sec. 8.2.4. □

As an example, if $N=2$, one has

$$\sigma_{\mathrm{ess}}(T^1_{\mu(\tau)\varphi} + V^1_{\mu(0)\psi}) = \{(\mathcal{F}_1\mathcal{F}_2\varphi)(\tau-\tau',\tau') + (\mathcal{F}_1\mathcal{F}_2\psi)(0,0): \tau' \in \mathbb{T}\}.$$

In the case of the Heisenberg model (see Proposition 2.2), one has to take $\varphi=-2a\chi_S$ and $\psi=2b\chi_S$. Since $(\mathcal{F}_1\mathcal{F}_2\chi_S)(\tau-\tau',\tau')=2\cos(2\pi\tau')+2\cos[2\pi(\tau-\tau')]$, the essential spectrum of the fiber operator coincides with the interval $\{8b-4a\cos(2\pi\tau')-4a\cos[2\pi(\tau-\tau')]: \tau' \in [0,1]\}$.

Remark 4.3: Results of this section (*and also of the next one*) *can easily be generalized to Toeplitz-like operators* $T^<_\varphi+V^<_\psi$ *acting on the subset*

$$E = (\mathbb{Z}^m_{\mathrm{lex}})^N_< := \{(x_1,\ldots,x_N) \in (\mathbb{Z}^m_{\mathrm{lex}})^N : x_1 < x_2 < \cdots < x_N\}$$

of $X=(\mathbb{Z}^m_{\mathrm{lex}})^N$, *where* $\mathbb{Z}^m_{\mathrm{lex}}$ *is the group* $\mathbb{Z}^m$ *ordered lexicographically. In analyzing the structure of* $\mathcal{T}^E(X)$ *for this case, the Toeplitz algebra* $\mathcal{T}$ *should be replaced by* $\mathcal{T}_m := \mathcal{T}^{(\mathbb{Z}^m_{\mathrm{lex}})_+}(\mathbb{Z}^m_{\mathrm{lex}})$, *where* $(\mathbb{Z}^m_{\mathrm{lex}})_+ := \{x \in \mathbb{Z}^m_{\mathrm{lex}} : 0 \le x\}$. *The only important change concerns the calculation of the quotients* $\mathcal{T}_m/\mathcal{K}_m$, *where* $\mathcal{K}_m := \mathcal{K}\{\ell^2[(\mathbb{Z}^m_{\mathrm{lex}})_+]\}$. *Namely one has to call for the rather deep result* (Ref. 13, Theorem 2.3), *which implies that* $\mathcal{T}_m/\mathcal{K}_m$ *and* $\mathcal{T}_{m-1} \otimes C(\mathbb{T})$ *are* $*$*-isomorphic*.

V. LOCALIZATION

In the sequel we determine localization properties of the operators $T^<_\varphi+V^<_\psi$ by adapting them to the Toeplitz algebra $\mathcal{T}^<(\mathbb{Z}^N)$, a technique developed in Ref. 2 (see also Ref. 10) for crossed product C^*-algebras, with applications to Schrödinger operators in $\mathbb{R}^n$.

Let H be a self-adjoint operator in $\ell^2(\mathbb{Z}^N_<)$ (or in some other L^2 space) and χ a nontrivial multiplication operator (for example the characteristic function of a set having a strictly positive measure). If κ is a continuous function with support intersecting the spectrum of H, the operator $\chi\kappa(H)$ has no reason to be small in general. The unique *a priori* bound would be

$$\|\chi\kappa(H)\| \le \|\chi\|_\infty \sup_{\lambda \in \sigma(H)} |\kappa(\lambda)|. \tag{5.1}$$

We are going to correlate χ to κ in such a way to make the norm small without asking any of the two factors on the r.h.s. of (5.1) to be small.

Theorem 5.1: *Fix* $j \in \{2,\ldots,N\}$ *and let* φ,ψ *be real elements of* $\ell^1(\mathbb{Z}^N)$. *For any* $n \in \mathbb{N}$ *set*

$$\Omega_j(n) := \{(y_1,\ldots,y_N) \in \mathbb{Z}^N_< : y_j - y_{j-1} \ge n\}.$$

Let $\kappa: \mathbb{R} \to \mathbb{R}$ *be a continuous function with*

$$\operatorname{supp}\kappa \cap [\cup_{\tau,\tau'\in\mathbb{T}}\Sigma_j(\tau,\tau')] = \emptyset\ .$$

Then for each $\varepsilon>0$ *there exists* $n_\varepsilon\in\mathbb{N}$ *such that*

$$\|\chi_{\Omega_j(n)}\kappa(T^<_\varphi + V^<_\psi)\| \le \varepsilon \tag{5.2}$$

for each $n\ge n_\varepsilon$.

Proof: Denote by $T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}+V^{\mathcal{E}}_{\psi\circ\theta^{-1}}$ the image of $T^<_\varphi+V^<_\psi$ through the isomorphism $\mathcal{T}^<(\mathbb{Z}^N)\simeq C(\mathbb{T})\otimes(\mathcal{T}^*)^{\otimes(N-1)}$, defined by the change of variables θ. One verifies easily that the estimate (5.2) is equivalent to

$$\|\chi_{\widetilde{\Omega_j(n)}}\kappa(T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}+V^{\mathcal{E}}_{\psi\circ\theta^{-1}})\|\le\varepsilon,$$

where $\widetilde{\Omega_j(n)}:=\theta[\Omega_j(n)]=\{(z_1,\ldots,z_N)\in\mathbb{Z}\times(\mathbb{N}^*)^{(N-1)}: z_j\ge n\}$. Moreover the operator $\kappa(T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}+V^{\mathcal{E}}_{\psi\circ\theta^{-1}})$ belongs to the ideal

$$\mathcal{I}_j := C(\mathbb{T})\otimes(\mathcal{T}^*)^{\otimes(j-2)}\otimes\mathcal{K}^*\otimes(\mathcal{T}^*)^{\otimes(N-j)}$$

of $\mathcal{C}:=C(\mathbb{T})\otimes(\mathcal{T}^*)^{\otimes(N-1)}$. Indeed the image of $T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}+V^{\mathcal{E}}_{\psi\circ\theta^{-1}}$ in the quotient

$$\mathcal{C}/\mathcal{I}_j\simeq C(\mathbb{T})\otimes(\mathcal{T}^*)^{\otimes(j-2)}\otimes C(\mathbb{T})\otimes(\mathcal{T}^*)^{\otimes(N-j)}\simeq C(\mathbb{T})^{\otimes 2}\otimes(\mathcal{T}^*)^{\otimes(N-2)}$$

is

$$\int^{\oplus}_{\mathbb{T}^2}\mathrm{d}\tau\,\mathrm{d}\tau'\,(T^{N-2}_{\nu_j(\tau')\mu(\tau)\varphi}+V^{N-2}_{\nu_j(0)\mu(0)\psi}),$$

with spectrum $\cup_{\tau,\tau'\in\mathbb{T}}\Sigma_j(\tau,\tau')\equiv\sigma_{\mathcal{I}_j}(T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}+V^{\mathcal{E}}_{\psi\circ\theta^{-1}})$. Thus, since $\operatorname{supp}(\kappa)\cap[\cup_{\tau,\tau'\in\mathbb{T}}\Sigma_j(\tau,\tau')]=\emptyset$, it follows by Ref. 2, Lemma 1 that $\kappa(T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}+V^{\mathcal{E}}_{\psi\circ\theta^{-1}})\in\mathcal{I}_j$. Now

$$\chi_{\widetilde{\Omega_j(n)}}=1_{j-1}\otimes\chi_{\{z_j\ge n\}}\otimes 1_{N-j},$$

where $\chi_{\{z_j\ge n\}}$ converges strongly to 0 in $\mathcal{B}[\ell^2(\mathbb{N}^*)]$ as $n\to\infty$. Thus, by examining the structure of $\mathcal{J}_j$, one gets

$$\|\chi_{\widetilde{\Omega_j(n)}}\kappa(T^{\mathcal{E}}_{\varphi\circ\theta^{-1}}+V^{\mathcal{E}}_{\psi\circ\theta^{-1}})\|\to 0$$

as $n\to\infty$. □

Let H be a self-adjoint operator in a Hilbert space $\mathcal{G}$ with spectral measure E^H, and let $f\in\mathcal{G}$ be an arbitrary vector. We call *spectral support of* f *with respect to* H, and write $\operatorname{supp}(f;H)$, for the smallest closed subset F of $\mathbb{R}$ such that $E^H(F)f=f$. Alternatively one can characterize $\operatorname{supp}(f;H)$ as follows:

$$\lambda\notin\operatorname{supp}(f;H)\quad\text{iff }\exists\,\varepsilon>0\text{ such that }E^H(\lambda-\varepsilon,\lambda+\varepsilon)f=0.$$

Obviously one has $\operatorname{supp}(f;H)\subset\sigma(H)$. If H is the Hamilton operator describing some quantum system in $\mathcal{G}$, we say that f is *a state with energy in* $\operatorname{supp}(f;H)$.

Corollary 5.2: Let φ,ψ *and* j *be as in Theorem 5.1. Then, for any* $\varepsilon>0$, *there exists* $n_\varepsilon\in\mathbb{N}$ *such that*

$$\|\chi_{\Omega_j(n)}e^{-it(T^<_\varphi+V^<_\psi)}f\|\le\varepsilon\|f\|$$

for all $n\ge n_\varepsilon$, $t\in\mathbb{R}$ *and all* $f\in\ell^2(\mathbb{Z}^N_<)$ *satisfying*

$$\operatorname{supp}(f;T^<_\varphi+V^<_\psi)\cap[\cup_{\tau,\tau'\in\mathbb{T}}\Sigma_j(\tau,\tau')]=\emptyset\ .$$

Corollary 5.2 follows trivially from Theorem 5.1. We put it into evidence for its physical interpretation in the case of the one-dimensional Heisenberg model: Intuitively, if f is a normalized initial state with energy outside $\cup_{\tau,\tau' \in \mathbb{T}} \Sigma_j(\tau,\tau')$, the decomposition of the system into two clusters of spins pointing up, one "at the left" composed of $j-1$ elements, and the other one "at the right" composed of $N-j+1$ elements, is highly unprobable *uniformly in time* if the distance n between the clusters is large enough.

It is obvious that several variants are available. One can consider ideals smaller than $\mathcal{I}_j$, by collapsing more than one factor to the ideal of compact operators in $\ell^2(\mathbb{N}^*)$. In this way, one gets more detailed clustering information for the one-dimensional Heisenberg model, but for *a priori* smaller sets of energy values. The fiber Hamiltonians $T^{N-1}_{\mu(\tau)\varphi}+V^{N-1}_{\mu(0)\psi}$ can be studied identically by using ideals in the C^*-algebra $(\mathcal{T}^*)^{\otimes(N-1)}$.

From Corollary 3.3 and Theorem 4.2 we know that

$$\bigcup_{j=2}^{N} \bigcup_{\tau,\tau' \in \mathbb{T}} \Sigma_j(\tau,\tau') = \bigcup_{\tau \in \mathbb{T}} \sigma_{\mathrm{ess}}(T^{N-1}_{\mu(\tau)\varphi} + V^{N-1}_{\mu(0)\psi}) \subset \sigma(T^{<}_{\varphi} + V^{<}_{\psi}).$$

It does not seem easy to determine under which conditions there is room in the spectrum of $T^{<}_{\varphi} + V^{<}_{\psi}$ outside $\cup_{\tau,\tau' \in \mathbb{T}} \Sigma_j(\tau,\tau')$ for a given j. However one may expect it is often the case.

We examine the general form of potentials with zero reflection coefficient in one-dimensional Hamiltonians connected with Casimir invariants of non-compact groups. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2259579]

I. INTRODUCTION

There are a number of potentials for the Schrödinger equation in one dimension for which the reflection amplitude vanishes identically while the transmission amplitude is a complex number of modulus 1 for all energy values.[1,2] Such potentials are called the reflectionless or transparent potentials. The best known of these is a modified Pöschl-Teller potential hole.[3] (For scattering of the Gaussian wave packet by the modified Pöschl-Teller potential hole see Ref. 4.) A number of authors have already discussed reflectionless potentials within the frameworks of inverse scattering theory,[5–12] supersymmetric quantum mechanics,[13–17] and a Darbox transformation approach.[18] The relation between the reflectionless potentials and the soliton solutions of nonlinear (such as Korteweg-de Vries, sine-Gordon, and nonlinear Schrödinger) equations has been investigated in Refs. 7 and 19–21 In the present work, we provide a group-theoretical approach to the problem.

In a previous paper,[22] G. A. K. discussed one-dimensional scattering problems related to the principal series of SO(2,2), in the sense that the Hamiltonian, H, of the system is related to the Casimir operator, C, of SO(2,2) as follows:

$$Q(H-E) = (C^{\mathrm{SO}(2,2)} - \sigma(\sigma+2))|_{\mathcal{H}},$$

where $\mathcal{H}$ are the subspaces occurring in the subgroup reductions, $\sigma(\sigma+2)$ is an eigenvalue of C, and Q is some nontrivial operator. In Ref. 22 it was shown that the scattering problem can be completely solved within the framework of group theory, without explicit knowledge of the interaction potentials. Namely, the S-matrices for systems under consideration are determined by diagonal elements of the intertwining operator, A, between Weyl-equivalent representations of SO(2,2).[23] At this stage we note that the operator A is said to be intertwining if relation

$$AU^{\chi}(g) = U^{\tilde{\chi}}(g)A \quad \text{for all } g \in G \tag{1}$$

or relation

$$AdU^{\chi}(b) = \mathrm{d}U^{\tilde{\chi}}(b)A \quad \text{for all } b \in \mathfrak{g} \tag{2}$$

holds, where U^{χ} and $U^{\tilde{\chi}}$ are Weyl-equivalent unitary irreducible representation's (UIRs) of principal series of the group G, while $\mathrm{d}U^{\chi}$ and $\mathrm{d}U^{\tilde{\chi}}$ are the corresponding representations of the algebra $\mathfrak{g}$ of G. It is worthwhile to point out that representations U^{χ} and $U^{\tilde{\chi}}$ have the same Casimir eigenvalues. Such representations are called Weyl equivalent. Equations (1) and (2) have much

a)Electronic mail: gkerimov@trakya.edu.tr

restriction power, determining the intertwining operator up to a constant. Therefore, one can evaluate the *S*-matrix without writing a Schrödinger equation, or computing the wave functions.[24]

Reference 22 explained a method of extracting the corresponding (Natanzon) potentials from the Casimir operator and applied it in detail to the reductions $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(2),\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes E(1)$, and $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(1,1)$. The same article explained the occurrence of reflection and transmission amplitudes in the *S*-matrix for potentials related to $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\otimes\mathrm{SO}(1,1)$ reduction: this happens because within a principal series of SO(2,2) each UIR of SO(1,1) appears twice. We notice that, in one-dimensional scattering problems, the *S*-matrix can be written as a 2×2 matrix[1]

$$S=\begin{pmatrix} R_l & T_r \\ T_l & R_r \end{pmatrix}, \tag{3}$$

where R_l and T_l are the reflection and transmission amplitudes for a wave incident from the left while R_r and T_r are the reflection and transmission amplitudes for a wave incident from the right. (For other definitions of *S*-matrix see, e. g., Ref. 25, and references therein.) If potential $V(x)$ is real and symmetric (i.e., $V(-x)=V(x)$) then $T_l=T_r$ and $R_l=R_r$.

If one chooses the chain $\mathrm{SO}(2,2)\supset\mathrm{SO}(2,1)\supset\mathrm{SO}(2)$ then both principal and discrete series representations of SO(2,1) appear in the reduction. Moreover, the principal series representation of SO(2,1) is double degenerate therein, while the discrete series representation of SO(2,1) appears at most once. One can calculate the matrix form of the intertwining operator in the basis corresponding to the reduction with respect to SO(2,1). Everything here follows exactly as in Appendix A of Ref. 23. As a result, we come to following conclusion: the *S*-matrices of one-dimensional scattering systems related to the $\mathrm{SO}(2,2)\supset\mathrm{SO}(2,1)\supset\mathrm{SO}(2)$ reduction have the form (3) with $R_l=R_r=R$ and $T_l=T_r=T$ where

$$R=c\frac{1}{\pi}\sin(\pi j)\Gamma(\sigma+j+2)\Gamma(\sigma-j+1),$$

$$T=c\frac{1}{\pi}\sin(\pi\sigma)\Gamma(\sigma+j+2)\Gamma(\sigma-j+1).$$

Here, c is a complex number of unit modulus, $j=-1/2-i\tau$, for principal series representations of SO(2,1), while $j=0,1,2,\ldots$, for discrete series representations of SO(2,1) and $\sigma=-1-i\rho$ labels the principal series of the most degenerate representations of SO(2,2) (see Sec. II).

The square modulus of the transmission amplitude is

$$|T|^2=\frac{\sinh^2\pi\rho}{\cosh^2\pi\tau+\sinh^2\pi\rho} \tag{4}$$

if j belongs to the continuous series, while

$$|T|^2=1, \tag{5}$$

if j belongs to the discrete series. Hence, the corresponding class of Natanzon potentials contains symmetric reflectionless potentials.

Moreover, it is not difficult to see that all the potentials related to the Poincaré group in 2+1 dimensions, ISO(2,1), are reflectionless, too. Indeed, the connection between anti de-Sitter group in 2+1 dimensions SO(2,2) and Poincaré group in 2+1 dimensions ISO(2,1) naturally indicates a connection between intertwining operators of these groups. We notice that the group SO(2,2) contracts with respect to SO(2,1) to the group ISO(2,1) in the sense of Inönü and Wigner (see, e.g., Refs. 26 and 27, and references therein). Thus, the intertwining operator of the group ISO(2,1) must arise through a limiting process $\rho\to\infty$ from the intertwining operators of the group SO(2,2). As a result, we obtain $|T|^2=1$ for all potentials related to ISO(2,1). Moreover, due to $|T|^2=1$ for both the discrete spectrum ($j=0,1,2,\ldots$) and the continuous spectrum $\left(j=-\frac{1}{2}-i\tau\right)$ of

$C^{\mathrm{SO}(2,1)}$, we can restrict ourselves to the Poincaré group in $1+1$ dimensions in our study. In fact, one can show that the one-dimensional potentials connected with Poincaré group in $n+1$ dimensions have the same shape. (The intertwining operators of ISO(1,1) are discussed in Sec. 4.2.3 of Ref. 28.) The general form of Hamiltonians for reflectionless potentials connected with Casimir invariants of noncompact groups SO(2,2) and ISO(1,1) will be constructed in the following in a systematic way. We show that the reflectionless potentials under considerations are given by solutions of nonlinear equations (33) and (95).

II. REFLECTIONLESS POTENTIALS RELATED TO SO(2,2)

By SO(2,2) we denote the connected component of the group of linear transformations of $R^{2,2}$ preserving the bilinear form

$$\xi\cdot\eta\equiv\xi_1\eta_1+\xi_2\eta_2-\xi_3\eta_3-\xi_4\eta_4,$$

with $\xi,\eta\in R^{2,2}$. We consider SO(2,2) matrices acting on $R^{2,2}$ on the right. In accordance with this, we write four-vectors ξ in row form: $\xi=(\xi_1\xi_2\xi_3\xi_4)$.

Let us denote $\{g_{ij}(t)\}, i<j, i,j=1,2,3,4$ the six one-parameter subgroups of SO(2,2) consisting of rotations or pseudorotations in the $\xi_i-\xi_j$ planes, that is, transformations of the form

$$\xi_k'=\xi_k,\quad k\neq i,j,\quad \xi_i'=\xi_i\cos t+\xi_j\sin t,\quad \xi_j'=-\xi_i\sin t+\xi_j\cos t,$$

or

$$\xi_k'=\xi_k,\quad k\neq i,j,\quad \xi_i'=\xi_i\cosh t+\xi_j\sinh t,\quad \xi_j'=\xi_i\sinh t+\xi_j\cosh t.$$

The matrices

$$a_{ij}=\frac{\mathrm{d}}{\mathrm{d}t}g_{ij}(t)|_{t=0},\quad i<j \tag{6}$$

form a basis of the Lie algebra, SO(2,2), of the group, with commutation relations

$$[a_{12},a_{13}]=a_{23},\quad [a_{12},a_{14}]=a_{24},$$

$$[a_{12},a_{23}]=-a_{13},\quad [a_{12},a_{24}]=-a_{14},$$

$$[a_{13},a_{23}]=-a_{12},\quad [a_{14},a_{24}]=-a_{12},$$

$$[a_{23},a_{24}]=-a_{34},\quad [a_{13},a_{14}]=-a_{34},$$

$$[a_{23},a_{34}]=-a_{24},\quad [a_{13},a_{34}]=-a_{14},$$

$$[a_{24},a_{34}]=a_{23},\quad [a_{14},a_{34}]=a_{13}.$$

The unitary irreducible representations (UIRs) of SO(2,2) are known to form three series:[26,28] principal, supplementary, and discrete. It is also known that only the principal series of SO(2,2) describe scattering states. Consequently, the relevant UIRs are those in the principal series. Moreover, the discussion will be limited to the most degenerate representations.

The principal series of the most degenerate representations of SO(2,2) is characterized by the pair of quantum numbers $\chi=(\rho,\varepsilon)$, where $\varepsilon=0$, or 1 and $0\leqslant\rho<+\infty$. The representations specified by labels $\chi=(\rho,\varepsilon)$ and $\tilde{\chi}=(-\rho,\varepsilon)$ are Weyl-equivalent. For the sake of simplicity, we consider here the representations with $\varepsilon=0$.

We want to construct the Hamiltonians for which the relation

$$Q(H-E) = [C^{\mathrm{SO}(2,2)} - \sigma(\sigma+2)]|_{\mathcal{H}}, \tag{7}$$

holds, where $\sigma=-1-i\rho$ specifies the most degenerate principal series of SO(2,2) and $\mathcal{H}$ is a subspace occurring in $\mathrm{SO}(2,2)\supset\mathrm{SO}(2,1)\supset\mathrm{SO}(2)$ subgroup reduction. The key to the construction of it lies in the observation that the Schrödinger energy eigenvalue equation for such systems is nothing but the condition imposed on the carrier space of SO(2,2) to be irreducible. Thus, in order to find the Hamiltonians for the systems under consideration, we should look for a reducible representation of SO(2,2) containing the principal series.

Let us consider a quasiregular representation $T(g)$ of SO(2,2) realized in the Hilbert space of square-integrable functions $f(\xi)$ on the hyperboloid $\Xi\sim\mathrm{SO}(2,2)/\mathrm{SO}(2,1)$ defined by

$$\xi_1^2+\xi_2^2-\xi_3^2-\xi_4^2=1. \tag{8}$$

In general, one can use for construction of the quasiregular representation the carrier space $L^2(\Xi,\mathrm{d}\mu)$ with any quasi-invariant measure $\mathrm{d}\mu(\xi)$ on Ξ.[26] Representations with different measures are unitarily equivalent, and are given by

$$T(g)f(\xi)=\left(\frac{\mathrm{d}\mu(\xi g)}{\mathrm{d}\mu(\xi)}\right)^{1/2} f(\xi g), \tag{9}$$

where $\mathrm{d}\mu(\xi g)/\mathrm{d}\mu(\xi)$ is the Radon-Nikodym derivative.

Without loss of generality, we can put

$$\mathrm{d}\mu(\xi)=h(\xi)\mathrm{d}\xi, \tag{10}$$

where $\mathrm{d}\xi=\mathrm{d}\xi_1\mathrm{d}\xi_2\mathrm{d}\xi_3/|\xi_4|$ is an invariant measure on Ξ. The requirement that the measure is quasi-invariant implies the condition

$$h(\xi)\geqslant 0. \tag{11}$$

Then, it is not difficult to see that the Hermitian infinitesimal operators

$$A_{jk}=-i\frac{\mathrm{d}}{\mathrm{d}t}T(g_{jk}(t))|_{t=0} \tag{12}$$

of the representation $T(g)$ corresponding to the one-parameter subgroup are given by

$$iA_{12}=h^{-1/2}\circ\left(\xi_2\frac{\partial}{\partial\xi_1}-\xi_1\frac{\partial}{\partial\xi_2}\right)\circ h^{1/2},$$

$$iA_{13}=h^{-1/2}\circ\left(\xi_3\frac{\partial}{\partial\xi_1}+\xi_1\frac{\partial}{\partial\xi_3}\right)\circ h^{1/2},$$

$$iA_{23}=h^{-1/2}\circ\left(\xi_3\frac{\partial}{\partial\xi_2}+\xi_2\frac{\partial}{\partial\xi_3}\right)\circ h^{1/2},$$

$$iA_{14}=h^{-1/2}\circ\left(\xi_4\frac{\partial}{\partial\xi_1}\right)\circ h^{1/2},$$

$$iA_{24}=h^{-1/2}\circ\left(\xi_4\frac{\partial}{\partial\xi_2}\right)\circ h^{1/2},$$

$$iA_{34} = h^{-1/2} \circ \left(\xi_4 \frac{\partial}{\partial \xi_3} \right) \circ h^{1/2}. \tag{13}$$

where $\circ$ denotes composition of operators. Here, we have assumed ξ_1, ξ_2, and ξ_3 as the independent variables on Ξ.

The representation $T(g)$ is decomposed into principal and discrete series of most degenerate UIRs of SO(2,2).[27] The irreducible components are obtained if all functions f are eigenfunctions of the Casimir operator $C^{\mathrm{SO}(2,2)}$,

$$C^{\mathrm{SO}(2,2)} f = \sigma(\sigma+2) f, \tag{14}$$

where $\sigma = -1 - i\rho, 0 \leqslant \rho < +\infty$ for the principal series representations, while $\sigma = l, l = 0,1,2,\ldots$, for discrete series representations and

$$C^{\mathrm{SO}(2,2)} = A_{12}^2 + A_{34}^2 - A_{13}^2 - A_{14}^2 - A_{23}^2 - A_{24}^2 = h^{-1/2} \circ \left[-\frac{\partial^2}{\partial \xi_1^2} - \frac{\partial^2}{\partial \xi_2^2} + \frac{\partial^2}{\partial \xi_3^2} + L(L+2) \right] \circ h^{1/2}, \tag{15}$$

with

$$L = \xi_1 \frac{\partial}{\partial \xi_1} + \xi_2 \frac{\partial}{\partial \xi_2} + \xi_3 \frac{\partial}{\partial \xi_3}. \tag{16}$$

Since we are interested only in the continuum, we put $\sigma = -1 - i\rho$. Next, imposing the reduction condition, we can extract the corresponding one-dimensional potentials from the Casimir operator.

We want to consider the $\mathrm{SO}(2,2) \supset \mathrm{SO}(2,1) \supset \mathrm{SO}(2)$ reduction chain; but there are four subgroups which are isomorphic to SO(2,1). Namely, the subgroups G_1, G_2, G_3, and G_4 generated by $\{a_{12}, a_{13}, a_{23}\}, \{a_{12}, a_{14}, a_{24}\}, \{a_{23}, a_{24}, a_{34}\}$, and $\{a_{13}, a_{14}, a_{34}\}$, respectively. Although these subgroups are mathematically equivalent, they may be related to different physical problems. For this reason we shall consider various SO(2,1) subgroup reductions

(i) The $\mathrm{SO}(2,2) \supset G_1$ reduction. Then, the reduction conditions are

$$A_{12} f_{jm} = m f_{jm}, \quad C^{G_1} f_{jm} = j(j+1) f_{jm}$$

where

$$C^{G_1} = A_{12}^2 - A_{13}^2 - A_{23}^2 = h^{-1/2} \circ \left[(1+\xi_4^2) \left(-\frac{\partial^2}{\partial \xi_1^2} - \frac{\partial^2}{\partial \xi_2^2} + \frac{\partial^2}{\partial \xi_3^2} \right) + L(L+1) \right] \circ h^{1/2}. \tag{17}$$

It is known that[26,27] the spectrum of C^{G_1} consists of a discrete part

$$j = l, \quad l = 0,1,2,\ldots \quad (|m| = l+1+n, n = 0,1,2,\ldots)$$

and a continuous part

$$j = -\tfrac{1}{2} - i\tau, \quad 0 \leqslant \tau < \infty \quad (m = 0, \pm 1, \pm 2, \ldots).$$

According to this, we impose $\mathrm{d}\mu$ to be invariant under G_1,

$$h(\xi g) = h(\xi), \tag{18}$$

where $g \in G_1$. Hence we can, without loss of generality, put $h = h(u)$, $u = \xi_1^2 + \xi_2^2 - \xi_3^2$.

The parametrization that we seek for manifold (8) must be such as to make A_{12} and C^{G_1} particularly simple. The corresponding coordinate system on (8) is obtained by sections of the manifold (8) by the planes $\xi_4 = c$. These sections are one-sheeted hyperboloids

$$\xi_1^2 + \xi_2^2 - \xi_3^2 = 1 + c^2$$

being invariant under G_1. Hence we introduce in place of ξ_1, ξ_2, and ξ_3 the new variables x, α, and φ by

$$\xi_1 = \frac{1}{\sqrt{1 - z^2(x)}} \cosh \alpha \cos \varphi,$$

$$\xi_2 = \frac{1}{\sqrt{1 - z^2(x)}} \cosh \alpha \sin \varphi,$$

$$\xi_3 = \frac{1}{\sqrt{1 - z^2(x)}} \sinh \alpha,$$

$$\xi_4 = \frac{z(x)}{\sqrt{1 - z^2(x)}}, \tag{19}$$

where $-\infty < x, \alpha < \infty, 0 \leqslant \varphi < 2\pi$ and $z(x)$ is a differentiable function on R with values in $[-1, +1]$. Then

$$A_{12} = i\frac{\partial}{\partial \varphi}, \quad C^{G_1} = \frac{\partial^2}{\partial \alpha^2} + \tanh \alpha \frac{\partial}{\partial \alpha} - \frac{1}{\cosh^2 \alpha} \frac{\partial^2}{\partial \varphi^2} \tag{20}$$

while

$$C^{\mathrm{SO}(2,2)} = \left(\frac{1 - z^2}{\dot{z}}\right)^2 \left[\frac{\partial^2}{\partial x^2} + \left(\frac{\dot{h}}{h} - \frac{\ddot{z}}{\dot{z}}\right) \frac{\partial}{\partial x} + \frac{1}{2}\frac{\ddot{h}}{h} - \frac{1}{4}\left(\frac{\dot{h}}{h}\right)^2 - \frac{\ddot{z}}{\dot{z}}\frac{\dot{h}}{2h} \right.$$
$$\left. + \frac{(\dot{z})^2}{1 - z^2}\left(\frac{\partial^2}{\partial \alpha^2} + \tanh \alpha \frac{\partial}{\partial \alpha} - \frac{1}{\cosh^2 \alpha} \frac{\partial^2}{\partial \varphi^2} \right) \right], \tag{21}$$

where dots represent derivatives with respect to x, i.e., $\dot{z} = \mathrm{d}z/\mathrm{d}x$, $\ddot{z} = \mathrm{d}^2 z/\mathrm{d}x^2$, and so on.

In order to eliminate the term that is linear in $\partial/\partial x$, we impose

$$\frac{\dot{h}}{h} - \frac{\ddot{z}}{\dot{z}} = 0. \tag{22}$$

Equation (22) is obviously satisfied by

$$h = \varkappa \dot{z}, \tag{23}$$

where $\varkappa$ is a constant. Substituting Eq. (23) into formula (21), we readily obtain

$$C^{\mathrm{SO}(2,2)} = \left(\frac{1 - z^2}{\dot{z}}\right)^2 \left[\frac{\partial^2}{\partial x^2} + \frac{1}{2}\frac{\dddot{z}}{\dot{z}} - \frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2 + \frac{(\dot{z})^2}{1 - z^2}\left(\frac{\partial^2}{\partial \alpha^2} + \tanh \alpha \frac{\partial}{\partial \alpha} - \frac{1}{\cosh^2 \alpha} \frac{\partial^2}{\partial \varphi^2} \right) \right]. \tag{24}$$

Let us denote by $C_{jm}^{\mathrm{SO}(2,2)}$ a restriction of $C^{\mathrm{SO}(2,2)}$ on the subspace $\mathcal{H}_{jm}$ spanned by functions f_{jm} with fixed j and m. It turns out that

$$C_{jm}^{\mathrm{SO}(2,2)} = \left(\frac{1 - z^2}{\dot{z}}\right)^2 \left[\frac{\mathrm{d}^2}{\mathrm{d}x^2} + \frac{1}{2}\frac{\dddot{z}}{\dot{z}} - \frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2 + j(j+1)\frac{(\dot{z})^2}{1 - z^2} \right], \tag{25}$$

where we have replaced the Casimir operator of G_1 on the right-hand side of formula (24) with its eigenvalue.

We allow now the eigenvalues of $C^{\mathrm{SO}(2,2)}$ and of C^{G_1} to be linear functions of the energy, i.e.,

$$j(j+1) = \gamma_1 E + \delta_1 \tag{26}$$

and

$$1 + \rho^2 = \gamma_2 E + \delta_2. \tag{27}$$

On the above-given conditions, we have

$$C_{jm}^{\mathrm{SO}(2,2)} - \sigma(\sigma+2) = -\left(\frac{1-z^2}{\dot{z}}\right)^2\left[-\frac{\mathrm{d}^2}{\mathrm{d}x^2} - \frac{1}{2}\frac{\dddot{z}}{\dot{z}} + \frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2 + \dot{z}^2\frac{ER(z) + \delta_1(1-z^2) + \delta_2}{(1-z^2)^2}\right], \tag{28}$$

where

$$R(z) = \gamma_1(1-z^2) + \gamma_2. \tag{29}$$

This equation is easily reduced to the form (7) with

$$Q = -\left(\frac{1-z^2}{\dot{z}}\right)^2, \tag{30}$$

and

$$H = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + V(z) = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} - \frac{1}{2}\frac{\dddot{z}}{\dot{z}} + \frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2 - \frac{\delta_1(1-z^2) + \delta_2}{R} \tag{31}$$

provided that

$$(\dot{z})^2 = \frac{(1-z^2)^2}{R(z)}. \tag{32}$$

(We are using units with $2M = \hbar = 1$.)

Taking into account Eq. (32), the potential, V, in Eq. (31) can be rewritten in the form

$$V(z) = -\frac{(4\delta_1+1)(1-z^2) + 4\delta_2 - 5}{4R(z)} - \frac{1}{2}\left[2\gamma_2 + \gamma_1 + \frac{\gamma_2}{2(1-z^2)} + \frac{5\Delta}{8R(z)}\right]\frac{1-z^2}{R(z)^2}, \tag{33}$$

where $\Delta = -4(\gamma_1+\gamma_2)\gamma_2$.

To make the potential V vanish as $|x| \to \infty$ (i.e., as $|z| \to 1$) we set $\delta_2 = 1$. Hence the relation (27) reduces to

$$\rho^2 = \gamma_2 E. \tag{34}$$

According to this we shall assume that $\gamma_2 > 0$.

The expression (33) simplifies for some convenient choice of γ_1 and γ_2. Let us start with the simplest case when $\gamma_1 = 0$, but γ_2 and δ_1 are still arbitrary. Then Eq. (32) reduces to

$$(\dot{z})^2 = \frac{1}{\gamma_2}(1-z^2)^2. \tag{35}$$

The solution to this equation is given by

$$z = \tanh\frac{x}{\sqrt{\gamma_2}}. \tag{36}$$

With this z, the Hamiltonian in (31) simplifies to the modified Pöschl-Teller Hamiltonian,[3]

$$H_{\mathrm{PT}} = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} - \frac{j(j+1)}{\gamma_2 \cosh^2(x/\sqrt{\gamma_2})}. \tag{37}$$

It is also worth noting that potentials (33) include important families of Ginocchio potentials.[29] Indeed, putting

$$\gamma_1 = \frac{1}{\lambda^2} - \frac{1}{\lambda^4}, \quad \gamma_2 = \frac{1}{\lambda^4}, \quad \delta_1 = \nu(\nu+1), \quad \delta_2 = 1 \tag{38}$$

with $0 < \lambda < \infty$ and introducing a new variable y, $-1 \leqslant y \leqslant 1$,

$$y = \frac{z}{\sqrt{z^2 + \lambda^2(1-z^2)}}, \tag{39}$$

Eqs. (33) and (32) reduce to

$$H = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} - \lambda^2\nu(\nu+1)(1-y^2) + \frac{(1-\lambda^2)}{4}[5(1-\lambda^2)y^4 - (7-\lambda^2)y^2 + 2](1-y^2) \tag{40}$$

and

$$\frac{\mathrm{d}y}{\mathrm{d}x} = (1-y^2)[1-(1-\lambda^2)y^2], \tag{41}$$

respectively. Moreover, it follows from (41) that

$$x = \frac{1-\lambda^2}{\lambda^2}\int \frac{\mathrm{d}y}{(1-\lambda^2)y^2 - 1} - \frac{1}{\lambda^2}\int \frac{\mathrm{d}y}{y^2-1}$$

or[30]

$$x = \begin{cases} \dfrac{1}{\lambda^2}[\operatorname{arctanh}(y) - \sqrt{1-\lambda^2}\,\operatorname{arctanh}(\sqrt{1-\lambda^2}y)] & \text{if } 0 < \lambda < 1 \\ \dfrac{1}{\lambda^2}[\operatorname{arctanh}(y) + \sqrt{\lambda^2-1}\,\arctan(\sqrt{\lambda^2-1}y)] & \text{if } 1 \leqslant \lambda < \infty, \end{cases} \tag{42}$$

which is just relation (2.8) of Ref. 29.

The family of potentials given in (40) is a two parameter generalization of the modified Pöschl-Teller potential hole. (Observe that (40) reduces to the modified Pöschl-Teller Hamiltonian when $\lambda = 1$.) They are symmetric about the origin as we expected. The parameter λ is related to the shape of the potential while the parameter ν is related to the depth of the potential and determines the nature of the scattering. If the depth parameter ν is an integer then $|T|^2 = 1$, $|R| = 0$ (see Eqs. (5.9) and (5.10) of Ref. 29).

By making use of traditional techniques, i.e., by considering the asymptotic behavior of the scattering wavefunctions, one can check that the potentials in (33) are reflectionless when j is an integer. In order to apply such a technique we require first a solution for the Schrödinger equation

$$H\Psi = E\Psi$$

with Hamiltonian (31). If we substitute $\Psi = (\dot{z})^{-1/2}\check{\Psi}$ the equation for $\check{\Psi}$ becomes

$$\left\{-(\dot{z})^2\frac{\mathrm{d}^2}{\mathrm{d}z^2} - \frac{\dot{z}^2}{(1-z^2)^2}[\delta_1(1-z^2) + \delta_2]\right\}\check{\Psi} = E\check{\Psi}. \tag{43}$$

Taking into account Eqs. (32), (26), and (27), we arrive at

$$\left[-(1-z^2)\frac{\mathrm{d}^2}{\mathrm{d}z^2} - j(j+1)(1-z^2) + \sigma(\sigma+2)\right]\check{\Psi} = 0. \tag{44}$$

If we set $w=z^2$ and substitute $\check{\Psi}=(1-w)^{(\sigma+2)/2}u$, this differential equation becomes

$$w(1-w)\frac{\mathrm{d}^2u}{\mathrm{d}w^2} + \left[\frac{1}{2} - \left(\sigma+\frac{5}{2}\right)w\right]\frac{\mathrm{d}u}{\mathrm{d}w} - \frac{1}{4}[(\sigma+2)(\sigma+1) - j(j+1)]u = 0. \tag{45}$$

This is equivalent to the hypergeometric equation[30]

$$w(1-w)\frac{\mathrm{d}^2u}{\mathrm{d}w^2} + [c-(a+b+1)w]\frac{\mathrm{d}u}{\mathrm{d}w} - abu = 0, \tag{46}$$

which has two linear independent solutions

$$u_1 = {}_2F_1(a,b;c;w),$$

$$u_2 = w^{1-c}{}_2F_1(a-c+1,b-c+1;2-c;w).$$

Before proceeding further, we note that with $\gamma_2>0$ the function z carries the points $x=\pm\infty$ to $z=\pm1$, respectively. It follows from (32) that

$$z \to \pm\left[1-2e^{-2(|x|-x_0)/\sqrt{\gamma_2}}\right] \quad \text{for } x \to \pm\infty, \tag{47}$$

where x_0 is a constant depending on γ_1 and γ_2. Hence, two linear independent scattering solutions Ψ_l and Ψ_r satisfying the boundary conditions

$$\Psi_l = \begin{cases} e^{ikx} + R_l e^{-ikx} & \text{for } x \to -\infty \\ T_l e^{ikx} & \text{for } x \to +\infty, \end{cases} \tag{48}$$

and

$$\Psi_r = \begin{cases} T_r e^{-ikx} & \text{for } x \to -\infty \\ e^{-ikx} + R_r e^{ikx} & \text{for } x \to +\infty \end{cases} \tag{49}$$

with $E=k^2$, are given by

$$\Psi_l = N\sqrt[4]{\gamma_1(1-z^2)+\gamma_2}(1-z^2)^{(\sigma+1)/2}\left[\Gamma\left(\frac{\sigma+j+2}{2}\right)\Gamma\left(\frac{\sigma-j+1}{2}\right)u_1 - \Gamma\left(\frac{\sigma+j+3}{2}\right)\Gamma\left(\frac{\sigma-j+2}{2}\right)u_2\right]$$

and

$$\Psi_r = N\sqrt[4]{\gamma_1(1-z^2)+\gamma_2}(1-z^2)^{(\sigma+1)/2}\left[\Gamma\left(\frac{\sigma+j+2}{2}\right)\Gamma\left(\frac{\sigma-j+1}{2}\right)u_1 + \Gamma\left(\frac{\sigma+j+3}{2}\right)\Gamma\left(\frac{\sigma-j+2}{2}\right)u_2\right],$$

where

$$N = \frac{\exp\left[\left(\frac{x_0}{\sqrt{\gamma_2}} + \ln\sqrt{2}\right)(\sigma+1)\right]}{2\sqrt{\pi}(\gamma_2)^{1/4}\Gamma(\sigma+1)}, \tag{50}$$

$$u_1 = {}_2F_1\left(\frac{\sigma+j+2}{2}, \frac{\sigma-j+1}{2}; \frac{1}{2}; z^2\right), \tag{51}$$

$$u_2 = z\,{}_2F_1\left(\frac{\sigma+j+3}{2}, \frac{\sigma-j+2}{2}; \frac{3}{2}; z^2\right). \tag{52}$$

Using (47) together with the transformation[30]

$$\begin{aligned} {}_2F_1(a,b;c;w) &= A_1\,{}_2F_1(a,b;a+b-c+1;1-w) \\ &\quad + A_2(1-w)^{c-a-b}\,{}_2F_1(c-a,c-b;c-a-b+1;1-w), \end{aligned}$$

where

$$A_1 = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}, \quad A_2 = \frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)},$$

one can check that the reflection and transmission amplitudes are

$$R_l = R_r = c\frac{1}{\pi}\sin(\pi j)\Gamma(\sigma+j+2)\Gamma(\sigma-j+1) \tag{53}$$

and

$$T_l = T_r = c\frac{1}{\pi}\sin(\pi\sigma)\Gamma(\sigma+j+2)\Gamma(\sigma-j+1), \tag{54}$$

where c is a complex number of unit modulus

$$c = \frac{\Gamma(-1-\sigma)}{\Gamma(1+\sigma)}\exp\left[\left(\frac{2x_0}{\sqrt{\gamma_2}} - \ln 2\right)(\sigma+1)\right]. \tag{55}$$

Thus, when j is an integer the family of potentials given in (33) is reflectionless as we expected.

Finally, by arguments very similar to those used to obtain (33) we can show that the potentials gained for $\mathrm{SO}(2,2) \supset G_2$ reduction have just the same shape as (33).

(ii) The $\mathrm{SO}(2,2) \supset G_3$ reduction. Then, the reduction conditions are

$$A_{34} f_{jm} = m f_{jm}, \quad C^{G_3} f_{jm} = j(j+1) f_{jm}, \tag{56}$$

where

$$C^{G_3} = A_{34}^2 - A_{23}^2 - A_{24}^2 = h^{-1/2} \circ \left[(\xi_1^2 - 1)\left(\frac{\partial^2}{\partial \xi_2^2} - \frac{\partial^2}{\partial \xi_3^2}\right) + M(M+1)\right] \circ h^{1/2} \tag{57}$$

with

$$M = \xi_2 \frac{\partial}{\partial \xi_2} + \xi_3 \frac{\partial}{\partial \xi_3}.$$

According to this, we impose $\mathrm{d}\mu$ to be invariant under G_3,

$$h(\xi g) = h(\xi), \tag{58}$$

where $g \in G_3$. Hence we can, without loss of generality, put $h = h(v)$, $v = \xi_2^2 - \xi_3^2 - \xi_4^2$.

Since A_{34} and $A_{34}^2 - A_{23}^2 - A_{24}^2$ are sought to be diagonal, the appropriate parametrization for (8) in these circumstances is obtained by sections of the manifold (8) by the planes $\xi_1 = c$. It is not difficult to see that the sections are one-sheeted hyperboloids

$$-\xi_2^2+\xi_3^2+\xi_4^2=c^2-1$$

if $|c|>1$ and two-sheeted hyperboloids

$$\xi_2^2-\xi_3^2-\xi_4^2=1-c^2$$

if $|c|<1$. The whole of Ξ can be expressed as the union of two regions, Ξ_1 in which $|\xi_1|>1$ and Ξ_2 in which $|\xi_1|<1$. Since the discrete series of SO(2,1) is related to the one-sheeted hyperboloid we shall restrict ourselves to Ξ_1.

We proceed with the determination of the new coordinates in Ξ_1:

$$\xi_1=\frac{z(x)}{\sqrt{z^2(x)-1}},$$

$$\xi_2=\frac{1}{\sqrt{z^2(x)-1}}\sinh\alpha,$$

$$\xi_3=\frac{1}{\sqrt{z^2(x)-1}}\cosh\alpha\sin\varphi,$$

$$\xi_4=\frac{1}{\sqrt{z^2(x)-1}}\cosh\alpha\cos\varphi, \tag{59}$$

where $-\infty<x,\ \alpha<\infty,\ 0\leqslant\varphi<2\pi$ and $z(x)$ is a differentiable function on R with values in $(-\infty,1)\cup(1,\infty)$. Then

$$A_{34}=-i\frac{\partial}{\partial\varphi},\quad C^{G_3}=\frac{\partial^2}{\partial\alpha^2}+\tanh\alpha\frac{\partial}{\partial\alpha}-\frac{1}{\cosh^2\alpha}\frac{\partial^2}{\partial\varphi^2} \tag{60}$$

while

$$C^{\mathrm{SO}(2,2)}=\left(\frac{1-z^2}{\dot z}\right)^2\left[\frac{\partial^2}{\partial x^2}+\left(\frac{\dot h}{h}-\frac{\ddot z}{\dot z}\right)\frac{\partial}{\partial x}+\frac{1}{2}\frac{\ddot h}{h}-\frac{1}{4}\left(\frac{\dot h}{h}\right)^2-\frac{\ddot z}{\dot z}\frac{\dot h}{2h}\right.$$
$$\left.+\frac{(\dot z)^2}{1-z^2}\left(\frac{\partial^2}{\partial\alpha^2}+\tanh\alpha\frac{\partial}{\partial\alpha}-\frac{1}{\cosh^2\alpha}\frac{\partial^2}{\partial\varphi^2}\right)\right]. \tag{61}$$

Although the operators (21) and (61) have the same form (in terms of z, α,φ), the functions z are not the same.

It is immediately evident from the above-noted sets of equations that the potentials gained for $\mathrm{SO}(2,2)\supset G_3$ reduction are also given by (33), but the values of z are in $(-\infty,1)\cup(1,\infty)$. Hence we have a new family of reflectionless potentials. For example, if $\gamma_1=0$ then z satisfies Eq. (35) whose (nonsingular) solution now becomes

$$z=\begin{cases}\coth\dfrac{x-a}{\sqrt{\gamma_2}} & \text{for } x<0\\[2ex] \coth\dfrac{x+a}{\sqrt{\gamma_2}} & \text{for } x>0,\end{cases} \tag{62}$$

where a, $0<a$, is a constant of integration. So that

$$V=\begin{cases}\dfrac{j(j+1)}{\gamma_2\sinh^2\left(\dfrac{x-a}{\sqrt{\gamma_2}}\right)} & \text{for } x<0\\ \dfrac{j(j+1)}{\gamma_2\sinh^2\left(\dfrac{x+a}{\sqrt{\gamma_2}}\right)} & \text{for } x>0.\end{cases} \tag{63}$$

(Observe that the potential (63) is symmetric about the origin.) This reflectionless potential has been discussed in detail in the context of supersymmetric quantum mechanics.[17]

Finally, we note that we have the same results for the $\mathrm{SO}(2,2)\supset G_4$ reduction.

III. REFLECTIONLESS POTENTIALS RELATED TO ISO(1,1)

We denote by M a two-dimensional Minkowski space with bilinear form

$$\xi\cdot\eta\equiv\xi_1\eta_1-\xi_2\eta_2. \tag{64}$$

Poincaré transformations in M are translations and hyperbolic rotations of the type[28]

$$\xi_1'=\xi_1\cosh\theta+\xi_2\sinh\theta+b_1,$$

$$\xi_2'=\xi_1\sinh\theta+\xi_2\cosh\theta+b_2,$$

where the three parameters b_1, b_2, and θ range from $-\infty$ to $+\infty$. The above-noted transformations can be conveniently written in matrix form

$$\xi'=\xi g, \tag{65}$$

with

$$g=\begin{pmatrix}\cosh\theta & \sinh\theta & 0\\ \sinh\theta & \cosh\theta & 0\\ b_1 & b_2 & 1\end{pmatrix},\quad \xi=(\xi_1,\xi_2,1). \tag{66}$$

The UIRs of the Poincaré group in $1+1$ dimensions are labeled with a quantum number, ρ, ranging from 0 to $+\infty$. Representations labeled with ρ and $-\rho$ are Weyl-equivalent.

The matrices corresponding to translations along the ξ_1 axis and the ξ_2 axis, as well as to hyperbolic rotations are, respectively,

$$g_1(t)=\begin{pmatrix}1&0&0\\0&1&0\\t&0&1\end{pmatrix},\quad g_2(t)=\begin{pmatrix}1&0&0\\0&1&0\\0&t&1\end{pmatrix},\quad g_3(t)=\begin{pmatrix}\cosh t&\sinh t&0\\\sinh t&\cosh t&0\\0&0&1\end{pmatrix}. \tag{67}$$

The generators of the corresponding Lie algebra, $\mathrm{ISO}(1,1)$, denoted by $a_k(k=1,2,3)$, are, by definition

$$a_k=\left.\frac{\mathrm{d}g_k}{\mathrm{d}t}\right|_{t=0}. \tag{68}$$

They satisfy the following commutation relations:

$$[a_1,a_2]=0,\quad [a_3,a_1]=-a_2,\quad [a_3,a_2]=-a_1. \tag{69}$$

Now, we want to construct the Hamiltonian H for which

$$Q(H-E) = (C-\rho^2)|_{\mathcal{H}_\tau}, \tag{70}$$

where $\mathcal{H}_\tau$ is a one-dimensional subspace occurring in the $\mathrm{ISO}(1,1)\supset\mathrm{SO}(1,1)$ reduction.

Let us consider a quasiregular representation of ISO(1,1) induced by a one-dimensional identity representation of SO(1,1). It is known that[28] this representation is decomposed into the direct integral of UIRs of ISO(1,1) labeled with $\rho(0<\rho<\infty)$ and each UIR appears in the decomposition four times.

The quasiregular representation can be realized in the Hilbert space $L^2(M,\mathrm{d}\mu)$ of square-integrable functions defined on $M\sim\mathrm{ISO}(1,1)/\mathrm{SO}(1,1)$. In general, for construction of the quasi-regular representation, one can use the carrier space, $L^2(M,\mathrm{d}\mu)$, with any quasi-invariant measure $\mathrm{d}\mu(\xi)$ on M. The representations with different measure are unitarily equivalent, and given by

$$T(g)f(\xi) = \left[\frac{\mathrm{d}\mu(\xi g)}{\mathrm{d}\mu(\xi)}\right]^{1/2} f(\xi g), \tag{71}$$

with inner product

$$(f,f') = \int \overline{f(\xi)} f'(\xi)\mathrm{d}\mu(\xi), \tag{72}$$

where $\overline{f(\xi)}$ is the complex conjugate of $f(\xi)$ and $\mathrm{d}\mu(\xi g)/\mathrm{d}\mu(\xi)$ is the Radon-Nikodym derivative.

Without loss of generality, we can put

$$\mathrm{d}\mu(\xi) = h(\xi)\mathrm{d}\xi, \tag{73}$$

where $\mathrm{d}\xi=\mathrm{d}\xi_1\mathrm{d}\xi_2$ is an invariant measure on M.

It is not difficult to show that the infinitesimal operators $A_k = -i(\mathrm{d}/\mathrm{d}t)T(g_k(t))|_{t=0}$ of the representation (71) corresponding to the three one-parameter subgroups of ISO(1,1) are given by

$$iA_1 = \frac{\partial}{\partial\xi_1} + \frac{1}{2h}\frac{\partial h}{\partial\xi_1}, \tag{74}$$

$$iA_2 = \frac{\partial}{\partial\xi_2} + \frac{1}{2h}\frac{\partial h}{\partial\xi_2}, \tag{75}$$

$$iA_3 = \xi_2\frac{\partial}{\partial\xi_1} + \xi_1\frac{\partial}{\partial\xi_2} + \frac{1}{2h}\left(\xi_2\frac{\partial h}{\partial\xi_1} + \xi_1\frac{\partial h}{\partial\xi_2}\right). \tag{76}$$

If we compute the Casimir operator $C=A_1^2-A_2^2$, it becomes

$$C = -\frac{\partial^2}{\partial\xi_1^2} + \frac{\partial^2}{\partial\xi_2^2} - \frac{1}{2h}\left(\frac{\partial h}{\partial\xi_1}\frac{\partial}{\partial\xi_1} - \frac{\partial h}{\partial\xi_2}\frac{\partial}{\partial\xi_2}\right) - \frac{1}{2h}\left(\frac{\partial^2 h}{\partial\xi_1^2} - \frac{\partial^2 h}{\partial\xi_2^2}\right) + \frac{1}{4h^2}\left(\left(\frac{\partial h}{\partial\xi_1}\right)^2 - \left(\frac{\partial h}{\partial\xi_2}\right)^2\right). \tag{77}$$

Hence, we can construct the irreducible representations of ISO(1,1) as subrepresentations of the quasi-regular representation (71). To do this, we require the representation space to be irreducible. Such a restriction is obtained if all functions f are eigenfunctions of the Casimir operator C of (71),

$$Cf = \rho^2 f. \tag{78}$$

Next, imposing the reduction condition, we can choose a different basis in the carrier space. In order to diagonalize the SO(1,1) subgroup, we exploit the reduction condition

$$A_3 f_\tau = \tau f_\tau. \tag{79}$$

According to this, we want $d\mu$ to be invariant under SO(1,1), i.e.,

$$h(g_3\xi) = h(\xi), \quad g_3 \in \mathrm{SO}(1,1). \tag{80}$$

As a consequence, we find

$$\left(\xi_2 \frac{\partial}{\partial \xi_1} + \xi_1 \frac{\partial}{\partial \xi_2}\right) h = 0. \tag{81}$$

The parametrization of M we are searching for must be such as to make A_3 particularly simple. For this purpose, we must introduce hyperbolic variables; this requires dividing the Minkowski space into two regions. The new variables x and α, both ranging from $-\infty$ to $+\infty$, are introduced in each region in this way:

$$\xi_1^2 > \xi_2^2: \quad \xi_1 = z(x)\cosh\alpha, \quad \xi_2 = z(x)\sinh\alpha, \tag{82}$$

$$\xi_1^2 < \xi_2^2: \quad \xi_1 = z(x)\sinh\alpha, \quad \xi_2 = z(x)\cosh\alpha, \tag{83}$$

where $z(x)$, $-\infty < z < \infty$, is a differentiable function on R.

Without loss of generality, we replace ξ_1 and ξ_2 with the new variables x and α via Eq. (82). Then, Eq. (81) reduces to

$$\frac{\partial h}{\partial \alpha} = 0. \tag{84}$$

Then operator A_3 (76) is simply

$$A_3 = i\frac{\partial}{\partial \alpha}, \tag{85}$$

as expected, and the Casimir operator becomes, in the new parametrization,

$$C = -\frac{1}{(\dot{z})^2}\left[\frac{\partial^2}{\partial x^2} + \left(\frac{1}{h}\frac{\mathrm{d}h}{\mathrm{d}x} + \frac{\dot{z}}{z} - \frac{\ddot{z}}{\dot{z}}\right)\frac{\partial}{\partial x} - \left(\frac{\dot{z}}{z}\right)^2 \frac{\partial^2}{\partial \alpha^2} - \frac{1}{4h^2}\left(\frac{\mathrm{d}h}{\mathrm{d}x}\right)^2 + \frac{1}{2h}\left(\frac{\mathrm{d}^2 h}{\mathrm{d}x^2} - \frac{\ddot{z}}{\dot{z}}\frac{\mathrm{d}h}{\mathrm{d}x} + \frac{\dot{z}}{z}\frac{\mathrm{d}h}{\mathrm{d}x}\right)\right], \tag{86}$$

where $\dot{z} \equiv \mathrm{d}z/\mathrm{d}x$, $\ddot{z} \equiv \mathrm{d}^2 z/\mathrm{d}x^2$, and so on. In order to eliminate the term containing $\partial/\partial x$, we require

$$\frac{1}{h}\frac{\mathrm{d}h}{\mathrm{d}x} + \frac{\dot{z}}{z} - \frac{\ddot{z}}{\dot{z}} = 0. \tag{87}$$

The solution to this equation is given by

$$h = \chi\frac{\dot{z}}{z}, \tag{88}$$

where χ is a constant. Substituting Eq. (88) into formula (86), we get

$$C = -\frac{1}{(\dot{z})^2}\left[\frac{\partial^2}{\partial x^2} + \left(\frac{\dot{z}}{z}\right)^2\left(\frac{1}{4} - \frac{\partial^2}{\partial \alpha^2}\right) + \frac{1}{2}\frac{\dddot{z}}{\dot{z}} - \frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2\right]. \tag{89}$$

Let $\mathcal{H}_\tau$ be a one-dimensional subspace spanned by functions f_τ with fixed τ: the Casimir operator restricted to $\mathcal{H}_\tau$ becomes a differential operator in x alone; it turns out that

$$C_\nu = -\frac{1}{(\dot{z})^2}\left[\frac{\mathrm{d}^2}{\mathrm{d}x^2} + (1+\nu^2)\left(\frac{\dot{z}}{z}\right)^2 + \frac{1}{2}\frac{\dddot{z}}{\dot{z}} - \frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2\right], \tag{90}$$

where C_τ denotes the restriction of C to $\mathcal{H}_\tau$.

Let the quantum numbers τ^2 and ρ^2 be linear functions of energy, E. Without loss of generality, we can assume

$$\tau^2 + \tfrac{1}{4} = \alpha_1 E + \beta_1, \tag{91}$$

and

$$\rho^2 = \alpha_2 E + \beta_2. \tag{92}$$

Then, formula (90) becomes

$$C_\nu - \rho^2 = \frac{1}{(\dot{z})^2}\left[-\frac{\mathrm{d}^2}{\mathrm{d}x^2} - (ER(z) + \beta_2 z^2 + \beta_1)\left(\frac{\dot{z}}{z}\right)^2 - \frac{1}{2}\frac{\dddot{z}}{\dot{z}} + \frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2\right], \tag{93}$$

where now

$$R(z) = \alpha_2 z^2 + \alpha_1. \tag{94}$$

In order that relation (70) be satisfied, with $Q = 1/(\dot{z})^2$, we now impose

$$(\dot{z})^2 = \frac{z^2}{R(z)}. \tag{95}$$

If the above-presented condition holds, the operator within square brackets on the right-hand side of Eq. (93) can be written as $H - E$, where

$$H = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + V(z) = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} - \frac{1}{2}\frac{\dddot{z}}{\dot{z}} + \frac{3}{4}\left(\frac{\ddot{z}}{\dot{z}}\right)^2 - \frac{\beta_2 z^2 + \beta_1}{R}.$$

Hence, the ISO(1,1) related potentials V are given by

$$V = -\frac{\beta_2 z^2 + \beta_1}{R} + \frac{3\alpha_1}{2R^2} - \frac{5\alpha_1^2}{4R^3}. \tag{96}$$

In order to make the potential V vanish as $|x| \to \infty$ (i.e., as $|z| \to \infty$) we set $\beta_2 = 0$. Hence relation (92) reduces to

$$\rho^2 = \alpha_2 E. \tag{97}$$

A simple case comes about by choosing $\alpha_1 = 0$. In this case Eq. (95) reduces to

$$(\dot{z})^2 = 1/\alpha_2, \tag{98}$$

whose solution is given by

$$z = \begin{cases} (x-a)/\sqrt{\alpha_2}, & \text{for } x < 0 \\ (x+a)/\sqrt{\alpha_2}, & \text{for } x > 0, \end{cases} \tag{99}$$

where a, $0 < a$, is a constant of integration. According to (96) and (99) we obtain

$$V(x)=\begin{cases} -\dfrac{\frac{1}{4}+\tau^2}{(x-a)^2}, & \text{for } x<0 \\ -\dfrac{\frac{1}{4}+\tau^2}{(x+a)^2}, & \text{for } x>0. \end{cases} \tag{100}$$

Furthermore one can check that the potential (63) with $j=-1/2-i\tau$ goes over in the limit $\gamma_2 \to \infty$ into (100). Hence (see Eq. (34)) we can obtain the S-matrix for (100) by the limiting process $\rho \to \infty$ from (53) and (54) as mentioned in Sec. I.

It is worthwhile to point out that potential (100) was obtained in the supersymmetric approach[17] as a partner of the null potential. (In Ref. 31 a singular potential $V \sim 1/x^2$ has been studied on the line.) Finally, we note that the potentials related to $\mathrm{ISO}(2,1) \supset \mathrm{SO}(2,1)$ are also given by (96), but the left-hand side of (91) must be replaced by $-j(j+1)$, where $j=-1/2-i\tau$, for principal series representations of SO(2,1), while $j=0,1,2,\ldots$, for discrete series representations of SO(2,1).

Decompositions of unitary evolutions and entanglement dynamics of bipartite quantum systems

Domenico D'Alessandro[a] and Raffaele Romano[b]
Department of Mathematics, Iowa State University, Ames, Iowa 50011

(Received 10 March 2006; accepted 11 July 2006; published online 29 August 2006)

We describe a decomposition of the Lie group of unitary evolutions for a bipartite quantum system of arbitrary dimensions. The decomposition is based on a recursive procedure that systematically uses the Cartan classification of the symmetric spaces of the Lie group $SO(n)$. The resulting factorization of unitary evolutions clearly displays the local and entangling character of each factor. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2245205]

I. INTRODUCTION

Decompositions of a Lie group G are methods to factorize every element $X \in G$ as

$$X = X_1 X_2 \dots X_m, \tag{1.1}$$

where the factors $X_1, \dots, X_m$ belong to one dimensional subgroups. Decompositions of unitary evolutions in simpler terms are of interest in quantum control and information theory for at least three reasons. They allow us to simplify the task of controlling the evolution of a quantum system to a target into a sequence of simpler subtasks, consisting of control problems to more easily reachable targets (see, e.g., Refs. 1–3). They allow the analysis of several features of quantum dynamics such as entanglement generation, time optimality, and parameter identification (see, e.g., Refs. 4–7). They give methods to produce unitary evolutions in a laboratory by combining a sequence of readily reproducible evolutions. In particular, in quantum information theory, a decomposition can be seen as a method to generate a quantum logic operation from a sequence of elementary operations.[6,8]

In many cases, decompositions of the unitary group $U(n)$ correspond to vector space decompositions of the corresponding Lie algebra $\mathfrak{u}(n)$, and each element $H \in i\mathfrak{u}(n)$ represents the Hamiltonian of a possible evolution. In the analysis of multipartite quantum systems, it is useful to distinguish Hamiltonians acting on single subsystems, called *local Hamiltonians*, and Hamiltonians describing the coupling between two or more systems, called *interaction (or entangling) Hamiltonians*. In the unitary group, these Hamiltonians generate local and entangling evolutions, respectively. In particular, if one considers a multipartite system composed of N subsystems of dimensions $n_1, \dots, n_N$, the space of all possible Hamiltonians is given by $i\mathfrak{u}(n_1 n_2 \cdots n_N)$. Once we have an orthogonal basis in $i\mathfrak{u}(n_j)$, $j=1, \dots, N$, given by $H_{l_j}^j$, $l_j=1, \dots, n_j^2$, then a basis of $\mathfrak{u}(n_1 n_2 \cdots n_N)$ is given by

$$iH_{l_1}^1 \otimes H_{l_2}^2 \otimes \cdots \otimes H_{l_N}^N. \tag{1.2}$$

The subalgebra of local Hamiltonians is spanned by elements where all the factors in the tensor product are equal to the identity except one. They produce unitary evolutions of the factorized form $X_1 \otimes X_2 \otimes \cdots \otimes X_N$, which correspond to transformations on the single subsystems. In this spirit, the decomposition given in Ref. 6 recursively factorizes a unitary transformation on n qubits

[a]Electronic mail: daless@iastate.edu
[b]Electronic mail: rromano@iastate.edu

in local and entangling transformations, the latter one acting on two subsystems at a time only. In a recent paper,[9] a method was given to generate decompositions in the tensor product space for general multipartite quantum systems of arbitrary dimensions, starting from decompositions of evolutions on the single subsystems.

In the spirit of the last two works cited, we present in this paper a recursive procedure to decompose the unitary evolution of a bipartite system *of arbitrary dimensions* so that every evolution is factorized into simple terms, and it is clear what the entangling and local contributions of a single transformation are. The procedure we present applies recursively the Cartan decomposition of the Lie algebra $\mathfrak{so}(n)$ by keeping the tensor product basis representation of the Lie algebra $\mathfrak{u}(n)$. In this basis, at the end of the procedure, it is easy to analyze the local and entangling character of each factor.

The paper is organized as follows: in the next section we review some basic concepts and results on the Cartan classification of symmetric spaces and Cartan decompositions. We shall mention only the facts needed in the sequel of the paper. A detailed treatment can be found in Ref. 10. The decomposition procedure we describe consists of an initial step that reduces the problem to a decomposition of the orthogonal group and a recursive procedure, which allows us to decompose further the elements of the orthogonal group. These steps are described in Secs. III and IV, respectively. We give several remarks highlighting the local and entangling factors needed in the factorization. Section V is devoted to a discussion and a numerical example.

Notation: In the following we will use several times the definition of the elementary matrices E_{mn},

$$(E_{mn})_{rs} = \delta_{mr}\delta_{ns}, \tag{1.3}$$

and of their antisymmetric and symmetric superposition, respectively as

$$\Delta_{mn} := E_{mn} - E_{nm}, \quad \Omega_{mn} := E_{mn} + E_{nm}. \tag{1.4}$$

We denote by A^T the transposed of the matrix A. An $n \times m$ rectangular matrix is denoted by $A_{n\times m}$; the $n \times n$ identity matrix by $\mathbf{1}_n$. Finally, we call a *sign* matrix a matrix of the form $\mathrm{diag}(\pm 1, \pm 1, \ldots, \pm 1)$ with all the possible combinations of + and −.

II. BACKGROUND MATERIAL

In the following, we shall use (in a recursive manner) *Cartan decompositions* of the Lie algebras $\mathfrak{su}(n)$ and $\mathfrak{so}(n)$ as well as Cartan decompositions of direct products of (isomorphic copies of) these Lie algebras. A Cartan decomposition of a semisimple Lie algebra $\mathfrak{L}$ is a vector space decomposition

$$\mathfrak{L} = \mathfrak{k} \oplus \mathfrak{p}, \tag{2.1}$$

where $\mathfrak{k}$ is a subalgebra, namely

$$[\mathfrak{k},\mathfrak{k}] \subseteq \mathfrak{k}, \tag{2.2}$$

and the complement subspace $\mathfrak{p} = \mathfrak{k}^{\perp}$ is such that

$$[\mathfrak{p},\mathfrak{p}] \subseteq \mathfrak{k}, \quad [\mathfrak{p},\mathfrak{k}] \subseteq \mathfrak{p}. \tag{2.3}$$

Here the orthogonal complement $\perp$ is with respect to the *Killing form*. The Killing form on a Lie algebra $\mathfrak{L}$ is an inner product defined in terms of the adjoint representation of $\mathfrak{L}$. In particular, every $l \in \mathfrak{L}$ acts on the vector space $\mathfrak{L}$ according to the linear map ad_l, defined as

$$\mathrm{ad}_l(x) := [l,x]. \tag{2.4}$$

The Killing form *Kill* is a bilinear form defined as

$$\mathrm{Kill}(x,y) := \mathrm{Tr}(\mathrm{ad}_x \mathrm{ad}_y). \tag{2.5}$$

For the Lie algebras $su(n)$ and $so(n)$, which are the main Lie algebras considered in this work, the Killing form is proportional to the matrix inner product $\langle x,y\rangle := \mathrm{Tr}(xy^*)$.[10] Therefore, we shall refer to this inner product in the following any time we mention orthogonality relations.

To a Cartan decomposition of $\mathfrak{L}$ there corresponds a factorization of $e^{\mathfrak{L}}$, the connected Lie group associated to $\mathfrak{L}$, such that every element $X \in e^{\mathfrak{L}}$ can be written as

$$X = KP, \tag{2.6}$$

where K belongs to $e^{\mathfrak{k}}$, the connected Lie group corresponding to $\mathfrak{k}$, and P is the exponential of an element in $\mathfrak{p}$. The coset space $e^{\mathfrak{L}}/e^{\mathfrak{k}}$ is called a *symmetric space* of $e^{\mathfrak{L}}$. A maximal Abelian subalgebra of $\mathfrak{L}$ in $\mathfrak{p}$ is called a *Cartan subalgebra* associated to the decomposition, and it is denoted by $\mathfrak{a}$. One can show, under appropriate assumptions, that

$$\bigcup_{K \in e^{\mathfrak{k}}} K\mathfrak{a}K^{-1} = \mathfrak{p}, \tag{2.7}$$

so that the factorization (2.6) refines to

$$X = K_1 A K_2, \tag{2.8}$$

with $K_1, K_2 \in e^{\mathfrak{k}}$, and $A \in e^{\mathfrak{a}}$. The dimension of the Cartan subalgebra $\mathfrak{a}$ is called the *rank* of the decomposition (or of the associated symmetric space).

Cartan has classified all the symmetric spaces of the classical Lie groups, i.e., the Lie groups $SU(n)$, $Sp(n)$, and $SO(n)$, and has shown that, up to conjugacy, the corresponding decompositions fall in one of few classes that he has described. [A conjugacy on $\mathfrak{L}$ is a map $m:\mathfrak{L}\to\mathfrak{L}$ such that $m(L)=MLM^{-1}$ for some $M \in e^{\mathfrak{L}}$.] In particular, for $\mathfrak{L}=\mathfrak{su}(n)$, there are three types of decompositions labeled by AI, AII, AIII. In the following, we shall use only decompositions of the type AI, given by

$$\mathfrak{k} = \mathfrak{so}(n), \quad \mathfrak{p} = \mathfrak{so}(n)^{\perp}, \tag{2.9}$$

with $\mathfrak{so}(n)^{\perp}$ the subspace of $\mathfrak{su}(n)$ spanned by purely imaginary matrices. The rank of this decomposition is $n-1$. Decompositions of the type AII and AIII will not be considered here.

We consider now the Lie algebra $\mathfrak{L}=\mathfrak{so}(n)$. If $n=1$, this algebra contains only the null matrix $\mathbf{0}$. For $n>2$, when n is odd there is only one type of Cartan decomposition, denoted by BDI. Fixing two positive integers r and q such that $r \geqslant q \geqslant 1$ and $r+q=n$, the matrices $k \in \mathfrak{k}$ have the form

$$k = \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}, \tag{2.10}$$

with $A \in \mathfrak{so}(r)$ and $B \in \mathfrak{so}(q)$. Matrices $p \in \mathfrak{p}$ have the form

$$p = \begin{pmatrix} 0 & C \\ -C^T & 0 \end{pmatrix}, \tag{2.11}$$

for a general $r \times q$ matrix C. The rank of this decomposition is q. In this paper, we will not consider other decompositions.

III. DECOMPOSITION OF UNITARY EVOLUTIONS IN $U(d_1d_2)$; INITIAL STEP

Consider two interacting quantum systems $\mathcal{S}_1$ and $\mathcal{S}_2$ whose associated Hilbert spaces have dimensions d_1 and d_2, respectively. According to the procedure described in Ref. 9, it is possible to obtain a decomposition for $\mathfrak{su}(d_1d_2)$ from decompositions of type AI of the Lie algebras associated to each subsystem, i.e., $\mathfrak{su}(d_1)$ and $\mathfrak{su}(d_2)$. In the following instead of decompositions of $su(n)$ we shall refer to decompositions of $u(n)$. To a decomposition of $su(n)$,

$$su(n) = \mathfrak{k} \oplus \mathfrak{p}, \tag{3.1}$$

with $\mathfrak{k}$ and $\mathfrak{p}$ satisfying the conditions (2.2) and (2.3), there corresponds a decomposition of $u(n)$,

$$u(n) = \mathfrak{k} \oplus \mathfrak{p}', \tag{3.2}$$

where $\mathfrak{p}'$ is defined by $\mathfrak{p}' := \mathfrak{p} \oplus \text{span}\{i\mathbf{1}\}$. $\mathfrak{k}$ and $\mathfrak{p}'$ still satisfy the relations (2.2) and (2.3), with $\mathfrak{p}$ replaced by $\mathfrak{p}'$. What we have said in the previous section, in particular for the decomposition of the associated Lie group, can be repeated by including $\text{span}\{i\mathbf{1}\}$ in the maximal Abelian subalgebra. With some abuse of terminology, we shall refer to this decomposition also as a *Cartan decomposition of* $u(n)$. We write

$$\mathfrak{u}(d_1) = \mathfrak{so}(d_1) \oplus \mathfrak{so}(d_1)^{\perp}, \quad \mathfrak{u}(d_2) = \mathfrak{so}(d_2) \oplus \mathfrak{so}(d_2)^{\perp}. \tag{3.3}$$

Let σ^j, $j=1,2$, be a generic element of an orthogonal basis of $i\mathfrak{so}(d_j)$, and S^j, $j=1,2$, a generic element of an orthogonal basis of $i\mathfrak{so}(d_j)^{\perp}$. Then the subalgebra of $\mathfrak{u}(d_1 d_2)$, defined by

$$\mathfrak{k} := \text{span}\{i\sigma^1 \otimes S^2, iS^1 \otimes \sigma^2\}, \tag{3.4}$$

along with its orthogonal complement in $\mathfrak{u}(d_1 d_2)$,

$$\mathfrak{p} := \text{span}\{i\sigma^1 \otimes \sigma^2, iS^1 \otimes S^2\}, \tag{3.5}$$

define a Cartan decomposition of $\mathfrak{u}(d_1 d_2)$ as

$$\mathfrak{u}(d_1 d_2) = \mathfrak{k} \oplus \mathfrak{p}. \tag{3.6}$$

This decomposition is of type AI[9] as $\mathfrak{k}$ is conjugate to $\mathfrak{so}(d_1 d_2)$ and $\mathfrak{p}$ to $\mathfrak{so}(d_1 d_2)^{\perp}$. The rank of this decomposition is $d_1 d_2$. A basis of the maximal Abelian subalgebra $\mathfrak{a} \subseteq \mathfrak{p}$ is given by tensor products of elements of the orthogonal basis of the maximal Abelian subalgebras associated to the single subsystems, which are of dimensions d_1 and d_2, respectively. Denoting by D^1 the diagonal elements of the type S^1, and by D^2 those of the type S^2, $\mathfrak{a}$ is given by

$$\mathfrak{a} := \text{span}\{iD^1 \otimes D^2\}. \tag{3.7}$$

The associated Cartan factorization of $X \in U(d_1 d_2)$ is

$$X = K_1 A K_2, \tag{3.8}$$

according to the notation of the previous section.

Remark III.1: Only in the simplest case of the decomposition of $\mathfrak{su}(4)$ (i.e., $d_1=2$ and $d_2=2$), studied, for example, in Ref. 7, the decomposition (3.8) is a decomposition in local and nonlocal transformations. The local transformations are products of exponentials of matrices of the form $iH \otimes \mathbf{1}$ or $\mathbf{1} \otimes iH$, where $\mathbf{1}$ is the identity matrix of appropriate dimensions and H is a generic matrix in $i\mathfrak{u}(d_1)$ or $i\mathfrak{u}(d_2)$. Both local and nonlocal transformations are possibly present in the K_1 and K_2 factors as well as in the A factor. However, obtaining a decomposition in terms of tensor product matrices will allow us to identify exactly where the local and nonlocal transformations are present in the final transformation.

Remark III.2: We notice that, in general, only one nonlocal transformation, along with the set of the local transformations, is sufficient to obtain all the possible values for A in (3.8). To see this, notice that the factor A is the finite product of exponentials of elements of the form $i\alpha_{jk} E_{jj} \otimes E_{kk}$, with $j=1,\ldots,d_1$, $k=1,\ldots,d_2$, and α_{jk} real numbers. Since, for every l, E_{ll} is unitarily equivalent to E_{11}, the Hamiltonian $H=E_{11} \otimes E_{11}$, along with local transformations, is sufficient to generate any element of the form A. Notice that an alternative (universal) *nonlocal Hamiltonian* is given by an Ising interaction between two spins, which in our notation reads as $(E_{11}-E_{d_1 d_1}) \otimes (E_{11}-E_{d_2 d_2})$.

We now turn our attention to decomposing the elements K_1 and K_2 in (3.8). This will be obtained through a recursive procedure via iterate decompositions of $\mathfrak{so}(n)$.

IV. DECOMPOSITION OF UNITARY EVOLUTIONS IN $U(d_1d_2)$; RECURSIVE PROCEDURE

The Lie algebra $\mathfrak{k}$ defined in (3.4) is conjugate to $\mathfrak{so}(d_1d_2)$. We rewrite its definition below:

$$\mathfrak{k} := \mathrm{span}\{i\sigma^1 \otimes S^2, iS^1 \otimes \sigma^2\},$$

with σ^j, $j=1,2$, belonging to an orthogonal basis of $i\mathfrak{so}(d_j)$ and S^j, $j=1,2$, belonging to an orthogonal basis of $i\mathfrak{so}(d_j)^{\perp}$.

A special case arises when $d_1=d_2=1$, and only the matrix $\mathbf{0}$ belongs to the corresponding Lie algebra. This case is not of physical interest, as it would imply a one-dimensional quantum system. However, it may arise as the final step of the recursive procedure we are going to present. A special, nonphysical case is also $d_1=2$ and $d_2=1$, or vice versa. In this case, the Lie algebra $\mathfrak{k}$ contains only one element. Another special case is given by $d_1=d_2=2$. In this case, consider the Pauli matrices,

$$\sigma_x := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_y := \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_z := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{4.1}$$

and the 2×2 identity matrix $\mathbf{1}$. Then $\mathfrak{k}=\mathfrak{so}(4)$ is the direct sum of two commuting subalgebras, $\mathfrak{s}_1$ and $\mathfrak{s}_2$, each isomorphic to $\mathfrak{so}(3)$, and given by

$$\begin{aligned} \mathfrak{s}_1 &:= \mathrm{span}\{i\sigma_y \otimes \mathbf{1}, i\sigma_x \otimes \sigma_y, i\sigma_z \otimes \sigma_y\}, \\ \mathfrak{s}_2 &:= \mathrm{span}\{i\mathbf{1} \otimes \sigma_y, i\sigma_y \otimes \sigma_x, i\sigma_y \otimes \sigma_z\}. \end{aligned} \tag{4.2}$$

Therefore K_1 (and analogously K_2) in (3.8) can be written as the product

$$K_1 = F_1F_2 = F_2F_1, \tag{4.3}$$

with F_1 and F_2 in the Lie group corresponding to $\mathfrak{s}_1$ and $\mathfrak{s}_2$, respectively. A Cartan decomposition can be performed on $\mathfrak{s}_1$ (and analogously on $\mathfrak{s}_2$), which is an Euler decomposition as $\mathfrak{s}_1$ is isomorphic to $\mathfrak{so}(3)$, and allows us to express F_1 as

$$F_1 = L_1NL_2, \tag{4.4}$$

with $L_j=e^{\alpha_j i\sigma_y\otimes\mathbf{1}}$, $j=1,2$, for real parameters α_j, and $N=e^{\beta i\sigma_x\otimes\sigma_y}$ for a real parameter β. Notice that L_1 and L_2 are local transformations while N is nonlocal. The same can be done for F_2, moreover, the nonlocal transformation for F_2 can be obtained using a local similarity transformation from the one for F_1, or vice versa, so that for F_1 and F_2 we need only one nonlocal Hamiltonian.

Consider now the case where at least one between d_1 and d_2 is greater than 2. As it was done for the initial step in the previous section, we look for decompositions concerning the single subsystems to induce a decomposition on the total bipartite system. The elements of the type $i\sigma^1$ and $i\sigma^2$ are real, skew-symmetric, square matrices of dimensions d_1 and d_2, respectively. Let $d_1>2$ without loss of generality. On the Lie algebra of $d_1\times d_1$, skew-symmetric matrices (that is, matrices of the type σ^1), we perform a decomposition of the type BDI (see the previous section) by selecting two positive integers $r_1\geqslant q_1\geqslant 1$ so that $r_1+q_1=d_1$. In the resulting Cartan decomposition, $\mathfrak{so}(d_1)=\mathfrak{k}\oplus\mathfrak{p}$, the Lie algebra $\mathfrak{k}$ is spanned by block diagonal skew-symmetric matrices with the upper block of dimension r_1 and the lower block of dimension q_1. We denote this type of matrices by $i\sigma^{1,D}$ (where D stands for "diagonal"). The skew-symmetric matrices in the complement $\mathfrak{p}$ will be denoted by $i\sigma^{1,A}$ (where A stands for "antidiagonal"). We as well separate matrices of the type S^1 into block diagonal and block antidiagonal and denote them by $iS^{1,D}$ and $iS^{1,A}$, respectively. Analogously, we define a decomposition of type BDI on $\mathfrak{so}(d_2)$ introducing two positive integers $r_2\geqslant q_2\geqslant 1$, with $r_2+q_2=d_2$ and matrices of the type $i\sigma^{2,D}$, $i\sigma^{2,A}$, $iS^{2,D}$ and $iS^{2,A}$. In the special case where $d_2=2$, we can only choose $r_2=q_2=1$ and we do not, in fact, obtain a decomposition of $\mathfrak{so}(d_2)$ of the type BDI. However, we still formally decompose matrices of the

form σ^2 and S^2 in (block) diagonal and (block) antidiagonal components and notice that, in this case, the only matrix of the type $i\sigma^{2,D}$ and $iS^{2,A}$ is the 2×2 zero matrix.

These decompositions on the two subsystems induce a decomposition on the overall bipartite system. More precisely we decompose $\mathfrak{k}$ in (3.4) as follows:

$$\mathfrak{k} := \mathfrak{k}' \oplus \mathfrak{p}', \tag{4.5}$$

with

$$\begin{aligned}\mathfrak{k}' &= \mathrm{span}\{i\sigma^{1,D}\otimes S^{2,D}, iS^{1,D}\otimes\sigma^{2,D}, i\sigma^{1,A}\otimes S^{2,A}, iS^{1,A}\otimes\sigma^{2,A}\},\\ \mathfrak{p}' &= \mathrm{span}\{i\sigma^{1,A}\otimes S^{2,D}, i\sigma^{1,D}\otimes S^{2,A}, iS^{1,D}\otimes\sigma^{2,A}, iS^{1,A}\otimes\sigma^{2,D}\}.\end{aligned} \tag{4.6}$$

The following Theorem summarizes the features of this decomposition. It also gives, in its proof, a coordinate transformation to write the elements of the subalgebra $\mathfrak{k}'$ and its complement $\mathfrak{p}'$ in the standard form.

Theorem 1: *The decomposition of* $\mathfrak{k}$ *defined in* (4.5), (4.6) *is a Cartan decomposition*, *i.e.*,

$$[\mathfrak{k}',\mathfrak{k}']\subseteq\mathfrak{k}', \quad [\mathfrak{k}',\mathfrak{p}']\subseteq\mathfrak{p}', \quad [\mathfrak{p}',\mathfrak{p}']\subseteq\mathfrak{k}'.$$

As a decomposition of $\mathfrak{so}(d_1d_2)$, *it is a Cartan decomposition of type BDI with indices r and q satisfying* $r\geqslant q\geqslant 1$, $r+q=d_1d_2$, *and with*

$$r = r_1r_2 + q_1q_2, \quad q = r_1q_2 + q_1r_2. \tag{4.7}$$

Accordingly, *the dimension of the associated Cartan subalgebra* $\mathfrak{a}'\subseteq\mathfrak{p}'$ *is* $q=r_1q_2+q_1r_2$.

Proof: We explicitly exhibit a conjugacy that transforms elements of $\mathfrak{k}'$ into the form (2.10) and elements of $\mathfrak{p}'$ into the form (2.11). In particular, notice that the matrices $i\sigma^{1,D}\otimes S^{2,D}$, $iS^{1,D}\otimes\sigma^{2,D}$ have the form

$$k_1 := \begin{pmatrix} A_{r_1\times r_1}\otimes C_{r_2\times r_2} & 0 & 0 & 0\\ 0 & A_{r_1\times r_1}\otimes D_{q_2\times q_2} & 0 & 0\\ 0 & 0 & B_{q_1\times q_1}\otimes C_{r_2\times r_2} & 0\\ 0 & 0 & 0 & B_{q_1\times q_1}\otimes D_{q_2\times q_2}\end{pmatrix}, \tag{4.8}$$

while the matrices $i\sigma^{1,A}\otimes S^{2,A}$ and $iS^{1,A}\otimes\sigma^{2,A}$ are of the form

$$k_2 := \begin{pmatrix} 0 & 0 & 0 & F_{r_1\times q_1}\otimes G_{r_2\times q_2}\\ 0 & 0 & \pm F_{r_1\times q_1}\otimes G^T_{q_2\times r_2} & 0\\ 0 & \mp F^T_{r_1\times q_1}\otimes G_{r_2\times q_2} & 0 & 0\\ -F^T_{q_1\times r_1}\otimes G^T_{q_2\times r_2} & 0 & 0 & 0\end{pmatrix}. \tag{4.9}$$

A straightforward calculation shows that, defining

$$R := \begin{pmatrix} \mathbf{1}_{r_1r_2} & 0 & 0 & 0\\ 0 & 0 & 0 & \mathbf{1}_{q_1q_2}\\ 0 & \mathbf{1}_{r_1q_2} & 0 & 0\\ 0 & 0 & \mathbf{1}_{r_2q_1} & 0\end{pmatrix}, \tag{4.10}$$

the matrices

$$\tilde{k}_1 := Rk_1R^T, \quad \tilde{k}_2 := Rk_2R^T, \tag{4.11}$$

have the form given in (2.10), where the upper block has dimension $r=r_1r_2+q_1q_2$ and the lower block has dimension $q=r_1q_2+q_1r_2$. Analogously one shows that the conjugacy defined in (4.10) transforms elements in $\mathfrak{p}'$ into elements of the form p in (2.11). □

In view of the decomposition (4.5), any element K_1 (and analogously for K_2) in (3.8) can be written as

$$K_1 = K_1' A' K_2', \tag{4.12}$$

where K_1' and K_2' belong to the Lie group associated with the Lie algebra $\mathfrak{k}'$, conjugate to $\mathfrak{so}(r) \oplus \mathfrak{so}(q)$, and are to be further factorized. The matrix A' belongs to the Abelian Lie subgroup associated to the maximal Abelian subalgebra $\mathfrak{a}' \in \mathfrak{p}'$. In the following proposition we find an orthogonal basis for such a Cartan subalgebra expressing it in terms of tensor products. [An alternative procedure is to transform the Lie algebra $\mathfrak{k}'$ according to the change of coordinates (4.10) and to find the Cartan subalgebra in the standard basis.]

Proposition IV.1: The $(r_1+q_1)q_2$ matrices

$$N_{jk} := E_{jj} \otimes \Delta_{k,r_2+k}, \quad j = 1, \ldots, r_1 + q_1, \quad k = 1, \ldots, q_2, \tag{4.13}$$

along with the $(r_2-q_2)q_1$ matrices

$$M_{fl} := \Delta_{f,r_1+f} \otimes E_{ll}, \quad l = q_2 + 1, \ldots, r_2, \quad f = 1, \ldots, q_1, \tag{4.14}$$

span a Cartan subalgebra $\mathfrak{a}' \in \mathfrak{p}'$.

Proof: The dimension of the vector space spanned by the matrices in (4.13) and (4.14) is, in fact, $(r_1+q_1)q_2+(r_2-q_2)q_1=r_1q_2+q_1r_2$. Therefore, we only have to verify that matrices of the type (4.13) and (4.14) commute with each other. The commutator between two matrices of the type (4.13) always vanishes. Analogously, matrices of the type (4.14) commute with each other. The Lie bracket of matrices of the type (4.13) and (4.14) vanishes too, since the products of matrices Δ_{k,r_2+k} and E_{ll} in the second factors are always zero.

Remark IV.2: It follows from Proposition IV.1 that the element A' in (4.12) is the exponential of a linear combination of matrices (4.13) and (4.14) or (equivalently) the product of exponentials of matrices proportional to these. The resulting unitary transformations may be entangling or local. However, since all the matrices of the form E_{jj} are unitarily equivalent to each other and the matrices of the type Δ_{kl} are also unitarily equivalent to each other, only one (entangling) Hamiltonian of the type (4.13), one of the type (4.14) along with local operations are sufficient (and necessary) to generate all the possible factors A' in (4.12).

Remark IV.3: A further reduction of the nonlocal Hamiltonians to be used is obtained by noticing that all the transformations in Remark III.2 and in Proposition IV.1 can be obtained with only one Ising Hamiltonian and local transformations. Therefore only one nonlocal Hamiltonian is needed to implement all of these transformations.

We now further factorize the elements K_1' and K_2' in (4.12) using, once again, a Cartan decomposition of the Lie algebra $\mathfrak{k}'$ isomorphic to $\mathfrak{so}(r) \oplus \mathfrak{so}(q)$, with r and q defined in (4.7). In particular, we decompose $\mathfrak{k}'$ as follows:

$$\mathfrak{k}' = \mathfrak{k}'' \oplus \mathfrak{p}'', \tag{4.15}$$

with

$$\begin{aligned} \mathfrak{k}'' &= \mathrm{span}\{i\sigma^{1,D} \oplus S^{2,D}, S^{1,D} \oplus i\sigma^{2,D}\}, \\ \mathfrak{p}'' &= \mathrm{span}\{i\sigma^{1,A} \otimes S^{2,A}, S^{1,A} \otimes i\sigma^{2,A}\}. \end{aligned} \tag{4.16}$$

The matrices in $\mathfrak{k}''$ are block diagonal matrices and $\mathfrak{k}''$ is

$$\mathfrak{k}'' = \mathfrak{so}(r_1 r_2) \oplus \mathfrak{so}(r_1 q_2) \oplus \mathfrak{so}(q_1 r_2) \oplus \mathfrak{so}(q_1 q_2), \tag{4.17}$$

where each term refers to a block on the diagonal. For example, the first block corresponding to $\mathfrak{so}(r_1 r_2)$ contains matrices obtained as tensor products $i\sigma^{1,D} \otimes S^{2,D}$ or $S^{1,D} \otimes \sigma^{2,D}$, where all matrices involved have the second block equal to zero. This corresponds to two decompositions of the type BDI: one on $\mathfrak{so}(r)$ and the other on $\mathfrak{so}(q)$. The Cartan subalgebra in $\mathfrak{p}''$ is the direct sum of the two Cartan subalgebras of the two decompositions. It has dimension $q_1 q_2 + \min\{r_1 q_2, q_1 r_2\}$. The following proposition explains how to find a basis of this Cartan subalgebra as tensor product matrices. [Alternatively, one can construct a basis for this Cartan subalgebra working in the standard representation using the conjugacy given in (4.10).]

Proposition IV.4: A Cartan subalgebra of the decomposition (4.15), (4.16) is spanned by the $q_1 q_2$ matrices,

$$N_{jm,ln} := \begin{pmatrix} 0 & E_{jl} \\ -E_{jl}^T & 0 \end{pmatrix} \otimes \begin{pmatrix} 0 & E_{mn} \\ E_{mn}^T & 0 \end{pmatrix} + \begin{pmatrix} 0 & E_{jl} \\ E_{jl}^T & 0 \end{pmatrix} \otimes \begin{pmatrix} 0 & E_{mn} \\ -E_{mn}^T & 0, \end{pmatrix} \tag{4.18}$$

with $1 \leqslant j \leqslant r_1$, $1 \leqslant l \leqslant q_1$ and $1 \leqslant m \leqslant r_2$, $1 \leqslant n \leqslant q_2$ satisfying

$$(j-1) r_2 + m = s, \quad (l-1) q_2 + n = s, \tag{4.19}$$

with $s = 1, \ldots, q_1 q_2$, along with matrices

$$M_{jm,ln} := \begin{pmatrix} 0 & E_{jl} \\ -E_{jl}^T & 0 \end{pmatrix} \otimes \begin{pmatrix} 0 & E_{mn} \\ E_{mn}^T & 0 \end{pmatrix} - \begin{pmatrix} 0 & E_{jl} \\ E_{jl}^T & 0 \end{pmatrix} \otimes \begin{pmatrix} 0 & E_{mn} \\ -E_{mn}^T & 0 \end{pmatrix}, \tag{4.20}$$

with $1 \leqslant j \leqslant r_1$, $1 \leqslant l \leqslant q_1$ and $1 \leqslant m \leqslant r_2$, $1 \leqslant n \leqslant q_2$ satisfying

$$(j-1) q_2 + n = s, \quad (l-1) r_2 + m = s, \tag{4.21}$$

with $s = 1, \ldots, \min\{r_1 q_2, q_1 r_2\}$.

Remark IV.5: For all s, there is a unique pair (l,n) so that the second relation in (4.19) is verified. There is some freedom in choosing the pairs (j,m) satisfying the first relation in (4.19). However, for every value of s, and therefore of l and n, one is allowed to choose a *unique* pair (j,m). The notation in (4.20) and (4.21) has an analogous meaning.

Proof: Matrices of the form (4.18) commute with matrices of the form (4.20), since these matrices form Cartan subalgebras associated to decompositions of $\mathfrak{so}(r)$ and $\mathfrak{so}(q)$, respectively. To show that matrices of type (4.18) commute, one verifies that the commutators of two matrices corresponding to indices $(j_1 m_1, l_1 n_1)$ and $(j_2 m_2, l_2 n_2)$ vanish. In fact, all the blocks of such matrices are zero except for the $1,1$ and $2,2$ blocks, which, from a direct calculation, turn out to be equal to

$$4(E_{j_2 j_1} \delta_{l_1 l_2} \otimes E_{m_2 m_1} \delta_{n_1 n_2} - E_{j_1 j_2} \delta_{l_1 l_2} \otimes E_{m_1 m_2} \delta_{n_1 n_2}), \tag{4.22}$$

and

$$4(E_{l_2 l_1} \delta_{j_1 j_2} \otimes E_{n_2 n_1} \delta_{m_1 m_2} - E_{l_1 l_2} \delta_{j_1 j_2} \otimes E_{n_1 n_2} \delta_{m_1 m_2}), \tag{4.23}$$

respectively. However these are also zero if $n_1 \neq n_2$ and/or $l_1 \neq l_2$ as well as in the case $l_1 = l_2$, $n_1 = n_2$ (and therefore $j_1 = j_2$, $m_1 = m_2$; see Remark IV.5). A perfectly analogous argument holds in the case of commutators of matrices of the form (4.20). □

Remark IV.6: Notice that all the Hamiltonians (4.18) are locally unitarily equivalent to each other. The same is true for the Hamiltonians (4.20). Therefore only two more entangling Hamiltonians are needed.

At this point we are left with the Lie algebra $\mathfrak{so}(p_1 p_1) \oplus \mathfrak{so}(q_1 q_2) \oplus \mathfrak{so}(p_1 q_2) \oplus \mathfrak{so}(p_2 q_1)$. The construction proceeds recursively by decomposing each one of the four component Lie algebras

and so on, until one finds one of the Lie algebras $\mathfrak{so}(1)$ (which we define as the element zero), $\mathfrak{so}(2)$ (which consists of a single element), $\mathfrak{so}(3)$, or $\mathfrak{so}(4)$ (which are treated as it was explained at the beginning of the procedure).

V. DISCUSSION AND AN EXAMPLE

In order to illustrate the Lie group decomposition described in the previous sections, we consider the *generalized SWAP* operator X_{sw} acting on three qubits and rotating their states in a cyclic fashion. Its action is defined in the tensor product basis as

$$X_{\mathrm{sw}}:|i\rangle_1 \otimes |j\rangle_2 \otimes |k\rangle_3 \rightarrow |k\rangle_1 \otimes |i\rangle_2 \otimes |j\rangle_3, \tag{5.1}$$

where $i,j,k=0,1$ and $\{|0\rangle,|1\rangle\}_{1,2,3}$ are orthonormal bases for the Hilbert spaces of the three systems.

This operator is relevant in quantum information and computation since it enables us to switch the quantum states of different systems. For example, assume that one is interested in the state of the third system, but only the first system is accessible and can be controlled; then the application of the generalized SWAP operator will enable to transfer the state of the third system to the first system. As local operations alone clearly cannot implement the generalized SWAP, this has to involve some degree of entanglement among the various subsystems. We consider an hypothetical situation where it is possible to create an interaction between the first qubit and the other two as a whole although it is difficult to create interactions with the single qubits 2 and 3. This justifies to consider the total Hilbert space as the tensor product of a two-dimensional subspace with a four-dimensional one (that is, $d_1=2$ and $d_2=4$). Therefore $X_{\mathrm{sw}} \in U(8)$ will be decomposed accordingly. (We believe that extensions of the procedure presented here to multipartite systems are possible at the price of an increased notational complexity.)

In the specified basis, with standard ordering, the matrix representation of this operator is given by

$$X_{\mathrm{sw}} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{5.2}$$

This transformation belongs to $SO(8)$, therefore the first step of the decomposition of $U(8)$ is trivial: $K_1=X_{sw}$ and $A=K_2=\mathbf{1}$.

For the first step of the recursive part of the procedure, we choose $r_1=q_1=1$ and $r_2=q_2=2$. We find it convenient to work in the basis of the Hilbert space such that $\mathfrak{k}'=\mathfrak{so}(2)\oplus\mathfrak{so}(4)$, obtained by performing the change of basis $R|ijk\rangle \rightarrow |ijk\rangle'$, with R given in (4.10), which, in this particular case ($r_1=q_1=1$, $r_2=q_2=2$), takes the form

$$R = \begin{pmatrix} \mathbf{1}_2 & 0 & 0 & 0 \\ 0 & 0 & 0 & \mathbf{1}_2 \\ 0 & \mathbf{1}_2 & 0 & 0 \\ 0 & 0 & \mathbf{1}_2 & 0 \end{pmatrix}. \tag{5.3}$$

In these coordinates, the SWAP operator is written as $\tilde{X}_{\mathrm{sw}}=RX_{\mathrm{sw}}R^T$, that is

$$\widetilde{X}_{\mathrm{sw}} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \end{pmatrix}. \tag{5.4}$$

The elements of the Cartan subalgebra $\mathfrak{a}'$ (defined in Proposition IV.1), which in this case are only of the form (4.13), are transformed by R into elements of the form

$$\widetilde{a}' = \begin{pmatrix} 0 & D \\ -D & 0 \end{pmatrix}.$$

The computational problem is to find two 4×4 diagonal matrices, D_1 and D_2, with

$$\widetilde{A}' = e^{\widetilde{a}'} = \begin{pmatrix} D_1 & D_2 \\ -D_2 & D_1 \end{pmatrix},$$

$\widetilde{A}' \in SO(8)$, and matrices $K_{ij} \in SO(4)$, $i,j=1,2$, such that

$$\widetilde{K}_1' = \begin{pmatrix} K_{11} & 0 \\ 0 & K_{12} \end{pmatrix}, \quad \widetilde{K}_2' = \begin{pmatrix} K_{21} & 0 \\ 0 & K_{22} \end{pmatrix} \tag{5.5}$$

and $\widetilde{X}_{\mathrm{sw}} = \widetilde{K}_1' \widetilde{A}' \widetilde{K}_2'$. To perform this task we propose an algorithm that uses ideas similar to the ones for other Cartan decompositions (cf., e.g., Ref. 5 and references therein). We illustrate this algorithm for the dimensions of our problem but generalizations to other dimensions are obvious. Let us write $\widetilde{X}_{\mathrm{sw}}$ with 4×4 blocks $\widetilde{X}_{ij}$, $i,j=1,2$, as

$$\widetilde{X}_{\mathrm{sw}} = \begin{pmatrix} \widetilde{X}_{11} & \widetilde{X}_{12} \\ \widetilde{X}_{21} & \widetilde{X}_{22} \end{pmatrix}. \tag{5.6}$$

Equation (5.5) is equivalent to the four matrix equations:

$$\widetilde{X}_{11} = K_{11} D_1 K_{21}, \tag{5.7}$$

$$\widetilde{X}_{12} = K_{11} D_2 K_{22}, \tag{5.8}$$

$$\widetilde{X}_{21} = -K_{12} D_2 K_{21}, \tag{5.9}$$

$$\widetilde{X}_{22} = K_{12} D_1 K_{22}. \tag{5.10}$$

From the first one, we obtain

$$\widetilde{X}_{11} \widetilde{X}_{11}^T K_{11} = K_{11} D_1^2, \tag{5.11}$$

which is an eigenvalue equation as D_1^2 is diagonal. In the generic case, when all the eigenvalues of $\widetilde{X}_{11}\widetilde{X}_{11}^T$ are different, Eq. (5.11) determines K_{11} and D_1 up to the right product by a sign matrix [and the fact that $\det(K_{11})=1$]. Moreover, D_1 gives D_2 up to a sign matrix from the requirement that $D_1^2 + D_2^2 = \mathbf{1}_4$. Using K_{11} and D_2 in (5.8), we obtain K_{22} up to a sign matrix. Plugging K_{22} in (5.10),

we get K_{12} up to a sign matrix and from (5.9) we find K_{21}. Finally, we adjust the sign matrices to make (5.7)–(5.10) consistently verified. In the case where $\tilde{X}_{11}\tilde{X}_{11}^T$ has multiple eigenvalues, there is more freedom in the choice of K_{11} at the initial step, but then one proceeds in the same way and determines the other matrices up to some degree of freedom. At the end of the procedure, these degrees of freedom are exploited to make (5.7)–(5.10) jointly satisfied.

Using this procedure, we have found, for our example,

$$K_{11}=\begin{pmatrix}1&0&0&0\\0&0&1&0\\0&1&0&0\\0&0&0&-1\end{pmatrix},\quad K_{12}=-\begin{pmatrix}0&0&0&1\\0&0&1&0\\0&1&0&0\\1&0&0&0\end{pmatrix},$$

$$K_{21}=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix},\quad K_{22}=\begin{pmatrix}0&-1&0&0\\0&0&0&1\\1&0&0&0\\0&0&1&0\end{pmatrix},\tag{5.12}$$

$$D_1=\begin{pmatrix}1&0&0&0\\0&0&0&0\\0&0&0&0\\0&0&0&-1\end{pmatrix},\quad D_2=\begin{pmatrix}0&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&0\end{pmatrix}.$$

We can repeat the same procedure as above to further factorize K_{11}, K_{12}, K_{21}, K_{22}, and to obtain $\tilde{K}_1'=\tilde{K}_1''\tilde{A}_1''\tilde{K}_2''$ and $\tilde{K}_2'=\tilde{K}_3''\tilde{A}_2''\tilde{K}_4''$. We finally get the decomposition of $\tilde{X}_{\mathrm{sw}}$,

$$\tilde{X}_{\mathrm{sw}}=\tilde{K}_1''\tilde{A}_1''\tilde{K}_2''\tilde{A}'\tilde{K}_3''\tilde{A}_2''\tilde{K}_4'',\tag{5.13}$$

where

$$\tilde{A}_1''=\mathrm{diag}\left\{\begin{pmatrix}1&0&0&0\\0&0&0&1\\0&0&1&0\\0&-1&0&0\end{pmatrix},\begin{pmatrix}0&0&-1&0\\0&0&0&1\\1&0&0&0\\0&-1&0&0\end{pmatrix}\right\},$$

$$\tilde{A}_2''=\mathrm{diag}\left\{\mathbf{1}_4,\begin{pmatrix}1&0&0&0\\0&0&0&1\\0&0&1&0\\0&-1&0&0\end{pmatrix}\right\},$$

$$\begin{aligned}\tilde{K}_1''&=\mathrm{diag}\left\{\mathbf{1}_2,\begin{pmatrix}0&-1\\1&0\end{pmatrix},\begin{pmatrix}0&-1\\1&0\end{pmatrix},\begin{pmatrix}0&1\\-1&0\end{pmatrix}\right\},\\ \tilde{K}_2''&=\mathrm{diag}\left\{\mathbf{1}_2,\begin{pmatrix}0&-1\\1&0\end{pmatrix},\mathbf{1}_2,\mathbf{1}_2\right\},\\ \tilde{K}_3''&=\mathrm{diag}\left\{\mathbf{1}_2,\mathbf{1}_2,\mathbf{1}_2,\begin{pmatrix}0&-1\\1&0\end{pmatrix}\right\},\end{aligned}\tag{5.14}$$

$$\tilde{K}_4'' = \mathrm{diag}\left\{\mathbf{1}_2, \mathbf{1}_2, \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \mathbf{1}_2\right\}.$$

We now use the transformation R in (5.3) to write X_{sw} in the original coordinates as

$$X_{\mathrm{sw}} = K_1'' A_1'' K_2'' A' K_3'' A_2'' K_4'', \tag{5.15}$$

with $A' = R^T \tilde{A}' R$, $A'' = R^T \tilde{A}'' R$, and $K_j'' = R^T \tilde{K}_j'' R$, $j = 1, 2$. We can write all the factors in (5.15) as exponentials of appropriate matrices in the tensor product basis:

$$\begin{gathered} A' = e^{a'}, \quad A_k'' = e^{a_k''}, \quad k = 1,2, \\ K_j'' = e^{k_j''}, \quad j = 1, \ldots, 4 \end{gathered} \tag{5.16}$$

where

$$a' = \frac{\pi}{2}(E_{11} \otimes \Delta_{24}) + \frac{3\pi}{2}(E_{22} \otimes \Delta_{13}) + \pi(E_{22} \otimes \Delta_{24}),$$

$$a_1'' = \frac{\pi}{4}(\Delta_{12} \otimes \Omega_{24} + \Omega_{12} \otimes \Delta_{24}) + \frac{\pi}{4}(\Delta_{12} \otimes \Omega_{24} - \Omega_{12} \otimes \Delta_{24}) + \frac{3\pi}{4}(\Delta_{12} \otimes \Omega_{13} - \Omega_{12} \otimes \Delta_{13}),$$

$$a_2'' = \frac{\pi}{4}(\Delta_{12} \otimes \Omega_{24} - \Omega_{12} \otimes \Delta_{24}),$$

$$k_1'' = \frac{3\pi}{2}(E_{22} \otimes \Delta_{34}) + \frac{\pi}{2}(E_{22} \otimes \Delta_{12}) + \frac{3\pi}{2}(E_{11} \otimes \Delta_{34}), \tag{5.17}$$

$$k_2'' = \frac{3\pi}{2}(E_{22} \otimes \Delta_{34}),$$

$$k_3'' = \frac{3\pi}{2}(E_{22} \otimes \Delta_{12}),$$

$$k_4'' = \frac{3\pi}{2}(E_{11} \otimes \Delta_{34}).$$

It is interesting to observe what number of nonlocal transformations are needed to perform the given task if we are able to perform any local transformation on the two subsystems. Notice that we are considering the system as a bipartite system of a two level system with a four level system. In essence, we assume that we have to decide appropriate interactions between the two subsystems (two and four dimensional), which along with local transformations will allow us to perform the given task. By grouping the matrices that are equivalent through local similarity transformations it is clear that the Hamiltonians

$$H_1 := E_{11} \otimes \Delta_{34},$$

$$H_2 := \Delta_{12} \otimes \Omega_{24} + \Omega_{12} \otimes \Delta_{24}, \tag{5.18}$$

$$H_3 := \Delta_{12} \otimes \Omega_{24} - \Omega_{12} \otimes \Delta_{24},$$

are sufficient. [In view of (5.17), one can replace H_2 with $\tilde{H}_2 := \Delta_{12} \otimes \Omega_{24}$.]

(Received 14 April 2006; accepted 4 July 2006; published online 30 August 2006; publisher error corrected 6 September 2006)

This work is intended as an attempt to study the nonperturbative renormalization of bound state problem of finitely many Dirac-delta interactions on Riemannian manifolds, $\mathbb{S}^2$, $\mathbb{H}^2$, and $\mathbb{H}^3$. We formulate the problem in terms of a finite dimensional matrix, called the characteristic matrix Φ. The bound state energies can be found from the characteristic equation $\Phi(-\nu^2)A=0$. The characteristic matrix can be found after a regularization and renormalization by using a sharp cut-off in the eigenvalue spectrum of the Laplacian, as it is done in the flat space, or using the heat kernel method. These two approaches are equivalent in the case of compact manifolds. The heat kernel method has a general advantage to find lower bounds on the spectrum even for compact manifolds as shown in the case of $\mathbb{S}^2$. The heat kernels for $\mathbb{H}^2$ and $\mathbb{H}^3$ are known explicitly, thus we can calculate the characteristic matrix Φ. Using the result, we give lower bound estimates of the discrete spectrum. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2259581]

I. INTRODUCTION

It is well known that the exactly solvable Dirac-delta interactions on the plane and three-dimensional Euclidean space in quantum mechanics give rise to some unphysical results for physical observables, i.e., bound state energy and scattering cross section are infinite and the problem is said to be ultraviolet divergent. Nevertheless, there is a systematic way to dispense with these infinities by means of a so-called regularization and renormalization, which is first introduced in quantum field theory for the same reason. This problem constitutes an analytical example of regularization and renormalization in quantum mechanics so that it helps us to understand and deal with it in a more elementary context rather than field theory and it has been studied in the literature from several point of views.[1–13] Moreover, a single point interaction in two-dimensional flat space is an instructive example of dimensional transmutation in nonrelativistic quantum mechanics.[3,14–16] That is, the original Hamiltonian does not contain any intrinsic energy scale due to the dimensionless coupling constant in natural units. Nevertheless, a new parameter μ^2, which specifies the bound state energy, must be introduced after the renormalization procedure which then fixes the energy scale of the system. (A detailed discussion of dimensional transmutation in nonrelativistic quantum mechanics is given in a relatively recent article.[16])

In this study, we consider a bound state problem in which a nonrelativistic particle living in a Riemannian manifold (in particular $\mathbb{S}^2$, $\mathbb{H}^2$, and $\mathbb{H}^3$) interacts with finitely many Dirac-delta interactions. Similar to the corresponding bound state problem on $\mathbb{R}^2$ and $\mathbb{R}^3$, we encounter divergences in this case as well. The main purpose of this paper is to show how to nonperturbatively regularize and renormalize the problem by means of heat kernel (even in the case where we do not have an explicit expression for it). After the renormalization, we estimate a lower bound for the ground state energy for each particular Riemannian manifold. This problem on two-dimensional Riemannian manifolds, such as $\mathbb{S}^2$ and $\mathbb{H}^2$, also displays a kind of dimensional transmutation,[16] where new energy scales different from the intrinsic energy scales of the system appear after the renormalization. We will briefly discuss it in Secs. III and IV B.

Many body version of this problem on $\mathbb{R}^2$ and $\mathbb{R}^3$ is known as the formal nonrelativistic limit of the $\lambda\phi^4$ scalar field theory in $(2+1)$ and $(3+1)$ dimensions. All these are extensively discussed first by Hoppe[31] and later from a new perspective in Ref. 17. Our primary motivation here is coming from the question of how the renormalization method for the singular interactions in quantum mechanics would be performed on Riemannian manifolds, hoping that this may help us to understand the problem in the realm of quantum field theory. However, we shall postpone the discussion of the many body extension of it for future work and study first the one-particle Schrödinger problem.

The paper is organized as follows. In Sec. II, we first define the bound state problem on compact and connected Riemannian manifolds and reformulate the problem in terms of a finite dimensional matrix Φ, which we will call the characteristic matrix.[17] Then, we emphasize the relation of the characteristic matrix with the corresponding spectral functions, resolvent and heat kernel. This allows us to reformulate the renormalization in terms of heat kernel. After that we continue to the discussion in the following sections by working out concrete examples. In Sec. III, we consider the delta interaction problem on $\mathbb{S}^2$ as an example for compact and connected manifolds. Considering the properties of the operator Φ and using some properties and upper bound estimates of the heat kernel, Geršgorin theorem allows us to estimate a lower bound for the ground state energy of the system. In Sec. IV, we apply a similar methodology, developed in the section of heat kernel method for $\mathbb{S}^2$, to the noncompact manifolds, such as $\mathbb{H}^2$ and $\mathbb{H}^3$, and show that the methods developed for compact manifolds work for some particular noncompact manifolds as well. Therefore, we renormalize the problem on hyperbolic spaces and give estimates on the ground state energy of each system.

II. RENORMALIZATION OF FINITELY MANY DIRAC-DELTA INTERACTIONS ON COMPACT AND CONNECTED RIEMANNIAN MANIFOLDS (M,g)

The canonical quantization on nontrivial manifolds is known to have some ambiguities in quantum mechanics. For the path integral approach to the quantum system, the ambiguity in the canonical formalism is replaced by the undetermined parameter λ and it can take various possible values.[18] We remove this term for simplicity in all our examples, in which the curvature term is constant and it corresponds to an overall shift in energy levels so that we can safely set λ to be zero.

Now, we consider a nonrelativistic point particle living on a Riemannian manifold M interacting with a finite number of delta interactions located on the manifold and study bound states of the problem. We first investigate the delta interactions on a compact and connected Riemannian manifold (M,g) without boundary, of dimension $D=2,3$ with the Riemannian metric g. The kinetic energy operator on Riemannian manifold (M,g) is just the Laplace-Beltrami operator or simply Laplacian, which is defined, in local coordinates $x\equiv(x^1,\ldots,x^D)$ for a neighborhood in the manifold, as follows:

$$\Delta_g = -\frac{1}{\sqrt{\det g}} \sum_{\alpha,\beta=1}^{D} \frac{\partial}{\partial x^\alpha}\left(g^{\alpha\beta}\sqrt{\det g}\frac{\partial}{\partial x^\beta}\right), \tag{1}$$

where $g_{\alpha\beta}$ is the metric tensor and $g=(g_{\alpha\beta})$. We shall usually denote the Laplacian as Δ_g to specify which metric structure on Riemannian manifold it is associated with.

The spectral theorem[19,20] states that the eigenvalue problem $\Delta_g\phi_l=\lambda_l\phi_l$ on a compact and connected Riemannian manifold (M,g) has a complete orthonormal system of C^∞ eigenfunctions $\phi_0,\phi_1,\ldots$ in $L^2(M)$ and the spectrum $\mathrm{Spec}\,(\Delta_g)\equiv\mathrm{Spec}(M,g)=\{\lambda_l\}=\{0=\lambda_0<\lambda_1\leqslant\lambda_2\leqslant\ldots\}$, with λ_l tending to infinity as $l\to\infty$. As a corollary of this theorem, the Laplacian on (M,g) provides us with all the tools of Fourier analysis, so that we can expand any "sufficiently good" function $\psi(x)$ on M in terms of the complete orthonormal eigenfunctions $\phi_l(x)$,

$$\psi(x) = \sum_{l\geqslant 0} C_l\phi_l(x), \tag{2}$$

with the normalization

$$\int_M \phi_l(x)\phi_{l'}^*(x)\sqrt{\det g}\,\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^D = \delta_{ll'},$$

where C_l's are expansion coefficients. Note that extra labels in the eigenfunction expansion must be taken into account if the problem admits degeneracy. Delta functions on M can also assumed to be represented by these eigenfunctions

$$\delta^D(x-a_i) = \sum_{l\geqslant 0}\phi_l(x)\phi_l^*(a_i), \tag{3}$$

with $a_i\in M$ and $\delta^D(x-a_i)$ being the D-dimensional normalized delta function at point a_i,

$$\int_M \delta^D(x-a_i)\sqrt{\det g}\,\mathrm{d}x^1\wedge\cdots\wedge\mathrm{d}x^D = 1.$$

A typical Hamiltonian operator in quantum theory consists of a kinetic term, the Laplacian Δ_g with the factor $\hbar^2/2m$, and a potential function of position, attractive delta interactions in our problem. The time-independent Schrödinger equation on M for the bound states of a particle under the influence of N attractive delta interactions reads

$$\left[\frac{\hbar^2}{2m}\Delta_g - \sum_{i=1}^{N} g_i\delta^D(x-a_i)\right]\psi(x) = -\nu^2\psi(x), \tag{4}$$

where $g_i\in\mathbb{R}^+$ is the strength of the delta interaction at a_i and $-\nu^2$ is the bound state energy of the system. If we substitute (2) and (3) into the Schrödinger equation, it yields

$$\sum_{l\geqslant 0}\left[\frac{\hbar^2}{2m}\lambda_l C_l - \sum_{i=1}^{N} A_i g_i\phi_l^*(a_i) + \nu^2 C_l\right]\phi_l(x) = 0,$$

where $A_i\equiv\psi(a_i)$ for simplicity of notation. The fact that ϕ_l's form a complete orthonormal system allows us to write C_l in terms of them:

$$C_l = \frac{1}{\dfrac{\hbar^2}{2m}\lambda_l+\nu^2}\sum_{i=1}^{N} A_i g_i\phi_l^*(a_i). \tag{5}$$

Substituting (5) into the definition of A_i,

$$A_i = \sum_{j=1}^{N} A_j g_j \sum_{l \geqslant 0} \frac{\phi_l(a_i)\phi_l^*(a_j)}{\frac{\hbar^2}{2m}\lambda_l + \nu^2},$$

and grouping the A_i terms we find

$$\left[g_i^{-1} - \sum_{l \geqslant 0} \frac{|\phi_l(a_i)|^2}{\frac{\hbar^2}{2m}\lambda_l + \nu^2} \right] A_i - \sum_{\substack{j=1 \\ j \neq i}}^{N} \left[\frac{g_j}{g_i} \sum_{l \geqslant 0} \frac{\phi_l(a_i)\phi_l^*(a_j)}{\frac{\hbar^2}{2m}\lambda_l + \nu^2} \right] A_j = 0.$$

The observation that the preceding equation is linear in A_i permits us to write it naturally as a matrix equation

$$\Phi(-\nu^2)A = 0, \tag{6}$$

where $\Phi(-\nu^2)$ is called the characteristic matrix and defined as

$$\Phi_{ij}(-\nu^2) = \begin{cases} g_i^{-1} - \sum_{l \geqslant 0} \frac{|\phi_l(a_i)|^2}{\frac{\hbar^2}{2m}\lambda_l + \nu^2} & \text{if } i = j \\ -\frac{g_j}{g_i} \sum_{l \geqslant 0} \frac{\phi_l(a_i)\phi_l^*(a_j)}{\frac{\hbar^2}{2m}\lambda_l + \nu^2} & \text{if } i \neq j. \end{cases} \tag{7}$$

As we shall see in the following the resolvent is intimately related to it and this allows us to state that the equation $\det \Phi(-\nu^2)=0$ gives the bound state energies of our problem. In other words, this equation is considered to be the determining equation of the ground state energy. Unfortunately, this nontrivial eigenvalue problem cannot be solved analytically, that is, we cannot obtain an exact expression for the bound state energy for arbitrary N since the characteristic matrix depends *nonlinearly* on the bound state energy. Indeed, the problem is even worse than that, because we do not have finite expressions in the matrix elements of $\Phi_{ij}(-\nu^2)$. Fortunately, there exists a way to redefine the problem so that the physical observables yield finite values with the help of regularization and renormalization. Before introducing this procedure for our problem, it would be good to review first the problem in flat spaces. The infinite sums in the characteristic matrix on $\mathbb{R}^2$ or $\mathbb{R}^3$ are then replaced by integrals. The idea in that case is to take Fourier transform of the wave function

$$\psi(x) = \int \tilde{\psi}(k) e^{ik.x} \frac{\mathrm{d}^D k}{(2\pi)^D},$$

and substitute into the Schrödinger equation. Then we find that the diagonal part of the characteristic matrix is

$$\frac{1}{g_i} - \frac{1}{(2\pi)^D} \int \frac{\mathrm{d}^D k}{k^2 + \nu^2},$$

where $D=2,3$. This integral does not converge as it stands. The well-known method to remove the divergence is to put a cut-off Λ to the integral's upper limit and consider the equation as a determining equation of bound state energy for a given coupling constant g. If this regularization is performed, we realize that as the cut-off goes to infinity, ground state energy becomes divergent. In order to get a physically acceptable result, one assumes that the coupling constant depends on this cut-off and performs the limit $\Lambda \to \infty$ in such a way that bound state energy remains finite. These infinities should be removed properly since all the physical observables are measured experimentally as finite quantities. The cut-off dependence of the coupling constant is chosen as

$$\frac{1}{g_i(\Lambda)} = \frac{1}{(2\pi)^D}\int_{|k|<\Lambda} \frac{\mathrm{d}^D k}{k^2+\mu_i^2}. \tag{8}$$

The determination of this coupling constant is called renormalization. Now, we follow the same idea to remove the divergence from our problem. By using Weyl's asymptotic formula,[21] one expects that the diagonal term

$$\sum_{l\geqslant 0} \frac{|\phi_l(a_i)|^2}{\frac{\hbar^2}{2m}\lambda_l + \nu^2}$$

in the above-noted matrix does not converge and this will be explicitly seen for a particular manifold $\mathbb{S}^2$. For a general compact manifold, we introduce cut-off to the upper bound of the infinite sum and choose the coupling constant as

$$g_i^{-1}(\Lambda) = \sum_{l=0}^{\Lambda} \frac{|\phi_l(a_i)|^2}{\frac{\hbar^2}{2m}\lambda_l + \mu_i^2}, \tag{9}$$

where $-\mu_i^2$ is the measured binding energy to a single delta interaction. Then, we take the limit $\Lambda\to\infty$,

$$\lim_{\Lambda\to\infty}\left[\sum_{l=0}^{\Lambda} \frac{|\phi_l(a_i)|^2}{\frac{\hbar^2}{2m}\lambda_l + \mu_i^2} - \sum_{l=0}^{\Lambda} \frac{|\phi_l(a_i)|^2}{\frac{\hbar^2}{2m}\lambda_l + \nu^2}\right], \tag{10}$$

and this should give us a finite result in two and three dimensions. Hence, the divergence has been removed and bound state energy becomes finite. A rigorous proof of this is not trivial, so we will stay at a heuristic level and study special cases only.

As we will show in Sec. II, the heat kernel is intimately related to the characteristic matrix Φ and this relation helps us to see easily which part of the matrix is divergent or convergent and then how to renormalize the problem nonperturbatively. Furthermore, heat kernel is especially very helpful to remove the divergences for our problem on noncompact manifolds, as we shall discuss in Sec. IV. We will see that the above-noted method can easily be extended to find the renormalized resolvent of the singular Hamiltonian.

A. The relation of matrix Φ with heat kernel and resolvent

The resolvent (or Green's function) and heat kernel play a very essential role in establishing the connection between spectral properties of the operator and corresponding geometrical notions. Up to now, we have been dealing with a matrix Φ, and do not refer to resolvent and heat kernel. In order to see the relation between the matrix Φ and heat kernel we consider the separable Hamiltonians $H=H_0-\Sigma_{i=1}^N g_i|f_i\rangle\langle f_i|$, where $|f_i\rangle$ is a particular Dirac ket. We work out the resolvent formula of H in terms of H_0 and assume that the two Dirac kets $|\psi\rangle$ and $|\chi\rangle$ are related in such a way that the equality $(H-z)|\psi\rangle=|\chi\rangle$ is satisfied. Then, we have

$$\left[H_0 - z - \sum_{j=1}^{N} g_j|f_j\rangle\langle f_j|\right]|\psi\rangle = |\chi\rangle, \tag{11}$$

assuming complex number $z\notin \mathrm{Spec}(H_0)$. Acting the operator $(H_0-z)^{-1}$ on both sides and projecting it onto $\langle f_i|$, we obtain

$$\sum_{j=1}^{N} \Phi_{ij}(z)\langle f_j|\psi\rangle = g_i^{-1}\langle f_i|(H_0-z)^{-1}|\chi\rangle,$$

where we define a matrix $\Phi_{ij}(z)$ as[1]

$$\Phi_{ij}(z) = \begin{cases} g_i^{-1} - \langle f_i|(H_0-z)^{-1}|f_i\rangle & \text{if } i=j \\ -\dfrac{g_j}{g_i}\langle f_i|(H_0-z)^{-1}|f_j\rangle & \text{if } i\neq j. \end{cases} \tag{12}$$

After a little algebra, it is evident that

$$(H-z)^{-1} = (H_0-z)^{-1} + (H_0-z)^{-1}\left[\sum_{i,j=1}^{N} |f_i\rangle\Phi_{ij}(z)^{-1}\langle f_j|\right](H_0-z)^{-1}, \tag{13}$$

as long as $\Phi_{ij}(z)^{-1}$ exists. Such formulas were extensively discussed in problems associated with self-adjoint extensions of operators, notably by Krein and his school, and also for such singular interactions in flat spaces.[12,22] Therefore, our problem can also be considered as a kind of self-adjoint extension of the free Hamiltonian. It is defined through regulating (or controlling) the behavior of the wave function in the vicinity of these interaction points.

If we take the matrix element of (13) by projecting on to the Dirac kets $\langle x|$ and $|y\rangle$, we have found the resolvent kernel $R(x,y|z)\equiv\langle x|(H-z)^{-1}|y\rangle$ corresponding to (11)

$$\begin{aligned} R(x,y|z) &= R_0(x,y|z) + \int \mathrm{d}x'\mathrm{d}y' R_0(x,x'|z)\left[\sum_{i,j=1}^{N} f_i(x')\Phi_{ij}(z)^{-1}f_j(y')\right]R_0(y',y|z) \\ &= R_0(x,y|z) + \sum_{i,j=1}^{N}\left[\int \mathrm{d}x' R_0(x,x'|z)f_i(x')\right]\Phi_{ij}(z)^{-1}\left[\int \mathrm{d}y' R_0(y',y|z)f_j(y')\right]. \end{aligned}$$

By choosing the functions $f_i(x)$'s as bump functions centered at $x=a_i$ such that the sequences of the functions admit the limit $f_i(x)\to\delta^D(x-a_i)$ (in the appropriate topology), it turns out that

$$R(x,y|z) = R_0(x,y|z) + \sum_{i,j=1}^{N} R_0(x,a_i|z)\Phi_{ij}(z)^{-1}R_0(a_j,y|z). \tag{14}$$

The important point to note here is the relation between the resolvent operator, defined on an infinite dimensional space and the characteristic matrix, defined on a finite dimensional space. This allows us to find the bound state spectrum of the separable Hamiltonian operator H with the help of a finite dimensional matrix $\Phi(z)^{-1}$. Since discrete spectrum is the set of complex numbers such that the resolvent does not exist, this proves that the equation $\det\Phi=0$ gives the bound state spectrum of our system. The fact that the free Hamiltonian is bounded from below allows us to write the free resolvent operator as an integral for $\Re(z)<0$,

$$(H_0-z)^{-1} = \frac{1}{\hbar}\int_0^{\infty} e^{-(t/\hbar)((\hbar^2/2m)\Delta_g - z)}\mathrm{d}t, \tag{15}$$

the result of which should be continued analytically to its largest set in the entire complex plane. As a consequence of this, the free resolvent kernel is

[1]There is no confusion in notation because we will see that this matrix Φ is exactly the same matrix considered in the previous sections.

$$\langle f_i|(H_0-z)^{-1}|f_j\rangle=\frac{1}{\hbar}\int_0^\infty e^{zt/\hbar}\langle f_i|e^{-\left[\frac{t}{\hbar}\right](\hbar^2/2m)\Delta_g}|f_j\rangle \mathrm{d}t.$$

Taking the limit $f_i(x)\to\delta^D(x-a_i)$, it results in

$$R_0(a_i,a_j|z)=\langle a_i|(H_0-z)^{-1}|a_j\rangle=\frac{1}{\hbar}\int_0^\infty e^{zt/\hbar}K_t(a_i,a_j)\mathrm{d}t, \tag{16}$$

where $K_t(a_i,a_j)$ is the so-called heat kernel, and the operator $e^{-[t/\hbar](\hbar^2/2m)\Delta_g)}$ is the formal solution to the heat equation.[19,20] Hence, the matrix Φ is written in terms of the heat kernel in the following way:

$$\Phi_{ij}(z)=\begin{cases} g_i^{-1}-\dfrac{1}{\hbar}\displaystyle\int_0^\infty e^{zt/\hbar}K_t(a_i,a_i)\mathrm{d}t & \text{if } i=j \\ -\dfrac{g_j}{g_i}\dfrac{1}{\hbar}\displaystyle\int_0^\infty e^{zt/\hbar}K_t(a_i,a_j)\mathrm{d}t & \text{if } i\neq j. \end{cases} \tag{17}$$

The matrix Φ_{ij} is exactly the same matrix mentioned in the previous sections. This can be shown easily from the spectral theorem[19] for compact manifolds

$$K_t(a_i,a_j)=\sum_{l\geqslant 0}e^{-(\hbar^2/2m)\lambda_l[t/\hbar]}\phi_l(a_i)\phi_l^*(a_j), \tag{18}$$

which converges uniformly on $M\times M$ for each $t>0$:

$$\begin{aligned}\langle f_i|(H_0-z)^{-1}|f_j\rangle\to\int_0^\infty e^{zt/\hbar}K_t(a_i,a_j)\frac{\mathrm{d}t}{\hbar}&=\sum_{l\geqslant 0}\phi_l(a_i)\phi_l^*(a_j)\int_0^\infty e^{-((\hbar^2/2m)\lambda_l-z)[t/\hbar]}\mathrm{d}t/\hbar \\ &=\sum_{l\geqslant 0}\frac{\phi_l(a_i)\phi_l^*(a_j)}{\frac{\hbar^2}{2m}\lambda_l-z},\end{aligned}$$

where summation and integral are interchanged since summation converges uniformly. This is the same result for $z=-\nu^2$ that we already obtained for the nondiagonal part of the characteristic matrix in Sec. II. One can understand how the nondiagonal part of it in (7) is convergent by using the smooth behavior of the heat kernel and the integral $\int_0^\infty(\mathrm{d}t/\hbar)e^{zt/\hbar}K_t(a_i,a_j)$ is convergent for $a_i\neq a_j$. However, the asymptotic behavior of the heat kernel as $t\to 0^+$ for every point x on a compact manifold M[19] is given by

$$K_t(x,x)\sim\left(4\pi\frac{\hbar t}{2m}\right)^{-D/2}\sum_{k=0}^\infty u_k(x,x)\left(\frac{\hbar t}{2m}\right)^k, \tag{19}$$

where D is the dimension of the manifold and the $u_k(x,x)$ are functions given in terms of the curvature tensor of M and its covariant derivatives at the point x. This result shows that the diagonal part of the heat kernel as $t\to 0^+$ for $D=2,3$ leads to a divergence since $u_0(x,x)=1$ (there are no infinities for $D=1$ as it can be easily realized). In other words, the sum in the diagonal term in Φ is divergent while the sum in the nondiagonal term is convergent. However, we have already shown that bound state energies are related to the characteristic matrix, i.e., $\det\Phi(z)=0$ contains information about bound states. If some of the elements of the characteristic matrix have infinities, it is impossible to get sensible bound state energies for our problem. Before establishing the renormalization of our problem with the help of heat kernel, we must indicate why this problem occurs. Although the delta interactions may approximately describe a system in which a particle interacting with a point-like centers when its de Broglie wavelength is large compared to the typical range of a potential, we have not encountered in nature this type of contact interaction.

This means that substituting the Dirac-Delta interactions into the Hamiltonian for $D=2,3$ directly is not a proper way. Therefore, we must modify our problem such that it has a finite range and then consider the zero range limit. In our renormalization method with heat kernel, short range is replaced with the short time as we will see.

We introduce a small constant ϵ, in the lower limit of the integral. We then take the limit as the cut-off ϵ goes to zero in such a way that the experimentally measured ground state energy remains finite. This requires that some quantities in the problem, e.g., coupling constant, should have a cut-off dependence in a definite way. For our problem, we naturally choose

$$g_i^{-1}(\epsilon,\mu_i)=\frac{1}{\hbar}\int_{\epsilon}^{\infty}e^{-\mu_i^2 t/\hbar}K_t(a_i,a_i)\mathrm{d}t. \tag{20}$$

After performing the limit $\epsilon\to 0$, we have the renormalized characteristic matrix

$$\Phi_{ij}(z)=\begin{cases}\dfrac{1}{\hbar}\displaystyle\int_0^{\infty}K_t(a_i,a_i)\left[e^{-\mu_i^2 t/\hbar}-e^{zt/\hbar}\right]\mathrm{d}t & \text{if } i=j\\ -\dfrac{1}{\hbar}\displaystyle\int_0^{\infty}e^{zt/\hbar}K_t(a_i,a_j)\mathrm{d}t & \text{if } i\neq j,\end{cases} \tag{21}$$

where $\Re(z)<0$ and $\Phi_{ij}(z)$ can be analytically continued to its largest set in the entire complex plane. One can naturally ask whether the renormalization performed with heat kernel is compatible with the one introduced in Sec. II. The answer is affirmative and one can easily show that the cut-off Λ for the infinite sum introduced in Sec. II corresponds to the cut-off ϵ for the lower bound of integral in the heat kernel method. This can be realized easily by using the spectral theorem in the diagonal part of Eq. (21) and taking $z=-\nu^2$:

$$\begin{aligned}&g_i^{-1}(\epsilon,\mu_i)-\frac{1}{\hbar}\int_{\epsilon}^{\infty}e^{-\nu^2 t/\hbar}\sum_{l\geq 0}e^{-(\hbar^2/2m)\lambda_l[t/\hbar]}\phi_l(a_i)\phi_l^*(a_i)\mathrm{d}t\\ &\quad=g_i^{-1}(\epsilon,\mu_i)-\frac{1}{\hbar}\sum_{l\geq 0}\phi_l(a_i)\phi_l^*(a_i)\int_{\epsilon}^{\infty}e^{-\nu^2 t/\hbar}e^{-(\hbar^2/2m)\lambda_l[t/\hbar]}\mathrm{d}t,\end{aligned} \tag{22}$$

where we have used the uniform convergence of the sum. Now, in order to remove the divergence, we can naturally choose the coupling constant as

$$g_i^{-1}(\epsilon,\mu_i)=\frac{1}{\hbar}\sum_{l\geq 0}\phi_l(a_i)\phi_l^*(a_i)\int_{\epsilon}^{\infty}e^{-\mu_i^2 t/\hbar}e^{-(\hbar^2/2m)\lambda_l[t/\hbar]}\mathrm{d}t. \tag{23}$$

Then, we have

$$\begin{aligned}&\lim_{\epsilon\to 0}\left\{\frac{1}{\hbar}\sum_{l\geq 0}\phi_l(a_i)\phi_l^*(a_i)\left[\int_{\epsilon}^{\infty}e^{-\mu_i^2 t/\hbar}e^{-(\hbar^2/2m)\lambda_l[t/\hbar]}\mathrm{d}t-\int_{\epsilon}^{\infty}e^{-\nu^2 t/\hbar}e^{-(\hbar^2/2m)\lambda_l[t/\hbar]}\mathrm{d}t\right]\right\}\\ &\quad=\frac{1}{\hbar}\sum_{l\geq 0}\frac{[\nu^2-\mu_i^2]\phi_l(a_i)\phi_l^*(a_i)}{\left[\dfrac{\hbar^2}{2m}\lambda_l+\mu_i^2\right]\left[\dfrac{\hbar^2}{2m}\lambda_l+\nu^2\right]},\end{aligned} \tag{24}$$

which is the same result we would have obtained by the eigenfunction expansion by introducing a cut-off Λ (Eq. (10)). After finding the renormalized characteristic matrix, the resolvent can be written explicitly

$$R(x,y|z) = R_0(x,y|z) + \sum_{i,j=1}^{N} R_0(x,a_i|z)\Phi_{ij}(z)^{-1}R_0(a_j,y|z), \tag{25}$$

where

$$R_0(x,y|z) = \frac{1}{\hbar}\int_0^\infty e^{zt/\hbar}K_t(x,y)\mathrm{d}t. \tag{26}$$

Once we have given the resolvent of an operator, all the information about the operator is contained in it. Nevertheless, it is instructive to check that the wave functions can also be obtained and they are normalizable. We write the normalized wave function with a cut-off Λ and then take the limit $\Lambda\to\infty$, this way we will not get a vanishing wave function. So the normalization constant can be found easily

$$\begin{aligned}|C(\Lambda)|^{-2} &= \sum_{i,j=1}^{N} g_i(\Lambda)g_j(\Lambda)A_i^*(\Lambda)A_j(\Lambda)\int \mathrm{d}^D x\sqrt{g}\sum_{l,l'=0}^{\Lambda}\frac{\phi_l(a_i)\phi_l^*(x)}{\left(\frac{\hbar^2}{2m}\lambda_l+\nu^2\right)}\frac{\phi_{l'}^*(a_j)\phi_{l'}(x)}{\left(\frac{\hbar^2}{2m}\lambda_{l'}+\nu^2\right)}\\ &= \sum_{i,j=1}^{N} g_i(\Lambda)g_j(\Lambda)A_i^*(\Lambda)A_j(\Lambda)\sum_{l=0}^{\Lambda}\frac{\phi_l(a_i)\phi_l^*(a_j)}{\left(\frac{\hbar^2}{2m}\lambda_l+\nu^2\right)^2}.\end{aligned} \tag{27}$$

One expects from the Weyl asymptotic formula that the wave function is not normalizable if we are on a space of dimension bigger than three. Moreover, we can see that the summation over the eigenmodes is exactly the derivative of $\Phi(-\nu^2)$ with respect to ν, hence we get

$$|C(\Lambda)|^{-2} = \frac{1}{2\nu}\sum_{i,j=1}^{N} g_j(\Lambda)^2A_i^*(\Lambda)\frac{\partial\Phi_{ij}(\Lambda,-\nu^2)}{\partial\nu}A_j(\Lambda). \tag{28}$$

Performing the limit $\Lambda\to\infty$, the properly normalized wave function of nth state becomes

$$\psi_n(x) = \sqrt{2\nu_n}\left[\sum_{r,s=1}^{N}A_r^*(\nu_n)\left.\frac{\partial\Phi_{rs}(-\nu^2)}{\partial\nu}\right|_{\nu=\nu_n}A_s(\nu_n)\right]^{-1/2}\sum_{l\geqslant 0}\sum_{i=1}^{N}A_i(\nu_n)\frac{\phi_l^*(a_i)\phi_l(x)}{\left(\frac{\hbar^2}{2m}\lambda_l+\nu_n^2\right)},$$

where ν_n is the nth root of the energy equation $\det\Phi(-\nu^2)=0$. This can further be simplified to an expression in terms of the heat kernel

$$\begin{aligned}\psi_n(x) &= \sqrt{2\nu_n}\left[\sum_{r,s=1}^{N}A_r^*(\nu_n)\left.\frac{\partial\Phi_{rs}(-\nu^2)}{\partial\nu}\right|_{\nu=\nu_n}A_s(\nu_n)\right]^{-1/2}\\ &\quad\times\sum_{l\geqslant 0}\sum_{i=1}^{N}A_i(\nu_n)\phi_l^*(a_i)\phi_l(x)\int_0^\infty e^{-(t/\hbar)((\hbar^2/2m)\lambda_l+\nu_n^2)}\frac{\mathrm{d}t}{\hbar}\\ &= \sqrt{2\nu_n}\left[\sum_{r,s=1}^{N}A_r^*(\nu_n)\left.\frac{\partial\Phi_{rs}(-\nu^2)}{\partial\nu}\right|_{\nu=\nu_n}A_s(\nu_n)\right]^{-1/2}\int_0^\infty e^{-t\nu_n^2/\hbar}\sum_{i=1}^{N}A_i(\nu_n)K_t(a_i,x)\frac{\mathrm{d}t}{\hbar},\end{aligned} \tag{29}$$

in which one can easily see that $\psi_n(x)$ is finite.

III. FINITELY MANY DIRAC-DELTA INTERACTIONS ON $\mathbb{S}^2$

Since the simplest and one of the most familiar compact manifolds is the sphere $\mathbb{S}^2$, we shall work out the problem of point interactions on a sphere as a concrete example. Suppose that point interactions are located at the points given by the local coordinates $(\theta_i, \phi_i)_{i=1}^N$ on a sphere of radius R. Then, the Schrödinger equation for the bound states of a particle living on the sphere under the influence of N attractive delta interactions becomes

$$\left[\frac{\hbar^2}{2m}\Delta_{\mathbb{S}^2} - \sum_{i=1}^{N} g_i \delta^2(\theta-\theta_i, \phi-\phi_i)\right]\psi = -\nu^2\psi, \tag{30}$$

where $\Delta_{\mathbb{S}^2}$ is Laplacian on the sphere in spherical coordinates

$$\Delta_{\mathbb{S}^2} = -\frac{1}{R^2 \sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right) - \frac{1}{R^2\sin^2\theta}\frac{\partial^2}{\partial\phi^2}, \tag{31}$$

and $\delta^2(\theta-\theta_i, \phi-\phi_i) = \delta(\theta-\theta_i)\delta(\phi-\phi_i)/R^2\sin^2\theta$ is the two-dimensional delta function on the sphere centered at (θ_i, ϕ_i). It is well known that spherical harmonics Y_l^m are eigenfunctions of the Laplacian $\Delta_{\mathbb{S}^2}$ with the eigenvalues $l(l+1)/R^2$ and form a complete orthonormal basis on $\mathbb{S}^2$. In order to be consistent with the standard normalization of spherical harmonics, we choose $\phi_{lm} = Y_l^m/R$. From the following identity

$$\sum_{m=-l}^{l} Y_l^m(\theta_i, \phi_i) Y_l^{m*}(\theta_j, \phi_j) = \frac{2l+1}{4\pi} P_l(\cos\theta_i\cos\theta_j + \cos(\phi_i-\phi_j)\sin\theta_i\sin\theta_j) = \frac{2l+1}{4\pi}P_l\left(1-\frac{\mathrm{d}_{ij}^2}{2}\right),$$

where $\mathrm{d}_{ij} = d_{ij}/R = |\hat{r}_i - \hat{r}_j| \in [0,2]$ being rescaled distance between point centers with radius of the sphere R, the matrix $\Phi_{ij}(-\nu^2)$ in (7) becomes

$$\Phi_{ij}(-\nu^2) = \begin{cases} g_i^{-1} - \dfrac{1}{4\pi R^2}\displaystyle\sum_{l\geqslant 0}\frac{2l+1}{\dfrac{\hbar^2}{2mR^2}l(l+1)+\nu^2} & i=j \\ -\dfrac{g_j}{g_i}\dfrac{1}{4\pi R^2}\displaystyle\sum_{l\geqslant 0}\frac{2l+1}{\dfrac{\hbar^2}{2mR^2}l(l+1)+\nu^2}P_l\left(1-\dfrac{\mathrm{d}_{ij}^2}{2}\right) & i\neq j. \end{cases} \tag{32}$$

It follows easily from the Cauchy-MacLaurin integral test that the infinite sum

$$\frac{1}{4\pi R^2}\sum_{l\geqslant 0}\frac{2l+1}{\dfrac{\hbar^2}{2mR^2}l(l+1)+\nu^2}$$

is divergent. To get a sensible result for our problem, we must modify our original problem as outlined in Sec. II. Therefore, considering our problem in light of this method, we first define the coupling constant g_i as a function of the parameter Λ (cut-off). Then, by choosing $g_i^{-1}(\Lambda)$'s naturally

$$g_i^{-1}(\Lambda) = \frac{1}{4\pi R^2}\sum_{l=0}^{\Lambda}\frac{2l+1}{\dfrac{\hbar^2}{2mR^2}l(l+1)+\mu_i^2},$$

where μ_i is the experimentally measured value of bound state energy for the single delta interaction and taking the limit $\Lambda\to\infty$ of the difference, we have obtained

$$\lim_{\Lambda\to\infty}\left[\frac{1}{4\pi R^2}\sum_{l=0}^{\Lambda}\frac{2l+1}{\frac{\hbar^2}{2mR^2}l(l+1)+\mu_i^2}-\frac{1}{4\pi R^2}\sum_{l=0}^{\Lambda}\frac{2l+1}{\frac{\hbar^2}{2mR^2}l(l+1)+\nu^2}\right]$$
$$\to\frac{1}{4\pi R^2\mu_R^2}\left[\phi\left(\frac{\mu_i}{\mu_R}\right)-\phi\left(\frac{\nu}{\mu_R}\right)\right],$$

where $\mu_R^2\equiv\hbar^2/2mR^2$. The function ϕ here is defined as

$$\phi(x)\equiv\frac{1}{x^2}-H_{1/2-\sqrt{1/4-x^2}}-H_{1/2+\sqrt{1/4-x^2}},\quad x\in\mathbb{R}^+,$$

where H's are the harmonic numbers, commonly defined on integers as $H_n=\Sigma_{k=1}^n 1/k$ and can be extended by analytical continuation to its largest domain in the entire complex plane as $H_z=\psi(z+1)+\gamma$, where $\psi(z)=\Gamma'(z)/\Gamma(z)$ being the digamma function and γ being the Euler-Mascheroni constant. The digamma function has several useful integral representations,[23] some of which are

$$\psi(z)=\int_0^\infty\left(\frac{e^{-t}}{t}-\frac{e^{-zt}}{1-e^{-t}}\right)dt, \tag{33}$$

$$\psi(z)=\log z+\int_0^\infty\left(\frac{1}{1-e^{-t}}+\frac{1}{t}-1\right)e^{-zt}dt, \tag{34}$$

where $\Re(z)>0$ and these can be useful for the estimates of its upper and lower bounds. Due to the Schwarz reflection principle of harmonic numbers ($\overline{H_z}=H_{\bar{z}}$), the function $\phi(x)$ is real valued ($\phi\in\mathbb{R}$) for all $x\in\mathbb{R}^+$. It is also easy to check $\lim_{\Lambda\to\infty}g_j(\Lambda)/g_j(\Lambda)\to 1$ in the nondiagonal part of (32), simply because of their same form of the divergence. Then, the renormalized matrix $\Phi(-\nu^2)$ for bound states can be eventually written as

$$\Phi_{ij}(-\nu^2)=\frac{1}{4\pi R^2\mu_R^2}\begin{cases}\phi\left(\frac{\mu_i}{\mu_R}\right)-\phi\left(\frac{\nu}{\mu_R}\right) & i=j\\ -\sum_{l\geqslant 0}\frac{2l+1}{l(l+1)+\frac{\nu^2}{\mu_R^2}}P_l\left(1-\frac{d_{ij}^2}{2}\right) & i\neq j.\end{cases} \tag{35}$$

By the analytical continuation of the characteristic matrix to its largest domain in the entire complex plane, we have

$$\Phi_{ij}(z)=\frac{1}{4\pi R^2\mu_R^2}\begin{cases}\phi\left(\frac{\mu_i}{\mu_R}\right)-\phi\left(\frac{\sqrt{-z}}{\mu_R}\right) & i=j\\ -\sum_{l\geqslant 0}\frac{2l+1}{l(l+1)-\frac{z}{\mu_R^2}}P_l\left(1-\frac{d_{ij}^2}{2}\right) & i\neq j,\end{cases} \tag{36}$$

from which we can write the resolvent equation (14). Hence, we have obtained a well-defined formulation of our problem, that is, the infinities have been removed. Moreover, we see that the problem realizes a generalized dimensional transmutation. In this case, the coupling constants g_i have the same dimension as $\hbar^2/2m$ by dimensional analysis. In contrast to the flat case, we have one more parameter R coming from the geometry of the space. Thus, we expect that the system must have an intrinsic energy scale $\hbar^2/2mR^2$ as well as $\hbar^2/md_{ij}^2$ terms. However, after the renormalization, we obtain a set of new dimensional parameters μ_i^2. Hence, the first set of scales we expect by naive dimensional analysis at the beginning is not sufficient. Instead, a specific combi-

nation of all these parameters together determine the scale of our problem. This means that delta potentials on a sphere are an example of a kind of dimensional transmutation. However, there is a slight difference, especially in the case of single delta attractor: in the flat case there is no combination of dimensional parameters to come up with an energy scale, whereas in the case of a sphere we have a geometric length scale R which already defines an energy scale $\hbar^2/2mR^2$. The dimensional transmutation is most striking in such cases where there is no intrinsic energy scale.

In order to estimate the nondiagonal part of the matrix Φ for sphere $\mathbb{S}^2$, we follow a different strategy, using the heat kernel.

A. Lower bound of E_{gr} by heat kernel method for $\mathbb{S}^2$

Heat kernel $K_t(x,y)$ is the unique fundamental solution to the heat equation $(\hbar^2/2m)\Delta_g\phi = -\hbar\,\phi_t$. It has the symmetry $(K_t(x,y)=K_t(y,x))$ and semigroup property.[19,20] As well as being a useful computational tool in establishing the existence and some of the properties of the spectrum of the Laplacian of the eigenfunctions on Riemannian manifolds, it is very helpful to understand the nature of the divergences for our purposes, as we have shown in the previous section.

By means of relation (21) and explicit form of the heat kernel, one can calculate the matrix Φ_{ij}. However, there are some situations in which one cannot calculate the heat kernel explicitly, e.g., we do not have an explicit expression of the heat kernel for two-dimensional sphere. In this case, one can still find some bound estimates on matrix Φ_{ij} without having an explicit form of the heat kernel, but instead some properties of it. In order to analyze this for $\mathbb{S}^2$, we will use some estimates on the heat kernel, based on a work by Li and Yau.[24] Let us recall the corollary of the theorem (3.1) in Ref. 24.

Let M be a complete manifold without boundary. If the Ricci curvature of M is bounded from below by $-K$, for some constant $K \geqslant 0$, then for $1<\alpha<2$ and $0<\varepsilon<1$, the heat kernel satisfies

$$K_t(x,y) \leqslant \frac{C(\varepsilon)^\alpha}{\sqrt{V(x,\sqrt{t})V(y,\sqrt{t})}} e^{C_7\varepsilon(\alpha-1)^{-1}Kt - d(x,y)^2/(4+\varepsilon)t},$$

where $V(x,r)=\mu(B(x,r))$, $B(x,r)$ is the geodesic ball of radius r centered at $x \in M$ and $d(x,y)$ is the geodesic distance between two points x and y on the manifold. The constant C_7 depends only on the dimension of the manifold D, while $C(\varepsilon)$ depends on ε with $C(\varepsilon)\to\infty$ as $\varepsilon\to 0$. When $K=0$, the above-noted estimate, after letting $\alpha\to 1$, can be written as

$$K_t(x,y) \leqslant \frac{C(\varepsilon)}{\sqrt{V(x,\sqrt{t})V(y,\sqrt{t})}} e^{-d(x,y)^2/(4+\varepsilon)t}. \tag{37}$$

Since $\mathbb{S}^2$ satisfies the above-noted conditions as a particular case, this corollary can be applied to it as well. On the other hand, we have a different purpose from the original corollary of the theorem for the estimates on the upper bound of the heat kernel, in which the sharp estimate for the heat kernel is found. Instead, we are trying to find a best lower bound of the ground state energy of the system. Therefore, we shall modify the original corollary in Ref. 24. Using this theorem with relaxed condition $0<\varepsilon<1$, we have found the upper bound estimate for heat kernel of sphere $\mathbb{S}^2$ in our problem:

$$K_t(a_i,a_j) \leqslant \frac{C'(\delta)}{\sqrt{V\left(x,\sqrt{\frac{\hbar t}{2m}}\right)V\left(y,\sqrt{\frac{\hbar t}{2m}}\right)}} e^{-2md_{ij}^2/D(\delta)\hbar t}, \tag{38}$$

where

$$C'(\delta) \equiv (1+\delta)^2 \exp\left[\frac{1}{4\delta(1+\delta)(1+2\delta)} + \frac{1}{2\delta(2+\delta)} + \frac{1}{4\delta}\right], \tag{39}$$

and

$$D(\delta) \equiv 4(1+2\delta)(1+\delta)^2, \tag{40}$$

δ is merely required to be positive. When we want to find a lower bound for the energy, the numerical values of the coefficients $C'(\delta)$ and $D(\delta)$ will be determined explicitly. It is easy to see that $V(x,\sqrt{\hbar t/2m})=V(y,\sqrt{\hbar t/2m})=2\pi R^2(1-\cos\sqrt{\hbar t/2mR^2})$ as long as $0\leqslant t\leqslant 2m\pi^2R^2/\hbar$. For $t \geqslant 2m\pi^2R^2/\hbar$, we have $V(x,\sqrt{\hbar t/2m})=V(y,\sqrt{\hbar t/2m})=4\pi R^2$. According to our corollary and positive definiteness of heat kernel, the following integral has an upper bound:

$$\frac{1}{\hbar}\int_0^\infty e^{-\nu^2 t/\hbar}K_t(a_i,a_j)\mathrm{d}t$$

$$\leqslant \frac{C'(\delta)}{\hbar}\int_0^{2m\pi^2R^2/\hbar}\frac{e^{-2md_{ij}^2/D(\delta)\hbar t-\nu^2 t/\hbar}}{2\pi R^2\left(1-\cos\sqrt{\dfrac{\hbar t}{2mR^2}}\right)}\mathrm{d}t+\frac{C'(\delta)}{4\pi R^2\hbar}\int_{2m\pi^2R^2/\hbar}^\infty e^{-2md_{ij}^2/D(\delta)\hbar t-\nu^2 t/\hbar}\mathrm{d}t,$$

where we have taken z as $-\nu^2$. With the help of the identity $1-\cos\sqrt{\hbar t/2mR^2}=2\sin^2\sqrt{\hbar t/8mR^2}$ and the inequality $1/\sin\theta\leqslant\pi/2\theta$ for $0\leqslant\theta\leqslant\pi/2$, we obtain

$$\frac{1}{\hbar}\int_0^\infty e^{-\nu^2 t/\hbar}K_t(a_i,a_j)\mathrm{d}t\leqslant\frac{m\pi C'(\delta)}{2\hbar^2}\int_0^\infty\frac{e^{-2md_{ij}^2/D(\delta)\hbar t-\nu^2 t/\hbar}}{t}\mathrm{d}t+\frac{C'(\delta)}{4\pi R^2\hbar}\int_0^\infty e^{-2md_{ij}^2/D(\delta)\hbar t-\nu^2 t/\hbar}\mathrm{d}t.$$

Evaluating these integrals, we find

$$|-\Phi_{i\neq j}(-\nu^2)|\equiv|\mathcal{K}_{ij}|=\frac{1}{\hbar}\int_0^\infty e^{-\nu^2 t/\hbar}K_t(a_i,a_j)\mathrm{d}t\leqslant C'(\delta)\left[\frac{m\pi}{\hbar^2}K_0(\alpha_{ij}\nu)+\frac{\alpha_{ij}}{4\pi}\frac{K_1(\alpha_{ij}\nu)}{\nu R^2}\right],$$

where

$$\alpha_{ij}\equiv\sqrt{\frac{8md_{ij}^2}{D(\delta)\hbar^2}}, \tag{41}$$

and $K_0(x)$, $K_1(x)$ are modified Bessel functions. This shows us that the infinite series in the nondiagonal part of the characteristic matrix is finite and bounded from above according to (41). In order to find a lower bound for the diagonal part, denoted by $\mathcal{D}$, of the matrix Φ for sphere $\mathbb{S}^2$, we first recall how the diagonal part of the matrix Φ appears in (36):

$$\mathcal{D}_i=\frac{1}{4\pi R^2}\lim_{\Lambda\to\infty}\left[\sum_{l=0}^{\Lambda}\frac{2l+1}{\dfrac{\hbar^2}{2mR^2}l(l+1)+\mu_i^2}-\sum_{l=0}^{\Lambda}\frac{2l+1}{\dfrac{\hbar^2}{2mR^2}l(l+1)+\nu^2}\right]\geqslant 0.$$

Instead of calculating explicitly this limit as we have done in Sec. III, we estimate a lower bound of it by means of integrals replaced by the sums as follows:

$$\mathcal{D}_i\geqslant\frac{1}{4\pi R^2}\lim_{\Lambda\to\infty}\left[\int_0^{\Lambda+1}\frac{2t+1}{\dfrac{\hbar^2}{2mR^2}t(t+1)+\mu_i^2}\mathrm{d}t-\int_0^{\Lambda}\frac{2t+1}{\dfrac{\hbar^2}{2mR^2}t(t+1)+\nu^2}\mathrm{d}t-\frac{1}{\nu^2}\right].$$

After taking the limit we find

$$\mathcal{D}_i\geqslant\left[\frac{m}{\pi\hbar^2}\log(\nu/\mu_i)-\frac{1}{4\pi R^2\nu^2}\right], \tag{42}$$

and using the estimate for logarithmic functions in Ref. 25

$$\log x > \frac{x-1}{x} \quad \text{for } x > 0,\ x \neq 1, \tag{43}$$

we obtain

$$\mathcal{D}_i \geqslant \left[\frac{m}{\pi\hbar^2} \log(\nu/\mu_i) - \frac{1}{4\pi R^2 \nu^2} \right] > \left[\frac{m}{\pi\hbar^2} - \frac{m\mu_i}{\pi\hbar^2 \nu} - \frac{1}{4\pi R^2 \nu^2} \right] > 0. \tag{44}$$

For positive definiteness, we have assumed ν is sufficiently large, which is not a particularly restrictive condition. In fact, one can try to find sharper estimates by means of the integral representations of digamma functions (33) and (34) without this assumption. However, the estimated functions in this case are too complicated to suggest a bound for ground state energy.

A well-known theorem in matrix analysis, called Geršgorin Theorem,[26] states that all the eigenvalues λ_i of the renormalized matrix Φ are located in the union of N discs

$$\bigcup_{i=1}^{N} \{|\lambda_i - \Phi_{ii}| \leqslant R_i'(\Phi)\} \equiv G(\Phi), \tag{45}$$

where $R_i'(\Phi) \equiv \Sigma_{i\neq j=1}^{N} |\Phi_{ij}|$ and $1 \leqslant i \leqslant N$. If we want $\lambda = 0$ not to be an eigenvalue, then none of the discs should contain $\lambda = 0$. Then, we should impose

$$|-\mathcal{D}_i(\nu)| > \sum_{i\neq j}^{N} |\mathcal{K}_{ij}(\nu)|, \tag{46}$$

for all i. This is possible for a critical value $\nu > \nu^*$ since the left-hand side is an increasing function of ν and the right-hand side is a decreasing function of it for a given d and N. In fact, this inequality obviously provides a lower bound for the bound state energy by just plotting the functions on both sides in spite of how complicated the form of functions are. However, we shall try to find an explicit expression for the lower bound of the ground state energy depending on the number of delta interactions. In order to achieve this, we choose ν such that

$$|-\mathcal{D}_i(\nu)| > \left[\frac{m}{\pi\hbar^2} - \frac{m\mu_i}{\pi\hbar^2 \nu} - \frac{1}{4\pi R^2 \nu^2} \right],$$

$$(N-1)C'(\delta) \left[\frac{m\pi}{\hbar^2} K_0(\alpha\nu) + \frac{\alpha}{4\pi} \frac{K_1(\alpha\nu)}{\nu R^2} \right] > \sum_{i\neq j}^{N} |\mathcal{K}_{ij}(\nu)|, \tag{47}$$

where we have used the monotonic behavior of the functions in $\mathcal{D}_{ij}$ and $\mathcal{K}_{ij}$ and defined $\mu \equiv \max_i \mu_i$ and $\alpha \equiv \min_{i\neq j} \alpha_{ij}$ or $d \equiv \min_{i\neq j} d_{ij}$. From the integral representations of the Bessel functions for $z \in \mathbb{R}^+$,[27]

$$K_0(z) = \int_0^\infty e^{-z \cosh t} dt,$$

$$K_1(z) = z \int_0^\infty e^{-z \cosh t} \sinh^2 t dt,$$

and using the inequalities $e^t/2 < \cosh t$, $\sinh^2 t < e^{2t}/4$ for all $t \in \mathbb{R}^+$, we can find the upper bounds for the functions K_0 and K_1,

$$K_0(\alpha\nu) < \frac{2e^{-\alpha\nu/2}}{\alpha\nu},$$

$$K_1(\alpha\nu) < e^{-\alpha\nu/2}\left(\frac{1}{\alpha\nu}+\frac{1}{2}\right), \tag{48}$$

where $\alpha\nu \in \mathbb{R}^+$. Considering the estimated bounds for Bessel functions, it is easy to see that

$$\frac{m}{\pi\hbar^2}(N-1)C'(\delta)\left[\frac{2\pi^2 e^{-\alpha\nu/2}}{\alpha\nu}+\frac{e^{-\alpha\nu/2}\mu_R^2}{2\nu^2}+\frac{e^{-\alpha\nu/2}\mu_R^2\alpha}{4\nu}\right]$$
$$> (N-1)C'(\delta)\left[\frac{m\pi}{\hbar^2}K_0(\alpha\nu)+\frac{\alpha}{4\pi}\frac{K_1(\alpha\nu)}{\nu R^2}\right].$$

Using the argument $\nu > \sqrt{2}\mu_R$ in Eq. (44) and the last inequality, we impose the following inequality with the help of the Geršgorin Theorem:

$$\nu > \mu + \frac{\mu_R}{2\sqrt{2}} + (N-1)C'(\delta)e^{-\alpha\nu/2}\left[\frac{2\pi^2}{\alpha}+\frac{\mu_R}{2\sqrt{2}}+\frac{\mu_R^2\alpha}{4}\right]. \tag{49}$$

Let us make the following reasonable assumptions and take these for granted for the present (we will later show that they indeed satisfy these conditions by finding the extremum of ground state energy with respect to the parameter δ)

$$\frac{\mu_R^2\alpha}{4} < \frac{2\pi^2}{\alpha}, \tag{50}$$

$$\frac{\mu_R}{2\sqrt{2}} < \frac{2\pi^2}{\alpha}, \tag{51}$$

$$\frac{1}{\sqrt{D(\delta)}} > \frac{1}{5}, \tag{52}$$

so that the inequality becomes

$$\nu > \mu + \frac{\mu_R}{2\sqrt{2}} + 3\pi^2\mu_d(N-1)C'(\delta)\sqrt{D(\delta)}e^{-\nu/5\mu_d}, \tag{53}$$

from which we conclude that there exists a critical value $\nu > \nu^*$ for a given N such that $\lambda \neq 0$ and then the ground state energy cannot be less than $-\nu^{*2}$:

$$E_{\mathrm{gr}} \geqslant -\nu^{*2} = -\left\{\mu + \frac{\mu_R}{2\sqrt{2}} + 5\mu_d W\left[\frac{3\pi^2}{5}C'(\delta)\sqrt{D(\delta)}(N-1)e^{-(\mu+\mu_R/2\sqrt{2})/5\mu_d}\right]\right\}^2, \tag{54}$$

where W is the Lambert W function, also called the Omega function or product-log function.[28] Now, we choose δ in such a way that the energy bound takes its minimum value. This is accomplished if δ is chosen approximately 0.508, which is independent of the parameters in the problem. This independence can be easily realized from the form of inequality (53). By substituting the values of $C'(\delta)$ and $D(\delta)$, we estimate a lower bound for the ground state energy:

$$E_{\mathrm{gr}} \geqslant -\nu^{*2} = -\left\{\mu + \frac{\mu_R}{2\sqrt{2}} + 5\mu_d W\left[28\pi^2(N-1)e^{-(\mu+\mu_R/2\sqrt{2})/5\mu_d}\right]\right\}^2. \tag{55}$$

By using this value of δ and the fact that $d < 2\pi R$, the consistency of the assumption we made can be shown easily. Finally, we shall consider the large N behavior of the ground state energy. The asymptotic expansion of product-log function W[28] for large z is given as

$$W(z) \sim \log z - \log\log z. \tag{56}$$

Hence, this leads to

$$E_{\mathrm{gr}} \sim -\mu_d^2[\log(N) - \log\log(N)]^2. \tag{57}$$

The method we have introduced for the two-dimensional sphere $\mathbb{S}^2$ can also be applied to a general compact manifold. The main idea is based on finding an upper and lower bound for the characteristic matrix or heat kernel (based on the work by Li and Yau). Then, Geršgorin theorem allows us to estimate a lower bound for the ground state energy.

IV. FINITELY MANY DIRAC-DELTA INTERACTIONS ON HYPERBOLIC SPACES

The hyperbolic space $\mathbb{H}^n$ is defined as maximally symmetric and simply connected complete n-dimensional Riemannian manifold with a constant negative sectional curvature $-1/R$, which is also in some sense considered to be the negative curvature analog of the sphere $\mathbb{S}^n$. We shall deal with the delta interactions on the hyperbolic spaces $\mathbb{H}^3$ and $\mathbb{H}^2$ in the following sections. The method developed in the previous sections for $\mathbb{S}^2$ will be useful as well for the hyperbolic spaces. The heat kernel on hyperbolic spaces,[29] written in terms of dimensionless quantities:

$$K_t(x,y) = \frac{1}{(4\pi t)^{3/2}} \frac{d}{\sinh d} e^{-t-d^2/4t} \quad \text{on } \mathbb{H}^3,$$

$$K_t(x,y) = \frac{\sqrt{2}}{(4\pi t)^{3/2}} e^{-t/4} \int_d^\infty \frac{s e^{-s^2/4t}}{(\cosh s - \cosh d)^{1/2}} \mathrm{d}s \quad \text{on } \mathbb{H}^2, \tag{58}$$

where $d \equiv \mathrm{dist}(x,y)$, geodesic distance between two points x and y on $\mathbb{H}^n$.

Although spectral theorem and asymptotic expansion of heat kernel discussed in the previous sections may not be valid for general noncompact manifolds, we shall demonstrate that for the specific examples in noncompact manifolds, such as $\mathbb{H}^2$ and $\mathbb{H}^3$, our viewpoint still works. It would be desirable to show the equivalence between the eigenfunction expansion and the heat kernel method for the regularization in noncompact manifolds rigourously. Nevertheless, we have not been able to do this. The main idea is similar in spirit to the renormalization procedure introduced for the compact manifolds.

A. Finitely many Dirac-delta interactions on hyperbolic space $\mathbb{H}^3$

In the hyperbolic space $\mathbb{H}^3 = \{x \in \mathbb{R}^3 \,|\, x_3 > 0\}$, the geodesic distance d is defined as

$$\cosh \frac{d(x,y)}{R} = 1 + \frac{|x-y|^2}{2x_3 y_3},$$

where R is the scaling parameter. The Schrödinger equation for the bound states of a particle living on $\mathbb{H}^3$ under the influence of N attractive delta interactions is

$$\left[\frac{\hbar^2}{2m} \Delta_{\mathbb{H}^3} - \sum_{i=1}^{N} g_i \delta^3(\chi - \chi_i, \theta - \theta_i, \phi - \phi_i) \right] \psi = -\nu^2 \psi, \tag{59}$$

where Laplacian $\Delta_{\mathbb{H}^3}$ in polar coordinates (χ, θ, ϕ),

$$\Delta_{\mathbb{H}^3} = -\frac{1}{R^3} \frac{\partial^2}{\partial \psi^2} - \frac{2\coth\psi}{R^3} \frac{\partial}{\partial \psi} + \frac{1}{R \sinh^2 \psi} \Delta_{\mathbb{S}^2}. \tag{60}$$

We have an explicit formula[29] for the heat kernel of the three-dimensional hyperbolic plane $\mathbb{H}^3$ written by using physical constants

$$K_t(x,y) = \frac{1}{R^3} \frac{\frac{d(x,y)}{R}}{\left(4\pi\left[\frac{\hbar}{2mR^2}\right]t\right)^{3/2} \sinh\frac{d(x,y)}{R}} \exp\left(-\frac{\hbar t}{2mR^2} - \frac{md(x,y)^2}{2\hbar t}\right) \tag{61}$$

such that as $R\to\infty$, we can obtain the heat kernel on $\mathbb{R}^3$. Hence we have the free resolvent kernel as

$$\begin{aligned}\langle a_i|(H_0-z)^{-1}|a_j\rangle &= \frac{1}{\hbar R^3}\int_0^\infty \frac{\frac{d_{ij}}{R}\exp\left(\frac{zt}{\hbar}-\frac{\hbar t}{2mR^2}-\frac{md_{ij}^2}{2\hbar t}\right)}{\left(4\pi\left[\frac{\hbar}{2mR^2}\right]t\right)^{3/2}\sinh\frac{d_{ij}}{R}}\mathrm{d}t \\ &= \left[\frac{1}{4\pi R^3}\frac{\frac{d_{ij}}{R}}{\sinh\frac{d_{ij}}{R}}\exp\left(-\frac{\mu_R}{\mu_{d_{ij}}}\sqrt{1-\frac{z}{\mu_R^2}}\right)\right]\frac{\mu_{d_{ij}}}{\mu_R^3},\end{aligned} \tag{62}$$

where $d_{ij}\equiv d(a_i,a_j)$, $\mu_R^2\equiv\hbar^2/2mR^2$, $\mu_{d_{ij}}^2\equiv\hbar^2/2md_{ij}^2$. It follows easily that this term gives infinity when $i=j$, that is, the diagonal term in the characteristic matrix is divergent. Then, we can now proceed to the regularization and renormalization schemes analogously for the hyperbolic spaces. However, the divergence in hyperbolic space $\mathbb{H}^3$ is due to fact that the lower bound t of integral (62) is zero. Hence we regularize the divergent term by introducing a lower cut-off ϵ, as we have shown in Sec. II and we expect this should in some way be related to the ultraviolet regularization. We next define the coupling constant as a function of this cut-off:

$$\Phi_{ii}(z) = \lim_{\epsilon\to 0^+}\left[g_i^{-1}(\epsilon) - \frac{1}{(4\pi)^{3/2}\mu_R^2R^3}\int_\epsilon^\infty u^{-3/2}e^{-[1-z/\mu_R^2]u}\mathrm{d}u\right],$$

where the integration variable $u\equiv(\hbar^2/2mR^2)t$ is introduced for simplicity. The natural choice for $g_i^{-1}(\epsilon)$ is simply

$$g_i^{-1}(\epsilon) = \frac{1}{(4\pi)^{3/2}\mu_R^2R^3}\int_\epsilon^\infty u^{-3/2}e^{-[1+\mu_i^2/\mu_R^2]u}\mathrm{d}u,$$

where μ_i is an experimentally measured bound state energy for the single delta interaction and it helps us to keep track of the strength of point interactions. In $\epsilon\to 0^+$ limit, we have found the explicit renormalized characteristic matrix for $\mathbb{H}^3$,

$$\Phi_{ij}(z) = \frac{1}{4\pi}\frac{1}{\mu_R^2R^3}\begin{cases}\sqrt{1-\frac{z}{\mu_R^2}}-\sqrt{1+\frac{\mu_i^2}{\mu_R^2}} & \text{if } i=j \\ -\frac{\mu_{d_{ij}}}{\mu_R}\frac{\frac{d_{ij}}{R}}{\sinh\frac{d_{ij}}{R}}\exp\left(-\frac{\mu_R}{\mu_{d_{ij}}}\sqrt{1-\frac{z}{\mu_R^2}}\right) & \text{if } i\neq j.\end{cases} \tag{63}$$

Then, we have the resolvent equation (14) with the free resolvent kernel $R_0(x,y|z)$ for $\mathbb{H}^3$ given by

$$R_0(x,y|z)=\frac{1}{4\pi}\frac{1}{\mu_R^2R^3}\frac{\mu_{d(x,y)}}{\mu_R}\frac{\dfrac{d(x,y)}{R}}{\sinh\dfrac{d(x,y)}{R}}\exp\left(-\frac{\mu_R}{\mu_{d(x,y)}}\sqrt{1-\frac{z}{\mu_R^2}}\right), \tag{64}$$

from which we can get all information about the system. Using the Geršgorin Theorem (45) for this matrix, and following the same ideas introduced for $\mathbb{S}^2$ we obtain

$$\left[\sqrt{1+\frac{\nu^2}{\mu_R^2}}-\sqrt{1+\frac{\mu^2}{\mu_R^2}}\right]>(N-1)\frac{\mu_d}{\mu_R}\frac{d}{R\sinh\dfrac{d}{R}}\exp\left(-\frac{\mu_R}{\mu_d}\sqrt{1+\frac{\nu^2}{\mu_R^2}}\right),$$

where we have taken $z=-\nu^2$ and chosen $d\equiv\min_{i\neq j}d_{ij}$, and $\mu\equiv\max_i\mu_i$. It turns out that this inequality indicates that there exists a critical $\nu>\nu^*$ for a given d and N for which this inequality is satisfied and zero is not an eigenvalue. Therefore, the ground state energy cannot be less than $-\nu^{*2}$:

$$\begin{aligned}E_{\mathrm{gr}}\geqslant-\nu^{*2}=&-\mu^2-2\mu_d\sqrt{\mu_R^2+\mu^2}W\left[\frac{e^{-(\mu_R/\mu_d)\sqrt{1+\mu^2/\mu_R^2}d(N-1)}}{R\sinh\dfrac{d}{R}}\right]\\&-\mu_d^2W\left[\frac{e^{-(\mu_R/\mu_d)\sqrt{1+\mu^2/\mu_R^2}d(N-1)}}{R\sinh\dfrac{d}{R}}\right]^2.\end{aligned} \tag{65}$$

For the large N behavior of the ground state energy, the estimate becomes

$$E_{\mathrm{gr}}\sim-2\mu_d\sqrt{\mu_R^2+\mu^2}[\log N-\log\log N]-\mu_d^2[\log N-\log\log N]^2.$$

Now let us consider the two center case on the hyperbolic plane $\mathbb{H}^3$ and assume again that their strengths (or bound state energies of each center) are the same. In this way, determining equation ($\det\Phi=0$) becomes

$$\sqrt{1+\frac{\nu^2}{\mu_R^2}}-\sqrt{1+\frac{\mu^2}{\mu_R^2}}=\pm\frac{\mu_d}{\mu_R}\frac{\dfrac{d}{R}}{\sinh\dfrac{d}{R}}\exp\left(-\frac{\mu_R}{\mu_d}\sqrt{1+\frac{\nu^2}{\mu_R^2}}\right).$$

If we expand it for small d we have

$$\sqrt{1+\frac{\nu^2}{\mu_R^2}}-\sqrt{1+\frac{\mu^2}{\mu_R^2}}=\pm\frac{\mu_d}{\mu_R}\left[1-\sqrt{\frac{\mu_R^2}{\mu_d^2}+\frac{\nu^2}{\mu_d^2}}\right],$$

from which we can conclude

$$E_{\mathrm{gr}}=-\nu^2\simeq\frac{3}{4}\mu_R^2-\frac{\mu^2}{4}-\frac{\mu_d^2}{4}-\frac{\mu_d\mu_R}{2}\sqrt{1+\frac{\mu^2}{\mu_R^2}}.$$

Similarly, for large values of d, the right-hand side of the energy equation for two dirac delta interactions vanishes, so that we obtain the ground state energy $E_{\mathrm{gr}}=-\nu^2=-\mu^2$.

B. Finitely many Dirac-delta interactions on hyperbolic plane $\mathbb{H}^2$

The geodesic distance on the hyperbolic plane $\mathbb{H}^2$ is defined by

$$\cosh\frac{d(x,y)}{R}=1+\frac{|x-y|^2}{2x_2y_2},$$

where R is a scale distance. Then, the Schrödinger equation for the bound states of a particle living on $\mathbb{H}^2$ in the presence of N attractive delta interactions is

$$\left[\frac{\hbar^2}{2m}\Delta_{\mathbb{H}^2}-\sum_{i=1}^{N}g_i\delta^2(\theta-\theta_i,\phi-\phi_i)\right]\psi=-\nu^2\psi, \tag{66}$$

where the Laplacian $\Delta_{\mathbb{H}^2}$ in polar coordinates (θ,ϕ) is given by

$$\Delta_{\mathbb{H}^2}=-\frac{1}{R^2}\frac{\partial^2}{\partial\theta^2}-\frac{2\coth\theta}{R^2}\frac{\partial}{\partial\theta}-\frac{1}{R^2\sinh^2\theta}\frac{\partial^2}{\partial\phi^2}. \tag{67}$$

The heat kernel for $\mathbb{H}^2$ (Ref. 29) with the proper physical parameters is

$$K_t(x,y)=\frac{\sqrt{2}}{\left(4\pi\left[\frac{\hbar}{2mR^2}\right]t\right)^{3/2}}\frac{e^{-(\hbar/2mR^2)t/4}}{R^2}\int_{\frac{d(x,y)}{R}}^{\infty}\frac{re^{-(r^2/4)(2mR^2/\hbar)1/t}}{\sqrt{\cosh r-\cosh\frac{d(x,y)}{R}}}\mathrm{d}r. \tag{68}$$

One can check that this goes to the heat kernel on $\mathbb{R}^2$ as $R\to\infty$. Then, the free resolvent kernel is immediately obtained

$$\begin{aligned}\langle a_i|(H_0-z)^{-1}|a_j\rangle&=\frac{1}{\hbar R^2}\int_0^{\infty}e^{zt/\hbar}\frac{\sqrt{2}}{\left(4\pi\left[\frac{\hbar}{2mR^2}\right]t\right)^{3/2}}e^{-(\hbar/2mR^2)t/4}\left[\int_{d_{ij}/R}^{\infty}\frac{re^{-(r^2/4)(2mR^2/\hbar)1/t}}{\sqrt{\cosh r-\cosh\frac{d_{ij}}{R}}}\mathrm{d}r\right]\mathrm{d}t\\&=\frac{1}{4\pi\mu_R^2R^2}\int_{d_{ij}/R}^{\infty}\frac{e^{-(1/2)r\sqrt{1-4z/\mu_R^2}}}{\sqrt{\cosh r-\cosh\frac{d_{ij}}{R}}}\mathrm{d}r.\end{aligned}$$

We see that the diagonal term, which corresponds to $d_{ij}=0$, is divergent, as expected. Therefore we again repeat the similar regularization and renormalization procedure as we have done for $\mathbb{H}^3$. After introducing a cut-off to the lower limit of the integral

$$\begin{aligned}\Phi_{ii}(z)&=\lim_{\epsilon\to0^+}\left[g_i^{-1}(\epsilon)-\frac{1}{4\pi\mu_R^2R^2}\int_{\epsilon}^{\infty}\frac{e^{-(1/2)r\sqrt{1-4z/\mu_R^2}}}{\sqrt{\cosh r-1}}\mathrm{d}r\right]\\&=\lim_{\epsilon\to0^+}\left[g_i^{-1}(\epsilon)-\frac{\sqrt{2}}{4\pi\mu_R^2R^2}\int_{\epsilon/2}^{\infty}\frac{e^{-u\sqrt{1-4z/\mu_R^2}}}{\sinh u}\mathrm{d}u\right].\end{aligned}$$

and by the natural choice for $g_i^{-1}(\epsilon)$,

$$g_i^{-1}(\epsilon)=\frac{\sqrt{2}}{4\pi\mu_R^2R^2}\int_{\epsilon/2}^{\infty}\frac{e^{-u\sqrt{1+4\mu_i^2/\mu_R^2}}}{\sinh u}\mathrm{d}u,$$

we have obtained the renormalized characteristic matrix for $\mathbb{H}^2$ in the $\epsilon\to0$ limit,

$$\Phi_{ij}(z)=\frac{1}{4\pi R^2}\frac{1}{\mu_R^2}\begin{cases}\sqrt{2}\left[\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}-\frac{z}{\mu_R^2}}\right)-\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\mu_i^2}{\mu_R^2}}\right)\right] & \text{if } i=j\\ -\int_{\frac{d_{ij}}{R}}^{\infty}\frac{e^{-(1/2)r\sqrt{1-4z/\mu_R^2}}}{\sqrt{\cosh r-\cosh\frac{d_{ij}}{R}}}\mathrm{d}r & \text{if } i\neq j,\end{cases} \tag{69}$$

where ψ is the digamma function. Then, we have the resolvent equation (14) in which the free resolvent kernel $R_0(x,y|z)$ for $\mathbb{H}^2$ is given by

$$R_0(x,y|z)=\frac{1}{4\pi R^2}\frac{1}{\mu_R^2}\int_{d(x,y)/R}^{\infty}\frac{e^{-(1/2)r\sqrt{1-4z/\mu_R^2}}}{\sqrt{\cosh r-\cosh\frac{d(x,y)}{R}}}\mathrm{d}r. \tag{70}$$

The integral on the right-hand side is in fact one of the integral representations of the Legendre polynomials of second type[27]

$$\sqrt{2}Q_\lambda\left(\cosh\frac{d(x,y)}{R}\right)=\int_{d(x,y)/R}^{\infty}\frac{e^{-(\lambda+1/2)r}}{\sqrt{\cosh r-\cosh\frac{d(x,y)}{R}}}\mathrm{d}r, \tag{71}$$

which are defined for $\Re(\lambda)>-1$ and in our case $\Re(\lambda)=\Re\left(\frac{1}{2}\sqrt{1-4z/\mu_{R^2}}-1/2\right)>-1$. Therefore, the free resolvent in terms of Q_λ,

$$R_0(x,y|z)=\frac{1}{4\pi R^2}\frac{1}{\mu_R^2}\sqrt{2}Q_{1/2\sqrt{1-4z/\mu_{R^2}}-1/2}\left(\cosh\frac{d(x,y)}{R}\right). \tag{72}$$

Geršgorin theorem allows us to estimate the lower bound for the bound state energy as done for $\mathbb{S}^2$ and $\mathbb{H}^3$. In order not to have zero as an eigenvalue, we must have

$$\sqrt{2}\left[\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\nu^2}{\mu_R^2}}\right)-\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\mu_i^2}{\mu_R^2}}\right)\right]>\sum_{i\neq j}\int_{d_{ij}/R}^{\infty}\frac{e^{-(1/2)r\sqrt{1+4\nu^2/\mu_R^2}}}{\sqrt{\cosh r-\cosh d_{ij}/R}}\mathrm{d}r, \tag{73}$$

for all i and we have taken $z=-\nu^2$ and $\nu>\max_i\mu_i$. It is easy to see this inequality is satisfied for some values of ν because the left-hand side is an increasing function, whereas the right-hand side is a decreasing function of ν. However, it is not so easy to give an explicit estimate for ν by this inequality so we will estimate the functions on both sides. The inequality for the digamma functions[30]

$$\psi(x)>\log x-\frac{1}{x},\quad x>0, \tag{74}$$

which can be obtained from the integral representation (34), and $1/2+\sqrt{1/4+x^2}\geqslant x$ for all $x>0$ helps us that we can find the following inequality by assuming ν is sufficiently large,

$$\left[\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\nu^2}{\mu_R^2}}\right)-\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\mu_i^2}{\mu_R^2}}\right)\right]>\left[\log\frac{\nu}{\mu_R}-\frac{\mu_R}{\nu}-\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\mu_i^2}{\mu_R^2}}\right)\right]. \tag{75}$$

Since the right-hand side of Eq. (73) is $(N-1)\sqrt{2}Q_\lambda(\cosh d_{ij}/R)$ we can find an upper bound for this function, using another integral representation of the second type Legendre polynomials:[27]

$$Q_\lambda\left(\cosh\frac{d_{ij}}{R}\right)=\frac{1}{\Gamma(\lambda+1)}\int_0^\infty e^{-t\cosh d_{ij}/R}K_0\left(t\sinh\frac{d_{ij}}{R}\right)t^\lambda \mathrm{d}t, \tag{76}$$

where $\Im(d_{ij}/R)=0$ and $\lambda=\frac{1}{2}\sqrt{1+4\nu^2/\mu_R^2}-1/2$. Using the estimate for the function K_0 given in Eq. (48), we obtain

$$\sqrt{2}Q_\lambda\left(\cosh\frac{d_{ij}}{R}\right)<\frac{2\sqrt{2}}{\Gamma(\lambda+1)\sinh\dfrac{d_{ij}}{R}}\int_0^\infty e^{-t(\cosh d_{ij}/R+(1/2)\sinh d_{ij}/R)}t^{\lambda-1}\mathrm{d}t$$

and the right-hand side is just the gamma function, then the estimate becomes

$$\sqrt{2}Q_\lambda\left(\cosh\frac{d_{ij}}{R}\right)<\frac{2\sqrt{2}\Gamma(\lambda)}{\Gamma(\lambda+1)\left(\cosh\dfrac{d_{ij}}{R}+\dfrac{1}{2}\sinh\dfrac{d_{ij}}{R}\right)^\lambda\sinh\dfrac{d_{ij}}{R}}.$$

Using identity $\Gamma(\lambda+1)=\lambda\Gamma(\lambda)$ and the assumption $\nu/\mu_R>1$ and $\sqrt{1+4\nu^2/\mu_R^2}>2\nu/\mu_R$, we get

$$\begin{aligned}\sqrt{2}Q_\lambda\left(\cosh\frac{d_{ij}}{R}\right)&<\frac{4\sqrt{2}}{\left(\dfrac{2\nu}{\mu_R}-1\right)}\frac{1}{\left(\cosh\dfrac{d_{ij}}{R}+\dfrac{1}{2}\sinh\dfrac{d_{ij}}{R}\right)^\lambda\sinh\dfrac{d_{ij}}{R}}\\&<\frac{4\sqrt{2}}{\dfrac{\nu}{\mu_R}}\frac{e^{-(\nu/\mu_R-1/2)\log(\cosh d_{ij}/R+(1/2)\sinh d_{ij}/R)}}{\sinh\dfrac{d_{ij}}{R}}.\end{aligned} \tag{77}$$

Also, by choosing $d\equiv\min_{i\neq j}d_{ij}$ and $\mu\equiv\max_i\mu_i$, we easily find

$$\left[\log\frac{\nu}{\mu_R}-\frac{\mu_R}{\nu}-\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\mu_i^2}{\mu_R^2}}\right)\right]>\left[\log\frac{\nu}{\mu_R}-\frac{\mu_R}{\nu}-\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\mu^2}{\mu_R^2}}\right)\right], \tag{78}$$

and

$$\frac{e^{-(\nu/\mu_R-1/2)\log(\cosh d_{ij}/R+(1/2)\sinh d_{ij}/R)}}{\sinh\dfrac{d_{ij}}{R}}<\frac{e^{-(\nu/\mu_R-1/2)\log(\cosh d/R+(1/2)\sinh d/R)}}{\sinh\dfrac{d}{R}}. \tag{79}$$

Therefore, we impose

$$\left[\log\frac{\nu}{\mu_R}-\frac{\mu_R}{\nu}-\psi\left(\frac{1}{2}+\sqrt{\frac{1}{4}+\frac{\mu^2}{\mu_R^2}}\right)\right]>\frac{4(N-1)}{\dfrac{\nu}{\mu_R}}\frac{e^{-(\nu/\mu_R-1/2)\log(\cosh d/R+(1/2)\sinh d/R)}}{\sinh\dfrac{d}{R}}. \tag{80}$$

It is immediately seen that there exists a critical value $\nu>\nu^*$ for a given d and N for which this inequality is satisfied and zero is not an eigenvalue. The last inequality can be written as

$$e^{(\nu/\mu_R-1/2)\log(\cosh d/R+(1/2)\sinh d/R)}\left(\frac{\nu}{\mu_R}\log\left(\frac{\nu}{\mu_R e^{\psi(1/2+\sqrt{1/4+\mu^2/\mu_R^2})}}\right)-1\right)>\frac{4(N-1)}{\sinh\dfrac{d}{R}}.$$

If $\nu/\mu_R>e^{\psi(1/2+\sqrt{1/4+\mu^2/\mu_R^2})+1}$ (independent of N), then we have the lower bound of the ground state energy

$$E_{\mathrm{gr}} \geqslant -\nu^{*2} = -\mu_R^2 \left[\frac{A + W\left(\dfrac{4(N-1)Ae^{-A/2}}{\sinh \dfrac{d}{R}} \right)}{A} \right]^2, \tag{81}$$

where we define $A \equiv \log(\cosh d/R + (1/2)\sinh d/R)$ for simplicity of notation. For large values of N as long as the ratio μ/μ_R and d/R is finite, the behavior of the bound state energy is given by

$$E_{\mathrm{gr}} \sim -\mu_R^2 \left[\frac{\log N - \log\log N}{\log\left(\cosh \dfrac{d}{R} + \dfrac{1}{2} \sinh \dfrac{d}{R} \right)} \right]^2. \tag{82}$$

This problem again is an example of a certain kind of dimensional transmutation in nonrelativistic quantum mechanics. By dimensional analysis, the Hamiltonian of the system contains intrinsic energy scales $\hbar^2/md_{ij}^2$ and $\hbar^2/2mR^2$. However, after the renormalization, we obtain new parameters μ_i^2 with energy dimensions. Hence, the number of parameters we expect for the energy at the beginning has changed after the renormalization. As it happens in the $\mathbb{S}^2$ case, the delta potentials on $\mathbb{H}^2$ are an example of a generalized dimensional transmutation.

V. CONCLUSION

In this work, we studied a particle moving under the influence of N attractive Dirac delta interactions on some special Riemannian manifolds. We renormalized the problem and find a finite dimensional matrix Φ, called the characteristic matrix, by means of which a well-defined expression for the resolvent can be written. All the information about the bound states can be obtained from the characteristic matrix. The renormalization can be done by means of the heat kernel and this is equivalent to the sharp cut-off method for the eigenvalues of the Laplacian, in the case of compact manifolds. We have studied the problem on particular compact and noncompact manifolds, $\mathbb{S}^2$, $\mathbb{H}^2$, and $\mathbb{H}^3$ and we give explicit lower bound estimates on the bound state energies for each problem. Although we are concerned with particular manifolds, the basic idea for the renormalization can be applied also to general manifolds.

We present new techniques for finding anomaly-free sets of fermions. Although the anomaly cancellation conditions typically include cubic equations with integer variables that cannot be solved in general, we prove by construction that any chiral set of fermions can be embedded in a larger set of fermions which is chiral and anomaly-free. Applying these techniques to extensions of the standard model, we find anomaly-free models that have arbitrary quark and lepton charges under an additional U(1) gauge group. © *2006 American Institute of Physics.*

I. INTRODUCTION

Gauge symmetries successfully describe the electromagnetic, weak, and strong interactions of particle physics. Nevertheless, unitarity and renormalizability of the standard model do not necessarily follow from a classical invariance of the Lagrangian under $SU(3)_C \times SU(2)_W \times U(1)_Y$ gauge transformations: one-loop SU(N) and U(1) gauge anomalies must also be absent.[1–3]

In order to avoid these local gauge anomalies, the sum over triangle diagrams with gauge bosons as external lines and charged fermions running in the loops must vanish. As a consequence, the sums over loops with more external lines and over higher-order diagrams automatically vanish.[4,2] Similarly, the sum over triangle diagrams involving two gravitons and one U(1) gauge boson in the external lines must vanish, or else this mixed gravitational U(1) anomaly will also lead to an explicit breaking of the gauge symmetry by gravitational interactions (for a review see Ref. 5). Finally, the SU(2) gauge symmetry may suffer from a global gauge anomaly unless the number of Weyl fermion doublets is even.[6]

A remarkable property of all elementary fermions discovered so far is that they form a chiral set—none of them can have a gauge invariant mass term. The cancellation of anomalies within a chiral set of fermions is highly nontrivial. Given the observed $SU(3)_C \times SU(2)_W$ representations found in the standard model, the anomaly cancellation conditions are restrictive enough to uniquely determine the $U(1)_Y$ charges, assuming that not all of them are zero. More strikingly, the *minimal* anomaly-free chiral set of fermions charged under $SU(3)_C \times SU(2)_W \times U(1)_Y$ is exactly given by a standard model generation.[7] Therefore, anomaly cancellation provides an explanation for the fermion structure of the standard model which is an alternative to the explanation provided by grand unified theories where, for example, an entire standard model generation and right-handed neutrino can be embedded in a single, anomaly-free SO(10) representation—although it must be noted that many low energy hypercharge assignments are consistent with this embedding.[8]

Anomaly cancellation will constrain the charges of the standard model fermions under any newly discovered gauge groups, whether these groups follow from grand unification or not. Many models of physics beyond the standard model incorporate new gauge groups, and the couplings of

[a)]Electronic mail: pbatra@post.harvard.edu

the standard model fermions to the gauge bosons associated with these groups are completely determined by the spectrum of charges. It is therefore useful to have methods that allow finding, in general, sets of fermions which are anomaly free under arbitrary gauge groups. Since vector-like pairs of fermions do not contribute to these anomalies, a complete description of anomaly-free sets hinges only on the identification of all *chiral* anomaly-free sets.

Furthermore, if the chiral set of standard model fermions is charged under a new gauge group, anomaly cancellation usually dictates the presence of additional fermions. The complete set of fermions under the full gauge group would most likely be chiral. Imagine instead that the full theory was completely vector-like—after the breaking of the extended gauge symmetry to $SU(3)_C \times SU(2)_W \times U(1)_Y$, one would be left with both the observed standard model fields and a set of conjugate partners. To avoid mixing with the standard model fields, these conjugate partners should have large masses that proceed through electroweak symmetry breaking, which would induce too large corrections to electroweak observables.

In the case of SU(N) gauge groups, comprehensive lists of anomaly-free sets have been identified using numerical methods.[9] By contrast, anomaly-free sets of chiral fermions charged under a U(1) gauge group, or under direct products of gauge groups including at least one U(1) group, have been less thoroughly catalogued, despite the common appearance of extra U(1) groups in connection to flavor symmetry (see, e.g., Refs. 10 and 11), supersymmetry breaking (see, e.g., Ref. 12), neutrino masses,[13–17] and many other model building issues (see, e.g., Ref. 18). Many of these constructions depend on the existence of a chiral set of fermions.

If the quarks and leptons have arbitrary charges under a new U(1), then there are a number of gauge anomalies that need to be cancelled. Usually, this is achieved by the inclusion of additional fermions with carefully chosen charges. An alternative is available in the context of string theory, when the U(1) symmetry is spontaneously broken at a scale close to the string scale: the four-dimensional gauge anomalies associated with the U(1) can be cancelled by the Green–Schwartz mechanism.[19] The question of when can anomalies be cancelled by additional fermions has not been given a general answer. It is often stated, though, that there are cases where the anomalies can be cancelled *only* by the Green–Schwartz mechanism[20,10] (in these cases it is usually said that there is an "anomalous U(1)," albeit this is a misleading phrase).

In this paper we prove that any set of fermions with arbitrary charges under a gauge symmetry involving any number of non-Abelian and U(1) groups can be embedded in an anomaly-free chiral set that contains additional fermions—even when any ratio of charges is a rational number. This conclusion is far from obvious: it involves cubic Diophantine equations (i.e., cubic equations with integer solutions), which include for the case of three fermions the (in)famous Fermat's last theorem.

We focus on rational charges since such charges seem more natural, but more importantly, they solve a real problem: any U(1) gauge theory eventually hits a Landau pole unless it is embedded in a non-Abelian group, which is possible only if these fermions have commensurate charges. (i.e., rational up to a normalization of the gauge coupling).[21] Even in string theory the gauge charges appear to be commensurate, although we are not aware of a general proof of this statement.

In particular, we find that any "anomalous U(1)" that can be made nonanomalous by the Green–Schwartz mechanism can also be made nonanomalous by new fermions. More importantly, our theorem shows that it is possible to add new fermions such that the anomalies cancel for any charges of the standard model fermions under a new U(1). This is relevant for the experimental searches for Z' bosons,[22,23] because the Z' couplings to quarks and lentons are fixed, up to an overall normalization, by the U(1) charges.

In Sec. II we discuss U(1) gauge anomalies, and derive our main results. These results are then generalized to any gauge group in Secs. III and IV. In Sec. V we apply our results to the phenomenologically interesting case of a U(1) extension of the standard model gauge group. Our conclusions are presented in Sec. VI.

II. U(1) GAUGE ANOMALIES

Consider a set of n left-handed Weyl fermions with charges $z_i, i=1,\ldots,n$ under a U(1) gauge theory. The $[\mathrm{U}(1)]^3$ and mixed U(1)-gravitational anomaly cancellation conditions are given by

$$\sum_{i=1}^{n} z_i^3 = 0,$$

$$\sum_{i=1}^{n} z_i = 0. \tag{2.1}$$

We are interested in chiral sets, so the charges of the fermions must satisfy

$$z_i + z_j \neq 0 \tag{2.2}$$

for any i, j, and in particular $z_i \neq 0$. For $n \leqslant 4$, the first Eq. (2.1) can be easily solved once the constraint given by the second Eq. (2.1) is imposed, and the result is that all the fermions are vector-like, i.e., do not satisfy Eq. (2.2). Hence, at least five chiral fermions are needed to satisfy Eqs. (2.1).[14,16]

When the charges are arbitrary real numbers, it is evident that there are solutions to Eqs. (2.1) for any $n \geqslant 5$. In realistic physics theories, however, it is generally expected that the charges are rational numbers up to an overall normalization of the gauge coupling. The reason for that is that the U(1) gauge coupling increases with the energy, and the gauge theory appears to need a cutoff above which some new physics would have to soften the running of the gauge coupling. Typically, that new physics involves the embedding of the U(1) group in a non-Abelian gauge group, which guarantees that the ratio of U(1) charges are rational numbers. We will therefore concentrate on the case where the ratio of any two z_i charges is rational. Furthermore, the overall normalization of the U(1) charges is arbitrary, so we can take all z_i to be integers without loss of generality. For integer charges z_i, Eqs. (2.1) are equivalent to identifying the integer points in the intersection of a cubic hypersurface and a hyperplane in $\mathbb{R}^n$. The first Eq. (2.1) is a cubic Diophantine equation, and there are no known methods of solving it in general for a fixed but arbitrary value of n.

A. Construction of anomaly-free chiral sets

There is often a more straightforward problem that arises in model building: given a chiral set of fermions, which is anomalous, is it possible to include more fermions such that the larger set is chiral and anomaly free? To address this issue, we make the important observation that any fermion with integer charge z is part of the following anomaly-free set:

$$\left\{1 \times (z), \quad \frac{z}{6}(z^2-1) \times (-2), \quad \frac{z}{3}(z^2-4) \times (1)\right\}. \tag{2.3}$$

where the notation $p \times (x)$ means that there are $|p|$ left-handed fermions with charge $\pm x$, the + and − signs corresponding to $p>0$ and $p<0$, respectively. It is not surprising that the two anomaly conditions can be satisfied by two numbers, the numbers of fields of charge 1 and −2. What is nontrivial is that the coefficients p are always integers for any integer z, as a physical number of fields must be. Since fermions with charge ±1, ±2 are central to this construction, we call them basic charges for U(1). If z is one of the basic charges, then the set is vector-like. Otherwise, the set is chiral.

Given a chiral set of charges $S=\{z_i, i=1,\ldots,n\}$ that may not be anomaly free, we construct a chiral anomaly free set that consists only of charges in S and, for each one, the appropriate number of fermions with the basic charges, ±1 and ±2, as in Eq. (2.3). If some of the charges in S are themselves basic charges, then we must initially rescale all charges so this is no longer the case. In many cases the resulting anomaly-free set will still contain some vector-like pairs of ±1 and ±2,

TABLE I. Anomaly-free chiral sets with $n=5,\ldots,9$ integer charges.

Number of fermions	Charges
5	{1,5,−7,−8,9}
	{2,4,−7,−9,10}
6	{1,1,1,−4,−4,5}
	{−1,2,3,−5,−5,6}
7	{1,2,2,−3,−3,−3,4}
	{−1,−1,3,4,−6,−6,7}
	{1,3,−4,5,−6,−6,7}
	{2,3,3,−4,−5,−6,7}
8	{1,1,2,3,−4,−4,−5,6}
	{2,2,2,2,−5,−5,−5,7}
9	{2,2,2,−3,−3,4,−5,−5,6}
	{1,1,1,2,−4,5,−7,−9,10}
	{1,−3,4,5,5,−6,−7,−9,10}

so the final step is to remove all such pairs. This completes our proof by construction that *for any chiral set of charges S there is a larger set which includes S and is chiral and anomaly free.*

B. Anomaly-free chiral sets with a small number of fermions

The above successful construction of chiral, anomaly-free sets often requires a disturbingly large number of basic charges. We now discuss methods for obtaining smaller sets of fermions which have the advantage of pushing the Landau pole to higher energies.

