(Received 12 August 2005; accepted 10 November 2005; published online 6 January 2006)

We examine a new application of the Holstein-Primakoff realization of the simple harmonic oscillator Hamiltonian. This involves the use of infinite-dimensional representations of the Lie algebra su(2). The representations contain nonstandard raising and lowering operators, which are nonlinearly related to the standard $a^\dagger$ and a. The new operators also give rise to a natural family of two-oscillator couplings. These nonlinear couplings are not generally self-adjoint, but their low-energy limits are self-adjoint, exactly solvable, and stable. We discuss the structure of a theory involving these couplings. Such a theory might have as its ultra-low-energy limit a Lorentz-violating Abelian gauge theory, and we discuss the extremely strong astrophysical constraints on such a model. © *2006 American Institute of Physics.*

I. INTRODUCTION

The simple harmonic oscillator is one of the best understood systems in quantum mechanics, with applications in essentially all areas of physics. However, there may remain many interesting properties of this system that have not been fully understood or elucidated (see Ref. 1, for instance). In this paper, we present an example of this. This example provides a possible way for nonlocal interactions to stabilize a Lorentz-violating modification to the free photon sector of the standard model.

We shall show how the Holstein-Primakoff realization of the angular momentum Lie algebra su(2) may be used in connection with the simple harmonic oscillator.[2] We first review the free oscillator, considered using the infinite-dimensional representations of this algebra. This leads naturally to a study of new nonlinear couplings between multiple identical harmonic oscillators. These couplings can be viewed in one of two ways. Taken at face value, the interactions are not self-adjoint, and the energy eigenvalues need not be real; however, the Hamiltonians in question do possess low-energy limits which are self-adjoint. The second possible viewpoint would be to take the formula which defines the real eigenvalues in the low-energy regime and extend that formula to cover the full range of the quantum numbers. This has the advantage of ensuring unitary evolution, but the additional complexity of the Hamiltonian is a corresponding disadvantage.

We shall describe how these new interactions may manifest themselves in a physical theory, with particular emphasis on couplings between the two polarization modes of the free electromagnetic field. However they are interpreted, the interactions we shall discuss may be relevant as part of a nonlocal, Lorentz-violating quantum field theory. Recently, there has been a great deal of interest in the possibility that Lorentz symmetry may not be exact in nature. A violation of this kind of fundamental symmetry could arise as part of the novel physics of the Planck scale. Relics of this violation would then persist even in the low-energy effective theory. The general local Lorentz-violating standard model extension (SME) has been developed,[3–5] and the stability[6] and

[a)]Electronic mail: baltschu@indiana.edu

renormalizability[7] of this extension have been studied. Lorentz violation is a very interesting area of theoretical physics, because even superficially simple questions about its physics may have subtle and even ambiguous answers. For example, the study of the gauge invariance properties of and finite radiative corrections to Lorentz-violating field theories has proven to be a fruitful source for new theoretical insights.[8–13]

One significant difficulty with Lorentz-violating quantum field theories is that they frequently exhibit problems with stability.[6,14] Yet it has been suggested that some form of nonlocality might overcome this problem.[6,15] The harmonic oscillator interactions we consider can provide a concrete example for how this stabilization might work, if we adopt the second interpretation of these interactions as described above. In the limit of very low energies, the nonlocal interactions may couple together the two polarization modes of a free photon in exactly the same way as would a local, renormalizable operator from the SME.[3,14] However, the nonlocality ensures that the theory remains stable, even for very large photon numbers. Weak forms on nonlocality have also been considered in other Lorentz-violating contexts.[16]

The kinds of infinite-dimensional representations of su(2) that we will consider have also been introduced in the context of the Dirac Coulomb problem[17,18] and in generalizations of the Dirac monopole,[19] where they provide useful insights. Moreover, other Lie algebras also possess infinite-dimensional representations that are not representations of any corresponding Lie group. These representations might be useful in the study of certain quantum-mechanical systems, through a generalization of the techniques used in Refs. 17–19 or developed in this paper.

II. SINGLE-OSCILLATOR OPERATORS

We shall begin by reviewing the Holstein-Primakoff realization of the harmonic oscillator raising and lowering algebra. Most frequently, when one studies the representations of su(2) in connection with quantum mechanics, one is interested only in the finite-dimensional representations, which are countable and parametrized by the total angular momentum ℓ. One considers an operator $\vec{J}=(J_1,J_2,J_3)=\left(\frac{1}{2}J_+ + \frac{1}{2}J_-, (1/2i)J_+ - (1/2i)J_-, J_3\right)$, with standard commutation relations. Beginning from a highest weight state $|\ell\rangle$, with $J_+|\ell\rangle=0$, one constructs each of the $2\ell+1$ states $|\ell-s\rangle$ by acting on $|\ell\rangle$ with J_- s times and normalizing appropriately.

When 2ℓ is a non-negative integer, there are only these $2\ell+1$ states, because $J_-|-\ell\rangle=0$. However, for more general values of the highest weight, the sequence of states does not terminate. Instead, one constructs an infinite tower of equally spaced states. This tower of states has a structure which is identical to that of the simple harmonic oscillator.

In fact, if we begin with a highest weight state $|\lambda\rangle$, with $J_3|\lambda\rangle=\lambda|\lambda\rangle$ (where 2λ is not a non-negative integer), we may construct states $|\lambda-n\rangle$ for all non-negative integers n, using $J_-|\lambda-n\rangle=\sqrt{\lambda(\lambda+1)-(\lambda-n)(\lambda-n-1)}|\lambda-n-1\rangle$. Then the Hamiltonian $H_\lambda=-\omega J_3+\omega\left(\lambda+\frac{1}{2}\right)$ has nondegenerate eigenvalues $\left(n+\frac{1}{2}\right)\omega$, which are precisely the energy eigenvalues of a harmonic oscillator (when we set $\hbar=1$). Since a quantum-mechanical system is entirely specified by its Hilbert space and the Hamiltonian acting on that space, this is equivalent to an alternate description of the harmonic oscillator. (Note that this description is completely distinct from Schwinger's development of the angular momentum algebra in terms of harmonic oscillator states.[20])

We should point out that the state space is a representation only of the Lie algebra su(2), not of the Lie group SU(2). That this is the case should be clear from an examination of the spectrum of the Hamiltonian $H_{\hat{n}}=\omega\hat{n}\cdot\vec{J}$. This would be a Zeeman effect Hamiltonian if the representation of $\vec{J}$ were finite dimensional, with $\vec{J}$ transforming in the adjoint representation of SU(2). The SU(2) symmetry would then dictate that the eigenenergies should be independent of the direction of $\hat{n}$. However, those energies are clearly not independent of $\hat{n}$ for the infinite-dimensional representations we are now considering. Specifically, if $\hat{n}=-\hat{e}_3$, then we have a harmonic oscillator system, but if $\hat{n}=+\hat{e}_3$, then the energy is not bounded from below. Therefore, the infinite-dimensional operators cannot form a representation of the group SU(2).

We shall now relabel our states, so that they match the usual harmonic oscillator nomencla-

ture. We make the replacement $|\lambda - n\rangle \rightarrow |n\rangle$. Now, in addition to the standard harmonic oscillator raising and lowering operators $a^\dagger$ and a, we have a new set of raising and lowering operators J_- and J_+, given by

$$J_-|n\rangle = \sqrt{\lambda(\lambda+1) - (\lambda - n)(\lambda - n - 1)}|n+1\rangle, \tag{1}$$

$$J_+|n\rangle = \sqrt{\lambda(\lambda+1) - (\lambda - n)(\lambda - n + 1)}|n-1\rangle, \tag{2}$$

or

$$J_- = a^\dagger \sqrt{2\lambda - a^\dagger a}, \tag{3}$$

$$J_+ = a\sqrt{2\lambda - a^\dagger a + 1}. \tag{4}$$

The square root operators are to be interpreted as having eigenvalues equal to the square roots of the eigenvalues of the operators inside, with the same eigenvectors. For a mechanical oscillator, we may further express the $J_\pm$ in terms of the position and momentum operators x and p, using the usual linear relations connecting x and p to $a^\dagger$ and a; however, this substitution must be made with the understanding that the proper interpretation of the $J_\pm$ operators requires the use of the discrete "number of quanta present" basis of states.

The $J_\pm$ give us a new family of raising and lowering operators, parametrized by λ. These operators are distinct from the $a^\dagger$ and a for all finite λ. This is clear from the differing commutation relations $[a, a^\dagger] = 1$ and $[J_+, J_-] = 2J_3$. In general, for large n (large in comparison with λ and unity), the matrix elements of $J_\pm$ are larger than those of a and $a^\dagger$ by a factor of $\mathcal{O}(\sqrt{n})$. However, the new operators do include the a and $a^\dagger$ as limiting cases. As $\lambda \rightarrow \infty$, $(J_+/\sqrt{2\lambda}) \rightarrow a$ and $(J_-/\sqrt{2\lambda}) \rightarrow a^\dagger$. (These limits are to be interpreted in terms of the matrix elements of the operators involved, and all half-integral values of λ must be avoided as the limit is taken.)

We can see from (3) and (4) that $J_+ \neq J_-^\dagger$ for finite, non-half-integral λ, because the square roots in (3) and (4) may become imaginary. This means that J_1 and J_2 are not self-adjoint, a difficulty which we glossed over when we discussed the Hamiltonian $H_{\hat{n}}$. The Casimir operator $\vec{J}^2$ is self-adjoint, however. Moreover, in the basis of eigenstates of J_3, $J_+ = J_-^T$. Since the matrix elements of J_- and $J_+^\dagger$ differ only by phase factors in the J_3 basis, there is no ambiguity in defining the entire state space starting from the ground state. Finally, we point out that if λ is large and positive, then the non-self-adjoint character of $\vec{J}$ does not become apparent unless n is at least comparable to 2λ. These facts will prove important when we discuss the coupling between two harmonic oscillators.

III. MULTIPLE COUPLED OSCILLATORS

We shall now consider a novel application of this description of the harmonic oscillator. We may determine the energy eigenvalues exactly for certain systems of coupled identical oscillators in which the couplings are nonlinear. Let us consider the Hamiltonian

$$H = H_\lambda + H_\mu + gH_{\text{int}} \tag{5}$$

$$H = \left[-\omega J_{A3} + \left(\lambda + \frac{1}{2}\right)\omega\right] + \left[-\omega J_{B3} + \left(\mu + \frac{1}{2}\right)\omega\right] + gH_{\text{int}}. \tag{6}$$

$\vec{J}_A$ and $\vec{J}_B$ are two independent vectors of operators of the type we have been considering, corresponding to the highest weights λ and μ, respectively. H_{int} is an interaction, whose form we shall discuss shortly. This Hamiltonian has three adjustable parameters. λ and μ determine the structure of the harmonic oscillator representations that we are using. However, like g, they may be seen as parameters describing the interaction, because we have shifted the total energy in such a way as to

make the spectrum of the free oscillators' Hamiltonian $H_\lambda + H_\mu$ independent of both λ and μ. These two parameters may be chosen freely, subject to the condition that neither 2λ nor 2μ is a non-negative integer.

We shall choose an interaction gH_{int} that is similar in form to $g\vec{J}_A \cdot \vec{J}_B$. If $g \neq 0$, $g\vec{J}_A \cdot \vec{J}_B$ is not self-adjoint; however, if λ and μ are large and positive, this problem will not be apparent in the vicinity of the ground state. So we take H_{int} to agree with $\vec{J}_A \cdot \vec{J}_B$ when $n_A + n_B + 1 < \min(2\lambda, 2\mu)$, where n_A and n_B are the principal quantum numbers of the two oscillators. We may then consider the effects of this interaction within this restricted ("low-energy") regime.

We may solve the *restricted* Hamiltonian using the ordinary techniques for the addition of angular momenta. The operator $\vec{J} = \vec{J}_A + \vec{J}_B$ has highest weights of the form $\lambda + \mu - i$ for all non-negative integers i, and each value of i corresponds to a single irreducible component of the representation. The Clebsch-Gordon coefficients for these representations can be calculated by the standard method of applying lowering operators and using Gram-Schmidt orthonormalization. However, our primary interest is in the energy levels.

The eigenvalues of $H_\lambda + H_\mu$ are just $(n_A + n_B + 1)\omega$. When we change the basis, to use the "total angular momentum" $\vec{J}$, this part of the Hamiltonian becomes

$$H_\lambda + H_\mu = -\omega J_3 + (\lambda + \mu + 1)\omega. \tag{7}$$

The eigenstates of the system are parametrized by the highest weight $\lambda + \mu - i$ and by the "number of quanta present" (that is, the number of applications of J_- on the highest weight state required to produce a given state), n. If we denote these states by $|i,n\rangle$, then it is clear that $(H_\lambda + H_\mu)|i,n\rangle = (i+n+1)\omega|i,n\rangle$. Since i and n have the same range as n_A and n_B (all must be non-negative integers), this verifies that the free system has the same spectrum in each basis.

The coupling term must be calculated in the $\vec{J}$ basis. This is easily done, using $\vec{J}_A \cdot \vec{J}_B = \frac{1}{2}(\vec{J}^2 - \vec{J}_A^2 - \vec{J}_B^2)$. For a state of specified i, $\vec{J}_A \cdot \vec{J}_B$ has the eigenvalue $\lambda\mu - (\lambda + \mu + \frac{1}{2})i + \frac{1}{2}i^2$. So the total energy is

$$E_{i,n} = \omega(i + n + 1) + g\left[\lambda\mu - \left(\lambda + \mu + \tfrac{1}{2}\right)i + \tfrac{1}{2}i^2\right]. \tag{8}$$

This formula holds exactly in the entire low-energy subspace.

We must now turn our attention to the general definition of H_{int}. There are two natural ways to define this interaction. The first possibility is that $H_{\text{int}} = \vec{J}_A \cdot \vec{J}_B$ exactly, and the fundamental Hamiltonian is not self-adjoint. The second possibility involves a less drastic modification of the structure of the theory. We simply take the exact Hamiltonian to be defined by its eigenvalues, which have the form (8). There is a complete set of states $\{|i,n\rangle\}$ corresponding to these eigenenergies, and for $i + n + 1 < \min(2\lambda, 2\mu)$, these states agree with the ones found above. The new Hilbert space is not equivalent to the old, two-oscillator Hilbert space, but the restricted, low-energy subspaces of these two Hilbert spaces are isomorphic. We shall henceforth adopt this second definition of H_{int} (although most of our statements will concern only the low-energy subspace, where the two definitions are equivalent).

A few words about the various parameters are now in order. Our coupled system is stable only if $g \geqslant 0$; if $g < 0$, the energy is not bounded below. We also see that the structure of the energy levels depends only on g and $\lambda + \mu$; the separate values of λ and μ only affect the zero-point energy.

This is a strongly nonlinearly coupled system. We may recover the more usual result for the spectrum in the presence of a linear coupling between the oscillators by setting $\lambda = \mu$ and expressing $a^\dagger$ and a in terms of the $\lambda \to \infty$ limits of J_+ and J_-. (Note that as $\lambda \to \infty$, there are no problems with the operators being self-adjoint.) The interaction $g(a_A a_B^\dagger + a_A^\dagger a_B)$ is the limit of $(g/\lambda)(\vec{J}_A \cdot \vec{J}_B - J_{A3}J_{B3})$ as λ approaches infinity. The two terms $(g/\lambda)\vec{J}_A \cdot \vec{J}_B$ and $(g/\lambda)J_{A3}J_{B3}$ each commute with the noninteracting Hamiltonian; and, although they do not commute with each other for finite values of λ, they do commute in the infinite limit. We may see this by evaluating the two operators

for finite λ in different bases. In the $\vec{J}$ basis, the first term is diagonal, with eigenvalues $g\{\lambda-[2+(1/2\lambda)]i+(1/2\lambda)i^2\}$, just as calculated above. The second term is diagonal in the J_A, J_B basis, with eigenvalues $(g/\lambda)(\lambda-n_A)(\lambda-n_B)$. As $\lambda\to\infty$, these eigenvalues become $g(\lambda-2i)$ and $g(\lambda-n_A-n_B)$, respectively. However, as we saw when we discussed the noninteracting case, the total number operator $n_A+n_B=n+i$ is diagonal in both bases, so $g(\lambda-n_A-n_B)=g(\lambda-n-i)$. Then the total energy shift, which is now the difference between $g(\lambda-2i)$ and $g(\lambda-n-i)$, becomes simply $g(n-i)$. That is, we have two decoupled oscillators with frequencies $\omega\pm g$, which is just the usual result.

More general interactions are also possible. We may replace $g\vec{J}_A\cdot\vec{J}_B$ with an arbitrary function of $\vec{J}_A\cdot\vec{J}_B$. Any such interaction will still commute with $H_\lambda+H_\mu$, and all the same considerations will still apply. Other generalizations are possible as well, through the use of other well-known properties of su(2). For example, we may generalize to the coupling of N identical oscillators, with the identity

$$\sum_{1\leqslant C<D\leqslant N}\vec{J}_C\cdot\vec{J}_D=\frac{1}{2}\left[\left(\sum_{C=1}^{N}\vec{J}_C\right)^2-\sum_{C=1}^{N}(\vec{J}_C)^2\right]. \tag{9}$$

However, it is important to keep in mind that many approximations that are typically used when one studies more than two interacting angular momenta will break down when working with infinite-dimensional representations of su(2).

IV. APPLICATION TO LORENTZ-VIOLATING QED

One of the simplest situations in which pairs of identical harmonic oscillators arise is in an Abelian gauge theory in 3+1 dimensions. An interaction of the form (6) might be relevant as a modification of the photon sector of quantum electrodynamics (QED). For the gauge sector alone, this interaction could be introduced separately at each value of the photon momentum. The selection of a specific basis of polarization states for each momentum, and the assignment of the couplings λ, μ, and g generally breaks Lorentz symmetry and may also break parity invariance. Moreover, the operators $J_\pm$ are nonlocal, since they involve the total energy present in a given mode of the electromagnetic field, and it is not possible to express this sort of interaction conveniently in terms of the ordinary electromagnetic field operators A^μ and $F^{\mu\nu}$. However, if we are willing to allow these modifications to the structure of the theory, the interaction is (in the absence of charges) exactly solvable. Since there is current interest in exotic modifications of QED, this type of interaction may be worthy of further investigation.

We must also say a word about the gauge invariance of this QED modification. The $\vec{J}_A\cdot\vec{J}_B$ interaction is formulated in terms of creation and annihilation operators (i.e., in the canonical quantization formalism), and so any discussion of gauge invariance will necessarily be complicated by the difficulties that are associated with the canonical quantization of gauge fields. However, at low energies, the interactions we have introduced are clearly consistent with gauge invariance in the following sense. If we specialize to the Coulomb gauge and quantize the transverse modes of the theory, then the low-energy interaction may be introduced without difficulty. It does not affect the number of polarization states (and is, in fact, strongly dependent upon this number), so it does not spoil gauge invariance in this fashion. However, it is possible that it may damage gauge invariance at higher energies or when interactions with matter are considered.

Although the interactions we are considering cannot be expressed simply in terms of the standard electromagnetic field operators, the ultra-low-energy limit of our theory could well be expressible in such a form. We shall shortly show that this is indeed the case for a particular class of models. The embedding of a ultra-low-energy Lorentz-violating effective field theory within the framework of our fundamental theory is attractive for several reasons. First, the interactions we have considered have eigenenergies that are exactly known. Second, although Lorentz-violating theories may exhibit stability problems, our theory does not; the i^2 term in (8) ensures this. This example shows that there can exist stable nonlocal interactions which have local, Lorentz-

violating Lagrangian theories as their ultra-low-energy limits. Third, such an embedding demonstrates the intriguing possibility that our conventional basis of polarization states may be inadequate for the description of the full Hilbert space of a more fundamental theory.

We shall therefore examine the ultra-low-energy behavior of our QED modification, to see to what sort of effective theory it may correspond. Since the energy-level differences depend only on $\lambda+\mu$, we shall set $\lambda=\mu$. We take λ to be a very large number, large in comparison with any relevant photon occupation number. (This is what we mean by "ultra-low-energy.") We may then neglect $a^\dagger a$ compared to λ in (3) and (4). It immediately follows that the energy eigenstates are approximately given by

$$|i,n\rangle \approx \frac{(a_A^\dagger - a_B^\dagger)^i (a_A^\dagger + a_B^\dagger)^n}{\sqrt{2^{i+n}(i!)(n!)}}|0,0\rangle. \tag{10}$$

Deviations from this expression are suppressed by a factor of $\mathcal{O}(\lambda^{-1/2})$. The corresponding energies, in the same approximation, are

$$E_{i,n} \approx (n+i)\omega + 2\lambda g i, \tag{11}$$

where we have dropped the zero-point energy.

These results imply that the polarization modes corresponding to $a_+^\dagger \equiv (1/\sqrt{2})(a_A^\dagger + a_B^\dagger)$ and $a_-^\dagger \equiv (1/\sqrt{2})(a_A^\dagger - a_B^\dagger)$ have different frequencies. The two frequencies are shifted from their mean value by $\pm\Delta\omega/2 \approx \pm g\lambda$, and the effective Hamiltonian is

$$H_{\text{eff}} = (\omega + 2\lambda g)a_-^\dagger a_- + \omega a_+^\dagger a_+. \tag{12}$$

This same effective Hamiltonian arises naturally in the context of a CPT-even, Lorentz-violating modification of the photon sector. For a theory with Lagrange density

$$\mathcal{L} = -\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu} - \tfrac{1}{4}k_{\kappa\tau\mu\nu}F^{\kappa\tau}F^{\mu\nu} \tag{13}$$

(where $k_{\kappa\tau\mu\nu}$ has the symmetries of a Riemann tensor and is double traceless), the expressions for the photon modes' frequencies are (to leading order in $k_{\kappa\tau\mu\nu}$)[6,7,11]

$$\omega_\pm = (1 + \rho \pm \sigma)|\vec{p}|. \tag{14}$$

Here, $\vec{p}$ is the photons' 3-momentum, $\rho = -\frac{1}{2}\tilde{k}_\alpha{}^\alpha$, and $\sigma^2 = \frac{1}{2}\tilde{k}_{\alpha\beta}\tilde{k}^{\alpha\beta} - \rho^2$, with $\tilde{k}_{\alpha\beta} = k_{\alpha\mu\beta\nu}\hat{p}^\mu\hat{p}^\nu$ and $\hat{p}^\mu = (1, \vec{p}/|\vec{p}|)$. The approximate frequencies given by (14) and (12) correspond if $\rho = \sigma = g\lambda$. So any theory with $\rho = \sigma \geqslant 0$ for all $\vec{p}$ will reproduce the entire low-energy behavior of our modified theory. Theories with this property indeed exist; for example, if $k_{\kappa\tau\mu\nu}$ has the form

$$k_{\kappa\tau\mu\nu} = (v_\kappa u_\tau - v_\tau u_\kappa)(v_\mu u_\nu - v_\nu u_\mu) - \tfrac{1}{6}[v^2u^2 - (v\cdot u)^2](g_{\kappa\mu}g_{\tau\nu} - g_{\kappa\tau}g_{\mu\nu}) + (\kappa \leftrightarrow \mu), \tag{15}$$

then $\rho = \sigma = -w^2$, where $w^\mu = v^\mu(u\cdot\hat{p}) - u^\mu(v\cdot\hat{p})$. If $v^\mu = (V, \vec{0})$ and $u^\mu = (0, \vec{u})$, with $|\vec{u}| = 1$, then $\rho = V^2 \sin^2\theta$, where θ is the angle between $\vec{u}$ and $\vec{p}$. This particular model is parity-preserving, with three independent parameters.

Moreover, any theory with nonvanishing σ will demonstrate a splitting between polarization modes, as would arise in our su(2)-modified QED. There is therefore a large theoretical parameter space in which the theory given by (13) can be embedded in a su(2) coupling model.

These embeddings all require that, for a fixed direction $\hat{p}$, the coupling $g\lambda$ must be proportional to $|\vec{p}|$. It would seem most natural for λ, which represents the number of photons that must be present in a mode of the electromagnetic field in order for the failure of the polarization state basis to be apparent, to remain large for all values of $|\vec{p}|$. We therefore speculate that λ may be a $|\vec{p}|$-independent (or $\vec{p}$-independent) constant, while g scales with the magnitude of $\vec{p}$.

Based upon astrophysical experiments, the physical value of σ is strongly constrained, to parts in 10^{31} or better.[21,22] This represents an even stronger constraint on the su(2) model, because λ is

necessarily very large. It follows that $g=\sigma/\lambda$ is correspondingly smaller. Our modification of QED is thus physically reasonable only in a very, very small region of parameter space.

However, the formalism we have developed could be useful for developing an effective model in any situation in which there is a frequency splitting between polarization modes. For example, when the quantum corrections due to virtual electron exchange are considered, the effective Lagrange density for the electromagnetic field acquires nonlinear terms and becomes[23,24]

$$\mathcal{L}=\frac{1}{2}(\vec{E}^2-\vec{B}^2)+\frac{e^4}{360\pi^2m^4}[(\vec{E}^2-\vec{B}^2)+7(\vec{E}\cdot\vec{B})^2]. \tag{16}$$

In the presence of a large background magnetic field $\vec{B}_0$, the speed of light propagation will become dependent on the polarization vector. Specifically, if we write the magnetic field as $\vec{B}=\vec{B}_0+\vec{b}$ and keep only the relevant nonlinear terms with two powers of $\vec{B}_0$, then $\mathcal{L}$ becomes

$$\mathcal{L}\approx\frac{1}{2}(\vec{E}^2-\vec{b}^2)+\frac{e^4\vec{B}_0^2}{360\pi^2m^4}[(7\cos^2\theta_E-2)\vec{E}^2+(4\cos^2\theta_b+2)\vec{b}^2], \tag{17}$$

where θ_E and θ_b are the angles that $\vec{B}_0$ forms with $\vec{E}$ and $\vec{b}$, respectively. Waves polarized in the plane formed by the wave vector and $\vec{B}_0$ and those polarized normal to this plane propagate at different speeds. For a given direction, specified by θ_E and θ_b, the wave speed is

$$c=\left[\frac{1-\dfrac{e^4\vec{B}_0^2}{180\pi^2m^4}(4\cos^2\theta_b+2)}{1+\dfrac{e^4\vec{B}_0^2}{180\pi^2m^4}(7\cos^2\theta_E-2)}\right]^{1/2}. \tag{18}$$

Multiplying this by $|\vec{p}|$ gives the frequency, which can be inserted into the formalism we have developed.

V. CONCLUSIONS

In summary, we have studied an application of the Holstein-Primakoff realization of the simple harmonic oscillator operator algebra. This has involved the introduction of a set of raising and lowering operators that obey the angular momentum commutation relations. The properties of these operators allow us to solve exactly for the low-energy behavior of a theory with a particular nonlinear interaction. The high-energy extension of this model may involve either a non-self-adjoint Hamiltonian or a new basis of states.

This model has an interesting application in Lorentz-violating physics, where stability is typically a problem. The ultra-low-energy limit of the interaction we have considered resembles the effect of a small Lorentz-violating correction to free QED. At higher energies, the nonlocality of the special harmonic oscillator interactions we are considering can stabilize the Lorentz-violating theory. Physically, these kinds of effects are extremely strongly constrained by astronomical observations. However, this theory provides a useful insight into how nonlocality and Lorentz violation may combine to form a well-behaved theory.

A bound on the mutual information, and properties of entropy reduction, for quantum channels with inefficient measurements

Kurt Jacobs

(Received 7 December 2004; accepted 1 November 2005; published online 13 January 2006)

The Holevo bound is a bound on the mutual information for a given quantum encoding. In 1996 Schumacher, Westmoreland, and Wootters [Phys. Rev. Lett. **76**, 3452 (1996)] derived a bound that reduces to the Holevo bound for complete measurements, but that is tighter for incomplete measurements. The most general quantum operations may be both incomplete and inefficient. Here we show that the bound derived by SWW can be further extended to obtain one that is yet again tighter for inefficient measurements. This allows us, in addition, to obtain a generalization of a bound derived by Hall, and to show that the average reduction in the von Neumann entropy during a quantum operation is concave in the initial state, for all quantum operations. This is a quantum version of the concavity of the mutual information. We also show that both this average entropy reduction and the mutual information for pure state ensembles, are Schur concave for unitarily covariant measurements; that is, for these measurements, information gain increases with initial uncertainty. © *2006 American Institute of Physics.*

I. INTRODUCTION

The celebrated Holevo bound, conjectured by Gordon[1] and Levitin[2] and proved by Holevo in 1973[3] gives a bound on the information that may be transmitted from A to B (strictly, the *mutual information*, M, between A and B) when A encodes information in a quantum system using a set of states $\{\rho_i\}$, chosen with probabilities $\{P(i)\}$, and B makes a subsequent measurement upon the system. The Holevo bound is

$$M(I{:}J) \leqslant \chi \equiv S(\rho) - \sum_i P(i)S(\rho_i), \tag{1}$$

where $\rho=\Sigma_i P(i)\rho_i$ (and which we will refer to as the *ensemble state*). We write the mutual information as $M(I:J)$ to signify that it is the mutual information between the random variables I and J, whose values i and j label, respectively, the encoding used by A, and the outcome of the measurement made by B. More recent proofs of the Holevo bound may be found in Refs. 4–6. The bound is achieved if and only if the encoding states, ρ_i, commute with each other, and the receiver, B, makes a von Neumann measurement in the basis in which they are diagonal. (A von Neumann measurement is one that projects the system onto one of a complete set of mutually orthogonal states. In this case the set of states is chosen to be the basis in which the coding states are diagonal.) With this choice of coding states and measurement the channel is classical, in that it can be implemented with a classical system. The Holevo bound takes into account that the sender may only be able to send mixed states, and this mixing reduces the amount of information that can be transmitted. However, if the receiver is not able to perform measurements that always project the system to a pure state (so-called *complete* measurements), then, in general, the information will be further reduced. In 1996 Schumacher, Westmoreland, and Wootters showed that when the receiv-

er's measurement is incomplete, it is possible to take this into account and derive a more stringent bound on the information. If the receiver's measurement is the POVM described by the operators $\{A_j\}$ (with $\Sigma_j A_j^\dagger A_j = 1$), so that the measurement outcomes are labeled by the index j, then the SWW bound is[6]

$$M(I{:}J) \leqslant \chi - \sum_j P(j)\chi_j, \tag{2}$$

where $P(j)$ is the probability of outcome j,[7] and χ_j is the Holevo quantity for the ensemble that the system remains in (from the point of view of the receiver), given outcome j. This bound can be at least partially understood by noting that if the system still remains in some ensemble of possible states after the measurement, then future measurements can potentially extract further information about the encoding, and so the information obtained by the first measurement must therefore be less than the maximum possible at least by this amount. What the SWW bound tells us is that the bound on the information is reduced not only by the amount of information that could be further extracted after outcome j has been obtained, but by the Holevo bound on this information, χ_j.

If the initial state of the system is ρ_i, then after outcome j the final state of the system is given by $\tilde{\rho}_{j|i} = A_j \rho_i A_j^\dagger / \mathrm{Tr}[A_j^\dagger A_j \rho_i]$. Thus the states that make up the final ensemble that remains after outcome j, are $\{\tilde{\rho}_{j|i}\}$, and the probability of each state in the ensemble is $P(i|j) = P(j|i)P(i)/P(j)$, with $P(j|i) = \mathrm{Tr}[A_j^\dagger A_j \rho_i]$. The Holevo quantity for ensemble j is thus

$$\chi_j = S(\tilde{\rho}_j) - \sum_i P(i|j) S(\tilde{\rho}_{j|i}), \tag{3}$$

where $\tilde{\rho}_j = A_j \rho A_j^\dagger / \mathrm{Tr}[A_j^\dagger A_j \rho]$. If at least one of the measurement operators A_j are higher than rank 1, then the measurement is incomplete. If the measurement is complete, then for each j all the final states $\tilde{\rho}_{j|i}$ are identical, χ_j is zero and the SWW bound reduces to the Holevo bound.

The most general kind of measurement can also be inefficient. A measurement is described as inefficient if the observer does not have full information regarding which of the outcomes actually occurred. The name *inefficient* comes from that fact that the need to consider such measurements first arose in the study of inefficient photo-detectors.[8] An inefficient measurement may be described by labeling the measurement operators with two indices, so that we have A_{kj}. The receiver has complete information about one of the indices, j, but no information about the other, k.[9] As a result, the final state for each j (given the value of i) is now

$$\rho'_{j|i} = \sum_k P(k|j) \frac{A_{kj} \rho_i A_{kj}^\dagger}{\mathrm{Tr}[A_{kj}^\dagger A_{kj} \rho_i]}. \tag{4}$$

Since inefficiency represents a loss of information, we wish to ask whether it is possible to take this into account and obtain a more stringent bound on the mutual information. If we merely apply the SWW bound to the measurement A_{kj}, then the bound involves the Holevo quantities of the ensembles that remain when both the values of k and j are known (the final ensembles that result from the efficient measurement). That is

$$M(I{:}J) \leqslant \chi - \sum_{kj} P(k,j)\chi_{kj}. \tag{5}$$

One therefore wishes to know whether it is possible to derive a bound that instead involves the Holevo quantities of the ensembles that remain after the inefficient measurement is made, that is, for the receiver who only has access to j.

In the first part of this paper we answer this question in the affirmative—for an inefficient measurement where the known outcomes are labeled by j, the bound given by Eq. (2) *remains true*, where now the χ_j are the Holevo quantities for the ensemble of states $\rho'_{j|i}$ that result from the inefficient measurement.

In the second part of the paper, we consider the average reduction in the von Neumann entropy induced by a measurement:

$$\langle \Delta S(\rho) \rangle \equiv S(\rho) - \sum_i P(j) S(\rho_j'). \tag{6}$$

Here ρ_j' is the state that results from outcome j, given that the initial state is ρ. Since the von Neumann entropy is a measure of how much we know about the state of the system, this is the difference between what we knew about the system state before we made the measurement, and what we know (on average) about the system state at the end of the measurement; it thus measures how much we learn about the final state of the system. Equivalently, it can be said to measure the degree of "state-reduction" that the measurement induces.

While it is the mutual information that is important for communication, the reduction in the von Neumann entropy is important for feedback control. Feedback control is the process of performing a sequence of measurements on a system, and applying unitary operations after each measurement in order control the evolution of the system. Such a procedure is useful for controlling systems that are driven by noise. If the ability to perform unitary operations is unlimited, then the von Neumann entropy provides a measure of the level of control that can be achieved: if the system has maximal entropy then the unitary operations have no effect on the system state whatsoever; conversely, if the state is pure then the system can be controlled precisely - that is, any pure state can be prepared. Thus the entropy measures the extent to which a pure state, or pure evolution can be obtained, and thus the level of predictability which can be achieved over the future behavior of the system.[10] The primary role of measurement in feedback control is therefore to reduce the entropy of the system. As such, the average reduction in von Neumann entropy provides a ranking of the effectiveness of different measurements for feedback control, other things being equal. Further details regarding quantum feedback control and von Neumann entropy can be found in Ref. 11.

The entropy reduction is also relevant to the transformation of pure-state entanglement, since the von Neumann entropy measures the entanglement of pure states. As a result this quantity gives the amount by which pure-state entanglement is broken by a local measurement.

We give two corollaries of the general information bound derived in the first part that involve $\langle \Delta S(\rho) \rangle$. The first is a generalization of a bound derived by Hall[12,13] to inefficient measurements. Hall's bound states that for efficient measurements the mutual information is bounded by $\langle \Delta S(\rho) \rangle$. We show that for inefficient measurements this becomes

$$M(I{:}J) \leqslant \langle \Delta S(\rho) \rangle - \sum_i P(i) \langle \Delta S(\rho_i) \rangle, \tag{7}$$

where $\langle \Delta S(\rho_i) \rangle$ is the average entropy reduction that would have resulted if the initial state had been ρ_i, and as above $\rho = \Sigma_i P(i) \rho_i$.

The second is the fundamental property that, for all quantum operations, the average reduction in von Neumann entropy is concave in the initial state ρ. That is,

$$\langle \Delta S(\rho) \rangle \geqslant \sum_i P(i) \langle \Delta S(\rho_i) \rangle. \tag{8}$$

Finally, in the third part of this paper, we use the above result to show that for measurements that are uniform in their sensitivity across state space (that is, measurements that are unitarily covariant), the amount that one learns about the final state always increases with the initial uncertainty, where this uncertainty is characterized by *majorization*. This is a quantum version of the much simpler classical result (which we also show) that the mutual information always increases with the initial uncertainty for classical measurements that are permutation symmetric. In addition, we show that, for unitarily covariant measurements, the mutual information for pure-state ensembles also has this property. One can sum up these results by saying that the statement

that information gain increases with initial uncertainty can fail to hold only if the measurement is asymmetric in its sensitivity.

II. AN INFORMATION BOUND FOR GENERAL QUANTUM OPERATIONS

We now show that the bound proved by SWW can be generalized to obtain a more stringent bound for channels in which the receiver's measurement is inefficient. To show this, it turns out that we can use the same method employed by SWW, but with the addition of an extra quantum system, which allows us to include the inefficiency of the measurement.

Theorem 1: *For a quantum channel in which the encoding ensemble is* $\epsilon=\{P(i),\rho_i\}$, *and the measurement performed by the receiver is described by operators* A_{kj} $(\Sigma_{kj}A_{kj}^\dagger A_{kj}=1)$, *where the measurement is, in general, inefficient so that the receiver knows j but not k; then the mutual information,* $M(I:J)$, *is bounded such that*

$$M(I:J) \leqslant \chi - \sum_j P(j)\chi_j, \tag{9}$$

where $P(j)$ *is the overall probability for outcome j,* $\chi=S(\rho)-\Sigma_i P(i)S(\rho_i)$ *is the Holevo quantity for the initial ensemble, and*

$$\chi_j = S(\sigma_j) - \sum P(i|j)S(\sigma_{j|i}), \tag{10}$$

is the Holevo quantity for the ensemble, ϵ_j, *that remains (from the point of view of the receiver) once the measurement has been made, so that the receiver has learned the outcome j, but not the value of k. Here the receiver's overall final state is*

$$\sigma_j = \frac{\sum_k A_{kj}\rho A_{kj}^\dagger}{P(j)} = \sum_{ik} P(i,k|j)\sigma_{kj|i}, \tag{11}$$

where $P(i,k|j)$ *is the probability for both i and outcome k given j, and* $\sigma_{kj|i}$ *is the final state that results given the initial state* ρ_i, *and both outcomes j and k. The remaining ensemble* $\epsilon_j=\{P(i|j),\sigma_{j|i}\}$, *where*

$$\sigma_{j|i} = \sum_k P(k|j,i)\sigma_{kj|i} = \frac{\sum_k A_{kj}\rho_i A_{kj}^\dagger}{P(j|i)}, \tag{12}$$

and where $P(k|j,i)$ *is the probability for outcome k given j and the initial state* ρ_i.

Proof: We begin by collecting various key facts. The first is that any efficient measurement on a system Q, described by $N=N_1N_2$ operators, A_{kj} $(j=1,\ldots,N_1$ and $k=1,\ldots,N_2)$ can be obtained by bringing up an auxiliary system A of dimension N, performing a unitary operation involving Q and A, and then making a von Neumann measurement on A.[14,15] If the initial state of Q is $\rho^{(Q)}$, then the final joint state of A and Q after the von Neumann measurement is

$$\sigma^{(AQ)} = |kj\rangle\langle kj|^{(A)} \otimes \frac{A_{kj}\rho^{(Q)}A_{kj}^\dagger}{P(k,j)}. \tag{13}$$

where $|kj\rangle$ is the state of A selected by the von Neumann measurement. The second fact is that the state that results from discarding all information about the measurement outcomes k and j can be obtained by performing a unitary operation between A and another system E that perfectly correlates the states $|kj\rangle$ of A with orthogonal states of E, and then tracing out E. The final key fact we require is a result proven by SWW,[6] which is that the Holevo χ quantity is nonincreasing under partial trace. That is, if we have two quantum systems A and B, and an ensemble of states $\rho_i^{(AB)}$ with associated probabilities P_i, then

$$\chi^{(A)} = S(\rho^{(A)}) - \sum_i S(\rho_i^{(A)}) \leqslant S(\rho^{(AB)}) - \sum_i S(\rho_i^{(AB)}) = \chi^{(AB)}, \tag{14}$$

where $\rho_i^{(A)} = \mathrm{Tr}_B[\rho_i^{(AB)}]$. To prove this result SWW use strong subadditivity.[16]

We now encode information in system Q using the ensemble $\boldsymbol{\epsilon}$, and consider the joint system that consists of the three systems Q, A, E and a forth system M, with dimension N_1. We now start with A, E and M in pure states, so that the Holevo quantity for the joint system is $\chi^{(QAEM)} = \chi^{(Q)}$. We then perform the required unitary operation between Q and A, and a unitary operation between A and E that perfectly correlates the states $|kj\rangle^{(A)}$ of A with orthogonal states of E. Unitary operations do not change the Holevo quantity. Then we trace over E, so that we are left with the state

$$|\psi\rangle\langle\psi|^{(M)} \otimes \sum_{jk} P(k,j)|k,j\rangle\langle k,j|^{(A)} \otimes \frac{A_{kj}\rho^{(Q)}A_{kj}^\dagger}{P(k,j)}. \tag{15}$$

After the two unitaries and the partial trace over E, the Holevo quantity for the remaining systems, which we will denote by $\chi'^{(QAM)}$, satisfies $\chi'^{(QAM)} \leqslant \chi^{(QAEM)} = \chi^{(Q)}$. We now perform one more unitary operation, this time between M and A, so that we correlate the states of M, which we denote by $|j\rangle\langle j|^{(M)}$ with the second index of the states of A, giving

$$\sum_j |j\rangle\langle j|^{(M)} \otimes \sum_k P(k,j)|k,j\rangle\langle k,j|^{(A)} \otimes \sigma_{kj}^{(Q)} \tag{16}$$

where $\sigma_{kj}^{(Q)} = A_{kj}\rho^{(Q)}A_{kj}^\dagger / P(k,j)$ is the final state resulting from knowing both outcomes k and j, with no knowledge of the initial choice of i. Finally we trace out A, leaving us with the state

$$\sigma^{(QM)} = \sum_j |j\rangle\langle j|^{(M)} \otimes \sum_k P(k,j)\sigma_{kj}^{(Q)}. \tag{17}$$

After this final unitary, and the partial trace over A, the Holevo quantity for the remaining systems Q and M, which we will denote by $\chi''^{(QM)}$, satisfies $\chi''^{(QM)} \leqslant \chi'^{(QAM)} \leqslant \chi^{(Q)}$. We have gone through the above process using the initial state ρ, but we could just as easily have started with any of the initial states, ρ_i, in the ensemble, and we will denote the final states that we obtain using the initial state ρ_i as $\sigma_i^{(QM)}$. Calculating $\chi''^{(QM)}$, we have

$$\chi''^{(QM)} = S(\sigma^{(QM)}) - \sum_i P(i)S(\sigma_i^{(QM)}) = H[J] - \sum_i P(i)H[J|i] + \sum_j P(j)\left[S(\sigma_j) - \sum_i P(i|j)\sigma_{j|i}\right] \tag{18}$$

$$= M(J{:}I) + \sum_j P(j)\chi_j^{(Q)} \leqslant \chi^{(Q)}. \tag{19}$$

Rearranging this expression gives the desired result. □

III. PROPERTIES OF ENTROPY REDUCTION

We now rewrite the above information bound using the fact that $P(i|j)P(j) = P(j|i)P(i)$. The result is

$$M(I{:}J) \leqslant \langle \Delta S(\rho)\rangle - \sum_i P(i)\langle \Delta S(\rho_i)\rangle, \tag{20}$$

where $\rho = \Sigma_i P_i\rho_i$. Ozawa has shown that for efficient measurements $\langle \Delta S(\rho)\rangle$ is always positive[17] (for more recent proofs of this result see Refs. 18 and 19). For efficient measurements, Eq. (20) is therefore in general stronger than, and gives immediately, Hall's bound,[12,13] which states that the mutual information is bounded by the reduction in the von Neumann entropy. The inequality in

Eq. (20) is then a generalization of Hall's bound to inefficient measurements. Since the mutual information is always positive, but for inefficient measurements the reduction in the von Neumann entropy can be negative (that is, the entropy of the quantum state can *increase* as a result of the measurement), the relation

$$M(I{:}J) \leqslant \langle \Delta S(\rho) \rangle \tag{21}$$

is not necessarily satisfied for such measurements. However, Eq. (20) tells us that if the entropy of the initial state, ρ, does increase, the average increase in the entropy for each of the coding states ρ_i is always *more* than this by at least the mutual information.

The second result that we obtain from Eq. (20) is that, because the mutual information is non-negative, we have

$$\langle \Delta S(\rho) \rangle \geqslant \sum_i P(i) \langle \Delta S(\rho_i) \rangle. \tag{22}$$

That is, the reduction in the von Neumann entropy is concave in the initial state. This parallels the fact that the mutual information is also concave in the initial state.

The fact that this is true for inefficient measurements means that once we have made an efficient measurement, no matter what information we throw away regarding the final outcomes (i.e., which outcomes we average over), $\langle \Delta S(\rho) \rangle$ is always greater than the average of the entropy reductions that would have been obtained through measurement in each of the coding states, when we throw away the same information regarding the measurement results.

IV. INFORMATION GATHERING AND STATE-SPACE SYMMETRY

In this section we show that measurements whose ability to extract information is uniform over the available state space (that is, does not vary from point to point in the state-space) always extract more information (strictly, never extract less information) the less that is known before the measurement is made. Thus, in this sense, one may regard "the more you know, the less you get" as a fundamental property of measurement. We will show that this is true both for the information obtained regarding the final state [being $\langle \Delta S(\rho) \rangle$], and the mutual information for a measurement on an ensemble of pure states. Here we will consider efficient measurements only; no doubt inefficient measurements will also have this property, but only if the information that is thrown away is also uniform with respect to the state space, and we do not wish to burden the treatment with this additional complication.

To proceed, we must make precise the notion that the sensitivity of a measurement is uniform over state space. This is captured by stating that such a measurement should be invariant under reversible transformations of the state space. For classical measurements (which are simply quantum measurements in which all operators and density matrices commute[20]) this means that the set of measurement operators is invariant under all permutations of the classical states: we will refer to these as *completely symmetric* measurements. Note that in this classical case, this is equivalent to saying that the measurement distinguishes all states from all other states equally well. The quantum generalization of this is invariance under all unitary transformations. Such measurements are referred to as being unitarily covariant.[21,22]

We must also quantify what we mean by the observer's lack of knowledge, or uncertainty, before the measurement is made. This is captured by the simple and elegant concept of *majorization*.[23,24] If two sets of probabilities $p \equiv \{P_i\}$ and $q \equiv \{Q_i\}$ satisfy the set of relations

$$\sum_{i=1}^{k} P_i \geqslant \sum_{i=1}^{k} Q_i, \quad \forall\, k, \tag{23}$$

where it is understood that the elements of both sets have been placed in decreasing order (e.g., $P_i > P_{i+1}, \ \forall\, i$), then p is said to majorize q, and this is written $q \prec p$. While at first Eq. (23) looks a little complicated, a few moments consideration reveals that it captures precisely what one

means by uncertainty—if p majorizes q, then p is more sharply peaked than q, and consequently describes a state of knowledge containing less uncertainty. What is more, majorization implies an ordering with Shannon entropy $H[\cdot]$. That is, if p majorizes q, then $H[p] \leqslant H[q]$.[23,24]

In a sense, majorization is a more basic notion of uncertainty than entropy in that it captures that concept alone—the Shannon entropy, on the other hand, characterizes the more specific notion of information. To characterize the uncertainty of a density matrix, we can apply majorization to the vector consisting of its eigenvalues. If ρ and σ are density matrices, then we will write $\sigma \prec \rho$ if ρ's eigenvalues majorize σ's. Various applications have been found for majorization in quantum information theory.[18,19,25–28]

We thus desire to show that for measurements with the specified symmetry, $\langle \Delta S(\sigma) \rangle \geqslant \langle \Delta S(\rho) \rangle$ whenever $\sigma \prec \rho$ (and similarly for the mutual information). Functions with this property [of which the von Neumann entropy, $S(\rho)$, is one example] are referred to as being *Schur concave*. To show that a function is Schur concave, it is sufficient to show that it is concave, and symmetric in its arguments,[23,24] which in our case are the eigenvalues of the density matrix ρ (if our functions did not depend only on the eigenvalues of ρ, then they could not be Schur concave, since the majorization condition only involves these eigenvalues).

The desired result for classical completely symmetric measurements is now immediate. In the classical case the mutual information is the unique measure of information gain, and $M(I:J) = \langle \Delta S(\rho) \rangle$. The mutual information is concave in the initial classical probability vector $\mathbf{P} = (P_1, \ldots, P_n)$ (being the vector of the eigenvalues of ρ in our quantum formalism), as is indeed implied by the concavity of $\langle \Delta S(\rho) \rangle$. Since all operators commute with the density matrix, $\langle \Delta S(\rho) \rangle$ is only a function of the $\{P_i\}$. From the form of $\langle \Delta S(\rho) \rangle$ we see that a permutation of the elements of $\mathbf{P}$ is equivalent to a permutation applied to the measurement operators, and since these are invariant under such an operation, $\langle \Delta S(\rho) \rangle$, and thus $M(I:J)$, is a symmetric function of its arguments. Thus $M(I:J)$ is Schur concave.

The Schur concavity of $\langle \Delta S(\rho) \rangle$ for unitarily covariant (UC) quantum measurements is just as immediate. Because of the unitary covariance of the measurement, we see from the form of $\langle \Delta S(\rho) \rangle$ that it is invariant under a unitary transformation of ρ. As a result, it only depends upon the eigenvalues of ρ. Since the permutations are a subgroup of the unitaries, it is also a symmetric function of its arguments (the eigenvalues), and thus Schur concave.

We wish finally to show that the mutual information is also Schur concave in ρ for unitarily covariant measurements on ensembles of pure states. This requires a little more work. First, we need to show that once we have fixed a set of encoding states, the mutual information is concave in the vector of the ensemble probabilities $P(i)$. This is straightforward if we first note that the mutual information, because it is, in fact, symmetric between i and j, can be written in the reverse form

$$M(I{:}J) = H[P(j)] - \sum_j P(i) H[P(j|i)]. \tag{24}$$

Since, for a fixed measurement, the mutual information is a function of the ensemble probabilities, we will write it as $M(\{P(i)\})$. Denoting the pure states in the encoding ensemble as $\rho_i = |\psi_i\rangle\langle\psi_i|$, and choosing the ensemble state $\rho = \Sigma_k P_k \sigma_k$, where the σ_k are built from the encoding states so that $\sigma_k = \Sigma_i P_{i|k} |\psi_i\rangle\langle\psi_i|$, then

$$\begin{aligned} M(\{P(i)\}) &= H\left[\sum_k P(k)P(j|k)\right] - \sum_i \sum_k P(i|k)P(k)H[P(j|i)] \\ &\geqslant \sum_k P(k)H[P(j|k)] - \sum_k P(k) \sum_i P(i|k)H[P(j|i)] \\ &= \sum_k P(k) M(\{P(i|k)\}), \end{aligned} \tag{25}$$

being the desired concavity relation. The inequality in the third line is merely a result of the

concavity of the Shannon entropy. Note that while we have written the measurement's outcomes explicitly as being discrete in the about derivation, the result also follows if they are a continuum (as in the case of UC measurements) by replacing the relevant sums with integrals.

Now we need to note some further points about UC measurements: A UC measurement may be generated by taking all unitary transformations of any single operator A, and dividing them by a common normalization factor. The resulting measurement operators are thus $A_U \propto UAU^\dagger$, where U ranges over all unitaries. The normalization for the A_U comes from $\int UA^\dagger AU^\dagger d\mu(U) = \mathrm{Tr}[A^\dagger A]I$, where $d\mu(U)$ is the (unitarily invariant) Haar measure[22,29] over unitaries.

It is not hard to show that all UC measurements can be obtained by *mixing* different UC measurements, each generated by a different operator. (Mixing a set of measurements means assigning to each a probability, and then making one measurement from the set at random based on these probabilities[30]).

Next, we need to show that for all UC measurements the mutual information depends only on the eigenvalues of the ensemble density matrix, and we state this as the following lemma.

Lemma 1: *The mutual information for a UC measurement on a pure-state ensemble*, $\epsilon = \{P(i), |\psi_i\rangle\}$ *depends on the ensemble only through the eigenvalues of the density matrix* $\rho = \Sigma_i P(i) |\psi_i\rangle\langle\psi_i|$.

Proof: We first show this for UC measurements generated from a single operator. Writing the mutual information in the reverse form, one has

$$M(I{:}J) = H[P(U)] - \sum_i P_i H[P(U|i)], \tag{26}$$

where U is the continuum index for the measurement operators (and thus the measurement outcomes) that are $A_U = UAU^\dagger$ for some appropriately normalized A. Naturally all this means is that $P(U|i)$ is a function of U, where U ranges over all unitaries. Since the measurement is unitarily covariant, $H[P(U|i)]$ is the same for all initial states $|\psi_i\rangle$, and therefore the second term is the same for all initial ensembles. Thus M depends only on the first term $H[P(U)] = H[\mathrm{Tr}[UA^\dagger AU^\dagger \rho]]$, which depends only on ρ, and is invariant under all unitary transformations of ρ. Thus M depends only on the eigenvalues of ρ. Since the mutual information for a mixture of measurements is merely a function of the respective mutual informations for each measurement (in particular, it is a linear combination of them), the result holds for all UC measurements. □

Since M depends only on ρ, in establishing the Schur concavity of M with respect to ρ, we need only consider one ensemble for each ρ. We therefore choose the eigenensemble $\{\lambda_i, |\phi_i\rangle\}$, where λ_i and $|\phi_i\rangle$ are the eigenvalues and eigenvectors of ρ, respectively. We know that the mutual information is concave in the vector of initial ensemble probabilities, and for the ensemble we have chosen, the initial probabilities are the eigenvalues of ρ. As a result, the mutual information is concave in the eigenvalues of ρ. Since M is invariant under unitary transformations, and since unitary transformations include permutations as a subgroup, it is also a symmetric function of the eigenvalues. Thus M is Schur concave.

V. CONCLUSION

In using a quantum channel, if there are limitations on the completeness (or alternatively the *strength*, in the terminology of Ref. 19) or efficiency of the measurements that the receiver can perform, then it is possible to give a bound on the mutual information that is stronger than the Holevo bound. Further, this bound has a very simple form in terms of the Holevo χ quantity, and the χ quantities of the ensembles, one of which remains after the measurement is made.

This bound also allows us to obtain a relationship between the mutual information and the average von Neumann entropy reduction induced by a measurement, and encompasses the fact that this von Neumann entropy reduction is concave in the initial state.

From the concavity of the mutual information and the von Neumann entropy reduction, it follows that these quantities are Schur concave (the former naturally for pure-state ensembles) for completely symmetric classical measurements, and for unitarily covariant quantum measurements.

Thus, the possibility that either of these kinds of information gain *decreases* with increasing initial uncertainty is associated with the asymmetry of the measurement in question.

[9] If the observer has only partial information about the outcome of a measurement, then if we label the outcomes by n (with associated measurement operators B_n), the most general situation is one in which the observer knows instead the value of a second variable m, where m is related to n by an arbitrary conditional probability $P(m|n)$. This general case is encompassed by the two-index formulation we use in the text. To see this, one sets $k=n$, $j=m$ and chooses $A_{nm}(\equiv A_{kj})=\alpha_{nm}B_n$. Then by giving the observer complete knowledge of j, and no knowledge of k, we reproduce precisely the general case described above by choosing α_{nm} so that $|\alpha_{nm}|^2=P(m|n)$.
[10] The von Neumann entropy is not the only quantity that can be used to measure the achieved level of control. The von Neumann entropy specifically gives the minimum possible entropy of the results of a measurement on the system. It therefore measures the maximum information (strictly, the minimum information deficit) that the user who is performing the control has about of the future behavior of the system under measurement. An example of another measure of control is the maximum eigenvalue of the density matrix. Under the assumption that all unitary operations are available to the controller, this measures the probability that the controlled system will be found in the desired state.

We construct entanglement monotones for multi-qubit states based on Plücker coordinate equations of Grassmann variety, which are a central notion in geometric invariant theory. As an illustrative example, we in detail investigate entanglement monotones of a three-qubit state. © *2006 American Institute of Physics.*

I. INTRODUCTION

The geometry of entanglement is a very interesting subject as much as quantification and classification of entanglement are.[1–6] It is possible to derive geometrical measures of entanglement invariant under stochastic local quantum operation and classical communication (SLOCC). All homogeneous positive functions of pure states that are invariant under determinant-one SLOCC operations are entanglement monotones.[7] In this paper, we will derive entanglement monotones based on a branch of the algebraic geometry called geometric invariant theory. In particular, let G be a group that acts on a set A, then the invariant theory is concerned with the study of the fixed points A^G and the orbits A/G associated to this action. The geometric invariant theory deals with the case where G is an algebraic group, e.g., a special linear group $\mathrm{SL}(r,\mathbf{C})$, that acts on a variety A via morphisms. Thus, based on the geometric invariant theory, we can construct a measure of entanglement that is invariant under action of $\mathrm{SL}(r,\mathbf{C})$ by construction. It has a well-defined geometrical structure called Grassmann variety or Grassmannian and it is generated by a quadratic polynomials called the Plücker coordinate equations. We will discuss our construction in detail in the following section. Recently, Lévay[8] has constructed a class of multi-qubit entanglement monotones, which was based on the construction of Emary.[9] His construction based on bipartite partitions of the Hilbert space and the invariants was expressed in terms of the Plücker coordinates of the Grassmannian. However, we do have different approaches and construction to solve the problem of quantifying multipartite states, but some of the results on entanglement monotones for multi-qubit states coincide. Now, let us start by denoting a general, pure, composite quantum system with m subsystems $\mathcal{Q}=\mathcal{Q}_m^p(N_1,N_2,\ldots,N_m)=\mathcal{Q}_1\mathcal{Q}_2\cdots\mathcal{Q}_m$, consisting of the pure state $|\Psi\rangle=\Sigma_{k_1=1}^{N_1}\Sigma_{k_2=1}^{N_2}\cdots\Sigma_{k_m=1}^{N_m}\ \alpha_{k_1,k_2,\ldots,k_m}|k_1,k_2,\ldots,k_m\rangle$ and corresponding to the Hilbert space $\mathcal{H}_\mathcal{Q}=\mathcal{H}_{\mathcal{Q}_1}\otimes\mathcal{H}_{\mathcal{Q}_2}\otimes\cdots\otimes\mathcal{H}_{\mathcal{Q}_m}$, where the dimension of the jth Hilbert space is given by $N_j=\dim(\mathcal{H}_{\mathcal{Q}_j})$. We are going to use this notation throughout this paper. In particular, we denote a pure two-qubit state by $\mathcal{Q}_2^p(2,2)$. Next, let $\rho_\mathcal{Q}$ denote a density operator acting on $\mathcal{H}_\mathcal{Q}$. The density operator $\rho_\mathcal{Q}$ is said to be fully separable, which we will denote by $\rho_\mathcal{Q}^{\mathrm{sep}}$, with respect to the Hilbert space decomposition, if it can be written as $\rho_\mathcal{Q}^{\mathrm{sep}}=\Sigma_{k=1}^{\mathrm{N}}p_k\otimes_{j=1}^m\rho_{\mathcal{Q}_j}^k$, $\Sigma_{k=1}^N p_k=1$ for some positive integer N, where p_k are positive real numbers and $\rho_{\mathcal{Q}_j}^k$ denotes a density operator on Hilbert space $\mathcal{H}_{\mathcal{Q}_j}$. If $\rho_\mathcal{Q}^p$ represents a pure state, then the quantum system is fully separable if $\rho_\mathcal{Q}^p$ can be written as $\rho_\mathcal{Q}^{\mathrm{sep}}=\otimes_{j=1}^m\rho_{\mathcal{Q}_j}$, where $\rho_{\mathcal{Q}_j}$ is the density operator on $\mathcal{H}_{\mathcal{Q}_j}$. If a state is not separable, then it is said to be an entangled state.

The general references for the complex projective space are Refs. 10 and 11. So, let $\{f_1, f_2, \ldots, f_q\}$ be continuous functions $\mathbf{K}^n \to \mathbf{K}$, where $\mathbf{K}$ is the field of real $\mathbf{R}$ or complex numbers $\mathbf{C}$. Then we define real (complex) space as the set of simultaneous zeroes of the functions

$$\mathcal{V}_{\mathbf{K}}(f_1, f_2, \ldots, f_q) = \{(z_1, z_2, \ldots, z_n) \in \mathbf{K}^n : f_i(z_1, z_2, \ldots, z_n) = 0 \ \ \forall\ 1 \leqslant i \leqslant q\}. \tag{1}$$

These real (complex) spaces become topological spaces by giving them the induced topology from $\mathbf{K}^n$. Now, if all f_i are polynomial functions in coordinate functions, then the real (complex) space is called a real (complex) affine variety. A complex projective space $\mathbf{CP}^n$ is defined to be the set of lines through the origin in $\mathbf{C}^{n+1}$, that is, $\mathbf{CP}^n = (\mathbf{C}^{n+1} - 0)/\sim$, where $\sim$ is an equivalence relation define by $(x_1, \ldots, x_{n+1}) \sim (y_1, \ldots, y_{n+1}) \Leftrightarrow \exists \lambda \in \mathbf{C} - 0$, such that $\lambda x_i = y_i \forall\, 0 \leqslant i \leqslant n$. For $n = 1$ we have a one-dimensional complex manifold $\mathbf{CP}^1$, which is a very important one, since as a real manifold it is homeomorphic to the two-sphere $\mathbf{S}^2$, e.g., the Bloch sphere. Moreover, every complex compact manifold can be embedded in some $\mathbf{CP}^n$. In particular, we can embed a product of two projective spaces into the third one. Let $\{f_1, f_2, \ldots, f_q\}$ be a set of homogeneous polynomials in the coordinates $\{\alpha_1, \alpha_2, \ldots, \alpha_{n+1}\}$ of $\mathbf{C}^{n+1}$. Then the projective variety is defined to be the subset

$$\mathcal{V}(f_1, f_2, \ldots, f_q) = \{[\alpha_1, \ldots, \alpha_{n+1}] \in \mathbf{CP}^n : f_i(\alpha_1, \ldots, \alpha_{n+1}) = 0 \ \forall\ 1 \leqslant i \leqslant q\}. \tag{2}$$

We can view the complex affine variety $\mathcal{V}_{\mathbf{C}}(f_1, f_2, \ldots, f_q) \subset \mathbf{C}^{n+1}$ as a complex cone over the projective variety $\mathcal{V}(f_1, f_2, \ldots, f_q)$. We can also view $\mathbf{CP}^n$ as a quotient of the unit $2n+1$ sphere in $\mathbf{C}^{n+1}$ under the action of $U(1) = \mathbf{S}^1$, that is $\mathbf{CP}^n = \mathbf{S}^{2n+1}/U(1) = \mathbf{S}^{2n+1}/\mathbf{S}^1$, since every line in $\mathbf{C}^{n+1}$ intersects the unit sphere in a circle.

II. GRASSMANN VARIETY

In this section, we will define the Grassmann variety. However, the standard reference on geometric invariant theory is Ref. 12. Let $\mathrm{Gr}(r, d)$ be the Grassmann variety of the $r-1$-dimensional linear projective subspaces of $\mathbf{CP}^{d-1}$. Now, we can embed $\mathrm{Gr}(r, d)$ into $\mathbf{P}(\wedge^r(\mathbf{C}^d)) = \mathbf{CP}^{\mathcal{N}}$, $\mathcal{N} = \binom{d}{r} - 1$, by using the Plücker map $L \to \wedge^r(L)$, where the exterior product $\wedge^r(\mathbf{C}^d)$ for $1 \leqslant r \leqslant d$ is a subspace of $\mathbf{C}^{N_1} \otimes \cdots \otimes \mathbf{C}^{N_m}$, spanned by the antisymmetric tensors. The Plücker coordinates $P_{i_1, i_2, \ldots, i_r}, 1 \leqslant i_1 < \cdots < i_r \leqslant d$ are the projective coordinates in this projective space. Next, let $\mathbf{C}[\Lambda(r, d)]$ be a polynomial ring with the Plücker coordinatesP_J indexed by elements of the set $\Lambda(r, d)$ of ordered r-tuples in $\{1, 2, \ldots d\}$ as its variables. Then the image of the map $\kappa : \mathbf{C}[\Lambda(r, d)] \to \mathrm{Pol}(\mathrm{Mat}_{r,d})$, which assigns $P_{i_1 i_2 \ldots i_r}$ the bracket polynomial $[i_1, i_2, \ldots, i_r]$ (the bracket function on the $\mathrm{Mat}_{r,d}$, whose values on a given matrix is equal to the maximal minor formed by the columns from a set of $\{1, 2, \ldots, d\}$) is equal to the subring of the invariant of the polynomials. Moreover, the kernel $\mathcal{I}_{r,d}$ of the map κ is equal to the homogeneous ideal of the Grassmann in its Plücker embedding. Furthermore, the homogeneous ideal $\mathcal{I}_{r,d}$ defining $\mathrm{Gr}(r, d)$ in its Plücker embedding is generated by the quadratic polynomials

$$\mathcal{P}_{I,J} = \sum_{t=1}^{r+1} (-)^t P_{i_1, \ldots, i_{r-1}, j_t} P_{j_1 \ldots j_{t-1} j_{t+1}, \ldots, j_{r+1}}, \tag{3}$$

where $I = (i_1 \ldots i_{r-1}), 1 \leqslant i_1 < \cdots < i_{r-1} < j_i$, and $J = (j_1, \ldots, j_{r+1}), 1 \leqslant j_1 < \cdots < j_{r+1} \leqslant d$ are two increasing sequences of numbers from the set $\{1, 2, \ldots, d\}$. Note that the equations $\mathcal{P}_{I,J} = 0$ define the Grassmannian $\mathrm{Gr}(r, d)$ are called the Plücker coordinate equations. For example, for $\mathrm{Gr}(2, d)$ and $n = 2$, we have

$$\mathcal{P}_{I,J} = \sum_{t=1}^{4} (-)^t P_{i_1, j_t} P_{j_1 \ldots j_{t-1} j_{t+1}, \ldots, j_3} = -P_{i_1, j_1} P_{j_2, j_3} + P_{i_1, j_2} P_{j_1, j_3} - P_{i_1, j_3} P_{j_1, j_2}, \tag{4}$$

where $I = (i_1)$, and $J = (j_1, j_2, j_3)$. Note that, by its construction, the Grassmannian $\mathrm{Gr}(2, d)$ is invariant under $\mathrm{SL}(2, \mathbf{C})$.

III. PLÜCKER COORDINATES AND MULTIPARTITE ENTANGLEMENT

In this section, we will construct entanglement monotones based on Plücker coordinate equations of the Grassmannian. Let us consider a quantum system $\mathcal{Q}_m^p(2,2,\ldots,2)$ and let

$$\mathcal{E}_{I,J}(\mathrm{Mat}_{r,d}^j)=\sum_{t=1}^{r+2}(P_j^{i_1,\ldots,i_{r-1},j_t}\overline{P^j}_{i_1,\ldots,i_{r-1},j_t}+P_j^{j_1\cdots j_{t-1}j_{t+1},\ldots,j_{r+1}}\overline{P^j}_{j_1\cdots j_{t-1}j_{t+1},\ldots,j_{r+1}}), \tag{5}$$

where $I=(i_1\ldots i_{r-1}),1\leqslant i_1<\cdots<i_{r-1}<j_i$, and $J=(j_1,\ldots,j_{r+1}),1\leqslant j_1<\cdots<j_{r+1}\leqslant d$ are two increasing sequences of numbers from the set $\{1,2,\ldots,d\}$. For example, for $\mathrm{Gr}(2,d)$ and $r=2$, that is invariant under $\mathrm{SL}(2,\mathbf{C})$, we have

$$\mathcal{E}_{I,J}(\mathrm{Mat}_{2,d}^j)=\sum_{t=1}^{4}(P_j^{i_1,j_t}\overline{P^j}_{i_1,j_t}+P_j^{j_1\cdots j_{t-1}j_{t+1},\ldots,j_3}\overline{P^j}_{j_1\cdots j_{t-1}j_{t+1},\ldots,j_3})=P_j^{i_1,j_1}\overline{P^j}_{i_1,j_1}+P_j^{j_2,j_3}\overline{P^j}_{j_2,j_3}+P_j^{i_1,j_2}\overline{P^j}_{i_1,j_2}$$
$$+P_j^{j_1,j_3}\overline{P^j}_{j_1,j_3}+P_j^{i_1,j_3}\overline{P^j}_{i_1,j_3}+P_j^{j_1,j_2}\overline{P^j}_{j_1,j_2}, \tag{6}$$

where $I=(i_1)$, and $J=(j_1,j_2,j_3)$. Now, we can write the coefficient of a general multi-qubit state as follows:

$$\mathrm{Mat}_{2,d}^1=\begin{pmatrix}\alpha_{1,1,\ldots,1} & \alpha_{1,1,\ldots,2} & \cdots & \alpha_{1,2,\ldots,2}\\ \alpha_{2,1,\ldots,1} & \alpha_{2,1,\ldots,2} & \cdots & \alpha_{2,2,\ldots,2}\end{pmatrix},$$
$$\mathrm{Mat}_{2,d}^2=\begin{pmatrix}\alpha_{1,1,\ldots,1} & \alpha_{1,1,\ldots,2} & \cdots & \alpha_{2,1,\ldots,2}\\ \alpha_{1,2,\ldots,1} & \alpha_{1,2,\ldots,2} & \cdots & \alpha_{2,2,\ldots,2}\end{pmatrix}, \tag{7}$$
$$\vdots$$
$$\mathrm{Mat}_{2,d}^m=\begin{pmatrix}\alpha_{1,1,\ldots,1} & \alpha_{1,1,\ldots,1} & \cdots & \alpha_{2,2,\ldots,1}\\ \alpha_{1,1,\ldots,2} & \alpha_{1,1,\ldots,2} & \cdots & \alpha_{2,2,\ldots,2}\end{pmatrix},$$

where $d=2^{m-1}$ and $\mathrm{Mat}_{2,d}^j$, which we get by permutation of j for $1\leqslant j\leqslant m$. Moreover, we assume that the sequences I,J denote the columns of the $\mathrm{Mat}_{2,d}^j$. Then we can define entanglement monotones for the multi-qubit states by

$$\mathcal{E}(\mathcal{Q}_m^p(2,2,\ldots,2))=\left(\mathcal{N}\sum_{j=1}^{m}\mathcal{E}_{I,J}(\mathrm{Mat}_{2,2^{m-1}}^j)\right)^{1/2}. \tag{8}$$

As an example, let us consider the quantum system $\mathcal{Q}_3^p(2,2,2)$. For such three-qubit states, if e.g., the subsystem $\mathcal{Q}_1$ is unentangled with the $\mathcal{Q}_2\mathcal{Q}_3$ subsystems, then the separable set of this state is generated by the six 2-by-2 subdeterminants of

$$\mathrm{Mat}_{2,4}^1=\begin{pmatrix}\alpha_{1,1,1} & \alpha_{1,1,2} & \alpha_{1,2,1} & \alpha_{1,2,2}\\ \alpha_{2,1,1} & \alpha_{2,1,2} & \alpha_{2,2,1} & \alpha_{2,2,2}\end{pmatrix}. \tag{9}$$

$\mathrm{Mat}_{2,4}^2$ and $\mathrm{Mat}_{2,4}^3$ can be obtained in similar way. Then the partial entanglement monotones for $\mathrm{Mat}_{2,4}^1$ is given by

$$\mathcal{E}_{I,J}(\mathrm{Mat}_{2,d}^1)=P_1^{i_1,j_1}\overline{P^1}_{i_1,j_1}+P_1^{j_2,j_3}\overline{P^1}_{j_2,j_3}+P_1^{i_1,j_2}\overline{P}_{i_1,j_2}+P_1^{j_1,j_3}\overline{P^1}_{j_1,j_3}+P_1^{i_1,j_3}\overline{P^1}_{i_1,j_3}+P_1^{j_1,j_2}\overline{P^1}_{j_1,j_2}, \tag{10}$$

where the Plücker coordinates for $\mathrm{Mat}_{2,4}^1$ are given by

$$P_{1,2}^1=\alpha_{1,1,1}\alpha_{2,1,2}-\alpha_{1,1,2}\alpha_{2,1,1},\ P_{1,3}^1=\alpha_{1,1,1}\alpha_{2,2,1}-\alpha_{1,2,1}\alpha_{2,1,1},$$

$$P^1_{1,4} = \alpha_{1,1,1}\alpha_{2,2,2} - \alpha_{1,2,2}\alpha_{2,1,1},\ P^1_{2,3} = \alpha_{1,1,2}\alpha_{2,2,1} - \alpha_{1,2,1}\alpha_{2,1,2},$$

$$P^1_{2,4} = \alpha_{1,1,2}\alpha_{2,2,2} - \alpha_{1,2,2}\alpha_{2,1,2},\ P^1_{3,4} = \alpha_{1,2,1}\alpha_{2,2,2} - \alpha_{1,2,2}\alpha_{2,2,1}.$$

Thus, entanglement monotones for three-qubit states are given by

$$\mathcal{E}(\mathcal{Q}^p_m(2,2,2)) = \left(\mathcal{N}\sum_{j=1}^{3}\mathcal{E}_{I,J}(\mathrm{Mat}^j_{2,4})\right)^{1/2}. \tag{11}$$

Moreover, for matrices $\mathrm{Mat}^j_{2,4}$, we have $\mathcal{P}^j_{I,J} = -P^j_{1,2}P^j_{3,4} + P^j_{1,3}P^j_{2,4} - P^j_{1,4}P^j_{2,3} = 0$. For three-qubit states, this result coincides with construction of the Segre variety.[6] However, multi-qubit states needs further investigation. Now, as an example, let us consider the state $|\Psi_W\rangle = \alpha_{1,1,2}|1,1,2\rangle + \alpha_{1,2,1}|1,2,1\rangle + \alpha_{2,1,1}|2,1,1\rangle$. Then we have

$$\mathcal{C}(\mathcal{Q}_3(2,2,2)) = (2\mathcal{N}[|\alpha_{1,2,1}\alpha_{2,1,1}|^2 + |\alpha_{1,1,2}\alpha_{2,1,1}|^2 + |\alpha_{1,1,2}\alpha_{1,2,1}|^2])^{1/2}.$$

In particular, for $\alpha_{1,1,2} = \alpha_{1,2,1} = \alpha_{2,1,1} = 1/\sqrt{3}$, we get $\mathcal{C}(\mathcal{Q}_3(2,2,2)) = (\frac{2}{3}\mathcal{N})^{1/2}$.

IV. HYPERDETERMINANT AND PLÜCKER COORDINATE EQUATIONS

In this section, we will review some results of the construction of entanglement measure based on the hyperdeterminant for three-qubit states and the relation between the Plücker coordinate equations and the hyperdeterminant. We also discuss a generalization of this construction. The hyperdeterminant of the elements of $\mathbf{C}^{N_1}\otimes\mathbf{C}^{N_2}\otimes\cdots\otimes\mathbf{C}^{N_m}$ was introduced by Gelfand, Kapranov, and Zelevinsky in Ref. 13. They proved that the dual variety of Segre product $\mathbf{CP}^{N_1-1}\times\mathbf{CP}^{N_2-1}\times\cdots\times\mathbf{CP}^{N_m-1}$ is a hypersurface if and only if $N_j \leqslant \Sigma_{i\neq j}N_i$ for $j=1,2,\ldots,m$. Whenever the dual variety is a hypersurface its equation is called the hyperdeterminant of the format $N_1\times N_2\times\cdots\times N_m$ and denoted by Det. The hyperdeterminant is a homogeneous polynomial function over $\mathbf{C}^{N_1}\otimes\mathbf{C}^{N_2}\otimes\cdots\otimes\mathbf{C}^{N_m}$, so that the condition $\mathrm{Det}\,A\neq 0$ is meaningful for $\mathcal{A}\in\mathbf{CP}^{N_1N_2\cdots N_m-1}$. Moreover, the hyperdeterminant Det is $\mathrm{SL}(N_1,\mathbf{C})\times\mathrm{SL}(N_2,\mathbf{C}))\otimes\cdots\otimes\mathrm{SL}(N_m,\mathbf{C})$-invariant. For example, for $m=2$ we have $\mathrm{Det}\,\mathcal{A} = \alpha_{1,1}\alpha_{2,2} - \alpha_{1,2}\alpha_{2,1}$ and for $m=3$, we have

$$\begin{aligned}\mathrm{Det}\,\mathcal{A} = {} & \alpha^2_{1,1,1}\alpha^2_{2,2,2} + \alpha^2_{1,1,2}\alpha^2_{2,2,1} + \alpha^2_{1,2,1}\alpha^2_{2,1,2} + \alpha^2_{2,1,1}\alpha^2_{1,2,2} \\ & - 2(\alpha_{1,1,1}\alpha_{1,1,2}\alpha_{2,2,1}\alpha_{2,2,2} + \alpha_{1,1,1}\alpha_{1,2,1}\alpha_{2,1,2}\alpha_{2,2,2} + \alpha_{1,1,1}\alpha_{2,1,1}\alpha_{1,2,2}\alpha_{2,2,2} \\ & + \alpha_{1,1,2}\alpha_{1,2,1}\alpha_{2,1,2}\alpha_{2,2,1} + \alpha_{1,1,2}\alpha_{2,1,1}\alpha_{1,2,2}\alpha_{2,2,1} + \alpha_{1,2,1}\alpha_{2,1,1}\alpha_{1,2,2}\alpha_{2,1,2}) \\ & + 4(\alpha_{1,1,1}\alpha_{2,2,1}\alpha_{2,1,2}\alpha_{1,2,2} + \alpha_{2,2,2}\alpha_{2,1,1}\alpha_{1,2,1}\alpha_{1,1,2}).\end{aligned} \tag{12}$$

Now, let us introduce the Diophantine function. For any sequence of numbers $\gamma_1,\gamma_2,\gamma_3,\gamma_4$, and $\delta_1,\delta_2,\delta_3,\delta_4$ we have

$$\mathcal{P}(\gamma_1,\gamma_2,\gamma_3,\gamma_4,\delta_1,\delta_2,\delta_3,\delta_4) = (\gamma_1\delta_1 + \gamma_2\delta_2 - \gamma_3\delta_3 - \gamma_4\delta_4)^2 - 4(\gamma_1\gamma_2 + \delta_3\delta_4)(\gamma_3\gamma_4 + \delta_1\delta_2). \tag{13}$$

This equation is equal to the hyperdeterminant $\mathrm{Det}\,\mathcal{A}$. For the quantum system $\mathcal{Q}^p_3(2,2,2)$ we have

$$\mathrm{Det}\,\mathcal{A} = \mathcal{P}(-\alpha_{1,1,1},\alpha_{2,2,1},\alpha_{2,1,2},\alpha_{1,2,2},-\alpha_{2,2,2},\alpha_{1,1,2},\alpha_{1,2,1},\alpha_{2,1,1}). \tag{14}$$

For the quantum system $\mathcal{Q}^p_3(2,2,2,2)$, one can wonder if it would be possible to find a generalization of the polynomial $\mathcal{P}$ such that the hyperdeterminant $\mathrm{Det}\,\mathcal{A}$ could be give by $\mathcal{P}$. We can also construct the hyperdeterminant in terms of the Plücker coordinates. For example, Lévay[5] has constructed such Plücker coordinates for three-qubit states as follows. Let $\alpha^p,\beta^q,p,q=1,2,3,4$ be two-four component vectors defined as $\alpha_{1,k_1,k_2} = (1/\sqrt{2})\alpha_p\Sigma^{p,k_1,k_2}$, and $\alpha_{2,k_1,k_2} = (1/\sqrt{2})\beta_p\Sigma^{p,k_1,k_2}$, where $\Sigma^s = -i\sigma_s, s=1,2,3$, and $\Sigma^4 = I_2$, where σ_p are Pauli matrices. Then the hyperdeterminant is

given by Det $\mathcal{A}=2P_{p,q}P^{p,q}$, where the Plücker coordinates are given by $P_{p,q}=\alpha_p\beta_q-\alpha_q\beta_p$. Thus, this construction can be at least extended into multi-qubit states following our definition of the Plücker coordinates for the multi-qubit states and further extending the definition of two 2^{m-1} components vectors $\alpha^p,\beta^q,p,q=1,2,\ldots,2^{m-1}$. For further progress in this direction see Ref. 8.

V. CONCLUSION

In this paper, we have constructed entanglement monotones for multipartite states based on the Grassmannian $\mathrm{Gr}(r,d)$, which was defined in terms of the Plücker coordinate equations. In particular, we have given an explicit expression for entanglement monotones for multi-qubit states. Moreover, we have investigated entanglement monotones for three-qubit state as an illustrative example.

Inequivalent quantizations of the $N=3$ Calogero model with scale and mirror-S_3 symmetry

(Received 21 October 2005; accepted 5 December 2005; published online 31 January 2006)

We study the inequivalent quantizations of the $N=3$ Calogero model by separation of variables, in which the model decomposes into the angular and the radial parts. Our inequivalent quantizations respect the "mirror-S_3" invariance (which realizes the symmetry under the cyclic permutations of the particles) and the scale invariance in the limit of vanishing harmonic potential. We find a two-parameter family of novel quantizations in the angular part and classify the eigenstates in terms of the irreducible representations of the S_3 group. The scale invariance restricts the quantization in the radial part uniquely, except for the eigenstates coupled to the lowest two angular levels for which two types of boundary conditions are allowed independently from all upper levels. It is also found that the eigenvalues corresponding to the singlet representations of the S_3 are universal (parameter-independent) in the family, whereas those corresponding to the doublets of the S_3 are dependent on one of the parameters. These properties are shown to be a consequence of the spectral preserving SU(2) (or its subgroup U(1)) transformations allowed in the family of inequivalent quantizations. © *2006 American Institute of Physics.*

I. INTRODUCTION

The N-body Calogero model, which describes N particles interacting with each other by the combined inverse square and harmonic potential on a line, is exactly solvable and yet admits a diversity of mathematical extensions and physical applications. For the mathematical side, Calogero's analysis[1] for $N=3$ has been extended to general N[2,3] as well as to models with modified potentials[4,5] and Lie-algebraic structures[6] (see also Refs. 7–12, and references therein). For the physical side, its relevance to high energy physics has been argued, albeit in specific circumstances, in various areas, e.g., in the Yang-Mills theory,[13] two-dimensional QCD,[14] superstrings,[15] and black holes.[16] Moreover, its potential application has also been argued in condensed matter physics, e.g., for spin chains,[17] quantum Hall effect,[18] magnons,[19] and the electron-hole interaction.[20]

In considering the application to particles with anyon statistics, Veigy[21] made an important observation that, when the coupling constant of the interaction lies in a certain range, the Calogero model admits a wider class of solutions than those obtained by Calogero. Technically, the possibility of the extension is found in the treatment of the singularities in the inverse square potential, where a specific (the Dirichlet) boundary condition has conventionally been adopted, allowing for only bosons and fermions for the possible statistics of the particles. It is shown in Ref. 21 that, if one adopts a different boundary condition at the singularities in the *angular* part of the model, which arises after the separation of variables is implemented for the $N=3$ case, one indeed finds extra eigenstates that correspond neither to bosons nor fermions. More recently, it has also been shown in Refs. 22–24 that the model admits novel solutions if we consider a general class of

[a]Electronic mail: yonezawa@post.kek.jp

boundary conditions for the *radial* part, even if the conventional boundary condition is adopted for the angular part.

To explore a fuller class of solutions available in the Calogero model, which amounts to exploring the possible *inequivalent quantizations* of the model, it is necessary to study the combined extension in the boundary conditions both in the angular and radial parts in more general terms, and this has been initiated in Ref. 25 for $N=3$. For the angular part, the class of boundary conditions considered in Ref. 25 forms a two-parameter family (containing the cases treated by Calogero and Veigy earlier) and respects a dihedral D_6 symmetry, which derives from the demand of indistinguishability of the particles. We found that the model can still be solvable, but the spectrum cannot be obtained explicitly except for a number of special cases such as the ones considered earlier. The purpose of the present paper is to provide another class of solutions allowed when we relax the demand from the D_6 symmetry to its subgroup S_3 and impose instead scale symmetry in the vanishing harmonic potential limit. In physical terms, the S_3 symmetry is equivalent to the invariance under cyclic permutations of the particles, while the additional scale symmetry ensures the smooth limit to the pure inverse square potential system at the quantum level. For the angular part, this leads to a novel two-parameter family of inequivalent quantizations, where the spectra can be obtained in closed form as well as the explicit solutions classified according to the irreducible representations of the group S_3. For the radial part, on the other hand, the scale symmetry specifies the quantization essentially uniquely to one obtained under the Dirichlet boundary condition, except for the eigenstates coupled to the lowest two angular levels for which the Neumann boundary condition is permitted as well. This allows us to have a number of possible combinations of boundary conditions for the angular and radial parts. We also observe that the levels which are singlets of S_3 are universal, i.e., independent of the parameters of the family, whereas the doublets of S_3 are dependent on one of the parameters. This will be seen as a consequence of the spectral preserving SU(2) (or its subgroup U(1)) transformations allowed in the family of inequivalent quantizations of the model.

The plan of the paper is as follows. We recapitulate in Sec. II the procedure of inequivalent quantizations of the $N=3$ Calogero model by separation of variables and present the symmetries we impose. We give a detailed discussion on the eigenstates and eigenvalues in the angular part in Sec. III. These results are then combined with the counterparts of the radial part discussed in Sec. IV to provide the solutions and the spectra of the entire system. Section V is devoted to the discussion of the universality of the S_3-singlets based on the spectral preserving $su(2)$ algebra found earlier.[26] Finally, our conclusion is presented in Sec. V.

II. THE $N=3$ CALOGERO MODEL

In the following we provide a framework for quantizing the $N=3$ Calogero model based on the separation of variables method, in which we split the model into the radial and angular parts. Concerning this, there are two important issues that require particular care, one of which is the treatment of the singularity in the potential and the other is the choice of the symmetry we shall adopt for our inequivalent quantizations.

A. Separation of variables

The N body Calogero model[2,3] is a system of N particles governed by the Hamiltonian,

$$H=-\frac{\hbar^2}{2m}\sum_{i=1}^{N}\frac{\partial^2}{\partial x_i^2}+\sum_{j=1}^{N}\sum_{i=j+1}^{N}\left\{\frac{g}{(x_i-x_j)^2}+\frac{1}{4}m\omega^2(x_i-x_j)^2\right\}, \tag{2.1}$$

where x_i, $i=1,\ldots,N$ represent the positions of the particles under interaction. As is well known, the system can be analyzed by the method of separation of variables (see, e.g., Ref. 25), which for the $N=3$ case begins with the use of the Jacobi coordinates,

$$x=\frac{x_1-x_2}{\sqrt{2}},\quad y=\frac{x_1+x_2-2x_3}{\sqrt{6}},\quad z=\frac{x_1+x_2+x_3}{\sqrt{3}},\tag{2.2}$$

and passes on to the polar coordinates $(x,y)=(r\sin\phi, r\cos\phi)$. In the unit $2m=1$, $\hbar=1$, this procedure brings the Hamiltonian to the separable form,

$$H=-\frac{\partial^2}{\partial r^2}-\frac{1}{r}\frac{\partial}{\partial r}-\frac{\partial^2}{\partial z^2}+\frac{3}{8}\omega^2r^2+\frac{1}{r^2}\left\{-\frac{\partial^2}{\partial\phi^2}+\frac{g}{2}\frac{9}{\sin^2 3\phi}\right\}.\tag{2.3}$$

It is also known that, if $g<-\frac{1}{2}$, the model does not admit a ground state,[27] and if $\frac{3}{2}\leqslant g$, the Hamiltonian H is essentially self-adjoint and leads to a unique quantization. In the present paper, we consider the cases $-\frac{1}{2}<g<\frac{3}{2}$, $g\neq 0$, where H admits self-adjoint extensions allowing for inequivalent quantizations. Here, the two particular points $g=0$ and $g=-\frac{1}{2}$ are excluded because the model becomes a harmonic oscillator in the former case while it requires an independent treatment technically in the latter case. For our later convenience, instead of g we use ν introduced as

$$g=2\nu(\nu-1),\quad \tfrac{1}{2}<\nu<\tfrac{3}{2},\quad \nu\neq 1.\tag{2.4}$$

On account of the separable form (2.3), we have the Hamiltonian $H=H_0+H_{\rm rel}$ with H_0 describing the center of mass system and $H_{\rm rel}$ the relative motion. The latter splits further into $H_{\rm rel}=H_r+H_\Omega$, where H_r and H_Ω are the Hamiltonians for the radial and angular parts, respectively. Consider now the angular eigenvalue equation,

$$H_\Omega\psi_\lambda(\phi)=\lambda\psi_\lambda(\phi),\quad H_\Omega=-\frac{d^2}{d\phi^2}+\frac{9\nu(\nu-1)}{\sin^2 3\phi},\tag{2.5}$$

with eigenvalue λ. To each λ, we further consider the effective radial Hamiltonian $H_{r,\lambda}=H_r+\lambda/r^2$ and its eigenvalue equation,

$$H_{r,\lambda}\psi_E(r;\lambda)=E\psi_E(r;\lambda),\quad H_{r,\lambda}=-\frac{\mathrm{d}^2}{\mathrm{d}r^2}-\frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}r}+\frac{3}{8}\omega^2r^2+\frac{\lambda}{r^2}.\tag{2.6}$$

The eigenfunction for the entire system (apart from that for the center-of-mass system in the z direction) with total energy E is obtained as $\psi_E(r;\lambda)\psi_\lambda(\phi)$ from the solutions of Eqs. (2.5) and (2.6).

B. Singularities and formal symmetries

In our quantization, an important point to note is that both the angular Hamiltonian H_Ω and the radial Hamiltonian $H_{r,\lambda}$ are ill-defined at the singular points of the potentials, i.e., at ϕ for which $\sin 3\phi=0$ and at $r=0$. Thus, to quantize the model properly and solve the eigenvalue equations, we need to consider self-adjoint extensions to each of the operators, that is, we provide an appropriate domain of definition in such a way that the entire Hamiltonian H be self-adjoint. In practice, this is accomplished by furnishing a set of connection conditions for the eigenfunctions at these singular points according to the general scheme for singular Hamiltonians (2.6) and (2.5), and in what follows we adopt the scheme presented in Ref. 28.

We start with the angular Hamiltonian, and for this we first note the formal symmetry of the operator H_Ω in (2.5). From the potential, it is clear that H_Ω is invariant under the reflections,

$$P_3:\phi\mapsto-\phi,\quad R_3:\phi\mapsto\frac{\pi}{3}-\phi,\tag{2.7}$$

and also under four other reflections P_i, R_i, $i=1,2$, analogously defined (see Fig. 1). It follows that the Hamiltonian is invariant under the rotation by angle $\pi/3$,

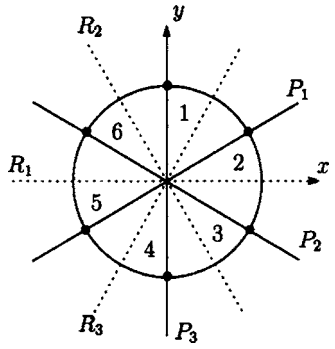

FIG. 1. Axes of reflections P_i, R_i, $i=1,2,3$, on the plane (x,y). The numbers $k=1,\ldots,6$ indicate the sectors $s_k=(\phi_{k-1},\phi_k)$ defined along the circle.

$$\mathcal{R}_{\pi/3}=R_3\circ P_3:\phi\mapsto\phi+\frac{\pi}{3}, \tag{2.8}$$

and hence under the successive ones $(\mathcal{R}_{\pi/3})^j$, $j=0,1,2,3,4,5$, as well. Combining all these reflections and rotations, we obtain a D_6 group as the group of the formal symmetry of H_Ω. On the angular wave function $\psi(\phi)$, the action of the operation $g\in D_6$ is realized by

$$\hat{g}\psi(\phi)=\psi(g^{-1}\phi). \tag{2.9}$$

It should be stressed, however, that the symmetry D_6 is still formal and the actual symmetry at the quantum level should be determined by taking account of the connection condition at the singularities.

In order to provide the connection condition at the singular points $\phi=\phi_k$,

$$\phi_k=\frac{k\pi}{3},\quad k=0,1,2,3,4,5, \tag{2.10}$$

we first focus on the singularity at $\phi=\phi_0=0$ and introduce the boundary vectors

$$B_0(\psi):=\begin{pmatrix}W[\psi,\varphi_1^0]_{0+}\\ W[\psi,\varphi_1^0]_{0-}\end{pmatrix},\quad B_0'(\psi):=\begin{pmatrix}W[\psi,\varphi_2^0]_{0+}\\ -W[\psi,\varphi_2^0]_{0-}\end{pmatrix}, \tag{2.11}$$

where $W[\psi_1,\psi_2]_{\phi\pm}=\lim_{\epsilon\to\pm0}W[\psi_1,\psi_2](\phi+\epsilon)$ are the limiting values of the Wronskian,

$$W[\psi_1,\psi_2]=\psi_1\frac{\mathrm{d}\psi_2}{\mathrm{d}\phi}-\psi_2\frac{\mathrm{d}\psi_1}{\mathrm{d}\phi}. \tag{2.12}$$

The functions φ_i^0 $(i=1,2)$ appearing in (2.11) are real eigenfunctions of H_Ω around $\phi=0$, called the "reference modes," which are normalized with respect to the Wronskian, $W[\varphi_1^0,\varphi_2^0]=1$. The most general form of the connection condition at $\phi=0$, which ensures the local continuity of the probability current there, is then given by

$$(U_0-\mathbf{1}_2)B_0(\psi)+i(U_0+\mathbf{1}_2)B_0'(\psi)=0, \tag{2.13}$$

where $U_0\in\mathrm{U}(2)$ is an arbitrary unitary matrix characterizing the connection condition (hence the singularity), and $\mathbf{1}_2$ is the identity matrix. In components, the condition (2.13) consists of two equations linear in ψ and its derivative $\mathrm{d}\psi/\mathrm{d}\phi$ at the singularity. The use of the Wronskians is to render the equations well-defined, since the quantities ψ and $\mathrm{d}\psi/\mathrm{d}\phi$ may be divergent at the singularity.

To provide the connection conditions at other singularities with $k=1,\ldots,5$ in (2.10) analogously to the case $k=0$, we need to choose the reference modes φ_i^k $(i=1,2)$ around each of the singularities ϕ_k. On account of the formal invariance of the Hamiltonian under D_6, these reference modes may simply be provided by the translations,

$$\varphi_i^k(\phi) := \varphi_i^0(\phi - \phi_k), \quad k=1,\ldots,5. \tag{2.14}$$

Note that, if we choose the reference modes for $k=0$ possessing the parity property,

$$\varphi_i^0(\phi) = (-1)^i \varphi_i^0(-\phi), \tag{2.15}$$

then (2.14) implies

$$\varphi_i^{k'}(\phi) = (-1)^i \varphi_i^k(R_l\phi), \tag{2.16}$$

which are fulfilled by the pair of reference modes at the two singular points ϕ_k and ϕ_k' mapped under the reflection R_l as

$$\phi_{k'} = R_l\phi_k. \tag{2.17}$$

With this choice of the reference modes, following (2.11) we introduce the boundary vectors

$$B_k(\psi) := \begin{pmatrix} W[\psi,\varphi_1^k]_{\phi_k+} \\ W[\psi,\varphi_1^k]_{\phi_k-} \end{pmatrix}, \quad B_k'(\psi) := \begin{pmatrix} W[\psi,\varphi_2^k]_{\phi_k+} \\ -W[\psi,\varphi_2^k]_{\phi_k-} \end{pmatrix}, \tag{2.18}$$

for $k=$even, and

$$B_k(\psi) := \begin{pmatrix} W[\psi,\varphi_1^k]_{\phi_k-} \\ W[\psi,\varphi_1^k]_{\phi_k+} \end{pmatrix}, \quad B_k'(\psi) := \begin{pmatrix} -W[\psi,\varphi_2^k]_{\phi_k-} \\ W[\psi,\varphi_2^k]_{\phi_k+} \end{pmatrix}, \tag{2.19}$$

for $k=$odd. As in (2.13), the connection conditions at $\phi=\phi_k$ for all k are provided by

$$(U_k - \mathbf{1}_2)B_k(\psi) + i(U_k + \mathbf{1}_2)B_k'(\psi) = 0, \tag{2.20}$$

with matrices $U_k \in \mathrm{U}(2)$ characterizing the singularities at $\phi=\phi_k$. We mention that (2.16) implies that these boundary vectors are related as

$$B_k(R_l\psi) = B_{k'}(\psi), \quad B_k'(R_l\psi) = B_{k'}'(\psi), \tag{2.21}$$

for the two singular points connected by (2.17).

Now, turning to the radial part, we introduce from the radial Hamiltonian $H_{r,\lambda}$ the new operator

$$\mathcal{H}_{r,\lambda} := \sqrt{r} \circ H_{r,\lambda} \circ \frac{1}{\sqrt{r}} = -\frac{\mathrm{d}^2}{\mathrm{d}r^2} + \frac{3}{8}\omega^2 r^2 + \frac{\lambda - \frac{1}{4}}{r^2}. \tag{2.22}$$

Note that the self-adjointness of $\mathcal{H}_{r,\lambda}$ with respect to the measure $\mathrm{d}r$ implies the self-adjointness of $H_{r,\lambda}$ with respect to the radial measure $r\,\mathrm{d}r$. It is known (see, *e.g.*, Ref. 25) that for $\lambda \geqslant 1$ the operator $\mathcal{H}_{r,\lambda}$ is essentially self-adjoint, while for $\lambda < 1$ it admits a $U(1)$ family of self-adjoint extensions. The family can be specified by the boundary condition for the radial wave function $\rho(r)$, which is given, using the Wronskian in the radial part, by

$$\frac{W[\rho,\varphi_1]_{0+}}{W[\rho,\varphi_2]_{0+}} = -\kappa(\lambda). \tag{2.23}$$

TABLE I. Character table of mirror-S_3.

Conjugacy class	$\{e\}$	$\{R_i\}$	$\{(\mathcal{R}_{\pi/3})^{\pm 2}\}$
Identity rep χ^+	1	1	1
Signature rep χ^-	1	−1	1
2-dim rep $\chi^{(2)}$	2	0	−1

Here, $\varphi_i(r)$ $(i=1,2)$ are the reference modes for the radial part which are eigenfunctions of $\mathcal{H}_{r,\lambda}$ and normalized as $W[\varphi_1,\varphi_2]=1$. Note that the real number $\kappa(\lambda)$ (which includes $\kappa(\lambda)=\infty$) characterizes the singularity at $r=0$ and is dependent on the angular eigenvalue λ in general.

C. Mirror-S_3 and scale invariant quantizations

In our scheme of quantization, we have the set of parameters in U_k, $k=0,\ldots,5$ and $\kappa(\lambda)$ which specify the connection/boundary conditions and thereby the self-adjoint extensions of the Hamiltonian. These conditions are subjected to the symmetry we wish to bestow with the quantized model. For the symmetry of the model, one may assume, for instance, that the three particles are identical physically. Since the three possible exchanges of the particles are generated by the reflections, P_i $(i=1,2,3)$, which form an S_3 group, the invariance under the reflections implies the "exchange-S_3" group as the symmetry of the model. One may further assume that the pairwise collision be physically independent of the position of the remaining spectator particle. This leads to the D_6 symmetry mentioned in Sec. I, and the quantizations with this symmetry have been presented in Ref. 25.

In this paper, we relax our demand and assume only the symmetry under the "mirror-S_3" group, which is generated by the reflections, R_i $(i=1,2,3)$, consisting of the elements $\{e,R_i,(\mathcal{R}_{\pi/3})^{\pm 2}\}$ with e being the identity. In physical terms, this demand ensures the invariance of the model under all cyclic permutations of the particles; for example, if $x_1<x_2<x_3$, the interaction in the limit $x_2\to x_1$ is identical to that in the limit $x_2\to x_3$ when the spectator particle is fixed. In our scheme, this is equivalent to the requirement that all U_k be identical, i.e.,

$$U_k = U, \quad k=0,1,2,3,4,5, \tag{2.24}$$

for some $U\in \mathrm{SU}(2)$. Indeed, when combined with (2.21), the property (2.24) ensures that the boundary conditions are compatible with all the reflections in the mirror-S_3 group. Once the mirror-S_3 is installed as a symmetry in the angular part, we can classify the eigenstates of the operator H_Ω in (2.5) in terms of the representations of the group S_3, which has two one-dimensional and one two-dimensional irreducible representations (see Table I).

Another property we wish to have comes from the observation that the Hamiltonian (2.3) acquires a formal scale invariance in the limit $\omega\to 0$. Namely, we demand that this scale symmetry be maintained in the limit in our inequivalent quantizations, so that our quantized model is smoothly connected to the model with a pure inverse square potential. Roughly speaking, the scale symmetry breaks down at the quantum level when we allow the parameters of self-adjoint extensions to bear nontrivial scale dimensions (see Ref. 28). For the mirror-S_3 invariant quantizations we are considering, a sufficient condition prohibiting such scale parameters is that

$$U=\pm \mathbf{1}_2, \quad \text{or} \quad U=V\sigma_3 V^{-1}, \quad V\in \mathrm{SU}(2), \tag{2.25}$$

for the angular part specified by (2.24), and that

$$\kappa(\lambda)=0, \quad \text{or} \quad \kappa(\lambda)=\infty \quad \text{for each } \lambda, \tag{2.26}$$

for the radial part (2.23). In the present paper, we shall restrict ourselves to the class of inequivalent quantizations fulfilling (2.24)–(2.26).

III. ANGULAR PART

We now discuss inequivalent quantizations for the angular part in detail. Among the scale invariant choices (2.25) the cases $U=\pm\mathbf{1}_2$, which are parity invariant, have already been treated in Ref. 25 and will not be discussed here. To analyze the remaining cases $U=V\sigma_3V^{-1}$, we consider V for which $U\neq\pm\sigma_3$ and $U=\pm\sigma_3$, separately. This separate treatment is required since for the latter case the angular part breaks into six sectors $s_k=(\phi_{k-1},\phi_k)$, $k=1,\ldots,6$, which are physically disconnected at the singular points (see Fig. 1). The treatment is based on a set of basic solutions, which are used to analyze both the connected and the separated cases later.

A. Basic solutions

For convenience, we first set $\lambda=9\mu^2$ allowing for complex μ for $\lambda<0$. The two independent solutions for (2.6) are given[25] by

$$v_{1,\mu}(\phi)=|\sin 3\phi|^{\nu}F\left(\frac{\nu+\mu}{2},\frac{\nu-\mu}{2},\nu+\frac{1}{2};\sin^2 3\phi\right), \tag{3.1}$$

$$v_{2,\mu}(\phi)=|\sin 3\phi|^{1-\nu}F\left(\frac{1-\nu-\mu}{2},\frac{1-\nu+\mu}{2},\frac{3}{2}-\nu;\sin^2 3\phi\right), \tag{3.2}$$

where $F(\alpha,\beta,\gamma;z)$ is the standard hypergeometric function. For the reference modes needed in the connection condition at the singularity $\phi=\phi_0$, we choose

$$\varphi_1^0(\phi)=\frac{1}{\sqrt{3(2\nu-1)}}v_{1,\mu_0}(\phi)[\Theta(\phi)-\Theta(-\phi)], \tag{3.3}$$

$$\varphi_2^0(\phi)=-\frac{1}{\sqrt{3(2\nu-1)}}v_{2,\mu_0}(\phi), \tag{3.4}$$

with some real μ_0, where $\Theta(\phi)$ is the Heaviside step function. The reference modes for the connection condition at the singularity $\phi=\phi_k$ are provided according to (2.14). We introduce the shorthand,

$$a_1(\mu)=v_{1,\mu}\left(\frac{\pi}{6}-0\right)=\frac{\Gamma\left(\nu+\frac{1}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{\nu+\mu+1}{2}\right)\Gamma\left(\frac{\nu-\mu+1}{2}\right)}, \tag{3.5}$$

$$a_2(\mu)=v_{2,\mu}\left(\frac{\pi}{6}-0\right)=\frac{\Gamma\left(\frac{3}{2}-\nu\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(1-\frac{\nu+\mu}{2}\right)\Gamma\left(1-\frac{\nu-\mu}{2}\right)}, \tag{3.6}$$

$$b_1(\mu)=v'_{1,\mu}\left(\frac{\pi}{6}-0\right)=\frac{6\Gamma\left(\nu+\frac{1}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{\nu+\mu}{2}\right)\Gamma\left(\frac{\nu-\mu}{2}\right)}, \tag{3.7}$$

$$b_2(\mu)=v'_{2,\mu}\left(\frac{\pi}{6}-0\right)=\frac{6\Gamma\left(\frac{3}{2}-\nu\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{1-\nu-\mu}{2}\right)\Gamma\left(\frac{1-\nu+\mu}{2}\right)}. \tag{3.8}$$

and

$$\alpha=\frac{a_1a_2}{3(2\nu-1)},\quad \beta=\frac{b_1b_2}{3(2\nu-1)},\quad \gamma=\frac{a_1b_2+a_2b_1}{3(2\nu-1)}=-\frac{\cos\pi\mu}{\cos\pi\nu}, \tag{3.9}$$

which fulfill the relation

$$\alpha\beta = \tfrac{1}{4}(\gamma^2 - 1). \tag{3.10}$$

In terms of these, as a set of basic solutions in sector s_1, we furnish the symmetric and antisymmetric eigenfunctions,

$$\eta^1_{+,\mu}(\phi) = \begin{cases} b_2(\mu)v_{1,\mu}(\phi) - b_1(\mu)v_{2,\mu}(\phi) & \left(0 < \phi \leqslant \dfrac{\pi}{6}\right) \\ b_2(\mu)v_{1,\mu}\left(\dfrac{\pi}{3} - \phi\right) - b_1(\mu)v_{2,\mu}\left(\dfrac{\pi}{3} - \phi\right) & \left(\dfrac{\pi}{6} \leqslant \phi < \dfrac{\pi}{3}\right) \\ 0 & \left(2\pi > \phi > \dfrac{\pi}{3}\right), \end{cases} \tag{3.11}$$

$$\eta^1_{-,\mu}(\phi) = \begin{cases} a_2(\mu)v_{1,\mu}(\phi) - a_1(\mu)v_{2,\mu}(\phi) & \left(0 < \phi \leqslant \dfrac{\pi}{6}\right) \\ -a_2(\mu)v_{1,\mu}\left(\dfrac{\pi}{3} - \phi\right) + a_1(\mu)v_{2,\mu}\left(\dfrac{\pi}{3} - \phi\right) & \left(\dfrac{\pi}{6} \leqslant \phi < \dfrac{\pi}{3}\right) \\ 0 & \left(2\pi > \phi > \dfrac{\pi}{3}\right). \end{cases} \tag{3.12}$$

Likewise, we also introduce the basic solutions in sector s_k from these by translation,

$$\eta^k_{\pm,\mu}(\phi) = \eta^1_{\pm,\mu}(\phi - \phi_{k-1}), \quad k = 2, \ldots, 6. \tag{3.13}$$

The general solution is then given by a linear combination of these basic solutions with appropriate coefficients $c^k_\pm$,

$$\psi_\mu(\phi) = \sum_{k=1}^{6} (c^k_+ \eta^k_{+,\mu}(\phi) + c^k_- \eta^k_{-,\mu}(\phi)). \tag{3.14}$$

Out of these basic solutions each having their support in one sector, we also introduce a set of solutions having supports on the sectors s_k with k odd or even only:

$$\eta_+ = \sum_{n=1}^{3} \eta^{2n-1}_{+,\mu}, \quad \tilde{\eta}_+ = \sum_{n=1}^{3} \eta^{2n}_{+,\mu}, \tag{3.15}$$

$$\eta_- = \sum_{n=1}^{3} (-1)^n \eta^{2n-1}_{-,\mu}, \quad \tilde{\eta}_- = \sum_{n=1}^{3} (-1)^n \eta^{2n}_{-,\mu}. \tag{3.16}$$

B. Connected case

To analyze the connected case

$$U = V\sigma_3 V^{-1}, \quad U \neq \pm\sigma_3, \tag{3.17}$$

we parametrize the characteristic matrix, using a real ξ and a complex ζ, as

$$U = \begin{pmatrix} \xi & \zeta \\ \zeta^* & -\xi \end{pmatrix}, \quad \xi^2 + |\zeta|^2 = 1. \tag{3.18}$$

In terms of the vectors defined from the coefficients in the general solutions (3.14),

$$C^k = \begin{pmatrix} c_+^k \\ c_-^k \end{pmatrix}, \tag{3.19}$$

we find that the connection conditions (2.20) become the matrix equations,

$$C^{2n} = T_+ C^{2n-1}, \quad C^{2n+1} = T_- C^{2n}, \tag{3.20}$$

with the transfer matrices defined at the singularities between odd-even and even-odd sectors,

$$T_+ = \frac{1}{\zeta}\begin{pmatrix} -\xi+\gamma & -2\alpha \\ -2\beta & \xi+\gamma \end{pmatrix}, \quad T_- = \frac{1}{\zeta^*}\begin{pmatrix} \xi+\gamma & -2\alpha \\ -2\beta & -\xi+\gamma \end{pmatrix}, \tag{3.21}$$

where α, β, and γ are given in (3.9). These relations lead to the consistency condition,

$$TC^1 = C^1, \quad T := T_- T_+ T_- T_+ T_- T_+. \tag{3.22}$$

From this we find $\det(T-I)=0$, which implies

$$\gamma^2 = 1 \quad \text{or} \quad \gamma^2 = \frac{1+3\xi^2}{4}. \tag{3.23}$$

These determine the spectrum μ in the angular part.

To examine the case $\gamma^2=1$ in (3.23), we note from (3.10) that the condition implies that either a_1, a_2, b_1 or b_2 must vanish. None of these are compatible with each other, and we consider them separately. First, we find that $a_1=0$ occurs when

$$\mu = \nu + 1 + 2m, \quad m = 0, 1, \ldots . \tag{3.24}$$

We then have

$$T = \begin{pmatrix} 1 & 0 \\ \dfrac{12\beta}{1-\xi} & 1 \end{pmatrix}, \tag{3.25}$$

and from this we find the coefficient vectors C^k to obtain, up to a constant, the corresponding eigenfunctions

$$\tilde{\psi}_-(\phi) = \frac{1-\xi}{\zeta^*}\eta_-(\phi) + \tilde{\eta}_-(\phi). \tag{3.26}$$

These eigenfunctions belong to the signature representation χ^- of S_3. Second, $a_2=0$ occurs when

$$\mu = 2m + 2 - \nu, \quad m = 0, 1, \ldots \tag{3.27}$$

and the transfer matrix is

$$T = \begin{pmatrix} 1 & 0 \\ -\dfrac{12\beta}{1+\xi} & 1 \end{pmatrix}. \tag{3.28}$$

The eigenfunctions are found to be

$$\psi_-(\phi) = \eta_-(\phi) - \frac{1-\xi}{\zeta}\tilde{\eta}_-(\phi), \tag{3.29}$$

which again belong to the signature representation χ^- of S_3. Third, $b_1=0$ occurs when

$$\mu = \nu + 2m, \quad m = 0,1, \ldots \ . \tag{3.30}$$

We then have

$$T = \begin{pmatrix} 1 & \dfrac{12\alpha}{1+\xi} \\ 0 & 1 \end{pmatrix}, \tag{3.31}$$

and the eigenfunctions

$$\tilde{\psi}_+(\phi) = -\frac{1-\xi}{\zeta^*}\eta_+(\phi) + \tilde{\eta}_+(\phi), \tag{3.32}$$

which belong to the identity representation χ^+ of S_3. Finally, if $b_2=0$, we find

$$\mu = |1 - \nu + 2m|, \quad m = 0,1,\ldots \tag{3.33}$$

and

$$T = \begin{pmatrix} 1 & -\dfrac{12\alpha}{1-\xi} \\ 0 & 1 \end{pmatrix}. \tag{3.34}$$

We obtain the eigenfunctions

$$\psi_+(\phi) = \eta_+(\phi) + \frac{1-\xi}{\zeta}\tilde{\eta}_+(\phi), \tag{3.35}$$

belonging to the identity representation χ^+ of S_3.

When the second condition $\gamma^2=(1+3\xi^2)/4$ in (3.23) holds, on the other hand, we have $T=\mathbf{1}_2$ and hence C^1 is left undetermined. For definiteness we may choose C^1 as an eigenvector of the rotation $\mathcal{R}^2_{\pi/3}$. The transfer matrix that corresponds to $\mathcal{R}^2_{\pi/3}$ is

$$T_-T_+ = \begin{pmatrix} -\dfrac{1}{2} & -\dfrac{4\alpha(\gamma+\xi)}{1-\xi^2} \\ -\dfrac{4\beta(\gamma-\xi)}{1-\xi^2} & -\dfrac{1}{2} \end{pmatrix}, \tag{3.36}$$

which has the eigenvectors

$$X_\pm = \begin{pmatrix} 2\alpha \\ \pm\sqrt{3}i(-\xi+\gamma) \end{pmatrix}. \tag{3.37}$$

With these eigenvectors, the vectors $C^k_\pm$ may be written as

$$C^{2n-1}_\pm = \mathrm{J}^{\mp n}X_\pm, \quad C^{2n}_\pm = \mathrm{J}^{\mp n}T_+X_\pm, \quad \mathrm{J} := \frac{-1+i\sqrt{3}}{2}. \tag{3.38}$$

If we denote by $\psi^{(\pm)}_1$ the eigenfunction corresponding to $C^k_\pm$ with $\gamma>0$, and similarly by $\psi^{(\pm)}_2$ the eigenfunction corresponding to $C^k_\pm$ with $\gamma<0$, then

$$\mathcal{R}^2_{\pi/3}\psi^{(\pm)}_i = \mathrm{J}^{\pm 1}\psi^{(\pm)}_i, \quad R_2\psi^{(\pm)}_i = \psi^{(\mp)}_i, \quad i = 1,2. \tag{3.39}$$

To find the spectrum of these eigenstates, we combine (3.23) and the last equation of (3.9) to obtain

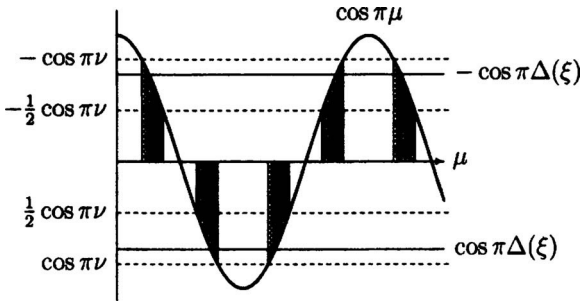

FIG. 2. Eigenvalues μ arise at the intersections of $\cos \pi\mu$ and the two lines $\pm\cos \Delta(\xi)$, which are shown here for the values $\nu=0.8$ and $\xi=\frac{5}{6}$. Dashed lines represent the upper and the lower limits of the lines, and the shaded regions indicate the allowed ranges of the eigenvalues.

$$\cos \pi\mu = \mp \cos \pi\Delta(\xi), \quad \Delta(\xi) := \frac{1}{\pi}\mathrm{Arccos}\left(\frac{\sqrt{1+3\xi^2}}{2}\cos \pi\nu\right). \tag{3.40}$$

The solutions for μ will furnish the eigenvalues, which occur periodically as displayed in Fig. 2. We then see that the eigenvalues for $\gamma>0$ are given by

$$\mu = \begin{cases} 2m+1-\Delta(\xi) \\ 2m+1+\Delta(\xi), \end{cases} \tag{3.41}$$

whereas the eigenvalues for $\gamma<0$ are

$$\mu = \begin{cases} 2m+2-\Delta(\xi) \\ 2m+\Delta(\xi), \end{cases} \tag{3.42}$$

where $m=0,1,\ldots$. Since $|\xi| \leqslant 1$, we find that $\Delta(\xi)$ stays in the range,

$$\Delta(0) \leqslant \Delta(\xi) \leqslant \Delta(1) = \nu. \tag{3.43}$$

The eigenvalues and eigenfunctions are summarized in Table II.

C. Separated case

Next we analyze the case

$$U = \sigma_3, \tag{3.44}$$

under which all the sectors s_k are physically separated from each other. (The other separated case $U=-\sigma_3$ can be dealt with similarly and will not be discussed here.) To proceed, we note that under the choice (3.44) the boundary condition (2.20) reads

TABLE II. Eigenvalues and eigenfunctions in the connected case.

Eigenvalue μ	Eigenfunction	Rep of S_3
$2m+1+\nu$	$\tilde{\psi}_-$	χ^-
$2m+2-\nu$	ψ_-	χ^-
$2m+\nu$	$\tilde{\psi}_+$	χ^+
$\lvert 2m+1-\nu\rvert$	ψ_+	χ^+
$2m+1-\Delta(\xi)$	$\psi_1^{(+)}, \psi_1^{(-)}$	$\chi^{(2)}$
$2m+1+\Delta(\xi)$		
$2m+2-\Delta(\xi)$	$\psi_2^{(+)}, \psi_2^{(-)}$	$\chi^{(2)}$
$2m+\Delta(\xi)$		

TABLE III. Eigenvalues and eigenfunctions in the separated case.

Eigenvalue μ	Eigenfunction	Rep of S_3
$2m+1+\nu$	$\tilde{\eta}_-$	χ^-
	$\tilde{\eta}_-^{(+)}, \tilde{\eta}_-^{(-)}$	$\chi^{(2)}$
$2m+\nu$	$\tilde{\eta}_+$	χ^+
	$\tilde{\eta}_+^{(+)}, \tilde{\eta}_+^{(-)}$	$\chi^{(2)}$
$2m+2-\nu$	η_-	χ^-
	$\eta_-^{(+)}, \eta_-^{(-)}$	$\chi^{(2)}$
$\lvert 2m+1-\nu \rvert$	η_+	χ^+
	$\eta_+^{(+)}, \eta_+^{(-)}$	$\chi^{(2)}$

$$b_2 C_+^{2n-1} = a_2 C_-^{2n-1} = b_1 C_+^{2n} = a_1 C_-^{2n} = 0. \tag{3.45}$$

As before, the vanishing conditions of a_1, a_2, b_1, and b_2 are not compatible, and we consider them separately. Recall, first, that $a_1=0$ is realized by μ in (3.24). The vectors C^k obtained in this case lead to the eigenfunctions $\tilde{\eta}_-$ belonging to the signature representation χ^-, and also

$$\tilde{\eta}_-^{(\pm)} = \sum_{n=1}^{3} \mathrm{J}^{\mp n} \eta_{-,\mu}^{2n}, \tag{3.46}$$

which belong to the doublet representation $\chi^{(2)}$. Second, $a_2=0$ is realized by μ in (3.27), and the corresponding eigenfunctions are given by η_- belonging to χ^-, and

$$\eta_-^{(\pm)} = \sum_{n=1}^{3} \mathrm{J}^{\mp n} \eta_{-,\mu}^{2n-1}, \tag{3.47}$$

which belong to $\chi^{(2)}$. Third, $b_1=0$ occurs when μ is given by (3.30). The eigenfunctions are found to be $\tilde{\eta}_+$ belonging to χ^+, and

$$\tilde{\eta}_+^{(\pm)} = \sum_{n=1}^{3} \mathrm{J}^{\mp n} \eta_{+,\mu}^{2n}, \tag{3.48}$$

which belong to $\chi^{(2)}$. Finally, $b_2=0$ occurs when μ is given by (3.33). The eigenfunctions are η_+ belonging to χ^+, and

$$\eta_+^{(\pm)} = \sum_{n=1}^{3} \mathrm{J}^{\mp n} \eta_{+,\mu}^{2n-1}, \tag{3.49}$$

which belong to $\chi^{(2)}$. These eigenvalues and the eigenfunctions are summarized in Table III. The spectral behavior of the two cases is shown in Fig. 3 (left).

At this point, we mention that the connected case discussed earlier has a smooth limit to the separated case, that is, the eigenfunctions in the former case can be obtained formally from those in the latter case by considering the limit $U \to \sigma_3$, even though the two cases require distinctive treatments. For the eigenstates which are singlets of the mirror-S_3, this can be seen at once since the eigenfunctions in the connected case reduce to

$$\psi_+ \to \eta_+, \quad \psi_- \to \eta_-, \quad \tilde{\psi}_+ \to \tilde{\eta}_+, \quad \tilde{\psi}_- \to \tilde{\eta}_-, \tag{3.50}$$

in the limit $\xi \to 1$, which is equivalent to $U \to \sigma_3$; see (3.18). To see that the same is true for the doublets, consider the case $a_1=0$ in which the eigenstates vanish $\psi_+^{(\pm)} \to 0$ in the limit. Nonvanishing outcomes in the limit may be obtained, however, by rescaling them properly as

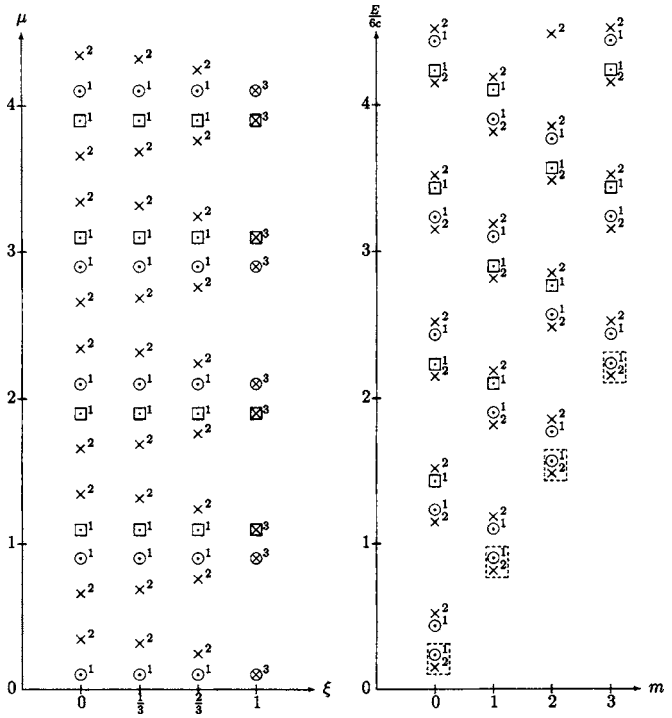

FIG. 3. The spectra of μ for various ξ (left), and the total energy E for $m=0,1,2,3$ (right). The spectra of μ are plotted for $\xi=0,\frac{1}{3},\frac{2}{3},1$ under $\nu=0.9$, which interpolate between $U=V^{-1}\sigma_3 V$ and $U=\sigma_3$. The energy spectrum of E (in units of $6c$) is obtained for $\nu=0.9$ and $\xi=\frac{5}{6}$. The signs inside the dashed squares for the lowest two levels to each m in the energy spectrum of E represent the levels arising for $\kappa(\lambda)=\infty$, which is allowed only for these two levels. All other levels are obtained for the choice $\kappa(\lambda)=0$. Symbols used to plot the levels show the representations of the mirror-S_3 group; the symbol $\odot$ stands for the identity representation χ^+, $\boxdot$ for the signature representation χ^-, and $\times$ for the two-dimensional representation $\chi^{(2)}$, respectively. (The superimposed symbols $\otimes$ and $\boxtimes$ indicate that the levels are degenerate by the corresponding distinct representations.) The numbers $1,2,3$ on the upper right of the symbols show the total multiplicities of the levels.

$$\frac{-8i}{\zeta^*\sqrt{3}}\psi_1^{(\pm)} \to \tilde{\eta}_-^{(\pm)}. \tag{3.51}$$

Similarly, for $a_2=0$, we find

$$\frac{i}{2\sqrt{3}}\psi_2^{(\pm)} \to \eta_-^{(\pm)}. \tag{3.52}$$

The continuity in the remaining cases $b_1=0$, $b_2=0$ can also be argued analogously.

IV. RADIAL PART AND THE TOTAL ENERGY SPECTRUM

A. Radial part

The eigenfunctions for the radial part can be obtained immediately, since there remain only two choices (2.26) for the inequivalent quantizations under the scale invariance we have imposed. Note that the radial Hamiltonian $\mathcal{H}_{r,\lambda}$ admits the two independent solutions,[25]

$$\rho_{E,1}(r) = (\sqrt{c}r)^{\sqrt{\lambda}+1/2} e^{-(1/2)cr^2} \Phi\left(\frac{1+\sqrt{\lambda}}{2} - \frac{E}{4c}, 1+\sqrt{\lambda}; cr^2\right), \tag{4.1}$$

$$\rho_{E,2}(r) = (\sqrt{c}r)^{-\sqrt{\lambda}+1/2} e^{-(1/2)cr^2} \Phi\left(\frac{1-\sqrt{\lambda}}{2} - \frac{E}{4c}, 1-\sqrt{\lambda}; cr^2 \right), \tag{4.2}$$

where $\Phi(a,b;z)$ is the confluent hypergeometric function and $c := \sqrt{(3/8)}\omega$. Since these two solutions diverge generically as $r \to \infty$, the square integrability requires that the eigenfunctions be proportional to their linear combination,

$$\rho_E(r) = \frac{\Gamma(1-\sqrt{\lambda})}{\Gamma\left(\frac{1-\sqrt{\lambda}}{2} - \frac{E}{4c} \right)} \rho_{E,1}(r) - \frac{\Gamma(1+\sqrt{\lambda})}{\Gamma\left(\frac{1+\sqrt{\lambda}}{2} - \frac{E}{4c} \right)} \rho_{E,2}(r), \tag{4.3}$$

which vanishes as $r \to \infty$.

To enforce (2.26), we choose the reference modes as

$$\varphi_1(r) = (2\sqrt{\lambda c})^{-1/2} \rho_{E,1}(r), \quad \varphi_2(r) = -(2\sqrt{\lambda c})^{-1/2} \rho_{E,2}(r). \tag{4.4}$$

With these the radial boundary condition (2.23) reads

$$\kappa(\lambda) = \frac{\Gamma(1+\sqrt{\lambda})\Gamma\left(\frac{1-\sqrt{\lambda}}{2} - \frac{E}{4c} \right)}{\Gamma(1-\sqrt{\lambda})\Gamma\left(\frac{1+\sqrt{\lambda}}{2} - \frac{E}{4c} \right)}. \tag{4.5}$$

For the case $\kappa(\lambda)=0$, the solutions and the energy eigenvalues are

$$\rho_E(r) = r^{\sqrt{\lambda}+1/2} e^{-(1/2)cr^2} L_m^{\sqrt{\lambda}}(cr^2), \quad E = E(m,\lambda) = 2c(2m+1+\sqrt{\lambda}), \tag{4.6}$$

for $m=0,1,\ldots$, where $L_m^{\sqrt{\lambda}}$ is the (generalized) Laguerre polynomial. Analogously, for the case $\kappa(\lambda)=\infty$ we find

$$\rho_E(r) = r^{-\sqrt{\lambda}+1/2} e^{-(1/2)cr^2} L_m^{-\sqrt{\lambda}}(cr^2), \quad E = E(m,\lambda) = 2c(2m+1-\sqrt{\lambda}), \tag{4.7}$$

for $m=0,1,\ldots$. As noted earlier, these two types of solutions arise only for $\lambda<1$; otherwise only the former solution (4.6) is allowed. This solution (4.6) is in fact the one used by Calogero[1] and also conventionally adopted by others[16,17,20] for all values of λ.

B. Total energy spectra

Having obtained the solutions for both the radial and the angular parts, we now construct the solutions for the entire (relative coordinates) system (2.5) by combining the solutions of the respective parts as

$$\psi_E(r;\lambda) = \frac{1}{\sqrt{r}} \rho_E(r) \psi_\mu(\phi), \quad E = E(m,\lambda = 9\mu^2), \tag{4.8}$$

where we have denoted the angular solutions by $\psi_\mu(\phi)$ collectively. These solutions $\rho_E(r)$ and $\psi_\mu(\phi)$ are dependent on the parameters $\kappa(\lambda)$ and ξ,ζ that specify the inequivalent quantizations of the respective part.

It is important, however, to note that not all combinations of them are allowed because the choice $\kappa(\lambda)=\infty$ is available only if $\lambda<1$. In fact, one can readily see that $\kappa(\lambda)=\infty$ is possible, at most, for the lowest two angular eigenvalues $\lambda=\lambda_1$ or $\lambda=\lambda_2$, where

$$\lambda_1 := 9(1-\nu)^2, \quad \lambda_2 := 9(1-\Delta)^2, \tag{4.9}$$

and that $\kappa(\lambda)=0$ for all other λ which are above the two. More explicitly, the case $\kappa(\lambda)=\infty$ is admitted for λ_1 if

TABLE IV. Possible choices of $\kappa(\lambda_1)$ and $\kappa(\lambda_2)$.

Range of ν	$\kappa(\lambda_1)$	$\kappa(\lambda_2)$
$\frac{1}{2}<\nu\leqslant\frac{2}{3}$	0	0
$\frac{2}{3}<\nu\leqslant 1-\nu_0$	0 or ∞	0
$1-\nu_0<\nu<1+\nu_0$	0 or ∞	0 or ∞
$1+\nu_0\leqslant\nu<\frac{4}{3}$	0 or ∞	0
$\frac{4}{3}\leqslant\nu<\frac{3}{2}$	0	0

$$\tfrac{2}{3}<\nu<\tfrac{4}{3}, \tag{4.10}$$

and for λ_2 if

$$1-\nu_0<\nu<1+\nu_0, \quad \nu_0=\frac{1}{\pi}|\arctan\sqrt{3}\xi|. \tag{4.11}$$

Since the condition (4.11) is stricter than (4.10), available choices for the inequivalent quantizations depend on the value of ν, as summarized in Table IV.

For illustration, we show in Fig. 3 the angular spectrum (left) for various values of ξ, and the total energy spectrum (right) for different choices of the $\kappa(\lambda)$ parameters. We observe that if $\kappa(\lambda)=0$ for all λ the energy levels are made of one single series, consisting of a regular pattern formed by four singlets and four doublets. The equispaced levels suggest that, for this case, the Calogero model may be solved by use of the ladder operator, as demonstrated for the special case[7,8] which amounts to $U=-I$ and $\kappa(\lambda)=0$ in our scheme.

V. SPECTRAL PRESERVING SU(2) AND THE ANGULAR SPECTRUM

The angular spectrum obtained in Sec. III is independent of the phase of the parameter ζ even though the eigenfunctions are dependent on it. In particular, the levels of the mirror-S_3 singlets depend on neither of the parameters ξ and ζ and hence are independent of the choice of V in $U=V\sigma_3V^{-1}$. In fact, these are a consequence of the spectral preserving SU(2) (or its subgroup U(1)) transformations[29] which are found in the family of inequivalent quantizations we are considering here.

To see this, let us first consider the reflection transformation Q_1 given by $Q_1:=P_3$ in (2.7). Observe that the action (2.9) on the states,

$$\psi(\phi)\to(Q_1\psi)(\phi)=\psi(-\phi), \tag{5.1}$$

is *spectrum-preserving* in the sense that if ψ_λ is an eigenstate of the angular operator H_Ω as in (2.5) with eigenvalue λ, then

$$H_\Omega(Q_1\psi_\lambda)(\phi)=\lambda(Q_1\psi_\lambda)(\phi), \tag{5.2}$$

on account of the formal invariance of the operator H_Ω under Q_1. Note that this does not imply that Q_1 is a symmetry unless it is compatible with the boundary conditions specified by U. For the boundary vectors, we find

$$B_k(Q_1\psi)=\sigma_1B_{6-k}(\psi), \quad B'_k(Q_1\psi)=\sigma_1B'_{6-k}(\psi), \tag{5.3}$$

for $k=0,\ldots,5$, with the identification $B_0=B_6$ and $B'_0=B'_6$. Thus, in effect, the transformation Q_1 induces in the connection conditions (2.20) the change

$$U\to\sigma_1U\sigma_1. \tag{5.4}$$

It follows that the operator H_Ω shares the same spectrum under the boundary conditions specified by U and $\sigma_1U\sigma_1$.

We next consider the "alternate reflection" defined by

$$\psi(x) \to (Q_3\psi)(\phi) := \begin{cases} \psi(\phi), & \phi_{2k} < \phi < \phi_{2k+1} \\ -\psi(\phi), & \phi_{2k+1} < \phi < \phi_{2k+2}. \end{cases} \tag{5.5}$$

Evidently, this is also spectral-preserving, and on the boundary vectors we have

$$B_k(Q_3\psi) = \sigma_3 B_k(\psi), \quad B'_k(Q_3\psi) = \sigma_3 B'_k(\psi). \tag{5.6}$$

Accordingly, we find that the alternate reflection (5.5) induces

$$U \to \sigma_3 U \sigma_3 \tag{5.7}$$

in the connection conditions (2.20). From Q_1 and Q_3 we further define the product transformation $Q_2 := iQ_1Q_3$ that yields

$$B_k(Q_2\psi) = \sigma_2 B_{6-k}(\psi), \quad B'_k(Q_2\psi) = \sigma_2 B'_{6-k}(\psi). \tag{5.8}$$

By construction, Q_2 is spectral-preserving and induces

$$U \to \sigma_2 U \sigma_2. \tag{5.9}$$

Consequently, we see that the connection conditions by U and $\sigma_i U \sigma_i$ for all $i=1,2,3$ give rise to the same spectrum for the operator H_Ω. Note that Q_i's form the $su(2)$ algebra,

$$[Q_i, Q_j] = 2i\epsilon^{ijk} Q_k. \tag{5.10}$$

Suppose, now that the state ψ is in a singlet representation of the mirror-S_3, i.e., it is an eigenstate of R_i with fixed eigenvalues ± 1 for all $i=1,2,3$. The state ψ is then a periodic function with period $2\pi/3$, and hence we have $B_k(\psi)=B_{-k}(\psi)$ and $B'_k(\psi)=B'_{-k}(\psi)$. The three relations (5.3), (5.6), and (5.8) can then be combined as

$$B_k(Q_i\psi) = \sigma_i B_k(\psi), \quad B'_k(Q_i\psi) = \sigma_i B'_k(\psi), \quad i = 1,2,3. \tag{5.11}$$

On account of the linearity of B_k and B'_k observed in (5.11) and the algebraic property (5.10), we find that a linear combination of the Q_i's,

$$Q = \sum_{i=1}^{3} c_i Q_i, \quad \sum_{i=1}^{3} c_i^2 = 1, \tag{5.12}$$

with arbitrary coefficients c_i fulfills $Q^2=I$ and is also spectral-preserving for singlet states. On the matrix U, this induces

$$U \to \sigma U \sigma, \quad \sigma = \sum_{i=1}^{3} c_i \sigma_i. \tag{5.13}$$

It can be shown[29] that by choosing c_i appropriately one finds σ such that $\sigma U \sigma = V^{-1}UV$ for any $V \in \mathrm{SU}(2)$. In other words, the transformation generated by Q in (5.12) yields the change

$$U \to V^{-1}UV, \tag{5.14}$$

without altering the spectrum. It then follows that, as far as the mirror-S_3 singlets are concerned, the operator H_Ω shares the same spectrum under $V^{-1}UV$ for any $V \in \mathrm{SU}(2)$. From this we see that for the scale invariant $U=V\sigma_3 V^{-1}$ we are considering, the spectrum of the mirror-S_3 singlets is independent of V, as we have observed in the last section.

This SU(2)-independence does not hold for the eigenstates in the doublet representation $\chi^{(2)}$ of the mirror-S_3, because for them the transformations Q_1 and Q_2 interchange different boundary vectors as seen in (5.3) and (5.8). However, the transformation Q_3 still maps the boundary vectors

to themselves as (5.6) and can be used to provide a one-parameter family of spectral-preserving transformations $e^{i\theta Q_3}$ for any real θ. On the matrix U, the transformations induce

$$U \to e^{-i\theta\sigma_3} U e^{i\theta\sigma_3}, \tag{5.15}$$

which form a U(1) subgroup of the SU(2) transformations (5.14). In parameters, this allows us to alter the phase of ζ in U freely, which implies that the whole spectrum depends only on $|\zeta|$ or ξ as seen earlier.

Finally, we mention that the universality in the spectrum is a general feature of a circle system with even number $2N$ of singularities that appears when it is quantized under mirror symmetries defined analogously to the present case $2N=6$.

VI. CONCLUSION

In the present paper we studied the inequivalent quantizations of the $N=3$ Calogero model based on the method of separation of variables. Our inequivalent quantizations respect both the mirror-S_3 invariance and the scale invariance. These quantizations are, in a sense, supplemental to the quantizations presented in Ref. 25 which respect the D_6 invariance, in view of the fact that the D_6 is restored when the scale invariance is exchanged for parity invariance in our case. Our symmetry requirement is that all the connection conditions at the singularities in the angular part are specified by a single matrix U of the form (2.26). For a system consisting of a line, this class of singularities is known as the scale invariant family and is given, except for the cases $U=\pm\mathbf{1}_2$, by an S^2 parameter space (see (3.18)). We mention that the scale invariant family supports the Berry phase (or anholonomy) when the singularities are tuned along a cycle on the scale invariant sphere S^2.[30]

In our inequivalent quantizations, we found the eigenstates and eigenvalues explicitly, both for the angular and radial parts that arise after the separation of variables is made. These eigenstates are classified in terms of the irreducible representations of the mirror-S_3 group. We observed that the eigenvalues corresponding to the singlets of the S_3 are independent of the choice of U in the family, whereas those corresponding to the doublets of the S_3 are dependent only on one parameter ξ which corresponds to the coordinate along a great circle on the S^2. We showed that these properties are due to the spectral-preserving SU(2) transformations or U(1) transformations that the scale invariant family possesses.

The scale invariance is strict enough to narrow the possible boundary conditions at $r=0$ in the radial part down to just two types, one given by the Dirichlet condition and the other by the Neumann condition. The Neumann condition is possible if $\lambda<1$, which occurs only for the eigenstates coupled to the lowest two angular levels. The possibility of the Neumann condition brings about a number of different spectra for the total energy, as we have seen in Fig. 3. When all the radial eigenstates adopt the Dirichlet condition irrespective of the eigenvalue λ of the radial level that couples to them, the energy spectrum exhibits a regular pattern consisting of a number of distinct sets of levels which are equispaced from each other. This suggests that for these cases we may also devise the method of the ladder operator to solve the model. In contrast, this seems to be impossible when the Neumann condition is adopted for the lower levels, where the regular pattern is broken at the lowest end of the spectrum. The appearance of the intriguing combination of inequivalent quantizations, which we found in the angular and radial parts in our model, is perhaps a generic feature to be observed in quantizing models of more than two dimensions in general frameworks.

(Received 21 September 2005; accepted 8 November 2005; published online 17 January 2006)

We discuss the φ^6 theory defined in $D=2+1$-dimensional space-time and assume that the system is in equilibrium with a thermal bath at temperature β^{-1}. We use the $1/N$ expansion and the method of the composite operator (Cornwall, Jackiw, and Tomboulis) for summing a large set of Feynman graphs. We demonstrate explicitly the Coleman-Mermin-Wagner theorem at finite temperature. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2159068]

I. INTRODUCTION

The conventional perturbation theory in the coupling constant or in $\hbar$, i.e., the loop expansion can only be used for the study of small quantum corrections to classical results. When discussing quantum mechanical effects to any given order in such an expansion, one is not usually able to justify the neglect of yet higher order. In other words, for theories with a large N dimensional internal symmetry group, there exist another perturbation scheme, the $1/N$ expansion, which circumvents this criticism. Each term in the $1/N$ expansion contains an infinite subset of terms of the loop expansion. The $1/N$ expansion has the nice property that the leading-order quantum corrections are of the same order as the classical quantities. Consequently, the leading order which adequately characterizes the theory in the large N limit preserves much of the nonlinear structure of the full theory.

The scalar field $(\varphi^4)_{D=4}$ theory at finite temperature is of great interest in the field of phase transitions in the early universe and heavy ion collisions. When used as a simple model for the Higgs particle in the standard model of electroweak interactions, it may allow the study of symmetry breaking phase transitions in the early universe. For $N=4$ scalar fields, it is also a model of chiral symmetry breaking in QCD and hence is relevant for the theoretical study of heavy ion collisions. Moreover, this theory is an excellent theoretical laboratory in which analytic nonperturbative methods can be tested. Now for the case $D=3$ it has been shown that, in the large N limit, the φ^6 theory has a UV fixed point and therefore must have a second IR fixed point[1] and for this we could say that at least for large N the $(\varphi^6)_{D=3}$ theory is known to be qualitatively different from $(\varphi^4)_{D=4}$ theory. For other ways, theories in less than four space-time dimensions can offer interesting and complex behavior as well as tractability, and, for example, the case of three space-time dimensions, they can even be directly physical, describing various planar condensed matter systems. For example, the introduction of the φ^6 term generates a rich phase diagram, with the possibility of second order, first order phase transitions or even both transitions occurring simultaneously. This situation defines the tricritical phenomenon. For example, some systems such antiferromagnets in the presence of a strong external field or the He^3-He^4 mixture exhibits such behavior.

FIG. 1. The 2PI vacuum graphs.

II. THE EFFECTIVE POTENTIAL

The theory for which we are interested is given by the Lagrangian,

$$\mathcal{L}(\varphi) = \frac{1}{2}(\partial_\mu \varphi)^2 - \frac{1}{2}m_0^2\varphi^2 - \frac{\lambda_0}{4!N}\varphi^4 - \frac{\eta_0}{6!N^2}\varphi^6, \tag{1}$$

is a theory of N real scalar fields with $O(N)$ symmetry.

For definiteness, we work at zero temperature; however, the finite temperature generalizations can be easily obtained.[2]

In this section we are going to use the method of composite operator developed by Cornwall, Jackiw, and Tomboulis (CJT)[3,4] in order to get the effective potential $\Gamma(\phi)$ at leading order in the $1/N$ expansion. The composite operator formalism reduces the problem to summing two particle irreducible (2PI) Feynman graphs by defining a generalized effective action $\Gamma(\phi, G)$ which is a functional not only of $\phi_a(x)$, but also of the expectation values $G_{ab}(x,y)$ of the time ordered product of quantum fields $\langle 0|T(\varphi(x)\varphi(y))|0\rangle$, i.e.,

$$\Gamma(\phi, G) = I(\phi) + \frac{i}{2}\mathrm{Tr\ Ln}\, G^{-1} + \frac{i}{2}\mathrm{Tr}\, D^{-1}(\phi)G + \Gamma_2(\phi, G) + \cdots, \tag{2}$$

where $I(\phi) = \int \mathrm{d}x^D\, \mathcal{L}(\phi)$, G and D are matrices in both the functional and the internal space whose elements are $G_{ab}(x,y)$, $D_{ab}(\phi; x, y)$, respectively, and D is defined by

$$iD^{-1} = \frac{\delta^2 I(\phi)}{\delta\phi(x)\,\delta\phi(y)}. \tag{3}$$

The quantity $\Gamma_2(\phi, G)$ is computed as follows. In the classical action $I(\varphi)$ we must shift the field φ by ϕ. The new action $I(\varphi+\phi)$ possesses terms cubic and higher in φ. This defines an interaction part $I_{\mathrm{int}}(\varphi, \phi)$ where the vertices depend on ϕ. $\Gamma_2(\phi, G)$ is given by sum of all (2PI) vacuum graphs in a theory with vertices determined by $I_{\mathrm{int}}(\varphi, \phi)$ and the propagators set equal to $G(x,y)$. The trace and logarithm in Eq. (2) are functional. After these procedures the interaction Lagrangian density becomes

$$\begin{aligned}\mathcal{L}_{\mathrm{int}}(\varphi, \phi) = &-\frac{1}{2}\left(\frac{\lambda_0\phi_a}{3N} + \frac{\eta_0\phi^2\phi_a}{30N^2}\right)\varphi_a\varphi^2 - \left(\frac{8\,\eta_0\phi_a\phi_b\phi_c}{6N^2}\right)\varphi_a\varphi_b\varphi_c - \frac{1}{4!N}\left(\lambda_0 + \frac{\eta_0\phi^2}{10N}\right)\varphi^4 \\ &- \left(\frac{12\,\eta_0\phi_a\phi_b}{6!N^2}\right)\varphi_a\varphi_b\varphi^2 - \frac{1}{5!}\left(\frac{\eta_0\phi_a}{N^2}\varphi_a\varphi^4\right) - \frac{\eta_0}{6!N^2}\varphi^6.\end{aligned} \tag{4}$$

The effective action $\Gamma(\phi)$ is found by solving for $G_{ab}(x,y)$ the equation

$$\frac{\delta\Gamma(\phi, G)}{\delta G_{ab}(x,y)} = 0, \tag{5}$$

and substituting the solution in the generalized effective action $\Gamma(\phi, G)$. The vertices in the above equation contain factors of $1/N$ or $1/N^2$, but a φ loop gives a factor of N provided the $O(N)$ isospin flows around it alone and not into another part of the graph. We usually call such loops bubbles. Then at leading order in $1/N$, the vacuum graphs are bubble trees with two or three bubbles at each vertex. The (2PI) graphs are shown in Fig. 1. It is straightforward to obtain

$$\Gamma_2(\phi,G)=\frac{-1}{4!N}\int d^Dx\left(\lambda_0+\frac{\eta_0\phi^2}{10N}\right)[G_{aa}(x,x)]^2-\frac{\eta_0}{6!N^2}\int d^Dx[G_{aa}(x,x)]^3. \tag{6}$$

Therefore Eq. (5) becomes

$$\frac{\delta\Gamma(\phi,G)}{\delta G_{ab}(x,y)}=\frac{1}{2}(G^{-1})_{ab}(x,y)+\frac{i}{2}D^{-1}(\phi)-\frac{1}{12N}\left(\lambda_0+\frac{\eta_0\phi^2}{10N}\right)[\delta_{ab}G_{cc}(x,x)]\delta^D(x-y)$$
$$-\frac{3\eta_0}{6!N}\delta_{ab}[G_{cc}(x,x)]^2\delta^D(x-y)=0. \tag{7}$$

Rewriting this equation, we obtain the gap equation

$$(G^{-1})_{ab}(x,y)=D^{-1}_{ab}(\phi;x,y)+\frac{i}{6N}\left(\lambda_0+\frac{\eta_0\phi^2}{10N}\right)[\delta_{ab}G_{cc}(x,x)]\delta^D(x-y)$$
$$+\frac{i\eta_0}{5!N^2}\delta_{ab}[G_{cc}(x,x)]^2\delta^D(x-y). \tag{8}$$

Hence

$$\frac{i}{2}\mathrm{Tr}\,D^{-1}G=\frac{1}{12N}\int d^Dx\left(\lambda_0+\frac{\eta_0\phi^2}{10N}\right)[G_{aa}(x,x)]^2+\frac{3\eta_0}{6!N^2}\int d^Dx[G_{aa}(x,x)]^3+cte. \tag{9}$$

Using Eqs. (8) and (9) in Eq. (6) we find the effective action

$$\Gamma(\phi)=I(\phi)+\frac{i}{2}\mathrm{Tr}[\mathrm{Ln}\,G^{-1}]+\frac{1}{4!N}\int d^Dx\left(\lambda_0+\frac{\eta_0\phi^2}{10N}\right)[G_{aa}(x,x)]^2+\frac{2\eta_0}{6!N^2}\int d^Dx[G_{aa}(x,x)]^3, \tag{10}$$

where G_{ab} is given implicitly by Eq. (8). The trace in (10) are both the functional and the internal space. The last two terms on the right-hand side of Eq. (10) are the leading contribution to the effective action in the $1/N$ expansion. As usual we may simplify the situation by separating G_{ab} into transverse and longitudinal components, so

$$G_{ab}=\left(\delta_{ab}-\frac{\phi_a\phi_b}{\phi^2}\right)g+\frac{\phi_a\phi_b}{\phi^2}\tilde{g}, \tag{11}$$

in this form we can invert G_{ab},

$$(G)^{-1}_{ab}=\left(\delta_{ab}-\frac{\phi_a\phi_b}{\phi^2}\right)g^{-1}+\frac{\phi_a\phi_b}{\phi^2}\tilde{g}^{-1}. \tag{12}$$

Now we can take the trace with respect to the indices of the internal space,

$$G_{aa}=Ng+O(1),\quad (G)^{-1}_{aa}=Ng^{-1}+O(1). \tag{13}$$

From this equation at leading order in $1/N$, G_{ab} is diagonal in a,b. Substituting Eq. (13) into Eq. (10) and Eq. (8) and keeping only the leading order one finds that the daisy and superdaisy resumed effective potential for the φ^6 theory is given by

$$\Gamma(\phi)=I(\phi)+\frac{iN}{2}\mathrm{tr}(\ln g^{-1})+\frac{N}{4!}\int d^Dx\left(\lambda_0+\frac{\eta_0\phi^2}{10N}\right)g^2(x,x)+\frac{2N\eta_0}{6!}\int d^Dxg^3(x,x)+O(1), \tag{14}$$

where the trace is only in the functional space, and the gap equation becomes

$$g^{-1}(x,y) = i\left[\Box + m_0^2 + \frac{\lambda_0}{6}\left(\frac{\phi^2}{N} + g(x,x)\right) + \frac{\eta_0}{5!}\left(\frac{\phi^2}{N} + g(x,x)\right)^2\right]\delta^D(x-y) + O\left(\frac{1}{N}\right). \quad (15)$$

It is important to point out that this calculation was done by Townsend.[5]

III. THE THEORY AT FINITE TEMPERATURE

In order to generalize these results to the case of finite temperature we are going to assume that the system is in equilibrium with a thermal bath a temperature $T=\beta^{-1}$. Since we are interested in the equilibrium situation it is convenient to use the Matsubara formalism (imaginary time). Consequently it is convenient to continue all momenta to Euclidean values ($p_0=ip_4$) and take the following Ansatz for $g(x,y)$:

$$g(x,y) = \int \frac{d^D p}{(2\pi)^D} \frac{\exp^{i(x-y)p}}{p^2 + M^2(\phi)}. \quad (16)$$

Substituting Eq. (16) in Eq. (15) we get the expression for the gap equation,

$$M^2(\phi) = m_0^2 + \frac{\lambda_0}{6}\left(\frac{\phi^2}{N} + F(\phi)\right) + \frac{\eta_0}{5!}\left(\frac{\phi^2}{N} + F(\phi)\right)^2, \quad (17)$$

where $F(\phi)$ is given by

$$F(\phi) = \int \frac{d^D p}{(2\pi)^D} \frac{1}{p^2 + M^2(\phi)}, \quad (18)$$

and the effective potential in the D-dimensional Euclidean space can be written as

$$V(\phi) = V_0(\phi) + \frac{N}{2}\int \frac{d^D p}{(2\pi)^D} \ln[p^2 + M^2(\phi)] - \frac{N}{4!}\left(\lambda_0 + \frac{\eta_0\phi^2}{10N}\right)F(\phi)^2 - \frac{2N\eta_0 F(\phi)^3}{6!}, \quad (19)$$

where $V_0(\phi)$ is the tree approximation of the potential.

Replacing the continuous four momenta k_4 by discrete ω_n and the integration by a summation ($\beta=1/T$). The effective potential at finite temperature is

$$V_\beta(\phi) = V_0(\phi) + \frac{N}{2\beta}\sum_n^\infty \int \frac{d^{D-1}}{(2\pi)^{D-1}} \ln[\omega_n + p^2 + M_\beta^2(\phi)] - \frac{N}{4!}\left(\lambda_0 + \frac{\eta_0\phi^2}{10N}\right)F_\beta(\phi)^2 - \frac{2N\eta F_\beta(\phi)^3}{6!}, \quad (20)$$

where the expression $F_\beta(\phi)$ is the finite temperature generalization of $F(\phi)$, and is given by

$$F_\beta(\phi) = \frac{1}{\beta}\sum_{n=-\infty}^{\infty} \int \frac{d^{D-1}p}{(2\pi)^{D-1}} \frac{1}{\omega_n^2 + p^2 + M_\beta^2(\phi)}. \quad (21)$$

The gap equation for this theory at finite temperature is

$$M_\beta^2(\phi) = m_0^2 + \frac{\lambda_0}{6}\left(\frac{\phi^2}{N} + F_\beta(\phi)\right) + \frac{\eta_0}{5!}\left(\frac{\phi^2}{N} + F_\beta(\phi)\right)^2. \quad (22)$$

In order to regularize $F_\beta(\phi)$ given by Eq. (21), we use a mixing between dimensional regularization and analytic regularization. For this purpose we define the following expression:

$$I_\beta(D,s,m)=\frac{1}{\beta}\sum_{n=-\infty}^{\infty}\int\frac{d^{D-1}k}{(2\pi)^{D-1}}\frac{1}{(\omega_n^2+k^2+m^2)^s}. \tag{23}$$

The analytic extension of the inhomogeneous Epstein zeta function can be done and the corresponding analytic extension of $I_\beta(D,s,m)$ is

$$I_\beta(D,s,m)=\frac{m^{D-2s}}{(2\pi^{1/2})^D\Gamma(s)}\left[\Gamma\left(s-\frac{D}{2}\right)+4\sum_{n=1}^{\infty}\left(\frac{2}{mn\beta}\right)^{D/2-s}K_{D/2-s}(mn\beta)\right], \tag{24}$$

where $K_\mu(z)$ is the modified Bessel function of the third kind. Fortunately for $D=2+1$ the analytic extension of the function $I_\beta(D,s=1,m=M_\beta(\phi))=F_\beta(\phi)$ is finite and can be expressed in a closed form[6]

$$F_\beta(\phi)=I_\beta(3,1,M_\beta(\phi))=-\frac{M_\beta(\phi)}{4\pi}\left(1+\frac{2\ln(1-e^{-M_\beta(\phi)\beta})}{M_\beta(\phi)\beta}\right). \tag{25}$$

We note that in $D=2+1$ we have no pole, at least in this approximation. To proceed to regularize the second term of Eq. (20), we define

$$LF_\beta(\phi)=\frac{1}{\beta}\sum_{n=1}^{\infty}\int\frac{d^{D-1}p}{(2\pi)^{D-1}}\ln[\omega_n+p^2+M_\beta^2(\phi)] \tag{26}$$

then,

$$\frac{\partial LF_\beta(\phi)}{\partial M_\beta}=(2M_\beta)\frac{1}{\beta}\sum_{n=1}^{\infty}\int\frac{d^{D-1}p}{(2\pi)^{D-1}}\frac{1}{\omega_n+p^2+M_\beta^2(\phi)} \tag{27}$$

and from Eq. (21), we have that

$$\frac{\partial LF_\beta(\phi)}{\partial M_\beta}=(2M_\beta)F_\beta(\phi). \tag{28}$$

For $D=2+1$, $F_\beta(\phi)$ is finite and is given by Eq. (29) (Ref. 6) and integrating the Eq. (28), we obtain

$$LF_\beta(\phi)_R=-\frac{M_\beta(\phi)^3}{6\pi}-\frac{M_\beta(\phi)Li_2(e^{-M_\beta(\phi)\beta})}{\pi\beta^2}-\frac{Li_3(e^{-M_\beta(\phi)\beta})}{\pi\beta^3}. \tag{29}$$

The definition of general polylogarithm function $Li_n(z)$ can be found in Ref. 7.

The daisy and super daisy resummed effective potential at finite temperature for $D=2+1$ is then given by

$$V_\beta(\phi)=V_0(\phi)+\frac{N}{2}LF_\beta(\phi)_R-\frac{N}{4!}\left(\lambda_0+\frac{\eta_0\phi^2}{10N}\right)(F_\beta(\phi)_R)^2-\frac{2N\eta(F_\beta(\phi)_R)^2}{6!} \tag{30}$$

and the corresponding gap equation [see Eq. (22)]

$$M_\beta^2(\phi)=m_0^2+\frac{\lambda_0}{6}\left(\frac{\phi^2}{N}-\frac{M_\beta(\phi)}{4\pi}\left[1+\frac{2\ln(1-e^{-M_\beta(\phi)\beta})}{M_\beta(\phi)\beta}\right]\right)+\frac{\eta_0}{5!}\left(\frac{\phi^2}{N}-\frac{M_\beta(\phi)}{4\pi}\left[1+\frac{2\ln(1-e^{-M_\beta(\phi)\beta})}{M_\beta(\phi)\beta}\right]\right)^2. \tag{31}$$

From this expression we can deduce that there is no possible way to find a solution for M_β going to zero, because the terms in Eq. (31) containing the logarithm will not permit, and this situation is similar to the scalar theory with $O(N)$ symmetry in two dimensions (2D) at zero temperature.[8]

This result is in agreement with the the Coleman-Mermin-Wagner theorem,[9] which statement is related to the fact that it is impossible to construct a consistent theory of massless scalar in 2D. If a spontaneous breaking of continuous symmetry were to happen at finite T, then one would be faced with this problem at momentum scales below T_c, i.e., it would be impossible to construct an effective 2D theory of the Goldstone bosons zero modes.

IV. CONCLUSIONS

In this paper we have found the daisy and super daisy effective potential for the theory φ^6 in $D=2+1$-dimensional Euclidean space at finite temperature. The form of effective potential have been found explicitly using resummation method in the leading order $1/N$ approximation (Hartree-Fock approximation). We found that in this approximation there is no symmetry breaking for any temperature and this is clearly a manifestation of the Coleman-Mermin-Wagner theorem which stipulates that the spontaneous symmetry breaking of continuous symmetry cannot happen in $D=2+1$ at finite temperature.

(Received 13 June 2005; accepted 14 November 2005; published online 18 January 2006)

In this paper we present, in a integral form, the Euclidean Green function associated with a massless scalar field in the five-dimensional Kaluza-Klein magnetic monopole superposed to a global monopole, admitting a nontrivial coupling between the field with the geometry. This Green function is expressed as the sum of two contributions: the first one related with uncharged component of the field, is similar to the Green function associated with a scalar field in a four-dimensional global monopole space-time. The second contains the information of all the other components. Using this Green function it is possible to study the vacuum polarization effects on this space-time. Explicitly we calculate the renormalized vacuum expectation value $\langle \Phi^{*}(x)\Phi(x)\rangle_{\mathrm{Ren}}$, which by its turn is also expressed as the sum of two contributions. © *2006 American Institute of Physics.*

I. INTRODUCTION

A few years ago, Gross and Perry,[1] and Sorkin[2] presented a solitonlike solution of the five-dimensional Kaluza-Klein theory corresponding to an Abelian magnetic monopole. As the Dirac solution, their solutions describe a gauge-dependent string singularity line, if the fifth coordinate is conveniently compactified. Moreover, their solutions depend on the parameter m related with the physical magnetic charge g and the radius of the Kaluza-Klein circle R by

$$m = g\sqrt{\pi G} = R/8, \tag{1}$$

being G the Newton's constant. Also Gegenberg and Kunstatter[3] found another magnetic monopole solution. Their solutions were obtained by applying the static and Ricci-flat requirement on the field equations.

A global monopole is a heavy topological object formed in the phase transition of a system composed by self-coupling isoscalar field ϕ^a, whose original global O(3) symmetry of the physical system is spontaneously broken down to U(1). The scalar matter field plays the role of an order parameter which outside the monopole's core, acquires a nonvanishing value. The simplest model which gives rise to a global monopole has been proposed by Barriola and Vilenkin,[4] and is described by the Lagrangian density below

$$\mathcal{L} = -\tfrac{1}{2} g^{\mu\nu}\partial_\mu \phi^a \partial_\nu \phi^a - \tfrac{1}{4}\lambda(\phi^a\phi^a - \eta^2)^2 \tag{2}$$

with $a=1,2,3$ and η being the scale energy where the symmetry is broken. The field configuration which describes a monopole is

a)Electronic mail: emello@fisica.ufpb.br

$$\phi^a(x) = \eta f(r)\hat{x}^a, \tag{3}$$

where $\hat{x}^a\hat{x}^a = 1$. Coupling this matter field with the Einstein equation, a spherically symmetric regular metric tensor solution is obtained. Barriola and Vilenkin also show that for points outside the global monopole's core the geometry of the manifold can be approximately given by the line element

$$\mathrm{d}s^2 = -\,\mathrm{d}t^2 + \frac{\mathrm{d}r^2}{\alpha^2} + r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\phi^2) \tag{4}$$

with $\alpha^2 = 1 - 8\pi G\eta^2$. This line element represents a three-geometry with a solid angle deficit and a nonvanishing scalar curvature.

Recently a new solution for the Kaluza-Klein magnetic monopole in a five-dimensional global monopole space-time has been found.[5] This solution corresponds to a composite topological object, i.e., an Abelian magnetic monopole superposed to a pointlike global monopole. It was obtained by coupling the energy-momentum tensor associated with the five-dimensional generalization of the global monopole system, with the respective Einstein equation in the presence of an Abelian magnetic monopole. Due to the presence of the matter source, the Ricci-flat condition is no longer fulfilled. The solution can be expressed by the following line element in terms of the five-dimensional coordinates $x^A = (x^\mu, \Psi) = (t, r, \theta, \phi, \Psi)$,

$$\mathrm{d}\hat{s}^2 = -\,\mathrm{d}t^2 + V(r)\left(\frac{\mathrm{d}r^2}{\alpha^2} + r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\phi^2)\right) + V(r)^{-1}(\mathrm{d}\Psi + 4m(1-\cos\theta)\mathrm{d}\phi)^2 \tag{5}$$

with

$$V(r) = 1 + \frac{4m}{\alpha r}. \tag{6}$$

As has been pointed out by Gross and Perry,[1] the gauge field associated with the magnetic monopole

$$A_\phi = 4m(1-\cos\theta), \tag{7}$$

presents a singularity at $\theta = \pi$. However, this singularity is gauge dependent if the period of the compactified coordinate Ψ is equal to $16\pi m$. This is the geometric description of the Dirac quantization. Adopting this period for the extra coordinate, it is possible to provide the Wu and Yang formalism[6] to describe the four-vector potential, A_μ, associated with the Abelian magnetic monopole without line of singularity. In order to do that it is necessary to construct two overlapping regions, R_a and R_b, which cover the whole space section of the manifold. Using spherical coordinate system, with the monopole at origin the only nonvanishing components for the vector potential are

$$\begin{aligned} (A_\phi)_a &= 4m(1-\cos\theta), \quad R_a\colon\ 0 \leqslant \theta < \tfrac{1}{2}\pi + \delta, \\ (A_\phi)_b &= -\,4m(1+\cos\theta), \quad R_b\colon\ \tfrac{1}{2}\pi - \delta < \theta \leqslant \pi, \end{aligned} \tag{8}$$

with $0 < \delta < \pi/2$. In the overlapping region, R_{ab}, the nonvanishing components are related by a gauge transformation. Using the appropriate normalization factor,[1] one can rewrite the above vector potential in terms of the physical one, A_ϕ^{ph}:

$$\sqrt{16\pi G}(A_{\phi}^{\mathrm{ph}})_a = \sqrt{16\pi G}\left[(A_{\phi}^{\mathrm{ph}})_b + \frac{i}{e}S\partial_{\phi}S^{-1}\right], \tag{9}$$

where $S=e^{2iq\phi}$, $q=eg=n/2$ in units $\hbar=c=1$ and g being the monopole strength. In terms of nonphysical vector potential this gauge transformation corresponds to subtract the quantity $8m$, which compensates the changing in the fifth coordinate $\Psi'=\Psi+8m\phi$.

Here, we shall consider the quantum analysis of a massless five-dimensional scalar field $\Theta(x)$ in the space-time described by (5). This field can be expanded in a Fourier series

$$\Theta(x) = \sum_{n=-\infty}^{\infty} e^{in\Psi/8m}\Theta^{(n)}(x^{\mu}) = \sum_{n=-\infty}^{\infty} e^{in\Psi/8m}e^{-iEt}R_n(r)Y_{lm}^{q}(\theta,\phi), \tag{10}$$

being $Y_{lm}^{q}(\theta,\phi)$, with $q=n/2$, the monopole harmonic[7] solution of the eigenvalue equations below

$$\vec{L}_q^2 Y_{lm}^{q} = l(l+1)Y_{lm}^{q} \quad \text{and } L_z Y_{lm}^{q} = mY_{lm}^{q}, \tag{11}$$

with $l=|q|, |q|+1, |q|+2,\ldots$, and $m=-l, -l+1,\ldots,l$. Where

$$\vec{L}_q = \vec{r}\times(\vec{p}-e\vec{A}) - q\hat{r}. \tag{12}$$

The Green function associated with the massless scalar field in this space-time can be obtained by solving the differential equation

$$(\Box + \xi R)G(x,x') = -\delta^{(5)}(x,x') = -\frac{\delta^{(5)}(x^A - x'^A)}{\sqrt{-g^{(5)}}}, \tag{13}$$

$g^{(5)}$ being the determinant of the metric tensor. Here we have introduced a nonminimal coupling between the field with the geometry, ξR, with ξ being an arbitrary constant and R the Ricci scalar curvature.

Green functions in a four-dimensional pointlike global monopole space-time have been obtained in Refs. 8 and 9 to massless scalar and fermionic fields, respectively. Also the effect of temperature on these functions has been considered in Ref. 10 More recently the Green function associated with a charged massless scalar field in the global monopole space-time superposed to an Abelian magnetic monopole, has been calculated in Ref. 11 The Green function is an important quantity to calculate vacuum polarization effects due to the presence of matter fields. Specifically for scalar field, the vacuum expectation value of the square of this field is formally given by

$$\langle\Phi^2(x)\rangle = \lim_{x'\to x} G(x',x). \tag{14}$$

So the objective of this paper is to calculate the Green function associated with a massless scalar field in the five-dimensional space-time, which takes into account the presence of the magnetic interaction between the matter field and the magnetic monopole in the unified formalism of Kaluza-Klein. Having this function, the next step is to calculate the vacuum polarization effect on this manifold, trying to understand the consequence of considering an extra compactified dimension.

This paper is organized as follows. In Sec. II, we explicitly calculate the Euclidean Green function associated with this system. As we shall see, this Green function, as the scalar field, will be expressed in terms of an infinite sum of all the Fourier components associated with the quantum number n. For the component $n=0$, the respective Green function, $G^{(0)}(x,x')$, is similar to the scalar Green function in a four-dimensional global monopole space-time. As to the other components, the respective Green function, $\overline{G}(x,x')$, will be expressed as the summation of all the $n\neq 0$ components $G^{(n)}(x,x')$. Although we have not found in the literature an explicit expression which provides to express $\overline{G}(x,x')$ in terms of any kind of special function, we were able to furnish an integral representation to it. In Sec. II A we calculate the renormalized vacuum expec-

tation value of the square of the scalar field, $\langle\Phi(x)^{*}\Phi(x)\rangle$. We show that this expectation value can be expressed as the sum of two contributions, the first, being given by the $n=0$ component of the total Green function, is associated with the uncharged component of the scalar field (10). The second contribution takes into account all the other Fourier components. In Sec. II B, we present a formal expression to the renormalized vacuum expectation value of the energy-momentum tensor, $\langle T_B^A(x)\rangle$. In Sec. III, we present our conclusions and the most important remarks about this system. In the Appendix we present the explicit calculation of the Green $\overline{G}(x',x)$ associated with the uncharged components of the field.

II. EUCLIDEAN GREEN FUNCTION

The Euclidean Green function can be obtained by the Schwinger-DeWitt formalism as follows:

$$G_E(x,x') = \int_0^\infty \mathrm{d}s\, K(x,x';s), \tag{15}$$

where $K(x,x';s)$ is the heat kernel, which can be expressed in terms of the sum over the complete normalized set of eigenstates of the Klein-Gordon operator. For the massless scalar field this operator reads

$$(\Box + \xi R)\Theta_\sigma(x) = -\sigma^2\Theta_\sigma(x). \tag{16}$$

So

$$K(x,x';s) = \sum_{\sigma^2} \Theta_\sigma^{*}(x')\Theta(x)_\sigma e^{-s\sigma^2}. \tag{17}$$

The covariant five-dimensional d'Alembertian operator

$$\Box = \frac{1}{\sqrt{-g^{(5)}}}\partial_A(\sqrt{-g^{(5)}}g^{AB}\partial_B), \tag{18}$$

in the space-time defined by (5) reads

$$\Box = -\partial_t^2 + \frac{1}{V(r)}\left\{\alpha^2\left(\partial_r^2 + \frac{2}{r}\partial_r\right) - \frac{\vec{L}^2}{r^2} - \frac{8m(1-\cos\theta)}{r^2\sin^2\theta}\partial_\phi\partial_\Psi + \frac{16m^2(1-\cos\theta)^2}{r^2\sin^2\theta}\partial_\Psi^2\right\} + V(r)\partial_\Psi^2. \tag{19}$$

On the other hand, the Ricci scalar curvature is

$$R = \frac{2(1-\alpha^2)}{V(r)r^2}. \tag{20}$$

Admitting to the eigenfunction $\Theta_\sigma(x)$ the form

$$\Theta_\sigma(x) = e^{-iEt}e^{in\Psi/8m}R_l^n(r)Y_{lm}^q(\theta,\phi) \tag{21}$$

and assuming $q=n/2$ it is possible to obtain the following differential equation:

$$\left\{-E^2 + \frac{1}{V(r)}\left[\alpha^2\left(\partial_r^2 + \frac{2}{r}\partial_r\right) - \frac{(\vec{L}_q^2 - q^2)}{r^2}\right] - \frac{q^2}{16m^2}V(r) + \frac{2\xi(\alpha^2-1)}{V(r)r^2}\right\}R_l^n(r)Y_{lm}^q(\theta,\phi)$$
$$= -\sigma^2 R_l^n(r)Y_{lm}^q(\theta,\phi), \tag{22}$$

where we identify

$$\vec{L}_q^2 = \vec{L}^2 + \frac{2iq(1-\cos\theta)}{\sin^2\theta}\partial_\phi + q^2\frac{(1-\cos\theta)^2}{\sin^2\theta} + q^2. \tag{23}$$

Admitting

$$\sigma^2 = E^2 + \alpha^2 p^2 + \frac{q^2}{16m^2} \tag{24}$$

we find the differential equation obeyed by the unknown radial function $R(r)$,

$$\frac{d^2R(r)}{dr^2} + \frac{2}{r}\frac{\mathrm{d}R(r)}{\mathrm{d}r} - \frac{\mu_{lq}}{r^2}R(r) - \gamma^2 V(r)^2 R(r) + \gamma^2 V(r)R(r) + p^2 V(r)R(r) = 0, \tag{25}$$

with

$$\gamma = \frac{q}{4m\alpha} \quad \text{and } \mu_{lq} = \frac{l(l+1) - q^2 - 2\xi(\alpha^2-1)}{\alpha^2}. \tag{26}$$

The solution to the above differential equation regular at origin is proportional to the Whittaker function[12] $M_{\lambda,\beta}(2ipr)$ with λ and β being given in terms of the parameters m and γ, and also in terms of the variable p. Unfortunately with this function it is not possible to present the Green function in a closed form. So at this point we should make an approximation in our calculations, we shall discard the terms proportional to m/r in (25). This means that we are considering points very far from the origin. [Discarding terms proportional to m/r does not reduce the system to a charged particle in the presence of an Abelian magnetic monopole.[11] Here the space-time remains five-dimensional, and this fact is present in the calculation of the heat kernel (17) where it is necessary to sum all the possible values for the parameter $q=n/2$.] In Ref. 1 an estimative value to the radius of the Kaluza-Klein circle is given, $R=3.7\times10^{-32}$ cm. So we are considering points at distance greater than 3.7×10^{-32} cm. Accepting this approximation (25) becomes

$$\frac{d^2R(r)}{\mathrm{d}r^2} + \frac{2}{r}\frac{\mathrm{d}R(r)}{dr} - \frac{\mu_{lq}}{r^2}R(r) + p^2R(r) = 0. \tag{27}$$

The solution to the above equation regular at the origin is

$$R_l^n(r) = \frac{J_{\nu_{l,q}}(pr)}{\sqrt{pr}}, \tag{28}$$

where J_ν is the Bessel function of order

$$\nu_l^q = \frac{1}{\alpha}\sqrt{(l+1/2)^2 - q^2 - 2(\alpha^2-1)(\xi-1/8)}. \tag{29}$$

So the normalized eigenstate of the Klein-Gordon operator (16) is

$$\Theta_\sigma(x) = \frac{1}{4\pi}\sqrt{\frac{\alpha p}{2mr}}e^{-iEt}e^{in\Psi/8m}J_{\nu_l^q}(pr)Y_{lm}^q(\theta,\phi). \tag{30}$$

By making a Wick rotation, $t \to i\tau$, and according to (17) the Euclidean heat kernel is given by

$$K(x,x';s) = \int_{-\infty}^{\infty} \mathrm{d}E \sum_{n=-\infty}^{\infty} \int_0^{\infty} \mathrm{d}p \sum_{l,m} \Theta_\sigma(x)\Theta_\sigma^*(x') e^{-s\sigma^2}$$

$$= \frac{1}{256\pi^{5/2} m\alpha} \frac{1}{\sqrt{rr'}} \frac{e^{-(\Delta\tau\alpha^2 + r^2 + r'^2)/4\alpha^2 s}}{s^{3/2}} \sum_{n=-\infty}^{\infty} e^{-sn^2/64m^2} e^{in[(\Psi - \Psi')/8m]}$$

$$\times \sum_{l=|q|}^{\infty} I_{\nu_l^q}\left(\frac{rr'}{2\alpha^2 s}\right) \sum_{m=-l}^{l} Y_{lm}^q(\theta,\phi)(Y_{lm}^q(\theta',\phi'))^*, \tag{31}$$

I_ν being the modified Bessel function. In Ref. 13, Wu and Yang have derived some properties of the monopole harmonics, including the generalization of spherical harmonics addition theorem. However, because we are interested in calculating the renormalized value of the Green function in the coincidence limit, a simpler expression is obtained by taking $\theta = \theta'$ and $\phi = \phi'$ in (31). In Appendix A of Ref. 11 we have shown the simplified result to the sum of the product of monopole harmonics in coincidence limit in the angular variables,

$$\sum_{m=-l}^{l} Y_{lm}^q(\theta,\phi)(Y_{lm}^q(\theta,\phi))^* = \frac{(2l+1)}{4\pi}. \tag{32}$$

Moreover we shall take the coincidence limit in the fifth coordinate $\Psi' = \Psi$ and the Euclidean temporal coordinate $\tau' = \tau$ in (31). Doing this we get a simpler expression to the heat kernel which depends on the quantum number n in its second power.

Now according to (15) we get

$$G(x,x') = \frac{1}{256\pi^{5/2} m\alpha} \frac{1}{\sqrt{rr'}} \sum_{l=0}^{\infty} (2l+1) \int_0^{\infty} \mathrm{d}s\, s^{-3/2} e^{-\Omega/4\alpha^2 s} I_{\nu_l^0}(\sigma/s)$$

$$+ \frac{1}{128\pi^{5/2} m\alpha} \frac{1}{\sqrt{rr'}} \sum_{n=1}^{\infty} \sum_{l=q}^{\infty} (2l+1) \int_0^{\infty} \mathrm{d}s\, s^{-3/2} e^{-\Omega/4\alpha^2 s}$$

$$\times I_{\nu_l^q}(\sigma/s) e^{-sn^2/64m^2}, \tag{33}$$

where

$$\Omega = r^2 + r'^2 \quad \text{and} \quad \sigma = \frac{rr'}{2\alpha^2}. \tag{34}$$

As we can see the above Green function is composed by two contributions, the first one, $G^{(0)}$, corresponds to the Fourier component $n=0$ of the scalar field operator, and the second, $\overline{G}$ to the other components. By using Ref. 12 it is possible to develop the integral in s for the first contribution. So we get

$$G^{(0)}(r,r') = \frac{1}{128\pi^3 m} \frac{1}{rr'} \sum_{l=0}^{\infty} (2l+1) Q_{\nu_l^0 - 1/2}(\cosh u), \tag{35}$$

with $\cosh u = (r^2 + r'^2)/2rr'$ and Q_ν being the Legendre function, whose integral representation is

$$Q_{\nu-1/2}(\cosh u) = \frac{1}{\sqrt{2}} \int_u^{\infty} \mathrm{d}t \frac{e^{-\nu t}}{\sqrt{\cosh t - \cosh u}}. \tag{36}$$

This Green function is exactly $1/16\pi m = 1/2\pi R$ times the Green function obtained in a four-dimensional space-time (see Ref. 8).

As to the second contribution of (33), we did not find in the literature the explicit expression to the integral in the variable s. In the Appendix we give the procedure adopted to provide a simpler and workable expression to $\overline{G}$, which will be adopted by us in the analysis of the vacuum polarization effect. The result to this contribution is

$$\overline{G}(r,r') = \sum_{n=1}^{\infty} G^{(n)}(r,r') \tag{37}$$

with

$$G^{(n)}(r,r') = \frac{1}{128\pi^{5/2}m\alpha}\frac{1}{\sqrt{rr'}}\sum_{l=n/2}^{\infty}(2l+1)I_n \tag{38}$$

being

$$I_n = \frac{1}{\sqrt{\pi\sigma}}\int_u^{\infty}\frac{\mathrm{d}t\, e^{-\nu_l^q t}}{\sqrt{\cosh t-\cosh u}}\cos((n/4m)\sqrt{\sigma(\cosh t-\cosh u)}). \tag{39}$$

Finally we can write

$$G^{(n)}(r,r') = \frac{1}{64\sqrt{2}\pi^3 m}\frac{1}{rr'}\sum_{l=n/2}^{\infty}(2l+1)\int_u^{\infty}\frac{\mathrm{d}t\, e^{-\nu_l^q t}}{\sqrt{\cosh t-\cosh u}}\times\cos((n/4m)\sqrt{\sigma(\cosh t-\cosh u)}). \tag{40}$$

As the $n=0$ component of the Green function, Eq. (35), it is not possible to develop the integral above and provide a closed expression to $G^{(n)}$. The best we can do is to express it in an integral representation. Moreover (40) is similar to the $n=0$ component; however its coefficient is two times bigger than the coefficient multiplying the uncharged sector.

Another point that should be mentioned is that because of the nontrivial dependence of the parameter ν_l^q with α and q, it is not possible to develop exactly the sum in l in (40). On the other hand, for $\xi=1/8$, the geometric series in (35) can be performed, providing a simpler expression to $G^{(0)}$.

Having these Green functions, it is possible to calculate the vacuum polarization effect in the gravitational background of the composite five-dimensional Kaluza-Klein magnetic and global monopoles.

A. Computation of $\langle\Phi^*(x)\Phi(x)\rangle_{\mathrm{Ren}}$

In this section we discuss the calculation of the vacuum expectation value of the square of the massless scalar field operator. This quantity is formally obtained by calculating the complete Green function in the coincidence limit,

$$\langle\Phi^*(x)\Phi(x)\rangle = \lim_{x'\to x} G(x',x) = \lim_{r'\to r}[G^{(0)}(r',r)+\overline{G}(r',r)]. \tag{41}$$

However, this procedure provides a divergent result. In order to obtain a finite and well-defined result it is necessary to introduce some renormalization procedure. In this paper we shall apply the point-splitting renormalization procedure. The basic idea of this method consists to examine the singular behavior of the above limit, identify the divergent terms and subtract them off.[14] Let us apply this method separately for each component of (41).

We shall first start with the uncharged component of the vacuum expectation value,

$$\langle\Phi^2(x)\rangle^{(0)} = \lim_{x'\to x} G^{(0)}(x',x). \tag{42}$$

As we have already said $G^{(0)}$ is proportional to the Green function obtained by Mazzitelli and Lousto in Ref. 8. So the procedure to renormalize this component is by subtracting from $G^{(0)}$ the Hadamard function below

$$G_H(x',x) = \frac{1}{16\pi m}\left\{\frac{1}{16\pi^2}\left[\frac{2}{\sigma(x',x)} + \left(\xi - \frac{1}{6}\right)\mathcal{R}\,\ln\left(\frac{\mu^2\sigma(x',x)}{2}\right)\right]\right\}, \tag{43}$$

where μ is an arbitrary cutoff energy scale, $\mathcal{R}=2(1-\alpha^2)/r^2$ the scalar curvature in the four-dimensional global monopole space-time, and $\sigma(x',x)$ one-half of the square of the geodesic distance between x' and x. For the radial point splitting, in our approximation we have $\sigma=(r'-r)^2/2\alpha^2$.

Because the calculation of the vacuum expectation value (VEV) of the square of the massless scalar field operator has been developed in Ref. 8 for an arbitrary value of the nonminimal coupling ξ, up to the first order in the parameter $\eta^2=1-\alpha^2\ll 1$, and in an exact form for $\xi=1/8$, we shall not develop here the calculation of the VEV below,

$$\langle\Phi^2(x)\rangle^{(0)}_{\mathrm{Ren}} = \lim_{r'\to r}[G^{(0)}(r,r') - G_H(r,r')]. \tag{44}$$

We shall give only the result obtained for $\xi=1/8$,

$$\langle\Phi^2(x)\rangle = \frac{1}{512\pi^3 mr^2}\int_0^\infty \frac{\mathrm{d}t}{\sinh(t/2)}\left[\frac{\cosh(t/2\alpha)}{\sinh^2(t/2\alpha)} - \alpha^2\frac{\cosh(t/2)}{\sinh^2(t/2)} + \frac{(\alpha^2-1)}{6}e^{-t/2}\right]$$
$$+ \frac{1}{1536\pi^3 mr^2}(1-\alpha^2)\ln(\mu r/\alpha). \tag{45}$$

The new calculation is to obtain the VEV associated with all charged components of the Green function. In order to get some information on how we should proceed, we first analyze the singular behavior of each component $G^{(n)}(r',r)$. First of all, it is necessary to develop the summation on the angular quantum number l in (40),

$$S = \sum_{l=q}^{\infty}(2l+1)e^{-\nu_l^q t}. \tag{46}$$

Unfortunately it is not possible to develop this summation in an exact way even for $\xi=1/8$. Here it is necessary to adopt an approximation procedure, we shall develop an expansion of ν_l^q in powers of $q^2/(l+1/2)^2<1$. Moreover, developing an extra expansion in powers of parameter η^2, we get a very large expansion as shown in Ref. 11. So in order to obtain a more compact expression to the summation above, which allows us to proceed with the summation in the quantum number n to get $\overline{G}(r',r)$, we shall adopt $\xi=1/8$. So doing this we obtain, up to the first order in $q^2/(l+1/2)^2$, the following expression:

$$S = e^{-qt/\alpha}\left[\frac{q}{\sinh(t/2\alpha)} + \frac{\coth(t/2\alpha)}{2\sinh^2(t/2\alpha)} + \frac{q^2 t}{\alpha}\frac{1}{2\sinh(t/2\alpha)}\right], \tag{47}$$

with $q=n/2$. So $G^{(n)}$ becomes

$$G^{(n)}(r,r') = \frac{1}{64\sqrt{2}\pi^3 m}\frac{1}{rr'}\int_u^\infty \frac{\mathrm{d}t\cos((q/2m)\sqrt{\sigma(\cosh t-\cosh u)})}{\sqrt{\cosh t-\cosh u}} \times e^{-qt/\alpha}\left[\frac{q}{\sinh(t/2\alpha)}+\frac{\coth(t/2\alpha)}{2\sinh^2(t/2\alpha)}+\frac{q^2 t}{\alpha}\frac{1}{2\sinh(t/2\alpha)}\right]. \tag{48}$$

Analyzing $G^{(n)}$ in the limit $r'\to r$, it is possible to observe that this Green function presents effectively a four-dimensional Hadamard singular structure. So to renormalize the VEV of the square of the n-component of the scalar field, we should take the following Hadamard function:

$$G_H(x',x) = \frac{1}{8\pi m}\left\{\frac{1}{16\pi^2}\left[\frac{2}{\sigma(x',x)}+\overline{a_1}\ln\left(\frac{\mu^2\sigma(x',x)}{2}\right)\right]\right\}, \tag{49}$$

where $\overline{a_1}=(\xi-1/6)\mathcal{R}+(2q/R)^2$, with $\xi=1/8$. $\mathcal{R}$ is the scalar curvature and $R=8m$ is the radius of the circle in the fifth dimension. So, although the singular structure of the Green function is of the same type as the four-dimensional Hadamard one, the coefficient $\overline{a_1}$ in the above function presents an extra contribution proportional to the inverse of the square of the radius when compared with the expression given in the literature to this coefficient.[15]

After this discussion let us return to the VEV of the square of the n component of the scalar field,

$$\langle\Phi^*(x)\Phi(x)\rangle^{(n)}_{\mathrm{Ren}} = \lim_{r'\to r}[G^{(n)}(r,r')-G_H(r,r')] = \frac{1}{128\pi^3 mr^2}\int_0^\infty \frac{\mathrm{d}t}{\sinh(t/2)}\left\{\cos\left(\frac{qr}{2\alpha m}\sinh(t/2)\right)e^{-qt/\alpha} \times\left[q+\frac{\coth(t/2\alpha)}{2}+\frac{q^2 t}{2\alpha}\right]\frac{1}{\sinh(t/2\alpha)}-\frac{\alpha^2\coth(t/2)}{\sinh^2(t/2)}+\left(\frac{qr}{4m}\right)^2 e^{-t/2}-\frac{1-\alpha^2}{12}e^{-t/2}\right\} -\frac{q^2}{1024\pi^3 m^3}\ln\left(\frac{\mu r}{2}\right)+\frac{1-\alpha^2}{768\pi^3 m}\frac{1}{r^2}\ln\left(\frac{\mu r}{2}\right), \tag{50}$$

with $q=n/2$, being $n=1,2,3,\ldots$. So the above result is valid only for charged Fourier components of the scalar field.

Now let us return to the complete Green function. According to (37), $\overline{G}$ is given by developing the summation on the quantum number n in (48). Doing this we found

$$\overline{G}(r,r') = \frac{1}{256\sqrt{2}\pi^3 m}\frac{1}{r'r}\int_u^\infty \frac{\mathrm{d}t}{\sqrt{\cosh t-\cosh u}}\frac{1}{\sinh(t/2\alpha)}\frac{1}{\cosh(t/2\alpha)-\cos\gamma} \times\left\{\frac{\cosh(t/2\alpha)\cos\gamma-1}{\cosh(t/2\alpha)-\cos\gamma}-\cosh(t/2\alpha)(e^{-t/2\alpha}-\cos\gamma) +\frac{t}{8\alpha}\frac{[\cos\gamma\sinh(t/\alpha)+\cos(2\gamma)\sinh(t/2\alpha)-3\sinh(t/2\alpha)]}{(\cosh(t/2\alpha)-\cos\gamma)^2}\right\} \tag{51}$$

with

$$\gamma = \frac{1}{4\alpha m}\sqrt{\frac{r'r}{2}}\sqrt{\cosh t-\cosh u} \quad \text{and} \quad \cosh u = \frac{r^2+r'^2}{2rr'}. \tag{52}$$

Now, at this point, we must analyze the singular behavior of $\overline{G}$. Taking $r'\to r$, we observe that its singular behavior becomes more severe than for $G^{(n)}(r',r)$. In fact it is possible to show that in this limit we have

$$\overline{G}(r,r') \approx \frac{1}{\sigma^{3/2}} + \frac{1}{\sigma} + \frac{1}{\sigma^{1/2}} + \ln(\sigma), \tag{53}$$

with $\sigma=(r-r')^2/2\alpha^2$. So it contains the structure of the five-dimensional Hadamard function

$$G^{(5)}(r,r') \approx \frac{1}{\sigma^{3/2}} + \frac{1}{\sigma^{1/2}}, \tag{54}$$

and also the four-dimensional Hadamard function

$$G^{(4)}(r,r') \approx \frac{1}{\sigma} + \ln(\sigma), \tag{55}$$

at the same time. If we are inclined to provide a finite and well-defined vacuum expectation value of the square of the sum of all charged components of the scalar field operator, we must extract all the divergences of $\overline{G}$. We shall do this by subtracting from this Green function the "Hadamard" one which presents the same kind of singularity as given in (53). So we have

$$\langle \Phi^*(x)\Phi(x)\rangle_{\mathrm{Ren}} = \lim_{r'\to r}[\overline{G}(r',r) - \overline{G}_H(r',r)], \tag{56}$$

with

$$\overline{G}_H(r',r) = \frac{c_3}{(r'-r)^3} + \frac{c_2}{(r'-r)^2} + \frac{c_1}{(r'-r)} + \frac{c_0}{r^2}\ln\left(\frac{\mu^2(r'-r)^2}{4\alpha^2}\right). \tag{57}$$

The coefficients above will be determined appropriately by imposing that (56) be finite. Expressing all the singular terms by using the identities

$$\frac{1}{(r'-r)^d} = \frac{\sqrt{2}\Gamma\left(1+1/d\right)}{2^d(r'r)^{d/2}\sqrt{\pi}\Gamma\left(d/2\right)}\int_u^\infty \frac{\mathrm{d}t}{\sqrt{\cosh t-\cosh u}}\frac{\cosh(t/2)}{\sinh^d(t/2)} \tag{58}$$

and

$$\ln\left(\frac{\mu^2(r'-r)^2}{4\alpha^2}\right) = \ln\left(\frac{\mu^2(r'+r)^2}{4\alpha^2}\right) - \frac{2}{\sqrt{2}}\int_u^\infty \frac{\mathrm{d}t}{\sqrt{\cosh t-\cosh u}}e^{-t/2}, \tag{59}$$

it is possible to obtain all coefficients of (57) according to our requirement. These coefficients are long ones; however, because of the approximation adopted in the beginning of the calculation, they can be written shortly as

$$c_3 \approx -\frac{m\alpha^3}{4\pi^2\sqrt{r'r}},$$

$$c_2 \approx \frac{m\alpha^2}{2\pi^3 r'r},$$

$$c_1 \approx -\frac{7\alpha}{1536m\pi^2\sqrt{r'r}},$$

$$c_0 \approx -\frac{1}{3072m\pi^3}. \tag{60}$$

At this point two important remarks should be mentioned, (i) we did not find in the literature expressions to the coefficients of the adiabatic expansion of the Hadamard function for this five-dimensional space-time, which presents a compactified dimension. (ii) Consequently we do not have any geometric explanation to them. They have been found to provide a finite result to (56). The general structure to this VEV is

$$\langle \Phi^{*}(x)\Phi(x)\rangle_{\mathrm{Ren}} = \frac{A}{mr^2} + \frac{Bm}{r^4} + \frac{1}{1536m\pi^3}\frac{1}{r^2}\ln(\mu r/\alpha). \tag{61}$$

B. Dimensional analysis of $\langle T_A^B \rangle$

The energy-momentum tensor associated with scalar field in an n-dimensional curved space-time is given in Ref. 16. For this five-dimensional space-time, considering a massless field and $\xi = 1/8$ it reads

$$T_{AB}(x) = \tfrac{3}{4}\nabla_A\Phi\nabla_B\Phi - \tfrac{1}{4}g_{AB}g^{CD}\nabla_C\Phi\nabla_B\Phi - \tfrac{1}{4}(\nabla_A\nabla_B\Phi)\Phi + \tfrac{1}{32}g_{AB}\mathcal{R}\Phi^2 - \tfrac{1}{8}\mathcal{R}_{AB}\Phi^2, \tag{62}$$

where $\mathcal{R}_{AB}$ and $\mathcal{R}$ are the Ricci tensor and the scalar curvature, respectively.

The vacuum expectation value of the energy-momentum tensor operator is formally given by

$$\langle T_{AB}(x)\rangle = \lim_{x'\to x} \mathcal{D}_{AB'}(x,x')G(x',x). \tag{63}$$

The nonlocal bivector differential operator, $\mathcal{D}_{AB'}(x',x)$, for this case reads

$$\mathcal{D}_{AB'}(x',x) = \tfrac{3}{4}\nabla_A\nabla_{B'} - \tfrac{1}{4}g_{AB}(x)g^{CD}(x',x)\nabla_C\nabla_{D'} - \tfrac{1}{8}[\nabla_A\nabla_B + \nabla_{A'}\nabla_{B'}] + \tfrac{1}{32}g_{AB}\mathcal{R}(x) - \tfrac{1}{8}\mathcal{R}_{AB}(x). \tag{64}$$

The primes denote the derivative acting at x' rather than at x.

The calculation of the VEV above provides a divergent result. So in order to obtain a finite and well-defined result we must apply some renormalization procedure. Adopting the point-splitting renormalization one, we subtract from the Green function, $G(x',x)$, the Hadamard one, $G_H(x',x)$,

$$\langle T_{AB}(x)\rangle_{\mathrm{Ren}} = \lim_{x'\to x} \mathcal{D}_{AB'}(x,x')[G(x',x) - G_H(x',x)]. \tag{65}$$

This quantity must be conserved,

$$\nabla_A\langle T_B^A(x)\rangle_{\mathrm{Ren}} = 0. \tag{66}$$

As to the trace anomaly, in principle it exists only for even-dimensional space-time. In fact, as has been shown by Christensen[17] the trace of the renormalized VEV of the energy-momentum tensor is given by

$$\langle T_\mu^\mu(x)\rangle_{\mathrm{Ren}} = \frac{1}{(4\pi)^{n/2}}a_{n/2}(x), \tag{67}$$

for an even n-dimensional space-time. [The analysis of the vacuum polarization associated with massless scalar field in five- and six-dimensional global monopole space-time have been developed by us in Ref. 18. There it is explicitly written, up to the first order in the parameter $\eta^2 = 1 - \alpha^2$, the $a_3(x)$ coefficient, of the adiabatic expansion of the Hadamard function.] On the other hand, in our previous calculations, we have found that in this five-dimensional space-time, there appears a logarithmic term in the $\langle \Phi^{*}(x)\Phi(x)\rangle_{\mathrm{Ren}}$, which should be absent in an odd-dimensional space. So we conclude that although being five dimensional, this space-time with the fifth coordinate compactified with period $16\pi m$, and for distance r much greater than m, presents a four-dimensional characteristic. So it is expected to be a nonvanishing trace for this case, i.e.,

$$\langle T_A^A(x)\rangle_{\text{Ren}} \neq 0. \tag{68}$$

Another point that we want to mention is that (65) presents two contributions, the first one coming from the uncharged component of the scalar field, $\langle T_{AB}(x)\rangle_{\text{Ren}}^{(0)}$, and the second coming from the other components, $\langle \overline{T}_{AB}(x)\rangle_{\text{Ren}}$. The dimensional analysis of the renormalized vacuum expectation value of the energy-momentum tensor associated with a scalar field in a four-dimensional global monopole space-time has been developed in Ref. 8 considering this object as a pointlike one. Although the authors did not calculate explicitly this quantity, they present its general structure.

Here in this paper we also shall not calculate explicitly $\langle T_{AB}(x)\rangle_{\text{Ren}}$. However we can say that the general structure for this tensor is

$$\langle T_A^B(x)\rangle_{\text{Ren}} = \frac{1}{mr^4}[F_A^B(r/m,\alpha) + G_A^B(r/m,\alpha)\ln(\mu r/\alpha)], \tag{69}$$

where F_A^B and G_A^B are polynomials in the ratio r/m and depending on the parameter α which codify the presence of the global monopole.

III. CONCLUDING REMARKS

In this paper we have explicitly calculated the complete Green function associated with a massless scalar field in a five-dimensional Kaluza-Klein magnetic monopole superposed to a global monopole, for points very far from the monopole's center. This function is given in terms of two distinct contributions, one coming from the uncharged component of the scalar field, and the other from the other components,

$$G(x',x) = G^{(0)}(x',x) + \sum_{n=1}^{\infty} G^{(n)}(x',x) = G^{(0)}(x',x) + \overline{G}(x',x). \tag{70}$$

Having this function, it was possible to analyze the vacuum polarization effects due to this field in this gravitational background. Explicitly we analyzed the vacuum expectation value of the square of the field. This quantity is formally given by

$$\langle \Phi^*(x)\Phi(x)\rangle = \lim_{x'\to x} G(x',x) = \lim_{x'\to x}[G^{(0)}(x',x) + \overline{G}(x',x)]. \tag{71}$$

However because this quantity provides a divergent result, to obtain a finite and well-defined result, we must apply some renormalization procedure. We have applied the point-splitting renormalization procedure. As we have said before, the basic idea of this method consists to examine the singular behavior and subtract the divergent terms off, getting a finite result. We did this in a systematic way, by subtracting from the Green function the "Hadamard" one. This procedure has been developed separately for the two distinct contributions. For the first one, we observed that the singular behavior of $G^{(0)}(x',x)$ is similar to the four-dimensional Green function. However for the second contribution, the singular behavior of $\overline{G}(x',x)$ contains structure of the five- and four-dimensional Green function.

The Hadamard function for the first contribution could be constructed by knowing the Hadamard function for an ordinary four-dimensional space-time, $G_H^{(4)}(x',x)$; however the second case presents a new structure. So we must construct the respective Hadamard function in an appropriate way, $\overline{G}_H(x',x)$. So the renormalized vacuum expectation value of the square of the scalar field becomes

$$\langle \Phi^*(x)\Phi(x)\rangle_{\mathrm{Ren}} = \lim_{x'\to x}[G^{(0)}(x',x) - G_H^{(4)}(x',x)] + \lim_{x'\to x}[\overline{G}(x',x) - \overline{G}_H(x',x)]. \tag{72}$$

By these analyses we may conclude that although being five dimensional, because of the compactification of the fifth coordinates, with period $16\pi m$, and also because we are considering points at distance to the monopole, r, much greater than m, this space presents four-dimensional behavior in the singular behavior of the Green function. Consequently, there appears a logarithmic contribution in the above renormalized VEV, which presents an arbitrary energy scale μ.

We also analyze the general structure of the renormalized vacuum expectation value of the energy-momentum tensor, $\langle T_{AB}(x)\rangle_{\mathrm{Ren}}$. By dimensional arguments and also by the result obtained in previous analysis, we infer that this quantity behaves as

$$\langle T_A^B(x)\rangle_{\mathrm{Ren}} = \frac{1}{mr^4}[F_A^B(r/m,\alpha) + G_A^B(r/m,\alpha)\ln(\mu r/\alpha)].$$

Unfortunately we did not calculate the explicit expressions to the two tensors above. By inspection we can see that they present dependence on the ratio r/m up to second power.

APPENDIX: CALCULATION OF THE SECOND CONTRIBUTION OF (33)

The second contribution to the Green function given by (33), $\overline{G}(r,r')$, is given by

$$\overline{G}(r,r') = \sum_{n=1}^{\infty} G^{(n)}(r,r') \tag{A1}$$

with

$$G^{(n)}(r,r') = \frac{1}{128\pi^{5/2}m\alpha}\frac{1}{\sqrt{rr'}}\sum_{l=q}^{\infty}(2l+1)I_n \tag{A2}$$

being

$$I_n = \int_0^{\infty} \mathrm{d}s\, s^{-3/2}e^{-\Omega/4\alpha^2 s}I_{\nu_l^q}(\sigma/s)e^{-sn^2/64m^2} \tag{A3}$$

with

$$\Omega = r^2 + r'^2 \quad \text{and } \sigma = \frac{rr'}{2\alpha^2}. \tag{A4}$$

Now let us first define a new variable $y=\sigma/s$. So we obtain

$$I_n = \frac{1}{\sigma^{1/2}}\int_0^{\infty}\frac{\mathrm{d}y}{\sqrt{y}}e^{-y(\Omega/4\alpha^2\sigma)}I_{\nu_l^q}(y)e^{-(\sigma/y)(n/8m)^2}. \tag{A5}$$

Unfortunately we did not find such integral in the literature. So in order to develop an expression to the Green function we expand $e^{-\sigma n^2/64m^2 y}$ in a series power getting

$$I_n = \frac{1}{\sigma^{1/2}} \sum_{k=0}^{\infty} \frac{[-(n/8m)^2\sigma]^k}{k!} \int_0^{\infty} dy\, y^{-k-1/2} e^{-y(\Omega/4\alpha^2\sigma)} I_{\nu_l^q}(y). \tag{A6}$$

On page 716 of Ref. 12, there is a similar formula for the above integral; however in that table there is a condition on the order of the modified Bessel function and the power of the variable y, that is not satisfied by the integrand of (A6), i.e., $\nu_l^q + 1/2 - k$ is not always a positive number. However adopting the correspondent formula, we obtain

$$I_n = \sqrt{\frac{2}{\sigma\pi}} \sum_{k=0}^{\infty} \frac{[(n/8m)^2\sigma]^k}{k!} Q^{-k}_{\nu_l^q - 1/2}(\cosh u) \sinh^k u. \tag{A7}$$

Now substituting the integral representation below to the Legendre function[12]

$$Q^{\mu}_{\nu}(\cosh u) = \sqrt{\frac{\pi}{2}} \frac{e^{\mu\pi i} \sinh^{\mu} u}{\Gamma(1/2-\mu)} \int_u^{\infty} \frac{dt e^{-(\nu+1/2)t}}{(\cosh t - \cosh u)^{\mu+1/2}}, \tag{A8}$$

we get

$$I_n = \frac{1}{\sqrt{\pi\sigma}} \sum_{k=0}^{\infty} \frac{[-(n/4m)^2\sigma]^k}{(2k)!} \int_u^{\infty} \frac{dt\, e^{-\nu_l^q t}}{\sqrt{\cosh t - \cosh u}} (\cosh t - \cosh u)^k. \tag{A9}$$

Although each integral of the series diverges for $k \geqslant \nu_l^q + 1/2$, interchanging the sum with the integral, we see that the total series obtained is the series of the cosine, so we finally get

$$I_n = \frac{1}{\sqrt{\pi\sigma}} \int_u^{\infty} \frac{dt\, e^{-\nu_l^q t}}{\sqrt{\cosh t - \cosh u}} \cos((n/4m)\sqrt{\sigma(\cosh t - \cosh u)}). \tag{A10}$$

(Received 10 July 2005; accepted 22 November 2005; published online 23 January 2006)

We investigate cohomological gauge theories in noncommutative $\mathbb{R}^{2D}$. We show that vacuum expectation values of the theories do not depend on noncommutative parameters, and the large noncommutative parameter limit is equivalent to the dimensional reduction. As a result of these facts, we show that a partition function of a cohomological theory defined in noncommutative $\mathbb{R}^{2D}$ and a partition function of a cohomological field theory in $\mathbb{R}^{2D+2}$ are equivalent if they are connected through dimensional reduction. Therefore, we find several partition functions of supersymmetric gauge theories in various dimensions are equivalent. Using this technique, we determine the partition function of the $\mathcal{N}=4$ U(1) gauge theory in noncommutative $\mathbb{R}^4$, where its action does not include a topological term. The result is common among (8-dim, $\mathcal{N}=2$), (6-dim, $\mathcal{N}=2$), (2-dim, $\mathcal{N}=8$) and the IKKT matrix model given by their dimensional reduction to 0-dim. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2162127]

I. INTRODUCTION

The first break through of the recent calculation technology for $\mathcal{N}=2$ supersymmetric Yang-Mills theories is brought by Nekrasov.[21,23] After Ref. 21, many kinds of developments appear in $\mathcal{N}\geqslant 2$ supersymmetric Yang-Mills theories and string theories corresponding to them. From those analysis, it is found that different dimension theories are related to each other.[7,17,18,33,35] There are more examples that the different dimensional theories are connected to each other. For example, Dijkgraaf and Vafa show that some correlation functions in matrix theories and $\mathcal{N}=1$ Yang-Mills theories are equivalent.[5] It goes on and on. These facts imply the existence of some kind of unified perspectives. One of the ideas to explain the unification is the 'tHooft's large N gauge theory and string correspondence. Until now, many investigations from this point of view are reported. Meanwhile, the large N gauge theories are similar to noncommutative theories in the operator formalism in some infinite-dimensional Hilbert space with discrete basis. In this paper, we suggest a simple way to understand the reason why partition functions of various dimensional supersymmetric gauge theories are given as the same form or have relations with each other. The basic idea of the way is given in Refs. 28, 29, and 27. Cohomological gauge theories in Euclidian spaces are invariant under the noncommutative parameter shifting, as we will see in the next section. When we take the large noncommutative parameter limit, kinetic terms become irrelevant like dimensional reduction, then the partition function is essentially computable by using lower dimensional theories. From this fact, we will explain that partition functions in various dimensions are equivalent.

[a)]Electronic mail: sako@math.keio.ac.jp
[b)]Electronic mail: tsuzuki@phys.ocha.ac.jp

Here is the organization of this paper. In Sec. II, invariance of cohomological field theories in noncommutative $\mathbb{R}^{2D}$ (NC $\mathbb{R}^{2D}$ for short) under deformation of noncommutative parameters will be proved formally. This invariance is not usual symmetry, because the action is deformed. Nevertheless, expectation values and partition functions are invariant. Particularly, we will treat the $\mathcal{N}=2$ and $\mathcal{N}=4$ Yang-Mills theories in NC $\mathbb{R}^4$ as examples. In Sec. III, universality of the partition functions will be investigated. By using the result of Sec. II, we will show that the several partition functions in different dimensions are equivalent. (In Appendix B, concrete discussions for some models will be given again.) In Sec. IV, by the technique of Sec. II we will calculate the partition function of the $\mathcal{N}=4$ U(1) gauge theory in NC $\mathbb{R}^4$ without the terms proportional to the instanton number $\int F\wedge F$. This partition function is equal to partition functions of several dimensions. In Sec. V, the moduli space of $\mathcal{N}=4$ U(1) gauge theory in NC $\mathbb{R}^4$ will be discussed. The partition function of $\mathcal{N}=4$ U(1) theory with $\int F\wedge F$ will be investigated, too. In Sec. VI, we will summarize this paper.

II. NC COHOMOLOGICAL YANG-MILLS THEORY

In this section, we investigate some important properties of the cohomological Yang-Mills theories in NC $\mathbb{R}^{2D}$ whose noncommutativity is defined as

$$[x^\mu,x^\nu]=i\theta^{\mu\nu}, \tag{1}$$

where the $\theta^{\mu\nu}$ is an element of an antisymmetric matrix and called noncommutative parameter.

Since action functionals of cohomological field theories are defined by BRS-exact functionals like $\hat{\delta}\Psi[\phi_i]$, where $\hat{\delta}$ is a some BRS operator and $\{\phi_i\}$ represent all considered fields and Ψ is a some fermionic functional, the partition function of the cohomological field theory is invariant under any infinitesimal variation δ' which commutes (or anticommutes) with the BRS transformation,

$$\hat{\delta}\delta' = \pm\,\delta'\hat{\delta},$$

$$\delta' Z_\theta=\int\prod_i \mathcal{D}\phi_i\,\delta'\left(-\int \mathrm{d}x^{2D}\,\hat{\delta}\Psi\right)\exp(-S_\theta)=\pm\int\prod_i \mathcal{D}\phi_i\,\hat{\delta}\left(-\int \mathrm{d}x^{2D}\delta'\Psi\right)\exp(-S_\theta)=0. \tag{2}$$

Let δ_θ be the infinitesimal deformation operator of the noncommutative parameter θ which operates as

$$\delta_\theta\theta^{\mu\nu}=\delta\theta^{\mu\nu}, \tag{3}$$

where $\delta\theta^{\mu\nu}$ are some infinitesimal antisymmetric two form elements. If δ_θ and BRS operator $\hat{\delta}$ commute each other, then the partition function is invariant. Indeed, there is some examples such that $\hat{\delta}\delta_\theta=\delta_\theta\hat{\delta}$, and partition functions are calculated by using this property.[28,29,27]

In this paper, cohomological Yang-Mills theories in noncommutative Euclidian spaces are discussed. If there is a gauge symmetry, the BRS-like transformation is slightly different from the one of nongauge theory. The BRS-like symmetry is not nilpotent but

$$\hat{\delta}^2=\delta_{g,\theta}, \tag{4}$$

where $\delta_{g,\theta}$ is a gauge transformation operator deformed by some noncommutative deformation method like the star product $*_\theta$. As occasion arises, the gauge transformation $\delta_{g,\theta}$ is defined as one including global symmetry transformations. The partition function of the noncommutative cohomological field theory is invariant under changing noncommutative parameters when the BRS transformation does not depend on the noncommutative parameters, because the BRS transformation $\hat{\delta}$ and the θ deformation δ_θ commute. Conversely, when the definition of the BRS-like

operator (4) depends on the noncommutative parameter θ, then $\hat{\delta}$ and δ_θ do not commute,

$$\delta_\theta \hat{\delta} \neq \hat{\delta}\delta_\theta \Rightarrow \delta_\theta \hat{\delta} = \hat{\delta}'\delta_\theta, \tag{5}$$

where $\hat{\delta}'$ is a BRS-like operator that generates the same transformations as the original BRS-like operator $\hat{\delta}$, except for the square. The square of $\hat{\delta}'$ is defined by

$$\hat{\delta}'^2 = \delta_{g,\theta+\delta\theta}. \tag{6}$$

Since the gauge symmetry is defined by using noncommutative parameter $\theta^{\mu\nu}+\delta\theta^{\mu\nu}$ after the δ_θ operation, this difference arises. This fact makes a little complex problem to prove the θ-shift invariance of noncommutative cohomological Yang-Mills theory in comparison with the case of nongauge theory.

Note that the essential point of this problem is not nilpotent property changing, but θ dependence of the definition of the BRS operator. (In fact, we can construct the BRS operator for the cohomological Yang-Mills theory as a nilpotent operator.[3])

However, we can prove the invariance of the partition function of cohomological Yang-Mills theory in NC $\mathbb{R}^{2D}$ under the noncommutative parameter deformation. For simplicity, we take

$$(\theta^{\mu\nu}) = \bigoplus_i \epsilon^{2i-1,2i}\theta = \theta\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \oplus \cdots \oplus \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},$$

where $\epsilon^{2i-1,2i}$ is an antisymmetric tensor such that $\epsilon^{2i-1,2i} = -\epsilon^{2i,2i-1} = 1$, and we restrict the θ deformation to

$$\theta \to \theta + \delta\theta.$$

In the following, we only use operator formalisms to describe the noncommutative field theory, therefore the fields are operators acting on the Hilbert space $\mathcal{H}$. Then differential operators ∂_μ are expressed by using commutation brackets $-i\theta^{-1}_{\mu\nu}[x^\nu, *] \equiv [\hat{\partial}_\mu, *]$ and $\int d^{2D}x$ is replaced with $\det(\theta)^{1/2}\,\mathrm{Tr}_{\mathcal{H}}$. Therefore the noncommutative parameter deformation is equivalent with replacing $-i\theta^{-1}_{\mu\nu}[x^\nu,]$ and $\det(\theta)^{1/2}\,\mathrm{Tr}_{\mathcal{H}}$ by $-i(\theta+\delta\theta)^{-1}_{\mu\nu}[x^\nu,]$ and $\det(\theta+\delta\theta)^{1/2}\,\mathrm{Tr}_{\mathcal{H}}$, respectively.

Let us consider Donaldson-Witten theory (topological twisted $\mathcal{N}=2$ Yang-Mills theory) on NC $\mathbb{R}^4$.[36] This theory is constructed by bosonic fields $(A_\mu, H^+_{\mu\nu}, \bar{\phi}, \phi)$ and fermionic fields $(\psi_\mu, \chi^+_{\mu\nu}, \eta)$, where $(A_\mu, H^+_{\mu\nu}, \bar{\phi})$ and $(\psi_\mu, \chi^+_{\mu\nu}, \eta)$ are supersymmetric (BRS) pairs,

$$\begin{gathered} \chi^+_{\mu\nu}, H^+_{\mu\nu} \in \Omega^{2,+}(\mathbb{R}^4, \mathrm{ad}\,P), \quad \psi_\mu \in \Omega^1(\mathbb{R}^4, \mathrm{ad}\,P), \\ \eta, \bar{\phi}, \phi \in \Omega^0(\mathbb{R}^4, \mathrm{ad}\,P). \end{gathered} \tag{7}$$

Their ghost numbers are assigned as $(A_\mu, \chi^+_{\mu\nu}, H^+_{\mu\nu}, \psi_\mu, \eta, \bar{\phi}, \phi) = (0,-1,0,1,-1,-2,2)$. The BRS-like operator is defined by

$$\begin{gathered} \hat{\delta}A_\mu = \psi_\mu, \quad \hat{\delta}\chi^+_{\mu\nu} = H^+_{\mu\nu}, \\ \hat{\delta}\psi_\mu = D_\mu\phi, \quad \hat{\delta}H^+_{\mu\nu} = i[\chi^+_{\mu\nu}, \phi], \\ \hat{\delta}\phi = 0, \quad \hat{\delta}\bar{\phi} = \eta, \quad \hat{\delta}\eta = i[\bar{\phi}, \phi], \end{gathered} \tag{8}$$

where the covariant derivative is defined by $D_\mu * := [\hat{\partial}_\mu + iA_\mu, *]$ with $\hat{\partial}_\mu := -i\theta^{-1}_{\mu\nu}x^\nu$. When we consider only the case of NC $\mathbb{R}^{2D}$, field theories are expressed by the Fock space formalism (See Appendix A). In the Fock space representation, fields are expressed as A_μ

$=\Sigma A^{n_1 n_2}_{\mu_{m_1 m_2}} |n_1, n_2\rangle\langle m_1, m_2|$, $\psi_\mu = \Sigma \psi^{n_1 n_2}_{\mu_{m_1 m_2}} |n_1, n_2\rangle\langle m_1, m_2|$, etc. Therefore, the above BRS transformations are expressed as

$$\hat{\delta} A^{n_1 n_2}_{\mu_{m_1 m_2}} = \psi^{n_1 n_2}_{\mu_{m_1 m_2}}, \quad \ldots . \tag{9}$$

Let us define gauge fermions as

$$\begin{aligned} \Psi &= \left[2\chi^+_{\mu\nu} \left(-iF^{+\mu\nu} + \tfrac{1}{2} H^{+\mu\nu} \right) \right], \\ \Psi_{\text{proj}} &= -[\bar{\phi} D_\mu \psi^\mu], \end{aligned} \tag{10}$$

then the action functional is given by

$$\begin{aligned} S &= \mathrm{Tr}_{\mathcal{H}} L(A_\mu, \ldots; \hat{\partial}_{z_i}, \hat{\partial}_{\bar{z}_i}) = \mathrm{Tr}_{\mathcal{H}} \, \mathrm{tr} \, \hat{\delta}(\Psi + \Psi_{\text{proj}}) \\ &= \mathrm{Tr}_{\mathcal{H}} \, \mathrm{tr}(F^{+2} - 4i\chi^{+\mu\nu} D_\mu \psi_\nu - \eta D_\mu \psi^\mu + i\phi\{\chi^+_{\mu\nu}, \chi^{+\mu\nu}\} - i\bar{\phi}\{\psi_\mu, \psi^\mu\} - \bar{\phi} D_\mu D^\mu \phi), \end{aligned} \tag{11}$$

where tr is trace for gauge group. In this paper, we omit to note $\det(\theta)^{1/2}$ that is an overall factor, for economy of space. Let us change the dynamical variables as

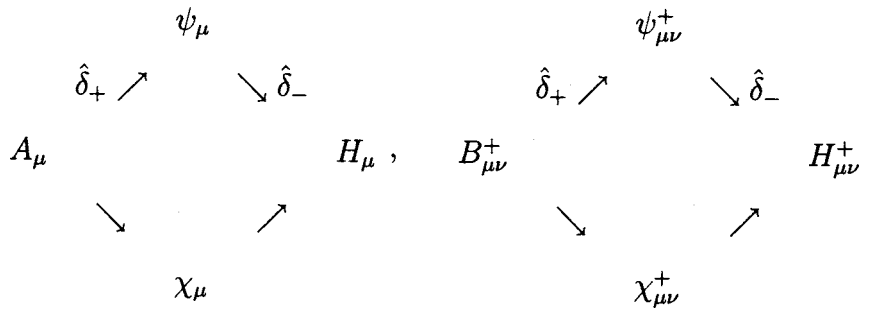
$$\begin{aligned} A_\mu \to \frac{1}{\sqrt{\theta}} \tilde{A}_\mu, \quad \psi_\mu \to \frac{1}{\sqrt{\theta}} \tilde{\psi}_\mu, \quad \bar{\phi} \to \frac{1}{\theta} \tilde{\bar{\phi}}, \quad \eta \to \frac{1}{\theta} \tilde{\eta}, \\ \chi^+_{\mu\nu} \to \frac{1}{\theta} \tilde{\chi}^+_{\mu\nu}, \quad H^+_{\mu\nu} \to \frac{1}{\theta} \tilde{H}^+_{\mu\nu}, \quad \phi \to \tilde{\phi}. \end{aligned} \tag{12}$$

Note that this changing does not cause nontrivial Jacobian from the path integral measure because of the BRS symmetry. Then, the action is rewritten as

$$S \to \frac{1}{\theta^2} \tilde{S}, \quad L(A_\mu, \ldots; \hat{\partial}_{z_i}, \hat{\partial}_{\bar{z}_i}) \to \frac{1}{\theta^2} L(\tilde{A}_\mu, \ldots; -a_i^\dagger, a_i). \tag{13}$$

Here the action on the left-hand side depends on θ because the derivative is given by $\partial_{z_i} = -\sqrt{\theta^{-1}}[a_i^\dagger,]$ and so on. In contrast, the action $\tilde{S}$ on the right-hand side does not depend on θ because all θ parameters are factorized out. Using the BRS symmetry or the fact of Eq. (2), it is proved that the partition function is invariant under the deformation of θ, because $\delta_\theta Z = -2(\delta\theta)\theta^{-3}\langle\tilde{S}\rangle = 0$. $\mathrm{Tr}_{\mathcal{H}_{2\ \mathrm{dim}}} \mathrm{tr}\left(\phi F + \frac{1}{2}\psi \wedge \psi\right)$ and $\mathrm{tr}\, \phi^n$ are known as observables of Donaldson-Witten theory. They are rewritten as $(1/\theta)\mathrm{Tr}_{\mathcal{H}} \mathrm{tr}\left(\tilde{\phi}\tilde{F} + \frac{1}{2}\tilde{\psi} \wedge \tilde{\psi}\right)$ and $\mathrm{tr}\, \tilde{\phi}^n$. We use O to represent such observables, then $\delta_\theta \langle O \rangle = 0$ are proved in a similar way to the proof of $\delta_\theta Z = 0$. Therefore, invariance of Donaldson-Witten theory under $\theta \to \theta + \delta\theta$ is proved.

We can discuss the topological twisted $\mathcal{N}=4$ Yang-Mills theory in noncommutative $\mathbb{R}^4$ similarly.[34] (There are many kinds of topological twisted theories of $\mathcal{N}=4$ Yang-Mills theory. We only consider Vafa-Witten-type theory.) There are additional fields $(B^+_{\mu\nu}, c, H_\mu)$ and $(\psi^+_{\mu\nu}, \bar{\eta}, \chi_\mu)$, where $(B^+_{\mu\nu}, c, H_\mu)$ are bosonic fields and $(\psi^+_{\mu\nu}, \bar{\eta}, \chi_\mu)$ are fermionic fields, where $B^+_{\mu\nu}, \psi^+_{\mu\nu} \in \Omega^{2,+}(\mathbb{R}^4, \mathrm{ad}\, P)$. They are supersymmetric partners, and the BRS multiplets are expressed by the following diagram:



There are two BRS-like operators $\hat{\delta}_+$ and $\hat{\delta}_-$ because of the R-symmetry of the $\mathcal{N}=4$. The $\hat{\delta}_+$ transformations are given by

$$\hat{\delta}_+ B^+_{\mu\nu} = \psi^+_{\mu\nu}, \quad \psi^+_{\mu\nu} = i[B^+_{\mu\nu}, \phi], \tag{14}$$

$$\hat{\delta}_+ \chi_\mu = H_\mu, \quad \hat{\delta}_+ H_\mu = i[\chi_\mu, \phi], \quad \hat{\delta}_+ c = \bar{\eta}, \quad \hat{\delta}_+ \bar{\eta} = i[c, \phi], \tag{15}$$

and the same transformations as (8) for other fields. The action of the topological twisted $\mathcal{N}=4$ Yang-Mills theory without the $\tau \int F \wedge F$ is

$$S = \mathrm{Tr}_{\mathcal{H}}\ \mathrm{tr}\ \hat{\delta}_+ \{\chi^+_{\mu\nu}(H^{+\mu\nu} - i(F^{+\mu\nu} - i[B^+_{\mu\rho}, B^+_{\nu\sigma}]\delta^{\rho\sigma} - i[B^+_{\mu\nu}, c]))\} + \mathrm{Tr}_{\mathcal{H}}\ \mathrm{tr}\ \hat{\delta}_+ \{\chi^\rho(H_\rho - i(-2D^\mu B^+_{\mu\rho} - D_\rho c))\} + \mathrm{Tr}_{\mathcal{H}}\ \mathrm{tr}\ \hat{\delta}_+ \{i[\phi, \bar{\phi}]\eta - i\bar{\eta}[c, \bar{\phi}] + i[B^{+\mu\nu}, \bar{\phi}]\psi^+_{\mu\nu} + (D_\mu \bar{\phi})\psi_\mu\}. \tag{16}$$

For this action, we change the variables as

$$B^+_{\mu\nu} \to \frac{1}{\sqrt{\theta}} \tilde{B}^+_{\mu\nu}, \quad \psi^+_{\mu\nu} \to \frac{1}{\sqrt{\theta}} \tilde{\psi}^+_{\mu\nu}, \quad c \to \frac{1}{\sqrt{\theta}} \tilde{c}, \quad \bar{\eta} \to \frac{1}{\sqrt{\theta}} \tilde{\bar{\eta}},$$

$$\chi_\mu \to \frac{1}{\theta} \tilde{\chi}_\mu, \quad H_\mu \to \frac{1}{\theta} \tilde{H}_\mu$$

with (12), then $S \to (1/\theta^2)\tilde{S}$, and $\tilde{S}$ does not depend on θ. At last, invariance of the $\mathcal{N}=4$ topological twisted theory under $\theta \to \theta + \delta\theta$ is proved as the same as the Donaldson-Witten theory.

It is worth commenting on the topological term $\int F \wedge F$ that exists in the usual Vafa-Witten theory but now is removed. This term is not written by a BRS exact term, so we cannot adapt the above discussion to the topological term. But, it is natural that we expect that $\int F \wedge F$ is invariant under the θ shift. Indeed, for instanton solutions constructed from noncommutative deformed ADHM data, we have proof of invariance of instanton number under θ shift.[14,26] This is why, we expect that the partition functions or vacuum expectation values are still invariants even if the action of the cohomological Yang-Mills theories include $\int F \wedge F$ (see also Sec. V).

By applying these facts for several physical models, some interesting information can be found. For example, as we will see soon, we can show that the partition function of the noncommutative cohomological gauge theory and the partition function of the IKKT matrix model have a correspondence. This correspondence is not only for certain classical background theory as we saw in Ref. 1. The reason is as follows. The IKKT matrix model is constructed as dimensional reduction of the 10-dimensional super U(N) Yang-Mills theory with large N limit.[2,12] This dimensional reduction is regarded as the large noncommutative parameter limit ($\theta \to \infty$ in Sec. IV). Taking the large N limit of the matrix model is similar to considering the Yang-Mills theories on noncommutative Moyal space, i.e., matrices are regarded as linear operators acting on the Hilbert space caused from noncommutativity. By the way, the noncommutative cohomological Yang-Mills model on Moyal space in the large θ limit is almost the same as the model of Moore, Nekrasov, and Shatashvili (MNS).[20] MNS show that the partition function is calculated by the cohomological

matrix model in Ref. 20 and related works are seen in Refs. 4, 11, and 31. This cohomological matrix model is almost equivalent to the IKKT matrix model. That is why we can produce similar result by using NC cohomological Yang-Mills theories. To show these facts concretely, we will calculate the partition function of $\mathcal{N}=4$, $d=4$ U(1) theory on NC $\mathbb{R}^4$ in Sec. IV by using the facts given in this section.

III. UNIVERSALITY OF PARTITION FUNCTIONS

In this section, we show that the large θ limit is equivalent to dimensional reduction. From this fact, we find the universal perspective for the partition functions of supersymmetric Yang-Mills theories in NC $\mathbb{R}^{2D}$.

In the preceding section, we consider the case of $\mathbb{R}^4$. There is two independent noncommutative parameters θ^1, θ^2 for the NC $\mathbb{R}^4$, that is to say, after choosing proper coordinate noncommutative parameters are expressed as

$$(\theta^{\mu\nu}) = \begin{pmatrix} 0 & \theta^1 & 0 & 0 \\ -\theta^1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \theta^2 \\ 0 & 0 & -\theta^2 & 0 \end{pmatrix}. \tag{17}$$

In the discussion of the preceding section, we take noncommutative parameter shift coincidently, that is $\theta^1=\theta^2=\theta\rightarrow\theta+\delta\theta$. However, we can shift θ^1, θ^2 independently without changing partition functions and vacuum expectations. Further, this discussion is extended to other dimensional theories.

Let us consider more general cases than NC $\mathbb{R}^4$. Let noncommutative parameter matrix of NC $\mathbb{R}^{2D}$ be $(\theta^{\mu\nu})=\oplus\theta^i\epsilon^{2i-1,2i}$. In the large θ^i limit, terms with derivative operators $\partial_{x_{2i}} := -i(\theta^i)^{-1}[x_{2i-1}, *]$ and $-\partial_{x_{2i-1}} := -i(\theta^i)^{-1}[x_{2i}, *]$ become irrelevant in Lagrangians. If the partition function and the VEV of arbitrary observables of the cohomological field theory are well defined, the terms including $\partial_{x_{2i}}$ or $\partial_{x_{2i-1}}$ are possible to be removed. (In Appendix B, concrete discussions and details are given.) In the complex coordinate expression, the terms including z_i and $\bar{z}_i$ derivatives are omitted. Meanwhile, an arbitrary operator is expressed as

$$\hat{\mathcal{O}} = \sum_{n_1,m_1} \cdots \sum_{n_D,m_D} \mathcal{O}^{n_1\cdots n_D}_{m_1\cdots m_D} |n_1, \ldots, n_D\rangle\langle m_1, \ldots, m_D|,$$

by using fock space basis (see Appendix A). We consider a quantum theory of infinite-dimensional matrix model, and $\mathcal{O}^{n_1\cdots n_D}_{m_1\cdots m_D}$ is a variable of path integration. Then we cannot distinguish dynamical variables

$$\mathcal{O}^{n_1\cdots n_{i-1}n_{i+1}\cdots n_D}_{m_1\cdots m_{i-1}m_{i+1}\cdots m_D} |n_1, \ldots, n_{i-1}, n_{i+1}, \ldots, n_D\rangle\langle m_1, \ldots, m_{i-1}, m_{i+1}, \ldots, m_D| \tag{18}$$

from $\mathcal{O}^{n_1\cdots n_D}_{m_1\cdots m_D}|n_1,\ldots,n_D\rangle\langle m_1,\ldots,m_D|$ because both of them are infinite-dimensional matrices. From the facts that there is no ∂_{z_i} or $\partial_{\bar{z}_i}$ and it is impossible to distinguish dynamical variables living in $\mathbb{R}^{2D}$ from variables in $\mathbb{R}^{2D-2}$, then we conclude that the large θ_i limit is equivalent to the dimensional reduction corresponding to x^{2i-1} and x^{2i} directions.

We must note two points, here. The first point is that naive path integrals contain zero mode integrals. To make the story precise, let us define the zero mode here. Let $\{\phi_i\}$ be a set of fields and $S[\phi_i]$ be an action functional of a considered theory. Here, we define the zero mode ϕ_i^0 by $S[\phi_i^0]=0$. To make the partition functions be well defined, we manage the zero modes, in general. But it is difficult that the dealing with the zero modes is discussed in general terms. To avoid this difficulty, the discussion of the zero mode integrals are taken up in the individual cases. In Sec. IV, we will closely study the handling of the zero modes for the case of $\mathcal{N}=4$ U(1) gauge theory in NC $\mathbb{R}^4$.

The second point is that there might be BPS solutions that become singular at $\theta^i \to \infty$ limit. To the authors' knowledge, such solutions have never been known until now, but we cannot deny their existence. Since we cannot estimate its contribution to the vacuum expectations when we calculate them at the large θ^i limit, we must rule out such singular configurations when we construct the correspondence between finite θ^i and infinite θ^i.

As a summary of these arguments, the following claim is obtained.

Claim: Let Z_{2D} *and* $\langle O \rangle_{2D}$ *be a partition function and vacuum expectation value of* O *of a cohomological field theory in* NC $\mathbb{R}^{2D}$ *with* $D \geqslant 1$ *such that* $\delta_\theta Z_{2D}=0$ *and* $\delta_\theta \langle O \rangle_{2D}=0$. *Here, zero mode integrals and contributions from BPS solutions that become singular at large noncommutative parameter limit are removed from the path integral of* Z_{2D} *and* $\langle O \rangle_{2D}$. *Let* Z_{2D-2} *and* $\langle O \rangle_{2D-2}$ *be the partition function and vacuum expectation value of* O *of a noncommutative cohomological field theory in* NC $\mathbb{R}^{2D-2}$, *where they are given by dimensional reduction of* Z_{2D} *and* $\langle O \rangle_{2D}$. *Then*,

$$Z_{2D} = Z_{2D-2}, \quad \langle O \rangle_{2D} = \langle O \rangle_{2D-2}, \tag{19}$$

i.e., the partition functions of such theories do not change under dimensional reduction from 2D *to* $2D-2$.

From this claim, we find that following partition functions of super Yang-Mills theories on NC $\mathbb{R}^{2D}$ are equivalent:

$$Z^{8\ \mathrm{dim}}_{\mathcal{N}=2} = Z^{6\ \mathrm{dim}}_{\mathcal{N}=2} = Z^{4\ \mathrm{dim}}_{\mathcal{N}=4} = Z^{2\ \mathrm{dim}}_{\mathcal{N}=8} = Z^{0\ \mathrm{dim}}_{***}, \tag{20}$$

where $Z^{I\ \mathrm{dim}}_{\mathcal{N}=J}$ is a partition function of the $\mathcal{N}=J$ super Yang-Mills theory in noncommutative $\mathbb{R}^I$ with arbitrary gauge group. They are obtained by dimensional reduction of the eight dimensional $\mathcal{N}=2$ super Yang-Mills theory. Note that the topological terms in the actions of the above theories should be removed because the topological term is not universal between the different dimensional theories. The proof of (20) is as follows. In the $\mathbb{R}^{2D}$, a topological twist exists at any time for $\mathcal{N} \geqslant 2$. Using the topological twist, the partition functions are described as the one of cohomological field theories. Therefore, $Z^{8\ \mathrm{dim}}_{\mathcal{N}=2}$ is invariant under θ-shift and satisfies the condition of the above claim. After all, Eq. (20) is obtained. We will calculate the partition functions concretely in the case of U(1) in the next section.

It is worth adding some comments about the above models. We consider noncommutative Euclidean spaces. $\mathcal{N}=4$ super Yang-Mills theory in NC $\mathbb{R}^4$ is given as follows. At first, we construct the four-dimensional $\mathcal{N}=4$ super Yang-Mills theory by dimensional reduction of the 10-dimensional $\mathcal{N}=1$ super Yang-Mills defined on Minkowski space with SO(9,1) symmetry. In four dimensions, spinor in Euclidean space is defined as well as the spinor in Minkowski space. Therefore, we can construct the $\mathcal{N}=4$ super Yang-Mills theory in $\mathbb{R}^4$ by formally replacing the metric, gamma matrices and so on. Since the θ-shift invariance of $Z^{4\ \mathrm{dim}}_{\mathcal{N}=4}$ was shown explicitly in Sec. II (see also Appendix B), theories connected to the $\mathcal{N}=4$ $d=4$ super Yang-Mills theory through the dimensional reduction appear in (20).

This discussion is valid not only for the $\mathcal{N}=4$ case. For example, we saw that the θ-shift invariance of $Z^{4\ \mathrm{dim}}_{\mathcal{N}=2}$ in Sec. II. Then, the similar relation should exist,

$$Z^{4\ \mathrm{dim}}_{\mathcal{N}=2} = Z^{2\ \mathrm{dim}}_{\mathcal{N}=4} = Z^{0\ \mathrm{dim}}_{***}. \tag{21}$$

Let us summarize this section. Universality of partition functions and vacuum expectation values of observables of NC cohomological field theories are discussed. From the claim, we found that $\mathcal{N} \geqslant 2$ supersymmetric models or cohomological field theories in NC $\mathbb{R}^{2D}$ are invariant under dimensional reduction from 2D to $2D-2$. In the following section, we will apply these facts to concrete calculations.

IV. $\mathcal{N}=4$ U(1) GAUGE THEORY IN NC $\mathbb{R}^4$

In this section, we calculate the partition function of the topological twisted $\mathcal{N}=4$ U(1) gauge theory in NC $\mathbb{R}^4$, without the topological term $\int F \wedge F$ in its action.

We perform the calculation in the $\theta\to\infty$ limit. The reason why we take this limit is as follows. As explained in Sec. II, the partition function and other correlation functions of cohomological field theories on noncommutative spaces are invariant under the shift transformation of the noncommutative parameter θ. So we obtain the exact result by taking $\theta\to\infty$ limit. Also this limit makes the calculation executable.

In the operator formalism, field theories in NC $\mathbb{R}^4$ are expressed as infinite dimensional matrix models whose symmetry is U(N) ($N\to\infty$). The size of matrices appearing in this model is infinite. To perform the calculation, we introduce a cutoff for the matrix size. In addition, this matrix model contains trace parts which correspond to zero modes in $\theta\to\infty$. Therefore we must carefully treat the trace parts to make the path integral well defined.

In Sec. IV A, we give the action of the topological twisted $\mathcal{N}=4$ U(1) gauge theory in NC $\mathbb{R}^4$ in the operator formalism, i.e., in terms of infinite-dimensional matrices. In Sec. IV B, we truncate the size of the matrices into finite size, a finite integer N. In Sec. IV C, we explain that the truncated $N\times N$ matrix model action obtained in the preceding section is equivalent to the dimension reduction of the 10 dimensional $\mathcal{N}=1$ U(N) super Yang-Mills action to 0 dimensions. This U(N) matrix model contains traceless parts and trace parts. In Sec. IV D, we calculate the partition function of the traceless sector. The traceless sector is a SU(N) matrix model. The partition function of this SU(N) matrix model was obtained by MNS.[20] By modifying their arguments, we evaluate the $N\to\infty$ limit of the partition function of the traceless sector. In Sec. IV E, we introduce extra parts into the matrices to handle the trace parts which are zero modes. The extra parts and trace parts are the next leading terms in the $1/\sqrt{\theta}$ expansion. In Sec. IV F, the calculation of the trace sector is performed. Our result is presented at the end of this section.

A. Setting

In the Fock space formalism, i.e., in terms of (infinite-dimensional) matrices, the action of the topological twisted $\mathcal{N}=4$ U(1) gauge theory on NC $\mathbb{R}^4$ is expressed as

$$S^{4\ \mathrm{dim}}_{\mathcal{N}=4}=\mathrm{Tr}_{\mathcal{H}}\ \hat{\delta}_+[+\chi^{+\mu\nu}\{H^+_{\mu\nu}-i(F^+_{\mu\nu}-i[B^+_{\mu\rho},B^+_{\nu\sigma}]\delta^{\rho\sigma}-i[B^+_{\mu\nu},c])\}+\chi^{\mu}\{H_\mu-i(-2D^\nu B^+_{\nu\mu}-D_\mu c)\}$$
$$+i[\phi,\bar{\phi}]\eta-i\bar{\eta}[c,\bar{\phi}]+i[B^{+\mu\nu},\bar{\phi}]\psi^+_{\mu\nu}+(D_\mu\bar{\phi})\psi_\mu]. \tag{22}$$

After acting $\hat{\delta}_+$, (22) is rewritten as

$$S^{4\ \mathrm{dim}}_{\mathcal{N}=4}=\mathrm{Tr}_{\mathcal{H}}[H^{+\mu\nu}\{H^+_{\mu\nu}-i(F^+_{\mu\nu}-i[B^+_{\mu\rho},B^+_{\nu\sigma}]\delta^{\rho\sigma}-i[B^+_{\nu\sigma},c])\}+\chi^{+\mu\nu}\{-i[\chi^+_{\mu\nu},\phi]+i(2D_\mu\psi_\nu$$
$$-2i[B^+_{\mu\rho},\psi^+_{\nu\sigma}]\delta^{\rho\sigma}-i[\psi^+_{\mu\nu},c]-i[B^+_{\mu\nu},\bar{\eta}])\}+H^\mu\{H_\mu-i(-2D^\nu B^+_{\nu\mu}-D_\mu c)\}+\chi^\mu\{-i[\chi_\mu,\phi]$$
$$-i(2D^\nu\psi^+_{\nu\mu}+2i[\psi^\nu,B^+_{\nu\mu}]-D_\mu\bar{\eta}+i[\psi_\mu,c])\}+[\phi,\bar{\phi}]^2+[c,\phi][c,\bar{\phi}]+[B^{+,\mu\nu},\bar{\phi}][B^+_{\mu\nu},\phi]$$
$$+D^\mu\bar{\phi}D_\mu\phi+i[\phi,\eta]\eta+i\bar{\eta}[\bar{\eta},\bar{\phi}]+i\bar{\eta}[c,\eta]+i[\psi^{+\mu\nu},\bar{\phi}]\psi^+_{\mu\nu}+i[B^{+\mu\nu},\eta]\psi^+_{\mu\nu}+D^\mu\eta\psi_\mu$$
$$+i[\psi^\mu,\bar{\phi}]\psi_\mu]. \tag{23}$$

From (22) or (23), we find the BPS equations. For example,

$$F^+_{\mu\nu}-i[B^+_{\mu\rho},B^+_{\nu\sigma}]\delta^{\rho\sigma}-i[B^+_{\mu\nu},c]=0,$$

$$-2D^\nu B^+_{\nu\mu}-D_\mu c=0. \tag{24}$$

In the following, we calculate the partition function $Z^{4\ \mathrm{dim}}_{\mathcal{N}=4}$ formally defined as

$$Z^{4\ \mathrm{dim}}_{\mathcal{N}=4}=\int\mathcal{D}f\,e^{-S^{4\ \mathrm{dim}}_{\mathcal{N}=4}[f]}, \tag{25}$$

where f represents all matrices $A_\mu, \psi_\mu, \ldots$. Also we use f_{boson} and f_{fermion} to denote bosonic matrices $A_\mu, H_\mu, \ldots$ and fermionic matrices $\psi_\mu, \chi_\mu, \ldots$, respectively.

In usual commutative spaces, U(1) gauge theories are free if all matters belong to the adjoint representation, because the gauge interactions between the fields belonging to the adjoint representation are described by commutators of matrices and all commutators vanish in the U(1) case. However, in noncommutative spaces, the noncommutativity of the multiplication induces the U(1) gauge theories to non-Abelian U(N) ($N\to\infty$) like gauge theories. This U(N) ($N\to\infty$) is identified with the unitary transformation group acting on state vectors of the Hilbert space $\mathcal{H}$. [It is a well-known fact that the U(∞) is different from $\lim_{N\to\infty}$ U(N), in the meaning of the topology. In this paper, we perform the calculation by using $\lim_{N\to\infty}$ U(N), and there is no denying that some extra collections appear from the difference. However, there is no doubt about validity of the calculation of U(N) ($N\to\infty$) as a good approximation even in this case.]

Let us consider to take the $\theta\to\infty$ limit in the calculation of the partition function $Z^{4\text{ dim}}_{\mathcal{N}=4}$. We can evaluate the partition function exactly in this limit, as explained in Sec. II. In the $\theta\to\infty$ limit we naively expect that all differential terms in the action vanish and dimensional reduction occurs as we saw in Sec. III. Therefore, we can perform the calculation by using a matrix model in 0-dimensional space whose symmetry is U(N) ($N\to\infty$). We define the action in 0-dimensional space-time as

$$S^{\infty}_{MM} = S^{4\text{ dim}}_{\mathcal{N}=4}\big|_{\theta\to\infty}: \quad \mathrm{U}(N)(N\to\infty) \text{ matrix model}, \tag{26}$$

then, we find $Z^{4\text{ dim}}_{\mathcal{N}=4}$ is equal to the partition function of the matrix model (26),

$$Z^{4\text{ dim}}_{\mathcal{N}=4} = \frac{1}{\mathrm{Vol\,U}(N)(N\to\infty)} \int \mathcal{D}f\, e^{-S^{\infty}_{MM}}. \tag{27}$$

To calculate the partition function of this infinite-dimensional U(N) ($N\to\infty$) matrix model (26), we need to overcome the following problems.

(i) The size of the matrices is infinite. To perform the calculation, we truncate the size of the matrices into a finite integer N.
(ii) The matrices contain trace parts. These trace parts play the role of zero modes. To make the path integral well defined, we must carefully treat the trace parts.

In the rest of this section, we solve these problems and obtain the partition function (27).

B. Cutoff for matrix size

In this section we truncate the size of the matrices, to calculate the partition function.

The Hilbert space of the $\mathcal{N}=4$ U(1) gauge theory on NC $\mathbb{R}^4$ is constructed by a Fock space

$$\mathcal{H} = \bigoplus_{n_1=0,n_2=0}^{n_1=\infty,n_2=\infty} \mathbb{C}|n_1,n_2\rangle. \tag{28}$$

We introduce a cutoff, a finite integer N_c, and truncate the Hilbert space into a finite-dimensional subspace $\mathcal{H}_N$ whose dimension is N. We can perform such truncation in several ways. For example, $\mathcal{H}_N$ is defined by

$$\mathcal{H}_N = \bigoplus_{n_1=0,n_2=0}^{n_1=N_c,n_2=N_c} \mathbb{C}|n_1,n_2\rangle. \tag{29}$$

For this case

$$\dim \mathcal{H}_{\mathcal{N}} = N = (N_c+1)^2, \tag{30}$$

and the unit matrix of $\mathcal{H}_N$ is given as

$$\mathbf{1}_N = \bigoplus_{n_1=0,n_2=0}^{n_1=N_c,n_2=N_c} |n_1,n_2\rangle\langle n_1,n_2|. \tag{31}$$

The results and calculations do not depend on the definition of the cutoff in the following discussion (see Appendix A). Therefore we do not use concrete expression of the example (29). By definition,

$$\mathrm{Tr}_{\mathcal{H}}\, \mathbf{1}_N = \dim \mathcal{H}_{\mathcal{N}} = N. \tag{32}$$

For later use, we define $\mathcal{I}$ as

$$\mathcal{I} = \frac{1}{\sqrt{N}}\mathbf{1}_N, \tag{33}$$

which satisfies

$$\mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}\mathcal{I} = 1. \tag{34}$$

We truncate the infinite-dimensional matrices appearing in (26) into finite-dimensional $N \times N$ matrices. We use the symbol f_N to denote the $N \times N$ truncation of f. For example, of (29), if

$$f = \sum_{n_i=0}^{\infty} \sum_{m_i=0}^{\infty} f^{n_1 n_2}_{m_1 m_2} |n_1,n_2\rangle\langle m_1,m_2|,$$

then

$$f_N = \sum_{n_i=0}^{N_c} \sum_{m_i=0}^{N_c} f^{n_1 n_2}_{m_1 m_2} |n_1,n_2\rangle\langle m_1,m_2|.$$

Now we consider the finite-dimensional $N \times N$ matrix model S^N_{MM} which is obtained by the truncation from (26)

$$S^N_{MM} = S^{\infty}_{MM}|_{N\times N \text{ truncation}}. \tag{35}$$

The partition function of the truncated matrix model (35) is defined by

$$Z^{4\ \dim}_{\mathcal{N}=4}|_N = \frac{1}{\mathrm{Vol}\ U(N)} \int \mathcal{D}f_N e^{-S^N_{MM}}. \tag{36}$$

$N \times N$ matrix f_N is decomposed into the traceless part and the trace part,

$$f_N = f^{\mathrm{su}} + f^{\mathrm{tr}}, \tag{37}$$

where f^{su} is the traceless part and f^{tr} is the trace part. The traceless part f^{su} is expanded by the generators of the Lie algebra su(N),

$$f^{\mathrm{su}} = \sum_{a=1}^{N^2-1} f_{(a)} \tau^a, \quad \tau^a \in \mathrm{su}(N), \tag{38}$$

and f^{tr} is proportional to $\mathcal{I}$,

$$f^{\mathrm{tr}} = f_{(1)}\mathcal{I}. \tag{39}$$

The basis, τ^a and $\mathcal{I}$, satisfy the following orthonormal conditions:

$$\mathrm{Tr}_{\mathcal{H}} \tau^a \tau^b = \delta^{ab}, \quad \mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}\mathcal{I} = 1, \quad \mathrm{Tr}_{\mathcal{H}}\, \tau^a \mathcal{I} = 0. \tag{40}$$

In the naive $\theta \to \infty$ limit (i.e., 0-dimension reduction), Eq. (35) contains no trace part f^{tr},

$$Z^N_{MM} = Z^N_{MM}|_{\text{traceless}} \int \mathcal{D}f^{\text{tr}}, \tag{41}$$

where $Z^N_{MM}|_{\text{traceless}}$ is defined by

$$Z^N_{MM}|_{\text{traceless}} = \frac{1}{\text{Vol SU}(N)} \int \mathcal{D}f^{\text{su}} e^{-S^N_{MM}[f^{\text{su}}]}. \tag{42}$$

[Precisely speaking, the trace part of the auxiliary fields appear in (35). After integrating out the auxiliary fields, no trace part appears in (35).] So the trace part f^{tr} plays the role of the zero mode such that $S^N_{MM}[f^{\text{tr}}]=0$. To make the path integral well defined, we must carefully treat it. For other handling the zero modes, see, for example, Ref. 32. However we postpone this task for the moment. First, we concentrate on the traceless sector. Before the calculation of the traceless sector, we explain the equivalence between (35) and the action considered in Ref. 20 in the next section.

C. Relation to the work of MNS and IKKT

To explain that the equivalence between (35) and the action considered in Ref. 20, we first recall the fact that the dimensional reduction model from the $D=10$ $\mathcal{N}=1$ super Yang-Mills theory to 0 dimension can be reformulated into a cohomological matrix model.[11,20] The 0-dimension matrix model given by dimensional reduction from the $D=10$ $\mathcal{N}=1$ super Yang-Mills theory is expressed as

$$S^{10\to 0 \text{ dim}}_{\mathcal{N}=1} = \text{tr}\left(\frac{1}{4}[A_M, A_N]^2 + \frac{i}{2}\bar{\Psi}\Gamma^M[A_M, \Psi]\right), \tag{43}$$

where A_M is the gauge vector fields and M,N takes $1,\ldots,10$ for the 10-dimension Euclid space, or $0,1,\ldots,9$ for the 10-dimension Minkowski space-time. Ψ is a Majorana-Weyl spinor of the 10-dimension space-time. It contains real 16 components. (Note that there is no Majorana-Weyl spinor in 10-dimension Euclidean space. So, if we consider the 10 dimensional model, we should take Minkowski space-time. To obtain the low-dimensional Euclidean model, we first perform dimensional reduction from 10 dimensions to lower dimensions, and then carry out Wick rotation.)

In Refs. 11 and 20, it is shown that (43) can be reformulated into a cohomological matrix model. The mapping rules between them are as follows.[20] A_M are arranged into complex matrices ϕ and B_i $(i=1,\ldots,4)$,

$$\begin{aligned} B_i &= A_{2i-1} + iA_{2i} \quad (\text{for } i=1,2,3), \\ B_4 &= A_9 + iA_8, \\ \phi &= A_7 + iA_{10}, \end{aligned} \tag{44}$$

and Ψ are arranged as

$$\Psi \to (\psi_i, \psi_i^\dagger) \oplus \vec{\chi} \oplus \eta, \tag{45}$$

where $\vec{\chi}$ belongs to the **7** representation of Spin (7). Introducing the bosonic auxiliary matrices $\vec{H}$, we can rewrite (43) into a cohomological form,

$$S_{\text{MNS}} = \text{tr}\ \hat{\delta}\left(\frac{1}{16}\eta[\phi,\bar{\phi}] - i\vec{\chi}\cdot\vec{\mathcal{E}} + \vec{\chi}\cdot\vec{H} + \frac{1}{4}\sum_{a=1}^{8}\Psi_a[A_a,\bar{\phi}]\right), \tag{46}$$

where $\vec{\mathcal{E}}$ is defined by

$$\vec{\mathcal{E}} = \left([B_i, B_j] + \frac{1}{2}\epsilon_{ijkl}[B_k^\dagger, B_l^\dagger](i<j), \sum_i [B_i, B_i^\dagger] \right). \tag{47}$$

The BRS transformation rules are given as

$$\begin{gathered} \hat{\delta}A_a = \Psi_a, \quad \hat{\delta}\Psi_a = [\phi, A_a], \\ \hat{\delta}\vec{\chi} = \vec{H}, \quad \hat{\delta}\vec{H} = [\phi, \vec{\chi}], \\ \hat{\delta}\bar{\phi} = \eta, \quad \hat{\delta}\eta = [\phi, \bar{\phi}], \\ \hat{\delta}\phi = 0. \end{gathered} \tag{48}$$

From (46) and (48), the following BPS equations are obtained:

$$\vec{\mathcal{E}} = 0, \quad [\phi, \bar{\phi}] = 0, \quad [A_a, \phi] = 0. \tag{49}$$

One can show that (46) is equivalent to (26), by using the following correspondence rule:[16]

$$\begin{gathered} (\phi, c, \bar{\phi}) \Leftrightarrow \left(\sqrt{2}\varphi_{34}, i\frac{1}{\sqrt{2}}(\varphi_{14} - \varphi_{23}), \sqrt{2}\varphi_{12} \right), \\ (B_{\mu\nu}^+\sigma_{11}^{\mu\nu}, B_{\mu\nu}^+\sigma_{12}^{\mu\nu}, B_{\mu\nu}^+\sigma_{22}^{\mu\nu}) \Leftrightarrow \left(\sqrt{2}\varphi_{13}, -\frac{1}{\sqrt{2}}(\varphi_{14} + \varphi_{23}), \varphi_{24} \right), \end{gathered} \tag{50}$$

where φ is defined by

$$\varphi_{k4} = -\varphi_{4k} = \frac{1}{\sqrt{2}}(A_{k+4} + iA_{k+7}), \quad \varphi_{ij} = (\epsilon^{ijk}\varphi_{k4})^*, \quad k = 1,2,3. \tag{51}$$

Remark that the equivalence among (35), (43), and (46) holds for both U(N) group and SU(N) group.

By choosing gauge group SU(N) and setting N to be a finite integer, we obtain the equivalence between (35) and (46),

$$S_{MM}^N|_{\text{traceless}} = S_{\text{MNS}}|_{\text{gauge group:SU}(N)}^{N:\text{finite}}. \tag{52}$$

Therefore

$$Z_{MM}^N|_{\text{traceless}} = Z_{\text{MNS}}|_{\text{gauge group:SU}(N)}^{N:\text{finite}}, \tag{53}$$

where

$$Z_{\text{MNS}}|_{\text{gauge group:SU}(N)}^{N:\text{finite}} = \frac{1}{\text{Vol SU}(N)} \int \mathcal{D}f^{\text{su}} \exp\{ -S_{\text{MNS}}[f^{\text{su}}]|_{\text{gauge group:SU}(N)}^{N:\text{finite}} \}. \tag{54}$$

MNS obtained the partition function (54).[20] (See also Ref. 6 where the partition function of the D-instanton model was calculated.)

On the other hand, by choosing gauge group U(N) and taking the $N \to \infty$ limit, the action (43) becomes the IKKT matrix model,[12]

$$S_{\text{IKKT}} = \lim_{N\to\infty} S_{\mathcal{N}=1}^{10\to 0 \text{ dim}}|_{\text{gauge group:U}(N)}. \tag{55}$$

So, we obtain the equivalence between (26) and (55),

$$S_{MM}^{\infty} = S_{\mathrm{IKKT}}. \tag{56}$$

D. Calculation of traceless sector

As explained in the preceding section the partition function (42) is calculated in Ref. 20. Their result tells us that

$$Z_{MM}^{N}|_{\mathrm{traceless}} = \sum_{d|N} \frac{1}{d^2}, \tag{57}$$

where the summation is taken over all divisor d of the finite integer N.

One might expect that to obtain the contribution of the traceless part f^{su} to $Z_{\mathcal{N}=4}^{4\ \mathrm{dim}}$, one takes the $N\to\infty$ limit,

$$Z_{MM}^{\infty}|_{\mathrm{traceless}} = \lim_{N\to\infty} Z_{MM}^{N}|_{\mathrm{traceless}}. \tag{58}$$

However $N\to\infty$ limit on the right-hand side of (57) is not well defined. The reason is as follows. We see that the right-hand side of (57) is finite,

$$\sum_{d|N} \frac{1}{d^2} < \sum_{n=1}^{N} \frac{1}{n^2} < 1 + \int_1^{\infty} \mathrm{d}x \frac{1}{x^2} = 2. \tag{59}$$

But $\Sigma_{d|N}(1/d^2)$ is not a monotonically increasing function of N. So it does not converge. For example, if we constrain N to be prime numbers,

$$\lim_{N\to\infty} \sum_{d|N} \frac{1}{d^2} = \lim_{N\to\infty} (1 + N^{-2}) = 1. \tag{60}$$

If we constrain $N=2^{N'}$,

$$\lim_{N\to\infty} \sum_{d|N} \frac{1}{d^2} = \lim_{N\to\infty} \sum_{n=0}^{N'} 2^{-2n} = \frac{4}{3}. \tag{61}$$

Therefore, we must give the proper definition of $N\to\infty$ limit.

To find a prescription which leads the definite answer of the $N=\infty$ case, let us recall the argument of Ref. 20 where the result (57) is concluded for a finite N.

(i) The authors of Ref. 20 separated the coupling constant g to g, $\tilde{g}$ and $\hat{g}$ (on the right-hand side of (46), we omitted the coupling constant g),

$$S_{\mathrm{MNS}} \to \mathrm{tr}\ \hat{\delta}\left(\frac{1}{16\tilde{g}} \eta[\phi, \bar{\phi}] - i\vec{\chi}\cdot\vec{\mathcal{E}} + g\vec{\chi}\cdot\vec{H} + \frac{1}{4\hat{g}} \sum_{a=1}^{8} \Psi_a[A_a, \bar{\phi}] \right). \tag{62}$$

(ii) They deformed the action by redefining $\mathcal{E}_{ij}$, the $(\mathbf{6}\oplus\bar{\mathbf{6}})_r$ part of $\vec{\mathcal{E}}$, as

$$\begin{aligned} \mathcal{E}_{ij} &= \Phi_{ij} - \tfrac{1}{2}\epsilon_{ijkl}\Phi_{kl}^{\dagger}, \\ \Phi_{ij} &= [B_i, B_j] - m\epsilon_{ijk4}B_k, \end{aligned} \tag{63}$$

where m is a mass parameter. This mass deformation corresponds to the supersymmetry breaking from $\mathcal{N}=4$ to $\mathcal{N}=1$ in the picture of four dimensional space.

(iii) They again separated the coupling constants g and $\hat{g}$ as

$$g\vec{\chi}\cdot\vec{H}\to g'\sum_{i<j}\chi_{ij}H_{ij}+g''\chi_7H_7,$$
$$\frac{1}{4\hat{g}}\sum_{a=1}^{8}\Psi_a[A_a,\bar{\phi}]\to\frac{1}{4\hat{g}'}\sum_{a=1}^{6}\Psi_a[A_a,\bar{\phi}]+\frac{1}{4\hat{g}''}\sum_{a=7,8}\Psi_a[A_a,\bar{\phi}]. \tag{64}$$

(iv) Then, they took the following limit:

$$g'\to 0\quad\text{and}\ \hat{g}'\to 0. \tag{65}$$

Notice that each term in the action is BRS exact. So the partition function is independent of separated coupling constants $g',g'',\ldots$. By taking (65), the partition function is dominated by configurations around solutions of the following fixed point equations:

$$[B_i,B_j]=m\epsilon_{ijk4}B_k,\quad [B_4,B_i]=0,\quad [B_4,\phi]=0,\quad i=1,2,3, \tag{66}$$

where B_i, B_4 and ϕ are all $N\times N$ matrices.

(v) The solution of (66) is given by

$$(B_i)_{N\times N}=(L_i)_{a\times a}\otimes\mathbf{1}_{d\times d},$$
$$(B_4)_{N\times N}=\mathbf{1}_{a\times a}\otimes(B_4)_{d\times d},\quad (\phi)_{N\times N}=\mathbf{1}_{a\times a}\otimes\phi_{d\times d}, \tag{67}$$

where a is a divisor of N and d is the quotient of N by a, and $(L_i)_{a\times a}$ denotes the generator of the SU(2) group in the $a\times a$ representation. Of course, there are other solutions of (66),

$$(B_i)_{N\times N}=\left(\begin{array}{c|c|c} (L_i)_{a_1\times a_1}\otimes\mathbf{1}_{d_1\times d_1} & 0 & 0 \\ \hline 0 & \ddots & 0 \\ \hline 0 & 0 & (L_i)_{a_k\times a_k}\otimes\mathbf{1}_{d_k\times d_k}\end{array}\right),$$
$$(B_4)_{N\times N}=\left(\begin{array}{c|c|c} \mathbf{1}_{a_1\times a_1}\otimes(B_4)_{d_1\times d_1} & 0 & 0 \\ \hline 0 & \ddots & 0 \\ \hline 0 & 0 & \mathbf{1}_{a_k\times a_k}\otimes(B_4)_{d_k\times d_k}\end{array}\right),$$
$$(\phi)_{N\times N}=\left(\begin{array}{c|c|c} \mathbf{1}_{a_1\times a_1}\otimes\phi_{d_1\times d_1} & 0 & 0 \\ \hline 0 & \ddots & 0 \\ \hline 0 & 0 & \mathbf{1}_{a_k\times a_k}\otimes\phi_{d_k\times d_k}\end{array}\right), \tag{68}$$

where $N=\Sigma_{l=1}^{k}N_l$, $N_l=a_l\times d_l$. However as mentioned in Ref. 20 these solutions do not contribute to the partition function. The solutions (68) contain bosonic zero modes, corresponding to extra U(1) parts $\mathrm{tr}_{N_l}\phi,\ldots$, and they are accompanied by their fermionic partners. The fermionic partners play a role of fermionic zero modes, and they vanish the path integral. So the solutions (68) do not contribute to the partition function.

(vi) In the above coupling limit (65) the authors integrated out B_i and corresponding fermionic partners around the solutions (67) by the Gaussian integral. The Gaussian integrals from bosons and the one from fermions cancel each other, so they produce no nontrivial factor. The resulting *effective* action is a matrix model of $d\times d$ matrices, B_4, its fermionic partner and ϕ.

(vii) The partition function of this $d\times d$ matrix model, we call it Z_d, is given by

$$Z_d = \frac{1}{d^2}, \tag{69}$$

which is another result obtained in the same paper.[20] The partition function $Z^N_{MM}|_{\text{traceless}}$ is given by the sum of the contributions from the solutions, $Z_d=1/d^2$, so they concluded (57).

Now let us turn to the $N\to\infty$ case. Our basic strategy is that taking large N limit is done after calculations with finite N. However, the result depends on the definition of the large N limit as mentioned above. To find the proper definition of the large N limit, we consider a naive $N=\infty$ case. That is, we do not take the $N\to\infty$ limit after obtaining the result of the finite N case, but we take the matrices as $\infty\times\infty$ from the starting point for a moment. For the case of $\infty\times\infty$ matrix, the steps (i)–(iv) need no change, but the step (v) should be reconsidered. In $\infty\times\infty$ matrix, we can embed a solution which has a direct product of an arbitrary finite-dimensional matrix and an infinite-dimensional matrix. Therefore we obtain solutions,

$$\begin{aligned}(B_i)_{\infty\times\infty} &= (L_i)_{\infty\times\infty}\otimes 1_{d\times d},\\ (B_4)_{\infty\times\infty} &= \mathbf{1}_{\infty\times\infty}\otimes(B_4)_{d\times d},\quad (\phi)_{\infty\times\infty} = \mathbf{1}_{\infty\times\infty}\otimes\phi_{d\times d}.\end{aligned} \tag{70}$$

Now d takes all natural numbers, and $(L_i)_{\infty\times\infty}$ are the generator of the SU(2) group in the $\infty\times\infty$ representations. Solutions, like (68), again do not contribute to the partition function. Moreover, one can construct other types of solutions,

$$\begin{aligned}(B_i)_{\infty\times\infty} &= (L_i)_{a\times a}\otimes\mathbf{1}_{\infty\times\infty},\\ (B_4)_{\infty\times\infty} &= \mathbf{1}_{a\times a}\otimes(B_4)_{\infty\times\infty},\quad (\phi)_{\infty\times\infty} = \mathbf{1}_{a\times a}\otimes\phi_{\infty\times\infty},\end{aligned} \tag{71}$$

and

$$\begin{aligned}(B_i)_{\infty\times\infty} &= (L_i)_{\infty\times\infty}\otimes\mathbf{1}_{\infty\times\infty},\\ (B_4)_{\infty\times\infty} &= \mathbf{1}_{\infty\times\infty}\otimes(B_4)_{\infty\times\infty},\quad (\phi)_{\infty\times\infty} = \mathbf{1}_{\infty\times\infty}\otimes\phi_{\infty\times\infty}.\end{aligned} \tag{72}$$

The step (vi), integrating out of B_i and their fermionic partners, again produces no nontrivial factor, because the cancellation of the Gaussian integrals between bosons and fermions holds for the case of infinite-dimensional integral. Therefore the partition function Z^∞_{MM} is given by the sum of contributions from the solutions (70) and (71), and (72),

$$Z^\infty_{MM} = Z^{(\infty\times d)}_{MM} + Z^{(a\times\infty)}_{MM} + Z^{(\infty\times\infty)}_{MM}, \tag{73}$$

where the first term on the right-hand side comes from (70), the second from (71), and the third from (72). $Z^{(\infty\times d)}_{MM}$ is still given by the sum of $Z_d=1/d^2$, as the step (vii), but in this $N=\infty$ case d runs all natural numbers $\mathbb{N}$. On the other hand, it is natural to expect that $Z^{(a\times\infty)}_{MM}$ and $Z^{(\infty\times\infty)}_{MM}$ vanish, because

$$Z^{(a\times\infty)}_{MM} \sim \sum \lim_{d\to\infty}\frac{1}{d^2} = 0,\quad Z^{(\infty\times\infty)}_{MM} \sim \sum \lim_{d\to\infty}\frac{1}{d^2} = 0, \tag{74}$$

if (69) is valid for $d=\infty$. So we conclude

$$Z^\infty_{MM}|_{\text{traceless}} = \sum_{d\in\mathbb{N}}\frac{1}{d^2} = \zeta(2) = \frac{\pi^2}{6}. \tag{75}$$

From these considerations, we propose the following definition of the large N limit. Let $N(n_i,k)$ be

$$N(n_i,k) \equiv \prod_{i=1}^{k} P_i^{n_i}, \tag{76}$$

where P_i are ordered prime numbers, i.e., $P_1=2<P_2=3<\cdots<P_k$, and k and n_i are positive integers. We define the large N limit by

$$\lim_{N\to\infty} \equiv \lim_{k\to\infty} \lim_{n_i\to\infty}. \tag{77}$$

Using this definition, we reproduce the same result as (75),

$$Z_{MM}^{\infty}|_{\text{traceless}} = \lim_{k\to\infty} \lim_{n_i\to\infty} \sum_{l_i=0}^{n_i} \frac{1}{(\prod_{i=1}^{k} P_i^{l_i})^2} = \prod_{i=1}^{\infty} \frac{1}{1-P_i^{-2}} = \zeta(2) = \frac{\pi^2}{6}. \tag{78}$$

[It is well known and will be seen in Sec. V that the partition function of this case is the sum of the Euler number of the moduli space, $\chi(\mathcal{M}_k)$ which takes a rational number in general. So one may expect that $Z_{MM}^{\infty}|_{\text{traceless}}$ is given by a rational number. However the summation is an infinite one, then it could take an irrational number, $\pi^2/6$.]

E. Introduction of extra terms

In this section, we deal with the zero mode problem. The origin of this problem is the fact that no trace part appears in (35). The reason why all trace parts vanish in (35) is that we drop all differential terms in the $\theta\to\infty$ limit. To solve the zero mode problem, we keep the next leading terms including the trace parts in the $1/\sqrt{\infty}$ expansion.

Let us explain the outline of our calculation. To keep the next leading term, we bring back some extra part f^{ex} living in the outside of $\mathcal{H}_N$. The definition of f^{ex} is given later in this section. Roughly speaking, f^{ex} are matrices appearing in kinetic terms $(1/\theta)f^{\text{ex}}\Box f^{\text{tr}}$ in (23). By keeping f^{ex}, the part of (22) or (23) which includes the trace part f^{tr} does not vanish,

$$S_{\text{tr}\oplus\text{ex}}[f^{\text{tr}},f^{\text{ex}}] = S_{\mathcal{N}=4}^{4\ \text{dim}}|_{\text{trace part}} - O(1/\theta^{1+\epsilon}) \neq 0, \tag{79}$$

where ϵ is an arbitrary positive real number. Then the partition function of (79) is well defined,

$$Z_{\text{tr}\oplus\text{ex}} = \int \mathcal{D}f^{\text{tr}}\mathcal{D}f^{\text{ex}} e^{-S_{\text{tr}\oplus\text{ex}}[f^{\text{tr}},f^{\text{ex}}]}: \text{ well defined.} \tag{80}$$

We suppose f^{ex} has the following expansion form:

$$f^{\text{ex}} = \sum_{\mu=1}^{4} f_{(\mu)}\mathcal{T}_{\mu}. \tag{81}$$

$\mathcal{T}_{\mu}$ is essentially defined by the commutator of $\hat{\partial}_{\mu}$ and $\mathbf{1}_N$. The precise definition of $\mathcal{T}_{\mu}$ is as follows. First of all, we define T_{μ} as the commutator of $\hat{\partial}_{\mu}$ and $\mathbf{1}_N$, i.e.,

$$T_{\mu} = [\hat{\partial}_{\mu}, \mathbf{1}_N]. \tag{82}$$

In the Fock space formalism, $\hat{\partial}_{\mu}$ is given as

$$\hat{\partial}_1 = \frac{1}{\sqrt{2\theta^{\text{l}}}}(a_1 - a_1^{\dagger}), \quad \hat{\partial}_2 = \frac{-i}{\sqrt{2\theta^{\text{l}}}}(a_1 + a_1^{\dagger}), \tag{83}$$

$$\hat{\partial}_3 = \frac{1}{\sqrt{2\theta^2}}(a_2 - a_2^\dagger), \quad \hat{\partial}_4 = \frac{-i}{\sqrt{2\theta^2}}(a_2 + a_2^\dagger),$$

where a_i is the annihilation operator and $a_i^\dagger$ is the creation operator. Given the definition of $\mathbf{1}_N$, for example (31), we obtain

$$\begin{aligned}
T_1 &= \frac{\sqrt{N+1}}{\sqrt{2\theta^1}}\left(-\sum_{n_2=0}^{N}|N,n_2\rangle\langle N+1,n_2| - \sum_{n_2=0}^{N}|N+1,n_2\rangle\langle N,n_2|\right),\\
T_2 &= \frac{-i\sqrt{N+1}}{\sqrt{2\theta^1}}\left(-\sum_{n_2=0}^{N}|N,n_2\rangle\langle N+1,n_2| + \sum_{n_2=0}^{N}|N+1,n_2\rangle\langle N,n_2|\right),\\
T_3 &= \frac{\sqrt{N+1}}{\sqrt{2\theta^2}}\left(-\sum_{n_1=0}^{N}|n_1,N\rangle\langle n_1,N+1| - \sum_{n_1=0}^{N}|n_1,N+1\rangle\langle n_1,N|\right),\\
T_4 &= \frac{-i\sqrt{N+1}}{\sqrt{2\theta^2}}\left(-\sum_{n_1=0}^{N}|n_1,N\rangle\langle n_1,N+1| + \sum_{n_1=0}^{N}|n_1,N+1\rangle\langle n_1,N|\right).
\end{aligned} \tag{84}$$

Using (84), we can show

$$\mathrm{Tr}_{\mathcal{H}}\, T_\mu T_\nu = \frac{N}{\theta^{i(\mu)}}\delta_{\mu\nu}, \tag{85}$$

where $i(\mu)=[(\mu+1)/2]$ with the symbol [ ] indicating a Gaussian symbol. $\mathcal{T}_\mu$ is defined by

$$\mathcal{T}_\mu = \frac{\sqrt{\theta^{i(\mu)}}}{\sqrt{N}}T_\mu, \tag{86}$$

to satisfy

$$\mathrm{Tr}_{\mathcal{H}}\, \mathcal{T}_\mu \mathcal{T}_\nu = \delta_{\mu\nu}. \tag{87}$$

Here we list some formulas about $\mathcal{I}$ and $\mathcal{T}_\mu$, which will be used in the calculation of the partition function. They are

$$\mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}\mathcal{I} = 1, \quad \mathrm{Tr}_{\mathcal{H}}\, \mathcal{T}_\mu \mathcal{T}_\nu = \delta_{\mu\nu}, \quad \mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}\mathcal{T}_\mu = 0, \tag{88}$$

$$\begin{aligned}
&\mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}[\hat{\partial}_\mu, \mathcal{I}] = 0, \quad \mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}[\hat{\partial}_\mu, \mathcal{T}_\nu] = -\frac{1}{\sqrt{\theta^{i(\mu)}}}\delta_{\mu\nu},\\
&\mathrm{Tr}_{\mathcal{H}}\, \mathcal{T}_\mu[\hat{\partial}_\nu, \mathcal{I}] = +\frac{1}{\sqrt{\theta^{i(\mu)}}}\delta_{\mu\nu}, \quad \mathrm{Tr}_{\mathcal{H}}\, \mathcal{T}_\mu[\hat{\partial}_\nu, \mathcal{T}_\rho] = 0,
\end{aligned} \tag{89}$$

and

$$\begin{aligned}
&\mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}[\mathcal{I}, \mathcal{I}] = 0, \quad \mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}[\mathcal{I}, \mathcal{T}_\mu] = 0,\\
&\mathrm{Tr}_{\mathcal{H}}\, \mathcal{I}[\mathcal{T}_\mu, \mathcal{T}_\nu] = +\frac{i\theta^{i(\mu)}}{\sqrt{N}}\theta^{-1}_{\mu\nu}, \quad \mathrm{Tr}_{\mathcal{H}}\, \mathcal{T}_\mu[\mathcal{T}_\nu, \mathcal{T}_\rho] = 0.
\end{aligned} \tag{90}$$

For the proof of (88)–(90), see Appendix A. Note that these formulas do not depend on the detail of the definition of the cutoff or (31).

Remark that, in the $N\to\infty$ limit, $\mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}[\mathcal{T}_\mu,\mathcal{T}_\nu]$ vanishes,

$$\lim_{N\to\infty}\mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}[\mathcal{T}_\mu,\mathcal{T}_\nu]=0. \tag{91}$$

We will use this $N\to\infty$ behavior to reduce the calculation of the partition function to the Gaussian integral.

F. Calculation of trace and extra sector

Now, let us calculate the partition function (80). First of all, we list the quantities appearing in the calculation. Because the model is constructed as a balanced topological field theory, it is natural to classify them into the BRS multiplets. For $\{A_\mu,H_\mu,\psi_\mu,\chi_\mu,H_\mu\}$,

$$\begin{array}{ccc} & \psi_{\mu(\mathbf{1})}\ ,\ \phi_{\mu(\alpha)} & \\ \hat{\delta}_+\nearrow & & \hat{\delta}_-\searrow \\ A_{\mu(\mathbf{1})}\ ,\ A_{\mu(\alpha)} & & H_{\mu(\mathbf{1})}\ ,\ H_{\mu(\alpha)} \\ \hat{\delta}_-\searrow & & \hat{\delta}_+\nearrow \\ & \chi_{\mu(\mathbf{1})}\ ,\ \chi_{\mu(\alpha)} & \end{array}\ , \tag{92}$$

and for $\{B^+_{\mu\nu},\psi^+_{\mu\nu},\chi^+_{\mu\nu},H^+_{\mu\nu}\}$,

$$\begin{array}{ccc} & \psi^+_{\mu\nu(\mathbf{1})}\ ,\ \psi^+_{\mu\nu(\alpha)} & \\ \hat{\delta}_+\nearrow & & \hat{\delta}_-\searrow \\ B^+_{\mu\nu(\mathbf{1})}\ ,\ B^+_{\mu\nu(\mu)} & & H^+_{\mu\nu(\mathbf{1})}\ ,\ H^+_{\mu\nu(\mu)} \\ \hat{\delta}_-\searrow & & \hat{\delta}_+\nearrow \\ & \chi^+_{\mu\nu(\mathbf{1})}\ ,\ \chi^+_{\mu\nu(\mu)} & \end{array}\ . \tag{93}$$

Note that $A_{\mu(\mathbf{1})}$ and $A_{\mu(\alpha)}$ are coefficients of $\mathcal{I}$ and $\mathcal{T}_\alpha$, i.e., $A_\mu=A_{\mu(\mathbf{1})}\mathcal{I}+\Sigma_{\mathrm{su}(N)}A_{\mu(a)}\tau^a+\Sigma A_{\mu(\alpha)}\mathcal{T}_\alpha$, and other fields are noted by similar manner.

It is necessary to comment on the net components of $\{A_{\mu(\alpha)},\psi_{\mu(\alpha)},\chi_{\mu(\alpha)},H_{\mu(\alpha)}\}$ in (92) and $\{B^+_{\mu\nu(\alpha)},\psi^+_{\mu\nu(\alpha)},\chi^+_{\mu\nu(\alpha)},H^+_{\mu\nu(\alpha)}\}$ in (93). In the following, we use the term (μ,ν) self-dual which means that $A_{\mu(\nu)}$ satisfies $A_{\mu(\nu)}=\frac{1}{2}\epsilon_{\mu\nu\rho\sigma}A_{\rho(\sigma)}$.

(i) $\{A_{\mu(\alpha)},\ldots\}$ have not 16 but four components. Three of them satisfy the self-dual relation and one is $A_{\mu(\mu)}$,

$$\left\{A_{\mu(\nu)}\middle|A_{\mu(\nu)}=\tfrac{1}{2}\epsilon_{\mu\nu\rho\sigma}A_{\rho(\sigma)}(\mu,\nu)\ \text{self-dual}\right\}\quad\text{and}\quad\left\{\sum_{\mu=1}^{4}A_{\mu(\mu)}\right\}. \tag{94}$$

(ii) $\{B^+_{\mu\nu(\mu)},\ldots\}$ have four components corresponding to $B^+_{\mu\nu(\mu)}$,

$$B^+_{\mu\nu(\mu)}=\sum_{\mu=1}^{4}B^+_{\mu\nu(\mu)}. \tag{95}$$

On the other hand, $\{\phi,c,\bar{\phi},\bar{\eta},\eta\}$ contain only trace parts

$$\begin{array}{ccc} \phi_{(\mathbf{1})} & & \\ & \hat{\delta}_- \searrow & \\ & & \overline{\eta}_{(\mathbf{1})} \\ & \hat{\delta}_+ \nearrow & \\ c_{(\mathbf{1})} & & \\ & \hat{\delta}_- \searrow & \\ & & \eta_{(1)} \\ & \hat{\delta}_+ \nearrow & \\ \overline{\phi}_{(\mathbf{1})} & & \end{array} . \tag{96}$$

Later we obtain the Gaussian action [(106)–(115), (119), and (120)]. For example, in (106) we find a term proportional to

$$\chi^+_{\mu\nu(\mathbf{1})}(A_{\nu(\mu)} - A_{\mu(\nu)}).$$

From this and other terms in (106)–(115), (119), and (120), we see that the net components (94)–(96) should be taken to remove the zero modes.

Taking the net components (94)–(96) and using (88)–(90), we obtain

$$\begin{aligned} S_{\mathrm{tr}\oplus\mathrm{ex}} = \mathrm{Tr}_{\mathcal{H}}\, \hat{\delta}_+[&+ \chi^{+\mu\nu}_{(\rho)}\mathcal{T}^p\{H^+_{\mu\nu(\sigma)}\mathcal{T}^\sigma - ([\hat{\partial}_\mu, A_{\nu(1)}\mathcal{I}] - [\hat{\partial}_\nu, A_{\mu(1)}\mathcal{I}])\} + \chi^{+\mu\nu}_{(1)}\mathcal{I}\{H^+_{\mu\nu(1)}\mathcal{I} - ([\hat{\partial}_\mu, A_{\nu(\rho)}\mathcal{T}^p] \\ &- [\hat{\partial}_\nu, A_{\mu(\rho)}\mathcal{T}^p])\} + \chi^{\mu}_{(\rho)}\mathcal{T}^p\{H_{\mu(\sigma)}\mathcal{T}^\sigma - (-2[\hat{\partial}^\nu, B^+_{\nu\mu(1)}\mathcal{I}] - [\hat{\partial}_\mu, c_{(1)}\mathcal{I}])\} + \chi^{\mu}_{(1)}\mathcal{I}\{H_{\mu(1)}\mathcal{I} \\ &- (-2[\hat{\partial}^\nu, B^+_{\nu\mu(\rho)}\mathcal{T}^p] - [\hat{\partial}_\mu, c_{(\rho)}\mathcal{T}^p])\} - [\hat{\partial}^\mu, \overline{\phi}_{(1)}\mathcal{I}]\psi_{\mu(\nu)}\mathcal{T}^\nu] + \mathcal{O}(N^{-1/2}). \end{aligned} \tag{97}$$

Note that $B^+_{\nu\mu(\rho)}$ may look like 12 components but only $B^+_{\nu\mu(\nu)}$ proportional terms survive in $\mathrm{Tr}_{\mathcal{H}}\, \chi^{\mu}_{(\mathbf{1})}\mathcal{I}[\hat{\partial}^\nu, B^+_{\nu\mu(\rho)}\mathcal{T}^p]$. In the $N\to\infty$ limit, only quadratic terms survive,

$$S^{\infty}_{\mathrm{tr}\oplus\mathrm{ex}} = \lim_{N\to\infty} S_{\mathrm{tr}\oplus\mathrm{ex}}\text{:quadratic action}. \tag{98}$$

[Alternatively, we can take the weak coupling limit in the calculation. In general, partition functions of cohomological field theories are independent of coupling constants. So they can be evaluated exactly in the weak coupling limit.]

The action (98) has the following gauge symmetry:

$$\delta_{\mathrm{gauge}} A_{\mu(\nu)} = \frac{1}{\sqrt{\theta^{i(\mu)}}}\delta_{\mu\nu}\varphi_{(\mathbf{1})}. \tag{99}$$

Note that the gauge parameter φ contains only one component $\varphi_{(\mathbf{1})}$,

$$\varphi = \varphi_{(\mathbf{1})}\mathcal{I}. \tag{100}$$

Now we give the BRS transformation rules for $f_{(\mathbf{1})}$ and $f_{(\mu)}$. Except for $A_{\mu(\nu)}, \psi_{\mu(\nu)}$ and $A_{\mu(\mathbf{1})}, \psi_{\mu(\mathbf{1})}$,

$$\begin{gathered} \hat{\delta}_+\mathcal{B}_{(\nu)} = \mathcal{F}_{(\nu)}, \quad \hat{\delta}_+\mathcal{F}_{(\nu)} = 0, \\ \hat{\delta}^2_+\mathcal{B}_{(\nu)} = 0, \quad \hat{\delta}^2_+\mathcal{F}_{(\nu)} = 0, \end{gathered} \tag{101}$$

and

$$\hat{\delta}_+\mathcal{B}_{(\mathbf{1})}=\mathcal{F}_{(\mathbf{1})},\quad \hat{\delta}_+\mathcal{F}_{(\mathbf{1})}=0,$$
$$\hat{\delta}_+^2\mathcal{B}_{(\mathbf{1})}=0,\quad \hat{\delta}_+^2\mathcal{F}_{(\mathbf{1})}=0, \tag{102}$$

where $\mathcal{B}$ denotes the bosonic matrix and $\mathcal{F}$ denotes the fermionic one.

For $A_{\mu(\nu)},\psi_{\mu(\nu)}$ and $A_{\mu(\mathbf{1})},\psi_{\mu(\mathbf{1})}$,

$$\hat{\delta}_+A_{\mu(\nu)}=\psi_{\mu(\nu)},\quad \hat{\delta}_+\psi_{\mu(\nu)}=+\frac{1}{\sqrt{\theta^{i(\mu)}}}\delta_{\mu\nu}\phi_{(\mathbf{1})},$$

$$\hat{\delta}_+^2A_{\mu(\nu)}=+\frac{1}{\sqrt{\theta^{i(\mu)}}}\delta_{\mu\nu}\phi_{(\mathbf{1})},\quad \hat{\delta}_+^2\psi_{\mu(\nu)}=0, \tag{103}$$

and

$$\hat{\delta}_+A_{\mu(\mathbf{1})}=\psi_{\mu(\mathbf{1})},\quad \hat{\delta}_+\psi_{\mu(\mathbf{1})}=0,$$
$$\hat{\delta}_+^2A_{\mu(\mathbf{1})}=0,\quad \hat{\delta}_+^2\psi_{\mu(\mathbf{1})}=0. \tag{104}$$

For simplicity, in this section we set $\theta^1=\theta^2=\theta$ in the following. Using (88), (89), (103), (104), and (98) is shown to be

$$S^{\infty}_{\mathrm{tr}\oplus\mathrm{ex}}=S^{\infty\ \mathrm{boson}}_{\mathrm{tr}\oplus\mathrm{ex}}+S^{\infty\ \mathrm{fermion}}_{\mathrm{tr}\oplus\mathrm{ex}}, \tag{105}$$

where

$$S^{\infty\ \mathrm{boson}}_{\mathrm{tr}\oplus\mathrm{ex}}=+H^{+\mu\nu}_{(\mathbf{1})}\left\{H^{+}_{\mu\nu(\mathbf{1})}+\frac{i}{\sqrt{\theta}}(A_{\nu(\mu)}-A_{\mu(\nu)})\right\} \tag{106}$$

$$+H^{+\mu\nu}_{(\alpha)}\left\{H^{+}_{\mu\nu(\alpha)}-\frac{i}{\sqrt{\theta}}(\delta^{\alpha}_{\mu}A_{\nu(\mathbf{1})}-\delta^{\alpha}_{\nu}A_{\mu(\mathbf{1})})\right\} \tag{107}$$

$$+H^{\mu}_{(\mathbf{1})}\left\{H_{\mu(\mathbf{1})}+\frac{i}{\sqrt{\theta}}(-2B^{+}_{\alpha\mu(\alpha)})\right\} \tag{108}$$

$$+H^{\mu}_{(\alpha)}\left\{H_{\mu(\alpha)}-\frac{i}{\sqrt{\theta}}(-2B^{+}_{\alpha\mu(\mathbf{1})}+\delta_{\mu\alpha}c_{(\mathbf{1})})\right\} \tag{109}$$

$$+\frac{4}{\theta}\bar{\phi}_{(\mathbf{1})}\phi_{(\mathbf{1})}, \tag{110}$$

and

$$S^{\infty\ \mathrm{fermion}}_{\mathrm{tr}\oplus\mathrm{ex}}=-\frac{i}{\sqrt{\theta}}\chi^{+\mu\nu}_{(\mathbf{1})}(\psi_{\nu(\mu)}-\psi_{\mu(\nu)}) \tag{111}$$

$$-\frac{2i}{\sqrt{\theta}}\chi^{+\mu\alpha}_{(\alpha)}\psi_{\mu(\mathbf{1})} \tag{112}$$

$$+\frac{i}{\sqrt{\theta}}\chi^{\mu}_{(\mathbf{1})}(2\psi^{+}_{\alpha\mu(\alpha)}) \tag{113}$$

$$-\frac{i}{\sqrt{\theta}}\chi^{\mu}_{(\alpha)}(2\psi^{+}_{\alpha\mu(\mathbf{1})}+\delta_{\mu\alpha}\bar{\eta}_{(\mathbf{1})}) \tag{114}$$

$$+\frac{i}{\sqrt{\theta}}\eta_{(\mathbf{1})}\psi^{\mu}_{(\mu)}. \tag{115}$$

Now we fix the gauge symmetry (99). We introduce the ghost ρ, the antighost $\bar{\rho}$ and the Nakanishi-Lautrup field b. Their ghost numbers are assigned as $(+1,-1,0)$ for $(\rho,\bar{\rho},b)$, respectively. BRS transformations for $\{\bar{\rho},b,\rho\}$ are defined as

$$\hat{\delta}_{+}b=\rho,\quad \hat{\delta}_{+}\rho=0,\quad \hat{\delta}_{+}\bar{\rho}=0. \tag{116}$$

Because the gauge symmetry is given by (99), $\{\bar{\rho},b,\rho\}$ contain only the trace parts.

Let us introduce a gauge fixing action by

$$S_{\mathrm{gf}}=\mathrm{Tr}_{\mathcal{H}}\,\hat{\delta}_{+}[\bar{\rho}_{(\mathbf{1})}\mathcal{I}(b_{(\mathbf{1})}\mathcal{I}+[\hat{\partial}^{\mu},A_{\mu(\nu)}\mathcal{T}^{\nu}])]. \tag{117}$$

To get the BRS exact action including the gauge fixing action, let us deform the BRS transformation rules for $A_{\mu(\nu)},\psi_{\mu(\nu)}$ (103) as

$$\begin{aligned}\hat{\delta}_{+}A_{\mu(\nu)}&=\psi_{\mu(\nu)}+\frac{1}{\sqrt{\theta}}\delta_{\mu\nu}\rho_{(\mathbf{1})},\\ \hat{\delta}_{+}\psi_{\mu(\nu)}&=+\frac{1}{\sqrt{\theta}}\delta_{\mu\nu}\phi_{(\mathbf{1})}.\end{aligned} \tag{118}$$

(117) is rewritten into

$$S_{\mathrm{gf}}=+b_{(\mathbf{1})}\left(b_{(\mathbf{1})}-\frac{1}{\sqrt{\theta}}A_{\mu,(\mu)}\right) \tag{119}$$

$$+\frac{4}{\theta}\bar{\rho}_{(\mathbf{1})}\rho_{(\mathbf{1})}+\frac{1}{\sqrt{\theta}}\bar{\rho}_{(\mathbf{1})}\psi_{\mu(\mu)}. \tag{120}$$

We list degrees of the Gaussian integral in (106)–(115), (119), and (120).

From bosons

degree			
3+3	$H^{+}_{\mu\nu(\mathbf{1})}$, $A_{\mu(\nu)}$ (μ,ν) self-dual	in (106)	
4+4	$H^{+\mu\nu}_{(\nu)}$, $A_{\mu(\mathbf{1})}$	in (107)	
4+4	$H^{\mu}_{(\mathbf{1})}$, $B^{+\alpha\mu}_{(\alpha)}$	in (108)	
3+1+3+1	$H_{\mu(\alpha)}$ (μ,α) self-dual, $H_{\mu(\mu)}$, $B^{+}_{\alpha\mu(\mathbf{1})}$, $c_{(\mathbf{1})}$	in (109)	
1+1	$\phi_{(\mathbf{1})}$, $\bar{\phi}_{(\mathbf{1})}$	in (110)	
1+1	$b_{(\mathbf{1})}$, $A_{\mu(\mu)}$	in (119)	(121)

	From fermions		
degree			
3+3	$\chi^{+}_{\mu\nu(\mathbf{1})}$, $\psi_{\nu(\mu)}$ (μ,ν) self-dual	in (111)	
4+4	$\chi^{+\mu\alpha}_{(\alpha)}$, $\psi_{\mu(\mathbf{1})}$	in (112)	
4+4	$\chi^{\mu}_{(\mathbf{1})}$, $\chi^{+\alpha\mu}_{(\alpha)}$	in (113)	
3+1+3+1	$\chi_{\mu(\nu)}$ (μ,ν) self-dual, $\chi^{\mu}_{(\mu)}$, $\chi^{+}_{\alpha\mu(\mathbf{1})}$, $\bar{\eta}_{(\mathbf{1})}$	in (114)	
1+1	$\eta_{(\mathbf{1})}$, $\psi^{\mu}_{(\mu)}$	in (115)	
1+1	$\rho_{(\mathbf{1})}$, $\bar{\rho}_{(\mathbf{1})}$	in (120)	(122)

From (121) and (122), we see that the path integral contains no zero mode, so we obtain a definite partition function. We adopt a standard path integral measure, which is largely expressed by

$$\mathcal{D}f = \prod \frac{\mathrm{d}f_{\mathrm{boson}}}{\sqrt{2\pi}} \prod \mathrm{d}f_{\mathrm{fermion}}, \tag{123}$$

where f_{boson} denotes a bosonic field and f_{fermion} denotes a fermionic field. For the precise definition of $\mathcal{D}f$ and the validity of this choice, see the next section and Appendix C. Then $Z^{\infty}_{\mathrm{tr}\oplus\mathrm{ex}}$ is calculated as 1,

$$Z^{\infty}_{\mathrm{tr}\oplus\mathrm{ex}} = \int \mathcal{D}f\, e^{-(S^{\infty}_{\mathrm{tr}\oplus\mathrm{ex}}+S_{\mathrm{gf}})} = 1. \tag{124}$$

G. Results and remarks of this section

From (78) and (124), we conclude that the partition function of the $\mathcal{N}=4$ U(1) gauge theory on NC $\mathbb{R}^4$ is given by

$$Z^{4\ \mathrm{dim}}_{\mathcal{N}=4} = Z^{\infty}_{MM} = Z^{\infty}_{MM}|_{\mathrm{traceless}} Z^{\infty}_{\mathrm{tr}\oplus\mathrm{ex}} = \frac{\pi^2}{6}. \tag{125}$$

We comment on the universality of partition function (20). Our calculation consists of largely two steps. In the first step the traceless part is treated, then in the second step the trace and extra parts are managed. The first step is manifestly dimensionally independent, because after the dimensional reduction to 0 dimensions all actions of (8-dim, $\mathcal{N}=2$), (6-dim, $\mathcal{N}=2$), (4-dim, $\mathcal{N}=4$), and (2-dim, $\mathcal{N}=8$) are the same as the IKKT matrix model action. On the other hand, the calculations in the second step may seem to depend on the dimension of the model, since we keep the derivatives, $\hat{\partial}_{\mu}$. However, the same result $Z^{\infty}_{\mathrm{tr}\oplus\mathrm{ex}}=1$ is expected to be universal. The reason is as follows. The second step, introducing the extra part and fixing the gauge symmetry (99), is a kind of regularization of the zero mode integral. As expected from the other regularization method, for example, naively dropping the trace part, equivalent to dividing the path integral measure by the U(1) gauge volume, the regularization should produce a trivial factor 1. In our regularization method, this is implemented by the supersymmetry. Also, as explained in Appendix C, our regularization is valid for all of (8-dim, $\mathcal{N}=2$), (6-dim, $\mathcal{N}=2$), (4-dim, $\mathcal{N}=4$), and (2-dim, $\mathcal{N}=8$). Then we conclude

$$Z^{8\ \mathrm{dim}}_{\mathcal{N}=2} = Z^{6\ \mathrm{dim}}_{\mathcal{N}=2} = Z^{4\ \mathrm{dim}}_{\mathcal{N}=4} = Z^{2\ \mathrm{dim}}_{\mathcal{N}=8} = \frac{\pi^2}{6}. \tag{126}$$

Finally, we make a remark relating the mathematical significance of (126). In topological field theories, the path integral can be decomposed into finite-dimensional integrals of the moduli space defined by the BPS equations and infinite-dimensional integrals of fluctuations around each vacuum. The absolute value of the infinite-dimensional integrals of the fluctuations should be normalized to 1 to make the partition functions well defined, then only the integrals of the moduli

space remain (see also Appendix C). If the moduli space is compact, the remained moduli integrals produce a definite number, which is the Euler number of some vector bundle over the moduli space. In the case of this section, each $1/d^2$ in (75) corresponds to the Euler number. In this light, our prescription above, adopting the measure (123) to obtain (124), is an almost unique choice, though it may seem to be chosen by hand. Also, for the traceless part, the similar prescription is performed in Ref. 20. To conclude, the result $\pi^2/6$ is decided without ambiguity and has an absolute meaning as a topological invariant.

V. MODULI SPACE AND INSTANTON NUMBER

In this section, we concentrate on the relation between the moduli space of the Monads and the partition function of the $\mathcal{N}=4$ supersymmetric Yang-Mills theory. The partition function of Vafa-Witten theory is given by the generating function of the Euler number of some vector bundle over the moduli space with sign ± 1,

$$Z = \sum_{k=1} \epsilon_k \chi(\mathcal{M}_k) q^k, \tag{127}$$

$$q^k = e^{2\pi i k \tau}, \quad \epsilon_k = \pm 1. \tag{128}$$

Here τ is the complex coupling constant and $\mathcal{M}_k$ is the moduli space defined by

$$\{A,B,c | F^{+\mu\nu} - i[B^+_{\mu\rho}, B^{+\rho}_{\nu}] - i[B^+_{\mu\nu}, c] = 0, 2D^\mu B_{+\mu\rho} + D_\rho c = 0\}/\mathcal{G}, \tag{129}$$

where $\mathcal{G}$ is the gauge transformation group. In addition, if $\chi^{\mu\nu}, \chi^\mu$ zero modes are sections of the cotangent bundle of $\mathcal{M}_k$, then $\chi(\mathcal{M}_k)$ is the Euler number of $\mathcal{M}_k$. Particularly, the base four-fold satisfies the vanishing theorem in Ref. 34, then the moduli space is identified with the instanton moduli space with its instanton number k. Therefore, it is important to investigate the $\mathcal{M}_k$.

It is natural to assume that the topology of the moduli space does not change under the θ-shift. After dimensional reduction (large θ limit), let us replace variables as (44), (50), and (51). As operators, fields are infinite-dimensional matrices. If matrix size of these B_i is cut off at N, BPS Eqs. (24) are replaced by hyper-Kähler momentum maps,

$$\begin{aligned} \mu_{\mathbb{C}} &:= [B_i, B_j] + \tfrac{1}{2}\epsilon_{ijkl}[B_k^\dagger, B_l^\dagger] = 0, \\ \mu_{\mathbb{R}} &:= \sum_{i=1}^{4} [B_i, B_i^\dagger] = 0, \end{aligned} \tag{130}$$

then the moduli space is determined by

$$\mathcal{M}_N = (\mu_{\mathbb{C}}^{-1}(0) \cap \mu_{\mathbb{R}}^{-1}(0))/\mathrm{U}(N). \tag{131}$$

It is known that the solutions of Eqs. (130) include the solutions of simultaneous ADHM equations.[25] θ deformation realizes the continuous connection between (129) and (131). This is a direct correspondence between BPS equations of noncommutative field theory and Monads by means of changing the noncommutative parameter.

Turning now to the next issue, let us study the partition function whose action functional includes the topological term. In Sec. VI, we perform the calculation with the action functional which does not include the term of $\tau \int F \wedge F$ (or $\tau \mathrm{Tr}_{\mathcal{H}} F \wedge F$). In the MNS calculation, they use the mass deformation to decompose the theory to more simple ones whose partition function is given by $1/d^2$ in (57). (See Sec. 7 in Ref. 20 and Sec. IV D in this paper.) This mass deformation causes supersymmetry breaking from $\mathcal{N}=4$ to $\mathcal{N}=1$. B_1, B_2, B_3 become massive, and $B_4, B_4^\dagger$ and $\phi, \bar{\phi}$ are left for massless fields. If we consider this mass deformation in the finite θ theory, we find that

gauge fields are given from $B_4, B_4^\dagger$ and $\phi, \bar{\phi}$ as four-dimensional theory, because the massless fields correspond to the unbroken gauge fields. In the reduced theory after integrating out B_1, B_2, and B_3, fixed point loci are defined by

$$[B_4, B_4^\dagger] = 0, \quad [\phi, \bar{\phi}] = 0, \quad [B_4, \phi] = 0, \tag{132}$$

where $B_4, B_4^\dagger$ and $\phi, \bar{\phi}$ are $d \times d$ matrices where d is a divisor of N and is appearing in the argument of (57). Furthermore, contributions for the partition function are given by isolated fixed points, as MNS mentioned in the end of Sec. V in Ref. 20. At least one of B_4 and ϕ is the rank d, when B_4 and ϕ are solutions of the fixed point equations and the fixed points contribute to the path integral. Because if rank $< d$ then there are zero modes of the equations

$$[\delta B_4, B_4^\dagger] + [B_4, \delta B_4^\dagger] = 0, \quad [\delta\phi, \bar{\phi}] + [\phi, \delta\bar{\phi}] = 0, \quad [\delta B_4, \phi] + [B_4, \delta\phi] = 0, \tag{133}$$

where these equations are given by variation of (132). These zero modes mean that the fixed point loci are nonzero dimension and path integrals vanish by the fermionic zero modes. With attention to these points, if we specify the instanton numbers corresponding to solutions of (132) labeled by d, then we determine the partition function whose action functional includes the topological term.

A hint to speculate the instanton number is ADHM correspondence. The solution of (132) is included in the set of solutions of noncommutative deformed ADHM equations corresponding to d instanton, i.e.,

$$[B_4, B_4^\dagger] + [\phi, \bar{\phi}] + II^\dagger - J^\dagger J = 0, \quad [B_4, \phi] + IJ = 0, \tag{134}$$

where I and $J^\dagger$ are d-dimensional. vectors. This is ADHM equations of noncommutative U(1) theories under the condition of noncommutativity $\theta^1 = -\theta^2$.[22,24] Here we must fix I and $J^\dagger$ to compare (134) with (132) as

$$I = 0_d, \quad J^\dagger = 0_d, \tag{135}$$

where 0_d is 0 vector of d-dimensions. Then, the solutions of (134) are given by the solutions of (132). From this observation, we find that the moduli space of $B_4, B_4^\dagger$ and $\phi, \bar{\phi}$, which are gauge fields in this case, is the submanifold in instanton moduli space of instanton number d.

Therefore, someone might think it is not so strange to expect that the instanton number is given as $-[\det(\theta)^{1/2}/16\pi^2]\mathrm{Tr}_{\mathcal{H}} F \wedge F = d$, where the gauge fields correspond to $B_4, B_4^\dagger$ and $\phi, \bar{\phi}$, and we conjecture that the partition function of the $\mathcal{N}=4$ U(1) gauge theory in noncommutative $\mathbb{R}^4$ with the topological term $\tau \int F \wedge F$ is given by $\tilde{Z}^{4\,\mathrm{dim}}_{\mathcal{N}=4,\tau} = \Sigma_{d=0}^{\infty}(1/d^2)e^{2\pi i \tau d}$. However, It would still be unwise to conclude $\tilde{Z}^{4\,\mathrm{dim}}_{\mathcal{N}=4,\tau} = \Sigma_{d=0}^{\infty}(1/d^2)e^{2\pi i \tau d}$, because the direct corresponding with the instanton number and $B_4, B_4^\dagger$ and $\phi, \bar{\phi}$ fixed point locus labeled by d is unknown. Meanwhile, it might be possible to investigate this conjecture from Montonen and Olive duality[19,34] if such a duality of noncommutative version exists (see also Ref. 8.) For example, if we assume that the partition function takes the form as

$$\tilde{Z}^{4\,\mathrm{dim}}_{\mathcal{N}=4,\tau} = \sum_{d=1}^{\infty} \frac{1}{d^2} e^{2\pi i \tau k(d)}, \tag{136}$$

where $k(d)$ is a instanton number depending on d, restriction to the modular like form

$$\tilde{Z}^{4\,\mathrm{dim}}_{\mathcal{N}=4,1/\tau} = \pm \left(\frac{\tau}{i}\right)^n \tilde{Z}^{4\,\mathrm{dim}}_{\mathcal{N}=4,\tau} \tag{137}$$

might determine $k(d)$, where n is some number. Unfortunately, we do not know how to choose a suitable modularlike form, and the above naive conjecture $\tilde{Z}^{4\,\mathrm{dim}}_{\mathcal{N}=4,\tau} = \Sigma_{d=0}^{\infty}(1/d^2)e^{2\pi i \tau d}$ does not sat-

isfy this condition. Anyway, further investigations are necessary to determine the contribution of the topological term.

At the end of this section, we consider the dimensional reduction of the theory with topological terms. In the discussions in Sec. III, we use cohomological field theory without topological terms like $\int F\wedge F$, and some of them are not supersymmetric gauge theories in the meaning of the usual supersymmetry. Now, let us consider the case including topological terms. As an example, let us consider the four-dimensional case whose action is given by cohomological terms and instanton number; $S=\int \mathrm{tr}\,\hat{\delta}\Psi+(i\vartheta/8\pi^2)\int \mathrm{tr}\,F\wedge F$. Let us consider perturbation around classical background fixed by instanton number, i.e., $A_\mu=A_\mu^{(k)}+\delta A_\mu^{(k)}$, $\int \mathrm{tr}\,F(A^{(k)})\wedge F(A^{(k)})=8\pi^2 k$. The partition function is given by

$$Z^{4\ \mathrm{dim}}=\sum_k e^{2\pi i\tau k}\int \mathcal{D}\delta A^{(k)}\cdots e^{-\int \mathrm{tr}\ \hat{\delta}\Psi_k},$$

where $\mathcal{D}\delta A^{(k)}\cdots$ is the path integral measure of the all fields and the functional Ψ_k depends on both $A_\mu^{(k)}$ and $\delta A_\mu^{(k)}$. The BRS transformations are induced from (8) and so on as $\hat{\delta}(\delta A_\mu^{(k)})=\psi_\mu^{(k)}$, etc. So we have

$$Z^{4\ \mathrm{dim}}=\sum_k e^{2\pi i\tau k}Z_k^{4\ \mathrm{dim}},$$

where $Z_k^{4\ \mathrm{dim}}$ is the perturbative partition function of the four-dimension theory without the topological term. The action $\hat{\delta}\Psi_k$ is still given by a BRS exact term. The arguments for the θ-shift invariance of the path integral are valid for $\int \mathcal{D}\delta A^{(k)}\cdots e^{-\int \mathrm{tr}\ \hat{\delta}\Psi_k}$. Then the dimensional reduction of the perturbative partition functions arises at the large θ limit,

$$Z_k^{4\ \mathrm{dim}}=Z_k^{2\ \mathrm{dim}}=Z_k^{0\ \mathrm{dim}}, \tag{138}$$

where $Z_k^{2\ \mathrm{dim}}$ and $Z_k^{0\ \mathrm{dim}}$ are possible to be described by partition functions of two- and 0-dimensional field theories, respectively. Therefore, we find that the universality of the perturbative partition functions $Z_k^{4\ \mathrm{dim}}$, $Z_k^{2\ \mathrm{dim}}$, and $Z_k^{0\ \mathrm{dim}}$, similar to the claim in Sec. III.

Now let us discuss the possibility that (138) means a universality of the partition functions of the usual supersymmetric theories in various dimensions. Consider the weighted sum of $Z_k^{4\ \mathrm{dim}}$, $Z_k^{2\ \mathrm{dim}}$, and $Z_k^{0\ \mathrm{dim}}$ with weight $e^{2\pi i\tau k}$,

$$\sum_k e^{2\pi i\tau k}Z_k^{4\ \mathrm{dim}}=\sum_k e^{2\pi i\tau k}Z_k^{2\ \mathrm{dim}}=\sum_k e^{2\pi i\tau k}Z_k^{0\ \mathrm{dim}}. \tag{139}$$

$\Sigma_k e^{2\pi i\tau k}Z_k^{4\ \mathrm{dim}}$ is equal to $Z^{4\ \mathrm{dim}}$, the partition of the four-dimension supersymmetric theory including the topological term. On the other hand, the meanings of the weighted sums $\Sigma_k e^{2\pi i\tau k}Z_k^{2\ \mathrm{dim}}$ and $\Sigma_k e^{2\pi i\tau k}Z_k^{0\ \mathrm{dim}}$ are obscure. It is unclear that they have the meaning of the partition functions of some lower dimension theories. If they can be interpreted as the partition functions of some supersymmetric theories in lower dimensions, (139) means a universality of the partition functions of supersymmetric theories in various dimensions. To answer whether this statement is true or not, we need to clarify the following questions.

(i) Is the number k expressed in terms of lower dimension theories?
(ii) Is the number k interpreted as a topological invariant? And does it characterize classical solutions of the lower dimension theories?
(iii) Is the total action, the sum of the action defining $Z_k^{2\ \mathrm{dim}}$ or $Z_k^{0\ \mathrm{dim}}$ and the action giving the number k, equivalent to a supersymmetric action in lower dimension?

At this time, we can only make a few comments on question (i). We calculated the large θ_2 limit of the elongated NC U(1) k-instanton, that is the reduction from four dimension to two dimension of the solution. [For construction of the elongated NC U(1) k-instanton, see Ref. 13.] For this case, we can show that k is expressed in terms of two-dimension theories,

$$\theta_1 \operatorname{Tr} F_{z_1,\bar{z}_1} = -k. \tag{140}$$

It may be that this fact implies that the number k is expressed in terms of lower dimension theories. However, we have no concrete answer to question (ii) and question (iii) at this time.

VI. CONCLUSIONS AND DISCUSSIONS

We investigated cohomological gauge theories in NC $\mathbb{R}^{2D}$. We saw that vacuum expectation values of the theories do not depend on noncommutative parameters, and the large noncommutative parameter limit is equivalent to the dimensional reduction. As a result of these facts, we showed that two types of cohomological theories defined in NC $\mathbb{R}^{2D}$ and NC $\mathbb{R}^{2D+2}$ are equivalent, if they are connected through dimensional reduction. Therefore, we found several partition functions of noncommutative supersymmetric Yang-Mills theories in various dimensions are equivalent, when they are connected by dimensional reduction from 2+2D to 2D. Using this technique and requiring some natural assumptions, we determine the partition function of the $\mathcal{N}=4$ U(1) gauge theory in NC $\mathbb{R}^4$, where the action does not include the topological term $\tau\int F\wedge F$, and the result is equivalent to the partition function of (8-dim, $\mathcal{N}=2$), (6-dim, $\mathcal{N}=2$), (2-dim, $\mathcal{N}=8$) and the IKKT matrix model given by their dimensional reduction to 0 dimensions. The case including the topological term was discussed, too.

Let us list some left over problems below. In this paper, concrete partition functions are given for the $\mathcal{N}=4$ U(1) gauge theory in NC $\mathbb{R}^4$ and the series connecting to it by dimensional reduction. So, we are interested in the NC non-Abelian cases. To calculate them, we must find some new formulation like MNS, because we know the partition function concerning su(N) but we need it for su(N)$\times$su(M) for U(M) theory.

Next, we had qualitative observation of $\mathcal{N}=2$ four-dimensional case but we do not do the quantitative approach. So, we must do the more detailed analysis for the $\mathcal{N}=2$ super Yang-Mills cases. We saw in Sec. V, after taking large θ limit, moduli space is described by Monads in $\mathcal{N}=4$ four-dimensional case. From the analogy with $\mathcal{N}=4$ four-dimensional case, direct and smooth connections between noncommutative instanton moduli spaces and ADHM spaces might be given in the $\mathcal{N}=2$ four-dimensional case.

Other important problems are applications to the various fuzzy spaces, T^d_θ, $\mathbb{C}P^d_N$, and so on. Since these noncommutative spaces are expressed by finite-dimensional Hilbert spaces, the dimensional reduction will not occur at the large θ limit despite omitting kinetic terms.

Wide spread applications of the technology of this paper are going to happen in many cases other than the above subjects. All of them are left for future works.

ACKNOWLEDGMENTS

The authors would like to thank Takuya Miyazaki for useful remarks and discussion. Discussions during the workshop "An International Meeting Noncommutative Geometry, K-theory and Physics 2005" were useful to complete this work.

APPENDIX A: FOCK SPACE

Let us consider NC $\mathbb{R}^{2D}$. First of all, we introduce the following operators:

$$a_i \equiv \frac{z_i}{\sqrt{\theta^{2i-1,2i}}}, \quad z_i \equiv \frac{1}{\sqrt{2}}(x^{2i-1} + ix^{2i}),$$

$$a_i^\dagger \equiv \frac{\bar{z}_i}{\sqrt{\theta^{2i-1,2i}}}, \quad \bar{z}_i \equiv \frac{1}{\sqrt{2}}(x^{2i-1} - ix^{2i}), \tag{A1}$$

where i runs from 1 to D, and a_i and $a_i^\dagger$ satisfy

$$[a_i, a_j^\dagger] = \delta_{ij}. \tag{A2}$$

We often use the symbol θ^i defined as

$$\theta^i = +\theta^{2i-1,2i} = -\theta^{2i,2i-1}. \tag{A3}$$

The Hilbert space is constructed as the Fock space,

$$\begin{gathered}\mathcal{H} = \oplus \mathbb{C}|n_1, \ldots, n_D\rangle, \\ |n_1, \ldots, n_D\rangle \equiv \frac{(a_1^\dagger)^{n_1} \cdots (a_D^\dagger)^{n_D}}{\sqrt{n_1! \cdots n_D!}}|0, \ldots, 0\rangle.\end{gathered} \tag{A4}$$

a_i and $a_i^\dagger$ operate on $|n_1, \ldots, n_D\rangle$ as follows:

$$\begin{gathered}a_i|n_1, \ldots, n_D\rangle = \sqrt{n_i}|n_1, \ldots, n_i - 1, \ldots, n_D\rangle, \\ a_i^\dagger|n_1, \ldots, n_D\rangle = \sqrt{n_i + 1}|n_1, \ldots, n_i + 1, \ldots, n_D\rangle.\end{gathered} \tag{A5}$$

$|n_1, \ldots, n_D\rangle$ are the eigenstates of the number operator $\hat{n}_i \equiv a_i^\dagger a_i$,

$$\hat{n}_i|n_1, \ldots, n_D\rangle = n_i|n_1, \ldots, n_D\rangle. \tag{A6}$$

The arbitrary operator has the following expression:

$$\hat{\mathcal{O}} = \sum_{n_1, m_1} \cdots \sum_{n_D, m_D} \mathcal{O}^{n_1 \cdots n_D}_{m_1 \cdots m_D}|n_1, \ldots, n_D\rangle\langle m_1, \ldots, m_D|.$$

Let us consider 2D=4 case. The Hilbert space $\mathcal{H}$ is expanded by the Fock basis $|n_1, n_2\rangle$,

$$\begin{gathered}\mathcal{H} = \oplus \mathbb{C}|n_1, n_2\rangle, \\ |n_1, n_2\rangle = \frac{(a_1^\dagger)^{n_1}(a_2^\dagger)^{n_2}}{\sqrt{n_1! n_2!}}|0, 0\rangle.\end{gathered} \tag{A7}$$

$a_i^\dagger$ and a_i are expressed as

$$\begin{gathered}a_1^\dagger = \sum_{n_1=0}^{\infty} \sqrt{n_1 + 1}|n_1 + 1, n_2\rangle\langle n_1, n_2|, \quad a_2^\dagger = \sum_{n_2=0}^{\infty} \sqrt{n_2 + 1}|n_1, n_2 + 1\rangle\langle n_1, n_2|, \\ a_1 = \sum_{n_1=0}^{\infty} \sqrt{n_1 + 1}|n_1, n_2\rangle\langle n_1 + 1, n_2|, \quad a_2 = \sum_{n_2=0}^{\infty} \sqrt{n_2 + 1}|n_1, n_2\rangle\langle n_1, n_2 + 1|.\end{gathered} \tag{A8}$$

The finite-dimensional truncation $\mathcal{H}_N$ can be defined by several ways. One definition of $\mathcal{H}_N$ is given by

$$\mathcal{H}_N = \bigoplus_{n_1=0, n_2=0}^{n_1=N_c, n_2=N_c} \mathbb{C}|n_1, n_2\rangle, \tag{A9}$$

where N_c is a finite integer number. By the definition, we obtain

$$\text{dim. of } \mathcal{H}_N = (N_c + 1)^2 = N \tag{A10}$$

and

$$\mathbf{1}_N = \sum_{n_1=0,n_2=0}^{n_1=N_c,n_2=N_c} |n_1,n_2\rangle\langle n_1,n_2|. \tag{A11}$$

Another definition of $\mathcal{H}_N$ is given by

$$\mathcal{H}_N = \bigoplus_{n_1=0,n_2=0}^{n_1+n_2=N_c} \mathbb{C}|n_1,n_2\rangle. \tag{A12}$$

In this case,

$$\text{dim. of } \mathcal{H}_N = \frac{(N_c+1)(N_c+2)}{2} = N \tag{A13}$$

and

$$\mathbf{1}_N = \sum_{n_1=0,n_2=0}^{n_1+n_2=N_c} |n_1,n_2\rangle\langle n_1,n_2|. \tag{A14}$$

By using the definition of $\mathbf{1}_N$, (A11) or (A14), and the following expressions of the differential operators $\hat{\partial}_\mu$ in terms of $a_i^\dagger$ and a_i:

$$\begin{aligned} \hat{\partial}_1 &= \frac{1}{\sqrt{2\theta^1}}(a_1 - a_1^\dagger), \quad \hat{\partial}_2 = \frac{-i}{\sqrt{2\theta^1}}(a_1 + a_1^\dagger), \\ \hat{\partial}_3 &= \frac{1}{\sqrt{2\theta^2}}(a_2 - a_2^\dagger), \quad \hat{\partial}_4 = \frac{-i}{\sqrt{2\theta^2}}(a_2 + a_2^\dagger), \end{aligned} \tag{A15}$$

Given the definition of $\mathcal{H}_N$, for example, by (31), we obtain

$$\begin{aligned} [a_1,\mathbf{1}_N] &= -\sqrt{N+1}\sum_{n_2=0}^{N} |N,n_2\rangle\langle N+1,n_2|, \\ [a_1^\dagger,\mathbf{1}_N] &= +\sqrt{N+1}\sum_{n_2=0}^{N} |N+1,n_2\rangle\langle N,n_2|, \\ [a_2,\mathbf{1}_N] &= -\sqrt{N+1}\sum_{n_1=0}^{N} |n_1,N\rangle\langle n_1,N+1|, \\ [a_2^\dagger,\mathbf{1}_N] &= +\sqrt{N+1}\sum_{n_1=0}^{N} |n_1,N+1\rangle\langle n_1,N|. \end{aligned} \tag{A16}$$

From (A16) and (A15), we obtain

$$T_1 = \frac{1}{\sqrt{2\theta^1}}\left(-\sqrt{N+1}\sum_{n_2=0}^{N} |N,n_2\rangle\langle N+1,n_2| - \sqrt{N+1}\sum_{n_2=0}^{N} |N+1,n_2\rangle\langle N,n_2| \right),$$

$$T_2 = \frac{-i}{\sqrt{2\theta^1}}\left(-\sqrt{N+1}\sum_{n_2=0}^{N}|N,n_2\rangle\langle N+1,n_2| + \sqrt{N+1}\sum_{n_2=0}^{N}|N+1,n_2\rangle\langle N,n_2|\right),$$

$$T_3 = \frac{1}{\sqrt{2\theta^2}}\left(-\sqrt{N+1}\sum_{n_1=0}^{N}|n_1,N\rangle\langle n_1,N+1| - \sqrt{N+1}\sum_{n_1=0}^{N}|n_1,N+1\rangle\langle n_1,N|\right),$$

$$T_4 = \frac{-i}{\sqrt{2\theta^2}}\left(-\sqrt{N+1}\sum_{n_1=0}^{N}|n_1,N\rangle\langle n_1,N+1| + \sqrt{N+1}\sum_{n_1=0}^{N}|n_1,N+1\rangle\langle n_1,N|\right). \tag{A17}$$

Using (A11) and (A17), we can show

$$\mathrm{Tr}_{\mathcal{H}}\,\mathbf{1}_N\mathbf{1}_N = N, \quad \mathrm{Tr}_{\mathcal{H}}\,T_\mu T_\nu = +\frac{1}{\theta^i}N\delta_{\mu\nu}, \quad \mathrm{Tr}_{\mathcal{H}}\,\mathbf{1}_N T_\mu = 0. \tag{A18}$$

Also, we can obtain

$$\begin{gathered}\mathrm{Tr}_{\mathcal{H}}\,\mathbf{1}_N[\hat{\partial}_\mu,\mathbf{1}_N] = 0, \quad \mathrm{Tr}_{\mathcal{H}}\,\mathbf{1}_N[\hat{\partial}_\mu,T_\nu] = -\frac{N}{\theta^i}\delta_{\mu\nu},\\ \mathrm{Tr}_{\mathcal{H}}\,T_\mu[\hat{\partial}_\nu,\mathbf{1}_N] = +\frac{N}{\theta^i}\delta_{\mu\nu}, \quad \mathrm{Tr}_{\mathcal{H}}\,T_\mu[\hat{\partial}_\nu,T_\rho] = 0,\end{gathered} \tag{A19}$$

and

$$\begin{gathered}\mathrm{Tr}_{\mathcal{H}}\,\mathbf{1}_N[\mathbf{1}_N,\mathbf{1}_N] = 0, \quad \mathrm{Tr}_{\mathcal{H}}\,\mathbf{1}_N[\mathbf{1}_N,T_\mu] = 0,\\ \mathrm{Tr}_{\mathcal{H}}\,\mathbf{1}_N[T_\mu,T_\nu] = +iN\theta^{-1}_{\mu\nu}, \quad \mathrm{Tr}_{\mathcal{H}}\,T_\mu[T_\nu,T_\rho] = 0.\end{gathered} \tag{A20}$$

Let us define $\mathcal{I}$ and $\mathcal{T}_\mu$ as

$$\mathcal{I} = \frac{1}{\sqrt{N}}\mathbf{1}_N, \tag{A21}$$

and

$$\mathcal{T}_\mu = \frac{\sqrt{\theta_i}}{\sqrt{N}}T_\mu. \tag{A22}$$

By definition,

$$\mathcal{T}_\mu = \sqrt{\theta_i}[\hat{\partial}_\mu,\mathcal{I}]. \tag{A23}$$

Using $\mathcal{I}$ and $\mathcal{T}_\mu$, (A18)–(A20) are rewritten into

$$\mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}\mathcal{I} = 1, \quad \mathrm{Tr}_{\mathcal{H}}\,\mathcal{T}_\mu\mathcal{T}_\nu = \delta_{\mu\nu}, \quad \mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}\mathcal{T}_\mu = 0, \tag{A24}$$

$$\begin{gathered}\mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}[\hat{\partial}_\mu,\mathcal{I}] = 0, \quad \mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}[\hat{\partial}_\mu,\mathcal{T}_\nu] = -\frac{1}{\sqrt{\theta^i}}\delta_{\mu\nu},\\ \mathrm{Tr}_{\mathcal{H}}\,\mathcal{T}_\mu[\hat{\partial}_\nu,\mathcal{I}] = +\frac{1}{\sqrt{\theta^i}}\delta_{\mu\nu}, \quad \mathrm{Tr}_{\mathcal{H}}\,\mathcal{T}_\mu[\hat{\partial}_\nu,\mathcal{T}_\rho] = 0,\end{gathered} \tag{A25}$$

and

$$\mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}[\mathcal{I},\mathcal{I}]=0,\quad \mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}[\mathcal{I},\mathcal{T}_\mu]=0,$$
$$\mathrm{Tr}_{\mathcal{H}}\,\mathcal{I}[\mathcal{T}_\mu,\mathcal{T}_\nu]=+\frac{i\theta^i}{\sqrt{N}}\theta^{-1}_{\mu\nu},\quad \mathrm{Tr}_{\mathcal{H}}\,\mathcal{T}_\mu[\mathcal{T}_\nu,\mathcal{T}_\rho]=0. \tag{A26}$$

The same formulas as (A24)–(A26) hold for the case of (A12). The difference between the definitions of $\mathcal{H}_N$'s, (A9) and (A12), are absorbed in dimensions of $\mathcal{H}_N$.

It is worthwhile to notice that the independence of the precise definitions of $\mathcal{H}_N$ holds generally. The proof is done by using the discrete version of Stokes's theorem for the boundary of the finite truncated Fock space.[14,26]

APPENDIX B: LARGE θ LIMIT

In this paper, we removed the terms including $\partial_\mu=-i\theta^{-1}_{\mu\nu}[x^\nu,*]$ in the Lagrangian when we calculated the partition function without zero mode integrals in the large θ limit. If we consider some specific fixed function $f(x)$, then expression of $\partial_\mu f(x)=-i\theta^{-1}_{\mu\nu}[x^\nu,f(x)]$ is not changed by taking large θ limit because $[x^\nu,f(x)]$ becomes large with θ. Therefore, someone might think that the process of removing terms including ∂_μ is not correct. However, we must recall that our Lagrangian is changed by θ variation and then the equations of motion and BPS equations, are changed. Then the solutions of the equations, which make much contribution to the partition functions and vacuum expectation values, are changed by θ changing. It follows that the terms including derivatives become irrelevant. In this section, we show concretely the validity of taking the terms including $\partial_\mu=-i\theta^{-1}_{\mu\nu}[x^\nu,*]$ away from Lagrangians at the large θ limit.

The BPS equations in this paper are given by differential equations of first order,

$$\sum_{i,I} c_{iI,k}\partial_{z_i}f_I+V_k(f_J)=0, \tag{B1}$$

where f_I are fields, $V_k(f_I)$ are some quadratic polynomial in f_I and $c_{iI,k}$ are some constants. $k=1,\ldots,n$, where n is the number of elements of f_I minus degree of gauge freedom. For example, BPS equations of $\mathcal{N}=4$ four-dimensional gauge theory are

$$F^{+\mu\nu}-i[B^+_{\mu\rho},B^{+\rho}_\nu]-i[B^+_{\mu\nu},c]=0,\quad 2D^\mu B^+_{\mu\rho}+D_\rho c=0. \tag{B2}$$

Let us consider (B1) by using the Fock basis,

$$B_k(\hat f_I,\theta)\equiv c^+_{iI,k}\frac{1}{\sqrt{\theta^i}}[a_i,\hat f_I]+c^-_{iI,k}\frac{1}{\sqrt{\theta^i}}[a_i^\dagger,\hat f_I]+V_k(\hat f_J)=d_{i,k}\frac{1}{\theta^i}. \tag{B3}$$

Here $d_{i,k}(1/\theta^i)$ are constants derived from $[\partial_{z_i},\partial_{\bar z_i}]$. For example, equations of $\mathcal{N}=4$ four-dimensional cases are given by

$$P^+_{\mu\nu\rho\tau}[\hat D^\rho,\hat D^\tau]+[B^+_{\mu\rho},B^{+\rho}_\nu]+[B^+_{\mu\nu},c]=i(P^+_{\mu\nu\rho\tau}(\theta^{-1})^{\rho\tau}), \tag{B4}$$

$$2[\hat D^\mu,B_{+\mu\rho}]+[\hat D_\rho,c]=0, \tag{B5}$$

where $P^+_{\mu\nu\rho\tau}$ is the self-dual projection operator and $\hat D_\mu=\hat\partial_\mu+iA_\mu$. When we take $\theta^{\mu\nu}$ as (17), the right-hand side of (B4) is rewritten as

$$P^+_{\mu\nu\rho\tau}(\theta^{-1})^{\rho\tau}=-\frac{\varepsilon_{\mu\nu}}{2}\left(\frac{1}{\theta^1}+\frac{1}{\theta^2}\right),$$

$$(\varepsilon_{\mu\nu}) \equiv \begin{pmatrix} 0 & 1 & & \\ -1 & 0 & & \\ & & 0 & 1 \\ & & -1 & 0 \end{pmatrix}.$$

$\hat{f}_I$ is a operator representation of f_I, i.e., $\hat{f}_I = \Sigma (f_I)^{m_1,\ldots m_D}_{n_1,\ldots,n_D} |n_1,\ldots,n_D\rangle\langle m_1,\ldots,m_D|$. In this representation, the BPS equations are just simultaneous quadratic equations, and the noncommutative parameters θ^i appear in only the first two terms and the right-hand side of (B3). Note that solutions of (B3) depend on θ^i but variables $(f_I)^{m_1,\ldots,m_D}_{n_1,\ldots,n_D}$ themselves do not depend on θ. For this reason, BPS equations are truncated to

$$B_k(\hat{f}_I, \infty) \equiv V_k(\hat{f}_J) = 0, \tag{B6}$$

at the $\theta \to \infty$ limit. Such truncations have been discussed in many works, see for example, Refs. 10, 9, and 15. Thus, it becomes clear that terms including $\partial_\mu = -i\theta^{-1}_{\mu\nu}[x^\nu, *]$ in the Lagrangian become irrelevant at the large θ limit.

However, the above discussion is insufficient for the proof which justifies removing terms including ∂_μ. Because we assume the convergency of path integral which has not been confirmed when we formally prove that partition functions and vacuum expectation values of observables do not depend on θ. Therefore, we must check our models satisfying the convergency conditions. To understand this statement, let us consider the following example.

Let f_i be dynamical variables and assume that action functional take the following form:

$$S_\epsilon[f] = S_0 + \epsilon S_1, \tag{B7}$$

where ϵ is a some constant, S_0 and S_ϵ are BRS exact actions, and they do not depend on ϵ. Let us expand the partition function as

$$Z_\epsilon = \int \mathcal{D}f\, e^{-S_\epsilon} \tag{B8}$$

$$= \int \mathcal{D}f\, e^{-S_0}\left(1 - \epsilon S_1 + \frac{1}{2}\epsilon^2 S_1^2 - \cdots\right) \tag{B9}$$

and introduce

$$Z_0 \equiv \int \mathcal{D}f\, e^{-S_0}. \tag{B10}$$

If e^{-S_0} damp the integrand, the integral

$$\int \mathcal{D}f\, e^{-S_0}\epsilon^n S_1^n \quad \text{for } n \geqslant 1 \tag{B11}$$

is well defined. Then, Z_ϵ does not depend on ϵ, i.e.,

$$Z_\epsilon = Z_0,$$

because S_1^n is a BRS exact term and

$$\int \mathcal{D}f\, e^{-S_0}\epsilon^n S_1^n = 0 \quad \text{for } n \geqslant 1.$$

Therefore, we found that we must verify that (B10) is well defined and e^{-S_0} damp integrands for proof of ϵ independence.

To get a feeling for how all of this should work out, consider simple toy models. At first, let us consider the toy model given by Vafa and Witten in Sec. II of Ref. 34. Let x, y, H_1 and H_2 be real bosonic variables, and ψ_x, ψ_y, χ_1 and χ_2 be fermionic variables. We define BRS transformations by

$$\hat{\delta}x = \psi_x, \quad \hat{\delta}y = \psi_y, \quad \hat{\delta}\chi_1 = H_1, \quad \hat{\delta}\chi_2 = H_2. \tag{B12}$$

Consider the following action:

$$S_\epsilon^{\text{toy1}} = \hat{\delta}\{\chi_1(H_1 + 2i(x^2 - \epsilon - y^2)) + \chi_2(H_2 + 2i(2xy))\} = S_0^{\text{toy1}} + \epsilon S_1^{\text{toy1}}, \tag{B13}$$

where

$$S_0^{\text{toy1}} = \hat{\delta}\{\chi_1(H_1 + 2i(x^2 - y^2)) + \chi_2(H_2 + 2i(2xy))\},$$

$$S_1^{\text{toy1}} = \hat{\delta}\chi_1.$$

$e^{-S_0^{\text{toy1}}}$ makes the integral

$$\int \mathcal{D}f\, e^{-S_0^{\text{toy1}}} \epsilon^n (S_1^{\text{toy1}})^n \quad \text{for } n \geqslant 1 \tag{B14}$$

be well defined, and

$$Z_\epsilon^{\text{toy1}} = Z_0^{\text{toy1}} \equiv \int \mathcal{D}f\, e^{-S_0^{\text{toy1}}}. \tag{B15}$$

Indeed, we can easily perform the direct calculations of the partition functions Z_ϵ^{toy1} and Z_0^{toy1}, respectively, and their results reproduce (B15). Note that degeneracy of the solutions does not affect the independence of ϵ. In this case, when $\epsilon \neq 0$ equations are given by $x^2 - \epsilon - y^2 = 0$ and $2xy = 0$, then the solutions are given as $(x, y) = (\pm\sqrt{\epsilon}, 0)$. These two sets of solutions become degenerate in $\epsilon \to 0$. Despite such singularities, path integrals moderate them, and the partition function is smooth at $\epsilon = 0$.

As the second example, consider the following action:

$$S_\epsilon^{\text{toy2}} = \hat{\delta}\{\chi_1(H_1 + 2i(x^2 - \epsilon)) + \chi_2(H_2 + 2i(2xy))\} = S_0^{\text{toy2}} + \epsilon S_1^{\text{toy2}}, \tag{B16}$$

where

$$S_0^{\text{toy2}} = \hat{\delta}\{\chi_1(H_1 + 2i(x^2)) + \chi_2(H_2 + 2i(2xy))\},$$

$$S_1^{\text{toy2}} = \hat{\delta}\chi_1.$$

At first glance, the partition function Z_ϵ^{toy2} looks independent of ϵ from the formal discussion. But $e^{-S_0^{\text{toy2}}}$ does not damp the integrals in this case, then Z_ϵ^{toy2} depends on ϵ. Indeed,

$$Z_\epsilon^{\text{toy2}} = \int \frac{\mathrm{d}x}{\sqrt{2\pi}} \frac{\mathrm{d}y}{\sqrt{2\pi}} \frac{\mathrm{d}H_1}{\sqrt{2\pi}} \frac{\mathrm{d}H_2}{\sqrt{2\pi}} \mathrm{d}\psi_x\, \mathrm{d}\psi_y\, \mathrm{d}\chi_1\, \mathrm{d}\chi_2 \exp(-S_\epsilon^{\text{toy2}}) = 1 + \frac{\epsilon}{2}\pi^{-1/2} + O(\epsilon^2). \tag{B17}$$

These observations show that we must check the convergency of e^{-S_0} where the action S_0 is the θ independent part of the total action, before removing terms including θ^{-1} from action.

Let us now attempt to investigate the specific case of $\mathcal{N}=4$ four dimensions. First we consider the case of $\theta^1 = -\theta^2$. This is a very special case and we can understand the validity of removing the terms including ∂_μ not from the above discussions but from the following discussions. Using $\theta^1 = -\theta^2$, the BPS Eqs. (B4) and (B5) are replaced by

$$P^{+}_{\mu\nu\rho\tau}[\hat{D}^{\rho},\hat{D}^{\tau}] + [B^{+}_{\mu\rho},B^{+\rho}_{\nu}] + [B^{+}_{\mu\nu},c] = 0, \tag{B18}$$

$$2[\hat{D}^{\mu},B_{+\mu\rho}] + [\hat{D}_{\rho},c] = 0. \tag{B19}$$

On the contrary, the BPS equations of the large θ limit are given by

$$-P^{+}_{\mu\nu\rho\tau}[A^{\rho},A^{\tau}] + [B^{+}_{\mu\rho},B^{+}_{\nu\tau}]\delta^{\tau\rho} + [B^{+}_{\mu\nu},c] = 0, \tag{B20}$$

$$2[A^{\mu},B^{+}_{\mu\rho}] + [A_{\rho},c] = 0. \tag{B21}$$

Equations (B20) and (B21) are equivalent to (B18) and (B19) with $1/\theta=0$. The correspondence of these and more general cases are already known in Refs. 1 and 30, that is, we can identify (B18) and (B19) with (B20) and (B21) by redefining

$$iA_{\mu} = \hat{D}_{\mu}. \tag{B22}$$

This is a trivial one-to-one correspondence between the large θ limit and finite $\theta^{1}=-\theta^{2}$ case. Under change of variables (B22), the path integral measure does not cause nontrivial Jacobian, the theory characterized (B18) and (B19) and the theory characterized (B20) and (B21) are equivalent quantum theories. From this correspondence, it is clear that we can remove the terms including ∂_{μ} from its action without changing.

Before investigating $\theta^{1}\neq-\theta^{2}$ case, let us consider

$$S_{\epsilon} = S_{0} + \epsilon S_{1},$$

$$S_{0} = \mathrm{Tr}_{\mathcal{H}}\ \mathrm{tr}\ \hat{\delta}_{+}\{\chi^{+}_{\mu\nu}(H^{+\mu\nu} - (P^{+}_{\mu\nu\rho\tau}[\hat{D}^{\rho},\hat{D}^{\tau}] + [B^{+}_{\mu\rho},B^{+}_{\nu\sigma}]\delta^{\rho\sigma} + [B^{+}_{\mu\nu},c]))\} + \mathrm{Tr}_{\mathcal{H}}\ \mathrm{tr}\ \hat{\delta}_{+}\{\chi^{\rho}(H_{\rho} - i($$
$$-2[\hat{D}^{\mu},B^{+}_{\mu\rho}] - [\hat{D}_{\rho},c]))\} + \mathrm{Tr}_{\mathcal{H}}\ \mathrm{tr}\ \hat{\delta}_{+}\{i[\phi,\bar{\phi}]\eta - i\bar{\eta}[c,\bar{\phi}] + i[B^{+\mu\nu},\bar{\phi}]\psi^{+}_{\mu\nu} + ([\hat{D}_{\mu},\bar{\phi}])\psi_{\mu}\},$$

$$S_{1} = i\chi^{+}_{\mu\nu}\varepsilon^{\mu\nu}, \tag{B23}$$

and their partition functions

$$Z_{\mathcal{N}=4,\epsilon} = \int \mathcal{D}f\, e^{-S_{\epsilon}}, \quad Z_{\mathcal{N}=4,0} = \int \mathcal{D}f\, e^{-S_{0}}. \tag{B24}$$

Note that S_{0} is equivalent to the action of the Yang-Mills theory of $\theta^{1}=-\theta^{2}$ and IKKT matrix model when its gauge group is U(1). Therefore, it is natural to assume that $\exp(-S_{0})$ damp the path integral of an arbitrary observable. Indeed, this assumption is required in MNS too.[20] From the above discussion and this assumption, we can conclude that

$$Z_{\mathcal{N}=4,\epsilon} = Z_{\mathcal{N}=4,0}. \tag{B25}$$

In the next step, we consider the $\theta^{1}\neq-\theta^{2}$ case. Its action is equivalent to (B23) if

$$\epsilon = -\frac{1}{2}\left(\frac{1}{\theta^{1}} + \frac{1}{\theta^{2}}\right).$$

Under the above assumption that $\exp(-S_{0})$ damp integrands of path integrals, as we saw in (B25), $Z_{\mathcal{N}=4,\epsilon}$ does not depend on ϵ. Therefore, the partition function of $\theta^{1}\neq-\theta^{2}$ case is equal to the partition function of $\theta^{1}=-\theta^{2}$ whose BPS equations are given by (B18) and (B19), furthermore the partition function is equal to the partition function whose action functional is given by removing derivative terms and its BPS equations are given by (B20) and (B21).

In the above discussion, we have closely studied the case of dimensional reduction from $\mathcal{N}=4$ four dimensions to 0 dimensions. But it is clear that we can apply the above general discussion

to other dimensional cases or the cases of the $\mathcal{N}=2$ four-dimensional model and the series given by its dimensional reduction. All these things make it clear that it is proper procedure to remove the terms including $\partial_\mu = -i\theta^{-1}_{\mu\nu}[x^\nu, *]$ from Lagrangians at the large θ limit, in the calculations of this paper.

APPENDIX C: NORMALIZATION OF THE PARTITION FUNCTION

In this appendix, we give the precise definition of the path integral measure to decide the partition function without ambiguity.

As mentioned in Sec. IVG, the absolute value of the infinite-dimensional integrals of fluctuations around each vacuum should be normalized to be 1. This is implemented by virtue of the supersymmetry.

When we normalize fields appropriately the action of topological field theory has the following form:

$$S_{\mathrm{TFT}} = \int \hat{\delta}_+[\chi_i\{H_i - iM_{ij}A_j\}], \tag{C1}$$

here we have omitted terms including fields like $\phi, \bar{\phi}, \eta$, often called "Higgs sector," for simplicity. The normalization of the Higgs sector is possible to be managed similarly to other fields when usual gauge fixing is done by using Nakanishi-Lautrup field, ghost and antighost fields. We can see this fact in the latter half of this section devoted to trace and extra parts. Also we have kept only quadratic terms of fluctuations, because the path integral of topological field theories is estimated exactly in the weak coupling limit. M_{ij} in (C1) depends on backgrounds and parameters in general, but as seen below, the M_{ij} dependence does not appear in the result up to sign. The BRS transformation rules are given by

$$\begin{aligned} &\hat{\delta}_+ A_i = \psi_i, \quad \hat{\delta}_+ \psi_i = 0, \\ &\hat{\delta}_+ \chi_i = H_i, \quad \hat{\delta}_+ H_i = 0. \end{aligned} \tag{C2}$$

For $A_i, \ldots$, we adopt the following path integral measure:

$$\prod_i \frac{\mathrm{d}H_i}{\sqrt{2\pi}} \frac{\mathrm{d}A_i}{\sqrt{2\pi}} \mathrm{d}\chi_i \, \mathrm{d}\psi_i, \tag{C3}$$

then we obtain

$$\left| \int \prod_i \frac{\mathrm{d}H_i}{\sqrt{2\pi}} \frac{\mathrm{d}A_i}{\sqrt{2\pi}} \mathrm{d}\chi_i \, \mathrm{d}\psi_i \, e^{-S_{\mathrm{TFT}}} \right| = 1. \tag{C4}$$

The M_{ij} dependence does not appear due to the supersymmetry.

Now we give a detailed argument for calculations about the trace and extra parts of our model as an example. The action including the trace and extra parts $S^{\infty}_{\mathrm{tr}\oplus\mathrm{ex}} + S_{\mathrm{gf}}$ is decomposed into two parts, S_1 and S_2. S_1 consists of (106)–(109) and (111)–(114), and also S_2 consists of (110), (115), (119), and (120). S_2 involves the Higgs sector and also includes the gauge fixing terms. S_1 involves all the rest.

We start with the S_1 part. S_1 is represented in the same form as (C1), therefore we obtain

$$\int \prod_i \frac{\mathrm{d}H_i}{\sqrt{2\pi}} \frac{\mathrm{d}A_i}{\sqrt{2\pi}} \mathrm{d}\chi_i \, \mathrm{d}\psi_i \, e^{-S_1} = 1. \tag{C5}$$

As mentioned above, the θ-dependence does not appear.

Let us turn to the S_2 part. The action is given as

$$S_2 = \frac{4}{\theta}\bar{\phi}_{(\mathbf{1})}\phi_{(\mathbf{1})} \tag{C6}$$

$$+ \frac{i}{\sqrt{\theta}}\eta_{(\mathbf{1})}\psi^{\mu}_{(\mu)} \tag{C7}$$

$$+ b_{(\mathbf{1})}\left(b_{(\mathbf{1})} - \frac{1}{\sqrt{\theta}}A_{\mu(\mu)}\right) \tag{C8}$$

$$+ \frac{4}{\theta}\bar{\rho}_{(\mathbf{1})}\rho_{(\mathbf{1})} + \frac{1}{\sqrt{\theta}}\bar{\rho}_{(\mathbf{1})}\psi_{\mu(\mu)}. \tag{C9}$$

We adopt the following measure:

$$\frac{\mathrm{d}\bar{\phi}_{(\mathbf{1})}}{\sqrt{2\pi}}\frac{\mathrm{d}\phi_{(\mathbf{1})}}{\sqrt{2\pi}}\mathrm{d}\bar{\rho}_{(\mathbf{1})}\,\mathrm{d}\rho_{(\mathbf{1})}\frac{\mathrm{d}b_{(\mathbf{1})}}{\sqrt{2\pi}}\frac{\mathrm{d}A_{\mu(\mu)}}{\sqrt{2\pi}}\mathrm{d}\eta_{(\mathbf{1})}\,\mathrm{d}\psi^{\mu}_{(\mu)}, \tag{C10}$$

then we obtain

$$\int \frac{\mathrm{d}\bar{\phi}_{(\mathbf{1})}}{\sqrt{2\pi}}\frac{\mathrm{d}\phi_{(\mathbf{1})}}{\sqrt{2\pi}}\mathrm{d}\bar{\rho}_{(\mathbf{1})}\,\mathrm{d}\rho_{(\mathbf{1})}\frac{\mathrm{d}b_{(\mathbf{1})}}{\sqrt{2\pi}}\frac{\mathrm{d}A_{\mu(\mu)}}{\sqrt{2\pi}}\mathrm{d}\eta_{(\mathbf{1})}\,\mathrm{d}\psi^{\mu}_{(\mu)}e^{-S_2} = 1. \tag{C11}$$

Notice that the result (C11) is again a consequence of the supersymmetry.

As a result of these normalizations, partition functions of the cohomological field theories are defined as well-defined functions or finite values without ambiguity from infinite-dimensional integral.

At the end of this appendix, we should notice a fact relating the dimension-independence of partition function, (20). The gauge symmetry (99) and the gauge fixing term (117) are expected to have the same form for all cases of (8-dim, $\mathcal{N}=2$), (6-dim, $\mathcal{N}=2$), (4-dim, $\mathcal{N}=4$) and (2-dim, $\mathcal{N}=8$). So we expect that the trace and extra sector produce a trivial factor 1 for all of those cases.

Gauged Wess–Zumino model in noncommutative Minkowski superspace

James S. Cook
Department of Mathematics, North Carolina State University, Raleigh, North Carolina 27695

(Received 15 September 2005; accepted 29 November 2005; published online 25 January 2006)

We develop a gauged Wess–Zumino model in noncommutative Minkowski superspace. This is the natural extension of the work of Carlson and Nazaryan, which extended $N=1/2$ supersymmetry written over deformed Euclidean superspace to Minkowski superspace. We investigate the coupling of the vector and chiral superfields. Noncommutativity is implemented by replacing products with star products. Although, in general, our star product is nonassociative, we prove that it is associative to the first order in the deformation parameter C. We show that our model reproduces the $N=1/2$ theory in the appropriate limit, namely when the deformation parameters $\bar{C}^{\dot{\alpha}\dot{\beta}}=0$. Essentially, we find the $N=1/2$ theory and a conjugate copy. As in the $N=1/2$ theory, a reparametrization of the gauge parameter, vector superfield, and chiral superfield are necessary to write standard C-independent gauge theory. However, our choice of parametrization differs from that used in the $N=1/2$ supersymmetry, which leads to some unexpected new terms. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2162330]

I. INTRODUCTION

In the past several years there has been much discussion of noncommutative superspaces; see Refs. 1–13 for a partial account. Much recent discussion has been motivated by the observation that noncommutativity can result from certain string models. Of particular interest to this paper is the deformed Euclidean superspace constructed by Seiberg in Ref. 8. Seiberg found a deformation of Euclidean superspace that broke half the supersymmetry and yet preserved the usual superfield constructions. Because only half of the $N=1$ supersymmetry is found in Seiberg's theory, it is commonly referred to as $N=1/2$ supersymmetry. Generally, the literature following Seiberg has focused on superspace with a Euclidean signature. One reason for that is that it is not entirely straightforward to modify the construction of $N=1/2$ supersymmetry to the Minkowski case. However, Carlson and Nazaryan found in Ref. 11 how to construct a deformed Minkowski superspace very similar to Seiberg's deformed Euclidean space. In particular, Ref. 11 deformed superspace so that

$$\{\hat{\theta}^{\alpha},\hat{\theta}^{\beta}\}=C^{\alpha\beta},\quad \{\hat{\bar{\theta}}^{\dot{\alpha}},\hat{\bar{\theta}}^{\dot{\beta}}\}=\bar{C}^{\dot{\alpha}\dot{\beta}}, \tag{1}$$

where $(C^{\alpha\beta})^{*}=\bar{C}^{\dot{\alpha}\dot{\beta}}$. In their paper, they implemented superspace noncommutativity with a star product that was Hermitian, but not associative in general. Their star product reproduces the deformation of $N=1/2$ supersymmetry in the limit that $\bar{C}^{\dot{\alpha}\dot{\beta}}$ is identically zero. Additionally, they studied the Wess–Zumino model (only chiral superfields, no gauge interactions) and found results similar to that of Seiberg in Ref. 8. Our goal here is to continue the work of Carlson and Nazaryan by constructing the Wess–Zumino model with gauge interactions in the noncommutative Minkowski superspace they constructed. We will carefully study how the $N=1/2$ theory must be modified in the presence of the Minkowski metric. We will find the modification of the gauge theory is not entirely straightforward; subtle superfield component redefinitions must be made for

certain components in order to maintain deformation-independent gauge transformations.

We mention that after the completion of this work, the author learned that Ref. 12 and Ref. 13 also studied the Wess–Zumino model on deformed Minkowski superspaces in some detail. Both of these works employ a star product that is associative but not Hermitian. The star product studied here is Hermitian but not associative in general. We also note that Ref. 5 and Ref. 10 study some general aspects of deformed Minkowski superspace that have relevance to this work.

A. Deformed coordinate algebra

We begin by considering $N=1$ rigid Minkowski superspace where a typical point is $(x^m, \theta^\alpha, \bar{\theta}^{\dot{\alpha}})$. In the commutative case, we have

$$\begin{aligned} &[x^m, x^n] = 0 \qquad [x^m, \theta^\alpha] = 0, \\ &\{\theta^\alpha, \theta^\beta\} = 0 \qquad [x^m, \bar{\theta}^{\dot{\alpha}}] = 0, \\ &\{\bar{\theta}^{\dot{\alpha}}, \bar{\theta}^{\dot{\beta}}\} = 0 \qquad \{\theta^\alpha, \bar{\theta}^{\dot{\beta}}\} = 0. \end{aligned} \tag{2}$$

The coordinates x^m are identified with spacetime coordinates, whereas the θ^α and $\bar{\theta}^{\dot{\alpha}}$ are Grassman variables. We then construct noncommutative Minkowski superspace by replacing coordinate functions $(x^m, \theta^\alpha, \bar{\theta}^{\dot{\alpha}})$ with operators $(\hat{x}^m, \hat{\theta}^\alpha, \hat{\bar{\theta}}^{\dot{\alpha}})$. In particular, following the construction of Ref. 11, we deform $N=1$ rigid Minkowski superspace as follows:

$$\begin{aligned} &\{\hat{\theta}^\alpha, \hat{\theta}^\beta\} = C^{\alpha\beta}, \qquad [\hat{x}^m, \hat{\theta}^\alpha] = iC^{\alpha\beta}\sigma^m_{\beta\dot{\beta}}\hat{\bar{\theta}}^{\dot{\beta}}, \\ &\{\hat{\bar{\theta}}^{\dot{\alpha}}, \hat{\bar{\theta}}^{\dot{\beta}}\} = \bar{C}^{\dot{\alpha}\dot{\beta}}, \qquad [\hat{x}^m, \hat{\bar{\theta}}^{\dot{\alpha}}] = i\bar{C}^{\dot{\alpha}\dot{\beta}}\hat{\theta}^\beta\sigma^m_{\beta\dot{\beta}}, \\ &\{\hat{\theta}^\alpha, \hat{\bar{\theta}}^{\dot{\beta}}\} = 0, \qquad [\hat{x}^m, \hat{x}^n] = (C^{\alpha\beta}\hat{\bar{\theta}}^{\dot{\alpha}}\hat{\bar{\theta}}^{\dot{\beta}} - \bar{C}^{\dot{\alpha}\dot{\beta}}\hat{\theta}^\alpha\hat{\theta}^\beta)\sigma^m_{\alpha\dot{\alpha}}\sigma^n_{\beta\dot{\beta}}, \end{aligned} \tag{3}$$

where $(C^{\alpha\beta})^* = \bar{C}^{\dot{\alpha}\dot{\beta}}$. This algebra was constructed in Ref. 11 so that the deformed chiral coordinates satisfy $\hat{y}^m = \hat{x}^m + i\hat{\theta}\sigma^m\hat{\bar{\theta}}$ and $\hat{\bar{y}}^m = \hat{x}^m - i\hat{\theta}\sigma^m\hat{\bar{\theta}}$ satisfy

$$\begin{aligned} &\{\hat{\theta}^\alpha, \hat{\theta}^\beta\} = C^{\alpha\beta}, \qquad [\hat{y}^m, \hat{\theta}^\alpha] = 0, \\ &\{\hat{\bar{\theta}}^{\dot{\alpha}}, \hat{\bar{\theta}}^{\dot{\beta}}\} = \bar{C}^{\dot{\alpha}\dot{\beta}}, \qquad [\hat{\bar{y}}^m, \hat{\bar{\theta}}^{\dot{\alpha}}] = 0, \\ &\{\hat{\theta}^\alpha, \hat{\bar{\theta}}^{\dot{\beta}}\} = 0. \end{aligned} \tag{4}$$

These relations will allow us to develop chiral and antichiral superfields in much the same way as in the commutative theory. In addition, we have

$$\begin{aligned} [\hat{\bar{y}}^m, \hat{\theta}^\alpha] &= 2iC^{\alpha\beta}\sigma^m_{\beta\dot{\beta}}\hat{\bar{\theta}}^{\dot{\beta}}, \\ [\hat{y}^m, \hat{\bar{\theta}}^{\dot{\alpha}}] &= 2i\bar{C}^{\dot{\alpha}\dot{\beta}}\hat{\theta}^\beta\sigma^m_{\beta\dot{\beta}}, \\ [\hat{y}^m, \hat{y}^n] &= (4\bar{C}^{\dot{\alpha}\dot{\beta}}\hat{\theta}^\alpha\hat{\theta}^\beta - 2C^{\alpha\beta}\bar{C}^{\dot{\alpha}\dot{\beta}})\sigma^m_{\alpha\dot{\alpha}}\sigma^n_{\beta\dot{\beta}}, \\ [\hat{\bar{y}}^m, \hat{\bar{y}}^n] &= (4C^{\alpha\beta}\hat{\bar{\theta}}^{\dot{\alpha}}\hat{\bar{\theta}}^{\dot{\beta}} - 2C^{\alpha\beta}\bar{C}^{\dot{\alpha}\dot{\beta}})\sigma^m_{\alpha\dot{\alpha}}\sigma^n_{\beta\dot{\beta}}, \\ [\hat{y}^m, \hat{\bar{y}}^n] &= 2C^{\alpha\beta}\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\sigma^n_{\beta\dot{\beta}}. \end{aligned} \tag{5}$$

In this deformation, all of the fermionic dimensions of superspace are deformed. A consequence of this is that Q and $\bar{Q}$ are broken symmetries (see the next section), so we say that this space has

$N=0$ supersymmetry. Despite this, the deformation still permits most of the usual superfield constructions just like the $N=1/2$ case.

B. Star product

The deformed coordinates have overcarets on them to emphasize that they are operators. The usual model is then deformed by simply putting an overcaret on all of the objects in the standard theory. In practice, we will not explicitly calculate anything in terms of these formal operators. Instead, we will find it useful to make the usual exchange of the operator product for the star product of ordinary functions of superspace;

$$\hat{F}\hat{G} \mapsto F * G. \tag{6}$$

This correspondence allows us to work out the details of noncommutative theory using ordinary calculus on superspace. In this sense we will obtain a noncommutative model by replacing ordinary products with star products.

The star product for our deformed Minkowski superspace is defined by

$$F * G = F(1+S)G, \tag{7}$$

where S is formed using the supercharges Q_α and $\bar{Q}_{\dot{\alpha}}$,

$$S = -\frac{1}{2}C^{\alpha\beta}\overleftarrow{Q}_\alpha\overrightarrow{Q}_\beta - \frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\overleftarrow{\bar{Q}}_{\dot{\alpha}}\overrightarrow{\bar{Q}}_{\dot{\beta}}$$

$$+\frac{1}{8}C^{\alpha\beta}C^{\gamma\delta}\overleftarrow{Q}_\alpha\overleftarrow{Q}_\gamma\overrightarrow{Q}_\delta\overrightarrow{Q}_\beta + \frac{1}{8}\bar{C}^{\dot{\alpha}\dot{\beta}}\bar{C}^{\dot{\gamma}\dot{\delta}}\overleftarrow{\bar{Q}}_{\dot{\alpha}}\overleftarrow{\bar{Q}}_{\dot{\gamma}}\overrightarrow{\bar{Q}}_{\dot{\delta}}\overrightarrow{\bar{Q}}_{\dot{\beta}}$$

$$+\frac{1}{4}C^{\alpha\beta}\bar{C}^{\dot{\alpha}\dot{\beta}}(\overleftarrow{\bar{Q}}_{\dot{\alpha}}\overleftarrow{Q}_\alpha\overrightarrow{\bar{Q}}_{\dot{\beta}}\overrightarrow{Q}_\beta - \overleftarrow{Q}_\alpha\overleftarrow{\bar{Q}}_{\dot{\alpha}}\overrightarrow{Q}_\beta\overrightarrow{\bar{Q}}_{\dot{\beta}}).$$

It is straightforward to check that this star product does yield the deformed coordinate algebra of the preceding section, provided we use star products in place of the usual products. We follow the conventions of Wess and Bagger in Ref. 14 for supercharges. In the chiral coordinates $y^m=x^m+i\theta\sigma^m\bar{\theta}$, the supercharges have the following familiar forms. Note that the derivatives of θ^α and $\bar{\theta}^{\dot{\alpha}}$ are taken at fixed y^m:

$$\begin{aligned} Q_\alpha &= \left.\frac{\partial}{\partial\theta^\alpha}\right|_y, \\ \bar{Q}_{\dot{\alpha}} &= -\left.\frac{\partial}{\partial\bar{\theta}^{\dot{\alpha}}}\right|_y + 2i\theta^\alpha\sigma^m_{\alpha\dot{\alpha}}\frac{\partial}{\partial y^m}, \end{aligned} \tag{8}$$

whereas when the derivatives are taken at fixed antichiral coordinates $\bar{y}^m=x^m-i\theta\sigma^m\bar{\theta}$, we have

$$Q_\alpha = \left.\frac{\partial}{\partial\theta^\alpha}\right|_y - 2i\sigma^m_{\alpha\dot{\alpha}}\bar{\theta}^{\dot{\alpha}}\frac{\partial}{\partial\bar{y}^m}, \tag{9}$$

$$\bar{Q}_{\dot{\alpha}} = -\left.\frac{\partial}{\partial \bar{\theta}^{\dot{\alpha}}}\right|_{\bar{y}}.$$

We will not make explicit $|_y$ or $|_{\bar{y}}$ elsewhere, since they are to be understood implicitly. Many other formulas can be found in Ref. 11. Some properties of this star product on functions F, G, and H are

$$\begin{aligned} &\overline{F * G} = \bar{G} * \bar{F}, \qquad (F+G) * H = F * H + G * H, \\ &F * G \neq G * F, \qquad F * (G * H) \neq (F * G) * H. \end{aligned} \tag{10}$$

The noncommutativity and nonassociativity will require some attention in general. However, to the first order in the deformation parameter, we note that

$$F * (G * H) = (F * G) * H, \tag{11}$$

the star product is associative. A proof is given in the Appendix .

C. $N=0$ Supersymmetry

The formulas below are stated for the operators acting on functions of the deformed Minkowki superspace. In particular, they should be understood as statements about how the operators act on star products of functions. We define the star brackets as

$$\{A,B\}_* = A * B + B * A \quad \text{and} \quad [A,B]_* = A * B - B * A. \tag{12}$$

Then calculate

$$\begin{aligned} \{\theta^{\alpha}, \theta^{\beta}\}_* &= \theta^{\alpha} * \theta^{\beta} + \theta^{\beta} * \theta^{\alpha} = C^{\alpha\beta}, \\ \{\bar{\theta}^{\dot{\alpha}}, \bar{\theta}^{\dot{\beta}}\}_* &= \bar{\theta}^{\dot{\alpha}} * \bar{\theta}^{\dot{\beta}} + \bar{\theta}^{\dot{\beta}} * \bar{\theta}^{\dot{\alpha}} = \bar{C}^{\dot{\alpha}\dot{\beta}}. \end{aligned} \tag{13}$$

It is important to note that products of both θ^{α} and $\bar{\theta}^{\dot{\alpha}}$ are deformed. This has the consequence of breaking all of the supersymmetry. Starting with the canonical forms of the supercharges, we obtain

$$\begin{aligned} \{Q_{\alpha}, Q_{\beta}\}_* &= -4\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\sigma^n_{\beta\dot{\beta}}\frac{\partial^2}{\partial \bar{y}^m\, \partial\, \bar{y}^n}, \\ \{\bar{Q}_{\dot{\alpha}}, \bar{Q}_{\dot{\beta}}\}_* &= -4C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}\sigma^n_{\beta\dot{\beta}}\frac{\partial^2}{\partial y^m\, \partial\, y^n}, \\ \{Q_{\alpha}, \bar{Q}_{\dot{\alpha}}\}_* &= 2i\sigma^m_{\alpha\dot{\alpha}}\frac{\partial}{\partial y^m}. \end{aligned} \tag{14}$$

Comparing this to Ref. 8, we note that when $\bar{C}^{\dot{\alpha}\dot{\beta}}=0$, then Q_{α} is an unbroken symmetry, hence the label $N=1/2$ supersymmetry. The author proposes that we call the theory constructed by Carlson and Nazaryan $N=0$ supersymmetry to be consistent. Now, although the supercharges are broken, we still have

$$\{D_{\alpha}, Q_{\beta}\}_* = \{\bar{D}_{\dot{\alpha}}, Q_{\beta}\}_* = \{D_{\alpha}, \bar{Q}_{\dot{\beta}}\}_* = \{\bar{D}_{\dot{\alpha}}, \bar{Q}_{\dot{\beta}}\}_* = 0,$$

$$\{D_\alpha, D_\beta\}_* = \{\bar{D}_{\dot\alpha}, \bar{D}_{\dot\alpha}\}_* = 0. \tag{15}$$

These relations are crucial. We can still define the chiral (Φ) and antichiral ($\bar{\Phi}$) superfields by the constraints $\bar{D}_{\dot\alpha} * \Phi = 0$ and $D_\alpha * \bar{\Phi} = 0$ on noncommutative Minkowski superspace. Thus, most of the usual techniques in Wess and Bagger, Ref. 14, still apply for our discussion. The primary difference is that products will be replaced with star products.

II. VECTOR SUPERFIELDS

Our goal in this section is to construct a non-Abelian gauge theory on deformed Minkowski superspace. Thus, we consider a vector superfield V that carries some matrix representation of the gauge group and is subject to the usual covariant constraint: $\bar{V} = V$. In the standard super-Yang–Mills theory, it is convenient to use a reduced set of component fields called the Wess Zumino gauge. We will show in Section III A that the Wess Zumino gauge can be generalized to the current discussion provided we make some C-dependent shifts. But, for now, we let V take the canonical Wess–Zumino parametrization

$$V = -\theta\sigma^m\bar{\theta}v_m + i\theta\theta\bar{\theta}\bar{\lambda} - i\bar{\theta}\bar{\theta}\theta\lambda + \frac{1}{2}\theta\theta\bar{\theta}\bar{\theta}(D - i\,\partial_m v^m), \tag{16}$$

where the above is in chiral coordinates y^m. Physically this is not quite the correct parametrization because it does not naturally embed the usual gauge transformations on the component fields. Later we will find the parametrization that allows for standard deformation-independent gauge transformations on the component fields. We abstain from introducing that reparametrization at this point because it would only serve to complicate the expressions without need.

A. Star exponential of vector superfield

We define the star exponential of the vector superfield in the natural way:

$$e^V = 1 + V + \frac{1}{2}V * V + \frac{1}{3!}V * V * V + \cdots . \tag{17}$$

Our notation for the usual exponential will be $\exp(V)$ and powers are to be understood as ordinary powers—for example, $V^2 = VV$. In this paper, star products will be explicitly indicated.