First, to show that smaller sets are even possible, let us first observe that *for any number* $n \geqslant 5$ *of chiral fermions there is a chiral set of* $U(1)$ *charges that is anomaly free.* To prove this statement it is sufficient to show that there is a chiral set for each $n=5,\ldots,9$. An anomaly-free chiral set with arbitrary $n \geqslant 10$ can always be constructed using linear combinations of chiral sets with $n=5,\ldots,9$. In Table I we show anomaly-free chiral sets with $n=5,\ldots,9$ integer charges that have the maximum charge, chosen to be positive, as small as possible (we include all sets with the two smallest values of the maximum charge).

To reduce the numbers of fermions in a set S we again rely on the construction of Eq. (2.3). Just as the anomaly contribution from a single charge z can be cancelled by the prescribed number of fields with charges $+1$ and -2, the reverse is also true: the anomaly contribution from a number of fields of charges $+1$ and -2 can be cancelled off by a single charge z'. In this way, large numbers of basic charges are exchanged for a single fermion with a large charge.

The numerical techniques that can address the problem of finding small anomaly-free sets are defined on lattices. For our purposes, a lattice is any set of vectors in $\mathbb{R}^n$, that is closed under addition and subtraction (i.e., for any two vectors x, y in a lattice, both $x+y$ and $x-y$ are also in the lattice). Each axis of $\mathbb{R}^n$ represents a possible value of fermion charge, and the coordinates on an axis indicate the *number* of fermions with that charge. Negative coordinates correspond to positive numbers of fermions with the conjugate charge.

The set of chiral, anomaly-free sets forms a lattice, denoted L. For any chiral set X, let $V(X)$ denote the vectorization of X, which is the image of X in the space $\mathbb{R}^n$. For example, if X is the set $\{1,5,-7,-8,9\}$, we would define $V(X)$ to be the vector $[1,0,0,0,1,0,-1,-1,1,0,0,\ldots]$ corresponding to the fact that there is one fermion of charge 1, zero of charge 2, one of charge -7, etc. Let L denote the set of all such vectorizations $L=\{V(X)\,|\,X \text{ is chiral and anomaly free}\}$. We can add elements of L: for any two chiral, anomaly-free sets X and Y, the sum $V(X)+V(Y)$ corresponds to the anomaly-free chiral set that contains all the fermions in both X and Y, followed by the removal of all vector-like pairs. We can similarly subtract any two elements of L to find another element of L; therefore L is a lattice.

For a given z, the vectorization of the construction given in Eq. (2.3) is an element of L, which we call $C(z)$. $C(z)$ contains one fermion with charge z, and the needed number of basic charges to

satisfy the anomaly equations. The set $\{C(z_i)|z_i \in \pm 3,4,5,\ldots\}$ actually spans L: any element of L can be written, by construction, as a unique linear combination of the $C(z_i)$.

It follows that finding the smallest sets of anomaly-free chiral fermions is similar to finding the shortest vectors in L. This latter problem is called the "short vector problem" and has been studied extensively by mathematicians and computer scientists (for a review, see Ref. 24). An important distinction is that short vectors are here defined in terms of the ℓ^2 norm, which can differ from the ℓ^1 norm actually used to determine the number of fermions. Nevertheless, shortness in the ℓ^2 norm is a good approximation to shortness in the ℓ^1 norm, and sufficient for our purposes of finding small sets.

Even finding a vector which is at most $\sqrt{2}$ times as long as the shortest vector remains an nondeterministic polynomial (NP)-hard problem, i.e., at least as hard as any NP time problem.[25] This means that for very large numbers of fermions, it is impossible to have both accuracy and speed in an algorithm.

To set up the problem concretely, consider searching for an anomaly-free, chiral set with at most N fermions, whose maximum charge is m. A simple iterative approach over all possible numbers of fermions has a time complexity of the order of

$$2^{m-1}\frac{(N+m)!}{N!\,m!}. \tag{2.4}$$

Given a computing power of 10^{10} operations per second, it would take ~ 100 years to find the shortest solution for $N=30$, $m=20$. A better algorithm would be to search over all linear combinations of the basis vectors, $C(z_i)$. This has a time complexity of the order of

$$2^{m-3}\frac{(N+m-2)!}{N!\,(m-2)}, \tag{2.5}$$

and would take ~ 1 year for $N=30$, $m=20$.

Consider instead the Lenstra–Lenstra–Lovasz (LLL) algorithm,[26] readily available in mathematical packages, for attacking the shortest vector problem. The LLL algorithm requires as input the basis vectors $C(z_i)$ for $|z_i| < m$, and outputs a shorter, closer to orthogonal set of basis vectors that span the same lattice. The LLL algorithm has a time complexity of $\mathcal{O}(m^4 \log m)$, and takes $\sim 10^{-5}$ s for $m=20$. Note that this is polynomial in m instead of exponential, and does not involve the number of fermions N (this is possible because the solutions found using the LLL algorithm are by no means guaranteed to be minimal). In fact, they can be up to $2^{(m-1)/2}$ times larger than the minimal solutions. In practice, however, the solutions found are almost always reasonably short, and the significant decrease in time and ease of implementation make this approach worthwhile.

Since the LLL algorithm actually returns a new basis of short vectors which spans L, the algorithm can easily be adapted to solving another common problem in polynomial time: finding the shortest vector that contains a specific spectrum of fermion charges. Consider a specific set of charges $\{x_i\}$. To make the LLL algorithm handle this problem, we exchange the basis vectors $C(x_i)$ for the single basis vector $\Sigma_i C(x_i)$. The output basis set is guaranteed to include at least one short vector that includes the specified charges $\{x_i\}$.

Since we are interested in numbers of fermions that are not particularly large, it may eventually prove useful to adapt even exponential-time solutions to the shortest vector problem in order to identify anomaly-free sets. Although these solutions are exponential in m, a recent algorithm has a time complexity of order $\mathcal{O}(2^{m \log m})$, which take ~ 1 s for $m=20$.[24]

III. $U(1)_1 \times \cdots \times U(1)_m$

Now consider a set of fermions, $\psi_i, i=1,\ldots,n$, which are charged under $U(1)_1 \times \cdots \times U(1)_m$ gauge group. Let us denote the charges of ψ_i under $U(1)_a$, $a=1,\ldots,m$, by $z_{a,i}$. The

construction of anomaly-free sets will proceed as in the case of a single U(1): we will identify the number and structure of basic charges that are needed to cancel off the anomalies for any single fermion.

A. $m=2$

In the case of $U(1)_1 \times U(1)_2$ gauge group there are six types of anomalies: $[U(1)_1]^3$, mixed $U(1)_1$ gravitational, $[U(1)_2]^3$, mixed $U(1)_2$ gravitational, $[U(1)_1]^2 U(1)_2$, and $U(1)_1[U(1)_2]^2$. These anomalies cancel if and only if

$$\sum_{i=1}^{n} z_{1,i}^3 = \sum_{i=1}^{n} z_{1,i} = \sum_{i=1}^{n} z_{2,i}^3 = \sum_{i=1}^{n} z_{2,i} = \sum_{i=1}^{n} z_{1,i}^2 z_{2,i} = \sum_{i=1}^{n} z_{1,i} z_{2,i}^2 = 0. \tag{3.1}$$

A set of fermions is chiral with respect to $U(1)_1 \times U(1)_2$ if

$$z_{1,i} + z_{1,j} \neq 0 \quad \text{or} \quad z_{2,i} + z_{2,j} \neq 0, \tag{3.2}$$

for any i and j. Note that a chiral set with respect to $U(1)_1 \times U(1)_2$ may be chiral, partially vector-like, or entirely vector-like with respect to each of the individual U(1)s.

We now show that any set of fermions which is chiral with respect to $U(1)_1 \times U(1)_2$ can be embedded into an anomaly-free set of chiral fermions, as we showed in the previous section for a U(1) gauge theory. This follows from the fact that any fermion with integer charges (z_1, z_2), is part of the following anomaly-free set

$$\left\{ (z_1,z_2), \quad -\frac{z_1 z_2}{2}(z_1+z_2)\times(1,1), \quad -\frac{z_1 z_2}{2}(z_1-z_2)\times(-1,1), \quad -\frac{z_1}{6}(z_1^2-1)\times(2,0), \right.$$
$$\left. \frac{z_1}{3}(z_1^2+3z_2^2-4)\times(1,0), \quad -\frac{z_2}{6}(z_2^2-1)\times(0,2), \quad \frac{z_2}{3}(3z_1^2+z_2^2-4)\times(0,1) \right\} \tag{3.3}$$

where the notation $p\times(x_1,x_2)$ means that there are $|p|$ left-handed fermions with $U(1)_1 \times U(1)_2$ charges (x_1,x_2) for $p>0$, or $(-x_1,-x_2)$ for $p<0$. We now have 12 basic pairs of charges $\pm\{(1,1),(1,-1),(2,0),(1,0),(0,2),(0,1)\}$ that are needed to ensure anomaly cancellation. Note that the number of fermions with basic charges prescribed by Eq. (3.3) is automatically an integer. The proof for constructing an anomaly-free chiral set from any chiral set S proceeds exactly as in Sec. II A.

Finding small anomaly-free sets from this construction proceeds through a lattice construction similar to that of Sec. II B. With the larger gauge group $U(1)\times U(1)$, the only change we make is to make each axis of $\mathbb{R}^n$ correspond to a specific (z_1,z_2) charge, instead of a single U(1) charge z. This adaptation works for finding small anomaly-free sets for all of the other gauge groups considered in the remainder of this paper.

B. $m\geqslant 3$

In the case where the number of U(1) gauge groups is $m\geqslant 3$, there are $m(m^2+3m+8)/6$ equations that must be satisfied to ensure that the theory is anomaly free:

$$\sum_{i=1}^{n} z_{a,i} = \sum_{i=1}^{n} z_{a,i} z_{b,i} z_{c,i} = 0, \tag{3.4}$$

for any a, b, $c=1,\ldots,m$.

We construct anomaly-free chiral sets by showing that the anomalies of any fermion ψ_i can be cancelled by the anomalies of a set of additional chiral fermions, which is a generalization of the basic charges $\{(1,1),(1,-1),(2,0),(1,0),(0,2),(0,1)\}$ from Eq. (3.3).

Consider a fermion ψ with charges $(z_1,\ldots,z_m)$. Its $U(1)_a U(1)_b U(1)_c$ anomalies can be cancelled for any unequal a, b, $c=1,\ldots,m$ by a number $(-z_a z_b z_c)$ of fermions, labeled by χ_{abc}, a

TABLE II. Anomaly-free chiral set of charges under three U(1) groups.

Number of fermions	$U(1)_1$	$U(1)_2$	$U(1)_3$
1	z_1	z_2	z_3
$-z_1z_2z_3$	+1	+1	+1
$-z_1z_2(z_1+z_2-2z_3)/2$	+1	+1	0
$-z_1z_2(z_1-z_2)/2$	−1	+1	0
$-z_2z_3(z_2+z_3-2z_1)/2$	0	+1	+1
$-z_2z_3(z_2-z_3)/2$	0	−1	+1
$-z_3z_1(z_3+z_1-2z_2)/2$	+1	0	+1
$-z_3z_1(z_3-z_1)/2$	+1	0	−1
$-z_1(z_1^2-1)/6$	+2	0	0
$z_1(z_1^2-4)/3+z_1(z_2^2+z_3^2-z_2z_3)$	+1	0	0
$-z_2(z_2^2-1)/6$	0	+2	0
$z_2(z_2^2-4)/3+z_2(z_3^2+z_1^2-z_3z_1)$	0	+1	0
$-z_3(z_3^2-1)/6$	0	0	+2
$z_3(z_3^2-4)/3+z_3(z_1^2+z_2^2-z_1z_2)$	0	0	+1

$<b<c$, with charges $(+1,+1,+1)$ under $U(1)_a\times U(1)_b\times U(1)_c$ and charge 0 under all other groups. Then the $[U(1)_a]^2U(1)_b$ anomalies of ψ and χ_{abc} can be cancelled for any unequal $a,b=1,\ldots,m$ by a set of fermions composed of N_{ab}^{ω} fermions, labeled by $\omega_{ab}, a<b$, with charges $(+1,+1)$ under $U(1)_a\times U(1)_b$ and charge 0 under all other groups, $N_{ab}^{\omega\prime}$ fermions, labeled by $\omega'_{ab}, a<b$, with charges $(-1,+1)$ under $U(1)_a\times U(1)_b$ and charge 0 under all other groups, where

$$N_{ab}^{\omega}=z_az_b\left[\sum_{c=1}^{m}z_c-\frac{3}{2}(z_a+z_b)\right],$$

$$N_{ab}^{\omega\prime}=-\frac{1}{2}z_az_b(z_a-z_b). \tag{3.5}$$

The remaining $[U(1)_a]^3$ and mixed $U(1)_a$ gravitational anomalies can be cancelled for any $a=1,\ldots,m$ by a set of fermions composed of N_a^{ξ} fermions, labeled by ξ_a, with charges +2 under $U(1)_a$ and charge 0 under all other groups, and $N_a^{\xi\prime}$ fermions, labeled by ξ'_a, with charges +1 under $U(1)_a$ and charge 0 under all other groups, where

$$N_a^{\xi}=-\frac{1}{6}z_a(z_a^2-1),$$

$$N_a^{\xi\prime}=\frac{1}{3}z_a(z_a^2-4)+z_a\sum_{b\neq a}\left(z_b^2-z_b\sum_{c\neq a,c>b}z_c\right). \tag{3.6}$$

Therefore, we have constructed an anomaly-free chiral set that includes a fermion ψ of arbitrary charges $(z_1,\ldots,z_m)$

$$\left\{\psi,\quad -z_az_bz_c\times(\chi_{abc}),\quad N_{ab}^{\omega}\times(\omega_{ab}),\quad N_{ab}^{\omega\prime}\times(\omega'_{ab}),\quad N_a^{\xi}\times(\xi_a),\quad N_a^{\xi\prime}\times(\xi'_a)\right\} \tag{3.7}$$

In Table II we show the charges in the particular case $m=3$. Here, the basic charges are the fields χ,ω,ξ.

The proof for constructing an anomaly-free chiral set S' from any set chiral set S proceeds exactly as in Sec. II A.

IV. GENERALIZATION TO ANY GAUGE GROUP

We now extend our results to $G\times U(1)$ gauge groups, where G is any non-Abelian group. Consider a set of chiral fermions ψ_i, $i=1,\ldots,n$, whose charges are (R_i,z_i) under $G\times U(1)$. R_i are some irreducible representations of G. In addition to the $U(1)$ and $U(1)^3$ anomalies, the G^3 and $G^2U(1)$ anomalies also must cancel (all other mixed anomalies are zero). The G^3 anomaly is given by

$$A_{GGG}=\sum_i A(R_i), \tag{4.1}$$

where the anomaly of R_i, $A(R_i)$, is defined by

$$\mathrm{Tr}\big(\{T^a(R_i),T^b(R_i)\}T^c(R_i)\big)=\tfrac{1}{2}A(R_i)d^{abc}. \tag{4.2}$$

The totally symmetric tensor d^{abc} is determined by the anticommutation relation among the group generators $T^a(R_i)$. The $G^2U(1)$ anomaly is given by

$$A_{GG1}=\sum_i C(R_i)z_i, \tag{4.3}$$

where the Casimir of R_i, $C(R_i)$, is defined by

$$\mathrm{Tr}\big(T^a(R_i)T^b(R_i)\big)=\delta_{ab}C(R_i). \tag{4.4}$$

Finally, the $U(1)$ and $U(1)^3$ anomalies take the following form up to an overall normalization:

$$A_{1GG}=\sum_i d(R_i)z_i,$$

$$A_{111}=\sum_i d(R_i)z_i^3, \tag{4.5}$$

where $d(R_i)$ is the dimension of R_i. The set of fermions ψ_i is anomaly free if

$$A_{GGG}=A_{GG1}=A_{1gg}=A_{111}=0. \tag{4.6}$$

If any of these conditions is not satisfied, then we prove by construction that one can add more fermions such that the larger set is both chiral and anomaly free.

For each fermion with charges (R,z) with $z\neq 0$, we can construct an anomaly-free set

$$\left\{(R,z),\quad \frac{z}{6}(z^2-1)\times(R,-2),\quad \frac{z}{3}(z^2-4)\times(\overline{R},1),\quad \frac{1}{6}(z+1)(z+2)(z-3)\times(R,0)\right\}, \tag{4.7}$$

where $\overline{R}$ is the conjugate of R: $A(\overline{R})=-A(R)$, $C(\overline{R})=C(R)$, $d(\overline{R})=d(R)$. The notation $p\times(R,x)$ means that if $p\geqslant 0$ then there are p left-handed fermions with charge (R,x), while if $p<0$ then there are $-p$ left-handed fermions with charge $(\overline{R},-x)$. The additional fermions with charge $(R,0)$ are included to make the entire set vector-like under the G group. We have chosen a basis that is easy to write down explicitly, but in many cases is larger than necessary—one could instead make some of the $(R,1)$ fermions into $(\overline{R},1)$ fermions and remove the appropriate number of $(R,0)$ fermions leaving at most one fermion with charge 0 under $U(1)$.

To render the entire set $\{\psi_i,i=1,\ldots,n\}$ anomaly free and chiral, we first rescale the z_i charges to be different than $+1$ and -2, add the fermions for each field ψ according to Eq. (4.7), then discard any remaining vector-like pairs. Note that if any of the z_i charges is zero, then one could

add other fermions which are neutral with respect to U(1) that belong to nontrivial representations of G such that the entire set is anomaly free and chiral [as done in Ref. 9 for the case where $G=\mathrm{SU}(N)$].

Typically, the total number of additional fermions can be further reduced if instead of fermions transforming nontrivially under G we add some fermions which are singlets (belong to the 1 representation of G). For example, consider the case where the set $\{\psi_i, i=1,\ldots,n\}$ is anomaly free with respect to the non-Abelian group $G(A_{GGG}=0)$. In order to cancel the $G^2\mathrm{U}(1)$ anomaly we could add two more fermions with charges (R,z) and $(\overline{R},z')$ such that

$$z+z'=-\frac{1}{C(R)}\sum_i C(R_i)z_i. \tag{4.8}$$

One may ensure that all the U(1) charges are integers by an appropriate rescaling. The U(1) and $\mathrm{U}(1)^3$ anomalies can be finally cancelled by including a number N_1 of fermions with charges $(1,+1)$, and a number N_2 of fermions with charges $(1,-2)$, as prescribed in Sec. II A

$$N_1=\frac{1}{3}\left\{\sum_i d(R_i)z_i(z_i^2-4)+d(R)[z(z^2-4)+z'(z'^2-4)]\right\},$$

$$N_2=\frac{1}{6}\left\{\sum_i d(R_i)z_i(z_i^2-1)+d(R)[z(z^2-1)+z'(z'^2-1)]\right\}. \tag{4.9}$$

The remarkable feature that enables this construction is that N_1 and N_2 are integers for any integer charges z, z', z_i.

This procedure can immediately be extended to groups of the form $G_1\times\ldots\times G_m\times\mathrm{U}(1)$, where G_i are non-Abelian gauge groups. For example, a single fermion ψ with charge $(R_i,\ldots,R_m,z)$ is part of the anomaly free set

$$\left\{(R_1,\ldots,R_m,z),\quad \frac{z}{6}(z^2-1)\times(R_1,\ldots,R_m,-2),\quad \frac{z}{3}(z^2-4)\times(\overline{R}_1,\ldots,\overline{R}_m,1),\right.$$
$$\left.\frac{1}{6}(z+1)(z+2)(z+3)\times(R_1,\ldots,R_m,0)\right\}. \tag{4.10}$$

To extend these results to arbitrary $G_1\times\ldots\times G_m\times\mathrm{U}(1)_1\times\ldots\times\mathrm{U}(1)_{m'}$ groups, one may simply use the coefficients and the set of fermions χ, ω, ω', ξ, ξ' described in Sec. III B in place of the single z charges written above.

V. U(1) EXTENSION OF THE STANDARD MODEL GAUGE GROUP

The results presented in the previous sections have various applications to physics beyond the standard model. In this section we study a particularly important application. The elementary fermions discovered in experiments so far, with charges under the $\mathrm{SU}(3)_C\times\mathrm{SU}(2)_W\times\mathrm{U}(1)_Y$ gauge group listed in Table III, may be charged under a new Abelian gauge group, $\mathrm{U}(1)_z$, provided this is spontaneously broken. The $\mathrm{U}(1)_z$ charges of these standard model fermions determine the relative couplings of the Z' boson [the heavy gauge boson associated with $\mathrm{U}(1)_z$], and therefore its experimental signatures.

The discovery of a Z' boson with couplings to the known fermions which are not proportional to hypercharge would imply the existence of certain additional fermions[27] or antisymmetric tensor fields in extra dimensions.[19] Here, as an application of our results, we show that *any* couplings of a Z' boson to the standard model fermions are allowed by anomaly cancellation if additional fermions are present. For simplicity, we concentrate on generation-independent couplings. The same method can be easily applied to generation-dependent couplings (in that case, though, there are stronger phenomenological constraints from flavor-changing neutral currents).[28,23]

TABLE III. Gauge charges of the Standard Model fermions in the presence of a new U(1) group. An index labeling the three generations is implicit.

	$SU(3)_C$	$SU(2)_W$	$U(1)_Y$	$U(1)_z$
q_L	3	2	$+1/3$	z_q
u_R	3	1	$-4/3$	z_u
d_R	3	1	$-2/3$	z_d
l_L	1	2	-1	z_l
e_R	1	1	-2	z_e

The $U(1)_z$ charges of the standard model fermions lead in general to six different gauge anomalies: $SU(3)_C^2U(1)_z$, $SU(2)_W^2U(1)_z$, $U(1)_Y^2U(1)_z$, $U(1)_YU(1)_z^2$, $U(1)_z^3$, and $U(1)_z$. It is imperative to ask whether these anomalies can all be cancelled simultaneously by including additional fermions. According to the prescription outlined in Sec. IV one can construct anomaly-free sets for any rational values of the $U(1)_z$ charges.

However, realistic extensions of the standard model need additional constraints to be satisfied. One constraint is that there are no new stable particles with fractional electric charges (for a review of experimental limits, see Ref. 29). To avoid fractional electric charges, we choose to introduce only fermions that transform under the standard model gauge group in the same representations (or the conjugated ones) as the observed fermions, or are not charged under the standard model gauge group. One could relax this restriction, for example, by including fermions with larger integer electric charges, but we will not need this freedom here.

Electroweak measurements restrict severely the number of new chiral fermions charged under $SU(2)_W$. In order to satisfy this constraint, we require the new fermions to be vector-like with respect to the $SU(3)_C \times SU(2)_W \times U(1)_Y$, but chiral with respect to $U(1)_z$. Another constraint is that both the standard model fermions and the new ones must have masses, so that some Yukawa-type couplings to Higgs fields need to be gauge invariant. For any specified Higgs sector, this leads to constraints on the $U(1)_z$ charges. However, one can keep the $U(1)_z$ charges of the fermions arbitrary and still give masses to all fermions by including a sufficient number of scalars with $U(1)_z$-breaking Vacuum Expectation Value (VEV)s that have higher-dimensional interactions with the fermions.

To allow for completely arbitrary charge for the standard model fields under the new $U(1)_z$, the spectrum of fields listed in Table IV suffice, although other choices are possible as long as

TABLE IV. New fermions which, together with the three standard model generations (see Table III), form an anomaly-free set. The charges under the new $U(1)_z$ gauge group are restricted by Eqs. (5.1) and (5.3), while N_1 and N_2 are given in Eq. (5.4)

	$SU(3)_C$	$SU(2)_W$	$U(1)_Y$	$U(1)_z$
ψ_L^l ψ_R^l	1	2	-1	z_L^l z_R^l
ψ_L^e ψ_R^e	1	1	-2	z_L^e z_R^e
ψ_L^d ψ_R^d	3	1	$\frac{2}{3}$	z_L^d z_R^d
$\nu_R^j, j=1,\ldots,N_1$	1	1	0	-1
$\nu_R'^k, k=1,\ldots,N_2$	1	1	0	$+2$

there is at least one fermion charged under SU(3), another one charged under $SU(2)_W$, and yet another one charged under $U(1)_Y$. We will eventually show that the anomaly cancellation conditions can be solved for arbitrary rational values of z_q, z_u, z_d, z_e, and z_l, as well as rational values of all other charges. Given the freedom in choosing the normalization of the gauge coupling, we can take z_q, z_u, z_d, z_e, and z_l to be integers. Our method of approach is to first impose that all of the anomalies cancel except for the $U(1)_z$ gravitational and $U(1)_z^3$ ones. Finding the $U(1)_z$ charges of the ψ fields requires solving three linear equations, corresponding to the $SU(3)_C^2U(1)_z$, $SU(2)_W^2U(1)_z$, and $U(1)_Y^2U(1)_z$ anomalies, and one quadratic equation, corresponding to the $U(1)_YU(1)_z^2$ anomaly. Note that if we can guarantee that the $U(1)_z$ values of all fields are still rational after having imposed these relations, then the $U(1)_z$ and $U(1)_z^3$ anomaly equations can be cancelled as described in Sec. II by adding the needed number of fields ν_R and ν_R'. The remaining anomaly conditions are not affected by the ν_R and ν_R' fields, so the most difficult part of satisfying the anomaly conditions, the cubic $U(1)_z^3$ equation, is removed from the process.

Notice that we have chosen some of the fermions in Tables III and IV to be right handed. Their contributions to the anomalies are the same as those of a left-handed fermion in the complex conjugated representation. The three linear equations due to the $SU(3)^2U(1)_z$, $SU(2)^2U(1)_z$, and $U(1)_Y^2U(1)_z$ anomalies constrain linear combinations of the charges of the new fields to be

$$z_L^d - z_R^d = -3(2z_q - z_u - z_d),$$

$$z_L^l - z_R^l = -3(3z_q + z_l),$$

$$z_L^e - z_R^e = 3(2z_q + z_u + z_e). \tag{5.1}$$

To proceed with the $U(1)_YU(1)_z^2$ anomaly cancellation condition, given by

$$(z_L^d)^2 - (z_R^d)^2 + (z_L^l)^2 - (z_R^l)^2 + (z_L^e)^2 - (z_R^e)^2 = 3(z_q^2 - 2z_u^2 + z_d^2 - z_l^2 + z_e^2), \tag{5.2}$$

we consider the particular case where the three remaining linear combinations of ψ charges can also be written as linear combinations of z_q, z_u, z_l, z_d, and z_e. This reduces the $U(1)_YU(1)_z^2$ anomaly equation to a linear equation in the unknown coefficients which has a three parameter solution for general values of z_q, z_u, z_l, z_d, and z_e. We find that the charges of the new fields are given by

$$z_L^d = \left(-2 - \frac{3}{2}a_2 + a_1\right)z_q + \left(1 + \frac{a_1}{2}\right)z_u + 2z_d - \frac{a_2}{2}z_l + \frac{a_1}{2}z_e,$$

$$z_L^l = (-6 + a_2 - a_3)z_q - \frac{1}{2}(a_2 + a_3)z_u - \frac{a_2}{2}z_d - z_l - \frac{a_3}{2}z_e,$$

$$z_L^e = \left(2 + a_1 - \frac{3}{2}a_3\right)z_q + \left(1 - \frac{a_1}{2}\right)z_u - \frac{a_1}{2}z_d - \frac{a_3}{2}z_l + 2z_e, \tag{5.3}$$

where a_1, a_2, and a_3 are arbitrary even integers.

To complete the proof, we add the necessary number of ν_R and ν_R' fields as described in Sec. II to cancel the $U(1)_z$ gravitational and $U(1)_z^3$ anomalies

$$N_1 = \frac{1}{3}\sum_f d_f z_f(z_f^2 - 4) = (z_L^d)^3 - (z_R^d)^3 + \frac{2}{3}[(z_L^l)^3 - (z_R^l)^3] + \frac{1}{3}[(z_L^e)^3 - (z_R^e)^3] + 6z_q^3 - 3z_u^3 - 3z_d^3 + 2z_l^3 - z_e^3 + 16z_q - 4z_u,$$

$$N_2 = \frac{1}{6}\sum_f d_f z_f(z_f^2 - 1) = \frac{1}{2}(N_1 - 12z_q + 3z_u), \tag{5.4}$$

where f runs over all fermions, z_f is the $U(1)_z$ charge of the fermion, and d_f is the dimensionality of the $SU(3)_C \times SU(2)_W$ representation times ± 1 for left-handed and right-handed fermions, respectively. We emphasize that Eqs. (5.4) yield integer values for N_1 and N_2 for any integers z_q, z_u, z_d, z_e, and z_l and the values of N_1 and N_2 can be reduced using the numerical methods of Sec. II B. Our construction shows that all couplings of a Z' boson to the standard model fermions are allowed by anomaly cancellation, as long as additional fermions are present.

For illustration, let us pick some simple $U(1)_z$ charges for the standard model fermions, $z_d = z_l = z_e = 0$ and $z_q = z_u = 1$, and compute the number of right-handed neutrinos in Table IV that need to be included in an anomaly-free set. We could use the freedom to choose a_1, a_2, and a_3 in order to minimize N_1 and N_2, but for this simple case we just take $a_1 = a_2 = a_3 = 0$. Therefore, the charges of the ψ fermions follow from Eqs. (5.3) and (5.2): $z_L^d = -1$, $z_R^d = 2$, $z_L^l = z_R^e = -6$, and $z_R^l = z_L^e = 3$. Equation (5.4) then gives $N_1 = -75$ and $N_2 = -42$, which means that there are 75 right-handed neutrinos of $U(1)_z$ charge $+1$ and 42 right-handed neutrinos of $U(1)_z$ charge -2. This large number of right-handed neutrinos can be substantially reduced using Eq. (2.3). For example, the set $\{42 \times (-2), 75 \times (+1)\}$ can be replaced by one of the following sets of five right-handed neutrinos: $\{2 \times (-5), 1 \times (-3), 2 \times (+2)\}$ or $\{1 \times (-6), 2 \times (-3), 1 \times (+2), 1 \times (+1)\}$.

VI. CONCLUSIONS

The need to embed new U(1) gauge groups in non-Abelian groups forces a focus on integer-valued charges, up to a possible rescaling of the gauge coupling constant. Our results show that anomaly cancellation in a gauge theory, while highly constraining, can occur for *any* set of integer fermion charges through the addition of new integer-charged fields. This is akin to gauging $U(1)_{B-L}$ in the standard model: one is forced to add a right-handed neutrino to prevent gauge anomalies from appearing. That such anomaly-free sets exist is obvious when one constructs vector-like sets, but highly nontrivial for chiral integer-valued sets.

The main result is presented in Sec. II A for fermions charged under a U(1) gauge group, and subsequently extended to any other gauge groups. The key observation is that there always exists a certain *integer* number of basic charges that can cancel off the anomaly from a single fermion. When the sets are large, the numerical techniques discussed in Sec. II B allow a quick reduction of the set size.

Our solution is a complete description of chiral anomaly-free sets for $U(1)^m$ gauge theories. For gauge groups that have additional non-Abelian factors $G_1 \times \ldots \times G_m \times U(1)^{m'}$ we have concentrated on chiral anomaly-free sets that include vector-like fermions with respect to some of the non-Abelian groups. This is sufficient to prove that any fermion can be included in a larger chiral set of fermions that is anomaly free. Nevertheless, it would be interesting to extend our results and find a complete description of anomaly-free sets under gauge groups of the form $G_1 \times \ldots \times G_m \times U(1)^{m'}$ which are chiral with respect to each of the G_i groups.

If a gauge extension of the standard model is discovered, then we have argued that the full spectrum of the new theory will still be chiral: a completely vector-like theory would leave behind both the observed standard model fermions *and* a set of conjugate partners after the extended gauge symmetry breaks to $SU(3)_C \times SU(2)_W \times U(1)_Y$, which is not phenomenologically acceptable. Therefore, our results should have applications to a variety of extensions of the standard model. In Sec. V we have presented a particular application: if the standard model gauge group is extended to include a new U(1) group, then the standard model fermions may have arbitrary rational charges under the new U(1) and still the anomalies would cancel in the presence of certain additional fermions with rational charges.

Exact analytical solution to the relativistic Klein-Gordon equation with noncentral equal scalar and vector potentials

F. Yasuk,[a] A. Durmus, and I. Boztosun
Department of Physics, Erciyes University, 38039 Kayseri, Turkey

(Received 24 January 2006; accepted 15 June 2006; published online 2 August 2006)

We present an alternative and simple method for the exact solution of the Klein-Gordon equation in the presence of the noncentral equal scalar and vector potentials by using Nikiforov-Uvarov method. The exact bound state energy eigenvalues and corresponding eigenfunctions are obtained for a particle bound in a potential of $V(r,\theta)=\alpha/r+\beta/(r^2\sin^2\theta)+\gamma\cos\theta/(r^2\sin^2\theta)$ type. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2227258]

I. INTRODUCTION

In nuclear and high energy physics, one of the interesting problems is to obtain exact solutions of the Klein-Gordon, Duffin-Kemmer-Petiau, and Dirac equations for mixed vector and scalar potentials. The Klein-Gordon, Dirac, and Duffin-Kemmer-Petiau wave equations are frequently used to describe the particle dynamics in relativistic quantum mechanics. In recent years, a great deal of effort has been spent to solve these relativistic wave equations for various potentials by using different methods. These relativistic equations contain two objects: the four-vector linear momentum operator and the scalar rest mass. They allow us to introduce two types of potential coupling, which are the four vector potential (V) and the space-time scalar potential (S).

The Klein-Gordon equation with the vector and scalar potentials can be written as follows:

$$\left[-\left(i\frac{\partial}{\partial t}-V(\vec{r})\right)^2-\vec{\nabla}^2+(S(\vec{r})+M)^2\right]\psi(\vec{r})=0. \tag{1}$$

For the case $S(\vec{r})=\pm V(\vec{r})$, the solution of the Klein-Gordon equation has been studied recently.[1,2] The exact solutions of these equations are possible only for certain potentials such as Coulomb, Morse, Pöschl-Teller, Hulthen, and harmonic oscillator, etc., by using different methods.[3] The other exactly solvable ones are the ring-shaped potentials introduced by Hartmann[4] and Quesne.[5] These potentials involve an attractive Coulomb potential with a repulsive inverse square potential one. In particular, the Coulombic ring-shaped potential[6] revived in quantum chemistry by Hartmann and co-workers[7] and the oscillatory ring-shaped potential, systematically studied by Quesne,[5] have been investigated from a quantum mechanical viewpoint by using various approaches. The special case of the potential in spherical coordinates is

$$V(r,\theta)=\frac{\alpha}{r}+\frac{\beta}{r^2\sin^2\theta}+\gamma\frac{\cos\theta}{r^2\sin^2\theta} \tag{2}$$

introduced by Makarov *et al.*[8] This potential can be used in quantum chemistry and nuclear physics to describe the ring-shaped molecules like benzene and the interactions between the deformed pairs of the nuclei.

[a]Electronic mail: yasuk@erciyes.edu.tr

In this paper, we introduce an alternative and simple method for the exact solution of the Klein-Gordon equation for the case where $S(\vec{r})=\pm V(\vec{r})$, considering a general angle dependent (noncentral) potential by using Nikiforov-Uvarov (NU) method.[9] This method is based on solving the second-order linear differential equations by reducing to a generalized equation of hypergeometric type.

The NU method is used to solve Schrödinger, Dirac, Klein-Gordon, and Duffin-Kemmer-Petiau wave equations in the presence of the exponential type potentials such as Woods-Saxon, Pöschl-Teller,[10] and Hulthen[11,12] and noncentral potential.[13] The aim of this study is to show that the NU method can be used to obtain exact solutions of noncentral potentials for Klein-Gordon equation. Thus, radial and angular parts of the Klein-Gordon equation with noncentral potential are solved by the NU method and it is seen that this method is applicable to noncentral type potential for relativistic wave equations.

In Sec. II, the Klein-Gordon equation with equal scalar and vector potentials is examined. In Sec. III, the Klein-Gordon equation in spherical coordinates for a particle in the presence of noncentral potential is separated into radial and angular parts. Section IV is devoted to a brief description of the NU method. Solutions of the radial and angular parts of the Klein-Gordon equation by using the NU method are presented in Sec. V. Finally, concluding remarks are given in Sec. VI.

II. KLEIN-GORDON EQUATION WITH EQUAL SCALAR AND VECTOR POTENTIALS

For the time-independent potentials we can write the total wave function as $\psi(\vec{r},t)=e^{-i\varepsilon t}\psi(\vec{r})$, where ε is the relativistic energy. The three-dimensional Klein-Gordon equation with the mixed vector and scalar potentials can be written as follows:

$$[\vec{\nabla}^2+(V(\vec{r})-\varepsilon)^2-(S(\vec{r})+M)^2]\psi(\vec{r})=0, \tag{3}$$

where M is the mass, ε is the energy, and $S(\vec{r})$ and $V(\vec{r})$ are the scalar and vectorial potentials, respectively. Now, if we take $S(\vec{r})=\pm V(\vec{r})$, the Klein-Gordon equation becomes

$$[\vec{\nabla}^2-2(\varepsilon\pm M)V(\vec{r})+\varepsilon^2-M^2]\psi(\vec{r})=0. \tag{4}$$

This equation describes a scalar particle, i.e., spin-0 particle. It is the Schrödinger equation for the potential $2V$ in the nonrelativistic limit. Thus, Alhaidari *et al.* conclude that only the choice $S=+V$ produces a nontrivial nonrelativistic limit with a potential function $2V$, and not V. Accordingly, it would be natural to scale the potential terms in Eq. (3) so that in the relativistic limit the interaction potential becomes V, not $2V$. Therefore, they modify Eq. (3) to read as follows:[1]

$$\left[\vec{\nabla}^2+\left(\tfrac{1}{2}V(\vec{r})-\varepsilon\right)^2-\left(\tfrac{1}{2}S(\vec{r})+M\right)^2\right]\psi(\vec{r})=0. \tag{5}$$

Thus, Eq. (4) is acquired as

$$[\vec{\nabla}^2-(\varepsilon\pm M)V(\vec{r})+\varepsilon^2-M^2]\psi(\vec{r})=0. \tag{6}$$

In Sec. III, for $S(\vec{r})=+V(\vec{r})$, if we take $V(\vec{r})$ as a general noncentral potential, the three-dimensional Klein-Gordon equation is separated into variables and the equation can be solved using the NU method.

III. SEPARATING VARIABLES OF THE KLEIN-GORDON EQUATION WITH NONCENTRAL POTENTIAL

In the spherical coordinates, the Klein-Gordon equation for a particle in the presence of a general noncentral potential $V(r,\theta)$ becomes

$$\left[\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial\varphi^2}-(\varepsilon+M)V(r,\theta)+\varepsilon^2-M^2\right]\psi(r,\theta,\varphi)=0, \tag{7}$$

where $V(r,\theta)$ is a general noncentral potential as given by Eq. (2). If one assigns the corresponding spherical total wave function as $\psi(r,\theta,\varphi)=(1/r)R(r)Y(\theta,\varphi)$, then by selecting $Y(\theta,\varphi)=\Theta(\theta)\Phi(\varphi)$, the wave equation (7) for a general noncentral potential is separated into variables and the following equations are obtained:

$$\left[\frac{\mathrm{d}^2}{\mathrm{d}r^2}-\frac{\lambda}{r^2}-(\varepsilon+M)\frac{\alpha}{r}+\varepsilon^2-M^2\right]R(r)=0, \tag{8}$$

$$\frac{\mathrm{d}^2\Theta(\theta)}{\mathrm{d}\theta^2}+\cot\theta\frac{\mathrm{d}\Theta(\theta)}{\mathrm{d}\theta}+\left[\lambda-\frac{m^2}{\sin^2\theta}-(\varepsilon+M)\left(\frac{\beta+\gamma\cos\theta}{\sin^2\theta}\right)\right]\Theta(\theta)=0, \tag{9}$$

$$\frac{\mathrm{d}^2\Phi(\varphi)}{\mathrm{d}\varphi^2}+m^2\Phi(\varphi)=0, \tag{10}$$

where m^2 and λ are the separation constants. The solution of Eq. (10) is well known and it is the azimuthal angle solution,

$$\Phi_m=Ae^{im\varphi}\quad(m=0,\pm1,\pm2,\ldots). \tag{11}$$

Equations (8) and (9) are radial and polar-angle equations and they will be solved by using the NU method,[9] given briefly in the following Sec. IV.

IV. NIKIFOROV-UVAROV METHOD

The nonrelativistic Schrödinger equation or similar time-independent second-order differential equations can be solved by using the NU method which is based on solutions of a general second-order linear differential equation with special orthogonal functions. In this method, for a given real or complex potential, the Schrödinger equation is transformed into a generalized equation of hypergeometric type with an appropriate $s=s(r)$ coordinate transformation and it can be written in the following form:

$$\psi(s)''+\frac{\tilde{\tau}(s)}{\sigma(s)}\psi'(s)+\frac{\tilde{\sigma}(s)}{\sigma^2(s)}\psi(s)=0, \tag{12}$$

where $\sigma(s)$ and $\tilde{\sigma}(s)$ are polynomials, at most second degree, and $\tilde{\tau}(s)$ is a first-degree polynomial. Hence, from Eq. (12), the Schrödinger equation or the Schrödinger-type equations can be solved by means of this method for potentials we consider. In order to find a particular solution of Eq. (12), we use the separation of variables with the transformation

$$\psi(s)=\phi(s)y(s), \tag{13}$$

it reduces Eq. (12) to an equation of hypergeometric type,

$$\sigma(s)y''+\tau(s)y'+\lambda y=0 \tag{14}$$

and $\phi(s)$ is defined as a logarithmic derivative in the following form and its solutions can be obtained from

$$\phi'(s)/\phi(s)=\pi(s)/\sigma(s). \tag{15}$$

The other part $y(s)$ is the hypergeometric type function whose polynomial solutions are given by the Rodrigues relation

$$y_n(s) = \frac{B_n}{\rho(s)} \frac{\mathrm{d}^n}{\mathrm{d}s^n}[\sigma^n(s)\rho(s)], \tag{16}$$

where B_n is a normalizing constant and the weight function $\rho(s)$ must satisfy the condition

$$(\sigma\rho)' = \tau\rho. \tag{17}$$

The function π and the parameter λ required for this method are defined as follows:

$$\pi(s) = \frac{\sigma' - \tilde{\tau}}{2} \pm \sqrt{\left(\frac{\sigma' - \tilde{\tau}}{2}\right)^2 - \tilde{\sigma} + k\sigma}, \tag{18}$$

$$\lambda = k + \pi'. \tag{19}$$

On the other hand, in order to find the value of k, the expression under the square root must be square of a polynomial. Thus, a new eigenvalue equation for the Schrödinger equation becomes

$$\lambda = \lambda_n = -n\tau' - \frac{n(n-1)}{2}\sigma'', \tag{20}$$

where

$$\tau(s) = \tilde{\tau}(s) + 2\pi(s) \tag{21}$$

and its derivative is negative. By comparison of Eqs. (19) and (20), we obtain the energy eigenvalues.

V. SOLUTIONS OF THE RADIAL AND ANGLE-DEPENDENT EQUATIONS

A. Solutions of the radial equation and energy eigenvalues

The radial part of the Klein-Gordon equation is given as

$$\left[\frac{\mathrm{d}^2}{\mathrm{d}r^2} - \frac{\lambda}{r^2} - (\varepsilon + M)\frac{\alpha}{r} + \varepsilon^2 - M^2\right]R(r) = 0. \tag{22}$$

This equation can be further arranged as

$$R''(r) + (-\eta^2 r^2 - \xi^2 r - \lambda)\frac{1}{r^2}R(r) = 0 \tag{23}$$

with

$$\varepsilon^2 - M^2 = -\eta^2, \quad (\varepsilon + M) = \xi^2, \quad \lambda = \ell(\ell+1), \quad \alpha = -Ze^2, \tag{24}$$

which is now amenable to a NU solution. In order to find the solution of this equation, it is necessary to compare Eq. (23) with Eq. (12). By comparison, we obtain the following polynomials:

$$\tilde{\tau} = 0, \quad \sigma = r, \quad \tilde{\sigma} = -\eta^2 r^2 - \xi^2 r - \lambda. \tag{25}$$

Substituting these polynomials in Eq. (18), we obtain π function as

$$\pi = \tfrac{1}{2} \pm \tfrac{1}{2}\sqrt{4\eta^2 r^2 + 4r(k + \xi^2) + 4\lambda + 1}. \tag{26}$$

The expression in the square root must be the square of polynomial in respect to the NU method.

Therefore, we can determine the constant k by using the condition that the discriminant of the square root is zero, that is

$$k = -\xi^2 \pm 2\sqrt{\eta^2}\left(\ell + \tfrac{1}{2}\right). \tag{27}$$

In view of that, one can find new possible functions for each k as

$$\pi = \begin{cases} \dfrac{1}{2} \pm \left[\sqrt{\eta^2} r + \left(\ell + \dfrac{1}{2}\right)\right], & \text{for } k = -\xi^2 + 2\sqrt{\eta^2}\left(\ell + \dfrac{1}{2}\right) \\ \dfrac{1}{2} \pm \left[\sqrt{\eta^2} r - \left(\ell + \dfrac{1}{2}\right)\right], & \text{for } k = -\xi^2 - 2\sqrt{\eta^2}\left(\ell + \dfrac{1}{2}\right). \end{cases} \tag{28}$$

For the polynomial of $\tau = \tilde{\tau} + 2\pi$ which has a negative derivative, we get

$$k = -\xi^2 - 2\sqrt{\eta^2}\left(\ell + \tfrac{1}{2}\right), \quad \pi = \tfrac{1}{2} - \left[\sqrt{\eta^2} r - \left(\ell + \tfrac{1}{2}\right)\right]. \tag{29}$$

Using $\chi = k + \pi'$ together with the values k and π, τ and χ can be respectively obtained as

$$\tau = 2(\ell + 1 - \sqrt{\eta^2} r), \tag{30}$$

$$\chi = -\xi^2 - \sqrt{\eta^2}(2\ell + 2). \tag{31}$$

Another definition of χ_N is given at Eq. (20),

$$\chi_N = 2N\sqrt{\eta^2}. \tag{32}$$

Comparing this with Eq. (31) and inserting the values of η and ξ, the exact energy eigenvalues of the radial part of the Klein-Gordon equation with the noncentral potential are derived as

$$\varepsilon_{N\ell} = M \frac{\left((N + \ell + 1)^2 - \dfrac{\alpha^2}{4}\right)}{\left((N + \ell + 1)^2 + \dfrac{\alpha^2}{4}\right)}, \tag{33}$$

where N denotes the radial quantum number. This is not equal to the well-known positive energy spectrum of the relativistic Klein-Gordon-Coulomb problem but gives the correct nonrelativistic limit in the case of weak coupling.

Using σ and π in Eqs. (14)–(16), we can find the wave functions $y(r) = y_{N\ell}(r)$ and $\phi(r)$:

$$R_{N\ell}(z) = C_{N\ell} z^{\ell+1} \exp\left(-\frac{z}{2}\right) L_N^{2\ell+1}(z), \tag{34}$$

where $L_N^{2\ell+1}(z)$ stands for the associated Laguerre functions whose argument is equal to $z = [(\varepsilon + M)Ze^2/(N + \ell + 1)]r$ and $C_{N\ell}$ is normalization constant determined by $\int_0^\infty R_{N\ell}^2(r)dr = 1$,[14] the corresponding normalized wave functions are finally obtained as

$$R_{n'\ell}(r) = \left(\frac{2(\varepsilon + M)Ze^2}{n'}\right)^{1/2} \left(\frac{(n' - \ell - 1)!}{n'\Gamma(n' + \ell + 1)}\right)^{1/2} \left(\frac{2(\varepsilon + M)Ze^2}{n'}\right)^{\ell+1} \times r^{\ell+1} \exp\left(-\frac{(\varepsilon + M)Ze^2}{n'} r\right) L_{n'-\ell-1}^{2\ell+1}\left(\frac{(\varepsilon + M)Ze^2}{n'} r\right), \tag{35}$$

where $n' = N + \ell + 1$. This equation is also stands for solution of the radial Klein-Gordon equation with Coulomb potential, since the radial Klein-Gordon equation with noncentral potential contains only Coulombic potential terms.

B. Eigenvalues and eigenfunctions of the angle-dependent equation

As for the solutions of the angle-dependent part of the Klein-Gordon equation, we may also derive eigenvalues and eigenfunctions of the polar angle part of the Klein-Gordon equation similar to the method as given in Sec. IV.

Equation (9) can be written in the following form by introducing a new variable, $x=\cos\theta$,

$$\frac{d^2\Theta(x)}{dx^2}-\frac{2x}{1-x^2}\frac{d\Theta(x)}{dx}+\left(\frac{\lambda(1-x^2)-m^2-(\varepsilon+M)(\beta+\gamma x)}{(1-x^2)^2}\right)\Theta(x)=0. \tag{36}$$

To apply the NU method, we compare Eq. (36) with Eq. (12). By comparison, we obtain the following polynomials:

$$\tilde{\tau}=-2x,\quad \sigma=1-x^2,\quad \tilde{\sigma}=-\lambda x^2-\gamma x+(\lambda-m^2-\beta). \tag{37}$$

The function π is obtained by putting the above-noted expression in Eq. (18),

$$\pi=\pm\sqrt{x^2(\lambda-k)+\gamma x-(\lambda-m^2-\beta-k)}. \tag{38}$$

The expression in the square root must be square of a polynomial. Then, one can find new possible functions for each k as

$$\pi=\pm\begin{cases} x\sqrt{\dfrac{m^2+\beta+u}{2}}+\sqrt{\dfrac{m^2+\beta-u}{2}}, & \text{for } k=\dfrac{2\lambda-m^2-\beta}{2}-\dfrac{1}{2}u \\ x\sqrt{\dfrac{m^2+\beta-u}{2}}+\sqrt{\dfrac{m^2+\beta+u}{2}}, & \text{for } k=\dfrac{2\lambda-m^2-\beta}{2}+\dfrac{1}{2}u, \end{cases} \tag{39}$$

where $u=\sqrt{(m^2+\beta)^2-\gamma^2}$. For the polynomial of $\tau=\tilde{\tau}+2\pi$ which has a negative derivative,

$$\tau=-2\sqrt{\frac{m^2+\beta-u}{2}}-2x\left(1+\sqrt{\frac{m^2+\beta+u}{2}}\right). \tag{40}$$

Using $\chi=k+\pi'$ and its other definition $\chi_n=-n\tau'-[n(n-1)/2]\sigma''$ given by Eqs. (19) and (20), following expressions for χ are obtained, respectively,

$$\chi=\frac{2\lambda-(m^2+\beta)}{2}-\frac{1}{2}u-\sqrt{\frac{m^2+\beta+u}{2}}, \tag{41}$$

$$\chi_n=2n\left(1+\sqrt{\frac{m^2+\beta+u}{2}}\right)+n(n-1). \tag{42}$$

Equating Eqs. (41) and (42) and using the definition of $\lambda=\ell(\ell+1)$, we obtain the ℓ values as

$$\ell=\sqrt{\frac{m^2+\beta+\sqrt{(m^2+\beta)^2-\gamma^2}}{2}}+n. \tag{43}$$

If we insert ℓ values obtained by Eq. (43) into eigenvalues of the radial part of the Klein-Gordon equation with the noncentral potential given by Eq. (33), we finally find the energy eigenvalues for a bound electron in the presence of a noncentral potential by Eq. (2)

$$E_{Nnm} = M\frac{\left[\left(N+\sqrt{\frac{m^2+\beta+\sqrt{(m^2+\beta)^2-\gamma^2}}{2}}n+1\right)^2-\frac{\alpha^2}{4}\right]}{\left[\left(N+\sqrt{\frac{m^2+\beta+\sqrt{(m^2+\beta)^2-\gamma^2}}{2}}+n+1\right)^2+\frac{\alpha^2}{4}\right]}, \tag{44}$$

where $\beta=(\varepsilon+M)\beta$ and $\gamma=(\varepsilon+M)\gamma$. The nonrelativistic limit ($\alpha\ll 1$) of the energy spectrum for the Hartmann problem where $\beta\neq 0$ and $\gamma=0$ is

$$E_{Nnm} = -\frac{M\alpha^2}{2}(N+n+1+\sqrt{m^2+\beta(\varepsilon+M)}). \tag{45}$$

Then, the wave functions of the polar-angle part of the Klein-Gordon equation, using σ and π in Eqs. (14)–(16), are obtained:

$$\phi = (1-x)^{B+C/2}(1+x)^{B-C/2}, \tag{46}$$

$$\rho = (1-x^2)^B\left(\frac{1+x}{1-x}\right)^{-C}, \tag{47}$$

$$y_n = B_n(1-x)^{-(B+C)}(1+x)^{-(B-C)}\frac{d^n}{dx^n}[(1+x)^{n+B-C}(1-x)^{n+B+C}], \tag{48}$$

where $B=\sqrt{[(m^2+\beta+u)/2]}$ and $C=\sqrt{[(m^2+\beta-u)/2]}$. The polynomial solution of y_n is expressed in terms of Jacobi polynomials which are one of the orthogonal polynomials, giving $\approx P_n^{(B+C,B-C)}(x)$. Substituting Eqs. (46)–(48) into Eq. (13), the corresponding wave functions are found to be

$$\Theta_n(x) = N_n(1-x)^{(B+C)/2}(1+x)^{(B-C)/2}P_n^{(B+C,B-C)}(x), \tag{49}$$

where N_n is normalization constant determined by $\int_{-1}^{+1}[\Theta_n(x)]^2 dx=1$ and using the orthogonality relation of Jacobi polynomials,[14,15] the normalization constant becomes

$$N_n = \sqrt{\frac{(2n+2B+1)\Gamma(n+1)\Gamma(n+2B+1)}{2^{2B+1}\Gamma(n+B+C+1)\Gamma(n+B-C+1)}}. \tag{50}$$

VI. CONCLUSIONS

This paper presented a different approach, the NU method, to the calculation of the nonzero angular momentum solutions of the relativistic Klein-Gordon equation. Exact eigenvalues and eigenfunctions for the Klein-Gordon equation in the presence of the noncentral equal scalar and vector potentials are derived easily. In the nonrelativistic limit, the energy eigenvalue spectrum is shown to be equivalent to the Hartmann one and the radial and polar angle wave functions are found in terms of Laguerre and Jacobi polynomials, respectively. The method presented in this study is general and worth extending to the solution of other interaction problems.

(Received 21 February 2006; accepted 16 May 2006; published online 7 August 2006)

We begin a systematic study of quantum energy inequalities (QEIs) in relation to local covariance. We define notions of locally covariant QEIs of both "absolute" and "difference" types and show that existing QEIs satisfy these conditions. Local covariance permits us to place constraints on the renormalized stress-energy tensor in one spacetime using QEIs derived in another, in subregions where the two spacetimes are isometric. This is of particular utility where one of the two spacetimes exhibits a high degree of symmetry and the QEIs are available in simple closed form. Various general applications are presented, including *a priori* constraints (depending only on geometric quantities) on the ground-state energy density in a static spacetime containing locally Minkowskian regions. In addition, we present a number of concrete calculations in both two and four dimensions that demonstrate the consistency of our bounds with various known ground- and thermal-state energy densities. Examples considered include the Rindler and Misner spacetimes, and spacetimes with toroidal spatial sections. In this paper we confine the discussion to globally hyperbolic spacetimes; subsequent papers will also discuss spacetimes with boundary and other related issues. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2212669]

I. INTRODUCTION

Over the past 30 years, much effort has been devoted to calculations of the renormalized stress-energy tensor in ground states of quantum fields on stationary background spacetimes. Many analogous calculations have been made in flat spacetime equipped with reflecting boundaries, in connection with the Casimir effect. However, it would be fair to say that only limited qualitative insight has been gained. For example, the energy density is sometimes positive and sometimes negative, and there is no known way of predicting the sign in any general situations without performing the full calculations.[1] At least analytically, these calculations are restricted to cases exhibiting a high degree of symmetry. The aim of this paper, and a companion paper,[2] is to point out that there are situations in which one may gain some qualitative insight into the possible magnitude of the stress-energy tensor based on simple geometric considerations.

The situation we study in this paper arises when a spacetime contains a subspacetime that is isometric to (a subspacetime of) another spacetime, which will usually have nontrivial symmetries. By using quantum energy inequalities (QEIs) together with the locality properties of quantum field theory, we are then able to use information about the second (symmetric) spacetime to yield information about the stress-energy tensor of states on the first spacetime (which need have no global symmetries) in the region where the isometry holds. We will work on globally hyperbolic

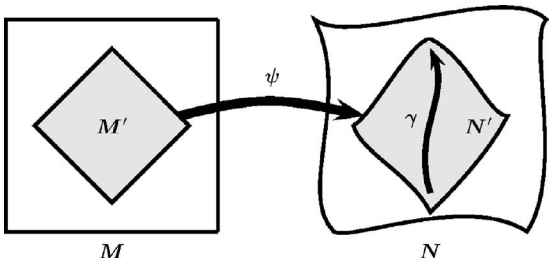

FIG. 1. Illustration for Example 1: The curve γ in $\boldsymbol{N}$ is enclosed in a causally embedded globally hyperbolic subspacetime $\boldsymbol{N}'$, which is causally isometric to a causally embedded globally hyperbolic subspacetime $\boldsymbol{M}'$ of four-dimensional Minkowski space $\boldsymbol{M}$ under $\psi:\boldsymbol{M}'\to\boldsymbol{N}'$.

spacetimes in this paper, deferring the issue of spacetimes with boundary to a companion paper.[2] As well as setting out the theory behind the method, we will demonstrate it in several locally Minkowskian spacetimes. Marecki[3] has also illustrated our approach by considering the case of spacetimes locally isometric to portions of exterior Schwarzschild. Also begun here for the free massless scalar field is a similar discussion for conformally related regions of two-dimensional spacetimes. In a separate paper we will extend this to the generalized Maxwell field in higher dimensional manifolds related by conformal diffeomorphisms.

To be more specific, consider a globally hyperbolic spacetime $\boldsymbol{N}$, consisting of a manifold of dimension $d\geqslant 2$, a Lorentzian metric with signature $+-\cdots-$, and choices of orientation and time-orientation (which, together, are required to fulfill the demands of global hyperbolicity.[4] Suppose an open subset of $\boldsymbol{N}$, when equipped with the metric and (time) orientation inherited from $\boldsymbol{N}$, is a globally hyperbolic spacetime $\boldsymbol{N}'$ in its own right. If, moreover, any causal curve in $\boldsymbol{N}$ whose endpoints lie in $\boldsymbol{N}'$ is contained completely in $\boldsymbol{N}'$, then we will call $\boldsymbol{N}'$ a *causally embedded globally hyperbolic subspacetime* (c.e.g.h.s.) of $\boldsymbol{N}$. Our main interest will be in the situation where a c.e.g.h.s. $\boldsymbol{N}'$ of $\boldsymbol{N}$ is isometric to a c.e.g.h.s. $\boldsymbol{M}'$ of a second globally hyperbolic spacetime $\boldsymbol{M}$, with the isometry also respecting the (time) orientation. (We speak of a *causal isometry* in this case.) By the principle of locality, we expect that any experiment conducted within $\boldsymbol{N}'$ should have the same results as the same experiment (i.e., its isometric image) conducted in $\boldsymbol{M}'$. No observer in $\boldsymbol{N}'$ should be able to discern, by such local experiments that she does not, in fact, inhabit $\boldsymbol{M}'$; in particular, energy densities in $\boldsymbol{N}'$ should be subject to the same QEIs as those in $\boldsymbol{M}'$. We will demonstrate explicitly that these expectations are met by the QEIs we employ.

Among our results are the following, which we state for the case of a Klein-Gordon field of mass $m\geqslant 0$ in four dimensions:

Example 1: Suppose a timelike *geodesic* segment γ of proper duration τ_0 in a globally hyperbolic spacetime $\boldsymbol{N}$ can be enclosed in a c.e.g.h.s. $\boldsymbol{N}'$ that is causally isometric to a c.e.g.h.s. of four-dimensional Minkowski space as shown in Fig. 1. Then any state ω of the Klein-Gordon field (of mass $m\geqslant 0$) on $\boldsymbol{N}$ obeys

$$\sup_{\gamma}\langle T_{ab}u^a u^b\rangle_\omega \geqslant -\frac{C_4}{\tau_0^4}, \tag{1}$$

where the constant $C_4=3.169858\ldots$ (if $m>0$, one may obtain even more rapid decay).

Example 2: Suppose a globally hyperbolic spacetime $\boldsymbol{N}$ is stationary with respect to a timelike Killing field t^a and admits the smooth foliation into constant time surfaces $\boldsymbol{N}\cong\mathbb{R}\times\Sigma$. Suppose the metric takes the Minkowski form (with respect to some coordinates) on $\mathbb{R}\times\Sigma_0$ for some subset Σ_0 of Σ with nonempty interior. (We may suppose that Σ_0 has been taken to be maximal.) For any x in the interior of Σ_0, let $r(x)$ be the radius of the largest Euclidean 3-ball that can be isometrically embedded in Σ_0, centered on x, as in Fig. 2. Then any stationary Hadamard state[5] ω_N on $\boldsymbol{N}$ obeys the bound

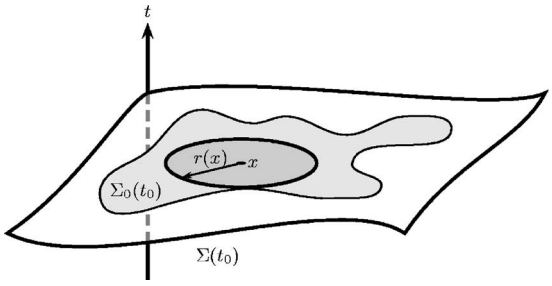

FIG. 2. Diagram showing open ball about the point x in Example 2.

$$\langle T_{ab}n^a n^b\rangle_{\omega_N}(t,x) \geqslant -\frac{C_4}{(2r(x))^4} \tag{2}$$

for any $x \in \Sigma_0$, where n^a is the unit vector along t^a.

Example 3: Suppose $\gamma: \mathbb{R} \to \boldsymbol{N}$ is a uniformly accelerated trajectory (parametrized by proper time) with proper acceleration α, and suppose γ can be enclosed within a c.e.g.h.s. $\boldsymbol{N}'$ of $\boldsymbol{N}$ that is causally isometric to a c.e.g.h.s. of four-dimensional Minkowski space. Then, for any Hadamard state ω on $\boldsymbol{N}$, and any smooth compactly supported real-valued g, with $\int_{-\infty}^{\infty} g(\tau)^2 \mathrm{d}\tau = 1$,

$$\liminf_{\tau_0 \to \infty} \frac{1}{\tau_0} \int_\gamma \langle T_{ab}u^a u^b\rangle_\omega \, g(\tau/\tau_0)^2 \mathrm{d}\tau \geqslant -\frac{11\alpha^4}{480\pi^2}. \tag{3}$$

Note the remarkable fact that the right-hand side is precisely the expected energy density in the Rindler vacuum state along the trajectory with constant proper accleration α. In particular, if the energy density in some state ω is constant along γ, it must exceed or equal that of the Rindler vacuum. We emphasize that our derivation does not involve the Rindler vacuum, but only the Minkowski vacuum state two-point function and the QEIs.

Variants of these results hold in other dimensions, and also for other linear field equations such as the Maxwell and Proca fields (which we will treat elsewhere).

To prepare for our main discussion, it will be useful to make a few general remarks about QEIs, also often called simply quantum inequalities (QIs). QEIs have been quite intensively developed over the past decade, following Ford's much earlier insight[6] that quantum field theory might act to limit the magnitude and duration of negative energy densities and/or fluxes, thereby preventing macroscopic violations of the second law of thermodynamics (see Ref. 7 for rigorous links between QEIs and thermodynamical stability). Detailed reviews of QEIs may be found in Refs. 8–10.

QEIs take various forms, but we will distinguish two basic types: absolute QEIs and difference QEIs. An absolute QEI bound consists of a set $\mathcal{F}$ of *sampling tensors*, i.e., second rank contravariant tensor fields against which the renormalized stress-energy tensor will be averaged, a class $\mathcal{S}$ of states of the theory (which may be chosen to have nice properties) and a map $\mathcal{Q}: \mathcal{F} \to \mathbb{R}$ such that

$$\int \langle T_{ab}\rangle_\omega \, f^{ab} \mathrm{dvol} \geqslant -\mathcal{Q}(\mathsf{f}) > -\infty \tag{4}$$

for all states $\omega \in \mathcal{S}$. [It would also be natural to demand that $\mathcal{F}$ be convex (i.e., if f_1 and f_2 are in $\mathcal{F}$ then so is $\lambda\mathsf{f}_1 + (1-\lambda)\mathsf{f}_2$ for all $\lambda \in [0,1]$, and for $\mathcal{Q}$ to obey $\mathcal{Q}(\lambda\mathsf{f}_1 + (1-\lambda)\mathsf{f}_2) \leqslant \lambda\mathcal{Q}(\mathsf{f}_1) + (1-\lambda)\mathcal{Q}(\mathsf{f}_2)$, but we shall not make these requirements.] Here T_{ab} is the renormalized stress-energy tensor defined in a manner compatible with Wald's axioms,[11] and we have adopted the convention that the same tensor may be written f (without indices) or f^{ab} (with). We will permit $\mathcal{F}$ to include tensors singularly supported on timelike curves or other submanifolds of spacetime, so, for example, we can treat worldline averages such as

$$\int_\gamma \langle T_{ab}\rangle_\omega f^{ab} \mathrm{d}\tau = \int_I \langle T_{ab}(\gamma(\tau))\rangle_\omega \, u^a u^b g(\tau)^2 \mathrm{d}\tau, \tag{5}$$

where γ is a smooth timelike curve parametrized by an open interval I of proper time τ, with velocity u^a, and for $g \in C_0^\infty(I)$. (To be precise, $\mathcal{F}$ is required to be a set of compactly supported distributions on smooth rank two covariant test tensor fields.)

Absolute QEIs are known (with explicit formulae for $\mathcal{Q}$, and specific $\mathcal{F}$ and $\mathcal{S}$) for (a) the scalar field of mass $m \geqslant 0$ in d-dimensional Minkowski space[12–14] (see also Ref. 15 for $d \geqslant 2$), (b) the massless scalar and Fermi fields in arbitrary two-dimensional globally hyperbolic spacetimes,[16–19] (c) general (interacting) conformal field theories in two-dimensional Minkowski space,[20] and (d) a variety of higher spin linear fields in two- and four-dimensional Minkowski space.[13,21–26] For the most part only worldline bounds involving averages of the form Eq. (5) have been studied; it has been found that replacing g by a scaled version $\tau_0^{-1/2} g(\tau/\tau_0)$ has the effect of sending the QEI bound to zero as τ_0^{-d} (or faster, for massive fields) as $\tau_0 \to \infty$, where d is the spacetime dimension.

Difference QEI bounds also involve the specification of $\mathcal{F}$ and $\mathcal{S}$ as before, but now the bound sought takes the form

$$\int [\langle T_{ab}\rangle_\omega - \langle T_{ab}\rangle_{\omega_0}] f^{ab} \mathrm{dvol} \geqslant -\mathcal{Q}(\mathsf{f}, \omega_0) > -\infty, \tag{6}$$

where ω_0 is called the reference state. If the theory were represented in a Fock space built on ω_0 (when this is possible), the left-hand side would be an average of the normal ordered stress-energy tensor. However, it is not always necessary to assume that ω and ω_0 are represented in this way. Difference QEIs have proved to be the easiest to establish in curved spacetimes, or where boundaries are present. First developed in the case of (ultra)static spacetimes with the (ultra)static ground state chosen as the reference state ω_0,[21,27–29] they are now known for scalar, spin-1/2, and spin-1 fields in arbitrary globally hyperbolic spacetimes.[22,30,31] In these general results, $\mathcal{S}$ is the class of Hadamard states and the bounds are sufficiently general that ω_0 may be any element of $\mathcal{S}$, so $\mathcal{Q}$ becomes a function $\mathcal{Q}: \mathcal{F} \times \mathcal{S} \to \mathbb{R}$. The general results do not make use of a Hilbert space representation.

Clearly, difference and absolute QEIs are quite closely related. In particular, Wald's fourth axiom requires $\langle T_{ab}\rangle_{\omega_0}$ to vanish identically if ω_0 is the Minkowski vacuum, so difference QEIs become absolute in this case. (The extension of this observation to locally Minkowskian spaces is a key idea in this paper.) More generally, we may convert a difference QEI to an absolute QEI by moving all the terms in ω_0 onto the right-hand side. In cases where the renormalized stress-energy tensor is known explicitly for the reference state, this is perfectly satisfactory. However, there are two (related) drawbacks: (i) there is no canonical choice of reference state ω_0 in a general spacetime (which might have no timelike Killing fields, for example); (ii) one does not normally have available a closed form expression for $\langle T_{ab}\rangle_{\omega_0}$ for *any* state on a general spacetime, so the QEI bound becomes somewhat inexplicit. This weakens the power of QEIs to constrain exotic spacetime configurations such as macroscopic traversable wormholes or "warp drive." (On sufficiently small scales, one expects that the absolute QEI bounds should strongly resemble those of Minkowski space—as first argued in Ref. 32, and proven in various situations in Refs. 28 and 19—however one still needs to know the magnitude of $\langle T_{ab}\rangle_{\omega_0}$ to know on what scales this approximation holds.)

The present paper and its companion represent first steps towards absolute QEIs in more general spacetimes, starting with spacetimes containing regions isometric to others where reference states are known. Work is under way on generally applicable absolute QEIs and will be reported elsewhere; however, we expect the results and methods presented here to be of continuing interest, as they reduce to very simple geometrical conditions.

The paper is structured as follows. In Sec. II we give a brief introduction to some of the relevant notions of locally covariant quantum field theory before defining locally covariant QEIs

and developing their simple properties in Sec. II C. The following two subsections show how existing QEIs in the literature may be expressed in the locally covariant framework, and address some technical points along the way. In Sec. III we show how local covariance permits *a priori* bounds to be placed on energy densities in spacetimes with Minkowskian subspacetimes using geometric data. The main technique here, in addition to local covariance, is the conversion of QEIs to eigenvalue problems, first introduced in Ref. 33. These are applied in Sec. IV to specific spacetime models where the energy densities of ground states and thermal states are known, permitting comparison with our *a priori* bounds. In some cases these bounds are saturated by the exact values. After a summary, the appendices collect various results needed in the main text.

II. QUANTUM ENERGY INEQUALITIES AND LOCAL COVARIANCE

A. Geometrical preliminaries

Suppose two globally hyperbolic spacetimes of the same dimension, $\boldsymbol{M}_1$ and $\boldsymbol{M}_2$, are given (we denote the corresponding manifolds and metrics by M_i, $\boldsymbol{g}_i$ for $i=1,2$). An *isometric embedding* of $\boldsymbol{M}_1$ in $\boldsymbol{M}_2$ is a smooth map $\psi: M_1 \to M_2$ which is a diffeomorphism of M_1 onto its range $\psi(M_1)$ in M_2 and so that the pull-back $\psi^* \boldsymbol{g}_2$ is everywhere equal to $\boldsymbol{g}_1$ on M_1. In local coordinates,

$$g_{1ab}(x) = \frac{\partial y^{a'}}{\partial x^a} \frac{\partial y^{b'}}{\partial x^b} g_{2a'b'}(y) \tag{7}$$

should hold for all $x \in M_1$, where $y = \psi(x)$. We *do* require that all of M_1 is mapped into M_2, but we do *not* require that the image of M_1 under ψ consists of the whole of M_2. There are two possible choices of orientation and time orientation on $\psi(M_1)$: that induced by ψ from the (time) orientation of $\boldsymbol{M}_1$, and that inherited from $\boldsymbol{M}_2$. If these coincide and we have the further property that every causal curve in $\boldsymbol{M}_2$ with endpoints in $\psi(M_1)$ lies entirely in $\psi(M_1)$, then we say that ψ is a *causal isometric embedding*. An important class of examples arises where $\boldsymbol{M}_1$ is a causally embedded globally hyperbolic subspacetime (c.e.g.h.s.) of $\boldsymbol{M}_2$ as defined in Sec. I, in which case ψ is simply the identity map. It is also worth mentioning an example of a noncausal embedding, namely, the "helical strip" described by Kay.[34] In this example a long thin diamond region of two-dimensional Minkowski space is isometrically embedded in a "timelike cylinder" that is the quotient of Minkowski space by a spacelike translation. The wrapping is arranged so that points that are spacelike separated in the original diamond are timelike separated in the geometry of the timelike cylinder. The definition of a causal embedding is designed precisely to ensure that the induced and inherited causal structures cannot differ in this way.

B. Local covariance

The relevance of local covariance to quantum field theory on manifolds has long been understood[35,36] but has recently been put in a new setting by Brunetti, Fredenhagen, and Verch[37] (see also Refs. 38 and 39) and related work of Hollands and Wald (see, e.g., Refs. 40 and 41). This provides a very elegant and general framework for local covariance in the language of category theory. The recent interest in local covariance has already had a significant impact in completing the renormalization program in curved spacetimes,[40,41] in providing a rigorous spin-statistics connection in curved spacetimes,[38] and in the theory of superselection sectors.[42] For our current purposes, we will only need a few of the main ideas of this analysis and will not describe the whole structure, referring the reader to the references just mentioned for further details. A discussion of QEIs in the categorical description of local covariance will appear elsewhere.[43]

In this section we will restrict ourselves to the Klein-Gordon field of mass $m \geqslant 0$, although similar comments can be made for the Dirac, Maxwell, and Proca fields. There is a well-defined quantization of the theory on any globally hyperbolic spacetime $\boldsymbol{M}$, in terms of an algebra of observables $\mathfrak{A}_{\boldsymbol{M}}$ and a space of Hadamard states $\mathcal{S}_{\boldsymbol{M}}$ which determine expectation values for observables in $\mathfrak{A}_{\boldsymbol{M}}$. For the purposes of this section, it suffices to know that $\mathfrak{A}_{\boldsymbol{M}}$ is generated by smeared field objects $\Phi_{\boldsymbol{M}}(f)$ labeled by smooth, compactly supported test functions $f \in C_0^\infty(\boldsymbol{M})$,

subject to relations expressing the field equation and commutation relations, and the hermiticity of the field. (The structure is given in detail in Appendix A.) The Hadamard states of the theory are those states on $\mathfrak{A}_{\boldsymbol{M}}$ whose two-point functions have singularities of the Hadamard form, which at leading order are just those of the Minkowski vacuum two-point function. More precisely,[44] on any causal normal neighborhood $\mathcal{O}$ in $\boldsymbol{M}$ there is a sequence of bidistributions H_n so that (for any n) the two-point function of any Hadamard state differs from H_n on $\mathcal{O}$ by a state-dependent function of class C^n. It is of key importance that $H_n(x,x')$ is fixed entirely by the local metric and causal structure, through the Hadamard recursion relations. Given a Hadamard state ω, we may construct the expected renormalized stress-energy tensor $\langle T_{ab}\rangle_\omega$ by the point-splitting technique (see, e.g., Ref. 11): first subtract H_n from the two-point function (for $n \geqslant 2$), then apply appropriate derivatives before taking the points together again. Next, one subtracts a term of the form Qg_{ab}, where Q is locally determined (and state independent), in order to ensure that the resulting tensor is conserved and vanishes in the Minkowski vacuum state. The tensor defined in this way obeys Wald's axioms mentioned above; however, these axioms would also be satisfied if one were to add a conserved local curvature term. Such terms are sometimes described as undetermined or arbitrary; we take the view, however, that they are part of the specification of the theory, just as the mass and conformal coupling are, even though they do not appear explicitly in the Lagrangian (a similar attitude is expressed in Ref. 45). For simplicity, and because our main applications will concern locally Minkowskian spacetimes, we will assume that these terms are absent—that is, we restrict to those scalar particle species for which this is the case.

The above structure is locally covariant in the following sense. Suppose a globally hyperbolic spacetime $\boldsymbol{M}$ is embedded in a globally hyperbolic spacetimes $\boldsymbol{N}$ by a causal isometry ψ, and let ψ_* denote the push-forward map on test functions. That is, $\psi_*: C_0^\infty(\boldsymbol{M}) \to C_0^\infty(\boldsymbol{N})$ is defined by

$$(\psi_* f)(y) = \begin{cases} f(\psi^{-1}(y)) & \text{if } y = \psi(x) \text{ for some } x \in \boldsymbol{M} \\ 0 & \text{otherwise.} \end{cases} \tag{8}$$

Then there is a natural mapping of the field on $\boldsymbol{M}$ to the field on $\boldsymbol{N}$ given by $\Phi_{\boldsymbol{M}}(f) \mapsto \Phi_{\boldsymbol{N}}(\psi_* f)$; we also write this as $\psi_*(\Phi_{\boldsymbol{M}}(f)) = \Phi_{\boldsymbol{N}}(\psi_* f)$. Moreover, ψ_* can be extended to any element of $\mathfrak{A}_{\boldsymbol{M}}$, respecting the algebraic relations and mapping the identity in $\mathfrak{A}_{\boldsymbol{M}}$ to the identity in $\mathfrak{A}_{\boldsymbol{N}}$; technically, it is a unit-preserving injective $*$-homomorphism of $\mathfrak{A}_{\boldsymbol{M}}$ into $\mathfrak{A}_{\boldsymbol{N}}$.

On account of the correspondence $\Phi_{\boldsymbol{M}}(f) \mapsto \Phi_{\boldsymbol{N}}(\psi_* f)$, we say that the field is covariant (the transformation goes "in the same direction" as ψ; see the remarks below on the underlying category theory at the end of Appendix A). By contrast, the state spaces transform in a contravariant way (in the "opposite direction" to ψ): for any state ω on $\mathfrak{A}_{\boldsymbol{N}}$ there is a pulled-back state, which we denote $\psi^*\omega$, on $\mathfrak{A}_{\boldsymbol{M}}$, so that the expectation values of $A \in \mathfrak{A}_{\boldsymbol{M}}$ and $\psi_* A \in \mathfrak{A}_{\boldsymbol{N}}$ are related by

$$\langle A \rangle_{\psi^*\omega} = \langle \psi_* A \rangle_\omega. \tag{9}$$

The correspondences just described are summarized graphically in Fig. 3. The use of pull-back notation may be justified by the observation that Eq. (9) entails that the n-point functions of the two states are related by

$$\langle \Phi_{\boldsymbol{M}}(x_1) \cdots \Phi_{\boldsymbol{M}}(x_n) \rangle_{\psi^*\omega} = \langle \Phi_{\boldsymbol{N}}(\psi(x_1)) \cdots \Phi_{\boldsymbol{N}}(\psi(x_n)) \rangle_\omega \tag{10}$$

(adopting an "unsmeared" notation). That is, the n-point function of $\psi^*\omega$ is simply the pull-back of the n-point function of ω by ψ (or more precisely, by the duplication of ψ across n copies of $\boldsymbol{M}$). This has an important consequence when the state ω is Hadamard, i.e., $\omega \in \mathcal{S}_{\boldsymbol{N}}$: because the Hadamard condition is based on the local metric and causal structure, both of which are preserved by ψ, it is clear that $\psi^*\omega$ is also Hadamard. (A more elegant proof of this[37] is to use Radzikowski's characterization of the Hadamard condition in terms of the wave-front set of the two-point function,[46] and the transformation properties of the wave-front set under pull-backs.) This may be expressed by the inclusion $\psi^* \mathcal{S}_{\boldsymbol{N}} \subset \mathcal{S}_{\boldsymbol{M}}$.

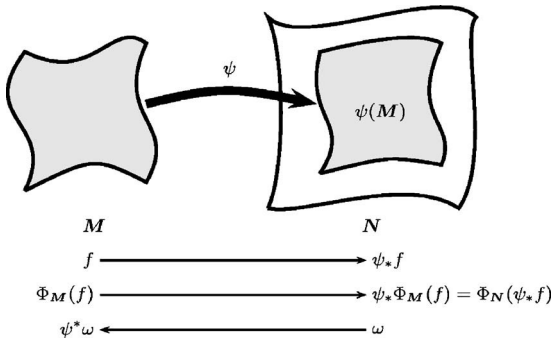

FIG. 3. If $\boldsymbol{M}$ is embedded in $\boldsymbol{N}$ by a causal isometry ψ, then test functions and smeared fields may be pushed forwards from $\boldsymbol{M}$ to $\boldsymbol{N}$, while states (and expectation values) are pulled back from $\boldsymbol{N}$ to $\boldsymbol{M}$.

As noted above, the expectation values of the stress-energy tensor are also constructed in a purely local fashion from the two-point function of the state. It therefore follows that

$$\langle T_{\boldsymbol{M}ab}(x)\rangle_{\psi^*\omega} = \frac{\partial y^{a'}}{\partial x^a}\frac{\partial y^{b'}}{\partial x^b}\langle T_{\boldsymbol{N}a'b'}(y)\rangle_{\omega}, \tag{11}$$

where we have written $y=\psi(x)$: like the n-point functions, the expected stress-energy tensor in state $\psi^*\omega$ is simply the pull-back of that in state ω. In coordinate-free notation we may write

$$\langle \mathbf{T}_{\boldsymbol{M}}\rangle_{\psi^*\omega} = \psi^*\langle \mathbf{T}_{\boldsymbol{N}}\rangle_{\omega}. \tag{12}$$

In the above equations we have written the stress-energy tensor as if it is an element of the algebra $\mathfrak{A}_{\boldsymbol{M}}$, which it is not. One may proceed in two ways: either interpreting Eq. (12) as the extension of Eq. (9) to an algebra of Wick polynomials that contains $\mathfrak{A}_{\boldsymbol{M}}$ as a subalgebra, and in which $\mathbf{T}_{\boldsymbol{M}}$ may be defined as a locally covariant field.[40,47] For our purposes, however, it will be simpler to define the smeared stress-energy tensor only through its expectation values; more technically, we think of it as a linear functional on the space of Hadamard states, with the notation $\langle \mathbf{T}_{\boldsymbol{M}}(\mathsf{f})\rangle_{\omega}$ expressing the value of this functional applied to the state ω. This has the advantage that one may deal with all Hadamard states, rather than those which extend to the Wick algebra.[47]

We emphasize the fact that states are pulled back in this setting; although one could push forward a state $\omega\in\mathcal{S}_{\boldsymbol{M}}$ to obtain a state on $\mathfrak{A}_{\psi(\boldsymbol{M})}$, there is no guarantee that this can be extended to a Hadamard state on $\mathfrak{A}_{\boldsymbol{N}}$, and indeed, such extensions do not always exist. For example, the Rindler vacuum state on the Rindler wedge is Hadamard in the interior of the wedge,[48] but cannot be extended to a Hadamard state on the whole of Minkowski because its stress-energy tensor diverges at the boundary of the wedge. See Ref. 49 for further discussion of these issues.

C. QEIs in a locally covariant setting

We now introduce two types of locally covariant QEIs. A more abstract (and general) definition can be given in the language of categories—this will be pursued elsewhere. Recall that a set of sampling tensors on a globally hyperbolic spacetime is a set of compactly supported distributions on smooth second rank covariant tensor fields.

Definition II.1: A locally covariant absolute QEI *assigns to each globally hyperbolic spacetime* $\boldsymbol{M}$ *a set of sampling tensors* $\mathcal{F}_{\boldsymbol{M}}$ *on* $\boldsymbol{M}$ *and a map* $\mathcal{Q}_{\boldsymbol{M}}:\mathcal{F}_{\boldsymbol{M}}\to\mathbb{R}$ *such that (i) we have*

$$\langle \mathbf{T}_{\boldsymbol{M}}(\mathsf{f})\rangle_{\omega} \geqslant -\mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}) \tag{13}$$

for all $\mathsf{f}\in\mathcal{F}_{\boldsymbol{M}}$ *and* $\omega\in\mathcal{S}_{\boldsymbol{M}}$, *and (ii) if* $\psi:\boldsymbol{M}\to\boldsymbol{N}$ *is a causal isometric embedding then* $\psi_*\mathcal{F}_{\boldsymbol{M}}\subset\mathcal{F}_{\boldsymbol{N}}$ *and*

$$\mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}) = \mathcal{Q}_{\boldsymbol{N}}(\psi_*\mathsf{f}) \tag{14}$$

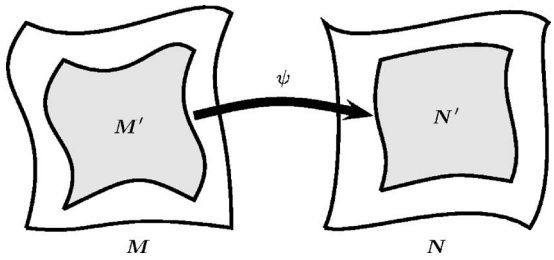

FIG. 4. (Color online) Diagram showing the various spacetimes and embeddings in Sec. II C.

for all $\mathsf{f} \in \mathcal{F}_{\boldsymbol{M}}$. (*We might also express this in the form* $\mathcal{Q}_{\boldsymbol{M}} = \psi^* \mathcal{Q}_{\boldsymbol{N}}$.)

A locally covariant difference QEI *assigns to each globally hyperbolic* $\boldsymbol{M}$ *a set of sampling tensors* $\mathcal{F}_{\boldsymbol{M}}$ *as before, and a map* $\mathcal{Q}_{\boldsymbol{M}}: \mathcal{F}_{\boldsymbol{M}} \times \mathcal{S}_{\boldsymbol{M}} \to \mathbb{R}$ *such that (i)*

$$\langle \mathsf{T}_{\boldsymbol{M}}(\mathsf{f}) \rangle_{\omega} - \langle \mathsf{T}_{\boldsymbol{M}}(\mathsf{f}) \rangle_{\omega_0} \geqslant - \mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}, \omega_0) \tag{15}$$

for each $\mathsf{f} \in \mathcal{F}_{\boldsymbol{M}}$ *and all* $\omega, \omega_0 \in \mathcal{S}_{\boldsymbol{M}}$; (*ii*)

$$\mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}, \psi^* \omega_0) = \mathcal{Q}_{\boldsymbol{N}}(\psi_* \mathsf{f}, \omega_0) \tag{16}$$

holds for all $\mathsf{f} \in \mathcal{F}_{\boldsymbol{M}}$ *and* $\omega_0 \in \mathcal{S}_{\boldsymbol{N}}$.

We will shortly give examples of each type: Flanagan's two-dimensional QEIs for massless fields[18] will be exhibited as a locally covariant absolute QEI, while (generalizations of) the QEI obtained in Ref. 30 provide examples of locally covariant difference QEIs. Before that, let us examine some simple consequences of these definitions.

First, suppose that $\boldsymbol{M}'$ is a c.e.g.h.s. of $\boldsymbol{M}$, so the identity map $\iota: \boldsymbol{M}' \to \boldsymbol{M}$ is a causal isometric embedding, and we must have $\iota_* \mathcal{F}_{\boldsymbol{M}'} \subset \mathcal{F}_{\boldsymbol{M}}$ and $\mathcal{Q}_{\boldsymbol{M}'}(\mathsf{f}) = \mathcal{Q}_{\boldsymbol{M}}(\iota_* \mathsf{f})$. It is sensible to drop the identity mappings, and write the above in the form

$$\mathcal{F}_{\boldsymbol{M}'} \subset \mathcal{F}_{\boldsymbol{M}}, \quad \text{and } \mathcal{Q}_{\boldsymbol{M}'}(\mathsf{f}) = \mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}) \text{ for all } \mathsf{f} \in \mathcal{F}_{\boldsymbol{M}'}. \tag{17}$$

If $\psi: \boldsymbol{M}' \to \boldsymbol{N}$ is a causal isometric embedding, as shown in Fig. 4, we then obtain

$$\mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}) = \mathcal{Q}_{\boldsymbol{M}'}(\mathsf{f}) = \mathcal{Q}_{\boldsymbol{N}}(\psi_* \mathsf{f}) \tag{18}$$

for all $\mathsf{f} \in \mathcal{F}_{\boldsymbol{M}'}$. As one would expect, this shows that locally covariant absolute QEIs are indifferent to the larger spacetime; one obtains the same bound whether one is in $\boldsymbol{M}'$ or its image $\boldsymbol{N}'$ in $\boldsymbol{N}$. Although this barely extends the original definition, it is worth isolating it as a separate result.

Proposition II.2: Suppose a c.e.g.h.s. $\boldsymbol{M}'$ *of* $\boldsymbol{M}$ *is causally isometric to a c.e.g.h.s.* $\boldsymbol{N}'$ *of* $\boldsymbol{N}$ *under the map* ψ. *Then a locally covariant absolute QEI obeys*

$$\mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}) = \mathcal{Q}_{\boldsymbol{N}}(\psi_* \mathsf{f}) \tag{19}$$

for all $\mathsf{f} \in \mathcal{F}_{\boldsymbol{M}'} \subset \mathcal{F}_{\boldsymbol{M}}$.

Let us now examine locally covariant difference QEIs in this situation. Given arbitrary Hadamard states $\omega_{\boldsymbol{M}} \in \mathcal{S}_{\boldsymbol{M}}$ and $\omega_{\boldsymbol{N}} \in \mathcal{S}_{\boldsymbol{N}}$ on the parent spacetimes $\boldsymbol{M}$ and $\boldsymbol{N}$, there are states $\iota^* \omega_{\boldsymbol{M}}$ and $\psi^* \omega_{\boldsymbol{N}}$ in $\mathcal{S}_{\boldsymbol{M}'}$, i.e., Hadamard states on $\mathfrak{A}_{\boldsymbol{M}'}$. Applying the difference QEI to $\psi^* \omega_{\boldsymbol{N}}$ with $\iota^* \omega_{\boldsymbol{M}}$ as reference state, we find

$$\langle \mathsf{T}_{\boldsymbol{M}'}(\mathsf{f}) \rangle_{\psi^* \omega_{\boldsymbol{N}}} - \langle \mathsf{T}_{\boldsymbol{M}'}(\mathsf{f}) \rangle_{\iota^* \omega_{\boldsymbol{M}}} \geqslant - \mathcal{Q}_{\boldsymbol{M}'}(\mathsf{f}, \iota^* \omega_{\boldsymbol{M}}) = - \mathcal{Q}_{\boldsymbol{M}}(\iota_* \mathsf{f}, \omega_{\boldsymbol{M}}), \tag{20}$$

where we have used the transformation property Eq. (16). On the other hand, we could equally well apply the difference QEI to $\iota^* \omega_{\boldsymbol{M}}$, with $\psi^* \omega_{\boldsymbol{N}}$ as reference state, to obtain

$$\langle \mathbf{T}_{\boldsymbol{M}'}(\mathsf{f})\rangle_{\iota^*\omega_{\boldsymbol{M}}} - \langle \mathbf{T}_{\boldsymbol{M}'}(\mathsf{f})\rangle_{\psi^*\omega_{\boldsymbol{N}}} \geqslant -\mathcal{Q}_{\boldsymbol{M}'}(\mathsf{f}, \psi^*\omega_{\boldsymbol{N}}) = -\mathcal{Q}_{\boldsymbol{N}}(\psi_*\mathsf{f}, \omega_{\boldsymbol{N}}). \tag{21}$$

Combining these inequalities yields

$$\mathcal{Q}_{\boldsymbol{N}}(\psi_*\mathsf{f}, \omega_{\boldsymbol{N}}) \geqslant \langle \mathbf{T}_{\boldsymbol{M}'}(\mathsf{f})\rangle_{\psi^*\omega_{\boldsymbol{N}}} - \langle \mathbf{T}_{\boldsymbol{M}'}(\mathsf{f})\rangle_{\iota^*\omega_{\boldsymbol{M}}} \geqslant -\mathcal{Q}_{\boldsymbol{M}}(\iota_*\mathsf{f}, \omega_{\boldsymbol{M}}); \tag{22}$$

we may also use the covariance of $\mathbf{T}$ to reexpress the central member of this inequality in terms of expectation values on $\boldsymbol{N}$ and $\boldsymbol{M}$, rather than $\boldsymbol{M}'$. The result, on dropping identity mappings from the notation, is the following.

Proposition II.3: Suppose a c.e.g.h.s. $\boldsymbol{M}'$ of $\boldsymbol{M}$ is causally isometric to a c.e.g.h.s. $\boldsymbol{N}'$ of $\boldsymbol{N}$ under the map ψ. *Then a locally covariant difference QEI obeys*

$$\mathcal{Q}_{\boldsymbol{N}}(\psi_*\mathsf{f}, \omega_{\boldsymbol{N}}) \geqslant \langle \mathbf{T}_{\boldsymbol{N}}(\psi_*\mathsf{f})\rangle_{\omega_{\boldsymbol{N}}} - \langle \mathbf{T}_{\boldsymbol{M}}(\mathsf{f})\rangle_{\omega_{\boldsymbol{M}}} \geqslant -\mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}, \omega_{\boldsymbol{M}}), \tag{23}$$

for all $\mathsf{f} \in \mathcal{F}_{\boldsymbol{M}'} \subset \mathcal{F}_{\boldsymbol{M}}$ *and any* $\omega_{\boldsymbol{M}} \in \mathcal{S}_{\boldsymbol{M}}$, $\omega_{\boldsymbol{N}} \in \mathcal{S}_{\boldsymbol{N}}$.

Note that the QEIs used are those associated with the full spacetimes $\boldsymbol{M}$ and $\boldsymbol{N}$; similarly, the states $\omega_{\boldsymbol{M}}$, $\omega_{\boldsymbol{N}}$ are states of the field on the full spacetimes. However, the isometry ψ connects only portions of the spacetime together and the restriction on the support of f is therefore crucial: in general, the above result will not hold when sampling extends outside the isometric region. It is also worth noting that we have both lower and upper bounds.

In this paper we will study the simplest possible setting for this result, in which $\boldsymbol{M}$ is Minkowski spacetime and $\omega_{\boldsymbol{M}}$ is the Minkowski vacuum state. However, other situations are possible. For example, Marecki[3] has employed our framework in the case where $\boldsymbol{M}$ is the exterior Schwarzschild spacetime and $\omega_{\boldsymbol{M}}$ is the Boulware vacuum. In the Minkowski case, the result simplifies because the renormalized stress-energy tensor vanishes in the state $\omega_{\boldsymbol{M}}$, and we have the following statement.

Corollary II.4: Suppose a c.e.g.h.s. $\boldsymbol{M}'$ of Minkowski space $\boldsymbol{M}$ is causally isometric to a c.e.g.h.s. $\boldsymbol{N}'$ of $\boldsymbol{N}$ under the map ψ. Then a locally covariant difference QEI obeys

$$\mathcal{Q}_{\boldsymbol{N}}(\psi_*\mathsf{f}, \omega_{\boldsymbol{N}}) \geqslant \langle \mathbf{T}_{\boldsymbol{N}}(\psi_*\mathsf{f})\rangle_{\omega_{\boldsymbol{N}}} \geqslant -\mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}, \omega_{\boldsymbol{M}}) \tag{24}$$

for all $\mathsf{f} \in \mathcal{F}_{\boldsymbol{M}'} \subset \mathcal{F}_{\boldsymbol{M}}$ *and any* $\omega_{\boldsymbol{N}} \in \mathcal{S}_{\boldsymbol{N}}$, *where* $\omega_{\boldsymbol{M}}$ *is the Minkowski vacuum state.*

D. A locally covariant absolute QEI for massless fields in two dimensions

The QEI we now describe was originally developed by Flanagan[16] for the massless scalar field in two-dimensional Minkowski space, in work which was subsequently generalized to curved spacetimes[17–19] and also to arbitrary unitary positive energy conformal field theories in two-dimensional Minkowski space.[20] The results of Ref. 18 were obtained for two-dimensional spacetimes globally conformal to the whole of Minkowski space; as noted in Ref. 19, however, any point of a globally hyperbolic two-dimensional spacetime has a (causally embedded) neighborhood that is conformal to the whole of Minkowski space, and to which Flanagan's result applies.

We first state the result of Ref. 18, and then show that it meets our definition of a locally covariant absolute QEI. Let $\boldsymbol{M}$ be a globally hyperbolic two-dimensional spacetime, and suppose that γ is a smooth, future-directed timelike curve, parametrized by proper time $\tau \in I$, which is completely contained within a c.e.g.h.s. $\boldsymbol{M}'$ of $\boldsymbol{M}$, such that $\boldsymbol{M}'$ is globally conformal to the whole of two-dimensional Minkowski space. Then all Hadamard states ω on $\boldsymbol{M}$ obey the QEI

$$\int_I \langle T_{\boldsymbol{M}ab} u^a u^b \rangle_\omega(\gamma(\tau)) g(\tau)^2 \mathrm{d}\tau \geqslant -\frac{1}{6\pi}\int_I [g'(\tau)^2 + g(\tau)^2\{R_{\boldsymbol{M}}(\gamma(\tau)) - a^c(\tau)a_c(\tau)\}]\mathrm{d}\tau \tag{25}$$

for any smooth, real-valued g compactly supported in I,[50] where u^a is the two-velocity of γ, a^c is its acceleration and $R_{\boldsymbol{M}}$ is the scalar curvature on $\boldsymbol{M}$. (Note that Ref. 18 uses conventions in which $u^a u_a < 0$ for timelike u^a; the bound is therefore modified slightly.)

As we now describe, Flanagan's bound is a locally covariant absolute QEI. Given I, γ, and g as above, we may define a compactly supported distribution $\mathsf{f}_{I,\gamma,g}$ acting on smooth second rank covariant tensor fields t, by

$$\mathsf{f}_{I,\gamma,g}(\mathsf{t}) = \int_I g(\tau)^2 u^a u^b t_{ab}|_{\gamma(\tau)} \mathrm{d}\tau. \tag{26}$$

Our set of sampling tensors $\mathcal{F}^{\mathrm{conf}}_{\boldsymbol{M}}$ ("conf" abbreviating "conformal") will be the set of all distributions formed in this way. [A distribution of the form $\mathsf{f}_{I,\gamma,g}$ is singularly supported on the curve γ; we could also write it in the form

$$f^{ab}_{I,\gamma,g}|_p = \int_I u^a u^b g(\tau)^2 \delta_{\gamma(\tau)}(p) \mathrm{d}\tau, \tag{27}$$

where $\delta_q(p)$ is the δ function at q, obeying $\int_{\boldsymbol{M}} \delta_q(p) F(p) \mathrm{dvol} = F(q)$.]

The QEI bound $\mathcal{Q}^{\mathrm{conf}}_M$ is then defined by

$$\mathcal{Q}^{\mathrm{conf}}_{\boldsymbol{M}}(\mathsf{f}) = \frac{1}{6\pi} \int_I [g'(\tau)^2 + g(\tau)^2 \{R_{\boldsymbol{M}}(\gamma(\tau)) - a^c(\tau) a_c(\tau)\}] \mathrm{d}\tau \tag{28}$$

for any I, γ, g for which $\mathsf{f} = \mathsf{f}_{I,\gamma,g}$. For this to make sense, we must ensure that the right-hand side is unchanged if we replace I, γ, and g by $\widetilde{I}$, $\widetilde{\gamma}$ and $\widetilde{g}$ such that $\mathsf{f}_{I,\gamma,g} = \mathsf{f}_{\widetilde{I},\widetilde{\gamma},\widetilde{g}}$. Since γ and γ' are both assumed to be parametrized by proper time, our two sampling tensors must be related in a simple way: supp $\widetilde{g}$ is the translation of supp g by some τ_0, so that $\widetilde{\gamma}(\tau) = \gamma(\tau + \tau_0)$, $\widetilde{g}(\tau)^2 = g(\tau + \tau_0)^2$ for all $\tau \in$ supp $\widetilde{g}$. The only possible ambiguity stems from the fact that $\widetilde{g}(\tau)$ and $g(\tau + \tau_0)$ might differ by a relative sign that can change at zeros of $\widetilde{g}$ of infinite order. However, it is simple to show that, nevertheless, $\widetilde{g}(\tau)^2 = g'(\tau + \tau_0)^2$,[51] ensuring that the right-hand side of Eq. (28) is unchanged under the reparametrization of f.

The bound Eq. (25) now takes the form of Eq. (13), so it remains only to verify that $\mathcal{F}^{\mathrm{conf}}_{\boldsymbol{M}}$ and $\mathcal{Q}^{\mathrm{conf}}_{\boldsymbol{M}}$ have the required transformation properties. Suppose $\psi : \boldsymbol{M} \to \boldsymbol{N}$ is a causal isometric embedding. The push-forward ψ_* acts on $\mathsf{f}_{I,\gamma,g} \in \mathcal{F}^{\mathrm{conf}}_{\boldsymbol{M}}$ so that, for any smooth tensor field t_{ab} on $\boldsymbol{N}$, we have

$$(\psi_* \mathsf{f}_{I,\gamma,g})(\mathsf{t}) = \mathsf{f}_{I,\gamma,g}(\psi^* \mathsf{t}) = \int_I g(\tau)^2 u^a u^b (\psi^* \mathsf{t})_{ab}|_{\gamma(\tau)} \mathrm{d}\tau = \int_I g(\tau)^2 (\psi^* \mathsf{u})^a (\psi^* \mathsf{u})^b t_{ab}|_{\gamma(\tau)} \mathrm{d}\tau = \mathsf{f}_{I,\psi\circ\gamma,g}(\mathsf{t}). \tag{29}$$

Now the image curve $\psi \circ \gamma$ can certainly be enclosed in a c.e.g.h.s. of $\boldsymbol{N}$ which is conformal to the whole of Minkowski space: namely the image under ψ of that which enclosed γ. Moreover, the image curve has velocity $\psi^* \mathsf{u}$. It is therefore clear that $\psi_* \mathsf{f}_{I,\gamma,g} = \mathsf{f}_{I,\psi\circ\gamma,g}$ is a legitimate sampling tensor in $\mathcal{F}^{\mathrm{conf}}_{\boldsymbol{N}}$, so we have shown that $\psi_* \mathcal{F}^{\mathrm{conf}}_{\boldsymbol{M}} \subset \mathcal{F}^{\mathrm{conf}}_{\boldsymbol{N}}$. It is obvious that $\mathcal{Q}^{\mathrm{conf}}_{\boldsymbol{M}}(\mathsf{f}) = \mathcal{Q}^{\mathrm{conf}}_{\boldsymbol{N}}(\psi_* \mathsf{f})$ because all quantities involved in the bound are invariant under the isometry.

We have thus shown that two-dimensional massless fields obey a locally covariant absolute QEI. One need not restrict to worldline averages such as those described above: see Refs. 16 and 18 for averages along spacelike or null curves, and Ref. 20 for worldvolume averages (in Minkowski space). We summarize as follows:

Theorem II.5: *Let $\boldsymbol{M}$ be a two-dimensional globally hyperbolic spacetime and let $\mathcal{S}_{\boldsymbol{M}}$ be the class of Hadamard states of the massless Klein-Gordon field on $\boldsymbol{M}$. Let $\mathcal{F}^{\mathrm{conf}}_{\boldsymbol{M}}$ consist of all sampling tensors of the form Eq. (26) where (i) $\gamma : I \to \boldsymbol{M}$ is a smooth future-directed timelike curve parametrized by proper time, with velocity $\mathsf{u} = \dot{\gamma}$; (ii) γ may be enclosed in a c.e.g.h.s. of $\boldsymbol{M}$ globally conformal to the whole of Minkowski space; (iii) $g \in C^\infty_0(I; \mathbb{R})$. Then, defining $\mathcal{Q}^{\mathrm{conf}}_{\boldsymbol{M}}(\mathsf{f})$ by Eq. (28) for any I, γ, g for which $\mathsf{f} = \mathsf{f}_{I,\gamma,g}$, the absolute QWEI*

$$\int_\gamma \langle T_{\boldsymbol{M}ab}\rangle_\omega \, u^a u^b g(\tau)^2 \mathrm{d}\tau \geqslant -\mathcal{Q}^{\mathrm{conf}}_{\boldsymbol{M}}(\mathsf{f}_{I,\gamma,g}) \tag{30}$$

holds for all $\omega \in \mathcal{S}_{\boldsymbol{M}}$ *and* $\mathsf{f}_{I,\gamma,g} \in \mathcal{F}^{\mathrm{conf}}_{\boldsymbol{M}}$, *and is locally covariant.*

E. Examples of locally covariant difference QEIs

We now give two related examples of locally covariant difference QEIs, based on methods first introduced in Ref. 30. The first is a quantum null energy inequality (QNEI), constraining averages of the null-contracted stress-energy tensor along timelike curves,[52] while the second is a quantum weak energy inequality (QWEI), constraining averages of the energy density along timelike curves.[30]

Suppose that $\boldsymbol{M}$ is any globally hyperbolic spacetime of dimension $d \geqslant 2$, and $\gamma: I \to M$ is any smooth, future-directed timelike curve. Suppose further that k^a is a smooth nonzero null vector field defined near γ. Then for any smooth, real-valued g, compactly supported in I, there is a difference QNEI,[52]

$$\int_\gamma [\langle T_{\boldsymbol{M}ab}\rangle_\omega - \langle T_{\boldsymbol{M}ab}\rangle_{\omega_0}] k^a k^b g(\tau)^2 \mathrm{d}\tau \geqslant -\int_0^\infty \frac{d\alpha}{\pi} \hat{F}_{\gamma,g,\mathsf{k},\omega_0}(-\alpha,\alpha) \tag{31}$$

for all $\omega, \omega_0 \in \mathcal{S}_{\boldsymbol{M}}$, where the hat denotes Fourier transform and

$$F_{\gamma,g,\mathsf{k},\omega_0}(\tau,\tau') = g(\tau)g(\tau')\langle \nabla_{\mathsf{k}}\Phi_{\boldsymbol{M}}(\gamma(\tau))\nabla_{\mathsf{k}}\Phi_{\boldsymbol{M}}(\gamma(\tau'))\rangle_{\omega_0}. \tag{32}$$

in which we have written ∇_{k} for $k^a\nabla_a$. (More precisely, the last factor is a distributional pull-back of the differentiated two-point function. We also adopt the nonstandard convention

$$\hat{f}(\lambda) = \int \mathrm{d}t \; e^{i\lambda t} f(t) \tag{33}$$

for Fourier transforms; for purposes of comparison, we note that the same convention was used in Ref. 30, but not in Ref. 52.) The integral on the right-hand side of Eq. (31) is finite as a consequence of ω_0 being Hadamard. We emphasize that there is no necessity for ω and ω_0 to be represented as vectors or density matrices in a common Hilbert space representation in order to prove the QEIs described in this section, because the proof may be phrased entirely in the algebraic formulation of QFT.

The above result was derived in Ref. 52 based on an earlier result in Ref. 30, described below. However, it is slightly easier to show that it is locally covariant, which is why we have presented it first. To accomplish our task, we define $\mathcal{F}^{\mathrm{null}}_{\boldsymbol{M}}$ to consist of all compactly supported distributions $\mathsf{f}_{I,\gamma,\mathsf{k},g}$ on smooth second rank covariant tensor fields t on $\boldsymbol{M}$, such that

$$\mathsf{f}_{I,\gamma,\mathsf{k},g}(\mathsf{t}) = \int_I g(\tau)^2 k^a k^b t_{ab} \mathrm{d}\tau \tag{34}$$

for γ, k^a, g, obeying the conditions already mentioned in this subsection *and* with g having connected support with no zeros of infinite order in its interior, for reasons to be explained shortly. We write $\widetilde{C}^\infty_0(I;\mathbb{R})$ for the set of functions g of this type. As in the two-dimensional case it is clear that the assignment $\boldsymbol{M} \to \mathcal{F}^{\mathrm{null}}_{\boldsymbol{M}}$ is covariant in the required sense.

The QEI bound is then defined by setting $\mathcal{Q}^{\mathrm{null}}_{\boldsymbol{M}}(\mathsf{f},\omega_0)$ equal to minus the right-hand side of Eq. (31), for any I, γ, k, and g such that $\mathsf{f}=\mathsf{f}_{I,\gamma,\mathsf{k},g}$. The particular parametrization is not important, for reasons similar to those explained in the previous subsection. However, here it is important that $g \in \widetilde{C}^\infty_0(I;\mathbb{R})$: otherwise we could change g to $h(\tau)=\sigma(\tau)g(\tau)$ with σ changing sign from $+1$ to -1 at a zero of g of infinite order, say at τ_0; although $\mathsf{f}_{I,\gamma,k,h}=\mathsf{f}_{I,\gamma,\mathsf{k},g}$, the two functions $F_{\gamma,h,\mathsf{k},\omega_0}$ and

$F_{\gamma,g,\mathsf{k},\omega_0}$ differ when, for example, $\tau<\tau_0<\tau'$. [The restriction to $\widetilde{C}_0^\infty(I;\mathbb{R})$ is not, however, very significant because it is dense in $C_0^\infty(I;\mathbb{R})$, as is shown in Appendix C.] Finally, the covariance property Eq. (16) follows because Eq. (10) (for the case $n=2$) implies

$$F_{\gamma,g,\mathsf{k},\psi^*\omega_0}(\tau,\tau')=F_{\psi\circ\gamma,g,\psi_*\mathsf{k},\omega_0}(\tau,\tau'). \tag{35}$$

We summarize what has been proved.

Theorem II.6: *Let $\boldsymbol{M}$ be a globally hyperbolic spacetime of dimension $d\geqslant 2$ and let $\mathcal{S}_{\boldsymbol{M}}$ be the class of Hadamard states of the Klein-Gordon field of mass $m\geqslant 0$ on $\boldsymbol{M}$. Let $\mathcal{F}_{\boldsymbol{M}}^{\mathrm{null}}$ consist of all sampling tensors of the form Eq. (34) where $\gamma:I\to\boldsymbol{M}$ is a smooth future-directed timelike curve parametrized by proper time, k is a smooth nonzero null field defined near the track of γ and $g\in\widetilde{C}_0^\infty(I;\mathbb{R})$. For each $\mathsf{f}\in\mathcal{F}_{\boldsymbol{M}}^{\mathrm{null}}$ and reference state $\omega_0\in\mathcal{S}_{\boldsymbol{M}}$ define*

$$\mathcal{Q}_{\boldsymbol{M}}^{\mathrm{null}}(\mathsf{f},\omega_0)=\int_0^\infty\frac{\mathrm{d}\alpha}{\pi}\hat{F}_{\gamma,g,\mathsf{k},\omega_0}(-\alpha,\alpha) \tag{36}$$

for any I,γ,k,g with $\mathsf{f}=\mathsf{f}_{I,\gamma,k,g}$. Then the difference QNEI

$$\int_\gamma[\langle T_{\boldsymbol{M}ab}\rangle_\omega-\langle T_{\boldsymbol{M}ab}\rangle_{\omega_0}]k^ak^bg(\tau)^2\mathrm{d}\tau\geqslant-\mathcal{Q}_{\boldsymbol{M}}^{\mathrm{null}}(\mathsf{f},\omega_0) \tag{37}$$

holds for all $\omega,\omega_0\in\mathcal{S}_{\boldsymbol{M}}$, and $\mathsf{f}_{I,\gamma,\mathsf{k},g}\in\mathcal{F}_{\boldsymbol{M}}^{\mathrm{null}}$, and is locally covariant.

Our second example of a locally covariant difference QEI constrains the energy density. We keep γ and g as before, but replace k^a by the velocity u^a of the trajectory. Then the following difference QWEI holds for all $\omega,\omega_0\in\mathcal{S}_{\boldsymbol{M}}$ (Ref. 30):

$$\int_\gamma[\langle T_{\boldsymbol{M}ab}\rangle_\omega-\langle T_{\boldsymbol{M}ab}\rangle_{\omega_0}]u^au^bg(\tau)^2\mathrm{d}\tau\geqslant-\int_0^\infty\frac{d\alpha}{\pi}\hat{G}_{\gamma,g,e,\omega_0}(-\alpha,\alpha), \tag{38}$$

where

$$G_{\gamma,g,\boldsymbol{e},\omega_0}(\tau,\tau')=\frac{1}{2}g(\tau)g(\tau')[\delta^{\mu\mu'}\langle\nabla_{\mathrm{e}_\mu}\Phi_{\boldsymbol{M}}(\gamma(\tau))\nabla_{\mathrm{e}_{\mu'}}\Phi_{\boldsymbol{M}}(\gamma(\tau'))\rangle_{\omega_0}+m^2\langle\Phi_{\boldsymbol{M}}(\gamma(\tau))\Phi_{\boldsymbol{M}}(\gamma(\tau'))\rangle_{\omega_0}] \tag{39}$$

and $\boldsymbol{e}=(e_\mu^a)_{\mu=0\ldots,d-1}$ is a smooth d-bein defined in a neighborhood of γ with $e_0^a=u^a$ on γ.

The frame $\boldsymbol{e}$ adds a new ingredient to the discussion of covariance, which was not explored in Ref. 30. Subject to the condition $e_0^a|_\gamma=u^a$, any choice of $\boldsymbol{e}$ will give a QEI bound, which may have differing numerical values. When considering a causal isometry $\psi:\boldsymbol{M}\to\boldsymbol{N}$, we must therefore find a way of choosing frames in the two spacetimes so as to give equal values to the QWEI bound, in accordance with covariance. One solution would be to incorporate the frame as part of the data in the QWEI, [i.e., writing $\mathcal{Q}_{\boldsymbol{M}}^{\mathrm{weak}}(\mathsf{f},\boldsymbol{e},\omega_0)$ and using the push-forward $\psi_*\boldsymbol{e}$ on $\psi(\boldsymbol{M})$] but this seems rather inelegant. Fortunately, a better solution is at hand: it turns out that we can covariantly specify a subclass of frames guaranteed to yield the same numerical bound. This is accomplished by requiring, in addition to $e_0^a|_\gamma=u^a$, that the d-bein $\boldsymbol{e}$ be invariant under Fermi-Walker transport along γ, i.e.,

$$\frac{D_{\mathrm{FW}}e_\mu^a}{\mathrm{d}\tau}\equiv u^b\nabla_be_\mu^a+a_be_\mu^bu^a-u_be_\mu^ba^a=0 \tag{40}$$

for each $\mu=0,\ldots,d-1$, where a^a is the acceleration of γ. If $\boldsymbol{e}'$ is another d-bein also invariant under Fermi-Walker transport and with $e'^a_0=e_0^a=u^a$, then it must be that $\boldsymbol{e}'$ is related to $\boldsymbol{e}$ by a rigid rotation along γ, i.e., $e'^a_i|_{\gamma(\tau)}=S_i^je_j^a|_{\gamma(\tau)}$ for some fixed $S\in\mathrm{SO}(d-1)$, because Fermi-Walker transport preserves inner products. It is now easy to see that $G_{\gamma,g,\boldsymbol{e},\omega_0}=G_{\gamma,g,\boldsymbol{e}',\omega_0}$, because the form of $\boldsymbol{e}$

off the curve γ is irrelevant, provided it is smooth. Accordingly this QEI depends only on the smearing tensor f [defined by analogy with Eq. (34)] and the reference state.

We emphasize that this is only one method of constructing a locally covariant bound in this setting, and others may be convenient in other contexts. For example, it would be possible to simply take the infimum of the bound over all d-beins with $\mathsf{e}_0=\mathsf{u}$; this is certainly locally covariant, but impractical for calculational purposes.

With this detail addressed, it is now straightforward to show that this QEI is locally covariant by exactly the same arguments as used in the null-contracted case, and the additional observation that $\psi_*\boldsymbol{e}$ is Fermi-Walker transported along $\psi\circ\gamma$ if $\boldsymbol{e}$ is along γ. Again, we summarize what has been established.

Theorem II.7: *Let $\boldsymbol{M}$ be a globally hyperbolic spacetime of dimension $d\geqslant 2$ and let $\mathcal{S}_{\boldsymbol{M}}$ be the class of Hadamard states of the Klein-Gordon field of mass $m\geqslant 0$ on $\boldsymbol{M}$. Let $\mathcal{F}^{\mathrm{weak}}_{\boldsymbol{M}}$ consist of all sampling tensors of the form Eq. (26) where $\gamma: I\to\boldsymbol{M}$ is a smooth future-directed timelike curve parametrized by proper time and with velocity $\mathsf{u}=\dot{\gamma}$, and $g\in\tilde{C}^\infty_0(I;\mathbb{R})$. For each $\mathsf{f}\in\mathcal{F}^{\mathrm{weak}}_{\boldsymbol{M}}$ and reference state $\omega_0\in\mathcal{S}_{\boldsymbol{M}}$ define*

$$\mathcal{Q}^{\mathrm{weak}}_{\boldsymbol{M}}(\mathsf{f},\omega_0)=\int_0^\infty\frac{\mathrm{d}\alpha}{\pi}\hat{G}_{\gamma,g,\boldsymbol{e},\omega_0}(-\alpha,\alpha) \tag{41}$$

for any I, γ, g with $\mathsf{f}=\mathsf{f}_{I,\gamma,g}$, and any smooth tetrad $\boldsymbol{e}$ defined near the track of γ with $\boldsymbol{e}_0|_\gamma=\mathsf{u}$ and which is invariant under Fermi-Walker transport along γ. Then the difference QWEI

$$\int_\gamma[\langle T_{\boldsymbol{M}ab}\rangle_\omega-\langle T_{\boldsymbol{M}ab}\rangle_{\omega_0}]u^au^bg(\tau)^2\mathrm{d}\tau\geqslant-\mathcal{Q}^{\mathrm{weak}}_{\boldsymbol{M}}(\mathsf{f},\omega_0) \tag{42}$$

hold for all $\omega,\omega_0\in\mathcal{S}_{\boldsymbol{M}}$ and $\mathsf{f}_{I,\gamma,g}\in\mathcal{F}^{\mathrm{weak}}_{\boldsymbol{M}}$, and is locally covariant.

Most cases considered in the sequel will actually involve averages in static spacetimes along timelike curves that are static trajectories (i.e., orbits of a hypersurface orthogonal timelike Killing field ξ) and with ω_0 chosen to be a static Hadamard state (with respect to the same Killing field). In these cases the bounds derived above simplify considerably, because the two-point function of ω_0 obeys

$$w_2(\psi_tx,\psi_tx')=w_2(x,x') \tag{43}$$

for any t, x,x', where ψ_t is the one-parameter group of isometries obtained from ξ. We fix a particular orbit $\gamma(\tau)=\psi_\tau(x_0)$, which may be assumed to be a proper-time parametrization (as $\xi_a\xi^a$ is constant along γ and may be set equal to unity). Then the two-point function, restricted to γ, can be expressed as

$$w_2(\gamma(\tau),\gamma(\tau'))=w_2(\psi_\tau(x_0),\psi_{\tau'}(x_0))=w(\tau-\tau'), \tag{44}$$

where $w(\tau)=w_2(\psi_\tau(x_0),x_0)$. The same time-translational invariance is obtained for derivatives $(\nabla_{\mathsf{v}}\otimes\nabla_{\mathsf{v}})w_2(\gamma(\tau),\gamma(\tau'))$, provided that v is invariant under the Killing flow, or equivalently, has vanishing Lie derivative with respect to ξ on γ, i.e., $\pounds_\xi\mathsf{v}|_\gamma=0$.

This simplifies the QWEI bound (38) as follows. If $\boldsymbol{e}$ is Lie-transported along γ then

$$G_{\gamma,g,\boldsymbol{e},\omega_0}(\tau,\tau')=g(\tau)g(\tau')T_{\gamma,\omega_0}(\tau-\tau') \tag{45}$$

holds for some "single variable" distribution T_{γ,ω_0}; moreover, $\boldsymbol{e}$ is also invariant under Fermi-Walker transport along γ (owing to hypersurface orthogonality of ξ).[53] Then, as shown in Refs. 7 and 30 the QEI Eq. (38) becomes

$$\int_\gamma [\langle T_{\mathbf{M}ab}\rangle_\omega - \langle T_{\mathbf{M}ab}\rangle_{\omega_0}]u^a u^b g(\tau)^2 \mathrm{d}\tau \geqslant -\int_{-\infty}^{\infty} du |\hat{g}(u)|^2 Q_{\gamma,\omega_0}(u), \tag{46}$$

where $Q_{\gamma,\omega_0}(u)$ is a positive polynomially bounded function defined by

$$Q_{\gamma,\omega_0}(u) = \frac{1}{2\pi^2}\int_{(-\infty,u)} \mathrm{d}v \hat{T}_{\gamma,\omega_0}(v). \tag{47}$$

Additionally, if ω_0 is a ground state (as was the case in Ref. 30) one may show that $\hat{T}_{\gamma,\omega_0}(\sigma)=0$ for $\sigma<0$, and so the function Q_{γ,ω_0} is supported on the positive half-line only. More generally, it is always the case that $\hat{T}_{\gamma,\omega_0}(\sigma)$ decays rapidly as $\sigma\to-\infty$, so Q_{γ,ω_0} is always well defined.[7] Technically, $\hat{T}_{\gamma,\omega_0}(\sigma)$ is a measure, and may have δ-function spikes that would exhibit themselves as discontinuities in $Q_{\gamma,\omega_0}(u)$. Since we define $Q_{\gamma,\omega_0}(u)$ as an integral over the open interval $(-\infty,u)$, it is continuous from the left.

A similar analysis holds for the QNEI Eq. (31), provided that the null vector field k has vanishing Lie derivative along γ, $\pounds_\xi \mathsf{k}=0$, because we have

$$F_{\gamma,g,\mathsf{k},\omega_0}(\tau,\tau') = g(\tau)g(\tau')S_{\gamma,\mathsf{k},\omega_0}(\tau-\tau') \tag{48}$$

for some distribution $S_{\gamma,\mathsf{k},\omega_0}$.

To conclude this section, we mention that more general QEI bounds may be constructed along similar lines, based on other decompositions of the contracted stress-energy tensor as a sum of squares. This includes bounds averaged over spacetime volumes (see, e.g., Ref. 9). However, we will not need this generality here, and observe only that one would need to ensure that such decompositions are made in a canonical fashion to obtain a locally covariant bound.

III. APPLICATIONS: GENERAL EXAMPLES

In this section we develop some simple consequences of the QEIs described in Secs. II D and II E specialized to Minkowski space. These will then be utilized in more general spacetimes using the local covariance properties of these bounds. Our results are obtained by converting QEI bounds into eigenvalue problems that can then be solved.

For the most part, we will consider the scalar field of mass $m\geqslant 0$ on d-dimensional globally hyperbolic spacetimes for $d\geqslant 2$; special features of massless fields in two dimensions will be treated in Sec. III C. Accordingly, let $\boldsymbol{N}$ be a d-dimensional globally hyperbolic spacetime, and let $\boldsymbol{M}_d$ denote d-dimensional Minkowski space. As illustrated in Fig. 1, let $\gamma: I\to\boldsymbol{N}$ be a smooth, future-directed timelike curve, parametrized by proper time $\tau\in I$, and assume γ may be enclosed in a c.e.g.h.s. $\boldsymbol{N}'$ of $\boldsymbol{N}$ so that $\boldsymbol{N}'$ is the image of a c.e.g.h.s. $\boldsymbol{M}'$ of $\boldsymbol{M}_d$ under a causal isometric embedding $\psi:\boldsymbol{M}'\to\boldsymbol{N}$. Thus the curve γ is the image of a curve $\tilde{\gamma}(\tau)=\psi^{-1}(\gamma(\tau))$ in $\boldsymbol{M}_d$; because ψ is an isometry, $\tau\mapsto\tilde{\gamma}(\tau)$ is also a proper time parametrization, and $\tilde{\gamma}$ has the same proper acceleration as γ for each $\tau\in I$.

Given any $g\in\tilde{C}_0^\infty(I;\mathbb{R})$, define a sampling tensor on Minkowski space $\mathsf{f}\in\mathcal{F}_{M_d}^{\mathrm{weak}}$ by

$$\mathsf{f}(\mathsf{t}) = \int_I t_{ab}|_{\tilde{\gamma}(\tau)}\tilde{u}^a\tilde{u}^b g(\tau)^2 \mathrm{d}\tau \tag{49}$$

on smooth covariant rank-two tensor fields t on $\boldsymbol{M}_d$, where $\tilde{\mathsf{u}}$ is the velocity of $\tilde{\gamma}$. [Recall that $g\in\tilde{C}_0^\infty(I;\mathbb{R})$ means that g is a real-valued smooth function whose support is compact, connected and contained in I, and that g has no zeros of infinite order in the interior of its support.] Under the isometry, f is mapped to $\psi_*\mathsf{f}$, with action

$$\psi_* \mathsf{f}(\mathsf{t}) = \int_I t_{ab}|_{\gamma(\tau)} u^a u^b g(\tau)^2 \mathrm{d}\tau, \tag{50}$$

where t is now any smooth covariant rank-2 tensor field on $\boldsymbol{N}$. Applied to the stress-energy tensor, $\psi_* \mathsf{f}$ therefore provides a weighted average of the energy density along γ. Our aim is to place constraints on these averages using the locally covariant difference QWEI given in Theorem II.7. By local covariance, Corollary II.4 guarantees that

$$\int_I \langle T_{\boldsymbol{N}ab} \rangle_\omega (\gamma(\tau)) u^a u^b g(\tau)^2 \mathrm{d}\tau = \langle \mathbf{T}_{\boldsymbol{N}}(\psi_* \mathsf{f}) \rangle_\omega \geqslant - \mathcal{Q}^{\mathrm{weak}}_{\boldsymbol{M}_d}(\mathsf{f}, \omega_{\boldsymbol{M}_d}), \tag{51}$$

where $\omega_{\boldsymbol{M}_d}$ is the Minkowski vacuum state.

We will be particularly interested in the least upper bound of the energy density along γ,

$$\mathcal{E} := \sup_\gamma \langle T_{\boldsymbol{N}ab} u^a u^b \rangle_\omega. \tag{52}$$

Since the energy density is smooth, this value must be the maximum value taken by the field on the closure of the track of γ. Using the trivial estimate $\mathcal{E} \geqslant \langle T_{\boldsymbol{N}ab} u^a u^b \rangle_\omega (\gamma(\tau))$ for each $\tau \in I$, we have

$$\mathcal{E} \int_I g(\tau)^2 \mathrm{d}\tau \geqslant \int_I \langle T_{\boldsymbol{N}ab} \rangle_\omega (\gamma(\tau)) u^a u^b g(\tau)^2 \mathrm{d}\tau \tag{53}$$

and, putting this together with Eq. (51), we obtain the inequality

$$\mathcal{E} \int_I g(\tau)^2 \mathrm{d}\tau \geqslant - \mathcal{Q}^{\mathrm{weak}}_{\boldsymbol{M}_d}(\mathsf{f}, \omega_{\boldsymbol{M}_d}), \tag{54}$$

which holds, in the first place, for all $g \in \widetilde{C}^\infty_0(I; \mathbb{R})$. In the next two subsections we will analyze this in two special cases: namely, inertial motion and uniform acceleration.

A. Inertial curves

When γ is inertial the QWEI of Theorem II.7 takes the simpler form described in Eqs. (46) and (47) above:[14]

$$\mathcal{Q}^{\mathrm{weak}}_{\boldsymbol{M}_d}(\mathsf{f}, \omega_{\boldsymbol{M}_d}) = K_d \int_m^\infty \frac{\mathrm{d}u}{\pi} u^d |\hat{g}(u)|^2 Q_d(u/m), \tag{55}$$

where

$$Q_d(x) = \frac{d}{x^d} \int_1^x \mathrm{d}y \; y^2 (y^2 - 1)^{(d-3)/2}, \tag{56}$$

and the constant K_d is $K_d = A_{d-2}/(2d(2\pi)^{d-1})$, where A_k is the area of the unit k-sphere. (Notation varies slightly from that used in Ref. 14.)

For all $d \geqslant 3$, it is clear that $Q_d(x) \leqslant 1$ for all $x \geqslant 1$, while one may show that $Q_2(x) < 1.2$ on the same domain.[54] Using these results, we may estimate Eq. (55) rather crudely by

$$\mathcal{Q}^{\mathrm{weak}}_{\boldsymbol{M}_d}(\mathsf{f}, \omega_{\boldsymbol{M}_d}) \leqslant K'_d \int_0^\infty \frac{\mathrm{d}u}{\pi} u^d |\hat{g}(u)|^2, \tag{57}$$

with $K'_d = K_d$ for $d \geqslant 3$ and $K'_2 = 1.2 K_2$. Note that we have made two changes here: (a) $Q_d(u/m)$ has been replaced by unity; (b) the lower integration limit m has been replaced by zero.

We now specialize to even dimensions $d=2k$, $k\geqslant 1$. Because g is real-valued, $|\hat{g}(u)|$ is even and we may write

$$\int_0^\infty \frac{\mathrm{d}u}{\pi} u^d |\hat{g}(u)|^2 = \int_{-\infty}^\infty \frac{\mathrm{d}u}{\pi} u^{2k} |\hat{g}(u)|^2 = \int_I \mathrm{d}\tau\, |(D^k g)(\tau)|^2, \tag{58}$$

where D is the differential operator $D=-i\mathrm{d}/\mathrm{d}\tau$ and we have used Parseval's theorem, and the fact that g vanishes outside I.

Inserting the above in Eq. (54), we have shown that $\mathcal{E}$ obeys the inequality

$$\mathcal{E}\int_I |g(\tau)|^2 d\tau \geqslant -K'_d \int_I d\tau\, |(D^k g)(\tau)|^2 \tag{59}$$

for all $g\in\widetilde{C}_0^\infty(I;\mathbb{R})$. The class $\widetilde{C}_0^\infty(I;\mathbb{R})$ is inconvenient to work with directly; fortunately, the same inequality holds for general $g\in C_0^\infty(I)$, as we now show. First, any $g\in\widetilde{C}_0^\infty(I;\mathbb{R})$ is the limit of a sequence of $g_n\in\widetilde{C}_0^\infty(I;\mathbb{R})$ for which $g_n\to g$ and $D^k g_n\to D^k g$ in $L^2(I)$ (see Appendix C). Applying the above inequality to each g_n, we may take the limit $n\to\infty$ to conclude that it holds for g as well. Having established the result for arbitrary real-valued $g\in C_0^\infty(I)$, we extend to general complex-valued g by applying it to real and imaginary parts separately, and then adding. Accordingly the inequality Eq. (59) holds for all $g\in C_0^\infty(I)$.

Integrating by parts k times, and noting that no boundary terms arise because g vanishes near the boundary ∂I of I, Eq. (59) may be rearranged to give

$$-\frac{\mathcal{E}}{K'_d} \leqslant \frac{\langle g|Lg\rangle}{\langle g|g\rangle}, \tag{60}$$

where $\langle\cdot|\cdot\rangle$ denotes the usual L^2-inner product on I, and the operator $L=(-1)^k\mathrm{d}^{2k}/\mathrm{d}\tau^{2k}$ on $C_0^\infty(I)$. Our aim is now to minimize the right-hand side over the class of g at our disposal (excluding the identically zero function). Now the operator L is symmetric[55] and positive, i.e., $\langle g|Lg\rangle\geqslant 0$ for all $g\in C_0^\infty(I)$. By Theorem X.23 in Ref. 56, the solution to our minimization problem is the lowest element λ_0 of the spectrum of $\hat{L}$, the so-called *Friedrichs extension* of L. This is a self-adjoint operator with the same action as L on $C_0^\infty(I)$, but which is defined on a larger domain in $L^2(I)$. In particular, every function in the domain of $\hat{L}$ obeys the boundary condition $g=g'=\cdots=g^{(k-1)}=0$ at ∂I. (See Ref. 33, where the technique of reformulating quantum energy inequalities as eigenvalue problems was first introduced, and which contains a self-contained exposition of the necessary operator theory.) One may think of this as a precise version of the Rayleigh-Ritz principle. Once we have determined λ_0, we then have the bound

$$\mathcal{E}\geqslant -\lambda_0 K'_d, \tag{61}$$

so the problem of determining the lower bound is reduced to the analysis of a Schrödinger-like equation, subject to the boundary conditions mentioned above.

The two examples of greatest interest to us are $k=1$ and $k=2$, representing two- and four-dimensional spacetimes. Starting with $k=1$, let us suppose that I is the interval $(-\tau_0/2,\tau_0/2)$ for some $\tau_0>0$. We therefore solve $-g''=\lambda g$ subject to Dirichlet boundary conditions at $\pm\tau_0/2$; as is well known, the lowest eigenvalue is $\lambda_0=\pi^2/\tau_0^2$ and corresponds to the eigenfunction $g(\tau)=\cos(\pi\tau/\tau_0)$. [A possible point of confusion is that, if g is extended so as to vanish outside I, it will not be smooth. However, there is no contradiction here: the point is that the infimum is not attained on $C_0^\infty(I)$.] Thus we have

$$\mathcal{E} \geqslant -\frac{3\pi}{10\tau_0^2}, \tag{62}$$

because $K_2' = 1.2K_2 = 1.2/(4\pi) = 3/(10\pi)$ (by convention, the zero sphere has area $A_0 = 2$). We may infer, without further calculation, that the bound must be zero if $I = \mathbb{R}$, because [returning to the Ritz quotient Eq. (60)], the infimum over all functions in $C_0^\infty(\mathbb{R})$ must be less than or equal to the infimum over all functions in $C_0^\infty(I)$ for any bounded I (a similar argument applies to the semi-infinite case). Thus λ_0 can be no greater than zero; on the other hand, the minimum cannot be negative either, because the original functional is nonnegative. Accordingly Eq. (62) holds in all cases, with τ_0 equal to the length of the interval I.

In the four-dimensional case $k=2$, we proceed in a similar way, solving $g'''' = \lambda g$ subject to $g = g' = 0$ at ∂I. In the case where I is bounded, $I = (-\tau_0/2, \tau_0/2)$ (without loss of generality), the spectrum consists only of positive eigenvalues. It is easy to see that the solutions to the eigenvalue equation $g'''' = \beta^4 g$ are linear combinations of trigonometric and hyperbolic functions. The lowest eigenfunction solution that obeys the boundary conditions is

$$g(\tau) = \cosh(\beta\tau/\tau_0) - \frac{\cosh(\beta/2)}{\cos(\beta/2)} \cos(\beta\tau/\tau_0), \tag{63}$$

where $\beta \approx 4.730\,040\,745$ is the minimum positive solution to

$$\tan(\beta/2) = -\tanh(\beta/2). \tag{64}$$

Since $K_4' = 1/(16\pi^2)$, we obtain

$$\mathcal{E} \geqslant -\frac{500.5639}{16\pi^2\tau_0^4} = -\frac{3.169\,858}{\tau_0^4}. \tag{65}$$

If I is semi-infinite or infinite, we may argue exactly as in the two-dimensional case that the bound vanishes, in agreement with the formal limit $\tau_0 \to \infty$.

Clearly this approach will give similar results in any even dimension, with a consequent increase in complexity in solving the eigenvalue problem. Nonetheless, it is clear that the resulting bound will always scale as τ_0^{-d}. In fact, this is even true in odd spacetime dimensions, where the eigenvalue problem would involve a nonlocal operator and is not easily tractable.

We summarize what has been proved so far in the following way.

Proposition III.1: Let $\mathbf{N}$ *be a globally hyperbolic spacetime of dimension* $d \geqslant 2$ *and suppose that a timelike geodesic segment* γ *of proper duration* τ_0 *may be enclosed in a c.e.g.h.s. of* $\mathbf{N}$, *which is causally isometric to a c.e.g.h.s. of Minkowski space* $\mathbf{M}_d$, *then*

$$\sup_\gamma \langle T_{\mathbf{N}ab} u^a u^b \rangle_\omega \geqslant -\frac{C_d}{\tau_0^d} \tag{66}$$

for all Hadamard states ω *of the Klein-Gordon field of mass* $m \geqslant 0$ *on* $\mathbf{N}$. *The constants* C_d *depend only on* d. *In particular*, $C_2 = 3\pi/10 = 0.942\,478\ldots$, *while* $C_4 = 3.169\,858\ldots$.

Remark: When the field has nonzero mass, we can expect rather more rapid decay than given by this estimate. To see why, return to the argument leading to Eq. (57). If we reinstate m as the lower integration limit, we have

$$\mathcal{Q}^{\text{weak}}_{\mathbf{M}_d}(\mathrm{f}, \omega_{\mathbf{M}_d}) \leqslant K_d' \int_m^\infty \frac{\mathrm{d}u}{\pi} u^d |\hat{g}(u)|^2. \tag{67}$$

Suppose for simplicity that $I = (-\tau_0/2, \tau_0/2)$. If we write $g_{\tau_0}(\tau) = \tau_0^{-1/2} g_0(\tau/\tau_0)$, for $g_0 \in C_0^\infty(-1/2, 1/2)$, a change of variables yields

$$\mathcal{Q}_{\boldsymbol{M}_d}(\mathsf{f}, \omega_{\boldsymbol{M}_2}) \leqslant \frac{K'_d G_d(m\tau_0)}{\tau_0^d}, \tag{68}$$

where the nonnegative quantity

$$G_d(x) = \int_x^\infty \frac{\mathrm{d}y}{\pi} y^d |\hat{g}_0(y)|^2 \tag{69}$$

decays rapidly as $x \to \infty$, owing to the rapid decay of $\hat{g}$. Thus the estimate Eq. (66) is quite crude when $m\tau_0 \gg 1$; it is hoped to return to this elsewhere.

Equipped with Proposition III.1, we may now address the first two examples presented in Sec. I. First, the proposition asserts that no Hadamard state can maintain an energy density lower than $-C_d/\tau_0^d$ for proper time τ_0 along an inertial curve in a Minkowskian c.e.g.h.s. of $\boldsymbol{N}$. In particular, this justifies the claim made in Example 1 in Sec. I.

Our bounds clearly depend only on τ_0, which in turn is controlled by the size of the Minkowskian region $\boldsymbol{N}'$. By choosing the curve γ and $\boldsymbol{N}'$ in an appropriate way, fairly simple geometrical considerations can thus provide good *a priori* bounds on the magnitude and duration of negative energy density. A good illustration is the following (which includes Example 2 in Sec. I).

Suppose that a d-dimensional globally hyperbolic spacetime $\boldsymbol{N}$ with metric $\boldsymbol{g}$ is stationary with respect to timelike Killing vector t^a and admits the smooth foliation into constant time surfaces $N \cong \mathbb{R} \times \Sigma$. Suppose there is a (maximal) subset Σ_0 of Σ, with nonempty interior, for which $\boldsymbol{g}$ takes the Minkowski form on $\mathbb{R} \times \Sigma_0$. Choose any point (t,x) in N, with $x \in \Sigma_0$, and suppose that we may isometrically embed a Euclidean $(d-1)$ ball of radius r in Σ_0, centered at x (see Fig. 2). Then the interior of the double cone $J^+(\{(t-r,x)\}) \cap J^-(\{(t+r,x)\})$ is a c.e.g.h.s. of $\boldsymbol{N}$, which is isometric to a c.e.g.h.s. of Minkowski space, and contains an inertial curve segment $\gamma(\tau) = (\tau, x)$ parametrized by the interval $(t-r, t+r)$ of proper time. Any Hadamard state ω on $\boldsymbol{N}$ therefore obeys

$$\sup_\gamma \langle T_{\boldsymbol{N}ab} u^a u^b \rangle_\omega \geqslant -\frac{C_d}{(2r)^d} \tag{70}$$

along γ. Writing $r(x)$ for the minimum distance from x to the boundary of Σ_0, it is clear that this inequality holds for all $r < r(x)$ and hence, by continuity, for $r = r(x)$. Moreover, if the state is stationary (for example, if it is the ground state), then the energy density takes a constant value along γ and we obtain

$$\langle T_{ab} n^a n^b \rangle_\omega (t,x) \geqslant -\frac{C_d}{(2r(x))^d} \tag{71}$$

for any $x \in \Sigma_0$, where n^a is the unit vector along t^a. In this way we obtain a universal bound on the fall-off of negative energy densities in such spacetimes, which could be used to provide a quantitative check on exact calculations, if these are possible, or to provide some precise information in situations where they are not. The bound is of course very weak close to the boundary of Σ_0: this does not imply that the energy density diverges as this boundary is approached, of course, but merely indicates that it would not be incompatible with the quantum inequalities for there to exist geometries on $\mathbb{R} \times (\Sigma \backslash \Sigma_0)$ for which the stationary energy density just outside might be very negative.

To conclude this subsection, let us briefly discuss the null-contracted QEI Eq. (31) in the present context. For simplicity, we restrict ourselves to four dimensions. Suppose $\tilde{k}^a$ is a nonzero null vector field that is covariantly constant along $\tilde{\gamma}$, so, in particular, $\tilde{u}^a \tilde{k}_a$ is also constant on $\tilde{\gamma}$. Our sampling tensor is now defined to be $\mathsf{f} \in \mathcal{F}^{\mathrm{null}}_{\boldsymbol{M}_4}$ with action

$$\mathsf{f}(t) = \int_I t_{ab}|_{\tilde{\gamma}(\tau)} \tilde{k}^a \tilde{k}^b g(\tau)^2 \mathrm{d}\tau \tag{72}$$

on smooth covariant rank-2 tensor fields t on $\boldsymbol{M}_4$. In exactly the same way as for the QWEI discussed above, we may apply local covariance to the QNEI of Theorem II.6, so yielding

$$\int \langle T_{\boldsymbol{N}ab} \rangle_\omega \, k^a k^b g(\tau)^2 \mathrm{d}\tau \geqslant - \mathcal{Q}^{\mathrm{null}}_{\boldsymbol{M}_4}(\mathsf{f}, \omega_{\boldsymbol{M}_4}), \tag{73}$$

where, as shown in Ref. 52,

$$\mathcal{Q}^{\mathrm{null}}_{\boldsymbol{M}_4}(\mathsf{f}, \omega_{\boldsymbol{M}_4}) = - \frac{(u^a k_a)^2}{12\pi^2} \int_{-\infty}^{\infty} g''(\tau)^2 \mathrm{d}\tau \tag{74}$$

for the massless scalar field (and in fact this bound also constrains the massive field too). This differs from the corresponding QWEI by a factor of $4(u^a k_a)^2/3$ [recall that $K_4' = 1/(16\pi^2)$], so we may immediately deduce the following result.

Proposition III.2: Let $\boldsymbol{N}$ *be a four-dimensional globally hyperbolic spacetime and suppose that a timelike geodesic segment* γ *of proper duration* τ_0 *may be enclosed in a c.e.g.h.s. of* $\boldsymbol{N}$*, which is causally isometric to a c.e.g.h.s. of Minkowski space. If* k^a *is a covariantly constant null vector field on* γ *then we have*

$$\sup_\gamma \langle T_{\boldsymbol{N}ab} \rangle_\omega k^a k^b \geqslant - \frac{C_4' (u^a k_a)^2}{\tau_0^4} \tag{75}$$

for any Hadamard state ω *of the Klein-Gordon field, where* $C_4' = 4C_4/3 = 4.226\,477\ldots$.

This result justifies the claim made above Eq. (38) of Ref. 57, where an application is presented.

B. Uniformly accelerated trajectories in four dimensions

We now turn to the case where γ has uniform constant proper acceleration α. For simplicity we consider only massless fields in four dimensions, but expect similar results in more general cases. We need to estimate $\mathcal{Q}^{\mathrm{weak}}_{M_4}(\mathsf{f}, \omega_{\boldsymbol{M}_4})$ where f is supported on the uniformly accelerated worldline $\tilde{\gamma}$ in $\boldsymbol{M}_4$. It will be convenient to drop the tilde from $\tilde{\gamma}$ and the subscript from $\boldsymbol{M}_4$. Without loss of generality, we may assume $\gamma: I \to \boldsymbol{M}$ is parametrized so that

$$\gamma(\tau) = \begin{pmatrix} \xi_o \sinh(\tau/\xi_o) \\ \xi_o \cosh(\tau/\xi_o) \\ y_o \\ z_o \end{pmatrix} \quad \text{with} \quad u^a(\tau) = \frac{\mathrm{d}\gamma(\tau)^a}{\mathrm{d}\tau} = \begin{pmatrix} \cosh(\tau/\xi_o) \\ \sinh(\tau/\xi_o) \\ 0 \\ 0 \end{pmatrix}, \tag{76}$$

where $\xi_o = \alpha^{-1}$.

The first step in our calculation is to set up an orthonormal tetrad field surrounding the worldline,

$$e_0^a = \frac{1}{\sqrt{x^2 - t^2}} \begin{pmatrix} x \\ t \\ 0 \\ 0 \end{pmatrix}, \quad e_1^a = \frac{1}{\sqrt{x^2 - t^2}} \begin{pmatrix} t \\ x \\ 0 \\ 0 \end{pmatrix}, \quad e_2^a = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}, \quad e_3^a = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}, \tag{77}$$

which satisfies the two properties required: namely, that e_0^a agrees with the velocity u^a on γ, and that the frame is invariant under Fermi-Walker transport along γ. The required bound is then given by

$$\mathcal{Q}_{\boldsymbol{M}}^{\mathrm{weak}}(\mathsf{f},\omega_{\boldsymbol{M}}) = \int_0^\infty \frac{\mathrm{d}\alpha}{2\pi}\hat{G}_{\gamma,g,\boldsymbol{e},\omega_{\boldsymbol{M}}}(-\alpha,\alpha), \tag{78}$$

where

$$G_{\gamma,g,\boldsymbol{e},\omega_{\boldsymbol{M}}}(\tau,\tau') = \frac{1}{2}g(\tau)g(\tau')\delta^{\mu\mu'}\langle\nabla_{\mathrm{e}_\mu}\Phi_{\boldsymbol{M}}(\gamma(\tau))\nabla_{\mathrm{e}_{\mu'}}\Phi_{\boldsymbol{M}}(\gamma(\tau'))\rangle_{\omega_{\boldsymbol{M}}}. \tag{79}$$

We evaluate this quantity in stages, beginning by noting that

$$\begin{aligned}&\delta^{\mu\mu'}\langle\nabla_{\mathrm{e}_\mu}\Phi_{\boldsymbol{M}}(x)\nabla_{e_{\mu'}}\Phi_{\boldsymbol{M}}(x')\rangle_{\omega_{\boldsymbol{M}}}\\ &\quad= \left[\frac{(xx'+tt')(\partial_t\partial_{t'}+\partial_x\partial_{x'})+(xt'+tx')(\partial_t\partial_{x'}+\partial_x\partial_{t'})}{\sqrt{x^2-t^2}\sqrt{x'^2-t'^2}}+\partial_y\partial_{y'}+\partial_z\partial_{z'}\right]W_{\boldsymbol{M}}^{(2)}(x,x'),\end{aligned} \tag{80}$$

where

$$W_{\boldsymbol{M}}^{(2)}(x,x') = -\lim_{\epsilon\to 0^+}\frac{1}{4\pi^2}[(t-t'-i\epsilon)^2-|\boldsymbol{x}-\boldsymbol{x}'|^2]^{-1} \tag{81}$$

is the Wightman function of the vacuum state. Performing the necessary derivatives and pulling back to the worldline, we obtain, after some calculation,

$$G_{\gamma,g,\boldsymbol{e},\omega_0}(\tau,\tau') = g(\tau)g(\tau')T(\tau-\tau'), \tag{82}$$

where T is the limit (in the distributional sense) as $\epsilon\to 0^+$ of

$$T_\epsilon(\sigma) = \frac{3}{32\pi^2\xi_o^4}\operatorname{cosech}^4\left(\frac{\sigma}{2\xi_o}-i\frac{\epsilon}{\xi_o}\right). \tag{83}$$

Thus we are in the situation of Eq. (45), and the bound becomes

$$\mathcal{Q}_{\boldsymbol{M}}^{\mathrm{weak}}(\mathsf{f},\omega_{\boldsymbol{M}}) = \int_{-\infty}^\infty \mathrm{d}u|\hat{g}(u)|^2 Q(u), \tag{84}$$

where

$$Q(u) = \frac{1}{2\pi^2}\int_{(-\infty,u)}\mathrm{d}v\hat{T}(v). \tag{85}$$

To obtain the required Fourier transform, we first use contour integration[58] to find

$$\hat{T}_\epsilon(u) = \frac{e^{-2u\epsilon}}{2\pi\xi_o^4}\left(\frac{\xi_o^4u^3+\xi_o^2u}{1-e^{-2\pi\xi_o u}}\right), \tag{86}$$

which decays exponentially as $u\to-\infty$, provided $\epsilon<\pi\xi_o$. Taking the limit $\epsilon\to 0^+$ it is easy to check that

$$\hat{T}(u) = \frac{1}{2\pi\xi_o^4}\left(\frac{\xi_o^4u^3+\xi_o^2u}{1-e^{-2\pi\xi_o u}}\right). \tag{87}$$

Note that this Fourier transform has support on the whole real line, not just the positive half-line. Thus

$$Q(u) = \frac{1}{4\pi^3 \xi_o^4} \int_{-\infty}^{u} \frac{\xi_o^4 v^3 + \xi_o^2 v}{1 - e^{-2\pi\xi_o v}} dv. \tag{88}$$

Our aim is now to estimate $Q(u)$ in order to obtain a bound that may be analyzed by eigenvalue techniques as in the previous subsection. Beginning in the half-line $u<0$, we may estimate

$$Q(u) < Q(0) = \frac{11}{960\pi^3 \xi_o^4} \tag{89}$$

since $Q(u)$ is everywhere increasing. On the other hand, for $u \geqslant 0$, we may split the integral into $Q(0)$ and the contribution from $[0,u]$ to give

$$Q(u) = \frac{11}{960\pi^3 \xi_o^4} + \frac{1}{4\pi^3 \xi_o^4} \left[\int_0^u (\xi_o^4 v^3 + \xi_0^2 v) \mathrm{d}v + \int_0^u \frac{\xi_o^4 v^3 + \xi_o^2 v}{e^{2\pi\xi_o v} - 1} \mathrm{d}v \right] \tag{90}$$

after rearranging. Now the last integral is increasing in u, so we may bound it by its limit as $u \to +\infty$ to yield

$$Q(u) \leqslant \frac{1}{16\pi^3 \xi_o^4} \left(\xi_o^4 u^4 + 2\xi_o^2 u^2 + \frac{11}{30} \right) \tag{91}$$

for $u>0$. Using the estimates Eqs. (89) and (91), and the fact that $|\hat{g}(u)|^2$ is even,

$$\begin{aligned} \mathcal{Q}_{\boldsymbol{M}}^{\mathrm{weak}}(\mathsf{f}, \omega_{\boldsymbol{M}}) &\leqslant \frac{11}{960\pi^3 \xi_o^4} \int_{-\infty}^{0} \mathrm{d}u |\hat{g}(u)|^2 + \frac{1}{16\pi^3 \xi_o^4} \int_0^{\infty} \mathrm{d}u |\hat{g}(u)|^2 \left(\xi_o^4 u^4 + 2\xi_o^2 u^2 + \frac{11}{30} \right) \\ &= \frac{1}{16\pi^2 \xi_o^4} \int_{-\infty}^{\infty} \frac{\mathrm{d}u}{2\pi} |\hat{g}(u)|^2 \left(\xi_o^4 u^4 + 2\xi_o^2 u^2 + \frac{11}{20} \right). \end{aligned} \tag{92}$$

Applying Parseval's theorem, we arrive at

$$\mathcal{Q}_{\boldsymbol{M}}^{\mathrm{weak}}(\mathsf{f}, \omega_{\boldsymbol{M}}) \leqslant \frac{1}{16\pi^2} \int_{-\infty}^{\infty} \mathrm{d}\tau \left(|g''(\tau)|^2 + \frac{2}{\xi_o^2} |g'(\tau)|^2 + \frac{11}{20\xi_o^4} |g(\tau)|^2 \right), \tag{93}$$

and, together with Eq. (54), we now have

$$\mathcal{E} \int_I |g(\tau)|^2 \mathrm{d}\tau \geqslant \frac{1}{16\pi^2} \int_{-\infty}^{\infty} \mathrm{d}\tau \left(|g''(\tau)|^2 + \frac{2}{\xi_o^2} |g'(\tau)|^2 + \frac{11}{20\xi_o^4} |g(\tau)|^2 \right), \tag{94}$$

for any $g \in \widetilde{C}_0^{\infty}(I;\mathbb{R})$. As in the previous subsection, we may extend this inequality to arbitrary $g \in C_0^{\infty}(I)$, and then optimize over this class. This leads to the conclusion that

$$\mathcal{E} \geqslant -\frac{\mu_0}{16\pi^2}, \tag{95}$$

where μ_0 is the lowest (positive) eigenvalue for the equation

$$g'''' - \frac{2}{\xi_o^2} g'' + \frac{11}{20\xi_o^4} g = \mu g \tag{96}$$

on I, subject to boundary conditions $g=g'=0$ at ∂I.

Let us suppose that I is bounded, writing $I=(-\tau_0/2, \tau_0/2)$ without loss of generality. It is convenient to write

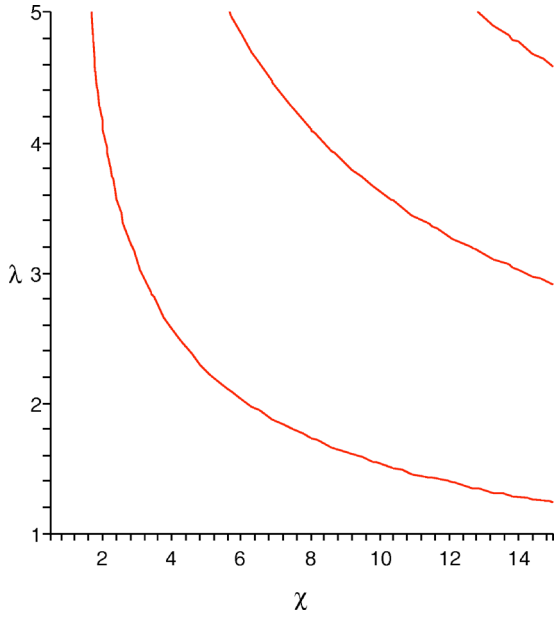

FIG. 5. (Color online) The first three solutions λ to Eq. (100), showing the dependence on $\chi=\tau_0/\xi_0$.

$$\mu = \frac{20\lambda^2 - 9}{20\xi_o^4} \tag{97}$$

for then the eigensolutions must be scalar multiples of

$$g(\tau) = \cosh \frac{\sqrt{\lambda+1}\,\tau}{\xi_o} + A \cos \frac{\sqrt{\lambda-1}\,\tau}{\xi_o}, \tag{98}$$

where

$$A = \frac{\sqrt{\lambda+1}\,\sinh(\sqrt{\lambda+1}\,\tau_0/(2\xi_o))}{\sqrt{\lambda-1}\,\sin(\sqrt{\lambda-1}\,\tau_0/(2\xi_o))} \tag{99}$$

and $\lambda > 1$ solves

$$\sqrt{\lambda+1}\,\tanh \frac{\sqrt{\lambda+1}\,\tau_0}{2\xi_o} = -\sqrt{\lambda-1}\,\tan \frac{\sqrt{\lambda-1}\,\tau_0}{2\xi_o}. \tag{100}$$

We shall denote the minimum solution to this equation in $(1,\infty)$ by λ_0 (see Fig. 5); clearly λ_0 depends only on the ratio of the sampling time τ_0 to the acceleration scale ξ_o. Two limits are of interest. First, when $\tau_0/\xi_0 \ll 1$, one may show that $\lambda_0^2 \sim \beta^4 \xi_o^4/\tau_0^4$ where β is as in Eq. (64). Thus we regain the usual short-timescale constraint Eq. (66). This supports the "usual assumption" (see Ref. 19 for references) that sampling at scales shorter than those determined by the acceleration or curvature is governed by the bound obtained for inertial curves in Minkowski space. On the other hand, if we take $\tau_0 \gg \xi_o$, we see that $\lambda_0 \to 1$, so

$$\mathcal{E} \gtrsim -\frac{11}{320\pi^2\xi_o^4} \tag{101}$$

in this limit.

In fact, more can be said for the inextendible case $\tau_0=\infty$, because the approximations made to gain Eq. (91) are rather wasteful in this limit. Choose any $g\in C_0^\infty((-1/2,1/2))$ with $g(0)\neq 0$ and define $g_{\tau_0}(\tau)=\tau_0^{-1/2}g(\tau/\tau_0)$, denoting the corresponding sampling tensor f_{τ_0}. Then a simple change of variables argument applied to Eq. (84) shows that

$$\mathcal{Q}_{\boldsymbol{M}}^{\text{weak}}(\mathsf{f}_{\tau_0},\omega_{\boldsymbol{M}})=\int_{-\infty}^{\infty}\mathrm{d}v|\hat{g}(v)|^2Q(v/\tau_0), \tag{102}$$

and the limit $\tau_0\to\infty$ may be taken under the integral sign to yield

$$\lim_{\tau_0\to\infty}\mathcal{Q}_{\boldsymbol{M}}(\mathsf{f}_{\tau_0},\omega_{\boldsymbol{M}})=2\pi Q(0)\int_{-\infty}^{\infty}\mathrm{d}\tau|g_{\tau_0}(\tau)|^2. \tag{103}$$

In particular, if g has unit L^2-norm, we have

$$\liminf_{\tau_0\to\infty}\frac{1}{\tau_0}\int_\gamma\langle T_{ab}u^au^b\rangle_\omega g(\tau/\tau_0)^2\mathrm{d}\tau\geqslant-\frac{11\alpha^4}{480\pi^2}, \tag{104}$$

where $\alpha=\xi_o^{-1}$ is the proper acceleration of the curve, as asserted in Example 3 in Sec. I. Thus long term averages of the energy density measured along the curve are bounded from below, and no energy density can be less than this bound over the entire worldline. This is an improvement by a factor of 3/2 over the bound given in Eq. (101). Using a more refined analysis one could presumably extract it as the limit of a result for general τ_0, but we will not pursue this here. To summarize, we have reached the following conclusions.

Proposition III.3: Let $\boldsymbol{N}$ *be a four-dimensional globally hyperbolic spacetime containing a timelike curve* γ *of proper duration* τ_0 *and constant proper acceleration* α. *If* γ *may be enclosed in a c.e.g.h.s. of* $\boldsymbol{N}$, *which is causally isometric to a c.e.g.h.s. of Minkowski space, then we have*

$$\sup_\gamma\langle T_{\boldsymbol{N}ab}u^au^b\rangle_\omega\geqslant-\frac{(20\lambda_0^2-9)\alpha^4}{320\pi^2} \tag{105}$$

for any Hadamard state ω *of the massless Klein-Gordon field, where* λ_0 *is the smallest solution to Eq.* (100) *in* $[1,\infty)$ *and depends on* $\alpha\tau_0$. *If* γ *has infinite proper duration, we also have the more stringent constraint Eq.* (104).

C. Massless fields in two dimensions

So far, we have only utilized the locally covariant difference QEIs of Sec. II E. For massless fields in two dimensions, however, we also have the absolute QEI developed by Flanagan and others, described in Sec. II D, which are also known to be optimal bounds. In this subsection we briefly discuss how the results of the previous subsections may be sharpened and generalized in this context. In fact the formula for the QEI bound is sufficiently simple that we may work directly in curved spacetime, rather than in Minkowskian subregions.

Let $\gamma:I\to\boldsymbol{N}$ be a smooth future-directed timelike curve, with velocity u^a and accleration a^c in a two-dimensional globally hyperbolic spacetime $\boldsymbol{N}$. As before, I is an open interval of proper time. In order to apply Flanagan's bound, we make the additional assumption that γ may be enclosed within a c.e.g.h.s. $\boldsymbol{N}'$ of $\boldsymbol{N}$, which is globally conformal to the whole of Minkowski space. Then Flanagan's QEI asserts that

$$\int_I\langle T_{\boldsymbol{N}ab}u^au^b\rangle_\omega(\gamma(\tau))g(\tau)^2\mathrm{d}\tau\geqslant-\frac{1}{6\pi}\int_I[g'(\tau)^2+g(\tau)^2\{R_{\boldsymbol{N}}(\gamma(\tau))-a^c(\tau)a_c(\tau)\}]\mathrm{d}\tau \tag{106}$$

for all Hadamard states ω and any smooth, real-valued g compactly supported in I, i.e., $g\in C_0^\infty(I;\mathbb{R})$.

We proceed as above, obtaining the estimate

$$\mathcal{E}\int_I g(\tau)^2 \mathrm{d}\tau \geqslant -\frac{1}{6\pi}\int_I [g'(\tau)^2 + g(\tau)^2\{R_{\boldsymbol{N}}(\gamma(\tau)) - a^c(\tau)a_c(\tau)\}]\mathrm{d}\tau, \tag{107}$$

for all $g \in C_0^\infty(I;\mathbb{R})$, where $\mathcal{E}=\sup_\gamma \langle T_{\mathbf{M}ab}u^a u^b\rangle_\omega$ as usual. Converting to an eigenvalue problem, we deduce that

$$\mathcal{E} \geqslant -\frac{\lambda_0}{6\pi}, \tag{108}$$

where λ_0 is the lowest element in the spectrum of the Friedrichs extension of the operator

$$(Lg)(\tau) = -g''(\tau) + (R_{\boldsymbol{N}}(\gamma(\tau)) - a^c(\tau)a_c(\tau))g(\tau), \tag{109}$$

on $C_0^\infty(I)$. Provided $R_{\boldsymbol{N}}$ and $a^c a_c$ are bounded along γ, the correct boundary conditions are Dirichlet conditions $g=0$ on ∂I (see, e.g., Ref. 33). We now give two illustrative examples.

Proposition III.4: Suppose $\boldsymbol{N}$ *is a globally hyperbolic two-dimensional spacetime with a c.e.g.h.s.* $\boldsymbol{N}'$*, which is globally conformal to the whole of Minkowski space. Then the following hold for all Hadamard states* ω *on* $\boldsymbol{N}$:

(*a*) *If* γ *is a curve of proper duration* τ_0 *contained in* $\boldsymbol{N}'$*, with* $R_{\boldsymbol{N}} - a^c a_c \equiv S$ *constant along* γ*, then*

$$\sup_{\tau\in I}\langle T_{\boldsymbol{N}ab}u^a u^b\rangle_\omega(\gamma(\tau)) \geqslant \frac{S}{6\pi} - \frac{\pi}{6\tau_0^2}. \tag{110}$$

(*b*) *If* $\gamma:\mathbb{R}\to\boldsymbol{N}$ *has (signed) proper acceleration growing linearly with proper time,* $\mathrm{d}\alpha/\mathrm{d}\tau = p$, and $R_{\boldsymbol{N}}\equiv 0$ on γ, then

$$\sup_{\tau\in I}\langle T_{\boldsymbol{N}ab}u^a u^b\rangle_\omega(\gamma(\tau)) \geqslant -\frac{|p|}{6\pi}. \tag{111}$$

The proof is straightforward: for (a), the eigenvalue problem is $-g''(\tau)=(\lambda+6\pi S)g(\tau)$ on an interval of length τ_0 subject to Dirichlet boundary conditions, which easily yields the stated result. For (b), we may choose the origin of proper time so that $a^c a_c = -p^2\tau^2$ for some constant p. The eigenvalue problem is then

$$-g''(\tau) + p^2\tau^2 g(\tau) = \lambda g(\tau), \tag{112}$$

which is the harmonic oscillator equation (and the Friedrichs extension is also the standard harmonic oscillator Hamiltonian). The minimum value of λ is therefore the "zero-point" value $\lambda_0 = |p|$. (The comparison with the usual quantum mechanical harmonic oscillator would correspond to units in which the mass and Planck's constant are both set to 2.) Thus we obtain the required result.

IV. CALCULATIONS IN SPECIFIC SPACETIMES

In this section we illustrate our general method by some concrete calculations in a variety of locally Minkowskian spacetimes in both two and four dimensions. For the most part, we focus on the lower bounds, but upper bound calculations are included where they are enlightening. For each spacetime we consider, exact values of the renormalized stress-energy tensor are known (or easily obtained from existing results) for one or more states. This permits comparison with the results of our method.

A. Two-dimensional timelike cylinder

Consider the massless scalar field on the two-dimensional timelike cylinder, $\boldsymbol{C}$, i.e., Minkowski space $\boldsymbol{M}_2$ quotiented by the group of translations $(t,x)\mapsto(t,x+nL)$ $(n\in\mathbb{Z})$. The Casimir vacuum $\omega_{\boldsymbol{C}}$ is the ground state of the scalar field on $\boldsymbol{C}$ (more precisely, it is a state on the

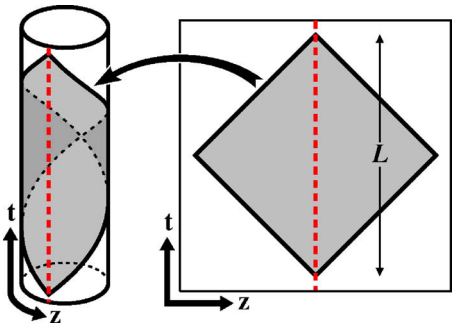

FIG. 6. (Color online) Diagram showing the "largest" causal diamond in two-dimensional Minkowski space that can be isometrically embedded into the two-dimensional cylinder spacetime with periodicity L in the z direction. To an observer inside the diamond in the cylinder spacetime, the quantum field theory and states would be indistinguishable from that in Minkowski space. The dashed vertical line is the worldline of a stationary observer.

algebra of first derivatives of the field—we will ignore this subtlety, which does not modify any of our conclusions below). The renormalized expectation value of the vacuum stress-tensor has the form

$$\langle T_{\boldsymbol{C}ab}\rangle_{\omega_{\boldsymbol{C}}}(x) = \rho_{\boldsymbol{C}}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{113}$$

where $\rho_{\boldsymbol{C}}$ is a constant. Our aim is to use quantum inequalities to provide upper and lower bounds on $\rho_{\boldsymbol{C}}$. The value of $\rho_{\boldsymbol{C}}$ is, of course, well known, and will satisfy the bounds we now derive; our aim is to demonstrate how it may be bounded without direct calculation.

In order to apply our method, we must identify suitable globally hyperbolic subspacetimes of $\boldsymbol{C}$. For any $0<\tau_0\leqslant L$, we may define a timelike geodesic $\gamma:(0,\tau_0)\to\boldsymbol{C}$ by $\gamma(\tau)=(\tau,0)$. Then the double cone $\mathrm{int}(J^+(\gamma(0))\cap J^-(\gamma(\tau_0)))$ is a causally embedded globally hyperbolic subspacetime of $\boldsymbol{C}$, containing γ. As this subspacetime is globally conformal to the whole of Minkowski space and the energy density is constant along γ, we have the lower bound

$$\rho_{\boldsymbol{C}} \geqslant -\frac{\pi}{6\tau_0^2}, \tag{114}$$

from Proposition III.4(a) (in the case $S=0$). This bound clearly becomes more stringent as τ_0 is increased, so we obtain the best bound possible (within this method) by taking $\tau_0=L$. As shown in Fig. 6, the corresponding diamond is one for which the corners of the diamond just barely fail to touch on the back of the cylinder. This gives the final result

$$\rho_{\boldsymbol{C}} \geqslant -\frac{\pi}{6L^2}. \tag{115}$$

We now demonstrate how to find an upper bound on $\rho_{\boldsymbol{C}}$ for which we must employ our locally covariant difference QWEI. Let $\tilde{\gamma}$ be the curve $\tilde{\gamma}(\tau)=(\tau,0)$ in $\boldsymbol{M}_2$ and let $\boldsymbol{M}'=\mathrm{int}\, J^+(\tilde{\gamma}(0))\cap J^-(\tilde{\gamma}(\tau_0))$, for some $0<\tau_0<L$, which is a c.e.g.h.s. of $\boldsymbol{M}_2$. Then the quotient map $q:\boldsymbol{M}_2\to\boldsymbol{C}$ defines a causal isometric embedding of $\boldsymbol{M}'$ in $\boldsymbol{C}$, with $q(\boldsymbol{M}')$ equal to the double cone constructed earlier in this subsection. By Corollary II.4 we have

$$\langle T_{\boldsymbol{C}}(q_*\mathsf{f})\rangle_{\omega_{\boldsymbol{C}}} \leqslant \mathcal{Q}^{\mathrm{weak}}_{\boldsymbol{C}}(\mathsf{f},\omega_{\boldsymbol{C}}) \tag{116}$$

for any sampling tensor $\mathsf{f}\in\mathcal{F}^{\mathrm{weak}}_{M'}$. We define f by Eq. (49) for $g\in\tilde{C}^\infty_0((0,\tau_0);\mathbb{R})$ and then use the constancy of the energy density along γ to find

$$\rho_C \int_0^{\tau_0} g(\tau)^2 \mathrm{d}\tau \leqslant \mathcal{Q}_C^{\mathrm{weak}}(\mathsf{f}, \omega_C) \leqslant \frac{1}{2\pi} \int (g'(\tau))^2 \mathrm{d}\tau, \tag{117}$$

where the last inequality is derived in Appendix B. As usual, this may be converted into an eigenvalue problem: here, $\rho_C \leqslant \lambda_0/(2\pi)$ where $\lambda_0 = (\pi/\tau_0)^2$ is the minimum eigenvalue of $-\mathrm{d}^2/\mathrm{d}\tau^2$ on $(0, \tau_0)$ subject to Dirichlet boundary conditions. Combining with our earlier lower bound, we thus have

$$-\frac{\pi}{6L^2} \leqslant \rho_C \leqslant \frac{\pi}{2L^2}. \tag{118}$$

The known value of ρ_C is exactly $-\pi/(6L^2)$ (see Ref. 59), which, remarkably, saturates the lower bound. Thus we have shown that, in the cylinder spacetime, the Casimir vacuum energy density is the lowest possible static energy density compatible with the quantum energy inequalities. This, however, is not always the case, as we will see in later examples.

Because the energy density is in fact negative, the upper bound was not particularly enlightening in this example. However, the situation is different for thermal equilibrium states. Let $\omega_{C,\beta}$ be the thermal equilibrium (KMS) state at inverse temperature β, relative to the static time translations. The stress-energy tensor is again diagonal

$$\langle T_{Cab} \rangle_{\omega_{C,\beta}}(x) = \rho_{C,\beta} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{119}$$

where

$$\rho_{C,\beta} = -\frac{\pi}{6L^2} + \frac{\pi}{L^2} \sum_{n=1}^{\infty} \operatorname{cosech}^2 \frac{n\pi\beta}{L}, \tag{120}$$

see, e.g., Sec. 4.2 of Ref. 59. By our general theory, these states should be constrained by the same lower bound as before, and this is evidently true, because the series contribution to $\rho_{C,\beta}$ is clearly positive. The upper bound depends on the temperature according to the formula

$$\rho_{C,\beta} \leqslant \frac{\mathcal{Q}_C^{\mathrm{weak}}(\mathsf{f}, \omega_{C,\beta})}{\displaystyle\int_0^{\tau_0} g(\tau)^2 \mathrm{d}\tau} \tag{121}$$

for any $g \in \widetilde{C}_0^\infty((0, \tau_0); \mathbb{R})$. In Appendix B we obtain the estimate

$$\mathcal{Q}_C^{\mathrm{weak}}(\mathsf{f}, \omega_{C,\beta}) \leqslant \frac{\mathcal{Q}_C^{\mathrm{weak}}(\mathsf{f}, \omega_C)}{1 - e^{-2\pi\beta/L}} + \frac{\pi e^{\pi\beta/L}}{2L^2 \sinh^3 \pi\beta/L} \int_{-\infty}^{\infty} |g(\tau)|^2 \mathrm{d}\tau \tag{122}$$

and we may now immediately optimize over g using our result for the ground state to obtain

$$-\frac{\pi}{6L^2} \leqslant \rho_{C,\beta} \leqslant \frac{\pi}{2L^2(1 - e^{-2\pi\beta/L})} + \frac{\pi e^{\pi\beta/L}}{2L^2 \sinh^3 \pi\beta/L}. \tag{123}$$

As shown in Fig. 7 this is consistent with the known value of $\rho_{C,\beta}$.

B. Spatial topology $\mathbb{R}^{3-j} \times \mathbb{T}^j$, $j = 1, 2, 3$

Let us now consider various quotients of four-dimensional Minkowksi space by subgroups of the group of spatial translations. To begin, consider the quotient of four-dimensional Minkowski space, with inertial coordinates (t, x, y, z) by the spatial translation subgroup $(t, x, y, z) \mapsto (t, x, y, z + nL_1)$ $(n \in \mathbb{Z})$ for some fixed periodicity length $L_1 > 0$. We will denote the resulting spacetime by $\boldsymbol{N}_1$, and consider the ground state $\omega_{\boldsymbol{N}_1}$, which has a nonzero Casimir

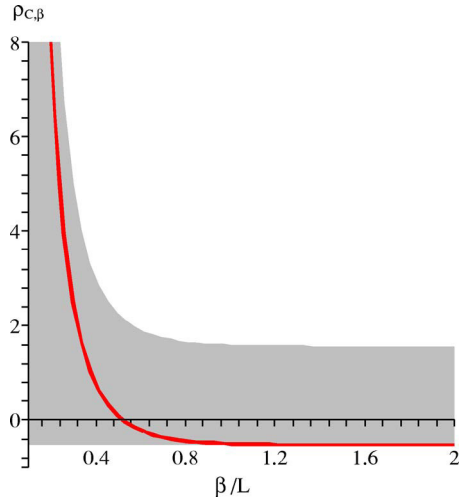

FIG. 7. (Color online) A graph showing the energy density $\rho_{C,\beta}$ in units of L^{-2} of the thermal equilibrium state at temperature β^{-1} on a cylinder of circumference L. The shaded region indicates the range permitted by the upper and lower bounds obtained from QEIs, illustrating Eq. (123).

vacuum stress-energy tensor. A calculation using the method of images and the Minkowski space vacuum two-point function yields the renormalized vacuum stress-tensor for the massless scalar field in this spacetime, (see, e.g., Ref. 60)

$$\langle T_{\boldsymbol{N}_1 ab}\rangle_{\omega_{\boldsymbol{N}_1}} = -\frac{\pi^2}{90L_1^4}\,\mathrm{diag}[1,-1,-1,3]. \tag{124}$$

We will now show that this is consistent with the lower bound arising from the QEIs. To this end, let $\gamma(\tau)=(\tau,x_0)$ for some fixed $x_0\in\mathbb{R}^2\times\mathbb{T}$. Then the double cone $\mathrm{int}(J^+(\gamma(0))\cap J^-(\gamma(L_1)))$ is a c.e.g.h.s. of $\boldsymbol{N}_1$, which is causally isometric to a double cone in Minkowski space. Thus the portion of γ parametrized by $(0,L_1)$ meets the hypotheses of Proposition III.1 and we have

$$\sup_{\gamma}\langle T_{\boldsymbol{N}_1 00}\rangle_\omega \geqslant -\frac{C_4}{L_1^4} \tag{125}$$

for any Hadamard state ω of the Klein-Gordon field. In particular, the state $\omega_{\boldsymbol{N}_1}$ obeys this bound, as $\pi^2/90\approx 0.109\,662 < C_4$. In fact, the energy density is about 30 times smaller than the QEI bound in this case.

Thus the QEI bounds can be rather weak. But this is necessary, as can be seen from the next examples, in which the same lower bound must constrain a more negative energy density. Consider the spacetime $\boldsymbol{N}_2\cong\mathbb{R}\times\mathbb{R}\times\mathbb{T}^2$, which may be obtained by quotienting $\boldsymbol{N}_1$ by the translation group $(t,x,y,z)\mapsto(t,x,y+nL_2,z)$ $(n\in\mathbb{Z})$ for some nonnegative L_2, which, without loss of generality, we take to be no less than L_1. Because $L_2\geqslant L_1$ we may apply Proposition III.1 to a double cone of the same size as before, so the lower bound is unchanged. However the stress tensor is now[60]

$$\langle T_{\boldsymbol{N}_2 ab}\rangle_{\omega_{\boldsymbol{N}_2}} = -\frac{1}{2\pi^2 L_1^4}\sum_{(m,n)\in\mathbb{Z}^2\setminus\{0\}}\frac{1}{(m^2+n^2)^2}\,\mathrm{diag}[1,-1,1,1] \tag{126}$$

in the special case $L_2=L_1$. The sum can no longer be given in closed form, but numerically the overall prefactor [equal to the energy density on the worldline $\tau\mapsto(\tau,x_0)$] is given in Ref. 60 as $-0.305/L_1^4$. This is still consistent with Eq. (125), with energy density now only around ten times smaller than the bound.

In exactly the same way we may quotient $\boldsymbol{N}_2$ by the translation subgroup $(t,x,y,z)\mapsto(t,x+nL_3,y,z)$ $(n\in\mathbb{Z})$, thereby forming $\boldsymbol{N}_3\cong\mathbb{R}\times\mathbb{T}^3$. If we again suppose that $L_1\leqslant L_2\leqslant L_3$, then the bound Eq. (125) still applies to the ground state on this spacetime. (Since this spacetime supports normalizable zero modes for the massless scalar field, one must regard this as a state on the algebra of derivatives of the field, much as for massless fields in two dimensions.) On the other hand, the stress-energy tensor in the natural ground state is

$$\langle T_{\boldsymbol{N}_3 ab}\rangle_{\omega_{\boldsymbol{N}_3}} = -\frac{1}{2\pi^2 L_1^4}\sum_{(l,m,n)\in\mathbb{Z}^3\setminus\{0\}}\frac{1}{(l^2+m^2+n^2)^2}\,\mathrm{diag}\left[1,\frac{1}{3},\frac{1}{3},\frac{1}{3}\right] \tag{127}$$

in the special case $L_1=L_2=L_3$. The energy density along $\tau\mapsto(\tau,x_0)$ in this case is numerically computed to be $0.838/L_1^4$, which is again consistent with the QEI constraint Eq. (125), which is now weaker by a factor of less than 4.

Let us note that the massless QEI bound also provides a lower bound on the ground state energy densities of *massive* scalar fields in these spacetimes. Consistency here is seen from the fact that the mass diminishes the magnitude of the energy density[61] (note the misprints in Ref. 61 noted in Ref. 62 that do not, however, affect the final result).

C. Misner universe

Our third example concerns (the globally hyperbolic portion of) the Misner universe $\boldsymbol{U}$; namely, the quotient of $(0,\infty)\times\mathbb{R}^3$ with metric

$$\mathrm{d}s^2 = \mathrm{d}t^2 - t^2(\mathrm{d}x^1)^2 - (\mathrm{d}x^2)^2 - (\mathrm{d}x^3)^2, \tag{128}$$

by the translation group $(t,x^1,x^2,x^3)\mapsto(t,x^1+na,x^2,x^3)$ $(n\in\mathbb{Z})$ for some constant $a>0$. That is, the x^1 coordinate has been compactified onto a circle. We restrict to $t>0$ to avoid the closed null geodesics that would appear at $t=0$ and the closed timelike curves appearing for $t<0$. Under the coordinate transformation

$$y^0 = t\cosh(x^1),\quad y^1 = t\sinh(x^1),\quad y^2 = x^2,\quad y^3 = x^3, \tag{129}$$

we may, equivalently, regard Misner space as the wedge $y^0>|y^1|$ of Minkowski spacetime with the points (y^0,y^1,y^2,y^3) and $(y^0\cosh(na)+y^1\sinh(na),y^1\cosh(na)+y^0\sinh(na),y^2,y^3)$ identified for each $n\in\mathbb{Z}$.

Define a curve $\gamma(\tau)=(\tau,\boldsymbol{x}_o)$ in the original coordinates, for some constant $x_0\in\mathbb{T}\times\mathbb{R}^2$. This is a timelike geodesic, with velocity $u^a=(1,0)$. In the Minkowski space cover, this worldline is given by

$$\gamma(\tau) = \begin{pmatrix}\tau\cosh(x_o^1)\\ \tau\sinh(x_o^1)\\ x_o^2\\ x_o^3\end{pmatrix}\quad\text{with}\quad u^a(\tau) = \begin{pmatrix}\cosh(x_o^1)\\ \sinh(x_o^1)\\ 0\\ 0\end{pmatrix}, \tag{130}$$

which is a constant velocity geodesic, as shown by the bold dashed line in Fig. 8. Let us consider a portion of this curve, running between $P=\gamma(\tau_P)$ and $F=\gamma(\tau_F)$, which is such that $\mathrm{int}(J^+(P)\cap J^-(F))$ is a c.e.g.h.s. of Misner space isometric to a double cone in Minkowski space. Assuming that this region is maximal, it must be that the geodesic joining the $n=+1$ image P_{+1} of P to F is null. Setting $\tau_O=(\tau_F+\tau_P)/2$ and $L=(\tau_F-\tau_P)/2$, this yields the condition

$$\left[\left(\tau_O+\frac{L}{2}\right)\cosh(x_o^1)-\left(\tau_O-\frac{L}{2}\right)\cosh(x_o^1+a)\right]^2-\left[\left(\tau_O+\frac{L}{2}\right)\sinh(x_o^1)-\left(\tau_O-\frac{L}{2}\right)\sinh(x_o^1+a)\right]^2=0, \tag{131}$$

which entails

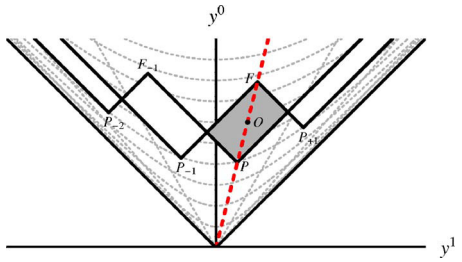

FIG. 8. (Color online) The covering space of the Misner universe is the wedge $y^0>|y^1|$ of Minkowski spacetime, shown here in cross section in the y^0-y^1 coordinates. Points in the covering space are identified, as described in the text, along the background hyperbolæ. Also shown is a stationary geodesic in the Misner universe, which in the covering space is a constant velocity observer (dashed line). For such an observer, the largest causal diamond for a given center point that is isomorphic to a subset of Minkowski space is shown in gray. Identified images of this diamond are also shown in white.

$$L = 2\tau_O \tanh\left(\frac{a}{2}\right). \tag{132}$$

This is the largest double cone of this type, centered on O, in which an observer cannot detect the compactified nature of the x^1 direction. We may therefore apply Proposition III.1 to the portion γ_{PF} of γ lying between P and F. This gives

$$\sup_{\gamma_{PF}} \langle T_{Uab} u^a u^b \rangle_\omega \geqslant -\frac{C_4}{L^4} = -\frac{C_4}{(2\tau_O \tanh(a/2))^4} \tag{133}$$

for any Hadamard state ω on Misner space. In particular, an energy density $\rho(\tau) = \langle T_{Uab} u^a u^b \rangle_\omega(\gamma(\tau))$ of the form $\rho(\tau) = -C/\tau^4$, for which $\sup_\gamma \rho = -C/\tau_F^4$, would be subject to the constraint

$$C \leqslant \frac{C_4}{16}(2 + \coth(a/2))^4. \tag{134}$$

By adapting the eigenvalue method, we may obtain a better bound. Let us suppose that ρ obeys

$$\rho(\tau) \leqslant \frac{K}{16\pi^2\tau^4} \tag{135}$$

on $I = (\tau_O - L/2, \tau_0 + L/2)$. Then by exactly the same arguments as in Sec. III A, we may deduce

$$K \geqslant -\inf_g \frac{\int |g''(\tau)|^2 \mathrm{d}\tau}{\int \tau^{-4}|g(\tau)|^2 \mathrm{d}\tau}, \tag{136}$$

where the τ^{-4} in the denominator comes from the form of ρ, and the infimum is taken over all $g \in C_0^\infty(I)$. The denominator can be reinterpreted as the norm of g in $L^2(I, \tau^{-4}d\tau)$. Integrating by parts twice, we may rewrite the numerator as $-\langle g | Lg \rangle$, where the inner product is that of $L^2(I, \tau^{-4}d\tau)$ and L is defined on $C_0^\infty(I)$ by

$$(Lg)(\tau) = \tau^4 g''''(\tau) \tag{137}$$

and is symmetric, i.e., $\langle h | Lg \rangle = \langle Lh | g \rangle$ for all $g, h \in C_0^\infty(I)$. The minimization problem is then solved by finding the lowest spectral point of the Friedrichs extension of L. It may be shown that the Friedrichs extension again amounts to the imposition of Dirichlet boundary conditions $g = g' = 0$ on ∂I,[63] and the problem now reduces to the study of the ODE

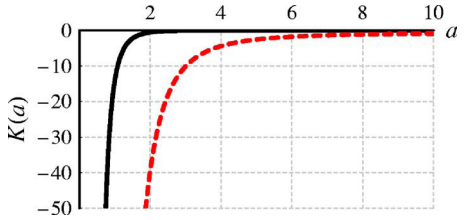

FIG. 9. (Color online) The numerical factor $K(a)$ for the vacuum stress tensor in the Misner universe (solid line) plotted for a range of the closure scale a. Also shown is the lower bounds from $-\lambda(a)$ (dashed line). The lower bound from Eq. (134) is so weak (it asymptotically approaches ~ -2500 from below for large a) that it is not included to preserve detail in the figure above.

$$g''''(\tau) - \frac{\lambda}{\tau^4} g(\tau) = 0. \tag{138}$$

Again we wish to determine the minimum eigenvalue λ for eigensolutions that satisfy the boundary conditions. The substitution $g(\tau) = h\left(\frac{1}{2}\ln(\tau)\right)$ converts the equation to a constant coefficient linear equation, and one may determine the general solution (e.g., using *Mathematica*) as

$$h(l) = c_1 e^{3l} \cos(l\sqrt{4\sqrt{\lambda+1}-5}) + c_2 e^{3l} \sin(l\sqrt{4\sqrt{\lambda+1}-5}) + c_3 e^{(3+\sqrt{4\sqrt{\lambda+1}+5})l} + c_4 e^{(3-\sqrt{4\sqrt{\lambda+1}+5})l}, \tag{139}$$

where (c_1, c_2, c_3, c_4) are constants. Imposing three of the boundary conditions fixes three of the constants in terms of the fourth, which serves as an overall magnitude for the test function. The fourth boundary condition can then be used to determine the eigenvalues. A somewhat involved calculation leads to the transcendental equation to determine λ implicitly in terms of a:

$$\frac{\sqrt{16\lambda-9}}{5} = \frac{\sin\left(\frac{a}{2}\sqrt{4\sqrt{\lambda+1}-5}\right)\sinh\left(\frac{a}{2}\sqrt{4\sqrt{\lambda+1}+5}\right)}{\cos\left(\frac{a}{2}\sqrt{4\sqrt{\lambda+1}-5}\right)\cosh\left(\frac{a}{2}\sqrt{4\sqrt{\lambda+1}+5}\right)-1}. \tag{140}$$

We denote λ, so determined, as $\lambda(a)$; this constrains our original value K by

$$K \geqslant -\lambda(a). \tag{141}$$

Our interest in energy densities proportional to τ^{-4} stems from the state constructed by Hiscock and Konkowski.[64] This quasifree state, which we denote ω_U, is obtained by applying the method of images to the Minkowski space two-point function in the wedge $y^0 > |y^1|$, and then carrying it back to the original Misner coordinates to find the renormalized vacuum expectation value of the stress tensor. Hiscock and Konkowski considered the conformally coupled scalar field, but their calculations can be easily reproduced in the minimally coupled case to yield

$$\langle T_{Uab}\rangle_{\omega_U}(t) = \frac{K(a)}{16\pi^2 t^4}\,\mathrm{diag}[1, 3t^2, -1, -1], \tag{142}$$

where

$$K(a) = -\sum_{n=1}^{\infty} \mathrm{cosech}^4\left(\frac{na}{2}\right) \tag{143}$$

is a negative constant depending on the x^1-period a.[65] Both the coefficient $K(a)$ and the numerical evaluation of the lower bound $-\lambda(a)$ are plotted in Fig. 9. It is obvious that $K(a)$, and thus the energy density obey the QEI constraint for all values of a. The bound Eq. (134) is still weaker.

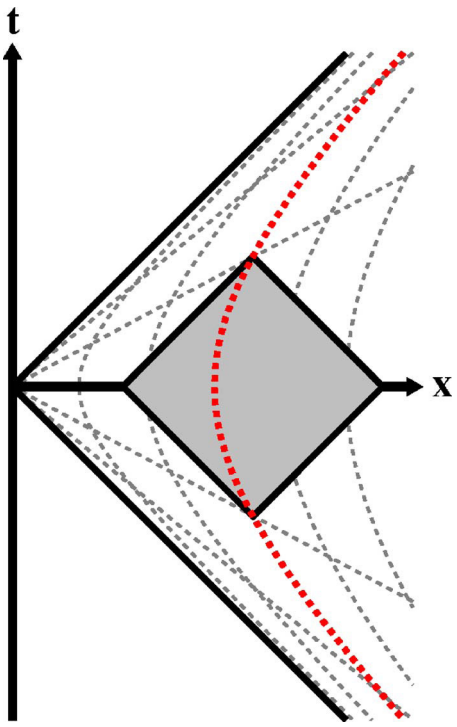

FIG. 10. Diagram showing Rindler spacetime (with the two perpendicular space dimensions suppressed) embedded into Minkowski spacetime. The dashed hyperbolic line, the worldline of a constantly accelerating observer, is the image of a constant ξ observer's worldline in Rindler coordinates. The gray diamond is a causal region that can be isometrically identified between the two "different" coordinate systems.

D. Rindler spacetime

The Rindler spacetime $\boldsymbol{R}$ is the "right wedge" of Minkowski space, i.e., the region $\{(t,x,y,z)\in\mathbb{R}^4: x>|t|\}$ in inertial coordinates (t,x,y,z). We may also make the coordinate transformation

$$t=\xi\sinh(\eta),\quad y=y,$$

$$x=\xi\cosh(\eta),\quad z=z, \tag{144}$$

to obtain the metric in the form

$$\mathrm{d}s^2=\xi^2\mathrm{d}\eta^2-\mathrm{d}\xi^2-\mathrm{d}y^2-\mathrm{d}z^2, \tag{145}$$

with coordinate ranges $\eta,y,z\in\mathbb{R}$, $\xi\in(0,\infty)$. Lines of constant ξ, when mapped into Minkowski space, are worldlines for observers undergoing constant proper acceleration $\alpha=\xi^{-1}$. Rindler spacetime is static with respect to η (corresponding to Lorentz invariance in the xt plane) and is invariant under Euclidean transformations of the yz plane. (See Fig. 10.)

Clearly any line of constant ξ meets the conditions of Proposition III.3 and we may immediately read off that any static Hadamard state ω on $\boldsymbol{R}$ must obey

$$\langle T_{\boldsymbol{R}ab}u^a u^b\rangle_\omega(\eta,\xi,y,z)\geqslant-\frac{11}{480\pi^2\xi^4}, \tag{146}$$

where u^a is the unit vector parallel to $\partial/\partial\eta$. In particular, this provides a constraint on the energy density $\rho_{\boldsymbol{R}}=\langle T_{\boldsymbol{R}ab}u^a u^b\rangle_{\omega_{\boldsymbol{R}}}$ in the ground state $\omega_{\boldsymbol{R}}$ (which is Hadamard). This may also be computed exactly: it was first computed for the conformally coupled scalar field by Candelas and Deutsch[66]

and one can easily generalize their results to the minimally coupled scalar field to obtain[67]

$$\rho_{\boldsymbol{R}} = -\frac{11}{480\pi^2\xi_o^4}, \tag{147}$$

which is exactly the lower bound given above. Thus, remarkably, the Rindler ground state saturates the QEI constraints, which were obtained using local covariance and the Minkowski vacuum, and nowhere involved $\omega_{\boldsymbol{R}}$.

Let us also examine how an upper bound might be obtained. Let $\gamma(\tau)=(\tau/\xi_o,\xi_o,0,0)$ in (η,ξ,y,z) coordinates and set $\mathsf{u}=\dot{\gamma}$ as usual. We consider sampling along γ, with sampling tensors of form

$$\mathsf{f}(\mathsf{t}) = \int t_{ab}|_{\gamma(\tau)} u^a u^b g(\tau)^2 \mathrm{d}\tau \tag{148}$$

for $g \in \widetilde{C}_0^\infty(\mathbb{R};\mathbb{R})$. Since the energy density is constant along γ, the upper bound of Corollary II.4 gives

$$\rho_{\boldsymbol{R}} \int g(\tau)^2 \mathrm{d}\tau = \langle \mathsf{T}_{\boldsymbol{R}}(\mathsf{f})\rangle_{\omega_{\boldsymbol{R}}} \leqslant \mathcal{Q}_{\boldsymbol{R}}^{\mathrm{weak}}(\mathsf{f},\omega_{\boldsymbol{R}}). \tag{149}$$

The right-hand side can be read off from the difference QEI derived by Pfenning[21] for the electromagnetic field, because the corresponding bound for the scalar field is exactly half of the electromagnetic expression[68]

$$\mathcal{Q}_{\boldsymbol{R}}^{\mathrm{weak}}(\mathsf{f},\omega_{\boldsymbol{R}}) = \frac{1}{16\pi^3}\int_0^\infty |\hat{g}(u)|^2(u^4+2\xi_o^{-2}u^2)\mathrm{d}u = \frac{1}{16\pi^2}\int_{-\infty}^\infty (|g''(\tau)|^2+2\xi_o^{-2}|g'(\tau)|^2)\mathrm{d}\tau. \tag{150}$$

Next consider scaling the test function, replacing g by $g_\alpha(\tau)=\alpha^{-1/2}g(\tau/\alpha)$. We find, considering the scaling behavior of the above expression,

$$\rho_{\boldsymbol{R}} \leqslant \frac{1}{16\pi^2}\frac{\displaystyle\int (|g''(\tau)|^2+2\alpha^2\xi_o^{-2}|g'(\tau)|^2)\mathrm{d}\tau}{\displaystyle\alpha^4\int g(\tau)^2\mathrm{d}\tau} \tag{151}$$

for which the right-hand side vanishes in the limit of $\alpha\to\infty$. Thus we find consistency with the known fact that the expectation value of the Rindler ground state is bounded above by zero, i.e., $\rho_{\boldsymbol{R}}\leqslant 0$.

V. SUMMARY

In this paper we have initiated the study of interrelations between quantum energy inequalities and local covariance. We have formulated definitions of locally covariant QEIs, and shown that existing QEIs obey them, modulo small additional restrictions (Sec. II). The main thrust of our work has been directed at providing *a priori* constraints on renormalized energy densities in locally Minkowskian regions, accomplished in Sec. III. The simple geometric nature of these bounds makes them easy to apply in practice, and a number of future applications are envisaged. In particular, we will discuss applications to the Casimir effect in a companion paper;[2] at the theoretical level, it is possible to place the present discussion in the categorical language of Ref. 37, and this will be done elsewhere. Equally important are the specific calculations reported in Sec. IV. Here we saw that, in some situations, the QEI bounds give best-possible constraints on the energy density, and that typical ground-state energy densities are not overestimated by the QEI bound by more than a factor of about 30 at worst (in the examples studied so far).

Finally, although we confined our attention largely to locally Minkowskian spacetimes in Secs. III and IV, we emphasize again that other interesting cases may be studied using our general formalism, as, for example, in the work of Marecki[3] on spacetimes with locally Schwarzschild subregions.

ACKNOWLEDGMENTS

This work was initiated at the Erwin Schrödinger Institute for Mathematical Physics, Vienna, during a program on Quantum Field Theory in Curved Spacetime. We are grateful to the organizers of this program and to the Institute for its hospitality and financial support. C.J.F. further thanks the Isaac Newton Institute, Cambridge, for support during the final stages of the work, and the organizers of the program on Global Problems in Mathematical Relativity. We also thank L.H. Ford, A. Higuchi, B.S. Kay, J. Loftin, and T.A. Roman for many illuminating discussions, and L. Osterbrink and C.J. Smith for comments on the manuscript. This work was partially supported by EPSRC Grant No. GR/R25019/01 to the University of York and by a grant from the U.S. Army Research Office through the USMA Photonics Research Center. M.J.P. also thanks the University of York for a grant awarded under its "Research Funding for Staff on Fixed Term Contracts" scheme.

APPENDIX A: THE LOCALLY COVARIANT QUANTUM FIELD THEORY OF A SCALAR FIELD

In this Appendix we describe the construction of the quantized Klein-Gordon field within the algebraic approach to quantum field theory, and explain the construction of pulled back states used in Sec. II B.

The free scalar field of mass $m \geqslant 0$ may be quantized on any globally hyperbolic spacetime $\boldsymbol{M}$ in the sense that one may construct a complex unital $*$-algebra $\mathfrak{A}(\boldsymbol{M})$ whose elements may be interpreted as "polynomials in smeared fields." A typical element of the algebra is a complex linear combination of the identity $\mathbf{1}$ and a finite number of terms, each of which is a finite product of a number of objects $\Phi_{\boldsymbol{M}}(f)$, where f is a test function (i.e., smooth and compactly supported) on M. The algebra also satisfies a number of relations:

1. $\Phi_{\boldsymbol{M}}(\lambda f+\mu g)=\lambda\Phi_{\boldsymbol{M}}(f)+\mu\Phi_{\boldsymbol{M}}(g)$
2. $\Phi_{\boldsymbol{M}}(f)^*=\Phi_{\boldsymbol{M}}(\bar{f})$
3. $\Phi_{\boldsymbol{M}}((\Box+m^2)f)=0$
4. $[\Phi_{\boldsymbol{M}}(f),\Phi_{\boldsymbol{M}}(g)]=iE_{\boldsymbol{M}}(f,g)\mathbf{1}$

for all test functions f,g on M and complex scalars λ,μ, where $E_{\boldsymbol{M}}$ is the advanced-minus-retarded fundamental solution to $\Box+m^2$ on $\boldsymbol{M}$. The first two axioms are necessary for compatibility with the idea of $\Phi_{\boldsymbol{M}}(f)$ as a smeared hermitian field; the third expresses the field equation in "weak" form; the fourth expresses the commutation relations.

Now let ψ be a causal isometric embedding of $\boldsymbol{M}_1$ into $\boldsymbol{M}_2$. Any test function f on M_1 now corresponds to a test function $\psi_* f$ on M_2, defined by $(\psi_* f)(x)=f(\psi^{-1}(x))$ for $x\in\psi(M_1)$ and $(\psi_* f)(x)=0$ otherwise. We may use this to define a map α_ψ between $\mathfrak{A}(\boldsymbol{M}_1)$ and $\mathfrak{A}(\boldsymbol{M}_2)$ such that

1. $\alpha_\psi\mathbf{1}_{\mathfrak{A}(\boldsymbol{M}_1)}=\mathbf{1}_{\mathfrak{A}(\boldsymbol{M}_2)}$
2. $\alpha_\psi(\Phi_{\boldsymbol{M}_1}(f))=\Phi_{\boldsymbol{M}_2}(\psi_* f)$ for all test functions f on M_1
3. α_ψ extends to general elements of $\mathfrak{A}(\boldsymbol{M}_1)$ as a $*$-homomorphism, i.e., α_ψ is linear and obeys $\alpha_\psi(AB)=\alpha_\psi(A)\alpha_\psi(B)$ and $\alpha_\psi(A^*)=\alpha_\psi(A)^*$ for all $A,B\in\mathfrak{A}(\boldsymbol{M}_1)$.

In the body of the text we have used the notation ψ_* for α_ψ, relying on the context for the appropriate meaning; here, it is convenient to distinguish the two maps. One must check that the last statement is compatible with the axioms stated above—the only nontrivial one is the commutation relation, where the causal nature of ψ plays a key role and guarantees that α_ψ is well-defined. What needs to be proved boils down to checking that

$$E_{\boldsymbol{M}_1}(f,g) = E_{\boldsymbol{M}_2}(\psi_* f, \psi_* g) \tag{A1}$$

for all test functions f,g on M_1. This equivalence is proved as follows. Writing $E^{\pm}_{\boldsymbol{M}}$ for the advanced $(-)$ and retarded $(+)$ Green functions on $\boldsymbol{M}$, $E^{\pm}_{\boldsymbol{M}_2}\psi_* f$ solves the inhomogeneous Klein-Gordon equation on $\boldsymbol{M}_2$ with source $\psi_* f$ and support in $J^{\pm}_{\boldsymbol{M}_2}(\mathrm{supp} f)$. Because ψ is a causal isometry, the pull-back $\psi^* E^{\pm}_{\boldsymbol{M}_2}\psi_* f$ solves the inhomogeneous Klein-Gordon equation on $\boldsymbol{M}_1$ with source f and support in $J^{\pm}_{\boldsymbol{M}_1}(\mathrm{supp} f)$; by uniqueness of solution, we have $E^{\pm}_{\boldsymbol{M}_1} f = \psi^* E^{\pm}_{\boldsymbol{M}_2}\psi_* f$. Accordingly $\psi_* E_{\boldsymbol{M}_1} = E_{\boldsymbol{M}_2}\psi_*$ and the required result follows.

In the algebraic approach we have been pursuing, a state of the quantum field on $\boldsymbol{M}$ is a linear map ω from $\mathfrak{A}(\boldsymbol{M})$ to the complex numbers, obeying $\omega(\mathbf{1})=1$ and $\omega(A^*A)\geqslant 0$ for any $A\in\mathfrak{A}(\boldsymbol{M})$. One interprets $\omega(A)$ as the expectation value of observable A in state ω. In particular, each state yields a hierarchy of n-point functions, i.e., maps of the form

$$(f_1,\ldots,f_n)\mapsto \omega(\Phi_{\boldsymbol{M}}(f_1)\cdots\Phi_{\boldsymbol{M}}(f_n)); \tag{A2}$$

we will restrict attention to those states whose corresponding n-point functions are distributions. A state ω is Hadamard if its two-point function has a particular singular structure, which is determined by the local metric and causal properties of the spacetime. Note that none of the structures introduced so far invoke any particular Hilbert space representation of the theory.