The vector superfield is even, thus no new signs arise from pushing the Q_α or $\bar{Q}_{\dot\alpha}$ past V in the star product. Thus,

$$\begin{aligned} V * V &= V(1+S)V \\ &= V^2 - \frac{1}{2}C^{\alpha\beta}(Q_\alpha V)(Q_\beta V) - \frac{1}{2}\bar{C}^{\dot\alpha\dot\beta}(\bar{Q}_{\dot\alpha}V)(\bar{Q}_{\dot\beta}V) \\ &\quad + \frac{1}{8}C^{\alpha\beta}C^{\gamma\delta}(Q_\alpha Q_\gamma V)(Q_\delta Q_\beta V) + \frac{1}{8}\bar{C}^{\dot\alpha\dot\beta}\bar{C}^{\dot\gamma\dot\delta}(\bar{Q}_{\dot\alpha}\bar{Q}_{\dot\gamma}V)(\bar{Q}_{\dot\delta}\bar{Q}_{\dot\beta}V) \\ &\quad + \frac{1}{4}C^{\alpha\beta}\bar{C}^{\dot\alpha\dot\beta}((\bar{Q}_{\dot\alpha}Q_\alpha V)(\bar{Q}_{\dot\beta}Q_\beta V) - (Q_\alpha\bar{Q}_{\dot\alpha}V)(Q_\beta\bar{Q}_{\dot\beta}V)). \end{aligned}$$

We will now calculate these terms in chiral coordinates, starting with

$$\begin{aligned} Q_\alpha V &= \partial_\alpha\left(-\theta\sigma^m\bar{\theta}v_m + i\theta\theta\bar{\theta}\bar{\lambda} - i\bar{\theta}\bar{\theta}\theta\lambda + \frac{1}{2}\theta\theta\bar{\theta}\bar{\theta}(D - i\partial_m v^m)\right) \\ &= -\sigma^m_{\alpha\dot\alpha}\bar{\theta}^{\dot\alpha}v_m + 2i\theta_\alpha\bar{\theta}\bar{\lambda} + \bar{\theta}\bar{\theta}(-i\lambda_\alpha + \theta_\alpha(D - i\partial_m v^m)). \end{aligned} \tag{18}$$

Continuing, we find that

$$Q_\beta Q_\alpha V = \partial_\beta(-\sigma^m_{\alpha\dot\alpha}\bar\theta^{\dot\alpha}v_m + 2i\theta_\alpha\bar\theta\bar\lambda + \bar\theta\bar\theta(-i\lambda_\alpha + \theta_\alpha(D - i\partial_m v^m))) = -2i\epsilon_{\beta\alpha}\bar\theta\bar\lambda - \epsilon_{\beta\alpha}\bar\theta\bar\theta(D - i\partial_m v^m). \tag{19}$$

Next, we calculate $\bar Q_{\dot\alpha}V$,

$$\begin{aligned}\bar Q_{\dot\alpha}V &= (-\partial_{\dot\alpha} + 2i\theta^\alpha\sigma^n_{\alpha\dot\alpha}\partial_n)\left(-\theta\sigma^m\bar\theta v_m + i\theta\theta\bar\theta\bar\lambda - i\bar\theta\bar\theta\theta\lambda + \frac{1}{2}\theta\theta\bar\theta\bar\theta(D - i\,\partial_m v^m)\right)\\ &= -\theta^\alpha\sigma^m_{\alpha\dot\alpha}v_m + (-2i\bar\theta_{\dot\alpha} + 2\bar\theta\bar\theta\sigma^m_{\alpha\dot\alpha}\theta^\alpha\partial_m)\theta\lambda + \theta\theta\\ &\quad\times\left(i\bar\lambda_{\dot\alpha} + \bar\theta_{\dot\alpha}(D - i\partial_m v^m) + i\epsilon^{\alpha\beta}\sigma^m_{\alpha\dot\alpha}\sigma^n_{\beta\dot\beta}\bar\theta^{\dot\beta}\,\partial_m v_n\right).\end{aligned} \tag{20}$$

The next calculation is a bit longer.

$$\begin{aligned}\bar Q_{\dot\alpha}\bar Q_{\dot\beta}V &= (-\partial_{\dot\alpha} + 2i\theta^\alpha\sigma^m_{\alpha\dot\alpha}\partial_m)(\bar Q_{\dot\beta}V) = -2i\epsilon_{\dot\alpha\dot\beta}\theta\lambda + \theta\theta(\epsilon_{\dot\alpha\dot\beta}(D - i\partial_m v^m)\\ &\quad + i\epsilon^{\alpha\beta}(\sigma^m_{\alpha\dot\beta}\sigma^n_{\beta\dot\alpha} - \sigma^m_{\alpha\dot\alpha}\sigma^n_{\beta\dot\beta})\partial_m v_n + 2(\sigma^m_{\alpha\dot\alpha}\bar\theta^{\dot\beta} - \bar\theta^{\dot\alpha}\sigma^m_{\alpha\dot\beta})\partial_m\lambda^\alpha).\end{aligned} \tag{21}$$

Now, for the mixed supercharges, using the previous results, we find that

$$\begin{aligned}Q_\alpha\bar Q_{\dot\alpha}V &= \partial_\alpha(\bar Q_{\dot\alpha}V) = -\sigma^m_{\alpha\dot\alpha}v_m + 2i(\theta_\alpha\bar\lambda_{\dot\alpha} - \bar\theta_{\dot\alpha}\lambda_\alpha) + \theta_\alpha(2\bar\theta_{\dot\alpha}(D - i\partial_m v^m)\\ &\quad + 2i\bar\theta^{\dot\beta}\epsilon^{\sigma\beta}\sigma^m_{\sigma\dot\alpha}\sigma^n_{\beta\dot\beta}\partial_m v_n + 2\bar\theta\bar\theta\sigma^m_{\beta\dot\alpha}\partial_m\lambda^\beta).\end{aligned} \tag{22}$$

Similarly, we find that

$$\begin{aligned}\bar Q_{\dot\alpha}Q_\alpha V &= (-\partial_{\dot\beta} + 2i\theta^\alpha\sigma^m_{\alpha\dot\alpha}\partial_m)(Q_\alpha V)\\ &= \sigma^m_{\alpha\dot\alpha}v_m - 2i(\theta_\alpha\bar\lambda_{\dot\alpha} - \bar\theta_{\dot\alpha}\lambda_\alpha) + 2\theta_\alpha\bar\theta_{\dot\alpha}(D - i\,\partial_m v^m) - 2i\theta^\beta\bar\theta^{\dot\beta}\,\sigma^m_{\beta\dot\alpha}\sigma^n_{\alpha\dot\beta}\,\partial_m v_n\\ &\quad - 2\theta\theta\sigma^m_{\alpha\dot\alpha}\partial_m(\bar\theta\bar\lambda) + \bar\theta\bar\theta(2\theta^\beta\sigma^m_{\beta\dot\alpha}\,\partial_m\lambda_\alpha + i\theta\theta\sigma^m_{\alpha\dot\alpha}\partial_m(D - i\,\partial_m v^m)).\end{aligned} \tag{23}$$

The next task is to calculate the products of the terms above. In the product below, we have omitted from the beginning those terms with $\bar\theta\bar\theta$ because there is a $\bar\theta$ in each term.

$$\begin{aligned}\frac{1}{2}C^{\alpha\beta}Q_\alpha V Q_\beta V &= \frac{1}{2}C^{\alpha\beta}(-\sigma^m_{\alpha\dot\alpha}\bar\theta^{\dot\alpha}v_m + 2i\theta_\alpha(\bar\theta\bar\lambda))(-\sigma^n_{\beta\dot\beta}\bar\theta^{\dot\beta}v_n + 2i\theta_\beta(\bar\theta\bar\lambda))\\ &= \frac{1}{4}C^{\alpha\beta}\epsilon^{\dot\alpha\dot\beta}\sigma^m_{\alpha\dot\alpha}\sigma^n_{\beta\dot\beta}v_m v_n\bar\theta\bar\theta + \frac{i}{2}C^{\alpha\beta}\theta_\beta\sigma^m_{\alpha\dot\alpha}[v_m,\bar\lambda^{\dot\alpha}]\bar\theta\bar\theta\\ &= \left(\frac{1}{2}C^{mn}v_m v_n - \frac{i}{2}C^{\alpha\beta}\sigma^m_{\alpha\dot\alpha}\theta_\beta[v_m,\bar\lambda^{\dot\alpha}]\right)\bar\theta\bar\theta,\end{aligned} \tag{24}$$

where we have used the identity $C^{mn} = 1/2\,C^{\alpha\beta}\epsilon^{\dot\alpha\dot\beta}\sigma^m_{\alpha\dot\alpha}\sigma^n_{\beta\dot\beta}$, following the conventions of Ref. 8. Continuing to compute the products, since every term has a θ this time, we can ignore the $\theta\theta$ terms from the outset:

$$\frac{1}{2}\bar{C}^{\alpha\dot{\beta}}\bar{Q}_{\dot{\alpha}}V\bar{Q}_{\dot{\beta}}V=\frac{1}{2}\bar{C}^{\alpha\dot{\beta}}(-\theta^{\alpha}\sigma^{m}_{\alpha\dot{\alpha}}v_m-2i\bar{\theta}_{\dot{\alpha}}\theta\lambda)(-\theta^{\beta}\sigma^{n}_{\beta\dot{\beta}}v_n-2i\bar{\theta}_{\dot{\beta}}\theta\lambda)$$

$$=-\frac{1}{4}\bar{C}^{\alpha\dot{\beta}}\epsilon^{\beta\alpha}\sigma^{m}_{\alpha\dot{\beta}}\sigma^{n}_{\beta\dot{\alpha}}v_mv_n\theta\theta-\frac{i}{2}\bar{C}^{\alpha\dot{\beta}}\bar{\theta}_{\dot{\beta}}\sigma^{m}_{\alpha\dot{\alpha}}[v_m,\lambda^{\alpha}]\theta\theta$$

$$=\left(\frac{1}{2}\bar{C}^{mn}v_mv_n+\frac{i}{2}\bar{C}^{\alpha\dot{\beta}}\sigma^{m}_{\alpha\dot{\alpha}}\bar{\theta}_{\dot{\beta}}[v_m,\lambda^{\alpha}]\right)\theta\theta, \tag{25}$$

where we identified $\bar{C}^{mn}=-1/2\,\bar{C}^{\alpha\dot{\beta}}\epsilon^{\alpha\beta}\sigma^{m}_{\alpha\dot{\alpha}}\sigma^{n}_{\beta\dot{\beta}}$ following Ref. 11. Next, consider the second order in deformation parameter terms:

$$\frac{1}{8}C^{\alpha\beta}C^{\gamma\delta}(Q_{\alpha}Q_{\gamma}V)(Q_{\delta}Q_{\beta}V)=\frac{1}{8}C^{\alpha\beta}C^{\gamma\delta}\epsilon_{\alpha\gamma}\epsilon_{\beta\delta}(2i\bar{\theta}\bar{\lambda}+\bar{\theta}\bar{\theta}(D-i\,\partial_mv^m))^2$$

$$=-\frac{1}{8}|C|^2\bar{\lambda}\bar{\lambda}\bar{\theta}\bar{\theta},$$

where we use $|C|^2=4C^{\alpha\beta}C^{\gamma\delta}\epsilon_{\alpha\gamma}\epsilon_{\delta\beta}$. Similarly, we find that the next term is easily calculated due to a sizable cancellation, since we may omit a $\theta\theta$ term from the start:

$$\frac{1}{8}\bar{C}^{\dot{\alpha}\beta}\bar{C}^{\dot{\gamma}\dot{\delta}}(\bar{Q}_{\dot{\alpha}}\bar{Q}_{\dot{\gamma}}V)(\bar{Q}_{\dot{\delta}}\bar{Q}_{\beta}V)=\frac{1}{8}\bar{C}^{\dot{\alpha}\beta}\bar{C}^{\dot{\gamma}\dot{\delta}}\epsilon_{\dot{\alpha}\dot{\gamma}}\epsilon_{\beta\dot{\delta}}(-2i\theta\lambda)^2$$

$$=-\frac{1}{8}|\bar{C}|^2\lambda\lambda\,\theta\theta,$$

where we use $|\bar{C}|^2=4\bar{C}^{\dot{\alpha}\beta}\bar{C}^{\dot{\gamma}\dot{\delta}}\epsilon_{\dot{\alpha}\dot{\gamma}}\epsilon_{\beta\dot{\delta}}$. The remaining term to consider in $V*V$ is $1/4\,C^{\alpha\beta}\bar{C}^{\dot{\alpha}\dot{\beta}}[(\bar{Q}_{\dot{\alpha}}Q_{\alpha}V)(\bar{Q}_{\dot{\beta}}Q_{\beta}V)-(Q_{\alpha}\bar{Q}_{\dot{\alpha}}V)(Q_{\beta}\bar{Q}_{\dot{\beta}}V)]$. We calculate

$$\frac{1}{4}C^{\alpha\beta}\bar{C}^{\dot{\alpha}\dot{\beta}}((\bar{Q}_{\dot{\alpha}}Q_{\alpha}V)(\bar{Q}_{\dot{\beta}}Q_{\beta}V)-(Q_{\alpha}\bar{Q}_{\dot{\alpha}}V)(Q_{\beta}\bar{Q}_{\dot{\beta}}V))$$

$$=\frac{1}{4}C^{\alpha\beta}\bar{C}^{\dot{\alpha}\dot{\beta}}(\sigma^{m}_{\alpha\dot{\alpha}}\{v_m,4i(\bar{\theta}^{\dot{\beta}}\lambda_{\beta}-\theta^{\beta}\bar{\lambda}_{\dot{\beta}})\}-2i\sigma^{m}_{\alpha\dot{\alpha}}\{v_m,\partial_lv_k(\theta^{\gamma}\sigma^{l}_{\gamma\dot{\beta}}\sigma^{k}_{\beta\dot{\gamma}}\bar{\theta}^{\dot{\gamma}}+\theta^{\beta}\epsilon^{\sigma\gamma}\sigma^{l}_{\delta\dot{\beta}}\sigma^{k}_{\gamma\dot{\gamma}}\bar{\theta}^{\dot{\gamma}})\}$$

$$+2\sigma^{m}_{\alpha\dot{\alpha}}\bar{\theta}\bar{\theta}\sigma^{l}_{\gamma\dot{\beta}}\{v_m,\theta^{\gamma}\,\partial_l\lambda_{\beta}-\theta^{\beta}\,\partial_l\lambda^{\gamma}\}-2\sigma^{m}_{\alpha\dot{\alpha}}\theta\theta\sigma^{l}_{\beta\dot{\beta}}\{v_m,\partial_l(\bar{\theta}\bar{\lambda})\}+i\sigma^{m}_{\alpha\dot{\alpha}}\theta\theta\bar{\theta}\bar{\theta}\sigma^{l}_{\beta\dot{\beta}}\{v_m,\partial_l(D$$

$$-i\partial_mv^m)\}-4\theta_{\alpha}\theta^{\gamma}\sigma^{m}_{\gamma\dot{\beta}}\sigma^{n}_{\beta\dot{\gamma}}\bar{\theta}^{\dot{\gamma}}\{\bar{\lambda}_{\dot{\alpha}},\partial_mv_n\}+4\bar{\theta}_{\dot{\alpha}}\theta^{\gamma}\sigma^{m}_{\gamma\dot{\beta}}\sigma^{n}_{\beta\dot{\gamma}}\bar{\theta}^{\dot{\gamma}}\{\lambda_{\alpha},\partial_mv_n\}+4i\theta_{\alpha}\bar{\theta}\bar{\theta}\theta^{\gamma}\sigma^{m}_{\gamma\dot{\beta}}\{\bar{\lambda}_{\dot{\alpha}},\partial_m\lambda_{\beta}\}$$

$$+4i\theta_{\alpha}\theta\theta\theta^{\gamma}\sigma^{m}_{\beta\dot{\beta}}\{\lambda_{\alpha},\partial_m\bar{\lambda}_{\dot{\gamma}}\}-4i\theta_{\alpha}\bar{\theta}_{\dot{\alpha}}\theta^{\gamma}\sigma^{m}_{\gamma\dot{\beta}}\sigma^{n}_{\beta\dot{\gamma}}\bar{\theta}^{\dot{\gamma}}\{(D-i\,\partial_mv^m),\partial_mv_n\}$$

$$-4\theta^{\gamma}\bar{\theta}^{\dot{\gamma}}\theta^{\sigma}\bar{\theta}^{\dot{\sigma}}\sigma^{k}_{\gamma\dot{\sigma}}\sigma^{l}_{\alpha\dot{\gamma}}\sigma^{m}_{\sigma\dot{\beta}}\sigma^{n}_{\beta\dot{\sigma}}\partial_kv_l\partial_mv_n). \tag{26}$$

We can see from the expression above the full second-order calculations will be lengthy. Additionally, we would have to deal with the nonassociativity of the star product. At present, the author has only calculated portions of the theory to the second order, mostly for the purpose of comparing the present work with Ref. 8. We leave the complete development of the second-order deformed gauge theory to a later paper.

We shall now find the correction to $V*V*V$ to the first order in $C^{\alpha\beta}$. First, recall first that in the commutative theory, V^3 is zero in the Wess–Zumino gauge. Thus, any nontrivial term in $V*V*V$ must arise from the deformation

$$V*(V*V)=V(V*V)-\frac{1}{2}C^{\alpha\beta}(Q_\alpha V)Q_\beta(V*V)-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}(\bar{Q}_{\dot{\alpha}}V)\bar{Q}_{\dot{\beta}}(V*V). \tag{27}$$

We can replace $V*V$ with V^2 as we are looking for the first order in $C^{\alpha\beta}$ terms:

$$V*(V*V)=V(V*V)-\frac{1}{2}C^{\alpha\beta}(Q_\alpha V)Q_\beta(V^2)-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}(\bar{Q}_{\dot{\alpha}}V)\bar{Q}_{\dot{\beta}}(V^2)=V(V*V). \tag{28}$$

The two terms vanish because $Q_\alpha V$ and $\bar{Q}_{\dot{\alpha}}V$ have a $\bar{\theta}$ and θ in each term, respectively, while $Q_\beta(V^2)$ and $\bar{Q}_{\dot{\beta}}(V^2)$ are proportional to $\bar{\theta}\bar{\theta}$ and $\theta\theta$, respectively. To the first order, we have

$$V*(V*V)=\left(-\theta\sigma^m\bar{\theta}v_m+i\theta\theta\bar{\theta}\bar{\lambda}-i\bar{\theta}\bar{\theta}\theta\lambda+\frac{1}{2}\theta\theta\bar{\theta}\bar{\theta}(D-i\,\partial_m v^m)\right)(V*V). \tag{29}$$

Now, if we examine the first-order terms in $V*V$, we notice that each term either has $\theta\theta$ or $\bar{\theta}\bar{\theta}$; thus, the product with V that is proportional to θ and $\bar{\theta}$ vanishes. Therefore, to the first order in the deformation parameter,

$$V*(V*V)=0. \tag{30}$$

It is not hard to see that this extends to higher star products. Thus, $(V)_*^n=0$ for $n\geqslant 3$ to the first order in the deformation parameter. That is, to the first order in C, we have $e^V=1+V+1/2\,V*V$. This is nice but it will clearly be spoiled if we include the second-order terms. For example, if one examines the mixed second-order term, Eq. (26), the first few lines have only θ or $\bar{\theta}$. Hence, in the product with V they will not vanish like the first-order case, thus generating a nontrivial term in $V*(V*V)$. We will not complete the development of e^V to the second order in this paper. Next, we shall show that in the limit of $\bar{C}^{\dot{\alpha}\dot{\beta}}=0$, we recover the terms found by Seiberg in Ref. 8.

Collecting the results of this section, we find that the star exponential of V in the canonical Wess–Zumino gauge is

$$\begin{aligned}e^V=1+V+\frac{1}{2}V*V=1&-\theta\sigma^m\bar{\theta}v_m+i\theta\theta\bar{\theta}\bar{\lambda}-i\bar{\theta}\bar{\theta}\theta^\alpha\lambda_\alpha+\frac{1}{2}\theta\theta\bar{\theta}\bar{\theta}(D-i\,\partial_m v^m)\\&-\left(\frac{1}{4}C^{mn}v_m v_n+\frac{i}{4}C^{\alpha\beta}\theta_\beta\sigma^m_{\alpha\dot{\alpha}}[\bar{\lambda}^{\dot{\alpha}},v_m]\right)\bar{\theta}\bar{\theta}-\left(\frac{1}{4}\bar{C}^{mn}v_m v_n+\frac{i}{4}\bar{C}^{\dot{\alpha}\dot{\beta}}\bar{\theta}_{\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}[v_m,\lambda^\alpha]\right)\theta\theta\\&-\frac{1}{16}|C|^2\bar{\lambda}\bar{\lambda}\bar{\theta}\bar{\theta}-\frac{1}{16}|\bar{C}|^2\lambda\lambda\theta\theta+\textit{other second-order terms containing }\bar{C}^{\dot{\alpha}\dot{\beta}}.\end{aligned} \tag{31}$$

B. $N=0$ verses $N=1/2$ star exponentials

To compare with the $N=1/2$ construction, we make the following dictionary:

$$\begin{aligned}m&\mapsto\mu\\v_m&\mapsto A_\mu\\\bar{\lambda}_{\dot{\alpha}}&\mapsto\bar{\lambda}_{\dot{\alpha}}\\\lambda_\alpha&\mapsto\lambda_\alpha+\frac{1}{4}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^\mu_{\gamma\dot{\gamma}}\{\bar{\lambda}^{\dot{\gamma}},A_\mu\}\end{aligned} \tag{32}$$

$$(D - i\,\partial_m v^m) \mapsto D - i\,\partial_\mu A^\mu.$$

We use Greek indices for Euclidean spacetime and Latin indices for Minkowski spacetime. In Ref. 8, only products of θ were deformed. It is clear that we can recover this deformation by setting $\bar{C}^{\dot{\alpha}\dot{\beta}}$ to zero wherever it occurs. Using the dictionary and setting $\bar{C}^{\dot{\alpha}\dot{\beta}}=0$, we have

$$\begin{aligned} e^V &= 1 + V + \frac{1}{2} V * V \\ &= 1 - \theta\sigma^\mu\bar{\theta}A_\mu + i\theta\theta\bar{\theta}\bar{\lambda} - i\bar{\theta}\bar{\theta}\theta^\alpha\left(\lambda_\alpha + \frac{1}{4}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^\mu_{\gamma\dot{\gamma}}\{\bar{\lambda}^{\dot{\gamma}}, A_\mu\}\right) \\ &\quad + \frac{1}{2}\theta\theta\bar{\theta}\bar{\theta}(D - i\,\partial_\mu A^\mu) - \frac{1}{4}C^{\mu\nu}A_\mu A_\nu\bar{\theta}\bar{\theta} - \frac{i}{4}C^{\alpha\beta}\theta_\beta\sigma^\mu_{\alpha\dot{\alpha}}[A_\mu, \bar{\lambda}^{\dot{\alpha}}]\bar{\theta}\bar{\theta} - \frac{1}{16}|C|^2\bar{\lambda}\bar{\lambda}\bar{\theta}\bar{\theta}. \end{aligned} \tag{33}$$

This is precisely the exponential that Seiberg found on noncommutative Euclidean superspace in Ref. 8. This demonstrates again that the deformed Minkowski superspace of Ref. 11 truly is a natural extension of the $N=1/2$ theory to the Minkowski case.

III. GAUGE THEORY ON $N=0$ MINKOWSKI SUPERSPACE

In this section, we generalize super Yang–Mills theory to deformed Minkowski superspace. Most of the usual constructions hold and the approach is similar to Seiberg's $N=1/2$ super-Yang Mills theory in Ref. 8. We simply replace products in Ref. 14 with star products. The main subtlety is finding the correct parametrization of the vector superfield.

A. Gauge transformations

Our goal is to find a way to embed the usual C-independent gauge transformations into superfield equations on noncommutative Minkowski superspace. Since our spinors are built on Minkowski space, we are forced to relate θ and $\bar{\theta}$ by conjugation. This means that we cannot directly follow the construction of Ref. 8. In Ref. 8, we can see that $\overline{\theta^\alpha} \neq \bar{\theta}^{\dot{\alpha}}$, $\bar{V} \neq V$, and $\overline{\Lambda + \bar{\Lambda}} \neq \Lambda + \bar{\Lambda}$. These relations are sensible for Seiberg, who wrote them in a Euclidean superspace. On Minkowski space, these inequalities must become equalities. We will find that these reality conditions and the requirement that we recover $N=1/2$ theory in the $\bar{C}^{\dot{\alpha}\dot{\beta}}=0$ limit almost uniquely fixes this construction.

Non-Abelian gauge transformations on the vector superfield are embedded into the following superfield equation on noncommutative Minkowski superspace:

$$e^V \mapsto e^{V\prime} = e^{-i\bar{\Lambda}} * e^V * e^{i\Lambda}. \tag{34}$$

This is the natural modification of the standard theory (see Ref. 14, for example). Infinitesimally, we have

$$\delta e^V = -i\bar{\Lambda} * e^V + i e^V * \Lambda. \tag{35}$$

The component fields of the vector superfield should transform in the adjoint representation of the gauge group as in the standard gauge theory. That is, under an infinitesimal gauge transformation, we should have

$$\begin{aligned} \delta v_m &= -2\,\partial_m\phi + i[\phi, v_m], \\ \delta\lambda_\alpha &= i[\phi, \lambda_\alpha], \end{aligned} \tag{36}$$

$$\delta D = i[\phi, D].$$

Our goal now is to find a suitable parametrization of the gauge parameter Λ and the vector superfield V such that Eq. (36) is embedded into Eq. (35). It is not surprising that the canonical Wess–Zumino gauge [Eq. (31)] does not work in the $N=0$ case, since it was also necessary for Ref. 8 to shift the λ component in the $N=1/2$ case. The reality of V requires that we cannot shift only λ; we must also shift $\bar{\lambda}$. To be precise, $\lambda \mapsto \lambda + A$ and $\bar{\lambda} \mapsto \bar{\lambda} + B$. We now determine what choice of A and B will preserve the reality of V while concurrently embedding Eq. (36). To the first order in C, we find under the above redefinitions that Eq. (31) becomes

$$e^V = 1 - \theta\sigma^m\bar{\theta}v_m - \frac{1}{4}\bar{C}^{mn}v_m v_n\theta\theta + \frac{1}{4}C^{mn}v_m v_n\bar{\theta}\bar{\theta} + \frac{1}{2}(D - i\,\partial_m v^m)\theta\theta\bar{\theta}\bar{\theta}$$
$$+ \bar{\theta}\bar{\theta}\theta^\alpha\left(-i\lambda_\alpha - iA + \frac{i}{4}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot{\alpha}}[v_m, \bar{\lambda}^{\dot{\alpha}}]\right) + \theta\theta\bar{\theta}^{\dot{\alpha}}\left(-i\bar{\lambda}_{\dot{\alpha}} - iB - \frac{i}{4}\epsilon_{\dot{\alpha}\dot{\beta}}\bar{C}^{\dot{\beta}\dot{\gamma}}\sigma^m_{\alpha\dot{\gamma}}[v_m, \lambda^\alpha]\right). \tag{37}$$

Additionally, we make a C-dependent shift of the gauge parameter Λ similar to that of Ref. 8. For the moment, let us make a reasonably general ansatz for the gauge parameter in terms of a variable p:

$$\Lambda_p = -\phi + ip\,\theta\sigma^m\bar{\theta}\,\partial_m\phi + \frac{i}{2}\theta\theta\bar{C}^{mn}\{v_n, \partial_m\phi\} - (p+1)\,\theta\theta\bar{\theta}\bar{\theta}\,\partial^2\phi$$
$$\bar{\Lambda}_p = -\phi + i(2-p)\,\theta\sigma^m\bar{\theta}\,\partial_m\phi - \frac{i}{2}\bar{\theta}\bar{\theta}C^{mn}\{\partial_m\phi, v_n\} - (p+1)\,\theta\theta\bar{\theta}\bar{\theta}\,\partial^2\phi, \tag{38}$$

where everything is a function of y in the above. Notice that modulo the higher θ components in Λ, this reduces to the choice of gauge parameter in Ref. 8 when $p=0$. We now determine which choice of p will embed Eq. (36) in Eq. (35). We calculate that the $\bar{\theta}\bar{\theta}\theta^\alpha$ term on the rhs of Eq. (35) is

$$[\phi, \lambda_\alpha] + [\phi, A] - \frac{1}{4}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot{\alpha}}([\phi, [\bar{\lambda}^{\dot{\alpha}}, v_m]] - 2i(p\bar{\lambda}^{\dot{\alpha}}\,\partial_m\phi + (2-p)\partial_m\phi\,\bar{\lambda}^{\dot{\alpha}})). \tag{39}$$

Similarly, the $\theta\theta\bar{\theta}^{\dot{\alpha}}$ term on the rhs of Eq. (35) is

$$[\phi, \bar{\lambda}_{\dot{\alpha}}] + [\phi, B] + \frac{1}{4}\bar{\epsilon}_{\dot{\alpha}\dot{\beta}}\bar{C}^{\dot{\beta}\dot{\gamma}}\sigma^m_{\alpha\dot{\gamma}}([\phi, [\lambda^\alpha, v_m]] + 2i(p\lambda^\alpha\,\partial_m\phi + (2-p)\partial_m\phi\lambda^\alpha)). \tag{40}$$

The $\bar{\theta}\bar{\theta}\theta^\alpha$ component of the lhs of Eq. (35) is

$$-i\,\delta\lambda_\alpha - i\,\delta A + \frac{i}{4}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot{\alpha}}\delta[\bar{\lambda}^{\dot{\alpha}}, v_m]. \tag{41}$$

Similarly, the $\theta\theta\bar{\theta}^{\dot{\alpha}}$ component of the lhs of Eq. (35) is

$$-i\,\delta\bar{\lambda}_{\dot{\alpha}} - i\,\delta B - \frac{i}{4}\bar{\epsilon}_{\dot{\alpha}\dot{\beta}}\bar{C}^{\dot{\beta}\dot{\gamma}}\sigma^m_{\alpha\dot{\gamma}}\delta[\lambda^\alpha, v_m]. \tag{42}$$

It is not difficult to show [applying Eq. (36)] that

$$i\delta[\lambda^\alpha, v_m] + [\phi, [\lambda^\alpha, v_m]] = -2i[\lambda^\alpha, \partial_m\phi],$$
$$i\delta[\bar{\lambda}^{\dot{\alpha}}, v_m] + [\phi, [\bar{\lambda}^{\dot{\alpha}}, v_m]] = 2i[\bar{\lambda}^{\dot{\alpha}}, \partial_m\phi],$$
$$i\delta\{\bar{\lambda}^{\dot{\alpha}}, v_m\} + [\phi, \{\bar{\lambda}^{\dot{\alpha}}, v_m\}] = 2i\{\bar{\lambda}^{\dot{\alpha}}, \partial_m\phi\}, \tag{43}$$

$$i\delta(v_m\lambda^\alpha)+[\phi,v_m\lambda^\alpha]=2i\partial_m\phi\lambda^\alpha,$$
$$i\delta(\bar\lambda^{\dot\alpha}v_m)+[\phi,\bar\lambda^{\dot\alpha}v_m]=2i\bar\lambda^{\dot\alpha}\partial_m\phi.$$

Next, equate Eq. (41) and Eq. (39). Then require that $\delta\lambda^\alpha=i[\phi,\lambda^\alpha]$ so that Eq. (43) holds. Some terms cancel and we find that

$$-i\,\delta A-[\phi,A]=\frac{i}{2}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot\alpha}((p+1)\bar\lambda^{\dot\alpha}\partial_m\phi+(1-p)\partial_m\phi\,\bar\lambda^{\dot\alpha}). \tag{44}$$

Likewise, equate Eq. (42) and Eq. (40). Then require that $\delta\bar\lambda^{\dot\alpha}=i[\phi,\bar\lambda^{\dot\alpha}]$ so that Eq. (43) holds. Some terms cancel, and we find that

$$-i\,\delta B-[\phi,B]=\frac{i}{2}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot\alpha}((p-1)\lambda^\alpha\,\partial_m\phi+(3-p)\partial_m\phi\,\lambda^\alpha). \tag{45}$$

When $p=0$, we find that Eq. (44) becomes

$$-i\,\delta A-[\phi,A]=\frac{i}{2}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot\alpha}\{\bar\lambda^{\dot\alpha},\partial_m\phi\}. \tag{46}$$

Hence, in view of Eq. (43), we can see why Ref. 8 shifted the λ_α component of the vector multiplet by $A=1/4\,\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot\alpha}\{\bar\lambda^{\dot\alpha},v_m\}$. If we tried to use this choice of gauge parameter, we would destroy the reality of V because Eq. (45) would lead us to choose $B=1/4\,\bar\epsilon_{\dot\alpha\dot\beta}\bar C^{\dot\beta\dot\gamma}\sigma^m_{\alpha\dot\gamma}$ $(-\lambda^\alpha v_m+3v_m\lambda^\alpha)$. The correct choice is $p=1$. With this choice of gauge parameter, we find the following conditions for A and B from Eq. (44) and Eq. (45):

$$\begin{aligned}-i\,\delta A-[\phi,A]&=i\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot\alpha}\bar\lambda^{\dot\alpha}\,\partial_m\phi\\ -i\,\delta B-[\phi,B]&=i\bar\epsilon_{\dot\alpha\dot\beta}\bar C^{\dot\beta\dot\gamma}\sigma^m_{\alpha\dot\gamma}\,\partial_m\phi\,\lambda^\alpha.\end{aligned} \tag{47}$$

These conditions are satisfied by

$$\begin{aligned}A&=\frac{1}{2}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot\alpha}\bar\lambda^{\dot\alpha}v_m\\ B&=\frac{1}{2}\bar\epsilon_{\dot\alpha\dot\beta}\bar C^{\dot\beta\dot\gamma}\sigma^m_{\alpha\dot\gamma}v_m\lambda^\alpha.\end{aligned} \tag{48}$$

It is easy to see that $\bar A=B$ and $\bar B=A$, which is necessary in order to preserve $\bar V=V$. This is the only parametrization of the vector superfield and gauge parameter for noncommutative Minkowski superspace if we wish to stay in a generalized Wess Zumino gauge. In principle, we could use the other lower θ components of the vector superfield to do more complicated shifts. Fortunately, we will not need to do that. Define the vector superfield to be

$$\begin{aligned}V(y)=&-\theta\sigma^m\bar\theta v_m+\theta\theta\bar\theta^{\dot\alpha}\left(-i\bar\lambda_{\dot\alpha}+\frac{i}{2}\bar\epsilon_{\dot\alpha\dot\beta}\bar C^{\dot\beta\dot\gamma}\sigma^m_{\alpha\dot\gamma}v_m\lambda^\alpha\right)+\bar\theta\bar\theta\theta^\alpha\left(-i\lambda_\alpha-\frac{i}{2}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot\alpha}\bar\lambda^{\dot\alpha}v_m\right)\\ &+\frac{1}{2}\theta\theta\bar\theta\bar\theta(D-i\,\partial_m v^m).\end{aligned} \tag{49}$$

It should be evident from the calculations in this section that this parametrization of V embeds Eq. (36) in Eq. (35) while maintaining the reality of V. This, of course, requires that we define the gauge parameters as functions of y to be

$$\Lambda(y) = -\phi + i\theta\sigma^m\bar{\theta}\,\partial_m\phi + \frac{i}{2}\theta\theta\bar{C}^{mn}\{v_n,\partial_m\phi\} - 2\theta\theta\bar{\theta}\bar{\theta}\,\partial^2\phi$$

$$\bar{\Lambda}(y) = -\phi + i\theta\sigma^m\bar{\theta}\,\partial_m\phi - \frac{i}{2}\bar{\theta}\bar{\theta}C^{mn}\{\partial_m\phi,v_n\} - 2\theta\theta\bar{\theta}\bar{\theta}\,\partial^2\phi. \tag{50}$$

For the remainder of this paper, we will assume that the vector superfield is parametrized as in Eq. (49) and that the gauge parameter is parametrized as in Eq. (50). Explicitly in this parametrization, to the first order in C, Eq. (31) becomes

$$e^V = 1 - \theta\sigma^m\bar{\theta}v_m - \frac{1}{4}\bar{C}^{mn}v_mv_n\theta\theta + \frac{1}{4}C^{mn}v_mv_n\bar{\theta}\bar{\theta} + \frac{1}{2}(D - i\,\partial_m v^m)\,\theta\theta\bar{\theta}\bar{\theta}$$
$$+ \bar{\theta}\bar{\theta}\theta^\alpha\left(-i\lambda_\alpha - \frac{i}{4}\epsilon_{\alpha\beta}C^{\beta\gamma}\sigma^m_{\gamma\dot{\alpha}}\{\bar{\lambda}^{\dot{\alpha}},v_m\}\right) + \theta\theta\bar{\theta}^{\dot{\alpha}}\left(-i\bar{\lambda}_{\dot{\alpha}} - \frac{i}{4}\epsilon_{\dot{\alpha}\dot{\beta}}\bar{C}^{\dot{\beta}\dot{\gamma}}\sigma^m_{\alpha\dot{\gamma}}\{\lambda^\alpha,v_m\}\right). \tag{51}$$

The $\bar{\theta}\bar{\theta}\theta^\alpha$ and $\theta\theta\bar{\theta}^{\dot{\alpha}}$ components in the previous equation stand in contrast to what might be naively expected from $N=1/2$ theory.

B. Spinor superfields

Again, we will construct these as in the commutative theory except that everywhere that we had a product in the commutative theory, we place a star product here. Define

$$W_\alpha = -\frac{1}{4}\bar{D}_{\dot{\alpha}} * \bar{D}^{\dot{\alpha}} * e^{-V} * D_\alpha * e^V. \tag{52}$$

Conveniently, in chiral coordinates $y^m = x^m + i\theta\sigma^m\bar{\theta}$, several of the star products in the above are ordinary products. Thus,

$$W_\alpha = -\frac{1}{4}\bar{D}_{\dot{\alpha}}\bar{D}^{\dot{\alpha}}e^{-V} * D^\alpha * e^V. \tag{53}$$

Likewise, define

$$\bar{W}_{\dot{\alpha}} = -\frac{1}{4}D^\alpha * D_\alpha * e^{-V} * \bar{D}_{\dot{\alpha}} * e^V. \tag{54}$$

Similarly, in antichiral coordinates $\bar{y}^m = x^m - i\theta\sigma^m\bar{\theta}$, the above simplifies to

$$\bar{W}_{\dot{\alpha}} = -\frac{1}{4}D^\alpha D_\alpha e^{-V} * \bar{D}_{\dot{\alpha}} * e^V. \tag{55}$$

We must determine the component field content of W_α and $\bar{W}_{\dot{\alpha}}$. Referring to Eq. (51) and keeping only up to the first order in C, we obtain

$$W_\alpha = W_\alpha(C=0) + \theta\theta\left(\frac{1}{2}\bar{C}^{mn}\{F_{mn},\lambda_\alpha\} + \bar{C}^{mn}\left\{v_n,\mathcal{D}_m\lambda_\alpha - \frac{i}{4}[v_m,\lambda_\alpha]\right\}\right) + C^{\gamma\beta}\epsilon_{\beta\alpha}\theta_\gamma\bar{\lambda}\bar{\lambda}, \tag{56}$$

where, following Wess and Bagger's conventions in Ref. 14, the field strength and covariant derivative of the gaugino are

$$F_{mn} = \partial_m v_n - \partial_n v_m + \frac{i}{2}[v_m,v_n] \tag{57}$$

$$\mathcal{D}_m\lambda_\alpha = \partial_m\lambda_\alpha + \frac{i}{2}[v_m,\lambda_\alpha].$$

Additionally, the spinor superfield of ordinary superspace is

$$W_\alpha(C=0) = -i\lambda_\alpha + \theta_\alpha D - \sigma_\alpha^{mn\beta}\theta_\beta F_{mn} + \theta\theta\sigma^m_{\alpha\dot\beta}\mathcal{D}_m\bar\lambda^{\dot\beta}. \tag{58}$$

Notice that when we set $\bar C^{\dot\alpha\dot\beta}=0$, we recover the result of Seiberg Ref. 8 for W_α. Likewise, we find that

$$\bar W_{\dot\alpha} = \bar W_{\dot\alpha}(C=0) + \bar\theta\bar\theta\left(\frac{1}{2}C^{mn}\{F_{mn},\bar\lambda_{\dot\alpha}\} + C^{mn}\left\{v_n,\mathcal{D}_m\bar\lambda_{\dot\alpha} - \frac{i}{4}[v_m,\bar\lambda_{\dot\alpha}]\right\}\right) + \bar C^{\dot\gamma\dot\beta}\epsilon^{\dot\beta\dot\alpha}\bar\theta_{\dot\gamma}\lambda\lambda, \tag{59}$$

where

$$\bar W_{\dot\alpha}(C=0) = i\bar\lambda_{\dot\alpha} + \bar\theta_{\dot\alpha}D - \sigma_{\dot\alpha}^{mn\dot\beta}\bar\theta_{\dot\beta}F_{mn} + \bar\theta\bar\theta\bar\sigma^{m\dot\alpha\beta}\mathcal{D}_m\lambda^\beta. \tag{60}$$

Again, we reproduce the result of Ref. 8 upon setting $\bar C^{\dot\alpha\dot\beta}=0$.

The spinor superfield transforms as in the commutative theory. From the non-Abelian gauge transformation [Eq. (34)], it follows that

$$W_\alpha \mapsto W'_\alpha = e^{-i\bar\Lambda} * W_\alpha * e^{i\Lambda}. \tag{61}$$

This can be shown by modifying the calculation used in the commutative theory. We simply change products to star products and utilize the algebra given in Eq. (15).

IV. CHIRAL AND ANTICHIRAL SUPERFIELDS

Chiral (Φ) and antichiral ($\bar\Phi$) superfields are defined as usual:

$$\bar D_{\dot\alpha} * \Phi = 0, \quad D_\alpha * \bar\Phi = 0. \tag{62}$$

The stars deform any multiplications that result. However, as $D_\alpha=\partial_\alpha$ in the chiral coordinates $y^\mu=x^\mu+i\theta\sigma^m\bar\theta$ and $\bar D_{\dot\alpha}=\partial_{\dot\alpha}$ in the antichiral coordinates $\bar y^\mu=x^\mu-i\theta\sigma^m\bar\theta$, we find that the star products are ordinary products. Consequently, we find the well-known solutions,

$$\begin{aligned}\Phi(y,\theta) &= A(y) + \sqrt{2}\theta\psi(y) + \theta\theta F(y),\\ \bar\Phi(\bar y,\bar\theta) &= \bar A(\bar y) + \sqrt{2}\bar\theta\bar\psi(\bar y) + \bar\theta\bar\theta\bar F(\bar y).\end{aligned} \tag{63}$$

These solutions follow from the chain rule as in the standard commutative theory. This construction need not be modified on noncommutative Minkowski superspace because the anticommutation relations given in Eq. (15) are unspoiled by the deformation.

A. Parametrizing the chiral and antichiral superfields

The matter fields in the Wess–Zumino model should transform in the fundamental and antifundamental representations of the gauge group. This is naturally embedded into the following superfield equation written on noncommutative Minkowski superspace (as Araki, Ito, and Ohtsuka did for the Euclidean case in Ref. 15),

$$\Phi \mapsto \Phi' = e^{-i\Lambda} * \Phi, \qquad \bar\Phi \mapsto \bar\Phi' = \bar\Phi * e^{i\bar\Lambda}. \tag{64}$$

Infinitesimally, we have

$$\delta\Phi = -i\Lambda * \Phi, \qquad \delta\bar{\Phi} = i\bar{\Phi} * \bar{\Lambda}. \tag{65}$$

At the level of component fields, Eq. (65) should embed

$$\begin{aligned} \delta A(y) &= i\phi A(y), & \delta\bar{A}(\bar{y}) &= -i\bar{A}\phi(\bar{y}) \\ \delta\psi(y) &= i\phi\psi(y), & \delta\bar{\psi}(\bar{y}) &= -i\bar{\psi}\phi(\bar{y}) \\ \delta F(y) &= i\phi F(y), & \delta\bar{F}(\bar{y}) &= -i\bar{F}\phi(\bar{y}). \end{aligned} \tag{66}$$

It was necessary for Ref. 15 to shift the $\bar{F}$ term in $\bar{\Phi}$ to maintain the usual C-independent gauge transformations on the component fields. Similarly, we must modify both Φ and $\bar{\Phi}$ from the canonical form given in Eq. (63),

$$\begin{aligned} \Phi(y) &= A + \sqrt{2}\theta\psi + \theta\theta(F + \eta), \\ \bar{\Phi}(\bar{y}) &= \bar{A} + \sqrt{2}\bar{\theta}\bar{\psi} + \bar{\theta}\bar{\theta}(\bar{F} + \beta), \end{aligned} \tag{67}$$

where the shifts η and β must be chosen as to embed Eq. (66) in Eq. (65). Now Λ and $\bar{\Lambda}$ were given in Eq. (50), however, it will be convenient to view $\bar{\Lambda}$ as a function of $\bar{y}$ for this section:

$$\begin{aligned} \Lambda(y) &= -\phi + i\theta\sigma^m\bar{\theta}\,\partial_m\phi + \frac{i}{2}\theta\theta\bar{C}^{mn}\{v_n, \partial_m\phi\} - 2\theta\theta\bar{\theta}\bar{\theta}\,\partial^2\phi, \\ \bar{\Lambda}(\bar{y}) &= -\phi - i\theta\sigma^m\bar{\theta}\,\partial_m\phi - \frac{i}{2}\bar{\theta}\bar{\theta}C^{mn}\{\partial_m\phi, v_n\} - 2\theta\theta\bar{\theta}\bar{\theta}\,\partial^2\phi. \end{aligned} \tag{68}$$

The $\theta\theta$ coefficient in Eq. (65) yields

$$\delta F + \delta\eta = i\phi F + i\phi\eta - 2i\bar{C}^{mn}\,\partial_m\phi\,\partial_n A + \frac{1}{2}\bar{C}^{mn}\{v_n, \partial_m\phi\}A. \tag{69}$$

Likewise, the $\bar{\theta}\bar{\theta}$ coefficient in Eq. (65) yields

$$\delta\bar{F} + \delta\beta = -i\bar{F}\phi - i\beta\phi - 2iC^{mn}\partial_n\bar{A}\,\partial_m\phi + \frac{1}{2}C^{mn}\bar{A}\{\partial_m\phi, v_n\}. \tag{70}$$

If we require that Eq. (66) holds, we then find that the following condition on β from Eq. (70) is

$$\delta\beta - i\phi\beta = -2iC^{mn}\,\partial_n\bar{A}\partial_m\phi + \frac{1}{2}C^{mn}\bar{A}\{\partial_m\phi, v_m\}. \tag{71}$$

Similarly, we find that the following condition on η from Eq. (69) is

$$\delta\eta - i\phi\eta = -2i\bar{C}^{mn}\partial_m\phi\,\partial_n A + \frac{1}{2}\bar{C}^{mn}\{v_n, \partial_m\phi\}A. \tag{72}$$

Following Ref. 15, we notice that

$$\begin{aligned} &\delta\left[iC^{mn}\partial_m(\bar{A}v_n) - \frac{1}{4}C^{mn}\bar{A}v_m v_n\right] + i\left[iC^{mn}(\partial_m\bar{A}v_n) - \frac{1}{4}C^{mn}\bar{A}v_m v_n\right]\phi \\ &\quad = -2iC^{mn}(\partial_m\bar{A})(\partial_n\phi) + \frac{1}{2}C^{mn}\bar{A}\{\partial_m\phi, v_n\}. \end{aligned} \tag{73}$$

Additionally, we note that

$$\delta\left[-i\bar{C}^{mn}\partial_m v_n A+\frac{1}{4}\bar{C}^{mn}v_m v_n A\right]-i\phi\left[-i\bar{C}^{mn}\partial_m(v_n A)+\frac{1}{4}\bar{C}^{mn}v_m v_n A\right]$$
$$=2i\bar{C}^{mn}(\partial_n\phi)(\partial_m A)+\frac{1}{2}\bar{C}^{mn}\{v_n,\partial_m\phi\}A. \tag{74}$$

Then, observe that Eq. (74) and Eq. (72) indicate that

$$\eta=-i\bar{C}^{mn}\partial_m(v_n A)+\frac{1}{4}\bar{C}^{mn}v_m v_n A. \tag{75}$$

Then, observe that Eq. (73) and Eq. (71) indicate that

$$\beta=iC^{mn}\partial_m(\bar{A}v_n)-\frac{1}{4}C^{mn}\bar{A}v_m v_n. \tag{76}$$

Thus, we define the chiral and antichiral superfields with respect to Eq. (50) as

$$\Phi=A+\sqrt{2}\theta\psi+\theta\theta\left(F-i\bar{C}^{mn}\partial_m(v_n A)+\frac{1}{4}\bar{C}^{mn}v_m v_n A\right),$$
$$\bar{\Phi}=\bar{A}+\sqrt{2}\bar{\theta}\bar{\psi}+\bar{\theta}\bar{\theta}\left(\bar{F}+iC^{mn}\partial_m(\bar{A}v_n)-\frac{1}{4}C^{mn}\bar{A}v_m v_n\right). \tag{77}$$

It should be clear from this section that this is the correct parametrization of the anti-(chiral) superfields. This definition embeds Eq. (66) in Eq. (65). This parametrization gives the component fields the standard C-independent gauge transformations.

V. GAUGED WESS–ZUMINO MODEL

We construct the gauge-invariant Lagrangian of the Wess–Zumino model on noncommutative Minkowski superspace:

$$\mathcal{L}=\frac{1}{16kg^2}\left(\int d^2\theta\,\mathrm{tr}\,W*W+\int d^2\bar{\theta}\,\mathrm{tr}\,\bar{W}*\bar{W}\right)+\int d^2\theta\,d^2\bar{\theta}\,\bar{\Phi}*e^V*\Phi. \tag{78}$$

Gauge invariance of $\mathcal{L}$ follows directly from the cyclicity of the trace and equations, Eq. (34), Eq. (61), and Eq. (64). Also, note that this Lagrangian is real as the star product has the property $\overline{F*G}=\bar{G}*\bar{F}$. To first order in the deformation parameter, we can calculate

$$\mathrm{tr}\,W*W|_{\theta\theta}=\mathrm{tr}\,W*W(C=0)|_{\theta\theta}-iC^{mn}\,\mathrm{tr}\,F_{mn}\bar{\lambda}\bar{\lambda}+i\bar{C}^{mn}\,\mathrm{tr}\,\lambda\lambda F_{mn},$$
$$\mathrm{tr}\,\bar{W}*\bar{W}|_{\bar{\theta}\bar{\theta}}=\mathrm{tr}\,\bar{W}*\bar{W}(C=0)|_{\bar{\theta}\bar{\theta}}-iC^{mn}\,\mathrm{tr}\,F_{mn}\bar{\lambda}\bar{\lambda}+i\bar{C}^{mn}\,\mathrm{tr}\,\lambda\lambda F_{mn}, \tag{79}$$

where

$$W*W(C=0)\Big|_{\theta\theta}=-2i\bar{\lambda}\bar{\sigma}^m\mathcal{D}_m\lambda-\frac{1}{2}F^{mn}F_{mn}+D^2+\frac{i}{4}F^{mn}F^{lk}\epsilon_{mnlk},$$
$$\bar{W}*\bar{W}(C=0)\Big|_{\bar{\theta}\bar{\theta}}=-2i\bar{\lambda}\bar{\sigma}^m\mathcal{D}_m\lambda-\frac{1}{2}F^{mn}F_{mn}+D^2-\frac{i}{4}F^{mn}F^{lk}\epsilon_{mnlk}. \tag{80}$$

To first order, these terms match those found by Ref. 8 if we set $\bar{C}^{mn}=0$. Next, consider the coupling of the vector and chiral multiplets. After some calculation, we find

$$\bar{\Phi} * e^V * \Phi \Big|_{\theta\theta\bar{\theta}\bar{\theta}} = \bar{F}F + i\sigma^m_{\alpha\dot{\alpha}}(\partial_m\bar{\psi}^{\dot{\alpha}})\psi^\alpha + \frac{1}{2}\bar{\psi}^{\dot{\alpha}}\sigma^m_{\alpha\dot{\alpha}}v_m\psi^\alpha + \frac{1}{2}\bar{A}(D - i\,\partial_m v^m)A - \frac{1}{4}\bar{A}v^m v_m A + (\partial^2\bar{A})A$$
$$- i(\partial_m\bar{A})v^m A + i\frac{\sqrt{2}}{2}\bar{A}\lambda\psi - i\frac{\sqrt{2}}{2}\bar{\psi}\bar{\lambda}A + iC^{mn}\partial_m(\bar{A}v_n)F - iC^{mn}(\partial_m\bar{A})v_n F$$
$$- i\bar{C}^{mn}\bar{F}\partial_m(v_n A) + i\bar{C}^{mn}\bar{F}v_n\partial_m A - \frac{1}{2}C^{mn}\bar{A}v_m v_n F + \frac{1}{2}\bar{C}^{mn}\bar{F}v_m v_n A$$
$$- i\frac{\sqrt{2}}{8}C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}\bar{A}\{\bar{\lambda}^{\dot{\alpha}}, v_m\}\psi_\beta - i\frac{\sqrt{2}}{8}\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\bar{\psi}_{\dot{\beta}}\{\lambda^\alpha, v_m\}A - \frac{\sqrt{2}}{2}C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}(\partial_m\bar{A})\bar{\lambda}^{\dot{\alpha}}\psi_\beta$$
$$- \frac{\sqrt{2}}{2}\bar{C}^{\dot{\alpha}\beta}\sigma^m_{\alpha\dot{\alpha}}\bar{\psi}_{\dot{\beta}}\lambda^\alpha\,\partial_m A. \tag{81}$$

We identify the terms without deformation parameters as the usual terms in the Wess Zumino model; that is, up to a total derivative we have

$$\bar{\Phi} * e^V * \Phi(C=0) \Big|_{\theta\theta\bar{\theta}\bar{\theta}} = \bar{F}F - i\bar{\psi}\bar{\sigma}^m\mathcal{D}_m\psi - (\mathcal{D}_m\bar{A})(\mathcal{D}^m A) + \frac{1}{2}\bar{A}DA + \frac{i}{\sqrt{2}}(\bar{A}\lambda\psi - \bar{\psi}\bar{\lambda}A), \tag{82}$$

where ψ and A are in the fundamental representation of the gauge group

$$\mathcal{D}_m\psi = \partial_m\psi + \frac{i}{2}v_m\psi, \quad \mathcal{D}_m A = \partial_m A + \frac{i}{2}v_m A. \tag{83}$$

In Eq. (81), we recover most of the terms found by Ref. 15 plus their conjugates. However, in comparison to the $N=1/2$ theory, terms that are linear in λ and $\bar{\lambda}$ are notably modified. The new shifts in the gauge parameters, Eq. (50), lead to the modification of the λ and $\bar{\lambda}$ components of the vector superfield V, which, in turn, give rise to the following terms in the Lagrangian $\mathcal{L}$:

$$- i\frac{\sqrt{2}}{8}C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}\bar{A}\{\bar{\lambda}^{\dot{\alpha}}, v_m\}\psi_\beta - \frac{\sqrt{2}}{2}C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}(\partial_m\bar{A})\bar{\lambda}^{\dot{\alpha}}\psi_\beta$$
$$- i\frac{\sqrt{2}}{8}\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\bar{\psi}_{\dot{\beta}}\{\lambda^\alpha, v_m\}A - \frac{\sqrt{2}}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\bar{\psi}_{\dot{\beta}}\lambda^\alpha\,\partial_m A. \tag{84}$$

Using covariant derivatives, these terms become

$$- i\frac{\sqrt{2}}{8}C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}\bar{A}[\bar{\lambda}^{\dot{\alpha}}, v_m]\psi_\beta - \frac{\sqrt{2}}{2}C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}(\mathcal{D}_m\bar{A})\bar{\lambda}^{\dot{\alpha}}\psi_\beta$$
$$+ i\frac{\sqrt{2}}{8}\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\bar{\psi}_{\dot{\beta}}[\lambda^\alpha, v_m]A - \frac{\sqrt{2}}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\bar{\psi}_{\dot{\beta}}\lambda^\alpha\mathcal{D}_m A. \tag{85}$$

The term $-(\sqrt{2}/2)C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}(\mathcal{D}_m\bar{A})\bar{\lambda}^{\dot{\alpha}}\psi_\beta$ was also found in Ref. 15. However, the commutator terms result from the choice of gauge parameter we made in Eq. (50). We might naively have expected only the terms without the commutators. Let us summarize:

$$\mathcal{L} = \frac{1}{16kg^2}\,\mathrm{tr}(-4i\bar{\lambda}\bar{\sigma}^m\mathcal{D}_m\lambda - F^{mn}F_{mn} + 2D^2) + \bar{F}F - i\bar{\psi}\bar{\sigma}^m\mathcal{D}_m\psi - \mathcal{D}_m\bar{A}\mathcal{D}^mA + \frac{1}{2}\bar{A}DA$$
$$+ \frac{i}{\sqrt{2}}(\bar{A}\lambda\psi - \bar{\psi}\bar{\lambda}A) + \frac{1}{16kg^2}\,\mathrm{tr}(-2iC^{mn}F_{mn}\lambda\lambda + 2i\bar{C}^{mn}\bar{\lambda}\bar{\lambda}F_{mn}) + \frac{i}{2}C^{mn}\bar{A}F_{mn}F$$
$$- \frac{i}{2}\bar{C}^{mn}\bar{F}F_{mn}A - i\frac{\sqrt{2}}{8}C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}\bar{A}[\bar{\lambda}^{\dot{\alpha}}, v_m]\psi_\beta - \frac{\sqrt{2}}{2}C^{\alpha\beta}\sigma^m_{\alpha\dot{\alpha}}(\mathcal{D}_m\bar{A})\bar{\lambda}^{\dot{\alpha}}\psi_\beta$$
$$+ i\frac{\sqrt{2}}{8}\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\bar{\psi}_{\dot{\beta}}[\lambda^\alpha, v_m]A - \frac{\sqrt{2}}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\sigma^m_{\alpha\dot{\alpha}}\bar{\psi}_{\dot{\beta}}\lambda^\alpha\mathcal{D}_mA\,. \tag{86}$$

VI. CONCLUSIONS

We have developed a non-Abelian gauge theory over deformed Minkowski superspace. In this deformation, all of the fermionic dimensions are deformed and, as a result, all of the supersymmetry is broken. To be consistent with the $N=1/2$ terminology, we say that this deformed superspace has $N=0$ supersymmetry. Many of the results directly mirror the results of $N=1/2$ from Ref. 8 or Ref. 15. This is due to the fact that the deformation we consider in this paper reduces to the deformation of $N=1/2$ supersymmetry upon setting $\bar{C}^{\dot{\alpha}\dot{\beta}}=0$. It is not surprising that we recover almost the same gauge theoretic results as Ref. 8 in the limit $\bar{C}^{\dot{\alpha}\dot{\beta}}=0$. The exception to this rule is the choice of gauge parameter introduced by Seiberg in Ref. 8. We found that it was not possible to use the same construction because it violated the hermiticity of the vector superfield. We fixed this by introducing a new gauge parameter that served to maintain both hermiticity and the C-independent gauge transformations on the component fields.

Next, we introduced the chiral superfield Φ. Again, we found it necessary to modify the canonical component field expansion in order to maintain the standard gauge transformations on the component fields. The modification is similar in spirit to that of Ref. 15. Essentially, what we found is the $N=1/2$ theory and conjugate copy, where all of the usual $N=1/2$ terms are accompanied by their conjugates due to the hermiticity properties of the star product used in this construction.

Finally, we constructed the Lagrangian that coupled the gauge and matter fields. The gauge invariance of $\mathcal{L}$ follows for reasons similar to the commutative theory. We simply modified the standard arguments for the gauged Wess–Zumino model by replacing products with star products. The primary obstacle to this construction was the task of finding the correct parametrization for the superfields. The Lagrangian is similar to that found by Ref. 15, however, there are several new terms. Most new terms come directly from the added deformation $\{\bar{\theta}^{\dot{\alpha}}, \bar{\theta}^{\dot{\beta}}\}_* = \bar{C}^{\dot{\alpha}\dot{\beta}}$ (which should have been expected from the outset). However, the reparametrization of the gauge parameter also led us to some terms that were not immediately obvious from the $N=1/2$ theory.

There is much work left to do. First, we should complete the program begun in this work to the second order in the deformation parameter. Nonassociativity will have to be addressed. It is likely that the constructions of this paper will need modification at the second order. Second, there are numerous papers, see Refs. 15–47, investigating $N=1/2$ supersymmetry. It would be interesting to find complementary results for the $N=0$ case where possible. We could try to find the dual results for, instantons as in Refs. 16–21, or renormalization as in Refs. 22–29, or the possibility of residual supersymmetry as in Ref. 30, or the Seiberg Witten map as in Ref. 31. We do not attempt to give a complete account of the $N=1/2$ developments; we just wish to point out the variety of novel directions future research might take. Finally, it would be interesting to derive the $N=0$ deformation from a string theoretical argument.

ACKNOWLEDGMENT

I would like to thank Daniel Robles-Llana, Manuela Kulaxizi, and Ronald Fulp for helpful discussions. Finally, I thank my wife for her considerable patience.

APPENDIX: FIRST ORDER ASSOCIATIVITY OF STAR PRODUCT

Define the parity of F to be ϵ^F. If F is even, then $\epsilon^F=1$. If F is odd, then $\epsilon^F=-1$. We can express the star product to the first order as:

$$F*G=FG-\frac{1}{2}C^{\alpha\beta}\epsilon^F(Q_\alpha F)(Q_\beta G)-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^F(\bar{Q}_{\dot{\alpha}}F)(\bar{Q}_{\dot{\beta}}G).$$

Let us then prove that the first order star product is associative. Consider:

$$\begin{aligned}(F*G)*H&=\left(FG-\frac{1}{2}C^{\alpha\beta}\epsilon^F(Q_\alpha F)(Q_\beta G)-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^F(\bar{Q}_{\dot{\alpha}}F)(\bar{Q}_{\dot{\beta}}G)\right)*H\\&=FGH-\frac{1}{2}C^{\alpha\beta}\epsilon^F(Q_\alpha F)(Q_\beta G)H-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^F(\bar{Q}_{\dot{\alpha}}F)(\bar{Q}_{\dot{\beta}}G)H\\&\quad-\frac{1}{2}C^{\alpha\beta}\epsilon^{FG}(Q_\alpha FG)(Q_\beta H)-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^{FG}(\bar{Q}_{\dot{\alpha}}FG)(\bar{Q}_{\dot{\beta}}H)\\&=FGH-\frac{1}{2}C^{\alpha\beta}\epsilon^F(Q_\alpha F)(Q_\beta G)H-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^F(\bar{Q}_{\dot{\alpha}}F)(\bar{Q}_{\dot{\beta}}G)H\\&\quad-\frac{1}{2}C^{\alpha\beta}\epsilon^{FG}[(Q_\alpha F)G+\epsilon^F F(Q_\alpha G)]Q_\beta H\\&\quad-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^{FG}[(\bar{Q}_{\dot{\alpha}}F)G+\epsilon^F F(\bar{Q}_{\dot{\alpha}}G)]\bar{Q}_{\dot{\beta}}H\\&=FGH-\frac{1}{2}C^{\alpha\beta}\epsilon^F(Q_\alpha F)(Q_\beta G)H-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^F(\bar{Q}_{\dot{\alpha}}F)(\bar{Q}_{\dot{\beta}}G)H\\&\quad-\frac{1}{2}C^{\alpha\beta}[\epsilon^F\epsilon^G(Q_\alpha F)G(Q_\beta H)+\epsilon^G F(Q_\alpha G)(Q_\beta H)]\\&\quad-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}[\epsilon^F\epsilon^G(\bar{Q}_{\dot{\alpha}}F)G(\bar{Q}_{\dot{\beta}}H)+\epsilon^G F(Q_\alpha G)(\bar{Q}_{\dot{\beta}}H)].\end{aligned}$$

Notice that we have used $\epsilon^{FG}=\epsilon^F\epsilon^G$ and $\epsilon^F\epsilon^F=1$ to complete the calculation above. Likewise, consider

$$\begin{aligned}F*(G*H)&=F*\left(GH-\frac{1}{2}C^{\alpha\beta}\epsilon^G(Q_\alpha G)(Q_\beta H)-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^G(\bar{Q}_{\dot{\alpha}}G)(\bar{Q}_{\dot{\beta}}H)\right)\\&=FGH-\frac{1}{2}C^{\alpha\beta}\epsilon^G F(Q_\alpha G)(Q_\beta H)-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^G F(\bar{Q}_{\dot{\alpha}}G)(\bar{Q}_{\dot{\beta}}H)\\&\quad-\frac{1}{2}C^{\alpha\beta}\epsilon^F(Q_\alpha F)(Q_\beta GH)-\frac{1}{2}\bar{C}^{\dot{\alpha}\dot{\beta}}\epsilon^F(\bar{Q}_{\dot{\alpha}}F)(\bar{Q}_{\dot{\beta}}GH)\end{aligned}$$

$$
\begin{aligned}
&= FGH - \frac{1}{2} C^{\alpha\beta} \epsilon^G F (Q_\alpha G)(Q_\beta H) - \frac{1}{2} \bar{C}^{\dot{\alpha}\dot{\beta}} \epsilon^G F (\bar{Q}_{\dot{\alpha}} G)(\bar{Q}_{\dot{\beta}} H) \\
&\quad - \frac{1}{2} C^{\alpha\beta} \epsilon^F (Q_\alpha F)[(Q_\beta G) H + \epsilon^G G (Q_\beta H)] \\
&\quad - \frac{1}{2} \bar{C}^{\dot{\alpha}\dot{\beta}} \epsilon^F (\bar{Q}_{\dot{\alpha}} F)[(\bar{Q}_{\dot{\beta}} G) H + \epsilon^G G (\bar{Q}_{\dot{\beta}} H)] \\
&= FGH - \frac{1}{2} C^{\alpha\beta} \epsilon^G F (Q_\alpha G)(Q_\beta H) - \frac{1}{2} \bar{C}^{\dot{\alpha}\dot{\beta}} \epsilon^G F (\bar{Q}_{\dot{\alpha}} G)(\bar{Q}_{\dot{\beta}} H) \\
&\quad - \frac{1}{2} C^{\alpha\beta} [\epsilon^F (Q_\alpha F)(Q_\beta G) H + \epsilon^F \epsilon^G (Q_\alpha F) G (Q_\beta H)] \\
&\quad - \frac{1}{2} \bar{C}^{\dot{\alpha}\dot{\beta}} [\epsilon^F (\bar{Q}_{\dot{\alpha}} F)(\bar{Q}_{\dot{\beta}} G) H + \epsilon^F \epsilon^G (Q_\alpha F) G (\bar{Q}_{\dot{\beta}} H)].
\end{aligned}
$$

Therefore, $F*(G*H)=(F*G)*H$ to the first order in the deformation parameter.

(Received 20 September 2005; accepted 30 November 2005; published online 26 January 2006)

We quantize, within the Loop Representation formalism, the electromagnetic field in the presence of a static magnetic pole. It is found that the loop-dependent physical wave functionals of the quantum Maxwell theory become multivalued, through a topological phase factor depending on the solid angle subtended at the monopole by a surface bounded by the loop. It is discussed how this fact generalizes what occurs in ordinary quantum mechanics in multiply connected spaces. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2162333]

I. INTRODUCTION

Dirac found that the mere existence of a single monopole would explain the quantized nature of the electric charge.[1,2] He discovered a relation between the unit of electric charge and that of the magnetic pole, which is currently known as Dirac's quantization condition. In rationalized units $(c=\hbar=1)$ it reads as

$$\frac{eg}{4\pi}=\frac{1}{2}n, \tag{1}$$

where n is an integer and e (g) is the unit of electric (magnetic) charge. Besides this remarkable prediction, the Dirac theory of magnetic monopoles has been a source of inspiration for the development of new ideas in theoretical physics. Often, it occurs that different approaches to understanding the formulation of Dirac bring out novelties or unexpected relationships between old things.

Being a gauge theory, the Dirac theory of magnetic poles should be a candidate to admit a quantum geometric representation, such as the Loop Representation (LR) of Maxwell theory.[3–5] In this article we address this point to some extent. Concretely, we study the LR formulation of quantum Maxwell theory in the presence of an external magnetic pole, taking as a starting point a first-order action of Schwinger,[6] which is based on the earlier Dirac theory.[1,2] We shall see that the LR formulation of the Maxwell theory with a static monopole corresponds to that of the *free theory*, except by the fact that the loop-dependent wave functional acquires a topological dependence on the manner that the loop "winds" around the monopole. This dependence is manifested through a topological phase factor picked up by the wave functional when the loop undergoes an adiabatic excursion in the presence of the monopole. It could be said that loop-dependent wave functionals become multivalued in the presence of the monopole, in the same sense that in ordinary quantum mechanics wave functions are allowed to be multivalued whenever the configu-

[a)]Electronic mail: lleal@fisica.ciens.ucv.ve
[b)]Electronic mail: alopez@ivic.ve

ration space is multiply connected.[7–9] These results are also related with previous studies about the quantum theory of strings in the presence of a Kalb–Ramond vortex,[10,11] where a generalization of the concept of anyons can be envisaged.

In the next section we present the model and discuss its quantization in the LR formulation. In the last section we study in which sense the magnetic monopole turns Maxwell theory into a loop-dependent theory with nontrivial boundary conditions in loop space.

II. QUANTIZATION AND LOOP REPRESENTATION

Electromagnetism with magnetic charges can be studied from the first-order Schwinger action,[6]

$$S = \int dx^4 \left(A_\mu J_e^\mu + B_\mu J_m^\mu - \frac{1}{2} F^{\mu\nu}(\partial_\mu A_\nu - \partial_\nu A_\mu) + \frac{1}{4} F^{\mu\nu} F_{\mu\nu} \right), \tag{2}$$

where B is given by

$$B_\mu(x) = \int dy^4 * F_{\mu\nu}(y) f^\nu(y - x) + \partial_\mu \lambda(x). \tag{3}$$

Here, f obeys

$$\partial_\mu f^\mu(y) = \delta^4(y), \tag{4}$$

and λ is an arbitrary function. The dual $*F$ is given by

$$* F_{\mu\nu} = \frac{1}{2} \epsilon_{\mu\nu\alpha\beta} F^{\alpha\beta}, \tag{5}$$

where $\epsilon_{\mu\nu\alpha\beta}$ is the completely antisymmetric symbol and J_e (J_m) denote the electric (magnetic) current density. The independent fields in (2) are A_ν and $F_{\mu\nu}$. Varying (2) with respect to A_μ gives

$$\partial_\nu F^{\mu\nu} = J_e^\mu, \tag{6}$$

whereas variations with respect to $F_{\mu\nu}$ yield

$$F_{\mu\nu}(x) = \partial_\mu A_\nu(x) - \partial_\nu A_\mu(x) - \frac{1}{2} \epsilon_{\mu\nu\alpha\beta} \int dy^4 \, J_m^\alpha(y) f^\beta(x - y), \tag{7}$$

which, with the use of Eqs. (3) and (4), implies

$$\partial_\nu * F^{\mu\nu} = J_m^\mu. \tag{8}$$

Thus, one obtains the Maxwell equations with both electric and magnetic currents. The duality electricity magnetism manifests through the invariance of the equations under the rotations

$$J_e \to \cos \phi J_e + \sin \phi J_m, \tag{9}$$

$$J_m \to - \sin \phi J_e + \cos \phi J_m, \tag{10}$$

$$F \to \cos \phi F + \sin \phi * F. \tag{11}$$

We are interested in studying how the presence of a magnetic monopole affects the loop-space formulation of the Maxwell field. Hence, we take $J_e = 0$ in Eq. (2) and restrict ourselves to consider a static monopole (we take it at the origin of space), which forces the magnetic current to be written as

$$J_m^\mu(x) = g\,\delta_0^\mu \delta^3(\vec{x}). \tag{12}$$

A convenient choice for f_μ [fulfilling Eq. (4)] is

$$f^\nu(y) = -\frac{1}{4\pi}\frac{y^i}{\vec{y}^3}\delta_i^\nu \delta(y_0). \tag{13}$$

The Hamiltonian formulation begins with the definition of the canonical momenta associated to A_0, F_{ij}, and A_i, which result to be

$$\Pi^0(x) \approx 0, \tag{14}$$

$$\Pi^{ij}(x) \approx 0, \tag{15}$$

$$\Pi^i(x) = -F^{0i}(x), \tag{16}$$

respectively. Equations (14), (15) are (primary) constraints in the sense of Dirac,[12] and we have introduced the weak equality symbol $\approx$ to mean that these equalities should not be used until Poisson brackets are calculated. Since F^{0i} is already a conjugate momentum, it is not necessary to treat it as a coordinate and to define its own canonical momentum.[13] Following Dirac's method to deal with constrained systems, one constructs the total Hamiltonian,[12]

$$H^* = H + \int d\vec{x}^3\, u(x)\Pi^0(x) + \int d\vec{x}^3\, u_{ij}(x)\Pi^{ij}(x), \tag{17}$$

where $u(x)$ and $u_{ij}(x)$ are Lagrange multipliers and H is the canonical Hamiltonian,

$$H = \int d\vec{x}^3 \left[\frac{1}{2}\Pi_i^2 - \frac{1}{4}F_{ij}^2 + \frac{1}{2}F_{ij}(f_{ij} - b_{ij})\right] + \int d\vec{x}^3\, \partial_i \Pi^i A_0. \tag{18}$$

Here we have defined

$$f_{ij}(x) = \partial_i A_j(x) - \partial_j A_i(x), \tag{19}$$

$$b_{ij}(x) = g\,\epsilon_{ijk} f^k(\vec{x}). \tag{20}$$

It is worth noticing that when the static monopole is absent, this Hamiltonian properly reduces to that of the conventional Maxwell theory, since in that case the magnetic field F_{ij} and the curl of the potential f_{ij} coincide.

The nonvanishing equal time canonical Poisson brackets are given by

$$\{F_{ij}(x), \Pi^{kl}(y)\} = \frac{1}{2}(\delta_i^k \delta_j^l - \delta_i^l \delta_j^k)\,\delta^3(\vec{x} - \vec{y}), \tag{21}$$

$$\{A_\alpha(x), \Pi^\beta(y)\} = \delta_\alpha^\beta \delta^3(\vec{x} - \vec{y}). \tag{22}$$

Following Dirac,[12] one must impose the time preservation of the constraints. From (14) one finds, as a secondary constraint, the Gauss Law,

$$\partial_i \Pi^i(x) \approx 0. \tag{23}$$

This constraint, in turn, has a vanishing Poisson bracket with the total Hamiltonian, hence, it does not produce further constraints. On the other hand, the time preservation of (15) gives the secondary constraint

$$K_{ij}(x) = F_{ij}(x) - f_{ij}(x) + b_{ij}(x) \approx 0. \tag{24}$$

Finally, the preservation of constraint (24) allows us to obtain the Lagrange multipliers u_{ij} in terms of the momenta Π^i,

$$u_{ij}(x) = -\frac{1}{2}(\partial_i F_{0j}(x) - \partial_j F_{0i}(x)), \tag{25}$$

which must be substituted into the expression for the total Hamiltonian.

It is found that constraints (23) and (14) are first class, while (15) and (24) are second class. Following Dirac's procedure, we must introduce Dirac brackets in order to obtain a quantum theory consistent with these second class constraints. Though it is not difficult to carry out the calculations of the matrix of the Poisson brackets between second class constraints and its inverse, which are the ingredients needed for building Dirac brackets, a simple argument suffices to obtain the result. Since Dirac brackets are going to be consistent with second class constraints, these may be put as strong equalities. Hence, we can write F_{ij} and its momentum Π^{ij} in terms of the remaining canonical variables, and substitute these expressions in the total Hamiltonian. Once this is done, we have only to consider Dirac brackets between the canonical variables that remain, which are A_i, A_0, and their canonical conjugates. But it is easy to see that these Dirac brackets just coincide with the Poisson ones. The net result is that we can eliminate F_{ij} and Π^{ij} using Eqs. (15) and (24), and continue using the Poisson brackets for the remaining variables.

At this point, it is also convenient to "eliminate" the constraint (14) of the formalism. This can be accomplished by fixing the temporal gauge $A_0=0$ and treating this equation as a new constraint, which, together with (14), can be considered as a pair of second class constraints. Then, we can put A_0 and Π^0 as strongly vanishing. As before, it can be seen that the new Dirac brackets are equal to the Poisson ones, as far as we consider only the remaining variables, namely A_i and their canonical conjugates.

Now we are ready to quantize the theory. First, promote canonical variables to operators obeying equal time canonical commutators,

$$[\hat{A}_i(x), \hat{A}_j(y)] = 0, \tag{26}$$

$$[\hat{\Pi}^i(x), \hat{\Pi}^j(y)] = 0, \tag{27}$$

$$[\hat{A}_i(x), \hat{\Pi}^j(y)] = i\delta_i^j \delta^3(\vec{x} - \vec{y}). \tag{28}$$

The first class constraints define the physical states $|\Psi>$ as those that satisfy

$$\partial_i \hat{\Pi}^i(x)|\Psi> 0. \tag{29}$$

On the physical subspace, the dynamics is given by the Schrödinger equation

$$i\partial_t|\Psi_t> = \hat{H}|\Psi_t> , \tag{30}$$

with

$$\hat{H} = \int d\vec{x}^3 \left[\frac{1}{2}\hat{\Pi}_i^2 + \frac{1}{4}(\partial_i \hat{A}_j - \partial_j \hat{A}_i - b_{ij})^2 \right]. \tag{31}$$

Thus, we obtain that the static monopole manifests in the theory just through the external field b_{ij}, which must be subtracted from the curl of the vector potential to give the magnetic field operator.

We are now prepared to discuss the LR of the model. We begin by recalling that the Abelian path space (PS) can be defined as the set of certain equivalence classes of curves γ in (for our purposes) R^3.[3–5,14] The equivalence relation is given by the so-called *form factor* $T^i(\vec{x}, \gamma)$ of the curve

$$T^i(\vec{x},\gamma)=\int_\gamma dy^i\ \delta(\vec{x}-\vec{y}), \tag{32}$$

as follows: γ and γ' are said to be equivalent (i.e., represent the same path) if their form factors coincide. Closed curves give rise to a subspace of the PS: the loop space. It can be seen that the usual composition of curves translates into a composition of paths that endows the PS with a group structure.

The path representation arises when one considers path-dependent wave functionals $\Psi[\gamma]$, and realizes the canonical field operators by means of operations onto these wave functionals.[3–5,14] We define the path and loop derivatives $\delta_i(\vec{x})$ and $\Delta_{ij}(\vec{x})$ by

$$(1+u^i(\vec{x})\delta_i(\vec{x}))\Psi[\gamma]=\Psi[\gamma\circ u], \tag{33}$$

$$\left(1+\frac{1}{2}\sigma^{ij}(\vec{x})\Delta_{ij}(\vec{x})\right)\Psi[\gamma]=\Psi[\gamma\circ \delta c], \tag{34}$$

where $\circ$ denotes the PS product.[4] The derivative $\delta_i(\vec{x})$ $(\Delta_{ij}(\vec{x}))$ measures the change in the path-dependent wave functional when an infinitesimal path δu (infinitesimal loop δc) is attached to its argument γ at the point $\vec{x}$. It is understood that these changes are considered up to first order in the infinitesimal vector u^i associated with the small path, or with the surface element,

$$\sigma^{ij}=u^iv^j-v^iu^j, \tag{35}$$

generated by the infinitesimal vectors $\vec{u}$ and $\vec{v}$ that define the small loop δc. It can be shown that both derivatives are related by[3–5,14]

$$\partial_i\delta_j(\vec{x})-\partial_j\delta_i(\vec{x})=\Delta_{ij}(\vec{x}). \tag{36}$$

With these tools at hand we represent the canonical field as operators acting on path-dependent wave functionals $\Psi[\gamma]$ by means of the prescriptions,

$$\hat{\Pi}^i(\vec{x})\to eT^i(\vec{x},\gamma), \tag{37}$$

$$\hat{A}_j(\vec{x})\to\frac{i}{e}\delta_j(\vec{x}). \tag{38}$$

It is readily seen that this realizes the algebra (26)–(28). We see that in this representation the form factor corresponds to Faraday lines of the electric field. The magnetic field operator, in turn, appends a small closed line of electric field to the argument of the wave functionals. The constant e is introduced to fix the scale of the Faradays lines of an electric field. In virtue of Gauss' law, e can at the same time be seen as the elementary unit of electric charge. In four dimensions (and using natural units) this constant is dimensionless (as well as the magnetic charge g).

Since the divergence of the form factor $T^i(\vec{x},\gamma)$ vanishes when the path is closed, the Gauss constraint (29) is identically satisfied if we restrict ourselves to deal with loop-dependent wave functionals.[3] Finally, the Schrödinger equation obeyed by the loop-dependent wave functional $\Psi[\gamma]$ that describes the Maxwell field quantized in the presence of the static external monopole can be written down as

$$i\,\partial_t\Psi[\gamma,t]=\int d\vec{x}^3\left[\frac{1}{2}e^2(T^i(\vec{x},\gamma))^2-\frac{1}{4e^2}(i\Delta_{ij}(\vec{x})-eb_{ij}(\vec{x}))^2\right]\Psi[\gamma,t]. \tag{39}$$

When $g=0$, this equation reduces to that corresponding to free electromagnetism in the LR,[3–5] as it should be.

The above formulation is empty unless an appropriate scalar product in loop space is defined. This is a rather subtle matter on which we shall just briefly comment. Nowadays it is known that

there exits a suitable integration measure in the quantum configuration space of gauge potentials (see Ref. 18 for a recent reference about this matter) that allows us to define an inner product in loop space for both Abelian and non-Abelian gauge theories. Moreover, it has also been understood how to relate the loop representation of Maxwell theory with its Fock representation,[19] which allows us to make contact with the familiar particle interpretation of field theory. This relationship between the "polymer-like" and photon-like representations heavily relies on the introduction of "smeared" Wilson loop operators, which, unlike the unsmeared ones, are well defined in Fock space. At last, it results that normalizable states in the Fock representation correspond to linear combinations of non-normalizable or distributional states of the loop representation.[19]

III. MULTIVALUED LOOP-DEPENDENT WAVE FUNCTIONALS

We have seen that introducing a static monopole in quantum Maxwell theory, in the LR, amounts to replacing the loop derivative $\Delta_{ij}(\vec{x})$ by a kind of "covariant derivative,"

$$i\Delta_{ij}(\vec{x}) \to i\Delta_{ij}(\vec{x}) - eb_{ij}(\vec{x}). \tag{40}$$

Now, we shall see that it is possible to recast the Schrödinger equation (39) as that corresponding to a *free* theory, provided that we deal with *multivalued loop-dependent* wave functionals. It should be emphasized that this *does not* mean that the Maxwell field plus a monopole is the same thing as that the Maxwell field alone. What this actually means is that one can convert the effect of the monopole into unusual boundary conditions for the wave functional.

To see how this happens we find it convenient to employ the space of surfaces framework,[15] which we summarize following very closely Ref. 16. One starts with the space of piecewise smooth oriented surfaces Σ in R^3. We define two surfaces as equivalent if they share the same "surface form factor,"

$$T^{ij}(\vec{x},\Sigma) = \int d\Sigma_y^{ij}\, \delta^{(3)}(\vec{x}-\vec{y}). \tag{41}$$

Here $d\Sigma_y^{ij}$ is the surface element,

$$d\Sigma_y^{ij} = \left(\frac{\partial y^i}{\partial s}\frac{\partial y^j}{\partial r} - \frac{\partial y^i}{\partial r}\frac{\partial y^j}{\partial s}\right) ds\, dr, \tag{42}$$

with s, r being surface parameters. Now we consider functionals $\Psi[\Sigma]$ and introduce the surface derivative $\delta_{ij}(\vec{x})$, that measures the response of $\Psi[\Sigma]$ when an element of surface whose infinitesimal area is σ_{ij} is attached to the argument Σ of $\Psi[\Sigma]$ at the point x, up to first order in σ_{ij}:

$$\Psi[\delta\Sigma \cdot \Sigma] = (1 + \sigma^{ij}\delta_{ij}(\vec{x}))\Psi[\Sigma]. \tag{43}$$

The surface derivative $\delta_{ij}(\vec{x})$ and the loop derivative $\Delta_{ij}(\vec{x})$ are different things. However, since in R^3 loop dependence is a particular case of surface dependence (a loop is always the boundary of an open surface in R^3), the loop derivative can be seen as the surface derivative restricted to loop-dependent functionals. Hence it makes sense to surface derive loop-dependent quantities. Soon we shall make use of the surface derivative of the form factor,

$$\delta_{ij}(\vec{x})T^{kl}(\vec{y},\Sigma) = \frac{1}{2}(\delta_i^k\delta_j^l - \delta_i^l\delta_j^k)\delta^{(3)}(\vec{x}-\vec{y}). \tag{44}$$

Turning back to our model, let us consider an open surface Σ whose boundary coincides with γ (i.e., $\partial\Sigma = \gamma$). Then define, from the path-dependent wave functional $\Psi[\gamma]$, the surface-dependent one,

$$\Psi[\Sigma] \equiv \exp\left(ie \int d\Sigma_{\vec{y}}^{km} b_{km}(\vec{y}) \right) \Psi[\gamma] = \exp\left(\frac{ieg}{4\pi} \Omega(\Sigma) \right) \Psi[\gamma], \tag{45}$$

where $\Omega(\Sigma)$ is the solid angle subtended by Σ, measured from the monopole. Using Eq. (44), it is easy to show that

$$\delta_{ij}(\vec{x}) \Psi[\Sigma] = \exp\left(\frac{ieg}{4\pi} \Omega(\Sigma) \right) (\Delta_{ij}(\vec{x}) + ieb_{ij}(\vec{x})) \Psi[\gamma]. \tag{46}$$

Then, the Schrödinger equation (39) of the model can also be written as

$$i\, \partial_t \Psi[\Sigma, t] = \int d\vec{x}^3 \left[\frac{1}{2} e^2 (T^i(\vec{x}, \partial\Sigma))^2 - \frac{1}{4e^2} (\delta_{ij}(\vec{x}))^2 \right] \Psi[\Sigma, t]. \tag{47}$$

[Unlike the loop dependence in Eq. (39), the surface dependence in Eq. (47) is not arbitrary: it is precisely given by the phase factor $\exp((ieg/4\pi)\Omega(\Sigma))$ carried by the wave functional, which just serves to compensate the contribution b_{ij} otherwise present in the Schrödinger equation. Hence, despite the appearances, we are not introducing extra degrees of freedom into the theory when working with surfaces instead of loops.]

Due to definition (45), we see that the properties of Σ that matter are the solid angle $\Omega(\Sigma)$ subtended at the monopole, and the boundary $\partial\Sigma$. This implies that the surface dependence of the wave functional $\Psi[\Sigma, t]$ is topological: if we replace Σ by another surface Σ' that has the same boundary γ, the wave functional changes as

$$\Psi[\Sigma'] = \exp(iegp) \Psi[\Sigma], \tag{48}$$

where p is the number of times that the closed surface $S = \Sigma' \circ (-\Sigma)$, that results from the composition of Σ' and the surface opposite to Σ, wraps around the monopole. Therefore we can rewrite Eq. (47) as the Schrödinger equation of the free Maxwell theory,

$$i\, \partial_t \Psi[\gamma, t] = \int d\vec{x}^3 \left[\frac{1}{2} e^2 (T^i(\vec{x}, \gamma))^2 - \frac{1}{4e^2} (\Delta_{ij}(\vec{x}))^2 \right] \Psi[\gamma, t], \tag{49}$$

provided that simultaneously we deal with nontrivial boundary conditions for the loop-dependent wave functionals: every time that the loop goes around a "closed trajectory" (i.e., a closed surface) that encloses p times the monopole, the wave function picks up the phase factor $\exp(iegp)$,

$$\Psi[[S] \,.\, \gamma] = \exp(iegp) \Psi[\gamma]. \tag{50}$$

In this equation, $[S].\gamma$ means that the loop γ has described a "closed trajectory" sweeping the closed surface S and wrapping p times to the monopole. The loop-dependent wave functional became multivalued due to the presence of the magnetic monopole.

This can be understood as a generalization of what occurs in ordinary quantum mechanics in multiply connected configuration spaces.[7–9] In such cases, multivaluedness of the wave function is allowed, being restricted to multiplication of the wave function by a phase factor carrying a representation of the fundamental group of the configuration space. But this is precisely what we have found in our study: since the configuration space of our quantum formulation is the space of loops in $R^3 - \{origin\}$, a "point" in the set is a loop, while the "closed curves" swept by loops will be closed surfaces, whose properties of contractibility in $R^3 - \{origin\}$ will define the fundamental group of the configuration space. Now, the phase factor $\exp(iegp)$ appearing in Eq. (48) just corresponds to a one-dimensional representation of this fundamental group, since it classifies the surfaces according to the manner in which they wrap the monopole.

Summarizing, we observe that there are three equivalent levels in the description of the model: (1) Eq. (39), where the wave functionals are loop dependent and single valued, and the interaction of the field with the monopole appears explicitly in the Hamiltonian. (2) Eq. (47), that uses a wave functional with a prescribed surface-dependence (45) that encodes the effect of the

monopole; and (3) the loop-dependent "free" equation (49), where the wave-functional carries a non trivial one-dimensional unitary representation of the fundamental group of the configuration space (which is the space of loops in $R^3-\{origin\}$) that takes into account the effect of the monopole.

To conclude, we should mention a feature that could look somewhat striking at first sight. If Dirac's quantization condition (1) holds, the topological phase factor appearing in (48) becomes unity and the dependence on the surface vanishes. But then the wave functional becomes single valued and the effect of the monopole seems to disappear at all!. What happens is that, in the absence of electrically charged particles, there is no need to quantize electric or magnetic charges. In fact, recall that in the formulation of Dirac, charge quantization arises when the wave function of the *charged particle* is asked to be single valued in the presence of the monopole. Or, alternatively, when the action functional of the *charge*-field-monopole system is asked to be independent of the string attached to the monopole [in our case, this corresponds to demanding that changing f^μ [given in (13)] by any other vector field obeying Eq. (4) does not modify the action]. Yet, there is another approach, which does not employ vector potentials, which derives charge quantization from the consistency of the Heisenberg equations of motion of a *charged* particle in the field of a magnetic monopole.[20] But in the absence of electric charges, all these requirements are automatically guaranteed, and Dirac's quantization condition is not required to have a consistent theory.

It would be interesting, in view of the above discussion, to study the LR formulation of the theory in the case with both charges and monopoles. Based on previous results about the LR of the Maxwell field coupled to dynamical point particles,[21] it can be expected in this case that the physical sector of loop space corresponds to both loops and open paths emanating or ending at the points where charges are located. This change in the configuration space of the quantum theory could modify the "striking consequence" regarding Dirac quantization condition discussed above.

The present approach could also be applied to the study of higher-rank Abelian theories, with their corresponding extended objects generalizing electric and magnetic charges.[17]

(Received 27 April 2005; accepted 14 October 2005; published online 31 January 2006)

We construct explicit Bogomolnyi, Prasad, Sommerfeld (BPS) and non-BPS solutions of the Yang-Mills equations on the noncommutative space $\mathbb{R}^{2n}_\theta \times S^2$ which have manifest spherical symmetry. Using SU(2)-equivariant dimensional reduction techniques, we show that the solutions imply an equivalence between instantons on $\mathbb{R}^{2n}_\theta \times S^2$ and non-Abelian vortices on $\mathbb{R}^{2n}_\theta$, which can be interpreted as a blowing-up of a chain of $D0$-branes on $\mathbb{R}^{2n}_\theta$ into a chain of spherical $D2$-branes on $\mathbb{R}^{2n}_\theta \times S^2$. The low-energy dynamics of these configurations is described by a quiver gauge theory which can be formulated in terms of new geometrical objects generalizing superconnections. This formalism enables the explicit assignment of $D0$-brane charges in equivariant K-theory to the instanton solutions. © *2006 American Institute of Physics.*

I. INTRODUCTION AND SUMMARY

One of the most basic questions that arises in trying to understand the nonperturbative structure of string theory concerns the classification of vector bundles over real and complex manifolds. In the presence of D-branes one encounters gauge theories in space-time dimensionalities up to 10. Already more than 20 years ago, BPS-type equations in higher dimensions were proposed[1,2] as a generalization of the self-duality equations in four dimensions. For non-Abelian gauge theory on a Kähler manifold the most natural BPS condition lies in the Donaldson-Uhlenbeck-Yau equations,[3] which arise, for instance, in compactifications down to four-dimensional Minkowski space-time as the condition for at least one unbroken supersymmetry.

While the criteria for solvability of these BPS equations are by now very well understood, in practice it is usually quite difficult to write down explicit solutions of them. One recent line of attack has been to consider noncommutative deformations of these field theories.[4–6] In certain instances, D-branes can be realized as noncommutative solitons,[7] which is a consequence[8,9] of the relationship between D-branes and K-theory.[10–13] All celebrated BPS configurations in field theories, such as instantons,[14] monopoles[15] and vortices,[16] have been generalized to the noncommutative case, originally in Ref. 17, in Refs. 18 and in Ref. 19, respectively (see Ref. 20 for reviews and further references). Solution generating techniques such as the Atiyah, Drinfeld, Hitchin, and Manin (ADHM) construction,[21] splitting,[22] and dressing[23] methods have also been generalized to the noncommutative setting in Refs. 17,24 and in Ref. 25. Solutions of the generalized self-duality equations[1,2] were investigated in Refs. 2 and 26, for example. Noncommutative instantons in

b)Electronic mail: r.j.szabo@ma.hw.ac.uk

higher dimensions and their interpretations as *D*-branes in string theory have been considered in Refs. 27–30. In all of these constructions the usual world volume description of *D*-branes emerges from the equivalence between analytic and topological formulations of *K*-homology.

In this paper we will complete the construction initiated in Refs. 29 and 30 of multi-instanton solutions of the Yang-Mills equations on the manifold which is the product of noncommutative Euclidean space $\mathbb{R}^{2n}_\theta$ with an ordinary two-sphere S^2. We consider both BPS and non-BPS solutions, and extend previous solutions to those which are explicitly SU(2)-equivariant for any value of the Dirac monopole charge characterizing the gauge field components along the S^2 directions. Dimensional reduction techniques are used to establish an equivalence between multi-instantons on $\mathbb{R}^{2n}_\theta \times S^2$ and non-Abelian vortices on $\mathbb{R}^{2n}_\theta$. The configurations can be interpreted in Type IIA superstring theory as *chains* of branes and antibranes with Higgs-type open string excitations between neighboring sets of *D*-branes. The equivalence between instantons and vortices may then be attributed to the decay of an unstable configuration of $D(2n)$-branes into a state of $D0$-branes (there are no higher brane charges induced because $\mathbb{R}^{2n}$ is equivariantly contractible). The $D0$-brane charges are classified by SU(2)-equivariant *K*-theory and the low-energy dynamics may be succinctly encoded into a simple quiver gauge theory. Unlike the standard brane-antibrane systems, the effective action cannot be recast using the formalism ofsuperconnections[31] but requires a more general formulation in terms of new geometrical entities that we call "graded connections." This formalism makes manifest the interplay between the assignment of *K*-theory classes to the explicit instanton solutions and their realization in terms of a quiver gauge theory.

The organization of this paper is as follows. The material is naturally divided into two parts. Sections II–V deal with *ordinary* gauge theory on a generic Kähler manifold of the form $M_{2n} \times \mathbb{C}P^1$ in order to highlight the geometric structures that arise due to dimensional reduction and which play a prominent role throughout the paper. Sections VI–X are then concerned with the noncommutative deformation $\mathbb{R}^{2n} \times \mathbb{C}P^1 \to \mathbb{R}^{2n}_\theta \times \mathbb{C}P^1$ and they construct explicit solutions of the dimensionally reduced Yang-Mills equations, emphasizing their interpretations in the context of equivariant *K*-theory, quiver gauge theory, and ultimately as states of *D*-branes. In Sec. II we introduce basic definitions and set some of our notation, and present the field equations that are to be solved. In Section III we write down an explicit ansatz for the gauge field which is used in the SU(2)-equivariant dimensional reduction. In Sec. IV we describe three different interpretations of the ansatz as configurations of *D*-branes, as charges in equivariant *K*-theory, and as field configurations in a quiver gauge theory (later on these three descriptions are shown to be equivalent). In Sec. V the dimensional reduction mechanism is explained in detail in the new language of graded connections and the resulting nonabelian vortex equations, arising from reduction of the Donaldson-Uhlenbeck-Yau equations, are written down. In Sec. VI we introduce the noncommutative deformations of all these structures. In Sec. VII we find explicit BPS and non-BPS solutions of the noncommutative Yang-Mills equations and show how they naturally realize representations of the pertinent quiver. In Sec. VIII we develop an SU(2)-equivariant generalization of the (noncommutative) Atiyah-Bott-Shapiro construction, which provides an explicit and convenient representation of our solution in terms of *K*-homology classes. In Sec. IX we compute the topological charge of our instanton solutions directly in the noncommutative gauge theory, and show that it coincides with the corresponding *K*-theory charge, which then allows us to assign $D0$-brane charges to the solutions from a world volume perspective. Finally, in Sec. X we construct some BPS solutions in the vacuum sectors of the noncommutative field theory and describe their relation to stable states of brane-antibrane systems.

II. YANG-MILLS EQUATIONS

In this section we will introduce the basic definitions and notation that will be used throughout this paper, as well as the pertinent field equations that we will solve.

The manifold $\mathcal{M}_q \times S^2$: Let $\mathcal{M}_q$ be a real q-dimensional Lorentzian manifold with nondegenerate metric of signature $(-+\cdots+)$, and $S^2 \cong \mathbb{C}P^1$ the standard two-sphere of constant radius R. We shall consider the manifold $\mathcal{M}_q \times S^2$ with local real coordinates $x' = (x^{\mu'}) \in \mathbb{R}^q$ on $\mathcal{M}_q$ and coordinates $\vartheta \in [0,\pi], \varphi \in [0,2\pi]$ on S^2. In these coordinates the metric on $\mathcal{M}_q \times S^2$ reads

$$\mathrm{d}\hat{s}^2 = g_{\hat{\mu}\hat{\nu}}\,\mathrm{d}x^{\hat{\mu}}\,\mathrm{d}x^{\hat{\nu}} = g_{\mu'\nu'}\,\mathrm{d}x^{\mu'}\,\mathrm{d}x^{\nu'} + R^2(d\vartheta^2 + \sin^2\vartheta\,\mathrm{d}\varphi^2), \tag{2.1}$$

where hatted indices $\hat{\mu},\hat{\nu},\ldots$ run over $0,1,\ldots,q+1$ while primed indices $\mu',\nu',\ldots$ run through $0,1,\ldots,q-1$. We use the Einstein summation convention for repeated space-time indices.

The Kähler manifold $M_{2n}\times\mathbb{C}P^1$: As a special instance of the manifold $\mathcal{M}_q$ we shall consider the product $\mathcal{M}_q=\mathbb{R}^1\times M_{2n}$ of dimension $q=2n+1$ with metric,

$$g_{\mu'\nu'}\,\mathrm{d}x^{\mu'}\,\mathrm{d}^{\nu'} = -(\mathrm{d}x^0)^2 + g_{\mu\nu}\,\mathrm{d}x^{\mu}\,\mathrm{d}x^{\nu}. \tag{2.2}$$

Here M_{2n} is a Kähler manifold of real dimension $2n$ with local real coordinates $x=(x^\mu)\in\mathbb{R}^{2n}$, where the indices $\mu,\nu,\ldots$ run through $1,\ldots,2n$. The Cartesian product $M_{2n}\times\mathbb{C}P^1$ is also a Kähler manifold with local complex coordinates $(z^1,\ldots,z^n,y)\in\mathbb{C}^{n+1}$ and their complex conjugates, where

$$z^a = x^{2a-1} - ix^{2a} \quad \text{and} \quad \overline{z^a} = x^{2a-1} + ix^{2a} \quad \text{with } a=1,\ldots,n \tag{2.3}$$

while

$$y = \frac{R\sin\vartheta}{1+\cos\vartheta}\exp(-i\varphi) \quad \text{and} \quad \overline{y} = \frac{R\sin\vartheta}{1+\cos\vartheta}\exp(i\varphi) \tag{2.4}$$

are stereographic coordinates on the northern hemisphere of S^2. In these coordinates the metric on $M_{2n}\times\mathbb{C}P^1$ takes the form

$$\mathrm{d}s^2 = g_{\mu\nu}\,\mathrm{d}x^{\mu}\,\mathrm{d}x^{\nu} + R^2(d\vartheta^2+\sin^2\vartheta\,\mathrm{d}\varphi^2) = 2g_{a\bar{b}}\mathrm{d}z^a\,\mathrm{d}\overline{z^b} + \frac{4R^4}{(R^2+y\overline{y})^2}\mathrm{d}y\,\mathrm{d}\overline{y}, \tag{2.5}$$

while the Kähler two-form ω is given by

$$\omega = \tfrac{1}{2}\omega_{\mu\nu}\,\mathrm{d}x^{\mu}\wedge\mathrm{d}x^{\nu} + R^2\sin\vartheta\,\mathrm{d}\vartheta\wedge\mathrm{d}\varphi = -2ig_{a\bar{b}}\mathrm{d}z^a\wedge\,\mathrm{d}\overline{z^b} - \frac{4iR^4}{(R^2+y\overline{y})^2}\mathrm{d}y\wedge\mathrm{d}\overline{y}. \tag{2.6}$$

Yang-Mills equations: Consider a rank k Hermitian vector bundle $\mathcal{E}\to\mathcal{M}_q\times S^2$ with gauge connection $\mathcal{A}$ of curvature $\mathcal{F}=\mathrm{d}\mathcal{A}+\mathcal{A}\wedge\mathcal{A}$. In local coordinates, wherein $\mathcal{A}=\mathcal{A}_{\hat{\mu}}\,\mathrm{d}x^{\hat{\mu}}$, the two-form $\mathcal{F}$ has components $\mathcal{F}_{\hat{\mu}\hat{\nu}}=\partial_{\hat{\mu}}\mathcal{A}_{\hat{\nu}}-\partial_{\hat{\nu}}\mathcal{A}_{\hat{\mu}}+[\mathcal{A}_{\hat{\mu}},\mathcal{A}_{\hat{\nu}}]$, where $\partial_{\hat{\mu}}:=\partial/\partial x^{\hat{\mu}}$. Both $\mathcal{A}_{\hat{\mu}}$ and $\mathcal{F}_{\hat{\mu}\hat{\nu}}$ take values in the Lie algebra $u(k)$. For the usual Yang-Mills Lagrangian (the Yang-Mills coupling constant g_{YM} can be introduced via the redefinition $\mathcal{A}\mapsto g_{\mathrm{YM}}\mathcal{A}$),

$$L_{\mathrm{YM}} = -\tfrac{1}{4}\sqrt{g}\,\mathrm{tr}_{k\times k}\,\mathcal{F}_{\hat{\mu}\hat{\nu}}\mathcal{F}^{\hat{\mu}\hat{\nu}} \tag{2.7}$$

the equations of motion are

$$\frac{1}{\sqrt{g}}\partial_{\hat{\mu}}(\sqrt{g}\mathcal{F}^{\hat{\mu}\hat{\nu}}) + [\mathcal{A}_{\hat{\mu}},\mathcal{F}^{\hat{\mu}\hat{\nu}}] = 0, \tag{2.8}$$

where $g=|\det(g_{\hat{\mu}\hat{\nu}})|$. The curvature two-form can be written in local coordinates on $\mathcal{M}_q\times\mathbb{C}P^1$ as

$$\mathcal{F} = \tfrac{1}{2}\mathcal{F}_{\mu'\nu'}\,\mathrm{d}x^{\mu'}\wedge\mathrm{d}x^{\nu'} + \mathcal{F}_{\mu' y}\,\mathrm{d}x^{\mu'}\wedge\mathrm{d}y + \mathcal{F}_{\mu'\bar{y}}\mathrm{d}x^{\mu'}\wedge\mathrm{d}\overline{y} + \mathcal{F}_{y\bar{y}}\mathrm{d}y\wedge\mathrm{d}\overline{y} \tag{2.9}$$

and the Yang-Mills Lagrangian becomes

$$L_{\mathrm{YM}} = -\tfrac{1}{4}\sqrt{g}\,\mathrm{tr}_{k\times k}\left[\mathcal{F}_{\mu'\nu'}\mathcal{F}^{\mu'\nu'} + \frac{(R^2+y\overline{y})^2}{R^4}g^{\mu'\nu'}(\mathcal{F}_{\mu' y}\mathcal{F}_{\nu'\bar{y}} + \mathcal{F}_{\mu'\bar{y}}\mathcal{F}_{\nu' y}) - \frac{1}{2}\left(\frac{(R^2+y\overline{y})^2}{R^4}\mathcal{F}_{y\bar{y}}\right)^2\right]. \tag{2.10}$$

Donaldson-Uhlenbeck-Yau equations: For static field configurations in the temporal gauge $\mathcal{A}_0=0$, the Yang-Mills equations (2.8) on $\mathbb{R}^1\times M_{2n}\times\mathbb{C}P^1$ reduce to equations on $M_{2n}\times\mathbb{C}P^1$. Their

stable solutions are provided by solutions of the Donaldson-Uhlenbeck-Yau (DUY) equations which can be formulated on any Kähler manifold.[3] The importance of these equations derives from the fact that they yield the BPS solutions of the full Yang-Mills equations.

The DUY equations on $M_{2n}\times\mathbb{C}P^1$ are

$$*\omega\wedge\mathcal{F}=0 \quad \text{and} \quad \mathcal{F}_{0,2}=0, \tag{2.11}$$

where * is the Hodge duality operator and $\mathcal{F}=\mathcal{F}^{2,0}+\mathcal{F}^{1,1}+\mathcal{F}^{0,2}$ is the Kähler decomposition of the gauge field strength. In the local complex coordinates (z^a,y) these equations take the form

$$g^{a\bar{b}}\mathcal{F}_{z^a\bar{z}^b}+\frac{(R^2+y\bar{y})^2}{2R^4}\mathcal{F}_{y\bar{y}}=0, \tag{2.12}$$

$$\mathcal{F}_{\bar{z}^a\bar{z}^b}=0=\mathcal{F}_{z^az^b}, \tag{2.13}$$

$$\mathcal{F}_{\bar{z}^a\bar{y}}=0=\mathcal{F}_{z^ay}, \tag{2.14}$$

where the indices $a,b,\ldots$ run through $1,\ldots,n$. Equation (2.12) is a Hermitian condition on the gauge field strength tensor, while Eqs. (2.13) and (2.14) are integrability conditions implying that the bundle $\mathcal{E}$ (and its connection $\mathcal{A}$) is holomorphic. It is easy to show that any solution of these $n(n+1)+1$ equations also satisfies the full Yang-Mills equations.

III. INVARIANT GAUGE FIELDS

In this section we shall write down the fundamental form of the gauge field $\mathcal{A}$ on $\mathcal{M}_q\times\mathbb{C}P^1$ that will be used later on to dimensionally reduce the Yang-Mills equations for $\mathcal{A}$ to equations on $\mathcal{M}_q$. This will be achieved by prescribing a specific $\mathbb{C}P^1$ dependence for $\mathcal{A}$, which we proceed to describe first.

Monopole bundles: Consider the Hermitian line bundle $\mathcal{L}^m\to\mathbb{C}P^1$ over the sphere with $\mathcal{L}^m:=(\mathcal{L})^{\otimes m}$ and unique SU(2)-invariant unitary connection a_m having, in the local complex coordinate y on $\mathbb{C}P^1$, the form

$$a_m=\frac{m}{2(R^2+y\bar{y})}(\bar{y}\,\mathrm{d}y-y\,\mathrm{d}\bar{y}), \tag{3.1}$$

where m is an integer. The curvature of this connection is

$$f_m=\mathrm{d}a_m=-\frac{mR^2}{(R^2+y\bar{y})^2}\mathrm{d}y\wedge\mathrm{d}\bar{y}. \tag{3.2}$$

The topological charge of this gauge field configuration is given by the first Chern number (equivalently the degree) of the associated complex line bundle as

$$\deg\mathcal{L}^m=\frac{i}{2\pi}\int_{\mathbb{C}P^1}f_m=m. \tag{3.3}$$

In terms of the spherical coordinates (ϑ,φ) the configuration (3.1) and (3.2) has the form

$$a_m=-\frac{im}{2}(1-\cos\vartheta)\mathrm{d}\varphi \quad \text{and} \quad f_m=\mathrm{d}a_m=-\frac{im}{2}\sin\vartheta\,\mathrm{d}\vartheta\wedge\mathrm{d}\varphi. \tag{3.4}$$

It describes $|m|$ Dirac monopoles or antimonopoles sitting on top of each other.

The m-monopole bundle is classified by the Hopf fibration $S^1\hookrightarrow S^3\to S^2$. For each $m\in\mathbb{Z}$ there is a one-dimensional representation $\boldsymbol{\nu}m=(\boldsymbol{\nu}_i)^{\otimes m}$ of the circle group $\mathrm{U}(1)\cong S^1$ defined by

$$\boldsymbol{\nu}_m : v \mapsto \zeta \cdot v = \zeta^m v \quad \text{with } \zeta \in S^1 \text{ and } v \in \mathbb{C}. \tag{3.5}$$

We denote this irreducible U(1)-module by $\underline{S}_m \cong \mathbb{C}$. Regarding the sphere as the homogeneous space $\mathbb{C}P^1 \cong \mathrm{SU}(2)/\mathrm{U}(1)$, the SU(2)-equivariant line bundle $\mathcal{L}^m \to \mathbb{C}P^1$ corresponds to the representation $\boldsymbol{\nu}_m$ in the sense that it can be expressed as

$$\mathcal{L}^m = \mathrm{SU}(2) \times_{\mathrm{U}(1)} \underline{S}_m, \tag{3.6}$$

where the quotient on $\mathrm{SU}(2) \times \underline{S}_m$ is by the U(1) action $\zeta \cdot (g, v) = (g\zeta^{-1}, \zeta^m v)$ for $g \in \mathrm{SU}(2), v \in \underline{S}_m$, and $\zeta \in \mathrm{U}(1)$. The action of SU(2) on $\mathrm{SU}(2) \times \underline{S}_m$ given by $g' \cdot (g, v) = (g'g, v)$ descends to an action on (3.6). Any SU(2)-equivariant Hermitian vector bundle over the sphere is a Whitney sum of bundles (3.6).

There is an alternative description in terms of the holomorphic line bundle $\mathcal{O}(m) \to \mathbb{C}P^1$ defined as the mth power of the tautological bundle over the complex projective line. The universal complexification of the Lie group SU(2) is $\mathrm{SL}(2,\mathbb{C})$, and we may regard the sphere as a projective variety through the natural diffeomorphism $\mathbb{C}P^1 \cong \mathrm{SU}(2)/\mathrm{U}(1) \cong \mathrm{SL}(2,\mathbb{C})/\mathrm{P}$, where P is the parabolic subgroup of lower triangular matrices in $\mathrm{SL}(2,\mathbb{C})$. The SU(2) action on (3.6) lifts to a smooth $\mathrm{SL}(2,\mathbb{C})$ action, and the complexification of (3.6) is realized as the $\mathrm{SL}(2,\mathbb{C})$-equivariant line bundle

$$\mathcal{O}(m) = \mathrm{SL}(2,\mathbb{C}) \times_{\mathrm{P}} \underline{S}_m \tag{3.7}$$

over $\mathbb{C}P^1$. Only the Cartan subgroup $\mathbb{C}^\times \subset P$ of nonzero complex numbers acts nontrivially on the modules $\underline{S}_m$, with the $\mathbb{C}^\times$ action defined analogously to (3.5). The two descriptions are equivalent after the introduction of a Hermitian metric on the fibers of $\mathcal{O}(m)$. This holomorphic line bundle has transition function y^m transforming sections from the northern hemisphere to the southern hemisphere of S^2. However, the monopole connection (3.1) is transformed on the intersection of the two patches covering $\mathbb{C}P^1$ via the transition function $(y/\overline{y})^{m/2}$, which is the unitary reduction of the holomorphic transition function y^m. Thus the bundle $\mathcal{O}(m)$ regarded as a Hermitian line bundle has transition function $(y/\overline{y})^{m/2}$ and can be substituted for the monopole bundle $\mathcal{L}^m$.

SU(2)-invariant gauge potential: The form of our ansatz for the gauge connection on $\mathcal{M}_q \times \mathbb{C}P^1$ is fixed by imposing invariance under the SU(2) isometry group of $\mathbb{C}P^1$ acting through rigid rotations of the sphere. Let $\mathcal{E} \to \mathcal{M}_q \times \mathbb{C}P^1$ be an SU(2)-equivariant U(k) bundle, with the group SU(2) acting trivially on $\mathcal{M}_q$ and in the standard way on $\mathbb{C}P^1 = \mathrm{SU}(2)/\mathrm{U}(1)$. Let $\mathcal{A}$ be a connection on $\mathcal{E}$. Imposing the condition of SU(2)-equivariance means that we should look for representations of the group SU(2) inside the U(k) structure group, i.e., for homomorphisms $\rho : \mathrm{SU}(2) \to \mathrm{U}(k)$. The ansatz for $\mathcal{A}$ is thus given by k-dimensional representations of SU(2). Up to isomorphism, for each positive integer d there is a unique irreducible SU(2)-module $\underline{V}_d \cong \mathbb{C}^d$ of dimension d. Therefore, for each positive integer m, the module

$$\underline{\mathcal{V}} = \bigoplus_{i=0}^{m} \underline{V}_{k_i}, \quad \text{with } \sum_{i=0}^{m} k_i = k \tag{3.8}$$

gives a representation ρ of SU(2) inside U(k). The total number of such homomorphisms is the number of partitions of the positive integer rank $(\mathcal{E}) = k$ into $\leqslant (m+1)$ components. The original U(k) gauge symmetry is then broken down to the centralizer subgroup of $\rho(\mathrm{SU}(2))$ in U(k) as

$$\mathrm{U}(k) \to \prod_{i=0}^{m} \mathrm{U}(k_i). \tag{3.9}$$

It is natural to allow for gauge transformations to accompany the SU(2) action,[32] and so some "twisting" can occur in the reduction of the connection $\mathcal{A}$ on $\mathcal{M}_q \times \mathbb{C}P^1$. The $\mathbb{C}P^1$ dependence in this case is uniquely determined by the above SU(2)-invariant Dirac monopole configurations.[33,34] The $u(k)$-valued gauge potential $\mathcal{A}$ thus splits into $k_i \times k_j$ blocks $\mathcal{A}^{ij}$,

$$\mathcal{A} = (\mathcal{A}^{ij}) \quad \text{with } \mathcal{A}^{ij} \in \mathrm{Hom}(\underline{V}_{k_j}, \underline{V}_{k_i}), \tag{3.10}$$

where the indices $i, j, \ldots$ run over $0, 1, \ldots, m, k_0 + k_1 + \cdots + k_m = k$ and

$$\mathcal{A}^{ii} = A^i(x') \otimes 1 + \mathbf{1}_{k_i} \otimes a_{m-2i}(y), \tag{3.11}$$

$$\mathcal{A}^{ii+1} =: \Phi_{i+1} = \phi_{i+1}(x') \otimes \overline{\beta}(y), \tag{3.12}$$

$$\mathcal{A}^{i+1i} = -(\mathcal{A}^{ii+1})^\dagger = -(\Phi_{i+1})^\dagger = -\phi_{i+1}^\dagger(x') \otimes \beta(y), \tag{3.13}$$

$$\mathcal{A}^{ii+l} = 0 = \mathcal{A}^{i+li} \quad \text{for } l \geqslant 2. \tag{3.14}$$

Here

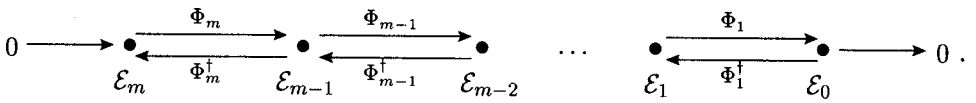
$$\beta = \frac{R\,\mathrm{d}y}{R^2 + y\overline{y}} \quad \text{and} \quad \overline{\beta} = \frac{R\,\mathrm{d}\overline{y}}{R^2 + y\overline{y}} \tag{3.15}$$

are the unique covariantly constant, SU(2)-invariant forms of type (1,0) and (0,1) such that the Kähler (1,1)-form on $\mathbb{C}P^1$ is $4R^2\beta\wedge\overline{\beta}$. They, respectively, take values in the bundles $\mathcal{L}^2$ and $\mathcal{L}^{-2}$.

It is easy to see that the gauge potential $\mathcal{A}$ given by (3.11)–(3.14) is anti-Hermitian and SU(2)-invariant. Note that we do not use the Einstein summation convention for the repeated indices i labelling the components of the irreducible representation $\underline{V}_{m+1} \cong \mathbb{C}^{m+1}$ of the group SU(2). Thus the gauge potential $\mathcal{A} \in u(k)$ decomposes into gauge potentials $A^i \in u(k_i)$ with $i = 0, 1, \ldots, m$ and a multiplet of scalar fields ϕ_{i+1} with $i = 0, 1, \ldots, m-1$ transforming in the bifundamental representations $\underline{V}_{k_i} \otimes \underline{V}_{k_i+1}^\vee$ of the subgroup $\mathrm{U}(k_i) \times \mathrm{U}(k_i+1)$ of the original $\mathrm{U}(k)$ gauge group. All fields (A^i, ϕ_{i+1}) depend only on the coordinates $x' \in \mathcal{M}_q$. Every SU(2)-invariant unitary connection $\mathcal{A}$ on $\mathcal{M}_q \times \mathbb{C}P^1$ is of the form given in (3.10)–(3.14),[34] which follow from the fact that the complexified cotangent bundle of $\mathbb{C}P^1$ is $\mathcal{L}^2 \otimes \mathcal{L}^{-2}$. This ansatz amounts to an equivariant decomposition of the original rank k SU(2)-equivariant bundle $\mathcal{E} \to \mathcal{M}_q \times \mathbb{C}P^1$ in the form

$$\mathcal{E} = \bigoplus_{i=0}^{m} \mathcal{E}_i \quad \text{with } \mathcal{E}_i = E_{k_i} \otimes \mathcal{L}^{m-2i}, \tag{3.16}$$

where $E_{ki} \to \mathcal{M}_q$ is a Hermitian vector bundle of rank k_i with typical fiber the module $\underline{V}_{ki}$, and $\mathcal{E}_i \to \mathcal{M}_q \times \mathbb{C}P^1$ is the bundle with fibers $(\mathcal{E}_i)_{(x',y,\overline{y})} = (E_{k_i})_{x'} \otimes (\mathcal{L}^{m-2i})_{(y,\overline{y})}$. By regarding $\Phi_i \in \mathrm{Hom}(\mathcal{E}_i, \mathcal{E}_{i-1}) \cong \mathrm{H}^0(\mathcal{M}_q \times \mathbb{C}P^1; \mathcal{E}_{i-1} \otimes \mathcal{E}_i^\vee)$ for $i = 1, \ldots, m$ and defining $\Phi_0 := 0 =: \Phi_{m+1}$, we can summarize our ansatz through the following chain of bundles:



(3.17)

Field strength tensor: The calculation of the curvature (2.9) for $\mathcal{A}$ of the form (3.10)–(3.14) yields,

$$\mathcal{F} = (\mathcal{F}^{ij}) \quad \text{with } \mathcal{F}^{ij} = \mathrm{d}\mathcal{A}^{ij} + \sum_{l=0}^{m} \mathcal{A}^{il} \wedge \mathcal{A}^{lj}, \tag{3.18}$$

where

$$\mathcal{F}^{ii} = F^i + f_{m-2i} + (\phi_{i+1}\phi_{i+1}^\dagger - \phi_i^\dagger\phi_i)\beta\wedge\overline{\beta}, \tag{3.19}$$

$$\mathcal{F}^{ii+1} = D\phi_{i+1}\wedge\overline{\beta}, \tag{3.20}$$

$$\mathcal{F}^{i+1i} = -(\mathcal{F}^{ii+1})^\dagger = -(D\phi_{i+1})^\dagger\wedge\beta, \tag{3.21}$$

$$\mathcal{F}^{ii+l} = 0 = \mathcal{F}^{i+li} \quad \text{for } l \geqslant 2. \tag{3.22}$$

Here we have defined $F^i := \mathrm{d}A^i + A^i\wedge A^i = \frac{1}{2}F^i_{\mu'\nu'}(x')\mathrm{d}x^{\mu'}\wedge\mathrm{d}x^{\nu'}$ and introduced the bifundamental covariant derivatives,

$$D\phi_{i+1} := \mathrm{d}\phi_{i+1} + A^i\phi_{i+1} - \phi_{i+1}A^{i+1}. \tag{3.23}$$

From (3.19)–(3.22) we find the nonvanishing field strength components

$$\mathcal{F}^{ii}_{\mu'\nu'} = F^i_{\mu'\nu'}, \tag{3.24}$$

$$\mathcal{F}^{ii+1}_{\mu'\overline{y}} = \frac{R}{R^2+y\overline{y}}D_{\mu'}\phi_{i+1} = -(\mathcal{F}^{i+1i}_{\mu' y})^\dagger, \tag{3.25}$$

$$\mathcal{F}^{ii}_{y\overline{y}} = -\frac{R^2}{(R^2+y\overline{y})^2}(m-2i+\phi_i^\dagger\phi_i - \phi_{i+1}\phi_{i+1}^\dagger). \tag{3.26}$$

IV. DESCRIPTION OF THE ANSATZ

In this section we shall clarify some features of the ansatz constructed in the preceding section from three different points of view. To set the stage for the string theory interpretations of the solutions that we will construct later on, we begin by indicating how the ansatz can be interpreted in terms of configurations of *D*-branes in Type II superstring theory. This leads into a discussion of how the ansatz is realized in topological *K*-theory, which classifies the Ramond-Ramond charges of these brane systems, and we will derive the decomposition (3.16) directly within the framework of SU(2)-equivariant *K*-theory. We will then explain how seeking explicit realizations of our ansatz is equivalent to finding representations of the A_{m+1} quiver. One of the goals of the subsequent sections will be to establish the precise link between these three descriptions, showing that they are all equivalent.

Physical interpretation: Before entering into the formal mathematical characterizations of the ansatz of the preceding section, let us first explain the physical situation which they will describe. Our ansatz implies an equivalence between brane-antibrane systems on $\mathcal{M}_q$ and wrapped branes on $\mathcal{M}_q\times\mathbb{C}P^1$. In the standard *D*-brane interpretation, our initial rank k Hermitian vector bundle $\mathcal{E}\to\mathcal{M}_q\times\mathbb{C}P^1$ corresponds to k coincident $D(q+1)$-branes wrapping the world volume manifold $\mathcal{M}_q\times\mathbb{C}P^1$. The condition of SU(2)-equivariance imposed on this bundle fixes the dependence on the coordinates of $\mathbb{C}P^1$ and breaks the gauge group U(k) as in (3.9). The rank k_i sub-bundle $E_{k_i}\to\mathcal{M}_q$ of this bundle is twisted by the Dirac multimonopole bundle $\mathcal{L}^{m-2i}\to\mathbb{C}P^1$. The system of k coincident $D(q+1)$-branes thereby splits into blocks of $k_0+k_1+\cdots+k_m=k$ coincident $D(q+1)$-branes, associated to irreducible representations of SU(2) and wrapping a common sphere $\mathbb{C}P^1$ with the monopole fields. This system is equivalent to a system of $k_0+k_1+\cdots+k_m=k$ $D(q-1)$-branes carrying different magnetic fluxes on their common world volume $\mathcal{M}_q$. The $D(q-1)$-branes which carry negative magnetic flux have opposite orientation with respect to the $D(q-1)$-branes with positive magnetic flux, i.e., they are antibranes. This will become evident

from the K-theory formalism, which will eventually lead to an explicit world volume construction, and also from the explicit calculation of the topological charges of the instanton solutions. In addition to the usual Chan-Paton gauge field degrees of freedom $A^i \in \mathrm{End}(E_{k_i})$ living on each block of branes, the field content on the brane configuration contains bifundamental scalar fields $\phi_{i+1} \in \mathrm{Hom}(E_{k_{i+1}}, E_{k_i})$ corresponding to massless open string excitations between neighboring blocks of k_i and k_{i+1} $D(q-1)$-branes. Other excitations are suppressed by the condition of SU(2)-equivariance.

However, as we shall see explicitly in the following, the fields ϕ_{i+1} should not be regarded as tachyon fields, but rather only as (holomorphic) Higgs fields responsible for the symmetry breaking (3.9). Only the brane-antibrane pairs whose constituents carry equal and opposite monopole charges are neutral and can thus annihilate to the vacuum, which carries no monopole charge (although it can carry a K-theory charge from the virtual Chan-Paton bundles over $\mathcal{M}_q$). Other brane pairs are stable because their overall nonvanishing Chern number over $\mathbb{C}P^1$ is an obstruction to decay, and the monopole bundles thereby act as a source of flux stabilization for such brane pairs by giving them a conserved topological charge. In particular, neighboring blocks of $D(q-1)$-branes are marginally bound by the massless open strings stretching between them. In this sense, the SU(2)-invariant reduction of D-branes on $\mathcal{M}_q \times \mathbb{C}P^1$ induces brane-antibrane systems on $\mathcal{M}_q$. Note that while the system on $\mathcal{M}_q$ is generically unstable, the original brane configuration on $\mathcal{M}_q \times \mathbb{C}P^1$ can be nonetheless stable.

K-theory charges: Given that the charges of configurations of D-branes in string theory are classified topologically by K-theory,[10,11,13] let us now seek the K-theory representation of the above physical situation. The one-monopole bundle $\mathcal{L}$ is a crucial object in establishing the Bott periodicity isomorphism

$$K(\mathcal{M}_q \times \mathbb{C}P^1) = K(\mathcal{M}_q) \tag{4.1}$$

in topological K-theory. The isomorphism is generated by taking the K-theory product of the tachyon field ϕ_1, $E_{k_1} \to E_{k_0}$ of a virtual bundle $[E_{k_0}, E_{k_1}; \phi_1] \in K(\mathcal{M}_q)$ with that of the class of the line bundle $\mathcal{L}$ which represents the Bott generator of $\widetilde{K}(\mathbb{C}P^1) = Z$.[11] The topological equivalence (4.1) then implies the equivalence of brane-antibrane systems on $\mathcal{M}_q \times \mathbb{C}P^1$ and $\mathcal{M}_q$. with the brane and antibrane systems each carrying a single unit of monopole charge. When they carry $m > 1$ units of charge, the isomorphism breaks down, and it is necessary to introduce the notion of "D-operations" to establish the relationship.[30] While these operations are natural, they are not isomorphisms and they reflect the fact that the explicit solutions in this setting are not SU(2)-invariant, so that the equivalence breaks downdue to spurious moduli dependences of the system of branes on the $\mathbb{C}P^1$ factor. In what follows we will derive a modification of the relation (4.1) in equivariant K-theory which will naturally give the desired isomorphism, reflecting the equivalence of the brane-antibrane systems for arbitrary monopole charge, and bypass the need for introducing D-operations. This is only possible by augmenting the basic brane-antibrane system to a *chain* of $(m+1)$ branes and antibranes with varying units of monopole charge as described above, and we will thereby arrive at an independent purely K-theoretic derivation of our ansatz.

The representation ring R_G of a group G (Ref. 35) is the Grothendieck ring of the category of finite-dimensional representations of G, with addition induced by direct sum of vector spaces, $[\underline{V}] + [\underline{V}'] := [\underline{V} \oplus \underline{V}']$, and multiplication induced by tensor product of modules, $[\underline{V}] \cdot [\underline{V}'] := [\underline{V} \otimes \underline{V}']$. As an Abelian group it is generated by the irreducible representations of G. Alternatively, since the isomorphism class of a G-module $\underline{V}$ is completely determined by its character $\chi_{\underline{V}} : G \to \mathbb{C}$, the map $\underline{V} \mapsto \chi_{\underline{V}}$ identifies R_G as a subring of the ring of G-invariant functions on G. If $\mathcal{M}_q$ is a G-space, then the Grothendieck group of G-equivariant bundles over $\mathcal{M}_q$ is called the G-equivariant K-theory group $K_G(\mathcal{M}_q)$. This group unifies ordinary K-theory with group representation theory, in the sense that for the trivial space $K_G(\mathrm{pt}) = R_G$ is the representation ring of G, while for the trivial group $K_{\mathrm{id}}(\mathcal{M}_q) = K(\mathcal{M}_q)$ is the ordinary K-theory of $\mathcal{M}_q$. The former property

implies that $K_G(\mathcal{M}_q)$ is an R_G-module and the coefficient ring in equivariant K-theory is R_G, rather than just $\mathbb{Z}$ as in the ordinary case. If the G-action on $\mathcal{M}_q$ is trivial, then any G-equivariant bundle $E\to\mathcal{M}_q$ may be decomposed as a finite Whitney sum

$$E=\bigoplus_{\underline{V}\in \mathrm{Rep}(G)} \mathrm{Hom}_G(\mathbb{1}_{\underline{V}},E)\otimes \mathbb{1}_{\underline{V}}, \tag{4.2}$$

where $\mathbb{1}_{\underline{V}}=\mathcal{M}_q\times \underline{V}$ is the trivial bundle over $\mathcal{M}_q$ with fiber the irreducible G-module $\underline{V}$. It follows that for trivial G-actions the equivariant K-theory takes the simple form

$$K_G(\mathcal{M}_q)=K(\mathcal{M}_q)\otimes R_G. \tag{4.3}$$

The K_G-functor behaves analogously to the ordinary K-functor, and in addition K_G is functorial with respect to group homomorphisms. A useful computational tool is the equivariant excision theorem. If F is a closed subgroup of G and $\mathcal{M}_q$ is an F-space, then the inclusion $\iota: F\hookrightarrow G$ induces an isomorphism[35]

$$\iota^*: K_G(G\times_F \mathcal{M}_q)\xrightarrow{\approx} K_F(\mathcal{M}_q), \tag{4.4}$$

where the quotient on $G\times\mathcal{M}_q$ is by the F-action $f\cdot(g,x')=(gf^{-1},f\cdot x')$ for $g\in G, x'\in\mathcal{M}_q$ and $f\in F$. The G-action on $G\times_F\mathcal{M}_q$ descends from that on $G\times\mathcal{M}_q$ given by $g'\cdot(g,x')=(g'g,x')$.

Let us specialize to our case of interest by taking $G=\mathrm{SU}(2)$, $F=\mathrm{U}(1)$ and the trivial action of SU(2) on the space $\mathcal{M}_q$. Using (4.3) and (4.4) we may then compute

$$K_{\mathrm{SU}(2)}(\mathcal{M}_q\times\mathbb{C}P^1)=K_{\mathrm{SU}(2)}(\mathrm{SU}(2)\times_{\mathrm{U}(1)}\mathcal{M}_q)=K_{\mathrm{U}(1)}(\mathcal{M}_q)=K(\mathcal{M}_q)\otimes R_{\mathrm{U}(1)}. \tag{4.5}$$

This K-theoretic equality asserts a one-to-one correspondence between classes of SU(2)-equivariant bundles over $\mathcal{M}_q\times\mathbb{C}P^1$ and classes of U(1)-equivariant bundles over $\mathcal{M}_q$ with U(1) acting trivially on $\mathcal{M}_q$. The isomorphism (4.5) of equivariant K-theory groups is constructed explicitly as follows.[35] Given an SU(2)-equivariant bundle $\mathcal{E}\to\mathcal{M}_q\times\mathbb{C}P^1$, we can induce a U(1)-equivariant bundle $E=i^*\mathcal{E}\to\mathcal{M}_q$ by restriction to the slice $\mathcal{M}_q\cong\mathcal{M}_q\times\mathrm{U}(1)/\mathrm{U}(1)\xrightarrow{\iota}\mathcal{M}_q\times\mathrm{SU}(2)/\mathrm{U}(1)$. Conversely, if $E\to\mathcal{M}_q$ is a U(1)-equivariant bundle, then $\mathcal{E}=\mathrm{SU}(2)\times_{\mathrm{U}(1)}E\to\mathcal{M}_q\times\mathbb{C}P^1$ is an SU(2)-equivariant bundle, where the quotient on $\mathrm{SU}(2)\times E$ is by the action of U(1) on both factors, $\zeta\cdot(g,e)=(g\zeta^{-1},\zeta\cdot e)$ for $g\in\mathrm{SU}(2), e\in E, \zeta\in\mathrm{U}(1)$, and the action of $g'\in\mathrm{SU}(2)$ on $\mathrm{SU}(2)\times_{\mathrm{U}(1)}E$ descends from that on $\mathrm{SU}(2)\times E$ given by $g'\cdot(g,e)=(g'g,e)$. This construction defines equivalence functors between the categories of SU(2)-equivariant vector bundles over $\mathcal{M}_q\times\mathbb{C}P^1$ and U(1)-equivariant vector bundles over $\mathcal{M}_q$, and hence the corresponding Grothendieck groups coincide, as in (4.5).

The role of the representation ring $R_{\mathrm{U}(1)}$ is unveiled by setting $\mathcal{M}_q=\mathrm{pt}$ in (4.5) to get

$$K_{\mathrm{SU}(2)}(\mathbb{C}P^1)=R_{\mathrm{U}(1)}, \tag{4.6}$$

which establishes a one-to-one correspondence between classes of homogeneous vector bundles over the sphere $\mathbb{C}P^1$ and classes of finite-dimensional representations of U(1). Since the corresponding irreducible representations are the $\boldsymbol{\nu}_m$ given by (3.5), the representation ring of U(1) is the ring of formal Laurent polynomials in the variable $\boldsymbol{\nu}_1$, $R_{\mathrm{U}(1)}=\mathbb{Z}[\boldsymbol{\nu}_1,\boldsymbol{\nu}_1^{-1}]$. Using (3.6) we can associate the monopole bundle $\mathcal{L}$ to the generator $\boldsymbol{\nu}_1$, and thereby identify (4.6) as the Laurent polynomial ring

$$K_{\mathrm{SU}(2)}(\mathbb{C}P^1)=\mathbb{Z}[\mathcal{L},\mathcal{L}^\vee]. \tag{4.7}$$

In particular, the relationship (4.5) can be expressed as

$$K_{\mathrm{SU}(2)}(\mathcal{M}_q \times \mathbb{C}P^1) = K(\mathcal{M}_q) \otimes \mathbb{Z}[\mathcal{L}, \mathcal{L}^\vee]. \tag{4.8}$$

This is the appropriate modification of the Bott periodicity isomorphism (4.1) to the present setting. The crucial difference now is that virtual bundles over $\mathcal{M}_q$ are multiplied by arbitrary powers of the one-monopole bundle, allowing us to extend the equivalence to arbitrary monopole charges $m \in \mathbb{Z}$. In the equivariant setting, there is no need to use external twists of the monopole bundle, nor the ensuing K-theory product as done in Ref. 30. The monopole fluxes are now naturally incorporated by the coefficient ring $R_{\mathrm{U}(1)}$ of the U(1)-equivariant K-theory, superseding the need for introducing D-operations.

It is instructive to see precisely how the correspondence (4.8) works. For this, it is convenient to work instead in the category of holomorphic $\mathrm{SL}(2,\mathbb{C})$-equivariant bundles.[34] If $\mathcal{E}$ is an SU(2)-equivariant vector bundle over $\mathcal{M}_q \times \mathbb{C}P^1$, then the action of SU(2) can be extended to an $\mathrm{SL}(2,\mathbb{C})$ action. Everything we have said above carries through by replacing the group SU(2) with its complexification $\mathrm{SL}(2,\mathbb{C})$ and the Cartan torus $\mathrm{U}(1) \subset \mathrm{SU}(2)$ with the subgroup $P \subset \mathrm{SL}(2,\mathbb{C})$ of lower triangular matrices. We are then interested in P-equivariant bundles over $\mathcal{M}_q$ with P acting trivially on $\mathcal{M}_q$. The Lie algebra $\mathrm{sl}(2,\mathbb{C})$ is generated by the three Pauli matrices,

$$\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \sigma_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \text{and} \quad \sigma_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \tag{4.9}$$

with the commutation relations

$$[\sigma_3, \sigma_\pm] = \pm 2\sigma_\pm \quad \text{and} \quad [\sigma_+, \sigma_-] = \sigma_3. \tag{4.10}$$

The Lie algebra of the subgroup P is generated by the elements σ_3 and σ_-, while the Cartan subgroup $\mathbb{C}^\times \subset P$ is generated by the element σ_3 with the corresponding irreducible representations being the $\boldsymbol{\nu}_m$ given by (3.5).

Since the manifold $\mathcal{M}_q$ carries a trivial action of the subgroup $\mathbb{C}^\times$, any $\mathbb{C}^\times$-equivariant bundle $E' \to \mathcal{M}_q$ can be written using (4.2) as a finite Whitney sum

$$E' = \bigoplus_{l \in \Delta(E')} E'_l \otimes \underline{S}_l, \tag{4.11}$$

where $\Delta(E') \subset \mathbb{Z}$ is the set of eigenvalues for the $\mathbb{C}^\times$-action on E' and $E'_l \to \mathcal{M}_q$ are bundles carrying the trivial $\mathbb{C}^\times$-action. The rest of the P-equivariant structure is determined by the generator σ_-. Since $[\sigma_3, \sigma_-] = -2\sigma_-$, the action of σ_- on $E'_l \otimes \underline{S}_l$ corresponds to holomorphic bundle morphisms $E'_l \to E'_{l-2}$ and the trivial σ_--action on the irreducible $\mathbb{C}^\times$-modules $\underline{S}_l$. Thus every indecomposable P-equivariant bundle $E' \to \mathcal{M}_q$ has weight set of the form $\Delta(E') = \{m_0, m_0 + 2, \ldots, m_{1-2}, m_1\}$ for some $m_0, m_1 \in \mathbb{Z}$ with $m_0 \leqslant m_1$. After an appropriate twist by a $\mathbb{C}^\times$-module and a relabelling, the σ_3-action is given by the $\mathbb{C}^\times$-equivariant decomposition,

$$E = \bigoplus_{i=0}^{m} E_{k_i} \otimes \underline{S}_{m-2i} \tag{4.12}$$

while the σ_--action is determined by a *chain*

$$0 \to E_{k_m} \xrightarrow{\phi_m} E_{k_{m-1}} \xrightarrow{\phi_{m-1}} \cdots \xrightarrow{\phi_2} E_{k_1} \xrightarrow{\phi_1} E_{k_0} \to 0 \tag{4.13}$$

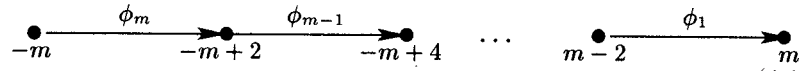
of holomorphic bundle maps between consecutive E_{k_i}'s. We can now consider the underlying U(1)-equivariant Hermitian vector bundle defined by the unitary $\mathrm{U}(k)$ reduction of the $\mathrm{GL}(k,\mathbb{C})$ structure group of the holomorphic bundle (4.12), after introducing a Hermitian metric on its fibers. Then the corresponding bundle $\mathcal{E} \to \mathcal{M}_q \times \mathbb{C}P^1$ is given by

$$\mathcal{E} = \mathrm{SU}(2) \times_{\mathrm{U}(1)} E. \tag{4.14}$$

Using (3.6) one finds that (4.14) coincides with the original equivariant decomposition (3.16). Conversely, given an SU(2)-equivariant bundle $\mathcal{E} \to \mathcal{M}_q \times \mathbb{C}P^1$, its restriction $E = \iota^* \mathcal{E}$ defines a U(l)-equivariant bundle over $\mathcal{M}_q$ which thereby admits an isotopical decomposition of the form (4.12) and $\mathcal{E}$ may be recovered from (4.14).

Quiver gauge theory: The ansatz for the gauge potential on $\mathcal{M}_q \times \mathbb{C}P^1$, represented symbolically by the bundle chain (3.17), corresponds to the disjoint union of two copies of the quiver,

A_{m+1} :



(4.15)

with the second copy obtained from (4.15) by reversing the directions of the arrows and replacing ϕ_i with $\phi_i^\dagger$ for each $i = 1, \ldots, m$. The vertices of the quiver are labelled by the degrees of the monopole bundles $\mathcal{L}^{m-2i}$, while the arrows correspond to module morphisms $\phi_i : \underline{V}_{k_i} \to \underline{V}_{k_{i-1}}$ (locally at each point $x' \in \mathcal{M}_q$). Equivalently, the vertices may be labelled by irreducible chiral representations of the group P. Thus our ansatz determines a representation of the quiver A_{m+1} in the category of complex vector bundles over the manifold $\mathcal{M}_q$.[36] Such a representation is called an A_{m+1}-bundle. Many properties of the explicit solutions that we construct later on find their most natural explanation in the context of such a quiver gauge theory, which provides a more refined description of the brane configurations than just their K-theory charges. This framework encompasses the algebraic and representation theoretic aspects of the problem.[37]

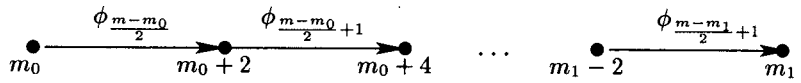
The quiver graph (4.15) is identical to the Dynkin diagram of the Lie algebra A_{m+1}. The adjacency matrix of the quiver has matrix elements specifying the number of links between each pair of vertices $m-2i$, $m-2j$, and in the case (4.15) it is given by $\mathrm{Adj}(\mathsf{A}_{m+1}) = (\delta_{i,j-1})_{i,j=0,1,\ldots,m}$. The matrix elements $C_{ij} = 2\delta_{ij} - \mathrm{Adj}(\mathsf{A}_{m+1})_{ij}$ are then identical to those of the Cartan matrix $C_{ij} = \vec{e}_i \cdot \vec{e}_j$, where $\vec{e}_i$, $i = 0, 1, \ldots, m$ are the simple roots of A_{m+1}. Corresponding to the gauge symmetry breaking (3.9), the dimension vector $\vec{k}_{\underline{V}} := (k_0, k_1, \ldots, k_m)$ can be regarded as a positive root of A_{m+1} associated with the Cartan matrix $C = (C_{ij})$ by writing it as

$$\vec{k}_{\underline{V}} = \sum_{i=0}^{m} k_i \vec{e}_i \quad \text{with } |\vec{k}_{\underline{V}}| := \sum_{i=0}^{m} k_i = k. \tag{4.16}$$

By Kac's theorem,[37] there is a one-to-one correspondence between the isomorphism classes of indecomposable representations of the quiver A_{m+1} and the set of positive roots of the Lie algebra A_{m+1}. This property is a consequence of the SU(2)-invariance of our ansatz.

Let us focus for a while on the case $\mathcal{M}_q = \mathrm{pt}$. In this case Eq. (3.16), with the m-monopole bundles $\mathcal{L}^m$ substituted everywhere by the holomorphic line bundles (3.7), gives a relation between the categories of homogeneous holomorphic vector bundles over $\mathbb{C}P^1 = \mathrm{SL}(2,\mathbb{C})/P$ and of finite-dimensional chiral representations of P, while the quiver representation further gives a relation with the Abelian category of finite-dimensional representations of A_{m+1}.[36] To describe this latter category, it is convenient to introduce the notion of a path P in A_{m+1}, which is generally defined as a sequence of arrows of the quiver which compose. In the present case any path is of the form

P :



(4.17)

with $-m \leq m_0 \leq m_1 \leq m$. We will denote it by the formal vector $|m_0, \ldots, m_1)$. The non-negative

integer $|\mathsf{P}| := 1/2(m_1 - m_0)$ is the length of the path (4.17). The trivial path of length 0 based at a single vertex m_0 is denoted $|m_0)$. The path algebra $\mathbb{C}\mathsf{A}_{m+1}$ of the quiver (4.15) is then defined as the algebra generated by all paths P of A_{m+1}, i.e., as the vector space

$$\mathbb{C}\mathsf{A}_{m+1} = \bigoplus_{\substack{m_0, m_1 = -m \\ m_0 \leq m_1}}^{m} \mathbb{C}|m_0, \dots, m_1) \tag{4.18}$$

together with the $\mathbb{C}$-linear multiplication induced by (left) concatenation of paths where possible,

$$|m_0, \dots, m_1) \cdot |n_0, \dots, n_1) = \delta_{m_1 n_0} |m_0, \dots, n_1). \tag{4.19}$$

This makes $\mathbb{C}\mathsf{A}_{m+1}$ into a finite-dimensional quasifree algebra. The path algebra has a natural $\mathbb{Z}_{m+1}$-grading by path length,

$$\mathbb{C}\mathsf{A}_{m+1} \bigoplus_{i=0}^{m} (\mathbb{C}\mathsf{A}_{m+1})_i \quad \text{with } (\mathbb{C}\mathsf{A}_{m+1})_i \bigoplus_{m_0 = -m}^{m-2i} \mathbb{C}|m_0, \dots, m_0 + 2i), \tag{4.20}$$

and can thereby be alternatively described as the tensor algebra over the ring

$$C_0 = \bigoplus_{i=0}^{m} \mathbb{C}|m - 2i) \cong \mathbb{C}^{m+1} \tag{4.21}$$

of the C_0-bimodule

$$C_1 = \bigoplus_{i=0}^{m} \mathbb{C}|m - 2i, m - 2i + 2). \tag{4.22}$$

The importance of the path algebra stems from the fact that the category of representations of the quiver A_{m+1} is equivalent to the category of (left) $\mathbb{C}\mathsf{A}_{m+1}$-modules.[37] Given a representation $\underline{W}_{m-2i} \to^{\eta_i} \underline{W}_{m-2i+2}$, $i = 1, \dots, m$, of A_{m+1}, the associated $\mathbb{C}\mathsf{A}_{m+1}$-module $\underline{\mathcal{W}}$ is

$$\underline{\mathcal{W}} = \bigoplus_{i=0}^{m} \underline{W}_{m-2i} \tag{4.23}$$

with multiplication extended $\mathbb{C}$-linearly from the definitions

$$|m - 2i) \cdot w_j = \delta_{ij} w_j \quad \text{and} \quad |m - 2i, m - 2i + 2) \cdot w_j = \delta_{i,j+1} \eta_j(w_j) \tag{4.24}$$

for $w_j \in \underline{W}_{m-2j}$. Conversely, given a left $\mathbb{C}\mathsf{A}_{m+1}$-module $\underline{\mathcal{W}}$, we can set $\underline{W}_{m-2i} := |m-2i) \cdot \underline{\mathcal{W}}$ for $i = 0, 1, \dots, m$ and define $\eta_i : \underline{W}_{m-2i} \to \underline{W}_{m-2i+2}$ for $i = 1, \dots, m$ by

$$\eta_i(w_i) = |m - 2i, m - 2i + 2) \cdot w_i. \tag{4.25}$$

One can further show that morphisms of representations of A_{m+1} correspond to $\mathbb{C}\mathsf{A}_{m+1}$-module homomorphisms.[37] Thus, the problem of determining finite-dimensional representations of the quiver A_{m+1}, or equivalently homogeneous vector bundles over $\mathbb{C}P^1$, is equivalent to finding representations of its path algebra.

As an example, consider the A quiver,

A_2 : 
. (4.26)

It represents the standard brane-antibrane system, and as expected SU(2)-equivariance implies that it can only carry $m = 1$ unit of monopole charge.[30] The corresponding path algebra is

$$\mathbb{C}\mathsf{A}_2 = \mathbb{C}|-1) \oplus \mathbb{C}|+1) \oplus \mathbb{C}|-1,+1) = \begin{pmatrix} \mathbb{C} & \mathbb{C} \\ 0 & \mathbb{C} \end{pmatrix}. \tag{4.27}$$

Representations of this algebra yield the standard superconnections characterizing the low-energy field content on the world volume of a brane-antibrane system.[31] In the next section we will show how to generalize the superconnection formalism to account for representations of generic path algebras (4.18). Later on we shall write down explicit solutions with generic monopole charge $m \in \mathbb{Z}$ that also correspond to the basic brane-antibrane system.

Our technique for generating D-branes from a quiver gauge theory on $\mathcal{M}_q$ arises via a quotient with respect to a generalized SU(2)-action on Chan-Paton bundles over $\mathcal{M}_q \times \mathbb{C}P^1$. This new construction is rather different from the well-known quiver gauge theories that arise from orbifolds with respect to the action of a *discrete* group G.[38] In the latter case the nodes of a quiver represent the irreducible representation fractional branes into which a regular representation D-brane decays into when it is taken to an orbifold point of $\mathcal{M}_q/G$, and they can be thought of in terms of a projection of branes sitting on the leaves of the covering space $\mathcal{M}_q$. While our quiver gauge theory is fundamentally different, it shares many of the physical features of orbifold theories of D-branes. For instance, the blowing up of vortices on $\mathcal{M}_q$ into instantons on $\mathcal{M}_q \times \mathbb{C}P^1$ is reminescent of the blowing up of fractional $D(q-1)$-branes into $D(q+1)$-branes wrapping a noncontractible $\mathbb{C}P^1$that is used to resolve the orbifold singularity in $\mathcal{M}_q/G$. Our solutions provide explicit realizations of this blowing up phenomenon, but in a completely smooth setting.

V. DIMENSIONAL REDUCTION

The condition of SU(2)-equivariance uniquely prescribes a specific $\mathbb{C}P^1$ dependence for the gauge potential $\mathcal{A}$ and reduces the Yang-Mills equations (2.8) on $\mathcal{M}_q \times \mathbb{C}P^1$ to equations on $\mathcal{M}_q$. In this section we will formulate this reduction in detail and relate it to representations of the path algebra (4.18). This will be done by developing a new formalism of $\mathbb{Z}_{m+1}$-graded connections which describes the field content corresponding to the bundle chains (3.17) and (4.13), and which generalizes the standard superconnection field theories on the world volumes of brane-antibrane systems.[31] This formalism will be the crux to merging together the three interpretations of the preceding section.

Reduction of the Yang-Mills functional: The dimensional reduction of the Yang-Mills equations can be seen at the level of the Yang-Mills Lagrangian (2.7). Substituting (3.24)–(3.26) into (2.10) and performing the integral over $\mathbb{C}P^1$ we arrive at the action (a set of Yang-Mills coupling constants g^i_{YM}, $i=0,1,\ldots,m$ can be introduced via the redefinitions $A^i \mapsto g^i_{\mathrm{YM}} A^i$)

$$\begin{aligned} S_{\mathrm{YM}} := \int_{\mathcal{M}_q \times \mathbb{C}P^1} \mathrm{d}^{q+2}x L_{\mathrm{YM}} = \pi R^2 \int_{\mathcal{M}_q} \mathrm{d}^q x' \sqrt{g'} \sum_{i=0}^{m} \mathrm{tr}_{k_i \times k_i} \Big(& (F^i_{\mu'\nu'})^\dagger (F^{i\mu'\nu'}) + \frac{1}{R^2} (D_{\mu'} \phi_{i+1})(D^{\mu'} \phi_{i+1})^\dagger \\ & + \frac{1}{R^2} (D_{\mu'} \phi_i)^\dagger (D^{\mu'} \phi_i) + \frac{1}{2R^4} (m - 2i + \phi_i^\dagger \phi_i - \phi_{i+1} \phi_{i+1}^\dagger)^2 \Big), \end{aligned} \tag{5.1}$$

where $g' = |\det(g_{\mu'\nu'})|$. In the remainder of this paper we shall only consider static field configurations on $\mathcal{M}_q = \mathbb{R}^1 \times M_{2n}$ in the temporal gauge $\mathcal{A}_0 = 0$. In this case one can introduce the corresponding energy functional,

$$\begin{aligned} E_{\mathrm{YM}} = \pi R^2 \int_{M_{2n}} \mathrm{d}^{2n}x \sqrt{g_n} \sum_{i=0}^{m} \mathrm{tr}_{k_i \times k_i} \Big(& (F^i_{\mu\nu})^\dagger (F^{i\mu\nu}) + \frac{1}{R^2} (D_\mu \phi_{i+1})(D^\mu \phi_{i+1})^\dagger + \frac{1}{R^2} (D_\mu \phi_i)^\dagger (D^\mu \phi_i) \\ & + \frac{1}{2R^4} (m - 2i + \phi_i^\dagger \phi_i - \phi_{i+1} \phi_{i+1}^\dagger)^2 \Big), \end{aligned} \tag{5.2}$$

where $g_n = \det(g_{\mu\nu})$. The functional (5.2) is non-negative.

Graded connections: The energy functional (5.2) is analyzed most efficiently by introducing a

framework specific to connections on the rank k $\mathbb{Z}_{m+1}$-graded vector bundle,

$$E := \bigoplus_{i=0}^{m} E_{k_i} \tag{5.3}$$

over M_{2n} whose typical fiber is the module (3.8). The endomorphism algebra bundle corresponding to (5.3) is given by the direct sum decomposition,

$$\mathrm{End}(E) = \bigoplus_{i=0}^{m} \mathrm{End}(E_{k_i}) \oplus \bigoplus_{\substack{i,j=0 \\ i\neq j}}^{m} \mathrm{Hom}(E_{k_i}, E_{k_j}). \tag{5.4}$$

We may naturally associate to (5.4) a distinguished representation of the A_{m+1} quiver. For this, we note that the path algebra $\mathbb{C}\mathsf{A}_{m+1}$ is itself a $\mathbb{C}\mathsf{A}_{m+1}$-module, and that the elements $|m-2i) \in \mathbb{C}\mathsf{A}_{m+1}$ define a complete set of orthogonal projectors of the path algebra, i.e., $|m-2i)\cdot|m-2j) = \delta_{ij}|m-2i)$ for $i,j=0,1,\dots,m$ with $\Sigma_{i=0}^{m}|m-2i)=1$. Analogously to the construction of (4.23)–(4.25), we may thereby define a *projective* $\mathbb{C}\mathsf{A}_{m+1}$-module $\underline{\mathsf{P}}_i := |m-2i)\cdot\mathbb{C}\mathsf{A}_{m+1}$ for each $i=0,1,\dots,m$,[37] which is the subspace of $\mathbb{C}\mathsf{A}_{m+1}$ generated by all paths which start at the ith vertex of the quiver A_{m+1}. Then $(\underline{\mathsf{P}}_i)_{m-2j} \cong \mathbb{C}$ is the vector space generated by the path from the ith vertex to the jth vertex, and the corresponding dimension vector is

$$\vec{k}_{\underline{\mathsf{P}}_i} = \sum_{j=i}^{m} \vec{e}_j. \tag{5.5}$$

The modules $\underline{P}_i$, $i=0,1,\dots,m$ are exactly the set of all indecomposable projective representations of the A_{m+1} quiver,[37] with

$$\mathbb{C}\mathsf{A}_{m+1} = \bigoplus_{i=0}^{m} \underline{\mathsf{P}}_i. \tag{5.6}$$

The importance of this path algebra representation stems from the fact that, for any quiver representation (3.8), there is a natural isomorphism[37]

$$\mathrm{Hom}(\underline{\mathsf{P}}_i, \underline{\mathcal{V}}) \cong \underline{V}_{k_i}. \tag{5.7}$$

We may thereby identify $\mathrm{Hom}(\underline{V}_{k_j}, \underline{V}_{k_i})$ in terms of appropriate combinations of the spaces

$$\mathrm{Hom}(\underline{\mathsf{P}}_j, \underline{\mathsf{P}}_i) \cong |m-2j)\cdot\mathbb{C}\mathsf{A}_{m+1}\cdot|m-2i) \cong \mathbb{C}. \tag{5.8}$$

This is the vector space generated by the path from the ith vertex to the jth vertex of A_{m+1}. A natural representation of this path is by a matrix of dimension $(m+1)\times(m+1)$ with 1 in its (ij)th entry and 0's everywhere else. The path algebra (5.6) is thereby identified with the algebra of upper triangular $(m+1)\times(m+1)$ complex matrices.[37] For a given quiver representation (3.8), this algebra may be represented by assembling the chiral Higgs fields $\phi_1,\dots,\phi_m$ into the $k\times k$ matrix,

$$\boldsymbol{\phi}_{(m)} := \begin{pmatrix} 0 & \phi_1 & 0 & \dots & 0 \\ 0 & 0 & \phi_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & \phi_m \\ 0 & 0 & 0 & \dots & 0 \end{pmatrix}, \tag{5.9}$$

with respect to the decomposition (5.3). This object generates a representation of the path algebra in the category of complex vector bundles over M_{2n}, corresponding to the off-diagonal $i<j$ components of the decomposition (5.4). The finite dimensionality of $\mathbb{C}\mathsf{A}_{m+1}$ is reflected in the property that generically

$$\boldsymbol{\phi}_{(m)}, (\boldsymbol{\phi}_{(m)})^2, \ldots, (\boldsymbol{\phi}_{(m)})^m \neq 0 \quad \text{but } (\boldsymbol{\phi}_{(m)})^{m+1} = 0. \tag{5.10}$$

The field configuration (5.9) generates the basic zero-form component of a geometric object that we shall refer to as a "$\mathbb{Z}_{m+1}$-graded connection" on M_{2n}. For $m=1$ it corresponds to a standard superconnection,[39] while for $m>1$ it is the appropriate entity that constructs representations corresponding to the enlargement of the path algebra $\mathbb{C}\mathsf{A}_{m+1}$. Its matrix form is similar to (3.10)–(3.14), but without the one-forms on $\mathbb{C}P^1$.

To formulate the definition precisely, we note that the algebra $\Omega(M_{2n},E)$ of differential forms on M_{2n} with values in the bundle (5.3) has a natural $\mathbb{Z}\times\mathbb{Z}_{m+1}$ grading, where the $\mathbb{Z}$-grading is by form degree. We can thereby induce a total $\mathbb{Z}_{m+1}$-grading by the decomposition

$$\Omega_\bullet(M_{2n},E) = \bigoplus_{p=0}^{m} \Omega_{(p)}(M_{2n},E) \quad \text{with } \Omega_{(p)}(M_{2n},E) = \bigoplus_{i+j\equiv_{m+1}p} \Omega^i(M_{2n},E_{k_j}), \tag{5.11}$$

where $\equiv_{m+1}$ denotes congruence modulo $(m+1)$. By using (5.4) and the usual tensor product grading, this induces a $\mathbb{Z}_{m+1}$-grading on the corresponding endomorphism algebra as

$$\Omega_\bullet(M_{2n},\mathrm{End}\,E) = \bigoplus_{p=0}^{m} \Omega_{(p)}(M_{2n},\mathrm{End}\,E) \tag{5.12}$$

with

$$\Omega_{(p)}(M_{2n},\mathrm{End}\,E) = \bigoplus_{i=0}^{m} \bigoplus_{a=0}^{p} \bigoplus_{i_a\equiv_{m+1}(p-a)} \Omega^{i_a}(M_{2n}) \otimes \mathrm{Hom}(E_{k_i},E_{k_{i+a}}). \tag{5.13}$$

A *graded connection* on (5.11) is defined to be a linear operator $\Omega_\bullet(M_{2n},E)\to\Omega_{\bullet+1}(M_{2n},E)$ which shifts the total $\mathbb{Z}_{m+1}$-grading by 1 modulo $(m+1)$, i.e., an element of

$$\Omega_{(1)}(M_{2n},\mathrm{End}\,E) = \bigoplus_{i=0}^{m}\Bigg(\bigoplus_{i_1\equiv_{m+1}1} \Omega^{i_1}(M_{2n}) \otimes \mathrm{End}(E_{k_i}) \oplus \bigoplus_{i_0\equiv_{m+1}0} \Omega^{i_0}(M_{2n}) \otimes \mathrm{Hom}(E_{k_i},E_{k_{i+1}})\Bigg), \tag{5.14}$$

and which satisfies the usual Leibniz rule on $\Omega(M_{2n})$. As in the standard cases, the $\mathbb{Z}_{m+1}$-graded connections form an affine space modelled on a set of local operators.

In our case we retain only the $i_0=0$ and $i_1=1$ components of (5.14) corresponding to the lowest lying massless degrees of freedom on the given configuration of D-branes. From the Leibniz rule it follows that the pertinent graded connections are then of the form $(d+\mathbf{A}^{(m)}+(\boldsymbol{\phi}_{(m)})+(\boldsymbol{\phi}_{(m)})^\dagger)$, where

$$\mathbf{A}^{(m)} := \sum_{i=0}^{m} A^i \otimes \Pi_i \tag{5.15}$$

and $\Pi_i : E\to E_{k_i}$ are the canonical orthogonal projections of rank 1,

$$\Pi_i\Pi_j = \delta_{ij}\Pi_i, \tag{5.16}$$

which may be represented, with respect to the decomposition (5.3), by diagonal matrices $\Pi_i = (\delta_{ji}\delta_{li})_{j,l=0,1,\ldots,m}$ of unit trace. In this geometric framework all ϕ_i are assumed to anticommute with a given local basis dx^μ of the cotangent bundle of the Kähler manifold M_{2n}, as if they were m basic odd complex elements of a superalgebra. This requisite property may be explicitly realized by extending the graded connection formalism to $M_{2n}\times\mathbb{C}P^1$. For this, we rewrite the ansatz (3.10)–(3.15) in terms of the above field configurations as

$$\mathcal{A}_\mu = (\mathbf{A}^{(m)})_\mu \otimes 1, \tag{5.17}$$

$$\mathcal{A}_y = \mathbf{1}_k \otimes (\mathbf{a}^{(m)})_y - (\boldsymbol{\phi}_{(m)})^\dagger \otimes \beta_y, \tag{5.18}$$

$$\mathcal{A}_{\overline{y}} = \mathbf{1}_k \otimes (\mathbf{a}^{(m)})_{\overline{y}} + (\boldsymbol{\phi}_{(m)}) \otimes \overline{\beta_{\overline{y}}}, \tag{5.19}$$

where

$$\mathbf{a}^{(m)} := \sum_{i=0}^{m} a_{m-2i} \otimes \Pi_i \tag{5.20}$$

and $\Pi_i : \mathcal{E} \to \mathcal{E}_i$ are the canonical projections on (3.16). The coupling of $\boldsymbol{\phi}_{(m)}$ to $\mathrm{d}\overline{y}$ in (5.19) yields the desired anticommutativity with $\mathrm{d}x^\mu$.

Alternatively, we may use the canonical isomorphism $\Omega(M_{2n} \times \mathbb{C}P^1) \cong C\ell(M_{2n} \times \mathbb{C}P^1)$ to map the cotangent basis $\mathrm{d}x^{\hat{\mu}} \mapsto \Gamma^{\hat{\mu}}$ onto the generators of the Clifford algebra

$$\Gamma^{\hat{\mu}}\Gamma^{\hat{\nu}} + \Gamma^{\hat{\nu}}\Gamma^{\hat{\mu}} = -2g^{\hat{\mu}\hat{\nu}}\mathbf{1}_{2^{n+1}} \quad \text{with } \hat{\mu}, \hat{\nu} = 1, \ldots, 2n+2. \tag{5.21}$$

The gamma matrices in (5.21) may be decomposed as

$$\{\Gamma^{\hat{\mu}}\} = \{\Gamma^\mu, \Gamma^y, \Gamma^{\overline{y}}\} \quad \text{with} \quad \Gamma^\mu = \gamma^\mu \otimes \mathbf{1}_2, \quad \Gamma^y = \gamma \otimes \gamma^y, \quad \text{and} \quad \Gamma^{\overline{y}} = \gamma \otimes \gamma^{\overline{y}}, \tag{5.22}$$

where the $2^n \times 2^n$ matrices $\gamma^\mu = -(\gamma^\mu)^\dagger$ act on the spinor module $\underline{\Delta}(M_{2n})$ over the Clifford algebra $C\ell(M_{2n})$,

$$\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = -2g^{\mu\nu}\mathbf{1}_{2^n} \quad \text{with } \mu, \nu = 1, \ldots, 2n, \tag{5.23}$$

while

$$\gamma = \frac{i^n}{(2n)!\sqrt{g_n}}\epsilon_{\mu_1\cdots\mu_{2n}}\gamma^{\mu_1}\cdots\gamma^{\mu_{2n}} \quad \text{with } (\gamma)^2 = \mathbf{1}_{2^n} \quad \text{and} \quad \gamma\gamma^\mu = -\gamma^\mu\gamma \tag{5.24}$$

is the corresponding chirality operator. Here $\epsilon_{\mu_1\cdots\mu_{2n}}$ is the Levi-Civita symbol with $\epsilon_{12\cdots 2n} = +1$. The action of the Clifford algebra $C\ell(\mathbb{C}P^1)$ on the spinor module $\underline{\Delta}(\mathbb{C}P^1)$ is generated by

$$\gamma^y = \frac{1}{R^2}(R^2 + y\overline{y})\sigma^y \quad \text{and} \quad \gamma^{\overline{y}} = \frac{1}{R^2}(R^2 + y\overline{y})\sigma^{\overline{y}} \tag{5.25}$$

with constant 2×2 Pauli matrices $\sigma^{\overline{y}} = \sigma_-$ and $\sigma^y = -\sigma_+$ obeying $[\sigma^y, \sigma^{\overline{y}}] = -\sigma_3$. The gauge potential (3.10)–(3.14) may then be written in an algebraic form as

$$\hat{\mathcal{A}} := \Gamma^{\hat{\mu}}\mathcal{A}_{\hat{\mu}} = \gamma^\mu(\mathbf{A}^{(m)})_\mu \otimes \mathbf{1}_2 + (\boldsymbol{\phi}_{(m)})\gamma \otimes \gamma^{\overline{y}}\overline{\beta_{\overline{y}}} - (\boldsymbol{\phi}_{(m)})^\dagger\gamma \otimes \gamma^y\beta_y + \gamma \otimes (\gamma^y(\mathbf{a}^{(m)})_y + y^{\overline{y}}(\mathbf{a}^{(m)})_{\overline{y}}), \tag{5.26}$$

and the coupling of (5.9) with the chirality operator (5.24) realizes the desired anticommutativity with the one-form representatives γ^μ. Note that the products

$$(\boldsymbol{\phi}_{(m)})\gamma \otimes \gamma^{\overline{y}}\overline{\beta_{\overline{y}}} = \frac{1}{R}(\boldsymbol{\phi}_{(m)})\gamma \otimes \sigma^{\overline{y}} \quad \text{and} \quad (\boldsymbol{\phi}_{(m)})^\dagger\gamma \otimes \gamma^y\beta_y = \frac{1}{R}(\boldsymbol{\phi}_{(m)})^\dagger\gamma \otimes \sigma^y \tag{5.27}$$

are independent of the coordinates $(y, \overline{y}) \in \mathbb{C}P^1$.

The curvature $(d + \mathbf{A}^{(m)} + (\boldsymbol{\phi}_{(m)}) + (\boldsymbol{\phi}_{(m)})^\dagger)^2 \in \Omega_{(2)}(M_{2n}, \mathrm{End}\, E)$ of the graded connection is also most elegantly expressed through dimensional reduction from $M_{2n} \times \mathbb{C}P^1$. From (3.18)–(3.26) it is given by

$$\hat{\mathcal{F}} := \frac{1}{4}[\Gamma^{\hat{\mu}},\Gamma^{\hat{\nu}}]\mathcal{F}_{\hat{\mu}\hat{\nu}} = \frac{1}{4}[\gamma^{\mu},\gamma^{\nu}](\mathbf{F}^{(m)})_{\mu\nu}\otimes\mathbf{1}_2 - \frac{1}{R}\gamma(\gamma^{\mu}D_{\mu}\boldsymbol{\phi}_{(m)})^{\dagger}\otimes\sigma^{y} - \frac{1}{R}\gamma(\gamma^{\mu}D_{\mu}\boldsymbol{\phi}_{(m)})\otimes\sigma^{\overline{y}}$$
$$+ \frac{1}{2R^2}(\mathbf{\Upsilon}_{(m)} + (\boldsymbol{\phi}_{(m)})^{\dagger}(\boldsymbol{\phi}_{(m)}) - (\boldsymbol{\phi}_{(m)})(\boldsymbol{\phi}_{(m)})^{\dagger})\mathbf{1}_{2^n}\otimes\sigma_3, \tag{5.28}$$

where $\mathbf{F}^{(m)} := \mathrm{d}\mathbf{A}^{(m)} + \mathbf{A}^{(m)}\wedge\mathbf{A}^{(m)}$ and

$$\mathbf{\Upsilon}_{(m)} := \sum_{i=0}^{m}(m-2i)\Pi_i. \tag{5.29}$$

The contribution (5.29) is generated by the monopole connection on $\mathbb{C}P^1$ in (5.26), while the Higgs potentials in (5.28) are produced by (5.27). The graded curvature is independent of $(y,\overline{y}) \in \mathbb{C}P^1$, and the standard gamma-matrix trace formulas,

$$\mathrm{Tr}_{\mathbb{C}^{2n+1}}(\gamma^{\mu}\gamma^{\nu}\otimes\mathbf{1}_2) = -2^{n+1}g^{\mu\nu}, \tag{5.30}$$

$$\mathrm{Tr}_{\mathbb{C}^{2n+1}}(\gamma^{\mu}\gamma^{\nu}\gamma^{\lambda}\gamma^{\rho}\otimes\mathbf{1}_2) = 2^{n+1}(g^{\mu\nu}g^{\lambda\rho} + g^{\mu\rho}g^{\nu\lambda} - g^{\mu\lambda}g^{\nu\rho}), \tag{5.31}$$

$$\mathrm{Tr}_{\mathbb{C}^{2n+1}}([\gamma^{\mu},\gamma^{\nu}][\gamma^{\lambda},\gamma^{\rho}]\otimes\mathbf{1}_2) = 2^{n+3}(g^{\mu\rho}g^{\nu\lambda} - g^{\mu\lambda}g^{\nu\rho}), \tag{5.32}$$

$$\mathrm{Tr}_{\mathbb{C}^{2n+1}}(\gamma^{\mu}\gamma\gamma^{\nu}\gamma\otimes\sigma^{\overline{y}}\sigma^{y}) = -2^{n}g^{\mu\nu} = \mathrm{Tr}_{\mathbb{C}^{2n+1}}(\gamma^{\mu}\gamma\gamma^{\nu}\gamma\otimes\sigma^{y}\sigma^{\overline{y}}) \tag{5.33}$$

imply that the energy functional (5.2) can be compactly written in terms of (5.28) as

$$E_{\mathrm{YM}} = \frac{\pi R^2}{2^n}\int_{M_{2n}}\mathrm{d}^{2n}x\sqrt{g_n}\,\mathrm{tr}_{k\times k}\,\mathrm{Tr}_{\mathbb{C}^{2n+1}}\,\hat{\mathcal{F}}^2. \tag{5.34}$$

Non-Abelian coupled vortex equations: Let us now examine the reduction of the DUY equations on $M_{2n}\times\mathbb{C}P^1$ for a gauge potential of the form proposed in Sec. III (with static configurations in the gauge $\mathcal{A}_0=0$). Substituting (3.19)–(3.22) into (2.12)–(2.14), we obtain

$$g^{a\overline{b}}F^{i}_{a\overline{b}} = \frac{1}{2R^2}(m-2i+\phi_i^{\dagger}\phi_i - \phi_{i+1}\phi_{i+1}^{\dagger}), \tag{5.35}$$

$$F^{i}_{\overline{a}\overline{b}} = 0 = F^{i}_{ab}, \tag{5.36}$$

$$\overline{\partial}_{\overline{a}}\phi_{i+1} + A^{i}_{\overline{a}}\phi_{i+1} - \phi_{i+1}A^{i+1}_{\overline{a}} = 0, \tag{5.37}$$

for each $i=0,1,\ldots,m$, where $\phi_0 := 0 =: \phi_{m+1}$. Recall that there is no summation over i in these equations. We have abbreviated $F^{i}_{ab} := F^{i}_{z^a z^b}$, etc., and defined the derivatives $\partial_a := \partial_{z^a} = \frac{1}{2}(\partial_{2a-1} + i\partial_{2a})$ and $\partial_{\overline{a}} := \partial_{\overline{z^a}} = \frac{1}{2}(\partial_{2a-1} + i\partial_{2a})$ with $a,b=1,\ldots,n$. We shall call (5.35)–(5.37) the non-Abelian coupled vortex equations.

Equation (5.36) implies that the vector bundles $E_{k_i}\to M_{2n}$ are holomorphic, while Eq. (5.37) implies that the Higgs fields $\phi_{i+1}: E_{k_{i+1}}\to E_{k_i}$ are holomorphic maps. By using a Bogomolny-type transformation[33] one can show that solutions to these equations realize absolute minima of the energy functional (5.2). These field configurations describe supersymmetric BPS states of *D*-branes.

Seiberg-Witten monopole equations: For $n=2$, $m=1$, and $k_0=k_1=1$ (so that $k=k_0+k_1=2$), the equations (5.35)–(5.37) coincide with the perturbed Abelian Seiberg-Witten monopole equations on a Kähler four-manifold M_4.[40] In this case we have

$$A^0 = -A^1 =: A \in u(1), \quad F^0 = -F^1 =: F \quad \text{and} \quad \phi_1 =: \phi \in \mathbb{C}, \tag{5.38}$$

and the equations (5.35)–(5.37) reduce to

$$g^{a\bar{b}}F_{a\bar{b}} = \frac{1}{2R^2}(1 - \phi\bar{\phi}), \tag{5.39}$$

$$F_{\bar{a}\bar{b}} = 0 = F_{ab}, \tag{5.40}$$

$$\bar{\partial}_{\bar{a}}\phi + 2A_{\bar{a}}\phi = 0. \tag{5.41}$$

The perturbation, i.e., the term $1/2R^2$ in (5.39), is needed whenever M_4 has non-negative scalar curvature in order to produce a nontrivial and nonsingular moduli space of finite energy L^2 solutions. It is usually introduced into the Seiberg-Witten equations by hand. In the present context, it arises automatically from the extra space $\mathbb{C}P^1$ and the reduction from $M_4 \times \mathbb{C}P^1$ to M_4.

VI. NONCOMMUTATIVE GAUGE THEORY

To build further on the interpretation of our ansatz in terms of configurations of *D*-branes as described in Sec. IV, we should now proceed to construct explicit solutions of the reduced Yang-Mills equations on M_{2n}. Unfortunately, even solutions of the vortex equations (5.35)–(5.37) are difficult to come by and there is no known general method for explicitly constructing the appropriate field configurations. As we will demonstrate in the following, explicit realizations of these *D*-brane states are possible in the context of *noncommutative* gauge theory, which can be mapped afterwards onto commutative world volume configurations. For this, we will now specialize the Kähler manifold $M_{2n} \times \mathbb{C}P^1$ to be $\mathbb{R}^{2n} \times \mathbb{C}P^1$ with metric tensor $g_{\mu\nu} = \delta_{\mu\nu}$ on $\mathbb{R}^{2n}$ and pass to a noncommutative deformation of the flat part of the space, i.e., $\mathbb{R}^{2n} \times \mathbb{C}P^1 \to \mathbb{R}^{2n}_\theta \times \mathbb{C}P^1$. Note that the $\mathbb{C}P^1$ factor remains a commutative space throughout this paper. Then we will deform the Yang-Mills, DUY and non-Abelian coupled vortex equations, and in the subsequent sections construct various solutions of them.

Noncommutative deformation: Field theory on $\mathbb{R}^{2n}_\theta$ may be realized in an operator formalism which turns Schwartz functions f on $\mathbb{R}^{2n}$ into compact operators $\hat{f}$ acting on the n-harmonic oscillator Fock space $\mathcal{H}$.[6] The noncommutative space $\mathbb{R}^{2n}_\theta$ is then defined by declaring its coordinate functions $\hat{x}^1, \ldots, \hat{x}^{2n}$ to obey the Heisenberg algebra relations

$$[\hat{x}^\mu, \hat{x}^\nu] = i\theta^{\mu\nu} \tag{6.1}$$

with a constant real antisymmetric tensor $\theta^{\mu\nu}$. Via an orthogonal transformation of the coordinates, the matrix $\theta = (\theta^{\mu\nu})$ can be rotated into its canonical block-diagonal form with nonvanishing components

$$\theta^{2a-1\ 2a} = -\theta^{2a\ 2a-1} =: \theta^a \tag{6.2}$$

for $a = 1, \ldots, n$. We will assume for definiteness that all $\theta^a > 0$. The noncommutative version of the complex coordinates (2.3) has the nonvanishing commutators,

$$[\hat{z}^a, \hat{\bar{z}}^{\bar{b}}] = -2\delta^{a\bar{b}}\theta^a =: \theta^{a\bar{b}} = -\theta^{\bar{b}a} \leqslant 0. \tag{6.3}$$

Taking the product of $\mathbb{R}^{2n}_\theta$ with the commutative sphere $\mathbb{C}P^1$ means extending the noncommutativity matrix θ by vanishing entries along the two new directions.

The Fock space $\mathcal{H}$ may be realized as the linear span

$$\mathcal{H} = \bigoplus_{r_1,\ldots,r_n=0}^{\infty} \mathbb{C}|r_1, \ldots, r_n\rangle, \tag{6.4}$$

where the orthonormal basis states

$$|r_1, \ldots, r_n\rangle = \prod_{a=1}^{n} (2\theta^a r_a\,!\,)^{-1/2} (\hat{z}^a)^{r_a}|0, \ldots, 0 \tag{6.5}$$

are connected by the action of creation and annihilation operators subject to the commutation relations

$$\left[\frac{\hat{z}^{\bar{b}}}{\sqrt{2\theta^b}}, \frac{\hat{z}^a}{\sqrt{2\theta^a}}\right] = \delta^{a\bar{b}}. \tag{6.6}$$

In the Weyl operator realization $f \mapsto \hat{f}$, coordinate derivatives are given by inner derivations of the noncommutative algebra according to

$$\widehat{\partial_{z^a} f} = \theta_{a\bar{b}}[\hat{z}^{\bar{b}}, \hat{f}] =: \partial_{\hat{z}^a}\hat{f} \quad \text{and} \quad \widehat{\partial_{\bar{z}^a} f} = \theta_{\bar{a}b}[\hat{z}^b, \hat{f}] =: \partial_{\hat{\bar{z}}^a}\hat{f}, \tag{6.7}$$

where $\theta_{a\bar{b}}$ is defined via $\theta_{b\bar{c}}\theta^{\bar{c}a} = \delta_b^a$ so that $\theta_{a\bar{b}} = -\theta_{b\bar{a}} = \delta_{a\bar{b}}/2\theta^a$. On the other hand, integrals are given by traces over the Fock space $\mathcal{H}$ as

$$\int_{\mathbb{R}^{2n}} \mathrm{d}^{2n}x\, f(x) = \left(\prod_{a=1}^{n} 2\pi\theta^a\right) \mathrm{Tr}_{\mathcal{H}}\, \hat{f}. \tag{6.8}$$

The transition to the noncommutative Yang-Mills and DUY equations is trivially achieved by going over to operator-valued objects everywhere. In particular, vector bundles $E \to \mathbb{R}^{2n}$ whose typical fibers are complex vector spaces $\underline{V}$ are replaced by the corresponding (trivial) projective modules $\underline{V} \otimes \mathcal{H}$ over $\mathbb{R}^{2n}_\theta$. The field strength components along $\mathbb{R}^{2n}_\theta$ in (2.8) and (2.12)–(2.14) read $\hat{\mathcal{F}}_{\mu\nu} = \partial_{\hat{x}^\mu}\hat{\mathcal{A}}_\nu - \partial_{\hat{x}^\nu}\hat{\mathcal{A}}_\mu + [\hat{\mathcal{A}}_\mu, \hat{\mathcal{A}}_\nu]$, where $\hat{\mathcal{A}}_\mu$ are simultaneously $\mathrm{u}(k)$ and operator valued. To avoid a cluttered notation, we drop the hats over operators from now on. Thus all our equations have the same form as previously but are considered now as operator equations.

Noncommutative coupled vortex equations: By reducing the noncommutative version of the DUY equations on $\mathbb{R}^{2n}_\theta \times \mathbb{C}P^1$ to $\mathbb{R}^{2n}_\theta$ we obtain the noncommutative non-Abelian coupled vortex equations. Instead of working with the gauge potentials A^i_μ we shall use the operators X^i_μ defined by

$$X^i_a := A^i_a + \theta_{a\bar{b}}\bar{z}^{\bar{b}} \quad \text{and} \quad X^i_{\bar{a}} := A^i_{\bar{a}} + \theta_{\bar{a}b} z^b. \tag{6.9}$$

In terms of these operators the field strength tensor reads

$$F^i_{a\bar{b}} = [X^i_a, X^i_{\bar{b}}] + \theta_{a\bar{b}}, \quad F^i_{\bar{a}\bar{b}} = [X^i_{\bar{a}}, X^i_{\bar{b}}] \quad \text{and} \quad F^i_{ab} = [X^i_a, X^i_b], \tag{6.10}$$

while the bifundamental covariant derivatives become

$$D_{\bar{a}}\phi_{i+1} = X^i_{\bar{a}}\phi_{i+1} - \phi_{i+1}X^{i+1}_{\bar{a}} \quad \text{and} \quad D_a\phi_{i+1} = X^i_a\phi_{i+1} - \phi_{i+1}X^{i+1}_a. \tag{6.11}$$

The non-Abelian vortex equations (5.35)–(5.37) can then be rewritten as

$$\delta^{a\bar{b}}([X^i_a, X^i_{\bar{b}}] + \theta_{a\bar{b}}) = \frac{1}{4R^2}(m - 2i + \phi_i^\dagger\phi_i - \phi_{i+1}\phi_{i+1}^\dagger), \tag{6.12}$$

$$[X^i_{\bar{a}}, X^i_{\bar{b}}] = 0 = [X^i_a, X^i_b], \tag{6.13}$$

$$X_a^i\phi_{i+1} - \phi_{i+1}X_a^{i+1} = 0 \tag{6.14}$$

for $i=0,1,\ldots,m$. Note that for $m=1$ we obtain the equations

$$\delta^{ab}F^0_{ab} = \frac{1}{4R^2}(1-\phi_1\phi_1^\dagger) \quad \text{and} \quad F^0_{\bar{a}\bar{b}} = 0 = F^0_{ab}, \tag{6.15}$$

$$\delta^{ab}F^1_{ab} = -\frac{1}{4R^2}(1-\phi_1^\dagger\phi_1) \quad \text{and} \quad F^1_{\bar{a}\bar{b}} = 0 = F^1_{ab}, \tag{6.16}$$

$$\bar{\partial}_{\bar{a}}\phi_1 + A^0_{\bar{a}}\phi_1 - \phi_1 A^1_{\bar{a}} = 0 \tag{6.17}$$

which are considered in Refs. 29 and 30. In particular, for $n=2$ and $k_0=k_1=1$ the equations (6.15)–(6.17) coincide with the perturbed Seiberg-Witten $\mathrm{U}_+(1)\times\mathrm{U}_-(1)$ monopole equations on $\mathbb{R}^4_\theta$ as considered in Ref. 41.

VII. EXPLICIT SOLUTIONS OF THE NONCOMMUTATIVE YANG-MILLS EQUATIONS

We are now ready to construct solutions to the Yang-Mills equations on $\mathbb{R}^{2n}_\theta\times\mathbb{C}P^1$. We shall first present the generic non-BPS solutions of the full Yang-Mills equations, and then proceed to solve the non-Abelian coupled vortex equations (6.12)–(6.14), and thus the DUY equations on $\mathbb{R}^{2n}_\theta\times\mathbb{C}P^1$, which describe the stable BPS states. Our technique will make use of appropriate partial isometry operators T_{N_i} in the noncommutative space.