Now suppose again that ψ is a causal isometric embedding of $\boldsymbol{M}_1$ into $\boldsymbol{M}_2$ and let ω_2 be a state on $\mathfrak{A}(\boldsymbol{M}_2)$. We obtain a state ω_1 on $\mathfrak{A}(\boldsymbol{M}_2)$ by

$$\omega_1(A) = \omega_2(\alpha_\psi(A)) \tag{A3}$$

for any $A\in\mathfrak{A}(\boldsymbol{M}_1)$; that is, $\omega_1=\alpha^*_\psi\omega_2$, where α^*_ψ is the dual map to α_ψ (in the body of the text, we have written ψ^* for α^*_ψ). The n-point functions are therefore related by

$$\omega_1(\Phi_{\boldsymbol{M}_1}(f_1)\cdots\Phi_{\boldsymbol{M}_1}(f_n)) = \omega_2(\alpha_\psi(\Phi_{\boldsymbol{M}_1}(f_1)\cdots\Phi_{\boldsymbol{M}_1}(f_n))) = \omega_2(\Phi_{\boldsymbol{M}_2}(\psi_* f_1)\cdots\Phi_{\boldsymbol{M}_2}(\psi_* f_n)). \tag{A4}$$

It is useful to write this in "unsmeared" notation. Let $w^{(n)}_j$ be the n-point functions of ω_j. Then the last equation becomes

$$\begin{aligned}
&\int_{\boldsymbol{M}_1}\mathrm{dvol}_{g_1}(x_1)\cdots\int_{\boldsymbol{M}_1}\mathrm{dvol}_{g_1}(x_n)w^{(n)}_1(x_1,\ldots,x_n)f_1(x_1)\cdots f_n(x_n)\\
&\quad=\int_{\boldsymbol{M}_2}\mathrm{dvol}_{g_2}(y_1)\cdots\int_{\boldsymbol{M}_2}\mathrm{dvol}_{g_2}(y_n)w^{(n)}_2(y_1,\ldots,y_n)\psi_* f_1(y_1)\cdots\psi_* f_n(y_n)\\
&\quad=\int_{\boldsymbol{M}_1^{\times n}}\mathrm{dvol}_{g_1}(x_1)\cdots\mathrm{dvol}_{g_1}(x_n)w^{(n)}_1(\psi(x_1),\ldots,\psi(x_n))f_1(x_1)\cdots f_n(x_n),
\end{aligned} \tag{A5}$$

where the change of variables employed in the last step is justified by the fact that ψ is an isometry. As this holds for all choices of f_k, we may deduce that

$$w^{(n)}_1(x_1,\ldots,x_n) = w^{(n)}_2(\psi(x_1),\ldots,\psi(x_n)); \tag{A6}$$

that is, the n-point functions of ω_1 are the pull-backs by ψ of those of ω_2. It follows that if ω_2 is Hadamard then so too is ω_1, because the two-point function is simply pulled back under ψ and the Hadamard series is constructed from the local causal and metric structure, which is preserved under ψ. Since the stress-energy tensor is renormalized by subtracting the first few terms of the Hadamard series from the two-point function, and then taking suitable derivatives before taking the coincidence limit (making a further locally constructed correction to ensure conservation of the stress tensor), we have the following important consequence, which we isolate as a theorem.

Theorem A.1: *Suppose ψ is a causal isometric embedding of globally hyperbolic spacetime*

$\boldsymbol{M}_1$ in a globally hyperbolic spacetime $\boldsymbol{M}_2$. Any Hadamard state of the massive Klein-Gordon quantum field on $\boldsymbol{M}_2$ induces a Hadamard state of the same theory on $\boldsymbol{M}_1$, whose n-point functions and renormalized expected stress-energy tensor are the pull-backs by ψ of the corresponding quantities on $\boldsymbol{M}_2$.

This fits in with the principle that one should not be able to tell, by local experiments, whether one is in $\boldsymbol{M}_1$ or its image within the larger spacetime $\boldsymbol{M}_2$. It also justifies us in the abuse of notation perpetrated in Sec. II B, where we wrote ψ^* in place of α^*_ψ, and (dually) ψ_* in place of α_ψ.

Let us conclude by briefly describing more of the structure set out by Ref. 37. The key is the observation that the globally hyperbolic spacetimes of given dimension form the objects of a category in which the morphisms are causal isometric embeddings. One may also consider a category of unital $*$-algebras with injective unit-preserving $*$-homomorphisms as morphisms. The association of a globally hyperbolic spacetime $\boldsymbol{M}$ with the corresponding algebra $\mathfrak{A}(\boldsymbol{M})$ is then shown to be a covariant functor between these categories and gives a precise meaning to the notion of "the same field theory on different spacetimes" (and the same would be true even for theories not necessarily described in terms of a Lagrangian). A similar functorial description may be given to the association of the state space of the theory, and quantum fields are reinterpreted as natural transformations between functors. We refer the reader to Ref. 37 for full details.

APPENDIX B: DERIVATION OF A SCALAR FIELD QUANTUM WEAK ENERGY INEQUALITY IN THE CYLINDER SPACETIME

In this Appendix we calculate quantum weak energy inequalities for the massless, minimally coupled real scalar field in the two-dimensional cylinder spacetime relative to the ground and thermal equilibrium states. We use the notation of Sec. IV A. The KMS state $\omega_{\boldsymbol{C},\beta}$ at inverse temperature β has two-point function [see, e.g., Eq. (2.43) of Ref. 69]

$$w_{2,\beta}(x,x') = \frac{1}{2L}\sum_{n\in\mathbb{Z}\setminus\{0\}} \frac{e^{ik_n(z-z')}}{\omega_n(1-e^{-\beta\omega_n})}(e^{-i\omega(t-t')} + e^{-\beta\omega_n}e^{i\omega(t-t')}), \tag{B1}$$

where $k_n = 2\pi n/L$ and $\omega_n = |k_n|$, and the sum converges in the distributional sense (i.e., after smearing each term with test functions, the resulting series converges and its sum depends continuously on the test functions). We exclude the zero mode $n=0$ as usual, regarding $\omega_{\boldsymbol{C},\beta}$ as a state on the derivative fields. The two-point function of the ground state $\omega_{\boldsymbol{C}}$ is obtained as the zero temperature ($\beta\to\infty$) limit of this expression. We will be interested in the static curve $\gamma(\tau) = (\tau, 0)$, and employ the tetrad $e_0 = \partial/\partial t$, $e_1 = \partial/\partial z$, which is invariant under Fermi-Walker transport along γ. Following the procedure of Sec. II E, we find

$$Q_{\gamma,\omega_{\boldsymbol{C},\beta}}(u) = \frac{1}{2\pi^2}\int_{(-\infty,u)} \mathrm{d}v\, \hat{T}_{\gamma,\omega_{\boldsymbol{C},\beta}}(v) \tag{B2}$$

and

$$T_{\gamma,\omega_{\boldsymbol{C},\beta}}(\sigma) = \frac{1}{L}\sum_{n=1}^{\infty} \frac{\omega_n}{1-e^{-\beta\omega_n}}(e^{-i\omega_n\sigma} + e^{-\beta\omega_n}e^{i\omega_n\sigma}). \tag{B3}$$

Taking the Fourier transform, we have

$$\hat{T}_{\gamma,\omega_{\boldsymbol{C},\beta}}(v) = \frac{2\pi}{L}\sum_{n=1}^{\infty} \frac{\omega_n}{1-e^{-\beta\omega_n}}(\delta(v-\omega_n) + e^{-\beta\omega_n}\delta(v+\omega_n)) \tag{B4}$$

and therefore obtain

$$Q_{\gamma,\omega_{C,\beta}}(u) = \frac{1}{\pi L}\left\{ \sum_{\substack{n\in\mathbb{N} \\ \text{s.t.}\omega_n<u}} \frac{\omega_n}{1-e^{-\beta\omega_n}} + \sum_{\substack{n\in\mathbb{N} \\ \text{s.t.}-\omega_n<u}} \frac{\omega_n e^{-\beta\omega_n}}{1-e^{-\beta\omega_n}} \right\}. \tag{B5}$$

Note that $Q_{\gamma,\omega_{C,\beta}}$ is supported on $\mathbb{R}^+$ in the $\beta=\infty$ case, but otherwise on the whole of $\mathbb{R}$, albeit exponentially suppressed on the negative half-line.

To arrive at convenient QEI bounds we estimate $Q_{\gamma,\omega_{C,\beta}}$ by

$$Q_{\gamma,\omega_{C,\beta}}(u) \leqslant Q_{\gamma,\omega_{C,\beta}}(0) + \frac{\vartheta(u)}{\pi L(1-e^{-2\pi\beta/L})} \sum_{\substack{n\in\mathbb{N} \\ \text{s.t.}\omega_n<u}} \omega_n, \tag{B6}$$

where ϑ is the Heaviside step function. To see that this estimate is valid, we note that $Q_{\gamma,\omega_{C,\beta}}(u)$ is clearly increasing on the negative half-line, so it is valid to bound it by $Q_{\gamma,\omega_{C,\beta}}(0)$ on $u\leqslant 0$; the second term in the estimate arises by noting that $(1-e^{-\beta\omega_n})^{-1}\leqslant(1-e^{-2\pi\beta/L})^{-1}$ for all n. Using this estimate again, we also have

$$Q_{\gamma,\omega_{C,\beta}}(0) = \sum_{n\in\mathbb{N}} \frac{\omega_n e^{-\beta\omega_n}}{1-e^{-\beta\omega_n}} \leqslant \frac{1}{\pi L(1-e^{-2\pi\beta/L})} \sum_{n=1}^{\infty} \frac{2\pi n}{L} e^{-2\pi\beta n/L} = \frac{e^{\pi\beta/L}}{4L^2\sinh^3\pi\beta/L}, \tag{B7}$$

while for $u>0$

$$\frac{1}{\pi L} \sum_{\substack{n\in\mathbb{N} \\ \text{s.t.}\omega_n<u}} \omega_n = \frac{1}{L^2}\tilde{n}(\tilde{n}+1) \leqslant \frac{2}{L^2}\tilde{n}^2 \leqslant \frac{u^2}{2\pi^2}, \tag{B8}$$

where $\tilde{n}$ is the greatest integer *strictly* less than $uL/(2\pi)$. Thus we have the estimate

$$Q_{\gamma,\omega_{C,\beta}}(u) \leqslant \frac{e^{\pi\beta/L}}{4L^2\sinh^3\pi\beta/L} + \frac{\vartheta(u)u^2}{2\pi^2(1-e^{-2\pi\beta/L})}. \tag{B9}$$

It then follows that, in the notation of Sec. IV A

$$\begin{aligned} \mathcal{Q}_C^{\text{weak}}(\mathsf{f},\omega_{C,\beta}) &= \int_{-\infty}^{\infty} \mathrm{d}u |\hat{g}(u)|^2 Q_{\gamma,\omega_{C,\beta}}(u) \\ &\leqslant \frac{e^{\pi\beta/L}}{4L^2\sinh^3\pi\beta/L} \int_{-\infty}^{0} |\hat{g}(u)|^2 \mathrm{d}u + \frac{1}{2\pi^2(1-e^{-2\pi\beta/L})} \int_0^{\infty} u^2 |\hat{g}(u)|^2 \mathrm{d}u \qquad \text{(B10)} \\ &\leqslant \frac{\pi e^{\pi\beta/L}}{2L^2\sinh^3\pi\beta/L} \int_{-\infty}^{\infty} |g(\tau)|^2 \mathrm{d}\tau + \frac{1}{2\pi(1-e^{-2\pi\beta/L})} \int_{-\infty}^{\infty} |g'(\tau)|^2 \mathrm{d}\tau, \qquad \text{(B11)} \end{aligned}$$

where we have used Parseval's theorem and the fact that $|\hat{g}(u)|$ is even for real-valued g to convert the integral over $\mathbb{R}^+$ into one over $\mathbb{R}$. For the ground state, of course, this yields

$$\mathcal{Q}_C^{\text{weak}}(\mathsf{f},\omega_C) \leqslant \frac{1}{2\pi}\int_{-\infty}^{\infty} |g'(\tau)|^2 \mathrm{d}\tau \tag{B12}$$

and Eq. (122) follows immediately. Although our estimates are not very sharp, they have led to a very simple quantum inequality. In fact, for the ground state, this inequality is only three times less restrictive than the optimal quantum inequality bound found in two-dimensional Minkowski spacetime.

APPENDIX C: A LEMMA CONCERNING SMOOTH FUNCTIONS

Recall from Sec. II E that we define $\tilde{C}_0^\infty(I;\mathbb{R})$ to be the set of smooth compactly supported real-valued functions g on I whose support is connected and which have no zeros of infinite order in the interior of that support (equivalently, g has no zeros in $(\inf \operatorname{supp} g, \sup \operatorname{supp} g)$ of infinite order). Our aim is to prove the following result.

Lemma 1: Let $g \in C_0^\infty(I;\mathbb{R})$ *and choose any* $\chi \in \tilde{C}_0^\infty(I;\mathbb{R})$ *with* $\chi=1$ *on* $\operatorname{supp} g$. *Then there is a sequence* $\epsilon_n \to 0$ *for which each* $g_n = g + \epsilon_n \chi$ *is an element of* $\tilde{C}_0^\infty(I;R)$.

Proof: If g is identically zero the result is trivial, so we assume henceforth that it is not, so $M = \sup|g''|$ is strictly positive. Suppose the stated result is false, so there exists an $\epsilon_0 > 0$ such that $g + \epsilon\chi \notin \tilde{C}_0^\infty(I;\mathbb{R})$ for all $|\epsilon| \leqslant \epsilon_0$. Choose $N \in \mathbb{N}$ sufficiently large that $(N-1)\sqrt{2\epsilon_0/(MN)}$ exceeds the diameter of the support of g. By hypothesis, for each $|\epsilon| < \epsilon_0$ the function $g + \varepsilon_n \chi$ has a zero of infinite order within its support; since $\chi \in \tilde{C}_0^\infty(I;\mathbb{R})$ this zero must lie in the support of g and is therefore a point at which g' vanishes, while g takes the value $-\epsilon_n$. We may therefore choose $z_1 < z_2 < \ldots < z_N$ such that $g'(z_k) = 0$ for each k and $g(z_k)$ runs through the values $\{-k\epsilon_0/N : k = 1, \ldots, N\}$ (not necessarily in order). Using Taylor's theorem with remainder at each z_k,

$$\frac{\epsilon_0}{N} \leqslant |g(z_{k+1}) - g(z_k)| \leqslant \frac{M}{2}(z_{k+1} - z_k)^2 \tag{C1}$$

so

$$z_N - z_1 = \sum_{k=1}^{N-1} (z_{k+1} - z_k) \geqslant (N-1)\sqrt{\frac{2\epsilon_0}{MN}} \geqslant \operatorname{diam} \operatorname{supp} g \tag{C2}$$

which is a contradiction, since z_1 and z_N must belong to the support of g. ■

Since $g_n - g = \epsilon_n \chi$, it is clear that $g_n \to g$ and $g_n^{(k)} \to g^{(k)}$ in $L^2(I)$ as $n \to \infty$. This is the property required in Sec. III A.

[1] This point has often been emphasized by L.H. Ford; however, for a situation where the sign can be predicted see, O. Kenneth and I. Klich, e-print quant-ph/0601011 (2006).

[3] P. Marecki, Phys. Rev. D **73**, 124009 (2006).
[4] To be more precise, the spacetime manifold is required to be connected, smooth, Hausdorff, and paracompact. The spacetime $\boldsymbol{N}$ is globally hyperbolic if it contains a Cauchy surface, i.e., a subset intersected exactly once by every inextendible timelike curve. For further elaboration on this point see B. O'Neill, *Semi-Riemannian Geometry* (Academic, New York, 1983). The globally hyperbolic spacetimes are the most general class of spacetimes on which quantum fields are typically formulated, but one should be aware that manifolds with boundary are not included.
[5] By a stationary state, we mean one whose n-point functions are invariant under translations along the Killing flow: $w_n(\psi_t(x_1), \ldots, \psi_t(x_n)) = w_n(x_1, \ldots, x_n)$, where ψ_t is the group of isometries associated with the Killing field.

[50] The proof employed in Refs. 18 and 16 proceeds by defining a function $V:\mathrm{supp}\ g\to R$ with $V'(v)=1/g(v)^2$, and therefore only applies in the first instance to the case where g has connected support and no zeros in the interior thereof. We extend the result to more general $g\in C_0^\infty(I;\mathbb{R})$ by choosing a nonnegative $\chi\in C_0^\infty(I)$ with no zeros in the interior of its support, assumed to be connected, and which is equal to unity on the support of g. Applying Flanagan's result to $g_\varepsilon(\tau)=\sqrt{g(\tau)^2+\varepsilon^2\chi(\tau)^2}$, we may take the limit $\varepsilon\to 0$ to obtain Eq. (25) (cf. Cor. A.2 in Ref. 20, where the notation $G=g^2$ is used).
[51] We have $\tilde{g}(\tau)^2=g(\tau+\tau_0)^2$, and want to show that $\tilde{g}(\tau)^2=g'(\tau+\tau_0)^2$ for all τ. Differentiating and squaring yields $4\tilde{g}(\tau)^2\tilde{g}(\tau)^2=4g(\tau+\tau_0)^2g'(\tau+\tau_0)^2$ from which it follows that $\tilde{g}(\tau)^2=g'(\tau+\tau_0)^2$ except perhaps at zeros of $\tilde{g}(\tau)$. If $\tilde{g}$ vanishes in a neighborhood of τ then so must $\tilde{g}$ and the result holds trivially. For the remaining case, choose a sequence $\tau_n\to\tau$ with $\tilde{g}(\tau_n)\neq 0$; since $\tilde{g}(\tau_n)^2=g'(\tau_n+\tau_0)^2$, we conclude the required result by continuity as $n\to\infty$.

[53] Let $f=\xi^a\xi_a$, and note that the curve γ has acceleration $a^a=-1/2\nabla^a f$. Suppose $\pounds_\xi v=0$. Then $\xi^a\nabla_a v^b=v^a\nabla_a\xi^b$, which permits us to write the Fermi-Walker derivative as $(D_{\mathrm{FW}}v/\mathrm{d}t)_b=v^a(\nabla_a\xi_b+\xi_{[a}\nabla_{b]}\log f)$. But this vanishes for hypersurface orthogonal ξ; see, e.g., Appendix C.3 in R. M. Wald, *General Relativity* (The University of Chicago Press, Chicago, IL, 1984).
[54] To see this, we note that $Q_2(\cosh\alpha)=\tanh\alpha+\alpha(1-\tanh^2\alpha)$ and that the maximum of this expression on $\mathbb{R}^+$ occurs at the (unique) solution to $\alpha\tanh\alpha=1$, which is numerically $\alpha_0=1.199679$. Now $Q_2(\cosh\alpha_0)=\alpha_0$, so we find that $Q_2(x)\leqslant\alpha_0<1.2$ on $[1,\infty)$ as claimed.
[55] An operator A is symmetric on a domain D if $\langle\psi|A\varphi\rangle=\langle A\psi|\varphi\rangle$ for all $\psi,\varphi\in D$, which shows that the adjoint A^* agrees with A on D, but does not exclude the possibility that A^* has a strictly larger domain of definition than A.

[58] The contour involved is the rectangle with "long" sides given by the interval $[-R,R]$ of the real axis, and its translate $[-R,R]+2\pi\xi_o i$. The contour encloses a single pole, of fourth order, at $z=2i\epsilon$ and the contribution of the "short" sides vanishes as $R\to\infty$. One also exploits the fact that the contributions from the two "long" sides are equal up to a factor of $-e^{-2\pi\xi_o}$.

[63] The Friedrichs extension has a domain contained in the closure of $C_0^\infty(I)$ in the norm $\|g\|_{+1}^2=\langle g|g\rangle+\langle g|Lg\rangle$, which is equivalent to the norm of the Sobolev space $W_0^2(I)$ since τ^{-4} is bounded and bounded away from zero on I. Accordingly, the closure of $C_0^\infty(I)$ is precisely $W_0^2(I)$ and the desired domain lies in this Sobolev space, all elements of which obey $g=g'=0$ on ∂I.

A few years ago Zamolodchikov and Zamolodchikov proposed an expression for the four-point classical Liouville action in terms of the three-point actions and the classical conformal block [Nucl. Phys. B **477**, 577 (1996)]. In this paper we develop a method of calculating the uniformizing map and the uniformizing group from the classical Liouville action on n-punctured sphere and discuss the consequences of Zamolodchikovs conjecture for an explicit construction of the uniformizing map and the uniformizing group for the sphere with four punctures. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2234272]

I. INTRODUCTION

The uniformization problem for n-punctured ($n \geqslant 3$) spheres can be formulated as follows:[2]

Given $X=\mathbb{C}\backslash\{z_1,\ldots,z_{n-1}\}$, *find the (unique to within conjugacy) Fuchsian group* $G\subset \mathrm{PSU}(1,1)$ *which makes* X *conformally equivalent to the quotient* Δ/G *of the unit disc* $\Delta=\{z\in\mathbb{C}:|z|<1\}$ *by* G.

The existence of solution to this problem, called the *uniformization theorem*, was first proved by Poincaré and Koebe in 1907. The universal covering map $\lambda:\Delta\to\Delta/G$ is however explicitly known only for the thrice-punctured sphere[3] and in a few very special, symmetric cases with a higher number of punctures.[2] In particular an explicit construction of this map for the four-punctured sphere is a long-standing and still open problem.

One possible approach, going back to Poincaré, is based on the relation of the uniformization problem to a certain Fuchs equation on X. If $\lambda:\Delta\to\Delta/G\cong X$ is the universal covering map, the inverse $\rho=\lambda^{-1}:X\to\Delta$ is a multivalued function with branching points z_j and with branches related by elements of the covering group $G\subset\mathrm{PSU}(1,1)$. One can show that the Schwarzian derivative of ρ is a holomorphic function on X of the form[2]

$$\{\rho,z\}=\frac{1}{2}\sum_{k=1}^{n-1}\frac{1}{(z-z_k)^2}+\sum_{k=1}^{n-1}\frac{2c_k}{z-z_k}, \tag{1.1}$$

$$\{\rho,z\}\overset{z\to\infty}{=}\frac{1}{2z^2}+\mathcal{O}(z^{-3}), \tag{1.2}$$

where the *accessory parameters* c_j satisfy the relations

[a)]Alexander von Humboldt Fellow; electronic mail: hadasz@physik.uni-bonn.de
[b)]Electronic mail: jask@ift.uni.wroc.pl

$$\sum_{k=1}^{n-1} c_k = 0, \quad \sum_{k=1}^{n-1} (4c_k z_k + 1) = 1. \tag{1.3}$$

It is a well-known property of the Schwarzian derivative[2,4] that the map ρ is, to within a Möbius transformation, a quotient of two linearly independent solutions of the Fuchs equation

$$\partial_z^2 \Psi + \frac{1}{2}\{\rho, z\}\Psi = 0. \tag{1.4}$$

This, in particular, means that there exists a unique to within SU(1,1) transformation fundamental system $\{\Psi_1, \Psi_2\}$ of normalized (i.e., with the Wronskian equal to 1) solutions for which

$$\rho = \frac{\Psi_1}{\Psi_2}. \tag{1.5}$$

Note that any such system has to have an SU(1,1) monodromy with respect to all punctures.

Whether the Fuchs equation can be used to calculate the map ρ depends on our ability to calculate the accessory parameters and to choose an appropriate fundamental system of normalized solutions. The first problem can be easily solved for three punctures where the accessory parameters are completely determined by relations (1.3). It is, however, difficult and still unsolved for $n > 3$.

One can get some more insight by relating this problems to the Liouville equation on X. Since PSU(1,1) is the isometry group of the Poincaré hyperbolic metric $g_\Delta = 4d\rho d\bar{\rho}/(1-|\rho|^2)^2$ on Δ the pull back

$$\rho^* g_\Delta = \frac{4}{(1-|\rho|^2)^2} \left| \frac{\partial \rho}{\partial z} \right|^2 \mathrm{d}z\, \mathrm{d}\bar{z} = e^{\varphi(z,\bar{z})} \mathrm{d}z\, \mathrm{d}\bar{z} \tag{1.6}$$

is a regular hyperbolic metric on X, conformal to the standard flat metric $\mathrm{d}z\, \mathrm{d}\bar{z}$ on $X \subset \mathbb{C}$. Its conformal factor φ satisfies the Liouville equation

$$\partial_z \partial_{\bar{z}} \varphi(z,\bar{z}) = \tfrac{1}{2} e^{\varphi(z,\bar{z})} \tag{1.7}$$

and has the following asymptotic behavior at punctures

$$\varphi(z,\bar{z}) = \begin{cases} -2\log|z-z_j| - 2\log|\log|z-z_j|| + O(1) & \text{as } z \to z_j \\ -2\log|z| - 2\log|\log|z|| + O(1) & \text{as } z \to \infty. \end{cases} \tag{1.8}$$

It is known that there exists a unique solution to (1.7) and (1.8).[5] One can show that the *energy-momentum tensor* $T(z)$ of this solution is equal to one half of the Schwarzian derivative (1.1):

$$T(z) \equiv -\tfrac{1}{4}(\partial\varphi)^2 + \tfrac{1}{2}\partial^2\varphi = \tfrac{1}{2}\{\rho, z\}. \tag{1.9}$$

This allows one to calculate all accessory parameters once the classical solution φ is known.

The problem of selecting an appropriate fundamental system is slightly less demanding. As we shall see it is sufficient to know the next to the first two leading terms of the asymptotic of the classical solution φ at one arbitrary puncture.

Unfortunately, the problem to find solutions to the Liouville equation seems to be at least as hard as the problem of calculating the map ρ itself, and the reformulation does not help much on this stage. In this framework however one can consider a more general problem of spheres with n elliptic singularities characterized by real parameters $0 < \xi_j < 1$. Instead of asymptotic conditions (1.8) we impose

$$\varphi(z,\bar{z}) = \begin{cases} -2(1-\xi_j)\log|z-z_j| + O(1) & \text{as } z \to z_j \\ -2(1+\xi_n)\log|z-z_j| + O(1) & \text{as } z \to \infty. \end{cases} \tag{1.10}$$

The existence and uniqueness of φ was in this case proved by Picard[6,7] (see also Ref. 8). The solution can be interpreted as a conformal factor of the complete, hyperbolic metric with the Gaussian curvature $R=-1$ on $X=\mathbb{C}\backslash\{z_1,\ldots,z_{n-1}\}$ and conical singularities of the opening angles $0<2\pi\xi_j<2\pi$ at the points z_j. The n-punctured sphere discussed so far corresponds to the limiting case $\xi_j \to 0$ for all $j=1,\ldots,n$.

The notion of accessory parameters can be introduced in terms of the energy momentum tensor of the solution φ. In the present case it takes the form:[4]

$$T(z) = \sum_{j=1}^{n-1} \left[\frac{\delta_j}{(z-z_j)^2} + \frac{c_j}{z-z_j} \right],$$
$$T(z) \overset{z\to\infty}{=} \frac{\delta_n}{z^2} + \mathcal{O}(z^{-3}), \tag{1.11}$$

where $\delta_j=(1-\xi_j^2)/4$, $j=1,\ldots,n$ are *classical conformal weights*. The multivalued function $\rho: X \to \Delta$ is still of interest although it is no longer an inverse to the universal covering of X. It can be used as before in formula (1.6) to construct solutions to the Liouville equation with asymptotic behavior (1.10).

The above-described ideas are classic and most of them were already pursued by Poincaré. For almost a century the problem of accessory parameters had remainded unsolved. An essentially new insight was brought in by the so-called Polyakov conjecture in 1982.[9] It states that the (properly defined and normalized) Liouville action functional evaluated on the classical solution $\varphi_{\mathrm{cl}}(z,\bar{z})$ is a generating function for the accessory parameters:

$$c_j = -\frac{\partial S^{(\mathrm{cl})}(\delta_i;z_i)}{\partial z_j}. \tag{1.12}$$

This formula was derived within path integral approach to the quantum Liouville theory as the quasiclassical limit of the conformal Ward identity.[10] In the case of the parabolic singularities on n-punctured Riemann sphere a rigorous proof based on the theory of quasiconformal mappings was given by Zograf and Takhtajan.[11] Other proofs, valid both in the case of parabolic and general elliptic singularities, were proposed in Refs. 12 and 14.

The next significant step was done by Zamolodchikov and Zamolodchikov.[1] Analyzing the classical limit of the four-point function of the quantum Liouville theory they argued that the classical Liouville action for four elliptic (parabolic) singularities can be expressed in terms of the classical Liouville action for three singularities and some special function called the *classical conformal block*. Recently this conjecture has been successfully tested by symbolic and numerical calculations in Ref. 13. It should be stressed however that it is still far from being rigorously proved. The basic problem is the classical block itself which is so far accessible only via term by term calculation of the classical limit of the quantum conformal block.

The aim of the present paper is to analyze to what extent the Zamolodchikovs conjecture can provide an explicit construction of the uniformization of four-punctured sphere. Our motivation is to get a better insight into a geometric content of this conjecture and to develop a theoretical framework for its new numerical tests. The results indicate that the classical conformal block plays a central role in the problem and certainly deserves further investigation.

The content of the paper is as follows. In Sec. II we analyze the problem of selecting an appropriate pair of solutions to the Fuchs equation in the case of elliptic weights. It is shown that all the information required is encoded in the derivatives of the classical Liouville action with respect to the parameters ξ_j. The case of parabolic singularities is obtained by taking an appro-

priate limit. The main result is that in order to calculate the map ρ from the Fuchs equation it is sufficient to know the classical Liouville action as a function of z_j's and ξ_j's.

In Sec. III we analyze the problem of calculating monodromies of the Fuchs equation once the accessory parameters are known. Only the case of four punctures is considered. For the standard locations $0,x,1,\infty$ we develop systematic expansions of monodromy matrices at $0,x,1$ in terms of power expansions in x and $1-x$. The results of Secs. II and III are general and are independent of the form in which the classical Liouville action is available.

In Sec. IV the Zamolodchikovs conjecture is formulated and some schemes of calculation of the classical Liouville action and accessory parameters are developed. They lead to very efficient methods of numerical calculations. It should be stressed, however, that many steps in their derivation still require sound mathematical proofs. Concluding this section we discuss some open problems and possible extensions of our work.

II. MAP $\rho: X \to \Delta$

In the case of the sphere with n elliptic singularities with weights $\delta_j=(1-\xi_j^2)/4$ we define the functional

$$S_L[\delta_i;\phi]=\frac{1}{4\pi}\lim_{\epsilon\to 0} S_L^{\epsilon}[\delta_i;\phi],$$

$$S_L^{\epsilon}[\delta_i;\phi]=\int_{X_\epsilon} \mathrm{d}^2z[|\partial\phi|^2+e^{\phi}]+\sum_{j=1}^{n-1}(1-\xi_j)\int_{|z-z_j|=\epsilon}|\mathrm{d}z|\kappa_z\phi+(1+\xi_n)\int_{|z|=1/\epsilon}|\mathrm{d}z|\kappa_z\phi$$
$$-2\pi\sum_{j=1}^{n-1}(1-\xi_j)^2\log\epsilon-2\pi(1+\xi_n)^2\log\epsilon,$$

where $X_\epsilon=\mathbb{C}\setminus(\cup_{j=1}^{n}\{|z-z_j|<\epsilon\}\cup\{|z|>1/\epsilon\})$.

The classical Liouville action $\mathcal{S}^{(\mathrm{cl})}(\delta_i;z_i)$ is then defined as[4,12]

$$S^{(\mathrm{cl})}(\delta_i,z_i)=S_L[\delta_i;\varphi_{\mathrm{cl}}],$$

where $\varphi_{\mathrm{cl}}(z,\bar{z})$ is the unique solution to (1.7) and (1.10).

Once the classical action is known one can use the Polyakov conjecture (1.12) to calculate the accessory parameters and write down the corresponding Fuchs equation

$$\partial_z^2\Psi+T\Psi=0, \tag{2.1}$$

with the energy momentum tensor T given by (1.11). Our aim in this section is to select a fundamental system of solutions to this equation such that their quotient yields a multivalued function $\rho: X\to\Delta$ with SU(1,1) monodromy at each z_j and regular for all $z\in X$.

To this end let us first observe that (1.7) and (1.9) imply that $e^{-\varphi(z,\bar{z})/2}$ is a real solution to the Fuchs equations (2.1) and its complex conjugate. It can therefore be expressed as a bilinear combination of any fundamental system and its complex conjugate. In order to fix the freedom related to the SU(1,1) transformations let us choose a normalized system with diagonal monodromy at an arbitrarily chosen singular point z_j:

$$\Psi_{\xi,\pm}^{(j)}(z)=\frac{A_j^{\pm 1}}{\sqrt{\xi_j}}(z-z_j)^{(1\pm\xi_j)/2}(1+\mathcal{O}(z-z_j)),\quad A_j\in\mathbb{R}. \tag{2.2}$$

It follows from reality, positivity, and single valuedness of $e^{-\varphi(z,\bar{z})/2}$ on X that the parameter A_j can be adjusted such that

$$e^{-\varphi(z,\bar{z})/2} = \frac{D_j}{2}[|\Psi^{(j)}_{\xi,-}(z)|^2 - |\Psi^{(j)}_{\xi,+}(z)|^2],$$

where D_j is a positive constant. Although the above-presented formula is derived by considering a small neighborhood of z_j, it holds for all $z \in X$. Using it one easily derives all the required properties of the map

$$\rho_j(z) = \frac{\Psi^{(j)}_{\xi,+}(z)}{\Psi^{(j)}_{\xi,-}(z)}.$$

One can in particular apply the formula (1.6) to construct the hyperbolic metric with Gaussian curvature -1 on X. As this metric coincides with $e^{\varphi(z,\bar{z})}\mathrm{d}z\,\mathrm{d}\bar{z}$, the constant D_j has to be equal to 1 and

$$e^{-\varphi(z,\bar{z})/2} = \tfrac{1}{2}[|\Psi^{(j)}_{\xi,-}(z)|^2 - |\Psi^{(j)}_{\xi,+}(z)|^2]. \tag{2.3}$$

Analyzing the limit $z \to z_j$ one finds that $A_j^2 = (1/2\xi_j)e^{(1/2)f_j}$, where f_j is the next to the leading term in the $\varphi_{\mathrm{cl}}(z,\bar{z})$ asymptotic at $z \to z_j$. On the other hand,

$$\frac{\partial S^{(\mathrm{cl})}(\delta_i;z_i)}{\partial \xi_j} = \lim_{\epsilon\to 0}\left[(1-\xi_j)\log\epsilon - \frac{1}{4\pi}\int_{|z-z_j|=\epsilon} |\mathrm{d}z|\,\kappa_z\phi\right] = \frac{1}{2}f_j, \tag{2.4}$$

and consequently

$$A_j^2 = \frac{1}{2\xi_j}\exp\left\{\frac{\partial}{\partial\xi_j}S^{(\mathrm{cl})}(\delta_i;z_i)\right\}. \tag{2.5}$$

This equation, along with the Polyakov conjecture, shows that the classical Liouville action contains all the information needed to calculate the map $\rho: X \to \Delta$ from the Fuchs equation.

To study the parabolic limit $\xi_j \to 0$ we shall first define the pair $\widetilde{\Psi}^{(j)}_{\xi,\pm}(z)$, related to $\Psi^{(j)}_{\xi,\pm}(z)$ through the SU(1,1) transformation,

$$\begin{pmatrix} \widetilde{\Psi}^{(j)}_{\xi,+}(z) \\ \widetilde{\Psi}^{(j)}_{\xi,-}(z) \end{pmatrix} = \frac{1}{2}\begin{pmatrix} \xi_j^{1/2} + \xi_j^{-1/2} & \xi_j^{1/2} - \xi_j^{-1/2} \\ \xi_j^{1/2} - \xi_j^{-1/2} & \xi_j^{1/2} + \xi_j^{-1/2} \end{pmatrix}\begin{pmatrix} \Psi^{(j)}_{\xi,+}(z) \\ \Psi^{(j)}_{\xi,-}(z) \end{pmatrix}.$$

From (2.5) it can be shown in the general case (and will be illustrated by the explicit calculation in the next section) that

$$A_j = 1 + \xi_j a_j + \mathcal{O}(\xi_j^2) = e^{\xi_j a_j} + \mathcal{O}(\xi_j^2), \tag{2.6}$$

with a_j independent of ξ_j. From this fact and (2.2) it follows that the limit

$$\begin{pmatrix} \Psi^{(j)}_{+}(z) \\ \Psi^{(j)}_{-}(z) \end{pmatrix} = \lim_{\xi_j\to 0}\begin{pmatrix} \widetilde{\Psi}^{(j)}_{\xi,+}(z) \\ \widetilde{\Psi}^{(j)}_{\xi,-}(z) \end{pmatrix} \tag{2.7}$$

exists.

The inverse of the map

$$\rho^{(j)}(z) = \frac{\Psi^{(j)}_{-}(z)}{\Psi^{(j)}_{+}(z)} \tag{2.8}$$

is the universal covering map of the punctured sphere X by the Poincaré disc Δ. In particular, as

$$\left| \lim_{z \to z_j} \frac{\Psi_-^{(j)}(z)}{\Psi_+^{(j)}(z)} \right| = 1,$$

the puncture is mapped onto the point on the boundary of the Poincaré disc.

III. MONODROMY MATRICES

In this section we shall consider the Riemann sphere with four punctures at the standard locations $z=0,x,1$ and ∞. In this case

$$T(z) = \frac{1}{4z^2} + \frac{1}{4(z-x)^2} + \frac{1}{4(z-1)^2} + \frac{c_1(x)}{z} + \frac{c_2(x)}{z-x} + \frac{c_3(x)}{z-1},$$

and the relations (1.3) can be written in the form

$$c_1(x) = \tfrac{1}{2} - (1-x)c_2(x), \quad c_3(x) = -\tfrac{1}{2} - xc_2(x). \tag{3.1}$$

Our aim is to calculate in this case the monodromies of the fundamental systems of solutions to the Fuchs equation (1.4) constructed in the previous section.

To this end we shall split $T(z)$ onto the "free" term $T_0(z)$ and the "interaction" $-V(z)$,

$$T(z) = T_0(z) - V(z).$$

$T_0(z)$ contains by construction all terms in $T(z)$ singular at $z=0$, term with a second-order pole at $z=x$ plus a "correction" enforcing the behavior $\sim z^{-2}$ at the infinity,

$$T_0(z) = \frac{1}{4z^2} + \frac{1}{4(z-x)^2} + \frac{c_1(x)}{z} - \frac{c_1(x)}{z-x} = \frac{1}{4z^2} + \frac{1}{4(z-x)^2} - \frac{xc_1(x)}{z(z-x)} \equiv \frac{1}{4z^2} + \frac{1}{4(z-x)^2} - \frac{1+\nu^2(x)}{4z(z-x)}$$

with

$$\nu^2(x) = 4xc_1(x) - 1 = -4x(1-x)c_2(x) + x - (1-x), \tag{3.2}$$

and

$$V(z) = -\frac{(1-x)c_3(x)}{(z-x)(z-1)} - \frac{1}{4(z-1)^2}.$$

Solutions to the "free" equation

$$\partial_z^2 f(z) + T_0(z) f(z) = 0$$

are then expressible through the hypergeometric functions with the well-known monodromies around $z=0,x$, while the solutions (and monodromies) of the "full" equation

$$\partial_z^2 \Psi(z) + T_0(z)\Psi(z) = V(z)\Psi(z) \tag{3.3}$$

can be obtained by perturbation theory with an nth order correction proportional to x^n.

One then repeats the above-presented calculation with $x \to 1-x$. Since this problem is related through the global conformal transformation $z \to w = 1-z$ to our original problem with the points 0 and 1 exchanged (and opposite orientation of the z and w planes) it is clear that the monodromy matrix around $w=0$ yields the monodromy matrix around $z=1$. Note however that this time the parameter in the perturbative expansion is $1-x$. Our method thus yields all three monodromy matrices (the monodromy matrix around the puncture $z=\infty$ is equal to the inverse of the product of the remaining three matrices) only for those x for which both x and $1-x$ are small enough.

Let

$$T_0^{(\xi,\epsilon)}(z) = \frac{1-\epsilon^2}{4z^2} + \frac{1-\xi^2}{4(z-x)^2} + \frac{\xi^2+\epsilon^2-\nu^2-1}{4z(z-x)}. \tag{3.4}$$

We can choose the normalized basis in the space of solutions to

$$\partial^2 f(z) + T_0^{(\xi,\epsilon)}(z) f(z) = 0$$

in the form of the pair of functions with the diagonal monodromy matrix around $z=0$,

$$\phi_\pm^{(\xi,\epsilon)}(z) = \sqrt{\frac{x}{\epsilon}}\left(\frac{z}{x}\right)^{(1\pm\epsilon)/2}\left(1-\frac{z}{x}\right)^{(1+\xi)/2} {}_2F_1\left(\frac{1+\xi+\nu\pm\epsilon}{2}, \frac{1+\xi-\nu\pm\epsilon}{2}, 1\pm\epsilon, \frac{z}{x}\right),$$

or in the form of the pair of functions with the diagonal monodromy matrix around $z=x$,

$$\psi_\pm^{(\xi,\epsilon)}(z) = e^{\pm\xi a}\sqrt{\frac{x}{\xi}}\left(\frac{z}{x}\right)^{(1+\epsilon)/2}\left(1-\frac{z}{x}\right)^{(1\pm\xi)/2} {}_2F_1\left(\frac{1\pm\xi+\nu+\epsilon}{2}, \frac{1\pm\xi-\nu+\epsilon}{2}, 1\pm\xi, 1-\frac{z}{x}\right).$$

These two pairs of functions are obviously expressible through each other,

$$\begin{pmatrix} \psi_+^{(\xi,\epsilon)}(z) \\ \psi_-^{(\xi,\epsilon)}(z) \end{pmatrix} = \mathcal{C}^{(\xi,\epsilon)} \cdot \begin{pmatrix} \phi_+^{(\xi,\epsilon)}(z) \\ \phi_-^{(\xi,\epsilon)}(z) \end{pmatrix}$$

with[14]

$$\mathcal{C}^{(\xi,\epsilon)} = \sqrt{\frac{\epsilon}{\xi}}\begin{pmatrix} \dfrac{e^{\xi a}\Gamma(-\epsilon)\Gamma(1+\xi)}{\Gamma\left(\frac{1+\xi+\nu-\epsilon}{2}\right)\Gamma\left(\frac{1+\xi-\nu-\epsilon}{2}\right)} & \dfrac{\Gamma(\epsilon)\Gamma(1+\xi)}{\Gamma\left(\frac{1+\xi+\nu+\epsilon}{2}\right)\Gamma\left(\frac{1+\xi-\nu+\epsilon}{2}\right)} \\ \dfrac{\Gamma(-\epsilon)\Gamma(1-\xi)}{\Gamma\left(\frac{1-\xi+\nu-\epsilon}{2}\right)\Gamma\left(\frac{1-\xi-\nu-\epsilon}{2}\right)} & \dfrac{e^{-\xi a}\Gamma(\epsilon)\Gamma(1-\xi)}{\Gamma\left(\frac{1-\xi+\nu+\epsilon}{2}\right)\Gamma\left(\frac{1-\xi-\nu+\epsilon}{2}\right)} \end{pmatrix}.$$

To take the limit $\epsilon\to 0$ we define, similar to (2.7),

$$\begin{pmatrix} \phi_+^{(\xi)}(z) \\ \phi_-^{(\xi)}(z) \end{pmatrix} = \lim_{\epsilon\to 0} B_\epsilon \begin{pmatrix} \phi_+^{(\xi,\epsilon)}(z) \\ \phi_-^{(\xi,\epsilon)}(z) \end{pmatrix} \tag{3.5}$$

and

$$\mathcal{C}^{(\xi)} = \lim_{\epsilon\to 0} \mathcal{C}^{(\xi,\epsilon)} \cdot B_\epsilon^{-1}$$

with

$$B_\epsilon = \frac{1}{2}\begin{pmatrix} \sqrt{\epsilon}+\dfrac{1}{\sqrt{\epsilon}} & \sqrt{\epsilon}-\dfrac{1}{\sqrt{\epsilon}} \\ \sqrt{\epsilon}-\dfrac{1}{\sqrt{\epsilon}} & \sqrt{\epsilon}+\dfrac{1}{\sqrt{\epsilon}} \end{pmatrix}.$$

For $z\to x$,

$$\phi_\pm^{(\xi)}(z) = \sqrt{z}\left(1 \pm \frac{1}{2}\log\frac{z}{x}\right) + o(z),$$

and the monodromy matrix of this pair around $z=0$ (for $z\to e^{2\pi i}z$) is

$$M_{\phi^{(\xi)}}^{(z=0)} = -\begin{pmatrix} 1+\frac{i\pi}{2} & \frac{i\pi}{2} \\ -\frac{i\pi}{2} & 1-\frac{i\pi}{2} \end{pmatrix}.$$

One thus gets a monodromy matrix of the pair $\psi_{\pm}^{(\xi)}=\lim_{\epsilon\to 0}\psi_{\pm}^{(\xi,\epsilon)}$ around $z=0$ in the form

$$M_{\psi^{(\xi)}}^{(z=0)} = \mathcal{C}^{(\xi)} \cdot M_{\phi^{(\xi)}}^{(z=0)} \cdot (\mathcal{C}^{(\xi)})^{-1}.$$

The limit $\xi\to 0$ can be taken as in (2.7),

$$\begin{pmatrix} \psi_+ \\ \psi_- \end{pmatrix} = \lim_{\xi\to 0} B_\xi \cdot \begin{pmatrix} \psi_+^{(\xi)} \\ \psi_-^{(\xi)} \end{pmatrix} \tag{3.6}$$

with

$$B_\xi = \frac{1}{2}\begin{pmatrix} \sqrt{\xi}+\frac{1}{\sqrt{\xi}} & \sqrt{\xi}-\frac{1}{\sqrt{\xi}} \\ \sqrt{\xi}-\frac{1}{\sqrt{\xi}} & \sqrt{\xi}+\frac{1}{\sqrt{\xi}} \end{pmatrix}.$$

We have

$$\psi_+(z) = \sqrt{x-z}(1+a) + \frac{1}{2}\sqrt{x-z}\log\left(1-\frac{z}{x}\right) + o(z-x),$$

$$\psi_-(z) = \sqrt{x-z}(1-a) - \frac{1}{2}\sqrt{x-z}\log\left(1-\frac{z}{x}\right) + o(z-x).$$

The monodromy matrix of this pair around $z=x$ (in the counterclockwise direction, $(z-x)\to e^{2\pi i}(z-x)$) thus reads

$$M_{\psi}^{(z=x)} = -\begin{pmatrix} 1-\frac{i\pi}{2} & -\frac{i\pi}{2} \\ \frac{i\pi}{2} & 1+\frac{i\pi}{2} \end{pmatrix},$$

and the monodromy matrix of the $\psi_\pm$ pair around $z=0$ (in the counterclockwise direction, $z\to e^{2\pi i}z$) can be calculated as

$$M_{\psi}^{(z=0)} = \lim_{\xi\to 0} B_\xi \cdot M_{\psi^{(\xi)}}^{(z=0)} \cdot B_\xi^{-1} = \frac{i}{2\pi}\begin{pmatrix} 2i\pi + (\beta^2(x)-4)\cos^2\frac{\pi\nu(x)}{2} & (\beta(x)-2)^2\cos^2\frac{\pi\nu(x)}{2} \\ -(\beta(x)+2)^2\cos^2\frac{\pi\nu(x)}{2} & 2i\pi - (\beta^2(x)-4)\cos^2\frac{\pi\nu(x)}{2} \end{pmatrix}. \tag{3.7}$$

Here

$$\beta(x) \equiv \psi_0\left(\frac{1-\nu(x)}{2}\right) + \psi_0\left(\frac{1+\nu(x)}{2}\right) + 2\gamma_E - 2a(x),$$

$\psi_0(z)=(\mathrm{d}/\mathrm{d}z)\log\Gamma(z)$ is the digamma function and γ_E denotes the Euler-Mascheroni constant.

Monodromy matrix around $z=1$ can now be obtained (paying attention to the opposite orientation of the planes z and $w=1-z$) by repeating the above-presented calculation with x substituted by $1-x$. As these calculations are fairly straightforward we refrain from writing them down explicitly.

We shall now turn to the power-like corrections. Define

$$(\hat{\mathcal{G}}f)(z)=\int_x^z \mathrm{d}z'(\psi_+(z)\psi_-(z')-\psi_-(z)\psi_+(z'))f(z')$$

with $\psi_\pm$ given by (3.6). Since

$$(\partial^2+T_0)\hat{\mathcal{G}}=1,$$

we can rewrite (3.3) in the form of an integral equation

$$\Psi_\pm=\psi_\pm+\hat{\mathcal{G}}V\Psi_\pm$$

with a (formal) solution

$$\Psi_\pm=(1-\hat{\mathcal{G}}V)^{-1}\psi_\pm. \tag{3.8}$$

From (3.8) one can read off the nth order correction to the functions $\psi_\pm(z)$,

$$\delta^{(n)}\psi_\pm(z)=\int_x^z \mathrm{d}z_n\mathcal{G}(z,z_n)V(z_n)\int_x^{z_n}\mathrm{d}z_{n-1}\mathcal{G}(z_n,z_{n-1})V(z_{n-1})\cdots\int_x^{z_2}\mathrm{d}z_1\mathcal{G}(z_2,z_1)V(z_1)\psi_\pm(z_1). \tag{3.9}$$

Let us discuss in some detail the case $n=1$,

$$\delta^{(1)}\psi_\pm(z)=\psi_+(z)\int_x^z \mathrm{d}z'\ \psi_-(z')V(z')\psi_\pm(z')-\psi_-(z)\int_x^z \mathrm{d}z'\ \psi_+(z')V(z')\psi_\pm(z').$$

The functions $\psi_\pm(z')V(z')\psi_\pm(z')$ have integrable (logarithmic) singularities for $z\to x$ and $z\to 0$. Consequently,

$$\delta^{(1)}\psi_\pm(z)=o(z-x)\quad \text{for } z\to x,$$

which means that the monodromy matrix of the $\psi_\pm$ pair remains unchanged. For $z\to 0$ the leading correction takes the form

$$\delta^{(1)}\psi_\pm(z)=\alpha^{(1)}_{\pm,+}\cdot\psi_+(z)+\alpha^{(1)}_{\pm,-}\cdot\psi_-(z)+o(z),$$

with

$$\alpha^{(1)}_{\pm,\pm}=\int_x^0 \mathrm{d}z'\ \psi_\pm(z')V(z')\psi_\pm(z').$$

The monodromy matrix of the $\psi_\pm+\delta^{(1)}\psi_\pm$ pair is therefore given by

$$M^{(0)}_{\psi+\delta^{(1)}\psi}=(1+\alpha^{(1)})M^{(0)}_{\psi}(1+\alpha^{(1)})^{-1}.$$

Notice further that $(1/\sqrt{x})\psi_\pm(x\zeta)$ does not depend on x and $V(xz)=\mathcal{O}(x^{-1})$, so that (with $z'=x\zeta$)

$$\alpha^{(1)}_{\pm,\pm}=x\int_1^0 \mathrm{d}\zeta\left(\frac{1}{\sqrt{x}}\psi_\pm(x\zeta)\right)xV(x\zeta)\left(\frac{1}{\sqrt{x}}\psi_\pm(x\zeta)\right)=\mathcal{O}(x).$$

Similarly one gets

$$\delta^{(n)}\psi_{\pm}(z) = o(z-x) \quad \text{for } z \to x,$$

and

$$\delta^{(n)}\psi_{\pm}(z) = \alpha^{(n)}_{\pm,+}\cdot\psi_{+}(z) + \alpha^{(n)}_{\pm,-}\cdot\psi_{-}(z) + o(z) \quad \text{for } z \to 0,$$

with

$$\alpha^{(n)}_{\pm,\pm} = \mathcal{O}(x^n).$$

Up to this order the monodromy of the pair $\Psi_{\pm}$ around $z=0$ is therefore given by

$$M^{(0)}_{\Psi} = \left(1 + \sum_{k=1}^{n}\alpha^{(k)}\right) M^{(0)}_{\psi} \left(1 + \sum_{k=1}^{n}\alpha^{(k)}\right)^{-1}.$$

Let us remark that although the matrices $\alpha^{(k)}$ are difficult to evaluate analytically, their numerical calculation is rather straightforward.

IV. ZAMOLODCHIKOVS CONJECTURE

The four-point function of the DOZZ theory with the operator insertions at $z_1=0$, $z_3=1$, $z_4=\infty$, and $z_2=x$, can be expressed as an integral of s-channel conformal blocks and DOZZ couplings over the continuous spectrum of the theory. In the semiclassical limit the integrand can be written in terms of three-point classical Liouville actions and the classical block,[1]

$$\langle V_4(\infty,\infty)V_3(1,1)V_2(x,\bar{x})V_1(0,0)\rangle \sim \int_0^{\infty} \mathrm{d}p\; e^{-Q^2 S(\delta_i;x;\delta)}, \tag{4.1}$$

where $\delta=\frac{1}{4}+p^2$ and

$$S(\delta_i;x;\delta) = S^{(\mathrm{cl})}(\delta_4,\delta_3,\delta) + S^{(\mathrm{cl})}(\delta,\delta_2,\delta_1) - f_{\delta}\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(x) - \bar{f}_{\delta}\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(\bar{x}). \tag{4.2}$$

The three-point classical Liouville action with a parabolic $\delta_1=\frac{1}{4}$, an elliptic $\delta_2=\frac{1}{4}(1-\xi^2)$, and a hyperbolic weight $\delta=\frac{1}{4}+p^2$, reads[1,15]

$$S^{(\mathrm{cl})}(\delta,\delta_2,\delta_1) = -(1-\xi)\log 2 + 2F\left(\frac{1-\xi}{2}+ip\right) + 2F\left(\frac{1-\xi}{2}-ip\right) - F(\xi) + H(2ip) + \pi|p| + \text{const}, \tag{4.3}$$

where

$$F(x) = \int_{1/2}^{x} \mathrm{d}y \log\frac{\Gamma(y)}{\Gamma(1-y)}, \quad H(x) = \int_0^x \mathrm{d}y \log\frac{\Gamma(-y)}{\Gamma(y)}.$$

$f_{\delta}\left[\begin{smallmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{smallmatrix}\right](x)$ is the classical conformal block[1] (or the "classical action" of Refs. 16 and 17), defined as the semiclassical asymptotic

$$\mathcal{F}_{1+6Q^2,\Delta}\begin{bmatrix}\Delta_3 & \Delta_2\\ \Delta_4 & \Delta_1\end{bmatrix}(x) \sim \exp\left(Q^2 f_{\delta}\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(x)\right) \tag{4.4}$$

of the BPZ conformal block.[18]

In the classical limit $Q^2\to\infty$ the integral on the right-hand side of relation (4.1) is dominated by its saddle point value. One thus gets

$$S^{(\mathrm{cl})}(\delta_i;x)=S(\delta_i;x;\delta_s)=S^{(\mathrm{cl})}(\delta_4,\delta_3,\delta_s)+S^{(\mathrm{cl})}(\delta_s,\delta_2,\delta_1)-f_{\delta_s}\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(x)-\bar{f}_{\delta_s}\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(\bar{x}), \tag{4.5}$$

where $\delta_s=\frac{1}{4}+p_s^2(x)$ and the *saddle point momentum* $p_s(x)$ is determined by

$$\frac{\partial}{\partial p}S\left(\delta_i;x;\frac{1}{4}+p^2\right)_{|p=p_s}=0. \tag{4.6}$$

Since the semiclassical limit should be independent of the choice of the channel in the factorization of the DOZZ four-point function the Zamolodchikovs' conjecture (4.5) yields three different expressions for the four-point classical Liouville action. The corresponding consistency equations (*classical bootstrap equations*) have been numerically verified for punctures[13] and for punctures and one and two elliptic singularities.[19]

Taking into account the classical geometry corresponding to hyperbolic weights[20] one may expect that the saddle point momentum $p_s(x)$ in the s-channel is related to the length $\ell_s(x)$ of the closed geodesic separating the "initial" $z=0,x$ from the "final" $z=1,\infty$ singularities:

$$\ell_s(x)=4\pi p_s(x). \tag{4.7}$$

In the case of punctures this conjecture has strong numerical support.[13]

The classical limit of the quantum conformal block is up to now the only method of calculating the classical conformal block. Let us note that it is by no means obvious that the quantum conformal block for "heavy" weights does have the asymptotic of the form assumed in (4.4). This is however very well supported by symbolic calculations for the first few terms in a number of cases. An efficient recursive method of calculating coefficients of the expansion of the quantum block in powers of x was developed by Zamolodchikov.[16] Using this method and taking the limit $Q\to\infty$ one can calculate term by term the coefficients of the power expansion

$$f_\delta\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(x)=(\delta-\delta_1-\delta_2)\log x+\sum_{n=1}^{\infty}x^n f_\delta^n\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}. \tag{4.8}$$

In the case of three punctures and one elliptic singularity the first few terms of this expansion read

$$f_{(1/4)+p^2}\begin{bmatrix}\frac{1}{4} & \frac{1-\xi^2}{4}\\ \frac{1}{4} & \frac{1}{4}\end{bmatrix}(x)=\left(p^2-\frac{1-\xi^2}{4}\right)\log x+\left(\frac{1-\xi^2}{8}+\frac{p^2}{2}\right)x$$
$$+\left(\frac{9(1-\xi^2)}{128}+\frac{13p^2}{64}+\frac{(1-\xi^2)^2}{1024(1+p^2)}\right)x^2+\mathcal{O}(x^3). \tag{4.9}$$

The limitation of formulas (4.8) and (4.9) is that the power series involved are supposed to converge only for $|x|<1$. A more convenient representation of the conformal block was developed by Zamolodchikov in Ref. 17, where he proposed to regard the block as a function of the variable

$$q(x)=e^{-\pi[K(1-x)/K(x)]},\quad K(x)=\int_0^1\frac{\mathrm{d}t}{\sqrt{(1-t^2)(1-xt^2)}}.$$

In terms of q the classical conformal block reads:

$$f_\delta\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(x)=\left(\frac{1}{4}-\delta_1-\delta_2\right)\log x+\left(\frac{1}{4}-\delta_2-\delta_3\right)\log(1-x)$$
$$+\left(\frac{3}{2}-2(\delta_1+\delta_2+\delta_3+\delta_4)\right)\log\left(\frac{2}{\pi}K(x)\right)$$
$$+\left(\delta-\frac{1}{4}\right)\log 16-\left(\delta-\frac{1}{4}\right)\pi\frac{K(1-x)}{K(x)}+h_\delta\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(q), \tag{4.10}$$

where

$$h_\delta\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix}(q)=\sum_{n=1}^{\infty}(16q)^n h_\delta^n\begin{bmatrix}\delta_3 & \delta_2\\ \delta_4 & \delta_1\end{bmatrix} \tag{4.11}$$

is supposed to converge uniformly on each subset $\{q:|q|<e^{-\epsilon}<1\}$.

The coefficients of power series (4.11) can be determined term by term using Zamolodchikovs recursive method to calculate coefficients in the q-expansion of the quantum block[17] and then taking the limit $Q\to\infty$. This for instance yields:

$$h_{(1/4)+p^2}\begin{bmatrix}\frac{1}{4} & \frac{1-\xi^2}{4}\\ \frac{1}{4} & \frac{1}{4}\end{bmatrix}(q)=\frac{(1-\xi^2)^2}{4(1+p^2)}q^2+\left[\frac{(1-\xi^2)^2(15+18\xi^2-\xi^4)}{128(1+p^2)}+\frac{(1-\xi^2)^2(9-\xi^2)^2}{128(4+p^2)}\right.$$
$$\left.+\frac{3(1-\xi^2)^4}{128(1+p^2)^2}-\frac{(1-\xi^2)^4}{32(1+p^2)^3}\right]q^4+\mathcal{O}(q^6). \tag{4.12}$$

In the case of four punctures the saddle point equation determining $p_s(x)$ reads

$$0=\frac{\partial}{\partial p}S\left(\frac{1}{4};x;\frac{1}{4}+p^2\right)=2\pi+4i\log\frac{\Gamma^2\left(\frac{1}{2}+ip\right)\Gamma(-2ip)}{\Gamma^2\left(\frac{1}{2}-ip\right)\Gamma(2ip)}-2\Re\frac{\partial}{\partial p}f_{(1/4)+p^2}\begin{bmatrix}\frac{1}{4} & \frac{1}{4}\\ \frac{1}{4} & \frac{1}{4}\end{bmatrix}(x), \tag{4.13}$$

and the classical Liouville action is given by

$$\mathcal{S}^{(\mathrm{cl})}\left(\frac{1}{4};x\right)=S\left(\frac{1}{4};x;\frac{1}{4}+p_s^2(x)\right). \tag{4.14}$$

Using (4.2), (4.3), and (4.9) one gets

$$c_2(x)=-\frac{\partial\mathcal{S}^{(\mathrm{cl})}\left(\frac{1}{4};x\right)}{\partial x}=-\left.\frac{\partial S\left(\frac{1}{4};x;\frac{1}{4}+p^2\right)}{\partial p}\right|_{p=p_s(x)}\cdot\frac{\partial p_s(x)}{\partial x}-\left.\frac{\partial S\left(\frac{1}{4};x;\frac{1}{4}+p^2\right)}{\partial x}\right|_{p=p_s(x)}$$
$$=-\left.\frac{\partial S\left(\frac{1}{4};x;\frac{1}{4}+p^2\right)}{\partial x}\right|_{p=p_s(x)}=\left.\frac{\partial}{\partial x}f_{(1/4)+p^2}\begin{bmatrix}\frac{1}{4} & \frac{1}{4}\\ \frac{1}{4} & \frac{1}{4}\end{bmatrix}(x)\right|_{p=p_s(x)}$$
$$=\frac{4p_s^2(x)-1}{4x}+\frac{1}{8}(4p_s^2(x)+1)+\left[\frac{9}{2}+13p_s^2(x)+\frac{1}{8}\frac{1}{1+p_s^2(x)}\right]\frac{x}{32}+\mathcal{O}(x^2) \tag{4.15}$$

or, employing the q expansion of the classical block,

$$c_2(x) = -\frac{1}{4x(1-x)}\left(\frac{E(x)}{K(x)} - x\right) - \frac{\pi^2}{4x(1-x)K^2(x)}\left[p_s^2(x) + \frac{1}{1+p_s^2(x)}\frac{q^2}{2} + \left(\frac{15}{1+p_s^2(x)} + \frac{81}{4+p_s^2(x)} + \frac{3}{(1+p_s^2(x))^2} - \frac{4}{(1+p_s^2(x))^3}\right)\frac{q^4}{32} + \mathcal{O}(q^6)\right], \tag{4.16}$$

where $E(x)$ denotes the complete elliptic integral of the second kind. Equations (4.15) and (4.16) are simple consequences of the Zamolodchikovs conjecture. They provide a new relation between the accessory parameters, the classical conformal block, and the geodesic length function $\ell_s(x)$ which is certainly worth further investigations.

In order to calculate $a_2 \equiv a$ for four punctures one can replace one puncture by an elliptic singularity and then take the limit

$$2a = \lim_{\xi\to 0}\frac{1}{\xi}\log A^2.$$

Using (2.5), (4.2), (4.3), and (4.9) one obtains

$$\begin{aligned} 2a(x) &= \lim_{\xi\to 0}\left\{\frac{1}{\xi}\log\frac{\Gamma\left(\frac{1+\xi}{2} - ip_s(x)\right)\Gamma\left(\frac{1+\xi}{2} + ip_s(x)\right)}{\Gamma\left(\frac{1-\xi}{2} - ip_s(x)\right)\Gamma\left(\frac{1-\xi}{2} + ip_s(x)\right)} - \frac{2}{\xi}\Re\frac{\partial}{\partial\xi}\ f_{(1/4)+p^2}\begin{bmatrix}\frac{1}{4} & \frac{1-\xi^2}{4}\\ \frac{1}{4} & \frac{1}{4}\end{bmatrix}(x)\Bigg|_{p=p_s(x)}\right\} \\ &= \psi_0\left(\frac{1}{2} + ip_s(x)\right) + \psi_0\left(\frac{1}{2} - ip_s(x)\right) - \frac{2}{\xi}\Re\frac{\partial}{\partial\xi}\ f_{(1/4)+p^2}\begin{bmatrix}\frac{1}{4} & \frac{1-\xi^2}{4}\\ \frac{1}{4} & \frac{1}{4}\end{bmatrix}(x)\Bigg|_{p=p_s(x),\xi=0} \\ &= \psi_0\left(\frac{1}{2} + ip_s(x)\right) + \psi_0\left(\frac{1}{2} - ip_s(x)\right) - \frac{1}{2}\log x\bar{x} + \frac{\Re x}{2} + \left[36 + \frac{1}{1+p_s^2(x)}\right]\frac{\Re x^2}{2^7} + \mathcal{O}(x^3), \end{aligned} \tag{4.17}$$

or, using (4.10) and (4.12):

$$\begin{aligned} 2a(x) = \psi_0\left(\frac{1}{2} + ip_s(x)\right) + \psi_0\left(\frac{1}{2} - ip_s(x)\right) - \frac{1}{2}\log x\bar{x} - \frac{1}{2}\log|1-x|^2 - \log\left|\frac{2}{\pi}K(x)\right|^2 \\ + \frac{2}{1+p_s^2(x)}\Re q^2 + \left[\frac{45}{4+p_s^2(x)} + \frac{3}{1+p_s^2(x)} + \frac{3}{(1+p_s^2(x))^2} - \frac{4}{(1+p_s^2(x))^3}\right]\frac{\Re q^4}{8} + \mathcal{O}(q^6). \end{aligned} \tag{4.18}$$

Note that in the above-mentioned formulas one only needs the saddle point momentum $p_s(x)$ for four punctures (ξ=0).

Let us finally turn to the problem of determining the saddle point momentum $p_s(x)$. As was discussed in Ref. 13 $p_s(x)$ can be determined numerically, using the q expansion of the classical block, with an essentially arbitrary high precision everywhere but at small vicinities of the singular points $x=1$ and $x=\infty$. On the other hand, the problem of analytic determination of the saddle point momentum still remains to be solved and only partial results are available.

Both geometrical arguments and the form of (4.9) indicate that for $x\to 0$ the solution of (4.13) should also tend to zero. For $p\to 0$,

$$4i\log\frac{\Gamma^2\left(\frac{1}{2}+ip\right)\Gamma(-2ip)}{\Gamma^2\left(\frac{1}{2}-ip\right)\Gamma(2ip)}=-4\pi+32p\log 2+16\sum_{k=1}^{\infty}\frac{(-1)^k\zeta(2k+1)}{2k+1}(2^{2k}-1)p^{2k+1} \tag{4.19}$$

so that, up to the leading terms, the saddle point equation (4.13) takes the form

$$-\pi+16p\log 2-p\log x\bar{x}=0 \tag{4.20}$$

and, to this order,

$$p_s(x)\sim\varepsilon(x)\equiv\frac{\pi}{-\log x\bar{x}+16\log 2}. \tag{4.21}$$

We can now solve (4.13) by iteration, in the form of a double series expansion in $\Re x$ and $\varepsilon(x)$ (since $x=\exp(-1/[1/(-\log x)])$, the powers of x can be viewed as "nonperturbative" corrections to the $\varepsilon(x)$ series). For instance, keeping in (4.13) terms up to p^3 and x^2 we get

$$\begin{aligned}
p_s&=\frac{\pi}{-\log x\bar{x}+16\log 2-\Re x-\frac{207}{512}\Re x^2}\\
&\quad+\frac{8\zeta(3)+\frac{1}{256}\Re x^2}{-\log x\bar{x}+16\log 2-\Re x-\frac{207}{512}\Re x^2}p_s^3+\mathcal{O}(\varepsilon(x)^6,x^3\varepsilon(x))\\
&=\frac{\pi}{-\log x\bar{x}+16\log 2-\Re x-\frac{207}{512}\Re x^2}\\
&\quad+\frac{8\pi^3\zeta(3)+\frac{\pi^3}{256}\Re x^2}{\left(-\log x\bar{x}+16\log 2-\Re x-\frac{207}{512}\Re x^2\right)^4}+\mathcal{O}(\varepsilon(x)^6,x^3\varepsilon(x))\\
&=\varepsilon(x)+\frac{8\zeta(3)}{\pi}\varepsilon^4(x)+\left(\frac{1}{\pi}\varepsilon^2(x)+\frac{32\zeta(3)}{\pi^2}\varepsilon^5(x)\right)\Re x+\frac{\varepsilon^2(x)}{\pi^2}(\Re x)^2\\
&\quad+\left(\frac{207}{512\pi}\varepsilon^2(x)+\frac{1}{256\pi}\varepsilon^4(x)+\frac{207\zeta(3)}{16\pi^2}\varepsilon^5(x)\right)\Re x^2+\mathcal{O}(\varepsilon(x)^6,x^3\varepsilon(x)).
\end{aligned} \tag{4.22}$$

As in the case of the accessory parameters, one can also work out the formula for the saddle point momentum involving the q expansion of the classical conformal block.

For a sufficiently small x the right-hand side of (4.22) agrees with the numerically calculated saddle point momentum and is well within the know analytic bounds on $\ell_s(x)/4\pi$.[2,13] However, to determine the radius of convergence of the series in (4.22) or to give an estimate on the omitted terms one would need to know the classical conformal block exactly.

As discussed in the previous section in order to determine the monodromy matrix at $x=1$ one needs a power expansion of $p_s(x)$ at this point. In other words, an analytic continuation of the classical block from the vicinity of $x=0$ to $x=1$ is required. One possible approach to this problem is to consider the classical limit of the braiding relation for the quantum BPZ block (for conformal blocks corresponding to degenerated fields this calculation is quite straightforward).

We believe that a better understanding of the classical conformal block and the geodesic length function may provide an essentially new insight into the problem of finding an analytic expressions for the map ρ and the uniformizing group. Further studies of these structures are definitely worth pursuing.

(Received 22 November 2005; accepted 2 June 2006; published online 23 August 2006)

A specific class of gauge theories is geometrically described in terms of fermions. In particular, it is shown how the geometrical frame presented naturally includes spontaneous symmetry breaking of Yang-Mills gauge theories without making use of a Higgs potential. In more physical terms, it is shown that the Yukawa coupling of fermions, together with gravity, necessarily yields a symmetry reduction provided the fermionic mass is considered as a globally well-defined concept. The structure of this symmetry breaking is shown to be compatible with the symmetry breaking that is induced by the Higgs potential of the minimal Standard Model. As a consequence, it is shown that the fermionic mass has a simple geometrical interpretation in terms of curvature and that the (semiclassical) "fermionic vacuum" determines the intrinsic geometry of space-time. We also discuss the issue of "fermion doubling" in some detail and introduce a specific projection onto the "physical subspace" that is motivated by the Standard Model. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2218673]

I. INTRODUCTION

The aim of this article is to put emphasis on the role of fermions in a geometrically unified description of different kinds of gauge theories as, for instance, Yang-Mills and Einstein's theory. Especially, we discuss in some detail the role of the "Yukawa coupling" of fermions with respect to the mechanism of spontaneous symmetry breaking. This may provide us with a better geometrical understanding of the relation between inertia and gravity.

Let us start out with some general remarks on the notion of "gauge symmetry." The notion of gauge symmetry, in general terms, expresses certain redundancies in the mathematical description of the interactions considered. In mathematics, by gauge theory one usually refers to gauge theories of the Yang-Mills type with the underlying geometry given by a principal G-bundle over a smooth orientable (compact) manifold endowed, in addition, with a (semi-)Riemannian structure (see, for instance, in Refs. 5, 34, 35, 38, and 49). This notion of gauge theory, however, is clearly far too restrictive when considered from a physical point of view. For instance, gravity is also usually regarded as a kind of gauge theory though it is certainly not of the Yang-Mills type. The underlying geometrical structure of gravity, regarded as a gauge theory, is that of a fiber bundle naturally associated with the frame bundle of the base manifold $\mathcal{M}$ with typical fiber given by $\mathrm{GL}(n)/\mathrm{SO}(p,q)$. Here, respectively, $\dim(\mathcal{M}) \equiv n = p+q$ equals the dimension of the oriented base manifold and $s = p-q$ is the signature. The bundle structure of the two gauge theories is obviously very different. In contrast to Yang-Mills theory, the bundle structure of gravity is fully determined (modulo diffeomorphisms) by fixing the (topology of the) base manifold and the signature s. In this sense, the bundle structure in Einstein's theory of gravity is more natural than in the Yang-Mills theory. Moreover, the mathematical notion of a local trivialization has a physical meaning in

[a)]Electronic mail: juergen.tolksdorf@mis.mpg.de
[b)]Electronic mail: thum@euler.math.uni-mannheim.de

the case of gravity, however, not in Yang-Mills gauge theories (there is no "exponential map" defined in Yang-Mills theories for, in contrast to gravity, Yang-Mills connections only determine second order vector fields but no spray fields).

The respective Lagrangian densities of gravity and Yang-Mills gauge theory differ in that the former is known to be linear in the curvature of the base manifold whereas the latter is quadratic in the curvature of the bundle space. This difference is known to yield far-reaching consequences, for example, when quantization is taken into account. But also on the purely "classical" level (i.e., gravity and electromagnetism) there are fundamental differences in these two kinds of gauge theories. For example, electromagnetism (more general, Yang-Mills gauge theories over even-dimensional base manifolds) is known to be scale invariant but not invariant with respect to the action of the diffeomorphism group (except isometries). In contrast, gravity is covariant with respect to diffeomorphisms but not scale invariant. Of course, despite these profound mathematical and physical differences there are, nonetheless, formal similarities between these two types of gauge theories. Especially, the dynamics that is defined by both theories can be expressed with respect to top-forms on the base manifold with the property of being invariant with respect to the action of their respective symmetry groups. A natural question then is whether these two fundamental kinds of gauge theories have a common geometrical root (for a discussion about the "naturality" of these two top-forms see Refs. 50 and 33).

Of course, over the last few decades there have been various attempts to geometrically unify gravity with the Yang-Mills gauge theory. This holds true for string theory and, in particular, for various aspects of noncommutative geometry, see, e.g., Refs. 8, 9, 14, and 40, and references there. The fruitful idea to consider the Higgs boson of the Standard Model as an integral part of the Yang-Mills theory goes back to fundamental works, e.g., Refs. 15–17 and 10. It is well known that this idea actually has had a tremendous impact on a vast variety of articles of the same theme (see, for instance, Refs. 18, 27, 36, and 37 in the context of noncommutative geometry, or Refs. 25 and 39 in the case of "superalgebras"). Basically, all of these geometrical descriptions of gauge theory use the purely algebraic content of gauge theories of the Yang-Mills type (e.g., the exterior differential is a nilpotent derivation and a connection is the sum of the latter and a one-form) as their starting point. However, gravity seems not to fit in this basic algebraic vision. Also, spontaneous symmetry breaking is described only in terms of (the algebraic aspects of) Yang-Mills gauge theories without using gravity. The notion of fermions only arises because in the algebraic context the exterior differential is defined in terms of specific generalizations of the notion of a Dirac operator. These purely algebraic generalizations of the latter, however, seem to have no geometrical counterpart (see, for instance, the "internal Dirac operator" in the geometrical description of the Standard Model in terms of "almost commutative models)."[26]

In the following we shall discuss a specific class of gauge theories including Einstein's theory of gravity and (spontaneously broken) Yang-Mills theory from the point of view of fermions. The latter will be geometrically treated as certain Hermitian vector bundles over arbitrary smooth orientable manifolds of even dimension. These "fermion bundles" correspond to a global specification of a certain class of first order differential operators, called "Dirac type operators." We introduce a canonical mapping which associates with every Dirac type operator a specific top-form on the base manifold. This canonical mapping is then referred to as the "Dirac-Lagrangian" on the setup to be discussed. The Dirac-Lagrangian turns out to be equivariant with respect to bundle equivalence. In particular, it is invariant with respect to the action of the Yang-Mills and the Einstein-Hilbert gauge groups. The diffeomorphism group of the base manifold is naturally included by the pull-back action. We also consider a distinguished class of Dirac type operators within this setup. The corresponding top-form associated with these Dirac type operators is shown to define a spontaneously broken gauge theory without referring to a Higgs potential. In more physical terms, it is shown that the Yukawa coupling together with gravity yields a symmetry reduction which is compatible with the symmetry breaking induced by a Higgs potential of the form used in the (minimal) Standard Model of Particle Physics. In fact, the latter is shown to be

naturally generated by a "fluctuation of the fermionic vacuum." We will also reformulate the notion of "unitary gauge" in terms of Dirac type operators and give necessary and sufficient conditions for its global existence.

The geometrical description of gauge theories discussed in the present article is a considerable refinement of the geometrical frame that has been introduced in Ref. 45 in the case of elliptic Dirac type operators on a smooth even-dimensional closed Riemannian spin manifold. In contrast to the latter we will consider in this article the more physically appropriate case of arbitrary signature and noncompact manifolds. Also, we do not assume that "space-time" has a spin structure (please see the following discussion). For this, however, we will focus on (globally defined) densities instead of action functionals. Accordingly, we have to demand that the densities themselves are covariant with respect to the underlying symmetry action and thus well defined on the appropriate moduli spaces. This is achieved mainly since the densities in question are derived from evaluating a natural object (within the frame considered) with respect to specific first order differential operators. As a consequence, one ends up with densities which are linear in the curvature of the base manifold and quadratic in the curvature of the bundle space. For instance, it is shown that the total curvature of the "fermionic vacuum" decomposes into the sum of the curvature of the base manifold together with the (square of the) fermionic mass operator. Also a basic difference relative to the frame considered here (and subsequent articles thereof) is that all bundles, including the Higgs and the Yang-Mills bundles, are considered as specific subbundles of the fermion bundle (respectively, of the bundle of endomorphisms of the latter). The fermion density will be considered as a specific mapping on the affine set of all Dirac type operators on a fermion bundle. Here, we also discuss the issue of the doubling of the fermionic degrees of freedom that is necessary to apply the general Bochner-Lichnerowicz-Weizenböck formula.

Finally, we want to comment on the notion of "fermions" without assuming the existence of spin structures. At least in the so-called "semi-classical approximation" of a full quantum field theory it is common to geometrically treat the "states of a fermion" as sections of a (twisted) spinor bundle over space-time. For this, of course, the topology of space-time must guarantee the existence of a spin structure (i.e., the vanishing of the second Stiefel-Whitney classes). Moreover, it is known that a noncompact Lorentzian four manifold possesses a spin structure if and only if its frame bundle is trivial ("Geroch's Theorem," c.f. Refs. 19 and 20). Therefore, the existence of a spin structure provides severe restrictions to the topology of space-time. However, the experiments performed to demonstrate that the double cover of the (proper orthochroneous) Lorentz group is more fundamental are purely local in nature. Also, in order to obtain a topologically nontrivial statement about the existence of spin structures, space-time has to be covered by at least three (trivializing) local charts. This, of course, raises the question of the physical sense of "locality" in this context to give the mathematical construction a physical meaning. Hence, from our point of view, the assumption of the existence of a spin structure is a purely mathematical one without a physically meaningful counterpart. In fact, in this respect the notion of locality, as it is used in mathematics, seems physically as spurious as in the case of the Yang-Mills gauge theories which do not provide any scale. Basically, this is the reason to consider in this work the more general notion of "Clifford module bundles" instead of "twisted spinor bundles" as an appropriate geometrical background. In contrast to the latter, the existence of Clifford module bundles yields no more topological restrictions on space-time than the existence of a metric itself. For instance, the bundle of Grassmann algebras serves as a natural Clifford module bundle for every space-time manifold. However, the topology of the Clifford module bundles cannot be arbitrary. The physical interpretation of the sections of Clifford module bundles in terms of the states of fermions yields restrictions to the topology of the considered Clifford module bundles (please, see the following text).

This article is organized as follows. In the next section we introduce the concept of fermion bundles as a specific class of Clifford module bundles and define Dirac type gauge theories. In the third section we consider a distinguished class of such gauge theories and discuss spontaneous symmetry breaking in this context. In the Sec. IV we introduce the fermionic density within the presented geometrical setup and discuss the issue of fermionic doubling. In the fifth section we

want to specify what we mean by a fluctuation of the fermionic vacuum. This is done in terms of yet another class of Dirac type operators. Finally, in Sec. VI we close with an outlook. In the Appendix we present a detailed proof of the explicit form of "simple type Dirac operators" of arbitrary signature, for these operators turn out to be fundamental, e.g., in our discussion of spontaneous symmetry breaking.

II. FERMION BUNDLES AND DIRAC TYPE GAUGE THEORIES

In this section we introduce a specific class of Clifford module bundles which will serve as our geometrical background for gauge theories. With respect to this background there exists a canonical mapping which permits to associate with the local data of a fermion bundle a specific top form on the base manifold. This top form turns out to be equivariant with respect to the automorphism group of the underlying geometrical structure.

A. Fermion bundles, Dirac type operators and connections

In this subsection we define our notion of *fermion bundles* as a specific class of Clifford module bundles. For this let $\xi := (\mathcal{E}, \pi_\varepsilon, \mathcal{M})$ be a smooth complex vector bundle with total space $\mathcal{E}$, base manifold $\mathcal{M}$ and projection map $\pi_\varepsilon : \mathcal{E} \to \mathcal{M}$. The rank, $\mathrm{rk}(\xi) \in \mathbb{N}$, of the bundle is $\mathrm{N} \geqslant 1$. In what follows the base manifold is assumed to be orientable and of even dimension $n \equiv 2k$. As a topological space $\mathcal{M}$ is a paracompact and (simply) connected Hausdorff-space. On this geometrical background we consider the following local data:

$$(\mathrm{G}, \rho_\mathrm{F}, D). \tag{1}$$

Here, G is a semisimple, compact and real Lie group and $\rho_\mathrm{F} : \mathrm{G} \to \mathrm{SU}(\mathrm{N}_\mathrm{F})$ is a unitary and faithful representation thereof. Moreover, $D : \Gamma(\xi) \to \Gamma(\xi)$ is a first order differential operator, acting on sections of the bundle ξ such that the bilinear extension g_M of the mapping $(df, dh) \mapsto \mathrm{tr}([D,f] \times [D,h])/\mathrm{rk}(\xi)$ is nondegenerated for all smooth functions $f, g \in \mathcal{C}^\infty(\mathcal{M})$. The operator D is said to have the signature $s \in \mathbb{Z}$, provided that the quadratic form associated with the (semi-) Riemannian metric g_M has signature s. The mapping g_M corresponds to a section of the "Einstein-Hilbert bundle" $\xi_\mathrm{EH} := (FM \times_{\mathrm{GL(n)}} \mathrm{GL}(n)/\mathrm{O}(p,q), \pi_\mathrm{EH}, \mathcal{M})$, with, respectively, FM the total space of the frame bundle $\mathcal{FM}$ of the base manifold $\mathcal{M}$ and $n \equiv p+q, s \equiv p-q$.

Let $\tau_\mathrm{Cl} \equiv \tau_\mathrm{Cl}^{(\pm)}$ be the algebra bundle of Clifford algebras which are point-wise generated by $(\tau_\mathrm{M}^*, g_\mathrm{M})$, with τ_M^* being the cotangent bundle of $\mathcal{M}$ (with total space T^*M). The corresponding Clifford relations are defined by $\alpha^2 := \pm g_\mathrm{M}(\alpha, \alpha)$ for all $\alpha \in T^*M \subset Cl(M)$ (the total space of τ_Cl). In the following, it is assumed that the principal symbol of the operator D induces a Clifford (left) action $\gamma : \tau_\mathrm{Cl} \to \mathrm{End}(\xi)$ via the mapping

$$\begin{aligned} \tau_\mathrm{Cl} \times \xi &\to \xi, \\ (df, \mathfrak{z}) &\mapsto [D,f]\mathfrak{z}, \end{aligned} \tag{2}$$

for all smooth functions $f \in \mathcal{C}^\infty(\mathcal{M})$. In other words, besides the assumption that $[D,f]^2$ induces an isomorphism $\tau_\mathrm{M} \simeq \tau_\mathrm{M}^*$, it is also supposed to be in the commutant of $\mathrm{End}(\xi)$. As a consequence, the algebra bundle of endomorphisms on ξ globally decomposes as

$$\mathrm{End}(\xi) \simeq \tau_\mathrm{Cl}^\mathbb{C} \otimes_\mathcal{M} \mathrm{End}_\mathrm{Cl}(\xi). \tag{3}$$

Here, $\mathrm{End}_\mathrm{Cl}(\xi) \subset \mathrm{End}(\xi)$ denotes the subbundle of endomorphisms which supercommute with the Clifford action γ (c.f., for instance, in Refs. 2 and 3).

Definition 2.1: *The vector bundle* $\xi \equiv \xi_\mathrm{F}$ *is called a "fermion bundle" with respect to the* (*local*) *data* (1) *if the structure group of* ξ *can be reduced to* $\mathrm{Spin}(p,q) \times \rho_\mathrm{F}(\mathrm{G})$. *A fermion bundle is called "chiral" provided* $\xi_\mathrm{F} = \xi_\mathrm{F}^+ \oplus \xi_\mathrm{F}^-$ *is* $\mathbb{Z}_2$*-graded with respect to some involution* $\Gamma \equiv \gamma_\mathrm{M} \otimes \chi \in \Gamma(\mathrm{End}(\xi_\mathrm{F}))$. *Here, the canonical involution* $\gamma_\mathrm{M} \in \Gamma(\tau_\mathrm{Cl}^\mathbb{C})$ *is defined in terms of the* (*semi-*) *Riemannian volume form* $\mu_\mathrm{M} \in \Omega^n(\mathcal{M})$ *that is induced by* g_M. *Moreover,* ξ_F *is called "real" if all of*

its odd Chern classes vanish. With respect to Γ *the operator* D *is supposed to be odd and the representation* ρ_{F} *is assumed to be even. In this case*, D *is called a "Dirac type operator" and* (1) *a "Dirac triple."*

A fermion bundle encodes the global data of a Dirac type gauge theory. With respect to these data we consider the set $\mathcal{D}(\xi_{\mathrm{F}})$ of all Dirac type operators $D' \in \mathcal{D}(\xi_{\mathrm{F}})$ to satisfy the condition $[D'-D,f] \equiv 0$ for all $f \in \mathcal{C}^{\infty}(\mathcal{M})$. The set $\mathcal{D}(\xi_{\mathrm{F}})$ naturally becomes an affine space with vector space $\Gamma(\mathrm{End}^{-}(\xi_{\mathrm{F}}))$. In what follows we summarize the basic features of this affine space.

The affine space $\mathcal{A}(\xi_{\mathrm{F}})$ of linear connections on ξ_{F} has a distinguished affine sub-space $\mathcal{A}_{\mathrm{Cl}}(\xi_{\mathrm{F}}) \subset \mathcal{A}(\xi_{\mathrm{F}})$ that is defined by all linear connections which are compatible with the Clifford action γ. That is, $A \in \mathcal{A}_{\mathrm{Cl}}(\xi_{\mathrm{F}})$ defines a covariant derivative ∂_A satisfying $[\partial_A, \gamma(a)] = \gamma(\nabla^{\mathrm{Cl}} a)$ for all sections $a \in \Gamma(\tau_{\mathrm{Cl}}^{\mathbb{C}})$ with ∇^{Cl} being the covariant derivative with respect to the lifted Levi-Civita connection of g_{M}. Accordingly, such a connection is referred to as a "Clifford connection." Hence, every $D' \in \mathcal{D}(\xi_{\mathrm{F}})$ may be written as $D' = \partial\!\!\!/_A + \Phi$ where, respectively, $\partial\!\!\!/_A \equiv \gamma \circ \partial_A$ is the analogue of a twisted spin Dirac operator in the case where $\mathcal{M}$ denotes a spin manifold and $\Phi \equiv D - \partial\!\!\!/_A \in \Gamma(\mathrm{End}(\xi_{\mathrm{F}}))$. Notice, however, that in general the zero order operator Φ also depends on the Clifford connection A. Moreover, the relation between the two affine spaces $\mathcal{D}(\xi_{\mathrm{F}})$ and $\mathcal{A}(\xi_{\mathrm{F}})$ on a fermion bundle is given by the (signature independent) bijection (c.f. Ref. 45)

$$\mathcal{D}(\xi_{\mathrm{F}}) \simeq \mathcal{A}(\xi_{\mathrm{F}})/\ker(\delta_{\gamma}), \tag{4}$$

where

$$\delta_{\gamma}\colon \Omega^1(\mathcal{M},\mathrm{End}(\mathcal{E})) \to \Omega^0(\mathcal{M},\mathrm{End}(\mathcal{E}))\ \alpha \mapsto \gamma(\alpha). \tag{5}$$

Therefore, to each Dirac type operator on ξ_{F} there corresponds an equivalence class of connections. However, each connection class has a natural representative that is constructed as follows: First, on every chiral fermion bundle there is a canonical odd one-form $\Theta \in \Omega^1(\mathcal{M},\mathrm{End}^{-}(\mathcal{E}))$ that is given by the (normalized) lifted soldering form of $\mathcal{FM}$. More precisely, let $\vartheta \in \Omega^1_{\mathrm{eq,hor}}(FM,\mathbb{R}^n)$ be the soldering form on the (total space of the) frame bundle of $\mathcal{M}$. Here, the canonical identification $\Omega^*_{\mathrm{eq,hor}}(FM,\mathbb{R}^n) \simeq \Omega^*(\mathcal{M},T\mathcal{M})$ and the injection (here, $\Omega^*_{\mathrm{eq,hor}}(FM,\mathbb{R}^n)$ denotes the "right-equivariant" and "horizontal" forms on the total space of the frame bundle of $\mathcal{M}$)

$$\Gamma(\tau_{\mathrm{M}}^* \otimes_{\mathcal{M}} \tau_{\mathrm{M}}) \overset{\mathrm{id}\otimes\ \flat}{\to} \Gamma(\tau_M^* \otimes_{\mathcal{M}} \tau_M^*) \hookrightarrow \Gamma(\tau_M^* \otimes_{\mathcal{M}} \tau_{\mathrm{Cl}}) \overset{\mathrm{id}\otimes\gamma}{\to} \Gamma(\tau_M^* \otimes_M \mathrm{End}(\xi_{\mathrm{F}})) \tag{6}$$

yields $\Theta := \pm\widetilde{\vartheta}/n$ with $\widetilde{\vartheta} \equiv \gamma \circ \vartheta^{\flat} \in \Omega^1(\mathcal{M},\mathrm{End}(\mathcal{E}))$. If $(X_1,\ldots,X_n)$ denotes a local frame on $\mathcal{M}$ and $(X^1,\ldots,X^n)$ its dual, then (throughout this article Einstein's summation convention is used in local formulas except where this may lead to confusions) $\widetilde{\vartheta} \overset{loc.}{=} X^k \otimes \gamma(X_k^{\flat}) \otimes \mathrm{id}$, with the usual "musical" isomorphism $u^{\flat}(v) := g_{\mathrm{M}}(u,v)$ for all $u,v \in T\mathcal{M}$. The normalized soldering form Θ has the two basic properties: It is covariantly constant with respect to every Clifford connection and it induces a canonical right inverse of the Clifford action, i.e., $\delta_{\gamma} \circ \mathrm{ext}_{\Theta} = \mathrm{id}$. Here, $\mathrm{ext}_{\Theta} \in \mathrm{End}(\tau^*_{\Lambda\mathrm{M}} \otimes_{\mathcal{M}} \mathrm{End}(\xi))$ denotes the operator of (point-wise) left-multiplication by Θ, and $\tau^*_{\Lambda\mathrm{M}}$ is the bundle of Grassmann algebras that is, again, generated by τ^*_{M}. Note that the linear equivalence $\tau_{\mathrm{Cl}} \simeq \tau^*_{\Lambda\mathrm{M}}$ is used but not explicitly indicated. Second, to each Dirac type operator $D' \in \mathcal{D}(\xi_{\mathrm{F}})$ there exists a correspondingly unique connection $\hat{A}'_{\mathrm{D}} \in \mathcal{A}(\xi_{\mathrm{F}})$ such that $D'^2 - \triangle'_{\mathrm{D}} \in \Gamma(\mathrm{End}(\xi_{\mathrm{F}}))$. The second order operator $\triangle'_{\mathrm{D}} := -\mathrm{tr}(\hat{\nabla}^{T^*\mathcal{M}\otimes\mathcal{E}} \circ \hat{\nabla}^{\mathcal{E}})$ is called the "Bochner-Laplacian" of D' (c.f., e.g., Refs. 3 and 6, or 21). Here, $\hat{\nabla}^{\mathcal{E}}$ denotes the covariant derivative that corresponds to the connection $\hat{A}'_{\mathrm{D}}$. As a consequence, the covariant derivative that is defined by

$$\partial_{D'} := \hat{\nabla}^{\mathcal{E}} + \Theta \wedge (D' - \gamma \circ \hat{\nabla}^{\mathcal{E}}) \tag{7}$$

yields a connection $A'_{\mathrm{D}} \in \mathcal{A}(\xi_{\mathrm{F}})$ which clearly represents the Dirac type operator D', i.e., $D' = \gamma \circ \partial_{D'}$. We call, respectively, A'_{D} the Dirac connection associated with D' and the one-form

$$\varpi'_{\mathrm{D}} := \Theta \wedge (D' - \gamma \circ \hat{\nabla}^{\mathcal{E}}) \in \Omega^1(\mathcal{M}, \mathrm{End}(\mathcal{E})) \tag{8}$$

the "Dirac form" associated with $D' \in \mathcal{D}(\xi_{\mathrm{F}})$. Of course, if the connections $\hat{A}'_{\mathrm{D}}$ and A'_{D} are identified with the respective connection forms $\hat{\omega}, \omega'_{\mathrm{D}} \in \Omega^1(\mathcal{E}, T\mathcal{E})$, then

$$\pi^*_{\mathcal{E}} \varpi'_{\mathrm{D}} = \omega'_{\mathrm{D}} - \hat{\omega}. \tag{9}$$

Remark: *As a first order differential operator each Dirac type operator D is known to be of the* (*local*) *form*: $D = \gamma^\mu(\partial_\mu + \omega_\mu)$ *with the appropriate* "γ-matrices" $\gamma^\mu \in \mathrm{End}(\mathbb{C}^{2^k})$ *satisfying either of the Clifford relations* $\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu \equiv \pm 2g^{\mu\nu}\mathbf{1}$, *and*

$$\omega_\mu \equiv \omega^{\mathrm{Cl}}_\mu \otimes \mathbf{1} + \mathbf{1} \otimes A_\mu \pm \tfrac{1}{n} g_{\mu\nu} \sum_{0 \leqslant k \leqslant n} \sum_{1 \leqslant i_1 < i_2 \cdots < i_k \leqslant n} \gamma^\nu \gamma^{j_1} \gamma^{j_2} \cdots \gamma^{j_k} \otimes \theta_{i_1 i_2 \cdots i_k}. \tag{10}$$

Here, *respectively*, ω^{Cl}_μ *is the component of the lifted Levi-Civita form with respect to the appropriate metric coefficients* $g_{\mu\nu}$, *and* $A_\mu, \theta_{i_1 i_2 \cdots i_k}$ *are the components of locally defined differential forms of various degrees which take their values in* $\rho'_{\mathrm{F}}(\mathrm{Lie}(\mathrm{G})) \subset \mathrm{End}(\mathbb{C}^{N_{\mathrm{F}}})$. *Obviously*, *these forms determine each specific Dirac type operator* $D \in \mathcal{D}(\xi_{\mathrm{F}})$ *locally. More precisely*, *let* $\{(U_\alpha, \chi_\alpha) \,|\, \alpha \in \Lambda\}$ *be a family of local trivializations of the underlying vector bundle* ξ, *i.e.*, $\chi_\alpha : \pi^{-1}_{\mathcal{E}}(U_\alpha) \xrightarrow{\simeq} U_\alpha \times \mathbb{C}^{\mathrm{N}}$. *Accordingly*, *let* $\chi_{\alpha\beta} : U_\alpha \cap U_\beta \to \mathrm{GL}(\mathrm{N}, \mathbb{C})$ *be the appropriate transition functions. Then*, *a family of first order differential operators* D_α *of the form* $D_\alpha = \gamma_\alpha \circ \nabla_\alpha$, *with* $\nabla_\alpha \equiv d + \omega_\alpha$ and ω_α *defined by* (10), *gives rise to a Dirac type operator D on* ξ *provided the principal symbols* γ_α *define a family of Clifford mappings* $\mathbb{R}^{p,q} \to \mathrm{End}(\mathbb{C}^{2^k}) \simeq \mathbb{C} \otimes \mathrm{Cl}_{p,q}$ *and the transition functions take their values in the subgroup* $\mathrm{Spin}(p,q) \times \rho_{\mathrm{F}}(\mathrm{G})$ *such that the family* $\{(U_\alpha, D_\alpha) \,|\, \alpha \in \Lambda\}$ *fulfills the compatibility condition* $D_\alpha = \chi_{\alpha\beta} \circ D_\beta \circ \chi^{-1}_{\alpha\beta}$ *for all* $x \in U_\alpha \cap U_\beta \subset \mathcal{M}$. *Hence*, *the notion of a Dirac triple on* ξ (i.e., ξ_{F}) *globalizes what is encoded in the local data specifying D. In other words*, *the notion of a fermion bundle simply permits globalization of the local data* $(U_\alpha, D_\alpha)_{\alpha \in \Lambda}$ *usually encountered in physics*.

B. Gauge theories of Dirac type and their gauge groups

In this subsection we show that the geometrical setup of fermion bundles permits to naturally introduce a specific class of gauge theories which we call *gauge theories of Dirac type* (GTDT). The corresponding gauge group is the automorphism group of the underlying geometrical structure. It is shown that this group decomposes into certain subgroups which can be identified with the usual Yang-Mills gauge group, the Einstein-Hilbert gauge group, and the diffeomorphism group of the base manifold.

Definition 2.2: *Two fermion bundles* ξ_{F} *and* ξ'_{F} *are considered to be equivalent if* $\mathrm{G} \simeq \mathrm{G}'$ *and* ρ_{F} *is similar to* ρ'_{F}. *Moreover*, *there is a bundle isomorphism* $(\alpha, \beta) : \xi \to \xi'$ (*i.e., diffeomorphisms* $\alpha : \mathcal{M} \to \mathcal{M}'$ *and* $\beta : \mathcal{E} \to \mathcal{E}'$, *with* β *being fiber-wise linear and* $\alpha \circ \pi_{\mathcal{E}} = \pi_{\mathcal{E}'} \circ \beta$) *such that* $D' = \beta \circ D \circ \beta^{-1}$.

Notice that the condition $D' = \beta \circ D \circ \beta^{-1}$ actually is equivalent to $g_{\mathrm{M}'} = \alpha^{-1*} g_{\mathrm{M}}$.

The presented geometrical setup permits the formulation of a class of gauge theories which are based on a "universal Lagrangian" that is covariant with respect to the action of the automorphism group

$$\mathcal{G}_{\mathrm{F}} \equiv \mathrm{Aut}(\xi_{\mathrm{F}}) := \{(\alpha, \beta) \in \mathrm{Diff}(\mathcal{M}) \times \mathrm{Aut}(\mathcal{E}) \,|\, \pi_{\mathcal{E}} \circ \beta = \alpha \circ \pi_{\mathcal{E}}\} \tag{11}$$

of the fermion bundle in question. This group may be identified with the group of right-equivariant automorphisms of the frame bundle associated with ξ_{F}. That is,

$$\mathcal{G}_{\mathrm{F}} \simeq \mathrm{Aut}_{\mathrm{eq}}(\mathcal{FE}) := \{f \in \mathrm{Aut}(F\mathcal{E}) | R_g \circ f = f \circ R_g, g \in \mathrm{G_F}\}, \tag{12}$$

where, respectively, $\mathcal{FE} \equiv (F\mathcal{E}, \mathcal{M}, \pi, \mathrm{G_F})$ is the associated frame bundle of the fermion bundle considered, $\mathrm{G_F} \equiv \mathrm{Spin}(p,q) \times \rho_{\mathrm{F}}(\mathrm{G})$ its structure group and R the right action of the latter on the total space $F\mathcal{E}$ of the frame bundle.

Therefore, the automorphism group (11) has several important subgroups. In particular, it contains the "inner gauge group" of the fermion bundle ξ_{F}:

$$\mathcal{G}_{\mathrm{in}} := \{(\alpha, \beta) \in \mathcal{G}_{\mathrm{F}} | \alpha := \mathrm{id}_{\mathcal{M}}\}, \tag{13}$$

which may be identified with the gauge group of $\mathcal{FE}$. The latter contains two mutually commuting normal subgroups $\mathcal{G}_{\mathrm{EH}}$ and $\mathcal{G}_{\mathrm{YM}}$, such that $\mathcal{G}_{\mathrm{EH}} \cap \mathcal{G}_{\mathrm{YM}} = \{e\}$. Therefore,

$$\mathcal{G}_{\mathrm{in}} \simeq \mathcal{G}_{\mathrm{EH}} \times_{\mathcal{M}} \mathcal{G}_{\mathrm{YM}}. \tag{14}$$

Here, the "Yang-Mills gauge group" $\mathcal{G}_{\mathrm{YM}}$ can be identified with the subgroup $\{(\alpha, \beta) \in \mathrm{Aut}(\xi_{\mathrm{F}}) | \alpha = \mathrm{id}_{\mathcal{M}}, \beta \in \mathrm{Aut}_{\mathrm{Cl}}(\mathcal{E})\}$ of the inner gauge group (14). Note that the Yang-Mills gauge group is in fact an invariant subgroup of the inner gauge group. Hence, with respect to the above-mentioned identification, the "Einstein-Hilbert gauge group" $\mathcal{G}_{\mathrm{EH}}$ may be identified with the quotient group $\mathcal{G}_{\mathrm{in}}/\mathcal{G}_{\mathrm{YM}}$ according to the decomposition (3).

Moreover, the diffeomorphism group of the base manifold $\mathcal{M}$ has a natural nontrivial embedding into $\mathrm{Aut}(\xi_{\mathrm{F}})$. Indeed, if ξ_{F} is merely considered as a vector bundle, one gets the (trivial) embedding

$$\begin{gathered} \mathrm{Diff}(\mathcal{M}) \hookrightarrow \mathrm{Aut}(\xi_{\mathrm{F}}), \\ \alpha \mapsto (\alpha, \beta := \pi_{\mathcal{E}}^{*} \alpha \times \mathrm{id}_{\mathcal{E}}). \end{gathered} \tag{15}$$

This embedding may actually be identified with the inclusion according to the definition (11) of the automorphism group and the identification

$$\alpha^{-1*}\mathcal{E} \equiv \{(y, \mathfrak{z}) \in \mathcal{M} \times \mathcal{E} | \pi_{\mathcal{E}}(\mathfrak{z}) = \alpha^{-1}(y)\} = \{(\pi^{*}\alpha(\mathfrak{z}), \mathfrak{z}) | \mathfrak{z} \in \mathcal{E}\} \simeq \mathcal{E}. \tag{16}$$

Hence, one has $\alpha^{-1*}\xi_{\mathrm{F}} = (\alpha^{-1*}\mathcal{E}, \mathcal{M}, \mathrm{pr}_1) = (\mathcal{E}, \mathcal{M}, \pi^{*}\alpha)$, which permits to replace $\beta = \pi^{*}\alpha \times \mathrm{id}_{\mathcal{E}}$ (with inverse given by pr_2) simply by $\beta := \mathrm{id}_{\mathcal{E}}$. However, as ξ_{F} is a Clifford module bundle over $(\mathcal{M}, g_{\mathrm{M}})$, the embedding of $\mathrm{Diff}(\mathcal{M})$ into $\mathrm{Aut}(\xi_{\mathrm{F}})$ becomes non-trivial. In other words, there is an inner automorphism on $\mathrm{End}(\mathcal{E})$, induced by α, such that $\gamma' = \widetilde{\alpha} \circ \gamma \circ \widetilde{\alpha}^{-1}$. Here, $\gamma'|_{TM} \equiv \gamma|_{TM} \circ T\alpha^{-1}$ is the Clifford action on $\alpha^{-1*}\xi_{\mathrm{F}}$ that is defined with respect to $\alpha^{-1*}g_{\mathrm{M}}$ and $\widetilde{\alpha} \in \mathrm{End}(\mathcal{E})$ an appropriate lift of α.

As a consequence, one obtains

$$\begin{gathered} \mathrm{Diff}(\mathcal{M}) \hookrightarrow \mathrm{Aut}(\xi_{\mathrm{F}}), \\ \alpha \mapsto (\alpha, \beta := \widetilde{\alpha}). \end{gathered} \tag{17}$$

We call the image of this embedding the "outer gauge group" of the fermion bundle ξ_{F}. It is denoted by $\mathcal{G}_{\mathrm{ex}}$.

Finally, since $\mathcal{G}_{\mathrm{in}} \subset \mathcal{G}_{\mathrm{F}}$ is normal and $\mathcal{G}_{\mathrm{in}} \cap \mathcal{G}_{\mathrm{ex}} = \{e\}$, one ends up with the semidirect decomposition of the automorphism group into the gauge and diffeomorphism group, i.e.,

$$\mathcal{G}_{\mathrm{F}} = \mathcal{G}_{\mathrm{in}} \rtimes \mathcal{G}_{\mathrm{ex}}. \tag{18}$$

In fact, each $g \in \mathcal{G}_{\mathrm{F}}$ may be written as $g = g_{\mathrm{in}} g_{\mathrm{ex}} \in \mathcal{G}_{\mathrm{in}} \rtimes \mathcal{G}_{\mathrm{ex}}$ such that

$$\mathcal{G}_{\mathrm{F}} \ni gg' = (g_{\mathrm{in}} g_{\mathrm{ex}})(g'_{\mathrm{in}} g'_{\mathrm{ex}}) \equiv (g_{\mathrm{in}} g_{\mathrm{ex}} g'_{\mathrm{in}} g_{\mathrm{ex}}^{-1})(g_{\mathrm{ex}} g'_{\mathrm{ex}}) \in \mathcal{G}_{\mathrm{in}} \rtimes \mathcal{G}_{\mathrm{ex}}. \tag{19}$$

We call the automorphism group $\mathcal{G}_{\mathrm{F}} \equiv \mathrm{Aut}(\xi_{\mathrm{F}})$ the "(fermionic) gauge group" of the fermion bundle ξ_{F}.

In order to define a $\mathcal{G}_{\mathrm{F}}$–covariant theory (by which we mean that symbolically $\mathcal{L} \circ (\alpha, \beta) = \alpha^{-1^*}\mathcal{L}$, where $\mathcal{L}$ is an appropriate "Lagrangian density" defining the theory) we first consider, for a given fermion bundle ξ_{F}, the canonical mapping

$$V_{\mathrm{D}} : \mathcal{D}(\xi_{\mathrm{F}}) \to \mathcal{C}^{\infty}(\mathcal{M})$$

$$D' \mapsto \mathrm{tr}(D'^2 - \triangle'_{\mathrm{D}}), \tag{20}$$

which is called the "Dirac potential" on ξ_{F}. Here again, the second order differential operator $\triangle'_{\mathrm{D}}$ denotes the Bochner-Laplacian that is uniquely defined with respect to D' such that $\triangle'_{\mathrm{D}} + (D'^2 - \triangle'_{\mathrm{D}})$ is the (general) Lichnerowicz decomposition of D'^2 (c.f. in Refs. 3 and 21).

The universal top form

$$\mathcal{L}_{\mathrm{D}} : \mathcal{D}(\xi_{\mathrm{F}}) \to \Omega^n(\mathcal{M}),$$

$$D' \to * V_{\mathrm{D}}(D') \tag{21}$$

is called the "Dirac-Lagrangian" on the fermion bundle ξ_{F}. This canonical mapping is universal in the sense that it is indeed covariant with respect to the action of $\mathcal{G}_{\mathrm{F}}$. In particular, it is invariant with respect to the action of the inner gauge group $\mathcal{G}_{\mathrm{in}} \subset \mathcal{G}_{\mathrm{F}}$.

Definition 2.3: *Let ξ_{F} be the fermion bundle with respect to the data $(\mathrm{G}, \rho_{\mathrm{F}}, D)$. We call* (*the* "*bosonic part*" *of*) *the theory defined by the corresponding Lagrangian density $\mathcal{L}_{\mathrm{D}}(D) \in \Omega^n(\mathcal{M})$ a* "*gauge theory of Dirac type*".

Let again $\mathcal{A}(\xi_{\mathrm{F}})$ be the set of all linear connections on ξ_{F} and $\mathcal{A}_{\mathrm{D}}(\xi_{\mathrm{F}}) \subset \mathcal{A}(\xi_{\mathrm{F}})$ be the subset of all connections which yield D (i.e., $\gamma \circ \nabla^{\mathcal{E}} = D$, with $\nabla^{\mathcal{E}}$ a corresponding covariant derivative). Then, the top form $\mathcal{L}_{\mathrm{D}}(D) \in \Omega^n(\mathcal{M})$ is indeed well-defined on the moduli-space $\mathfrak{M}_{\mathrm{D}}(\xi_{\mathrm{F}}) \equiv \mathcal{A}_{\mathrm{D}}(\xi_{\mathrm{F}})/\mathcal{G}_{\mathrm{in}}$. Moreover, it transforms covariantly with respect to the (left) action of the fermionic gauge group $\mathcal{G}_{\mathrm{F}}$, i.e.,

$$\mathcal{L}'_{\mathrm{D}}(\beta \circ D \circ \beta^{-1}) = (\alpha^{-1^*}\mathcal{L}_{\mathrm{D}})(D). \tag{22}$$

To obtain an explicit formula for the top form $\mathcal{L}_{\mathrm{D}}(D)$ associated with a Dirac type operator D, one could use the generalized Bochner-Lichnerowicz-Weizenböck formula of $D^2 - \triangle_{\mathrm{D}} \in \Gamma(\mathrm{End}(\xi_{\mathrm{F}}))$. As a consequence, the Dirac potential reads

$$V_{\mathrm{D}}(D) = \mathrm{tr}(\gamma(\mathcal{F}_D) + \mathrm{ev}_{g_{\mathrm{M}}}(\partial_D^{T^*\mathcal{M} \otimes \mathrm{End}(\mathcal{E})} \Xi + \Xi^2)). \tag{23}$$

Here, respectively, $\mathcal{F}_D \in \Omega^2(\mathcal{M}, \mathrm{End}(\mathcal{E}))$ is the total curvature with respect to the Dirac connection $A_{\mathrm{D}} \in \mathcal{A}(\xi_{\mathrm{F}})$ and the one-form $\Xi \in \Omega^1(\mathcal{M}, \mathrm{End}(\mathcal{E}))$ measures the deviation of A_{D} from being a Clifford connection. With respect to a local co-frame $(X^1, \ldots, X^n)$ on $\mathcal{M}$ this one-form reads

$$\Xi \overset{loc.}{=} -\tfrac{1}{2} g_{li} X^l \otimes \gamma(X^j)([\partial_{D,X_j}, \gamma(X^i)] + \omega^i_{jk} \gamma(X^k)), \tag{24}$$

where $(X_1, \ldots, X_n)$ is the dual frame of $(X^1, \ldots, X^n)$ and $\omega^i_{jk} := X^i(\nabla^{TM}_{X_j} X_k)$ are the corresponding Levi-Civita connection coefficients with respect to g_{M} and the chosen frame. Again, $g_{ij} \in \mathcal{C}^{\infty}(U_\alpha)$ is the matrix element of $(g_{\mathrm{M}}(X^i, X^j))^{-1}$. Also, $\mathrm{ev}_{g_{\mathrm{M}}}$ denotes the evaluation map (contraction) with respect to the isomorphism $\tau^*_{\mathrm{M}} \simeq \tau_{\mathrm{M}}$ of the tangent and the cotangent bundle of $\mathcal{M}$ that is provided by g_{M} (c.f. Refs. 1 and 45).

Remark: Let again, $\{(U_\alpha, \chi_\alpha) \,|\, \alpha \in \Lambda\}$ be a family of local trivializations of a given fermion bundle ξ_{F}. According to (10), *$D_\alpha := \chi_\alpha \circ D \circ \chi_\alpha^{-1}$ is fully determined by $(\gamma_\alpha, A_\alpha, \theta_\alpha)$. Hence, $\mathcal{A}_{\mathrm{D}}(\xi_{\mathrm{F}}) \subset \mathcal{A}(\xi_{\mathrm{F}})$ may locally be identified with the set of differential forms ω_α*

$\in \Omega^*(U_\alpha, \mathrm{End}(\mathbb{C}^N))$ *which, together with* $g^{ik} \in \mathcal{C}^\infty(U_\alpha)$, *determine* D_α. *Accordingly, the Euler-Lagrange equations*

$$\mathcal{EL}_D(D) = 0 \tag{25}$$

are obtained by the first variation of the (*locally defined*) *functional* ($\Omega \subset U_\alpha$, *compact*)

$$\mathcal{S}[\gamma_\alpha, A_\alpha, \theta_\alpha] := \int_\Omega \mathcal{L}(\gamma_\alpha, A_\alpha, \theta_\alpha), \tag{26}$$

with $\mathcal{L}(\gamma_\alpha, A_\alpha, \theta_\alpha) \equiv (\chi_\alpha^{-1*}\mathcal{L}_D)(D) \in \Omega^n(U_\alpha)$. *Notice, however, it can easily be inferred from the local version of the Dirac potential* (20) that $\mathcal{S} = \mathcal{S}[\gamma_\alpha, \theta_\alpha]$. *Indeed, the local version of* (23) *reads*

$$V(\gamma_\alpha, A_\alpha, \theta_\alpha) \equiv (\chi_\alpha^{-1*}V_D)(D) = \tfrac{N}{2} r_M + \tfrac{1}{2}\,\mathrm{tr}([\gamma_\alpha^j, \gamma_\alpha^j][\theta_{\alpha,i}, \theta_{\alpha,j}]) + \tfrac{1}{8} g_{ij}\mathrm{tr}(\gamma_\alpha^k[\theta_{\alpha,k}, \gamma_\alpha^j]\gamma_\alpha^j[\theta_{\alpha,l}, \gamma_\alpha^j]). \tag{27}$$

The notation used is as follows: $\theta_\alpha \equiv X^i \otimes \theta_{\alpha,i} := \pm(1/n) g_{\mu\nu} \Sigma_{0 \leqslant k \leqslant n} \Sigma_{1 \leqslant i_1 < i_2 \cdots < i_k \leqslant n} X^\mu \otimes \gamma_\alpha^\nu \gamma_\alpha^{j_1} \gamma_\alpha^{j_2} \cdots \gamma_\alpha^{j_k} \otimes \theta_{i_1 i_2 \cdots i_k}$, *with the abbreviation* $\gamma_\alpha^j := \gamma_\alpha(X^i) \equiv \chi_\alpha \circ \gamma(X^i) \circ \chi_\alpha^{-1}$. *Moreover,* $r_M \in \mathcal{C}^\infty(\mathcal{M})$ *denotes the scalar curvature of* $\mathcal{M}$ *with regard to* g_M.

It follows that Einstein's field equation of gravity is an integral part of the Euler-Lagrange equations of Dirac type gauge theories. In particular, the "energy-momentum tensor" is specified by the Dirac type operator in question (i.e., locally fixed by the one-form $\theta \in \Omega^1(U, \mathrm{End}(\mathcal{E}))$).

In the next section we discuss a specific class of Dirac type operators which is distinguished by its Lichnerowicz decomposition (c.f. Ref. 30). Moreover, it is shown that, as a solution of the Euler-Lagrange equations, these Dirac type operators spontaneously break the gauge symmetry.

III. SIMPLE TYPE DIRAC OPERATORS AND SPONTANEOUS SYMMETRY BREAKING

In what follows we discuss a specific class of Dirac type gauge theories. The main feature of this class consists of permitting us to naturally include the notion of "spontaneous symmetry breaking" in the realm of Dirac type gauge theories. Eventually, we will show that the Yukawa coupling of the fermions, together with gravity, induces spontaneous symmetry breaking without use of a "Higgs potential." The inner geometry of $\mathcal{M}$ (i.e., of space-time in the case of $(n,s) = (4, \mp 2)$) in the "ground state" of the gauge theory is fully determined (up to boundary conditions) by the "fermionic masses." Here, the latter are shown to correspond to the spectrum of a certain Hermitian section of the bundle $\mathrm{End}(\xi_F)$. Because this spectrum turns out to be constant over $\mathcal{M}$ one may thus decompose the fermion bundle ξ_F into the Whitney sum of the appropriate eigenbundles of the "fermionic mass operator" that is induced by spontaneous symmetry breaking. If the spectrum is non-degenerated (like in the case of the Standard Model) the eigenbundles are Hermitian line bundles which one may consider to geometrically model "asymptotically free fermions."

Let ξ_F be a chiral fermion bundle with respect to some Dirac triple (G, ρ_F, D).

Definition 3.1: A Dirac type operator $D' \in \mathcal{D}(\xi_F)$ *is called of "simple type" if the Bochner-Laplacian of* D' *is defined by a Clifford connection, i.e.,* $\hat{A}'_D \in \mathcal{A}_{Cl}(\xi_F) \subset \mathcal{A}(\xi_F)$.

We denote the corresponding covariant derivative again by ∂_A. As a result, the covariant derivative of the Dirac connection $A'_D \in \mathcal{A}(\xi_F)$ reads

$$\partial_{D'} = \partial_A + \varpi'_D \tag{28}$$

with a unique one-form $\varpi'_D \in \Omega^1(\mathcal{M}, \mathrm{End}(\mathcal{E}))$. The next Proposition permits us to characterize the Dirac forms of simple type Dirac operators of arbitrary signature.

Proposition 3.1: A Dirac type operator $D' \in \mathcal{D}(\xi_F)$ *is of simple type if and only if it reads*

$$D' = \not{\partial}_A + \gamma_M \otimes \phi, \tag{29}$$

with $\phi \in \Gamma(\mathrm{End}^-_{\mathrm{Cl}}(\xi_{\mathrm{F}}))$.

Proof: The proof of the statement is lengthy and somewhat technical though elementary. It is similar to the proof already presented in Ref. 1 for the special case $s=n$. A detailed proof for arbitrary signature s can be found in the Appendix. □

Note that a simple type Dirac operator is fully determined by a Clifford connection in the case where ξ_{F} is not chiral and thus has a vanishing Dirac form. In general, however, the Dirac connection of a simple type Dirac operator is given by a unique Clifford connection $A \in \mathcal{A}_{\mathrm{Cl}}(\xi_{\mathrm{F}})$ together with the specific Dirac form

$$\varpi'_{\mathrm{D}} = \Theta \wedge (\gamma_{\mathrm{M}} \otimes \phi). \tag{30}$$

With respect to a local trivialization (U_α, χ_α) of ξ_{F} the Dirac form is determined by

$$\theta_\alpha = \pm \tfrac{1}{n} g_{ij} X^i \otimes \gamma^j_\alpha \gamma_{\mathrm{M}} \otimes \phi_\alpha, \tag{31}$$

with $1 \otimes \phi_\alpha := \chi_\alpha \circ (1 \otimes \phi) \circ \chi_\alpha^{-1} \in \mathcal{C}^\infty(U_\alpha, \mathrm{End}^-(\mathbb{C}^{\mathrm{N_F}}))$ and $\theta_\alpha \equiv \chi_\alpha^{-1*} \varpi'_{\mathrm{D}}$.

Dirac operators of simple type define the largest class of Dirac type operators with the corresponding Bochner-Laplace operators defined by Clifford connections. Of course, the most important subclass of Dirac type operators is given by $D' = \not{\partial}_A$. They correspond to "twisted spin Dirac operators" in the case where $\mathcal{M}$ denotes a spin manifold. Notice that in the elliptic case, Dirac operators of simple type turn out to be of importance in the discussion of the family index theorem (c.f. Refs. 4 and 41). They are also known to play a fundamental role in the description of the minimal Standard Model within the realm of noncommutative geometry (please see, e.g., the corresponding references already cited in Sec. I). This kind of first order differential operator is thus well known in physics (please, see the following), as well as in mathematics. However, in this article we discuss them from a purely geometrical perspective of gauge theories.

We turn now to the discussion of spontaneous symmetry breaking within the realm of the presented geometrical frame. For this let again ξ_{F} be a chiral fermion bundle with respect to $(\mathrm{G}, \rho_{\mathrm{F}}, D)$ where D is of simple type.

Proposition 3.2: Let D be a global solution of the Euler-Lagrange equation

$$\mathcal{EL}_{\mathrm{D}}(D) = 0 \tag{32}$$

such that $\mathcal{G}_{\mathrm{YM}}$ *acts transitively on the image of* $D - \not{\partial}_A$. *Consequently*, *there exists a constant* (*skew-Hermitian*) *section* $\mathcal{D} \in \Gamma(\mathrm{End}^-_{\mathrm{Cl}}(\xi_{\mathrm{F}}))$ *such that* $(\mathcal{M}, g_{\mathrm{M}})$ *is an Einstein manifold with the scalar curvature given by*

$$r_{\mathrm{M}} = \lambda \|\mathrm{M_F}\|^2. \tag{33}$$

Here, $\|\mathrm{M_F}\|^2 \equiv \mathrm{tr}(\mathrm{M_F^\dagger M_F})$ *with* $i\mathrm{M_F} := \gamma_{\mathrm{M}} \otimes \mathcal{D}$ *representing the* "*total fermionic mass operator*"; $\lambda \in \mathbb{R}$ *is an appropriate nonzero constant which may also depend on a suitable normalization of* $\mathcal{L}_{\mathrm{D}}(D)$.

Proof: The Dirac-Lagrangian of a simple type Dirac operator reads

$$\mathcal{L}_{\mathrm{D}}(D) = 2^k (\mathrm{N_F} r_{\mathrm{M}} + \mathrm{tr}\,\phi^2) \mu_{\mathrm{M}}. \tag{34}$$

We remark that this Lagrangian depends on the connection that is defined only with respect to (g_{M}, ϕ). Moreover, the Euler-Lagrange equation concerning $\phi \in \Gamma(\mathrm{End}^-_{\mathrm{Cl}}(\xi_{\mathrm{F}}))$ is trivial. Whence, one may conclude that a global solution of (32) yields: $D = \not{\partial}_A$ with $A \in \mathcal{A}_{\mathrm{Cl}}(\xi_{\mathrm{F}})$ arbitrary and $(\mathcal{M}, g_{\mathrm{M}})$ Ricci flat. However, there is actually a bigger class of solutions of (32). As the latter does not provide any dynamical condition on the sections ϕ one may treat the latter as "background fields", similar to the metric in the case of pure Yang-Mills gauge theory. The Euler-Lagrange equations with respect to the corresponding Dirac-Lagrangian then reduces to the Einstein equation

$$\mathrm{Ric}(g_{\mathrm{M}}) = \lambda_{\mathrm{gr}} \mathrm{tr}\phi^2 \mathrm{id}_{\mathrm{TM}} \tag{35}$$

with $\lambda_{\mathrm{gr}} \in \mathbb{R}$ being some nonzero constant which also depends on the chosen normalization of $\mathcal{L}_{\mathrm{D}}(D)$. It also takes into account the appropriate physical (length) dimension, where ϕ is accordingly rescaled. The section $\mathrm{Ric} \in \Gamma(\mathrm{End}(\tau_{\mathrm{M}}))$ denotes the Ricci tensor with respect to g_{M}. From the Einstein equation it follows that $\mathrm{d}(\mathrm{tr}\,\phi^2)=0$. Hence, the Dirac-Lagrangian (34) of a simple type Dirac operator reduces, in general, to the Einstein-Hilbert Lagrangian with a "cosmological constant" included. This constant is generated by a section $\phi \in \Gamma(\mathrm{End}^-_{\mathrm{Cl}}(\xi_{\mathrm{F}}))$ subject to the condition that $\|\phi\|^2 := <\phi,\phi> \equiv \mathrm{tr}(\phi^\dagger\phi)$ must be constant. Note that $\phi^\dagger = \pm\phi$, depending on whether D is supposed to be Hermitian or skew-Hermitian. The basic idea here is to make a polar decomposition $\phi \overset{loc.}{=} \rho_{\mathrm{F}}(g)\circ\mathcal{D}\circ\rho_{\mathrm{F}}(g)^{-1}$ with $\mathcal{D}$ being a fixed vector of the same length as ϕ. To make this more precise let $\mathcal{W} := \mathrm{End}^-_{\mathrm{Cl}}(\xi_{\mathrm{F}})$ be the Hermitian vector bundle of (complex) rank $\mathrm{N}_{\mathrm{F}}^2$ with total space $W := \mathrm{End}^-_{\mathrm{Cl}}(\mathcal{E})$. Accordingly, let $\mathfrak{P} := (P,\mathcal{M},\pi_{\mathrm{P}})$ be the frame bundle associated with $\mathcal{W}$. Also, let $\mathfrak{E} := (E,\mathcal{M},\pi_{\mathrm{E}})$ be the associated Hermitian vector bundle with total space defined by $E := P\times_{\mathrm{G}}\mathrm{End}(\mathbb{C}^{\mathrm{N_F}})$. By construction $\mathfrak{E} \simeq \mathcal{W}$, and we do not distinguish between these two vector bundles. In particular, we may write $W \ni \mathfrak{Z} = [(p,\mathfrak{z})]$. Equivalently, if $\phi \neq 0$ we may consider the normalized section $\varphi := \phi/\|\phi\| \in \Gamma(\mathcal{S})$ with $\mathcal{S} \subset \mathcal{W}$ being the sphere sub-bundle. According to the identification $\mathfrak{E} \simeq \mathcal{W}$ any section φ corresponds to a G-equivariant mapping $\tilde{\varphi}: P \to \mathrm{S}^{\mathrm{N}'-1}$ ($\mathrm{N}' = 2\mathrm{N}_{\mathrm{F}}^2$), such that $\varphi(x) = [(p,\tilde{\varphi}(p)]\big|_{p\in\pi_{\mathrm{P}}^{-1}(x)}$. By assumption, G acts transitively on $\mathrm{im}(\tilde{\varphi}) \subset \mathrm{S}^{\mathrm{N}'-1}$. Hence, for arbitrarily chosen $\mathfrak{z}_0 \in \mathrm{im}(\tilde{\varphi})$ we may identify the orbit of $\mathfrak{z}_0$, $\mathrm{orbit}(\mathfrak{z}_0)$, with $\mathrm{im}(\tilde{\varphi})$. Let $\mathrm{I}(\mathfrak{z}_0) \subset \rho_{\mathrm{F}}(\mathrm{G})$ be the isotropy group of $\mathfrak{z}_0$. The mapping

$$\nu_\phi : P \to \mathrm{orbit}(\mathfrak{z}_0).$$

$$p \mapsto \rho_{\mathrm{F}}(g)\mathfrak{z}_0\rho_{\mathrm{F}}(g^{-1}), \tag{36}$$

defines an "H-reduction" $(\mathcal{Q}_\phi, \iota_\phi)$ of $\mathfrak{P}$ with $g \in \mathrm{G}$ being determined (modulo $\mathrm{I}(\mathfrak{z}_0)$) by the relation $\tilde{\varphi}(pg) = \mathfrak{z}_0$. Indeed, the corresponding section

$$\mathcal{V}_\phi : \mathcal{M} \to P\times_{\mathrm{G}}\mathrm{G/H}$$

$$x \mapsto \left[(p,\nu_\phi(p))\right]\Big|_{p\in\pi_{\mathrm{P}}^{-1}(x)} \tag{37}$$

is known to be equivalent to a specific principal H-bundle $\mathcal{Q}_\phi \equiv (Q,\mathcal{M},\pi_{\mathrm{Q}},\mathrm{H})$ together with an equivariant embedding $\iota_\phi : \mathcal{Q}_\phi \hookrightarrow \mathcal{P}$ of principal bundles (c.f., e.g., Ref. 29). For "bundle reduction" in the context of Yang-Mills-Higgs gauge theories see also, e.g., Refs. 11, 43, and 49. Here, $\mathrm{H} \subset \mathrm{G}$ is the unique sub-group equivalent to $\mathrm{I}(\mathfrak{z}_0)$, and thus $\mathrm{orbit}(\mathfrak{z}_0) \simeq \mathrm{G/H}$. Finally, we may define $\mathcal{D} \in \Gamma(\mathrm{End}^-_{\mathrm{Cl}}(\xi_{\mathrm{F}}))$ by the section

$$\mathcal{D} : \mathcal{M} \to E$$

$$x \mapsto [(\iota_\phi(q),\mathfrak{z}_0)]\big|_{q\in\pi_{\mathrm{Q}}^{-1}(x)}. \tag{38}$$

Of course, the section $\mathcal{D}$ also gives rise to an (equivalent) H-reduction $(\mathcal{Q},\iota)$ of $\mathfrak{P}$ which may be identified with $(\mathcal{Q}_\phi,\iota_\phi)$ by $\mathrm{H} \simeq \mathrm{I}(\tilde{g}\mathfrak{z}_0\tilde{g}^{-1})$. Here, $\tilde{g} \in \mathrm{G}$ is determined (up to $\mathrm{I}(\mathfrak{z}_0)$) by a choice of $q_0 \in \mathcal{Q}_\phi$ and the corresponding relation $\varphi(\iota_\phi(q_0)) \equiv \tilde{\mathfrak{z}}_0 =: \tilde{g}\mathfrak{z}_0\tilde{g}^{-1}$. The rest of the statement is a direct consequence of the Einstein equation. □

A simple type Dirac operator D is said to be in the unitary gauge provided it reads

$$D = \not{\partial}_A + \gamma_{\mathrm{M}} \otimes \mathcal{D}. \tag{39}$$

A necessary condition for the existence of the unitary gauge is that $D-\not{b}_A \neq 0$. If $\mathcal{G}_{\mathrm{YM}}$ acts transitively on the image of the latter operator, this condition is also sufficient. A simple type Dirac operator in the unitary gauge spontaneously breaks the Yang-Mills gauge symmetry since in general

$$\mathcal{H}_{\mathrm{YM}} := \{g \in \mathcal{G}_{\mathrm{YM}} | [\mathcal{D}, g] = 0\} \tag{40}$$

is a proper sub-group of the Yang-Mills gauge group $\mathcal{G}_{\mathrm{YM}} \subset \mathcal{G}_{\mathrm{F}}$. In this case, the Lagrangian $\mathcal{L}_{\mathrm{D}}(D)$ is said to define a "spontaneously broken fermionic gauge theory." Note that in the case where $\mathcal{G}_{\mathrm{YM}}$ acts transitively on the sphere subbundle $\mathcal{S} \subset \mathrm{End}_{\mathrm{Cl}}(\xi_{\mathrm{F}})$ any global solution of (32) satisfying $D-\not{b}_A \neq 0$ defines a spontaneously broken fermionic gauge theory.

Remark: The notion of unitary gauge and its existence is similar to that presented in (Ref. 46) (Proposition 3.2) *in the case of rotationally symmetric Higgs potentials. However, the* "*mass term*" $\|\phi\|^2$ *in the Lagrangian of a simple type Dirac operator itself does not break the symmetry, of course. The symmetry breaking is caused by assuming that the fermionic mass generates a non-trivial geometry. Indeed, the geometry is fully determined by the spectrum of the* (*square of the*) *fermionic mass operator* $\mathrm{M}_{\mathrm{F}}^2 \in \Gamma(\mathrm{End}(\xi_{\mathrm{F}}))$. *Also, since the spectrum* $\mathrm{spec}(\mathrm{M}_{\mathrm{F}}^2)$ *is constant throughout* $\mathcal{M}$, *one may decompose the fermion bundle into the Whitney sum of the corresponding eigenbundles of* $\mathrm{M}_{\mathrm{F}}^2$, *i.e.* (c.f. Ref. 47),

$$\xi_{\mathrm{F}} = \bigoplus_{\mathrm{m}^2 \in \mathrm{spec}(\mathrm{M}_{\mathrm{F}}^2)} \xi_{\mathrm{F},\mathrm{m}^2} = \ker(\mathrm{M}_{\mathrm{F}}^2) \oplus \left[\bigoplus_{\mathrm{m}^2 \in \mathrm{spec}(\mathrm{M}_{\mathrm{F}}^2)\setminus\{0\}} \xi_{\mathrm{F},\mathrm{m}^2} \right]. \tag{41}$$

The total curvature on ξ_{F} *with respect to a simple type Dirac operator satisfying* (32) *is given by*

$$\mathcal{F}_D = \not{R} + F_A + \mathrm{M}_{\mathrm{F}}^2 \Theta \wedge \Theta - \partial_A^{\mathrm{End}(\mathcal{E})} \mathrm{M}_{\mathrm{F}} \wedge \Theta. \tag{42}$$

Here, respectively, $\not{R} \in \Omega^2(\mathcal{M}, \mathrm{End}(\mathcal{E}))$ *is the lifted* (*semi-*)*Riemannian curvature with respect to* g_{M}, *and* $F_A \equiv \mathcal{F}_{\not{b}_A} - \not{R} \in \Omega^2(\mathcal{M}, \mathrm{End}(\mathcal{E}))$ *is the* "*twisting curvature*" *with respect to the Clifford connection* $A \in \mathcal{A}_{\mathrm{Cl}}(\xi_{\mathrm{F}})$ *that is determined by D. In contrast to* $\not{R}$, *which is determined by the spectrum of* $\mathrm{M}_{\mathrm{F}}^2$, *the twisting curvature* F_A *is completely arbitrary. For this reason it is natural to assume that A is purely topological, i.e., flat. In this case, the curvature of* ξ_{F} *is fully determined by the spectrum of the fermionic mass operator. As a consequence, for* $n=4$ *the chiral fermion bundle must indeed be real. If in addition* $\mathcal{M}$ *is a spin manifold, then* $\xi_{\mathrm{F},\mathrm{m}^2} \simeq \tau_{\mathrm{spin}} \otimes_{\mathcal{M}} \zeta_{\mathrm{F},\mathrm{m}^2}$, *where the latter is a Hermitian line bundle if and only if* $\mathrm{spec}(\mathrm{M}_{\mathrm{F}}^2)\setminus\{0\}$ *is non-degenerated. Consequently, when restricted to the residual group H, the fermionic representation* ρ_{F} *decomposes into the sum of the trivial representation and irreducible* $U(1)$*-representations.* (*To date, electromagnetism is the only Abelian gauge theory that is physically well-established. Moreover, as a matter of fact, massless but electrically charged particles are unknown in nature*). *The latter are either trivial, and hence* $\xi_{\mathrm{F},\mathrm{m}^2}$ *corresponds to an electrically uncharged but massive fermion or, for non-trivial representations,* $\xi_{\mathrm{F},\mathrm{m}^2}$ *corresponds to a massive electrically charged particle. Apparently, together with spin, the assumption that the Clifford connection A is flat imposes crucial restrictions on the fermion bundle. In fact, in this case* (*up to algebraic torsion*) $\xi_{\mathrm{F}} \simeq \oplus_{k=1}^{\mathrm{N_F}} \tau_{\mathrm{spin}}$. *Note that, if* $n=4$ *and* $\mathrm{spec}(\mathrm{M}_{\mathrm{F}}^2)$ *is nondegenerate, the existence of a flat Clifford connection on* ξ_{F} (*again, up to torsion*) *becomes equivalent to the reality of the latter.*

Definition 3.2: A fermion bundle ξ_{F} *is said to be in the unitary gauge provided it is defined with respect to a Dirac triple* $(\mathrm{G}, \rho_{\mathrm{F}}, D)$ *such that D is in the unitary gauge. More generally, a fermion bundle is called* "*massive*" *if it is gauge equivalent to a fermion bundle in the unitary gauge. The corresponding element of* $\mathcal{G}_{\mathrm{YM}} \subset \mathcal{G}_{\mathrm{F}}$ *is referred to as a* "*unitary gauge transformation.*"

On a massive fermion bundle there exists a distinguished class of connections.

Definition 3.3: A connection $A \in \mathcal{A}(\xi_{\mathrm{F}})$ *on a massive fermion bundle* ξ_{F} *is called compatible with D provided the corresponding covariant derivative* $\nabla^{\mathcal{E}}$ *commutes with the appropriate total fermionic mass operator. That is,*

$$\nabla_X^{\mathrm{End}(\mathcal{E})} \mathrm{M}_{\mathrm{F}} = 0 \tag{43}$$

for all smooth tangent vector fields $X \in \Gamma(\tau_M)$.

This definition expresses the H-reducibility of a connection on ξ_F in terms of Dirac type operators which spontaneously break the gauge symmetry. The Definition (3.3) is in fact analogous to the Definition 2.1 in Ref. 46 for a spontaneously broken Yang-Mills-Higgs gauge theory. Note that (43) is equivalent to the condition

$$D' \circ M_F = - M_F \circ D', \tag{44}$$

with $D' \in \mathcal{D}(\xi_F)$ being identified with $\gamma \circ \nabla^{\mathcal{E}}$. In particular, one may assume that the Clifford connection which defines the Bochner-Laplacian of $D = \not{\partial}_A + iM_F$ is compatible with the latter. This holds true if and only if

$$D^2 = \not{\partial}_A^2 - M_F^2. \tag{45}$$

Hence, the Clifford connection of the Bochner-Laplacian $\triangle_D$ is compatible with spontaneous symmetry breaking if and only if "the square of the sum equals the sum of the squares." We note that, from a geometrical point of view, it is the condition $\nabla^{\mathrm{End}(\mathcal{E})} M_F \neq 0$ that yields "massive vector bosons" (please see the following). In other words, the existence of a nontrivial "Yang-Mills mass operator" can be expressed by the violation of compatibility condition (45).

Definition 3.4: We consider a Dirac operator D of simple type to define a "(*semi-classical*) *fermionic vacuum*" *if D is gauge equivalent to* $\not{\partial}_A + iM_F$ *where the corresponding Clifford connection* $A \in \mathcal{A}(\xi_F)$ *is purely topological. In this case*, *D in the unitary gauge is denoted by*

$$\not{\partial}_{\mathcal{D}} \equiv \not{\partial} + iM_F. \tag{46}$$

Clearly, when restricted to the appropriate eigenbundles this operator corresponds to Dirac's well-known first order differential operator $i\not{\partial} - m$ and thus provides us with the appropriate physical interpretation of $\mathrm{spec}(M_F^2)$ (and hence also with $\mathcal{D}$). For example, in the case of $(n,s) = (4, \mp 2)$ there is always a local frame such that the total symbol $\sigma(i\not{\partial}_{\mathcal{D}})$ coincides with the principal symbol of (46). Every time-like $\xi \in T^*\mathcal{M} \subset \mathrm{End}(\mathcal{E})$ and eigenvector $\mathfrak{z} \in \mathcal{E}$ of M_F^2 (with eigenvalue m^2) yields $\sigma(i\not{\partial})(\xi)\mathfrak{z} \overset{loc}{=} \gamma(\xi)\mathfrak{z} = \pm m\mathfrak{z}$. Hence, one obtains the usual relation between momentum and mass: $g_M(\xi,\xi) = \pm m^2$ of a point-like particle.

From a geometrical point of view a fermionic vacuum may be regarded as a fermion bundle $\xi_{F,\mathrm{red}} := (\mathcal{E}_{\mathrm{red}}, \mathcal{M}, \pi_{\mathcal{E},\mathrm{red}})$ with respect to the Dirac triple $(H, \rho_{F,\mathrm{red}}, \not{\partial}_{\mathcal{D}})$. Here, respectively, $\mathcal{E}_{\mathrm{red}} := Q \times_H \mathbb{C}^{2^k} \otimes \mathbb{C}^{N_F}$ and $\rho_{F,\mathrm{red}} := \rho_F|_H$. Notice that $\xi_F \simeq \xi_{F,\mathrm{red}}$ via the bundle mapping $[(q,z)] \mapsto [(\iota(q),z)]$. Accordingly, we shall not distinguish between these two bundles and proceed to say that a fermion bundle ξ_F can be generated from a fermionic vacuum if it is determined by a Dirac triple of the form $(H, \rho_{F,\mathrm{red}}, \not{\partial}_{\mathcal{D}})$. In other words, ξ_F is generated from a fermionic vacuum provided the corresponding frame bundle $\mathcal{P}$ can be considered as a prolongation of the frame bundle $\mathcal{Q}$ that corresponds to some fermion bundle $\xi_{F,\mathrm{red}}$. Finally, the Dirac potential of a fermionic vacuum has the particular simple form (c.f. Ref. 47)

$$V_D(\not{\partial}_{\mathcal{D}}) = \frac{\lambda}{2} < M_F^2 >, \tag{47}$$

where $< M_F^2 > := (1/N_F) \Sigma_{a=1}^{N_F} m_a^2$ and $\lambda \in \mathbb{R}$ is a suitable nonzero constant.

The idea of a fermionic vacuum is mainly motivated by a geometrical description of perturbation theory used in quantum field theory. As already mentioned the fermion bundle ξ_F is considered as a "perturbation" of a fermionic vacuum $\xi_{F,\mathrm{red}}$. Such a perturbation cannot change the topology of ξ_F but its geometry. The notion of a fermionic vacuum itself puts severe topological restrictions on a fermion bundle. (One might speculate that "quantum fluctuations" will lead to a change of the topology of the fermionic vacuum for it basically adds "quantum corrections" to the fermionic mass spectrum). Before we explain this in more detail, however, we shall discuss in the next section a more specific class of simple type Dirac operators which takes into account that, within the Standard Model of Particle Physics, the Higgs boson is described by a subrepresenta-

tion of ρ_F instead of the fundamental representation. Moreover, we shall discuss the need for "fermionic doubling" and the fermionic Lagrangian within the presented setup.

IV. DIRAC-YUKAWA OPERATORS AND THE FERMIONIC LAGRANGIAN

In the previous section we discussed a distinguished class of Dirac type operators on a fermion bundle. Their basic feature is to give rise to a reduction of the underlying gauge symmetry. Moreover, these Dirac type operators also determine a distinguished class of connections on the fermion bundle. In the next two sections we specialize the presented frame in order to geometrically describe the action of the Standard Model of Particle Physics in terms of a specific Dirac-Lagrangian. For this, we first discuss a certain "refinement" of simple type Dirac operators which we call "Dirac-Yukawa operators." In what follows, we also discuss an important consequence of the occurrence of the grading involution γ_M in the definition of simple type Dirac operators. This turns out to parallel the occurrence of this grading involution in A. Connes' noncommutative geometry (c.f., e.g., Refs. 12, 22, 23, 28, 31, 32, and 42).

A. Yukawa bundles and Dirac operators of Yukawa type

To start with, let again ξ_F be a chiral fermion bundle with respect to (G,ρ_F,D), where D is of simple type. Also let $\xi_H \subset \xi_F$ be a sub-vector bundle of rank $N_H < N_F$ on which τ_{Cl} acts trivially. We denote its dual by ξ_H^*. The structure group of ξ_H is a specific subgroup of $\rho_F(G)$. It will be denoted by $\rho_H(G)$. The gauge group of ξ_H is accordingly denoted by $\mathcal{G}_H \subset \mathcal{G}_{YM} \subset \mathrm{Aut}(\xi_H) \subset \mathrm{Aut}(\xi_F)$ (the bundle automorphisms of ξ_H over the identity on $\mathcal{M}$.)

Definition 4.1: *Let $E_H \subset \mathcal{E}$ be the total space of ξ_H, and let π_H be the appropriate projection mapping onto the base manifold $\mathcal{M}$. Also, let again $W := \mathrm{End}_{Cl}^-(\mathcal{E})$. We call the subvector bundle $\xi_Y \subset \xi_H^* \otimes_{\mathcal{M}} \xi_W$ the "Yukawa bundle" (with respect to the previous data) if its structure group acts as follows: For each $h \in \mathrm{Aut}(E_H)$ there is a unique $g \in \mathrm{Aut}_{Cl}^+(\mathcal{E})$ such that $\mathcal{Y}(h^{-1}\mathfrak{z}) = \mathrm{Ad}_{g^{-1}}(\mathcal{Y}(\mathfrak{z}))$ for all $\mathfrak{z} \in E_H$ and $\mathcal{Y} \in E_H^* \otimes W$. In this case we call ξ_H the "Higgs bundle" (again, with respect to the previous data). A section $\mathcal{Y} \in \Gamma(\xi_Y)$ of the Yukawa bundle is called a "Yukawa mapping" provided that it fulfills the following conditions: Considered as a bundle mapping the Yukawa mapping $\mathcal{Y}$ is injective and anti-Hermitian, i.e., $\mathcal{Y}(\mathfrak{z})^\dagger = -\mathcal{Y}(\mathfrak{z})$ for all $\mathfrak{z} \in E_H$. Moreover, we assume that it satisfies the requirement $\mathcal{Y}(\partial_{A,X}\varphi) = [\partial_{A,X}, \mathcal{Y}(\varphi)]$ for all Clifford connections on ξ_F (and thus for all induced connections on ξ_H), sections $\varphi \in \Gamma(\xi_H)$ and tangent vector fields $X \in \Gamma(\tau_M)$.*

Note that for each connection on ξ_F with covariant derivative $\nabla^{\mathcal{E}}$, the operator

$$[\nabla_X^{\mathcal{E}}, \mathcal{Y}(\varphi)] - \mathcal{Y}(\nabla_X^{E_H}\varphi) \tag{48}$$

on the fermion bundle ξ_F defines a connection on $\xi_H^* \otimes \xi_W$ with the covariant derivative $\nabla^{E_H^* \otimes W} \equiv \nabla^{E_H^*} \otimes 1 + 1 \otimes \nabla^W$. Hence, a Yukawa mapping is assumed to be covariantly constant with respect to any Clifford connection. By the definition of the Yukawa bundle it then follows that a Yukawa mapping (4.1) has to be a constant section. For instance, in the case of the Standard Model the Yukawa mapping (4.1) is parameterized by the "Yukawa coupling constants." The representations ρ_H and ρ_F are known to be related by the "hypercharges" of the fermions and the Higgs boson.

Definition 4.2: *We call a Dirac type operator D on a fermion bundle ξ_F a "Dirac-Yukawa operator" if there is a section of the Higgs bundle, $\varphi \in \Gamma(\xi_H)$, such that*

$$D = \not{\partial}_A + \gamma_M \otimes \mathcal{Y}(\varphi). \tag{49}$$

According to its physical interpretation we call the section $\mathcal{Y}(\varphi) \in \Gamma(\mathrm{End}_{Cl}^-(\xi_F))$ the "Yukawa coupling term" with respect to $(\mathcal{Y},\varphi) \in \Gamma(\xi_Y \times_{\mathcal{M}} \xi_H)$.

A Yukawa mapping defines an additional data on a fermion bundle which in some sense is not natural within the frame of Dirac type gauge theories. For this reason we shall refer to the data (G,ρ_F,D), with D being a Dirac-Yukawa operator, as a "Dirac-Yukawa model." A necessary condition for a Dirac-Yukawa operator to spontaneously break the underlying gauge symmetry is that $\varphi \in \Gamma(\xi_H)$ does not vanish. Again, this condition is also sufficient provided G acts transitively

on the image of the section $\mathcal{Y}(\varphi)$. Assuming this is the case it follows from the definition of the Higgs bundle and the Yukawa mapping that there must exist a constant section $\mathcal{V} \in \Gamma(\xi_H) \backslash \{\mathcal{O}\}$ (with $\mathcal{O}$ being the zero-section) such that in the unitary gauge

$$D = \partial\!\!\!/_A + \gamma_M \otimes \mathcal{Y}(\mathcal{V}). \tag{50}$$

Analogously to our previous definition we consider a Dirac-Yukawa operator to define a (semiclassical) fermionic vacuum if it is gauge equivalent to $\partial\!\!\!/_{\mathcal{V}} \equiv \partial\!\!\!/ + iM_F$ with the total fermionic mass operator $iM_F := \gamma_M \otimes \mathcal{Y}(\mathcal{V})$. Notice that the spectrum of the total fermionic mass operator is independent of the choice of $\mathfrak{Z}_0 \in \mathrm{End}(\mathbb{C}^{N_F})$. This reduces to $\mathfrak{Z}_0 = G_Y(\mathbf{z}_0)$ in the case where the gauge symmetry is spontaneously broken by a Dirac-Yukawa operator. Here, $G_Y \in \mathrm{Hom}(\mathbb{C}^{N_H}, \mathrm{End}(\mathbb{C}^{N_F}))$ is the matrix of the Yukawa coupling constants and $\mathbf{z}_0 \in \mathbb{C}^{N_H}$. In particular, we obtain $\mathrm{orbit}(\mathfrak{Z}_0) = G_Y(\mathrm{orbit}(\mathbf{z}_0))$. Hence, from the properties of the Yukawa mapping it can be inferred that the "little group" $H \subset G$ crucially depends on $\rho_H \subset \rho_F$.

B. The fermionic Lagrangian

Next, we discuss the fermionic Lagrangian within the presented frame. By definition, the grading involution of a chiral fermion bundle $\xi_F = \xi_F^+ \oplus \xi_F^-$ reads $\Gamma = \gamma_M \otimes \chi$. Consequently, the total space $\mathcal{E}$ of the fermion bundle decomposes as

$$\mathcal{E} = \mathcal{E}^+ \oplus \mathcal{E}^- = (\mathcal{E}_{LL} \oplus \mathcal{E}_{RR}) \oplus (\mathcal{E}_{RL} \oplus \mathcal{E}_{LR}), \tag{51}$$

where, respectively,

$$\begin{aligned}
\mathcal{E}_{LL} &:= \{\mathfrak{z} \in \mathcal{E} | (\gamma_M \otimes 1)\mathfrak{z} = -\mathfrak{z}, (1 \otimes \chi)\mathfrak{z} = -\mathfrak{z}\},\\
\mathcal{E}_{RR} &:= \{\mathfrak{z} \in \mathcal{E} | (\gamma_M \otimes 1)\mathfrak{z} = \mathfrak{z}, (1 \otimes \chi)\mathfrak{z} = \mathfrak{z}\},\\
\mathcal{E}_{RL} &:= \{\mathfrak{z} \in \mathcal{E} | (\gamma_M \otimes 1)\mathfrak{z} = \mathfrak{z}, (1 \otimes \chi)\mathfrak{z} = -\mathfrak{z}\},\\
\mathcal{E}_{LR} &:= \{\mathfrak{z} \in \mathcal{E} | (\gamma_M \otimes 1)\mathfrak{z} = -\mathfrak{z}, (1 \otimes \chi)\mathfrak{z} = \mathfrak{z}\}.
\end{aligned} \tag{52}$$

Let $\pi_{R/L} := \frac{1}{2}(1 \pm (\gamma_M \otimes 1))$ and $\rho_{R/L} := \frac{1}{2}(1 \pm (1 \otimes \chi))$. The appropriate projection mappings of the respective subspaces (52) of $\mathcal{E}$ are denoted by $\pi_{LL} \equiv \pi_L \circ \rho_L = \rho_L \circ \pi_L$, $\pi_{RR} \equiv \pi_R \circ \rho_R = \rho_R \circ \pi_R$, $\pi_{RL} \equiv \pi_R \circ \rho_L = \rho_L \circ \pi_R$ and $\pi_{LR} \equiv \pi_L \circ \rho_R = \rho_R \circ \pi_L$. Consequently, $\pi_+ = \pi_{RR} + \pi_{LL}$ and $\pi_- = \pi_{RL} + \pi_{LR}$. For $\phi \in \Gamma(\mathrm{End}_{Cl}(\xi_F))$ we also define $1 \otimes \phi_{LL} := \rho_L \circ (1 \otimes \phi) \circ \rho_L \in \Gamma(\mathrm{End}_{Cl}(\xi_{F,LL} \oplus \xi_{F,RL})) \simeq \Gamma(\mathrm{End}_{Cl}(\xi_{F,LL})) \oplus \Gamma(\mathrm{End}_{Cl}(\xi_{F,RL}))$, $1 \otimes \phi_{RL} := \rho_R \circ (1 \otimes \phi) \circ \rho_L \in \Gamma(\mathrm{Hom}_{Cl}(\xi_{F,LL} \oplus \xi_{F,RL}, \xi_{F,LR} \oplus \xi_{F,RR})) \simeq \Gamma(\mathrm{Hom}_{Cl}(\xi_{F,LL}, \xi_{F,LR})) \oplus \Gamma(\mathrm{Hom}_{Cl}(\xi_{F,RL}, \xi_{F,RR}))$, etc.

If $\mathcal{M}$ denotes a spin manifold, then $\mathcal{E} \simeq S \otimes E_F$, where S is the total space of the spinor bundle τ_{spin} (with respect to some chosen spin structure) and E_F is the total space of some Hermitian vector bundle ζ_F. In this case, the fermion bundle $\xi_F \simeq \tau_{spin} \otimes \zeta_F$ is chiral if and only if ζ_F is $\mathbb{Z}_2$−graded, i.e., $E_F = E_{F,R} \oplus E_{F,L}$. Here, $E_{F,R/L}$ are considered as the eigenspaces of χ with respect to the eigenvalues ± 1. Then, for instance, $\mathcal{E}_{LL} \simeq S_L \otimes E_{F,L}$, etc. Consequently, like in noncommutative geometry, the fermionic degrees of freedoms are doubled in the geometrical description presented here (c.f. again the corresponding discussion in Refs. 31 and 32). Indeed, as far as the Standard Model is concerned only

$$\mathcal{E}_{phy} \equiv \mathcal{E}^+ = (\mathcal{E}_{LL} \oplus \mathcal{E}_{RR}) \tag{53}$$

represents the "true" physical degrees of freedom.

With this in mind the "fermionic Lagrangian" of D may be defined as the following specific quadratic form on $\Gamma(\xi_F)$ (taking its value in the top forms of $\mathcal{M}$):

$$\mathcal{L}_F : \mathcal{D}(\xi_F) \to \Gamma(\xi_F \otimes_{\mathcal{M}} \Lambda^n \tau_M^*)$$

$$D \mapsto \begin{cases} \Gamma(\xi_{\mathrm{F}}) & \to & \Omega^{\mathrm{n}}(\mathcal{M}) \\ \psi & \mapsto & <\psi, D_+\psi>_{\mathcal{E}}\mu_{\mathrm{M}}. \end{cases} \tag{54}$$

Here, $<\cdot,\cdot>_{\mathcal{E}}$ is the Hermitian product on $\mathcal{E}$ and $D_\pm \equiv \pi_{\mp}\circ D\circ \pi_\pm : \Gamma(\xi_{\mathrm{F}}^{\pm}) \to \Gamma(\xi_{\mathrm{F}}^{\mp})$ such that $D \in \mathcal{D}(\xi_{\mathrm{F}})$ reads

$$D = \begin{pmatrix} 0 & D_- \\ D_+ & 0 \end{pmatrix} : \begin{matrix} \Gamma(\xi_{\mathrm{F}}^{+}) \\ \oplus \\ \Gamma(\xi_{\mathrm{F}}^{-}) \end{matrix} \to \begin{matrix} \Gamma(\xi_{\mathrm{F}}^{+}) \\ \oplus \\ \Gamma(\xi_{\mathrm{F}}^{-}) \end{matrix}. \tag{55}$$

It is common use to also refer to the operators $D_\pm$ themselves as Dirac type operators although the square of these operators is usually not defined. (Equivalently, if, for instance, the operator $D_+ : \Gamma(\xi_{\mathrm{F}}^{+}) \to \Gamma(\xi_{\mathrm{F}}^{-})$ is identified by the operator $\begin{pmatrix} 0 & 0 \\ D_+ & 0 \end{pmatrix} : \Gamma(\xi_{\mathrm{F}}) \to \Gamma(\xi_{\mathrm{F}})$ it follows that $D_+^2 \equiv 0$. Hence, it is not a Dirac type operator in the sense presented here. However, every (anti-) symmetric Dirac type operator D is fully determined by D_+.) The Hermitian product on $\mathcal{E}$ depends on the signature of D. For instance, in the respective cases of Lorentzian and Euclidean signature the following is obtained for all $\mathfrak{z}, \mathfrak{z}' \in \mathcal{E}$:

$$<\mathfrak{z}, \mathfrak{z}'>_{\mathcal{E}} := \begin{cases} \overline{\mathfrak{z}}_-\mathfrak{z}'_+ + \overline{\mathfrak{z}}_+\mathfrak{z}'_- & \text{(Lorentzian sign.)} \\ \overline{\mathfrak{z}}_+\mathfrak{z}'_+ + \overline{\mathfrak{z}}_-\mathfrak{z}'_- & \text{(Euclidean sign.)}, \end{cases}$$

where $\overline{\mathfrak{z}}$ means either the Dirac or Hermitian conjugate of the "spinor degrees" of freedom of $\mathfrak{z}$. More precisely, let $\pi : \mathrm{F}\mathcal{E} \to \mathcal{M}$ be the frame bundle of ξ_{F}, such that $\mathcal{E} \ni \mathfrak{z} \simeq [(p, \mathbf{z} = \Sigma_{i=1}^{2^{\mathrm{k}}} \mathbf{s}_i \otimes \mathbf{z}_i)] \in \mathrm{F}\mathcal{E} \times_{\mathrm{spin(n)} \times \rho_{\mathrm{F}}(\mathrm{G})} \mathbb{C}^{2^{\mathrm{k}}} \otimes \mathbb{C}^{\mathrm{N_F}}$. Then, the notation $\overline{\mathfrak{z}_1}\mathfrak{z}_2$ means: $\overline{\mathfrak{z}_1}\mathfrak{z}_2 \equiv \overline{\mathbf{z}_1}\mathbf{z}_2 := \Sigma_{i=1}^{2^{\mathrm{k}}} (\overline{\mathbf{s}_{1,i}}\, \mathbf{s}_{2,i})(\mathbf{z}_{1,i}^{\dagger}\, \mathbf{z}_{2,i})$. By the definition of the fermion bundle, this value is clearly independent of the choice of $p \in \mathrm{F}\mathcal{E}$ and thus independent of the representative $\mathbf{z}$ of $\mathfrak{z}$. Hence, in the cases considered, the fermionic Lagrangian (54) reads

$$\mathcal{L}_{\mathrm{F}}(D)(\psi) := \begin{cases} (\overline{\psi_+} D_+ \psi_+)\mu_{\mathrm{M}} & \text{(Lorentzian sign.)} \\ (\overline{\psi_-} D_+ \psi_+)\mu_{\mathrm{M}} & \text{(Euclidean sign.)}. \end{cases}$$

The D_+ part of simple type Dirac operators has the form

$$D_+ = \begin{pmatrix} \partial\!\!\!/_A & \Phi_{\mathrm{LR}} \\ -\Phi_{\mathrm{RL}} & \partial\!\!\!/_A \end{pmatrix} \equiv \partial\!\!\!/_A + \gamma_{\mathrm{M}} \otimes \phi_+ \tag{56}$$

where, respectively, $\Phi_{\mathrm{LR}} := \gamma_{\mathrm{M}} \otimes \widetilde{\phi}_{\mathrm{LR}} \in \Gamma(\mathrm{Hom}(\xi_{\mathrm{F,RR}}, \xi_{\mathrm{F,RL}}))$ and $\Phi_{\mathrm{RL}} := -\gamma_{\mathrm{M}} \otimes \widetilde{\phi}_{\mathrm{RL}} \in \Gamma(\mathrm{Hom}(\xi_{\mathrm{F,LL}}, \xi_{\mathrm{F,LR}}))$. The mapping $\widetilde{\phi}_{\mathrm{LR}}$ equals ϕ_{LR} restricted to $\Gamma(\mathrm{Hom}_{\mathrm{Cl}}(\xi_{\mathrm{F,LL}}, \xi_{\mathrm{F,LR}}))$ and $\widetilde{\phi}_{\mathrm{RL}}$ equals $-\phi_{\mathrm{RL}}$, restricted to the sub-space $\Gamma(\mathrm{Hom}_{\mathrm{Cl}}(\xi_{\mathrm{F,RR}}, \xi_{\mathrm{F,RL}}))$. As (56) formally looks like a simple type Dirac operator, we also refer to it as a Dirac operator of simple type. For Lorentzian or Euclidean signature the corresponding fermionic Lagrangian reads:

$$\mathcal{L}_{\mathrm{F}}(\partial\!\!\!/_A + \gamma_{\mathrm{M}} \otimes \phi)(\psi) = \begin{cases} (\overline{\psi_+}(\partial\!\!\!/_A + \gamma_{\mathrm{M}} \otimes \phi_+)\psi_+)\mu_{\mathrm{M}} & \text{(Lorentzian sign.)} \\ (\overline{\psi_-}(\partial\!\!\!/_A + \gamma_{\mathrm{M}} \otimes \phi_+)\psi_+)\mu_{\mathrm{M}} & \text{(Euclideansign.)} \end{cases}$$

$$= \begin{cases} (\overline{\psi_{\mathrm{LL}}}\partial\!\!\!/_A\psi_{\mathrm{LL}} + \overline{\psi_{\mathrm{RR}}}\partial\!\!\!/_A\psi_{\mathrm{RR}})\mu_{\mathrm{M}} + \\ (\overline{\psi_{\mathrm{LL}}}(1 \otimes \widetilde{\phi}_{\mathrm{LR}})\psi_{\mathrm{RR}} + \overline{\psi_{\mathrm{RR}}}(1 \otimes \widetilde{\phi}_{\mathrm{RL}})\psi_{\mathrm{LL}})\mu_{\mathrm{M}}, \\ (\overline{\psi_{\mathrm{RL}}}\partial\!\!\!/_A\psi_{\mathrm{LL}} + \overline{\psi_{\mathrm{LR}}}\partial\!\!\!/_A\psi_{\mathrm{RR}})\mu_{\mathrm{M}} + \\ (\overline{\psi_{\mathrm{RL}}}(1 \otimes \widetilde{\phi}_{\mathrm{LR}})\psi_{\mathrm{RR}} + \overline{\psi_{\mathrm{LR}}}(1 \otimes \widetilde{\phi}_{\mathrm{RL}})\psi_{\mathrm{LL}})\mu_{\mathrm{M}}. \end{cases}$$

Note that D is formally self-adjoint if and only if $D_-=D_+^\dagger$. Also note that $\phi^\dagger=-\phi$ if and only if $\phi_+^\dagger=-\phi_+$, which in turn is equivalent to $(1\otimes\tilde{\phi}_{\mathrm{RL}})=(1\otimes\tilde{\phi}_{\mathrm{LR}})^\dagger$. Here, all mappings are considered to be defined on the total space $\Gamma(\xi_{\mathrm{F}})$. In case of D being (anti-) Hermitian we may set, respectively, $(1\otimes\tilde{\phi}):=(1\otimes\tilde{\phi}_{\mathrm{LR}})$ and $\tilde{\Phi}\equiv\gamma_{\mathrm{M}}\otimes\tilde{\phi}$.

Finally, for a Dirac-Yukawa operator one obtains

$$D_+=\begin{pmatrix} \partial\!\!\!/_A & \mathcal{G}_{\mathrm{Y}}(\varphi) \\ -\mathcal{G}_{\mathrm{Y}}(\varphi)^\dagger & \partial\!\!\!/_A \end{pmatrix} \equiv \partial\!\!\!/_A+\gamma_{\mathrm{M}}\otimes\tilde{\mathcal{Y}}(\varphi), \tag{57}$$

with a smooth mapping

$$\mathcal{G}_{\mathrm{Y}}:\Gamma(\xi_{\mathrm{H}})\to\Gamma(\mathrm{Hom}(\xi_{\mathrm{F,RR}},\xi_{\mathrm{F,RL}}))$$

$$\varphi\mapsto\gamma_{\mathrm{M}}\otimes\tilde{\phi}:=\mathcal{G}_{\mathrm{Y}}(\varphi) \tag{58}$$

that is induced by an appropriate Yukawa mapping (4.1) and where $\varphi\in\Gamma(\xi_{\mathrm{H}})$ is a section of the Higgs bundle. We may therefore formally refer to the operator (57) also as a Dirac-Yukawa operator.

As an example, we consider the fermionic Lagrangian of a Dirac-Yukawa type operator of Lorentzian signature which spontaneously breaks the gauge symmetry. In the case of $\mathrm{N}_{\mathrm{F,L}}:=2,\mathrm{N}_{\mathrm{F,R}}:=1$ the fermionic Lagrangian (54) reads

$$\mathcal{L}_{\mathrm{F}}(iD)(\psi)=<\nu_{\mathrm{L}},i\partial\!\!\!/\nu_{\mathrm{L}}>_{\mathcal{E}_\nu}\mu_{\mathrm{M}}+<e,(i\partial\!\!\!/-m)e>_{\mathcal{E}_e}\mu_{\mathrm{M}}, \tag{59}$$

with the physical notation $\psi_{\mathrm{LL}}\equiv(\nu_{\mathrm{L}},e_{\mathrm{L}})$ and $\psi_{\mathrm{RR}}\equiv e_{\mathrm{R}}$ for the "state" of the left-handed and right-handed leptons, respectively. Here, $\nu_{\mathrm{L}}\equiv\nu_{\mathrm{LL}}\oplus\nu_{\mathrm{RL}}$ and $e\equiv e_{\mathrm{L}}\oplus e_{\mathrm{R}}$ are considered as eigensections of the total fermionic mass matrix which correspond to the eigenvalues zero and $m\in\mathbb{R}_+^\times$. Physically, one may interpret the corresponding (isomorphism class of) eigenbundles ξ_{F}^ν and ξ_{F}^e (with $\xi_{\mathrm{F}}\simeq\xi_{\mathrm{F}}^\nu\oplus\xi_{\mathrm{F}}^e$) as "asymptotically free particles."

Remark: *To "lowest order" (c.f. our discussion in the next section) the energy-momentum current* $\mathcal{L}_{\mathrm{tot}}^*\vartheta_{\mathrm{M}}\in\Gamma(\mathrm{End}(\tau_{\mathrm{M}}))$ *of the "total Lagrangian"*

$$\mathcal{L}_{\mathrm{tot}}(i\partial\!\!\!/-\mathrm{M}_{\mathrm{F}})(\psi)\equiv\mathcal{L}_{\mathrm{F}}(i\partial\!\!\!/-\mathrm{M}_{\mathrm{F}})(\psi)+\mathcal{L}_{\mathrm{D}}(i\partial\!\!\!/-\mathrm{M}_{\mathrm{F}}) \tag{60}$$

reads

$$\mathcal{L}_{\mathrm{tot}}^*\vartheta_{\mathrm{M}}\sim_{\epsilon\to0}\lambda_{\mathrm{gr}}\mathrm{tr}\,\mathrm{M}_{\mathrm{F}}^2\mathrm{id}_{\mathrm{TM}}+\mathcal{O}(\epsilon). \tag{61}$$

This holds true for every gauge theory that is based on a Dirac-Yukawa type operator.

In this section we introduced the Higgs bundle as a specific Hermitian subvector bundle of a chiral fermion bundle and discussed a specific subclass of simple type Dirac operators, called Dirac-Yukawa operators. We also introduced the fermionic Lagrangian within our geometrical setup. In particular, in the case of the Lorentzian signature the definition of the fermionic Lagrangian simply looks like the restriction to the physical subbundle ξ_{phy} of the fermion bundle. However, this is not the case. In order to obtain the "correct" fermionic couplings one also needs $\xi_{\mathrm{F}}^-\subset\xi_{\mathrm{F}}$. Indeed this doubling of the fermionic degrees of freedom is necessary in order to consider a Dirac type operator as an endomorphism on the vector space of sections of a fermion bundle. It is only in this case that one can make use of the general Lichnerowicz decomposition of (the square of) a Dirac type operator which in turn permits to consider the universal Lagrangian (21) as a canonical mapping between the affine set of all Dirac type operators on a fermion bundle and the top forms of the underlying base manifold $\mathcal{M}$.

In the next section we will consider a natural generalization of Dirac-Yukawa type operators which encodes the dynamics of the sections of the Higgs bundle ξ_{H} and the "Yang-Mills bundle"

ξ_{YM}. It also yields the appropriate mass matrices in such a way that spontaneous symmetry breaking induced by a minimum of the Higgs potential is in accordance with spontaneous symmetry breaking induced by the Yukawa coupling and gravity.

V. THE LAGRANGIAN OF THE STANDARD MODEL AS THE "SQUARE" OF PAULI-DIRAC-YUKAWA TYPE OPERATORS

From our discussion of the preceding section it follows that the total Lagrangian of a simple type Dirac operator to lowest order only yields the "free field" equations of the eigensections of the fermionic mass matrix. (This is because the energy momentum current is at least homogeneous of degree two with respect to the appropriate sections.) Moreover, space-time should be an Einstein manifold that is physically determined by the (sum of the) fermionic masses. As a consequence, one has to appropriately generalize simple type Dirac operators in order to obtain nontrivial Euler-Lagrange equations also for the Yang-Mills gauge fields and the sections of the Higgs bundle. Of course, such a generalization of a simple type Dirac operator on a fermion bundle must be done in such a way that it is consistent with spontaneous symmetry breaking induced by the Yukawa coupling and gravity. For this we first introduce a new class of Dirac type operators which we call "Dirac operators of Pauli type" (PD). These operators act on sections of a specific subbundle of the doubled fermion bundle, where the latter is defined by the data of a simple type Dirac operator that underlies the corresponding PD. Doubling the fermion bundle has the physical meaning of simultaneously dealing with "particles and antiparticles." The above mentioned subbundle turns out to be equivalent to the fermion bundle one starts with, and the corresponding fermionic Lagrangian reduces to the one which is defined only by the underlying Dirac operator of simple type. To make this precise, we have to consider real fermion bundles.

A. Real fermion bundles and operators of Pauli type

Let $\zeta_{2\mathrm{F}}$ be a real vector bundle of rank 2N and total space $\mathcal{W}_{2\mathrm{F}}$. Also let $\mathcal{I}_{2\mathrm{F}} \in \mathrm{End}_{\mathbb{R}}(\zeta_{2\mathrm{F}})$ be a complex structure. We denote by ξ_{F} the complex vector bundle of rank N which is defined by the $\mathbb{C}$–action: $z\mathfrak{z} := x\mathfrak{z} + y\mathcal{I}_{2\mathrm{F}}(\mathfrak{z})$, for all $z \equiv x + iy \in \mathbb{C}$ and $\mathfrak{z} \in \mathcal{W}_{2\mathrm{F}}$. The corresponding total space is denoted again by $\mathcal{E}$. Also, let $\xi_{2\mathrm{F}} := \mathbb{C} \otimes \zeta_{2\mathrm{F}}$ with total space $\mathcal{E}_{2\mathrm{F}} := \mathbb{C} \otimes \mathcal{W}_{2\mathrm{F}}$. The complex vector bundle $\xi_{2\mathrm{F}}$ of rank 2N is naturally $\mathbb{Z}_2$–graded as

$$\xi_{2\mathrm{F}} \simeq \xi_{\mathrm{F}} \oplus \overline{\xi_{\mathrm{F}}}. \tag{62}$$

Here, $\overline{\xi_{\mathrm{F}}}$ is the conjugate complex vector bundle of ξ_{F}. The elements of its total space $\overline{\mathcal{E}}$ are denoted by $\overline{\mathfrak{z}}$. They may be identified either with elements $\mathfrak{z} \in \mathcal{W}_{2\mathrm{F}}$, such that $z\mathfrak{z} := x\mathfrak{z} - y\mathcal{I}_{2\mathrm{F}}(\mathfrak{z})$, or considered as antilinear functionals on $\mathcal{E}^*$ (dual of $\mathcal{E}$). Of course, the subspaces of decomposition (62) are but the eigenspaces of $\mathcal{I}_{2\mathrm{F}}$ (considered as a complex linear mapping) with respect to the eigenvalues $\pm i$.

The canonical real structure on $\xi_{2\mathrm{F}}$ is denoted by $\mathcal{J}_{2\mathrm{F}}$. It is given by $\mathcal{J}_{2\mathrm{F}}(\mathfrak{z}_1, \overline{\mathfrak{z}_2}) := (\mathfrak{z}_2, \overline{\mathfrak{z}_1})$. The corresponding real sub-space

$$\{(\mathfrak{z}, \overline{\mathfrak{z}}) \in \mathcal{E}_{2\mathrm{F}} | \mathfrak{z} \in \mathcal{E}\} \simeq \mathcal{W}_{2\mathrm{F}} \tag{63}$$

can be identified with $\mathcal{E}$ via the canonical complex structure: $i(\mathfrak{z}, \overline{\mathfrak{z}}) := (i\mathfrak{z}, -i\overline{\mathfrak{z}})$. Note that, likewise, $\mathcal{E}_{2\mathrm{F}}$ may be viewed as the complex space $\mathcal{W}_{4\mathrm{F}} \equiv \mathcal{W}_{2\mathrm{F}} \oplus \mathcal{W}_{2\mathrm{F}}$ with the complex structure given by the action $\mathcal{I}_{4\mathrm{F}}(\mathfrak{w}_1, \mathfrak{w}_2) := (-\mathfrak{w}_2, \mathfrak{w}_1)$. Clearly, this complex structure in turn can be identified with $\mathcal{I}_{2\mathrm{F}}$ under the identification of $\mathcal{W}_{2\mathrm{F}}$ with $\mathcal{E}$.

In what follows, it is assumed that the complex vector bundle ξ_{F} is a fermion bundle with respect to $(\mathrm{G}, \rho_{\mathrm{F}}, D)$. Both the signature $s \in \mathbb{Z}$ of D and the dimension $n = 2k \in \mathbb{N}$ of the orientable base manifold $\mathcal{M}$ are again arbitrary, although we are mainly interested in the physically distinguished case of $(n, s) = (4, \mp 2)$. Likewise, the complex vector bundle $\overline{\xi_{\mathrm{F}}}$ is treated as the conjugate complex ("charge conjugate") fermion bundle with respect to $(\mathrm{G}, \overline{\rho}_{\mathrm{F}}, \overline{D})$. Here, $\overline{\rho}_{\mathrm{F}}$ is the conjugate representation of G, and the (charge conjugate) Dirac type operator $\overline{D}$ is defined by $\overline{D}\overline{\psi} := \overline{D\psi}$ for

all $\overline{\psi} \in \Gamma(\overline{\xi_F})$. If $<\cdot,\cdot>_{\mathcal{E}}$ denotes again the Hermitian product (the Hermitian product on $\mathcal{E}$ is assumed to be antilinear in the first, and linear in the second argument; also, the "bar" notation, as for instance $\bar{\mathfrak{z}}$, should not be confounded with the Dirac conjugation in the case of the Lorentz signature) on $\mathcal{E}$, one has $<\bar{\mathfrak{z}}_1,\bar{\mathfrak{z}}_2>_{\bar{\mathcal{E}}} := <\mathfrak{z}_2,\mathfrak{z}_1>_{\mathcal{E}}$. Hence, the sum $<\psi,D\psi>_{\mathcal{E}} + <\overline{\psi},\bar{D}\overline{\psi}>_{\bar{\mathcal{E}}}$ vanishes if D is anti-symmetric.

Although they are anti-isomorphic to each other, there is no natural way to identify the fermion bundle ξ_F with its charge conjugate $\overline{\xi_F}$. In order to do so we still have to give additional input. For this let $\mathcal{J}$ be a real structure on ξ_F such that

$$\mathcal{C}:\mathcal{E} \to \bar{\mathcal{E}}$$

$$\mathfrak{z} \mapsto \bar{\mathcal{J}}(\mathfrak{z}) \tag{64}$$

defines a linear bundle isomorphism over the identity on $\mathcal{M}$, usually referred to as "charge conjugation" (see, for instance, in Ref. 7 in the context of Clifford algebras and in Ref. 13 in the context of noncommutative geometry). Notice that $\mathcal{C}^{-1}(\bar{\mathfrak{z}}) = \mathcal{J}(\mathfrak{z})$. As a result, the charge conjugate Dirac operator may be written as

$$\bar{D} = \mathcal{C}_J \circ D \circ \mathcal{C}_J^{-1}, \tag{65}$$

where $\mathcal{C}_J(\mathfrak{z}) := \mathcal{C}(\mathcal{J}(\mathfrak{z})) = \bar{\mathfrak{z}}$.

The existence of $\mathcal{J}$ depends on the topology of ξ_F. Indeed, it can be shown that a complex vector bundle possesses a real structure if and only if all of its odd Chern classes vanish (see, for instance, Ref. 24).

Definition 5.1 *Let ξ_F be a real fermion bundle over $\mathcal{M}$ with respect to the Dirac triple (G,ρ_F,D). Also, let $F_D \in \Omega^2(\mathcal{M},\mathrm{End}^+_{Cl}(\mathcal{E}))$ be the twisting curvature of ∂_D. We call the associated first order differential operator*

$$D_P := \begin{pmatrix} D + i\gamma(F_D) & 0 \\ 0 & \mathcal{C}_J^{-1} \circ (\overline{D - i\gamma(F_D)}) \circ \mathcal{C}_J \end{pmatrix} : \begin{matrix} \Gamma(\xi_F) & \Gamma(\xi_F) \\ \oplus & \to \quad \oplus \\ \Gamma(\xi_F) & \Gamma(\xi_F) \end{matrix} \tag{66}$$

a Dirac operator of "*Pauli type*" (*or* "*Pauli-Dirac operator*") *with respect to the grading involution Γ_{2F} that is defined by the action $\Gamma_{2F}(\mathfrak{z}_1,\mathfrak{z}_2) := (\Gamma(\mathfrak{z}_2),\Gamma(\mathfrak{z}_1))$ and the real structure $\mathcal{J}$.*

Equivalently, one may also express a Pauli-Dirac operator with respect to the diagonal representation of the grading involution Γ_{2F} (i.e., where $\Gamma_{2F} = \mathrm{diag}(\Gamma,-\Gamma)$), in which case

$$D_P = \begin{pmatrix} D & -\gamma(F_D) \\ \gamma(F_D) & D \end{pmatrix} \equiv D + \mathcal{I} \otimes \gamma(F_D). \tag{67}$$

The bundle mapping $\mathcal{I} \in \mathrm{End}_C(\mathcal{E} \oplus \mathcal{E})$, which is defined by $\mathcal{I}(\mathfrak{z}_1,\mathfrak{z}_2) := (-\mathfrak{z}_2,\mathfrak{z}_1)$, corresponds to the complex structure $\mathcal{I}_{4F}$ with help of the identification of $\mathcal{W}_{2F} \subset \mathcal{E} \oplus \bar{\mathcal{E}}$ with $\mathcal{E}$.

If $D \equiv \not{\partial}_A$, then the zero order term $D_P - \not{\partial}_A$ formally looks like the well-known "Pauli-term" $i\gamma(F_A)$ which has been introduced by physicists in order to correctly describe the anomalous magnetic moment of the proton. However, the first order operator $\not{\partial}_A + i\gamma(F_A)$ is not a Dirac type operator in our sense for the Pauli term is an even operator. To remedy this flaw we again have to "double the fermionic degrees of freedom," in this case, however, by adding the corresponding "antifermions." As a consequence, for diagonal sections, which one may physically interpret as representing the state of a "particle-antiparticle" (with the help of the identification $\overline{\xi_F} \simeq \xi_F$), $\Psi \equiv (\psi,\psi) \in \Gamma(\xi_F) \oplus \Gamma(\xi_F) = \Gamma(\xi_F \oplus \xi_F) \simeq \Gamma(\xi_{2F})$, we obtain the identity

$$<\Psi, D_{\mathrm{P}}\Psi>_{\mathcal{E}_{2\mathrm{F}}} = 2<\psi, D\psi>_{\mathcal{E}}. \tag{68}$$

Hence, the Pauli term does not contribute to the fermionic Lagrangian as far as "particle-anti-particle states" are simultaneously taken into account. This is certainly desirable, for it is well-known that the coupling of the fermions to the curvature actually spoils the theory of their renormalizability. Hence, to lift the first order differential operator $\not{\partial}_A + i\gamma(F_{\mathrm{A}})$ to a true Dirac type operator restores a basic feature of (perturbative) quantum field theory. Again, by formal similarity we also refer to the operator $\not{\partial}_A + i\gamma(F_{\mathrm{A}})$ itself as a Dirac operator of Pauli type, analogous to operator (57) is formally referred to as Dirac operator of Yukawa type.

Let ξ_{F} be the real chiral fermion bundle with respect to $(\mathrm{G}, \rho_{\mathrm{F}}, D)$, with D being of simply type.

Proposition 5.1: The top form of D_{P} decomposes into the sum

$$\mathcal{L}_{\mathrm{D}}(D_{\mathrm{P}}) = \mathcal{L}_{EH} \pm \mathcal{L}_{YM} \pm \mathcal{L}_{H} \tag{69}$$

where, respectively, $\mathcal{L}_{EH}$ is the Einstein-Hilbert Lagrangian, $\mathcal{L}_{YM}$ the Yang-Mills Lagrangian and $\mathcal{L}_{H}$ the "Higgs" Lagrangian of the Standard Model of Particle Physics.

Proof: The proof is basically a copy of the proof of the corresponding statement that has been presented already in Ref. 45 in the case of $s=n$ (c.f. Theorem 1). We note that the top form $\mathcal{L}_{\mathrm{D}}(D') \in \Omega^{\mathrm{n}}(\mathcal{M})$ is independent of the connection representing $D' \in \mathcal{D}(\xi_{\mathrm{F}})$. Hence, one may choose any representative of the connection class that corresponds to D_{P} to define the Pauli term $i\gamma(F_A)$. The relative signs of (69) depend on the signature of D and of the definition of the Clifford multiplication. In particular, the relative sign in front of the kinetic term $\langle \partial_A^W \phi, \partial_A^W \phi \rangle$ of the Higgs Lagrangian depends on whether (the complexified) $\tau_{\mathrm{Cl}}^{(+)}$ or $\tau_{\mathrm{Cl}}^{(-)}$ is considered to act on ξ_{F}. Finally, we stress that decomposition (69) is actually independent of the existence of a real structure on ξ_{F}. In particular, it does not depend on the choice of $\mathcal{J}$. □

The top form (69) clearly reduces to the combined Einstein-Hilbert-Yang-Mills Lagrangian in the case where ξ_{F} is not chiral. However, if D denotes a Dirac-Yukawa type operator, then the total Lagrangian

$$\mathcal{L}_{\mathrm{tot}}(D_{\mathrm{P}})(\Psi) \equiv \mathcal{L}_{\mathrm{F}}(D_{\mathrm{P}})(\Psi) + \mathcal{L}_{\mathrm{D}}(D_{\mathrm{P}}) = \mathcal{L}_{\mathrm{F}}(D)(\psi) + \mathcal{L}_{\mathrm{D}}(D_{\mathrm{P}}) \tag{70}$$

equals the total Lagrangian of the Standard Model, including Einstein's theory of gravity. Here, we used the homogeneity property of the fermionic density: $\mathcal{L}_{\mathrm{F}}(D_{\mathrm{P}})(\lambda\Psi) = \lambda^2 \mathcal{L}_{\mathrm{F}}(D_{\mathrm{P}})(\Psi)$ and put $\Psi \equiv (\psi, \psi)/\sqrt{2}$. Note that the corresponding Euler-Lagrange equations form a dynamically closed system. For this reason, we refer to D_{P} also as a Dirac operator of "Pauli-Yukawa" type (or "Pauli-Dirac-Yukawa" operator, PDY) if operator (66) is defined in terms of a Dirac-Yukawa type operator (49). Therefore,

$$(\xi_{\mathrm{F}}, D_{\mathrm{P}}) \tag{71}$$

may be regarded as a "square root" of (the Lagrangian of) the Standard Model. (Of course, the data $(\xi_{\mathrm{F}}, D_{\mathrm{P}})$ covers the geometrical properties of the Standard Model only up to the semiclassical approximation of the latter. It also seems worth noting that because decomposition (69) is independent of the existence of the reality of the fermion bundle, it is possible to also take into account magnetic monopoles within the Standard Model as topologically nontrivial ground states of the Higgs boson. Moreover, it is well-known that the weak interaction actually spoils the symmetry under charge conjugation).

B. "Fluctuation" of a fermionic vacuum and the YM-mass matrix

Before we proceed let us come back to the notion of a "(semiclassical) fermionic vacuum" and how this is related to the reality of a fermion bundle. Essentially, a chiral fermion bundle $\xi_{\mathrm{F}} = \xi_{\mathrm{F}}^{+} \oplus \xi_{\mathrm{F}}^{-}$ is related to a Dirac triple $(\mathrm{G}, \rho_{\mathrm{F}}, D)$, with D being of simple type. The existence of a fermionic vacuum crucially depends on the existence of a non-vanishing section $\phi \in \Gamma(\mathrm{End}_{\mathrm{Cl}}^{-}(\xi_{\mathrm{F}}))$ and a purely topological Clifford connection $A \in \mathcal{A}_{\mathrm{Cl}}(\xi_{\mathrm{F}})$. This in fact reduces the

previous Dirac triple to $(\mathrm{H},\rho_{\mathrm{F,red}},\not{\partial})$ and ξ_{F} may be regarded, accordingly, as a perturbation of the corresponding $\xi_{\mathrm{F,red}}$. Clearly, such a reduction causes severe topological restrictions on a fermion bundle. Of course, this holds true also for the existence of a Dirac-Yukawa type operator. For example, in the case of the electroweak interaction, a fermionic vacuum exists if and only if the corresponding Yang-Mills gauge bundle of the electroweak interaction is trivial. This in turn holds true if and only if the (charged) electroweak vector bosons are charge conjugate to each other (c.f. Ref. 48). In the (algebraic) torsion free case this is equivalent to the existence of a flat Yang-Mills connection. This example may motivate the following

Definition 5.2: A fermion bundle ξ_{F} is called "perturbative" provided there is a Dirac type operator $D\in\mathcal{D}(\xi_{\mathrm{F}})$ such that $\mathcal{F}_D=\not{R}$.

A fermionic vacuum is thus geometrically described by a perturbative massive fermion bundle. Next, we introduce a specific subvector bundle of $\xi_{\mathrm{F}}^{*}\otimes_{\mathcal{M}}\xi_{\mathrm{F}}$ and discuss the "bosonic mass matrix" within the presented fermionic frame.

Definition 5.3: Let again ξ_{F} be a massive fermion bundle with respect to a Dirac-Yukawa model $(\mathrm{G},\rho_{\mathrm{F}},D)$. The real sub-bundle

$$\xi_{\mathrm{YM}}:=\tau_{\mathrm{M}}^{*}\otimes_{\mathcal{M}}\mathrm{End}_{\mathrm{Cl}}^{+}(\xi_{\mathrm{F}})\subset\mathrm{End}(\xi_{\mathrm{F}}) \tag{72}$$

is called the Yang-Mills bundle with respect to the appropriate fermionic vacuum $\xi_{\mathrm{F,red}}$.

With respect to a fermionic vacuum the (real form of the) Higgs bundle decomposes into the Whitney sum of two real vector bundles

$$\xi_{\mathrm{H}}\simeq\xi_{\mathrm{G}}\oplus\xi_{\mathrm{H,phys}} \tag{73}$$

with $\xi_{\mathrm{G}}\subset\xi_{\mathrm{H}}\subset\xi_{\mathrm{F}}$ being the "Goldstone bundle" and $\xi_{\mathrm{H,phys}}\subset\xi_{\mathrm{F}}$ being the "physical Higgs bundle" (c.f. Lemma 3.1 in Ref. 46 for Yang-Mills-Higgs gauge theories). Therefore, any Dirac-Yukawa type operator on a massive fermion bundle ξ_{F} is parametrized by $(A,\varphi_{\mathrm{H}})\in\Gamma(\xi_{\mathrm{YM}}\times_{\mathcal{M}}\xi_{\mathrm{H,phys}})$. In particular, for $t\in[0,1]$ one may consider the one-parameter family $(A_t,\varphi_t)\in\mathcal{A}(\xi_{\mathrm{H}})\times\Gamma(\xi_{\mathrm{H}})$ which is defined by $\partial_{A,t}:=\partial+tA$, $\varphi_t:=\mathcal{V}+t\varphi_{\mathrm{H}}$. Hence, the "Yang-Mills-Higgs pair" $(A,\varphi_{\mathrm{H}})\in\Gamma(\xi_{\mathrm{YM}}\times_{\mathcal{M}}\xi_{\mathrm{H,phys}})$ may be physically regarded as a "fluctuation" of the corresponding fermionic vacuum $\xi_{\mathrm{F,red}}$.

Like in the Yang-Mills-Higgs gauge theories, a fluctuation (A,φ_{H}) of a fermionic vacuum yields a self-adjoint section $\mathrm{M}_{\mathrm{H}}\in\Gamma(\mathrm{End}(\xi_{\mathrm{H}}))\subset\Gamma(\mathrm{End}_{\mathrm{Cl}}(\xi_{\mathrm{F}}))$ such that the rank of the Goldstone bundle equals the dimension of the kernel of the "Higgs mass operator" M_{H}. Moreover, $\xi_{\mathrm{H,phys}}$ decompose into the Whitney sum of eigenbundles of the Higgs mass matrix. Likewise, since in general $A\in\Gamma(\xi_{\mathrm{YM}})$ gives rise to a connection on ξ_{F} that is not compatible with the fermionic vacuum (i.e., the corresponding covariant derivative does not commute with the total fermionic mass operator), a fluctuation of the fermionic vacuum also yields a nontrivial Yang-Mills mass operator $\mathrm{M}_{\mathrm{YM}}\in\Gamma(\mathrm{End}(\xi_{\mathrm{YM}}))$ (see Ref. 46). As a consequence, the Yang-Mills bundle decomposes into the eigenbundles of M_{YM} for again $\mathrm{spec}(\mathrm{M}_{\mathrm{YM}})$ is constant throughout $\mathcal{M}$. In particular, one obtains the decomposition (see, again, Ref. 46)

$$\xi_{\mathrm{YM}}\simeq\tau_{\mathrm{M}}^{*}\otimes_{\mathcal{M}}(\mathfrak{ad}(\mathcal{Q})\oplus\xi_{\mathrm{G}}) \tag{74}$$

with $\mathfrak{ad}(\mathcal{Q})\equiv\mathrm{Lie}(\mathcal{H}_{\mathrm{YM}})$ being the "adjoint bundle" of the reduced frame bundle $\mathcal{Q}\overset{\iota}{\hookrightarrow}\mathcal{P}$ associated with the fermionic vacuum $\xi_{\mathrm{F,red}}$. As $\mathrm{rk}(\mathrm{M}_{\mathrm{YM}})=\mathrm{rk}(\xi_{\mathrm{G}})$ the equivalence (74) is a geometrical variant of the famous "Higgs-Dinner." It follows that $A\in\Gamma(\xi_{\mathrm{YM}})$ decomposes into $A=A_{\mathrm{YM}}+A_{\mathrm{G}}$. Hence, the deviation from A being compatible with the fermionic vacuum can be expressed by

$$\partial_A^{\mathrm{End}(\mathcal{E})}\mathrm{M}_{\mathrm{F}}=\mathrm{ad}(A_{\mathrm{G}})\mathrm{M}_{\mathrm{F}}. \tag{75}$$

As already mentioned, the nonvanishing of the right-hand side (i.e., of $A_{\mathrm{G}}\in\tau_{\mathrm{M}}^{*}\otimes_{\mathcal{M}}\xi_{\mathrm{G}}$) yields a nontrivial Yang-Mills mass operator M_{YM}. In fact, one has

$$\mathrm{M}_{\mathrm{YM}}(A) = \mathrm{ad}(\mathrm{M}_{\mathrm{F}})(A) \tag{76}$$

with $\|\mathrm{M}_{\mathrm{YM}}(A)\|^2 = \mathrm{M}^2_{\mathrm{YM}}(A,A)$ and the symmetric bilinear form

$$\mathrm{M}^2_{\mathrm{YM}}: \Gamma(\xi_{\mathrm{YM}} \times_{\mathcal{M}} \xi_{\mathrm{YM}}) \to \mathcal{C}^\infty(\mathcal{M})$$

$$(A, A') \mapsto \tfrac{1}{2}\mathrm{M}^2_{\mathrm{YM}}(T_a, T_b) g_{\mathrm{M}}(A^a, A'^b). \tag{77}$$

Here, respectively, $\overset{\mathrm{loc}}{A} = A^a \otimes T_a, \overset{\mathrm{loc}}{A'} = A'^a \otimes T_a$ and

$$\mathrm{M}^2_{\mathrm{YM}}(T_a, T_b)|_x := 2\|\mathcal{G}_{\mathrm{Y}}\|^2 < \mathcal{V}(x), [T_a, T_b]_+ \mathcal{V}(x) >_{\mathcal{E}} \tag{78}$$

is the (squared) "Yang-Mills mass matrix," with $[\cdot,\cdot]_+$ being the anticommutator. Note that we used $\xi_{\mathrm{H}} \subset \xi_{\mathrm{F}}$, such that a vacuum section $\mathcal{V}$ can also be regarded as a section of the fermion bundle. We also extensively used the properties of the Yukawa mapping (4.1). In particular, we made use of the fact that $\mathrm{ad}(\mathcal{D})A = \mathcal{Y}(A\mathcal{V})$ where, by abuse of notation, A refers to two different representations. Also note that the eigenvalues of (78) are actually independent of $x \in \mathcal{M}$. Of course, the rank of (78) equals the rank of the Goldstone bundle $\xi_{\mathrm{G}} \subset \xi_{\mathrm{F}}$. Accordingly, one may rewrite (75) as

$$\|\partial_A^{\mathrm{End}(\mathcal{E})} \mathrm{M}_{\mathrm{F}}\|^2 = 2^n \mathrm{M}^2_{\mathrm{YM}}(A, A). \tag{79}$$

That is, the fermionic mass matrix is covariantly constant with respect to a Clifford connection on a massive fermion bundle iff this Clifford connection is in the kernel of the Yang-Mills mass matrix. The latter, of course, is in one-to-one correspondence with the residual gauge fields.

Let $D \in \mathcal{D}(\xi_{\mathrm{F}})$ be a Dirac operator of simple type such that $D - \not{b}_A \neq 0$ and $\mathcal{G}_{\mathrm{YM}}$ acts transitively on the image of $D - \not{b}_A$. Then, there is a nonvanishing smooth function $\chi \in \mathcal{C}^\infty(\mathcal{M})$ such that $D = \not{b}_A + i\chi \mathrm{M}_{\mathrm{F}}$. Let $\xi_{\mathrm{F,red}} \simeq \xi_{\mathrm{F}}$ be a fermionic vacuum with respect to $(\mathrm{H}, \rho_{\mathrm{F,red}}, \not{b}_{\mathcal{D}})$. Then, D defines a fluctuation of $\xi_{\mathrm{F,red}}$ iff

$$D = \not{b}_A + \chi(\not{b}_{\mathcal{D}} - \not{b}). \tag{80}$$

Note that this condition is in full accordance with the usual definition of the Higgs boson as being in the unitary gauge. Here, however, this condition is expressed purely in terms of fermions.

Proposition 5.2: Let $\xi_{\mathrm{F,red}} \simeq \xi_{\mathrm{F}}$ be a fermionic vacuum with respect to a Dirac-Yukawa model $(\mathrm{H}, \rho_{\mathrm{F,red}}, \not{b}_{\mathcal{V}})$. Also, let $(A, \varphi_{\mathrm{H}}) \in \Gamma(\xi_{\mathrm{YM}} \times_{\mathcal{M}} \xi_{\mathrm{H,phys}})$ be a fluctuation of the fermionic vacuum. Then, the total curvature on ξ_{F} of the connection determined by the Dirac-Yukawa operator

$$D = \not{b}_A + \gamma_{\mathrm{M}} \otimes \not{\phi} = \not{b} + \gamma_{\mathrm{M}} \otimes \mathcal{Y}(\mathcal{V}) + \gamma(A) + \gamma_{\mathrm{M}} \otimes \mathcal{Y}(\varphi_{\mathrm{H}}) \equiv \not{b}_{\mathcal{D}} + \gamma(A_{\mathrm{fl}}) \tag{81}$$

reads

$$\mathcal{F}_D = \mathbb{R} + F_A + F_{\mathrm{H}} + F_{\mathrm{mass}} = \mathbb{R} + F_{\mathrm{YM}} + F_{\mathrm{G}} + F_{\mathrm{H}} + F_{\mathrm{mass}}. \tag{82}$$

Here, respectively,

$$F_{\mathrm{YM}} := \partial A_{\mathrm{YM}} + A_{\mathrm{YM}} \wedge A_{\mathrm{YM}},$$

$$F_{\mathrm{G}} := \partial A_{\mathrm{G}} + A_{\mathrm{G}} \wedge A_{\mathrm{G}},$$

$$F_{\mathrm{H}} := \partial A_{\mathrm{H}} + A_{\mathrm{H}} \wedge A_{\mathrm{H}} \tag{83}$$

are the Yang-Mills curvature with respect to the reduced Yang-Mills gauge group $\mathcal{H}_{\mathrm{YM}} \subset \mathcal{G}_{\mathrm{YM}} \subset \mathcal{G}_{\mathrm{F}}$, the curvature on ξ_{F} of the (massive) vector boson that corresponds to the Goldstone boson and the curvature induced by the (physical part of the) Higgs boson according to the decomposition

$$A_{\mathrm{fl}} = A + A_{\mathrm{H}} = A_{\mathrm{YM}} + A_{\mathrm{G}} + A_{\mathrm{H}}, \tag{84}$$

with $A_{\mathrm{H}} := \mathrm{ext}_{\Theta}(\gamma_{\mathrm{M}} \otimes \mathcal{Y}(\varphi_{\mathrm{H}}))$.

Finally, the "mass-curvature" $F_{\mathrm{mass}} \in \Omega^2(\mathcal{M}, \mathrm{End}(\mathcal{E}))$ *is given by*

$$F_{\mathrm{mass}} := (1 - 2\|\varphi_{\mathrm{H}}\|)\mathrm{M}_{\mathrm{F}}^2\Theta \wedge \Theta + (1 + \|\varphi_{\mathrm{H}}\|)\mathrm{M}_{\mathrm{YM}}(A_{\mathrm{G}}) \wedge \Theta = \mathrm{ext}_{\Theta}[(1 - 2\|\varphi_{\mathrm{H}}\|)\mu_{\mathrm{F}} + (1 + \|\varphi_{\mathrm{H}}\|)\mu_{\mathrm{YM}}]. \tag{85}$$

We call, respectively, $\mu_{\mathrm{F}} := \mathrm{ext}_{\Theta}(\mathrm{M}_{\mathrm{F}}^2) \in \Omega^1(\mathcal{M}, \mathrm{End}(\mathcal{E}))$ *and* $\mu_{\mathrm{YM}} := \mathrm{M}_{\mathrm{YM}}(A_{\mathrm{G}}) \equiv \gamma_{\mathrm{M}} \otimes \mathrm{M}_{\mathrm{YM}}(A) \in \Omega^1(\mathcal{M}, \mathrm{End}(\mathcal{E}))$ *the "fermionic mass form" and the "Yang-Mills mass form."*

Proof: First, note that the Yang-Mills mass form μ_{YM} contributes to the total curvature even if $F_{\mathrm{A}} = \varphi_{\mathrm{H}} = 0$ is supposed to hold true. Hence, it also gives rise to a fluctuation of g_{M}. In contrast to what one may infer from F_{mass}, however, the contribution of the bosonic mass is of "higher order" in comparison to the curvature that is induced by the fermionic mass. In other words, $F_{\mathrm{mass}} = \mathrm{ext}_{\Theta}(\mu_{\mathrm{F}}) + \mathcal{O}(t)$ in accordance with (42). We stress that (82) indeed reduces to (42) if $\varphi_{\mathrm{H}} = 0$. Hence, it gives a physical interpretation, in particular, of the last term of the decomposition (42) of the curvature of a simple type Dirac operator which spontaneously breaks the gauge symmetry. One may express this also in more physical terms by saying that it is the interaction of the gauge field with the fermionic vacuum that yields massive vector bosons.