Ansatz for explicit solutions: Let us fix a monopole charge $m>0$ and an arbitrary integer $0<r\leqslant k$. Consider the ansatz

$$X_a^i = \theta_{a\bar{b}}T_{N_i}\bar{z}^{\bar{b}}T_{N_i}^\dagger \quad \text{and} \quad X_{\bar{a}}^i = \theta_{\bar{a}b}T_{N_i}z^bT_{N_i}^\dagger, \tag{7.1}$$

$$\phi_{i+1} = \alpha_{i+1}T_{N_i}T_{N_{i+1}}^\dagger \quad \text{and} \quad \phi_{i+1}^\dagger = \bar{\alpha}_{i+1}T_{N_{i+1}}T_{N_i}^\dagger, \tag{7.2}$$

for $i=0,1,\ldots,m$, where $\alpha_i\in\mathbb{C}$ are some constants with $\alpha_0=\alpha_{m+1}=0$. Denoting by $\mathcal{H}$ the n-oscillator Fock space, the Toeplitz operators $T_{N_i}:\mathbb{C}^r\otimes\mathcal{H}\to\underline{V}_{k_i}\otimes\mathcal{H}$ are partial isometries described by *rectangular* $k_i\times r$ matrices (with operator entries acting on $\mathcal{H}$) possessing the properties

$$T_{N_i}^\dagger T_{N_i} = \mathbf{1}_r \quad \text{while } T_{N_i}T_{N_i}^\dagger = \mathbf{1}_{k_i} - P_{N_i}, \tag{7.3}$$

where P_{N_i} is a Hermitian projector of finite rank N_i on the Fock space $\underline{V}_{k_i}\otimes\mathcal{H}$ so that

$$P_{N_i}^2 = P_{N_i} = P_{N_i}^\dagger \quad \text{and} \quad \mathrm{Tr}_{\underline{V}_{k_i}\otimes\mathcal{H}}P_{N_i} = N_i. \tag{7.4}$$

From (7.3) it follows that the operator T_{N_i} has a trivial kernel, while the kernel of $T_{N_i}^\dagger$ is the N_i-dimensional subspace of $\underline{V}_{k_i}\otimes\mathcal{H}$ corresponding to the range of P_{N_i}. Thus

$$\dim\ker T_{N_i} = 0 \quad \text{but } \dim\ker T_{N_i}^\dagger = N_i. \tag{7.5}$$

Substituted into (6.10) this ansatz yields the gauge field strength,

$$F^i_{ab} = \theta_{ab}P_{N_i} = \frac{1}{2\theta^a}\delta_{ab}P_{N_i} \quad \text{and} \quad F^i_{\bar{a}\bar{b}} = 0 = F^i_{ab}, \tag{7.6}$$

while from (6.11) one finds the covariant derivatives

$$D_{\bar{a}}\phi_{i+1} = 0 = D_a\phi_{i+1}. \tag{7.7}$$

Thus our ansatz describes *holomorphic* fields, and the projector P_{N_i} defines a noncommutative

gauge field configuration of rank N_i and constant curvature in the subspace $\ker T^\dagger_{N_i} \subset \underline{V}_{k_i} \otimes \mathcal{H}$. In particular, the Higgs fields ϕ_{i+1} are covariantly constant with

$$\phi_i^\dagger \phi_i = |\alpha_i|^2 (\mathbf{1}_{k_i} - P_{N_i}) \quad \text{and} \quad \phi_{i+1} \phi_{i+1}^\dagger = |\alpha_{i+1}|^2 (\mathbf{1}_{k_i} - P_{N_i}). \tag{7.8}$$

The ranks Ni are generically non-negative integers. If some $N_i = 0$, then we should formally set $P_{N_i} = 0$, $T_{N_i} = 1$, and $\phi_{i+1} = 0$ in the ith component of the ansatz, so that the noncommutative version of the bundle chain (4.13) collapses near the ith node to

$$\cdots \to \underline{V}_{k_{i+1}} \otimes \mathcal{H} \to 0 \to \underline{V}_{k_{i-1}} \otimes \mathcal{H} \to \cdots . \tag{7.9}$$

Then

$$X_a^i = \theta_{ab} \bar{z}^b \quad \text{and} \quad X_{\bar{a}}^i = \theta_{\bar{a}b} z^b \tag{7.10}$$

which leads to the vacuum gauge field configuration

$$A^i = 0 \quad \text{and} \quad F^i = 0. \tag{7.11}$$

These matter fields correspond to open strings with one end on a D-brane and the other end on the closed string vacuum.

Our ansatz has a natural interpretation in quiver gauge theory. Consider the module

$$\underline{\mathcal{T}} := \bigoplus_{i=0}^{m} \ker T^\dagger_{N_i} \quad \text{with } \vec{k}_{\underline{\mathcal{T}}} = \sum_{i=0}^{m} N_i \vec{e}_i \tag{7.12}$$

over the quiver A_{m+1}, which is a finite-dimensional submodule of the infinite-dimensional representation $\mathcal{V} \otimes \mathcal{H}$ of A_{m+1} given by the noncommutative quiver bundle. Let us fix an integer $0 \leqslant s \leqslant m$, and take $N_i \neq 0$ for all $i \leqslant s$ and $N_i = 0$ for all $i > s$. The quiver representation (7.12) is a combination of the indecomposable projective representations $\underline{\mathsf{P}}_i$ of A_{m+1} that we encountered in Sec. V. The $\underline{\mathsf{P}}_i$'s form a complete set of projective representations in the sense that any quiver representation has a projective resolution in terms of sums of them.[37] In particular, the canonical Ringel resolution of (7.12) is given by the exact sequence

$$0 \to \bigoplus_{i=1}^{s} \underline{\mathsf{P}}_{i-1} \otimes \ker T^\dagger_{N_i} \to \bigoplus_{i=0}^{s} \underline{\mathsf{P}}_i \otimes \ker T^\dagger_{N_i} \to \underline{\mathcal{T}} \to 0. \tag{7.13}$$

Solving the Yang-Mills equations: We shall now demonstrate that the field configurations (7.1)–(7.3) yield solutions of the full Yang-Mills equations on $\mathbb{R}^{2n}_\theta \times \mathbb{C}P^1$ for any values of m, $N_0, N_1, \ldots, N_m$ and $\alpha_1, \ldots, \alpha_m$. For this, we write the ansatz in the form

$$\mathcal{A}_a - \theta_{ab} \bar{z}^b = \sum_{i=0}^{m} X_a^i \otimes \Pi_i = \theta_{ab} \sum_{i=0}^{m} T_{N_i} \bar{z}^b T^\dagger_{N_i} \otimes \Pi_i, \tag{7.14}$$

$$\mathcal{A}_{\bar{a}} - \theta_{\bar{a}b} z^b = \sum_{i=0}^{m} X_{\bar{a}}^i \otimes \Pi_i = \theta_{\bar{a}b} \sum_{i=0}^{m} T_{N_i} z^b T^\dagger_{N_i} \otimes \Pi_i. \tag{7.15}$$

We also have

$$\mathcal{A}_y^{ii} = \frac{(m - 2i)\bar{y}}{2(R^2 + y\bar{y})} \mathbf{1}_{k_i}, \tag{7.16}$$

$$\mathcal{A}_{\overline{y}}^{ii} = -\frac{(m-2i)y}{2(R^2+y\overline{y})}\mathbf{1}_{k_i}, \tag{7.17}$$

$$\mathcal{A}_{\overline{y}}^{ii+1} = \frac{R}{R^2+y\overline{y}}\phi_{i+1} = \frac{R\alpha_{i+1}}{R^2+y\overline{y}}T_{N_i}T_{N_{i+1}}^{\dagger}, \tag{7.18}$$

$$\mathcal{A}_{y}^{i+1i} = -\frac{R}{R^2+y\overline{y}}\phi_{i+1}^{\dagger} = -\frac{R\overline{\alpha}_{i+1}}{R^2+y\overline{y}}T_{N_{i+1}}T_{N_i}^{\dagger}, \tag{7.19}$$

with

$$\mathcal{A}_{y}^{ij} = 0 = \mathcal{A}_{y}^{i+1j} \quad \text{for } j \neq i, i+1. \tag{7.20}$$

Thus for the ansatz (7.1)–(7.3) the field strength tensor is given by

$$\mathcal{F}_{a\overline{b}} = \theta_{a\overline{b}}\sum_{i=0}^{m} P_{N_i} \otimes \Pi_i, \tag{7.21}$$

$$\mathcal{F}_{y\overline{y}} = -\frac{R^2}{(R^2+y\overline{y})^2}\sum_{i=0}^{m}(m-2i+(|\alpha_i|^2-|\alpha_{i+1}|^2)(\mathbf{1}_{k_i}-P_{N_i}))\otimes\Pi_i, \tag{7.22}$$

with all other components of $\mathcal{F}_{\hat{\mu}\hat{\nu}}$ vanishing.

Let us now insert these expressions into the Yang-Mills equations (2.8) (for static configurations with $\mathcal{A}_0=0$). It is enough to consider the cases $\hat{\nu}=c$ and $\hat{\nu}=\overline{y}$, since the cases $\hat{\nu}=\overline{c}$ and $\hat{\nu}=y$ can be obtained by Hermitian conjugation of (2.8) due to the anti-Hermiticity of $\mathcal{A}_{\hat{\mu}}$ and $\mathcal{F}_{\hat{\mu}\hat{\nu}}$. For $\hat{\nu}=c$, Eq. (2.8) becomes

$$\delta^{\overline{c}a}\delta^{\overline{b}c}(\partial_{\overline{c}}\mathcal{F}_{a\overline{b}} + [\mathcal{A}_{\overline{c}}, \mathcal{F}_{a\overline{b}}]) = 0 \tag{7.23}$$

which is equivalent to

$$\delta^{\overline{c}a}\delta^{\overline{b}c}[\mathcal{A}_{\overline{c}} - \theta_{\overline{c}\overline{b}}z^b, \mathcal{F}_{a\overline{b}}] = 0. \tag{7.24}$$

Substituting (7.15) and (7.21), we see that (7.24) is satisfied due to the identities (5.16) and

$$T_{N_i}^{\dagger}P_{N_i} = P_{N_i}T_{N_i} = 0. \tag{7.25}$$

In the case $\hat{\nu}=\overline{y}$, Eq. (2.8) simplifies to

$$\partial_y(\sqrt{g}\mathcal{F}^{y\overline{y}}) + \sqrt{g}[\mathcal{A}_y, \mathcal{F}^{y\overline{y}}] = 0 \tag{7.26}$$

with $\sqrt{g}=2R^4/(R^2+y\overline{y})^2$. Substituting (7.16), (7.19), (7.20), (7.21), and (7.22), we find that (7.26) is also satisfied due to the identities (5.16) and (7.25). Hence, the Yang-Mills equations on $\mathbb{R}_{\theta}^{2n} \times \mathbb{C}P^1$ are solved by our choice of ansatz.

Finite-energy solutions: The arbitrary coefficients $\alpha_i \in \mathbb{C}$ can be fixed (up to a phase) by demanding that the solution (7.1)–(7.3) yield finite-energy field configurations. For this, we evaluate the energy functional (5.2) using (6.8). From (7.6) we may compute

$$(F_{\mu\nu}^i)^{\dagger}(F^{i\mu\nu}) = 8\,\delta^{a\overline{c}}\delta^{d\overline{b}}F_{ab}^{i}F_{d\overline{c}}^{i} = 2\left(\sum_{a=1}^{n}\frac{1}{(\theta^a)^2}\right)P_{N_i}, \tag{7.27}$$

and combining this with (7.7) and (7.8) we find the noncommutative Yang-Mills energy

$$E_{YM} = 2\pi R^2 \left(\prod_{a=1}^{n} 2\pi\theta^a \right) \sum_{i=0}^{m} \mathrm{Tr}_{\underline{V}_{k_i} \otimes \mathcal{H}} \left[\left(\sum_{b=1}^{n} \frac{1}{(\theta^b)^2} \right) P_{N_i} + \frac{1}{4R^4} (m - 2i + (|\alpha_i|^2 - |\alpha_{i+1}|^2)(\mathbf{1}_{k_i} - P_{N_i}))^2 \right]. \tag{7.28}$$

Because of the trace over the infinite-dimensional Fock space $\mathcal{H}$, the constant terms in (7.28) which are not proportional to the projectors P_{N_i} must all vanish in order for the energy to be finite. This leads to the finite-energy conditions

$$m - 2i + |\alpha_i|^2 - |\alpha_{i+1}|^2 = 0 \tag{7.29}$$

for each $i = 0, 1, \ldots, m$.

With $\alpha_0 = \alpha_{m+1} = 0$, the constraints (7.29) are solved by

$$|\alpha_{i+1}|^2 = (i+1)m - 2\sum_{j=0}^{i} j = (i+1)(m-i) \tag{7.30}$$

and the energy (7.28) can thereby be written as

$$E_{\mathrm{YM}} = 2\pi R^2 \left(\sum_{a=1}^{n} 2\pi\, \theta^a \right) \sum_{i=0}^{[m/2]} (N_i + N_{m-i}) \left[\left(\sum_{b=1}^{n} \frac{1}{(\theta^b)^2} \right) + \frac{(m-2i)^2}{4R^4} \right]. \tag{7.31}$$

We have naturally split the sum over nodes i into contributions from Dirac monopoles and anti-monopoles, which for each $i = 0, 1, \ldots, m$ have the same Yang-Mills energy on the sphere $\mathbb{C}P^1$. Later on we will see that this splitting corresponds to a $\mathbb{Z}_2$-grading of the chain of D-branes into brane-antibrane pairs. The monopole independent terms in (7.31) can be interpreted as the tension of $\Sigma_{i=0}^{m} N_i$ $D0$-branes inside a $D(2n)$-brane[42] in the Seiberg-Witten decoupling limit.[5]

BPS solutions: The solutions we have described generically yield non-BPS solutions of the full Yang-Mills equations on $\mathbb{R}^{2n}_{\theta} \times \mathbb{C}P^1$. On the other hand, the DUY equations on $\mathbb{R}^{2n}_{\theta} \times \mathbb{C}P^1$ are BPS conditions for the Yang-Mills equations. Inserting (7.1)–(7.3) and (7.6)–(7.8) into our non-Abelian vortex equations (6.12)–(6.14), we find that (6.13) and (6.14) are automatically satisfied. The vanishing of the constant term (not proportional to P_{N_i}) in (6.12) is precisely the finite-energy constraint (7.29), whose solution is given in (7.30). Equating the coefficients of P_{N_i} in (6.12) for each $N_i \neq 0$ leads to the additional constraints

$$\sum_{a=1}^{n} \frac{1}{\theta^a} = \frac{m-2i}{2R^2} \quad \text{with } i = 0, 1, \ldots, s. \tag{7.32}$$

For $s > 0$ the conditions (7.32) are incompatible with one another, implying that the ansatz (7.1)–(7.3) with $s > 0$ does not allow for BPS configurations. For $s = 0$, the equation (7.32) relates the radius R of the sphere to the noncommutativity parameters θ^a of $\mathbb{R}^{2n}_{\theta}$. In this case we obtain the explicit solutions of the noncommutative vortex and DUY equations parametrized by the partial isometry operators T_{N_0} as

$$X_a^0 = \theta_{a\bar{b}} T_{N_0} \bar{z}^{\bar{b}} T_{N_0}^{\dagger} \quad \text{and} \quad \phi_1 = \alpha_1 T_{N_0}, \tag{7.33}$$

$$X_a^i = \theta_{a\bar{b}} \bar{z}^{\bar{b}} \quad \text{and} \quad \phi_i = \alpha_i \mathbf{1}_{k_1} \text{ for } 0 < i \leq m. \tag{7.34}$$

The BPS conditions (6.12)–(6.14) force us to take $k_1 = \cdots = k_m$ corresponding to the gauge symmetry breaking $U(k) \to U(k_0) \times U(k_1)^m$, so that $r = k_1$, $k_0 + mk_1 = k$ with $k_0 > 0$ and $k_1 > 0$. The configurations with $i > 0$ correspond to the vacuum gauge fields (7.11) with trivial bundle maps ϕ_i given as multiplication by the complex numbers α_i satisfying (7.30). Using (7.32) and (7.31) we find that the energies of these BPS states are given by

$$E_{\mathrm{BPS}} = 2(2\pi)^{n+1}R^2\left(\sum_{\substack{b,c=1\\ b\leqslant c}}^{n}\prod_{\substack{a=1\\ a\neq b,c}}^{n}\theta^a\right)N_0. \tag{7.35}$$

These solutions have a natural physical interpretation along the lines described in Sec. IV. The original noncommutative DUY equations are fixed by the positive integers n and k. Our ansatz (3.10)–(3.14) and (7.1)–(7.3) is labelled by the collection of positive integers (m,k_i,N_i) with $i=0,1,\ldots,s$. According to the standard identification of D-branes as noncommutative solitons,[42] the configuration (7.33) and (7.34) with $s=0$ describes a collection of mN_0 BPS $D0$-branes as a stable bound state (i.e., a vortexlike solution on $\mathbb{R}^{2n}_\theta$) in a system of $k_0+mk_1=k$ $D(2n)$ branes and antibranes. But from the point of view of the initial branes wrapped on $\mathbb{R}^{2n}_\theta\times\mathbb{C}P^1$, they are spherical mN_0 $D2$-branes. This means that instantons on $\mathbb{R}^{2n}_\theta\times\mathbb{C}P^1$ are the spherical extensions of vortices which are points in $\mathbb{R}^{2n}_\theta$. For $s>0$ the configuration (7.1)–(7.3) describes an unstable system of $mN_0+|m-2|N_1+\cdots+|m-2s|N_s$ $D0$-branes (vortices) in a $D(2n)$ brane-antibrane system, because $\deg\mathcal{L}^{m-2i}=m-2i$ for each $i=0,1,\ldots,s$. Again they form a system of spherical $D2$-branes [i.e., an SU(2)-symmetric multi-instanton] in the initial brane-antibrane system on $\mathbb{R}^{2n}_\theta\times\mathbb{C}P^1$. Their orientation depends on the sign of the magnetic charge $m-2i$ for each $i=0,1,\ldots,s$, which determines whether we have $D2$-branes or $D2$-antibranes. If more than one $N_i\neq 0$ then the ansatz either describes pairs of $D0$-branes with overall nonvanishing monopole charges, or both $D0$-branes, and anti-$D0$-branes. Such systems cannot be stable, i.e., the corresponding configuration (7.1)–(7.3) cannot satisfy the noncommutative vortex and DUY equations.

The distinction between BPS versus non-BPS solutions is very natural in quiver gauge theory. The BPS configurations are described by the simple Schur representations $\underline{\mathsf{L}}_i$, $i=0,1,\ldots,m$ of the A_{m+1} quiver given by a one-dimensional vector space at vertex i with all maps equal to 0, i.e., the A_{m+1}-module with $(\underline{\mathsf{L}}_i)_{m-2j}=\delta_{ij}\,\mathbb{C}$ and dimension vector $\vec{k}_{\underline{\mathsf{L}}_i}=\vec{e}_i$. The BPS states constructed above then correspond to the quiver representations $(\underline{\mathsf{L}}_0)^{\oplus N_0}$. Together with the projective modules $\underline{\mathsf{P}}_i$, the Schur modules $\underline{\mathsf{L}}_i$ admit the projective resolutions

$$0\to\underline{\mathsf{P}}_0\to\underline{\mathsf{L}}_0\to 0, \tag{7.36}$$

$$0\to\underline{\mathsf{P}}_{i-1}\to\underline{\mathsf{P}}_i\to\underline{\mathsf{L}}_i\to 0\quad\text{for } i=1,\ldots,s \tag{7.37}$$

and satisfy the relations[37]

$$\mathrm{Hom}(\underline{\mathsf{L}}_i,\underline{\mathsf{L}}_j)=\delta_{ij}\mathbb{C}=\mathrm{Hom}(\underline{\mathsf{P}}_i,\underline{\mathsf{L}}_j). \tag{7.38}$$

The resolutions (7.13) and (7.36), (7.37) exhibit a sharp homological distinction between BPS and non-BPS solutions. The constituent D-branes at the vertices of the quiver A_{m+1} are associated with the basic representations $\underline{\mathsf{L}}_i$. Sums $(\underline{\mathsf{L}}_i)^{\oplus N_i}$ for fixed i correspond to BPS states, associated generally with the symmetry breaking $U(k)\to U(k_i)\times U(k_{i+1})^m$, which are constructed analogously to (7.33), (7.34) but with the vacuum Higgs configurations $\phi_j=\alpha_j\,\mathbf{1}_{k_i}$ for $j<i$ and $\phi_j=\alpha_j\,\mathbf{1}_{k_{i+1}}$ for $j>i$. A generic non-BPS state, associated to the quiver representation (7.12), corresponds to the decay of the original SU(2)-symmetric branes wrapped on $\mathbb{R}^{2n}_\theta\times\mathbb{C}P^1$ into the collection of constituent branes $(\underline{\mathsf{L}}_0)^{\oplus N_0}\oplus(\underline{\mathsf{L}}_1)^{\oplus N_1}\oplus\cdots\oplus(\underline{\mathsf{L}}_s)^{\oplus N_s}$ in $\mathbb{R}^{2n}_\theta$. For $s>0$ this collection is unstable. In the quiver gauge theory, we have thereby arrived at a natural construction of the unstable D-brane configurations in terms of stable BPS states of D-branes, which may be succinctly summarized through the sequence of distinguished triangles of quiver representations

$$\begin{array}{ccccccccccccc}
(\underline{\mathsf{L}}_0)^{\oplus N_0}= & \underline{\mathcal{T}}_0 & & \to & & \underline{\mathcal{T}}_1 & \to\ \cdots\ \to & \underline{\mathcal{T}}_{m-1} & & \to & & \underline{\mathcal{T}}_m & =\ \underline{\mathcal{T}} \\
& \nwarrow & & & \swarrow & & & \nwarrow & & & \swarrow & & \\
& & (\underline{\mathsf{L}}_1)^{\oplus N_1} & & & & \cdots & & & (\underline{\mathsf{L}}_m)^{\oplus N_m} & & & ,
\end{array} \tag{7.39}$$

where $\mathcal{T}_s:=\oplus_{i=0}^{s}\ker T^\dagger_{N_i}=\ker T^\dagger_{N_s}\oplus\underline{\mathcal{T}}_{s-1}$ and the horizontal maps are the canonical inclusions of submodules. This exact sequence expresses the fact that, for each $s=1,\ldots,m$, the non-BPS mod-

ule $\underline{\mathcal{T}}_s$ is an extension of the BPS module $(\underline{\mathsf{L}}_s)^{\oplus N_s}$ by the non-BPS module $\underline{\mathcal{T}}_{s-1}$.

VIII. GENERALIZED ATIYAH-BOTT-SHAPIRO CONSTRUCTION

In this section we shall construct an explicit realization of the basic partial isometry operators T_{N_i} which will be particularly useful for setting the *D*-brane interpretation of our noncommutative multi-instanton solutions on firmer ground. It is based on an SU(2)-equivariant generalization of the (noncommutative) Atiyah-Bott-Shapiro (ABS) construction of tachyon field configurations.[9–11]

Equivariant ABS construction: If G is a group and $C\ell_{2n} := C\ell(\mathbb{R}^{2n})$, we denote by $R_{\mathrm{spin}_G(2n)}$ the Grothendieck group of isomorphism classes of finite-dimensional $\mathbb{Z}_2$-graded $G \times C\ell_{2n}$ modules, i.e., Clifford modules possessing an even ($\mathbb{Z}_2$-degree preserving) G-action which commutes with the $C\ell_{2n}$-action. More precisely, we consider representations of $\mathbb{C}[G] \otimes C\ell_{2n}$ with $\mathbb{C}[G]$ the group ring of G. The inclusion $\iota(2n): C\ell_{2n} \hookrightarrow C\ell_{2n+1}$ of Clifford algebras induces a restriction map

$$\iota_G(2n)^*: R_{\mathrm{Spin}_G(2n+1)} \to R_{\mathrm{Spin}_G(2n)} \tag{8.1}$$

on equivariant Clifford modules. Following the standard ABS construction,[43] we may then obtain the G-equivariant K-theory $K_G(\mathbb{R}^{2n})$ (with compact support) through the descendent isomorphism

$$K_G(\mathbb{R}^{2n}) = \mathrm{coker}\ \iota_G(2n)^* = R_{\mathrm{Spin}_G(2n)} / \iota_G(2n)^* R_{\mathrm{Spin}_G(2n+1)}. \tag{8.2}$$

The image of $\iota_G(2n)^*$ in $R_{\mathrm{Spin}_G(2n)}$ contains classes of Clifford modules $[\underline{V}]$ which admit a $G \times C\ell_{2n}$-equivariant involution $\underline{V} \cong \underline{V}^\vee$, where $\underline{V}^\vee$ is the Clifford module $\underline{V}$ with its $\mathbb{Z}_2$-parity reversed.

In our case, we take $G = \mathrm{U}(1) \subset \mathrm{SU}(2)$ acting trivially on $\mathbb{R}^{2n}$, and thereby consider $\mathrm{U}(1) \times C\ell_{2n}$-modules with the U(1)-action commuting with the Clifford action. Any such module is a direct sum of tensor products of a U(1)-module and a spinor module, and hence

$$R_{\mathrm{Spin}_{\mathrm{U}(1)}(2n)} = R_{\mathrm{Spin}(2n)} \otimes R_{\mathrm{U}(1)} \quad \text{and} \quad \iota_{\mathrm{U}(1)}(2n)^* = \iota(2n)^* \otimes \mathbf{1}. \tag{8.3}$$

Since from the standard ABS construction one has the isomorphism[43]

$$K(\mathbb{R}^{2n}) = \mathrm{coker}\ \iota(2n)^* = R_{\mathrm{Spin}(2n)} / \iota(2n)^* R_{\mathrm{Spin}(2n+1)} \tag{8.4}$$

of Abelian groups, we can reduce (8.2) for $G = \mathrm{U}(1)$ to the isomorphism

$$K_{\mathrm{U}(1)}(\mathbb{R}^{2n}) = K(\mathbb{R}^{2n}) \otimes R_{\mathrm{U}(1)} \tag{8.5}$$

of $R_{\mathrm{U}(1)}$-modules, where $K(\mathbb{R}^{2n}) \cong \mathbb{Z}$ [note that the isomorphism $K_{\mathrm{U}(1)}(\mathbb{R}^{2n}) \cong \mathbb{R}_{\mathrm{U}(1)}$ also follows from the fact that $\mathbb{R}^{2n}$ is equivariantly contractible to a point]. We may describe the isomorphism (8.5) along the lines explained in Sec. IV. In particular, the spinor module $\underline{\Delta}_{2n} := \underline{\Delta}(\mathbb{R}^{2n})$ admits the isotopical decomposition

$$\underline{\Delta}_{2n} = \bigoplus_{i=0}^{m} \Delta_i \otimes \underline{S}_{m-2i} \quad \text{with } \Delta_i = \mathrm{Hom}_{\mathrm{U}(1)}(\underline{S}_{m-2i}, \underline{\Delta}_{2n}) \tag{8.6}$$

obtained by restricting $\underline{\Delta}_{2n}$ to representations of $\mathrm{U}(1) \subset \mathrm{Spin}(2n) \subset C\ell_{2n}$. The Δ_i's in (8.6) are the corresponding multiplicity spaces.

The most instructive and useful way to explicitly realize the decomposition (8.6) is to use the equivariant excision theorem (4.5) directly and consider the SU(2)-invariant dimensional reduction of spinors from $\mathbb{R}^{2n} \times \mathbb{C}P^1$ to $\mathbb{R}^{2n}$. For this, we introduce the twisted Dirac operator on $\mathbb{R}^{2n} \times \mathbb{C}P^1$ using the graded connection formalism of Sec. V to write the $\mathbb{Z}_{m+1}$-graded Clifford connection

$$\hat{\not{D}} := \Gamma^{\hat{\mu}} D_{\hat{\mu}} = \gamma^{\mu} D_{\mu} \otimes \mathbf{1}_2 + (\boldsymbol{\phi}_{(m)})\gamma \otimes \gamma^{\overline{y}} \beta_{\overline{y}} - (\boldsymbol{\phi}_{(m)})^{\dagger} \gamma \otimes \gamma^{y} \beta_{y} + \gamma \otimes \not{D}_{\mathbb{C}P^1}, \tag{8.7}$$

where

$$\not{D}_{\mathbb{C}P^1} := \gamma^{y} D_{y} + \gamma^{\overline{y}} D_{\overline{y}} = \gamma^{y} (\partial_{y} + \omega_{y} + (\mathbf{a}^{(m)})_{y}) + \gamma^{\overline{y}} (\partial_{\overline{y}} + \omega_{\overline{y}} + (\mathbf{a}^{(m)})_{\overline{y}}) \tag{8.8}$$

and $\omega_y, \omega_{\overline{y}}$ are the components of the Levi-Civita spin connection on the tangent bundle of $\mathbb{C}P^1$. From (8.7) we see that the monopole charges $m-2i$ in the Yang-Mills energy functional (5.2) can be understood as originating from the Dirac operator (8.8) on $\mathbb{C}P^1$. The operator (8.7) acts on spinors Ψ which are sections of the bundle

$$\Psi = \begin{pmatrix} \Psi^{+} \\ \Psi^{-} \end{pmatrix} \in \bigoplus_{i=0}^{m} (E_{k_i} \otimes \underline{\Delta}_{2n}) \otimes \begin{pmatrix} \mathcal{L}^{m-2i+1} \\ \mathcal{L}^{m-2i-1} \end{pmatrix} \tag{8.9}$$

over $\mathbb{R}^{2n} \times \mathbb{C}P^1$, where $\mathcal{L}^{m-2i+1} \oplus \mathcal{L}^{m-2i-1}$ are the twisted spinor bundles of rank 2 over the sphere $\mathbb{C}P^1$. We are therefore interested in the twisted spinor module $\underline{\Delta}_{\mathcal{V}}(\mathbb{R}^{2n} \times \mathbb{C}P^1)$ over the Clifford algebra $\mathrm{C}\ell(\mathbb{R}^{2n} \times \mathbb{C}P^1)$ which is the product of the spinor module $\underline{\Delta}_{2n} \otimes \underline{\Delta}(\mathbb{C}P^1)$ with the fundamental representation (3.8) of the gauge group $\mathrm{U}(k)$ broken as in (3.9).

The symmetric fermions on $\mathbb{R}^{2n}$ that we are interested in correspond to SU(2)-invariant spinors on $\mathbb{R}^{2n} \times \mathbb{C}P^1$. They belong to the kernel of the Dirac operator (8.8) on $\mathbb{C}P^1$ and will be massless on $\mathbb{R}^{2n}$. One can write

$$\not{D}_{\mathbb{C}P^1} = \bigoplus_{i=0}^{m} \not{D}_{m-2i} = \bigoplus_{i=0}^{m} \begin{pmatrix} 0 & \not{D}^{-}_{m-2i} \\ \not{D}^{+}_{m-2i} & 0 \end{pmatrix}, \tag{8.10}$$

where

$$\not{D}^{+}_{m-2i} = \frac{1}{R^2} \left((R^2 + y\overline{y}) \partial_{\overline{y}} - \frac{1}{2}(m-2i+1) y \right), \tag{8.11}$$

$$\not{D}^{-}_{m-2i} = -\frac{1}{R^2} \left((R^2 + y\overline{y}) \partial_{y} + \frac{1}{2}(m-2i-1) \overline{y} \right). \tag{8.12}$$

The operator (8.10) acts on sections of the bundle (8.9) which we write with respect to this decomposition as

$$\Psi = \bigoplus_{i=0}^{m} \begin{pmatrix} \psi^{+}_{(m-2i)} \\ \psi^{-}_{(m-2i)} \end{pmatrix}, \tag{8.13}$$

where $\psi^{\pm}_{(m-2i)}$ are sections of $\mathcal{L}^{m-2i\pm1}$ taking values in $\underline{\Delta}_{2n} \otimes \underline{V}_{k_i}$ with coefficients depending on $x \in \mathbb{R}^{2n}$.

To describe the kernel of the Dirac operator (8.10), we need to solve the differential equations

$$\not{D}^{+}_{m-2i} \psi^{+}_{(m-2i)} = 0 \quad \text{and} \quad \not{D}^{-}_{m-2i} \psi^{-}_{(m-2i)} = 0 \tag{8.14}$$

for the positive and negative chirality spinors $\psi^{+}_{(m-2i)}$ and $\psi^{-}_{(m-2i)}$ in $\ker \not{D}^{+}_{m-2i}$ and $\ker \not{D}^{-}_{m-2i}$. By recalling the form of the transition functions for the monopole bundles from Sec. III, one easily sees that the only solutions of these equations which are regular on both the northern and southern hemispheres of S^2 are of the form

$$\psi^{+}_{(m-2i)} = \frac{1}{(R^2 + y\overline{y})^{t_i/2}} \sum_{\ell=0}^{t_i} \psi^{+}_{(m-2i)\ell}(x) y^{\ell} \quad \text{and} \quad \psi^{-}_{(m-2i)} = 0 \quad \text{for } m-2i < 0 \tag{8.15}$$

and

$$\psi^-_{(m-2i)} = \frac{1}{(R^2+y\overline{y})^{t_i/2}} \sum_{\ell=0}^{t_i} \psi^-_{(m-2i)\ell}(x)\overline{y}^{\ell} \quad \text{and} \quad \psi^+_{(m-2i)} = 0 \quad \text{for } m-2i>0. \tag{8.16}$$

Here $t_i=|m-2i|-1$ and the component functions $\psi^{\pm}_{(m-2i)\ell}(x)$ on $\mathbb{R}^{2n}$ with $\ell=0,1,\ldots,t_i$ form the irreducible representation $\underline{V}_{t_i+1}\cong\mathbb{C}^{|m-2i|}$ of the group SU(2). Thus the chirality grading is by the sign of the magnetic charges.

This analysis is valid when the monopole charge m is an even or odd integer. However, when m is even there is precisely one term in (8.9) with $m=2i$ for which the sub-bundle $E_{k(m/2)}\to\mathbb{R}^{2n}$ is twisted by the ordinary spinor bundle $\mathcal{L}\oplus\mathcal{L}^{\vee}\to\mathbb{C}P^1$ of vanishing magnetic charge. This bundle admits an infinite-dimensional vector space of symmetric L^2-sections comprised of spinor harmonics $\Psi_{lq}\in\mathbb{C}^2$ with $l\in\mathbb{N}_0+\frac{1}{2}$, $q\in\{-l,-l+1,\ldots,l-1,l\}$ and $\not{D}_0\Psi_{lq}\neq 0$.[44] The spectrum of the (untwisted) Dirac operator $\not{D}_0$ consists of the eigenvalues $\pm\left(l+\frac{1}{2}\right)$, each of multiplicity $p+1=2l+1$. After dimensional reduction, this produces an infinite tower of massive spinors on $\mathbb{R}^{2n}$, and such fermions of zero magnetic charge have no immediate interpretation in the present context. However, one has $\dim\ker\not{D}_0=0$, and this will be enough for our purposes. We will therefore fix one of these vector spaces, such that after integration over $\mathbb{C}P^1$ it corresponds to the space

$$\underline{H}_p \cong \mathbb{C}^2\otimes\mathbb{C}^{p+1} \quad \text{with } p=1,3,5,\ldots. \tag{8.17}$$

All of our subsequent results will be independent of the particular choice of eigenspace (8.17).

We have thereby shown that the SU(2)-equivariant reduction of the twisted spinor representation of $C\ell(\mathbb{R}^{2n}\times\mathbb{C}P^1)$ decomposes as a $\mathbb{Z}_2$-graded bundle giving

$$\underline{\Delta}_{\underline{\mathcal{V}}}(\mathbb{R}^{2n}\times\mathbb{C}P^1)^{\mathrm{SU}(2)} = \underline{\Delta}_{2n}\otimes(\underline{\Delta}^+_{\underline{\mathcal{V}}}\otimes\underline{\Delta}^-_{\underline{\mathcal{V}}}) \quad \text{for } m \text{ odd}, \tag{8.18}$$

where

$$\underline{\Delta}^+_{\underline{\mathcal{V}}} = \bigoplus_{i=m_+}^{m} \underline{V}_{k_i}\otimes\underline{V}_{|m-2i|} \quad \text{and} \quad \underline{\Delta}^-_{\underline{\mathcal{V}}} = \bigoplus_{i=0}^{m_-} \underline{V}_{k_i}\otimes\underline{V}_{m-2i} \tag{8.19}$$

with $m_+=\lfloor(m+1)/2\rfloor$ and $m_-=\lfloor(m-1)/2\rfloor$. When m is an even integer, one should also couple the eigenspace (8.17) giving

$$\underline{\Delta}_{\underline{\mathcal{V}}}(\mathbb{R}^{2n}\times\mathbb{C}P^1)^{\mathrm{SU}(2)} = \underline{\Delta}_{2n}\otimes(\underline{\Delta}^+_{\underline{\mathcal{V}}}\otimes(\underline{V}_{k\frac{m}{2}}\otimes\underline{H}_p)\oplus\underline{\Delta}^-_{\underline{\mathcal{V}}}) \quad \text{for } m \text{ even} \tag{8.20}$$

with $m_+=\lfloor(m+3)/2\rfloor$ and $m_-=\lfloor(m+1)/2\rfloor$. It remains to work out the corresponding action of Clifford multiplication

$$\mu_{\underline{\mathcal{V}}}:\underline{\Delta}^-_{\underline{\mathcal{V}}}\to\underline{\Delta}^+_{\underline{\mathcal{V}}}. \tag{8.21}$$

For this, we recall from Sec. IV that the action of the generators of the parabolic subgroup $P\subset\mathrm{SL}(2,\mathbb{C})$ on the equivariant decomposition (8.18), (8.19) is given by $\sigma_3(\underline{V}_{k_i}\otimes\underline{V}_{|m-2i|})=(m-2i)(\underline{V}_{k_i}\otimes\underline{V}_{|m-2i|})$ and $\sigma_-:\underline{V}_{k_i}\otimes\underline{V}_{|m-2i|}\to\underline{V}_{k_{i-1}}\otimes\underline{V}_{|m-2i|}$. Since the Clifford action is required to commute with this action, the map (8.21) is thereby uniquely fixed on the isotopical components in the form

$$\mu_{\underline{\mathcal{V}}}\circ\Pi_i:\underline{V}_{k_i}\otimes\underline{V}_{|m-2i|}\to\underline{V}_{k_{i+\lfloor\frac{m}{2}\rfloor+1}}\otimes\underline{V}_{|m-2i|} \quad \text{for } i=0,1,\ldots,m_-. \tag{8.22}$$

Furthermore, since $\sigma_3(\underline{H}_p)=0$ for all p, the space of spinor harmonics must lie in the kernel of the Clifford map and one has

$$\mu_{\underline{\mathcal{V}}}\circ\Pi_{m/2}=0 \quad \text{for } m \text{ even}. \tag{8.23}$$

It is also illuminating to formulate this equivariant dimensional reduction from a dynamical point of view, as we did for the gauge fields in Sec. V. Using the gauged Dirac operator (8.7) we may define a fermionic energy functional on the space of sections of the bundle (8.9) by

$$E_D := \int_{\mathbb{R}^{2n}\times\mathbb{C}P^1} \mathrm{d}^{2n+2}x\sqrt{g}\Psi^\dagger \hat{\not{D}}\Psi . \tag{8.24}$$

One has

$$\Psi^\dagger(\gamma(\boldsymbol{\phi}_{(m)})\otimes\sigma^{\bar{y}} - \gamma(\boldsymbol{\phi}_{(m)})^\dagger\otimes\sigma^y)\Psi = ((\Psi^+)^\dagger(\Psi^-)^\dagger)\begin{pmatrix}\gamma(\boldsymbol{\phi}_{(m)})^\dagger(\Psi^-)\\ \gamma(\boldsymbol{\phi}_{(m)})(\Psi^+)\end{pmatrix}. \tag{8.25}$$

Substituting (8.10)–(8.16), we see that (8.25) vanishes on symmetric spinors and after integration over $\mathbb{C}P^1$ the energy functional (8.24) for m odd becomes

$$E_D = 4\pi R^2\int_{\mathbb{R}^{2n}}\mathrm{d}^{2n}x\left[\sum_{i=m_+}^{m}\sum_{\ell=0}^{|m-2i|-1}(\psi^+_{(m-2i)\ell})^\dagger\gamma^\mu D_\mu(\psi^+_{(m-2i)\ell}) + \sum_{i=0}^{m_-}\sum_{\ell=0}^{m-2i-1}(\psi^-_{(m-2i)\ell})^\dagger\gamma^\mu D_\mu(\psi^-_{(m-2i)\ell})\right]. \tag{8.26}$$

The symmetric fermion energy functional for m even also contains mass terms for fermions of vanishing magnetic charge which are proportional to the multiplicity $(p+1)$ of the spinor harmonics.

Explicit form of the operators: $\boldsymbol{T_{N_i}}$: The operators T_{N_i} parametrizing the solutions of the preceding section may be realized explicitly by appealing to a noncommutative version of the above construction. For this, we first note that the (trivial) action of $\mathrm{U}(1)\subset\mathrm{SU}(2)$ on $\mathbb{R}^{2n}$ induces an action on functions f on $\mathbb{R}^{2n}$ by $(\zeta\cdot f)(x) := f(\zeta^{-1}\cdot x)$ for $\zeta\in\mathrm{U}(1)$. This in turn defines an action of $\mathrm{U}(1)$ on the noncommutative space $\mathbb{R}^{2n}_\theta$ through automorphisms $\hat{f}\mapsto\widehat{\zeta\cdot f}$ of the Weyl operator algebra, i.e., a representation of $\mathrm{U}(1)$ in the automorphism group of the algebra. We will assume that the Fock space (6.4) carries a unitary representation of $\mathrm{U}(1)$. We can then decompose it into its isotopical components in the usual way as

$$\mathcal{H} = \bigoplus_{i=0}^{m}\mathcal{H}_i\otimes\underline{S}_{m-2i}. \tag{8.27}$$

For $\zeta\in\mathrm{U}(1)$ we denote the corresponding unitary operator on $\mathcal{H}$ by $\hat{\zeta}$. If we demand that the representations of $\mathrm{U}(1)$ above are covariant with respect to each other,[45]

$$\hat{\zeta}\hat{f}\hat{\zeta}^{-1} = \widehat{\zeta\cdot f}, \tag{8.28}$$

then they define a representation of the crossed-product of the algebra of Weyl operators with the group $\mathrm{U}(1)$. This defines the (trivial) noncommutative $\mathrm{U}(1)$-space $\mathbb{R}^{2n}_\theta\rtimes\mathrm{U}(1)$, and equivariant field configurations are operators belonging to the commutant of $\mathrm{U}(1)$ in the crossed-product algebra. In quiver gauge theory, the pertinent representation of A_{m+1} thus labels isotopical components of the Hilbert space of the noncommutative gauge theory. Since the $\mathrm{U}(1)$-action is trivial here, the isotopical components of the Fock space (8.27) are given by $\mathcal{H}_i\cong\mathcal{H}$ for each $i=0,1,\ldots,m$. Note that one has an isomorphism $(\mathcal{H})^{\otimes(m+1)}\cong\mathcal{H}$ by the usual Hilbert hotel argument.

We will now construct a representation on (8.27) of the partial isometry operators T_{N_i} in $\mathbb{R}^{2n}_\theta\rtimes\mathrm{U}(1)$. For this, let us set $r := 2^{n-1}$ and consider the operators[9]

$$\Sigma = (\sigma\cdot x)^\dagger \frac{1}{\sqrt{(\sigma\cdot x)(\sigma\cdot x)^\dagger}} \quad \text{and} \quad \Sigma^\dagger = \frac{1}{\sqrt{(\sigma\cdot x)(\sigma\cdot x)^\dagger}}(\sigma\cdot x), \tag{8.29}$$

where $\sigma\cdot x := \sigma_\mu x^\mu$, $\mu,\ \nu = 1,\dots,2n$ and the $r\times r$ matrices σ_μ are subject to the anticommutation relations

$$\sigma_\mu^\dagger\sigma_\nu + \sigma_\nu^\dagger\sigma_\mu = 2\delta_{\mu\nu}\mathbf{1}_r = \sigma_\mu\sigma_\nu^\dagger + \sigma_\nu\sigma_\mu^\dagger. \tag{8.30}$$

Equation (8.30) implies that the matrices

$$\gamma_\mu = \begin{pmatrix} 0 & \sigma_\mu^\dagger \\ -\sigma_\mu & 0 \end{pmatrix} \quad \text{with } \gamma_\mu\gamma_\nu + \gamma_\nu\gamma_\mu = -2\delta_{\mu\nu}\mathbf{1}_{2r} \tag{8.31}$$

generate the Clifford algebra $C\ell_{2n}$. Note that for $n=1$ we have $r=1$, $\sigma_1=1$, and $\sigma_2=i$, which yields

$$\Sigma^\dagger = \frac{1}{\sqrt{z^\dagger z}}z^\dagger = \sum_{\ell=1}^{\infty} |\,\ell-1\rangle\langle\ell\,| \tag{8.32}$$

and we obtain the standard shift operator $(\Sigma)^N$ on the Fock space $\mathcal{H}$ in this case. Generally, the operators (8.29) obey

$$(\Sigma^\dagger)^{N_i}(\Sigma)^{N_i} = \mathbf{1}_r \quad \text{and} \quad (\Sigma)^{N_i}(\Sigma^\dagger)^{N_i} = \mathbf{1}_r - \mathcal{P}_{N_i}, \tag{8.33}$$

where $\mathcal{P}_{N_i}$ is a projector of rank N_i on the vector space $\underline{\Delta}_{2n}^+\otimes\mathcal{H}$, and $\underline{\Delta}_{2n}^+\cong\mathbb{C}^r$ are the irreducible chiral spinor modules of dimension $r=2^{n-1}$ (with $\underline{\Delta}_{2n}=\underline{\Delta}_{2n}^+\oplus\underline{\Delta}_{2n}^-$) on which the matrices σ_μ act.

The partial isometry operators $(\Sigma)^{N_i}$ in $\mathbb{R}_\theta^{2n}$ do not act on the isotopical decomposition (8.27) and thus do not properly incorporate the SU(2)-equivariant reduction of the original system of D-branes. The desired operators T_{N_i} in $\mathbb{R}_\theta^{2n}\rtimes\mathrm{U}(1)$ are obtained by first projecting these partial isometries onto constituent brane subspaces. With Π_i the rank 1 projector onto the ith isotopical component in (8.27), we thereby define the $r\times r$ matrices

$$T_{N_i}^{(0)} = \mathbf{1}_r\otimes(1-\Pi_i) + (\Sigma)^{N_i}\otimes\Pi_i. \tag{8.34}$$

The operator $T_{N_i}^{(0)}$ acts as the shift operator $(\Sigma)^{N_i}$ on $\mathcal{H}_i$ and as the identity operator $\mathbf{1}_r$ on $\mathcal{H}_j$ for all $j\neq i$. It is easy to see that these matrices satisfy the equations

$$(T_{N_i}^{(0)})^\dagger(T_{N_i}^{(0)}) = \mathbf{1}_r \quad \text{and} \quad (T_{N_i}^{(0)})(T_{N_i}^{(0)})^\dagger = \mathbf{1}_r - \mathcal{P}_{N_i}^{(0)} \tag{8.35}$$

with

$$P_{N_i}^{(0)} = \mathcal{P}_{N_i}\otimes\Pi_i \tag{8.36}$$

a projector of rank N_i on the Fock space $\underline{\Delta}_{2n}^+\otimes\mathcal{H}$. They also satisfy the algebra

$$(T_{N_i}^{(0)})^N = T_{N_iN}^{(0)} \quad \text{and} \quad T_{N_i}^{(0)}T_{N_j}^{(0)} = T_{N_i}^{(0)} + T_{N_j}^{(0)} - \mathbf{1}_r = T_{N_j}^{(0)}T_{N_i}^{(0)} \quad \text{for } i\neq j. \tag{8.37}$$

The operator (8.34) may be regarded as a linear map

$$T_{N_i}^{(0)}:\underline{\Delta}_{2n}^-\otimes\mathcal{H}\to\underline{\Delta}_{2n}^+\otimes\mathcal{H}. \tag{8.38}$$

In particular, the map $(T_1^{(0)})$ has a trivial kernel, while $(T_1^{(0)})^\dagger$ has a one-dimensional kernel which is spanned by the vector $|\psi\rangle\otimes|0,\dots,0\rangle$ where $|\psi\rangle$ denotes the lowest-weight spinor of SO($2n$).

Finally, the desired *rectangular* $k_i\times r$ Toeplitz operators T_{N_i} may be realized in terms of the partial isometries (8.34) by appealing to the Hilbert hotel argument. For this, we introduce a lexicographic ordering $\mathbb{N}_0^n\sim\mathbb{N}_0$ on the Fock space $\mathcal{H}$ so that $|r_1,\dots,r_n\rangle=|q\rangle$ with $q=0,1,2,\dots$, and fix an orthonormal basis $\vec{\rho}_0,\vec{\rho}_1,\dots,\vec{\rho}_{r-1}$ of the chiral spinor representation space $\underline{\Delta}_{2n}^+\cong\mathbb{C}^r$.

Then $\vec{\rho}_a \otimes |q\rangle$, $a=0,1,\ldots,r-1$ is an orthonormal basis for $\underline{\Delta}^+_{2n} \otimes \mathcal{H}$ and there is a one-to-one correspondence $\vec{\rho}_a \otimes |q\rangle \leftrightarrow |rq+a\rangle$ of basis states. Similarly, by fixing an orthonormal basis $\vec{\lambda}^i_0, \vec{\lambda}^i_1, \ldots, \vec{\lambda}^i_{k_i-1}$ of the SU(2) representation space $\underline{V}_{k_i} \cong \mathbb{C}^{k_i}$, there is a one-to-one correspondence $\vec{\lambda}^i_{a_i} \otimes |q_i\rangle \leftrightarrow |k_i q_i + a_i\rangle$, $a_i=0,1,\ldots,k_i-1$ for the corresponding orthonormal basis of $\underline{V}_{k_i} \otimes \mathcal{H}$. Let us now introduce unitary isomorphisms $U_i : \underline{\Delta}^+_{2n} \otimes \mathcal{H} \to \underline{V}_{k_i} \otimes \mathcal{H}$ and $U_i^\dagger : \underline{V}_{k_i} \otimes \mathcal{H} \to \underline{\Delta}^+_{2n} \otimes \mathcal{H}$ by the formulas

$$U_i = \sum_{a=0}^{r-1} \sum_{a_i=0}^{k_i-1} \sum_{\substack{q,q_i=0 \\ rq+a=k_i q_i+a_i}}^{\infty} |k_i q_i + a_i\rangle\langle rq+a| = \sum_{a=0}^{r-1} \sum_{a_i=0}^{k_i-1} \sum_{\substack{q,q_i=0 \\ rq+a=k_i q_i+a_i}}^{\infty} \vec{\lambda}^i_{a_i} \vec{\rho}^\dagger_a \otimes |q_i\rangle\langle q|, \tag{8.39}$$

$$U_i^\dagger = \sum_{a=0}^{r-1} \sum_{a_i=0}^{k_i-1} \sum_{\substack{q,q_i=0 \\ rq+a=k_i q_i+a_i}}^{\infty} |rq+a\rangle\langle k_i q_i + a_i| = \sum_{a=0}^{r-1} \sum_{a_i=0}^{k_i-1} \sum_{\substack{q,q_i=0 \\ rq+a=k_i q_i+a_i}}^{\infty} \vec{\rho}_a \vec{\lambda}^{i\dagger}_{a_i} \otimes |q\rangle\langle q_i|. \tag{8.40}$$

By using the shift operators (8.34), we then define the operators

$$T_{N_i} = U_i(T^{(0)}_{N_i}) \quad \text{and} \quad T^\dagger_{N_i} = (T^{(0)}_{N_i})^\dagger U_i^\dagger \tag{8.41}$$

on $\underline{\Delta}^-_{2n} \otimes \mathcal{H} \to \underline{V}_{k_i} \otimes \mathcal{H}$ and $\underline{V}_{k_i} \otimes \mathcal{H} \to \underline{\Delta}^-_{2n} \otimes \mathcal{H}$. They satisfy the requisite equations (7.3), with the $k_i \times k_i$ matrix

$$P_{N_i} = U_i(\mathcal{P}_{N_i} \otimes \Pi_i) U_i^\dagger \tag{8.42}$$

a projector of rank N_i on the Fock space $\underline{V}_{k_i} \otimes \mathcal{H}$.

Notice that the rank $r=2^{n-1}$ used in this construction is an even integer for $n \geqslant 2$. To work with odd ranks r one may introduce the $(2^{n-1}+1) \times (2^{n-1}+1)$ matrices

$$T^{(0)\prime}_{N_i} = \begin{pmatrix} T^{(0)}_{N_{i-1}} & 0 \\ 0 & \Sigma'_1 \end{pmatrix}, \tag{8.43}$$

where $T^{(0)}_{N_i-1}$ is defined as above and

$$\Sigma'_1 = \sum_{\ell=1}^{\infty} |0,\ldots,0,\ell\rangle\langle\ell-1,0,\ldots,0| \tag{8.44}$$

is a shift operator on the Fock space $\mathcal{H}$. Then the operators (8.43) satisfy the equations (8.35) with

$$P^{(0)\prime}_{N_i} = \begin{pmatrix} \mathcal{P}_{N_i-1} \otimes \Pi_i & 0 \\ 0 & |0,\ldots,0\rangle\langle 0,\ldots,0| \end{pmatrix} \tag{8.45}$$

a projector of rank N_i on the Fock space $(\underline{\Delta}^+_{2n} \otimes \mathcal{H}) \oplus \mathcal{H} \cong \mathbb{C}^r \otimes \mathcal{H}$, where $r=2^{n-1}+1$. In this case the Toeplitz operators T_{N_i} are obtained by substituting (8.43) into (8.41) with the replacement $\underline{\Delta}^\pm_{2n} \to \underline{\Delta}^\pm_{2n} \oplus \mathbb{C}$.

Note also that the partial isometry operator

$$T^{(0)} := \prod_{i=0}^{m} T^{(0)}_{N_i} = \mathbf{1}_r + \sum_{i=0}^{m} (T^{(0)}_{N_i} - \mathbf{1}_r) = \mathbf{1}_r + \sum_{i=0}^{m} ((\Sigma)^{N_i} - \mathbf{1}_r), \tag{8.46}$$

together with the above representations of the U(1) group on the Weyl operator algebra of $\mathbb{R}^{2n}_\theta$ and on the Fock space $\mathcal{H}$, defines a cycle in the U(1)-equivariant analytic K-homology $K^a(\mathbb{R}^{2n}_\theta \rtimes \mathrm{U}(1)) \cong K^a_{\mathrm{U}(1)}(\mathbb{R}^{2n})$. After a twisting appropriate to the inclusion of the pertinent magnetic monopole bundles, it describes the SU(2)-invariant configurations of D-branes as branes on

the (trivial) quotient space $\mathbb{R}^{2n}/\mathrm{U}(1)$. The charge of this class is the same as that of the cocycle $[\underline{\Delta}_{\underline{\mathcal{V}}}^{+},\underline{\Delta}_{\underline{\mathcal{V}}}^{-};\mu_{\underline{\mathcal{V}}}]$ built earlier in the topological K-theory (8.5) from the standard ABS brane-antibrane class $[\underline{\Delta}_{2n}^{+},\underline{\Delta}_{2n}^{-};\mu]$ which is the generator of (8.4)[9–11,43]. The computation of the topological charge, as well as the equivalence between the commutative (topological) and noncommutative (analytic) K-homology descriptions of the D-brane configurations, will be presented in the next section.

Moduli space of solutions: The realization (8.34) can be generalized in order to introduce $2n\Sigma_{i=0}^{m}N_i$ real moduli into the solution which specify the locations of the various noncommutative solitons in $\mathbb{R}^{2n}$.[45] For this, one first must introduce "shifted ground states" centered at $(b_{\ell_i}^{i\mu})$, $\ell_i=1,\ldots,N_i$ for each $i=0,1,\ldots,m$. The operators (8.34) are rewritten as

$$T_{N_i}^{(0)}=\mathbf{1}_r\otimes(1-\Pi_i)+(\Sigma_1^i\Sigma_2^i\cdots\Sigma_{N_i}^i)\otimes\Pi_i, \tag{8.47}$$

where each $\Sigma_{\ell_i}^i$, $\ell_i=1,\ldots,N_i$, $i=0,1,\ldots,m$ is of the form of the shift operator Σ in (8.29) but with the coordinates x shifted to $x_{\ell_i}^i:=x-b_{\ell_i}^i$. They behave just like Σ except that now the kernel of $(\Sigma_{\ell_i}^i)^\dagger$ is spanned by the vector $|\psi\rangle\otimes|\overline{b_{\ell_i}^i}\rangle$, where $|\psi\rangle$ is the fermionic ground state and the shifted ground state $|\overline{b_{\ell_i}^i}\rangle$ is a coherent state in the n-oscillator Fock space $\mathcal{H}$, i.e., $\overline{z_{\ell_i}^{i\alpha}}|\overline{b_{\ell_i}^i}\rangle=0$. The states $|\psi\rangle\otimes|\overline{b_1^i}\rangle$ and $\Sigma_1^i\cdots\Sigma_{\ell_i-1}^i(|\psi\rangle\otimes|\overline{b_{\ell_i}^i}\rangle)$ for $\ell_i=2,\ldots,N_i$ span the kernel of the operator $(T_{N_i}^{(0)})^\dagger$ given by (8.47), and we find that the equations (8.35) are obeyed with $P_{N_i}^{(0)}$ the orthogonal projection onto $\ker(T_{N_i}^{(0)})^\dagger$.

The space of partial isometries (8.46) may thereby be described as the complex manifold $\Pi_{i=0}^{m}(\mathbb{C}^n)^{N_i}$. After a quotient by the appropriate discrete symmetry group, the moduli space for the full solution consisting of the rectangular Toeplitz operators (8.41) is given by

$$\mathcal{M}(n;\vec{k}_{\underline{\mathcal{V}}},\vec{k}_{\underline{\mathcal{I}}})=\mathcal{Q}(\vec{k}_{\underline{\mathcal{V}}})\times\prod_{i=0}^{m}\mathrm{Hilb}^{N_i}(\mathbb{C}^n), \tag{8.48}$$

where $\mathrm{Hilb}^{N_i}(\mathbb{C}^n)$ is the moduli space of N_i noncommutative solitons on $\mathbb{R}_\theta^{2n}$ (Ref. 46) which is given as the (singular) Hilbert scheme of N_i points in $\mathbb{C}^n$, i.e., the set of ideals $\mathcal{I}$ of codimension N_i in the polynomial ring $\mathbb{C}[b_1^i,\ldots,b_{N_i}^i]$. The factor $\mathcal{Q}(\vec{k}_{\underline{\mathcal{V}}})$ is the moduli space of isomorphism classes of quiver representations (3.8) of dimension[37]

$$\dim\mathcal{Q}(\vec{k}_{\underline{\mathcal{V}}})=1-\frac{1}{2}\vec{k}_{\underline{\mathcal{V}}}\cdot C\vec{k}_{\underline{\mathcal{V}}}=1+\sum_{i=0}^{m}k_i(k_{i+1}-k_i). \tag{8.49}$$

Note that real roots (having $\vec{k}_{\underline{\mathcal{V}}}\cdot C\vec{k}_{\underline{\mathcal{V}}}=2$) correspond to rigid representations of the quiver A_{m+1} with no moduli, while imaginary roots (having $\vec{k}_{\underline{\mathcal{V}}}\cdot C\vec{k}_{\underline{\mathcal{V}}}\leqslant 0$) carry moduli associated to the gauge symmetry breaking (3.9). The points of the moduli space (8.48) label the positions of well-separated D-branes, and it coincides in the low-energy limit with the moduli space of the commutative brane description.[45]

IX. *D*-BRANE CHARGES

In this section we will compute the topological charge of our multi-instanton solutions in essentially two distinct ways. The first one is a direct field theoretic calculation of the $(n+1)$th Chern number of our gauge field configurations on $\mathbb{R}_\theta^{2n}\times S^2$, which can also be computed using the $\mathbb{Z}_{m+1}$-graded connection formalism of Sec. V. The second one is a homological calculation of the index class of our solutions in K-theory, which is also equivalent to the Euler-Ringel character of the pertinent representations of the quiver A_{m+1}. The equivalence of these two calculations will then lead us directly into a world volume description whereby we can interpret the topological charge in terms of cycles in topological equivariant K-homology, yielding the claimed D-brane

interpretation of our solutions. The results of this section bridge together the descriptions presented in Sec. IV and justify the brane interpretations that have been given throughout this paper thus far.

Field theory calculation: We will first compute the topological charge of the configurations (7.1)–(7.3). For this, it is convenient to parametrize the two-sphere by the angular coordinates $0 \leqslant \varphi \leqslant 2\pi$ and $0 \leqslant \vartheta < \pi$ defined in (2.4). In these coordinates

$$\mathcal{F}_{y\overline{y}} = \left| \frac{\partial(\vartheta,\varphi)}{\partial(y,\overline{y})} \right| \mathcal{F}_{\vartheta\varphi} = \frac{1}{2i} \frac{\sin\vartheta}{y\overline{y}} \mathcal{F}_{\vartheta\varphi} = \frac{1}{2i} \frac{(1+\cos\vartheta)^2}{R^2 \sin\vartheta} \mathcal{F}_{\vartheta\varphi}, \tag{9.1}$$

and we have

$$\mathcal{F}_{2a-1\,2a} = 2i\mathcal{F}_{a\overline{a}} = -\frac{i}{\theta^a} \sum_{i=0}^{m} P_{N_i} \otimes \Pi_i, \tag{9.2}$$

$$\mathcal{F}_{\vartheta\varphi} = -i \frac{\sin\vartheta}{2} \sum_{i=0}^{m} (m-2i) P_{N_i} \otimes \Pi_i \tag{9.3}$$

giving

$$\begin{aligned} \mathcal{F}_{12}\mathcal{F}_{34}\cdots\mathcal{F}_{2n-12n}\mathcal{F}_{\vartheta\varphi} &= (-i)^{n+1} \frac{\sin\vartheta}{2\prod_{a=1}^{n} \theta^a} \left(\sum_{i=0}^{m} P_{N_i} \otimes \Pi_i \right)^n \left(\sum_{j=0}^{m} (m-2j) P_{N_j} \otimes \Pi_j \right) \\ &= (-i)^{n+1} \frac{\sin\vartheta}{2\prod_{a=1}^{n} \theta^a} \sum_{i=0}^{m} (m-2i) P_{N_i} \otimes \Pi_i, \end{aligned} \tag{9.4}$$

where we have used the definitions (7.4) and (5.16) of the projectors P_{N_i} and Π_i.

The instanton charge is then given by the $(n+1)$th Chern number

$$\begin{aligned} Q &:= \frac{1}{(n+1)!} \left(\frac{i}{2\pi} \right)^{n+1} \left(\prod_{a=1}^{n} 2\pi\theta^a \right) \int_{S^2} \mathrm{Tr}_{\underline{\mathcal{V}}\otimes\mathcal{H}} \underbrace{\mathcal{F} \wedge \cdots \wedge \mathcal{F}}_{n+1} \\ &:= \left(\frac{i}{2\pi} \right)^{n+1} \frac{(-i)^{n+1}}{2\prod_{b=1}^{n} \theta^b} \left(\prod_{a=1}^{n} 2\pi\theta^a \right) \sum_{i=0}^{m} (m-2i) N_i \int_{S^2} \sin\vartheta \, \mathrm{d}\vartheta \wedge \mathrm{d}\varphi. \end{aligned} \tag{9.5}$$

After splitting the sum over i into contributions from monopoles and antimonopoles analogously to (7.31), this becomes

$$Q = \sum_{i=0}^{[m/2]} (m-2i)(N_i - N_{m-i}), \tag{9.6}$$

where we recall that $N_i \geqslant 0$ for $i = 0, 1, \ldots, m$. The formula (9.6) clarifies the D-brane interpretation of the configuration (7.1)–(7.3). It describes a collection of $(m-2i)N_i$ $D0$-branes for $2i < m$ and $(2i-m)N_i$ anti-$D0$-branes for $2i > m$ as a bound state (i.e., a vortexlike configuration on $\mathbb{R}^{2n}_\theta$) in a

system of $k_0+k_1+\cdots+k_m=k$ $D(2n)$ branes and antibranes. However, from the point of view of the initial brane-antibrane system on $\mathbb{R}^{2n}_\theta\times S^2$, they are spherical $|m-2i|N_i$ $D2$-branes or $D2$-antibranes depending on the sign of the monopole charge $m-2i$. Note that the vortices with $2i=m$, which always exist for even m, have vanishing instanton charge since they couple with the trivial line bundle $\mathcal{L}^0=S^2\times\mathbb{C}$. Thus they are not extended to instantons on $\mathbb{R}^{2n}_\theta\times S^2$, but are rather unstable and simply decay into the vacuum.

The topological charge can be alternatively computed within the graded connection formalism of Sec. V. Recalling the equivariant ABS construction (8.18)–(8.20), we note that the $\mathbb{Z}_{m+1}$-graded vector space (3.8) [the fiber of the $\mathbb{Z}_{m+1}$-graded bundle (5.3)] also has a *natural* $\mathbb{Z}_2$-grading by the sign of the magnetic charge, i.e., by the involution $\epsilon:\underline{\mathcal{V}}\to\underline{\mathcal{V}}$ defined by $\epsilon(v_i):=\mathrm{sgn}(m-2i)\ v_i$ for $v_i\in\underline{V}_{k_i}$, where throughout we use the convention $\mathrm{sgn}(0):=0$. The corresponding supertrace is given by

$$\mathrm{str}_{k\times k}X:=\mathrm{tr}_{k\times k}(\epsilon\circ X)=\sum_{i=0}^{m}\mathrm{sgn}(m-2i)\ \mathrm{tr}_{k_i\times k_i}X_i \tag{9.7}$$

for any linear operator $X\in\mathrm{End}(\underline{\mathcal{V}})$ with block-diagonal components $X_i\in\mathrm{End}(\underline{\mathcal{V}}_{k_i})$. This extends to a supertrace $\mathrm{STr}_{\underline{\mathcal{V}}\otimes\mathcal{H}}:=\mathrm{Tr}_{\mathcal{H}}\,\mathrm{str}_{k\times k}$ which we may use to express the Chern number in terms of the graded curvature (5.28) as

$$Q=\frac{R^2}{2^n(n+1)!}\left(\frac{i}{2\pi}\right)^{n+1}\left(\prod_{a=1}^{n}2\pi\theta^a\right)\mathrm{STr}_{\underline{\mathcal{V}}\otimes\mathcal{H}}\mathrm{Tr}_{\mathbb{C}^{2n+1}}(\Gamma\hat{\mathcal{F}}^{n+1})_{\mathrm{asym}}, \tag{9.8}$$

where $\Gamma:=(2/\sqrt{g})\Gamma^1\cdots\Gamma^{2n+2}=\gamma\otimes\sigma_3$ and the antisymmetrized product of gamma matrices,

$$(\Gamma^{\hat\mu_1}\cdots\Gamma^{\hat\mu_q})_{\mathrm{asym}}:=\frac{1}{q!}\sum_{\pi\in S_q}\mathrm{sgn}(\pi)\Gamma^{\hat\mu_{\pi(1)}}\cdots\Gamma^{\hat\mu_{\pi(q)}} \tag{9.9}$$

mimicks the algebraic structure of the exterior product of differential forms. The formula (9.6) follows from (9.8) upon repeated application of the Clifford algebra and the trace identities (5.30)–(5.33), with the supertrace (9.7) giving the appropriate sign alternations.

K-theory calculation: The origin of the topological charge lies in the *graded Chern character* $\mathrm{ch}(\underline{\mathcal{V}}\otimes\mathcal{H}):=\mathrm{str}_{k\times k}\exp\hat{\mathcal{F}}/2\pi i$. Standard transgression arguments can be used to show that the cohomology class defined by this closed differential form is independent of the choice of graded connection.[39] In particular, we may either compute it by setting the off-diagonal Higgs fields $\phi_i=0$ or by setting the diagonal gauge fields $A^i=0$. It is instructive to recall how this works in the case $m=1$ corresponding to the basic brane-antibrane system represented by the chain (4.26).[8,31] In the former case we would obtain the difference $\mathrm{ch}(\underline{V}_{k_1}\otimes\mathcal{H})-\mathrm{ch}(\underline{V}_{k_0}\otimes\mathcal{H})$ of topological charges on the branes and antibranes. In the latter case we would compute the index of the tachyon field ϕ_1, or equivalently the Euler characteristic of the two-term complex $0\to\underline{V}_{k_1}\otimes\mathcal{H}\xrightarrow{\phi_1}\underline{V}_{k_0}\otimes\mathcal{H}\to 0$. The virtual Euler class generated by the cohomology of this complex is the analytic K-homology class $[\phi_1]\in K^{\mathrm{a}}(\mathbb{R}^{2n})$ of the brane configuration. The equivalence of the two computations is asserted by the index theorem.

The situation for $m>1$ is more subtle. The action of the graded connection zero-form (5.9) on the bundle (5.3) produces the holomorphic chain (4.13). In general this is *not* a complex because, according to (5.10), $(\boldsymbol{\phi}_{(m)})^2\neq 0$ for $m>1$, i.e., $\phi_i\phi_{i+1}\neq 0$. The only physical instance in which such a chain generates a complex is when it corresponds to an alternating sequence of branes and antibranes.[47] But if one has a tachyon field which is a holomorphic map from an antibrane to a brane, then the adjoint map is antiholomorphic. Recalling (5.37), we see that in our chain (4.13) all maps ϕ_i are *holomorphic* and thus do not represent tachyon fields between pairs of branes and antibranes. Furthermore, the maps ϕ_i obtained as solutions of the vortex equations, which can be

associated with the A_{m+1} quiver and are obtained by SU(2)-invariant reduction, can never satisfy the constraints $\phi_i\phi_{i+1}=0$.[34,36]

The solution to this problem is to fold the given holomorphic chain into maps between branes and antibranes. Let us first carry out the calculation in the case that the monopole Chern number m is an odd integer. By using the $\mathbb{Z}_2$-grading $\boldsymbol{\epsilon}:\underline{\mathcal{V}}\to\underline{\mathcal{V}}$ introduced above, we explicitly decompose (3.8) as a $\mathbb{Z}_2$-graded module into the ±1 eigenspaces of the involution $\boldsymbol{\epsilon}$ giving

$$\underline{\mathcal{V}}=\underline{\mathcal{V}}_+\otimes\underline{\mathcal{V}}_- \quad \text{with } \underline{\mathcal{V}}_+=\bigoplus_{i=0}^{m_-}\underline{V}_{k_i} \quad \text{and} \quad \underline{\mathcal{V}}_-=\bigoplus_{i=m_+}^{m}\underline{V}_{k_i}. \tag{9.10}$$

Using (5.9) and (5.10) we now introduce the operator

$$\mathbf{T}_{(m)}:=(\phi_{(m)})^{\lfloor m/2\rfloor+1}. \tag{9.11}$$

With respect to the $\mathbb{Z}_2$-grading (9.10), it is an odd map

$$\mathbf{T}_{(m)}:\underline{\mathcal{V}}_-\otimes\mathcal{H}\to\underline{\mathcal{V}}_+\otimes\mathcal{H} \quad \text{with } (\boldsymbol{T}_{(m)})^2=0. \tag{9.12}$$

Thus the triple $[\underline{\mathcal{V}}_+\otimes\mathcal{H},\underline{\mathcal{V}}_-\otimes\mathcal{H};\mathbf{T}_{(m)}]$ defines a two-term complex and represents a brane-antibrane system with tachyon field given in terms of the graded connection by (9.11). The corresponding index class $[\mathbf{T}_{(m)}]\in K^{\mathrm{a}}(\mathbb{R}^{2n})$ is thus the analytic K-homology class of our configuration of D-branes. In particular, on isotopical components one has

$$\mathbf{T}_{(m)}\circ\Pi_{i+1+\lfloor m/2\rfloor}=\phi_{i+1}\cdots\phi_{i+1+\lfloor m/2\rfloor}=(\alpha_{i+1}\cdots\alpha_{i+1+\lfloor m/2\rfloor})T_{N_i}T^\dagger_{N_{i+1+\lfloor m/2\rfloor}} \tag{9.13}$$

while $\mathbf{T}_{(m)}\circ\Pi_i=0$, where $i=0,1,\dots,m_-$. The tachyon field is thus a holomorphic map between branes of equal and opposite magnetic charge,

$$\mathbf{T}_{(m)}\circ\Pi_{i+\lfloor m/2\rfloor+1}:\underline{V}_{k_{i+\lfloor m/2\rfloor+1}}\otimes\mathcal{H}\to\underline{V}_{k_i}\otimes\mathcal{H}, \tag{9.14}$$

and from (7.5) it follows that it has a finite dimensional kernel and cokernel with

$$\dim\ker(\mathbf{T}_{(m)}\circ\Pi_{i+\lfloor m/2\rfloor+1})=N_{i+\lfloor m/2\rfloor+1} \quad \text{and} \quad \dim\ker(\mathbf{T}_{(m)}\circ\Pi_{i+\lfloor m/2\rfloor+1})^\dagger=N_i. \tag{9.15}$$

To incorporate the twistings by the magnetic monopole bundles, we use the ABS construction (8.18)–(8.23) to define the tachyon field

$$\boldsymbol{\mathcal{T}}_{(m)}:=\mathbf{T}_{(m)}\otimes\mathbf{1}:\underline{\Delta}^+_{\underline{\mathcal{V}}}\otimes\mathcal{H}\to\underline{\Delta}^-_{\underline{\mathcal{V}}}\otimes\mathcal{H}. \tag{9.16}$$

It behaves like a noncommutative version of Clifford multiplication $\underline{\mu}^\dagger_{\underline{\mathcal{V}}}$ in (8.21) and (8.22). Since $\dim\underline{V}_{|m-2i|}=|m-2i|$, from (9.15) it follows that the index of the tachyon field (9.16) is given by

$$\operatorname{index}\boldsymbol{\mathcal{T}}_{(m)}=\dim\ker(\boldsymbol{\mathcal{T}}_{(m)})-\dim\ker(\boldsymbol{\mathcal{T}}_{(m)})^\dagger=\sum_{i=m_+}^{m}|m-2i|N_i-\sum_{i=0}^{m_-}|m-2i|N_i=-Q. \tag{9.17}$$

Thus the K-theory charge of the noncommutative soliton configuration (7.1)–(7.3) coincides with the Yang-Mills instanton charge (9.5), (9.6) on $\mathbb{R}^{2n}_\theta\times S^2$.

When the monopole charge m is even, we introduce the tachyon field $\mathbf{T}_{(m)}$ by the same formula (9.11). The only difference now is that the subspace $\underline{V}_{k_{\frac{m}{2}}}\otimes\mathcal{H}$ is annihilated by both operators $(\mathbf{T}_{(m)})$ and $(\mathbf{T}_{(m)})^\dagger$ so that

$$\underline{V}_{k_{\frac{m}{2}}}\otimes\mathcal{H}\subset\ker(\boldsymbol{T}_{(m)})\cap\ker(\boldsymbol{T}_{(m)})^\dagger. \tag{9.18}$$

According to (8.20), this subspace should be coupled to the eigenspace (8.17) of spinor harmonics on $\mathbb{C}P^1$ when defining the extended tachyon field (9.16). Analogously to (8.23), one then has

$$\ker(\mathcal{T}_{(m)}\circ\Pi_{m/2})=\ker(\mathcal{T}_{(m)}\circ\Pi_{m/2})^{\dagger}=\underline{V}_{k_{m/2}}\otimes\underline{H}_p\otimes\mathcal{H}. \tag{9.19}$$

With a suitable regularization of the infinite dimensions of the kernel and cokernel of the operator $\mathcal{T}_{(m)}\circ\Pi_{m/2}$, these subspaces will make no contribution to the index (9.17). This statement will be justified below by the fact that index $\not{D}_0=0$ and that the index class of the noncommutative tachyon field coincides with that of the twisted SU(2)-invariant Dirac operator on $\mathbb{R}^{2n}\times\mathbb{C}P^1$.

We can give a more detailed picture of how the topological charge of the system of D-branes arises by relating the index to a homological computation in the corresponding quiver gauge theory, which shows precisely how the original brane configuration folds itself into branes and antibranes. Consider the A_{m+1}-module (7.12) defined by a generic (non-BPS) solution of the Yang-Mills equations on $\mathbb{R}^{2n}_{\theta}\times\mathbb{C}P^1$, and let

$$\underline{\mathcal{W}}=\bigoplus_{i=0}^{m}\underline{W}_i\quad\text{with }\vec{k}_{\underline{\mathcal{W}}}=\sum_{i=0}^{m}w_i\vec{e}_i \tag{9.20}$$

be any quiver representation. Applying the functor $\mathrm{Hom}(-,\underline{\mathcal{W}})$ to the projective resolution (7.13) gives a complex whose cohomology in the pth position defines the extension groups $\mathrm{Ext}^p(\underline{\mathcal{T}},\underline{\mathcal{W}})\cong H^p(\mathbb{R}^{2n}_{\theta};\underline{\mathcal{W}}\otimes\underline{\mathcal{T}}^{\vee})$, with $\mathrm{Ext}^0=\mathrm{Hom}$ and $\mathrm{Ext}^1=\mathrm{Ext}$. We may then define the relative Euler character between these two representations through the corresponding Euler form

$$\chi(\mathcal{T},\mathcal{W}):=\sum_{p\geqslant 0}(-1)^p\dim\mathrm{Ext}^p(\underline{\mathcal{T}},\underline{\mathcal{W}}). \tag{9.21}$$

Since the A_{m+1} quiver has no relations, one has $\mathrm{Ext}^p(\underline{\mathcal{T}},\underline{\mathcal{W}})=0$ for all $p\geqslant 2$ in the present case.[37]

By using (5.7), the resolution (7.13) induces an exact sequence of extension groups given by

$$0\to\mathrm{Hom}(\underline{\mathcal{T}},\underline{\mathcal{W}})\to\bigoplus_{i=0}^{s}\mathrm{Hom}(\ker T^{\dagger}_{N_i},\underline{\mathcal{W}}_i)\to\bigoplus_{i=0}^{s-1}\mathrm{Hom}(\ker T^{\dagger}_{N_{i+1}},\underline{\mathcal{W}}_i)\to\mathrm{Ext}(\underline{\mathcal{T}},\underline{\mathcal{W}})\to 0 \tag{9.22}$$

from which we may compute the Euler form (9.21) explicitly to get

$$\begin{aligned}\chi(\underline{\mathcal{T}},\underline{\mathcal{W}})&=\dim\mathrm{Hom}(\underline{\mathcal{T}},\underline{\mathcal{W}})-\dim\mathrm{Ext}(\underline{\mathcal{T}},\underline{\mathcal{W}})=\sum_{i=0}^{s}\dim\mathrm{Hom}(\ker T^{\dagger}_{N_i},\underline{W}_i)\\&\quad-\sum_{i=0}^{s-1}\dim\mathrm{Hom}(\ker T^{\dagger}_{N_{i+1}},\underline{W}_i)=\sum_{i=0}^{m}N_iw_i-\sum_{i=0}^{m-1}N_{i+1}w_i.\end{aligned} \tag{9.23}$$

Thus the relative Euler character depends only on the dimension vectors of the corresponding representations and coincides with the Ringel form $\langle\vec{k}_{\underline{\mathcal{T}}},\vec{k}_{\underline{\mathcal{W}}}\rangle$ on the representation ring $R_{\mathsf{A}_{m+1}}$ of the A_{m+1} quiver.[37] The map $[\underline{\mathcal{W}}]\mapsto\vec{k}_{\underline{\mathcal{W}}}$ gives a linear map $R_{\mathsf{A}_{m+1}}\to\mathbb{Z}^{m+1}$ which is an isomorphism of Abelian groups since $R_{\mathsf{A}_{m+1}}$ is generated by the Schur modules $\underline{\mathsf{L}}_i, i=0,1,\ldots,m$. By using (7.2) and (7.5) we can write this bilinear pairing in the suggestive form

$$\chi(\underline{\mathcal{T}},\underline{\mathcal{W}})=-\sum_{i=0}^{m}w_i\,\mathrm{index}(\phi_{i+1}). \tag{9.24}$$

The appropriate representation $\underline{\mathcal{W}}$ to couple with in the present case is dictated by the correct incorporation of magnetic charges. As before, the fact that the Higgs fields ϕ_{i+1} in (9.24) themselves are not tachyonic, i.e., do not generate a complex, means that we must fold the SU(2) representations $\underline{V}_{|m-2i|}$ appearing in the ABS construction (8.19) appropriately. The correct folding is expressed by the collection of distinguished triangles (7.39) which shows that we should couple and increasing sequence $\underline{W}_0\subset\underline{W}_1\subset\cdots\subset\underline{W}_m$ of representations as we move along the chain of constituent D-branes of the quiver, so that the SU(2)-module $\underline{W}_i$ gives an extension of the mono-

pole field carried by the elementary brane state at vertex i by the SU(2)-module $\underline{W}_{i-1}$. Thus we take $\underline{W}_i=\oplus_{j=0}^{i}\underline{V}_{|m-2j|}=\underline{V}_{|m-2i|}\oplus\underline{W}_{i-1}$ and embed its class into the representation ring $R_{\mathsf{A}_{m+1}}$ using the $\mathbb{Z}_2$-grading above as the element

$$[\underline{W}_i]=\sum_{j=0}^{i}\operatorname{sgn}(m-2j)[\underline{V}_{|m-2j|}]=\operatorname{sgn}(m-2i)[\underline{V}_{|m-2i|}]+[\underline{W}_{i-1}] \tag{9.25}$$

of virtual dimension

$$w_i=\sum_{j=0}^{i}(m-2j)=(i+1)(m-i) \tag{9.26}$$

for each $i=0,1,\dots,m$. In this case the Euler-Ringel form (9.23) becomes

$$\chi(\underline{\mathcal{T}},\underline{\mathcal{W}})=\sum_{i=0}^{m}(i+1)(m-i)(N_i-N_{i+1})=\sum_{i=0}^{m}(m-2i)N_i=Q \tag{9.27}$$

and it also coincides with the instanton charge of the gauge field configurations on $\mathbb{R}^{2n}_{\theta}\times S^2$. The equivalence of the relative Euler character with the index of the tachyon field above is a consequence of the Grothendieck-Riemann-Roch theorem.

World volume construction: We can now present a very explicit geometric description of the equivalence between the brane configurations on $\mathbb{R}^{2n}\times\mathbb{C}P^1$ and on $\mathbb{R}^{2n}$. The crux of the formulation is the well-known map in K-theory between analytic (noncommutative) and topological (commutative) descriptions.[9,12,30,48] If $\underline{\not{D}}:=-i\sigma\cdot\partial:L^2(\mathbb{R}^{2n},\underline{\Delta}^-_{2n})\to L^2(\mathbb{R}^{2n},\underline{\Delta}^+_{2n})$ is the usual Dirac operator on $\mathbb{R}^{2n}$, then its index coincides with that of the noncommutative ABS configuration (8.29) giving

$$\operatorname{index}\Sigma=\operatorname{index}\underline{\not{D}}. \tag{9.28}$$

This coincides with the K-theory charge of the Bott class $[\underline{\Delta}^+_{2n},\underline{\Delta}^-_{2n};\mu]\in K(\mathbb{R}^{2n})$ given by the ordinary ABS construction,[43] where $\mu_x=\sigma\cdot x/|x|:\underline{\Delta}^-_{2n}\to\underline{\Delta}^+_{2n}$ is Clifford multiplication by $x\in\mathbb{R}^{2n}$. In particular, the Dirac operator itself can be used to represent the analytic K-homology class $[\Sigma]=[\underline{\not{D}}]$ described by the noncommutative ABS field.

Let us represent a system of k Type IIA D-branes wrapped on $\mathbb{R}^{2n}\times\mathbb{C}P^1$ with virtual Chan-Paton bundle $\Xi\in K(\mathbb{R}^{2n}\times\mathbb{C}P^1)$ by the K-cycle $[\mathbb{R}^{2n}\times\mathbb{C}P^1,\Xi,\mathrm{id}]$ in the topological K-homology $\mathbf{K}^t(\mathbb{R}^{2n}\times\mathbb{C}P^1)$. Its equivalence class is invariant under the usual relations of bordism, direct sum and vector bundle modification.[12,30,48] There is an isomorphism $K^t(\mathbb{R}^{2n}\times\mathbb{C}P^1)\cong\mathbf{K}^a(\mathbb{R}^{2n}\times\mathbb{C}P^1)$ of Abelian groups which sends this K-cycle to the analytic K-homology class $[\hat{\not{D}}_\Xi]$ defined by the corresponding twisted Dirac operator on $\mathbb{R}^{2n}\times\mathbb{C}P^1$. Similarly, if $\xi\in K(\mathbb{R}^{2n})$ and $\iota:\mathbb{R}^{2n}\hookrightarrow\mathbb{R}^{2n}\times\mathbb{C}P^1$ is the slice induced by the inclusion $\mathrm{U}(1)\hookrightarrow\mathrm{SU}(2)$ of groups, then the topological K-cycle $[\mathbb{R}^{2n},\xi,\iota]\in K^t(\mathbb{R}^{2n}\times\mathbb{C}P^1)$ corresponds to the analytic K-homology class $\iota_*[\not{D}_\xi]\in K^a(\mathbb{R}^{2n}\times\mathbb{C}P^1)$, where $\not{D}_\xi$ is the twisted Dirac operator on $\mathbb{R}^{2n}$.

Now consider the SU(2)-equivariant reduction of these cycles. From the construction of the preceding section with $\boldsymbol{\phi}_{(m)}=0$ and the equivariant excision theorem of Sec. IV we have the equality

$$[\hat{\not{D}}_\Xi]^{\mathrm{SU}(2)}=\iota_*[\not{D}_{\iota^*\Xi}]^{\mathrm{U}(1)} \tag{9.29}$$

in $K^a_{\mathrm{SU}(2)}(\mathbb{R}^{2n}\times\mathbb{C}P^1)$ which leads to

$$[\mathbb{R}^{2n},\xi,\iota]=[\mathbb{R}^{2n}\times\mathbb{C}P^1,\Xi,\mathrm{id}]\quad\text{with }\Xi=\mathrm{SU}(2)\times_{\mathrm{U}(1)}\xi \tag{9.30}$$

in $K^t_{\mathrm{SU}(2)}(\mathbb{R}^{2n}\times\mathbb{C}P^1)$. The left-hand side of (9.30) corresponds to the class of $D(2n)$ brane-antibrane pairs wrapping $\mathbb{R}^{2n}$, while the right-hand side corresponds to $D(2n+2)$ brane-antibrane

pairs wrapping $\mathbb{R}^{2n}\times\mathbb{C}P^1$. This is just the equivalence between instantons on $\mathbb{R}^{2n}\times\mathbb{C}P^1$ and vortices on $\mathbb{R}^{2n}$. We note that in the case $m=1$, the monopole field is automatically spherically symmetric on $\mathbb{C}P^1$ and one can formulate the equivalence (9.30) using only the requirement of vector bundle modification in *ordinary* topological K-homology,[30] which is equivalent to Bott periodicity (4.1). In contrast, for $m>1$ one must appeal to an SU(2)-equivariant framework and the identification (9.30) of K-cycles is far more intricate. In this case it is a result of the equivariant excision theorem, and *not* of Bott periodicity in equivariant K-theory. It is this intricacy that leads to a more complicated brane-antibrane system when $m>1$.

Using the equivariant ABS construction of the preceding section, the K-homology class of the multi-instanton solution (7.1)–(7.3) is given by the left-hand side of (9.30) with

$$\xi=[\Delta_E^+,\Delta_E^-;\mu_{N_0,N_1,\ldots,N_m}], \tag{9.31}$$

where

$$\Delta_E^+=\bigoplus_{i=m_+}^{m} E_{k_i}\otimes \underline{V}_{|m-2i|} \quad\text{and}\quad \Delta_E^-=\bigoplus_{i=0}^{m_-} E_{k_i}\otimes \underline{V}_{m-2i} \tag{9.32}$$

while

$$\mu_{N_0,N_1,\ldots,N_m}=\prod_{i=0}^{m_-}(\mu_E\circ\Pi_i)^{N_i}\prod_{j=m_+}^{m}(\mu_E^\dagger\circ\Pi_j)^{N_j} \tag{9.33}$$

with $\mu_E:\Delta_E^+\to\Delta_E^+$ acting fiberwise as Clifford multiplication (8.21) and (8.22). The class (9.31) is the K-theory class of the noncommutative soliton field (8.46). The relation (9.30) equates the resulting K-homology class with that defined by

$$\Xi=[\mathrm{SU}(2)\times_{\mathrm{U}(1)}\Delta_E^+,\mathrm{SU}(2)\times_{\mathrm{U}(1)}\Delta_E^-;\pi^*\circ\mu_{N_0,N_1,\ldots,N_m}\circ\iota^*], \tag{9.34}$$

where the projection $\pi:\mathbb{R}^{2n}\times\mathbb{C}P^1\to\mathbb{R}^{2n}$ is a left inverse to the inclusion ι, i.e., $\pi\circ\iota=\mathrm{id}$. Through the standard process of tachyon condensation on the system of $D(2n+2)$ branes and antibranes wrapping $\mathbb{R}^{2n}$, the right-hand side of (9.30) then describes $\Sigma_{2i<m}(m-2i)N_i$ $D2$-branes and $\Sigma_{2i>m}|m-2i|N_i$ $D2$-antibranes. On the left-hand side of (9.30), these are instead $D0$-branes corresponding to vortices left over from condensation in the transverse space $\mathbb{R}^{2n}$.

One can also compute the topological charge in this world volume picture and explicitly demonstrate that the K-theory charges on both sides of (9.30) are the same. The natural charge of branes defined by elements of equivariant K-theory is given by the equivariant index $\mathrm{index}_{\mathrm{SU}(2)}\times(\hat{\not{D}}_\Xi)\in R_{\mathrm{SU}(2)}$, which may be computed by using the SU(2)-index theorem,[49]

$$\mathrm{index}_{\mathrm{SU}(2)}\hat{\not{D}}_\Xi=-\int_{\mathbb{R}^{2n}\times\mathbb{C}P^1}\mathrm{ch}_{\mathrm{SU}(2)}(\Xi)\wedge\hat{A}(\mathbb{R}^{2n}\times\mathbb{C}P^1), \tag{9.35}$$

where $\mathrm{ch}_{\mathrm{SU}(2)}:K_{\mathrm{SU}(2)}(\mathbb{R}^{2n}\times\mathbb{C}P^1)\to H^\bullet_{\mathrm{SU}(2)}(\mathbb{R}^{2n}\times\mathbb{C}P^1;\mathbb{Q})$ is the equivariant Chern character taking values in SU(2)-equivariant rational cohomology. Since this index depends only on the equivariant K-homology class of the Dirac operator on $\mathbb{R}^{2n}\times\mathbb{C}P^1$, we may explicitly use (9.29) and perform the dimensional reduction to write the index (9.35) as

$$\mathrm{index}_{\mathrm{SU}(2)}\hat{\not{D}}_\Xi=-\int_{\mathbb{R}^{2n}}\mathrm{ch}_{\mathrm{SU}(2)}(\xi). \tag{9.36}$$

Since the Chern character in (9.36) is a ring homomorphism between $K_{\mathrm{SU}(2)}(\mathbb{R}^{2n})\cong R_{\mathrm{SU}(2)}$ and $H^\bullet(\mathbb{R}^{2n};\mathbb{Q})\otimes R_{\mathrm{SU}(2)}$, upon substitution of (9.31), (9.32) we can use its additivity and multiplicativity to compute

$$\mathrm{ch}_{\mathrm{SU}(2)}(\xi)=\mathrm{ch}_{\mathrm{SU}(2)}(\Delta_E^+\ominus\Delta_E^-)=\sum_{i=m_+}^{m}\mathrm{ch}(E_{k_i})\otimes\chi_{\underline{V}_{|m-2i|}}-\sum_{i=0}^{m_-}\mathrm{ch}(E_{k_i})\otimes\chi_{\underline{V}_{|m-2i|}},\tag{9.37}$$

where $\chi_{\underline{V}_{|m-2i|}}:\mathrm{SU}(2)\to\mathbb{C}$ are the characters of the SU(2) representations $\underline{V}_{|m-2i|}\cong\mathbb{C}^{|m-2i|}$. This enables us to write the equivariant index on $\mathbb{R}^{2n}\times\mathbb{C}P^1$ in terms of ordinary indices on $\mathbb{R}^{2n}$ to get

$$\mathrm{index}_{\mathrm{SU}(2)}\,\hat{\not{D}}_\Xi=\sum_{i=0}^{m_-}\mathrm{index}(\not{D}_{E_{k_i}})\otimes\chi_{\underline{V}_{|m-2i|}}-\sum_{i=m_+}^{m}\mathrm{index}(\not{D}_{E_{k_i}})\otimes\chi_{\underline{V}_{|m-2i|}}.\tag{9.38}$$

We can turn (9.38) into a linear map $K_{\mathrm{SU}(2)}(\mathbb{R}^{2n}\times\mathbb{C}P^1)\to\mathbb{Z}$ by composing it with the projection $\pi_0:R_{\mathrm{SU}(2)}\to\mathbb{Z}$ onto the trivial representation. Acting on the character ring this gives

$$\pi_0(\chi_{\underline{V}_{|m-2i|}})=\chi_{\underline{V}_{|m-2i|}}(\mathrm{id})=\dim\underline{V}_{|m-2i|}=|m-2i|\tag{9.39}$$

and one finally arrives at

$$\pi_0(\mathrm{index}_{\mathrm{SU}(2)}\,\hat{\not{D}}_\Xi)=\sum_{i=0}^{m_-}|m-2i|\mathrm{index}(\not{D}_{E_{k_i}})-\sum_{i=m_+}^{m}|m-2i|\mathrm{index}(\not{D}_{E_{k_i}}).\tag{9.40}$$

Alternatively, one may arrive at the same formula by directly computing the *ordinary* index of the Dirac operator (8.7) with $\boldsymbol{\phi}_{(m)}=0$ using (8.10) and (8.14)–(8.16). Since

$$\mathrm{index}\,\not{D}_{m-2i}=\dim\ker\not{D}_{m-2i}^+-\dim\ker\not{D}_{m-2i}^-=-(m-2i),\tag{9.41}$$

the index of (8.7) acting on sections of the bundle (8.9) coincides with (9.40). For a gauge field configuration appropriate to the *K*-theory class defined by the tachyon field (9.33), these topological charges coincide with (9.6).

X. VACUUM SOLUTIONS

The extremal cases for which the Higgs fields have the configurations $\{\phi_{i+1}=0,\ i=0,1,\dots,m-1\}$ and $\{\partial_\mu\phi_{i+1}=0,\ i=0,1,\dots,m-1\}$, fall outside of the general scope of the previous analysis and are worth special consideration. They correspond to vacuum sectors of the noncommutative gauge theory and are associated with indecomposable representations of the quiver A_{m+1} that have no arrows. Nevertheless, these vacuum sectors admit nontrivial BPS solutions which signal the presence of stable *D*-branes attached to the closed string vacuum after condensation on the brane-antibrane system. We shall now study them in some detail.

Monopole vacuum: Let us first look at the case $\partial_\mu\phi_{i+1}=0$, $i=0,1,\dots,m-1$. The non-Abelian coupled vortex equations (6.12)–(6.14) then imply

$$A^0=A^1=\cdots=A^m=:A\quad\text{and}\quad F^0=F^1=\cdots=F^m=:F,\tag{10.1}$$

which is only possible in the equal rank case $r=k_0=k_1=\cdots=k_m$ corresponding to the gauge symmetry breaking pattern $\mathrm{U}(k)\to\mathrm{U}(r)^{m+1}$ with $k=(m+1)r$. Thus we take $\phi_{i+1}=\alpha_{i+1}\mathbf{1}_r$ and $\phi_{i+1}^\dagger=\overline{\alpha_{i+1}}\mathbf{1}r$ with $i=0,1,\dots,m-1$, where α_{i+1} are given in (7.30). In quiver gauge theory, the BPS conditions in this sector thus correspond to the representation of A_{m+1} which is r copies of the indecomposable quiver representation $\underline{\mathsf{L}}_0\oplus\underline{\mathsf{L}}_1\oplus\cdots\oplus\underline{\mathsf{L}}_m$. They also require

$$\delta^{a\bar{b}}F_{a\bar{b}}=0\quad\text{and}\quad F_{\bar{a}\bar{b}}=0=F_{ab},\tag{10.2}$$

which are simply the DUY equations on $\mathbb{R}_\theta^{2n}$. Note that (3.26) implies $\mathcal{F}_{y\bar{y}}=0$ in this case, giving the trivial dimensional reduction to $\mathbb{R}_\theta^{2n}$. After switching to matrix form via (6.9), we obtain

$$\delta^{a\bar{b}}[X_a,X_{\bar{b}}]+\delta^{a\bar{b}}\theta_{a\bar{b}}=0\quad\text{and}\quad[X_{\bar{a}},X_{\bar{b}}]=0=[X_a,X_b].\tag{10.3}$$

The obvious solution to (10.3) is the trivial one with $X_a=\theta_{a\bar{b}}\bar{z^b}$, giving $F_{a\bar{b}}=0$. This sector can be understood physically as the endpoint of tachyon condensation, wherein the Higgs fields ϕ_{i+1} have rolled to their minima at $\phi_{i+1}=\alpha_{i+1}\mathbf{1}_r$ and the fluxes have been radiated away to infinity. Here the $D0$-branes have been completely dissolved into the $D(2n)$-branes.

However, nontrivial solutions of the equations (10.3) also exist. For this, let us restrict ourselves to the Abelian case $r=1$ and simplify matters by taking $\theta^a=\theta$ for all $a=1,\ldots,n$. We fix an integer $l\geqslant 1$ and consider the ansatz[28]

$$X_a=\theta_{a\bar{c}}\Sigma_l^\dagger f(\mathcal{N})\bar{z^c}\Sigma_l \quad \text{and} \quad X_{\bar{a}}=\theta_{\bar{a}c}\Sigma_l^\dagger z^c f(\mathcal{N})\Sigma_l, \tag{10.4}$$

where f is a real function of the "total number operator"

$$\mathcal{N}:=\frac{1}{2\theta}\sum_{a=1}^{n} z^a\bar{z^a} \tag{10.5}$$

with the property that $f(r)=0$ for $r\leqslant l-1$. The shift operator Σ_l in (10.4) is defined to obey

$$\Sigma_l^\dagger\Sigma_l=1 \quad \text{while } \Sigma_l\Sigma_l^\dagger=1-P_l \tag{10.6}$$

with

$$P_l:=\sum_{|\vec{r}|\leqslant l-1}|r_1,\ldots,r_n\rangle\langle r_1,\ldots,r_n|, \tag{10.7}$$

where $\vec{r}=(r_1,\ldots,r_n)$ with $|\vec{r}|:=r_1+\cdots+r_n$. Note that

$$\Sigma_l^\dagger P_l=P_l\Sigma_l=0 \quad \text{and} \quad f(\mathcal{N})P_l=P_l f(\mathcal{N})=0, \tag{10.8}$$

and $\Sigma_l^\dagger$ projects all states with $|\vec{r}|<l$ out of the Fock space $\mathcal{H}$.

One easily sees that (10.4) fulfills the homogeneous equations in (10.3). Remembering that $\theta_{a\bar{b}}=-\theta_{\bar{b}a}=(1/2\theta)\delta_{a\bar{b}}$, we also obtain

$$\begin{aligned}[X_a,X_{\bar{b}}]&=\theta_{a\bar{c}}\theta_{\bar{b}d}\Sigma_l^\dagger\{f(\mathcal{N})\bar{z^c}(1-P_l)z^d f(\mathcal{N})-z^d f(\mathcal{N})(1-P_l)f(\mathcal{N})\bar{z^c}\}\Sigma_l\\&=-\frac{1}{4\theta^2}\delta_{a\bar{c}}\delta_{\bar{d}b}\Sigma_l^\dagger\{f^2(\mathcal{N})\bar{z^c}z^d-f^2(\mathcal{N}-1)z^d\bar{z^c}\}\Sigma_l\end{aligned} \tag{10.9}$$

with the help of the identities $\bar{z^c}P_l=P_{l-1}\bar{z^c}$ where $P_0:=0$. We have also used

$$\bar{z^c}f(\mathcal{N})=f(\mathcal{N}+1)\bar{z^c} \quad \text{and} \quad z^d f(\mathcal{N})=f(\mathcal{N}-1)z^d. \tag{10.10}$$

Substituting (10.9) into (10.3), we employ

$$\delta_{\bar{c}d}z^d\bar{z^c}=2\theta\mathcal{N} \quad \text{and} \quad \delta_{\bar{c}d}\bar{z^c}z^d=2\theta(\mathcal{N}+n) \tag{10.11}$$

to find the conditions

$$\begin{aligned}0=\delta^{a\bar{b}}[X_a,X_{\bar{b}}]+\delta^{a\bar{b}}\theta_{a\bar{b}}&=-\frac{1}{2\theta}\Sigma_l^\dagger\{f^2(\mathcal{N})(\mathcal{N}+n)-f^2(\mathcal{N}-1)\mathcal{N}\}\Sigma_l+\frac{n}{2\theta}\\&=\frac{1}{2\theta}\Sigma_l^\dagger\{\mathcal{N}f^2(\mathcal{N}-1)-(\mathcal{N}+n)f^2(\mathcal{N})+n\}\Sigma_l\end{aligned} \tag{10.12}$$

on the operator f. With the initial conditions $f(0)=f(1)=\cdots=f(l-1)=0$ and the finite-energy condition $f(r)\to 1$ as $r\to\infty$, these recursion relations are solved by

$$f^2(\mathcal{N}) = \left(1 - \frac{Qn!}{(\mathcal{N}+1)\cdots(\mathcal{N}+n)}\right)(1-P_l), \tag{10.13}$$

where

$$Q := \frac{l(l+1)\cdots(l+n-1)}{n!} \tag{10.14}$$

is the number of states in $\mathcal{H}$ with $\mathcal{N}\leqslant l-1$, i.e., the number of states removed by the operator $\Sigma_l^\dagger$.

We arrive finally at the nontrivial gauge field configuration given by

$$X_a = \frac{1}{2\theta}\Sigma_l^\dagger \sqrt{1 - \frac{Qn!}{(\mathcal{N}+1)\cdots(\mathcal{N}+n)}}(1-P_l)\,\delta_{a\bar{c}}\bar{z}^{\bar{c}}\Sigma_l. \tag{10.15}$$

The field strength F on $\mathbb{R}^{2n}_\theta$ obtained from (10.15) has finite nth Chern number Q.[28] The topological charge Q given by (10.14) is calculated here via an integral over $\mathbb{R}^{2n}_\theta$. However, the $(n+l)$th Chern number for this configuration considered as a gauge field on $\mathbb{R}^{2n}_\theta \times \mathbb{C}P^1$ with $\mathcal{F}_{y\bar{y}}=0=\mathcal{F}_{\vartheta\varphi}$ vanishes. Moreover, this configuration has finite energy (5.2) proportional to the topological charge,[28]

$$E_{\mathrm{BPS}} = (2\pi)^{n+1}R^2 n(n-1)Q, \tag{10.16}$$

as usual for a BPS instanton solution.

Higgs vacuum: The choice $\phi_{i+1}=0$ for all $i=0,1,\dots,m-1$ is somewhat more interesting since from (3.26) and (5.29) we then have $\mathcal{F}_{y\bar{y}}\neq 0$ with

$$\mathcal{F}_{y\bar{y}} = -\frac{R^2}{(R^2+y\bar{y})^2}\mathbf{\Upsilon}_{(m)}. \tag{10.17}$$

This configuration gives the local maximum of the Higgs potential corresponding to the open string vacuum containing D-branes. In this case the vortex equations (6.12)–(6.14) reduce to

$$\delta^{a\bar{b}}F^i_{a\bar{b}} = \frac{m-2i}{4R^2} \quad \text{and} \quad F^i_{a\bar{b}} = 0 = F^i_{ab}. \tag{10.18}$$

After switching to matrix form via (6.9) we obtain

$$\delta^{a\bar{b}}[X^i_a, X^i_{\bar{b}}] + \delta^{a\bar{b}}\left(1 - \frac{(m-2i)\theta}{2nR^2}\right)\theta_{a\bar{b}} = 0 \quad \text{and} \quad [X^i_{\bar{a}}, X^i_{\bar{b}}] = 0 = [X^i_a, X^i_b], \tag{10.19}$$

where we have used the formula $\theta_{a\bar{b}}=(1/2\theta)\delta_{a\bar{b}}$. Recall that there is no summation over the index $i=0,1,\dots,m$ in the equations (10.19).

By comparing (10.19) and (10.3), we conclude that (10.19) can be solved for each i by the same ansatz as for (10.3). For this, let us restrict ourselves again to the Abelian case for all nodes $i=0,1,\dots,m$ (so that $k=m+1$), and fix $m+1$ positive integers $l_0, l_1, \dots, l_m$. We take

$$X^i_a = \theta_{a\bar{c}}\Sigma^\dagger_{l_i} f_i(\mathcal{N})\bar{z}^{\bar{c}}\Sigma_{l_i} \quad \text{and} \quad X^i_{\bar{a}} = \theta_{\bar{a}c}\Sigma^\dagger_{l_i} z^c f_i(\mathcal{N})\Sigma_{l_i} \tag{10.20}$$

analogously to (10.4)–(10.7). Producing then the same calculations as before, we obtain the gauge field configuration

$$X^i_a = \frac{1}{2\theta^i}\Sigma^\dagger_{l_i}\sqrt{1 - \frac{Q_i n!}{(\mathcal{N}+1)\cdots(\mathcal{N}+n)}}(1-P_{l_i})\,\delta_{a\bar{c}}\bar{z}^{\bar{c}}\Sigma_{l_i}, \tag{10.21}$$

where

$$\theta^i := \frac{\theta}{\sqrt{1-\frac{(m-2i)\theta}{2nR^2}}} \tag{10.22}$$

and

$$Q_i = \frac{l_i(l_i+1)\cdots(l_i+n-1)}{n!}. \tag{10.23}$$

We have chosen the radius R of the sphere so that $R^2 > m\theta/2n$.

The solutions (10.21) coincide with those given by (10.15) if one assigns different noncommutativity parameters θ^i to the world volumes of $D(2n)$-branes carrying different magnetic fluxes proportional to $m-2i$. Then the field strength $F^i(\theta^i)$ on $\mathbb{R}^{2n}_{\theta^i}$ obtained from (10.21) will have finite topological charge Q_i given by (10.23) and corresponding finite BPS energy analogous to (10.16), and the configuration thus described extends to instantons on $\mathbb{R}^{2n}_{\theta}\times\mathbb{C}P^1$. The interesting idea of introducing distinct noncommutativity parameters on multiple coincident D-branes, generated by different magnetic fluxes on their world volumes,[50] was discussed in Ref. 51 as a means (among other things) of stabilizing brane-antibrane systems. This proposal gains support from our Higgs vacuum BPS solutions (10.21) which carry different magnetic fluxes on different branes.

(Received 4 July 2005; accepted 7 November 2005; published online 12 January 2006)

A single Israel layer can be created when two metrics adjoin with no continuous metric derivative across the boundary. The properties of the layer depend only on the two metrics it separates. By using a fractional derivative match, a family of Israel layers can be created between the same two metrics. The family is indexed by the order of the fractional derivative. The method is applied to Tolman IV and V interiors and a Schwarzschild vacuum exterior. The method creates new ranges of modeling parameters for fluid spheres. A thin shell analysis clarifies pressure/tension in the family of boundary layers. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2158436]

I. INTRODUCTION

There is long-standing interest in fluid sphere solutions, largely because of their astrophysical implications. An astrophysical model is often an interior fluid sphere metric matched to a Schwarzschild vacuum or Kottler exterior across a bounding surface. The standard technique matches metric functions and extrinsic curvatures on the boundary. When the extrinsic curvatures do not match, an Israel boundary layer[1,2] can be created. The layer depends only on the properties of the two bounding metrics. Methods that will create a family of surface layers between the bounds could prove useful in exploring models of spheres with variable crusts. One way of creating variable surface layers is to modify the boundary conditions at the fluid–vacuum interface.

While an extrinsic curvature match is the boundary condition currently most used, there are three types of boundary conditions that have been used to match analytic solutions across non-null boundaries. The three methods have been discussed by Bonnor and Vickers,[3] and they all involve derivatives of the metric functions. The boundary conditions can be generalized by broadening the idea of derivatives to include fractional derivatives.[4,5]

There are two simple ways to proceed with the generalization. The first is to assume a straight fractional derivative match on the boundary metrics and then to use the fractional relations in the usual formalism for the boundary stress energy. This would be a generalization of the Lichnerowicz boundary condition. It would not generalize the extrinsic curvature to fractional values. The second would be to use fractional derivatives to define a fractional extrinsic curvature and then use it to define a fractional boundary layer. This would be a generalization of the usual Lie derivative to fractional values. The use of fractional calculus is motivated by the possible fractional nature of the growth processes forming the boundary layer. Fractional transport processes are one of the main areas of application for fractional calculus, and boundary layers formed by these processes could reflect this fractional formation process.

Beyond the fractional generalizations of techniques and tensor functions, one must consider the various definitions of fractional differentiation. Use of fractional calculus in diverse areas of physics has increased enormously since fractional derivatives were first considered by Leibnitz and L'Hospital[4] in 1695. Many different definitions have been proposed for different applications. In this article we use the Caputo form of the Riemann–Liouville and Weyl definitions. The Caputo derivative is an integral transform of the regular partial derivative and preserves the zero fractional

derivative of a constant. While considering generalizations of relativistic gravity to include fractional calculus, the different definitions must be explored to determine their applicability.

This work has two goals: first to develop a variable layer model that could be applied to astrophysical problems, and second to better understand the role that fractional derivatives might play within a general relativistic framework. In this paper we will apply the first method and use fractional derivatives to create a family of Israel boundary layers between two bounding metrics. The family is parametrized by the order of the fractional derivative and may be used to model fluid spheres with variable crusts. Even when a regular derivative match is possible, the fractional match will broaden the parameter ranges for the fluid interior.

In the next section we discuss the metrics and describe the boundary layer. In the third section several models are considered: the Misner–Zapolsky (MZ) solution,[6,7] and Tolman's solutions IV and V.[8] The thin shell pressure balance is treated in the fourth section and some details of the fractional match are discussed in Sec. V. Details of the fractional derivatives and the standard fluid sphere formalism are given in the Appendices.

II. THEORETICAL FRAMEWORK

A. The space-time

The two regions to be considered are covered by an exterior Schwarzschild solution bounding an interior spherical fluid. The metrics are, with functions $\psi_{\rm Sch}=1-2m_0/y$, $\nu(r)$, $\lambda(r)$, $H(r)$:

$$\text{Exterior: } g^{\rm Sch}_{\alpha\beta}\,dx^\alpha\,dx^\beta=-\psi_{\rm Sch}\,dt^2+\psi^{-1}_{\rm Sch}\,dy^2+y^2\,d\Omega^2, \tag{1}$$

$$\text{Interior: } g^{\rm fluid}_{\alpha\beta}\,dx^\alpha\,dx^\beta=-e^{\nu}\,d\tau^2+e^{\lambda}\,dr^2+H^2\,d\Omega^2. \tag{2}$$

The bounding surface is located at $y=y_0$ in the exterior and $r=R_0$ in the interior. The corresponding normals to the surface are

$$\text{Exterior: } n^E_\mu\,dx^\mu=\psi^{-1/2}_{\rm Sch}\,dy, \tag{3}$$

$$\text{Interior: } n^I_\mu\,dx^\mu=e^{\lambda/2}\,dr. \tag{4}$$

Fractional derivatives leave these metrics unchanged. Our fractional extension provides a crust layer between the interior and exterior metrics.

B. Matching conditions

On the boundary, the metric match conditions are

$$(1-2m_0/R_0)=e^{\nu(R_0)},$$

$$R_0=H(R_0). \tag{5}$$

The second matching condition is the extrinsic curvature match, K^a_b, on the bounding surface. If the curvatures do not match, an Israel boundary layer is created. The stress–energy content of the Israel layer is constructed from the mismatch in the extrinsic curvatures. The stress–energy of the boundary layer is[2]

$$-8\pi S^a_b=\langle K^a_b\rangle-\langle K\rangle g^a_b. \tag{6}$$

Here $K=K^a_a$. The stress–energy components on the boundary are

$$-8\pi S^0_0=[\langle K^0_0\rangle-\langle K^0_0+2K^\theta_\theta\rangle g^0_0]=-2\langle K^\theta_\theta\rangle,$$

$$-8\pi S_\theta^\theta = -8\pi S_\phi^\phi = [\langle K_\theta^\theta\rangle - \langle K_0^0 + 2K_\theta^\theta\rangle g_\theta^\theta] = -[\langle K_\theta^\theta\rangle + \langle K_0^0\rangle],$$

and the stress–energy of the boundary is

$$8\pi S_0^0 = \frac{1}{(g_{yy}^E)^{1/2}}\frac{g_{\theta\theta,y}^E}{g_{\theta\theta}^E} - \frac{1}{(g_{rr}^I)^{1/2}}\frac{g_{\theta\theta,r}^I}{g_{\theta\theta}^I}$$

$$8\pi S_\theta^\theta = 8\pi S_\phi^\phi = \frac{1}{2}\left[\frac{1}{(g_{yy}^E)^{1/2}}\frac{g_{\theta\theta,y}^E}{g_{\theta\theta}^E} - \frac{1}{(g_{rr}^I)^{1/2}}\frac{g_{\theta\theta,r}^I}{g_{\theta\theta}^I}\right] + \frac{1}{2}\left[\frac{1}{(g_{yy}^E)^{1/2}}\frac{g_{00,y}^E}{g_{00}^E} - \frac{1}{(g_{rr}^I)^{1/2}}\frac{g_{00,r}^I}{g_{00}^I}\right]. \quad (7)$$

C. Match of fractional derivatives

The stress–energy of the Israel layer is evaluated on the boundary between the interior and exterior metrics. The actual finite thickness boundary layer is modeled by the single bounding surface at $r=R_0$. The stress–energy content is governed by regular derivatives of the metric functions. The metric match coupled with some derivative match of the metric on the layer, sets relations between the parameters of the interior and exterior solutions. With the usual extrinsic curvature or other derivative matches, the properties of the layer are set by the parameters of the bounding metric. With a fractional match, the order of the fractional derivative enters along with the other parameters and a family of fractional boundary layers is created. The fluid sphere examples considered in this paper have boundary metrics of the form

$$ds^2 = -F(r)dt^2 + r^2\, d\Omega^2.$$

The fractional match is applied only to the differing part of the Israel layer metric, the g_{00} metric potential. The actual calculation of the fractional derivatives involves a choice of definition. We use the Caputo definition (see Appendix A) with the $(0\leqslant r\leqslant R_0)$ Riemann–Liouville limits for the interior and the $(R_0\leqslant r\leqslant\infty)$ Weyl limits for the exterior. The limits themselves, as well as the choice of different limits for interior and exterior derivatives, reflect the nonlocality of the fractional derivative operation. Nonlocality in fractional time derivatives is an expression of system memory.[9] It has proven especially useful in modeling jump processes with long wait times.[10] Similarly, spatial nonlocality implies that the derivative on the boundary depends on values away from the boundary; fractional spatial derivatives have been useful in modeling processes with very large jump distances.[11] When the jump distance depends on the jump time, fractional time and spatial derivatives enter into the transport equations.[12] The examples discussed here are static, but the structure of the boundary layer could reflect the transport process. The fractional matching condition is

$$\frac{1}{\Gamma(n-\alpha)}\int_0^{R_0}\frac{d^nF_I(x)/dx^n}{(r-x)^{\alpha-n+1}}dx = \frac{(-1)^{n-1}}{\Gamma(n-\alpha)}\int_{R_0}^{\infty}\frac{d^nF_E(x)/dx^n}{(x-r)^{\alpha-n}}dx,$$

and is applied at $r=R_0$. We note that the single layer at $r=R_0$ only approximates a boundary of finite thickness and that using a nonlocal operator might be a better approximation to the actual match over a finite thickness than the usual derivative match over a zero thickness surface.

In the next sections, we apply the formalism to Tolman IV and V solutions.

III. MODEL CALCULATIONS

A. Tolman's Solution V

1. The solution

We consider a parametrization of Tolman's Vth solution.[8,13] The metric, with constants n and C, is

$$ds^2 = -(r/r_0)^{N_1}\,dt^2 + a(1-aCr^{2+b})^{-1}\,dr^2 + r^2\,d\Omega^2. \tag{8}$$

The parameters formed from n are

$$N_1 = 4n/(1+n), \qquad N_2 = 1+6n+n^2,$$

$$a = \frac{N_2}{(1+n)^2}, \qquad b = \frac{N_1(1-n)}{(1+3n)}.$$

The interior density and pressure for this solution are

$$\begin{aligned} 8\pi\rho &= \left(\frac{4n}{N_2}\right)\frac{1}{r^2} + C(3+b)r^b, \\ 8\pi P &= \left(\frac{4n^2}{N_2}\right)\frac{1}{r^2} - C\frac{(1+5n)}{1+n}r^b. \end{aligned} \tag{9}$$

For $C=0$, the solution reduces to the MZ solution.[6,7,15] This solution was originally used to describe neutron star models with equation of state $P=n\rho$. The solution with $C=0$ does not admit a zero-pressure boundary; the $C\neq 0$ solution does. Both solutions are singular at the origin and are used to represent an ultrahigh density core. The MZ solution, lacking a vacuum boundary, is generally matched to a gaseous envelope. It may be more realistic in some cases to match these solutions to a crust with surface stresses.

For $C\neq 0$, the zero-pressure boundary, R_z, relates constants C and n,

$$C = \frac{4n^2(1+n)}{(1+5n)N_2}\frac{1}{R_z^{2+b}}. \tag{10}$$

Substituting for C, the pressure and density can be written as

$$8\pi P_{C\neq 0} = \frac{4n^2}{N_2}\left(\frac{1}{r^2} - \frac{r^b}{R_z^{2+b}}\right), \tag{11}$$

$$8\pi\rho_{C\neq 0} = \frac{4n}{N_2}\left(\frac{1}{r^2}\right) + \frac{4n^2}{N_2}\frac{(n+3)}{(1+3n)}\left(\frac{r^b}{R_z^{2+b}}\right). \tag{12}$$

The condition $P_{C\neq 0}\geqslant 0$ requires

$$R_0 \leqslant R_z. \tag{13}$$

Fractional matching will allow a broader family of sphere sizes. Below, we graph values for the case $n=1/3$. For $C=0$, there is no zero-pressure boundary and no constraint.

2. Matching conditions

The matching conditions are the same for any C value. Matching the interior metric to vacuum Schwarzschild, we find

$$1 - 2m_0/R_0 = (R_0/r_0)^{N_1}$$

[recall $N_1=4n/(1+n)$],

$$\frac{2m_0}{R_0^{1+\alpha}}\Gamma(1+\alpha) = \left(\frac{R_0}{r_0}\right)^{N_1}\left(\frac{N_1}{R_0^{\alpha}}\right)\frac{\Gamma(N_1)}{\Gamma(N_1+1-\alpha)}.$$

Combining the two relations, we find that the scaled radius of the interior is

$$\frac{R_0}{2m_0} = 1 + \frac{\Gamma(1+\alpha)\Gamma(N_1+1-\alpha)}{\Gamma(1+N_1)}. \tag{14}$$

Note that the boundary radius is always greater than $2m_0$. For $\alpha<1$, there are no limits imposed by Eq. (14). For $\alpha\geqslant 1$ we require

$$1+N_1 > \alpha.$$

The metric parameter r_0 is described by

$$\left(\frac{r_0}{R_0}\right)^{N_1} = 1 + \frac{\Gamma(1+N_1)}{\Gamma(1+\alpha)\Gamma(N_1+1-\alpha)}. \tag{15}$$

The sizes of the fractional spheres are discussed in Sec. V.

3. The crust stress–energy

The stress–energy of the crust for general C is, with $\gamma_0 := \sqrt{1-2m_0/R_0}$,

$$8\pi S_0^0 = \frac{2}{R_0}\left[\gamma_0 - (1+n)N_2^{-1/2}\sqrt{1-aCR_0^{2+b}}\right]$$

$$8\pi S_\theta^\theta = 8\pi S_\phi^\phi = \frac{1}{2R_0}\left[\gamma_0 + 1/\gamma_0 - (1+n)(2+N_1)N_2^{-1/2}\sqrt{1-aCR_0^{2+b}}\right].$$

For $C\neq 0$, the boundary layer has a stress–energy content [recall $N_1=4n/(1+n)$, $N_2=1+6n+n^2$],

$$8\pi S_0^0 = \frac{2}{R_0}\left[\gamma_0 - (1+n)N_2^{-1/2}\sqrt{1-\frac{nN_1}{(1+5n)}(R_0/R_z)^{2+b}}\right],$$

$$8\pi S_\theta^\theta = 8\pi S_\phi^\phi = \frac{1}{2R_0}\left[\gamma_0 + 1/\gamma_0 - 2(1+3n)N_2^{-1/2}\sqrt{1-\frac{nN_1}{(1+5n)}(R_0/R_z)^{2+b}}\right]. \tag{16}$$

For $C=0$ the fluid energy density and stress are

$$8\pi S_0^0 = (2/R_0)\left[\gamma_0 - (1+n)N_2^{-1/2}\right]$$

$$= (2/R_0)\left[(R_0/r_0)^{2n/(1+n)} - (1+n)N_2^{-1/2}\right], \tag{17}$$

$$8\pi S_\theta^\theta = 8\pi S_\phi^\phi = (1/R_0)\left[(1-m_0/R_0)/\gamma_0 - (1+3n)N_2^{-1/2}\right],$$

and describe a much richer modeling environment.

B. Tolman's Solution IV

1. Metric and stress–energy

This solution describes an object with finite central presssure and density. A stiff fluid core is not possible in this model. The interior metric for this solution is, with constants A, B, and C,

$$ds^2 = -B^2(1+r^2/A^2)dt^2 + \frac{1+2r^2/A^2}{(1-r^2/C^2)(1+r^2/A^2)}dr^2 + r^2\,d\Omega^2. \tag{18}$$

The interior density and pressure are

$$8\pi\rho = \frac{1}{A^2}\left[\frac{1+3(A^2/C^2+r^2/C^2)}{1+2r^2/A^2} + 2\frac{1-r^2/C^2}{(1+2r^2/A^2)^2}\right], \tag{19}$$

$$8\pi P = \frac{1}{A^2}\left[\frac{1-(A^2/C^2+3r^2/C^2)}{1+2r^2/A^2}\right]. \tag{20}$$

Constants A and C can be expressed in terms of the central fluid values. We have

$$8\pi\rho_c = \frac{3}{A^2}\left[1+A^2/C^2\right],$$

$$8\pi P_c = \frac{1}{A^2}\left[1-A^2/C^2\right],$$

$$A^2 = \frac{2}{8\pi(\rho_c/3+P_c)},$$

$$C^2 = \frac{2}{8\pi(\rho_c/3-P_c)}.$$

Note that the central fluid equation of state (EOS) is constrained: $P_c < \rho_c/3$. The zero-pressure boundary that occurs in the regular derivative match has size

$$R_z^2 = C^2/3 - A^2/3. \tag{21}$$

2. Metric match

The match to vacuum Schwarzschild provides

$$B^2(1+R_0^2/A^2) = 1-2m_0/R_0. \tag{22}$$

The fractional match is

$$\frac{B^2}{A^2}\frac{1}{R_0^{\alpha-2}}\frac{1}{\Gamma(3-\alpha)} = \frac{m_0}{R_0^{1+\alpha}}\Gamma(1+\alpha),$$
$$B^2R_0^3 = A^2m_0\Gamma(3-\alpha)\Gamma(1+\alpha). \tag{23}$$

Combining with the metric match, we obtain

$$A^2 = R_0^2\frac{(R_0/m_0)-[2+\Gamma(3-\alpha)\Gamma(1+\alpha)]}{\Gamma(3-\alpha)\Gamma(1+\alpha)},$$

$$B^2 = \frac{m_0}{R_0}\left[\frac{R_0}{m_0}-[2+\Gamma(3-\alpha)\Gamma(1+\alpha)]\right], \tag{24}$$

$$R_0/m_0 > 2+\Gamma(3-\alpha)\Gamma(1+\alpha).$$

The boundary size depends on the central EOS as well as the order of the fractional derivative:

$$\left(\frac{R_0}{m_0}\right)^3 - \left(\frac{R_0}{m_0}\right)^2[2+\Gamma(3-\alpha)\Gamma(1+\alpha)] - \frac{\Gamma(3-\alpha)\Gamma(1+\alpha)}{4\pi m_0^2(P_c+\rho_c/3)} = 0. \tag{25}$$

3. Crust stress–energy

We introduce scaled parameters $r_A^2 := R_0^2/A^2$, $r_C^2 := R_0^2/C^2$, and $r_z^2 := R_z^2/A^2$.

$$8\pi S_0^0 = \frac{1}{(g_{yy}^E)^{1/2}}\frac{g_{\theta\theta,y}^E}{g_{\theta\theta}^E} - \frac{1}{(g_{rr}^I)^{1/2}}\frac{g_{\theta\theta,r}^I}{g_{\theta\theta}^I} = \frac{2}{R_0}\left[\sqrt{1-2m_0/R_0} - \sqrt{\frac{(1-r_C^2)(1+r_A^2)}{1+2r_A^2}}\right]$$
$$= \frac{2}{R_0}\sqrt{1+r_A^2}\left[B - \frac{A}{C}\sqrt{\frac{1+3r_z^2-r_A^2}{1+2r_A^2}}\right], \tag{26}$$

$$8\pi S_\theta^\theta = 8\pi S_\phi^\phi = \frac{1}{2}\left[\frac{1}{(g_{yy}^E)^{1/2}}\frac{g_{\theta\theta,y}^E}{g_{\theta\theta}^E} - \frac{1}{(g_{rr}^I)^{1/2}}\frac{g_{\theta\theta,r}^I}{g_{\theta\theta}^I}\right] + \frac{1}{2}\left[\frac{1}{(g_{yy}^E)^{1/2}}\frac{g_{00,y}^E}{g_{00}^E} - \frac{1}{(g_{rr}^I)^{1/2}}\frac{g_{00,r}^I}{g_{00}^I}\right]$$
$$= \frac{1}{R_0}\sqrt{1+r_A^2}\left[B - \frac{A}{C}\sqrt{\frac{1+3r_z^2-r_A^2}{1+2r_A^2}}\right] + \frac{1}{R_0\sqrt{1+r_A^2}}\left[\frac{m_0/R_0}{B} - (r_A^2)\sqrt{\frac{1-r_C^2}{1+2r_A^2}}\right]. \tag{27}$$

Some examples of radius variation and crust stress energy are given in Sec. V.

IV. EQUILIBRIUM IN THE PRESENCE OF SURFACE STRESSES

A. Stress–energy

The Israel layer is the zero-thickness idealization of a bounding layer with finite thickness, d. The physical crust runs from an outer boundary R_0 to an interior fluid boundary R_i with $d=R_0-R_i$. We know that the interior fluid solutions will satisfy the[22] Tolman–Oppenheimer-Volkov (TOV) equation. The Israel layers generated in this work are obtained by introducing a discontinuity in the derivative of g_{00}. The analog of the TOV equation for the layer, requiring that the solutions remain static, will provide relations among the model parameters. To develop the TOV analog for the layer, consider the general static spherical metric for an interior fluid with pressure P and density ρ,

$$ds^2 = -e^\nu dt^2 + e^\lambda dr^2 + r^2 d\Omega^2. \tag{28}$$

The details of the field equations are given in Appendix B. The covariant derivative of the general energy–momentum tensor provides the conservation equation

$$-\frac{\partial T_r^r}{\partial r} - \left(\frac{\nu'}{2} + \frac{2}{r}\right)T_r^r + \left(\frac{\nu'}{2}\right)T_0^0 + \left(\frac{2}{r}\right)T_\theta^\theta = 0. \tag{29}$$

For an isotropic fluid matched to vacuum, this is the usual TOV equation,

$$\frac{\partial P}{\partial r} + \frac{\nu'}{2}(P+\rho) = 0. \tag{30}$$

It is the analog of this equation that we want for the Israel layer.

B. The conservation equation over a limiting shell

Consider a bounding shell that will approximate a thin surface layer. The central radius of the shell is R with the outer boundary $R^{(+)}=R+d/2$, and the inner interior fluid boundary at $R^{(-)}=R-d/2$. d is the coordinate shell thickness. In the $d\to 0$ limit, $R\to R_0$. A general stress-energy T_j^i can be related to a surface stress–energy S_b^a by[2]

$$T_j^i = \delta(l) S_b^a e_a^i e_j^b, \tag{31}$$

where e_a^i is a tangent vector to the shell, and l the proper distance along a radial geodesic, $l = e^{\lambda/2}d$. The shell stress–energy has a perfect fluid analog,

$$S^{ij} = \sigma U^i U^j + \tau(h^{ij} + U^i U^j),$$

$$h^{ij} = g^{ij} - n^i n^j,$$

$$n^i = (0, e^{-\lambda}, 0, 0),$$

where $S_0^0/c^2 = -\sigma(\mathrm{g/cm^2})$ and $S_\theta^\theta = \pm\tau(\mathrm{dynes/cm})$. Following Poisson[2], we take $l=0$ on the hypersurface defined by R, with l negative for $r<R$ and positive on the vacuum side, $r>R$. The T_r^r content of the shell can be described using a Heaviside function, $\Theta(l)$, as

$$T_r^r = \Theta(l)T_r^{(+)r} + \Theta(-l)T_r^{(-)r} + \delta(l)S_r^r. \tag{32}$$

The last term will be zero for the 2+1 shell stress energy. Forming the derivative needed in the conservation equation, we have

$$\frac{\partial T_r^r}{\partial r} = \delta(l)\frac{dl}{dr}T_r^{(+)r} + \Theta(l)\frac{\partial T_r^{(+)r}}{\partial r} - \delta(l)\frac{dl}{dr}T_r^{(-)r} + \Theta(-l)\frac{\partial T_r^{(-)r}}{\partial r}.$$

In the $l\to 0$ limit we have

$$\frac{\partial T_r^r}{\partial r} = -\lim_{l\to 0}\left[\delta(l)\frac{dl}{dr}T_r^{(-)r}\right] = -\lim_{l\to 0}[\delta(l)\mathrm{Pe}^{\lambda/2}], \tag{33}$$

where the first term is zero with no radial pressure on the outer boundary. The stress–energy function evaluated at the inner boundary is P and $\lambda^{(-)}$ is an interior metric function. Substituting into the conservation equation in the $l\to 0$ hypersurface limit, we have

$$\mathrm{Pe}^{\lambda^{(-)}/2} + (\nu'/2)S_0^0 + (2/R_0)S_\theta^\theta = 0. \tag{34}$$

C. Evaluating $\partial_t g_{00}$

The derivative, ν', on the hypersurface, can be written as a difference equation,

$$\nu'(R) = \frac{\nu(R+d/2) - \nu(R-d/2)}{(R+d/2)-(R-d/2)} = \frac{\nu(R+d/2) - \nu(R) + \nu(R) - \nu(R-d/2)}{(R+d/2)-(R-d/2)}$$

$$= \frac{\nu(R+d/2) - \nu(R)}{d} + \frac{\nu(R) - \nu(R-d/2)}{d}.$$

Expanding, we can write

$$\nu(R \pm d/2) = \nu(R) \pm \nu'[R^{(\pm)}]\frac{d}{2} + \cdots.$$

Substituting in the thin shell limit, we have

$$\nu'(R) \approx \frac{\nu'[R^{(+)}] + \nu'[R^{(-)}]}{2}.$$

The first term follows from the Schwarzschild metric match and the second is given in Appendix B. We have

$$\nu'(R) \approx (2m/R^2 + 4\pi RP)(1-2m/R)^{-1},$$

where we have identified the Schwarzschild mass parameter with the interior mass of the fluid. Substituting into Eq. (34), we have

$$-P(1-2m/R)^{-1/2} = (m/R^2 + 2\pi RP)(1-2m/R)^{-1}S_0^0 + (2/R)S_\theta^\theta, \tag{35}$$

which describes the thin shell pressure balance. The classical limit of this equation follows from $c \to \infty$ and is

$$P - \sigma\frac{m}{R^2} = \left(\frac{2}{R}\right)(-\tau).$$

If the fluid pressure at the interior boundary dominates, this can be interpreted as a tension in the shell, balancing the outward interior fluid pressure at the boundary minus the inward pressure due to the gravitational attraction of the shell by the interior fluid. If the shell mass term dominates, the stress in the boundary layer will be a pressure. In the next section we explore the stress–energy structure of the boundary layer, and will see parameter ranges with both layer tension and pressure.

V. DETAILS OF THE FRACTIONAL MATCH

A. Sphere radii

The sizes of the sphere are described by

$$\text{TolmanV: } \frac{R_0}{2m_0} = 1 + \frac{\Gamma(1+\alpha)\Gamma(4n/(1+n)+1-\alpha)}{\Gamma(1+4n/(1+n))}, \tag{36}$$

$$\text{TolmanIV: } \left(\frac{R_0}{m_0}\right)^3 - \left(\frac{R_0}{m_0}\right)^2[2+\Gamma(3-\alpha)\Gamma(1+\alpha)] - \frac{\Gamma(3-\alpha)\Gamma(1+\alpha)}{4\pi m_0^2(P_c+\rho_c/3)} = 0. \tag{37}$$

The scaled boundary radius, R_0/m_0, for Tolman V is plotted as a function of alpha for various n in Fig. 1.

The overall effect of the fractional match is to increase the range of sphere sizes for a given EOS. The largest differences are for low- n fluids, where a very much smaller sphere radius is possible than for the zero-pressure match. The Buchdahl bound[14] limits the ratio of $2m_0/R_0$ for fluid spheres whose g_{00} component is continuous across the boundary and whose density is

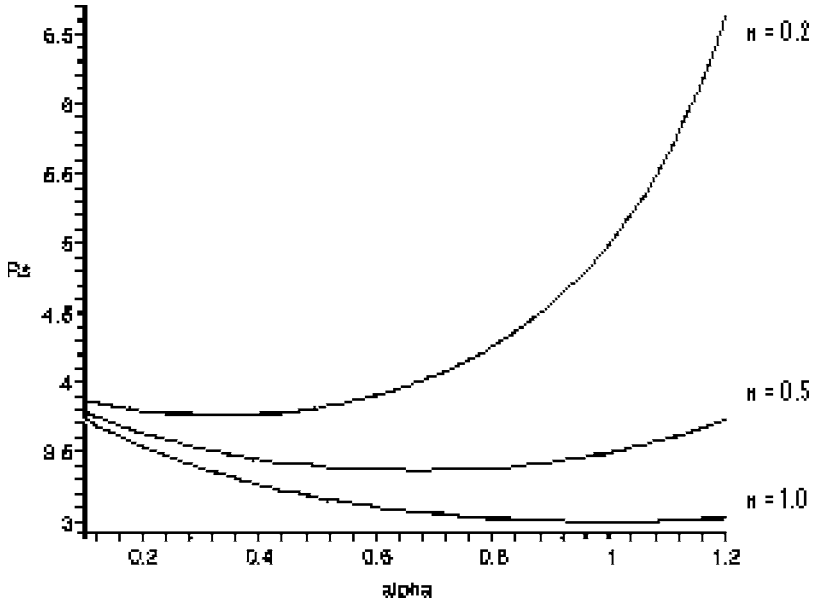

FIG. 1. Scaled radius versus fractional order.

decreasing outward. We have matched fractional derivatives rather than first derivatives and it is not clear that the conditions of the Buchdahl bound are satisfied, but from Fig. 1, it is seen that the Buchdahl bound, $2m_0/R_0 \leqslant 8/9$, is not violated.

The radius for Tolman IV is a cubic root of Eq. (37), but some general description can be given. The modeling term in the equation is the denominator of the last term. Consider the factor

$$c_1 \sim 4\pi m_0^2 \rho_c/3$$

describing an object with mass $m_0 = Nm_\odot = N(2\times 10^{30}\ \mathrm{kg})$, and central density and pressure of neutron star order, $\rho_c \sim 10^{17}\ \mathrm{kg/m^3}$, $P_c \sim 10^{33}$ Newton/$\mathrm{m^2}$. Numerical scaled radius values using these values are described in Table I for a range of N and alpha values. For $N \sim 100$ or larger, the last term in the cubic is negligible and the radius is essentially given by the limiting value

$$R_0/m_0 \sim 2 + \Gamma(3-\alpha)\Gamma(1+\alpha).$$

The masses for these radii are well out of the neutron star range. The reflection symmetry about $\alpha = 1$ is the result of a product equivalence of the two gamma functions for paired alpha values, i.e., $\alpha = (0.6, 1.4)$ give the same gamma function product. From Table I, it is clear that the low N values have masses and radii of neutron star orders of magnitude.[16] For example, for $N=1$, the radii are approximately $R_0 \sim 11.44 m_0 \sim 17$ km. Smaller central densities, describing more ordinary fluid objects, result in much larger fluid spheres. For a central density of $\rho_c \sim 10^{10}\ \mathrm{kg/m^3}$, the radii for $\alpha = 1$, $R_0(N)$ are $R_0(1) = 2228.33 m_0$, $R_0(10) = 480.87 m_0$, $R_0(100) = 104.39 m_0$, $R_0(1000) = 23.32 m_0$, with the values for larger and smaller α paired and increasing, just as for the larger central density.

TABLE I. R_0/M_0—Tolman IV—$\rho_c \sim 10^{17}\ \mathrm{kg/m^3}$.

α	$N=1$	$N=10$	$N=100$	$N=1000$
0.2	13.24	4.41	3.55	3.54
0.4	12.39	4.10	3.28	3.27
0.6	11.85	3.91	3.12	3.11
0.8	11.54	3.81	3.04	3.03
1	11.44	3.78	3.01	3
1.2	11.54	3.81	3.04	3.03
1.4	11.85	3.91	3.12	3.11
1.6	12.39	4.10	3.28	3.27

B. Crust stress–energy

Figures 2 and 3 describe the variation of the boundary energy density and pressure, in Tolman V, $n = 1/3$, as the size of the fluid sphere varies. Over a large part of the R_0/R_z range, a crust tension contains the interior fluid, with the tension increasing in size as the fluid sphere becomes smaller, essentially acting to squeeze the fluid into smaller volumes. The results are similar for $C=0$.

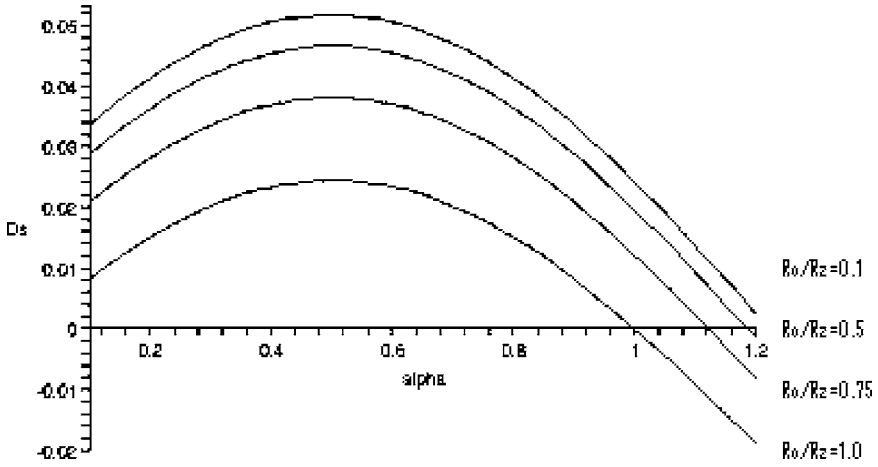

FIG. 2. $Ds=-8\pi m_0 S_0^0$ versus fractional order.

For Tolman IV, the crust energy density is

$$8\pi\sigma=\frac{2}{R_0}\left[-\sqrt{1-2m_0/R_0}+\sqrt{\frac{(1-R_0^2/C^2)(1+R_0^2/A^2)}{1+2R_0^2/A^2}}\right]$$

$$=\frac{2}{R_0}\left[-\sqrt{1-2m_0/R_0}+\sqrt{\frac{[1-4\pi R_0^2\rho_c(1/3-n)][1+4\pi\rho_c R_0^2(1/3+n)]}{1+R_0^2 8\pi\rho_c(1/3+n)}}\right].$$

The modeling factor of importance is the term

$$4\pi\frac{R_0^2}{m_0^2}\rho_c m_0^2=3c_1\frac{R_0^2}{m_0^2}.$$

For nuclear central densities, $\rho_c\sim 10^{14}$ g/cm^3, this is

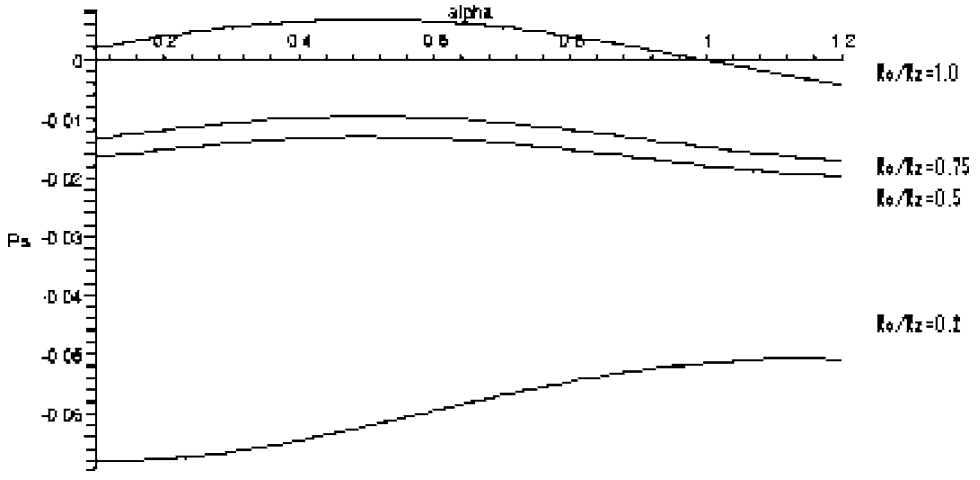

FIG. 3. $Ps=8\pi m_0 S_\vartheta^\vartheta$ versus fractional order.

$$20.35N^2 \times 10^{-4}\frac{R_0^2}{m_0^2}.$$

In order to have real values, we require

$$N=1, \quad R_0 \sim 12m_0, \quad [0.293 \times (1/3-n)] < 1,$$

$$N=10, \quad R_0 \sim 4m_0, \quad [3.26 \times (1/3-n)] < 1,$$

$$N=100, \quad R_0 \sim 3m_0, \quad [183 \times (1/3-n)] < 1.$$

It is clear that the broadest range of central equations of state for nuclear central densities is for the lower mass objects. Higher mass objects require a central EOS very close to the $1/3$ limit. For smaller values of the central density, the central EOS range is much broader. For a central density of $\rho_c \sim 10^7$ g/cm^3, the modeling factor is

$$4\pi\frac{R_0^2}{m_0^2}\rho_c m_0^2 = 20.35N^2 \times 10^{-11}\frac{R_0^2}{m_0^2},$$

and for real values require

$$N=1, \quad R_0 \sim 2228m_0, \quad [0.10 \times 10^{-2}(1/3-n)] < 1,$$

$$N=10, \quad R_0 \sim 480m_0, \quad [0.47 \times 10^{-2}(1/3-n)] < 1,$$

$$N=100, \quad R_0 \sim 104m_0, \quad [0.022 \times (1/3-n)] < 1,$$

$$N=1000, \quad R_0 \sim 23m_0, \quad [0.11 \times (1/3-n)] < 1.$$

VI. CONCLUSION

In this work we have examined a family of boundary layers created by matching fractional derivatives across a boundary.[17,18] The boundary layers considered have structure that depends on the order of the fractional derivative. One of the reasons that fractional calculus may be important for boundary layers is the mechanism by which a boundary layer is formed. One of the possible ways to build a variable density crust is by a diffusive process; a process whose underlying cause is Brownian motion. This motion, as analyzed by statistical mechanics, involves diffusion, dissipation, and the fluctuation-dissipation theorem. The dynamical model of Brownian motion was provided by Langevin in 1908 using a stochastic differential equation. It seems apparent from the nature of randomness that such macroscopic stochastic equations are incompatible with the continuous and differentiable character of microscopic Hamiltonian dynamics. (Think of the conventional diffusion equation, with the diffusion process described by a second-order spatial derivative.) Therefore, the mathematical description rests on either ordinary analytical functions describing the dynamics, or on conventional differential operators describing the phase space evolution. The differentiable nature of the macroscopic picture is, in a sense, a natural consequence of microscopic randomness. This means that use can be made of ordinary differential calculations on the macroscopic scale, even if the microscopic dynamics are incompatible with ordinary calculus methods. On the other hand, in the case where a time scale separation between macroscopic and microscopic levels of description does not exist, the nondifferentiable nature of the microscopic dynamics is transmitted to the macroscopic level. Since fractional calculus has been shown to provide a good description for a range of diffusive processes,[19] one might expect a boundary condition based on fractional calculus would reflect the fractional growth process. An

example, given by Allegrini, Grigolini, and West,[20] shows that a diffusion process generated by a fluctuation with no time scale at the macroscopic level generates a diffusion process well described by a fractional Laplacian.

While diffusion is a possible mechanism for generating a layer with structure, the method of generating the fractional family of layers is independent of the production mechanism and generates a family whose stress–energy and size depends on the order of the fractional derivative. The result is a much broader range in fluid sphere properties. For example, in Tolman V, a much larger range of spheres sizes can be described with the fractional layer than without, with the energy density of the layer decreasing as the size of the sphere increases. The $C \neq 0$ Tolman V spheres have a zero-pressure boundary solution. For spheres smaller than the zero-pressure sphere, the layer has a tension, while for spheres larger than the zero-pressure sphere, the layer has positive stress over much of the range of the fractional order. The fractional boundary could prove to be a valuable modeling tool in more realistic neutron star models.

The range of stress–energy in the fractional boundary layers implies differences in structure as a function of the fractional order. The differences in density could be modeled in several ways: for example, with different crust materials or different incomplete fluid coverings (tilings).[21] The layer itself is a model of a thin crust and there could be differences in the geometry of the $2+1$ shells that fill the real crust. The interior fluid geometry and the exterior Schwarzschild vacuum do not have to match for a crust with finite thickness.

The models presented in this paper matched an integral transform of the regular derivative across a spatial boundary. It is not a fractional generalization of general relativity, but a fractional generalization of a boundary condition. The next step is to explore the range of fractional generalizations of other sets of boundary conditions and other derivative definitions to applicable spacetimes.

APPENDIX A: DERIVATIVES

1. Regular

For functions f and F continuous on $[a,b] \in \mathit{Reals}$,

$$F(x) := \int_a^x f(t)dt,$$

$F(x)$ is differentiable such that $dF/dx = f$. The nth integer derivative is simply d^nF/dx^n. For example,

$$\frac{d^n}{dx^n}x^k = \frac{k!}{(k-n)!}x^{k-n}.$$

With the gamma function this is

$$\frac{d^n}{dx^n}x^\alpha = \frac{\Gamma(\alpha+1)}{\Gamma(\alpha-n+1)}x^{\alpha-n}.$$

The gamma function, $\Gamma(z)$, is defined as

$$\Gamma(z) = \int_0^\infty e^{-t}t^{z-1}\,dt, \quad \Gamma(1/2) = \sqrt{\pi}, \quad \Gamma(1) = 1,$$

$$\Gamma(n+1) = n\Gamma(n) = n\,!\,, \quad \text{for } n > 0.$$

2. Fractional

A. Riemann–Liouville

The Riemann-Liouville definition for the α fractional derivative of $f(x)$ is, with $\alpha \geqslant 0$,

$$D^{\alpha} f(x) = \frac{d^{\alpha}}{dx^{\alpha}} f(x) := \frac{1}{\Gamma(n-\alpha)} \frac{d^n}{dx^n} \int_c^x \frac{f(t)}{(x-t)^{\alpha-n+1}} dt, \tag{A1}$$

where n is the smallest integer larger than α when it is fractional, that is, $n=[\alpha]+1$. In the $\alpha=1$ limit, the derivative produces the integer result. The constant c in the limit of the integral is usually set to 0 (Riemann definition) or to $-\infty$ (Liouville definition). For example, the Riemann–Liouville derivative of x^k for $\alpha \leqslant 1$ with $n=1$, we have

$$D^{\alpha} x^k = \frac{1}{\Gamma(1-\alpha)} \frac{d}{dx} \int_0^x t^k (x-t)^{-\alpha}\, dt$$

$$= \frac{1}{\Gamma(1-\alpha)} \frac{d}{dx} \int_0^x t^k x^{-\alpha} \left(1 - \frac{t}{x}\right)^{-\alpha} dt$$

$$= \frac{1}{\Gamma(1-\alpha)} \frac{d}{dx} \int_0^1 w^k x^{-\alpha+1+k} (1-w)^{-\alpha}\, dw.$$

Using the definition of the beta function,

$$\int_0^1 w^{p-1} (1-w)^{q-1}\, dw = \frac{\Gamma(p)\Gamma(q)}{\Gamma(p+q)},$$

we have

$$D^{\alpha} x^k = \frac{1}{\Gamma(1-\alpha)} \frac{dx^{-\alpha+1+k}}{dx} \frac{\Gamma(k+1)\Gamma(1-\alpha)}{\Gamma(k+2-\alpha)}$$

$$= (1+k-\alpha) x^{k-\alpha} \frac{\Gamma(k+1)}{\Gamma(k+2-\alpha)}$$

$$= x^{k-\alpha} \frac{\Gamma(k+1)}{\Gamma(k+1-\alpha)}.$$

For $\alpha=1$, this is the usual result $D^1 x^k = dx^{k-1}$. Note that, for $k=-1$, this operation fails. This is an example of one of the problems encountered in applying fractional derivatives to general relativity. Not all definitions of fractional derivatives work for all functions. The fractional derivative of x^k for $\alpha \geqslant 1$ is identical to the fractional derivative for $\alpha \leqslant 1$. For this function, the derivative is continuous across the $\alpha=1$ boundary.

$$D^{\alpha} x^k = \frac{1}{\Gamma(2-\alpha)} \frac{d^2}{dx^2} \int_0^x t^k x^{1-\alpha} \left(1 - \frac{t}{x}\right)^{1-\alpha} dt$$

$$= \frac{1}{\Gamma(2-\alpha)} \frac{d^2}{dx^2} \int_0^1 w^k x^{k+2-\alpha} (1-w)^{1-\alpha}\, dw$$

$$= x^{k-\alpha}\frac{\Gamma(1+k)}{\Gamma(1+k-\alpha)}.$$

One should note that the Riemann–Liouville fractional derivative of a constant is not zero.

B. Caputo

The Caputo derivative is the integral transform of the regular derivative and is found by moving the derivative in the Riemann–Liouville definition inside the integral to act on the function. We have

$$D^{\alpha}f(x) = \frac{1}{\Gamma(n-\alpha)}\int_0^x \frac{\frac{d^n}{dt^n}f(t)}{(x-t)^{\alpha-n+1}}dt. \tag{A2}$$

Example: $f(x)=x^b$, $\beta \geqslant 0$,

$$D^{\alpha}(x-a)^k = \frac{1}{\Gamma(n-\alpha)}\int_0^x \frac{\frac{d^n}{dt^n}t^k}{(x-t)^{\alpha-n+1}}dt.$$

For $\alpha \leqslant 1$, $n=1$ we have

$$D^{\alpha}(x-a)^k = \frac{1}{\Gamma(1-\alpha)}\int_0^x kt^{k-1}(x-t)^{-\alpha}\,dt = \frac{kx^{k-\alpha}}{\Gamma(1-\alpha)}\int_0^1 w^{k-1}(1-w)^{-\alpha}\,dw = kx^{k-\alpha}\frac{\Gamma(k)}{\Gamma(k+1-\alpha)}, \tag{A3}$$

which is identical to the Riemann–Liouville derivative for this function. This derivative also is not defined for $k=-1$. In general relativity, one of the space-times one would like to treat is vacuum Schwarzschild, but the Riemann–Liouville derivative will not give finite answers for the $1/r$ structure. The derivative of $1/r$ can be taken with the Weyl derivative.

C. Weyl

The Weyl derivative differs from the Riemann–Liouville derivatives over the range of the fractional transform. To take the fractional derivatives of $1/r$ we use the Weyl derivative over the range (R_0, ∞). The Weyl derivative of $f(r)$ can be written as

$$D^{\alpha}f(r) = \frac{(-1)^{n-1}}{\Gamma(n-\alpha)}\int_r^{\infty} \frac{d^n f(t)}{dt^n}(t-r)^{n-\alpha}\,dt,$$

where n is the smallest integer above α when it is fractional. This paper is concerned with the fractional derivative across the boundary and the phase $(-1)^{n-1}$, was chosen to make D^{α} continuous across $\alpha=1$. Applying the derivative definition to $1/r$ for $\alpha \leqslant 1$ $(n=1)$ we find

$$D^{\alpha}r^{-1} = -r^{-(1+\alpha)}\Gamma(1+\alpha), \quad \alpha \leqslant 1. \tag{A4}$$

For $\alpha=1$, this gives the usual first derivative of $1/r$. For $\alpha>1$ $(n=2)$ the derivative is the same. One should be careful not to interpret the derivative for $\alpha=2$ as the second derivative. The second derivative would follow from a double application of D^{α}. For this function the single derivative at $\alpha=2$ is not the same as the double application of the derivative operator.

APPENDIX B: FLUID SPHERE FORMALISM

Consider the general static spherical metric over the interior fluid with $\nu(r)$ and $\lambda(r)$,

$$ds^2 = -e^{\nu}\,dt^2 + e^{\lambda}\,dr^2 + r^2\,d\Omega^2.$$

With Einstein's field equations as $G_{ij}=8\pi T_{ij}$, the energy–momentum components are

$$8\pi T_0^0 = -e^{-\lambda}(\lambda'/r - 1/r^2) - 1/r^2,$$

$$8\pi T_r^r = e^{-\lambda}(\nu'/r + 1/r^2) - 1/r^2,$$

$$8\pi T_\theta^\theta = 8\pi T_\phi^\phi = (e^{-\lambda}/2)[\nu^{\nu''} + (\nu'/2 + 1/r)(\nu' - \lambda')].$$

For the fluid interior, the energy–momentum, with four-velocity $U^i=(e^{\nu/2},0,0,0)$, is

$$T^{ij} = (\rho + P)U^iU^j + Pg^{ij}.$$

In the comoving frame the fluid stress energy is

$$T_0^0 = -\rho, \quad T_r^r = T_\theta^\theta = T_\phi^\phi = P.$$

It is common to use the function $m(r)$ in g_{rr} with

$$e^{\lambda} = [1 - 2m(r)/r]^{-1},$$

so that

$$\lambda' = 2(m'/r - m/r^2)(1 - 2m/r)^{-1}.$$

From the first field equation we have

$$m' = 4\pi r^2\rho.$$

The second field equation provides a relation between the fluid pressure, P, and ν',

$$\nu'/2 = (4\pi rP + m/r^2)(1 - 2m/r)^{-1}$$

Colliding wave solutions from five-dimensional black holes and black *p*-branes

E. Halilsoy,[a] M. Halilsoy,[b] and O. Unver[c]
Physics Department, Eastern Mediterranean University, G.Magosa (N. Cyprus), Mersin 10, Turkey

(Received 22 July 2005; accepted 9 November 2005; published online 13 January 2006)

We consider both the five-dimensional Myers-Perry and Reissner-Nordstrom black holes (BHs) and black *p*-branes in $(4+p)$-dimensions. By employing the isometry with the colliding plane waves (CPWs) we generate Cauchy-Horizon (CH) forming CPW solutions. From the five-dimensional vacuum solution through the Kaluza-Klein reduction the corresponding Einstein-Maxwell-dilaton solution is obtained. This CH forming cross polarized solution with the dilaton turns out to be a rather complicated nontype *D* metric. Since we restrict ourselves to the five-dimensional BHs we obtain exact solutions for colliding 2- and 3-form fields in $(p+4)$-dimensions for $p \geqslant 1$. By dualizing these forms we can obtain also colliding $(p+1)$- and $(p+2)$-forms which are important processes in the low energy limit of the string theory. All solutions obtained are CH forming, implying that an analytic extension beyond is possible. © *2006 American Institute of Physics.*

I. INTRODUCTION

Black holes (BHs) are known to have region isometric to the space of colliding plane waves (CPW).[1,2] This may be either in between the two horizons (i.e., inner and outer) or given the case with single horizon the inner region of the event horizon. Such an isometry renders it possible to generate CPW solutions from known solutions of BHs. In a recent paper[3] we gave a prescription for generating CPW solutions from an Einstein-Maxwell-Dilaton-Axion (EMDA) theory. In this theory the dilaton was linear and the BH was not asymptotically flat. In this solution the axion arises as the cross polarizing agent for the CPWs. This means that the limit of linear polarization removes the axion leaving behind only the Einstein-Maxwell-Dilaton (EMD) theory. Another solution with similar features but valid only in the zero dilaton limit was obtained previously.[4] Interesting physical property shared by both of these solutions is that the space-time subsequent to the collision of waves emerges free of physical singularities. Horizon forming CPW[1,2,5–7] solutions in the EMDA theory are naturally of utmost important to the string theory. Since the idea of higher dimensions has already gained enough momentum it is important to investigate the collision of waves in higher dimensions.[8,9] It is known already that the four-dimensional EMDA theory is equivalent to the six-dimensional Ricci flat, vacuum solution.[10,11]

In this paper we restrict ourselves to the five- (and four-) dimensional space-times and their extension through the brane world. We consider first the five-dimensional collision of gravitational (impulse and shock) waves obtained from the isometry with the Myer-Perry black hole (MPBH).[12,13] This particular BH contains two rotation parameters in addition to the mass. For simplicity we make the special choice in which the two angular momenta are equal. Then we identify the (r,θ) sector of the BH at hand with the null coordinates sector (u,v) of the colliding

[a]Electronic mail: elif.halilsoy@emu.edu.tr
[b]Electronic mail: mustafa.halilsoy@emu.edu.tr
[c]Electronic mail: ozlem.unver@emu.ed

waves and accompany this with the necessary coordinate transformation. Inclusion of the Heaviside step functions along with the null coordinates must guarantee that no additional current sheets are created at the boundaries. In the standard Einstein and Einstein-Maxwell (EM) theories these are summarized in the O'Brian-Synge[14] boundary conditions, respectively. Similar arguments rightly follow in the higher dimensional space-times as well.

The static MPBH is transferred to the linearly polarized CPWs, which turns out to be a nonsingular type-*D* solution. The rotating MPBH transforms through the Kaluza-Klein (KK) reduction procedure to the CPW space-time with cross polarization in the four-dimensional EMD theory. This space-time is also regular but it does not belong to the type-*D* class. As a matter of fact the dilaton involved cross polarization (instead of axion, as it arises in the above-mentioned solutions) makes the space-time structure rather involved.

As a second example we consider the Reissner-Nordstrom (RN) BH[15] in five dimensions from which we obtain CPW solution in the five-dimensional EM theory. Similar to the CPW solution obtained from the MPBH this one also is singularity free. Our examples of five-dimensional BHs exclude the extremal limits because in such a limit which removes the isometric region of BHs with CPWs the equivalence fails to work. Under such circumstances an alternative transformation, analogous to the RN-Bertotti-Robinson equivalence, must be pursed which is out of our scope in this paper.

As a third example we consider the black-branes in the $(d+p)$-dimensional brane world. We find regular CPW solutions to colliding 3-form fields in higher dimensions. Another solution that we obtain from the same black-brane metric is colliding (EM) (2-form) fields in higher dimensions.

Our study may lay the foundation for promoting the string theory in approximation in low energies from single plane wave background to the more realistic CPW background. The regular initial data of CPWs provides a natural choice among the nonunique Penrose limits of space-times.[16–18] It is known that the incoming region of a CPW space-time admits automatically a Penrose limit of the interaction region. The advantage is that we have the double Penrose limits which are both well-defined initial data. Any Penrose limit does not qualify as an initial data toward construction of the interaction region.

Finally we wish to express the view that our technique can be extrapolated to higher dimensions provided some associated difficulties are overcome. The most important problem is the analytic integration of the radial coordinate (r) of BHs in terms of the prolate-type coordinate (τ) of CPWs. And as the second major difficulty we cite of the necessary proper representation of the higher dimensional spherical line element suitable for the ideals of the geometry of CPWs.

The organization of the paper is as follows. In Sec. II we obtain CPW solutions from the five-dimensional BHs, whose details are tabulated in Appendixes A, B, and C. Section III investigates the physical properties of the metrics obtained in Sec. II. Section IV contains solutions for colliding 3-form fields in higher dimensions and their KK reductions. Section V focuses attention on a class of by-product solutions of colliding EM shock waves in higher dimensions. We dualize our 2-form fields of Sec. V in Sec. VI to obtain colliding $(p+2)$-form fields in $(p+4)$-dimensions. Our conclusion and discussion is in Sec. VII.

II. CPW SOLUTIONS FROM FIVE-DIMENSIONAL BHs

In this section we concentrate on the two well-known types of BHs in five-dimensions. First we consider the MPBH and then RNBH. Our analysis applies, however, to any five-dimensional BHs that possesses two nonoverlapping horizons albeit the technical difficulties. We comment on this point at the end of the section in concentration with the Schwarzschild-de(-anti) Sitter BH.

(A) The MPBH in five dimensions with two equal angular momenta is given

$$ds_5^2 = \tilde{g}_{AB}\, dx^A\, dx^B \quad (A,B,\ldots = 0,\ldots 4),$$

$$ds_5^2 = dt^2 - \frac{\mu}{\rho^2}\left[dt + \frac{\overline{a}}{2}(d\varphi - \cos\theta\, d\eta)\right]^2 - \frac{\rho^4\, d\rho^2}{\rho^4 - \mu\rho^2 + \mu\overline{a}^2} - \rho^2\, d\Omega_3^2, \tag{1}$$

where μ and $\overline{a}$ are, respectively, proportional to the mass and angular momentum of the BH. We note that five-dimensional suffices are denoted by capital italic letters while four dimensional ones by greek letters. A tilde over specifies also the five-dimensional geometrical object. For the three-dimensional metric of S^3 we choose the representation

$$d\Omega_{(3)}^2 = \tfrac{1}{4}(d\theta^2 + d\eta^2 + d\varphi^2 - 2\cos\theta\, d\eta\, d\varphi), \tag{2}$$

where $0 < \theta < \pi$, and the angles η and φ are defined modulo 2π. The static MPBH corresponds to $a=0$, while the extreme case is defined by $\mu = 4\overline{a}^2$. The CPW form in five dimensions is obtained by imposing the identification of the (ρ, θ) sector in the above metric with the (τ, σ) sector of CPW as follows:[3]

$$\left(\frac{4\rho^2\, d\rho^2}{\mu\rho^2 - \rho^4 - \mu\overline{a}^2} - d\theta^2\right) = \left(\frac{d\tau^2}{1-\tau^2} - \frac{d\sigma^2}{1-\sigma^2}\right). \tag{3}$$

In the sequel, for simplicity we choose $\mu = 1$ leading us to the solution

$$\begin{gathered} 2\rho^2 = 1 + \sqrt{1 - 4\overline{a}^2}\tau, \\ \cos\theta = \sigma \end{gathered} \tag{4}$$

implying further that we impose $|\overline{a}| < \frac{1}{2}$. Supplementing this transformation with the identifications

$$\begin{gathered} t \to x, \\ \varphi \to y, \\ \eta \to z, \\ a_o^2 = 2\overline{a}^2 \end{gathered} \tag{5}$$

followed by an appropriate rescaling of coordinates we obtain the five-dimensional vacuum metric apt for CPWs:

$$ds_5^2 = F\left(\frac{d\tau^2}{\Delta} - \frac{d\sigma^2}{\delta}\right) - \frac{1}{F}[Z_o(dy - 2\sigma\, dz)dy + Z\, dz^2 + 4a_o(dy - \sigma\, dz)dx - (1 - k\tau)dx^2]. \tag{6}$$

Our abbreviations in this metric stand as follows:

$$\Delta = 1 - \tau^2,$$

$$\delta = 1 - \sigma^2,$$

$$F = 1 + k\tau,$$

$$Z = F^2 + 2a_o^2\sigma^2,$$

$$Z_o = F^2 + 2a_o^2,$$

$$k = \sqrt{1 - 2a_o^2},$$

$$0 < k \leqslant 1, \tag{7}$$

where the coordinates (τ, σ) are related to the null coordinates (u, v) through

$$\tau = \sin(au + bv),$$

$$\sigma = \sin(au - bv), \tag{8}$$

$$(a, b\text{:constants}).$$

Now, the crucial point toward the interpretation of this metric as a CPW metric is by making the substitutions

$$u \to u\,\theta(u),$$

$$v \to v\,\theta(v) \tag{9}$$

in the metric functions, where θ stands for the Heaviside unit step function. This process must not create currents (sources) on the null boundaries $u=0=v$. Alternatively this implies that the five-dimensional Ricci terms all vanish globally

$$\tilde{R}_{AB} = 0$$

$$(x^A\text{:}u, v, x, y, z). \tag{10}$$

The Riemann tensor components $\tilde{R}_{ABCD}$, however, involve Dirac delta functions, indicative of impulsive gravitational waves in addition to the shock waves required commonly by the step functions. In Appendix A we tabulate all components exhaustively from which we can easily identify the nonvanishing ones in the incoming regions. By setting $v<0 (u<0)$ we restrict ourselves to the incoming region II (III), comprising of five-dimensional gravitational plane waves alone. Obviously, for both $u<0$ and $v<0$ we obtain the region I which is a five-dimensional flat space-time given by

$$ds_5^2 = 4ab\,du\,dv - (1 + a_o^2)dy^2 - dz^2 - 4a_o\,dx\,dy - dx^2. \tag{11}$$

The Kretschmann scalar in the interaction region (region IV, $u>0, v>0$) turns out to be

$$K = \tilde{R}_{ABCD}\tilde{R}^{ABCD} = \frac{6}{(1 + k\tau)^6}[4k^2(k + \tau)^2 - (1 + k\tau)^2] \tag{12}$$

which is free of singularities.

We wish now to apply the KK reduction procedure to our five-dimensional metric (6) in order to obtain CPWs of the EMD theory in four dimensions. We follow the KK reduction procedure through the identification

$$\tilde{g}_{AB} = \phi^{-1/3}\begin{pmatrix} g_{\mu\nu} + 4\phi A_\mu A_\nu & 2\phi A_\mu \\ 2\phi A_\nu & -\phi \end{pmatrix}. \tag{13}$$

This makes it possible to read both the four-dimensional metric $g_{\mu\nu}$, as well as the dilaton ϕ, and the EM potential A_μ. The results are as follows:

$$ds_4^2 = (FZ)^{\frac{1}{2}}\left[\frac{d\tau^2}{\Delta} - \frac{d\sigma^2}{\delta} - \frac{1}{Z}\left(\frac{L}{F}dx^2 + \delta Z_o\,dy^2 - 4a_o\delta\,dx\,dy\right)\right],$$

$$\phi = \left(\frac{Z}{F}\right)^{\frac{3}{2}},$$

$$A_\mu = \frac{\sigma}{Z}\left(0,0,a_o,\frac{1}{2}Z_o\right), \tag{14}$$

where the notations are as in (7), and in addition we have labelled $L=2F-Z$. The action of the resulting four-dimensional EMD theory is

$$S = \frac{1}{16\pi}\int |g|^{\frac{1}{2}}\,\mathrm{d}x^4\left[-R-\phi F_{\mu\nu}F^{\mu\nu}+\frac{(\nabla\phi)^2}{6\phi^2}\right] \tag{15}$$

so that the dilaton and Maxwell equations take the respective forms

$$\Box(\ln\phi) = -3\phi F_{\mu\nu}F^{\mu\nu}, \tag{16}$$

$$\nabla_\alpha(\phi F^\alpha_\mu) = 0, \tag{17}$$

in which $\Box$ stands for the covariant Laplacian. To complete the set of Einstein equations we need also the Ricci tensor which is given by

$$R_{\mu\nu} = \frac{1}{6}\frac{\phi_{,\mu}\phi_{,\nu}}{\phi^2} - 2\phi\left(F_{\mu\alpha}F^\alpha_\nu - \frac{1}{4}g_{\mu\nu}F_{\alpha\beta}F^{\alpha\beta}\right). \tag{18}$$

We note that this representation of dilaton is different from the standard one expressed as an exponential function in the action. This more familiar latter form is related to the present one by the substitution

$$\phi = e^{-2a\sigma} \tag{19}$$

which casts the action into

$$S = \frac{1}{16\pi}\int |g|^{\frac{1}{2}}\,\mathrm{d}x^4[-R+2(\nabla\sigma)^2 - e^{-2a\sigma}F_{\mu\nu}F^{\mu\nu}], \tag{20}$$

where the dilatonic parameter is $\sqrt{3}$. The physical properties of the EMD space-time obtained hitherto will be studied in the next section.

(B) The five-dimensional RNBH is given by

$$\mathrm{d}s_5^2 = \left(1-\frac{m}{r^2}+\frac{q^2}{r^4}\right)\mathrm{d}t^2 - \left(1-\frac{m}{r^2}+\frac{q^2}{r^4}\right)^{-1}\mathrm{d}r^2 - r^2\,\mathrm{d}\Omega^2_{(3)}, \tag{21}$$

where m and q are, respectively, related to the mass and charge of the BH. The EM vector potential one-form is given by

$$A = A_\mu\,\mathrm{d}x^\mu = \frac{\sqrt{3}q}{2r^2}\mathrm{d}t. \tag{22}$$

Here also, similar to the MP case we choose the S^3 line element as in (2). The transition to the CPW metric is accomplished here by the identification

$$\frac{4\,\mathrm{d}r^2}{m-r^2-\frac{q^2}{r^2}} - \mathrm{d}\theta^2 = \frac{\mathrm{d}\tau^2}{1-\tau^2} - \frac{\mathrm{d}\sigma^2}{1-\sigma^2}. \tag{23}$$

A possible integral for $r(\tau)$ is readily available as

$$r^2 = \frac{m}{2}(1 + l\tau), \tag{24}$$

where

$$l = \sqrt{1 - \frac{4q^2}{m^2}} > 0.$$

By choosing $m=1$ in addition to the identifications

$$\sigma = \cos\theta = \sin(au - bv),$$

$$t \to x, \varphi \to y, \eta \to z,$$

$$\tau = \sin(au + bv),$$

$$(a,b = \text{constants}) \tag{25}$$

we obtain the metric (after rescaling of coordinates)

$$ds_5^2 = (1 + l\tau)(4ab\, du\, dv - dy^2 - dz^2 - 2\sin(au - bv)dy\, dz) - \frac{\Delta}{(1 + l\tau)^2}dx^2. \tag{26}$$

The EM vector potential one-form takes the form under the above transformation

$$A = \frac{\sqrt{3}q}{2\sqrt{2}l(1 + l\tau)}dx. \tag{27}$$

The interpretation of this metric as a CPW is completed by inserting the step functions into the null coordinates u and v. This metric represents collision of EM plane waves in five dimensions. For $l=1$ (or $q=0$) it reduces to the CPW metric of the five-dimensional pure gravity and coincides with the $a_o=0$ case of the metric (6). Thus, (26) is the EM extension while (6) was the rotational extension of the same CPW metric obtained from the five-dimensional Schwarzschild metric. The Riemann components of the metric (26) are given in Appendix B from which we compute the Kretschmann scalar to find (for $u>0$ and $v>0$).

$$K = \frac{127l^4 + 180l^3\tau - 2l^2 - 72\Delta l^2 + 19 - 36l\tau}{4(1 + l\tau)^4} \tag{28}$$

which is also regular to the future of the collision point $u=0=v$.

Finally we wish to comment on other BHs and corresponding CPW solutions in five dimensions. Although our method applies to any such BH that admits inner and outer horizons such that the region in between possesses two spacelike Killing vectors technically some cases are not tractable. As an example we cite the Schwarzschild-de(-anti) Sitter BH given by the line element

$$ds_5^2 = h(r)dt^2 - h(r)^{-1}\, dr^2 - r^2\, d\Omega_{(3)}^2, \tag{29}$$

where $h(r)=k-(m/r^2)\pm(r^2/l^2)$, in which $k=\pm 1$, m is related to mass and l to the cosmological constant. To obtain the associated CPW solution we demand now that

$$\int \frac{\mathrm{d}\rho}{\sqrt{\rho}\sqrt{m - k\rho \pm \frac{\rho^2}{l^2}}} = \pm \sin^{-1} \tau, \tag{30}$$

where we have used $\rho = r^2$. The inversion of such an elliptical integral seems to be beyond analytical calculation which must therefore be handled within the scope of numerical analysis.

III. PROPERTIES OF THE COLLIDING EMD SPACE-TIME

The linearly polarized CPW metric (14) is rather transparent so we restrict ourselves to the case $a_o = 0$, first. Upon rescaling of x and y we have the metric

$$\mathrm{d}s^2 = (1+\tau)^{\frac{3}{2}}\left(2\,\mathrm{d}u\,\mathrm{d}v - \frac{1-\tau}{(1+\tau)^2}\mathrm{d}x^2 - \delta\,\mathrm{d}y^2\right) \tag{31}$$

in which τ and σ are implied with the step functions. By the choice of Newman-Penrose (NP) null-tetrad basis one-forms,

$$l = (1+\tau)^{\frac{3}{4}}\,\mathrm{d}u,$$

$$n = (1+\tau)^{\frac{3}{4}}\,\mathrm{d}v,$$

$$\sqrt{2}m = (1-\tau)^{\frac{1}{2}}(1+\tau)^{-1/4}\,\mathrm{d}x + i\sqrt{\delta}(1+\tau)^{\frac{3}{4}}\,\mathrm{d}y, \tag{32}$$

we obtain all Ricci and Weyl components as tabulated in the Appendix C. It is observed by studying the Weyl scalars Ψ_o, Ψ_2, and Ψ_4 that the space-time is regular everywhere for $(u>0, v>0)$. On the boundaries, however, both Ψ_o and Ψ_4 suffer from singularities at $(u=0, bv=\pi/2)$ and $(v=0, au=\pi/2)$, respectively. These are the typical null singularities inherited from the problem of colliding EM shock waves, therefore such singularities in the present problem is not unexpected at all. From the metric (31) we observe that $\tau=1$ and $\sigma=1$ are spurious, removable coordinate singularities since they do not show up in the Weyl scalars. In particular, $\tau=1$ is the location of the horizon in the interaction region beyond which the metric can be extended analytically. The other coordinate singularity $\sigma=1$ is out of question since it does not belong to the interaction region. The incoming EMD waves prior to the collision can also be easily identified from Appendix C. In the region II we have

$$\begin{aligned}
\Psi_2 &= -\frac{3}{8}a^2\theta(u)\frac{(5+\sin(au))}{(1+\sin(au))^{\frac{5}{2}}}, \\
\Phi_{22} &= \frac{1}{16}a^2\theta(u)\frac{(7+\sin(au))}{(1+\sin(au))^{\frac{5}{2}}},
\end{aligned} \tag{33}$$

while in the region III we must replace $au \leftrightarrow bv$ to obtain Ψ_o and Φ_{oo}. The incoming waves that comprise Ricci components $\Phi_{22}(\Phi_{oo})$ is obviously constructed from both the EM and the dilaton parts. Inside the collision region we observe also that the condition

$$9\Psi_2^2 = \Psi_0\Psi_4 \tag{34}$$

holds among the Weyl scalars, showing its type-D character. Direct choice of a Kinnersley type tetrad eliminates both Ψ_o and Ψ_4 components of the Weyl scalars.[19] Such a tetrad is given by the basis one-forms

$$l = \frac{\sqrt{1+\tau}}{1-\tau}\mathrm{d}\tau - \mathrm{d}x,$$

$$2n = \mathrm{d}\tau + \frac{1-\tau}{\sqrt{1+\tau}}\mathrm{d}x,$$

$$\sqrt{2}m = (1+\tau)^{\frac{3}{4}}\left(\frac{\mathrm{d}\sigma}{\sqrt{\sigma}} - i\sqrt{\delta}\,\mathrm{d}y\right). \tag{35}$$

This choice gives now the only nonzero component

$$\psi_2 = -\frac{1}{8}\frac{(5+\tau)}{(1+\tau)^{\frac{5}{2}}} \tag{36}$$

verifying its manifestly type-D character.

Now returning to the general CPW metric (14) with $a_o \neq 0$, we can discuss again the interaction region alone. For this reason we omit all step functions and consider an NP tetrad basis one-form

$$\sqrt{2}l = (FZ)^{\frac{1}{4}}\left(\frac{\mathrm{d}\tau}{\sqrt{\Delta}} + \frac{\mathrm{d}\sigma}{\sqrt{\delta}}\right),$$

$$\sqrt{2}n = (FZ)^{\frac{1}{4}}\left(\frac{\mathrm{d}\tau}{\sqrt{\Delta}} - \frac{\mathrm{d}\sigma}{\sqrt{\delta}}\right),$$

$$\sqrt{2}m = \frac{\sqrt{L}}{(FZ)^{\frac{1}{4}}}\left[\mathrm{d}x + \left(\frac{a_o\delta F}{L} + i\sqrt{\frac{\delta F Z_o}{L}}\right)\mathrm{d}y\right]. \tag{37}$$

The results are rather tedious so we shall refrain from tabulating the Ricci and Weyl components. Instead, relying on a numerical computation we have verified that the condition (34) fails to hold in the present case. Thus, we have seen numerically at least that our space-time is not type-*D*. By the same numerical analysis we conclude that our space-time is not singular. Another approach to study this space-time is to search for a possible Kinnersley tetrad that serves to generalize (35). To attain this goal we define the null vector l^μ out of the geodesics equation. Unfortunately, in contrast to the BH case the choice $\theta = \theta_o = \text{constant}$ which used to simplify the problem significantly, remains ineffective. By this analysis we obtain a set of Kinnersley-type tetrad as follows:

$$l^\mu = \frac{\sqrt{F}}{\Delta}\{k\Delta S, 0, F, -a_o\},$$

$$2n^\mu = \frac{1}{k^2 F\sqrt{Z}S^2}\{k\Delta S, 0, -F, a_o\},$$

$$\sqrt{2}m^\mu = \frac{F^{\frac{1}{4}}}{\sqrt{\delta}Z^{\frac{3}{4}}S}\left\{0, -\delta S\sqrt{\frac{Z}{F}}, -ia_o\delta, i\right\}, \tag{38}$$

where $S = Z^{-1/2}(F - a_o^2\delta)^{\frac{1}{2}}$.

In the limit $a_o=0$, this tetrad reduces to (35), as it should. This fact that our space-time is not type-*D* reflects in the computation of the spin coefficients since none turn out to vanish.

In conclusion, we state that colliding cross-polarized EMD space-time obtained from the five-dimensional MPBH through the KK reduction procedure turns out to be nonsingular in spite of all its complication. This reflects the highly transcendental coupling between the dilaton and the other fields. Linear polarization limit removes all complication and we obtain a much simpler space-time structure.

IV. CPW SOLUTIONS FROM BLACK *p*-BRANES

A class of black *p*-brane solutions in *d*-dimensions of the action

$$S=\int d^{(d+p)}x\sqrt{-g}\left(R-\frac{2}{(d-p)!}F^2_{(d-2)}\right) \tag{39}$$

with

$$F_{(d-2)}=\frac{1}{(d-2)!}F_{\mu_1\cdots\mu_{(d-2)}}\,\mathrm{d}x^{\mu_1}\wedge\cdots\wedge\mathrm{d}x^{\mu_{d-2}}$$

is given by the metric.[20]

$$\mathrm{d}s^2_{(d+p)}=A_dB_d^{(1-p)/(1+p)}\mathrm{d}t^2-(A_dB_d)^{-1}\,\mathrm{d}r^2-B_d^{2/(p+1)}\mathrm{d}y\,\mathrm{d}y-r^2\,\mathrm{d}\Omega^2_{(d-2)} \tag{40}$$

in which

$$A_d=1-\left(\frac{r_+}{r}\right)^{d-3},$$

$$B_d=1-\left(\frac{r_-}{r}\right)^{d-3}.$$

We consider here only the nonextremal case $r_+>r_-$, where the region $r_-<r<r_+$ enables us to construct nonsingular CPW solutions. As examples we shall present solutions for $p=1$, $p=6$, and $p\to\infty$, however, our procedure applies for any $p\geqslant 1$. In particular, the six-dimensional magnetically charged metric (40) becomes

$$\mathrm{d}s^2_6=A_5\,\mathrm{d}t^2-(A_5B_5)^{-1}\,\mathrm{d}r^2-B_5\,\mathrm{d}y^2-r^2\,\mathrm{d}\Omega^2_{(3)},$$

$$F_{(3)}=Q\epsilon_3, \tag{41}$$

where ϵ_3 is the volume form on the 3-sphere and $Q^2=2(r_+r_-)^2$. By the KK reduction procedure the six-dimensional action is reduced to the five-dimensional one

$$S=\int d^5x\sqrt{-g}\left[R-2(\nabla\phi)^2-\frac{1}{3}e^{-2c\phi}F^2_{(3)}\right], \tag{42}$$

where $c=\sqrt{\frac{2}{3}}$ and the metric, dilaton and 3-form fields are

$$\mathrm{d}s^2_5=B_5^{\frac{1}{3}}[A_5\,\mathrm{d}t^2-(A_5B_5)^{-1}\,\mathrm{d}r^2-B_5\,\mathrm{d}y^2-r^2\,\mathrm{d}\Omega^2_{(3)}],$$

$$e^{c\phi}=B_5^{-\frac{1}{3}},$$

$$F_{(3)} = \sqrt{2}(r_+ r_-)\epsilon_3. \tag{43}$$

The corresponding CPW solutions are obtained by the transformation

$$r^2 = \tfrac{1}{2}(a_o + b_o\tau),$$

$$\cos\theta = \sigma,$$

$$t = 2x,$$

$$\varphi = z,$$

$$\eta = w, \tag{44}$$

in which we have adopted the representation for $d\Omega^2_{(3)}$ and introduced the abbreviations

$$a_o = r_+^2 + r_-^2,$$

$$b_o = r_+^2 - r_-^2. \tag{45}$$

The resulting CPW metric, dilaton and the 3-form fields are

$$ds_5^2 = \left(\frac{1+\tau}{k+\tau}\right)^{1/3}\left\{(k+\tau)\left[2\,du\,dv - dz^2 - dw^2 + 2\sigma\,dz\,dw - \frac{1-\tau}{k+\tau}dx^2\right]\right\},$$

$$e^{c\phi} = \left(\frac{1+\tau}{k+\tau}\right)^{-1/3},$$

$$F_{(3)uzw} = Qa\,\theta(u)\sqrt{\delta}, \tag{46}$$

$$F_{(3)vzw} = -Qb\,\theta(v)\sqrt{\delta},$$

where $Q=(1/\sqrt{2})(k^2-1)$ and $k=a_o/b_o>1$. Our notation for τ, σ, and δ are as in the preceding sections and in transforming (43) into (46) we used the freedom of rescaling of x and ds^2. This metric has the scalar curvature (for $u>0$, $v>0$)

$$R = \frac{4}{3}\frac{ab(k-1)}{(1+\tau)^{4/3}(k+\tau)^{5/3}} \tag{47}$$

which is regular in the interaction region. The colliding 3-form metric corresponding to (41) becomes

$$ds_6^2 = (k+\tau)(2\,du\,dv - dz^2 - dw^2 + 2\sigma\,dz\,dw) - \frac{1}{k+\tau}[(1-\tau)dx^2 + (1+\tau)dy^2], \tag{48}$$

whereas the 3-form field preserves its form. This metric represents the collision of 2-form fields in flat background. The 3-form field is obviously obtained from the 2-form potential by

$$F_{(3)} = dA_{(2)}, \tag{49}$$

where

$$A_{(2)} = \tfrac{1}{2}A_{zw}\,dz \wedge dw,$$

$$A_{zw} = Q \sin(au\theta(u) - bv\theta(v)).$$

By a similar analysis we obtain the collision of these 3-form fields in 11-dimensional space. The result is

$$ds_{11}^2 = (k+\tau)(2\,du\,dv - dz^2 - dw^2 + 2\sigma\,dz\,dw) - \left(\frac{1+\tau}{k+\tau}\right)^{\frac{2}{7}} \sum_{i=1}^{6} (dy^i)^2 - \left(\frac{1-\tau}{k+\tau}\right)\left(\frac{1+\tau}{k+\tau}\right)^{-5/7} dx^2 \tag{50}$$

which has the regular scalar curvature,

$$R = -\frac{5}{7}\frac{ab(k^2-1)}{(k+\tau)^3}. \tag{51}$$

The KK reduction of this 11-dimensional metric to the fifth dimension is expressed by

$$ds^2 = \left(\frac{1+\tau}{k+\tau}\right)^{\frac{4}{7}} \left\{ \begin{array}{c} (k+\tau)[2\,du\,dv - dz^2 - dw^2 + 2\sigma\,dz\,dw] \\ -\left(\frac{1-\tau}{k+\tau}\right)\left(\frac{1+\tau}{k+\tau}\right)^{\frac{-5}{7}} dx^2 \end{array} \right\},$$
$$e^{c\phi} = \left(\frac{1+\tau}{k+\tau}\right)^{-4/7}, \tag{52}$$

and $F_{(3)}$ components are as in (49).

V. COLLIDING EM WAVE SOLUTION IN ANY HIGHER DIMENSION

The action for the $(4+p)$-branes is given by

$$S = \int d^{(4+p)}x\sqrt{-g}(R - F_{(2)}^2), \tag{53}$$

in which $F_{(2)}$ stands for the EM 2-form.

Solution is given by[20]

$$ds_{4+p}^2 = AB^{(1-p)/(1+p)}\,dt^2 - B^{2/(p+1)}dy\,dy - (AB)^{-1}\,dr^2 - r^2\,d\Omega_{(2)}^2, \tag{54}$$

where

$$A = 1 - \frac{r_+}{r},$$

$$B = 1 - \frac{r_-}{r},$$

and

$$F = Q\epsilon_2.$$

Now, the transformation (with $r_+ = a_o + b_o$ and $r_- = a_o - b_o$)

$$r = a_o + b_o\tau,$$

$$\cos\theta = \sigma,$$

$$\varphi = z,$$

$$t = x, \tag{55}$$

yields the CPW metric,

$$ds_{4+p}^2 = (k+\tau)^2(2\,du\,dv - \delta\,dz^2) - \left(\frac{1+\tau}{k+\tau}\right)^{2/(p+1)} \sum_{i=1}^{p} (dy^i)^2 - \left(\frac{1-\tau}{k+\tau}\right)\left(\frac{1+\tau}{k+\tau}\right)^{(1-p)/(1+p)} dx^2 \tag{56}$$

in which we have introduced $k=a_o/b_o>1$, and rescaled the coordinates. The EM potential 1-form is given by

$$A = -Q\sin(au\theta(u) - bv\theta(v))dz.$$

So that the nonzero field 2-form components are

$$F_{uz} = -Qa\theta(u)\sqrt{\delta},$$
$$F_{vz} = Qb\theta(v)\sqrt{\delta}. \tag{57}$$

It is observed now, that it is a simple matter to obtain the CPW metrics for an arbitrary $p \geqslant 1$. In particular, for $p=1$ and $p=7$ we have

$$ds_5^2 = (k+\tau)^2(2\,du\,dv - \delta\,dz^2) - \frac{1}{k+\tau}[(1+\tau)dy^2 + (1-\tau)dx^2] \tag{58}$$

and

$$ds_{11}^2 = (k+\tau)^2(2\,du\,dv - \delta\,dz^2) - \left(\frac{1+\tau}{k+\tau}\right)^{\frac{1}{4}} \sum_{i=1}^{7} (dy^i)^2 - \left(\frac{1-\tau}{k+\tau}\right)\left(\frac{1+\tau}{k+\tau}\right)^{-3/4} dx^2, \tag{59}$$

respectively. By letting $p\to\infty$, we can easily obtain also the colliding EM wave solutions in the ∞-brane world. The KK reduction to the fourth dimension for an arbitrary p-brane is

$$ds_4^2 = \left(\frac{1+\tau}{k+\tau}\right)^{p/(p+1)} \left\{ (k+\tau)^2(2\,du\,dv - \delta\,dz^2) - \left(\frac{1-\tau}{k+\tau}\right)\left(\frac{1+\tau}{k+\tau}\right)^{(1-p)/(1+p)} dx^2 \right\} \tag{60}$$

with

$$e^{c\phi} = \left(\frac{1+\tau}{k+\tau}\right)^{-p/[2(p+1)]},$$

$$c = \sqrt{\frac{p}{p+2}},$$

$$F_{uz} = -Qa\theta(u)\sqrt{\delta},$$

$$F_{vz} = Qb\,\theta(v)\sqrt{\delta},$$

$$Q^2 = \frac{1}{2}(k^2-1)\left(\frac{p+2}{p+1}\right).$$

This metric describes the collision of dilaton coupled EM waves in four dimensions.

VI. COLLIDING $(p+2)$-FORMS IN $(p+4)$-DIMENSION

In Sec. V we have constructed CPW solutions for the 2-form fields in $(p+4)$-dimension. By applying the duality principle we can obtain $(p+2)$-form fields and consider their collision at equal ease. We define the duality

$$\tilde{F}^{\mu_1\cdots\mu_k} = \frac{|g|^{-1/2}}{(n-k)!}\epsilon^{\mu_1\cdots\mu_k\mu_{k+1}\cdots\mu_n}F_{\mu_{k+1}\cdots\mu_n}, \tag{61}$$

where $(n>k)$ and $F_{\mu_{k+1}\cdots\mu_n}$ is assumed known.

The permutation symbol $\epsilon^{\mu_1\cdots\mu_n}$ satisfies[21]

$$\epsilon^{\mu_1\cdots\mu_n}\epsilon_{\mu_1\cdots\mu_n} = (-1)^l n!\ , \tag{62}$$

where l=number of minus signs in $g_{\mu\nu}$. Since we have readily available 2-form at hand we define its dual

$$\tilde{F}^{\mu_1\cdots\mu_{p+2}} = \frac{1}{2!}|g_{p+4}|^{-1/2}\epsilon^{\mu_1\cdots\mu_{p+4}}F_{\mu_{p+3}\mu_{p+4}} \tag{63}$$

in $(p+4)$-dimension. The action of (gravity $+\tilde{F}_{p+2}$) is taken as

$$S = \int d^{4+p}x\sqrt{g}\left(R - \frac{2}{(p+2)!}\tilde{F}^2_{p+2}\right) \tag{64}$$

with the field equations

$$R_{\mu\nu} = \frac{2}{(p+2)!}\left(\tilde{F}_{\mu\mu_1\cdots\mu_{p+1}}\tilde{F}^{\mu_p\cdots\mu_{p+1}}_{\nu} - \frac{(p+1)}{(p+2)^2}g_{\mu\nu}\tilde{F}^2\right)$$

$$\partial_\mu(|g_{p+4}|^{1/2}\tilde{F}^{\mu\mu_1\cdots\mu_{p+1}}) = 0, \tag{65}$$

where $\tilde{F}^2 = \tilde{F}_{\mu_1\cdots\mu_{p+2}}\tilde{F}^{\mu_p\cdots\mu_{p+2}}$.

We proceed with two particular examples, $p=1$ and $p=6$.

(i) $p=1$ case. The 3-form field $\tilde{F}_3$ is from the metric (58) and $F_{uz}=-Qa\,\theta(u)\sqrt{\delta}$, $F_{vz}=-Qb\,\theta(v)\sqrt{\delta}$. It is given by

$$\tilde{F}_3 = \frac{Q\sqrt{\Delta}}{(k+\tau)^2}(a\,\theta(u)\mathrm{d}u + b\,\theta(v)\mathrm{d}v)\wedge\mathrm{d}x\wedge\mathrm{d}y \tag{66}$$

which can be associated through $\tilde{F}_3=\mathrm{d}\tilde{A}_2$ to the 2-form potential

$$\tilde{A}_2 = -\frac{Q}{(k+\tau)}\mathrm{d}x\wedge\mathrm{d}y. \tag{67}$$

The incoming region (II) metric and 3-form fields can also be expressed in the Brinkmann form since they are given here in the Rosen form. For this we define new coordinates (U,V,X,Y,Z) as follows:

$$U = \int (k + \sin au)^2 \, du,$$

$$X = A(u)x, \quad Y = B(u)y, \quad Z = C(u)z,$$

$$V = v + \frac{x^2}{2}AA_u + \frac{y^2}{2}BB_u + \frac{z^2}{2}CC_u,$$

where

$$A^2(u) = \frac{1 - \sin au\theta}{k + \sin au\theta},$$

$$B^2(u) = \frac{1 + \sin au\theta}{k + \sin au\theta},$$

$$C = (k + \sin au\theta)\cos au\theta. \tag{68}$$

The relation between U and u can be chosen as

$$U = \frac{3}{2}u + \frac{2}{a}(1 - \cos au) - \frac{1}{4a}\sin 2au, \tag{69}$$

so that $u=0$ and $U=0$ coincide. Further, the graph of $U(u)$ reveals that in the interval $0<au<\pi/2$, $u>0$ implies that $U>0$. However, as it is observed we cannot invert u in terms of U, and this enforces us to keep the Brinkman form in an implicit form. We have ultimately

$$ds^2 = 2\,dU\,dV - dX^2 - dY^2 - dZ^2 - 2H(u(U),X,Y,Z)dU^2,$$

where

$$H(u(U),X,Y,Z) = \frac{a}{2}\delta(U)\left[Y^2 - X^2 + \frac{1}{k}(2Z^2 - X^2 - Y^2)\right] + \frac{a^2\theta(U)}{4(k + \sin au)^2}[(k+1)(3 - k + 2\sin au)X^2 - (k-1)(3 + k - 2\sin au)Y^2 - (k + \sin au)(k + 4\sin au)Z^2]. \tag{70}$$

We recall that a general class of metrics given by

$$ds^2 = 2\,dU\,dV - \left(\sum_{i,j} A_{ij}(U)X^iX^j\right)du^2 - \sum_i (dX^i)^2,$$

where A_{ij}=constant, is known as Cahen-Wallach space.[22]

It is clear that we have $\nabla^2 H \neq 0$ in our case, indicating the presence of energy momentum for the 3-form field as it should. The 3-form field, in the Brinkman form for region II is

$$\tilde{F}_3 = \frac{aQ\theta(U)}{(k + \sin au)^3}dU \wedge dX \wedge dY, \tag{71}$$

where the inversion of the expression (69) is implied.

(ii) $p=6$ case. The 8-form field $\tilde{F}_8$ is found from the metric (56),

$$\tilde{F}_8 = \tilde{F}_{uxy^1\cdots y^6}\,du \wedge dx \wedge dy^1 \wedge \cdots \wedge dy^6 + \tilde{F}_{vxy^1\cdots y^6}\,dv \wedge dx \wedge dy^1 \wedge \cdots \wedge dy^6, \tag{72}$$

where

$$\tilde{F}^{uxy^1\cdots y^6} = \frac{Qb\,\theta(v)\sqrt{\delta}}{|g_{10}|^{1/2}},$$

$$\tilde{F}^{vxy^1\cdots y^6} = \frac{Qa\,\theta(u)\sqrt{\delta}}{|g_{10}|^{1/2}}$$

and we have chosen $\epsilon^{uvzxy^1\cdots y^6} = +1$. The corresponding 7-form potential is

$$\tilde{A}_7 = \frac{-Q}{k+\tau} \mathrm{d}x \wedge \mathrm{d}y^1 \wedge \cdots \wedge \mathrm{d}y^6 \tag{73}$$

which derives $\tilde{F}_8$ through $\tilde{F}_8 = \mathrm{d}\tilde{A}_7$.

It is seen that the collision problem of these 8-form fields is automatically solved with well-defined incoming states. The solutions, as we stated earlier are regular but our procedure does not allow at the moment to obtain the collision problem of arbitrary *n*-form fields. Our procedure limits itself only with the 2(3)-form fields and their duals. Different authors addressed themselves to the more general problem but they obtained only perturbative and singular solutions.[23,24]

VII. CONCLUSIONS

In this paper we have concentrated first on two five-dimensional BHs, namely Myers-Perry (MP) and Reissner-Nordstrom (RN). These are both extensions of the five-dimensional Schwarzschild BH, MP with rotation while RN with electric charge. The inherent isometry between the BHs and colliding plane waves (CPWs) yields regular, horizon forming solutions to the latter. By regular, throughout the paper we imply a Cauchy-Horizon (CH) forming space-time with finite curvature invariants. We have not attempted to extend our space-time beyond CH. Once this is done by Chandrasekhar and Xanthopoulos,[1] we may face various singularities ranging from timelike to spacelike ones or no singularities at all. Another issue that we have not addressed ourselves in the paper is the stability of the CH formed in the collision. There are strong arguments that under certain perturbations the CHs of the CPWs transform into curvature singularities.[25] Definitely this matter is far from being conclusive and requires further investigation. We note also that beside the BHs the more general Weyl solutions can be employed in the generating of CPWs.[26]

Our particular cross-polarized dilatonic non-type-*D* metric with CH provides an example to be taken into account other than the singular ones used in string theory.[27,28] Our procedure is extendible to higher dimensional BHs provided technical matters are overcome. One such problem is to find representation for the *n*-dimensional spherical line element which admits $(n-1)$-dimensional Abelian subspace. Equation (2) performs just this for the three-dimensional sphere. Although we obtain colliding 2(3)-form fields by our procedure through, employing five-dimensional BHs, we can dualize our forms and obtain colliding $(p+1)$- and $(p+2)$-form fields in $(p+4)$-dimensions. Extension of our work to arbitrary form fields will be the next stage of our study. Presumably all these metrics will find application in higher dimensional space-times and low energy limit of the string theory.

APPENDIX A

The nonzero components of the metric (6) are given below

$$\tilde{R}_{uvuv} = -2a^2b^2k^2\theta(u)\,\theta(v),$$

$$\tilde{R}_{uvyz} = -2abka_o^2\theta(u)\,\theta(v),$$

$$\tilde{R}_{uvzx} = 2abka_o\theta(u)\theta(v),$$

$$\tilde{R}_{uyvy} = abk^2a_o^2\theta(u)\theta(v),$$

$$\tilde{R}_{uyvx} = abk^2a_o^2\theta(u)\theta(v) = \tilde{R}_{uxvy},$$

$$\tilde{R}_{uzvy} = abka_o^2\theta(u)\theta(v) = -\tilde{R}_{uyvz},$$

$$\tilde{R}_{uzvz} = -aba_o^2\theta(u)\theta(v),$$

$$\tilde{R}_{uzvx} = abka_o\theta(u)\theta(v) = -\tilde{R}_{uxvz},$$

$$\tilde{R}_{uxvx} = abk^2\theta(u)\theta(v),$$

$$\tilde{R}_{yzyz} = -\left(\tfrac{1}{2} + 2a_o^4\right)\theta(u)\theta(v),$$

$$\tilde{R}_{yzzx} = 2a_o^3\theta(u)\theta(v),$$

$$\tilde{R}_{yxyx} = \tfrac{1}{2}k^2\theta(u)\theta(v),$$

$$\tilde{R}_{zxzx} = \left(k^2 - \tfrac{1}{2}\right)\theta(u)\theta(v),$$

$$\tilde{R}_{uyuy} = -a^2\theta(u)Y_1 + a\delta(u)\cos(bv\,\theta(v))Y_2,$$

$$\tilde{R}_{vyvy} = -b^2\theta(v)Y_1 + b\delta(v)\cos(au\,\theta(u))Y_2,$$

$$\tilde{R}_{uxux} = -2a^2\theta(u)Y_3 - \frac{2ak}{D^2}\delta(u)\cos(bv\,\theta(v)),$$

$$\tilde{R}_{vxvx} = -2b^2\theta(v)Y_3 - \frac{2bk}{D^2}\delta(v)\cos(au\,\theta(u)),$$

$$\tilde{R}_{uyux} = -a^2a_o\theta(u)Y_4 - \frac{2aa_ok}{D^2}\delta(u)\cos(bv\,\theta(v)),$$

$$\tilde{R}_{vyvx} = -b^2a_o\theta(v)Y_4 - \frac{2ba_ok}{D^2}\delta(v)\cos(au\,\theta(u)),$$

$$\tilde{R}_{uzuz} = a^2\theta(u)Y_5 + a\delta(u)\cos(bv\,\theta(v))Y_6,$$

$$\tilde{R}_{vzvz} = b^2\theta(v)Y_5 + b\delta(v)\cos(au\,\theta(u))Y_6,$$

$$\tilde{R}_{uzux} = -a^2 a_o \theta(u) Y_7 - 2aa_o \frac{(1+2k\tau)}{D^2} \delta(u) \cos(bv\,\theta(v)),$$

$$\tilde{R}_{vzvx} = b^2 a_o \theta(v) Y_7 + 2ba_o \frac{(1+2k\tau)}{D^2} \delta(v) \cos(au\,\theta(u)),$$

$$\tilde{R}_{uyuz} = -a^2 \theta(u) Y_8 - a\delta(u) \cos(bv\,\theta(v)) Y_9,$$

$$\tilde{R}_{vyvz} = b^2 \theta(v) Y_8 + b\delta(v) \cos(au\,\theta(u)) Y_9,$$

where we have used the following abbreviations:

$$D = 1 + k\tau,$$

$$Y_1 = \frac{1}{D^3}[4(1+k\tau - a_o^2) - k^2\Delta(3(1+a_o^2) + k\tau)],$$

$$Y_2 = \frac{k^2}{D^3}[\tau(k^2+2) + k(1+3\tau^2 + k\tau^3)],$$

$$Y_3 = \frac{a_o^2 - k^2\Delta}{D^3},$$

$$Y_4 = \frac{1}{D^3}[2(1+k\tau) - 3k^2\Delta],$$

$$Y_5 = \frac{1}{D^3}\{-4(1+k\tau - a_o^2) + \Delta[a_o^2(11+12k^2\tau^2) + k\tau(7-6k^2) - 3(1-2k^2)]\},$$

$$Y_6 = \frac{1}{D^3}[k + \tau(3-10a_o^2) + k\tau^2(3-16a_o^2) + k^2\tau^3(1-8a_o^2)],$$

$$Y_7 = \frac{1}{D^3}[2(k+\tau) - k\Delta(5+6k\tau)],$$

$$Y_8 = \frac{1}{D^3}[4(k + \tau(1-a_o^2)) + k\Delta(k^2\Delta - 5 - a_o^2 - 3k\tau(1+2a_o^2))],$$

$$Y_9 = \frac{1}{D^3}[(2-k^2)(1+3k\tau) + k^2\tau^2(5+k\tau - 2k^2)].$$

APPENDIX B

The nonzero Riemann components of the metric (26) are with the step functions inserted as follows:

$$\tilde{R}_{uvuv} = \frac{-2la^2b^2}{C}(l+\tau)\theta(u)\theta(v),$$

$$\tilde{R}_{uxux} = -\frac{a^2\theta(u)}{C^4}(3l^2+2l\tau-1) - \frac{2a}{C^3}\delta(u)\cos(bv\,\theta(v))(l+\tau),$$

$$\tilde{R}_{uxvx} = \frac{ab}{C^4}\theta(u)\theta(v)(2l^2+l\tau-1),$$

$$\tilde{R}_{uyuy} = -\frac{a^2\theta(u)}{4C}(3l^2+4l\tau+1) + a\delta(u)l\cos(bv\,\theta(v)),$$

$$\tilde{R}_{uyuz} = -\frac{a^2\theta(u)\sigma}{4C}(3l^2+4l\tau+1) + a\delta(u)\cos(bv\,\theta(v)),$$

$$\tilde{R}_{uyvy} = \frac{ab}{4C}(1-l^2)\theta(u)\theta(v),$$

$$\tilde{R}_{uyvz} = \frac{ab\sigma}{4C}(1-l^2)\theta(u)\theta(v),$$

$$\tilde{R}_{uzuz} = -\frac{a^2\theta(u)}{4C}(3l^2+4l\tau+1) + a\delta(u)l\cos(bv\,\theta(v)),$$

$$\tilde{R}_{uzvz} = \frac{ab}{4C}(1-l^2)\theta(u)\theta(v),$$

$$\tilde{R}_{vxvx} = -\frac{b^2\theta(v)}{C^4}(3l^2+2l\tau-1) - \frac{2b}{C^3}\delta(v)\cos(au\,\theta(u))(1+\tau),$$

$$\tilde{R}_{vyvy} = -\frac{b^2\theta(v)}{4C}(3l^2+4l\tau+1) + b\delta(v)l\cos(au\,\theta(u)),$$

$$\tilde{R}_{vyvz} = -\frac{b^2\theta(v)\sigma}{4C}(3l^2+4l\tau+1) - b\delta(v)\cos(au\,\theta(u)),$$

$$\tilde{R}_{vzvz} = -\frac{b^2\theta(v)}{4C}(3l^2+4l\tau+1) + b\delta(v)l\cos(au\,\theta(u)),$$

$$\tilde{R}_{xyxy} = \frac{l\Delta}{2C^4}\theta(u)\theta(v)(l+\tau),$$

$$\tilde{R}_{xyxz} = \frac{l\Delta\sigma}{2C^4}\theta(u)\theta(v)(l+\tau),$$

$$\tilde{R}_{xzxz} = \frac{l\Delta}{2C^4}\theta(u)\theta(v)(l+\tau),$$

$$\tilde{R}_{yzyz} = \frac{-\delta\theta(u)\theta(v)}{4C}(1+2l\tau+l^2),$$

where we have used $C=1+l\tau$.

APPENDIX C

The nonzero NP quantities for the metric (31) are

$$\Psi_2 = \frac{1}{8}ab\theta(u)\theta(v)\frac{(5+\tau)}{(1+\tau)^{\frac{5}{2}}},$$

$$\Psi_4 = -\frac{3}{8}a^2\theta(u)\frac{(5+\tau)}{(1+\tau)^{\frac{5}{2}}} + \frac{a}{4}\frac{\delta(u)}{\cos bv(\theta(v))}\frac{(3+\tau)}{(1+\tau)^{3/2}},$$

$$\Psi_0 = -\frac{3}{8}b^2\theta(v)\frac{(5+\tau)}{(1+\tau)^{\frac{5}{2}}} + \frac{b}{4}\frac{\delta(v)}{\cos au(\theta(u))}\frac{(3+\tau)}{(1+\tau)^{3/2}},$$

$$\Phi_{22} = \frac{1}{16}a^2\theta(u)\frac{(7+\tau)}{(1+\tau)^{\frac{5}{2}}},$$

$$\Phi_{00} = \frac{1}{16}b^2\theta(v)\frac{(7+\tau)}{(1+\tau)^{\frac{5}{2}}},$$

$$\Phi_{02} = -\frac{1}{4}\frac{ab\theta(u)\theta(v)}{(1+\tau)^{\frac{3}{2}}},$$

$$\Phi_{11} = \frac{3}{32}ab\theta(u)\theta(v)\frac{(1-\tau)}{(1+\tau)^{\frac{5}{2}}} = -3\Lambda.$$

(Received 11 October 2005; accepted 30 November 2005; published online 27 January 2006)

Explicit solutions of the classical Calogero (rational with/without harmonic confining potential) and Sutherland (trigonometric potential) systems is obtained by diagonalization of certain matrices of simple time evolution. The method works for Calogero & Sutherland systems based on any root system. It generalizes the well-known results by Olshanetsky and Perelomov for the *A* type root systems. Explicit solutions of the (rational and trigonometric) higher Hamiltonian flows of the integrable hierarchy can be readily obtained in a similar way for those based on the classical root systems. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2162334]

I. INTRODUCTION

The classical and quantum integrability/solvability of Calogero-Moser systems[1–5] manifests itself in many guises; the existence of Lax pairs and/or Dunkl operators, algebraic linearization, quadratic algebras, associated integrable spin chains, "quantized" classical spectra, etc. Among them, a most intuitive understanding of solvability/integrability is provided by the fact that explicit solutions of the classical equations of motion are obtained by diagonalization of certain matrices having trivial time evolution, as shown by Olshanetsky and Perelomov[6] for the rational and trigonometric potential cases.[7] Their results are for the systems based on the *A*-type roots. Here we will show that the same results hold universally for systems based on any root system. To be more precise, for the rational potential (without/with harmonic confining potential) cases, the diagonalization method works for any root system, including the noncrystallographic ones. For the trigonometric and hyperbolic potential cases, we show that the explicit diagonalization method holds for any crystallographic root system based on the *universal* Lax pair.[8] A simpler form of explicit diagonalization is provided by the *minimal* Lax pair,[9,8] which exists only for those based on the *A*, *D*, E_6, and E_7 root systems. The basic idea of the explicit solution method is very closely related to the notion of algebraic linearization, proved universally for any root system by Caseiro–Françoise–Sasaki.[10] We will follow the notation of Ref. 10 throughout this paper and Eq. (a.b) of this paper will be cited as (Ia.b). Explicit solutions in terms of diagonalization is readily obtained for the *higher* (rational and trigonometric) *Hamiltonian flows* belonging to the integrable hierarchy. This works, however, only for those based on the classical root systems, *A*, *B*, *C*, and *D*. The conventional Lax pair in terms of the set of vector weights (*A*, *C*, and *D*) or the set of short roots (*B*) is indispensable.

This paper is organized as follows. In Sec. II, the historical background and the logical structure of the Calogero–Moser systems necessary for the present paper are briefly reviewed. The Hamiltonian and the universal Lax pair with rational potential are introduced. The explicit integration in terms of diagonalization is achieved by relating the Lax pair matrices *L* and *M* to a matrix *W* of the same size with trivial time evolution, $\ddot{W}=0$. Section III is devoted to the explicit solution of the systems with rational plus the harmonic confining potential. In Sec. IV, we show

the explicit solutions of the Sutherland systems, which have trigonometric/hyperbolic potentials. In Sec. IV A a simple form of explicit diagonalization is obtained by reinterpreting the formulas of the algebraic linearization method developed by Caseiro–Françoise–Sasaki.[10] This is based on the minimal Lax pair, which exists for those based on A, D, E_6, and E_7 root systems. A general treatment of explicit integration of the Sutherland systems in terms of the universal Lax pair is provided in Sec. IV B. This applies to any crystallographic root system. Sections V and VI are devoted to the problem of explicit integration of the higher Hamiltonian flows of the integrable hierarchy. The rational potential case is discussed in Sec. V and the trigonometric case in Sec. VI. The final section is for a summary and comments.

II. RATIONAL POTENTIAL

The integrability of the Calogero–Moser systems has a long history. First, various types of the integrable potentials are recognized; starting from the Calogero model[1] with rational $(1/q^2)$ plus a harmonic confining (q^2) potential followed by the Sutherland model[2] with a trigonometric $(1/\sin^2 q)$ potential. Then the pure rational potential $(1/q^2)$[3] and the hyperbolic $(1/\sinh^2 q)$[4] and the elliptic $[\wp(q)]$ potentials[5] are added to the list of the integrable potentials. As seen in many other subjects in mathematical physics, the quantum groups, the integrable spin chains, Yang–Baxter equations, etc., the elliptic case is the generic one, giving all the rest in various degenerations. However, each degenerate case, the rational, trigonometric, and the hyperbolic, has its own special properties and merits not shared by the more generic ones; for example, the algebraic linearization[10] of the degenerate Calogero–Moser systems and the quadratic algebras[11] for the quantum systems with the superintegrable rational $(1/q^2)$ potential. In the present article we deal with one of such properties of the degenerate Calogero–Moser systems and it is in fact very closely related to the algebraic linearization.[10] Second, the nature of the multiparticle interactions of the Calogero–Moser systems is recognized to be governed by the root systems associated with finite reflection (Coxeter/Weyl) groups.[12,13] The original models[1–5]are all based on the A-type root system related to the symmetric group S_N, with N being the number of the particles. The S_N is also the Weyl group of the special unitary group $SU(N)$. The integrability (the Lax pair) of the systems based on the classical root systems (A, B, C, and D) is noticed immediately by Olshanetsky and Perelomov,[12,13] but the actual demonstration of the integrability of the Calogero–Moser systems based on the exceptional[9,14] and noncrystallographic root systems[8] took more years. The classical universal Lax pair applicable for all types of potentials and for any root system[8] and the quantum universal Lax pair applicable for all degenerate potentials and for any root system[15] have been known for some years.

Let us denote by Δ a root system of rank r. It is a finite set of $\mathbf{R}^r$ vectors that is invariant under reflections in the hyperplane perpendicular to each vector in Δ. A reflection s_ρ in terms of a root ρ is defined by

$$s_\rho(x) = x - \rho(\rho^\vee \cdot x), \quad x \in \mathbf{R}^r, \tag{2.1}$$

in which $\rho^\vee = 2\rho/\rho^2$. Thus Δ is characterized by

$$s_\rho(\eta) \in \Delta, \quad \forall\, \rho, \eta \in \Delta. \tag{2.2}$$

The dynamical variables are the coordinates $q_i \in \mathbf{R}$, $i=1,\ldots,r$ and their canonically conjugate momenta $p_i \in \mathbf{R}$, $i=1,\ldots,r$, except for the A_r case in the ordinary embedding, in which the number of particles is $r+1$. The Hamiltonian for the classical Calogero–Moser system with the rational potential but without the harmonic confining potential is

$$\mathcal{H} = \frac{1}{2}p^2 + \frac{1}{2}\sum_{\rho\in\Delta_+} \frac{g_{|\rho|}^2 |\rho|^2}{(\rho\cdot q)^2}, \tag{2.3}$$

in which the real and positive coupling constants $g_{|\rho|}$ are defined on orbits of the corresponding Coxeter group. That is, for the simple Lie algebra cases $g_{|\rho|}=g$ for all roots in simply laced models and $g_{|\rho|}=g_L$ for long roots and $g_{|\rho|}=g_S$ for short roots in nonsimply laced models. In order to define Lax pair matrices L and M, let us choose a set of $\mathbf{R}^r$ vectors $\mathcal{R}=\{\alpha,\beta,\ldots,\}$, $\#\mathcal{R}=\mathcal{D}$, permuting under the action of the reflection group:

$$s_\rho(\alpha)\in\mathcal{R},\quad \forall\,\alpha\in\mathcal{R},\quad \forall\,\rho\in\Delta. \tag{2.4}$$

We demand that it consists of a single orbit of the Coxeter group, for irreducibility. Then we define $\mathcal{D}\times\mathcal{D}$ matrices indexed by the elements of $\mathcal{R}$:

$$p\cdot\hat{H}:\quad (p\cdot\hat{H})_{\alpha\beta}=(p\cdot\alpha)\delta_{\alpha\beta}, \tag{2.5}$$

$$\hat{s}_\rho:\quad (\hat{s}_\rho)_{\alpha\beta}=\delta_{\alpha,s_\rho(\beta)}. \tag{2.6}$$

Introduce next the $\mathcal{D}\times\mathcal{D}$ matrices X, L, and M:[9,8]

$$X=i\sum_{\rho\in\Delta_+} g_{|\rho|}(\rho\cdot\hat{H})\frac{1}{(\rho\cdot q)}\hat{s}_\rho, \tag{2.7}$$

$$L=p\cdot\hat{H}+X, \tag{2.8}$$

$$M=-\frac{i}{2}\sum_{\rho\in\Delta_+} g_{|\rho|}\frac{|\rho|^2}{(\rho\cdot q)^2}\hat{s}_\rho, \tag{2.9}$$

and a *diagonal matrix*:

$$Q=q\cdot\hat{H}:\quad (Q)_{\alpha\beta}=(q\cdot\alpha)\delta_{\alpha\beta}. \tag{2.10}$$

Here L and Q are Hermitian $L^\dagger=L$, $Q^\dagger=Q$, and M is anti-Hermitian $M^\dagger=-M$.

As shown in Ref. 10, Eqs. (I2.7a), (I2.7b) the time evolution of the matrix L along the flow of the Hamiltonian (2.3) displays the following equations:

$$\frac{\partial L}{\partial t}=[L,M], \tag{2.11}$$

$$\frac{\partial Q}{\partial t}=[Q,M]+L. \tag{2.12}$$

Next let us define another $\mathcal{D}\times\mathcal{D}$ unitary matrix $U(t)$ by the linear equation and the initial condition:

$$\frac{\partial U}{\partial t}=UM,\quad U(0)=1_{\mathcal{D}}, \tag{2.13}$$

in which $1_{\mathcal{D}}$ is the $\mathcal{D}\times\mathcal{D}$ unit matrix. The final step is the introduction of $W(t)$:

$$W(t)\equiv U(t)Q(t)U^{-1}(t), \tag{2.14}$$

which has a simple time evolution

$$\dot{W} = U(\dot{Q} - [Q,M])U^{-1} = ULU^{-1}, \tag{2.15}$$

$$\ddot{W} = U(\dot{L} - [L,M])U^{-1} = 0. \tag{2.16}$$

The solution is

$$W(t) = W(0) + t\,\dot{W}(0), \tag{2.17}$$

with the initial values

$$W(0) = Q(0), \quad \dot{W}(0) = L(0), \tag{2.18}$$

which are determined by the initial values of the canonical variables $q_j(0)$, $p_j(0)$, $j=1,\ldots,r$. Due to the defining relation of $W(t)$ in terms of the *diagonal matrix* $Q(t)$ (2.14), the solution $\{q(t)\}$ of the canonical equations of motion,

$$\frac{\partial q_j}{\partial t} = \frac{\partial \mathcal{H}}{\partial p_j}, \quad \frac{\partial p_j}{\partial t} = -\frac{\partial \mathcal{H}}{\partial q_j}, \quad j = 1, \ldots, r, \tag{2.19}$$

with the above Hamiltonian (2.3), is simply obtained by *diagonalizing* the above matrix solution (2.17). The conjugate momenta $\{p(t)\}$ are obtained by differentiation $p_j(t) = \partial q_j(t)/\partial t$.

As promised, this is the universal proof applicable for any root system including the noncrystallographic one. The spectrum of $W(t)$ (2.17) is highly constrained, since its dimension $\mathcal{D}$ is usually much greater than the degree of freedom r. The high symmetry of the spectrum is guaranteed by the Coxeter invariance of the theory:

$$\mathcal{H}(s_\rho(p), s_\rho(q)) = \mathcal{H}(p,q), \quad \forall\, \rho \in \Delta, \tag{2.20}$$

$$L(s_\rho(p), s_\rho(q)) = \hat{s}_\rho L(p,q)\hat{s}_\rho, \quad M(s_\rho(q)) = \hat{s}_\rho M(q)\hat{s}_\rho. \tag{2.21}$$

The original proof of the explicit integration of the A type systems by Olshanetsky and Perelomov[6] is the very special case in which the spectrum of $W(t)$ (2.17) is not constrained. Our proof reduces to that of Ref. 6 when $\Delta = A_r$ and the set of vector weights is chosen as $\mathcal{R} = \mathbf{V}$, $\#\mathcal{R} = \mathcal{D} = r+1$.

III. RATIONAL WITH HARMONIC CONFINING POTENTIAL

The Hamiltonian is now

$$\mathcal{H}_\omega = \frac{1}{2}p^2 + \frac{1}{2}\omega^2 q^2 + \frac{1}{2}\sum_{\rho\in\Delta_+} \frac{g_{|\rho|}^2 |\rho|^2}{(\rho\cdot q)^2}. \tag{3.1}$$

With the same matrices introduced above in the preceding section, the time evolution displays (I3.2a), (I3.2b):

$$\dot{L} = [L,M] - \omega^2 Q, \tag{3.2}$$

$$\dot{Q} = [Q,M] + L. \tag{3.3}$$

With the same definition of the unitary matrix $U(t)$ as above (2.13), the matrix

$$W(t) \equiv U(t)Q(t)U^{-1}(t), \tag{3.4}$$

evolves harmonically in time:

$$\dot{W} = U(\dot{Q} - [Q,M])U^{-1} = ULU^{-1} \tag{3.5}$$

$$\ddot{W} = U(\dot{L} - [L,M])U^{-1} = -\omega^2 W. \tag{3.6}$$

The solution is

$$W(t) = \cos \omega t W(0) + \omega^{-1} \sin \omega t \dot{W}(0), \tag{3.7}$$

with the initial values

$$W(0) = Q(0), \quad \dot{W}(0) = L(0). \tag{3.8}$$

Again the explicit solution $\{q(t)\}$ is obtained by *diagonalizing* the above matrix $W(t)$ (3.7) with the harmonic time dependence.

IV. TRIGONOMETRIC POTENTIAL

The Hamiltonian of the trigonometric (Sutherland) model[2] is written as:

$$\mathcal{H} = \frac{1}{2}p^2 + \frac{1}{2}\sum_{\rho \in \Delta_+} \frac{g_{|\rho|}^2 |\rho|^2}{\sin^2(\rho \cdot q)}. \tag{4.1}$$

In order to get the hyperbolic case, it suffices to change sin into sinh. In the following, we only demonstrate the explicit integration of the trigonometric case. The hyperbolic case can be deduced easily by the above replacement.

Two types of Lax pairs are known[9,8] for the trigonometric cases: the minimal and the universal Lax pairs. While the latter, the universal lax pair, applies to any crystallographic root system, the former, the minimal Lax pair, requires $\mathcal{R}$ to be the set of minimal weights, which exists only for the A, D, E_6, and E_7 root systems. Let us start with the minimal Lax pair, which has a simpler structure thanks to the restriction to the minimal weights, satisfying the condition

$$\mu\text{: minimal weight} \Leftrightarrow \alpha^\vee \cdot \mu = 0, \pm 1, \quad \forall\, \alpha \in \Delta. \tag{4.2}$$

A. Minimal Lax pair

We consider the matrices[9,8]

$$L = p \cdot \hat{H} + X, \tag{4.3}$$

$$X = i \sum_{\rho \in \Delta_+} g_{|\rho|} (\rho \cdot \hat{H}) \frac{1}{\sin(\rho \cdot q)} \hat{s}_\rho, \tag{4.4}$$

$$M = -\frac{i}{2} \sum_{\rho \in \Delta_+} g_{|\rho|} \frac{|\rho|^2 \cos(\rho \cdot q)}{\sin^2(\rho \cdot q)} (\hat{s}_\rho - 1_{\mathcal{D}}) + i \sum_{\rho \in \Delta_+} g_{|\rho|} \frac{(\rho \cdot \hat{H})^2}{\sin^2(\rho \cdot q)}, \tag{4.5}$$

and *diagonal matrices*:

$$Q = q \cdot \hat{H}: \quad (Q)_{\alpha\beta} = (q \cdot \alpha)\delta_{\alpha\beta}, \tag{4.6}$$

$$R = \mathrm{e}^{2iQ}. \tag{4.7}$$

Again L and Q are Hermitian $L^\dagger = L$, $Q^\dagger = Q$ and M is anti-Hermitian $M^\dagger = -M$. Thus R is unitary.

As shown in Ref. 10 (I5.3a), (I5.3b), when the root system admits a minimal representation, and $\mathcal{R}$ being the set of minimal weights, the time evolution along the flow of the Hamiltonian (4.1) displays

$$\frac{\partial L}{\partial t} = [L, M], \tag{4.8}$$

$$\frac{\partial R}{\partial t} = [R, M] + i(RL + LR). \tag{4.9}$$

With the same definition of the unitary matrix $U(t)$ as above (2.13),

$$\frac{\partial U}{\partial t} = UM, \quad U(0) = 1_{\mathcal{D}}, \tag{4.10}$$

we introduce a matrix

$$\mathcal{W}(t) = U(t)R(t)U(t)^{-1} = U(t)\mathrm{e}^{2iQ(t)}U(t)^{-1}. \tag{4.11}$$

It satisfies a simple first-order linear differential equation,

$$\frac{\partial \mathcal{W}}{\partial t} = U(\partial R/\partial t - [R, M])U^{-1} = iU(RL + LR)U^{-1} \tag{4.12}$$

$$= i(\mathcal{W}ULU^{-1} + ULU^{-1}\mathcal{W}), \tag{4.13}$$

since as in (2.15), (2.16), ULU^{-1} is a constant matrix:

$$\frac{\partial}{\partial t}(ULU^{-1}) = U(\partial L/\partial t - [L, M])U^{-1} = 0, \tag{4.14}$$

$$U(t)L(t)U(t)^{-1} = L(0). \tag{4.15}$$

The solution is

$$\mathcal{W}(t) = \mathrm{e}^{itL(0)}\mathrm{e}^{2iQ(0)}\mathrm{e}^{itL(0)}. \tag{4.16}$$

By *diagonalizing* the above matrix solution, we obtain the explicit solution $\{q(t)\}$ of the classical Sutherland model (4.1). One might naturally wonder if the coordinates $\{q(t)\}$ could be determined uniquely from the unitary matrix (4.16). The answer is affirmative since the motion is always restricted to one of the Weyl alcoves due to the periodicity and singularity of the potential. Near the boundary of a Weyl alcove, for example, at $\rho \cdot q = 0$, $\rho \in \Delta$, the singularity of the potential $\sim 1/(\rho \cdot q)^2$ can never be surpassed classically. Therefore if $\{q(0)\}$ is in the principal Weyl alcove,

$$PW_T = \{q \in \mathbf{R}^r | \rho \cdot q > 0, \quad \rho \in \Pi, \quad \rho_h \cdot q < \pi\}, \tag{4.17}$$

$\{q(t)\}$ will always remain there. Here Π is the set of the simple roots and ρ_h is the highest weight. This removes any ambiguity in determining $\{q(t)\}$ from the eigenvalues of (4.16). As in the rational potential cases, the spectrum of $\mathcal{W}(t)$ is highly constrained as a consequence of the Weyl invariance (2.20), (2.21).

B. Universal Lax pair

The universal Lax pair has $\cot(\rho \cdot q)$ function in L instead of $1/\sin(\rho \cdot q)$ in (4.4),

$$L = p \cdot \hat{H} + X, \tag{4.18}$$

$$X = i \sum_{\rho \in \Delta_+} g_{|\rho|} (\rho \cdot \hat{H}) \cot(\rho \cdot q) \hat{s}_\rho, \tag{4.19}$$

$$M = -\frac{i}{2} \sum_{\rho \in \Delta_+} g_{|\rho|} \frac{|\rho|^2}{\sin^2(\rho \cdot q)} (\hat{s}_\rho - 1_D), \tag{4.20}$$

which satisfy $\partial L/\partial t = [L,M]$ for the Hamiltonian flow, but the additional equation (4.9) takes a different form.

For $\mathcal{R}$ being the set of minimal weights, it reads as

$$\frac{\partial R}{\partial t} = [R,M] + i(R(L+K) + (L-K)R), \tag{4.21}$$

in which K is a non-negative constant matrix commuting with M:

$$K \equiv \sum_{\rho \in \Delta_+} g_{|\rho|} (\rho \cdot \hat{H})(\rho^\vee \cdot \hat{H}) \hat{s}_\rho, \quad [K,M] = 0. \tag{4.22}$$

It is a very important quantity in Calogero–Moser systems appearing in many contexts. For example, it is a commutator of Q (2.10) and the rational Lax matrix L (2.8), (2.7) [see (4.36) of Ref. 15 and (2.40) of Ref. 16):

$$[Q,L] = iK. \tag{4.23}$$

It should be noted that if K is defined as above, the expression (4.22) is *universal*, which is valid for any root system Δ and any choice of $\mathcal{R}$. Various properties of the K matrix, whose eigenvalues are all "integers," are discussed in detail by Corrigan-Sasaki, in the Appendix of Ref. 16.

For $\mathcal{R}$ being the set of all roots Δ (for the simply laced root systems) or the set of short roots Δ_S (for nonsimply laced root systems) and also the set of vector weights ($\mathbf{V}$) for the C, the relation corresponding to (4.9) and (4.21) reads as

$$\frac{\partial R}{\partial t} = [R,M] + i(R(L+\tilde{K}) + (L-\tilde{K})R), \tag{4.24}$$

in which $\tilde{K}$ is another constant matrix commuting with M,

$$\tilde{K} = \sum_{\rho \in \Delta_+} g_{|\rho|} |\rho \cdot \hat{H}| \hat{s}_\rho, \quad [\tilde{K},M] = 0, \tag{4.25}$$

introduced by Corrigan-Sasaki, as (5.32) of Ref. 16.

Now the explicit solution of the Sutherland system is achieved for any crystallographic root system, since one can choose at least one Lax pair satisfying (4.24). We proceed as before by defining the unitary matrix $U(t)$ by (4.10) and introduce a matrix

$$\mathcal{W}(t) = U(t)R(t)U(t)^{-1} = U(t)\mathrm{e}^{2iQ(t)}U(t)^{-1}. \tag{4.26}$$

It satisfies a simple first-order linear differential equation,

$$\frac{\partial \mathcal{W}}{\partial t} = U(\partial R/\partial t - [R,M])U^{-1} = iU(R(L+\tilde{K}) + (L-\tilde{K})R)U^{-1}, \tag{4.27}$$

$$= i(\mathcal{W}U(L+\tilde{K})U^{-1} + U(L-\tilde{K})U^{-1}\mathcal{W}), \tag{4.28}$$

since as in (2.15), (2.16), $U(L \pm \tilde{K})U^{-1}$ is a constant matrix:

$$\frac{d}{dt}(U(L\pm\tilde{K})U^{-1}) = U(\partial L/\partial t - [L,M])U^{-1} = 0, \tag{4.29}$$

$$U(t)(L(t)\pm\tilde{K})U(t)^{-1} = L(0)\pm\tilde{K}. \tag{4.30}$$

The solution is

$$\mathcal{W}(t) = \mathrm{e}^{it(L(0)-\tilde{K})}\mathrm{e}^{2iQ(0)}\mathrm{e}^{it(L(0)+\tilde{K})}. \tag{4.31}$$

By *diagonalizing* the above matrix solution, we obtain the explicit solution $\{q(t)\}$ of the classical Sutherland system (4.1) for any root system.

The very fact that $\tilde{K}$ (K) commutes with M simply means that a spectral parameter λ can be introduced trivially into the Lax pair for degenerate potentials:[8]

$$L_\lambda \equiv L + \lambda\tilde{K}, \quad \dot{L}_\lambda = [L_\lambda, M]. \tag{4.32}$$

V. RATIONAL HIGHER FLOWS

The integrable hierarchy of the Calogero–Sutherland systems consists of Hamiltonians generated by higher conserved quantities, which are constructed, for example, from the trace of the higher powers of the L matrix, $\mathcal{H}_n \propto \mathrm{Tr}(L^{2n})$. The method of explicit integration as described in the preceding sections applies also to these higher Hamiltonian flows, as shown by Suris[7] for the A-type root systems with the conventional Lax pair, $\mathcal{R}=\mathbf{V}$. However, in contrast to the basic Calogero–Sutherland flows, it works only for those systems based on the classical root systems, the A, B, C, and D. Let us denote by $\mathcal{R}$ the set of vector weights $\mathbf{V}$, for the A, C, and D root systems and the set of short roots Δ_S for the B root system. These particular sets $\mathcal{R}$ have a unique orthogonality property,

$$\text{if } \mu \neq \pm\nu, \quad \mu\cdot\nu = 0, \quad \forall\, \mu,\nu \in \mathcal{R}, \tag{5.1}$$

which endows a very special structure to the Lax pair represented on $\mathcal{R}$. The dimensions of the corresponding Lax matrices are $\mathcal{D}=r+1$ for the A_r and $\mathcal{D}=2r$ for the B_r, C_r, and D_r. It is through these special Lax matrices that the explicit integration of the higher rational and trigonometric flows is realized.

Let us start with the explicit forms of the rational L matrices:

$$(A)\colon L, \quad L_{jk} = p_j\delta_{jk} + ig(1-\delta_{jk})/(q_j - q_k), \tag{5.2}$$

$$(B)\colon L = \begin{pmatrix} A & B \\ -B & -A \end{pmatrix}, \quad A_{jk} = p_j\delta_{jk} + ig_L(1-\delta_{jk})/(q_j - q_k),$$

$$B_{jk} = i(g_S/q_j)\delta_{jk} + ig_L(1-\delta_{jk})/(q_j + q_k). \tag{5.3}$$

The rational C system will not be discussed since it is equivalent to the rational B system. The rational D system is obtained by constraining $g_S=0$ in the rational B system.

The higher Hamiltonians are

$$(A)\colon \mathcal{H}_n = \mathrm{Tr}(L^{n+1})/(n+1), \quad n \geqslant 1, \tag{5.4}$$

$$(B,D)\colon \mathcal{H}_n = \mathrm{Tr}(L^{2n})/(4n), \quad n \geqslant 1. \tag{5.5}$$

The lowest $\mathcal{H}_1$ is the original Hamiltonian (2.3). The basic idea is to rewrite the Hamiltonian flow,

$$\frac{\partial q_j}{\partial t_n} = \frac{\partial \mathcal{H}_n}{\partial p_j}, \quad \frac{\partial p_j}{\partial t_n} = -\frac{\partial \mathcal{H}_n}{\partial q_j}, \tag{5.6}$$

into equivalent matrix forms,

$$\frac{\partial L}{\partial t_n} = [L, M_n], \tag{5.7}$$

$$\frac{\partial Q}{\partial t_n} = [Q, M_n] + L^n \ (L^{2n-1}), \tag{5.8}$$

as in the lowest flow (2.11), (2.12).

In contrast to the lowest flow case in which the explicit form of M is given (2.9), we can interpret part of (5.7) and (5.8) as determining M_n. The diagonal part of the Q equation (5.8) is equivalent to the first half of the canonical equations (5.6). The off-diagonal part of the Q equation (5.8) determines the off-diagonal part of M_n completely:

$$(M_n)_{\mu\nu} = -(L^n)_{\mu\nu}/q\cdot(\mu-\nu), \quad (-(L^{2n-1})_{\mu\nu}/q\cdot(\mu-\nu)), \quad \mu \neq \nu. \tag{5.9}$$

Whereas the diagonal part of M_n does not enter the Q equation (5.8), it can be determined from the off-diagonal part of the Lax equation. The result is very simple:

$$(M_n)_{\mu\mu} = -\sum_{\nu\neq\mu} (M_n)_{\nu\mu} = -\sum_{\nu\neq\mu} (M_n)_{\mu\nu}, \quad M_n^\dagger = -M_n. \tag{5.10}$$

The proof that the diagonal part of the higher flow Lax equation (5.7) is equivalent to the second half of the canonical equations (5.6) goes almost parallel to that of the lowest flow.

After the equivalence of the canonical equations (5.6) with the two matrix equations (5.7) and (5.8) is established, the explicit integration by diagonalization is straightforward. Let us define a $\mathcal{D}\times\mathcal{D}$ unitary matrix $U_n(t_n)$ by the linear equation and the initial condition:

$$\frac{\partial U_n}{\partial t_n} = U_n M_n, \quad U_n(0) = 1_{\mathcal{D}}. \tag{5.11}$$

Then a matrix function $W_n(t_n)$, defined by

$$W_n(t_n) \equiv U_n(t_n) Q(t_n) U_n^{-1}(t_n), \tag{5.12}$$

has a simple time evolution,

$$\frac{\partial W_n}{\partial t_n} = U_n(\partial Q/\partial t_n - [Q, M_n])U_n^{-1} = (U_n L U_n^{-1})^n \quad ((U_n L U_n^{-1})^{2n-1}), \tag{5.13}$$

$$\frac{\partial}{\partial t_n}(U_n L U_n^{-1}) = U_n(\partial L/\partial t_n - [L, M_n])U_n^{-1} = 0, \tag{5.14}$$

$$\Rightarrow U_n(t_n) L(t_n) U_n(t_n)^{-1} = L(0). \tag{5.15}$$

The solution is

$$W_n(t_n) = W_n(0) + t_n\, \partial W_n(0)/\partial t_n, \tag{5.16}$$

with the initial values

$$W_n(0) = Q(0), \quad \partial W_n(0)/\partial t_n = L(0)^n \quad [L(0)^{2n-1}], \tag{5.17}$$

which are determined by the initial values of the canonical variables $q_j(0)$, $p_j(0)$, $j=1,\ldots,r$. Due

to the defining relation of $W_n(t_n)$ in terms of the *diagonal matrix* $Q(t_n)$ (5.12), the solution $\{q(t_n)\}$ of the canonical equations of motion (5.6) with the above Hamiltonian (5.4) or (5.5), is simply obtained by *diagonalizing* the above matrix solution (5.16). Determination of the conjugate momenta $\{p(t_n)\}$ requires a solution of the second half of the canonical equations of motion (5.6), which are now *algebraic* since $\{\partial q/\partial t_n\}$ are now known functions of time. An extension to the generic higher flows of the hierarchy

$$\mathcal{H} = \sum_n c_n \mathcal{H}_n, \quad c_n: \text{const}, \tag{5.18}$$

is straightforward since the matrix equations (5.7) and (5.8) are linear in M_n. However, some higher flows cannot be treated this way. For example, in the D_r (r: odd) theory, there exists another conserved quantity (Hamiltonian) of the form $p_1 p_2 \cdots p_r + \cdots$, which cannot be written as (5.18).

VI. TRIGONOMETRIC HIGHER FLOWS

The basic logics of the explicit integration of the trigonometric higher flows is almost the same as that of the rational higher flows, except that we have to consider two different types of Lax pairs; the minimal and the universal. So we just write down the key formulas without a detailed derivation.

A. Minimal Lax pair

We discuss the explicit integration of the trigonometric higher flows of the A and D theory in terms of the minimal Lax pair, although the formulation in terms of the universal Lax pair works well for them, too.

The explicit forms of the trigonometric minimal L matrices are

$$(A)\text{: } L, \quad L_{jk} = p_j \delta_{jk} + ig(1-\delta_{jk})/\sin(q_j - q_k), \tag{6.1}$$

$$(D)\text{: } L = \begin{pmatrix} A & B \\ -B & -A \end{pmatrix}, \quad A_{jk} = p_j \delta_{jk} + ig(1-\delta_{jk})/\sin(q_j - q_k),$$

$$B_{jk} = ig(1-\delta_{jk})/\sin(q_j + q_k). \tag{6.2}$$

The higher Hamiltonians take exactly the same form as (5.4) and (5.5). The lowest $\mathcal{H}_1$ is the original Hamiltonian (4.1). We rewrite the higher Hamiltonian flow (5.6) into equivalent matrix forms,

$$\frac{\partial L}{\partial t_n} = [L, M_n], \tag{6.3}$$

$$\frac{\partial R}{\partial t_n} = [R, M_n] + i(RL^n + L^n R) \quad (i(RL^{2n-1} + L^{2n-1}R)), \tag{6.4}$$

as in the lowest flow (4.8), (4.9). The off-diagonal part of M_n is

$$(M_n)_{\mu\nu} = -(L^n)_{\mu\nu} \cot[q\cdot(\mu-\nu)] \quad (-(L^{2n-1})_{\mu\nu} \cot[q\cdot(\mu-\nu)]), \quad \mu \neq \nu. \tag{6.5}$$

The diagonal part is

$$(M_n)_{\mu\mu} = \sum_{\nu\neq\mu} (L^n)_{\nu\mu}/\sin[q\cdot(\nu-\mu)] = \sum_{\nu\neq\mu} (L^n)_{\mu\nu}/\sin[q\cdot(\mu-\nu)], \quad M_n^\dagger = -M_n. \tag{6.6}$$

The $\mathcal{D}\times\mathcal{D}$ matrix $\mathcal{W}_n(t_n)$ obeys a simple time evolution:

$$\mathcal{W}_n(t_n) = U_n(t)R(t_n)U_n(t_n)^{-1} = U_n(t_n)\mathrm{e}^{2iQ(t_n)}U_n(t_n)^{-1}, \tag{6.7}$$

$$= \mathrm{e}^{it_nL(0)^n}\mathrm{e}^{2iQ(0)}\mathrm{e}^{it_nL(0)^n}(\mathrm{e}^{it_nL(0)^{2n-1}}\mathrm{e}^{2iQ(0)}\mathrm{e}^{it_nL(0)^{2n-1}}). \tag{6.8}$$

By *diagonalizing* the above matrix solution (6.8), we obtain the explicit solution $\{q(t_n)\}$ of the higher flows of the Sutherland system (5.4) and (5.5) for the A and D root systems.

B. Universal Lax pair

The explicit integration of the higher flows of the B and C Sutherland systems is achieved in terms of the universal Lax pairs based on the set of short roots ($\mathcal{R}=\Delta_S$) for B and the set of vector weights ($\mathcal{R}=\mathbf{V}$) for C. For the rank r system, both have $\mathcal{D}=2r$.

The Lax matrix L and the constant matrix $\widetilde{K}$ (4.25) are

$$L = \begin{pmatrix} A & B \\ -B & -A \end{pmatrix}, \quad \widetilde{K} = \begin{pmatrix} S & T \\ T & S \end{pmatrix}, \tag{6.9}$$

$$(B): A_{jk} = p_j\delta_{jk} + ig_L(1-\delta_{jk})\cot(q_j - q_k), \quad S_{jk} = g_L(1-\delta_{jk}), \tag{6.10}$$

$$B_{jk} = ig_S\cot q_j\delta_{jk} + ig_L(1-\delta_{jk})\cot(q_j + q_k), \quad T_{jk} = g_S\delta_{jk} + g_L(1-\delta_{jk}), \tag{6.11}$$

$$(C): A_{jk} = p_j\delta_{jk} + ig_S(1-\delta_{jk})\cot(q_j - q_k), \quad S_{jk} = g_S(1-\delta_{jk}), \tag{6.12}$$

$$B_{jk} = 2ig_L\cot 2q_j\delta_{jk} + ig_S(1-\delta_{jk})\cot(q_j + q_k), \quad T_{jk} = 2g_L\delta_{jk} + g_S(1-\delta_{jk}). \tag{6.13}$$

It is easy to see

$$\mathrm{e}^{iQ}(L+\widetilde{K})\mathrm{e}^{-iQ} = \mathrm{e}^{-iQ}(L-\widetilde{K})\mathrm{e}^{iQ}, \tag{6.14}$$

$$\Rightarrow \mathrm{Tr}(L+\widetilde{K})^n = \mathrm{Tr}(L-\widetilde{K})^n, \tag{6.15}$$

which are conserved quantities of the Sutherland flow (4.1). It differs from the usual one $\mathrm{Tr}(L^n)$ by a linear combination of lower-order conserved quantities. The canonical equations of the higher flow Hamiltonian,

$$\mathcal{H}_n = \mathrm{Tr}((L\pm\widetilde{K})^{2n})/(4n) \tag{6.16}$$

are equivalent to the matrix equations

$$\frac{\partial L}{\partial t_n} = [L, M_n], \tag{6.17}$$

$$\frac{\partial R}{\partial t_n} = [R, M_n] + i(R(L+\widetilde{K})^{2n-1} + (L-\widetilde{K})^{2n-1}R). \tag{6.18}$$

The off-diagonal part of M_n is

$$(M_n)_{\mu\nu} = -[e^{iq\cdot(\mu-\nu)}(L+\widetilde{K})^n_{\mu\nu} + e^{-iq\cdot(\mu-\nu)}(L-\widetilde{K})^n_{\mu\nu}]/\sin[q\cdot(\mu-\nu)], \quad \mu\neq\nu. \tag{6.19}$$

The diagonal part is

$$(M_n)_{\mu\mu} = -\sum_{\nu\neq\mu}(M_n)_{\nu\mu} = -\sum_{\nu\neq\mu}(M_n)_{\mu\nu}, \quad M_n^\dagger = -M_n. \tag{6.20}$$

The $\mathcal{D}\times\mathcal{D}$ matrix $\mathcal{W}_n(t_n)$ obeys simple time evolution:

$$\mathcal{W}_n(t_n) = U_n(t)R(t_n)U_n(t_n)^{-1} = U_n(t_n)\mathrm{e}^{2iQ(t_n)}U_n(t_n)^{-1}, \tag{6.21}$$

$$= \mathrm{e}^{it_n(L(0)-\tilde{K})^{2n-1}}\mathrm{e}^{2iQ(0)}\mathrm{e}^{it_n(L(0)+\tilde{K})^{2n-1}}. \tag{6.22}$$

By *diagonalizing* the above matrix solution (6.22), we obtain the explicit solution $\{q(t_n)\}$ of the higher flows of the Sutherland system (6.16) for the B and C root systems.

VII. SUMMARY AND COMMENTS

Explicit integration of the Calogero and Sutherland systems by means of diagonalization is demonstrated for any root system, the exceptional as well as the classical and the noncrystallographic. It is based on the universal Lax pair for the degenerate potentials, which is the rational with/without the harmonic confining potential and the trigonometric/hyperbolic potentials. As emphasized in the text, it is very closely related to the concept of algebraic linearization by Caseiro–Françoise–Sasaki.[10] The method is extended to the higher Hamiltonian flows of the rational and trigonometric/hyperbolic interactions. In contrast to the basic Calogero–Sutherland flows, the applicability is limited to those systems based on the classical root systems, the A, B, C, and D root systems.

The theory of explicit integration of higher Hamiltonian flows is very closely related to the dynamical r matrix[7,17,18] and the Hamiltonian reduction.[19,13] In the case of the most classical rational potential of the A type, the method of Hamiltonian reduction starts from the large phase space of the matrix dynamical variable W and its conjugate momentum variable Z, which are both assumed to be Hermitian. The Hamiltonians,

$$\mathcal{H}_n = \mathrm{Tr}(Z^{n+1})/(n+1), \tag{7.1}$$

generate the flows

$$\frac{\partial W}{\partial t_n} = Z^n, \quad \frac{\partial Z}{\partial t_n} = 0. \tag{7.2}$$

This Hamiltonian system is invariant under the action $(W,Z)\to(UWU^{-1},UZU^{-1})$ of unitary matrices U. The reduced phase space is obtained by imposing the constraint

$$[W,Z] = iK \tag{7.3}$$

and factoring out the constrained phase space by residual symmetries (i.e., by the group of unitary matrices that commute with K). The (Q,L) pair (4.23) is nothing but a representative of a point of the reduced phase space, which is connected with the point (W,Z) of the large phase space by a (t-dependent) unitary matrix U as

$$Q = U^{-1}WU, \quad L = U^{-1}ZU. \tag{7.4}$$

The linear flows of (W,Z) are thereby mapped to the Calogero flows of (Q,L). This is the way to understand the rational Calogero system of the A type as a Hamiltonian reduction;[19] a similar interpretation has been proposed for a few other cases.[13] The dynamical r matrix has been constructed in this framework of Hamiltonian reduction.[7] We expect that all the cases discussed in this paper can be treated in the same way.

(Received 26 September 2005; accepted 13 October 2005; published online 30 January 2006)

The parametric equations of the surfaces on which highly resonant quasiperiodic motions develop (lower-dimensional tori) cannot be analytically continued, in general, in the perturbation parameter ε, i.e., they are not analytic functions of ε. However rather generally quasiperiodic motions whose frequencies satisfy only one rational relation ("resonances of order 1") admit formal perturbation expansions in terms of a fractional power of ε depending on the degeneration of the resonance. We find conditions for this to happen, and in such a case we prove that the formal expansion is convergent after suitable resummation. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2157052]

I. INTRODUCTION

Resonances play an important role in the theory of dynamical systems. A possible application is provided by problems of celestial mechanics, such as the phenomenon of resonance locking between rotation and orbital periods of the satellites.[17] In fact, the presence of friction can select resonant motions which remain stable when friction (on astronomical time scales) becomes negligible. In such a case maximal KAM tori can be really observed only approximately and on very short time scale, whereas, on very large time scales one expects that only periodic motions survive. On intermediate time scales one can imagine that quasiperiodic motions, involving a number of frequencies less than the total number of degrees of freedom (and decreasing with time), describe most of the observed dynamics. This makes interesting and important to study quasiperiodic motions occurring on lower-dimensional tori for nearly integrable Hamiltonian systems. These quasiperiodic motions are characterized by frequencies satisfying s rational relations, with $r=N-s$ ranging between 1 (periodic motions) and the number N of degrees of freedom (KAM tori). The number s equals the number of normal frequencies appearing in the perturbed motions, whereas r is the number of independent components of the rotation vector.

The analysis of such motions is simpler under some (generic) nondegeneracy assumptions on the perturbations. On the contrary the situation becomes immediately very complicated if no restriction at all is made on the perturbation. Situations of this kind arise also in similar contexts, we can mention the conservation of KAM tori under perturbations for systems of N harmonic oscillators, proved for $N=2$ but conjectured to hold in general,[18,24] and the stability of Hill's equation under quasiperiodic perturbations.[14] In the case of lower-dimensional tori, the nondegeneracy assumption is that the normal frequencies become different from zero when the perturbation is switched on. If such an assumption is removed, then only partial results hold, and only in the case $s=1$, that is only in the case of one normal frequency.[2,3]

Starting from the work of Eliasson,[6] a new approach to KAM theory of quasiintegrable

[a)]On leave from Dipartimento di Matematica, Università di Roma Due, Roma, I-00133 Italy.

Hamiltonian systems arose, based on the analysis of cancellations in the "Lindstedt series" for the functions mapping unperturbed motions (uniform rotations, in suitable coordinates) into corresponding perturbed ones.

A convenient way to exploit cancellations to resolve apparent divergences in the Lindstedt series is through methods inspired by quantum field theory, consisting in graphical expansions, summation of classes of diverging subdiagrams, iterative study of the flow of the effective constants and the possible introduction of counterterms. With these techniques and ideas, a number of known results have been reproduced and new ones have been obtained; see Refs. 7, 11, 13, and 9 for some reviews.

In this paper we follow the latter approach to investigate the conservation of $(N-1)$-dimensional tori for systems with N degrees of freedom. More precisely we consider N degrees of freedom systems described by analytic Hamiltonians of the form

$$H(I,\varphi) = H_0(I) + \varepsilon f(I,\varphi), \tag{1.1}$$

with $(I,\varphi) \in \mathcal{D} \times \mathbb{T}^N$, where $\mathbb{T} = \mathbb{R} \backslash 2\pi\mathbb{Z}$ is the standard torus, $\mathcal{D}$ is an open subset of $\mathbb{R}^N$, ε is a real parameter, and the free Hamiltonian $H_0(I)$ is assumed to be uniformly convex, $\partial_I^2 H_0(I) \geqslant C > 0$ for all $I \in \mathcal{D}$.

Definition 1 (simple resonance): A simple Diophantine resonance *for the unperturbed system is a motion taking place on the torus* $\{I_0\} \times \mathbb{T}^N$ *with* $\omega_0 := \partial_I H_0(I_0)$ *satisfying a rational relation* $\omega_0 \cdot \nu_0 = 0$ *for some* $\nu_0 \in \mathbb{Z}^N$ *and* $|\omega_0 \cdot \nu| > C|\nu|^{-\tau}$ *for suitable* $C, \tau > 0$ *and for all* $0 \neq \nu \in \mathbb{Z}^N$ *not parallel to* ν_0.

Thus, if $\varepsilon = 0$, the motions with rotation velocity ω_0 will foliate the torus $\{I_0\} \times \mathbb{T}^N$ into a one parameter family of invariant tori of dimension $N-1$.

For $\varepsilon \neq 0$ invariant tori with dimension $N-1$ run by quasiperiodic motions with spectrum ω_0 will, in general, only continue to exist "close" to some of the unperturbed tori $\{I_0\} \times \mathbb{T}^N$. The problem is simpler under nondegeneracy assumptions on the average $\langle f \rangle$ of the perturbing function f on the torus $\{I_0\} \times \mathbb{T}^N$; it has been studied in Refs. 10 and 15 with techniques employed, under different assumptions on the perturbation, in this paper. Define the average of f on $\{I_0\} \times \mathbb{T}^N$ as

$$\langle f(\varphi) \rangle := \lim_{T \to \infty} \frac{1}{T} \int_0^T f(\varphi + \omega_0 t) \mathrm{d}t. \tag{1.2}$$

It depends nontrivially on φ in the sense that in general it is a nonconstant periodic function of φ. This is more easily visualized in coordinates *adapted* to the resonance: they are defined by a linear canonical transformation $(I,\varphi) := (I_0 + S^{-1}(\mathbf{A},B), S^T(\boldsymbol{\alpha},\beta))$, with S a nonsingular integer components $N \times N$ matrix with determinant $\det S = 1$ such that $\omega_0 \equiv S^T(\boldsymbol{\omega},0)$ with $\boldsymbol{\omega} \in \mathbb{R}^{N-1}$, $|\boldsymbol{\omega} \cdot \boldsymbol{\nu}| > C_0 |\boldsymbol{\nu}|^{-\tau_0}$ for *all* $\mathbf{0} \neq \boldsymbol{\nu} \in \mathbb{Z}^{N-1}$ and $\mathbf{A} \in \mathbb{R}^{N-1}$, $B \in \mathbb{R}$, $\boldsymbol{\alpha} \in \mathbb{T}^{N-1}$, $\beta \in \mathbb{T}$.

In the coordinates $(\mathbf{A},B,\boldsymbol{\alpha},\beta)$ the Hamiltonian becomes an analytic function of $(\mathbf{A},B)$, in the domain obtained from $\mathcal{D}$ under the transformation S, and $(\boldsymbol{\alpha},\beta) \in \mathbb{T}^{N-1} \times \mathbb{T}$. It will be of the form $H(\mathbf{A},B,\boldsymbol{\alpha},\beta) = H_0'(\mathbf{A},B) + \varepsilon f(\boldsymbol{\alpha},\beta)$, where $H_0'(\mathbf{A},B) = \boldsymbol{\omega} \cdot \mathbf{A} + H_0(\mathbf{A},B)$, with H_0 vanishing to second order at $\mathbf{A} = \mathbf{0}$, $B = 0$ and uniformly convex in the domain where it is defined. Of course the functions H, H_0, f have a different meaning with respect to those appearing in (1.1), but we prefer to use the same notation for simplicity. For the same reason we still shall use the notation (I,φ) to denote the new action-angle variables, by setting $I = (\mathbf{A},B)$ and $\varphi = (\boldsymbol{\alpha},\beta)$.

So in the new coordinates the Hamiltonian H, the rotation vector $\boldsymbol{\omega} \in \mathbb{R}^{N-1}$ and the average $f_{\mathbf{0}}(\mathbf{A},B,\beta)$ of the perturbing function can be supposed to be such that

$$H = \boldsymbol{\omega} \cdot \mathbf{A} + H_0(\mathbf{A},B) + \varepsilon f(\mathbf{A},B,\boldsymbol{\alpha},\beta), \quad |\boldsymbol{\omega} \cdot \boldsymbol{\nu}| \geqslant \frac{C_0}{|\boldsymbol{\nu}|^{\tau_0}} \quad \forall\, \mathbf{0} \neq \boldsymbol{\nu} \in \mathbb{Z}^{N-1},$$

$$f_0(\mathbf{A},B,\beta) := \int \frac{\mathrm{d}\alpha}{(2\pi)^{N-1}} f(\mathbf{A},B,\boldsymbol{\alpha},\beta) \quad \text{if } f(\mathbf{A},B,\boldsymbol{\alpha},\beta) = \sum_{\boldsymbol{\nu} \in \mathbb{Z}^{N-1}} e^{i\boldsymbol{\nu}\cdot\boldsymbol{\alpha}} f_{\boldsymbol{\nu}}(\mathbf{A},B,\beta), \tag{1.3}$$

near the unperturbed resonance and *without any loss of generality*. The corresponding equations of motion for $X(t)\equiv(\mathbf{A}(t),B(t),\boldsymbol{\alpha}(t),\beta(t))$ are

$$\begin{aligned}&\dot{\mathbf{A}}=-\varepsilon\partial_{\boldsymbol{\alpha}}f,\\&\dot{B}=-\varepsilon\partial_{\beta}f,\\&\dot{\boldsymbol{\alpha}}=\boldsymbol{\omega}+\partial_{\mathbf{A}}H_0+\varepsilon\partial_{\mathbf{A}}f,\\&\dot{\beta}=\partial_{B}H_0+\varepsilon\partial_{B}f,\end{aligned}\qquad\text{or } \dot{X}=E\partial_X H(X),\quad\text{with } E=\begin{pmatrix}0&-1\\1&0\end{pmatrix},\tag{1.4}$$

where E is the standard $2N\times 2N$ symplectic matrix. We study the existence of motions which can be described by a constant β_0 and by functions $\mathbf{A}(\boldsymbol{\psi})$, $B(\boldsymbol{\psi})$, $\mathbf{a}(\boldsymbol{\psi})$, $b(\boldsymbol{\psi})$ of $\boldsymbol{\psi}\in\mathbb{T}^{N-1}$, which tend to 0 as $\varepsilon\to 0$, such that, by posing

$$\begin{gathered}\mathbf{A}(t)=\mathbf{A}(\boldsymbol{\psi}+\boldsymbol{\omega}t),\quad B(t)=B(\boldsymbol{\psi}+\boldsymbol{\omega}t),\\\boldsymbol{\alpha}(t)=\boldsymbol{\psi}+\boldsymbol{\omega}t+\mathbf{a}(\boldsymbol{\psi}+\boldsymbol{\omega}t),\quad \beta(t)=\beta_0+b(\boldsymbol{\psi}+\boldsymbol{\omega}t),\end{gathered}\tag{1.5}$$

one obtains, for all $\boldsymbol{\psi}\in\mathbb{T}^{N-1}$, solutions to the equations of motion (1.4). For brevity we shall sometimes write $X(t)$, instead of $X(\boldsymbol{\psi}+\boldsymbol{\omega}t)$, to indicate solutions of (1.4) of the form (1.5).

Note that, for $\varepsilon=0$, the motions (1.5) reduce to

$$\mathbf{A}^{(0)}(t)=\mathbf{0},\quad B^{(0)}(t)=0,\quad \boldsymbol{\alpha}^{(0)}(t)=\boldsymbol{\psi}+\boldsymbol{\omega}t,\quad \beta^{(0)}(t)=\beta_0,\tag{1.6}$$

where $\psi\in\mathbb{T}^{N-1}$ are arbitrary. The motions $X^{(0)}(t)=(\mathbf{A}^{(0)}(t),B^{(0)}(t),\boldsymbol{\alpha}^{(0)}(t),\beta^{(0)}(t))$ represent the unperturbed resonant motions filling a one parameter family of $N-1$ dimensional invariant tori (parametrized by β_0).

Given any function $G(\boldsymbol{\psi},\varepsilon)$ we shall denote by $G_{\boldsymbol{\nu}}$ the $\boldsymbol{\nu}$th Fourier component of its Fourier expansion in $\boldsymbol{\psi}$ and we shall call $[G]^k$ the kth order term obtained by expanding in ε the function G. Furthermore we shall denote by $[G]^k_{\boldsymbol{\nu}}$ the $\boldsymbol{\nu}$th Fourier component of the Fourier expansion of $[G]^k$ and by $G_{\neq\mathbf{0}}$ the function $G-G_{\mathbf{0}}$.

A formal solution of (1.4) and (1.5), as a power series in ε, $X(\boldsymbol{\psi})=X^{(0)}(\boldsymbol{\psi})+\varepsilon X^{(1)}(\boldsymbol{\psi})+\ldots$, is well known to exist if $\beta_0\in\mathbb{T}$ is a stationarity point for the average $f_{\mathbf{0}}(\mathbf{0},0,\beta)$ [i.e., a point such that $\partial_\beta f_{\mathbf{0}}(\mathbf{0},0,\beta_0)=0$] which is not degenerate [i.e., $\partial^2_\beta f_0(\mathbf{0},0,\beta_0)\neq 0$]; cf. for instance, Refs. 21, 19, and 10. *Here we consider explicitly the case in which the nondegeneracy condition on* $\partial^2_\beta f_{\mathbf{0}}(\mathbf{0},0,\beta_0)$ *fails to hold. This is a case in which in general no formal solution in powers of* ε *can be constructed.*

If β_0 is such that $\partial_\beta f_{\mathbf{0}}(\beta_0)=0$, then there exists a function X' such that $X^{(0)}+\varepsilon X'$ solves (1.4) up to terms of order ε^2 (excluded). Namely $X'(\boldsymbol{\psi})=(\mathbf{A}'(\boldsymbol{\psi}),B'(\boldsymbol{\psi}),\mathbf{a}'(\boldsymbol{\psi}),b'(\boldsymbol{\psi}))$ is obtained by applying the operator $(\boldsymbol{\omega}\cdot\partial_{\boldsymbol{\psi}})^{-1}$ to the vector

$$(-\partial_\varphi f(\mathbf{0},0,\boldsymbol{\psi},\beta_0),\partial_I f(\mathbf{0},0,\boldsymbol{\psi},\beta_0)+\partial^2_I H_0(\mathbf{0},0)(\mathbf{A}'(\boldsymbol{\psi}),B'(\boldsymbol{\psi}))),\tag{1.7}$$

where $\partial_\varphi,\partial_I$ denote, respectively, the derivatives with respect to the angle and action variables. This means that one first determines $\mathbf{A}'(\boldsymbol{\psi})$ and $B'(\boldsymbol{\psi})$ by solving $(\boldsymbol{\omega}\cdot\partial_{\boldsymbol{\psi}})(\mathbf{A}'(\boldsymbol{\psi}),B'(\boldsymbol{\psi}))=-\partial_\varphi f(\mathbf{0},0,\boldsymbol{\psi},\beta_0)$; the (otherwise arbitrary) averages $\mathbf{A}'_0,B'_0$ are fixed by requiring that the operator $(\boldsymbol{\omega}\cdot\partial_{\boldsymbol{\psi}})^{-1}$ can be applied to the vector formed by the last N components of (1.7), i.e., $\partial_I f_{\mathbf{0}}(\mathbf{0},0,\beta_0)+\partial^2_I H_0(\mathbf{0},0)(\mathbf{A}'_{\mathbf{0}},B'_{\mathbf{0}})=\mathbf{0}$. In this way also $\mathbf{a}'(\boldsymbol{\psi})$ and $b'(\boldsymbol{\psi})$ can be obtained. The averages of the angle variables will be chosen $\mathbf{a}'_{\mathbf{0}}=\mathbf{0}$ while we leave $b'_{\mathbf{0}}$ as a free parameter [to be suitably fixed at higher orders to make the equations (1.4) formally solvable].

There are, however other solutions which are correct up to order ε^2 (excluded). If $\partial^j_\beta f_{\mathbf{0}}(\mathbf{0},0,\beta_0)=0$ for all $j\leqslant k_0$ and $\partial^{k_0+1}_\beta f_{\mathbf{0}}(\mathbf{0},0,\beta_0)\neq 0$, one can imagine to add to the free parameter $b'_{\mathbf{0}}$ any polynomial in powers of $\eta=|\varepsilon|^{1/k_0}$ of degree $<k_0$. It can be checked (and it will be explicitly shown in next sections) that, for any choice of this polynomial, a solution of the equation of motions correct up to terms of order ε^2 (excluded) exists. This is, ultimately, the

reason why consistent expansions in powers of ε cannot in general be continued beyond first order. The consistency condition of the equations of motion necessary to improve (to second order included) the solution fixes one coefficient of such (*a priori* arbitrary) polynomials in η and, in general, this really forces the expansion to be an expansion in powers of η different from $\eta^{k_0}=\varepsilon$.

The analysis below shows that an expansion in η is actually possible at all orders if the following assumptions are satisfied.

Assumptions:

(a) *The constant* $a:=[\partial_\beta f(X^{(0)}+\varepsilon X_0')]_0^1$ *is* $a\neq 0$.
(b) *The matrix* $\partial_I^2 H_0(\mathbf{0},0)$ *is positive definite*.
(c) *There is* $k_0>0$ *such that* $\partial_\beta^j f_{\mathbf{0}}(\mathbf{0},0,\beta_0)=0$ *for all* $j\leqslant k_0$ *and* $c:=(1/k_0!)\partial_\beta^{k_0+1} f_{\mathbf{0}}(\mathbf{0},0,\beta_0)\neq 0$.

The constant a appearing in assumption (a), written explicitly, is

$$a := [\partial_{\beta,\varphi} f(X^{(0)}(\boldsymbol{\psi}))\cdot(\boldsymbol{\omega}\cdot\partial_{\boldsymbol{\psi}})^{-1}(\partial_I f(X^{(0)}(\boldsymbol{\psi}))+\partial_I^2 H_0(\mathbf{0},0)(\mathbf{A}'(\boldsymbol{\psi}),B'(\boldsymbol{\psi})))_{\neq\mathbf{0}} - \partial_{\beta,I} f(X^{(0)}(\boldsymbol{\psi}))\cdot(\boldsymbol{\omega}\cdot\partial_{\boldsymbol{\psi}})^{-1}\partial_\varphi f(X^{(0)}(\boldsymbol{\psi}))_{\neq\mathbf{0}}]_{\mathbf{0}}. \tag{1.8}$$

For instance if f depends only on the angle variables φ and $\partial_I^2 H(\mathbf{0},0)=\mathbb{1}$ the constant a is

$$a = \frac{1}{2}\partial_\beta \sum_{\boldsymbol{\nu}\neq\mathbf{0}} \frac{|\boldsymbol{\nu}|^2|f_{\boldsymbol{\nu}}(\beta)|^2+|\partial_\beta f_{\boldsymbol{\nu}}(\beta)|^2}{(\boldsymbol{\omega}\cdot\boldsymbol{\nu})^2}\Bigg|_{\beta=\beta_0}. \tag{1.9}$$

The number k_0 appearing in assumption (c) is a measure of the "degeneration" of the resonance, while the *order* of the resonance is the number of rational relations between the unperturbed frequencies, which is 1 in our case as the unperturbed motions have $N-1$ independent frequencies. The case $k_0=1$ was considered in Ref. 15 and we will not consider it again here. We shall focus on the case $k_0\geqslant 2$, in which case a formal power solution in ε to (1.4) does not exist. In fact, one checks that, as a consequence of assumptions (a) and (c), the average over $\boldsymbol{\psi}$ of the right-hand side (rhs) of the second equation in (1.4) is different from 0 at order ε^2, for any possible choice of the free parameter $b_{\mathbf{0}}'$ introduced after (1.7).

However, under the assumptions above, it is possible to find a formal solution to (1.4) such that the average of b is $b_{\mathbf{0}}=O(|\varepsilon|^{1/k_0})$: the average of b will be fixed in terms of the constants a and c in such a way that the average over $\boldsymbol{\psi}$ of the rhs of the second equation in (1.4) is 0 at all orders in $|\varepsilon|^{1/k_0}$.

The necessity of a fractional powers expansion can be seen by a heuristic argument sketched in Appendix A, the argument also suggests, as a conjecture, the forthcoming Theorem 1 and motivates the assumptions (a) *to* (c).

In Appendix A it is in fact shown that, in the simple case $H_0(\mathbf{A},B)=\frac{1}{2}(\mathbf{A}^2+B^2)$ and f depending only on the angles, a canonical transformation (explicitly constructed in Appendix A), defined in a neighborhood of $\{\mathbf{0}\}\times\{0\}\times\mathbb{T}^{N-1}\times\{\beta_0\}$, maps $\boldsymbol{\omega}\cdot\mathbf{A}+H_0(\mathbf{A},B)+\varepsilon f(\boldsymbol{\alpha},\beta)$ into

$$\boldsymbol{\omega}\cdot\mathbf{A}+H_0(\mathbf{A},B)+\frac{\varepsilon c}{k_0+1}(\beta-\beta_0)^{k_0+1}+\varepsilon^2 a(\beta-\beta_0)+O(\varepsilon(\beta-\beta_0)^{k_0+2})+O(\varepsilon^2(\beta-\beta_0)^2)+O(\varepsilon I^2) + O(\varepsilon^3). \tag{1.10}$$

As discussed in Appendix A, the Hamiltonian equations corresponding to (1.10) can be consistently solved to order ε^2. In particular, for some choices of the signs of ε,a,c, the angle β admits an approximate *quadratic* equilibrium point $O(|\varepsilon|^{1/k_0})$, whose stability depends again on the relative signs of ε,a,c. This second order computation suggests the conjecture that the unperturbed motion $X^{(0)}(t)$ can be continued at $\varepsilon\neq 0$, provided the average of β is chosen $O(|\varepsilon|^{1/k_0})$. The perturbed motion, if existing beyond second order, will take place on a torus (a small perturbation of the free one) which we shall call elliptic or hyperbolic, depending on the stability of the behavior of the linearization of the motion of β in the vicinity of its equilibrium point: if the

corresponding pair of nonzero Lyapunov exponents is imaginary then the torus will be said *elliptic*, if it is real it will be said *hyperbolic*.

In the following a *sparse Cantor set dense at* 0 will mean a set $\mathcal{E}$ contained in an interval $I=[-\varepsilon_0,0]$ or $I=[0,\varepsilon_0]$ with an open dense complement in I and with 0 as a density point in the sense of Lebesgue integration. In particular $\mathcal{E}$ will have positive measure.

Theorem 1: *Consider the system described by the Hamiltonian (1.3), under the assumptions* (a), (b), *and* (c). *There exists* $\varepsilon_0>0$ *such that for* $|\varepsilon|<\varepsilon_0$ *the following holds.*

(i) If k_0 *is odd and* $c\varepsilon<0$ *there is at least one hyperbolic invariant torus of dimension* $N-1$ *with rotation vector* $\boldsymbol{\omega}$. *If* $c\varepsilon>0$ *there is a sparse Cantor set* $\mathcal{E}\subset[-\varepsilon_0,0]$ *with the property that for* $\varepsilon\in\mathcal{E}$ *there is at least one elliptic torus of dimension* $(N-1)$ *with rotation vector* $\boldsymbol{\omega}$.

(ii) If k_0 *is even and* εc *has the same sign of* $-a$, *there is at least one hyperbolic invariant torus of dimension* $N-1$ *with rotation vector* $\boldsymbol{\omega}$. *Moreover, there is a sparse Cantor set* $\mathcal{E}$ *dense at* 0 *such that, if* $\varepsilon\in\mathcal{E}$ *and* εc *has the same sign of* $-a$, *there is at least one elliptic invariant torus of dimension* $N-1$ *with rotation vector* $\boldsymbol{\omega}$.

Remarks: (1) If assumption (c) is violated, since f is analytic in β, then $f_{\mathbf{0}}(\mathbf{0},0,\beta)\equiv 0$ as a function of β. In this case we can perform a canonical transformation removing the perturbation at order ε and casting the Hamiltonian into the form $H'=H_0'+\varepsilon^2 f'$, for some new analytic functions H_0' and f'. If f' satisfies the assumptions above we can apply Theorem 1 to H'. If H' satisfies assumption (c) and violates assumption (a) we cannot say much. If H' violates assumption (c) we can again remove the perturbation at lowest order through a new canonical transformation and cast the Hamiltonian into the new form $H''=H_0''+\varepsilon^4 f''$ and hope to be able to apply Theorem 1 to H''. And so on.

(2) Assumption (a) is essential and, if it does not hold, our expansion may fail to be convergent. In fact, in some cases (k_0 even), it is easy to show that if assumption (a) fails there cannot be perturbed motions of the form (1.5), see Appendix B for an example. If k_0 is odd, Ref. 2 proved existence of hyperbolic tori even if assumption (a) fails; in these cases we expect that a new perturbation parameter must be identified. The heuristic analysis in Appendix A concretely suggests plausible results to be expected if $a=0$ (under alternative assumptions).

(3) We expect that assumption (b) is not essential and that it could be weakened into the request that $\partial_I^2 H_0(\mathbf{0},0)$ is nondegenerate and that $\partial_{BB}^2 H_0(\mathbf{0},0)\neq 0$. Certainly the convexity assumption simplifies some of the estimates (see Appendix F) and we did not attempt to eliminate it.

(4) The only known result on the problems considered here is in Ref. 2, where conservation of $(N-1)$-dimensional "hyperbolic tori" is proved under weaker assumptions, although we study conservation of both hyperbolic and elliptic $(N-1)$-dimensional tori under assumptions (a) to (c) above.

(5) In principle one could proceed in a different way rather than following our approach. One could first perform the canonical transformation described in Appendix A and leading to the Hamiltonian (1.10), then study the system so obtained with other techniques, such as those in Refs. 5, 22, and 23 or 19. To this aim one should use that in the new coordinates the unperturbed Hamiltonian contains terms of order η^{2k_0-1}, while the perturbation is of order η^{2k_0}, hence has a further η.

(6) The analysis via Lindstedt series and summations of classes of diagrams is the main aspect of this work. Also the analyticity properties in η at $\boldsymbol{\omega}$ fixed are, to our knowledge, new.

(7) Technically the present work is strongly inspired by Refs. 10, 12, and 15. The proofs that can be taken literally from Ref. 15 will not be repeated here, hence familiarity with the latter reference is essential.

(8) The resummed series has manifest holomorphy properties which show that the set $\mathcal{E}$ is in the boundary of a complex domain where the functions $X(\boldsymbol{\psi})$ are analytic in ε, we do not discuss the details (see Refs. 10 and 15).

The paper is organized as follows. In Secs. II and III we prove formal solvability of the equation of motion in power series in $|\varepsilon|^{1/k_0}$ and we describe a graphical representation of the terms appearing in the formal power series. Such a representation involves labeled rooted trees, and is very similar to diagrammatic representations through Feynman diagrams arising in quantum

field theory. In Secs. IV–VI we describe an iterative resummation scheme which eliminates some classes of divergent subdiagrams and iteratively changes the power expansion, and we prove convergence of the resummed series. Some details of the proofs are deferred to the Appendixes.

II. LINDSTEDT SERIES

We define $\varepsilon=\sigma\eta^{k_0}$, with $\sigma\in\{\pm1\}$, $\eta>0$, and look for a family of formal solutions of the equations of motion in powers of η parametrized by $\boldsymbol{\psi}\in\mathbb{T}^{N-1}$, in the special form $X(t)=(\mathbf{A}(t),B(t),\boldsymbol{\alpha}(t),\beta(t))$

$$\mathbf{A}(t)=\sum_{k=k_0}^{\infty}\eta^k\sum_{\boldsymbol{\nu}\in\mathbb{Z}^{N-1}}e^{i\boldsymbol{\nu}\cdot(\boldsymbol{\psi}+\boldsymbol{\omega}t)}\mathbf{A}_{\boldsymbol{\nu}}^{(k)},$$

$$B(t)=\sum_{k=k_0}^{\infty}\eta^k\sum_{\boldsymbol{\nu}\in\mathbb{Z}^{N-1}}e^{i\boldsymbol{\nu}\cdot(\boldsymbol{\psi}+\boldsymbol{\omega}t)}B_{\boldsymbol{\nu}}^{(k)},$$

$$\boldsymbol{\alpha}(t)=\boldsymbol{\psi}+\boldsymbol{\omega}t+\mathbf{a}(t),\quad \mathbf{a}(t)=\sum_{k=k_0}^{\infty}\eta^k\sum_{\boldsymbol{\nu}\neq\mathbf{0}}e^{i\boldsymbol{\nu}\cdot(\boldsymbol{\psi}+\boldsymbol{\omega}t)}a_{\boldsymbol{\nu}}^{(k)},$$

$$\beta(t)=\beta_0+b(t),\quad b(t)=\sum_{k=k_0}^{\infty}\eta^k\sum_{\boldsymbol{\nu}\neq\mathbf{0}}e^{i\boldsymbol{\nu}\cdot(\boldsymbol{\psi}+\boldsymbol{\omega}t)}b_{\boldsymbol{\nu}}^{(k)}+\sum_{k=1}^{\infty}\eta^k b_{\mathbf{0}}^{(k)},\tag{2.1}$$

where all the involved functions have also a dependence on β_0 which has not been made explicit. The formal series (2.1) will be called *Lindstedt series* as it extends the corresponding notions already used in the theory of quasiperiodic motions on maximal tori.

In the following the average $b_{\mathbf{0}}^{(k)}$ will be abbreviated as β_k.

Remarks: (1) The functions $\mathbf{A},B,\mathbf{a}$ and $b-b_0$ have been chosen as power series in η starting with the k_0th order as the first nontrivial order; $\mathbf{a}$ has been chosen with zero average (this just corresponds to a redefinition of the origin of $\mathbb{T}^{N-1}$), while the average of b has been chosen as a series in η starting with the first order; the coefficients $\beta_k:=b_{\mathbf{0}}^{(k)}$ will be chosen in such a way that the Lindstedt series admits a formal solution.

(2) With the choices in (2.1), Eqs. (1.4) are identically solved for any order $k<k_0$ in η. The parameters β_k, $k<k_0$, are left as free parameters, to be explicitly chosen below.

To write the generic kth order of (1.4) we introduce the following definitions: given any function $\boldsymbol{\psi}\to F(X(\boldsymbol{\psi}))$, let $[F]^{(k)}$ be the kth order in the Taylor expansion of F in η and let $[F]_{\boldsymbol{\nu}}^{(k)}$ be the $\boldsymbol{\nu}$th Fourier component of the Fourier expansion of $[F]^{(k)}$. Note that this notation concerns expansions in η and is different from the one introduced after (1.6) which dealt with expansions in ε, with the new notation the quantity denoted $a=[\partial_\beta f(X^{(0)})+\varepsilon X')]_{\mathbf{0}}^{1}$ before (1.8) must be written as $a=\sigma[\partial_\beta f(X^{(0)}+\sigma\eta^{k_0}X')]_{\mathbf{0}}^{(k_0)}$ as the superscript k denotes kth order in ε while (k) denotes kth order in η. Then, if $\boldsymbol{\nu}\neq\mathbf{0}$ and $k\geqslant k_0$, the Eqs. (1.4) become

$$\begin{aligned}
(i\boldsymbol{\omega}\cdot\boldsymbol{\nu})\mathbf{A}_{\boldsymbol{\nu}}^{(k)}&=-\sigma[\partial_{\boldsymbol{\alpha}}f]_{\boldsymbol{\nu}}^{(k-k_0)},\\
(i\boldsymbol{\omega}\cdot\boldsymbol{\nu})B_{\boldsymbol{\nu}}^{(k)}&=-\sigma[\partial_\beta f]_{\boldsymbol{\nu}}^{(k-k_0)},\\
(i\boldsymbol{\omega}\cdot\boldsymbol{\nu})\mathbf{a}_{\boldsymbol{\nu}}^{(k)}&=[\partial_{\mathbf{A}}H_0]_{\boldsymbol{\nu}}^{(k)}+\sigma[\partial_{\mathbf{A}}f]_{\boldsymbol{\nu}}^{(k-k_0)},\\
(i\boldsymbol{\omega}\cdot\boldsymbol{\nu})b_{\boldsymbol{\nu}}^{(k)}&=[\partial_B H_0]_{\boldsymbol{\nu}}^{(k)}+\sigma[\partial_B f]_{\boldsymbol{\nu}}^{(k-k_0)},
\end{aligned}\tag{2.2}$$

and, since $\boldsymbol{\omega}$ satisfies the Diophantine property, they can be solved *provided*

$$\begin{aligned}
\mathbf{0} &= [\partial_{\boldsymbol{\alpha}} f]_{\mathbf{0}}^{(k-k_0)},\\
0 &= [\partial_{\beta} f]_{\mathbf{0}}^{(k-k_0)},\\
\mathbf{0} &= [\partial_{\mathbf{A}} H_0]_{\mathbf{0}}^{(k)} + \sigma[\partial_{\mathbf{A}} f]_{\mathbf{0}}^{(k-k_0)},\\
0 &= [\partial_{B} H_0]_{\mathbf{0}}^{(k)} + \sigma[\partial_{B} f]_{\mathbf{0}}^{(k-k_0)}.
\end{aligned} \tag{2.3}$$

If assumptions (a), (b), and (c) in Sec. I are satisfied, such a formal solution can be shown to exist provided the formal series for the average b_0 is suitably chosen.

Lemma 1: *Under the assumptions* (a), (b), *and* (c) *if k_0 is odd, a formal solution of (1.4) in the form (2.1) always exists; if k_0 is even, a formal solution of (1.4) in the form (2.1) exists if $\sigma ac<0$. When a formal solution exists, $\mathbf{A}^{(k)}, B^{(k)}, \mathbf{a}^{(k)}, b^{(k)}$ are uniquely fixed in the case k_0 odd. If k_0 is even, there are two possible such sequences corresponding to the choices $\beta_1 \equiv b_{\mathbf{0}}^{(1)} = \pm(-\sigma a/c)^{1/k_0}$.*

Proof: Let $X^{(0)}(\boldsymbol{\psi}) = (\mathbf{0}, 0, \boldsymbol{\psi}, \beta_0)$, $\varepsilon = \sigma\eta^{k_0}$ with $\sigma = \mathrm{sign}(\varepsilon)$ and $\eta > 0$, and look for a formal solution $t \to (\mathbf{A}(t), B(t), \boldsymbol{\alpha}(t), \beta(t))$ obtained by setting $\boldsymbol{\psi} = \boldsymbol{\psi} + \boldsymbol{\omega} t$ in

$$X(\boldsymbol{\psi}) = X^{(0)}(\boldsymbol{\psi}) + \sum_{k=k_0}^{\infty} \eta^k X^{(k)}(\boldsymbol{\psi}) + \sum_{k=1}^{\infty} \eta^k \xi^{(k)}, \tag{2.4}$$

where $\xi^{(k)} = (\mathbf{0}, 0, \mathbf{0}, \beta_k)$. Set $X^{(h)} \equiv 0$ for $0 < h < k_0$ and $\xi^{(0)} = 0$.

Suppose inductively that $X^{(h)}$ has been determined for $h = 0, 1, \ldots, k-1$, for $k \geqslant 1$. Consider a generic polynomial $Y(\boldsymbol{\psi}) := \sum_{h=0}^{k-1} \eta^h Y^{(h)}(\boldsymbol{\psi})$ and suppose, inductively, that if $Y^{(h)} = X^{(h)} + \xi^{(h)}$ the function $Y(\boldsymbol{\omega} t)$ solves the equation of motion $\dot{X} = E\partial_X H(X)$ up to order $k-1$. This is true for $k = 1$. Let $\Delta := (\boldsymbol{\omega} \cdot \partial_{\boldsymbol{\psi}})$ and remark that the identities $\int \sum_{j=1}^{2N} \partial_{\psi_i} Y_j \cdot \partial_{Y_j} H(Y) \mathrm{d}\boldsymbol{\psi} = 0$ and $\int \sum_{j=1}^{2N} \partial_{\psi_i} Y_j \cdot (E\Delta Y)_j \, \mathrm{d}\boldsymbol{\psi} = 0$ are identities *for all periodic functions* $Y(\boldsymbol{\psi})$.

Then $0 \equiv \int \Sigma_j \partial_{\psi_i} Y_j \cdot ((E\Delta Y)_j + \partial_{Y_j} H(Y)) \mathrm{d}\boldsymbol{\psi}$ and $\dot{Y} = E\partial_Y H(Y) + O(\eta^k)$ imply (note that Y has degree $< k$ in η) $\int \partial_{\psi_i} Y_j^{(0)} \cdot [\partial_{Y_j} H(Y)]^{(k)} \mathrm{d}\boldsymbol{\psi} = \mathbf{0}$, i.e., $\int [\partial_{\boldsymbol{\alpha}} H(Y)]^{(k)} \, \mathrm{d}\boldsymbol{\psi} = \mathbf{0}$ or

$$\left[\partial_{\boldsymbol{\alpha}} f \left(\sum_{h=0}^{k-1} \eta^h (X^{(h)} + \xi^{(h)}) \right) \right]_{\mathbf{0}}^{(k-k_0)} = \mathbf{0}, \tag{2.5}$$

which is the first of the compatibility conditions (2.3). This leaves $\mathbf{a}_{\mathbf{0}}^{(k)}$ as an arbitrary parameter: we can set $\mathbf{a}_{\mathbf{0}}^{(k)} = \mathbf{0}$. We also remark that, if $I \equiv (\mathbf{A}, B)$, the last two of the four equations in (2.3) have the form

$$(E\partial)_{\varphi} \partial_I H_0(\mathbf{0}, 0) I_{\mathbf{0}}^{(k)} + F^{(k)}(\{X^{(h)}, \xi^{(h)}\}_{0 \leqslant h \leqslant k-1}) = 0. \tag{2.6}$$

By assumption (b) in Sec. I, $\partial_I^2 H_0(\mathbf{0}, 0) \equiv (E\partial)_{\varphi} \partial_I H_0(\mathbf{0}, 0)$ is invertible; hence to impose the last two compatibility conditions in (2.3), it suffices to fix $I_{\mathbf{0}}^{(k)} = -[\partial_I^2 H_0(\mathbf{0}, 0)]^{-1} F^{(k)}(\{X^{(h)}, \xi^{(h)}\}_{0 \leqslant h \leqslant k-1})$, which is a known function of $\{X^{(h)}, \xi^{(h)}\}_{0 \leqslant h \leqslant k-1}$, for any possible choice of the functions $\{\xi^{(h)}\}_{0 \leqslant h \leqslant k-1}$.

So, to fulfill the compatibility conditions (2.3) and to continue the inductive construction of $X^{(k)}, \xi^{(k)}$, we are left with imposing the second of (2.3), which can only hold if β_{k-2k_0+1} satisfies certain compatibility properties. In fact if $k < 2k_0$ there is no requirement because the necessary condition that $[\partial_{\beta} f]_0^{(k-k_0)} = 0$ is automatically satisfied by assumption (c).

For $k = 2k_0$ the condition $[\partial_{\beta} f]_{\mathbf{0}}^{(k_0)} = 0$ can be expressed as follows. Let $c := (1/k_0!) \partial_{\beta}^{k_0+1} f_{\mathbf{0}}(\mathbf{0}, 0, \beta_0)$ and remark that with the notations leading to (1.8) it is $X^{(k_0)} \equiv \sigma X'$: then the second of (2.3) becomes

$$\left[\partial_{\beta X} f(X^{(0)}) \cdot X^{(k_0)} + \frac{1}{k_0!} \partial_\beta^{k_0+1} f(X^{(0)})(\beta_1)^{k_0} \right]_{\mathbf{0}} \equiv \sigma a + c\beta_1^{k_0} = 0, \tag{2.7}$$

which means

$$\beta_1 = \begin{cases} (-a\sigma/c)^{1/k_0} & \text{if } k_0 \text{ is odd,} \\ \pm(-a\sigma/c)^{1/k_0} & \text{if } k_0 \text{ is even and } a\sigma c < 0, \end{cases} \tag{2.8}$$

which is the compatibility condition to which β_1 must be subject.

For $k > 2k_0$ the second of (2.3) only involves a sum of quantities depending on $X^{(h)}$ with $h \leqslant k-k_0$ and on $\xi^{(h)}$ with $h \leqslant k-2k_0$ *with the exception of a single term*, proportional to $ck_0\beta_1^{k_0-1}\beta_{k-2k_0+1}$, involving $\xi^{(k-2k_0+1)}$. Therefore the second compatibility condition in (2.3) can be fulfilled by properly fixing β_{k-2k_0+1} in terms of $X^{(h)}$ with $h \leqslant k-k_0$ and of $\xi^{(h)}$ with $h \leqslant k-2k_0$, *provided* β_1 *exists and* $\beta_1 \neq 0$, i.e. *provided* $a \neq 0$ as assumed here.

This means that if k_0 is odd all β_k are uniquely determined while if k_0 is even there are two possible sequences β_k depending on the two choices for β_1 in (2.8). ■

Remarks: (1) For k_0 even the choice of β_k will be possible only if ε has sign σ such that $-\sigma a/c > 0$.

(2) With the notation (2.1) one has $X_{\mathbf{0}}^{(k)} = (\mathbf{A}_{\mathbf{0}}^{(k)}, B_{\mathbf{0}}^{(k)}, \mathbf{0}, 0)$ as $\mathbf{a}_{\mathbf{0}}^{(k)} = \mathbf{0}$ and $b_{\mathbf{0}}^{(k)} = \xi^{(k)}$.

III. TREE FORMALISM AND FORMAL SERIES

Given that the formal Lindstedt series is well defined, by proceeding as in Ref. 8 a graphical representation of the contributions to the perturbative series will be introduced. The idea to get the rules explained below is to start by representing the rhs of (2.2) as a power series in η by simply expanding the functions $\partial_\varphi f, \partial_I H$ in their arguments around $X^{(0)}(\boldsymbol{\psi})$ and then each argument again in powers until one obtains a power series in η.

Since the arguments of f depend on the $X^{(h)}$ with $h < k$ we obtain recursively a natural representation in terms of trees. Consider $(X_{\boldsymbol{\nu}}^{(k)})_\gamma$ where γ ranges in the symbols list

$$\mathcal{A} := \{A_1, \cdots, A_{N-1}, B, \alpha_1, \cdots, \alpha_{N-1}, \beta\}. \tag{3.1}$$

This notation is more convenient than the alternative one which would simply label the components with a label $\gamma = 1, 2, \ldots, N, N+1, \ldots, 2N$ because the first $N-1$ components play a very different role than the Nth or the remaining ones. It can be disturbing as the labels in (3.1) have the meaning of canonical variables when they do not appear as labels: hence the reader should keep this in mind in what follows. Occasionally, only in cases of possible confusion, we shall use the labels $1, \ldots, 2N$ instead of (3.1).

It will be convenient to call the first N labels *action components* and the last N *angle components;* the first $N-1$ of the two groups will be called, respectively, *fast actions* and *fast angles* component labels while the last will be called a *slow action* or, respectively, *slow angle* component label. When, occasionally, it will turn out to be useful, we shall denote the N action labels simply by I and the angle labels by φ. If $\gamma \in \mathcal{A}$ and γ is one of the first N labels (i.e., it is an action component), then $\gamma+N$ will indicate the corresponding label of the angle components and vice versa if $\gamma \in \mathcal{A}$ is an angle component then $\gamma-N$ will denote the corresponding label in the group of action components. With a slight abuse of notation, given $\gamma \in \mathcal{A}$, we shall write $\gamma \in I$ if γ is an action component and $\gamma \in \varphi$ if it is an angle component. If $\gamma, \gamma' \in \mathcal{A}$ then $\delta_{\gamma\gamma'}$ denotes the Kronecker delta; we shall also use the notation

$$\delta_{\gamma\varphi} = \begin{cases} 1 & \text{if } \gamma \in \varphi, \\ 0 & \text{if } \gamma \in I, \end{cases} \qquad \delta_{\gamma I} = \begin{cases} 1 & \text{if } \gamma \in I, \\ 0 & \text{if } \gamma \in \varphi. \end{cases} \tag{3.2}$$

Looking at (2.2) we see that, for $\boldsymbol{\nu} \neq \mathbf{0}$ and $k \geqslant k_0$, we can write it as

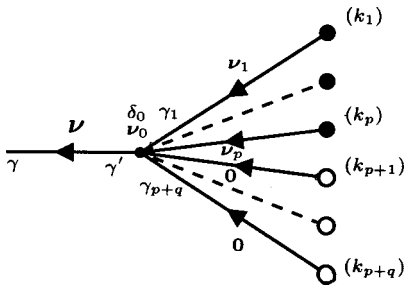

FIG. 1. Graphical representation of Eqs. (3.3) and (3.4). For $\boldsymbol{\nu}\neq\mathbf{0}$ the graph represents (3.3), while for $\boldsymbol{\nu}=\mathbf{0}$ it represents (3.4).

$$(X^{(k)}_{\boldsymbol{\nu}})_\gamma=\frac{\delta_{\gamma\gamma'}}{i\boldsymbol{\omega}\cdot\boldsymbol{\nu}}\Bigg[\sigma\sum_{p\geqslant 1}\sum_{\substack{\boldsymbol{\nu}_0+\boldsymbol{\nu}_1+\cdots+\boldsymbol{\nu}_p=\boldsymbol{\nu}\\ k_1+\cdots+k_p=k-k_0}}\frac{1}{p!}(E\partial)_{\gamma'}\partial_{\gamma_1\cdots\gamma_p}f_{\boldsymbol{\nu}_0}(\mathbf{0},0,\beta_0)\prod_{n=1}^{p}(X^{(k_n)}_{\boldsymbol{\nu}_n}+\xi^{(k_n)}\delta_{\boldsymbol{\nu}_n\mathbf{0}})_{\gamma_n}$$
$$+\sum_{p\geqslant 1}\sum_{\substack{\boldsymbol{\nu}_1+\cdots+\boldsymbol{\nu}_p=\boldsymbol{\nu}\\ \mathbf{k}_1+\cdots+k_p=k}}\frac{1}{p!}(E\partial)_{\gamma'}\partial_{\gamma_1\cdots\gamma_p}H_0(\mathbf{0},0)\prod_{n=1}^{p}(X^{(k_n)}_{\boldsymbol{\nu}_n})_{\gamma_n}\Bigg]. \tag{3.3}$$

Here the symbols ∂_γ must be interpreted as derivatives of $f_{\boldsymbol{\nu}}$ with respect to action arguments of f if γ is an action component, as derivatives with respect to β if $\gamma=\beta$ and as multiplications by $i\boldsymbol{\nu}_i$ if $\gamma=\alpha_i$, $i=1,\ldots,N-1$. *A summation convention is conveniently adopted for pairs of repeated component labels*. In the second line no $\xi^{(k_n)}$ appears because $\xi^{(h)}$ has only angle components but H_0 does not depend on the angles.

For $\boldsymbol{\nu}=\mathbf{0}$ and $\gamma\in I$ [i.e., γ an action component; cf. Remark (2) at the end of Sec. II], we use (2.6) and write

$$(X^{(k)}_{\mathbf{0}})_\gamma=-(\partial^2_I H_0(\mathbf{0},0)^{-1})_{\gamma,\gamma'-N}\delta_{\gamma'\varphi}\Bigg[\sum_{p=2}^{\infty}\sum_{\substack{k_1+\cdots k_p=k\\ \boldsymbol{\nu}_1+\cdots+\boldsymbol{\nu}_p=\mathbf{0}}}\frac{1}{p!}(E\partial)_{\gamma'}\partial_{\gamma_1\cdots\gamma_p}H_0(\mathbf{0},0)\prod_{n=1}^{p}(X^{(k_n)}_{\boldsymbol{\nu}_n})_{\gamma_n}$$
$$+\sigma\sum_{p=1}^{\infty}\sum_{\substack{k_1+\cdots k_p=k-k_0\\ \boldsymbol{\nu}_0+\boldsymbol{\nu}_1+\cdots+\boldsymbol{\nu}_p=\mathbf{0}}}\frac{1}{p!}(E\partial)_{\gamma'}\partial_{\gamma_1\cdots\gamma_p}f_{\boldsymbol{\nu}_0}(\mathbf{0},0,\beta_0)\prod_{n=1}^{p}(X^{(k_n)}_{\boldsymbol{\nu}_n}+\xi^{(k_n)}\delta_{\boldsymbol{\nu}_n\mathbf{0}})_{\gamma_n}\Bigg]. \tag{3.4}$$

For $\boldsymbol{\nu}=\mathbf{0}$ and γ an angle label the (2.2) are identically satisfied if the $\xi^{(h)}$ are determined as prescribed in Sec. II. The equation that fixes $\xi^{(h)}$ is again a relation of the type of (3.3) and (3.4) as we shall discuss in detail later.

Proceeding as in Refs. 8 and 10 we represent $(X^{(h)}_{\boldsymbol{\nu}})_\gamma$ as γ ◀—— $\boldsymbol{\nu}$ ● (k) and $\xi^{(h)}\equiv(\mathbf{0},0,\mathbf{0},\beta^{(k)})$ as γ ◀—— 0 ○ (k) and we realize that (3.3) and (3.4) can be very conveniently (as it turns out) represented by graphs of the type represented in Fig. 1.

The label $\delta_0=0,1$, that we call the *degree label* of the node to which it is associated, identifies the terms in (3.3) or (3.4) which contain inside the square brackets H_0 (then $\delta_0=0$) or f (then $\delta_0=1$). The other label attached to the first node indicates the harmonic $\boldsymbol{\nu}_0$ (mode label) selected in the terms with f (i.e., with $\delta_0=1$) and we take $\boldsymbol{\nu}_0=\mathbf{0}$ if $\delta_0=0$ (because H_0 does not depend on the angles). A further component label γ' is attached to the right extreme of the line exiting the central node in Fig. 1 and it indicates the derivative $(E\partial)_{\gamma'}$ in (3.3) and (3.4). We call a component label a "right" or "left" component label if it is attached at the beginning or at the end of the (oriented) line.

The component labels attached to the first node determine the components of the tensors defined by the derivatives of $f_{\boldsymbol{\nu}_0}$ or of H_0. The labels attached to the left extreme of each endline (to the right of the bifurcation point in the figure) determine which component of $(X^{(k_n)}_{\boldsymbol{\nu}_n})_{\gamma_n}$ is taken in the products of X's in (3.3) or (3.4). Finally the root line symbolizes the factor that is outside the square brackets in the expression (3.3) or in the expression (3.4): it will be called *propagator* of the line  . Hence the propagator of the line will be the matrix

$$\tilde{g}_{\gamma\gamma'}(\boldsymbol{\nu}) = \begin{cases} (i\boldsymbol{\omega}\cdot\boldsymbol{\nu})^{-1}\delta_{\gamma\gamma'} & \text{if } \boldsymbol{\nu}\neq\mathbf{0}, \\ -(\partial_I^2 H_0(\mathbf{0},0)^{-1})_{\gamma,\gamma'-N}\delta_{\gamma I}\delta_{\gamma'\varphi} & \text{if } \boldsymbol{\nu}=\mathbf{0}, \end{cases} \tag{3.5}$$

and $\boldsymbol{\nu}$ will be called the *momentum* of the line.

Finally the endpoints are divided into endpoints representing $X^{(h)}$ for some h, marked by bullets, and others representing $\xi^{(h)}$ marked by white disks that we shall call *leaves*.

It follows from the analysis of Sec. II that, setting β_1 equal to the constant in (2.8) and replacing $1/(k_0-1)!\partial_\beta^{k_0+1}f_{\mathbf{0}}(\mathbf{0},0,\beta_0)$ with $k_0 c$ by the definition of c before (2.7), the coefficients β_h with $h\geqslant 2$ can be derived in terms of β_1 from the relation

$$\beta_{k-2k_0+1} = \frac{1}{k_0 c\beta_1^{k_0-1}}\sum_{s\geqslant 1}\sum_{\substack{k_1+\cdots+k_s=k-k_0 \\ \boldsymbol{\nu}_0+\boldsymbol{\nu}_1+\cdots+\boldsymbol{\nu}_s=\mathbf{0}}}^{*}\frac{1}{s!}(E\partial)_B\partial_{\gamma_1\cdots\gamma_s}f_{\boldsymbol{\nu}_0}\prod_{m=1}^{s}(X^{(k_m)}_{\boldsymbol{\nu}_m}+\xi^{(k_m)}\delta_{\boldsymbol{\nu}_m\mathbf{0}})_{\gamma_m}, \tag{3.6}$$

where the derivatives of $f_{\boldsymbol{\nu}_0}$ are, as above, evaluated at $(\mathbf{0},0,\beta_0)$ and the $*$ on the sum recalls that we are excluding from the sum the contribution equal to $-k_0 c\beta_1^{k_0-1}\beta_{k-2k_0+1}$.

At this point we can repeat the construction and replace each endpoint of Fig. 1 ending in a node or in a leaf with a node into which merge several lines each of which comes out of a node or a leaf with some labels $(h),\boldsymbol{\nu},\gamma$ representing $(X^{(h)}_{\boldsymbol{\nu}})_\gamma$ for some $h,\boldsymbol{\nu},\gamma$ or, in the case of leaves, $(\xi^{(h)})_\gamma$.

Using also the relations (3.4) and (3.6), the construction can be iterated until we are left with a tree θ whose endpoints either carry a degree label 1 or are leaves representing β_1, we denote by $L(\theta)$ the set of endpoints representing such leaves. The constraint (3.6) can be automatically implied by imagining that the propagator of a line ℓ with momentum $\boldsymbol{\nu}$ is

$$g_{\gamma\gamma'}(\boldsymbol{\nu}) = \begin{cases} (i\boldsymbol{\omega}\cdot\boldsymbol{\nu})^{-1}\delta_{\gamma\gamma'} & \text{if } \boldsymbol{\nu}\neq\mathbf{0}, \\ \delta_{\gamma\gamma'} & \text{if } \boldsymbol{\nu}=\mathbf{0}, \quad \mathfrak{v}\in L(\theta), \\ -(\partial_I^2 H_0(\mathbf{0},0)^{-1})_{\gamma,\gamma'-N}\delta_{\gamma I}\delta_{\gamma'\varphi}+\dfrac{\delta_{\gamma\beta}\delta_{\gamma' B}}{\sigma\eta^{2k_0-1}k_0 c\beta_1^{k_0-1}} & \text{if } \boldsymbol{\nu}=\mathbf{0}, \quad \mathfrak{v}\notin L(\theta), \end{cases} \tag{3.7}$$

where $\mathfrak{v}$ is the node preceding ℓ on τ. We can write $(X_{\boldsymbol{\nu}})_\gamma$ as a formal power series in η, whose terms can be computed in terms of tree values. Let a tree θ be a tree diagram with nodes which look like the node drawn in Fig. 1 and let $V(\theta)$, $L(\theta)$, and $\Lambda(\theta)$ denote the sets of nodes, leaves and lines of θ, respectively. The *tree value* $\mathrm{Val}(\theta)$ will be a monomial in η obtained by multiplying

(1) a factor

$$\begin{aligned} [F(\boldsymbol{\nu}_{\mathfrak{v}})]_{\gamma'_{\ell_{\mathfrak{v}}},\boldsymbol{\gamma}(\mathfrak{v})} &= \sigma\eta^{k_0}(E\partial)_{\gamma'_{\ell_{\mathfrak{v}}}}\partial_{\gamma_{\mathfrak{v}1}\ldots\gamma_{\mathfrak{v}p_{\mathfrak{v}}}}f_{\boldsymbol{\nu}_{\mathfrak{v}}}(\mathbf{0},0,\beta_0) \quad \text{if } \delta_{\mathfrak{v}}=1, \\ [F(\boldsymbol{\nu}_{\mathfrak{v}})]_{\gamma'_{\ell_{\mathfrak{v}}},\boldsymbol{\gamma}(\mathfrak{v})} &= (E\partial)_{\gamma'_{\ell_{\mathfrak{v}}}}\partial_{\gamma_{\mathfrak{v}1}\ldots\gamma_{\mathfrak{v}p_{\mathfrak{v}}}}H_0(\mathbf{0},0) \quad \text{if } \delta_{\mathfrak{v}}=0, \end{aligned} \tag{3.8}$$

per each node $\mathfrak{v}\in V(\theta)$ into which merge $p_{\mathfrak{v}}\geqslant 1$ lines carrying component labels $\boldsymbol{\gamma}(\mathfrak{v})=(\gamma_{\mathfrak{v}1}\cdots\gamma_{\mathfrak{v}p_{\mathfrak{v}}})$ and emerges a line $\ell_{\mathfrak{v}}$ carrying a label $\gamma'_{\ell_{\mathfrak{v}}}$;

(2) a factor $\sigma\eta^{k_0}(E\partial)_{\gamma'_{\ell_\mathfrak{v}}} f_{\boldsymbol{\nu}_\mathfrak{v}}(\mathbf{0},0,\beta_0)$ per each endnode $\mathfrak{v}\notin L(\theta)$ (note that necessarily $\delta_\mathfrak{v}=1$); (3) a factor $\eta\beta_1$ per each leaf $\mathfrak{v}\in L(\theta)$ (note that necessarily $\boldsymbol{\nu}_\mathfrak{v}=\mathbf{0}$ and $\gamma_{\ell_\mathfrak{v}}=B$); (4) a factor $g_{\gamma_\ell\gamma'_\ell}(\boldsymbol{\nu})$ per line $\ell\in\Lambda(\theta)$, given by (3.7).

Note that the construction described above and in Sec. II forbids the presence in the tree diagrams of some configurations of nodes. More precisely, calling *trivial* the nodes $\mathfrak{v}$ with $p_\mathfrak{v}=1$ and $\boldsymbol{\nu}_\mathfrak{v}=\mathbf{0}$ and *b-trivial* the nodes $\mathfrak{v}$ with $p_\mathfrak{v}=k_0$, $\boldsymbol{\nu}_\mathfrak{v}=\mathbf{0}$, $\gamma'_{\ell_\mathfrak{v}}=B$ and immediately preceded by at least k_0-1 leaves, the following configurations of nodes:

(i) *trivial nodes with* $\delta_\mathfrak{v}=0$ *and the entering line with* $\mathbf{0}$ *momentum* and
(ii) *b-trivial nodes with the exiting line with* $\mathbf{0}$ *momentum and all the entering lines with left component labels equal to* β.

are not allowed, in the sense that $\mathrm{Val}(\theta)=0$ if θ contains such configurations of nodes. The reason why the trees containing such configurations of nodes are forbidden is a consequence of the use of the relations (3.4) and (3.6). Trees with no forbidden node will be called *allowed trees*

The result is that the perturbed motion runs on a $(n-1)$-dimensional torus whose equations are formally written as a sum of values of (allowed) tree diagrams, computable by using rules very similar to those listed in Ref. 10, with the value of an allowed tree θ defined as

$$\mathrm{Val}(\theta)=\frac{1}{|\Lambda(\theta)|!}\Big(\prod_{\mathfrak{v}\in V(\theta)}\varepsilon^{\delta_\mathfrak{v}}\Big)(\eta\beta_1)^{|L(\theta)|}\Big(\prod_{\mathfrak{v}\in V(\theta)}F_\mathfrak{v}\Big)\Big(\prod_{\ell\in\Lambda(\theta)}G_\ell\Big),\tag{3.9}$$

where $G_\ell:=g_{\gamma_\ell\gamma'_\ell}(\boldsymbol{\nu}_\ell)$ with $\boldsymbol{\nu}_\ell=\boldsymbol{\nu}_{\ell_\mathfrak{v}}=\Sigma_{\mathfrak{w}\preceq\mathfrak{v}}\boldsymbol{\nu}_\mathfrak{v}$, while $F_\mathfrak{v}$ is the node factor (a tensor) defined in items (1) and (2) above. In the product all the labels are summed over, except for the root label γ_{ℓ_0}, where ℓ_0 is the line entering the root. We call $\Theta^o_{k,\boldsymbol{\nu},\gamma}$ the set of trees with *degree* $|L(\theta)|+k_0\Sigma_{\mathfrak{v}\in V(\theta)}\delta_\mathfrak{v}-(2k_0-1)\Sigma_{\ell\in\Lambda(\theta)}\delta_{\boldsymbol{\nu}_\ell 0}\delta_{\gamma_\ell\beta}\delta_{\gamma'_\ell B}=k$, $\boldsymbol{\nu}_{\ell_0}=\boldsymbol{\nu}$ and $\gamma_{\ell_0}=\gamma$ (these are trees whose value is proportional to η^k). As in Ref. 15, we denote by $\Theta_{k,\boldsymbol{\nu},\gamma}$ the set of trees with k nodes, and with labels $\boldsymbol{\nu}_{\ell_0}=\boldsymbol{\nu}$ and $\gamma_{\ell_0}=\gamma$ associated with the root line.

The definitions above are given so that the formal series for X_γ is given by the sum

$$X^{(0)}_\gamma+\sum_{\boldsymbol{\nu}\in\mathbb{Z}^{N-1}}e^{i\boldsymbol{\nu}\cdot(\boldsymbol{\psi}+\boldsymbol{\omega}t)}\sum_{k=1}^{\infty}\sum_{\theta\in\Theta_{k,\boldsymbol{\nu},\gamma}}\mathrm{Val}(\theta).\tag{3.10}$$

The above rules give, order by order in powers of η, the solution of the perturbed equations of motion. In particular one can check that the trees contributing a monomial in η of degree $k\geq 1$ to the conjugating function have a number of lines that is bounded above and below proportionally to k. This is a property extensively used in the convergence analysis, for instance to show that the number of non-numbered trees of degree k is bounded by a constant to the power k; cf. Ref. 15 for details. An explicit bound is $\geq k/k_0$ and $\leq 3k_0k$, see Appendix C.

IV. ELIMINATION OF THE TRIVIAL NODES

The problem of proving convergence of the series just defined is very similar to that treated in Ref. 15. As in Ref. 15 the difficulty is that even exploiting the cancellations analogous to those of the maximal tori case, we are left with tree graphs containing chains of subdiagrams with one entering and one exiting lines, carrying the same momentum, that we call "self-energy (sub)diagrams." Naively such subdiagrams are the source of bad bounds on the kth the contribution proportional to η^k to the series. Proceeding as in in Ref. 15 we iteratively resum such chains into "renormalized propagators" and change step by step the structure of the perturbation series. At each step we define different rules to compute the tree values: we assign at each line ℓ a scale label $[n_\ell]$, with $n_\ell\geq -1$, depending on the size of its propagators, and, at the nth step ($n=0,1,\ldots$), we will not allow trees containing chains of self-energy diagrams on scale $\geq n-1$; at the same time we will assign to each line a propagator different from that in (3.7), depending on the value of its scale label, as explained below.

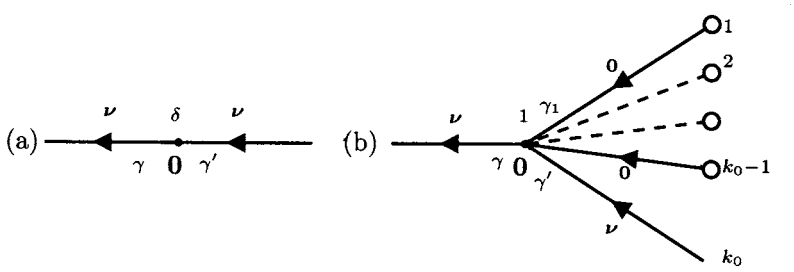

FIG. 2. Examples of lowest order self-energy clusters on scale $[-1]$. In (a) one has $\gamma=B$ and $\gamma' \in I$ or vice versa, while in (b) one has $\gamma=B$ and $\gamma'=\beta$. The order label δ in the first graph can be $\delta=0,1$. The leaves in the second graph represent factors β_1 so that they contribute to the order of the self-energy cluster with a power η^{k_0-1}.

The first step is the removal of the trivial nodes and of a class of few other subgraphs that can be present in *allowed trees*, see Sec. III, whose value is not 0. Assign, in a way similar to that described in Ref. 15, a scale label $[-1]$ to the $\mathbf{0}$-momentum propagator and let $\mathcal{S}^{\mathcal{R}}_{k,-1}$ be the set of self-energy clusters T on scale $[-1]$ and degree k (i.e. such that $k=|L(T)|+\Sigma_{\mathfrak{v}\in V(T)}\delta_{\mathfrak{v}}k_0-(2k_0-1)\Sigma_{\ell\in\Lambda(T)}\delta_{\boldsymbol{\nu}_\ell\mathbf{0}}\delta_{\gamma_\ell\beta}\delta_{\gamma'_\ell B}$), consistently with the notion of degree defined after (3.9).

A *cluster on scale* $[-1]$ is either a single node or a maximal connected set of nodes and lines, such that all the lines are on scale $[-1]$; the lines of nonzero momentum that enter or exit the nodes of the cluster are called *external lines*. A *self-energy cluster on scale* $[-1]$ is defined as a cluster on scale $[-1]$ such that there are only two external lines (one exiting and one entering), and they are connected to the same node of the cluster. This means that a self-energy cluster is formed by a node $\mathfrak{v}$ with $\mathbf{0}$-mode together with all lines (if any) of momentum $\mathbf{0}$, hence on scale $[-1]$, which are linked to $\mathfrak{v}$ by a path consisting of lines of momentum $\mathbf{0}$; see Fig. 2. *A cluster on scale* $[-1]$ *with only one exiting and one entering line, which are not connected to the same node, will not be considered a self-energy cluster on scale* $[-1]$.

The self-energy value, i.e., the value $\mathcal{V}_T(\eta)$ of the self-energy cluster T on scale $[-1]$, is defined, similarly to (3.9), as

$$\mathcal{V}_T(\eta)=\frac{1}{|\Lambda(T)|!}\Big(\prod_{\mathfrak{v}\in V(T)}\varepsilon^{\delta_{\mathfrak{v}}}\Big)(\eta\beta_1)^{|L(T)|}\Big(\prod_{\mathfrak{v}\in V(T)}F_{\mathfrak{v}}\Big)\Big(\prod_{\mathfrak{v}\in\Lambda(T)}G_\ell\Big), \tag{4.1}$$

where $V(T)$, $L(T)$, and $\Lambda(T)$ are the set of nodes, leaves, and lines, respectively, contained inside T. Then we can define

$$\mathcal{M}^{[0]}(\eta)=\sum_{k=k_0}^{\infty}\sum_{T\in\mathcal{S}^{\mathcal{R}}_{k,-1}}\mathcal{V}_T(\eta), \tag{4.2}$$

where the sum runs over all the self-energy clusters on scale $[-1]$.

Remarks: (1) The clusters T in (4.1) and (4.2) with $k=k_0$ correspond to the trivial nodes appearing in the tree expansion of the preceding section. In the next section the general notion of cluster will be introduced.

(2) The clusters on scale $[-1]$ must contain only lines on scale $[-1]$ and there are infinitely many of them and (4.2) can be illustrated by the two clusters in Fig. 2. The self-energy values $\mathcal{V}_T(\eta)$ corresponding to the graphs in Fig. 2 give the lowest order (in powers of η) contributions to different entries of the matrix $\mathcal{M}^{[0]}$, as discussed in the caption of Fig. 2.

(3) Unlike the case in Ref. [15], Eq. (4.1), defining the matrix $\mathcal{M}^{[0]}(\eta)$, is really an infinite series; but it is still convergent, if η is sufficiently small. Convergence of the series defining $\mathcal{M}^{[0]}$ is a straightforward consequence of the fact that a self-energy cluster of degree k has a number of lines bounded by constant times k, see Appendix C, and of the fact that the propagators of the lines

with **0**-momentum can be bounded by an $O(1)$ constant if the line is preceded by a leaf or if $\gamma = I_i, \gamma' = \varphi_j$ and can be bounded by an $O(1)$ constant times η^{-2k_0+1} if the line is not preceded by a leaf and $\gamma = \beta, \gamma' = B$.

By construction, $\mathcal{M}^{[0]}(\eta)$ is real and has the following special structure:

$$\mathcal{M}^{[0]}(\eta) = \sum_{k=k_0}^{\infty} \sum_{T \in \mathcal{S}^{\mathcal{R}}_{k,-1}} \mathcal{V}_T = \begin{pmatrix} Q & R \\ P & -Q^\dagger \end{pmatrix}, \tag{4.3}$$

where the superscript dagger denotes Hermitian conjugation and P, Q, R are $N \times N$ matrices which to lowest order in η have the form [with a natural meaning of the symbols, in agreement with our convention on the component labels (3.1)]

$$P = \partial_I^2 H_0 + \varepsilon \partial_I^2 f_{\mathbf{0}}, \quad Q = \begin{pmatrix} 0 \\ -\varepsilon \partial_{\beta I} f_{\mathbf{0}} \end{pmatrix}, \quad R = \begin{pmatrix} 0 & 0 \\ 0 & -\dfrac{\varepsilon \eta^{k_0-1}}{(k_0-1)!} \partial_\beta^{k_0+1} f_{\mathbf{0}} \beta_1^{k_0-1} \end{pmatrix}, \tag{4.4}$$

where $f_{\mathbf{0}}$ has $(\mathbf{0}, 0, \beta_0)$ as arguments. The complete expression, including the higher orders in η, simply replaces the *nonzero* terms in (4.4) by convergent series that we can write

$$P = \partial_I^2 H_0 + \varepsilon \bar{M}_{II}, \quad Q = \begin{pmatrix} 0 \\ -\varepsilon \bar{M}_{\beta I} \end{pmatrix}, \quad R = \begin{pmatrix} 0 & 0 \\ 0 & -\varepsilon \eta^{k_0-1} \bar{M}_{\beta\beta} \end{pmatrix}, \tag{4.5}$$

where the entries $\bar{M}_{\gamma\gamma'}(\eta)$ are bounded uniformly in η, for η small enough. They can be computed order by order using the rules of the last section. *The vanishing entries of the matrix* $\mathcal{M}^{[0]}(\eta)$ *remain zero to all orders*: a property which simply follows from the definition of value of a self-energy cluster and from the remark that a derivative ∂_γ with $\gamma = \boldsymbol{\alpha}$ acting on f_0 must be interpreted as a multiplication by **0**. Note that, since P, Q, R are real and P, R are symmetric, $\mathcal{M}^{[0]}(\eta)$ satisfies the following symmetry properties:

$$E\mathcal{M}^{[0]}(\eta)E = [\mathcal{M}^{[0]}(\eta)]^T, \quad [\mathcal{M}^{[0]}(\eta)]^* = \mathcal{M}^{[0]}(\eta), \tag{4.6}$$

where $*$ denotes complex conjugation and T transposition. A consequence of (4.6) is that $\mathcal{M}^{[0]}E$ is Hermitian.

Now, we formally resum the chains of self-energy clusters on scale $[-1]$ into the new propagator

$$g^{[\geqslant 0]}(x; \eta) = \frac{1}{ix - \mathcal{M}^{[0]}(\eta)}, \tag{4.7}$$

where $x \neq 0$. This means that we modify the tree expansion described in the preceding section, the new expansion will involve only trees not containing self-energy graphs on scale $[-1]$ (and in particular containing neither trivial nor b-trivial nodes) and with the propagator of the lines with nonzero momentum replaced by (4.7). It is not clear at all that the new resummed series is well defined, on the contrary it will become clear that it is affected by divergence problems similar to those of the original series. In some sense, we just eliminated a few of the possible source of problems (that are actually an infinite class of divergent subdiagrams). However, the idea is to begin by eliminating this first few sources of problems and then, step by step, iteratively eliminate one after the other all possible sources of problems (first the less "dangerous" and then the more and more dangerous ones).

Certainly we must at least suppose that $ix - \mathcal{M}^{[0]}(\eta)$ can be inverted, otherwise the values of the trees representing the new series might even be meaningless. To give a meaning to $(ix - \mathcal{M}^{[0]}(\eta))^{-1}$ it is sufficient to impose $\det(ix - \mathcal{M}^{[0]}(\eta)) \neq 0$ for $x \neq 0$, by eliminating a denumer-

able dense set of values of η. One can compute the determinant of $(ix-\mathcal{M}^{[0]}(\eta))$, finding $\det(ix-\mathcal{M}^{[0]}(\eta))=-(ix)^{2(N-1)}\cdot[x^2+\varepsilon\eta^{k_0-1}\bar{M}_{\beta\beta}(\partial^2_{BB}H_0+\varepsilon\bar{M}_{BB})+\varepsilon^2|\bar{M}_{\beta B}|^2]$, so that the condition of invertibility of $(ix-\mathcal{M}^{[0]}(\eta))$ for $x\neq 0$ becomes

$$x^2+\varepsilon\eta^{k_0-1}\bar{M}_{\beta\beta}(\partial^2_{BB}H_0+\varepsilon\bar{M}_{BB})+\varepsilon^2|\bar{M}_{\beta B}|^2\neq 0 \tag{4.8}$$

for all $x=\boldsymbol{\omega}\cdot\boldsymbol{\nu}$, $\boldsymbol{\nu}\in\mathbb{Z}^{N-1}$. In computing $\det(ix-\mathcal{M}^{[0]}(\eta))$ the property $\bar{M}_{\beta B}=-\bar{M}_{B\beta}\in\mathbb{R}$ has been used.

If η is chosen according to (4.8), we have that the norm of $g^{[\geq 0]}(x;\eta)$ is equal to the eigenvalue of $[ix-\mathcal{M}^{[0]}(\eta)]E$ with smallest absolute value, this is because $\|ix-\mathcal{M}^{[0]}(\eta)\|=\|(ix-\mathcal{M}^{[0]}(\eta))E\|$ and, as remarked after (4.6), $(ix-\mathcal{M}^{[0]}(\eta))E$ is Hermitian. Here and in the following we use the uniform norm, given a $2N\times 2N$ complex matrix g, we define $\|g\|=\sup_{z\in\mathbb{C}^{2N},|z|=1}|gz|$, where $|z|=\Sigma_{i=1}^{2N}|z_i|$.

An approximate computation of the eigenvalues of $[ix-\mathcal{M}^{[0]}(\eta)]E$, see Appendix D, implies the following result.

Lemma 2: *There exists an* $O(1)$ *constant* $\rho>0$ *such that if* $x^2>\rho\eta^{2k_0-1}$ *then the resummed propagator* $g^{[\geq 0]}(x;\eta)$ *in (4.7) can be bounded as*

$$|g^{[\geq 0]}(x;\eta)|\leq\max\left\{\frac{2\mu_N^{(0)}}{x^2},\frac{2}{\mu_1^{(0)}}\right\}, \tag{4.9}$$

where $\mu_1^{(0)}$ *and* $\mu_N^{(0)}$ *are, respectively, the minimum and maximum eigenvalues of* P, *see (4.3) and (4.5).*

From now on we shall proceed following. Ref. [15]. First we assume that $|\varepsilon|$ is in an interval $(\bar{\varepsilon}/4,\bar{\varepsilon}]$ such that, by setting $\bar{\varepsilon}=\bar{\eta}^{k_0}$, we can define the integer n_0 through

$$C_0^2 2^{-2(n_0+1)}<\rho\bar{\varepsilon}\,\bar{\eta}^{k_0-1}\leq C_0^2 2^{-2n_0}, \tag{4.10}$$

with ρ as in Lemma 2.

In the first range of scales (in which $x^2\geq 2C_0^2 2^{-2n_0}$) the small denominators can be bounded by the "classical" small divisor x^2 and we proceed as described in the section "Non-resonant resummations" of Ref. [15].

For smaller scales we shall see below that the small divisor will bounded below by an $O(1)$ constant times $\min\{x^2,|x^2+\varepsilon\eta^{k_0-1}\lambda^{[n]}(x;\varepsilon)|\}$, with $\lambda^{[n]}(x;\varepsilon)$ a suitable $O(1)$ function. However here the distinction between the *hyperbolic* case $[\varepsilon\eta^{k_0-1}\lambda^{[n]}(x;\varepsilon)>0]$ and the *elliptic* one $[\varepsilon\eta^{k_0-1}\lambda^{[n]}(x;\varepsilon)<0]$ must be made, in the hyperbolic case the small divisors will be always bounded by an $O(1)$ constant times x^2, even for $x^2\leq O(\varepsilon\eta^{k_0-1})$, while in the elliptic case we will have to proceed differently, essentially as described in the section "Infrared resummations" of Ref. [15].

V. MULTISCALE ANALYSIS AND NONRESONANT RESUMMATION

The resummations will be defined via trees with no self-energy clusters on scale $[-1]$ and with lines bearing further labels. Moreover the definition of propagator will be changed, hence the values of the trees will be different from the ones in Sec. III, they are constructed recursively as follows.

We introduce a *multiscale decomposition* (see Ref. [15]), we call $\psi(D)$ a C^∞ nondecreasing compact support function defined for $D\geq 0$,

$$\psi(D)=1\quad\text{for } D\geq C_0^2,\quad \psi(D)=0\quad\text{for } D\leq C_0^2/4, \tag{5.1}$$

where C_0 is the Diophantine constant of $\boldsymbol{\omega}$, and let $\chi(D)=1-\psi(D)$. Define also $\psi_n(D)=\psi(2^{2n}D)$ and $\chi_n(D)=\chi(2^{2n}D)$ for all $n\geq 0$. Hence $\psi_0=\psi,\chi_0=\chi$ and

$$1 \equiv \psi_n(D(x)) + \chi_n(D(x)) \quad \text{for all } n \geqslant 0, \tag{5.2}$$

for all choices of the function $D(x) \geqslant 0$, in particular for $D(x) = x^2$, that we shall now use.

A simple way to represent the value of a tree as sum of many terms is to make use of the identity in (5.2). The resummed propagator $g^{[\geqslant 0]}(x;\eta) := (ix - \mathcal{M}^{[0]}(\eta))^{-1}$ of each line with non-zero momentum (hence with $x \neq 0$) is written as

$$g^{[\geqslant 0]}(x;\eta) = \psi_0(x^2) g^{[\geqslant 0]}(x;\eta) + \chi_0(x^2) g^{[\geqslant 0]}(x;\eta) := g^{[0]}(x;\eta) + g^{\{\geqslant 1\}}(x;\eta), \tag{5.3}$$

and we note that $g^{[0]}(x;\eta)$ vanishes if x^2 is smaller than $(C_0/2)^2$.

If we replace each $g^{[\geqslant 0]}(x;\eta)$ with the sum in (5.3) then the value of each tree with k nodes is split as a sum of up to 2^k terms which can be identified by affixing on each line with momentum $\boldsymbol{\nu} \neq \mathbf{0}$ a label $[0]$ or $\{\geqslant 1\}$. Further splittings of the tree values can be achieved as follows.

Definition 2 (Propagators): *Let n_0 be an integer, and for $1 \leqslant p < n_0$, give $2N \times 2N$ matrices $\mathcal{M}^{[p]}(x;\eta)$ satisfying the symmetry properties*,

$$E\mathcal{M}^{[p]}(x;\eta)E = [\mathcal{M}^{[p]}(-x;\eta)]^T, \quad [\mathcal{M}^{[p]}(x;\eta)]^* = \mathcal{M}^{[p]}(-x;\eta). \tag{5.4}$$

Let $\mathcal{M}^{[0]}(x;\eta) \equiv \mathcal{M}^{[0]}(\eta)$ and $\mathcal{M}^{[\leqslant n]}(x;\eta) = \Sigma_{p=0}^{n} \mathcal{M}^{[p]}(x;\eta)$. Define for $n_0 \geqslant n \geqslant 1$ the propagators

$$g^{[n-1]}(x;\eta) := \frac{\psi_n(x^2) \prod_{m=0}^{n-1} \chi_m(x^2)}{ix - \mathcal{M}^{[\leqslant n-1]}(x;\eta)},$$

$$g^{\{\geqslant n\}}(x;\eta) := \frac{\prod_{m=0}^{n-1} \chi_m(x^2)}{ix - \mathcal{M}^{[\leqslant n-1]}(x;\eta)},$$

$$g^{[\geqslant n]}(x;\eta) := \frac{\prod_{m=0}^{n-1} \chi_m(x^2)}{ix - \mathcal{M}^{[\leqslant n]}(x;\eta)}, \tag{5.5}$$

and $g^{[0]}(x;\eta) = \psi_0(x^2)(ix - \mathcal{M}^{[0]}(\eta))^{-1}$. We call the labels $[n], \{\geqslant n\}, [\geqslant n]$ scale labels.

Remarks: (1) The matrices $\mathcal{M}^{[p]}(x;\eta)$ will be defined recursively under the requirement that the functions $(\mathbf{A}, B, \mathbf{a}, b)$ defining the parametric equations (2.1) of the invariant torus will be expressed in terms of trees whose lines carry scale labels indicating that their values are computed with the propagators in (5.5).

(2) To have the propagators in (5.5) well defined, we must eliminate for each value of p a denumerable set of ε's, by imposing that $(ix - \mathcal{M}^{[\leqslant p]}(x;\eta))$ be invertible, in analogy with (4.8).

(3) So far n_0 can be any integer number. It will be fixed as prescribed after Lemma 2, in such a way that a bound like (4.9) will hold for all propagators $g^{[p]}$ with $p < n_0$.

To define recursively the matrices we introduce the notions of clusters and of self-energy clusters of a tree whose lines and nodes carry the same labels introduced so far and *in addition* each line carries a scale label which can be either $[-1]$, if the momentum of the line is zero, or $[p]$, with $0 \leqslant p < n_0$, or $[\geqslant n_0]$, with n_0 the same integer appearing in the statement of Definition 2 (still to be suitably fixed). Given a tree θ decorated in this way we give the following definition, for $n < n_0$.

Definition 3 (clusters): *(i) A cluster T on scale $[n]$, with $0 \leqslant n$, is a maximal set of nodes and lines connecting them with propagators on scales $[p]$, $p \leqslant n$, one of which, at least, on scale exactly $[n]$. We denote with $V(T)$, $L(T)$,* and $\Lambda(T)$ *the set of nodes, the set of leaves and the set of lines, respectively, contained in T. The number of nodes in T will be denoted by k_T.*

(ii) The $m_T \geqslant 0$ lines entering the cluster T and the possible line coming out of it (unique if existing at all) are called the external lines *of the cluster T.*

(iii) Given a cluster T on scale $[n]$, we shall call $n_T = n$ its scale.

Remarks: (1) The clusters on scale $[-1]$ were defined before (4.1), they can contain either only

lines with scale $[-1]$ or no line at all (i.e., they can contain just a single node).

(2) Here $n<n_0$. However the definition above is given in such a way that it will extend unchanged when also scales equal to or larger than n_0 will be introduced.

(3) The clusters of a tree can be regarded as sets of lines hierarchically ordered by inclusion and have hierarchically ordered scales.

(4) A cluster T is not a tree (in our sense); however we can uniquely associate a tree with it by adding the entering and the exiting lines and by imagining that the lower extreme of the exiting line is the root and that the highest extremes of the entering lines are nodes carrying a mode label equal to the momentum flowing into them (cf. Ref. [15], Fig. 3).

Definition 4 (self-energy clusters): A self-energy cluster *on scale* $[n]$, *with* $n\geqslant 0$, *of a tree* θ *will be any cluster* T *on scale* $[n]$ *with the following properties:*

(i) *T has only one entering line ℓ_T^2 and one exiting line ℓ_T^1;*
(ii) $\Sigma_{\mathbf{v}\in V(T)}\boldsymbol{\nu}_{\mathfrak{v}}=\mathbf{0}$;
(iii) *there is no line on scale $[-1]$ along the path connecting ℓ_T^2 to ℓ_T^1.*

We call k_T the number of nodes in $V(T)$.

Remarks: (1) The essential property of a self-energy cluster is that it has necessarily just one entering line and one exiting line, and both have *equal momentum* (because $\Sigma_{\mathfrak{v}\in V(T)}\nu_{\mathfrak{v}}=\mathbf{0}$). Note that both scales of the external lines of a self-energy cluster T are strictly larger than the scale of T regarded as a cluster, but they can be different from each other by just one unit.

(2) The self-energy clusters on scale $[-1]$ were defined before (4.1).

(3) For $n\geqslant 0$, the number of nodes of any self-energy cluster on scale $[n]$ is $\geqslant 2$, and the corresponding degree is $\geqslant 2k_0$. This can be seen as follows. Call T_0 the connected subset of T containing no line on scale $[-1]$ and containing the two nodes to which the external lines are attached. Then T_0 must have at least two nodes with $\delta=1$, and $T\backslash T_0$ is the union of subtrees with positive degree.

(4) The clusters which satisfy properties (i) and (ii), but not (iii) are not considered self-energy clusters. The same happened for the self-energy clusters on scale $[-1]$. The reason for such a definition is that the cancellation mechanisms that will imply the bounds needed on the derivatives of the self-energy values (see next definition and Lemma 3 below) can be derived only under such an extra condition. On the other hand, the clusters which verify only the first two properties, but contain lines on scale $[-1]$ along the path connecting the external lines, require no resummation, and can be dealt with in the same way as the other clusters which are not self-energy clusters. We note that in Ref. [15] property (iii) was explicitly required only for self-energy clusters on scale $[-1]$ but it was not mentioned any more for the others, the proofs in Ref. [15] however, implicitly used property (iii) also for the self-energy clusters on scale >-1.

Definition 5 (renormalized trees): Let $\Theta^{\mathcal{R}}_{k,\boldsymbol{\nu},\gamma}$ *be the set of trees with degree k [see comments after (3.9)], root line momentum* $\boldsymbol{\nu}$ *and root label* γ *which contain no self-energy clusters. Such trees will be called* renormalized trees.

Definition 6 (self-energy matrices): *(i) We denote with $\mathcal{S}^{\mathcal{R}}_{k,n}$ the set of self-energy clusters with degree k and scale $[n]$ which do not contain other self-energy clusters; we call them* renormalized self-energy clusters *on scale n.*

(ii) Given a self-energy cluster $T\in\mathcal{S}^{\mathcal{R}}_{k,n}$ we shall define the self-energy value *of T as the matrix*[1]

$$\mathcal{V}_T(\boldsymbol{\omega}\cdot\boldsymbol{\nu};\eta)=\frac{1}{|\Lambda(T)|!}\Big(\prod_{\mathfrak{v}\in V(T)}\varepsilon^{\delta_{\mathfrak{v}}}\Big)(\eta\beta_1)^{|L(T)|}\Big(\prod_{\mathfrak{v}\in V(T)}F_{\mathfrak{v}}\Big)\Big(\prod_{\ell\in\Lambda(T)}g_\ell^{[n_\ell]}\Big),\tag{5.6}$$

where $g_\ell^{[n_\ell]}=g^{[n_\ell]}(\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell;\eta)$. Note that, necessarily, $n_\ell\leqslant n$. The k_T-1 lines of the self-energy cluster T will be imagined as distinct and to carry a number label ranging in $\{1,\dots,k_T-1\}$.

[1]This is a matrix because the self-energy cluster inherits the labels γ,γ' attached to the endnote of the entering line and to the initial node of the existing line

(iii) The self-energy matrices $\mathcal{M}^{[n]}(x;\eta)$, $n\geqslant 1$, *will be defined recursively as*

$$\mathcal{M}^{[n]}(x;\eta)=\left(\prod_{p=0}^{n-1}\chi_p(x^2)\right)\sum_{k=2k_0}^{\infty}\sum_{T\in\mathcal{S}^{\mathcal{R}}_{k,n-1}}\mathcal{V}_T(x;\eta)\coloneqq\left(\prod_{p=0}^{n-1}\chi_p(x^2)\right)M^{[n]}(x;\eta), \tag{5.7}$$

where the self-energy values are evaluated by means of the propagators on scales $[p]$, *with* $p=-1,0,\ldots,n$.

The definition (5.7) makes sense because we have already defined the propagators on scale $[0]$ and the matrices $\mathcal{M}^{[0]}(x;\eta)\equiv\mathcal{M}^{[0]}(\eta)$ (cf. Definition 2). Of course we must still check that the series converges.

With the above new definitions let $h_{\boldsymbol{\nu},\gamma}$ with $\gamma=\mathbf{A},B,\boldsymbol{\alpha},\beta$ be the values of $A_{\boldsymbol{\nu}},B_{\boldsymbol{\nu}},\mathbf{a}_{\boldsymbol{\nu}},b_{\boldsymbol{\nu}}$. We have the formal identities

$$h_{\boldsymbol{\nu},\gamma}=\sum_{k=1}^{\infty}\sum_{\theta\in\Theta^{\mathcal{R}}_{k,\boldsymbol{\nu},\gamma}}\mathrm{Val}(\theta), \tag{5.8}$$

where we have redefined the *value* of a tree $\theta\in\Theta^{\mathcal{R}}_{k,\boldsymbol{\nu},\gamma}$ as

$$\mathrm{Val}(\theta)=\frac{1}{|\Lambda(\theta)|!}\left(\prod_{\mathfrak{v}\in V(\theta)}\varepsilon^{\delta_{\mathfrak{v}}}\right)(\eta\beta_1)^{|L(T)|}\left(\prod_{\ell\in\Lambda(\theta)}g^{[n_\ell]}(\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell;\eta)\right)\left(\prod_{\mathfrak{v}\in V(\theta)}F_{\mathfrak{v}}\right), \tag{5.9}$$

with $[n_\ell]=[-1],[0],\ldots,[n_0-1],[\geqslant n_0]$. Note that (5.8) is not a power series in η.

The statement in (5.8) is checked to be an identity between formal series (as in the corresponding check in Ref. [15]).

As a first step to bypass the formal level, the series (5.7) defining $M^{[n]}(x;\eta)$ must be shown to be really convergent. This will be true because in the evaluation of $M^{[n]}(x;\eta)$ *the only involved propagators have scales* $[p]$ *with* $p\leqslant n-1$ so that, see the factors $\psi_n(x^2),\chi_n(x^2)$ in (5.5), their denominators not only do not vanish but have controlled sizes that can be bounded below proportionally to x^2 by (4.9), i.e., simply by a constant times $C_0^2|\boldsymbol{\nu}|^{-2\tau_0}$. Using this fact one can actually show that the matrices $M^{[n]}(x;\eta)$ are well defined and satisfy symmetry properties similar to (5.4).

Furthermore *cancellations* similar to the maximal KAM tori cancellations hold even in this case so that $M^{[n]}(x;\eta)$ has a special structure, as described in the following Lemma (see Appendixes E and F for a proof).

Lemma 3: *Let* $\bar{\varepsilon}<\varepsilon_0$ *with* ε_0 *small enough, and* $\varepsilon\in I(\bar{\varepsilon})=(\bar{\varepsilon}/4,\bar{\varepsilon}]$. *Define also* $\bar{\eta}$ *through* $\bar{\varepsilon}=\bar{\eta}^{k_0}$. *If* $1\leqslant n<n_0$, *with* n_0 *defined in (4.10), the following properties hold.*

(i) The series defining the matrices $\mathcal{M}^{[\leqslant n]}(x;\eta)$, $x=\boldsymbol{\omega}\cdot\boldsymbol{\nu}$, *converge and the matrices satisfy the same symmetry properties noted for* $\mathcal{M}^{(0)}$,

$$E\mathcal{M}^{[\leqslant n]}(x;\eta)E=[\mathcal{M}^{[\leqslant n]}(-x;\eta)]^T,\quad[\mathcal{M}^{[\leqslant n]}(x;\eta)]^*=\mathcal{M}^{[\leqslant n]}(-x;\eta), \tag{5.10}$$

where E *is the* $2N\times 2N$ *symplectic matrix (1.4). Hence, by (5.10),* $(ix-\mathcal{M}^{[\leqslant n]})E$ *is Hermitian.*

(ii) The matrix $\mathcal{M}^{[\leqslant n]}(x;\eta)$ *can be written in the form*

$$\begin{pmatrix} Q^{[\leqslant n]}(x;\eta) & R^{[\leqslant n]}(x;\eta)\\ P^{[\leqslant n]}(x;\eta) & -Q^{[\leqslant n]\dagger}(x;\eta)\end{pmatrix}, \tag{5.11}$$

where, if $\chi_{n-1}(x^2)\neq 0$,

$$P^{[\leqslant n]}(x;\eta)=\begin{pmatrix}\partial^2_{\mathbf{AA}}H_0+\varepsilon\bar{M}^{[\leqslant n]}_{\mathbf{AA}}(x;\eta) & \partial^2_{\mathbf{A}B}H_0+\varepsilon\bar{M}^{[\leqslant n]}_{\mathbf{A}B}(x;\eta)\\ \partial^2_{B\mathbf{A}}H_0+\varepsilon\bar{M}^{[\leqslant n]}_{B\mathbf{A}}(x;\eta) & \partial^2_{BB}H_0+\varepsilon\bar{M}^{[\leqslant n]}_{BB}(x;\eta)\end{pmatrix}=[P^{[\leqslant n]}(x;\eta)]^\dagger,$$

$$Q^{[\leqslant n]}(x;\varepsilon)=\begin{pmatrix} ix\varepsilon^2\bar{M}^{[\leqslant n]}_{\boldsymbol{\alpha}\boldsymbol{\Lambda}}(x;\eta) & ix\varepsilon^2\bar{M}^{[\leqslant n]}_{\boldsymbol{\alpha}B}(x;\eta) \\ \varepsilon\bar{M}^{[\leqslant n]}_{\beta\boldsymbol{\Lambda}}(x;\eta) & \varepsilon\bar{M}^{[\leqslant n]}_{\beta B}(x;\eta)\end{pmatrix}, \tag{5.12}$$

$$R^{[\leqslant n]}(x;\varepsilon)=\begin{pmatrix} x^2\varepsilon^2\bar{M}^{[\leqslant n]}_{\boldsymbol{\alpha}\boldsymbol{\alpha}}(x;\eta) & ix\varepsilon^2\bar{M}^{[\leqslant n]}_{\boldsymbol{\alpha}\beta}(x;\eta) \\ -ix\varepsilon^2\bar{M}^{[\leqslant n]}_{\beta\boldsymbol{\alpha}}(x;\eta) & \varepsilon\eta^{k_0-1}\bar{M}^{[\leqslant n]}_{\beta\beta}(x;\eta)\end{pmatrix}=[R^{[\leqslant n]}(x;\eta)]^{\dagger}.$$

(iii) The entries $\bar{M}^{[\leqslant n]}_{\gamma,\gamma'}$ *are such that the corrections* $\bar{M}^{[n]}_{\gamma,\gamma'}(x;\eta)=\bar{M}^{[\leqslant n]}_{\gamma,\gamma'}(x;\eta)-\bar{M}^{[\leqslant n-1]}_{\gamma,\gamma'}(x;\eta)$ *are bounded, uniformly in* x *and* ε *for* ε *small enough, by* $Be^{-\kappa_1 2^{n/\tau}}$ *for* $n<n_0$ *and for suitable* n_0*-independent constants* $B,\kappa_1,\tau>0$; *one can take* $\tau=\tau_0$.

(iv) One has

$$\|\partial_x\mathcal{M}^{[\leqslant n]}(x,\eta)\|\leqslant B\varepsilon^2,\quad \|\partial_\varepsilon[\mathcal{M}^{[\leqslant n]}(x,\eta)-\mathcal{M}^{[0]}(x,\eta)]\|\leqslant B\varepsilon, \tag{5.13}$$

where the derivatives must be interpreted in the sense of Whitney and the constants $B,\kappa_1,\tau>0$ *can be taken the same as in item (iii).*

Remarks: (1) The symmetry property (5.10) is proved in Appendix E. Note that at the first step $\mathcal{M}^{[0]}(x;\eta)$ satisfies it, see (4.6).

(2) The key property in (5.12) is that some entries of $Q^{[\leqslant n]}(x;\eta)$ and $R^{[\leqslant n]}(x;\eta)$ are proportional to x or x^2, this is proved by exploiting cancellations among families of self-energy clusters, as described in detail in Appendix F; note that the single self-energy clusters contributing to $\mathcal{M}^{[\leqslant n]}(x;\eta)$ do not have in general the structure in (5.12) and only their sum has.

A crucial technical point in the proof of Lemma 3 is the fact that, if the scale n_ℓ of a line ℓ is smaller than n_0, as defined in (4.10), then the corresponding propagator admits a bound that is qualitatively the same as (4.9). More precisely the following result holds.

Lemma 4: *Let* $\varepsilon\in(\bar{\varepsilon}/4,\bar{\varepsilon}]$. *The propagator* $g^{[0]}(x;\eta)$ *admits the same bound as* $g^{[\leqslant 0]}(x;\eta)$ *in (4.9). For* $1\leqslant n<n_0$, *with* n_0 *given by (4.10), the propagator on scale* $[n]$ *can be bounded by*

$$|g^{[n]}(x;\eta)|\leqslant\frac{C}{x^2}, \tag{5.14}$$

for some positive constant C.

The proof of Lemma 4 proceeds as that of Lemma 2, in Appendix D, and we do not repeat it here. Once the bound (5.14) is established, the proof of convergence is the same as the one discussed in Appendix A3 of Ref. 15 and we do not repeat it here. Item (ii) of Lemma 3 simply follows from convergence and from the remark that $\mathcal{M}^{[\leqslant n]}(x;\eta)-\mathcal{M}^{[0]}(x;\eta)$ is of order ε^2 [cf. Remark (3) after Definition 4]. The bounds in items (iii) and (iv) of Lemma 3 also follow from the proof of convergence, see Appendix A3 of Ref. 15.

We have therefore constructed a new representation of the formal series for the parametric equations for the invariant torus, in it only trees with lines carrying a scale label $[-1],[0],\ldots,[n_0-1]$ or $[\geqslant n_0]$ and *no self-energy clusters* are present (note that, so far, self-energy clusters may have only scales $[n]$ with $n<n_0$). The above lemma will be the starting block of the construction that follows.

VI. RENORMALIZATION: THE INFRARED RESUMMATION

From the proof of Lemma 2 it is clear that for $x^2\leqslant\rho\eta^{2k_0-1}$ and $n\geqslant n_0$ it will not be possible to bound $g^{[n]}(x;\eta)$ by a constant times x^{-2}.

So, the first problem to face when reaching scales $n\geqslant n_0$ is the computation of the eigenvalues of $(ix-\mathcal{M}^{[\leqslant n]}(x;\eta))E$, in terms of which an estimate of the size of the propagator $g^{[n]}$ can be deduced.

If $\mathcal{M}^{[\leqslant n]}(x;\eta)$ does have the structure in (5.12) then an approximate computation of the eigenvalues of $(ix-\mathcal{M}^{[\leqslant n]})E$ leads to the following Lemma, proved in Appendix G.

Lemma 5: *Let* $n\geqslant n_0$ *and let us assign a matrix* $\mathcal{M}^{[\leqslant n]}(x;\eta)$ *satisfying the properties in (5.12)*

admitting right and left derivatives with respect to x and ε, *bounded as the derivatives in (5.13), and having the structure described by (5.12), with the entries* $\bar{M}^{[\le n]}_{\gamma,\gamma'}(x;\eta)$ *such that the corrections* $\bar{M}^{[n]}_{\gamma,\gamma'}(x;\eta)=\bar{M}^{[\le n]}_{\gamma,\gamma'}(x;\eta)-\bar{M}^{[\le n-1]}_{\gamma,\gamma'}(x;\eta)$ *can be bounded [as in item (iii) of Lemma 3] by* $|\bar{M}^{[n]}_{\gamma,\gamma'}(x;\eta)|\le Be^{-\kappa_1 2^{n/\tau_1}}$, *for suitable constants B,* κ_1, *and* τ_1. *Then the uniform norm of* $(ix-\mathcal{M}^{[\le n]}(x;\eta))$ *can be bounded below by*

$$\|ix-\mathcal{M}^{[\le n]}(x;\eta)\| \ge \frac{1}{4\mu}\min\{x^2,|x^2-\lambda^{[n]}(x;\eta)|\}, \tag{6.1}$$

where $\mu=\mu_N^{(0)}$ *is the largest eigenvalue of* $P^{[0]}$ *and* $\lambda^{[n]}(x;\eta)=\ell^{[n]}(x;\eta)\varepsilon\eta^{k_0-1}$ *is a real function with* $\ell^{[n]}(x;\eta)=ck_0\partial_{BB}^2 H_0\beta_1^{k_0-1}(1+O(\eta))$. *Furthermore* $\lambda^{[n]}(x;\eta)$ *is right and left differentiable in* ε *and x and the derivatives satisfy the following dimensional bounds:*

$$C^{-1}\eta^{k_0-1}\le|\partial_\varepsilon^{\pm}\lambda^{[n]}(x;\eta)|\le C\eta^{k_0-1},\quad |\partial_x^{\pm}\lambda^{[n]}(x;\eta)|\le C\eta^{k_0}, \tag{6.2}$$

for some positive constant C.

Remarks: (1) The bound (6.1) suggests to replace the classical small divisor x^2 used in the preceding sections by the (n-dependent) quantity $\min\{x^2,|x^2-\lambda^{[n]}(x;\eta)|\}$, that is essentially what we shall do below. In particular we shall replace the argument x^2 of the support functions ψ,χ by a quantity $\Delta^{[n]}(x;\eta)$, behaving like $\min\{x^2,|x^2-\lambda^{[n]}(x;\eta)|\}$, which will be the measure of the strength of the resonance for scales larger than n_0. With this choice we shall in general introduce a singularity in the definition of the propagators and self-energy matrices on scales $n\ge n_0$, this is due to the presence of a minimum and of an absolute value in the definition of $\Delta^{[n]}(x;\eta)$. This is ultimately why in (6.2) the right and left derivatives appear, rather than the plain derivatives, as in (5.13) above. This could be avoided by using a smoothed version of the quantity $\Delta^{[n]}(x;\eta)$ introduced below, but we shall not discuss it here.

(2) The bound on the derivatives of $\lambda^{[n]}(x;\eta)$ with respect to ε follows from the expression of $\mathcal{M}^{[0]}(\eta)$, in (4.3)–(4.5), and from the bounds (5.13), which allow to control the corrections. On the contrary the bound on the derivatives of $\lambda^{[n]}(x;\eta)$ with respect to x does not follow directly from (5.13), and it is explained in Appendix G.

Depending on the sign of ε, from now on, the analysis changes qualitatively. If ε is such that $c\varepsilon\beta_1^{k_0-1}<0$ [so that $\lambda^{[n]}(x;\eta)$ in (6.1) is negative], the minimum in (6.1) is always realized by the classical small divisor x^2. This implies that in this range of scales it is possible to proceed in the same way discussed above in Sec. V. We do not repeat the details, and we concentrate on the opposite case, namely ε with the sign such that $\lambda^{[n]}(x;\eta)>0$, which presents new difficulties.

In this case convergence problems can still arise from the propagators $g^{[\ge n_0]}(x;\eta)$, which become uncontrollably large for $x=\boldsymbol{\omega}\cdot\boldsymbol{\nu}$ close to the eigenvalue $\lambda^{[n]}(x;\eta)$ in (6.1).

We introduce a sequence of *self-energies* $\underline{\lambda}^{[n]}(\eta)$, Ref. 15 representing the locations of the singularities of $ix-\mathcal{M}^{[\le n]}(x;\eta)$ and, correspondingly, we introduce a sequence of *propagator divisors* $\Delta^{[n]}(x;\eta)$, which will give a bound for the size of the propagator on scale $n\ge n_0$. Then, we modify the scale decomposition, measuring the strength of the singularity in terms of $\Delta^{[n]}(x;\eta)$ rather than, as done in Sec. V, in terms of the classical small divisor x^2.

The choice of the scale decomposition will be done in such a way that the dimensional bounds for the propagators will be the same as for those with scales $n<n_0$, this will reduce the analysis of the infrared resummations to the same convergence proof discussed in Appendix C of Ref. 15.

We introduce the following definition.

Definition 7 (self-energies and propagator divisors): *Let the function* $\lambda^{[n]}(x;\eta)$ *be as in Lemma 5.*

(i) The sequence of self-energies $\underline{\lambda}^{[n]}(\eta)$ *is defined for* $n\ge n_0$ *by*

$$\underline{\lambda}^{[n]}(\eta):=\lambda^{[n]}(\sqrt{\underline{\lambda}^{[n-1]}(\eta)},\eta),\quad \underline{\lambda}^{[n_0]}(\eta):=\lambda^{[n_0]}(0;\eta), \tag{6.3}$$

provided $\underline{\lambda}^{[n]}(\eta)\ge 0$, $n\ge n_0$.

(ii) The propagator divisors *are defined for* $n\ge n_0$ by

$$\Delta^{[n]}(x;\eta) := \min\{x^2, |x^2 - \underline{\lambda}^{[n]}(\eta)|\}. \tag{6.4}$$

By repeating the analysis of Sec. V we can represent the function $X(\boldsymbol{\psi})$ via sums of values of trees whose lines can carry scale labels $[-1],[0],\dots,[n_0-1],[n_0],[n_0+1],\dots$, and which contain no self-energy clusters (i.e., they are renormalized trees; see Definition 5 in Sec. V). The new propagators will be defined by the same procedure used to eliminate the self-energy clusters on scales $[n]$ with $n \leqslant n_0-1$. However for $n \geqslant n_0$ the scale of a line will be determined in terms of the recursively defined $\Delta^{[n]}(x;\eta)$, (6.4), rather than in terms of x^2, see (5.2).

Set $X_{n_0-1}(x) := \Pi_{m=0}^{n_0-1}\chi_m(x^2)$, $Y_n(x;\eta) := \Pi_{m=n_0}^{n}\chi_m(\Delta^{[m]}(x;\eta))$ for $n \geqslant n_0$ and $Y_{n_0-1} \equiv 1$. The definition of the new propagators will be

$$\begin{aligned} g^{[n_0]} &:= X_{n_0-1}(x)\psi_{n_0}(\Delta^{[n_0]}(x;\eta))(x^2 - \mathcal{M}^{[\leqslant n_0]}(x;\eta))^{-1}, \\ g^{[n_0+1]} &:= X_{n_0-1}(x)\chi_{n_0}(\Delta^{[n_0]}(x;\eta))\psi_{n_0+1}(\Delta^{[n_0+1]}(x;\eta))(x^2 - \mathcal{M}^{[\leqslant n_0+1]}(x;\eta))^{-1}, \\ &\dots, \\ g^{[n]} &:= X_{n_0-1}(x)Y_{n-1}(x;\eta)\psi_n(\Delta^{[n]}(x;\eta))(x^2 - \mathcal{M}^{[\leqslant n]}(x;\eta))^{-1}, \end{aligned} \tag{6.5}$$

and so on, using indefinitely the identity $1 \equiv \psi_n(\Delta^{[n]}(x;\eta)) + \chi_n(\Delta^{[n]}(x;\eta))$ to generate the new propagators.

In this way we obtain a formal representation of $X(\boldsymbol{\psi})$ as a sum of tree values in which only renormalized trees appear and in which each line ℓ carries a *scale label* $[n_\ell]$. This means that we can formally write $X(\psi)$ as in (5.8), with $\mathrm{Val}(\theta)$ defined according to (5.9), but now the scale label $[n_\ell]$ is such that n_ℓ can assume all integer values $\geqslant -1$, and no line carries a scale label like $[\geqslant n]$: *only scale labels* $[n]$ *are possible*.

We can summarize the discussion above in the following definition.

Definition 8 (propagators and self-energy matrices): *Given a sequence of* $2N\times 2N$ *matrices* $\mathcal{M}^{[\leqslant m]}(x;\eta)$, $m \geqslant 1$, *let* $\mathcal{M}^{[n]}(x;\eta) = \mathcal{M}^{[\leqslant n]}(x;\eta) - \mathcal{M}^{[\leqslant n-1]}(x;\eta)$ *with* $\mathcal{M}^{[\leqslant 0]}(x;\eta) \equiv \mathcal{M}^{[0]}(\eta)$ [see (4.2)], *so that* $\mathcal{M}^{[\leqslant n]}(x;\eta) = \Sigma_{m=0}^{n}\mathcal{M}^{[m]}(x;\eta)$. *Setting* $\Delta^{[n]}(x;\eta) \equiv x^2$ *if* $n < n_0$, *define for all* $n \geqslant 0$

$$g^{[n]}(x;\eta) = \frac{\psi_n(\Delta^{[n]}(x;\eta))\prod_{m\geqslant 0}^{n-1}\chi_m(\Delta^{[m]}(x;\eta))}{x^2 - \mathcal{M}^{[\leqslant n]}(x;\eta)}. \tag{6.6}$$

[*for* $n=0$ *this means* $\psi_0(x^2)$ $(ix^2 - \mathcal{M}^{[0]}(\eta))^{-1}$]. *We say that* $g_\ell^{[n]} = g^{[n]}(\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell;\varepsilon)$ *is a propagator on scale* $[n]$. *The matrices* $\mathcal{M}^{[m]}(x;\eta)$ *will be defined as in Sec. V for* $n < n_0$ *and will be defined recursively also for* $n \geqslant n_0$ *in terms of the self-energy clusters* $\mathcal{S}^{\mathcal{R}}_{k,n-1}$ *introduced in Definition 4, Sec. V, setting for* $n > n_0$ *[cf. (5.7)],*

$$\mathcal{M}^{[n]}(x;\eta) = \left(\prod_{m=0}^{n-1}\chi_m(\Delta^{[m]}(x;\eta))\right)\sum_{k=2}^{\infty}\sum_{T\in\mathcal{S}^{\mathcal{R}}_{k,n-1}}\mathcal{V}_T(x;\eta), \tag{6.7}$$

where the self-energy values $\mathcal{V}_T(x;\eta)$ *are evaluated by means of propagators on scales less than* $[n]$. *Note that we have already defined [consistently with (6.7)] the matrices* $\mathcal{M}^{[\leqslant n]}$ *with* $n < n_0$ *and the propagators on scale* $[-1],[0],\dots,[n_0-1]$ *[so that (6.6) defines also* $g^{[n_0]}(x;\eta)$*].*

Of course the above definition makes sense only if the series (6.7) can be shown to be convergent for all n. For this purpose an inductive assumption on the propagators on the scales $[m]$, $0 \leqslant m < n$ is necessary.

Inductive assumption: *Let* n_0 *be fixed as in Lemma 3.*

(i) For $0 \leqslant m \leqslant n-1$ *the matrices* $\mathcal{M}^{[m]}(x;\eta)$ *are defined by convergent series for all* $|\varepsilon| \in I(\bar{\varepsilon}) = [\bar{\varepsilon}/4, \bar{\varepsilon}]$ *and, for all* x, *they satisfy the properties (i) and (iv) of Lemma 3. Moreover they*

can be represented as in (5.11), with $P^{[\leqslant n]}, Q^{[\leqslant n]}, R^{[\leqslant n]}$ *as in (5.12) and the entries* $\bar{M}^{[\leqslant n]}_{\gamma'\gamma}$ *bounded as described after (5.12).*

(ii) There exist $K>0$ *and open sets* $\mathcal{E}^o_m$, $m=0,\dots,n$, *with* $\mathcal{E}^o_m \subset I(\bar{\varepsilon})$, *such that, defining recursively* $\underline{\lambda}^{[m]}(\eta)$ *in terms of* $\underline{\lambda}^{[m-1]}(\eta)$ *for* $m=n_0,\dots,n-1$ *by (i) in Definition 7 above, while setting* $\underline{\lambda}^{[m]}(\eta)\equiv 0$ *for* $m=0,\dots,n_0-1$, *and defining* $\tau_1 := \tau_0(1+\delta_1)+N$, *with* $\delta_1>0$, *one has for* $\varepsilon \notin \mathcal{E}^o_m$,

$$\Gamma^{[m]}(x;\eta) := \left||x| - \sqrt{\underline{\lambda}^{[m]}(\eta)}\right| \geqslant 2^{-m/2}\frac{C_0}{|\boldsymbol{\nu}|^{\tau_1}},$$

$$|\mathcal{E}^o_m| \leqslant K 2^{-m/2}\bar{\varepsilon}\,\bar{\eta}^{\delta_1(k_0-1/2)}, \tag{6.8}$$

with $\bar{\varepsilon}=\bar{\eta}^{k_0}$, *for all* $m\leqslant n-1$ *and all* x.

Remark: As in Ref. 15, a key point is checking that $\Delta^{[n]}(x;\eta)$ can be used to bound below the denominators of the nonvanishing propagators on scale $[n]$. If x has scale $[n]$, with $n\geqslant n_0$, one has

$$\begin{aligned}
|x^2-\lambda^{[n]}(x;\eta)| &\geqslant |x^2-\underline{\lambda}^{[n]}(\eta)| - |\underline{\lambda}^{[n]}(\eta)-\lambda^{[n]}(x;\eta)| \\
&\geqslant \frac{1}{2}|x^2-\underline{\lambda}^{[n]}(\eta)| + 2^{-(n+2)}C_0 - |\lambda^{[n]}(\sqrt{\underline{\lambda}^{[n-1]}(\eta)},\eta)-\lambda^{[n]}(x;\eta)| \\
&\geqslant \frac{1}{2}|x^2-\underline{\lambda}^{[n]}(\eta)| \Rightarrow \|x^2-\mathcal{M}^{[n]}(x,\eta)\| \geqslant \frac{1}{8\mu}\Delta^{[n]}(x;\eta),
\end{aligned} \tag{6.9}$$

having used the lower cutoff $\psi_n(\Delta^{[n]}(x;\eta))$ in the propagator [see (6.5)] to obtain the first two terms in the second line while the upper cutoff $\chi_{n-1}(\Delta^{[n-1]}(x;\eta))$ has been used to obtain positivity of the difference between the second and third terms in the second line, after applying the second inequality in (6.2), so that the last term in the second line of (6.9) can be bounded above proportionally to $\varepsilon 2^{-n}C_0$.

The inequality (6.9) allows us a complete word by word reduction of the proof of the inductive assumption above to the corresponding inductive assumption of Ref. 15. The symbols here and in Ref. 15 have been chosen to coincide so that the analysis in Sec. VI and Appendix A3 of Ref. 15 can be taken over and reinterpreted, with no change, as proofs of the above inductive hypothesis, apart for the check of the measure $\mathcal{E}^0_m$ in (6.8), which in the present case is slightly different from the corresponding computation in Ref. 15. The estimate (6.8) of the measure of $\mathcal{E}^0_m$ is explicitly given in Appendix H.

We can summarize the previous discussion into the following lemma.

Lemma 6: *There is* ε_0 *small enough such that for* $\bar{\varepsilon}<\varepsilon_0$ *and* $\varepsilon \in I(\bar{\varepsilon})$, *if the inductive hypothesis is assumed for* $0\leqslant m\leqslant n-1$ *then it holds for* $m=n$.

The series for $X(\psi)$ is now fully "renormalized" and its terms are well defined for ε in a set $\mathcal{E}$ whose measure is large (near 0). The series is expressed as a sum of renormalized tree values of tree graphs without any self-energy graph. Therefore the series is convergent (by Siegel's lemma); see the corresponding discussion in Appendix A3 of Ref. 15.

In the derivation geometric series with ratio $z>1$ have been considered and the rule $\Sigma_{k=0}^{\infty}z^k = (1-z)^{-1}$ has been repeatedly used, this is not mathematically rigorous and therefore an *a posteriori* check must be made that the function $X(\boldsymbol{\psi})$, via (1.5), actually does satisfy the equations (1.4). The check, however, is a repetition of the corresponding (essentially algebraic) check in Appendix A5 of Ref. 15.

Therefore the proof of Theorem 1 is complete.

VII. CONCLUSIONS

We conclude by mentioning some problems that seem to us of interest.

(1) First we note that the proof of Theorem 1 also provided some information about the analyticity properties in η, hence in ε, of the surviving lower-dimensional tori; cf. Refs. 10 and 15 for further details. As in the quoted papers, it can be interesting to further investigate such properties, and related ones, such as Borel summability.