To prove decomposition (82) one uses decomposition (73) and the Higgs-Dinner (74), as well as $[\mathrm{M}_{\mathrm{F}}^2, \Theta] = [\mathrm{M}_{\mathrm{YM}}, \Theta] = 0$. Moreover, due to our previous remark concerning fluctuations one may take into account that $\varphi_{\mathrm{H}} = \|\varphi_{\mathrm{H}}\| \mathcal{V}$ (where $\|\mathcal{V}\| = 1$ is assumed without loss of generality). Note also that both the (lifted) soldering form Θ and the Yukawa-mapping $\mathcal{Y}$ are covariantly constant with respect to any Clifford connection. Finally, taking also into account that ∂ acts on A_{fl} like the usual exterior derivative, the proof actually becomes a straightforward calculation. □

We emphasize that spontaneous symmetry breaking induced by a fermionic vacuum is compatible with spontaneous symmetry breaking induced by the Higgs potential arising from a fluctuation of the fermionic vacuum (i.e., $\not{\partial}_{\mathcal{D}} \mapsto D_{\mathrm{P}}$). Clearly, G acts transitively on $\mathrm{im}(\phi) \subset \mathrm{Orbit}(\mathfrak{Z}_0) \simeq \mathrm{P} \times_{\mathrm{G}} \mathrm{G}/\mathrm{H}$ for any chosen minimum $\mathfrak{Z}_0 \in \mathrm{End}(\mathbb{C}^{\mathrm{N_H}})$ of the Higgs potential induced by D_{P}. Therefore, the condition $\phi \in \Gamma(\mathrm{End}(\xi_{\mathrm{H}})) \backslash \{\mathcal{O}\}$ is necessary and sufficient for the unitary gauge to exist. In particular, if ξ_{F} is defined with respect to a Dirac-Yukawa model, then for each $\varphi \in \Gamma(\xi_{\mathrm{H}}) \backslash \{\mathcal{O}\}$ there exists a "vacuum section" $\mathcal{V}_{\varphi} \in \Gamma(\mathcal{O}rbit(\mathbf{z}_0)) \subset \Gamma(\xi_{\mathrm{H}})$ such that $\varphi \in \Gamma(\xi_{\mathrm{H,phys}})$. This holds true for any rotationally symmetric Higgs potential (like the Higgs potential generated by a Pauli-Dirac type operator). By the very definition of the Yukawa mapping the structure group G then acts transitively also on $\mathrm{im}(\mathcal{Y}(\varphi)/\|\mathcal{Y}(\varphi)\|) \subset \mathcal{S} \subset \mathrm{End}_{\mathrm{Cl}}(\xi_{\mathrm{F}})$.

VI. OUTLOOK

We discussed a certain class of gauge theories with the basic property of having a square root in the sense of the data of Dirac type operators. These Dirac type gauge theories have in common that they are derived by a universal Lagrangian which is shown to be equivariant with respect to bundle automorphisms. Moreover, these gauge theories naturally include Einstein's theory of gravity, and the fermionic gauge group of the universal (Dirac-) Lagrangian contains both Yang-Mills and Einstein-Hilbert type symmetry groups. In particular, the action of the diffeomorphism group of the base manifold is naturally represented by pull-back. We also considered a distinguished class of Dirac type operators whose associated top form gives rise to spontaneous symmetry breaking without using Higgs-like potentials. Indeed, the latter naturally arises when a fluctuation of the fermionic vacuum is taken into account. The geometrical meaning of the induced bosonic mass operators can be shown to consist of defining the extrinsic curvature of the "physical space-time" $\mathcal{M}_{\mathrm{phys}}$. The intrinsic curvature of the latter, however, was shown to be defined by the fermionic vacuum. In the case where the fermionic vacuum is defined with respect to a Dirac-Yukawa model, the appropriate Higgs and Yang-Mills bundle can be naturally regarded as specific sub-vector bundles of ξ_{F}, respectively, of $\xi_{\mathrm{F}}^* \otimes_{\mathcal{M}} \xi_{\mathrm{F}}$. For this we discussed the Yukawa couplings from a geometrical point of view in terms of specific sections of the Yukawa bundle, which is

shown to yield the connection between the fermion and the Higgs bundle. To consider the Yukawa bundle ξ_Y as a specific sub-vector bundle of $\xi_H^* \otimes_{\mathcal{M}} \xi_F^* \otimes_{\mathcal{M}} \xi_F$ permits a geometrical understanding of the well-known "hypercharge relations" between the physical Higgs boson $\xi_{H,phy}$ and the asymptotically free fermions $\xi_{F,m^2} \subset \xi_F$ in the case of the minimal Standard Model. In this sense, the presented frame makes it possible to treat the geometrical properties of spontaneously broken Yang-Mills-Higgs gauge theories in terms of fermions, as discussed in Ref. 46. In particular, it is shown that this kind of gauge theories can be expressed in the geometrical setup needed to describe fermions without use of spin structures. Note that the latter actually has no obvious physical meaning. Indeed, all experiments carried out to date demonstrating the physical significance of the twofold cover of SO(3) are local. The assumption of orientability, however, is necessary to derive the Einstein equation from a globally defined density which seems to also have some significance in our understanding of mass.

The "fermion doubling" within the presented geometrical setup is shown to be tied to the Lichnerowicz decomposition of a Dirac type operator. As the latter gives rise to the universal Lagrangian and, moreover, to a specific class of Dirac type operators which yield spontaneous symmetry breaking, the projection onto the physical sub-space $\xi_{phy} \subset \xi_F$ clearly indicates a nontrivial relation between the fermionic Lagrangian $\mathcal{L}_F$ and the Dirac Lagrangian $\mathcal{L}_D$.

As the Dirac Lagrangian is a canonical element within the presented geometrical frame, it will be useful to discuss it also in terms of the geometry of variational bicomplexes. This may offer a more profound mathematical understanding of operators of Pauli-Dirac type as has been introduced here as a "fluctuation of a fermionic vacuum." These kinds of Dirac type operators obviously play a fundamental role in the Standard Model of Particle Physics. In a forthcoming article we shall thus discuss the Dirac triple of the Standard Model in more detail. In particular, we shall show how this triple permits specification of $\mathrm{spec}(M_H)$. In the case of the "minimal" Standard Model $\mathrm{rk}(\xi_{H,phys})=1$ which allows a prediction of the mass of the Higgs boson. For this, however, one still has to carefully take into account possible "coupling constants" within the frame of Dirac type gauge theories. In general, one may modify the total Lagrangian $\mathcal{L}_{tot}$ as

$$\mathcal{L}_{tot}(D)(\psi) \rightsquigarrow \mathcal{L}_{phys}(D)(\psi) := \mathcal{L}_F(D)(\psi) + \lambda \mathcal{L}_D(D), \tag{86}$$

with the Dirac-Lagrangian being refined by

$$\mathcal{L}_D(D) := * \,\mathrm{tr}(\zeta[D^2 - \triangle_D]). \tag{87}$$

Here, respectively, $\lambda \in \mathbb{R}$ is a "relative weight" between the fermionic and bosonic Lagrangian and ζ is the most general element of the commutant with respect to the fermionic representation ρ_F of the structure group G. More precisely, $\zeta \in \Gamma(\mathrm{End}^+_{Cl}(\xi_F))$ is a positive Hermitian operator satisfying: $[D,\zeta]=0=[\zeta,g]$, for all $g \in \mathcal{G}_{YM}$. It therefore may be considered as generalizing the Yang-Mills coupling constant of a "pure" Yang-Mills gauge theory. Actually, the constant λ may be fixed by an appropriate normalization of the Einstein-Hilbert Lagrangian.

Due to formula (78) the Yang-Mills mass matrix is proportional to the (squared) norm of the Yukawa-coupling constants $\mathcal{G}_Y$. However, the "physical" Yang-Mills mass matrix is known to be proportional to the Yang-Mills coupling constants $g_{YM}>0$ which parameterize the most general Killing form on Lie(G). Hence, we have to re-scale A_G by a positive constant g_G for each simple factor of G, i.e., $A^a_G \rightsquigarrow A^a_G / g^{(a)}_G$ (no summation involved), such that

$$g^{(a)}_{YM} = g^{(a)}_G g_Y \tag{88}$$

with the abbreviation $g_Y \equiv \|\mathcal{G}_Y\|$.

Finally, one also has to take into account that in general $\|\mathcal{V}\| \neq 1$, and that the various differential forms defining the Dirac type operator in question have different dimensions. Besides the "Planck scale" (which comes in because of the generic Einstein-Hilbert part of the total Lagrangian) this will bring in an additional length scale within Dirac type gauge theories. However, in the case of the Lagrangian of a PDY this additional length scale turns out to be proportional to the (inverse of the) Higgs mass. Hence, in the case of the Standard Model the two length scales

decouple within GTDT, and gravity effects can be neglected as it is commonly expected. For this to be consistent, however, we stress again the necessity of the compatibility of the two different symmetry reductions obtained by the fermionic vacua (i.e., simple type Dirac operators) and the ground states of the Higgs boson (i.e., Pauli type Dirac operators).

ACKNOWLEDGMENTS

The authors would like to thank E. Binz for very interesting and stimulating discussions on the presented subject. Also, one of the authors (J.T.) would like to thank K. Marathe for his interests and valuable comments.

APPENDIX

Because of its relevance within Dirac type gauge theories we present here in some detail the proof of Proposition 3.1. In particular, it is shown that it holds true for arbitrary signature of D. In Ref. 1 a similar proof was presented for the special case of elliptic Dirac type operators.

1. Tensor decomposition

In this subsection we collect some useful formulas which will be needed to prove the explicit form of the Dirac forms $\varpi_{\rm D} \in \Omega^1(\mathcal{M}, {\rm End}(\mathcal{E}))$ of simple type Dirac operators. Though interesting in its own we will not prove these formulae here (since the proof would be technical but straightforward).

To get started let $\omega \in \Gamma(\tau^*_{\rm M} \otimes_{\mathcal{M}} \Lambda^{\rm n-1} \tau^*_{\rm M} \otimes_{\mathcal{M}} {\rm End}(\xi_{\rm F}))$. Throughout this Appendix, let $(X_1, \ldots, X_n)$ be a locally defined orthonormal frame on $\mathcal{M}$ and $(X^1, \ldots, X^n)$ its dual frame. Then, locally one has

$$\begin{aligned} \omega(X_{i_1}, \ldots, X_{i_n}) &=: \omega_{i_1 \cdots i_n} \equiv \omega_{i_1[i_2 \cdots i_n]}, \\ \gamma(\omega) &=: \not{\omega} \equiv \gamma^{j_1} \ldots \gamma^{j_n} \circ \omega_{i_1 \cdots i_n}. \end{aligned} \tag{A1}$$

Here, the square brackets $[\cdots]$ indicate skew-symmetrization with the convention: $n!\,\omega_{[i_1 \cdots i_n]} = \Sigma_{\sigma \in S_n} \mathrm{sgn}\,\sigma \omega_{\sigma(\mathrm{i}_1) \cdots \sigma(\mathrm{i}_n)}$ and, again, $\gamma^k \equiv \gamma(X^k)$. In what follows, we restrict ourselves to the Clifford relation $\alpha\beta + \beta\alpha = +2g_{\rm M}(\alpha, \beta)$ for all $\alpha, \beta \in T^*M \hookrightarrow Cl(M)$ (the total space of $\tau^{(+)}_{\rm Cl}$).

First, we have the following decomposition (the "$\underset{j}{\uparrow}$" means that i_1 is at the jth position)

$$\omega_{i_1 \cdots i_n} = \omega_{[i_1 \cdots i_n]} + \frac{1}{n} \sum_{j=2}^{n} \left(\omega_{i_1 \cdots i_n} + \omega_{\substack{ij \;\; i_2 \;\; \cdots \;\; i_1 \;\; \cdots \;\; i_n \\ \uparrow \\ j}} \right). \tag{A2}$$

As a consequence, it follows that $\gamma(\omega)$ may locally be written as

$$\begin{aligned} \gamma^{j_1} \gamma^{j_3} \cdots \gamma^{j_n} \circ \omega_{i_1 \mu i_3 \cdots i_n} = &- \frac{n}{n-1} \gamma^{j_1} \gamma^{j_3} \cdots \gamma^{j_n} \circ \omega_{[\mu i_1 i_3 \cdots i_n]} + \frac{1}{n-1} \gamma^{j_1} \gamma^{j_3} \cdots \gamma^{j_n} \circ \omega_{\mu i_1 i_3 \cdots i_n} \\ &- (n-2) g^{\alpha\beta} \gamma^{j_4} \cdots \gamma^{j_n} \circ \omega_{\alpha\beta\mu i_4 \cdots i_n} \end{aligned} \tag{A3}$$

where, again, $g^{ij} \equiv g_{\rm M}(X^i, X^j)$.

Using these two formulas one finally proves the following local decomposition which turns out to be particularly useful in what follows:

$$\gamma(\omega) \overset{loc.}{=} \gamma^{j_1} \cdots \gamma^{j_n} \circ \omega_{[i_1 \cdots i_n]} + (n-1) g^{\alpha\beta} \gamma^{j_3} \cdots \gamma^{j_n} \circ \omega_{\alpha\beta i_3 \cdots i_n}. \tag{A4}$$

2. Proof of Proposition 3.1

Let $\xi=(\mathcal{E},\mathcal{M},\pi_\epsilon)$ be an arbitrary $\mathbb{Z}_2$−graded Clifford module bundle over any smooth (semi-) Riemannian manifold $(\mathcal{M},g_{\mathrm{M}})$ with $\dim\mathcal{M}=n$ and n even. Every Dirac type operator D may be globally decomposed as $D=\not{\partial}_A+\not{\omega}$, with A being a Clifford connection and $\omega\in\Omega^1(\mathcal{M},\mathrm{End}^+(\mathcal{E}))$ being given by $\omega:=\Theta\wedge(D-\not{\partial}_A)$. Notice again that ω may also depend on the choice of A unless D is of simple type. Locally, ω reads

$$\overset{loc.}{\omega}=X^i\otimes\omega_i^a\otimes\mathfrak{e}_a\equiv X^i\otimes\left(\sum_{k=0}^{n}\gamma^{j_1}\cdots\gamma^{j_k}\omega^a_{ij_1\cdots j_k}\right)\otimes\mathfrak{e}_a, \tag{A5}$$

with $\omega^a_{ij_1\cdots j_k}=\omega^a_{i[j_1\cdots j_k]}$ and $(\mathfrak{e}_1,\ldots,\mathfrak{e}_N)$ being a local frame in $\mathrm{End}_{\mathrm{Cl}}(\xi)$ such that ω is odd with respect to the total grading.

By definition, D is of simple type if the Clifford connection A also defines the Bochner-Laplacian of D. Using the general Bochner-Lichnerowicz-Weizenböck decomposition of D^2 it can be shown that, independently of the signature of g_{M}, this holds true if and only if (in the case $s=n$ this has been proved in Ref. 1; the more general case of arbitrary signature has been proved in Ref. 44)

$$2g^{ij}\omega^a_j+\gamma^i[\omega^a_j,\gamma^j]=0. \tag{A6}$$

As this relation is linear with respect to the frame $(\mathfrak{e}_1,\ldots,\mathfrak{e}_N)$ we may suppress the index a in what follows.

Lemma 7.1: Let $\omega\in\Gamma(\overset{*}{\tau}_{\mathrm{M}}\otimes_{\mathcal{M}}\tau^{(+)}_{\mathrm{Cl}})$ *be a Clifford algebra valued one-form where the coefficients* ω_ν *fulfill the relation* (A6). *Then, the most general form of* ω_ν *reads*

$$\omega_\nu=\sum_{k=0}^{n}\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{\nu[j_1\cdots j_k]} \tag{A7}$$

where the coefficients satisfy the relations:

$$\omega^{(n)}_{[\nu i_1\cdots i_n]}=0,$$

$$\omega^{(n-1)}_{[\nu i_1\cdots i_{n-1}]}=\varepsilon_{\nu i_1\cdots i_{n-1}}f,$$

$$kg^{\alpha\beta}\omega^{(k)}_{\alpha\beta i_1\cdots i_{k-1}}+\omega^{(k-2)}_{[i_1\cdots i_{k-1}]}=0,\quad k=n-1,\ldots,2,$$

$$g^{\alpha\beta}\omega^{(1)}_{\alpha\beta}=0. \tag{A8}$$

Here, respectively, $\omega^{(k)}_{\nu i_1\cdots i_k}\equiv\omega^{(k)}_{\nu[i_1\cdots i_k]}:=\omega^{(k)}_\nu(X_{i_1},\ldots,X_{i_k})$ *are the local coefficients of appropriate k-forms* $\omega^{(k)}_\nu\in\Omega^1(U)$ $(U\subset\mathcal{M}$ *open,* $\nu=1,\ldots,n)$, $f\in\mathcal{C}^\infty(U)$ *and* $\epsilon_{i_1\ldots i_n}\equiv\mu_{\mathrm{M}}(X_{i_1},\ldots,X_{i_n})$ *the Levi-Civita symbol.*

Proof: To get started we rewrite condition (A6) as $\gamma^\mu\gamma^\nu\omega_\nu+\gamma^\nu\omega_\nu\gamma^\mu=0$ and then appropriately rearrange both terms on the left-hand side.

$$\gamma^\nu\omega_\nu\gamma^\mu=\sum_{k=0}^{n}(-1)^k(\gamma^\nu\gamma^\nu\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{\nu i_1\cdots i_k}-2kg^{\mu i_1}\gamma^\nu\gamma^{j_2}\cdots\gamma^{j_k}\omega^{(k)}_{\nu i_1 i_2\cdots i_k}). \tag{A9}$$

Using this re-arrangement and formula (A3) one obtains

$$0=\sum_{k=0}^{n}((1-(-1)^k)(\gamma^\mu\gamma^\nu\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{[\nu i_1\cdots i_k]}+k\gamma^\mu\gamma^{j_2}\cdots\gamma^{j_k}g^{\alpha\beta}\omega^{(k)}_{\alpha\beta i_2\cdots i_k})+(-1)^k2(k+1)g^{\mu\nu}\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{[\nu i_1\cdots i_k]}+(-1)^k2k(k-1)g^{\mu\nu}\gamma^{j_3}\cdots\gamma^{j_k}g^{\alpha\beta}\omega^{(k)}_{\alpha\beta\nu i_3\cdots i_k}). \tag{A10}$$

This sum may be further split into two sums of an even and odd number of Clifford elements. Since these terms are linearly independent one may evaluate each sum separately. For example, the sum of an odd number of Clifford elements gives rise to the condition:

$$0=\sum_{\substack{k=1\\(\text{k odd})}}^{n}(\gamma^\mu\gamma^\nu\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{[\nu i_1\cdots i_k]}+k\gamma^\mu\gamma^{j_2}\cdots\gamma^{j_k}g^{\alpha\beta}\omega^{(k)}_{\alpha\beta i_2\cdots i_k}-(k+1)g^{\mu\nu}\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{[\nu i_2\cdots i_k]}-k(k-1)g^{\mu\nu}\gamma^{j_3}\cdots\gamma^{j_k}g^{\alpha\beta}\omega^{(k)}_{\alpha\beta\nu i_3\cdots i_k}). \tag{A11}$$

As (the caret denotes the omission of the "hated" object)

$$\gamma^\mu\gamma^\nu\gamma^{j_1}\cdots\gamma^{j_{n-1}}\omega^{(n-1)}_{[\nu i_1\cdots i_{n-1}]}=ng^{\mu\nu}\gamma^{j_1}\cdots\hat{\gamma^{j_\mu}}\cdots\gamma^{j_n}\omega^{(n-1)}_{[\nu i_1\cdots\hat{i_\mu}\cdots i_n]}, \tag{A12}$$

condition (A11) becomes equivalent to

$$0=\gamma^\mu\gamma^{j_2}\cdots\gamma^{j_{n-1}}((n-1)g^{\alpha\beta}\omega^{(n-1)}_{\alpha\beta i_2\cdots i_{n-1}}+\omega^{(n-3)}_{[i_2\cdots i_{n-1}]})+\sum_{\substack{k=3\\(\text{k odd})}}^{n-3}(-(k+1)g^{\mu\nu}\gamma^{j_1}\cdots\gamma^{j_k}((k+2)g^{\alpha\beta}\omega^{(k+2)}_{\alpha\beta\nu i_1\cdots i_k}+\omega^{(k)}_{[\nu i_1\cdots i_k]})+\gamma^\mu\gamma^{j_2}\cdots\gamma^{j_k}(kg^{\alpha\beta}\omega^{(k)}_{\alpha\beta i_2\cdots i_k}+\omega^{(k-2)}_{[i_2\cdots i_k]}))+\gamma^\mu g^{\alpha\beta}\omega^{(1)}_{\alpha\beta}. \tag{A13}$$

The term with the highest degree in the γ^{j_j} vanishes. By an induction argument one ends up with the recursion relation:

$$kg^{\alpha\beta}\omega^{(k)}_{\alpha\beta i_2\cdots i_k}+\omega^{(k-2)}_{[i_2\cdots i_k]}=0,\quad k=3,\ldots,n-1. \tag{A14}$$

As a consequence, it follows that $g^{\alpha\beta}\omega^{(1)}_{\alpha\beta}=0$. Moreover, the term $\omega^{(n-1)}_{[\nu i_1\ldots i_{n-1}]}$ drops out and thus is undetermined. Its most general form is given by

$$\omega^{(n-1)}_{[\nu i_1\ldots i_{n-1}]}=\varepsilon_{\nu i_1\ldots i_{n-1}}f, \tag{A15}$$

with f being an arbitrary locally defined smooth function on $\mathcal{M}$.

Next, we consider the sum of an even number of Clifford elements. This yields the relation

$$\sum_{\substack{k=0\\(\text{k even})}}^{n}((k+1)g^{\mu\nu}\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{[\nu i_1\cdots i_k]}+k(k-1)g^{\mu\nu}\gamma^{j_3}\cdots\gamma^{j_k}g^{\alpha\beta}\omega^{(k)}_{\alpha\beta\nu i_3\cdots i_k})=0, \tag{A16}$$

which in turn gives rise to the following constraint equations:

$$0=(n+1)g^{\mu\nu}\gamma^{j_1}\cdots\gamma^{j_n}\omega^{(n-1)}_{[\nu i_1\cdots i_n]},$$

$$0=(n-1)g^{\mu\nu}\gamma^{j_1}\cdots\gamma^{j_{n-2}}(ng^{\alpha\beta}\omega^{(n)}_{\alpha\beta\nu i_1\cdots i_{n-2}}+\omega^{(n-2)}_{[\nu i_1\cdots i_{n-2}]}),$$

$$\vdots$$

$$0=(k+1)g^{\mu\nu}\gamma^{j_1}\cdots\gamma^{j_k}((k+2)g^{\alpha\beta}\omega^{(k+2)}_{\alpha\beta\nu i_1\cdots i_k}+\omega^{(k)}_{[\nu i_1\cdots i_k]}),$$

$$\vdots$$

$$0 = g^{\mu\nu}\gamma^j\gamma^j(2g^{\alpha\beta}\omega^{(2)}_{\alpha\beta\nu} + \omega^{(0)}_{\nu}). \tag{A17}$$

These are satisfied provided that

$$0 = \omega^{(n)}_{[\nu i_1\cdots i_n]}$$

$$0 = (k+2)g^{\alpha\beta}\omega^{(k+2)}_{\alpha\beta\nu i_1\cdots i_k} + \omega^{(k)}_{[\nu i_1\cdots i_k]}, \quad k = 0, \ldots, n \tag{A18}$$

which, when combined with our previous result with respect to the sum of an odd number of Clifford elements, finally proves the statement. □

Corollary 7.1: Let ξ_F *be the chiral fermion bundle with respect to the Dirac triple* (G, ρ_F, D), *with D being of simple type and of arbitrary signature. The Dirac form of D reads* $\varpi_D = \Theta \wedge (\gamma_M \otimes \phi)$, *with* $\phi \in \Gamma(\mathrm{End}^-_{Cl}(\xi_F))$ *uniquely determined by D.*

Proof: Again, in the sequel we shall suppose that the induced Clifford relations, defining τ_{Cl}, are given by $\alpha\beta + \beta\alpha = +2g_M(\alpha, \beta)$. Locally, we may write $\varpi_D(X_\mu) = \omega^a_\mu \otimes \mathfrak{e}_a$ and, again, decompose the coefficients into the sum of odd and even terms with respect to the canonical involution $\alpha \mapsto -\alpha$ for all $\alpha \in T^*M \hookrightarrow Cl(M)$:

$$\omega^a_\mu = \sum_{k=1}^{n} \gamma^{j_1}\cdots\gamma^{j_k}\omega^a_{\mu[i_1\cdots i_k]} = \sum_{\substack{k=1 \\ (\text{k odd})}}^{n-1} \gamma^{j_1}\cdots\gamma^{j_k}\omega^a_{\mu[i_1\cdots i_k]} + \sum_{\substack{k=0 \\ (\text{k even})}}^{n} \gamma^{j_1}\cdots\gamma^{j_k}\omega^a_{\mu[i_1\cdots i_k]} \equiv \alpha^a_\mu + \beta^a_\mu. \tag{A19}$$

We then compute $\gamma^\mu\omega^a_\mu \equiv \gamma^\mu\alpha^a_\mu + \gamma^\mu\beta^a_\mu$ to show that $\gamma^\mu\omega^a_\mu \otimes \mathfrak{e}_a = \gamma_M \otimes \phi$.

With the help of formula (A4) one obtains (for notational convenience the index a is again suppressed)

$$\gamma^\mu\alpha_\mu = \gamma^\mu\gamma^{j_1}\cdots\gamma^{j_{n-1}}\omega^{(n-1)}_{[\mu i_1\cdots i_{n-1}]} + 2g^{ij}\omega^{(1)}_{ij} + \sum_{\substack{k=1 \\ (\text{k odd})}}^{n-3} ((k+2)\gamma^{j_2}\cdots\gamma^{j_{k+2}}g^{ij}\omega^{(k+2)}_{ij[i_2\cdots i_{k+2}]}$$
$$+ \gamma^\mu\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{[\mu i_1\cdots i_k]}). \tag{A20}$$

Hence, using Lemma 7.1, one concludes that

$$\gamma^\mu\alpha_\mu = \gamma^\mu\gamma^{j_1}\cdots\gamma^{j_{n-1}}\omega^{(n-1)}_{[\mu i_1\cdots i_{n-1}]}. \tag{A21}$$

Next, we consider $\gamma^\mu\beta_\mu$ and find, using similar arguments like those given earlier, that

$$\gamma^\mu\beta_\mu = \gamma^\mu\gamma^{j_1}\cdots\gamma^{j_n}\omega^{(n)}_{[\mu i_1\cdots i_n]} + \sum_{\substack{k=0 \\ (\text{k even})}}^{n-2} ((k+2)\gamma^{j_2}\cdots\gamma^{j_{k+2}}g^{ij}\omega^{(k+2)}_{ij[i_2\cdots i_{k+2}]} + \gamma^\mu\gamma^{j_1}\cdots\gamma^{j_k}\omega^{(k)}_{[\mu i_1\cdots i_k]}) = 0. \tag{A22}$$

Finally, using Lemma 7.1 again, we end up with

$$\gamma^\mu\omega_\mu = \gamma^\mu\gamma^{j_1}\cdots\gamma^{j_{n-1}}\omega^{(n-1)}_{[\mu i_1\cdots i_{n-1}]} = f\gamma^1\cdots\gamma^n = \tilde{f}\gamma_M. \tag{A23}$$

If we set $\phi \equiv \tilde{f}^\alpha\mathfrak{e}_a$, where $(\mathfrak{e}_1, \ldots, \mathfrak{e}_{N^-})$ is a local frame in $\mathrm{End}^-_{Cl}(\xi_F)$, we obtain the desired result and thus have also proved Proposition 3.1 in the case of τ_M. Of course, for $\tau^{(-)}_{Cl}$ the proof is similar. □

q stars in scalar-tensor gravitational theories in extra dimensions

Athanasios Prikas[a)]
Department of Physics, National Technical University, Zografou Campus, 157 80 Athens, Greece

(Received 24 May 2005; accepted 4 July 2006; published online 21 August 2006)

We present Jordan-Brans-Dicke and general scalar-tensor gravitational theory in extra dimensions in an asymptotically flat or anti de Sitter spacetime. We consider a special gravitating, boson field configuration, a *q* star, in three, four, five, and six dimensions, within the framework of the above gravitational theory, and find that the parameters of the stable stars are a few percent different from the case of General Relativity. © *2006 American Institute of Physics.*

I. INTRODUCTION — JORDAN-BRANS-DICKE THEORY IN ANY DIMENSION

Boson stars are stable configurations of a massive, complex scalar field coupled to gravity.[1,2] Self-interactions,[3,4] the coupling of the matter scalar field to a gauge field,[5] or the rotation of the solitonic object,[6] were taken into account. When the nonrelativistic theory admits nontopological soliton solutions, the corresponding relativistic generalizations, which are very large field configurations, are the soliton stars.[7–9] *Q* balls is a special class of nontopological solitons, appearing in Lagrangians with a global $U(1)$ symmetry,[10] a local $U(1)$,[11] or a non-Abelian $SU(3)$ or $SO(3)$ symmetry.[12] Q-stars have been investigated in various models, with one and two scalar fields,[13] non-Abelian symmetries,[14] with a scalar and a fermion field,[15] and with a local $U(1)$ symmetry[16] in asymptotically anti de Sitter spacetime,[17] and in four or more dimensions.[18]

Scalar-tensor gravitational theories appeared in the original papers of Brans and Dicke and Jordan.[19,20] The Newtonian constant G is replaced by the inverse mean value of a scalar field, ϕ_{BD}, and the total action contains kinetic terms for the new field times an ω_{BD} quantity, which is regarded as a constant in the original theory. The theory can be generalized by replacing the constant ω_{BD} by a function usually of the Brans-Dicke (BD) scalar field.[21,22] The theory of a scalar field with quartic self-interactions coupled to the metric and the BD scalar formulated in Ref. 23. Various properties of such configurations have been studied in a series of papers,[24,25] where especially the matter of gravitational memory of boson stars in scalar tensor gravity has been analyzed.[26,27] Their results generalized in scalar-tensor gravitational theories with ω_{BD} no more a constant, but a function of the BD scalar.[30–32]

The purpose of the present work is two-fold: We write the BD gravitational theory in D dimensions and apply our results in a realistic case of a scalar field, admitting *q*-ball type solutions in the absence of gravity. We compare our results with the corresponding ones obtained in General Relativity and we investigate the influence of the space-time dimensionality in the parameters of the star.

All the field configurations under consideration are spherically symmetric and static, so we use a static, spherically symmetric metric in D dimensions:

[a)]Electronic mail: aprikas@central.ntua.gr

$$ds^2 = -e^{\nu}\,dt^2 + e^{\lambda}\,d\rho^2 + \rho^2\,d\Omega_{D-2}^2, \tag{1}$$

with $g_{tt}=-e^{\nu}$ and $d\Omega_{D-2}^2$ the line element on a $(D-2)$-dimensional unit sphere. The action is

$$S = \frac{1}{16\pi}\int d^D x\sqrt{-g_D}\left[\phi_{\mathrm{BD}}(R-2\Lambda) - \frac{\omega_{\mathrm{BD}} g^{\mu\nu}\,\partial^{\lambda}\phi_{\mathrm{BD}}\,\partial_{\lambda}\phi_{\mathrm{BD}}}{\phi_{\mathrm{BD}}^2}\right] + S_{\mathrm{matter}}, \tag{2}$$

with S_{matter} the contribution to the total action of the matter fields. Λ stands for the negative, or zero, cosmological constant. The Einstein equations take the form

$$G_{\mu\nu} = \frac{8\pi}{\phi_{\mathrm{BD}}}T_{\mu\nu} + \frac{\omega_{\mathrm{BD}}}{\phi_{\mathrm{BD}}^2}\left(\partial_{\mu}\phi_{\mathrm{BD}}\,\partial_{\nu}\phi_{\mathrm{BD}} - \frac{1}{2}g_{\mu\nu}\,\partial^{\lambda}\phi_{\mathrm{BD}}\,\partial_{\lambda}\phi_{\mathrm{BD}}\right) + \frac{1}{\phi_{\mathrm{BD}}}\left(\phi_{\mathrm{BD},\mu;\nu} - g_{\mu\nu}\phi_{\mathrm{BD}}{}_{;\lambda}^{;\lambda}\right) - \Lambda g_{\mu\nu}, \tag{3}$$

where $T_{\mu}^{\nu}=\mathrm{diag}(-\varepsilon,p,\ldots,p)$ is the energy momentum tensor with trace $T=\varepsilon+Dp$. The equation of motion for the BD field is

$$\frac{2\omega_{\mathrm{BD}}}{\phi_{\mathrm{BD}}}\phi_{\mathrm{BD}}{}_{;\lambda}^{;\lambda} - \frac{\omega_{\mathrm{BD}}\,\partial^{\lambda}\phi_{\mathrm{BD}}\,\partial_{\lambda}\phi_{\mathrm{BD}}}{\phi_{\mathrm{BD}}^2} + R - 2\Lambda = 0. \tag{4}$$

Contracting Eq. (3), and substituting the trace in Eq. (4), we find the final form for the equation of motion of the BD field

$$\phi_{\mathrm{BD}}{}_{;\lambda}^{;\lambda} = \frac{8\pi T - 2\Lambda\phi_{\mathrm{BD}}}{(D-2)\omega_{\mathrm{BD}} + D - 1}. \tag{5}$$

Equation (5) reveals the dimensional sensitivity of the BD theory. Both T and the ω_{BD}-dependent factor depend on the space-time dimensionality.

We will now find the asymptotic relation for the BD field. For $p \ll \varepsilon$ and $\Lambda=0$, the tt component of the Einstein equations gives

$$G_t^t = -\frac{8\pi\varepsilon}{\phi_{\mathrm{BD}}}\frac{(D-2)\omega_{\mathrm{BD}} + D}{(D-2)\omega_{\mathrm{BD}} + D - 1}. \tag{6}$$

The corresponding result of the Einstein gravity is

$$G_t^t = -8\pi G_D\varepsilon. \tag{7}$$

We know that for $\varepsilon \ll$, the limit of the BD theory is the Einstein gravity. So, for localized matter configurations, the right boundary value at infinity for the BD field is

$$\phi_{\mathrm{BD}} = \frac{1}{G_D}\frac{(D-2)\omega_{\mathrm{BD}} + D}{(D-2)\omega_{\mathrm{BD}} + D - 1}. \tag{8}$$

One can verify that Eqs. (6) and (8) give the right result for the well-known four-dimensional case. We will now apply our results to a certain case of gravitating scalar matter, namely q stars. See (Figs. 1–4).

II. *q* STARS IN BD GRAVITATIONAL THEORY

The Lagrangian resulting from the presence of a matter scalar field is:

$$\mathcal{L}_{\mathrm{matter}} = -(\partial_{\mu}\phi)^{*}(\partial^{\nu}\phi) - U, \tag{9}$$

where ϕ is the matter scalar and U a suitable potential, admitting q-ball type solutions in the absence of gravity. We will now insert the q-soliton ansatz:

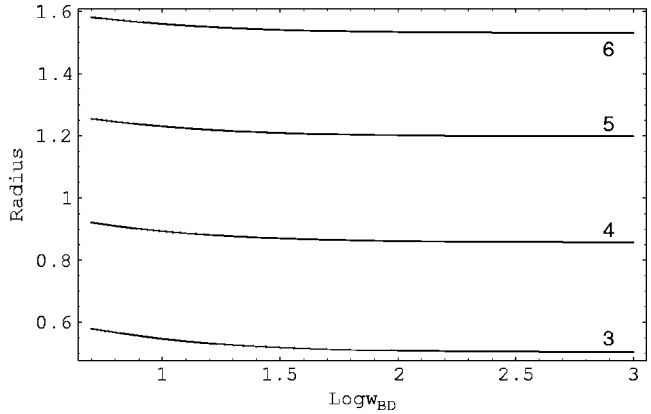

FIG. 1. The radius of a q star as a function of ω_{BD}. The numbers within the figures denote the space-time dimensionality. For $\omega_{BD} \simeq 1000$, the results of General Relativity are approximately reproduced. In Figs. 1–4 and 6–14 (later) we use $\omega=0.45$; equivalently $A_{sur}=0.81$. When decreasing ω_{BD}, the star parameters are a few percent larger.

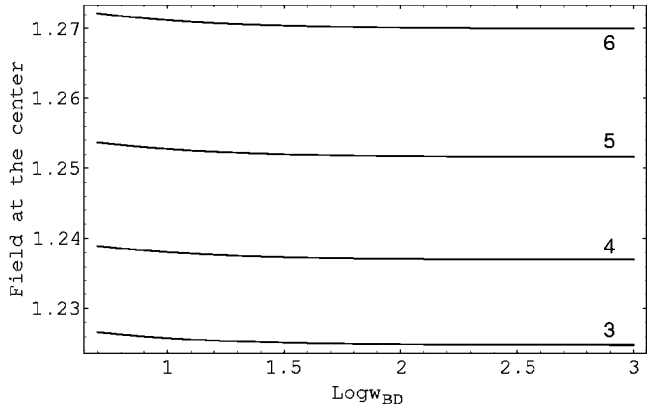

FIG. 2. The value of the matter scalar field at the center of the q star as a function of ω_{BD}.

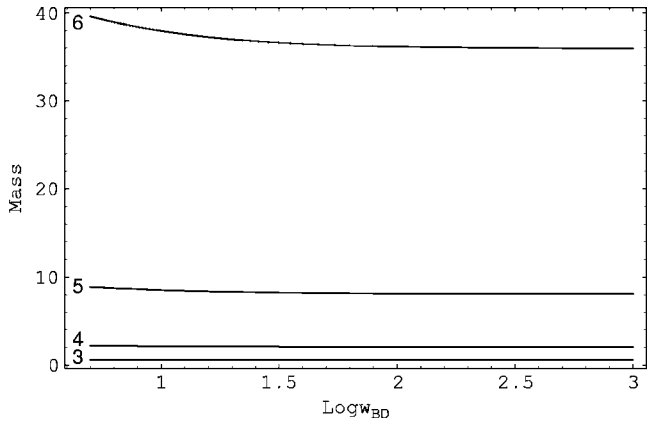

FIG. 3. The total energy of a q star as a function of ω_{BD}.

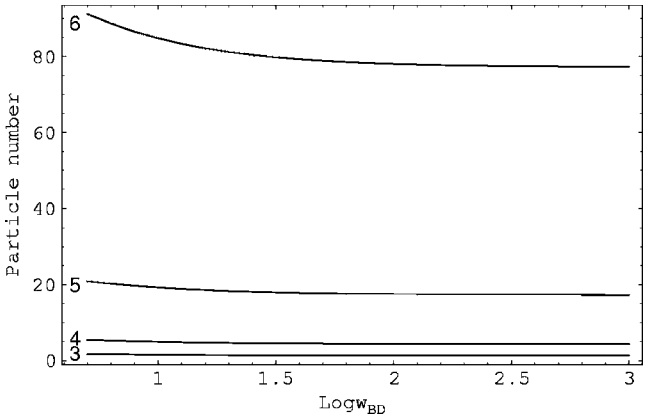

FIG. 4. The particle number of a q star as a function of ω_{BD}.

$$\phi(\vec{\rho},t)=\sigma(\rho)e^{-\iota\omega t}. \tag{10}$$

The equation of motion for the scalar field,

$$\phi_{;\lambda}{}^{;\lambda}-\frac{dU}{d|\phi|^2}\phi=0, \tag{11}$$

now takes the form

$$\sigma''+\left[\frac{D-2}{\rho}+\frac{1}{2}(\nu'-\lambda')\right]\sigma'+e^{\lambda}\omega^2e^{-\nu}\sigma-e^{\lambda}\frac{dU}{d\sigma^2}\sigma=0, \tag{12}$$

where the prime denotes the derivative with respect to ρ. We define

$$A=e^{-\lambda},\quad B=e^{-\nu}, \tag{13}$$

$$W\equiv e^{-\nu}\left(\frac{\partial\phi}{\partial t}\right)^{*}\left(\frac{\partial\phi}{\partial t}\right)=e^{-\nu}\omega^2\sigma^2,$$

$$V\equiv e^{-\lambda}\left(\frac{\partial\phi}{\partial\rho}\right)^{*}\left(\frac{\partial\phi}{\partial\rho}\right)=e^{-\lambda}\sigma'^2, \tag{14}$$

and rescale:

$$\tilde{\rho}=\rho m,\quad \tilde{\omega}=\omega/m,\quad \tilde{\phi}=\phi/m^{D-2/2},$$

$$\widetilde{U}=U/m^D,\quad \widetilde{W}=W/m^D,\quad \widetilde{V}=V/m^D. \tag{15}$$

We also rescale for convenience the BD scalar field:

$$\Phi_{\mathrm{BD}}=\phi_{\mathrm{BD}}G_D\frac{(D-2)\omega_{\mathrm{BD}}+D-1}{(D-2)\omega_{\mathrm{BD}}+D}. \tag{16}$$

Comparing Eqs. (8) and (16) we find that $\Phi_{\mathrm{BD}}\to 1$ for $\rho\to\infty$ and for localized field configurations.

Gravity becomes important when $R^{D-3}\sim G_DM(R)$, where $M(R)$ is a parameter, dependent on the mass trapped within a sphere of radius R. We define

$$\epsilon \equiv \sqrt{8\pi G_D m^{D-2}}, \tag{17}$$

which is a very small quantity for m of the order of magnitude of some (hundreds) GeV. We find for the interior of a q star that $U \sim W \sim m^D$, $V \sim \epsilon^2 m^D$, so the energy resulting from the spatial variation of matter field can be neglected within the star. We also define

$$\tilde{r} = \epsilon \tilde{\rho}. \tag{18}$$

We use a rescaled potential:

$$\tilde{U} = |\tilde{\phi}|^2 \left(1 - |\tilde{\phi}|^2 + \frac{1}{3}|\tilde{\phi}|^4\right) = \tilde{\sigma}^2 \left(1 - \tilde{\sigma}^2 + \frac{1}{3}\tilde{\sigma}^4\right). \tag{19}$$

This potential admits q-ball type solutions in the absence of gravity with $1 > \omega \geqslant (\sqrt{U/|\phi|^2}_{\min}) = 1/2$. Dropping from now on the overtildes and the $O(\epsilon)$ quantities, we find an analytical solution for the scalar field:

$$\sigma = (1 + \omega B^{1/2})^{1/2}, \quad W = B\omega^2(1 + \omega B^{1/2}), \quad U = \frac{1}{3}(1 + \omega^3 B^{3/2}). \tag{20}$$

The eigenvalue equation for the frequency ω of the scalar field can be found from the equation of motion of the matter field within the surface. As we know from Refs. 13–15 q-type solitons are characterized by a large interior where the scalar field is approximately constant and a thin surface of width of order of m^{-1}, where the scalar field varies rapidly from the σ value at the inner edge of the surface, to the zero value at the outer edge. The soliton exterior is clearly distinguished from the soliton interior and the surface, because the scalar field vanishes at the exterior. The situation is different in the case of *nonsolitonic* boson stars, where the star radius is of order of m^{-1}, the scalar field varies from $\sim M_{\mathrm{PI}}$ at the center of the soliton to the zero value outside, and there is no clear distinction between the star interior and the star surface. In the case of solitonic stars, the soliton radius is uniquely definned by the outer edge of the surface. Dropping the $O(\epsilon)$ quantities from the Lagrange equation within the surface, we find

$$V + W - U = 0. \tag{21}$$

The above equation holds true only within the surface. At the inner edge of the surface σ' and, consequently, V are zero, in order to match the interior with the surface solution, so $W = U$. Using also Eq. (20), we find

$$\omega = \frac{A_{\mathrm{sur}}^{1/2}}{2} = \frac{B_{\mathrm{sur}}^{-1/2}}{2}, \tag{22}$$

where $A_{\mathrm{sur}}, B_{\mathrm{sur}}$ denote the value of the metrics at the surface of the star. In the absence of gravity, $A(r) = B(r) = 1$, so $\omega = 1/2$.

We will now turn to the Einstein equations. In D dimensions,

$$G_t^{\ t} = \frac{A-1}{2r^2}(D-3)(D-2) + \frac{A'}{2r}(D-2),$$

$$G_r^{\ r} = \frac{A-1}{2r^2}(D-3)(D-2) - \frac{AB'}{2Br}(D-2). \tag{23}$$

The energy-momentum tensor for the matter scalar field is

$$T_{\mu\nu} = (\partial_\mu \phi)^*(\partial_\nu \phi) + (\partial_\mu \phi)(\partial_\nu \phi)^* - g_{\mu\nu}[g^{\alpha\beta}(\partial_\alpha \phi)^*(\partial_\beta \phi)] - g_{\mu\nu}U. \tag{24}$$

Using Eqs. (10), (13)–(15), and (20), and dropping the $O(\epsilon)$ quantities, we can write the Einstein equations:

$$G_t^{\ t} = \frac{(D-2)\omega_{\rm BD}+D-1}{[(D-2)\omega_{\rm BD}+D]\Phi_{\rm BD}} \times \left[-W-U-\frac{(D-2)W-DU-2\Lambda\Phi_{\rm BD}\dfrac{(D-2)\omega_{\rm BD}+D}{(D-2)\omega_{\rm BD}+D-1}}{(D-2)\omega_{\rm BD}+D-1} \right] - \frac{\omega_{\rm BD}A\Phi'^{\,2}_{\rm BD}}{2\Phi^2_{\rm BD}} - \frac{AB'\Phi'_{\rm BD}}{2\Phi_{\rm BD}B}, \tag{25}$$

$$G_r^{\ r} = \frac{(D-2)\omega_{\rm BD}+D-1}{[(D-2)\omega_{\rm BD}+D]\Phi_{\rm BD}} \times \left[W-U-\frac{(D-2)W-DU-2\Lambda\Phi_{\rm BD}\dfrac{(D-2)\omega_{\rm BD}+D}{(D-2)\omega_{\rm BD}+D-1}}{(D-2)\omega_{\rm BD}+D-1} \right] - \frac{\omega_{\rm BD}A\Phi'^{\,2}_{\rm BD}}{2\Phi^2_{\rm BD}} + \frac{A\Phi''_{\rm BD}}{\Phi_{\rm BD}} + \frac{A'\Phi'_{\rm BD}}{2\Phi_{\rm BD}}, \tag{26}$$

and the equation of motion for the BD field,

$$A\left[\Phi''_{\rm BD}+\left(\frac{D-2}{r}+\frac{A'}{2A}-\frac{B'}{2B}\right)\Phi'_{\rm BD}\right] = \frac{(D-2)W-DU-2\Lambda\Phi_{\rm BD}\dfrac{(D-2)\omega_{\rm BD}+D}{(D-2)\omega_{\rm BD}+D-1}}{(D-2)\omega_{\rm BD}+D}. \tag{27}$$

We numerically solve the coupled system of equations (25)–(27).

We can find the total mass of the field configuration by the relation

$$A(\rho) = 1 - \frac{2G_D m_\rho}{\rho^{D-3}} - \frac{2\Lambda\rho^2}{(D-2)(D-1)}, \tag{28}$$

where m_ρ is straightforward connected to the total mass, M_ρ, trapped within a sphere of radius ρ:

$$M_\rho = \frac{D-2}{8\pi}\frac{2\pi^{(D-2)/2}}{\Gamma\left(\dfrac{D-1}{2}\right)} m_\rho, \tag{29}$$

which, with our rescalings, gives for the total mass, M:

$$M = (D-2)\frac{\pi^{(D-1)/2}}{\Gamma\left(\dfrac{D-1}{2}\right)} r^{D-3}\left[1-A(r)-\frac{2\Lambda r^2}{(D-2)(D-1)}\right], \quad r\to\infty. \tag{30}$$

In the case of a rotating star, one should embed General Relativity in a more general framework, Metric-affine Gravity, where the correct renormalized mass is (in four dimensions):

$$\frac{M}{1+\dfrac{\Lambda}{3}\dfrac{J^2}{M^2}},$$

with J the total angular momentum of the star.[28,29] In our case the anti de Sitter mass is identical with the above renormalized mass, because $J=0$. The mass of Eqs. (28)–(30) is the Schwarzschild mass, which corresponds to the ADM mass in the Jordan frame. In the literature,[25,26] apart from the above mentioned mass, one also defines the ADM mass in the Einstein frame, or tensor mass M_T, and the Keplerian mass, $M_{\rm K}$. In the framework of a scalar tensor gravitational theory, these masses are obtained from the relations

$$M_{\mathrm{K}} = M + \Phi_1 \quad M_T = M + \frac{\Phi_1}{2}, \tag{31}$$

with

$$\Phi_1 = \lim_{r\to\infty}(r^2 \Phi'_{\mathrm{BD}}). \tag{32}$$

In our case we used the ADM mass in the Jordan frame for three reasons: It comes naturally from the Schwarzschild mass, we can deduce the Keplerian and tensor mass from Eqs. (31) and (32), and in our case is always larger from M_{K} and M_T. For the $\omega_{\mathrm{BD}}=-1$ case, and according to the literature,[25,26] $\Phi'_{\mathrm{BD}}>0$ holds at infinity. For our case ($\omega_{\mathrm{BD}}>5$), we found numerically that $\Phi'_{\mathrm{BD}}<0$, not only at infinity, but also for the whole region outside the soliton star. Because, in our case, $M>M_{\mathrm{K}}, M_T$, and because the energy of the same number of free particles is larger than M, we find that the energy of the free particles is always larger than M_{K} and M_T, confirming the stability of the soliton with respect to fission into free particles.

The Noether current that leads to the conserved particle number is

$$j^{\mu} = i\sqrt{-g_D}\, g^{\mu\nu}(\phi\, \partial_\nu \phi^* - \phi^*\, \partial_\nu \phi), \tag{33}$$

which gives a conserved Noether charge:

$$N = \int_0^{\infty} d^{D-1}x\, j^t = \frac{4\pi^{(D-2)/2}}{\Gamma\left(\frac{D-1}{2}\right)} \int_0^R dr\, \omega\sigma^2 r^{D-2} \sqrt{\frac{B}{A}}. \tag{34}$$

III. GENERAL SCALAR-TENSOR THEORY

In the original BD gravitational theory ω_{BD} is a constant. In a more general theory it may be regarded as a function, usually of the BD scalar. We use one of the simple functions investigated in a cosmological framework,[33,34] namely,

$$(D-2)\omega_{\mathrm{BD}} + D - 1 = \omega_0 \phi_{\mathrm{BD}}^n, \tag{35}$$

with ω_0 and n constants. The equation of motion for the BD field is

$$\phi_{\mathrm{BD}_{;\lambda}}{}^{;\lambda} = \frac{1}{(D-2)\omega_{\mathrm{BD}} + D - 1}\left(8\pi T - \frac{d\omega_{\mathrm{BD}}}{d\phi_{\mathrm{BD}}} \phi_{\mathrm{BD}}{}^{,\rho} \phi_{\mathrm{BD};\rho}\right). \tag{36}$$

We set for simplicity $\Lambda=0$. We rescale

$$\tilde{\omega}_0 = \frac{(D-2)\omega_{\mathrm{BD}} + D - 1}{(D-2)\omega_{\mathrm{BD}} + D} G_D^n \omega_0, \tag{37}$$

and the other quantities as in Eqs. (15)–(18). We will use for our calculations $n=1$. For $n=2,3,4$ the behavior of the star parameters is similar. Dropping the overtildes and the $O(\epsilon)$ quantities we find for the Einstein equations:

$$G_t{}^t = \frac{\omega_0}{\omega_0\Phi_{\mathrm{BD}} + 1}\left[-W - U - \frac{1}{\omega_0 \Phi_{\mathrm{BD}}} \quad \times \left((D-2)W - DU - \frac{A\Phi'^2_{\mathrm{BD}}}{D-2}\frac{\omega_0\Phi_{\mathrm{BD}} + 1}{\Phi_{\mathrm{BD}}}\right)\right]$$

$$- \frac{\omega_0\Phi_{\mathrm{BD}} - D + 1}{D-2}\frac{A\Phi'^2_{\mathrm{BD}}}{2\Phi^2_{\mathrm{BD}}} - \frac{AB'\Phi'_{\mathrm{BD}}}{2\phi_{\mathrm{BD}} B}, \tag{38}$$

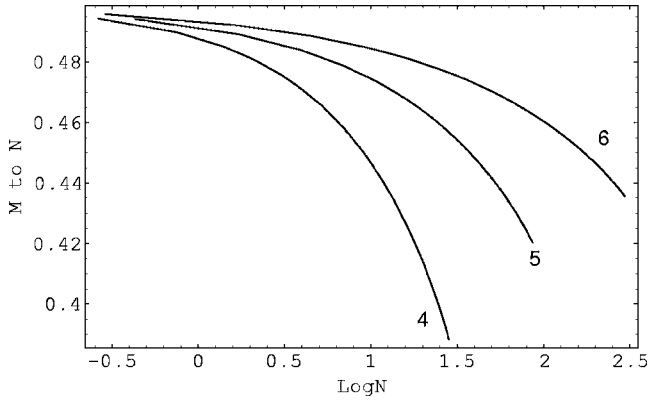

FIG. 5. The ratio of the star mass to its particle number as a function of the particle number for $\omega_{\mathrm{BD}}=500$. Small values of the particle number correspond to small stars, whose limiting value is the nongravitating q ball.

$$G_r{}^r = \frac{\omega_0}{\omega_0\Phi_{\mathrm{BD}}+1}\left[W-U-\frac{1}{\omega_0\Phi_{\mathrm{BD}}} \quad \times\left((D-2)W-DU-\frac{A\Phi'^{\,2}_{\mathrm{BD}}}{D-2}\frac{\omega_0\Phi_{\mathrm{BD}}+1}{\Phi_{\mathrm{BD}}}\right)\right]$$

$$-\frac{\omega_0\Phi_{\mathrm{BD}}-D+1}{D-2}\frac{A\Phi'^{\,2}_{\mathrm{BD}}}{2\Phi^2_{\mathrm{BD}}}+\frac{A\Phi''_{\mathrm{BD}}}{\phi_{\mathrm{BD}}}+\frac{A'\Phi'_{\mathrm{BD}}}{2\Phi_{\mathrm{BD}}}. \tag{39}$$

The equation of motion for the BD field is

$$A\left[\Phi''_{\mathrm{BD}}+\left(\frac{D-2}{r}+\frac{A'}{2A}-\frac{B'}{2B}\right)\Phi'_{\mathrm{BD}}\right]$$

$$=\frac{1}{\omega_0\Phi_{\mathrm{BD}}+1}\left[(D-2)W-DU-\frac{A\Phi'^{\,2}_{\mathrm{BD}}}{D-2}\frac{\omega_0\Phi_{\mathrm{BD}}+1}{\Phi_{\mathrm{BD}}}\right]. \tag{40}$$

We solve numerically the coupled system of equations (38)–(40). The mass and particle number of the star are given by Eqs. (30) and (34), respectively. We start from $\omega_0=5$ up to $\omega_0=1000$, where the results of general relativity are approximately reproduced.

IV. CONCLUSIONS

In the present work we write the Brans-Dicke and a simple scalar-tensor gravitational theory in D dimensions and apply it in a special case of stable, gravitating, scalar field configuration, namely that of a q star. The results of general relativity are reproduced for $\omega_{\mathrm{BD}},\omega_0\to\infty$. A generally accepted, lower experimental limit is $\omega_{\mathrm{BD}}\simeq 500$. Even for this value, the results almost coincide with General Relativity, and one can regard that the results of General Relativity are practically obtained from our figures when $\omega_{\mathrm{BD}},\omega_0=1000$. We investigate the phase space from $\omega_{\mathrm{BD}},\omega_0=5$ up to 1000 so as to gain a detailed picture of the behavior of the star parameters, radius, value of the matter scalar field at the center of the star, total mass, and particle number. For $\omega_{\mathrm{BD}},\omega_0<500$ the star parameters are a few percent larger than in the case of General Relativity. These differences are D dependent. For example, for $\omega_{\mathrm{BD}}=5$ the particle number is 33%, 24%, 21%, and 18% larger from the corresponding results in General Relativity, for $D=3,4,5$, and 6 dimensions, respectively; the radius is 15%, 7%, 4%, and 3% larger, respectively; and the total mass is $\gtrsim$0%, 7%, 9%, and 10% larger. One can find similar differences for the scalar-tensor theory.

The results of Figs. 1–5 and 11–14 refer to a zero cosmological constant. Figure 5 shows the ratio M/N of the star as a function of its particle number (M is the ADM star mass and N is the

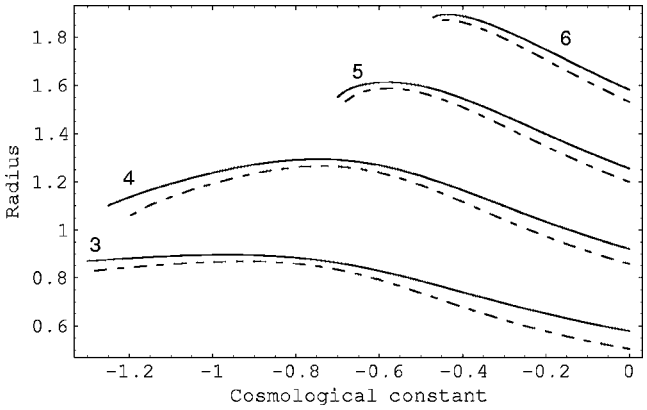

FIG. 6. The radius of a q star as a function of the cosmological constant. In Figs. 6–10, the dashed lines correspond to $\omega_{\mathrm{BD}}=500$ and the solid lines to $\omega_{\mathrm{BD}}=5$.

particle number). As one can see, every field configuration is stable with respect to fission into free particles. This feature is characteristic for solitonic gravitating objects, which are stable even in the absence of gravity. For example, a q star with very small particle number and mass corresponds to a (nongravitating) q ball (in the thin-wall approximation). For small q stars, one can see from Fig. 5 that $M/(mN)\rightarrow 0.5$, with m the mass of the free particles (here equal to unity with our rescalings). This is the correct limiting value in the absence of gravity, for the potential of 19, for which $\omega_{\mathrm{min}}\equiv(\sqrt{U/\sigma^2})_{\mathrm{min}}=0.5$. The picture is absolutely different for nonsolitonic boson stars,[35] where gravity and not the scalar potential is the main stabilizing factor. This means that for some region of the phase space, gravity is not strong enough to make the binding energy negative [equivalently, to make $M/(mN)<1$]. In Figs. 6–9 and for four, five, and six dimensions we start from a zero value of the cosmological constant, gradually decrease its value, and stop our calculations when $B(0)\rightarrow\infty$, or $\sigma(0)\rightarrow\infty$, showing in this way the formation of an anomaly at the center of the star. For $D=3$, when decreasing the value of Λ, we find that both mass and particle number increase up to their maximum value at approximately $\lambda\simeq -3$, and below this value, the energy is approximately constant, when the particle number decreases slowly. Below $\Lambda\simeq -10$, the energy of the free particles (identified with the particle number for $m=1$) is less than the soliton energy, which means that the decay into free particles is energetically favorable. All the other field configurations depicted in our figures are stable with respect to decay into free particles. (See Figs. 10–14).

In this paper, we provide mathematical analysis for the controllability of chaos in wavelet subspaces. We prove that depending on the scale of the wavelet operation and the number of the coupled oscillators, the critical coupling strength for the occurrence of chaos synchronization becomes many times smaller if the original coupling matrix is appropriately treated with the wavelet transform. Moreover, we obtain rigorous relations connecting the critical values and the wavelet subspace operations. Our mathematical results are completely consistent with early numerical simulations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2203229]

I. INTRODUCTION

Chaos is ubiquitous in nature. Controlling chaos is of both theoretical and of practical importance.[1–5] Recently, a new paradigm of chaos control via wavelet transform has been introduced by Wei, Zhan, and Lai in Ref. 6 (also see Ref. 7). It is found that the transverse stability of the synchronous manifold of a chaotic system could be dramatically enhanced by the means of modifying a tiny fraction of the wavelet subspaces of a coupling matrix. Nevertheless, rigorous mathematical analysis of the aforementioned control has not been reported in the literature. Our objective in the present work is to present detailed mathematical analyses of the wavelet approach.[6]

To be more precise, let $du/dt=f(u)$ be a given chaotic oscillator. Consider a coupled nonlinear dynamical system of N chaotic oscillators,

$$\frac{d\mathbf{u}}{dt}=\mathbf{F}(\mathbf{u})+\epsilon\mathbf{A}\mathbf{u},\quad \mathbf{u}=(u_1,u_2,\ldots,u_N)^{\mathsf{T}}, \tag{1.1}$$

where $(\mathbf{F}(\mathbf{u}))_i=f(u_i)$ is a nonlinear function of the ith oscillator, which has a state function $u_i \in [0,\infty)\times\mathbb{R}^n$, ϵ is a coupling strength, and $\mathbf{A}$ is a coupling matrix having the periodic structure at the boundaries.

The synchronous manifold of the chaotic system, as a subspace of the original coupled system, Eq. (1.1), can be studied by setting $u_1(t)=u_2(t)=\cdots=u_N(t)=s(t)$, where the chaotic solution $s(t)$ satisfies the single oscillator equation $ds/dt=f(s(t))$. The stability property of the synchronous manifold can be studied in the space of difference variables $\delta u_i(t)=u_i(t)-s(t)$, which are governed by

a)Corresponding author.

$$\frac{d\delta\mathbf{u}}{dt} = (D\mathbf{F}(\mathbf{S}(t)) + \epsilon\mathbf{A})\delta\mathbf{u}, \quad \delta\mathbf{u} = (\delta u_1, \delta u_2, \cdots, \delta u_N)^{\mathsf{T}}, \tag{1.2}$$

where $D\mathbf{F}(\mathbf{u}) = \mathrm{diag}(f'(u_1), f'(u_2), \cdots, f'(u_N))$ and $\mathbf{S}(t)^T = (s(t), s(t), \ldots, s(t))_{1\times N}$. The second largest eigenvalue λ_2 of the matrix $\mathbf{A}$ plays a dominant role in controlling the stability of chaotic synchronization.[8–10] A critical coupling strength ϵ_c can be determined in terms of λ_2,

$$\epsilon_c = \frac{L_{\max}}{-\lambda_2}, \tag{1.3}$$

where $L_{\max} > 0$ is the largest Lyapunov exponent of a single chaotic oscillator.

For the nearest neighbor coupling case, the eigenvalue spectrum of an appropriately normalized $\mathbf{A}$ is given by

$$-4\sin^2\frac{\pi(i-1)}{N}, \quad i = 1,2,\ldots,N. \tag{1.4}$$

In general, a wider coupling width gives a smaller λ_2, while a larger number of oscillators requires a larger ϵ_c. In controlling a given system, it is desirable to reduce the critical coupling strength ϵ_c.

Denote the two dimensional wavelet decomposition and its inverse with periodic boundary condition by $\mathbf{W}$ and $\mathbf{W}^{-1}$, respectively. For a given matrix $\mathbf{A}$, the wavelet decomposition allows a perfect reconstruction, by which there is nothing to gain: $\mathbf{A} = \mathbf{W}^{-1}(\mathbf{W}(\mathbf{A}))$. In Ref. 6, a simple operation is used to attain a desirable coupling matrix:

$$\tilde{\mathbf{A}} = \mathbf{W}^{-1}(\mathbf{O}_K(\mathbf{W}(\mathbf{A}))), \tag{1.5}$$

where $\mathbf{O}_K$ is limited to be the multiplication of a scalar factor K on the elements of subspaces $\mathbf{LL}_1$, which corresponds to the lowest resolution subspace in both the horizontal and vertical directions in a two-dimensional multiscale wavelet decomposition. A numerical simulation of a coupled system of 512 Lorenz oscillators in Ref. 6 shows that for the nearest neighbor coupling case, the critical coupling strength ϵ_c decreases linearly with respect to the increase of K up to a critical value K_c. The smallest ϵ_c is about 6, which is about 10^3 times smaller than the original critical coupling strength, indicating the efficiency of the proposed approach.

In this paper we will provide a rigid mathematical analysis of the above wavelet scheme. For simplicity and without loss of generality, we only consider the wavelet transformation and the reverse transformation based on the Daubechies wavelet, $db1$.[11]

By an i-scale wavelet operation $\mathbf{W} = \mathbf{W}(i)$ based on the $db1$ wavelet, a $2^k \times 2^k$ matrix $\mathbf{A}$ is transformed into another $2^k \times 2^k$ matrix $\mathbf{W}(\mathbf{A})$. Moreover, the subspaces $\mathbf{LL}_1$ or equally the $2^{k-i} \times 2^{k-i}$ up-left block of $\mathbf{W}(\mathbf{A})$ equals $\mathbf{\Omega A \Omega}^{\mathsf{T}}$, where

$$\mathbf{\Omega} = \frac{1}{2^{2i}}\begin{bmatrix} \mathbf{e} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{e} & \cdots & \mathbf{0} & \mathbf{0} \\ \cdot & \cdot & \cdots & \cdot & \cdot \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{e} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{e} \end{bmatrix}_{2^{k-i}\times 2^k},$$

with $\mathbf{e} = (1,1,\ldots,1)_{1\times 2^i}$ and $\mathbf{0} = (0,0,\ldots,0)_{1\times 2^i}$. In other words, every entry of $\mathbf{\Omega A \Omega}^{\mathsf{T}}$ is the average value of all items of some $2^i \times 2^i$ block of $\mathbf{A}$. With the transformation $\mathbf{O}_K$, $\mathbf{\Omega A \Omega}^{\mathsf{T}}$ is transformed into $K\mathbf{\Omega A \Omega}^{\mathsf{T}}$. Since $\mathbf{A} = \mathbf{W}^{-1}(\mathbf{W}(\mathbf{A}))$, we have that

$$\tilde{\mathbf{A}} = \mathbf{W}^{-1}(\mathbf{O}_K(\mathbf{W}(\mathbf{A}))) = \mathbf{A} + (K-1)\mathbf{\Omega A \Omega}^{\mathsf{T}}. \tag{1.6}$$

Before stating the main theorem, we introduce some notations. Define series $\{\rho_i\}_{i=1}^{\infty}$ by

$$\rho_i = 2\cos\frac{\pi}{2^i} - 2, \quad i = 1,2,3,\ldots . \tag{1.7}$$

Moreover, we denote

$$K_c(i,N) = \frac{-2^i\rho_i}{4\sin^2\dfrac{2^i\pi}{N}} + 1, \quad i = 1,2,3,\ldots . \tag{1.8}$$

Theorem 1: *For any $i \in \mathcal{N}$, assume ρ_i is defined as in* (1.7) *and the nature numbers N satisfy $N/2^{i+2} \in \mathcal{N}$. Let* $\mathbf{A}$ *be the nearest neighbor-coupling matrix of order $N \times N$ defined as in Eq.* (1.1). *Suppose by i-scale wavelet operation* (1.5) *with the scalar factor $K \geq 1$ that the coupling matrix is transformed from* $\mathbf{A}$ *to* $\tilde{\mathbf{A}}$. *Then for any such K, all the eigenvalues of* $\tilde{\mathbf{A}}$ *are nonpositive; Moreover, it holds that ρ_i is an eigenvalue of the matrix* $\tilde{\mathbf{A}}$.

Theorem 2: *Let i, ρ_i, N,* $\mathbf{A}$, $\tilde{\mathbf{A}}$, *K be defined as in Theorem 1. Assume $K_c(i,N)$ are defined by* (1.8). *Then the second largest eigenvalue of* $\tilde{\mathbf{A}}$ *is a decreasing function of K. Moreover, the second largest eigenvalue of* $\tilde{\mathbf{A}}$ *is equal to ρ_i for any $K \geq K_c(i,N)$ and is strictly larger than ρ_i (thus its absolute value is strictly less than $-\rho_i$) for any $1 \leq K < K_c(i,N)$.*

Since the critical coupling strength is determined in terms of the second largest eigenvalue of the coupling matrix, by Theorem 2 and (1.4) we have the following result.

Corollary 1.1: *The i-scale wavelet control method with $K_c(i,N)$ as the scalar factor can enhance the stability of a synchronous manifold of an N coupled system by reducing the critical coupling strength as much as $\rho_i/4\sin^2(\pi/N)$ time.*

In the following, we denote a "block circulant matrix" with blocks $\mathbf{A}_1, \mathbf{A}_2, \ldots, \mathbf{A}_n$ by

$$b\mathrm{circ}(\mathbf{A}_1,\mathbf{A}_2,\ldots,\mathbf{A}_n) = \begin{bmatrix} \mathbf{A}_1 & \mathbf{A}_2 & \mathbf{A}_3 & \cdots & \cdots & \mathbf{A}_n \\ \mathbf{A}_n & \mathbf{A}_1 & \ddots & \ddots & \ddots & \ddots \\ \ddots & \ddots & \ddots & \ddots & \ddots & \ddots \\ \mathbf{A}_4 & \ddots & \ddots & \ddots & \mathbf{A}_2 & \mathbf{A}_3 \\ \mathbf{A}_3 & \mathbf{A}_4 & \ddots & \ddots & \mathbf{A}_1 & \mathbf{A}_2 \\ \mathbf{A}_2 & \mathbf{A}_3 & \mathbf{A}_4 & \cdots & \mathbf{A}_n & \mathbf{A}_1 \end{bmatrix}.$$

Moreover, we denote average values of all elements of a matrix $\mathbf{A} = (a_{ij})_{n\times n}$ by $\mathrm{aver}(\mathbf{A})$, that is, $\mathrm{aver}(\mathbf{A}) = (1/n^2)\sum_{i,j=1}^{n} a_{ij}$.

II. PROOF OF THE MAIN THEOREMS

In this section, we will prove Theorem 1 and Theorem 2. First, we introduce some useful lemmas.

A. Preliminaries

Lemma 2.1: Assume matrix $\mathbf{A}$ *is of order $N \times N$ and* $\tilde{\mathbf{A}}$ *is defined by i-scale wavelet operation* (1.5) *with the scalar factor $K \geq 1$. Then it holds that*

$$\tilde{\mathbf{A}} - \mathbf{A} = \frac{K-1}{2^{2i}}\mathbf{A}_{N_i} \otimes \mathbf{B}_i, \tag{2.1}$$

with

$$\mathbf{A}_{N_i}=\begin{bmatrix} -2 & 1 & & & 1 \\ 1 & -2 & \ddots & & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & 1 \\ 1 & & & 1 & -2 \end{bmatrix}_{N_i\times N_i}$$

and

$$\mathbf{B}_i=\mathbf{e}^{\mathsf{T}}\mathbf{e},$$

where $N_i=N/2^i$, $\mathbf{e}$ *is defined as in the introduction, and* $\otimes$ *represents tensor product of matrices.*

Proof: First note that the nearest neighbor matrix $\mathbf{A}$ can be written in the form

$$b\text{circ}(\mathbf{A}_1,\mathbf{A}_2,\ldots,\mathbf{A}_{N_i}),\quad N_i=\frac{N}{2^i},$$

where matrix $\mathbf{A}_j$ of order $2^i\times 2^i$ $(j=1,2,\ldots,N_i)$ satisfies

$$\mathbf{A}_1=\begin{bmatrix} -2 & 1 & & \cdots & 0 \\ 1 & -2 & \ddots & & \vdots \\ & \ddots & \ddots & \ddots & \\ \vdots & & \ddots & \ddots & 1 \\ 0 & \cdots & & 1 & -2 \end{bmatrix},\quad \mathbf{A}_2=\mathbf{A}_{N_i}^{\mathsf{T}}=\begin{bmatrix} 0 & \ldots & 0 & 0 \\ \vdots & & \vdots & \vdots \\ 0 & \ldots & 0 & 0 \\ 1 & \ldots & 0 & 0 \end{bmatrix},\tag{2.2}$$

$$\mathbf{A}_l=\mathbf{0},\quad 3\le l\le\frac{N}{2^i}-1.\tag{2.3}$$

It is obvious to see that $\text{aver}(\mathbf{A}_1)=-1/2^{2i-1}$ and $\text{aver}(\mathbf{A}_2)=\text{aver}(\mathbf{A}_{N_i})=1/2^{2i}$.

From (1.6), we obtain that $\tilde{\mathbf{A}}$ is of the form

$$\tilde{\mathbf{A}}=b\text{circ}(\tilde{\mathbf{A}}_1,\tilde{\mathbf{A}}_2,\ldots,\tilde{\mathbf{A}}_{N_i}),\tag{2.4}$$

with

$$\tilde{\mathbf{A}}_1=-\frac{K-1}{2^{2i-1}}\mathbf{B}_i+\mathbf{A}_1,\quad \tilde{\mathbf{A}}_2=\frac{K-1}{2^{2i}}\mathbf{B}_i+\mathbf{A}_2,\quad \tilde{\mathbf{A}}_{N_i}=\frac{K-1}{2^{2i}}\mathbf{B}_i+\mathbf{A}_{N_i},$$

$$\tilde{\mathbf{A}}_j=\mathbf{0},\quad 3\le j\le N_i-1.\tag{2.5}$$

Thus the lemma can be obtained easily. □

Proposition 2.1: Let $\mathbf{A}=b\text{circ}(\mathbf{A}_1,\mathbf{A}_2,\ldots,\mathbf{A}_n)$ *be a real symmetric block circulant matrix. Denote* $\mathbf{C}_k=\Sigma_{j=1}^{n}e^{\iota[k(j-1)/n]2\pi}\mathbf{A}_j$, $k=0,1,\ldots,n-1$, $\iota=\sqrt{-1}$. *Then eigenvalues of* $\mathbf{A}$ *consist of eigenvalues of* $\mathbf{C}_k$, $k=0,1,\ldots,n-1$.

Proof: See p. 211 in Ref. 12. □

B. Proof of Theorem 1

Proof of nonpositivity: First, we prove that for any $K\ge 1$, all the eigenvalues of $\tilde{\mathbf{A}}$ are nonpositive. From Lemma 2.1, we have that

$$\tilde{\mathbf{A}} = \mathbf{A} + \frac{K-1}{2^{2i}} \mathbf{A}_{N_i} \otimes \mathbf{B}_i. \tag{2.6}$$

We will prove that $[(K-1)/2^{2i}]\mathbf{A}_{N_i} \otimes \mathbf{B}_i$ is seminegative definite. Then by the seminegative definiteness of $\mathbf{A}$ and the fact that the sum of two seminegative definite matrices is seminegative definite, we obtain that $\tilde{\mathbf{A}}$ is also seminegative definite. Thus all its eigenvalues are nonpositive. Since $[(K-1)/2^{2i}]\mathbf{A}_{N_i} \otimes \mathbf{B}_i$ is a real symmetric block circulant, by Proposition 2.1, it is sufficient to prove the nonpositivity of eigenvalues of matrices,

$$-2\mathbf{B}_i + e^{\mathrm{i}(k2^i/N)2\pi}\mathbf{B}_i + e^{\mathrm{i}[k(N-2^i)/N]2\pi}\mathbf{B}_i, \quad k = 0,1,\ldots,\frac{N}{2^i} - 1, \tag{2.7}$$

or equally,

$$\left(-2 + 2\cos\frac{k2^i}{N}2\pi\right)\mathbf{B}_i, \quad k = 0,1,\ldots,\frac{N}{2^i} - 1. \tag{2.8}$$

Obviously, $\mathbf{B}_i$ has 0 and 1 as its eigenvalues and the term in the parentheses is less than or equal to 0. Thus, each eigenvalue of the matrices defined in (2.7) and (2.8) is nonpositive. Then from the symmetry, we obtain that $(K-1)/2^{2j}\mathbf{A}_{N_i} \otimes \mathbf{B}_i$ is seminegative definite. Thus, the proof is completed. □

Remark 2.1: From the fact that $\mathbf{A}$ *has only one zero eigenvalue, we conclude that* $\tilde{\mathbf{A}}$ *has at most one zero eigenvalue. On the other hand, since the sum of elements in every column of* $\tilde{\mathbf{A}}$ *is zero, we obtain that* $\tilde{\mathbf{A}}$ *has at least one zero eigenvalue. In a word, it has and only has one zero eigenvalue.*

Now we prove the second part of Theorem 1, that is, for any $K \geq 1$, ρ_i is an eigenvalue of the matrix $\tilde{\mathbf{A}}$.

Combining (2.4), (2.5) and Proposition 2.1, we have that the set of eigenvalues of $\tilde{\mathbf{A}}$ is equal to the collection of the eigenvalue of the $2^i \times 2^i$ matrix,

$$\mathbf{D}_1(l) + d_l\mathbf{D}_2(l) := \begin{bmatrix} -2 & 1 & & & e^{-i(2\pi l/n)} \\ 1 & -2 & \ddots & & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & 1 \\ e^{i(2\pi l/n)} & & & 1 & -2 \end{bmatrix} + d_l \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} [1 \ldots 1],$$

$$l = 0,1,\ldots,n-1,$$

with $n = N/2^i$, $d_l = (c/2^{2i})[2\cos(2\pi l/n) - 2]$, $c = K-1$.

The following two propositions are useful for the proof of Theorem 1 and Theorem 2.

Proposition 2.2 (rank one update for Hermitian matrices): *Let* $\mathbf{A}$ *be an* $N \times N$ *Hermitian matrix and* $\mathbf{u} \in \mathcal{C}^{\mathbf{N}}$. *Suppose* $(\lambda_k, \mathbf{u}_k)$ *and* $(\tilde{\lambda}_k(\alpha), \tilde{\mathbf{u}}_k(\alpha))$, $k = 1,\ldots,N$, *be, respectively, the eigenpairs for* $\mathbf{A}$ *and* $\mathbf{A} + \alpha\mathbf{u}\mathbf{u}^H$ *with the order* $\lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_N$ *and* $\tilde{\lambda}_1 \leq \tilde{\lambda}_2 \leq \cdots \leq \tilde{\lambda}_N$.

(i) Assume $\alpha > 0$. *If* $\mathbf{u}^H\mathbf{u}_k \neq 0$ *and* $\mathbf{u}^H\mathbf{u}_{k'} \neq 0$ *for some* $k' > k$; *then* $\lambda_k \leq \tilde{\lambda}_k(\alpha) \leq \lambda_{k'}$.

(ii) If $\mathbf{u}^H\mathbf{u}_{k''} = 0$ *for some* k''; *then* $\tilde{\lambda}_{k''}(\alpha) = \lambda_{k''}$ *for all* α.

Proof: See Ref. 13. □

Proposition 2.3: Denote $(\lambda_k, \mathbf{u}_k)$, $k=0,\ldots,m-1$, *the eigenpair of the matrix*

$$\mathbf{G} = \begin{bmatrix} -2 & 1 & & & e^{-\imath\alpha} \\ 1 & -2 & \ddots & & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & 1 \\ e^{\imath\alpha} & & & 1 & -2 \end{bmatrix}_{m\times m}$$

with α *any real number. Then*

$$\lambda_k = 2\cos\theta_k - 2$$

and

$$\mathbf{u}_k = (u_{k,j})_{j=1}^{m},$$

where

$$\theta_k = \frac{2k\pi}{m} + \frac{\alpha}{m}, \quad k = 0, \ldots, m-1,$$

and

$$u_{k,j} = \begin{cases} 1, & \text{if } k^2+\alpha^2 = 0, \\ c_1(\sin j\theta_k + e^{-\imath\alpha}\sin(m+j)\theta_k) + c_2(\sin(m+1+j)\theta_k + e^{\imath\alpha}\sin(j+1)\theta_k), & \text{otherwise.} \end{cases}$$

Here c_1 *and* c_2 *are arbitrary complex numbers.*

Proof: By directly solving the eigenvalue problem for $\mathbf{G}$, $\mathbf{Gu}=\lambda\mathbf{u}$, we obtain the difference equation

$$u_{j+1} - (2+\lambda)u_j + u_{j-1} = 0, \quad j = 2, \ldots, m-1, \tag{2.9}$$

with

$$u_0 = e^{-\imath\alpha}u_m,$$

$$u_{m+1} = e^{\imath\alpha}u_1. \tag{2.10}$$

Equation (2.9) has characteristic equation $r^2-(2+\lambda)r+1=0$, which yields

$$r_{1,2} = \frac{(2+\lambda) \pm \sqrt{(2+\lambda)^2-4}}{2} =: e^{\pm\imath\theta}. \tag{2.11}$$

The second equality holds since eigenvalues of $\mathbf{G}$ are nonpositive. Now set

$$u_j = Ar_1^j + Br_2^j = Ae^{\imath j\theta} + Be^{-\imath j\theta}, \tag{2.12}$$

where A and B are constant coefficient to be determined. Substituting (2.12) into (2.10), we obtain

$$A + B = e^{-\imath\alpha}(Ae^{\imath m\theta} + Be^{-\imath m\theta}),$$

$$Ae^{\imath(m+1)\theta} + Be^{-\imath(m+1)\theta} = e^{\imath\alpha}(Ae^{\imath\theta} + Be^{-\imath\theta}). \tag{2.13}$$

Since (A,B) is a nonzero solution of Eq. (2.13), it turns out that

$$\begin{vmatrix} 1-e^{\imath(m\theta-\alpha)} & 1-e^{-(\imath m\theta+\alpha)} \\ e^{\imath(m+1)\theta}-e^{\imath(\theta+\alpha)} & e^{-\imath(m+1)\theta}-e^{-\imath(\theta-\alpha)} \end{vmatrix} = 0,$$

or, equivalently,

$$\cos m\theta = \cos \alpha.$$

Thus, $\theta_k = 2k\pi/m + \alpha/m$, $k=0,\ldots,m-1$, and, hence, by using (2.11), we have $\lambda_k = 2\cos\theta_k - 2$. This gives the proof of the first assertion.

To see the eigenvector of $\mathbf{G}$ corresponding to eigenvalue λ_k, we first consider that for $\alpha=0$ and $k=0$, i.e., $\lambda_0=0$. It is easy to see that the vector $(1,\ldots,1)^{\mathsf{T}}$ is the eigenvector of $\mathbf{G}$ corresponding to 0. Now, assume $\alpha\neq 0$ and $k\neq 0$. For convenience, we write $\theta=\theta_k$ and $u_j=u_{k\cdot j}$. Choose $A_1=1-e^{\imath(m\theta-\alpha)}$, $B_1=-1+e^{-\imath(m\theta+\alpha)}$, $A_2=e^{\imath(m+1)\theta}-e^{\imath(\theta+\alpha)}$, and $B_2=-e^{-\imath(m+1)\theta}+e^{-\imath(\theta-\alpha)}$ with $\theta=\theta_k$ for some k. Note that (A_1,B_1) and (A_2,B_2) are solutions of (2.13). Set $u_j=\frac{1}{2}(c_1A_1+c_2A_2)e^{\imath j\theta}+\frac{1}{2}(c_1B_1+c_2B_2)e^{-\imath j\theta}=c_1(\sin j\theta_k+e^{-\imath\alpha}\sin(m+j)\theta_k)+c_2(\sin(m+1+j)\theta_k+e^{\imath\alpha}\sin(j+1)\theta_k)$ and the second assertion follows. □

Proof of the second part of Theorem 1: Let $\alpha=\pi$ and $m=2^i$. From Proposition 2.3, it follows that ρ_i is an eigenvalue of $\mathbf{D}_1(n/2)$. To see that ρ_i is also an eigenvalue of $\mathbf{D}_1(n/2)+d_{n/2}\mathbf{D}_2(n/2)$, we choose $c_1=1$ and $c_2=0$. From Proposition 2.3 again, $\mathbf{D}_1(n/2)$ has an eigenvector $\mathbf{u}=[\sin(j\pi/m)]_{j=1}^m$ corresponding to the eigenvalue ρ_i. Since $\mathbf{D}_2=\mathbf{e}\mathbf{e}^{\mathsf{T}}$ and $\mathbf{e}^{\mathsf{T}}\mathbf{u}=\Sigma_{j=1}^m\sin(j\pi/m)=0$, applying (ii) of Proposition 2.2, we see that ρ_i is an eigenvalue of $\mathbf{D}_1(n/2)+d_{n/2}\mathbf{D}_2(n/2)$. □

C. Proof of Theorem 2

Proof of the first part of Theorem 2: Let $n=N/2^i$ and $\mathbf{D}_1(l),\mathbf{D}_2(l),d_l,l=0,1,\cdots,n-1$ be defined as in the last subsection. Since $d_l\leq 0$, applying Proposition 2.2 to $-\mathbf{D}_1(l)-d_l\mathbf{D}_2(l)$, we have that the eigenvalues of $\mathbf{D}_1(l)+d_l\mathbf{D}_2(l)$ are increasing functions of d_l, which, by Proposition 2.1, implies the first part of Theorem 2, that is, the second largest eigenvalue of $\tilde{\mathbf{A}}$ is a decreasing function of K. □

Now we are in a position to prove the second part of Theorem 2.

Denote $\alpha=2\pi l/n$. We have

$$\mathbf{D}_1(l)=\begin{bmatrix} -2 & 1 & & & e^{-\imath\alpha} \\ 1 & -2 & \ddots & & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & 1 \\ e^{\imath\alpha} & & & 1 & -2 \end{bmatrix}. \tag{2.14}$$

From Proposition 2.3, we have that any eigenvalue of $\mathbf{D}_1(l)$ can be written in the form

$$\lambda = 2\cos\theta(k,l) - 2,$$

with $\theta(k,l)=2k\pi/2^i+\alpha/2^i$, $k=0,1,\ldots,2^i-1$, $l=0,1,\ldots,n-1$. Obviously, for every such l and k_1,k_2 with $k_1\neq k_2$, it holds that $|\theta(k_1,l)-\theta(k_2,l)|\geq 2\cdot\pi/2^i$, which implies that there is at most one $k\in\{0,1,\ldots,2^i-1\}$ such that $|\theta(k,l)|\leq\pi/2^i$. Then we have that for every matrix $\mathbf{D}_1(l)+d_l\mathbf{D}_2(l)$ $(l=0,1,\ldots,n-1)$, there is at most one nonzero eigenvalue that is larger than or equal to $\rho_i=2\cos(\pi/2^i)-2$. It implies that if for some $d_l=d_l^*$, $\mathbf{D}_1(l)+d_l\mathbf{D}_2(l)$ has eigenvalue ρ_i, then all its other eigenvalues are less than ρ_i.

Remark 2.2: If such d_l^* exists for $\mathbf{D}_1(l)+d_l\mathbf{D}_2(l)$, then by the first part of Theorem 2, we have that all its eigenvalues will be less than or equal to ρ_i for all $d_l<d_l^*$. Then for the proof of the second part of Theorem 2, it is sufficient to prove that the existence of such d_l^* for every l.

The following proposition will help us to complete the proof of Theorem 2.

Proposition 2.4: Let $d=[2\cos(\pi/m)-2]/m$. *Then the matrix*

$$\mathbf{G}=\begin{bmatrix} -2 & 1 & & & e^{-\imath\alpha} \\ 1 & -2 & \ddots & & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & 1 \\ e^{\imath\alpha} & & & 1 & -2 \end{bmatrix}+d\begin{bmatrix} 1 \\ \vdots \\ \vdots \\ 1 \end{bmatrix}[1,\ldots,1]\in\mathbb{R}^{m\times m},$$

has eigenvalue $2\cos(\pi/m)-2$ *for and* $\alpha\neq 0,\pm\pi$.

Proof: Consider the eigenproblem of the matrix **G**, which is equivalent to

$$u_{k-1}-(\lambda+2)u_k+u_{k+1}+d\sum_{j=1}^{m}u_j=0,\quad k=2,\ldots,m-1, \tag{2.15}$$

$$u_2-2u_1+e^{-\imath\alpha}u_m+d\sum_{j=1}^{m}u_j=0, \tag{2.16}$$

$$u_{m-1}-2u_m+e^{\imath\alpha}u_1+d\sum_{j=1}^{m}u_j=0. \tag{2.17}$$

Denote $\tilde{u}_k=u_k/\Sigma_{j=1}^{m}u_j$. Then we have

$$\tilde{u}_{k-1}-(\lambda+2)\tilde{u}_k+\tilde{u}_{k+1}+d=0,$$

$$\tilde{u}_2-2\tilde{u}_1+e^{-\imath\alpha}\tilde{u}_m+d=0,$$

$$\tilde{u}_{m-1}-2\tilde{u}_m+e^{\imath\alpha}\tilde{u}_1+d=0. \tag{2.18}$$

In the following, for the sake of notation without leading confusion, we use the notation u_k with the restriction $\Sigma_{j=1}^{m}u_j=1$ to replace the notation $\tilde{u}_k$.

Obviously, (2.18) has a special solution of the form $u_k=d/\lambda$, $k=1,\ldots,m$. Thus the general solution of (2.18) is of the form

$$u_k=C_1e^{\imath k\theta}+C_2e^{-\imath k\theta}+\frac{d}{\lambda}, \tag{2.19}$$

with the boundary condition

$$u_0=e^{-\imath\alpha}u_m,\quad u_{m+1}=e^{\imath\alpha}u_1, \tag{2.20}$$

where $\cos\theta=(\lambda+2)/2$.

Now we determine C_1 and C_2 with the boundary condition

$$C_1+C_2+\frac{d}{\lambda}=C_1e^{\imath(-\alpha+m\theta)}+C_2e^{-\imath(\alpha+m\theta)}+e^{-\imath\alpha}\frac{d}{\lambda} \tag{2.21}$$

and

$$C_1e^{\imath(m+1)\theta}+C_2e^{-\imath(m+1)\theta}+\frac{d}{\lambda}=C_1e^{\imath(\theta+\alpha)}+C_2e^{\imath(-\theta+\alpha)}+e^{i\alpha}\frac{d}{\lambda}. \tag{2.22}$$

Thus we have

$$\begin{bmatrix} 1 & 1 \\ -e^{\imath(\theta+\alpha)} & -e^{\imath(-\theta+\alpha)} \end{bmatrix} \begin{bmatrix} 1-e^{\imath(-\alpha+m\theta)} & 0 \\ 0 & 1-e^{-\imath(\alpha+m\theta)} \end{bmatrix} \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} = \frac{d}{\lambda} \begin{bmatrix} e^{-\imath\alpha}-1 \\ e^{\imath\alpha}-1 \end{bmatrix}.$$

Then we have

$$C_1 = \frac{-(e^{-\imath\alpha}-1)e^{-\imath(\theta-\alpha)} - (e^{\imath\alpha}-1)}{(1-e^{\imath(-\alpha+m\theta)})(e^{\imath(\theta+\alpha)} - e^{\imath(-\theta+\alpha)})} \frac{d}{\lambda} \tag{2.23}$$

and

$$C_2 = \frac{e^{\imath\alpha} - 1 + (e^{-\imath\alpha}-1)e^{\imath(\theta+\alpha)}}{(1-e^{-\imath(\alpha+m\theta)})(e^{\imath(\theta+\alpha)} - e^{\imath(-\theta+\alpha)})} \frac{d}{\lambda}. \tag{2.24}$$

From $\Sigma_{j=1}^{m} u_j = 1$, we obtain that

$$C_1 \frac{e^{\imath\theta}(1-e^{\imath m\theta})}{1-e^{\imath\theta}} + C_2 \frac{e^{-\imath\theta}(1-e^{-\imath m\theta})}{1-e^{-\imath\theta}} + m\frac{d}{\lambda} = 1. \tag{2.25}$$

Combining (2.23)–(2.25), we have

$$\frac{e^{\imath\alpha}-1}{e^{\imath\theta}-e^{-\imath\theta}} \left(\frac{1-e^{\imath m\theta}}{e^{\imath\alpha}-e^{\imath m\theta}} - \frac{1-e^{-\imath m\theta}}{e^{\imath\alpha}-e^{-\imath m\theta}} \right) + m = \frac{\lambda}{d}. \tag{2.26}$$

We note that $\theta = \arccos[(\lambda+2)/2] = \pi/m$. Substituting $d = [2\cos(\pi/m) - 2]/m$ into (2.26) and by direct computation, we obtain that $2\cos(\pi/m) - 2$ is a root of (2.26) thus an eigenvalue of $\mathbf{G}$. □

Proof of the second part of Theorem 2: Denote $\lambda_1^{(l)}(K)$ and $\lambda_2^{(l)}(K)$, respectively, the largest and second largest eigenvalue of $\mathbf{D}_1(l) + d_l \mathbf{D}_2(l)$. From Proposition 2.3, it follows that

$$\lambda_1^{(l)}(1) = \begin{cases} 2\cos\left(\dfrac{2\pi l}{mn}\right) - 2, & 0 < l < \dfrac{n}{2}, \\ 2\cos\dfrac{\pi}{m} - 2 = \rho_i, & l = \dfrac{n}{2}, \\ 2\cos\left(\dfrac{2(m-1)\pi}{m} + \dfrac{2\pi l}{mn}\right) - 2, & \dfrac{n}{2} + 1 < l < n-1, \end{cases}$$

and

$$\lambda_2^{(l)}(1) = \begin{cases} 2\cos\left(\dfrac{2(m-1)\pi}{m} + \dfrac{2\pi l}{mn}\right) - 2, & 0 < l < \dfrac{n}{2}, \\ 2\cos\dfrac{\pi}{m} - 2 = \rho_i, & l = \dfrac{n}{2}, \\ 2\cos\left(\dfrac{2\pi l}{mn}\right) - 2, & \dfrac{n}{2} + 1 < l < n-1, \end{cases}$$

where $m = 2^i$ and $n = N/m$. Here we note that $\lambda_1^{(l)}(1) > \rho_i > \lambda_2^{(l)}(1)$ for $l = 0, \ldots, n/2-1, n/2+1, \ldots, n-1$. Since the largest eigenvalue of $\tilde{\mathbf{A}}$ equals $0 = \lambda^{(0)}(K) \equiv \bar{\lambda}_1(K)$, we see that the second largest eigenvalue of $\tilde{\mathbf{A}}$ at $K=1$ equals $\max\{\lambda_1^{(l)}(1) \,|\, l = 0, \ldots, n/2-1, n/2+1, \ldots, n-1\}$. On the other hand, applying Proposition 2.4 with $m = 2^i$, we have that for $l \neq 0, n/2$ and $d_l = \rho_i/m$, i.e.,

$$K = \frac{m\rho_i}{2\cos\dfrac{2\pi l}{n} - 2} + 1 \equiv K_c^{(l)},$$

$\mathbf{D}_1(l) + d_l \mathbf{D}_2(l)$ has eigenvalue ρ_i. By using Proposition 2.2, $\lambda_1^{(l)}(K)$ is decreasing in K. Hence

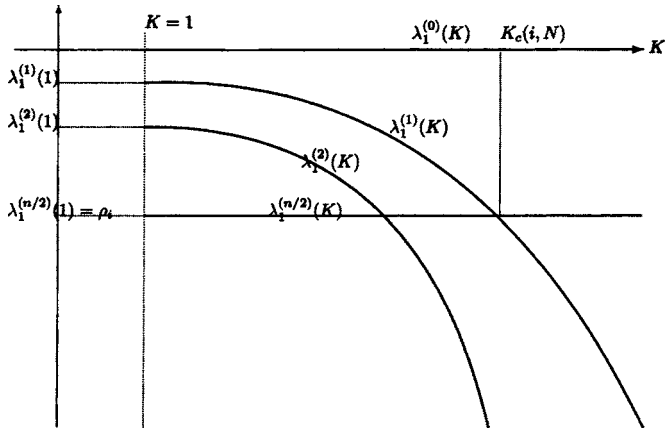

FIG. 1. An illustration of the eigenvalues curves of $\tilde{\mathbf{A}}$.

$$\lambda_1^{(l)}(K) < \rho_i,$$

for $K > K_c^{(l)}$ and $l \neq 0, n/2$. Thus, for $K > \max_{l\neq 0,n/2}\{K_c^{(l)}\} = K_c^{(1)} = K_c(i,N)$, we have $\bar{\lambda}_2(K) = \rho_i$. Also, for $1 < K < K_c(i,N)$, $\bar{\lambda}_2 = \max_{l\neq 0,n/2} \lambda_1^{(l)}(K)$ (see Fig. 1 for an illustration). This completes the proof. □

A new *solvable* many-body problem of goldfish type is identified and used to revisit the connection between two different approaches to *solvable* dynamical systems. An *isochronous* variant of this model is identified and investigated. Alternative versions of these models are presented. The behavior of the alternative *isochronous* model near its equilibrium configurations is investigated, and a remarkable *Diophantine* result, as well as related *Diophantine* conjectures, are thereby obtained. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2235035]

I. INTRODUCTION

Recently a method has been introduced and exploited to identify new *exactly solvable* (namely solvable by purely algebraic operations, such as diagonalizing a matrix) many-body problems characterized by equations of motion of Newtonian type ("the acceleration of each particle is determined by the positions and velocities of all particles"), including in particular models of goldfish type (see, for instance, Ref. 4, and the following). The main idea of this approach—hereafter referred to as the *direct* method—is to start from an *explicitly solvable* matrix evolution equation (possibly even quite a trivial one), and to then focus on the time evolution of the *eigenvalues* of this matrix. For an overview of this method (including an explanation of the terminology used herein) of the main results yielded by it so far, and the quotation of relevant references, we refer to the very recent paper Ref. 2.

Another method has been introduced some years ago to treat certain well-know *solvable* dynamical systems and to illuminate their connection with developments in theoretical particle physics. The main idea of this approach—hereafter referred to as the *gauge theory* method—is to start from a *gauge invariant* matrix evolution equation and to exploit the possibility that in one gauge this evolution be trivially simple hence *solvable* while in another gauge it can be related to interesting evolutions, in particular to the equations of motion of Newtonian type of certain many-body problems. For an overview of this approach and the quotation of relevant references, we refer to the relatively recent paper (Ref. 1). An analysis of the *gauge theory* approach entailing a clarification of the relation of this method to the *direct* approach is already provided in the more recent paper published by one of us.[11]

In the present paper, in the context of revisiting this connection, we identify a new *solvable* many-body problem of goldfish type. This finding hinges on a result obtained many years ago by Inozemtsev.[10] We also present the *isochronous* variant of this many-body problem, as well as alternative formulations of these two models, and by investigating the behavior of the alternative *isochronous* model in the neighborhood of its equilibrium configurations we identify certain remarkable *Diophantine* relations.

The main *new* results obtained in this paper are reported in Sec. II. The hasty browser eager

[a)]Electronic mail: francesco.calogero@roma1.infn.it
[b)]Electronic mail: langmann@kth.se

to see immediately the equations of motion of the new *solvable* many-body problems of goldfish type should jump to (1) and for the *isochronous* variant to (6), and for the alternative versions of these models to (14) and (21); a *Diophantine* finding and related conjectures are reported at the end of Sec. II. In Sec. III the *solvable* character of the new many-body problems of goldfish type is demonstrated, first via the *direct* method and then via the *gauge theory* method; the connection among these two approaches is thereby illuminated. In Sec. IV *solvable* dynamical systems are derived, which constitute nontrivial alternative reformulations of the many-body problems of goldfish type treated in Sec. III. In Sec. V the behavior of the alternative *isochronous* model in the neighborhood of its equilibrium configurations is investigated and remarkable *Diophantine* relations are thereby obtained. In Sec. VI possible future developments are mentioned. The Appendix contains some findings the insertion of which where they are first mentioned (see *Remark 2.9* in Sec. II) would have been too distracting.

II. MAIN RESULTS

In this section we report the main *new* findings obtained in subsequent sections.

The *solvable N*-body problem of goldfish type identified in this paper is characterized by the following equations of motion of Newtonian type:

$$\ddot{z}_n = 2z_n(z_n^2 - a^2) + 2\sum_{m=1,m\neq n}^{N} \frac{(\dot{z}_n + z_n^2 - a^2)(\dot{z}_m + z_m^2 - a^2)}{z_n - z_m}. \tag{1}$$

Notation: $z_n \equiv z_n(t)$ are the dependent variables, t is the independent variable ("time"), superimposed dots denote time-differentiations, a^2 is an *arbitrary* constant (we use a^2 rather than a merely for notational convenience, see the following), N is a positive integer (generally we assume $N>1$), and indices such as n,m generally take all the values $1,2,\ldots,N$ unless otherwise mentioned.

Remark 2.1: Trivially related models involving additional arbitrary constants could of course be obtained by rescaling the (dependent and independent) variables and by shifting by a constant amount the dependent variables; note incidentally that the first factor 2 on the right-hand side of (1) could be changed by rescaling (we put it there for notational convenience, see the following), while the second factor 2 (that multiplying the sum) cannot of course be changed.

Remark 2.2: Although for *real* a^2 and for *real* initial data $z_n(0)$, $\dot{z}_n(0)$ the time evolution (for *real* time) of this many-body model entails that the dependent variables $z_n(t)$ are as well *real*, we generally assume the time evolution to take place in the *complex* z-plane (and generally allow the constant a to be as well *complex*); indeed such an evolution is much more interesting due to the possibility of the "particles" characterized by the *complex* coordinates $z_n(t)$ to go round each other and the related fact that initial data $z_n(0)$, $\dot{z}_n(0)$ leading to particle collisions are then *exceptional* (they generally have vanishing dimensionality relative to *generic* initial data). (If attention is instead restricted to *real* motions, then the trivial change of dependent variables $z_n \to iy_n$ with y_n *real* might be expedient in order to deal with *confined* motions.) It is possible to reformulate these *complex* equations of motions as *real* (and even *covariant*, even *rotation-invariant*) equations of motion describing the motion of *real* point particles in the *real* (say, *horizontal*) plane, but we will not take space here to reformulate them in this manner, since the technique to do so is well known (see for instance Ref. 5).

The *solvable* character of these equations of motion is evidenced by the well-known fact[10,5] that the $N\times N$ matrix evolution equation

$$\ddot{U} = 2U(U^2 - a^2) \tag{2}$$

is itself *solvable* (in terms of appropriate sigma functions[10]), together with the following.

Proposition 2.3: *The solution of the initial-value problem for the equations of motion (1) is provided by the following prescription: the coordinates* $z_n(t)$ *are the N eigenvalues of the* $N\times N$ *matrix* $U(t)$ *solution of (2) and determined by the following initial data:*

$$U_{nm}(0) = \delta_{nm} z_n(0), \tag{3a}$$

$$\dot{U}_{nm}(0) = -\delta_{nm}[z_n^2(0) - a^2] + [\dot{z}_n(0) + z_n^2(0) - a^2]^{1/2}[\dot{z}_m(0) + z_m^2(0) - a^2]^{1/2}. \tag{3b}$$

Note that the matrix $U(0)$ is *diagonal*, while the matrix $\dot{U}(0)$ is the sum of a *diagonal* matrix and a *dyadic* matrix.

Notation: here and hereafter $\delta_{nm} \equiv \delta_{n,m}$ is the Kronecker delta symbol, $\delta_{nm}=1$ if $n=m$, $\delta_{nm}=0$, if $n \neq m$.

To obtain the *isochronous* variant of this many-body problem one starts from the equations of motion

$$\zeta_n'' = 2\zeta_n^3 + 2 \sum_{m=1, m\neq n}^{N} \frac{(\zeta_n' + \zeta_n^2)(\zeta_m' + \zeta_m^2)}{\zeta_n - \zeta_m}, \tag{4}$$

which correspond to (1) with $a=0$ and with the merely notational replacement of the dependent variables $z_n(t)$ with the dependent variables $\zeta_n(\tau)$ (and of course now the appended primes denote differentiations with respect to τ). One can then apply the procedure usually referred to as "the trick" (see for instance Refs. 4 and 5), i.e. (in this case) the following change of dependent and independent variables:

$$\tilde{z}_n(t) = \exp(it)\zeta_n(\tau), \tag{5a}$$

$$\tau = i[1 - \exp(it)]. \tag{5b}$$

This yields the equations of motion

$$\ddot{\tilde{z}}_n = 3i\dot{\tilde{z}}_n + 2\tilde{z}_n(1 + \tilde{z}_n^2) + 2 \sum_{m=1, m\neq n}^{N} \frac{(\dot{\tilde{z}}_n - i\tilde{z}_n + \tilde{z}_n^2)(\dot{\tilde{z}}_m - i\tilde{z}_m + \tilde{z}_m^2)}{\tilde{z}_n - \tilde{z}_m}. \tag{6}$$

The solution of the initial-value problem is then obviously given by the solution (via Proposition 2.3) of the problem (4) and by the "trick" relations (5), which clearly also imply

$$\zeta_n(0) = \tilde{z}_n(0), \quad \zeta'(0) = \dot{\tilde{z}}_n(0) - i\tilde{z}_n(0). \tag{7}$$

Equivalently, the solution of this model (6) is clearly given by the following.

Proposition 2.4: *The dependent variables $\tilde{z}_n(t)$ that solve the initial-value problem for the Newtonian N-body problem (6) are the N eigenvalues of the $N \times N$ matrix $\tilde{U}(t)$ evolving according to the solvable matrix evolution equation*

$$\ddot{\tilde{U}} - 3i\dot{\tilde{U}} - 2\tilde{U} = 2\tilde{U}^3 \tag{8}$$

and being moreover characterized by the following initial data:

$$\tilde{U}_{nm}(0) = \delta_{nm}\tilde{z}_n(0), \tag{9a}$$

$$\dot{\tilde{U}}_{nm}(0) = -\delta_{nm}[\tilde{z}_n^2(0)] + [\dot{\tilde{z}}_n(0) - i\tilde{z}_n(0) + \tilde{z}_n^2(0)]^{1/2}[\dot{\tilde{z}}_m(0) - i\tilde{z}_m(0) + \tilde{z}_m^2(0)]^{1/2}. \tag{9b}$$

Note that the matrix $\tilde{U}(0)$ is *diagonal*, while the matrix $\dot{\tilde{U}}(0)$ is the sum of a *diagonal* matrix and a *dyadic* matrix.

The *solvable* character of the matrix evolution equation (8) is implied by the "trick" formula

$$\widetilde{U}(t) = \exp(it)U(\tau), \quad \tau = i[1 - \exp(it)] \tag{10}$$

relating the $N \times N$ matrix $\widetilde{U}(t)$ evolving according to (8) to the $N \times N$ matrix $U(t)$ evolving according to (2) with $a=0$.

Remark 2.5: The *solvable* character[10] of the matrix evolution equation (2) entails that *all* its solutions $U(t)$ are *meromorphic* functions of the independent variable t. Hence (see (10)) *all* the *nonsingular* solutions $\widetilde{U}(t)$ of the matrix evolution equation (8) are *periodic* with period 2π,

$$\widetilde{U}(t + 2\pi) = \widetilde{U}(t). \tag{11}$$

The *singular* solutions of (8) are *exceptional*, corresponding to a set of initial data having *vanishing* measure with respect to the set of *generic* initial data.

As an immediate consequence of Proposition 2.4 and of this *Remark 2.5* there holds the following.

Proposition 2.6: *All the solutions of the many-body problem (6) (except those* exceptional *ones that run into a collision of two or more particles, which correspond to* nongeneric *initial data) are* completely periodic *with a period which is a* positive integer multiple p *of* 2π:

$$\widetilde{z}_n(t + 2p\pi) = \widetilde{z}_n(t), \quad p = 1 \text{ or } 2 \text{or} \ldots \text{or } N. \tag{12}$$

The positive integer p *accounts for the possibility that the eigenvalues get exchanged among each other through the motion: it depends on the initial data, but it does not change for sufficiently small, if finite, changes of these data and it clearly is* not larger *than* N.

This proposition displays the *isochronous* character of the N-body problem (6), indeed it justifies considering it as one more instance of *nonlinear harmonic oscillators*.[7]

There exists a, by now rather standard, technique to reformulate these types of N-body problems, by identifying the N "particle coordinates" $z_n(t)$ as the N zeros of a (*monic*) polynomial in z of degree N, and by then focusing on the corresponding time evolution of the N coefficients $c_m(t)$ of this polynomial (see for instance Refs. 6 and 5):

$$\psi(z,t) = \prod_{n=1}^{N} [z - z_n(t)] = \sum_{m=0}^{N} c_m(t) z^{N-m}, \quad c_0 = 1. \tag{13}$$

In Sec. IV we show how such a procedure is applicable in our case, and we thereby obtain the following alternative formulation of the N-body problem (1):

$$\ddot{c}_m + 2(m-1)\dot{c}_{m+1} - 2c_1\dot{c}_m + 2(N+1-m)a^2\dot{c}_{m-1} + (m+2)(m-3)c_{m+2} - 2(m-1)c_1c_{m+1} + 2[m(N + 2 - m)a^2 + \dot{c}_1 - c_1^2 + 3c_2]c_m - 2(N+1-m)a^2c_1c_{m-1} + (N+2-m)(N+1-m)a^4c_{m-2} = 0,$$
$$m = 1, \ldots, N, \quad c_0 = 1, \quad c_{-1} = c_{N+1} = c_{N+2} = 0. \tag{14}$$

Remark 2.7: The ODE of this system with $m=0$ is identically satisfied; the ODE with $m=N+1$ is also satisfied provided one sets $c_{N+3}=0$, and even the ODE with $m=N+2$ is identically satisfied if one moreover sets $c_{N+4}=0$.

Remark 2.8: A superficial look at this system of ODEs might suggest that it is a *linear* system of evolution equations for the quantities $c_m(t)$; but this is of course *not* the case, due to the presence of the quantities $c_1(t)$ and $c_2(t)$. Indeed the highly nonlinear character of this system is already evident by looking at the $N=2$ case, in which case it yields the following (*solvable*!) fourth-order ODE for $f(t) \equiv c_1(t)$:

$$f'''' f^2 - 2f''' f' f^2 - 2f''' f^3 - 2(f'')^2 f + 2f''(f')^2 + 4f'' f' f^2 - 2f'' f^4 - 4(f')^2 f^3 + 4f' f^5 + 4a^2(f'' f^2 - 2f' f^3) = 0 \tag{15}$$

(here for typographical convenience differentiations are denoted by appended primes rather than superimposed dots).

Remark 2.9: Two equilibrium (namely, time-independent) solutions of this system (14) are provided by the formula

$$c_m = (\pm a)^m \binom{N}{m}. \tag{16}$$

They are not, however, the only equilibrium configurations of this system. A technique to obtain *all* these configurations (including this one!) is described in the Appendix.

As indicated earlier, see (13), the quantities $c_m(t)$ that evolve according to the system of ODEs (14) are just the *coefficients* of the *monic* polynomial $\psi(z,t)$ of degree N in z, the N zeros $z_n(t)$ of which evolve according to the equations of motion (1). Hence (see Proposition 2.3) the solution of the system of ODEs (14) is given by the following.

Proposition 2.10: *The dependent variables $c_m(t)$ that solve the initial-value problem for the system of nonlinear ODEs (14) are the N coefficients of the polynomial $\psi(z,t)$, see (13), which is itself given by the formula*

$$\psi(z,t) = \det[z - U(t)], \tag{17}$$

where the $N \times N$ matrix $U(t)$ evolves according to the solvable *matrix evolution equation (2) and is moreover characterized by the initial data (3), with the initial values $z_n(0)$, $\dot{z}_n(0)$ related to the initial values $c_m(0)$, $\dot{c}_m(0)$ by the formulas implied by (13),*

$$\prod_{n=1}^{N} [z - z_n(0)] = \sum_{m=0}^{N} c_m(0) z^{N-m}, \quad c_0 = 1, \tag{18a}$$

$$-\sum_{n=1}^{N} \dot{z}_n(0) \prod_{m=1, m\neq n}^{N} [z - z_n(0)] = \sum_{m=1}^{N} \dot{c}_m(0) z^{N-m}. \tag{18b}$$

To obtain an alternative version of the *isochronous N*-body problem (6) we use the following version of the "trick:"

$$\tilde{c}_m(t) = (-i)^m \exp(mit)\, \gamma_m(\tau), \tag{19a}$$

$$\tau = i[1 - \exp(it)]. \tag{19b}$$

Here the quantities $\gamma_m(\tau)$ are the dependent variables of the previous model, (14), with $a=0$, up to the (purely notational) change consisting in calling the independent variable τ (instead of t) and the dependent variables γ_m (instead of c_m), so that these variables satisfy the following system of ODEs:

$$\gamma_m'' + 2(m-1)\gamma_{m+1}' - 2\gamma_1\gamma_m' + (m+2)(m-3)\gamma_{m+2} - 2(m-1)\gamma_1\gamma_{m+1} + 2(\gamma_1' - \gamma_1^2 + 3\gamma_2)\gamma_m = 0,$$

$$m = 1, \ldots, N, \quad \gamma_0 = 1, \quad \gamma_{-1} = \gamma_{N+1} = \gamma_{N+2} = 0, \tag{20}$$

where of course appended primes denote differentiations with respect to the independent variable τ (which we allow to be complex, see (19b)).

Then clearly by applying the "trick" (19) to the system (20) the following new system of nonlinear ODEs is obtained:

$$\ddot{\tilde{c}}_m + 2(m-1)i\dot{\tilde{c}}_{m+1} - (2m+1+2\tilde{c}_1)i\dot{\tilde{c}}_m - (m+2)(m-3)\tilde{c}_{m+2} + 2(m-1)(m+1+\tilde{c}_1)\tilde{c}_{m+1}$$
$$+ [-m(m+1) + 2i\dot{\tilde{c}}_1 - 2(m-1)\tilde{c}_1 + 2\tilde{c}_1^2 - 6\tilde{c}_2]\tilde{c}_m = 0,$$

$$m = 1, \ldots, N, \quad \tilde{c}_0 = 1, \quad \tilde{c}_{-1} = \tilde{c}_{N+1} = \tilde{c}_{N+2} = 0. \tag{21}$$

Remark 2.11: The prefactor $(-i)^m$ in (19a) is of course unessential, it has been introduced merely to give a marginally nicer look to this system (21) and to some other formulas, see the following. With this version, (19), of the "trick" the relation among the particle coordinates satisfying the equations of motion of the *isochronous N*-body problem (6) and the quantities $\tilde{c}_m(t)$ satisfying this system of ODEs (21) reads now

$$\tilde{\psi}(z,t) = \prod [z - \tilde{z}_n(t)] = \sum_{m=0}^{N} (i)^m \tilde{c}_m(t) z^{N-m}, \quad \tilde{c}_0 = 1, \tag{22}$$

see (5), (19), and (13). Note that we introduced here the (new) *monic* polynomial $\tilde{\psi}(z,t)$ having as its N zeros the N dependent variables $\tilde{z}_n(t)$ satisfying (6) and as its N coefficients the N dependent variables $\tilde{c}_m(t)$ satisfying (21).

This model, (21), is obviously just as *solvable* as the previous one, (14), indeed the solution of its initial-value problem can be obtained from the solution of the corresponding problem for (14) via the formulas (19) that clearly imply the following relations among the initial data of the two models:

$$\tilde{c}_m(0) = (-i)^m \gamma_m(0), \tag{23a}$$

$$\dot{\tilde{c}}_m(0) - mi\tilde{c}_m(0) = (-i)^m \gamma_m(0). \tag{23b}$$

Equivalently, the solution of this model (21) is clearly given by the following.

Proposition 2.12: *The dependent variables $\tilde{c}_m(t)$ that solve the initial-value problem for the system of nonlinear ODEs (21) are the N coefficients of the polynomial $\tilde{\psi}(z,t)$, see (22), which is itself given by the formula*

$$\tilde{\psi}(z,t) = \det[z - \tilde{U}(t)], \tag{24}$$

where the $N \times N$ matrix $\tilde{U}(t)$ evolves according to the solvable *matrix evolution equation* (8) *and is moreover characterized by the initial data (9) with the initial values $\tilde{z}_n(0)$, $\dot{\tilde{z}}_n(0)$ related to the initial values $\tilde{c}_m(0)$, $\dot{\tilde{c}}_m(0)$ by the following formulas implied by (22),*

$$\prod_{n=1}^{N} [z - \tilde{z}_n(0)] = \sum_{m=0}^{N} (i)^m \tilde{c}_m(0) z^{N-m}, \quad \tilde{c}_0 = 1, \tag{25a}$$

$$-\sum_{n=1}^{N} [\dot{\tilde{z}}_n(0) - i\tilde{z}_n(0)] \prod_{m=1, m\neq n}^{N} [z - \tilde{z}_n(0)] = \sum_{m=1}^{N} (i)^m \dot{\tilde{c}}_m(0) z^{N-m}. \tag{25b}$$

As an immediate consequence of this Proposition 2.12 and of *Remark 2.5* there holds the following.

Proposition 2.13: *All the* nonsingular *solutions of the system of ODEs (21) are* completely periodic *with period* 2π,

$$\tilde{c}_m(t + 2\pi) = \tilde{c}_m(t), \tag{26}$$

while the singular *solutions are* exceptional, *corresponding to a set of initial data having* vanishing *measure with respect to the set of* generic *initial data.*

This proposition displays the *isochronous* character of the *N*-body problem (21), indeed it justifies considering it as one more instance of *nonlinear harmonic oscillators*.[7]

Finally, in Sec. V we obtain *all* the *equilibrium configurations* of the *isochronous* systems (6) and (21) and we study the behavior of the system of *nonlinear harmonic oscillators* (21) in the neighborhood of its equilibrium configurations. The interested reader will find these results in that

section, but we advertise here the *Diophantine* findings arrived at via this study.

Proposition 2.14: *Let the two $N\times N$ matrices A and B be defined componentwise as follows:*

$$A_{nm} = 2(n-1)\,\delta_{n+1,m} - (2n+1+2\bar{c}_1)\,\delta_{n,m} + 2\bar{c}_n\delta_{1,m}, \tag{27a}$$

$$B_{nm} = (n+2)(n-3)\,\delta_{n+2,m} - 2(n-1)(n+1+\bar{c}_1)\,\delta_{n+1,m} + [n(n+1) + 2(n-1)\bar{c}_1 - 2\bar{c}_1^2 + 6\bar{c}_2]\,\delta_{n,m} + 2[-(n-1)\bar{c}_{n+1} + (n-1-2\bar{c}_1)\bar{c}_n]\,\delta_{1,m} + 6\bar{c}_n\delta_{2,m}, \tag{27b}$$

with the numbers $\bar{c}_m$ defined as follows:

$$\text{for } \nu=0, \quad \bar{c}_m = (-)^m\binom{\mu}{m}, \tag{28a}$$

$$\text{for } \nu=1, \quad \bar{c}_m = \delta_{0m} + \delta_{1m} \text{ if } \mu=1, \quad \bar{c}_m = (-)^m\left[\binom{\mu-2}{m} - \binom{\mu-2}{m-2}\right] \text{ if } \mu>1, \tag{28b}$$

$$\text{for } \nu=3, \ \bar{c}_m = (-)^m\left[\binom{\mu-3}{m} + 6\binom{\mu-3}{m-1} + 14\binom{\mu-3}{m-2} + 14\binom{\mu-3}{m-3}\right], \tag{28c}$$

$$\text{for } \nu=4, \quad \bar{c}_m = (-)^m\sum_{k=0}^{4}\binom{\mu-4}{m-k}\binom{5}{k}, \tag{28d}$$

$$\text{for } \nu=5, \quad \bar{c}_m = (-)^m\left[c\binom{\mu-5}{m-5} + \sum_{k=0}^{5}\binom{\mu-5}{m-k}\binom{5}{k}\right], \quad c \text{ arbitrary}. \tag{28e}$$

As indicated earlier the parameter ν (the role of which here is mainly to distinguish five different cases) can take any one of the 5 *values* 0, 1, 3, 4, 5, *while the parameter μ can take any* positive integer *value in the range $\nu\leqslant\mu\leqslant N$. Let the* $2N$ *numbers $p_n^{(\pm)}$ be the eigenvalues of the generalized eigenvalue problem*

$$(p^2 + Ap + B)\underline{r} = 0, \tag{29a}$$

(where $\underline{r}\equiv(r_1,\ldots,r_N)$ denotes the corresponding eigenvector) implying

$$\det(p^2 + Ap + B) = \prod_{n=1}^{N}[(p - p_n^{(+)})(p - p_n^{(-)})]. \tag{29b}$$

Then the $2N$ *numbers $p_n^{(\pm)}$ are* all integers.

Notation: here and throughout the symbol $\binom{x}{y}$ is the standard binomial coefficient,

$$\binom{x}{y} = \frac{\Gamma(x+1)}{\Gamma(y+1)\Gamma(x-y+1)}. \tag{30}$$

We have verified with the help of symbolic programing languages (we used MAPLE and MATHEMATICA) and for an ample sample of values of N and of the other parameters the validity of this proposition (proven in Sec. V), and from these computer-aided checks we are led to formulate the following *Diophantine* conjectures.

Conjecture 2.15: *For ν=*0, 1, 3, 4, 5 *and μ integer in the range $\nu\leqslant\mu\leqslant N$ the eigenvalues of the generalized eigenvalue problem (29a) (with (27) and (28)) are given by the following formulas:*

$$\text{for } \nu=0, \quad \det(p^2+Ap+B)=\left\{\prod_{n=1}^{N-\mu}[(p-n)(p-n-1)]\right\}\left\{\prod_{n=1}^{\mu}[(p+n)(p+n-5)]\right\}, \tag{31a}$$

$$\text{for } \nu=1, \quad \det(p^2+Ap+B)=(p+1)(p-4)\left\{\prod_{n=1}^{N-\mu}[(p-n)(p-n-5)]\right\} \times\left\{\prod_{n=1}^{\mu-1}[(p+n)(p+n-7)]\right\}, \tag{31b}$$

$$\text{for } \nu=3, \quad \det(p^2+Ap+B)=(p+1)(p-4)\left\{\prod_{n=1}^{N-\mu}[(p-n)(p-n+5)]\right\} \times\left\{\prod_{n=1}^{\mu-1}[(p+n)(p-n+\mu-7)]\right\}, \tag{31c}$$

$$\text{for } \nu=4, \quad \det(p^2+Ap+B)=(p+1)\left[\prod_{n=1}^{3}(p-n-1)\right]\left\{\prod_{n=1}^{N-\mu}[(p-n)(p-n+1)]\right\}\left[\prod_{n=1}^{\mu-4}(p+n)\right] \times\left[\prod_{n=1}^{\mu}(p+n+1)\right], \tag{31d}$$

$$\text{for } \nu=5, \quad \det(p^2+Ap+B)=\left\{\prod_{n=1}^{N-\mu}[(p-n)(p-n-1)]\right\}\left\{\prod_{n=1}^{\mu}[(p+n)(p-n+\mu-4)]\right\}. \tag{31e}$$

Here we use the standard convention according to which a product equals unity *if the lower limit of the running index exceeds the upper limit.*

Remark 2.16: For $\mu=\nu=0$ the validity of this conjecture is certainly true, indeed trivially so (see below the *Remark 5.4*).

The Conjecture 2.15 only refers to *integer* values of the parameter μ in the range $\nu\leqslant\mu\leqslant N$. But our computer-aided exploration also indicates the validity, for *arbitrary* values of the parameter μ, of the following conjecture (which is only formulated in the following for sufficiently large values of N, to avoid less interesting complications).

Conjecture 2.17: *The generalized eigenvalue problem* (29a) (*with* (27) and (28a)) *features, for* arbitrary μ, *the* $N-1$ *eigenvalues*

$$2,3,4,5-\mu,6-\mu,\ldots,N-\mu, \quad \textit{if } \nu=0 \textit{ or } \nu=5 \textit{ and } N\geqslant 5, \tag{32a}$$

$$2,3,4,4-\mu,5-\mu,\ldots,N-1-\mu, \quad \textit{if } \nu=4 \textit{ and } N\geqslant 5, \tag{32b}$$

and the $N-4$ *eigenvalues*

$$-1,4,6,8-\mu,9-\mu,\ldots,N-\mu, \quad \textit{if } \nu=1 \textit{ and } N\geqslant 8, \tag{32c}$$

$$-1,4,6,3-\mu,4-\mu,\ldots,N-5-\mu, \quad \textit{if } \nu=3 \textit{ and } N\geqslant 8. \tag{32d}$$

Remark 2.18: The Conjecture 2.17—in contrast to the Conjecture 2.15—does *not* provide the *entire* spectrum of the eigenvalue problem (29a), which of course features $2N$ eigenvalues.

Some aspects of these conjectures are easy to prove. For instance Conjecture 2.15 can be proven by induction for all $N>\mu$ if one assumes its validity for $N=\mu$. But complete proofs of them do not seem quite trivial (see Sec. VI).

III. TWO PROOFS OF PROPOSITION 2.3

In this section (part of) the results reported in the Sec. II are proven, first by the *direct* method, then by the *gauge theory* method.

A. Direct method

The starting point of the *direct* method is the *solvable* $N\times N$ matrix evolution equation (2). We then introduce the eigenvalues of the matrix $U(t)$ and the corresponding diagonalizing matrix $R(t)$ via the formulas

$$U(t)=R(t)Z(t)[R(t)]^{-1}, \tag{33a}$$

$$Z(t)=\mathrm{diag}[z_n(t)], \tag{33b}$$

with moreover

$$R(0)=\mathbf{1}. \tag{33c}$$

Here and in the following $\mathbf{1}$ is the $N\times N$ identity matrix. Note that the first two of these equations, (33a) and (33b), identify (consistent with Proposition 2.3) the N coordinates $z_n(t)$ as the N eigenvalues of the $N\times N$ matrix $U(t)$, while the third, (33c), is consistent via the first two with the assignment (3a).

It is then easy to see (for the derivation of these formulas see, if need be, for instance Ref. 2) that, after introducing the $N\times N$ matrix $M(t)$ via the assignment

$$M(t)=[R(t)]^{-1}\dot{R}(t), \tag{34}$$

one gets

$$\dot{U}(t)=R(t)\{\dot{Z}(t)+[M(t),Z(t)]\}[R(t)]^{-1}, \tag{35a}$$

entailing (see (33c))

$$\dot{U}(0)=\dot{Z}(0)+[M(0),Z(0)], \tag{35b}$$

as well as the following system of evolution ODEs for the coordinates $z_n(t)$ and for the matrix elements $M_{nm}(t)$ of the matrix $M(t)$:

$$\ddot{z}_n=2z_n(z_n^2-a^2)+2\sum_{m=1,m\neq n}^{N}(z_n-z_m)M_{nm}M_{mn}, \tag{36a}$$

$$\frac{\dot{M}_{nm}}{M_{nm}}=-2\frac{\dot{z}_n-\dot{z}_m}{z_n-z_m}-M_{nn}+M_{mm}+\sum_{\ell=1;\ell\neq n,m}^{N}\frac{(z_n+z_m-2z_\ell)}{z_n-z_m}\frac{M_{n\ell}M_{\ell m}}{M_{nm}},\quad n\neq m. \tag{36b}$$

Note that the time evolutions of the *diagonal* elements $M_{nn}(t)$ of the matrix $M(t)$ remain unrestricted: it is indeed clear from (33) (implying that $R(t)$ is defined only up to multiplication from the right by an *arbitrary* diagonal matrix $D(t)$) and from (34) that these N functions of time can be chosen arbitrarily without affecting the eigenvalues of $U(t)$, namely the coordinates $z_n(t)$. Indeed it is clear that the $N\times N$ matrix evolution equation (2), characterizing the time evolution of the N^2 matrix elements $M_{nm}(t)$, has now been turned into the system (36), characterizing the time evo-

lution of the N coordinates $z_n(t)$ and the $N(N-1)$ *off-diagonal* elements $M_{nm}(t)$ (with $n \neq m$) of the $N \times N$ matrix $M(t)$.

Clearly this system (36) is *no less solvable* than the original matrix evolution (2), because its solution can be retrieved from the solution of (2) by purely algebraic operations (essentially, by diagonalizing an $N \times N$ matrix).

But we are interested in obtaining an N-body problem involving *only* the N "particle coordinates" $z_n(t)$, hence our next task is to eliminate the $N(N-1)$ "auxiliary quantities" $M_{nm}(t)$ (with $n \neq m$). To do this one must find (assuming it exists) an appropriate *ansatz* expressing the $N(N-1)$ auxiliary quantities $M_{nm}(t)$ (with $n \neq m$) in terms of the N particle coordinates $z_n(t)$, taking advantage if need be of the freedom to assign the N quantities $M_{nn}(t)$ at our convenience.

An *ansatz* that works (in the sense of turning the $N(N-1)$ evolution equations (36b) into identities) is

$$M_{nn}(t) = -\sum_{\ell=1}^{N} \frac{g}{[z_n(t) - z_\ell(t)]^2}, \tag{37a}$$

$$M_{nm}(t) = \frac{g}{[z_n(t) - z_m(t)]^2}, \quad n \neq m, \tag{37b}$$

with g an *arbitrary constant*. This leads however to an N-body model the *solvable* character of which is already well known,[9,13,3,12] hence we do not pursue this development here (we elaborate on this point a little further in the following version of the proof).

Remark 3.1: Clearly insertion of this *ansatz* (37) in the more general matrix evolution equation

$$\ddot{U} = \Phi(U), \tag{38a}$$

with $\Phi(z)$ an *arbitrary* scalar function would also work (since this does not depend on the equations of motion satisfied by the coordinates z_n, see the following), and it would lead to the N-body problem characterized by the Newtonian equations of motion

$$\ddot{z}_n = \Phi(z_n) - 2\sum_{n=1, m\neq n}^{N} \frac{g^2}{(z_n - z_m)^3}. \tag{38b}$$

This was already noted, many years ago, by Veselov.[12] But it appears that, so far, the most general (up to trivial transformations) *solvable* $N \times N$ matrix evolution of type (38a) is just (2).

Another *ansatz* that also does (as it were *miraculously*) work (namely, transform the evolution equations (36b) into identities) reads as follows:

$$M_{nm}(t) = -\frac{\{[\dot{z}_n + z_n^2 - a^2][\dot{z}_m + z_m^2 - a^2]\}^{1/2}}{z_n - z_m}, \quad n \neq m. \tag{39}$$

Note that this *ansatz,* in contrast to the previous one, contains no arbitrary ("coupling") constant g. In this case the appropriate assignment for the diagonal elements $M_{nn}(t)$ is quite trivial: $M_{nn}(t) = 0$, or equivalently (see (36b)) $M_{nn}(t) = \mu(t)$, $\mu(t)$ being an arbitrary function of time (but independent of the index n). The truth of this assertion can be verified by a trivial if tedious calculation: note that the evolution equations (36a) must also be used in the process.

And it is now clear that the insertion of this *ansatz* in (36a) yields (1), while its insertion in (35b) yields the assignment (3b). The proof of Proposition 2.3 is thus completed.

B. Gauge theory approach

Let us now prove again Proposition 2.3, but via the *gauge theory* method. Although this entails some repetitions we believe it is useful to go through this exercise in some detail, especially because we will now use a somewhat different language—and one purpose of this paper is precisely to clarify the relations among these two different approaches. Moreover this presentation provides some indication of the extent to which these kinds of fishing expeditions are likely to yield new goldfishes, namely new interesting *solvable* models.

Let us start by reviewing (but in a notation more conducive to a direct comparison with the preceding treatment) the gauge theory approach to a more standard model referred to in the literature as rCM[1,11] characterized by the Newtonian equations of motion

$$\ddot{z}_n = -z_n - 2\sum_{m=1,m\neq n}^{N} \frac{g^2}{(z_n - z_m)^3}. \tag{40}$$

We then present a variant of this approach which leads us to the new *solvable N*-body model of goldfish type presented earlier.

We start with the following system of dynamical equations for the $N\times N$ matrices $U\equiv U(t)$, $M\equiv M(t)$, and $W\equiv W(t)$:

$$\dot{U} + [M,U] = W, \tag{41a}$$

$$\dot{W} + [M,W] = \Phi(U), \tag{41b}$$

with the square brackets indicating matrix commutators. As discussed in the following, to get the rCM model one should assign the function $\Phi(U)$ as follows:

$$\Phi(U) = -U. \tag{42}$$

It is however convenient to leave this function Φ unspecified for the moment; but we require that it contain no other matrix besides U, so that $R^{-1}\Phi(U)R=\Phi(R^{-1}UR)$ for any (invertible) matrix R.

Equation (41) has a natural interpretation as gauge theory in $0+1$ dimensions: they are indeed of the form $[D_t,U]=P$, $[D_t,P]=\Phi(U)$, with $D_t=\partial_t+M$ being the so-called *covariant time derivative* with M regarded as *gauge field*. In particular, they are invariant under the following *gauge transformations*,

$$U \to \tilde{U} = R^{-1}UR, \quad W \to \tilde{W} = R^{-1}WR, \tag{43a}$$

$$M \to \tilde{M} = R^{-1}MR + R^{-1}\dot{R}, \tag{43b}$$

where the matrix $R\equiv R(t)$ characterizing the gauge transformation is an arbitrarily time-dependent invertible matrix (the transformation rule for M follows from $R^{-1}D_tR=\partial_t+R^{-1}\dot{R}+R^{-1}MR$). One can exploit this invariance to impose additional conditions. In particular for any solution $U(t)$, $M(t)$, and $W(t)$ of (41), one can find a gauge transformation $R(t)$ such that the gauge-transformed matrix $\tilde{M}(t)$, see (43b), vanishes, $\tilde{M}(t)=0$. Indeed, this is implied by the fact that the linear first-order matrix ODE

$$\dot{R} + MR = 0, \quad R(0) = \mathbf{1} \tag{44a}$$

always has a (unique) solution, which can be written as

$$R(t) = \mathcal{T}\exp\left[-\int_0^t \mathrm{d}s\, M(s)\right] \tag{44b}$$

where the symbol $\mathcal{T}$ denotes time-ordering. This shows that we can impose the condition

$$M(t) = 0 \tag{45}$$

for all times t, without loss of generality. Note that this also implies that, if we impose (45), we will not lose any solution: indeed any solution to our gauge theory equations can be obtained by solving these equations with the condition (45) imposed, and performing a gauge transformation afterwards. In particle physics this latter condition is often called *Weyl gauge*. We will also use another gauge condition, namely

$$U_{nm}(t) = \delta_{nm} z_n(t) \tag{46}$$

for all times t, which we call *diagonal Coulomb gauge*. Note that we can impose this latter condition if the matrix $U(t)$ is such that there exists an invertible matrix $R(t)$ such that $R^{-1}(t)U(t)R(t)$ is a *diagonal* matrix, and this is obviously true in the generic case when the matrix $U(t)$ is nondegenerate. The cases when the matrix $U(t)$ is degenerate correspond to particles in our N-body system colliding, and then our solution breaks down (as it should): but this can only happen for exceptional—i.e., *nongeneric*—initial data, if we allow the particle coordinates $z_n(t)$ to move in the complex plane, as we generally do (see *Remark 2.2*).

The idea now is that, by imposing the gauge condition (45), we get the matrix equation $\ddot{U} = \Phi(U)$ which might be (chosen to be) exactly solvable, whereas by imposing the condition (46), we get a (hopefully) interesting dynamical system for the variables $z_n(t)$. The latter dynamical system can then be solved explicitly as follows: one first determines the solution $U(t)$ of the matrix equation obtained from (41) in the Weyl gauge and with the initial conditions

$$U_{nm}(0) = \delta_{nm} z_n(0), \quad \dot{U}_{nn}(0) = \dot{z}_n(0). \tag{47}$$

Then the eigenvalues of $U(t)$ give the solution of the dynamical system. Note that we can only assign the *diagonal* elements of $\dot{U}(0)$ since, as we will see, the *off-diagonal* elements of $\dot{U}(0)$ are determined by another condition which we have to add.

Indeed, to get an interesting dynamical system, we need to add one more gauge invariant equation to (41). In particular, to get the rCM model (40), one has to add

$$[W, U] = J, \tag{48}$$

which is often called *Gauss law* or *momentum map*. This latter equation is gauge invariant if the matrix $J=J(t)$ introduced here transforms under gauge transformations as $J \to \widetilde{J} = R^{-1}JR$. It turns out indeed[1,11] that if one makes the assignment

$$J_{nm}(0) = g(1 - \delta_{nm}) \tag{49}$$

and chooses $\Phi(U)$ as in (42), then the coordinates $z_n(t)$ obey the equations of motion of the rCM model (40).

To obtain goldfish type dynamical systems one must instead replace the Gauss' law condition (48) by

$$B_{nm}B_{n'm'} = B_{nm'}B_{n'm} \tag{50a}$$

with

$$B = W + f(U), \tag{50b}$$

where $f(x)$ is another function to be assigned later. To see that this condition is gauge invariant we note that it can be written as $B \otimes B = \mathcal{P}B \otimes B$ where $\otimes$ is the tensor product (so that $(B \otimes B)(u$

$\otimes v)=(Bu)\otimes(Bv)$ where u and v are N-vectors) and $\mathcal{P}$ is the permutation matrix defined as follows, $\mathcal{P}u\otimes v=v\otimes u$: the gauge invariance of (50a) follows from the obvious fact that $\mathcal{P}$ commutes with $R\otimes R$.

A new finding (proved at the end of this section) is then given by the following.

Proposition 3.2: *The gauge theory equations (41) and (50) are consistent if*

$$f(x)=\alpha+\beta x+\gamma x^2, \tag{51a}$$

$$\Phi(x)=(\alpha+\beta x+\gamma x^2)(\beta+2\gamma x)=f(x)f'(x), \tag{51b}$$

for arbitrary constants α,β,γ. *Imposing the diagonal Coulomb gauge (46) these equations imply*

$$\ddot{z}_n=\Phi(z_n)+\sum_{m=1,m\neq n}^{N}\frac{[\dot{z}_n+f(z_n)][\dot{z}_m+f(z_m)]}{z_n-z_m}, \tag{52}$$

and thus the solution of the initial-value problem for this dynamical system can be obtained by solving the corresponding gauge theory equations in the Weyl gauge, see (45). More specifically: the solution of the initial-value problem for this dynamical system, (52), is given by the eigenvalues of the matrix equation

$$\ddot{U}=\Phi(U) \tag{53}$$

with the initial conditions

$$U_{nm}(0)=\delta_{mn}z_n(0) \tag{54}$$

and

$$\dot{U}_{nn}(0)=\dot{z}_n, \tag{55a}$$

$$\dot{U}_{nm}(0)=\{[\dot{z}_n(0)+f[z_n(0)]\}^{1/2}\{[\dot{z}_m(0)+f[z_m(0)]\}^{1/2},\quad n\neq m. \tag{55b}$$

Remark 3.3: In the special case $\gamma=0$ a model is obtained whose solvability was already known.[8] Our new model reported in Sec. II (and already derived by our other method in Sec. III A) is obtained for $\beta=0$, $\gamma=1$, and $\alpha=-a^2$. But the greater generality of the result as formulated in Proposition 3.2 is only apparent: if $\gamma\neq 0$, one can always reduce this more general case to the special case with $\beta=0$ by the (rather trivial) transformations $U\to\breve{U}=U-(\beta/2\gamma)\mathbf{1}$, $t\to\breve{t}=\gamma t$. And note that, for $f(z)=z^2-a^2$, the right-hand sides of (55) and (3b) coincide: the apparent differences are merely notational.

Let us end this section by outlining the proof of this result, whose analogy with that proven in the first part of this section is we trust evident enough not to require further elaboration. We first write out (41) and (50) by imposing condition (45). Then (41a) becomes

$$\delta_{nm}\dot{z}_n+M_{nm}(z_m-z_n)=W_{nm}, \tag{56}$$

which for the *diagonal* elements (i.e., $n=m$) implies

$$W_{nn}=\dot{z}_n. \tag{57}$$

For the *off-diagonal* elements we obtain the assignment

$$M_{nm}=-\frac{1}{z_n-z_m}W_{nm},\quad n\neq m, \tag{58}$$

whereas the diagonal elements M_{nn} remain unassigned. Then (41b) reads

$$\dot{W}_{nm} + \sum_{\ell=1}^{N} (M_{n\ell} W_{\ell m} - W_{n\ell} M_{\ell m}) = \delta_{nm} \Phi(z_n). \tag{59}$$

The *diagonal* elements of this equation give (via (58) and (57))

$$\ddot{z}_n - 2 \sum_{\ell=1, \ell \neq n}^{N} \frac{W_{n\ell} W_{\ell n}}{z_n - z_\ell} = \Phi(z_n), \tag{60}$$

while the *off-diagonal* elements imply the following important consistency conditions,

$$W_{nm} + (M_n - M_m)\dot{W}_{nm} + \frac{\dot{z}_n - \dot{z}_m}{z_n - z_m} W_{nm} - \sum_{\ell=1, \ell \neq n,m}^{N} W_{n\ell} W_{\ell m} \left(\frac{1}{z_n - z_\ell} - \frac{1}{z_\ell - z_m} \right) = 0, \quad n \neq m. \tag{61}$$

In particular (50a) implies $B_{nm}B_{mn} = B_{nn}B_{mm}$. Inserting in this equation the assignment $B_{nm} = W_{nm} + \delta_{nm} f(z_n)$ (see (50b)) and in particular $B_{nn} = \dot{z}_n + f(z_n)$ (see (57)), we get

$$W_{nm} W_{mn} + \delta_{nm} [2\dot{z}_n + f(z_n)] f(z_n) = [\dot{z}_n + f(z_n)][\dot{z}_m + f(z_m)]. \tag{62}$$

Thus the solution of (50) for $n' = m$ and $m' = n$ is

$$W_{nm} = \exp(\varphi_n - \varphi_m) \{ - \delta_{nm} [2\dot{z}_n + f(z_n)] f(z_n) + [\dot{z}_n + f(z_n)][\dot{z}_m + f(z_m)] \}^{1/2}, \tag{63}$$

where the functions $\varphi_n(t)$ are *arbitrary*, and it is easy to check that this is a solution of (50) also for all the other values of n', m'. Inserting this in (60) we obtain

$$\ddot{z}_n = \Phi(z_n) + 2 \sum_{\ell=1, \ell \neq n}^{N} \frac{[\dot{z}_n + f(z_n)][\dot{z}_\ell + f(z_\ell)]}{z_n - z_\ell}. \tag{64}$$

It remains to check the consistency relations (61). We note that, for $\ell \neq n, m$ and $n \neq m$, (63) entails $W_{n\ell} W_{\ell m} = W_{nm} [\dot{z}_\ell + f(z_\ell)]$, hence (61) is implied by

$$\frac{\dot{W}_{nm}}{W_{nm}} = - (M_n - M_m) - \frac{\dot{z}_n - \dot{z}_m}{z_n - z_m} + \sum_{\ell=1, \ell \neq n,m}^{N} [\dot{z}_\ell + f(z_\ell)] \left(\frac{1}{z_n - z_\ell} - \frac{1}{z_\ell - z_m} \right), \quad n \neq m. \tag{65}$$

Inserting the logarithmic derivative of (63) for $n \neq m$ and using (64) we find by straightforward computations that the condition (61) is identically satisfied provided

$$\dot{\varphi}_n = - M_n \tag{66}$$

and the functions f and Φ satisfy the following functional equations,

$$f'(x) + f'(y) = 2 \frac{f(x) - f(y)}{x - y}, \quad \Phi(x) = f(x) f'(x), \tag{67}$$

for all $x \neq y$. The general solution of these functional equations is given by (51), and this concludes our proof. Note that at the end we can make the simplifying assignment $\varphi_n = M_n = 0$.

IV. ALTERNATIVE FORMULATIONS

The strategy to obtain alternative formulations of "goldfish-type" N-body problems is by now standard (and quite old;[6] for a convenient up-to-date presentation see Ref. 2). One introduces a *monic* polynomial $\psi(z,t)$ of degree N in z, the N zeros $z_n(t)$ of which evolve according to the equations of motion of the N-body problem under consideration, and then investigates the corresponding evolution of the N coefficients $c_m(t)$ of this polynomial. The route we follow to obtain the equations of motions satisfied by the coefficients $c_m(t)$—equations that are of course no less

solvable than the equations of motion satisfied by the zeros $z_n(t)$, since the relationship among these quantities, the N zeros z_n and the N coefficients c_m of a polynomial of degree N, is purely *algebraic*—is via the evolution equation satisfied by the polynomial $\psi(z,t)$: note that this entails that this evolution equation is itself *solvable*. Since this technique is by now standard, and appropriate formulas to implement it are available (see in particular the Appendix in Ref. 2), we present without further ado the relevant results.

The evolution equation satisfied by the polynomial $\psi(z,t)$ (see (13)) the zeros of which evolve according to the equations of motion (1) reads

$$\psi_{tt} - 2(z^2-a^2)\psi_{tz} + 2[(N-2)z - c_1]\psi_t + (z^2-a^2)^2\psi_{zz} - 2[(N-3)z - c_1](z^2-a^2)\psi_z + \{N(N-5)z^2 - 2(N-2)c_1 z + 2[2Na^2 + \dot{c}_1 - c_1^2 + 3c_2]\}\psi = 0. \tag{68}$$

Notation: Here and hereafter subscripted variables denote partial differentiations with respect to them.

Remark 4.1: This evolution equation, (68), contains also certain coefficients $c_m \equiv c_m(t)$, which are obviously (linearly) related to the function $\psi(z,t)$, indeed clearly (see (13))

$$c_m(t) = [(N-m)!]^{-1} \left.\frac{\partial^{N-m}\psi(z,t)}{\partial z^{N-m}}\right|_{z=0}. \tag{69}$$

Hence (68) is in fact a nonlinear functional equation satisfied by the polynomial $\psi(z,t)$, and the fact that it is indeed satisfied by a polynomial of degree N in z, while not evident, is implied by the way it has been obtained.

From this evolution equation one obtains (using if need be the results in Ref. 2) the corresponding system of ODEs satisfied by the coefficients $c_m(t)$, see (14); and this of course justifies the relevant results about the solvability of this system reported in Sec. II.

Exactly the same procedure yields (21) from (6), although a more direct route is via the "trick" formula (5), as indicated in Sec. II. Anyway we also display here, for completeness, the equation for the polynomial $\tilde{\psi}(z,t)$ (see (22)) that provides the bridge connecting these two systems of ODEs (deriving this equation is particularly easy using the formulas given in the Appendix in Ref. 2; but beware of the slight notational change in the definition of the coefficients c_m due to the $(i)^m$ factor on the right-hand side of (22)):

$$\tilde{\psi}_{tt} - 2z(z-i)\tilde{\psi}_{tz} + [2(N-2)z - (2N+1)i - 2i\tilde{c}_1]\tilde{\psi}_t + z^2(z-i)^2\tilde{\psi}_{zz} - 2z(z-i)[N(z-i) - 3z - i\tilde{c}_1]\tilde{\psi}_z + [N(N-5)z^2 - 2N^2 iz - N(N+1) - 2(N-2)i\tilde{c}_1 z - 2(N-1)\tilde{c}_1 + 2(i\cdot\tilde{c}_1 + \tilde{c}_1^2 - 3\tilde{c}_2)]\tilde{\psi} = 0. \tag{70}$$

V. EQUILIBRIUM CONFIGURATIONS, BEHAVIOR IN THEIR VICINITY, *DIOPHANTINE* RELATIONS

In this section we discuss the equilibrium configurations (namely, the time-independent solutions) of the *isochronous* models (6) and (21) and the behavior of these models in the vicinity of their equilibria. A motivation for focusing on the *isochronous* models is that they lead to the remarkable *Diophantine* relations reported at the end of Sec. II, as indicated below.

Clearly the equilibrium configuration $\tilde{c}_m(t) = \bar{c}_m$, $\dot{c}_m(t) = 0$ of the system of ODEs (21) is characterized by the following system of N algebraic equations:

$$-(m+2)(m-3)\bar{c}_{m+2} + 2(m-1)(m+1+\bar{c}_1)\bar{c}_{m+1} + [-m(m+1) - 2(m-1)\bar{c}_1 + 2\bar{c}_1^2 - 6\bar{c}_2]\bar{c}_m = 0,$$

$$m = 1, \ldots, N, \quad \bar{c}_0 = 1, \quad \bar{c}_{-1} = \bar{c}_{N+1} = \bar{c}_{N+2} = 0. \tag{71}$$

Likewise the equilibrium configuration $\tilde{z}_n(t) = \bar{z}_n$, $\dot{\tilde{z}}_n = 0$, of the N-body problem (6) is characterized by the following N algebraic equations:

$$\bar{z}_n(\bar{z}_n - i)\left[\bar{z}_n + i + \sum_{m=1, m\neq n}^{N} \frac{\bar{z}_m(\bar{z}_m - i)}{\bar{z}_n - \bar{z}_m}\right] = 0. \tag{72}$$

These two configurations are related to each other by the polynomial formula (see (22))

$$\bar{\psi}(z) = \prod_{n=1}^{N} (z - \bar{z}_n) = \sum_{n=0}^{N} (i)^m \bar{c}_m z^{N-m}, \quad \bar{c}_0 = 1, \tag{73}$$

where $\bar{\psi}(z)$ is the "equilibrium" (namely, time-independent) polynomial solution of (70).

The general solution of the algebraic problem (72) can clearly be broken down as follows:

$$\bar{z}_n + i + \sum_{m=1, m\neq n}^{\nu} \frac{\bar{z}_m(\bar{z}_m - i)}{\bar{z}_n - \bar{z}_m} = 0 \quad \text{for } n = 1, \ldots, \nu, \tag{74a}$$

$$\bar{z}_n = i \quad \text{for } n = \nu + 1, \ldots, \mu, \tag{74b}$$

$$\bar{z}_n = 0 \quad \text{for } n = \mu + 1, \ldots, N, \tag{74c}$$

with ν and μ *non-negative integers*, $0 \leqslant \nu \leqslant \mu \leqslant N$. Of course each of these three sectors will be empty if the corresponding range of values of n is empty (recall that $n = 1, \ldots, N$).

Remark 5.1: In any equilibrium configuration the labeling of the particles can be freely permuted. To write the breakdown (74) we identified, without loss of generality, a (somewhat) definite assignment of particle labels.

Remark 5.2: Genuine equilibrium configurations of the N-body problem (6) are characterized by the requirement that $\bar{z}_n \neq \bar{z}_m$ if $n \neq m$: indeed, whenever this condition is violated, the equilibrium condition (72) becomes *ambiguous* due to the vanishing of some denominator in the sum, compensated by a vanishing of the corresponding numerator or by some other cancellation. Hence a *necessary* condition in order that the configuration associated with the breakdown indicated in (74) correspond to a *genuine* equilibrium configuration of the N-body problem (6) is that $\mu \geqslant N - 1$ and $\nu \geqslant \mu - 1$, so that at most one of the $\bar{z}_n$'s vanishes (in which case we assign to it the highest label, $\bar{z}_N = 0$) and at most one takes the value i (in which case we assign to it the highest or next-to-highest label, $\bar{z}_N = i$, or $\bar{z}_{N-1} = i$ if $\bar{z}_N = 0$). But in the following it is convenient to consider *all* possible equilibrium configurations, including *nongenuine* ones, because, as we will see, such configurations, while problematic to deal with in the context of the N-body problem (6), correspond to equilibrium configurations $\bar{c}_m$ of the system of ODEs (21) which are instead perfectly legitimate in the context of this *nonlinear harmonic oscillators* model. Indeed their consideration in such a context yields interesting findings (see the following).

To get more information on the roots $\bar{z}_n$ of (74a) we now introduce a *monic* polynomial $\varphi(z)$ of degree ν having the ν numbers $\bar{z}_n$ with $n = 1, \ldots, \nu$ as its zeros:

$$\varphi(z) = \prod_{n=1}^{\nu} (z - \bar{z}_n) = \sum_{m=0}^{\nu} (i)^m \varphi_m z^{\nu-m}, \quad \varphi_0 = 1. \tag{75}$$

Note that via this formula we also introduced the ν coefficients φ_m of this polynomial.

It is now straightforward (and particularly easy using the formulas given in the Appendix in Ref. 2; but beware of the slight notational change in the definition of the coefficients $\bar{c}_m$ due to the $(i)^m$ factor on the right-hand side of (75)) to conclude that this polynomial must then satisfy the following equation, implied by (74a):

$$z^2\varphi'' - 2(\nu - 3)z\varphi' + \nu(\nu - 5)\varphi = i[z\varphi'' - 2(\nu + \varphi_1)\varphi']. \tag{76}$$

It is now easily seen that, via (75), this ODE (76) yields for the coefficients φ_m the recurrence relation

$$m(m-5)\varphi_m = (m-\nu-1)(m+\nu+2\varphi_1)\varphi_{m-1}, \tag{77a}$$

which must be complemented by the two extremal conditions (see (75))

$$\varphi_{-1} = \varphi_{\nu+1} = 0 \tag{77b}$$

and by the normalization condition (see (75))

$$\varphi_0 = 1. \tag{77c}$$

Clearly the two extremal conditions (77b) are identically satisfied (for $m=0$, respectively, $m=\nu+1$), while the condition (77c) yields (for $m=1$)

$$\varphi_1 = \frac{\nu(\nu+1)}{2(2-\nu)}, \tag{78}$$

entailing the requirement (hereafter assumed to hold)

$$\nu \neq 2. \tag{79}$$

Insertion of (78) in (77a) yields finally the recursion

$$m(m-5)\varphi_m = (m-\nu-1)\left(m+\frac{3\nu}{2-\nu}\right)\varphi_{m-1}, \tag{80}$$

the solution of which is easily seen to exist only if $\nu \leqslant 5$. For the remaining cases,

$$\nu = 0 \text{ or } 1 \text{ or } 3 \text{ or } 4 \text{ or } 5, \tag{81}$$

see (79), we get the following solutions (recall (77c)):

$$\text{for } \nu = 0, \quad \varphi(z) = \varphi_0 = 1, \tag{82a}$$

$$\text{for } \nu = 1, \quad \varphi_0 = \varphi_1 = 1, \quad \varphi(z) = z + i, \tag{82b}$$

$$\text{for } \nu = 3, \quad \varphi_0 = 1, \quad \varphi_1 = -6, \quad \varphi_2 = 14, \quad \varphi_3 = -14, \tag{82c}$$

$$\text{for } \nu = 4, \quad \varphi_m = (-)^m \binom{5}{m}, \quad m = 0,1,\ldots,4, \tag{82d}$$

$$\text{for } \nu = 5, \quad \varphi_m = (-)^m \binom{5}{m}, \quad m = 0,1,\ldots,4, \quad \varphi_5 \text{ arbitrary}. \tag{82e}$$

Via (74) and (75) it is clear that the *monic* polynomial $\bar{\psi}(z)$ of degree N in z, see (73)—which identifies as its N zeros $\bar{z}_n$, respectively, its N coefficients $\bar{c}_m$ the equilibrium configurations of the models (6), respectively, (21)—is given by the formula

$$\bar{\psi}(z) = \varphi(z)(z-i)^{\mu-\nu} z^{N-\mu}. \tag{83}$$

It is thereby seen, via (82), that the coefficients $\bar{c}_m$ are given by the formulas (28) (with the *arbitrary* constant $c=\varphi_5-1$ in (28e), see (28e)).

Remark 5.3: Clearly the coefficients $\bar{c}_m$ vanish for $m>\mu$, hence they *all* vanish (except of course $\bar{c}_0=1$) if $\mu=0$ (this assignment provides indeed a solution of (71)).

Next, let us discuss the behavior of the system (21) in the neighborhood of its equilibrium configurations. To this end we set

$$\tilde{c}_n(t) = \bar{c}_n + \varepsilon\rho_n(t) + O(\varepsilon^2), \tag{84}$$

with $\bar{c}_m$ the coefficients c_m at equilibrium (as determined in the following) and ε a small parameter. We thereby obtain in the standard manner the *linearized* equations of motion

$$\ddot{\rho}_m + 2(m-1)i\dot{\rho}_{m+1} - (2m+1+2\bar{c}_1)i\dot{\rho}_m - (m+2)(m-3)\rho_{m+2} + 2(m-1)(m+1+\bar{c}_1)\rho_{m+1} + [-m(m+1) - 2(m-1)\bar{c}_1 + 2\bar{c}_1^2 - 6\bar{c}_2]\rho_m + 2i\bar{c}_m\dot{\rho}_1 + 2[(m-1)\bar{c}_{m+1} - (m-1-2\bar{c}_1)\bar{c}_m]\rho_1 - 6\bar{c}_m\rho_2 = 0,$$

$$m = 1, \ldots, N, \quad \rho_0 = 0, \quad \rho_{N+1} = \rho_{N+2} = 0. \tag{85}$$

The general solution of this linear system of ODEs, (85), reads

$$\rho_m(t) = \sum_{n=1}^{N} [a_n^{(+)} r_m^{(+)(n)} \exp(ip_n^{(+)}t) + a_n^{(-)} r_m^{(-)(n)} \exp(ip_n^{(-)}t)], \tag{86}$$

where the $2N$ numbers $a_n^{(\pm)}$ are *arbitrary* (to be fixed by the initial data) while the $2N$ numbers $p_n^{(\pm)}$, respectively, the $2N$ corresponding (t-independent) N-vectors $\underline{r}^{(\pm)(n)} \equiv (r_1^{(\pm)(n)}, \ldots, r_N^{(\pm)(n)})$, are the eigenvalues, respectively, the eigenvectors, of the (N-vector) generalized eigenvalue equation (29a). This implies (29b) with the two $N \times N$ matrices A and B defined (componentwise) by the formulas (27). But we know (see Proposition 2.13) that *all* the *nonsingular* solutions of the system of *nonlinear harmonic oscillators* (21) are *completely periodic* with period 2π, hence the (certainly *nonsingular*) solutions describing the behavior of this system around equilibrium must have the same periodicity property, implying that *all* the eigenvalues $p_n^{(\pm)}$ yielded by the generalized eigenvalue problem (29a) must be *integers.* And this entails the validity of Proposition 2.14.

Remark 5.4: In the special case of the equilibrium configuration $\bar{c}_m = 0$ (for $m = 1, \ldots, N$, while of course $\bar{c}_0 = 1$; see the *Remark 5.3*), the matrices A and B become *triangular* and the computation of the eigenvalues $p_n^{(\pm)}$ is then a trivial task, yielding

$$p_n^{(+)} = n + 1, \quad p_n^{(-)} = n. \tag{87}$$

VI. OUTLOOK

It is remarkable that a research project started with the main purpose to clarify a methodological issue—namely, the relationship among two different approaches to the same question: that of identifying *solvable* many-body problems—resulted in the identification of a *novel* solvable many-body problem. To the readers who might imagine—in view of the recent discovery of several such new models, as reviewed in Ref. 2—that this is a relatively trivial task, we suggest to try and find themselves some new model. Our educated guess is that such a task is quite challenging. We are nevertheless ourselves hopeful that new many-body models exist, and that they might be discovered/manufactured by the techniques described in this paper. In any case this possibility remains as a tantalizing prospect, until a way is found to ascertain conclusively that these approaches have exhausted their capability to yield many-body models of the kind investigated herein which are both new and interesting (although the second of these two qualities involves of course a value judgment).

Another research direction (perhaps suitable as a PhD project) is toward proving the *Diophantine* conjectures proffered in this paper (see the end of Sec. II) and in previous ones (see Ref. 2) and other papers referred to there), as well as obtaining additional findings of this kind (for instance by applying techniques analogous to those of Sec. V to the model (14), taking advantage of the results reported in the Appendix).

ACKNOWLEDGMENTS

We gratefully acknowledge financial support by the European Union project RTN "Enigma" and the "Göran Gustafsson Foundation" which made possible a two-week visit to Sweden in February 2006 by F.C. when the results reported in this paper emerged. F.C. would also like to thank the Japan Society for the Promotion of Science (JSPS) and the Yukawa Institute at Kyoto University, in particular Ryu Sasaki, for the pleasant hospitality during a six-week visit to Japan in March-April 2006, when this work was (almost) completed. It is moreover a pleasant duty to acknowledge with thanks the assistance provided to F.C. by Ryu Sasaki by performing some computer-aided checks, by Andrea La Malfa with the handling of MATHEMATICA, and by V. I. Inozemtsev with useful suggestions concerning references. E.L. is supported by the Swedish Science Research Council (VR).

APPENDIX: EQUILIBRIUM CONFIGURATIONS OF MODELS (14) AND (1)

In *Remark 2.9* it was mentioned that there exist additional equilibrium (i.e., time-independent) solutions of the model (14) besides (16). In this appendix we first list *all* these equilibrium configurations (as obtained via MAPLE) for $N=2$, 3, 4, and 5. We then outline a technique allowing one to obtain *all* the equilibrium configurations for *arbitrary N* (we of course did check that these findings reproduce, for $N=2,3,4,5$, those obtained via MAPLE).

These equilibrium configurations are clearly solutions of the following set of N algebraic equations (see (14)):

$$(m+2)(m-3)c_{m+2}-2(m-1)c_1c_{m+1}+2[m(N+2-m)a^2-c_1^2+3c_2]c_m-2(N+1-m)a^2c_1c_{m-1}$$
$$+(N+2-m)(N+1-m)a^4c_{m-2}=0,$$

$$m=1,\ldots,N,\quad c_0=1,\quad c_{-1}=c_{N+1}=c_{N+2}=0. \tag{A1}$$

The following solutions of this algebraic system have been obtained via MAPLE.

For $N=2$

$$c_1=0,\quad c_2=-a^2, \tag{A2a}$$

or

$$c_2=\frac{c_1^2}{3}-\frac{a^2}{3},\quad c_1 \text{ arbitrary} \tag{A2b}$$

(the equilibrium configurations (16) correspond to the latter one, (A2b), with $c_1=\pm 2a$).

For $N=3$,

$$c_2=\frac{c_1^2}{3}\pm\frac{ac_1}{3}-a^2,\quad c_3=\pm\frac{ac_1^2}{3}-\frac{2a^2c_1}{3},\quad c_1 \text{ arbitrary} \tag{A3}$$

(the equilibrium configurations (16) obtain for $c_1=\pm 3a$).

For $N=4$,

$$c_2=\frac{c_1^2}{3}-\frac{4a^2}{3},\quad c_3=-a^2c_1,\quad c_4=-\frac{a^2c_1^2}{3}+\frac{a^4}{3},\quad c_1 \text{ arbitrary}, \tag{A4a}$$

or

$$c_2 = \frac{c_1^2}{3} \pm \frac{2ac_1}{3} - 2a^2, \quad c_3 = \pm \frac{2ac_1^2}{3} - \frac{5a^2c_1}{3},$$

$$c_4 = \frac{a^2c_1^2}{3} \mp \frac{4a^3c_1}{3} + a^4, \quad c_1 \text{ arbitrary} \tag{A4b}$$

(the equilibrium configurations (16) obtain from (A4b) for $c_1 = \pm 4a$.

For $N=5$,

$$c_2 = \frac{c_1^2}{3} \pm \frac{ac_1}{3} - 2a^2, \quad c_3 = \pm \frac{ac_1^2}{3} - \frac{5a^2c_1}{3}, \quad c_4 = -\frac{a^2c_1^2}{3} \mp \frac{a^3c_1}{3} + a^4,$$

$$c_5 = \mp \frac{a^3c_1^2}{3} + \frac{2a^4c_1}{3}, \quad c_1 \text{ arbitrary}, \tag{A5a}$$

or

$$c_2 = \frac{c_1^2}{3} \pm ac_1 - \frac{10a^2}{3}, \quad c_3 = \pm ac_1^2 - 3a^2c_1, \quad c_4 = a^2c_1^2 p 5a^3c_1 + 5a^4,$$

$$c_5 = \pm \frac{a^3c_1^2}{3} - 2a^4c_1 \pm \frac{8a^5}{3}, \quad c_1 \text{ arbitrary} \tag{A5b}$$

(the equilibrium configurations (16) obtain from (A5b) for $c_1 = \pm 5a$).

The route we follow to obtain *all* the solutions of the system (A1) is analogous to that followed in Sec. V. The starting point is to introduce a *monic* polynomial $\bar{\psi}(z)$ of degree N that has the N numbers c_m solutions of (A1) as its N coefficients:

$$\bar{\psi}(z) = \prod_{n=1}^{N} (z - \bar{z}_n) = \sum_{m=0}^{N} c_m z^{N-m}, \quad c_0 = 1. \tag{A6}$$

Note the analogy of these formulas with (13), and the fact that we also introduced the N zeros $\bar{z}_n$ of this polynomial $\bar{\psi}(z)$, which clearly provide the equilibrium configuration of the N-body problem (1) (although not necessarily a *genuine* equilibrium configuration), hence satisfy the following system of N algebraic ODEs:

$$(\bar{z}_n^2 - a^2)\left[\bar{z}_n + \sum_{m=1, m\neq n}^{N} \frac{\bar{z}_m^2 - a^2}{\bar{z}_n - \bar{z}_m}\right] = 0. \tag{A7}$$

Our strategy to find all the solutions of the system (A1) is to find first all the solutions of this system, (A7), and then use (A6).

Clearly the solutions of (A7) can be broken down as follows:

$$\bar{z}_n + \sum_{m=1, m\neq n}^{\nu} \frac{\bar{z}_m^2 - a^2}{\bar{z}_n - \bar{z}_m} = 0 \quad \text{for } n = 1, \ldots, \nu, \tag{A8a}$$

$$\bar{z}_n = a \quad \text{for } n = \nu + 1, \ldots, \nu + \mu, \tag{A8b}$$

$$\bar{z}_n = -a \quad \text{for } n = \nu + \mu + 1, \ldots, N, \tag{A8c}$$

with the two *non-negative integers* ν and μ *arbitrary* except for the constraint

$$\nu + \mu \leqslant N \tag{A8d}$$

(implying of course that neither one of these two non-negative integers can exceed N).

This assignment, (A8), clearly entails that

$$\bar{\psi}(z) = (z-a)^{\mu}(z+a)^{N-\mu-\nu}\phi_{\nu}(z), \tag{A9a}$$

with $\phi_{\nu}(z)$ the *monic* polynomial of degree ν,

$$\phi_{\nu}(z) = \prod_{n=1}^{\nu}(z-\bar{z}_n) = \sum_{m=0}^{\nu} f_m z^{\nu-m}, \quad f_0 = 1, \tag{A9b}$$

the zeros of which satisfy the algebraic relations (A8a). Hence this polynomial $\phi_{\nu}(z)$ satisfies

$$(z^2-a^2)\phi_{\nu}'' - 2[(\nu-3)z - f_1]\phi_{\nu}' + \nu(\nu-5)\phi_{\nu} = 0, \tag{A10}$$

as implied by the (by now standard) technique to transform algebraic equations such as (A8a) into differential equations (see for instance the Appendix in Ref. 2). Here and in the following primes denote of course differentiations with respect to the argument of the function they are appended to.

Before proceeding to discuss the solution of this equation let us consider the special case with $\nu=0$ entailing $\phi_0(z)=1$ (which solves (A10) trivially). In this case (A9a) and (A8d) yield

$$\bar{\psi}(z) = (z-a)^{\mu}(z+a)^{N-\mu}, \quad \mu = 0,1,\ldots,N. \tag{A11a}$$

It is then easily seen from (A6) that this entails

$$c_m = a^m \sum_{\ell=\max(0,m+\mu-N)}^{\min(\mu,m)} (-)^{\ell}\binom{\mu}{\ell}\binom{N-\mu}{m-\ell}. \tag{A11b}$$

This formula provides a set of equilibrium configurations, characterized by the integer μ in the range $0 \leqslant \mu \leqslant N$; in particular the two solutions corresponding to $\mu=0$ and to $\mu=N$ are easily seen to yield the two solutions (16).

Let us now return to (A10), assuming hereafter that the integer ν is *positive*, $\nu>0$ (to avoid unnecessary notational complications). To solve this equation, (A10), we set

$$\phi_{\nu}(z) = a^{\nu}\chi(x), \quad z = a(x-1). \tag{A12}$$

This formula implies that $\chi(x)$ is again a *monic* polynomial of degree ν (although for notational simplicity we do not signal this via a subscript ν). We also set (in analogy to (A9b))

$$\chi(x) = \prod_{n=1}^{\nu}(x-x_n) = \sum_{m=0}^{\nu}\chi_m x^{\nu-m}, \quad \chi_0 = 1, \tag{A13}$$

and we then note that this formula, together with (A9b), entails

$$f_m = a^m \sum_{\ell=0}^{m}\binom{\nu-\ell}{m-\ell}\chi_{\ell}, \tag{A14a}$$

hence in particular

$$f_1 = a(\nu + \chi_1). \tag{A14b}$$

Via this formula and (A12) the differential equation (A10) now reads

$$x(x-2)\chi'' - 2[(\nu-3)x - 2\nu + 3 - \chi_1]\chi' + \nu(\nu-5)\chi = 0, \tag{A15a}$$

entailing, via (A13), the two-term recurrence

$$m(m-5)\chi_m = 2(\nu+1-m)(3-\nu-\chi_1-m)\chi_{m-1}, \tag{A15b}$$

implying (for $m=0$ and $m=\nu+1$) the extremal conditions $\chi_{-1}=\chi_{\nu+1}=0$ (consistent with (A13)).

For $m=1$ the recurrence formula (A15b) (together with $\chi_0=1$, see (A13)) yields the relation

$$(\nu-2)\chi_1 = -\nu(\nu-2), \tag{A16}$$

requiring that the two cases with $\nu=2$ and $\nu\neq 2$ be treated separately.

For $\nu=2$ one easily obtains the solution

$$\chi_0 = 1, \quad \chi_1 \text{ arbitrary}, \quad \chi_2 = \frac{\chi_1(\chi_1+1)}{3}. \tag{A17a}$$

Remark A.1: Let us note as a curiosity that the recursion (A15b) with $\nu=2$ allows this solution (A17a) to be extended as follows:

$$\chi_3 = \chi_4 = 0, \quad \chi_5 \text{ also arbitrary},$$

$$\chi_m = \frac{2^{m-3}15}{m(m-1)(m-2)}\binom{m-1+\chi_1}{m-5}\chi_5, \quad m=5,6,\ldots . \tag{A17b}$$

But we are only interested in the solution (A17a) with $\chi_m=0$ for $m>2$, entailing that $\chi(x)$ is a polynomial of degree $\nu=2$.

So in this $\nu=2$ case we get

$$\chi(x) = x^2 + \chi_1 x + \frac{\chi_1(\chi_1+1)}{3} \tag{A18}$$

hence, via (A12),

$$\phi_2(z) = z^2 + f_1 z + \frac{f_1^2 - a^2}{3}, \quad f_1 \text{ arbitrary}, \tag{A19}$$

where we set, consistent with (A9b), $f_1=(2+\chi_1)a$.

For $\nu\neq 2$ the recursion (A15b) with (A16) yields

$$\chi_0 = 1, \quad \chi_1 = -\nu, \quad \chi_2 = \frac{\nu(\nu-1)}{3}, \quad \chi_3 = \chi_4 = 0, \quad \chi_5 \text{ arbitrary},$$

$$\chi_m = \frac{(-)^{m-1}2^{m-3}15}{m(m-1)(m-2)}\binom{\nu-5}{m-5}\chi_5, \quad m=6,\ldots,\nu. \tag{A20}$$

Of course the second line of this equation is only relevant if $\nu>5$, which can only happen if $N>5$.

From these results, via (A9a) with (A8d) and (A12), we arrive finally, after a bit of trivial algebra, at the following two determinations of the polynomial $\bar{\psi}(z)$ (see (A6)):

$$\bar{\psi}(z) = \left(z^2 + cz + \frac{c^2-a^2}{3}\right)(z-a)^{\mu}(z+a)^{N-2-\mu}, \quad \mu=0,1,\ldots,N-2, \tag{A21a}$$

$$\bar{\psi}(z) = (z-a)^{\mu}(z+a)^{N-\mu}\left[1 - \frac{\nu a}{z+a} + \frac{\nu(\nu-1)a^2}{3(z+a)^2} + c\sum_{\ell=0}^{\nu-5}\frac{(-2)^{\ell}}{(\ell+5)(\ell+4)(\ell+3)}\binom{\nu-5}{\ell}\left(\frac{a}{z+a}\right)^{\ell+5}\right],$$

$$\nu = 5,6,\ldots,N, \quad \mu = 0,1,\ldots,N-\nu. \tag{A21b}$$

The first, (A21a), of these two formulas is applicable for $N \geqslant 2$, having been obtained from the previous results corresponding to $\nu=2$, with $c=f_1$ an *arbitrary* number. It includes the results obtainable from the cases with $\nu=1$ and $\nu=3$; likewise, the result corresponding to $\nu=4$ has not be reported, as it is encompassed by the result (A11a). The second, (A21b), of these two formulas is of course only applicable provided $N \geqslant 5$, having being obtained from (A20) for $\nu \geqslant 5$, with $c = \chi_5/60$ an *arbitrary* number. Together with (A11a) these two formulas determine *all* the equilibrium configurations c_m of the system (14) (and as well *all* the equilibrium configurations–not necessarily *genuine*—of the N-body problem (1))—up to a final (trivial but tedious) step, to be performed using (A6) (as done earlier to obtain (A11b) from (A11a)), which we leave as a task for the diligent reader.

This paper concerns optimization problems related to bi-harmonic equations subject to either Navier or Dirichlet homogeneous boundary conditions. Physically, in dimension two, our equation models the deformation of an elastic plate which is either hinged or clamped along the boundary, under load. We discuss existence, uniqueness, and properties of the optimizers. © *2006 American Institute of Physics.*

I. INTRODUCTION

Let Ω be a bounded domain in $\mathbb{R}^N$. This paper is concerned with optimization problems related to either the following boundary value problem (with Navier boundary conditions)

$$\Delta^2 u = f \text{ in } \Omega, \quad u = \Delta u = 0, \quad \text{on } \partial\Omega, \tag{1}$$

or to the problem (with Dirichlet boundary conditions)

$$\Delta^2 v = f \text{ in } \Omega, \quad v = |\nabla v| = 0, \quad \text{on } \partial\Omega. \tag{2}$$

As usual, $\Delta^2 = \Delta(\Delta)$. Let $f_0 \in L^2(\Omega)$, $f_0 \not\equiv 0$, and let $\mathcal{F} = \mathcal{F}(f_0)$ be the class of rearrangements of f_0. Similarly, let $g_0 \in L^2(\Omega)$, $g_0 \not\equiv 0$, and let $\mathcal{G} = \mathcal{G}(g_0)$ be the class of rearrangements of g_0. We say that $f(x) \not\equiv 0$ if the set $\{x \in \Omega : f(x) \neq 0\}$ has a positive measure. We are interested in the following problems:

$$\sup_{f\in\mathcal{F}, g\in\mathcal{G}} \int_\Omega g u_f \, dx, \quad \inf_{f\in\mathcal{F}, g\in\mathcal{G}} \int_\Omega g u_f \, dx, \tag{3}$$

$$\sup_{f\in\mathcal{F}, g\in\mathcal{G}} \int_\Omega g v_f \, dx, \quad \inf_{f\in\mathcal{F}, g\in\mathcal{G}} \int_\Omega g v_f \, dx, \tag{4}$$

where u_f is the (unique) solution of (1), and v_f is the (unique) solution of (2).

In dimension two, problem (1) models the deformation of an elastic plate which is hinged along the boundary (under load f), whereas problem (2) models the deformation of an elastic plate which is clamped along the boundary. The solution u_f stands for the deformation of the hinged plate from the rest position. Therefore, the functional $\int_\Omega g u_f \, dx$ measures the average deformation (with respect to the measure $g \, dx$) of the plate and similarly for v_f. Thus, any solution to (3) or (4) determines an *extremal* configuration.

[a)]Electronic mail: bemamizadeh@pi.ac.ae
[b)]Electronic mail: porru@unica.it

Our interest in the above-mentioned optimization problems spans questions such as existence, uniqueness (in case Ω is a ball), and qualitative properties of maximizers or minimizers. The case of the equation $-\Delta u=f$ is well understood, see Refs. 3–6 and 13. As far as we know, the optimization problems for bi-harmonic equations have not been investigated yet. We show that the corresponding results of existence continue to hold. In the case of hinged plates we also find a result of representation of the optimizers and, for the maximizer, a result of uniqueness in the ball. An example of interest is the following.

Example 1: Suppose $g_0=1$ and $f_0=\chi_{F_0}$, where χ_{F_0} is the characteristic functions of the measurable sets $F_0\subset\Omega$ with $|F_0|<|\Omega|$. Denoting by f_M a maximizer of (3) in this special situation, and denoting by w the solution to problem (1) with $f=1$, we show that (see Theorem 5) $f_M=\chi_{F_M}$ for the measurable set $F_M=\{w(x)>t_M\}$ with t_M such that $|F_M|=|F_0|$. Moreover, denoting by f_m a minimizer of (3) we prove that $f_m=\chi_{F_m}$ for the measurable set $F_m=\{w(x)<t_m\}$ with t_m such that $|F_m|=|F_0|$. So, physically speaking, in order to maximize the average deformation of the linear hinged plate under uniform loads (given by the appropriate rearrangement class) it is best to place the load away from the boundary (independent of the geometry of the plate); in order to minimize the average deformation it is best to place the load in a tubular neighborhood of the boundary. The above-mentioned results give some information on the location of extremal domains.

For clamped plates the representation result seems to be more difficult due to the lack of appropriate maximum principles for the corresponding equation; however, if the domain is a ball we prove a particular result of symmetry for the optimizers. A special example is the following.

Example 2: Let Ω be a disc. Suppose $g=\chi_G$, where $G\subset\Omega$ is a disc concentric with Ω. Let $f_0=\chi_{F_0}$, with $F_0\subset\Omega$. Denoting a maximizer of

$$\sup_{f\in\mathcal{F}}\int_\Omega gv_f\,dx$$

by $\bar{f}$ we show that (see Theorem 7) $\bar{f}=\chi_{F_M}$, where F_M is the disc concentric with Ω with $|F_M|=|F_0|$. Similarly, denoting a minimizer of

$$\inf_{f\in\mathcal{F}}\int_\Omega gv_f\,dx$$

by $\underline{f}$ we have $\underline{f}=\chi_{F_m}$, where F_m is the annulus concentric with Ω with $|F_m|=|F_0|$ and such that its exterior boundary coincides with $\partial\Omega$. So, physically speaking, in order to maximize the average deformation over the set G of the linear circular clamped plate under uniform loads (given by the appropriate rearrangement class) it is best to place the load centered with Ω. To minimize the analogous deformation it is best to place the load close to the boundary of Ω. Of course, these results agree with the physical intuition.

Some theorems of the present paper are based on results by Burton summarized by Lemmas 1–3 in the following. Burton and McLeod have used these results to investigate the problems

$$\sup_{f\in\mathcal{F}}\int_\Omega fu_f\,dx,\quad \inf_{f\in\mathcal{F}}\int_\Omega fu_f\,dx,$$

where u_f is the solution of the homogeneous Dirichlet problem $-\Delta u=f$.

We study the problems (3) and (4), where $\mathcal{F}$ and $\mathcal{G}$ are two (possibly different) classes of rearrangements. A remarkable fact is that (Theorem 3) when $\mathcal{F}=\mathcal{G}$ then

$$\sup_{f,g\in\mathcal{F}}\int_\Omega gu_f\,dx=\sup_{f\in\mathcal{F}}\int_\Omega fu_f\,dx.$$

II. PRELIMINARIES

In this section we collect some well-known results.

Recall that a function $u \equiv u_f \in W_0^{1,2}(\Omega)$ with $\Delta u_f \in W_0^{1,2}(\Omega)$ is a weak solution of (1) provided

$$\int_\Omega \Delta u \Delta \phi \, dx = \int_\Omega f\phi \, dx, \quad \forall\, \phi \in W_0^{1,2}(\Omega) \quad \text{with } \Delta\phi \in W_0^{1,2}(\Omega).$$

This problem can be described by a system of second-order elliptic equations with Dirichlet boundary conditions. It is well known that it has a unique solution. Alternatively, in smooth domains, one could work in $H^2(\Omega) \cap H_0^1(\Omega)$ with the test functions in the same space. The difference between these two approaches in nonsmooth domains is investigated in Ref. 12. See also, Refs. 8, 9, and 16. Using standard results on regularity (see Refs. 1 and 10) we find that u is a classical solution in the sense that $u \in W^4(\Omega) \cap C^3(\Omega)$. Moreover, using the continuity (with respect to weak convergence) of the inverse of the Laplacian, one proves the following result: If $\{f_i\}$ is a sequence of functions in $L^2(\Omega)$ which converges weakly (in $L^2(\Omega)$) to a function ξ then the corresponding solutions u_{f_i} to problem (1) converge strongly in $L^2(\Omega)$ to the solution u_ξ.

A function $v \equiv v_f \in W_0^{2,2}(\Omega)$ is a weak solution of (2) provided

$$\int_\Omega \Delta v \Delta \psi \, dx = \int_\Omega f\psi \, dx, \quad \forall\, \psi \in W_0^{2,2}(\Omega).$$

For results of the existence and regularity of this problem we refer to Refs. 1 and 11. It has a unique solution. Moreover, if $\{f_i\}$ is a sequence of functions in $L^2(\Omega)$ which converges weakly (in $L^2(\Omega)$) to a function ξ then the corresponding solutions v_{f_i} to problem (2) converges weakly in $W_0^{2,2}(\Omega)$ to the solution v_ξ. As a consequence, v_{f_i} converges strongly in $L^2(\Omega)$ to the solution v_ξ.

If u_g is the solution of (1) with f replaced by g then we have

$$\int_\Omega g u_f \, dx = \int_\Omega (\Delta u_g)(\Delta u_f) dx = \int_\Omega f u_g \, dx. \tag{5}$$

Similarly, if v_g is the solution of (2) with f replaced by g then we have

$$\int_\Omega g v_f \, dx = \int_\Omega (\Delta v_g)(\Delta v_f) dx = \int_\Omega f v_g \, dx. \tag{6}$$

Definition: Suppose $f, f_0 : \Omega \to \mathbb{R}$ are (Lebesgue) measurable functions. We say that f and f_0 are rearrangements of each other if and only if

$$|\{f(x) \geqslant \alpha\}| = |\{f_0(x) \geqslant \alpha\}|, \quad \forall\, \alpha \in \mathbb{R}.$$

Here and in what follows we write $\{f(x) \geqslant \alpha\}$ instead of $\{x \in \Omega : f(x) \geqslant \alpha\}$, and denote with $|E|$ the Lebesgue measure of the (measurable) set E. For any $f : \Omega \to \mathbb{R}$, f^* denotes the decreasing Schwarz rearrangement of f; that is, f^* is radially symmetric, decreases as $|x|$ increases, and it is a rearrangement of f. Recall that f^* is defined on B, the ball centered at the origin with volume equal to $|\Omega|$.

Lemma 1: *Let $f, u \in L^2(\Omega)$. Suppose that every level set of u (that is, sets of the form $u^{-1}(\{\alpha\})$) has measure zero. Then there exists an increasing function ϕ such that $\phi \circ u$ is a rearrangement of f.*

Lemma 2: *Let $\mathcal{F}$ be the set of rearrangements of a fixed function $f_0 \in L^2(\Omega)$, $f_0 \not\equiv 0$, and let $u \in L^2(\Omega)$, $u \not\equiv 0$. If there is an increasing function ϕ such that $\phi(u) \in \mathcal{F}$ then*: (*a*)

$$\int_\Omega f u \, dx \leqslant \int_\Omega \phi(u) u \, dx, \quad \forall\, f \in \bar{\mathcal{F}};$$

(*b*) *the function* $\phi(u)$ *is the unique maximizer relative to* $\bar{\mathcal{F}}$.

Lemma 3: *Let* $\mathcal{F}$ *be the set of rearrangements of a fixed function* $f_0 \in L^2(\Omega)$, $f_0 \not\equiv 0$, *and let* $u \in L^2(\Omega)$, $u \not\equiv 0$. *There exists* $\hat{f} \in \mathcal{F}$ *such that*

$$\int_\Omega fu \, dx \leqslant \int_\Omega \hat{f}u \, dx, \quad \forall f \in \bar{\mathcal{F}}.$$

In the above-mentioned lemmas and in what follows, we denote with $\bar{\mathcal{F}}$, the weak closure of $\mathcal{F}$ in $L^2(\Omega)$. For the proof of Lemma 1, see Ref. 4 (Lemma 2.9), and for Lemmas 2 and 3, see Ref. 4 (Lemma 2.4).

Next we recall a well-known rearrangement inequality. If $u \in W_0^{1,2}(\Omega)$ is non-negative and if u^* denotes the Schwarz rearrangement of u, then $u^* \in W_0^{1,2}(\Omega)$ and the inequality

$$\int_B |\nabla u^*|^2 \, dx \leqslant \int_\Omega |\nabla u|^2 \, dx \tag{7}$$

holds. The case of equality in (7) has been considered in Ref. 2. The following result can be deduced from Lemma 3.2, Theorem 1.1, and Lemma 2.3(v), in Ref. 2.

Theorem 1: *Let* $u \in W_0^{1,2}(\Omega)$ *be non-negative*, *and suppose equality holds in* (7). *Then* $u^{-1}(\alpha, \infty)$ *is a translate of* $u^{*-1}(\alpha, \infty)$, *for every* $\alpha \in [0, M]$, *where* M *is the essential superior of* u *over* Ω, *modulo sets of measure zero*. *Moreover*, *if*

$$|\{x \in \Omega : \nabla u(x) = 0, 0 < u(x) < M\}| = 0, \tag{8}$$

then u *is a translation of* u^*.

III. EXISTENCE RESULTS

To state the next theorem we use the notion of weak continuity in the following sense: A linear operator $K : L^2(\Omega) \to L^2(\Omega)$ is weakly continuous if for every sequence f_i which converges weakly in $L^2(\Omega)$ to f, the sequence Kf_i converges strongly to Kf.

The existence of solutions to problems (3) and (4) follows from the following.

Theorem 2: *Let* $K : L^2(\Omega) \to L^2(\Omega)$ *be a linear operator weakly continuous and such that*

$$\int_\Omega gKf \, dx = \int_\Omega fKg \, dx, \quad \forall g, f \in L^2(\Omega).$$

Then there exist $f_M \in \mathcal{F}$ *and* $g_M \in \mathcal{G}$ *such that*

$$\int_\Omega g_M K f_M \, dx = \sup_{g \in \mathcal{G}, f \in \mathcal{F}} \int_\Omega gKf \, dx;$$

furthermore, *there exist* $f_m \in \mathcal{F}$ *and* $g_m \in \mathcal{G}$ *such that*

$$\int_\Omega g_m K f_m \, dx = \inf_{g \in \mathcal{G}, f \in \mathcal{F}} \int_\Omega gKf \, dx.$$

Proof: Let

$$I = \sup_{g \in \mathcal{G}, f \in \mathcal{F}} \int_\Omega gKf \, dx.$$

We first show that I is finite. Since K is continuous we must have

$$\|Kf\|_2 \leqslant C\|f\|_2, \quad \forall f \in L^2(\Omega).$$

Moreover, since

$$\|g\|_2\|Kf\|_2 \leqslant C\|g_0\|_2\|f_0\|_2,$$

I is finite. Let $\{g_i,f_i\}$ be a maximizing sequence and let $u_i=Kf_i$. Since $\{f_i\}$ is bounded in $L^2(\Omega)$, it must contain a subsequence (still denoted $\{f_i\}$) converging weakly to $\xi \in L^2(\Omega)$. Note that $\xi \in \bar{\mathcal{F}}$, the weak closure of $\mathcal{F}$ in $L^2(\Omega)$. Since K is assumed to be weakly continuous, Kf_i converges (strongly) in $L^2(\Omega)$ to $K\xi$. Moreover, $\{g_i\}$ must contain a subsequence (still denoted $\{g_i\}$) converging weakly to $\eta \in L^2(\Omega)$, with $\eta \in \bar{\mathcal{G}}$. Thus,

$$I = \lim_{i\to\infty}\int_\Omega g_i Kf_i \,\mathrm{d}x = \int_\Omega \eta K\xi \,\mathrm{d}x. \tag{9}$$

By Lemma 3 we infer existence of $g_M \in \mathcal{G}$ that maximizes the linear functional $\int_\Omega hK\xi \,\mathrm{d}x$, relative to $h \in \bar{\mathcal{G}}$. As a consequence we obtain

$$\int_\Omega \eta K\xi \,\mathrm{d}x \leqslant \int_\Omega g_M K\xi \,\mathrm{d}x. \tag{10}$$

By assumption we also have

$$\int_\Omega g_M K\xi \,\mathrm{d}x = \int_\Omega \xi K g_M \,\mathrm{d}x.$$

Applying again Lemma 3, we find $f_M \in \mathcal{F}$ such that

$$\int_\Omega g_M K\xi \,\mathrm{d}x = \int_\Omega \xi K g_M \,\mathrm{d}x \leqslant \int_\Omega f_M K g_M \,\mathrm{d}x = \int_\Omega g_M K f_M \,\mathrm{d}x \leqslant I.$$

From (9) and (10) and the last inequality it follows that

$$I = \int_\Omega g_M K f_M \,\mathrm{d}x.$$

Thus (g_M,f_M) is a maximizer, as desired.

Now define $-\mathcal{G}=\{h \in L^2(\Omega): -h \in \mathcal{G}\}$. The class $-\mathcal{G}$ coincides with the class of all rearrangements of $-g_0$. Since

$$\inf_{g\in\mathcal{G},f\in\mathcal{F}}\int_\Omega gKf \,\mathrm{d}x = -\sup_{g\in\mathcal{G},f\in\mathcal{F}}\int_\Omega (-g)Kf \,\mathrm{d}x = -\sup_{h\in-\mathcal{G},f\in\mathcal{F}}\int_\Omega hKf \,\mathrm{d}x,$$

the existence of a minimizer follows by the proof for the maximizer. □

Theorem 3: *Let* $K: L^2(\Omega)\to L^2(\Omega)$ *satisfy the assumptions of Theorem 2 and, in addition,*

$$\int_\Omega fKf \,\mathrm{d}x \geqslant 0, \quad \forall f \in L^2(\Omega), \quad \int_\Omega fKf \,\mathrm{d}x = 0 \Leftrightarrow f = 0.$$

Then,

$$\sup_{f,g\in\mathcal{F}}\int_\Omega gKf \,\mathrm{d}x = \sup_{f\in\mathcal{F}}\int_\Omega fKf \,\mathrm{d}x.$$

Proof: Let (g_M,f_M) be a maximizing pair. From

$$0 \leqslant \int_\Omega (g_M - f_M)K(g_M - f_M)\mathrm{d}x = \int_\Omega g_M K g_M \,\mathrm{d}x + \int_\Omega f_M K f_M \,\mathrm{d}x - 2\int_\Omega g_M K f_M \,\mathrm{d}x,$$

it follows that

$$2\int_\Omega g_M K f_M \leqslant \int_\Omega f_M K f_M \,\mathrm{d}x + \int_\Omega g_M K g_M \,\mathrm{d}x$$

with equality if and only if $g_M = f_M$. We can rewrite the latter inequality as

$$\int_\Omega g_M K f_M \leqslant \int_\Omega \frac{f_M + g_M}{2}\frac{Kf_M + Kg_M}{2}. \tag{11}$$

Since $\bar{\mathcal{F}}$ is convex (Ref. 3, Theorem 6), we have $(f_M+g_M)/2 \in \bar{\mathcal{F}}$. Moreover, since K is linear we have $(Kf_M+Kg_M)/2=K((f_M+g_M)/2)$. Hence, using (11) we find

$$I = \int_\Omega g_M K f_M \leqslant \int_\Omega \frac{f_M + g_M}{2} K\left(\frac{f_M + g_M}{2}\right) \leqslant I.$$

It follows that equality must hold in (11). Hence, $g_M = f_M$. The theorem follows. □

Remark: Note that all conditions in Theorems 2 and 3 hold when $Kf = u_f$, the solution to problem (1), and when $Kf = v_f$, the solution to problem (2). In particular, by theorems 2 and 3 we have existence for the problems

$$\sup_{f\in\mathcal{F}}\int_\Omega f u_f \,\mathrm{d}x, \quad \sup_{f\in\mathcal{F}}\int_\Omega f v_f \,\mathrm{d}x.$$

We cannot have, in general, a corresponding result for the inferior.

IV. NAVIER BOUNDARY CONDITIONS

In this section we consider optimizers of problems (3). We will use a strong maximum principle for Eq. (1). That is, if $f(x) \geqslant 0$, $f \not\equiv 0$, we must have $-\Delta u_f(x) > 0$ in Ω. This fact follows easily from the strong maximum principle of the Laplacian and from the special boundary conditions of problem (1). A further application of the strong maximum principle for the Laplacian yields $u_f(x) > 0$ in Ω.

Theorem 4: *Let* $g_0(x) \not\equiv 0$ *with either* $g_0(x) \geqslant 0$ *or* $g_0(x) \leqslant 0$, *and let* $\mathcal{G} = \mathcal{G}(g_0)$. *Let* $f_0(x) \not\equiv 0$ *with either* $f_0(x) \geqslant 0$ *or* $f_0(x) \leqslant 0$, *and let* $\mathcal{F} = \mathcal{F}(f_0)$.

(i) If (g_M, f_M) *is a maximizing pair of* (3) *then there exist increasing functions* ϕ *and* ψ *such that*

$$f_M = \phi(u_{g_M}), \quad g_M = \psi(u_{f_M}), \tag{12}$$

almost everywhere in Ω.

(ii) If (g_m, f_m) *is a minimizing pair of* (3) *then there exist decreasing functions* $\underline{\phi}$ *and* $\underline{\psi}$ *such that*

$$f_m = \underline{\phi}(u_{g_m}), \quad g_m = \underline{\psi}(u_{f_m}), \tag{13}$$

almost everywhere in Ω.

Proof: (i) Let (g_M, f_M) be a maximizing pair and let u_{g_M} (u_{f_M}) be the corresponding solutions to (1) with g_M (f_M) in place of f. If $g_0(x) \geqslant 0$, the set $\{x \in \Omega : g_M(x) > 0\}$ has a positive measure, and by (1) (with g_M in place of f) we get $-\Delta u_{g_M}(x) > 0$ in Ω. If $g_0(x) \leqslant 0$, the set $\{x \in \Omega : g_M(x) < 0\}$ has a positive measure, and by (1) we get $-\Delta u_{g_M}(x) < 0$ in Ω. In both cases, all level sets $A_\alpha = \{x \in \Omega : u_{g_M}(x) = \alpha\}$ have measure zero (this follows from Ref. 10, Lemma 7.7). By Lemma 1

we infer the existence of ϕ increasing such that $\phi(u_{g_M})$ is a rearrangement of f_M. Since f_M is a maximizer of $\int_\Omega f u_{g_M}\,dx$ for $f\in\mathcal{F}$, by Lemma 2 we must have $f_M=\phi(u_{g_M})$. We have proved the first equation of (12). To prove the second equation of (12), we can proceed as before interchanging the roles of f_M and g_M. We find a function ψ increasing such that $g_M=\psi(u_{f_M})$.

(ii) Let (g_m,f_m) be a minimizing pair. As already observed in the proof of Theorem 2, we have

$$\int_\Omega g_m u_{f_m}\,dx=-\sup_{h\in-\mathcal{G},f\in\mathcal{F}}\int_\Omega hu_f\,dx,$$

where $-\mathcal{G}=\mathcal{G}$ $(-g_0)$. We can write the previous equation as

$$\int_\Omega(-g_m)u_{f_m}\,dx=\sup_{h\in-\mathcal{G},f\in\mathcal{F}}\int_\Omega hu_f\,dx.$$

By our previous result there exist $\tilde{\phi}$ and $\tilde{\psi}$ increasing such that

$$f_m=\tilde{\phi}(u_{-g_m}),\quad -g_m=\tilde{\psi}(u_{f_m}).$$

We can rewrite the previous equations as

$$f_m=\tilde{\phi}(-u_{g_m})=\underline{\phi}(u_{g_m}),\quad g_m=-\tilde{\psi}(u_{f_m})=\underline{\psi}(u_{f_m}),$$

with $\underline{\phi}(s)=\tilde{\phi}(-s)$, and $\underline{\psi}(s)=-\tilde{\psi}(s)$. Of course, $\underline{\phi}(s)$ and $\underline{\psi}(s)$ are decreasing. The theorem is proved. □

Theorem 5: *Let $g_0(x)\geqslant 0$, $g_0(x)\not\equiv 0$, $f_0(x)\geqslant 0$, $f_0(x)\not\equiv 0$. Let (g_M,f_M) be a maximizing pair of* (3). *If $G_M=\{g_M(x)>0\}$ then (up to sets of zero measure) we have*

$$G_M=\{u_{f_M}(x)>t_M\},\quad t_M=\inf_{x\in G_M}u_{f_M}(x);\tag{14}$$

if $F_M=\{f_M(x)>0\}$ then (up to sets of zero measure) we have

$$F_M=\{u_{g_M}(x)>\tau_M\},\quad \tau_M=\inf_{x\in F_M}u_{g_M}(x).\tag{15}$$

Moreover, let (g_m,f_m) be a minimizing pair of (3). *If $G_m=\{g_m(x)>0\}$ then (up to sets of zero measure) we have*

$$G_m=\{u_{f_m}(x)<t_m\},\quad t_m=\sup_{x\in G_m}u_{f_m}(x);\tag{16}$$

if $F_m=\{f_m(x)>0\}$ then (up to sets of zero measure) we have

$$F_m=\{u_{g_m}(x)<\tau_m\},\quad \tau_m=\sup_{x\in F_m}u_{g_m}(x).\tag{17}$$

Proof: Let us prove that

$$\{u_{f_M}(x)>t_M\}\subset G_M\subset\{u_{f_M}(x)\geqslant t_M\}.\tag{18}$$

The inclusion on the right follows from the definition of t_M. If we define

$$\delta=\sup_{x\in\Omega\setminus G_M}u_{f_M}(x),$$

the inclusion on the left is clear if we prove that $t_M\geqslant\delta$. To derive a contradiction assume $t_M<\delta$. Let us fix $t_M<\xi_1<\xi_2<\delta$. Since $\xi_1>t_M$, there exists a set $A\subset G_M$, with positive measure, such that $u_{f_M}(x)\leqslant\xi_1$ on A. Similarly, $\xi_2<\delta$ implies that there exists a set $B\subset\Omega\setminus G_M$, with positive measure, such that $u_{f_M}(x)\geqslant\xi_2$ on B. Without loss of generality we may assume that $|A|=|B|$. Next,

consider a measure preserving map $T:A\to B$, see Ref. 14. Using T we define a particular rearrangement of $g_M(x)$, denoted $\bar{g}$,

$$\bar{g}(x)=\begin{cases} g_M(Tx), & x\in A \\ g_M(T^{-1}x), & x\in B \\ g_M(x) & \Omega\setminus(A\cup B). \end{cases}$$

Thus

$$\int_\Omega \bar{g}u_{f_M}\,dx-\int_\Omega g_M u_{f_M}\,dx=\int_{A\cup B}\bar{g}u_{f_M}\,dx-\int_{A\cup B}g_M u_{f_M}\,dx=\int_B \bar{g}u_{f_M}\,dx-\int_A g_M u_{f_M}\,dx$$
$$\geqslant \xi_2\int_B \bar{g}\,dx-\xi_1\int_A g_M\,dx=(\xi_2-\xi_1)\int_A g_M\,dx>0.$$

Therefore

$$\int_\Omega \bar{g}u_{f_M}\,dx>\int_\Omega g_M u_{f_M}\,dx,$$

which contradicts the maximality of g_M. Hence, $t_M\geqslant\delta$, and (18) follows. By the proof of Theorem 4 we know that the level sets of $u_{f_M}(x)$ have zero measure, hence, (14) follows from (18). The proof of (15) is the same (interchanging the roles of g_M and f_M). To prove (16), we observe that

$$\int_\Omega g_m u_{(-f_m)}=\sup_{g\in\mathcal{G},f\in\mathcal{F}}\int_\Omega g u_{(-f)}.$$

If $G_m=\{g_m(x)>0\}$, by our previous result we have

$$G_m=\{u_{(-f_m)}(x)>\bar{t}_M\},\quad \bar{t}_M=\inf_{x\in G_m}u_{(-f_m)}(x).$$

Equivalently, since $u_{(-f_m)}=-u_{f_m}$, we have

$$G_m=\{u_{f_m}(x)<t_m\},\quad t_m=\sup_{x\in G_m}u_{f_m}(x),$$

with $t_m=-\bar{t}_M$. Similarly, one proves (17) interchanging the roles of g_m and f_m. The proof of the theorem is complete. □

Remark: Note that $|\{g_M(x)>0\}|=|\{g_m(x)>0\}|=|\{g_0(x)>0\}|$. Therefore, if $|\{g_0(x)>0\}|<|\Omega|$, by Theorem 5 it follows that t_M and t_m are strictly positive. If we assume $f_0\in L^\infty(\Omega)$ then we have the continuity of the solutions u_{f_M} and u_{f_m} (see Ref. 10). In this situation, by Theorem 5 we have

$$\partial G_M\subset\{u_{f_M}=t_M\},\quad \partial(\Omega\setminus G_m)\subset\{u_{f_m}=t_m\}.$$

This result establishes a link between g_M and f_M or g_m and f_m. We remark that we may have different solutions of the optimization problems, and the above link holds for any solution.

We now address the question of uniqueness in a ball.

Theorem 6: *Suppose* Ω *is a ball centered at the origin. Suppose* $f_0(x)\geqslant 0$, $f_0(x)\not\equiv 0$ *and* $g_0(x)\geqslant 0$, $g_0(x)\not\equiv 0$. *Then the maximization problem in* (3) *has a unique solution, namely*, (g_0^*,f_0^*).

Proof: Let (g,f) be a maximizing pair. If u_f and u_g are the solutions of problem (1) with f and g, respectively, put

$$-\Delta u_f=z_f,\quad -\Delta u_g=z_g.$$

We have

$$-\Delta z_f = f \text{ in } \Omega, \quad z_f = 0 \text{ on } \partial\Omega, \tag{19}$$

and

$$-\Delta z_g = g \text{ in } \Omega, \quad z_g = 0 \text{ on } \partial\Omega. \tag{20}$$

Then

$$\int_\Omega g u_f \, dx = \int_\Omega (\Delta u_g)(\Delta u_f) \, dx = \int_\Omega z_g z_f \, dx. \tag{21}$$

By a well-known result of Talenti (Ref. 15) we have

$$z_f^*(x) \leqslant z_{f^*}(x), \quad z_g^*(x) \leqslant z_{g^*}(x) \text{ in } \Omega, \tag{22}$$

where $z_{f^*}(x)$ is the solution to problem (19) with f^* in place of f and $z_{g^*}(x)$ is the solution to problem (20) with g^* in place of g. Using (21), the Hardy-Littlewood inequality and (22) we find

$$\int_\Omega g u_f \, dx = \int_\Omega z_g z_f \, dx \leqslant \int_\Omega z_g^* z_f^* \, dx \leqslant \int_\Omega z_{g^*} z_{f^*} \, dx = \int_\Omega g^* u_{f^*} \, dx \leqslant \int_\Omega g u_f \, dx,$$

where u_{f^*} denotes the solution to (1) with f^* in place of f. Therefore

$$\int_\Omega z_g^* z_f^* \, dx = \int_\Omega z_{g^*} z_{f^*} \, dx.$$

The latter equation and (22) yield

$$z_f^*(x) = z_{f^*}(x), \quad z_g^*(x) = z_{g^*}(x) \text{ in } \Omega. \tag{23}$$

By using (23), the variational characterization of the solution of (19) and standard inequalities about rearrangements we find

$$\int_\Omega |\nabla z_f|^2 \, dx = \int_\Omega (2 f z_f - |\nabla z_f|^2) dx \leqslant \int_\Omega (2 f^* z_f^* - |\nabla z_f^*|^2) dx = \int_\Omega (2 f^* z_{f^*} - |\nabla z_{f^*}|^2) dx$$

$$= \int_\Omega |\nabla z_{f^*}|^2 \, dx = \int_\Omega |\nabla z_f^*|^2 \, dx.$$

The last inequality and (7) yield

$$\int_\Omega |\nabla z_f^*|^2 \, dx = \int_\Omega |\nabla z_f|^2 \, dx.$$

We find easily that

$$|\{x \in \Omega : \nabla z_f^*(x) = 0\}| = |\{x \in \Omega : \nabla z_{f^*}(x) = 0\}| = 0.$$

Therefore, using Theorem 1 and (23) we find $z_f(x) = z_f^*(x) = z_{f^*}(x)$. As a consequence, by (19) we get $f(x) = f^*(x) = f_0^*(x)$. Similarly, one finds that $g(x) = g^*(x) = g_0^*(x)$. The theorem is proved. □

V. DIRICHLET BOUNDARY CONDITIONS

This problem seems to be more complicated than that with Navier boundary conditions. We prove the following (partial) result.

Theorem 7: *Let Ω be an N-ball centered at the origin. Let $0 \leqslant g(x) \leqslant M$, $g(x) \not\equiv 0$, $g(x) = g^*(x)$ in Ω, and let $0 \leqslant f_0(x) \leqslant M$, $f_0(x) \not\equiv 0$. Let $\mathcal{F}$ be the family of rearrangements of f_0 in Ω. For $f \in \mathcal{F}$, let v_f be the solution to problem* (2). *Then*

$$\sup_{f\in\mathcal{F}}\int_\Omega gv_f\,\mathrm{d}x \tag{24}$$

has a unique solution $\bar{f}$; *namely* $\bar{f}=f_0^*$. *Moreover*,

$$\inf_{f\in\mathcal{F}}\int_\Omega gv_f\,\mathrm{d}x \tag{25}$$

has a unique solution $\underline{f}$; *namely* $\underline{f}=-(-f_0)^*$.

The following lemma, which is an extension of Ref. 3, Theorem 2.4 to weak solutions, will be used in the proof of Theorem 7.

Lemma 4: Suppose $0\leqslant g(x)\leqslant M$ *is a radial function defined in the N-ball* Ω, *and suppose* $v=v_g$ *is the corresponding solution to problem* (2). *Then* $v(x)=v^*(x)$, *almost everywhere in* Ω.

Proof: We begin by showing that $v(x)$ is radial. To do this we fix a rotation map R. Let G denote the Green function given by (see Ref. 7)

$$G(x,y)=C_N|x-y|^{4-N}\int_0^{(1-|x|^2)(1-|y|^2)/|x-y|^2} t(1+t)^{-\frac{N}{2}}\,\mathrm{d}t,$$

where C_N is a positive constant. Then

$$v(x)=\int_\Omega G(x,y)g(y)\mathrm{d}y.$$

Simple calculations confirm that $G(Rx,Ry)=G(x,y)$, hence

$$v(Rx)=\int_\Omega G(Rx,y)g(y)\mathrm{d}y=\int_\Omega G(Rx,Ry)g(Ry)\mathrm{d}y=\int_\Omega G(x,y)g(y)\mathrm{d}y=v(x),$$

so v is radial. Next, note that $v(x)$ is non-negative since $g(x)$ is non-negative. Consider a radial test function $\psi\in C_0^\infty(\mathbb{R}^N)$, say

$$\psi(x)=\begin{cases} c_N e^{-1/(1-\|x\|^2)}, & \|x\|<1\\ 0, & \|x\|\geqslant 1,\end{cases}$$

where c_N is a suitable normalizing constant. Let us set $\psi_\epsilon(x)=\epsilon^{-n}\psi(x/\epsilon)$, the standard mollifier. By extending g to all of $\mathbb{R}^N$, defining it to be zero outside Ω, we have $g_\epsilon:=\phi_\epsilon * g\to g$, in $L^2(\Omega)$, as $\epsilon\to 0$. Next we consider

$$\Delta^2 v_\epsilon=g_\epsilon \text{ in } \Omega,\quad v_\epsilon=|\nabla v_\epsilon|=0 \text{ on } \partial\Omega. \tag{26}$$

Since $g_\epsilon\in C_0^\infty(\bar{\Omega})$, v_ϵ belongs (at least) to $C^4(\bar{\Omega})$. Also g_ϵ is radial, indeed for R, a rotation map, we have

$$g_\epsilon(Rx)=\int_{\mathbb{R}^N} g(y)\psi_\epsilon(Rx-y)\mathrm{d}y=\int_{\mathbb{R}^N} g(Ry)\psi_\epsilon(Rx-Ry)\mathrm{d}y=\int_{\mathbb{R}^N} g(y)\psi_\epsilon(x-y)\mathrm{d}y=g_\epsilon(x).$$

Now applying Ref. 3, Theorem 2.4 we derive $v_\epsilon=v_\epsilon^*$. By the weak formulation of the solutions of (26) we have

$$\int_\Omega \Delta v_\epsilon\Delta w\,\mathrm{d}x=\int_\omega g_\epsilon w\,\mathrm{d}x,\quad \forall\, w\in H_0^2(\Omega).$$

So $\|v_\epsilon\|^2_{H_0^2(\Omega)}=\int_\Omega g_\epsilon v_\epsilon\,\mathrm{d}x\leqslant\|g_\epsilon\|_{L^2(\Omega)}\|v_\epsilon\|_{L^2(\Omega)}$. An application of the Sobolev embedding theorem then yields $\|v_\epsilon\|_{H_0^2(\Omega)}\leqslant C$, for some constant C. Thus $\{v_\epsilon\}$ is bounded (uniformly with respect to ϵ)

in $H_0^2(\Omega)$. Therefore it has a subsequence, denoted $\{v_i\}$, that converges to some $\bar{v} \in H_0^2(\Omega)$, weakly in $H_0^2(\Omega)$ and strongly in $L^2(\Omega)$. As a consequence we find

$$\int_\Omega \Delta \bar{v} \Delta w \, dx = \int_\Omega g w \, dx, \quad \forall \, w \in H_0^2(\Omega),$$

since $g_i \to g$ in $L^2(\Omega)$. Therefore $\bar{v}$ is the solution of the following boundary value problem:

$$\Delta^2 \bar{v} = g \text{ in } \Omega, \quad \bar{v} = |\nabla \bar{v}| = 0, \text{ on } \partial\Omega,$$

and $\bar{v}=v$. On the other hand, from a standard property of rearrangements, we have

$$\|v_i^* - v^*\|_{L^2(\Omega)} \leqslant \|v_i - v\|_{L^2(\Omega)},$$

so $v_i^* \to v^*$, in $L^2(\Omega)$, since $v_i \to v$, in $L^2(\Omega)$. Since $v_i^* = v_i$, it readily follows that $v=v^*$, almost everywhere in Ω, as desired. □

We are now ready to prove Theorem 7.

Proof of Theorem 7: Let v_g denote the solution of

$$\Delta^2 v_g = g \text{ in } \Omega, \quad v_g = |\nabla v_g| = 0 \text{ on } \partial\Omega.$$

Since $0 \leqslant g(x) \leqslant M$, $g(x) \not\equiv 0$, an inspection of the representation formula via Green's function shows that $v_g(x)$ is strictly positive in Ω and continuous on $\bar{\Omega}$.

It is easy to show that

$$\int_\Omega g v_f \, dx = \int_\Omega f v_g \, dx,$$

for every $f \in \mathcal{F}$, where v_f is the solution of (2). Therefore, we are interested in the following maximization problem:

$$\sup_{f \in \mathcal{F}} \int f v_g \, dx.$$

By Lemma 3 we know that there is a maximizer $\bar{f}$. Now let us prove that all level sets $A_\alpha = \{x \in \Omega : v_g(x) = \alpha\}$ have measure zero. If B is the ball $\{x \in \Omega : g(x) > 0\}$, the set $A_\alpha \cap B$ has measure zero because $\Delta^2 v_g = g > 0$ there. The boundary of B has (N-dimensional) measure zero. On $\Omega \backslash \bar{B}$ we have $\Delta^2 v_g = 0$. If the set $A_\alpha \cap (\Omega \backslash \bar{B})$ has a positive measure then $v_g(x) = \alpha$ on $\Omega \backslash \bar{B}$. Since $v_g(x) = 0$ on $\partial\Omega$, if $\alpha > 0$ we find a contradiction. If $\alpha = 0$ we have $v_g(x) = 0$ on a set of positive measures, but we know that $v_g(x) > 0$ in Ω. Therefore, all sets A_α have measure zero. Then, by Lemma 1, there is an increasing function ϕ such that $\phi(v_g(x))$ is a rearrangement of $\bar{f}$. Finally, by Lemma 2 we get $\bar{f} = \phi(v_g(x))$. As a consequence, since (by Lemma 4) $v_g(x) = v_g^*(x)$ and ϕ is increasing, we must have $\bar{f}(x) = \bar{f}^*(x) = f_0^*(x)$. The first assertion of the theorem is proved. The proof of the second assertion is very similar. We have

$$-\inf_{f \in \mathcal{F}} \int_\Omega g v_f \, dx = \sup_{f \in \mathcal{F}} \int_\Omega (-g) v_f \, dx = \sup_{f \in \mathcal{F}} \int_\Omega f v_{-g} \, dx,$$

where v_{-g} denotes the solution to (2) with $-g$ in place of f. By Lemma 3 we find a maximizer (of the last functional) $\underline{f}$. The level sets $A_\alpha = \{x \in \Omega : v_{-g}(x) = \alpha\}$ have measure zero (note that $v_{-g} = -v_g$, with v_g as in the previous case). Therefore, by Lemma 1, there is an increasing function $\tilde{\psi}$

such that $\tilde{\psi}(v_{-g}(x))$ is a rearrangement of $\underline{f}$. Finally, by Lemma 2 we get $\underline{f}=\tilde{\psi}(v_{-g}(x))$. Equivalently, since $v_{-g}(x)=-v_g(x)$, we have $-\underline{f}=\psi(v_g(x))$, with ψ increasing. As a consequence, since $v_g(x)=v_g^*(x)$ and ψ is increasing, we must have $-\underline{f}(x)=(-\underline{f})^*(x)=(-f_0)^*(x)$. Therefore, $f(x)=-(-f0)^*(x)$ as claimed. The theorem is proved. □

Two nonlinear anelastic models with fractional derivatives, describing the properties of a series of materials as polymers, and polycrystalline materials are presented in this paper. These models are studied analytically, using a variational iteration method. The paper clarifies the different ways in which the fractional differentiation operator can be defined. A Volterra series method of model parameters identification from the experimental data is also presented. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2234273]

I. INTRODUCTION

In order to describe accurately the anelastic properties of polymers, anelastic rheologic equations were used, in which terms containing fractional derivatives[1–3] appear. The validity of these models is extensively discussed.

Linear five-parameter fractional anelastic models[4] are currently used to explain the anelastic properties of plastics or rubber.

It was found that the difference between the order of strain and stress time derivatives is related to the high frequency limit value of the loss factor.[5]

The investigation of the constitutive equations, which describes these models, is based on Fourier[6,7] and Laplace transform,[8] averaging methods,[9] finite element method,[4] and numerical methods.[10,11]

Unfortunately, only a restricted number of differential equations involving fractional derivatives have exact, or closed form solutions.

The aim of this paper is to build a nonlinear anelastic model with fractional damping, and to express the efficiency of the variational iteration method of He,[12–15] based on the Lagrange multiplier. The advantages of this method were widely presented in Ref. 16 as being useful for all kinds of differential equations, including strongly nonlinear equations. The method is strongly convergent, and was applied to a series of problems as waves,[17] fractional differential equations,[18] and differential equations with convolution product nonlinearity.[19] It is important to underline that the variational iteration method of He is not yet sufficiently investigated, which in the case of linear differential equations yields the solution after one iteration.

While the method has been applied to various nonlinear problems by many authors, a complete review is available in the He's monograph.[20]

This paper also tries to clarify the different ways in which the fractional differentiation operator can be defined.

II. FRACTIONAL DIFFERENTIATION

The fractional derivative represents a generalization of the standard derivative and was introduced 300 years ago by Leibniz, and investigated by mathematicians such as Liouville, Riemann, Fourier, and Laplace.

The fractional derivative $D_{t,a}^{\mu}$, operator represents a linear operator, which can be written with the aid of the Riemann-Liouville definition as[21]

$$D_{t,a}^{\mu}x(t) = \begin{cases} \dfrac{1}{\Gamma(n-\mu)}\dfrac{\mathrm{d}^n}{\mathrm{d}t^n}\displaystyle\int_a^t (t-y)^{n-\mu-1}f(y)\mathrm{d}y, & n-1<\mu<n \\ \dfrac{\mathrm{d}^n}{\mathrm{d}x^n}f(t), & \mu=n, \end{cases} \tag{1}$$

where μ is a noninteger number which verifies $n-1<\mu<n$, $n=0,1,\ldots$. This definition of the fractional derivative is useful since for negative values of μ, the operator D^{μ} represents the fractional integration operator.

The fractional differentiation operator also verifies the following rules:

Composition or semigroup rule:

$$D_{t,a}^{\alpha}D_{t,a}^{\beta} = D_{t,a}^{\alpha+\beta}.$$

Zero rule:

$$D_{t,a}^{0}x(t) = x(t).$$

Fractional differentiation of a product of two functions $f(t)g(t)$ (Leibniz rule):

$$D_{t,a}^{\mu}f(t)g(t) = \sum_{k=0}^{\infty}\binom{k}{\mu}D_{t,a}^{k}f(t)D_{t,a}^{\mu-k}g(t). \tag{2}$$

For different values of a, different particular derivatives result, for which different differentiation rules result. This apparent contradiction was discussed and pointed out in the paper of Lavoie, Osler, and Tremblay.[22]

The value $a=-\infty$ gives the $D_{t,-\infty}^{\mu}$ operator, to which the following differentiation rule corresponds:

$$D_{t,-\infty}^{\mu}\exp(ut) = u^{\mu}\exp(ut), \tag{3}$$

where u is a complex valued quantity, $u \in C$.

The following differentiation rules result:

$$D_{t,-\infty}^{\mu}\exp(iat) = a^{\mu}\exp\left(i\left(at+\frac{\pi}{2}\mu\right)\right),$$

$$D_{t,-\infty}^{\mu}\sin(\omega t) = \omega^{\mu}\sin\left(\omega t+\frac{\pi}{2}\mu\right), \tag{4}$$

$$D_{t,-\infty}^{\mu}\cos(\omega t) = \omega^{\mu}\cos\left(\omega t+\frac{\pi}{2}\mu\right).$$

For $a=0$ the differentiation operator,

$$D_t^\mu = D_{t,0}^\mu, \tag{5}$$

results, which will be used in our calculation since the process investigated by us corresponds to positive values of time. For this kind of fractional derivative it results:[21,22,28]

$$D_t^\mu t^k = \frac{n!}{\Gamma(k-\mu+1)} t^{k-\mu}, \tag{6}$$

where $k \in N$.

The differentiation rule for the constant function $f(t)=1$[21,22] is

$$D_t^\mu 1 = \frac{n!}{\Gamma(1-\mu)} t^{-\mu}, \tag{7}$$

and it is valid for $\mu \geqslant 0$ and $t>0$, where Γ represents the Euler function.[27]

An interesting category of functions are the Mittag-Leffler functions, $E_\alpha(t)$ and $E_{\alpha,\beta}(t)$:[21]

$$E_\mu(z) = \sum_{k=0}^{\infty} \frac{z^k}{\Gamma(\mu k+1)}, \quad E_{\mu,\alpha}(z) = \sum_{k=0}^{\infty} \frac{z^k}{\Gamma(\mu k+\alpha)}, \tag{8}$$

valid for $\mu \geqslant 0$, $\alpha \in C$ and $z \in C$.

It is important to note that the eigenfunctions $\psi_\mu(t)$ of the $D_{t,0}^\mu$ operator can be expressed in terms of $E_{\mu,\alpha}$ and the initial conditions $x(0)=x_0$, $\dot{x}(0)=x_1$, $\ddot{x}(0)=x_2,\ldots$, in the form[23]

$$\psi_\mu(t) = \sum_{j=0}^{[\mu]-1} x_j E_{\mu,j+1}(\lambda t^\mu), \tag{9}$$

which obeys the eigenvalue equation:

$$D_{t,0}^\mu \psi_\mu(t) = \lambda \psi_\mu(t). \tag{10}$$

The identity:

$$D_{t,0}^\mu E_\mu(-(at)^\mu) = -a^\mu E_\mu(-(at)^\mu), \tag{11}$$

can also be proved.

III. THE FRACTIONAL ANELASTIC MODELS

So far, a series of linear fractional anelastic models have been introduced in the literature for the investigation of a number of materials, as presented in Sec. II. We introduce the stress σ and the strain ε. A general linear anelastic model of this type can be written in the following form:[6]

$$\sigma + \sum_{i=1}^{n} \tau_\varepsilon^{\alpha_i} D_{t,a}^{\alpha_i} \sigma = E_0 \left(\varepsilon + \sum_{j=1}^{m} \tau_\sigma^{\beta_j} D_{t,a}^{\beta_j} \varepsilon \right), \tag{12}$$

where $n, m \in N$ are positive integers, $\tau_\sigma, \tau_\varepsilon$ are time constants, α_i, β_j are fractional and/or integer parameters (where $\alpha_i>0$, $0<\beta_j<1$), and E_0 the relaxed elastic modulus. $D_{t,a}^{\alpha_i,\beta_j}$ are the Riemann-Liouville differentiation operators.

There are known nonlinear anelastic models with fractional damping,[24] used for the study of rubbers and plastic materials.

Also, there are nonlinear anelastic models, based on the structural properties of polycrystalline solids, in which the rate of the relaxation process is a linear function of the stress applied on the grain boundaries:[25]

$$v \sim \frac{1}{\tau} = \frac{\alpha\sigma + \beta}{\tau_0}, \tag{13}$$

where τ is the nonlinear relaxation time, α and β are constants of the material, and τ_0 is the time constant in the linear model approximation.

The relaxed and the unrelaxed Young moduli, will be denoted by E_r and by $E_u = E_r + \delta E$, respectively. If the nonlinear processes are weak, α is a small parameter, and $\beta \approx 1$. For this kind of material, the nonlinear constitutive equation was established:[25]

$$(\dot{\sigma} - E_r\dot{\varepsilon}) + \frac{1}{\tau_0}[\alpha(\sigma - E_r\varepsilon) + \beta](\sigma - E_r\varepsilon) = \delta E\dot{\varepsilon}. \tag{14}$$

We consider the case of harmonic excitation

$$\varepsilon = A \sin \omega t,$$

where A is the amplitude of the excitation strain and ω is the angular frequency of the excitation.

Equation (14) can be written in a more general form, considering the dependency on fractional derivatives:

$$D^1_{t,a}x + \gamma D^\mu_{t,a}x + \beta x + \alpha x^2 = \mathcal{A}_0 \cos \omega t, \tag{15}$$

where $x = \sigma - E_r\varepsilon$, $\mathcal{A}_0 = \delta E \omega A$, μ has noninteger values, and γ and β are positive material constants.

Assuming that the initial condition at $t=0$ is

$$\sigma_0 = (E_r + \delta E)\varepsilon_0, \tag{16}$$

it corresponds to instantaneous response to the constant strain ε_0.

If $\beta = 1$ and $\alpha = 0$ the standard case of linear anelastic model results. Considering that α is a small parameter $0 < \alpha < 1$) the anelastic solid with small nonlinearities is obtained.

By optimal selection of the parameters of this model solutions with a strong linear behavior of the response to vibrations and with a nonlinear manifestation for the exponential response can be obtained.

IV. VARIATIONAL ITERATION METHOD

In order to find an analytical solution of Eq. (15) we will use a powerful variational iteration method established by He,[12,13] a new type of Lagrange multiplier method.

This universal method gives the possibility to solve all kinds of nonlinear equations. The application of the powerful method is limited to the case of a nonlinear system of type:

$$Lx(t) + Nx(t) = g(t), \tag{17}$$

where L is a linear operator, N is a nonlinear operator, and $g(t)$ is a known excitation function.

The variational iteration method gives the possibility to write the solution of Eq. (17) with the aid of the correction functional:

$$x_{n+1}(t) = x_n(t) + \int_0^t \lambda(\tau)(Lx(\tau) + N\tilde{x}(\tau) - g(\tau))\mathrm{d}\tau, \tag{18}$$

where x_n is an initial approximation with possible unknowns, λ is a Lagrange multiplier, and $\tilde{y}$ represents a term with a restricted variation, i.e., $\delta\tilde{y} = 0$. The λ multiplier can be found from the stationary condition of the correction functional $\delta x_{n+1} = 0$.

The variational iteration method was proposed in 1998, and it is used to solve fractional differential equations arising in seepage flow.[14]

We will use this method to obtain the solution of the constitutive equation (15). In our case we take

$$L = \frac{\mathrm{d}x}{\mathrm{d}t} + \beta x,$$

$$g = \mathcal{A}_0 \cos \omega t,$$

$$N = \gamma D^{\mu}_{t,a} x + \alpha x^2.$$

Imposing the stationary condition ($\delta x_{n+1}=0$) on the correction functional it results

$$\dot{\lambda}(\tau) - \beta\lambda(\tau) = 0, \tag{19}$$

$$[1 + \lambda(\tau)]\big|_{\tau=t} = 0, \tag{20}$$

from which the Lagrange multiplier can be identified as

$$\lambda(\tau) = -\exp(\beta(\tau - t)). \tag{21}$$

We will consider an initial approximation of the solution of

$$x_0(t) = c\exp(-\beta t) + \frac{\mathcal{A}_0\omega}{\omega^2+\beta^2}\sin\omega t + \frac{\mathcal{A}_0\beta}{\omega^2+\beta^2}\cos\omega t \tag{22}$$

containing the integration constant c.

We will investigate the solution of Eq. (15) for two particular forms of the fractional derivative, i.e., for $D^{\mu}_{t,0}$ and $D^{\mu}_{t,-\infty}$.

A. Case of $D^{\mu}_{t,0}$

A fractional oscillator was studied on the basis of He's method in a previous paper.[26]

In this case, for the linear model $\alpha=0$ replacing (19), (21), and (22) in (18) based on differentiation rules (6) and (7), it results:

$$\begin{aligned} x_{\mathrm{lin}}(t) = c\Bigg\{ & \exp(-\beta t) - \frac{\gamma}{\beta t^{\mu}\Gamma(1-\mu)}\Bigg[-e^{-\beta t}\sum_{n=0}^{\infty}\frac{(-\beta t)^n {}_1F_1(n-\mu;n+1-\mu;\beta t)}{(1-\mu)_n} \\ & + {}_1F_1(1;1-\mu;-\beta t)\Bigg]\Bigg\} + \frac{\mathcal{A}_0\omega}{\omega^2+\beta^2}\sin\omega t + \frac{\mathcal{A}_0\beta}{\omega^2+\beta^2}\cos\omega t - \gamma\mathcal{A}_0\frac{1}{(\omega^2+\beta^2)\beta t^{\mu}\Gamma(1-\mu)} \\ & \times\Bigg\{(\beta - i\omega)\Bigg[-e^{-\beta t}\sum_{n=0}^{\infty}\frac{(i\omega t)^n {}_1F_1(n-\mu;n+1-\mu;\beta t)}{(1-\mu)_n} + {}_1F_1(1;1-\mu;i\omega t)\Bigg] \\ & + (\beta + i\omega)\Bigg[-e^{-\beta t}\sum_{n=0}^{\infty}\frac{(-i\omega t)^n {}_1F_1(n-\mu;n+1-\mu;\beta t)}{(1-\mu)_n} + {}_1F_1(1;1-\mu;-i\omega t)\Bigg]\Bigg\}, \end{aligned} \tag{23}$$

where ${}_1F_1(a;b;z)$ represents the confluent hypergeometric function:[27,28]

$${}_1F_1(a;b;z) = \sum_{n=0}^{\infty}\frac{(a)_n z^n}{(b)_n n1}.$$

The quantity $(a)_n$ represents[27]

$$(a)_n = a(a+1)(a+2)\ldots(a+n-1),$$

where $(a)_0=1$. The quantity $(a)_n$ is connected to the Γ function by

$$(a)_n = \frac{\Gamma(a+n)}{\Gamma(a)}.$$

For the nonlinear case ($\alpha \neq 0$) we obtain

$$x_1(t) = x_{\text{lin}}(t) + x_n(t), \tag{24}$$

where $x_n(t)$ is

$$\begin{aligned} x_n(t) = -\frac{\alpha}{\beta}e^{-\beta t}\Bigg\{ & c^2(1-e^{-\beta t}) + \frac{1}{2}\frac{\mathcal{A}_0^2}{(\omega^2+\beta^2)}(e^{\beta t}-1) + \frac{1}{2}\frac{\mathcal{A}_0^2(\beta^2-\omega^2)\beta}{(\omega^2+\beta^2)^2(4\omega^2+\beta^2)} \\ & \times[-\beta+\beta e^{\beta t}\cos 2\omega t + 2\omega e^{\beta t}\sin 2\omega t] + \frac{\mathcal{A}_0^2(\beta^2\omega)}{(\omega^2+\beta^2)^2(4\omega^2+\beta^2)} \\ & \times[2\omega - 2\omega e^{\beta t}\cos 2\omega t + \beta e^{\beta t}\sin 2\omega t] + 2\frac{\mathcal{A}_0 c}{(\omega^2+\beta^2)}\left[-2\beta(\cos\omega t - 1) + \frac{\beta^2}{\omega}\sin\omega t\right]\Bigg\}, \end{aligned} \tag{25}$$

It is important to underline that for the linear case, the first iteration of solution (23) must be in principle the exact solution.

It can be noted that, using the properties of the hypergeometric functions, the series which appear in (23) can be written in a more compact form:

$$\sum_{n=0}^{\infty}\frac{(at)^n F(n-\mu;n+1-\mu;\beta t)}{(1-\mu)_n} = \sum_{n=0}^{\infty}\frac{(at)^n}{(-\mu)_n}\left(\frac{\mathrm{d}}{\mathrm{d}(\beta t)}\right)^n F(-\mu;1-\mu;\beta t) = HF(-\mu;1-\mu;\beta t),$$

where H is a linear operator.

An alternate way to find the solution consists of taking the linear operator L from (17) as $L = D^{\mu}_{t,a}x + (\beta/\gamma)x$ and expressing the solution for $Lx_0=0$ in terms of Mittag-Leffler E_{μ} or $E_{\mu,j}$ functions due to properties (10) and (11).

The stress response resulting after the use of the initial condition (16), for the both cases, is

$$\sigma(t) = x + E_r A\sin\omega t,$$

where $x=x_{\text{lin}}$ or $x=x_1$.

B. Case of $D^{\mu}_{t,-\infty}$

In this case, for the linear model $\alpha=0$ replacing (19), (21), and (22) in (18), based on differentiation rules (3) and (4) it results:

$$\begin{aligned} x_{\text{lnr}}(t) = {} & c(1-\gamma(-\beta)^{\mu}t)\exp(-\beta t) + \frac{\mathcal{A}_0\omega}{\omega^2+\beta^2}\sin\omega t + \frac{\mathcal{A}_0\beta}{\omega^2+\beta^2}\cos\omega t - \frac{\gamma\mathcal{A}_0}{\omega^2+\beta^2}e^{-\beta t} \\ & \times\Bigg[-\frac{\omega\left(-\omega\cos\left(\frac{\pi\mu}{2}\right)+\beta\sin\left(\frac{\pi\mu}{2}\right)+\omega e^{\beta t}\cos\left(\omega t+\frac{\pi\mu}{2}\right)-\beta e^{\beta t}\sin\left(\omega t+\frac{\pi\mu}{2}\right)\right)}{\beta^2+\omega^2} \\ & -\frac{\beta\left(\beta\cos\left(\frac{\pi\mu}{2}\right)+\omega\sin\left(\frac{\pi\mu}{2}\right)-\beta e^{\beta t}\cos\left(\omega t+\frac{\pi\mu}{2}\right)-\omega e^{\beta t}\sin\left(\omega t+\frac{\pi\mu}{2}\right)\right)}{\beta^2+\omega^2}\Bigg]. \end{aligned} \tag{26}$$

For the nonlinear case ($\alpha \neq 0$) the solution will be of the form:

$$x_1(t) = x_{\text{lnr}}(t) + x_n(t), \tag{27}$$

where x_n is given by (25).

It is important to underline that also for this linear case, the first iteration of solution (26) must be in principle the exact solution.

The use of $D^{\mu}_{t,-\infty}$ differentiation operator gives different results with respect to $D^{\mu}_{t,0}$. It must be noted that this situation is more restrictive, and can be considered similar to the use of the Fourier transform for solving nonhomogeneous differential linear equations: this case gives only the part of solution connected to the permanent response.

Also, the results become incorrect when $(-\beta)^{\mu}$ are complex valued. Consequently, in order to obtain valid solutions, the terms containing complex valued quantities must be eliminated from the solution.

The stress response that results after the use of the initial condition (16), for the both cases, is

$$\sigma(t) = x + E_r A \sin \omega t,$$

where $x = x_{\text{lnr}}$ or $x = x_1$.

V. VOLTERRA SERIES METHOD

There are methods for the identification of nonlinear systems from experimental data. For a nonlinear system described by equations of type (15) the response can be expressed in terms of Volterra series:[29,30]

$$\begin{aligned} x(t) = &\int_0^{\infty} h_1(\tau_1) u(t-\tau_1) \mathrm{d}\tau_1 + \int_0^{\infty}\int_0^{\infty} h_2(\tau_1,\tau_2) u(t-\tau_1) u(t-\tau_2) \mathrm{d}\tau_1 \mathrm{d}\tau_2 \\ &+ \int_0^{\infty}\int_0^{\infty}\int_0^{\infty} h_3(\tau_1,\tau_2,\tau_3) u(t-\tau_1) u(t-\tau_2) u(t-\tau_3) \mathrm{d}\tau_1 \mathrm{d}\tau_2 \mathrm{d}\tau_3 + \cdots , \end{aligned} \tag{28}$$

where $h_i(\tau_1, \tau_2, \ldots)$ (with $i = 1, 2, 3, \ldots.$) is the ith order transfer function, and u represents the input function. In our case $u(t) = \dot{\varepsilon}(t)$.

If we consider that the excitation is $\varepsilon(t) = Ae^{i\omega t}$, by replacing (28) in (15) we can calculate different orders of the transfer function for harmonic excitation. In this case the response will have the form:[29,30]

$$x(t) = \sum_{i=1}^{+\infty} (i\tau_0 \omega \delta E)^n H_i(\omega, \omega, \ldots.) \exp[in\omega t] = \sum \xi_n e^{in\omega t}, \tag{29}$$

representing a superposition of harmonics.

The amplitudes ξ_n can be found from the constitutive equation (15). The problem can be correctly formulated only for systems described by constitutive equations with fractional differentiation operators connected to the Fourier transforms, i.e., for $D^{\mu}_{t,-\infty}$. We take (15), for the case of $D^{\mu}_{t,-\infty}$, and use the notation:

$$F(p) = ip + \gamma e^{i(\pi\mu/2)} \omega^{\mu} \beta.$$

Thus, the following results are obtained:

$$\xi_1 = \frac{1}{F(\omega)},$$

$$\xi_2 = -2 \frac{\alpha}{\tau_0} \frac{\xi_1^2}{F(2\omega)}, \tag{30}$$

$$\xi_3 = -6\frac{\alpha}{\tau_0}\frac{\xi_1\xi_2}{F(3\omega)}.$$

The different amplitudes ξ_1 and finally the parameters of the rheologic model may be obtained from experimental data.

VI. CONCLUSIONS

In order to find an analytical solution of Eq. (15) we used a powerful variational iteration method established by He,[12,13] a new type of Lagrange multiplier method. The strength of this method consists in its convergence. We limited our investigations to the first iteration.

We used these methods to establish the solution for a class of linear and nonlinear anelastic models, (15), in which the dependency of fractional damping process (fractional differentiation) appears.

We introduced an anelastic model using a more general definition of fractional differentiation of order μ, using Riemann-Liouville $D_{t,a}^{\mu}$ operator.

Two cases were investigated. For $a=0$ we established the solution for linear and nonlinear cases. It is important to underline that for the linear case, the first iteration of the solution (23) must be in principle the exact solution.

The case $a=-\infty$ was also investigated, establishing the solution for linear and nonlinear situations. The obtained solution was simpler. It was underlined that this situation was more restrictive, and could be considered similar to the use of the Fourier transform for solving nonhomogeneous differential linear equations: this case gives only the part of solution connected to the permanent response. The results cannot be valid when $(-\beta)^{\mu}$ are complex valued.

The variational iteration method of He can be used for finding general solutions for the partial differential equations, starting with a particular solution, as suggested in Ref. 31.

As a generalization of the Fourier transform rheology we introduced the Volterra-Fourier series in order to study the response of nonlinear systems to harmonic excitation.

On the simultaneous presence of unilateral and kinetic constraints in time-dependent impulsive mechanics

Stefano Pasquero[a)]
Dipartimento di Matematica dell'Università di Parma, Parco Area delle Scienze, 53/A - 43100 Parma, Italia

(Received 22 May 2006; accepted 15 June 2006; published online 24 August 2006)

The simultaneous presence of unilateral and kinetic constraints acting on a mechanical system with a finite number of degrees of freedom is framed in the geometric context of left and right jet-bundles of the classical space–time bundle of the system. The survey gives three main cases and several subcases, some of which are mathematically correct but physically meaningless. The existence of at least one frame of reference for which the whole set of constraints can be at rest is the criterion selecting the physically relevant systems. For these systems, the conservation of kinetic energy, possibly together with a standard Gauss's requirement on the impulsive reaction, is shown to give a well posed criterion of ideality of the constraints. The application of the criterion to several examples is presented and the corresponding results are critically analyzed. © *2006 American Institute of Physics.*

I. INTRODUCTION

Differential geometric techniques have been recently discovered again as useful tools for the study of classical impulsive mechanics of systems with a finite number of degrees of freedom, in both cases of free or constrained systems. Besides the usual instruments of differential geometry (for whose applications to impulsive mechanics see, e.g. Refs. 1–5), several results in time-dependent impulsive mechanics were obtained by the author by introducing the framework of left and right jet-bundles of the classical configuration space–time of the mechanical system. In particular, this setup allows deeper insights into the study of the behavior of free systems subject to active impulses,[6] of constrained systems subject to ideal bilateral positional or kinetic constraints,[7,8] and in the study of the concept of ideality for unilateral positional constraints.[9]

In this paper, going in the same direction as the previous cited papers of the author, we present a geometric framework for the study of impulsive systems simultaneously subject to unilateral and kinetic constraints. In particular, we distinguish three different cases: when the system is subject to a kinetic constraint only when it impacts with a unilateral positional constraint (the kinetic constraint "lives" on the positional unilateral constraint); when the system is permanently subject to a kinetic constraint and impacts with unilateral positional constraints; when both situations simultaneously occur, i.e., the system is subject to a permanent kinetic constraint and impacts with a unilateral positional constraint where an ulterior kinetic constraint acts on the system.

For all three cases, following the same line of thought presented in Ref. 9, we propose an ideality criterion of the constraints based on the conservation of the kinetic energy of the system together with, when this requirement turns out to be insufficient to restore the principle of determinism, a Gauss's "extremality" requirement for the impulsive reaction. As usually happens in impulsive problems involving kinetic constraints, Gauss's condition is automatically well posed if

[a)]Electronic mail: stefano.pasquero@unipr.it

the kinetic constraint has a linear-affine nature, but, if the constraint has a nonlinear nature, the existence of the extremum, in general, is not ensured (see Ref. 7). Nevertheless, linear-affine constraints can provide several meaningful examples.

The paper is divided into four sections. Section II presents, in order to fix notation, a brief survey on the general geometric setup for the study of systems subject to bilateral constraints, positional or kinetic, and systems subject to unilateral positional ones. Almost all its material is not new and can be found in literature (see, for example, Refs. 10, 11, 6, 7, and 9). Nevertheless, the reorganization of this material in a form suitable to approach the subsequent problems is new stuff. Section III presents the geometric framing of the three possible cases of coexistence of kinetic and positional unilateral constraints in the general context illustrated in Sec. II, together with a detailed discussion on the conditions determined by the geometry itself on the impulsive reaction. Moreover it presents, for all three possibilities, the ideality criterion based on the conservation of kinetic energy and Gauss's principle. Section IV is devoted to examples of the three possibilities, and it presents a detailed discussion of the behavior of four simple mechanical systems: a cogwheel moving in the plane and impacting with a linear rack; a cogwheel rolling on a horizontal rack and impacting in a smooth vertical wall; a ball rolling on a horizontal plane and impacting in a smooth vertical wall; a ball rolling on a horizontal plane and impacting in a rough vertical wall. Section V briefly presents a critical analysis of the results obtained in Sec. IV, together with conclusions.

II. PRELIMINARIES

A. Geometric aspects of bilateral constraints

The configuration space–time of a mechanical system with a finite number n of degrees of freedom is a bundle $\pi:\mathcal{V}\to\mathbb{E}_1$, where $\mathbb{E}_1$ is the affine line. The set $\mathcal{V}$ is an $(n+1)$-dimensional differentiable manifold (noncanonically) diffeomorphic to the Cartesian product $\mathbb{R}\times\mathcal{Q}$, where the manifold $\mathcal{Q}$ is the usual configuration space of the system. The composition of π with the Cartesian coordinate of $\mathbb{E}_1$ determines the absolute time function $t:\mathcal{V}\to\mathbb{R}$. The bundle $\mathcal{V}$ will be referred to admissible coordinates $(t,x^1,\ldots,x^n)$.

The first jet-extension $\pi:J_1(\mathcal{V})\to\mathcal{V}$ of the configuration space–time represents the absolute velocity space of the system. It can be viewed as a subbundle of the tangent bundle $T(\mathcal{V})$ of $\mathcal{V}$ given by those vectors having the form $\mathbf{p}=\partial/(\partial t)+\dot{x}^i\partial/(\partial x^i)$ or, that is the same, determined by the condition $\{\mathbf{X}\in T(\mathcal{V})\,|<dt,\mathbf{X}>=1\}$. This condition also shows that $J_1(\mathcal{V})$ is an affine bundle, modeled on the so-called vertical vector bundle $\pi:V(\mathcal{V})\to\mathcal{V}$ of the tangent vectors $\mathbf{X}\in T(\mathcal{V})$ satisfying the condition $\{\mathbf{X}\in T(\mathcal{V})\,|<dt,\mathbf{X}>=0\}$, or that is the same, having the form $\mathbf{V}=X^i\partial/(\partial x^i)$. The bundles $J_1(\mathcal{V})$ and$V(\mathcal{V})$ will be both referred to admissible jet-coordinates $(t,x^i,\dot{x}^i)$.

The fibers of $V(\mathcal{V})$ are endowed with a positive definite scalar product $\Phi:V(\mathcal{V})\times_{\mathcal{V}}V(\mathcal{V})\to\mathbb{R}$, where $\times_{\mathcal{V}}$ denotes the usual fiber product of bundles on $\mathcal{V}$. The map Φ is called the vertical scalar product of $\mathcal{V}$ and can be locally described by the functions $g_{ij}(p)=\Phi((\partial/(\partial x^i))_p,(\partial/(\partial x^j))_p)$. We recall that Φ takes intrinsically into account the mass properties of the system (for a detailed discussion of these arguments, see, e.g., Ref. 11, and the references therein).

A frame of reference for the system (without any assumption of rigidity) is a global section $\mathbf{h}:\mathcal{V}\to J_1(\mathcal{V})$. It can be represented by a globally defined vector field $\mathbf{h}=\partial/(\partial t)+H^i(t,x^j)\partial/(\partial x^i)$ and it determines a "vectorialization" of $J_1(\mathcal{V})$, i.e., a diffeomorphism $\Delta_{\mathbf{h}}$ defined by

$$\Delta_{\mathbf{h}}:J_1(\mathcal{V})\to V(\mathcal{V})\quad\text{such that}\quad\Delta_{\mathbf{h}}(\mathbf{p})=\mathbf{p}-\mathbf{h}(\pi(\mathbf{p})).$$

Given a frame $\mathbf{h}$, the vertical vector

$$\Delta_{\mathbf{h}}(\mathbf{p})=\mathbf{p}-\mathbf{h}=(\dot{x}^i-H^i(t,x^j))\frac{\partial}{\partial x^i}$$

represents the *relative velocity* of $\mathbf{p}\in J_1(\mathcal{V})$ with respect to $\mathbf{h}$. Moreover, the function

$$ {}^{\mathbf{h}}\mathcal{K}: J_1(\mathcal{V}) \to \mathbb{R} \quad \text{such that} \quad {}^{\mathbf{h}}\mathcal{K}(\mathbf{p}) = \tfrac{1}{2}\Phi(\mathbf{p}-\mathbf{h}, \mathbf{p}-\mathbf{h}) \tag{1} $$

is the *kinetic energy* of the system with respect to **h**.

Additional positional constraints acting on the system are given by a globally time-fibered subbundle $i: \mathcal{S} \to \mathcal{V}$, where the manifold $\mathcal{S}$ has dimension $(r+1), r<n$. Of course, the bundle $t: \mathcal{S} \to \mathbb{R}$ is the space–time bundle of the system that takes into account the constraint $\mathcal{S}$ as a bilateral constraint. The bundle $\mathcal{S}$ will be referred to admissible coordinates $(t, q^1, \ldots, q^r)$, and the immersion i can be briefly described by the relations $x^i = x^i(t, q^1, \ldots, q^r)$. The bundle $\mathcal{S}$ determines its own first jet-extension $\pi: J_1(\mathcal{S}) \to \mathcal{S}$ with its vertical bundle $\pi: V(\mathcal{S}) \to \mathcal{S}$. They both are described by admissible jet-coordinates $(t, q^\eta, \dot{q}^\eta)$, and their elements have the vector representations $\mathbf{q} = \partial/(\partial t) + \dot{q}^\eta \partial/(\partial q^\eta)$ and $\mathbf{V} = V^\eta \partial/(\partial q^\eta)$, respectively.

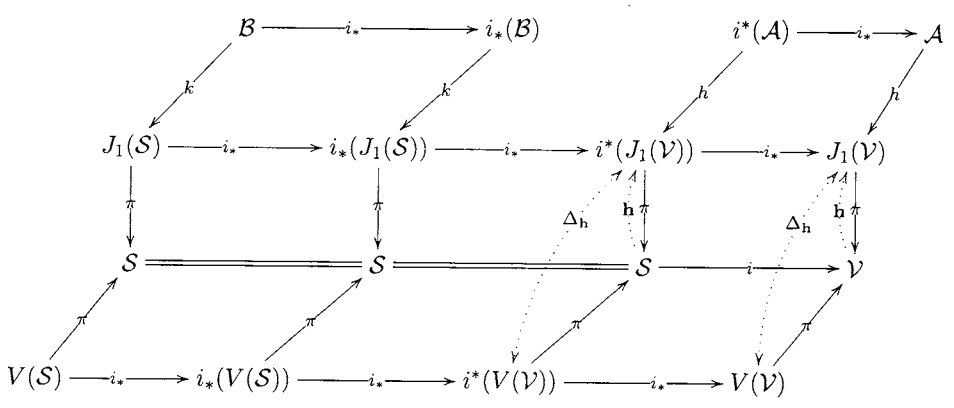
The tangent map $i_*: T(\mathcal{S}) \to T(\mathcal{V})$ determines by restriction the fibered immersions $i_*: J_1(\mathcal{S}) \to J_1(\mathcal{V})$ and $i_*: V(\mathcal{S}) \to V(\mathcal{V})$. As a consequence, the vertical scalar product Φ of $\mathcal{V}$ can be pulled back to $V(\mathcal{S})$, defining the vertical scalar product φ of $\mathcal{S}$.

The standard pull-back techniques allow the construction of the pull-back bundles $\pi: i^*(J_1(\mathcal{V})) \to \mathcal{S}$ and $\pi: i^*(V(\mathcal{V})) \to \mathcal{S}$ (see Ref. 9), both referred to fibered admissible coordinates $(t, q^\eta, \dot{x}^i)$. A frame of reference **h** and the corresponding vectorialization $\Delta_{\mathbf{h}}$ and kinetic energy ${}^{\mathbf{h}}\mathcal{K}$ can be naturally restricted to maps $\mathbf{h}: \mathcal{S} \to i^*(J_1(\mathcal{V})), \Delta_{\mathbf{h}}: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ and ${}^{\mathbf{h}}\mathcal{K}: i^*(J_1(\mathcal{V})) \to \mathbb{R}$.

The framing of kinetic constraints in this global geometric context needs some clarifications. The presence of kinetic constraints permanently acting on the system (without considering the possible presence of additional positional constraint) is modeled, as it is well known (see, e.g., Ref. 10), by a subbundle $h: \mathcal{A} \to J_1(\mathcal{V})$. The manifold $\mathcal{A}$ is globally fibered over $\mathcal{V}$ (and then over the real line), and $\mathcal{A}$ has dimension $(n+s+1), s<n$. The bundle $\mathcal{A}$ will be called a *permanent* kinetic constraint and will be referred to admissible coordinates $(t, x^i, \dot{\xi}^A)$. The standard pull-back procedure determines the subbundle $\pi: i^*(\mathcal{A}) \to \mathcal{S}$ of the bundle $\pi: i^*(J_1(\mathcal{V})) \to \mathcal{S}$ described by admissible coordinates $(t, q^\alpha, \dot{\xi}^A)$.

However, in the presence of an additional positional constraint $\mathcal{S}$, a kinetic constraint can be defined only on $\mathcal{S}$. Then a subbundle $k: \mathcal{B} \to J_1(\mathcal{S})$ can be introduced for the bundle $J_1(\mathcal{S})$, with the manifold $\mathcal{B}$ globally fibered over $\mathcal{S}$, and $\mathcal{B}$ of dimension $(r+m+1)$, $m<r$. The bundle $\mathcal{B}$ will be referred to admissible coordinates $(t, q^\eta, \dot{\theta}^Y)$. This kinetic constraint can act on the system only when the system is in a configuration of $\mathcal{S}$: for this reason, slightly improperly, $\mathcal{B}$ will be called an *instantaneous* kinetic constraint.

Of course, both kinds of kinetic constraints can be simultaneously present on the system. The whole situation is summarized with the following diagram:



B. Geometric aspects of impulsive constraints

In order to approach the study of impulsive aspects of the system, it is useful to introduce the bundles $\pi: L_1(\mathcal{V}) \to \mathcal{V}$ of the left velocities of the system and $\pi: R_1(\mathcal{V}) \to \mathcal{V}$ of the right velocities

of the system (see Ref. 6). They are both affine bundles canonically diffeomorphic to $J_1(\mathcal{V})$ in the geometric sense, with diffeomorphism $Id_L: J_1(\mathcal{V}) \to L_1(\mathcal{V})$ and $Id_R: J_1(\mathcal{V}) \to R_1(\mathcal{V})$, but their physical interpretation is slightly different from that of $J_1(\mathcal{V})$. The action of the diffeomorphisms Id_L and Id_R will frequently be implicitly understood. We will use jet-coordinates $(t, x^i, \dot{x}^i_L)$ to describe $L_1(\mathcal{V})$ and $(t, x^i, \dot{x}^i_R)_i$ to describe $R_1(\mathcal{V})$. The elements $\mathbf{p}_L$ of $L_1(\mathcal{V})$ can be represented in the vector form $\mathbf{p}_L = \partial/(\partial t) + \dot{x}^i_L \partial/(\partial x^i)$, and, analogously, $\mathbf{p}_R \in R_1(\mathcal{V})$ can be written as $\mathbf{p}_R = \partial/(\partial t) + \dot{x}^i_R \partial/(\partial x^i)$.

Due to the affine structure of $L_1(\mathcal{V})$ and $R_1(\mathcal{V})$ and to the diffeomorphisms Id_L and Id_R, we can define two fibered maps

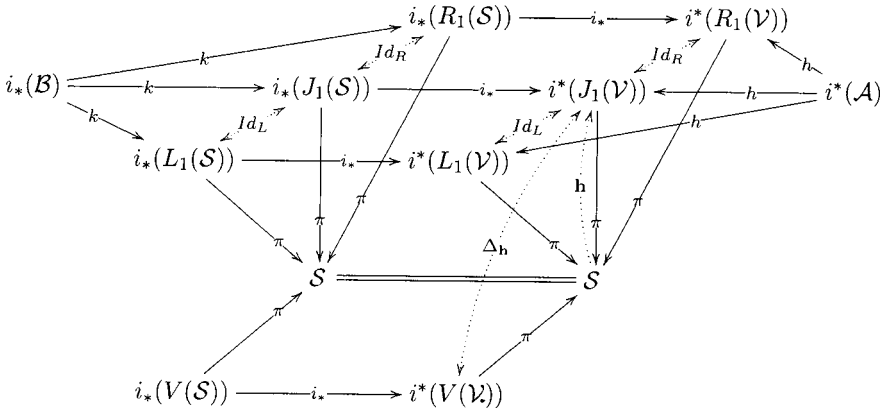
$$\begin{aligned} &\Xi\colon L_1(\mathcal{V}) \times_{\mathcal{V}} V(\mathcal{V}) \to R_1(\mathcal{V}) \text{such that} \quad \Xi(\mathbf{p}_L, \mathbf{V}) = \mathbf{p}_L + \mathbf{V}, \\ &\Delta\colon L_1(\mathcal{V}) \times_{\mathcal{V}} R_1(\mathcal{V}) \to V(\mathcal{V}) \quad \text{such that} \quad \Delta(\mathbf{p}_L, \mathbf{p}_R) = \mathbf{p}_R - \mathbf{p}_L. \end{aligned} \tag{2}$$

In the presence of additional positional constraints, identical constructions can be repeated for the bundle $t: \mathcal{S} \to \mathbb{R}$, obtaining the bundles $L_1(\mathcal{S})$ and $R_1(\mathcal{S})$ canonically diffeomorphic to $J_1(\mathcal{S})$ with diffeomorphisms $Id_L: J_1(\mathcal{S}) \to L_1(\mathcal{S})$ and $Id_R: J_1(\mathcal{S}) \to R_1(\mathcal{S})$. They are described by jet-coordinates $(t, q^\eta, \dot{q}^\eta_L)$ and $(t, q^\eta, \dot{q}^\eta_R)$ respectively, and their elements admit the vector representation $\mathbf{q}_L = \partial/(\partial t) + \dot{q}^\eta_L \partial/(\partial q^\eta)$ and $\mathbf{q}_R = \partial/(\partial t) + \dot{q}^\eta_R \partial/\partial q^\eta$.

The immersion $i_*: J_1(\mathcal{S}) \to J_1(\mathcal{V})$ determines, thanks to the diffeomorphisms Id_L, Id_R, the immersions $i_*: L_1(\mathcal{S}) \to L_1(\mathcal{V})$ and $i_*: R_1(\mathcal{S}) \to R_1(\mathcal{V})$. Therefore, applying once again the pull-back procedure, we can construct the bundles $\pi: i^*(L_1(\mathcal{V})) \to \mathcal{S}$ and $\pi: i^*(R_1(\mathcal{V})) \to \mathcal{S}$, locally described by coordinates $(t, q^\eta, \dot{x}^i_L)$ and $(t, q^\eta, \dot{x}^i_R)$, respectively. Of course, as it happens for the immersion $i_*: J_1(\mathcal{S}) \to i^*(J_1(\mathcal{V}))$, the images $i_*(L_1(\mathcal{S}))$ and $i_*(R_1(\mathcal{S}))$ are affine subbundles of $i^*(L_1(\mathcal{V}))$ and $i^*(R_1(\mathcal{V}))$, respectively.

The pull-back bundle $h: i^*(\mathcal{A}) \to i^*(J_1(\mathcal{V}))$ of the permanent kinetic constraint $\mathcal{A}$ determines, using the diffeomorphisms Id_L and Id_R, the subbundles $h: i^*(\mathcal{A}) \to i^*(L_1(\mathcal{V}))$ and $h: i^*(\mathcal{A}) \to i^*(R_1(\mathcal{V}))$. Similarly, the instantaneous constraint $\mathcal{B}$ gives rise to subbundles $k: i_*(\mathcal{B}) \to i_*(L_1(\mathcal{S}))$ and $k: i_*(\mathcal{B}) \to i_*(R_1(\mathcal{S}))$. Later on, when no confusion can arise, the action of the immersion h and k will be often omitted and implicitly understood.

Focusing our attention only on the part of the construction that will be intensively used in the paper, the geometric setup is synthesized by the following diagram:



(3)

An impulse acting on the system can be equivalently described by a map $\mathcal{I}: L_1(\mathcal{V}) \to R_1(\mathcal{V})$ assigning to each left velocity $\mathbf{p}_L$ of the system a corresponding right velocity $\mathbf{p}_R$, or, preferably in order to preserve some similarities with the usual definition of forces (see, e.g., Refs. 10 and 11), by a map $\mathbf{I}: J_1(\mathcal{V}) \to V(\mathcal{V})$ assigning to each velocity $\mathbf{p}$ of the system the corresponding jump of velocity $\mathbf{V} = \mathbf{I}(\mathbf{p})$ (see, e.g., Ref. 6). The equivalence of the two definitions is synthesized by the relation $\mathbf{p}_R = \mathbf{p}_L + \mathbf{I}(\mathbf{p}_L)$ and it is easily proved taking into account the maps (2).

C. Geometric aspects of unilateral constraints

The bundle $i^*(J_1(\mathcal{V}))$ is, by its very nature, the set of all possible absolute velocities of the system when the system itself is in a configuration of $\mathcal{S}$, but without thinking of $\mathcal{S}$ as a constraint. Therefore, $i^*(J_1(\mathcal{V}))$ is the most suitable geometric environment to approach the analysis of $\mathcal{S}$ as a unilateral constraint acting on the system.

Every map $\mathbf{I}: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ defined on the bundle $i^*(J_1(\mathcal{V}))$ can be thought of as an assignment of the impulsive reaction of $\mathcal{S}$ considered as a unilateral constraint acting on the system: given an "entrance" velocity of the system in a configuration of $\mathcal{S}$, the map $\mathbf{I}$ determines, through the map Ξ defined in (2), a corresponding "exit" velocity of the system from the same configuration of $\mathcal{S}$. Therefore, once $\mathcal{S}$ is assigned, every criterion fit to determine a unique impulse $\mathbf{I}: i^*(J_1(\mathcal{V})) \to i^*(V(\mathcal{V}))$ is a so-called (impulsive) *constitutive characterization* of the unilateral constraint $\mathcal{S}$ (see Ref. 9).

The immersions $i_*: J_1(\mathcal{S}) \to i^*(J_1(\mathcal{V}))$ and $i_*: V(\mathcal{S}) \to i^*(V(\mathcal{V}))$ play a crucial role in the geometric model of $\mathcal{S}$ as unilateral constraint. Since their images $i_*(J_1(\mathcal{S}))$ and $i_*(V(\mathcal{S}))$ are an affine subbundle of $i^*(J_1(\mathcal{V}))$ and a vector subbundle of $i^*(V(\mathcal{V}))$, respectively, then the vertical metric Φ defined on $i^*(V(\mathcal{V}))$ determines, with obvious meaning of the notation, the splits

$$i^*(V(\mathcal{V})) = i_*(V(\mathcal{S})) \oplus (i_*(V(\mathcal{S})))^\perp,$$

$$\Phi = \varphi \otimes \psi, \tag{4}$$

and the projection operators

$$\mathcal{P}^{\|}: i^*(V(\mathcal{V})) \to i_*(V(\mathcal{S})), \quad \mathcal{P}^{\perp}: i^*(V(\mathcal{V})) \to (i_*(V(\mathcal{S})))^\perp.$$

It is a straightforward matter[9] to show that an analogous split

$$i^*(J_1(\mathcal{V})) = i_*(J_1(\mathcal{S})) \oplus (i_*(V(\mathcal{S})))^\perp \tag{5}$$

and analogous projection operators

$$\mathcal{P}^{\|}_{\mathcal{S}}: i^*(J_1(\mathcal{V})) \to i_*(J_1(S)), \quad \mathcal{P}^{\perp}_{\mathcal{S}}: i^*(J_1(\mathcal{V})) \to (i_*(V(\mathcal{S})))^\perp$$

can be introduced for the affine bundle $i^*(J_1(\mathcal{V}))$. Note moreover that (see, for example, Refs. 10 and 3), from the computational point of view, the operators $\mathcal{P}^{\|}_{\mathcal{S}}$ and $P^{\perp}_{\mathcal{S}}$ can be determined through a minimum principle, since, for every point $\mathbf{p} \in i^*(J_1(\mathcal{V}))$, the projection $\mathcal{P}^{\|}_{\mathcal{S}}(\mathbf{p})$ realizes the minimum of the scalar function

$$f_{\mathbf{p}}: i_*(J_1(\mathcal{S})) \to \mathbb{R} \quad \text{such that} \quad f_{\mathbf{p}}(\mathbf{y}) = \Phi(\mathbf{p}-\mathbf{y}, \mathbf{p}-\mathbf{y}).$$

The presence of the constraint $\mathcal{S}$ allows the selection of the class $\mathcal{H}$ of the frames of reference that are tangent to $\mathcal{S}$. The set $\mathcal{H}$ is formed by all the frames of reference whose one-parameter group of transformations maps the constraint $\mathcal{S}$ into itself. The kinematical meaning of this property is that $\mathcal{H}$ is formed by those frames for which $\mathcal{S}$ can be "at rest" (see Ref. 9).

For every absolute velocity $\mathbf{p} \in i^*(J_1(\mathcal{V}))$, the component $\mathcal{P}^{\perp}(\mathbf{p}-\mathbf{h}) \in (i_*(V(\mathcal{S})))^\perp$ of the relative velocity $\mathbf{p}-\mathbf{h}$ orthogonal to the constraint $\mathcal{S}$ is invariant with respect to the choice of the frame $\mathbf{h}$ in $\mathcal{H}$. Equivalently, given an absolute velocity $\mathbf{p} \in i^*(J_1(\mathcal{V}))$, the condition $\mathcal{P}^{\perp}(\mathbf{p}-\mathbf{h}) = \mathcal{P}^{\perp}_{\mathcal{S}}(\mathbf{p})$ holds if and only if $\mathbf{h} \in \mathcal{H}$ (see Ref. 9). Restricting our attention to the frames in $\mathcal{H}$, the vertical vector $\mathcal{P}^{\perp}_{\mathcal{S}}(\mathbf{p}) \in (i_*(V(\mathcal{S})))^\perp$ assumes the absolute (in the sense of independent of the frame) meaning of *orthogonal* (to $\mathcal{S}$) absolute velocity of $\mathbf{p}$. The component $\mathcal{P}^{\|}_{\mathcal{S}}(\mathbf{p}) \in i_*(J_1(\mathcal{S}))$ can be called the *tangent* (component of the) absolute velocity.

Suitable splits and projection operators defined on vector or affine bundles and special classes of frames of reference will turn out to be very useful in the analysis of possible constitutive characterizations also when both kinetic and unilateral constraints act on the system. For the analysis of these cases we need the following two lemmas:

Lemma 1.1: Let $\mathbf{K}$ *be an affine space modeled on a* (*finite dimensional*) *vector space* $\mathbf{W}$ *endowed with a scalar product* Φ, *and let* $\mathbf{A}$ *be an affine subspace of* $\mathbf{K}$ *modeled on the vector subspace* $\mathbf{U}$ *of* $\mathbf{W}$. *Then*

(1) $\mathbf{K}=\mathbf{A}\oplus\mathbf{U}^{\perp}$ (*where, of course,* $\mathbf{W}=\mathbf{U}\oplus\mathbf{U}^{\perp}$) *or, that is the same,* $\forall k\in\mathbf{K}$ *there exists a unique pair* $a\in\mathbf{A},\mathbf{u}\in\mathbf{U}^{\perp}$ *such that* $k-a=\underline{\mathbf{u}}$;
(2) *introduced the natural projection operators* $\mathcal{P}_{\mathbf{W},\mathbf{U}^{\perp}}:\mathbf{W}\to\mathbf{U}^{\perp}$ *and* $\mathcal{P}_{\mathbf{K},\mathbf{U}^{\perp}}:\mathbf{K}\to\mathbf{U}^{\perp}$, *determined by the splits* $\mathbf{W}=\mathbf{U}+\mathbf{U}^{\perp}$ *and* $\mathbf{K}=\mathbf{A}\oplus\mathbf{U}^{\perp}$, *then* $\mathcal{P}_{\mathbf{W},\mathbf{U}^{\perp}}(k-a)=\mathcal{P}_{\mathbf{K},\mathbf{U}^{\perp}}(k)$ *if and only if* $a\in\mathbf{A}$.

To prove the first part of the lemma, it is sufficient to consider the pair $a\in\mathbf{A},\mathbf{u}\in\mathbf{U}^{\perp}$ that realizes the minimum of the function

$$f_k{:}A\to\mathbb{R}\quad\text{such that}\quad f_k(x)=\Phi(k-x,k-x).$$

This is the unique pair giving the split.

To prove the second part, it is sufficient to show that, due to the linearity of the operators involved, for every pair $k_1,k_2\in\mathbf{K}$, the identity

$$\mathcal{P}_{\mathbf{W},\mathbf{U}^{\perp}}(k_1-k_2)=\mathcal{P}_{\mathbf{K},\mathbf{U}^{\perp}}(k_1)-\mathcal{P}_{\mathbf{K},\mathbf{U}^{\perp}}(k_2)$$

holds. The details of both these proofs are straightforward and left to the reader.

Lemma 1.2: Let $\mathbf{K}$ *be an affine space modeled on the vector space* $\mathbf{W}$, *and let* $\mathbf{A}$, $\mathbf{B}$ *be two affine subspaces of* $\mathbf{K}$ *respectively modeled on the vector subspaces* $\mathbf{U}$, $\mathbf{V}$ of $\mathbf{W}$. *Let* $\mathbf{A}$, $\mathbf{B}$ *be such that* $\mathbf{A}\cap\mathbf{B}\neq\emptyset$. *Then* $\mathbf{A}\cap\mathbf{B}$ *is an affine subspace of* $\mathbf{K}$ (*possibly given by a single point of* $\mathbf{K}$) *modeled on the vector space* $\mathbf{U}\cap\mathbf{V}$.

Once again the proof is straightforward and it is left to the reader.

III. CLASSIFICATION OF CONSTRAINTS AND IDEALITY CRITERION

Taking into account diagram (3), we can note that three distinct impulsive situations can occur to the system when it impacts with a unilateral positional constraint $\mathcal{S}$:

Case I: No permanent kinetic constraints $\mathcal{A}$ act on the system, and an impulsive kinetic constraint $\mathcal{B}$ must be satisfied when the system impacts with $\mathcal{S}$. The geometric setup is illustrated in diagram (3) without the part on the right involving the bundle $\mathcal{A}$. A simple mechanical system described by this situation is a cogwheel moving in a plane and impacting with a linear rack.

Case II: The motion of the system obeys a permanent kinetic condition $\mathcal{A}$ before and after the impact with $\mathcal{S}$, but no impulsive kinetic constraint $\mathcal{B}$ is present on $\mathcal{S}$. The geometric setup is illustrated by (3) but this time without the part on the left involving the bundle $\mathcal{B}$. Examples of this situation are a cogwheel rolling on a horizontal rack and impacting with a smooth vertical wall or, more significantly, a sphere rolling on a horizontal plane and impacting with a smooth vertical wall.

Case III: Both a permanent kinetic constraint $\mathcal{A}$ and an impulsive kinetic constraint $\mathcal{B}$ must be satisfied by the motion of the system, the first before and after the impact with $\mathcal{S}$, and the second during the impact. This case requires the whole diagram (3) to be illustrated. A simple example of this situation is a sphere rolling on a horizontal plane and impacting with a rough vertical wall where an ulterior condition of rolling must be satisfied.

The next part of the section presents a separate analysis of the three cases, in the following hypotheses:

H1: The positional constraint $\mathcal{S}$ has codimension 1 as subbundle of $\mathcal{V}$, or, that is the same, $r=n-1$.

H2: The kinetic constraints $\mathcal{A}$ and $\mathcal{B}$ are affine subbundles of $J_1(\mathcal{V})$ and $J_1(\mathcal{S})$, respectively.

The first hypothesis is required mainly with the intention of avoiding some pathological (and physically almost meaningless) systems, such as a point mass moving in a three-dimensional space and impacting with a one-dimensional thread. This intention will permeate through the whole section, since it will be shown that, depending on the nature of the constraints $\mathcal{A}$, $\mathcal{B}$ and $\mathcal{S}$ (in

Cases II and III), several physically meaningless situations can occur. Note moreover that hypothesis *H1* implies that the vector bundle $(i_*(V(\mathcal{S})))^\perp$ is a (line) bundle whose fibers have dimension 1. Therefore we can introduce a vector field $\mathbf{V}_{\mathcal{S}}^{\perp}$ such that $(i_*(V(\mathcal{S})))^\perp = \mathcal{L}\{\mathbf{V}_{\mathcal{S}}^{\perp}\}$.

The second hypothesis, as we already pointed out, is required mainly in order to avoid technicalities regarding the existence of the extremum in the Gauss's requirement about the reaction. Using admissible coordinates, this means that the immersion $h:\mathcal{A}\to J_1(\mathcal{V})$ can be synthesized by the relations $\dot{x}^i = E_A^i \dot{\xi}^A + F^i$, and the immersion $k:\mathcal{B}\to J_1(\mathcal{S})$ can be synthesized by the relations $\dot{q}^\alpha = M_\Upsilon^\alpha \dot{\theta}^\Upsilon + N^\alpha$, with the coefficients $E_A^i, F^i, M_\Upsilon^\alpha, N^\alpha$ independent of dotted coordinates. In particular, when *H2* holds, the affine structure of the constraints $\mathcal{A}$ and $\mathcal{B}$ implies that the sets

$$V(\mathcal{A}) = \{\mathbf{A} = \mathbf{a}_1 - \mathbf{a}_2 | \mathbf{a}_1, \mathbf{a}_2 \in i^*(\mathcal{A})\},$$

$$V(\mathcal{B}) = \{\mathbf{B} = \mathbf{b}_1 - \mathbf{b}_2 | \mathbf{b}_1, \mathbf{b}_2 \in i_*(\mathcal{B})\}, \tag{6}$$

have the structure of vector subbundles of $i^*(V(\mathcal{V}))$ and $i_*(V(\mathcal{S}))$, respectively.

We underline however that, even imposing conditions *H1* and *H2*, the situation remains general enough to describe a wide variety of mechanical systems, such as the four examples described earlier.

The determination of a constitutive characterization of the constraints follows the same line of thought for all three cases. This line of thought is analogous to the one presented in Ref. 9, when a single unilateral positional constraint acts on the system, and it is synthetically described by the following step-by-step procedure:

Step 1: A geometric analysis of the case is performed in order to determine the set of the admissible left and right velocities $\mathbf{p}_L, \mathbf{p}_R$ of the system, the corresponding admissible impulsive reactions $\mathbf{I}(\mathbf{p}_L)$, the set $\mathcal{H}$ of the frames of reference for which all the constraints can be at rest (if it exists), and a particular component $\mathbf{V}^\perp(\mathbf{p}_L)$ of the left velocity that, in the simplest cases, coincides with the component orthogonal to the whole set of constraints.

Step 2: Conservation of kinetic energy before and after the impact is required, if possible, for all the frames in $\mathcal{H}$.

Step 3: If the impulsive reaction is not uniquely determined, a Gauss's criterion is imposed.

We will show that the procedure can already fail at the first step since the set $\mathcal{H}$ of rest frames can be empty. However, the corresponding systems do not have a clear physical meaning. In fact, the integral lines of the elements of $\mathcal{H}$ represent the possible motions of the system respecting the whole set of constraints, and the condition $\mathcal{H}=\emptyset$ implies that no such motions exist. This is mathematically admissible, but physically meaningless. In a Poisson-type approach, with the impulsive reaction divided in a first part determined by the entrance of the system in the unilateral constraint and a second part determined by the exit of the system out of the constraint (see Ref. 9), if $\mathcal{H}=\emptyset$ the first part of the impulse is undeterminable. Two simple examples should clarify these situations:

Example 1: A point mass moving in the xy-plane is subject to the permanent kinetic constraint $\dot{y}=c_1\neq 0$ and impacts with a horizontal guide $y=0$.

Example 2: A point mass moving in the xy-plane is subject to the permanent kinetic constraint $\dot{x}=c_1$ and impacts with a horizontal guide $y=0$ where an instantaneous kinetic constraint $\dot{x}=c_2$, $c_2\neq c_1$ is defined.

When the first step can be performed with meaningful results, taking into account (1), the second step consists in the requirement

$${}^{\mathbf{h}}\mathcal{K}(\mathbf{p}_L) = {}^{\mathbf{h}}\mathcal{K}(\mathbf{p}_R), \quad \forall\, \mathbf{h} \in \mathcal{H}.$$

A straightforward calculation shows that this condition is equivalent to

$$\Phi(2(\mathbf{p}_L - \mathbf{h}), \mathbf{I}(\mathbf{p}_L)) + \Phi(\mathbf{I}(\mathbf{p}_L), \mathbf{I}(\mathbf{p}_L)) = 0, \quad \forall\, \mathbf{h} \in \mathcal{H} \tag{7}$$

or, that is the same,

$$\Phi(2(\mathbf{p}_L - \mathbf{h}) + \mathbf{I}(\mathbf{p}_L), \mathbf{I}(\mathbf{p}_L)) = 0, \quad \forall\, \mathbf{h} \in \mathcal{H}. \tag{8}$$

Of course, the trivial solution $\mathbf{I}(\mathbf{p}_L)=0$ is not admissible, since it implies that the constraints do not act on the system.

However, depending on the nature of the constraints, conditions (7) or (8) could not determine a unique nontrivial impulsive reaction $\mathbf{I}(\mathbf{p}_L)$. In this case, in order to restore the principle of determinism, we should perform the third step of the procedure.

We advance that, in all the meaningful situations, the result of the above-described procedure is $\mathbf{I}(\mathbf{p}_L)=-2\mathbf{V}^{\perp}(\mathbf{p}_L)$, once again analogous to the impulsive reaction in the case of single unilateral positional constraint acting on the system. However, this conclusion is the result of a detailed analysis of two subcases of Case I, four subcases (with only two of them physically meaningful) of Case II and the other five (once again with only three of them physically meaningful) subcases of Case III. Before delving, in the following, into this analysis, we list the vector expressions in admissible coordinates of the elements of the involved affine and vector spaces, recalling that the vectors must be thought of as having base point in $\mathcal{S}$:

$$\begin{aligned}
i^*(J_1(\mathcal{V})) &= \left\{ \mathbf{p} = \frac{\partial}{\partial t} + \dot{x}^i \frac{\partial}{\partial x^i} \right\}, \\
i^*(V(\mathcal{V})) &= \left\{ \mathbf{V} = X^i \frac{\partial}{\partial x^i} \right\} = \mathcal{L}\left\{ \frac{\partial}{\partial x^i} \right\}, \\
i^*(J_1(\mathcal{S})) &= \left\{ \mathbf{q} = \frac{\partial}{\partial t} + \left(\frac{\partial x^i}{\partial t} + \dot{q}^\alpha \frac{\partial x^i}{\partial q^\alpha} \right) \frac{\partial}{\partial x^i} \right\}, \\
i_*(V(\mathcal{S})) &= \left\{ \mathbf{U} = Q^\alpha \frac{\partial x^i}{\partial q^\alpha} \frac{\partial}{\partial x^i} \right\} = \mathcal{L}\left\{ \frac{\partial x^i}{\partial q^\alpha} \frac{\partial}{\partial x^i} \right\}, \\
i^*(\mathcal{A}) &= \left\{ \mathbf{a} = \frac{\partial}{\partial t} + \left(E^i_A \dot{\xi}^A + F^i \right) \frac{\partial}{\partial x^i} \right\}, \\
V(\mathcal{A}) &= \left\{ \boldsymbol{\Xi} = \Xi^A E^i_A \frac{\partial}{\partial x^i} \right\} = \mathcal{L}\left\{ E^i_A \frac{\partial}{\partial x^i} \right\}, \\
i_*(\mathcal{B}) &= \left\{ \mathbf{b} = \frac{\partial}{\partial t} + \left(\frac{\partial x^i}{\partial t} + \left(M^\alpha_\Upsilon \dot{\theta}^\Upsilon + N^\alpha \right) \frac{\partial x^i}{\partial q^\alpha} \right) \frac{\partial}{\partial x^i} \right\}, \\
V(\mathcal{B}) &= \left\{ \Theta = \Theta^\Upsilon M^\alpha_\Upsilon \frac{\partial x^i}{\partial q^\alpha} \frac{\partial}{\partial x^i} \right\} = \mathcal{L}\left\{ M^\alpha_\Upsilon \frac{\partial x^i}{\partial q^\alpha} \frac{\partial}{\partial x^i} \right\}.
\end{aligned} \tag{9}$$

A. Case I

By the nature of the constraints acting on the system, the admissible left velocities $\mathbf{p}_L$ of the system are elements of $i^*(L_1(\mathcal{V}))$, and the admissible right velocities $\mathbf{p}_R$ of the system are elements of $i^*(R_1(\mathcal{V}))$. Then, the reactive impulse $\mathbf{I}(\mathbf{p}_L)=\mathbf{p}_R-\mathbf{p}_L$ given by the constraints must be in general an element of $i^*(V(\mathcal{V}))$.

Since $i_*(\mathcal{B})$ is an affine subbundle of $i_*(J_1(\mathcal{S}))$, applying Lemma 1.1 to $i_*(J_1(\mathcal{S}))$, modeled on the vector bundle $i_*(V(\mathcal{S}))$ endowed with the scalar product φ induced by Φ, we obtain the splits

$$i_*(V(\mathcal{S})) = V(\mathcal{B}) \oplus (V(\mathcal{B}))^\perp,$$

$$i_*(J_1(\mathcal{S})) = i_*(\mathcal{B}) \oplus (V(\mathcal{B}))^\perp. \tag{10}$$

Replacing them in (4) and (5), we have

$$i_*(V(\mathcal{V})) = V(\mathcal{B}) \oplus (V(\mathcal{B}))^\perp \oplus (i_*(V(\mathcal{S})))^\perp,$$

$$i^*(J_1(\mathcal{V})) = i_*(\mathcal{B}) \oplus (V(\mathcal{B}))^\perp \oplus (i_*(V(\mathcal{S})))^\perp. \tag{11}$$

The space $\mathcal{H}$ of the frames of rest of the whole set of constraints coincides with $i_*(\mathcal{B})$. In fact, since $i^*(\mathcal{B}) \subset i_*(J_1(\mathcal{S}))$, every $\mathbf{h} \in i^*(\mathcal{B})$ is automatically tangent to $\mathcal{S}$. This implies that $\mathcal{H}$ is not empty (even if it can be given by a single point).

Given a left velocity $\mathbf{p}_L \in i^*(L_1(\mathcal{V})) \simeq i^*(J_1(\mathcal{V}))$, we can therefore determine, by introducing the natural projection operators $\mathcal{P}^{\parallel}{}_{\mathcal{B}}: i^*(J_1(\mathcal{V})) \to i_*(\mathcal{B})$ and $\mathcal{P}^{\perp}{}_{\mathcal{B}}: i^*(J_1(\mathcal{V})) \to (V(\mathcal{B}))^\perp \oplus (i_*(V(\mathcal{S})))^\perp$ induced by the second split of (11), the component $\mathbf{V}^\perp(\mathbf{p}_L) = \mathcal{P}^{\perp}{}_{\mathcal{B}}(\mathbf{p}_L)$ of the velocity orthogonal to the whole set of constraints. Lemma 1.1 ensures that, introducing the natural projection operators $\mathcal{P}^{\parallel}: i^*(V(\mathcal{V})) \to V(\mathcal{B})$ and $\mathcal{P}^{\perp}: i^*(V_1(\mathcal{V})) \to (V(\mathcal{B}))^\perp \oplus (i_*(V(\mathcal{S})))^\perp$ induced by the first split of (11), for every $\mathbf{h} \in i_*(\mathcal{B})$ the vector $\mathbf{V}^\perp(\mathbf{p}_L)$ coincides with the component $\mathcal{P}^\perp(\mathbf{p}_L - \mathbf{h})$ of the relative velocity $\mathbf{p}_L - \mathbf{h}$. This concludes Step 1 of the procedure.

In order to determine possible constitutive characterizations $\mathbf{I}(\mathbf{p}_L)$ of the constraints, we impose the conservation of kinetic energy in the impact with respect to all the frames in $\mathcal{H}$. Taking into account the natural decompositions $\mathbf{p}_L - \mathbf{h} = \mathcal{P}^{\parallel}(\mathbf{p}_L - \mathbf{h}) + \mathcal{P}^{\perp}(\mathbf{p}_L - \mathbf{h})$ and $\mathbf{I}(\mathbf{p}_L) = \mathcal{P}^{\parallel}(\mathbf{I}(\mathbf{p}_L)) + \mathcal{P}^{\perp}((\mathbf{p}_L))$, condition (7) gives

$$\begin{aligned}\Phi(2(\mathcal{P}^{\parallel}(\mathbf{p}_L - \mathbf{h}), \mathcal{P}^{\parallel}(\mathbf{I}(\mathbf{p}_L))) + \Phi(2\mathbf{V}^\perp(\mathbf{p}_L), \mathcal{P}^\perp(\mathbf{I}(\mathbf{p}_L))) + \Phi(\mathcal{P}^{\parallel}(\mathbf{I}(\mathbf{p}_L)), \mathcal{P}^{\parallel}(\mathbf{I}(\mathbf{p}_L)))\\ + \Phi(\mathcal{P}^\perp(\mathbf{I}(\mathbf{p}_L)), \mathcal{P}^\perp(\mathbf{I}(\mathbf{p}_L))) = 0.\end{aligned} \tag{12}$$

The first addendum is the only one depending on the frame $\mathbf{h} \in \mathcal{H}$. So (omitting for brevity the dependence on $\mathbf{p}_L$) we have that:

Case Ia: If $\mathcal{H}$ is not formed by a single frame, a straightforward computation using admissible coordinates (see Ref. 9) shows that $\mathcal{P}^{\parallel}(\mathbf{I}) = 0$ and then $\mathbf{I} = \mathcal{P}^\perp(\mathbf{I})$. The conservation of kinetic energy can be expressed by the condition

$$\Phi(2\mathbf{V}^\perp + \mathcal{P}^\perp(\mathbf{I}), \mathcal{P}^\perp(\mathbf{I})) = 0, \tag{13}$$

completely analogous to the one presented in Ref. 9. This concludes Step 2 of the procedure.

However, in this situation, both $\mathbf{V}^\perp$ and $\mathcal{P}^\perp(\mathbf{I})$ belong to $(V(\mathcal{B}))^\perp \oplus (i_*(V(\mathcal{S})))^\perp$, that is a vector bundle whose fibers have dimension greater than 1, and therefore condition (13) alone does not determine $\mathcal{P}^\perp(\mathbf{I}) = -2\mathbf{V}^\perp$ as unique nontrivial solution. In complete analogy with Ref. 9, this result can be recovered only with an additional Gauss's "maximality" requirement on the impulsive admissible reaction $\mathbf{I}$. This concludes Step 3 and the whole procedure.

To conclude the analysis of this case, note moreover that, with obvious notation, the impulsive reaction $\mathbf{I}(\mathbf{p}_L) \in (V(\mathcal{B}))^\perp \oplus (i_*(V(\mathcal{S})))^\perp$ can be decomposed a part $\mathbf{I}^\perp{}_{\mathcal{B}}$ tangent to the unilateral constraint $\mathcal{S}$ but orthogonal to the instantaneous kinetic constraint $\mathcal{B}$, and a part $\mathbf{I}^\perp{}_{\mathcal{S}}$ orthogonal to the unilateral constraint $\mathcal{S}$.

Case Ib: if $\mathcal{H} = \{\overline{\mathbf{h}}\}$, then $V(\mathcal{B}) = \{\underline{\mathbf{0}}\}$, and the splits (4) and (5) become

$$i^*(V(\mathcal{V})) = \{\underline{\mathbf{0}}\} \oplus (V(\mathcal{B}))^\perp \oplus (i_*(V(\mathcal{S})))^\perp, \quad i^*(J_1(\mathcal{V})) = \{\overline{\mathbf{h}}\} \oplus (V(\mathcal{B}))^\perp \oplus (i_*(V(\mathcal{S})))^\perp.$$

Then, for every admissible impulsive reaction $\mathbf{I} \in i^*(V(\mathcal{V}))$, we have $\mathcal{P}^{\parallel}(\mathbf{I}) = 0$ and for every admissible left velocity $\mathbf{p}_L \in i^*(J_1(\mathcal{V}))$ we have $\mathbf{p}_L = \overline{\mathbf{h}} + \mathbf{V}^\perp$. Condition (8) directly assumes the form (13) and, using the same arguments of Case Ia about the Gauss's "maximality" requirement, we obtain the impulsive reaction $\mathbf{I}(\mathbf{p}_L) = -2\mathbf{V}^\perp(\mathbf{p}_L)$.

B. Case II

By the nature of the constraints acting on the system, both the admissible left velocities $\mathbf{p}_L$ and the admissible right velocities $\mathbf{p}_R$ of the system are elements of $i^*(\mathcal{A})$. Then, the reactive impulse $\mathbf{I}(\mathbf{p}_L)=\mathbf{p}_R-\mathbf{p}_L$ given by the constraints must be an element of $V(\mathcal{A})$. Moreover, the set $\mathcal{H}$ is obviously given by the intersection $\mathcal{H}=i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))$. Taking into account Lemma 1.2 and recalling that the fibers of the vector bundles $V(\mathcal{A})$ and $i_*(V(\mathcal{S}))$ have dimensions $s<n$ and $n-1$, respectively (so that, in particular, the fibers of $i_*(V(\mathcal{S}))$ have codimension 1), we have three possible situations:

- $V(\mathcal{A})\subset i_*(V(\mathcal{S}))$ and $i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))=\emptyset$. Then $\mathcal{H}=\emptyset$ and the system does not have physical meaning (this is the situation of Example 1 described earlier).
- $V(\mathcal{A})\subset i_*(V(\mathcal{S}))$ and $i^*(\mathcal{A})\subset i_*(J_1(\mathcal{S}))$. Then the system cannot impact with the positional constraint $\mathcal{S}$, since every admissible left velocity $\mathbf{p}_L\in i^*(\mathcal{A})$ is already tangent to the positional constraint $\mathcal{S}$. In this case $\mathbf{V}^\perp(\mathbf{p}_L)=0$ and the corresponding impulsive reaction is $\mathbf{I}(\mathbf{p}_L)=0$.
- $V(\mathcal{A})\neq\subset i_*(V(\mathcal{S}))$. This situation can be divided into two cases: $V(\mathcal{A})\cap i_*(V(\mathcal{S}))\neq\{\underline{\mathbf{0}}\}$, which we will study as Case IIa, and $V(\mathcal{A})\cap i_*(V(\mathcal{S}))=\{\underline{\mathbf{0}}\}$, which we will study as Case IIb.

The only nontrivial situation is the last one. To start the geometric analysis when $V(\mathcal{A})\not\subset i_*(V(\mathcal{S}))$, we need the following:

Lemma 2.1: $V(\mathcal{A})\not\subset i_*(V(\mathcal{S}))$ if and only if $i^*(\mathcal{A})\not\subset i_*(J_1(\mathcal{S}))$ and $i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))\neq\emptyset$.

Proof: "$\Leftarrow$" Let $\bar{a}\in i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))$ and let a be such that $a\in i^*(\mathcal{A})$ and $a\notin i_*(J_1(\mathcal{S}))$. Then $a-\bar{a}\in V(\mathcal{A})$ and $a-\bar{a}\notin i_*(V(\mathcal{S}))$.

"$\Rightarrow$" Of course $i^*(\mathcal{A})\not\subset i_*(J_1(\mathcal{S}))$, since otherwise, for the definition (6) of $V(\mathcal{A})$, it would follow the inclusion $V(\mathcal{A})\subset i_*(V(\mathcal{S}))$. Moreover, since $V(\mathcal{A})\not\subset i_*(V(\mathcal{S}))$ and $i_*(V(\mathcal{S}))$ has dimension $n-1$, the (nondirect) sum $V(\mathcal{A})+i_*(V(\mathcal{S}))$ generates the whole $i^*(V(\mathcal{V}))$. Introducing two bases of the vector bundles $V(\mathcal{A})$ and $i_*(V(\mathcal{S}))$, or equivalently taking into account the vector forms (9), the existence of an element in $i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))$can be proved by solving a nonhomogeneous underdetermined linear system with maximum rank. □

Case IIa: If $V(\mathcal{A})\cap i_*(V(\mathcal{S}))\neq\{\underline{\mathbf{0}}\}$, then, applying Lemma 2.1, we have $i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))\neq\emptyset$. Now taking into account Lemma 1.2, we have that $i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))$ is an affine subspace of $i^*(\mathcal{A})$ modeled on the vector space $V(\mathcal{A})\cap i_*(V(\mathcal{S}))$. Therefore we have the splits

$$V(\mathcal{A})=(V(\mathcal{A})\cap i_*(V(\mathcal{S})))\otimes(V(\mathcal{A})\cap i_*(V(\mathcal{S})))^\perp,$$

$$i^*(\mathcal{A})=(i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S})))\otimes(V(\mathcal{A})\cap i_*(V(\mathcal{S})))^\perp. \tag{14}$$

This case is then structurally similar to Case Ia, with the vector bundle $V(\mathcal{A})$ of the admissible impulsive reaction split into a vector bundle $V(\mathcal{A})\cap i_*(V(\mathcal{S}))$ modeling the affine bundle of the frames of rest of the constraints and the vector bundle $(V(\mathcal{A})\cap i_*(V(\mathcal{S})))^\perp$ of the admissible orthogonal velocities. The requirement (12) of conservation of kinetic energy for all the frames in $\mathcal{H}$ implies once again $\mathcal{P}^{\|}(\mathbf{I})=0$ and then $\mathbf{I}=\mathcal{P}^\perp(\mathbf{I})$. Furthermore, the conservation of kinetic energy can be once again expressed by condition (13). However, in this case, the result $\mathbf{I}=-2\mathbf{V}^\perp$ can be obtained without imposing additional Gauss's "maximality" requirement as in Case Ia, but as a straightforward consequence of the following:

Proposition 2.1: The vector bundle $(V(\mathcal{A})\cap i_*(V(\mathcal{S})))^\perp$ is a line bundle. In particular, if $\mathbf{U}_{\mathcal{A}}^\perp$ is the projection on $V(\mathcal{A})$ of the velocity $\mathbf{V}_{\mathcal{S}}^\perp$, then $(V(\mathcal{A})\cap i_*(V(\mathcal{S})))^\perp=\mathcal{L}\{\mathbf{U}_{\mathcal{A}}^\perp\}$.

Proof: The first statement easily follows by dimensionality arguments: since the fibers of $i_*(V(\mathcal{S}))$ are of dimension $n-1$, then those of $V(\mathcal{A})\cap i_*(V(\mathcal{S}))$ have dimension $s-1$ (that is greater than 0, for the condition $V(\mathcal{A})\cap i_*(V(\mathcal{S}))\neq\{\underline{\mathbf{0}}\}$). Then $(V(\mathcal{A})\cap i_*(V(\mathcal{S})))^\perp$ is a line bundle.

The second statement can be proved in two steps: the first shows that $\mathbf{U}_{\mathcal{A}}^\perp\neq 0$, the second shows that $\mathbf{U}_{\mathcal{A}}^\perp\in(V(\mathcal{A})\cap i_*(V(\mathcal{S})))^\perp$.

If $\mathbf{U}_{\mathcal{A}}^{\perp}=0$, then, since $\mathbf{U}_{\mathcal{A}}^{\perp}$ is the projection on $V(\mathcal{A})$ of $\mathbf{V}_{S}^{\perp}$, we should have $\Phi(\mathbf{V}_{S}^{\perp},\boldsymbol{\Xi})=0\ \forall \boldsymbol{\Xi}(\mathcal{A})$, and therefore $V(\mathcal{A})\subset i_*(V(\mathcal{S}))$, that is not possible in this case.

Moreover, a straightforward computation using admissible coordinates and the vector representations (9) shows that for every $\boldsymbol{\Xi}\in V(\mathcal{A})$ we have that $\Phi(\boldsymbol{\Xi},\mathbf{U}_{\mathcal{A}}^{\perp})=0$ if and only if $\Phi(\boldsymbol{\Xi},\mathbf{V}_{S}^{\perp})=0$, that is if and only if $\boldsymbol{\Xi}\in i_*(V(\mathcal{S}))$. Then $\mathbf{U}_{\mathcal{A}}^{\perp}$ is orthogonal to $V(\mathcal{A})\cap i_*(V(\mathcal{S}))$, or, that is the same, $\mathbf{U}_{\mathcal{A}}^{\perp}\in(V(\mathcal{A})\cap i_*(V(\mathcal{S})))^{\perp}$.

Case IIb: If $V(\mathcal{A})\cap i_*(V(\mathcal{S}))=\{\underline{\mathbf{0}}\}$ with the condition $V(\mathcal{A})\not\subset i_*(V(\mathcal{S}))$, then the fibers of $V(\mathcal{A})$ must have dimension 1. However, applying Lemma 2.1, we have once again $i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))\neq\emptyset$ and then $\mathcal{H}=\{\overline{\mathbf{h}}\}$.

The splits (14) assume the trivial aspect

$$V(\mathcal{A})=\{\underline{\mathbf{0}}\}\oplus V(\mathcal{A}),$$

$$i^*(\mathcal{A})=\{\overline{\mathbf{h}}\}\oplus V(\mathcal{A}).$$

Similar to Case Ib, for every admissible impulsive reaction $\mathbf{I}\in V(\mathcal{A})$, we have $\mathcal{P}^{\|}(\mathbf{I})=0$ and for every admissible left velocity $\mathbf{p}_L\in i^*(\mathcal{A})$ we have $\mathbf{p}_L=\overline{\mathbf{h}}+\mathbf{V}^{\perp}$. Condition (8) directly assumes the form (13) and, if we take into account that $V(\mathcal{A})$ is a line bundle, once again without Gauss's requirement, it follows that $\mathbf{I}=-2\mathbf{V}^{\perp}$.

C. Case III

Clearly, since both kinds of kinetic constraints $\mathcal{A}$ and $\mathcal{B}$ and the unilateral constraint $\mathcal{S}$ simultaneously act on the system, both splits (10) and (14) hold.

Once again, both the admissible left and right velocities $\mathbf{p}_L$ and $\mathbf{p}_R$ are elements of $i^*(\mathcal{A})$. Then, the reactive impulse $\mathbf{I}(\mathbf{p}_L)=\mathbf{p}_R-\mathbf{p}_L$ given by the constraints must be an element of $V(\mathcal{A})$. Moreover, the set $\mathcal{H}$ is obviously given by the intersection $\mathcal{H}=i_*(\mathcal{B})\cap i^*(\mathcal{A})$. Since $i_*(\mathcal{B})\subset i_*(J_1(\mathcal{S}))$ and $V(\mathcal{B})\subset i_*(V(\mathcal{S}))$, the splits (14) do not have relevance in this case.

Taking into account Lemma 1.2 and recalling that the fibers of the vector bundles $V(\mathcal{B})$ and $V(\mathcal{A})$ have dimensions $m<n-1$ and $s<n$, respectively (so that this time, in the general case, we do not have bundles with fibers of codimension 1), we have five possibilities about the nature of $\mathcal{H}$:

- The intersection $i_*(\mathcal{B})\cap i^*(\mathcal{A})$ is not trivial. Then we have two possible situations:

(1) $V(\mathcal{B})\cap V(\mathcal{A})\neq\{\underline{\mathbf{0}}\}$, which we will study as Case IIIa;
(2) $V(\mathcal{B})\cap V(\mathcal{A})=\{\underline{\mathbf{0}}\}$, which we will study as Case IIIb.

- The intersection $i_*(\mathcal{B})\cap i^*(\mathcal{A})$ is trivial. Then we have three possible situations:

(1) $i_*(\mathcal{B})\cap i^*(\mathcal{A})=\emptyset$. Then $\mathcal{H}=\emptyset$ and the system does not have physical meaning (this is the situation of Example 2 described earlier).
(2) $i^*(\mathcal{A})\subset i_*(\mathcal{B})$. Then the system cannot impact with the positional constraint $\mathcal{S}$, since every admissible left velocity $\mathbf{p}_L\in i^*(\mathcal{A})$ is already tangent to the positional constraint $\mathcal{S}$ and $\mathbf{p}_L$ also obeys the instantaneous kinetic constraint $\mathcal{B}$. In this case $\mathbf{V}^{\perp}(\mathbf{p}_L)=0$ and the corresponding impulsive reaction is $\mathbf{I}(\mathbf{p}_L)=0$.
(3) $i_*(\mathcal{B})\subset i^*(\mathcal{A})$, which can be considered as a particular case of Case IIIa if the fibers of $i_*(\mathcal{B})$ are not given by a single point, or a particular case of Case IIIb otherwise.

Case IIIa: If $i_*(\mathcal{B})\cap i^*(\mathcal{A})\neq\emptyset$ and $V(\mathcal{B})\cap V(\mathcal{A})\neq\{\underline{\mathbf{0}}\}$, taking into account Lemma 1.2, with obvious notation we have the splits

$$V(\mathcal{A})=(V(\mathcal{B})\cap V(\mathcal{A}))\oplus(V(\mathcal{B})\cap V(\mathcal{A}))^{\perp},$$

$$i^*(\mathcal{A}) = (i_*(\mathcal{B}) \cap i^*(\mathcal{A})) \oplus (V(\mathcal{B}) \cap V(\mathcal{A}))^\perp.$$

The procedure is then completely similar to Cases Ia and IIa. The conservation of kinetic energy (12) for all the frames in $\mathcal{H}$ implies once again $\mathcal{P}^{\|}(\mathbf{I})=0$, so that $\mathbf{I}=\mathcal{P}^{\perp}(\mathbf{I})$. The conservation of kinetic energy can therefore be rewritten as (13) and, if the vector bundle $(V(\mathcal{B})\cap V(\mathcal{A}))^\perp$ is a line bundle, this suffices to conclude that $\mathbf{I}=-2\mathbf{V}^\perp$. If the bundle $(V(\mathcal{B})\cap V(\mathcal{A}))^\perp$ has fibers of dimension greater than 1, we need Gauss's requirement to reach the same conclusion.

Case IIIb: If $i_*(\mathcal{B})\cap\ i^*(\mathcal{A})\neq\emptyset$ and $V(\mathcal{B})\cap V(\mathcal{A})=\{\underline{\mathbf{0}}\}$, then $\mathcal{H}=i_*(\mathcal{B})\cap i^*(\mathcal{A})=\{\overline{\mathbf{h}}\}$. With obvious notation we have the splits

$$V(\mathcal{A}) = \{\underline{\mathbf{0}}\} \oplus V(\mathcal{A}),$$

$$i^*(\mathcal{A}) = \{\overline{\mathbf{h}}\} \oplus V(\mathcal{A}).$$

Similar to Cases Ib and IIb, for every admissible impulsive reaction $\mathbf{I}\in V(\mathcal{A})$, we have $\mathcal{P}^{\|}(\mathbf{I})=0$ and for every admissible left velocity $\mathbf{p}_L\in i^*(\mathcal{A})$ we have $\mathbf{p}_L=\overline{\mathbf{h}}+\mathbf{V}^\perp$. Condition (8) directly assumes the form (13). Similar to Case IIIa, dimension of the bundle $V(\mathcal{A})$ of the admissible impulsive reactions determines whether or not we need Gauss's requirement to obtain the result $\mathbf{I}=-2\mathbf{V}^\perp$.

IV. EXAMPLES

It is clear that a list of examples exhausting all the possibilities described in the previous section would be very tedious and, in some cases, even of minimum interest, since the corresponding mechanical systems would be rather artful. Therefore, although several significant examples could be listed and analyzed, in this section we present only the four examples described at the beginning of Sec. II.

In the following we extensively use the representations in admissible coordinates listed in (9) of the elements of the various bundles involved in the description.

A. Example of Case I

A cogwheel of mass m and radius R is moving in a plane and impacts with a straight rack. The space–time bundle $\mathcal{V}$ is a four-dimensional manifold, locally described by admissible coordinates (t,x,y,ϑ) where x,y are the Cartesian coordinates of the center of the cogwheel in the plane of the motion and ϑ is the orientation of the cogwheel. The vertical scalar product Φ on $\mathcal{V}$ is described by the matrix $g_{ij}=\mathrm{diag}(m,m,A)$ with $A=\frac{1}{2}mR^2$. The unilateral constraint $\mathcal{S}$ can be described by the condition $y=R$ or, choosing admissible coordinates (t,x,ϑ) in $\mathcal{S}$, by the injection

$$i:S\to\mathcal{V} \quad \text{such that} \quad (t,x,\vartheta)\rightsquigarrow(t,x,R,\vartheta).$$

The instantaneous kinetic constraint $\mathcal{B}$ is given by the condition $\dot{x}+R\dot{\vartheta}=0$, or by the injection

$$k:\mathcal{B}\to J_1(\mathcal{S}) \quad \text{such that} \quad (t,x,\vartheta,\dot{\vartheta})\rightsquigarrow(t,x,\vartheta,-R\dot{\vartheta},\dot{\vartheta}).$$

The velocity and vertical spaces are

$$i^*(J_1(\mathcal{V})) = \left\{\mathbf{p}=\frac{\partial}{\partial t}+\dot{x}\frac{\partial}{\partial x}+\dot{y}\frac{\partial}{\partial y}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}\right\},$$

$$i^*(V(\mathcal{V})) = \mathcal{L}\left\{\frac{\partial}{\partial x},\frac{\partial}{\partial y},\frac{\partial}{\partial\vartheta}\right\},$$

$$i^*(J_1(\mathcal{S})) = \left\{ \mathbf{q} = \frac{\partial}{\partial t} + \dot{x}\frac{\partial}{\partial x} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} \right\},$$

$$i_*(V(\mathcal{S})) = \mathcal{L}\left\{ \frac{\partial}{\partial x}, \frac{\partial}{\partial \vartheta} \right\},$$

$$(i_*(V(\mathcal{S})))^\perp = \mathcal{L}\left\{ \frac{\partial}{\partial y} \right\},$$

$$i_*(\mathcal{B}) = \left\{ \mathbf{b} = \frac{\partial}{\partial t} - R\dot{\vartheta}\frac{\partial}{\partial x} + \dot{\vartheta}\frac{\partial}{\partial \vartheta} \right\},$$

$$V(\mathcal{B}) = \mathcal{L}\left\{ -R\frac{\partial}{\partial x} + \frac{\partial}{\partial \vartheta} \right\},$$

$$(V(\mathcal{B}))^\perp = \mathcal{L}\left\{ -\frac{A}{mR}\frac{\partial}{\partial x} + \frac{\partial}{\partial \vartheta} \right\}.$$

Since $\mathcal{H} = i_*(\mathcal{B})$ is not given by a single frame, the situation is the one described in Case Ia.

Given a left velocity $\mathbf{p}_L = \partial/(\partial t) + \dot{x}_L \partial/(\partial x) + \dot{y}_L \partial/(\partial y) + \dot{\vartheta}_L \partial/(\partial \vartheta)$, we have

$$\mathbf{V}^\perp(\mathbf{p}_L) = \frac{A}{mR^2 + A}(\dot{x}_L + R\dot{\vartheta}_L)\frac{\partial}{\partial x} + \dot{y}_L\frac{\partial}{\partial y} + \frac{mR}{mR^2 + A}(\dot{x}_L + R\dot{\vartheta}_L)\frac{\partial}{\partial \vartheta}.$$

The corresponding ideal reactive impulse $\mathbf{I}(\mathbf{p}_L) = -2\mathbf{V}^\perp(\mathbf{p}_L)$ gives then the right velocity

$$\mathbf{p}_R = \mathbf{p}_L + \mathbf{I}(\mathbf{p}_L) = \frac{\partial}{\partial t} + \left(\frac{mR^2 - A}{mR^2 + A}\dot{x}_L - \frac{2A}{mR^2 + A}R\dot{\vartheta}_L \right)\frac{\partial}{\partial x} - \dot{y}_L\frac{\partial}{\partial y} + \left(-\frac{2mR}{mR^2 + A}\dot{x}_L + \frac{A - mR^2}{mR^2 + A}\dot{\vartheta}_L \right)\frac{\partial}{\partial \vartheta}.$$

Clearly the result does not have an immediate physical interpretation. However it is worth noticing that, such as in the case of smooth unilateral constraint (i.e., in the absence of the instantaneous constraint $\mathcal{B}$—see Ref. 9), the velocity of the cogwheel along the y-axis simply reverses.

Simple tests of reasonableness of the result follow from the analysis of particular impact configurations. A first possibility is the impact of the cogwheel without initial spin, that is in the case $\mathbf{p}_L = \partial/(\partial t) + \dot{x}_L \partial/(\partial x) + \dot{y}_L \partial/(\partial y)$. The corresponding right velocity is

$$\mathbf{p}_R = \frac{\partial}{\partial t} + \frac{mR^2 - A}{mR^2 + A}\dot{x}_L\frac{\partial}{\partial x} - \dot{y}_L\frac{\partial}{\partial y} - \frac{2mR}{mR^2 + A}\dot{x}_L\frac{\partial}{\partial \vartheta}.$$

This result shows that, unlike the smooth situation, the rule "incidence angle equal to reflection angle" is not fulfilled, since the rack clasps the cogwheel, giving it a (correctly directed) spin but bringing the exit direction nearer to the direction orthogonal to the rack.

A second possibility of particular impact is when the cogwheel has an initial "pure rolling" spin, that is in the case $\mathbf{p}_L = \partial/(\partial t) - R\dot{\vartheta}_L \partial/(\partial x) + \dot{y}_L \partial/(\partial y) + \dot{\vartheta}_L \partial/(\partial \vartheta)$. The corresponding right velocity is $\mathbf{p}_R = \partial/(\partial t) - R\dot{\vartheta}_L \partial/(\partial x) - \dot{y}_L \partial/(\partial y) + \dot{\vartheta}_L \partial/(\partial \vartheta)$, which shows that, this time, the rack does not clasp the cogwheel and the rule "incidence angle equal to reflection angle" is fulfilled.

B. Examples of Case II

Example 1: A cogwheel of mass m and radius R is moving in a plane rolling on a horizontal rack and impacts with a vertical smooth wall. Due to the integrability of the pure rolling kinetic constraint given by the rack on the cogwheel, the system can be studied as a "one degree of

freedom" system subject to an ideal unilateral constraint given by the wall, without the introduction of kinetic constraints. The results presented in Ref. 9 immediately give the (obvious) behavior of the cogwheel.

Nevertheless, the system can also be viewed as a "two degrees of freedom" system subject to a kinetic constraint. The space–time bundle $\mathcal{V}$ can be chosen as a three-dimensional manifold, locally described by admissible coordinates (t,x,ϑ) where x is the Cartesian abscissa of the center of the cogwheel in the plane of the motion and ϑ is the orientation of the cogwheel. The vertical scalar product Φ on $\mathcal{V}$ is described by the matrix $g_{ij}=\mathrm{diag}(m,A)$ with $A=\frac{1}{2}mR^2$. The unilateral constraint $\mathcal{S}$ is given by the condition $x=K=$constant or, choosing admissible coordinates (t,ϑ) in $\mathcal{S}$, by the injection

$$i:\mathcal{S}\to\mathcal{V} \quad \text{such that} \quad (t,\vartheta)\rightsquigarrow(t,K,\vartheta).$$

The kinetic constraint $\mathcal{A}$ is given by the condition $\dot{x}+R\dot{\vartheta}=0$, or by the injection

$$h:\mathcal{A}\to J_1(\mathcal{V}) \quad \text{such that} \quad (t,x,\vartheta,\dot{\vartheta})\rightsquigarrow(t,x,\vartheta,-R\dot{\vartheta},\dot{\vartheta}).$$

The velocity and vertical spaces are

$$i^*(J_1(\mathcal{V}))=\left\{\mathbf{p}=\frac{\partial}{\partial t}+\dot{x}\frac{\partial}{\partial x}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}\right\},$$

$$i^*(V(\mathcal{V}))=\mathcal{L}\left\{\frac{\partial}{\partial t},\frac{\partial}{\partial\vartheta}\right\},$$

$$i_*(J_1(\mathcal{S}))=\left\{\mathbf{q}=\frac{\partial}{\partial t}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}\right\},$$

$$i_*(V(\mathcal{S}))=\mathcal{L}\left\{\frac{\partial}{\partial\vartheta}\right\},$$

$$(i_*(V(\mathcal{S})))^\perp=\mathcal{L}\left\{\frac{\partial}{\partial x}\right\},$$

$$i^*(\mathcal{A})=\left\{\mathbf{a}=\frac{\partial}{\partial t}-R\dot{\vartheta}\frac{\partial}{\partial x}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}\right\},$$

$$V(\mathcal{A})=\mathcal{L}\left\{-R\frac{\partial}{\partial x}+\frac{\partial}{\partial\vartheta}\right\}.$$

Since $V(\mathcal{A})\cap i_*(V(\mathcal{S}))=\{\underline{\mathbf{0}}\}$, the situation is the one described in Case IIb. In fact we have $\mathcal{H}=i^*(\mathcal{A})\cap i_*(J_1(\mathcal{S}))=\{\partial/\partial t\}$.

Given a left velocity $\mathbf{p}_L=\partial/(\partial t)-R\dot{\vartheta}_L\partial/(\partial x)+\dot{\vartheta}_L\partial/(\partial\vartheta)$, we have

$$\mathbf{V}^\perp(\mathbf{p}_L)=-R\dot{\vartheta}_L\frac{\partial}{\partial x}+\dot{\vartheta}_L\frac{\partial}{\partial\vartheta}.$$

The corresponding ideal reactive impulse $\mathbf{I}(\mathbf{p}_L)=-2\mathbf{V}^\perp(\mathbf{p}_L)$ gives then a right velocity $\mathbf{p}_R=\partial/(\partial t)+R\dot{\vartheta}_L\partial/(\partial x)-\dot{\vartheta}_L\partial/(\partial\vartheta)$, as it can be easily foreseen.

Passing over the obviousness of the result, this approach shows that the impulsive reaction $\mathbf{I}(\mathbf{p}_L)=2R\dot{\vartheta}_L\partial/(\partial x)-2\dot{\vartheta}_L\partial/(\partial\vartheta)$ cannot be due only to the smooth unilateral constraint $\mathcal{S}$, that can give only impulsive reactions in $(i_*(V(\mathcal{S})))^\perp$, but also to the kinetic constraint $\mathcal{A}$.

Example 2: A homogeneous billiard ball of mass m and radius R is rolling on a horizontal plane and impacts with a smooth vertical wall. The space–time bundle $\mathcal{V}$ is a six-dimensional manifold, locally described by admissible coordinates $(t,x,y,\psi,\vartheta,\varphi)$ where x,y are the Cartesian coordinates of the center of the ball and ψ,ϑ,φ are the usual Euler angles describing the orientation of the ball. The vertical scalar product Φ on $\mathcal{V}$ is given by the matrix

$$g_{ij}=\begin{pmatrix} m & 0 & 0 & 0 & 0 \\ 0 & m & 0 & 0 & 0 \\ 0 & 0 & A & 0 & A\cos\vartheta \\ 0 & 0 & 0 & A & 0 \\ 0 & 0 & A\cos\vartheta & 0 & A \end{pmatrix}$$

with $A=\frac{2}{5}mR^2$ (and it is nonsingular when $\sin\vartheta\neq 0$). The unilateral constraint $\mathcal{S}$ is given by the condition $y=R$ or, choosing admissible coordinates $(t,x,\psi,\vartheta,\varphi)$ in $\mathcal{S}$, by the injection

$$i:\mathcal{S}\to\mathcal{V} \quad \text{such that} \quad (t,x,\psi,\vartheta,\varphi)\rightsquigarrow(t,x,R,\psi,\vartheta,\varphi).$$

The permanent kinetic constraint $\mathcal{A}$ is given by the conditions

$$\dot{x}-R\dot{\vartheta}\sin\psi+R\dot{\varphi}\sin\vartheta\cos\psi=0,$$

$$\dot{y}+R\dot{\vartheta}\cos\psi+R\dot{\varphi}\sin\vartheta\sin\psi=0,$$

or by the injection

$$h:\mathcal{A}\to J_1(\mathcal{V}) \quad \text{such that}$$

$$(t,\psi,\vartheta,\varphi,\dot{\psi},\dot{\vartheta},\dot{\varphi})\rightsquigarrow(t,\psi,\vartheta,\varphi,R\dot{\vartheta}\sin\psi-R\dot{\varphi}\sin\vartheta\cos\psi,-R\vartheta\cos\psi-R\dot{\varphi}\sin\vartheta\sin\psi,\dot{\psi},\dot{\vartheta},\dot{\varphi}).$$

The velocity and vertical spaces are

$$i^*(J_1(\mathcal{V}))=\left\{\mathbf{p}=\frac{\partial}{\partial t}+\dot{x}\frac{\partial}{\partial x}+\dot{y}\frac{\partial}{\partial y}+\dot{\psi}\frac{\partial}{\partial y}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}+\dot{\varphi}\frac{\partial}{\partial\varphi}\right\},$$

$$i^*(V(\mathcal{V}))=\mathcal{L}\left\{\frac{\partial}{\partial x},\frac{\partial}{\partial y},\frac{\partial}{\partial\psi},\frac{\partial}{\partial\vartheta},\frac{\partial}{\partial\varphi}\right\},$$

$$i_*(J_1(\mathcal{S}))=\left\{\mathbf{q}=\frac{\partial}{\partial t}+\dot{x}\frac{\partial}{\partial x}+\dot{\psi}\frac{\partial}{\partial\psi}+\dot{\vartheta}\frac{\partial}{\partial\vartheta}+\dot{\varphi}\frac{\partial}{\partial\varphi}\right\},$$

$$i_*(V(\mathcal{S}))=\mathcal{L}\left\{\frac{\partial}{\partial x},\frac{\partial}{\partial\psi},\frac{\partial}{\partial\vartheta},\frac{\partial}{\partial\varphi}\right\},$$

$$(i_*(V(\mathcal{S})))^\perp=\mathcal{L}\left\{\frac{\partial}{\partial y}\right\},$$

$$
\begin{aligned}
i^*(\mathcal{A}) = \Bigg\{ & \mathbf{a} = \frac{\partial}{\partial t} + (R\dot{\vartheta}\sin\psi - R\dot{\varphi}\sin\vartheta\cos\psi)\frac{\partial}{\partial x} \\
& + (-R\dot{\vartheta}\cos\psi - R\dot{\varphi}\sin\vartheta\sin\psi)\frac{\partial}{\partial y} + \dot{\psi}\frac{\partial}{\partial\psi} + \dot{\vartheta}\frac{\partial}{\partial\vartheta} + \dot{\varphi}\frac{\partial}{\partial\varphi}\Bigg\}, \\
V(\mathcal{A}) = \Bigg\{ & \mathbf{V} = (RV^4\sin\psi - RV^5\sin\vartheta\cos\psi)\frac{\partial}{\partial x} \\
& + (-RV^4\cos\psi - RV^5\sin\vartheta\sin\psi)\frac{\partial}{\partial y} + V^3\frac{\partial}{\partial\psi} + V^4\frac{\partial}{\partial\vartheta} + V^5\frac{\partial}{\partial\varphi}\Bigg\}.
\end{aligned} \tag{15}
$$

Since $V(\mathcal{A}) \cap i_*(V(\mathcal{S})) \neq \{\underline{\mathbf{0}}\}$, the situation is the one described in Case IIa. Given a left velocity

$$
\begin{aligned}
\mathbf{p}_L = & \frac{\partial}{\partial t} + (R\dot{\vartheta}_L\sin\psi - R\dot{\varphi}_L\sin\vartheta\cos\psi)\frac{\partial}{\partial x} + (-R\dot{\vartheta}_L\cos\psi - R\dot{\varphi}_L\sin\vartheta\sin\psi)\frac{\partial}{\partial y} \\
& + \dot{\psi}_L\frac{\partial}{\partial\psi} + \dot{\vartheta}_L\frac{\partial}{\partial\vartheta} + \dot{\varphi}_L\frac{\partial}{\partial\varphi},
\end{aligned} \tag{16}
$$

we have

$$
\begin{aligned}
\mathbf{V}^{\perp}(\mathbf{p}_L) = & (-R\dot{\vartheta}_L\cos\psi - R\dot{\varphi}_L\sin\vartheta\sin\psi)\frac{\partial}{\partial y} + \left(-\dot{\vartheta}_L\frac{\cos\vartheta\sin\psi\cos\psi}{\sin\vartheta} - \dot{\varphi}_L\cos\vartheta\sin^2\psi\right)\frac{\partial}{\partial\psi} \\
& + \left(\dot{\vartheta}_L\cos^2\psi + \dot{\varphi}_L\sin\vartheta\sin\psi\cos\psi\right)\frac{\partial}{\partial\vartheta} + \left(\dot{\vartheta}_L\frac{\sin\psi\cos\psi}{\sin\vartheta} + \dot{\varphi}_L\sin^2\psi\right)\frac{\partial}{\partial\varphi}.
\end{aligned}
$$

The corresponding ideal reactive impulse $\mathbf{I}(\mathbf{p}_L) = -2\mathbf{V}^{\perp}(\mathbf{p}_L)$ gives then a right velocity

$$
\begin{aligned}
\mathbf{p}_R = & \frac{\partial}{\partial t} + (R\dot{\vartheta}\sin\psi - R\dot{\varphi}\sin\vartheta\cos\psi)\frac{\partial}{\partial x} \\
& + (R\dot{\vartheta}_L\cos\psi + R\dot{\varphi}_L\sin\vartheta\sin\psi)\frac{\partial}{\partial y} \\
& + \left(\dot{\psi}_L + 2\dot{\vartheta}_L\frac{\cos\vartheta\sin\psi\cos\psi}{\sin\vartheta} + 2\dot{\varphi}_L\cos\vartheta\sin^2\psi\right)\frac{\partial}{\partial\psi} \\
& + \left(\dot{\vartheta}_L(1-\cos^2\psi) - 2\dot{\varphi}_L\sin\vartheta\sin\psi\cos\psi\right)\frac{\partial}{\partial\vartheta} \\
& + \left(-2\dot{\vartheta}_L\frac{\sin\psi\cos\psi}{\sin\vartheta} + \dot{\varphi}_L(1-\sin^2\psi)\right)\frac{\partial}{\partial\varphi}.
\end{aligned}
$$

Although the result seems quite complicated, some tests can be performed in order to prove the reasonableness of the result. The results $\dot{x}_R = \dot{x}_L, \dot{y}_R = -\dot{y}_L$ show that the impact obeys the rule "incidence angle equal to reflection angle." Moreover, if we assume a very classical point of view, and we denote with $\underline{\omega} = \omega^1\underline{\mathbf{e}}_1 + \omega^2\underline{\mathbf{e}}_2 + \omega^3\underline{\mathbf{e}}_3$ the usual angular velocity of the ball, where $\underline{\mathbf{e}}_1$ is a unit vector in the direction x, $\underline{\mathbf{e}}_2$ is a unit vector in the direction y, and $\underline{\mathbf{e}}_3$ is a unit vector in the direction orthogonal to the horizontal plane where the ball rolls, a tedious but straightforward calculation shows that, independent of the angles $(\psi, \vartheta, \varphi)$ for which the impact happens, we have $\omega_R^1 = -\omega_L^1, \omega_R^2 = \omega_L^2$ (that once again proves the rule "incidence angle equal to reflection angle") and $\omega_R^3 = \omega_L^3$, which proves that the smooth vertical wall (obviously) does not clasp the ball during the impact.

Note also that, such as in the previous example, the impulsive reaction cannot be due only to the smooth unilateral constraint $\mathcal{S}$, which can give only impulsive reactions in $(i_*(V(\mathcal{S})))^\perp$, but also to the kinetic constraint $\mathcal{A}$.

C. Example of Case III

The same billiard ball of the previous example is rolling on the horizontal plane but this time impacts with a rough vertical wall where a kinetic condition of rolling must be fulfilled. The space–time bundle $\mathcal{V}$, the admissible coordinates $(t,x,y,\psi,\vartheta,\varphi)$, and the vertical scalar product Φ on $\mathcal{V}$ are the same as in the previous example, such as the unilateral constraint $\mathcal{S}$ and the permanent kinetic constraint $\mathcal{A}$, with their Cartesian or parametric representations. The instantaneous kinetic constraint $\mathcal{B}$ is given by the conditions

$$\begin{aligned}&\dot{x}+R\dot{\psi}+R\dot{\varphi}\cos\vartheta=0,\\&\dot{y}=0,\\&\dot{\vartheta}\cos\psi+\dot{\varphi}\sin\vartheta\sin\psi=0\end{aligned}$$

(with the second condition that simply expresses the fact that $\mathcal{B}$ "lives" on $i_*(J_1(\mathcal{S}))$ or by the injection

$$k:\mathcal{B}\to J_1(\mathcal{S}) \quad \text{such that}$$

$$(t,x,\psi,\vartheta,\varphi,\dot{\psi},\dot{\varphi})\rightsquigarrow\left(t,x,\psi,\vartheta,\varphi,-R\dot{\psi}-R\dot{\varphi}\cos\vartheta,\dot{\psi},-\dot{\varphi}\frac{\sin\vartheta\sin\psi}{\cos\psi},\dot{\vartheta}\right).$$

Then, together with the spaces given by (15), we have also the bundles

$$i_*(\mathcal{B})=\left\{\mathbf{b}=\frac{\partial}{\partial t}+(-R\dot{\psi}-R\dot{\varphi}\cos\vartheta)\frac{\partial}{\partial x}+\dot{\psi}\frac{\partial}{\partial\psi}-\dot{\varphi}\frac{\sin\vartheta\sin\psi}{\cos\psi}\frac{\partial}{\partial\vartheta}+\dot{\varphi}\frac{\partial}{\partial\varphi}\right\},$$

$$V(\mathcal{B})=\left\{\mathbf{W}=(-RV^3-RV^5\cos\vartheta)\frac{\partial}{\partial x}+V^3\frac{\partial}{\partial\psi}-\frac{\sin\vartheta\sin\psi}{\cos\psi}V^5\frac{\partial}{\partial\vartheta}+V^5\frac{\partial}{\partial\varphi}\right\}.$$

We have $V(\mathcal{B})\cap V(\mathcal{A})\neq\{\underline{\mathbf{0}}\}$ and the space $\mathcal{H}$ is given by

$$\mathcal{H}=\left\{\frac{\partial}{\partial t}-R\dot{\varphi}\frac{\sin\vartheta}{\cos\psi}\frac{\partial}{\partial x}+\dot{\varphi}\left(\frac{\sin\vartheta}{\cos\psi}-\cos\vartheta\right)\frac{\partial}{\partial\psi}-\dot{\varphi}\frac{\sin\vartheta\sin\psi}{\cos\psi}\frac{\partial}{\partial\vartheta}+\dot{\varphi}\frac{\partial}{\partial\varphi}\right\}.$$

Then the situation is the one described in Case IIIa. Given a left velocity $\mathbf{p}_L$ as in (16), we obtain

$$\begin{aligned}\mathbf{V}^\perp(\mathbf{p}_L)=&[R(\dot{\vartheta}_L\sin\psi-\dot{\varphi}_L\sin\vartheta\cos\psi-\Gamma_L)]\frac{\partial}{\partial x}+[R(-\dot{\vartheta}_L\cos\psi-\dot{\varphi}_L\sin\vartheta\sin\psi)]\frac{\partial}{\partial y}\\&+\left[\dot{\psi}_L-\left(1-\frac{\cos\vartheta\cos\psi}{\sin\vartheta}\right)\Gamma_L\right]\frac{\partial}{\partial\psi}+\left[\dot{\vartheta}_L+(\sin\psi)\Gamma_L\right]\frac{\partial}{\partial\vartheta}+\left[\dot{\varphi}_L-\left(\frac{\cos\psi}{\sin\vartheta}\right)\Gamma_L\right]\frac{\partial}{\partial\varphi}\end{aligned}$$

with

$$\Gamma_L=\frac{A}{mR^2+2A}\dot{\psi}_L-\left(\frac{mR^2+A}{mR^2+2A}\sin\psi\right)\dot{\vartheta}_L+\left(\frac{mR^2+A}{mR^2+2A}\sin\vartheta\cos\psi+\frac{A}{mR^2+2A}\cos\vartheta\right)\dot{\varphi}_L.$$

The corresponding ideal reactive impulse $\mathbf{I}(\mathbf{p}_L)=-2\mathbf{V}^\perp(\mathbf{p}_L)$ gives the right velocity

$$\mathbf{p}_R = \frac{\partial}{\partial t} + [-R(\dot{\vartheta}_L \sin\psi - \dot{\varphi}_L \sin\vartheta\cos\psi + 2\Gamma_L)]\frac{\partial}{\partial x} + [R(\dot{\vartheta}_L \cos\psi + \dot{\varphi}_L \sin\vartheta \sin\psi)]\frac{\partial}{\partial y}$$
$$+ \left[-\dot{\psi}_L + 2\left(1 - \frac{\cos\vartheta\cos\psi}{\sin\vartheta}\right)\Gamma_L\right]\frac{\partial}{\partial\psi} + [-\dot{\vartheta}_L - 2(\sin\psi)\Gamma_L]\frac{\partial}{\partial\vartheta}$$
$$+ \left[-\dot{\varphi}_L + 2\left(\frac{\cos\psi}{\sin\vartheta}\right)\Gamma_L\right]\frac{\partial}{\partial\varphi}.$$

Once again, the result does not have an immediate reading. If we assume the classical point of view, denoting with $\underline{\omega} = \omega^1\underline{\mathbf{e}}_1 + \omega^2\underline{\mathbf{e}}_2 + \omega^3\underline{\mathbf{e}}_3$ the angular velocity of the ball and with $\underline{\mathbf{u}} = \dot{x}\underline{\mathbf{e}}_1 + \dot{y}\underline{\mathbf{e}}_2$ the linear velocity of the center of mass of the ball, a straightforward calculation shows that, independent of the angles $(\psi, \vartheta, \varphi)$ for which the impact happens, we have the relations

$$\dot{x}_L = R\omega_L^2, \quad \dot{x}_R = R\left(\frac{mR^2}{mR^2 + 2A}\omega_L^2 - \frac{2A}{mR^2 + 2A}\omega_L^3\right),$$

$$\dot{y}_L = -R\omega_L^1, \quad \dot{y}_R = R\omega_L^1.$$

This shows that, in general, the rule "incidence angle equal to reflection angle" is not fulfilled, and that the vertical wall clasps the ball. Moreover, this also shows that the exit direction is influenced by the initial spin in the direction $\underline{\mathbf{e}}_3$ orthogonal to the horizontal plane. The same result can be deduced by the relations

$$\omega_R^1 = -\omega_L^1,$$

$$\omega_R^2 = \frac{mR^2}{mR^2 + 2A}\omega_L^2 - \frac{2A}{mR^2 + 2A}\omega_L^3,$$

$$\omega_R^3 = -2\frac{mR^2 + A}{mR^2 + 2A}\omega_L^2 - \frac{mR^2}{mR^2 + 2A}\omega_L^3,$$

which prove that the impact with the vertical wall changes the spin in the direction $\underline{\mathbf{e}}_3$ orthogonal to the horizontal plane.

V. FINAL REMARKS AND CONCLUSIONS

Let us delve more deeply into the analysis of the results of the examples described in Sec. III.

It is intuitively clear that the behavior of the billiard ball of Example 2 of Case II is the most natural and foreseeable. Unfortunately, we cannot say the same for the examples of Cases I and III.

We focus our attention on the example of Case III in the particular situation when the motion of the ball before the impact is a *pure* rolling, so that $\omega_L^3 = 0$: if we denote with μ_L the "incident" angle formed by the direction of the entrance velocity $\underline{\mathbf{u}}_L = \dot{x}_L\underline{\mathbf{e}}_1 + \dot{y}_L\underline{\mathbf{e}}_2$ of the center of mass of the ball and the orthogonal to the vertical wall and with μ_R the "reflection" angle formed by the direction of the exit velocity $\underline{\mathbf{u}}_R = \dot{x}_R\underline{\mathbf{e}}_1 + \dot{y}_R\underline{\mathbf{e}}_2$ and the orthogonal to the vertical wall, we have the relation

$$\tan\mu_R = \frac{mR^2}{mR^2 + 2A}\tan\mu_L = \frac{5}{9}\tan\mu_L. \tag{17}$$

If, on the one side, this relation has some correct behaviors (such as $\mu_R = 0$ if and only if $\mu_L = 0$ or $\lim_{\mu_L \to \pi/2}\mu_R = \pi/2$), on the other side Eq. (17) shows that the vertical wall clasps the ball very hard (too much with respect to the behavior of the true billiard game, like every billiard player

knows). Moreover, the wall gives to the ball a (correctly oriented but) very great spin $\omega_R^3 = -\frac{14}{9}\omega_L^2$ in the vertical direction. Furthermore, the "clasp" effect shows itself both for almost orthogonal ($\dot{x}_L \simeq 0$) and almost tangent ($\dot{x}_L \gg \dot{y}_L$) impacts with the vertical wall.

Completely analogous considerations can be done for the results of Example 1. Let us denote with $\underline{\mathbf{u}} = \dot{x}\underline{\mathbf{e}}_1 + \dot{y}\underline{\mathbf{e}}_2$ the linear velocity of the center of mass of the cogwheel, where $\underline{\mathbf{e}}_1$ is a unit vector in the direction x of the rack, $\underline{\mathbf{e}}_2$ is a unit vector in the direction y orthogonal to the rack, and once again let us denote with μ_L and μ_R the "incident" and the "reflection" angles formed by the direction of the entrance and exit velocities with the direction orthogonal to the rack. Then, in the case of initial motion of the cogwheel without spin, we obtain the relation

$$\tan \mu_R = \frac{mR^2 - A}{mR^2 + A} \tan \mu_L = \frac{1}{3} \tan \mu_L.$$

Moreover, the cogwheel assumes (with obvious notation) an angular velocity $\underline{\omega} = -\frac{4}{3}(\dot{x}_L/R)\underline{\mathbf{e}}_3$. If it is intuitively clear that a rack clasps very hard a cogwheel, it is also intuitively clear that a similar situation is very difficult to realize in practice.

Then we must conclude by pointing out that the theoretical approach described in the paper gives results that are correct from the qualitative point of view but, when compared with the real (in the sense of "in the real world") behaviors of some simple and well-known systems, the results are improvable from the quantitative point of view. This improvability is obviously due to the sternness of the ideality requirement on the constraints: the analysis of nonideal unilateral constraints, starting from a coherent definition of the coefficient of restitution, should improve the results in this direction and will be the argument of a forthcoming paper.

Many physical models have boundaries. For the Boltzmann equation, the study on the boundary layer in the region of the width in the order of the Kundsen number along the boundary is important both in mathematics and physics. In this paper, we consider the nonlinear stability of boundary layer solutions to the Boltzmann equation for hard potentials with angular cut-off. The boundary condition is imposed on incoming particles of the Dirichlet type and the solution tends to a global Maxwellian in the far field. For the existence of the boundary layer solutions, it is proved by Chen *et al.* [Anal. Appl. **2**, 337–363 (2004)] by introducing a weight function which is a function of both position and velocity to overcome the difficulty from the sublinear growth in the collision frequency. Unlike the hard sphere model, even for stability in the case when the Mach number of the far field is less than -1, exponential decay in time cannot be expected for the cutoff hard potentials. Instead, an algebraic decay in time to the boundary layer solution is proved in this paper by using some recursive weighted energy estimates and the bootstrap argument. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2229421]

I. INTRODUCTION

Consider the Boltzmann equation for the rarefied gas

$$F_t + \xi \cdot \nabla_x F = \frac{1}{\kappa} Q(F,F),$$

where $F(t,x,\xi)$ is the number density distribution function of particles at space-time $(t,x) = (t,x_1,x_2,x_3)$ with velocity ξ. When the problem involves a boundary, there is usually a layer of width of order κ along the boundary which is called the boundary layer. The equation for the boundary layer is a stationary equation which can be obtained by the standard scaling in the neighborhood of the boundary. In this paper, we consider the case when the boundary is an infinite plane, such as the (x_2,x_3) plane, and the layer depends only on (t,x_1,ξ). In this case, the dimension of the space variable becomes one, while the velocity variable is still three dimensional. In what follows, we still use x to denote x_1 for simplicity of notations. For general knowledge of the Boltzmann equation, please refer to Refs. 3–5, 10, and 11 and references therein.

[a)]Electronic mail: matyang@cityu.edu.hk

Since it is expected that the gas tends to an equilibrium away from the layer, the distribution function is assumed to be a global Maxwellian. Moreover, for the problem to be well-posed, the Dirichlet boundary condition is imposed by giving the incoming particle distribution. Under these assumptions, the problem in its linearized version and some other settings has been extensively studied, cf. Refs. 2, 12, 13, and 7–9. In addition, there are some elaborate numerical studies on this problem, cf. Ref. 1, and references therein. For the nonlinear problem, the existence for both hard sphere model and hard potentials with angular cut-off were obtained in Refs. 15 and 6, respectively. Furthermore, the stability of the boundary layer for the hard sphere model was proved when the Mach number of the far field is less than -1 in Ref. 16. In this stability analysis, the linear growth in the collision frequency is crucially used where exponential decay in time to the boundary layer can be proved by combining the energy method and a bootstrap argument. However, for the cut-off hard potentials, the sublinear growth in the collision frequency prevents the exponential decay both in space and time. Therefore, the analysis on the stability which is the topic in this paper is more subtle. By using some new recursive energy estimates, an algebraic decay rate will be proved for the convergence of the time evolutional solution to the boundary layer when Mach number of the far field is also less than -1.

From now on, F is assumed to be a function of time $t \in \mathbf{R}_+$, position $x \in \mathbf{R}$ and particle velocity $\xi=(\xi_1,\xi_2,\xi_3) \in \mathbf{R}^3$. Here, ξ_1 stands for the velocity component along the x axis. The boundary layer $F(x,\xi)$ is governed by the stationary Boltzmann equation

$$\xi_1 F_x = Q(F,F), \quad x>0,\ \xi \in \mathbf{R}^3,$$

$$F|_{x=0} = F_b(\xi), \quad \xi_1 > 0,\ (\xi_2,\xi_3) \in \mathbf{R}^2, \tag{1.1}$$

$$F \to M_\infty(\xi)(x \to \infty), \quad \xi \in \mathbf{R}^3,$$

where

$$M_\infty = M_{(\rho_\infty,u_\infty,T_\infty)}(\xi) = \frac{\rho_\infty}{(2\pi T_\infty)^{3/2}} \exp\left(-\frac{|\xi-u_\infty|^2}{2T_\infty}\right). \tag{1.2}$$

Here $\rho_\infty>0, u_\infty=(u_{\infty,1},u_{\infty,2},u_{\infty,3}) \in \mathbf{R}^3$ and $T_\infty>0$ represent the macroscopic density, velocity, and temperature, respectively, and the gas constant R is normalized to one. Up to a linear transformation in the ξ variable, $u_{\infty,2}$ and $u_{\infty,3}$ can be assumed to be zero. In this case, the sound speed and Mach number of the far field equilibrium state are given, respectively, by

$$c_\infty = \sqrt{\frac{5}{3}T_\infty}, \quad \mathcal{M}^\infty = \frac{u_{\infty,1}}{c_\infty}.$$

As usual, the collision operator Q which is a bilinear integral operator takes the form

$$Q(F,F) = \int \int_{\mathbf{R}^3\times\mathbf{S}^2} (F(\xi')F(\xi'_*) - F(\xi)F(\xi_*))q(V,\theta)\mathrm{d}\xi_*\mathrm{d}\omega,$$

where

$$\xi' = \xi - [(\xi-\xi_*)\cdot\omega]\omega, \quad \xi'_* = \xi_* + [(\xi-\xi_*)\cdot\omega]\omega$$

are the relations between velocities before and after an elastic collision by using the conservation of momentum and energy. Here the relative velocity $V=\xi-\xi_*$ and collision angle $\theta=\cos^{-1}(\langle V,\omega\rangle/|V|)$ with $\omega \in S^2$.

Set

$$F = M_\infty + M_\infty^{1/2} f.$$

Then the problem (1.1) is reduced to

$$\xi_1 f_x - Lf = h, \quad x > 0,\ \xi \in \mathbf{R}^3,$$

$$f|_{x=0} = b_0(\xi) = M_\infty^{-1/2}(F_b(\xi) - M_\infty), \quad \xi_1 > 0,\ (\xi_2, \xi_3) \in \mathbf{R}^2, \tag{1.3}$$

$$f \to 0\ (x \to \infty), \quad \xi \in \mathbf{R}^3,$$

where

$$h \equiv \Gamma(f,f) = M_\infty^{-1/2} Q(M_\infty^{1/2} f, M_\infty^{1/2} f), \quad Lf = M_\infty^{-1/2}\{Q(M_\infty, M_\infty^{1/2} f) + Q(M_\infty^{1/2} f, M_\infty)\}$$

are the nonlinear and linear parts in the collision operator.

It is known that the operator L can be written as, cf. Ref. 6,

$$L = -\nu(|\xi|) - K_1 + K_2,$$

where K_1 and K_2 are compact operators with kernels $k_1(\xi, \xi_*)$ and $k_2(\xi, \xi_*)$, respectively. For cut-off hard potentials, there exists $0 \leqslant \delta_1 < 1$ such that

$$k_1(\xi, \xi_*) \leqslant C(|\xi - \xi_*| + |\xi - \xi_*|^{-\delta_1}) \exp\left(-\frac{|\xi - u_\infty|^2}{4T_\infty} - \frac{|\xi_* - u_\infty|^2}{4T_\infty}\right),$$

$$k_2(\xi, \xi_*) \leqslant C|\xi - \xi_*|^{-1} \exp\left(-\frac{(|\xi - u_\infty|^2 - |\xi_* - u_\infty|^2)^2}{8T_\infty |\xi - \xi_*|^2} - \frac{|\xi - \xi_*|^2}{8T_\infty}\right).$$

Sometimes, we use the notation $K = -K_1 + K_2$.

In the following discussion, the same assumption on the collision kernel as in Ref. 6 for the existence of the boundary layer is imposed. That is, assume, cf. Ref. 14:

Assumption 1: There is $0 \leqslant \delta_1 < 1$ such that

$$0 \leqslant q(V, \theta) \leqslant c(|V| + |V|^{-\delta_1})|\cos\theta|.$$

Assumption 2: There exists a positive constant $c > 0$ such that

$$\int_{\mathbf{R}^3}\int_{\mathbf{R}^3} e^{-|\xi_*|^2/2} q(\xi - \xi_*, \theta) \mathrm{d}\xi_* \mathrm{d}\omega \left(\int_{\mathbf{R}^3}\int_{\mathbf{R}^3} e^{-|\xi_*|^2} q(\xi - \xi_*, \theta) \mathrm{d}\xi_* \mathrm{d}\omega\right)^{-1} \leqslant c.$$

Assumption 3: There are constants $0 < \beta_1 \leqslant \beta_2 \leqslant 1$ such that

$$c_1(1 + |\xi|)^{\beta_1} \leqslant \nu(\xi) \leqslant c_2(1 + |\xi|)^{\beta_2}.$$

For both hard sphere model and cut-off hard potentials, the results in Refs. 15 and 6 show that the existence of boundary layer solution depends on the Mach number $\mathcal{M}^\infty$ at $x = \infty$. When $\mathcal{M}^\infty \neq 0, \pm 1$, a solvability condition can be obtained implicitly with given co-dimensions of the manifold for the admissible boundary data $F_b(\xi)$. In particular, when $\mathcal{M}^\infty < -1$, the boundary layer solution exists as long as the boundary data $F_b(\xi)$ is close to the Maxwellian at $x = \infty$ because all the information at infinity in some sense goes into the layer.

To prove the existence of the boundary layers for the cut-off hard potentials, the following weight function $\sigma(x, \xi)$ is introduced in Ref. 6. Let $\eta: [0, \infty) \to \mathbf{R}$ be a smooth nonincreasing function satisfying $\eta(s) = 1$, for $s \leqslant 1$, $\eta(s) = 0$ for $s \geqslant 2$, and $0 \leqslant \eta \leqslant 1$. The weight function to cope with the sublinear growth in the collision frequency is

$$\sigma(x,\xi) = 5(\delta x + l)^{2/(3-\beta_1)}\left(1 - \eta\left(\frac{\delta x + l}{(1+|\xi - u_\infty|)^{3-\beta_1}}\right)\right)$$
$$+\left(\frac{\delta x + l}{(1+|\xi - u_\infty|)^{1-\beta_1}} + 3|\xi - u_\infty|^2\right)\eta\left(\frac{\delta x + l}{(1+|\xi - u_\infty|)^{3-\beta_1}}\right),$$

for some large positive constant l and a small positive constant δ. For later use, set

$$\mathbf{W}_\beta(\xi) = (1+|\xi|)^{-\beta}(M_{[1,u_\infty,T_\infty]})^{1/2}. \tag{1.4}$$

In the study on the nonlinear stability of the boundary layer for the hard sphere model when $\mathcal{M}^\infty < -1$ given in Ref. 16, the perturbation decays exponentially in time because the collision frequency has linear growth in the velocity. However, for the hard potentials with angular cutoff, the convergence rate will be shown to be algebraic depending on the spatial decay of the initial data.

In what follows, we will use the following norm for the perturbation of the layer in the time evolution equation,

$$[[f]]_\beta = \sup_{x,\xi} \sigma_x^{1/2}(1+|\xi|)^\beta |f(x,\xi)|.$$

Consider the initial boundary value problem,

$$\begin{gathered} F_t + \xi_1 F_x = Q(F,F), \quad t>0, x>0,\ \xi \in \mathbf{R}^3, \\ F|_{t=0} = F_0(x,\xi), \quad x>0,\ \xi \in \mathbf{R}^3, \\ F|_{x=0} = F_b(\xi), \quad t>0, \xi_1>0,\ (\xi_2,\xi_3) \in \mathbf{R}^2, \\ F \to M_\infty(\xi),\ (x \to \infty), \quad t>0,\ \xi \in \mathbf{R}^3. \end{gathered} \tag{1.5}$$

The main result in this paper can be stated as follows.

Theorem 1.1: *When the Mach number $\mathcal{M}^\infty < -1$, if the boundary data satisfy*

$$|F_b(\xi) - M_\infty(\xi)| \leqslant \epsilon_0 \sigma_x^{-1/2}(0,\xi) e^{-\epsilon\sigma(0,\xi)} \mathbf{W}_\beta(\xi), \quad \xi \in \mathbf{R}^3_+, \quad \beta > \tfrac{5}{2},$$

where the weight function $\mathbf{W}_\beta$ and $\sigma(x,\xi)$ are defined above and ϵ_0 is a sufficiently small positive constant, then there exists a boundary layer solution $\bar{F}(x,\xi)$ to (1.1) *obtained in Ref.* 6. *For the initial boundary value problem* (1.5), *if the initial data satisfy*

$$\|\sigma_x^{-1} e^{\epsilon\sigma(x,\xi)} M_\infty^{-1/2}(F_0 - \bar{F})\|_{L^2_{x,\xi}} + [[e^{\epsilon\sigma(x,\xi)} M_\infty^{-1/2}(F_0 - \bar{F})]]_\beta < \epsilon_1, \quad \beta > 3 - \frac{\beta_1}{2}, \tag{1.6}$$

where $\epsilon_1 > 0$ is a sufficiently small constant, and l satisfies $l \geqslant \epsilon^{-3+\beta_1}$, then there exists a unique solution $F(t,x,\xi)$ such that

$$[[e^{\epsilon\sigma(x,\xi)} M_\infty^{-1/2}(F - \bar{F})]]_\beta \leqslant C\epsilon_1 (1+t)^{-3/2}.$$

This implies that the perturbation of the boundary layer converges to zero in time with an algebraic rate $(1+t)^{-3/2}$, that is, the boundary layer solution is nonlinearly stable.

Remark 1.2: If we impose faster spatial decay on the initial data, then faster time decay on the perturbation can be obtained. More precisely, for $m \geqslant 2$, if we replace (1.6) by

$$\|\sigma_x^{-m/2} e^{\epsilon\sigma(x,\xi)} M_\infty^{-1/2}(F_0 - \bar{F})\|_{L^2_{x,\xi}} + [[e^{\epsilon\sigma(x,\xi)} M_\infty^{-1/2}(F_0 - \bar{F})]]_\beta < \epsilon_1, \quad \text{for } \beta > \frac{m+4}{2} - \frac{m-1}{2}\beta_1,$$

then similar analysis gives that the decay rate as $(1+t)^{-(m+1)/2}$.

The rest of the paper is organized as follows. In Sec. II, we will recall some lemmas from Ref. 6 and present some basic lemmas for the later stability analysis. In Sec. III, we will consider the linearized equation and derive some recursive energy estimates using various weight functions. Based on this, the time decay estimate of perturbation is proved by a bootstrap argument in the last section.

II. PRELIMINARIES

For later use, we introduce some notations $\Theta=(1-\beta_1)/(3-\beta_1)$ and $\tilde{\xi}=\xi-u_\infty$. c and C are generic positive numbers. For the weight function $\sigma(x,\xi)$ defined in the previous section, we have the following estimates on its derivative by straightforward calculation.

Lemma 2.1: There exists a constant $c>0$ such that

$$\sigma_x(x,\xi)=\begin{cases}\delta(1+|\tilde{\xi}|)^{-1+\beta_1} & (x,\xi)\in\Omega_1\\ c\,\delta((\delta x+l)^{-\Theta}+|\tilde{\xi}|^{-1+\beta_1}) & (x,\xi)\in\Omega_2\\ \dfrac{10\delta}{3-\beta_1}(\delta x+l)^{-\Theta} & (x,\xi)\in\Omega_3,\end{cases}$$

where

$$\Omega_1=\{(x,\xi)|\,\delta x+l<(1+|\tilde{\xi}|)^{3-\beta_1}\},\quad \Omega_3=\{(x,\xi)|\,\delta x+l\geqslant 2(1+|\tilde{\xi}|)^{3-\beta_1}\},$$

$$\Omega_2=\{(x,\xi)|(1+|\tilde{\xi}|)^{3-\beta_1}\leqslant\delta x+l<2(1+|\tilde{\xi}|)^{3-\beta_1}\}.$$

Furthermore,

$$|\sigma_{xx}(x,\xi)|\leqslant\begin{cases}0 & (x,\xi)\in\Omega_1\\ c(\delta x+l)^{-\Theta-1} & (x,\xi)\in\Omega_2\cup\Omega_3.\end{cases}$$

It is well known that the collision operator Q has five collision invariants

$$\varrho_0=1,\quad \varrho_i=\xi(i=1,2,3),\quad \varrho_4=|\xi|^2,$$

satisfying

$$\langle\varrho_\alpha,Q(F,F)\rangle=0,\quad \alpha=0,1,\ldots,4,$$

for any distribution function F. Here $\langle .,.\rangle$ is the inner product in L^2_ξ. The null space of the linearized collision operator L in the space L^2_ξ is

$$\mathbf{N}=\mathrm{span}\{M_\infty^{1/2}\varrho_\alpha,\alpha=0,1,2,3,4\}=\mathrm{span}\{\psi_\alpha,\alpha=0,1,2,3,4\}.$$

In what follows, $\mathbf{N}^\perp$ denotes the orthogonal complement of $\mathbf{N}$ in L^2_ξ. With these notations, the dissipation of the modified linearized collision operator on $\mathbf{N}^\perp$ is given as follows.

Lemma 2.2: There is constant $\epsilon_2>0$ such that for $0<\epsilon<\epsilon_2$ and $g\in\mathbf{N}^\perp$,

$$\langle g,\sigma_x^{-m/2}e^{\epsilon\sigma}Le^{-\epsilon\sigma}\sigma_x^{m/2}g\rangle\leqslant-\nu_1\langle\nu(|\xi|)g,g\rangle,\quad m=-1,0,1,2,$$

for some positive constant $\nu_1=\nu_1(\epsilon_2)$.

Proof: Similar to Lemma 2.2 in Ref. 6, we only need to estimate the term related to the operator K_2 as follows. It is because $L=-\nu(|\xi|)-K_1+K_2$ and $\nu(|\xi|)$ commutes with the multiple operator and the estimation on the terms related to K_1 is simpler. Set

$$s(\epsilon,\xi,\xi_*)=\sigma_x^{-m/2}(x,\xi)\exp\left(-\frac{1}{8T_\infty}\frac{(|\tilde{\xi}|^2+|\tilde{\xi}_*|^2)^2}{|\xi-\xi_*|^2}-\frac{1}{8T_\infty}|\xi-\xi_*|^2\right)$$
$$\times(\exp[\epsilon(\sigma(x,\xi)-\sigma(x,\xi_*))]-1)\sigma_x^{m/2}(x,\xi_*).$$

It suffices to show that

$$\sup_{\xi,\xi_*} s(\epsilon,\xi,\xi_*)\to 0 \quad as\ \epsilon\to 0, \tag{2.1}$$

because of the classical dissipative effect of L on the functions in $\mathbf{N}^\perp$. (2.1) can be proved by considering the cases when (x,ξ) in different $\Omega_i, i=1,2,3$. For illustration, we only consider two cases for $m=-1$ because the other cases can be discussed similarly.

Case 1: When (x,ξ) *and* $(x,\xi_*)\in\Omega_3$, $\sigma_x(x,\xi)=\sigma_x(x,\xi_*)=[10\delta/(3-\beta_1)](\delta x+l)^{-\Theta}$. In this case, we have

$$|\sigma(x,\xi)-\sigma(x,\xi_*)|\leqslant c\|\tilde{\xi}|^2-|\tilde{\xi}_*|^2|,$$

which implies (2.1).

Case 2: When $(x,\xi)\in\Omega_1$ *and* $(x,\xi_*)\in\Omega_3, \sigma_x(x,\xi)^{-1}\leqslant c(1+|\tilde{\xi}|)^{1-\beta_1}+(1+|\xi-\xi_*|)^{1-\beta_1})$ and $|\sigma(x,\xi)-\sigma(x,\xi_*)|\leqslant c\|\tilde{\xi}|^2-|\tilde{\xi}_*|^2|$. In this case, we have

$$s(\epsilon,\xi,\xi_*)\leqslant\exp\left(-\frac{1}{16T_\infty}\frac{(|\tilde{\xi}|^2-|\tilde{\xi}_*|^2)^2}{|\xi-\xi|^2}-\frac{1}{16T_\infty}|\xi-\xi_*|^2\right)(\exp[\epsilon\|\tilde{\xi}|^2-|\tilde{\xi}_*|^2|]-1),$$

which also implies (2.1).

This completes the proof of the lemma.

To apply the energy method, define the following orthogonal projections on the macroscopic and microscopic subspaces:

$$\mathbf{P}_0:L^2_\xi\to\mathbf{N},\quad \mathbf{P}_1:L^2_\xi\to\mathbf{N}^\perp.$$

Notice that the macroscopic convection $A=\mathbf{P}_0\xi_1\mathbf{P}_0$ is a linear bounded self-adjoint operator on $\mathbf{N}$. It is straightforward to show that A has five eigenvalues

$$\lambda_1=u_{\infty,1}-c_\infty,\quad \lambda_i=u_{\infty,1}(i=2,3,4),\quad \lambda_5=u_{\infty,1}+c_\infty.$$

Thus, A is negative definite on $\mathbf{N}$ when $\mathcal{M}^\infty<-1$. For later use, denote

$$\phi_0=\mathbf{P}_0\phi=\sum_{j=0}^{4}b_j\psi_j=\sum_{j=0}^{4}\langle\phi,\psi_j\rangle\psi_j,\quad \phi_1=\mathbf{P}_1\phi=\phi-\mathbf{P}_0\phi.$$

The following lemma is from Ref. 6 and we include it here for the self-containess of the paper.

Lemma 2.3: Assume $\mathcal{M}^\infty<-1$, *and the constant* l *in* $\sigma(x,\xi)$ *is sufficiently large. Then there is* $\nu_2>0$ *such that for any* $\phi\in L^2_\xi$,

$$\int_{|\tilde{\xi}|^{3-\beta_1}\leqslant l/2}\phi\mathbf{P}_0\xi_1\mathbf{P}_0\phi\mathrm{d}\xi\leqslant-\nu_2\int_{\mathbf{R}^3}^{s}\phi_0^2\mathrm{d}\xi.$$

Denote $L_\epsilon=e^{\epsilon\sigma}Le^{-\epsilon\sigma}$. Lemmas 2.2 and 2.3 imply the following lemma.

Lemma 2.4: Assume that $\mathcal{M}^\infty<-1$, ϵ *is sufficiently small, and* $l\geqslant\epsilon^{-1}$. *Then there exist* $c,C>0$ *such that*

$$-\langle\sigma_x\xi_1\phi,\phi\rangle\geqslant\frac{C\nu_2}{4}\langle(\delta x+l)^{-\Theta/2}\phi_0,(\delta x+l)^{-\Theta/2}\phi_0\rangle-c\langle\nu(\xi)\phi_1,\phi_1\rangle,$$

$$-\langle L_\epsilon \phi, \phi\rangle \geqslant -c\epsilon^2\langle(\delta x+l)^{-\Theta/2}\phi_0,(\delta x+l)^{-\Theta/2}\phi_0\rangle + C\nu_2\langle\nu(\xi)\phi_1,\phi_1\rangle.$$

Furthermore,

$$-\varepsilon\langle\sigma_x\xi_1\phi,\phi\rangle - \langle L_\epsilon\phi,\phi\rangle \geqslant \frac{C\nu_2\epsilon}{8}\langle(\delta x+l)^{-\Theta/2}\phi,(\delta+l)^{-\Theta/2}\phi\rangle.$$

The following lemma is also needed in the convergence rates analysis.

Lemma 2.5: When $\mathcal{M}^\infty<-1$, ϵ *is sufficiently small, and* $l\geqslant\epsilon^{-3+\beta_1}$, *there exists a constant* $c>0$ *such that for any* ϕ,

$$\left|\int_{\mathbf{R}^3}\frac{\sigma_{xx}}{\sigma_x}\xi_1\phi^2\mathrm{d}\xi\right| \leqslant c\epsilon^2(\delta x+l)^{-\Theta}\langle\phi_0,\phi_0\rangle + c\epsilon^{4/3}\langle\nu(|\xi|)\phi_1,\phi_1\rangle.$$

Proof: The integral on the left-hand side of the above-presented estimate can be discussed as follows. First, notice that by Lemma 2.1,

$$\left|\frac{\sigma_{xx}}{\sigma_x}\right| \leqslant \begin{cases} 0 & (x,\xi)\in\Omega_1 \\ c(\delta x+l)^{-1}\leqslant c(\delta x+l)^{-1+\Theta}\sigma_x & (x,\xi)\in\Omega_2\cup\Omega_3. \end{cases}$$

Then, for $l\geqslant\epsilon^{3-\beta_1}$, we have

$$\begin{aligned}\left|\int_{\mathbf{R}^3}\frac{\sigma_{xx}}{\sigma_x}\xi_1\phi_0^2\mathrm{d}\xi\right| &= \left|\int_{\Omega_2\cup\Omega_3}\frac{\sigma_{xx}}{\sigma_x}\xi_1\phi_0^2\mathrm{d}\xi\right| \leqslant c(\delta x+l)^{-1}\langle|\xi|\phi_0,\phi_0\rangle \\ &\leqslant c\epsilon^2(\delta x+l)^{-\Theta}\langle\phi_0,\phi_0\rangle. \end{aligned} \tag{2.2}$$

Thus,

$$\begin{aligned}\int_{\mathbf{R}^3}\frac{\sigma_{xx}}{\sigma_x}\xi_1\phi_0^2\mathrm{d}\xi &\leqslant 2\int_{\mathbf{R}^3}\frac{\sigma_{xx}}{\sigma_x}\xi_1\phi_0^2\mathrm{d}\xi + \ +2\int_{\mathbf{R}^3}\frac{\sigma_{xx}}{\sigma_x}\xi_1\phi_0^2\mathrm{d}\xi \\ &\leqslant c\epsilon^2(\delta x+l)^{-\Theta}\langle\phi_0,\phi_0\rangle + c(\delta x+l)^{-1+\Theta}\langle\nu(|\xi|)\phi_1,\phi_1\rangle \\ &\leqslant c\epsilon^2(\delta x+l)^{-\Theta}\langle\phi_0,\phi_0\rangle + c\epsilon^{4/3}\langle\nu(|\xi|)\phi_1,\phi_1\rangle.\end{aligned}$$

Here we have used $|\sigma_x\xi_1|\leqslant c\nu(|\xi|)$, $-1\leqslant-1+\Theta<-\frac{2}{3}$ for $0<\beta_1\leqslant1$, $(\delta x+l)^{-1+\Theta}\leqslant\epsilon^{2(3-\beta_1)/3}\leqslant\epsilon^{4/3}$ when $l\geqslant\epsilon^{3-\beta_1}$. And this completes the proof of the lemma.

Denote $\widetilde{K}=e^{\epsilon\sigma}Ke^{-\epsilon\sigma}$. The following properties of the operator $\widetilde{K}$ are also proved in Ref. 6.

Lemma 2.6: When ϵ *is sufficiently small, then* $\widetilde{K}$ *satisfies*:

1. $\sigma_x^{1/2}\widetilde{K}\sigma_x^{-1/2}$ *is a bounded operator from* L^2_ξ *to itself.*
2. $\sigma_x^{1/2}\widetilde{K}\sigma_x^{-1/2}$ *is a bounded operator from* L^2_ξ *to* L^∞_ξ.
3. $[[\widetilde{K}h]]_\beta\leqslant c[[h]]_{\beta-1}$, *for* $\beta\in\mathbf{R}$.

We now recall some property on the nonlinear term $\Gamma(g,h)$ from Lemma 4.5 in Ref. 6.

Lemma 2.7: The projection of $\Gamma(g,h)$ *on the null space of L vanishes and there exists a positive constant c such that, for all* $(x,\xi)\in\mathbf{R}\times\mathbf{R}^3$,

$$|\sigma_x^{1/2}\nu^{-1}(e^{\epsilon\sigma}g,e^{-\epsilon\sigma}h)(x,\xi)| \leqslant C(1+|\xi|)^{-\beta}\exp(-\epsilon^2(\delta x+l)^{2/(3-\beta_1)})[[g]]_\beta[[h]]_\beta$$

for any $\beta>(1-\beta_1)/2$ *and sufficiently small constant* $\epsilon>0$.

The last lemma in this section is about how to transfer the decay in space to the decay in time through some recursive relations in terms of energy inequalities. This lemma is used to obtain the time convergence rate for the solution to the initial boundary value problem (1.5).

Lemma 2.8: Suppose that y *and* $\Xi(t,x,\xi)\geqslant1$ *are functions of* (t,x,ξ). *Define*

$$\mathbf{I}_m(t) = \int_{\mathbf{R}\times\mathbf{R}^3} \Xi(t,x,\xi)^m y(t,x,\xi)^2 \mathrm{d}x\,\mathrm{d}\xi \quad \textit{for all } m \geqslant -1.$$

If there exists a positive constant ϵ *such that*

$$\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{I}_{-1} \leqslant 0, \cdots, \quad \frac{\mathrm{d}}{\mathrm{d}t}\mathbf{I}_{m-1} + \epsilon\mathbf{I}_{m-2} \leqslant 0, \quad \frac{\mathrm{d}}{\mathrm{d}t}\mathbf{I}_m + \epsilon\mathbf{I}_{m-1} \leqslant 0, \tag{2.3}$$

then there exists constant $c_{m,\epsilon}$, *for* $-1 \leqslant n \leqslant m$, *we have*

$$(1+t)^{m-n}\mathbf{I}_n(t) \leqslant c_{m,\epsilon}\mathbf{I}_m(0). \tag{2.4}$$

Proof: By definition, notice that $\mathbf{I}_{-1}(t) \leqslant \mathbf{I}_0(t) \leqslant \cdots \leqslant \mathbf{I}_m(t)$ *for all* $t \geqslant 0$ because $\Xi \geqslant 1$. Define

$$F(t) = \frac{m!\,\epsilon}{(m+1)!}(1+t)^{m+1}\mathbf{I}_{-1} + \frac{m!}{m!}(1+t)^m\mathbf{I}_0 + \cdots + \frac{m!}{1!}\epsilon^{-m+1}(1+t)\mathbf{I}_{m-1} + \frac{m!}{0!}\epsilon^{-m}\mathbf{I}_m.$$

From (2.3), it is straightforward to obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}F(t) = \frac{(1+t)^{m+1}\epsilon}{m+1}\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{I}_{-1} + (1+t)^m\left[\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{I}_0 + \epsilon\mathbf{I}_{-1}\right] + \cdots + m!\,\epsilon^{-m}\left[\frac{\mathrm{d}}{\mathrm{d}t}\mathbf{I}_m + \epsilon\mathbf{I}_{m-1}\right] \leqslant 0.$$

Thus, $F(t) \leqslant F(0)$ which implies that there exists a constant $c_{m,\epsilon}$ such that

$$(1+t)^{m-n}\mathbf{I}_n(t) \leqslant c_{m,\epsilon}\mathbf{I}_m(0) \quad \textit{for } -1 \leqslant n \leqslant m.$$

The proof of the lemma is then completed.

III. LINEARIZED PROBLEM

The purpose of this section is to obtain some time decay estimate on the solutions to the linearized problem. Recall $F = M_\infty + M_\infty^{1/2} f$, and let $f = e^{-\epsilon\sigma} g$. Then the problem (1.5)

$$\begin{aligned}
&g_t + \xi_1 g_x - \epsilon\sigma_x\xi_1 g - L_\epsilon g = e^{\epsilon\sigma}\Gamma(e^{-\epsilon\sigma}g, e^{-\epsilon\sigma}g), \quad t>0,\ x>0,\ \xi\in\mathbf{R}^3,\\
&g|_{t=0} = g_0(x,\xi) = e^{\epsilon\sigma}M_\infty^{-1/2}(F_0 - M_\infty), \quad x>0,\ \xi\in\mathbf{R}^3,\\
&g|_{x=0} = b_0(\xi) = e^{\epsilon\sigma}M_\infty^{-1/2}(F_b - M_\infty), \quad t>0,\ \xi_1>0,\ (\xi_2,\xi_3)\in\mathbf{R}^2,\\
&g \to 0 (x\to\infty), \quad t>0,\ \xi\in\mathbf{R}^3.
\end{aligned} \tag{3.1}$$

Denote the corresponding stationary boundary layer solution to (3.1) by $\bar{g}$ and let the initial g_0 be a small perturbation of $\bar{g}$. Then the problem on the perturbation $\tilde{g}$ is

$$\begin{aligned}
&\tilde{g}_t + \xi_1\tilde{g}_x - \epsilon\sigma_x\xi_1\tilde{g} - L_\epsilon\tilde{g} = e^{\epsilon\sigma}\{\bar{L}_\epsilon\tilde{g} + \Gamma(e^{-\epsilon\sigma}\tilde{g}, e^{-\epsilon\sigma}\tilde{g})\}, \quad t>0,\ x>0,\ \xi\in\mathbf{R}^3,\\
&\tilde{g}|_{t=0} = \tilde{g}_0 = e^{\epsilon\sigma}M_\infty^{-\frac{1}{2}}(F_0 - \bar{F}), \quad x>0,\ \xi\in\mathbf{R}^3,\\
&\tilde{g}|_{x=0} = 0(\xi_1>0), \quad t>0,\ (\xi_2,\xi_3)\in\mathbf{R}^2,\\
&\tilde{g} \to 0 (x\to\infty), \quad t>0,\ \xi\in\mathbf{R}^3.
\end{aligned} \tag{3.2}$$

here $\tilde{g} = g - \bar{g}$, $\tilde{g}_0 = g_0 - \bar{g}$ and $\bar{L}_\epsilon = 2\Gamma(e^{-\epsilon\sigma}\bar{g}, e^{-\epsilon\sigma}\tilde{g})$.

We are going to derive some energy estimates on the solution to the corresponding linearized equation using several weight functions. Let $S(t)$ be the solution operator of the linear problem:

$$h_t + \xi_1 h_x - \varepsilon\sigma_x\xi_1 h - L_\epsilon h = 0, \quad t > 0,\ x > 0,\ \xi \in \mathbf{R}^3,$$

$$h\big|_{x=0} = 0(\xi_1 > 0), h \to 0(x \to \infty), \quad t > 0,\ \xi \in \mathbf{R}^3, \tag{3.3}$$

$$h\big|_{t=0} = h_0(x,\xi), \quad x > 0,\ \xi \in \mathbf{R}^3.$$

That is, $h(t)=S(t)h_0(x,\xi)$.

For the hard sphere model, the solution operator $S(t)$ has exponential decay property when the Mach number $\mathcal{M}^\infty$ is less than -1. For the cut-off hard potentials, we will use the spatial-temporal estimates in Lemma 2.8 to derive an algebraic decay.

In what follows, $(\cdot,\cdot)$ denotes the inner product of $L^2_{x,\xi}$ with norm $\|\cdot\|=\|\cdot\|_{L^2_{x,\xi}}$. The inner product corresponding to the boundary value is $<\cdot,\cdot>_-=(\cdot,\cdot)_{L^2_{x,\xi}(\xi_1>0)}$.

Set

$$\rho^{-1} = \sigma_x^{1/2}h, \quad \rho^0 = h, \quad \rho^1 = \sigma_x^{-1/2}h, \quad \rho^2 = \sigma_x^{-1}h.$$

It is straightforward to derive the following equations for $\rho^i, i=-1,\dots,2$:

$$\begin{aligned}
&\rho_t^{-1} + \xi_1\rho_x^{-1} - \frac{\sigma_{xx}}{2\sigma_x}\xi_1\rho^{-1} - \epsilon\sigma_x\xi_1\rho^{-1} - \sigma_x^{1/2}L_\epsilon\sigma_x^{-1/2}\rho^{-1} = 0,\\
&\rho_t^0 + \xi_1\rho_x^0 - \epsilon\sigma_x\xi_1\rho^0 - L_\epsilon\rho^0 = 0,\\
&\rho_t^1 + \xi_1\rho_x^1 + \frac{\sigma_{xx}}{2\sigma_x}\xi_1\rho^1 - \epsilon\sigma_x\xi_1\rho^1 - \sigma_x^{-1/2}L_\epsilon\sigma_x^{1/2}\rho^1 = 0,\\
&\rho_t^2 + \xi_1 j_x^2 + \frac{\sigma_{xx}}{\sigma_x}\xi_1\rho^2 - \epsilon\sigma_x\xi_1\rho^2 - \sigma_x^{-1}L_\epsilon\sigma_x\rho^2 = 0.
\end{aligned} \tag{3.4}$$

By multiplying $(3.4)_1$ by ρ^{-1} and integrating it over $\mathbf{R}^+\times\mathbf{R}^3$, when ϵ is sufficiently small, Lemmas 2.4 and 2.5 give

$$(\rho^{-1},\rho^{-1})_t + \langle|\xi_1|\rho^{-1},\rho^{-1}\rangle_- + c\epsilon((\delta x+l)^{-\Theta/2}\rho^{-1}, \quad (\delta x+l)^{-\frac{\Theta}{2}}\rho^{-1}) \leqslant 0. \tag{3.5}$$

Similarly, for sufficiently small ϵ, we have

$$\begin{aligned}
&(\rho^0,\rho^0)_t + \langle|\xi_1|\rho^0,\rho^0\rangle_- + c\epsilon((\delta x+l)^{-\Theta/2}\rho^0, \quad (\delta x+l)^{-\Theta/2}\rho^0) \leqslant 0,\\
&(\rho^1,\rho^1)_t + \langle|\xi_1|\rho^1,\rho^1\rangle_- + c\epsilon((\delta x+l)^{-\Theta/2}\rho^1, \quad (\delta x+l)^{-\Theta/2}\rho^1) \leqslant 0,\\
&(\rho^2,\rho^2)_t + \langle|\xi_1|\rho^2,\rho^2\rangle_- + c\epsilon((\delta x+l)^{-\Theta/2}\rho^2, \quad (\delta x+l)^{-\Theta/2}\rho^2) \leqslant 0.
\end{aligned}$$

Since $\sigma_x(x,\xi)\leqslant(\delta x+l)^{-\Theta}$ and $\langle|\xi_1|\rho^i,\rho^i\rangle_-\geqslant 0$ *for* $i=-1,\dots,2$, by the definition of ρ^i, $i=-1,0,1,2$, we have

$$\begin{aligned}
&(\rho^{-1},\rho^{-1})_t \leqslant 0, \quad (\rho^0,\rho^0)_t + c\epsilon(\rho^{-1}, \quad \rho^{-1}) \leqslant 0,\\
&(\rho^1,\rho^1)_t + c\epsilon(\rho^0,\rho^0) \leqslant 0, \quad (\rho^2,\rho^2)_t + c\epsilon(\rho^1,\rho^1) \leqslant 0.
\end{aligned}$$

Corresponding to Lemma 2.8, if we choose $y=\rho^{-1}, \Xi=\sigma_x^{-1/2}, m=2$ and $n=-1$, then

$$(\rho^{-1},\rho^{-1})(t) \leqslant c_\epsilon(1+t)^{-3}(\rho^2,\rho^2)(0),$$

that is,

$$\|\sigma_x^{1/2}S(t)h_0\|_{L^2_{x,\xi}} \leqslant c_\epsilon(1+t)^{-\frac{3}{2}}\|\sigma_x^{-1}h_0\|_{L^2_{x,\xi}}. \tag{3.6}$$

Based on this energy estimate, the following decay estimate on the solution operator $S(t)$ in $[[\cdot]]_\beta$ norm is essential to obtain the global existence and convergence rate for the nonlinear problem through the fixed point theorem in Sec. IV. That is, we want to show that for some $\beta > 0$,

$$[[S(t)h_0]]_\beta \leqslant c(1+t)^{-3/2}\{[[h_0]]_\beta + \|\sigma_x^{-1}h_0\|_{L^2_{x,\xi}}\}, \tag{3.7}$$

where $[[\cdot]]_\beta$ is defined in Sec. I. To prove (3.7), we consider a simpler linear solution operator. Let $S_0(t)$ be the solution operator of

$$\begin{gathered} h_t + \xi_1 h_x - \epsilon\sigma_x\xi_1 h + \nu(\xi)h = 0, \quad t>0,\ x>0,\ \xi\in\mathbf{R}^3, \\ h|_{t=0} = h_0(x,\xi), \quad x>0,\ \xi\in\mathbf{R}^3, \\ h|_{x=0} = 0, \quad t>0,\ \xi_1>0,\ (\xi_2,\xi_3)\in\mathbf{R}^2, \\ h\to 0 (x\to\infty), \quad t>0,\ \xi\in\mathbf{R}^3. \end{gathered} \tag{3.8}$$

It is straightforward to check that the solution to the above-presented linear initial boundary value problem has the following explicit expression:

$$h(x,t) = S_0(t)h_0 = h_0(x-\xi_1 t,\xi)\chi(x-\xi_1 t)\exp\left(-\int_0^t [\nu(\xi) - \epsilon\sigma_x(x-\xi_1(t-s),\xi)\xi_1]\mathrm{d}s\right),$$

where $\chi(y)$ is the characteristic function for $y>0$. By using this expression and the positive lower bound of the collision frequency $\nu(|\xi|)$, the following lemma gives the exponential decay estimate on the operator $S_0(t)$.

Lemma 3.1: For $S_0(t)$ defined earlier, there exist positive constants C and κ such that

$$\|S_0(t)h_0\|_X \leqslant Ce^{-\kappa t}\|h_0\|_X, \tag{3.9}$$

where the norm in X can be $[[\cdot]]_\beta$ and $\|\cdot\|_{L^2_{x,\xi}}$.

Proof: We only prove (3.9) for the norm $[[\cdot]]_\beta$, and the case for the norm $\|\cdot\|_{L^2_{x,\xi}}$ can be proved similarly.

For δ being sufficiently small, $|\sigma_x\xi_1| \leqslant \nu(|\xi|)$ and $\nu(|\xi|)\geqslant \nu_0$. Thus, there exists a positive constant κ such that

$$|(1+|\xi|)^\beta\sigma_x^{1/2}(x,\xi)h(t,x,\xi)| \leqslant H(t,x,\xi)e^{-\kappa t}[[h_0]]_\beta,$$

where $H(x,t,\xi)=\sigma_x^{1/2}(x,\xi)\sigma_x^{-1/2}(x,-\xi_1 t,\xi)e^{-\nu(|\xi|)t/4}$. We now show that there exists a constant c such that $H(t,x,\xi)\leqslant c$ by considering the following two cases.

Case 1: When $(x,\xi)\in\Omega_1\cup\Omega_2$, if $(x-\xi_1 t,\xi)\in\Omega_1\cup\Omega_2$, we have both $\sigma_x(x,\xi)\sim(1+|\widetilde{\xi}|)^{-1+\beta_1}$ and $\sigma_x^{-1}(x-\xi_1 t,\xi)\sim(1+|\widetilde{\xi}|)^{1-\beta_1}$. Thus, it is obvious that there exists a constant c such that $H(t,x,\xi)\leqslant c$. On the other hand, if $(x-\xi_1 t,\xi)\in\Omega_3$, we have $\sigma_x(x,\xi)\leqslant c(\delta x+l)^{-\Theta}$ and $\sigma_x(x-\xi_1 t,\xi)=10\delta/(3-\beta_1)(\delta x+l)^{-\Theta}$ which also immediately implies $H(t,x,\xi)\leqslant c$ for some c.

Case 2: For $(x,\xi)\in\Omega_3$. If $(x-\xi_1 t,\xi)\in\Omega_1$, then $|\xi_1|t=|(\delta x+l)-(\delta x+l-\xi_1 t)|\geqslant(1+|\widetilde{\xi}|)^{3-\beta_1}\geqslant c(1+|\xi|)^{3-\beta_1}$. Thus, for $\xi_1\neq 0$,

$$\nu(|\xi|)t \geqslant c(1+|\xi|)^{\beta_1}t \geqslant c(1+|\xi|)^{\beta_1}\frac{(1+|\xi|)^{3-\beta_1}}{|\xi_1|} \geqslant c(1+|\xi|)^2.$$

This implies that

$$H(t,x,\xi) \leqslant c(1+|\xi|)^{(1-\beta_1)/2} e^{-c(1+|\xi|)^2} \leqslant c.$$

If $(x-\xi_1 t,\xi) \in \Omega_2 \cup \Omega_3$, then $\sigma_x^{-1}(x-\xi_1 t,\xi) \leqslant c(\delta(x-\xi_1 t)+l)^{\Theta}$. Since $\sigma_x(x,\xi) = 10\delta/(3-\beta_1)(\delta x + l)^{-\Theta}$. Hence, it is straightforward to see that there exists constant c such that $H(t,x,\xi) \leqslant c$ by using the decay property of $e^{-\nu(|\xi|)^t/4}$ and $\beta_1 > 0$. This completes the proof of the lemma.

As in Ref. 16, from (3.3) and (3.8), we can rewrite $S(t)$ in terms of $S_0(t)$ and $\tilde{K} = e^{\epsilon\sigma} K e^{-\epsilon\sigma}$:

$$\begin{aligned} S(t)h_0 &= S_0(t)h_0 + \int_0^t S_0(t-s)\tilde{K}S(s)h_0 \mathrm{d}s \\ &= \sum_{j=0}^{m-1} I_j(t) + J_m(t), \end{aligned}$$

$$I_0(t) = S_0(t)h_0,$$

$$I_j(t) = \int_0^t S_0(t-s)\tilde{K}I_{j-1}(s)ds = S_0\tilde{K} * I_{j-1},$$

$$J_m(t) = \underbrace{(S_0\tilde{K}) * (S_0\tilde{K}) * \cdots * (S_0\tilde{K})}_{m} * h,$$

with $h = S(t)h_0$. Here, the notation $*$ stands for the convolution in t. By using the estimate (3.9) and the regularizing property of the compact operator $\tilde{K}$ given in Lemma 2.6, we have for $\beta \geqslant j \geqslant 0$, cf. Ref. 16,

$$[[I_j(t)]]_\beta \leqslant C_j e^{-\kappa t}[[h_0]]_\beta.$$

The estimate on J_m given in the following is more complicated and can be obtained by a bootstrap argument as in Ref. 16 for the hard sphere model.

Lemma 3.2: For $\beta \geqslant 0$, there exists a constant C such that

$$[[J_{\beta+3}(t)]]_\beta \leqslant C(1+t)^{-3/2}\|\sigma_x^{-1}h_0\|_{L_x^\infty(L_\xi^2)}.$$

Proof: The following proof mainly follows from the proof of Lemma 2.2 in Ref. 16 with K replaced by $\sigma_x^{1/2}\tilde{K}\sigma_x^{-1/2}$ and the norm $\|\cdot\|_\beta$ replaced by $[[\cdot]]_\beta$. Moreover, the exponential decay for the hard sphere model in Ref. 16 becomes the algebraic decay.

By using the property of $\sigma_x^{1/2}\tilde{K}\sigma_x^{-1/2}$ in Lemma 2.6 and (3.9), it is straightforward to have

$$[[J_{\beta+3}(t)]]_\beta \leqslant \frac{C}{\beta!}\int_0^t (t-\tau)^\beta e^{-\kappa\tau}\|J_2\|_{L_{x,\xi}^2}(\tau)\mathrm{d}\tau, \tag{3.10}$$

where

$$J_2(t) = \sigma_x^{1/2}(S_0\tilde{K}) * (S_0\tilde{K}) * h = S_0 * \bar{J}, \tag{3.11}$$

with

$$\bar{J} = \sigma_x^{1/2}\tilde{K}S_0\tilde{K} * h = \int_0^t \bar{J}_0(t-s,s)\mathrm{d}s.$$

$\bar{J}_0(t,s)$ can be estimated as follows by using the properties of the operator $\sigma_x^{1/2}\tilde{K}\sigma_x^{-1/2}$. In fact, since

$$\bar{J}_0(t,s) = \sigma_x^{1/2}\widetilde{K}S_0(t)\widetilde{K}h(s) = \int_{\mathbf{R}^3\times\mathbf{R}^3} \sigma_x^{1/2}\widetilde{K}(\xi,\xi')\widetilde{K}(\xi',\xi'')$$
$$\times\exp\left(-\int_0^t [\nu(\xi') - \epsilon\xi_1'\sigma_y(x-\xi_1's,\xi')]\mathrm{d}s\right)\chi(y)h(t,y,\xi'')\mathrm{d}\xi'\,\mathrm{d}\xi'',$$

where $y=x-\xi_1't$, we have

$$|\bar{J}_0(t,s)| \leqslant e^{-\kappa t}\int_{\mathbf{R}\times\mathbf{R}^3} \widetilde{K}_0(\xi,\xi_1',\xi'')\chi(y)\sigma_x^{1/2}h(t,y,\xi'')\mathrm{d}\xi'\,\mathrm{d}\xi'',$$

where

$$\widetilde{K}_0(\xi,\xi_1',\xi'') = \int_{\mathbf{R}^2} \sigma_x^{1/2}|\widetilde{K}(\xi,\xi')|\sigma_x^{-1/2}\sigma_x^{1/2}|\widetilde{K}(\xi',\xi'')|\sigma_x^{-1/2}\mathrm{d}\xi_2'\mathrm{d}\xi_3', \quad \xi' = (\xi_1',\xi_2',\xi_3').$$

Similar to the properties of the kernel $K(\xi,\xi')$ stated in Ref. 16, it is straightforward to check that the following estimates hold:

$$\int_{\mathbf{R}^3} \sigma_x^{1/2}|\widetilde{K}(\xi,\xi')|\sigma_x^{-1/2}\mathrm{d}\xi' = \int_{\mathbf{R}^3} \sigma_x^{1/2}|\widetilde{K}(\xi',\xi)|\sigma_x^{-1/2}\mathrm{d}\xi' \leqslant C_0,$$

$$\int_{\mathbf{R}^3} \sigma_x^{1/2}|\widetilde{K}(\xi,\xi')|\sigma_x^{-1/2}\mathrm{d}\xi_2'\,\mathrm{d}\xi_3' \leqslant C_1,$$

where C_0 and C_1 are some positive constants depending only on the parameters ρ_∞, u_∞, T_∞. Thus,

$$\int_{\mathbf{R}\times\mathbf{R}^3} \widetilde{K}_0(\xi,\xi_1',\xi'')\mathrm{d}\xi_1'\,\mathrm{d}\xi'' \leqslant C_0^2, \quad \int_{\mathbf{R}^3} \widetilde{K}_0(\xi,\xi_1',\xi'')\mathrm{d}\xi \leqslant C_0C_1,$$

which implies that

$$|\bar{J}_0(t,s)|^2 \leqslant e^{-2\kappa t}\left[\int_{\mathbf{R}\times\mathbf{R}^3} \widetilde{K}_0(\xi,\xi_1',\xi'')\mathrm{d}\xi_1'\,\mathrm{d}\xi''\right]\left[\int_{\mathbf{R}\times\mathbf{R}^3} \widetilde{K}_0(\xi,\xi_1',\xi'')\chi(y)|\sigma_x^{1/2}h(s,y,\xi'')|^2\mathrm{d}\xi_1'\,\mathrm{d}\xi''\right]$$
$$\leqslant C_0^2e^{-2\kappa t}\int_{\mathbf{R}\times\mathbf{R}^3} \widetilde{K}_0(\xi,\xi_1',\xi'')\chi(y)|\sigma_x^{1/2}h(s,y,\xi'')|^2\mathrm{d}\xi_1'\,\mathrm{d}\xi''.$$

Hence, we have

$$\|\bar{J}_0(t,s)\|^2_{L_x^\infty(L_\xi^2)} = \sup_{x>0}\int_{\mathbf{R}^3} |\bar{J}_0(t,s)|^2\mathrm{d}\xi \leqslant C_0^2C_0C_1e^{-2\kappa t}\int_{\mathbf{R}\times\mathbf{R}^3} \chi(y)|\sigma_x^{1/2}h(s,y,\xi'')|^2\mathrm{d}\xi_1'\,\mathrm{d}\xi''$$
$$= \frac{ce^{-2\kappa t}}{t}\int_0^\infty\int_{\mathbf{R}^3} |\sigma_x^{1/2}h(s,y,\xi'')|^2\mathrm{d}\xi''\,\mathrm{d}y \leqslant \frac{ce^{-2\kappa t}}{t}(1+s)^{-3}\|\sigma_x^{-1}h_0\|^2_{L^2_{x,\xi}}.$$

Here, we have used the $L^2_{x,\xi}$ decay estimate (3.6). Hence, the definition of $\bar{J}$ and the above-presented estimate give

$$\|\bar{J}(t)\|_{L_x^\infty(L_\xi^2)} \leqslant \int_0^t \|\bar{J}_0(t-s,s)\|_{L_x^\infty(L_\xi^2)}\mathrm{d}s \leqslant c\int_0^t \frac{e^{-\kappa t-s}}{\sqrt{t-s}}(1+s)^{-3/2}\|\sigma_x^{-1}h_0\|_{L^2_{x,\xi}}\mathrm{d}s \leqslant c(1+t)^{-3/2}\|\sigma_x^{-1}h_0\|_{L^2_{x,\xi}}.$$

Thus, (3.9) and (3.11) yield

$$\|J_2(t)\|_{L_x^\infty(L_\xi^2)} = c\|S_0 * \bar{J}\|_{L_x^\infty(L_\xi^2)} \int_0^t e^{-\kappa(t-s)} \|\bar{J}\|_{L_x^\infty(L_\xi^2)}(s)\mathrm{d}s$$

$$\leqslant c\int_0^t e^{-\kappa(t-s)}(1+s)^{-3/2}\mathrm{d}s\|\sigma_x^{-1}h_0\|_{L_x^\infty(L_\xi^2)} \leqslant c(1+t)^{-3/2}\|\sigma_x^{-1}h_0\|_{L_x^\infty(L_\xi^2)},$$

which together with (3.10) give

$$[[J(t)]]_{\beta+3} \leqslant \frac{C}{\beta!}\int_0^t (t-\tau)^\beta e^{-\kappa(t-\tau)}\|\sigma_x^{1/2}h\|_{L_x^\infty(L_\xi^2)}(\tau)\mathrm{d}\tau \leqslant C(1+t)^{-3/2}\|\sigma_x^{-1}h_0\|_{L_x^\infty(L_\xi^2)}.$$

This completes the proof of the lemma.

As a consequence of Lemmas 3.1 and 3.2,. the main estimate in this section stated in (3.7) about the time decay for the solutions to the linearized Boltzmann equation holds.

IV. NONLINEAR STABILITY

In this section, we will prove the main result on the stability of the boundary layer. In order to estimate the nonlinear term and the coupling term with the boundary layer defined in (3.2), we need the following lemma.

Lemma 4.1: When $\beta>0$, *for the two semigroups* S_0 *and* S *defined in* Sec. III, *we have*

$$[[S_0 * \nu h]]_\beta(t) \leqslant C(1+t)^{-3/2}\sup_{0\leqslant\tau\leqslant t}\{(1+\tau)^{3/2}[[h]]_\beta(\tau)\},$$

$$[[S * \nu h]]_\beta(t) \leqslant C(1+t)^{-3/2}\sup_{0\leqslant\tau\leqslant t}\{(1+\tau)^{3/2}[[h]]_\beta(\tau) + (1+\tau)^{3/2}\|\sigma_x^{-1}\nu h\|_{L^2_{x,\xi}}(\tau)\},$$

for any function $h(t,x,\xi)$ *with the corresponding norm bounded.*

Proof: The explicit expression for S_0 gives

$$[[S_0(t) * \nu h]]_\beta \leqslant \sup_{x,\xi}\int_0^t \sigma_x^{1/2}(1+|\xi|)^\beta e^{-\nu(\xi)/2(t-s)}\chi(x-\xi_1 s)\nu h(s,x-\xi_1 s,\xi)\mathrm{d}s$$

$$\leqslant c\sup_{0\leqslant\tau\leqslant t}\{(1+\tau)^{3/2}[[h]]_\beta(\tau)\}\sup_\xi\left\{\int_0^t e^{-(\nu/2)(t-s)}(1+s)^{-3/2}\nu(\xi)\mathrm{d}s\right\}$$

$$\leqslant c(1+t)^{-3/2}\sup_{0\leqslant\tau\leqslant t}\{(1+\tau)^{3/2}[[h]]_\beta(\tau)\}.$$

The estimate on $S(t)$ can be obtained by using the relation between $S(t)$ and $S_0(t)$:

$$S(t) = S_0(t) + S_0(t) * \tilde{K}S(t).$$

Since (3.7) implies that

$$[[S(t)h_0]]_\beta \leqslant C(1+t)^{-3/2}\{\{h_0\}\}_\beta \tag{4.1}$$

with

$$\{\{h\}\}_\beta \equiv [[h]]_\beta + \|\sigma_x^{-1}h\|_{L^2_{x,\xi}}, \quad \beta>0.$$

For $\beta\geqslant 1$, by the regularizing property of the operator $\tilde{K}$, we have

$$
\begin{aligned}
[[S_0 * \tilde{K}S * \nu h]]_\beta &\leqslant \int_0^t e^{-\kappa(t-s)}[[\tilde{k}S * \nu h]]_\beta(s)\mathrm{d}s \leqslant \int_0^t e^{-\kappa(t-s)}[[S * \nu h]]_{\beta-1}(s)\mathrm{d}s \\
&\leqslant \int_0^t e^{-\kappa(t-s)} \int_0^s (1+s-\tau)^{-3/2}\{\{\nu h\}\}_{\beta-1}(\tau)\mathrm{d}\tau\,\mathrm{d}s \\
&\leqslant c \sup_{0\leqslant\tau\leqslant t}\left[(1+\tau)^{3/2}\{\{\nu h\}\}_{\beta-1}(\tau)\right]\int_0^t e^{-\kappa(t-s)}(1+s)^{-3/2}\mathrm{d}s \\
&\leqslant c(1+t)^{-3/2} \sup_{0\leqslant\tau\leqslant t}[(1+\tau)^{3/2}\{\{\nu h\}\}_{\beta-1}(\tau)].
\end{aligned}
$$

Combining this with the estimate for S_0 yields

$$
[[S * \nu h]]_\beta \leqslant C(1+t)^{-3/2} \sup_{0\leqslant\tau\leqslant t}[(1+\tau)^{3/2}[[h]]_\beta(\tau) + (1+\tau)^{3/2}\{\{\nu h\}\}_{\beta-1}(\tau)].
$$

With this estimate, the sublinear growth of $\nu(\xi)$ and the definition $\{\{\cdot\}\}$ give the estimate in the lemma.

With the above-presented estimates, the global solution to the nonlinear problem (3.2) can be proved as follows. Note that, we formally have

$$
\tilde{g} = S(t)\tilde{g}_0 + S * \{e^{\epsilon\sigma}(\bar{L}_\epsilon\tilde{g} + \Gamma(e^{-\epsilon\sigma}\tilde{g}, e^{-\epsilon\sigma}\tilde{g}))\}.
$$

By denoting the right-hand side of the above equation by $T[\tilde{g}]$, we have

$$
\begin{aligned}
[[T[\tilde{g}]]]_\beta &\leqslant [[S(t)\tilde{g}_0]]_\beta + [[S * \nu\nu^{-1}e^{\epsilon\sigma}(L_\epsilon\tilde{g} + \Gamma(\epsilon^{-\epsilon\sigma}\tilde{g}, e^{-\epsilon\sigma}\tilde{g}))]]_\beta \\
&\leqslant C(1+t)^{-3/2}\Bigg\{\{\{\sigma_x^{-1}\tilde{g}_0\}\}_\beta + \sup_{0\leqslant\tau\leqslant t}((1+\tau)^{3/2}[[\nu^{-1}e^{\epsilon\sigma}(\bar{L}_\epsilon\tilde{g} + \Gamma(e^{-\epsilon\sigma}\tilde{g}, e^{-\epsilon\sigma}\tilde{g}))]]_\beta) \\
&\quad + \sup_{0\leqslant\tau\leqslant t}((1+\tau)^{3/2}\|\sigma_x^{-1}\nu\nu^{-1}e^{\epsilon\sigma}(\bar{L}_\epsilon\tilde{g} + \Gamma(e^{-\epsilon\sigma}\tilde{g}, e^{-\epsilon\sigma}\tilde{g}))\|_{L^2_{x,\xi}})\Bigg\} \\
&\leqslant c(1+t)^{\frac{3}{2}}\{\{\{\tilde{g}_0\}\}_\beta + [[\bar{g}]]|||\tilde{g}||| + |||\tilde{g}|||^2\},
\end{aligned}
$$

where

$$
|||h||| = \sup_{t\geqslant 0}\{(1+t)^{\frac{3}{2}}[[h]]_\beta(t)\}.
$$

Here, we have used Lemma 2.7 in estimating

$$
\begin{aligned}
\|\sigma_x^{-1}e^{\epsilon\sigma}\Gamma(e^{-\epsilon\sigma}g, e^{-\epsilon\sigma}h)\|^2_{L^2_{x,\xi}} &= \int_0^\infty \mathrm{d}x \int_{\mathbf{R}^3} |\sigma_x^{-3}\nu(|\xi|)^2||\nu(|\xi|)^{-1}\sigma_x^{1/2}e^{\epsilon\sigma}\Gamma(e^{-\epsilon\sigma}g, e^{-\epsilon\sigma}h)|^2\mathrm{d}\xi \\
&\leqslant c\int_0^\infty \mathrm{d}x \int_{\mathbf{R}^3} |\sigma_x^{-3}\nu(|\xi|)^2|e^{-c\epsilon^2}(\delta x + l)^{2/(3-\beta_1)}(1+|\xi|)^{-2\beta}\mathrm{d}\xi[[g]]_\beta[[h]]_\beta \\
&\leqslant c\int_0^\infty \mathrm{d}x \int_{\mathbf{R}^3} ((\delta x + l)^{3\Theta} + (1+|\tilde{\xi}|)^{3(1-\beta_1)})e^{-c\epsilon^2(\delta x + l)2/(3-\beta_1)} \\
&\quad \times (1+|\xi|)^{-2(\beta-\beta_1)}\mathrm{d}\xi[[g]]_\beta[[h]]_\beta \leqslant c[[g]]_\beta[[h]]_\beta \quad \text{for } \beta > 3 - \frac{\beta_1}{2}.
\end{aligned}
$$

Consequently,

$$
|||T[\tilde{g}]||| \leqslant c(\{\{\tilde{g}_0\}\}_\beta + [[\bar{g}]]_\beta|||\tilde{g}||| + |||\tilde{g}|||^2).
$$

Similar argument gives

$$|||T[\tilde{g}] - T[\tilde{h}]||| \leqslant c([[\bar{g}_0]]_\beta |||\tilde{g} - \tilde{h}||| + |||\tilde{g} + \tilde{h}|||||\tilde{g} - \tilde{h}|||),$$

for the some constant c.

Finally, the smallness assumptions on $\{\{\tilde{g}_0\}\}_\beta$ and $[[\tilde{g}]]_\beta$ coming from the smallness assumption on the initial data $\tilde{g}_0$ and the boundary data b_0 in (3.1) assure that the nonlinear map T is contractive in a small neighborhood of the origin in the Banach space with the norm $[[\cdot]]_\beta$. Therefore, there is a unique fixed point which implies that (3.2) has a unique global in time solution converging to 0 with an algebraic rate as $c(1+t)^{-3/2}$. This gives the proof of Theorem 1.1.

Statistical quantum probabilities in coherent bosonic and fermionic states

(Received 4 June 2006; accepted 5 July 2006; published online 31 August 2006)

A derivation of the statistical nature of quantum probabilities is presented by considering a system of bosonic particles in a coherent state. A comparison between the current approach and a former derivation is also discussed. The current approach, which is an evaluation of the field operator matrix in the coherent Glauber state, proved to be a concise method which can be applied to relativistic particles as well. An extension of the coherent state method to the fermionic type of particles is also presented and thus the generality of the coherent state method is established.
 [DOI: 10.1063/1.2259583]

I. INTRODUCTION

In an attempt to relate the quantum probabilities to the statistical probabilities the Wigner transform[1] was applied[2] to the field operator $\hat{\psi}^{\dagger}(\vec{x})$, the operator which creates a particle at point $\vec{x}$, and the resulting function was related to the quantum mechanical state function, the square of which should yield the probability density. Wigner transforms[3] are transformation procedures which assign a classical function to every quantum operator. When applying the Wigner transformation to the density operator one gets the Wigner function which has been widely used to investigate quantum mechanics in phase space.[4] However, usage of the Wigner transformation to deduce the statistical nature of the quantum probabilities turned out to be a difficult, if not impossible, method. For example, one of the steps that was needed to connect the quantum probability to the statistical probability was to impose the ansatz $\phi_i(\vec{x}\pm\vec{z}/2)=\phi_i(\vec{x})\phi_i(\pm\vec{z}/2)$. This condition is not satisfied if the set $\{\phi_i\}$ consists of single particle solutions of the Schrödinger equation with a nonzero potential operator. Another difficult condition to satisfy was the neglect of fluctuations. The relative fluctuations[5] are defined as $f=\langle n_k\rangle^{-1}-a$ where $\langle n_k\rangle$ is the average occupation number per mode and a is a constant which depends on particle type. For classical Maxwell-Boltzmann particles $a=0$, for bosons $a=-1$, and for fermions $a=+1$. Therefore, one may neglect relative fluctuations for classical particles only, and in the limit when $\langle n_k\rangle \gg 1$. Yet another disadvantage of the previous method[2] is the fact that the result for N particles needed to be inductive in the sense that the general result for N particles relied on the result for two and three particles and that one may not do the calculations for N particles in an exact way.

A far more legitimate and elegant way of relating the quantum probabilities to statistical probabilities is by calculating the field operator $\hat{\psi}^{\dagger}(\vec{x},t)$ in the coherent state which is a clever quantum state invented by Glauber.[6] One will not need the above-mentioned disadvantageous approximations, and the calculations are quite simple and exact. A possible shortcoming in using the coherent state is the fact that the method is limited to bosons only as one may not speak of a single particle state being occupied by more than one fermion. However, the application of the coherent states method to fermionic particles is simple as one will just need to reinterpret the results of the coherent state for bosons. A more serious problem to think about in the current approach is the fact that there needs to be a physical justification for the presence of the N bosons,

[a)]Electronic mail: aliamh@hotmail.com

or the N fermionic orbitals, by means of which one may attribute a statistical nature to the wave function $\psi(\vec{x},t)$ for the single bosonic or the single fermionic particle at $\vec{x}$ and t. For bosons one can contemplate an analogy between this situation and that of the zero point field (ZPF) bosons. Haisch *et al.*[7] argue that while the quantization of the radiation field predicts the existence of an electromagnetic ZPF, there is, on theoretical grounds, a possibility of assuming a ZPF *a priori*. In fact, they explain, that several quantum effects can be derived by assuming a ZPF and using the theoretical method of stochastic electrodynamics. while it is tempting to think of the ZPF bosons as the N bosons needed for the present situation, the fact is the N bosons in the present paper are massive and the ZPF bosons are massless. Thus, one is compelled to assume the existence of massive bosons with an uncertainty in their number which promotes the statistical nature of the bosonic particle field. As for fermions one needs to assume the existence of an infinite number of orbitals which by themselves are bosons, nevertheless they are occupied by fermions and their numerical uncertainty will promote an uncertainty in the number of fermions and this will lead to a formalism appropriate for fermions yet quite similar to that of the bosons.