(2) The uniqueness of the resonant tori appears to be a hard problem. Even a proof of Borel summability would not resolve the problem as there could be solutions which are not Borel summable. Just as in the maximal tori case analyticity is not sufficient to guarantee uniqueness. The very recent Ref. 1 does not settle the question, as it proves uniqueness of the C^∞ diffeomorphism mapping the unperturbed invariant tori which are conserved into those which are explictly constructed, but it does not eliminate the possibility that other nearby quasiperiodic motions with the same rotation vectors exist.

(3) Another open problem concerns the possibility of removing the assumptions we made in this paper. We have been able to do this in several particular cases but we did not find a satisfactory general formulation, for instance can something be said in general in the case in which the average of the perturbation vanishes identically?

(4) Finally, it would be interesting to understand what happens in the case of n-dimensional tori, with n strictly less than $N-1$ (that is in the case of several normal frequencies), by relaxing the assumptions on the perturbing potential with respect the results existing in literature, as done here and in Cheng's paper[2,3] for $n=N-1$. This is a substantially more difficult endeavour with respect to that considered here and in Cheng's quoted papers.

APPENDIX A: HEURISTIC ANALYSIS LEADING TO FRACTIONAL SERIES

Consider the simple case $H(\mathbf{A},B,\boldsymbol{\alpha},\beta)=\boldsymbol{\omega}\cdot\mathbf{A}+\frac{1}{2}(\mathbf{A}^2+B^2)+\varepsilon f(\boldsymbol{\alpha},\beta)$, and let assumptions (a) and (c) in Sec. I be satisfied by f. Let us consider the generating function,

$$\Gamma(\mathbf{A}',B',\boldsymbol{\alpha},\beta)=\boldsymbol{\alpha}\cdot\mathbf{A}'+\beta B'+\varepsilon\Psi_1(\mathbf{A}',B',\boldsymbol{\alpha},\beta)+\varepsilon^2\Psi_2(\mathbf{A}',B',\boldsymbol{\alpha},\beta)+\varepsilon^2\boldsymbol{\alpha}\cdot\boldsymbol{\zeta}+\varepsilon^2\beta\rho, \tag{A1}$$

where, if $\Delta:=\boldsymbol{\omega}\cdot\partial_{\boldsymbol{\alpha}}$,

$$\Psi_1(\mathbf{A}',B',\boldsymbol{\alpha},\beta):=-\Delta^{-1}[1-(\mathbf{A}'\cdot\partial_{\boldsymbol{\alpha}}+B'\partial_\beta)\Delta^{-1}]f_{\neq\mathbf{0}}(\boldsymbol{\alpha},\beta), \tag{A2}$$

and, if $\Phi(\mathbf{A}',B',\boldsymbol{\alpha},\beta)=\frac{1}{2}[(\partial_{\boldsymbol{\alpha}}\Psi_1)^2+(\partial_\beta\Psi_1)^2]$,

$$\begin{aligned}\Psi_2(\mathbf{A}',B',\boldsymbol{\alpha},\beta)&:=-\Delta^{-1}[1-(\mathbf{A}'\cdot\partial_{\boldsymbol{\alpha}}+B'\partial_\beta)\Delta^{-1}]\boldsymbol{\Phi}_{\neq\mathbf{0}}(\mathbf{A}',B',\boldsymbol{\alpha},\beta),\\ \boldsymbol{\zeta}&=-\partial_{\mathbf{A}'}\boldsymbol{\Phi}_{\mathbf{0}}(\mathbf{A}',0,\beta_0)|_{\mathbf{A}'=\mathbf{0}},\quad \rho=-\partial_{B'}\boldsymbol{\Phi}_{\mathbf{0}}(\mathbf{0},B',\beta_0)|_{B'=0}.\end{aligned} \tag{A3}$$

The canonical map $(\mathbf{A},B,\boldsymbol{\alpha},\beta)\leftrightarrow(\mathbf{A}',B',\boldsymbol{\alpha}',\beta')$ generated by $\Gamma(\mathbf{A}',B',\boldsymbol{\alpha},\beta)$ transforms the Hamiltonian $H(\mathbf{A},B,\boldsymbol{\alpha},\beta)$ into

$$\begin{aligned}H'(\mathbf{A}',B',\boldsymbol{\alpha}',\beta')=\boldsymbol{\omega}\cdot\mathbf{A}'+\tfrac{1}{2}(\mathbf{A}'^2+B'^2)+\varepsilon f_{\mathbf{0}}(\beta')-\varepsilon^2\partial_{\beta'}f_{\mathbf{0}}(\beta')\cdot\Delta^{-2}\partial_{\beta'}f_{\neq\mathbf{0}}(\boldsymbol{\alpha}',\beta')\\ +\varepsilon^2\boldsymbol{\Phi}_{\mathbf{0}}(\mathbf{0},0,\beta')+O(\varepsilon I'^2)+O(\varepsilon^3).\end{aligned} \tag{A4}$$

Writing the Hamiltonian equations generated by (A4), we realize that in a small neighborhood of β_0 the evolution equation for β' takes the form

$$\ddot{\beta}' = -c\varepsilon(\beta' - \beta_0)^{k_0} - \varepsilon^2 a + \varepsilon^2 a'(\beta - \beta_0) + O(\varepsilon(\beta' - \beta_0)^{k_0+1}) + O(\varepsilon^2(\beta' - \beta_0)^2) + O(\varepsilon^3), \tag{A5}$$

where $a = \partial_{\beta'} \mathbf{\Phi_0}(\mathbf{0}, 0, \beta_0)$ is the same constant defined in (1.9) and a' is a suitable constant.

Therefore, under the assumption that both a and c are nonzero, the perturbed equilibrium of the angle β' is equal, *up to high order corrections*, to $\beta_0' = \beta_0 + \delta\beta_0$, with

$$\delta\beta_0 = \begin{cases} (-a\varepsilon/c)^{1/k_0} & \text{if } k_0 \text{ is odd,} \\ \pm(-a\varepsilon/c)^{1/k_0} & \text{if } k_0 \text{ is even and } a\varepsilon/c < 0. \end{cases} \tag{A6}$$

If k_0 is odd and $c\varepsilon > 0$ the approximate perturbed equilibrium point β_0' is quadratically stable, while if $c\varepsilon < 0$ β_0' is quadratically unstable: hence we shall say that the resonant invariant torus is elliptic if $c\varepsilon > 0$ and hyperbolic if $c\varepsilon < 0$. The center of oscillations is displaced by $O(\varepsilon^{1/k_0})$ so that a fractional series in powers of $\eta = \varepsilon^{1/k_0}$ has to be expected (at best).

If k_0 is even the unperturbed equilibrium point β_0 can be continued into a perturbed equilibrium $\beta_0' = \beta_0 + \delta\beta_0$ (with $\delta\beta_0$ vanishing as $\varepsilon \to 0$) *only if* $a\varepsilon c < 0$. In this case, if $c\varepsilon\delta\beta_0 > 0$ the approximate perturbed equilibrium point β_0' is quadratically stable, while if $c\varepsilon\delta\beta_0 < 0$ β_0' it is quadratically unstable: hence we shall say that the resonant invariant torus is elliptic if $c\varepsilon\delta\beta_0 > 0$ and hyperbolic if $c\varepsilon\delta\beta_0 < 0$. Given the results known for elliptic and hyperbolic resonances Theorem 1 becomes a natural conjecture.

If $c \neq 0$ and $a = 0$ the theory depends on the corrections in (A5), for instance if $a' \neq 0$ a natural conjecture is that the new equilibrium point for β' is approximately $\beta_0' + \delta\beta_0$, with $\delta\beta_0$ satisfying the equation $(\delta\beta_0)^{k_0 - 1} = \varepsilon a'/c$, whenever this equation is solvable. The stability of this equilibrium point can be again analyzed in terms of the relative signs of ε, a, c. If $a' = 0$ one expects that the higher order terms must be studied in details.

APPENDIX B: ON ASSUMPTION (a)

Here we want to show that assumption (a) is not a purely technical assumption; that is we want to show that generically a Hamiltonian of the form (1.3) violating assumption (a) cannot admit quasiperiodic motions of codimension 1 continuously connected to an unperturbed motion of the form (1.6) in the limit $\varepsilon \to 0$. We show this by producing an explicit example, given by a Hamiltonian of the form (1.3), satisfying assumptions (c) and (b) and violating assumption (a), for which we can prove absence of quasiperiodic motions of codimension 1 tending to an unperturbed motion of the form (1.6) as $\varepsilon \to 0$.

The counterexample is given by the following Hamiltonian:

$$H = A + \frac{1}{2}A^2 + \frac{1}{2}B^2 + \varepsilon\left(\frac{\sin^3\beta}{3} + \sin\beta\cos\alpha\right), \tag{B1}$$

where $A, B \in \mathbb{R}^1$ and $\alpha, \beta \in \mathbb{T}^1$. If $\varepsilon = 0$ the Hamiltonian (B1) is strictly convex [then it satisfies assumption (b)] and it admits the unperturbed periodic motions

$$A(t) = 0, \quad \alpha(t) = t, \quad B(t) = 0, \quad \beta(t) = \beta_0, \tag{B2}$$

parametrized by the choice of $\beta_0 \in \mathbb{T}^1$. Choosing $\beta_0 = 0$, we see that $f_{\mathbf{0}}(0) = \partial_\beta f_{\mathbf{0}}(0) = \partial_\beta^2 f_{\mathbf{0}}(0) = 0$ and $\partial_\beta^3 f_{\mathbf{0}}(0) = 2 \neq 0$ [so that assumption (c) is satisfied with $k_0 = 2$]. Using the fact that f is independent of the action variables and that $f(\alpha, \beta = 0) = \partial_\beta^2 f(\alpha, \beta = 0) \equiv 0$, we see that the quantity a defined in (1.8) is identically 0: this means that assumption (a) is violated in the case under analysis.

We now investigate the possible existence of periodic motions of the form

$$\alpha(t) = t + a(t;\varepsilon), \quad A(t) = \dot{a}(t;\varepsilon), \quad \beta(t) = \eta(\varepsilon) + b(t;\varepsilon), \quad B(t) = \dot{b}(t;\varepsilon), \tag{B3}$$

where $\eta(\varepsilon)$ is a continuous function of ε such that $\lim_{\varepsilon\to 0}\eta(\varepsilon)=0$ and $a(t;\varepsilon), b(t;\varepsilon)$ are 0 average periodic functions of t of period 2π. We want to show that it is impossible that a motion of the form (B3) satisfies the Hamiltonian equations of motion

$$\begin{aligned} \ddot{a}(t;\varepsilon) &= \varepsilon \sin(t + a(t;\varepsilon))\sin(\eta + b(t;\varepsilon)), \\ \ddot{b}(t;\varepsilon) &= -\varepsilon[\sin^2(\eta + b(t;\varepsilon))\cos(\eta + b(t;\varepsilon)) + \cos(t + a(t;\varepsilon))\cos(\eta + b(t;\varepsilon))]. \end{aligned} \tag{B4}$$

In fact a 0 average periodic solution to (B4) is necessarily of the form

$$a(t;\varepsilon) = -\varepsilon\left(\eta \sin t + \frac{\varepsilon}{4}\sin t \cos t\right) + \varepsilon^2 O(\varepsilon^2 + \eta^2),$$

$$b(t;\varepsilon) = \varepsilon \cos t + \varepsilon O(\varepsilon^2 + \eta^2). \tag{B5}$$

Averaging over t the second of (B4) we find

$$\int_0^{2\pi} \frac{\mathrm{d}t}{2\pi}(\cos(t + a(t;\varepsilon))\cos(\eta + b(t;\varepsilon)) + \sin^2(\eta + b(t;\varepsilon))\cos(\eta + b(t;\varepsilon))) = 0. \tag{B6}$$

Now, using the expressions (B5), we see that (B6) is equal to $\eta^2 + (\varepsilon^2/2)$, plus terms of order at least $\eta^4 + \varepsilon^4$, and this leads to a contradiction.

APPENDIX C: COUNTING THE NUMBER OF TREES LINES

We want to show that the number of lines of a tree contributing to $\mathbf{A}^{(k)}$, $B^{(k)}$, $\mathbf{a}^{(k)}$ or $b^{(k)}$ can be bounded, above and below, by an $O(1)$ constant times k. A lower bound k/k_0 is an immediate consequence of the definitions.

We proceed by induction, using that

(1) the trees contributing to $\mathbf{A}^{(k_0)}$ and $B^{(k_0)}$ have one line [see (2.2)]; those contributing to $\mathbf{A}^{(k_0+1)}$ and $B^{(k_0+1)}$ have two lines;
(2) the trees contributing to $\mathbf{a}_{\boldsymbol{\nu}}^{(k_0)}$ and $b_{\boldsymbol{\nu}}^{(k_0)}$, with $\boldsymbol{\nu}\neq\mathbf{0}$, have at most two lines and those contributing to $\mathbf{a}_{\boldsymbol{\nu}}^{(k_0+1)}$ and $b_{\boldsymbol{\nu}}^{(k_0+1)}$, with $\boldsymbol{\nu}\neq\mathbf{0}$, have at most three lines;
(3) $b_{\mathbf{0}}^{(1)} \equiv \beta_1$ is represented by a trivial tree (i.e., a tree with one line) and the trees contributing to $b_{\mathbf{0}}^{(2)} \equiv \beta_2$ have at most k_0+2 lines.

We introduce the following definitions:
$B_k(I)$ is the maximum number of lines of the trees contributing to $\mathbf{A}^{(k)}$, $B^{(k)}$,
$B_k(\varphi)$ is the maximum number of lines of the trees contributing to $\mathbf{a}_{\boldsymbol{\nu}}^{(k)}$, $b_{\boldsymbol{\nu}}^{(k)}$, $\boldsymbol{\nu}\neq\mathbf{0}$,
$B_k(b_0)$ is the maximum number of lines of the trees contributing to $b_0^{(k)} \equiv \beta_k$.

We shall make the following inductive assumption:

$$\begin{aligned} B_k(I) &\leqslant 3k_0(k - k_0 + 1) - 4k_0 - 2, \quad k \geqslant k_0 + 1, \\ B_k(\varphi) &\leqslant 3k_0(k - k_0 + 1) - 4k_0 - 1, \quad k \geqslant k_0 + 1, \\ B_{k-k_0+1}(b_0) &\leqslant 3k_0(k - k_0 + 1) - 4k_0, \quad k \geqslant k_0 + 1. \end{aligned} \tag{C1}$$

By the remarks above and the fact that $k_0 \geqslant 2$ it follows that at the first step (that is $k=k_0+1$) the inequalities above are verified.

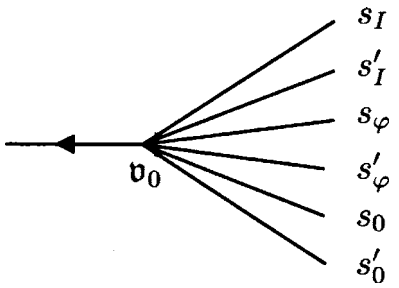

FIG. 3. The lines entering v_0 represent *symbolically* the bundle of subtrees entering $\mathfrak{v}_0$ and with root lines of types $I^{(k)}, I^{(k_0)}, \varphi^{(k)}_{\boldsymbol{\nu}}, \varphi^{(k_0)}_{\boldsymbol{\nu}}$, with $k \geq k_0+1$, and β_k, β_1, with $k \geq 2$. The number of subtrees in each bundle is indicated by the right labels.

Assume inductively the inequalities in (C1) for $k_0+1 \leq k \leq h-1$ and let us prove them for $k = h \geq k_0+2$. Let us start with the third inequality. We call $\mathfrak{v}_0$ the first node preceding the root. By the rules explained in Sec. III we have that the sum of the orders of the $s = s_{\mathfrak{v}_0}$ subtrees entering $\mathfrak{v}_0$ must be h. So, using the inductive assumptions, and calling (see Fig. 3)
s_I the number of subtrees of type $I^{(k)}$, $k \geq k_0+1$, entering $\mathfrak{v}_0$,
s'_I the number of subtrees of type $I^{(k_0)}$ entering $\mathfrak{v}_0$,
s_φ the number of subtrees of type $\varphi^{(k)}_{\boldsymbol{\nu}}$, $k \geq k_0+1$, $\boldsymbol{\nu} \neq \mathbf{0}$, entering $\mathfrak{v}_0$,
s'_φ the number of subtrees of type $\varphi^{(k_0)}_{\boldsymbol{\nu}}$, $\boldsymbol{\nu} \neq \mathbf{0}$, entering $\mathfrak{v}_0$,
s_0 the number of subtrees of type $b^{(k)}_{\mathbf{0}}$, $k \geq 2$, entering $\mathfrak{v}_0$,
s'_0 the number of subtrees of type $b^{(1)}_0$ entering $\mathfrak{v}_0$,
$B_{h-k_0+1}(b_{\mathbf{0}})$ can be bounded by the maximum over the choices of $s_I, s'_I, s_\varphi, s'_\varphi, s_0, s'_0$ of

$$1 + 3k_0 h - \{(3k_0^2 + k_0 + 2)s_I + (3k_0^2 - 1)s'_I + (3k_0^2 + k_0 + 1)s_\varphi + (3k_0^2 - 2)s'_\varphi + 4k_0 s_0 + (3k_0 - 1)s'_0\}. \tag{C2}$$

Let us first consider the case $s_I + s'_I + s_\varphi + s'_\varphi \geq 1$.

In this case, if $s=1$, since $h \geq k_0+2$, we must have that either s_φ or s_I is $=1$, and, in both cases, we can bound (C2) by $1+3k_0h-(3k_0^2+k_0+1)$, that is the desired bound; if, on the contrary, $s \geq 2$, then (C2) can be bounded by $1+3k_0h-(3k_0^2-2)-(3k_0-1) \leq 3k_0h-3k_0^2-k_0$. Let us now consider the case $s_I+s'_I+s_\varphi+s'_\varphi=0$, in which case $s=s_0+s'_0$ and necessarily $s \geq k_0$ [note that in this case the $s+1$ derivatives in (3.6) must be derivatives with respect to β so that $s \geq k_0$]. If $s \geq k_0+0$, then (C2) can be bounded by $1+3k_0h-(k_0+1)(3k_0-1) \leq 3k_0h3k_0^2-k_0$. If $s=k_0$, by the rules in Sec. III it must be $s'_0 \leq k_0-2$, so that (C2) can be bounded by $1+3h_0h-4k_0(k_0-s'_0)-(3k_0-1)s'_0 \leq 1+3k_0h-4k_0^2 +(k_0-2)(k_0+1)$ that implies the desired inductive bound.

Let us now consider the first of the three inequalities in (C1). By the rules explained in Sec. III we have that the sum of the degrees of the s subtrees entering $\mathfrak{v}_0$ is $h-k_0$ or h if, respectively, $\delta_{\mathfrak{v}_0}=1,0$. If $\delta_{\mathfrak{v}_0}=1$, $B_h(I)$ can be bounded by the maximum over the choices of $s_I, s'_I, s_\varphi, s'_\varphi, s_0, s'_0$ of $1+3k_0(h-k_0)-\{\cdots\}$, where the brackets include the same expression as in (C2), and we can bound this number by $1+3k_0h-3k_0^2-(3k_0-1)$ that is even better than the desired bound. If $\delta_{\mathfrak{v}_0} =0$, one must have $s=s_I+s'_I \geq 2$ (as $s=1$ corresponds to a not allowed tree graph) and $B_h(I)$ can be bounded by $1+3k_0h-2(3k_0^2-1)$, that is even better than the desired bound.

We finally consider the second of the three inequalities in (C1). By the rules explained in Sec. III we have that the sum of the orders of the s subtrees entering $\mathfrak{v}_0$ must be $h-k_0$ or h, if, respectively, $\delta_{\mathfrak{v}_0}=1,0$. If $\delta_{\mathfrak{v}_0}=1$ the number of lines of the corresponding trees can be bounded in the same way as we proceeded above for the first inequality in (C1). If $\delta_{\mathfrak{v}_0}=0$, only lines of type I can enter $\mathfrak{v}_0$, and then the corresponding trees have a number of lines bounded by $1+3k_0h$ $-\{(3k_0^2+k_0+2)s_I+(3k_0^2-1)s'_I\}$. So, if $s_I \geq 1$ the desired bound follows. If $s_I=0$, since $h \geq k_0+2$, we must have $s'_I \geq 2$, and again the bound follows.

APPENDIX D: PROOF OF LEMMA 2

To estimate the eigenvalues of $(ix-\mathcal{M}^{[0]}(\eta))E$, we start by rewriting $(ix-\mathcal{M}^{[0]}(\eta))E$ in the form

$$(ix-\mathcal{M}^{[0]}(\eta))E=\begin{pmatrix} -R & -ix+Q \\ ix+Q^{\dagger} & P \end{pmatrix}. \tag{D1}$$

Note that, by the strict convexity of the Hessian of H_0 if ε is small enough, P admits N positive eigenvalues $0<\mu_1^{(0)}\leqslant\cdots\leqslant\mu_N^{(0)}\equiv\mu$. Let $v_\alpha(x;\eta)=\binom{u}{v}$ be an eigenvector of $(ix-\mathcal{M}^{[0]})E$ with eigenvalue α (here u and v are two column vectors of dimension N),

$$\begin{pmatrix} -R & -ix+Q \\ ix+Q^{\dagger} & P \end{pmatrix}\begin{pmatrix} u \\ v \end{pmatrix}=\begin{pmatrix} -Ru+(-ix+Q)v \\ (ix+Q^{\dagger})u+Pv \end{pmatrix}=\alpha\begin{pmatrix} u \\ v \end{pmatrix}. \tag{D2}$$

Now, either $|\alpha|\geqslant\mu_1^{(0)}/2$ or $P/2<P-\alpha<3P/2$. In the latter case $(P-\alpha)$ is invertible, $2/(3\mu_N^{(0)})\leqslant(P-\alpha)^{-1}\leqslant 2/\mu_1^{(0)}$, and we can rewrite (D2) as

$$v=-(P-\alpha)^{-1}(ix+Q^{\dagger})u,\quad -Ru-(-ix+Q)(P-\alpha)^{-1}(ix+Q^{\dagger})u=\alpha u. \tag{D3}$$

The second equation in (D3) is of the form

$$[-x^2(P-\alpha)^{-1}+O(\varepsilon x)+O(\varepsilon\eta^{k_0-1})]u=\alpha u, \tag{D4}$$

so that $|\alpha|\geqslant(2/3\mu)x^2+O(\varepsilon x)+O(\varepsilon\eta^{k_0-1})$. If $x^2\geqslant\rho|\varepsilon|\eta^{k_0-1}$, for ρ large enough, the latter estimate implies $|\alpha|\geqslant(1/2\mu)x^2$, and Lemma 2 is proven.

APPENDIX E: SYMMETRY PROPERTIES OF THE SELF-ENERGY MATRICES

In this section we discuss the symmetry properties (5.10) of $\mathcal{M}^{[\leqslant n]}(x;\eta)$.

We begin with proving (5.10) for $\mathcal{M}^{[n]}(x;\eta)$. We inductively suppose that the same symmetry properties hold for both $\mathcal{M}^{[p]}(x;\eta)$ and $g^{[p]}(x;\eta)$, for $0\leqslant p<n$,

$$Eg^{[p]}(x;\eta)E=[g^{[p]}(-x;\eta)]^T,\quad [g^{[p]}(x;\eta)]^*=g^{[p]}(-x;\eta), \tag{E1}$$

where the $*$ denotes complex conjugation and T transposition. Note that if $p=0$, $\mathcal{M}^{[0]}(\eta)$ and $g^{[0]}(x;\eta)$ satisfy the desired symmetry properties, as discussed in Sec. IV.

Consider the representation of $\mathcal{M}^{[n]}(x;\eta)$ given by (5.6) and (5.7) in the following confusion between T denoting transposition and T denoting a self-energy cluster will be avoided by renaming the cluster T with a new symbol D. Note that $F^*(\boldsymbol{\nu}_{\mathfrak{v}})=F(-\boldsymbol{\nu}_{\mathfrak{v}})$, so that, using the second of (E1), $[\mathcal{V}_D(x;\eta)]^*$ can be written as[2]

$$\begin{aligned}[\mathcal{V}_D(x;\eta)]^* &= \frac{(\eta\beta_1)^{|L(D)|}}{|\Lambda(D)|!}\Big(\prod_{\mathfrak{v}\in V(D)}\varepsilon^{\delta_{\mathfrak{v}}}\Big)\Big(\prod_{\mathfrak{v}\in V(D)}F^*(\boldsymbol{\nu}_{\mathfrak{v}})\Big)\Big(\prod_{\ell\in\Lambda(D)}[g^{[n_\ell]}(x_\ell;\eta)]^*\Big)\\ &= \frac{(\eta\beta_1)^{|L(D)|}}{|\Lambda(D)|!}\Big(\prod_{\mathfrak{v}\in V(D)}\varepsilon^{\delta_{\mathfrak{v}}}\Big)\Big(\prod_{\mathfrak{v}\in V(D)}F(-\boldsymbol{\nu}_{\mathfrak{v}})\Big)\Big(\prod_{\ell\in\Lambda(D)}g^{[n_\ell]}(-x_\ell;\eta)\Big)=\mathcal{V}_{D^*}(-x;\varepsilon),\end{aligned} \tag{E2}$$

where D^* is a cluster topologically equivalent to D, with opposite mode labels (clearly the correspondence $D\leftrightarrow D^*$ is one-to-one). Summing over the choices of D [see (5.7)] the second of (5.10) follows.

[2]We stress that we use the convention that the internal γ indices of D are summed over, while the momentum labels are not summed over; in this way the value $\mathcal{V}_D$ explicitly depends only on the momenta of the internal nodes, the external momentum, and the two γ labels associated to the incoming and outcoming lines.

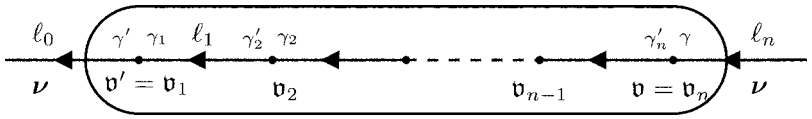

FIG. 4. A self-energy cluster D and the path $\mathcal{L}$ connecting its external lines. The subtrees internal to D with root on $\mathcal{L}$ are not drawn.

To prove the first of (5.10), it is convenient to shorten notations; see Fig. 4 for a pictorial representation of the symbols. Given a self-energy cluster D, let us denote by $\mathfrak{v}$ and $\mathfrak{v}'$ the nodes such that the exiting line of D comes out from $\mathfrak{v}'$ and the entering line of D enters $\mathfrak{v}$.

(1) Let $\mathfrak{v}' \equiv \mathfrak{v}_1, \dots, \mathfrak{v}_n \equiv \mathfrak{v}$ be the nodes on the path $\mathcal{L} \equiv \mathcal{L}(D)$ joining $\mathfrak{v}$ to $\mathfrak{v}'$, and $\boldsymbol{\nu}_j$ be their mode labels; let also $\ell_j = (\mathfrak{v}_{j+1}\mathfrak{v}_j)$ be the line joining the two successive nodes $\mathfrak{v}_{j+1}$ and $\mathfrak{v}_j$ in $\mathcal{L}$; let γ'_j, γ_j be the component labels at the beginning of the line in $\mathcal{L}$ exiting from $\mathfrak{v}_j$ and at the end of the line in $\mathcal{L}$ entering the node $\mathfrak{v}_j$ (they are, respectively, the lines ℓ_{j-1} and ℓ_j). Recall that, by definition of self-energy cluster, any propagator g_j associated to the lines $\ell_j \in \mathcal{L}$ has a scale $[n_{\ell_j}]$, with $n_{\ell_j} \geqslant 0$, i.e., there cannot be $\mathbf{0}$-momentum propagators along the path $\mathcal{L}$.

(2) Let $\boldsymbol{\vartheta}_j$ be the (possibly empty) family of subtrees of D with root in $\mathfrak{v}_j$ and with no line in common with $\mathcal{L}$ (not represented in Fig. 4, $\boldsymbol{\vartheta}_j$ can be imagined to be a set of trees with the root line ending in $\mathfrak{v}_j$ or, possibly, $\boldsymbol{\vartheta}_j$ may consist just in $\mathfrak{v}_j$).

(3) Let N_j be the $N \times N$ symmetric matrix $\partial_{\gamma'_j \gamma_j} f_{\boldsymbol{\nu}_j}(\beta_0, \boldsymbol{\vartheta}_j)$, where $f_{\boldsymbol{\nu}_j}(\beta_0, \boldsymbol{\vartheta}_j)$ is a function depending only on the set of trees $\boldsymbol{\vartheta}_j$ and on $f_{\boldsymbol{\nu}_j}(\beta)$ [it can be read off (5.6) and (5.7)] and $\partial_{\gamma'}$, ∂_{γ} must be interpreted as explained after (3.2).

(4) The momentum flowing in a generic line ℓ of the graph D will be the sum of the momentum $\boldsymbol{\nu}^0_\ell$ that would flow on the line if the entering line momentum $\boldsymbol{\nu}$ was $\mathbf{0}$ plus $\boldsymbol{\nu}$ if the line is on the path $\mathcal{L}$; then the propagator matrix g_j associated to the line ℓ_j of $\mathcal{L}$ is equal to $g^{[n_{\ell_j}]} \times (x^0_j + x; \eta)$, where x^0_j is the scalar product of $\boldsymbol{\omega} \cdot \boldsymbol{\nu}^0_{\ell_j}$ and $x = \boldsymbol{\omega} \cdot \boldsymbol{\nu}$.

Then the matrix $\mathcal{V}_D(x; \eta)$, see (E1), can be concisely written as

$$(\mathcal{V}_D(x;\eta))_{\gamma'\gamma} = (EN_1 g_1 EN_2 g_2 \cdots g_{n-2} EN_{n-1} g_{n-1} EN_n)_{\gamma'\gamma}. \tag{E3}$$

Interchanging the external lines (i.e., having $\mathfrak{v}'$ as entering node and $\mathfrak{v}$ as exiting node) generates a new self-energy cluster D' in which the momenta flowing in the lines of the subtrees $\boldsymbol{\vartheta}_j$ with roots on the nodes $\mathfrak{v}_j \in \mathcal{L}$ are unchanged while the momentum on the line $\ell_j \in \mathcal{L}$ changes from $\boldsymbol{\nu}^0_{\ell_j} + \boldsymbol{\nu}$, with $\boldsymbol{\nu}^0_{\ell_j}$ equal to the momentum which would flow on ℓ_j if the external momentum $\boldsymbol{\nu}$ was set equal to $\mathbf{0}$, to a new value $-\boldsymbol{\nu}^0_{\ell_j} + \boldsymbol{\nu}$.

The matrix $\mathcal{V}_{D'}(x; \eta)$ can therefore be written as

$$(\mathcal{V}_{D'}(x;\eta))_{\gamma'\gamma} = (EN_n g'_{n-1} EN_{n-1} g'_{n-2} \cdots g'_2 EN_2 g'_1 EN_1)_{\gamma'\gamma}, \tag{E4}$$

where $g'_j = g^{[n_{\ell_j}]}(-x^0_{\ell_j} + x; \eta)$. Inserting $\mathbb{1} \equiv E^T E$ after $N_n, \dots, N_2$ and using the symmetry of $N_1, \dots, N_n$, the inductive validity of the first of (E1) and the transposition rules for matrix products, we get

$$(\mathcal{V}^T_{D'}(x;\eta))_{\gamma'\gamma} = (N_1 g''_1 EN_2 g''_2 \cdots g''_{n-2} EN_{n-1} g''_{n-1} EN_n E^T)_{\gamma'\gamma}, \tag{E5}$$

where $g''_j \equiv g^{[n_{\ell_j}]}(x^0_{\ell_j} - x; \eta)$. Hence $E\mathcal{V}^T_{D'}(x;\eta)E \equiv \mathcal{V}_D(-x;\eta)$ completing the inductive proof of (E1), because $\mathcal{M}^{[n]}(x;\eta)$ is defined as a sum over D of the values $\mathcal{V}_D$ [see (5.7)].

Remark: From (5.10) and (E1) follows that $g^{[\geqslant n]}(x;\eta)$ satisfies the same symmetry properties as $\mathcal{M}^{[n]}(x;\eta)$,

$$Eg^{[\geqslant n]}(x;\eta)E = [g^{[\geqslant n]}(-x;\eta)]^T, \quad [g^{[\geqslant n]}(x;\eta)]^* = g^{[\geqslant n]}(-x;\eta). \tag{E6}$$

APPENDIX F: CANCELLATIONS

In this section we discuss the cancellations needed to show that $\mathcal{M}^{[\le n]}(x;\eta)$ has the structure described in (5.11) and (5.12). In particular we want to show that the elements $(\mathcal{M}^{[n]}(x;\eta))_{\gamma'\gamma}$ with either $\gamma'=A_i$ or $\gamma=\alpha_j$ are proportional to x, while the elements with $\gamma'=A_i$ and $\gamma=\alpha_j$ are proportional to x^2, for $x^2\le\rho\eta^{2k_0-1}$.

As in, Ref. 15 the contributions to $\mathcal{M}^{[n]}(x;\eta)$ coming from clusters such that

$$\sum_{\mathfrak{v}\in V(T)}|\boldsymbol{\nu}_{\mathfrak{v}}|\ge(C_0/2^6|x|)^{1/\tau_0} \tag{F1}$$

require no cancellations, in fact the exponential decay as $\boldsymbol{\nu}_{\mathfrak{v}}\to\infty$ of the node functions implies that the contributions coming from clusters satisfying (F1) are smaller than Cx^2, for some constant $C>0$.

When (F1) does not hold we need to exploit cancellations, because *a priori* there is no reason for some of the entries of $\mathcal{M}^{[n]}(x;\eta)$ to be proportional to x or x^2 for small x. Following the same strategy used in Appendix A2 of Ref. 15 (and of Appendix A4 of Ref. 10), the necessary cancellations can be checked to occur by collecting clusters violating condition (F1) into families. Such cancellations are due to the same mechanism pointed out first in Refs. 7, 8, and 4. The following analysis follows Ref. 16.

Given a self-energy cluster D on scale $[n-1]$, let us call D_0 the connected subset of D containing no line on scale $[-1]$ and containing the nodes $\mathfrak{v}$ and $\mathfrak{v}'$ to which the entering and exiting lines are attached. By definition $\Sigma_{\mathfrak{v}\in D_0}\boldsymbol{\nu}_{\mathfrak{v}}=\mathbf{0}$. Note also that, if the path $\mathcal{L}$ connecting $\mathfrak{v}$ and $\mathfrak{v}'$ is nontrivial (i.e., $\mathfrak{v}\ne\mathfrak{v}'$), $\mathcal{L}$ is completely contained into D_0; moreover, if D does not contain lines on scale $[-1]$, then $D_0\equiv D$. We define the family $\mathcal{F}\equiv\mathcal{F}_D$ as the set of self-energy clusters obtained from D by shifting the entering and exiting lines by reattaching them to the nodes of D_0 in all possible ways. We then consider the sum

$$\mathcal{V}_{\mathcal{F}}(x;\eta)=\sum_{D\in\mathcal{F}}\mathcal{V}_D(x;\eta), \tag{F2}$$

contributing to the rhs of (5.7). When summing $\mathcal{V}_{\mathcal{F}}(x;\eta)$ over all distinct families of clusters on scale $[n-1]$, we recover the quantity $M^{[n]}(x;\eta)$ defined in (5.7). To prove that $\mathcal{M}^{[\le n]}$ has the structure described by (5.11) and (5.12), we proceed in the following way. We first note that, by the same analysis of Sec. VI of Ref. 15, $\mathcal{V}_{\mathcal{F}}(x;\eta)$ is differentiable with respect to x in the sense of Whitney; then, we show that $(\mathcal{V}_{\mathcal{F}}(0;\eta))_{\gamma'\gamma}=0$ if $\gamma'=A_i$ or $\gamma=\alpha_j$ and $(\partial_x\mathcal{V}_{\mathcal{F}}(0;\eta))_{\gamma'\gamma}=0$ if $\gamma'=A_i$ and $\gamma=\alpha_j$.

Let us begin with proving that $(\mathcal{V}_{\mathcal{F}}(0;\eta))_{\gamma'\gamma}=0$ if $\gamma'=A_i$ or $\gamma=\alpha_j$, and to be definite let us assume that $\gamma=\alpha_j$ for some $j=1,\dots,N-1$. Recall that, employing the notation of Appendix E, we can write each matrix $\mathcal{V}_D(x;\eta)$ appearing in the sum (F2) in the form (E3). By the explicit expression of (E3) and of the matrices N_j, we see that, when computing $\mathcal{V}_D(x;\eta)$ in $x=0$, we find $(\mathcal{V}_D(0;\eta))_{\gamma'\alpha_j}=O(\mathcal{F},\mathfrak{v}',\eta)_{\gamma'}(\boldsymbol{\nu}_{\mathfrak{v}})_j$ for some function $O(\mathcal{F},\mathfrak{v}',\eta)_{\gamma'}$ *independent* of the choice of the node $\mathfrak{v}$ to which the entering line with label $\gamma=\alpha_j$ is attached to.

If we change D within $\mathcal{F}$ by attaching the entering line to all possible nodes in D_0 (keeping $\mathfrak{v}'$ fixed), we see that the global contribution from such self-energy clusters is equal to $O(\mathcal{F},\mathfrak{v}',\eta)_{\gamma'}\cdot\cdot\Sigma_{\mathfrak{v}\in D_0}(\boldsymbol{\nu}_{\mathfrak{v}})_j$, which is 0 by the property $\Sigma_{\mathfrak{v}\in D_0}(\boldsymbol{\nu}_{\mathfrak{v}})_j=\mathbf{0}$. So, if $\gamma=\alpha_j$, the proof of the fact that $(\mathcal{V}_{\mathcal{F}}(0;\eta))_{\gamma'\gamma}=0$ is complete. In the case that $\gamma'=A_i$ the proof is completely analogous and we do not repeat it here.

Let us now turn to the proof of the fact that, if $\gamma'=A_i$ and $\gamma=\alpha_j$, then $(\partial_x\mathcal{V}_{\mathcal{F}}(0;\eta))_{\gamma'\gamma}=0$. First note that, by the explicit form (E3) of the value $\mathcal{V}_D(x;\eta)$ and in particular by the fact that $\mathcal{V}_D(x;\eta)$ depends on x only through the propagators along the path $\mathcal{L}$, we find that, when differentiating $\mathcal{V}_D(x;\eta)$ with respect to x, the effect of the derivative is as follows:

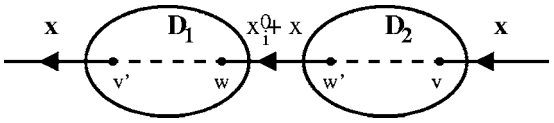

FIG. 5. Subdiagrams D_1 and D_2 in a self-energy cluster D. The drawn lines connected to $\mathbf{v}$ and $\mathbf{v}'$ are the external lines of D.

$$\partial_x \mathcal{V}_D(x;\eta) = \sum_{i=1}^{n-1} (EN_1 g_1 \cdots g_{i-1} EN_i)\partial_x g_i (EN_{i+1} g_{i+1} \cdots g_{n-1} EN_n). \tag{F3}$$

Given the line $\ell_i \in D_0$, we call D_1 and D_2 the two connected distinct subsets of D_0 obtained from D_0 by detaching the line ℓ_i and such that D_1 contains the node $\mathfrak{v}'$ to which the line exiting from D is attached, while D_2 contains the node $\mathfrak{v}$ to which the line entering D is attached. D_1 and D_2 are two subgraphs of D with two external lines, one coinciding with one of the external lines of D, the other coinciding with ℓ_i, see Fig. 5.

If we define the values of D_1, D_2 by formulas analogous to (E3), we can rewrite each term under the sum in (F3) as $\mathcal{V}_{D_1}(x;\eta)\partial_x g^{[n_{\ell_i}]}(x_i^0+x;\eta)\mathcal{V}_{D_2}(x;\eta)$, where, with the same notations of Appendix E, we defined $x_i^0 = \boldsymbol{\vartheta}\cdot\boldsymbol{\nu}_{\ell_i}^0$, with $\boldsymbol{\nu}_{\ell_i}^0$ equal to the momentum which would flow on ℓ_i if the external momentum $\boldsymbol{\nu}$ was set equal to $\mathbf{0}$.

In particular let us consider the value $(\mathcal{V}_{D_1}(0;\eta)\partial_x g^{[n_{\ell_i}]}(x_i^0;\eta)\mathcal{V}_{D_2}(0;\eta))_{A_i\alpha_j}$ at $x=0$, that is one of the contributions we are interested in, and again note that by the very definition of $\mathcal{V}_{D_1}$ and $\mathcal{V}_{D_2}$, it holds that $(\mathcal{V}_{D_1}(0;\eta))_{A_i\gamma_1} = (\boldsymbol{\nu}_{\mathfrak{v}'})_i \Omega(\mathfrak{w})_{\gamma_1}$ and $(\mathcal{V}_{D_2}(0;\eta))_{\gamma_2\alpha_j} = \Omega(\mathfrak{w}')_{\gamma_2}(\boldsymbol{\nu}_{\mathfrak{v}})_j$, where $\mathfrak{w}$, $\mathfrak{w}'$ are the two nodes where ℓ_i enters into and exists from, see Fig. 5, and $\Omega(\mathfrak{w})_{\gamma_1}$, $\Omega(\mathfrak{w}')_{\gamma_2}$ are two functions depending on the structure of D_1 and D_2, *but not on the choices of* $\mathfrak{v}'$, $\mathfrak{v}$ within D_1, D_2.

This implies that if we change D within $\mathcal{F}$ by attaching the entering line to all possible nodes in $D_2 \cap D_0$ and by attaching the exiting line to all possible nodes in $D_1 \cap D_0$, keeping ℓ_i fixed, the sum of the contributions of the form $(\mathcal{V}_{D_1}(0;\eta)\partial_x g^{[n_{\ell_i}]}(x_i^0;\eta)\mathcal{V}_{D_2}(0;\eta))_{A_i\alpha_j}$ from this class of graphs is equal to

$$\left(\sum_{\mathfrak{v}'\in D_1\cap D_0} (\boldsymbol{\nu}_{\mathfrak{v}'})_i\right)\Omega(\mathfrak{w})_{\gamma_1}(\partial_x g^{[n_{\ell_i}]}(x_i^0;\eta))_{\gamma_1\gamma_2}\Omega(\mathfrak{w}')_{\gamma_2}\left(\sum_{\mathfrak{v}\in D_2\cap D_0} (\boldsymbol{\nu}_{\mathfrak{v}})_j\right). \tag{F4}$$

Note that, given any graph D with the structure in Fig. 5, the graph D' in which the entering and exiting lines are interchanged (so that the external lines enter in $\mathfrak{v}'$ and exit from $\mathfrak{v}$, see Fig. 6) the momentum through the line ℓ_i changes from $\boldsymbol{\nu}_{\ell_i^0}+\boldsymbol{\nu}$ to $-\boldsymbol{\nu}_{\ell_i^0}+\boldsymbol{\nu}$.

At $x=0$, if we change D into D', the value $\mathcal{V}_{D_1}(0;\eta)\partial_x g^{[n_{\ell_i}]}(x_i^0;\eta)\mathcal{V}_{D_2}(0;\eta)$ is changed into $\mathcal{V}_{D_2'}(0;\eta)\partial_x g^{[n_{\ell_i}]}(-x_i^0;\eta)\mathcal{V}_{D_1'}(0;\eta)$. In analogy with the results of Appendix E, employing the symmetry relations (E1), we find $\mathcal{V}_{D_2'}(0;\eta) = E[\mathcal{V}_{D_2}(0;\eta)]^T E$ and $\mathcal{V}_{D_1'}(0;\eta) = E[\mathcal{V}_{D_1}(0;\eta)]^T E$. Using also the symmetry $E\partial_x g^{[n_{\ell_i}]}(-x_i^0;\eta)E = -\partial_x[g^{[n_{\ell_i}]}]^T(x_i^0;\eta)$, we find that the element (A_i,α_j) of the contribution corresponding to the graph in Fig. 6 can be written as

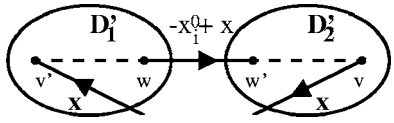

FIG. 6. The self-energy cluster D' obtained from D by interchanging the external lines of D, the exiting line is attached to a node $\mathbf{v}\in D_2'$ and the entering line is attached to a node $\mathbf{v}\in D_1'$.

$$(\mathcal{V}_{D_2'}(0;\eta)\partial_x g^{[n\ell_i]}(-x_i^0;\eta)\mathcal{V}_{D_1'}(0;\eta))_{A_i\alpha_j} = -(E[\mathcal{V}_{D_2}(0;\eta)]^T\partial_x[g^{[n\ell_i]}]^T(x_i^0;\eta)\mathcal{V}_{D_1}^T(0;\eta)E)_{A_i\alpha_j}$$
$$= -(E\mathcal{V}_{D_1}(0;\eta)\partial_x g^{[n\ell_i]}(x_i^0;\eta)\mathcal{V}_{D_2}(0;\eta)E)_{\alpha_j A_i}$$
$$= -(\mathcal{V}_{D_1}(0;\eta)\partial_x g^{[n\ell_i]}(x_i^0;\eta)\mathcal{V}_{D_2}(0;\eta))_{A_j\alpha_i}. \tag{F5}$$

Repeating the discussion leading to (F4) we see that, if we sum (F5) over the graphs obtained by attaching the entering line to all possible nodes $\mathfrak{v}' \in D_1' \cap D_0$ and attaching the exiting line to all possible nodes $\mathfrak{v} \in D_2' \cap D_0$, we get

$$-\left(\sum_{\mathfrak{v}' \in D_1' \cap D_0} (\boldsymbol{\nu}_{\mathfrak{v}'})_j\right)\Omega(\mathfrak{w})_{\gamma_1}(\partial_x g^{[n\ell_i]}(x_i^0;\eta))_{\gamma_1\gamma_2}\Omega(\mathfrak{w}')_{\gamma_2}\left(\sum_{\mathfrak{v} \in D_2' \cap D_0} (\boldsymbol{\nu}_{\mathfrak{v}})_i\right). \tag{F6}$$

Now, using the fact that $\Sigma_{\mathfrak{v} \in D_0}\boldsymbol{\nu}_{\mathfrak{v}} = \mathbf{0}$ and that D_1', D_2' and D_1, D_2 are topologically equivalent, we also find that

$$\sum_{\mathfrak{v}' \in D_1' \cap D_0} (\boldsymbol{\nu}_{\mathfrak{v}'})_j = -\sum_{\mathfrak{v} \in D_2 \cap D_0} (\boldsymbol{\nu}_{\mathfrak{v}})_j, \qquad \sum_{\mathfrak{v} \in D_2' \cap D_0} (\boldsymbol{\nu}_{\mathfrak{v}})_i = -\sum_{\mathfrak{v}' \in D_1 \cap D_0} (\boldsymbol{\nu}_{\mathfrak{v}'})_i, \tag{F7}$$

so that (F4) and (F6) sum up to 0.

This completes the proof of the fact that

$$\sum_{D \in \mathcal{F}} \mathcal{V}_D(\varepsilon;0)_{A_i\alpha_j} = 0, \quad \partial_x \sum_{D \in \mathcal{F}} \mathcal{V}_D(\varepsilon;x)_{A_i\alpha_j}\big|_{x=0} = 0. \tag{F8}$$

Remark: It can be checked that the symmetry (E1) "only" implies that, if we define $C_{ij}(x) := \Sigma_{D \in \mathcal{F}}\mathcal{V}_D(\varepsilon;x)_{A_i\alpha_j}$, it holds $C_{ij}(x) = C_{ji}(-x) = C_{ji}^*(x)$: therefore the cancellation to second order (in x), expressed by (F7), *is not a parity cancellation* [unless $i=j$ where by the self-adjointness of the matrix C it follows that $C_{ii}(x)$ is real and, hence, even in x]. If the coefficients $f_{\boldsymbol{\nu}}(\beta)$ are assumed real then the self-adjointness property (E1) implies that $C_{ij}(x)$ is even in x and the second order cancellation at $x=0$ is an obvious parity cancellation and the proof above is greatly simplified, as remarked in the simple cases considered in Refs. 7 and 8.

Having proved that $(\mathcal{M}^{[n]}(0;\eta))_{\gamma'\gamma}=0$ if either $\gamma'=A_i$ or $\gamma=\alpha_j$ and that $(\partial_x\mathcal{M}^{[n]}(0;\eta))_{\gamma'\gamma}=0$ if $\gamma'=A_i$ and $\gamma=\alpha_j$, it must still be shown that the elements $(\mathcal{M}^{[n]}(x;\eta))_{\gamma'\gamma}$ (with the suitable choices of γ' and γ) satisfy appropriate bounds once the factors x determining the order of zero at $x=0$ are extracted. From convergence one expects that the bounds on the rests of the Taylor series in x around $x=0$ should still be proportional to ε^2.

This is in fact true, *under the condition that* (F1) *does not hold*, if (F1) does not hold, then changing the nodes where the external lines are attached to *does not change the scale* of the internal lines. And this implies that the bounds on the derivatives with respect to x are qualitatively the same as the bounds on $\mathcal{M}^{[n]}(x;\eta)$ and boundedness of the entries of $\bar{M}^{[\le n]}$ follows, see (5.12).

APPENDIX G: BOUNDS ON THE PROPAGATOR

In this section we want to get a lower bound for the norm of $(ix-\mathcal{M}^{[n]}(x;\eta))E$, by an approximate computation of its eigenvalue which is lowest in absolute value, for $x^2 \le \rho\eta^{2k_0-1}$, with ρ the same constant appearing in Lemma 3. Moreover we want to prove dimensional bounds for the derivatives in x and ε of the approximate lowest eigenvalue.

Write $(ix-\mathcal{M}^{[\le n]}(x;\eta))E$ as

$$(ix-\mathcal{M}^{[\le n]}(x;\eta))E = \begin{pmatrix} -R^{[\le n]}(x;\eta) & -ix+Q^{[\le n]}(x;\eta) \\ ix+Q^{[\le n]\dagger}(x;\eta) & P^{[\le n]}(x;\eta) \end{pmatrix},$$

where $P^{[\le n]}, Q^{[\le n]}, R^{[\le n]}$ are the matrices defined in (5.12).

The N eigenvalues of $P^{[\leqslant n]}(x;\eta)$ are of order 1 and positive; call them $\mu_1^{(n)} \leqslant \cdots \leqslant \mu_N^{(n)}$. Since $P^{[\leqslant n]}(x;\eta)$ differs from $P^{[0]}(x;\eta)$ by $O(\varepsilon^2)$, the eigenvalues $\mu_i^{(n)}$ can be written as $\mu_i^{(n)} = \mu_i^{(0)}(1 + O(\varepsilon^2))$.

To estimate the smallest eigenvalue of $(ix - \mathcal{M}^{[\leqslant n]}(x;\eta))E$ we can follow a strategy adapted from the proof of Lemma 2. Let $v_\alpha(x;\eta) = \binom{u}{v}$ be an eigenvector of $(ix - \mathcal{M}^{[\leqslant n]}(x;\eta))E$ with eigenvalue α (here u and v are two column vectors of dimension N),

$$\begin{pmatrix} -R^{[\leqslant n]}(x;\eta) & -ix + Q^{[\leqslant n]}(x;\eta) \\ ix + Q^{[\leqslant n]\dagger}(x;\eta) & P^{[\leqslant n]}(x;\eta) \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} -R^{[\leqslant n]}u + (-ix + Q^{[\leqslant n]})v \\ (ix + Q^{[\leqslant n]\dagger})u + P^{[\leqslant n]}v \end{pmatrix} = \alpha \begin{pmatrix} u \\ v \end{pmatrix}. \tag{G1}$$

To estimate the eigenvalue α with smallest absolute value, we restrict attention to the case $P^{[\leqslant n]} - \alpha \geqslant P^{[\leqslant n]}/2$, as in the opposite case $|\alpha| > \mu_1^{(n)}/2$. Then $(P^{[\leqslant n]} - \alpha)$ is invertible, $(P^{[\leqslant n]} - \alpha)^{-1} = [P^{[\leqslant n]}]^{-1} + O(\alpha)$ and we can rewrite (G1) as

$$\begin{aligned} v &= -(P^{[\leqslant n]} - \alpha)^{-1}(ix + Q^{[\leqslant n]\dagger})u, \\ -R^{[\leqslant n]} &- (-ix + Q^{[\leqslant n]})(P^{[\leqslant n]} - \alpha)^{-1}(ix + Q^{[\leqslant n]\dagger})u = \alpha u. \end{aligned} \tag{G2}$$

From the second of (G2) we see that α must solve an equation of the form

$$\det[N^{[\leqslant n]} - \alpha(1 + O(x) + O(\varepsilon))] = 0, \tag{G3}$$

where we defined $N^{[\leqslant n]} := -R^{[\leqslant n]} - (-ix + Q^{[\leqslant n]})[P^{[\leqslant n]}]^{-1}(ix + Q^{[\leqslant n]\dagger})$ and we used that $Q^{[\leqslant n]} = O(\varepsilon)$. This means that α is an eigenvalue of a Hermitian matrix of the form $N^{[\leqslant n]}(1 + O(x) + O(\varepsilon))$, so that, calling $\lambda_i^{[n]}$ the eigenvalues of $N^{[\leqslant n]}$, we have (see Ref. 20)

$$\alpha = \lambda_i^{[n]}(1 + O(x) + O(\varepsilon)), \tag{G4}$$

for some $i = 1, \ldots, N$. The conclusion of the previous discussion is that the problem of computing the smallest eigenvalue of $(ix - \mathcal{M}^{[n]}(x;\eta))E$ is essentially equivalent to the problem of computing the smallest eigenvalue of $N^{[\leqslant n]}$.

An explicit computation of $N^{[\leqslant n]}$ shows that it can be written in the form

$$\begin{aligned} N^{[\leqslant n]} &= -x^2\mathcal{H}_0^{-1} + \{-R^{[\leqslant n]} + x^2\mathcal{H}_0^{-1} - (-ix + Q^{[\leqslant n]})[P^{[\leqslant n]}]^{-1}(ix + Q^{[\leqslant n]\dagger})\} \\ &= -x^2\mathcal{H}_0^{-1} + \begin{pmatrix} 0 & i\varepsilon x D(\eta) \\ -i\varepsilon x D^\dagger(\eta) & -\varepsilon\eta^{k_0-1}\tilde{M}_{\beta\beta}(\eta) \end{pmatrix} + O(\varepsilon x^2), \end{aligned} \tag{G5}$$

where

$$\mathcal{H}_0 := \begin{pmatrix} \partial_{\mathbf{A}\mathbf{A}}^2 H_0 & \partial_{\mathbf{A}B}^2 H_0 \\ \partial_{B\mathbf{A}}^2 H_0 & \partial_{BB}^2 H_0 \end{pmatrix}, \quad \tilde{M}_{\beta\beta}(\eta) = -ck_0\beta_1^{k_0-1}(1 + O(\eta)), \quad \text{and } D(\eta) = D_0 + O(\eta),$$

with

$$\begin{pmatrix} D_0 \\ 0 \end{pmatrix} := -\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\mathcal{H}_0^{-1}\begin{pmatrix} \partial_{\mathbf{A}\beta}^2 f_{\mathbf{0}}(\beta_0) \\ \partial_{B\beta}^2 f_{\mathbf{0}}(\beta_0) \end{pmatrix}. \tag{G6}$$

The off-diagonal $O(\varepsilon x)$ elements can be eliminated through a small rotation of $N^{[\leqslant n]}$. In fact, defining the Hermitian matrix Z as

$$Z = \begin{pmatrix} 0 & [\tilde{M}_{\beta\beta}(\eta)]^{-1}D(\eta) \\ [\tilde{M}_{\beta\beta}(\eta)]^{-1}D(\eta) & 0 \end{pmatrix}, \tag{G7}$$

a computation shows that

$$e^{ix\eta^{-k_0+1}Z}N^{[\leqslant n]}e^{-ix\eta^{-k_0+1}Z} \equiv -x^2\mathcal{H}_0^{-1} + \delta N^{[\leqslant n]} = -x^2\mathcal{H}_0^{-1} + \begin{pmatrix} 0 & 0 \\ 0 & -\varepsilon\eta^{k_0-1}\tilde{M}_{\beta\beta}(\eta) \end{pmatrix} + O(\eta^{1/2}x^2), \tag{G8}$$

where we used the property $x\eta^{-k_0+1} \leqslant (\rho\eta)^{1/2}$, if $x^2 \leqslant \rho\varepsilon\eta^{k_0-1}$. Multiplying the rhs of (G8) times $\mathcal{H}_0^{1/2}$ both from the left and from the right [remark that $\mathcal{H}_0^{1/2}$ is a well-defined positive $O(1)$ operator] we see that the norm of $N^{[\leqslant n]}$ can be bounded above and below by an $O(1)$ constant times the norm of

$$-x^2 + \mathcal{H}_0^{1/2}\delta N^{[\leqslant n]}\mathcal{H}_0^{1/2}. \tag{G9}$$

Finally, using the explicit structure of $\delta N^{[\leqslant n]}$, see (G8), $N-1$ of the eigenvalues of (G9) are equal to $-x^2(1+O(\eta^{1/2}))$, while the last one is $-x^2(1+O(\eta^{1/2}))-\varepsilon\eta^{k_0-1}\tilde{M}_{\beta\beta}(\varepsilon)\partial_B^2 H_0$.

From this computation, the bound (6.1) of Lemma 5 follows. To address the differentiability of $\lambda^{[n]}(x;\eta)$ with respect to ε and x, we note that $\mathcal{H}_0^{1/2}\delta N^{[\leqslant n]}\mathcal{H}_0^{1/2}$ is C^∞ in the sense of Whitney (because such is $\mathcal{M}^{[\leqslant n]}$, see the corresponding discussion in Appendix A3 of Ref. 15) and its derivatives admit the following dimensional bounds:

$$\|\partial_\varepsilon(\mathcal{H}_0^{1/2}\delta N^{[\leqslant n]}\mathcal{H}_0^{1/2})\| \leqslant C\eta^{k_0-1}, \quad \|\partial_x(\mathcal{H}_0^{1/2}\delta N^{[\leqslant n]}\mathcal{H}_0^{1/2})\| \leqslant C\eta^{k_0}. \tag{G10}$$

Given this and the fact that the last eigenvalue of $\mathcal{H}_0^{1/2}\delta N^{[\leqslant n]}\mathcal{H}_0^{1/2}$ is isolated [it is nondegenerate and its distance from the others is $O(\varepsilon\eta^{k_0-1})$], we can represent $\lambda^{[n]}(x;\eta)$ in the form

$$\lambda^{[n]}(x;\eta) = -\eta^{2k_0-1}\,\mathrm{Tr}\left(\frac{1}{2\pi i}\oint_\gamma \frac{z\,dz}{z-\eta^{1-2k_0}\mathcal{H}_0^{1/2}\delta N^{[\leqslant n]}\mathcal{H}_0^{1/2}}\right), \tag{G11}$$

where z is a complex variable *independent of* ε, x, and γ is a circle in the complex plane around $\tilde{M}_{\beta\beta}(\eta)\partial_B^2 H_0$ not surrounding the origin, with ε-independent radius. The derivatives of $\lambda^{[n]}(x;\eta)$ with respect to ε and x can be computed differentiating the rhs of (G11) and, using the dimensional bounds (G10), we find the same dimensional bounds for the derivatives of $\lambda^{[n]}(x;\eta)$,

$$|\partial_\varepsilon\lambda^{[n]}(x;\eta)| \leqslant C\eta^{k_0-1}, \quad |\partial_x\lambda^{[n]}(x;\eta)| \leqslant C\eta^{k_0}. \tag{G12}$$

The proof of Lemma 5 is concluded.

APPENDIX H: EXCLUDED VALUES OF THE PERTURBATION PARAMETER

In this section we want to check that, by imposing the first condition in (6.8), the measure of excluded values of ε can be bounded by the second of (6.8). To estimate the measure of the excluded ε's we proceed as in Appendix A2 of Ref. 15. We present a proof valid for any $n \geqslant n_0$. The dimensional bounds (6.2) and the property $|\lambda^{[n]}(\eta)-\lambda^{[n-1]}(\eta)| \leqslant Ce^{-\kappa_1 2^{n/\tau_1}}$ (see Lemma 5) implies the following dimensional bound for the derivative of $\sqrt{\lambda^{[n]}(\eta)}$:

$$|\partial_\varepsilon\sqrt{\lambda^{[n]}(\eta)}| \leqslant C'\eta^{-1/2}. \tag{H1}$$

Then the first condition in (6.8) excludes, for each $\boldsymbol{\nu}$, a subinterval of $I(\bar{\varepsilon})$ whose measure is bounded by

$$\frac{C_0 2^{-m/2}\eta^{1/2}}{C'|\boldsymbol{\nu}|^{\tau_1}.} \tag{H2}$$

The Diophantine condition on $\boldsymbol{\omega}$ implies that if the first condition in (6.8) is invalid then $|\boldsymbol{\nu}|$ cannot be too small,

$$\frac{C_0 2^{-m/2}}{|\boldsymbol{\nu}|^{\tau_1}} + \sqrt{\lambda^{[n]}(\eta)} \geqslant |x| \geqslant C_0 |\boldsymbol{\nu}|^{-\tau_0}. \tag{H3}$$

Therefore $C_0/2|\boldsymbol{\nu}|^{\tau_0} \geqslant C'' \eta^{k_0-1/2}$, hence in this case we only have to consider the values of $\boldsymbol{\nu}$ such that $|\boldsymbol{\nu}|^{\tau_0} \geqslant (C_0/2C'')\eta^{1/2-k_0}$. Summing (H2) over the $\boldsymbol{\nu}$'s satisfying this constraint, and using the definition $\tau_1 = \tau_0(1+\delta_1)+N$ we find that the total measure of excluded ε's can be bounded by

$$\frac{C_0 2^{-m/2}\eta^{1/2}}{C'}\left(\frac{2C''\eta^{k_0-1/2}}{C_0}\right)^{1+\delta_1} \sum_{|\boldsymbol{\nu}|\neq 0} \frac{1}{|\boldsymbol{\nu}|^N} \equiv K C_0 2^{-m/2} |\varepsilon| \eta^{\delta_1(k_0-1/2)}, \tag{H4}$$

which is in fact the second inequality in (6.8).

Covariant irreducible parametrization of electromagnetic fields in arbitrary space-time

David Sundkvist[a)]
Laboratoire de Physique et Chimie de l'Environnement, CNRS, Orléans, France

(Received 29 September 2005; accepted 21 November 2005;
published online 20 January 2006; publisher error corrected 30 January 2006)

We present a new unified covariant description of electromagnetic field properties for an arbitrary space-time. We derive a complete set of irreducible components describing a six-dimensional electromagnetic field from the Maxwell and metric tensors using the symmetry group SL(2,C). For the special case of a flat space-time metric the components are shown to correspond to the scalar invariants of the electromagnetic field, the energy-momentum-stress tensor and in addition, three new tensors expressing physical observables of rank two and four, respectively. We make a physical interpretation of one of the new rank two tensor as describing a classical intrinsic spin of the electromagnetic field. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2162107]

I. INTRODUCTION

The electromagnetic field in Maxwells theory is since long known to satisfy important symmetries and consequently satisfy conservation laws. For example, the conservation law $T^{\alpha\beta}{}_{,\beta}=0$ where $T^{\alpha\beta}$ is the usual energy-momentum-stress tensor expresses the conservation of energy, momentum (Poynting) and stress densities of the electromagnetic field in a (local) Minkowski space. However, these are not the only symmetries and conserved quantities of physical relevance. In Minkowski space the Maxwell equations are invariant under the important inhomogeneous Lorentz group, or as sometimes called, the Poincaré group. The flat space-time of Minkowski space exhibits the maximum degree of symmetry one can obtain.

Moving to the curved space-time of general relativity many of the symmetries are lost, and conservation laws applies only locally. A group arising naturally in the study of general relativity is the group SL(2,C), the group of complex unimodular 2×2 matrices. There exist a homomorphism between SL(2,C) and the proper, orthochronous homogeneous Lorentz group L,

$$\mathrm{SL}(2,\mathrm{C}) \rightarrow \mathrm{L}, \tag{1}$$

reflecting the fact that SL(2,C) is the covering group of L and indicating how local Lorentz invariance is retained.

In this paper we present a new unified treatment of the symmetries of the electromagnetic field in a general Riemannian space-time by calculating the irreducible components of the covariant spectral density tensor. By performing a Fourier transform in time and considering the complex spectral densities we have further generalized to wave fields.

In Sec. II we define the problem of finding the irreducible components by expressing the possible bilinear forms of the electromagnetic field in terms of the covariant spectral density. We then translate this to an equivalent problem under the group SL(2,C) by transforming to the tangent spinor space. After decomposing the spectral density spinor into irreducible components under SL(2,C) we transform back to the equivalent tensors in Riemann space. In Sec. III we study the important special case of a flat space-time and calculate the components explicitly. Some of

[a)]Now at Swedish Institute of Space Physics, Uppsala, Sweden. Electronic mail: davids@irfu.se

them are shown to correspond to well-known objects in Maxwells theory, while other components obtained have not previously been found in the literature. Finally, in Sec. IV we discuss our conclusions and present ideas for future work.

II. SL(2,C) THEORY OF WAVE FIELD SPECTRAL DENSITIES

A. Covariant spectral density tensor

The fundamental physical object describing the electromagnetic field is the electromagnetic field tensor $f_{\mu\nu}$ which is skew-symmetric in its two indices,

$$f_{\mu\nu} = -f_{\nu\mu}. \tag{2}$$

It is comprised of the six components of the electromagnetic field. We wish to categorize an electromagnetic *wave* field and therefore decompose the electric and magnetic fields in their spectral components. Let $\mathbf{f}(t,\mathbf{r})$ denote either the electric field $\mathbf{E}$ or magnetic field $\mathbf{B}$ at a point in space and time,

$$\mathbf{f}(t,\mathbf{r}) = \begin{pmatrix} f_x(t,\mathbf{r}) \\ f_y(t,\mathbf{r}) \\ f_z(t,\mathbf{r}) \end{pmatrix}. \tag{3}$$

The Fourier transform in time, denoted by capital letters, is then given by

$$\mathbf{F}(\omega,\mathbf{r}) = \int_{-\infty}^{\infty} \mathbf{f}(t,\mathbf{r}) e^{i\omega t}. \tag{4}$$

In the following we assume that the fields $\mathbf{E}$, $\mathbf{B}$, and hence the tensor $F_{\mu\nu}$ are Fourier transformed according to (4). This implies that the tensor $F_{\mu\nu}(\omega,\mathbf{r})$ is now complex. We form all possible bilinear forms of the electromagnetic field by constructing the outer product

$$S = F \otimes F^{\dagger} \tag{5}$$

which in tensor notation becomes

$$S_{\alpha\beta\gamma\delta} = F_{\alpha\beta}\overline{F_{\delta\gamma}}, \tag{6}$$

where the bar denotes complex conjugate. We call the complex tensor $S_{\alpha\beta\gamma\delta}$ in Eq. (6) the *covariant spectral density tensor*. From its definition and the skew-symmetry of $F_{\mu\nu}$, Eq. (2), the symmetries of $S_{\alpha\beta\gamma\delta}$ follows as

$$S_{\alpha\beta\gamma\delta} = -S_{\beta\alpha\gamma\delta} = -S_{\alpha\beta\delta\gamma} = S_{\beta\alpha\delta\gamma}, \tag{7a}$$

$$S_{\alpha\beta\gamma\delta} = \overline{S_{\gamma\delta\alpha\beta}}. \tag{7b}$$

Note that the decomposition in this section is not dependent on the particular transform used, but rather on the local structure and symmetry of the tensor $S_{\alpha\beta\gamma\delta}$. This tensor has $4^4 = 256$ complex components, but only 36 of these are independent due to the symmetries expressed in Eq. (7a). This number is further decreased to half by the symmetry in Eq. (7b). Accordingly, we find that $S_{\alpha\beta\gamma\delta}$ behaves as a six-dimensional Hermitian matrix and has 36 independent real valued components. To find these we will find it convenient to reduce $S_{\alpha\beta\gamma\delta}$ into its irreducible parts. This will be done in the spinor formalism of SL(2,C).

B. Spinor representation of spectral density

Spinors arise in the representation theory of the group SL(2,C). For a short review of the theory of spinors, see the Appendix, or a general reference such as Ref. 1. According to Eq. (A7) we find the spinor equivalent of the covariant spectral density tensor to be given by

$$S_{AB'CD'EF'GH'} = \sigma^{\alpha}_{AB'}\sigma^{\beta}_{CD'}\sigma^{\gamma}_{EF'}\sigma^{\delta}_{GH'}S_{\alpha\beta\gamma\delta}, \tag{8}$$

where the $\sigma^{\mu}_{AB'}$ matrices are the Infeld van der Waerden symbols, related to the metric tensor $g_{\mu\nu}$ by Eq. (A2). We call the spinor $S_{AB'CD'EF'GH'}$ the *spectral density spinor*. The symmetry condition Eq. (7a) and Eq. (8) implies

$$S_{AB'CD'EF'GH'} = -S_{CD'AB'EF'GH'} = -S_{AB'CD'GH'EF'}. \tag{9a}$$

Since $S_{\alpha\beta\gamma\delta}$ is complex, the spectral density spinor is not Hermitian in its indices. To find how $S_{AB'CD'EF'GH'}$ transforms under complex conjugation we consider Eq. (8) and Eqs. (7) with the result

$$S_{AB'CD'EF'GH'} = \overline{S_{HG'FE'DC'BA'}} = \overline{S}_{H'GF'ED'CB'A}. \tag{9b}$$

To find the decomposition of the spectral density spinor we make the observation that the equivalent spectral density tensor satisfies some of the same symmetries, Eq. (7a), as the Riemann tensor. We therefore let Refs. 1 and 2 inspire us in the decomposition and make use of the identities Eqs. (A11) and (A12). Writing the spectral density spinor in a symmetric form

$$S_{AB'CD'EF'GH'} = \tfrac{1}{2}(S_{AB'CD'EF'GH'} - S_{CB'AD'EF'GH'}) + \tfrac{1}{2}(S_{CB'AD'EF'GH'} - S_{CD'AB'EF'GH'}) \tag{10}$$

and applying Eq. (A12) gives

$$S_{AB'CD'EF'GH'} = \tfrac{1}{2}(\varepsilon_{AC}S_{IB'}{}^{I}{}_{D'EF'GH'} + S_{CJ'A}{}^{J'}{}_{EF'GH'}\varepsilon_{B'D'}). \tag{11}$$

Writing Eq. (11) in symmetric form and using Eq. (A12) once more on each term results in

$$\begin{aligned} S_{AB'CD'EF'GH'} = {} & \tfrac{1}{4}\varepsilon_{AC}(S_{IB'}{}^{I}{}_{D'JF'}{}^{J}{}_{H'}\varepsilon_{EG} + S_{IB'}{}^{I}{}_{D'EK'G}{}^{K'}\varepsilon_{F'H'}) \\ & + \tfrac{1}{4}(S_{AI'C}{}^{I'}{}_{JF'}{}^{J}{}_{H'}\varepsilon_{EG} + S_{AI'C}{}^{I'}{}_{EK'G}{}^{K'}\varepsilon_{F'H'})\varepsilon_{B'D'}. \end{aligned} \tag{12}$$

For the spinors in the last three terms in Eq. (12) we introduce the notation

$$\Gamma_{B'D'EG} = \tfrac{1}{4}S_{IB'}{}^{I}{}_{D'EK'G}{}^{K'}, \tag{13}$$

$$\Delta_{ACF'H'} = \tfrac{1}{4}S_{AI'C}{}^{I'}{}_{JF'}{}^{J}{}_{H'}, \tag{14}$$

$$\Sigma_{ACEG} = \tfrac{1}{4}S_{AI'C}{}^{I'}{}_{EK'G}{}^{K'}. \tag{15}$$

From Eq. (9a) and Eqs. (13)–(15) it follows that the symmetries of the decomposed spinors are

$$\Gamma_{B'D'EG} = \Gamma_{D'B'EG} = \Gamma_{B'D'GE}, \tag{16}$$

$$\Delta_{ACF'H'} = \Delta_{CAF'H'} = \Delta_{ACH'F'}, \tag{17}$$

$$\Sigma_{ACEG} = \Sigma_{CAEG} = \Sigma_{ACGE}. \tag{18}$$

For the first term in Eq. (12) we obtain

$$\tfrac{1}{4}S_{IB'\ D'JF'\ H'}^{\ \ I\ \ \ \ J} = \tfrac{1}{4}\overline{S_{FJ'H\ \ BI'D}^{\ \ \ J'\ \ \ \ I'}} = \overline{\Sigma}_{F'H'B'D'}, \tag{19}$$

where we have used Eqs. (9) and Eq. (15). The Γ and Δ spinors in the second and third terms of Eq. (12) both contain mixed indices and do not satisfy a relation similar to Eq. (19). Instead they transform under complex conjugation as

$$\Gamma_{B'D'EG} = \overline{\Gamma_{E'G'BD}} = \overline{\Gamma}_{EGB'D'}, \tag{20}$$

$$\Delta_{ACF'H'} = \overline{\Delta_{FHA'C'}} = \overline{\Delta}_{F'H'AC}, \tag{21}$$

where we have used Eqs. (9). Hence, Eq. (12) can be written as

$$S_{AB'CD'EF'GH'} = \varepsilon_{AC}(\overline{\Sigma}_{F'H'B'D'}\varepsilon_{EG} + \Gamma_{B'D'EG}\varepsilon_{F'H'}) + (\Delta_{ACF'H'}\varepsilon_{EG} + \Sigma_{ACEG}\varepsilon_{F'H'})\varepsilon_{B'D'}. \tag{22}$$

C. Number of independent parameters

From Eq. (22) we may find the number of independent parameters needed to fully describe an electromagnetic wave field. Introducing the notation $(1,2,3)=(00,01=10,11)$ we can write the components of the Σ_{ACEG} spinor as $\Sigma_{0000}=\Sigma_{11}$, $\Sigma_{1000}=\Sigma_{0100}=\Sigma_{21}$, $\Sigma_{1100}=\Sigma_{31}$, and similarily for the other components. From the symmetries in Eq. (18) we can then view the components of Σ_{ACEG} as a matrix $\boldsymbol{\Sigma}$ with nine independent complex components

$$\boldsymbol{\Sigma} = \begin{pmatrix} \Sigma_{11} & \Sigma_{12} & \Sigma_{13} \\ \Sigma_{21} & \Sigma_{22} & \Sigma_{23} \\ \Sigma_{31} & \Sigma_{32} & \Sigma_{33} \end{pmatrix} \tag{23}$$

or equivalently 18 real independent components. The $\Delta_{ACF'H'}$ and $\Gamma_{B'D'EG}$ spinors in addition to Eq. (16) and Eq. (17) also satisfies Eq. (21) and Eq. (20). Hence the corresponding matrices behave like Hermitian 3×3 matrices $\Delta_{ij}=\overline{\Delta}_{ji}$, $\Gamma_{ij}=\overline{\Gamma}_{ji}$ where $(i,j)\in(1,2,3)$, i.e., $\Delta=\Delta^\dagger$, $\Gamma=\Gamma^\dagger$. Therefore the spinor $\Delta_{ACF'H'}$ has three real components $\Delta_{11},\Delta_{22},\Delta_{33}$ and three complex components $\Delta_{12},\Delta_{13},\Delta_{23}$, in total nine real independent components. The same applies to the $\Gamma_{B'D'EG}$ spinor. In total we find $18+9+9=36$ real independent components describing the wave electromagnetic field in the spinor formulation, in accordance with the discussion following Eq. (7).

D. Irreducible spinor representation

Equation (22) is still not on an irreducible form. To find the first irreducible component we form the contracted spinor

$$S_{AB'CD'} = S^{EF'}{}_{AB'EF'CD'} = \varepsilon_{AC}\varepsilon_{B'D'}\tfrac{1}{2}(\lambda + \lambda^*) - \Gamma_{B'D'AC} - \Delta_{ACB'D'}, \tag{24}$$

where we have defined λ as the trace of the Σ spinor,

$$\lambda = \Sigma_{AE}^{\ \ AE} \tag{25}$$

and used

$$\Sigma_{AE\ C}^{\ E} = \frac{\lambda}{2}\varepsilon_{AC}, \tag{26}$$

$$\overline{\Sigma}_{D'F'\ B'}^{\ \ F'} = \frac{\lambda^*}{2}\varepsilon_{D'B'}. \tag{27}$$

The trace S of the contracted spinor $S_{AB'CD'}$,

$$S = S_{AB'}{}^{AB'} = \varepsilon^{AG}\varepsilon^{B'H'}S_{AB'GH'} = 2(\lambda + \lambda^*) - \Gamma_{B'}{}^{B'}{}_{A}{}^{A} - \Delta_{A}{}^{A}{}_{B'}{}^{B'} = 2(\lambda + \lambda^*) \tag{28}$$

is thus real. We now form the spinor

$$M_{AB'CD'} = S_{AB'CD'} - \tfrac{1}{4}g_{AB'CD'}S \tag{29}$$

which is traceless by construction and hence irreducible. From its definition we find the relations

$$M_{AB'CD'} = -\Gamma_{B'D'AC} - \Delta_{ACB'D'}, \tag{30}$$

$$M_{AB'CD'} = M_{CD'AB'}, \tag{31}$$

$$M_{AB'CD'} = \overline{M_{BA'DC'}}. \tag{32}$$

Calculating the trace of the terms involving the Γ and Δ spinors in Eq. (22) we find

$$M_{AB'CD'} = \varepsilon^{EG}\varepsilon^{F'H'}(\varepsilon_{GA}\varepsilon_{F'D'}\Gamma_{H'B'EC} + \varepsilon_{EC}\varepsilon_{H'B'}\Delta_{GAF'D'}). \tag{33}$$

We therefore write these terms in a form symmetric and antisymmetric in exchange of the first and second against the third and fourth pair of indices with the result

$$\begin{aligned}&\varepsilon_{AC}\varepsilon_{F'H'}\Gamma_{B'D'EG} + \varepsilon_{EG}\varepsilon_{B'D'}\Delta_{ACF'H'}\\ &\quad = \tfrac{1}{2}(\varepsilon_{EG}\varepsilon_{B'D'}D_{AF'CH'} - \varepsilon_{AC}\varepsilon_{F'H'}D_{EB'GD'} - \varepsilon_{AC}\varepsilon_{F'H'}M_{EB'GD'} - \varepsilon_{EG}\varepsilon_{B'D'}M_{AF'CH'}),\end{aligned} \tag{34}$$

where we have also defined

$$D_{AB'CD'} = -\Gamma_{B'D'AC} + \Delta_{ACB'D'} \tag{35}$$

which has the same symmetries as $M_{AB'CD'}$ and is also traceless.

It remains to find the irreducible parts of the Σ spinors in Eq. (22). To this end we write Σ in a form utilizing the symmetries expressed in Eq. (18),

$$\begin{aligned}\Sigma_{ABCD} = \Psi_{ABCD} &+ \frac{1}{3!}(\Sigma_{ABCD} - \Sigma_{DABC}) + \frac{1}{3!}(\Sigma_{ABCD} - \Sigma_{CDAB}) + \frac{1}{3!}(\Sigma_{ABCD} - \Sigma_{BCDA})\\ &+ \frac{1}{3!}(\Sigma_{ABCD} - \Sigma_{DBAC}) + \frac{1}{3!}(\Sigma_{ABCD} - \Sigma_{ACDB}),\end{aligned} \tag{36}$$

where

$$\Psi_{ABCD} = \frac{1}{3!}(\Sigma_{ABCD} + \Sigma_{DABC} + \Sigma_{CDAB} + \Sigma_{BCDA} + \Sigma_{DBAC} + \Sigma_{ACDB}) \tag{37}$$

is a completely symmetric spinor,

$$\Psi_{ABCD} = \Psi_{BACD} = \Psi_{ABDC} = \Psi_{ACBD}. \tag{38}$$

Using Eqs. (A12) and (26) on the remaining terms of Eq. (36) we find

$$\Sigma_{ABCD} = \Psi_{ABCD} + \frac{\lambda}{6}(\varepsilon_{AC}\varepsilon_{BD} + \varepsilon_{AD}\varepsilon_{BC}) + \xi_{ABCD} \tag{39}$$

where we have defined the spinor

$$\xi_{ABCD} = \tfrac{1}{6}(\Sigma_{ABCD} - \Sigma_{CDAB}) \tag{40}$$

satisfying the symmetries

$$\xi_{ABCD} = \xi_{BACD} = \xi_{ABDC} = -\xi_{CDAB}. \tag{41}$$

Inserting Eq. (39) and its complex conjugate equivalent into (22) and using (34) finally gives

$$\begin{aligned} S_{AB'CD'EF'GH'} = C_{AB'CD'EF'GH'} &+ \frac{\lambda}{6}\varepsilon_{B'D'}\varepsilon_{F'H'}(\varepsilon_{AE}\varepsilon_{CG} + \varepsilon_{AG}\varepsilon_{CE}) + \frac{\lambda^*}{6}\varepsilon_{AC}\varepsilon_{EG}(\varepsilon_{F'B'}\varepsilon_{H'D'} \\ &+ \varepsilon_{F'D'}\varepsilon_{H'B'}) + \frac{1}{2}(\varepsilon_{EG}\varepsilon_{B'D'}D_{AF'CH'} - \varepsilon_{AC}\varepsilon_{F'H'}D_{EB'GD'} - \varepsilon_{AC}\varepsilon_{F'H'}M_{EB'GD'} \\ &- \varepsilon_{EG}\varepsilon_{B'D'}M_{AF'CH'}). \end{aligned} \tag{42}$$

The spinor $C_{AB'CD'EF'GH'}$ is defined by

$$C_{AB'CD'EF'GH'} = A_{AB'CD'EF'GH'} + B_{AB'CD'EF'GH'}, \tag{43}$$

where

$$A_{AB'CD'EF'GH'} = \Psi_{ACEG}\varepsilon_{F'H'}\varepsilon_{B'D'} + \overline{\Psi}_{F'H'B'D'}\varepsilon_{AC}\varepsilon_{EG}, \tag{44}$$

and

$$B_{AB'CD'EF'GH'} = \xi_{ACEG}\varepsilon_{F'H'}\varepsilon_{B'D'} + \overline{\xi}_{F'H'B'D'}\varepsilon_{AC}\varepsilon_{EG}. \tag{45}$$

The decomposition of $C_{AB'CD'EF'GH'}$ into A and B is equivalent to a decomposition of the spinor into real and imaginary parts, $A_{AB'CD'EF'GH'} = \Re(C_{AB'CD'EF'GH'})$ and $B_{AB'CD'EF'GH'} = \Im(C_{AB'CD'EF'GH'})$. The spinor $A_{AB'CD'EF'GH'}$ is identically zero when contracted over the first and third pair of indices,

$$A^{EF'}{}_{AB'EF'CD'} = 0, \tag{46}$$

due to its symmetries and real valuedness which is readily verified after some straightforward algebra. The spinor $B_{AB'CD'EF'GH'}$ can be contracted to form

$$\Upsilon_{AB'CD'} = B^{EF'}{}_{AB'EF'CD'} \tag{47}$$

satisfying

$$\Upsilon_{AB'CD'} = -\Upsilon_{CD'AB'} = \overline{\Upsilon}_{CD'AB'} \tag{48}$$

and which is traceless in turn

$$\Upsilon^{AB'CD'}{}_{AB'CD'} = 0. \tag{49}$$

Equations (42)–(47) is comprised only of scalars or traceless spinors and hence is the sought irreducible representation of the spectral density spinor. In summary the decomposition is

$$S_{AB'CD'EF'GH'} = A_{AB'CD'EF'GH'} \oplus \Upsilon_{AB'CD'} \oplus M_{AB'CD'} \oplus D_{AB'CD'} \oplus \lambda. \tag{50}$$

Counting components we find that Eq. (43) has 5 plus 3 complex components from Ψ and ξ, respectively, which follows from the symmetries. From the discussion in Sec. II C we know that the Γ and Δ spinors have nine real components each which implies that M and D have 18 real components in total. Together with the complex invariant λ it adds up to 36 independent real components, in agreement with the above discussion.

E. Relation to the Riemann tensor

We may note that if the covariant spectral density tensor was real and satisfied $S_{\alpha\beta\gamma\delta}=S_{\gamma\delta\alpha\beta}$ instead of Eq. (7b) it would satisfy the same symmetries as the Riemann tensor, $S_{\alpha\beta\gamma\delta}=R_{\alpha\beta\gamma\delta}$. Indeed in such a case $D_{AB'CD'}=0$, $\xi_{AB'CD'}=0$, $\Gamma_{AB'CD'}=\overline{\Delta}_{CD'AB'}$ so that $M_{AB'CD'}=2\Delta_{AB'CD'}$ would be the traceless Ricci spinor, $A_{AB'CD'EF'GH'}=\Psi_{ACEG}\varepsilon_{F'H'}\varepsilon_{B'D'}+\overline{\Psi}_{F'H'B'D'}\varepsilon_{AC}\varepsilon_{EG}$ the traceless Weyl spinor and $\lambda=\lambda^{*}=R$ would be the Ricci scalar curvature. Hence Eq. (42) would be completely analogous to the irreducible spinor representation of the Riemann curvature tensor.

F. Irreducible tensor representation

It is interesting to transform Eq. (42) to its tensor form, using the relation between a spinor and its equivalent tensor, given by Eq. (A9). In summary, we can write this decomposition of the covariant spectral density tensor into its irreducible components symbolically as

$$S_{\alpha\beta\gamma\delta}=A_{\alpha\beta\gamma\delta}\oplus\Upsilon_{\alpha\beta}\oplus M_{\alpha\beta}\oplus D_{\alpha\beta}\oplus\lambda, \tag{51}$$

with the number of independent components $10+6+9+9+2=36$. In connection to this it is worthwhile noting that the complex scalar invariant λ, the only quantity of the electromagnetic field different observers agree on, satisfies

$$\Re(\lambda)=\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}, \tag{52}$$

$$\Im(\lambda)=-\tfrac{1}{8}F_{\mu\nu}{}^{*}F^{\mu\nu}, \tag{53}$$

where ${}^{*}F^{\mu\nu}$ is the dual tensor

$${}^{*}F^{\mu\nu}=\tfrac{1}{2}\varepsilon^{\mu\nu\rho\sigma}F_{\rho\sigma}. \tag{54}$$

Hence, we recover the two scalar invariants of electromagnetic field theory as the real and imaginary parts of the complex scalar invariant of the covariant spectral density tensor.

III. SPECIAL CASE: FLAT SPACE-TIME

In this section we treat the important special case of a flat space-time in the absence of gravitation, with the prescribed metric given by

$$g_{\mu\nu}=\begin{pmatrix}1&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&-1\end{pmatrix}. \tag{55}$$

The electromagnetic field tensor is represented by

$$F_{\mu\nu}=\begin{pmatrix}0&-E_x&-E_y&-E_z\\E_x&0&B_z&-B_y\\E_y&-B_z&0&B_x\\E_z&B_y&-B_x&0\end{pmatrix} \tag{56}$$

in natural units where we have put $c=1$.

The solution to Eq. (A2) for the given Minkowskian metric Eq. (55) gives the Infeld van der Waerden symbols

$$\sigma^0_{AB'} = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \sigma^1_{AB'} = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$
$$\sigma^2_{AB'} = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}, \quad \sigma^3_{AB'} = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \tag{57}$$

proportional to the Pauli matrices.[1] We now follow the following scheme:

(1) Form the spectral density tensor Eq. (6).
(2) Calculate the spectral density spinor Eq. (8) using Eq. (57).
(3) Calculate Γ, Σ, Δ using Eqs. (13)–(15).
(4) Calculate the irreducible spinor components λ from Eq. (25), $M_{AB'CD'}$ from Eq. (30), $D_{AB'CD'}$ from Eq. (35), Ψ from Eq. (37) and ξ using Eq. (40).
(5) Transform the spinors obtained to their irreducible tensor counterparts using Eq. (A9) and the spinorally contravariant form of Eq. (57).

A. Fundamental objects as irreducible components

By following the above scheme we find the SL(2,C) irreducible tensor components that comprise the spectral density tensor according to Eq. (51). The first tensor, the complex scalar invariant λ is found to be

$$\lambda = \tfrac{1}{2}[|\mathbf{E}|^2 - |\mathbf{B}|^2] + i\Re(\mathbf{E}\cdot\mathbf{B}^*). \tag{58}$$

We identify the real and imaginary parts as the scalar Lagrangian invariant and the pseudoscalar invariant (here expressed in complex form since the fields are Fourier transformed). As is well known, these are the only two invariants that exist in Maxwells theory. This is verified here by the fact that only scalars are true invariants under a general spin frame transformation.

Calculating the components of the first rank two tensor $M_{\alpha\beta}$ we find

$$M_{\alpha\beta} = \begin{pmatrix} \sigma & P_x & P_y & P_z \\ P_x & T_{xx} & T_{xy} & T_{xz} \\ P_y & T_{yx} & T_{yy} & T_{yz} \\ P_z & T_{zx} & T_{zy} & T_{zz} \end{pmatrix}, \tag{59}$$

where we have used the notation

$$\sigma = \tfrac{1}{2}(|\mathbf{E}|^2 + |\mathbf{B}|^2), \tag{60}$$

$$P_x = \tfrac{1}{2}[\Re(E_y B_z^*) - \Re(B_y^* E_z)], \tag{61}$$

$$P_y = \tfrac{1}{2}[\Re(E_z B_x^*) - \Re(B_z^* E_x)], \tag{62}$$

$$P_z = \tfrac{1}{2}[\Re(E_x B_y^*) - \Re(B_x^* E_y)], \tag{63}$$

$$T_{ij} = -\Re[E_i E_j^* + B_i B_j^*] + \delta_{ij}\sigma. \tag{64}$$

We immediately recognize Eq. (59) as the energy-momentum-stress tensor in Maxwells theory, here obtained as one of the irreducible components of the spectral density tensor under SL(2,C). We identify as usual σ as the energy density of the electromagnetic field, $(P_x, P_y, P_z) = \frac{1}{2}\Re(\mathbf{E}\times\mathbf{B}^*)$ as the complex Poynting vector and T_{ij} as the three-dimensional Maxwell stress tensor.

Turning our attention to the second rank two irreducible tensor $D_{\alpha\beta}$ we find analogously

$$D_{\alpha\beta}=\begin{pmatrix} K & Q_x & Q_y & Q_z \\ Q_x & U_{xx} & U_{xy} & U_{xz} \\ Q_y & U_{yx} & U_{yy} & U_{yz} \\ Q_z & U_{zx} & U_{zy} & U_{zz} \end{pmatrix}, \tag{65}$$

where we have used the notation

$$K=-\Im(\mathbf{E}\cdot\mathbf{B}^*), \tag{66}$$

$$\mathbf{Q}=-\frac{i}{2}(\mathbf{E}\times\mathbf{E}^*+\mathbf{B}\times\mathbf{B}^*), \tag{67}$$

$$U_{ij}=-\Im[E_i^*B_j-B_i^*E_j]+\delta_{ij}K. \tag{68}$$

We identify the D_{00} component as the imaginary part of the pseudoscalar invariant of the electromagnetic field. Since also, e.g., $Q_x=-\Im(E_zE_y^*+B_zB_y^*)$ we note that all components of the tensor $D_{\alpha\beta}$ can be written as imaginary parts. In analogy with σ, the energy density Eq. (60), we may denote Eq. (66) the spin density of the electromagnetic field. This is because **Q**, Eq. (67), is only different from zero in the case when the electromagnetic field is elliptically (i.e., not linearly) polarized. We call **Q** the "spin flux density."

Finally we calculate the components of the remaining rank four tensor $C_{\alpha\beta\gamma\delta}$. Its real part $A_{\alpha\beta\gamma\delta}$ is traceless

$$A^{\gamma}{}_{\alpha\gamma\beta}=0 \tag{69}$$

when contracted. This tensor has 10 independent components. In order to write this rank four tensor on a compact form, we introduce the bijective mapping of the index pairs $(1,0)\leftrightarrow(1)$, $(2,0)\leftrightarrow(2)$, $(3,0)\leftrightarrow(3)$, $(3,2)\leftrightarrow(4)$, $-(3,1)\leftrightarrow(5)$, $(2,1)\leftrightarrow(6)$. We can then construct the column sixtors A_k, where, for example, the first vector is $A_1=(A_{1010},A_{1020},A_{1030},A_{1032},-A_{1031},A_{1021})^T$. The tensor $A_{\alpha\beta\gamma\delta}$ is then equivalent to the 6×6 matrix $A_{kl}=(A_1A_2A_3A_4A_5A_6)$. In index notation it becomes

$$A_{\alpha\beta\gamma\delta}\leftrightarrow\begin{pmatrix} E & F \\ F & -E \end{pmatrix}, \tag{70}$$

where the two block matrices

$$E=E_{ij}=-\tfrac{1}{2}\Re(E_i^*E_j-B_i^*B_j)+\tfrac{2}{6}\Re(\lambda)\delta_{ij} \tag{71}$$

and

$$F=F_{ij}=-\tfrac{1}{2}\Re(E_i^*B_j+B_i^*E_j)+\tfrac{2}{6}\Im(\lambda)\delta_{ij} \tag{72}$$

each contains five independent components.

The contracted imaginary part of $C_{\alpha\beta\gamma\delta}$ behaves as an antisymmetric Hermitian matrix and have the components

$$\Upsilon_{\alpha\beta}=\begin{pmatrix} 0 & \cdot & \cdot & \cdot \\ S_x & 0 & \cdot & \cdot \\ S_y & V_{yx} & 0 & \cdot \\ S_z & V_{zx} & V_{zy} & 0 \end{pmatrix}, \tag{73}$$

where

$$S = (S_x, S_y, S_z) = -\frac{i}{3}\Im(\mathbf{E} \times \mathbf{B}^*) \tag{74}$$

is the imaginary part of the complex Poynting vector and

$$V_{ij} = -\frac{i}{3}\Im(E_i^* E_j - B_i^* B_j) \tag{75}$$

is a three-tensor.

B. Physical interpretation

Interestingly, as we noted above, the real part of the scalar invariant Eq. (58) of the electromagnetic field would play the role of the Ricci scalar curvature in the case of real valued fields. Similarly the energy-momentum-stress tensor $M_{\alpha\beta}$ would play the role of the Ricci tensor, while the rank four tensor $A_{\alpha\beta\gamma\delta}$ would be analogous to the Weyl conformal tensor. While we could proceed with the analogy of curvature of space-time to the "curvature" of the electromagnetic field, we will not pursue this topic further in the present paper.

The fact that the two possible true invariants of the electromagnetic field are found as the real and imaginary parts of the complex scalar invariant is natural, since all inertial observers should agree upon their measured values. That the energy-momentum-stress tensor is found to be an irreducible component under SL(2,C) is encouraging and stress its importance in Maxwells theory.

More surprising is the (pseudo-) tensor $D_{\alpha\beta}$ found as the second irreducible rank two component. To the authors knowledge, this rank two tensor has not been written down explicitly in this form before.[3] We stress that this tensor is obtained on equal footing and occur as naturally as the energy-momentum stress tensor in our analysis. The components of $D_{\alpha\beta}$ represents observables, with a clear physical meaning of classical "spin". The new rank four tensor $C_{\alpha\beta\gamma\delta}$ is complex valued. Although the contracted imaginary part $\Upsilon_{\alpha\beta}$ is containing the imaginary part of the complex Poynting vector its physical interpretation is not yet clear and is left for a future study.

IV. CONCLUSIONS AND OUTLOOK

We have considered all possible bilinear forms of the electromagnetic Fourier transformed field for an arbitrary time-independent metric in Riemannian space-time. The constructed spectral density tensor was decomposed into irreducible components by considering the spectral density spinor in the complex tangent space introduced under the group SL(2,C). The spectral density was found to be comprised of the following irreducible components: a complex scalar invariant corresponding to the two known invariants of the electromagnetic field, the rank two energy-momentum-stress tensor, another new rank two tensor expressing the spin (polarization) properties of the electromagnetic field, another rank two tensor, containing the imaginary part of the complex Poynting vector, and finally a new rank four tensor. This decomposition is expressed in Eqs (50) and (51). While the first two tensors (scalar and stress tensor) are well-known important objects in Maxwells theory, the new rank two and rank four tensors are very little or not at all previously studied. Since they are irreducible components under the group transformations we propose that they also are conserved quantities of the electromagnetic field. Considering how they arise as naturally and inevitably as the ususal energy-momentum-stress tensor, they certainly deserve further study. We leave the detailed study of the discovered components and their conservation laws to a future investigation.

ACKNOWLEDGMENTS

The author thanks and acknowledges Dr. T. D. Carozzi for useful discussions regarding the identfication of the tensors obtained, and for pointing out the need for a covariant formulation of polarization states and that spinors could be a possible way to accomplish it.

APPENDIX: SPINOR REPRESENTATION OF THE GROUP SL(2,C) IN CURVED SPACE-TIME

In this appendix we review the theory of spinors and how they are applied to general relativity. In a Riemannian space one can to each point in space-time introduce a complex two-dimensional tangent space. For every tensor in Riemannian space there is then a corresponding complex spinor in the tangent spinor space. For every tensor index labeled with greek letters running over 0, 1, 2, 3 there are then two spinor indices labeled with capital letters running over 0, 1. Primed spinor indices belong to the complex conjugate spinor space and and runs over $0',1'$. Spinors originate from the representation theory of the group SL(2,C). We use a matrix representation in which a typical element g of the group SL(2,C) is represented by the matrix

$$g=\begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad ad-bc=1 \tag{A1}$$

with determinant unity.

The correspondence between tensors and spinors are established by the Infeld van der Waerden symbols, a set of four 2×2 Hermitian matrices $\sigma^{\mu}_{AB'}(x^{\nu})$, which are functions of space-time. These objects transform as a tensor in greek indices, and as a spinor in italic indices. They satisfy the relation

$$g_{\mu\nu}\sigma^{\mu}_{AB'}\sigma^{\nu}_{CD'}=\varepsilon_{AC}\varepsilon_{B'D'} \tag{A2}$$

relating the Infeld van der Waerden symbols to the metric tensor of Riemannian space and the Levi-Cevita symbols, represented by

$$\varepsilon_{AC}=\varepsilon_{B'D'}=\varepsilon^{AC}=\varepsilon^{B'D'}=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{A3}$$

The Levi-Cevita symbols play the spinor role analog to the metric tensors. The operation of raising and lowering spinor indices are accomplished by

$$\eta^{A}=\varepsilon^{AB}\eta_{B}, \quad \eta_{A}=\eta^{B}\varepsilon_{BA} \tag{A4}$$

and analogously for primed indices

$$\xi^{A'}=\varepsilon^{A'B'}\xi_{B'}, \quad \xi_{A'}=\xi^{B'}\varepsilon_{B'A'}. \tag{A5}$$

One can easily check that the spinor of the metric tensor satisfies

$$g_{AB'CD'}=\varepsilon_{AC}\varepsilon_{B'D'}. \tag{A6}$$

The relation between a tensor $T_{\mu\nu}$ and the corresponding spinor is given by

$$T_{AB'CD'}=\sigma^{\mu}_{AB'}\sigma^{\nu}_{CD'}T_{\mu\nu} \tag{A7}$$

and analogously for tensors with more indices. If the tensor is real valued, the spinor equivalent is Hermitian, e.g., the real valued vector A_{μ} has an equivalent Hermitian spinor

$$A_{AB'}=\overline{A_{BA'}}=\overline{A}_{B'A}. \tag{A8}$$

If the tensor is complex the hermicity condition of the spinor does not hold. This is the case for most spinors encountered in this paper. Finally, given a spinor $T_{AB'CD'}$ its tensor equivalent $T_{\mu\nu}$ is given by

$$\sigma^{AB'}_{\mu}\sigma^{CD'}_{\nu}T_{AB'CD'}=T_{\mu\nu}. \tag{A9}$$

We also list the following useful spinor relations:

$$\varepsilon^{AB}\varepsilon_{CA} = -\,\delta_C^{\ B}, \tag{A10}$$

$$\xi_{AB} - \xi_{BA} = \xi_C^{\ C}\varepsilon_{AB} = \varepsilon^{CD}\xi_{CD}\varepsilon_{AB}, \tag{A11}$$

$$\psi_{ABCD} - \psi_{BACD} = \psi_F^{\ F}{}_{CD}\varepsilon_{AB} = \varepsilon^{FG}\psi_{FGCD}\varepsilon_{AB}. \tag{A12}$$

Some mathematical properties of Maxwell's equations for macroscopic dielectrics

A. Tip[a)]
FOM Instituut voor Atoom-en Molecuulfysica AMOLF, Kruislaan 407, 1098 SJ Amsterdam, The Netherlands

(Received 14 July 2005; accepted 31 October 2005; published online 25 January 2006)

We consider a number of mathematical properties of Maxwell's equations for linear dispersive and absorptive dielectric media using the auxiliary field method developed earlier by the author [A. Tip, Phys. Rev. A **57**, 4818 (1998)]. Here the fields are interpreted as square integrable functions of $\mathbf{x} \in \mathbb{R}^3$. In case the susceptibility $\chi(\mathbf{x},t)$ is piecewise constant in $\mathbf{x}$, we show rigorously that a decomposition into independent equations for longitudinal and transverse fields can be made. We point out its relevance for the study of spectral properties of photonic crystals. Again, for the piecewise constant case we discuss the usual boundary conditions at interfaces and discuss the different nature of those for the longitudinal and transverse fields. Then we consider energy conservation for dispersive, nonabsorptive, media. We show that additional contributions to the free field energy density, as given in the literature, are associated with the energy stored in the auxiliary field modes. Finally, we show that also for nonlinear dielectrics it is possible to obtain a conserved energy by introducing auxiliary fields. © *2006 American Institute of Physics.*

I. INTRODUCTION

In the present paper we discuss some mathematical properties of the classical phenomenological Maxwell's equations for linear dielectrics, considering the fields as square integrable functions. Indeed, outside the realm of electrostatics, the propagation of electromagnetic waves is a major issue and it can be advantageous to employ a Hilbert space formulation. Then concepts known from the Schrödinger case can be taken over, notably for scattering and spatially periodic systems. In the first Møller (wave) operators naturally appear, whereas in the second the Bloch–Floquet decomposition is a convenient tool to study the spectral band structure of photonic crystals (PCs). A basic observation is here that the energy

$$\mathcal{E}_{\mathrm{em}}(t) = \frac{1}{2}\int d\mathbf{x}\{\mathbf{E}(\mathbf{x},t)^2 + \mathbf{B}(\mathbf{x},t)^2\} \tag{1.1}$$

of an electromagnetic system in vacuum, is a conserved quantity, so Eq. (1.1) can be used to introduce a norm and associated Hilbert space, leading to a unitary time evolution. However, macroscopic dielectrics have a more complicated structure and the situation is not as straightforward. The main obstacle is the appearance of a time convolution in the constitutive equation relating the displacement $\mathbf{D}(\mathbf{x},t)$ and electric field $\mathbf{E}(\mathbf{x},t)$,

[a)]Electronic mail: tip@amolf.nl

$$\mathbf{D}(\mathbf{x},t) = \mathbf{E}(\mathbf{x},t) + \mathbf{P}(\mathbf{x},t), \quad \mathbf{P}(\mathbf{x},t) = \int_{t_0}^{t} ds\, \chi(\mathbf{x},t-s)\mathbf{E}(\mathbf{x},s). \tag{1.2}$$

Nevertheless, as shown earlier by the author,[1] it is possible, by introducing two auxiliary fields, to obtain once more a description as a unitary time evolution in an appropriate Hilbert space. In a subsequent paper, with Moroz and Combes,[2] a mathematically precise theory of photonic crystals made up from general dispersive or absorptive dielectric material was given.

In the present work, after introducing the general formalism for macroscopic absorptive and dispersive systems, the emphasis will be on systems where the electric susceptibility $\chi(\mathbf{x},t)$ is piecewise constant as a function of $\mathbf{x}$, which is the typical situation for the scattering of electromagnetic waves from a homogeneous dielectric object and for PCs. For this case we show that an exact decomposition into separate sets of equations of motion for the transverse and longitudinal field components is possible. Here we use the momentum space definition of longitudinal and transverse components, valid for general square integrable fields, which reduces to the usual characterizations $\partial_{\mathbf{x}} \cdot \mathbf{f} = 0$ for transverse and $\partial_{\mathbf{x}} \times \mathbf{f} = 0$ for longitudinal fields for sufficiently smooth $\mathbf{f}$.

We then turn to the discussion of initial and boundary conditions. Although in electrostatics the continuity across interfaces of the normal component of the displacement $\mathbf{D}$ and the tangential components of the electric field $\mathbf{E}$ are often treated in a similar way, using Gauss' and Stokes' theorems, we show that they are of a different nature. The first is actually an initial condition on the system, whereas the second is not required at all for the existence of a time evolution, but makes its appearance in the differential form of Maxwell's equations and in eigenvalue problems. In this connection we note that we are dealing with elements of a Hilbert space, which are equivalence classes of square integrable functions. Within this context, continuity means that the equivalence class contains a continuous element.

Next we consider the conservation of energy for dispersive dielectrics. Although energy is expected to be conserved in the absence of absorption, it depends on which energy is actually considered. We show that the existing approximate expressions for the conserved energy density in fact consist of the sum of the electromagnetic one and the part contained in the auxiliary field modes.

Since the existence of a conserved energy plays an important role in the development of the theory presented here, we finally show that it is also possible to define a conserved energy for nonlinear dielectrics. Here we take the opportunity to discuss an alternative, equivalent, method to introduce auxiliary fields.

II. MAXWELL'S EQUATIONS AND THE LINEAR SUSCEPTIBILITY

A. Maxwell's equations

Here we summarize our earlier results[1] and start off by proceeding formally, but in the next section will end up with a precise setting where Maxwell's equations are recast as a unitary time evolution on a Hilbert space. As said this is *a priori* not evident in view of the time convolution in Eq. (1.2).

The macroscopic Maxwell's equations pertaining to absorptive and dispersive dielectrics are (we set $\varepsilon_0 = \mu_0 = 1$ and, in quantum situations, also $\hbar = 1$)

$$\partial_t \mathbf{D}(\mathbf{x},t) = \partial_{\mathbf{x}} \times \mathbf{B}(\mathbf{x},t), \quad \partial_t \mathbf{B}(\mathbf{x},t) = -\partial_{\mathbf{x}} \times \mathbf{E}(\mathbf{x},t),$$

$$\partial_{\mathbf{x}} \cdot \mathbf{D}(\mathbf{x},t) = \partial_{\mathbf{x}} \cdot \mathbf{B}(\mathbf{x},t) = 0, \quad \mathbf{D}(\mathbf{x},t) = \mathbf{E}(\mathbf{x},t) + \mathbf{P}(\mathbf{x},t), \tag{2.1}$$

where, in the isotropic linear case considered here, the polarization field $\mathbf{P}(\mathbf{x},t)$ is related to the electric field according to

$$\mathbf{P}(\mathbf{x},t) = \int_{t_0}^{t} ds\, \chi(\mathbf{x},t-s)\mathbf{E}(\mathbf{x},s), \quad \chi(\mathbf{x},t) = 0, \quad t \leqslant 0, \tag{2.2}$$

with $\chi(\mathbf{x},t)$ the electric susceptibility, which we consider as a given quantity. We are primarily concerned with the situation where the dielectric of interest fills the part of space outside of which we have a vacuum or an isotropic, spatially homogeneous, background medium, characterized by the dielectric constant $\varepsilon_{\mathrm{bg}}$, so $\mathbf{D}(\mathbf{x},t)=\varepsilon_{\mathrm{bg}}\mathbf{E}(\mathbf{x},t)$ for $\mathbf{x}$ in the background. By a simple rescaling, both cases can be treated in the same way. In Ref. 1 the situation where $\varepsilon_{\mathrm{bg}}$ depends on $\mathbf{x}$ was also considered.

We assume that $\chi(\mathbf{x},t)$ is measurable in $\mathbf{x}$ and differentiable in t [we denote $\partial_t\chi(\mathbf{x},t) = \chi'(\mathbf{x},t)$], satisfying

$$\chi(\mathbf{x},t) = 0, \quad t < 0, \quad \chi(\mathbf{x},0) = 0, \quad |\chi'(\mathbf{x},t)| \leqslant c' < \infty, \quad \forall\, \mathbf{x},t. \tag{2.3}$$

The vanishing of $\chi(\mathbf{x},t)$ for negative times is a consequence of causality, whereas its vanishing at $t=0$ excludes nonphysical initial surges in the current density $\mathbf{J}(\mathbf{x},t)=\partial_t\mathbf{P}(\mathbf{x},t)$.

An important special case is the situation where the material is contained in a set $\mathcal{A}\subset\mathbb{R}^3$, surrounded by the background medium, where $\mathcal{A}$ may be made up from a collection of nonoverlapping subsets, $\mathcal{A}=\cup_j\mathcal{A}_j$, $\mathcal{A}_j\cap\mathcal{A}_h=\varnothing$, $j\neq h$, with the boundaries of the subsets having certain regularity properties (spheres, cubes, a set of parallel layers or a half-space). In order to keep the bookkeeping simple, we assume that the susceptibility is homogeneous over each $\mathcal{A}_j$, so

$$\chi(\mathbf{x},t) = \sum_j \mathbf{I}_{\mathcal{A}_j}(\mathbf{x}) g_j(t), \tag{2.4}$$

where $\mathbf{I}_{\mathcal{M}}(\mathbf{x})$ is the characteristic function for the set $\mathcal{M}$, $\mathbf{I}_{\mathcal{M}}(\mathbf{x})=1$, $\mathbf{x}\in\mathcal{M}$, and vanishes otherwise. For PCs (see Sec. IV) the $\mathcal{A}_j$'s are identical sets with identical positions in the unit cells with the same $g(t)$.

Definition: We refer to the situation given by Eq. (2.4) as the piecewise constant case.

B. The susceptibility

We now turn to the general properties of the electric susceptibility $\chi(\mathbf{x},t)$. First we recast the first of Eqs. (2.1) according to

$$\partial_t\mathbf{E}(\mathbf{x},t) = \partial_{\mathbf{x}} \times \mathbf{B}(\mathbf{x},t) - \mathbf{J}(\mathbf{x},t), \quad \mathbf{J}(\mathbf{x},t) = \int_{t_0}^{t} ds\, \chi'(\mathbf{x},t-s)\mathbf{E}(\mathbf{x},s). \tag{2.5}$$

With $\mathcal{E}_{\mathrm{em}}(t)$ as given by Eq. (1.1), we noted in Ref. 5 that, adapting to the present notation,

$$\Delta\mathcal{E}_{\mathrm{em}}(t) \equiv \mathcal{E}_{\mathrm{em}}(t) - \mathcal{E}_{\mathrm{em}}(t_0) = -\int d\mathbf{x} \int_{t_0}^{t} ds \int_{t_0}^{t} du\, \chi'(\mathbf{x},s-u)\mathbf{E}(\mathbf{x},u)\cdot\mathbf{E}(\mathbf{x},s). \tag{2.6}$$

Denoting Laplace transforms with an overcaret,

$$\hat{f}(z) = \int_0^\infty dt\, \exp[izt] f(t), \quad \mathrm{Im}\, z > 0, \quad f(t) = \frac{1}{2\pi}\int d\omega\, \exp[-i(\omega+i\delta)t]\hat{f}(\omega+i\delta), \quad \delta > 0, \tag{2.7}$$

we then have, since $\chi(\mathbf{x},0)=0$,

$$\hat{\chi}'(\mathbf{x},z) = -iz\hat{\chi}(\mathbf{x},z), \tag{2.8}$$

and both $\hat{\chi}(\mathbf{x},z)$ and $\hat{\chi}'(\mathbf{x},z)$ are analytic in the open upper complex half-plane $\mathbb{C}^+$. In addition, we note that, in view of Eqs. (2.3), for $y>0$,

$$y|\hat{\chi}'(\mathbf{x},iy)| \leqslant c'. \tag{2.9}$$

We now write

$$\begin{aligned}\Delta\mathcal{E}_{\mathrm{em}}(t) &= -\frac{1}{2\pi}\int d\mathbf{x}\int d\omega\,\hat{\chi}'(\mathbf{x},\omega+i\delta)\left|\int_{t_0}^{t} ds\,\exp[-i(\omega+i\delta)s]\mathbf{E}(\mathbf{x},s)\right|^2 \\ &= -\frac{1}{2\pi}\int d\mathbf{x}\int d\omega\,\mathrm{Re}\,\hat{\chi}'(\mathbf{x},\omega+i\delta)\left|\int_{t_0}^{t} ds\,\exp[-i(\omega+i\delta)s]\mathbf{E}(\mathbf{x},s)\right|^2. \end{aligned}\tag{2.10}$$

Definition: We define the class of dispersive and absorptive systems as that for which $\Delta\mathcal{E}_{\mathrm{em}}(t)$ is nonincreasing.

For such systems $\mathrm{Re}\,\hat{\chi}'(\mathbf{x},z)\geqslant 0$, $z\in\mathbb{C}^+$, and taking the other properties of $\hat{\chi}'(\mathbf{x},z)$ into account, we conclude that $i\hat{\chi}'(\mathbf{x},z)$ is a Herglotz function (for a useful summary of the properties of Herglotz functions, see Ref. 4). Hence, $\hat{\chi}'(\mathbf{x},z)$ can be represented as

$$\hat{\chi}'(\mathbf{x},z) = -i\int \nu(\mathbf{x},d\lambda)\frac{1}{\lambda-z}, \tag{2.11}$$

where $\nu(\mathbf{x},d\lambda)$ is a non-negative measure with finite total measure $\nu(\mathbf{x},\mathbb{R})$. Then $\chi'(\mathbf{x},t)=\int\nu(\mathbf{x},d\lambda)\exp[-i\lambda t]$ and since $\chi'(\mathbf{x},t)$ is real, we can, without loss of generality, assume that $\nu(\mathbf{x},d\lambda)$ is even in λ. We discussed these matters before in Ref. 5, but in a more roundabout way. We now decompose $\nu(\mathbf{x},d\lambda)$ into parts that are absolutely continuous and singular continuous with respect to Lebesgue measure and a pure point (discrete) part,

$$\nu(\mathbf{x},d\lambda) = \nu_{ac}(\mathbf{x},d\lambda)+\nu_{\mathrm{sing}}(\mathbf{x},d\lambda)+\nu_p(\mathbf{x},d\lambda) = \nu(\mathbf{x},\lambda)d\lambda+\nu_{\mathrm{sing}}(\mathbf{x},d\lambda)+\sum_n \nu_n(\mathbf{x})\delta(\lambda-\omega_n)d\lambda. \tag{2.12}$$

We shall dismiss $\nu_{\mathrm{sing}}(\mathbf{x},d\lambda)$ since it has no apparent physical applications, and in the sequel we shall absorb the point measure part in $\nu(\mathbf{x},\lambda)d\lambda$, so

$$\chi'(\mathbf{x},t) = \int d\lambda\ \nu(\mathbf{x},\lambda)\cos\lambda t, \quad t\geqslant 0, \quad \nu(\mathbf{x},\lambda) = \frac{1}{\pi}\int_0^\infty dt\ \chi'(\mathbf{x},t)\cos\lambda t,$$

$$\hat{\chi}(\mathbf{x},z) = \int d\lambda\ \nu(\mathbf{x},\lambda)\frac{1}{\lambda^2-z^2}, \quad \hat{\chi}'(\mathbf{x},z) = -iz\int d\lambda\ \nu(\mathbf{x},\lambda)\frac{1}{\lambda^2-z^2},$$

$$\mathrm{Re}\,\hat{\chi}'(\mathbf{x},\omega+i0) = \omega\,\mathrm{Im}\,\hat{\chi}(\mathbf{x},\omega+i0) = \pi\nu(\mathbf{x},\omega),$$

$$\Delta\mathcal{E}_{\mathrm{em}}(t) = -\frac{1}{2}\int d\mathbf{x}\int d\lambda\ \nu(\mathbf{x},\lambda)\left|\int_{t_0}^{t} ds\,\exp[i\lambda s]\mathbf{E}(\mathbf{x},s)\right|^2. \tag{2.13}$$

Definition: Absorptive systems are those for which $\nu(\mathbf{x},\lambda)$ is absolutely continuous and dispersive systems those for which it is a set of point measures. Obviously we can refine this to absorptive and dispersive intervals.

The general Drude–Lorentz susceptibility in a space region where $\chi(\mathbf{x},t)$ does not depend on $\mathbf{x}$, is

$$\hat{\chi}(z) = -\frac{\Omega_0^2}{z^2 + i\gamma_0 z} - \sum_{n=1}^{\infty} \frac{\Omega_n^2}{z^2 + i\gamma_n z - \omega_n^2}, \quad \Omega_0, \Omega_n, \omega_n, \gamma_n > 0. \tag{2.14}$$

The point measure case is then obtained by setting $\gamma_n = 0$, i.e., the dispersive Drude–Lorentz susceptibility is

$$\hat{\chi}(z) = -\frac{\Omega_0^2}{z^2} - \sum_{n=0}^{\infty} \frac{\Omega_n^2}{z^2 - \omega_n^2}, \quad \chi(t) = \Omega_0^2 t + \sum_{n=1}^{\infty} \Omega_n^2 \frac{\sin \omega_n t}{\omega_n}, \quad \chi'(t) = \Omega_0^2 + \sum_{n=1}^{\infty} \Omega_n^2 \cos \omega_n t, \quad t \geqslant 0. \tag{2.15}$$

The dispersive Drude case, $\hat{\chi}(z) = -\Omega_0^2/z^2$, is somewhat pathological, $\chi(t)$ growing linearly in t. But it still fits into the formalism we are going to develop.

Returning to our original notation, it follows from

$$\partial_z\{z\hat{\chi}(\mathbf{x}, z)\} = \int d\lambda\ \nu(\mathbf{x}, \lambda) \frac{\lambda^2 + z^2}{(\lambda^2 - z^2)^2}, \tag{2.16}$$

that in the dispersive case, for real $\omega \neq \omega_n$,

$$\partial_\omega\{\omega\hat{\chi}(\mathbf{x}, \omega)\} = \sum_n \nu_n(\mathbf{x}) \frac{\omega^2 + \omega_n^2}{(\omega^2 - \omega_n^2)^2} \geqslant 0, \tag{2.17}$$

a quantity that occurs in work concerning the energy of dispersive dielectrics,[6,7] as discussed later on.

C. The Helmholtz equation

If $t_0 = 0$, so $\mathbf{D}(\mathbf{x}, 0) = \mathbf{E}(\mathbf{x}, 0)$, we can Laplace transform Maxwell's equations, resulting in the inhomogeneous Helmholtz equation

$$[z^2\varepsilon(\mathbf{x}, z) - \mathbf{h}] \cdot \hat{\mathbf{E}}(\mathbf{x}, z) = iz\mathbf{E}(\mathbf{x}, 0) - \partial_{\mathbf{x}} \times \mathbf{B}(\mathbf{x}, 0), \quad \operatorname{Im} z > 0, \tag{2.18}$$

where

$$\hat{\mathbf{D}}(\mathbf{x}, z) = \varepsilon(\mathbf{x}, z)\hat{\mathbf{E}}(\mathbf{x}, z), \quad \varepsilon(\mathbf{x}, z) = 1 + \hat{\chi}(\mathbf{x}, z), \quad \mathbf{h} = \partial_{\mathbf{x}} \times (\partial_{\mathbf{x}} \times \cdots). \tag{2.19}$$

But if $t_0 = -\infty$ this becomes problematic since then there is an additional term $\hat{\chi}(\mathbf{x}, z)\int_{-\infty}^{0} dt \exp[izt]\mathbf{E}(\mathbf{x}, t)$, which can be infinite. In this case we can try to Fourier transform Maxwell's equations. Proceeding formally, we find for

$$\tilde{\mathbf{E}}(\mathbf{x}, \omega) = (2\pi)^{-1/2} \int dt \exp[i\omega t]\mathbf{E}(\mathbf{x}, t), \tag{2.20}$$

that $[\varepsilon(\mathbf{x}, \omega) = 1 + \hat{\chi}(\mathbf{x}, \omega + i0)$, so $\operatorname{Im} \omega\varepsilon(\mathbf{x}, \omega) = \pi\nu(\mathbf{x}, \omega) \geqslant 0]$

$$[\omega^2\varepsilon(\mathbf{x}, \omega) - \mathbf{h}] \cdot \tilde{\mathbf{E}}(\mathbf{x}, \omega) = 0. \tag{2.21}$$

Assuming $\tilde{\mathbf{E}}(\mathbf{x}, \omega)$ to be locally square integrable in $\mathbf{x}$, we have for a bounded measurable set $\mathcal{M} \subset \mathbb{R}^3$,

$$\operatorname{Im} \int_{\mathcal{M}} d\mathbf{x}\{[\omega^2\varepsilon(\mathbf{x}, \omega) - \mathbf{h}] \cdot \tilde{\mathbf{E}}(\mathbf{x}, \omega)\} \cdot \overline{\tilde{\mathbf{E}}(\mathbf{x}, \omega)} = \pi\omega \int_{\mathcal{M}} d\mathbf{x}\ \nu(\mathbf{x}, \omega)|\tilde{\mathbf{E}}(\mathbf{x}, \omega)|^2 = 0. \tag{2.22}$$

For a dispersive system this becomes

$$\pi\omega\sum_n \delta(\omega-\omega_n)\int_{\mathcal{M}} d\mathbf{x}\ \nu_n(\mathbf{x})|\tilde{\mathbf{E}}(\mathbf{x},\omega_n)|^2=0, \tag{2.23}$$

so $\tilde{\mathbf{E}}(\mathbf{x},\omega_n)=0$, for all $\mathbf{x}$ for which $\nu_n(\mathbf{x})\neq 0$, i.e., Eq. (2.20) has no solutions for $\omega=\omega_n$. Then, letting $t_0\to-\infty$ and $t\to\infty$,

$$\Delta\mathcal{E}_{\rm em}=\mathcal{E}_{\rm em}(\infty)-\mathcal{E}_{\rm em}(-\infty)=-\frac{1}{2}\int d\mathbf{x}\int d\lambda\ \nu(\mathbf{x},\lambda)|\tilde{\mathbf{E}}(\mathbf{x},\lambda)|^2=-\frac{1}{2}\sum_n\ \int d\mathbf{x}\ \nu_n(\mathbf{x})|\tilde{\mathbf{E}}(\mathbf{x},\omega_n)|^2=0, \tag{2.24}$$

so $\Delta\mathcal{E}_{\rm em}=0$ for dispersive systems, justifying the above definition. Thus, although $\Delta\mathcal{E}_{\rm em}(t)$ is time dependent, asymptotically it turns back to its initial value. Note that the above manipulations are of a formal nature. But, as shown later on for the PC case, the result can be rigorously justified. For the absorptive PC case, as we showed in Ref. 2, Eq. (2.20) has no solutions for real ω in frequency intervals, where $\mathrm{Im}\,\varepsilon(\mathbf{x},\omega)\neq 0$. This can also be obtained in a formal manner from Eq. (2.21). It implies that the Fourier expansion, Eq. (2.20), does not exist. This situation is rather unsatisfactory, but it can be improved by using the auxiliary field formalism to which we turn now.

III. THE AUXILIARY FIELD FORMALISM

A. Absorptive case

We define for the absorptive case, where we can write $\nu(\mathbf{x},\lambda)=\sigma(\mathbf{x},\lambda)^2$, $\sigma(\mathbf{x},\lambda)\geqslant 0$,

$$\mathbf{F}_1(\mathbf{x},t)=\mathbf{E}(\mathbf{x},t),\quad \mathbf{F}_3(\mathbf{x},t)=\mathbf{B}(\mathbf{x},t),$$

$$\mathbf{F}_2(\mathbf{x},\lambda,t)=\sigma(\mathbf{x},\lambda)\int_{t_0}^{t} ds\,\sin\lambda(t-s)\mathbf{E}(\mathbf{x},s),$$

$$\mathbf{F}_4(\mathbf{x},\lambda,t)=\sigma(\mathbf{x},\lambda)\int_{t_0}^{t} ds\,\cos\lambda(t-s)\mathbf{E}(\mathbf{x},s). \tag{3.1}$$

Then, omitting $\mathbf{x}$ and λ dependencies for brevity, denoting

$$\mathbf{F}(t)=\begin{pmatrix}\mathbf{F}_e(t)\\ \mathbf{F}_m(t)\end{pmatrix}=\begin{pmatrix}\mathbf{F}_1(t)\\ \mathbf{F}_2(t)\\ \mathbf{F}_3(t)\\ \mathbf{F}_4(t)\end{pmatrix}, \tag{3.2}$$

we have

$$\partial_t\mathbf{F}(t)=-i\mathbf{K}\mathbf{F}(t), \tag{3.3}$$

where ($\boldsymbol{\epsilon}=\{\epsilon_{klm}\}$ is the Levi-Civita symbol, $\epsilon_{123}=1$ and ϵ_{klm} changes sign under the interchange of each two subscripts, so $(\boldsymbol{\epsilon}\cdot\mathbf{a})\cdot\mathbf{b}=-\mathbf{a}\times\mathbf{b}$, whereas $\mathbf{p}=-i\partial_{\mathbf{x}}$ is the generator of translations, i.e., the momentum operator of quantum mechanics),

$$\mathbf{K}=\begin{pmatrix}0 & \mathbf{K}_{em}\\ \mathbf{K}_{me} & 0\end{pmatrix},\quad \mathbf{K}_{em}=\begin{pmatrix}\boldsymbol{\epsilon}\cdot\mathbf{p} & -i\int d\lambda\ \sigma(\mathbf{x},\lambda)\dots\\ 0 & i\lambda\end{pmatrix},\quad \mathbf{K}_{me}=\begin{pmatrix}-\boldsymbol{\epsilon}\cdot\mathbf{p} & 0\\ i\sigma(\mathbf{x},\lambda) & -i\lambda\end{pmatrix}. \tag{3.4}$$

We note that Eq. (3.3) is equivalent to Maxwell's equations, provided

$$\mathbf{F}_2(\mathbf{x},t_0)=\mathbf{F}_4(\mathbf{x},t_0)=0, \tag{3.5}$$

where it is understood that the limits $t_0\to-\infty$ are meant in case $t_0=-\infty$. Let $\mathcal{H}=\oplus_{j=1}^4\mathcal{H}_j$, $\mathcal{H}_1=\mathcal{H}_3=L^2(\mathbb{R}^3,d\mathbf{x};\mathbb{C}^3)$, $\mathcal{H}_2=\mathcal{H}_4=L^2(\mathbb{R}^3,d\mathbf{x};\mathbb{C}^3)\otimes L^2(\mathbb{R},d\lambda)$, so we have for the inner product and norm squared,

$$\begin{aligned}(\mathbf{f},\mathbf{g})&=\int d\mathbf{x}[\mathbf{f}_1(\mathbf{x})\cdot\overline{\mathbf{g}_1(\mathbf{x})}+\mathbf{f}_3(\mathbf{x})\cdot\overline{\mathbf{g}_3(\mathbf{x})}+\int d\lambda\{\mathbf{f}_2(\mathbf{x},\lambda)\cdot\overline{\mathbf{g}_2(\mathbf{x},\lambda)}+\mathbf{f}_4(\mathbf{x},\lambda)\cdot\overline{\mathbf{g}_4(\mathbf{x},\lambda)}\}]\\&=\sum_{j=1}^4(\mathbf{f}_j,\mathbf{g}_j)_j,\end{aligned}$$

$$\|\mathbf{f}\|^2=\sum_{j=1}^4(\mathbf{f}_j,\mathbf{f}_j)_j=\sum_{j=1}^4\|\mathbf{f}_j\|_j^2. \tag{3.6}$$

As already noted in Ref. 7, $\mathbf{K}$ defines a self-adjoint operator in $\mathcal{H}$. To see this we write $\mathbf{K}=\mathbf{K}_0+\mathbf{K}_1$, with

$$\mathbf{K}_0=\begin{pmatrix}0&\mathbf{K}_{0em}\\\mathbf{K}_{0me}&0\end{pmatrix},\quad \mathbf{K}_{0em}=\begin{pmatrix}\boldsymbol{\epsilon}\cdot\mathbf{p}&0\\0&i\lambda\end{pmatrix},\quad \mathbf{K}_{0me}=\begin{pmatrix}-\boldsymbol{\epsilon}\cdot\mathbf{p}&0\\0&-i\lambda\end{pmatrix}. \tag{3.7}$$

In Fourier (momentum) space $\mathbf{K}_0$ is a matrix multiplication operator, which is easily seen to have a unique self-adjoint extension, whereas a simple estimate, using $|\chi'(\mathbf{x},0)|\leqslant c'$, shows that $\mathbf{K}_1$ is a bounded self-adjoint operator. We note further that

$$\mathbf{K}^2=\begin{pmatrix}\mathbf{H}_e&0\\0&\mathbf{H}_m\end{pmatrix},\quad \mathbf{H}_e=\begin{pmatrix}\mathbf{h}+\chi'(\mathbf{x},0)&-\int d\lambda\,\lambda\sigma(\mathbf{x},\lambda)\ldots\\-\lambda\sigma(\mathbf{x},\lambda)&\lambda^2\end{pmatrix}, \tag{3.8}$$

$$\mathbf{H}_m=\begin{pmatrix}\mathbf{h}&i\boldsymbol{\epsilon}\cdot\mathbf{p}\int d\lambda\,\sigma(\mathbf{x},\lambda)\ldots\\i\sigma(\mathbf{x},\lambda)\boldsymbol{\epsilon}\cdot\mathbf{p}&\lambda^2\end{pmatrix}.$$

Here, in dyadic notation, with $\mathbf{U}$ the unit 3×3 matrix,

$$\mathbf{h}=\mathbf{p}^2\mathbf{U}-\mathbf{pp}=\mathbf{p}^2\boldsymbol{\Delta}_\mathbf{p},\quad \boldsymbol{\Delta}_\mathbf{p}=\mathbf{U}-\mathbf{e}_\mathbf{p}\mathbf{e}_\mathbf{p},\quad \mathbf{e}_\mathbf{p}=\mathbf{p}/|\mathbf{p}|=\mathbf{p}/p, \tag{3.9}$$

so $\mathbf{h}\cdot\mathbf{f}(\mathbf{x})=\partial_\mathbf{x}\times(\partial_\mathbf{x}\times\mathbf{f}(\mathbf{x}))$ for sufficiently smooth $\mathbf{f}(\mathbf{x})$. Thus we have obtained a precise setting for Maxwell's equations for an absorptive dielectric as a unitary time evolution for a set of square integrable functions in a Hilbert space $\mathcal{H}$ under the assumption $\mathbf{F}_2(\mathbf{x},\lambda,t_0)=\mathbf{F}_4(\mathbf{x},\lambda,t_0)=0$. We note in passing that it is an appropriate starting point for a quantized theory as discussed fully in Ref. 1. Since there the fields become operators the initial condition $\mathbf{F}_2(\mathbf{x},\lambda,t_0)=\mathbf{F}_4(\mathbf{x},\lambda,t_0)=0$ loses its meaning and is dropped.

$\mathbf{K}$ being self-adjoint, it has the spectral decompositions

$$\mathbf{K}=\int\omega\mathbf{E}(d\omega). \tag{3.10}$$

Then, if $\mathbf{K}$ possesses an eigenfunction expansion (α labels a possible degeneracy),

$$\mathbf{E}(d\omega)=\sum_\alpha|\mathbf{u}_{\omega\alpha}\rangle\langle\mathbf{u}_{\omega\alpha}|d\omega,\quad \langle\mathbf{u}_{\omega\alpha}|\mathbf{u}_{\mu\beta}\rangle=\mathbf{U}\delta(\omega-\mu)\delta_{a\beta}, \tag{3.11}$$

the Fourier transform $\tilde{\mathbf{F}}(\omega)$ satisfies the eigenvalue equation

$$\mathbf{K}\tilde{\mathbf{F}}(\omega) = \omega\tilde{\mathbf{F}}(\omega), \tag{3.12}$$

or,

$$\mathbf{H}_e\tilde{\mathbf{F}}_e(\omega) = \omega^2\tilde{\mathbf{F}}_e(\omega), \tag{3.13}$$

which, in contrast to Eq. (2.21), make sense for real ω. Thus the problem noted at the end of Sec. II can be circumvented. We shall not go into the proof of the existence of eigenfunction expansions. In scattering situations $\mathbf{H}_e$ is not very different from the Schrödinger operator case with a simple bounded potential, see Ref. 8, but here we also encounter the variable $\lambda \in \mathbb{R}$. In the dispersive case, see below, we deal with a discrete set of ω_n's and for PCs the problem can be reduced by means of a Bloch–Floquet decomposition to one involving square integrable eigenfunctions.

B. Dispersive case

In the dispersive case we can no longer write $\nu(\mathbf{x},\lambda)=\sigma(\mathbf{x},\lambda)^2$ and the formalism needs modification. In Ref. 1 a general formulation was given, with $\nu(\mathbf{x},\lambda)$ as a weight function in the inner product. But we can also proceed by writing

$$\mathbf{J}(\mathbf{x},t) = \sum_n \nu_n(\mathbf{x})\int_{t_0}^{t} ds\, \cos\,\omega_n(t-s)\mathbf{E}(\mathbf{x},s) = \sum_n \sigma_n(\mathbf{x})\mathbf{F}_{4n}(\mathbf{x},t), \quad \nu_n(\mathbf{x}) = \sigma_n(\mathbf{x})^2, \quad \sigma_n(\mathbf{x}) \geqslant 0. \tag{3.14}$$

Thus, with

$$\mathbf{F}_1(\mathbf{x},t) = \mathbf{E}(\mathbf{x},t), \quad \mathbf{F}_3(\mathbf{x},t) = \mathbf{B}(\mathbf{x},t),$$

$$\mathbf{F}_{2n}(\mathbf{x},t) = \sigma_n(\mathbf{x})\int_{t_0}^{t} ds\, \sin\,\omega_n(t-s)\mathbf{E}(\mathbf{x},s),$$

$$\mathbf{F}_{4n}(\mathbf{x},t) = \sigma_n(\mathbf{x})\int_{t_0}^{t} ds\, \cos\,\omega_n(t-s)\mathbf{E}(\mathbf{x},s), \tag{3.15}$$

we have

$$\partial_t\mathbf{F}_1(\mathbf{x},t) = -i\left[(\boldsymbol{\epsilon}\cdot\mathbf{p})\mathbf{F}_3(\mathbf{x},t) - i\sum_n \sigma_n(\mathbf{x})\mathbf{F}_{4n}(\mathbf{x},t)\right],$$

$$\partial_t\mathbf{F}_{2n}(\mathbf{x},t) = -i[i\omega_n\mathbf{F}_{4n}(\mathbf{x},t)],$$

$$\partial_t\mathbf{F}_3(\mathbf{x},t) = -i[-(\boldsymbol{\epsilon}\cdot\mathbf{p})\mathbf{F}_1(\mathbf{x},t)],$$

$$\partial_t\mathbf{F}_{4n}(\mathbf{x},t) = -i[i\sigma_n(\mathbf{x})\mathbf{F}_1(\mathbf{x},t) - i\omega_n\mathbf{F}_{2n}(\mathbf{x},t)]. \tag{3.16}$$

We can now define $\mathbf{K}$ acting in $\mathcal{H}=\oplus_j\mathcal{H}_0$, $\mathcal{H}_0=L^2(\mathbb{R}^3,d\mathbf{x};\mathbb{C}^3)$. Of particular interest is the case of a single n and $\sigma_n(\mathbf{x})=\Omega P_{\mathcal{A}}$, where $P_{\mathcal{A}}$ is the projector associated with $\mathbf{I}_{\mathcal{A}}(\mathbf{x})$. Then, setting $\omega_n = \omega_0$,

$$\mathbf{K} = \begin{pmatrix} 0 & \mathbf{K}_{em} \\ \mathbf{K}_{me} & 0 \end{pmatrix}, \quad \mathbf{K}_{em} = \begin{pmatrix} \boldsymbol{\epsilon}\cdot\mathbf{p} & -i\Omega P_{\mathcal{A}} \\ 0 & i\omega_0 \end{pmatrix}, \quad \mathbf{K}_{me} = \begin{pmatrix} -\boldsymbol{\epsilon}\cdot\mathbf{p} & 0 \\ i\Omega P_{\mathcal{A}} & -i\omega_0 \end{pmatrix},$$

$$\mathbf{H}_e = \begin{pmatrix} \mathbf{h} + \Omega^2 P_{\mathcal{A}} & -\omega_0 \Omega P_{\mathcal{A}} \\ -\omega_0 \Omega P_{\mathcal{A}} & \omega_0^2 \end{pmatrix}, \quad \mathbf{H}_m = \begin{pmatrix} \mathbf{h} & i\boldsymbol{\epsilon}\cdot\mathbf{p}\Omega P_{\mathcal{A}} \\ i\Omega P_{\mathcal{A}}\boldsymbol{\epsilon}\cdot\mathbf{p} & \omega_0^2 + \Omega^2 P_{\mathcal{A}} \end{pmatrix}. \tag{3.17}$$

The Drude case is obtained by setting $\omega_0 = 0$, leading to

$$\mathbf{H}_e = \begin{pmatrix} \mathbf{h} + \Omega^2 P_{\mathcal{A}} & 0 \\ 0 & 0 \end{pmatrix}, \quad \mathbf{H}_m = \begin{pmatrix} \mathbf{h} & i\boldsymbol{\epsilon}\cdot\mathbf{p}\Omega P_{\mathcal{A}} \\ i\Omega P_{\mathcal{A}}\boldsymbol{\epsilon}\cdot\mathbf{p} & \Omega^2 P_{\mathcal{A}} \end{pmatrix}. \tag{3.18}$$

Here the properties of $\mathbf{H}_e$ are essentially those of $\mathbf{h}+\Omega^2 P_{\mathcal{A}}$, its transverse part (see below) $\mathbf{p}^2 + \Omega^2 P_{\mathcal{A}}$ being the Schrödinger operator for a potential consisting of a number of humps. In the piecewise constant case with randomly placed $\mathcal{A}_j$'s and Ω^2 sufficiently large, it cannot be ruled out that spectral intervals showing Anderson localization exist.

IV. PHOTONIC CRYSTALS

Three-dimensional photonic crystals are dielectrics with spatial periodicity,

$$\chi(\mathbf{x},t) = \chi\left(\mathbf{x} + \sum_{j=1}^{3} n_j \mathbf{a}_j, t\right), \quad n_j \in \mathbb{Z}, \tag{4.1}$$

with the $\mathbf{a}_j$'s three linearly independent real vectors (other cases are those with only two independent $\mathbf{a}_j$'s or only a single one). In practice, the dielectric fills an identical region $\mathcal{A}_j$ in each unit cell $\mathcal{C}_j$ over which $\chi(\mathbf{x},t)$ is homogeneous in $\mathbf{x}$ (piecewise constant case). Then a Bloch–Floquet decomposition can be made, so that $\mathbf{K}$ is reduced to $\mathbf{K}(\boldsymbol{\kappa})$ on $\mathcal{H}_{\mathcal{C}}$, where in the $\mathcal{H}_j$'s of Sec. III the $\mathbf{x}$ integration is restricted to the unit cell $\mathcal{C}\subset\mathbb{R}^3$ containing the origin. The vector $\boldsymbol{\kappa}\in\mathcal{B}$, the first Brillouin zone, labels the (Bloch) boundary conditions on $\partial_{\mathcal{C}}$. For details, see Ref. 2. In this case the operator $\mathbf{h}$ changes into $\mathbf{h}(\boldsymbol{\kappa})$, the closure of $-\partial_{\mathbf{x}}^2\mathsf{U}+\partial_{\mathbf{x}}\partial_{\mathbf{x}}$ with Bloch boundary conditions on $\partial_{\mathcal{C}}$. Instead of Eq. (2.21) we then have

$$[\omega^2\varepsilon(\mathbf{x},\omega) - \mathbf{h}(\boldsymbol{\kappa})]\cdot\tilde{\mathbf{E}}(\mathbf{x},\boldsymbol{\kappa},\omega) = 0, \tag{4.2}$$

In dispersive intervals, i.e., intervals over which $\varepsilon(\mathbf{x},\omega)$ is real, the transverse parts of the corresponding $\mathbf{K}(\boldsymbol{\kappa})$ and $\mathbf{H}_e(\boldsymbol{\kappa})$ have a discrete point spectrum, each eigenvalue having finite multiplicity. As in the solid state case, band gaps (intervals containing no eigenvalues for any $\boldsymbol{\kappa}\in\mathcal{B}$) are possible. In the absorptive case there are resonances rather than eigenvalues, giving rise to a complex band spectrum.[2] A practical consequence is that now Eq. (4.2) has solutions with complex $\omega=\omega(\boldsymbol{\kappa})$ in the lower complex half-plane $\mathbb{C}^-$. After complex dilatation, letting $\boldsymbol{\kappa}$ run through $\mathcal{B}$, we obtain the spectrum of the complex dilated original operator $\mathbf{K}$, a set of islands in $\mathbb{C}^-$. In Ref. 9 we calculated the latter for a two-dimensional case with dielectric cylinders. It is possible that in other cases the situation is similar but this may be hard to establish since here we could first deal with the situation for a single $\boldsymbol{\kappa}$ and then reconstruct the full spectrum, which is not possible in general. In the sequel, when referring to a photonic crystal, we mean the arrangement sketched above.

V. DECOMPOSITION INTO LONGITUDINAL AND TRANSVERSE COMPONENTS

The piecewise constant case, Eq. (2.4), is often encountered in practical situations, in particular PCs. In the absence of external charges and currents the Laplace transform,

$$\hat{\mathbf{D}}(\mathbf{x},z) = \varepsilon(\mathbf{x},z)\hat{\mathbf{E}}(\mathbf{x},z), \tag{5.1}$$

satisfies $\partial_{\mathbf{x}}\cdot\hat{\mathbf{D}}(\mathbf{x},z)=0$, so $\hat{\mathbf{D}}(\mathbf{x},z)$ is transverse. Then

$$\varepsilon(\mathbf{x},z)\partial_{\mathbf{x}}\cdot\hat{\mathbf{E}}(\mathbf{x},z)=-\{\partial_{\mathbf{x}}\varepsilon(\mathbf{x},z)\}\cdot\hat{\mathbf{E}}(\mathbf{x},z), \tag{5.2}$$

which is, in general, nonzero, so $\hat{\mathbf{E}}(\mathbf{x},z)$ can have both longitudinal and transverse components. But here $\partial_{\mathbf{x}}\varepsilon(\mathbf{x},z)$ is nonzero only on the boundary $\partial_{\mathcal{A}}$ of $\mathcal{A}$, where it is, in fact, singular. Thus $\hat{\mathbf{E}}(\mathbf{x},z)$ is transverse except on a set of measure zero in $\mathbb{R}^3$ and, since it is square integrable, we expect this to be irrelevant. But in order to proceed we first have to define the decomposition into longitudinal and transverse components for general square integrable fields. Thus let $\mathbf{f}(\mathbf{x})\in L^2(\mathbb{R}^3,d\mathbf{x};\mathbb{C}^3)$ with Fourier transform $\tilde{\mathbf{f}}(\mathbf{k})$. Then we can write, indicating longitudinal fields by $\|$ and transverse ones by $\perp$,

$$\tilde{\mathbf{f}}(\mathbf{k})=\mathbf{e}_{\mathbf{k}}\mathbf{e}_{\mathbf{k}}\cdot\tilde{\mathbf{f}}(\mathbf{k})+\boldsymbol{\Delta}_{\mathbf{k}}\cdot\tilde{\mathbf{f}}(\mathbf{k})=P^{\|}\tilde{\mathbf{f}}(\mathbf{k})+P^{\perp}\tilde{\mathbf{f}}(\mathbf{k})=\tilde{\mathbf{f}}^{\|}(\mathbf{k})+\tilde{\mathbf{f}}^{\perp}(\mathbf{k}), \tag{5.3}$$

so $\tilde{\mathbf{f}}^{\|}(\mathbf{k})$ is along $\mathbf{k}$ and $\tilde{\mathbf{f}}^{\perp}(\mathbf{k})$ orthogonal to $\mathbf{k}$. This defines the corresponding decomposition in coordinate space. It is easily verified that, for sufficiently smooth $\mathbf{f}(\mathbf{x})$, indeed $\partial_{\mathbf{x}}\cdot\mathbf{f}^{\perp}(\mathbf{x})=0$ and $\partial_{\mathbf{x}}\times\mathbf{f}^{\|}(\mathbf{x})=0$.

For a general absorptive dielectric,

$$\sigma(\mathbf{x},\lambda)=\sum_j \mathbf{l}_{\mathcal{A}_j}(\mathbf{x})s_j(\lambda)=\sum_j P_j s_j(\lambda), \tag{5.4}$$

where $P_j=P_{\mathcal{A}_j}$ is the projector associated with $\mathbf{l}_{\mathcal{A}_j}(\mathbf{x})$. Let the longitudinal and transverse projectors on $\mathcal{H}$ be defined by

$$\mathbf{E}^{\|}=P^{\|}\mathbf{V},\quad \mathbf{E}^{\perp}=P^{\perp}\mathbf{V},\quad \mathcal{H}^{\|}=\mathbf{E}^{\|}\mathcal{H},\quad \mathcal{H}^{\perp}=\mathbf{E}^{\perp}\mathcal{H}, \tag{5.5}$$

with $\mathbf{V}$ the unit 4×4 matrix. We are interested in the commutation properties of $\mathbf{E}^{\|}$ and $\mathbf{K}$. We first consider the commutation properties of $P^{\|}$ and $P_{\mathcal{A}}$.

Lemma: On $\mathcal{H}_0=L^2(\mathbb{R}^3,d\mathbf{x};\mathbb{C}^3)$ the operators $P_{\mathcal{A}}$ and $P^{\|}$ (and hence also $P_{\mathcal{A}}$ and $P^{\perp}$) commute.

Proof: Let $\mathcal{F}\subset\mathcal{H}_0$ be the dense subset of compactly supported smooth functions that vanish in a neighborhood of $\partial_{\mathcal{A}}$. Then $\mathcal{G}=\{\mathbf{g}=\mathbf{p}^2\mathbf{f}\,|\,\mathbf{f}\in\mathcal{F}\}$ also has these properties. Now let $\mathbf{g}=\mathbf{p}^2\mathbf{f}\in\mathcal{G}$. Then $(P^{\|}\mathbf{g})(\mathbf{x})=(\mathbf{pp}\cdot\mathbf{f})(\mathbf{x})=-\partial_{\mathbf{x}}\partial_{\mathbf{x}}\cdot\mathbf{f}(\mathbf{x})$ and noting that $\mathbf{f}(\mathbf{x})$ vanishes in a neighborhood of $\partial_{\mathcal{A}}$,

$$(P_{\mathcal{A}}P^{\|}\mathbf{g})(\mathbf{x})=-\mathbf{l}_{\mathcal{A}}(\mathbf{x})\partial_{\mathbf{x}}\partial_{\mathbf{x}}\cdot\mathbf{f}(\mathbf{x})=-\partial_{\mathbf{x}}\partial_{\mathbf{x}}\cdot\mathbf{l}_{\mathcal{A}}(\mathbf{x})\mathbf{f}(\mathbf{x})=(\mathbf{pp}\cdot P_{\mathcal{A}}\mathbf{f})(\mathbf{x})=(P^{\|}\mathbf{p}^2P_{\mathcal{A}}\mathbf{f})(\mathbf{x}). \tag{5.6}$$

But

$$(\mathbf{p}^2P_{\mathcal{A}}\mathbf{f})(\mathbf{x})=-\partial_{\mathbf{x}}^2\mathbf{l}_{\mathcal{A}}(\mathbf{x})\mathbf{f}(\mathbf{x})=-\mathbf{l}_{\mathcal{A}}(\mathbf{x})\partial_{\mathbf{x}}^2\mathbf{f}(\mathbf{x})=(P_{\mathcal{A}}\mathbf{p}^2\mathbf{f})(\mathbf{x})=(P_{\mathcal{A}}\mathbf{g})(\mathbf{x}), \tag{5.7}$$

so $(P_{\mathcal{A}}P^{\|}\mathbf{g})(\mathbf{x})=(P^{\|}P_{\mathcal{A}}\mathbf{g})(\mathbf{x})$. Since $\mathcal{G}$ is dense in $\mathcal{H}_0$ and $P^{\|}$ and $P_{\mathcal{A}}$ are bounded operators, we conclude that they commute and hence so do $P^{\perp}$ and $P_{\mathcal{A}}$. ■

Remark: The above result sensitively depends on the topology. In the proof the existence of a dense set of functions, vanishing in a neighborhood of $\partial_{\mathcal{A}}$ is essential. The result is somewhat surprising since, in contrast to $P_{\mathcal{A}}$, $P^{\|}$ and $P^{\perp}$ are not obviously local operators in coordinate space.

We now turn to functions from the domain $\mathcal{D}(\mathbf{K})$ of $\mathbf{K}$. Noting that $\mathcal{D}(\mathbf{K})=\mathcal{D}(\mathbf{K}_0)$ and $\mathbf{f}\in\mathcal{D}(\mathbf{K}_0)$ can be written as

$$\mathbf{f}=[z-\mathbf{K}_0]^{-1}\mathbf{g}=[z+\mathbf{K}_0][z^2-\mathbf{K}_0^2]^{-1}\mathbf{g}, \tag{5.8}$$

where $\mathrm{Im}\,z\neq0$ and $\mathbf{g}\in\mathcal{H}$, we have, using $(\boldsymbol{\epsilon}\cdot\mathbf{p})\cdot[z^2-\mathbf{h}]^{-1}=(\boldsymbol{\epsilon}\cdot\mathbf{p})[z^2-\mathbf{p}^2]^{-1}=[z^2-\mathbf{p}^2]^{-1}(\boldsymbol{\epsilon}\cdot\mathbf{p})$,

$$\mathbf{f}_1=z[z^2-\mathbf{h}]^{-1}\mathbf{g}_1-[z^2-\mathbf{p}^2]^{-1}(\boldsymbol{\epsilon}\cdot\mathbf{p})\cdot\mathbf{g}_3,\quad \mathbf{f}_2=z[z^2-\lambda^2]^{-1}\mathbf{g}_2+i\lambda[z^2-\lambda^2]^{-1}\mathbf{g}_4, \tag{5.9}$$

and similar for the other components. Since $P^{\perp}\mathbf{h}=P^{\perp}\mathbf{p}^2=\mathbf{p}^2P^{\perp}$ and $\boldsymbol{\epsilon}\cdot\mathbf{p}=P^{\perp}\boldsymbol{\epsilon}\cdot\mathbf{p}=\boldsymbol{\epsilon}\cdot\mathbf{p}P^{\perp}$, we have

$$P^{\perp}\mathbf{f}_1 = P^{\perp}[z^2 - \mathbf{p}^2]^{-1}\{z\mathbf{g}_1 - (\boldsymbol{\epsilon}\cdot\mathbf{p})\cdot\mathbf{g}_3\}, \tag{5.10}$$

and it follows that $\mathbf{f}_1^{\perp}$ and $\mathbf{f}_3^{\perp}$ are in $\mathcal{D}(\boldsymbol{\epsilon}\cdot\mathbf{p})$. Also, since $P^{\parallel}\boldsymbol{\epsilon}\cdot\mathbf{p}=0$, $P^{\parallel}\mathsf{h}=0$,

$$P^{\parallel}\mathbf{f}_1 = \frac{1}{z}P^{\parallel}\mathbf{g}_1, \quad P^{\parallel}\mathbf{f}_3 = \frac{1}{z}P^{\parallel}\mathbf{g}_3, \tag{5.11}$$

so there are no restrictions on the longitudinal parts $\mathbf{f}_1^{\parallel}$ and $\mathbf{f}_3^{\parallel}$. As to $\mathbf{f}_2$ and $\mathbf{f}_4$, we note that there is only a square integrability requirement in λ. Let now $\mathbf{F}\in\mathcal{D}(\mathbf{K})$. Then, in view of the lemma and the above remarks, we find that

$$\mathbf{E}^{\perp}\mathbf{K}\mathbf{F} = \mathbf{K}\mathbf{E}^{\perp}\mathbf{F} = \mathbf{K}^{\perp}\mathbf{E}^{\perp}\mathbf{F}, \quad \mathbf{E}^{\parallel}\mathbf{K}\mathbf{F} = \mathbf{K}\mathbf{E}^{\parallel}\mathbf{F} = \mathbf{K}^{\parallel}\mathbf{E}^{\parallel}\mathbf{F}, \tag{5.12}$$

where $\mathbf{K}^{\perp}$ has the same form as $\mathbf{K}$, but in $\mathbf{K}^{\parallel}$ the $\boldsymbol{\epsilon}\cdot\mathbf{p}$ terms are missing, so it reduces to a matrix-valued multiplication operator only depending on $\mathbf{x}$. In summary:

Proposition: The operators $\mathbf{E}^{\perp}$ and $\mathbf{E}^{\parallel}$ reduce $\mathbf{K}$.

We note, furthermore, that there is a corresponding decomposition of $\mathbf{H}_e$ acting in $\mathcal{H}_e=\mathcal{H}_1\oplus\mathcal{H}_2=\mathcal{H}_e^{\perp}\oplus\mathcal{H}_e^{\parallel}$ and similar for $\mathbf{H}_m$. Thus

$$\mathbf{H}_e^{\perp} = \begin{pmatrix} \mathbf{p}^2 + P_{\mathcal{A}}g'(0) & -P_{\mathcal{A}}\int d\lambda\, \lambda s(\lambda)\ldots \\ -\lambda s(\lambda)P_{\mathcal{A}} & \lambda^2 \end{pmatrix}, \quad \mathbf{H}_e^{\parallel} = \begin{pmatrix} P_{\mathcal{A}}g'(0) & -P_{\mathcal{A}}\int d\lambda\, \lambda s(\lambda)\ldots \\ -\lambda s(\lambda)P_{\mathcal{A}} & \lambda^2 \end{pmatrix}. \tag{5.13}$$

We observe that $\mathbf{H}_e^{\perp}$ and $\mathbf{H}_m^{\perp}$ have empty null space [note that $g'(0)=\int d\lambda s(\lambda)^2$ and consider the inner product $(\mathbf{H}_j^{\perp}\mathbf{f},\mathbf{f})=0$]. In the same way we obtain the decomposition for the dispersive case.

VI. INITIAL AND BOUNDARY CONDITIONS

Since we are dealing with a unitary time evolution any $\mathbf{F}\in\mathcal{H}$ is acceptable as an initial set of fields. On the other hand, boundary conditions for normal and tangential field components often appear in piecewise constant situations. Here we shall discuss how this comes about. It turns out that the two types of conditions are of a different nature. As we show below, the first are basically an initial condition, whereas the second type only comes into play if we require the fields to satisfy Maxwell's equations in the usual differential equation form.

We start with determining $\mathcal{N}(\mathbf{K})$, the null space of $\mathbf{K}$. Let $\mathbf{f}\in\mathcal{N}(\mathbf{K})$, i.e., $\mathbf{K}\mathbf{f}=0$. It then follows in the absorptive case (the dispersive case goes similarly) that $\mathbf{f}_4=0$, $(\boldsymbol{\epsilon}\cdot\mathbf{p})\cdot\mathbf{f}_3=0$, implying that $\mathbf{f}_3=P^{\parallel}\mathbf{g}_3$, $(\boldsymbol{\epsilon}\cdot\mathbf{p})\cdot\mathbf{f}_1=0$, so $\mathbf{f}_1=P^{\parallel}\mathbf{g}_1$, and $\mathbf{f}_2=\lambda^{-1}\sigma(\mathbf{x},\lambda)P^{\parallel}\mathbf{g}_1$ or

$$\mathbf{f} = \begin{pmatrix} P^{\parallel}\mathbf{g}_1 \\ \dfrac{\sigma(\mathbf{x},\lambda)}{\lambda}P^{\parallel}\mathbf{g}_1 \\ P^{\parallel}\mathbf{g}_3 \\ 0 \end{pmatrix}, \tag{6.1}$$

where $\mathbf{g}\in\mathcal{H}$ is arbitrary. Setting $\mathbf{f}=\mathbf{M}\mathbf{g}$, we have, for the projector $\mathbf{E}_0$ on $\mathcal{N}(\mathbf{K})$, $\mathbf{E}_0=\mathbf{M}(\mathbf{M}^*\mathbf{M})^{-1}\mathbf{M}^*$. Working things out, using $1+\int d\lambda(\sigma(\mathbf{x},\lambda)^2/\lambda^2)=1+\hat{\chi}(\mathbf{x},0)=\varepsilon(\mathbf{x},0)=\varepsilon_{\mathrm{stat}}(\mathbf{x})$, the static permeability [we exclude Drude contributions for which $\varepsilon_{\mathrm{stat}}(\mathbf{x})$ does not exist and a slightly different approach is needed],

$$\mathbf{E}_0 = \begin{pmatrix} \mathbf{E}_{0e} & 0 \\ 0 & \mathbf{E}_{0m} \end{pmatrix}, \quad \mathbf{E}_{0e} = \begin{pmatrix} 1 & 0 \\ \dfrac{\sigma(\mathbf{x},\lambda)}{\lambda} & 0 \end{pmatrix} P^{\parallel}[P^{\parallel}\varepsilon_{\mathrm{stat}}(\mathbf{x})P^{\parallel}]^{-1}P^{\parallel}\begin{pmatrix} 1 & \displaystyle\int d\lambda\frac{\sigma(\mathbf{x},\lambda)}{\lambda}\ldots \\ 0 & 0 \end{pmatrix}, \tag{6.2}$$

$$\mathbf{E}_{0m} = \begin{pmatrix} P^{\|} & 0 \\ 0 & 0 \end{pmatrix}.$$

Remark: We have $\mathcal{N}(\mathbf{K}) \subset \mathcal{H}^{\|}$ but, in general, $\mathcal{N}(\mathbf{K}) \neq \mathcal{H}^{\|}$. Thus time-dependent longitudinal solutions of Eqs. (2.1) can exist.

We note that $\mathbf{E}_0\mathbf{F}(t)$ is conserved in time, leading to the conservation of $P^{\|}\{\mathbf{F}_1(t) + \int d\lambda(\sigma(\mathbf{x},\lambda)/\lambda)\mathbf{F}_2(\lambda,t)\}$ and $P^{\|}\mathbf{F}_3(t)$. Since

$$\mathbf{F}_1(\mathbf{x},t) + \int d\lambda \frac{\sigma(\mathbf{x},\lambda)}{\lambda}\mathbf{F}_2(\mathbf{x},\lambda,t) = \mathbf{D}(\mathbf{x},t), \tag{6.3}$$

we see that $\mathbf{D}^{\|}(\mathbf{x},t) = \mathbf{D}^{\|}(\mathbf{x})$ and $\mathbf{B}^{\|}(\mathbf{x},t) = \mathbf{B}^{\|}(\mathbf{x})$ are time independent. Note that here no differentiability conditions are required but that continuity of the longitudinal fields at the initial time implies continuity for all later times, so continuity is basically an initial condition. The standard, heuristic, procedure to obtain such a result, follows from Maxwell's equations,

$$\partial_t \partial_{\mathbf{x}} \cdot \mathbf{D}(\mathbf{x},t) = 0, \quad \partial_t \partial_{\mathbf{x}} \cdot \mathbf{B}(\mathbf{x},t) = 0, \tag{6.4}$$

so, formally,

$$\partial_{\mathbf{x}} \cdot \mathbf{D}(\mathbf{x},t) = \rho_e(\mathbf{x}), \quad \partial_{\mathbf{x}} \cdot \mathbf{B}(\mathbf{x},t) = \rho_m(\mathbf{x}), \tag{6.5}$$

where $\rho_m(\mathbf{x}) \equiv 0$ since magnetic charges are absent. Thus $\mathbf{B}^{\|}(\mathbf{x}) \equiv 0$. In the absence of free electric charges, also $\mathbf{D}^{\|}(\mathbf{x}) = 0$. In the literature (see, for instance, Ref. 3) Gauss' theorem is sometimes applied to Eq. (6.5) to obtain the continuity of the normal component of $\mathbf{D}(\mathbf{x})$ across an interface in electrostatics. Note that in more general situations, where transverse components are present, it is a statement about $\mathbf{D}^{\|}(\mathbf{x})$. Also, since the procedure works for any surface and not only an interface between two regions with different electric permeability, the result is that $\mathbf{D}^{\|}(\mathbf{x})$ is continuous. But there seems to be some circularity in the argument since the starting point is a relation for the divergence of $\mathbf{D}^{\|}(\mathbf{x})$, which already requires the existence of its space derivatives.

A similar matter is the application of Stokes' theorem to the relation

$$\partial_{\mathbf{x}} \times \mathbf{E}(\mathbf{x},t) = \partial_{\mathbf{x}} \times \mathbf{E}^{\perp}(\mathbf{x},t) = -\partial_t \mathbf{B}(\mathbf{x},t), \tag{6.6}$$

to obtain the continuity of the tangential components of $\mathbf{E}^{\perp}(\mathbf{x},t)$ across an interface.

In our approach there are no conditions on $\mathbf{E}^{\perp}(\mathbf{x},t_0)$ except its square integrability. This seems to be different from what is commonly found in textbooks. However, if we consider the differential equation $\partial_t \mathbf{F}(t) = -i\mathbf{K}\mathbf{F}(t)$, we must have $\mathbf{F}(t) \in \mathcal{D}(\mathbf{K})$, which is true if $\mathbf{F}(t_0) \in \mathcal{D}(\mathbf{K})$ since $\exp[-i\mathbf{K}t]\mathcal{D}(\mathbf{K}) = \mathcal{D}(\mathbf{K})$. As we noted earlier, this requires $\mathbf{E}^{\perp}(t_0) \in \mathcal{D}(\boldsymbol{\epsilon}\cdot\mathbf{p})$. Thus, dropping t_0,

$$\begin{aligned} \mathbf{E}^{\perp} &= [1 + i\boldsymbol{\epsilon}\cdot\mathbf{p}]^{-1}\mathbf{f}^{\perp} = [1+\mathbf{h}]^{-1}[1 - i\boldsymbol{\epsilon}\cdot\mathbf{p}]\mathbf{f}^{\perp} = [1+\mathbf{p}^2]^{-1}[1 - i\boldsymbol{\epsilon}\cdot\mathbf{p}]\mathbf{f}^{\perp} \\ &= [i-p]^{-1}[1 - i\boldsymbol{\epsilon}\cdot\mathbf{p}][-i-p]^{-1}\mathbf{f}^{\perp} = [i-p]^{-1}\mathbf{g}^{\perp}, \end{aligned} \tag{6.7}$$

with $\mathbf{f}^{\perp}$ an arbitrary square integrable transverse function (note that $[1 - i\boldsymbol{\epsilon}\cdot\mathbf{p}][-i-p]^{-1}$ is a bounded operator, so $\mathbf{g}^{\perp}$ is square integrable). Now

$$\mathbf{E}^{\perp}(\mathbf{x}) = ([i-p]^{-1}\mathbf{g}^{\perp})(\mathbf{x}) = (2\pi i)^{-1}\int d\mathbf{y} \frac{\exp[-y]}{y}\mathbf{g}^{\perp}(\mathbf{x}+\mathbf{y}), \tag{6.8}$$

and Young's inequality gives $\mathbf{E}^{\perp}(\mathbf{x}) \in L^2(\mathbb{R}^3, d\mathbf{x}; \mathbb{C}^3) \cap L^{\infty}(\mathbb{R}^3, d\mathbf{x}; \mathbb{C}^3)$. A further estimate results in

$$|\mathbf{E}^{\perp}(\mathbf{x}+\mathbf{a}) - \mathbf{E}^{\perp}(\mathbf{x})| \leqslant (2\pi)^{1/2}[2\|\mathbf{g}^{\perp}\|^2 - (\exp[i\mathbf{p}\cdot\mathbf{a}]\mathbf{g}^{\perp}, \mathbf{g}^{\perp}) - (\mathbf{g}^{\perp}, \exp[i\mathbf{p}\cdot\mathbf{a}]\mathbf{g}^{\perp})], \tag{6.9}$$

where the right-hand side tends to 0 with $\mathbf{a}$, so $\mathbf{E}^{\perp}(\mathbf{x})$ is continuous. Obviously we have the same result for $\mathbf{B}^{\perp}(\mathbf{x}) = \mathbf{B}(\mathbf{x})$. In eigenvalue problems, even stronger conditions hold. Thus, if H is a self-adjoint operator in a Hilbert space $\mathcal{H}$ and $Hf = \lambda f$, then $H^n f = \lambda^n f$ so $f \in \mathcal{D}(H^n)$. This applies

directly to dispersive PC's, where the Bloch-decomposed spectrum is discrete and the eigenvectors at nonzero eigenvalues are transverse.

VII. PHOTONIC CRYSTALS, THE PIECEWISE CONSTANT CASE

In Ref. 2 the presence of a nonempty null space of $\mathbf{H}_e$ gave rise to complications in applying the analytic Fredholm theorem in a discussion of spectral properties. But in the piecewise constant case the present results allow us to concentrate directly on $\mathbf{H}_e^{\perp}$, thus avoiding this problem. In the Bloch-decomposed situation on the unit cell either the definitions of $P^{\parallel}$ and $P^{\perp}$ must be modified[2] or a direct Bloch decomposition of $P^{\parallel}$ and $P^{\perp}$ can be made with the same result. An important observation is that the Bloch-decomposed projectors do not depend on $\boldsymbol{\kappa}$.

Let us now consider the transverse eigenvalue problem for the dispersive piecewise constant, case,

$$\mathbf{K}^{\perp}(\boldsymbol{\kappa})\cdot\mathbf{F}=\lambda\mathbf{F},\quad \mathbf{H}_e^{\perp}(\boldsymbol{\kappa})\cdot\mathbf{F}_e=\lambda^2\mathbf{F}_e. \tag{7.1}$$

Then

$$\left[\mathbf{p}^2(\boldsymbol{\kappa})+\sum_n \sigma_n(\mathbf{x})^2\right]\mathbf{F}_1-\sum_n \omega_n\sigma_n(\mathbf{x})\mathbf{F}_{2n}=[\mathbf{p}^2(\boldsymbol{\kappa})+\chi'(\mathbf{x},0)]\mathbf{F}_1-\sum_n \omega_n\sigma_n(\mathbf{x})\mathbf{F}_{2n}=\lambda^2\mathbf{F}_1,$$

$$-\omega_n\sigma_n(\mathbf{x})\mathbf{F}_1+\omega_n^2\mathbf{F}_{2n}=\lambda^2\mathbf{F}_{2n}. \tag{7.2}$$

We observed earlier that $\mathbf{H}_e^{\perp}$ has an empty null space, so $\lambda\neq 0$. Setting $\lambda=\omega_n$ the second equation implies that $\mathbf{F}_1=0$ for $\mathbf{x}\in\mathcal{A}$. Also, from the first, $\omega_n^2\mathbf{F}_1=\mathbf{p}^2(\boldsymbol{\kappa})\mathbf{F}_1$, $\mathbf{x}\notin\mathcal{A}$. Then the continuity conditions on $\partial_{\mathcal{A}}$ imply that $\mathbf{F}_1$ vanishes everywhere (see Ref. 2 Sec. IV), i.e., ω_n is not an eigenvalue.

VIII. ENERGY CONSERVATION FOR DISPERSIVE SYSTEMS

A. The conserved energy

Since we found that $\mathcal{E}=\mathcal{E}_{\mathrm{em}}+\mathcal{E}_{\mathrm{aux}}$ is conserved in time, this is the proper conserved energy and, in fact, becomes the Hamiltonian in a quantized theory.[1] Also, in view of the above result that ω_n is not an eigenvalue of $\mathbf{K}^{\perp}$ in the dispersive PC case, we rigorously have [see Eq. (2.23)] that in this case $\Delta\mathcal{E}_{\mathrm{em}}=0$. But also in the general piecewise constant transverse case, provided an eigenfunction expansion exists, considering a single dispersive Lorentz term for simplicity, we obtain from

$$\mathbf{H}_e^{\perp}\tilde{\mathbf{F}}_e(\omega)=\omega^2\tilde{\mathbf{F}}_e(\omega), \tag{8.1}$$

that

$$[\mathbf{p}^2+\Omega^2P_{\mathcal{A}}]\tilde{\mathbf{F}}_1(\omega)-\omega_0\Omega P_{\mathcal{A}}\tilde{\mathbf{F}}_2(\omega)=\omega^2\tilde{\mathbf{F}}_1(\omega),$$

$$-\omega_0\Omega P_A\tilde{\mathbf{F}}_1(\omega)+\omega_0^2\tilde{\mathbf{F}}_2(\omega)=\omega^2\tilde{\mathbf{F}}_2(\omega). \tag{8.2}$$

So, once more,

$$\mathbf{p}^2\tilde{\mathbf{F}}_1(\mathbf{x},\omega_0)=\omega_0^2\tilde{\mathbf{F}}_1(\mathbf{x},\omega_0),\quad \mathbf{x}\notin\mathcal{A},\quad \tilde{\mathbf{F}}_1(\mathbf{x},\omega_0)=0,\quad \mathbf{x}\in\mathcal{A}, \tag{8.3}$$

and again continuity across $\partial_{\mathcal{A}}$ implies that $\tilde{\mathbf{F}}_1(\mathbf{x},\omega_0)$ and hence $\tilde{\mathbf{F}}(\omega_0)$ vanishes everywhere. The situation remains the same in the general dispersive situation.

Next we consider, again for the piecewise constant case and transverse fields, the situation where $t_0=-\infty$, so, according to Eq. (3.15),

$$\mathbf{F}_{0n}(\mathbf{x},t)=\mathbf{F}_{4n}(\mathbf{x},t)+i\mathbf{F}_{2n}(\mathbf{x},t)=\lim_{\delta\downarrow 0}\sigma_n(\mathbf{x})\int_{-\infty}^{t}ds\,\exp[-\delta|s|]\exp[i\omega_n(t-s)]\mathbf{E}(\mathbf{x},s). \tag{8.4}$$

In terms of Fourier transforms,

$$\mathbf{F}(\mathbf{x},t)=\int d\omega\,\exp[-i\omega t]\widetilde{\mathbf{F}}(\mathbf{x},\omega), \tag{8.5}$$

we then obtain

$$\mathbf{F}_{0n}(\mathbf{x},t)=\lim_{\delta\downarrow 0}\sigma_n(\mathbf{x})\exp[i\omega_n t]\int d\omega\, i[\{[\omega+\omega_n+i\delta]^{-1}-[\omega+\omega_n-i\delta]^{-1}\}+i[\omega+\omega_n-i\delta]^{-1}$$
$$\times\exp[-\delta t]\exp[-i(\omega+\omega_n)t]]\widetilde{\mathbf{E}}(\mathbf{x},\omega). \tag{8.6}$$

Letting $\delta\downarrow 0$, the first term on the right gives the δ function $\delta(\omega+\omega_n)$, which does not contribute since $\widetilde{\mathbf{F}}(\mathbf{x},\pm\omega_n)=0$. Next, we make the technical assumption that $[\omega+\omega_n-i\delta]^{-1}\widetilde{\mathbf{E}}(\mathbf{x},\omega)=[\omega+\omega_n-i\delta]^{-1}\{\widetilde{\mathbf{E}}(\mathbf{x},\omega)-\widetilde{\mathbf{E}}(\mathbf{x},\omega_n)\}$ has an absolutely integrable limit as $\delta\downarrow 0$, denoted as $[\omega+\omega_n]^{-1}\widetilde{\mathbf{E}}(\mathbf{x},\omega)$. This is, for instance, trivially the case if we assume that $\widetilde{\mathbf{E}}(\mathbf{x},\omega)$ vanishes in a neighborhood of each ω_n. Then, noting that $\widetilde{\mathbf{E}}(\mathbf{x},\omega)=\widetilde{\mathbf{E}}(\mathbf{x},-\omega)$,

$$\mathbf{F}_{0n}(\mathbf{x},t)=i\sigma_n(\mathbf{x})\int d\omega\,\exp[-i\omega t][\omega+\omega_n]^{-1}\widetilde{\mathbf{E}}(\mathbf{x},\omega),$$

$$\mathbf{F}_{2n}(\mathbf{x},t)=-\sigma_n(\mathbf{x})\int d\omega\,\omega_n\exp[-i\omega t][\omega^2-\omega_n^2]^{-1}\widetilde{\mathbf{E}}(\mathbf{x},\omega),$$

$$\mathbf{F}_{4n}(\mathbf{x},t)=\sigma_n(\mathbf{x})\int d\omega\, i\omega\exp[-i\omega t][\omega^2-\omega_n^2]^{-1}\widetilde{\mathbf{E}}(\mathbf{x},\omega). \tag{8.7}$$

According to the above assumption, $[\omega+\omega_n]^{-1}\widetilde{\mathbf{E}}(\mathbf{x},\omega)$ is absolutely integrable and hence the auxiliary fields vanish as $t\to\pm\infty$ by the Riemann–Lebesgue lemma (recall that $t_0=-\infty$). This applies to the situation where an electromagnetic wave packet is scattered from a finite piece of dielectric material. Then the wave packet is initially freely moving in the direction of the material and becomes free again as $t\to\infty$.

For a monochromatic field,

$$\mathbf{E}(\mathbf{x},t)=\mathbf{E}_0(\mathbf{x})\cos\omega t,\quad \mathbf{B}(\mathbf{x},t)=\mathbf{B}_0(\mathbf{x})\sin\omega t,\quad 0\neq\omega\neq\omega_n, \tag{8.8}$$

we obtain

$$\mathbf{F}_{2n}(\mathbf{x},t)=-\frac{\omega_n\sigma_n(\mathbf{x})}{\omega^2-\omega_n^2}\mathbf{E}_0(\mathbf{x})\cos\omega t,\quad \mathbf{F}_{4n}(\mathbf{x},t)=\frac{\omega\sigma_n(\mathbf{x})}{ega^2-\omega_n^2}\mathbf{E}_0(\mathbf{x})\sin\omega t. \tag{8.9}$$

In this case, the energy $\mathcal{E}$ is infinite but the energy density,

$$U_\omega(\mathbf{x},t)=\frac{1}{2}\left[\mathbf{F}_1(\mathbf{x},t)^2+\mathbf{F}_3(\mathbf{x},t)^2+\sum_n\{\mathbf{F}_{2n}(\mathbf{x},t)^2+\mathbf{F}_{4n}(\mathbf{x},t)^2\}\right], \tag{8.10}$$

still makes sense. Taking the time average over a field period $2\pi/\omega$ (cycle averaging), using some results from Sec. II, we arrive at

$$U_\omega(\mathbf{x}) = \langle U_\omega(\mathbf{x},t)\rangle = \frac{1}{4}[\partial_\omega\{\omega\varepsilon(\mathbf{x},\omega)\}\mathbf{E}_0(\mathbf{x})^2 + \mathbf{B}_0(\mathbf{x})^2]. \tag{8.11}$$

We see by comparison with the vacuum case that the contribution to the energy density from the auxiliary fields is given by

$$\frac{1}{4}[\partial_\omega\{\omega\varepsilon(\mathbf{x},\omega)\} - 1]\mathbf{E}_0(\mathbf{x})^2. \tag{8.12}$$

However, the use of monochromatic fields is somewhat unsatisfactory since the current density $\mathbf{J}(\mathbf{x},t)$ remains oscillating as $t\to-\infty$, which is usually not the case for actual physical systems. To remedy this, we have to use wave packets containing a continuous range of ω's, but then cycle averaging loses its meaning. However, if $\widetilde{\mathbf{E}}(\mathbf{x},\omega)$ is strongly peaked around some value ω_0 and $\varepsilon(\mathbf{x},\omega)$ has no sharp peaks in a neighborhood of ω_0, then $U_{\omega_0}(\mathbf{x})$ is approximately conserved.

For longitudinal fields the situation is quite different. As can be seen from Eq. (3.17), which refers to a single Lorentz contribution inside the dielectric material,

$$\mathbf{H}^{\parallel}_{e\mathcal{A}} = \begin{pmatrix} \Omega^2 & -\omega_0\Omega \\ -\omega_0\Omega & \omega_0^2 \end{pmatrix} P_{\mathcal{A}}, \tag{8.13}$$

which has the eigenvalues 0 and $\pm\sqrt{\Omega^2+\omega_0^2}$. Thus $\mathbf{F}^{\parallel}_{\mathcal{A}}(t)$ is a sum of constant and harmonic functions, which is also true in the general case. This means that we cannot set $t_0=-\infty$. But $t_0=0$ is a possible choice. In the above case we then obtain, for $\mathbf{x}\in\mathcal{A}$, applying the inverse Laplace transform to the longitudinal component of Eq. (2.18), the explicit expressions

$$\mathbf{E}^{\parallel}(\mathbf{x},t) = [\Omega^2+\omega_0^2]^{-1}[\omega_0^2 + \Omega^2\cos\sqrt{\Omega^2+\omega_0^2}t]\mathbf{E}^{\parallel}(\mathbf{x},0),$$

$$\mathbf{F}^{\parallel}_0(\mathbf{x},t) = \Omega[\Omega^2+\omega_0^2]^{-1}[i\omega_0\{1-\cos\sqrt{\Omega^2+\omega_0^2}t\} + \sqrt{\Omega^2+\omega_0^2}\sin\sqrt{\Omega^2+\omega_0^2}t]\mathbf{E}^{\parallel}(\mathbf{x},0), \tag{8.14}$$

resulting in $U(\mathbf{x},t)=\frac{1}{2}\mathbf{E}^{\parallel}(\mathbf{x},0)^2$, which is time independent and differs in form from the expression for the transverse fields. In fact, a difference is to be expected since longitudinal fields are not propagating waves. Note that the contributions of the auxiliary fields must be taken into account to obtain the above result.