II. DERIVATION OF THE BOSONIC STATISTICAL QUANTUM PROBABILITY

The best theoretical way to describe a physical state with an uncertainty in particle number is by means of the coherent state.[8,9] The general coherent state is given by $|\ \rangle=\Pi_{j=1}^{\infty}|\alpha_j\rangle=|\alpha_1\alpha_2\cdots\alpha_k\cdots\rangle$, where for the jth mode, or the jth quantum number, the coherent state is given by

$$|\alpha_j\rangle=\sum_{n_j=0}^{\infty}\frac{\alpha_j^{n_j}}{\sqrt{n_j!}}e^{-1/2|\alpha_j|^2}|n_j\rangle \tag{1}$$

and where $\{|n_j\rangle\}_{n_j=0}^{\infty}$ is a complete orthonormal set of basis in the Fock space. The norm $|\alpha_j|^2=\alpha_j^*\alpha_j$ is equal to the average occupation number for the jth mode, and that can be seen by calculating the number operator $\hat{n}=\hat{a}_j^{\dagger}\hat{a}_j$ in the coherent state representation

$$\begin{aligned}\langle\alpha_j|\hat{n}_j|\alpha_j\rangle&=\sum_{m_j=0}^{\infty}\sum_{n_j=0}^{\infty}\frac{\alpha_j^{*m_j}\alpha_j^{n_j}}{\sqrt{m_j!}\sqrt{n_j!}}e^{-|\alpha_j|^2}n_j\langle m_j|n_j\rangle=\sum_{n_j=0}^{\infty}\frac{\alpha_j^{*n_j}\alpha_j^{n_j}}{n_j!}n_je^{-|\alpha_j|^2}\\&=e^{-|\alpha_j|^2}\alpha_j^*\alpha_j\sum_{n_j=1}^{\infty}\frac{\alpha_j^{*n_j-1}\alpha_j^{n_j-1}}{(n_j-1)!}=e^{-|\alpha_j|^2}\alpha_j^*\alpha_je^{|\alpha_j|^2}=\alpha_j^*\alpha_j=|\alpha_j|^2\end{aligned} \tag{2}$$

or by observing the fact that the norm square of the coefficients in the coherent state expansion is just the Poisson distribution $P(n_j)=(|\alpha_j|^{2n_j}e^{-|\alpha_j|^2})/n_j!$,[9]

$$\langle n_j\rangle=\sum_{n_j=0}^{\infty}n_jP(n_j)=\sum_{n_j=0}^{\infty}\frac{n_j|\alpha_j|^{2n_j}}{n_j!}e^{-|\alpha_j|^2}=\left(\frac{1}{2}|\alpha_j|\frac{\mathrm{d}e^{|\alpha_j|^2}}{\mathrm{d}\alpha_j}\right)e^{-|\alpha_j|^2}=|\alpha_j|^2. \tag{3}$$

Equation (2) relates a diagonal element to an expectation value which is the quantum mechanical method of calculating average values, however, Eq. (3) does not follow that recipe and for that reason it is better to refer to Eq. (3) in this derivation. Given the complete orthonormal set $\{\phi_j(\vec{x})\}_{j=1}^{\infty}$, where each function $\phi_j(\vec{x})$ is the solution to the Schrödinger equation for a particle with mass m, the evaluation of the field operator $\hat{\psi}^{\dagger}(\vec{x})=\Sigma_{j=1}^{\infty}\hat{a}_j^{\dagger}\phi_j^*(\vec{x})$, which creates a particle at point $\vec{x}$, in the coherent states representation will make the relation of quantum probabilties to statistical probabilities evident. Therefore one should evaluate the matrix element given by

$$\langle\,|\hat{\psi}^{\dagger}(\vec{x})|\,\rangle=\sum_{j=1}^{\infty}\langle\alpha_1\alpha_2\cdots\alpha_k\cdots|\hat{a}_j^{\dagger}\phi_j^{*}(\vec{x})|\alpha_1\alpha_2\cdots\alpha_k\cdots\rangle=\langle\alpha_1|\hat{a}_1^{\dagger}|\alpha_1\rangle\phi_1^{*}(\vec{x})\prod_{j=2}^{\infty}\langle\alpha_j|\alpha_j\rangle$$

$$+\langle\alpha_2|\hat{a}_2^{\dagger}|\alpha_2\rangle\phi_2^{*}(\vec{x})\prod_{\substack{j=1\\ j\neq 2}}^{\infty}\langle\alpha_j|\alpha_j\rangle+\cdots+\langle\alpha_k|\hat{a}_k^{\dagger}|\alpha_k\rangle\phi_k^{*}(\vec{x})\prod_{\substack{j=1\\ j\neq k}}^{\infty}\langle\alpha_j|\alpha_j\rangle+\cdots$$

$$=\sum_{j=1}^{\infty}\langle\alpha_j|\hat{a}_j^{\dagger}|\alpha_j\rangle\phi_j^{*}(\vec{x})=\sum_{m_j=0}^{\infty}\sum_{n_j=0}^{\infty}\sum_{j=1}^{\infty}\frac{\alpha_j^{*m_j}\alpha_j^{n_j}}{\sqrt{m_j!}\sqrt{n_j!}}e^{-|\alpha_j|^2}\langle m_j|\hat{a}_j^{\dagger}|n_j\rangle\phi_j^{*}(\vec{x}),\tag{4}$$

where $\langle\alpha_j|\alpha_j\rangle=1$, and where $|\alpha_j\rangle$ is given by Eq. (1). The equation $\hat{a}_j^{\dagger}|n_j\rangle=\sqrt{n_j+1}|n_j+1\rangle$, and the orthonormal property of the Fock space basis $\{|n_j\rangle\}_{n_j=0}^{\infty}$ can be used in Eq. (4),

$$\langle\,|\hat{\psi}^{\dagger}(\vec{x})|\,\rangle=\sum_{j=1}^{\infty}\sum_{n_j=0}^{\infty}\frac{\alpha_j^{*(n_j+1)}\alpha_j^{n_j}}{\sqrt{(n_j+1)!}\sqrt{n_j!}}e^{-|\alpha_j|^2}\sqrt{n_j+1}\,\phi_j^{*}(\vec{x})=\sum_{j=1}^{\infty}\sum_{n_j=0}^{\infty}\frac{\alpha_j^{*n_j}\alpha_j^{*}\alpha_j^{n_j}}{\sqrt{n_j!}\sqrt{n_j!}}e^{-|\alpha_j|^2}\phi_j^{*}(\vec{x}).\tag{5}$$

A simple rearrangement of Eq. (5) will give the final result

$$\langle\,|\hat{\psi}^{\dagger}(\vec{x})|\,\rangle=\sum_{j=1}^{\infty}\alpha_j^{*}\left(\sum_{n_j=0}^{\infty}\frac{|\alpha_j|^{2n_j}}{n_j!}\right)e^{-|\alpha_j|^2}\phi_j^{*}(\vec{x})=\sum_{j=1}^{\infty}\alpha_j^{*}e^{|\alpha_j|^2}e^{-|\alpha_j|^2}\phi_j^{*}(\vec{x})=\sum_{j=1}^{\infty}\alpha_j^{*}\phi_j^{*}(\vec{x}).\tag{6}$$

The coefficients in the final form of Eq. (6) are complex, and one may write them as $\alpha_j=|\alpha_j|e^{i\delta_{\alpha_j}}$. Also, Eq. (3) indicates that $|\alpha_j|=\sqrt{\langle n_j\rangle}$ which means that $\alpha_j^{*}=|\alpha_j|e^{-i\delta_{\alpha_j}}$ or

$$\alpha_j^{*}=\sqrt{\langle n_j\rangle}e^{-i\delta_{\alpha_j}}.\tag{7}$$

Now define the function

$$\psi^{*}(\vec{x})=\frac{\langle\,|\hat{\psi}^{\dagger}(\vec{x})|\,\rangle}{\sqrt{N}},\tag{8}$$

which along with Eqs. (6) and (7) will give

$$\psi^{*}(\vec{x})=\sum_{j=1}^{\infty}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}e^{-i\delta_{\alpha_j}}\phi_j^{*}(\vec{x}).\tag{9}$$

By employing the grand canonical equation[5] $N=\Sigma_{j=1}^{\infty}\langle n_j\rangle$, and the orthonormal property of the set $\{\phi_j(\vec{x})\}_{j=1}^{\infty}$ one can show that the integral of the product $\psi^{*}(\vec{x})\psi(\vec{x})\mathrm{d}^3x$ is unity

$$\int\psi^{*}(\vec{x})\psi(\vec{x})\mathrm{d}^3x=\sum_{j=1}^{\infty}\sum_{k=1}^{\infty}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}\left(\frac{\langle n_k\rangle}{N}\right)^{1/2}e^{-i\delta_{\alpha_j}}e^{i\delta_{\alpha_k}}\int\phi_j^{*}(\vec{x})\phi_k(\vec{x})\mathrm{d}^3x=\sum_{j=1}^{\infty}\left(\frac{\langle n_j\rangle}{N}\right)=1.\tag{10}$$

Furthermore the function $\psi(\vec{x})$, defined as the Hermitian conjugate of Eq. (9), obeys the Schrödinger equation for a particle at point $\vec{x}$ as one can see by applying the Hamiltonian, $\hat{H}=-(\hbar^2/2m)\nabla^2+V(\vec{x})$, to the function $\psi(\vec{x},t)$,

$$\hat{H}\psi(\vec{x},t)=\sum_{j=1}^{\infty}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}e^{i\delta_{\alpha_j}}\hat{H}\phi_j(\vec{x},t)=\sum_{j=1}^{\infty}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}e^{i\delta_{\alpha_j}}i\hbar\frac{\partial\phi_j(\vec{x},t)}{\partial t}$$

$$=i\hbar\frac{\partial}{\partial t}\sum_{j=1}^{\infty}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2}e^{i\delta_{\alpha_j}}\phi_j(\vec{x},t)=i\hbar\frac{\partial\psi(\vec{x},t)}{\partial t},\tag{11}$$

where

$$\hat{H}\phi_j(\vec{x},t)=i\hbar\frac{\partial\phi_j(\vec{x},t)}{\partial t}$$

and where $\phi_j(\vec{x},t)=\phi_j(\vec{x})e^{-i\epsilon_j t/\hbar}$, which is the time dependence that one gets when solving the Heisenberg equation for the annihilation operator.[2] Alternatively, one can evaluate the bosonic field equation

$$-\frac{\hbar^2}{2m}\nabla^2\hat{\psi}(\vec{x},t)+V(\vec{x})\hat{\psi}(\vec{x},t)=i\hbar\frac{\partial\hat{\psi}(\vec{x},t)}{\partial t}\tag{12}$$

in the coherent state representation and that, together with the Hermitian conjugate of Eq. (8), will prove that the function $\psi(\vec{x},t)$ obeys the Schrödinger equation. In fact, using the alternative method one can show that the relativistic $\psi(\vec{x},t)$ function can be retrieved from the field operator $\hat{\psi}(\vec{x},t)$ which obeys[10]

$$\nabla^2\hat{\psi}(\vec{x},t)-\frac{1}{c^2}\frac{\partial^2\hat{\psi}(\vec{x},t)}{\partial t^2}=\frac{m^2c^2}{\hbar^2}\hat{\psi}(\vec{x},t),\tag{13}$$

where the relation between $\psi(\vec{x},t)$ and $\hat{\psi}(\vec{x},t)$ is again given by the Hermitian conjugate of Eq. (8). The field operator in Eq. (13) satisfies the equal-time commutation relations, and consequently will satisfy the Bose-Einstein statistics.[10] For a charged Klein-Gordon field[10] one may write the box normalized non-Hermitian field as

$$\hat{\psi}(\vec{x},t)=\hat{\psi}^{(+)}(\vec{x},t)+\hat{\psi}^{(-)}(\vec{x},t)=\sum_{\ell}\hat{a}_{p_\ell}\phi_{p_\ell}(\vec{x},t)+\hat{b}^{\dagger}_{p_\ell}\phi^{*}_{p_\ell}(\vec{x},t),\tag{14}$$

where the positive sign indicates particle, and the negative sign indicates antiparticle. The set $\{\phi_{p_\ell}(\vec{x},t)\}$ is a complete orthonormal set of solutions to the Klein-Gordon equation, and for a box volume $V=L^3$ the momentum is $\vec{p}_\ell=(2\pi/L)\vec{\ell}$ with $\vec{\ell}=(\ell_1,\ell_2,\ell_3)$, and $\ell_i=0,\pm1,\pm2,\ldots$, where $i=1,2,3$. The Glauber state which should be used in Eq. (8) is

$$|\ \rangle=\prod_{\ell=1}^{\infty}|\alpha_\ell\rangle\prod_{\ell=1}^{\infty}|\overline{\alpha_\ell}\rangle\tag{15}$$

and the total number of particles is given by $N=\Sigma_\ell(\langle n_\ell\rangle+\langle\overline{n_\ell}\rangle)$, where $\langle\overline{n_\ell}\rangle$ is the average number of antiparticles that occupies the ℓth mode. The elements of the set $\{|\alpha_\ell\rangle\}$ are coherent states which correspond to particles and are defined in Eq. (1). Those of the set $\{|\overline{\alpha_\ell}\rangle\}$ correspond to antiparticles and one may define them as

$$|\overline{\alpha_\ell}\rangle=\sum_{\overline{n_\ell}=0}^{\infty}\frac{\overline{\alpha_\ell}^{\overline{n_\ell}}}{\sqrt{\overline{n_\ell}!}}e^{-1/2|\overline{\alpha_\ell}|^2}|\overline{n_\ell}\rangle.$$

One may define the relativistic wave function by means of the Hermitian conjugate of Eqs. (8), (14), and (15). Therefore, using plane wave solutions to the Klein-Gordon equation one can write the relativistic $\psi(\vec{x},t)$ as

$$\psi(\vec{x},t) = \frac{1}{\sqrt{N}}\langle\,|\hat{\psi}(\vec{x},t)|\,\rangle = \frac{1}{\sqrt{N}}(\langle\,|\hat{\psi}^{(+)}(\vec{x},t)|\,\rangle + \langle\,|\hat{\psi}^{(-)}(\vec{x},t)|\,\rangle)$$

$$= \frac{1}{\sqrt{N}}\sum_{\ell}\langle\alpha_\ell|\hat{a}_\ell|\alpha_\ell\rangle N_\ell e^{(i/\hbar)(\vec{p}_\ell\cdot\vec{x}-|E_\ell|t)} + \frac{1}{\sqrt{N}}\sum_{\ell}\langle\overline{\alpha_\ell}|\hat{b}_\ell^{\dagger}|\overline{\alpha_\ell}\rangle N_\ell^{*} e^{-(i/\hbar)(\vec{p}_\ell\cdot\vec{x}-|E_\ell|t)}, \tag{16}$$

where $N_\ell=(mc^2/L^3|E_\ell|)^{1/2}$ is the normalization constant,[11] $|E_\ell|=\sqrt{p^2c^2+m^2c^4}$, and the summation index is simplified. The particle part in Eq. (16) should be evaluated using the coherent state defined in Eq. (1),

$$\sum_{\ell}\langle\alpha_\ell|\hat{a}_\ell|\alpha_\ell\rangle\phi_\ell(\vec{x},t) = \sum_{\ell}\sum_{n_\ell=0}^{\infty}\frac{\alpha_\ell^{*(n_\ell-1)}\alpha_\ell^{n_\ell}}{\sqrt{(n_\ell-1)!}\sqrt{n_\ell!}}\sqrt{n_\ell}e^{-|\alpha_\ell|^2}\phi_\ell(\vec{x},t) = \sum_{\ell}\sum_{n_\ell=0}^{\infty}\frac{\alpha_\ell^{*n_\ell}\alpha_\ell^{n_\ell}}{\sqrt{n_\ell!}\sqrt{n_\ell!}}\frac{n_\ell}{\alpha_\ell^{*}}e^{-|\alpha_\ell|^2}\phi_\ell(\vec{x},t)$$

$$= \sum_{\ell}\sum_{n_\ell=0}^{\infty}\frac{|\alpha_\ell|^{2n_\ell}}{n_\ell!}\frac{n_\ell}{\alpha_\ell^{*}}e^{-|\alpha_\ell|^2}\phi_\ell(\vec{x},t) = \sum_{\ell}\left(\frac{1}{2}|\alpha_\ell|\frac{de^{|\alpha_\ell|^2}}{d\alpha_\ell}\right)\frac{1}{\alpha_\ell^{*}}e^{-|\alpha_\ell|^2}\phi_\ell(\vec{x},t)$$

$$= \sum_{\ell}\frac{|\alpha_\ell||\alpha_\ell|}{|\alpha_\ell|e^{-i\delta_{\alpha_\ell}}}\phi_\ell(\vec{x},t) = \sum_{\ell}|\alpha_\ell|e^{i\delta_{\alpha_\ell}}\phi_\ell(\vec{x},t) = \sum_{\ell}\sqrt{\langle n_\ell\rangle}e^{i\delta_{\alpha_\ell}}\phi_\ell(\vec{x},t), \tag{17}$$

where in getting Eq. (17) one needs to refer to Eq. (7). The antiparticle part in Eq. (16) is similar to the result in Eq. (9) except that the average occupation number will be for antiparticles. With Eqs. (9) and (17) one may write Eq. (16) in terms of average occupation numbers of particles and antiparticles

$$\psi(\vec{x},t) = \sum_{\ell}\left(\frac{\langle n_\ell\rangle}{N}\right)^{1/2}e^{i\delta_{\alpha_\ell}}N_\ell e^{(i/\hbar)(\vec{p}_\ell\cdot\vec{x}-|E_\ell|t)} + \sum_{\ell}\left(\frac{\langle\overline{n_\ell}\rangle}{N}\right)^{1/2}e^{-i\delta_{\overline{\alpha}_\ell}}N_\ell^{*}e^{-(i/\hbar)(\vec{p}_\ell\cdot\vec{x}-|E_\ell|t)}. \tag{18}$$

Equation (18) can now be substituted into the equation which is supposed to be the probability density for relativistic particles[11]

$$\rho(\vec{x}) = \frac{i\hbar}{2mc^2}\left(\psi^{*}(\vec{x},t)\frac{\partial\psi(\vec{x},t)}{\partial t} - \psi(\vec{x},t)\frac{\partial\psi^{*}(\vec{x},t)}{\partial t}\right). \tag{19}$$

Integration of Eq. (19) along with the orthonormal property of the basis set[12] will give

$$\int d^3x\rho(\vec{x}) = \sum_{\ell}\frac{\langle n_\ell\rangle - \langle\overline{n_\ell}\rangle}{N}. \tag{20}$$

Equation (20) can be utilized to investigate a possible physical condition which will cause the failure of Eq. (19) to represent the probability density. It states that if particles and antiparticles are equal in number then there is no chance of finding any massive entity which may be interpreted as a total annihilation. This can be seen be setting $\langle n_\ell\rangle=\langle\overline{n_\ell}\rangle$ which will lead to

$$\int d^3x\rho(\vec{x}) = 0. \tag{21}$$

On the other hand, if there are no antiparticles present then the system consists of particles only and $N=\Sigma_\ell\langle n_\ell\rangle$ which will lead to

$$\int d^3x\rho(\vec{x}) = \sum_{\ell}\frac{\langle n_\ell\rangle}{N} = 1, \tag{22}$$

which is similar to the result Eq. (10). The third possibility is when there are no particles and the system consists of antiparticles only in which case Eq. (20) will be

$$\int \mathrm{d}^3x\rho(\vec{x}) = -\sum_{\ell} \frac{\langle \overline{n_\ell} \rangle}{N} = -1. \tag{23}$$

However, a negative sign for a function which is supposed to represent a probability density is a direct indication that Eq. (19) fails to be a probability density for the third possibility being discussed here. The reasons for the negative sign have been traced to Eq. (19) which one derives from the Klein-Gordon equation.[11] It is said that since $\psi(\vec{x},t)$ and its time derivative may have arbitrary value the function in Eq. (19) can be negative. Nevertheless, one may think in terms of Eq. (20) in which the function that is supposed to represent the probability density will acquire a negative sign only under one physical circumstance, and that is whenever the total number of antiparticles exceed the total number of particles. On physical grounds this line of reasoning provides a better arguement for the failure of that function to represent the probability density.

The application of the coherent states method to fermions is an important task which will generalize the statistical nature of quantum wave functions and will render it nonaxiomatic. However, to apply it to fermions one needs to make up a state that does not include uncertainties in particle number and that suggests a different kind of Glauber state, one which does not consist of a superposition of states with many particles in each state. Although that might seem to be a formidable task at first, the fact is one can easly extend the bosonic formalism to include the fermionic particles as well.

III. DERIVATION OF THE FERMIONIC STATISTICAL QUANTUM PROBABILITY

Here one needs to think in terms of quantum orbitals and fermions which can occupy the orbitals in accordance with the Pauli principle. The orbitals may be occupied by either one fermion or no fermion. If the total number of orbitals in the jth quantum state is k_j then n_j will be the number of orbitals which are filled with a single fermion. This situation is similar to the Bernoulli trials[13] in which there are two possible outcomes for each trial. The probabilities of the two outcomes are denoted by p as the probability of a success S, and q as the probability of a failure F. In this approach the trials are independent, and the probability of any specific sequence, say $(SSFSF\cdots FFS)$, is given by

$$P\{(SSFSF\cdots FFS)\} = ppqpq\cdots qqp. \tag{24}$$

Thus if one defines a filled orbital as a success and an empty one as a failure then the above sequence can be written for the jth quantum state

$$P\{(11010\cdots001)\} = p_jp_jq_jp_jq_j\cdots q_jq_jp_j, \tag{25}$$

where there are k_j elements in the set $(11010\cdots001)$, n_j of them are ones and k_j-n_j of them are zeros, and where $p_j+q_j=1$; $\forall j$. For example, if $n_j=1$ then there are k_j ways of placing the one fermion in the orbitals with the jth quantum state. One can define the mutually exclusive sets $A_1=(10000\cdots000)_j, A_2=(01000\cdots000)_j, A_3=(00100\cdots000)_j, \cdots, A_{k_j}=(00000\cdots001)_j$, and that will give $\cap_{i=1}^{k_j} A_i=\varnothing$, which along with the definition $P\{\varnothing\}=0$ will give the probability of the union of all the events as[13]

$$P\left\{\bigcup_{i=1}^{k_j} A_i\right\} = \sum_{i=1}^{k_j} P\{A_i\} = p_jq_jq_j\cdots q_j + q_jp_jq_j\cdots q_j + q_jq_jp_j\cdots q_j + \cdots + q_jq_jq_j\cdots p_j$$

$$= k_jp_jq_jq_j\cdots q_j = \frac{k_j!}{1!(k_j-1)!}p_j^1q_j^{(k_j-1)}. \tag{26}$$

In general, the probability that k_j orbitals (Bernoulli trials), with probabilities p_j for finding a fermion in one of the k_j orbitals and $q_j=1-p_j$ for failure to find one, results in n_j successes (filled orbitals) and k_j-n_j failures (empty orbitals) is

$$P(n_j) = \frac{k_j!}{n_j!(k_j - n_j)!} p_j^{n_j} q_j^{(k_j - n_j)}, \tag{27}$$

which is the binomial distribution. Note that the multiplicative factor in Eq. (27) is precisely the one which corresponds to the Fermi-Dirac statistics of distributing n_j fermions among k_j energy levels. This probability satistfies the axiom of a probability function as one can see by summing over all possible values of n_j,

$$\sum_{n_j=0}^{k_j} P(n_j) = \sum_{n_j=0}^{k_j} \frac{k_j!}{n_j!(k_j - n_j)!} p_j^{n_j} q_j^{(k_j - n_j)} = (p_j + q_j)^{k_j} = 1. \tag{28}$$

When considering the limit $k_j \gg 1$ such that the product $k_j p_j$ is moderate then the binomial distribution may be approximated by the Poisson distribution.[13] Therefore, the probability that n_j orbitals among a total of k_j orbitals are filled is

$$P(n_j) = \frac{\lambda_j^{n_j}}{n_j!} e^{-\lambda_j}, \tag{29}$$

where $\lambda_j = k_j p_j$, and $k_j \gg 1$. Accordingly

$$\langle n_j \rangle = \sum_{n_j=0}^{\infty} n_j P(n_j) = \sum_{n_j=0}^{\infty} n_j \frac{\lambda_j^{n_j}}{n_j!} e^{-\lambda_j} = \sum_{n_j=1}^{\infty} \frac{\lambda_j^{n_j}}{(n_j - 1)!} e^{-\lambda_j} = \lambda_j e^{-\lambda_j} \sum_{n_j=1}^{\infty} \frac{\lambda_j^{n_j - 1}}{(n_j - 1)!} = \lambda_j e^{-\lambda_j} e^{+\lambda_j} = \lambda_j \tag{30}$$

and therefore

$$P(n_j) = \frac{\langle n_j \rangle^{n_j}}{n_j!} e^{-\langle n_j \rangle}. \tag{31}$$

Now one can construct a state for fermions which may be expanded in terms of the Fock space basis given by the form $|\beta_j\rangle = \Sigma_{n_j=0}^{\infty} C_{n_j} |n_j\rangle$, where $|C_{n_j}|^2$ should be the probability that n_j of the k_j orbitals are filled with fermions. To ensure the normalization of the set $\{|\beta_j\rangle\}$ it must be true that $\Sigma_{n_j}^{\infty} |C_{n_j}|^2 = 1$ which along with Eq. (31) suggests that

$$C_{n_j} = \frac{(\langle n_j \rangle e^{i\delta_j})^{n_j/2}}{\sqrt{n_j!}} e^{-\langle n_j \rangle/2}. \tag{32}$$

Now define the annihilation operator $\hat{a}_j$, which annihilates an orbital of the filled type when it operates on the state $|n_j\rangle$. One needs to be aware of the fact that the state $|\beta_j\rangle$ describes fermionic particles by using a formalism which is similar to the bosonic particles. There are no bosonic particles here, however, for the jth quantum state there can be an infinite number of orbitals and any number of these may be occupied by fermions such that each fermion occupy only one orbital. It is easy to show the equality

$$\hat{a}_j |\beta_j\rangle = \sqrt{\langle n_j \rangle} e^{i\delta_j/2} |\beta_j\rangle \tag{33}$$

from which it follows that

$$\langle \beta_j | \hat{a}_j^{\dagger} = \langle \beta_j | \sqrt{\langle n_j \rangle} e^{-i\delta_j/2}. \tag{34}$$

The operator $\hat{\psi}(\vec{x}) = \Sigma_j \hat{a}_j \phi_j(\vec{x})$ annihilates a filled orbital at position $\vec{x}$, and hence annihilates one fermion at that position. The quantum state of the totality of all the fermions can be defined by the direct product

$$|\ \rangle = \prod_{j=1}^{\infty} |\beta_j\rangle. \tag{35}$$

This state accommodates an infinite number of orbitals for each quantum state j with each orbital either being filled with one fermion or with no fermion. The function

$$\psi(\vec{x}) = \frac{1}{\sqrt{N}}\langle\ |\hat{\psi}(\vec{x})|\ \rangle \tag{36}$$

will now be the state function for a fermionic particle, and $N=\Sigma_j\langle n_j\rangle$ is the total number of filled orbitals, or the total number of fermions. With Eq. (35) a direct evaluation of Eq. (36) will give

$$\psi(\vec{x}) = \frac{1}{\sqrt{N}}\sum_{j=1}^{\infty}\langle\beta_1\beta_2\cdots\beta_k\cdots|\hat{a}_j|\beta_1\beta_2\cdots\beta_k\cdots\rangle\phi_j(\vec{x}) = \frac{1}{\sqrt{N}}\sum_{j=1}^{\infty}\langle\beta_j|\hat{a}_j|\beta_j\rangle\phi_j(\vec{x}). \tag{37}$$

With the help of Eq. (33) one can achieve the final form of the fermionic state function which embeds the statistical information

$$\psi(\vec{x}) = \sum_{j=1}^{\infty}\left(\frac{\langle n_j\rangle}{N}\right)^{1/2} e^{i\delta_j/2}\phi_j(\vec{x}). \tag{38}$$

The orthonormality of the set $\{\phi_j(\vec{x})\}$ will directly lead to the result

$$\int \mathrm{d}^3x\psi^*(\vec{x})\psi(\vec{x}) = 1, \tag{39}$$

which makes clear the statistical interpretation of the fermionic state function $\psi(\vec{x})$.

In conclusion, using coherent states is a far superior way to derive the statistical nature of quantum probabilities as the Wigner transformation method necessitated some unfavorable approximations. The coherent state method can be applied to relativistic as well as nonrelativistic particles. It can also be applied to both bosons and fermions which makes the coherent state method as general as the previous method but at the same time more reliable and much more precise.

(Received 10 April 2006; accepted 19 June 2006; published online 4 August 2006)

Cartan calculi on the extended quantum superplane are given. To this end, the noncommutative differential calculus on the extended quantum superplane is extended by introducing inner derivations and Lie derivatives. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2227638]

I. INTRODUCTION

Noncommutative geometry[1] has started to play an important role in different fields of mathematical physics over the past decade. The basic structure giving a direction to the noncommutative geometry is a differential calculus on an associative algebra. The noncommutative differential geometry of quantum groups was introduced by Woronowicz.[2,3] In this approach the differential calculus on the group is deduced from the properties of the group and it involves functions on the group, differentials, differential forms, and derivatives. The other approach, initiated by Wess and Zumino,[4] followed Manin's emphasis[5] on the quantum spaces as the primary objects. Differential forms are defined in terms of noncommuting coordinates, and the differential and algebraic properties of quantum groups acting on these spaces are obtained from the properties of the spaces. The natural extension of their scheme to superspace[6] was introduced by Soni in Ref. 7 and Chung in Ref. 8. The noncommutative geometry of the quantum superplane was given in Ref. 9.

The differential calculus on the quantum superplane similarly involves functions on the superplane, differentials, differential forms, and derivatives. The exterior derivative is a linear operator d acting on k-forms and producing $(k+1)$-forms, such that for scalar functions (0-forms) f and g we have

$$\begin{aligned} \mathsf{d}(1) &= 0, \\ \mathsf{d}(fg) &= (\mathsf{d}f)g + (-1)^{\deg(f)} f(\mathsf{d}g), \end{aligned} \tag{1}$$

where $\deg(f)=0$ for even variables and $\deg(f)=1$ for odd variables, and for a k-form ω_1 and any form ω_2,

$$\mathsf{d}(\omega_1 \wedge \omega_2) = (\mathsf{d}\omega_1) \wedge \omega_2 + (-1)^k \omega_1 \wedge (\mathsf{d}\omega_2). \tag{2}$$

A fundamental property of the exterior derivative d is

$$\mathsf{dd} =: \mathsf{d}^2 = 0. \tag{3}$$

There is a relationship between the exterior derivative and the Lie derivative. To describe the relation between exterior derivative and the Lie derivative, we introduce a new operator: the inner derivation. Hence the differential calculus on the quantum superplane can be extended into a large calculus. We call this new calculus the Cartan calculus. The connection of the inner derivation denoted by $\mathbf{i}_a$ and the Lie derivative denoted by $\mathcal{L}_a$ is given by the Cartan formula:

[a)]Electronic mail: sacelik@yildiz.edu.tr

$$\mathcal{L}_a = \mathrm{d} \circ \mathbf{i}_a + \mathbf{i}_a \circ \mathrm{d}. \tag{4}$$

This and other formulas are explained in Refs. 10–12. Here we do not give any details. In the related section we shall give a brief overview without much discussion.

The extended calculus on the quantum plane was introduced in Ref. 13 using the approach of Ref. 10. In this work we explicitly set up the Cartan calculi on the quantum superplane. In Secs. II and III we give some information on the Hopf algebra structures of the quantum superplane and its differential calculus which we shall use in order to establish our notions. The differential structures of Types II and III which appeared in Sec. III A exist in Ref. 8, but here they are repeated because we need them. In Sec. IV we present the commutation rules of the inner derivations and the Lie derivatives with functions on the quantum superplane, differentials, and partial differentials.

II. REVIEW OF HOPF ALGEBRA $\mathcal{A}$

Elementary properties of the quantum superplane are described in Ref. 9. We state briefly the properties we are going to need in this work.

A. The algebra of functions on the quantum superplane

Let us begin with the definition of the coordinate ring of the quantum superplane $\mathcal{R}_q^{1|1}$. It is well known that the quantum superplane[6] is defined as an associative algebra generated by two noncommuting coordinates x and θ with the relations

$$\begin{aligned} x\theta &= q\theta x, \\ \theta^2 &= 0, \end{aligned} \tag{5}$$

where q is a nonzero complex deformation parameter. The algebra of q polynomials will be called the algebra of functions on the quantum superplane and will be denoted by $\mathcal{A}_0 =: A(\mathcal{R}_q^{1|1})$. In the limit $q \to 1$, this algebra is commutative and can be considered as the algebra of polynomials $\mathcal{R}^{1|1}$ over the usual superplane, where x and θ are the two coordinate functions.

Let $\mathcal{A}_0 = A(\mathcal{R}_q^{1|1})$ be a free unital associative algebra generated by even coordinate x and odd coordinate θ obeying relations (5). We extend the algebra $\mathcal{A}_0$ by including the inverse of x which satisfies

$$xx^{-1} = 1 = x^{-1}x$$

and we denote it by $\mathcal{A}$. We know that the algebra $\mathcal{A}$ is a graded Hopf algebra with the following costructures.[9]

B. Hopf algebra structure on $\mathcal{A}$

The definitions of a coproduct, a counit, and a coinverse on the algebra $\mathcal{A}$ are as follows:

(1) the coproduct $\Delta_{\mathcal{A}}: \mathcal{A} \to \mathcal{A} \otimes \mathcal{A}$ is an algebra homomorphism and is defined by

$$\begin{aligned} \Delta_{\mathcal{A}}(x) &= x \otimes x, \\ \Delta_{\mathcal{A}}(\theta) &= \theta \otimes x + x \otimes \theta. \end{aligned} \tag{6}$$

(2) The counit $\epsilon_{\mathcal{A}}$ is an algebra homomorphism from $\mathcal{A}$ to the complex numbers $\mathcal{C}$ and is given by

$$\begin{aligned} \epsilon_{\mathcal{A}}(x) &= 1, \\ \epsilon_{\mathcal{A}}(\theta) &= 0. \end{aligned} \tag{7}$$

(3) The antipode $S_{\mathcal{A}}:\mathcal{A}\to\mathcal{A}$ is an algebra antihomomorphism and is given by

$$S_{\mathcal{A}}(x)=x^{-1},$$
$$S_{\mathcal{A}}(\theta)=-x^{-1}\theta x^{-1}. \tag{8}$$

These comaps satisfy the Hopf algebra axioms:

$$(\Delta_{\mathcal{A}}\otimes \mathrm{id})\circ\Delta_{\mathcal{A}}=(\mathrm{id}\otimes\Delta_{\mathcal{A}})\circ\Delta_{\mathcal{A}},$$
$$m_{\mathcal{A}}\circ(\epsilon_{\mathcal{A}}\otimes \mathrm{id})\circ\Delta_{\mathcal{A}}=m_{\mathcal{A}}\circ(\mathrm{id}\otimes\epsilon_{\mathcal{A}})\circ\Delta_{\mathcal{A}}, \tag{9}$$
$$m_{\mathcal{A}}\circ(S_{\mathcal{A}}\otimes \mathrm{id})\circ\Delta_{\mathcal{A}}=\epsilon_{\mathcal{A}}=m_{\mathcal{A}}\circ(\mathrm{id}\otimes S_{A})\circ\Delta_{\mathcal{A}},$$

where id denotes the identity map on $\mathcal{A}$ and $m_{\mathcal{A}}$ stands for the algebra product $\mathcal{A}\otimes\mathcal{A}\to\mathcal{A}$. The multiplication in $\mathcal{A}\otimes\mathcal{A}$ is defined with the rule

$$(A\otimes B)(C\otimes D)=(-1)^{\deg(B)\deg(C)}(AC\otimes BD). \tag{10}$$

III. DIFFERENTIAL CALCULI ON THE QUANTUM SUPERPLANE

Here, we shall build up the noncommutative differential calculi on the quantum superplane with help of the covariance point of view, using the Hopf algebra structure of the quantum superplane.[14]

A. Differential algebra

It is well known that in classical differential calculus, functions commute with differentials. From algebraic point of view, the space of one-forms is a free bimodule over the algebra of smooth functions generated by the first-order differentials and the commutativity shows how its left and right structures are related to each other.

In order to establish a noncommutative differential calculus on the quantum superplane, we assume that the commutation relations between the coordinates and their differentials are of the following form:

$$x\mathrm{d}x=Q\mathrm{d}xx,$$
$$x\mathrm{d}\theta=Q_{11}\mathrm{d}\theta x+Q_{12}\mathrm{d}x\theta,$$
$$\theta\mathrm{d}x=Q_{21}\mathrm{d}x\theta+Q_{22}\mathrm{d}\theta x, \tag{11}$$
$$\theta\mathrm{d}\theta=\mathrm{d}\theta\theta.$$

The coefficients Q and Q_{ij} $(1\leqslant i,j\leqslant 2)$ will be determined using the covariance of the noncommutative differential calculus. We also have assumed that

$$\mathrm{d}x\wedge\mathrm{d}\theta=Q'\mathrm{d}\theta\wedge\mathrm{d}x,\quad \mathrm{d}x\wedge\mathrm{d}x=0, \tag{12}$$

where Q' is a parameter that will be described later.

We shall denote the algebra generated with relations (11) by Ω^1 and the algebra generated with relations (12) by Ω^2.

B. Covariance

We first note that consistency of a differential calculus with commutation relations (5) means that the differential algebra is a graded associative algebra generated by the elements of the set

$\{x,\theta,\mathrm{d}x,\mathrm{d}\theta\}$. Let Ω be a free left module over the algebra $\mathcal{A}$ generated by the elements of this set. So the Ω has to be generated by $\Omega^0\cup\Omega^1\cup\Omega^2$, where Ω^0 is isomorphic to $\mathcal{A}$. One says that (Ω,d) is a *first-order differential calculus* over the Hopf algebra $(\mathcal{A},\Delta_{\mathcal{A}},\epsilon_{\mathcal{A}},S_{\mathcal{A}})$. We begin with the definitions of a left- and right-covariant bimodule.

(1) Let Ω be a bimodule over $\mathcal{A}$ and $\Delta^R:\Omega\to\Omega\otimes\mathcal{A}$ be a linear homomorphism. We say that (Ω,Δ^R) is a right-covariant bimodule if

$$\Delta^R(a\rho+\rho' a')=\Delta_{\mathcal{A}}(a)\Delta^R(\rho)+\Delta^R(\rho')\Delta_{\mathcal{A}}(a') \tag{13}$$

for all $a,a'\in\mathcal{A}$ and $\rho,\rho'\in\Omega$, and

$$\begin{gathered}(\Delta^R\otimes\mathrm{id})\circ\Delta^R=(\mathrm{id}\otimes\Delta_{\mathcal{A}})\circ\Delta^R,\\ (\mathrm{id}\otimes\epsilon)\circ\Delta^R=\mathrm{id}.\end{gathered} \tag{14}$$

The action of Δ^R on the first-order differentials is

$$\begin{gathered}\Delta^R(\mathrm{d}x)=\mathrm{d}x\otimes x,\\ \Delta^R(\mathrm{d}\theta)=\mathrm{d}\theta\otimes x+\mathrm{d}x\otimes\theta\end{gathered} \tag{15}$$

since

$$\Delta^R(\mathrm{d}a)=(\mathrm{d}\otimes\mathrm{id})\Delta_{\mathcal{A}}(a);\quad \forall\, a\in\mathcal{A}. \tag{16}$$

We now apply the linear map Δ^R to relations (11):

$$\begin{gathered}\Delta^R(x\mathrm{d}x)=\Delta_{\mathcal{A}}(x)\Delta^R(\mathrm{d}x)=Q\Delta^R(\mathrm{d}xx),\\ \Delta^R(x\mathrm{d}\theta)=\Delta^R(Q_{11}\mathrm{d}\theta x+Q_{12}\mathrm{d}x\theta)+(qQ-Q_{11}-qQ_{12})\mathrm{d}xx\otimes\theta x,\\ \Delta^R(\theta\mathrm{d}x)=\Delta^R(Q_{21}\mathrm{d}x\theta+Q_{22}\mathrm{d}\theta x)-(q^{-1}Q+Q_{21}+q^{-1}Q_{22})\mathrm{d}xx\otimes x\theta,\\ \Delta^R(\theta\mathrm{d}\theta)=\Delta^R(\mathrm{d}\theta\theta)+(q^{-1}Q_{11}+Q_{22}-1)\mathrm{d}\theta x\otimes x\theta+(Q_{12}+qC_{21}+1)\mathrm{d}x\theta\otimes\theta x.\end{gathered} \tag{17}$$

So we must have

$$\begin{gathered}Q_{11}+qQ_{12}=qQ,\quad Q_{11}+qQ_{22}=q,\\ Q_{12}+qQ_{21}=-1,\quad qQ_{21}+C_{22}=-Q.\end{gathered} \tag{18}$$

(2) Let Ω be a bimodule over $\mathcal{A}$ and $\Delta^L:\Omega\to\mathcal{A}\otimes\Omega$ be a linear homomorphism. We say that (Ω,Δ^L) is a left-covariant bimodule if

$$\Delta^L(a\rho+\rho' a')=\Delta_{\mathcal{A}}(a)\Delta^L(\rho)+\Delta^L(\rho')\Delta_{\mathcal{A}}(a') \tag{19}$$

for all $a,a'\in\mathcal{A}$ and $\rho,\rho'\in\Omega$, and

$$\begin{gathered}(\Delta_{\mathcal{A}}\otimes\mathrm{id})\circ\Delta^L=(\mathrm{id}\otimes\Delta^L)\circ\Delta^L,\\ (\epsilon\otimes\mathrm{id})\circ\Delta^L=\mathrm{id}.\end{gathered} \tag{20}$$

Since

$$\Delta^L(\mathrm{d}a)=(\tau\otimes\mathrm{d})\Delta_{\mathcal{A}}(a),\quad \forall\, a\in\mathcal{A} \tag{21}$$

the action of Δ^L on the first-order differentials gives rise to the relations

$$\Delta^L(\mathrm{d}x) = x \otimes \mathrm{d}x,$$
$$\Delta^L(\mathrm{d}\theta) = x \otimes \mathrm{d}\theta - \theta \otimes \mathrm{d}x. \tag{22}$$

Here $\tau: \Omega \to \Omega$ is the linear map of degree zero which gives $\tau(a) = (-1)^{\deg(a)}a$. If we apply Δ^L to relations (11), we do not have any new relations between Q's. Consequently, we may have three distinct solutions:

Type I: includes one deformation parameter

$$Q_{12} = 0, \quad Q_{22} = 0 \Rightarrow \begin{cases} Q = 1 \\ Q_{11} = q \\ Q_{21} = -q^{-1} \\ Q' = q. \end{cases} \tag{23}$$

Type II: includes two parameters

$$Q_{22} = 0, \quad Q = r \Rightarrow \begin{cases} Q_{11} = q \\ Q_{12} = r - 1 \\ Q_{21} = -q^{-1}r \\ Q' = qr^{-1}. \end{cases} \tag{24}$$

Type III: includes two parameters

$$Q_{12} = 0, \quad Q = p \Rightarrow \begin{cases} Q_{11} = pq \\ Q_{21} = -q^{-1} \\ Q_{22} = 1 - p \\ Q' = pq. \end{cases} \tag{25}$$

Hence we see that solution of the form Type I is a special case of solution of the form Type II for $r=1$ or Type III for $p=1$. Therefore it may be omitted. However the Type I solution, as we will see in Sec. IV, gives rise to interesting and important results. Therefore it is convenient as a special type.

Note that it can be checked that the identities (14) and (20) and also the following identities are satisfied:

$$(\mathrm{id} \otimes \mathrm{d})\Delta_{\mathcal{A}}(a) = \Delta^L(\mathrm{d}a),$$
$$(\mathrm{d} \otimes \mathrm{id})\Delta_{\mathcal{A}}(a) = \Delta^R(\mathrm{d}a), \tag{26}$$
$$(\Delta^L \otimes \mathrm{id}) \circ \Delta^R = (\mathrm{id} \otimes \Delta^R) \circ \Delta^L.$$

Note that the Type I has a special importance. We will see in Sec. IV, that in this case the extended calculus on the quantum superplane has linear commutation relations, for example, the commutation rules of the Lie derivatives with functions do not contain the inner derivations.

We call the $\mathcal{A}_0 = A(\mathcal{R}_q^{1|1})$-bimodule generated by $\mathrm{d}x$, $\mathrm{d}\theta$ with relations (11) a *cotangent bimodule* and denote it by $\Omega(T^*\mathcal{R}_q^{1|1})$. Further work on this and on the tangent bimodule is in progress.

C. Cartan-Maurer one-forms on $\mathcal{A}$

In analogy with the left-invariant one-forms on a Lie group in classical differential geometry, one can construct two one-forms using the generators of $\mathcal{A}$ as follows:[9]

$$\omega_x = \mathrm{d}x x^{-1},$$
$$\omega_\theta = \mathrm{d}\theta x^{-1} - \mathrm{d}x x^{-1}\theta x^{-1}. \tag{27}$$

The commutation relations between the generators of $\mathcal{A}$ and one-forms are

$$x\omega_x = Q\omega_x x,$$
$$x\omega_\theta = Q_{11}\omega_\theta x,$$
$$\theta\omega_x = -Q\omega_x\theta + Q_{22}\omega_\theta x, \tag{28}$$
$$\theta\omega_\theta = Q_{11}\omega_\theta\theta.$$

The commutation rules of the one-forms ω_x and ω_θ are

$$\omega_x \wedge \omega_\theta = \omega_\theta \wedge \omega_x,$$
$$\omega_x \wedge \omega_x = 0. \tag{29}$$

We denote the algebra of the forms generated by the two elements ω_x and ω_θ by $\mathcal{W}$. We make the algebra $\mathcal{W}$ into a graded Hopf algebra with the following co-structures:[9] the coproduct $\Delta_\mathcal{W}: \mathcal{W} \to \mathcal{W} \otimes \mathcal{W}$ is defined by

$$\Delta_\mathcal{W}(\omega_x) = \omega_x \otimes 1 + 1 \otimes \omega_x,$$
$$\Delta_\mathcal{W}(\omega_\theta) = \omega_\theta \otimes 1 + 1 \otimes \omega_\theta. \tag{30}$$

The counit $\epsilon_\mathcal{W}: \mathcal{W} \to \mathcal{C}$ is given by

$$\epsilon_\mathcal{W}(\omega_x) = 0,$$
$$\epsilon_\mathcal{W}(\omega_\theta) = 0 \tag{31}$$

and the coinverse $S_\mathcal{W}: \mathcal{W} \to \mathcal{W}$ is defined by

$$S_\mathcal{W}(\omega_x) = -\omega_x,$$
$$S_\mathcal{W}(\omega_\theta) = -\omega_\theta. \tag{32}$$

D. The algebra of partial derivatives

Here, we introduce commutation relations between the coordinates of the quantum superplane and their partial derivatives. Later, we illustrate the connection between the relations in Sec. III E.

To proceed, let us obtain the relations of the coordinates with their partial derivatives. We know that the exterior differential d can be expressed in the form

$$\mathrm{d}f = (\mathrm{d}x\partial_x + \mathrm{d}\theta\partial_\theta)f. \tag{33}$$

Then, for example,

$$\mathrm{d}(xf) = \mathrm{d}x f + x\mathrm{d}f = [\mathrm{d}x(1 + Qx\partial_x + Q_{12}\theta\partial_\theta) + Q_{11}\mathrm{d}\theta\partial_\theta]f = (\mathrm{d}x\partial_x x + \mathrm{d}\theta\partial_\theta x)f$$

so that, after some calculations

$$\partial_x x = 1 + Qx\partial_x + Q_{12}\theta\partial_\theta,$$

$$\partial_x \theta = -Q_{21}\theta\partial_x,$$

$$\partial_\theta x = Q_{11}x\partial_\theta, \tag{34}$$

$$\partial_\theta \theta = 1 - \theta\partial_\theta - Q_{22}x\partial_x.$$

We shall denote the $\mathcal{A}$-module generated by the partial derivatives ∂_x and ∂_θ with relations (34) by $\mathcal{D}^1$. This space $\mathcal{D}^1$ is the bimodule of first-order partial differential operators.

The commutation relations between derivatives are

$$\partial_x\partial_\theta = Q'\partial_\theta\partial_x,$$

$$\partial_\theta^2 = 0. \tag{35}$$

The relations between partial derivatives and differentials are found as

$$\partial_x \mathsf{d}x = Q^{-1}\mathsf{d}x\partial_x - (1 + Q'^{-1}Q_{21}^{-1})\mathsf{d}\theta\partial_\theta,$$

$$\partial_x \mathsf{d}\theta = Q_{11}^{-1}\mathsf{d}\theta\partial_x,$$

$$\partial_\theta \mathsf{d}x = Q_{21}^{-1}\mathsf{d}x\partial_\theta, \tag{36}$$

$$\partial_\theta \mathsf{d}\theta = \mathsf{d}\theta\partial_\theta + (1 - Q'Q_{11}^{-1})\mathsf{d}x\partial_x.$$

The relations between partial derivatives and the exterior derivative, which guarantee the consistence with the basic requirement for the nilpotency of d, are

$$\partial_x \mathsf{d} = Q^{-1}\mathsf{d}\partial_x,$$

$$\partial_\theta \mathsf{d} = -Q^{-1}\mathsf{d}\partial_\theta. \tag{37}$$

E. Quantum Lie superalgebra

The commutation relations of Cartan-Maurer forms allow us to construct the algebra of the generators. In order to obtain the quantum Lie superalgebra of the algebra generators we first write the Cartan-Maurer forms as

$$\mathsf{d}x = \omega_x x,$$

$$\mathsf{d}\theta = \omega_x\theta + \omega_\theta x. \tag{38}$$

The differential d can then be expressed in the form

$$\mathsf{d} = \omega_x H + \omega_\theta \nabla\,. \tag{39}$$

Here H and ∇ are the quantum Lie superalgebra generators (vector fields). We now shall obtain the commutation relations of these generators. Considering an arbitrary function f of the coordinates of the quantum superplane and using that $\mathsf{d}^2 = 0$ and

$$\mathsf{d}\omega_x = 0,$$

$$\mathsf{d}\omega_\theta = 0, \tag{40}$$

one has the following commutation relations for the quantum Lie superalgebra:

$$H\nabla = \nabla H,$$
$$\nabla^2 = 0. \tag{41}$$

The commutation relation (41) of the algebra generators should be consistent with monomials of the coordinates of the quantum superplane. To do this, we evaluate the commutation relations between the generators of algebra and the coordinates. The commutation relations of the generators with the coordinates can be extracted from the graded Leibniz rule:

$$\mathrm{d}(xf) = (\mathrm{d}x)f + x(\mathrm{d}f) = \omega_x(x + QxH)f + \omega_\theta(x\nabla)f = (\omega_x H + \omega_\theta \nabla)xf$$

and

$$\mathrm{d}(\theta f) = (\mathrm{d}\theta)f + \theta(\mathrm{d}f) = \omega_x(\theta + Q\theta H)f + \omega_\theta(x - Q_{11}\theta\nabla - Q_{22}xH)f = (\omega_x H + \omega_\theta \nabla)\theta f.$$

This yields

$$Hx = x + QxH,$$
$$H\theta = \theta + Q\theta H,$$
$$\nabla x = Q_{11}x\nabla, \tag{42}$$
$$\nabla\theta = x - Q_{11}\theta\nabla - Q_{22}xH.$$

We know, from Sec. III D, that the exterior differential d can be expressed in the form (33), which we repeat here,

$$\mathrm{d}f = (\mathrm{d}x\partial_x + \mathrm{d}\theta\partial_\theta)f.$$

Considering (39) together with (33) and using (27) one has

$$H \equiv x\partial_x + \theta\partial_\theta,$$
$$\nabla \equiv x\partial_\theta. \tag{43}$$

Note that, using relations (34) and (35) one can check that the relation of the generators in (43) coincide with (41). It can also be verified that the action of the generators in (43) on the coordinates coincide with (42). Of course, these relations can also be found using the dual pairing. This case will be considered at the end of this section.

The commutation relations of the vector fields H and ∇ with the differentials are the following:

$$H\mathrm{d}x = \mathrm{d}xH,$$
$$H\mathrm{d}\theta = \mathrm{d}\theta H,$$
$$\nabla\mathrm{d}x = QQ_{21}^{-1}\mathrm{d}x\nabla, \tag{44}$$
$$\nabla\mathrm{d}\theta = Q_{11}\mathrm{d}\theta\nabla + Q_{12}\mathrm{d}xH.$$

Here we used that

$$Q_{22} - Q_{11}Q_{21} - Q_{11}Q'^{-1} = 0, \quad Q_{12} + Q_{21}(Q_{11} - Q') = 0,$$
$$Q(Q_{11} - Q') - Q_{11}Q_{12} = 0, \tag{45}$$

$$Q_{12}(1+Q'Q_{21})=0, \quad Q_{22}(Q_{11}-Q')=0.$$

Using relations (44) together with (42) we obtain the commutation rules of the vector fields with one-forms as follows:

$$\begin{aligned} H\omega_x &= -Q^{-1}\omega_x + Q^{-1}\omega_x H, \\ H\omega_\theta &= -Q^{-1}\omega_\theta + Q^{-1}\omega_\theta H, \\ \nabla\omega_x &= -\omega_x \nabla, \\ \nabla\omega_\theta &= Q^{-1}\omega_x + \omega_\theta \nabla + (Q-1)\omega_x H \end{aligned} \tag{46}$$

or taking

$$T = \mathbf{1} + (Q-1)H \tag{47}$$

one has

$$\begin{aligned} T\omega_x &= Q^{-1}\omega_x T, \\ T\omega_\theta &= Q^{-1}\omega_\theta T, \\ \nabla\omega_x &= -\omega_x \nabla, \\ \nabla\omega_\theta &= \omega_\theta \nabla + Q^{-1}\omega_x T. \end{aligned} \tag{48}$$

Here we used that

$$Q_{12} - Q_{22} = Q - 1. \tag{49}$$

Similarly, we can find the commutation relations between the vector fields and the partial derivatives as

$$\begin{aligned} \partial_x H &= \partial_x + QH\partial_x, \\ \partial_\theta H &= \partial_\theta + QH\partial_\theta, \\ \partial_x \nabla &= \partial_\theta + QQ' \nabla \partial_x, \\ \partial_\theta \nabla &= -\nabla\partial_\theta. \end{aligned} \tag{50}$$

We here again used that

$$Q_{12} - Q'Q_{21} = 1, \quad Q_{11} - Q'(Q + Q_{22}) = 0. \tag{51}$$

We know that the differential operator d satisfies the graded Leibniz rule. Therefore, the generators H and ∇ are endowed with a natural coproduct. To find them, we need the following commutation relation:

$$Hx^m = \frac{1-Q^m}{1-Q}x^m + Q^m x^m H, \tag{52}$$

where use was made of the first relation of (42). Relation (52) is understood as an operator equation. This implies that when H acts on arbitrary monomials $x^m\theta$,

$$H(x^m\theta) = \frac{1-Q^{m+1}}{1-Q}(x^m\theta) + Q^{m+1}(x^m\theta)H \tag{53}$$

from which we obtain

$$H = \frac{\mathbf{1}-Q^N}{1-Q}, \tag{54}$$

where N is a number operator acting on a monomial as

$$N(x^m\theta) = (m+1)x^m\theta. \tag{55}$$

We also have

$$\nabla(x^m\theta) = Q_{11}^m x^{m+1} - Q_{11}^{m+1}(x^m\theta)\,\nabla - Q_{11}Q_{22}x^{m+1}H. \tag{56}$$

So, applying the graded Leibniz rule to the product of functions f and g, we write

$$\mathsf{d}(fg) = [(\omega_x H + \omega_\theta \nabla)f]g + f(\omega_x H + \omega_\theta \nabla)g \tag{57}$$

with help of (39). From the commutation relations of the Cartan-Maurer forms with the coordinates of the quantum superplane, we can compute the corresponding relations of ω_x and ω_θ with functions of the coordinates. From (28) we have

$$\begin{aligned}(x^m\theta)\omega_x &= -Q^{m+1}\omega_x(x^m\theta) + Q^m Q_{22}\omega_\theta x^{m+1},\\ (x^m\theta)\omega_\theta &= Q_{11}^{m+1}\omega_\theta(x^m\theta).\end{aligned} \tag{58}$$

Inserting (58) in (57) and equating coefficients of the Cartan-Maurer forms, we get, for example,

$$H(fg) = (Hf)g + (\mathbf{1} + (Q-1)H)f(Hg). \tag{59}$$

Consequently, we have the coproducts for Type II

$$\begin{aligned}\Delta(H) &= H\otimes\mathbf{1} + (\mathbf{1} + (r-1)H)\otimes H,\\ \Delta(\nabla) &= \nabla\otimes\mathbf{1} + (\mathbf{1} + (r-1)H)^{h_2/h_1}\otimes\nabla,\end{aligned} \tag{60}$$

where

$$h_1 = \ln r, \quad h_2 = \ln q, \tag{61}$$

or with (54)

$$\begin{aligned}\Delta(N) &= N\otimes\mathbf{1} + \mathbf{1}\otimes N,\\ \Delta(\nabla) &= \nabla\otimes\mathbf{1} + q^N\otimes\nabla.\end{aligned} \tag{62}$$

The counit and coinverse may be calculated by using the axioms of Hopf algebra:

$$\begin{aligned}m(\epsilon\otimes\mathrm{id})\Delta(u) &= u = m(\mathrm{id}\otimes\epsilon)\Delta(u),\\ m(\mathrm{id}\otimes S)\Delta(u) &= \epsilon(u) = m(S\otimes\mathrm{id})\Delta(u).\end{aligned} \tag{63}$$

So we have

$$\epsilon(N) = 0,$$

$$\epsilon(\nabla) = 0,$$
$$S(N) = -N, \tag{64}$$
$$S(\nabla) = -q^N \nabla .$$

The dual of $\mathcal{A}$, denoted by $\mathcal{U}$ is generated by the elements H and ∇ obeying relations (41). Multiplication and comultiplication in $\mathcal{U}$ can be obtained from the corresponding ones in its dual $\mathcal{A}$, but in the above we get the relevant formulas [Eqs. (41), (62), and (64)] without using its duality with $\mathcal{A}$. We now call $\langle U,a\rangle$ the evaluation of U on a where $U \in \mathcal{U}$ and $a \in \mathcal{A}$. Using

$$\langle U_1 U_2, a\rangle = \langle U_1 \otimes U_2, \Delta_{\mathcal{A}}(a)\rangle,$$
$$\langle U, a_1 a_2\rangle = \langle \Delta_{\mathcal{U}}(U), a_1 \otimes a_2\rangle \tag{65}$$

and

$$\langle U, \mathbf{1}_{\mathcal{A}}\rangle = \epsilon_{\mathcal{U}}(U), \quad \langle \mathbf{1}_{\mathcal{U}}, a\rangle = \epsilon_{\mathcal{A}}(a) \tag{66}$$

we then can compute all possible pairings from those between the generators H, ∇, and x, θ. They are given by for Type II

$$\left\langle T, \begin{pmatrix} x \\ \theta \end{pmatrix} \right\rangle = \begin{pmatrix} r \\ 0 \end{pmatrix}, \quad \left\langle \nabla, \begin{pmatrix} x \\ \theta \end{pmatrix} \right\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{67}$$

To obtain the (left) action of the elements of $\mathcal{U}$ on the elements of $\mathcal{A}$, we now may use the following properties:[15]

$$U[a] = a_{(1)}\langle U, a_{(2)}\rangle,$$
$$U[af] = m \circ \Delta_{\mathcal{U}}(U)[a \otimes f], \tag{68}$$

where $\Delta_{\mathcal{A}}(a) = \Sigma a_{(1)} \otimes a_{(2)}$ is the coproduct of a. For example, one has

$$T[xf] = m \circ \Delta_{\mathcal{U}}(T)[x \otimes f] = m(T \otimes T)[x \otimes f] = T[x]T[f] = rxT[f], \tag{69}$$

so that

$$Tx = rxT. \tag{70}$$

Similarly, we find

$$T\theta = r\theta T,$$
$$\nabla x = qx\nabla , \tag{71}$$
$$\nabla\theta = x - q\theta\nabla .$$

IV. EXTENDED CALCULUS ON THE QUANTUM SUPERPLANE

A Lie derivative is a derivation on the algebra of tensor fields over a manifold. The Lie derivative should be defined in three ways: on scalar functions, vector fields, and tensors.

The Lie derivative can also be defined on differential forms. In this case, it is closely related to the exterior derivative. The exterior derivative and the Lie derivative are set to cover the idea of a derivative in different ways. These differences can be hasped together by introducing the idea of an antiderivation which is called an inner derivation.

A. Inner derivations

Let us begin with some information about the inner derivations. Generally, for a smooth vector field X on a manifold the inner derivation, denoted by $\mathbf{i}_X$, is a linear operator which maps k-forms to $(k-1)$-forms. If we define the inner derivation $\mathbf{i}_X$ on the set of all differential forms on a manifold, we know that $\mathbf{i}_X$ is an antiderivation of degree -1:

$$\mathbf{i}_X(\alpha \wedge \beta) = (\mathbf{i}_X\alpha) \wedge \beta + (-1)^k \alpha \wedge (\mathbf{i}_X\beta), \tag{72}$$

where α and β are both differential forms. The inner derivation $\mathbf{i}_X$ acts on zero- and one-forms as follows:

$$\begin{aligned} \mathbf{i}_X(f) &= 0, \\ \mathbf{i}_X(\mathrm{d}f) &= X(f). \end{aligned} \tag{73}$$

We now wish to find the commutation relations between the coordinates x, θ, and the inner derivations associated with them. In order to obtain the commutation rules of the coordinates with inner derivations, we shall assume that they are of the following form:

$$\begin{aligned} \mathbf{i}_x x &= A_1 x \mathbf{i}_x + A_2 \theta \mathbf{i}_\theta, \\ \mathbf{i}_x \theta &= A_3 \theta \mathbf{i}_x + A_4 x \mathbf{i}_\theta, \\ \mathbf{i}_\theta x &= A_5 x \mathbf{i}_\theta + A_6 \theta \mathbf{i}_x, \\ \mathbf{i}_\theta \theta &= A_7 \theta \mathbf{i}_\theta + A_8 x \mathbf{i}_x. \end{aligned} \tag{74}$$

The coefficients A_k $(1 \leqslant k \leqslant 8)$ will be determined in terms of the deformation parameters in relations (11). But the use of the relations (5) does not give rise to any solution in terms of the parameters Q and Q_{ij} $(1 \leqslant i, j \leqslant 2)$ in (11). Howover, we have, at least, the system

$$\begin{aligned} &A_4(A_1 - qA_5) = 0, \quad A_4(A_3 + qA_7) = 0, \quad A_2A_8 = 0, \\ &A_8(A_5 - qA_1) = 0, \quad A_8(qA_1 + A_7) = 0, \quad A_4A_8 = 0. \end{aligned} \tag{75}$$

To find the coefficients, we need the commutation relations of the inner derivations with the differentials of x and θ. Since

$$\mathbf{i}_{X_i}(\mathrm{d}X_j) = \delta_{ij} \tag{76}$$

we can assume that the relations between the differentials and the inner derivations are of the following form

$$\begin{aligned} \mathbf{i}_x \mathrm{d}x &= 1 + a_1 \mathrm{d}x \mathbf{i}_x + a_2 \mathrm{d}\theta \mathbf{i}_\theta, \\ \mathbf{i}_x \mathrm{d}\theta &= a_3 \mathrm{d}\theta \mathbf{i}_x + a_4 \mathrm{d}x \mathbf{i}_\theta, \\ \mathbf{i}_\theta \mathrm{d}x &= a_5 \mathrm{d}x \mathbf{i}_\theta + a_6 \mathrm{d}\theta \mathbf{i}_x, \\ \mathbf{i}_\theta \mathrm{d}\theta &= 1 + a_7 \mathrm{d}\theta \mathbf{i}_\theta + a_8 \mathrm{d}x \mathbf{i}_x. \end{aligned} \tag{77}$$

Using relations (12) we get the system

$$a_2(a_5 - Q') = 0, \quad a_5 = Q'(1 + a_8), \quad a_1 = -1,$$
$$a_2(a_7 - Q'a_3) = 0, \quad a_2 = Q'a_3 - 1, \quad a_2 a_6 = 0. \tag{78}$$

Now the use of the relations (11) will give

$$A_1 = Q, \quad A_2 = Q_{12}, \quad A_3 = Q_{21}, \quad A_4 = 0,$$
$$A_5 = Q_{11}, \quad A_6 = 0, \quad A_7 = 1, \quad A_8 = Q_{22} \tag{79}$$

and some additional relations consisting A_k, a_k and

$$a_6 = 0.$$

To find the remaining parameters a_k, this time we assume that the commutation relations of the inner derivations with the partial derivatives ∂_x and ∂_θ are in the following form:

$$\mathbf{i}_x \partial_x = B_1 \partial_x \mathbf{i}_x + B_2 \partial_\theta \mathbf{i}_\theta,$$
$$\mathbf{i}_x \partial_\theta = B_3 \partial_\theta \mathbf{i}_x + B_4 \partial_x \mathbf{i}_\theta,$$
$$\mathbf{i}_\theta \partial_x = B_5 \partial_x \mathbf{i}_\theta + B_6 \partial_\theta \mathbf{i}_x, \tag{80}$$
$$\mathbf{i}_\theta \partial_\theta = B_7 \partial_\theta \mathbf{i}_\theta + B_8 \partial_x \mathbf{i}_x.$$

Then using the relations (34) we obtain

$$B_1 = Q^{-1}, \quad B_2 = 0,$$
$$B_3 = Q_{21}^{-1}, \quad B_4 = -Q_1^{-1} Q_{21}^{-1} Q_{12},$$
$$B_5 = Q_{11}^{-1}, \quad B_6 = -Q_{11}^{-1} Q_{21}^{-1} Q_{22}, \tag{81}$$
$$B_7 = 1, \quad B_8 = 0.$$

If we demand that the commutation rules of the inner derivations with d in the form

$$\mathbf{i}_x \circ \mathsf{d} - F \mathsf{d} \circ \mathbf{i}_x = \partial_x,$$
$$\mathbf{i}_\theta \circ \mathsf{d} - F' \mathsf{d} \circ \mathbf{i}_\theta = \partial_\theta, \tag{82}$$

one has

$$F = -Q^{-1}, \quad F' = -F,$$
$$a_2 = -Q^{-1} Q_{12}, \quad a_4 = 0, \quad a_7 = Q^{-1}, \tag{83}$$
$$a_3 = -Q^{-1} Q_{21}, \quad a_5 = Q^{-1} Q_{11}, \quad a_8 = Q'^{-1} Q^{-1} Q_{22}.$$

Consequently, we have the following commutation relations:

- the commutation relations of the inner derivations with x and θ

$$\mathbf{i}_x x = Q x \mathbf{i}_x + Q_{12} \theta \mathbf{i}_\theta,$$

$$\begin{aligned}
\mathbf{i}_x\theta &= Q_{21}\theta\mathbf{i}_x,\\
\mathbf{i}_\theta x &= Q_{11}x\mathbf{i}_\theta,\\
\mathbf{i}_\theta\theta &= \theta\mathbf{i}_\theta + Q_{22}x\mathbf{i}_x,
\end{aligned} \tag{84}$$

- the commutation relations between the differentials and the inner derivations

$$\begin{aligned}
\mathbf{i}_x\mathrm{d}x &= 1 - \mathrm{d}x\mathbf{i}_x - Q^{-1}Q_{12}\mathrm{d}\theta\mathbf{i}_\theta,\\
\mathbf{i}_x\mathrm{d}\theta &= -Q^{-1}Q_{21}\mathrm{d}\theta\mathbf{i}_x,\\
\mathbf{i}_\theta\mathrm{d}x &= Q^{-1}Q_{11}\mathrm{d}x\mathbf{i}_\theta,\\
\mathbf{i}_\theta\mathrm{d}\theta &= 1 + Q^{-1}\mathrm{d}\theta\mathbf{i}_\theta + (QQ')^{-1}Q_{22}\mathrm{d}x\mathbf{i}_x,
\end{aligned} \tag{85}$$

- the relations of the inner derivations with the partial derivatives ∂_x and ∂_θ,

$$\begin{aligned}
\mathbf{i}_x\partial_x &= Q^{-1}\partial_x\mathbf{i}_x,\\
\mathbf{i}_x\partial_\theta &= Q_{21}^{-1}\partial_\theta\mathbf{i}_x - (Q_{11}Q_{21})^{-1}Q_{12}\partial_x\mathbf{i}_\theta,\\
\mathbf{i}_\theta\partial_x &= Q_{11}^{-1}\partial_x\mathbf{i}_\theta - (Q_{11}Q_{21})^{-1}Q_{22}\partial_\theta\mathbf{i}_x,\\
\mathbf{i}_\theta\partial_\theta &= \partial_\theta\mathbf{i}_\theta.
\end{aligned} \tag{86}$$

B. Lie derivatives

We know, from the classical differential geometry, that the Lie derivative $\mathcal{L}$ can be defined as a linear map from the exterior algebra into itself which takes k-forms to k-forms. For a zero-form, that is, an ordinary function f, the Lie derivative is just the contraction of the exterior derivative with the vector field X:

$$\mathcal{L}_X f = \mathbf{i}_X\mathrm{d}f. \tag{87}$$

For a general differential form, the Lie derivative is likewise a contraction, taking into account the variation in X:

$$\mathcal{L}_X\alpha = \mathbf{i}_X\mathrm{d}\alpha + \mathrm{d}(\mathbf{i}_X\alpha). \tag{88}$$

The Lie derivative has the following properties. If $\mathcal{F}(M)$ is the algebra of functions defined on the manifold M then

$$\mathcal{L}_X{:}\mathcal{F}(M) \to \mathcal{F}(M) \tag{89}$$

is a derivation on the algebra $\mathcal{F}(M)$:

$$\begin{aligned}
\mathcal{L}_X(af + bg) &= a(\mathcal{L}_X f) + b(\mathcal{L}_X g),\\
\mathcal{L}_X(fg) &= (\mathcal{L}_X f)g + f(\mathcal{L}_X g),
\end{aligned} \tag{90}$$

where a and b real numbers.

The Lie derivative is a derivation on $\mathcal{F}(M)\times\mathcal{V}(M)$ where $\mathcal{V}(M)$ is the set of vector fields on M:

$$\mathcal{L}_{X_1}(fX_2) = (\mathcal{L}_{X_1}f)X_2 + f(\mathcal{L}_{X_1}X_2). \tag{91}$$

The Lie derivative also has an important property when acting on differential forms. If α and β are two differential forms on M then

$$\mathcal{L}_X(\alpha \wedge \beta) = (\mathcal{L}_X\alpha) \wedge \beta + (-1)^k \alpha \wedge (\mathcal{L}_X\beta), \tag{92}$$

where α is a k-form.

In this section we now wish to find the commutation rules of the Lie derivatives with functions, i.e., the elements of the algebra $\mathcal{A}$, their differentials, etc. For example, the relation of $\mathcal{L}_x$ with x can be obtained, using relations (74) and (77), as follows:

$$\begin{aligned}
\mathcal{L}_x x &= (\mathbf{i}_x \circ \mathsf{d} + \mathsf{d} \circ \mathbf{i}_x)x \\
&= \mathbf{i}_x \mathsf{d}x + \mathsf{d}(\mathbf{i}_x x) \\
&= 1 + a_1 \mathsf{d}x \mathbf{i}_x + a_2 \mathsf{d}\theta \mathbf{i}_\theta + \mathsf{d}(A_1 x \mathbf{i}_x + A_2 \theta \mathbf{i}_\theta) \\
&= 1 + A_1 x \mathcal{L}_x + A_2 \theta \mathcal{L}_\theta + (A_1 + a_1)\mathsf{d}x \mathbf{i}_x + (A_2 + a_2)\mathsf{d}\theta \mathbf{i}_\theta = 1 + Qx\mathcal{L}_x + Q_{12}\theta\mathcal{L}_\theta + (Q-1)(\mathsf{d}x\mathbf{i}_x \\
&\quad + Q^{-1}Q_{12}\mathsf{d}\theta\mathbf{i}_\theta).
\end{aligned} \tag{93}$$

Similarly, one has

$$\mathcal{L}_x\theta = -Q_{21}\theta\mathcal{L}_x + Q_{21}(1-Q^{-1})\mathsf{d}\theta\mathbf{i}_x,$$

$$\mathcal{L}_\theta x = (\mathbf{i}_\theta \circ \mathsf{d} - \mathsf{d} \circ \mathbf{i}_\theta)x = Q_{11}x\mathcal{L}_\theta + Q_{11}(Q^{-1}-1)\mathsf{d}x\mathbf{i}_\theta, \tag{94}$$

$$\mathcal{L}_\theta\theta = 1 - \theta\mathcal{L}_\theta - Q_{22}x\mathcal{L}_x - Q_{22}((QQ')^{-1}-1)\mathsf{d}x\mathbf{i}_x + (Q^{-1}-1)\mathsf{d}\theta\mathbf{i}_\theta.$$

The following relations can be obtained from (85):

$$\begin{aligned}
\mathcal{L}_x\mathsf{d}x &= \mathsf{d}x\mathcal{L}_x + Q^{-1}Q_{12}\mathsf{d}\theta\mathcal{L}_\theta, \\
\mathcal{L}_x\mathsf{d}\theta &= -Q^{-1}Q_{21}\mathsf{d}\theta\mathcal{L}_x, \\
\mathcal{L}_\theta\mathsf{d}x &= -Q^{-1}Q_{11}\mathsf{d}x\mathcal{L}_\theta, \\
\mathcal{L}_\theta\mathsf{d}\theta &= Q^{-1}\mathsf{d}\theta\mathcal{L}_\theta + (QQ')^{-1}Q_{22}\mathsf{d}x\mathcal{L}_x.
\end{aligned} \tag{95}$$

Other commutation relations can be similarly obtained. To complete the description of the above-presented scheme, we get in the following the remaining commutation relations as follows:

- the Lie derivatives and partial derivatives

$$\begin{aligned}
\mathcal{L}_x\partial_x &= \partial_x\mathcal{L}_x, \\
\mathcal{L}_x\partial_\theta &= -QQ_{21}^{-1}\partial_\theta\mathcal{L}_x + Q(Q_{11}Q_{21})^{-1}Q_{12}\partial_x\mathcal{L}_\theta, \\
\mathcal{L}_\theta\partial_x &= QQ_{11}^{-1}\partial_x\mathcal{L}_\theta - Q(Q_{11}Q_{21})^{-1}Q_{22}\partial_\theta\mathcal{L}_x, \\
\mathcal{L}_\theta\partial_\theta &= -Q\partial_\theta\mathcal{L}_\theta,
\end{aligned} \tag{96}$$

- the inner derivations

$$\mathbf{i}_x\mathbf{i}_\theta = -Q_{11}(Q_{12}-Q)^{-1}\mathbf{i}_\theta\mathbf{i}_x,$$
$$\mathbf{i}_x\mathbf{i}_x = 0. \tag{97}$$

- the Lie derivatives and the inner derivations

$$\mathcal{L}_x\mathbf{i}_x = \mathbf{i}_x\mathcal{L}_x,$$

$$\mathcal{L}_x\mathbf{i}_\theta = -QQ_{21}^{-1}\mathbf{i}_\theta\mathcal{L}_x + Q_{12}(Q-Q_{12})^{-1}\mathbf{i}_x\mathcal{L}_\theta,$$
$$\mathcal{L}_\theta\mathbf{i}_x = -QQ_{11}^{-1}\mathbf{i}_x\mathcal{L}_\theta - (Q'Q_{21})^{-1}QQ_{22}\mathbf{i}_\theta\mathcal{L}_x, \tag{98}$$

$$\mathcal{L}_\theta\mathbf{i}_\theta = Q^{-1}\mathbf{i}_\theta\mathcal{L}_\theta,$$

- the Lie derivatives

$$\mathcal{L}_x\mathcal{L}_\theta = Q_{21}^{-1}(Q_{12}-Q)\mathcal{L}_\theta\mathcal{L}_x,$$
$$\mathcal{L}_\theta^2 = 0. \tag{99}$$

Note that the Lie derivatives can be written as follows:

$$\mathcal{L}_x = \partial_x + (1-Q^{-1})\mathsf{d}\circ\mathbf{i}_x,$$
$$\mathcal{L}_\theta = \partial_\theta - (1-Q^{-1})\mathsf{d}\circ\mathbf{i}_\theta, \tag{100}$$

or in terms of vector fields and coordinates

$$\mathcal{L}_x = x^{-1}H - x^{-1}\theta x^{-1}\nabla + (1-Q^{-1})\mathsf{d}\circ\mathbf{i}_x,$$
$$\mathcal{L}_\theta = x^{-1}\nabla - (1-Q^{-1})\mathsf{d}\circ\mathbf{i}_\theta. \tag{101}$$

A connection between the Yang-Baxter relation for maps and the multidimensional consistency property of integrable equations on quad-graphs is investigated. The approach is based on the symmetry analysis of the corresponding equations. It is shown that the Yang-Baxter variables can be chosen as invariants of the multiparameter symmetry groups of the equations. We use the classification results by Adler, Bobenko, and Suris to demonstrate this method. Some new examples of Yang-Baxter maps are derived in this way from multifield integrable equations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2227641]

I. INTRODUCTION

The quantum Yang-Baxter (YB) equation has its origins in the theory of solvable models in statistical mechanics[1,2] and the quantum inverse scattering method.[3] The fact that this equation has also found many applications in representation theory, the construction of invariants in knot theory and that it lies at the foundation of quantum groups, gives to the quantum YB equation a prominent position among the basic equations in mathematical physics, see, e.g., Refs. 4 and 5, and references therein.

In its original form, the quantum YB equation is a relation for a linear operator $R: V \otimes V \to V \otimes V$, where V is a vector space. The relation has the form

$$R^{23}R^{13}R^{12} = R^{12}R^{13}R^{23}, \tag{1}$$

in End $(V \otimes V \otimes V)$, where R^{13} is meant as the identity in the second factor of the tensor product $V \otimes V \otimes V$ and as R in the first and third factors, and analogously for R^{12}, R^{23}. Supposing that X is any set, the maps R from the Cartesian product $X \times X$ into itself, which satisfy the relation (1) of composite maps are called set theoretic solutions of the quantum YB relation. The study of set theoretic solutions of the quantum YB equation was originally suggested by Drinfeld[6] (see also earlier work by Sklyanin[7] where the first interesting example of such solutions was found) and since then they have attracted the interest of many researchers.

More recently, a general theory on the set theoretic solutions to the YB relation was developed in Ref. 8 and the notion of transfer maps, which can be considered as the dynamical analogues of the monodromy and transfer matrices in the theory of solvable models in statistical mechanics, was introduced in Ref. 9. In many interesting examples of YB maps,[10] such as maps arising from

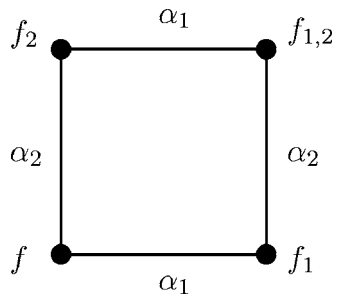

FIG. 1. An elementary quadrilateral.

geometric crystals,[11] the set X has the structure of an algebraic variety and R is a birational isomorphism. The case of $\mathbb{CP}^1 \times \mathbb{CP}^1$ has been recently discussed in Ref. 12 in relation to the classification of the so-called *quadrirational maps*.

In this paper we investigate the relation between the YB property for maps and the *multidimensional consistency* condition for equations on quad-graphs, which is now commonly accepted as a definition of integrability for such equations (see Refs. 13–15). Although the link between these two notions was known before (see, e.g., concluding remarks in Ref. 15) it was never explored systematically.

Our approach is based on the symmetry analysis of integrable equations on quad-graphs. The main idea is that the YB variables are suitable invariants of their symmetry groups. A good example is the *discrete potential Korteweg–de Vries* equation (dpKdV)[16–18]

$$(f_{1,2}-f)(f_1-f_2)-\alpha_1+\alpha_2=0 \tag{2}$$

(see notation in Fig. 1). It is clearly invariant under the translation $f \to f+\text{const}$. The invariants

$$x=f_1-f, \quad y=f_{1,2}-f_1, \quad u=f_{1,2}-f_2, \quad v=f_2-f, \tag{3}$$

satisfy the relation

$$x+y=u+v. \tag{4}$$

and Eq. (2) is written in terms of them as

$$(x+y)(x-v)=\alpha_1-\alpha_2. \tag{5}$$

This allows one to express u,v as functions of x,y, which leads to the following YB map:

$$u=y+\frac{\alpha_1-\alpha_2}{x+y}, \quad v=x-\frac{\alpha_1-\alpha_2}{x+y}, \tag{6}$$

known as the Adler map.[19] Note that the YB variables x, y, u, v, are attached to the edges of the lattice. The fact that the corresponding map satisfies the YB property follows directly from the three dimensional (3D) consistency property of dpKdV (see Fig. 5). This construction works for integrable equations on quad-graphs with one-parameter symmetry group.

One of the main findings of our paper is that this idea works for multiparameter symmetry groups if one considers the extension of the equation on a multidimensional lattice. In that case the edges are replaced by higher dimensional faces. We show that in such a way one can derive from the same discrete potential KdV the following YB map:

$$u=yQ, \quad v=xQ^{-1}, \quad Q=\frac{(1-\gamma_2)+(\gamma_2-\gamma_1)x+\gamma_2(\gamma_1-1)xy}{(1-\gamma_1)+(\gamma_1-\gamma_2)y+\gamma_1(\gamma_2-1)xy}. \tag{7}$$

We will call it *Harrison* map since it is closely related to the superposition formula of the

Bäcklund transformation for the Ernst equation in general relativity introduced by Harrison.[20] After the change of variables $x \mapsto 1/x, v \mapsto 1/v, y \mapsto y/\gamma_2, u \mapsto u/\gamma_1$ it coincides with the F_I quadrirational map in Ref. 12, which corresponds to the most general case of two conics. Note that the most degenerate case F_V in the classification of Ref. 12 is simply related to the Adler map.

The plan of the paper is the following. We start in Sec. II with the discussion of the 3D consistency property for equations on quad-graphs. As examples we choose three equations from the classification list in Ref. 15. By considering the invariants of their one-parameter symmetry groups we derive all five types of the quadrirational maps from Ref. 12. Next, in Sec. III, we show how this symmetry method can be generalized in the case where the lattice equation admits a multiparameter symmetry group. This is demonstrated on the example of the lattice KdV equation by extending it to a three-dimensional cube and using the invariants of a two-parameter symmetry group as YB variables. Finally, we show how the Harrison map can be retrieved from the lattice KdV equation by exploiting its full three-parameter symmetry group and the consistency property on a four-dimensional cube.

In Sec. IV we show that the same idea works equally well for multifield integrable lattice equations and we derive certain examples of multidimensional YB maps from lattice equations in the Boussinesq family, vector Calapso equation and its specialization to an integrable discrete version of the $O(n+2)$ nonlinear σ model, introduced recently by Schief.[21] The paper concludes with perspectives where we address some questions for future study.

II. MULTIDIMENSIONAL CONSISTENCY AND YB MAPS

A. Equations on quad-graphs and the 3D consistency property

Central to our considerations are integrable discrete equations on quad-graphs, which are specific equations associated to planar graphs with elementary quadrilaterals faces. In the simplest case one has complex fields $f: \mathbb{Z}^2 \to \mathbb{C}$ assigned on the vertices at sites (n_1, n_2) and two complex lattice parameters α_1, α_2 assigned on the edges of an elementary square being equal on opposite edges (see Fig. 1). The basic building block of such equations consists of a relation of the form

$$\mathcal{E}(f, f_1, f_2, f_{1,2}; \alpha_1, \alpha_2) = 0, \tag{8}$$

between the values of four fields residing on the vertices of each elementary quadrilateral for which we use the shorthand notation:

$$f := f(n_1, n_2), \quad f_1 := f(n_1+1, n_2), \quad f_2 := f(n_1, n_2+1), \quad f_{1,2} := f(n_1+1, n_2+1). \tag{9}$$

Integrable discrete equations of the above mentioned type (8) are listed in a recent classification[15] where the 3D consistency property (see the following) and some additional conditions were imposed. From that list we consider the following:

$$\mathcal{E}_1: \quad (f_{1,2} - f)(f_1 - f_2) - \alpha_1 + \alpha_2 = 0, \tag{10}$$

$$\mathcal{E}_2: \quad \alpha_1(f f_1 + f_2 f_{1,2}) - \alpha_2(f f_2 + f_1 f_{1,2}) + \delta(\alpha_1^2 - \alpha_2^2) = 0, \tag{11}$$

$$\mathcal{E}_3: \quad (1-\alpha_2^2)(f_1 - \alpha_1 f)(f_2 - \alpha_1 f_{1,2}) - (1-\alpha_1^2)(f_2 - \alpha_2 f)(f_1 - \alpha_2 f_{1,2}) = 0. \tag{12}$$

Equation $\mathcal{E}_1$ is already mentioned as the dpKdV equation. Equation $\mathcal{E}_2$ with $\delta=0$ is the modified discrete KdV or *Hirota equation*.[16] If $\delta \neq 0$, we may always assume that $\delta=1$ using an appropriate gauge. Equation $\mathcal{E}_3$ corresponds to the equation labeled as $Q3_{\delta=0}$ in the classification of Ref. 15. It is contained in the four-parameter family of the equations derived earlier in Ref. 22, which contains also discrete versions of potential KdV, modified KdV, and Schwarzian KdV (see Ref. 23 for a more recent discussion).

The integrability of such equations can be defined using the *three-dimensional consistency* property. This means that the overdetermined system consisting of the difference equations

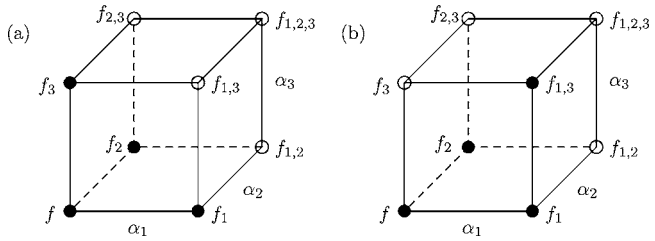

FIG. 2. Elementary initial value problems on the cube.

$$\mathcal{E}(f,f_i,f_j,f_{i,j};\alpha_i,\alpha_j)=0, \quad 1\leqslant i<j\leqslant 3, \tag{13}$$

and their shifted versions, is consistent on the three-dimensional lattice $\mathbb{Z}^3$. In practice, this property is verified as follows.[13–15] Consider an elementary initial value problem on the three-dimensional cube with initial data assigned on four vertices, exactly three of them lying on the same face. One such initial configuration is depicted in Fig. 2(a) with initial values $f,f_i,1\leqslant i\leqslant 3$. Using Eq. (13) on the three faces adjacent to the vertex with value f, we determine uniquely the values $f_{i,j},1\leqslant i<j\leqslant 3$, in terms of the initial data. Then using shifted versions of (13) on each of the remaining three faces, we evaluate $f_{1,2,3}$ in three different ways. Consistency means that one obtains the same value for $f_{1,2,3}$ in terms of the initial data $f,f_i,1\leqslant i\leqslant 3$ (independent of the way we choose to evaluate it). For the dpKdV equation (2) this value is

$$f_{1,2,3}=\frac{(\alpha_1-\alpha_2)f_1f_2+(\alpha_3-\alpha_1)f_1f_3+(\alpha_2-\alpha_3)f_2f_3}{(\alpha_2-\alpha_1)f_3+(\alpha_1-\alpha_3)f_2+(\alpha_3-\alpha_2)f_1}. \tag{14}$$

Note that the right-hand side of Eq. (14) is invariant under any permutation of the indices (1,2,3) which label the field variables and the associated lattice parameters.

Another initial data configuration, which is best adapted to the YB property that we consider, is depicted in Fig. 2(b). A third possible initial configuration is to give the values $f,f_1,f_2,f_{1,2,3}$. The latter two configurations are equivalent to the first one by using the equation on one of the faces. For example, by using the front face equation we can exchange the value $f_{1,3}$ to f_3 in the set of initial data.

Using the fact that dpKdV equation possesses the 3D consistency property, one can show in a similar manner that it can be consistently imposed on each two-dimensional face of a four-cube. Since we are going to use this property later on we describe explicitly its derivation.

For given initial values $f,f_i\ i=1,2,3,4$, we determine the shifted values of the fields involving any two different directions, using

$$(f_{i,j}-f)(f_i-f_j)=\alpha_i-\alpha_j, \tag{15}$$

$1\leqslant i<j\leqslant 4$ (see Fig. 3). Successively, since dpKdV is three-dimensional consistent, we determine the values $f_{ijk},1\leqslant i<j<k\leqslant 4$. Then the value $f_{1,2,3,4}$ can be found in six different ways, using the dpKdV equations on the six two-dimensional facets containing the vertex where the value $f_{1,2,3,4}$ is assigned. This vertex is contained also in four cubes, each one of them containing three of the six facets, and the incidence relations are such that taking into account the three-dimensional consistency on each of the four cubes one proves that the value $f_{1,2,3,4}$ is uniquely determined in terms of initial data. By direct calculations also we find that this value is independent of the way that we used to calculate it, and equals

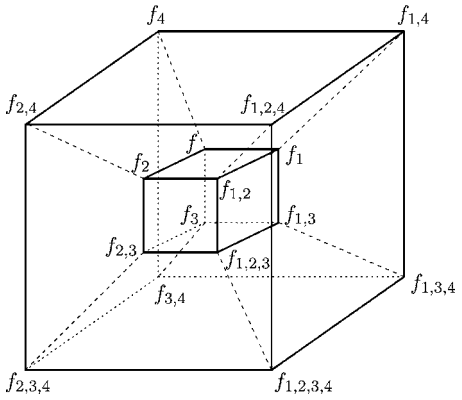

FIG. 3. Discrete potential KdV in $\mathbb{Z}^4$.

$$f_{1,i,j,k} = \frac{\boldsymbol{\sigma}_{ijk}(\alpha_1\alpha_i f_{i,j} + \alpha_j\alpha_k f_{j,k})(f_1 - f_i)(f_j - f_k)}{\boldsymbol{\sigma}_{ijk}(\alpha_1\alpha_i + \alpha_j\alpha_k)(f_1 - f_i)(f_j - f_k)}, \tag{16}$$

where $\boldsymbol{\sigma}_{ijk}$ denotes the cyclic sum over the subscripts $(i,j,k)=(2,3,4),(4,2,3),(3,4,2)$. It can be easily checked that $f_{1,2,3,4}$ given by (16) remains invariant under any permutation of the indices (1,2,3,4), thus dpKdV is four-dimensional consistent.

B. YB relation and 3D consistency property

Let $\mathbb{X}$ be any set and R a map of $\mathbb{X}\times\mathbb{X}$ into itself. Let R^{ij}: $\mathbb{X}^n \to \mathbb{X}^n$, where $\mathbb{X}^n = \mathbb{X}\times\mathbb{X}\times\cdots\times\mathbb{X}$, denotes the map which acts as R on the i and j factors and as the identity on the others. More explicitly, let us write $R(x,y), x,y \in \mathbb{X}$, as

$$R(x,y) = (f(x,y), g(x,y)). \tag{17}$$

Then, for $n \geqslant 2$ and $1 \leqslant i,j \leqslant n, i \neq j$ we define

$$R^{ij}(x^1,x^2,\ldots,x^n) = \begin{cases} (x^1,\ldots,x^{i-1},f(x^i,x^j),x^{i+1},\ldots,x^{j-1},g(x^i,x^j),x^{j+1},\ldots,x^n), & i<j \\ (x^1,\ldots,x^{j-1},g(x^i,x^j),x^{j+1},\ldots,x^{i-1},f(x^i,x^j),x^{i+1},\ldots,x^n), & i>j \end{cases}. \tag{18}$$

In particular, for $n=2$ we find that $R^{12}=R$ and $R^{21}(x,y)=(g(y,x),f(y,x))$. The latter map can be written as a composition of maps as follows:

$$R^{21} = PRP, \tag{19}$$

where P is the permutation map, i.e., $P(x,y)=(y,x)$.

A map R is called a *YB map* if it satisfies the YB relation (1), regarded as an equality of maps from $\mathbb{X}\times\mathbb{X}\times\mathbb{X}$ into itself. If in addition the relation $R^{21}R=\mathrm{Id}$ holds, then R is called reversible YB map.

In a more general setting we may consider a whole family of YB maps parametrized by continuous parameters α_i rather than a single map. The YB relation then takes the parameter-dependent form

$$R^{23}(\alpha_2,\alpha_3)R^{13}(\alpha_1,\alpha_3)R^{12}(\alpha_1,\alpha_2) = R^{12}(\alpha_1,\alpha_2)R^{13}(\alpha_1,\alpha_3)R^{23}(\alpha_2,\alpha_3), \tag{20}$$

and the reversibility condition becomes

$$R^{21}(\alpha_2,\alpha_1)R(\alpha_1,\alpha_2) = \mathrm{Id}. \tag{21}$$

The relation between YB maps and integrable equations on quad-graphs can be demonstrated in the example of the discrete potential KdV equation $\mathcal{E}_1$. As we have already shown in Sec. I, by considering the differences of the values of the fields assigned on two adjacent vertices (3), we arrive at the Adler map (6). There is a different combination for the variables assigned on the edges of the square, namely

$$x = ff_1, \quad y = f_1 f_{1,2}, \quad u = f_2 f_{1,2}, \quad v = ff_2. \tag{22}$$

From the above-noted relations (22) we deduce that

$$xu = yv. \tag{23}$$

Moreover, dpKdV can also be written in terms of the variables (22) as follows:

$$y + v - x - u = \alpha_1 - \alpha_2. \tag{24}$$

Solving Eqs. (23) and (24) for (u,v) we get the following map:

$$u = y\left(1 + \frac{\alpha_1 - \alpha_2}{x - y}\right), \quad v = x\left(1 + \frac{\alpha_1 - \alpha_2}{x - y}\right). \tag{25}$$

The maps (6) and (25) *automatically* satisfy the parameter dependent YB relation (20). Indeed, it is easily shown that the consistency property for a configuration of initial data on the vertices of a cube, as depicted in Fig. 2, is equivalent to that with initial values $f, f_1, f_{1,2}, f_{1,2,3}$. These initial data correspond to the values (x,y,z) on the edges (Fig. 5). The 3D consistency property guarantees that the composite maps

$$(a): \quad (x,y,z) \overset{R^{12}}{\to} (x_2,y_{-1},z) \overset{R^{13}}{\to} (x_{2,3},y_{-1},z_{-2}) \overset{R^{23}}{\to} (x_{2,3},y_{-1,3},z_{-1,-2}), \tag{26}$$

$$(b): \quad (x,y,z) \overset{R^{23}}{\to} (x,y_3,z_{-2}) \overset{R^{13}}{\to} (x_3,y_3,z_{-1,-2}) \overset{R^{12}}{\to} (x_{2,3},y_{-1,3},z_{-1,-2}) \tag{27}$$

appearing in Eq. (20), applied on (x,y,z) give identical values for $(x_{2,3}, y_{-1,3}, z_{1,-2})$.

Analyzing these two examples one notices that the variables x,y,u,v, which we call YB variables, are *invariants* of certain *symmetry groups* of the relevant lattice equation. Now we are going to show that this symmetry method can be applied in more general situations as well.

C. Lattice invariants of symmetry groups and YB variables

Let us first recall the basic notions of Lie symmetry methods applied to lattice equations of the form (8). With minor modifications these are in accordance with the symmetry methods applied to algebraic or differential equations (see, e.g., Ref. 24 for an extensive study on the subject).

Consider a lattice equation of the form (8) involving one field $f: \mathbb{Z}^2 \to \mathbb{C}$(or $\mathbb{CP}^1$). Let G be a one-parameter group of transformations acting on the domain of the dependent variables,

$$G: f \mapsto \Phi(n_1,n_2,f;\varepsilon), \quad \varepsilon \in \mathbb{C}. \tag{28}$$

The prolongation of the group action on the lattice jet space J with coordinates $(f,f_1,f_2,f_{1,2})$ is specified by

$$G: (f,f_1,f_2,f_{1,2}) \mapsto (\Phi(n_1,n_2,f;\varepsilon), \Phi(n_1+1,n_2,f_1;\varepsilon), \Phi(n_1,n_2+1,f_2;\varepsilon), \Phi(n_1+1,n_2+1,f_{1,2};\varepsilon)). \tag{29}$$

The infinitesimal generator of the group action of G on f is the vector field

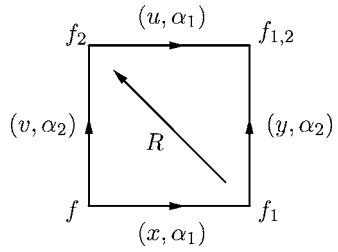

FIG. 4. An oriented quadrilateral for the map $R(x,y)=(u,v)$.

$$\mathbf{v} = Q(n_1,n_2,f)\partial_f, \quad \text{where } Q(n_1,n_2,f) = \frac{\mathrm{d}}{\mathrm{d}\varepsilon}\Phi(n_1,n_2,f;\varepsilon)_{\varepsilon=0}. \tag{30}$$

There is a one-to-one correspondence between connected groups of transformations and their associated infinitesimal generators since the group action is reconstructed by the flow of the vector field $\mathbf{v}$ by exponentiation

$$\Phi(n_1,n_2,f;\varepsilon) = \exp(\varepsilon\mathbf{v})f. \tag{31}$$

The prolongation of the infinitesimal action of G given by (29) is generated by the prolonged vector field

$$\hat{\mathbf{v}} = Q\partial_f + Q_1\partial_{f_1} + Q_2\partial_{f_2} + Q_{1,2}\partial_{f_{1,2}}, \tag{32}$$

where subscripts denote $Q_1=Q(n_1+1,n_2,f_1), Q_{1,2}=Q(n_1+1,n_2+1,f_{1,2})$, and so on.

The transformation G is a symmetry of the lattice equation (8), if it transforms any solution of (8) to another solution of the same equation. Equivalently, G is a symmetry of Eq. (8), if the equation is not affected by the transformation (29). The infinitesimal criterion for G to be a symmetry of Eq. (8) is

$$\hat{\mathbf{v}}(\mathcal{E}(f,f_1,f_2,f_{1,2};\alpha_1,\alpha_2)) = 0, \tag{33}$$

whenever Eq. (8) holds.

A function $I:J\to\mathbb{C}$ is a *lattice invariant* of the transformation group G, if I is not affected under the action of G. The infinitesimal invariance condition for the lattice invariants is

$$\hat{\mathbf{v}}(I) = 0. \tag{34}$$

Once we have determined a symmetry generator $\mathbf{v}$ of the lattice equation (8), the corresponding lattice invariants can be found from the solution of the first-order partial differential equation (34), by using the method of characteristics. From the corresponding system of ordinary differential equations we may easily obtain the general solution, since it consists of equations with separated variables. We assign now to the edges of an elementary quadrilateral the following YB variables (Fig. 4):

$$x = I(f,f_1), \quad y = I(f_1,f_{1,2}), \quad u = I(f_2,f_{1,2}), \quad v = I(f,f_2), \tag{35}$$

where I is an invariant depending on two neighboring values of f. Since G is a symmetry of the lattice equation, the latter can be written in terms of these variables:

$$\mathcal{D}(x,y,u,v;\alpha_1,\alpha_2) = 0. \tag{36}$$

This can be done in different ways since the variables (35) are not independent; there exists a relation among them

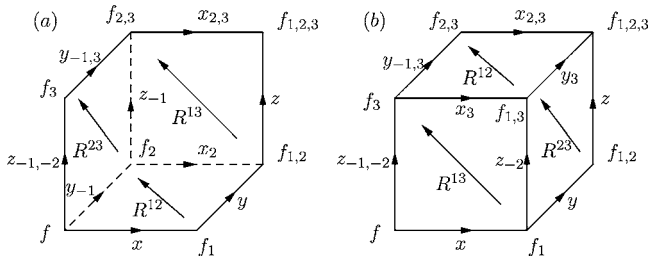

FIG. 5. Three-dimensional representation of the YB relation.

$$\mathcal{F}(x,y,u,v;\alpha_1,\alpha_2)=0, \tag{37}$$

following from the fact that the space of G-orbits is three-dimensional.

Solving the system of equations (36) and (37) for u,v in terms of x,y and assuming that the solution is unique, we obtain a map $R(x,y)=(u,v)$.

Proposition II.1: *If the discrete equation $\mathcal{E}$ satisfies the 3D consistency property, then the map $R(x,y)=(u,v)$, which relates the lattice invariants* (35)*, satisfies the YB relation.*

The proof follows from Fig. 5. Similar considerations hold for multifield lattice equations, which give rise to multicomponent YB maps (see Sec. IV).

Example II.2: Consider the dpKdV equation (2). Two infinitesimal symmetry generators of the latter equation are

$$\mathbf{v}_1=\partial_f, \quad \mathbf{v}_2=(-1)^{n_1+n_2}f\partial_f \tag{38}$$

(see Ref. 25). They generate the symmetry transformations

$$G^1{:}f\mapsto f+\varepsilon_1, \quad G^2{:}f\mapsto f\exp(\varepsilon_2(-1)^{n_1+n_2}), \quad \varepsilon_1,\varepsilon_2\in\mathbb{C}, \tag{39}$$

respectively. The lattice invariants assigned on the edges of a square for each one of the above-noted symmetry transformations are the variables (3) and (22), respectively.

The consideration of the remaining two equations from the list (10)–(12), with the corresponding symmetry generators

$$\mathbf{v}_{\mathcal{E}_2}=(-1)^{n_1+n_2}f\partial_f, \quad \mathbf{v}_{\mathcal{E}_3}=f\partial_f, \tag{40}$$

leads to the results summarized in the Table I.

These maps are simply related to quadrirational maps $F_{\mathrm{I}}-F_{\mathrm{III}}$ from the Adler-Bobenko-Suris (ABS) list of Ref. 12. Namely, setting $\delta=0$ in the YB map constructed from $\mathcal{E}_2$, we retrieve the map labeled as F_{III} map in Ref. 12. The case $\delta=-1$ corresponds to the F_{II} map. Finally, the YB map constructed from $\mathcal{E}_3$ under the transformation $x\mapsto 1/x$, $v\mapsto 1/v$, $y\mapsto y/\gamma_2$, $u\mapsto u/\gamma_1$ turns into

$$u=\gamma_1 y\widetilde{Q}, \quad v=\gamma_2 x\widetilde{Q}, \quad \widetilde{Q}=\frac{(1-\gamma_2)x+\gamma_2-\gamma_1+(\gamma_1-1)y}{\gamma_2(1-\gamma_1)x+(\gamma_1-\gamma_2)xy+\gamma_1(\gamma_2-1)y}, \tag{41}$$

which corresponds to the F_{I} map in the classification in Ref. 12. As we have already mentioned it is closely related to the superposition formula of the Bäcklund transformation for the Ernst equation in general relativity introduced by Harrison,[20] cf. Ref. 26.

The remaining maps F_{IV} and F_{V} from Ref. 12 are related in a simple way to the maps (6) and (25) derived from dpKdV already in Sec. II B.

Thus all five types of quadrirational maps from the ABS classification are equivalent to the YB maps coming from the integrable equations on quad-graphs.

Remark II.3: We should mention that the equivalence of the quadrirational maps considered in Ref. 12 allows independent change of variables x,y,u,v and therefore does not respect the YB property, which is preserved in general only under the diagonal action of the Möbius group. In

TABLE I. YB maps arising from equations $\mathcal{E}_2$ and $\mathcal{E}_3$.

	YB variables	Functional relation and lattice equation	YB Map
$\mathcal{E}_2$	$x=ff_1/\alpha_1$ $y=f_1f_{1,2}/\alpha_2$ $u=f_2f_{1,2}/\alpha_1$ $v=ff_2/\alpha_2$	$\gamma_1xu=\gamma_2yv$ $\gamma_1(x+u+\delta)=\gamma_2(y+v+\delta)$ where $\gamma_i=\alpha_i^2$	$u=\frac{y}{\gamma_1}\frac{\gamma_1(x+\delta)-\gamma_2(y+\delta)}{x-y}$ $v=\frac{x}{\gamma_2}\frac{\gamma_1(x+\delta)-\gamma_2(y+\delta)}{x-y}$
$\mathcal{E}_3$	$x=f_1/(\alpha_1f)$ $y=f_{1,2}/(\alpha_2f_1)$ $u=f_{1,2}/(\alpha_1f_2)$ $v=f_2/(\alpha_2f)$	$xy=uv$ $\frac{1-x^{-1}}{1-v^{-1}}=\frac{1-\gamma_1}{1-\gamma_2}\frac{1-\gamma_2y}{1-\gamma_1u}$ where $\gamma_i=\alpha_i^2$	$u=yQ,\quad v=xQ^{-1}$ $Q=\frac{(1-\gamma_2)+(\gamma_2-\gamma_1)x+\gamma_2(\gamma_1-1)xy}{(1-\gamma_1)+(\gamma_1-\gamma_2)y+\gamma_1(\gamma_2-1)xy}$

particular, quadrirational maps in general do not satisfy the YB relation (contrary to what one might conclude from Ref. 12). However sometimes two YB maps are related by nondiagonal action (see the example of Harrison map and F_V noted earlier). The question how many such pairs exist needs further investigation (see the discussion of this in Ref. 27).

III. MULTIPARAMETER SYMMETRY GROUPS AND MULTIDIMENSIONAL CONSISTENCY

The purpose of this section is to show that the symmetry method described in the preceding section works equally well for multiparameter symmetry groups. The idea is to consider the extension of the equation into many dimensions using the 3D-consistency property and then prescribe the YB variables not to the edges but, for example, to higher dimensional faces.

We demonstrate how the method works in the example of dpKdV equation, which is invariant under the three-parameter symmetry group G with infinitesimal generators

$$\mathbf{v}_1=\partial_f,\quad \mathbf{v}_2=(-1)^{n_1+n_2}f\partial_f,\quad \mathbf{v}_3=(-1)^{n_1+n_2}\partial_f. \tag{42}$$

Their commutators are

$$[\mathbf{v}_1,\mathbf{v}_2]=\mathbf{v}_3,\quad [\mathbf{v}_2,\mathbf{v}_3]=-\mathbf{v}_1,\quad [\mathbf{v}_1,\mathbf{v}_3]=0, \tag{43}$$

from which it is immediately seen that $\{\mathbf{v}_1,\mathbf{v}_2,\mathbf{v}_3\}$ span a solvable Lie algebra. This algebra is actually isomorphic to the Lie algebra of the group Iso $(\mathbb{R}^{1,1})$ of isometries of the Minkowski plane, so G can be considered as the connected component of identity of this group.

A. Consistency of dpKdV around a three-cube and the F_{III} map

Consider the dpKdV equation imposed on each face of an elementary cube (see Fig. 2) and the Abelian subgroup H of the full symmetry group G generated by $\{\mathbf{v}_1,\mathbf{v}_3\}$ (translations of the Minkowski plane). These two symmetries can be extended to the corresponding system on $\mathbb{Z}^3$, e.g., $\mathbf{v}_3=(-1)^{n_1+n_2+n_3}\partial_f$.

We consider now the following invariants of the subgroup H:

$$x=f_1-f_3,\quad y=f_{1,2}-f_{1,3},\quad u=f_{1,2}-f_{2,3},\quad v=f_2-f_3, \tag{44}$$

assigned on four faces of the three-cube. Using the dpKdV equations

$$f_{1,2}-f=\frac{\alpha_1-\alpha_2}{f_1-f_2},\quad f_{1,3}-f=\frac{\alpha_1-\alpha_3}{f_1-f_3},\quad f_{2,3}-f=\frac{\alpha_2-\alpha_3}{f_2-f_3}, \tag{45}$$

we easily find that the invariants (44) are related by

$$uv=xy,\quad u-\frac{\beta_1}{x}=y-\frac{\beta_2}{v}, \tag{46}$$

where $\beta_1=\alpha_1-\alpha_3,\beta_2=\alpha_2-\alpha_3$. Solving the system (46) for (u,v) in terms of (x,y) we obtain the map

$$u=yP,\quad v=xP^{-1},\quad P=\frac{\beta_1+xy}{\beta_2+xy}, \tag{47}$$

which satisfies the YB relation as it can be checked by direct calculations. This fact is also related to the higher dimensional consistency of dpKdV on $\mathbb{Z}^4$ as it is explained in the following.

Considering the five initial values $f_3,f_{1,3},f_1,f_{1,2},f_{1,2,4}$ on the vertices of the four-cube (see Fig. 3) one can find the values on all other vertices in a unique way using the dpKdV equation on each two-dimensional face because of its four-dimensional consistency. From these five initial values we form the differences

$$x=f_1-f_3,\quad y=f_{1,2}-f_{1,3}\quad z=f_{1,2,4}-f_{1,2,3}, \tag{48}$$

which are assigned on (the diagonals of) the two-dimensional faces of the four-cube (Fig. 3). We note that the value $f_{1,2,3}$ can be expressed already in terms of $f_3,f_{1,3},f_1,f_{1,2}$ through the three-dimensional consistency of dpKdV on the "inner" cube. Next we apply successively the map $R:(x,y)\mapsto(u,v)$ given by (47) on the (a) "inner," "front," "left" and (b) "right," "back," "outer" three-dimensional cubes to obtain the following composite maps:

$$(a):\quad (x,y,z)\overset{R^{12}}{\to}(x_2,y_{-1},z)\overset{R^{13}}{\to}(x_{2,4},y_{-1},z_{-1})\overset{R^{23}}{\to}(x_{2,4},y_{-1,4},z_{-1,-2}), \tag{49}$$

$$(b):\quad (x,y,z)\overset{R^{23}}{\to}(x,y_4,z_{-2})\overset{R^{13}}{\to}(x_4,y_4,z_{-1,-2})\overset{R^{12}}{\to}(x_{2,4},y_{-1,4},z_{-1,-2}). \tag{50}$$

The fact that the two ways of obtaining the values for $(x_{2,4},y_{-1,4},z_{-1,-2})$ lead to identical results, and thus to the YB property of the map (47), is guaranteed by the four-dimensional consistency. One can notice that the evolution of the Yang-Baxter variables takes place on two parallel layers of the $\mathbb{Z}^3$ lattice, i.e., $\{(n_1,n_2,0),(n_1,n_2,1),n_1,n_2\in\mathbb{Z}\}$. This is reflected to the fact that there are six out of the eight three-dimensional faces (cubes) of the four-cube involved in the compatibility.

A final comment about the map (47) is that under the transformation $x\mapsto -x^{-1}$, $v\mapsto v^{-1}$, $u\mapsto\beta_1 u$, $y\mapsto\beta_2 y$ it becomes the first YB map in Table I for $\delta=0$. Thus the F_{III} map in the classification of Ref. 12 is also retrieved from dpKdV in $\mathbb{Z}^3$, by using the invariants of the symmetry subgroup H.

B. Consistency of dpKdV around a four-cube and the Harrison map

We are going to show that the Harrison map (7) appears in a similar manner as previously using now the invariants of the *full* symmetry group G of dpKdV and extending both the equation and its symmetry group in $\mathbb{Z}^4$.

The symmetry group G can be naturally extended to the corresponding system in $\mathbb{Z}^4$. Now let us consider the following invariants of this group:

$$x=\frac{f_1-f_3}{f_2-f_3},\quad v=\frac{f_1-f_4}{f_2-f_4},\quad y=\left(\frac{f_1-f_4}{f_2-f_4}\right)_3,\quad u=\left(\frac{f_1-f_3}{f_2-f_3}\right)_4, \tag{51}$$

where the subscript i means the shift in the ith direction. The natural place for them to live in are the corresponding two-dimensional faces. Next we derive the relations between these variables.

First of all Eq. (15) and its forward shifts with respect to the lattice directions 3 and 4 imply that the following relations:

$$(f_1-f_3)(f_1-f_4)_3=(f_1-f_4)(f_1-f_3)_4, \tag{52a}$$

$$(f_2-f_3)(f_2-f_4)_3=(f_2-f_4)(f_2-f_3)_4, \tag{52b}$$

$$(f_{1,3}-f)(f_{1,4}-f)_3=(f_{1,4}-f)(f_{1,3}-f)_4, \tag{52c}$$

$$(f_{2,3}-f)(f_{2,4}-f)_3=(f_{2,4}-f)(f_{2,3}-f)_4, \tag{52d}$$

hold on the "back" and "left" three-cubes of the four-cube depicted in Fig. 3. Dividing memberwise Eqs. (52a), (52b) and rearranging terms we get

$$\frac{f_1-f_3}{f_2-f_3}\left(\frac{f_1-f_4}{f_2-f_4}\right)_3=\frac{f_1-f_4}{f_2-f_4}\left(\frac{f_1-f_3}{f_2-f_3}\right)_4. \tag{53}$$

In terms of the variables (51) Eq. (53) reads

$$xy=uv. \tag{54}$$

On the other hand, we can rewrite Eq. (52c) in the equivalent form

$$(f_{1,3}-f)\left(1-\frac{(f_{2,3}-f)_4}{(f_{1,3}-f)_4}\right)=(f_{1,4}-f)\left(1-\frac{(f_{2,4}-f)_3}{(f_{1,4}-f)_3}\right), \tag{55}$$

which by using Eq. (15) reads

$$\frac{\alpha_1-\alpha_3}{f_1-f_3}\left(1-\frac{\alpha_2-\alpha_3}{\alpha_1-\alpha_3}\left(\frac{f_1-f_3}{f_2-f_3}\right)_4\right)=\frac{\alpha_1-\alpha_4}{f_1-f_4}\left(1-\frac{\alpha_2-\alpha_4}{\alpha_1-\alpha_4}\left(\frac{f_1-f_4}{f_2-f_4}\right)_3\right). \tag{56}$$

Multiplying both terms of Eq. (56) with $(\alpha_1-\alpha_2)(f_1-f_2)$ and rearranging terms, the latter takes the form

$$\left(1-\frac{\alpha_2-\alpha_4}{\alpha_1-\alpha_4}\right)\left(1-\frac{f_2-f_3}{f_1-f_3}\right)\left(1-\frac{\alpha_2-\alpha_3}{\alpha_1-\alpha_3}\left(\frac{f_1-f_3}{f_2-f_3}\right)_4\right)=\left(1-\frac{\alpha_2-\alpha_3}{\alpha_1-\alpha_3}\right)\left(1-\frac{f_2-f_4}{f_1-f_4}\right)\left(1-\frac{\alpha_2-\alpha_4}{\alpha_1-\alpha_4}\left(\frac{f_1-f_4}{f_2-f_4}\right)_3\right). \tag{57}$$

Finally, recalling the defining relations of the variables x,y,u,v, Eq. (57) becomes

$$(1-\gamma_2)(1-x^{-1})(1-\gamma_1 u)=(1-\gamma_1)(1-v^{-1})(1-\gamma_2 y), \tag{58}$$

where

$$\gamma_1=\frac{\alpha_2-\alpha_3}{\alpha_1-\alpha_3},\quad \gamma_2=\frac{\alpha_2-\alpha_4}{\alpha_1-\alpha_4}. \tag{59}$$

A similar calculation starting with (52d) and using (54), delivers the same relation (58).

Proposition III.1: *The invariants* (51) *of the symmetry group G of the dpKdV equation extended to* $\mathbb{Z}^4$ *are related by the YB map*, *which coincides with the Harrison map* (7).

Indeed, comparing (54) and (58) with the relations from which we obtain the last map in Table I, we deduce that x,y and u,v are related by the Harrison map. The fact that this map satisfies the YB relation can also be derived from the consistency property and geometry of the five-dimensional lattice.

IV. MULTICOMPONENT YB MAPS

In this section we show that YB maps can be constructed equally well from 3D consistent multifield discrete equations, for which no classification scheme exploiting the multidimensional consistency property has been obtained yet.

A. YB map from the discrete modified Boussinesq system

The discrete modified Boussinesq (dmBSQ) equations[28] involve two fields $f,g:\mathbb{Z}^2\to\mathbb{CP}^1$ and are given by the system

$$f_{1,2}=g\frac{\alpha_1 f_2-\alpha_2 f_1}{\alpha_1 g_1-\alpha_2 g_2},\quad g_{1,2}=\frac{g}{f}\frac{\alpha_1 f_1 g_2-\alpha_2 f_2 g_1}{\alpha_1 g_1-\alpha_2 g_2}. \tag{60}$$

Its 3D consistency is provided by a lengthy but straightforward calculation that delivers the symmetric values

$$f_{1,2,3}=f\frac{\underset{ijk}{\boldsymbol{\sigma}}\alpha_i\alpha_j f_k(\alpha_i g_i-\alpha_j g_j)}{\underset{ij}{\boldsymbol{\sigma}}\alpha_i\alpha_j(\alpha_i f_i g_j-\alpha_j f_j g_i)},\quad g_{1,2,3}=g\frac{\underset{ijk}{\boldsymbol{\sigma}}\alpha_i\alpha_j g_k(\alpha_i f_j-\alpha_j f_i)}{\underset{ij}{\boldsymbol{\sigma}}\alpha_i\alpha_j(\alpha_i f_i g_j-\alpha_j f_j g_i)}, \tag{61}$$

with respect to any permutation of the indices (1,2,3). Here the cyclic sum $\boldsymbol{\sigma}$ is over the subscripts $(i,j,k)=(1,2,3)$, (3,1,2), (2,3,1), and similarly the cyclic sum $\underset{ij}{\boldsymbol{\sigma}}$ is over $(i,j)=(1,2)$, (2,3), (3,1). The explicit dependence of $f_{1,2,3},g_{1,2,3}$ on the values f,g implies that dmBSQ does not satisfy the so-called *tetrahedron* property, which is an additional assumption in the classification scheme in Ref. 15 for one-field discrete equations.

Using the symmetry generators

$$\mathbf{v}_1=f\partial_f,\quad \mathbf{v}_2=g\partial_g, \tag{62}$$

of the dmBSQ equations, we define as YB variables the following joint lattice invariants:

$$x^1=\frac{f_1}{f},\quad y^1=\frac{f_{1,2}}{f_1},\quad u^1=\frac{f_{1,2}}{f_2},\quad v^1=\frac{f_2}{f}, \tag{63}$$

$$x^2=\frac{g_1}{g},\quad y^2=\frac{g_{1,2}}{g_1},\quad u^2=\frac{g_{1,2}}{g_2},\quad v^2=\frac{g_2}{g}. \tag{64}$$

It is immediately seen that the above-mentioned equations imply that

$$x^1y^1=u^1v^1,\quad x^2y^2=u^2v^2. \tag{65}$$

Moreover, the lattice equation (60) can be expressed in terms of the above-noted invariants as follows:

$$u^1v^1=\frac{\alpha_1 v^1-\alpha_2 x^1}{\alpha_1 x^2-\alpha_2 v^2},\quad u^2v^2=\frac{\alpha_1 x^1v^2-\alpha_2 v^1x^2}{\alpha_1 x^2-\alpha_2 v^2}. \tag{66}$$

Finally, solving Eqs. (65), (66) for (u^i,v^i) we obtain the reversible YB map

$$u^1 = y^1 A, \quad v^1 = x^1 A^{-1}, \quad A = \frac{\alpha_1^2 x^1 + \alpha_2^2 x^1 x^2 y^1 + \alpha_1 \alpha_2 x^2 y^2}{\alpha_1 \alpha_2 x^1 + \alpha_1^2 x^1 x^2 y^1 + \alpha_2^2 x^2 y^2}, \tag{67a}$$

$$u^2 = y^2 B, \quad v^2 = x^2 B^{-1}, \quad B = \frac{\alpha_1^2 x^1 + \alpha_2^2 x^1 x^2 y^1 + \alpha_1 \alpha_2 x^2 y^2}{\alpha_2^2 x^1 + \alpha_1 \alpha_2 x^1 x^2 y^1 + \alpha_1^2 x^2 y^2}. \tag{67b}$$

B. YB map from the discrete potential Boussinesq system

Discrete potential Boussinesq (dpBSQ) equations is the second member in the so-called lattice Gel'fand-Dikii hierarchy.[29] The dpBSQ equations, in the form they were studied recently in Ref. 30, involve three fields $f, g, h: \mathbb{Z}^2 \to \mathbb{CP}^1$, and they are given by the following system:

$$h_1 = f f_1 - g, \tag{68a}$$

$$h_2 = f f_2 - g, \tag{68b}$$

$$h = f f_{1,2} - g_{1,2} - \frac{\alpha_1 - \alpha_2}{f_1 - f_2}. \tag{68c}$$

For the purposes of the present discussion, Eq. (68) exhibits the interesting feature that the joint invariants of two symmetry generators are enough to construct a YB map. In connection with this issue we note that for an elementary Cauchy problem on a staircase, we should impose initial values (f, g, h), (f_1, g_1), (f_2, g_2), only. From these data the values (h_1, h_2) and $(f_{1,2}, g_{1,2}, h_{1,2})$ are determined uniquely. In particular, Eqs. (68a), (68b) imply that

$$f_{1,2} = \frac{g_1 - g_2}{f_1 - f_2}, \tag{69}$$

and subsequently the values $h_{1,2}$ and $g_{1,2}$ are determined from Eq. (68a) [or equivalently (68b) and (68c)], respectively.

Using the infinitesimal invariance criterion (33) to determine the symmetries of Eq. (68), we find that two particular symmetry generators are given by the following vector fields:

$$\mathbf{v}_1 = \partial_f + f\partial_g + f\partial_h, \quad \mathbf{v}_2 = \partial_g - \partial_h. \tag{70}$$

They generate the symmetry transformations

$$G^1: (f, g, h) \mapsto \left(f + \varepsilon_1, g + \varepsilon_1 f + \frac{\varepsilon_1^2}{2}, h + \varepsilon_1 f + \frac{\varepsilon_1^2}{2} \right), \tag{71}$$

$$G^2: (f, g, h) \mapsto (f, g + \varepsilon_2, h - \varepsilon_2), \tag{72}$$

respectively. We now define as YB variables the following invariants:

$$\begin{aligned}
&x^1 = f_1 - f, && y^1 = f_{1,2} - f_1, \\
&x^2 = g_1 - g - f(f_1 - f), && y^2 = g_{1,2} - g_1 - f_1(f_{1,2} - f_1), \\
&x^3 = h_1 - h - f(f_1 - f), && y^3 = h_{1,2} - g_1 - f_1(f_{1,2} - f_1), \\
&u^1 = f_{1,2} - f_2, && v^1 = f_2 - f, \\
&u^2 = g_{1,2} - g_2 - f_2(f_{1,2} - f_2), && v^2 = g_2 - g - f(f_2 - f), \\
&u^3 = h_{1,2} - h_2 - f_2(f_{1,2} - f_2), && v^3 = h_2 - h - f(f_2 - f).
\end{aligned} \tag{73}$$

They are functionally related by

$$u^1 + v^1 = x^1 + y^1, \tag{74a}$$

$$u^2 + v^2 = x^2 + y^2 + x^1y^1 - u^1v^1, \tag{74b}$$

$$u^3 + v^3 = x^3 + y^3 + x^1y^1 - u^1v^1 \tag{74c}$$

Moreover, the system of equations formed by (68a)–(68c), (68b), (68c), and (69) can be written in terms of the above-mentioned invariants as follows:

$$x^1 = -y^1 + \frac{x^2}{x^1 - v^1} - \frac{v^2}{x^1 - v^1}, \tag{75a}$$

$$x^3 = x^2 + y^2 + x^1y^1 + \frac{\alpha_1 - \alpha_2}{x^1 - v^1}, \tag{75b}$$

$$v^3 = u^2 + v^2 + u^1v^1 + \frac{\alpha_1 - \alpha_2}{x^1 - v^1}. \tag{75c}$$

Solving the system of Eqs. (74), (75) for (u^i, v^i) we obtain the following YB map:

$$\begin{aligned}
&u^1 = y^1 - (\alpha_1 - \alpha_2)\Gamma^{-1}, && v^1 = x^1 + (\alpha_1 - \alpha_2)\Gamma^{-1},\\
&u^2 = y^2 + (\alpha_1 - \alpha_2)(\alpha_1 - \alpha_2 - 2y^1\Gamma)\Gamma^{-2}, && v^2 = x^2 + (\alpha_1 - \alpha_2)(x^1 + y^1)\Gamma^{-1},\\
&u^3 = y^3 + (\alpha_1 - \alpha_2)(\alpha_1 - \alpha_2 + (x^1 - y^1)\Gamma)\Gamma^{-2}, && v^3 = x^3,
\end{aligned} \tag{76}$$

where $\Gamma = x^2 - x^3 + x^1y^1 + y^2$.

C. YB map from discrete Calapso equation and nonlinear σ-model

In a recent study on discrete isothermic surfaces, Schief[21] introduced the following vector generalization of the dpKdV:

$$(\boldsymbol{f}_{1,2} - \boldsymbol{f}) = \frac{\alpha_1 - \alpha_2}{|\boldsymbol{f}_1 - \boldsymbol{f}_2|^2}(\boldsymbol{f}_1 - \boldsymbol{f}_2), \tag{77}$$

$\boldsymbol{f}: \mathbb{Z}^2 \mapsto \mathbb{C}^n$, under the name *discrete Calapso equation*. Equation (77) is three-dimensional consistent since for an initial value configuration $\boldsymbol{f}, \boldsymbol{f}_i$ as in Fig. 2(a), one finds that the value $\boldsymbol{f}_{1,2,3}$ is given by

$$\boldsymbol{f}_{1,2,3} = \frac{\lambda|\boldsymbol{f}_2 - \boldsymbol{f}_3|^2\boldsymbol{f}_1 - \mu|\boldsymbol{f}_1 - \boldsymbol{f}_3|^2\boldsymbol{f}_2 + \nu|\boldsymbol{f}_1 - \boldsymbol{f}_2|^2\boldsymbol{f}_3}{\lambda|\boldsymbol{f}_2 - \boldsymbol{f}_3|^2 - \mu|\boldsymbol{f}_1 - \boldsymbol{f}_3|^2 + \nu|\boldsymbol{f}_1 - \boldsymbol{f}_2|^2}, \tag{78}$$

where

$$\lambda = (\alpha_1 - \alpha_2)(\alpha_1 - \alpha_3), \quad \mu = (\alpha_1 - \alpha_2)(\alpha_2 - \alpha_3), \quad \nu = (\alpha_1 - \alpha_3)(\alpha_2 - \alpha_3). \tag{79}$$

The consistency property is readily checked since $\boldsymbol{f}_{1,2,3}$ is invariant under any permutation of the indices (1, 2, 3) labeling the field variables and the corresponding lattice parameters.

The aim now is to construct a YB map from Eq. (77). Using the translational invariance of Eq. (77), we define the following YB variables:

$$\boldsymbol{x} = \boldsymbol{f}_1 - \boldsymbol{f}, \quad \boldsymbol{y} = \boldsymbol{f}_{1,2} - \boldsymbol{f}_1, \quad \boldsymbol{u} = \boldsymbol{f}_{1,2} - \boldsymbol{f}_2, \quad \boldsymbol{v} = \boldsymbol{f}_2 - \boldsymbol{f}, \tag{80}$$

on the edges of a square, which are related by

$$\boldsymbol{x}+\boldsymbol{y}=\boldsymbol{u}+\boldsymbol{v}. \tag{81}$$

On the other hand, Eq. (10) can be written in terms of the variables (80) in the form

$$(\boldsymbol{u}-\boldsymbol{y})=\frac{\alpha_1-\alpha_2}{|\boldsymbol{x}+\boldsymbol{y}|^2}(\boldsymbol{x}+\boldsymbol{y}). \tag{82}$$

Hence, Eqs. (81) and (82) deliver the following reversible YB map:

$$\boldsymbol{u}=\boldsymbol{y}+\frac{\alpha_1-\alpha_2}{|\boldsymbol{x}+\boldsymbol{y}|^2}(\boldsymbol{x}+\boldsymbol{y}),\quad \boldsymbol{v}=\boldsymbol{x}-\frac{\alpha_1-\alpha_2}{|\boldsymbol{x}+\boldsymbol{y}|^2}(\boldsymbol{x}+\boldsymbol{y}). \tag{83}$$

Moreover, in Ref. 21 it was shown that discrete Calapso equation (77) can be specialized to an integrable discrete version of the $O(n+2)$ nonlinear σ-model. This reduction is accomplished by imposing the constraint

$$|\boldsymbol{f}|^2=1, \tag{84}$$

on the discrete Calapso equation (77). Since the shifted values of $\boldsymbol{f}$ with respect to any lattice directions should also satisfy constraint (84), Eq. (77) is compatible with this constraint whenever

$$2\boldsymbol{f}\cdot\boldsymbol{f}_2-2\boldsymbol{f}\cdot\boldsymbol{f}_1=\alpha_1-\alpha_2. \tag{85}$$

This requirement can be satisfied by taking

$$-2\boldsymbol{f}\cdot\boldsymbol{f}_1=\alpha_1,\quad -2\boldsymbol{f}\cdot\boldsymbol{f}_2=\alpha_2. \tag{86}$$

In terms of the variables (80), the above-mentioned constraints translate to

$$|\boldsymbol{x}|^2=2+\alpha_1,\quad |\boldsymbol{y}|^2=2+\alpha_2. \tag{87}$$

In view of the previous relations the map (83) obtains the form

$$\boldsymbol{u}=\boldsymbol{y}+\frac{|\boldsymbol{x}|^2-|\boldsymbol{y}|^2}{|\boldsymbol{x}+\boldsymbol{y}|^2}(\boldsymbol{x}+\boldsymbol{y}),\quad \boldsymbol{v}=\boldsymbol{x}-\frac{|\boldsymbol{x}|^2-|\boldsymbol{y}|^2}{|\boldsymbol{x}+\boldsymbol{y}|^2}(\boldsymbol{x}+\boldsymbol{y}). \tag{88}$$

By straightforward calculations one finds that

$$|\boldsymbol{u}|^2=|\boldsymbol{x}|^2,\quad |\boldsymbol{v}|^2=|\boldsymbol{y}|^2. \tag{89}$$

Using the above-mentioned identity it is easily established that the map $R:(\boldsymbol{x},\boldsymbol{y})\mapsto(\boldsymbol{u},\boldsymbol{v})$ given by (88) is a reversible YB map. Up to a permutation this map was first considered by Adler[31] in the geometric problem about recuttings of polygons.

V. PERSPECTIVES

We have shown how the symmetry analysis of integrable equations on quad-graphs can be used in order to construct YB maps. In particular, we derived the Harrison map from the consistently extended discrete potential Korteweg–de Vries equation to the four-dimensional lattice. The main question now is how far this example can be generalized. In particular, for a given multiparametric symmetry group, is there a general relation between the structure of the invariants and the geometry of the objects which the YB variables are assigned to? What is the dimension of the lattice in which the discrete equation should be extended to? The analysis of other equations from Ref. 15 may clarify these issues.

A new multisymplectic scheme for generalized Kadomtsev-Petviashvili equation

Bin Jiang, Yushun Wang, and Jiaxiang Cai
Department of Mathematics, Nanjing Normal University, Nanjing 210097, People's Republic of China

(Received 10 May 2006; accepted 13 June 2006; published online 8 August 2006)

From the multisymplectic Euler box scheme, we derive a new multisymplectic 16-point scheme for the generalized Kadomtsev-Petviashvili equation by eliminating the auxiliary variables. The new scheme is an explicit scheme in sense that it does not need iteration. The results of backward error analysis for the Euler box scheme show that the modified equation associated with the new scheme is not multisymplectic but of a high order approximation to a multisymplectic partial differential equations with a modified structure. Numerical results on one soliton and lump-type solitary waves are reported to illustrate the efficiency of the multisymplectic scheme. © *2006 American Institute of Physics.*

I. INTRODUCTION

Many years ago, Korteweg and de Vries[1] (KdV) derived an equation equivalent to

$$u_t + (3u^2)_x + u_{xxx} = 0 \ (t > 0, -\infty < x < +\infty), \tag{1.1}$$

to describe approximately the slow evolution of long water waves of moderate amplitude as they propagate under the influence of gravity in one direction in shallow of uniform depth.

The two-dimensional KdV, or the generalized Kadomtsev-Petviashvili (GKP) equation

$$(u_t + \partial_x f(u) + u_{xxx})_x + \sigma u_{yy} = 0 \ (t > 0, -\infty < x, y < +\infty), \tag{1.2}$$

was first introduced by Kadomtsev and Petviashvili[2] in order to study the stability of one-dimensional solitons against transverse perturbations, where σ is a constant and $f(u)$ is a smooth function. In the case of $f(u)=3u^2$ and $\sigma=-3$, Eq. (1.2) is usually called the KPI equation, whereas the KPII equation with $f(u)=3u^2$ and $\sigma=3$. In this paper, we mainly discuss the KPI equation. The KPII equation can be discussed similarly.

As far as we know, several numerical schemes have been proposed for the KP equation. These include the following: the explicit finite difference method proposed by Katsis;[3] the pseudospectral method developed by Fornberg and Whitham;[4,5] a linearized implicit method proposed by Feng,[6] and so on.

Recently, Marsden, Patrik, and Shkoller[7] and Bridges and Reich[8] proposed the concept of multisymplectic partial differential equations (PDEs) and multisymplectic schemes that can be viewed as the generalization of symplectic schemes. The KPI equation can be described in the language of multisymplectic geometry and reformulated to the multisymplectic form, which was first proposed by Bridges in Ref. 9. Liu and Qin,[10] from the Preissman scheme for multisymplectic equations, derived a multisymplectic numerical scheme for the KPI equation that can be simplified to an implicit 45-point scheme. They also claimed the robusticity of the 45-point scheme by several numerical experiments. In this paper, the multisymplectic Euler box scheme for the KPI equation is investigated and an explicit scheme is derived. So, the first question we must address is, why another study of numerics for the KPI equation? We start with several reasons: First, the 45-point scheme, as well as many other schemes for the GKP equation, is fully implicit and thus

cumbersome and expensive to work with for the high dimensional equations like the GKP equation. An efficient explicit scheme is of value in this case. Second, there is growing interest in the multisymplectic PDEs and multisymplectic schemes. As we know, there are two basic multisymplectic schemes: the Preissman scheme and the Euler box scheme. For details, we refer to Refs. 8, 19, and 22 for a recent survey. The Preissman scheme has been a hot topic in the past years,[10–15] however, little work has been done with the Euler box scheme. We know that the Preissman scheme is compact while the Euler box scheme is not. So, we want to know whether the noncompact Euler box scheme has as good a numerical performance as has the Preissman scheme. Third, many of numerical experiments have been reported to illustrate the good numerical performance of the multisymplectic schemes. However, all of them are implicit. We may ask the following question, as to whether only implicit multisymplectic schemes have a good numerical performance.

In this paper, we derive a new multisymplectic numerical scheme for the GKP equation that can be simplified to the 16-point scheme. This is an explicit scheme in sense that it does not need iteration in each time integration because the nonlinear term $(f(u))_{xx}$ is treated explicitly. Numerical results show that it is a good-performance scheme. Furthermore, the new scheme can be easily carried out, so it may be a useful tool for engineering applications to study the GKP equation.

The backward error analysis (BEA) for ODEs is a useful technique for studying the qualitative behavior of a discretization. This helps us to understand why the symplectic schemes for Hamiltonian systems can give accurate and efficient results for long time integration.[16,17] BEA for multisymplectic schemes was developed by Moore and Reich[18,19] and later by Islas and Schober in Ref. 20. Though their results show that the multisymplectic structure of the modified system has changed, they still help us to get further insight into the multisymplectic discretizations. In this paper, following their methods, we take BEA for the Euler box scheme for the KPI equation. We obtain the associated modified equations and the modified multisymplectic structure. However, the auxiliary variables in the modified equations cannot be eliminated completely to generate the corresponding modified equation associated with the 16-point scheme. Actually, a high order approximation is generated.

The paper is organized as follows: In Sec. II we take a brief view of multisymplectic structure of the KPI equation. We derive a new scheme and verify that it satisfies the multisymplectic conservation law. In Sec. III we implement BEA for PDE discretizations of the Euler box scheme for the KPI equation. In Sec. IV, some numerical results on one soliton and lump-type solitary waves over long time intervals are given. Section V gives concluding remarks.

II. DERIVATION OF A NEW EXPLICIT SCHEME FOR THE KPI EQUATION

The KPI equation can be written as

$$(u_t + 6uu_x + u_{xxx})_x + \sigma u_{yy} = 0 \ (t > 0, -\infty < x, y < +\infty), \tag{2.1}$$

where $\sigma = -3$. To put the KPI equation in the variational framework, we let $\varphi_{xx} = u$, then φ satisfies the following equation:

$$\varphi_{xxxt} + 6\varphi_{xx}\varphi_{xxxx} + 6\varphi_{xxx}^2 + \varphi_{xxxxxx} + \sigma\varphi_{xxyy} = 0. \tag{2.2}$$

Now, we introduce some variables: $v = \varphi_x$, $u = \varphi_{xx}$, $w = \varphi_{xy}$, $p = \frac{1}{2}\varphi_{xt}$, $p^x = -\varphi_{xxt} - 6\varphi_{xx}\varphi_{xxx} - \sigma\varphi_{xyy} - \varphi_{xxxxx}$, $p^{xx} = \frac{1}{2}\varphi_{xt} + 3\varphi_{xx}^2 + \varphi_{xxxx}$, $p^{xt} = \varphi_{xx}$, $p^{xy} = \sigma\varphi_{xy}$, and $p^{xxx} = -\varphi_{xxx}$.

According to the covariant De Donder-Weyl Hamilton function theories and the multisymplectic concept introduced by Bridges,[21] the KPI equation can be reformulated as a system of ten first-order partial differential equations, which can be written in the form

$$Mz_t + Kz_x + Lz_y = \nabla_z S(z), \quad z = (\varphi, v, u, w, p, p^x, p^{xx}, p^{xy}, p^{xt}, p^{xxx})^T \in R^{10}, \tag{2.3}$$

where

$$\mathbf{M} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -\frac{1}{2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\mathbf{K} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\mathbf{L} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

where $S(z)=up+\frac{1}{2}(p^{xxx})^2+\sigma/2w^2+u^3-p^xv-p^{xx}u-p^{xt}p-p^{xy}w$. For details, we refer to Ref. 10. $\nabla_z S(z)$ is the gradient of $S(z)$ with respect to the standard inner product on R^{10}. The system (2.3) is a Hamiltonian formulation of the KPI equation on a multisymplectic structure, where $M,K,L \in R^{n\times n}$ are skew-symmetric matrices and $S(z):R^n\to R$ is a smooth function of the $z(x,y,t)$.

For Eq. (2.3), one of the most important characteristic is that it satisfies the multisymplectic conservation law

$$\frac{\partial w}{\partial t}+\frac{\partial k}{\partial x}+\frac{\partial q}{\partial y}=0, \tag{2.4}$$

where

$$w = \frac{1}{2}(dz \wedge Mdz), \quad k = \frac{1}{2}(dz \wedge Kdz), \quad q = \frac{1}{2}(dz \wedge Ldz), \tag{2.5}$$

are differential two-forms. So, when a numerical scheme is developed, we expect that the multisymplectic conservation law (2.4) should be preserved. Bridges and Reich defined a numerical scheme as a multisymplectic scheme if the scheme preserves a discrete multisymplectic conservation law.[8] Specifically, if we discretize Hamiltonian PDEs (2.3) as follows,

$$M\partial_t^{i,j,n} z_{i,j}^n + K\partial_x^{i,j,n} z_{i,j}^n + L\partial_y^{i,j,n} z_{i,j}^n = (\nabla_z S(z))_{i,j}^n, \tag{2.6}$$

where $z_{i,j}^n = z(x_i, y_j, t_n)$, $\partial_t^{i,j,n}$, $\partial_x^{i,j,n}$, and $\partial_y^{i,j,n}$ are the discretizations of the derivatives ∂_t, ∂_x, and ∂_y, respectively, then the scheme is multisymplectic provided that it can preserve the following discrete conservation law:

$$\partial_t^{i,j,n} w_{i,j}^n + \partial_x^{i,j,n} k_{i,j}^n + \partial_y^{i,j,n} q_{i,j}^n = 0, \tag{2.7}$$

where

$$w_{i,j}^n = \frac{1}{2}(dz_{i,j}^n \wedge Mdz_{i,j}^n), \quad k_{i,j}^n = \frac{1}{2}(dz_{i,j}^n \wedge Kdz_{i,j}^n), \quad q_{i,j}^n = \frac{1}{2}(dz_{i,j}^n \wedge Ldz_{i,j}^n). \tag{2.8}$$

Set t_n, $n=1,2,\ldots,N_1$; x_i, $i=1,2,\ldots,N_2$; y_j, $j=1,2,\ldots,N_3$ is the regular grids of the integral domain, $z_{i,j}^n$ is an approximation to $z(x_i, y_j, t_n)$, Δt is the time step, Δx is the x direction step, Δy is the y direction step, and

$$D_t^{\pm} z_{i,j}^n = \pm \frac{z_{i,j}^{n\pm1} - z_{i,j}^n}{\Delta t}, \quad D_x^{\pm} z_{i,j}^n = \pm \frac{z_{i\pm1,j}^n - z_{i,j}^n}{\Delta x}, \quad D_y^{\pm} z_{i,j}^n = \pm \frac{z_{i,j\pm1}^n - z_{i,j}^n}{\Delta y}.$$

The Euler box scheme for (2.3) is

$$M_+ D_t^+ z_{i,j}^n + M_- D_t^- z_{i,j}^n + K_+ D_x^+ z_{i,j}^n + K_- D_x^- z_{i,j}^n + L_+ D_y^+ z_{i,j}^n + L_- D_y^+ z_{i,j}^n = (\nabla_z S(z))_{i,j}^n, \tag{2.9}$$

where M_+, M_-, K_+, K_-, L_+, and L_- are matrix splitting for the symplectic structure matrices M, K, and L, respectively, s.t.,

$$M = M_+ + M_-, \quad M_+^T = -M_-,$$

$$K = K_+ + K_-, \quad K_+^T = -K_-,$$

$$L = L_+ + L_-, \quad L_+^T = -L_-. \tag{2.10}$$

Scheme (2.9) satisfies the discrete multisymplectic conservation law.

Theorem 1. (Ref. 19) Euler box scheme (2.9) is multisymplectic with the following discrete multisymplectic conservation law:

$$D_t^+ w_{i,j}^n + D_x^+ k_{i,j}^n + D_y^+ q_{i,j}^n = 0, \tag{2.11}$$

where

$$w_{i,j}^n = \frac{1}{2}(dz_{i,j}^{n-1} \wedge M_+ dz_{i,j}^n), \quad k_{i,j}^n = \frac{1}{2}(dz_{i-1,j}^n \wedge K_+ dz_{i,j}^n), \quad q_{i,j}^n = \frac{1}{2}(dz_{i,j-1}^n \wedge L_+ dz_{i,j}^n).$$

Proof: The variational equation associated with (2.9) is

$$M_+ D_t^+ dz_{i,j}^n + M_- D_t^- dz_{i,j}^n + K_+ D_x^+ dz_{i,j}^n + K_- D_x^- dz_{i,j}^n + L_+ D_y^+ dz_{i,j}^n + L_- D_y^- dz_{i,j}^n = S_{zz} dz_{i,j}^n. \tag{2.12}$$

For $dz_{i,j}^n \wedge S_{zz} dz_{i,j}^n = 0$, then we have

$$dz_{i,j}^n \wedge (M_+ D_t^+ dz_{i,j}^n + M_- D_t^- dz_{i,j}^n + K_+ D_x^+ dz_{i,j}^n + K_- D_x^- dz_{i,j}^n + L_+ D_y^+ dz_{i,j}^n + L_- D_y^- dz_{i,j}^n) = 0. \tag{2.13}$$

Note that

$$dz_{i,j}^n \wedge M_+ D_t^+ dz_{i,j}^n + dz_{i,j}^n \wedge M_- D_t^- dz_{i,j}^n = dz_{i,j}^n \wedge M_+ D_t^+ dz_{i,j}^n + D_t^- dz_{i,j}^n \wedge M_+ dz_{i,j}^n = - D_t^+ dz_{i,j}^n \wedge M_+ dz_{i,j}^n - dz_{i,j}^n \wedge D_t^- M_+ dz_{i,j}^n = - D_t^+ (dz_{i,j}^{n-1} \wedge M_+ dz_{i,j}^n); \tag{2.14}$$

similarly, we have

$$dz_{i,j}^n \wedge K_+ D_x^+ dz_{i,j}^n + dz_{i,j}^n \wedge K_- D_x^- dz_{i,j}^n = - D_x^+ (dz_{i-1,j}^n \wedge K_+ dz_{i,j}^n), \tag{2.15}$$

$$dz_{i,j}^n \wedge L_+ D_y^+ dz_{i,j}^n + dz_{i,j}^n \wedge L_- D_y^- dz_{i,j}^n = - D_y^+ (dz_{i,j-1}^n \wedge L_+ dz_{i,j}^n). \tag{2.16}$$

Combining (2.14)–(2.16), we have

$$D_t^+ (dz_{i,j}^{n-1} \wedge M_+ dz_{i,j}^n) + D_x^+ (dz_{i-1,j}^n \wedge K_+ dz_{i,j}^n) + D_y^+ (dz_{i,j-1}^n \wedge L_+ dz_{i,j}^n) = 0. \tag{2.17}$$

The proof is completed. □

We start from the Euler box scheme (2.9). Note that the matrix splitting (2.10) is not unique. We can obtain different schemes with different splitting methods. Now we take M_+, K_+, and L_+ as upper triangle matrices. They are

$$\mathbf{M}_+ = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\mathbf{K}_+ = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\mathbf{L}_+ = \begin{pmatrix} 0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&1&0&0\\ 0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0\\ 0&0&0&0&0&0&0&0&0&0 \end{pmatrix}.$$

Substituting the above splitting into Euler box scheme (2.10), we get the discrete forms of the multisymplectic PDEs (2.3):

$$D_x^+ p^x = 0, \tag{2.18}$$

$$\frac{1}{2} D_t^+ p^{xt} + D_x^+ p^{xx} + D_y^+ p^{xy} = -p^x, \tag{2.19}$$

$$D_x^+ p^{xxx} = p + 3u^2 - p^{xx}, \tag{2.20}$$

$$p^{xy} = \sigma w, \tag{2.21}$$

$$p^{xt} = u, \tag{2.22}$$

$$D_x^- \varphi = v, \tag{2.23}$$

$$D_x^- v = u, \tag{2.24}$$

$$D_y^- v = w, \tag{2.25}$$

$$\frac{1}{2} D_t^- v = p, \tag{2.26}$$

$$D_x^- u = -p^{xxx}. \tag{2.27}$$

Substituting (2.26) and (2.27) into (2.20), we have

$$-D_x^+ D_x^- u = \frac{1}{2} D_t^- v + 3u^2 - p^{xx}. \tag{2.28}$$

Combining (2.21), (2.22), (2.25), and (2.19), then

$$\frac{1}{2} D_t^+ u + D_x^+ p^{xx} + \sigma D_y^+ D_y^- v = -p^x. \tag{2.29}$$

Applying D_x^- to Eq. (2.28), $D_x^+ D_x^-$ to (2.29), noting that the finite difference operators mutually commute, and combining (2.18), we have

$$-D_x^+D_x^-D_x^-u=\frac{1}{2}D_t^-D_x^-v+3D_x^-(u^2)-D_x^-p^{xx}, \tag{2.30}$$

$$\frac{1}{2}D_x^+D_x^-D_t^+u+D_x^+D_x^+D_x^-p^{xx}+\sigma D_x^+D_y^+D_y^-D_x^-v=-D_x^+p^x=0. \tag{2.31}$$

Note that $D_x^-v=u$, (2.30) and (2.31) can be reformulated as follows:

$$D_x^-p^{xx}=\frac{1}{2}D_t^-u+3D_x^-(u^2)+D_x^+D_x^-D_x^-u, \tag{2.32}$$

$$\frac{1}{2}D_x^+D_x^-D_t^+u+D_x^+D_x^+D_x^-p^{xx}+\sigma D_x^+D_y^+D_y^-u=0. \tag{2.33}$$

Substituting (2.32) into (2.33), we obtain the following multisymplectic 16-point scheme:

$$\frac{1}{2}D_t^+D_x^-D_x^+u_{i,j}^n+D_x^+D_x^+\left(\frac{1}{2}D_t^-u_{i,j}^n+3D_x^-f_{i,j}^n+D_x^+D_x^-D_x^-u_{i,j}^n\right)+\sigma D_x^+D_y^+D_y^-u_{i,j}^n=0, \tag{2.34}$$

where $f=u^2$. In finite difference format the 16-point scheme is given as follows:

$$\begin{aligned}\frac{1}{2\Delta t(\Delta x)^2}(u_{i+1,j}^{n+1}-2u_{i,j}^{n+1}+u_{i-1,j}^{n+1})=&\frac{1}{2\Delta t(\Delta x)^2}(u_{i+1,j}^{n}-2u_{i,j}^{n}+u_{i-1,j}^{n})\\&-\frac{1}{2\Delta t(\Delta x)^2}(u_{i+2,j}^{n}-2u_{i+1,j}^{n}+u_{i,j}^{n}-u_{i+2,j}^{n-1}+2u_{i+1,j}^{n-1}-u_{i,j}^{n-1})\\&-\frac{3}{(\Delta x)^3}((u^2)_{i+2,j}^{n}-3(u^2)_{i+1,j}^{n}+3(u^2)_{i,j}^{n}-(u^2)_{i-1,j}^{n})\\&-\frac{1}{(\Delta x)^5}(u_{i+3,j}^{n}-5u_{i+2,j}^{n}+10u_{i+1,j}^{n}-10u_{i,j}^{n}+5u_{i-1,j}^{n}-u_{i-2,j}^{n})\\&-\frac{\sigma}{\Delta x(\Delta y)^2}(u_{i+1,j+1}^{n}-u_{i,j+1}^{n}-2u_{i+1,j}^{n}+2u_{i,j}^{n}+u_{i+1,j-1}^{n}-u_{i,j-1}^{n}).\end{aligned} \tag{2.35}$$

It couples three time levels (see Figs. 1 and 2). It is an explicit scheme in the sense that the scheme does not need iteration because the third time level ($t=n+1$) does not include nonlinear terms.

III. BACKWARD ERROR ANALYSIS FOR THE SCHEME

We now assume z is a sufficiently smooth function that, when evaluated at the lattice points, satisfies (2.10). Using the Taylor series expansions in t about $z(x_i,y_j,t_n)$,

$$z_{i,j}^{n\pm1}=z_{i,j}^n\pm\Delta t(z_{i,j}^n)_t+\frac{1}{2}(\Delta t)^2(z_{i,j}^n)_{tt}\pm\ \dots, \tag{3.1}$$

and equivalent expansions in x and y, then we have the following first order equation:

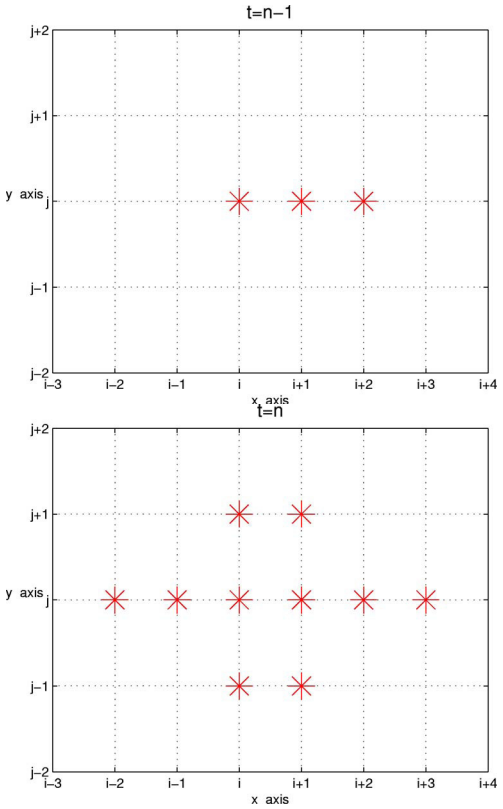

FIG. 1. (Color online) Left: points used by the first time level. Right: points used by the second time level.

$$Mz_t = (M_+ + M_-)z_t = \left[\left(M_+ z_t + \frac{1}{2}\Delta t M_+ z_{tt}\right) + \left(M_- z_t - \frac{1}{2}\Delta t M_- z_{tt}\right)\right] + o(\Delta t)$$

$$= Mz_t + \frac{1}{2}\Delta t(M_+ - M_-)z_{tt} + o(\Delta t). \tag{3.2}$$

Similarly, the space terms are approximated by

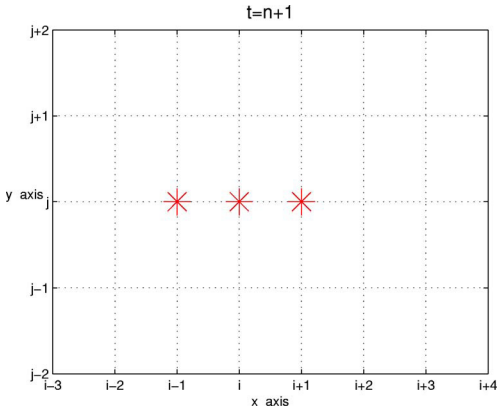

FIG. 2. (Color online) Points used by the third time level.

$$Kz_x = Kz_x + \frac{1}{2}\Delta x(K_+ - K_-)z_{xx} + o(\Delta x), \tag{3.3}$$

$$Lz_y = Lz_y + \frac{1}{2}\Delta y(L_+ - L_-)z_{yy} + o(\Delta y). \tag{3.4}$$

Substituting these expansions into (2.3), we obtain to first order the following modified equation:

$$Mz_t + \frac{1}{2}\Delta t(M_+ - M_-)z_{tt} + Kz_x + \frac{1}{2}\Delta x(K_+ - K_-)z_{xx} + Lz_y + \frac{1}{2}\Delta y(L_+ - L_-)z_{yy} = \nabla_z S(z). \tag{3.5}$$

Equation (3.5) can be written in the multisymplectic form:

$$\widetilde{M}\widetilde{z}_t + \widetilde{K}\widetilde{z}_x + \widetilde{L}\widetilde{z}_y = (\nabla_{\widetilde{z}}\widetilde{S}(\widetilde{z})), \tag{3.6}$$

where $\widetilde{z}=(z,z_t,z_x,z_y)^T$ and

$$\widetilde{\mathbf{M}} = \begin{pmatrix} M & \Delta tP & 0 & 0 \\ -\Delta tP & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \widetilde{\mathbf{K}} = \begin{pmatrix} K & 0 & \Delta xQ & 0 \\ 0 & 0 & 0 & 0 \\ -\Delta xQ & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\widetilde{\mathbf{L}} = \begin{pmatrix} L & 0 & 0 & \Delta yR \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -\Delta yR & 0 & 0 & 0 \end{pmatrix},$$

$\widetilde{S}(\widetilde{z})=S-\frac{1}{2}\Delta t z_t^T P z_t - \frac{1}{2}\Delta x z_x^T Q z_x - \frac{1}{2}\Delta y z_y^T R z_y$, P, Q, and R are new matrices

$$P = \frac{1}{2}(M_+ - M_-), \quad Q = \frac{1}{2}(K_+ - K_-), \quad R = \frac{1}{2}(L_+ - L_-). \tag{3.7}$$

Applying Eq. (3.5) to the example, we can obtain

$$(p^x)_x + \frac{1}{2}\Delta x(p^x)_{xx} = 0,$$

$$\frac{1}{2}(p^{xt})_t + (p^{xx})_x + (p^{xy})_y + \frac{1}{4}\Delta t(p^{xt})_{tt} + \frac{1}{2}\Delta x(p^{xx})_{xx} + \frac{1}{2}\Delta y(p^{xy})_{yy} = -p^x,$$

$$(p^{xxx})_x + \frac{1}{2}\Delta x(p^{xxx})_{xx} = p + 3u^2 - p^{xx},$$

$$p^{xy} = \sigma w,$$

$$p^{xt} = u,$$

$$(\varphi)_x - \frac{1}{2}\Delta x(\varphi)_{xx} = v,$$

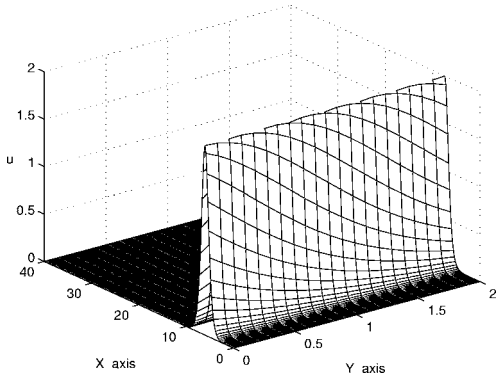

FIG. 3. The wave form of one soliton at $t=0$.

$$(v)_x - \frac{1}{2}\Delta x(v)_{xx} = u,$$

$$(v)_y - \frac{1}{2}\Delta y(v)_{yy} = w,$$

$$\frac{1}{2}(v)_t - \frac{1}{4}\Delta t(v)_{tt} = p,$$

$$(u)_x - \frac{1}{2}\Delta x(u)_{xx} = -p^{xxx}. \tag{3.8}$$

We tried to eliminate the auxiliary variables in Eqs. (3.8) to get the expected modified equation associated with the 16-point scheme. Unfortunately, we failed. We just obtain the following approximate equation, by ignoring the high order items,

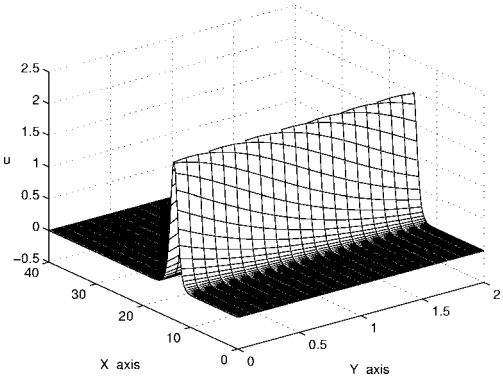

FIG. 4. Numerical solution of one soliton at $t=3$ with $\Delta x=0.1$, $\Delta y=0.1$, and $\Delta t=0.00005$.

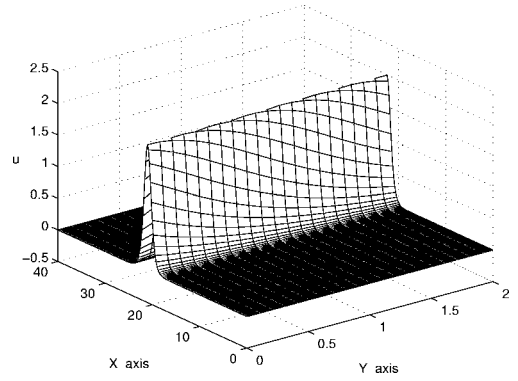

FIG. 5. Numerical solution of one soliton at $t=6$ with $\Delta x=0.1$, $\Delta y=0.1$, and $\Delta t=0.00005$.

$$(u_t + 6uu_x + u_{xxx})_x + \sigma u_{yy} = -\Delta x[u_{xxt} + (3u^2)_{xxx} + u_{xxxxx} + \sigma u_{xyy}] + \frac{1}{4}\Delta x\Delta t(u_{xxtt}) + \frac{1}{4}\Delta y^2(u_{yyyy}) + \frac{1}{4}\Delta x\Delta y^2(u_{xyyyy}) + O(\Delta t^2 + \Delta x^2 + \Delta y^3), \tag{3.9}$$

which is an $O(\Delta t+\Delta x+\Delta y^2)$ perturbation of the KPI.

IV. SOME NUMERICAL RESULTS

For our numerical experiments, we test the 16-point scheme on one soliton and lump-type solitary over long time intervals. We consider the KPI equation with an exact boundary condition. First we consider the one soliton with initial conditions

$$u(x,y,0) = 2\,\mathrm{sech}^2\left(x - \frac{\sqrt{2}}{2}y - 6\right). \tag{4.1}$$

The KPI equation has the theoretic solution

$$u(x,y,t) = 2\,\mathrm{sech}^2\left(x - \frac{\sqrt{2}}{2}y - \frac{5}{2}t - 6\right), \tag{4.2}$$

which represents one soliton propagating with the velocity $\frac{5}{2}$ in the direction with the angle of $\tan^{-1}(\sqrt{2})$ to the positive x axis. We carry out our numerical computation on the domain

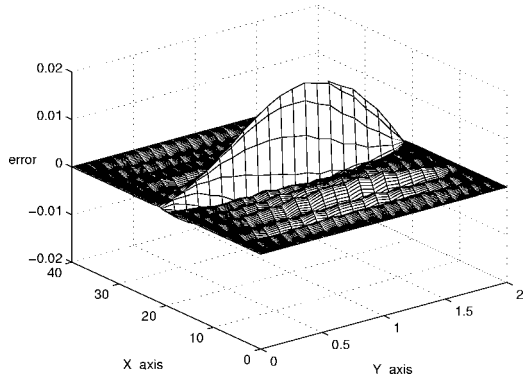

FIG. 6. The error between the numerical solution and the exact solution of one soliton at $t=6$ with $\Delta x=0.1$, $\Delta y=0.1$, and $\Delta t=0.00005$.

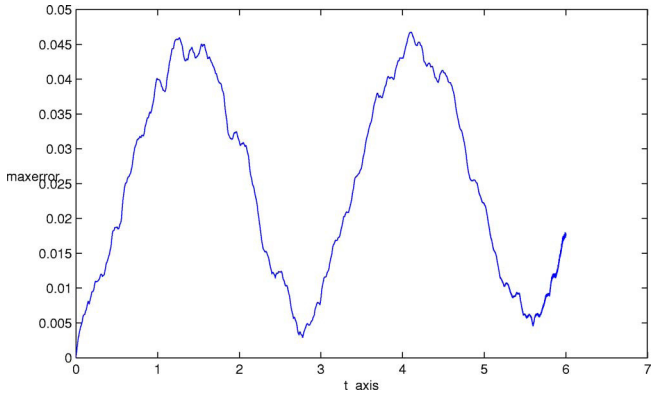

FIG. 7. (Color online) The trend of the maxerror(n) of one soliton as time evolves with $\Delta x=0.1$, $\Delta y=0.1$, and $\Delta t=0.00005$.

$[0,40]\times[0,2]$ and choose $\Delta x=0.1$, $\Delta y=0.1$, $\Delta t=0.00005$. Figure 3 shows the wave form of one soliton at $t=0$. Figures 4 and 5 show the numerical solution at $t=3$ and $t=6$, respectively. We can see the moving of one soliton from the graph. Figure 6 shows the error between the numerical solution and the exact solution at $t=6$. For fixed n, we give the definition of maxerror(n):

$$\text{maxerror}(n) = \max_{ij} |u_{i,j}^n - u(x_i, y_j, t_n)|, \tag{4.3}$$

where $u_{i,j}^n$ is the numerical solution while $u(x_i, y_j, t_n)$ is the exact solution. Figure 7 shows the trend of the maxerror(n) as time evolves. From that, we can see that the scheme has the good numerical performance over long time intervals.

Next, we try the lump-type solitary waves of the KPI equation with the following initial condition:

$$u(x,y,0) = 4\frac{\left(-(x-x_0)^2 + \mu^2(y-y_0)^2 + \frac{1}{\mu^2}\right)}{\left((x-x_0)^2 + \mu^2(y-y_0)^2 + \frac{1}{\mu^2}\right)^2}. \tag{4.4}$$

We compute in a rectangle $[0,20]\times[0,20]$ with the parameters $\mu^2=1.0$, $x_0=10.0$, $y_0=10.0$, and choose $\Delta x=0.1$, $\Delta y=0.2$, $\Delta t=0.00005$. The lump solution of the KPI equation can be expressed as

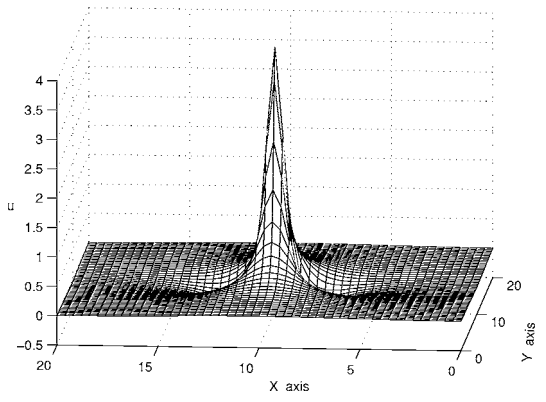

FIG. 8. The lump-type solitary wave at $t=0$.

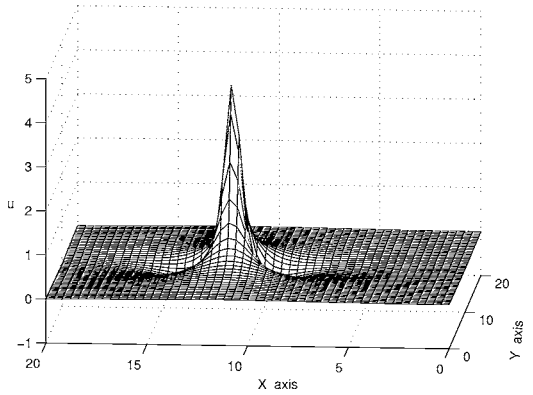

FIG. 9. Numerical solution of lump-type solitary wave at $t=0.5$ with $\Delta x=0.1$, $\Delta y=0.2$, and $\Delta t=0.00005$.

$$u(x,y,t)=4\frac{\left(-(x-x_0-3\mu^2t)^2+\mu^2(y-y_0)^2+\frac{1}{\mu^2}\right)}{\left((x-x_0-3\mu^2t)^2+\mu^2(y-y_0)^2+\frac{1}{\mu^2}\right)^2}. \tag{4.5}$$

Figure 8 shows the lump-type solitary wave at $t=0$. Figures 9 and 10 show the numerical solution at $t=0.5$ and $t=1$, respectively. Figure 11 shows the error between the numerical solution and the exact solution at $t=1$.

According to (4.5), this lump-type solitary wave will move to the positive x direction with velocity $3\mu^2$. Figures 9 and 10 shows the moving of the lump-type solitary wave.

V. CONCLUDING REMARKS

We investigate the noncompact Euler box for the GKP equation. A new equivalent scheme 16-point for KPI equation is derived. It is an explicit scheme, therefore it could be faster, less storage consuming, and more easy to carry out than the multisymplectic 45-point scheme when it is applied into computers. The good numerical performance of the derived scheme in several numerical experiments illustrates that the multisymplectic Euler box scheme is as good the as multisymplectic Preissman scheme. Thus we may draw the conclusion that not only compact implicit multisymplectic schemes but also noncompact explicit multisymplectic can be high quality schemes for the long time integration of nonlinear PDEs.

Remark. In Ref. 23, Frank, Moore, and Reich have shown that the explicit noncompact

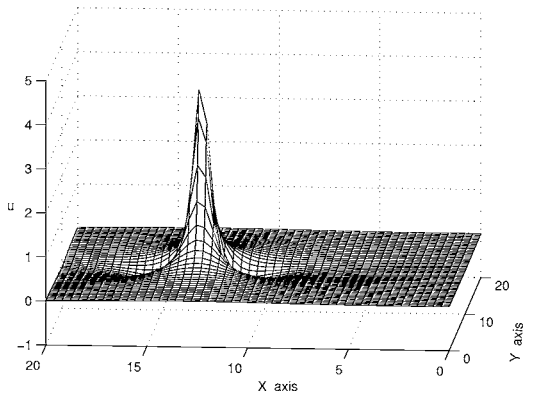

FIG. 10. Numerical solution of lump-type solitary wave at $t=1$ with $\Delta x=0.1$, $\Delta y=0.2$, and $\Delta t=0.00005$.

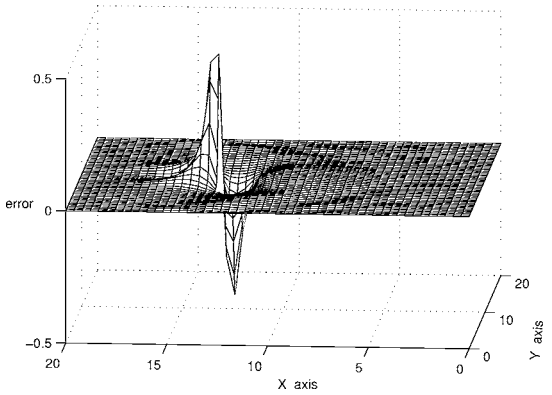

FIG. 11. The error between the numerical solution and the exact solution of lump-type solitary wave at $t=1$ with $\Delta x=0.1$, $\Delta y=0.2$, and $\Delta t=0.00005$.

midpoint multisymplectic scheme may exhibit spurious roots in the numerical dispersion relation for any value of $\Delta t/\Delta x$. This may lead to numerical instabilities. Our 16-point scheme is also an explicit multisymplectic and the numerical experiments do not exhibit instabilities. In future work, we will take the dispersion relation analysis for the new scheme and the von Neumann stability analysis to get a linear stability condition. Further, we will test numerically the scheme on a more challenging problem, which was reported by Bridges in Ref. 24.

(Received 16 December 2005; accepted 19 June 2006; published online 8 August 2006)

We study *pseudo Yang–Mills fields* on a compact strictly pseudoconvex CR manifold M, i.e., the critical points of the functional $\mathcal{PYM}(D)=\frac{1}{2}\int_M \|\pi_H R^D\|^2\theta\wedge(d\theta)^n$, where D is a connection in a Hermitian CR holomorphic vector bundle $(E,h)\to M$. Let $\Omega=\{\varphi<0\}\subset\mathbb{C}^n$ be a smoothly bounded strictly pseudodoconvex domain and g the Bergman metric on Ω. We show that boundary values D_b of Yang–Mills fields D on (Ω,g) are pseudo Yang–Mills fields on $\partial\Omega$, provided that $i_T R^{D_b}=0$ and $i_N R^D=0$ on $H(\partial\Omega)$. If $S^1\to C(M)\xrightarrow{\pi} M$ is the canonical circle bundle and π^*D is a Yang–Mills field with respect to the Fefferman metric F_θ of (M,θ) then D is a pseudo Yang–Mills field on M. The Yang–Mills equations $\delta^{\pi^*D}R^{\pi^*D}=0$ project on the Euler–Lagrange equations $\delta_b^D R^D=0$ of the variational principle $\delta\mathcal{PYM}(D)=0$, provided that $i_T R^D=0$. When M has vanishing pseudohermitian Ricci curvature the pullback π^*D of the (CR invariant) Tanaka connection D of (E,h) is a Yang–Mills field on $C(M)$. We derive the second variation formula $\{d^2\mathcal{PYM}(D^t)/dt^2\}_{t=0}=\int_M\langle\mathcal{S}_b^D(\varphi),\varphi\rangle\theta\wedge(d\theta)^n$, $D^t=D+A^t$ [provided that D is a pseudo Yang–Mills field and $\varphi\equiv\{dA^t/dt\}_{t=0}\in\mathrm{Ker}(\delta^D)$], and show that $\mathcal{S}_b^D(\varphi)\equiv\Delta_b^D\varphi+\mathcal{R}_b^D(\varphi)$, $\varphi\in\Omega^{0,1}[\mathrm{Ad}(E)]$, is a subelliptic operator. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2222082]

I. INTRODUCTION

A series of papers published in the last decade[21,24,25] are devoted to exploring the relationship among CR structures on three-dimensional manifolds and null solutions to Einstein equations, Maxwell equations, and Yang–Mills equations (see also Ref. 28). Specifically, if $[M,T_{1,0}(M)]$ is a nondegenerate three-dimensional CR manifold endowed with the contact form θ and with the (locally defined) complex 1-form θ^1 such that $\theta^1(T_1)=1$, $\theta^1(T_{\bar{1}})=0$ [where T_1 is a local generator of the CR structure $T_{1,0}(M)$] let us consider the semi-Riemannian metric

$$F=2p^2[(\pi^*\theta^1)\odot(\pi^*\theta^{\bar{1}})-(\pi^*\theta)\odot\sigma], \tag{1}$$

on $M\times\mathbb{R}$, where p is a real valued function on $M\times\mathbb{R}$ and σ is a real 1-form on $M\times\mathbb{R}$ such that

$$\pi^*(\theta\wedge\theta^1\wedge\theta^{\bar{1}})\wedge\sigma\neq 0.$$

Here $\pi: M\times\mathbb{R}\to M$ is the projection. Nurowski[24] has determined local solutions to the Yang–Mills equations on $(M\times\mathbb{R},F)$, under the additional assumption that the shear-free congruence of

[a]Electronic mail: barletta@unibas.it
[b]Electronic mail: dragomir@unibas.it
[c]Electronic mail: urakawa@math.is.tohoku.ac.jp

null geodesics tangent to $\partial/\partial\gamma$ (γ is the natural coordinate function on $\mathbb{R}$) possesses three linearly independent symmetries $\{X_i: 1\leqslant i\leqslant 3\}$. Let D be a SU(3) connection in a vector bundle $\hat{E}\to M\times\mathbb{R}$ locally described by a matrix of 1-forms $A=b\pi^*\theta^1+\bar{b}\pi^*\theta^{\bar{1}}+c\pi^*\theta+e\sigma$, where a, b, c, and e are $\mathcal{G}\otimes\mathbb{C}$-valued functions $[\mathcal{G}=\mathbf{su}(3)]$ on $M\times\mathbb{R}$. When the Lie group G_3 (whose Lie algebra is generated by the X_is) consists of symmetries of D (i.e., each element of G_3 induces a gauge transformation of A) then (by a result of Harnad *et al.*[12]) up to some gauge transformation A is strictly invariant under G_3. Then $\mathcal{L}_{X_i}A=0$, conditions which may be exploited to show that locally D may be looked for in the form $A=B\pi^*\Omega^1+\bar{B}\pi^*\Omega^{\bar{1}}+C\pi^*\Omega$, with $B,C\in\mathcal{G}\otimes\mathbb{C}$. Here Ω and Ω^1 are a new contact form and a new local coframe such that

$$\mathcal{L}_{\tilde{X}_i}\Omega=0,\quad \mathcal{L}_{\tilde{X}_i}\Omega^1=0,\quad d\Omega=2\sqrt{-1}\Omega^1\wedge\Omega^{\bar{1}}, \tag{2}$$

while $\tilde{X}_i$ are the projections on M of the (nontrivial) symmetries X_i. Finally the Yang–Mills equations [for SU(3) fields] on $M\times\mathbb{R}$ may be solved [together with the condition that D is null, i.e., $dA+A\wedge A=(\pi^*\Omega)\wedge(\Phi\pi^*\Omega^1+\bar{\Phi}\pi^*\Omega^{\bar{1}})$, for some $\mathcal{G}\otimes\mathbb{C}$-valued function Φ]. For instance [see Eq. (5.10) in Ref. 24, p. 805]

$$A=\rho\mathbf{n}\cdot f\pi^*(e^{i\phi}\Omega^1+e^{-i\phi}\Omega^{\bar{1}}) \tag{3}$$

is a solution, where $\mathbf{n}\in\mathbb{R}^3$ is a unit vector, $\rho\in\mathbb{R}$, $\phi\in[0,2\pi]$, and $f=(e_1,e_2,e_3)$ is a basis in $\mathcal{G}$. It is noteworthy that $\tilde{X}_i$ turn out to be symmetries of the CR structure $T_{1,0}(M)$ (in a sense that will be explained in Sec. III) and that the CR structures admitting the three-dimensional symmetry group G_3 are fully classified in Ref. 21, according to the Bianchi type of G_3. For instance, if $M=\{(x,y,z)\in\mathbb{R}^3: y\neq 0\}$ carries the CR structure $T_{1,0}(M)=\mathbb{C}T_1$ with

$$T_1=\frac{y}{1+y^2}\frac{\partial}{\partial x}-\frac{iy}{2}\frac{\partial}{\partial y}+\frac{1}{y(1+y^2)}\frac{\partial}{\partial z} \tag{4}$$

and the contact form $\theta=(1/y)dx-ydz$ (such M possesses a symmetry group of Bianchi type VI_0) then a local solution A (to the Yang–Mills equations) of the form (3) may be produced. The example (4) of a CR structure on $\mathbb{R}^3\setminus\{y=0\}$ will be encountered again in Sec. III. Now let M be a compact strictly pseudoconvex CR manifold, of arbitrary CR dimension n. Let $S^1\to C(M)\xrightarrow{\pi}M$ be the canonical circle bundle (cf. Sec. III for definitions). Note that $C(M)$ and $M\times\mathbb{R}$ are locally diffeomorphic. If θ is a contact form on M then $C(M)$ carries a natural Lorentz metric F_θ (the Fefferman metric) and a moment's thought [compare to Eq. (70) in Sec. V] shows that when M is three-dimensional the Fefferman metric F_θ is of the form (1). Then, under the symmetry assumptions above, (3) is a (local) solution to the Yang–Mills equations

$$\delta^{\mathrm{D}}R^{\mathrm{D}}=0 \tag{5}$$

on $[C(M),F_\theta]$ (with $n=1$), and in general it is conceivable that when the CR structure $T_{1,0}(M)$ possesses a symmetry group G_{2n+1}, Nurowski's scheme may produce local symmetric null solutions to (5). A first step toward the achievement of this goal is performed in Sec. III. Note that (3) is the pullback (via π) to $M\times\mathbb{R}$ of a field on M. It is then a natural question whether given a Yang–Mills field on $[C(M),F_\theta]$ of the form π^*D, it follows that D is a Yang–Mills field on (M,g_θ), where g_θ is the Webster metric. This question is answered in Sec. V, where we integrate along the fiber in the Yang–Mills functional $\widehat{\mathcal{YM}}$ on $C(M)$ and produce the new functional (7). As it turns out, D is a *pseudo Yang–Mills* field [i.e., a critical point of (7)] rather than a Yang–Mills field on (M,g_θ) (however, the two notions coincide in the special case $i_TR^D=0$). The converse [i.e., whether given a pseudo Yang–Mills field D on M its pullback π^*D is a Yang–Mills field on $C(M)$] is examined in Theorem 2. Solving (5) on $C(M)$ is therefore closely related to solving the pseudo Yang–Mills equations

$$\delta_b^D R^D = 0 \tag{6}$$

on M, and indeed (5) projects (under additional conditions, cf. Sec. V) on M to give (6). One of the main results in this paper is that solutions to (6) occur as boundary values of Yang–Mills fields on a strictly pseudoconvex bounded domain $\Omega \subset \mathbb{C}^n$ endowed with the Bergman metric g (cf. Theorem 1). For the proof of Theorem 1 we draw inspiration from Ref. 11 and make use of their canonical connection ∇ (the *Graham–Lee connection*) whose pointwise restriction to a level set (near $\partial\Omega$) of a defining function of Ω is the better known Tanaka–Webster connection of the level set. Using the fine asymptotic properties of the Bergman kernel of Ω we may choose a defining function allowing an explicit relationship among the Bergman metric g and the Webster metric of each level set, and therefore an explicit relationship among the Levi–Civita connection of (Ω, g) and the Graham–Lee connection. In the end, an elementary asymptotic analysis shows that boundary values D_b of Yang–Mills fields D on (Ω, g) satisfy (6) provided that D_b satisfy certain compatibility conditions along $\partial\Omega$ (cf. Sec. IV). In Secs. VI and VII we obtain the first and second variation formulae for the functional (7). The relevant operator occurring in the second variation formula is shown to be subelliptic of order $\frac{1}{2}$ (cf. Theorem 3). The problem of building an appropriate stability theory (along the lines of Ref. 4, yet relying on the subelliptic rather than on the elliptic theory) remains open. We feel that the importance of the Graham–Lee connection ∇ in applications deserves the Appendix: there we provide a new axiomatic description of ∇ together with a index-free proof.

II. STATEMENT OF MAIN RESULTS

Let $(M, T_{1,0}(M))$ be a compact strictly pseudoconvex CR manifold, of CR dimension n, and θ a contact form on M. Let $(E, \bar{\partial}_E) \to M$ be a CR-holomorphic vector bundle and h a Hermitian metric in E. Let $\mathcal{C}(E,h)$ be the affine space of all connections D in E such that $Dh=0$. We consider the functional

$$\mathcal{PYM}(D) = \frac{1}{2}\int_M \|\pi_H R^D\|^2 \theta \wedge (d\theta)^n. \tag{7}$$

Here $\pi_H : \Omega^2(\mathrm{Ad}\, E) \to \Omega^2(\mathrm{Ad}\, E)/\mathcal{J}_\theta^2$ is the natural projection and $\mathcal{J}_\theta^\bullet$ the ideal generated by θ in $\Omega^\bullet(\mathrm{Ad}\, E)$. A *pseudo Yang–Mills field* on M is a critical point of $\mathcal{PYM} : \mathcal{C}(E,h) \to [0, +\infty)$.

Let T be the characteristic direction of $(\partial\Omega, \theta)$, $\theta \equiv i/2(\bar{\partial} - \partial)\varphi$, and let $H(\partial\Omega)$ be the Levi distribution of (the CR manifold) $\partial\Omega$. Also we set $N = -JT$ (where J is the complex structure on $\mathbb{C}^n$). We shall show that:

Theorem 1: *Let $\Omega = [z \in U : \varphi(z) < 0]$ be a smoothly bounded strictly pseudoconvex domain in $\mathbb{C}^n$ and g its Bergman metric. Let $\pi : F \to U$ be a holomorphic vector bundle and h a Hermitian metric on F. Let $D_b \in \mathcal{C}(E,h)$ $[E = \pi^{-1}(\partial\Omega)]$ be the boundary values of a Yang–Mills field $D \in \mathcal{C}(F,h)$ on (Ω, g). Assume that $i_T R^{D_b} = 0$. Then D_b is a pseudo Yang–Mills field if and only if $i_N R^D = 0$ on $H(\partial\Omega)$.*

The proof relies on the explicit relationship among the Levi–Civita connection ∇^g of (Ω, g) and the Graham–Lee connection ∇ of φ (cf. Ref. 11 and our Appendix for the description and main properties of the Graham–Lee connection).

Urakawa 30–32 has started a study of Yang–Mills fields on M, that is of critical points of the functional

$$\mathcal{YM}(D) = \frac{1}{2}\int_M \|R^D\|^2 \mathrm{d\ vol}(g_\theta),$$

where $\mathrm{d\ vol}(g_\theta)$ is the canonical volume form associated to the Webster metric g_θ of (M, θ). As it will be shortly shown, $\mathcal{YM}$ and $\mathcal{PYM}$ are related. To motivate the definition of $\mathcal{PYM}$ let F_θ be the Fefferman metric of (M, θ) [a Lorentz metric on $C(M)$, the total space of the canonical circle bundle $\pi : C(M) \to M$ (cf. e.g., Lee,[18])]. By a result of Barletta *et al.*,[2] the base map $\phi : M \to N$

corresponding to any smooth S^1-invariant harmonic map $\Phi: C(M) \to N$ from $[C(M), F_\theta]$ into a Riemannian manifold (N, g_N) is locally a subelliptic harmonic map (in the sense of Jost and Xu[15]). Also ϕ is a critical point of the functional $E(\phi) = \frac{1}{2}\int_M \mathrm{trace}_{G_\theta}(\pi_H \phi^* g_N)\theta \wedge (d\theta)^n$, where G_θ is the Levi form. Here, if B is a bilinear form on $T(M)$, then $\pi_H B$ denotes the restriction of B to $H(M)$, the Levi distribution of $[M, T_{1,0}(M)]$. The functional E itself is obtained by integration along the fiber in the Dirichlet functional $\mathbb{E}(\Phi) = \frac{1}{2}\int_{C(M)} \mathrm{trace}_{F_\theta}(\Phi^* g_N)\mathrm{d\,vol}(F_\theta)$, where $\Phi = \phi \circ \pi$. Then perhaps subelliptic harmonic maps (rather than harmonic maps, with respect to the Webster metric) are the natural objects of study in CR geometry. Another example of the sort is the *CR Yamabe problem*, i.e., given a contact form θ on M such that G_θ is positive definite, find a contact form $\hat{\theta} = e^u \theta$, $u \in C^\infty(M)$, such that the pseudohermitian scalar curvature $\hat{\rho}$ of $(M, \hat{\theta})$ is a constant λ. By the result of Lee,[18] the Fefferman metric changes conformally $F_{\hat{\theta}} = e^{u \circ \pi} F_\theta$. Also the scalar curvature $K: C(M) \to \mathbb{R}$ of $[C(M), F_\theta]$ is S^1 invariant and the corresponding base function $\pi_* K: M \to \mathbb{R}$ is, up to a constant, the pseudohermitian scalar curvature ρ of (M, θ) [precisely $\pi_* K = (2n+1)/(n+1)\rho$]. Therefore, the CR Yamabe problem is nothing but the Yamabe problem for the Fefferman metric and the relevant equation (the Yamabe equation on $[C(M), F_\theta]$) projects on $c_n \Delta_b u + \rho u = \lambda u^{p-1}$ (the *CR Yamabe equation*), a nonlinear subelliptic equation on M (which may be analyzed with the techniques in Ref. 9, cf. Jerison and Lee,[13,14] and Gamara and Yacoub,[10] for a complete solution to the CR Yamabe problem). The common feature of the two examples above is that both provide natural objects on M, as projections of (S^1 invariant) geometric quantities on $C(M)$, associated to the Fefferman metric. A more refined statement is that both examples lead to nonlinear subelliptic problems on M. This has already been emphasized for the CR Yamabe problem. As to the example of S^1-invariant harmonic maps $\Phi: C(M) \to N$, the base map is a solution to $\Delta_b \phi^i + g^{\alpha\bar{\beta}} T_\alpha(\phi^j) T_{\bar{\beta}}(\phi^k)[(\Gamma_N)^i_{jk} \circ \phi] = 0$, where $(\Gamma_N)^i_{jk}$ are the Christoffel symbols of the second kind of g_N. On the same line of thought, we may state the following:

Theorem 2: *Let M be a compact strictly pseudoconvex CR manifold, of CR dimension n. Let θ be a contact form on M with G_θ positive definite. Let $(E, \bar{\partial}_E) \to M$ be a CR-holomorphic vector bundle and h a Hermitian metric in E. (i) There is a constant c_n depending only on the dimension and the orientation of M such that*

$$c_n \mathcal{YM}(D) = \mathcal{PYM}(D) + 2\int_M \|i_T R^D\|^2 \theta \wedge (d\theta)^n, \quad D \in \mathcal{C}(E,h). \tag{8}$$

Consequently, given a Hermitian connection D in E whose curvature R^D is of type $(1,1)$, D is a pseudo Yang–Mills field on M if and only if D is the Tanaka connection of $(E, \bar{\partial}_E, h)$. (ii) Let $\mathcal{Y}\hat{\mathcal{M}}(\mathbb{D}) = \frac{1}{2}\int_{C(M)} \langle R^{\mathbb{D}}, R^{\mathbb{D}} \rangle \mathrm{d\,vol}(F_\theta)$ be the Yang–Mills functional on $C(M)$, for $\mathbb{D} \in \mathcal{C}(\pi^* E, \pi^* h)$. Then

$$\mathcal{Y}\hat{\mathcal{M}}(\pi^* D) = 2\pi \mathcal{PYM}(D), \quad D \in \mathcal{C}(E,h). \tag{9}$$

Consequently, if $\pi^* D$ is a Yang–Mills field on $[C(M), F_\theta]$ then D is a pseudo Yang–Mills field on M. Vice versa, let D be a pseudo Yang–Mills field on M such that $i_T R^D = 0$. Then $\pi^* D$ is a Yang–Mills field on $C(M)$ if and only if

$$\left[R^{\alpha\bar{\beta}} - \frac{\rho}{2(n+1)} g^{\alpha\bar{\beta}} \right] R^D(T_\alpha, T_{\bar{\beta}}) u = 0, \tag{10}$$

for some local frame $\{T_\alpha : 1 \leqslant \alpha \leqslant n\}$ of $T_{1,0}(M)$ at any point $x \in M$, and

$$\Lambda_\theta R^D = 0. \tag{11}$$

In particular, if M is (pseudohermitian) Ricci flat then the pullback $\pi^* D$ of the canonical Tanaka connection D of (E,h) is a Yang–Mills field.

The main ingredients in the proof of Theorem 2 are a local coordinate calculation of the Fefferman metric of (M, θ), the explicit relationship among the Levi–Civita connection $\nabla^{C(M)}$ of

$[C(M), F_\theta]$, and the Tanaka–Webster connection ∇ of (M, θ) (cf. Lemma 2), and Theorem 2.3 in Ref. 30, p. 551. We may also state (delegating the definitions to Sec. II):

Theorem 3: *Let D be a pseudo Yang–Mills field and $D^t = D + A^t$, $|t| < \epsilon$, a smooth variation of D whose first order part $\varphi \equiv (\mathrm{d}A^t/\mathrm{d}t)_{t=0}$ satisfies $i_T\varphi = 0$ and $\delta_b^D \varphi = 0$. Then*

$$\frac{d^2}{dt^2}[\mathcal{PYM}(D^t)]_{t=0} = \int_M \langle \mathcal{S}_b^D(\varphi), \varphi \rangle \theta \wedge (\mathrm{d}\theta)^n \tag{12}$$

where $\mathcal{S}_b^D(\varphi) \equiv \Delta_b^D \varphi + \mathcal{R}_b^D(\varphi)$ and $\Delta_b^D \varphi \equiv d_b^D \delta_b^D \varphi + \delta_b^D d_b^D \varphi$ is the generalized sublaplacian. The operator $\mathcal{S}_b^D : \Omega^{0,1}[\mathrm{Ad}(E)] \to \Omega^{0,1}[\mathrm{Ad}(E)]$ is subelliptic of order $\frac{1}{2}$.

As $\mathcal{R}_b^D$ is a zero order operator, the crucial point in the proof of Theorem 3 is to show that

$$(\Delta_b^D \varphi) \otimes e_j = 2\{\Box_b \varphi_j^i + (n-1)(\nabla_T \varphi_j^i + \varphi_j^i \circ \tau) \circ J\} \otimes e_i + \textit{lower order terms}, \tag{13}$$

for any $\varphi \in \Omega^{0,1}[\mathrm{Ad}(E)]$, $\varphi e_j = \varphi_j^i \otimes e_i$, and then exploit the subellipticity of the Kohn–Rossi operator $\Box_b$ on scalar (0, 1) forms.

III. CR AND PSEUDOHERMITIAN GEOMETRY

A. Basic definitions and results

Let M be a C^∞ manifold, of real dimension $(2n+1)$. A complex subbundle $T_{1,0}(M) \subset T(M) \otimes \mathbb{C}$, of complex rank n, is a *CR structure* on M (of *CR dimension n*) if

$$T_{1,0}(M) \cap T_{0,1}(M) = (0),$$

$$Z, W \in \Gamma^\infty[T_{1,0}(M)] \Rightarrow (Z, W) \in \Gamma^\infty[T_{1,0}(M)].$$

Here $T_{0,1}(M) = \overline{T_{1,0}(M)}$ is the complex conjugate of $T_{1,0}(M)$. Also, if $E \to M$ is a vector bundle then $\Gamma^\infty(E)$ denotes the space of C^∞ sections in E (eventually defined on some open set $U \subseteq M$, to be understood from the context). The *tangential Cauchy–Riemann operator*

$$\bar{\partial}_b : C^\infty(M) \to \Gamma^\infty[T_{0,1}(M)^*]$$

is given by $(\bar{\partial}_b f)\bar{Z} = \bar{Z}(f)$, for any C^∞ function $f : M \to \mathbb{C}$ and any $Z \in T_{1,0}(M)$. Let $E \to M$ be a complex vector bundle over a CR manifold. A *pre-$\bar{\partial}$-operator* is a first-order differential operator

$$\bar{\partial}_E : \Gamma^\infty(E) \to \Gamma^\infty[T_{0,1}(M)^* \otimes E]$$

such that

$$\bar{\partial}_E(fu) = f\bar{\partial}_E u + (\bar{\partial}_b f) \otimes u,$$

for any $f \in C^\infty(M)$ and any $u \in \Gamma^\infty(E)$. A pair $(E, \bar{\partial}_E)$ consisting of a complex vector bundle and a pre-$\bar{\partial}$-operator is a *CR-holomorphic* vector bundle if $\bar{\partial}_E$ satisfies the *integrability condition*

$$(\bar{Z}, \bar{W}) \cdot u = \bar{Z} \cdot \bar{W} \cdot u - \bar{W} \cdot \bar{Z} \cdot u,$$

for any $u \in \Gamma^\infty(E)$, $Z, W \in T_{1,0}(M)$. Here $\bar{Z} \cdot u$ is short for $(\bar{\partial}_E u)\bar{Z}$.

Let $H(M) = \mathrm{Re}\{T_{1,0}(M) \oplus T_{0,1}(M)\}$ be the *Levi distribution* and $J : H(M) \to H(M)$, $J(Z + \bar{Z}) = i(Z - \bar{Z})$, $Z \in T_{1,0}(M)$, its complex structure $(i = \sqrt{-1})$. When M is oriented, which is assumed throughout this paper, the conormal bundle $H(M)_x^\perp = \{\omega \in T_x^*(M) : \mathrm{Ker}(\omega) \supseteq H(M)_x\}$, $x \in M$, is an oriented real line bundle, hence trivial [$H(M)^\perp \approx M \times \mathbb{R}$, a vector bundle isomorphism]. Therefore $H(M)^\perp \to M$ admits globally defined nowhere zero sections $\theta \in \Gamma^\infty[H(M)^\perp]$, each of which is referred to as a *pseudohermitian structure* on M. The *Levi form* is

$$L_\theta(Z,\bar{W}) = -i(\mathrm{d}\theta)(Z,\bar{W}),$$

for any $Z, W \in T_{1,0}(M)$. $[M, T_{1,0}(M)]$ is *nondegenerate* if L_θ is nondegenerate for some θ. If this is the case, each pseudohermitian structure θ is a *contact form*, i.e., $\theta \wedge (d\theta)^n$ is a volume form on M. Two pseudohermitian structures $\theta, \hat{\theta} \in \Gamma^\infty[H(M)^\perp]$ are related by $\hat{\theta} = f\theta$, for some C^∞ function $f: M \to \mathbb{R}\setminus\{0\}$. Then $L_{\hat{\theta}} = fL_\theta$, hence nondegeneracy is a CR invariant notion (i.e., invariant under a transformation $\theta \mapsto f\theta$ of the pseudohermitian structure). Let T be the unique nowhere zero globally defined tangent vector field on M, transverse to the Levi distribution, determined by $\theta(T) = 1$ and $i_T \mathrm{d}\theta = 0$ (the *characteristic direction* of $\mathrm{d}\theta$). Also, let us consider the semi-Riemannian metric g_θ [the *Webster metric* of (M, θ)] given by

$$g_\theta(X,Y) = G_\theta(X,Y), \quad g_\theta(X,T) = 0, \quad g_\theta(T,T) = 1,$$

where $G_\theta(X,Y) = (d\theta)(X, JY)$, $X, Y \in H(M)$, is the (real) *Levi form* (note that L_θ and [the $\mathbb{C}$-linear extension of) G_θ coincide on $T_{1,0}(M) \otimes T_{0,1}(M)$]. $[M, T_{1,0}(M)]$ is *strictly pseudoconvex* if L_θ is positive definite for some θ. For instance, if $M = \{(x,y,u) \in \mathbb{R}^3 : y \neq 0\}$ is endowed with the CR structure given by (4) in Sec. I then a calculation shows that the characteristic direction [corresponding to the contact form $\theta = (1/y)dx - ydz$] is

$$T = \frac{y(3+y^2)}{4(1+y^2)}\frac{\partial}{\partial x} - \frac{i}{8}y(1-y^2)\frac{\partial}{\partial y} - \frac{1+3y^2}{4y(1+y^2)}\frac{\partial}{\partial z}$$

so that

$$[T_1, T_{\bar{1}}] = \frac{i}{2}T_1 - \frac{i}{2}T_{\bar{1}} - \frac{2i}{1+y^2}T$$

(where $T_{\bar{1}} = \bar{T}_1$). Consequently,

$$L_\theta(T_1, T_{\bar{1}}) = (i/2)\theta[(T_1, T_{\bar{1}})] = 1/(1+y^2),$$

hence M is strictly pseudoconvex. A fundamental result in pseudohermitian geometry (established independently by Tanaka[29] and Webster[34]) is that on any nondegenerate CR manifold on which a contact form θ has been fixed there is a unique linear connection ∇ [the *Tanaka–Webster connection* of (M, θ)] such that (i) $H(M)$ is parallel with respect to ∇; (ii) $\nabla g_\theta = 0$, $\nabla J = 0$; and (iii) the torsion T_∇ of ∇ is *pure*, i.e.,

$$T_\nabla(Z,W) = 0, \quad T_\nabla(Z,\bar{W}) = 2iL_\theta(Z,\bar{W})T, \quad Z, W \in T_{1,0}(M),$$

$$\tau \circ J + J \circ \tau = 0,$$

where $\tau(X) = T_\nabla(T, X)$, $X \in T(M)$, is the *pseudohermitian torsion*. If M is three dimensional ($n = 1$) and T_1 is a local generator of the CR structure we set

$$\nabla_{T_1} T_1 = \Gamma^1_{11} T_1, \quad \nabla_{T_{\bar{1}}} T_1 = \Gamma^1_{\bar{1}1} T_1, \quad \nabla_T T_1 = \Gamma^1_{01} T_1.$$

A calculation [based on (i)-(iii)] shows that

$$\Gamma^1_{11} = g^{1\bar{1}}\{T_1(g_{1\bar{1}}) - g_\theta[T_1, (T_1, T_{\bar{1}})]\}, \tag{14}$$

$$\Gamma^1_{\bar{1}1} = g^{1\bar{1}} g_\theta[(T_{\bar{1}}, T_1), T_{\bar{1}}], \tag{15}$$

$$\Gamma_{01}^{1} = g^{1\bar{1}} g_{\theta}[(T,T_1),T_{\bar{1}}]. \tag{16}$$

Here $g_{1\bar{1}}=L_\theta(T_1,T_{\bar{1}})$ and $g^{1\bar{1}}=1/g_{1\bar{1}}$. Going back to the example $\mathbb{R}^3\backslash\{y=0\}$ with the CR structure (4) we have

$$(T,T_1) = \frac{i}{8}(1-y^2)T_1 + \frac{i}{8}(1+y^2)T_{\bar{1}}$$

hence [by (14)–(16)]

$$\Gamma_{11}^{1} = i\left(\frac{1}{2} + \frac{y^2}{1+y^2}\right), \quad \Gamma_{\bar{1}1}^{1} = -\frac{i}{2}(1+y^2), \quad \Gamma_{01}^{1} = \frac{i}{8}(1-y^2).$$

We assume from now on that, unless otherwise stated, M is strictly pseudoconvex. A complex valued differential p form η on M is *of type* $(p,0)$ [or a $(p,0)$ *form* on M] if $T_{0,1}(M)\rfloor\eta=0$. Let θ be a contact form on M and T the characteristic direction of $\mathrm{d}\theta$. Let $\{T_\alpha: 1\leqslant\alpha\leqslant n\}$ be a local frame in $T_{1,0}(M)$, defined on an open set $U\subseteq M$. Let $\{\theta^\alpha: 1\leqslant\alpha\leqslant n\}$ be the corresponding *admissible coframe*, i.e, the (locally defined) complex 1-forms determined by $\theta^\alpha(T_\beta)=\delta^\alpha_\beta$, $\theta^\alpha(T_{\bar{\beta}})=0$, and $\theta^\alpha(T)=0$. Here $T_{\bar{\beta}}=\overline{T_\beta}$. Then $\{\theta^\alpha,\theta^{\bar{\alpha}},\theta\}$ is a (local) frame of $T^*(M)\otimes\mathbb{C}$ on U and a $(p,0)$ form η on M may be locally expressed as sums of monomials of the form $\theta^{\alpha_1}\wedge\cdots\wedge\theta^{\alpha_p}$ or $\theta\wedge\theta^{\alpha_1}\wedge\cdots\wedge\theta^{\alpha_{p-1}}$ [with $C^\infty(U)$ coefficients]. Therefore, the top degree complex forms η such that $T_{1,0}(M)\rfloor\eta=0$ are (unlike the case of complex manifolds, where the top degree is the complex dimension) the forms of type $(n+1,0)$ (where n is the CR dimension). Let $K(M)=\Lambda^{n+1,0}(M)\to M$ be the bundle of $(n+1,0)$ forms on M (the *canonical line bundle*). There is a natural action of $\mathbb{R}^+=(0,+\infty)$ on $K(M)\backslash\{zero\ section\}$. Let $C(M)$ be the quotient space and $\pi: C(M)\to M$ the projection. Then $C(M)\to M$ is a principal S^1 bundle (the *canonical circle bundle*). Its locally trivial structure is described by

$$\pi^{-1}(U)\to U\times S^1, \quad [\omega]\mapsto(x,\lambda/|\lambda|),$$

$$\omega=\lambda(\theta\wedge\theta^1\wedge\cdots\wedge\theta^n)_x, \quad x\in U, \quad \lambda\in\mathbb{C}^*=\mathbb{C}\backslash\{0\}.$$

We shall need the local fiber coordinate

$$\gamma:\pi^{-1}(U)\to\mathbb{R}, \quad \gamma([\omega])=\arg(\lambda/|\lambda|),$$

where arg: $S^1\to[0,2\pi)$. Let $(E,\bar{\partial}_E)\to M$ be a CR holomorphic vector bundle. Let h be a Hermitian metric in E. Let $\mathcal{C}(E,h)$ be the affine space of all connections D in E such that $Dh=0$, i.e.

$$X[h(u,v)]=h(D_X u,v)+h(u,D_{\bar{X}}v),$$

for any $X\in T(M)\otimes\mathbb{C}$ and any $u,v\in\Gamma^\infty(E)$. A connection $D\in\mathcal{C}(E,h)$ is *Hermitian* if $D^{0,1}=\bar{\partial}_E$. Here $D^{0,1}u$ is the restriction of Du to $T_{0,1}(M)$. Let $\mathrm{Ad}(E)\to M$ be the subbundle of $\mathrm{End}(E)\to M$ consisting of all skew-symmetric endomorphisms S, i.e., $h(Su,v)+h(u,Sv)=0$, for any $u,v\in\Gamma^\infty(E)$. By a result in Ref. 6 p. 43, given a contact form θ and an endomorphism $S\in\Gamma^\infty[\mathrm{Ad}(E)]$ there is a unique Hermitian connection $D=D(h,\theta,S)$ in E (the *canonical Sconnection*) such that

$$\Lambda_\theta R^D = 2nS. \tag{17}$$

Here $R^D=D\circ D:\Omega^0(E)\to\Omega^2(E)$ is the curvature 2-form of D. Also we set $\Omega^k(E)=\Gamma^\infty[\Lambda^k T^*(M)\otimes E]$, $k\geqslant 0$. If $F\to M$ is a vector bundle and $\varphi\in\Gamma^\infty[T^*(M)\otimes T^*(M)\otimes F]$ the trace $\Lambda_\theta\varphi$ of φ is given by

$$i(\Lambda_\theta\varphi)_x = \sum_{\alpha=1}^{n} \varphi(Z_\alpha, Z_{\bar{\alpha}})_x,$$

where $\{Z_\alpha\}$ is a (local) orthonormal [i.e., $L_\theta(Z_\alpha, Z_{\bar{\beta}}) = \delta_{\alpha\beta}$] frame of $T_{1,0}(M)$ on $U \ni x$. Therefore $\Lambda_\theta\varphi \in \Gamma^\infty(F)$. When $S=0$ the canonical S connection is the *Tanaka connection* $D(h,\theta,0)$ in $E \to M$ (cf. Ref. 29). $D(h,\theta,0)$ is a CR invariant. Assume M to be compact. The *Yang–Mills functional* $\mathcal{YM}:\mathcal{C}(E,h)\to[0,+\infty)$ is given by

$$\mathcal{YM}(D) = \frac{1}{2}\int_M \|R^D\|^2 \theta \wedge (\mathrm{d}\theta)^n.$$

A *Yang–Mills field* on M is a critical point $D \in \mathcal{C}(E,h)$ of $\mathcal{YM}$, i.e., a solution to the Yang–Mills equations

$$\delta^D R^D = 0. \tag{18}$$

Let Ω be a differential 2-form on M. Then Ω is *of type* $(1,1)$ if $\Omega(Z,W)=0$, $\Omega(\bar{Z},\bar{W})=0$, for any $Z, W \in T_{1,0}(M)$, and $i_T\Omega=0$. Let $D \in \mathcal{C}(E,h)$ be a Hermitian connection such that its curvature R^D is a form of type $(1,1)$. By a result in Ref. 30, D is a Yang–Mills field if and only if D is the Tanaka connection $D(h,\theta,0)$. In general, canonical S connections solve the inhomogeneous Yang–Mills equations $\delta^D R^D = f$, in the presence of suitable compatibility conditions satisfied by f (cf. Theorem 2 in Ref. 6, pp. 44–45).

B. Symmetric CR structures

The CR structure $T_{1,0}(M)$ is *symmetric* if there is $X \in \mathcal{X}(M)$ such that

$$\mathcal{L}_X\theta = t\theta, \quad \mathcal{L}_X\theta^\alpha = w^\alpha_\beta\theta^\beta + \ell^\alpha\theta,$$

for some functions $t, w^\alpha_\beta, \ell^\alpha$ on M (t real valued) and X is a *symmetry* of $T_{1,0}(M)$. If

$$\hat{\theta} = e^u\theta, \quad \hat{\theta}^\alpha = U^\alpha_\beta\theta^\beta + v^\alpha\theta,$$

[where $[U^\alpha_\beta]$ is $\mathrm{GL}(n,\mathbb{C})$ valued] and X is a symmetry of the CR structure then

$$\mathcal{L}_X\hat{\theta} = \hat{t}\hat{\theta}, \quad \hat{t} \equiv t + X(u), \tag{19}$$

$$\mathcal{L}_X\hat{\theta}^\alpha = \hat{w}^\alpha_\beta\hat{\theta}^\beta + \hat{\ell}^\alpha\hat{\theta},$$

$$\hat{w}^\alpha_\beta \equiv (U^{-1})^\gamma_\beta[X(U^\alpha_\gamma) + U^\alpha_\rho w^\rho_\gamma],$$

$$\hat{\ell}^\alpha \equiv e^{-u}\{X(v^\alpha) + U^\alpha_\beta\ell^\beta + v^\alpha t - (U^{-1})^\gamma_\rho v^\rho[X(U^\alpha_\gamma) + U^\alpha_\beta w^\beta_\gamma]\}. \tag{20}$$

In particular (19) and (20) show that the notion of symmetric CR structure is globally defined. Assume from now on that the CR structure $T_{1,0}(M)$ admits $2n+1$ linearly independent symmetries $\widetilde{X}_1, \cdots, \widetilde{X}_{2n+1} \in \mathcal{X}(M)$ such that $[\widetilde{X}_i, \widetilde{X}_j] = c^k_{ij}\widetilde{X}_k$, for some $c^k_{ij} \in \mathbb{R}$.

Proposition 1: (Ref. 24) Let M *be a strictly pseudoconvex CR manifold with* $H^1(M;\mathbb{R})=0$. *There is a transformation* $\{\theta,\theta^\alpha\} \mapsto \{\Omega,\Omega^\alpha\}$ of the form

$$\Omega = e^u\theta, \quad \Omega^\alpha = U^\alpha_\beta\theta^\beta + v^\alpha\theta, \tag{21}$$

where $[U^\alpha_\beta]$ is $\mathrm{GL}(n,\mathbb{C})$ valued, such that

$$\mathcal{L}_{\widetilde{X}_i}\Omega = 0, \quad \mathcal{L}_{\widetilde{X}_i}\Omega^\alpha = 0, \quad 1 \leqslant i \leqslant 2n+1.$$

Here $H^1(M;\mathbb{R})$ is the first de Rham cohomology group. Its vanishing guarantees that the solution u to (22) is globally defined.

Proof of Proposition 2: As $\widetilde{X}_i$ are symmetries of the CR structure

$$\mathcal{L}_{\widetilde{X}_i}\theta = t_i\theta, \quad \mathcal{L}_{\widetilde{X}_i}\theta^\alpha = w_{i\beta}^\alpha\theta^\beta + \ell_i^\alpha\theta.$$

We must solve the system of first-order linear Partial different equations

$$t_i + \widetilde{X}_i(u) = 0, \tag{22}$$

$$\widetilde{X}_i(U_\beta^\alpha) + U_\gamma^\alpha w_{i\beta}^\gamma = 0, \tag{23}$$

$$\widetilde{X}_i(v^\alpha) + U_\beta^\alpha\ell_i^\beta + v^\alpha t_i = 0, \tag{24}$$

with the unknowns u, U_β^α, and v^α. Let $\eta \in \Omega^1(M)$ be defined by $\eta(\widetilde{X}_i) = t_i$, $1 \leqslant i \leqslant 2n+1$. Then (22) may be written $du + \eta = 0$. We have

$$\mathcal{L}_{\widetilde{X}_i}\mathcal{L}_{\widetilde{X}_j}\theta = \mathcal{L}_{\widetilde{X}_j}\mathcal{L}_{\widetilde{X}_i}\theta + \mathcal{L}_{[\widetilde{X}_i,\widetilde{X}_j]}\theta$$

hence

$$\widetilde{X}_i(t_j) - \widetilde{X}_j(t_i) - c_{ij}^k t_k = 0$$

that is $d\eta = 0$. Thus there is a globally defined real valued function $g \in C^\infty(M)$ such that $\eta = dg$ and $u \equiv -g$ solves (22). Next, we consider the (locally defined) 1-forms η_β^α and η^α given by

$$\eta_\beta^\alpha(\widetilde{X}_i) = w_{i\beta}^\alpha, \quad \eta^\alpha(\widetilde{X}_i) = \ell_i^\alpha, \quad 1 \leqslant i \leqslant 2n+1.$$

Then (23) and (24) may be written

$$dU_\beta^\alpha + U_\gamma^\alpha\eta_\beta^\gamma = 0, \tag{25}$$

$$dv^\alpha + v^\alpha\eta + U_\beta^\alpha\eta^\beta = 0. \tag{26}$$

Assuming that (25) has been solved in a neighborhood U of each point, let us solve (26). Multiplying in both sides by e^{-u} [where u is a solution to (22)] leads to

$$d(e^{-u}v^\alpha) + e^{-u}U_\beta^\alpha\eta^\beta = 0.$$

Therefore, to prove existence of a (local) solution v^α to (26) it suffices to show that $e^{-u}U_\beta^\alpha\eta^\beta$ is exact (in a neighborhood of a point). The identity

$$\mathcal{L}_{\widetilde{X}_i}\mathcal{L}_{\widetilde{X}_j}\theta^\alpha = \mathcal{L}_{\widetilde{X}_j}\mathcal{L}_{\widetilde{X}_i}\theta^\alpha + \mathcal{L}_{[\widetilde{X}_i,\widetilde{X}_j]}\theta^\alpha$$

yields

$$d\eta_\beta^\alpha = \eta_\gamma^\alpha \wedge \eta_\beta^\gamma, \tag{27}$$

$$d\eta^\alpha = \eta_\beta^\alpha \wedge \eta^\beta + \eta^\alpha \wedge \eta. \tag{28}$$

Let U_β^α be a solution to (25). Then [by (28)]

$$d(e^{-u}U^{\alpha}_{\beta}\eta^{\beta}) = e^{-u}(\mathrm{d}U^{\alpha}_{\beta}\wedge\eta^{\beta} + U^{\alpha}_{\beta}\mathrm{d}\eta^{\beta} - U^{\alpha}_{\beta}\mathrm{d}u\wedge\eta^{\beta}) = e^{-u}U^{\alpha}_{\beta}(\mathrm{d}\eta^{\beta} - \eta^{\beta}_{\gamma}\wedge\eta^{\gamma} - \eta^{\beta}\wedge\eta) = 0.$$

Thus there is a function $f^{\alpha}\in C^{\infty}(U)$ such that $e^{-u}U^{\alpha}_{\beta}\eta^{\beta}=\mathrm{d}f^{\alpha}$ and $v^{\alpha}\equiv -e^{u}f^{\alpha}$ solves (26). To solve (25) let (U,x^{i}) be a normal coordinate neighborhood at a point $x_0\in M$ (we think of M as a Riemannian manifold with the Webster metric g_{θ}). We shall show that for any $c^{\alpha}_{\beta}\in\mathbb{C}$ there is a unique solution to (25) with the initial condition $U^{\alpha}_{\beta}(x_0)=c^{\alpha}_{\beta}$. Let $a=(a^{1},\cdots,a^{2n+1})\in U$ be an arbitrary point and let us consider the geodesic $a_t=(a^{1}t,\cdots,a^{2n+1}t)$. Let $f^{\alpha}_{\beta}(t)$ be the solution to the Cauchy problem for the system of ordinary differential equations

$$\frac{df^{\alpha}_{\beta}}{dt} + f^{\alpha}_{\gamma}(t)\,\eta^{\gamma}_{\beta}(\dot{a}_t) = 0,$$

with the initial condition $f^{\alpha}_{\beta}(0)=c^{\alpha}_{\beta}$, where $\dot{a}_t$ is the tangent vector at a_t. We define $U^{\alpha}_{\beta}\in C^{\infty}(U)$ by setting $U^{\alpha}_{\beta}(a)=f^{\alpha}_{\beta}(1)$. Of course, if we start with $\det(c^{\alpha}_{\beta})\neq 0$ then $[U^{\alpha}_{\beta}]$ is $\mathrm{GL}(m,\mathbb{C})$ valued on a neighborhood of x_0. We wish to show that U^{α}_{β} satisfies (25), i.e.

$$Y(U^{\alpha}_{\beta}) + U^{\alpha}_{\gamma}(a)\,\eta^{\gamma}_{\beta,a}(Y) = 0, \tag{29}$$

for any $Y=b^{j}(\partial/\partial x^{j})_{a}\in T_a(M)$. We start by extending Y to the vector field $Y=b^{j}\partial/\partial x^{j}$ with constant components b^{j} on U. Similarly, let us extend the vector field $\dot{a}_t$ along the geodesic a_t to the vector field $X=a^{i}\partial/\partial x^{i}$. We shall show that along a_t

$$X[Y(U^{\alpha}_{\beta}) + U^{\alpha}_{\rho}\eta^{\rho}_{\beta}(Y)] + [Y(U^{\alpha}_{\gamma}) + U^{\alpha}_{\rho}\eta^{\rho}_{\gamma}(Y)]\eta^{\gamma}_{\beta}(X) = 0. \tag{30}$$

When this is done, we see that $Y(U^{\alpha}_{\beta})+U^{\alpha}_{\rho}\eta^{\rho}_{\beta}(Y)$, clearly satisfying $Y(U^{\alpha}_{\beta})+U^{\alpha}_{\rho}\eta^{\rho}_{\beta}(Y)=0$ at x_0, must be the zero function [which satisfies (30) with the same initial condition], i.e. (29) is verified. It remains that we prove (30). This follows from (27). Indeed (as $[X,Y]=0$)

$$X[\eta^{\alpha}_{\beta}(Y)] = Y[\eta^{\alpha}_{\beta}(X)] + \eta^{\alpha}_{\gamma}(X)\,\eta^{\gamma}_{\beta}(Y) - \eta^{\alpha}_{\gamma}(Y)\,\eta^{\gamma}_{\beta}(X)$$

and the proof of (30) is straightforward. Proposition 1 is a first step toward recovering the methods of Nurowski,[24] (eventually leading to local solutions of the Yang–Mills equations on $[C(M),F_{\theta}]$) as mentioned in Sec. I. The result in Proposition 1 may be refined to show that there is a coframe $\{\Omega,\Omega^{\alpha}\}$ such that

$$\mathcal{L}_{\tilde{X}_i}\Omega = 0, \quad \mathcal{L}_{\tilde{X}_i}\Omega^{\alpha} = 0, \quad d\Omega = 2i\sum_{\alpha=1}^{n}\Omega^{\alpha}\wedge\Omega^{\bar{\alpha}}$$

[compare to Eq. (2) in Sec. I]. The proof is illustrative of the local methods in pseudohermitian geometry. Let $\{\Omega,\Omega^{\alpha}\}$ be the 1-forms furnished by Proposition 21, given by a transformation of the form (21). If $\{T,T_{\alpha}\}$ is such that $\theta(T)=1$, $i_T\,\mathrm{d}\theta=0$, and $\theta^{\alpha}(T_{\beta})=\delta^{\alpha}_{\beta}$, $\theta^{\alpha}(T_{\bar{\beta}})=0$, $\theta^{\alpha}(T)=0$, let us set $W_{\alpha}=(U^{-1})^{\beta}_{\alpha}T_{\beta}$. One may easily show that

$$\mathrm{d}\Omega = 2iG_{\alpha\bar{\beta}}\Omega^{\alpha}\wedge\Omega^{\bar{\beta}} + \Phi\wedge\Omega, \tag{31}$$

where $G_{\alpha\bar{\beta}}=e^{u}(U^{-1})^{\gamma}_{\alpha}U^{\bar{\rho}}_{\bar{\beta}}g_{\gamma\bar{\rho}}$ and $\Phi=e^{-u}[W_{\alpha}(u)\Omega^{\alpha}+W_{\bar{\alpha}}(u)\Omega^{\bar{\alpha}}]$. By $\mathcal{L}_X=d\circ i_X+i_X\circ d$ it follows that $\mathcal{L}_{\tilde{X}_i}d\Omega=0$. Taking the Lie derivative of (31) gives

$$0 = \mathcal{L}_{\tilde{X}_i}\mathrm{d}\Omega = 2\sqrt{-1}\,\mathcal{L}_{\tilde{X}_i}(G_{\alpha\bar{\beta}})\Omega^{\alpha}\wedge\Omega^{\bar{\beta}} + (\mathcal{L}_{\tilde{X}_i}\Phi)\wedge\Omega$$

hence (as $\mathcal{L}_{\tilde{X}_i}\Phi\equiv 0$, mod Ω) on one hand $\tilde{X}_i(G_{\alpha\bar{\beta}})=0$, i.e., $G_{\alpha\bar{\beta}}=a_{\alpha\bar{\beta}}\in\mathbb{C}$, and on the other $\mathcal{L}_{\tilde{X}_i}\Phi=0$. The latter may be written $\mathrm{d}u_{\alpha}-u_{\alpha}\,\mathrm{d}u=0$ [where $u_{\alpha}=W_{\alpha}(u)$]. Hence $d(e^{-u}u_{\alpha})=0$, i.e., $u_{\alpha}=c_{\alpha}e^{u}$, for some $c_{\alpha}\in\mathbb{C}$. Therefore $\Phi=c_{\alpha}\Omega^{\alpha}+c_{\bar{\alpha}}\Omega^{\bar{\alpha}}$. Finally, let $[b^{\alpha}_{\beta}]$ be a square root of $[a_{\alpha\bar{\beta}}]$ (as $[a_{\alpha\bar{\beta}}]$ is positive definite) and consider the transformation

$$\hat{\Omega}^{\alpha} = b^{\alpha}_{\beta}\Omega^{\beta} + \frac{i}{2}c_{\bar{\beta}}(b^{-1})^{\bar{\beta}}_{\bar{\alpha}}\Omega.$$

Then $d\Omega = 2i\ \Sigma_{\alpha=1}^{n}\hat{\Omega}^{\alpha}\wedge\hat{\Omega}^{\bar{\alpha}}$ and $\mathcal{L}_{\tilde{X}_i}\hat{\Omega}^{\alpha}=0$. Q.E.D.

IV. BOUNDARY VALUES OF YANG–MILLS FIELDS

Let $\Omega\subset\mathbb{C}^n$ be a bounded domain with smooth boundary $\partial\Omega$, i.e., there is a neighborhood $U\supset\bar{\Omega}$ and a real valued function $\varphi\in C^{\infty}(U)$ such that $\Omega=[z\in U:\varphi(z)<0]$, $\partial\Omega=[z\in U:\varphi(z)=0]$, and $\nabla\varphi(z)\neq 0$, for any $z\in\partial\Omega$. We assume that Ω is strictly pseudoconvex, i.e., $\partial\Omega$ is a strictly pseudoconvex CR manifold (with the natural CR structure $T_{1,0}(\partial\Omega)=T^{1,0}(\mathbb{C}^n)\cap[T(\partial\Omega)\otimes\mathbb{C}]$ induced by the complex structure of the ambient space).

Let $\pi:F\to U$ be a holomorphic vector bundle. The portion $E=\pi^{-1}(\partial\Omega)$ of F over the boundary of Ω is CR holomorphic. Indeed, as F is holomorphic, there is a natural differential operator

$$\bar{\partial}_F:\Gamma^{\infty}(F)\to\Gamma^{\infty}[T^{0,1}(U)^{*}\otimes F]$$

where $T^{0,1}(U)$ is the antiholomorphic tangent bundle over U. Given $u\in\Gamma^{\infty}(E)$ let $\tilde{u}\in\Gamma^{\infty}(F)$ be a C^{∞} extension of u as a cross section in F and set $(\bar{\partial}_E u)_z=(\bar{\partial}_F\tilde{u})_z$ for any $z\in\partial\Omega$. The definition of $(\bar{\partial}_E u)_z$ does not depend upon the choice of extension $\tilde{u}$ of u because $(\bar{\partial}f)|_{T_{0,1}(\partial\Omega)}=\bar{\partial}_b(f|_{\partial\Omega})$ for any C^{∞} function $f:U\to\mathbb{C}$. Let $\{\Phi_{\alpha}:\pi^{-1}(\Omega_{\alpha})\to\Omega_{\alpha}\times\mathbb{C}^m:\alpha\in I\}$ be a trivialization atlas for F and $G_{\beta\alpha}:\Omega_{\beta}\cap\Omega_{\alpha}\to\mathrm{GL}(m,\mathbb{C})$ the corresponding transition functions. Set $U_{\alpha}=\Omega_{\alpha}\cap\partial\Omega$ and $g_{\beta\alpha}=G_{\beta\alpha}|_{U_{\alpha}\cap U_{\beta}}$. As $G_{\beta\alpha}$ are holomorphic, it follows that $E\to\partial\Omega$ is a peculiar type of CR-holomorphic vector bundle (called *locally trivial* by Le Brun[17]) in that its transition functions $g_{\beta\alpha}$ are matrix valued CR functions on $\partial\Omega$.

Let $K(\zeta,z)$ be the Bergman kernel of Ω. By a classical result in Ref. 8

$$K(\zeta,z)=c_{\Omega}|\nabla\varphi(z)|^2\cdot\det L_{\varphi}(z)\cdot\Psi(\zeta,z)^{-(n+1)}+H(\zeta,z), \tag{32}$$

(the *Fefferman asymptotic expansion formula* for the Bergman kernel) where $H\in C^{\infty}(\bar{\Omega}\times\bar{\Omega}\backslash\Delta)$, Δ is the diagonal of $\partial\Omega\times\partial\Omega$, and H satisfies the estimate

$$|H(\zeta,z)|\leqslant c'_{\Omega}|\Psi(\zeta,z)|^{-(n+1)+1/2}\cdot|\log|\Psi(\zeta,z)||. \tag{33}$$

Here $L_{\varphi}=\partial\bar{\partial}\varphi$. Also we set

$$\Psi(\zeta,z)=[F(\zeta,z)-\varphi(z)]\chi(|\zeta-z|)+[1-\chi(|\zeta-z|)]|\zeta-z|^2$$

where

$$F(\zeta,z)=-\sum_{j=1}^{n}\frac{\partial\varphi}{\partial z^j}(z)(\zeta^j-z^j)-\frac{1}{2}\sum_{j,k=1}^{n}\frac{\partial^2\varphi}{\partial z^j\partial z^k}(z)(\zeta^j-z^j)(\zeta^k-z^k)$$

and $\chi(t)$ is a C^{∞} cutoff function with $\chi(t)=1$ for $|t|<\epsilon_0/2$ and $\chi(t)=0$ for $|t|\geqslant 3\epsilon_0/4$. As a consequence of (32)

$$K(z,z)^{-1/(n+1)}=|\varphi(z)|[\Phi(z)+H(z,z)|\varphi(z)|^{n+1}]^{-1/(n+1)}$$

where $\Phi(z)\equiv c_{\Omega}|\nabla\varphi(z)|^2\det L_{\varphi}(z)$ stays finite near $\partial\Omega$ and [by (33)]

$$|H(z,z)||\varphi(z)|^{n+1}\leqslant c'_{\Omega}|\varphi(z)|^{1/2}|\log|\varphi(z)||\to 0,\quad as\ z\to\partial\Omega.$$

Therefore $K(z,z)^{-1/(n+1)}$ vanishes at $\partial\Omega$. Also, as $\Phi(z)\neq 0$ near the boundary, $\nabla K(z,z)^{-1/(n+1)}\neq 0$ along $\partial\Omega$, hence $K(z,z)^{-1/(n+1)}$ may be used as a defining function for Ω.

For the rest of this section we assume that $\varphi(z)\equiv -K(z,z)^{-1/(n+1)}$ and set $\theta\equiv(i/2)(\bar{\partial}-\partial)\varphi$. Then $\mathrm{d}\theta=i\partial\bar{\partial}\varphi$. Let us differentiate $\log|\varphi|=-[1/(n+1)]\log K$ [where K is short for $K(z,z)$] so that to obtain

$$\frac{1}{\varphi}\bar{\partial}\varphi=-\frac{1}{n+1}\bar{\partial}\log K.$$

Applying the operator $i\partial$ leads to

$$\frac{1}{\varphi}d\theta-\frac{i}{\varphi^2}\partial\varphi\wedge\bar{\partial}\varphi=-\frac{i}{n+1}\partial\bar{\partial}\log K. \tag{34}$$

We shall need the Bergman metric

$$g=\frac{\partial^2\log K}{\partial z^j\partial\bar{z}^k}\mathrm{d}z^j\odot\mathrm{d}\bar{z}^k.$$

As is well known, g is a Kähler metric on Ω (Kähler–Einstein when Ω is homogeneous). Here $\odot$ denotes the symmetric tensor product, i.e., $\alpha\odot\beta=\frac{1}{2}(\alpha\otimes\beta+\beta\otimes\alpha)$. Let us set $\omega(X,Y)=g(X,JY)$ [the Kähler 2-form of (Ω,J,g), where J is the underlying complex structure]. Then $\omega=-i\partial\bar{\partial}\log K$ and (34) may be written

$$g(X,Y)=\frac{n+1}{\varphi}\left[\frac{i}{\varphi}(\partial\varphi\wedge\bar{\partial}\varphi)(X,JY)-d\theta(X,JY)\right], \tag{35}$$

for any $X,Y\in\mathcal{X}(\Omega)$.

We denote by $M_\delta=\{z\in\Omega:\varphi(z)=-\delta\}$ ($\delta>0$) the level sets of φ. For δ sufficiently small M_δ is still a strictly pseudoconvex CR manifold (of CR dimension $n-1$). Therefore, there is a one-sided neighborhood V of $\partial\Omega$ which is foliated by the (strictly pseudoconvex) level sets of φ. Let $\mathcal{F}$ be the relevant foliation and let us denote by $H(\mathcal{F})\to V$ [respectively, by $T_{1,0}(\mathcal{F})\to V$] the bundle whose portion over M_δ is the Levi distribution $H(M_\delta)$ [respectively, the CR structure $T_{1,0}(M_\delta)$]. Note that

$$T_{1,0}(\mathcal{F})\cap T_{0,1}(\mathcal{F})=(0),$$

$$\{\Gamma^\infty[T_{1,0}(\mathcal{F})],\Gamma^\infty[T_{1,0}(\mathcal{F})]\}\subseteq\Gamma^\infty[T_{1,0}(\mathcal{F})].$$

Here $T_{0,1}(\mathcal{F})=\overline{T_{1,0}(\mathcal{F})}$. By a result in,[20] there is a unique complex vector field ξ on V, of type (1,0), such that $\partial\varphi(\xi)=1$ and ξ is orthogonal to $T_{1,0}(\mathcal{F})$ with respect to $\partial\bar{\partial}\varphi$, i.e., $\partial\bar{\partial}\varphi(\xi,\bar{Z})=0$, for any $Z\in T_{1,0}(\mathcal{F})$. We set $r\equiv 2\partial\bar{\partial}\varphi(\xi,\bar{\xi})$ (r is the *transverse curvature* of φ). Let $\xi=\frac{1}{2}(N-iT)$ be the real and imaginary parts of ξ. Then

$$(d\varphi)(N)=2,\quad (d\varphi)(T)=0,$$

$$\theta(N)=0,\quad \theta(T)=1,$$

$$\partial\varphi(N)=1,\quad \partial\varphi(T)=i.$$

In particular, T is tangent to (the leaves of) $\mathcal{F}$. $\mathcal{F}$ carries the tangential Riemannian metric g_θ [defined by (A1) in the Appendix]. Note that the pullback of g_θ to each leaf M_δ of $\mathcal{F}$ is the Webster metric of M_δ (associated to the contact form $j_\delta^*\theta$, where $j_\delta:M_\delta\subset V$). As a consequence of (35)

$$g(X,Y) = -\frac{n+1}{\varphi} g_\theta(X,Y), \quad X,Y \in H(\mathcal{F}). \tag{36}$$

Also (by $JT=-N$ and (A4))

$$g(X,T) = 0, \quad g(X,N) = 0, \quad X \in H(\mathcal{F}), \tag{37}$$

$$g(T,N) = 0, \quad g(T,T) = g(N,N) = \frac{n+1}{\varphi}\left(\frac{1}{\varphi} - r\right). \tag{38}$$

In particular $1-r\varphi>0$ everywhere in Ω. Using (36)–(38) we may relate the Levi–Civita connection ∇^g of (V,g) to the Graham–Lee connection ∇ (see the Appendix). By (36) [as $X(\varphi)=0$, $X \in T(\mathcal{F})$]

$$g(\nabla^g_X Y, Z) = g(\nabla_X Y, Z), \quad X,Y,Z \in H(\mathcal{F}). \tag{39}$$

Note that any tangent vector field $X \in T(V)$ decomposes as

$$X = \pi_H X + \theta(X)T + \frac{1}{2}(d\varphi)(X)N,$$

[$\pi_H : T(V) \to H(\mathcal{F})$ is the projection]. By (A3) $\theta([T,X])=0$, $X \in H(\mathcal{F})$. Also $[T,X] \in T(\mathcal{F})$, hence $[T,X] \in H(\mathcal{F})$, for any $X \in H(\mathcal{F})$. Taking into account the identity

$$2g(\nabla^g_X Y, Z) = X(g(Y,Z)) + Y[g(X,Z)] - Z(g(X,Y)) + g([X,Y],Z) + g([Z,X],Y) + g(X,[Z,Y]), \tag{40}$$

for any $X,Y,Z \in T(V)$, one has [by (37)]

$$2g(\nabla^g_X Y, T) = -T[g(X,Y)] + g[(X,Y),T] + g[(T,X),Y] + g[X,(T,Y)] = \frac{n+1}{\varphi}\{T[g_\theta(X,Y)]$$

$$- g_\theta[(T,X),Y] - g_\theta[X,(T,Y)]\} + \frac{n+1}{\varphi}\left(\frac{1}{\varphi} - r\right)\theta[(X,Y)],$$

for any $X,Y \in H(\mathcal{F})$. By (A13) and (A14) and $\nabla_X Y \in H(\mathcal{F})$ it follows that

$$T[g_\theta(X,Y)] - g_\theta[(T,X),Y] - g_\theta[X,(T,Y)] = 2g_\theta(\tau X, Y)$$

[note that one makes use of the fact that $\tau : H(\mathcal{F}) \to H(\mathcal{F})$ is self-adjoint, i.e., $g_\theta(\tau X, Y) = g_\theta(X, \tau Y)$, $X,Y \in H(\mathcal{F})$] hence

$$g(\nabla^g_X Y, T) = -g(\tau X, Y) - \frac{n+1}{\varphi}\left(\frac{1}{\varphi} - r\right)(\mathrm{d}\theta)(X,Y)$$

or

$$g(\nabla^g_X Y, T) = -g(\tau X, Y) - \left(\frac{1}{\varphi} - r\right)g(X, \phi Y), \tag{41}$$

for any $X,Y \in H(\mathcal{F})$. Exploiting again $\nabla^g g=0$ (and $g[(X,Y),N]=0$) we get

$$2g(\nabla^g_X Y, N) = -(\mathcal{L}_N g)(X,Y), X,Y \in H(\mathcal{F}).$$

Hence [by (A23) in Lemma 4]

$$2g(\nabla^g_X Y,N) = -\frac{n+1}{\varphi^2}N(\varphi)g_\theta(X,Y) + \frac{n+1}{\varphi}(\mathcal{L}_N g_\theta)(X,Y) = 2\left(\frac{1}{\varphi} - r\right)g(X,Y) + \frac{2(n+1)}{\varphi}(\mathrm{d}\theta)(X,\tau Y)$$

that is

$$g(\nabla^g_X Y,N) = \left(\frac{1}{\varphi} - r\right)g(X,Y) + g(X,\phi\tau Y), \tag{42}$$

for any $X,Y \in H(\mathcal{F})$. Note that (42) may be also derived from (41) by using the fact that g is a Kähler metric. Indeed

$$g(\nabla^g_X Y,N) = g(J\nabla^g_X Y,JN) = g(\nabla^g_X JY,T) = -g(\tau X,\phi Y) - \left(\frac{1}{\varphi} - r\right)g(X,\phi^2 Y),$$

etc. For further use, let us also remember that

$$(\mathcal{L}_N g)(X,Y) = -2\left(\frac{1}{\varphi} - r\right)g(X,Y) - 2g(X,\phi\tau Y), \tag{43}$$

for any $X,Y \in H(\mathcal{F})$. At this point, the identities (39) and (41) and (42) lead to

$$\nabla^g_X Y = \nabla_X Y + \left[\frac{\varphi}{1-\varphi r}g_\theta(\tau X,Y) + g_\theta(X,\phi Y)\right]T - \left[g_\theta(X,Y) + \frac{\varphi}{1-\varphi r}g_\theta(X,\phi\tau Y)\right]N, \tag{44}$$

for any $X,Y \in H(\mathcal{F})$. To compute $\nabla^g_X T$ we use (44) and

$$g(\nabla^g_X T,Y) = -g(T,\nabla^g_X Y)$$

so that

$$g(\nabla^g_X T,Y) = g(\tau X,Y) + \left(\frac{1}{\varphi} - r\right)g(X,\phi Y). \tag{45}$$

The component along T is $\frac{1}{2}X(\|T\|^2)$ hence

$$g(\nabla^g_X T,T) = -\frac{n+1}{2\varphi}X(r). \tag{46}$$

Moreover [by (A5) in the Appendix A]

$$2g(\nabla^g_X T,N) = g[X,(N,T)] = -g(X,\phi\nabla^H r)$$

that is

$$g(\nabla^g_X T,N) = -\frac{n+1}{2\varphi}(\phi X)(r). \tag{47}$$

Summing up [by (45)–(47)]

$$\nabla^g_X T = \tau X - \left(\frac{1}{\varphi} - r\right)\phi X - \frac{\varphi}{2(1-r\varphi)}[X(r)T + (\phi X)(r)N], \tag{48}$$

for any $X \in H(\mathcal{F})$. Again by (44) and

$$g(\nabla^g_X N,Y) = -g(N,\nabla^g_X Y)$$

we get

$$g(\nabla^g_X N, Y) = -\left(\frac{1}{\varphi} - r\right) g(X,Y) - g(X, \phi\tau Y). \tag{49}$$

Next [by (A5)]

$$g(\nabla^g_X N, T) = \frac{n+1}{2\varphi}(\phi X)(r). \tag{50}$$

Finally, the component along N is $\frac{1}{2}X(\|N\|^2)$ hence

$$g(\nabla^g_X N, N) = -\frac{n+1}{2\varphi} X(r). \tag{51}$$

Summing up [by (49)–(51)]

$$\nabla^g_X N = -\left(\frac{1}{\varphi} - r\right) X + \tau\phi X + \frac{\varphi}{2(1-r\varphi)}[(\phi X)(r) T - X(r) N], \tag{52}$$

for any $X \in H(\mathcal{F})$. We wish to compute $\nabla^g_T X$. To this end (by $\nabla g_\theta = 0$)

$$2g_\theta(\nabla_T X, Y) = T[g_\theta(X,Y)] + g_\theta[(T,X),Y] + g_\theta[(Y,T),X] + g_\theta[T,(Y,X)] + g_\theta(\tau X, Y) - g_\theta(\tau Y, X) - 2(\mathrm{d}\theta)(X,Y)$$

yielding [upon multiplication by $-(n+1)/\varphi$]

$$T[g(X,Y)] + g[(T,X),Y] + g[(Y,T),X] = 2g(\nabla_T X, Y).$$

Therefore (by $\nabla^g g = 0$)

$$2g(\nabla^g_T X, Y) = T[g(X,Y)] + g[(T,X),Y] + g[(Y,T),X] + g[T,(Y,X)] = 2g(\nabla_T X, Y) - \theta[(X,Y)]\|T\|^2$$

or

$$g(\nabla^g_T X, Y) = g(\nabla_T X, Y) + \left(\frac{1}{\varphi} - r\right) g(X, \phi Y). \tag{53}$$

Similar to the above

$$g(\nabla^g_T X, T) = -\frac{n+1}{2\varphi} X(r), \tag{54}$$

$$g(\nabla^g_T X, N) = -\frac{n+1}{2\varphi}(\phi X)(r). \tag{55}$$

Collecting the information in (53)–(55), we have proved

$$\nabla^g_T X = \nabla_T X - \left(\frac{1}{\varphi} - r\right)\phi X - \frac{\varphi}{2(1-r\varphi)}[X(r) T + (\phi X)(r) N], \tag{56}$$

for any $X \in H(\mathcal{F})$. Let us compute $\nabla^g_N X$. We have

$$2g(\nabla^g_N X, Y) = N[g(X,Y)] + g[(N,X),Y] + g[(Y,N),X] = 2g[(N,X),Y] + (\mathcal{L}_N g)(X,Y).$$

Using (43) and

$$(N,X) = \nabla_N X - rX - \tau(\phi X)$$

(see the Appendix) one shows that

$$g(\nabla^g_N X, Y) = g(\nabla_N X, Y) - \frac{1}{\varphi} g(X, Y). \tag{57}$$

Calculations similar to the above also furnish

$$g(\nabla^g_N X, T) = \frac{n+1}{2\varphi}(\phi X)(r), \tag{58}$$

$$g(\nabla^g_N X, N) = -\frac{n+1}{2\varphi} X(r). \tag{59}$$

Using (57)–(59) we may now conclude that

$$\nabla^g_N X = \nabla_N X - \frac{1}{\varphi} X + \frac{\varphi}{2(1-r\varphi)}[(\phi X)(r) T - X(r) N], \tag{60}$$

for any $X \in H(\mathcal{F})$. Moreover (omitting the details)

$$g(\nabla^g_N T, X) = -\frac{n+1}{2\varphi}(\phi X)(r),$$

$$g(\nabla^g_N T, T) = -\frac{n+1}{2\varphi}\left(N(r) + \frac{4}{\varphi^2} - \frac{2r}{\varphi}\right),$$

$$g(\nabla^g_N T, N) = -\frac{n+1}{2\varphi} T(r),$$

so that

$$\nabla^g_N T = -\frac{1}{2}\phi \nabla^H r - \frac{\varphi}{2(1-r\varphi)}\left[\left(N(r) + \frac{4}{\varphi^2} - \frac{2r}{\varphi}\right) T + T(r) N\right]. \tag{61}$$

Similarly we find

$$\nabla^g_T N = \frac{1}{2}\phi \nabla^H r - \frac{\varphi}{2(1-r\varphi)}\left[\left(N(r) + \frac{4}{\varphi^2} - \frac{6r}{\varphi} + 4r^2\right) T + T(r) N\right], \tag{62}$$

$$\nabla^g_T T = -\frac{1}{2}\nabla^H r - \frac{\varphi}{2(1-r\varphi)}\left[T(r) T - \left(N(r) + \frac{4}{\varphi^2} - \frac{6r}{\varphi} + 4r^2\right) N\right], \tag{63}$$

$$\nabla^g_N N = -\frac{1}{2}\nabla^H r + \frac{\varphi}{2(1-r\varphi)}\left[T(r) T - \left(N(r) + \frac{4}{\varphi^2} - \frac{2r}{\varphi}\right) N\right]. \tag{64}$$

Let us consider a holomorphic vector bundle $\pi: F \to U$, carrying the Hermitian metric h, and set $E_\delta = \pi^{-1}(M_\delta)$ (the portion of F over a leaf of $\mathcal{F}$). A connection $D \in \mathcal{C}(F, h)$ induces a connection $D^\delta \in \mathcal{C}(E_\delta, h_\delta)$ (where $h_{\delta,z} = h_z$, $z \in M_\delta$). D^δ is most easily described with respect to a local trivialization $\Phi: \pi^{-1}(O) \to O \times C^m$ of F, for some open subset $O \subseteq U$. Let us set $\sigma_i(z) = \Phi^{-1}(z, e_i)$, $z \in O$, $1 \leqslant i \leqslant m$, where $\{e_1, \cdots, e_m\}$ is the canonical linear basis in C^m. If $u_i \equiv \sigma_i|_{O \cap M_\delta}$ then D^δ is given by

$$(D_X^{\delta}u)_z = X(f^i)_z u_i(z) + f^i(z)(D_{(dj_{\delta})X}\sigma_i)_z, \quad z \in O \cap M_{\delta},$$

for any section $u=f^i u_i$, $f^i \in C^{\infty}(O \cap M_{\delta})$, and any $X \in \mathcal{X}(M_{\delta})$. It is easily shown that the definition of $(D_X^{\delta}u)_z$ doesn't depend upon the local trivialization chart Φ at z [i.e., if $g=[g_{ij}]: O \cap O' \to \mathrm{GL}(m,C)$, $g(z)=\Phi'_z \circ \Phi_z^{-1}$, are the transition functions of F then $(D_X^{\delta}u)_z$ is invariant under the transformation $\sigma_j(z)=g_j^i(z)\sigma'_i(z)$]. Let $R^D \in \Omega^2[\mathrm{Ad}(F)]$ and ω_j^i be the curvature tensor field and connection 1-forms of D ($D\sigma_j=\omega_j^i \otimes \sigma_i$), so that $R^D\sigma_j=2(d\omega_j^i-\omega_k^i \wedge \omega_j^k)\otimes\sigma_i$. Also, let $R^{\delta} \in \Omega^2[\mathrm{Ad}(E_{\delta})]$ and $(\omega_{\delta})_j^i$ be the curvature tensor field and the connection 1-forms of D^{δ}, respectively. Then $(\omega_{\delta})_j^i=j_{\delta}^*\omega_j^i$ yields

$$R^{\delta}u_i = (j_{\delta}^* R^D)\sigma_i, \quad 1 \leqslant i \leqslant m. \tag{65}$$

Let $\{W_{\alpha}\}$ be a local orthonormal $[g_{\theta}(W_{\alpha}, W_{\bar{\beta}})=\delta_{\alpha\beta}]$ frame of $T_{1,0}(\mathcal{F})$ and set

$$E_{\alpha} \equiv \sqrt{-\frac{\varphi}{n+1}}W_{\alpha}, \quad 1 \leqslant \alpha \leqslant n-1, \quad E_n \equiv \sqrt{\frac{2f\varphi}{n+1}}\xi,$$

where $f \equiv \varphi/(1-r\varphi)$. Then, given a connection D in $F \to U$, for any $X \in H(M_{\delta})$

$$(\delta^D R^D)X = -\sum_{a=1}^{n}[(D_{E_a}R^D)(E_{\bar{a}},X)+(D_{E_{\bar{a}}}R^D)(E_a,X)] = \frac{\varphi}{n+1}\sum_{\alpha=1}^{n-1}[(D_{W_{\alpha}}R^D)(W_{\bar{\alpha}},X)+(D_{W_{\bar{\alpha}}}R^D)$$
$$\times(W_{\alpha},X)] - \frac{2f\varphi}{n+1}[(D_{\xi}R^D)(\bar{\xi},X)+(D_{\bar{\xi}}R^D)(\xi,X)]$$

and

$$\sum_{\alpha=1}^{n-1}(D_{W_{\alpha}}R^D)(W_{\bar{\alpha}},X)\sigma_j = \sum_{\alpha}[D_{W_{\alpha}}(R^D(W_{\bar{\alpha}},X)\sigma_j) - R^D(W_{\bar{\alpha}},X)D_{W_{\alpha}}\sigma_j - R^D(\nabla^g_{W_{\alpha}}W_{\bar{\alpha}},X)\sigma_j$$
$$- R^D(W_{\bar{\alpha}},\nabla^g_{W_{\alpha}}X)\sigma_j] = [by\ (44)] = \sum_{\alpha}\{(D^{\delta}_{W_{\alpha}}R^{\delta})(W_{\bar{\alpha}},X)u_j - [fg_{\theta}(\tau W_{\alpha},W_{\bar{\alpha}})$$
$$+ g_{\theta}(W_{\alpha},\phi W_{\bar{\alpha}})]R^D(T,X)\sigma_j + [g_{\theta}(W_{\alpha},W_{\bar{\alpha}}) + fg_{\theta}(W_{\alpha},\phi\tau W_{\bar{\alpha}})]R^D(N,X)\sigma_j$$
$$- [fg_{\theta}(\tau W_{\alpha},X) + g_{\theta}(W_{\alpha},\phi X)]R^D(W_{\bar{\alpha}},T)\sigma_j + [g_{\theta}(W_{\alpha},X)$$
$$+ fg_{\theta}(W_{\alpha},\phi\tau X)]R^D(W_{\bar{\alpha}},N)\sigma_j\}.$$

Therefore [by the purity axiom (A6)]

$$\sum_{\alpha}(D_{W_{\alpha}}R^D)(W_{\bar{\alpha}},X) = \sum_{\alpha}(D^{\delta}_{W_{\alpha}}R^{\delta})(W_{\bar{\alpha}},X)u_j + i(n-1)R^D(T,X)\sigma_j + (n-1)R^D(N,X)\sigma_j$$
$$- fR^D(\pi_{0,1}\tau X,T) - R^D(\pi_{0,1}\phi X,T) + R^D(\pi_{0,1}X,N) + fR^D(\pi_{0,1}\phi\tau X,N).$$

We obtain

$$\sum_{\alpha}[(D_{W_{\alpha}}R^D)(W_{\bar{\alpha}},X)+(D_{W_{\bar{\alpha}}}R^D)(W_{\alpha},X)] = -(\delta_b^{D^{\delta}}R^{\delta})_X u_j + [R^D(N,(2n-3)X - f\phi\tau X)$$
$$+ R^D(T,\phi X + f\tau X)]\sigma_j \tag{66}$$

(cf. Sec. V for the definition of the operator $\delta_b^{D^{\delta}}$). Moreover

$$[(D_{\xi}R^D)(\bar{\xi},X)+(D_{\bar{\xi}}R^D)(\xi,X)]\sigma_j=\frac{1}{2}\{D_N[R^D(N,X)\sigma_j]+D_T[R^D(T,X)\sigma_j]-R^D(N,X)D_N\sigma_j$$
$$-R^D(T,X)D_T\sigma_j-R^D(\nabla^g_N N,X)\sigma_j-R^D(\nabla^g_T T,X)\sigma_j-R^D(N,\nabla^g_N X)\sigma_j$$
$$-R^D(T,\nabla^g_T X)\sigma_j\}.$$

Substitution from (56), (60), (63), and (64) gives

$$-R^D(\nabla^g_N N,X)-R^D(\nabla^g_T T,X)-R^D(N,\nabla^g_N X)-R^D(T,\nabla^g_T X)=R^D(\nabla^H r,X)-R^D(T,\nabla_T X)-R^D(N,\nabla_N X)$$
$$+\frac{1}{f}R^D(T,\phi X)+f(\phi X)(r)R^D(T,N)+\left(\frac{1}{\varphi}+2r\right)R^D(N,X).$$

We conclude that

$$[(D_{\xi}R^D)(\bar{\xi},X)+(D_{\bar{\xi}}R^D)(\xi,X)]\sigma_j=\frac{1}{2}\{(D_N i_N R^D)X\}+(D_T i_T R^D)X+R^D(\nabla^H r,X)+\frac{1}{f}R^D(T,\phi X)$$
$$+f(\phi X)(r)R^D(T,N)+\left(\frac{1}{\varphi}+2r\right)R^D(N,X) \tag{67}$$

[the covariant derivatives in the right hand member of (67) are defined with respect to D and ∇]. Finally [by (66) and (67)]

$$(\delta^D R^D)_X\sigma_j=\frac{\varphi}{n+1}\{-(\delta_b^{D^\delta}R^\delta)_X u_j+[R^D[N,(2n-3)X-f\phi\tau X]+R^D(T,\phi X+f\tau X)]\sigma_j\}$$
$$-\frac{f\varphi}{n+1}\left\{(D_N i_N R^D)X+(D_T i_T R^D)X+R^D(\nabla^H r,X)+R^D\left[T,\frac{1}{f}\phi X+f(\phi X)(r)N\right]\right.$$
$$\left.+\left(\frac{1}{\varphi}+2r\right)R^D(N,X)\right\}\sigma_j.$$

Assume that D is a Yang–Mills field on (Ω,g), i.e., $\delta^D R^D=0$ in Ω. Then, for $\varphi\to 0$ (as r and $\nabla^H r$ remain finite near $\partial\Omega$, (see Ref. 11, p. 164)

$$(\delta_b^{D_b}R^{D_b})_X u_j=2(n-2)R^D(N,X)\sigma_j, \tag{68}$$

where $D_b\equiv D^0$ is the boundary values of D. Therefore, if $i_T R^{D_b}=0$ then [cf. (86) in Sec. V] D_b is a pseudo Yang–Mills field on $\partial\Omega$ if and only if $i_N R^D=0$ on $H(\partial\Omega)$. Theorem 1 is proved. With the same techniques we may show that

Corollary 1: Let $D\in\mathcal{C}(F,h)$ be a Yang-Mills field on (Ω,g) such that $i_N R^D=0$. Then the boundary values D_b of D satisfy $\Lambda_\theta R^{D_b}=0$.

Corollary 1 shows that the axiom (17) (with $S=0$) in the description of the Tanaka connection, as well as (11) in Theorem 2, are rather natural occurrences. The proof is

$$0=(\delta^D R^D)_T\sigma_j=\frac{\varphi}{n+1}\sum_\alpha[(D_{W_\alpha}R^D)(W_{\bar{\alpha}},T)+(D_{W_{\bar{\alpha}}}R^D)(W_\alpha,T)]\sigma_j-\frac{2f\varphi}{n+1}\{D_N[R^D(N,T)\sigma_j]$$
$$-R^D(N,T)D_N\sigma_j-R^D(\nabla^g_N N,T)-R^D(N,\nabla^g_N T)\sigma_j\}$$

or [by (44), (48), (61), and (64)]

$$0=\varphi[(\delta^{D^\delta}R^\delta)_T u_j+2(n-1)R^D(T,N)\sigma_j]+\frac{1}{2}\varphi\{f[R^D(T,\nabla^H r)+R^D(N,\phi\nabla^H r)]+\text{trace }\pi_H R^D(\cdot,\tau\cdot)\}\sigma_j$$

$$+(n+1)f[2(D_N i_N R^D)T+R^D(N,\phi\nabla^H r)-R^D(T,\nabla^H r)]\sigma_j-\frac{2\varphi}{f}\Lambda_\theta R^D\sigma_j$$

$$-(n+1)f^2\left[N(r)+\frac{4}{\varphi^2}-\frac{2r}{\varphi}\right]R^D(T,N)\sigma_j.$$

When $\varphi\to 0$ one observes $\varphi/f\to 1$ and $f^2/\varphi^2\to 1$ hence

$$(\Lambda_\theta R^{D_b})u_j=-2(n+1)R^D(T,N)\sigma_j.$$

Q.E.D.

Summing up, in this section we considered the Dirichlet problem for the Yang–Mills equations

$$\delta^D R^D=0 \quad \text{in } \Omega$$

$$D=D^0 \quad \text{on } \partial\Omega \tag{69}$$

and dealt with the C^∞ regularity up to the boundary of a solution to (69). As a consequence of (68) we may also state:

Corollary 2: Let $\Omega\subset\mathbb{C}^2$ *be a smoothly bounded strictly pseudoconvex domain and* $D\in\mathcal{C}(F,h)$ *a solution to* (69) *for some* C^∞ *connection* $D^0\in\mathcal{C}(E,h)$. *Then* $D_b\equiv D^0$ *must satisfy the compatibility relations* $\delta_b^{D_b}R^{D_b}=0$. *If moreover* $i_T R^{D_b}=0$ *then* D_b *is a pseudo Yang–Mills field on* $\partial\Omega$.

The problem whether a given a pseudo Yang–Mills field D^0 on $\partial\Omega$ may be extended to a Yang–Mills field at the interior of Ω [i.e., the existence question for (69)] is open.

V. YANG–MILLS FIELDS AND THE FEFFERMAN METRIC

We wish to relate $\mathcal{PYM}$ to the Yang–Mills functional on $C(M)$. Given a contact form θ on M such that the Levi form L_θ is positive definite, let F_θ be the corresponding *Fefferman metric* [a Lorentz metric on $C(M)$]. We recall (cf. Ref. 18) that

$$F_\theta=\pi^*\widetilde{G}_\theta+2(\pi^*\theta)\odot\sigma, \tag{70}$$

$$\sigma=\frac{1}{n+2}\left\{d\gamma+\pi^*\left[i\omega_\alpha^\alpha-\frac{i}{2}g^{\alpha\bar\beta}dg_{\alpha\bar\beta}-\frac{\rho}{4(n+1)}\theta\right]\right\}. \tag{71}$$

Here ω_β^α are the connection 1-forms of the Tanaka–Webster connection of (M,θ), i.e., $\nabla T_\beta=\omega_\beta^\alpha\otimes T_\alpha$, and $g_{\alpha\bar\beta}=L_\theta(T_\alpha,T_{\bar\beta})$. Moreover $\rho=g^{\alpha\bar\beta}R_{\alpha\bar\beta}$ is the *pseudohermitian scalar curvature* (cf. e.g., Ref. 5, p. 229). The (0,2)-tensor field $\widetilde{G}_\theta$ is obtained by extending the Levi form G_θ to the whole of $T(M)$. Precisely, one requests that $\widetilde{G}_\theta=G_\theta$ on $H(M)\otimes H(M)$, while $\widetilde{G}_\theta(X,T)=0$, for any $X\in T(M)$ (obviously $\widetilde{G}_\theta$ is degenerate). Note that when M is compact $C(M)$ is compact, as well. It is noteworthy that σ [given by (71)] is a connection 1-form in $S^1\to C(M)\to M$. Let $T^\uparrow$ be the horizontal lift (with respect to σ) of the characteristic direction of $d\theta$ and S the tangent to the S^1 action. Then $T^\uparrow-S$ is timelike, hence $[C(M),F_\theta]$ is time oriented by $T^\uparrow-S$, i.e., $[C(M),F_\theta]$ is a space–time (see Ref. 3, p. 17). However, as M is compact $[C(M),F_\theta]$ is not chronological (cf. Proposition 2.6 in Ref. 3, p. 23).

Let $S\in\mathcal{X}[C(M)]$ be the tangent to the S^1 action {locally $S=[(n+2)/2]\partial/\partial\gamma$}. Then [by (70)] $F_\theta(S,S)=0$. Next (by Lemma 2) $\nabla_S^{C(M)}S=0$, i.e., the integral curves of S are (null) geodesics of $[C(M),F_\theta]$. Also $\mathcal{L}_S F_\theta=0$, hence [cf. (28) in Ref. 26 p. 185] S generates a *shear-free congruence* of null geodesics. The congruence is *symmetric* if there is a vector field $X\in\mathcal{X}[C(M)]$ such that

$$\mathcal{L}_X(\pi^*\theta) = t\pi^*\theta, \quad \mathcal{L}_X(\pi^*\theta^\alpha) = w^\alpha_\beta \pi^*\theta^\beta + \ell^\alpha \pi^*\theta,$$

where t is a real function and $w^\alpha_\beta, \ell^\alpha$ are complex functions on $C(M)$. We say that X is a *symmetry* of the congruence. We may look for $\mathcal{L}_X S$ in the form

$$\mathcal{L}_X S = a^\alpha T^\uparrow_\alpha + a^{\bar\alpha} T^\uparrow_{\bar\alpha} + bT^\uparrow + fS.$$

As X is a symmetry $a^\alpha = 0$, $b = 0$ and $f = -2(\mathcal{L}_X\sigma)S$. Therefore

$$\mathcal{L}_X S = fS. \tag{72}$$

Also one may easily check (by using the local frame $\{T^\uparrow_\alpha, T^\uparrow_{\bar\alpha}, T^\uparrow, S\}$ of $T[C(M)]\otimes\mathbb{C}$) that

$$\mathcal{L}_S(\pi^*\theta) = 0, \quad \mathcal{L}_S(\pi^*\theta^\alpha) = 0. \tag{73}$$

Using (72) and (73) and $\mathcal{L}_Y\mathcal{L}_Z\omega = \mathcal{L}_Z\mathcal{L}_Y\omega + \mathcal{L}_{[Y,Z]}\omega$ [for any $Y, Z \in \mathcal{X}(C(M))$, $\omega \in \Omega^1[C(M)]$] we obtain

$$S(t) = 0, \quad S(w^\alpha_\beta) = 0, \quad S(\ell^\alpha) = 0. \tag{74}$$

For instance

$$S(t)\pi^*\theta = \mathcal{L}_{[S,X]}\pi^*\theta = -f\mathcal{L}_S\pi^*\theta - (\pi^*\theta)(S)\mathrm{d}f = 0.$$

Our considerations draw inspiration from the calculations in Ref. 24 [which are both purely local and confined to the three-dimensional case $(n=1)$]. For this reason some of the results (e.g., Propositions 1 and 2) are attributed to Ref. 24 (the proofs are however new). (74) implies that $t, w^\alpha_\beta, \ell^\alpha$ are vertical lifts of functions on M. A vector field of the form ρS, for some function $\rho \neq 0$, is a *trivial* symmetry of the congruence.

Proposition 2: (Ref. 24) *Each nontrivial symmetry of the shear-free congruence* [*of null geodesics on* $C(M)$] *projects on a unique symmetry of the CR structure on* M.

Indeed, if X is a symmetry of S then $X - 2\sigma(X)S \in \mathrm{Ker}(\sigma)$, hence there is a unique vector field $\widetilde{X} \in \mathcal{X}(M)$ such that

$$\widetilde{X}^\uparrow = X - 2\sigma(X)S.$$

Then

$$\pi^*(t\theta) = \mathcal{L}_X(\pi^*\theta) = \mathcal{L}_{\widetilde{X}^\uparrow}(\pi^*\theta) + 2\mathcal{L}_{\sigma(X)S}(\pi^*\theta) = \mathcal{L}_{\widetilde{X}^\uparrow}(\pi^*\theta).$$

Consequently, for any $Z \in \mathcal{X}(M)$

$$t\theta(Z) = [\pi^*(t\theta)]Z^\uparrow = [\mathcal{L}_{\widetilde{X}^\uparrow}(\pi^*\theta)]Z^\uparrow = \widetilde{X}[\theta(Z)] - (\pi^*\theta)[\widetilde{X}^\uparrow, Z^\uparrow]$$

hence, as $[\widetilde{X}, Z]^\uparrow$ is the $\mathrm{Ker}(\sigma)$-component of $[\widetilde{X}^\uparrow, Z^\uparrow]$ [with respect to the decomposition $T[C(M)] = \mathrm{Ker}(\sigma)\oplus\mathbb{R}S$], we obtain $\mathcal{L}_{\widetilde{X}}\theta = t\theta$. It may be shown in a similar manner that $\mathcal{L}_{\widetilde{X}}\theta^\alpha = w^\alpha_\beta\theta^\beta + \ell^\alpha\theta$, i.e., $\widetilde{X}$ is a symmetry of the CR structure. Q.E.D.

Let $E \to M$ be a complex vector bundle and $\hat{E} = \pi^*E \to C(M)$ the pullback of E via π. The *natural lift* $\hat{u}: \pi^{-1}(U) \to \hat{E}$ of a section $u: U \to E$ is given by $\hat{u}(z) = \{x, u[\pi(z)]\}$, $z \in \pi^{-1}(U)$. If E carries a Hermitian metric h then so does $\hat{E}$. Indeed we may set $\hat{h}(\hat{e}_i, \hat{e}_j) = h_{i\bar{j}} \circ \pi$, where $h_{i\bar{j}} = h(e_i, e_j)$ and $\{e_1, \cdots, e_m\}$ is a (local) frame in E on U. There is a natural inner product $\langle,\rangle$ on $\Omega^2[\mathrm{Ad}(\hat{E})]$ induced by the inner product on scalar 2-forms

$$F_\theta^*(\alpha,\beta)d\,\mathrm{vol}(F_\theta)=\alpha\wedge *\beta,$$

$\alpha,\beta\in\Gamma^\infty\{\Lambda^2T^*[C(M)]\}$, and by the Killing–Cartan form of $\mathbf{u}(m)$, $m=\mathrm{rank}_{\mathbb{C}}E$, respectively. Here $*$ is the Hodge operator associated with the Fefferman metric F_θ. Precisely, if $S,T\in\Omega^0[\mathrm{Ad}(\hat{E})]$ then

$$\langle\alpha\otimes S,\beta\otimes T\rangle=F_\theta^*(\alpha,\beta)(S_j^i)\cdot(T_j^i),$$

where $S\hat{e}_j=S_j^i\hat{e}_i$, $T\hat{e}_j=T_j^i\hat{e}_i$ with respect to a (local) orthonormal $[h(e_i,e_j)=\delta_{ij}]$ frame $\{e_j\}$ in E, and $A\cdot B=-\mathrm{trace}(AB)$, $A,B\in\mathbf{u}(m)$. The Yang–Mills functional is given by

$$\mathcal{Y}\hat{\mathcal{M}}(\mathbb{D})=\frac{1}{2}\int_{C(M)}\langle R^{\mathbb{D}},R^{\mathbb{D}}\rangle d\,\mathrm{vol}(F_\theta),\quad \mathbb{D}\in\mathcal{C}(\hat{E},\hat{h}).$$

Any $D\in\mathcal{C}(E,h)$ induces a connection $\hat{D}=\pi^*D\in\mathcal{C}(\hat{E},\hat{h})$ which is described (in local coordinates) as follows. Let (U,x^A) be a local coordinate system on M. Then $[\pi^{-1}(U),\hat{x}^A:=x^A\circ\pi,\gamma]$ are local coordinates on $C(M)$. We set by definition

$$\hat{D}_{\partial/\partial\hat{x}^A}\hat{e}_j=(\Gamma_{Aj}^i\circ\pi)\hat{e}_i,\quad \hat{D}_{\partial/\partial\gamma}\hat{e}_j=0,$$

where $D_{\partial/\partial x^A}e_j=\Gamma_{Aj}^ie_i$. Our conventions as to the range of indices are $A,B,C,\cdots\in(1,\cdots,2n+1)$ and $i,j,k,\cdots\in(1,\cdots,m)$. We consider the linear map

$$\pi^*:\Gamma^\infty(U,\Lambda^kT^*(M)\otimes E)\to\Gamma^\infty\{\pi^{-1}(U),\Lambda^kT^*[C(M)]\otimes\hat{E}\}$$

given by

$$\pi^*(\omega^j\otimes e_j)=(\pi^*\omega^j)\otimes\hat{e}_j,\quad \omega^j\in\Omega^k(U),$$

(pullback and natural lifting). As $\{\hat{e}_j\}$ is a local frame in $\hat{E}\to C(M)$ it suffices to specify $\hat{D}$ on natural lifts of sections in $E\to M$. Then $\hat{D}$ admits the following coordinate-free description:

$$\hat{D}\hat{u}=\pi^*(Du),\quad u\in\Omega^0(E).$$

Clearly, if $Dh=0$ then $\hat{D}\hat{h}=0$. Let us consider the functional $\mathcal{PYM}:\mathcal{C}(E,h)\to[0,+\infty)$ given by

$$\mathcal{P}YM(D)=\frac{1}{2}\int_M\|\pi_HR^D\|^2\theta\wedge(\mathrm{d}\theta)^n.$$

Here $\pi_H:\Omega^2[\mathrm{Ad}(E)]\to\Omega^2[\mathrm{Ad}(E)]/\mathcal{J}_\theta^2$ is the projection described in Sec. II. Of course, when an admissible coframe $\{\theta^\alpha\}$ is fixed $\Omega^\cdot[\mathrm{Ad}(E)]/\mathcal{J}_\theta$ may be identified with the subalgebra $\Omega_H^\cdot[\mathrm{Ad}(E)]=\{\omega\in\Omega^\cdot[\mathrm{Ad}(E)]:i_T\omega=0\}$. Integration along the fiber in $\mathcal{Y}\hat{\mathcal{M}}(\pi^*D)$, $D\in\mathcal{C}(E,h)$, leads to (9) in Theorem 2. Indeed, let us set

$$R_{ABj}^ie_i=(R^De_j)(\partial/\partial x^A,\partial/\partial x^B).$$

Then

$$R^{\hat{D}}\hat{e}_j=[(R_{ABj}^i\circ\pi)d\hat{x}^A\wedge d\hat{x}^B]\otimes\hat{e}_i$$

hence

$$R^{\hat{D}}\hat{e}_j=\pi^*(R^De_j).\tag{75}$$

Given $\Omega=\Omega^j\otimes e_j\in\Omega^2(E)$, $\Omega^j=\Omega_{AB}^j\,\mathrm{d}x^A\wedge\mathrm{d}x^B$, we set

$$\langle \pi^*\Omega, \pi^*\Omega\rangle = F^*_\theta(\pi^*\Omega^j, \pi^*\Omega^{\bar{k}})(h_{j\bar{k}}\circ\pi). \tag{76}$$

Of course $\pi^*\Omega^j=(\Omega^j_{AB}\circ\pi)\mathrm{d}\hat{x}^A\wedge\mathrm{d}\hat{x}^B$ and the main technical difficulty in calculating (76) is the need for $F^{AB}=F^*_\theta(\mathrm{d}\hat{x}^A,\mathrm{d}\hat{x}^B)$, where $[F^{AB}]=[F_{AB}]^{-1}$ and $F_{AB}:=F_\theta(\partial/\partial\hat{x}^A,\partial/\partial\hat{x}^B)$. Let

$$F_\theta:\begin{bmatrix} F_{AB} & F_{A,2n+2} \\ F_{2n+2,B} & F_{2n+2,2n+2}\end{bmatrix}$$

be the components of the Fefferman metric with respect to $(\hat{x}^A,\gamma)$. Let us set $\partial/\partial x^A=\lambda^B_A T_B$, $\lambda^B_A\in C^\infty(U)$. Here one either adopts the convention $A,B,C,\cdots\in\{0,1,\cdots,n,\bar{1},\cdots,\bar{n}\}$ (with $T_0=T$) or relabels the vector fields $\{T,T_\alpha,T_{\bar{\alpha}}:1\leqslant\alpha\leqslant n\}$. Then [by (70)]

$$F_{AB}=\widetilde{G}_\theta\left(\frac{\partial}{\partial x^A},\frac{\partial}{\partial x^B}\right)+\theta\left(\frac{\partial}{\partial x^A}\right)\sigma\left(\frac{\partial}{\partial\hat{x}^B}\right)+\theta\left(\frac{\partial}{\partial x^B}\right)\sigma\left(\frac{\partial}{\partial\hat{x}^A}\right)=g_{\alpha\bar{\beta}}(\lambda^\alpha_A\lambda^{\bar{\beta}}_B+\lambda^\alpha_B\lambda^{\bar{\beta}}_A)+\lambda^0_A\sigma_B+\lambda^0_B\sigma_A$$

where $\sigma_A=\sigma(\partial/\partial\hat{x}^A)$. A calculation based on (71) shows that

$$\sigma_A=\frac{1}{n+2}\left\{i\lambda^B_A\left[\Gamma^\alpha_{B\alpha}-\frac{1}{2}g^{\alpha\bar{\beta}}T_B(g_{\alpha\bar{\beta}})\right]-\frac{\rho}{4(n+1)}\lambda^0_A\right\}\circ\pi$$

where $\Gamma^\beta_{B\alpha}$ are (among) the coefficients of the Tanaka–Webster connection of (M,θ) (i.e., $\nabla_{T_B}T_\alpha=\Gamma^\beta_{B\alpha}T_\beta$). Moreover [by (70)]

$$F_{A,2n+2}=2[(\pi^*\theta)\odot\sigma]\left(\frac{\partial}{\partial\hat{x}^A},\frac{\partial}{\partial\gamma}\right)=\frac{1}{n+2}\lambda^0_A,$$

$$F_{2n+2,2n+2}=0.$$

Next, using $F^{ab}F_{bc}=\delta^a_c$ (with $a,b,c,\cdots\in\{1,\cdots,2n+2\}$) we find

$$\begin{gathered} F^{AB}F_{BC}+\frac{\lambda^0_C}{n+2}F^{A,2n+2}=\delta^A_C \\ F^{AB}\lambda^0_B=0 \\ F^{2n+2,B}F_{BC}+\frac{\lambda^0_C}{n+2}F^{2n+2,2n+2}=0 \\ F^{2n+2,B}\lambda^0_B=n+2. \end{gathered} \tag{77}$$

Let us set

$$P_{AB}{}^i{}_j e_i=(R^D e_j)(T_A,T_B)$$

so that $R^i_{ABj}=\lambda^C_A\lambda^D_B P_{CD}{}^i{}_j$. In the sequel, for the sake of simplicity, we do not distinguish notationally between $f\in C^\infty(M)$ and its vertical lift $f\circ\pi$. Then

$$\begin{aligned}\langle R^{\hat{D}},R^{\hat{D}}\rangle &= h^{j\bar{k}}\langle R^{\hat{D}}\hat{e}_j,R^{\hat{D}}\hat{e}_k\rangle = h^{j\bar{k}}h_{r\bar{s}}F^*_\theta(R^r_{ABj}\,\mathrm{d}\hat{x}^A\wedge\mathrm{d}\hat{x}^B,R^s_{CDk}\,\mathrm{d}\hat{x}^C\wedge\mathrm{d}\hat{x}^D)\\ &= \frac{1}{2}h^{j\bar{k}}h_{r\bar{s}}R^r_{ABj}R^{\bar{s}}_{CD\bar{k}}(F^{AC}F^{BD}-F^{AD}F^{BC}),\end{aligned}$$

where $R^{\bar{i}}_{AB\bar{j}}=\overline{R^i_{ABj}}$. We obtain

$$\langle R^{\hat{D}}, R^{\hat{D}} \rangle = \frac{1}{2} h^{j\bar{k}} h_{r\bar{s}} \lambda_A^E \lambda_B^F \lambda_C^{\bar{G}} \lambda_D^{\bar{H}} P_{EF}{}^{r}{}_{j} P_{\bar{G}\bar{H}}{}^{\bar{s}}{}_{\bar{k}} (F^{AC} F^{BD} - F^{AD} F^{BC}), \tag{78}$$

where $\lambda_A^{\bar{B}} = \overline{\lambda_A^B}$ and $P_{\bar{A}\bar{B}}{}^{\bar{i}}{}_{\bar{j}} = \overline{P_{AB}{}^{i}{}_{j}}$. Note that λ_A^0 is real valued while $\lambda_A^{\bar{\alpha}} = \lambda_A^{\alpha+n}$. To calculate $\lambda_A^E \lambda_B^F \lambda_C^{\bar{G}} \lambda_D^{\bar{H}} (F^{AC} F^{BD} - F^{AD} F^{BC})$ we need the identities

$$F^{AB} \lambda_A^{\alpha} \lambda_B^{\bar{\beta}} = g^{\alpha\bar{\beta}}, \tag{79}$$

$$F^{AB} \lambda_A^{\alpha} \lambda_B^{\beta} = 0. \tag{80}$$

The proof of (79) and (80) follows from (77). Indeed (77) may be written

$$F^{AB} g_{\alpha\bar{\beta}} (\lambda_B^{\alpha} \lambda_C^{\bar{\beta}} + \lambda_C^{\alpha} \lambda_B^{\bar{\beta}}) + F^{AB} \lambda_C^0 \sigma_B + \frac{1}{n+2} F^{A,2n+2} \lambda_C^0 = \delta_C^A,$$

$$F^{AB} \lambda_B^0 = 0,$$

$$F^{2n+2,B} g_{\alpha\bar{\beta}} (\lambda_B^{\alpha} \lambda_C^{\bar{\beta}} + \lambda_C^{\alpha} \lambda_B^{\bar{\beta}}) + (n+2)\sigma_C + F^{2n+2,B} \lambda_C^0 \sigma_B + \frac{1}{n+2} F^{2n+2,2n+2} \lambda_C^0 = 0,$$

$$F^{2n+2,B} \lambda_B^0 = n+2.$$

If $\mu := = \lambda^{-1}$ then (by the first of the previous four identities)

$$\mu_D^A = \left(\frac{1}{n+2} F^{A,2n+2} + F^{AB} \sigma_B \right) \delta_D^0 + F^{AB} g_{\alpha\bar{\beta}} (\lambda_B^{\alpha} \delta_D^{\beta+n} + \lambda_B^{\bar{\beta}} \delta_D^{\alpha})$$

yielding

$$\mu_0^A = \frac{1}{n+2} F^{A,2n+2} + F^{AB} \sigma_B$$

$$\mu_{\alpha}^A = F^{AB} g_{\alpha\bar{\beta}} \lambda_B^{\bar{\beta}} \tag{81}$$

$$\mu_{\beta+n}^A = F^{AB} g_{\alpha\bar{\beta}} \lambda_B^{\alpha}.$$

The second and third of the identities (81) lead to (79) and (80), respectively. A calculation based on (79) and (80) shows that (78) may be written

$$\langle R^{\hat{D}}, R^{\hat{D}} \rangle = P^{\bar{\alpha}\bar{\beta}\bar{k}j} P_{\bar{\alpha}\bar{\beta}\bar{k}j} + P^{\alpha\beta\bar{k}j} P_{\alpha\beta\bar{k}j} + P^{\bar{\alpha}\bar{\beta}\bar{k}j} P_{\bar{\alpha}\beta\bar{k}j} + P^{\alpha\bar{\beta}\bar{k}j} P_{\alpha\bar{\beta}\bar{k}j} \tag{82}$$

where $P_{AB\bar{k}j} = h_{j\bar{s}} P_{AB\bar{k}}{}^{\bar{s}}$ and $P^{AB\bar{k}j} = h^{r\bar{k}} P^{AB}{}_{r}{}^{j}$. Also $P^{\alpha\beta}{}_{r}{}^{j} = g^{\alpha\bar{\lambda}} g^{\beta\bar{\mu}} P_{\bar{\lambda}\bar{\mu}r}{}^{j}$, etc. As $R^D e_j = (P_{AB}{}^{i}{}_{j} \theta^A \wedge \theta^B) \otimes e_i$ it follows that

$$\begin{aligned} \langle \pi_H R^D, \pi_H R^D \rangle &= h^{j\bar{k}} \langle (\pi_H R^D) e_j, (\pi_H R^D) e_k \rangle \\ &= h^{j\bar{k}} h_{r\bar{s}} G_{\theta}^{*} (P_{\alpha\beta}{}^{r}{}_{j} \theta^{\alpha} \wedge \theta^{\beta} + 2 P_{\alpha\bar{\beta}}{}^{r}{}_{j} \theta^{\alpha} \wedge \theta^{\bar{\beta}} + P_{\bar{\alpha}\bar{\beta}}{}^{r}{}_{j} \theta^{\bar{\alpha}} \wedge \theta^{\bar{\beta}}, \end{aligned}$$

$$P_{\lambda\mu}{}^{s}{}_{k}\theta^{\lambda}\wedge\theta^{\mu}+2P_{\lambda\bar{\mu}}{}^{s}{}_{k}\theta^{\lambda}\wedge\theta^{\bar{\mu}}+P_{\bar{\lambda}\bar{\mu}}{}^{s}{}_{k}\theta^{\bar{\lambda}}\wedge\theta^{\bar{\mu}})=\frac{1}{2}P_{\alpha\beta}{}^{\bar{k}j}P_{\bar{\lambda}\bar{\mu}\bar{k}j}(g^{\alpha\bar{\lambda}}g^{\beta\bar{\mu}}-g^{\alpha\bar{\mu}}g^{\beta\bar{\lambda}})$$
$$+2g^{\alpha\bar{\lambda}}g^{\bar{\beta}\mu}P_{\alpha\bar{\beta}}{}^{\bar{k}j}P_{\bar{\lambda}\mu\bar{k}j}+\frac{1}{2}P_{\bar{\alpha}\bar{\beta}}{}^{\bar{k}j}P_{\lambda\mu\bar{k}j}(g^{\bar{\alpha}\lambda}g^{\bar{\beta}\mu}$$
$$-g^{\bar{\alpha}\mu}g^{\bar{\beta}\lambda})=P^{\bar{\lambda}\bar{\mu}\bar{k}j}P_{\bar{\lambda}\bar{\mu}\bar{k}j}+2P^{\bar{\lambda}\mu\bar{k}j}P_{\bar{\lambda}\mu\bar{k}j}$$
$$+P^{\lambda\mu\bar{k}j}P_{\lambda\mu\bar{k}j}$$

hence [by (75) and (82)]

$$\langle R^{\hat{D}},R^{\hat{D}}\rangle=(\|\pi_{H}R^{D}\|\circ\pi)^{2}.$$

Finally we may integrate over $C(M)$ and use the identity

$$\int_{C(M)}(f\circ\pi)d\,\mathrm{vol}(F_{\theta})=2\pi\int_{M}f\theta\wedge(\mathrm{d}\theta)^{n},\quad f\in C^{\infty}(M).$$

The identity (9) in Theorem 1 is proved. (The symbol π on the right hand side denotes the irrational number $\pi\in\mathbb{R}$.) Assume now that $\hat{D}=\pi^{*}D$ is a Yang–Mills field on $C(M)$. Let $D^{t}=D+t\varphi$, $\varphi\in\Omega^{1}[\mathrm{Ad}(E)]$, be a variation of D. Then

$$\pi^{*}D^{t}=\hat{D}+t\pi^{*}\varphi.\tag{83}$$

A word on the conventions in (83). As seen earlier in this section, there is a natural map $\pi^{*}:\Omega^{1}[\mathrm{Ad}(E)]\to\Omega^{1}[\pi^{*}\mathrm{Ad}(E)]$. Yet $\mathrm{Ad}(\pi^{*}E)\approx\pi^{*}\,\mathrm{Ad}(E)$ (a vector bundle isomorphism) hence $\pi^{*}\varphi$ is an $\mathrm{Ad}(\pi^{*}E)$-valued 1-form on $C(M)$. Then [by (9)]

$$0=\frac{d}{dt}[\mathcal{Y}\hat{\mathcal{M}}(\hat{D}+t\pi^{*}\varphi)]_{t=0}=\frac{d}{dt}[\mathcal{Y}\hat{\mathcal{M}}(\pi^{*}D^{t})]_{t=0}=2\pi\frac{d}{dt}[\mathcal{P}YM(D^{t})]_{t=0},$$

i.e., D is a pseudo Yang–Mills field on M. The converse requires the first variation formula for the functional $\mathcal{PYM}$ [as well as the fact that the Yang–Mills equations on $C(M)$ project on M via π to give the Euler–Lagrange equations of the variational principle $\delta\mathcal{PYM}=0$, see Sec. IV]. To establish (8) we need the following:

Lemma 1: Let M be a nondegenerate CR manifold, θ a contact form on M, and $d\,\mathrm{vol}(g_{\theta})$ the canonical volume form associated to the Webster metric g_{θ}. Then $\theta\wedge(\mathrm{d}\theta)^{n}=\pm c_{n}d\,\mathrm{vol}(g_{\theta})$ where $c_{n}=(-1)^{s}2^{n}n!$, provided that the Levi form L_{θ} has s negative eigenvalues.

This corrects the constant c_{n} from Ref. 30, p. 546. If the Levi form L_{θ} has r positive and s negative eigenvalues $(r+s=n)$ then g_{θ} is a semi-Riemannian metric of signature $(2r+1,2s)$. Let $\mathcal{O}$ be a fixed orientation of M. To prove Lemma 1, let G_{AB} be the components of the Webster metric with respect to a chart $(U,x^{A})\in\mathcal{O}$, so that $d\,\mathrm{vol}(g_{\theta})=\sqrt{|\det(G_{AB})|}\mathrm{d}x^{1}\wedge\cdots\wedge\mathrm{d}x^{2n+1}$. Let $\{T_{\alpha}\}$ be a local frame of $T_{1,0}(M)$ and $\mu\in GL(2n+1,\mathbb{C})$ such that $T_{A}=\mu_{A}^{B}\partial/\partial x^{B}$. Then $d\,\mathrm{vol}(g_{\theta})=\sqrt{|\det(G_{AB})|}\det(\mu)\theta^{01\cdots n\bar{1}\cdots\bar{n}}$, where $\theta^{01\cdots n\bar{1}\cdots\bar{n}}$ is short for $\theta\wedge\theta^{1}\wedge\cdots\wedge\theta^{n}\wedge\theta^{\bar{1}}\wedge\cdots\wedge\theta^{\bar{n}}$, hence $\overline{\det(\mu)}=(-1)^{n^{2}}\det(\mu)$ [as $d\,\mathrm{vol}(g_{\theta})$ is a real form]. It follows that $\sqrt{|\det(G_{AB})|}=(-1)^{s}|\det(\mu)|^{-1}\det(g_{\alpha\bar{\beta}})$. A calculation shows that

$$\theta\wedge(d\theta)^{n}=2^{n}i^{n^{2}}n!\det(g_{\alpha\bar{\beta}})\theta^{01\cdots n\bar{1}\cdots\bar{n}}$$

(see also Ref. 19) and then $\theta\wedge(d\theta)^{n}=\pm c_{n}d\,\mathrm{vol}(g_{\theta})$. The sign is +1 if $\mathcal{O}$ and the orientation of $H(M)$ (induced by its complex structure J) agree. Lemma 1 is proved. Let us prove (8). As

$$R^{D}e_{j}=(\pi_{H}R^{D})e_{j}-2P_{0A}{}^{i}{}_{j}(\theta\wedge\theta^{A})\otimes e_{i}$$

it follows that

$$\|R^D\|^2 = \|\pi_H R^D\|^2 + 4g^{A\bar{B}} P_{0A}{}^i{}_j P_{0\bar{B}}{}^j{}_i.$$

Yet $i_T R^D = \theta^B \otimes [P_{0B}{}^i{}_j] \in \Omega^1[\mathrm{Ad}(E)]$ hence $\|R^D\|^2 = \|\pi_H R^D\|^2 + 4\|i_T R_D\|^2$. At this point we may integrate over M with respect to $\theta \wedge (d\theta)^n$ and use Lemma 1. The proof of the last statement in (i) of Theorem 2 is delegated to the next section.

VI. THE FIRST VARIATION FORMULA

Let $E \to M$ be a vector bundle and D a connection in E. We shall need the differential operator $d^D: \Omega^k(E) \to \Omega^{k+1}(E)$ given by

$$(d^D\varphi)(X_1, \cdots, X_{k+1}) = \sum_{i=1}^{k+1} (-1)^{i+1} D_{X_i}[\varphi(X_1, \cdots, \hat{X}_i, \cdots, X_{k+1})]$$
$$+ \sum_{1 \leqslant i < j \leqslant k+1} (-1)^{i+j} \varphi([X_i, X_j], X_1, \cdots, \hat{X}_i, \cdots, \hat{X}_j, \cdots, X_{k+1})$$

for any $\varphi \in \Omega^k(E)$ and any $X_i \in T(M)$, $1 \leqslant i \leqslant k$. Here a hat indicates, as usual, the suppression of a term. Let $D \in \mathcal{C}(E,h)$ and let us denote by the same symbol the connection induced by D in $\mathrm{Ad}(E) \to M$. The operator δ^D in (18) is the formal adjoint of $d^D: \Omega^1[\mathrm{Ad}(E)] \to \Omega^2[\mathrm{Ad}(E)]$ with respect to the inner product

$$(\varphi, \psi) = \int_M \langle \varphi, \psi \rangle \theta \wedge (\mathrm{d}\theta)^n, \quad \varphi, \psi \in \Omega^k(E). \tag{84}$$

Let $\varphi \in \Omega^1[\mathrm{Ad}(E)]$. A standard calculation shows that $R^{D+t\varphi} = R^D + td^D\varphi + t^2[\varphi \wedge \varphi]$ (where $[\varphi \wedge \psi]_{X,Y} = [\varphi_X, \psi_Y] - [\varphi_Y, \psi_X]$, $X, Y \in T(M)$, $\varphi, \psi \in \Omega^1[\mathrm{Ad}(E)]$) hence

$$\|\pi_H R^{D+t\varphi}\|^2 = \|\pi_H R^D\|^2 + 2t\langle \pi_H R^D, \pi_H d^D\varphi \rangle + O(t^2)$$

and

$$\frac{d}{dt}[\mathcal{PYM}(D + t\varphi)]_{t=0} = \frac{1}{2}\int_M \frac{d}{dt}(\|\pi_H R^{D+t\varphi}\|^2)_{t=0}\theta \wedge (\mathrm{d}\theta)^n = \int_M \langle \pi_H R^D, d^D\varphi \rangle \theta \wedge (\mathrm{d}\theta)^n$$
$$= \int_M \langle \delta^D \pi_H R^D, \varphi \rangle \theta \wedge (d\theta)^n.$$

Then $(d/dt)[\mathcal{PYM}(D+t\varphi)]_{t=0} = 0$ yields

$$\delta^D \pi_H R^D = 0. \tag{85}$$

Let $D \in \mathcal{C}(E,h)$ such that $i_T R^D = 0$. Then [by (18) and (85)] D is a pseudo Yang–Mills field if and only if D is a Yang–Mills field, and the last statement in part (i) of Theorem 2 follows from Theorem 2.3 in Ref. 30, p. 551.

Let us consider the operator $\delta_b^D: \Omega^{k+1}(E) \to \Omega^k(E)$ given by

$$(\delta_b^D\varphi)(X_1, \cdots, X_k) = -\sum_{a=1}^{2n} (D_{E_a}\varphi)(E_a, X_1, \cdots, X_k),$$

for any $\varphi \in \Omega^{k+1}(E)$ and $X_i \in T(M)$, $1 \leqslant i \leqslant k$, where $\{E_a : 1 \leqslant a \leqslant 2n\}$ is a local G_θ orthonormal frame of $H(M)$. Clearly, if $\varphi \in \Omega_H^k(E)$ then $\delta^D\varphi = \delta_b^D\varphi$ and $i_T\delta_b^D\varphi = 0$. Consequently, if $i_T R^D = 0$ then Eqs. (85) may also be written

$$\delta_b^D R^D = 0. \tag{86}$$

Now we attack the problem whether the pullback $\hat{D}=\pi^* D$ of a pseudo Yang–Mills field D on M is a Yang–Mills field on $C(M)$. As argued in the previous section, this doesn't follow directly from (9). In turn, the Yang–Mills equations on $C(M)$ are related to (85) due to

$$(\delta^{\hat{D}} R^{\hat{D}})(X^{\uparrow})\hat{u} = [(\delta_b^D R^D)(X)u + R^D(T,JX)u]\hat{}, \tag{87}$$

$$(\delta^{\hat{D}} R^{\hat{D}})(T^{\uparrow})\hat{u} = [(\delta_b^D R^D)(T)u]\hat{} - \frac{i}{n+2}\left[R^{\alpha\bar{\beta}} - \frac{\rho}{2(n+1)}g^{\alpha\bar{\beta}}\right][R^D(T_\alpha, T_{\bar{\beta}})u]\hat{}, \tag{88}$$

$$(\delta^{\hat{D}} R^{\hat{D}})(S)\hat{u} = 2[(\Lambda_\theta R^D)u]\hat{}, \tag{89}$$

for any $X \in H(M)$ and $u \in \Omega^0(E)$. Here $X^{\uparrow}$ is the horizontal lift of X with respect to the connection 1-form σ in $S^1 \to C(M) \to M$. Let $D \in \mathcal{C}(E,h)$ be a pseudo Yang–Mills field with $i_T R^D = 0$. Then [by (87)–(89)] $\delta^{\hat{D}} R^{\hat{D}} = 0$ if and only if (10) and (11) hold. This completes the proof of Theorem 2.

It remains that we prove (87)–(89). The formal adjoint $\delta^{\mathbb{D}}$ of $d^{\mathbb{D}}: \Omega^1[\mathrm{Ad}(\pi^* E)] \to \Omega^2[\mathrm{Ad}(\pi^* E)]$ is given by

$$(\delta^{\mathbb{D}}\psi)(Y)v = -\sum_{j=1}^{2n+2} \epsilon_j (\mathbb{D}_{X_j}\psi)(X_j, Y)v = -\sum_{j=1}^{2n+2} [\mathbb{D}_{X_j}\psi(X_j, Y)v - \psi(\nabla^{C(M)}_{X_j} X_j, Y)v - \psi(X_j, \nabla^{C(M)}_{X_j} Y)v - \psi(X_j, Y)\mathbb{D}_{X_j} v],$$

for any $\psi \in \Omega^2[\mathrm{Ad}(\pi^* E)]$, $Y \in T[C(M)]$, and $v \in \Omega^0(\pi^* E)$, where $\{X_j : 1 \leqslant j \leqslant 2n+2\}$ is a local orthonormal [i.e., $F_\theta(X_j, X_k) = \epsilon_j \delta_{jk}$, $\epsilon_1 = \cdots = \epsilon_{2n+1} = -\epsilon_{2n+2} = 1$] frame of $T[C(M)]$ and $\nabla^{C(M)}$ is the Levi–Civita connection of $[C(M), F_\theta]$. As $S^1 \to C(M) \to M$ is a principal bundle, the projection π is a submersion. However, if $S = [(n+2)/2]\partial/\partial\gamma$ then $F_\theta(S,S) = 0$, i.e., S is null, so that π is not a semi-Riemannian submersion [in the sense of Ref. 22, p. 212, as the fibers of π are degenerate submanifolds]. Nevertheless, we may relate $\nabla^{C(M)}$ to the Tanaka–Webster connection ∇ of (M, θ), very much in the spirit of Ref. 23. Precisely, we may state

Lemma 2: For any $X, Y \in H(M)$

$$\nabla^{C(M)}_{X^{\uparrow}} Y^{\uparrow} = (\nabla_X Y)^{\uparrow} - (d\theta)(X,Y)T^{\uparrow} - [A(X,Y) + (d\sigma)(X^{\uparrow}, Y^{\uparrow})]S,$$

$$\nabla^{C(M)}_{X^{\uparrow}} T^{\uparrow} = (\tau X + \phi X)^{\uparrow},$$

$$\nabla^{C(M)}_{T^{\uparrow}} X^{\uparrow} = (\nabla_T X + \phi X)^{\uparrow} + 2(d\sigma)(X^{\uparrow}, T^{\uparrow})S,$$

$$\nabla^{C(M)}_{X^{\uparrow}} S = \nabla^{C(M)}_S X^{\uparrow} = (JX)^{\uparrow},$$

$$\nabla^{C(M)}_{T^{\uparrow}} T^{\uparrow} = V^{\uparrow}, \quad \nabla^{C(M)}_S S = 0,$$

$$\nabla^{C(M)}_S T^{\uparrow} = \nabla^{C(M)}_{T^{\uparrow}} S = 0,$$

where $\phi: H(M) \to H(M)$ is given by $G_\theta(\phi X, Y) = (\mathrm{d}\sigma)(X^{\uparrow}, Y^{\uparrow})$, and $V \in H(M)$ is given by $G_\theta(V, Y) = 2(\mathrm{d}\sigma)(T^{\uparrow}, Y^{\uparrow})$.

Proof of Lemma 2: Let us recall that

$$2F_\theta(\nabla^{C(M)}_{\widetilde{X}}\widetilde{Y},\widetilde{Z}) = \widetilde{X}[F_\theta(\widetilde{Y},\widetilde{Z})] + \widetilde{Y}[F_\theta(\widetilde{X},\widetilde{Z})] - \widetilde{Z}[F_\theta(\widetilde{X},\widetilde{Y})] + F_\theta[(\widetilde{X},\widetilde{Y}),\widetilde{Z}] + F_\theta[(\widetilde{Z},\widetilde{X}),\widetilde{Y}] + F_\theta[\widetilde{X},(\widetilde{Z},\widetilde{Y})] \tag{90}$$

for any $\widetilde{X},\widetilde{Y},\widetilde{Z}\in T[C(M)]$. In particular for $\widetilde{X}=X^\uparrow$, $\widetilde{Y}=Y^\uparrow$, $\widetilde{Z}=Z^\uparrow$, for any $X,Y,Z\in H(M)$

$$F_\theta(\nabla^{C(M)}_{X^\uparrow}Y^\uparrow,Z^\uparrow) = g_\theta(\nabla^M_X Y,Z),$$

where ∇^M is the Levi–Civita connection of (M,g_θ). Here one used the fact that $[X,Y]^\uparrow$ is the horizontal component of $[X^\uparrow,Y^\uparrow]$, with respect to σ (cf., e.g., Ref. 16 Vol. I, p. 65). The Levi–Civita connection ∇^M and the Tanaka–Webster connection ∇ of (M,θ) are related by [cf. (1) in Ref. 1 p. 238)

$$\nabla^M = \nabla - (d\theta + A)\otimes T + \tau\otimes\theta + 2\theta\odot J, \tag{91}$$

where $A(X,Y)=g_\theta(X,\tau Y)$. Recall that A is symmetric and τ traceless (cf. Ref. 34). As $H(M)$ is ∇ parallel $\pi_H\nabla^M_X Y=\nabla_X Y$, where $\pi_H: T(M)\to H(M)$ is the projection associated with the direct sum decomposition $T(M)=H(M)\oplus\mathbb{R}T$. Therefore, by taking into account the decomposition $T[C(M)]=\mathrm{Ker}(\sigma)\oplus\mathrm{Ker}(d\pi)=H(M)^\uparrow\oplus\mathbb{R}T^\uparrow\oplus\mathbb{R}S$

$$\nabla^{C(M)}_{X^\uparrow}Y^\uparrow = (\nabla_X Y)^\uparrow + \lambda T^\uparrow + \mu S, \tag{92}$$

for some $\lambda,\mu\in C^\infty[C(M)]$, depending on X,Y. We may determine λ, μ by taking the inner product with S, $T^\uparrow$, respectively. To this end let us first observe that

$$F_\theta(\nabla^{C(M)}_{X^\uparrow}Y^\uparrow,S) = -(\mathrm{d}\theta)(X,Y).$$

Here we again used (90) together with the fact that $[X^\uparrow,S]=0$ (cf. e.g. Ref. 16 Vol. I, p. 79). Similarly

$$2F_\theta(\nabla^{C(M)}_{X^\uparrow}Y^\uparrow,T^\uparrow) = \sigma[(X^\uparrow,Y^\uparrow)] - T[g_\theta(X,Y)] + g_\theta[(T,X),Y] + g_\theta[X,(T,Y)]$$

and

$$2g_\theta(\nabla^M_X Y,T) = -T[g_\theta(X,Y)] + \theta[(X,Y)] + g_\theta[(T,X),Y] + g_\theta[X,(T,Y)]$$

hence

$$2F_\theta(\nabla^{C(M)}_{X^\uparrow}Y^\uparrow,T^\uparrow) = 2\theta(\nabla^M_X Y) - \theta[(X,Y)] + \sigma[(X^\uparrow,Y^\uparrow)]$$

or [by (91)]

$$F_\theta(\nabla^{C(M)}_{X^\uparrow}Y^\uparrow,T^\uparrow) = -A(X,Y) - (d\sigma)(X^\uparrow,Y^\uparrow).$$

Summing up, (92) leads to the first identity in Lemma 2. The proof of the remaining identities in Lemma 2 may be obtained in a similar manner. Let us go back to the proof of (87)–(89). Let $\{E_a: 1\leqslant a\leqslant 2n\}$ be a local orthonormal frame of the Levi distribution $H(M)$. Then $\{E^\uparrow_a, T^\uparrow\pm S\}$ is a local orthonormal frame of $T[C(M)]$ with respect to the Feferman metric F_θ. We make use of $i_S(\hat{D}\hat{u})=0$ and $i_S(\hat{R^D}\hat{u})=0$, for any $u\in\Omega^0(E)$. Then (by Lemma 2)

$$(\delta^{\hat{D}}R^{\hat{D}})(X^{\uparrow})\hat{u} = -\sum_{a=1}^{2n}(\hat{D}_{E_a^{\uparrow}}R^{\hat{D}})(E_a^{\uparrow},X^{\uparrow}) - (\hat{D}_{T^{\uparrow}+S}R^{\hat{D}})(T^{\uparrow}+S,X^{\uparrow}) + (\hat{D}_{T^{\uparrow}-S}R^{\hat{D}})(T^{\uparrow}-S,X^{\uparrow})$$

$$= [(\delta_b^D R^D)(X)u + 2R^D(T,JX)u] - \sum_{a=1}^{2n}[(\mathrm{d}\theta)(E_a,X)R^D(E_a,T)u]$$

and

$$\sum_{a=1}^{2n}(\mathrm{d}\theta)(E_a,X)E_a = -JX$$

hence (87) is proved. Similarly

$$(\delta^{\hat{D}}R^{\hat{D}})(T^{\uparrow})\hat{u} = [(\delta_b^D R^D)(T)u] + \sum_{a=1}^{2n}[R^D(E_a,\tau E_a + \phi E_a)u]. \tag{93}$$

Now, on one hand

$$\sum_{a=1}^{2n}R^D(E_a,\tau E_a)u = g^{\alpha\bar{\beta}}[R^D(T_\alpha,\tau T_{\bar{\beta}})u + R^D(T_{\bar{\beta}},\tau T_\alpha)u] = A^{\alpha\gamma}R^D(T_\alpha,T_\gamma)u + A^{\bar{\beta}\bar{\gamma}}R^D(T_{\bar{\beta}},T_{\bar{\gamma}})u = 0$$

(as $A_{\alpha\beta}=A_{\beta\alpha}$) with the corresponding simplification of (93). On the other hand

$$\sum_{a=1}^{2n}R^D(E_a,\phi E_a)u = \phi^{\alpha\gamma}R^D(T_\alpha,T_\gamma)u + \phi^{\alpha\bar{\gamma}}R^D(T_\alpha,T_{\bar{\gamma}})u + \phi^{\bar{\beta}\gamma}R^D(T_{\bar{\beta}},T_\gamma)u + \phi^{\bar{\beta}\bar{\gamma}}R^D(T_{\bar{\beta}},T_{\bar{\gamma}})u,$$

where $\phi T_\alpha = \phi_\alpha{}^\beta T_\beta + \phi_\alpha{}^{\bar{\beta}}T_{\bar{\beta}}$, $\phi^{\alpha\beta}=g^{\alpha\bar{\gamma}}\phi_{\bar{\gamma}}{}^{\beta}$, etc. Let us take the exterior derivative of (71) so that to obtain

$$(n+2)\mathrm{d}\sigma = \pi^*\left[i\mathrm{d}\omega_\alpha{}^\alpha - \frac{i}{2}\mathrm{d}g^{\alpha\bar{\beta}}\wedge\mathrm{d}g_{\alpha\bar{\beta}} - \frac{1}{4(n+1)}d(\rho\theta)\right].$$

Using the identities $\mathrm{d}g_{\alpha\bar{\beta}}=g_{\alpha\bar{\gamma}}\omega_{\bar{\beta}}{}^{\bar{\gamma}}+\omega_\alpha{}^\gamma g_{\gamma\bar{\beta}}$ (a consequence of $\nabla g_\theta=0$) and $\mathrm{d}g^{\alpha\bar{\beta}}=-g^{\gamma\bar{\beta}}g^{\alpha\bar{\rho}}\mathrm{d}g_{\bar{\rho}\gamma}$ (a consequence of $g^{\alpha\bar{\beta}}g_{\bar{\beta}\gamma}=\delta_\gamma^\alpha$) it follows that

$$\mathrm{d}g^{\alpha\bar{\beta}}\wedge\mathrm{d}g_{\alpha\bar{\beta}} = \omega_{\alpha\bar{\beta}}\wedge\omega^{\alpha\bar{\beta}} + \omega_{\bar{\alpha}\beta}\wedge\omega^{\bar{\alpha}\beta} = 0.$$

Also (cf. e.g., Ref. 34)

$$d\omega_\alpha{}^\alpha = R_{\lambda\bar{\mu}}\theta^\alpha\wedge\theta^{\bar{\mu}} + (W_{\alpha\lambda}^{\alpha}\theta^\lambda - W_{\alpha\bar{\mu}}^{\alpha}\theta^{\bar{\lambda}})\wedge\theta$$

where $R_{\lambda\bar{\mu}}$ is the pseudohermitian Ricci curvature and $W_{\alpha\lambda}^{\alpha}$ (respectively $W_{\alpha\bar{\mu}}^{\alpha}$) are certain contractions of the covariant derivatives of $A_{\bar{\beta}}^{\alpha}$. It follows that

$$(n+2)G_\theta(\phi X,Y) = i(R_{\alpha\bar{\beta}}\theta^\alpha\wedge\theta^{\bar{\beta}})(X,Y) - \frac{\rho}{4(n+1)}(\mathrm{d}\theta)(X,Y),$$

for any $X,Y\in H(M)$. Therefore

$$\phi^{\bar{\alpha}\beta} = \frac{i}{2(n+2)}\left(R^{\bar{\alpha}\beta} - \frac{\rho}{2(n+1)}g^{\bar{\alpha}\beta}\right), \quad \phi^{\alpha\beta}=0.$$

We may conclude that

$$\sum_{A=1}^{2n} R^D(E_a,\phi E_a)u = -\frac{i}{n+2}\left(R^{\alpha\bar{\beta}} - \frac{\rho}{2(n+1)}g^{\alpha\bar{\beta}}\right)R^D(T_\alpha,T_{\bar{\beta}})u$$

and (93) leads to (88). Finally (again by Lemma 2)

$$(\delta^{\hat{D}}R^{\hat{D}})(S)\hat{u} = \sum_{a=1}^{2n}[R^D(E_a,JE_a)u] = -2i[g^{\alpha\bar{\beta}}R^D(T_\alpha,T_{\bar{\beta}})u] = 2[(\Lambda_\theta R^D)u]$$

and (89) is proved.

The functional (7) may be generalized by considering $\mathcal{PYM}_p(D)=\int_M\|\pi_H R^D\|^p\theta\wedge(\mathrm{d}\theta)^n$ with $p\geqslant 0$. As well known, in Riemannian geometry there is a choice of p such that $\mathcal{YM}_p(D)=\int_M\|R^D\|^p d\,\mathrm{vol}(g)$ becomes a conformal invariant [precisely $2p$ should be the dimension of the given Riemannian manifold (M,g)] and it is a natural question (raised by the Referee) whether for an appropriate p the number $\mathcal{PYM}_p(D)$ is a CR invariant, i.e., invariant under a transformation $\tilde{\theta}=e^{2u}\theta$ with $u\in C^\infty(M)$. Unfortunately, unlike the Riemannian case beside from the norm and volume form the integrand $\pi_H R^D$ transforms as well according to the law

$$(\tilde{\pi}_H R^D)e_j = (\pi_H R^D)e_j + i[(2u^\beta\Omega^i_{j\alpha\beta} - u^{\bar{\beta}}\Omega^i_{j\alpha\bar{\beta}})\theta^\alpha\wedge\theta - (2u^{\bar{\beta}}\Omega^i_{j\bar{\alpha}\bar{\beta}} + u^\beta\Omega^i_{j\beta\bar{\alpha}})\theta^{\bar{\alpha}}\wedge\theta]\otimes e_i$$

where $R^D e_j=\Omega^i_j\otimes e_i$ and $\tilde{\pi}_H:\Omega^2[\mathrm{Ad}(E)]\to\Omega^2[\mathrm{Ad}(E)]/\mathcal{J}^2_{\tilde{\theta}}$ is the natural projection. The problem of building a CR invariant version of $\mathcal{PYM}(D)$ [an analog to $\mathcal{YM}_{n+1/2}(D)$, $g=g_\theta$] is open.

VII. THE SECOND VARIATION FORMULA

Let $\{D^t:|t|<\epsilon\}$ be a smooth family of connections in E, where $D=D^0$ is a pseudo Yang–Mills field. We write $D^t=D+A^t$, where $A^t\in\Omega^1[\mathrm{Ad}(E)]$ for each $|t|<\epsilon$. The curvature R^t of D^t is then given by

$$R^t = R^D + d^D A^t + \frac{1}{2}[A^t\wedge A^t]$$

(cf. e.g., (6.2) in Ref. 4, p. 212). Next, let us set $\varphi=\{dA^t/dt\}_{t=0}$ and $\psi=\{d^2A^t/dt^2\}_{t=0}$ and observe that

$$\|\pi_H R^t\|^2 = \|\pi_H R^D\|^2 + 2t\langle\pi_H R^D, d^D\varphi\rangle + t^2\{2\langle\pi_H R^D, d^D\psi\rangle + \langle\pi_H R^D,[\varphi\wedge\varphi]\rangle + \|\pi_H d^D\varphi\|^2\} + O(t^3).$$

Integrating by parts and using $\delta^D\pi_H R^D=0$ we obtain

$$\frac{d^2}{dt^2}[\mathcal{PYM}(D^t)]_{t=0} = \int_M(\|\pi_H d^D\varphi\|^2 + \langle\pi_H R^D,[\varphi\wedge\varphi]\rangle)\theta\wedge(\mathrm{d}\theta)^n. \tag{94}$$

We shall need the (zero order) operator $\mathcal{R}^D:\Omega^1[\mathrm{Ad}(E)]\to\Omega^1[\mathrm{Ad}(E)]$ given by

$$\mathcal{R}^D(\varphi)_X = \sum_{A=1}^{2n+1}[R^D_{E_A,X},\varphi_{E_A}],$$

for any $X\in T(M)$, $\varphi\in\Omega^1[\mathrm{Ad}(E)]$, where $\{E_A\}$ is a local orthonormal frame of $[T(M),g_\theta]$. Then (see (6.7) in Ref. 4, p. 213)

$$\langle[\varphi\wedge\varphi],R^D\rangle = \langle\varphi,\mathcal{R}^D(\varphi)\rangle. \tag{95}$$

Let us set

$$\mathcal{R}_b^D(\varphi)_X = \sum_{a=1}^{2n} [R^D_{E_a,X}, \varphi_{E_a}], \quad \mathcal{R}_0^D(\varphi)_X = [R^D_{T,X}, \varphi_T],$$

where $\{E_a\}$ is a local orthonormal frame of $(H(M), G_\theta)$, so that $\mathcal{R}^D = \mathcal{R}_b^D + \mathcal{R}_0^D$. Taking into account the identities

$$[\varphi \wedge \varphi] e_j = 4(\varphi_k^i \wedge \varphi_j^k) \otimes e_i,$$

$$(\theta \wedge i_T R^D) e_j = (P_{0A}{}^i{}_j \theta \wedge \theta^A) \otimes e_i,$$

$$\mathcal{R}_0^D(\varphi) e_j = [\varphi_j^k(T) P_{0A}{}^i{}_k - P_{0A}{}^k{}_j \varphi_k^i(T)] \theta^A \otimes e_i,$$

where $\varphi e_j = \varphi_j^i \otimes e_i$, $\varphi_j^i \in \Omega^1(U)$, we may conduct the calculations

$$\langle [\varphi \wedge \varphi], \theta \wedge i_T R^D \rangle = h^{j\bar{r}} \langle [\varphi \wedge \varphi] e_j, (\theta \wedge i_T R^D) e_r \rangle = 4 h^{j\bar{r}} h_{i\bar{s}} g_\theta^*(\varphi_k^i \wedge \varphi_j^k, P_{0A}{}^s{}_r \theta \wedge \theta^A)$$
$$= 2 h^{j\bar{r}} h_{i\bar{s}} g^{A\bar{B}} [\varphi_k^i(T) \varphi_j^k(T_A) - \varphi_k^i(T_A) \varphi_j^k(T)] P_{0\bar{B}}{}^{\bar{s}}{}_{\bar{r}},$$

and

$$\langle \varphi, \mathcal{R}_0^D(\varphi) \rangle = h^{j\bar{r}} h_{i\bar{s}} \varphi_j^i(T_A) [\varphi_{\bar{r}}^{\bar{k}}(T) P_{0\bar{B}}{}^{\bar{s}}{}_{\bar{k}} - P_{0\bar{B}}{}^{\bar{k}}{}_{\bar{r}} \varphi_{\bar{k}}^{\bar{s}}(T)] g^{A\bar{B}} = \varphi_j^i(T_A) g^{A\bar{B}} [h^{j\bar{k}} h_{i\bar{s}} \varphi_{\bar{k}}^{\bar{r}}(T) - h^{j\bar{r}} h_{i\bar{k}} \varphi_{\bar{s}}^{\bar{k}}(T)] P_{0\bar{B}}{}^{\bar{s}}{}_{\bar{r}}.$$

Assume now that $\{e_j\}$ is orthonormal ($h_{i\bar{j}} = \delta_{ij}$), so that $\varphi_{\bar{j}}^{\bar{i}} = -\varphi_i^j$ [as φ is Ad(E) valued]. Then

$$\langle [\varphi \wedge \varphi], \theta \wedge i_T R^D \rangle = 2 \sum_{i,j} [\varphi_k^i(T) \varphi_j^k(T_A) - \varphi_k^i(T_A) \varphi_j^k(T)] g^{A\bar{B}} P_{0\bar{B}}{}^{\bar{i}}{}_{\bar{j}}$$

$$\langle \varphi, \mathcal{R}_0^D(\varphi) \rangle = \sum_{r,s} [\varphi_i^s(T) \varphi_r^i(T_A) - \varphi_j^s(T_A) \varphi_r^j(T)] g^{A\bar{B}} P_{0\bar{B}}{}^{\bar{s}}{}_{\bar{r}}$$

hence

$$\langle [\varphi \wedge \varphi], \theta \wedge i_T R^D \rangle = 2 \langle \varphi, \mathcal{R}_0^D(\varphi) \rangle.$$

Finally, let us take into account (95) and the identity

$$R^D = \pi_H R^D + 2\theta \wedge i_T R^D.$$

We obtain

$$\langle [\varphi \wedge \varphi], \pi_H R^D \rangle = \langle \varphi, \mathcal{R}^D(\varphi) - 4\mathcal{R}_0^D(\varphi) \rangle,$$

so that (94) becomes

$$\frac{d^2}{dt^2} [\mathcal{P}YM(D^t)]_{t=0} = \int_M \langle \delta^D \pi_H d^D \varphi + \mathcal{R}^D(\varphi) - 4\mathcal{R}_0^D(\varphi), \varphi \rangle \theta \wedge (\mathrm{d}\theta)^n. \tag{96}$$

We now restrict our variations to those whose first-order part φ satisfies $i_T \varphi = 0$ and $\delta^D \varphi = 0$. Also, let us introduce the first-order differential operator $d_b^D : \Omega^1[\mathrm{Ad}(E)] \to \Omega_H^2[\mathrm{Ad}(E)]$ given by $d_b^D \equiv \pi_H \circ d^D$. Then $\delta^D \pi_H d^D \varphi = \delta_b^D d_b^D \varphi = \Delta_b^D \varphi$ and $\mathcal{R}_0^D(\varphi) = 0$, so that (96) yields (12) in Theorem 3. Here $\Delta_b^D \equiv d_b^D \delta_b^D + \delta_b^D d_b^D$ is the *generalized sublaplacian*. The Riemannian counterpart $\mathcal{S}^D = \Delta^D + \mathcal{R}^D$ (cf. Ref. 4, p. 213, where Δ^D is the generalized Hodge–de Rham laplacian) of $\mathcal{S}_b^D = \Delta_b^D + \mathcal{R}_b^D$ in Theorem 3 is an elliptic operator, hence its restriction to $\mathrm{Ker}(\delta^D) \subset \Omega^1[\mathrm{Ad}(E)]$ has a discrete spectrum tending to $+\infty$ and the eigenspace corresponding to each eigenvalue of $\mathcal{S}^D$ is finite dimensional. This allows one to employ concepts from Morse theory (cf. Definition 6.10 in

Ref. 4, p. 213) in order to discuss stability and weak stability of Yang–Mills fields (cf. Ref. 4, p. 214). The CR analog of this phenomenon is that $\Delta_b^D:\Omega^{0,1}[\mathrm{Ad}(E)]\to\Omega^{0,1}[\mathrm{Ad}(E)]$ is subelliptic of order $\frac{1}{2}$, where $\Omega^{0,q}[\mathrm{Ad}(E)]=\Gamma^\infty[\Lambda^{0,q}(M)\otimes\mathrm{Ad}(E)]$. A complex valued q-form η on M is of *type* $(0,q)$, or a $(0,q)$ *form*, if $T_{1,0}(M)\rfloor\eta=0$ and $i_T\eta=0$. We denote by $\Lambda^{0,q}(M)\to M$ the relevant bundle and set $\Omega^{0,q}(M)=\Gamma^\infty[\Lambda^{0,q}(M)]$. Let M be a strictly pseudoconvex CR manifold (not necessarily compact). It is the proper place to recall that a formally self-adjoint second-order differential operator $L:C^\infty(M)\to C^\infty(M)$ is *subelliptic* (of order $0<\epsilon\leqslant 1$) at a point $x\in M$ if there is a neighborhood U of x such that

$$\|u\|_\epsilon^2\leqslant C[(Lu,u)+\|u\|^2]$$

for any $u\in C_0^\infty(U)$, where $\|u\|_\epsilon$ is the Sobolev norm u of order ϵ, $\|u\|=(u,u)^{1/2}$, and

$$(u,v)=\int_M uv\,d\,\mathrm{vol}(g_\theta) \tag{97}$$

is the ordinary L^2 inner product. L is subelliptic (of order ϵ) if it is subelliptic at any $x\in M$. A typical example is the *sublaplacian*

$$\Delta_b u=-\operatorname{div}(\nabla^H u),\quad u\in C^\infty(M),$$

where $\nabla^H u\equiv\pi_H\nabla u$, ∇u is the gradient of u with respect to the Webster metric g_θ, and the divergence is defined with respect to the volume form $\omega\equiv\theta\wedge(d\theta)^n$, i.e.,

$$\mathcal{L}_X\omega=\operatorname{div}(X)\omega,$$

for any $X\in\mathcal{X}(M)$, where $\mathcal{L}_X$ is the Lie derivative. It is easily seen that $\Delta_b u=-\Sigma_{a=1}^{2n}E_a^*E_a u$, for any local orthonormal frame $\{E_a\}$ of $H(M)$ hence, by a well known lemma of Radkevic,[27] it follows that $\|u\|_{1/2}^2\leqslant C[(\Delta_b u,u)+\|u\|^2]$, for any $u\in C_0^\infty(U)$, i.e., Δ_b is subelliptic of order $\frac{1}{2}$. Here E_a^* is the formal adjoint of E_a with respect to the inner product (97). In the next section we relate Δ_b^D to the Kohn–Rossi operator $\Box_b$ and explain the subellipticity of $\Box_b$ on (0, 1) forms.

VIII. SUBELLIPTICITY OF Δ_b^D

Let $\{T_\alpha\}$ be a local frame of $T_{1,0}(M)$. We start by computing

$$(\delta_b^D d_b^D\varphi)T_\lambda=-\sum_{a=1}^{2n}(D_{E_a}d_b^D\varphi)(E_a,T_\lambda),$$

for any $\varphi\in\Omega_H^1[\mathrm{Ad}(E)]$. Let us take into account the identities

$$g^{\alpha\bar\beta}(D_{T_\alpha}d_b^D\varphi)(T_{\bar\beta},T_\lambda)=g^{\alpha\bar\beta}\{D_{T_\alpha}[(d_b^D\varphi)(T_{\bar\beta},T_\lambda)]-\Gamma_{\alpha\bar\beta}^{\bar\gamma}(d_b^D\varphi)(T_{\bar\gamma},T_\lambda)-\Gamma_{\alpha\lambda}^{\gamma}(d_b^D\varphi)(T_{\bar\beta},T_\gamma)\},$$

$$(d_b^D\varphi)(T_\alpha,T_{\bar\beta})e_j=[(\nabla_{T_\alpha}\varphi_j^i)T_{\bar\beta}-(\nabla_{T_{\bar\beta}}\varphi_j^i)T_\alpha+2(\omega_k^i\wedge\varphi_j^k+\varphi_k^i\wedge\omega_j^k)(T_\alpha,T_{\bar\beta})]e_i,$$

where ω_j^i are the connection 1-forms of D with respect to $\{e_i\}$. Also, let us set

$$\nabla_{\bar\mu}\nabla_\lambda\psi_{\bar\alpha}\equiv(\nabla_{T_{\bar\mu}}\nabla\psi)(T_\lambda,T_{\bar\alpha})=T_{\bar\mu}(\nabla_\lambda\psi_{\bar\alpha})-\Gamma_{\bar\mu\lambda}^{\rho}\nabla_\rho\psi_{\bar\alpha}-\Gamma_{\bar\mu\bar\alpha}^{\bar\rho}\psi_{\bar\rho},$$

for any $\psi=\psi_{\bar\alpha}\theta^{\bar\alpha}\in\Omega^{0,1}(M)$, where $\nabla_\alpha\psi_{\bar\beta}\equiv(\nabla_{T_\alpha}\psi)T_{\bar\beta}$. We obtain

$$g^{\alpha\bar{\beta}}(D_{T_\alpha}d_b^D\varphi)(T_{\bar{\beta}},T_\lambda)e_j = -g^{\alpha\bar{\beta}}\{\nabla_\alpha\nabla_\lambda\varphi^i_{j\bar{\beta}} - \nabla_\alpha\nabla_{\bar{\beta}}\varphi^i_{j\lambda} + \omega_j^k(T_{\bar{\beta}})A_k^i(T_\alpha,T_\lambda) - \omega_j^k(T_\lambda)A_k^i(T_\alpha,T_{\bar{\beta}})$$
$$+ \omega_k^i(T_\lambda)B_j^k(T_\alpha,T_{\bar{\beta}}) - \omega_k^i(T_{\bar{\beta}})B_j^k(T_\alpha,T_\lambda) + \omega_k^i(T_\alpha)[(\nabla_{T_\lambda}\varphi_j^k)T_{\bar{\beta}} - (\nabla_{T_{\bar{\beta}}}\varphi_j^k)T_\lambda]$$
$$+ \omega_j^k(T_\alpha)[(\nabla_{T_{\bar{\beta}}}\varphi_k^i)T_\lambda - (\nabla_{T_\lambda}\varphi_k^i)T_{\bar{\beta}}] + \varphi^k_{j\bar{\beta}}C_k^i(T_\alpha,T_\lambda) - \varphi^k_{j\lambda}C_k^i(T_\alpha,T_{\bar{\beta}})$$
$$+ \varphi^i_{k\lambda}D_j^k(T_\alpha,T_{\bar{\beta}}) - \varphi^i_{k\bar{\beta}}D_j^k(T_\alpha,T_{\bar{\beta}})\}\otimes e_i$$

where

$$A_j^i \equiv \nabla\varphi_j^i + \omega_k^i\otimes\varphi_j^k, \quad B_j^i \equiv \nabla\varphi_j^i - \omega_j^k\otimes\varphi_k^i,$$

$$C_j^i \equiv \nabla\omega_j^i + \omega_k^i\otimes\omega_j^k, \quad D_j^i \equiv \nabla\omega_j^i - \omega_j^k\otimes\omega_k^i,$$

and $\varphi^i_{jA}=\varphi_j^i(T_A)$, so that $\nabla_\alpha\nabla_{\bar{\beta}}\varphi^i_{j\lambda}$ (respectively, $\nabla_\alpha\nabla_\beta\varphi^i_{j\bar{\lambda}}$) is the second-order covariant derivative of the (1,0) form $\pi_{1,0}\varphi_j^i$ [respectively, of the (0,1)-form $\pi_{0,1}\varphi_j^i$] [$\pi_{1,0}:\Omega^1(M)\to\Omega^{1,0}(M)$ and $\pi_{0,1}:\Omega^1(M)\to\Omega^{0,1}(M)$ are the natural projections]. The previous identity is rather involved, yet one is interested in the second-order terms alone. Together with the similar expression for $g^{\alpha\bar{\beta}}(D_{T_{\bar{\beta}}}d_b^D\varphi)(T_\alpha,T_\lambda)e_j$ this leads to

$$(\delta_b^Dd_b^D\varphi)(T_\lambda)e_j = g^{\alpha\bar{\beta}}(\nabla_\alpha\nabla_\lambda\varphi^i_{j\bar{\beta}} + \nabla_{\bar{\beta}}\nabla_\lambda\varphi^i_{j\alpha} - \nabla_\alpha\nabla_{\bar{\beta}}\varphi^i_{j\lambda} - \nabla_{\bar{\beta}}\nabla_\alpha\varphi^i_{j\lambda})e_i + \textit{lower order terms}. \tag{98}$$

By *lower order terms* (l.o.t.) we mean a linear combination of $\nabla_A\varphi^i_{jB}$ and φ^i_{jB} [with $C^\infty(U)$ coefficients]. Next, we need to compute

$$(d_b^D\delta_b^D\varphi)T_\lambda = D_{T_\lambda}(\delta_b^D\varphi) = -\sum_{a=1}^{2n} D_{T_\lambda}[(D_{E_a}\varphi)E_a].$$

We have

$$\{D_{T_\lambda}[g^{\alpha\bar{\beta}}(D_{T_\alpha}\varphi)T_{\bar{\beta}}]\}e_j = g^{\alpha\bar{\beta}}[\nabla_\lambda\nabla_\alpha\varphi^i_{j\bar{\beta}} - \omega_j^k(T_\lambda)A_k^i(T_\alpha,T_{\bar{\beta}}) + \omega_k^i(T_\lambda)B_j^k(T_\alpha,T_{\bar{\beta}}) - \omega_k^j(T_\alpha)(\nabla_{T_\lambda}\varphi_k^i)T_{\bar{\beta}}$$
$$+ \omega_k^i(T_\alpha)(\nabla_{T_\lambda}\varphi_j^k)T_{\bar{\beta}} + \varphi^k_{j\bar{\beta}}C_k^i(T_\lambda,T_\alpha) - \varphi^i_{k\bar{\beta}}D_j^k(T_\lambda,T_\alpha)]e_i.$$

Together with a similar expression for $D_{T_\lambda}[g^{\alpha\bar{\beta}}(D_{T_{\bar{\beta}}}\varphi)T_\alpha]$ this yields

$$(d_b^D\delta_b^D\varphi)(T_\lambda)e_j = -g^{\alpha\bar{\beta}}(\nabla_\lambda\nabla_\alpha\varphi^i_{j\bar{\beta}} + \nabla_\lambda\nabla_{\bar{\beta}}\varphi^i_{j\alpha})e_i + l.o.t. \tag{99}$$

We shall need the commutation formulae

$$\nabla_\alpha\nabla_\beta\eta_{\bar{\gamma}} - \nabla_\beta\nabla_\alpha\eta_{\bar{\gamma}} = -\eta_{\bar{\rho}}R_{\bar{\gamma}\ \alpha\beta}^{\ \bar{\rho}},$$

$$\nabla_{\bar{\beta}}\nabla_\alpha\eta_\gamma - \nabla_\alpha\nabla_{\bar{\beta}}\eta_\gamma = 2ig_{\alpha\bar{\beta}}\nabla_0\eta_\gamma - \eta_\rho R_{\gamma\ \bar{\beta}\alpha}^{\ \rho},$$

where the convention for the curvature components (of the Tanaka–Webster connection) is $R(T_A,T_B)T_C = R_C^{\ D}{}_{AB}T_D$. Then [by (98) and (99)]

$$(\Delta_b^D\varphi)(T_\lambda)e_j = g^{\alpha\bar\beta}(\nabla_\alpha\nabla_\lambda\varphi^i_{j\bar\beta} - \nabla_\lambda\nabla_\alpha\varphi^i_{j\bar\beta} + \nabla_{\bar\beta}\nabla_\lambda\varphi^i_{j\alpha} - \nabla_\lambda\nabla_{\bar\beta}\varphi^i_{j\alpha} - \nabla_\alpha\nabla_{\bar\beta}\varphi^i_{j\lambda} - \nabla_{\bar\beta}\nabla_\alpha\varphi^i_{j\lambda})e_i + l.o.t.$$

$$= [-\varphi^i_j(T_{\bar\rho})g^{\alpha\bar\beta}R_{\bar\beta}{}^{\bar\rho}{}_{\alpha\lambda} + 2\sqrt{-1}\nabla_0\varphi^i_{j\lambda} - \varphi^i_j(T_\rho)g^{\alpha\bar\beta}R_\alpha{}^\rho{}_{\bar\beta\lambda} - 2g^{\alpha\bar\beta}\nabla_{\bar\beta}\nabla_\alpha\varphi^i_{j\lambda}$$

$$+ 2\sqrt{-1}n\nabla_0\varphi^i_{j\lambda} - \varphi^i_j(T_\rho)g^{\alpha\bar\beta}R_\lambda{}^\rho{}_{\bar\beta\alpha}]e_i + l.o.t.$$

At this point we need the Kohn–Rossi operator $\Box_b$ on $\Omega^{0,1}(M)$. We start by extending $\bar\partial_b$ (originally defined on functions, see Sec. III) to (0,1) forms. Precisely, if $\eta\in\Omega^{0,1}(M)$ then $\bar\partial_b\eta$ is the unique (0,2) form on M coinciding with $d\eta$ on $T_{0,1}(M)\otimes T_{0,1}(M)$. Next, let us set $\Box_b\equiv\bar\partial_b^*\bar\partial_b + \bar\partial_b\bar\partial_b^*$, where $\bar\partial_b^*$ is the formal adjoint of $\bar\partial_b$ with respect to the L^2 inner product $(\alpha,\beta) = \int_M g_\theta^*(\alpha,\bar\beta)\omega$. A straightforward calculation leads to

$$\Box_b\eta = (-g^{\alpha\bar\beta}\nabla_\alpha\nabla_{\bar\beta}\eta_{\bar\gamma} - 2i\nabla_0\eta_{\bar\gamma} + \eta_{\bar\rho}R^{\bar\rho}{}_{\bar\gamma})\theta^{\bar\gamma}, \tag{100}$$

for any $\eta=\eta_{\bar\gamma}\theta^{\bar\gamma}\in\Omega^{1,0}(U)$. Consequently

$$\bar\Box_b(\pi_{1,0}\varphi^i_j) = [\Box_b(\pi_{1,0}\varphi^i_j)^-]^- = [-g^{\alpha\bar\beta}\nabla_{\bar\beta}\nabla_\alpha\varphi^i_{j\lambda} + 2i\nabla_0\varphi^i_{j\lambda} + \varphi^i_j(T_\rho)R^\rho{}_\lambda]\theta^\lambda$$

hence

$$(\Delta_b^D\varphi)(T_\lambda)\theta^\lambda\otimes e_j = 2\bar\Box_b(\pi_{1,0}\varphi^i_j)e_i + \{2(n-1)\sqrt{-1}\nabla_0\varphi^i_{j\lambda} - \varphi^i_j(T_{\bar\rho})g^{\alpha\bar\beta}R_{\bar\beta}{}^{\bar\rho}{}_{\alpha\lambda} - \varphi^i_j(T_\rho)[2R^\rho{}_\lambda$$

$$+ g^{\alpha\bar\beta}(R_\alpha{}^\rho{}_{\bar\beta\lambda} + R_\lambda{}^\rho{}_{\bar\beta\alpha})]\}\theta^\lambda\otimes e_i + l.o.t.$$

To compute the curvature terms we need the identities

$$R_{\lambda\bar\mu} = R_\lambda{}^\alpha{}_{\alpha\bar\mu},$$

$$R_\alpha{}^\rho{}_{\lambda\mu} = 2i(A_{\mu\alpha}\delta^\rho_\lambda - A_{\lambda\alpha}\delta^\rho_\mu),$$

$$R_\alpha{}^\rho{}_{\bar\lambda\bar\mu} = 2i(g_{\alpha\bar\lambda}A^\rho_{\bar\mu} - g_{\alpha\bar\mu}A^\rho_{\bar\lambda}),$$

$$R_{\alpha\bar\beta\lambda\bar\mu} = R_{\lambda\bar\beta\alpha\bar\mu}, \quad R_{\alpha\bar\beta\lambda\bar\mu} = -R_{\bar\beta\alpha\lambda\bar\mu},$$

following essentially by the techniques developed in Ref. 34. Indeed we have

$$g^{\alpha\bar\beta}R_{\bar\beta}{}^{\bar\rho}{}_{\alpha\lambda} = -2i(n-1)A^{\bar\rho}_\lambda,$$

$$2R^\rho{}_\lambda + g^{\alpha\bar\beta}(R_\alpha{}^\rho{}_{\bar\beta\lambda} + R_\lambda{}^\rho{}_{\bar\beta\alpha}) = 0,$$

hence

$$(\Delta_b^D\varphi)(T_\lambda)\theta^\lambda\otimes e_j = 2\bar\Box_b(\pi_{1,0}\varphi^i_j)\otimes e_i + 2(n-1)\sqrt{-1}[(\nabla_T\varphi^i_j)T_\lambda + A^{\bar\rho}_\lambda\varphi^i_j(T_{\bar\rho})]\theta^\lambda\otimes e_i + l.o.t. \tag{101}$$

Recall that $\tau T_\alpha = A^{\bar\beta}_\alpha T_{\bar\beta}$. Then (101) together with the similar identity $(\Delta_b^D\varphi)(T_{\bar\lambda})e_j = 2[(\Box_b\pi_{0,1}\varphi^i_j)_{\bar\lambda} - (n-1)\sqrt{-1}(\nabla_0\varphi^i_{j\bar\lambda} + A^\rho_{\bar\lambda}\varphi^i_{j\rho})]e_i + l.o.t.$. leads to

$$(\Delta_b^D\varphi)\otimes e_j = 2[\Box_b(\pi_{0,1}\varphi_j^i) + \bar{\Box}_b(\pi_{1,0}\varphi_j^i) + (n-1)(\nabla_T\varphi_j^i + \varphi_j^i\circ\tau)\circ J]\otimes e_i + l.o.t.$$

and therefore to (13) when φ is a (0,1) form. Finally, let us show that $\Box_b$ is subelliptic on (scalar) (0,1) forms. As $\nabla\omega=0$, the sublaplacian may be computed as

$$\Delta_b f = -\operatorname{trace}\{T_A \mapsto \nabla_{T_A}\nabla^H f\} = -\nabla_\alpha f^\alpha - \nabla_{\bar\alpha} f^{\bar\alpha},$$

for any C^∞ function $f: M\to\mathbb{C}$, where $f^\alpha = g^{\alpha\bar\beta}T_{\bar\beta}(f)$. As $\nabla g_\theta = 0$

$$g^{\alpha\bar\beta}\nabla_\alpha\nabla_{\bar\beta}\eta_{\bar\lambda} = \nabla_\alpha(g^{\alpha\bar\beta}\nabla_{\bar\beta}\eta_{\bar\lambda}) = \nabla_\alpha(\eta_{\bar\lambda})^\alpha - \nabla_\alpha(g^{\alpha\bar\beta}\Gamma^{\bar\rho}_{\bar\beta\bar\lambda}\eta_{\bar\rho}).$$

A similar expression holds for $g^{\alpha\bar\beta}(\nabla_{\bar\beta}\nabla_\alpha\eta_{\bar\lambda})$. Adding up the two identities leads to

$$g^{\alpha\bar\beta}(\nabla_\alpha\nabla_{\bar\beta}\eta_{\bar\lambda} + \nabla_{\bar\beta}\nabla_\alpha\eta_{\bar\lambda}) = -\Delta_b\eta_{\bar\lambda} + l.o.t.$$

or [by the commutation formulae for the second order derivatives and (100)]

$$2(\Box_b\eta)_{\bar\lambda} - 2i(n-1)\nabla_0\eta_{\bar\lambda} - \eta_{\bar\rho}R^{\bar\rho}{}_{\bar\lambda} = \Delta_b\eta_{\bar\lambda} + g^{\alpha\bar\beta}[\nabla_\alpha(\Gamma^{\bar\rho}_{\bar\beta\bar\lambda}\eta_{\bar\rho}) + \nabla_{\bar\beta}(\Gamma^{\bar\rho}_{\alpha\bar\lambda}\eta_{\bar\rho})].$$

Hence $\Box_b$ is subelliptic on $\Omega^{0,1}(M)$, i.e., $\Box_b\eta$ is locally given by a subelliptic operator acting on the coefficients of η, plus lower order terms. In particular [by (13)] $(\Delta_b^D\varphi)\otimes e_j = \Delta_b[\varphi_j^i(T_{\bar\alpha})]\theta^{\bar\alpha}\otimes e_i$+l.o.t. Theorem 3 is completely proved.

APPENDIX: THE GRAHAM–LEE CONNECTION

Let $\Omega=\{\varphi<0\}\subset\mathbb{C}^n$ be a strictly pseudoconvex domain and $\mathcal{F}$ the foliation by level sets of φ of a one-sided neighborhood V of $\partial\Omega$ (as in Sec. III of this paper). Let $\{W_\alpha: 1\leqslant\alpha\leqslant n-1\}$ be a local frame of $T_{1,0}(\mathcal{F})$, so that $\{W_\alpha,\xi\}$ is a local frame of $T^{1,0}(V)$. Let g_θ be the tensor field given by

$$g_\theta(X,Y) = (d\theta)(X,JY),\quad g_\theta(X,T)=0,\quad g_\theta(T,T)=1, \tag{A1}$$

for any $X,Y\in H(\mathcal{F})$. Then g_θ is a tangential Riemannian metric for $\mathcal{F}$, i.e., a Riemannian metric in $T(\mathcal{F})\to V$. We consider as well

$$L_\theta(Z,\bar W) \equiv -i(d\theta)(Z,\bar W),\quad Z,W\in T_{1,0}(\mathcal{F}).$$

Note that L_θ and (the C-linear extension of) g_θ coincide on $T_{1,0}(\mathcal{F})\otimes T_{0,1}(\mathcal{F})$. We set $g_{\alpha\bar\beta} = g_\theta(W_\alpha, W_{\bar\beta})$. Let $\{\theta^\alpha: 1\leqslant\alpha\leqslant n-1\}$ be the (locally defined) complex 1 forms on V determined by

$$\theta^\alpha(W_\beta) = \delta^\alpha_\beta,\quad \theta^\alpha(W_{\bar\beta})=0,\quad \theta^\alpha(T)=0, \theta^\alpha(N)=0.$$

Then $(\theta^\alpha,\theta^{\bar\alpha},\theta,d\varphi)$ is a local frame of $T(V)\otimes\mathbb{C}$ and we may look for $\mathrm{d}\theta$ in the form

$$\mathrm{d}\theta = B_{\alpha\beta}\theta^\alpha\wedge\theta^\beta + B_{\alpha\bar\beta}\theta^\alpha\wedge\theta^{\bar\beta} + B_{\bar\alpha\bar\beta}\theta^{\bar\alpha}\wedge\theta^{\bar\beta} + (B_\alpha\theta^\alpha + B_{\bar\alpha}\theta^{\bar\alpha})\wedge\theta + (C_\alpha\theta^\alpha + C_{\bar\alpha}\theta^{\bar\alpha})\wedge\mathrm{d}\varphi + D\,\mathrm{d}\varphi\wedge\theta.$$

As $\mathrm{d}\theta = i\partial\bar\partial\varphi\in\Omega^{1,1}(U)$ it follows that $B_{\alpha\beta}=0$, $B_{\bar\alpha\bar\beta}=0$. Also

$$g_{\alpha\bar\beta} = g_\theta(W_\alpha,W_{\bar\beta}) = -i(d\theta)(W_\alpha,W_{\bar\beta}) = -\frac{i}{2}B_{\alpha\bar\beta}$$

i.e., $B_{\alpha\bar\beta}=2ig_{\alpha\bar\beta}$. Next

$$\frac{1}{2}B_\alpha = (d\theta)(W_\alpha, T) = i\partial\bar{\partial}\varphi(W_\alpha, T) = 0$$

as $T = i(\xi - \bar{\xi})$ [and ξ is orthogonal to $T_{1,0}(\mathcal{F})$ with respect to $\partial\bar{\partial}\varphi$], i.e., $B_\alpha = 0$, $B_{\bar{\alpha}} = 0$. Similarly $C_\alpha = 0$, $C_{\bar{\alpha}} = 0$. Finally

$$D = (\mathrm{d}\theta)(N, T) = i\partial\bar{\partial}\varphi(N, T) = 2\partial\bar{\partial}\varphi(\xi, \bar{\xi}) = r$$

i.e., $D = r$. We obtain the identity

$$\mathrm{d}\theta = 2ig_{\alpha\bar{\beta}}\theta^\alpha \wedge \theta^{\bar{\beta}} + r\,\mathrm{d}\varphi \wedge \theta. \tag{A2}$$

As an immediate consequence

$$i_T\,\mathrm{d}\theta = -\frac{r}{2}\mathrm{d}\varphi, \tag{A3}$$

$$i_N\,\mathrm{d}\theta = r\theta. \tag{A4}$$

For instance [by Eq. (A2)]

$$(\mathrm{d}\theta)(X, T) = \frac{r}{2}[(\mathrm{d}\varphi)(X) - (\mathrm{d}\varphi)(T)\,\theta(X)],$$

for any $X \in T(\mathcal{F})$, hence [as $(\mathrm{d}\varphi)(T) = 0$] one derives (A3). As an application of (A2) we decompose $[T, N]$ [according to $T(V) \otimes \mathbb{C} = T_{1,0}(\mathcal{F}) \oplus T_{0,1}(\mathcal{F}) \oplus \mathbb{C}T \oplus \mathbb{C}N$]. This is a bit trickier, as shown below. By (A3)

$$\theta([T, N]) = -2(\mathrm{d}\theta)(T, N) = r\,\mathrm{d}\varphi(N) = 2r.$$

Next

$$\begin{aligned} 2(\mathrm{d}\theta)[W_\alpha, (T, N)] &= 2W_\alpha(r) - \theta\{[W_\alpha, (T, N)]\} = (\textit{Jacobi's identity}) = 2W_\alpha(r) + \theta\{[T, (N, W_\alpha)]\} \\ &\quad + \theta\{[N, (W_\alpha, T)]\} = 2W_\alpha(r) + 2(\mathrm{d}\theta)[T, (W_\alpha, N)] - T\{\theta[(W_\alpha, N)]\} \\ &\quad + 2(\mathrm{d}\theta)[N, (T, W_\alpha)] - N\{\theta[(T, W_\alpha)]\} \end{aligned}$$

hence [by (A3) and (A4)]

$$(\mathrm{d}\theta)[W_\alpha, (T, N)] = W_\alpha(r).$$

We conclude that

$$(T, N) = iW^\alpha(r)W_\alpha - iW^{\bar{\alpha}}(r)W_{\bar{\alpha}} + 2rT, \tag{A5}$$

where $W^\alpha(r) = g^{\alpha\bar{\beta}}W_{\bar{\beta}}(r)$ and $W^{\bar{\alpha}}(r) = \overline{W^\alpha(r)}$.

Let ∇ be a linear connection on V. Let us consider the $T(V)$-valued 1 form τ on V defined by

$$\tau(X) = T_\nabla(T, X), \quad X \in T(V),$$

where T_∇ is the torsion tensor field of ∇. We say T_∇ is *pure* if

$$T_\nabla(Z, W) = 0, \quad T_\nabla(Z, \bar{W}) = 2iL_\theta(Z, \bar{W})T, \tag{A6}$$

$$T_\nabla(N, W) = rW + i\tau(W), \tag{A7}$$

for any $Z, W \in T_{1,0}(\mathcal{F})$, and

$$\tau[T_{1,0}(\mathcal{F})] \subseteq T_{0,1}(\mathcal{F}), \tag{A8}$$

$$\tau(N) = -J\nabla^H r - 2rT. \tag{A9}$$

Here $\nabla^H r$ is defined by $\nabla^H r = \pi_H \nabla r$ and $g_\theta(\nabla r, X) = X(r)$, $X \in T(\mathcal{F})$. Also $\pi_H : T(\mathcal{F}) \to H(\mathcal{F})$ is the projection associated to the direct sum decomposition $T(\mathcal{F}) = H(\mathcal{F}) \oplus \mathbb{R}T$. The Appendix is aimed at the following:

Theorem 4: (Ref. 11) *There is a unique linear connection* ∇ *on* V *such that:* (i) $T_{1,0}(\mathcal{F})$ *is parallel with respect to* ∇, (ii) $\nabla L_\theta = 0$, $\nabla T = 0$, $\nabla N = 0$, *and* (iii) T_∇ *is pure*.

∇ given by Theorem 4 is the *Graham–Lee connection*. Compare to Proposition 1.1 in Ref. 11, pp. 701–702. The axiomatic description in Theorem 4 is however new (cf. also Theorem 2 in Ref. 7). We first establish

Lemma 3: Let $\phi : T(\mathcal{F}) \to T(\mathcal{F})$ *be the bundle morphism given by* $\phi(X) = JX$, *for any* $X \in H(\mathcal{F})$, *and* $\phi(T) = 0$. *Then*

$$\phi^2 = -I + \theta \otimes T,$$

$$g_\theta(X, T) = \theta(X),$$

$$g_\theta(\phi X, \phi Y) = g_\theta(X, Y) - \theta(X)\theta(Y),$$

for any $X, Y \in T(\mathcal{F})$. *Moreover, if* ∇ *is a linear connection on* V *satisfying the axioms* (i)–(iii) *in Theorem* 4 *then*

$$\phi \circ \tau + \tau \circ \phi = 0 \tag{A10}$$

along $T(\mathcal{F})$. *Consequently* τ *may be computed as*

$$\tau(X) = -\frac{1}{2}\phi(\mathcal{L}_T \phi)X, \tag{A11}$$

for any $X \in H(\mathcal{F})$.

Proof: For any $X \in T(\mathcal{F})$

$$\phi(X) = \phi[\pi_H X + \theta(X)T] = J(\pi_H X) \in H(\mathcal{F}),$$

$$\phi^2(X) = J^2(\pi_H X) = -\pi_H X = -X + \theta(X)T.$$

The second statement in Lemma 112 follows from definitions [cf. (A1)]. The third identity follows from

$$g_\theta(\phi X, \phi Y) = (\mathrm{d}\theta)(\phi \pi_H X, \phi^2 \pi_H Y) = g_\theta(\pi_H Y, \pi_H X) = g_\theta(Y, X) - \theta(X) g_\theta(Y, T).$$

Let us prove (A10). As $\tau[T_{1,0}(\mathcal{F})] \subseteq T_{0,1}(\mathcal{F})$ [cf. axiom (A8)] there are complex valued functions $A_\alpha^{\bar{\beta}}$ such that $\tau(W_\alpha) = A_\alpha^{\bar{\beta}} W_{\bar{\beta}}$. Then

$$(\tau \circ \phi + \phi \circ \tau) W_\alpha = i\tau(W_\alpha) + A_\alpha^{\bar{\beta}} \phi(W_{\bar{\beta}}) = 0.$$

It remains that we check (A11). As $T_{1,0}(\mathcal{F})$ is parallel with respect to ∇ and ∇ is a real operator it follows that $T_{0,1}(\mathcal{F})$ is parallel, hence both $H(\mathcal{F})$ and its complex structure $J_{\mathcal{F}} \equiv J|_{H(\mathcal{F})}$ are parallel. Moreover, as $\nabla T = 0$, it follows that ϕ is parallel, as well. Let $X \in H(\mathcal{F})$. Then [by (A10)]

$$\phi \tau X = -T_\nabla(T, \phi X) = -\nabla_T \phi X + [T, \phi X].$$

Applying ϕ in both sides gives (as $\nabla \phi = 0$)

$$\tau X = -\nabla_T X - \phi[T,\phi X] = -[T,X] - \tau X - \phi[T,\phi X]$$

or

$$2\tau X = -\mathcal{L}_T X - \phi\mathcal{L}_T\phi X.$$

Q.E.D.

Proof of Theorem: To establish uniqueness, note first that, for any $X=X^{1,0}+X^{0,1}+\theta(X)T \in T(\mathcal{F})$ [with $X^{1,0}\in T_{1,0}(\mathcal{F})$, $X^{0,1}=\overline{X^{1,0}}$] one has (by $\nabla N=0$)

$$\nabla_N X = [N,X] + T_\nabla(N,X) = [by\ (A6)-(A7),\ (A9)] = [N,X] + rX^{1,0} + i\tau X^{1,0} + rX^{0,1} - i\tau X^{0,1} + \theta(X) \times (J\nabla^H r + 2rT)$$

that is

$$\nabla_N X = rX + \tau\phi X - [X,N] + \theta(X)(J\nabla^H r + rT), \tag{A12}$$

for any $X\in T(\mathcal{F})$. In view of (A11) $\nabla_N X$ is determined. As $\nabla N=0$, $\nabla T=0$ it remains that we compute $\nabla_X Z$, for $X\in T(\mathcal{F})$ and $Z\in T_{1,0}(\mathcal{F})$. Note that $\nabla T=0$, $\nabla L_\theta=0$ and $\nabla J_{\mathcal{F}}=0$ yield $\nabla g_\theta=0$, i.e.,

$$X[g_\theta(Y,Z)] = g_\theta(\nabla_X Y,Z) + g_\theta(Y,\nabla_X Z),$$

for any $X,Y,Z\in T(\mathcal{F})$. The well known Christoffel process then leads to

$$2g_\theta(\nabla_X Y,Z) = X[g_\theta(Y,Z)] + Y[g_\theta(X,Z)] - Z[g_\theta(X,Y)] + g_\theta[(X,Y),Z] + g_\theta[T_\nabla(X,Y),Z] + g_\theta[(Z,X),Y] + g_\theta[T_\nabla(Z,X),Y] + g_\theta[X,(Z,Y)] + g_\theta[X,T_\nabla(Z,Y)]. \tag{A13}$$

Note that (again by the purity axioms)

$$T_\nabla(X,Y) = 2(\mathrm{d}\theta)(X,Y)T + 2(\theta\wedge\tau)(X,Y), \tag{A14}$$

for any $X,Y\in T(\mathcal{F})$. Indeed [by (A6)]

$$T_\nabla(X,Y) = -2g_\theta(X,\phi Y)T + 2(\theta\wedge\tau)(X,Y).$$

Moreover

$$g_\theta(X,\phi Y) = g_\theta(\pi_H X,\phi\pi_H Y) + \theta(X)g_\theta(T,\phi\pi_H Y) = -(\mathrm{d}\theta)(\pi_H X,\pi_H Y) = -(\mathrm{d}\theta)(X,Y) + \theta(X)(\mathrm{d}\theta)(T,Y) + \theta(Y)(\mathrm{d}\theta)(X,T).$$

Finally [by (A3)] $(\mathrm{d}\theta)(X,T)=0$, $X\in T(\mathcal{F})$, and (A14) is proved. Replacing the torsion terms [from (A14) into (A13)] leads to

$$2g_\theta(\nabla_X Z,\bar{W}) = X[g_\theta(Z,\bar{W})] + Z[g_\theta(X,\bar{W})] - \bar{W}[g_\theta(X,Z)] + g_\theta[(X,Z),\bar{W}] + g_\theta[(\bar{W},X),Z] + g_\theta[X,(\bar{W},Z)], \tag{A15}$$

for any $X\in T(\mathcal{F})$ and $Z,W\in T_{1,0}(\mathcal{F})$, as [by (A8)]

$$\theta(X)[g_\theta(\tau Z,\bar{W}) - g_\theta(\tau\bar{W},Z)] = 0.$$

The uniqueness statement in Theorem 4 is proved. The following explicit expressions of (the various components of) ∇ are also available. By (A6)

$$\nabla_Z\bar{W} = \pi_{0,1}(Z,\bar{W}), \quad Z,W\in T_{1,0}(\mathcal{F}), \tag{A16}$$

where $\pi_{0,1}: T(\mathcal{F})\otimes\mathbb{C}\to T_{0,1}(\mathcal{F})$ is the projection. Of course

$$\nabla_{\bar{Z}}W = \overline{\nabla_Z \bar{W}}.$$

Moreover [by $\nabla L_\theta = 0$ and (A16)]

$$L_\theta(\nabla_Z W, \bar{V}) = Z[L_\theta(W,\bar{V})] - L_\theta[W, \pi_{0,1}(Z,\bar{V})],$$

for any $Z, W, V \in T_{1,0}(\mathcal{F})$, i.e.,

$$\nabla_Z W = g^{\alpha\bar{\beta}}\{Z[L_\theta(W, W_{\bar{\beta}})] - L_\theta[W, \pi_{0,1}(Z, W_{\bar{\beta}})]\}W_\alpha \tag{A17}$$

and

$$\nabla_{\bar{Z}}\bar{W} = \overline{\nabla_Z W}.$$

Next [by (A7) and (A8)]

$$\nabla_N Z = rZ + \pi_{1,0}[N,Z], \tag{A18}$$

for any $Z \in T_{1,0}(\mathcal{F})$, and

$$\nabla_N \bar{Z} = \overline{\nabla_N Z}.$$

Finally

$$\nabla_T Z = -\frac{1}{2}\phi(\mathcal{L}_T\phi)Z - [Z,T],$$

$$\nabla_T \bar{Z} = \overline{\nabla_T Z}, \quad Z \in T_{1,0}(\mathcal{F}). \tag{A19}$$

To establish the existence statement in Theorem 4 let ∇ be the linear connection on V defined by (A16)–(A19) and $\nabla T = 0$, $\nabla N = 0$. Let us check (i)–(iii) in Theorem 4. Clearly

$$\nabla_Z W, \quad \nabla_{\bar{Z}} W, \quad \nabla_N W \in T_{1,0}(\mathcal{F}),$$

for any $W \in T_{1,0}(\mathcal{F})$, by the very definitions [cf. (A16)–(A18). Moreover [by (A19)]

$$\nabla_T Z = \frac{1}{2}(\mathcal{L}_T Z - i\phi\mathcal{L}_T Z)$$

as [by (A3)] $\mathcal{L}_T Z \in H(\mathcal{F}) \otimes \mathbb{C}$. Therefore

$$\phi\nabla_T Z = i\nabla_T Z$$

that is [as $T_{1,0}(\mathcal{F})$ is the eigenspace corresponding to the eigenvalue i of [the $\mathbb{C}$-linear extension to $H(\mathcal{F})$ of] ϕ] $\nabla_T Z \in T_{1,0}(\mathcal{F})$. We conclude that ∇ obeys to (i). Let us check purity. By (A17)

$$L_\theta[\nabla_Z W - \nabla_W Z - (Z,W), \bar{V}] = Z[L_\theta(W,\bar{V})] - L_\theta[W, \pi_{0,1}(Z,\bar{V})] - W[L_\theta(Z,\bar{V})] + L_\theta[Z, \pi_{0,1}(W,\bar{V})]$$
$$- L_\theta[(Z,W),\bar{V}] = 3(\mathrm{d}^2\theta)(Z,W,\bar{V}) = 0.$$

Therefore $T_\nabla(Z,W) = 0$. Next [by (A16) and $\overline{\pi_{0,1}X} = \pi_{1,0}\bar{X}$, $X \in T(\mathcal{F}) \otimes \mathbb{C}$]

$$T_\nabla(Z,\bar{W}) = \pi_{0,1}[Z,\bar{W}] - \overline{\pi_{0,1}(W,\bar{Z})} - (Z,\bar{W}) = -\theta[(Z,\bar{W})]T = 2iL_\theta(Z,\bar{W})T.$$

Moreover [by (A18)]

$$T_\nabla(N,Z) = \nabla_N Z - (N,Z) = rZ - \pi_{0,1}(N,Z).$$

Also [by (A19)]

$$\tau(Z) = -\frac{1}{2}\phi(\mathcal{L}_T\phi)Z, \quad Z \in T_{1,0}(\mathcal{F}),$$

so that on one hand (A8) is satisfied, and on the other

$$\tau(Z) = -\frac{1}{2}[i\phi(T,Z) + (T,Z)] = -\pi_{0,1}(T,Z) = i[\pi_{0,1}(\bar{\xi},Z) - \pi_{0,1}(\xi,Z)] = i\pi_{0,1}(\bar{\xi},Z)$$

i.e.,

$$\tau(Z) = i\pi_{0,1}(N,Z), \quad Z \in T_{1,0}(\mathcal{F}). \tag{A20}$$

Here we made use of $T=i(\xi-\bar{\xi})$, $N=\xi+\bar{\xi}$, and $\pi_{0,1}(\xi,Z)=0$. Then (A20) yields (A7). Finally $\nabla T=\nabla N=0$ and (A5) yield (A9) and we conclude that ∇ obeys to (iii). It remains that we check $\nabla L_\theta=0$. Clearly $\nabla_Z L_\theta=0$, $Z\in T_{1,0}(\mathcal{F})$ [by (A16) and (A17)]. Next [by (A19) and (A8)]

$$(\nabla_T L_\theta)(Z,\bar{W}) = (\mathcal{L}_T L_\theta)(Z,\bar{W}), \quad Z,W \in T_{1,0}(\mathcal{F}),$$

and

$$(\mathcal{L}_T L_\theta)(Z,\bar{W}) = -i\{T[d\theta(Z,\bar{W})] - \mathrm{d}\theta[(T,Z),\bar{W}] - \mathrm{d}\theta[Z,(T,\bar{W})]\} = \frac{i}{2}(T\{\theta[(Z,\bar{W})]\} - \theta\{[(T,Z),\bar{W}]\}$$

$$- \theta\{[Z,(T,\bar{W})]\}) = (\text{by applying the Jacobi identity to the term } \theta\{[(T,Z),\bar{W}]\})$$

$$= \frac{i}{2}(T\{\theta[(Z,\bar{W})]\} + \theta\{[(Z,\bar{W}),T]\}) = i(\mathrm{d}\theta)[T,(Z,\bar{W})] = -\frac{ir}{2}(d\varphi)[(Z,\bar{W})] = 0$$

[by (A3) and $(Z,\bar{W})\in T(\mathcal{F})\otimes\mathbb{C}$]. Hence $\nabla_T L_\theta=0$. Finally [by (A18)]

$$(\nabla_N L_\theta)(Z,\bar{W}) = -2rg_\theta(Z,\bar{W}) + (\mathcal{L}_N g_\theta)(Z,\bar{W}), \quad Z,W \in T_{1,0}(\mathcal{F}),$$

and $\nabla_N L_\theta=0$ follows from (A23) in Lemma 124 below.

Lemma 4: *The following identities hold for any* $X\in T(\mathcal{F})$:

$$T_\nabla(N,X) = rX + \tau(\phi X) + \theta(X)(\phi\nabla^H r + rT), \tag{A21}$$

$$[N,\phi X] - \phi[N,X] = 2\tau(X) - \theta(X)\nabla^H r, \tag{A22}$$

Moreover

$$(\mathcal{L}_N g_\theta)(X,Y) = 2rg_\theta(X,Y) + 2(\mathrm{d}\theta)[X,\tau(Y)], \tag{A23}$$

for any $X,Y\in H(\mathcal{F})$.

Proof: (A21) follows from (A7). Let us replace X by ϕX in (A21)

$$\nabla_N\phi X - (N,\phi X) = r\phi X - \tau(X)$$

and subtract the identity got from (A21) by applying ϕ to both sides. Since $\nabla\phi=0$ we obtain (A22). The proof of (A23) is a consequence of (A4) and (A22), and the Jacobi identity

$$(\mathcal{L}_N g_\theta)(X,Y) = N[(\mathrm{d}\theta)(X,\phi Y)] - (\mathrm{d}\theta)[(N,X),\phi Y] + 2(\mathrm{d}\theta)[X,\tau(Y)] - (\mathrm{d}\theta)[X,(N,\phi Y)]$$

$$= -\frac{1}{2}N\{\theta[(X,\phi Y)]\} + \frac{1}{2}\theta\{[(N,X),\phi Y]\} + 2(\mathrm{d}\theta)[X,\tau(Y)] + \frac{1}{2}\theta\{[X,(N,\phi Y)]\}$$

$$= -\frac{1}{2}N\{\theta[(X,\phi Y)]\} - \frac{1}{2}\theta\{[(X,\phi Y),N]\} - \theta\{[X,\tau(Y)]\} = -(\mathrm{d}\theta)[N,(X,\phi Y)]$$

$$-\theta\{[X,\tau(Y)]\} = -r\theta[(X,\phi Y)] - \theta\{[X,\tau(Y)]\}$$

$$= 2r(\mathrm{d}\theta)(X,\phi Y) + 2(\mathrm{d}\theta)[X,\tau(Y)] = 2rg_\theta(X,Y) + 2(\mathrm{d}\theta)[X,\tau(Y)].$$

Theorem 4 is proved. Q.E.D.

As to the local calculations, if φ_β^α are the connection 1 forms of the Graham–Lee connection (i.e., $\nabla W_\beta = \varphi_\beta^\alpha \otimes W_\alpha$) then we may look for $\mathrm{d}\theta^\alpha$ in the form

$$\mathrm{d}\theta^\alpha = B_{\beta\gamma}^\alpha \theta^\beta \wedge \theta^\gamma + B_{\beta\bar{\gamma}}^\alpha \theta^\beta \wedge \theta^{\bar{\gamma}} + B_{\bar{\beta}\bar{\gamma}}^\alpha \theta^{\bar{\beta}} \wedge \theta^{\bar{\gamma}} + (B_\beta^\alpha \theta^\beta + B_{\bar{\beta}}^\alpha \theta^{\bar{\beta}}) \wedge \theta + (C_\beta^\alpha \theta^\beta + C_{\bar{\beta}}^\alpha \theta^{\bar{\beta}}) \wedge \mathrm{d}\varphi$$
$$+ D\,\mathrm{d}\varphi \wedge \theta. \tag{A24}$$

Indeed, applying this identity to the pair (W_β, W_γ) [respectively, to $(W_\beta, W_{\bar{\gamma}})$ and (W_β, T)] gives

$$B_{\beta\gamma}^\alpha - B_{\gamma\beta}^\alpha = \varphi_\beta^\alpha(W_\gamma) - \varphi_\gamma^\alpha(W_\beta), \quad B_{\beta\bar{\gamma}}^\alpha = \varphi_\beta^\alpha(W_{\bar{\gamma}}), \quad B_\beta^\alpha = \varphi_\beta^\alpha(T).$$

Similarly [applying (A24) to $(W_{\bar{\beta}}, T)$, (W_β, N), and $(W_{\bar{\beta}}, N)$ respectively]

$$B_{\bar{\beta}}^\alpha = -A_{\bar{\beta}}^\alpha, \quad C_\beta^\alpha = \frac{1}{2}[\varphi_\beta^\alpha(N) - r\delta_\beta^\alpha], \quad C_{\bar{\beta}}^\alpha = \frac{i}{2}A_{\bar{\beta}}^\alpha.$$

Finally [by (A5)]

$$D\,\mathrm{d}\varphi(N) = 2(\mathrm{d}\theta^\alpha)(N,T) = -\theta^\alpha[(N,T)] = iW^\alpha(r).$$

Summing up

$$\mathrm{d}\theta^\alpha = \theta^\beta \wedge \varphi_\beta^\alpha - i\partial\varphi \wedge \tau^\alpha + \frac{i}{2}W^\alpha(r)\mathrm{d}\varphi \wedge \theta + \frac{r}{2}\mathrm{d}\varphi \wedge \theta^\alpha, \tag{A25}$$

where $\tau^\alpha \equiv A_{\bar{\beta}}^\alpha \theta^{\bar{\beta}}$.

Given a linear connection ∇ on V we set $\alpha(X,Y) \equiv \Pi\nabla_X Y$, for any $X, Y \in T(\mathcal{F})$. If ∇ is the Graham–Lee connection then (by the proof of Theorem 4) $\alpha = 0$. One may identify, as usual, the normal bundle $\nu(\mathcal{F}) = T(V)/T(\mathcal{F})$ with $\mathbb{R}N$. If $\Pi^\perp : T(V) \to T(\mathcal{F})$ is the projection, let us set $\nabla^{\mathcal{F}} \equiv \Pi^\perp \nabla$. It is easily seen that $\nabla^{\mathcal{F}}$ is the Tanaka–Webster connection of each M_δ (i.e., the pointwise restriction of the Graham–Lee connection to a leaf of $\mathcal{F}$ is the Tanaka–Webster connection of the leaf). In particular $\tau : T(\mathcal{F}) \to T(\mathcal{F})$ is the pseudohermitian torsion of each leaf [hence $g_\theta(\tau X, Y) = g_\theta(X, \tau Y)$, for any $X, Y \in T(\mathcal{F})$].[9,20,31–33]

(Received 8 May 2006; accepted 19 June 2006; published online 9 August 2006)

There are many examples in theoretical physics where a fundamental quantity can be considered a quadratic form $\rho=\Sigma_i\rho_i=|\Psi|^2$ and the corresponding linear form $\Psi=\Sigma_i\psi_i$ is highly relevant for the physical problem under study. This, in particular, is the case of the density and the wave function in quantum mechanics. In the study of N-identical-fermion systems we have the additional feature that Ψ is a function of the $3N$ configuration space coordinates and ρ is defined in three-dimensional real space. For many-electron systems in the ground state the wave function and the Hamiltonian are to be expressed in terms of the configuration space (CS), a replica of real space for each electron. Here we present a geometric formulation of the CS, of the wave function, of the density, and of the Hamiltonian to compute the electronic structure of the system. Then, using the new geometric notation and the indistinguishability and equivalence of the electrons, we obtain an alternative computational method for the ground state of the system. We present the method and discuss its usefulness and relation to other approaches. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2229423]

I. INTRODUCTION

Since the creation of wave quantum mechanics, in 1926, the calculation of the electronic structure of a many electron system, in its ground state, or near it, is an open subject. This central problem, with no exact analytic solution, has been studied from many points of view. When the study is to be used for the analysis of atoms, molecules, or condensed matter a first useful approximation is to solve the many electron Schrödinger equation for the system. This implies the use of the Coulomb potential of a configuration of nuclei as external potentials and of the electron-electron interaction potentials to a desired degree of accuracy. In this paper, after a brief review of the basic problem for a many electron system in a molecule, we start a systematic analysis of the problem using an accurate formulation, compatible with the initial conditions of the calculation, and through a systematic, geometric algebra based, definition of the configuration space, of the external potentials, of the one electron operators for a many electron system and of the electron-electron interaction terms, we arrive at a formal equation for the total energy. From this, using the fact that we are interested either in the ground state or in stationary states near the ground state, we formulate a variational problem from which a set of tractable equations, which self-consistently define the many electron wave function and density, is obtained. Finally we compare our resulting formalism with the more widely used procedures, showing that those methods are contained as special cases of ours.

The basic approach for the calculation of the ground state electronic structures of atoms, molecules, and solids[1–3] considers the steady state Born-Oppenheimer approximation: a fixed given configuration of positively charged point-like nuclei, the so-called "structure" of the molecule, cluster, or crystal. The computational procedure involves the simultaneous calculation of: the N electron ground state electronic wave function Ψ_N a function of $3N$ coordinates, the (ground state) electronic density $\rho_N(x)$ a function of three coordinates, the total electronic energy E_N for the N electrons, a set of $M \geqslant N$ auxiliary spin-orbitals φ (called the SO), and the SO-energy eigenvalues ε_a. A minimum set of N auxiliary functions is required by Pauli's exclusion principle. The SO and the ε_a are important as far as they are related to the different type of response functions of the electronic system and as such to the set of its spectroscopic properties. The electronic density, wave function, SO, and ε_a are not observable in themselves but, through several spectroscopies, they can be studied as indirect observables. Point-contact spectroscopy and other recent techniques (see Ref. 4, and references therein) are good examples of such tools. The computational techniques can also be extended to time dependent[5,6] and to beyond Born-Oppenheimer[7] cases. In these approaches the electron is defined as a physical entity which obeys the Dirac equation for the electron's experimental mass and charge, the nonrelativistic limit of the Dirac equation is given by the Schrödinger equation if the spin of the electron is considered for magnetic interactions and for statistics.

Recently we have shown that there is a new, geometrical, starting point for formulating a mathematical theory for the density and for the related wave function,[8–12] we call KKW. There is a resulting methodology developed here.

In the calculation of the stationary ground state of the many electron (many indistinguishable equivalent fermions in general) wave function and densities a variational approach optimizes the solutions with respect to desirability criteria, in our case, the lowest ground state energy E. The variational procedure provides a suitable set of constants and a set of auxiliary functions. For computational method $\mathcal{M}$ of lowest ground state energy $E=\int \bar{\Psi}\hat{H}_{\mathcal{M}}\Psi dV$ we should consider the variation of a functional

$$\delta\left(\left[\int \bar{\Psi}\hat{H}_{\mathcal{M}}\Psi \mathrm{d}V - E\right] - \mu\left[\int \bar{\Psi}\Psi dV - N\right]\right) = 0, \tag{1}$$

where the second square parentheses impose the condition that this is an N electron system. Note that both $\bar{\Psi}\hat{H}_{\mathcal{M}}\Psi = \mathcal{E}(x)$ and $\bar{\Psi}\Psi = \rho_N(x)$ imply a projection into real space.

The basic formulation can be summarized as follows: to the N equivalent electron system, in real space $x \subset \mathbb{R}^3$, in volume V, obeying the Pauli's exclusion principle, corresponds an *analytical finite non-negative* total density function $\rho_N(x)$ such that the total electronic energy $E = \int \varepsilon \rho_N(x) \mathrm{d}V$ is well defined in the system's volume. To fulfill this condition there should exist a many electron *analytical square integrable* wave function $\Psi_N(\{x_n\}; n=1,\ldots,N)$ with $\{x_n\} \subset (\mathbb{R}^3)^N$ such that $\rho_N(x) \doteq |\Psi_N|^2 = \bar{\Psi}\Psi = \Sigma_{c=1}^{N}\rho_c(x) = \Sigma_{u=1}^{M\geqslant N}\rho_u(x)$.

Notice that two different expansions of the density are used simultaneously: one $(\Sigma_{c=1}^{N}\rho_c(x))$ is the description of the N equivalent electrons in the system, the second $(\Sigma_{u=1}^{M\geqslant N}\rho_u(x))$ describes the shell structure (M atomic or molecular orbitals). This generates a matrix of descriptions: one description, the shell structure, corresponds to the $M \geqslant N$ columns and the other, the per equivalent electron contribution, to the N rows of the matrix.

We have also indicated that this Hermitian square should be describable as either a sum of non-negative, finite analytical functions $\rho_c(x) = |\psi_c|^2$, one equivalent ψ_c for each electron in the system, or (to be able to agree with the Pauli's principle) as a sum of $M \geqslant N$, weighted by $w_u = |b_u|^2$, spin-orbital ϕ_u contributions $\rho_u(x) = |b_u\phi_u|^2$. This ensures that the physical conditions, which must be obeyed by the wave function itself and by the density, are fulfilled. In the case of the many electron (fermion) system *all N electrons* (*fermions*) *are equivalent*. The "system" to be studied is such that no electron can be distinguished by position. This equivalence requires that the density itself should be describable as a sum of N equal densities $\rho_{\text{one electron}}(x)$ which should be generated by equivalent contributions. That is $\rho_{\text{one electron}}(x) = 1/N\Sigma_u\rho_u(x)$. The many-electron

wave function $\Psi_N(\{x_n\};n=1,\ldots,N)$ should be used to compute the total energy and other properties of this ground state of the system. Historically the Hartree-Fock method (and its complement configuration interaction) fulfilled the conditions above.

What is needed is to find the analytical, possible complex, function $\mathbf{\Psi}(\{x_n\})$ of a set $\{x_n;n=1,\ldots,N\}$ of N coordinates which allows the factorization of a *finite non-negative* function

$$\rho(x)=\mathbf{\Psi}^{\dagger}(\{x_n\})\hat{N}(x,\{x_n\},\{x_n'\})\mathbf{\Psi}(\{x_n'\})\subset\mathbb{R}^{+}$$

(the real numbers $\mathbb{R}=\{\mathbb{R}^{-},0,\mathbb{R}^{+}\}$ are either negative, zero or positive). Here $\hat{N}(x,\{x_n\},\{x_{n'}\})=\Sigma_{nn'}\delta x_n x_n',\delta x x_n$ is a projector from configuration space X into the real space coordinates x.

In the KKW theory (all relevant points are presented in the following) the basic idea is that the density appears as a sum of densities and then the wave function Ψ_N should both be the square root of the total density function $\rho(x)=\Sigma_u\rho_u(x)$ and also provide the square root ϕ_u of each one of the contributions $\rho_u(x)$ to the total density. For this we require the use of geometric (multivector analysis) techniques. In fact the problem is similar to that of finding the linear form (geometric square root) $\mathbf{d}=a\mathbf{e}_1+b\mathbf{e}_2+c\mathbf{e}_3+\cdots$, which corresponds to the quadratic form $d^2=a^2+b^2+c^2+\cdots\subset\mathbb{R}^{+}$. Here $\mathbf{d}$ is the *geometric square root* of the scalar quantity d^2.

For a positive definite function $\rho(x)=\mathbf{d}^{\dagger}(x)\mathbf{d}(x)\subset\mathbb{R}^{+}$ an ordinary (scalar) square root $d(x)=\sqrt{\mathbf{d}^{\dagger}(x)\mathbf{d}(x)}=\sqrt{a^2(x)+b^2(x)+c^2(x)+\ldots}$ is not necessarily *analytical*, whereas the geometric square root function $\mathbf{d}(x)=a(x)\mathbf{e}_1+b(x)\mathbf{e}_2+c(x)\mathbf{e}_3+\cdots$, through the use of an *analytical* set ϕ of auxiliary complex functions $\phi=\{a(x),b(x),c(x),\ldots\}\subset\mathbb{C}$, can be demanded to be *analytical*. The Hermitian squares $\{a^2(x),b^2(x),c^2(x),\ldots\}\subset\mathbb{R}^{+}$. The analyticity property allows that a set of differential equations $\hat{D}a(x)=\epsilon_a a(x)$, $\hat{D}b(x)=\epsilon_b b(x),\ldots$, which incorporates physical and mathematical boundary conditions can be found.

The geometric square root. There is a freedom to choose for the description of the shell structure the most convenient anticommuting normalized basis set $\{\alpha_u,|\alpha_u|^2=1;$ and $\alpha_u\alpha_v=-\alpha_v\alpha_u,\ u\neq v,\ u,v=1,\ldots,M\geqslant N\}$.

Otherwise, as the electrons are equivalent, we will also need a symmetrized form of $\mathbf{d}$. For this purpose we will simultaneously introduce a second (one basis element per electron) anticommuting normalized basis set $\{\omega_i^S,|\omega_i^S|^2=1;$ and $\omega_i^S\omega^S j=-\omega_j^S\omega_i^S,\ j\neq i,\ i=1,\ldots,N\}$ and a normalized vector $\underline{\mathbf{S}}=\sqrt{1/N}(\omega_1^S+\omega_2^S+\omega_3^S+\cdots+\omega_N^S)$ where our definitions imply that $(\sqrt{1/N}(\omega_1^S+\omega_2^S+\omega_3^S+\cdots+\omega_N^S))^2=\underline{\mathbf{S}}^2=1$. The ω_i^S, therefore $\underline{\mathbf{S}}$, are defined to commute with the α_u. Consider $\mathbf{d}=(b_1\alpha_1+b_2\alpha_2+b_3\alpha_3+\cdots+b_M\alpha_M)\underline{\mathbf{S}}$, then $d^2=\Sigma_i|b_i|^2$. There is a double summation: over the basis set $\{\alpha_u\}$ and over the per electron in the system set $\{\omega_i^S\}$. The summations can be interchanged. This is what is called the geometric procedure as used in the following. The algebra of the $\{\alpha_u\}$ or of the $\{\omega_i^S\}$ is a Grassmann-Clifford algebra (see Refs. 10–12). Although there is no need to define a vector scalar-product we will define in the following an equivalent procedure to simplify the reading of the equations.

II. GEOMETRIC FORMULATION OF THE CALCULATION OF THE STATIONARY GROUND STATE OF A MANY-ELECTRON SYSTEM

Here we present the formalism for the calculation of the stationary ground state of the many electron (many equivalent fermions in general) wave function and densities and the corresponding variational approach.

A. Configuration space and real space

A basic concept in the study of a many-electron system (N interacting fermions) is, from the above-noted considerations, the simultaneous, repeated, use of real space (the space of the observer) for each one of the fermions of the system: configuration space. Then, if $\mathbf{x}$ represents a point in real space, it is customary to represent by $\mathbf{X}=\{\mathbf{x}_a;a=1,\ldots,N\}\}$ the set of points in the configuration space $\mathbf{X}$ for N fermions.

The volume integral $\int d\Omega$ when referred to the coordinates of fermion a is denoted by $\int d\Omega_a$. Also $\int d\Omega_N$ indicates the integration over all N space replicas $\int d\Omega_a$. In the formal notation to follow we introduce an integration operator $\int \widehat{d\Omega_N}$ to denote that repeated space integration for all N electrons is to be performed. Also $\int \widehat{d\Omega_{N-i}}$ to denote that the repeated space integration for all N electrons except the ith is to be performed. The absolute value of the distance between two fermion points $x_{ab}=|\mathbf{x}_b-\mathbf{x}_a|$.

Here and in the rest of our presentation we use a geometric notation

$$\mathbf{X}=\sum_a \omega_a \mathbf{x}_a;\{a=1,\ldots,N;\omega_a\omega_b=-\omega_b\omega_a, b\neq a\}, \tag{2}$$

introducing the per electron operator ω_a and, also, the projection operators $\bar{\omega}_a$ such that $\bar{\omega}_a\omega_b=\delta_{ab}$ selecting the part of the configuration space which corresponds to electron a; this is $\bar{\omega}_a\mathbf{X}=\mathbf{x}_a$.

This construction allows a clear formal definition of the electrons involved in each part of the calculation. Our geometric procedure introduces one feature of the statistics of the fermion system from the beginning because the interchange $\omega_a \leftrightarrow \omega_b$ in the products $\omega_a\omega_b$ for two electrons, in any given expression, will change the sign of the corresponding terms.

When the argument of a function is position, for $a=1$ for example, we will also use a nonbold notation or the fermion's numeral, say $\phi(\mathbf{x}_1)\doteq\phi(x_1)=\phi(1)$, as equivalent argument.

B. Basic principles

The Principles implied without further discussion in this paper are the same as those of the so-called *ab initio* approaches:[1]

- The total energy is a functional of the wave function.
- The possibility of using the Schrödinger equation for the N electron system. The kinetic energy is the sum of independent-electron-like kinetic energies for each electron.
- The ground state of the many electron system corresponds to the lowest total energy.
- The Pauli exclusion principle requires that the description for N electrons, included in the wave function, contains the occupancy of at least $M\geqslant N$ pseudo-electron orthonormal spin-orbitals ϕ_u.
- The equivalency and indistinguishability of the electrons require that all electrons are equivalently described.
- The operators acting on the ϕ_u are: multiplicative operators (constant, variable, and self-consistent variable functions, differential (the Laplace operator $\nabla^2_{(x_u)}$, in our case) and the integral operators $\int \widehat{d\Omega_u}$ defined earlier.
- A variational approach can be used.

The electronic structure calculation of a many electron system in the ground state requires then the simultaneous calculation of: the ground state electronic wave function Ψ_N, the (ground state) electronic density $\rho_N(x)$, the total electronic energy E_N for the N electrons, a set of $M\geqslant N$ auxiliary spin-orbitals (SO), and the SO-energy eigenvalues ϵ_a. A minimum set of N functions is required by Pauli's principle.

From $\rho(\mathbf{x})=\bar{\Psi}\Psi$ both quantities, wave function $\Psi(\mathbf{X})$ and density $\rho(\mathbf{x})$ could be considered as the fundamental variable, provided that derivatives of $\rho(\mathbf{x})$ are considered derivatives of $\bar{\Psi}\Psi$.

In our theory the density appears as a sum of densities and then the wave functions $\{\bar{\Psi},\Psi\}$ should together:

(1) be a factorization of the total density $\rho(x)=\Sigma_{n=1}^{N}\rho_{\text{one electron}}(x)=\Sigma_{i=1}^{M}\rho_i(x)=|\Psi|^2$, the first equality from the equivalence of the electrons, and
(2) provide the square root of each one of the M shell structure contributions $\rho_i(x)=|b_i\phi_i|^2$ to the total density.

C. The energy calculation

We rewrite the usual expression for the total nonrelativistic electronic energy operator or Hamiltonian $\hat{H}_0$ in correspondence with our formal definition of configuration space (an atomic electron structure is used in the following to simplify the notation, otherwise a summation Σ_A and the relative distances x_{aA} should be used in the electron-nucleus potential energy). We use the above-defined per electron geometric notation $\{\omega_b, \bar{\omega}_b\}$ to select, from the wave function Ψ_N^{KKW} and its conjugate $\overline{\Psi_N^{\mathrm{KKW}}}$, the corresponding contributions. A *per electron* operator is an *effective one-body* operator.

We consider first the per electron "a" kinetic energy operator

$$-\omega_a(\hbar^2\nabla^2_{(x_a)}/2m_e)\bar{\omega}_a$$

and the electron a to nucleus A (considered at the origin of coordinates) potential energy operator $-\omega_a(Z_Ae^2/|x_a|)\bar{\omega}_a$. The sum of the contributions of these two terms will be called "core" energy in the following.

Second, the pairwise Coulomb interaction $V^{\mathrm{Coul}}_{e-e,}$ between the electrons: a half of the sum over all a, of the for electron "a" in the pair a,b, electron-electron potential energy, we have

$$V^{\mathrm{Coul}}_{e-e} = \frac{1}{2}\sum\nolimits_{a=1}^{N} \omega_a \int \widehat{\mathrm{d}\Omega_{N-a}} \sum_{b\neq a} \left(\omega_b \frac{e^2}{|x_{ab}|}\bar{\omega}_b \right)\bar{\omega}_a$$

(notice that after performing the indicated $\int \widehat{\mathrm{d}\Omega_{N-a}}$ integration for all $b\neq a$ each term has been reduced to a per electron operator).

Then

$$\hat{H}_0 = \sum\nolimits_{a=1}^{N} \omega_a \left[-\frac{\hbar^2\nabla^2_{(x_a)}}{2m_e} - \frac{Z_Ae^2}{|x_a|} + \frac{1}{2}\int \widehat{\mathrm{d}\Omega_{N-a}} \sum_{b\neq a}^{N} \left(\omega_b \frac{e^2}{|x_{ab}|}\bar{\omega}_b \right) \right]\bar{\omega}_a. \tag{3}$$

Correspondingly, the wave function Ψ_N^{KKW} is (first in a per electron $n\subset N$ basis and second in a per orbital $i\subset M$ description, using the geometric operators α_i per auxiliary basis function ϕ_i (SO) with weight b_i, obeying $\alpha_i\alpha_j=-\alpha_j\alpha_i$, $j\neq i$, and the projection operators $\bar{\alpha}_i\alpha_j=\delta_{ij}$):

$$\Psi_N^{\mathrm{KKW}} = \sum_{n=1}^{N} (\omega\psi)_n, \tag{4}$$

$$\text{where } (\omega\psi)_n = \omega_n \left[\sum_{i=1}^{M\geqslant N} b_i\alpha_i\phi_i(x_n) \right], \tag{5}$$

$$\text{and} \quad \overline{\Psi_N^{\mathrm{KKW}}} = \sum_{n=1}^{N} (\bar{\psi}\varpi)_n, \tag{6}$$

$$\text{where } (\bar{\psi}\varpi)_n = \left[\sum_{i=1}^{M\geqslant N} b_i^*\bar{\alpha}_i\phi_i^*(x_n) \right]\varpi_n, \tag{7}$$

with normalization

$$N = \int \overline{\Psi_N^{\mathrm{KKW}}}\Psi_N^{\mathrm{KKW}}\mathrm{d}\Omega_N \doteq \sum_{c=1}^{N} \int \{\overline{\Psi_N^{\mathrm{KKW}}}\omega_c\bar{\omega}_c\Psi_N^{\mathrm{KKW}}\mathrm{d}\Omega_c\}, \tag{8}$$

and, when written in terms of the auxiliary spin-orbitals ϕ_i,

$$N = N \int \bar{\psi}\psi \mathrm{d}\Omega = N \sum_{i=1}^{M \geqslant N} \int \phi_i^* b_i^* \overline{\alpha_i} \alpha_i b_i \phi_i \mathrm{d}\Omega = N \sum_{i=1}^{M \geqslant N} |b_i|^2 \int |\phi_i|^2 \mathrm{d}\Omega \doteq N \sum_{i=1}^{M \geqslant N} |b_i|^2 \langle i|i\rangle. \quad (9)$$

In this paper we assume equal number of spin up and spin down electrons, the spin restricted case. The second line in (8), from the definition of $\int \mathrm{d}\Omega_N$ in Sec. II A is an identity. In (9) we use the orthonormality generated by $\overline{\alpha_i}\alpha_j = \delta_{ij}$.

Note that a double set of Grassmann (anticommuting) numbers $\{\omega_a; \alpha_i\}$ has been introduced, this has an analytical analogue in the determinants of the *ab initio* methods where either the exchange of columns or of rows change the sign of the determinant. Formally the wave function Ψ could be represented by a rectangular $M \times N$ matrix with entries $\alpha_i \omega_a$. The second line in (4) would correspond to the (real positive number) trace of $\bar{\Psi}\Psi$. Exchange terms will arise from (4) when used in (3). The ϕ_i's are defined to form an orthonormal set of spin-orbitals $\langle i|j\rangle \equiv \int \phi_i^* \phi_j \mathrm{d}\Omega = \delta_{ij}\delta_{s_i}^{s_j}$. The $\delta_{s_i}^{s_j}$ ensures that the spin of i and j are the same, this is superfluous here but will be used in the following. We introduce the normalization $\Sigma_i |b_i|^2 = 1$, then the one electron density $\rho_1(\mathbf{x}) = \bar{\psi}(\mathbf{x})\psi(\mathbf{x}) = \Sigma_i |b_i|^2 \phi_i^*(\mathbf{x})\phi_i(\mathbf{x})$.

In (3) the Hamiltonian $\hat{H}_0$ for electron n: $H^{\mathrm{core}}(x) + H^{\mathrm{interaction}}(x)$ where the second term is an effective local one-electron operator, even if the electron repulsion, being dependent on the inter-electron distance, is a two-electron (i for n, j for m) operator. The resulting potential is the same for all components of ψ.

D. Core energy

Rewrite the first two terms in (3) as $\Sigma_{c=1}^{N} \omega_c \hat{H}^{\mathrm{core}}(c)\bar{\omega}_c$, then

$$E_{\mathrm{core}} = \sum_{c=1}^{N} \int \bar{\Psi}\{\omega_c \hat{H}^{\mathrm{core}}(c)\bar{\omega}_c\}\Psi \mathrm{d}\Omega_c = \sum_{c=1}^{N} \int \sum_{d'} \bar{\omega}_{d'} \bar{\psi}_{d'}(\mathbf{x}_{d'})\{\omega_c \hat{H}^{\mathrm{core}}(c)\bar{\omega}_c\} \times \sum_{d} \omega_d \psi_d(\mathbf{x}_d)\mathrm{d}\Omega_c, \quad (10)$$

and from (5) and (7), orthonomality and equivalence:

$$E_{\mathrm{core}} = N \int \bar{\psi}_1(\mathbf{x}_1)\hat{H}^{\mathrm{core}}(1)\psi_1(\mathbf{x}_1)\mathrm{d}\Omega_1 = N \int \sum_i |b_i|^2 \phi_i^* \hat{H}^{\mathrm{core}} \phi_i \mathrm{d}\Omega. \quad (11)$$

The above-mentioned $\{\omega_c, \varpi_c\}$ and the $\{\alpha_i, \overline{\alpha_i}\}$ have selected the sum of the diagonal elements in (10). Note that the shell structure cannot be avoided.[8,9]

E. Electron-electron interaction energy

For the electron-electron interaction (e-e)

$$E^{e\text{-}e} = \int \overline{\Psi_N^{\mathrm{KKW}}} \sum\nolimits_a \omega_a \times \left[\frac{1}{2} \sum_{b \neq a}^{N} \int \left(\omega_b \frac{e^2}{|x_{ab}|} \bar{\omega}_b \right) \mathrm{d}\Omega_b \right] \bar{\omega}_a \Psi_N^{\mathrm{KKW}} \mathrm{d}\Omega_a. \quad (12)$$

Here, from the equivalence of the N electrons, we have N equal pairwise $\{1 \Leftrightarrow 2\}$ contributions which consider all spin-orbitals. Using the expansion of the ψ, we obtain

$$E^{e\text{-}e} = \frac{N}{2} \int \int \sum_i \phi_i^*(1) b_i^* \bar{\alpha}_i \sum_j \phi_i^*(2)\bar{\alpha}_j \frac{e^2}{|x_{12}|} \times \sum_k \phi_i(2)\alpha_k \sum_l \phi_i(1)\alpha_l \mathrm{d}\mathbf{\Omega}_1 \mathrm{d}\Omega_2. \quad (13)$$

Considering the property $\bar{\alpha}_i \alpha_j = \delta_{ij}$ there are three types of e-e terms:
(I) $j=k$ and $i=l$ which gives

$$\frac{N}{2}\int\left\{\sum_i \int\left[\sum_{j\neq i}|b_j|^2|\phi_j(2)|^2\frac{e^2}{|x_{12}|}\right]\mathbf{1}(x_2)\mathrm{d}\Omega_2\times|b_i|^2|\phi_i(1)|^2\right\}\mathbf{1}(x_1)\mathrm{d}\Omega_1$$
$$=\frac{N}{2}\sum_i\sum_{j\neq i}|b_j|^2|b_i|^2(ij,ij)=\frac{N}{2}E_{\mathrm{I}}, \tag{14}$$

where we have introduced the notation (ij,ij) for the integrals, as they are "Coulomb integrals" in the accepted electronic structure calculation language. Also the formal local unit factor $\mathbf{1}(x)=\bar{\psi}(x)\psi(x)/\rho_1(x)$ will be fundamental to perform the variational procedure in the following to find the effective equations for the $\psi(x)$. Note that the $\mathbf{1}(x)$ appear twice in this term, this will result in a factor 2 in the variational wave equation.

(II) $j=l\neq i$ and $i=k$ (the $\delta^{s_j}_{s_i}$ from spin orthonormality, and one change of sign from the interchange $\alpha_i\alpha_j=-\alpha_j\alpha_i$ is needed!)

$$-\frac{N}{2}\sum_{i,j\neq i}\delta^{s_j}_{s_i}|b_j|^2|b_i|^2\times\int\int\left[\phi^*_j(1)\phi^*_i(2)\frac{e^2}{|x_{12}|}\phi_i(1)\phi_j(2)\right]\mathrm{d}\Omega_2\mathbf{1}(x_1)\mathrm{d}\Omega_1$$
$$=-\frac{N}{2}\sum_{i,j\neq i}\delta^{s_j}_{s_i}|b_j|^2|b_i|^2(ji,ij)=\frac{N}{2}E_{\mathrm{II}}, \tag{15}$$

where we have used the notation $\delta^{s_j}_{s_i}(ji,ij)$ for the integrals, as they are "exchange integrals" corresponding to the $[i,j]$ pair of spin-orbitals in the accepted electronic structure calculation language; the $\delta^{s_j}_{s_i}$ requires $s_i=s_j$ and ensures that the product $\phi^*_j(1)\phi_i(1)$ of the SO, with spin s_i and s_j, respectively, is not null. We use again the formal local unit factor $\mathbf{1}(x)$.

(III) Null terms, all others, where $(i\neq l$ and $i\neq k)$ or $(j\neq l$ and $j\neq k)$.

E_{I} and E_{II} also contribute to the formal interpretation of the Pauli exclusion principle: first a given electron is not interacting with itself and, second, there is an "exchange" term for fermions, where from $\alpha_i\alpha_j=-\alpha_j\alpha_i$ a negative sign appears.

III. VARIATION OF THE TOTAL ENERGY WITH RESPECT TO THE $\bar{\psi}$

Here we consider the total energy in terms of the ψ as noted earlier. From the normalization (9) the per electron density is $\rho_{\text{one-electron}}(x)=\bar{\psi}(x)\psi(x)$ and the total density $N\rho_{\text{one-electron}}(x)$.

We write the total energy

$$E_{\text{total}}=E_{\text{core}}+\frac{N}{2}(E^{e\text{-}e}_{\mathrm{I}}+E^{e\text{-}e}_{\mathrm{II}}). \tag{16}$$

For the *core* term

$$E_{\text{core}}/N=\int\bar{\psi}_1(\mathbf{x}_1)\hat{H}^{\text{core}}(1)\psi_1(\mathbf{x}_1)\mathrm{d}\Omega_1, \tag{17}$$

the variation with respect to $\bar{\psi}_1(\mathbf{x}_1)$ gives

$$\hat{H}^{\text{core}}(1)\psi_1(\mathbf{x}_1)=\left\{-\frac{\hbar^2\nabla^2_{(1)}}{2m_e}-\frac{Z_Ae^2}{|\mathbf{x}_1|}\right\}\psi_1(\mathbf{x}_1). \tag{18}$$

For the variation of $E^{e\text{-}e}_{\mathrm{I}}/2$ with respect to $\bar{\psi}_1(\mathbf{x}_1)$ we obtain, defining

$$V_{\mathrm{I}}(\mathbf{x}_1)=\sum_i\left\{\frac{|b_i|^2|\phi_i(\mathbf{x}_1)|^2}{\rho_1(\mathbf{x}_1)}\times\int\left[\sum_{j\neq i}|b_j|^2|\phi_j(2)|^2\frac{e^2}{|x_{12}|}\right]\right\}\mathrm{d}\Omega_2, \tag{19}$$

and, considering that the factor $\mathbf{1}(\mathbf{x}_k)$ appears twice in (14), the repulsive electron-electron term

$$2\tfrac{1}{2}V_{\mathrm{I}}(\mathbf{x}_1)\bar{\psi}_1(\mathbf{x}_1) = V_{\mathrm{I}}(\mathbf{x}_1)\bar{\psi}_1(\mathbf{x}_1). \tag{20}$$

Finally for the variation of $E_{\mathrm{II}}^{e\text{-}e}/2$ with respect to $\bar{\psi}_1(\mathbf{x}_1)$ we obtain (assuming here, for simplicity not as a restriction in the method, to avoid introducing summations over spin coordinates, equal number of spins "up" and "down"), defining

$$V_{\mathrm{II}}(\mathbf{x}_1) = -\sum_{i,j\neq i}\frac{\delta_{s_i}^{s_j}|b_j|^2|b_i|^2}{2\rho_1(\mathbf{x}_1)} \times \int\left[\phi_j^*(1)\phi_i^*(2)\frac{e^2}{|x_{12}|}\phi_i(1)\phi_j(2)\right]\mathrm{d}\Omega_2, \tag{21}$$

the "attractive-like functions interchange" electron-electron term

$$V_{\mathrm{II}}(\mathbf{x}_1)\bar{\psi}_1(\mathbf{x}_1). \tag{22}$$

A. The KKW auxiliary equations

The variational procedure has been carried with respect to the $\bar{\psi}$'s, to obtain the formal equation which describes any electron n in the system (reminder ψ is a vectorial sum of functions ϕ_i). We collected the different terms of $\int\Psi_N^\dagger\hat{H}_0\Psi_N\mathrm{d}\Omega$ from (11) to (15) as in (16), and performed the variation with respect to $\bar{\psi}(x)$, as shown in the previous section. We obtain all together an effective Hamiltonian $\widehat{H^{\mathrm{KKW}}}$ eigenvalue equation

$$\widehat{H^{\mathrm{KKW}}}\psi(x) = \mu\psi(x),$$

$$\widehat{H^{\mathrm{KKW}}} \equiv \left\{-\frac{\hbar^2\nabla^2}{2m_e} - \frac{Ze^2}{|\mathbf{x}|} + V_{\mathrm{I}}(\mathbf{x}) + V_{\mathrm{II}}(\mathbf{x})\right\}. \tag{23}$$

This is not yet a practical equation. Use now the expansion of the ψ in terms of the ϕ for a further reduction. Write (23) as

$$\widehat{H^{\mathrm{KKW}}}\sum_{i=1}^{M\geqslant N} b_i\alpha_i\phi_i(x_n) = \mu\sum_{i=1}^{M\geqslant N} b_i\alpha_i\phi_i(x_n), \tag{24}$$

apply on both sides the projector $\bar{\alpha}_i$ to obtain the practical equations for the set of auxiliary orthonormal functions ϕ_i (from $\bar{\alpha}_i\psi=b_i\phi_i$),

$$\widehat{H^{\mathrm{KKW}}}\phi_i = \varepsilon_i\phi_i. \tag{25}$$

Finally we obtain, by left multiplication with $\bar{\psi}$ of (23), integration and the normalization $\langle\psi|\psi\rangle = 1$, $\langle\phi_i|\phi_i\rangle = 1$, a relation between the μ and the ε_i's given by $\mu=\Sigma_i\varepsilon_i|b_i|^2=\bar{\varepsilon}$, that is: μ in (23) is the weighted average eigenvalue.

B. A more familiar and practical form of the auxiliary wave equations

We can rewrite the electron-electron interaction energy in a computationally more practical form (related to the *ab initio* methods.[1]) Consider

$$E^{e\text{-}e} = \frac{N}{2}\{E_{\mathrm{I}} + E_{\mathrm{II}}\},$$

and rewrite as

$$\Rightarrow \frac{N}{2}\int \bar{\psi}(x_1)\{E_{\mathrm{Coul}}(\mathbf{x}_1)+E_{\mathrm{XC}}(\mathbf{x}_1)\}\psi(x_1)\mathrm{d}\Omega_1,$$

obtained if, in the above-presented definitions, the "self-Coulomb" integrals $|b_i|^2(ii,ii)$ are added to remove the condition $j\neq i$, to E_{I}. The "self-exchange" integrals $-|b_i|^2(ii,ii)$ are added to remove the condition $j\neq i$, to E_{II}. [The E_{II} is now as in the formally equivalent considerations of the first part of the Slater (1951) idea,[13] which here is no longer an approximation.] Then

$$\widehat{H^{\mathrm{KKW}}}\equiv\left\{-\frac{\hbar^2\nabla^2}{2m_e}-\frac{Ze^2}{|\mathbf{x}|}+V_{\mathrm{Coul}}(\mathbf{x})+V_{\mathrm{xc}}(\mathbf{x})\right\},$$

$$V_{\mathrm{Coul}}(\mathbf{x}_1)=N\int\left[\rho(2)\frac{e^2}{|x_{12}|}\right]\mathrm{d}\Omega_2,$$

$$V_{\mathrm{xc}}(\mathbf{x}_1)=-\frac{N}{\rho(\mathbf{x})}\sum_{i,j}\delta^{s_j}_{s_i}|b_j|^2|b_i|^2\times\int\left[\phi_j^*(1)\phi_i^*(2)\frac{e^2}{|x_{12}|}\phi_i(1)\phi_j(2)\right]\mathrm{d}\Omega_2. \tag{26}$$

By substitution of (26) in (25)

$$\left\{-\frac{\hbar^2\nabla^2}{2m_e}-\frac{Ze^2}{|\mathbf{x}|}+V_{\mathrm{Coul}}(\mathbf{x})+V_{\mathrm{xc}}(\mathbf{x})\right\}\phi_i(\mathbf{x})=\varepsilon_i\phi_i(\mathbf{x}). \tag{27}$$

Reminder $\widehat{H^{\mathrm{KKW}}}$ is the same for all ϕ_i's.

The total energy is obtained by direct integration of the set of equations (27) multiplied on the left by $\Sigma_i|b_i|^2\phi_i^*$ and comparing with (16):

$$E[\Psi]=\sum_i|b_i|^2\varepsilon_i-\frac{E_{\mathrm{Coul}}}{2}-\int V_{\mathrm{XC}}(\mathbf{x})\rho(\mathbf{x})\mathrm{d}\Omega+E_{\mathrm{XC}} \tag{28}$$

(we must remember that E_{Coul} and E_{XC} include the "self-Coulomb" and the "self-exchange," respectively).

With additional variational constants b_{ij} defined through $b_i=\sqrt{(1-\Sigma_{j>N}b_{ij})/N}$ for $i\leqslant N$ and $b_j=\sqrt{\Sigma_{i\leqslant N}b_{ij})/N}$ $j>N$, we obtain a (twice) variational procedure to obtain a set $\{b_{ij}\}$ and the ϕ_i. A secular determinant can be constructed and solved. If the basis $\{\phi_i\}$ is large enough a time-dependent formulation with $\Delta V(t)$ can be constructed where $b_i\Rightarrow b_i(t)$ and the $b_{ij}\Rightarrow b_{ij}(t)$ describe induced transitions.

Finally the basic definition for the total energy $E=E[\bar{\psi}(x)\psi(x)]$ of N ***equivalent*** carriers (electrons), can be *formally* written in terms of the density $N\bar{\psi}(x)\psi(x)$ defining

$$E_{\mathrm{core}}=N\int\left[\sum_i\frac{|b_i|^2\phi_i^*(\mathbf{x}_1)\hat{H}^{\mathrm{core}}\phi_i(\mathbf{x}_1)}{\rho_1(\mathbf{x}_1)}\right]\times\bar{\psi}(\mathbf{x}_1)\psi(\mathbf{x}_1)\mathrm{d}\Omega_1=N\int\varepsilon^{\mathrm{core}}(\mathbf{x}_1)\bar{\psi}(\mathbf{x}_1)\psi(\mathbf{x}_1)\mathrm{d}\Omega_1. \tag{29}$$

$$E=N\int\{\varepsilon^{\mathrm{core}}(\mathbf{x}_1)+\varepsilon^{\mathrm{inter}}(\mathbf{x}_1)\}\bar{\psi}(x)\psi(x)\mathrm{d}\Omega_1, \tag{30}$$

and, considering $E=N\int\varepsilon\bar{\psi}(x)\psi(x)\mathrm{d}\Omega_1$, we define

$$\varepsilon^{\mathrm{core}}(\mathbf{x}_1)+\varepsilon^{\mathrm{inter}}(\mathbf{x}_1)=\varepsilon.$$

IV. THE PROPERTIES OF THE WAVE FUNCTION: CONCLUSIONS

The KKW wave function describes a system of N electrons with an expansion based on $M \geqslant N$ auxiliary, mutually orthogonal functions, solutions of the same "KKW" Hamiltonian. The complete wave function, then the one density, is directly optimized and not each auxiliary function at a time.

From the many possibilities to construct the ψ it is useful to choose the one presented here because the eigenvalues ε_i, by construction the rate of change of the total energy with respect to occupation of the "i" spin-orbital, are an approximation to the removal energy of one electron, from that ϕ_i, in the system. Also because the SO functions, being related to the response function of the system, have become observables.

- The KKW method offers a complete variational solution to the problem of finding the wave function and simultaneously the energy of the ground state of the N electron system.
- To find the limit for the ground state energy of the system the number of auxiliary functions to be considered is $M > N$. The practical approach to this calculation will be twice variational, first in the sense that the auxiliary functions are found from the variation of a functional, and second because the weight of the contributions of the set of $M > N$ functions requires a set of variational parameters to be found.
- The new method systematically includes the kinetic and the potential energy for all the $M \geqslant N$ auxiliary functions. It has the advantage that all spin-orbitals are simultaneously optimized. An alternative would be to obtain $M' > N$ functions from the results for $M = N$ and, in a second step, the best possible b_{ij} for the M' case.
- The calculations can include the use in the Hamiltonian of selective pairwise interaction terms

$$(\Delta V_{e\text{-}e})_{ab} = \omega_a \omega_b (\Delta V_{mn}) \bar{\omega}_b \bar{\omega}_a,$$

  allowing the description of pair-correlations of any origin: magnetic, or electron-phonon or from any other indirect type. Also specific one spin-orbital cases $(\Delta V)_a = \omega_a (\Delta V_a) \bar{\omega}_a$. This being a further advantage of the geometric notation.
- The self-consistent solution requires, in general, numerical solutions. Nevertheless all analytic and computational methodologies in usual practice can be used without major changes.

Comparison with previous methodologies: Conclusions. In practice several features made the, now known as the Hartree-Fock method (HF[2,3]), the reference for atomic, molecular, and ground state condensed matter calculations: it is a formally correct variational procedure based on the use of a determinant of auxiliary functions for which a differential equation is deduced within the method. It includes (through the basic properties of the Slater determinant) the Pauli exclusion principle as well as the indistinguishability of equivalent fermions. HF is also a suitable starting calculation for establishing the procedure known as configuration interaction (CI), introducing a set of variational constants, when the spin-orbitals resulting from the HF calculation are used to construct a formally complete wave function as a sum of mutually orthogonal Slater determinants. The standard definition of "exchange energy" and of "correlation energy" is given in relation to the HF+CI procedures. In the determinants no two-electron-relative-coordinates functions are used, neither in these approaches nor in the one described earlier.

Another widely used methodology, based on the density functional theory (DFT) a correct formal procedure itself,[14,15] can be considered as related to HF+CI as the standard calculations include local density functionals for the exchange and correlation energies and potentials.

The methodology developed here shares both all the favorable features of the HF+CI method and the advantages of the DFT procedure. This suggests that there should be a relation among all three procedures HF+CI, DFT, and KKW.

- The KKW method ($M = N$) requires the self-consistent solution of N differential equations,

as in DFT, unlike the HF which is an $N\times N$ formulation. Compared to the *ab initio* techniques, our methodology employs a simpler set of equations.

- If, as in the HF method, using $M=N$, each auxiliary function were to be optimized separately one at a time in a self-consistent set, from our expressions (16) for the total energy, we go back to the HF procedure and results. Our method has the advantage that the complete set is optimized simultaneously to search for the lowest total energy.
- The KKW method in the minimum auxiliary functions procedure is equivalent to the Slater (1951) average exchange proposal (with the so-called "exact" exchange) and in fact transforms this Slater "approximation" into a nonapproximate procedure where all auxiliary functions are optimized simultaneously. This is independent of the DFT approximation for E_{XC}.
- The formal structure of the new method enriches the methodology of the DFT by showing that the Slater exchange and the Kohn-Sham procedures are formally integrated to the general scheme and also because an N-electron wave function Ψ, which is required in the theorems of the formal DFT theory, is constructed and used within the formalism.

The KKW approach also shows, from the different analysis presented here, DFT both as an *ab initio* and as a first principles method. This is an important formal contribution of our study.

In the following we quote standard use of the so called *ab initio* and DFT methods, see, for example Refs. 1, 16, and 17.

Computationally there is no need to consider a self-Coulomb energy. As all electrons have equivalent descriptions, with the same density per electron, there is an exact resultant factor $((N-1)/N)$ in the electron-electron Coulomb interaction. It is basic for the calculation of the hydrogen atom. It is dominant in the calculation of the helium atom where each of the two electrons interact with the other but not with itself, and progressively less important for larger systems where the interchange part of the interaction grows. Standard DFT programs[18,19] for atomic electronic structure calculations are easily modified, an $(N-1)/N$ factor in the Coulomb potential, replacement of the exchange-correlation and total energy subroutines, to solve the KKW equations (27). As a numerical test the relativistic program "David"[19] was adapted, the H atom calculation used as a first check of the numerical procedures, the He atom with $M=N$, the Hartree-Fock limit for the Coulomb interaction, and the He atom with $(1s,2s,2p)$ for the $M>N$ case, beryllium and krypton in the $M=N$ as further tests. All results are acceptable in the limit of the corresponding approximations (Hartree atomic units):

Atom	E_{total}	E_{HF}	E_{DFT}	E_{exp}
H	−0.5	−0.5	⋯	−0.5
He	−2.886	−2.864	−2.867	−2.90
Be	−14.603	−14.573	−14.592	−14.673
Ne	−128.87	−128.55	−128.62	−128.94
Kr	−2799.49	−2796.72	−2787.80	⋯

In our analysis we have gone beyond complex algebra and calculus, in fact we have gone to the more general domain of the Grassmann-Clifford algebra and analysis.

ACKNOWLEDGMENTS

J.K. wishes to gratefully acknowledge the hospitality and fundamental discussions with the group of Professor Peter Weinberger, and also the technical assistance of Irma Vigil de Aragón. A preliminary form of this methodology was presented by J.K. and Alejandro Keller at the Seventh International Conference on Clifford Algebras, 2005 Toulouse. This project was additionally supported by the UNAM Program PAPIIT No. IN113102-3.

We provide a complete picture of contractivity of trace preserving positive maps with respect to p-norms. We show that for $p>1$ contractivity holds in general if and only if the map is unital. When the domain is restricted to the traceless subspace of Hermitian matrices, then contractivity is shown to hold in the case of qubits for arbitrary $p\geqslant 1$ and in the case of qutrits if and only if $p=1, \infty$. In all noncontractive cases best possible bounds on the p-norms are derived. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2218675]

I. INTRODUCTION

This article addresses the following question: *Given a positive and trace preserving linear map T between matrix spaces, when is T contractive with respect to the p-norm, with* $1\leqslant p\leqslant\infty$.

This problem has come up in several contexts in recent years. For instance, Olkiewicz,[1] in his investigation of the superselection structure of dynamical semigroups, needs as a starting point the fact that a 2-positive map that is contractive with respect to both the trace and operator norm is also contractive with respect to the Hilbert-Schmidt norm. The same result is needed by Raginsky[2] in his study of entropy production of a quantum channel. In the context of quantum information this question arose again in Ref. 3, in the study of entanglement measures. It is shown there that any distance (in the space of matrices) that is contractive under completely positive trace preserving maps gives rise to a "suitable" entanglement measure. Their conjecture that the Hilbert-Schmidt norm is such a distance was disproved shortly thereafter by Ozawa in Ref. 4. In Ref. 5, Nielsen stated (without proof) that the Hilbert-Schmidt distance is contractive in the space of qubits, with respect to any completely positive trace preserving map. He also encouraged further study of this problem. Recently, the fact that a completely positive trace preserving map is contractive with respect to the trace norm was used in Ref. 6 in the context of condensed matter theory in a theoretical justification for the high accuracy of renormalization group algorithms.

Motivated by the appearance of the previous question in so many different areas of physics, we will try in this note to give a complete picture of the solution. We will first study the general case and then restrict the domain of the maps to the traceless hyperplane.

II. THE GENERAL CASE

In the following $\mathcal{M}_n$ will denote the space of $n\times n$ matrices. A linear map $T:\mathcal{M}_n\to\mathcal{M}_r$ is called *positive* if it maps positive semidefinite matrices to positive semidefinite matrices, *trace preserving* if $\mathrm{tr}\,T(A)=\mathrm{tr}\,A$ for all $A\in\mathcal{M}_n$, and *unital* if $T(\mathbb{1})=\mathbb{1}$. It is easy to see that T is trace preserving if and only if its adjoint $T^*:\mathcal{M}_r\to\mathcal{M}_n$ is unital, and that T is positive if and only if T^* is positive.

The p-norm (we will assume always $1\leqslant p\leqslant\infty$) of a matrix A is defined as $(\mathrm{tr}|A|^p)^{1/p}=(\Sigma_i\lambda_i^p)^{1/p}$, where the λ_i are the singular values of A (i.e., the eigenvalues of $|A|\equiv\sqrt{A^*A}$). We write $\mathcal{S}_p^n$ for $\mathcal{M}_n$ endowed with the p-norm. For $T:\mathcal{M}_n\to\mathcal{M}_r$, we use $\|T\|_{p-p}$ to denote the operator norm of T when we consider the p-norm in both the original and the final space, i.e., $\|T\|_{p-p}=\sup_{A\in\mathcal{M}_n}(\|T(A)\|_p/\|A\|_p)$. T is called *contractive* under the p-norm if $\|T\|_{p-p}\leqslant 1$. Our first result is

Theorem 2.1: *If $T:\mathcal{M}_n\to\mathcal{M}_r$ is positive and trace preserving, then $\|T\|_{p-p}\leqslant n^{1-1/p}$.*

Moreover, the bound $n^{1-1/p}$ is attained when T is the the trace operator $\mathrm{tr}:\mathcal{M}_n\to\mathbb{C}$ (which is completely positive and trace preserving).