B. Other approaches

Let us consider once more a situation where the material is confined to $\mathcal{A}\subset\mathbb{R}^3$ over which $\chi(\mathbf{x},t)$ is homogeneous in $\mathbf{x}$ and given by the absorptive Lorentz expression, Eq. (2.15). Then, for $\mathbf{x}\in\mathcal{A}$,

$$\mathbf{P}(\mathbf{x},t) = \sum_n \mathbf{P}_n(\mathbf{x},t), \mathbf{P}_n(\mathbf{x},t) = \int_{t_0}^{t} ds\ \chi_n(\mathbf{x},t-s)\mathbf{E}(\mathbf{x},s). \tag{8.15}$$

A little calculation then results in

$$\partial_t^2\mathbf{P}_n(\mathbf{x},t) + 2\gamma_n\,\partial_t\mathbf{P}_n(\mathbf{x},t) + \omega_n^2\mathbf{P}_n(t) = \Omega_n^2\mathbf{E}(\mathbf{x},t). \tag{8.16}$$

Note that this expression is similar to the one obtained by Loudon,[6] who started from a damped oscillator model. He then went on by considering

$$-\partial_{\mathbf{x}}\cdot\mathbf{S}(\mathbf{x},t) = \mathbf{E}(\mathbf{x},t)\cdot\partial_t x\mathbf{D}(\mathbf{x},t) + \mathbf{H}(\mathbf{x},t)\cdot\partial_t\mathbf{B}(\mathbf{x},t), \tag{8.17}$$

where $\mathbf{S}(\mathbf{x},t)=\mathbf{E}(\mathbf{x},t)\times\mathbf{H}(\mathbf{x},t)$ is the Poynting vector, a relation that is generally valid for sufficiently smooth fields. The aim is here to try to write the right-hand side as a time derivative so that a continuity equation is obtained. Note that in our case $\mathbf{H}(\mathbf{x},t)=\mathbf{B}(\mathbf{x},t)$. Next, we write

$$\mathbf{E}(\mathbf{x},t)\cdot\partial_t\mathbf{D}(\mathbf{x},t)+\mathbf{H}(\mathbf{x},t)\cdot\partial_t\mathbf{B}(\mathbf{x},t)=\partial_t\frac{1}{2}\{\mathbf{E}(\mathbf{x},t)^2+\mathbf{B}(\mathbf{x},t)^2\}+\mathbf{E}(\mathbf{x},t)\cdot\partial_t\mathbf{P}(\mathbf{x},t)$$
$$=\partial_t U_{\mathrm{em}}(\mathbf{x},t)+\mathbf{E}(\mathbf{x},t)\cdot\partial_t\mathbf{P}(\mathbf{x},t), \tag{8.18}$$

where $U_{\mathrm{em}}(\mathbf{x},t)$ is the electromagnetic energy density. Inside $\mathcal{A}$,

$$\mathbf{E}(t)\cdot\partial_t\mathbf{P}(t)=\sum_n\mathbf{E}(t)\cdot\partial_t\mathbf{P}_n(t)=\sum_n\frac{1}{\Omega_n^2}\{\partial_t^2\mathbf{P}_n(t)+\gamma_n\,\partial_t\mathbf{P}_n(t)+\omega_n^2\mathbf{P}_n(t)\}\cdot\partial_t\mathbf{P}_n(t)$$
$$=\partial_t\sum_n\frac{1}{2\Omega_n^2}\{\partial_t\mathbf{P}_n(t)^2+\omega_n^2\mathbf{P}_n(t)^2\}+\sum_n\frac{\gamma_n}{\Omega_n^2}\partial_t\mathbf{P}_n(t)^2, \tag{8.19}$$

so

$$-\partial_{\mathbf{x}}\cdot\mathbf{S}(\mathbf{x},t)=\partial_t\left[U_{\mathrm{em}}(\mathbf{x},t)+\mathbf{l}_{\mathcal{A}}(\mathbf{x})\sum_n\frac{1}{2\Omega_n^2}\{\partial_t\mathbf{P}_n(\mathbf{x},t)^2+\omega_n^2\mathbf{P}_n(\mathbf{x},t)^2\}\right]+\sum_n\frac{\gamma_n}{\Omega_n^2}\partial_t\mathbf{P}_n(\mathbf{x},t)^2. \tag{8.20}$$

In the dispersive case, $\gamma_n\equiv 0$, so

$$\partial_t U(\mathbf{x},t)+\partial_{\mathbf{x}}\cdot\mathbf{S}(\mathbf{x},t)=0,$$

$$U(\mathbf{x},t)=U_{\mathrm{em}}(\mathbf{x},t)+\mathbf{l}_{\mathcal{A}}(\mathbf{x})\sum_n\frac{1}{2\Omega_n^2}\{\partial_t\mathbf{P}_n(\mathbf{x},t)^2+\omega_n^2\mathbf{P}_n(\mathbf{x},t)^2\}]. \tag{8.21}$$

Then, for a harmonic field, as given by Eq. (8.8), we have

$$\mathbf{P}_n(\mathbf{x},t)=-\frac{\Omega_n^2}{\omega^2-\omega_n^2}\mathbf{E}_0(\mathbf{x})\cos\,\omega t,\quad \mathbf{B}(\mathbf{x},t)=\mathbf{B}_0(\mathbf{x})\sin\,\omega t, \tag{8.22}$$

so

$$U_\omega(\mathbf{x},t)=\frac{1}{2}\left[\mathbf{E}_0(\mathbf{x})^2\cos^2\,\omega t+\mathbf{B}_0(\mathbf{x})^2\sin^2\,\omega t+\mathbf{l}_{\mathcal{A}}(\mathbf{x})\sum_n\frac{\Omega_n^2}{(\omega^2-\omega_n^2)^2}\right.$$
$$\left.\times\{\omega^2\sin^2\,\omega t+\omega_n^2\cos^2\,\omega t\}\mathbf{E}_0(\mathbf{x})^2\right], \tag{8.23}$$

and upon cycle averaging we obtain $\langle\partial_t\mathbf{S}(\mathbf{x},t)\rangle=0$, whereas the averaged energy density is

$$U_\omega(\mathbf{x})=\langle U_\omega(\mathbf{x},t)\rangle=\frac{1}{4}\left[\left\{1+\mathbf{l}_{\mathcal{A}}(\mathbf{x})\sum_n\frac{\Omega_n^2(\omega^2+\omega_n^2)}{(\omega^2-\omega_n^2)^2}\right\}\mathbf{E}_0(\mathbf{x})^2+\mathbf{B}_0(\mathbf{x})^2\right]$$
$$=\frac{1}{4}[\partial_\omega\{\omega\varepsilon(\mathbf{x},\omega\,\}\mathbf{E}_0(\mathbf{x})^2+\mathbf{B}_0(\mathbf{x})^2], \tag{8.24}$$

a result obtained earlier by various authors (see Ref. 6 and references cited) and that coincides with Eq. (8.11). Since we used the general expression for the dispersive susceptibility χ, this expression is generally valid. Thus we see that the contribution $\frac{1}{4}[\partial_\omega\{\omega\varepsilon(\mathbf{x},\omega\,\}-1]\mathbf{E}_0(\mathbf{x})^2$ is precisely the energy stored in the auxiliary field modes.

Loudon also applies the averaging procedure to the absorptive situation but this does not seem to be correct since then harmonic solutions of Maxwell's equations with real ω do not exist. The same issue is encountered in Ref. 10, where once more a harmonic dependence is assumed for the absorptive case. In Refs. 2 and 9 we found that for absorptive PC's transverse solutions of the

Helmholtz equation generically exist only for a set of complex frequencies $\zeta=\omega-i\gamma$, $\gamma>0$, contained in the spectral islands in $\mathbb{C}^-$; see Sec. IV. Thus, for given ω, there is, in general, a whole interval of allowed γ's. Then a specific solution has the form

$$\mathbf{E}(\mathbf{x},t)=\mathbf{E}_0(\mathbf{x})\exp[-\gamma t]\cos(\omega t-\delta), \quad t\geqslant 0, \tag{8.25}$$

which gives a significantly more complicated form for $\mathbf{P}_n(\mathbf{x},t)$. In addition a cycle average over the interval $[t,t+2\pi/\omega]$ now depends on t. Actually it is rather obvious that a damping factor should be present in Eq. (8.25) since the field amplitudes will decrease in time due to absorption.

Landau and Lifshits,[7] considering the dispersive case, took a slightly different approach. They considered fields with Fourier components sharply peaked around a central frequency ω_0, $\mathbf{E}(t)=\mathbf{E}_0(t)\cos\omega_0 t$ with $\mathbf{E}_0(t)$ only slowly time dependent on the scale set by ω_0. A crucial point in their development is the expansion of $\hat{\chi}(\omega_0+\alpha)$ to first order in α. But this is questionable if there is a sharp peak in $\hat{\chi}(\omega)$ in ω_1 close to ω_0. Here again an average over $2\pi/\omega_0$ is taken, once more resulting in the contribution $\frac{1}{4}\partial_\omega\{\omega\varepsilon(\mathbf{x},\omega\,\}\mathbf{E}_0(\mathbf{x})^2$ to the averaged energy density.

We note that cycle averaging can be relevant in experimental situations where the detection time interval extends over a large number of periods of the field. But in phase-sensitive cases, the situation may become different.

IX. ENERGY CONSERVATION FOR NONLINEAR DIELECTRICS

In this section we consider the conserved energy for nonlinear systems. We use an alternative method, also applicable to the linear case, featuring an additional time variable u rather than a frequency λ.

A. The conserved energy

We consider nonlinear dielectrics, characterized by a set of nonlinear susceptibilities $\{\boldsymbol{\chi}_n(\mathbf{x},t_1,\ldots,t_n)\}$, where $n\in\mathbb{N}$ but, in practice, only the first few n play a role. Thus ($\odot$ indicates an n-fold tensorial contraction with the object following it)

$$\mathbf{P}(\mathbf{x},t)=\sum_{n=1}^{\infty}\mathbf{P}_n(\mathbf{x},t),$$

$$\mathbf{P}_n(\mathbf{x},t)=\int_{t_0}^{t}ds_1\ldots\int_{t_0}^{t}ds_n\,\boldsymbol{\chi}_n(\mathbf{x},t-s_1,\ldots,t-s_n)\odot\mathbf{E}(\mathbf{x},s_1)\ldots\mathbf{E}(\mathbf{x},s_n). \tag{9.1}$$

We make the following assumptions for the susceptibilities $\boldsymbol{\chi}_n$ (see Ref. 11 for detailed information about nonlinear susceptibilities):

A: $\boldsymbol{\chi}_n(\mathbf{x},t_1,\ldots,t_n)=0$ if at least one $t_j<0$, which is a causality requirement.

B: $\boldsymbol{\chi}_n(\mathbf{x},0,t_2\ldots,t_n)=0$, which excludes sudden surges in the current density at the initial time.

C: The rank $n+1$ tensors $\boldsymbol{\chi}_n(\mathbf{x},t_1,\ldots,t_n)$ possess the symmetry property (cf. Ref. 11)

$$(\boldsymbol{\chi}_n)_{kk_1\ldots k_n}(\mathbf{x},t_1,\ldots,t_n)=(\boldsymbol{\chi}_n)_{kk'_1tsk'_n}(\mathbf{x},t'_1,\ldots,t'_n), \tag{9.2}$$

with $\{(k'_1,t'_1),\ldots(k'_n,t'_n)\}$ any permutation of $\{(k_1,t_1),\ldots(k_n,t_n)\}$, i.e., $(\boldsymbol{\chi}_2)_{kk_1k_2}(\mathbf{x},t_1,t_2)=(\boldsymbol{\chi}_2)_{kk_2k_1}(\mathbf{x},t_2,t_1)$, etc.

D: $(\boldsymbol{\chi}_1)_{kl}(\mathbf{x},t)=(\boldsymbol{\chi}_1)_{lk}(\mathbf{x},t)$.

These properties can be verified for material systems subject to a time-dependent external field by expanding the expectation of the polarization in powers of the driving field. Property D holds if the system Hamiltonian is real (time-reversal invariant). Here we note that time reversal invariance apparently does not lead to useful additional relations between the components of the higher-order $\boldsymbol{\chi}_n$'s.

The polarization current density $\mathbf{J}(\mathbf{x},t)$ is now given by

$$\mathbf{J}(\mathbf{x},t) = \partial_t \mathbf{P}(\mathbf{x},t) = \sum_{n=1}^{\infty} \mathbf{J}_n(\mathbf{x},t),$$

$$\mathbf{J}_n(\mathbf{x},t) = \int_{t_0}^{t} ds_1 \ldots \int_{t_0}^{t} ds_n \, \boldsymbol{\chi}_n'(\mathbf{x},t-s_1,\ldots,t-s_n) \odot \mathbf{E}(\mathbf{x},s_1)\ldots\mathbf{E}(\mathbf{x},s_n), \tag{9.3}$$

where

$$\boldsymbol{\chi}_n'(\mathbf{x},t_1,\ldots,t_n) = (\partial_{t_1} + \ldots \partial_{t_n})\boldsymbol{\chi}_n(\mathbf{x},t_1,\ldots,t_n). \tag{9.4}$$

We have

$$\partial_t \mathcal{E}_{\mathrm{em}}(t) = -\int d\mathbf{x}\, \mathbf{E}(\mathbf{x},t)\cdot\mathbf{J}(\mathbf{x},t) = -\sum_{n=1}^{\infty} \int d\mathbf{x}\mathbf{E}(\mathbf{x},t)\cdot\mathbf{J}_n(\mathbf{x},t) \tag{9.5}$$

and we define

$$\mathcal{E}(t) = \mathcal{E}_{\mathrm{em}}(t) + \int_{t_0}^{t} ds \int d\mathbf{x}\, \mathbf{E}(\mathbf{x},s)\cdot\mathbf{J}(\mathbf{x},s) = \mathcal{E}_{\mathrm{em}}(t) + \mathcal{E}_{\mathrm{aux}}(t), \tag{9.6}$$

where

$$\mathcal{E}_{\mathrm{aux}}(t) = \sum_{n=1}^{\infty} \mathcal{E}_n(t), \quad \mathcal{E}_n(t) = \int_{t_0}^{t} ds \int d\mathbf{x}\, \mathbf{E}(\mathbf{x},s)\cdot\mathbf{J}_n(\mathbf{x},s). \tag{9.7}$$

We shall refer to $\mathcal{E}(t)$ as the energy of the system. However, note that, as in the linear case, it does not depend on the fields at time t only. As before we remedy this by introducing auxiliary fields. Dropping $\mathbf{x}$ in the various objects for brevity, we have

$$\begin{aligned}
\mathcal{E}_n(t) &= \int d\mathbf{x} \int_{t_0}^{t} ds_0\, \mathbf{E}(s_0)\cdot\int_{t_0}^{s_0} ds_1\ldots ds_n\, \boldsymbol{\chi}_n'(s_0-s_1,\ldots,s_0-s_n)\odot\mathbf{E}(s_1)\ldots\mathbf{E}(s_n) \\
&= \int d\mathbf{x}\int_{t_0}^{t} ds_0\ldots ds_n \mathbf{E}(s_0)\cdot\boldsymbol{\chi}_n'(s_0-s_1,\ldots,s_0-s_n)\odot\mathbf{E}(s_1)\ldots\mathbf{E}(s_n) = \int d\mathbf{x}\int ds_0\ldots ds_n \\
&\quad \Theta(t-s_0)\Theta(s_0-t_0)\mathbf{E}(s_0)\cdot\boldsymbol{\chi}_n'(s_0-s_1,\ldots,s_0-s_n)\odot\Theta(s_0-s_1)\Theta(s_1-t_0)\mathbf{E}(s_1)\ldots\Theta(s_0-s_n) \\
&\quad \Theta(s_n-t_0)\mathbf{E}(s_n), \quad t>t_0,
\end{aligned} \tag{9.8}$$

or, with $u_j = t - s_j$,

$$\begin{aligned}
\mathcal{E}_n(t) &= \int d\mathbf{x}\int du_0\ldots du_n\, \Theta(u_0)\Theta(t-t_0-u_0)\mathbf{E}(t-u_0)\cdot\boldsymbol{\chi}_n'(u_1-u_0,\ldots,u_n-u_0)\odot\Theta(u_1) \\
&\quad \Theta(t-t_0-u_1)\mathbf{E}(t-u_1)\ldots\Theta(u_n)\Theta(t-t_0-u_n)\mathbf{E}(t-u_n) = \int d\mathbf{x}\int_0^{\infty} du_0\ldots du_n\, \Theta(t-t_0-u_0) \\
&\quad \times \mathbf{E}(t-u_0)\cdot\boldsymbol{\chi}_n'(u_1-u_0,\ldots,u_n-u_0)\odot\Theta(t-t_0-u_1)\mathbf{E}(t-u_1)\ldots\Theta(t-t_0-u_n)\mathbf{E}(t-u_n).
\end{aligned} \tag{9.9}$$

Now let

$$\mathbf{F}_0(u,t) = \Theta(u)\Theta(t-t_0-u)\mathbf{E}(t-u). \tag{9.10}$$

Then

$$\mathcal{E}_n(t) = \int d\mathbf{x} \int du_0 \dots du_n \, \mathbf{F}_0(u_0,t) \cdot \boldsymbol{\chi}_n'(u_1-u_0, \dots, u_n-u_0) \odot \mathbf{F}_0(u_1,t) \dots \mathbf{F}_0(u_n,t). \tag{9.11}$$

Similarly, for the current density,

$$\mathbf{J}_n(\mathbf{x},t) = \int du_1 \dots du_n \, \boldsymbol{\chi}_n'(u_1, \dots, u_n) \odot \mathbf{F}_0(u_1,t) \dots \mathbf{F}_0(u_n,t). \tag{9.12}$$

Note that

$$\mathbf{F}_0(u,t) = 0, \quad t < t_0,$$

$$\mathbf{F}_0(u,t_0) = 0, \quad u \neq 0,$$

$$\mathbf{F}_0(0,t) = \Theta(t-t_0)\mathbf{E}(t)\{=\mathbf{E}(t), t \geqslant t_0\}, \tag{9.13}$$

and $\mathbf{F}_0(u,t)$ satisfies the differential equation

$$\partial_t \mathbf{F}_0(u,t) = -\partial_u \mathbf{F}_0(u,t) + \delta(u)\mathbf{E}(t). \tag{9.14}$$

It is easily checked, using the equations of motion for the electromagnetic fields with Eq. (9.12) for the current densities and Eq. (9.14) for $\mathbf{F}_0(u,t)$ that indeed $\mathcal{E}$, expressed in terms of the fields at time t, is a constant of the motion.

B. The equation of motion for $\mathbf{F}_0(u,t)$

We note that in the previous section only $u \geqslant 0$ enter the formalism, so we consider Eq. (9.14) as an equation of motion for $\mathbf{F}_0(u,t)$ in the real Hilbert space $\mathcal{H}=L_r^2([0,\infty),du)$, interpreting $\delta(u)du$ as the unit point measure concentrated in $0 \in [0,\infty)$. In this space the operator $-\partial_u$ is antisymmetric when acting upon smooth functions with compact support avoiding zero. It has a unique anti-self-adjoint extension $\mathbf{L}$, with the property that the functions in its domain vanish in $u=0$ and

$$(\exp[\mathbf{L}t]f)(u) = \begin{cases} f(u-t), & u \geqslant t \\ 0, & u < t \end{cases} = \Theta(u-t)f(u-t), \tag{9.15}$$

so Eq. (9.14) becomes

$$\partial_t \mathbf{F}_0(u,t) = \mathbf{L}\mathbf{F}_0(u,t) + \delta(u)\Theta(t-t_0)\mathbf{E}(t). \tag{9.16}$$

Its general solution for $t > t_0$ is

$$\begin{aligned} \mathbf{F}_0(u,t,t_0) &= \exp[\mathbf{L}(t-t_0)]\mathbf{F}_0^{\text{in}}(u,t_0) + \int_{t_0}^{t} ds \, \exp[\mathbf{L}(t-s)]\delta(u)\Theta(s-t_0)\mathbf{E}(s) \\ &= \Theta(u-t+t_0)\mathbf{F}_0^{\text{in}}(u-t+t_0,t_0) + \int_{t_0}^{t} ds \, \delta(u-t+s)\Theta(s-t_0)\mathbf{E}(s) \\ &= \Theta(u-t+t_0)\mathbf{F}_0^{\text{in}}(u-t+t_0,t_0) + \Theta(t-t_0-u)\mathbf{E}(t-u), \end{aligned} \tag{9.17}$$

where the initial field $\mathbf{F}_0^{\text{in}}(u,t_0)$ is arbitrary, square integrable in u. Note that this solution reduces to the earlier one if we require $\mathbf{F}_0(u,t_0,t_0)=0$ since then $\mathbf{F}_0^{\text{in}}(u,t_0)$ must vanish.

C. Connection with earlier approach

The Fourier transform $\widetilde{\mathbf{F}}_0(\lambda,t)$ of $\mathbf{F}_0(u,t)$ is

$$\widetilde{\mathbf{F}}_0(\lambda,t)=\int_0^\infty du\,\exp[-i\lambda u]\mathbf{F}_0(u,t)=\exp[-i\lambda(t-t_0)]\int_0^\infty du\,\exp[-i\lambda u]\mathbf{F}_0^{\mathrm{in}}(u,t_0)$$
$$+\int_{t_0}^t ds\,\exp[-i\lambda(t-s)]\mathbf{E}(s), \tag{9.18}$$

which reduces to

$$\widetilde{\mathbf{F}}_0(\mathbf{x},\lambda,t)=\int_{t_0}^t ds\,\exp[-i\lambda(t-s)]\mathbf{E}(\mathbf{x},s)=\widetilde{\mathbf{F}}_4(\mathbf{x},\lambda,t)+i\widetilde{\mathbf{F}}_2(\mathbf{x},\lambda,t), \tag{9.19}$$

in the Maxwell case, $\mathbf{F}_0(u,t_0)=0$. Note that, apart from the factors $\sigma(\mathbf{x},\lambda)$, these are the fields $\mathbf{F}_{2,4}(\mathbf{x},\lambda,t)$ introduced earlier in Eqs. (3.1). Note also that $\sigma(\mathbf{x},\lambda)$ is specific for the absolutely continuous linear case and it makes no sense to introduce it here. In our earlier discussion we could have dropped the condition (we omit the overtildes from now on for notational simplicity) $\mathbf{F}_{2,4}(\mathbf{x},\lambda,t_0)=0$ leading to a term $\exp[-i\lambda(t-t_0)]\mathbf{F}_0(\mathbf{x},\lambda,t_0)$ but here we have a bonus since it follows from Eq. (9.18) that $\mathbf{F}_0(\mathbf{x},\lambda,t_0)$ and $\mathbf{F}_0(\mathbf{x},\lambda,t)$ are analytic upon continuation in $\mathbb{C}^-$, the open lower complex half-plane. This can be of importance in a quantization procedure since there the initial fields can no longer be set equal to zero.

We can also express $\mathcal{E}$ in terms of the Fourier transformed fields. Setting **($\boldsymbol{\lambda}=(\lambda_1,\ldots\lambda_n)$, $\mathbf{t}=(t_1,\ldots t_n)$, $\int_a^b d\mathbf{t}$ means that each t_j is integrated over $[a,b)$)**

$$\boldsymbol{\chi}_n'(\mathbf{x},\mathbf{t})=\int d\boldsymbol{\lambda}\,\exp[-i\boldsymbol{\lambda}\cdot\mathbf{t}]\boldsymbol{\mu}_n(\mathbf{x},\boldsymbol{\lambda}),$$

$$\boldsymbol{\mu}_n(\mathbf{x},\boldsymbol{\lambda})=(2\pi)^{-n}\int_0^\infty d\mathbf{t}\,\exp[i\boldsymbol{\lambda}\cdot\mathbf{t}]\boldsymbol{\chi}_n'(\mathbf{x},\mathbf{t}), \tag{9.20}$$

we arrive at

$$\mathcal{E}_n(t)=\int d\mathbf{x}\int d\boldsymbol{\lambda}\,\bar{\mathbf{F}}_0(\lambda_1+\ldots\lambda_n,t)\cdot\boldsymbol{\mu}_n(\boldsymbol{\lambda})\odot\mathbf{F}_0(\lambda_1,t)\ldots\mathbf{F}_0(\lambda_n,t). \tag{9.21}$$

We can once more check the time independence of $\mathcal{E}$ expressed in terms of the Fourier transformed fields by using the equations of motion. In doing so we also need

$$\int d\lambda_j\,\bar{\mathbf{F}}_0(\lambda_1+\ldots+\lambda_n,t)\cdot\boldsymbol{\mu}_n(\boldsymbol{\lambda})=0,$$

$$\int d\lambda_j\ldots d\lambda_r\,\bar{\mathbf{F}}_0(\lambda_1+\ldots+\lambda_n,t)\cdot\boldsymbol{\mu}_n(\boldsymbol{\lambda})\bar{\mathbf{F}}_0(\lambda_j,t)\ldots\bar{\mathbf{F}}_0(\lambda_r,t)=0, \tag{9.22}$$

which are a consequence of the analyticity properties of $\boldsymbol{\mu}_n(\boldsymbol{\lambda})$ and those of $\mathbf{F}_0(\mathbf{x},\lambda,t)$ that follow from Eq. (9.18). Note that, in particular, $\mathbf{F}_0(\mathbf{x},\lambda,t_0)$ has this analyticity property. Starting from the Fourier transformed formalism, this would not have followed.

It is interesting to note that if $\mathbf{F}_0(\lambda,t)$ has harmonic time dependence, $\mathbf{F}_0(\lambda,t)=\exp[-i\omega t]\mathbf{F}_0(\lambda,0)$ (which is true if we decouple the electromagnetic and auxiliary fields) that each $\mathcal{E}_n(t)$ is conserved in time, i.e., all $\mathcal{E}_n$'s are constants of the motion. However, the construction of a Lagrange–Hamilton setup and its quantization are at present open problems. Finding such a formalism is an important issue since nonlinear equations of motion are usually based on models

starting from an *ad hoc* Hamiltonian with the appropriate number of higher-order terms in creation and annihilation operators.

X. DISCUSSION

A. Summary of results

In the present work we discussed an number of issues connected with the macroscopic Maxwell's equations for dispersive and absorptive dielectrics with the emphasis on systems where the electric susceptibility $\chi(\mathbf{x},t)$ is a piecewise constant function of $\mathbf{x}$. This covers the important cases of scattering from finite objects and photonic crystals. A complicating factor is here the time convolution in the relation

$$\mathbf{P}(\mathbf{x},t) = \int_{t_0}^{t} ds\, \chi(\mathbf{x},t-s)\mathbf{E}(\mathbf{x},s), \tag{10.1}$$

between the polarization and the electric field. However, the existence of an equivalent unitary time evolution in an enlarged Hilbert space made it possible to treat the problem by standard Hilbert space methods. We showed rigorously that in the piecewise constant case the equations of motion for longitudinal and transverse field components decouple. This gives a significant simplification in the discussion of band structure of, in general absorptive, photonic crystals. In our original setup[2] quite a number of steps were necessary to remove an infinite-dimensional null space in an application of the analytic Fredholm theorem. With the present results we can directly concentrate on the transverse case where the null space is empty.

We then considered boundary and initial value problems, again for the piecewise constant case. We found that continuity of the longitudinal component of the displacement, in particular, the continuity of the normal component across an interface, enters as a condition at the initial time t_0. Without it the time evolution still exists for general square integrable fields. Since magnetic charges are absent, $\mathbf{B}^{\parallel}=0$, as is also the case for $\mathbf{D}^{\parallel}$ if there are no external electric charges. But if a static external charge distribution $\rho_e(\mathbf{x}) \in L^1(\mathbb{R}^3,d\mathbf{x}) \cap L^{6/5}(\mathbb{R}^3,d\mathbf{x})$ is present, it is easily verified that $\mathbf{D}^{\parallel}(\mathbf{x},t_0)$ is continuous in $\mathbf{x}$ and then this is also true at all later times. We can also deal with nonstationary external charge and current distributions, but then a corresponding external current must be added in Eqs. (2.1). There are no conditions on the initial transverse fields $\mathbf{E}^{\perp}(\mathbf{x},t_0)$ and $\mathbf{B}^{\perp}(\mathbf{x},t_0)=\mathbf{B}(\mathbf{x},t_0)$, but in the usual differential form of Maxwell's equations these fields must be in the domain of the generator of the time evolution, and this implies their continuity in $\mathbf{x}$, which is then true for all times. This also applies to eigenvalue problems, thus recovering the usual boundary conditions.

We also considered energy conservation for dispersive, nonabsorptive systems. It is expected that, since no absorption takes place, the electromagnetic energy $\mathcal{E}_{\mathrm{em}}$ is conserved. This turns out to be asymptotically true ($t_0=-\infty$, $t\to\infty$), implying conservation in scattering problems, but, in general, $\mathcal{E}_{\mathrm{em}}(t)$ oscillates for finite t. In the literature an approximate conserved energy is obtained for harmonic motion by cycle averaging. In Sec. VIII we identified the excess energy associated with $\partial_\omega\{\omega\varepsilon(\mathbf{x},\omega)\}-1$ as the energy stored in the auxiliary field modes. Somewhat surprisingly, the energy density associated with the longitudinal modes, including the auxiliary ones, is constant in time. This seems not to have been noted before. In this case, since there is no differential operator in the relevant Helmholtz equation, everything is strictly local in $\mathbf{x}$. Although oscillating modes can exist inside dispersive dielectrics it is not obvious how to excite the latter since an external current inside the dielectric is required.

A quite unexplored subject is the mathematical description of nonlinear dielectrics. We showed that here once more a conserved energy exists. We took the opportunity to introduce an alternative setup for the auxiliary fields, also applicable to the linear case, which involves an additional time variable rather than a frequency λ.

In closing this part we note that the initial time t_0 can be $-\infty$ or a finite time. In the second case there is no loss in generality in setting $t_0=0$. In the first case, if the dielectric material is confined to a bounded space region $\mathcal{A}\subset\mathbb{R}^3$ or a half-space we can have a situation where the electromag-

netic fields constitute a wave packet that is initially away from the material and propagates toward it. Thus the front of the wave packet will reach the material at some finite time before which the polarization vanishes. This is typical for a scattering situation, which was studied earlier by the author.[1] But in other cases, such as PCs, the material is spread out through all space and the above argument breaks down. Here we encounter a problem that is specific for infinite systems. Production and detection apparatus must necessarily be embedded in the system, and this does not correspond to actual physical situations. In practice, a PC is a finite object and in usual experiments radiation is produced and observed outside it. This can involve elastic scattering but also the incoming radiation can be absorbed and reemitted, possibly at a different frequency. However, it is advantageous to consider infinite PCs since the spatial periodicity allows a Bloch–Floquet decomposition, reducing the spectral problem to that of an operator on the unit cell. For a sufficiently large PC the actual spectral properties will not deviate much from those of an infinite one.

B. Related work

The construction of a formalism without time convolutions from one that has this property is in itself an interesting issue. In a recent publication, Figotin and Schenker[12] give a mathematical analysis of this matter. In particular, they addressed the matter of uniqueness of the auxiliary field formalism.

C. Outlook

Most of the results obtained here were for the piecewise constant case. If $\chi(\mathbf{x},t)$ is a smooth function of $\mathbf{x}$, longitudinal and transverse modes become coupled and the situation changes. This complicates the eigenvalue problem for photonic crystals and also the approximate expressions for energy conservation need revision. A more challenging problem is the possible existence of a Hamiltonian formulation for nonlinear systems. Although it is straightforward in the linear case,[1] it is far from obvious that an affirmative result exists in case quadratic or cubic terms are added to the polarization.

(Received 5 April 2005; accepted 18 November 2005; published online 18 January 2006)

In this paper we propose a model for a proper kinetic description of the Auger effect as a generation/recombination mechanism for electrons and holes in a bipolar device. Boltzmann-type equations for the two-species population in a phonon background are presented, and equilibria and their stability are investigated. Particles and quasiparticles are allowed to obey generalized statistics, in order to possibly include nonstandard or nonextensive effects. The macroscopic recombination/generation rate is recovered as hydrodynamic limit. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2161020]

I. INTRODUCTION

Analytical and numerical investigation of Boltzmann-type equations in semiconductors is a subject of growing interest in the scientific literature (see, for instance, Refs. 1 and 2). On the other hand, it is well known that emission/absorption phenomena must be taken into account in the interaction of electrons and positively charged carriers (holes) with phonons in bipolar devices.[3,4] Another important effect to be accounted for, essential in driving the process, is generation/recombination of a pair electron-hole, which may occur in several ways.[5] On the other hand, as pointed out by Koponen, fractal or inverse power law distributions are of interest in modelling various meaningful situations in solid state physics. An example, treated in Ref. 6, is the thermalization of a nonequilibrium electron-phonon system. Until recently, however, there has been little guidance on how to generalize the kinetic theory of electrons and phonons obeying non-Gibbsian statistics. An attempt in this direction has been performed in Refs. 7 and 8, where the kinetic theory of electrons and phonons has been generalized in the sense that electrons and phonons do not obey necessarily Fermi-Dirac and Bose-Einstein, respectively, but also other, generalized, statistics are allowed to them. The case of electrons and holes interacting with a phonon background has been treated in a generalized way and the band-trap capture and emission has been included in the model.[9]

Another important generation/recombination mechanism, that cannot be neglected when both the electron and hole densities are not too small, is the Auger effect.[5] This is what is dealt with in this paper, which moves in the frame of the mathematical methods of kinetic theory,[10] and follows the lines of Ref. 9, so that proofs that are only slight modifications of those given there will be skipped. In our opinion, in fact, a kinetic approach is needed in order to investigate rigorously the whole process and to possibly deduce, in some continuum limit, the macroscopic implications of practical relevance. In the present work (necessarily confined to a formal level, at this stage) we introduce Boltzmann-type equations for interacting populations of electrons (distribution function f_e) and holes (distribution function f_h) in a phonon background in local thermodynamical equi-

[a)]Author to whom correspondence should be addressed. Electronic mail: giampiero.spiga@unipr.it

librium, and include specific three-body collision terms for the Auger recombination/generation. Collision integrals are represented in terms of suitable transition probabilities, and the investigation, based on their structure and general properties only, leads to the determination of collision invariants and collision equilibria, and to the proof of an H theorem.[10] Hydrodynamic limit is studied by a preliminary asymptotic procedure with respect to the proper Knudsen numbers.

The Auger effect consists of two different processes and their inverse.

(a) Electron capture, an electron fills a hole. Its energy is transferred to another electron, and vice versa,

$$e + e + h \rightleftharpoons e^{\sharp},$$

where $\sharp$ means "more energetic."

(b) Hole capture, a hole is filled by an electron. Its energy is transferred to another hole, and vice versa,

$$h + h + e \rightleftharpoons h^{\sharp}.$$

The governing equations for the two interacting species in the phonon background are presented in Sec. II under general statistics. Mathematical results on equilibrium and stability are given in Sec. III in terms of an appropriate Lyapunov functional. Finally, in Sec. IV, a very simple zero-order singular perturbation approach is employed for deriving, as hydrodynamic limit in the low density approximation, the macroscopic recombination/generation rate, recovering well-known classical results available in the literature.[5]

II. KINETIC EQUATIONS

Consider two populations, conduction band (CB) electrons [quasi-momentum (QM) $\mathbf{p}$, energy $\epsilon_e(\mathbf{p})$] and holes [QM $\mathbf{k}$, energy $\epsilon_h(\mathbf{k})$], in a phonon background [QM $\mathbf{q}$, energy $\omega(\mathbf{q})$] in thermal equilibrium at temperature T. The distribution functions are normalized in such a way that the concentrations and the energy densities are given by

$$n_\alpha(\mathbf{x},t) = \int f_\alpha(\mathbf{p},\mathbf{x},t) 2\, \mathrm{d}\mathbf{p}, \quad E_\alpha(\mathbf{x},t) = \int f_\alpha(\mathbf{p},\mathbf{x},t)\epsilon_\alpha(\mathbf{p}) 2\, \mathrm{d}\mathbf{p} \tag{1}$$

($\alpha = e,h$), respectively (the factor 2 inside these integrals accounts for degeneracy). Interaction mechanisms to be taken into account are the following:

(i) Absorption and emission of a phonon by a CB electron,
(ii) Absorption and emission of a phonon by a hole,
(iii) Auger recombination/generation.

All processes are assumed to satisfy microreversibility and to fulfill their specific laws of transformation between pre- and post-collision momenta and energies. For the sake of generality, all types of particles are allowed to obey a given statistics, defined by a pair of suitable smooth functions $(\varphi_\alpha, \psi_\alpha)$, $\alpha = e,h$, describing saturation or enhancement effects in the departure/arrival state, respectively. These functions depend on the relevant distribution functions, and appear in the collision terms given below, in the gain and loss terms. Specifically, fermions are characterized by the option $\varphi_\alpha(f_\alpha) = f_\alpha$, $\psi_\alpha(f_\alpha) = 1 - f_\alpha$, whereas the choice underlying the Bose-Einstein statistics would be $\varphi_\alpha(f_\alpha) = f_\alpha$, $\psi_\alpha(f_\alpha) = 1 + f_\alpha$. Other expressions (generalized or fractional statistics) have been found recently to be in order for nonextensive systems with nonadditive entropies,[11,12] occurring for instance in electronic plasmas, anomalous diffusion, galaxy clusters, long-range memory effects. Quantities like $\varphi_e[f_e(\mathbf{p})]$ will be written as $\varphi_e(\mathbf{p})$ for brevity. By following Ref. 7, we assume that $\varphi_\alpha/\psi_\alpha$ is monotonically increasing as a function of f_α, as it occurs in all physical situations of interest. Phonons belong to the various branches g of the phonon spectrum, and their statistics is defined by the pair of functions Φ_g and Ψ_g, functions of the distribution function f_g. Their equilibrium distribution f_g^* (a star is meant to label equilibria throughout) is defined by[9]

$$\ln \frac{\Phi_g^*}{\Psi_g^*} = -\frac{\omega_g(\mathbf{q})}{T}. \tag{2}$$

For simplicity, only the space homogeneous version of the kinetic equations will be considered here, and dependence on t will not be explicitly shown, unless strictly necessary.

Taking into account the processes in which a specific species may be gained or lost, the kinetic equations read as

$$\frac{\partial f_e}{\partial t} = \left(\frac{\partial f_e}{\partial t}\right)_{ep} + \left(\frac{\partial f_e}{\partial t}\right)_A, \quad \frac{\partial f_h}{\partial t} = \left(\frac{\partial f_h}{\partial t}\right)_{hp} + \left(\frac{\partial f_h}{\partial t}\right)_A, \tag{3}$$

where subscripts αp and A are used to label interactions with phonons and Auger effect, respectively. Like in Ref. 9 the collision terms relevant to phonons read as

$$\left(\frac{\partial f_\alpha}{\partial t}\right)_{\alpha p}(\mathbf{p}) = \sum_g \int\int [G^g_{\alpha p}(\mathbf{p}',\mathbf{q};\mathbf{p}) - G^g_{\alpha p}(\mathbf{p},\mathbf{q};\mathbf{p}')]\mathrm{d}\mathbf{q}\,\mathrm{d}\mathbf{p}', \tag{4}$$

where the kernels G are given by

$$G^g_{\alpha p}(\mathbf{p}',\mathbf{q};\mathbf{p}) = V^g_{\alpha p}(\mathbf{p}',\mathbf{q};\mathbf{p})[\Phi^*_g(\mathbf{q})\varphi_\alpha(\mathbf{p}')\psi_\alpha(\mathbf{p}) - \varphi_\alpha(\mathbf{p})\psi_\alpha(\mathbf{p}')\Psi^*_g(\mathbf{q})] \tag{5}$$

in terms of the transition probabilities V. The latter must be understood in the sense of distributions, and account for momentum and energy balance. More precisely,

$$V^g_{\alpha p}(\mathbf{p}',\mathbf{q};\mathbf{p}) = \mathcal{V}^g_{\alpha p}(\mathbf{p}',\mathbf{q};\mathbf{p})\,\delta(\mathbf{p}-\mathbf{p}'-\mathbf{q}+\mathbf{b})\,\delta[\epsilon_\alpha(\mathbf{p}) - \epsilon_\alpha(\mathbf{p}') - \omega_g(\mathbf{q})], \tag{6}$$

where δ denotes Dirac's delta measure, $\mathbf{b}$ is a suitable vector of the reciprocal lattice, and $\mathcal{V}^g_{\alpha p}$ are positive smooth functions. Of course, delta functions are used to mean that integrations in (4) actually range only on the appropriate two-dimensional manifolds of the whole six-dimensional domain.

In a similar fashion the Auger contributions can be written as

$$\begin{aligned}\left(\frac{\partial f_e}{\partial t}\right)_A(\mathbf{p}) = {} & \int\int\int G^A_e(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p})\mathrm{d}\mathbf{k}\,\mathrm{d}\mathbf{p}_1\,\mathrm{d}\mathbf{p}_2 - 2\int\int\int G^A_e(\mathbf{k},\mathbf{p},\mathbf{p}_2;\mathbf{p}_1)\mathrm{d}\mathbf{k}\,\mathrm{d}\mathbf{p}_1\,\mathrm{d}\mathbf{p}_2 \\ & - \int\int\int G^A_h(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k})\mathrm{d}\mathbf{k}\,\mathrm{d}\mathbf{k}_1\,\mathrm{d}\mathbf{k}_2,\end{aligned} \tag{7}$$

$$\begin{aligned}\left(\frac{\partial f_h}{\partial t}\right)_A(\mathbf{k}) = {} & \int\int\int G^A_h(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k})\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{k}_1\,\mathrm{d}\mathbf{k}_2 - 2\int\int\int G^A_h(\mathbf{p},\mathbf{k},\mathbf{k}_2;\mathbf{k}_1)\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{k}_1\,\mathrm{d}\mathbf{k}_2 \\ & - \int\int\int G^A_e(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p})\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{p}_1\,\mathrm{d}\mathbf{p}_2,\end{aligned} \tag{8}$$

with kernels

$$\begin{aligned}G^A_e(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p}) &= W(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p})[\varphi_h(\mathbf{k})\varphi_e(\mathbf{p}_1)\varphi_e(\mathbf{p}_2)\psi_e(\mathbf{p}) - \psi_h(\mathbf{k})\psi_e(\mathbf{p}_1)\psi_e(\mathbf{p}_2)\varphi_e(\mathbf{p})] \\ G^A_h(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k}) &= U(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k})[\varphi_e(\mathbf{p})\varphi_h(\mathbf{k}_1)\varphi_h(\mathbf{k}_2)\psi_h(\mathbf{k}) - \psi_e(\mathbf{p})\psi_h(\mathbf{k}_1)\psi_h(\mathbf{k}_2)\varphi_h(\mathbf{k})].\end{aligned} \tag{9}$$

The Auger transition probabilities are once more distributions and account for momentum and energy balance,

$$W(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p}) = \mathcal{W}(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p})\,\delta(\mathbf{p}-\mathbf{k}-\mathbf{p}_1-\mathbf{p}_2+\mathbf{b}_e)\,\delta[\epsilon_e(\mathbf{p}) - \epsilon_h(\mathbf{k}) - \epsilon_e(\mathbf{p}_1) - \epsilon_e(\mathbf{p}_2)], \tag{10}$$

$$U(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k}) = \mathcal{U}(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k})\,\delta(\mathbf{k}-\mathbf{p}-\mathbf{k}_1-\mathbf{k}_2+\mathbf{b}_h)\,\delta\left[\epsilon_h(\mathbf{k})-\epsilon_e(\mathbf{p})-\epsilon_h(\mathbf{k}_1)-\epsilon_h(\mathbf{k}_2)\right],$$

where $\mathbf{b}_\alpha$ are appropriate vectors in the reciprocal lattice and $\mathcal{W}$ and $\mathcal{U}$ are smooth positive functions. Again, delta functions mean that ninefold integrations in (7) and (8) actually collapse to fivefold.

As usual in kinetic theory, the weak form of the kinetic equations (3) is essential for any further development. So, take a string of two smooth test functions $(\gamma_e(\mathbf{p}),\gamma_h(\mathbf{k}))$ and multiply each of them by the corresponding collision operator appearing in (3). Then integrate each pair with respect to the relevant kinetic variable and sum them up (after multiplication by 2 because of degeneracy), to get, as usual, a functional $F(\gamma_e,\gamma_h)$.

It is possible to prove, after suitable rearrangement and some algebra, not reported here since they follow closely similar steps in Ref. 9, the following important result.

Proposition 1: For any test function $(\gamma_e(\mathbf{p}),\gamma_h(\mathbf{k}))$ *we have*

$$\begin{aligned} F(\gamma_e,\gamma_h) = &\int\int\int\int G_e^A(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p})[\gamma_e(\mathbf{p})-\gamma_h(\mathbf{k})-\gamma_e(\mathbf{p}_1)-\gamma_e(\mathbf{p}_2)]\mathrm{d}\mathbf{k}\,\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{p}_1\,\mathrm{d}\mathbf{p}_2 \\ &+\int\int\int\int G_h^A(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k})[\gamma_h(\mathbf{k})-\gamma_e(\mathbf{p})-\gamma_h(\mathbf{k}_1)-\gamma_h(\mathbf{k}_2)]\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{k}\,\mathrm{d}\mathbf{k}_1\,\mathrm{d}\mathbf{k}_2 \\ &+\sum_\alpha\sum_g\int\int\int G_{\alpha p}^g(\mathbf{p}',\mathbf{q};\mathbf{p})[\gamma_\alpha(\mathbf{p}')-\gamma_\alpha(\mathbf{p})]\mathrm{d}\mathbf{q}\,\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{p}'. \end{aligned} \tag{11}$$

From a physical point of view, F represents the net production by collision of the molecular property defined by the string $\{\gamma_\alpha\}$. Collision invariants are determined by the condition of remaining constant through all possible collisions, and make then the functional F vanish. It is easily seen that this amounts to requiring that indeed all square brackets in (11) vanish identically with respect to their independent variables. Such a strong constraint implies immediately that both γ_α must be constant, and that they must take opposite values. Since the space of these invariants is linear, we can conclude that it is one dimensional, and the unique independent collision invariant may be chosen as the string $(-1,1)$, representing electric charge. Notice that energy, namely the string $(\epsilon_e(\mathbf{p}),\epsilon_h(\mathbf{k}))$, would be conserved by the Auger collision integrals [first two addends in (11)], thanks to the δ functions present in (10). It is clear that it cannot be conserved in the whole process, since it is actually exchanged with the lattice. In conclusion we may state the following.

Proposition 2: Collision invariants constitute a one-dimensional linear space, exhausted by the strings of test functions proportional to

$$(-1,1), \tag{12}$$

representing (*dimensionless*) *electric charge*.

III. EQUILIBRIUM AND STABILITY

The structure of (11) suggests that it is useful to introduce a new functional $\mathcal{D}$ as a suitable specialization of F,

$$\mathcal{D}(f_e,f_h) = F\left[\ln\left(\frac{\varphi_e(\mathbf{p})}{\psi_e(\mathbf{p})}\exp\left(\frac{\epsilon_e(\mathbf{p})}{T}\right)\right),\ln\left(\frac{\varphi_h(\mathbf{k})}{\psi_h(\mathbf{k})}\exp\left(\frac{\epsilon_h(\mathbf{k})}{T}\right)\right)\right], \tag{13}$$

since we get, after some algebra,

$$\mathcal{D}(f_e,f_h)=\int\int\int\int G_e^A(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p})\ln\frac{\psi_h(\mathbf{k})\psi_e(\mathbf{p}_1)\psi_e(\mathbf{p}_2)\varphi_e(\mathbf{p})}{\varphi_h(\mathbf{k})\varphi_e(\mathbf{p}_1)\varphi_e(\mathbf{p}_2)\psi_e(\mathbf{p})}\mathrm{d}\mathbf{k}\,\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{p}_1\,\mathrm{d}\mathbf{p}_2$$
$$+\int\int\int\int G_h^A(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k})\ln\frac{\psi_e(\mathbf{p})\psi_h(\mathbf{k}_1)\psi_h(\mathbf{k}_2)\varphi_h(\mathbf{k})}{\varphi_e(\mathbf{p})\varphi_h(\mathbf{k}_1)\varphi_h(\mathbf{k}_2)\psi_h(\mathbf{k})}\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{k}\,\mathrm{d}\mathbf{k}_1\,\mathrm{d}\mathbf{k}_2$$
$$+\sum_\alpha\sum_g\int\int\int G_{\alpha p}^g(\mathbf{p}',\mathbf{q};\mathbf{p})\ln\frac{\varphi_\alpha(\mathbf{p})\psi_\alpha(\mathbf{p}')\Psi_g^*(\mathbf{q})}{\psi_\alpha(\mathbf{p})\varphi_\alpha(\mathbf{p}')\Phi_g^*(\mathbf{q})}\mathrm{d}\mathbf{q}\,\mathrm{d}\mathbf{p}\,\mathrm{d}\mathbf{p}'. \tag{14}$$

In each logarithmic function of (14) numerator and denominator are exactly the two addends that are subtracted in the square brackets of the corresponding kernels G_e^A, G_h^A, and $G_{\alpha p}^g$, respectively, as given by (9) and (5). Therefore, once the integrations are restricted to lower dimensional smooth integrals by the delta measures, the usual convexity arguments of kinetic theory may be applied. In particular, all addends making up $\mathcal{D}$ turn out to be nonpositive and therefore $\mathcal{D}$ is definite in sign. Moreover, it vanishes if and only if all integrals in (14) vanish, and, since $(1-x)\ln x\leqslant 0$ with equal sign only for $x=1$, this occurs if and only if all arguments of the logarithmic functions are unity. In other words we have a sort of Boltzmann lemma.

Proposition 3: $\mathcal{D}\leqslant 0$ *for any admissible distribution function* (f_e,f_h). *In particular* $\mathcal{D}=0$ *iff*

$$\varphi_h(\mathbf{k})\varphi_e(\mathbf{p}_1)\varphi_e(\mathbf{p}_2)\psi_e(\mathbf{p})=\psi_h(\mathbf{k})\psi_e(\mathbf{p}_1)\psi_e(\mathbf{p}_2)\varphi_e(\mathbf{p}),$$

$$\varphi_e(\mathbf{p})\varphi_h(\mathbf{k}_1)\varphi_h(\mathbf{k}_2)\psi_h(\mathbf{k})=\psi_e(\mathbf{p})\psi_h(\mathbf{k}_1)\psi_h(\mathbf{k}_2)\varphi_h(\mathbf{k}), \tag{15}$$

$$\psi_\alpha(\mathbf{p})\varphi_\alpha(\mathbf{p}')\Phi_g^*(\mathbf{q})=\varphi_\alpha(\mathbf{p})\psi_\alpha(\mathbf{p}')\Psi_g^*(\mathbf{q}),$$

for all admissible values of the independent variables in each of the relevant collisions.

But now it is clear from (14) and from Proposition 3 that $\mathcal{D}=0$ implies (and then is equivalent to) vanishing of the whole collision operator in (3). On the other hand, (15) may be reformulated in terms of logarithms and, bearing in mind (9), (5), and (2), this shows that the string

$$\left(\ln\frac{\varphi_e(\mathbf{p})}{\psi_e(\mathbf{p})}+\frac{\epsilon_e(\mathbf{p})}{T},\ln\frac{\varphi_h(\mathbf{k})}{\psi_h(\mathbf{k})}+\frac{\epsilon_h(\mathbf{k})}{T}\right) \tag{16}$$

must be a collision invariant. We may state then a detailed balance principle.

Proposition 4: The collision equilibrium condition,

$$\left(\frac{\partial f_e}{\partial t}\right)_{ep}+\left(\frac{\partial f_e}{\partial t}\right)_A=0,\quad \left(\frac{\partial f_h}{\partial t}\right)_{hp}+\left(\frac{\partial f_h}{\partial t}\right)_A=0, \tag{17}$$

for all admissible distribution functions, *is equivalent to the requirement that (16) be a collision invariant*.

At this point, Proposition 2 applies, which means that there is exactly one one-parameter family of equilibria, given by

$$\ln\frac{\varphi_e^*}{\psi_e^*}=\frac{\mu-\epsilon_e}{T},\quad \ln\frac{\varphi_h^*}{\psi_h^*}=\frac{-\mu-\epsilon_h}{T}, \tag{18}$$

for all real μ. Solvability of the transcendental equations (18) is discussed in Ref. 9. Notice that, in terms of the chemical potentials μ_α,[5] equilibrium is characterized by

$$\mu_e=-\mu_h=\mu. \tag{19}$$

Concerning stability of the above equilibria, it is possible to establish an H theorem, again along the lines of kinetic theory. Introduce the functional

$$H = H_e + H_h + \int \frac{\epsilon_e(\mathbf{p}) f_e(\mathbf{p}) + \epsilon_h(\mathbf{p}) f_h(\mathbf{p})}{T} \mathrm{d}\mathbf{p}, \tag{20}$$

where

$$H_\alpha = \int \mathcal{H}_\alpha[f_\alpha(\mathbf{p})]\mathrm{d}\mathbf{p}, \quad \frac{\mathrm{d}\mathcal{H}_\alpha(x)}{\mathrm{d}x} = 2 \ln \frac{\varphi_\alpha(x)}{\psi_\alpha(x)}. \tag{21}$$

Notice that in our assumptions all $\mathcal{H}_\alpha$ are convex functions of their argument because of the monotonicity assumption on the ratios $\varphi_\alpha/\psi_\alpha$. The additional integral in (20) is due to the fact that our system is not closed, but interacts with the background lattice. We can then prove the H theorem.

Proposition 5: H is a strict Lyapunov functional for the initial value problem (3).

For a sketch of the proof, which goes along the same lines as in Ref. 9, we first remark that, following a solution of (3), the time derivative of H coincides exactly with $\mathcal{D}$, and therefore it has the required definiteness in sign. Then, the conclusion follows by usual convexity arguments provided we are able to show that

$$\sum_\alpha \int \left(\frac{\partial \mathcal{H}_\alpha}{\partial f_\alpha}\right)^* (f_\alpha - f_\alpha^*)(\mathbf{p})\mathrm{d}\mathbf{p} + \int \frac{\epsilon_e(f_e - f_e^*) + \epsilon_h(f_h - f_h^*)}{T} \mathrm{d}\mathbf{p} = 0, \tag{22}$$

and it is not difficult to verify that this is true thanks to the expressions of $(\ln(\varphi_\alpha/\psi_\alpha))^*$ and to charge conservation (see Proposition 2).

IV. RECOMBINATION/GENERATION RATE

In kinetic theory it is appropriate to introduce a convenient scaling in Eq. (3), also in order to derive, by a suitable asymptotic procedure, macroscopic equations at a hydrodynamic level. In our case, the most significant macroscopic quantity needed for practical applications is the Auger recombination/generation rate.[5] We shall deduce a formula for such a rate in a very simple way from the kinetic level as a suitable asymptotic limit. We perform our scaling according to the fact that the microscopic relaxation times of the considered interaction mechanisms are typically much shorter than the pertinent macroscopic time. Upon adimensionalization, this leads to the appearance of a small parameter ε, ratio of the two time scales (the Knudsen number), downstairs in front of the collision terms, making the initial value problem of singular perturbation type. The limiting form when $\varepsilon \to 0$ of the evolution equations (3) are just the equilibrium equations (17). If we then restrict ourselves to the low density limit of Gibbsian statistics $\varphi_\alpha(f_\alpha) = f_\alpha$ and $\psi_\alpha(f_\alpha) = 1$, the limiting solution is the Maxwellian-type equilibrium,

$$f_e^*(\mathbf{p}) = \exp\left(\frac{\mu - \epsilon_e(\mathbf{p})}{T}\right) = n_e M_e(\mathbf{p}), \quad f_h^*(\mathbf{k}) = \exp\left(-\frac{\mu + \epsilon_h(\mathbf{k})}{T}\right) = n_h M_h(\mathbf{k}), \tag{23}$$

where the normalized shape functions M_α are

$$M_e(\mathbf{p}) = \frac{\exp(-\epsilon_e(\mathbf{p})/T)}{\int \exp(-\epsilon_e(\mathbf{p})/T)\mathrm{d}\mathbf{p}}, \quad M_h(\mathbf{k}) = \frac{\exp(-\epsilon_h(\mathbf{k})/T)}{\int \exp(-\epsilon_h(\mathbf{k})/T)\mathrm{d}\mathbf{k}}. \tag{24}$$

By multiplying the two equilibrium distributions in (23) and integrating then over both momenta $\mathbf{p}$ and $\mathbf{k}$, we see that the chemical equilibrium condition $\mu_e^* + \mu_h^* = 0$ may be cast as

$$n_e^* n_h^* = \int \exp(-\epsilon_e(\mathbf{p})/T)\mathrm{d}\mathbf{p} \int \exp(-\epsilon_h(\mathbf{k})/T)\mathrm{d}\mathbf{k} = \mathcal{K}, \tag{25}$$

(where $\mathcal{K}$ is an intrinsic constant depending only on the energy functions ϵ and on the lattice temperature) which can be regarded as a sort of mass action law. For the general evolution problem, we see that, from Proposition 2, the only macroscopic conservation equation which is in order for (3) is charge conservation, obtained after integration over the kinetic variables and subtraction, which reads as

$$n_e(t) - n_h(t) = B, \tag{26}$$

where B is a constant depending only on initial conditions. The only equilibrium which is compatible with given initial conditions is then easily obtained by combining Eqs. (25) and (26), which leads to

$$n_e^* = \frac{B}{2} + \left(\frac{B^2}{4} + \mathcal{K}\right)^{1/2}, \quad n_h^* = -\frac{B}{2} + \left(\frac{B^2}{4} + \mathcal{K}\right)^{1/2}. \tag{27}$$

The most important physical information is constituted by the evolution equations for densities, which are obtained instead by simple separate integrations of (3). They are of course exact but not closed, and the simplest hydrodynamic closure is represented by the relevant Euler equations, zero order approximation of any asymptotic technique, which may be deduced by approximating the distribution functions appearing in the collision terms by the equilibria (23). We get in this way

$$\dot{n}_e = \dot{n}_h = -A_{21} n_e^2 n_h + A_{10} n_e - A_{12} n_e n_h^2 + A_{01} n_h, \tag{28}$$

where

$$\begin{aligned}
A_{21} &= \int\int\int\int W(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p}) M_h(\mathbf{k}) M_e(\mathbf{p}_1) M_e(\mathbf{p}_2) \mathrm{d}\mathbf{k}\, \mathrm{d}\mathbf{p}_1\, \mathrm{d}\mathbf{p}_2\, \mathrm{d}\mathbf{p}, \\
A_{10} &= \int\int\int\int W(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p}) M_e(\mathbf{p}) \mathrm{d}\mathbf{k}\, \mathrm{d}\mathbf{p}_1\, \mathrm{d}\mathbf{p}_2\, \mathrm{d}\mathbf{p}, \\
A_{12} &= \int\int\int\int U(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k}) M_e(\mathbf{p}) M_h(\mathbf{k}_1) M_h(\mathbf{k}_2) \mathrm{d}\mathbf{k}\, \mathrm{d}\mathbf{k}_1\, \mathrm{d}\mathbf{k}_2\, \mathrm{d}\mathbf{p}, \\
A_{01} &= \int\int\int\int U(\mathbf{p},\mathbf{k}_1,\mathbf{k}_2;\mathbf{k}) M_h(\mathbf{k}) \mathrm{d}\mathbf{k}\, \mathrm{d}\mathbf{k}_1\, \mathrm{d}\mathbf{k}_2\, \mathrm{d}\mathbf{p}.
\end{aligned} \tag{29}$$

Making explicit use of (24) and (25), we can write now

$$\begin{aligned}
A_{21}\mathcal{K} \int \exp(-\epsilon_e(\mathbf{p})/T)\mathrm{d}\mathbf{p} = \int\int\int\int W(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p}) \exp[-(\epsilon_h(\mathbf{k}) + \epsilon_e(\mathbf{p}_1) \\
+ \epsilon_e(\mathbf{p}_2))/T] \mathrm{d}\mathbf{k}\, \mathrm{d}\mathbf{p}_1\, \mathrm{d}\mathbf{p}_2\, \mathrm{d}\mathbf{p},
\end{aligned}$$

$$A_{10} \int \exp(-\epsilon_e(\mathbf{p})/T)\mathrm{d}\mathbf{p} = \int\int\int\int W(\mathbf{k},\mathbf{p}_1,\mathbf{p}_2;\mathbf{p}) \exp(-(\epsilon_e(\mathbf{p})/T) \mathrm{d}\mathbf{k}\, \mathrm{d}\mathbf{p}_1\, \mathrm{d}\mathbf{p}_2\, \mathrm{d}\mathbf{p}, \tag{30}$$

and similarly for A_{12} and A_{01}. Then, thanks to energy conservation in the Auger effect, accounted for by the δ functions in W and U, we finally end up with

$$A_{10} = \mathcal{K} A_{21}, \quad A_{01} = \mathcal{K} A_{12}. \tag{31}$$

In conclusion, the macroscopic Auger generation/recombination rate[5]

$$\dot{n}_e = \dot{n}_h = -(C_e n_e + C_h n_h)(n_e n_h - C_i^2) \tag{32}$$

is recovered, as first approximation deduced from kinetic theory, by putting together (28) and (31), with specification of coefficients as $C_i^2 = \mathcal{K}$, $C_e = A_{21}$, and $C_h = A_{12}$.

With the help of the factorizing F-matrix, the scalar products of the $U_q(\mathrm{gl}(1|1))$ free fermion model are represented by determinants. By means of these results, we obtain the determinant representations of correlation functions of the model.
 [DOI: 10.1063/1.2161019]

I. INTRODUCTION

The computation of correlation functions is one of the challenging problems in the theory of quantum integrable lattice models.[1,2] In this paper, we compute the correlation functions of the free fermion model by means of the algebraic Bethe ansatz method.[1–3] Our computations are based on the recent progress on the Drinfeld twists. Working in the F-bases provided by the F-matrices (Drinfeld twists), the authors in Refs. 4 and 5 managed to derive the determinant representations of the form factors and correlation functions of the XXX and XXZ models in the framework of algebraic Bethe ansatz.

Recently we have constructed the Drinfeld twists for both the rational $\mathrm{gl}(m|n)$ and the quantum $U_q(\mathrm{gl}(m|n))$ supersymmetric models and resolved the hierarchy of their nested Bethe vectors in the F-basis.[6–8] These results serve as the basis of our computation in this paper of the correlation functions of the $U_q(\mathrm{gl}(1|1))$ free Fermion model.

Correlation functions of the free Fermion model based on the $XX0$ spin chain (XY model[9]) with periodic boundary condition were studied in Refs. 10–15. As is seen in Sec. VI, by using the Jordan-Wigner transform, our $U_q(\mathrm{gl}(1|1))$ free Fermion model is equivalent to a twisted $XX0$ model, and the one-point functions we obtained [see Eqs. (5.5) and (5.7) below] give the m-point correlation functions of the twisted $XX0$ model [see e.g., Eq. (6.6)].

The present paper is organized as follows. In Sec. II, we review the background of the $U_q(\mathrm{gl}(1|1))$ model and its algebraic Bethe ansatz. In Sec. III, we construct the Drinfeld twists for the model. In Sec. IV, we obtain the determinant representation of the scalar products of the $U_q(\mathrm{gl}(1|1))$ Bethe states. Then in Sec. V, we compute correlation functions of the local Fermionic operators of the model. We conclude the paper by offering some discussions in Sec. VI.

II. $U_q(\mathrm{gl}(1|1))$ FREE FERMION MODEL

A. The background of the model

Let V be the two-dimensional $U_q(\mathrm{gl}(1|1))$-module and $R \in \mathrm{End}(V \otimes V)$ the R-matrix associated with this module. V is Z_2-graded, and in the following we choose the FB grading for V, i.e., $[1]=1$, $[2]=0$. The R-matrix depends on the difference of two spectral parameters u_1 and u_2 associated with the two copies of V, and is, in the FB grading, given by

$$R_{12}(u_1,u_2) = R_{12}(u_1-u_2) = \begin{pmatrix} c_{12} & 0 & 0 & 0 \\ 0 & a_{12} & b_{12}^{+} & 0 \\ 0 & b_{12}^{-} & a_{12} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \tag{2.1}$$

where

$$a_{12} = a(u_1,u_2) \equiv \frac{\sinh(u_1-u_2)}{\sinh(u_1-u_2+\eta)}, \quad b_{12}^{\pm} = b^{\pm}(u_1,u_2) \equiv \frac{e^{\pm(u_1-u_2)}\sinh\eta}{\sinh(u_1-u_2+\eta)},$$

$$c_{12} = c(u_1,u_2) \equiv \frac{\sinh(u_1-u_2-\eta)}{\sinh(u_1-u_2+\eta)} \tag{2.2}$$

with $\eta \in C$ being the crossing parameter. One can easily check that the R-matrix satisfies the unitary relation

$$R_{21}R_{12} = 1. \tag{2.3}$$

Here and throughout $R_{ij} \equiv R_{ij}(u_i,u_j)$. The R-matrix satisfies the graded Yang-Baxter equation (GYBE)

$$R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}. \tag{2.4}$$

In terms of the matrix elements defined by

$$R(u)(v^{i'} \otimes v^{j'}) = \sum_{i,j} R(u)_{ij}^{i'j'}(v^i \otimes v^j), \tag{2.5}$$

the GYBE reads

$$\sum_{i',j',k'} R(u_1-u_2)_{ij}^{i'j'} R(u_1-u_3)_{i'k}^{i''k'} R(u_2-u_3)_{j'k'}^{j''k''}(-1)^{[j']([i']+[i''])}$$
$$= \sum_{i',j',k'} R(u_2-u_3)_{jk}^{j'k'} R(u_1-u_3)_{ik'}^{i'k''} R(u_1-u_2)_{i'j'}^{i''j''}(-1)^{[j']([i]+[i'])}. \tag{2.6}$$

The quantum monodromy matrix $T(u)$ of the free Fermion model on a lattice of length N is defined as

$$T_0(u) = R_{0N}(u,z_N)R_{0N-1}(u,z_{N-1})\cdots R_{01}(u,z_1), \tag{2.7}$$

where the index 0 refers to the auxiliary space and $\{z_i\}$ are arbitrary inhomogeneous parameters depending on site i. $T(u)$ can be represented in the auxiliary space as the 2×2 matrix whose elements are operators acting on the quantum space $V^{\otimes N}$,

$$T_0(u) = \begin{pmatrix} A(u) & B(u) \\ C(u) & D(u) \end{pmatrix}_{(0)}. \tag{2.8}$$

By using the GYBE, one may prove that the monodromy matrix satisfies the GYBE,

$$R_{12}(u-v)T_1(u)T_2(v) = T_2(v)T_1(u)R_{12}(u-v) \tag{2.9}$$

or in matrix form

$$\sum_{i',j'} R(u-v)_{ij}^{i'j'} T(u)_{i'}^{i''} T(v)_{j'}^{j''} (-1)^{[j']([i']+[i''])} = \sum_{i',j'} T(v)_j^{j'} T(u)_i^{i'} R(u-v)_{i'j'}^{i''j''} (-1)^{[j']([i]+[i'])}. \tag{2.10}$$

Define the transfer matrix $t(u)$

$$t(u) = \mathrm{str}_0\, T_0(u), \tag{2.11}$$

where str_0 denotes the supertrace over the auxiliary space. With the help of the GYBE, one may check that the transfer matrix satisfies the commutation relation $[t(u),t(v)]=0$, ensuring the integrability of the system. The transfer matrix gives the Hamiltonian of the system,

$$\begin{aligned} H &= \left.\frac{d \ln t(u)}{du}\right|_{u=0} \\ &= \frac{1}{\sinh \eta} \sum_{j=1}^{N} (E_{(j)}^{12} E_{(j+1)}^{21} + E_{(j)}^{21} E_{(j+1)}^{12} - 2\cosh \eta E_{(j)}^{11} E_{(j+1)}^{11} - (e^{\eta} E_{(j)}^{11} E_{(j+1)}^{22} + e^{-\eta} E_{(j)}^{22} E_{(j+1)}^{11})), \end{aligned} \tag{2.12}$$

where $E_{(k)}^{ij}$ are generators, which act on the kth space, of the superalgebra $U_q(\mathrm{gl}(1|1))$.

Using the standard Fermionic representation

$$E_{(k)}^{12} = c_k, \quad E_{(k)}^{21} = c_k^{\dagger}, \quad E_{(k)}^{11} = 1 - n_k, \quad E_{(k)}^{22} = n_k, \quad n_k = c_k^{\dagger} c_k, \tag{2.13}$$

the Hamiltonian can be rewritten as

$$H = \frac{1}{\sinh \eta} \sum_{j=1}^{N} (c_j c_{j+1}^{\dagger} + c_j^{\dagger} c_{j+1} - 2\cosh \eta (1 - n_j)). \tag{2.14}$$

B. Algebraic Bethe ansatz

The transfer matrix (2.11) can be diagonalized by using the algebra Bethe ansatz. Define the Bethe state of the system

$$\Phi_N(v_1, v_2, \ldots, v_n) = \prod_{i=1}^{n} C(v_i)|0\rangle, \tag{2.15}$$

where $|0\rangle$ is the pseudovacuum,

$$|0\rangle = \prod_{k=1}^{N} \begin{pmatrix} 0 \\ 1 \end{pmatrix}_{(k)} \tag{2.16}$$

and the index (k) indicates the kth space.

Applying the elements of the monodromy matrix (2.8) to the pseudovacuum $|0\rangle$ and its dual, we easily obtain

$$B(u)|0\rangle = 0, \quad \langle 0|C(u) = 0, \quad D|0\rangle = |0\rangle, \quad \langle 0|D(u) = \langle 0|,$$

$$A(u)|0\rangle = \prod_{i=1}^{N} a(u,z_i)|0\rangle, \quad \langle 0|A(u) = \prod_{i=1}^{N} a(u,z_i)\langle 0|. \tag{2.17}$$

With the help of the GYBE (2.9), we obtain the commutation relations between the elements of the monodromy matrix,

$$C(u)C(v) = -c(u,v)C(v)C(u), \tag{2.18}$$

$$D(u)D(v) = D(v)D(u), \tag{2.19}$$

$$A(u)C(v) = \frac{c(u,v)}{a(u,v)}C(v)A(u) + \frac{b^+(u,v)}{a(u,v)}C(u)A(v), \tag{2.20}$$

$$D(u)C(v) = \frac{1}{a(v,u)}C(v)D(u) - \frac{b^-(v,u)}{a(v,u)}C(u)D(v), \tag{2.21}$$

$$\begin{aligned} B(u)C(v) &= -C(v)B(u) + \frac{b^+(u,v)}{a(u,v)}[D(v)A(u) - D(u)A(v)] \\ &= -C(v)B(u) + \frac{b^+(u,v)}{a(u,v)}[D(u)t(v) - D(v)t(u)]. \end{aligned} \tag{2.22}$$

Thus applying the transfer matrix $t(u)=D(u)-A(u)$ to the Bethe state and using the commutation relations repeatedly, we obtain the eigenvalues of $t(u)$ as

$$t(u)\Phi_N = \Lambda(u,\{v_k\})\Phi_N = \left[\prod_{k=1}^{n}\frac{1}{a(v_k,u)} - \prod_{j=1}^{N}a(u,z_j)\prod_{k=1}^{n}\frac{c(u,v_k)}{a(u,v_k)}\right]\Phi_N \tag{2.23}$$

providing v_k $(k=1,2,\ldots,n)$ satisfying the Bethe ansatz equations (BAE),

$$\prod_{j=1}^{N}a(v_k,z_j) = 1. \tag{2.24}$$

For late use, we define the state of the free Fermion chain of length N,

$$|a_1a_2\cdots a_N\rangle = |a_1\rangle_{(1)}|a_2\rangle_{(2)}\cdots|a_N\rangle_{(N)} \tag{2.25}$$

and its dual

$$|a_1a_2\cdots a_N\rangle^\dagger = \langle a_N|_{(N)}\langle a_{N-1}|_{(N-1)}\cdots\langle a_1|_{(1)} \equiv \langle a_Na_{N-1}\cdots a_1|. \tag{2.26}$$

III. DRINFELD TWISTS OF THE MODEL

A. Factorizing *F*-matrix and its inverse

Following Ref. 4, we now introduce the notation $R^{\sigma}_{1,\ldots,N}$, where σ is any element of the permutation group $\mathcal{S}_N$. We note that we may rewrite the GYBE as

$$R^{\sigma_{23}}_{23}T_{0,23} = T_{0,32}R^{\sigma_{23}}_{23}, \tag{3.1}$$

where $T_{0,23}\equiv R_{03}R_{02}$ and σ_{23} is the transposition of space labels (2,3). It follows that $R^{\sigma}_{1,\ldots,N}$ is a product of elementary R-matrices,[4,6] corresponding to a decomposition of σ into elementary transpositions. With the help of the GYBE, one may generalize (3.1) to a N-fold tensor product of spaces,

$$R^{\sigma}_{1,\ldots,N}T_{0,1,\ldots,N} = T_{0,\sigma(1,\ldots,N)}R^{\sigma}_{1,\ldots,N}, \tag{3.2}$$

where $T_{0,1,\ldots,N} \equiv R_{0N}\cdots R_{01}$. This implies the "decomposition" law

$$R^{\sigma'\sigma}_{1,\ldots,N} = R^{\sigma}_{\sigma'(1,\ldots,N)} R^{\sigma'}_{1,\ldots,N}, \tag{3.3}$$

for a product of two elements in $\mathcal{S}_N$. Note that $R^{\sigma}_{\sigma'(1,\ldots,N)}$ satisfies the relation

$$R^{\sigma}_{\sigma'(1,\ldots,N)} T_{0,\sigma'(1,\ldots,N)} = T_{0,\sigma'\sigma(1,\ldots,N)} R^{\sigma}_{\sigma'(1,\ldots,N)}. \tag{3.4}$$

Let us write the elements of $R^{\sigma}_{1,\ldots,N}$ as

$$(R^{\sigma}_{1,\ldots,N})^{\alpha_{\sigma(N)}\cdots\alpha_{\sigma(1)}}_{\beta_N\cdots\beta_1}, \tag{3.5}$$

where the labels in the upper indices are permuted relative to the lower indices according to σ.

We proved in Refs. 6–8 that for the R-matrix $R^{\sigma}_{1,\ldots,N}$, there exists a nondegenerate lower-diagonal F-matrix (the Drinfeld twist) satisfying the relation

$$F_{\sigma(1,\ldots,N)}(z_{\sigma(1)}, \ldots, z_{\sigma(N)}) R^{\sigma}_{1,\ldots,N}(z_1, \ldots, z_N) = F_{1,\ldots,N}(z_1, \ldots, z_N). \tag{3.6}$$

Explicitly,

$$F_{1,\ldots,N} = \sum_{\sigma\in\mathcal{S}_N} \sum_{\alpha_{\sigma(1)}\cdots\alpha_{\sigma(N)}}^{*} \prod_{j=1}^{N} P^{\alpha_{\sigma(j)}}_{\sigma(j)} S(c,\sigma,\alpha_\sigma) R^{\sigma}_{1,\ldots,N}, \tag{3.7}$$

where the sum Σ^* is over all nondecreasing sequences of the labels $\alpha_{\sigma(i)}$,

$$\alpha_{\sigma(i+1)} \geqslant \alpha_{\sigma(i)}, \quad \text{if } \sigma(i+1) > \sigma(i),$$

$$\alpha_{\sigma(i+1)} > \alpha_{\sigma(i)}, \quad \text{if } \sigma(i+1) < \sigma(i), \tag{3.8}$$

and the c-number function $S(c,\sigma,\alpha_\sigma)$ is given by

$$S(c,\sigma,\alpha_\sigma) \equiv \exp\left\{ \frac{1}{2} \sum_{l>k=1}^{N} (1-(-1)^{[\alpha_{\sigma(k)}]}) \delta_{\alpha_{\sigma(k)},\alpha_{\sigma(l)}} \ln(1+c_{\sigma(k)\sigma(l)}) \right\}. \tag{3.9}$$

The inverse of the F-matrix is given by

$$F^{-1}_{1,\ldots,N} = F^{*}_{1,\ldots,N} \prod_{i<j} \Delta^{-1}_{ij} \tag{3.10}$$

with

$$\Delta_{ij} = \mathrm{diag}((1+c_{ij})(1+c_{ji}), a_{ji}, a_{ij}, 1) \tag{3.11}$$

and

$$F^{*}_{1,\ldots,N} = \sum_{\sigma\in\mathcal{S}_N} \sum_{\alpha_{\sigma(1)}\cdots\alpha_{\sigma(N)}}^{**} S(c,\sigma,\alpha_\sigma) R^{\sigma^{-1}}_{\sigma(1,\ldots,N)} \prod_{j=1}^{N} P^{\alpha_{\sigma(j)}}_{\sigma(j)}, \tag{3.12}$$

where the sum Σ^{**} is taken over all possible α_i which satisfies the following nonincreasing constraints:

$$\alpha_{\sigma(i+1)} \leqslant \alpha_{\sigma(i)} \quad \text{if } \sigma(i+1) < \sigma(i),$$

$$\alpha_{\sigma(i+1)} < \alpha_{\sigma(i)} \quad \text{if } \sigma(i+1) > \sigma(i). \tag{3.13}$$

B. Symmetric representation of the Bethe state

The nondegeneracy of the F-matrix means that its column vectors form a complete basis, which is called the F-basis. By the procedure in Ref. 8, we find that in the F-basis, the simple generators of the superalgebra $U_q(\mathrm{gl}(1|1))$ have the symmetric form,

$$\tilde{E}^{12} = F_{12,\ldots,N} E^{12} F^{-1}_{12,\ldots,N} = \sum_{i=1}^{N} E^{12}_{(i)} \otimes_{j\neq i} \mathrm{diag}(2e^{-\eta}\cosh\,\eta, e^{-\eta})_{(j)}, \tag{3.14}$$

$$\tilde{E}^{21} = F_{12,\ldots,N} E^{21} F^{-1}_{12,\ldots,N} = \sum_{i=1}^{N} E^{12}_{(i)} \otimes_{j\neq i} \mathrm{diag}(e^{\eta}(2a_{ji}\cosh\,\eta)^{-1}, e^{\eta}a_{ji}^{-1})_{(j)}. \tag{3.15}$$

Similarly, the diagonal element $D(u)$ of the monodromy matrix in the F-basis is given by

$$\tilde{D}(u) = F_{12,\ldots,N} D(u) F^{-1}_{12,\ldots,N} = \otimes_{j=1}^{N} \mathrm{diag}(a_{0j}, 1), \tag{3.16}$$

where $a_{0j} \equiv a(u, z_j)$.

Then, the creation and annihilation operators $C(u)$ and $B(u)$ read, in the F-basis,

$$\begin{aligned}\tilde{C}(u) &= F_{12,\ldots,N} C(u) F^{-1}_{12,\ldots,N} = (q^{-1}\tilde{E}^{12}_{(i)}\tilde{D}(u) - \tilde{D}(u)\tilde{E}^{12}_{(i)}) q^{-\Sigma_{i=1}^{N} h_{(i)}} \\ &= \sum_{i=1}^{N} b_{0i}^{-} E^{12}_{(i)} \otimes_{j\neq i} \mathrm{diag}(2a_{0j}\cosh\,\eta, 1)_{(j)},\end{aligned} \tag{3.17}$$

$$\begin{aligned}\tilde{B}(u) &= F_{12,\ldots,N} B(u) F^{-1}_{12,\ldots,N} = q^{\Sigma_{i=1}^{N} h_{(i)}} (\tilde{E}^{21}\tilde{D} - q\tilde{D}\tilde{E}^{21}) \\ &= -\sum_{i=1}^{N} b_{0i}^{+} E^{21}_{(i)} \otimes_{j\neq i} \mathrm{diag}(a_{0j}(2a_{ji}\cosh\,\eta)^{-1}, a_{ji}^{-1})_{(j)},\end{aligned} \tag{3.18}$$

where $b^{\pm}_{0j} \equiv b^{\pm}(u, z_j)$, $q = e^{\eta}$, and $h \equiv -E^{11} - E^{22}$.

Acting the F-matrix (3.7) on the state (2.16), one sees that the pseudovacuum is invariant. Therefore in the F-basis, the Bethe state (2.15) becomes

$$\tilde{\Phi}_N(v_1, v_2, \ldots, v_n) \equiv F_{1,\ldots,N} \Phi_N(v_1, \ldots, v_n) = \prod_{i=1}^{n} \tilde{C}(v_n)|0\rangle. \tag{3.19}$$

Substituting (3.17) into (3.19), we obtain

$$\tilde{\Phi}_N(v_1, \ldots, v_n) = (2\cosh\,\eta)^{[n(n-1)]/2} \sum_{i_1<\cdots<i_n} B_n^{-}(v_1, \ldots, v_n | z_{i_1}, \ldots, z_{i_n}) E^{12}_{(i_1)} \cdots E^{12}_{(i_n)}|0\rangle, \tag{3.20}$$

where

$$B_n^{\pm}(v_1, \ldots, v_n | z_{i_1}, \ldots, z_{i_n}) = \sum_{\sigma\in\mathcal{S}_n} \mathrm{sign}(\sigma) \prod_{k=1}^{n} b^{\pm}(v_k, z_{i_{\sigma(k)}}) \prod_{l=k+1}^{n} a(v_k, z_{i_{\sigma(l)}}) = \det \mathcal{B}^{\pm}(\{v_k\}, \{z_j\}) \tag{3.21}$$

with $\mathcal{B}^{\pm}(\{v_i\}, \{z_j\})$ being a $n \times n$ matrix with matrix elements,

$$\mathcal{B}^{\pm}_{\alpha\beta} = b^{\pm}(v_\alpha, z_\beta) \prod_{\gamma=1}^{\alpha-1} a(v_\gamma, z_\beta). \tag{3.22}$$

Similarly, acting $\widetilde{B}(u_n)\cdots\widetilde{B}(u_1)$ on the dual pseudovacuum state, we have

$$\langle 0|\widetilde{B}(u_n)\cdots\widetilde{B}(u_1) = (-1)^n(2\cosh\eta)^{[-n(n-1)]/2}\sum_{i_1<\cdots<i_n}\prod_{l=1}^{n}\prod_{k=1,\neq i_l}^{N}a^{-1}(z_k,z_{i_l}) \times \det\mathcal{B}^{+}(\{v_k\},\{z_{i_j}\})\langle 0|E^{21}_{(i_n)}\cdots E^{21}_{(i_1)}. \tag{3.23}$$

IV. DETERMINANT REPRESENTATION OF THE SCALAR PRODUCT OF THE BETHE STATES

In Refs. 2 and 5 the authors gave the determinant representation of the scalar product of the Bethe state for the spin-1/2 *XXZ* model. In this section, we derive the determinant representation of the scalar product of the $U_q(\mathrm{gl}(1|1))$ Bethe states defined by

$$S_n(\{u_j\},\{v_k\}) = \langle 0|B(u_n)\cdots B(u_1)C(v_1)\cdots C(v_n)|0\rangle. \tag{4.1}$$

The F-invariance of the pseudovacuum state $|0\rangle$ and its dual state $\langle 0|$ leads to

$$S_n(\{u_j\},\{v_k\}) = \langle 0|\widetilde{B}(u_n)\cdots\widetilde{B}(u_1)\widetilde{C}(v_1)\cdots\widetilde{C}(v_n)|0\rangle. \tag{4.2}$$

Following Ref. 5, we define

$$G^{(m)}(\{v_k\},u_1,\ldots,u_m,i_{m+1},\ldots,i_n) = \langle i_n,\ldots,i_{m+1}|\widetilde{B}(u_m)\cdots\widetilde{B}(u_1)\widetilde{C}(v_1)\cdots\widetilde{C}(v_n)|0\rangle, \tag{4.3}$$

where i_k $(k=m+1,\ldots,n)$, ordered as $i_{m+1}<\cdots<i_n$, indicate the positions having state $\binom{1}{0}$, and other positions have state $\binom{0}{1}$. One sees that when $m=n$, $G^{(n)}=S_n$. Inserting a complete set and noticing (3.18) and (4.3) becomes

$$G^{(m)}(\{v_k\},u_1,\ldots,u_m,i_{m+1},\ldots,i_n) = \sum_{j\neq i_{m+1},\ldots,i_n}^{N}\langle i_n,\ldots,i_{m+1}|\widetilde{B}(u_m)|i_{m+1},\ldots,i_{m+p},j,i_{m+p+1},\ldots,i_n\rangle \times G^{(m-1)}(\{v_k\},u_1,\ldots,u_{m-1},i_{m+1},\ldots,i_{m+p},j,i_{m+p+1},\ldots,i_n). \tag{4.4}$$

In view of (3.18), we have

$$\langle i_n,\ldots,i_{m+1}|\widetilde{B}(u_m)|i_{m+1},\ldots,i_{m+p},j,i_{m+p+1},\ldots,i_n\rangle = -(2\cosh\eta)^{-(n-m)} \times(-1)^p b^{+}(u_m,z_j)\prod_{k\neq j}^{N}a^{-1}(z_k,z_j)\prod_{l=m+1}^{n}a(u_m,z_{i_l}). \tag{4.5}$$

With the help of (3.20), we obtain $G^{(0)}$,

$$G^{(0)}(\{v_k\},i_1,\ldots,i_n) = \langle i_n,\ldots,i_1|\prod_{k=1}^{n}\widetilde{C}(v_k)|0\rangle = (2\cosh\eta)^{[n(n-1)]/2}\det\mathcal{B}^{-}(\{v_k\},\{z_{i_l}\}). \tag{4.6}$$

We now compute $G^{(1)}$ by using the recursion relation (4.4). Substituting (4.5) and (4.6) into (4.4), we obtain

$$G^{(1)}(\{v_k\},u_1,i_2,\ldots,i_n)=\sum_{j\neq i_2,\ldots,i_n}^{N}\langle i_n,\ldots,i_2|\tilde{B}(u_1)|i_2,\ldots,i_{p+1},j,i_{p+2},\ldots,i_n\rangle$$
$$\times G^{(0)}(\{v_k\},i_2,\ldots,i_{p+1},j,i_{p+2},\ldots,i_n)$$
$$=-(2\cosh\eta)^{[(n-1)(n-2)]/2}\sum_{j\neq i_2,\ldots,i_n}^{N}(-1)^p b^+(u_1,z_j)\prod_{k\neq j}^{N}a^{-1}(z_k,z_j)\prod_{l=2}^{n}a(u_1,z_{i_l})$$
$$\times\det\mathcal{B}^-(\{v_k\},z_{i_2},\ldots,z_{i_{p+1}},z_j,z_{i_{p+2}},\ldots,z_{i_n})\quad(k=1,\cdots,n).\tag{4.7}$$

Let v_k $(k=1,\ldots,n)$ label the row and z_l $(l=i_2,\ldots,j,\ldots,i_n)$ label the column of the matrix $\mathcal{B}^-$. From (4.6), one sees that the column indices in (4.7) satisfy the sequence $i_2<\cdots<j<\cdots<i_n$. Therefore, moving the column j in the matrix $\mathcal{B}^-$ to the first column, we have

$$G^{(1)}(\{v_k\},u_1,i_2,\ldots,i_n)=-(2\cosh\eta)^{[(n-1)(n-2)/2]}\sum_{j\neq i_1,\ldots,i_n}^{N}b^+(u_1,z_j)\prod_{k\neq j}^{N}a^{-1}(z_k,z_j)\prod_{l=2}^{n}a(u_1,z_{i_l})$$
$$\times\det\mathcal{B}(\{v_k\},z_j,z_{i_2},\ldots,z_{i_n})$$
$$=-(2\cosh\eta)^{[(n-1)(n-2)/2]}\det(\mathcal{B}^-)^{(1)}(\{v_k\},u_1,z_{i_2},\ldots,z_{i_n}),\tag{4.8}$$

where the matrix $(\mathcal{B}^-)^{(1)}(\{v_k\},u_1,z_{i_2},\ldots,z_{i_n})$ is given by

$$(\mathcal{B}^-_{\alpha\beta})^{(1)}=a(u_1,z_{i_\beta})\mathcal{B}^-_{\alpha\beta}\quad\text{for }\beta\geqslant 2,\tag{4.9}$$

$$(\mathcal{B}^-_{\alpha 1})^{(1)}=\sum_{j\neq i_2,\ldots,i_n}^{N}b^+(u_1,z_j)b^-(v_\alpha,z_j)\prod_{\gamma=1}^{\alpha-1}a(v_\gamma,z_j)\prod_{k=1,\neq j}^{N}a^{-1}(z_k,z_j).\tag{4.10}$$

Using the properties of determinant, one finds that if $j=i_2,\ldots,i_n$, the corresponding terms in (4.10) contribute zero to the determinant. Thus, we may rewrite (4.10) as

$$(\mathcal{B}^-_{\alpha 1})^{(1)}=\sum_{j=1}^{N}\frac{e^{u_1-v_\alpha}\sinh^2\eta}{\sinh(u_1-z_j+\eta)\sinh(v_\alpha-z_j+\eta)}\prod_{\gamma=1}^{\alpha-1}\frac{\sinh(v_\gamma-z_j)}{\sinh(v_\gamma-z_j+\eta)}\prod_{k=1,\neq j}^{N}\frac{\sinh(z_k-z_j+\eta)}{\sinh(z_k-z_j)}$$
$$\equiv e^{u_1}f(u_1).\tag{4.11}$$

Thanks to the Bethe ansatz equation (2.24), we may construct the function

$$\mathcal{M}^{\pm}_{\alpha\beta}=e^{\mp u_\beta}g(u_\beta)=\frac{e^{\pm(v_\alpha-u_\beta)}\sinh\eta}{\sinh(v_\alpha-u_\beta)}\prod_{\gamma=1}^{\alpha-1}\frac{\sinh(v_\gamma-u_\beta-\eta)}{\sinh(v_\gamma-u_\beta)}\left\{1-\prod_{k=1}^{N}\frac{\sinh(u_\beta-z_k)}{\sinh(u_\beta-z_k+\eta)}\right\}.\tag{4.12}$$

Comparing $f(u_1)$ in (4.11) with $g(u_1)$ in (4.12), one finds that as functions of u_1, they have the same residues at the simple pole $u_1=z_j-\eta\,\mathrm{mod}(i\pi)$, and that when $u_1\to\infty$, they are bounded. Moreover, one may prove that the residues of $g(u_1)$ at $u_1=v_\nu\,\mathrm{mod}(i\pi)$ $(\nu=1,\ldots,\alpha)$ are zero because v_ν are solutions of the Bethe ansatz equation (2.24). Therefore, we have

$$(\mathcal{B}^-_{\alpha 1})^{(1)}=\mathcal{M}^-_{\alpha 1}=\frac{b^-(v_\alpha,u_1)}{a(v_\alpha,u_1)}\prod_{\gamma=1}^{\alpha-1}a^{-1}(u_1,v_\gamma)\left(1-\prod_{k=1}^{N}a(u_1,z_k)\right).\tag{4.13}$$

Then, by using the function $G^{(0)}$, $G^{(1)}$ and the intermediate function (4.4) repeatedly, we obtain $G^{(m)}$ as

$$G^{(m)}(\{v_k\},u_1,\ldots,u_m,i_{m+1},\ldots,i_n)=(-1)^m(2\cosh\eta)^{[n(n-1)-m(2n-m-1)]/2}\prod_{1\leqslant j<k\leqslant m}a^{-1}(u_k,u_j)$$
$$\times\det(\mathcal{B}^-)^{(m)}(\{v_k\},u_1,\ldots,u_m,i_{m+1},\ldots,i_n) \tag{4.14}$$

with the matrix elements

$$(\mathcal{B}^-_{\alpha\beta})^{(m)}=\prod_{k=1}^{m}a(u_k,z_{i_\beta})\mathcal{B}^-_{\alpha\beta},\quad \text{for } \beta>m,$$

$$(\mathcal{B}^-_{\alpha\beta})^{(m)}=\mathcal{M}^-_{\alpha\beta}\quad \text{for } \beta\leqslant m. \tag{4.15}$$

Equation (4.14) can be proved by induction. First from (4.8), (4.9), (4.13), and (4.14) is true for $m=1$. Assume (4.14) for $G^{(m-1)}$. Let us show (4.14) for general m. Substituting $G^{(m-1)}$ and (4.5) into intermediate function (4.4), we have

$$\begin{aligned}
&G^{(m)}(\{v_k\},u_1,\ldots,u_m,i_{m+1},\ldots,i_n)\\
&=\sum_{j\neq i_{m+1},\ldots,i_n}^{N}\langle i_n,\ldots,i_{m+1}|\tilde{B}(u_m)|i_{m+1},\ldots,i_{m+p},j,i_{m+p+1},\ldots,i_n\rangle\\
&\quad\times G^{(m-1)}(\{v_k\},u_1,\ldots,u_{m-1},i_{m+1},\ldots,i_{m+p},j,i_{m+p+1},\ldots,i_n)\\
&=-(2\cosh\eta)^{-(n-m)}\sum_{j\neq i_{m+1},\ldots,i_n}^{N}b^+(u_m,z_j)\prod_{k\neq j}^{N}a^{-1}(z_k,z_j)\prod_{l=m+1}^{n}a(u_m,z_{i_l})\\
&\quad\times G^{(m-1)}(\{v_k\},u_1,\ldots,u_{m-1},j,i_{m+1},\ldots,i_n)\\
&=(-1)^m(2\cosh\eta)^{[n(n-1)-m(2n-m-1)]/2}\prod_{1\leqslant j<k\leqslant m-1}a^{-1}(u_k,u_j)\\
&\quad\times\det\mathcal{B}'^{(m)}(\{v_k\},u_1,\ldots,u_m,i_{m+1},\ldots,i_n),
\end{aligned} \tag{4.16}$$

where the matrix elements $\mathcal{B}'^{(m)}_{\alpha\beta}$ are given by

$$\mathcal{B}'^{(m)}_{\alpha\beta}=\prod_{k=1}^{m}a(u_k,z_{i_\beta})\mathcal{B}^-_{\alpha\beta}\quad \text{for } \beta>m,$$

$$\mathcal{B}'^{(m)}_{\alpha\beta}=\mathcal{M}^-_{\alpha\beta}\quad \text{for } \beta<m,$$

$$\mathcal{B}'^{(m)}_{\alpha m}=\prod_{i=1}^{m-1}a(u_i,z_j)\sum_{j\neq i_{m+1},\ldots,i_n}b^+(u_m,z_j)b^-(v_\alpha,z_j)\prod_{\gamma=1}^{\alpha-1}a(v_\gamma,z_j)\prod_{k=1,\neq j}^{N}a^{-1}(z_k,z_j). \tag{4.17}$$

Thus, by the procedure leading to $(\mathcal{B}^-_{\alpha\beta})^{(1)}$, we can prove

$$\mathcal{B}'^{(m)}_{\alpha m}=\prod_{i=1}^{m-1}a^{-1}(u_m,u_i)\mathcal{M}^-_{\alpha m}. \tag{4.18}$$

Then one sees that $\mathcal{B}'^{(m)}_{\alpha\beta}=\mathcal{B}^{(m)}_{\alpha\beta}$. Therefore we have proved that (4.14) holds for all m.

When $m=n$, we obtain the scalar product $S_n(\{u_i\},\{v_j\})$,

$$S_n(\{u_i\},\{v_j\})=(-1)^n\prod_{k>l}^{n}a^{-1}(u_k,u_l)\det\mathcal{M}^-(\{v_j\},\{u_i\}), \tag{4.19}$$

where the matrix elements of $\mathcal{M}^-$ are given by

$$\mathcal{M}^{\pm}_{\alpha\beta}=\frac{b^{\pm}(v_\alpha,u_\beta)}{a(v_\alpha,u_\beta)}\prod_{\gamma=1}^{\alpha-1}a^{-1}(u_\beta,v_\gamma)\left(1-\prod_{k=1}^{N}a(u_\beta,z_k)\right). \tag{4.20}$$

By using the expression of the eigenvalues of the system (2.23), the scalar product (4.19) can be rewritten as

$$S_n(\{u_i\},\{v_j\})=(-1)^n\prod_{k>l}^{n}a^{-1}(u_k,u_l)\det\hat{\mathcal{M}}^{-}(\{v_j\},\{u_i\}) \tag{4.21}$$

with the matrix $\hat{\mathcal{M}}^{\pm}$ being

$$\hat{\mathcal{M}}^{\pm}_{\alpha\beta}=e^{\pm(v_\alpha-u_\beta)}\sinh(u_\beta-v_\alpha)\prod_{\mu\neq\alpha}a(v_\mu,u_\beta)\prod_{\gamma=1}^{\alpha-1}a^{-1}(u_\alpha,v_\gamma)\frac{\partial\Lambda(u_\beta,\{v_\alpha\})}{\partial v_\alpha}. \tag{4.22}$$

Remark: In the derivation of (4.19), the parameters v_i in the state $\tilde{C}(v_1)\cdots\tilde{C}(v_n)|0\rangle$ are required to satisfy the BAE (2.24). However, the parameters u_j $(j=1,\ldots,n)$ in the dual state $\langle 0|\tilde{B}(u_n)\cdots\tilde{B}(u_1)$ do not need to satisfy the BAE.

On the other hand, if we compute the scalar product by starting from the dual state $\langle 0|B(v_n)\cdots B(v_1)$, then by using the same procedure, we have

$$S_n(\{v_i\},\{u_j\})=\langle 0|\tilde{B}(v_n)\cdots\tilde{B}(v_1)\tilde{C}(u_1)\cdots\tilde{C}(u_n)|0\rangle=(-1)^n\prod_{k>l}^{n}a^{-1}(u_k,u_l)\det\mathcal{M}^{+}(\{v_i\},\{u_j\}). \tag{4.23}$$

In the above equation, we have assumed that $\{v_i\}$ satisfy the BAE.

Noticing the BAE (2.24), one sees that the scalar product $S_n(\{u_i\},\{v_j\})=0$ if both parameter sets $\{u_i\}$ and $\{v_j\}(\{v_j\}\neq\{u_i\}i,j=1,\ldots,n)$ in (4.19) and (4.23) satisfy the BAE.

Let $u_\alpha\to v_\alpha$ $(\alpha=1,\ldots,n)$ in (4.19), we obtain the Gaudin formula for the norm of the $U_q(\mathrm{gl}(1|1))$ Bethe state,

$$\begin{aligned}\mathcal{S}_n&=S_n(\{v_j\},\{v_k\})=\langle 0|B(v_n)\cdots B(v_1)C(v_1)\cdots C(v_n)|0\rangle\\&=(-1)^n\sinh^n\eta\prod_{k>j}^{n}\frac{\sinh^2(v_k-v_j+\eta)}{\sinh^2(v_k-v_j)}\left[\prod_{\alpha=1}^{n}\frac{1}{v_\alpha-u_\alpha}\left(1-\prod_{l=1}^{N}\frac{\sinh(u_\alpha-z_l)}{\sinh(u_\alpha-z_l+\eta)}\right)\right]_{u_\alpha\to v_\alpha}\\&=(-1)^n\sinh^n\eta\prod_{k>j}^{n}\frac{\sinh^2(v_k-v_j+\eta)}{\sinh^2(v_k-v_j)}\left[\prod_{\alpha=1}^{n}\frac{\partial}{\partial u_\alpha}\ln\left(\prod_{l=1}^{N}\frac{\sinh(u_\alpha-z_l)}{\sinh(u_\alpha-z_l+\eta)}\right)\right]_{u_\alpha\to v_\alpha}\\&=(-1)^n\sinh^{2n}\eta\prod_{k>j}^{n}\frac{\sinh^2(v_k-v_j+\eta)}{\sinh^2(v_k-v_j)}\prod_{\alpha=1}^{n}\sum_{l=1}^{N}\frac{1}{\sinh(v_\alpha-z_l)\sinh(v_\alpha-z_l+\eta)},\end{aligned} \tag{4.24}$$

where we have used the BAE (2.24).

V. CORRELATION FUNCTIONS

Having obtained the scalar product and the norm, we are now in the position to compute the k-point correlation functions of the model. In general, a k-point correlation function is defined by

$$F_n^{\epsilon^1,\ldots,\epsilon^k}=\langle 0|B(u_n)\cdots B(u_1)\epsilon^1_{i_1}\cdots\epsilon^k_{i_k}C(v_1)\cdots C(v_n)|0\rangle, \tag{5.1}$$

where $\epsilon^j_{i_j}$ stand for the local Fermion operators c_{i_j}, $c^{\dagger}_{i_j}$ or n_{i_j}, and the lower indices i_j indicate the positions of the Fermion operators.

The authors in Ref. 16 proved that the local spin and field operators of the fundamental graded models can be represented in terms of monodromy matrix. Specializing to the current system, we obtain

$$c_j^\dagger = \prod_{k=1}^{j-1} (-A(z_k) + D(z_k)) \cdot B(z_j) \cdot \prod_{k=j+1}^{N} (-A(z_k) + D(z_k)), \tag{5.2}$$

$$c_j = \prod_{k=1}^{j-1} (-A(z_k) + D(z_k)) \cdot C(z_j) \cdot \prod_{k=j+1}^{N} (-A(z_k) + D(z_k)), \tag{5.3}$$

$$n_j = \prod_{k=1}^{j-1} (-A(z_k) + D(z_k)) \cdot D(z_j) \cdot \prod_{k=j+1}^{N} (-A(z_k) + D(z_k)). \tag{5.4}$$

A. One-point functions

In this section, we compute the one-point functions for the local operators $c_m^\dagger$, c_m, and n_m, respectively.

We first calculate $c_m^\dagger$. Noticing that the Bethe state and its dual are eigenstates of the transfer matrix under the constraint of the BAE, we have, from (5.2),

$$\begin{aligned}
F_n^-(\{u_j\},z_m,\{v_k\}) &= \langle 0|B(u_n)\cdots B(u_1)c_m^\dagger C(v_1)\cdots C(v_{n+1})|0\rangle \\
&= \phi_{m-1}(\{u_j\})\phi_m^{-1}(\{v_k\})\langle 0|B(u_n)\cdots B(u_1)B(z_m)C(v_1)\cdots C(v_{n+1})|0\rangle \\
&= \phi_{m-1}(\{u_j\})\phi_m^{-1}(\{v_k\})\langle 0|\widetilde{B}(u_n)\cdots \widetilde{B}(u_1)\widetilde{B}(z_m)\widetilde{C}(v_1)\cdots \widetilde{C}(v_{n+1})|0\rangle \\
&= \phi_{m-1}(\{u_j\})\phi_m^{-1}(\{v_k\})S_{n+1}(u_n,\ldots,u_1,z_m,\{v_j\}) \\
&= (-1)^{n+1}\phi_{m-1}(\{u_j\})\phi_m^{-1}(\{v_k\})\prod_{k>j}^{n} a^{-1}(u_k,u_j)\prod_{l=1}^{n} a^{-1}(u_l,z_m) \\
&\quad \times \det \mathcal{M}^-(\{v_j\},z_m,u_1,\ldots,v_n),
\end{aligned} \tag{5.5}$$

where $\phi_i(\{u_j\})=\Pi_{k=1}^{i}\Pi_{l=1}^{n}a(u_l,u_k)$. As mentioned in the remark of the preceding section, $F_n^-=0$ if the parameter set $\{u_i\}$ $(i=1,\ldots,n)$ is not a subset of $\{v_j\}$ $(j=1,\ldots,n+1)$. When $\{u_i\}\subset\{v_j\}$, (5.5) can be simplified to a simple function. For example, if $u_i=v_{i+1}$ $(i=1,\ldots,n)$, the one-point function F^- becomes

$$\begin{aligned}
&F_n^-(v_{n+1},\ldots,v_2,z_m,v_1,\ldots,v_{n+1}) \\
&\quad = (-1)^{n+1}\frac{\phi_{m-1}(\{u_j\})}{\phi_m(\{v_k\})}\frac{e^{-(v_1-z_m)}\sinh^{2n+1}\eta}{\sinh(v_1-z_m)}\prod_{k>j=2}^{n+1}\frac{\sinh^2(v_k-v_j+\eta)}{\sinh^2(v_k-v_j)} \\
&\qquad \times\prod_{j=2}^{n+1}\frac{\sinh(v_j-z_m+\eta)}{\sinh(v_j-z_m)}\prod_{j=2}^{n+1}\frac{\sinh(v_j-v_1+\eta)}{\sinh(v_j-v_1)}\prod_{\alpha=2}^{n+1}\sum_{l=1}^{N}\frac{1}{\sinh(v_\alpha-z_l)\sinh(v_\alpha-z_l+\eta)}.
\end{aligned} \tag{5.6}$$

Similarly, when $\{u_i\}\subset\{v_j\}$, we obtain the one-point function involving the operator c_m,

$$
\begin{aligned}
F_n^+(\{v_k\},z_m,\{u_j\}) &= \langle 0|B(v_{n+1})\cdots B(v_1)c_m C(u_1)\cdots C(u_n)|0\rangle \\
&= \phi_{m-1}(\{v_j\})\phi_m^{-1}(\{u_k\})S_{n+1}(\{v_j\},z_m,u_1,\ldots,u_n) \\
&= (-1)^{n+1}\phi_{m-1}(\{v_j\})\phi_m^{-1}(\{u_k\})\prod_{k>j}^{n} a^{-1}(u_k,u_j)\prod_{l=1}^{n} a^{-1}(u_l,z_m) \\
&\quad \times \det \mathcal{M}^+(\{v_j\},z_m,u_1,\ldots,v_n). \qquad (5.7)
\end{aligned}
$$

F_n^+ is nonvanishing if $\{u_i\}\subset\{v_j\}$. When $\{u_i\}\subset\{v_j\}$, (5.7) can also be simplified to a simple function. In the case $u_i=v_{i+1}$ $(i=1,\ldots,n)$, the one-point function F^+ becomes

$$
\begin{aligned}
&F_n^+(v_{n+1},\ldots,v_2,z_m,v_1,\ldots,v_{n+1}) \\
&= (-1)^{n+1}\frac{\phi_{m-1}(\{v_j\})}{\phi_m(\{u_k\})}\frac{e^{(v_1-z_m)}\sinh^{2n+1}\eta}{\sinh(v_1-z_m)}\prod_{k>j=2}^{n+1}\frac{\sinh^2(v_k-v_j+\eta)}{\sinh^2(v_k-v_j)} \\
&\quad \times\prod_{j=2}^{n+1}\frac{\sinh(v_j-z_m+\eta)}{\sinh(v_j-z_m)}\prod_{j=2}^{n+1}\frac{\sinh(v_j-v_1+\eta)}{\sinh(v_j-v_1)}\prod_{\alpha=2}^{n+1}\sum_{l=1}^{N}\frac{1}{\sinh(v_\alpha-z_l)\sinh(v_\alpha-z_l+\eta)}. \qquad (5.8)
\end{aligned}
$$

The one-point function involving the operator n_m is defined by

$$
F_n^{n_m}(\{u_j\},z_m,\{v_k\}) = \langle 0|B(u_n)\cdots B(u_1)n_m C(v_1)\cdots C(v_n)|0\rangle. \qquad (5.9)
$$

Substituting (5.4) into the above equation and considering the BAE, we have

$$
\begin{aligned}
F_n^{n_m}(\{u_j\},z_m,\{v_k\}) &= \langle 0|B(u_n)\cdots B(u_1)n_m C(v_1)\cdots C(v_n)|0\rangle \\
&= \frac{\phi_{m-1}(\{u_j\})}{\phi_{m-1}(\{v_k\})}\langle 0|\tilde{B}(u_n)\cdots\tilde{B}(u_1)\tilde{D}(z_m)\tilde{C}(v_1)\cdots\tilde{C}(v_n)|0\rangle. \qquad (5.10)
\end{aligned}
$$

With the help of (2.21), we see

$$
\begin{aligned}
D(z_m)C(v_1)\cdots C(v_n)|0\rangle &= \prod_{k=1}^{n} a^{-1}(v_k,z_m)C(v_1)\cdots C(v_n)|0\rangle \\
&\quad -\sum_{j=1}^{n}\frac{b^-(v_j,z_m)}{a(v_j,z_m)}\prod_{l=1}^{j-1}\frac{c(v_l,v_j)}{c(v_l,z_m)}\prod_{k=1,\neq j}^{n} a^{-1}(v_k,v_j) \\
&\quad \times C(v_1)\cdots C(v_{j-1})C(z_m)C(v_{j+1})\cdots C(v_n)|0\rangle. \qquad (5.11)
\end{aligned}
$$

Therefore, substituting (5.11) into (5.10), we obtain

$$
\begin{aligned}
F_n^{n_m}(\{u_j\},z_m,\{v_k\}) &= \frac{\phi_{m-1}(\{u_j\})}{\phi_{m-1}(\{v_k\})}\prod_{k=1}^{n} a^{-1}(v_k,z_m)S_n(\{u_i\},\{v_j\}) \\
&\quad -\sum_{j=1}^{n}\frac{b^-(v_j,z_m)}{a(v_j,z_m)}\prod_{l=1}^{j-1}\frac{c(v_l,v_j)}{c(v_l,z_m)}\prod_{k=1,\neq j}^{n} a^{-1}(v_k,v_j)S_n(\{u_i\},v_1,\ldots,v_{j-1},z_m,v_{j+1},\ldots,v_n) \\
&= (-1)^n\frac{\phi_{m-1}(\{u_j\})}{\phi_{m-1}(\{v_k\})}\prod_{k=1}^{n} a^{-1}(v_k,z_m)\prod_{k>j} a^{-1}(v_k,v_j)\det[M^+(\{u_i\},\{v_j\}) \\
&\quad -\mathcal{N}(\{u_i\},\{v_j\},z_m)], \qquad (5.12)
\end{aligned}
$$

where $\mathcal{N}$ is a rank-one matrix with the following matrix elements:

$$\mathcal{N}_{\alpha\beta}(\{u_i\},\{v_j\},z_m)=\frac{e^{u_\alpha-v_\beta}\sinh^2\eta}{\sinh(u_\alpha-z_m)\sinh(v_\beta-z_m+\eta)}\prod_{i=1}^{\alpha-1}\frac{\sinh(z_m-u_i+\eta)}{\sinh(z_m-u_i)}. \tag{5.13}$$

In the above derivation, we have used the following property of determinant: If $\mathcal{A}$ is an arbitrary $n\times n$ matrix and $\mathcal{B}$ is a rank-one $n\times n$ matrix, then the determinant of $\mathcal{A}+\mathcal{B}$ is given by

$$\det(\mathcal{A}+\mathcal{B})=\det\mathcal{A}+\sum_{i=1}^{n}\det\mathcal{A}^{(i)}, \tag{5.14}$$

where

$$\mathcal{A}^{(i)}_{\alpha\beta}=\mathcal{A}_{\alpha\beta}\quad\text{for }\beta\neq i,$$

$$\mathcal{A}^{(i)}_{\alpha i}=\mathcal{B}_{\alpha i}.$$

B. Correlation function of two adjacent operators

In this section, we compute the correlation function of two adjacent operators c_m and c_{m+1} defined by

$$F_n^{-+}(\{u_i\},z_m,z_{m+1},\{v_j\})=\langle 0|B(u_n)\cdots B(u_1)c_m c^\dagger_{m+1}C(v_1)\cdots C(v_n)|0\rangle. \tag{5.15}$$

Substituting (5.3) and (5.2) into the above definition and considering the fact $\Pi_{k=1}^N t(z_k)=1$, we have

$$F_n^{-+}(\{u_i\},\{v_j\},z_m,z_{m+1})=\frac{\phi_{m-1}(\{u_i\})}{\phi_{m+1}(\{v_j\})}\langle 0|\tilde{B}(u_n)\cdots\tilde{B}(u_1)\tilde{C}(z_m)\tilde{B}(z_{m+1})\tilde{C}(v_1)\cdots\tilde{C}(v_n)|0\rangle. \tag{5.16}$$

By using the commutation relation (2.22), we obtain

$$\begin{aligned}B(z_{m+1})C(v_1)\cdots C(v_n)|0\rangle&=(-1)^nC(v_1)\cdots C(v_n)B(z_{m+1})|0\rangle\\&+\sum_{j=1}^{n}(-1)^{j+1}\frac{b^+(z_{m+1},v_j)}{a(z_{m+1},v_j)}C(v_1)\cdots C(v_{j-1})D(z_{m+1})t(v_j)C(v_{j+1})C(v_n)|0\rangle\\&+\sum_{j=1}^{n}(-1)^{j}\frac{b^+(z_{m+1},v_j)}{a(z_{m+1},v_j)}C(v_1)\cdots C(v_{j-1})t(z_{m+1})D(v_j)C(v_{j+1})C(v_n)|0\rangle,\end{aligned} \tag{5.17}$$

where $\tilde{t}(u)\equiv F_{1\cdots N}t(u)F^{-1}_{1\cdots N}$. On the right-hand side (rhs) of the above equation, one easily finds that the first term is zero. Using the BAE, one may check that the second term also equals zero. Therefore, only the third term survives on the rhs of the above equation and we have

$$\begin{aligned}&B(z_{m+1})C(v_1)\cdots C(v_n)|0\rangle\\&=\sum_{j=1}^{n}(-1)^j\frac{b^+(z_{m+1},v_j)}{a(z_{m+1},v_j)}\prod_{k=j+1}^{n}a^{-1}(v_k,z_{m+1})\prod_{l=j+1}^{n}a^{-1}(v_l,v_j)\\&\quad\times C(v_1)\cdots C(v_{j-1})C(v_{j+1})C(v_n)|0\rangle\\&\quad+\sum_{j=1}^{n}(-1)^{j+1}\frac{b^+(z_{m+1},v_j)}{a(z_{m+1},v_j)}\prod_{k=j+1}^{n}a^{-1}(v_k,z_{m+1})\end{aligned}$$

$$\times \sum_{l=j+1}^{n} \frac{b^{-}(v_l,v_j)}{a(v_l,v_j)} \prod_{m=j+1}^{l-1} \frac{c(v_m,v_l)}{c(v_m,v_j)} \prod_{i=j+1,\neq l}^{n} a^{-1}(v_i,v_l)$$

$$\times C(v_1)\cdots C(v_{j-1})C(v_{j+1})\cdots C(v_{l-1})C(v_j)C(v_{l+1})\cdots C(v_n)|0\rangle$$

$$\equiv \sum_{j=1}^{n} M_j C(v_1)\cdots C(v_{j-1})C(v_{j+1})C(v_n)|0\rangle$$

$$+ \sum_{j=1}^{n}\sum_{l=j+1}^{n} M_{j,l} C(v_1)\cdots C(v_{j-1})C(v_{j+1})\cdots C(v_{l-1})C(v_j)C(v_{l+1})\cdots C(v_n)|0\rangle. \quad (5.18)$$

Substituting (5.18) into (5.16), we obtain two-point correlation function F_n^{-+},

$$F_n^{-+}(\{u_i\},z_m,z_{m+1},\{v_j\}) = \frac{\phi_{m-1}(\{u_i\})}{\phi_{m+1}(\{v_j\})}\Bigg[\sum_{j=1}^{n} M_j S_n(\{u_i\},z_m,v_1,\ldots,v_{j-1},v_{j+1},v_n)$$

$$+ \sum_{j=1}^{n}\sum_{l=j+1}^{n} M_{j,l} S_n(\{u_i\},z_m,v_1,\ldots,v_{j-1},v_{j+1},\ldots,v_{l-1},v_j,v_{l+1},\ldots,v_n)\Bigg]. \quad (5.19)$$

VI. DISCUSSION

In this paper, with the help of the factorizing F-matrix (F-basis), we have obtained the determinant representations of the scalar products and correlation functions of the $U_q(\mathrm{gl}(1|1))$ free Fermion model.

In Refs. 10–15, the authors studied the correlation Functions of the free Fermion model based on the finite $XX0$ spin chain (XY model[9]) with periodic boundary condition

$$H_{XX0} = \sum_{j=1}^{N} (\sigma_j^x\sigma_{j+1}^x + \sigma_j^y\sigma_{j+1}^y + h\sigma_j^z), \quad (6.1)$$

where σ^{ϵ} ($\epsilon = x,y,z$) are the Pauli matrices and h is an external classical magnetic field. The equivalence between the free Fermion model and the $XX0$ model can be proved by using the Jordan-Wigner transform

$$c_k = \exp[i\pi Q_{k-1}]\sigma_k^{+}, \quad (6.2)$$

$$c_k^{\dagger} = \sigma_k^{-}\exp[i\pi Q_{k-1}], \quad (6.3)$$

where $\sigma^{\pm} = \frac{1}{2}(\sigma^x \pm \sigma^y)$, $Q_k = \sum_{j=1}^{k}\frac{1}{2}(1-\sigma_k^z)$. Because of the periodic boundary condition of the finite $XX0$ spin chain, we have

$$\sigma_{N+1}^{\pm} = \sigma_1^{\pm}. \quad (6.4)$$

Substituting the Jordan-Wigner transforms into the above relation, we obtain

$$c_{N+1} = \exp[i\pi Q_N]c_1, \quad c_{N+1}^{\dagger} = c_1^{\dagger}\exp[i\pi Q_N]. \quad (6.5)$$

Thus, comparing the above boundary condition with that of the $U_q(\mathrm{gl}(1|1))$ free Fermion model (2.14), we find that the free Fermion model arising from the $XX0$ model has a twisted boundary condition which depends on the operator $\sigma^z = \sum_{i=1}^{N}\sigma_i^z$.

On the other hand, by means of the Jordan-Wigner transform, the $U_q(\mathrm{gl}(1|1))$ free Fermion model is equivalent to a twisted $XX0$ model, and the one-point correlation functions (5.5) and (5.7) give rise to the m-point correlation functions of the twisted $XX0$ model. For example, substituting (6.3) into (5.5), we obtain

$$\begin{aligned} F_n^-(\{u_j\},z_m,\{v_k\}) &= \langle 0|B(u_n)\cdots B(u_1)c_m^\dagger C(v_1)\cdots C(v_{n+1})|0\rangle \\ &= \langle 0|B(u_n)\cdots B(u_1)\sigma_1^z\cdots\sigma_{m-1}^z\sigma_m^- C(v_1)\cdots C(v_{n+1})|0\rangle. \end{aligned} \tag{6.6}$$

The equivalence problem for fourth order differential equations under fiber preserving diffeomorphisms

Raouf Dridi[a] and Sylvain Neut[b]
L.I.F.L., University of Lille I, Villeneuve D'Ascq, Nord 59655, France

(Received 2 October 2005; accepted 4 November 2005; published online 4 January 2006)

In the present work we use the method of equivalence to determine necessary and sufficient conditions for a general fourth order ordinary differential equation to be equivalent to the flat model under a fiber preserving transformation. As a result, explicit and simple conditions are obtained. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2157050]

I. INTRODUCTION

Introduced and developed by Élie Cartan in the beginning of the 1920s, the method of equivalence is a systematic procedure that allows one to decide whether two systems of differential equations can be mapped one to each other by a transformation taken in a given pseudogroup. For instance, the method of equivalence answers questions like: find necessary and sufficient conditions on f such that

$$y'' = f\left(x, y, \frac{dy}{dx}\right)$$

can be mapped to

$$\frac{d^2Y}{dX} = 0$$

under a point transformation $X=X(x,y)$, $Y=Y(x,y)$.

Thanks to C. Erhesmann and S. Chern who introduced two important concepts to the method of equivalence: jets spaces and G-structures. Actually a G-structure on manifold is a G-subbundle of the frame bundle. Applying the equivalence method leads to $\{e\}$-structure, which is invariantly associated to the given equation.

In the 1960s, Singer, Sternberg, Guillemin, Kuranishi, Kodaira, and Spencer made major contributions making the equivalence method more rigorous. We refer the reader to Refs. 4,3 or even to Cartan paper[1] for detailed exposition.

In recent years, with the help of algebraic computers, many authors have successfully used the method of equivalence to many interesting problems: classifications of differential equations (Kamran, Olver and Fels), holonomy groups (Bryant), inverse variational problems (Fels), general relativity (Newman).

In this paper we completely characterize the fourth order differential equations which are equivalent to the flat model under fiber preserving transformations.

II. MAIN RESULT

Consider the fourth order equation

[a]Electronic mail: dridi@lifl.fr
[b]Electronic mail: neut@lifl.fr

$$y^{(4)} = f(x,y,y',y'',y''') \tag{1}$$

and let Φ be a fiber preserving transformation from J^3 to J^3 with $\mathrm{x} := (x,y,p=y',q=y'',r=y''') \in \mathbb{R}^5$ as local coordinates. Recall that a map Φ is said to be fiber preserving if there exists a map $\phi:\mathbb{R}\to\mathbb{R}$ such that

$$\phi \circ (\mathrm{proj}) = (\mathrm{proj}) \circ \Phi.$$

Thus in terms of local coordinates on J^0, we have

$$\begin{cases} \bar{x} \circ \Phi = \phi(x), \\ \bar{y} \circ \Phi = \psi(x,y). \end{cases} \tag{2}$$

The main result of the paper is

Thorem 1: *The following propositions for a fourth order ordinary differential equation* $y^{(4)} = f(x,y,p,q,r)$ *are equivalent*

(i) *The equation is equivalent to the flat model* $y^{(4)}=0$ *under a fiber preserving transformation.*

(ii) *The equation admits an eight dimensional symmetry group of fiber preserving transformations.*

(iii) f *satisfies*

$$f_{rr} = 0, \quad f_{qr} = 0,$$

$$-f_r^{\,3} + 6D_x f_r f_r - 4f_q f_r - 8f_p + 8D_x f_q - 4D_x^{\,2} f_r = 0,$$

$$\begin{aligned} &1512 D_x f_r f_r^{\,2} - 1440 f_r D_x^{\,2} f_r + 832 f_q D_x f_r + 2000 D_x f_q f_r - 1600 f_p f_r - 808 f_q f_r^{\,2} - 1120 D_x^{\,2} f_q \\ &\quad + 480 D_x^{\,3} f_r + 1600 D_x f_p - 864 (D_x f_r)^2 - 1600 f_y - 144 f_q^{\,2} - 189 f_r^{\,4} = 0, \end{aligned} \tag{3}$$

$$-800 D_x^{\,2} f_r + 1600 D_x f_q - 200 f_r^{\,3} - 1600 f_p + 1200 D_x f_r f_r - 800 f_q f_r = 0$$

where $D_x = \partial_x + p\partial_y + q\partial_p + r\partial_q + f(x,y,p,q,r)\partial_r$ *is the total derivative.*

III. PROBLEM FORMULATION

Any fiber preserving diffeomorphism has a standard lift to J^3 (called the *third prolongation*) which preserves the Pfaffian system

$$\omega^1 = -f(x,y,p,q,r)\mathrm{d}x + \mathrm{d}r, \quad \omega^2 = -p\mathrm{d}x + \mathrm{d}y, \quad \omega^3 = -q\mathrm{d}x + \mathrm{d}p, \quad \omega^4 = -r\mathrm{d}x + \mathrm{d}q. \tag{4}$$

In local coordinates, the equivalence of $y^{(4)}=f(x,y,p,q,r)$ and $\bar{y}^{(4)}=\bar{f}(\bar{x},\bar{y},\bar{p},\bar{q},\bar{r})$ under fiber preserving transformations is expressed as local equivalence problem for G-structures B and $\bar{B}$ given by

$$\underbrace{\begin{pmatrix} \bar{a}_1 & \bar{a}_2 & \bar{a}_3 & \bar{a}_4 & 0 \\ 0 & \bar{a}_5 & 0 & 0 & 0 \\ 0 & \bar{a}_6 & \bar{a}_7 & 0 & 0 \\ 0 & \bar{a}_8 & \bar{a}_9 & \bar{a}_{10} & 0 \\ 0 & 0 & 0 & 0 & \bar{a}_{11} \end{pmatrix}}_{S(\bar{a})\in G} \bar{\omega}(\bar{x}) = \underbrace{\begin{pmatrix} a_1 & a_2 & a_3 & a_4 & 0 \\ 0 & a_5 & 0 & 0 & 0 \\ 0 & a_6 & a_7 & 0 & 0 \\ 0 & a_8 & a_9 & a_{10} & 0 \\ 0 & 0 & 0 & 0 & a_{11} \end{pmatrix}}_{S(a)\in G} \omega(\mathrm{x}) \tag{5}$$

where $\omega=(\omega^1,\ldots,\omega^5)^t$ and $\omega^5=\mathrm{d}x$.

IV. SOLUTION

According to Cartan we take the lifts $\theta=S(a)\omega$ and $\bar{\theta}=S(\bar{a})\bar{\omega}$. By differentiation we obtain the following *structure equations*

$$\begin{pmatrix} \mathrm{d}\theta^1 \\ \mathrm{d}\theta^2 \\ \mathrm{d}\theta^3 \\ \mathrm{d}\theta^4 \\ \mathrm{d}\theta^5 \end{pmatrix} = \begin{pmatrix} \pi^1 & \pi^2 & \pi^3 & \pi^4 & 0 \\ 0 & \pi^5 & 0 & 0 & 0 \\ 0 & \pi^6 & \pi^7 & 0 & 0 \\ 0 & \pi^8 & \pi^9 & \pi^{10} & 0 \\ 0 & 0 & 0 & 0 & \pi^{11} \end{pmatrix} \wedge \begin{pmatrix} \theta^1 \\ \theta^2 \\ \theta^3 \\ \theta^4 \\ \theta^5 \end{pmatrix} \tag{6}$$

$$+ \begin{pmatrix} I_1\theta^1\wedge\theta^5 + I_2\theta^2\wedge\theta^5 + I_3\theta^3\wedge\theta^5 + I_4\theta^4\wedge\theta^5 \\ I_5\theta^2\wedge\theta^5 + I_6\theta^3\wedge\theta^5 \\ I_7\theta^2\wedge\theta^5 + I_8\theta^3\wedge\theta^5 + I_9\theta^4\wedge\theta^5 \\ I_{10}\theta^1\wedge\theta^5 + I_{11}\theta^2\wedge\theta^5 + I_{12}\theta^3\wedge\theta^5 + I_{13}\theta^4\wedge\theta^5 \\ 0 \end{pmatrix}. \tag{7}$$

The torsion of the pseudoconnection π is $T_\pi := T^i_{jk} v_i \otimes v^j \wedge v^k \in \Gamma(B, V\otimes\wedge^2 V^*)$ (here $V=\mathbb{R}^5$) and we are less interested in T_π than in the intrinsic torsion which is independent of any choice of π. Recall that (see Ref. 2) the intrinsic torsion of a linear Pfaffian system with tableau $A\subseteq W\otimes V^*$ lies in $H^{0,2}(A)=(W\otimes\wedge^2 V^*)/\delta(A\otimes V^*)$, where δ is the skew-symmetrization map. In the theory of the equivalence problems we have $W=V$ and $A=\mathfrak{g}$ the Lie algebra of G.

Lemma 1: $H^{0,2}(\mathfrak{g})\neq 0$. Indeed, the absorption of the apparent torsion (that is, factorizing the above structure equations according to the $\{\theta^j\}$ and renaming the new forms of the pseudoconnection such that $\pi^\rho := \pi^\rho + \lambda^\rho_j \theta^j$) yields

$$\begin{pmatrix} \mathrm{d}\theta^1 \\ \mathrm{d}\theta^2 \\ \mathrm{d}\theta^3 \\ \mathrm{d}\theta^4 \\ \mathrm{d}\theta^5 \end{pmatrix} = \begin{pmatrix} \pi^1 & \pi^2 & \pi^3 & \pi^4 & 0 \\ 0 & \pi^5 & 0 & 0 & 0 \\ 0 & \pi^6 & \pi^7 & 0 & 0 \\ 0 & \pi^8 & \pi^9 & \pi^{10} & 0 \\ 0 & 0 & 0 & 0 & \pi^{11} \end{pmatrix} \wedge \begin{pmatrix} \theta^1 \\ \theta^2 \\ \theta^3 \\ \theta^4 \\ \theta^5 \end{pmatrix} + \begin{pmatrix} 0 \\ I_1\theta^3\wedge\theta^5 \\ I_2\theta^4\wedge\theta^5 \\ I_3\theta^1\wedge\theta^5 \\ 0 \end{pmatrix}. \tag{8}$$

Now, define the structure map $\tau: B\to H^{0,2}(\mathfrak{g})$ such that for every $p=(x,u)\in B$ we have $\tau(p)=[T_p]$. The torsion lies in a single orbit of G in $H^{0,2}(\mathfrak{g})$. Thus we can can choose a normal form T_0 in the image of the structure map so that $B_1 := \{p\in B: \tau(p)=T_0\}$ and $G_1 := \{g\in G: \forall p \in B, \tau(p.g)=\tau(p)\}$ define a normalization of *first order constant type*, i.e., B_1 is G_1-structure. G_1 is the matrix group defined by normalizing a_5, a_7, a_{10} in the following manner:

$$I_1 = -\frac{a_5}{a_7 a_{11}} = -1, \quad I_2 = -\frac{a_7}{a_{10}a_{11}} = -1, \quad I_3 = -\frac{a_{10}}{a_1 a_{11}} = -1.$$

Let us denote by $\mathfrak{g}_1$ the new Lie algebra and we continue to denote by π the pull back of the pseudoconnection. The calculations give

$$\begin{pmatrix} d\theta^1 \\ d\theta^2 \\ d\theta^3 \\ d\theta^4 \\ d\theta^5 \end{pmatrix} = \begin{pmatrix} \pi^{10}-\pi^{11} & \pi^2 & \pi^3 & \pi^4 & 0 \\ 0 & \pi^{10}+2\pi^{11} & 0 & 0 & 0 \\ 0 & \pi^6 & \pi^{10}+\pi^{11} & 0 & 0 \\ 0 & \pi^8 & \pi^9 & \pi^{10} & 0 \\ 0 & 0 & 0 & 0 & \pi^{11} \end{pmatrix} \wedge \begin{pmatrix} \theta^1 \\ \theta^2 \\ \theta^3 \\ \theta^4 \\ \theta^5 \end{pmatrix} + \begin{pmatrix} I_1\theta^1\wedge\theta^5 + I_2\theta^2\wedge\theta^5 + I_3\theta^3\wedge\theta^5 + I_4\theta^4\wedge\theta^5 \\ I_5\theta^2\wedge\theta^5 - \theta^3\wedge\theta^5 \\ I_6\theta^2\wedge\theta^5 + I_7\theta^3\wedge\theta^5 - \theta^4\wedge\theta^5 \\ -\theta^1\wedge\theta^5 + I_8\theta^2\wedge\theta^5 + I_9\theta^3\wedge\theta^5 + I_{10}\theta^4\wedge\theta^5 \\ 0 \end{pmatrix} \tag{9}$$

Lemma 2: $H^{0,2}(\mathfrak{g}_1)\neq 0$. Indeed since we can absorb the apparent torsion to obtain

$$\begin{pmatrix} d\theta^1 \\ d\theta^2 \\ d\theta^3 \\ d\theta^4 \\ d\theta^5 \end{pmatrix} = \begin{pmatrix} \pi^7-\pi^8 & \pi^1 & \pi^2 & \pi^3 & 0 \\ 0 & \pi^7+2\pi^8 & 0 & 0 & 0 \\ 0 & \pi^4 & \pi^7+\pi^8 & 0 & 0 \\ 0 & \pi^5 & \pi^6 & \pi^7 & 0 \\ 0 & 0 & 0 & 0 & \pi^8 \end{pmatrix} \wedge \begin{pmatrix} \theta^1 \\ \theta^2 \\ \theta^3 \\ \theta^4 \\ \theta^5 \end{pmatrix} + \begin{pmatrix} 0 \\ I_1\theta^2\wedge\theta^5 \\ -\theta^4\wedge\theta^5 \\ -\theta^1\wedge\theta^5 + I_2\theta^4\wedge\theta^5 \\ 0 \end{pmatrix}.$$

Again the torsion lies in single orbit of G_1 in $H^{0,2}(\mathfrak{g}_1)$ thus we can define B_2 by setting $I_1=I_2=0$ where

$$I_1 = -\frac{1}{2}\frac{-5a_6+3a_9a_{11}+{a_{11}}^2f_{,}a_1+{a_{11}}^2a_4}{a_1{a_{11}}^3}$$

and

$$I_2 = \frac{1}{2}\frac{-3a_9a_{11}+3{a_{11}}^2a_4+a_6+{a_{11}}^2f_{,}a_1}{a_1{a_{11}}^3}.$$

This normalizes (a_6,a_9) and gives a new Lie algebra $\mathfrak{g}_2$.

Lemma 3: $H^{0,2}(\mathfrak{g}_2)\neq 0$. In the same manner as above the precesses of absorption of torsion leads

$$\begin{pmatrix} d\theta^1 \\ d\theta^2 \\ d\theta^3 \\ d\theta^4 \\ d\theta^5 \end{pmatrix} = \begin{pmatrix} pi^6+\pi^5 & \pi^1 & \pi^2 & \frac{3}{4}\pi^4 & 0 \\ 0 & \pi^5+2\pi^6 & 0 & 0 & 0 \\ 0 & \frac{3}{4}\pi^4 & \pi^5+\pi^6 & 0 & 0 \\ 0 & \pi^3 & \pi^4 & \pi^5 & 0 \\ 0 & 0 & 0 & 0 & \pi^6 \end{pmatrix} \wedge \begin{pmatrix} \theta^1 \\ \theta^2 \\ \theta^3 \\ \theta^4 \\ \theta^5 \end{pmatrix} + \begin{pmatrix} I_1\theta^1\wedge\theta^4 + I_2\theta^4\wedge\theta^5 \\ -\theta^3\wedge\theta^5 \\ I_3\theta^1\wedge\theta^2 + I_4\theta^2\wedge\theta^4 - \theta^4\wedge\theta^5 \\ -\theta^1\wedge\theta^5 \\ 0 \end{pmatrix}.$$

New normalization is possible:

$$I_2 = \frac{118a_{11}a_4f_ra_1 - 48a_{11}f_q{a_1}^2 - 84a_3a_1a_{11} + 32a_{11}{a_4}^2 + 18D_xf_r{a_1}^2a_{11} + 36a_8a_1 - 9a_{11}f_r{}^2{a_1}^2)}{48{a_1}^2{a_{11}}^3} = 0,$$

$$I_5 = -\frac{132a_{11}{a_4}^2 + 38a_{11}a_4f_ra_1 - 84a_8a_1 + 6D_xf_r{a_1}^2a_{11} + 9a_{11}f_r{}^2{a_1}^2 + 36a_3a_1a_{11})}{48{a_1}^2{a_{11}}^3} = 0.$$

The normalized parameters are (a_8, a_3) and Lie algebra is now reduced to $\mathfrak{g}_3$. Thus the absorbed structure equations read

$$\begin{pmatrix} d\theta^1 \\ d\theta^2 \\ d\theta^3 \\ d\theta^4 \\ d\theta^5 \end{pmatrix} = \begin{pmatrix} \pi^3 - \pi^4 & \pi^1 & 0 & \frac{3}{4}\pi^2 & 0 \\ 0 & \pi^3 + 2\pi^4 & 0 & 0 & 0 \\ 0 & \frac{3}{4}\pi^2 & \pi^3 + \pi^4 & 0 & 0 \\ 0 & 0 & \pi^2 & \pi^3 & 0 \\ 0 & 0 & 0 & 0 & \pi^4 \end{pmatrix} \wedge \begin{pmatrix} \theta^1 \\ \theta^2 \\ \theta^3 \\ \theta^4 \\ \theta^5 \end{pmatrix} + \begin{pmatrix} I_1\theta^1 \wedge \theta^4 + I_2\theta^3 \wedge \theta^5 \\ -\theta^3 \wedge \theta^5 \\ I_3\theta^1 \wedge \theta^2 + I_4\theta^2 \wedge \theta^4 - \theta^4 \wedge \theta^5 \\ I_5\theta^1 \wedge \theta^2 - \theta^1 \wedge \theta^5 + I_6\theta^2 \wedge \theta^5 \\ I_7\theta^2 \wedge \theta^5 + I_8\theta^3 \wedge \theta^5 \end{pmatrix}.$$

This proves the following lemma

Lemma 4: $H^{0,2}(\mathfrak{g}_3) \neq 0$.

We arrive at the last normalization of the parameter a_2: $I_2 = \frac{1}{720}(54{a_1}^2{f_r}^2a_4 - 396f_q{a_1}^3f_1 + 240a_1f_r{a_4}^2 + 432f_r{a_1}^3D_xf_r - 81{f_r}^3{a_1}^3 - 720f_p{a_1}^3 - 216f_q{a_1}^2a_4 - 720a_2{a_1}^2 + 160{a_4}^3 + 144a_4D_xf_r{a_1}^2 - 216{a_1}^3D_x^2f_r + 504{a_1}^3D_xf_q)/({a_{11}}^3{a_1}^3) = 0$ and just as before, $\mathfrak{g}_4$ is the new lie algebra.

We can absorb the torsion to get

$$\begin{pmatrix} d\theta^1 \\ d\theta^2 \\ d\theta^3 \\ d\theta^4 \\ d\theta^5 \end{pmatrix} = \begin{pmatrix} \pi^2 - \pi^3 & 0 & 0 & \frac{3}{4}\pi^1 & 0 \\ 0 & \pi^2 + 3\pi^3 & 0 & 0 & 0 \\ 0 & \frac{3}{4}\pi^1 & \pi^2 + \pi^3 & 0 & 0 \\ 0 & 0 & \pi^1 & \pi^2 & 0 \\ 0 & 0 & 0 & 0 & \pi^3 \end{pmatrix} \wedge \begin{pmatrix} \theta^1 \\ \theta^2 \\ \theta^3 \\ \theta^4 \\ \theta^5 \end{pmatrix} + \begin{pmatrix} I_1\theta^2 \wedge \theta^3 + I_2\theta^2 \wedge \theta^4 + I_3\theta^2 \wedge \theta^5 \\ -\theta^3 \wedge \theta^5 \\ I_4\theta^1 \wedge \theta^2 + I_5\theta^2 \wedge \theta^4 + I_6\theta^3 \wedge \theta^4 - \theta^4 \wedge \theta^5 \\ I_7\theta^1 \wedge \theta^2 - \theta^1 \wedge \theta^5 + I_8\theta^2 \wedge \theta^4 + I_9\theta^2 \wedge \theta^5 \\ I_{10}\theta^2 \wedge \theta^5 + I_{11}\theta^3 \wedge \theta^5 + I_{12}\theta^4 \wedge \theta^5 \end{pmatrix}. \tag{10}$$

The Cartan characters are $s_1 = 3$, $s_2 = 0$, $s_3 = 0$ and the indetermination degree is 0 thus the involution test fails:

Lemma 5: The above system is not in involution.

In this circumstances we define $\hat{V} = \mathfrak{g}_4 \oplus V$ and $\mathfrak{g}^{(1)} = (\mathfrak{g}_4 \otimes V^*) \cap (V \otimes S^2V^*)$ the *prolongation* of $\mathfrak{g}_4$. In fact, $\mathfrak{g}^{(1)}$ is just the Lie algebra of the Lie group formed by the λ_ρ^j remaining arbitrary after

the last absorption. Since the indetermination degree is 0, $\mathfrak{g}^{(1)}$ is reduced to the identity which means that $\mathfrak{g}$ is of finite type. Thus the necessary and sufficient condition for the G_4-structure B_4 to be locally flat is that the structure functions of all prolongations of $\mathfrak{g}_4$ must vanish. On the other hand, the Cartan's lemma applied to (10) gives

$$\begin{cases} \mathrm{d}\pi^1 = I_{13}\theta^1\wedge\theta^2 + I_{14}\theta^1\wedge\theta^3 + I_{15}\theta^1\wedge\theta^4 + I_{16}\theta^1\wedge\theta^5 + I_{17}\theta^2\wedge\theta^3 \\ \quad + I_{18}\theta^2\wedge\theta^4 + I_{19}\theta^2\wedge\theta^5 + I_{20}\theta^2\wedge\pi^1 + I_{21}\theta^3\wedge\theta^4 + I_{22}\theta^3\wedge\theta^5 \\ \quad + I_{23}\theta^4\wedge\theta^5 + I_{24}\theta^4\wedge\pi^1 + \pi^1\wedge\pi^3, \\ \mathrm{d}\pi^2 = I_{25}\theta^1\wedge\theta^2 + I_{26}\theta^1\wedge\theta^3 + I_{27}\theta^1\wedge\theta^4 + I_{28}\theta^1\wedge\theta^5 + I_{29}\theta^2\wedge\theta^3 \\ \quad + I_{30}\theta^2\wedge\theta^4 + I_{31}\theta^2\wedge\theta^5 + I_{32}\theta^3\wedge\theta^4 + I_{33}\theta^3\wedge\theta^5 + I_{34}\theta^4\wedge\theta^5 \\ \quad - \frac{1}{4}\theta^5\wedge\pi^1, \\ \mathrm{d}\pi^3 = I_{35}\theta^1\wedge\theta^2 + I_{36}\theta^1\wedge\theta^3 + I_{37}\theta^1\wedge\theta^4 + I_{38}\theta^1\wedge\theta^5 + I_{39}\theta^2\wedge\theta^3 \\ \quad + I_{40}\theta^2\wedge\theta^4 + I_{41}\theta^2\wedge\theta^5 + I_{42}\theta^2\wedge\pi^1 + I_{43}\theta^3\wedge\theta^4 + I_{44}\theta^3\wedge\theta^5 \\ \quad + I_{45}\theta^4\wedge\theta^5 + \frac{1}{2}\theta^5\wedge\pi^1 \end{cases}. \tag{11}$$

Now the degree of indetermination is 0 and the Cartan characters are $s_1=0$, $s_2=0$. Thus we obtain the involution

Proposition 1: The system (10) and (11) is in involution.

Going back to our main result, the achievement of the proof is due to the fundamental identity $d^2=0$. Indeed, we prove that

Proposition 2: All the structure functions vanish if and only if

$$I_4 = \frac{f_{rr}}{a_1 a_{11}}, \quad I_{34} = \frac{f_{qr}a_1 - f_{rr}a_4}{{a_{11}}^2 {a_1}^2},$$

$$I_9 = (-{f_r}^3 + 6D_x f_r f_r - 4f_q f_r - 8f_p + 8D_x f_q - 4{D_x}^2 f_r)/{a_{11}}^3,$$

$$\begin{aligned} I_3 = ((&1512D_x f_r {f_r}^2 - 1440 f_r {D_x}^2 f_r + 832 f_q D_x f_r + 2000 D_x f_q f_r - 1600 f_p f_r - 808 f_q {f_r}^2 - 1120 {D_x}^2 f_q \\ &+ 480 {D_x}^3 f_r + 1600 D_x f_p - 864 (D_x f_r)^2 - 1600 f_y - 144 {f_q}^2 - 189 {f_r}^4) a_1 + (-800 {D_x}^2 f_r + 1600 D_x f_q \\ &- 200 {f_r}^3 - 1600 f_p + 1200 D_x f_r f_r - 800 f_q f_r) a_4)/(a_1 {a_{11}}^4) \end{aligned}$$

vanish.

Again $d^2=0$ shows that if the invariants are constant then they must vanish. Combining this with the fact that the dimension of the symmetry group is equal to the dimension of the coframing $\{\theta^i, \pi^j\}$ minus the rank of the coframing (actually the number of functionally independent invariants), we prove the equivalence between *(ii)* and *(iii)*. The equivalence between *(i)* and *(iii)* is straightforward.

(Received 26 May 2005; accepted 31 October 2005; published online 4 January 2006)

The quantum group and space theory is reformulated from the standard skew-symmetric basis to an arbitrary one. The N-dimensional quantum Cayley–Klein spaces are described in Cartesian basis and the quantum analogs of $(N-1)$-dimensional constant curvature spaces are introduced. Part of the four-dimensional constant curvature spaces are interpreted as the noncommutative analogs of $(1+3)$ space-time models. As a result the quantum (anti) de Sitter, Minkowski, Newton, Galilei, Carroll kinematics with the fundamental length and the fundamental time are suggested. © *2006 American Institute of Physics.*

I. INTRODUCTION

Space-time is a fundamental conception that underlines the most significant physical theories. Therefore the analysis of a possible space-time model (or kinematics) has the fundamental meaning for physics. Space and time in nonrelativistic physics were regarded as independent what mathematically is connected with the fiber property of Galilei kinematics. In special relativity it was determined that space and time depend on each other and must be regarded as an integrated object, namely flat Minkowski space-time with a pseudo-Euclidean metric. The notion of curvature was introduced in physics by general relativity. Anti-de Sitter and de Sitter kinematics with constant positive and negative curvature, respectively, are the simplest relativistic space-time models with curvature. Possible kinematics, which satisfy the natural physical postulates: space is isotropic and rotations in space-time planes form a noncompact subgroup, were described in Ref. 1 on the level of Lie algebras. From the point of view of geometry these kinematics are realized as constant curvature spaces, which can be obtained from the spherical space by contractions and analytical continuations known as a Cayley–Klein (CK) scheme.[2]

The Snyder quantized space-time coordinates[3] or, respectively, the curved momentum space, are the oldest example of using the noncommutative geometry in physics. The simplest curved de Sitter geometry with constant curvature was used instead of flat Minkowski space in different generalizations of quantum field theory[4–7] as a momentum space model. The universal constant, the fundamental length l, or fundamental mass M, related to l by $l=\hbar/Mc$, where $\hbar$ is the Plank constant and c is the velocity of light, enters necessarily into the theory.[4,6,7]

A new possibility for construction of the noncommutative space-time models is provided by quantum groups and quantum vector spaces.[8] According to Dirac[9] from the early 30s, "The most powerful method of advance that can be suggested at present is to employ all the resources of pure mathematics in attempts to perfect and generalize the mathematical formalism that forms the existing basis of theoretical physics, and *after* each success in this direction, to try to interpret the new mathematical features in terms of physical entities." Similar views were expressed by Faddeev,[10] where we found this cite. The quantum Poincaré group related to the κ-Poincaré algebra as well as the κ-Minkowski kinematics were suggested.[11–13] A general formalism that allows the construction of field theory in κ-Minkowski space-time was developed.[14]

[a]Electronic mail: gromov@dm.komisc.ru

On the other hand, the quantum deformations can be useful in the large-scale limit, in particular, for a dark matter problem. If one uses a so-called Maslanka mapping,[15]

$$\widetilde{P}_0 = 2\kappa \operatorname{arcsinh} \frac{P_0}{2\kappa},$$

where P_0 ($\widetilde{P}_0$) is the energy of the particle for Minkowski (κ-Minkowski) kinematics, then, as it was pointed out by Bacry,[16] the energy of a system S composed of two subsystems, $S_{(1)}$ and $S_{(2)}$, reads as

$$2\kappa \sinh \frac{\widetilde{P}_0}{2\kappa} = 2\kappa \sinh \frac{\widetilde{P}_{0(1)}}{2\kappa} + 2\kappa \sinh \frac{\widetilde{P}_{0(2)}}{2\kappa},$$

rather then $P_0 = P_{0(1)} + P_{0(2)}$. Actually, the above implies that $\widetilde{P}_0 < \widetilde{P}_{0(1)} + \widetilde{P}_{0(2)}$. It means that the total energy of the universe is not proportional to the number of particles it contains. Hence there is no need for dark matter due to the kinematical reason.

Our purpose in this paper is to obtain the noncommutative (quantum) analogs of the possible kinematics. It is made just in the same way as for the commutative case, with the exception of the initial Euclidean space, which is substituted by the quantum Euclidean space associated with the quantum orthogonal group. The CK scheme of contractions and analytical continuations was developed in the Cartesian basis, whereas the standard quantum group theory[8] was formulated in a different skew-symmetric one. Therefore, first of all, this theory is reformulated in the Cartesian basis; then the noncommutative analogs of constant curvature spaces (CCS) including fiber (or flag) spaces are investigated and some of them are interpreted as noncommutative kinematics.

The paper is organized as follows. In Sec. II, we briefly recall the description of the classical commutative kinematics as spaces of constant curvature. In Sec. III, the general formalism of quantum Cayley–Klein orthogonal groups and associated spaces is developed. Section IV is devoted to the investigation of noncommutative four-dimensional space-time models.

II. COMMUTATIVE KINEMATICS

Classical four-dimensional space-time models can be obtained[2] by the physical interpretation of the orthogonal coordinates of the most symmetric spaces, namely constant curvature spaces. All 3^N N-dimensional CCS are realized on the spheres,

$$S_N(j) = \{\xi_1^2 + j_1^2\xi_2^2 + \ \dots\ + (1,N+1)^2\xi_{N+1}^2 = 1\}, \tag{1}$$

where

$$(i,k) = \prod_{l=\min(i,k)}^{\max(i,k)-1} j_l, \quad (k,k) \equiv 1, \tag{2}$$

and each of parameters j_k takes the values $1, \iota_k, i$, $k=1,\dots,N$. Here ι_k are nilpotent generators $\iota_k^2=0$, with commutative law of multiplication $\iota_k\iota_m = \iota_m\iota_k \neq 0$, $k \neq m$.

The intrinsic Beltrami coordinates $x_k = \xi_{k+1}\xi_1^{-1}$, $k=1,2,\dots,N$ present the coordinate system in CCS, which coordinate lines $x_k=$const are geodesic. CCS has positive curvature for $j_1=1$, negative for $j_1=i$, and it is flat for $j_1=\iota_1$. For a flat space the Beltrami coordinates coincide with the Cartesian ones. Nilpotent values $j_k=\iota_k$, $k>1$ correspond to a fiber (flag) spaces and imaginary values $j_k=i$ correspond to pseudo-Riemannian spaces.

Classical (1+3) kinematics[1] are obtained from CCS for $N=4$, $j_1=1,\iota_1,i$, $j_2=\iota_2,i$, $j_3=j_4=1$ if one interprets x_1 as the time axis $t=\xi_2\xi_1^{-1}$ and the rest as the space axes $r_k=\xi_{k+2}\xi_1^{-1}$, $k=1,2,3$.

The standard de Sitter kinematics $S_4^{(-)}$ with constant negative curvature is realized for $j_1=j_2=i$, anti-de Sitter kinematics $S_4^{(+)}$ with positive curvature—for $j_1=1$, $j_2=i$. Relativistic flat Minkowski kinematics M_4 appears for $j_1=\iota_1$, $j_2=i$. Nonrelativistic Newton $N_4^{(\pm)}$ and Galilei G_4 kinematics correspond to $j_2=\iota_2$, $j_1=1$, i and $j_1=\iota_1$, respectively.

If one interprets three first Beltrami coordinates as space axes, while the last one as a time axis, and puts $j_2=j_3=1,j_4=\iota_4$, then three exotic Carroll kinematics[1,17] are obtained, namely C_4^0 for $j_1=\iota_1$, with zero curvature, $C_4^{\pm}$ for $j_1=1,i$, with positive and negative curvature. The Carroll space and time have contrary properties as compared with those of Galilei kinematics. The Galilei time is absolute, i.e., two events simultaneous in some reference frame remain simultaneous in any reference frame that is obtained by Galilei boost (or space-time rotation) from the initial one. On the contrary, in Carroll kinematics the space is absolute, i.e. two events with the equal spatial coordinates in some reference frame have the same spatial coordinates in any reference frame that is obtained from the initial one by space-time rotation.

III. QUANTUM ORTHOGONAL GROUPS AND QUANTUM CAYLEY–KLEIN SPACES

According to FRT theory,[8] the algebra function on quantum orthogonal group $Fun(SO_q(N))$ [or simply quantum orthogonal group $SO_q(N)$] is the algebra of noncommutative polynomials of n^2 variables t_{ij}, $i,j=1,\ldots,n$, that are the subject of commutation relations,

$$R_qT_1T_2=T_2T_1R_q, \tag{3}$$

and additional relations of q orthogonality,

$$TCT^t=C,\quad T^tC^{-1}T=C^{-1}. \tag{4}$$

Here $T_1=T\otimes I$, $T_2=I\otimes T\in M_{n^2}(\mathbf{C}\langle t_{ij}\rangle)$, $T=(t_{ij})_{i,j=1}^n\in M_n(\mathbf{C}\langle t_{ij}\rangle)$, I is the unit matrix in $M_n(\mathbf{C})$, $C=C_0q^{\rho}$, $\rho=\mathrm{diag}(\rho_1,\ldots,\rho_N)$, $(C_0)_{ij}=\delta_{i'j}$, $i'=N+1-i$, $i,j=1,\ldots,N$, that is, $(C)_{ij}=q^{\rho_{i'}}\delta_{i'j}$ and $C^{-1}=C$,

$$(\rho_1,\ldots,\rho_N)=\begin{cases}\left(n-\frac{1}{2},n-\frac{3}{2},\ldots,\frac{1}{2},0,-\frac{1}{2},\ldots,-n+\frac{1}{2}\right), & N=2n+1,\\ (n-1,n-2,\ldots,1,0,0,-1,\ldots,-n+1), & N=2n.\end{cases} \tag{5}$$

The numerical matrix R_q is the well-known solution[8] of Yang–Baxter equation and its elements fulfils the role of the structure constant of quantum group generators.

Let us remind the definition of the quantum vector space.[8] An algebra $O_q^N(\mathbf{C})$ with generators $x_1,\ldots,x_N$ and commutation relations

$$\hat{R}_q(x\otimes x)=qx\otimes x-\frac{q-q^{-1}}{1+q^{N-2}}x^tCxW_q, \tag{6}$$

where $\hat{R}_q=PR_q$, $Pu\otimes v=v\otimes u$, $\forall u,v\in\mathbf{C}^n$, $W_q=\sum_{i=1}^N q^{\rho_{i'}}e_i\otimes e_{i'}$,

$$x^tCx=\sum_{i,j=1}^N x_iC_{ij}x_j=\epsilon x_{n+1}^2+\sum_{k=1}^n\left(q^{-\rho_k}x_kx_{k'}+q^{\rho_k}x_{k'}x_k\right), \tag{7}$$

$\epsilon=1$ for $N=2n+1$, $\epsilon=0$ for $N=2n$ and vector $(e_i)_k=\delta_{ik}$, $i,k=1,\ldots,N$ is called the algebra of functions on N-dimensional quantum Euclidean space (or simply the quantum Euclidean space) $O_q^N(\mathbf{C})$.

The coaction of the quantum group $SO_q(N)$ on the noncommutative vector space $O_q^N(\mathbf{C})$ is given by

$$\delta(x) = T\dot{\otimes}x, \quad \delta(x_i) = \sum_{k=1}^{n} t_{ik} \otimes x_k, \quad i = 1, \ldots, n, \tag{8}$$

and quadratic form (7) is invariant $\mathrm{inv}=x^tCx$ with respect to this coaction.

The matrix C has nonzero elements only on the secondary diagonal. They are equal to unity in the commutative limit $q=1$. Therefore the quantum group $SO_q(N)$ and the quantum vector space $O_q^N(\mathbf{C})$ are described by equations (3), (4), (6), (7) in a skew-symmetric basis, where for $q=1$ the invariant form $\mathrm{inv}=x^tC_0x$ is given by the matrix C_0 with the only nonzero elements on the secondary diagonal that are all equal to real units.

New generators $y=D^{-1}x$ of the vector space $O_q^N(\mathbf{C})$ in *arbitrary* basis are obtained[18,19] with the help of nondegenerate matrix $D \in M_N$ and they are subject of the commutation relations,

$$\hat{R}(y \otimes y) = qy \otimes y - \frac{\lambda}{1+q^{N-2}} y^t C' y W, \tag{9}$$

where $\hat{R}=(D\otimes D)^{-1}\hat{R}_q(D\otimes D)$, $W=(D\otimes D)^{-1}W_q$, $C'=D^tCD$. The corresponding quantum group $SO_q(N)$ is generated in arbitrary basis by $U=(u_{ij})_{i,j=1}^N$, where $U=D^{-1}TD$. The commutation relations of the new generators are

$$\tilde{R}U_1U_2 = U_2U_1\tilde{R} \tag{10}$$

and q-orthogonality relations look as follows:

$$U\tilde{C}U^t = \tilde{C}, \quad U^t(\tilde{C})^{-1}U = (\tilde{C})^{-1}, \tag{11}$$

where $\tilde{R}=(D\otimes D)^{-1}R_q(D\otimes D)$, $\tilde{C}=D^{-1}C(D^{-1})^t$.

In the case of kinematics, the most natural basis is the Cartesian basis, where the invariant form $\mathrm{inv}=y^ty$ is given by the unit matrix I. The transformation from the skew-symmetric basis x to the Cartesian basis y is described by the matrix D, which is a solution of the following equation:

$$D^tC_0D = I. \tag{12}$$

This equation has many solutions. Take one of these, namely

$$D = \frac{1}{\sqrt{2}} \begin{pmatrix} I & 0 & -i\tilde{C}_0 \\ 0 & \sqrt{2} & 0 \\ \tilde{C}_0 & 0 & iI \end{pmatrix}, \quad N = 2n+1, \tag{13}$$

where $\tilde{C}_0$ is the $n\times n$ matrix with real units on the secondary diagonal. For $N=2n$ the matrix D is given by (13) without the middle column and row. The matrix (13) provides one of the possible combinations of the quantum group structure and the CK scheme of group contractions. All other similar combinations are given by the matrices $D_\sigma=DV_\sigma$, obtained from (13) by the right multiplication on the matrix $V_\sigma \in M_N$ with elements $(V_\sigma)_{ik}=\delta_{\sigma_i,k}$, where $\sigma \in S(N)$ is a permutation of the Nth order.[20] The matrices D_σ are solutions of Eq. (12).

We derive the quantum Cayley–Klein spaces with the same transformation of the Cartesian generators $y=\psi\xi$, $\psi=\mathrm{diag}[1,(1,2),\ldots,(1,N)] \in M_N$, as in the commutative case.[2,19] The transformation $z=Jv$ of the deformation parameter $q=e^z$ should be added in the quantum case. The commutation relations of the Cartesian generators of the quantum N-dimensional Cayley–Klein space are given by the equations

$$\hat{R}_\sigma(j)\xi \otimes \xi = e^{Jv}\xi \otimes \xi - \frac{2shJv}{1+e^{Jv(N-2)}} \xi^t C_\sigma(j) \xi W_\sigma(j),$$

where

$$\hat{R}_\sigma(j) = \Psi^{-1}\hat{R}_\sigma\Psi, \quad W_\sigma(j) = \Psi^{-1}W_\sigma,$$

$$C_\sigma(j) = \psi D^t_\sigma C D_\sigma \psi = \psi V^t_\sigma D^t C D V_\sigma \psi, \quad \Psi = \psi \otimes \psi, \tag{14}$$

and in explicit form are

$$\xi_{\sigma_k}\xi_{\sigma_m} = \xi_{\sigma_m}\xi_{\sigma_k}\cosh Jv - i\xi_{\sigma_m}\xi_{\sigma_{k'}}(1,\sigma_{k'})(1,\sigma_k)^{-1}\sinh Jv, \quad k<m<k', \quad k\neq m',$$

$$\xi_{\sigma_k}\xi_{\sigma_m} = \xi_{\sigma_m}\xi_{\sigma_k}\cosh Jv - i\xi_{\sigma_{m'}}\xi_{\sigma_k}(1,\sigma_{m'})(1,\sigma_m)^{-1}\sinh Jv, \quad m'<k<m, \quad k\neq m',$$

$$[\xi_{\sigma_k},\xi_{\sigma_{k'}}] = 2i\epsilon\sinh\left(\frac{Jv}{2}\right)(\cosh Jv)^{n-k}\xi^2_{\sigma_{n+1}}\frac{(1,\sigma_{n+1})^2}{(1,\sigma_k)(1,\sigma_{k'})}$$
$$+ i\frac{\sinh(Jv)}{(\cosh Jv)^{k+1}(1,\sigma_k)(1,\sigma_{k'})}\sum_{m=k+1}^{n}(\cosh Jv)^m[(1,\sigma_m)^2\xi^2_{\sigma_m} + (1,\sigma_{m'})^2\xi^2_{\sigma_{m'}}], \tag{15}$$

where $k,m=1,2,\ldots,n$. The invariant form of the Cayley–Klein space $O^N_v(j;\sigma;\mathbf{C})$ is written as

$$\mathrm{inv}(j) = \cosh(Jv\rho_1)\left(\epsilon(1,\sigma_{n+1})^2\xi^2_{\sigma_{n+1}}\frac{(\cosh Jv)^n}{\cosh(Jv/2)} + \sum_{k=1}^{n}((1,\sigma_k)^2\xi^2_{\sigma_k} + (1,\sigma_{k'})^2\xi^2_{\sigma_{k'}})(\cosh Jv)^{k-1}\right). \tag{16}$$

The multiplier J in the transformation $z=Jv$ of the deformation parameter is chosen as $J=\cup^n_{k=1}(\sigma_k,\sigma_{k'})$. This is the minimal multiplier, which guarantees the existence of the Hopf algebra structure for the associated quantum group $SO_v(N;j;\sigma)$. The "union" $(\sigma_k,\sigma_p)\cup(\sigma_m,\sigma_r)$ is understood as the first power multiplication of all parameters j_k, which occur at least in one multiplier (σ_k,σ_p) or (σ_m,σ_r), for example, $(j_1j_2)\cup(j_2j_3)=j_1j_2j_3$.

The quantum orthogonal Cayley–Klein sphere $S^{(N-1)}_v(j;\sigma)$ is obtained as the quotient of $O^N_v(j;\sigma)$ by $\mathrm{inv}(j)=1$. The quantum analogs of the intrinsic Beltrami coordinates on this sphere are given by the sets of independent right or left generators,

$$r_{\sigma_i-1} = \xi_{\sigma_i}\xi_1^{-1}, \quad \hat{r}_{\sigma_i-1} = \xi_1^{-1}\xi_{\sigma_i}, \quad i=1,\ldots,N, \quad i\neq k, \quad \sigma_k = 1. \tag{17}$$

In the case of quantum Euclidean spaces $O^N_q(\mathbf{C})$, the use of different D_σ for $\sigma\in S(N)$ makes no sense, because all similarly obtained quantum spaces are isomorphic. However, the situation is radically different for the quantum Cayley–Klein spaces. In this case the Cartesian generators ξ_k are multiplied by $(1,k)$ and for nilpotent values of all or some parameters j_k this isomorphism of quantum vector spaces is destroyed. The necessity of using different D_σ arises as well if there is some physical interpretation of generators. In this case physically different generators may be confused by permutations σ, for example, time and space generators of kinematics. Mathematically isomorphic kinematics may be physically nonequivalent.

IV. QUANTUM KINEMATICS

For $N=5$ the thorough analysis of the multiplier $J=(\sigma_1,\sigma_5)\cup(\sigma_2,\sigma_4)$, which appears in the transformation of the deformation parameter $z=Jv$, and commutation relations (15) of the quantum space generators for different permutations allowed to find three permutations giving different J and a physically nonequivalent kinematics, namely $\sigma_0=(1,2,3,4,5)$, $\sigma'=(1,4,3,5,2)$, $\tilde{\sigma}=(2,3,1,4,5)$.

In order to clarify the relation with the standard Inonu–Wigner contraction procedure,[21] the mathematical parameter j_1 is replaced by the physical one $\tilde{j}_1T^{-1}$, and the parameter j_2 is replaced

by ic^{-1}, where $\tilde{j}_1=1,i$. The limit $T\to\infty$ corresponds to the contraction $j_1=\iota_1$, and the limit $c\to\infty$ corresponds to $j_2=\iota_2$. The parameter T is interpreted as the curvature radius and has the physical dimension of time $[T]=[\text{time}]$, the parameter c is the light velocity $[c]=[\text{length}]\times[\text{time}]^{-1}$.

As far as the generator ξ_1 does not commute with others, it is convenient to introduce right and left time $t=\xi_2\xi_1^{-1}$, $\hat{t}=\xi_1^{-1}\xi_2$ and space $r_k=\xi_{k+2}\xi_1^{-1}$, $\hat{r}_k=\xi_1^{-1}\xi_{k+2}$, $k=1,2,3$, generators. The reason for this definition is the simplification of expressions for commutation relations of quantum kinematics. It is possible to use only, say, right generators, but its commutators are cumbersome in the case of the (anti-)de Sitter kinematics. The commutation relations of the independent generators are obtained (see Ref. 22 for details) in the form

$$S_v^{4(\pm)}(\sigma_0)=\left\{t,\mathbf{r}|\hat{t}r_1=\hat{r}_1t\cos\frac{\tilde{j}_1v}{cT}+i\hat{r}_1r_2\frac{1}{c}\sin\frac{\tilde{j}_1v}{cT},\ \hat{t}r_2-\hat{r}_2t=-2i\hat{r}_1r_1\frac{1}{c}\sin\frac{\tilde{j}_1v}{2cT},\ \hat{t}r_3=\hat{r}_3t\cos\frac{\tilde{j}_1v}{cT}\right.$$
$$\left.-it\frac{cT}{\tilde{j}_1}\sin\frac{\tilde{j}_1v}{cT},\ \hat{r}_1r_2=\hat{r}_2r_1\cos\frac{\tilde{j}_1v}{cT}-i\hat{t}r_1c\sin\frac{\tilde{j}_1v}{cT},\ \hat{r}_pr_3=\hat{r}_3r_p\cos\frac{\tilde{j}_1v}{cT}-ir_p\frac{cT}{\tilde{j}_1}\sin\frac{\tilde{j}_1v}{cT}\right\},\tag{18}$$

where the right and left generators are connected as follows:

$$r_3-\hat{r}_3=2i\frac{\tilde{j}_1}{cT}\left(\left(\hat{t}t-\frac{1}{c^2}\hat{r}_2r_2\right)\cos\frac{\tilde{j}_1v}{2cT}-i\frac{1}{c^2}\hat{r}_1r_1\cos\frac{\tilde{j}_1v}{cT}\right)\sin\frac{\tilde{j}_1v}{2cT},$$

$$\hat{r}_p=r_p\cos\frac{\tilde{j}_1v}{cT}-i\hat{r}_3r_p\frac{\tilde{j}_1}{cT}\sin\frac{\tilde{j}_1v}{cT},\quad p=1,2,\tag{19}$$

$$\hat{t}=t\cos\frac{\tilde{j}_1v}{cT}-i\hat{r}_2t\frac{\tilde{j}_1}{cT}\sin\frac{\tilde{j}_1v}{cT}.$$

$$S_v^{4(\pm)}(\sigma')=\left\{t,\mathbf{r}|\hat{r}_kt=\hat{t}r_k\cosh\frac{\tilde{j}_1v}{T}-ir_k\frac{T}{\tilde{j}_1}\sinh\frac{\tilde{j}_1v}{T},\ \hat{r}_2r_1=\hat{r}_1r_2\cosh\frac{\tilde{j}_1v}{T}-i\hat{r}_1r_3\sinh\frac{\tilde{j}_1v}{T},\ \hat{r}_1r_3\right.$$
$$\left.=\hat{r}_3r_1\cosh\frac{\tilde{j}_1v}{T}-i\hat{r}_2r_1\sinh\frac{\tilde{j}_1v}{T},\ \hat{r}_2r_3-\hat{r}_3r_2=2i\hat{r}_1r_1\sinh\frac{\tilde{j}_1v}{2T}\right\},\tag{20}$$

where the right and left generators are connected as

$$\hat{r}_k=r_k\cosh\frac{\tilde{j}_1v}{T}+i\hat{t}r_k\frac{\tilde{j}_1}{T}\sinh\frac{\tilde{j}_1v}{T},$$

$$\hat{t}=t+2i\frac{\tilde{j}_1}{c^2T}\left(\hat{r}_1r_1\cosh\frac{\tilde{j}_1v}{T}+(\hat{r}_2r_2+\hat{r}_3r_3)\cosh\frac{\tilde{j}_1v}{2T}\right)\sinh\frac{\tilde{j}_1v}{2T},\tag{21}$$

$$S_v^{4(\pm)}(\tilde{\sigma})=\left\{t,\mathbf{r}|\hat{t}r_p=\hat{r}_pt\cos\frac{v}{c}+i\hat{r}_pr_3\frac{1}{c}\sin\frac{v}{c},\ \hat{t}r_3-\hat{r}_3t=2i\frac{cT^2}{\tilde{j}_1^2}\left(\cos\frac{v}{c}-\frac{\tilde{j}_1^2}{c^2T^2}(\hat{r}_1r_1+\hat{r}_2r_2)\cos\frac{v}{2c}\right)\right.$$

$$\times \sin\frac{v}{2c},\ \hat{r}_p r_3 = \hat{r}_3 r_p \cos\frac{v}{c} - i\hat{t} r_p c \sin\frac{v}{c},\ \hat{r}_1 r_2 - \hat{r}_2 r_1 = 2\frac{c^2 T^2}{\widetilde{j}_1^2}\sin\frac{v}{2c}\Bigg\} \tag{22}$$

where $k=1,2,3$, $p=1,2$, and the left and right generators are connected by the following relations:

$$\hat{t} = t\cos\frac{v}{c} + ir_3\frac{1}{c}\sin\frac{v}{c}, \quad \hat{r}_1 = r_1\cos\frac{v}{c} + r_2\sin\frac{v}{c},$$
$$\hat{r}_2 = r_2\cos\frac{v}{c} - r_1\sin\frac{v}{c}, \quad \hat{r}_3 = r_3\cos\frac{v}{c} + itc\sin\frac{v}{c}. \tag{23}$$

In the case of the identical permutation σ_0, deformation parameter v for the system units, where $\hbar=1$, has the physical dimension of length $[v]=[cT]=[\text{length}]$ and may be interpreted as the fundamental length. For the permutation σ', the quantum (anti-) de Sitter kinematics (20) are characterized by the fundamental time $[v]=[\text{time}]$ and for the permutation $\widetilde{\sigma}$ are characterized by the fundamental velocity $[v]=[\text{velocity}]$. Recall that the same physical dimensions of the deformation parameter have been obtained for the quantum algebras $so_v(3;j;\sigma)$ and corresponding $(1+1)$ kinematics for different permutations.[23]

As it follows from (22), (23), both contractions $T\to\infty$, $c\to\infty$ are not permitted, therefore the quantum (anti-) de Sitter kinematics $S_v^{4(\pm)}(\widetilde{\sigma})$ do not have Minkowski, Newton, and Galilei kinematics as limiting cases.

In the zero curvature limit $T\to\infty$ two quantum Minkowski kinematics are obtained,

$$M_v^4(\sigma_0) = \{t,\mathbf{r}|[t,r_p]=0,\ [r_3,t]=ivt,\ [r_2,r_1]=0,\ [r_3,r_p]=ivr_p,\ p=1,2,\},$$
$$M_v^4(\sigma') = \{t,\mathbf{r}|[t,r_k]=ivr_k,\ [r_i,r_k]=0,\ i,k=1,2,3\}. \tag{24}$$

The first one is isomorphic to the tachyonic κ-Minkowski kinematics, the second one to the standard κ-deformation.[11–13] For both κ-Minkowski kinematics in the system units $\hbar=c=1$, the deformation parameter $\Lambda=\kappa^{-1}$ has the physical dimension of length and is interpreted as the fundamental length. But in the system units $\hbar=1$ the deformation parameter has different dimensions, namely v is the fundamental length for $M_v^4(\sigma_0)$ and v is the fundamental time for $M_v^4(\sigma')$.

As far as the commutation relations (24) do not depend on c, they do not change in the limit $c\to\infty$, therefore the generators of the quantum Galilei kinematics $G_v^4(\sigma_0)$ and $G_v^4(\sigma')$ are the subject of the same commutation relations. The only difference consists in the following statement: for the Galilei kinematics there are two invariants $\text{inv}_1=t^2$, $\text{inv}_2=r_1^2+r_2^2+r_3^2$ with respect to the coaction of the corresponding quantum groups, whereas for the Minkowski kinematics there is only one invariant $\text{inv}=t^2-(r_1^2+r_2^2+r_3^2)$. Thereby the quantum deformations of the flat kinematics are identical up to the coaction of the corresponding quantum groups for both relativistic and nonrelativistic kinematics.

In the nonrelativistic limit $c\to\infty$ there are two noncommutative analogs of the Newton kinematics:

$$N_v^{4(\pm)}(\sigma_0) = \left\{t,\mathbf{r}|[t,r_p]=0,\ [r_3,t]=ivt\left(1+\widetilde{j}_1^2\frac{t^2}{T^2}\right),\ [r_1,r_2]=0,\ [r_3,r_p]=ivr_p\left(1+\widetilde{j}_1^2\frac{t^2}{T^2}\right),\ p=1,2\right\},$$

$$N_v^{4(\pm)}(\sigma') = \left\{t,\mathbf{r}|[t,r_k]=i\left(r_k+\frac{\widetilde{j}_1^2}{T^2}tr_k t\right)\frac{T}{\widetilde{j}_1}\tanh\frac{\widetilde{j}_1 v}{T},\ r_2r_1 = r_1r_2\cosh\frac{\widetilde{j}_1 v}{T} - ir_1r_3\sinh\frac{\widetilde{j}_1 v}{T},\ r_1r_3\right.$$
$$\left. = r_3r_1\cosh\frac{\widetilde{j}_1 v}{T} - ir_2r_1\sinh\frac{\widetilde{j}_1 v}{T},\ [r_2,r_3]=2ir_1^2\sinh\frac{\widetilde{j}_1 v}{2T}\right\}, \tag{25}$$

where in the last case the deformation parameter is not transformed under contraction. The mul-

tiplier T^{-1} appears as the result of the physical interpretation of the quantum space generators. For nonzero curvature kinematics commutation relations of generators depend on c and are different for relativistic and nonrelativistic cases, unlike Minkowski and Galilei kinematics.

The exotic Carroll kinematics are also realized as constant curvature spaces, but with different interpretation of the Beltrami coordinates, namely $r_k=\xi_{k+1}\xi_1^{-1}$, $k=1,2,3$ are the space generators and $t=\xi_5\xi_1^{-1}$ is the time generator. Due to this interpretation the new physical dimensions of the contraction parameters appear: the parameter j_1 is replaced by $\tilde{j}_1 R^{-1}$, where $R\to\infty$ corresponds to $j_1=\iota_1$ and $[R]=[\text{length}]$; the parameter j_4 is replaced by c, where $c\to 0$ corresponds to $j_4=\iota_4$ and $[c]=[\text{velocity}]$. There are three noncommutative analogs of the exotic nonzero curvature Carroll kinematics:

$$C_v^{4(\pm)}(\sigma_0)=\left\{t,\mathbf{r}|[t,r_k]=iv r_k\left(1+\frac{\tilde{j}_1^2}{R^2}\mathbf{r}^2\right),\ [r_i,r_k]=0,\right\},$$

$$C_v^{4(\pm)}(\sigma')=\left\{t,\mathbf{r}|[t,r_1]=0,\ [t,r_2]=iv\frac{\tilde{j}_1}{R}r_3r_2,\ [r_3,t]=iv\frac{\tilde{j}_1}{R}r_1^2,\ [r_i,r_k]=0,\right\}, \tag{26}$$

$$C_v^{4(\pm)}(\tilde{\sigma})=\left\{t,\mathbf{r}|[t,r_p]=0,\ [r_i,r_k]=0,\ [r_1,t]=iv\left(\frac{R^2}{\tilde{j}_1^2}+\mathbf{r}^2\right)\right\}.$$

Two quantum analogs of the zero curvature Carroll kinematics are achieved in the limit $R\to\infty$ and are as follows:

$$\begin{aligned} C_v^{4(0)}(\sigma_0)&=\{t,\mathbf{r}|[t,r_k]=iv r_k,\ [r_i,r_k]=0,\ i,k=1,2,3\},\\ C_v^{4(0)}(\sigma')&=\{t,\mathbf{r}|[t,r_k]=0,\ [r_i,r_k]=0,\ i,k=1,2,3\}. \end{aligned} \tag{27}$$

For the permutations σ_0, σ' the deformation parameter $v=Rc^{-1}$ has the physical dimension of time $[v]=[\text{time}]$ and is interpreted as the fundamental time. For the permutation $\tilde{\sigma}$ the deformation parameter $v=c^{-1}$ has the dimension of inverse velocity $[v]=[\text{velocity}]^{-1}$ and may be interpreted as the fundamental velocity.

V. CONCLUSION

We have reformulated the quantum orthogonal group $SO_q(N)$ and the corresponding q-Euclidean space O_q^N in Cartesian coordinates and then used the standard trick with real, complex, and dual numbers in order to define the quantum Cayley–Klein spaces of constant curvature $O_q^N(j;\sigma)$ uniformly, using a q analog of Beltrami coordinates. The different combinations of quantum structure and CK scheme of contractions and analytical continuations are described with the help of permutations σ. As a result, for $N=5$, the quantum deformations of (anti-) de Sitter, Minkowski, Newton, Galilei, and Carroll kinematics are obtained.

We have found two types of the noncommutative realistic space-time models with fundamental length and fundamental time, which admit nonrelativistic and zero curvature limits and one type of the (anti-) de Sitter kinematics with fundamental velocity, where both limits are forbidden. For the exotic Carroll kinematics there are two types with fundamental time, which admit zero curvature limit and one type with fundamental velocity, where this limit is forbidden.

The quantum Galilei kinematics $G_v^4(\sigma_0)$ and $G_v^4(\sigma')$ have the same commutation relations (24) as the quantum Minkowski kinematics $M_v^4(\sigma_0)$ and $M_v^4(\sigma')$. In other words, the quantum deformations of the flat kinematics are identical up to the coaction of the corresponding quantum groups, whereas for nonzero curvature kinematics commutation relations of generators are different for relativistic and nonrelativistic cases.

In spite of the fact that the commutation relations of generators of Carroll $C_v^{4(0)}(\sigma_0)$ (27) and Minkowski $M_v^4(\sigma')$ (24) kinematics are identical, both kinematics are physically different. Mathematically isomorphic kinematics may be physically nonequivalent.

Noncommutative kinematics are obtained by the interpretation of some mathematical constructions associated with quantum groups and quantum spaces. The deformation parameter is free parameter of these models. Which type of model is more appropriate and what is the value of deformation parameter are questions of experimental study.

In this paper we investigate the equation for time-like extremal surfaces in the Minkowski space $\mathbb{R}^{2+n}$, and show that this kind of equation enjoys many interesting properties nonstrict hyperbolicity, constant multiplicity of eigenvalues, boundedness of characteristic propagation speeds, linear degeneracy of all characteristic fields, richness, etc. Without any smallness assumption of initial data, we give the necessary and sufficient condition on the global existence of classical solutions of the Cauchy problem. Based on this, we prove some global existence theorems on classical solutions of the Dirichlet problem and Neumann problem for this kind of equation. Finally, we present an explicit exact representation, involving two independent arbitrary functions of general solution. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2158435]

I. INTRODUCTION AND MAIN RESULTS

Let (t,x,y) be points in the $(1+2)$-dimensional Minkowski space. A time-like surface takes the form

$$y = \phi(t,x). \tag{1.1}$$

This surface is called to be *extremal surface* if ϕ is the critical point of the area functional,

$$I_1 = \int\int \sqrt{1+\phi_x^2-\phi_t^2}\,dx\,dt. \tag{1.2}$$

The corresponding Euler–Lagrange equation is

$$\left(\frac{\phi_t}{\sqrt{1+\phi_x^2-\phi_t^2}}\right)_t - \left(\frac{\phi_x}{\sqrt{1+\phi_x^2-\phi_t^2}}\right)_x = 0. \tag{1.3}$$

Recently, Brenier[1] discussed an equation for generalized extremal surfaces in the five-dimensional Minkowski space, from which the Vlasov-Maxwell system of classical electrodynamics can be formlly derived. Similar to the geometric ideas of the Born-Infeld nonlinear theory of the electromagnetic field (see Ref. 2), Brenier[3] tried to design a nonlinearly cutoff theory for classical electrodynamics, instead of considering springs linking two particles of opposite charges, he considered surfaces $(t,s)\to X(t,s)$ spanning curves $t\to X_-(t)$ and $t\to X_+(t)$ followed by two particles of opposite charge, so that $X(s=-1,t)=X_-(t)$ and $X(s=1,t)=X_+(t)$, $s\in[-1,1]$ standing for the *interpolation* parameter between the two trajectories. Just by prescribing (t,s)

a)Corresponding author.

$\rightarrow (t,s,X(t,s))$ to be an extremal surface in the five-dimensional Minkowski space (t,s,x_1,x_2,x_3) with the signature $(-,+,+,+,+)$, he got the building block of the model: the individual action of each surface is

$$I_3 = \int\int \sqrt{1+|\partial_s X|^2 - |\partial_t X|^2 - |\partial_s X \times \partial_t X|^2}\, ds\, dt, \tag{1.4}$$

which is basically the Nambu–Goto action of classical string theory. The Euler–Lagrange equation corresponding to the functional (1.4) is

$$\left(\frac{\phi_t}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t\times\phi_x|^2}}\right)_t - \left(\frac{\phi_x}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t\times\phi_x|^2}}\right)_x + \left(\frac{\phi_x\times(\phi_t\times\phi_x)}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t\times\phi_x|^2}}\right)_t - \left(\frac{\phi_t\times(\phi_t\times\phi_x)}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t\times\phi_x|^2}}\right)_x = 0, \tag{1.5}$$

where x stands for s in (1.4) and $\phi=(\phi_1,\phi_2,\phi_3)^T$ represents X in (1.4).

More generally, we consider a vector function $\phi=(\phi_1,\ldots,\phi_n)^T$, which is the critical point of the area functional,

$$I_n = \int\int \sqrt{1+|\phi_x|^2-|\phi_t|^2|\phi_x|^2+\langle\phi_t,\phi_x\rangle^2}\, dx\, dt, \tag{1.6}$$

where $\langle\cdot,\cdot\rangle$ stands for the inner product. The Euler–Lagrange equation is

$$\left(\frac{\phi_t+|\phi_x|^2\phi_t-\langle\phi_t,\phi_x\rangle\phi_x}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t|^2|\phi_x|^2+\langle\phi_t,\phi_x\rangle^2}}\right)_t - \left(\frac{\phi_x+\langle\phi_t,\phi_x\rangle\phi_t-|\phi_t|^2\phi_x}{\sqrt{1+|\phi_x|^2-|\phi_t|^2-|\phi_t|^2|\phi_x|^2+\langle\phi_t,\phi_x\rangle^2}}\right)_x = 0. \tag{1.7}$$

Remark 1.1: When $n=1$, *the equation (1.7) is nothing but the equation (1.3); moreover, if*

$$1+\phi_x^2-\phi_t^2>0, \tag{1.8}$$

i.e., the surface is time-like, then (1.3) is just the Born–Infeld equation (see Ref. 2). The Born–Infeld as well as the hydrodynamic version of the equation has been considered by Arik et al.[4] *On the other hand, when* $n=3$, *the equation (1.7) goes back to the equation (1.5).*

(1.7) is the equation for time-like extremal surfaces in the Minkowski space $\mathbb{R}^{2+n}$. The extremal surfaces in the Minkowski space are C^2 surfaces with vanishing mean curvature. The time-like case have been investigated by several authors (e.g., Refs. 5 and 6). Barbashov, Nesterenko, and Chervyakov[5] studied the nonlinear differential equations describing in differential geometry the minimal surfaces in the pseudo-Euclidean space. The geometric nature of these equations allows one to obtain explicitly their general solutions. Milnor[6] described all entire time-like minimal surfaces in the three-Minkowski space via a kind of Weierstrass representation. Gu[7–10] studied the extremal surfaces of mixed type in the n-dimensional Minkowski space (Refs. 11, 7, and 9 for the case $n=3$). Under the assumptions that the surfaces is C^3 (C^2 for the case $n=3$), and the gradient of the square of the area density does not vanish on the light-like points of the surface, by linearizing the equation via the Legendre transformation or the generalized isothermal coordinates, Gu obtained the general explicit expression of the surface and proved that (i) the time-like part and space-like part are separated by a null curve; (ii) the surface is analytic not only on the space-like part but also in some mixed region. Moreover, many complete extremal surfaces of mixed type in the three-Minkowski space are constructed with explicit expressions (see Ref. 10). In addition, the multidimensional versions of the system (1.7) has been addressed recently and successfully by Lindblad[12] and, later, by Chae and Huh[13] in a more general framework. They proved the existence of global smooth solutions for small initial data, using the null forms in the style of Christodoulou and Klainerman style (see Refs. 14 and 15).

In the present paper, we study the equation (1.7) using a different method and obtain a complete result on global classical solutions of the Cauchy problem, Dirichlet problem, and Neumann problem for this kind of equation. Moreover, we also present an explicit exact representation, involving two independent arbitrary functions, of a general solution of the equation (1.7). Here we particularly emphasize that, in our arguments, we do not require the smallness of the initial data.