The main ingredient in the proof is a noncommutative version of the Riesz-Thorin theorem. (See Ref. 7 or Sec. IX.4 of Ref. 8.) We will also use a theorem of Russo and Dye (Ref. 9, Corollary 2.9).

Theorem 2.2 (Noncommutative Riesz-Thorin): *If $T:\mathcal{M}_n\to\mathcal{M}_r$ is a linear map, then*

$$\|T\|_{p-p}\leqslant\|T\|_{1-1}^{1/p}\|T\|_{\infty-\infty}^{1-1/p}.$$

Theorem 2.3 (Russo-Dye). *If $T:\mathcal{M}_n\to\mathcal{M}_r$ is positive, then $\|T\|_{\infty-\infty}=\|T(\mathbb{1})\|_\infty$.*

Proof. To prove Theorem 2.1, first note that under its hypotheses, T^* is positive and unital. Then Theorem 2.3 implies that $\|T^*\|_{\infty-\infty}=\|T^*(\mathbb{1})\|_\infty=\|\mathbb{1}\|_\infty=1$. Hence, using the duality $(S_1^n)^*=S_\infty^n$, we can conclude that $\|T\|_{1-1}=1$. Moreover, $\|T\|_{\infty-\infty}=\|T(\mathbb{1})\|_\infty\leqslant\|T(\mathbb{1})\|_1=\|\mathbb{1}\|_1=n$. Combining these bounds with Theorem 2.2 gives the claimed result. □

We used the fact that when T is trace preserving, then T positive implies $\|T\|_{1-1}=1$. In Ref. 9, Proposition 2.11 it is shown that for T trace preserving, T is positive if and only if $\|T\|_{1-1}=1$.

When T is positive, trace preserving and unital the argument used to prove Theorem 2.1 shows that $\|T\|_{1-1}=\|T\|_{\infty-\infty}=1$. Then Theorem 2.2 implies that T is contractive for all p-norms. The next Theorem shows that this is an equivalence.

Theorem 2.4: *If $T:\mathcal{M}_n\to\mathcal{M}_n$ is positive and trace preserving, the following are equivalent*:

(i) $\|T(\mathbb{1})\|_p\leqslant n^{1/p}$ *for some* $1<p\leqslant\infty$;
(ii) *T is unital*;
(iii) *T is contractive for the p-norm for every* $1\leqslant p\leqslant\infty$; and
(iv) *T is contractive for the p-norm for some* $1<p\leqslant\infty$.

Proof. It only remains to prove that (i)⇒(ii). To do this, let $(\lambda_i)_{i=1}^n$ denote the eigenvalues of $T(\mathbb{1})$. Since T is positive, $\lambda_i\geqslant 0$; and since T is trace-preserving, $\Sigma_i\lambda_i=\mathrm{tr}\,T(\mathbb{1})=\mathrm{tr}\,\mathbb{1}=n$. Hölder's inequality can then be used to conclude that $\Sigma_i\lambda_i^p\geqslant n$ with equality if and only if $\lambda_i=1$ for all i. But, by assumption, $\|T(\mathbb{1})\|_p\leqslant n^{1/p}$ for some $p>1$. Thus, we must have equality so that $T(\mathbb{1})=\mathbb{1}$.□

The hypothesis that T is both unital and trace preserving can only be satisfied when $r=n$. In that case, when T is trace preserving, but not unital, it follows that $\|T\|_{p-p}>1$. When $n\neq r$, this does not hold, i.e., there are non-unital trace-preserving completely positive maps $T:\mathcal{M}_n\to\mathcal{M}_r$ for which $\|T\|_{p-p}<1$. To see this one needs Jencova's result[10] that $\|T\|_{p-p}=\omega_p(T^C)$ where $\omega_p(T)$ is the completely bounded $1\to p$ norm studied in Ref. 11 and T^C denotes the conjugate or complementary channel defined in Refs. 12 and 13. From the results in Ref. 11 one can find depolarizing channels T_{dep} such that $\omega_p(T_{\mathrm{dep}})<1$. To see this let $\mu=1/(n+1)$ in Eq. (5.4) in Ref. 11. Since $\mu=1/(n+1)$ is the boundary between depolarizing channels which are entanglement breaking and those which are not, this yields examples in both classes. As the conjugate T_{dep}^C is *not* unital,[13] we have explicit examples of non-unital trace-preserving completely positive maps $T:\mathcal{M}_n\to\mathcal{M}_{n^2}$ for which $\|T\|_{p-p}<1$.

The implication (ii)⇒(iii) was proved using complex interpolation. For $p=2$, one can obtain

an elementary proof by using that $\|T\|_{2-2}^2$ is the largest eigenvalue of $T^*\circ T$ considered as an operator on the Hilbert space $\mathcal{M}_n$ with inner product $\langle A,B\rangle=\mathrm{tr}\,A^*B$. When T is both trace-preserving and unital, $\mathbb{1}$ is an eigenvector with eigenvalue 1, and the orthogonality of eigenvectors implies that $\mathrm{tr}\,G=\mathrm{tr}\,\mathbb{1}G=0$ for any other eigenvector G (which we can assume is Hermitian without loss of generality). Now let G be one of these eigenvectors and let ω be the largest real number for which $\mathbb{1}+\omega G$ is positive semi-definite. Since $T^*\circ T$ is also positive, $(T^*\circ T)(\mathbb{1}+\omega G)=\mathbb{1}+\lambda\omega G\geqslant 0$. But this implies that $\lambda\leqslant 1$ by the definition of ω so that $\|T^*\circ T\|_\infty=1$.

III. THE TRACELESS HYPERPLANE

Using the p-norm to measure the distance between density matrices, gives expressions of the form $\|\rho-\rho'\|_p$, where $\rho-\rho'$ is a Hermitian matrix with trace 0. In this section we investigate the behavior of such distances under positive and trace preserving maps. Let $T|_{\mathcal{H}_0}$ denote the restriction of T to the hyperplane $\mathcal{H}_0$ of traceless Hermitian matrices.

Theorem 3.1. *Let $T:\mathcal{M}_n\to\mathcal{M}_n$ be a positive trace preserving linear map. Then*

$$\|T|_{\mathcal{H}_0}\|_{p-p}\leqslant\begin{cases}\left(\dfrac{n}{2}\right)^{1-1/p}, & n \text{ even}\\ \left(\dfrac{2^{2-p}}{(n-1)^{1-p}+(n+1)^{1-p}}\right)^{1/p}, & n \text{ odd}\end{cases}.$$

Moreover, this bound is optimal, as there exists a completely positive trace preserving map that saturates the inequality.

Proof. We begin by proving the upper bound. For an arbitrary positive trace preserving map $T:\mathcal{M}_n\to\mathcal{M}_n$, consider A Hermitian, traceless and with $\|A\|_p\leqslant 1$. We can write $A=A_+-A_-$ with A_+ and A_- both positive semi-definite and $A_+A_-=0$. As T is positive, $[T(A)]_+\leqslant T(A_+)$ and $[T(A)]_-\leqslant T(A_-)$. Then,

$$\|T(A)\|_p^p=\mathrm{tr}|T(A)|^p=\mathrm{tr}([T(A)]_+)^p+\mathrm{tr}([T(A)]_-)^p=\|[T(A)]_+\|_p^p+\|[T(A)]_-\|_p^p\leqslant\|T(A_+)\|_p^p+\|T(A_-)\|_p^p.$$

Call $r=\mathrm{range}(A_+)$ and $s=\mathrm{range}(A_-)$ and denote the eigenvalues of A_+ and A_- by $\lambda_1,\ldots,\lambda_r$ and $\mu_1,\ldots,\mu_s$, respectively. It follows from Theorem 2.4 that $\|T(A_+)\|_p^p\leqslant r^{p-1}\|A_+\|_p^p$ and $\|T(A_-)\|_p^p\leqslant s^{p-1}\|A_-\|_p^p$. Using Lagrange multipliers in the problem

$$\text{maximize}\left\{r^{p-1}\sum_{i=1}^{r}\lambda_i^p+s^{p-1}\sum_{i=1}^{s}\mu_i^p\right\}$$

restricted to

$$\sum_{i=1}^{r}\lambda_i^p+\sum_{i=1}^{s}\mu_i^p=1,$$

$$\sum_{i=1}^{r}\lambda_i-\sum_{i=1}^{s}\mu_i=0$$

one finds that at least one of the following two conditions is satisfied: $\lambda_i=\lambda_j$ and $\mu_i=\mu_j$ for every i,j, or $s=r$.

In the first case we have that [assuming now without loss of generality that $\mathrm{tr}(A_+)=1$]

$$\frac{\|T(A)\|_p^p}{\|A\|_p^p}\leqslant\frac{2}{r^{1-p}+s^{1-p}}.$$

This is in turn maximized and leads to the inequality in Theorem 3.1 if $s=n-r$ and $r=n/2$ for even n, and $r=(n+1)/2$ for odd n respectively. In the second case $r=s$ we have that

$$\|T(A)\|_p^p \leqslant r^{p-1}(\|A_+\|_p^p + \|A_-\|_p^p),$$

yielding the sought inequality for $r=n/2$ (even n); whereas $r<n/2$ does not lead to a new inequality.

To prove optimality of the bound above, consider the completely positive and trace preserving map $T:\mathcal{M}_n\to\mathcal{M}_n$ given by

$$T(A) = |0\rangle\langle 0|\mathrm{tr}[PA] + |1\rangle\langle 1|\mathrm{tr}[(\mathbb{1}-P)A],$$

where P is a projector of dimension $d=\mathrm{tr}\,P$. If we apply this map to a traceless Hermitian operator of the form $A=P-(d/(n-d))(\mathbb{1}-P)$ we obtain

$$\frac{\|T(A)\|_p}{\|A\|_p} = \left(\frac{2d^p}{d+d^p(n-d)^{1-p}}\right)^{1/p}.$$

This achieves the above bound if $d=n/2[d=(n+1)/2]$ for n even (odd). □

Any trace-preserving map can be written uniquely in the form $T(A)=N\,\mathrm{tr}(A)+T_1(A)$ where $T_1(A)$ is a unital trace-preserving map and $N=(1/d)[T(\mathbb{1})-\mathbb{1}]$ is traceless. If T_1 is also positive, it follows from Theorem 2.4, that $\|T|_{\{\mathrm{tr}=0\}}\|_{p-p}\leqslant 1$ and we can drop the restriction to Hermitian matrices. Unfortunately, the previous results demonstrate that even when T is positive and trace preserving, T_1 need not be positive.

A. Maps on qubits

When $n=2$, Theorem 3.1 implies contractivity in the traceless subspace of Hermitian matrices, i.e., $\|T|_{\mathcal{H}_0}\|_{p-p}=1$. Here, however, there is no need to restrict to Hermitian matrices. For qubits, T positive and trace preserving implies that the previous map T_1 is always positive.

Theorem 3.2. *For any positive trace preserving linear map* $T:\mathcal{M}_2\to\mathcal{M}_2$ and $1\leqslant p\leqslant\infty$ *we have that*

$$\max_{\mathrm{tr}(A)=0,\|A\|_p=1} \|T(A)\|_p \leqslant 1.$$

Proof. The theorem is proved by showing that the T_1 defined above is indeed positive. Consider the action of T on a density operator $\rho=\frac{1}{2}(\mathbb{1}+w\cdot\sigma)$ represented as a vector $w\in\mathbb{R}^3$ on the Bloch sphere. Any trace preserving and positive linear map acts as

$$T(\mathbb{1}+w\cdot\sigma) = \mathbb{1} + [r+Rw]\cdot\sigma,$$

where $r\in\mathbb{R}^3$ and R is a real 3×3 matrix. T is positive iff $\|w\|_2\leqslant 1$ implies $\|r+Rw\|_2\leqslant 1$. Let λ be the largest singular value of R. Then there are unit vectors $u,w\in\mathbb{R}^3$ such that $Rw=\lambda u$. As $R(-w)=\lambda(-u)$, one can choose the sign of w such that $r\cdot u\geqslant 0$, and thus $1\geqslant\|r+\lambda u\|_2\geqslant\lambda$. This implies that the unital trace preserving map $T_1(\mathbb{1}+w\cdot\sigma):=\mathbb{1}+[Rw]\cdot\sigma$ is indeed positive, and the result follows from Theorem 2.4. □

B. The case of qutrits

Theorem 3.1 still implies contractivity in $\mathcal{H}_0$ for the case $n=3$ if $p=1$ or $p=\infty$ (whereas this fails for $1<p<\infty$). As in the case of qubits one might expect that the result for $p=\infty$ also extends to non Hermitian matrices. This is, however, not the case. A simple counterexample is given by the map

$$T(A) = \sum_{i=0}^{1}\langle i|A|i\rangle|0\rangle\langle 0| + \langle 2|A|2\rangle|1\rangle\langle 1|,$$

acting on $A=a_0|0\rangle\langle 0|+a_1|1\rangle\langle 1|+a_2|2\rangle\langle 2|$, where a_0,a_1,a_2 are the three complex cubic roots of unity. In this case we have that $\mathrm{tr}(A)=0$, $\|A\|_\infty=1$, but $\|T(A)\|_\infty>1$.

Contraction of broken symmetries via Kac-Moody formalism

Jamil Daboul[a)]
Centro de Ciencias Físicas, Universidad Nacional Autónoma de México, Apartado Postal 48-3, Cuernavaca, Morelos 62251, Mexico

(Received 26 December 2005; accepted 28 June 2006; published online 14 August 2006)

I investigate contractions via Kac-Moody formalism. In particular, I show how the symmetry algebra of the standard two-dimensional Kepler system, which was identified by Daboul and Slodowy as an infinite-dimensional Kac-Moody loop algebra, and was denoted by $\mathbb{H}_2$, gets reduced by the symmetry breaking term, defined by the Hamiltonian $H(\beta)=(1/2m)(p_1^2+p_2^2)-\alpha/r-\beta r^{-1/2}\cos((\varphi-\gamma)/2)$. For this $H(\beta)$ I define two symmetry loop algebras $\mathfrak{L}_i(\beta)$, $i=1,2$, by choosing the "basic generators" differently. These $\mathfrak{L}_i(\beta)$ can be mapped isomorphically onto subalgebras of $\mathbb{H}_2$, of codimension two or three, revealing the reduction of symmetry. Both factor algebras $\mathfrak{L}_i(\beta)/I_i(E,\beta)$, relative to the corresponding energy-dependent ideals $I_i(E,\beta)$, are isomorphic to $\mathfrak{so}(3)$ and $\mathfrak{so}(2,1)$ for $E<0$ and $E>0$, respectively, just as for the pure Kepler case. However, they yield two different nonstandard contractions as $E\to 0$, namely to the Heisenberg-Weyl algebra $\mathfrak{h}_3=\mathfrak{tw}_1$ or to an Abelian Lie algebra, instead of the Euclidean algebra $\mathfrak{e}(2)$ for the pure Kepler case. The above-noted example suggests a general procedure for defining generalized contractions, and also illustrates the "*deformation contraction hysteresis*," where contraction which involves two contraction parameters can yield different contracted algebras, if the limits are carried out in different order. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2234726]

I. INTRODUCTION

In 1926 Pauli[1] obtained the energy levels of the relativistic hydrogen atom algebraically, by using the conserved angular-momentum $\mathbf{L}=\mathbf{r}\times\mathbf{p}$ and the Hermitian form of the Laplace-Runge-Lenz vector

$$\mathbf{A}=\frac{1}{2}[\mathbf{p}\times\mathbf{L}-\mathbf{L}\times\mathbf{p}]-m\alpha\hat{\mathbf{r}}. \tag{1}$$

The commutation relations among their components are given by

$$\begin{aligned}
&[L_i,L_j]=i\hbar\epsilon_{ijk}L_k, \quad i,j,k=1,2,3,\\
&[L_i,A_j]=i\hbar\epsilon_{ijk}A_k,\\
&[A_i,A_j]=-i2mH\hbar\epsilon_{ijk}L_k,
\end{aligned} \tag{2}$$

where H is the Hamiltonian of the nonrelativistic three-dimensional (3D) hydrogen atom. The commutation relations in (2) do not define a closed algebra, since the H on the right-hand side of (2) is an *operator* and not a number. To nevertheless obtain closed algebras physicists for 70 years

[a)]On Sabbatical leave from the Physics Department, Ben Gurion University of the Negev, 84105 Beer Sheva, Israel; electronic mail: daboul@bgu.ac.il

have replaced the Hamiltonian H by its eigenvalues E, and thus obtained three different identifications of the symmetry algebra of the hydrogen atom, namely $\mathfrak{so}(4)$, $\mathfrak{so}(3,1)$ and $\mathfrak{e}(3)$, for $E<0$, $E>0$ and $E=0$, respectively.[2] The same conclusion can be reached by formally "normalizing" the Runge-Lenz vector $\mathbf{A}$ by dividing it by $\sqrt{2m|H|}$, but the resulting quotient vector becomes infinite for $H=0$.

Instead of the above-noted "conventional procedure," Daboul and Slodowy[3] showed that one can obtain a single closed algebra based on the commutation relations (2). This algebra is spanned by the following infinite set of generators:

$$\mathbb{H}_3 := \{h^n L_i, h^n A_i | i=1,2,3, n=0,1,\ldots\}, \quad \text{where } h := -2mH. \tag{3}$$

The algebra $\mathbb{H}_3$ and its generalizations $\mathbb{H}_N$, the symmetry algebras of the N-dimensional hydrogen atom, were identified[3,4] as positive loop algebras of twisted or untwisted Kac-Moody algebras,[5,6] for N odd or even, respectively. They were called the *hydrogen algebras*. The above-mentioned formalism will be reviewed in Sec. II, and applied to $\mathbb{H}_2$, the hydrogen algebra of the standard two-dimensional (2D) Kepler system, defined by the Hamiltonian H_0 of Eq. (5).

The algebras $\mathbb{H}_N$ depend on the Hamiltonian H, but *not* on its energy eigenvalues E. However, one can reproduce the usual three corresponding finite-dimensional algebras, $\mathfrak{so}(N+1)$, $\mathfrak{so}(N,1)$, and $\mathfrak{e}(N)$, as factor algebras $\mathbb{H}_N/I(E)$ relative to energy-dependent ideals $I(E)$; The ideals and factor-algebra formalism will be discussed and applied to $\mathbb{H}_2$ in Sec. II A.

In the present paper I investigate *what happens to the algebra* $\mathbb{H}_2$ *and its factor algebra, if the original symmetry of the 2D hydrogen atom is broken*. In particular, I shall study the following Hamiltonian:

$$H := H_0 - \beta r^{-1/2} \cos\left[\tfrac{1}{2}(\varphi-\gamma)\right] \quad (\gamma=0 \text{ in the present paper}), \tag{4}$$

where H_0 is the Hamiltonian of the two-dimensional Kepler problem

$$H_0 := \frac{1}{2m}(p_1^2+p_2^2) - \frac{\alpha}{r} = \frac{1}{2m}\left(p_r^2 + \frac{p_\varphi^2}{r^2}\right) - \frac{\alpha}{r}. \tag{5}$$

Throughout this paper I shall set the phase angle γ in (4) equal to zero, since it can always be removed by appropriate choice of the coordinate system (see, however, the discussion in Sec. V).

The Hamiltonian (4) has an interesting history: It was discovered by Winternitz *et al.*[7] already in 1967 in their systematic search for super-integrable systems. It was also derived in a more general complex form by Sen [Ref. 8, Eq. (3.14)] in 1987.

The symmetry of (4) was originally studied by Gorringe and Leach[9] in 1993 and recently reviewed by Leach and Flessas—Ref. 10, Sec. §3.3 (see also Ref. 11). The above-noted authors followed the conventional method and found that the symmetry algebras of (4) are $\mathfrak{so}(3)$ and $\mathfrak{so}(2,1)$ for $E<0$ and $E>0$, exactly as for the pure 2D Kepler problem (5). However, for $E=0$ they obtained the Heisenberg-Weyl algebra $\mathfrak{h}_3=\mathfrak{w}_1$ [which they denoted by $W(3,1)$],[9,10] instead of the Euclidean algebra $\mathfrak{e}(2)$ for the Kepler case (5).

This result was intriguing, since the symmetry breaking does not affect the symmetry for $E\neq 0$, and only affect it for $E=0$. And I wondered whether and how the above type of symmetry breaking can be treated via the Kac-Moody formalism. It turned out that the symmetry algebra of (4) can be treated, via the Kac-Moody formalism, similar to the pure Kepler case, with some important modifications. For example, it is possible to describe the symmetry algebra of (4) by two loop algebras, $\mathfrak{L}_1$ and $\mathfrak{L}_2$, depending on the choice of the "*basic generators*." It is remarkable that these two algebras can be mapped onto subalgebras of $\mathbb{H}_2$ of codimension two and three, i.e., $\mathbb{H}_2$ is larger than these image subalgebras by only two and three generators, out of infinitely many. The "missing" generators are manifestations of the symmetry breaking.

Moreover, I will show that the factor algebras $\mathfrak{L}_i/I_i(E,\beta)$ relative to the corresponding energy-

TABLE I. The three factor algebras $\mathbb{H}_2/I(E)$ and $\mathfrak{L}_i/I_i$ of the loop algebras $\mathbb{H}_2$ and $\mathfrak{L}_i$ relative to the corresponding energy-dependent ideals $I(E)$ and $I_i(E,\beta)$. For $E\neq 0$ all three factor algebras are isomorphic to $\mathfrak{so}(3)$ for $E<0$ and to $\mathfrak{so}(2,1)$ for $E>0$, but yield *different contractions* for $E\to 0$.

Hamiltonian	Factor algebra	$E<0$	$E=0$	$E<0$
H_0 in (5)	$\mathbb{H}_2/I(E)$	$\mathfrak{so}(3)$	$\mathfrak{e}(2)$	$\mathfrak{so}(2,1)$
H in (4)	$\mathfrak{L}_1(\beta)/I_1(E,\beta)$	$\mathfrak{so}(3)$	$\mathfrak{h}_3=\mathfrak{w}_1$	$\mathfrak{so}(2,1)$
H in (4)	$\mathfrak{L}_2(\beta)/I_2(E,\beta)$	$\mathfrak{so}(3)$	R^3	$\mathfrak{so}(2,1)$

dependent ideals yield different types of *contractions*,[12–14] which are included in Table I. This result is important, since the contraction procedure for the above-noted specific system can be generalized to other algebras, as discussed in Sec. VI.

In Sec. II I review Inönü-Wigner contraction and its generalization and in Sec. III I review the construction of the hydrogen algebra $\mathbb{H}_2$ for the pure 2D Kepler problem (5). In Secs. IV and V I construct two loop algebras $\mathfrak{L}_1$ and $\mathfrak{L}_2$ for the system (4) and their factor algebras $\mathfrak{L}_i/I_i(E,\beta)$. In Sec. VI I map the $\mathfrak{L}_i$ onto subalgebras $\mathbb{H}_2$, and as I already noted, I shall suggest a general procedure for defining contraction via Kac-Moody formalism and then give some conclusions.

II. REVIEW OF GENERALIZED INÖNÜ-WIGNER CONTRACTION

There are many formulations of contractions.[12,13] I shall give my own definition and notation:

Definition: Let $\mathfrak{g}:=\langle X_a, C_{ab}^c\rangle$ be a finite-dimensional Lie algebra with a basis X_a, $a=1,2,\ldots,N$ and structure constants C_{ab}^c, and let the parameter-dependent Lie algebra $\mathfrak{g}^\epsilon := \langle X_a^\epsilon, C_{ab}^c(\epsilon)\rangle$ be defined, such that the one-to-one linear map f_ϵ between $\mathfrak{g}$ and $\mathfrak{g}^\epsilon$,

$$f_\epsilon:\mathfrak{g}\mapsto\mathfrak{g}^\epsilon,\quad f_\epsilon(X_a)=\epsilon^{-n_a}X_a^\epsilon, \tag{6}$$

is an isomorphism of Lie algebras as long as $\epsilon\neq 0$. If the powers n_a satisfy the condition,

$$n_a+n_b\geqslant n_c \tag{7}$$

then the limit algebra $\mathfrak{g}^0=\langle X_a^0, C_{ab}^c(0)\rangle$ with the structure constants

$$C_{ab}^c(0):=\lim_{\epsilon\to 0} C_{ab}^c(\epsilon)$$

exists and it is called the *contracted algebra*. I shall refer to $\mathfrak{g}^\epsilon$ as the *contracting algebra* and to its generators X_a^ϵ as the *contracting generators*.

It is important to emphasize that X_a^ϵ and X_a^0 *denote the generators of the Lie algebras* $\mathfrak{g}^\epsilon$ *and* $\mathfrak{g}^0$ *which are defined via the structure constants* $C_{ab}^c(\epsilon)$ *and* $C_{ab}^c(0)$, *respectively*. Therefore, the X_a^0 *are not to be regarded as the limits of* X_a^ϵ *for* $\epsilon\to 0$. Thus, the X_a^0 *always* exist, by definition, as generators of the contracted algebra $\mathfrak{g}^0$, even though representations $r(X_a^\epsilon)$ of $\mathfrak{g}^\epsilon$ might exist with some of the generators having vanishing limits, i.e., $\lim_{\epsilon\to 0} r(X_b^\epsilon)=0$. Such representations could be called *not saved or unsaved*. Otherwise, they are called *saved representations*.[15] Actually in Sec. V I shall give a realization of a saved representation of an algebra whose contraction yields an Abelian algebra, i.e., $C_{ab}^c=0$ for all a,b,c. For this contraction even the adjoint representation[13] is not saved.

Usually X_a is used also to denote the contracting and contracted generators X_a^ϵ and X_a^0.[13] This convention is probably used to avoid confusing X_a^0 as the limit of X_a^ϵ for $\epsilon\to 0$. To distinguish the algebras $\mathfrak{g}^\epsilon$ from $\mathfrak{g}$ and $\mathfrak{g}^0$ one attaches an index ϵ to the commutators $[,]_\epsilon$, as it is done in Eq. (8) below. I find this usual notation confusing, since X_a^0 are the generators of a different algebra $\mathfrak{g}^0$. I prefer attaching the ϵ to the generators but keep the commutator symbol $[,]$ unchanged. This

notation is more useful and user-friendly, especially if matrix representations exist, since one uses $[A,B]=AB-BA$ and the standard matrix multiplication, whether the matrices A and B represent generators of the original or the contracted algebras.

In contrast to the formal definition of X_a^0, the limits $r(X_b^0) := \lim_{\epsilon\to 0} r(X_b^\epsilon)$ of *representations or realizations* $r(X_a^\epsilon)$, if they exist, should satisfy the commutation relations of $\mathfrak{g}^0$, although some of these representations may not be saved.

The condition (7) is necessary and sufficient to make the limit algebra $\mathfrak{g}^0$ well defined. It ensures that the *contracting structure constants* $C_{ab}^c(\epsilon)$, defined by

$$\sum_{c=1}^{N} C_{ab}^c(\epsilon) X_c^\epsilon := [X_a^\epsilon, X_b^\epsilon]_\epsilon = \epsilon^{n_a+n_b}[f_\epsilon(X_a), f_\epsilon(X_b)]_\epsilon = \epsilon^{n_a+n_b} f_\epsilon([X_a,X_b]) = \epsilon^{n_a+n_b} f_\epsilon\left(\sum_{c=1}^{N} C_{ab}^c X_c\right)$$
$$= \sum_{c=1}^{N} \epsilon^{n_a+n_b-n_c} C_{ab}^c X_c^\epsilon, \tag{8}$$

have finite limits for $\epsilon\to 0$.

The *Inönü-Wigner contraction* is a special case of the above-presented definition, where

$$\begin{aligned} n_i &= 0 \quad \text{for } i = 1,2,\ldots,M, \\ n_\alpha &= \text{const} > 0 \quad \text{for } \alpha = M+1, M+2, \ldots, N. \end{aligned} \tag{9}$$

In this case, and by choosing const$=1$ for convenience, we obtain for $\epsilon\to 0$:

$$\begin{aligned} [X_i^\epsilon, X_j^\epsilon] &= \sum_{k=1}^{M} C_{ij}^k X_k^\epsilon \Rightarrow \sum_{k=1}^{M} C_{ij}^k X_k^0, \\ \text{where } X_k^0 &:= \lim_{\epsilon\to 0} X_k^\epsilon, \end{aligned} \tag{10}$$

$$[X_i^\epsilon, X_\alpha^\epsilon] = \sum_{k=1}^{M} \epsilon C_{i\alpha}^k X_k^\epsilon + \sum_{\beta=M+1}^{N} C_{i\alpha}^\beta X_\beta^\epsilon \Rightarrow \sum_{\beta=M+1}^{N} C_{i\alpha}^\beta X_\beta^0, \tag{11}$$

$$[X_\alpha^\epsilon, X_\beta^\epsilon] = \sum_{k=1}^{M} \epsilon^2 C_{\alpha\beta}^k X_k^\epsilon + \sum_{\gamma=M+1}^{N} \epsilon C_{\alpha\beta}^\gamma X_\gamma^\epsilon \Rightarrow 0. \tag{12}$$

We see that the commutation relations (10) define a subalgebra $\mathfrak{g}_R := \langle X_i^0 \rangle \simeq \langle X_i \rangle$, because C_{ij}^α must vanish to satisfy the condition (7), as was originally concluded in Ref. 12. Note that (12) tells us that $I^0 = \langle X_\alpha^0 \rangle$ is an Abelian subalgebra, whereas (11) tells us that I^0 is an ideal of $\mathfrak{g}^0$.

The contractions which are not of the Inönü-Wigner type are called *generalized Inönü-Wigner contractions*. In the present paper we shall encounter one example of Inönü-Wigner contractions and two examples of generalized Inönü-Wigner contractions.

To give the reader an intuitive understanding of the above-presented definitions and notation, let us consider the famous example of contracting the Lorentz algebra to the Galilean algebra: Let e_{ij} denote a basis of 4×4 matrices, defined by $(e_{ij})_{kl} = \delta_{ik}\delta_{jl}$. They have the following commutation relations:

$$[e_{ij}, e_{st}] = \delta_{js} e_{it} - \delta_{it} e_{sj}, \quad i,j,s,t = 1,2,3,4. \tag{13}$$

We define the three contracting boosts by

$$B_i^\epsilon := \epsilon^2 e_{i4} + e_{4i} = \epsilon\left(\epsilon e_{i4} + \frac{1}{\epsilon} e_{4i}\right) =: \epsilon f_\epsilon(B_i), \quad i = 1,2,3. \tag{14}$$

These commute as follows:

$$[B_i^\epsilon, B_j^\epsilon] = \epsilon^2 [e_{i4}, e_{4j}] = \epsilon^2 (e_{ij} - e_{ji}) =: -\epsilon^2 L_{ij} \Rightarrow 0, \tag{15}$$

which shows how the Lorentz algebra $\mathfrak{so}(3,1)$ for $\epsilon=1$ is contracted to the Galilei algebra, which is the Euclidean algebra $\mathfrak{e}(3)$, in which the limits of the boosts $B_i^0 = e_{4i}$ generate an Abelian ideal.

III. THE HYDROGEN ALGEBRA $\mathbb{H}_2$ of H_0

Instead of the six generators **L** and **A** for the 3D Kepler problem, only three generators are conserved for the 2D Kepler problem.[10] These are the third component of angular momentum L_3 and two components of the Runge-Lenz vector **A**:

$$\begin{aligned} L \equiv L_3 &:= x p_y - y p_x = p_\varphi, \\ \mathbf{A} &:= (A_1, A_2) = L p_y \hat{\mathbf{x}} - L p_x \hat{\mathbf{y}} - m\alpha \hat{\mathbf{r}}. \end{aligned} \tag{16}$$

In the following I shall use the following notation:

$$h_0 \equiv -2mH_0, \quad h \equiv -2mH, \quad \varepsilon \equiv -2mE. \tag{17}$$

For simplicity and also in order to compare my results with those of Ref. 10, I shall use from now on *Poisson brackets* instead of commutation relations. But I shall nevertheless refer sometimes to these Poisson brackets as commutators.

The Poisson brackets of the above-mentioned generators are

$$\begin{aligned} \{L, A_1\} &= A_2, \\ \{A_2, L\} &= A_1, \\ \{A_1, A_2\} &= h_0 L, \end{aligned} \tag{18}$$

where $h_0 := -2mH_0$. The loop algebra $\mathbb{H}_2$ is spanned by the following generators:

$$L^{(2n)} := h_0^n L, \quad A_i^{(2n+1)} := h_0^n A_i \quad (i = 1,2), \quad n \geqslant 0. \tag{19}$$

I call the upper index the *grade* of the corresponding operator. According to the above-presented construction, every multiplication by h_0 raises the grade of the generators by 2. With the commutators (18) the set

$$\mathbb{H}_2 := \{A_1^{(2n+1)}, A_2^{(2n+1)}, L^{(2n)} | n \geqslant 0\} \tag{20}$$

becomes a closed Lie algebra, which is a subalgebra of the affine Kac-Moody algebra $A_1^{(1)}$.

A. The factor algebra $\mathbb{H}_2/I(E)$

The three standard finite-dimensional algebras, $\mathfrak{so}(3)$, $\mathfrak{so}(2,1)$, and $\mathfrak{e}(2)$ can be recovered from $\mathbb{H}_2$, as in Refs. 3 and 4, as follows: First we define an energy-dependent ideal of $\mathbb{H}_2$ by

$$\begin{aligned} I(E) &:= (H_0 - E)\mathbb{H}_2 = (h_0 - \varepsilon)\mathbb{H}_2, \\ &\text{where } \varepsilon := -2mE. \end{aligned} \tag{21}$$

Next, we define the *energy-dependent* factor algebra $\mathbb{H}_2/I(E)$ relative to the above-noted ideal. This factor algebra consists of three elements or classes,

$$\mathbb{H}_2/I(E) = \{\mathcal{A}_1^\varepsilon, \mathcal{A}_2^\varepsilon, \mathcal{L}^\varepsilon\}, \tag{22}$$

which obey the following commutation relations:

$$\{\mathcal{L}^\varepsilon, \mathcal{A}_1^\varepsilon\} = \mathcal{A}_2^\varepsilon, \quad \{\mathcal{A}_2^\varepsilon, \mathcal{L}^\varepsilon\} = \mathcal{A}_1^\varepsilon, \quad \{\mathcal{A}_1^\varepsilon, \mathcal{A}_2^\varepsilon\} = \varepsilon \mathcal{L}^\varepsilon. \tag{23}$$

The commutation relations (23) are exactly those of (18), except that the operator h_0 in (18) is now replaced by the numerical parameter ε. This is what physicists usually obtain by *directly* replacing the Hamiltonian H by its energy eigenvalue E.

The above-mentioned classes can be identified by their representatives as follows:

$$\mathcal{A}_1^\varepsilon = A_1 + I(E), \quad \mathcal{A}_2^\varepsilon = A_2 + I(E), \quad \mathcal{L}^\varepsilon = L + I(E). \tag{24}$$

To see why each "*basic element*" becomes a representative of its class, we recall that quite generally an ideal I of an algebra $\mathfrak{g}$ acts additively as the zero element of the factor algebra $\mathfrak{g}/I$. In our case, this fact yields the following equivalence relation in $\mathbb{H}_2/I(E)$:

$$h_0^n X_i \equiv \varepsilon^n X_i, \quad \text{mod } (I(E)), \tag{25}$$

where X_i is a basic generator, i.e., the element which generates the whole infinite "tower" $\{h_0^n X_i | n = 0, 1, \ldots\}$. The above-mentioned equivalence relation can be proved easily as follows:

$$h_0^n X_i - \varepsilon^n X_i = (h_0^n - \varepsilon^n) X_i = (h_0 - \varepsilon) \left(\sum_{k=0}^{n-1} \varepsilon^{n-1-k} h_0^k \right) X_i \in I(E). \tag{26}$$

Equation (25) tells us that in the factor algebra we can replace every element $h_0^n X_i \in \mathbb{H}_2$ by $\varepsilon^n X_i$, which is simply a numerical multiple of X_i. Hence, in $\mathbb{H}_2/I(E)$ we can replace every element in the tower $\{h_0^n X_i | n = 0, 1, \ldots\}$ by a single element X_i, so that $\mathbb{H}_2/I(E)$ is a finite-dimensional algebra generated by the X_i, which in our case are the three elements given in (24).

Note that *the Hamiltonian H_0 by itself is not an element of the ideal $I(E)$*.

B. Contraction of the factor algebra $\mathbb{H}_2/I(E)$

It is easy to check that the map

$$\begin{gathered} f_\varepsilon(\sqrt{\operatorname{sgn}(\varepsilon)} L_i) = \frac{1}{\sqrt{|\varepsilon|}} \mathcal{A}_i^\varepsilon, \quad i = 1, 2, \\ f_\varepsilon(L_3) = \mathcal{L}^\varepsilon, \end{gathered} \tag{27}$$

defines an isomorphism between the algebras $\mathfrak{so}(3)$, $\mathfrak{so}(2,1)$, and the factor algebra $\mathbb{H}_2/I(E)$ for $\varepsilon < 0$, $\varepsilon > 0$. Hence, by treating $\varepsilon = -2mE$ as a contraction parameter ϵ, the classes $\mathcal{A}_1^\varepsilon$, $\mathcal{A}_2^\varepsilon$, and $\mathcal{L}^\varepsilon$ with the commutation relations (23) can be regarded as the generators of a *contracting* algebra $\mathfrak{g}^\epsilon$ (see Sec. II), for $\varepsilon \neq 0$ (!).

For $\varepsilon \to 0$ the algebras $\mathbb{H}_2/I(\varepsilon)$ are contracted to $\mathbb{H}_2/I(0)$, whose commutation relations follow from (23)

$$\{\mathcal{L}^0, \mathcal{A}_1^0\} = \mathcal{A}_2^0, \quad \{\mathcal{A}_2^0, \mathcal{L}^0\} = \mathcal{A}_1^0, \quad \{\mathcal{A}_1^0, \mathcal{A}_2^0\} = 0. \tag{28}$$

Since these are the commutation relations of the Euclidean algebra $\mathfrak{e}(2)$, it follows that $\mathbb{H}_2/I(0) \simeq \mathfrak{e}(2)$. Since f_ϵ is an isomorphism for $\varepsilon \neq 0$, we conclude that a contraction of $\mathbb{H}_2/I(\varepsilon)$ for the nonbroken Hamiltonian H_0 in (5) is the same as the well-known contraction of $\mathfrak{so}(3)$ and $\mathfrak{so}(2,1)$ to the Euclidean algebra $\mathfrak{e}(2)$, as $\varepsilon \to 0$. Note that the number of generators remains the same after contraction. In the present case, the contraction is of the Inönü-Wigner type.

In the next two sections we shall see that the Factor algebras associated with the "broken Hamiltonian" H of (4) yield two contractions of the generalized Inönü-Wigner type.

IV. THE LOOP ALGEBRA $\mathfrak{L}_1(\beta)$ of H in (4)

For the Hamiltonian (4) there exist a generalized conserved Runge-Lenz vector,[10] which is given by

$$\mathbf{M} \equiv \mathbf{M}(\beta) := \mathbf{A} - m\beta\sqrt{r}\sin(\varphi/2)\hat{\boldsymbol{\phi}}(\varphi) = \left(\frac{p_\varphi^2}{r} - m\beta\right)\hat{\mathbf{r}}(\varphi) - (p_r p_\varphi + m\beta\sqrt{r}\sin(\varphi/2))\hat{\boldsymbol{\phi}}(\varphi). \tag{29}$$

Note that $\mathbf{M}(0)=\mathbf{A}$. The commutator of the two components of $\mathbf{M}$ in (29) yield a third conserved quantity, which I shall denote by S (It is called $-I$ in Ref. 10): It is defined by[10]

$$S := \{M_1, M_2\} = hp_\varphi - m\beta(p_r r^{1/2}\sin(\varphi/2) + p_\varphi r^{-1/2}\cos(\varphi/2)). \tag{30}$$

The commutators of S with M_i are[10]

$$\{S, M_1\} = hM_2, \quad N_1 := \{M_2, S\} = hM_1 - m^2\beta^2/2. \tag{31}$$

We can summarize the above-mentioned commutators as follows:

$$\{S, N_1\} = h^2 M_2, \quad \{M_2, S\} = N_1, \quad \{N_1, M_2\} = hS. \tag{32}$$

Therefore, I call the following three generators "*basic generators:*"

$$N_1, \quad M_2, \quad S, \tag{33}$$

because they can yield a closed algebra by multiplying them with powers of h as in (34). *The above-mentioned basic generators were chosen, such that none of them vanishes nor blows up for* $H=0$.

As before, since H commutes with the basic generators, we can close the algebra in (32) by including the following generators:

$$h^n M_2, \quad h^n N_1, \quad h^n S, \quad n \geqslant 0. \tag{34}$$

It is interesting to note that by commuting the basis generators N_1, M_2, and S, among themselves and with their commutators, we can never produce hM_2. This means that it is possible to obtain a closed algebra even without hM_2. Nevertheless, I included hM_2 in (34) in order to obtain a closed algebra which is generated by the basic generators over the polynomial ring $R[h]$.

A crucial step in identifying the algebra generated by the operators in (34) is to *assign grades* to each operator, because for Lie algebras of the Kac-Moody type the sum of the grades (which I am writing as upper indices) must be conserved under commutation. It is easy to check that the following identification of the grades is consistent:

$$M_2^{(2n+1)} := h^n M_2, \quad N_1^{(2n+3)} := h^n N_1, \quad S^{(2n+2)} := h^n S, \quad n \geqslant 0. \tag{35}$$

For example, using (32) we obtain

$$\{N_1^{(2m+3)}, M_2^{(2n+1)}\} = h^{m+n}\{N_1, M_2\} = h^{m+n+1}S = S^{(2m+2n+4)}.$$

Therefore the above-presented infinite generators span the following graded Loop algebra of the Kac-Moody type,

$$\mathfrak{L}_1(\beta) := \{M_2^{(2n+1)}, N_1^{(2n+3)}, S^{(2n+2)} | n \geqslant 0\}. \tag{36}$$

Note that the basic generators are graded as follows:

$$M_2 = M_2^{(1)}, \quad S = S^{(2)}, \quad N_1 = N_1^{(3)}.$$

A. The factor algebra $\mathfrak{L}_1(\beta)/I_1(E,\beta)$

As before, the factor algebra

$$\mathfrak{L}_1(\beta)/I_1(E,\beta) = \{\mathcal{M}_2^\varepsilon, \mathcal{N}_1^\varepsilon, \mathcal{S}^\varepsilon\}, \tag{37}$$

relative to the following energy-dependent ideal

$$I_1(E,\beta) \coloneqq (H-E)\mathfrak{L}_1(\beta) = (h-\varepsilon)\mathfrak{L}_1(\beta), \tag{38}$$

where $\varepsilon = -2mE$, has three classes, which commute as follows:

$$\{\mathcal{S}^\varepsilon, \mathcal{N}_1^\varepsilon\} = \varepsilon^2 \mathcal{M}_2^\varepsilon, \quad \{\mathcal{M}_2^\varepsilon, \mathcal{S}^\varepsilon\} = \mathcal{N}_1^\varepsilon, \quad \{\mathcal{N}_1^\varepsilon, \mathcal{M}_2^\varepsilon\} = \varepsilon \mathcal{S}^\varepsilon. \tag{39}$$

B. Contraction of the factor algebra $\mathfrak{L}_1/I_1(E,\beta)$

In the present case we need a different map

$$\begin{aligned} f_\varepsilon(\sqrt{\mathrm{sgn}(\varepsilon)}L_1) &= \mathcal{N}_1^\varepsilon/|\varepsilon|^{3/2} =: \hat{\mathcal{N}}_1{}^\varepsilon, \\ f_\varepsilon(\sqrt{\mathrm{sgn}(\varepsilon)}L_2) &= \mathcal{M}_2^\varepsilon/|\varepsilon|^{1/2} =: \hat{\mathcal{M}}_2{}^\varepsilon, \\ f_\varepsilon(L_3) &= \mathcal{S}^\varepsilon/|\varepsilon| =: \hat{\mathcal{S}}^\varepsilon, \end{aligned} \tag{40}$$

which again defines an isomorphism between the algebras $\mathfrak{so}(3)$, $\mathfrak{so}(2,1)$ and the factor algebra $\mathfrak{L}_1/I_1(E,\beta)$ for $\varepsilon<0$, $\varepsilon>0$. The three generators $\hat{\mathcal{N}}_1^\varepsilon$, $\hat{\mathcal{M}}_2^\varepsilon$, and $\hat{\mathcal{S}}^\varepsilon$ may be called "normalized" generators.

The contraction of the factor algebras $\mathfrak{L}_1/I_1(E,\beta)$ yields $\mathfrak{L}_1/I_1(0,\beta)$, whose commutation relations follow from (39). They are given by

$$\begin{aligned} [\mathcal{N}_1^0, \mathcal{M}_2^0] &= \lim_{\varepsilon\to 0} \varepsilon^{3/2+1/2-1}\mathcal{S}^\varepsilon = 0, \\ [\mathcal{S}^0, \mathcal{N}_1^0] &= \lim_{\varepsilon\to 0} \varepsilon^{1+3/2-1/2}\mathcal{M}_2^\varepsilon = 0, \end{aligned} \tag{41}$$

$$[\mathcal{M}_2^0, \mathcal{S}^0] = \lim_{\varepsilon\to 0} \varepsilon^{1/2+1-3/2}\mathcal{N}_1^\varepsilon = \mathcal{N}_1^0. \tag{42}$$

These are the commutation relations of the Heisenberg-Weyl algebra $\mathfrak{h}_3 = \mathfrak{w}_1$, as we can see by using the following map:

$$\mathcal{M}_2^0 \to \partial_x, \quad \mathcal{S}^0 \to x, \quad \mathcal{N}_1^0 \to 1.$$

It is important to note that in the factor algebra $\mathfrak{L}_1(\beta)/I_1(E,\beta)$ we are *not* allowed to replace the h in N_1 of (31) by ε, since neither h nor $(h-\varepsilon)M_1$ are elements of the ideal $I_1(E,\beta)$. Hence, N_1 is independent of E and thus it should *not* be replaced by the constant $-m^2\beta^2/2$ for $E=0$.

V. A SECOND LOOP ALGEBRA $\mathfrak{L}_2(\beta)$ OF H IN (4)

In this section I show that a different choice of the basic generators yields different contractions. Instead of the three generators in (33) I now choose the basic generators as follows:

$$N_1, \quad N_2 \coloneqq hM_2, \quad S. \tag{43}$$

The choice of N_2 in (43) may seem unjustified. But I chose it nevertheless in order to illustrate

how we can obtain different contractions by simply removing some generators from the *same* loop algebra.

The choice (43) would seem less strange, had I kept the phase angle γ in (4) arbitrary: In this case I would have obtained

$$\begin{aligned}\widetilde{N}_1 &:= \{\widetilde{M}_2, \widetilde{S}\} = \widetilde{h}\widetilde{M}_1 - \tfrac{1}{2}m^2\beta^2 \cos\,\gamma,\\ \widetilde{N}_2 &:= \{\widetilde{S}_1, \widetilde{M}_1\} = \widetilde{h}\widetilde{M}_2 - \tfrac{1}{2}m^2\beta^2 \sin\,\gamma,\end{aligned} \tag{44}$$

where the tilde over the quantities denotes the quantities of the previous section, but with $\gamma \neq 0$. Hence, for γ arbitrary, the $\widetilde{N}_1$, $\widetilde{N}_2$, and $\widetilde{S}$ would have seemed to be the natural choice for the basic generators. In fact, these generators were originally chosen by Leach and Flessas [Ref. 10, Eq. (3.4.5)] as the symmetry generators of the Hamiltonian (4) for $E \neq 0$. However, for $E=0$ they made a different choice, and chose the following linear combinations of $\widetilde{N}_1$ and $\widetilde{N}_2$:

$$\begin{aligned}N_1 &= \cos\,\gamma\widetilde{N}_1 + \sin\,\gamma\widetilde{N}_2 = hM_1 - \tfrac{1}{2}m^2\beta^2,\\ M_2 &= \frac{1}{h}(\sin\,\gamma\widetilde{N}_1 - \cos\,\gamma\widetilde{N}_2).\end{aligned} \tag{45}$$

We see that their second choice (45) corresponds exactly to the generators which I used in Sec. IV, by setting $\gamma=0$ from the beginning. This explains why they were able to obtain the algebra $\mathfrak{w}_1$ as the symmetry algebra for $E=0$; for $E \neq 0$ it does not matter which linear combinations one chooses: one always obtains $\mathfrak{so}(3)$ or $\mathfrak{so}(2,1)$.

The generators in (43) commute as follows:

$$\{N_1, N_2\} = h^2 S, \quad \{N_2, S\} = hN_1, \quad \{S, N_1\} = hN_2. \tag{46}$$

Following the same procedure as before, the following operators

$$\begin{aligned}N_1^{(2n+3)} &:= h^n N_1,\\ N_2^{(2n+3)} &:= h^n N_2.\\ S^{(2n+2)} &:= h^n S,\end{aligned} \tag{47}$$

for $n \geqslant 0$, yield the following Loop algebra, provided one uses the grading in (47)

$$\mathfrak{L}_2 := \{N_1^{(2n+3)}, N_2^{(2n+3)}, S^{(2n+2)} | n \geqslant 0\}. \tag{48}$$

The factor algebra $\mathfrak{L}_2(\beta)/I_2(E,\beta)$. The factor algebra in this case consists also of three classes, namely

$$\mathfrak{L}_2(\beta)/I_2(E,\beta) = \{\mathcal{N}_1^\varepsilon, \mathcal{N}_2^\varepsilon, \mathcal{S}^\varepsilon\}, \tag{49}$$

where

$$I_2(E,\beta) := (H-E)\mathfrak{L}_2(\beta) = (h-\varepsilon)\mathfrak{L}_2(\beta). \tag{50}$$

These classes commute as follows:

$$\{\mathcal{N}_1^\varepsilon, \mathcal{N}_2^\varepsilon\} = \varepsilon^2 \mathcal{S}^\varepsilon, \quad \{\mathcal{N}_2^\varepsilon, \mathcal{S}^\varepsilon\} = \varepsilon \mathcal{N}_1^\varepsilon, \quad \{\mathcal{S}^\varepsilon, \mathcal{N}_1^\varepsilon\} = \varepsilon \mathcal{N}_2^\varepsilon. \tag{51}$$

Hence, in this case we obtain for $\varepsilon \to 0$ a contraction of $\mathfrak{so}(3)$ and $\mathfrak{so}(2,1)$ to an Abelian algebra, which I denote by R^3. This is a generalized Inönü-Wigner contraction.

Note that if $N_2=hM_2$, as defined in (43), then $N_2^{(2n+3)}=M_2^{(2n+3)}$, so that $\mathfrak{L}_2$ is just a subalgebra of $\mathfrak{L}_1$, with just the element M_2 removed, i.e.,

$$\mathfrak{L}_2 = \mathfrak{L}_1 \setminus M_2^{(1)} = \mathfrak{L}_1 \setminus M_2. \tag{52}$$

Again note that in the factor algebra $\mathfrak{L}_2(\beta)/I_2(E,\beta)$ we are *not* allowed to replace $N_2=hM_2$ by εM_2, since $(h-\varepsilon)M_2$ is NOT an element of the ideal $I_2(E,\beta)$, because (52) tells us that $M_2 \notin \mathfrak{L}_2$. Thus, the class $\mathcal{N}_2^0=N_2+I_2(0)\neq I_2(0)$, which means that the contracted factor algebra $\mathfrak{L}_2(\beta)/I_2(0,\beta)$ remains 3D, as it should. Note that with the formal factor-algebra construction every one of the three generators is well defined and will not vanish in the limit $\varepsilon\to 0$, so that this realization is *saved.*[15] *In contrast, if instead we follow the standard procedure and work directly with the generators* N_1, N_2, *and* S *and just replace the* h *by* ε, *then* $N_2=hM_2$ *will become* $N_2=\varepsilon M_2$ *and thus it will vanish in the limit* $\varepsilon\to 0$, so that N_2 will not be saved.

VI. SUMMARY AND CONCLUSIONS

In the present paper I constructed two Kac-Moody loop algebras $\mathfrak{L}_1(\beta)$ and $\mathfrak{L}_2(\beta)$. The second algebra $\mathfrak{L}_2(\beta)$ was studied simply to show that one has the freedom of constructing more than one loop algebra from the conserved constants of motion, M_1, M_2, S, and H. These two infinite-dimensional algebras are operator-valued and thus do *not* depend on energy E.

To study contractions I first constructed E-dependent factor algebras, in order to obtain finite-dimensional algebras out of the infinite-dimensional ones. As I explained in Eq. (25), this construction enables us to replace all the higher generations $X_i^n := h^n X_i$ by $\varepsilon^n X_i$, so that within the factor algebras all the generators X_i^n become numerical multiples of the basic generators $X_i=X_i^0$. In particular, for $E=0$ we obtain $\varepsilon^n X_i=0$ for $n\geqslant 1$.

To avoid any misunderstanding, I want to emphasize again that I am *not* contracting the infinite-dimensional Kac-Moody loop algebras, $\mathbb{H}_2$, $\mathfrak{L}_1(\beta)$ and $\mathfrak{L}_2(\beta)$; *I am only contracting their (3D) factor algebras*, $\mathbb{H}_2/I(E)$, $\mathfrak{L}_1(\beta)/I_1(E,\beta)$, and $\mathfrak{L}_2(\beta)/I_2(E,\beta)$, by using the energy E as the contraction parameter. It is interesting that although all three factor algebras are isomorphic to $\mathfrak{so}(3)$ and $\mathfrak{so}(2,1)$ for $E<0$ and $E>0$, they contract for $E\to 0$ to three different algebras $\mathfrak{e}(2)$, $\mathfrak{w}_1$, and R^3, which are also 3D. The first contraction is of the Inönü-Wigner type while the other two are of the generalized Inönü-Wigner type. In all these contractions the dimension of the algebras is preserved, since the factor algebras do not change their dimensions as $E\to 0$. These contractions are summarized in Table I.

The effect of symmetry breaking in $H(\beta)$ manifests itself differently in the standard and the Kac-Moody treatments: In the standard procedure, which was followed by Leach *et al.*,[9,10] the symmetry algebras for H_0 and $H(\beta)$ are exactly the same, namely $\mathfrak{so}(3)$ and $\mathfrak{so}(2,1)$. The effect of symmetry breaking manifests itself only for $E\neq 0$.

In contrast, as we shall now see, the Loop algebras $\mathfrak{L}_1$ and $\mathfrak{L}_2$ for the "broken Hamiltonian" $H(\beta)$ are *smaller* than the hydrogen algebra $\mathbb{H}_2$ for H_0 (irrespective of the energy !). They are smaller by two and three elements, respectively, thereby revealing the symmetry breaking:

To compare $\mathfrak{L}_1$ and $\mathfrak{L}_2$ with $\mathbb{H}_2$, I define two maps, as follows: $f_1:\mathfrak{L}_1\mapsto\mathbb{H}_2$, defined by

$$f_1(N_1^{(2n+3)}(\beta)) := A_1^{(2n+3)},$$

$$f_1(M_2^{(2n+1)}(\beta)) := A_2^{(2n+1)},$$

$$f_1(S^{(2n+2)}(\beta)) := L^{(2n+2)}, \tag{53}$$

for $n\geqslant 0$, and $f_2:\mathfrak{L}_2\mapsto\mathbb{H}_2$, defined by

$$f_2(N_1^{(2n+3)}(\beta)) := A_1^{(2n+3)},$$

$$f_2(N_2^{(2n+3)}(\beta)) := A_2^{(2n+3)}, \tag{54}$$

$$f_2(S^{(2n+2)}(\beta)) := L^{(2n+2)},$$

for $n \geqslant 0$. It is easy to check that these two maps, which keep the grades of the generators unchanged, define isomorphisms from $\mathfrak{L}_1$ and $\mathfrak{L}_2$ onto subalgebras of $\mathbb{H}_2$ of codimension two and three, respectively. Hence,

$$\mathbb{H}_2 = \begin{cases} f_1(\mathfrak{L}_1(\beta)) \cup \{L, A_1\} \\ f_2(\mathfrak{L}_2(\beta)) \cup \{L, A_1, A_2\}. \end{cases} \tag{55}$$

Thus, we can conclude that symmetry breaking of the type (4) reduces the loop algebra $\mathbb{H}_2$ of the original system H_0 by only finite number of generators. By constructing the corresponding factor algebras, I obtained different contractions depending on the missing terms (see Table I).

By defining the ε-dependent ideals and constructing the factor algebras, we are essentially replacing each infinite-dimensional "*tower*" $\{X_i^n\}$ by one element $X_i^{n_i^{\min}}$ which has the *lowest grade*. *By removing generators from the original loop algebra, we increase the grade of the corresponding basic generators*. This in turn increases the powers of the contraction parameter ε which multiply the structure constants of the original algebra $\mathfrak{g}$, which is being contracted.

The results obtained in the present paper suggest a *general procedure for defining contractions via Kac-Moody formalism* as follows:

- Start with of a finite dimensional Lie algebra $\mathfrak{g}$, which may be graded, via s-dimensional automorphism, as follows:

$$\mathfrak{g} = \bigoplus_{k=0}^{s-1} \mathfrak{g}_k \quad \text{with } [\mathfrak{g}_i, \mathfrak{g}_j] \subseteq \mathfrak{g}_{i+j}, \tag{56}$$

  where the indices are modulo s.
- Then consider the *positive* subalgebra of a general (twisted or untwisted) loop algebra of a finite dimensional algebra $\mathfrak{g}$,

$$\mathfrak{L} = \{ \bigoplus_{k=0}^{s-1} z^{sn+k} \otimes \mathfrak{g}_k | n \geqslant 0 \}, \tag{57}$$

  where z may be a scalar or an operator which commutes with all the generators of $X_i \in \mathfrak{g}$.
- Then remove some generators from $\mathfrak{L}$, and make sure that the *remaining set* $\mathfrak{L}_R$ yields a subalgebra of $\mathfrak{L}$. This is not automatic: see, for example, the conditions in (60). Then make sure that the set

$$I_R(\varepsilon) = (z - \varepsilon)\mathfrak{L}_R \tag{58}$$

  is an ideal of $\mathfrak{L}_R$, since for some choices $(z-\varepsilon)\mathfrak{L}_R$ is not a subalgebra of $\mathfrak{L}_R$.
- Finally, define the factor algebras $\mathfrak{L}_R / I_R(\varepsilon)$, which will be isomorphic to one or two real forms of $\mathfrak{g}$, depending on the sign of parameter ε. The ε can be used as a contraction parameter. One may get different contractions for the same original algebra $\mathfrak{g}$ as $\varepsilon \to 0$, depending on the removed generators.

For example, we can define subalgebras of $\mathbb{H}_2$ by

$$\mathbb{H}_2(n_1, n_2, n_3) := \langle h^{n_1+n} A_1, h^{n_2+n} A_2, h^{n_3+n} L_3, n \geqslant 0 \rangle \tag{59}$$

if the n_i satisfy the following conditions:

$$n_1 + n_2 - n_3 + 1 \geqslant 0, \quad n_3 + n_1 - n_2 \geqslant 0, \quad n_3 + n_2 - n_1 \geqslant 0. \tag{60}$$

In particular, as I showed explicitly in (53) and (54), the loop algebras $\mathfrak{L}_i$ are isomorphic to the following subalgebras of $\mathbb{H}_2$, and thus give us intuitive physical realizations of the formal definition in (59):

$$\mathfrak{L}_1 \simeq \mathbb{H}_2(1,0,1), \quad \mathfrak{L}_2 \simeq \mathbb{H}_2(1,1,1). \tag{61}$$

In these subalgebras of $\mathbb{H}_2$ the conditions (60) are clearly satisfied.

The conditions (60) follow from two different arguments:

(1) The generators of the subalgebra $\mathbb{H}_2(n_1,n_2,n_3)$ commute as follows:

$$\begin{aligned}
&[h^{n_1}A_1, h^{n_2}A_2] = h^{n_1+n_2+1}L_3, \quad \text{hence } n_3 \leqslant n_1+n_2+1,\\
&[h^{n_3}L_3, h^{n_1}A_1] = h^{n_3+n_1}A_2, \quad \text{hence } n_2 \leqslant n_3+n_1,\\
&[h^{n_3}L_3, h^{n_2}A_2] = -h^{n_3+n_2}A_1, \quad \text{hence } n_1 \leqslant n_3+n_2.
\end{aligned} \tag{62}$$

The conditions (60) are necessary to ensure that the right-hand side of the above-mentioned commutators are elements of $\mathbb{H}_2(n_1,n_2,n_3)$.

(2) In the factor algebra $\mathbb{H}_2(n_1,n_2,n_3)/((h-\varepsilon)\mathbb{H}_2(n_1,n_2,n_3))$ only the generators with lowest grade are linearly independent. Their commutators are

$$\begin{aligned}
&[\epsilon^{n_1}A_1, \epsilon^{n_2}A_2] = \epsilon^{n_1+n_2-n_3+1}(\epsilon^{n_3}L_3),\\
&[\epsilon^{n_3}L_3, \epsilon^{n_1}A_1] = \epsilon^{n_3+n_1-n_2}(\epsilon^{n_2}A_2),\\
&[\epsilon^{n_3}L_3, \epsilon^{n_2}A_2] = -\epsilon^{n_3+n_2-n_1}(\epsilon^{n_1}A_1).
\end{aligned} \tag{63}$$

Hence, in order for the right-hand side of the above three equations to exist as $\epsilon \to 0$, the exponents of ϵ must be non-negative. This requirement yields exactly the same conditions on the n_i as those given in (62), which were necessary for the existence of subalgebras of $\mathbb{H}_2$.

- More generally, given an N-dimensional semisimple algebra $\mathfrak{g}$, we can define subalgebras $\mathfrak{g}_n$ by

$$\mathfrak{g}_n := \langle h^{n_i}X_i | n \geqslant 0 \text{ and } i = 1,2,\ldots,N\rangle. \tag{64}$$

  Instead of an operator h, with $[h,X_i]=0$, we can also use a formal variable z.

  These subalgebras yield well-defined contractions via the factor-algebra $\mathfrak{g}_n/((h-\epsilon)\mathfrak{g}_n)$, provided the n_i satisfy the general condition (7), namely $\epsilon^{n_i+n_j-n_k}C_{ij}^k < \infty$.

Finally, we note that by taking the limit $\beta \to 0$ in the "*deformed Hamiltonian*" $H(\beta)$ of (4) we recover the original Hamiltonian H_0 and thus obtain the symmetry algebra $\mathbb{H}_2$. In contrast, for as $\beta \to 0$ the loop symmetry algebras $\mathfrak{L}_i(\beta)$ (and thus also their factor algebras) remain unchanged and do *not* go back to $\mathbb{H}_2$ (and its factor algebras). I call this phenomenon the *DC (deformation-contraction) hysteresis*, since *we obtain different contractions depending on the order of taking the limits* $E \to 0$ *and* $\beta \to 0$. The subtlety of the DC hysteresis, which yields $\mathfrak{w}_1$ instead of $\mathfrak{e}_2$, is illustrated in Fig. 1.

ACKNOWLEDGMENTS

I am happy to thank my daughter, Claudia Daboul, for reading the manuscript and making useful comments. It is also a pleasure to thank the members of CCF, and in particular Bernardo Wolf, for their hospitality.

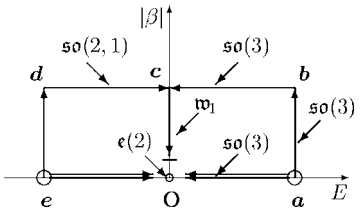

FIG. 1. The "*DC hysteresis*" in the (E,β) parameter plane, by comparing the contraction limits $E\to 0$ of the factor algebras $\mathbb{H}_2/I(E)$ and $\mathfrak{L}_1/I_1(E,\beta)$, is illustrated: If we contract the factor algebras $\mathbb{H}_2/I(E)$ of H_0 along the horizontal energy E-axis, which corresponds to $\beta=0$, we obtain $\mathfrak{e}(2)$. This contraction is indicated by the double arrows ($\mathbf{e}\Rightarrow\mathbf{O}\Leftarrow\mathbf{a}$). In contrast, for $\beta\neq 0$ the contraction of $\mathfrak{L}_1/I_1(E,\beta)$ of H yields the Weyl algebra $\mathfrak{L}_1/I_1(0,\beta)=\mathfrak{w}_1$, as illustrated by $\mathbf{d}\to\mathbf{c}\leftarrow\mathbf{b}$. Finally, taking the limit of $\mathfrak{L}_1/I_1(0,\beta)$ as $\beta\to 0$ downwards along the vertical $|\beta|$-axis to the origin $(E,\beta)=(0,0)$ leaves the algebra $\mathfrak{w}_1$ unchanged. Thus, the two paths originating in **a** yield different limits: $\mathfrak{so}(3)\simeq\mathbb{H}_2/I(E)\simeq\mathfrak{L}_1(\beta)/I_1(E,\beta)\to\mathfrak{L}_1(\beta)/I_1(0,\beta)\simeq\mathfrak{L}_1(0)/I_1(0,0)\simeq\mathfrak{w}_1\neq\mathfrak{e}(2)\simeq\mathbb{H}_2/I(0)\Leftarrow\mathbb{H}_2/I(E)$.

In this paper, we consider the initial boundary value problem for the primitive equations of moist atmospheric dynamics that are used to describe the turbulent behavior of long-term weather prediction and climate changes. By the Faedo-Galerkin method, we obtain the existence of global weak solutions to the problem in a large-scale atmosphere. By studying the long-time behavior of solutions, we obtain trajectory and global attractors for the primitive equations of moist atmosphere. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2245207]

I. INTRODUCTION

There are two ways to describe the mechanism of long-term weather prediction and climate changes. First, one can use history records and numerical computations to predict the future weather and possible global changes. Second, since the atmosphere is a specific compressible fluid, one can study the mathematical equations and models governing the motion of the atmosphere. Bjerkness, one of the pioneers of meteorology, said that the weather forecasting can be thought of as an initial boundary value problem in mathematical physics. In 1922, Richardson introduced the so-called primitive atmospheric equations that consisted of the hydrodynamic, thermodynamic, and state equations with Coriolis force; cf. Ref. 1. At that time, the primitive atmospheric equations were too complicated to be studied theoretically or to be solved numerically. However, there were some simple numerical models, such as the barotropic model formulated by Neumann, etc. in Ref. 2 and the quasigeostrophic model introduced by Charney and Philips in Ref. 3.

In recent years, due to the considerable improvement in computer capacity and the development of atmospheric science, there were some mathematicians who began to consider the primitive equations of atmosphere. Since the momentum conservation equation in the vertical direction can be replaced by the hydrostatic equation given later, which satisfies meteorological observations and history data in a large-scale atmosphere, the fundamental equations governing the motion of the atmosphere can be reduced to the primitive equations of large-scale atmosphere; cf. Ref. 1. In Ref. 4, introducing the viscosity terms and some technical treatment, Lions, Temam, and Wang obtained a new formulation of the primitive equations of large-scale dry atmosphere that was amenable to mathematical treatment. In a p-coordinate system (the definition will be given later), the new formulation of the primitive equations is similar to but more complicated than Navier-Stokes equations of incompressible fluid. By the methods used to solve Navier-Stokes system in Ref. 5, they obtained the existence of global weak solutions of the initial boundary value problem for the new formulation of the primitive equations. And under the hypothesis that there exist global strong solutions for the problem, they established some physically relevant estimates for the Hausdorff and fractal dimensions of attractors for the primitive equations. By the same methods, in Ref. 6 they established some mathematical theory for the models of the coupled

[a)]Corresponding author. Electronic mail: hdw55@tom.com

atmosphere and ocean introduced in Ref. 7. In Refs. 8 and 9, under the hypothesis of the existence of the global strong solutions for the initial boundary value problem of the dry and moist atmospheric fundamental equations, Li and Chou studied asymptotic behavior of solutions for the problem. By taking advantage of the geostrophic balance and other geophysical consideration, several intermediate models have been the subject of studying the long-time dynamics and global attractors in order to describe the mechanism of weather prediction and climate dynamics (see, e.g., Refs. 10–13).

In the present paper, we are interested in finding the existence of global weak solutions, trajectory, and global attractors for the large-scale moist atmospheric primitive equations. Our main results are Theorem 3.8 and Theorem 4.15. Without the hypothesis that there exist global strong solutions for the initial boundary problem of the new formulation of large-scale moist atmospheric primitive equations (IBVP), which will be given in Sec. II, we obtain global attractors for the moist atmospheric primitive equations in some weak sense (the details will be given in Sec. IV). (IBVP) generalizes the work in Ref. 4, where the authors considered the dry atmospheric primitive equations. Since the moist atmospheric equations are more complicated than the dry atmospheric primitive equations, we must study more nonlinear terms than those in Ref. 4. Under some technical treatment, (IBVP) is corresponding to Problem 3.1 given in the Sec. III C. Using the methods in Ref. 4, we can make full use of the hydrostatic equation, which provides a relation between pressure and density to obtain the existence of global weak solutions for Problem 3.1. Problem 3.1 is similar to but more complicated than Navier-Stokes systems of incompressible fluids. In particular, the nonlinear terms in Problem 3.1 is more complicated than those in the Navier-Stokes system. Since the existence of global strong solutions of Problem 3.1 remains unproved (recently, in Ref. 14, Cao and Titi have proved the global existence and uniqueness of strong solutions to a three-dimensional viscous primitive equations in a cylindrical domain), we cannot use the well-known methods based on the analysis of global attractors of the corresponding semigroup. Our approach to finding the existence of trajectory and global attractors for the moist atmospheric equations is inspired by Refs. 15 and 16. In those papers, Vishik and Chepyzhov obtained the trajectory and global attractors of three-dimensional Navier-Stokes system without the assumption that there exist global strong solutions for the system. Here, the trajectory and global attractors is related to the time translation semigroup $\{T(t)\}$ given in the subsection IV A.

The paper is organized as follows: In Sec. II, we shall pose the new formulation of the primitive equations of a large-scale moist atmosphere. In Sec. III, we shall give a mathematical setting for the initial boundary value problem for the new formulation of primitive equations of large-scale moist atmosphere and obtain the existence of global weak solutions to Problem 3.1. In Sec. IV, we shall prove the existence of trajectory and global attractors of the moist atmospheric primitive equations.

II. THE PRIMITIVE EQUATIONS OF LARGE-SCALE MOIST ATMOSPHERE

Inspired by the methods used by Lions, Temam, and Wang introduced in Refs. 4 and 7, we shall give the new formulation of the primitive equations of large-scale moist atmosphere in this section.

In a noninertial coordinate system, the atmosphere motion is described by the following equations (see, e.g., Refs. 17, 9, and 18):

The momentum conservation equation,

$$\frac{dV_3}{dt} = -\frac{1}{\rho}\,\mathrm{grad}_3\, p + G - 2\Omega \times V_3 + D. \tag{2.1}$$

The continuity equation;

$$\frac{d\rho}{dt} + \rho\,\mathrm{div}_3\, V_3 = 0. \tag{2.2}$$

The first law of thermodynamics,

$$c_p\frac{dT}{dt}-\frac{RT}{p}(1+cq)\frac{dp}{dt}=\frac{dQ}{dt}. \tag{2.3}$$

The equation of state,

$$p=R\rho T(1+cq). \tag{2.4}$$

The conservation equation of water vapor in the air,

$$\frac{dq}{dt}=\frac{1}{\rho}W_1+W_2, \tag{2.5}$$

where the unknown functions are V_3, ρ, q, p, T. V_3 is the three-dimensional velocity, ρ density, p pressure, $q=\rho_1/\rho$ the mixing ratio of water vapor in the air, ρ_1 density of water vapor in the air, T temperature, G gravity, $-2\Omega\times V_3$ Coriolis force, Ω angular velocity of the earth, D the viscosity terms (which include the diabatic heating and the friction of the atmosphere), dQ/dt the heat flux per unit density in a unit time interval, W_1 the rate of condensation of water vapor per unit volume, W_2 the time rate of change of water vapor content per unit mass due to the vertical and horizontal diffusion of water vapor, R gas constants for dry air, c_p specific heat of air at constant pressure, c is a positive constant ($c\approx 0.618$), grad_3 and div_3 gradient and divergence in the three-dimensional atmosphere, respectively.

Remark 2.1: The equations (2.1)–(2.5) are different from the atmospheric equations in Ref. 7, where the authors only considered the equations (2.1), (2.2), (2.5) with (2.3) and (2.4) when $c=0$.

In the spherical coordinate system, let $\theta(0\le\theta\le\pi)$ denote the colatitude of the earth, $\varphi(0\le\varphi\le 2\pi)$ the longitude of the earth, r the radial distance, $z=r-a$ the height above sea level, a the radius of the earth,

$$V_3=v_\theta e_\theta+v_\varphi e_\varphi+v_r e_z,$$

where e_θ, e_φ and e_z are unit vectors in the θ, φ, z direction, and

$$e_\theta=\frac{1}{a}\frac{\partial}{\partial\theta},\quad e_\varphi=\frac{1}{a\sin\theta}\frac{\partial}{\partial\varphi},\quad e_z=\frac{\partial}{\partial z}.$$

Then the equations (2.1)–(2.5) can be written as the following fundamental equations of the moist atmosphere (see, for details, Ref. 17)

$$\frac{dv_\theta}{dt}+\frac{1}{r}(v_r v_\theta-v_\varphi^2\cot\theta)=-\frac{1}{\rho r}\frac{\partial p}{\partial\theta}+2\Omega\cos\theta v_\varphi+D_\theta, \tag{2.6}$$

$$\frac{dv_\varphi}{dt}+\frac{1}{r}(v_r v_\varphi+v_\theta v_\varphi\cot\theta)=-\frac{1}{\rho r\sin\theta}\frac{\partial p}{\partial\varphi}-2\Omega\cos\theta v_\theta-2\Omega\sin\theta v_r+D_\varphi, \tag{2.7}$$

$$\frac{dv_r}{dt}-\frac{1}{r}(v_\theta^2+v_\varphi^2)=-\frac{1}{\rho}\frac{\partial p}{\partial r}-g+2\Omega\sin\theta v_\varphi+D_r, \tag{2.8}$$

$$\frac{d\rho}{dt}+\rho\left(\frac{1}{r\sin\theta}\frac{\partial v_\theta\sin\theta}{\partial\theta}+\frac{1}{r\sin\theta}\frac{\partial v_\varphi}{\partial\varphi}+\frac{1}{r^2}\frac{\partial r^2 v_r}{\partial r}\right)=0, \tag{2.9}$$

$$c_p\frac{dT}{dt}-\frac{RT}{p}(1+cq)\frac{dp}{dt}=\frac{dQ}{dt}, \tag{2.10}$$

$$p = R\rho T(1 + cq), \tag{2.11}$$

$$\frac{dq}{dt} = \frac{1}{\rho} W_1 + W_2, \tag{2.12}$$

where

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \frac{v_\theta}{r}\frac{\partial}{\partial \theta} + \frac{v_\varphi}{r \sin\theta}\frac{\partial}{\partial \varphi} + v_r \frac{\partial}{\partial r},$$

and $D=(D_\theta, D_\varphi, D_r)$ are the viscosity terms.

Under the coordinate transformation $(t, \theta, \varphi, z) \to (t, \theta, \varphi, p)$ (p denotes pressure) and some technical treatment, Eq. (2.8) being replaced by the hydrostatic equation

$$\frac{\partial p}{\partial r} = -\rho g,$$

and the specific viscosity terms being introduced, Eqs. (2.6)–(2.12) can be written as the following nondimensional form (for details, we refer the readers to Refs. 4 and 7 and references therein),

$$\frac{\partial v}{\partial t} + \nabla_v v + \omega \frac{\partial v}{\partial \xi} + \frac{f}{R_0} k \times v + \operatorname{grad} \Phi - \frac{1}{\mathrm{Re}_1}\Delta v - \frac{1}{\mathrm{Re}_2}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\bar{T}}\right)^2 \frac{\partial v}{\partial \xi}\right] = f_1, \tag{2.13}$$

$$\operatorname{div} v + \frac{\partial \omega}{\partial \xi} = 0, \tag{2.14}$$

$$\frac{\partial \Phi}{\partial \xi} + \frac{bP}{p}(1 + cq)T = 0, \tag{2.15}$$

$$a_1\left(\frac{\partial T}{\partial t} + \nabla_v T + \omega \frac{\partial T}{\partial \xi}\right) - \frac{bP}{p}(1 + cq)\omega - \frac{1}{Rt_1}\Delta T - \frac{1}{Rt_2}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\bar{T}}\right)^2 \frac{\partial T}{\partial \xi}\right] = f_2, \tag{2.16}$$

$$\frac{\partial q}{\partial t} + \nabla_v q + \omega \frac{\partial q}{\partial \xi} - \frac{1}{Rt_3}\Delta q - \frac{1}{Rt_4}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\bar{T}}\right)^2 \frac{\partial q}{\partial \xi}\right] = f_3, \tag{2.17}$$

where the unknown functions are v, ω, Φ, q, T. $v=(v_\theta, v_\varphi)$ the horizontal velocity, $\Phi = gz$ the geopotential, $\omega = dp/dt$ vertical velocity in the $p-$ coordinate system, $f = 2\cos\theta$ Coriolis parameter, k vertical unit vector, P an approximate value of pressure at the surface of the earth, Re_1, Re_2, Rt_1, Rt_2, Rt_3, Rt_4 Reynolds numbers, $\bar{T}$ a given vertical distribution of the standard temperature on the interval $[p_0, P]$, $\overline{T_0}$ reference value of the temperature T, p_0 pressure of the upper atmosphere, and $p_0 > 0$, the variable ξ satisfying $p=(P-p_0)\xi + p_0$, f_1, f_2, f_3 given functions on $S^2 \times (0,1)$, a_1, b positive constants. The definitions of operators $\nabla_v v$, Δv, ΔT, Δq, $\nabla_v q$, $\nabla_v T$, $\operatorname{div} v$, $\operatorname{grad}\Phi$ will be given in the Sec. III A. Equations (2.13)–(2.17) are called the primitive equations of the large-scale moist atmosphere.

Remark 2.2: In the real physical situation, f_1, f_2, f_3 are taken as zero. However, from the mathematical point of view, we can consider the general case that f_1, f_2, f_3 are not always equal to zero.

The space domain of the equations is

$$M = S^2 \times (0,1),$$

where S^2 is two-dimensional unit sphere. The boundary value conditions are given by

$$\xi = 1(p = P):(v, \omega) = 0, \frac{\partial T}{\partial \xi} = \alpha_s(\overline{T_s} - T), \quad \frac{\partial q}{\partial \xi} = \beta_s(\overline{q_s} - q), \tag{2.18}$$

$$\xi = 0(p = p_0):(v, \omega) = 0, \quad \frac{\partial T}{\partial \xi} = 0, \frac{\partial q}{\partial \xi} = 0, \tag{2.19}$$

where α_s, β_s are constants, $\overline{T_s}$ the given temperature on the surface of the earth, $\overline{q_s}$ the given mixing ratio of water vapor on the surface of the earth.

Integrating (2.14) and using the boundary conditions (2.18), (2.19), we have

$$\omega(t; \theta, \varphi, \xi) = W(v)(t; \theta, \varphi, \xi) = \int_{\xi}^{1} \operatorname{div} v(t; \theta, \varphi, \xi') d\xi', \tag{2.20}$$

$$\int_0^1 \operatorname{div} v \, d\xi = 0. \tag{2.21}$$

Suppose that Φ_s is a certain unknown function at the isobaric surface $p=P$. Integrating (2.15), we obtain

$$\Phi(t; \theta, \varphi, \xi) = \Phi_s(t; \theta, \varphi, \xi) + \int_{\xi}^{1} \frac{bP}{p}(1 + cq)T \, d\xi'. \tag{2.21'}$$

Then Eqs. (2.13)–(2.17) can be written as

$$\frac{\partial v}{\partial t} + \nabla_v v + W(v)\frac{\partial v}{\partial \xi} + \frac{f}{R_0}k \times v + \operatorname{grad} \Phi_s + \int_{\xi}^{1} \frac{bP}{p} \operatorname{grad}(1 + cq)T \, d\xi' - \frac{1}{\mathrm{Re}_1}\Delta v - \frac{1}{\mathrm{Re}_2}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\overline{T}}\right)^2 \frac{\partial v}{\partial \xi}\right] = f_1, \tag{2.22}$$

$$a_1\left(\frac{\partial T}{\partial t} + \nabla_v T + W(v)\frac{\partial T}{\partial \xi}\right) - \frac{bP}{p}(1 + cq)W(v) - \frac{1}{\mathrm{Rt}_1}\Delta T - \frac{1}{\mathrm{Rt}_2}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\overline{T}}\right)^2 \frac{\partial T}{\partial \xi}\right] = f_2, \tag{2.23}$$

$$\frac{\partial q}{\partial t} + \nabla_v q + W(v)\frac{\partial q}{\partial \xi} - \frac{1}{\mathrm{Rt}_3}\Delta q - \frac{1}{\mathrm{Rt}_4}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\overline{T}}\right)^2 \frac{\partial q}{\partial \xi}\right] = f_3, \tag{2.24}$$

$$\int_0^1 \operatorname{div} v \, d\xi = 0, \tag{2.25}$$

where the definitions of grad T, grad Φ_s will be given in the Sec. III A. The boundary value conditions of Eqs. (2.22)–(2.25) are given by

$$\xi = 1(p = P):v = 0, \quad \frac{\partial T}{\partial \xi} = \alpha_s(\overline{T_s} - T), \quad \frac{\partial q}{\partial \xi} = \beta_s(\overline{q_s} - q), \tag{2.26}$$

$$\xi = 0(p = p_0):v = 0, \quad \frac{\partial T}{\partial \xi} = 0, \quad \frac{\partial q}{\partial \xi} = 0; \tag{2.27}$$

the initial value conditions can be given as

$$U_0 = (v_0, T_0, q_0). \tag{2.28}$$

We call (2.22)–(2.28) as the initial boundary problem of the new formulation of the primitive equations of large-scale moist atmosphere, denoted by (IBVP).

Remark 2.3: In this paper, we only study the primitive equations of large-scale moist atmosphere with viscosity terms given for horizontal velocity. In the future work, we can consider the equations with viscosity terms for the three-dimensional velocity.

III. EXISTENCE OF GLOBAL WEAK SOLUTIONS FOR THE PROBLEM (IBVP)

The section is divided into four subsections. In Sec. III A, some function spaces for the problem (IBVP) will be given. In Sec. III B, we shall give properties of some functionals corresponding to Eqs. (2.22)–(2.25). In Sec. III C, we shall introduce weak formulation for the problem (IBVP). The proof of the existence of global weak solutions to the problem (IBVP) will be given in Sec. III D.

A. Some function spaces

Let e_θ, e_φ, e_ξ be the unit vectors in θ, φ, and ξ directions of the space domain M, respectively,

$$e_\theta = \frac{\partial}{\partial \theta}, \quad e_\varphi = \frac{1}{\sin\theta}\frac{\partial}{\partial \varphi}, \quad e_\xi = \frac{\partial}{\partial \xi}.$$

The inner product and norm on $T_{(\theta,\varphi,\xi)}M$ [the tangent space of M at the point (θ,φ,ξ)] are given by

$$(X,Y)_T = X \cdot Y = X_1Y_1 + X_2Y_2 + X_3Y_3, |X|_T = (X,X)^{1/2}$$

for

$$X = X_1e_\theta + X_2e_\varphi + X_3e_\xi, \quad Y = Y_1e_\theta + Y_2e_\varphi + Y_3e_\xi \in T_{(\theta,\varphi,\xi)}M.$$

$L^2(M) := \{h; h: M \to \mathbb{R}, \int_M |h|^2\, dM < +\infty\}$ with the norm $|h|_2 = (\int_M |h|^2\, dM)^{1/2}$. $|\cdot|_p$ is the usual norm in $L^p(M)$. $L^2(TM|TS^2) = \{v; v: M \to TS^2\}$ is the first two components of L^2 vector fields on M with the norm $|v|_2 = (\int_M (|v_\theta|^2 + |v_\varphi|^2) dM)^{1/2}$, where TM, TS^2 are the tangent space of M and S^2, respectively, $v = (v_\theta, v_\varphi)$. $C^\infty(S^2)$ is the function space for all smooth functions from S^2 to $\mathbb{R}$. $C^\infty(M)$ is the function space for all smooth functions from M to $\mathbb{R}$. $C^\infty(\mathrm{TM}|\mathrm{TS}^2)$ is the first two components of smooth vector fields on M. $C_0^\infty(M) := \{u; u \in C^\infty(M), \mathrm{supp}\, u$ is a compact subset in $M\}$. $C_0^\infty(\mathrm{TM}|\mathrm{TS}^2) := \{u; u \in C^\infty(\mathrm{TM}|\mathrm{TS}^2), \mathrm{supp}\, u$ is a compact subset in $M\}$. $H^m(M)$ is the Sobolev space of functions that are in L^2,together with all their covariant derivatives with respect to e_θ, e_φ, e_ξ of order $\leq m$, with the norm

$$\|h\|_m = \left(\int_M \left(\sum_{1 \leq k \leq m} \sum_{i_j = 1,2,3; j = 1,\ldots,k} |\nabla_{i_1} \cdots \nabla_{i_k} h| + |h|^2 \right) dM \right)^{1/2},$$

where $\nabla_1 = \nabla_{e_\theta}$, $\nabla_2 = \nabla_{e_\varphi}$, $\nabla_3 = \nabla_{e_\xi} = \partial/\partial\xi$ (the definitions of $\nabla_{e_\theta}, \nabla_{e_\varphi}$ will be given later). $H^m(\mathrm{TM}|\mathrm{TS}^2) = \{v; v = (v_\theta, v_\varphi): M \to TS^2, v_\theta, v_\varphi \in H^m(M)\}$, the norm of which is similar to that of $H^m(M)$, that is, in the above formula of norm, we can let $h = (v_\theta, v_\varphi) = v_\theta e_\theta + v_\varphi e_\varphi$.

The horizontal divergence div, the horizontal gradient $\nabla = \mathrm{grad}$, the horizontal covariant derivative ∇_v and horizontal Laplace-Beltrami operator Δ for scalar and vector functions are defined by

$$\mathrm{div}\, v = \mathrm{div}(v_\theta e_\theta + v_\varphi e_\varphi) = \frac{1}{\sin\theta}\left(\frac{\partial v_\theta \sin\theta}{\partial\theta} + \frac{\partial v_\varphi}{\partial\varphi} \right), \tag{3.1}$$

$$\nabla T = \operatorname{grad} T = \frac{\partial T}{\partial \theta} e_\theta + \frac{1}{\sin\theta}\frac{\partial T}{\partial \varphi} e_\varphi, \tag{3.2}$$

$$\operatorname{grad} \Phi_s = \frac{\partial \Phi_s}{\partial \theta} e_\theta + \frac{1}{\sin\theta}\frac{\partial \Phi_s}{\partial \varphi} e_\varphi, \tag{3.3}$$

$$\nabla_v \tilde{v} = \left(v_\theta \frac{\partial \tilde{v}_\theta}{\partial \theta} + \frac{v_\varphi}{\sin\theta}\frac{\partial \tilde{v}_\theta}{\partial \varphi} - v_\varphi \tilde{v}_\varphi \cot\theta \right) e_\theta + \left(v_\theta \frac{\partial \tilde{v}_\varphi}{\partial \theta} + \frac{v_\varphi}{\sin\theta}\frac{\partial \tilde{v}_\varphi}{\partial \varphi} + v_\varphi \tilde{v}_\theta \cot\theta \right) e_\varphi, \tag{3.4}$$

$$\nabla_v T = v_\theta \frac{\partial T}{\partial \theta} + \frac{v_\varphi}{\sin\theta}\frac{\partial T}{\partial \varphi}, \tag{3.5}$$

$$\nabla_v q = v_\theta \frac{\partial q}{\partial \theta} + \frac{v_\varphi}{\sin\theta}\frac{\partial q}{\partial \varphi}, \tag{3.6}$$

$$\Delta T = \frac{1}{\sin\theta}\left[\frac{\partial}{\partial \theta}\left(\sin\theta \frac{\partial T}{\partial \theta} \right) + \frac{1}{\sin\theta}\frac{\partial^2 T}{\partial \varphi^2} \right], \tag{3.7}$$

$$\Delta q = \frac{1}{\sin\theta}\left[\frac{\partial}{\partial \theta}\left(\sin\theta \frac{\partial q}{\partial \theta} \right) + \frac{1}{\sin\theta}\frac{\partial^2 q}{\partial \varphi^2} \right], \tag{3.8}$$

$$\Delta v = \left(\Delta v_\theta - \frac{2\cos\theta}{\sin^2\theta}\frac{\partial v_\varphi}{\partial \varphi} - \frac{v_\theta}{\sin^2\theta} \right) e_\theta + \left(\Delta v_\varphi + \frac{2\cos\theta}{\sin^2\theta}\frac{\partial v_\theta}{\partial \varphi} - \frac{v_\varphi}{\sin^2\theta} \right) e_\varphi, \tag{3.9}$$

where $v = v_\theta e_\theta + v_\varphi e_\varphi$, $\tilde{v} = \tilde{v}_\theta e_\theta + \tilde{v}_\varphi e_\varphi \in C^\infty(\mathrm{TM}|\mathrm{TS}^2)$, T, $q \in C^\infty(M)$, $\Phi_s \in C^\infty(S^2)$.

Now we can define our working spaces for the problem (IBVP). Let

$$\tilde{V} := \left\{ v; v \in C_0^\infty(\mathrm{TM}|\mathrm{TS}^2),\ \int_0^1 \operatorname{div} v \, d\xi = 0 \right\},$$

V_1 = the closure of $\tilde{V}$ with respect to the norm $\|\cdot\|_1$,

$$V_2 = H^1(M),$$

H_1 = the closure of $\tilde{V}$ with respect to the norm $|\cdot|_2$,

$$H_2 = L^2(M),$$

$$V = V_1 \times V_2 \times V_2,$$

$$H = H_1 \times H_2 \times H_2,$$

$V_1^{(3)}$ = the closure of $\tilde{V}$ with respect to the norm $\|\cdot\|_3$,

$$V_2^{(3)} = H^3(M),$$

$$V^{(3)} = V_1^{(3)} \times V_2^{(3)} \times V_2^{(3)},$$

$$V^{(-3)} = (V^{(3)})',$$

where $(V^{(3)})'$ is the dual space of $V^{(3)}$. In order to study the nonlinear terms of the equations (2.22)–(2.24), we have to introduce the spaces $V^{(3)}$ and $V^{(-3)}$. The inner product and norm on V, V_1, V_2 are given by

$$(v,v_1)_{V_1} = \int_M \left(\nabla_{e_\theta} v \cdot \nabla_{e_\theta} v_1 + \nabla_{e_\varphi} v \cdot \nabla_{e_\varphi} v_1 + \frac{\partial v}{\partial \xi} \frac{\partial v_1}{\partial \xi} + v \cdot v_1 \right) dM,$$

$$\|v\|_{V_1} = (v,v)_{V_1}^{1/2}, \quad \forall\, v,v_1 \in V_1,$$

$$(T,T_1)_{V_2} = \int_M \left(\operatorname{grad} T \cdot \operatorname{grad} T_1 + \frac{\partial T}{\partial \xi} \frac{\partial T_1}{\partial \xi} + T T_1 \right) dM,$$

$$\|T\|_{V_2} = (T,T)_{V_2}^{1/2}, \quad \forall\, T,\ T_1 \in V_2,$$

$$(q,q_1)_{V_2} = \int_M \left(\operatorname{grad} q \cdot \operatorname{grad} q_1 + \frac{\partial q}{\partial \xi} \frac{\partial q_1}{\partial \xi} + q q_1 \right) dM,$$

$$\|q\|_{V_2} = (q,q)_{V_2}^{1/2}, \quad \forall\, q,\ q_1 \in V_2,$$

$$(U,U_1)_H = (v,v_1) + (a_1 T, T_1) + (q,q_1),$$

$$(U,U_1)_V = (v,v_1)_{V_1} + (T,T_1)_{V_2} + (q,q_1)_{V_2},$$

$$\|U\| = (U,U)_V^{1/2}, \quad |U|_2 = (U,U)_H^{1/2}, \quad \forall\, U = (v,T,q), \quad U_1 = (v_1,T_1,q_1) \in V,$$

$$\|U\|_{(3)} = (\|v\|_3^3 + \|T\|_3^3 + \|q\|_3^3)^{1/3}, \quad \forall\, U \in V^{(3)},$$

$$(T,T_1)_{H_2} = (a_1 T, T_1), \quad |T|_2 = (T,T)_{H_2}^{1/2}, \quad |v|_2 = (v,v)^{1/2},$$

where $(\cdot,\cdot)$ denotes the L^2 inner products in H_1, H_2. By the definitions of V, H, we can obtain

$$V \subset H = H' \subset V' \subset V^{(-3)},$$

where V' is the dual space of V.

B. Properties of some functionals and their associated operators

In this section, we shall define some functionals and their corresponding operators that are related to the equations (2.22)–(2.25) and give some estimates about those functionals.

Now, we define the functionals $\tilde{a}: V \times V \to \mathbb{R}$, $\tilde{a}_1: V_1 \times V_1 \to \mathbb{R}$, $\tilde{a}_2: V_2 \times V_2 \to \mathbb{R}$, $\tilde{a}_3: V_2 \times V_2 \to \mathbb{R}$, and their corresponding linear operators $A: V \to V'$, $A_1: V_1 \to V_1'$, $A_2: V_2 \to V_2'$, $A_3: V_2 \to V_2'$ by

$$\tilde{a}(U,U_1) = (AU,U_1) = \tilde{a}_1(v,v_1) + \tilde{a}_2(T,T_1) + \tilde{a}_3(q,q_1),$$

where

$$\tilde{a}_1(v,v_1)=(A_1v,v_1)=\int_M\left[\frac{1}{\mathrm{Re}_1}(\nabla_{e_\theta}v\cdot\nabla_{e_\theta}v_1+\nabla_{e_\varphi}v\cdot\nabla_{e_\varphi}v_1+v\cdot v_1)+\frac{1}{\mathrm{Re}_2}\left(\frac{p\overline{T_0}}{P\bar{T}}\right)^2\frac{\partial v}{\partial\xi}\frac{\partial v_1}{\partial\xi}\right]dM,$$

$$\tilde{a}_2(T,T_1)=(A_2T,T_1)=\int_M\left[\frac{1}{\mathrm{Rt}_1}\,\mathrm{grad}\,T\cdot\mathrm{grad}\,T_1+\frac{1}{\mathrm{Rt}_2}\left(\frac{p\overline{T_0}}{P\bar{T}}\right)^2\frac{\partial T}{\partial\xi}\frac{\partial T_1}{\partial\xi}\right]dM+\int_{\Gamma_1}\frac{\alpha_s}{\mathrm{Rt}_2}\left(\frac{p\overline{T_0}}{P\bar{T}}\right)^2TT_1\,dS^2,$$

$$\tilde{a}_3(q,q_1)=(A_3q,q_1)=\int_M\left[\frac{1}{\mathrm{Rt}_3}\,\mathrm{grad}\,q\cdot\mathrm{grad}\,q_1+\frac{1}{\mathrm{Rt}_4}\left(\frac{p\overline{q_0}}{P\bar{q}}\right)^2\frac{\partial q}{\partial\xi}\frac{\partial q_1}{\partial\xi}\right]dM+\int_{\Gamma_1}\frac{\beta_s}{Rt_4}\left(\frac{p\overline{q_0}}{P\bar{q}}\right)^2qq_1\,dS^2,$$

$$\Gamma_1=S^2\times 1.$$

Lemma 3.1:

(1) a is coercive and continuous. $A:V\to V'$ is an isomorphism. Moreover,

$$a(U,U_1)\le c_1\max\left\{\frac{1}{\mathrm{Re}_1},\frac{1}{\mathrm{Re}_2}\right\}\|v\|_{V_1}\|v_1\|_{V_1}+c_2\max\left\{\frac{1}{\mathrm{Rt}_1},\frac{1}{\mathrm{Rt}_2},\frac{\alpha_s}{\mathrm{Rt}_2}\right\}\|T\|_{V_2}\|T_1\|_{V_2}+c_3\max\left\{\frac{1}{\mathrm{Rt}_3},\frac{1}{\mathrm{Rt}_4},\frac{\beta_s}{\mathrm{Rt}_4}\right\}\|q\|_{V_2}\|q_1\|_{V_2}\le\frac{1}{R_{\min}}\|U\|\|U_1\|,\tag{3.10}$$

$$a(U,U)\ge c_4\min\left\{\frac{1}{\mathrm{Re}_1},\frac{1}{\mathrm{Re}_2}\right\}\|v\|_{V_1}^2+c_5\min\left\{\frac{1}{\mathrm{Rt}_1},\frac{1}{\mathrm{Rt}_2},\frac{\alpha_s}{\mathrm{Rt}_2}\right\}\|T\|_{V_2}^2+c_6\min\left\{\frac{1}{\mathrm{Rt}_3},\frac{1}{\mathrm{Rt}_4},\frac{\beta_s}{\mathrm{Rt}_4}\right\}\|q\|_{V_2}^2\ge\frac{1}{R_{\max}}\|U\|^2,\tag{3.11}$$

where

$$R_{\min}=\frac{1}{\min\{c_1,c_2,c_3\}}\min\left\{\mathrm{Re}_1,\mathrm{Re}_2,\mathrm{Rt}_1,\mathrm{Rt}_2,\mathrm{Rt}_3,\mathrm{Rt}_4,\frac{\mathrm{Rt}_2}{\alpha_s},\frac{\mathrm{Rt}_4}{\beta_s}\right\},$$

$$R_{\max}=\frac{1}{\max\{c_4,c_5,c_6\}}\min\left\{\mathrm{Re}_1,\mathrm{Re}_2,\mathrm{Rt}_1,\mathrm{Rt}_2,\mathrm{Rt}_3,\mathrm{Rt}_4,\frac{\mathrm{Rt}_2}{\alpha_s},\frac{\mathrm{Rt}_4}{\beta_s}\right\}.$$

In this paper, c_i will denote positive constants and can be determined in concrete conditions.

(2) The isomorphism $A:V\to V'$ can be extended to a self-adjoint unbounded linear operator on H with a compact inverse $A^{-1}:H\to H$ and with the domain of definition of the operator $D(A)=V\cap(H^2(TM\,|\,TS^2)\times H^2(M)\times H^2(M))$.

Proof: The operator A is similar to the usual positive symmetric operator $-\Delta$ on H_0^1. Therefore we omit the details of the proof. For details, the readers can refer to [Ref. 4 Lemma 2.3].

Concerning the nonlinear terms of the equations (2.22)–(2.24), we can define the functional $\tilde{b}:V\times V\times V\to\mathbb{R}$ and its corresponding operator $B:H\times H\to H$ by

$$\tilde{b}(U,U_1,U_2)=(B(U,U_1),U_2)_H=b_1(v,v_1,v_2)+b_2(v,T_1,T_2)+b_3(v,q_1,q_2),$$

where

$$b_1(v,v_1,v_2)=\int_M\left[\nabla_v v_1+\left(\int_\xi^1 \operatorname{div} v\, d\xi'\right)\frac{\partial v_1}{\partial \xi}\right]\cdot v_2\, dM,$$

$$b_2(v,T_1,T_2)=\int_M\left[\nabla_v T_1+\left(\int_\xi^1 \operatorname{div} v\, d\xi'\right)\frac{\partial T_1}{\partial \xi}\right]T_2\, dM,$$

$$b_3(v,q_1,q_2)=\int_M\left[\nabla_v q_1+\left(\int_\xi^1 \operatorname{div} v\, d\xi'\right)\frac{\partial q_1}{\partial \xi}\right]q_2\, dM.$$

Let

$$b_4(U,U,U_2)=\int_M\left[\left(\int_\xi^1 \frac{bP}{p}\operatorname{grad}(Tcq)d\xi'\right)\cdot v_2-\frac{bP}{p}cqW(v)T_2\right]dM$$

and

$$b(U,U_1,U_2)=\tilde{b}(U,U_1,U_2)+b_4(U,U,U_2).$$

Lemma 3.2:
(1) For any $U,\ U_1\in D(A)$,

$$b_1(v,v_1,v_1)=b_2(v,T_1,T_1)=b_3(v,q_1,q_1)=0,\quad b_4(U,U,U)=0.$$

(2) For any $U\in D(A),\ U_2\in D(A)\cap V^{(3)}$,

$$|b(U,U,U_2)|\le c_7\|U\||U|_2\|U_2\|_{(3)}. \tag{3.12}$$

Proof: (1) By (3.4), for any $U=(v,T,q),\ U_1=(v_1,T_1,q_1)\in D(A)$, we can obtain

$$\nabla_v|v_1|^2=\nabla_v v_1\cdot v_1+v_1\cdot\nabla_v v_1=2\nabla_v v_1\cdot v_1.$$

Then

$$\begin{aligned}
b_1(v,v_1,v_1)&=\int_M\left[\nabla_v v_1\cdot v_1+\frac{1}{2}\left(\int_\xi^1 \operatorname{div} v d\xi'\right)\frac{\partial|v_1|^2}{\partial\xi}\right]dM\\
&=\int_M\left[\frac{1}{2}\nabla_v|v_1|^2+\frac{1}{2}\left(\int_\xi^1 \operatorname{div} v d\xi'\right)\frac{\partial|v_1|^2}{\partial\xi}\right]dM\\
&=\frac{1}{2}\int_M\left[\operatorname{div}(v|v_1|^2)-|v_1|^2\operatorname{div} v+\left(\int_\xi^1 \operatorname{div} v\, d\xi'\right)\frac{\partial|v_1|^2}{\partial\xi}\right]dM\\
&=\frac{1}{2}\int_M\left[-|v_1|^2\operatorname{div} v+\left(\int_\xi^1 \operatorname{div} v\, d\xi'\right)\frac{\partial|v_1|^2}{\partial\xi}\right]dM\\
&=-\frac{1}{2}\int_M\left[|v_1|^2\left(\operatorname{div} v+\frac{\partial W(v)}{\partial\xi}\right)\right]dM+\int_M|v_1|^2\left(\int_\xi^1 \operatorname{div} v d\xi'\right)\Bigg|_{\xi=0,1}dM=0.
\end{aligned}$$

Similarly, we prove $b_2(v,T_1,T_1)=b_3(v,q_1,q_1)=0$,

$$b_4(U,U,U)=\int_M\left[\left(\int_\xi^1\frac{bP}{p}\,\mathrm{grad}(Tcq)d\xi'\right)\cdot v-\frac{bP}{p}cqW(v)T\right]dM,$$

$$=\int_M\left[\left(-\int_\xi^1\frac{bP}{p}(Tcq)d\xi'\right)\cdot \mathrm{div}\,v-\frac{bP}{p}cqW(v)T\right]dM,$$

$$=\int_M\left[\left(-\int_\xi^1\frac{bP}{p}(Tcq)d\xi'\right)\cdot\frac{\partial\left(\int_\xi^1\mathrm{div}\,vd\xi'\right)}{\partial\xi}-\frac{bP}{p}cqW(v)T\right]dM,$$

$$=\int_M\left(\frac{bP}{p}TcqW(v)-\frac{bP}{p}cqW(v)T\right)dM=0.$$

(2) For any $U=(v,T,q),U_1=(v_1,T_1,q_1)\in D(A),\ U_2=(v_2,T_2,q_2)\in D(A)\cap V^{(3)}$,

$$\left|\int_M\left[\left(\int_\xi^1\mathrm{div}\,vd\xi'\right)\frac{\partial v_1}{\partial\xi}\right]\cdot v_2\,dM\right|\le\int_M\left|v_1\cdot\left(\frac{\partial v_2}{\partial\xi}\int_\xi^1\mathrm{div}\,vd\xi'+v_2\,\mathrm{div}\,v\right)\right|dM$$

$$\le\|v\|_{V_1}|v_1|_2\left|\frac{\partial v_2}{\partial\xi}\right|_{L^\infty}\le\|U\||U_1|_2\left|\frac{\partial U_2}{\partial\xi}\right|_{L^\infty}$$

$$\le C\|U\||U_1|_2\|U_2\|_{(3)},$$

where C is a positive constant. Similarly, we derive

$$|b(U,U,U_2)|\le c_7\|U\||U|_2\|U_2\|_{(3)}.$$

Related to the linear terms, we can define a bilinear functional $e:V\times V\to\mathbb{R}$ and its corresponding operator $\tilde{E}:H\to H$ by

$$e(U,U_1)=(\tilde{E}U,U_1)_H$$

$$=\int_M\left[\frac{f}{R_0}(k\times v)\cdot v_1+\left(\int_\xi^1\frac{bP}{p}\,\mathrm{grad}\,T\,d\xi'\right)\cdot v_1-\frac{bP}{p}W(v)T_1\right]dM.$$

Lemma 3.3:
(1) For any $U,\ U_1\in V$,

$$|e(U,U_1)|\le C\|U\|\|U_1\|,\tag{3.13}$$

where C is a positive constant.
(2) For any $U,\ U\in V$,

$$|e(U,U)|=0.$$

Proof: The first part of the Lemma is obvious, so we omit the details of the proof. The proof of the second part is similar to the proof of $b_4(U,U,U)=0$.

C. Weak formulation for the problem (IBVP)

In this section, we will introduce a weak formulation for the problem (IBVP) by eliminating the geopotential Φ_s in the equation (2.22). The method is similar to eliminating the pressure in obtaining the existence of global weak solutions for the Navier-Stokes system.

First, we shall homogenize the boundary value condition (2.26) for T, q. By

$$\frac{\partial T'}{\partial \xi} = \alpha_s(\overline{T_s} - T'), \quad \frac{\partial q'}{\partial \xi} = \beta_s(\overline{q_s} - q'),$$

we obtain

$$T' = \overline{T_s}(1 - \exp(-\alpha_s \xi)), \quad q' = \overline{q_s}(1 - \exp(-\beta_s \xi)).$$

Let

$$T'_\varepsilon = T' \psi_\varepsilon(\xi), \quad q'_\varepsilon = q' \psi_\varepsilon(\xi),$$

where $0 < \varepsilon < \frac{1}{2}$,

$$\psi_\varepsilon(\xi) := \begin{cases} 1, & 1-\varepsilon \le \xi \le 1, \\ \text{increasing}, & 1-2\varepsilon \le \xi \le 1-\varepsilon, \\ 0, & 0 \le \xi \le 1-2\varepsilon. \end{cases}$$

Then, by letting $\widetilde{U} = (v, \widetilde{T}, \widetilde{q}) = U - U'_\varepsilon = (v, T, q) - (0, T'_\varepsilon, q'_\varepsilon)$, the problem (IBVP) can be rewritten as the following equations:

$$\begin{aligned} &\frac{\partial v}{\partial t} + \nabla_v v + W(v)\frac{\partial v}{\partial \xi} + \frac{f}{R_0} k \times v + \operatorname{grad} \Phi_s + \int_\xi^1 \frac{bP}{p} \operatorname{grad}(1 + c\widetilde{q})\widetilde{T}\, d\xi' + \int_\xi^1 \frac{bP}{p} \operatorname{grad}(cq'_\varepsilon \widetilde{T} \\ &\quad + cT'_\varepsilon \widetilde{q}) d\xi' - \frac{1}{\mathrm{Re}_1}\Delta v - \frac{1}{\mathrm{Re}_2}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\overline{T}}\right)^2 \frac{\partial v}{\partial \xi}\right] = \widetilde{f_1} = f_1 - \int_\xi^1 \frac{bP}{p} \operatorname{grad}(1 + cq'_\varepsilon) T'_\varepsilon \, d\xi', \end{aligned} \tag{3.14}$$

$$\begin{aligned} &a_1\left(\frac{\partial \widetilde{T}}{\partial t} + \nabla_v \widetilde{T} + W(v)\frac{\partial \widetilde{T}}{\partial \xi}\right) + a_1\left(\nabla_v T'_\varepsilon + W(v)\frac{\partial T'_\varepsilon}{\partial \xi}\right) - \frac{bP}{p}(1 + c\widetilde{q})W(v) - \frac{bP}{p}(cq'_\varepsilon)W(v) - \frac{1}{Rt_1}\Delta \widetilde{T} \\ &\quad - \frac{1}{Rt_2}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\overline{T}}\right)^2 \frac{\partial \widetilde{T}}{\partial \xi}\right] = \widetilde{f_2} = f_2 + \frac{1}{\mathrm{Rt}_1}\Delta T'_\varepsilon + \frac{1}{\mathrm{Rt}_2}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\overline{T}}\right)^2 \frac{\partial T'_\varepsilon}{\partial \xi}\right], \end{aligned} \tag{3.15}$$

$$\begin{aligned} &\frac{\partial \widetilde{q}}{\partial t} + \nabla_v \widetilde{q} + W(v)\frac{\partial \widetilde{q}}{\partial \xi} + \nabla_v q'_\varepsilon + W(v)\frac{\partial q'_\varepsilon}{\partial \xi} - \frac{1}{\mathrm{Rt}_3}\Delta \widetilde{q} - \frac{1}{\mathrm{Rt}_4}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\overline{T}}\right)^2 \frac{\partial \widetilde{q}}{\partial \xi}\right] \\ &\quad = \widetilde{f_3} = f_3 + \frac{1}{\mathrm{Rt}_3}\Delta q'_\varepsilon + \frac{1}{\mathrm{Rt}_4}\frac{\partial}{\partial \xi}\left[\left(\frac{p\overline{T_0}}{P\overline{T}}\right)^2 \frac{\partial q'_\varepsilon}{\partial \xi}\right], \end{aligned} \tag{3.16}$$

$$\int_0^1 \operatorname{div} v \, d\xi = 0, \tag{3.17}$$

with the initial and boundary value conditions

$$\xi = 1 (p = P): v = 0, \quad \frac{\partial \widetilde{T}}{\partial \xi} + \alpha_s \widetilde{T} = 0, \quad \frac{\partial \widetilde{q}}{\partial \xi} + \beta_s \widetilde{q} = 0, \tag{3.18}$$

$$\xi = 0 (p = p_0): v = 0, \quad \frac{\partial \widetilde{T}}{\partial \xi} = 0, \quad \frac{\partial \widetilde{q}}{\partial \xi} = 0. \tag{3.19}$$

$$\tilde{U}_0 = (v_0, \widetilde{T_0}, \widetilde{q_0}). \tag{3.20}$$

Now we can introduce the weak formulation for the problem (IBVP).

Problem 3.1: For $\tilde{f}=(\widetilde{f_1}, \widetilde{f_2}, \widetilde{f_3})$, $\tilde{U}_0=(v_0, \widetilde{T_0}, \widetilde{q_0}) \in H$ given, find $\tilde{U}=(v, \tilde{T}, \tilde{q})$ such that

$$\tilde{U} \in L^2(0,\mathcal{T};V) \cap L^\infty(0,\mathcal{T};H), \quad \forall\, \mathcal{T}>0, \tag{3.21}$$

$$\frac{d}{dt}(\tilde{U}, U_1)_H + (A\tilde{U}, U_1)_H + ((B\tilde{U}, \tilde{U}), U_1)_H + ((B\tilde{U}, U_\varepsilon'), U_1)_H + ((F\tilde{U}, U_\varepsilon'), U_1)_H + (\tilde{E}\tilde{U}, U_1)_H$$
$$= (\tilde{f}, U_1)_H, \quad \text{in } (C_0^\infty(0,\mathcal{T}))', \quad \forall\, U_1 \in D(A) \tag{3.22}$$

$$\tilde{U}|_{t=0} = \tilde{U}_0, \quad \text{in } V^{(-3)}, \tag{3.23}$$

where

$$((F\tilde{U}, U_\varepsilon'), U_1)_H = \int_M \left[\left(\int_\xi^1 \frac{bP}{p} \operatorname{grad}(cq_\varepsilon' \tilde{T} + cT_\varepsilon' \tilde{q}) d\xi' \right) \cdot v_1 - \frac{bP}{p}(cq_\varepsilon') W(v) T_1 \right] dM.$$

D. Proof of the existence of global weak solutions

In this section, we shall prove the existence of global weak solutions for the problem (IBVP) by proving the existence of global weak solutions for Problem 3.1. In order to do this, we need some lemmas.

Lemma 3.4: (cf. Ref. 4 Lemma 2.1):

(1) If $v \in H_1$, $\int_M v v_1\, dM = 0$, $\forall v_1 \in C_0^\infty(\mathrm{TM}|\mathrm{TS}^2)$, then

$$v = \operatorname{grad} \Phi_s, \quad \Phi_s \in (C_0^\infty(S^2))'.$$

(2) Let $H_1^\perp$ be the orthogonal complement of H_1 in $L^2(\mathrm{TM}|\mathrm{TS}^2)$. Then

$$H_1^\perp = \{v; v \in L^2(\mathrm{TM}|\mathrm{TS}^2), \quad v = \operatorname{grad} l,\ l \in H^1(S^2)\}, \tag{3.24}$$

$$H_1 = \left\{ v; v \in L^2(\mathrm{TM}|\mathrm{TS}^2), \quad \int_0^1 \operatorname{div} v\, d\xi = 0 \right\}, \tag{3.25}$$

$$V_1 = \left\{ v; v \in H_0^1(\mathrm{TM}|\mathrm{TS}^2), \quad \int_0^1 \operatorname{div} v\, d\xi = 0 \right\}. \tag{3.26}$$

By this lemma, we know that if there is a solution $\tilde{U}=(v, \tilde{T}, \tilde{q})$ for Problem 3.1, then there is a unique $\Phi_s \in (C_0^\infty(S^2))'$ (up to a constant) such that (v, T, q, Φ_s) is a solution for the problem (IBVP). On other hand, if (v, T, q, Φ_s) is a solution for the problem (IBVP) [(v, T, q, Φ_s) is sufficiently smooth], then $\tilde{U}=(v, \tilde{T}, \tilde{q})$ is a solution to Problem 3.1.

In order to solve Problem 3.1 by the Faedo-Galerkin method, we need the following three lemmas.

Lemma 3.5: The eigenvalue problem,

$$AU = \mu U, \quad U \in V,$$

exists a sequence of eigenvalues, $0 < \mu_1 < \mu_2 \le \mu_3 \le \cdots \le \mu_n \le \cdots$, of finite multiplicity and going to infinity, with the first eigenvalue being simple, having a positive eigenfunction. Moreover, the eigenfunction sequence $\{\phi_n\}$ is an orthonormal basis of V.

Proof: This lemma is a corollary of Lemma 3.1.

Lemma 3.6: For any $\delta>0$, there is $0<\varepsilon<1/2$ such that

$$|((F\widetilde{U},U_\varepsilon'),\widetilde{U})_H|\le\delta\|\widetilde{U}\|^2, \tag{3.27}$$

$$|((B\widetilde{U},U_\varepsilon'),\widetilde{U})_H|\le\delta\|\widetilde{U}\|^2,\quad \forall\ \widetilde{U}\in V. \tag{3.28}$$

Proof: By the definition, for any $U_1\in V$,

$$\begin{aligned}
|((F\widetilde{U},U_\varepsilon'),U_1)_H| &= \left|\int_M\left[\left(\int_\xi^1\frac{bP}{p}\,\mathrm{grad}(cq_\varepsilon'\widetilde{T}+cT_\varepsilon'\widetilde{q})d\xi'\right)\cdot v_1-\frac{bP}{p}(cq_\varepsilon')W(v)T_1\right]dM\right| \\
&\le \left|\int_M\left(\int_\xi^1\frac{bP}{p}cq_\varepsilon'\,\mathrm{grad}\,\widetilde{T}\,d\xi'\right)\cdot v_1\,dM\right| \\
&\quad+\left|\int_M\left(\int_\xi^1\frac{bP}{p}c\widetilde{T}\,\mathrm{grad}\,q_\varepsilon'\,d\xi'\right)\cdot v_1\,dM\right| \\
&\quad+\left|\int_M\left(\int_\xi^1\frac{bP}{p}cT_\varepsilon'\,\mathrm{grad}\,\widetilde{q}\,d\xi'\right)\cdot v_1\,dM\right| \\
&\quad+\left|\int_M\left(\int_\xi^1\frac{bP}{p}c\widetilde{q}\,\mathrm{grad}\,T_\varepsilon'\,d\xi'\right)\cdot v_1 dM\right| \\
&\quad+\left|\int_M\frac{bP}{p}cq_\varepsilon'\left(\int_\xi^1\mathrm{div}\,v\,d\xi'\right)T_1\,dM\right|\le I_1+I_2+I_3+I_4+I_5.
\end{aligned}$$

By the definition of q_ε',

$$\begin{aligned}
I_1 &= \left|\int_M\left(\int_\xi^1\frac{bP}{p}cq_\varepsilon'\,\mathrm{grad}\,\widetilde{T}\,d\xi'\right)\cdot v_1\,dM\right|\le\left|\int_{S^2\times[1-2\varepsilon]}\left(\int_{1-2\varepsilon}^1\frac{bP}{p}cq_\varepsilon'\,\mathrm{grad}\,\widetilde{T}\,d\xi'\right)\cdot v_1\,dM\right| \\
&\le c_8|q_\varepsilon'|_{L^\infty(S^2)}\left|\int_{S^2\times[1-2\varepsilon]}\left(\int_{1-2\varepsilon}^1\mathrm{grad}\,\widetilde{T}\,d\xi'\right)\cdot v_1\,dM\right|\le 4c_8\varepsilon^2|q_\varepsilon'|_{L^\infty(S^2)} \\
&\quad\times\left|\int_{S^2}\left(\int_{1-2\varepsilon}^1|\mathrm{grad}\,\widetilde{T}|^2\,d\xi'\right)^{1/2}\left(\int_{1-2\varepsilon}^1|v_1|^2\,d\xi'\right)^{1/2}dS^2\right|\le 4c_8\varepsilon^2|q_\varepsilon'|_{L^\infty(S^2)}\|\|T\|_{V_2}\|v_1\|_{V_1} \\
&\le c_9\varepsilon\|U\|\|U_1\|.
\end{aligned}$$

Similarly, we can prove

$$I_i\le c_{8+i}\varepsilon\|U\|\|U_1\|,\quad i=2,3,4,5.$$

So

$$|((F\widetilde{U},U_\varepsilon'),\widetilde{U})_H|\le\delta\|\widetilde{U}\|^2.$$

Since the proof of (3.28) is similar to the proof of $I_1\le c_9\varepsilon\|U\|\|U_1\|$, we omit the details of the proof.

Lemma 3.7 (Lions-Magenes) (Ref. 19): Suppose that $g\in L^\infty(0,\mathcal{T};E)$ and the function $g(t)$ is weakly continuous in E_0: $g\in C_\omega(0,\mathcal{T};E_0)$, that is, for any function $\phi\in(E_0)'$ the function $\langle g(t),\phi\rangle$ belongs to $C[0,\mathcal{T}]$, where E, $E_0(E\subset E_0)$ are Banach spaces. Then $g(t)\in E$ for all $0\le t\le\mathcal{T}$ and $g(t)$ is weakly continuous in E.

Now we can state one of our main results.

Theorem 3.8: Under the assumptions of Problem 3.1 and for any $\mathcal{T}>0$, there is at least one solution $\tilde{U}=(v,\tilde{T},\tilde{q})$ on the time interval $[0,\mathcal{T}]$ to Problem 3.1, and $\tilde{U}=(v,\tilde{T},\tilde{q})$ satisfies

$$\widetilde{U_t} \in L^2(0,\mathcal{T};V^{(-3)}), \tag{3.29}$$

$$\tilde{U} \in C_\omega(0,\mathcal{T};H). \tag{3.30}$$

Moreover, $\tilde{U}$ satisfies the energy inequality

$$-\int_0^\infty |\tilde{U}(t)|_2^2\psi'(s)ds + \frac{1}{R_{\max}}\int_0^\infty \|\tilde{U}(s)\|^2\psi(s)ds \le 2\int_0^\infty (\tilde{f},\tilde{U}(s))_H\psi(s)ds, \tag{3.31}$$

where $\psi(s)\in C_0^\infty(]0,\mathcal{T}[), \psi(s)\ge 0$.

Proof: We shall prove Theorem 3.8 by the Faedo-Galerkin method. Since the procedure is similar to the proof of the existence of Leray-Hopf weak solutions to the Navier-Stokes system in Ref. 5, Theorem 6.1, we only give the outline of the proof. First, we can look for an approximate solution $\tilde{U}_m(x,t)$ for Problem 3.1, where $\tilde{U}_m(x,t)=\Sigma_{i=1}^m \alpha_{i,m}(t)\phi_i(x)$ and $\phi_i(x)$ is defined in Lemma 3.5. The function $\tilde{U}_m$ satisfies

$$\frac{d}{dt}(\tilde{U}_m,\phi_i(x))_H + (A\tilde{U}_m,\phi_i(x))_H + ((B\tilde{U}_m,\tilde{U}_m),\phi_i(x))_H + ((B\tilde{U}_m,U_\varepsilon'),\phi_i(x))_H + ((F\tilde{U}_m,U_\varepsilon'),\phi_i(x))_H$$
$$+ (\tilde{E}\tilde{U}_m,\phi_i(x))_H = (\tilde{f},\phi_i(x))_H, \quad i=1,2,\ldots,m, \tag{3.32}$$

$$\tilde{U}_m|_{t=0} = \tilde{U}_{0,m}, \tag{3.33}$$

where $\tilde{U}_{0,m}\to\tilde{U}_0$ in H. As usually, it is straightforward (see Ref. 5) from (3.32) and Lemma 3.6 that

$$\frac{1}{2}\frac{d}{dt}|\tilde{U}_m(s)|_2^2 + \frac{1}{R_{\max}}\|\tilde{U}_m(s)\|^2 \le \frac{1}{2R_{\max}}\|\tilde{U}_m(s)\|^2 + (\tilde{f},\tilde{U}_m(s))_H. \tag{3.34}$$

Integrating (3.34) from 0 to t, $t\in]0,\mathcal{T}]$, we can obtain

$$|\tilde{U}_m(t)|_2^2 + \frac{1}{R_{\max}}\int_0^t \|\tilde{U}_m(s)\|^2\,ds \le |\tilde{U}_{0,m}|_2^2 + 2\int_0^t (\tilde{f},\tilde{U}_m(s))_H\,ds, \quad t\in 0,\mathcal{T}. \tag{3.35}$$

By the Gronwall inequality and (3.34), we have

$$|\tilde{U}_m(t)|_2^2 + c_{14}\int_0^t \|\tilde{U}_m(t)\|^2\,ds \le |\tilde{U}_{0,m}|_2^2 + c_{15}\int_0^t \|\tilde{f}(s)\|_{V'}\,ds, \quad t\in 0,\mathcal{T}. \tag{3.36}$$

So $\{\tilde{U}_m\}$ is bounded in the space $L^2(0,\mathcal{T};V)\cap L^\infty(0,\mathcal{T};H)$. Going if necessary to a subsequence $\{\tilde{U}_m\}$ (that we label the same), $\tilde{U}_m\to\tilde{U}$ $(m\to\infty)$ weakly in $L^2(0,\mathcal{T};V)$ and * weakly in $L^\infty(0,\mathcal{T};H)$. Due to a compactness theorem (see Ref. 5), we can extract a subsequence $\{\tilde{U}_m\}$ denoted by the same such that $\tilde{U}_m\to\tilde{U}$ $(m\to\infty)$strongly in $L^2(0,\mathcal{T};H)$. By passing to the limit in (3.32), we conclude that $\tilde{U}$ is a weak solution to Problem 3.1. By Lemmas 3.1, 3.2, 3.3, we know that

$$\{(\tilde{U}_m)_t\} \text{ is bounded set of } L^2(0,\mathcal{T};V^{(-3)}).$$

Therefore, $\tilde{U}_t \in L^2(0,\mathcal{T};V^{(-3)})$. Finally, by Lemma 3.7 and $\tilde{U} \in C(0,\mathcal{T};V^{(-3)})$, we have $\tilde{U} \in C_\omega(0,\mathcal{T};H)$.

Now let us prove the energy inequality. From $\tilde{U}_m \to \tilde{U}$ $(m\to\infty)$ strongly in $L^2(0,\mathcal{T};H)$, it follows that $|\tilde{U}_m|_2 \to |\tilde{U}|_2$ $(m\to\infty)$ strongly in $L^2(0,\mathcal{T})$. Going if necessary to a subsequence, $|\tilde{U}_m|_2 \to |\tilde{U}|_2$ $(m\to\infty)$, a.e. in $[0,\mathcal{T}]$. Let $\psi(s) \in C_0^\infty(]0,\mathcal{T}[)$, $\psi(s)\geq 0$. By (3.31) and the Lebesgue Dominated Theorem, we have

$$\int_0^\infty |\tilde{U}_m(t)|_2^2 \psi'(s)ds \to \int_0^\infty |\tilde{U}(t)|_2^2 \psi'(s)ds, \quad m\to\infty. \tag{3.37}$$

$\tilde{U}_m \to \tilde{U}$ $(m\to\infty)$ weakly in $L^2(0,\mathcal{T};V)$ implies that $\tilde{U}_m\psi^{1/2}(s) \to \tilde{U}\psi^{1/2}(s)$ $(m\to\infty)$ weakly in $L^2(0,\mathcal{T};V)$. By the lower weak semicontinuity of the norm, we get

$$\int_0^\infty \|\tilde{U}(s)\|^2 \psi(s)ds \leq \liminf_{m\to\infty} \int_0^\infty \|\tilde{U}_m(s)\|^2 \psi(s)ds. \tag{3.38}$$

Using (3.32) and (3.33), we have

$$-\int_0^\infty |\tilde{U}_m(t)|_2^2 \psi'(s)ds + \frac{1}{R_{\max}} \int_0^\infty \|\tilde{U}_m(s)\|^2 \psi(s)ds \leq 2\int_0^\infty (\tilde{f}, \tilde{U}_m(s))_H \psi(s)ds. \tag{3.39}$$

Combining (3.37) with (3.38), we pass to the limit in (3.39) and obtain the energy inequality. The proof is complete.

IV. TRAJECTORY AND GLOBAL ATTRACTORS FOR THE MOIST ATMOSPHERIC EQUATIONS

This section is divided into two subsections. In Sec. IV A, we give some preliminaries about trajectory and global attractors. In Sec. IV B, we shall prove the existence of trajectory and global attractors for the system (2.22)–(2.27).

A. Preliminaries

We recall the Trajectory Attractors Theory of Vishik and Chepyzhov; cf. Refs. 15 and 16.

Let E, E_0 be two Banach spaces such that $E\subseteq E_0$. An autonomous evolution equation,

$$\frac{\partial u}{\partial t} = G(u), \tag{4.1}$$

where G is a differential operator. Denote a specific family of solutions to the equation (4.1) by $\mathcal{K}^+$, $\mathcal{K}^+ \subset C(\mathbb{R}_+;\, E_0)\cap L^\infty(\mathbb{R}_+;\, E)$. $\mathcal{K}^+$ will be called the *trajectory space* of the equation (4.1) and its elements are *trajectories* of (4.1). $\mathcal{K}^+$ is *translation invariant* in the following sense: if $\forall u(s) \in \mathcal{K}^+$, $h\in\mathbb{R}_+$, then $u(s+h)\in\mathcal{K}^+$.

The action of translation operators $T(t)(t\geq 0)$ on the space $C(\mathbb{R}_+;E_0)\cap L^\infty(\mathbb{R}_+;E)$ is defined by

$$T(t)u(s) = u(t+s), \quad \forall\, t\geq 0, \quad u\in C(\mathbb{R}_+;E_0)\cap L^\infty(\mathbb{R}_+;E).$$

By the definition, we have $T(t_1+t_2)=T(t_1)T(t_2)$ for $t_1,t_2\geq 0$, and $T(0)$ is the identity operator on the space $C(\mathbb{R}_+;E_0)\cap L^\infty(\mathbb{R}_+;E)$. The semigroup $\{T(t)\}=\{T(t);t\geq 0\}$ is known as the *time translation group* on $C(\mathbb{R}_+;\, E_0)\cap L^\infty(\mathbb{R}_+;E)$.

We shall introduce a topology in the trajectory space $\mathcal{K}^+$. We call that the sequence $\{f_n(s)\}$ **(**$\{f_n(s)\}\subset C(\mathbb{R}_+;E_0)$**)** converges to $f(s)$**(**$f(s)\in C(\mathbb{R}_+;E_0)$**)** in the topology space $C_{\text{loc}}(\mathbb{R}_+;E_0)$ if

$$\max_{s\in[0,\mathcal{T}]}\|f_n(s)-f(s)\|_{E_0}\to 0,\quad \text{as } n\to\infty,\quad \forall\,\mathcal{T}>0. \tag{4.2}$$

The topology in $\mathcal{K}^+$ is induced by the topological space $C_{\text{loc}}(\mathbb{R}_+;E_0)$. It is clear that the translation semigroup $\{T(t)\}$ is continuous in the space $C_{\text{loc}}(\mathbb{R}_+;E_0)$, in particular, it is continuous in $\mathcal{K}^+$. A set Ξ is said to be bounded in $\mathcal{K}^+$ if

$$\|u\|_{L^\infty(\mathbb{R}_+;E)}=\operatorname{ess\,sup}_{s\ge 0}\|u(s)\|_E\le c_{16},\quad \forall\, u\in\Xi. \tag{4.3}$$

Definition 4.1: A set $\Lambda\subset C(\mathbb{R}_+;E_0)\cap L^\infty(\mathbb{R}_+;\,E)$ is said to be attracting for the trajectory space $\mathcal{K}^+$ of the equation (4.1) in the topology of $C_{\text{loc}}(\mathbb{R}_+;E_0)$, if for any bounded [in $L^\infty(\mathbb{R}_+;E)$] set $\Xi\subseteq\mathcal{K}^+$ and any number $\mathcal{T}\ge 0$, the following relation holds:

$$\operatorname{dist}_{C(0,\mathcal{T};E_0)}(\Pi_{\mathcal{T}}T(t)\Xi,\Pi_{\mathcal{T}}\Lambda)\to 0,\quad \text{as } t\to\infty, \tag{4.4}$$

where $\Pi_{\mathcal{T}}$ is the restriction operator to the interval $[0,\mathcal{T}]$: if $u\in C(\mathbb{R}_+;E_0)\cap L^\infty(\mathbb{R}_+;E)$, then

$$\Pi_{\mathcal{T}}u\in C(0,\mathcal{T};E_0)\cap L^\infty(0,\mathcal{T};E),\quad \Pi_{\mathcal{T}}u(s)=u(s),\quad \text{for } s\in[0,\mathcal{T}];$$

and

$$\operatorname{dist}_{C(0,\mathcal{T};E_0)}(\Pi_{\mathcal{T}}T(t)\Xi,\Pi_{\mathcal{T}}\Lambda)=\sup_{a\in\Xi}\inf_{b\in\Lambda}\max_{s\in[0,\mathcal{T}]}\|a(s+t)-b(s)\|_{E_0}.$$

Definition 4.2: A set $\mathcal{H}\subseteq\mathcal{K}^+$ is called the **trajectory attractor** in the trajectory space $\mathcal{K}^+$ with respect to the topology $C_{\text{loc}}(\mathbb{R}_+;E_0)$ if we have the following.

(1) $\mathcal{H}$ is a compact set in $C_{\text{loc}}(\mathbb{R}_+;\,E_0)$ and bounded in $L^\infty(\mathbb{R}_+;\,E)$;

(2) $\mathcal{H}$ is strictly invariant with respect to $\{T(t)\}$, i.e.,

$$T(t)\mathcal{H}=\mathcal{H},\quad \forall\, t\ge 0;$$

(3) $\mathcal{H}$ is an attracting set in $\mathcal{K}^+$ in the topology of $C_{\text{loc}}(\mathbb{R}_+;E_0)$.

Theorem 4.3: (cf. Ref. 16): Suppose that the trajectory space $\mathcal{K}^+$ is translation invariant. Assume also that for $\mathcal{K}^+$ there exists an attracting set Λ such that $\Lambda\subseteq\mathcal{K}^+$, Λ is compact set in $C_{\text{loc}}(\mathbb{R}_+;E_0)$ and bounded in $L^\infty(\mathbb{R}_+;E)$. Then in $\mathcal{K}^+$ there exists a trajectory attractor $\mathcal{H}\subseteq\Lambda$ and $\mathcal{H}$ is unique in $\mathcal{K}^+$, moreover,

$$\mathcal{H}=\bigcap_{\mathcal{T}\ge 0}\overline{\bigcup_{t\ge\mathcal{T}}T(t)\Lambda}, \tag{4.5}$$

where $\overline{\cup_{t\ge\mathcal{T}}T(t)\Lambda}$ is the closure of the set $\cup_{t\ge\mathcal{T}}T(t)\Lambda$ in the space $C_{\text{loc}}(\mathbb{R}_+;E_0)$.

Now we shall recall the definition of global attractors. First, we introduce some notations. For a set $\Xi\subseteq E$, we define $\Xi(t)\subseteq E$ for $t\ge 0$ as follows:

$$\Xi(t)=\{u(t);\ u\in\Xi\}\subseteq E.$$

In a similar way, for the trajectory attractor $\mathcal{H}$ we define the set

$$\mathcal{H}(t)=\{u(t);\ u\in\mathcal{H}\}\subseteq E,\quad \text{for } t\ge 0.$$

We note that $\mathcal{H}(t)$ is independent of time t.

Definition 4.4: A set $\mathcal{A}\subseteq E$ is called the *global attractor* in E_0 of the equation (4.1) if we have the following:

(1) $\mathcal{A}$ is a compact set in E_0 and bounded in E;

(2) any bounded [in $L^\infty(\mathbb{R}_+;E)$] set of trajectories $\Xi\subset\mathcal{K}^+$ satisfies the property that the section $\Xi(t)$ are attracted to $\mathcal{A}$ as $t\to\infty$ with respect to the norm of E_0:

$$\operatorname{dist}_{E_0}(\Xi(t),\mathcal{A})\to 0,\ \text{as } t\to\infty; \tag{4.6}$$

(3) $\mathcal{A}$ is the minimal set satisfying (1) and (2), that is, $\mathcal{A}$ belongs to any attracting set compact in E_0 and bounded in E.

Theorem 4.5: (cf. Ref. 16): If the assumptions of Theorem 4.3 are satisfied, then the global attractor (in E_0) $\mathcal{A}$ of the equation (4.1) exists and $\mathcal{A}=\mathcal{H}(0)$.

Remark 4.6: Definition 4.4 generalizes the well-known notion of global (E,E_0)—the attractor of the semigroup corresponding to the Cauchy problem for the equation (4.1) under the assumption that the solution for the problem is unique (see Refs. 20–22). Assume that for any u_0, there exists a unique trajectory $u\in\mathcal{K}^+$ such that $u(0)=u_0$. Then the global attractor (in E_0) is identical to the usual global (E,E_0)—attractor of the semigroup. We shall explain the point in Theorem 4.8.

Under the assumption that there is a unique solution for the Cauchy problem,

$$\frac{\partial u}{\partial t}=G(u),\quad u(0)=u_0, \tag{4.7}$$

following the standard approach, we can introduce an operator semigroup $\{S(t);t\geq 0\}$ in the space E corresponding to the problem (4.7) by the formula

$$S(t)u_0=u(t),\quad t\geq 0. \tag{4.8}$$

Definition 4.7: A set $\mathcal{A}_1\subseteq E$ is called the global (E,E_0) attractor of the semigroup $\{S(t)\}$ acting in E if we have the following:

(1) $\mathcal{A}_1$ is a compact set in E_0 and bounded in E;
(2) $S(t)\mathcal{A}_1=\mathcal{A}_1,\ \forall t\geq 0$;
(3) any bounded (in E) set $\Xi_0\subset E$ satisfies

$$\mathrm{dist}_{E_0}(S(t)\Xi_0,\mathcal{A}_1)\to 0,\quad \text{as } t\to\infty. \tag{4.9}$$

Theorem 4.8. (cf. Ref. 16): Suppose that the assumptions of Theorem 4.5 are satisfied and the semigroup $\{S(t)\}$ is bounded [for any bounded (in E) set $\Xi_0\subset E$, the set $\overline{\cup_{t\geq 0}S(t)\Xi_0}$ is bounded in E]. Then the global (E_0,E) attractor $\mathcal{A}_1$ of the equation (4.1) exists and $\mathcal{A}_1=\mathcal{A}=\mathcal{H}(0)$, where $\mathcal{A}$ is the global attractor (in E_0) of the equation (4.1).

B. Existence of trajectory and global attractors

At first, we shall construct the trajectory space $\mathcal{K}^+$ of the system (2.22)–(2.27). By Theorem 3.8, if $\tilde{U}$ is a weak solution to Problem 3.1, then $\tilde{U}\in L^2(0,\mathcal{T};V)\cap L^\infty(0,\mathcal{T};H)$ and $\tilde{U}$ satisfies the energy inequality

$$-\int_0^\infty |\tilde{U}(t)|_2^2\psi'(s)ds+\frac{1}{R_{\max}}\int_0^\infty \|\tilde{U}(s)\|^2\psi(s)ds\leq 2\int_0^\infty (\tilde{f},\tilde{U}(s))_H\psi(s)ds, \tag{4.10}$$

where $\psi(s)\in C_0^\infty(]0,\mathcal{T}[),\psi(s)\geq 0$. The inequality can be interpreted as follows:

$$\frac{1}{2}\frac{d}{dt}|\tilde{U}(s)|_2^2+\frac{1}{R_{\max}}\|\tilde{U}(s)\|^2\leq\frac{1}{2R_{\max}}\|\tilde{U}(s)\|^2+(\tilde{f},\tilde{U}(s))_H,\quad s\in]0,\mathcal{T}]. \tag{4.11}$$

Definition 4.9: The trajectory space $\mathcal{K}^+$ of the system (2.22)–(2.27) consists of all functions,

$$\tilde{U}\in L^2_{\mathrm{loc}}(\mathbb{R}_+;V)\cap L^\infty(\mathbb{R}_+;H),$$

where $\tilde{U}$ satisfies the condition: for any $\mathcal{T}>0$; the function $\Pi_{\mathcal{T}}\tilde{U}$ is a weak solution for Problem 3.1 on the time interval $[0,\mathcal{T}]$ satisfying the energy inequality (4.10).

Lemma 4.10 (cf. Ref. 23): If Y is a Banach space and $E\subset\subset E_0\subset Y$, where $\subset\subset$ denotes compact embedding, then we have the following embedding:

$$W^{\infty,p}(0,\mathcal{T};E,Y) \subset\subset C(0,\mathcal{T};E_0),$$

where $W^{\infty,p}(0,\mathcal{T};E,Y)=\{u(s);\ s\in(0,\mathcal{T}),u\in L^{\infty}(0,\mathcal{T};E),\ u_t\in L^p(0,\mathcal{T};Y)\}$, $p>1$, with the norm

$$\|u\|_{W^{\infty,p}}=\operatorname{ess}\sup_{\mathcal{T}\geq s\geq 0}\|u\|_E+\left(\int_0^{\mathcal{T}}\|u_t(s)\|_Y^p ds\right)^{1/p}.$$

Proposition 4.11: If $\mathcal{K}^+$ is a trajectory space in Definition 4.9, then we have the following.

(1) For any $\tilde{U}_0\in H$, there exists a trajectory $\tilde{U}(t)\in\mathcal{K}^+$ such that $\tilde{U}(0)=\tilde{U}_0$;

(2) $\mathcal{K}^+\subset C(\mathbb{R}_+;V^{(-3)})\cap L^{\infty}(\mathbb{R}_+;H)$;

(3) $\mathcal{K}^+$ is trajectory invariant, i.e., $T(t)\mathcal{K}^+\subseteq\mathcal{K}^+$.

Proof: By Definition 4.9, we can know that (1), (2) are corollaries of Theorem 3.8 and Lemma 4.10. Since the equations (3.14)–(3.16) are autonomous, $\mathcal{K}^+$ is trajectory invariant for the time translation semigroup $\{T(t)\}$.

Proposition 4.12: For any $\tilde{U}\in\mathcal{K}^+$, the following inequality holds:

$$\begin{aligned}\|T(t)\tilde{U}\|_{L^{\infty}(\mathbb{R}_+;H)}+\|T(t)\tilde{U}\|_{L^2(0,1;V)}+\|T(t)\tilde{U}_t\|_{L^2(0,1;V^{(-3)})}&=\operatorname{ess}\sup_{s\geq t}|\tilde{U}(s)|+\left(\int_t^{t+1}\|\tilde{U}(s)\|^2 ds\right)^{1/2}\\&+\left(\int_t^{t+1}\|\tilde{U}_t(s)\|_{V^{(-3)}}^2\,ds\right)^{1/2}\leq c_{22}\|\tilde{U}\|_{L^{\infty}(0,1;H)}^2\exp(-c_{23}t)+c_{24}\|\tilde{U}\|_{L^{\infty}(0,1;H)}\exp(-c_{23}t)\\&+c_{25},\quad\forall\, t\geq 0.\end{aligned}\tag{4.12}$$

In order to prove Proposition 4.12, we need the following general Gronwall Lemma.

Lemma 4.13. (cf. Ref. 15): Let $y(s)$, $\varphi(s)\in L^1_{\mathrm{loc}}(0,\infty)$, and

$$-\int_0^{\infty}y(s)\psi'(s)ds+\alpha\int_0^{\infty}y(s)\psi(s)ds\leq\int_0^{\infty}\varphi(s)\psi(s)ds,\tag{4.13}$$

for any $\psi(s)\in C_0^{\infty}(\mathbb{R}_+)$, $\psi(s)\geq 0$, where $\alpha\in\mathbb{R}$; then

$$y(t)e^{\alpha t}-y(\tau)e^{\alpha\mathcal{T}}\leq\int_{\mathcal{T}}^{t}\varphi(s)e^{\alpha s}\,ds,$$

for any t, $\mathcal{T}\in\mathbb{R}_+\backslash\tilde{Q}$, $t\geq\mathcal{T}$, where $\mu(\tilde{Q})=0$, and the Lebesgue measure of $\tilde{Q}$ is equal to zero.

Proof of Proposition 4.12: (1) By the definitions of the spaces V, H, $\mathcal{K}^+$, we have

$$c_{17}|\tilde{U}(s)|_2^2\leq\|\tilde{U}(s)\|^2,\quad\forall\,\tilde{U}\in\mathcal{K}^+,\quad s\geq 0.\tag{4.14}$$

By (4.10), we obtain

$$\begin{aligned}-\int_0^{\infty}|\tilde{U}(s)|_2^2\psi'(s)ds+\frac{c_{17}}{2R_{\max}}\int_0^{\infty}|\tilde{U}(s)|_2^2\psi(s)ds\leq\int_0^{\infty}\Bigg(&2R_{\max}\|\tilde{f}\|_{V'}^2-\frac{1}{2R_{\max}}(\|\tilde{U}(s)\|^2\\&-c_{17}|\tilde{U}(s)|_2^2)\Bigg)\psi(s)ds.\end{aligned}\tag{4.15}$$

Applying Lemma 4.13, we get the following inequality:

$$|\widetilde{U}(t)|_2^2 e^{c_{18}t} - |\widetilde{U}(\mathcal{T})|_2^2 e^{c_{18}\mathcal{T}} \le \int_{\mathcal{T}}^{t} \left(2R_{\max}\|\widetilde{f}\|_{V'}^2 - \frac{1}{2R_{\max}}(\|\widetilde{U}(s)\|^2 - c_{17}|\widetilde{U}(s)|_2^2) \right) e^{c_{18}s}\, ds, \tag{4.16}$$

for any t, $\mathcal{T} \in \mathbb{R}_+ \backslash \widetilde{Q}$, $t \ge \mathcal{T}$, $c_{18} = c_{17}/2R_{\max}$, where $\mu(\widetilde{Q}) = 0$. Combining (4.14) with (4.16), we obtain

$$|\widetilde{U}(t)|_2^2 e^{c_{18}t} - |\widetilde{U}(\mathcal{T})|_2^2 e^{c_{18}\mathcal{T}} \le \int_{\mathcal{T}}^{t} 2R_{\max}\|\widetilde{f}\|_{V'} e^{c_{18}s}\, ds. \tag{4.17}$$

By (4.17), we get

$$\|T(t)\widetilde{U}\|_{L^\infty(\mathbb{R}_+;H)} \le \|\widetilde{U}\|_{L^\infty(0,1;H)} \exp(-c_{18}t) + c_{19}, \quad \forall\, t \ge 0. \tag{4.18}$$

(2) Combining (4.16) with (4.18), we get

$$\frac{1}{2R_{\max}} \int_t^{t+1} (\|\widetilde{U}(s)\|^2 - c_{17}|\widetilde{U}(s)|_2^2) e^{c_{18}s}\, ds \le c_{19}(e^{c_{18}(t+1)} - e^{c_{18}t}) + |\widetilde{U}(t)|_2^2 e^{c_{18}t} \le c_{19}(e^{c_{18}(t+1)} - e^{c_{18}t}) + \|\widetilde{U}\|_{L^\infty(0,1;H)}^2 + c_{19}e^{c_{18}t} \le \|\widetilde{U}\|_{L^\infty(0,1;H)}^2 + c_{19}e^{c_{18}(t+1)},$$

i.e.,

$$\frac{1}{2R_{\max}} \int_t^{t+1} \|\widetilde{U}(s)\|^2 e^{c_{18}s}\, ds \le c_{18} \int_t^{t+1} |\widetilde{U}(s)|_2^2 e^{c_{18}s}\, ds + \|\widetilde{U}\|_{L^\infty(0,1;H)}^2 + c_{19}e^{c_{18}(t+1)}. \tag{4.19}$$

By (4.18), we have

$$c_{18} \int_t^{t+1} |\widetilde{U}(s)|_2^2 e^{c_{18}s}\, ds \le c_{18}\|\widetilde{U}\|_{L^\infty(0,1;H)}^2 + c_{19}(e^{c_{18}(t+1)} - e^{c_{18}t}). \tag{4.20}$$

Combining (4.19) with (4.20), we obtain

$$\frac{1}{2R_{\max}} \int_t^{t+1} \|\widetilde{U}(s)\|^2 e^{c_{18}s}\, ds \le (c_{18}+1)\|\widetilde{U}\|_{L^\infty(0,1;H)}^2 + c_{19}(2e^{c_{18}(t+1)} - e^{c_{18}t}).$$

Therefore

$$\frac{1}{2R_{\max}} \int_t^{t+1} \|\widetilde{U}(s)\|^2\, ds \le (c_{18}+1)\|\widetilde{U}\|_{L^\infty(0,1;H)}^2 e^{-c_{18}t} + c_{19}(2e^{c_{18}} - 1). \tag{4.21}$$

(3) By Lemma 3.2, Lemma 3.3, Lemma 3.6, assumptions of Problem 3.1 and (3.22), we obtain

$$\|\widetilde{U}_t(s)\|_{V^{(-3)}} \le \|\widetilde{U}(s)\|\,|\widetilde{U}(s)|_2 + c_{20}\|\widetilde{U}(s)\| + \|\widetilde{f}\|_{V'}.$$

So

$$\left(\int_t^{t+1}\|\widetilde{U}_t(s)\|^2_{V^{(-3)}}\,ds\right)^{1/2}\le\left(\int_t^{t+1}\|\widetilde{U}(s)\|^2|\widetilde{U}(s)|_2^2\,ds\right)^{1/2}+c_{21}+c_{21}\left(\int_t^{t+1}\|\widetilde{U}(s)\|^2\,ds\right)^{1/2}$$
$$\le c_{21}\|\widetilde{U}\|_{L^\infty(t,t+1;H)}\left(\int_t^{t+1}\|\widetilde{U}(s)\|^2\,ds\right)^{1/2}+c_{21}$$
$$+c_{21}\left(\int_t^{t+1}\|\widetilde{U}(s)\|^2\,ds\right)^{1/2},\quad\forall\, t\ge 0. \tag{4.22}$$

Therefore, by (4.18), (4.21), (4.22), there exist two positive constants c_{20},c_{21}, such that

$$\|T(t)\widetilde{U}\|_{L^\infty(\mathbb{R}_+;H)}+\|T(t)\widetilde{U}\|_{L^2(0,1;V)}+\|T(t)\widetilde{U}_t\|_{L^2(0,1;V^{(-3)})}\le c_{22}\|\widetilde{U}\|^2_{L^\infty(0,1;H)}\exp(-c_{23}t)$$
$$+c_{24}\|\widetilde{U}\|_{L^\infty(0,1;H)}\exp(-c_{23}t)+c_{25},\quad\forall\, t\ge 0.$$

The proof is complete.

Proposition 4.14: If $\{\widetilde{U}_n\}\subset\mathcal{K}^+$ is a bounded sequence in $L^\infty(\mathbb{R}_+;H)$, and for some $\widetilde{U}\in C(\mathbb{R}_+;V^{(-3)})$ the following relation holds:

$$\widetilde{U}_n\to\widetilde{U}\quad\text{in } C_{\mathrm{loc}}(\mathbb{R}_+;V^{(-3)}),\quad\text{as } n\to\infty.$$

Then $\widetilde{U}\in\mathcal{K}^+$.

Proof: We only give the outline of the proof. Since $\{\widetilde{U}_n\}\subset\mathcal{K}^+$ is bounded in $L^\infty(\mathbb{R}_+;H)$, by Proposition 4.12, we know, if necessary going to the subsequence of $\{\widetilde{U}_n\}$,

$$(\widetilde{U}_n)_t+A\widetilde{U}_n+(B\widetilde{U}_n,\widetilde{U}_n)+(B\widetilde{U}_n,U')+(F\widetilde{U}_n,U')+\widetilde{E}\widetilde{U}_n-\widetilde{f}\rightharpoonup(\widetilde{U})_t+A\widetilde{U}+(B\widetilde{U},\widetilde{U})+(B\widetilde{U},U')$$
$$+(F\widetilde{U},U')+\widetilde{E}\widetilde{U}-\widetilde{f},$$

weakly in $L^2(0,\mathcal{T};V^{(-3)})$, for any $\mathcal{T}>0$. Hence $\widetilde{U}$ is a weak solution for Problem 3.1.

In order to prove that $\widetilde{U}\in\mathcal{K}^+$, we should check that $\widetilde{U}$ satisfies the energy inequality (4.10). By $\{\widetilde{U}_n\}\subset\mathcal{K}^+$, for every n, $\widetilde{U}_n$ satisfies

$$-\int_0^\infty|\widetilde{U}_n(t)|_2^2\psi'(s)ds+\frac{1}{R_{\max}}\int_0^\infty\|\widetilde{U}_n(s)\|^2\psi(s)ds\le 2\int_0^\infty(\widetilde{f},\widetilde{U}_n(s))_H\psi(s)ds,$$

where $\psi(s)\in C_0^\infty(]0,\mathcal{T}[)$, $\psi(s)\ge 0$. Since $\{\widetilde{U}_n\}\subset\mathcal{K}^+$ is bounded in $L^\infty(\mathbb{R}_+;H)$, by Proposition 4.12, going if necessary to a subsequence, we obtain that $\widetilde{U}_m\to\widetilde{U}$ $(m\to\infty)$ weakly in $L^2(0,\mathcal{T};V)$ and * weakly in $L^\infty(0,\mathcal{T};H)$. Similarly to prove (3.39), we can take a limit in the above inequality and get the energy inequality

$$-\int_0^\infty|\widetilde{U}(t)|_2^2\psi'(s)ds+\frac{1}{R_{\max}}\int_0^\infty\|\widetilde{U}(s)\|^2\psi(s)ds\le 2\int_0^\infty(\widetilde{f},\widetilde{U}(s))_H\psi(s)ds.$$

Now we can state the main result of this section.

Theorem 4.15: Under the assumptions of Problem 3.1, there is a trajectory attractor $\mathcal{H}\subseteq\mathcal{K}^+$ for the system (2.22)–(2.27) and $\mathcal{H}$ is unique in $\mathcal{K}^+$. Moreover $\mathcal{A}=\mathcal{H}(0)$ is the global attractor for the system (2.22)–(2.27) in the space $V^{(-3)}$.

Proof: In order to apply Theorem 4.3 and Theorem 4.5, we have to construct an attracting set Λ for the time translation semigroup $\{T(t)\}$, where $\Lambda\subseteq\mathcal{K}^+$ and Λ is a compact set in $C_{\mathrm{loc}}(\mathbb{R}_+;V^{(-3)})$ and bounded in $L^\infty(\mathbb{R}_+;H)$. Let

$$\Lambda = \left\{ \widetilde{U} \in \mathcal{K}^+;\ \operatorname*{ess\,sup}_{t\geq 0}\{\|\widetilde{U}\|_{L^\infty(t,t+1;H)} + \|\widetilde{U}_t\|_{L^2(t,t+1;V^{(-3)})}\} \leq 3c_{25} \right\}. \tag{4.23}$$

We claim that Λ is an attracting set that satisfies the conditions in Theorem 4.3. Indeed, assume $\Xi \subseteq \mathcal{K}^+$ and Ξ is a bounded in $L^\infty(\mathbb{R}_+;\ H)$, i.e.,

$$\|\widetilde{U}\|_{L^\infty(\mathbb{R}_+;\ H)} = \operatorname*{ess\,sup}_{s\geq 0}\|\widetilde{U}\|_E \leq c_{26}, \quad \forall\ u \in \Xi.$$

By Proposition 4.12, there exists $t_1 > 0$ such that $T(t)\Xi \subseteq \Lambda$ for $t \geq t_1$. By the definition of Λ, we can know that Λ is bounded in $L^\infty(\mathbb{R}_+;\ H)$. By (4.23), for any $\mathcal{T} > 0$, $\Pi_{\mathcal{T}}\Lambda$ is bounded in $W^{\infty,2}(0,\mathcal{T};H,V^{(-3)})$. Applying Lemma 4.10, we can obtain that the closure of $\Pi_{\mathcal{T}}\Lambda$ is compact in $C(0,\mathcal{T};\ V^{(-3)})$, that is, the closure of Λ is compact in $C_{\mathrm{loc}}(\mathbb{R}_+;V^{(-3)})$. Now, we shall prove that Λ is closed in $C_{\mathrm{loc}}(\mathbb{R}_+;V^{(-3)})$. Suppose that there is a sequence $\{\widetilde{U}_n\} \subset \Lambda$ that satisfies

$$\widetilde{U}_n \to \widetilde{U} \quad \text{in } C_{\mathrm{loc}}(\mathbb{R}_+;V^{(-3)}), \quad \text{as } n \to \infty .$$

On the other hand, by (4.23), $\{\widetilde{U}_n\}$ is bounded in $L^\infty(\mathbb{R}_+;H)$. Applying Proposition 4.14, we get that $\widetilde{U} \in \mathcal{K}^+$. By the lower weak continuity of the norm and

$$\|\widetilde{U}_n\|_{L^\infty(t,t+1;H)} + \|(\widetilde{U}_n)_t\|_{L^2(t,t+1;V^{(-3)})} \leq 3c_{25},$$

we can have

$$\|\widetilde{U}\|_{L^\infty(t,t+1;H)} + \|\widetilde{U}_t\|_{L^2(t,t+1;V^{(-3)})} \leq 3c_{25}.$$

Therefore, $\widetilde{U} \in \Lambda$, that is, Λ is compact in $C_{\mathrm{loc}}(\mathbb{R}_+;\ V^{(-3)})$. Applying Theorem 4.3 and Theorem 4.5, we obtain Theorem 4.15 and the trajectory attractor

$$\mathcal{H} = \cap_{\mathcal{T}\geq 0}\overline{\cup_{t\geq \mathcal{T}} T(t)\Lambda},$$

where $\overline{\cup_{t\geq \mathcal{T}} T(t)\Lambda}$ is the closure of the set $\cup_{t\geq \mathcal{T}} T(t)\Lambda$ in the space $C_{\mathrm{loc}}(\mathbb{R}_+;\ V^{(-3)})$. The proof is complete.

Remark 4.16: In Lemma 4.10, we can let $E_0 = V^{(-\delta)}$, $0 < \delta \leq 3$, $E = H$, $Y = V^{(-3)}$, where E_0 is in Theorem 4.8, $V^{(-\delta)} = (V^{(\delta)})'$ and the definition of $V^{(\delta)}$ is similar to $V^{(3)}$. Thus, we can replace $V^{(-3)}$ in Propositions 4.11, 4.14 by $V^{(-\delta)}$. Therefore, we obtain the trajectory attractor $\mathcal{H} \subseteq \mathcal{K}^+ \subset C(\mathbb{R}_+;V^{(-\delta)}) \cap L^\infty(\mathbb{R}_+;H)$ and the global attractor of the system (2.22)–(2.27) in the space $V^{(-\delta)}$.

(Received 19 April 2006; accepted 19 June 2006; published online 16 August 2006)

The idea of associating particle trajectories with wave propagation rays is examined in the context of general relativity. The additional assumption that also Hamilton-Jacobi particle equation and wave front equation of motion can be identified in an $n>3$ coordinate space leads to a Kaluza-Klein type theory involving Klein-Gordon and Dirac equations. Moreover de Broglie and Einstein-Planck quantum relations can be deduced in a natural way. © *2006 American Institute of Physics.*

I. INTRODUCTION

In the present paper we attempt to suggest a new point of view on the intriguing problems of wave-particle duality and the relationship between general relativity and quantum mechanics.[1]

A. Historical context

In 1970, Boillat[2] proposed the idea that the trajectories of motion of (*stable*) *particles* could be identified with the rays of propagation of (*exceptional*) *waves* across the physical space. Such an idea somehow reminds one of the concept of *pilot wave* earlier introduced by de Broglie[3] and also the so-called "realistic" interpretation of Schrödinger equation given by Bohm.[4] Boillat's approach is significantly different with respect to previous ones since he operates in the context of a quite general *nonlinear* wave propagation theory[5] obtaining the well-known Born-Infeld electrodynamics[6] and some other relevant results (for interesting physical applications see, e.g., Refs. 7 and 8).

B. Our contribution

Here we will come back to the idea of identifying *wave rays* and *particle trajectories* but we add a further assumption by also requiring that the *evolution equation*, along wave rays (provided by wave kinematics), and the *Hamilton-Jacobi equation* (governing the particles dynamics) must be identified. As we shall see, we will be able to tune wave and particle motions provided that the *normal speeds* of waves are equal to the speed of light c across an *n-dimensional* coordinate space. This condition leads to the dynamics of a zero rest mass particle across the same *n-dimensional* space, the projection of which onto the physical *three-dimensional* subspace embedded into it can be interpreted as the motion of a massive relativistic particle.[9] (For models treating mass as related to higher dimensional space-time see, e.g., Refs. 10–18). We look also for the Lagrangian governing the *field* candidate to fit the conditions arising from the previous assumptions and we obtain Klein-Gordon and Dirac equations arising in the embedded physical space from a D'Alembert equation holding in the embedding space.

II. WAVES AND PARTICLE DYNAMICS

Let us consider an $n+1$ dimensional real differentiable manifold V^{n+1}, representing a space-time endowed with a symmetric metric g of signature $(+,-,\cdots,-)$ and a torsionless connection Γ. On V^{n+1} we represent any system of curvilinear coordinates with $x^{\mu},\mu=0,I$, with $I=1,2,\ldots,n$. The phyisically observable space-time is then described by a four-dimensional sub-manifold V^4 on which the observable coordinates are labeled by the indices $0,i$, where $i=1,2,3$, while we will label the remaining coordinates $x^4,x^5,\ldots,x^n$ by underlined Latin indices $\underline{i}=4,5,\ldots,n$. (We point out that the signature relative to the extra dimensions seems to be relevant for our purposes and cannot be taken otherwise.) For our purposes it proves convenient to adopt the synchronous gauge which requires the following $n+1$ conditions on the metric tensor:

$$g_{00}=1, \quad g_{0I}=g_{I0}=0, \tag{1}$$

implying the synchronization of time:

$$x^0=ct. \tag{2}$$

Let us now consider any differentiable real valued function $\varphi(t,x^I)$, which we can always assume to be dimensionless, such that

$$g^{\mu\nu}\frac{\partial\varphi}{\partial x^{\mu}}\frac{\partial\varphi}{\partial x^{\nu}}\leqslant 0, \tag{3}$$

$g^{\mu\nu}$ being the contravariant components of the metric tensor defined as usual by the relation

$$g^{\mu\nu}g_{\nu\rho}=\delta^{\mu}_{\rho}. \tag{4}$$

Then

$$\varphi(t,x^I)=0 \tag{5}$$

may be interpreted as the world sheet of a wave front traveling across the n-space. We point out that φ is determined by (5) except for an arbitrary nonvanishing factor. The trajectory (*ray*) of each point of the wave front can be described by its parametric equations:

$$x^I\equiv x^I(t). \tag{6}$$

Substituting (6) into (5) and differentiating with respect to t we obtain the differential equation governing the wave kinematics:

$$\frac{\partial\varphi}{\partial t}+V^I\frac{\partial\varphi}{\partial x^I}=0, \tag{7}$$

where

$$V^I=\frac{\mathrm{d}}{\mathrm{d}t}x^I(t) \tag{8}$$

is the ray velocity of the point of the wave front. Assuming $\varphi_{,I}\neq 0$, Eq. (7) can be written also in the equivalent form:

$$\frac{\partial\varphi}{\partial t}+V|\nabla\varphi|=0, \quad |\nabla\varphi|=\sqrt{-g^{IK}\varphi_{,I}\varphi_{,K}}, \tag{9}$$

where the contravariant components of the metric tensor, in the gauge (1), result to be

$$g^{00}=1, \quad g^{0I}=g^{I0}=0, \quad g^{IJ}g_{JK}=\delta^I_K. \tag{10}$$

Then the normal wave speed is given by

$$V = V^I n_I, \quad n_I = \frac{\varphi_{,I}}{|\nabla\varphi|}, \quad g^{IK} n_I n_K = -1, \tag{11}$$

the comma denoting partial derivative, as usual. The first step of our work consists in asking whether and at which conditions the first equation in Eq. (9)—the wave front equation—can be interpreted also as a Hamilton-Jacobi equation:

$$\frac{\partial S}{\partial t} + H = 0, \tag{12}$$

governing the motion of some particle. In order to make possible such interpretation we may think of the function φ as proportional to the Hamilton generating function of the particle dynamics according to

$$S = \alpha\varphi, \tag{13}$$

where α is a suitable dimensional (positive) constant which will be specified later coherently with a physical interpretation of the theory. Then we can write the first equation in (9) in the form (12) provided that the Hamiltonian of the particle is given by

$$H = V|\nabla S|, \quad |\nabla S| = \sqrt{-g^{IK} S_{,I} S_{,K}}. \tag{14}$$

Since, according to Hamilton-Jacobi's theory,

$$p_I = S_{,I}, \quad E = H \tag{15}$$

(where p_I is the canonical momentum of the particle, and the Hamiltonian H is the generalized energy) from (14) it results:

$$E = V\sqrt{-g^{IK} p_{,I} p_{,K}}. \tag{16}$$

It is immediate to see that (16) is compatible with relativity if and only if

$$V = c, \tag{17}$$

and the particle has zero rest mass. In fact at those conditions it results:

$$E = cp, \quad p = \sqrt{-g^{IK} p_I p_K}. \tag{18}$$

The Hamilton equations,

$$\frac{\mathrm{d}p_I}{\mathrm{d}t} = -\frac{\partial H}{\partial x^I}, \quad \frac{\mathrm{d}x^I}{\mathrm{d}t} = \frac{\partial H}{\partial p_I}, \tag{19}$$

result:

$$\frac{\mathrm{d}p_I}{\mathrm{d}t} = g^{JK}{}_{,I} \frac{c p_J p_K}{2p}, \tag{20}$$

$$\frac{\mathrm{d}x^I}{\mathrm{d}t} = -c\frac{p^I}{p}. \tag{21}$$

One realizes that (20) is also equivalent to the geodesic condition:

$$\frac{\mathrm{d}p_I}{\mathrm{d}t} - \Gamma^K_{IJ} p_K \frac{\mathrm{d}x^J}{\mathrm{d}t} = 0, \tag{22}$$

which, thanks to (21), becomes

$$\frac{\mathrm{d}p_I}{\mathrm{d}t} + \Gamma^K_{IJ}\frac{cp^J p_K}{p} = 0. \tag{23}$$

In fact,

$$\tfrac{1}{2}g^{JK}{}_{,I}p_J p_K \equiv -\Gamma^K_{JI}p_K p^J,$$

being

$$g^{JK}{}_{;I} \equiv g^{JK}{}_{,I} + \Gamma^J_{IM}g^{MK} + \Gamma^K_{IM}g^{JM} = 0, \tag{24}$$

because of the metricity of g^{JK}, where

$$\Gamma^K_{JI} = \tfrac{1}{2}g^{KM}(g_{JM,I} + g_{IM,J} - g_{JI,M}). \tag{25}$$

Therefore we may conclude that the differential equation governing wave kinematics may be identified with the Hamilton-Jacobi equation governing the motion of a massless particle traveling at the speed of light across the *n-dimensional* space, provided that the wave itself travels at the speed of light. Now we can split the n-vectors $(p_I),(x^I)$ into their components onto the physical space and p_i,x^i and the extra components $p_{\underline{i}},x^{\underline{i}}$ and write

$$\frac{\mathrm{d}p_i}{\mathrm{d}t} = g^{jk}{}_{,i}\frac{cp_j p_k}{2p} + g^{\underline{jk}}{}_{,i}\frac{cp_{\underline{j}}p_{\underline{k}}}{2p} + g^{j\underline{k}}{}_{,i}\frac{cp_j p_{\underline{k}}}{p}, \quad \frac{\mathrm{d}x^i}{\mathrm{d}t} = -c\frac{p^i}{p}, \tag{26}$$

$$\frac{\mathrm{d}p_{\underline{i}}}{\mathrm{d}t} = g^{jk}{}_{,\underline{i}}\frac{cp_j p_k}{2p} + g^{\underline{jk}}{}_{,\underline{i}}\frac{cp_{\underline{j}}p_{\underline{k}}}{2p} + g^{j\underline{k}}{}_{,\underline{i}}\frac{cp_j p_{\underline{k}}}{p}, \quad \frac{\mathrm{d}x^{\underline{i}}}{\mathrm{d}t} = -c\frac{p^{\underline{i}}}{p}. \tag{27}$$

Moreover we can interpret

$$m = \frac{1}{c}\sqrt{-(2g^{\underline{ik}}p_k + g^{\underline{ik}}p_{\underline{k}})p_{\underline{i}}}, \tag{28}$$

as a constant rest mass of some particle provided that we assume

$$(2g^{\underline{ik}}p_k + g^{\underline{ik}}p_{\underline{k}})p_{\underline{i}} = \text{const}. \tag{29}$$

Such a choice is always possible since $p_I = \alpha\varphi_{,I}$ and φ is defined except for a nonvanishing factor according to (5). Then we gain the Hamiltonian of a massive particle:

$$H = c\sqrt{m^2c^2 + \vec{p}^2}, \quad \vec{p}^2 = -g^{ik}p_i p_k. \tag{30}$$

We point out that when

$$\tfrac{1}{2}g^{\underline{jk}}{}_{,i}p_j p_{\underline{k}} + g^{j\underline{k}}{}_{,i}p_j p_{\underline{k}} = 0, \tag{31}$$

and g_{jk} depends only on the observable variables t,x^i, the first equation in (26) becomes the equation of the geodesic trajectory of a particle of rest mass m crossing the physical 3D space in the presence of a gravitational field. More (nongravitational fields) described by $g_{\underline{jk}},g_{j\underline{k}}$, can be introduced in a Kaluza-Klein type theory (see Sec. VII).

III. dE BROGLIE AND EINSTIEN-PLANCK RELATIONS

The Hamilton generating function S, proportional to the function φ, can easily be evaluated by integration of Eq. (7), in which the ray velocity V^I has the direction of the normal vector n^I, resulting in

$$V^I = -cn^I. \tag{32}$$

Then the equation to be integrated becomes

$$\frac{\partial S}{\partial t} - cn^I \frac{\partial S}{\partial x^I} = 0, \tag{33}$$

or

$$\frac{\partial S}{\partial t} + c\frac{\partial S}{\partial x_n} = 0, \tag{34}$$

since

$$n^I S_{,I} = -\frac{\partial S}{\partial x_n}, \quad x_n = x^I n_I.$$

The solution is

$$S = f(x_n - ct) \equiv f(x^I n_I - ct) \equiv f(x^i n_i + x^{\underline{i}} n_{\underline{i}} - ct), \tag{35}$$

where f may be any differentiable function of its argument $x_n - ct$. Such kind of solution is what in wave propagation theory is called a *simple wave*.[19–21] Since $S = \alpha\varphi$, it results also that

$$\varphi = \frac{1}{\alpha} f(x^i n_i + x^{\underline{i}} n_{\underline{i}} - ct). \tag{36}$$

Then the canonical momenta, evaluated during the wave-particle motion, become

$$p_I = \alpha\varphi' n_I, \Leftrightarrow p_i = \alpha\varphi' n_i, \quad p_{\underline{i}} = \alpha\varphi' n_{\underline{i}}, \tag{37}$$

and the Hamiltonian:

$$H \equiv E = \alpha c \varphi'. \tag{38}$$

It proves convenient to introduce the following quantities related to wave propagation:

$$k_I = \varphi' n_I, \Leftrightarrow k_i = \varphi' n_i, \quad k_{\underline{i}} = \varphi' n_{\underline{i}}, \tag{39}$$

$$\omega = c\varphi'. \tag{40}$$

On identifying the constant α with Planck's constant the following well-known relations arise naturally:

$$p_I = \hbar\, k_I \Leftrightarrow p_i = \hbar\, k_i, \quad p_{\underline{i}} = \hbar\, k_{\underline{i}} \text{ (de Broglie)}, \tag{41}$$

$$E = \hbar\, \omega \text{ (Einstien-Planck)}. \tag{42}$$

In the special case of a periodic wave it is immediate to recognize in the quantities $\omega, (k_I) \equiv (k_i, k_{\underline{i}})$, the frequency and the wave number vectors.

IV. WAVE DYNAMICS AND FIELD EQUATIONS

The problem of wave dynamics consists in determining a class of field equation candidates to explain the wave kinematics equivalent to Hamilton-Jacobi particle mechanics, as examined in the previous sections. Of course the main condition required by the system of field equations is that it must provide waves traveling with the speed of light across an *n-dimensional* space, but that condition alone is too wide to characterize a physically meaningful class of field equations. So we need some other reasonable assumptions. Therefore we will require the following ones:

(i) The system of field equations must be Lagrangian. This condition is usual for physical fields and needs no special explanation.
(ii) The production term of the system must be zero (at least in correspondence to the simple wave solutions). This second assumption is required in order to provide regular solutions to the system as simple waves,[19–21] ensuring that the particles travel along the rays at characteristic speeds. In principle also discontinuity waves[22] could be considered, but if we want to be able to compare the results with quantum mechanical ones we need regular solutions which can be expanded into Fourier series.
(iii) The normal speed of all simple waves must be equal to the speed of light c. This is the true kinematic condition we have previously examined.

The Lagrangian system. Let us consider a candidate field $\boldsymbol{\psi}$, which in general may be a complex column vector belonging to an N-dimensional Euclidean complex space, and is assumed to be a set of regular functions of x^I,t, invariant with respect to any regular coordinate transformation; and let

$$L \equiv \sqrt{|g|}\mathcal{L}(\boldsymbol{v},\boldsymbol{v}^+,\boldsymbol{w}_I,\boldsymbol{w}_I^+), \quad \boldsymbol{v} = \frac{\partial \boldsymbol{\psi}}{\partial t}, \quad \boldsymbol{w}_I = \frac{\partial \boldsymbol{\psi}}{\partial x^I} \tag{43}$$

be a Lagrangian density governing the field dynamics (where $^+$ denotes the transposed complex conjugation). Such Lagrangian is supposed to depend only on $\boldsymbol{v},\boldsymbol{w}_I$, in order to fulfill assumption (ii). Then the system of first-order field equations is

$$\frac{\partial}{\partial t}\left(\sqrt{|g|}\frac{\partial \mathcal{L}}{\partial \boldsymbol{v}^+}\right) + \frac{\partial}{\partial x^I}\left(\sqrt{|g|}\frac{\partial \mathcal{L}}{\partial \boldsymbol{w}_I^+}\right) = 0, \tag{44}$$

$$\frac{\partial \boldsymbol{w}_I}{\partial t} - \frac{\partial \boldsymbol{v}}{\partial x^I} = 0 \tag{45}$$

(together with its complex conjugate). On applying the correspondence rules,[19]

$$\frac{\partial}{\partial t}(\cdot) \to -\lambda\frac{\partial}{\partial \varphi}(\cdot) \equiv -\lambda(\cdot)', \quad \frac{\partial}{\partial x^I}(\cdot) \to n_I\frac{\partial}{\partial \varphi}(\cdot) \equiv n_I(\cdot)', \tag{46}$$

prime denoting differentiation respect to φ, we obtain, according to wave propagation theory, the algebraic system for the simple waves:

$$-\lambda\left(\sqrt{|g|}\frac{\partial \mathcal{L}}{\partial \boldsymbol{v}^+}\right)' + n_I\left(\sqrt{|g|}\frac{\partial \mathcal{L}}{\partial \boldsymbol{w}_I^+}\right)' = 0, \tag{47}$$

$$-\lambda \boldsymbol{w}_I' - n_I \boldsymbol{v}' = 0, \tag{48}$$

in which λ is the characteristic normal speed of the simple waves and the unknown field variables $\boldsymbol{v},\boldsymbol{w}_I$ are functions of φ. We point out that even if the wave propagation theory we are applying here was originally carried out in the context of real valued fields, its extension to complex fields is straightforward (see, e.g., Ref. 23). Simple manipulations on (47) and (48), after eliminating $\boldsymbol{w}_I$ by direct substitution, lead to

$$n_I\left\{\lambda^2\frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{v}^+\,\partial \boldsymbol{v}}g^{IJ} - \lambda\left(n^I\frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{v}^+\,\partial \boldsymbol{w}_J} + \frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{w}_I^+\,\partial \boldsymbol{v}}n^J\right) - \frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{w}_I^+\,\partial \boldsymbol{w}_J}\right\}n_J\boldsymbol{v}' = 0. \tag{49}$$

Since the Lagrangian density cannot depend on the wave front geometry, i.e., on n_I, the following conditions must hold:

$$\lambda^2 \frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{v}^+ \partial \boldsymbol{v}} g^{IJ} - \frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{w}_I^+ \partial \boldsymbol{w}_J} = 0, \tag{50}$$

$$\frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{v}^+ \partial \boldsymbol{w}_J} = 0 \Leftrightarrow \frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{w}_I^+ \partial \boldsymbol{v}} = 0. \tag{51}$$

The latter condition implies that

$$\mathcal{L} = \mathcal{L}_1(\boldsymbol{v}, \boldsymbol{v}^+) + \mathcal{L}_2(\boldsymbol{w}_I, \boldsymbol{w}_I^+), \tag{52}$$

which introduced into the former yields

$$\lambda^2 \frac{\partial^2 \mathcal{L}_1}{\partial \boldsymbol{v}^+ \partial \boldsymbol{v}} g^{IJ} - \frac{\partial^2 \mathcal{L}_2}{\partial \boldsymbol{w}_I^+ \partial \boldsymbol{w}_J} = 0. \tag{53}$$

Thanks to our assumption (iii), the normal speeds of simple wave propagation must equal the speed of light, and therefore (53) becomes

$$c^2 \frac{\partial^2 \mathcal{L}_1}{\partial \boldsymbol{v}^+ \partial \boldsymbol{v}} g^{IJ} = \frac{\partial^2 \mathcal{L}_2}{\partial \boldsymbol{w}_I^+ \partial \boldsymbol{w}_J}. \tag{54}$$

The Hessian matrices of $\mathcal{L}_1, \mathcal{L}_2$ are manifestly independent of the fields $\boldsymbol{v}, \boldsymbol{w}_I$, so we may write them as

$$\frac{\partial^2 \mathcal{L}_1}{\partial \boldsymbol{v}^+ \partial \boldsymbol{v}} = \frac{1}{c^2} \mathsf{a}, \tag{55}$$

$$\frac{\partial^2 \mathcal{L}_2}{\partial \boldsymbol{w}_I^+ \partial \boldsymbol{w}_J} = g^{IJ} \mathsf{a}, \tag{56}$$

where a is a nonsingular Hermitian matrix, independent of the fields. From those conditions the form of Lagrangian density is determined as

$$L = \tfrac{1}{2} \sqrt{|g|} \left(g^{IJ} \boldsymbol{w}_I^+ \mathsf{a} \boldsymbol{w}_J + \frac{1}{c^2} \boldsymbol{v}^+ \mathsf{a} \boldsymbol{v} \right). \tag{57}$$

The Euler-Lagrange equations are given by

$$\frac{\partial}{\partial t} (\sqrt{|g|} \mathsf{a} \boldsymbol{v}) + \frac{\partial}{\partial x^J} (c^2 \sqrt{|g|} g^{IJ} \mathsf{a} \boldsymbol{w}_J) = 0, \tag{58}$$

or

$$(\mathsf{a} \boldsymbol{v})_{;0} + (c g^{IJ} \mathsf{a} \boldsymbol{w}_J)_{;I} = 0. \tag{59}$$

We observe that a, beside being independent of the fields $\boldsymbol{v}, \boldsymbol{w}_I$, must be independent also of x^I, t, otherwise a nonvanishing production term will arise into the field equations. Then, since a is a nonsingular matrix, taking account of the metricity condition ($g^{IJ}{}_{;K}=0$), the field equations result simply:

$$\boldsymbol{v}_{;0} + c g^{IJ} \boldsymbol{w}_{J;I} = 0, \quad c \boldsymbol{w}_{I;0} - \boldsymbol{v}_{;I} = 0. \tag{60}$$

The coefficient matrix a disappears from the equations and its role becomes irrelevant in the Lagrangian; so it is not a restriction to choose:

$$\mathsf{a} = k\mathsf{I}, \tag{61}$$

with k the dimensional constant and I the identity matrix in the field space. Then the scalar Lagrangian density becomes

$$\mathcal{L} = \frac{1}{2}k\left(g^{IJ}\boldsymbol{w}_I^+\boldsymbol{w}_J + \frac{1}{c^2}\boldsymbol{v}^+\boldsymbol{v}\right). \tag{62}$$

We point out that the algebraic system which determines the simple waves, arising from (60), which is given by

$$\frac{1}{c}\lambda\boldsymbol{v}' - cn^I\boldsymbol{w}_I' = 0, \quad \lambda\boldsymbol{w}_I' + n_I\boldsymbol{v}' = 0, \tag{63}$$

yields, through direct substitution,

$$(\lambda^2 - c^2)\boldsymbol{v}' = 0, \tag{64}$$

from which the characteristic speeds become

$$\lambda = \pm c. \tag{65}$$

Such values imply, significantly, that the energy of the particle associated to wave propagation, thanks to (16), taking into account that $V=\lambda$, results to be

$$E = \pm\sqrt{m^2c^4 + c^2\vec{p}^2}. \tag{66}$$

The latter result states that, corresponding to any simple wave front traveling at normal speed $+c$, there exists an identical wave front traveling in the opposite sense at speed $-c$; that is usual in wave propagation. And, corresponding to a particle of energy $+|E|$, associated with the former wave, there exists another particle of negative energy $-|E|$, associated to the latter wave. Such circumstance, as it is well known, was noticed for the first time by Dirac, examining the solutions of his famous equation. According to our present approach the result arises naturally as a consequence of wave particle correlation expressed by (16), being $V=\lambda$, and the assumption that the system of field equations is Lagrangian.

V. THE KLEIN-GORDON EQUATION

Let us now study in more detail the system of field equations (60).

A. Second-order formulation

First of all we point out that we can always replace the fields $\boldsymbol{v}, \boldsymbol{w}_I$, with their original definitions in terms of derivatives of the field $\boldsymbol{\psi}$, according to (43), obtaining a system of N second-order equations, instead of the original system of $2N$ first-order equations:

$$\boldsymbol{\psi}_{;0;0} + g^{IJ}\boldsymbol{\psi}_{;I;J} = 0. \tag{67}$$

This generalized D'Alembert equation governing the propagation of the field $\boldsymbol{\psi}$ across the *n-dimensional* space is equivalent to a generalized Klein-Gordon equation for the propagation of the same field across the physical *three-dimensional* space. In fact the solutions of the field, being simple waves, depend on the argument $x_n - ct$ being composite functions through φ of the same argument. Now:

$$x_n - ct \equiv \frac{1}{p}(p_I x^I - cpt) \equiv \frac{c}{E}(p_I x^I - Et). \tag{68}$$

Therefore we can consider the field $\boldsymbol{\psi}$ as a function of the form:

$$\boldsymbol{\psi} \equiv \boldsymbol{\psi}(p_i x^i + p_{\underline{i}} x^{\underline{i}} - Et). \tag{69}$$

Without affecting time we may choose the space coordinates $x^{\underline{i}}$ in such a way that

$$x^n = x^i N_{\underline{i}}, \quad g^{nn} \equiv g^{\underline{jk}} N_{\underline{j}} N_{\underline{k}} = -1, \quad g^{ij} = g^{j\underline{i}} = 0, \tag{70}$$

with

$$p_{\underline{i}} = -mcN_{\underline{i}}, \quad N_{\underline{i}} = \frac{p_{\underline{i}}}{\sqrt{-g^{\underline{jk}} p_{\underline{j}} p_{\underline{k}}}}. \tag{71}$$

Then the simple wave will travel across a five-dimensional sub-space-time, resulting in (69)

$$\boldsymbol{\psi} \equiv \boldsymbol{\psi}(p_i x^i + mcx^n - Et). \tag{72}$$

If we require the additional assumption that $\boldsymbol{\psi}$ belongs to the Hilbert space L^2, so that it can be expanded into Fourier series, we can write

$$\boldsymbol{\psi} = \sum_{r=-\infty}^{+\infty} \boldsymbol{c}_r e^{(i/\hbar)(p_{ri}x^i + mcx^n - E_r t)} \equiv e^{(i/\hbar)mcx^n} \sum_{r=-\infty}^{+\infty} \boldsymbol{c}_r e^{(i/\hbar)(p_{ri}x^i - E_r t)}, \tag{73}$$

where the energies result to be

$$E_r = c\sqrt{\vec{p}_r^{\,2} + m^2c^2}. \tag{74}$$

Then we are able to evaluate the Laplacian:

$$g^{\underline{ij}} \boldsymbol{\psi}_{;\underline{i};\underline{j}} = \frac{m^2c^2}{\hbar^2} \boldsymbol{\psi}.$$

Then the field equation (67) leads to the Klein-Gordon equation in generalized coordinates:

$$\boldsymbol{\psi}_{;0;0} + g^{ij} \boldsymbol{\psi}_{;i;j} + \frac{m^2c^2}{\hbar^2} \boldsymbol{\psi} = 0. \tag{75}$$

B. First-order formulation

A further relevant consideration arises on evaluating the divergence of $\boldsymbol{w}_I$ in terms of the field variables $\boldsymbol{w}_i, \boldsymbol{w}_{\underline{i}}$. Taking account of the previous results we have

$$\boldsymbol{w}_{\underline{j}} = \boldsymbol{w}_n \delta_{\underline{jn}}, \quad \boldsymbol{w}_{\underline{j};\underline{i}} = \frac{imc}{\hbar} \boldsymbol{w}_n \delta_{\underline{jn}}. \tag{76}$$

It follows into the system (60):

$$\boldsymbol{v}_{;0} + cg^{ij} \boldsymbol{w}_{j;i} + i\frac{mc^2}{\hbar} \boldsymbol{w} = 0, \tag{77}$$

$$c\boldsymbol{w}_{i;0} - \boldsymbol{v}_{;i} = 0, \quad c\boldsymbol{w}_{n;0} - \boldsymbol{v}_{;n} = 0. \tag{78}$$

That result is equivalent to saying that we need only *one* extra space dimension to introduce the rest mass. Then the space-time needs to have five dimensions if the particle travels across a gravitational field or six if the electromagnetic field is added or more if other fundamental fields are present (Kaluza-Klein type theories).

VI. THE DIRAC EQUATION

In the *N-dimensional* linear space of the field variables $\boldsymbol{v}, \boldsymbol{w}_I$ it is always possible to find a set of n nonsingular matrices α^I relating the n vectors $(\boldsymbol{w}_I)$ with the vector $\boldsymbol{v}$ in such a way that

$$\boldsymbol{v} = c\alpha^I \boldsymbol{w}_I. \tag{79}$$

Thanks to (79), the field equations (60) may be written only in terms of $\boldsymbol{w}_I$ as

$$\alpha^I_{;0}\boldsymbol{w}_I + \alpha^I \boldsymbol{w}_{I;0} + g^{IJ}\boldsymbol{w}_{J;I} = 0, \tag{80}$$

$$\boldsymbol{w}_{I;0} - \alpha^J_{;I}\boldsymbol{w}_J - \alpha^J \boldsymbol{w}_{J;I} = 0. \tag{81}$$

On taking the scalar product of (81) by α^I we have

$$\alpha^I \boldsymbol{w}_{I;0} - \alpha^I \alpha^J_{;I}\boldsymbol{w}_J - \alpha^I \alpha^J \boldsymbol{w}_{J;I} = 0. \tag{82}$$

Now we need to remember that $\boldsymbol{w}_J$ is a gradient of a field which is scalar with respect to any regular coordinate transformation, being by its definition given by the third equation in (43):

$$\boldsymbol{w}_J = \boldsymbol{\psi}_{;J} \equiv \boldsymbol{\psi}_{,J}.$$

Then,

$$\boldsymbol{w}_{J;I} \equiv \boldsymbol{\psi}_{;J;I} \equiv \boldsymbol{\psi}_{,J,I} - \Gamma^K_{IJ}\boldsymbol{\psi}_K$$

is symmetric with respect to I, J. Therefore (82) becomes

$$\alpha^I \boldsymbol{w}_{I;0} - \alpha^I \alpha^J_{;I}\boldsymbol{w}_J - \tfrac{1}{2}(\alpha^I \alpha^J + \alpha^J \alpha^I)\boldsymbol{w}_{J;I} = 0. \tag{83}$$

Subtraction of (83) from (80), after few manipulations, leads to

$$(\alpha^J_{;0} + \alpha^I \alpha^J_{;I})\boldsymbol{w}_J + \tfrac{1}{2}(\alpha^I \alpha^J + \alpha^J \alpha^I - 2g^{IJ}\mathrm{I})\boldsymbol{w}_{J;I} = 0. \tag{84}$$

The last condition (84) holds for any value of the field $\boldsymbol{w}_J$ and its derivatives $\boldsymbol{w}_{J;I}$, iff

$$\alpha^J_{;0} + \alpha^I \alpha^J_{;I} = 0, \tag{85}$$

$$\alpha^I \alpha^J + \alpha^J \alpha^I = -2g^{IJ}\mathrm{I}. \tag{86}$$

It is easy to recognize in the last relation a general relativistic extension of the same anticommutation rule holding for the Dirac matrices.[24] The matrices α^I must also fulfill condition (85). Equations (60) are now dependent and lead to a field equation of the form:

$$\boldsymbol{v}_{;0} - \alpha^I \boldsymbol{v}_{;I} + c\alpha^I \alpha^J_{;I} w_J = 0, \tag{87}$$

which represents a generalized form of the Dirac equation.

We point out that each matrix α^J, when multiplied by itself, becomes equal to the identity matrix. Then its eigenvalues are ± 1. With a suitable choice of a locally flat coordinate system we can always diagonalize one of such matrices. When $N=4$ the last choice, together with the anticommutation rule (86) and the assumption that the matrices are constant, yields to the known Dirac matrices. Moreover the field equation (87) becomes the usual Dirac equation:

$$\frac{\partial \boldsymbol{v}}{\partial t} + c\vec{\alpha}\cdot\vec{\nabla}\boldsymbol{v} + i\frac{mc^2}{\hbar}\beta\boldsymbol{v} = 0. \tag{88}$$

VII. KALUZA-KLEIN TYPE THEORIES

Starting from the previous results, having arisen in the context of wave propagation theory versus Hamiltonian mechanics, we are naturally led to include the field $\boldsymbol{\psi} \equiv (\psi^{(\bar{h})}), \bar{h} = 1, 2, \ldots, N$ among the components of the metric tensor of the manifold V^{n+1} following a Kaluza-Klein type scheme.[25] Some authors proposed different methods to deduce the Klein-Gordon equation, for a scalar field, from a Kaluza-Klein theory, dealing with the physical space-time (V^4) filled by matter, as embedded into a higher dimensional empty space-time: see, e.g., Refs. 10–18. Here we propose a way to involve even more fields $\psi^{(\bar{h})}$.

A. Particle traveling across a gravitational field

In the absence of electromagnetic and Yang-Mills fields we suppose to work in a V^{5+N} space-time manifold on which we represent the metric tensor and its inverse as,

$$(g_{AB}) \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & g_{ij} & 0 & 0 \\ 0 & 0 & -(\psi^{(\bar{h})})^2 \delta_{\bar{h}\bar{k}} & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \tag{89}$$

$$(g^{AB}) \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & g^{ij} & 0 & 0 \\ 0 & 0 & -\dfrac{1}{(\psi^{(\bar{h})})^2} \delta^{\bar{h}\bar{k}} & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \tag{90}$$

where no summation is intended under the repeated couples $(\bar{h})$-$\bar{h}$ or $(\bar{k})$-$\bar{k}$.

If we assume that $g_{jk}(t, x^i), \psi^{(\bar{h})}(t, x^i, x^n)$, according to the coordinate choice (70), the non-null field equations become

$$\tilde{R}_{00} - \tfrac{1}{2}\tilde{R} = \kappa T_{00}, \tag{91}$$

$$\tilde{R}_{jk} - \tfrac{1}{2}\tilde{R} g_{jk} = \kappa T_{jk}, \tag{92}$$

$$\psi^{(\bar{h})}_{;0;0} + g^{jk} \psi^{(\bar{h})}_{;j;k} = \psi^{(\bar{h})}_{;n;n}, \tag{93}$$

where $\tilde{R}_{00}, \tilde{R}_{jk}$ denote the non-null components of the Ricci tensor related to the V^4 physical space-time, and

$$\kappa T_{00} = -\sum_{\bar{h}=1}^{N} \frac{\psi^{(\bar{h})}_{;0;0}}{\psi^{(\bar{h})}}, \quad \kappa T_{jk} = -\sum_{\bar{h}=1}^{N} \frac{\psi^{(\bar{h})}_{;j;k}}{\psi^{(\bar{h})}}, \tag{94}$$

are the nonvanishing energy-momentum tensor components arising on V^4.

Moreover it results that

$$p_{\underline{j}} \equiv \hbar\, \varphi_{,\underline{j}} = \hbar\, \delta_{\underline{j}n} \varphi_{,n} \equiv \delta_{\underline{j}n} p_n. \tag{95}$$

Then the particle equation of motion [the first equation in (26)] becomes

$$\frac{\mathrm{d}p_i}{\mathrm{d}t} = g^{jk}{}_{,i}\frac{cp_jp_k}{2p} + g^{nn}{}_{,i}\frac{cp_n^2}{2p}, \tag{96}$$

since $g^{nn}=-1$, the previous equation becomes the geodesic condition on the physical space:

$$\frac{\mathrm{d}p_i}{\mathrm{d}t} = g^{jk}{}_{,i}\frac{cp_jp_k}{2p}. \tag{97}$$

B. Adding the electromagnetic field

The electromagnetic field can be added according to a Kaluza-Klein scheme, by the metric tensor:

$$(g_{AB}) \equiv \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & \bar{g}_{ij} & \kappa\phi^2 A_k & 0 & 0 \\ 0 & \kappa\phi^2 A_j & -\phi^2 & 0 & 0 \\ 0 & 0 & 0 & -(\psi^{(\bar{h})})^2\delta_{\bar{h}\bar{k}} & 0 \\ 0 & 0 & 0 & 0 & -1 \end{pmatrix}, \tag{98}$$

with

$$\bar{g}_{ij} = g_{ij} - \kappa^2\phi^2 A_jA_k, \tag{99}$$

ϕ being the Kaluza-Klein dilaton scalar field and A_j the electromagnetic vector potential.

We emphasize that we need to choose the *radiation gauge* $g_{40}\equiv A_0=0$ in order to preserve the synchronization assumption (1).

C. Adding the Yang-Mills fields

In a similar way one can introduce also Yang-Mills fields into the metric tensor:[26–28]

$$(g_{AB}) \equiv \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & \hat{g}_{ij} & \kappa\phi^2 A_k & \kappa(\phi^{(a)})^2 A_k^b & 0 \\ 0 & \kappa\phi^2 A_j & -\phi^2 & 0 & 0 \\ 0 & \kappa\phi^2 A_j & \kappa(\phi^{(a)})^2 A_j^a & -(\phi^{(a)})^2\delta^{ab} & 0 \\ 0 & 0 & 0 & 0 & -(\psi^{(\bar{h})})^2\delta_{\bar{h}\bar{k}} \\ 0 & 0 & 0 & 0 & -1 \end{pmatrix},$$

$$\hat{g}_{ij} = g_{ij} - \kappa^2\{\phi^2 A_jA_k + (\phi^{(a)})^2\delta_{ab}A_j^aA_k^b\}, \tag{100}$$

with the gauge choices $A_0=0, A_0^a=0$.

VIII. CONCLUSION

We have examined in some detail, in the context of general relativity, in a synchronous gauge, the idea that particle trajectories of motion can be the same as the rays of suitable waves propagating across the space. Moreover we have suggested that the wave front propagation equation and the Hamilton-Jacobi equation of some particle motion could represent two ways of interpreting the same differential equation. Such assumption has led us to the condition that the wave normal speed must be equal to the speed of light in empty space and the consequence that massive free particles can exist only if the space has more than three dimensions. In order to establish a Lagrangian complex field theory capable of generating the waves we need, we found that the field equation needs to be linear with respect to the new field variables and assume the form of a

D'Alembert equation in general coordinates. We have also shown that the field equations we obtained can be written either in the form of Klein-Gordon equation (second-order formulation) or as Dirac equation (first-order formulation) when $N=4$. Moreover we have shown how to include the new additional field ψ into the frame of Kaluza-Klein type theories.

ACKNOWLEDGMENT

I want to thank the referee for interesting suggestions and helpful bibliographical remarks.

Separation of unistochastic matrices from the double stochastic ones: Recovery of a 3×3 unitary matrix from experimental data

Petre Diţă[a)]
Institute of Physics and Nuclear Engineering, P.O. Box MG6, Bucharest, Romania

(Received 12 May 2006; accepted 19 June 2006; published online 17 August 2006)

The aim of the paper is to provide a constructive method for recovering a unitary matrix from experimental data. Since there is a natural immersion of unitary matrices within the set of double stochastic ones, the problem to solve is to find necessary and sufficient criteria that separate the two sets. A complete solution is provided for the three-dimensional case, accompanied by a χ^2 test necessary for the reconstruction of a unitary matrix from error affected data. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2229424]

I. INTRODUCTION

An $n\times n$ matrix M is said to be double stochastic if its elements satisfy the relations

$$m_{ij}\geqslant 0,\quad \sum_{i=1}^{n} m_{ij}=1,\quad \sum_{j=1}^{n} m_{ij}=1. \tag{1}$$

All such matrices form a convex set called the Birkhoff's polytope.[1] The unistochastic matrices are a subset of the double stochastic ones defined by

$$m_{ij}=|U_{ij}|^2, \tag{2}$$

where U is a unitary matrix, i.e., satisfies the relation

$$UU^{\dagger}=U^{\dagger}U=I_n, \tag{3}$$

where † denotes the adjoint, and I_n is the n-dimensional unit matrix.

It is well known that for $n\geqslant 3$ there are double stochastic matrices that are not unistochastic,[2] and from a mathematical point of view there are a few interesting problems that deserve to be solved:

(i) Given a double stochastic matrix, $M=(m_{ij})$, $i,j=1,\ldots,n$, what are the necessary and sufficient conditions for M to be unistochastic?
(ii) Supposing M unistochastic, to what extent the matrix U is determined by M, i.e., how many solutions one could get.
(iii) If M is unistochastic, how one can reconstruct the unitary U from the given data.

The problem (i) was completely solved only for the three-dimensional case.[3] A characterization of the subset of double stochastic matrices that come from unistochastic ones, Eq. (2), for $n=3$, was given in Refs. 3 and 4. For $n\geqslant 4$ only partial results are known, see, e.g., Refs. 5–12. In general the theoretical physicists working on this problem were not aware of the embedding of the unitary matrices into the double stochastic ones, Eq. (2), hence there was not an intrinsic pressure for solving problem (i). In this respect see Ref. 9, Introduction, where it is said: "*We are not*

[a)]Electronic mail: dita@zeus.theory.nipne.ro

concerned here with the **consistency** *problem, which amounts to obtaining necessary and sufficient conditions on the set of numbers* $|U_{jk}|$ *for this set to represent the moduli of a unitary matrix*."

In this paper we will provide necessary and sufficient conditions for the separation of the two sets, conditions expressed in terms of the entries of a double stochastic matrix on the independent parameters entering the unitary matrix. We mention also that the Theorem 1 in Ref. 3, which provides necessary and sufficient conditions in the $n=3$ case, is only an existence theorem, and it does not provide a constructive method for recovering a unitary matrix from a double stochastic one.

Concerning problem (ii) it was shown that the generic situation, for $n \geqslant 4$ is the existence of a continuum of solutions, see Refs. 6–9 and 11 and 12. In particular complex Hadamard matrices, i.e., unitary matrices with equal moduli, $|U_{ij}|=1/\sqrt{n}$, have been found that depend on arbitrary phases, see Refs. 13–17.

The solution of the mathematical problem (iii) for $n=3$ can be easily obtained, as we show in the following, but its applications in high energy physics presented some challenges since the measured numbers are affected by errors. Usually one starts with a theoretical model formalized by a unitary matrix, and the problem is to recover the unitary matrix from measurements of its moduli, or of some "angular looking objects," $U_{ij}U_{lk}U_{ik}^{*}U_{lj}^{*}$, where * means complex conjugation. When $|U_{ij}|^2$ are measured one gets a numerical matrix as

$$V=(V_{ij}^2), \tag{4}$$

where every V_{ij} is affected by errors, so we do not know how far from $|U_{ij}|$ are the measured values V_{ij}, and by consequence the double stochasticity relations (1) are only approximately satisfied, if any. More generally, that means that we have to test the full compatibility between the data and the unistochastic property. Second, by supposing the data are compatible with the existence of a unitary matrix we need a reliable algorithm for an explicit recovery of a unitary matrix from data, because some parameters entering the unitary matrix may have a physical significance, and we want to know them, an example being the CP-violating phase from the Cabibbo-Kobayashi-Maskawa (CKM) matrix.

Indeed the recovery of a unitary matrix from experimental data is a central problem in the electro-weak interactions[18] where the (assumed) unitary CKM matrix[19] plays a fundamental role. Hence the recovery problem of a unitary matrix from experimental data is not an academic problem, it has many practical consequences. Let us recall that there are two big collaborations, BaBar in the United States, and Belle in Japan whose efforts are to measure as exact as possible the b-quark related entries of the CKM matrix. In Europe, at CERN, there is under construction the LHC machine, one of its main aims being a better understanding of the so called B-physics. Thus a reliable algorithm for recovery of unitary matrices, able to obtain the independent parameters of the CKM matrix, could have consequences on both the design of future experiments, as well as on the design of future high energy machines, including neutrino factories.

The main goal of the paper is to provide a reliable algorithm for the reconstruction of a unitary matrix from experimental data, when these ones are compatible with the theoretical model. We mention that nowadays the algorithm for reconstruction of a 3×3 unitary matrix from experimental data does not make use of the double stochasticity relations (1), and the phenomenological model used to describe the data and to reconstruct a unitary matrix from them is mainly based on the use of a *single* orthogonality relation, expressed as a triangle in the complex plane,[20–29] although the proof of Theorem 1 from Ref. 3 explicitly stresses the necessity of using at least *two* orthogonality relations.

The paper is organized as follows. In Sec. II starting from the properties of double stochastic matrices and the embedding relation (2) of unitary matrices within that set, we describe the gauge group of unitary matrices, i.e., the group of the most elementary transformations whose action on the unitary matrices does not change the unitarity property, or the physical content. In Sec. III we provide a parametrization of unitary matrices that is essential in devising a reconstruction algorithm in terms of physically relevant quantities. In Sec. IV we define two phenomenological

models, unitarity condition method, and unitarity triangles method, by using the embedding (2) and the double stochasticity properties (1). We find the necessary and sufficient conditions the data have to satisfy in each model in order to be consistent with the unitarity properties, and give the reconstruction algorithm of unitary matrices from double stochastic matrices. In Sec. V we show that both approaches are completely equivalent, then and only then, when they are formulated in terms of *four* independent moduli; a consequence will be that the second model has to use at least *two* orthogonality relations. In Sec. VI we describe the reconstruction algorithm of unitary matrices from experimental data that are compatible with the double stochasticity property. With this aim in view we define χ^2-tests that allow the recovery of unitary matrices from error affected data, including a method for doing statistics on moduli of unitary matrices. The paper ends with conclusions.

II. UNITARY MATRICES AND THEIR GAUGE SUBGROUP