Let

$$u = \phi_x, \quad v = \phi_t, \tag{1.9}$$

where $u=(u_1,\ldots,u_n)^T$ and $v=(v_1,\ldots,v_n)^T$. Then (1.7) can be equivalently rewritten as

$$u_t - v_x = 0,$$

$$\left(\frac{v+|u|^2v-\langle u,v\rangle u}{\sqrt{1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2}}\right)_t - \left(\frac{u+\langle u,v\rangle v-|v|^2u}{\sqrt{1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2}}\right)_x = 0, \tag{1.10}$$

for classical solutions. In this paper, we investigate many interesting properties enjoyed by the system (1.10) such as nonstrict hyperbolicity, constant multiplicity of eigenvalues, boundedness of characteristic propagation speeds, linear degeneracy of all characteristic fields, richness, etc. Based on this, we prove some global existence theorems on classical solutions of the Cauchy problem, Dirichlet problem, and Neumann problem for the equation (1.7), and present an explicit exact representation, involving two independent arbitrary functions, of the general solution of (1.7).

Let

$$\Delta(u,v) = 1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2. \tag{1.11}$$

Our main results are the following Theorem 1.1 and Theorem 1.2.

Theorem 1.1: *Suppose* $n\geqslant 2$ *and suppose furthermore that on the domain under consideration*,

$$\Delta(u,v) > 0, \tag{1.12}$$

holds, then (1.10) is a nonstrictly hyperbolic system with two n-constant multiple eigenvalues; moreover, the characteristic propagation speeds are bounded (not larger than the light speed), all characteristic fields are linearly degenerate in the sense of Lax (see Ref. 16) and the system (1.10) is rich in the sense of Serre (see Ref. 17).

Remark 1.2: For the case $n=1$, *if (1.8) is satisfied, then as pointed out in Remark 1.1, (1.7) is nothing but the Born–Infeld equation. In this case, it is easy to verify that the system (1.10) is a* 2×2 *strictly hyperbolic system, and both characteristic fields are linearly degenerate. Moreover, the richness of the system (1.10) becomes trivial in the present situation.*

Remark 1.3: In fact, the assumption (1.12) is nothing but the condition which guarantees that the surface is timelike. When $n=1$, *(1.12) is just (1.8). Thus, for every timelike surface the conclusion of Theorem 1.1 is always true.*

We next consider the Cauchy problem for Eq. (1.7) with the initial data

$$\phi(0,x) = f(x), \quad \phi_t(0,x) = g(x), \tag{1.13}$$

where f is a given C^2 vector-valued function and g is a given C^1 vector-valued function. Define

$$\Lambda_\pm(x) = \frac{1}{1+|f'(x)|^2}\left[-\langle f'(x),g(x)\rangle \pm \sqrt{\Delta(f'(x),g(x))}\right]. \tag{1.14}$$

We assume that

$$\Lambda_+(x) > \Lambda_-(y), \quad \forall\, x,y \in \mathbb{R}. \tag{1.15}$$

In Sec. III, we shall prove the following global existence theorem.

Theorem 1.2: *The Cauchy problem [(1.7) and (1.13)] admits a unique global C^2 solution $\phi=\phi(t,x)$ on $\mathbb{R}^+\times\mathbb{R}$ if and only if* (1.15) *is satisfied. Moreover, if the global classical solution $\phi=\phi(t,x)$ exists, then it satisfies*

$$\Delta(\phi_x(t,x),\phi_t(t,x)) > 0, \quad \forall\, (t,x) \in \mathbb{R}^+\times\mathbb{R}. \tag{1.16}$$

Remark 1.4: The assumption (1.15) guarantees the validity of the hypothesis (1.12). That is, under the assumption (1.15) the surface is timelike. If (1.15) is not satisfied, then the solution may enlarge in finite time and singularities will appear. In this case, Eq. (1.7) loses the hyperbolicity at the points where the fast characteristic meets the slow characteristic. In geometry, this corresponds to the fact that the surface is no longer timelike at these points.

Remark 1.5: Theorem 1.2 solves an open problem of Brenier (see [6]).

The paper is organized as follows. In Sec. II, we first simplify the system (1.10) and then give the eigenvalues, the left and right eigenvectors of the system (1.10); based on this, we investigate many interesting properties enjoyed by the system (1.10) and then prove Theorem 1.1. Section III is devoted to the proof of Theorem 1.2. Based on Theorem 1.2, in Sec. IV, we study the global existence of the classical C^2 solutions of the Dirichlet and Neumann problems for Eq. (1.7). In Sec. V, we present an explicit exact representation, involving two independent arbitrary functions, of general solution of Eq. (1.7). Finally, the global existence of the classical solutions is discussed in Sec. VI for the inhomogeneous Dirichlet problem for (1.7).

II. PROPERTIES ENJOYED BY THE SYSTEM (1.10)—PROOF OF THEOREM 1.1

This section is devoted to the study on many interesting properties enjoyed by the system (1.10).

To do so, we first simplify (1.10). Let

$$\Phi = (1+|u|^2)v - \langle u,v\rangle u, \quad \Psi = (1-|v|^2)u + \langle u,v\rangle v. \tag{2.1}$$

The second equation in (1.10) can be rewritten as

$$\left(\frac{\Phi}{\sqrt{\Delta(u,v)}}\right)_t - \left(\frac{\Psi}{\sqrt{\Delta(u,v)}}\right)_x = 0, \tag{2.2}$$

namely,

$$\Phi\frac{\partial\Delta(u,v)}{\partial t} - \Psi\frac{\partial\Delta(u,v)}{\partial x} + 2\Delta(u,v)(\Psi_x - \Phi_t) = 0. \tag{2.3}$$

Substituting (1.11) and (2.1) into (2.3) gives

$$(1+|u|^2)O - 2\langle u,v\rangle P - (1-|v|^2)Q = 0, \tag{2.4}$$

where

$$\begin{aligned}
O &= \Delta(u,v)v_t + (1+|u|^2)\langle v,v_t\rangle v - \langle u,v\rangle\langle u,v_t\rangle v - \langle u,v\rangle\langle v,v_t\rangle u - (1-|v|^2)\langle u,v_t\rangle u,\\
P &= \Delta(u,v)v_x + (1+|u|^2)\langle v,v_x\rangle v - \langle u,v\rangle\langle u,v_x\rangle v - \langle u,v\rangle\langle v,v_x\rangle u - (1-|v|^2)\langle u,v_x\rangle u,\\
Q &= \Delta(u,v)u_x + (1+|u|^2)\langle v,u_x\rangle v - \langle u,v\rangle\langle u,u_x\rangle v - \langle u,v\rangle\langle v,u_x\rangle u - (1-|v|^2)\langle u,u_x\rangle u.
\end{aligned} \tag{2.5}$$

We can write the system (2.4) as the following matrix equation:

$$M\mathbf{v}_t - \frac{2\langle u,v\rangle}{1+|u|^2}M\mathbf{v}_x - \frac{1-|v|^2}{1+|u|^2}M\mathbf{u}_x = 0, \tag{2.6}$$

where

$$M = \Delta(u,v)I_{n\times n} + (1+|u|^2)vv^T - \langle u,v\rangle vu^T - \langle u,v\rangle uv^T - (1-|v|^2)uu^T, \tag{2.7}$$

$$\mathbf{v} = \begin{bmatrix} v_1 & 0 & \cdots & 0 & 0 \\ 0 & v_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & v_{n-1} & 0 \\ 0 & 0 & \cdots & 0 & v_n \end{bmatrix}, \quad \mathbf{u} = \begin{bmatrix} u_1 & 0 & \cdots & 0 & 0 \\ 0 & u_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & u_{n-1} & 0 \\ 0 & 0 & \cdots & 0 & u_n \end{bmatrix}. \tag{2.8}$$

Therefore, the system (1.10) can be equivalently rewritten as

$$u_t - v_x = 0,$$

$$M\mathbf{v}_t - \frac{2\langle u,v\rangle}{1+|u|^2}M\mathbf{v}_x - \frac{1-|v|^2}{1+|u|^2}M\mathbf{u}_x = 0. \tag{2.9}$$

Lemma 2.1: If A is a nonsingular $m_1\times m_1$ square matrix, D is a nonsingular $m_2\times m_2$ square matrix, B is a $m_1\times m_2$ matrix, and C is a $m_2\times m_1$ matrix, where m_1, m_2 are two positive integers, then it holds that

$$|A|\cdot|D - CA^{-1}B| = |D|\cdot|A - BD^{-1}C|. \tag{2.10}$$

Proof: In fact, (2.10) follows from the following identities directly:

$$\begin{vmatrix} A & B \\ C & D \end{vmatrix} = \begin{vmatrix} A & B \\ 0 & D - CA^{-1}B \end{vmatrix} = \begin{vmatrix} A - BD^{-1}C & B \\ 0 & D \end{vmatrix}.$$

■

Lemma 2.2: If

$$\Delta(u,v) > 0, \tag{2.11}$$

then

$$|M| = (\Delta(u,v))^{n-1} > 0. \tag{2.12}$$

Proof: By (1.11), we have

$$\Delta(u,v) = (1+|u|^2)(1-|v|^2) + \langle u,v\rangle^2. \tag{2.13}$$

On the other hand, it follows from (2.7) that

$$M = \Delta(u,v)I_{n\times n} + [u,v]\begin{bmatrix} a & b \\ c & d \end{bmatrix}\begin{bmatrix} u^T \\ v^T \end{bmatrix}, \tag{2.14}$$

where

$$a = -(1-|v|^2), \quad b = c = -\langle u,v\rangle, \quad d = 1+|u|^2. \tag{2.15}$$

Noting (2.13) and (2.15) gives

$$\Delta(u,v) = bc - ad. \tag{2.16}$$

Let

$$A=\Delta(u,v)I_{n\times n},\quad B=[u,v],\quad C=\begin{bmatrix}u^T\\ v^T\end{bmatrix},\quad D=-\begin{bmatrix}a & b\\ c & d\end{bmatrix}^{-1}. \tag{2.17}$$

By (2.11) and (2.16), we find that A is a nonsingular $n\times n$ matrix, D is a nonsingular 2×2 matrix. On the other hand, it follows from (2.14) that

$$|M|=|A+B(-D)^{-1}C|=|A-BD^{-1}C|=\frac{1}{|D|}\cdot|D|\cdot|A-BD^{-1}C|. \tag{2.18}$$

We now apply Lemma 2.1 and obtain

$$|M|=\frac{1}{|D|}\cdot|A|\cdot|D-CA^{-1}B|. \tag{2.19}$$

Substituting (2.17) into (2.19) and noting (2.15) yields

$$\begin{aligned}|M|&=\frac{|\Delta(u,v)I_{n\times n}|}{\left|-\begin{bmatrix}a & b\\ c & d\end{bmatrix}^{-1}\right|}\left|-\begin{bmatrix}a & b\\ c & d\end{bmatrix}^{-1}-\begin{bmatrix}u^T\\ v^T\end{bmatrix}(\Delta(u,v)I_{n\times n})^{-1}[u,v]\right|\\ &=\frac{(\Delta(u,v))^n}{(-\Delta(u,v))^{-1}}\left|\frac{1}{\Delta(u,v)}\begin{bmatrix}d & -b\\ -c & a\end{bmatrix}-\frac{1}{\Delta(u,v)}\begin{bmatrix}u^Tu & u^Tv\\ v^Tu & v^Tv\end{bmatrix}\right|\\ &=-(\Delta(u,v))^{n-1}\begin{vmatrix}d-u^Tu & -b-u^Tv\\ -c-v^Tu & a-v^Tv\end{vmatrix}=-(\Delta(u,v))^{n-1}\begin{vmatrix}1 & 0\\ 0 & -1\end{vmatrix}=(\Delta(u,v))^{n-1}>0.\end{aligned} \tag{2.20}$$

Thus, the proof of Lemma 2.2 is completed. ■

Remark 2.1: In particular, when $n=1$, we have $|M|=1$.

Throughout this section, we always assume that (2.11) is satisfied. Thus, by Lemma 2.2, the system (2.9) can be simplified as

$$u_t-v_x=0,$$

$$v_t-\frac{2\langle u,v\rangle}{1+|u|^2}v_x-\frac{1-|v|^2}{1+|u|^2}u_x=0. \tag{2.21}$$

Let

$$U=(u_1,\ldots,u_n,v_1,\ldots,v_n)^T. \tag{2.22}$$

Then, we can rewrite (2.21) as

$$\frac{\partial U}{\partial t}+\mathbf{A}(U)\frac{\partial U}{\partial x}=0, \tag{2.23}$$

where

$$\mathbf{A}(U)=\begin{bmatrix}0 & -I_{n\times n}\\ -\dfrac{1-|v|^2}{1+|u|^2}I_{n\times n} & -\dfrac{2\langle u,v\rangle}{1+|u|^2}I_{n\times n}\end{bmatrix}. \tag{2.24}$$

By a direct calculation, the eigenvalues of $\mathbf{A}(U)$ are

$$\lambda_1\equiv\cdots\equiv\lambda_n=\lambda_-,\quad \lambda_{n+1}\equiv\cdots\equiv\lambda_{2n}=\lambda_+, \tag{2.25}$$

where

$$\lambda_{\pm}=\frac{1}{1+|u|^2}(-\langle u,v\rangle\pm\sqrt{1+|u|^2-|v|^2-|v|^2|u|^2+\langle u,v\rangle^2}). \tag{2.26}$$

The right eigenvector corresponding to $\lambda_i(i=1,\ldots,2n)$ can be chosen as

$$r_i=(e_i^T,-\lambda_- e_i^T)^T\ (i=1,\ldots,n),\quad r_i=(e_{i-n}^T,-\lambda_+ e_{i-n}^T)^T\ (i=n+1,\ldots,2n), \tag{2.27}$$

where

$$e_\alpha=(0,\ldots,0,\overset{(\alpha)}{1},0,\ldots,0)^T\ (\alpha=1,\ldots,n); \tag{2.28}$$

while the left eigenvector corresponding to $\lambda_i(i=1,\ldots,2n)$ can be taken as

$$l_i=(\lambda_+ e_i^T,e_i^T)\ (i=1,\ldots,n),\quad l_i=(\lambda_- e_{i-n}^T,e_{i-n}^T)\ (i=n+1,\ldots,2n). \tag{2.29}$$

Thus we have proved the following Property 2.1.

Property 2.1: Under the assumption of Theorem 1.1, (1.10) is a nonstrictly hyperbolic system with two n-constant multiple eigenvalues [see (2.25)], and the right (resp., left) eigenvectors can be chosen as (2.27) [resp., (2.29)].

Property 2.2: Under the assumption (1.12), the characteristic propagation speeds $\lambda_\pm$ *satisfy*

$$\lambda_+\in(-1,1],\quad \lambda_-\in[-1,1). \tag{2.30}$$

Proof: Let

$$r=|u|,\quad s=|v|. \tag{2.31}$$

Then

$$\langle u,v\rangle=rs\cos\theta, \tag{2.32}$$

where $\theta\in[0,\pi]$ is the angle between vectors u and v. Thus, we have

$$\lambda_{\pm}=\frac{1}{1+r^2}(-rs\cos\theta\pm\sqrt{1+r^2-s^2-r^2s^2\sin^2\theta}), \tag{2.33}$$

where

$$\theta\in[0,\pi],\quad 1+r^2-s^2-r^2s^2\sin^2\theta>0. \tag{2.34}$$

We only prove the first part in (2.30). The proof of the second part in (2.30) is similar. Noting (2.33), we have

$$(1+r^2)\lambda_+=-rs\cos\theta+\sqrt{1+r^2-s^2-r^2s^2\sin^2\theta}, \tag{2.35}$$

that is,

$$(1+r^2)\lambda_++rs\cos\theta=\sqrt{1+r^2-s^2-r^2s^2\sin^2\theta}. \tag{2.36}$$

Squaring both sides of (2.36) yields

$$(1+r^2)^2\lambda_+^2+2(1+r^2)\lambda_+rs\cos\theta+r^2s^2\cos^2\theta=1+r^2-s^2-r^2s^2\sin^2\theta. \tag{2.37}$$

Dividing (2.37) by $1+r^2$ leads to

$$(\lambda_+r\cos\theta+s)^2+\lambda_+^2r^2\sin^2\theta=1-\lambda_+^2. \tag{2.38}$$

This implies

$$\lambda_+^2\leqslant 1. \tag{2.39}$$

We now claim that $\lambda_+ \neq -1$.

In fact, if $\lambda_+ = -1$, then it follows from (2.38) that

$$r \sin\theta = 0, \quad s - r\cos\theta = 0. \tag{2.40}$$

Case I: If $r=0$, then it follows from the second equation in (2.40) that $s=0$. In this case, noting (2.33), we have

$$\lambda_+ = 1. \tag{2.41}$$

This contradicts the assumption that $\lambda_+ = -1$.

Case II: If $r \neq 0$, then $\theta = 0, \pi$, and then $s = \pm r$. In the present situation, by (2.33) we have

$$\lambda_+ = \frac{1 \pm r^2}{1 + r^2} > -1. \tag{2.42}$$

This also contradicts the assumption that $\lambda_+ = -1$.

Therefore, noting (2.39), we obtain the first part in (2.30). Thus, the proof of Property 2.2 is completed. ■

Property 2.3: Under the assumption (1.12), the characteristic fields $\lambda_\pm$ are linearly degenerate in the sense of Lax, that is, the system (1.10) is linearly degenerate in the sense of Lax.

Proof: We calculate the invariants $\nabla\lambda_- \cdot r_\alpha (\alpha = 1, \ldots, n)$ and $\nabla\lambda_+ \cdot r_\beta (\beta = n+1, \ldots, 2n)$.

For every $\alpha \in \{1, \ldots, n\}$, by a direct calculation, we have

$$\nabla\lambda_- \cdot r_\alpha = \left(\frac{\partial\lambda_-}{\partial u}, \frac{\partial\lambda_-}{\partial v}\right) \cdot (e_\alpha^T, -\lambda_- e_\alpha^T)^T = \left(\frac{\partial\lambda_-}{\partial u} - \lambda_- \frac{\partial\lambda_-}{\partial v}\right) \cdot e_\alpha = 0. \tag{2.43}$$

Similarly, we can prove

$$\nabla\lambda_+ \cdot r_\beta \equiv 0, \quad \forall\, \beta \in \{n+1, \ldots, 2n\}. \tag{2.44}$$

Thus, the proof of Property 2.3 is finished. ■

Remark 2.2: When $n \geqslant 2$, the linear degeneracy of $\lambda_\pm$ follows from Boillat[18] and Freistühler[11] directly.

Property 2.4: Under the assumption (1.12), the system (1.10) is rich in the sense of Serre.

Remark 2.3: The rich systems (see page 144 in Ref. 17 for the definition) generalize the class of 2×2 systems while preserving their essential properties:

(1) *diagonalization with the help of the strict Riemann invariants*;
(2) *the infinite dimension of the entropy space*.

Proof of Property 2.4: On the domain under consideration, we consider the following linear system:

$$\nabla w \cdot r_\mu = 0 \quad (\mu = 1, \ldots, n), \tag{2.45}$$

where $w = w(u,v)$ is the unknown function of (u,v); r_μ are given by (2.27). In the $2n$-dimensional U space, the system (2.45) has n linearly independent solutions denoted by $R_\alpha = R_\alpha(U)(\alpha = 1, \ldots, n)$. Similarly, let $R_\beta = R_\beta(U)(\beta = n+1, \ldots, 2n)$ be the linearly independent solutions of the following linear system:

$$\nabla w \cdot r_\nu = 0 \quad (\nu = n+1, \ldots, 2n), \tag{2.46}$$

where r_ν are defined by (2.27). Noting (2.27) and (2.29), we have

$$\nabla R_\alpha = \sum_{\nu=n+1}^{2n} c_{\alpha,\nu} l_\nu \ (\alpha = 1, \ldots, n), \quad \nabla R_\beta = \sum_{\mu=1}^{n} c_{\beta,\mu} l_\mu \ (\beta = n+1, \ldots, 2n), \tag{2.47}$$

with

$$\det(c_{\alpha,\nu}) \neq 0 \quad \text{and} \quad \det(c_{\beta,\mu}) \neq 0, \tag{2.48}$$

where $c_{\alpha,\nu}=c_{\alpha,\nu}(U)$, $c_{\beta,\mu}=c_{\beta,\mu}(U)$ are smooth functions of U, and $l_i(i=1,\ldots,2n)$ are given by (2.29). Notice that

$$l_\mu\left(\frac{\partial U}{\partial t} + \lambda_- \frac{\partial U}{\partial x}\right) = 0 \ (\mu = 1, \ldots, n). \tag{2.49}$$

Multiplying (2.49) by $c_{\beta,\mu}$ and summing up them with respect to μ gives

$$\nabla R_\beta\left(\frac{\partial U}{\partial t} + \lambda_- \frac{\partial U}{\partial x}\right) = 0 \ (\beta = n+1, \ldots, 2n),$$

that is,

$$\frac{\partial R_\beta}{\partial t} + \lambda_- \frac{\partial R_\beta}{\partial x} = 0 \ (\beta = n+1, \ldots, 2n). \tag{2.50}$$

Similarly, we have

$$\frac{\partial R_\alpha}{\partial t} + \lambda_+ \frac{\partial R_\alpha}{\partial x} = 0 \ (\alpha = 1, \ldots, n). \tag{2.51}$$

Take $R_i=R_i(U)(i=1,\ldots,2n)$ as the new unknown functions. Then, (2.50) and (2.51) show that the system (1.10) can be diagonalized (at least in a local domain). On the other hand, since the system (1.10) is in a conservative form, it follows from Ref. 17 that it is rich. Thus, the proof of Property 2.4 is completed. ■

Remark 2.4: The system (2.50) and (2.51) is called the Riemann-invariant representation of the system (1.10).

Introduce

$$R_i = v_i + \lambda_- u_i, \quad R_{i+n} = v_i + \lambda_+ u_i \ (i = 1, \ldots, n). \tag{2.52}$$

It is easy to verify that R_i (resp., R_{i+n}) are Riemann invariants corresponding to λ_+ (resp., λ_-), and then they satisfy

$$\frac{\partial R_i}{\partial t} + \lambda_+ \frac{\partial R_i}{\partial x} = 0, \quad \frac{\partial R_{i+n}}{\partial t} + \lambda_- \frac{\partial R_{i+n}}{\partial x} = 0 \ (i = 1, \ldots, n). \tag{2.53}$$

On the other hand, λ_- (resp., λ_+) is also a Riemann invariant corresponding to λ_+ (resp., λ_-), and $\lambda_\pm$ satisfy

$$\frac{\partial \lambda_-}{\partial t} + \lambda_+ \frac{\partial \lambda_-}{\partial x} = 0, \quad \frac{\partial \lambda_+}{\partial t} + \lambda_- \frac{\partial \lambda_+}{\partial x} = 0. \tag{2.54}$$

The systems (2.53) and (2.54) play an important role in the proof of Theorem 1.2.

Proof of Theorem 1.1: Theorem 1.1 follows from Properties (2.1)–(2.4) directly. ■

III. GLOBAL EXISTENCE OF CLASSICAL SOLUTIONS OF THE CAUCHY PROBLEM—PROOF OF THEOREM 1.2

In this section, we prove Theorem 1.2.

Proof of Theorem 1.2: By (2.54), the necessity comes from Theorem 2.1 in Kong and Tsuji[19] directly. (Here we have made use of Property 2.2.)

In what follows, we prove the sufficiency and (1.16).

As a matter of fact, the C^2 solution of the Cauchy problem (1.7) and (1.13) is equivalent to the C^1 solution of the Cauchy problem for the system (1.10) with the following initial data:

$$t=0: u=f'(x),\ v=g(x). \tag{3.1}$$

Therefore, in order to prove Theorem 1.2, it suffices to prove that, under the assumption of Theorem 1.2, the Cauchy problem (1.10) and (3.1) has a unique global C^1 solution $U=(u^T,v^T)^T$ on $\mathbb{R}^+\times\mathbb{R}$; moreover, it holds that

$$\Delta(u(t,x),v(t,x))>0, \quad \forall\,(t,x)\in\mathbb{R}^+\times\mathbb{R}. \tag{3.2}$$

For any given interval $\mathbb{I}=[x_1,x_2]\subset\mathbb{R}$, define the *strong determinate region*,

$$\Delta_{\mathbb{I}}=\{(t,x)|t\geqslant 0, x_1+t\leqslant x\leqslant x_2-t\}, \tag{3.3}$$

where x_1,x_2 are arbitrary given real numbers with $x_1<x_2$. Thus, in order to prove that the Cauchy problem (1.10) and (3.1) has a unique global C^1 solution $U=(u^T,v^T)^T$ with (3.2) on $\mathbb{R}^+\times\mathbb{R}$; it suffices to prove that, under the assumption of Theorem 1.2, for any given interval $\mathbb{I}\subset\mathbb{R}$ the Cauchy problem for the system (1.10) with the initial data

$$t=0: u=f'(x),\ v=g(x), \quad \forall\, x\in\mathbb{I} \tag{3.1a}$$

has a unique C^1 solution $U=(u^T,v^T)^T$ on the domain $\Delta_{\mathbb{I}}$; moreover, it holds that

$$\Delta(u(t,x),v(t,x))>0, \quad \forall\,(t,x)\in\Delta_{\mathbb{I}}. \tag{3.4}$$

To do so, we first consider the Cauchy problem for the system (2.54) with the initial data

$$t=0: \lambda_{\pm}=\Lambda_{\pm}(x), \quad \forall\, x\in\mathbb{I}, \tag{3.5}$$

on the domain $\Delta_{\mathbb{I}}$.

In the present situation, noting the assumption (1.15), we have

$$\|\Lambda_{\pm}(x)\|_{C^1(\mathbb{I})}\leqslant c_{\mathbb{I}}, \quad \inf_{x\in\mathbb{I}}\Lambda_+(x)-\sup_{x\in\mathbb{I}}\Lambda_-(x)\triangleq\delta_{\mathbb{I}}>0, \tag{3.6}$$

where $c_{\mathbb{I}}$, $\delta_{\mathbb{I}}$ are two positive constants. Under the condition (3.6), by the existence and uniqueness of local C^1 solution of Cauchy problem for quasilinear hyperbolic system (see Ref. 20), there exists a positive number τ such that the Cauchy problem (2.54) and (3.5) has a unique C^1 solution, denoted by $(\lambda_-,\lambda_+)=(\lambda_-^{\mathbb{I}}(t,x),\lambda_+^{\mathbb{I}}(t,x))$, on the domain

$$\Delta_{\mathbb{I}}(\tau)=\{(t,x)|0\leqslant t\leqslant\tau, x_1+t\leqslant x\leqslant x_2-t\}. \tag{3.7}$$

It is easy to see that, on the existence domain of the classical solution of the Cauchy problem (2.54) and (3.5),

$$\sup\lambda_{\pm}=\sup_{x\in\mathbb{I}}\Lambda_{\pm}(x), \quad \inf\lambda_{\pm}=\inf_{x\in\mathbb{I}}\Lambda_{\pm}(x), \tag{3.8}$$

and then by (3.6),

$$\lambda_+(t,x) - \lambda_-(t',x') \geqslant \delta_{\mathbb{I}} > 0, \tag{3.9}$$

where (t,x) (t',x') stand for two arbitrary points in the existence domain of classical solution. Thus, by Ref. 21, the Cauchy problem (2.54) and (3.5) has a unique global C^1 solution, still denoted by $(\lambda_-,\lambda_+)=(\lambda_-^{\mathbb{I}}(t,x),\lambda_+^{\mathbb{I}}(t,x))$, on the domain $\Delta_{\mathbb{I}}$; moreover it holds that

$$\sup_{(t,x)\in\Delta_{\mathbb{I}}} \lambda_\pm^{\mathbb{I}}(t,x) = \sup_{x\in\mathbb{I}} \Lambda_\pm(x), \qquad \inf_{(t,x)\in\Delta_{\mathbb{I}}} \lambda_\pm^{\mathbb{I}}(t,x) = \inf_{x\in\mathbb{I}} \Lambda_\pm(x) \tag{3.10}$$

and

$$\lambda_+^{\mathbb{I}}(t,x) - \lambda_-^{\mathbb{I}}(t',x') \geqslant \delta_{\mathbb{I}} > 0, \quad \forall\, (t,x),(t',x') \in \Delta_{\mathbb{I}}. \tag{3.11}$$

We next consider the Cauchy problem for the following linear system:

$$\frac{\partial R_i}{\partial t} + \lambda_+^{\mathbb{I}}(t,x)\frac{\partial R_i}{\partial x} = 0, \quad \frac{\partial R_{i+n}}{\partial t} + \lambda_-^{\mathbb{I}}(t,x)\frac{\partial R_{i+n}}{\partial x} = 0 \ (i=1,\ldots,n), \tag{3.12}$$

with the initial data

$$t=0: \begin{cases} R_i = g_i(x) + \Lambda_-(x) f_i'(x) \triangleq R_i^0(x) \\ R_{i+n} = g_i(x) + \Lambda_+(x) f_i'(x) \triangleq R_{i+n}^0(x) \end{cases} \quad (i=1,\ldots,n), \quad \forall\, x \in \mathbb{I}, \tag{3.13}$$

on the domain $\Delta_{\mathbb{I}}$, where f_i (resp., g_i) is the ith component of f (resp., g).

Noting the assumptions on $f(x)$ and $g(x)$, we have

$$\|R_j^0(x)\|_{C^1(\mathbb{I})} \leqslant c_{\mathbb{I}}' \quad (j=1,\ldots,2n), \tag{3.14}$$

where $c_{\mathbb{I}}'$ is a positive constant. On the other hand, noting (1.14) and (3.10), and using (2.30), we have

$$-1 \leqslant \lambda_\pm^{\mathbb{I}}(t,x) \leqslant 1, \quad \forall\, (t,x) \in \Delta_{\mathbb{I}}. \tag{3.15}$$

Thus, noting (3.14) and (3.15) and using the method of characteristics, we can easily prove that the Cauchy problem (3.12) and (3.13) has a unique global C^1 solution, denoted by $(R_1,\ldots,R_{2n})^T = (R_1^{\mathbb{I}}(t,x),\ldots,R_{2n}^{\mathbb{I}}(t,x))^T$, on the domain $\Delta_{\mathbb{I}}$.

By (2.52), the C^1 solution of the Cauchy problem (1.10) and (3.1a) on the domain $\Delta_{\mathbb{I}}$ is uniquely determined by

$$u_i = \frac{R_{i+n}^{\mathbb{I}}(t,x) - R_i^{\mathbb{I}}(t,x)}{\lambda_+^{\mathbb{I}}(t,x) - \lambda_-^{\mathbb{I}}(t,x)}, \quad v_i = \frac{\lambda_+^{\mathbb{I}}(t,x)R_i^{\mathbb{I}}(t,x) - \lambda_-^{\mathbb{I}}(t,x)R_{i+n}^{\mathbb{I}}(t,x)}{\lambda_+^{\mathbb{I}}(t,x) - \lambda_-^{\mathbb{I}}(t,x)} \ (i=1,\ldots,n). \tag{3.16}$$

Moreover, (3.4) comes from (3.11) directly. Thus, the proof of Theorem 1.2 is completed. ■

Remark 3.1: If (1.15) is not satisfied, then the solution must blow up in finite time and singularities will appear. In this case, the equation (1.7) loses the hyperbolicity at the points where $\lambda_+=\lambda_-$. *In geometry, this corresponds to the fact that the surface is no longer time-like at these points. In the forthcoming paper, we shall investigate the blowup phenomena of the solution.*

IV. GLOBAL EXISTENCE OF CLASSICAL SOLUTIONS OF THE DIRICHLET AND NEUMANN PROBLEMS

Here, we study the global existence of the classical C^2 solutions, $\phi=\phi(t,x)$, satisfying (1.7) on a time–space region of the form $[0,\infty)\times[0,L]$ and obeying either the Dirichlet boundary condition

$$\phi(t,x)\Big|_{x=L}^{x=0} = 0, \quad \text{for } t>0, \tag{4.1}$$

or the Neumann boundary condition

$$\frac{\partial \phi}{\partial x}(t,x)\Big|_{x=L}^{x=0} = 0, \quad \text{for } t > 0, \tag{4.2}$$

on the sidewalls, together with the initial conditions

$$\phi(0,x) = f(x), \quad \phi_t(0,x) = g(x), \tag{4.3}$$

where $(f,g) \in C^2([0,L]) \times C^1([0,L])$. In order for ϕ to belong to $C^2([0,\delta] \times [0,L])$ for arbitrarily small $\delta > 0$, the initial data f and g must necessarily satisfy the compatibility conditions

$$f(x)\Big|_{x=L}^{x=0} = f''(x)\Big|_{x=L}^{x=0} = 0, \quad g(x)\Big|_{x=L}^{x=0} = 0, \quad \text{for the Dirichlet conditions;} \tag{4.4}$$

$$\frac{\partial f}{\partial x}(t,x)\Big|_{x=L}^{x=0} = 0, \quad \frac{\partial g}{\partial x}(t,x)\Big|_{x=L}^{x=0} = 0, \quad \text{for the Neumann conditions.} \tag{4.5}$$

We have the following consequences of Theorem 1.2.

Theorem 4.1: (I) *Suppose that the compatibility conditions in (4.4) are satisfied and suppose furthermore that*

$$\min\{\inf_{x\in[0,L]} \Gamma_+(\pm f(x), g(x))\} > \max\{\sup_{x\in[0,L]} \Gamma_-(\pm f(x), g(x))\}, \tag{4.6}$$

where $\Gamma_\pm$ *are defined by*

$$\Gamma_\pm(\mu(x), \nu(x)) = \frac{1}{1+|\mu'(x)|^2}[-\langle \mu'(x), \nu(x)\rangle \pm \sqrt{\Delta(\mu'(x), \nu(x))}]. \tag{4.7}$$

Then the Dirichlet problem for (1.7) with the initial data (4.3) admits a unique global C^2 *solution* $\phi = \phi(t,x)$ *on* $[0,\infty) \times [0,L]$; *moreover, it holds that*

$$\Delta(\phi_x(t,x), \phi_t(t,x)) > 0, \quad \forall\, (t,x) \in [0,\infty) \times [0,L]. \tag{4.8}$$

(II) *Suppose that the compatibility conditions in (4.5) are satisfied and suppose furthermore that (4.6) holds. Then the Neumann problem for (1.7) with the initial data (4.3) admits a unique global* C^2 *solution* $\phi = \phi(t,x)$ *on* $[0,\infty) \times [0,L]$; *moreover, (4.8) still holds.*

Remark 4.1: As a special case, if

$$\Gamma_+(f(x), g(x)) > 0 > \Gamma_-(f(y), g(y)), \quad \forall\, x,y \in [0,L], \tag{4.6a}$$

then the hypothesis (4.6) *is satisfied, and then the conclusions of Theorem 4.1 hold.*

Proof of Theorem 4.1. For the Dirichlet problem for (1.7), we extend any C^2 solution $\phi = \phi(t,x)$ to the interval $[-L,L]$ by

$$\phi(t,x) = -\phi(t,-x), \quad \text{for } x \in [-L,0], \tag{4.9}$$

and then extend $\phi(t,x)$ to be $2L$ periodic. One easily checks that if the given initial data has the form in (4.3), the extended initial data is $2L$ periodic and given by

$$\tilde{f} \triangleq \phi(0,x) = \begin{cases} -f(-x), & \text{for } x \in [-L,0], \\ f(x), & \text{for } x \in [0,L], \end{cases} \qquad \tilde{g} \triangleq \phi_t(0,x) = \begin{cases} -g(-x), & \text{for } x \in [-L,0], \\ g(x), & \text{for } x \in [0,L]. \end{cases} \tag{4.10}$$

When the compatibility conditions in (4.4) are satisfied, this extended ϕ is a C^2 solution of (1.7) with the initial data $(\tilde{f}, \tilde{g})$. Therefore, under the assumptions of Theorem 4.1(I), we may make use of Theorem 1.2 and obtain the following lemma.

Lemma 4.1: Under the assumptions of Theorem 4.1(I), the Cauchy problem for (1.7) with the following $2L$*-periodic initial data:*

$$\phi(0,x)=\tilde{f}(x),\quad \phi_t(0,x)=\tilde{g}(x) \tag{4.11}$$

admits a unique global C^2 *solution* $\phi=\tilde{\phi}(t,x)$ *on* $\mathbb{R}^+\times\mathbb{R}$; *moreover, it holds that*

$$\Delta(\tilde{\phi}_x(t,x),\tilde{\phi}_t(t,x))>0,\quad \forall\,(t,x)\in\mathbb{R}^+\times\mathbb{R}. \tag{4.12}$$

Let $\phi(t,x)$ be the restriction of $\tilde{\phi}(t,x)$ on the region $[0,\infty)\times[0,L]$. It is obvious that $\phi(t,x)$ is the unique global C^2 solution of the Dirichlet problem for (1.7) with the initial data (4.3). On the other hand, (4.8) comes from (4.12) directly. This proves Theorem 4.1(I).

Similarly, for the Neumann problem, we extend ϕ by

$$\phi(t,x)=\phi(t,-x),\quad \text{for } x\in[-L,0]. \tag{4.13}$$

Then, $\phi(t,x)$ can be extended to be a classical $2L$-periodic C^2 solution of the equation (1.7) with $2L$-periodic initial data given by

$$\tilde{f}\equiv\phi(0,x)=\begin{cases} f(-x), & \text{for } x\in[-L,0],\\ f(x), & \text{for } x\in[0,L],\end{cases}\qquad \tilde{g}\equiv\phi_t(0,x)=\begin{cases} g(-x), & \text{for } x\in[-L,0],\\ g(x), & \text{for } x\in[0,L].\end{cases} \tag{4.14}$$

When the compatibility conditions in (4.5) are satisfied, by a similar argument as used above, we can prove Theorem 4.1(II). Thus, the proof of Theorem 4.1 is completed. ■

V. EXPLICIT EXACT REPRESENTATION OF GENERAL SOLUTIONS

In this section we present an explicit exact representation, involving two independent arbitrary functions, of general solution of the equation (1.7).

To do so, we consider the global C^2 solution of the Cauchy problem (1.7) and (1.13). As pointed out in Sec. III, the C^2 solution of the Cauchy problem (1.7) and (1.13) is equivalent to the C^1 solution of the Cauchy problem (1.10) and (3.1). Thus, it suffices to give an explicit exact representation of the C^1 solution of the Cauchy problem (1.10) and (3.1).

As before, throughout this section we assume that the condition (1.15) is satisfied.

We now solve the Cauchy problem for the system (2.54) with the following initial data:

$$t=0{:}\lambda_\pm=\Lambda_\pm(x). \tag{5.1}$$

Following Peng,[22] we define

$$Y_0(x)=\int_0^x\frac{2}{\Lambda_+(\xi)-\Lambda_-(\xi)}d\xi \tag{5.2}$$

and let $x=X_0(y)$ be the inverse function of $y=Y_0(x)$. Similarly, define

$$X(t,y)=\frac{1}{2}\int_0^{y+t}\Lambda_+(X_0(\xi))d\xi-\frac{1}{2}\int_0^{y-t}\Lambda_-(X_0(\xi))d\xi \tag{5.3}$$

and let $y=Y(t,x)$ be the inverse function of $x=X(t,y)$. Similar to Ref. 22, the solution of the Cauchy problem (2.54) and (5.1) can be explicitly given by

$$\lambda_\pm(t,x)=\Lambda_\pm(X_0(Y(t,x)\pm t)), \tag{5.4}$$

provided that the hypothesis (1.15) is satisfied.

We next solve the Cauchy problem for the following linear system:

$$\frac{\partial R_i}{\partial t}+\lambda_+(t,x)\frac{\partial R_i}{\partial x}=0,\quad \frac{\partial R_{i+n}}{\partial t}+\lambda_-(t,x)\frac{\partial R_{i+n}}{\partial x}=0\ (i=1,\ldots,n),\tag{5.5}$$

with the initial data

$$t=0:\begin{cases}R_i=g_i(x)+\Lambda_-(x)f_i'(x)\triangleq R_i^0(x),\\ R_{i+n}=g_i(x)+\Lambda_+(x)f_i'(x)\triangleq R_{i+n}^0(x)\end{cases}\quad (i=1,\ldots,n),\tag{5.6}$$

where $\lambda_\pm(t,x)$ are given by (5.4), and f_i and g_i are the ith component of f and g, respectively.

Consider the following initial value problems for ODEs:

$$\frac{d\zeta_\pm}{d\tau}=\lambda_\pm(\tau,\zeta_\pm(\tau)),\quad \zeta_\pm(t)=x.\tag{5.7}$$

Let $\zeta_\pm=\zeta_\pm(\tau;t,x)$ be the solutions of the above initial value problems and define

$$\alpha_\pm(t,x)=\zeta_\pm(0;t,x).\tag{5.8}$$

Noting (5.4) and using (2.54) yields

$$\alpha_\pm(t,x)=X_0(Y(t,x)\mp t).\tag{5.9}$$

By the method of characteristics, the solution of the Cauchy problem (5.5) and (5.6) is given by

$$R_i(t,x)=R_i^0(\alpha_+(t,x)),\quad R_{i+n}(t,x)=R_{i+n}^0(\alpha_-(t,x))\ (i=1,\ldots,n),\tag{5.10}$$

that is,

$$R_i(t,x)=R_i^0(X_0(Y(t,x)-t)),\quad R_{i+n}(t,x)=R_{i+n}^0(X_0(Y(t,x)+t))\ (i=1,\ldots,n).\tag{5.11}$$

Noting (1.15) and using (2.52), we obtain the solution of the Cauchy problem (1.10) and (3.1)

$$u_i=\frac{R_{i+n}(t,x)-R_i(t,x)}{\lambda_+(t,x)-\lambda_-(t,x)},\quad v_i=\frac{\lambda_+(t,x)R_i(t,x)-\lambda_-(t,x)R_{i+n}(t,x)}{\lambda_+(t,x)-\lambda_-(t,x)}\ (i=1,\ldots,n),\tag{5.12}$$

where $\lambda_\pm(t,x)$ and $R_j(t,x)(j=1,\ldots,2n)$ are given by (5.4) and (5.11), respectively. Therefore, the solution of the Cauchy problem (1.7) and (1.13) is

$$\phi(t,x)=f(x)+\int_0^t v(s,x)ds,\tag{5.13}$$

where $v=(v_1,\ldots,v_n)^T$ in which v_i are defined in (5.12). By the assumption (1.15), $\phi(t,x)$ is well defined for all $(t,x)\in\mathbb{R}\times\mathbb{R}$.

(5.13) gives an explicit exact representation, involving two independent arbitrary functions $f(x)$ and $g(x)$, of general solution of the equation (1.7), where $f(x)$ and $g(x)$ are chosen such that the condition (1.15) is satisfied.

Remark 5.1: The referee kindly points out that, using the hodograph transform, Barbashov and Chernikov[23] *derived the solution representation.*

VI. INHOMOGENEOUS DIRICHLET PROBLEM

Inhomogeneous Dirichlet problem for the equation (1.7) plays an important role in the Breniers theory (see Ref. 1) and other physical problems. In this section, we investigate the global existence of the classical C^2 solutions, $\phi=\phi(t,x)$, satisfying (1.7) on a time-space region of the form $[0,\infty)\times[0,L]$ and obeying inhomogeneous Dirichlet boundary conditions,

$$\phi(t,0)=\varphi_0(t),\quad \phi(t,L)=\varphi_L(t),\quad \text{for } t>0\tag{6.1}$$

on the sidewalls together with the initial conditions

$$\phi(0,x) = F(x), \quad \phi_t(0,x) = G(x), \quad \forall\, x \in [0,L], \tag{6.2}$$

where $F \in C^2([0,L])$ and $G \in C^1([0,L])$. In order for ϕ to belong to $C^2([0,\delta]\times[0,L])$ for arbitrarily small $\delta>0$, the initial data F and G must necessarily satisfy certain compatibility conditions (here we omit them).

Stimulated by (1.15), we assume that

$$\min_{x\in[0,L]} \tilde{\Lambda}_+(x) > \max_{x\in[0,L]} \tilde{\Lambda}_-(x), \tag{6.3}$$

where

$$\tilde{\Lambda}_\pm(x) = \frac{1}{1+|F'(x)|^2}[-\langle F'(x), G(x)\rangle \pm \sqrt{\Delta(F'(x), G(x))}]. \tag{6.4}$$

Define two functions on $\mathbb{R}$, still denoted by f and g, which satisfy the following:

$$(i)\ f \in C^2, \quad g \in C^1;$$

$$(ii)\ f(x) = F(x), \quad \text{on } [0,L]; \quad g(x) = G(x), \quad \text{on } [0,L];$$

$$(iii)\ \Lambda_+(x) > \Lambda_-(y), \quad \forall\, x,y \in \mathbb{R},$$

where $\Lambda_\pm(x)$ are defined by (1.14). Noting the condition (*iii*), for such functions f,g, we know that the Cauchy problem (1.7) and (1.13) has a unique global C^2 solution, moreover this solution can be explicitly exactly given by (5.13).

Definition 6.1: The boundary conditions (φ_0,φ_L) *are said to be globally solvable if there exist two functions f and g satisfying (i)–(iii), such that*

$$\phi(t,0) = \varphi_0(t), \quad \phi(t,L) = \varphi_L(t), \quad \text{for } t > 0, \tag{6.5}$$

where $\phi(t,x)$ *is defined by (5.13).*

Theorem 6.1: *Suppose that certain compatibility conditions and (6.3) are satisfied. Then the inhomogeneous Dirichlet problem (1.7), (6.1), and (6.2) has a unique global* C^2 *solution if and only if the boundary condition* (φ_0,φ_L) *is globally solvable.*

Proof: The sufficiency is obvious. In order to prove the necessity, it suffices to interchange the role of t and x variables, then solve two Cauchy problems that initial data are given on two half-lines, $x=0$ and $x=L$ with $t\geqslant 0$, respectively. After that, we can easily construct the desired functions f and g. Thus, the proof is completed. ■

Remark 6.1: For globally solvable boundary conditions (φ_0,φ_L), *the functions* (f,g) *may not be unique.*

Remark 6.2: It follows from Sec. IV that, under the hypotheses (4.4) and (4.6), the homogeneous boundary conditions (0,0) are globally solvable.

(Received 13 October 2005; accepted 7 November 2005; published online 11 January 2006)

In this paper, we mainly study several problems on the weakly dissipative periodic Camassa-Holm equation. At first, the local well-posedness of the equation is obtained by Kato's theorem, a necessary and sufficient condition of the blow-up of the solution and some criteria guaranteeing the blow-up of the solution are established. Then, the blow-up rate of the solution is discussed. Moreover, we prove that the equation has global solutions and these global solutions decay to zero as time goes to infinite provided the potentials associated to their initial date are of one sign. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2158437]

I. INTRODUCTION

The Camassa-Holm equation

$$u_t - u_{txx} + 3uu_x = 2u_x u_{xx} + uu_{xxx}, \quad t > 0,\ x \in \mathbf{R}$$

is a model for wave motion on shallow water, where $u(t,x)$ represents the fluid's free surface above a flat bottom (or equivalently, the fluid velocity at time $t \geqslant 0$ in the spatial x direction).

Since the equation was derived physically by Camassa and Holm (see Refs. 3 and 4), many researchers have paid extensive attention to it. The equation has a bi-Hamiltonian structure[15] and is completely integrable (see Refs. 1, 4, 6, and 16). Its solitary waves are peaked,[6] and they are orbitally stable and interact like solitons (see Refs. 2, 13, and 14). There are also numerous papers devoted recently to study this equation on the other issues, such as local well-posedness, global existence and blow-up of strong solutions, the existence and uniqueness of global weak solutions (see Refs. 5, 7–12, 18, 20, 21, 23–25, and 28, etc.).

In Ref. 11, Constantin and Escher give a quite detailed description of the blow-up phenomenon for the periodic Camassa-Holm equation. They find that the equation offers a very nice picture of the wave-breaking phenomena. Namely, if the maximal existence time $T < \infty$, they have

$$\lim_{t \to T} \left(\min_{x \in \mathbf{S}} \{u_x(t,x)\} \right) = -\infty$$

and the exact blow-up rate is

[a)]Electronic mail: isswsy@zsu.edu.cn
[b)]Electronic mail: mcsyzy@zsu.edu.cn
[c)]Electronic mail: yin@ifam.uni-hannover.de

$$\lim_{t\to T}\left((T-t)\min_{x\in\mathbf{S}}\{u_x(t,x)\}\right)=-2.$$

Furthermore, the authors show that for a large class of odd initial data the waves break at a discrete set of points and anything "bad" at breaking time is not observed elsewhere.

In general, it is difficult to avoid energy dissipation mechanisms in a real world. For example, Ott and Sudan[22] investigated how KdV equation was modified by the presence of dissipation and the effect of such dissipation on the solitary solution of KdV equation, and Ghidaglia[17] investigated the long time behavior of solutions to the weakly dissipative KdV equation as a finite-dimensional dynamical system.

Similarly, we would like to consider the dissipative Camassa-Holm equation,

$$u_t-u_{txx}+3uu_x+L(u)=2u_xu_{xx}+uu_{xxx},\quad t>0,\ x\in\mathbf{R},$$

where $L(u)$ is a dissipative term, L can be a differential operator or a quasidifferential operator according to different physical situations. We are interested in the effect of the weakly dissipative term on the Camassa-Holm equation. In the paper, we mainly consider the following weakly dissipative periodic Camassa-Holm equation:

$$y_t+uy_x+2u_xy+\lambda y=0,\quad t>0,\quad x\in\mathbf{R},$$

$$y=u-u_{xx},\quad t>0,\quad x\in\mathbf{R},$$

$$u(0,x)=u_0(x),\quad x\in\mathbf{R},$$

$$u(t,x+1)=u(t,x),\quad t>0,\quad x\in\mathbf{R},\tag{1.1}$$

where $\lambda y=\lambda(I-\partial_{xx})u$ is the weakly dissipative term, $\lambda>0$ is a constant, u_0 is a given periodic initial value.

We find that the behaviors of the equation (1.1) are similar to the Camassa-Holm equation in a finite interval of time, such as, the local well-posedness and the blow-up phenomena. But there are considerable differences between the equation (1.1) and the Camassa-Holm equation in their long time behaviors. Global solution of the equation (1.1) decays to zero as time goes to infinite provided the potential $y_0=(I-\partial_{xx})u_0$ is of one sign. This long time behavior is an important feature that the Camassa-Holm equation does not possess. It is well known that the Camassa-Holm equation has peaked traveling wave solutions. Lemma 2.2 in the sequel shows that any global solution decays in the H^1 norm. This means that there are no traveling wave solutions of the equation (1.1). This is also another considerable difference between the equation (1.1) and the Camassa-Holm equation in their long time behaviors.

It is very interesting that the equation (1.1) has the same blow-up rate as the Camassa-Holm equation does when the blow-up occurs. This fact shows that the blow-up rate of the Camassa-Holm equation are not affected by the weakly dissipative term. But the occurrence of blow-up of the equation (1.1) is affected by the dissipative parameter.

It should be noticed that the equation (1.1) does not have the conservation laws

$$I_1=\int_{\mathbf{S}}u\,\mathrm{d}x,\quad I_2=\int_{\mathbf{S}}(u^2+u_x^2)\mathrm{d}x,$$

which play an important role in the study of the Camassa-Holm equation.

II. LOCAL WELL-POSEDNESS AND BLOW-UP

We first state Kato's theorem so as to obtain the local well-posedness of the equation (1.1). Consider the abstract quasilinear evolution equation,

$$\frac{dv}{dt} + A(v)v = f(v), \quad t \geqslant 0, \quad v(0) = v_0. \tag{2.1}$$

Let X and Y be Hilbert spaces such that Y is continuously and densely embedded in X and let $Q: Y \to X$ be a topological isomorphism. $L(Y,X)$ denotes the space of all bounded linear operators from Y to X [$L(X)$, if $X=Y$]. Assume that

(i) $A(y) \in L(Y,X)$ for $y \in X$ with

$$\|(A(y) - A(z))w\|_X \leqslant \mu_1 \|y - z\|_X \|w\|_Y, \quad y,z,w \in Y,$$

and $A(y) \in G(X,1,\beta)$ [i.e., $A(y)$ is quasi-m-accretive], uniformly on bounded sets in Y.

(ii) $QA(y)Q^{-1} = A(y) + B(y)$, where $B(y) \in L(X)$ is bounded, uniformly on bounded sets in Y. Moreover,

$$\|(B(y) - B(z))w\|_X \leqslant \mu_2 \|y - z\|_Y \|w\|_X, \quad y,z \in Y, \quad w \in X.$$

(iii) $f: Y \to Y$ and extends also to a map from X into X. f is bounded on bounded sets in Y, and

$$\|f(y) - f(z)\|_Y \leqslant \mu_3 \|y - z\|_Y, \quad y,z \in Y,$$

$$\|f(y) - f(z)\|_X \leqslant \mu_4 \|y - z\|_X, \quad y,z \in Y.$$

Here μ_1, μ_2, μ_3, and μ_4 depend only on $\max\{\|y\|_Y, \|z\|_Y\}$.

Theorem 2.1 (*Kato's theorem*[19]*): Assume that* (*i*), (*ii*), *and* (*iii*) *hold. Given* $v_0 \in Y$, *there is a maximal* $T > 0$ *depending only on* $\|v_0\|_Y$ *and a unique solution* v *to Eq. (2.1) such that*

$$v = v(\cdot, v_0) \in C([0,T);Y) \cap C^1([0,T);X).$$

Moreover, the map $v_0 \mapsto v(\cdot, v_0)$ *is continuous from* Y *to* $C([0,T);Y) \cap C^1([0,T);X)$.

In order to apply Kato's theorem, we reformulate now Eq. (1.1).

First, we identify all spaces of periodic functions with function spaces over the unit circle **S** in **R**, where $\mathbf{S} = \mathbf{R}/\mathbf{Z}$; for simplicity, we drop **S** from our notation. Additionally, we denote by $\|\cdot\|_r$ the norm in the Sobolev spaces H^r, $r \geqslant 0$.

We note that if

$$G(x) = \frac{\cosh\left(x - [x] - \frac{1}{2}\right)}{2\sinh\left(\frac{1}{2}\right)},$$

here $[x]$ stands for the integer part of $x \in \mathbf{R}$, then $(1 - \partial_x^2)^{-1} f = G * f$ for all $f \in L^2(\mathbf{S})$ and $G * y = u$, we denote by * the convolution. Using this identity, we can rewrite the equation (1.1) as follows:

$$u_t + uu_x = -\partial_x\left(G * \left(u^2 - \lambda u_x + \tfrac{1}{2}u_x^2\right)\right) - \lambda G * u, \quad t > 0, \quad x \in \mathbf{R},$$

$$u(0,x) = u_0(x), \quad x \in \mathbf{R},$$

$$u(t,x+1) = u(t,x), \quad t > 0, \quad x \in \mathbf{R}, \tag{2.2}$$

or the equivalent form:

$$u_t + uu_x = -\partial_x(1 - \partial_x^2)^{-1}\left(u^2 - \lambda u_x + \tfrac{1}{2}u_x^2\right) - \lambda(1 - \partial_x^2)^{-1}u, \quad t > 0, \quad x \in \mathbf{R},$$

$$u(0,x) = u_0(x), \quad x \in \mathbf{R},$$

$$u(t,x+1)=u(t,x), \quad t>0, \quad x\in \mathbf{R}. \tag{2.3}$$

Set $A(u)=u\partial_x$, $f(u)=-\partial_x(1-\partial_x^2)^{-1}\left(u^2-\lambda u_x+\frac{1}{2}u_x^2\right)-\lambda(1-\partial_x^2)^{-1}u$, $Y=H^r$, $X=H^{r-1}$, $r>\frac{3}{2}$, and $Q=(1-\partial_x^2)^{\frac{1}{2}}$. Obviously, Q is an isomorphism of Y onto X. Analogous to the proofs in Ref. 26 or Ref. 27, we can prove that $A(u)$ and $f(u)$ satisfy the conditions (i)–(iii). Hence, we obtain the following theorem for the local well-posedness of Eq. (1.1) [or Eq. (2.3)].

Theorem 2.2: *Given $u_0\in H^r$, $r>\frac{3}{2}$, there exist a maximal $T=T(\lambda,\|u_0\|_r)>0$, and a unique solution u to Eq. (1.1) [or Eq. (2.3)], such that*

$$u=u(\cdot,u_0)\in C([0,T);H^r)\cap C^1([0,T);H^{r-1}),$$

and the solution depends continuously on the initial data, i.e., the mapping $u\to u(\cdot,u_0):H^r\to C([0,T);H^r)\cap C^1([0,T);H^{r-1})$ is continuous. Moreover, T may be chosen independent of r in the following sense: if

$$u=u(\cdot,u_0)\in C([0,T);H^r)\cap C^1([0,T);H^{r-1})$$

to Eq. (1.1), and if $u_0\in H^{r'}$ for some $r'\neq r$, $r'>\frac{3}{2}$, then

$$u\in C([0,T);H^{r'})\cap C^1([0,T);H^{r'-1})$$

with the same T.

The following results are only proved with regard to $r=3$, since we can obtain the same conclusion for general case $r>\frac{3}{2}$ by using denseness.

We prove now a necessary and sufficient condition of the blow-up of the solution for Eq. (1.1).

Theorem 2.3: *Given $u_0\in H^3$, the solution of Eq. (1.1) blows up in a finite time $T>0$ if and only if*

$$\lim_{t\uparrow T}\inf\left\{\inf_{x\in \mathbf{S}}[u_x(t,x)]\right\}=-\infty.$$

Proof: Notice that

$$\int_{\mathbf{S}} uyy_x\,dx=-\frac{1}{2}\int_{\mathbf{S}} u_xy^2\,dx, \quad \int_{\mathbf{S}} uy_xy_{xx}\,dx=-\frac{1}{2}\int_{\mathbf{S}} u_xy_x^2\,dx,$$

$$\int_{\mathbf{S}} u_{xx}yy_x\,dx=-\frac{1}{2}\int_{\mathbf{S}} u_xy^2\,dx.$$

Then, we have by Eq. (1.1),

$$\frac{d}{dt}\int_{\mathbf{S}} y^2\,dx=2\int_{\mathbf{S}} yy_t\,dx=-4\int_{\mathbf{S}} u_xy^2\,dx-2\int_{\mathbf{S}} uyy_x\,dx-2\lambda\int_{\mathbf{S}} y^2\,dx=-3\int_{\mathbf{S}} u_xy^2\,dx-2\lambda\int_{\mathbf{S}} y^2\,dx. \tag{2.4}$$

If $u_0\in H^4$, we can obtain by Eq. (1.1)

$$\begin{aligned}\frac{d}{dt}\int_{\mathbf{S}} y_x^2\,dx&=2\int_{\mathbf{S}} y_xy_{xt}\,dx=-4\int_{\mathbf{S}} u_{xx}yy_x\,dx-6\int_{\mathbf{S}} u_xy_x^2\,dx-2\int_{\mathbf{S}} uy_xy_{xx}\,dx-2\lambda\int_{\mathbf{S}} y_x^2\,dx\\&=-5\int_{\mathbf{S}} u_xy_x^2\,dx+2\int_{\mathbf{S}} u_xy^2\,dx-2\lambda\int_{\mathbf{S}} y_x^2\,dx.\end{aligned} \tag{2.5}$$

As for $u_0 \in H^3$, we will show that (2.5) still holds. In fact, we can approximate u_0 in H^3 by function $u_0^n \in H^4$. Moreover, we write $u^n = u^n(\cdot, u_0^n)$ for the solution of Eq. (1.1) with initial data u_0^n.

By Theorem 2.2, we know that

$$u^n \in C([0,T_n);H^4) \cap C^1([0,T_n);H^3), \quad n \geqslant 1,$$

$$y^n = u^n - u^n_{xx} \in C([0,T_n);H^2) \cap C^1([0,T_n);H^1), \quad n \geqslant 1,$$

$u^n \to u$ in H^3 and $T_n \to T$ as $n \to \infty$.

Due to $u_0^n \in H^4$, we have by (2.5)

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_{\mathbf{S}} (y_x^n)^2 \,\mathrm{d}x = -5\int_{\mathbf{S}} u_x^n (y_x^n)^2 \,\mathrm{d}x + 2\int_{\mathbf{S}} u_x^n (y^n)^2 \,\mathrm{d}x - 2\lambda \int_{\mathbf{S}} (y_x^n)^2 \,\mathrm{d}x.$$

Since $u^n \to u$ in H^3 as $n \to \infty$, it follows that $u_x^n \to u_x$ in L^∞ as $n \to \infty$. Note also that $y^n \to y$ in H^1 and $y_x^n \to y_x$ in L^2 as $n \to \infty$. Letting n go to infinity in the above equation, we can easily deduce that (2.5) holds for $u_0 \in H^3$.

Adding (2.4) and (2.5), we get

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\int_{\mathbf{S}} y^2 \,\mathrm{d}x + \int_{\mathbf{S}} y_x^2 \,\mathrm{d}x\right) = -5\int_{\mathbf{S}} u_x y_x^2 \,\mathrm{d}x - \int_{\mathbf{S}} u_x y^2 \,\mathrm{d}x - 2\lambda\left(\int_{\mathbf{S}} y^2 \,\mathrm{d}x + \int_{\mathbf{S}} y_x^2 \,\mathrm{d}x\right). \tag{2.6}$$

If u_x is bounded from below on $[0,T)$, for example, $u_x \geqslant -k$, k is a positive constant, we get by (2.6) and Gronwall's inequality

$$\|y\|_1^2 \leqslant e^{(5k-2\lambda)t}\|y(0)\|_1^2,$$

it means that the H^3-norm of the solution u of Eq. (1.1) does not blow up in finite time. □

In the following, we provide two blow-up criteria for Eq. (1.1) guaranteeing the occurrence of this phenomenon.

Let us first introduce the following two useful lemmas:

Lemma 2.1 (Ref. 8): Let $T>0$ and $v \in C^1([0,T);H^2)$, then for every $t \in [0,T)$ there exists at least one point $\xi(t) \in \mathbf{S}$ with

$$m(t) := \inf_{x \in \mathbf{S}}[v_x(t,x)] = v_x(t,\xi(t)).$$

The function $m(t)$ is almost everywhere differentiable on $(0,T)$ with

$$\frac{\mathrm{d}m}{\mathrm{d}t} = v_{tx}(t,\xi(t)), \quad \text{a.e. on } (0,T).$$

Lemma 2.2: Let $u_0 \in H^1$, then, as long as the solution $u(t)$ given by Theorem 2.2 exists, we have

$$\|u\|_1^2 = e^{-2\lambda t}\|u_0\|_1^2, \quad \forall\, t \in [0,T).$$

Proof: Taking the scalar product of Eq. (1.1) with u in $L^2(\mathbf{S})$, and noting that

$$\int_{\mathbf{S}} u^2 y_x \,\mathrm{d}x + 2\int_{\mathbf{S}} u u_x y \,\mathrm{d}x = 0,$$

we obtain

$$\frac{1}{2}\frac{d}{dt}\int_{\mathbf{S}}(u^2+u_x^2)dx+\lambda\int_{\mathbf{S}}(u^2+u_x^2)dx=0,$$

or

$$\frac{d}{dt}\|u\|_1^2+2\lambda\|u\|_1^2=0.$$

By integration between 0 and t, we have

$$\|u\|_1^2=e^{-2\lambda t}\|u_0\|_1^2,\quad \forall\, t\in[0,T).$$

Hence, the lemma is proved. □

Theorem 2.4: *Let $u_0\in H^3$, and assume that there exists $x_0\in\mathbf{S}$ such that*

$$u_0'(x_0)<-\lambda-\sqrt{\lambda^2+\|u_0\|_1^2}.$$

Then the corresponding solution of Eq. (1.1) blows up in finite time.

Proof: Let $T>0$ be the existence time of the solution $u(t,\cdot)$ of Eq. (1.1) [or Eq. (2.2)] with the initial data u_0. Differentiating Eq. (2.2) with respect to x, we get

$$u_{tx}=-u_x^2-uu_{xx}-\partial_x^2G*\left(u^2+\tfrac{1}{2}u_x^2\right)-\lambda\partial_xG*(u-u_{xx}).$$

Note that

$$\partial_x^2G*\left(u^2+\tfrac{1}{2}u_x^2\right)=G*\left(u^2+\tfrac{1}{2}u_x^2\right)-\left(u^2+\tfrac{1}{2}u_x^2\right),\quad G*(u-u_{xx})=u.$$

Thus, we have

$$u_{tx}=-\tfrac{1}{2}u_x^2-uu_{xx}+u^2-G*\left(u^2+\tfrac{1}{2}u_x^2\right)-\lambda u_x. \tag{2.7}$$

We infer from Theorem 2.2 and Lemma 2.1 that for every $t\in[0,T)$, there exists at least one point $\xi(t)\in\mathbf{S}$ with $u_x(t,\xi(t))=\inf_{x\in\mathbf{S}}[u_x(t,x)]$. Let $m(t)=u_x(t,\xi(t))=\inf_{x\in\mathbf{S}}[u_x(t,x)]$, then $u_{xx}(t,\xi(t))=0$, $\forall t\in[0,T)$. Hence we have from (2.7)

$$\frac{dm}{dt}=-\frac{1}{2}m^2(t)+u^2(t,\xi(t))-\left[G*\left(u^2+\frac{1}{2}u_x^2\right)\right](t,\xi(t))-\lambda m(t)\quad \text{a.e. on } (0,T). \tag{2.8}$$

Note that $G*\left(u^2+\frac{1}{2}u_x^2\right)\geqslant 0$, $t\in[0,T)$, and (by the Sobolev imbedding theorem and Lemma 2.2)

$$\|u(t,\cdot)\|_{L^\infty}^2\leqslant\tfrac{1}{2}\|u(t,\cdot)\|_1^2\leqslant\tfrac{1}{2}\|u_0\|_1^2. \tag{2.9}$$

Then, we obtain

$$\frac{dm}{dt}\leqslant-\frac{1}{2}(m^2(t)+2\lambda m(t)-\|u_0\|_1^2)$$

$$=-\frac{1}{2}(m(t)+\lambda-\sqrt{\lambda^2+\|u_0\|_1^2})(m(t)+\lambda+\sqrt{\lambda^2+\|u_0\|_1^2}).$$

From the hypothesis, we have $m(0)<-\lambda-\sqrt{\lambda^2+\|u_0\|_1^2}$, thus $dm/dt|_{t=0}<0$. By continuity with respect to t of $m(t)$, we have $dm/dt<0$, $\forall t\in[0,T)$. Therefore, $m(t)<-\lambda-\sqrt{\lambda^2+\|u_0\|_1^2}$, $\forall t\in[0,T)$. So, we can solve the above inequality to obtain

$$\frac{m(0)+\lambda+\sqrt{\lambda^2+\|u_0\|_1^2}}{m(0)+\lambda-\sqrt{\lambda^2+\|u_0\|_1^2}}e^{(\sqrt{\lambda^2+\|u_0\|_1^2}t)}-1\leqslant\frac{2\sqrt{\lambda^2+\|u_0\|_1^2}}{m(t)+\lambda-\sqrt{\lambda^2+\|u_0\|_1^2}}\leqslant 0.$$

Since

$$0<\frac{m(0)+\lambda+\sqrt{\lambda^2+\|u_0\|_1^2}}{m(0)+\lambda-\sqrt{\lambda^2+\|u_0\|_1^2}}<1,$$

there exists T,

$$T\leqslant\frac{1}{\sqrt{\lambda^2+\|u_0\|_1^2}}\ln\left(\frac{m(0)+\lambda-\sqrt{\lambda^2+\|u_0\|_1^2}}{m(0)+\lambda+\sqrt{\lambda^2+\|u_0\|_1^2}}\right),$$

such that $\lim_{t\uparrow T}m(t)=-\infty$. Hence, the above theorem is proved according to Theorem 2.3. □

Theorem 2.5: *Assume that* $u_0\in H^3$ *is odd,* $u_0'(0)<-2\lambda$. *Then the corresponding solution of Eq.* (1.1) *blows up infinite time.*

Proof: Let $T>0$ be the existence time of the solution $u(t,\cdot)$ of Eq. (1.1) [or Eq. (2.2)] with the initial data u_0. AS one can check, the function

$$v(t,x):=-u(t,-x),\quad t\in[0,T),\ x\in\mathbf{R},$$

is also a solution of Eq. (1.1) in $C([0,T);H^3)]\cap C^1([0,T);H^2)$ with initial data u_0. By uniqueness we conclude that $v\equiv u$ and therefore $u(t,\cdot)$ is odd for any $t\in[0,T)$. In particular, by continuity with respect to the spatial variable of u and u_{xx}, we get

$$u(t,0)=u_{xx}(t,0)=0,\quad t\in[0,T). \tag{2.10}$$

Define $g(t):=u_x(t,0)$ for $t\in[0,T)$ and note that $g\in C^1([0,T),\mathbf{R})$. From (2.7) and (2.10), we get

$$\frac{\mathrm{d}g}{\mathrm{d}t}(t)=-\frac{1}{2}g^2(t)-\lambda g(t)-\int_{\mathrm{S}}G(x-\eta)\left(u^2+\frac{1}{2}u_x^2\right)\mathrm{d}\eta$$

$$\leqslant-\frac{1}{2}(g(t)+2\lambda)g(t),\quad t\in[0,T).$$

From the hypothesis, we have $g(0)<-2\lambda$. Therefore, $g(t)<-2\lambda$, $\forall t\in[0,T)$. Solving the above inequality, we get

$$1-\frac{g(0)}{g(0)+2\lambda}e^{-\lambda t}\leqslant\frac{2\lambda}{g(t)+2\lambda}\leqslant 0.$$

Since

$$\frac{g(0)}{g(0)+2\lambda}>1,$$

we conclude that there exists T,

$$T\leqslant-\frac{1}{\lambda}\ln\frac{g(0)+2\lambda}{g(0)},$$

such that $\lim_{t\uparrow T}g(t)=-\infty$. We complete the proof of the above theorem by Theorem 2.3. □

III. BLOW-UP RATE

In this section, we give more insight into the blow-up mechanism for the wave-breaking solutions to Eq. (1.1).

Theorem 3.1: *Let $u_0 \in H^3$, and let $T>0$ be the maximal existence time of the corresponding solution to Eq. (1.1). If T is finite, we have*

$$\lim_{t\to T}(T-t)\min_{x\in\mathbf{S}} u_x(t,x) = -2.$$

Proof: We already know by Theorem 2.3 that

$$\liminf_{t\to T}\min_{x\in\mathbf{S}} u_x(t,x) = -\infty. \tag{3.1}$$

Define now $m(t) := \min_{x\in\mathbf{S}}[u_x(t,x)]$, $t\in[0,T)$, and let $\xi(t)\in\mathbf{S}$ be a point where this minimum is attained. Clearly $u_{xx}(t,\xi(t))=0$ since $u(t,\cdot)\in H^3\subset C^2$. From (2.8) we have

$$\frac{\mathrm{d}m}{\mathrm{d}t}+\frac{1}{2}m^2(t)+\lambda m(t) = u^2(t,\xi(t)) - \left[G*\left(u^2+\frac{1}{2}u_x^2\right)\right](t,\xi(t)) \quad \text{a.e. on } (0,T). \tag{3.2}$$

By Young's inequality and Lemma 2.2, we have for $t\in[0,T)$ that

$$\left\|G*\left(u^2+\frac{1}{2}u_x^2\right)(t,\cdot)\right\|_{L^\infty} \le \|G\|_{L^\infty}\left\|u^2+\frac{1}{2}u_x^2\right\|_{L^1} \le \frac{\cosh\left(\frac{1}{2}\right)}{2\sinh\left(\frac{1}{2}\right)}\|u(t,\cdot)\|_1^2 \le \frac{\cosh\left(\frac{1}{2}\right)}{2\sinh\left(\frac{1}{2}\right)}\|u_0\|_1^2. \tag{3.3}$$

Then, we infer from (2.9) and (3.3) that

$$\left|u^2(t,\xi(t)) - \left[G*\left(u^2+\frac{1}{2}u_x^2\right)\right](t,\xi(t))\right| \le \left(\frac{1}{2}+\frac{\cosh\left(\frac{1}{2}\right)}{2\sinh\left(\frac{1}{2}\right)}\right)\|u_0\|_1^2.$$

Set

$$K = \left(\frac{1}{2}+\frac{\cosh\left(\frac{1}{2}\right)}{2\sinh\left(\frac{1}{2}\right)}\right)\|u_0\|_1^2.$$

We infer from (3.2) that

$$-K \le \frac{\mathrm{d}m}{\mathrm{d}t}+\frac{1}{2}m^2(t)+\lambda m(t) \le K \quad \text{a.e. on } (0,T).$$

Hence,

$$-K-\frac{1}{2}\lambda^2 \le \frac{\mathrm{d}m}{\mathrm{d}t}+\frac{1}{2}(m(t)+\lambda)^2 \le K+\frac{1}{2}\lambda^2 \quad \text{a.e. on } (0,T). \tag{3.4}$$

Let $\epsilon\in\left(0,\frac{1}{2}\right)$. Since $\lim_{t\to T}\inf(m(t)+\lambda)=-\infty$ [by (3.1)], there is some $t_0\in(0,T)$ with $m(t_0)+\lambda<0$ and

$$(m(t_0)+\lambda)^2 > \frac{1}{\epsilon}\left(K+\frac{1}{2}\lambda^2\right).$$

We claim that

$$(m(t)+\lambda)^2 > \frac{1}{\epsilon}\left(K+\frac{1}{2}\lambda^2\right), \quad t \in [t_0,T). \tag{3.5}$$

In fact, since $m(t)$ is locally Lipschitz [it belongs to $W^{1,\infty}_{\mathrm{loc}}(\mathbf{R})$ by Lemma 2.1] there is some $\delta > 0$ such that

$$(m(t)+\lambda)^2 > \frac{1}{\epsilon}\left(K+\frac{1}{2}\lambda^2\right), \quad t \in (t_0,t_0+\delta).$$

From (3.4), we have

$$\frac{\mathrm{d}m}{\mathrm{d}t} < \left(\epsilon-\frac{1}{2}\right)(m(t)+\lambda)^2 < 0 \quad \text{a . e . on } (t_0,t_0+\delta).$$

Being locally Lipschitz, the function $m(t)$ is absolutely continuous. Therefore, by integrating the above relation on $[t_0,t_0+\delta]$, we obtain that $m(t_0+\delta) \leqslant m(t_0)$. Thus,

$$m(t_0+\delta)+\lambda \leqslant m(t_0)+\lambda < 0.$$

By the above inequality, we have

$$(m(t_0+\delta)+\lambda)^2 \geqslant (m(t_0)+\lambda)^2 > \frac{1}{\epsilon}\left(K+\frac{1}{2}\lambda^2\right).$$

The relation (3.5) is proved by continuous extension.

A combination of (3.4) and (3.5) enables us to infer

$$-\frac{1}{2}-\epsilon < \frac{\frac{\mathrm{d}m}{\mathrm{d}t}}{(m(t)+\lambda)^2} < -\frac{1}{2}+\epsilon \quad \text{a . e . on } (t_0,T). \tag{3.6}$$

For $t \in (t_0,T)$, integrating (3.6) on (t,T), we obtain

$$-\frac{1}{2}-\epsilon < \frac{1}{(m(t)+\lambda)(T-t)} < -\frac{1}{2}+\epsilon, \quad t \in (t_0,T).$$

Letting ϵ goes to zero, we obtain

$$\lim_{t\to T}[m(t)(T-t)+\lambda(T-t)] = -2,$$

that is

$$\lim_{t\to T}(T-t)m(t) = -2.$$

So, the proof of the above theorem is completed. □

Remark 3.1: Although the occurrence of blow-up of strong solutions to Eq. (1.1) is affected by the dissipative parameter (*see Theorems 2.4 and 2.5*), *Theorem 3.1 shows that the blow-up rate of strong solutions to the Camassa-Holm equation is not affected by the weakly dissipative term.*

IV. GLOBAL SOLUTION AND ITS DECAY

In this section we will show that there exist global strong solutions to the equation (1.1) provided the initial data u_0 satisfying certain sign conditions and some global solutions decay to zero at time goes to infinite provided the dissipative parameter being in a certain range.

Given a strong solution u to Eq. (1.1) with initial data $u_0 \in H^3$ and with maximal existence time $T>0$, we can associate it with the differential equation

$$q_t = u(t,q), \quad t \in (0,T),$$

$$q(0,x)=x, \quad x\in \mathbf{R}. \tag{4.1}$$

Lemma 4.1: Let $u_0\in H^3$ and let $T>0$ be the maximal existence time of the corresponding solution u to Eq. (1.1). *Then Eq.* (4.1) *has a unique solution $q\in C^1([0,T)\times\mathbf{R},\mathbf{R})$. Moreover, for each fixed $t\in[0,T)$, the map $q(t,\cdot)$ in an increasing diffeomorphism of $\mathbf{R}$ with $q_x(t,x)>0$ for $(t,x)\in[0,T)\times\mathbf{R}$.*

The proof of the above lemma is similar to the proof of Lemma 2 in Ref. 11, so we omit it.□

Lemma 4.2: Let $u_0\in H^3$ and let $T>0$ be the maximal existence time of the corresponding solution u to (1.1). *Then we have*

$$y(t,q(t,x))q_x^2(t,x)=y_0(x)e^{-\lambda t},$$

where $y_0=u_0-\partial_x^2u_0$.

Proof: Differentiation of the system (4.1) with respect to x yields

$$\frac{d}{dt}q_x=u_x(t,q)q_x, \quad t\in(0,T),$$

$$q_x(0,x)=1, \quad x\in\mathbf{R}. \tag{4.2}$$

Let $p(t,x)=y(t,q(t,x))q_x^2(t,x)$, and we infer from (1.1) and (4.1) and (4.2) that

$$\frac{d}{dt}p(t,x)=-\lambda p(t,x),$$

we integrate the above relation between 0 and t and complete the proof. □

Theorem 4.1: *Assume that $u_0\in H^3$ does not change sign ($y_0\geqslant 0$ or $y_0\leqslant 0$ on $\mathbf{S}$), then the corresponding solution u to (1.1) exists globally. Moreover, the global solution decays to 0 as time goes to infinite.*

Proof: We consider first the case when $y_0(x)\geqslant 0$, $x\in\mathbf{S}$. Let $T>0$ be the existence time of the solution u with initial data u_0 given by Theorem 2.2. By Lemma 4.2, we obtain for $t\in[0,T)$ that $y(t,x)\geqslant 0$, $x\in\mathbf{S}$.

From Sec. II we know that

$$u(t,x)=\int_{\mathbf{S}}G(x-\eta)y(t,\eta)\,d\eta, \quad (t,x)\in[0,T)\times\mathbf{S},$$

where $G(x):=\cosh\left(x-[x]\frac{1}{2}\right)/2\sinh\left(\frac{1}{2}\right)$, $x\in\mathbf{S}$.

Fix $(t,x)\in[0,T)\times\mathbf{S}$ and let $\sigma:=1/4\sinh\left(\frac{1}{2}\right)$. We have

$$\begin{aligned}u(t,x)=&\sigma e^x\int_0^x e^{-\eta-1/2}y(t,\eta)\,d\eta+\sigma e^{-x}\int_0^x e^{\eta+1/2}y(t,\eta)\,d\eta+\sigma e^x\int_x^1 e^{-\eta+1/2}y(t,\eta)\,d\eta\\&+\sigma e^{-x}\int_x^1 e^{\eta-1/2}y(t,\eta)\,d\eta.\end{aligned} \tag{4.3}$$

Differentiation with respect to x yields for $(t,x)\in[0,T)\times\mathbf{S}$,

$$\begin{aligned}u_x(t,x)=&\sigma e^x\int_0^x e^{-\eta-1/2}y(t,\eta)\,d\eta-\sigma e^{-x}\int_0^x e^{\eta+1/2}y(t,\eta)\,d\eta+\sigma e^x\int_x^1 e^{-\eta+1/2}y(t,\eta)\,d\eta\\&-\sigma e^{-x}\int_x^1 e^{\eta-1/2}y(t,\eta)\,d\eta.\end{aligned} \tag{4.4}$$

From (4.3) and (4.4), (2.9) and Lemma 2.2, we infer that

$$-u_x(t,x) \leqslant u(t,x) \leqslant \|u\|_{L^\infty} \leqslant \frac{e^{-\lambda t}}{\sqrt{2}}\|u_0\|_1. \tag{4.5}$$

So, by Theorem 2.3 we know that $T=\infty$.

By (4.5), we obtain that $-u_x \leqslant \lambda/5$ for sufficiently large t. This yields in combination with (2.6) and Gronwall's inequality,

$$\|y\|_1^2 \leqslant Ce^{-\lambda t}$$

for large t, where C is a positive constant. Hence, the second conclusion of the above theorem is proved.

For the case when $y_0(x) \leqslant 0$, $x \in \mathbf{S}$, we can repeat the above proof to get the desired result.□

Remark 4.1: Note that the global solution to the Camassa-Holm equation does not generally decay to zero as time goes to infinite. Theorem 4.1 shows that there is a considerable difference between the equation (1.1) and the Camassa-Holm equation in their long time behaviors. More precisely, the energy dissipation will affect the long time behavior of global solutions to the Camassa-Holm equation.

Remark 4.2: It is well-known the Camassa-Holm equation has peaked traveling wave solutions. Theorem 4.1 shows that global H^3 solutions with y_0 of one sign decay in the H^3 norm. Lemma 2.2 shows that any global solution decays in the H^1 norm. This means that there are no traveling wave solutions of the dissipative equation (1.1) . This is also another considerable difference between the equation (1.1) and the Camassa-Holm equation in their long time behaviors.

The approximation of the transmutation kernel

Amin Boumenir[a)]

(Received 1 November 2005; accepted 7 November 2005; published online 11 January 2006)

The transformation operator plays an important role in the direct and inverse spectral theory of Sturm-Liouville operators. In this paper we would like to approximate the kernel of the transformation operator used in the Gelfand-Levitan theory. The analytic properties of the solution allows for its representation by either a Taylor series about the diagonal or a Fourier cosine series. Example illustrating how the coefficients can be computed are provided. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2159067]

I. INTRODUCTION

We are concerned with the approximation of the kernel $K(x,t)$ appearing in the transformation operator[2–4,6,7]

$$y(x,\lambda)=\cos(x\lambda)+\int_0^x K(x,t)\cos(t\lambda)\mathrm{d}t, \tag{1.1}$$

where y is the eigensolution of the singular Sturm-Liouville operator L,

$$\begin{gathered} L(y):=-y''(x,\lambda)+q(x)y(x,\lambda)=\lambda^2 y(x,\lambda), \quad x\in[0,\infty), \\ hy(0,\lambda)-y'(0,\lambda)=0. \end{gathered} \tag{1.2}$$

The transformation operator $1+\mathbf{K}$ in (1.1) links the eigensolutions of (1.2) to $\cos(x\lambda)$ which are also eigensolutions of (1.2) when $q=h=0$. Its kernel K stores all the spectral information of the operator L (1.2) and consequently plays a fundamental role in the direct and inverse spectral theory of L.[6] For example, the Gelfand-Levitan theory is based on the solution of the linear integral equation which is defined by

$$F(x,t)+\int_0^x K(x,s)F(s,t)\mathrm{d}s=-K(x,t), \tag{1.3}$$

where

$$F(x,t)=\int_0^\infty \cos(x\lambda)\cos(t\lambda)\mathrm{d}\sigma(\lambda^2)+\int_{-\infty}^0 \cosh(x\lambda)\cosh(t\lambda)\mathrm{d}\rho(-\lambda^2) \tag{1.4}$$

and $\sigma(\lambda)=\rho(\lambda)-(2/\pi)\sqrt{\lambda_+}$. In (1.4), the measure ρ is the spectral function of the operator L in (1.2), and its support is the spectrum of the operator. If ρ is absolutely continuous and supp $\rho\subset[0,\infty)$ then

[a)]Electronic mail: boumenir@westga.edu

$$\left(2\lambda\rho'(\lambda^2)-\frac{2}{\pi}\right)\cos(t\lambda)=\frac{2}{\pi}\int_0^\infty F(x,t)\cos(x\lambda)\mathrm{d}x \tag{1.5}$$

and letting $t\to 0$, formally yields

$$\lambda\rho'(\lambda)=\frac{1}{\pi}+\frac{1}{\pi}\int_0^\infty F(x,0)\cos(x\lambda)\mathrm{d}x. \tag{1.6}$$

A more direct method using operational calculus and the kernel of the inverse transmutation can be found in Ref. 1. Thus the first step towards computing the function F, ρ or the solution $y(x,\lambda)$ is obviously to start with the kernel K, which is the main objective of this paper.

Another possible application of (1.1) is to express the solution of a singular Sturm-Liouville operator,

$$\begin{gathered}-\varphi''(x)+q(x)\varphi(x)=f(x),\quad \text{where } x\geqslant 0,\\ \varphi(0)=1\quad\text{and}\quad \varphi'(0)=h.\end{gathered} \tag{1.7}$$

Since $(1+\mathbf{K})$ is a transmutation,[3] we have

$$[-D^2+q(x)](1+\mathbf{K})=(1+\mathbf{K})(-D^2)$$

and the solution of (1.7) is then given by $\varphi(x)=(1+\mathbf{K})s(x)$ where $-s''(x)=(1+\mathbf{K})^{-1}f$. Once the operators $(1+\mathbf{K})$ and its inverse are known, the solution φ can be computed symbollically.

The Fourier transform provides yet another way for (1.7). Define $\varphi(x)=\int_0^\infty(1/\lambda)\hat{f}(\lambda)y(x,\lambda)\mathrm{d}\rho(\lambda)$, where $\hat{f}(\lambda)=\int_0^\infty f(x)y(x,\lambda)\mathrm{d}x$, $y(x,\lambda)$ is given by (1.1) and ρ by (1.5). Thus there are many ways where the kernel K can be used to solve computational problems related to the Sturm-Liouville theory.

Recall that Povzner and Marchenko,[7] to prove the existence of the kernel K, used a fixed point argument, since the kernel K solves a hyperbolic equation,

$$\begin{gathered}\frac{\partial^2}{\partial x^2}K(x,t)-\frac{\partial^2}{\partial t^2}K(x,t)=q(x)K(x,t),\quad 0\leqslant t\leqslant x,\\ \frac{\mathrm{d}}{\mathrm{d}x}K(x,x)=\frac{1}{2}q(x),\\ \frac{\partial}{\partial t}K(x,0)=0.\end{gathered}$$

Unfortunately, the idea of successive approximations cannot easily be implemented numerically, since the iterates involve two-dimensional integrals. Finite differences also are difficult to use since the domain is a sector.

We briefly mention a different numerical method of approximating ρ directly by Fulton and Pruess.[5] Their algorithm approximates ρ by step functions by computing the integral $\int_0^N|y(x,\lambda)|^2\,\mathrm{d}x$ for large values of N. For example, if λ belongs to the continuous spectrum then we know that $\lim_{N\to\infty}\int_0^N|y(x,\lambda)|^2\,\mathrm{d}x=\infty$ and so $\rho(\lambda+)-\rho(\lambda-)=(\lim_{N\to\infty}\int_0^N|y(x,\lambda)|^2\,\mathrm{d}x)^{-1}=0$, i.e., ρ is continuous. On the other hand, if λ is an eigenvalue then $\rho(\lambda+)-\rho(\lambda-)=(\lim_{N\to\infty}\int_0^N|y(x,\lambda)|^2\,\mathrm{d}x)^{-1}\neq 0$ and so ρ has a jump at λ. This idea can also be implemented by our method since we approximate symbollically the solution $y(x,\lambda)$ when $\lambda\neq 0$.

II. PRELIMINARIES

We first prove the following.

Proposition 1: *Assume that* $q^{(m)}\in L^{\mathrm{loc}}[0,\infty)$ *for* $m\geqslant 1$, *then there exists* α_k *and* β_k *such that*

$$y(x,\lambda)=\cos(x\lambda)\sum_{k=0}^{[m/2]}\frac{\alpha_k(x)}{\lambda^{2k}}+\sin(x\lambda)\sum_{k=0}^{[(m-1)/2]}\frac{\beta_k(x)}{\lambda^{2k+1}}+\frac{1}{\lambda^{m+1}}\epsilon(x,m+1,\lambda), \tag{2.1}$$

where $\alpha_k^{(m+2-2k)}$, $\beta_k^{(m+1-2k)}\in L^{\mathrm{loc}}[0,\infty)$ *and* $\epsilon(x,m+1,\lambda)=o(1)$ *as* $\lambda\to\infty$.

Proof: From the Gelfand-Levitan-Gasymov theorem we recall that,[6] if $q^{(m)}\in L^{\mathrm{loc}}[0,\infty)$ then $\partial_t^{m+1}K(x,.)\in L(0,x)$. Thus for each fixed x, we can integrate by parts at least m times in t, say $m=2n+1$ is odd,

$$\begin{aligned}\int_0^x K(x,t)\cos(t\lambda)\mathrm{d}t &= K(x,x)\frac{1}{\lambda}\sin(x\lambda)-K_t(x,x)\frac{1}{\lambda^2}\cos(x\lambda)+K_t(x,0)\frac{1}{\lambda^2}-\int_0^x K_{tt}(x,t)d\frac{1}{\lambda^3}\sin(t\lambda)\\ &=\cos(x\lambda)\sum_{k=0}^{2n}\frac{\alpha_k(x)}{\lambda^{2k}}+\sin(x\lambda)\sum_{k=1}^{2n}\frac{\beta_k(x)}{\lambda^{2k+1}}+\sum_{k=1}^{2n}\frac{\gamma_k(x)}{\lambda^{2k}}\\ &\quad+\frac{1}{\lambda^{2n+2}}\int_0^x\frac{\partial^{2n+2}}{\partial t^{2n+2}}K(x,t)\cos(t\lambda)\mathrm{d}t.\end{aligned} \tag{2.2}$$

Clearly, by Riemann-Lebesgue's theorem, we have

$$\epsilon(x,m+1,\lambda)=\int_0^x\frac{\partial^{m+1}}{\partial t^{m+1}}K(x,t)\cos(t\lambda)\mathrm{d}t=o(1)\quad\text{as }\lambda\to\infty\,. \tag{2.3}$$

From (2.2), $\sin(x\lambda)$ appears with odd powers of $1/\lambda$ while $\cos(x\lambda)$ with even powers of $1/\lambda$. If we denote by

$$\beta_k(x)=(-1)^k\frac{\partial^{2k}}{\partial t^{2k}}K(x,x)\quad\text{and}\quad\alpha_k(x)=(-1)^k\frac{\partial^{2k-1}}{\partial t^{2k-1}}K(x,x) \tag{2.4}$$

then $\alpha_k^{(m+2-2k)}$, $\beta_k^{(m+1-2k)}\in L^{\mathrm{loc}}[0,\infty)$. The next step we need to show that in (2.2),

$$\gamma_{2k}(x)=\frac{\partial^{2k-1}}{\partial t^{2k-1}}K(x,0)=0$$

for $k=0,\ldots,m$. This can be done directly by looking at the linear integral equation (1.3). Since $(\partial^{2k+1}/\partial t^{2k+1})F(x,t)=(-1)^k\lambda^{2k+1}\int\cos(x\lambda)\sin(t\lambda)\mathrm{d}\sigma(\pm\lambda^2)$ we have $(\partial^{2k+1}/\partial t^{2k+1})F(x,0)=0$ and hence (1.3) implies

$$\frac{\partial^{2k+1}}{\partial t^{2k+1}}K(x,0)=0\Rightarrow\gamma_{2k}(x)=0. \tag{2.5}$$

By checking (2.2) when m is even, we deduce the upper bounds of the sum in (2.1). □

Remark: In Ref. 8, Sec. 2.8, Olver works out a formal infinite series solution, which is similar to (2.1), with $\exp(x\lambda)$ instead of $\sin(x\lambda)$ and $\cos(x\lambda)$. However the Gelfand-Levitan theory makes the argument plain and explains how the number of terms in the expansion depends on the smoothness of q, and thus cannot in general be an infinite series; moreover it yields an explicit error term.

III. COMPUTING THE COEFFICIENTS α_k, β_k

Equation (2.4) shows that we can recover the partial derivative of K, if we can compute the coefficients α_k, β_k. To this end use the fact that

$$L(fg)=-f''g-2f'g'+fLg$$

to obtain

$$L(\cos(x\lambda)\alpha_n) = \lambda^2 \cos(x\lambda)\alpha_n + 2\lambda \sin(x\lambda)\alpha_n' + \cos(x\lambda)L\alpha_n,$$

$$L(\sin(x\lambda)\beta_n) = \lambda^2 \sin(x\lambda)\beta_n - 2\lambda \cos(x\lambda)\beta_n' + \sin(x\lambda)L\beta_n.$$

Thus from (2.1), it follows

$$\begin{aligned} Ly &= \cos(x\lambda)\sum_{n=0}^{N}\left(\frac{\alpha_n}{\lambda^{2n-2}} + \frac{L\alpha_n - 2\beta_n'}{\lambda^{2n}}\right) + \sin(x\lambda)\sum_{n=0}^{N}\left(\frac{\beta_n + 2\alpha_n'}{\lambda^{2n-1}} + \frac{L\beta_n}{\lambda^{2n+1}}\right) \\ &= \cos(x\lambda)\sum_{n=0}^{N}\left(\frac{\alpha_n - 2\beta_{n-1}' + L\alpha_{n-1}}{\lambda^{2n-2}}\right) + \sin(x\lambda)\sum_{n=0}^{N}\left(\frac{\beta_n + 2\alpha_n' + L\beta_{n-1}}{\lambda^{2n-1}}\right) \end{aligned} \tag{3.1}$$

with the understanding that $\alpha_{-1}=\beta_{-1}=0$. Since

$$Ly = \lambda^2 y = \cos(x\lambda)\sum_{n=0}^{N-2}\frac{\alpha_n}{\lambda^{2n-2}} + \sin(x\lambda)\sum_{n=0}^{N-2}\frac{\beta_n}{\lambda^{2n-1}} \tag{3.2}$$

by identifying the different coefficients in (3.1) and (3.2), we end up with for $n \geqslant 1$,

$$-2\beta_{n-1}' + L\alpha_{n-1} = 0$$

$$2\alpha_n' + L\beta_{n-1} = 0$$

or

$$\beta_{n-1}(x) = \beta_{n-1}(0) + \frac{1}{2}\int_0^x L\alpha_{n-1}(t)\mathrm{d}t,$$

$$\alpha_n(x) = \alpha_n(0) - \frac{1}{2}\int_0^x L\beta_{n-1}(t)\mathrm{d}t.$$

The constants $\alpha_n(0)$ and $\beta_n(0)$ are obtained from the asymptotic behavior of y (1.2),

$$y(x,\lambda) = 1 + xh + o(x^2) \quad \text{as } x \to 0$$

while the representation (2.1) as $x \to 0$, reduces to

$$y(x,\lambda) \approx \sum_{n=0}\frac{\alpha_n(0)}{\lambda^{2n}} + x\sum_{n=0}\frac{\beta_n(0)}{\lambda^{2n}},$$

$$\alpha_0(0) = 1, \quad \beta_0(0) = h, \tag{3.3}$$

$$\alpha_n(0) = 0 \quad \text{and} \quad \beta_n(0) = 0 \quad \text{for } n \geqslant 1.$$

The algorithm is easy to see, taking into account that $\alpha_{-1}=\beta_{-1}=0$,

$$\begin{aligned} &\alpha_0(x) = 1 && \alpha_1(x) = -\frac{1}{2}\int_0^x L\beta_0(t)\mathrm{d}t && \alpha_2(x) = -\frac{1}{2}\int_0^x L\beta_1(t)\mathrm{d}t \\ &\beta_0(x) = h + \frac{1}{2}\int_0^x q(x)\mathrm{d}t \Rightarrow && \beta_1(x) = \frac{1}{2}\int_0^x L\alpha_1(t)\mathrm{d}t && \Rightarrow \quad \beta_2(x) = \frac{1}{2}\int_0^x L\alpha_2(t)\mathrm{d}t \end{aligned} \tag{3.4}$$

$$\beta_n(x) = \frac{1}{2}\left(\alpha_n'(0) - \alpha_n'(x) + \int_0^x q(t)\alpha_n(t)\mathrm{d}t\right).$$

$$\alpha_n(x) = \frac{-1}{2}\left(\beta_{n-1}'(0) - \beta_{n-1}'(x) + \int_0^x q(t)\beta_{n-1}(t)\mathrm{d}t\right),$$

In this case we need only one derivation and a simple integration that could be performed symbolically. For a faster algorithm, we can combine both sequences (α_n) and (β_n) into one

$$\alpha_0 \to \beta_0 \to \alpha_1 \to \beta_1 \to \alpha_2 \to \beta_2 \to \cdots \to \alpha_n \to \beta_n \to \alpha_{n+1} \to \cdots .$$

Let $\{c_n\}$ be a new sequence defined by

$$c_{2n}(x) = \alpha_n(x) \quad \text{while } c_{2n+1}(x) = \beta_n(x)$$

then it can be defined recursively for $n \geqslant 3$ by

$$c_n(x) = \frac{(-1)^{n-1}}{2}\int_0^x Lc_{n-1}(t)\mathrm{d}t. \tag{3.5}$$

Proposition 1 reduces to the following.

Proposition 2: *Assume that* $q^{(m)} \in L^{\mathrm{loc}}[0,\infty)$ *for* $m \geqslant 1$, *then*

$$y(x,\lambda) = \cos(x\lambda)\sum_{k=0}^{[m/2]}\frac{c_{2k}(x)}{\lambda^{2k}} + \sin(x\lambda)\sum_{k=0}^{[(m-1)/2]}\frac{c_{2k+1}(x)}{\lambda^{2k+1}} + \frac{1}{\lambda^{m+1}}\epsilon(x,m+1,\lambda), \tag{3.6}$$

where $\epsilon(x,m+1,\lambda) = o(1)$ *as* $\lambda \to \infty$ *and the sequence* c_n *can be computed iteratively by* (3.5).

Since our solution starts with $\cos(x\lambda)$, we have $c_0(x) = 1$ while $c_1(x) = h + \int_0^x q(t)\mathrm{d}t$. The second independent solution, can be generated by

$$\varphi(0,\lambda) = 0 \quad \text{and} \quad \varphi'(0,\lambda) = 1$$

represented by[6]

$$\varphi(x,\lambda) = \frac{\sin(x\lambda)}{\lambda} + \int_0^x L(x,t)\frac{\sin(t\lambda)}{\lambda}\mathrm{d}t,$$

and so by comparing with (2.1), we see that it starts with $\sin(x\lambda)/\lambda$, which means $c_0(x) = 0$ and $c_1(x) = 1$.

Having the coefficients c_k we now show how to approximate the kernel $K(x,t)$ close to the region $x = t$.

Proposition 3: *Assume that* $q^{(m)} \in L^{\mathrm{loc}}(0,\infty)$, *then the kernel K can be approximated by*

$$K(x,t) = \sum_{n=0}^{m} a_n(x)\frac{1}{n!}(x-t)_+^n + \epsilon_m(x,t),$$

where

$$\alpha_{2k}(x) = (-1)^k c_{2k+1}(x), \quad \alpha_{2k-1}(x) = (-1)^k c_{2k}(x),$$

and the remainder

$$\epsilon_m(x,t) = (1/m\,!)\int_x^t \partial_t^{m+1}K(x,n)(t-\eta)^m\mathrm{d}\eta.$$

Proof: Since $\partial_t^{m+1}K(x,\eta)\in L(0,x)$, for any fixed $x>0$, its Taylor expansion yields for $0\leqslant t\leqslant x$,

$$K(x,t)=\sum_{n=0}^{m}\partial_t^n K(x,x)\frac{1}{n!}(x-t)_+^n+\epsilon_m(x,t).$$

The functions $\partial_t^n K(x,x)$ were already found in terms of α_k and β_k (2.4). □

IV. THE COSINE SERIES

For any fixed $x>0$, we can recover $K(x,t)$, which is continuous for $t\in(0,x)$, by a cosine series expansion

$$K(x,t)=\frac{1}{2}\hat{K}(x,0)+\sum_{n\geqslant 1}\hat{K}(x,n)\cos\left(nt\frac{\pi}{x}\right)\quad\text{for } t\in(0,x),$$

where the Fourier coefficients are readily available when $n\neq 0$,

$$\begin{aligned}\hat{K}(x,n)&=\frac{2}{x}\int_0^x K(x,t)\cos\left(tn\frac{\pi}{x}\right)\mathrm{d}t=\frac{2}{x}\left[y\left(x,n\frac{\pi}{x}\right)-\cos(n\pi)\right]=\frac{2}{x}\cos(n\pi)\sum_{j=1}^{[m/2]}\frac{c_{2j}(x)}{\left(n\frac{\pi}{x}\right)^{2j}}\\&+\frac{2}{x}\frac{x^{m+1}}{(n\pi)^{m+1}}\epsilon\left(x,m+1,n\frac{\pi}{x}\right)=(-1)^n 2\sum_{j=1}^{[m/2]}\frac{c_{2j}(x)}{(n\pi)^{2j}}x^{2j-1}+\frac{2x^m}{n^{m+1}\pi^{m+1}}\epsilon\left(x,m+1,n\frac{\pi}{x}\right),\end{aligned}\tag{4.1}$$

where $\epsilon(x,m+1,n(\pi/x))=o(1)$ as $n\to\infty$ is the truncation error defined by (2.3). For the remaining coefficient $n=0$, use

$$\frac{1}{2}\hat{K}(x,0)=\frac{1}{x}(y(x,0)-1)$$

which can be easily computed independently since it does not contain the parameter λ. For example, successive approximations to solve

$$y(x,0)=1+xh+\int_0^x(x-t)q(t)y(t,0)\mathrm{d}t\tag{4.2}$$

yields (4.2), $y(x,0)=1+xh+\int_0^x(x-t)q(t)(1+th)\mathrm{d}t+\cdots$.

Proposition 4: *If* $q^{(m)}\in L^{\mathrm{loc}}[0,\infty)$, *then the kernel* K *can be approximated for* $t\in(0,x)$, $x>0$ *by*

$$K(x,t)=\frac{1}{x}(y(x,0)-1)+\sum_{n\geqslant 1}(-1)^n 2\sum_{j=1}^{[m/2]}\frac{c_{2j}(x)}{(n\pi)^{2j}}x^{2j-1}\cos\left(nt\frac{\pi}{x}\right)+C(m),$$

where

$$C(m)=\sum_{n\geqslant 1}\frac{2x^m}{n^{m+1}\pi^{m+1}}\epsilon\left(x,m+1,n\frac{\pi}{x}\right)\cos\left(nt\frac{\pi}{x}\right)\to 0\quad\text{as } m\to\infty.$$

The kernel can then be approximated by combining (4.1) and a solution of (4.2),

$$K(x,t)=\frac{1}{2}\hat{K}(x,0)+\sum_{n\geqslant 0}\hat{K}(x,n)\cos\left(nt\frac{\pi}{x}\right).$$

Observe that a simple formula can be obtained from the convergence of the Fourier series at the endpoint $t=x$.

Corollary 1: *We have*

$$K(x,0)=-h-1-\frac{1}{2}\int_0^x q(\eta)\mathrm{d}\eta+y(x,0)+\frac{4}{x}\sum_{n\geqslant 0}(-1)^n\left(y\left(x,n\frac{\pi}{x}\right)-\cos(xn)\right).$$

V. EXAMPLES

It is enough to see that the true solution $y(x,\lambda)$ and its approximation are close for $\lambda>0$.

Example 1: Consider $-y''+\cos(x)y=\lambda^2 y$, where $y(0,\lambda)=1$ and $y'(0,\lambda)=-2$. The exact solution is

$$y_e(x,\lambda)=\mathrm{MathieuC}(4\mu^2,2,1/2x)-4\mathrm{MathieuS}(4\mu^2,2,1/2x).$$

The coefficients are easily computed,

$$a[0]=1,$$

$$a[1]=-2+1/2\sin(x),$$

$$a[2]=1/4\cos(x)+\sin(x)-1/8\sin(x)^2-1/4,$$

$$a[3]=-1/2\cos(x)+3/16\cos(x)\sin(x)+1/16x-1/4\cos(x)^2-1/48\sin(x)^3+1/2+1/4+1/48,$$

$$a[4]=-1/24\sin(x)-3/16\sin(x)^2+3/8\cos(x)\sin(x)+1/8x-1/96\cos(x)\sin(x)^2$$
$$-5/96\cos(x)+5/96\cos(x)^3-1/32\sin(x)x+1/24\cos(x)^2\sin(x)+1/384\sin(x)^4$$
$$+5/96-5/96.$$

Here we compare few values from $y(3,n)$, $n=1,\ldots,36$,

(Received 9 July 2005; accepted 2 November 2005; published online 17 January 2006)

For the direct sum of several copies of sl_n, a family of Lie brackets compatible with the initial one is constructed. The structure constants of these brackets are expressed in terms of θ functions associated with an elliptic curve. The structure of Casimir elements for these brackets is investigated. A generalization of this construction to the case of vector-valued θ-functions is presented. A different procedure for constructing compatible Lie brackets based on the argument shift method for quadratic Poisson brackets is discussed. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2158434]

I. INTRODUCTION

Two Lie brackets $[\cdot,\cdot]_1$ and $[\cdot,\cdot]_2$, defined on the same finite-dimensional vector space $\mathbf{V}$, are said to be compatible if

$$[\cdot,\cdot]_u=[\cdot,\cdot]_1+u[\cdot,\cdot]_2 \tag{1.1}$$

is a Lie bracket for any constant u. As a matter of fact, this notion coincides with the concept of two compatible linear Poisson structures (see Ref. 1). Indeed, the formula

$$\{x_i,\ x_j\}=c_{ij}^k x_k,\quad i,j=1,\ldots,N \tag{1.2}$$

defines a Poisson bracket iff c_{ij}^k are structural constants of a Lie algebra and the compatibility of two Poisson brackets of this form is equivalent to the compatibility of the two corresponding Lie structures.

The Casimir functions of the Poisson bracket $\{\cdot,\cdot\}_u$ corresponding to (1.1) are polynomials in u, whose coefficients commute with respect to both Poisson brackets. This way for constructing completely integrable Hamiltonian dynamical systems of compatible Poisson brackets is called the Lenard–Magri scheme.[1,2] Pairs of compatible Lie brackets have been considered in this context in Refs. 3 and 4.

However, possible applications of compatible pairs of Lie algebras in the integrability theory are not exhausted by this construction. For example, it was shown in Ref. 5 that the system of nonlinear hyperbolic equations,

$$U_x=[U,V]_1,\quad V_y=[V,U]_2,\quad U,V\in\mathbf{V},$$

is integrable for compatible Lie brackets. If the brackets $[\cdot,\cdot]_{1,2}$ coincide, this system is just the principal chiral model.

[a)]Present address: Landau Institute for Theoretical Physics, Kosygina 2, 119334, Moscow, Russia.

Compatible Lie brackets also are closely related to decompositions of infinite-dimensional Lie algebras into a vector direct sum of two subalgebras.[6–8] Furthermore, it was shown in Ref. 9 that any pair of compatible Lie brackets having a common quadratic Casimir function produces a (nonconstant) solution of the classical Yang–Baxter equation.

The following classification problem arises: to describe all possible brackets $[\cdot,\cdot]_2$ on a vector space $\mathbf{V}$, compatible with a given semisimple bracket $[\cdot,\cdot]_1$. Since any semisimple Lie algebra is rigid, the bracket (1.1) is isomorphic to $[\cdot,\cdot]_1$ for almost all values of the parameter u. It is well known that for the semisimple case the second bracket $[\cdot,\cdot]_2$ is given by the formula

$$[X,Y]_2=[R(X),Y]_1+[X,R(Y)]_1-R([X,Y]_1),$$

where R is a linear operator on $\mathbf{V}$.

Some examples of compatible brackets are known (see Refs. 4 and 5). Similar to solutions of classical Yang–Baxter equations (Ref. 10), these examples are (in some sense) rational, trigonometric, or elliptic.

In this paper, we construct a class of compatible semisimple Lie brackets related to an elliptic curve. By analogy with other "elliptic" models in integrability theory, one can expect that a very wide class of compatible Lie brackets can be obtained by different degenerations of these basic "elliptic" pairs and by deformations of degenerate pairs, which are usually not as rigid as the elliptic models.

The paper is organized as follows. In Sec. II we present a construction of compatible elliptic $\oplus_{i=1}^{m} sl_n$-Lie brackets. The initial date for our construction is a pair of θ functions of order m without common zeros on an elliptic curve $\mathcal{E}$. To demonstrate the main idea, let us consider a slightly different situation of two compatible associative structures.

Let $\mathbf{V}$ be the k-dimensional vector space of all polynomials of degree $\leqslant k-1$ in one variable, let μ_1 and μ_2 be given polynomials of degree k without common roots. It is clear that any polynomial Z, where $\deg Z\leqslant 2k-1$, can be uniquely represented in the form $Z=\mu_1 P+\mu_2 Q$, where $P,Q\in\mathbf{V}$. The explicit form of P and Q can be found with the help of the Lagrange interpolation formula. Let us define two multiplications $\circ$ and $\star$ on $\mathbf{V}$ by the formula

$$XY=\mu_1(X\circ Y)+\mu_2(X\star Y),\quad X,Y\in\mathbf{V}.$$

It can be checked that any linear combination of these two products is associative. We consider an analog of this construction for Lie algebras replacing polynomials by θ functions on $\mathcal{E}$ with values in sl_n.

In Sec. III we investigate properties of the Lie algebra $\mathcal{G}_u$ with the bracket (1.1) constructed in Sec. II. Since for generic u the Lie algebra $\mathcal{G}_u$ is isomorphic to $\oplus_{i=1}^{m} sl_n$, we know that the center of the universal enveloping algebra $\mathbf{U}(\mathcal{G}_u)$ is generated by $m(n-1)$ elements of $\mathbf{U}(\mathcal{G}_u)$. More precisely, we have m generators of degree p, where $p=2,3,\ldots,n$. Usually the elements of the center are called the Casimir elements.

Since (1.1) is linear in u, the Casimir elements can be chosen to be polynomial in u. It turns out that for each p there exists one Casimir element $K_{p,1}$ of degree $p-2$ in u, $m-2$ Casimir elements $K_{p,2},\ldots,K_{p,m-1}$ of degree $p-1$ and one element $K_{p,m}$ of degree p. In particular, there exists one quadratic Casimir element, which does not depend on u. This element can be regarded as an invariant bilinear form, common for both brackets $[\cdot,\cdot]_{1,2}$.

This picture is in accordance with general results and conjectures by Gelfand and Zakharevich[11] about "good" bi-Hamiltonian structures that in our case states, in particular, that $\Sigma_{i,j}(2\deg_u K_{ij}+1)$ should be equal to $\dim \mathcal{G}_u=m(n^2-1)$.

In Sec. III we find explicit formulas for of all these Casimir elements K_{ij}.

In Sec. IV we generalize the results of Sec. II to the case of vector-valued θ functions or, which is the same, to the case of l-dimensional indecomposable holomorphic vector bundles over the elliptic curve. As the result, we get an $(l+1)$-dimensional vector space of pairwise compatible Lie brackets.[11]

In Sec. V we discuss a different way for constructing compatible linear Poisson brackets starting with a quadratic Poisson bracket of Sklyanin type. This construction is based on the argument shift method. We conjecture that the family of compatible brackets thus obtained coincides with the brackets constructed in Sec. IV.

II. COMPATIBLE LIE BRACKETS RELATED TO SCALAR θ-FUNCTIONS

Let $\Gamma \subset \mathbb{C}$ be a lattice generated by 1 and τ, where $\operatorname{Im}\tau > 0$. Let $m \in \mathbb{N}$. We denote by $\Theta_m(\tau)$ the vector space of holomorphic functions $\phi: \mathbb{C} \to \mathbb{C}$, such that

$$\phi(z+1) = \phi(z), \quad \phi(z+\tau) = (-1)^m \exp(-2\pi i m z)\phi(z).$$

Elements of this vector space are called θ functions of order m. Properties of θ functions are described, for example, in the Appendix to the review.[12] In particular, the dimension of $\Theta_m(\tau)$ is equal to m. We fix a generator of $\Theta_1(\tau)$ and denote it by $\theta(z)$. It is known that any element $f \in \Theta_m(\tau)$ has m roots modulo Γ and the sum of these roots is equal to zero modulo Γ. In particular, $\theta(z)$ has only one root modulo Γ at $z=0$. If $x_1, \ldots, x_m$ are all roots of $f \in \Theta_m(\tau)$, then $f(z) = c\,\theta(z-x_1)\cdots\theta(z-x_m)$, where c is a constant.

Let us fix relatively prime natural numbers k and n such that $1 \leqslant k < n$. Let $\mathbf{a}$ and $\mathbf{b}$ be $n \times n$ matrices, such that

$$\mathbf{a}^n = \mathbf{b}^n = 1, \quad \mathbf{ba} = \exp\left(\frac{2\pi i k}{n}\right)\mathbf{ab}. \tag{2.1}$$

Note that such a pair of matrices $(\mathbf{a}, \mathbf{b})$ is a necessary ingredient of several "elliptic" constructions related to sl_n (see Refs. 10, 13, and 14). It is clear that the matrices $\mathbf{a}^\alpha \mathbf{b}^\beta$, where $\alpha, \beta = 0, \ldots, n-1$, $(\alpha, \beta) \neq (0,0)$, form a basis in sl_n. The commutator relations between these matrices are given by

$$[\mathbf{a}^{\alpha_1}\mathbf{b}^{\beta_1},\ \mathbf{a}^{\alpha_2}\mathbf{b}^{\beta_2}] = \left[\exp\left(\frac{2\pi i k \beta_1 \alpha_2}{n}\right) - \exp\left(\frac{2\pi i k \beta_2 \alpha_1}{n}\right)\right]\mathbf{a}^{\alpha_1+\alpha_2}\mathbf{b}^{\beta_1+\beta_2}. \tag{2.2}$$

We denote by $\mathbf{V}_m$ the vector space of holomorphic functions $f: \mathbb{C} \to sl_n$ satisfying the following quasiperiodic conditions:

$$f(z+1) = \mathbf{a} f(z) \mathbf{a}^{-1}, \quad f(z+\tau) = (-1)^m \exp(-2\pi i m z)\mathbf{b} f(z) \mathbf{b}^{-1}. \tag{2.3}$$

Note that if $f_1 \in \mathbf{V}_{m_1}$ and $f_2 \in \mathbf{V}_{m_2}$, then $f_1 f_2 \in \mathbf{V}_{m_1+m_2}$. It follows from (2.3) that if

$$f(z) = \sum f_{\alpha,\beta}(z)\mathbf{a}^\alpha \mathbf{b}^\beta,$$

then

$$f_{\alpha,\beta}(z+1) = \exp\left(-\frac{2\pi i k \beta}{n}\right) f_{\alpha,\beta}(z),$$

$$f_{\alpha,\beta}(z+\tau) = (-1)^m \exp\left(-2\pi i m z + \frac{2\pi i k \alpha}{n}\right) f_{\alpha,\beta}(z). \tag{2.4}$$

These identities imply that

$$f_{\alpha,\beta}(z) = \exp\left(-\frac{2\pi i k \beta}{n} z\right) g_{\alpha,\beta}\left(z - \frac{k\alpha}{mn} - \frac{k\beta}{mn}\tau\right), \tag{2.5}$$

where $g_{\alpha,\beta}(z)$ belongs to $\Theta_m(\tau)$.

Lemma 1: *Let $\mu_1, \mu_2 \in \Theta_m(\tau)$ be a pair of θ functions that have no common zeros. Then any element $Z \in \mathbf{V}_{2m}$ can be uniquely represented in the form*

$$Z = \mu_1 P + \mu_2 Q, \quad P, Q \in \mathbf{V}_m.$$

Proof: Consider a linear mapping $L: \mathbf{V}_m \oplus \mathbf{V}_m \to \mathbf{V}_{2m}$ given by the formula

$$L(P,Q) = \mu_1 P + \mu_2 Q.$$

We should prove that L is an isomorphism. Since $\dim(\mathbf{V}_m \oplus \mathbf{V}_m) = \dim \mathbf{V}_{2m} = 2m(n^2-1)$, it suffices to prove that $\operatorname{Ker} L = 0$. Substituting

$$P = \sum P_{\alpha,\beta}(z)\mathbf{a}^\alpha \mathbf{b}^\beta, \quad Q = \sum Q_{\alpha,\beta}(z)\mathbf{a}^\alpha \mathbf{b}^\beta$$

into $L(P,Q)=0$, we find that $\mu_1(z)P_{\alpha,\beta}(z) + \mu_2(z)Q_{\alpha,\beta}(z) = 0$ for all $(\alpha,\beta) \neq 0$. Since $\mu_1(z)$ and $\mu_2(z)$ have no common roots, we see that any root of $\mu_1(z)$ is a root of $Q_{\alpha,\beta}(z)$. We know that $\mu_1(z) \in \Theta_m(\tau)$ has exactly m zeros modulo Γ and the sum of all these zeros equals 0. It follows from (2.5) that if $Q_{\alpha,\beta}(z) \not\equiv 0$, then $Q_{\alpha,\beta}(z)$ also has exactly m zeros, but their sum is equal to $k\alpha/n + (k\beta/n)\tau$. Hence $Q_{\alpha,\beta}(z) \equiv 0$, which implies that $Q \equiv P \equiv 0$. □

Using Lemma 1, for any $f_1, f_2 \in \mathbf{V}_m$, we define $[f_1,f_2]_1$ and $[f_1,f_2]_2$ by the formula

$$[f_1,f_2] = \mu_1[f_1,f_2]_1 + \mu_2[f_1,f_2]_2. \tag{2.6}$$

Proposition 1: *The bilinear operations* $[f_1,f_2]_1$ *and* $[f_1,f_2]_2$ *are compatible Lie brackets on* $\mathbf{V}_m$.

Proof: It is clear that the standard bracket $[f_1,f_2] = f_1 f_2 - f_2 f_1$ is a Lie bracket on the vector space $\oplus_{p>0}\mathbf{V}_p$. Lemma 1 shows that $[\cdot,\cdot]_{1,2}$ are well-defined brackets on $\mathbf{V}_m$. Substituting (2.6) into the antisymmetricity condition $[f_1,f_2]+[f_2,f_1]=0$ for the standard bracket, we get $\mu_1([f_1,f_2]_1+[f_2,f_1]_1)+\mu_2([f_1,f_2]_2+[f_2,f_1]_2)=0$. It follows from Lemma 1 that $[f_1,f_2]_i+[f_2,f_1]_i = 0$ for $i=1,2$. Substituting (2.6) into the Jacobi identity for the standard bracket, we obtain an identity of the form $\mu_1^2 P + \mu_1\mu_2 Q + \mu_2^2 R = 0$ for some $P,Q,R \in \mathbf{V}_m$. Using the same argument as in the proof of Lemma 1, one can prove that $P \equiv Q \equiv R \equiv 0$. It is easy to verify that the identities $P=0$ and $R=0$ coincide with the Jacobi identity for the brackets $[\cdot,\cdot]_1$ and $[\cdot,\cdot]_2$, respectively. The identity $Q=0$ is equivalent to the compatibility of the brackets $[\cdot,\cdot]_{1,2}$. □

Let $x_i(u)$ be all roots of $\mu_2(z) - u\mu_1(z)$:

$$\mu_2(z) - u\mu_1(z) = c(u)\,\theta(z - x_1(u)) \cdots \theta(z - x_m(u)).$$

If $x_1(u), \ldots, x_m(u)$ are distinct modulo Γ, we say that u is regular. For brevity, we use the notation x_j instead of $x_j(u)$.

Now we are going to prove that the linear combination,

$$[f_1,f_2]_u = [f_1,f_2]_1 + u[f_1,f_2]_2, \tag{2.7}$$

of brackets (2.6) is isomorphic to $\oplus_{i=1}^m sl_n$ for all regular values of u.

Consider the following elements $v_{\alpha,\beta,\gamma}(u,z) \in \mathbf{V}_m$, defined by

$$v_{\alpha,\beta,\gamma}(u,z) = P_{\alpha,\beta,\gamma}(u)\, g_{\alpha,\beta,\gamma}(u,z), \tag{2.8}$$

where

$$P_{\alpha,\beta,\gamma}(u) = \frac{\mu_1(x_\gamma)}{\theta(x_\gamma - x_1)\cdots\hat{\gamma}\cdots\theta(x_\gamma - x_m)\,\theta\left(-\dfrac{k\alpha}{n} - \dfrac{k\beta}{n}\tau\right)} \tag{2.9}$$

and

$$g_{\alpha,\beta,\gamma}(u,z)=\exp\left(-\frac{2\pi ik\beta}{n}z\right)\theta(z-x_1)\cdots\hat{\gamma}\cdots\theta(z-x_m)\times\theta\left(z-x_\gamma-\frac{k\alpha}{n}-\frac{k\beta}{n}\tau\right)\mathbf{a}^\alpha\mathbf{b}^\beta. \tag{2.10}$$

Here the symbol $\hat{\gamma}$ means that the factor $\theta(z-x_\gamma)$ is omitted in the product, $\alpha,\beta=0,\ldots,n-1$, where $(\alpha,\beta)\neq(0,0)$ and $\gamma=1,\ldots,m$.

Theorem 1: *The elements* $v_{\alpha,\beta,\gamma}(u)$ *satisfy the following commutator relations*;

$$[v_{\alpha_1,\beta_1,\gamma_1},v_{\alpha_2,\beta_2,\gamma_2}]_u=0, \tag{2.11}$$

for $\gamma_1\neq\gamma_2$ *and* [cf. (2.2)]

$$[v_{\alpha_1,\beta_1,\gamma},v_{\alpha_2,\beta_2,\gamma}]_u=\left[\exp\left(\frac{2\pi ik\beta_1\alpha_2}{n}\right)-\exp\left(\frac{2\pi ik\beta_2\alpha_1}{n}\right)\right]v_{\alpha_1+\alpha_2,\beta_1+\beta_2,\gamma}. \tag{2.12}$$

The proof of Theorem 1 is based on the following.

Lemma 2: *Suppose* $x_1,\ldots,x_m\in\mathbb{C}$ *are distinct modulo* Γ *and* $x_1+\cdots+x_m\neq k\alpha/n+(k\beta/n)\tau$ *modulo* Γ *for* $0\leqslant\alpha,\beta<n$, $(\alpha,\beta)\neq(0,0)$. *Then for any* $\sigma_1,\ldots,\sigma_m\in sl_n$ *there exists a unique element* $f\in\mathbf{V}_m$ *such that* $f(x_\delta)=\sigma_\delta$ for $\delta=1,\ldots,m$.

Proof of Lemma 2: Consider a linear mapping $M:\mathbf{V}_m\to\oplus_{i=1}^m sl_n$ given by the formula $M(f)=(f(x_1),\ldots,f(x_m))$. Since $\dim\mathbf{V}_m=\dim\oplus_{i=1}^m sl_n=m(n^2-1)$, it suffices to prove that $\operatorname{Ker}M=0$. Suppose $M(f)=0$, where $f=\Sigma_{\alpha,\beta}f_{\alpha,\beta}(z)\mathbf{a}^\alpha\mathbf{b}^\beta$. Then $f_{\alpha,\beta}(x_\delta)=0$ for all α,β,δ. But it follows from (2.5) that if $f_{\alpha,\beta}\not\equiv 0$, then the sum of all zeros for $f_{\alpha,\beta}$ is equal to $k\alpha/n+(k\beta/n)\tau$. □

Proof of Theorem 1: The basic idea is to verify that the identities (2.11), (2.12) hold if we substitute $z=x_\delta$, $\delta=1,\ldots,m$. Then Lemma 2 concludes the proof. It is easy to check that

$$\begin{aligned}[g_{\alpha_1,\beta_1,\gamma_1},g_{\alpha_2,\beta_2,\gamma_2}]=&\exp\left(-\frac{2\pi ik(\beta_1+\beta_2)}{n}z\right)\theta(z-x_1)\cdots\hat{\gamma}_1\cdots\theta(z-x_m)\\&\times\theta(z-x_1)\cdots\hat{\gamma}_2\cdots\theta(z-x_m)\times\theta\left(z-x_{\gamma_1}-\frac{k\alpha_1}{n}-\frac{k\beta_1}{n}\tau\right)\\&\times\theta\left(z-x_{\gamma_2}-\frac{k\alpha_2}{n}-\frac{k\beta_2}{n}\tau\right)\left[\exp\left(\frac{2\pi ik\beta_1\alpha_2}{n}\right)-\exp\left(\frac{2\pi ik\beta_2\alpha_1}{n}\right)\right]\\&\times\mathbf{a}^{\alpha_1+\alpha_2}\mathbf{b}^{\beta_1+\beta_2}.\end{aligned} \tag{2.13}$$

Using the formula

$$[\cdot,\cdot]=\mu_1[\cdot,\cdot]_u+(\mu_2-u\mu_1)[\cdot,\cdot]_2, \tag{2.14}$$

we find that

$$[g_{\alpha_1,\beta_1,\gamma_1},g_{\alpha_2,\beta_2,\gamma_2}]_u(x_\delta)=0,$$

for $\gamma_1\neq\gamma_2$, which implies (2.11) by Lemma 2. If $\gamma_1=\gamma_2=\gamma$, then it follows from (2.13), (2.14) that

$$[g_{\alpha_1,\beta_1,\gamma},\ g_{\alpha_2,\beta_2,\gamma}]_u(x_\delta)=0,$$

for $\delta\neq\gamma$. This proves that (2.12) holds for $z=x_\delta$, $\delta\neq\gamma$. A simple straightforward computation shows that (2.12) also holds for $z=x_\gamma$. □

Remark 1: Suppose the functions $\mu_1(z)$ and $\mu_2(z)$ have distinct roots modulo Γ; then the points $u=0$ and $u=\infty$ are regular and the brackets $[\cdot,\cdot]_1$ and $[\cdot,\cdot]_2$ correspond to the Lie algebra isomorphic to $\oplus_{i=1}^m sl_n$.

Remark 2: It is possible to construct "trigonometric" and "rational" degenerations of the

elliptic brackets described above. Namely, in the trigonometric case one should replace $\theta(z)$ by $1-\exp(2\pi i z)$, the space $\Theta_m(\tau)$ by the space of functions of the form

$$a_0 + a_1 \exp(2\pi i z) + \cdots + a_m \exp(2\pi i m z),$$

such that $a_m=(-1)^m a_0$, and the space $\mathbf{V}_m$ by the space of $sl(n)$-valued functions of the form

$$\sum c_{\alpha,\beta} \exp\left(2\pi i \frac{\beta}{n} z\right) \mathbf{a}^\alpha \mathbf{b}^\beta, \quad 0 \leqslant \alpha \leqslant n, \quad 0 \leqslant \beta \leqslant mn,$$

where $c_{\alpha,0}=(-1)^m c_{\alpha,mn}$. In this formula we assume that $\mathbf{a}^n=\mathbf{b}^n=1$, $\mathbf{ba}=\exp(2\pi i/n)\mathbf{ab}$. We should also modify the definitions of $P_{\alpha,\beta,\gamma}(u)$ and $g_{\alpha,\beta,\gamma}(u)$ given by (2.9) and (2.10) in the following way:

$$P_{\alpha,\beta,\gamma}(u) = \frac{\mu_1(x_\gamma)}{\theta_t(x_\gamma - x_1)\cdots \hat{\gamma} \cdots \theta_t(x_\gamma - x_m)\theta_t\left(-\frac{\alpha}{n}\right)},$$

$$g_{\alpha,\beta,\gamma}(u,z) = \exp\left(-\frac{2\pi i \beta}{n} z\right) \theta_t(z-x_1)\cdots \hat{\gamma} \cdots \theta_t(z-x_m)$$

$$\times \theta_t\left(z - x_\gamma - \frac{\alpha}{n}\right) \mathbf{a}^\alpha \mathbf{b}^\beta,$$

if $\alpha \neq 0$ and

$$P_{0,\beta,\gamma}(u) = \frac{\mu_1(x_\gamma)}{\theta_t(x_\gamma - x_1)\cdots \hat{\gamma} \cdots \theta_t(x_\gamma - x_m)},$$

$$g_{0,\beta,\gamma}(u,z) = \exp\left(-\frac{2\pi i \beta}{n} z\right) \theta_t(z-x_1)\cdots \hat{\gamma} \cdots \theta_t(z-x_m)\mathbf{b}^\beta.$$

Here $\theta_t(z)=1-\exp(2\pi i z)$.

In the rational case $\theta(z)$ has to be replaced by z, the space $\Theta_m(\tau)$ by the space of polynomials of the form $\Sigma_{i=0}^m c_\alpha z^\alpha$, $c_{m-1}=0$, and $\mathbf{V}_m$ by the space of polynomials $\Sigma_{i=0}^{m-1} g_\alpha z^\alpha$, $g_\alpha \in sl_n$. In this case

$$P_{\alpha,\beta,\gamma}(u) = \frac{\mu_1(x_\gamma)}{(x_\gamma - x_1)\cdots \hat{\gamma} \cdots (x_\gamma - x_m)},$$

$$g_{\alpha,\beta,\gamma}(u,z) = (z-x_1)\cdots \hat{\gamma} \cdots (z-x_m) \times \mathbf{a}^\alpha \mathbf{b}^\beta.$$

In both cases $v_{\alpha,\beta,\gamma}(u,z)$ is defined by (2.8).

III. STRUCTURE OF CASIMIR ELEMENTS

A. Casimir elements for sl_n

Let $\mathbf{e}_\alpha$, $\alpha=1,\ldots,n^2-1$, be a basis in sl_n, and let $\mathbf{e}^\alpha$ be the dual basis with respect to the invariant form $<X,Y>=\mathrm{tr}(XY)$. Then the Casimir elements,

$$C_p = \sum_{1 \leqslant \alpha_1, \ldots \alpha_p \leqslant n^2-1} \mathrm{tr}(\mathbf{e}^{\alpha_1}\cdots \mathbf{e}^{\alpha_p}) \mathbf{e}_{\alpha_1} \circ \cdots \circ \mathbf{e}_{\alpha_p}, \quad p=2,\ldots,n,$$

where $\circ$ denotes the multiplication in the universal enveloping algebra $\mathbf{U}(sl_n)$, generate the center of $\mathbf{U}(sl_n)$.

Let us take $\mathbf{t}_{\alpha,\beta}=\mathbf{a}^{\alpha}\mathbf{b}^{\beta}$ for a basis in sl_n, where $\mathbf{a},\mathbf{b}$ are defined by (2.1), $0\leqslant\alpha,\beta<n$, and $(\alpha,\beta)\neq(0,0)$. Then, up to a common multiplicative constant, the dual basis is given by

$$\mathbf{t}^{\alpha,\beta}=\exp\left(\frac{2\pi ik\alpha\beta}{n}\right)\mathbf{t}_{-\alpha,-\beta}.$$

In this basis the Casimir elements have the form

$$C_p=\sum_{\mathbb{D}_p}\exp\left(\frac{2\pi ik}{n}\sum_{1\leqslant j_1\leqslant j_2\leqslant p}\alpha_{j_1}\beta_{j_2}\right)\mathbf{t}_{\alpha_1,\beta_1}\circ\cdots\circ\mathbf{t}_{\alpha_p,\beta_p},$$

where

$$\mathbb{D}_p=\{(\alpha_1,\ldots,\alpha_p,\beta_1,\ldots\beta_p)|\quad 0\leqslant\alpha_i,\beta_j<n,\quad(\alpha_j,\beta_j)\neq(0,0),\quad\alpha_1+\cdots+\alpha_p\equiv 0 \bmod n,$$
$$\beta_1+\cdots+\beta_p\equiv 0 \bmod n\}.$$

In particular, the quadratic Casimir element is given by

$$C_2=\sum_{\alpha,\beta}\exp\left(\frac{2\pi ik\alpha\beta}{n}\right)\mathbf{t}_{\alpha,\beta}\circ\mathbf{t}_{-\alpha,-\beta}.$$

B. Polynomial Casimir elements for $\mathcal{G}_u$

In the previous section, we have equipped the vector space $\mathbf{V}_m$ with the Lie bracket (2.7). For generic u the corresponding Lie algebra $\mathcal{G}_u$ is isomorphic to $\oplus_{i=1}^{m}sl_n$.

It was shown that the vector space $\mathbf{V}_m$ is isomorphic to $\oplus_{\alpha,\beta}\mathbf{F}_{\alpha,\beta}$, where $\mathbf{F}_{\alpha,\beta}$ is the vector space of holomorphic functions satisfying (2.4). Denote by $\mathbf{F}_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p}$ the vector space of holomorphic functions of variables $z_1,\ldots,z_p$ satisfying the conditions

$$f(z_1,\ldots,z_j+1,\ldots,z_p)=\exp\left(-\frac{2\pi ik\beta_j}{n}\right)f(z_1,\ldots,z_p),$$
$$f(z_1,\ldots,z_j+\tau,\ldots,z_p)=(-1)^m\exp\left(-2\pi imz_j+\frac{2\pi ik\alpha_j}{n}\right)f(z_1,\ldots,z_p). \tag{3.1}$$

Calculating the number of free coefficients in the Fourier decomposition of a function satisfying (3.1), we find that $\dim\mathbf{F}_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p}=m^p$. In particular, $\dim\mathbf{F}_{\alpha,\beta}=m$. Hence, the vector space $\mathbf{F}_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p}$ is spanned by the products $f_1(z_1)\cdots f_p(z_p)$, where $f_i(z)\in\mathbf{F}_{\alpha_i,\beta_i}$. In other words, $\mathbf{F}_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p}$ is isomorphic to $\mathbf{F}_{\alpha_1,\beta_1}\otimes\cdots\otimes\mathbf{F}_{\alpha_p,\beta_p}$.

We use functions from $\mathbf{F}_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p}$ to represent elements of the universal enveloping algebra $\mathbf{U}(\mathcal{G}_u)$. Namely, to the product $f_1(z_1)\cdots f_p(z_p)\in\mathbf{F}_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p}$ we assign the element $f_1(z)\mathbf{t}_{\alpha_1,\beta_1}\bullet\cdots\bullet f_p(z)\mathbf{t}_{\alpha_p,\beta_p}\in\mathbf{U}(\mathcal{G}_u)$, where $\bullet$ is the multiplication in $\mathbf{U}(\mathcal{G}_u)$. Denote the corresponding linear mapping from $\oplus_{\mathbb{D}_p}\mathbf{F}_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p}$ to $\mathbf{U}(\mathcal{G}_u)$ by σ_p.

Suppose u is regular, that is, all roots $x_1,\ldots,x_m$ of the function $\mu_2(z)-u\mu_1(z)$ are distinct. Let $v_{\alpha,\beta,\gamma}(u,z)=s_{\alpha,\beta,\gamma}(u,z)\mathbf{t}_{\alpha,\beta}$ be the basis of $\mathbf{V}_m$ given by (2.8)–(2.10).

By Theorem 1, for each γ the elements of this basis satisfy the same commutator relations as $\mathbf{t}_{\alpha,\beta}$. Hence, the center of $\mathbf{U}(\mathcal{G}_u)$ is generated by

$$C_{\gamma,p}=\sum_{\mathbb{D}_p}\exp\left(\frac{2\pi ik}{n}\sum_{1\leqslant j_1\leqslant j_2\leqslant p}\alpha_{j_1}\beta_{j_2}\right)\sigma_p(f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p,\gamma}), \tag{3.2}$$

where $f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p,\gamma}(z_1,\dots,z_p)=s_{\alpha_1,\beta_1,\gamma}(u,z_1)\cdots s_{\alpha_p,\beta_p,\gamma}(u,z_p)$.

Now our goal is to find linear combinations of generators (3.2) that are polynomial in u. Let $W_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}\subset\mathbf{F}_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}$ be the vector subspace spanned by $f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p,\gamma}$, where $\gamma=1,\dots,m$. The following statement gives us an inner description of this subspace.

Lemma 3: *The vector space* $W_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}$ *consists of holomorphic functions* $f(z_1,\dots,z_p)$ *satisfying* (3.1) *and vanishing on the surfaces* $\{z_{j_1}=x_{\delta_1}$ *and* $z_{j_2}=x_{\delta_2}\}$ *for all* $j_1\neq j_2$ *and* $\delta_1\neq\delta_2$.

Proof: It is clear that the functions $f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p,\gamma}(z_1,\dots,z_p)$ enjoy these properties. On the other hand, since $\{s_{\alpha,\beta,\gamma}(z),\ \gamma=1,\dots,m\}$ is a basis in $\mathbf{F}_{\alpha,\beta}$, the products $s_{\alpha_1,\beta_1,\gamma_1}(z_1)\cdots s_{\alpha_p,\beta_p,\gamma_p}(z_p)$, where $\gamma_j=1,\dots,m$, $j=1,\dots,p$, form a basis in $\mathbf{F}_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}$. Suppose a function

$$f(z_1,\dots,z_p)=\sum a_{\gamma_1,\dots,\gamma_p}s_{\alpha_1,\beta_1,\gamma_1}(z_1)\cdots s_{\alpha_p,\beta_p,\gamma_p}(z_p) \tag{3.3}$$

satisfies the conditions of Lemma 3. We have to prove that $a_{\gamma_1,\dots,\gamma_p}=0$ if $\gamma_{j_1}\neq\gamma_{j_2}$. To show this, it suffices to substitute $x_{\gamma_{j_1}}$ and $x_{\gamma_{j_2}}$ for z_{j_1} and z_{j_2} in (3.3) and to take into account formulas (2.8)–(2.10). □

Let $W_p\subset\oplus_{\mathbb{D}_p}W_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}$ be the vector space spanned by $\{\oplus_{\mathbb{D}_p}f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p,\gamma},\ \gamma=1,\dots,m\}$. Similar to the proof of Lemma 3, one can prove the following.

Lemma 4: *The vector space* W_p *consists of elements of the form* $\oplus_{\mathbb{D}_p}g_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}$, *where* $g_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}(z_1,\dots,z_p)$ *satisfies the conditions of Lemma 3 and, in addition*,

$$\exp\left(\frac{2\pi ik}{n}x_\gamma(\beta_1+\cdots+\beta_p)\right)g_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}(x_\gamma,\dots,x_\gamma)$$

$$=\exp\left(\frac{2\pi ik}{n}x_\gamma(\beta_1'+\cdots+\beta_p')\right)g_{\alpha_1',\beta_1',\dots,\alpha_p',\beta_p'}(x_\gamma,\dots,x_\gamma),$$

for any $\alpha_1,\beta_1,\dots,\alpha_p,\beta_p$, $\alpha_1',\beta_1',\dots,\alpha_p',\beta_p'$ *and* $\gamma=1,\dots,m$.

Using Lemmas 3,4, we construct polynomials in u that span W_p for generic u.

Theorem 2: *For arbitrary* $g(z)\in\Theta_m(\tau)$, *put*

$$f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}(z_1,\dots,z_p)=\exp\left[-\frac{2\pi ik}{n}(\beta_1z_1+\cdots+\beta_pz_p)\right]\sum_{1\leqslant t\leqslant p}g(z_t)\theta\left(\frac{k\alpha_t}{n}+\frac{k\beta_t}{n}\tau\right)$$
$$\times\prod_{1\leqslant j\leqslant p,j\neq t}\frac{\theta\left(z_t-z_j+\frac{k\alpha_j}{n}+\frac{k\beta_j}{n}\tau\right)}{\theta(z_t-z_j)}\prod_{1\leqslant j\leqslant p,j\neq t}(\mu_2(z_j)-u\mu_1(z_j)). \tag{3.4}$$

Then $\oplus_{\mathbb{D}_p}f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}$ *belongs to* W_p *and, therefore, the formula*

$$\sum_{\mathbb{D}_p}\exp\left(\frac{2\pi ik}{n}\sum_{1\leqslant j_1\leqslant j_2\leqslant p}\alpha_{j_1}\beta_{j_2}\right)\sigma_p(f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p})$$

defines a Casimir element in $\mathbf{U}(\mathcal{G}_u)$.

Proof: We must prove that $f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}$ satisfies the assumptions of Lemmas 3,4. Using the quasiperiodic properties of the functions $\mu_1(z),\mu_2(z)\in\Theta_m(\tau)$ and $\theta(z)\in\Theta_1(\tau)$, one can verify condition (3.1) by a simple computation. To prove that $f_{\alpha_1,\beta_1,\dots,\alpha_p,\beta_p}$ is holomorphic, one can check that the only possible pole at $z_t=z_j$ is cancelled after summation. It is clear that if we put $z_{j_1}=x_{\delta_1}$ and $z_{j_2}=x_{\delta_2}$, where $\delta_1\neq\delta_2$, then all summands in (3.4) vanish. Thus the assumptions of

Lemma 3 hold. The assumption of Lemma 4 can be checked by a straightforward computation.□

Remark 3: If $g(z) \in \Theta_m(\tau)$ does not depend on u, then the function (3.4) is polynomial in u, of degree $p-1$.

Remark 4: Since the Casimir function given by (3.4) is linear in $g(z)$, we have constructed a linear map $T: \Theta_m(\tau) \to$ center of $\mathbf{U}(\mathcal{G}_u)$.

Lemma 5: *The kernel of T is generated by the element* $g(z)=\mu_2(z)-u\mu_1(z)$ *and, therefore,* dim Ker $T=1$.

Proof: It follows from (3.4) that

$$T(\mu_2(z)-u\mu_1(z)) = \prod_{1\leqslant j\leqslant p}(\mu_2(z_j)-u\mu_1(z_j))\exp\left[-\frac{2\pi ik}{n}(\beta_1 z_1+\cdots+\beta_p z_p)\right]$$

$$\times \sum_{1\leqslant t\leqslant p}\theta\left(\frac{k\alpha_t}{n}+\frac{k\beta_t}{n}\tau\right)\prod_{1\leqslant j\leqslant p, j\neq t}\frac{\theta\left(z_t-z_j+\frac{k\alpha_j}{n}+\frac{k\beta_j}{n}\tau\right)}{\theta(z_t-z_j)}.$$

Consider the function

$$\frac{T(\mu_2(z)-u\mu_1(z))}{\prod_{1\leqslant j\leqslant p}(\mu_2(z_j)-u\mu_1(z_j))}.$$

It can be checked that this function is holomorphic and satisfies (3.1) with $m=0$. Analyzing its Fourier decomposition, we see that such a function is identically zero. Hence $T(\mu_2(z)-u\mu_1(z))=0$. Suppose now that $T(g(z))=0$. Substituting a root x of $\mu_2(z)-u\mu_1(z)$ for z in (3.4), we see that $g(x)=0$. Since $g(z)$ has exactly m zeros mod Γ, the function $g(z)$ is proportional to $\mu_2(z)-u\mu_1(z)$. □

It follows from Lemma 5 that $T(\mu_2)$ is a polynomial of degree $p-2$ in u. Therefore, formula (3.4) yields an $(m-1)$-dimensional subspace in the m-dimensional vector space W_p such that one generator of this subspace is the polynomial $T(\mu_2)$ of degree $p-2$ and $m-2$ generators are polynomials of degree $p-1$ in u.

In the following statement we construct a remaining generator of W_p.

Theorem 3: *Let*

$$h_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p}(z_1,\ldots,z_p) = \sum_{1\leqslant t\leqslant p}A_t\times(\mu_2'(z_t)-u\mu_2'(z_t))\prod_{1\leqslant j\leqslant p, j\neq t}(\mu_2(z_j)-u\mu_1(z_j))$$

$$-B\times\prod_{1\leqslant j\leqslant p}(\mu_2(z_j)-u\mu_1(z_j)),$$

where A_t *is given by*

$$A_t=\exp\left[-\frac{2\pi ik}{n}(\beta_1 z_1+\cdots+\beta_p z_p)\right]\theta\left(\frac{k\alpha_t}{n}+\frac{k\beta_t}{n}\tau\right)\prod_{1\leqslant j\leqslant p, j\neq t}\frac{\theta\left(z_t-z_j+\frac{k\alpha_j}{n}+\frac{k\beta_j}{n}\tau\right)}{\theta(z_t-z_j)}$$

and B is defined by the formula

$$B=\frac{m}{n}\exp\left[-\frac{2\pi ik}{n}(\beta_1 z_1+\cdots+\beta_p z_p)\right](B_1+B_2),$$

where

$$B_1 = \sum_{1\leqslant t\leqslant p, 1\leqslant j\leqslant p, j\neq t} \theta\left(\frac{k\alpha_t}{n}+\frac{k\beta_t}{n}\tau\right)\frac{\theta'\left(z_t-z_j+\frac{k\alpha_j}{n}+\frac{k\beta_j}{n}\tau\right)}{\theta(z_t-z_j)}$$

$$\times \prod_{1\leqslant l\leqslant p, l\neq j,t} \frac{\theta\left(z_t-z_l+\frac{k\alpha_l}{n}+\frac{k\beta_l}{n}\tau\right)}{\theta(z_t-z_l)}$$

$$B_2 = \sum_{1\leqslant t\leqslant p} \theta'\left(\frac{k\alpha_t}{n}+\frac{k\beta_t}{n}\tau\right) \prod_{1\leqslant l\leqslant p, l\neq t} \frac{\theta\left(z_t-z_l+\frac{k\alpha_l}{n}+\frac{k\beta_l}{n}\tau\right)}{\theta(z_t-z_l)}.$$

Then the formula

$$\sum_{\mathbb{D}_p} \exp\left(\frac{2\pi i k}{n} \sum_{1\leqslant j_1\leqslant j_2\leqslant p} \alpha_{j_1}\beta_{j_2}\right)\sigma_p(h_{\alpha_1,\beta_1,\ldots,\alpha_p,\beta_p})$$

defines a Casimir element in $\mathbf{U}(\mathcal{G}_u)$.

The proof is similar to the proof of Theorem 2.

Remark 5: It is clear that the Casimir element constructed in Theorem 3 is polynomial in u, of degree p.

Remark 6: We have constructed the Casimir elements for $\mathbf{U}(\mathcal{G}_u)$, whereas in the Lenard–Magri scheme Casimir functions of the corresponding Poisson algebra are needed. However, these two kinds of Casimirs are given by the same formulas. Indeed, if a Casimir element is written in such a way that it is homogeneous with respect to elements of Lie algebra, then the same formula defines also a Casimir function of the corresponding Poisson algebra.

IV. FAMILIES OF COMPATIBLE LIE BRACKETS ASSOCIATED WITH VECTOR θ FUNCTIONS

In this section we generalize the construction in Sec. II replacing the usual θ functions by vector-valued θ functions. All proofs are similar to those in Sec. II.

Let $\Gamma\subset\mathbb{C}$ be a lattice spanned by 1 and τ, where $\operatorname{Im}\tau>0$. Our general construction will depend on $d,l,m\in\mathbb{N}$, such that $1\leqslant l<m$ and m, l are relatively prime. Denote by $V\Theta^d_{m/l}$ the vector space consisting of holomorphic functions $f:\mathbb{C}^{l+1}\to\mathbb{C}$ of variables z, $x_0,\ldots,x_{l-1}$, possessing the following properties:

- $f(z,x_0,\ldots,x_{l-1})$ is a homogeneous polynomial of degree d in variables $x_0,\ldots,x_{l-1}$,
- $$f(z+1,x_0,\ldots,x_{l-1}) = f(z,\mathbf{p}(x_0),\ldots,\mathbf{p}(x_{l-1})),$$
- $$f(z+\tau,x_0,\ldots,x_{l-1}) = \exp\left[-2\pi i\left(\frac{m}{l}z+\frac{m-l-1}{2l}\right)d\right]f(z,\mathbf{q}(x_0),\ldots,\mathbf{q}(x_{l-1})),$$

where

$$\mathbf{p}(x_\alpha) = \exp\left(-2\pi i\frac{m}{l}\alpha\right)x_\alpha, \quad \mathbf{q}(x_\alpha) = x_{\alpha+1}, \quad \alpha\in\mathbb{Z}/l\mathbb{Z}.$$

Lemma 6:

$$\dim V\Theta^d_{m/l} = m\frac{(l+1)\cdots(l+d-1)}{(d-1)!}.$$

It follows from this formula that in the case $d=1$, which is of most importance for us, $\dim V\Theta^1_{m/l}=m$.

Remark 7: Our space $V\Theta^d_{m/l}$ is a space of holomorphic sections of an indecomposable vector bundle of degree m and rank l on the elliptic curve. The classification of holomorphic vector bundles on elliptic curves was obtained in the paper of Ref. 15.

Let $1\leqslant k<n$ and let k,n be relatively prime. Denote by $\mathbf{V}^d_{m,l}$ the vector space of all holomorphic functions $f:\mathbb{C}^{l+1}\to sl_n$ such that we have the following.

- $f(z,x_0,\ldots,x_{l-1})$ is a homogeneous polynomial of degree d in variables $x_0,\ldots,x_{l-1}$,
- $$f(z+1,x_0,\ldots,x_{l-1}) = \mathbf{a}f(z,\mathbf{p}(x_0),\ldots,\mathbf{p}(x_{l-1}))\mathbf{a}^{-1}$$
- $$f(z+\tau,x_0,\ldots,x_{l-1}) = \exp\left[-2\pi i\left(\frac{m}{l}z+\frac{m-l-1}{2l}\right)d\right]\mathbf{b}f(z,\mathbf{q}(x_0),\ldots,\mathbf{q}(x_{l-1}))\mathbf{b}^{-1},$$

where $\mathbf{a}$ and $\mathbf{b}$ satisfy (2.1).

Lemma 7: *Suppose* $\mu_1,\ldots,\mu_{l+1}\in V\Theta^1_{m/l}$ *have no common zeros for* $(x_0,\ldots,x_{l-1})\neq 0$. *Then any element* $Z\in\mathbf{V}^2_{m,l}$ *can be uniquely represented in the form*

$$Z=\mu_1P_1+\cdots+\mu_{l+1}P_{l+1},\quad P_i\in\mathbf{V}^1_{m,l}.$$

It is clear that if $f,g\in\mathbf{V}^1_{m,l}$, then $fg-gf$ belongs to $\mathbf{V}^2_{m,l}$. Using Lemma 7, we define $[\cdot,\cdot]_1,\ldots,[\cdot,\cdot]_{l+1}$ by the formula

$$f_1f_2-f_2f_1=\mu_1[f_1,f_2]_1+\cdots+\mu_{l+1}[f_1,f_2]_{l+1},\quad f_1,f_2\in\mathbf{V}^1_{m,l}.$$

Proposition 2: *The bilinear operations* $[\cdot,\cdot]_1,\ldots,[\cdot,\cdot]_{l+1}$ *are Lie brackets on the m-dimensional vector space* $\mathbf{V}^1_{m,l}$. *All these Lie brackets are pairwise compatible*.

It is clear that any linear combination of brackets from Proposition 2 is a Lie bracket. We call a d-dimensional vector space of pairwise compatible Lie brackets a *d-Lie structure*.

Remark 8: Suppose that one of the sections $\mu_1,\ldots,\mu_{l+1}\in V\Theta^1_{m/l}$, say, μ_{l+1}, is nonzero for each z. In this case the subbundle generated by μ_{l+1} is trivial. Consider the quotient bundle modulo this subbundle. It has degree m and rank $l-1$. It is clear that the l-Lie structure obtained from this quotient bundle is a substructure of our $(l+1)$-Lie structure. The counting of parameters shows that any generic l-Lie structure is obtained in this way. Therefore, any $(l+1)$-Lie structure constructed in this section is embedded into an m-Lie structure corresponding to $l=m-1$.

Remark 9: Any l-Lie structure yields a family of l compatible linear Poisson brackets. We don't know whether the Lenard–Magri scheme can be generalized to the case $l>2$. However, applying the Lenard–Magri scheme to two generic Poisson brackets from the family, we get an integrable system containing $2l$ parameters. It is clear that we can reduce the number of parameters to l, bringing one of the brackets to a canonical form. But the remaining l parameters turn out to be essential parameters of the model.

V. ARGUMENT SHIFT METHOD FOR QUADRATIC POISSON BRACKETS

The standard argument shift method allows one to get a family of constant Poisson brackets compatible with any linear Poisson bracket (1.2). Namely, if we perform a shift of coordinates $x_i\mapsto x_i+ua_i$, where a_i are arbitrary constants, we will have as the result an inhomogeneous linear bracket of the form $\{\cdot,\cdot\}_u=\{\cdot,\cdot\}+u\{\cdot,\cdot\}_1$, where the operation $\{\cdot,\cdot\}_1$ is a constant Poisson bracket depending on the shift vector $\mathbf{a}=(a_1,\ldots,a_N)$. Moreover, since the shift vector $\mathbf{a}$ is arbitrary, we

have got an N-dimensional vector space of constant Poisson brackets such that each of these brackets is compatible with (1.2) and any two of them are pairwise compatible.

Consider now the case of a finite-dimensional quadratic Poisson bracket. Suppose we have a Poisson bracket of the form

$$\{x_i,x_j\}=\Gamma_{i,j}^{p,q}x_px_q,\quad i,j=1,\ldots,N. \tag{5.1}$$

The shift $x_i\to x_i+ua_i$ yields a Poisson bracket of the form $\{\cdot,\cdot\}_u=\{\cdot,\cdot\}+u\{\cdot,\cdot\}_1+u^2\{\cdot,\cdot\}_2$. If the coefficient of u^2 is equal to zero, then this formula defines a compatible pair consisting of the quadratic bracket (5.1) and a linear Poisson bracket. This means that the shift vector **a** is not arbitrary one but satisfies the following overdetermined system of algebraic equations:

$$\Gamma_{i,j}^{p,q}a_pa_q=0,\quad i,j=1,\ldots,N. \tag{5.2}$$

Such a vector is said to be *admissible*. It is clear that the set of admissible vectors coincides with the set of zero-dimensional symplectic leaves of the Poisson structure (5.1). Note that if the set of admissible vectors contains a p-dimensional vector space, then shifting by vectors from this space we obtain p compatible linear brackets, and each of them is compatible with the quadratic bracket (5.1).

Let us apply this construction to quadratic elliptic Poisson structures (see Ref. 12). For most of these brackets, the system of equations (5.2) has no nontrivial solutions. Nevertheless, for some important brackets of Sklyanin type non-trivial admissible vectors exist.

Example: Consider the following quadratic Poisson brackets between variables $x_0,\ldots,x_7$ (subscripts are taken modulo 8):

$$\begin{aligned}
\{x_i,x_{i+1}\}&=p_1x_ix_{i+1}+k_1x_{i+2}x_{i+7}-2k_2x_{i+3}x_{i+6}+p_2x_{i+4}x_{i+5},\\
\{x_i,x_{i+2}\}&=p_3(x_{i+1}^2-x_{i+5}^2),\\
\{x_i,x_{i+3}\}&=p_1x_ix_{i+3}+k_1x_{i+5}x_{i+6}-2k_2x_{i+1}x_{i+2}+p_2x_{i+4}x_{i+7},\\
\{x_i,x_{i+4}\}&=p_4(x_{i+1}x_{i+3}-x_{i+5}x_{i+7}),
\end{aligned} \tag{5.3}$$

where

$$p_1=-\frac{1}{2}k_1^{1/2}k_2^{-1/2}(4k_2^2+k_1^2)^{1/2},\quad p_2=k_2^{1/2}k_1^{-1/2}(4k_2^2+k_1^2)^{1/2},$$

$$p_3=k_2^{1/4}k_1^{1/4}(4k_2^2+k_1^2)^{1/4},\quad p_4=k_2^{-1/4}k_1^{-1/4}(4k_2^2+k_1^2)^{3/4};$$

k_1,k_2 are arbitrary parameters. These brackets depend on the only essential parameter k_1/k_2.

Brackets (5.3) possess the following four Casimir functions:

$$C_i=k_2(x_i^2+x_{i+4}^2)+p_3(x_{i+3}x_{i+5}+x_{i+1}x_{i+7})+k_1x_{i+2}x_{i+6},\quad i=0,1,2,3.$$

The admissible vectors are given by

$$\mathbf{a}_\pm=(t_1,0,t_2,0,\pm t_1,0,\pm t_2,0),\quad \mathbf{b}_\pm=(0,t_1,0,t_2,0,\pm t_1,0,\pm t_2),$$

where t_1,t_2 are arbitrary parameters. We see that the admissible vectors form four two-dimensional vector spaces such that $\mathbb{R}^8$ is their direct sum.

Consider the shift of coordinates defined by $\mathbf{a}_+$. As the result, we get a linear bracket $\{\cdot,\cdot\}_a=t_1\{\cdot,\cdot\}_1+t_2\{\cdot,\cdot\}_2$. Hence, we obtain a pair of compatible linear Poisson brackets $\{\cdot,\cdot\}_{1,2}$. For generic t_1,t_2, the bracket $\{\cdot,\cdot\}_a$ is isomorphic to $gl_2\oplus gl_2$. It is easy to verify that the bracket $\{\cdot,\cdot\}_a$ has two linear Casimir functions $K_1=x_0+x_4$ and $K_2=x_2+x_6$. After reducting the linear brackets to the surface $K_1=K_2=0$, we get a pair of compatible $sl_2\oplus sl_2$ brackets. It is important to mention

that the initial quadratic bracket (5.3) cannot be restricted to the surface $K_1=K_2=0$ since K_i are not Casimir functions for (5.3). One can check that the Lenard–Magri scheme applied to the reduced brackets $\{\cdot,\cdot\}_{1,2}$ produces the so(4) Schottky–Manakov top.

In the paper,[12] the Poisson algebra (5.3) is denoted by $q_{8,3}$. It turns out that the situation is the same for a wide class of quadratic elliptic Poisson algebras. Namely, let n and k be coprime positive integers such that $1\leqslant k<n$. Let $\tau\in\mathbb{C}$, where $\operatorname{Im}\tau>0$. Let us define a Poisson algebra $q_{n,k}(\tau)$ on the space of polynomials in x_i, $i\in\mathbb{Z}/n\mathbb{Z}$ as follows:

$$\{x_i,x_j\}=\left(\frac{\theta'_{j-i}(0)}{\theta_{j-i}(0)}+\frac{\theta'_{k(j-i)}(0)}{\theta_{k(j-i)}(0)}-2\pi i n\right)x_ix_j+\theta'_0(0)\sum_{r\in\mathbb{Z}/n\mathbb{Z},r\neq 0,j-i}\frac{\theta_{j-i+r(k-1)}(0)}{\theta_{kr}(0)\theta_{j-i-r}(0)}x_{j-r}x_{i+r}.$$

Here $\theta_\alpha(z)$ are defined by

$$\theta_\alpha(z)=\theta\left(z+\frac{\alpha}{n}\tau\right)\theta\left(z+\frac{1}{n}+\frac{\alpha}{n}\tau\right)\cdots\theta\left(z+\frac{n-1}{n}+\frac{\alpha}{n}\tau\right)e^{2\pi i(\alpha z+\alpha(\alpha-n)/2n\tau+\alpha/2n)}.$$

It can be readily seen that $\theta_{\alpha+n}(z)=\theta_\alpha(z)$, $\theta_\alpha(-z)=-e^{-2\pi i(nz-\alpha/n)}\theta_{-\alpha}(z)$, and

$$\theta_\alpha\left(z+\frac{1}{n}\right)=e^{2\pi i\alpha/n}\theta_\alpha(z),\quad \theta_\alpha\left(z+\frac{1}{n}\tau\right)=e^{-2\pi i(z+1/2n-(n-1)/2n\tau)}\theta_{\alpha+1}(z).$$

Using these relations, one can check that the bracket described above satisfies the Jacobi identity (see Refs. 12 and 16 for details).

Theorem 4: *For the quadratic Poisson algebras $q_{mn^2,kmn-1}(\tau)$, the set of admissible vectors is a union of n^2 components which are m-dimensional vector spaces. The space of generators of the algebra is the direct sum of these spaces.*

Theorem 4 can be proved using the so-called functional realization of these Poisson algebras (see Refs. 16 and 12). The proof will be given in another publication. The case $m=1$ was considered in detail in Refs. 17–19.

It is clear that for any m-dimensional vector space of admissible vectors for the quadratic Poisson algebra $q_{mn^2,kmn-1}(\tau)$ we obtain m compatible linear Poisson structures shifting the quadratic bracket by these vectors.

Conjecture 1: Each of the corresponding Lie algebras is isomorphic to $\oplus_{i=1}^m gl_n$. Moreover, all these Lie algebras have a common center. After factorization with respect to the center, one obtains m compatible $\oplus_{i=1}^m sl_n$ brackets. These m-Lie structures are isomorphic to the one constructed in Sec. IV, where $l=m-1$.

Conjecture 2: Each of the $(l+1)$-Lie structures constructed in Sec. III is a substructure of this m-Lie structure.

Remark 10: The Lenard–Magri scheme applied to the pair of compatible linear brackets described in Secs. II and III gives rise to an integrable model with the $\oplus_{i=1}^m sl_n$ Poisson brackets. Probably this integrable system is nothing but the elliptic Gaudin model.[17,18] However, the family of integrals for the $\oplus_{i=1}^m sl_2$-Gaudin model considered in Ref. 18 contains one parameter related to the elliptic curve plus $m-1$ additional constant parameters. In our construction, we have $2m-2$ additional parameters. But if Conjectures 1 and 2 are true, then all these additional parameters are inessential in the following sense. The complete set of integrals is given by the Casimir functions of the quadratic brackets. These integrals depend on the elliptic curve only. Furthermore, there exist linear brackets $\{\cdot,\cdot\}_1,\ldots,\{\cdot,\cdot\}_m$ that depend on the elliptic curve only such that any linear combination of these brackets is a Poisson bracket as well. The integrals commute with respect to the whole family of these brackets. If we choose two generic brackets,

$$\sum_{i=1}^{m} c_i\{\cdot,\cdot\}_i \quad \text{and} \quad \sum_{i=1}^{m} \bar{c}_i\{\cdot,\cdot\}_i,$$

and bring the first one to the canonical form $\oplus_{i=1}^{m} sl_n$ by a linear transformation, then the coefficients c_i appear as parameters in the integrals and the second bracket becomes dependent on parameters $c_i, \bar{c}_i$.

Remark 11: One more construction of families of compatible linear Poisson brackets is known.[6] It would be interesting to understand whether these families coincide with those described in our paper or not.

ACKNOWLEDGEMENTS

The paper has been written during the visit of both authors to the Max Planck Institute (Bonn). The authors are grateful to MPI for hospitality and financial support. The authors are grateful to G. Falqui, S. Lando, and M.A. Semenov-Tian-Shansky for useful discussions. Recursive parametrization and invariant phases of unitary matrices

C. Jarlskog

(Received 13 October 2005; accepted 8 November 2005; published online 19 January 2006)

We present further properties of a previously proposed recursive scheme for parametrization of n-by-n unitary matrices. We show that the factors in the recursive formula may be introduced in any desired order. The method is used to study the invariant phases of unitary matrices. The case of four-by-four unitary matrices is investigated in detail. We also address the question of how to construct symmetric unitary matrices (i.e., unitary matrices U that satisfy the condition $U_{ij}=U_{ji}$) using the recursive approach. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2159069]

I. INTRODUCTION

Unitary matrices play a central role in physics. For example, the standard model of particle physics is defined by a $SU(3)\times SU(2)\times U(1)$ symmetry group and many popular grand unified models are again based on unitary symmetries. Indeed explicit representations of unitary matrices are often so badly needed that there is already a vast literature on the subject (see, for example, Ref. 1 and references therein).

Recently we have presented a simple-looking recursive parametrization of general n-by-n unitary matrices,[2] applicable also, of course, to subcategories such as special unitary matrices and orthogonal matrices which are of great importance in physics.

In recent publications Fujii and his collaborators[3] have found that the parametrization in Ref. 2 looks interesting for constructing unitary gates for quantum computation but for that purpose more study is needed. In this paper we present further results on the structure of the recursive parametrization hoping that it will be useful for future applications. You use the method to study the "invariant phases" (to be defined below) of unitary matrices, by considering the symmetries of the recursive parametrization. Subsequently, we give detailed attention to the case of four-by-four unitary matrices.

It should be emphasized that *all* parametrization of a general n-by-n unitary matrix are equivalent to each another. However, for a specific application a certain parametrization may be more convenient than others. Therefore, it is important to provide new parametrizations, a topic which has been addressed by other authors as well. See, for example, Ref. 4, a paper which contains an extended list of references and presents yet another representation of unitary matrices.

II. THE PARAMETRIZATION

A general n-by-n unitary matrix $X^{(n)}$ may be expressed as a product of three unitary matrices,

$$X^{(n)}=\Phi^{(n)}(\vec{\alpha})V^{(n)}\Phi^{(n)}(\vec{\beta}), \tag{1}$$

where the matrices Φ are diagonal unitary matrices,

$$\Phi^{(n)}(\vec{\alpha})=\mathrm{diag}(e^{i\alpha_1},e^{i\alpha_2},\ldots,e^{i\alpha_n}) \tag{2}$$

$\Phi(\vec{\beta})$ is defined analogously, the α's and β's being real. We shall refer to Φ's as external (pure phase) matrices.

The matrix $X^{(n)}$ has n^2 real parameters. The quantities $\vec{\alpha}$ and $\vec{\beta}$ take care of $2n-1$ of these parameters because only the sums $\alpha_i+\beta_j$ enter, where i and j run from 1 to n. The remaining $(n-1)^2$ real parameters reside in the nontrivial matrix $V^{(n)}$ which was the subject of the study presented in Ref. 2 and will be further investigated in this paper. For simplicity, whenever no confusion may arise, we refer to $V^{(n)}$ as the most general n-by-n unitary matrix leaving out the qualifying statement that this is only true modulo the external matrices $\Phi(\vec{\alpha})$ and $\Phi(\vec{\beta})$. In Ref. 2 it was shown that the matrix $V^{(n)}$ may be written in the form (note that the notations in this paper are a simplified version of that in Ref. 2)

$$V^{(n)} = A_{n,2}A_{n,3}\ldots A_{n,n-1}A_{n,n}, \tag{3}$$

where the $A_{n,k}$ are unitary matrices defined by

$$A_{n,k} = \begin{pmatrix} \mathbb{A}^{(k)} & 0 \\ 0 & I_{n-k} \end{pmatrix}. \tag{4}$$

Here I_{n-k} is the unit matrix of order $n-k$. For $k=n$ this unit matrix is absent. $\mathbb{A}^{(k)}$ is a k-by-k unitary matrix,

$$\mathbb{A}^{(k)} \equiv \begin{pmatrix} I_{k-1} - (1-c_k)|A^{(k)}\rangle\langle A^{(k)}| & s_k|A^{(k)}\rangle \\ -s_k\langle A^{(k)}| & c_k \end{pmatrix}. \tag{5}$$

Here c_k and s_k stand for cosine and sine of an angle denoted by θ_k. Furthermore, $|A^{(k)}\rangle$ is a $k-1$ dimensional complex vector normalized to one,

$$|A^{k)}\rangle = \begin{pmatrix} a_1^{(k)} \\ a_2^{(k)} \\ \cdots \\ \cdots \\ a_{k-1}^{(k)} \end{pmatrix}, \quad \langle A^{k)}|A^{k)}\rangle = 1 \tag{6}$$

and $(|A^{(k)}\rangle\langle A^{(k)}|)_{ij} = a_i^{(k)}a_j^{(k)\star}$. We shall refer to $|A^{(k)}\rangle$ as the characteristic vector of order k.

The parameter counting was presented in Ref. 2 where it was shown that $V^{(n)}$, thus obtained, is the most general n-by-n unitary matrix, again modulo the external matrices Φ. The essential point is that $|A^{k)}\rangle$ introduces $2(k-2)$ real parameters and not $2(k-1)$, the reason being that it is normalized and its overall phase can be absorbed into the definition of the external matrices Φ.

To summarize, in this recursive parametrization the n-by-n unitary matrix is represented by a product of $n-1$ unitary matrices, each with its own angle θ and characteristic vector $|A\rangle$ while, for example, in the conventional approach in particle physics one would write the matrix as a product of at least $n(n-1)/2$ matrices, these being Euler rotation matrices, $(n-1)(n-2)/2$ of them modified by phases (see, for example, Ref. 5 and references therein). Note also that in Ref. 4 the matrix is parametrized by a product of n diagonal unitary matrices interlaced with $n-1$ orthogonal matrices.

A. Reordering of the factors

At the first sight, the recursive parametrization appears highly ordered and rigid. In Eq. (3), the two-by-two structure is immediately followed by the three-by-three and so on. Actually, we may write these factors *in any order* we wish by observing that the order of factors in a given product, $A_{n,r}A_{n,s}$, may be flipped as follows. For $r<s$ we have

$$A_{n,r}A_{n,s} = (A_{n,r}A_{n,s}A_{n,r}^{\dagger})A_{n,r} \equiv A'_{n,s}A_{n,r}, \tag{7}$$

where $A'_{n,s}$ has the same form as $A_{n,s}$. The two characteristic vectors appearing in these matrices are related by a unitary rotation,

$$|A'^{(s)}\rangle = \hat{\mathbb{A}}^{(r)}|A^{(s)}\rangle, \tag{8}$$

$$\hat{\mathbb{A}}^{(r)} = \begin{pmatrix} \mathbb{A}^{(r)} & 0 \\ 0 & I_{s-1-r} \end{pmatrix}. \tag{9}$$

For the case $s<r$ we have

$$A_{n,r}A_{n,s} = A_{n,s}(A^{\dagger}_{n,s}A_{n,r}A_{n,s}) \equiv A_{n,s}A''_{n,r}, \tag{10}$$

where now the two characteristic vectors are related by

$$|A''^{(r)}\rangle = \hat{\mathbb{A}}^{\dagger(s)}|A^{(r)}\rangle. \tag{11}$$

Obviously, by inserting as many factors $A^{\dagger}_{n,j}A_{n,j}=1$ as needed in the recursion formula, Eq. (3), one may move the factors around as one wishes. The upshot is that in the reordering process a factor of lower rank simply "tunnels" through that of a higher rank without being affected but induces a unitary rotation of the characteristic vector of the latter. Thus the ensuing parametrization remains the most general one. Note that the angles θ_k remain invariant under reordering.

The recursive parametrization looks highly asymmetric. However, using the above reordering procedure, one may construct manifestly symmetric unitary matrices (see the Appendix).

B. Further properties of the recursive parametrization

We wish to study, in more detail, the properties of the matrices $\mathbb{A}^{(k)}$ in Eq. (5) as these are the building blocks of the recursive parametrization.

To begin with we simplify the notation, to avoid indices, and introduce a generic matrix $\mathbb{A}$ defined by

$$\mathbb{A} \equiv \begin{pmatrix} I-(1-c)|A\rangle\langle A| & s|A\rangle \\ -s\langle A| & c \end{pmatrix}. \tag{12}$$

Here, as usual, I denotes the appropriate unit matrix and c and s stand for cosine and sine of an angle, respectively. The angle itself will be denoted by θ. Defining

$$Y \equiv |A\rangle\langle A| \tag{13}$$

we have that Y is Hermitian and satisfies

$$Y|A\rangle = |A\rangle, \quad Y^2 = Y, \quad \text{tr } Y = 1, \quad \det Y = 0, \tag{14}$$

where the vanishing of the determinant is, of course, only valid when Y is a matrix and not just a number as is the case when $|A\rangle$ is one dimensional. Following Fujii,[3] we introduce a matrix $\mathbb{G}$ which generates $\mathbb{A}$,

$$\mathbb{G} \equiv \begin{pmatrix} 0 & -i|A\rangle \\ i\langle A| & 0 \end{pmatrix}. \tag{15}$$

This matrix is hermitian and satisfies $\mathbb{G}^3=\mathbb{G}$. A simple computation, using Eqs. (14), yields

$$\mathbb{A} = e^{i\theta\mathbb{G}} = I + is\mathbb{G} - (1-c)\mathbb{G}^2. \tag{16}$$

This relation is reminiscent of the expansion of exponentials containing Pauli matrices σ (in a short-hand notation, $e^{i\theta\sigma}=c+is\sigma$). The essential point here is that the series expansion of $e^{i\theta\mathbb{G}}$, for arbitrarily $\mathbb{G}$, terminates rapidly and does not continue for ever as the exponentials often tend to do. Furthermore we have

$$\mathrm{tr}\,\mathbb{G}=0,\quad \mathrm{tr}\,\mathbb{G}^2=2,\quad \det\mathbb{A}=1. \tag{17}$$

Note also that, for a fixed $\mathbb{G}$, the matrix $\mathbb{A}$ is Abelian with respect to θ,

$$\mathbb{A}(\theta_i)\mathbb{A}(\theta_j)=\mathbb{A}(\theta_i+\theta_j) \tag{18}$$

and

$$\mathbb{A}^{-1}(\theta)=\mathbb{A}(-\theta). \tag{19}$$

To rewrite the recursion formula, Eq. (3), in terms of $\mathbb{G}$ and $\mathbb{A}$ we must attach appropriate indices to our generic $\mathbb{G}$ (or $\mathbb{A}$) to distinguish the relevant factors. We introduce

$$\mathbb{G}_{n,k}=\begin{pmatrix}\begin{pmatrix}0 & -i|A^{(k)}\rangle\\ i\langle A^{(k)}| & 0\end{pmatrix} & 0\\ 0 & 0\end{pmatrix}, \tag{20}$$

where the required number of zeros have been added to make $\mathbb{G}_{n,k}$ an n-by-n matrix. This yields that the factor $A_{n,k}$ in the recursion formula Eq. (3) is given by

$$A_{n,k}\equiv e^{i\theta_k\mathbb{G}_{n,k}}=I_n+is_k\mathbb{G}_{n,k}-(1-c_k)\mathbb{G}_{n,k}^2. \tag{21}$$

III. INVARIANT PHASES OF UNITARY MATRICES

The invariant phases of a unitary n-by-n matrix V^n are defined as those phases of the matrix that cannot be "removed" with any choice of the external phase matrices Φ in Eq. (1). These phases play an important role in particle physics as they are measurable quantities related to CP violation (for a review see, for example, Ref. 6).

Given a unitary matrix, the simplest way to detect the presence of invariant phases in it is to construct

$$(\alpha\beta;jk)\equiv \mathrm{Im}(V_{\alpha j}V_{\beta k}V_{\alpha k}^{\star}V_{\beta j}^{\star}), \tag{22}$$

where we have suppressed the superscript n. The symbols α,β and j,k now refer to rows and columns of the matrix and the indices are not summed. These imaginary parts are manifestly invariant under multiplication by the external phase matrices. Therefore if any of them is nonzero that would be a signal of the presence of a nonremovable phase in the matrix. We refer to these imaginary parts as invariant phases of the matrix instead of calling them invariants of the matrix that contain nonremovable phases. One may easily construct higher order invariants, containing properly chosen, six or more, elements of the matrix but these are in general reducible to the above set unless the matrix would have vanishing elements. For example, for $V_{\beta j}\neq 0$,

$$\mathrm{Im}(V_{\alpha j}V_{\beta k}V_{\gamma l}V_{\alpha k}^{\star}V_{\beta l}^{\star}V_{\gamma j}^{\star})=\frac{1}{|V_{\beta j}|^2}\,\mathrm{Im}\{(V_{\alpha j}V_{\beta k}V_{\alpha k}^{\star}V_{\beta j}^{\star})(V_{\beta j}V_{\gamma l}V_{\beta l}^{\star}V_{\gamma j}^{\star})\} \tag{23}$$

$$=\frac{1}{|V_{\beta j}|^2}\{(\alpha\beta,jk)\langle\beta\gamma,jl\rangle+\langle\alpha\beta,jk\rangle(\beta\gamma,jl)\}, \tag{24}$$

where none of the indices is summed and

$$\langle\alpha\beta;jk\rangle\equiv \mathrm{Re}[V_{\alpha j}V_{\beta k}V_{\alpha k}^{\star}V_{\beta j}^{\star}]. \tag{25}$$

These real parts are also invariant under the action of the external matrices. The above reduction would not work if $V_{\alpha j}=0$ but then the analysis is much simpler to begin with (see below) as the matrix contains fewer invariant phases.

Returning to the simplest invariant phases, there are altogether $[n(n-1)/2]^2$ quantities $(\alpha\beta;jk)$, because these are antisymmetric under the interchange of the row indices, $\alpha\leftrightarrow\beta$, as well as under the interchange of the column indices, $j\leftrightarrow k$. However, we know that the most general $V^{(n)}$ has "only" $(n-1)(n-2)/2$ independent invariant phases. One may therefore look for $(n-1)\times(n-2)/2$ independent $(\alpha\beta;jk)$'s and use them as a basis for expressing the remaining ones.

As mentioned above, the invariants in Eq. (22) play an essential role in the n-family version of the standard model of particle physics as they are measurable quantities related to CP violation. For the case of $n=3$ there is only one such quantity

$$(\alpha\beta;jk) \equiv J\sum_{\gamma,i} \epsilon_{\gamma\alpha\beta}\epsilon_{ijk}. \tag{26}$$

The row and column unitarity conditions for a three-by-three unitary matrix define six triangles. One may show that[7] all these triangles have the same area and this unique area equals $J/2$.

For $n=4$ there are 36 possible invariants $(\alpha\beta;jk)$ but only three independent ones. In Ref. 8 an attempt was made to find an appropriate basis and carry through the above program. The treatment of this issue is much simpler in the recursive parametrization, as will be shown in the next section.

A. Invariant phases of four-by-four unitary matrices

For $n=4$ we have from Eq. (3)

$$V^{(4)} = A_{4,2}A_{4,3}A_{4,4}, \tag{27}$$

where each factor comes with its own θ and characteristic vector $|A\rangle$. We denote the latter by

$$|A^{(2)}\rangle = 1, \quad |A^{(3)}\rangle = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \quad |A^{(4)}\rangle = \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} \tag{28}$$

remembering that x's and y's are complex numbers and $\langle A^{(k)}|A^{(k)}\rangle=1$, $k=2,3,4$. We shall now spell out this four-by-four matrix in order to exhibit its symmetries in a manifest fashion. This will also enable us to understand the general case of n-by-n matrices. Equation (3) yields

$$V^{(4)} = \begin{pmatrix} c_2 & s_2 & 0 & 0 \\ -s_2 & c_2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1-(1-c_3)x_1x_1^\star & -(1-c_3)x_1x_2^\star & s_3x_1 & 0 \\ -(1-c_3)x_2x_1^\star & 1-(1-c_3)x_2x_2^\star & s_3x_2 & 0 \\ -s_3x_1^\star & -s_3x_2^\star & c_3 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$
$$\times \begin{pmatrix} 1-(1-c_4)y_1y_1^\star & -(1-c_4)y_1y_2^\star & -(1-c_4)y_1y_3^\star & s_4y_1 \\ -(1-c_4)y_2y_1^\star & 1-(1-c_4)y_2y_2^\star & -(1-c_4)y_2y_3^\star & s_4y_2 \\ -(1-c_4)y_3y_1^\star & -(1-c_4)y_3y_2^\star & 1-(1-c_4)y_3y_3^\star & s_4y_3 \\ -s_4y_1^\star & -s_4y_2^\star & -s_4y_3^\star & c_4 \end{pmatrix}. \tag{29}$$

We now focus on the symmetries of this matrix. By symmetries we mean transformations that leave $V^{(4)}$ invariant modulo the external matrices Φ in Eq. (1). A simple inspection shows that this matrix has two such symmetries, denoted by S_1 and S_2 and defined by

$$S_1, \quad \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \to e^{i\phi_2}\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \quad y_3 \to e^{-i\phi_2}y_3, \tag{30}$$

$$S_2, \quad \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} \to e^{i\phi_3} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix}, \tag{31}$$

where ϕ_2 and ϕ_3 are arbitrary phases. The indices are to remind us of the dimension of the corresponding vector. Therefore the three independent phases in $V^{(4)}$ can be chosen to be

$$\omega_1 = \phi(x_2) - \phi(x_1),$$

$$\omega_2 = \phi(y_2) - \phi(y_1), \tag{32}$$

$$\omega_3 = \phi(x_2) + \phi(y_3) - \phi(y_2).$$

Here $\phi(x_j)$ and $\phi(y_k)$ denote the phases of the corresponding parameters. These phases are not invariant under the above symmetries and thus cannot appear as independent entities in computations of invariants of $V^{(4)}$. Allowed to appear are the ω's or any combination of them because these are invariant under the action of both S_1 and S_2. We may, if we so wish, use the symmetry S_1 to rotate the phase of x_2 to zero, and then employ the symmetry S_2 to do the same with the ensuing y_3 whereby x_2 and y_3 may be taken to be real and say positive. The invariant phases in this "frame" are then $\phi(x_1)$, $\phi(y_1)$, and $\phi(y_2)$. These constitute the maximum number of independent phases that $V^{(4)}$ can possess. By imposing further relations on the angles or the x's and y's this number could be smaller as shall be considered further below.

B. Generalization to larger *n*

Going one order higher to $n=5$, we must introduce the relevant characteristic vector

$$|A^{(5)}\rangle \equiv \begin{pmatrix} z_1 \\ z_2 \\ z_3 \\ z_4 \end{pmatrix}. \tag{33}$$

The corresponding matrix $V^{(5)}$ has three symmetries given by

$$S_1, \quad \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \to e^{i\phi_2} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \quad y_3 \to e^{-i\phi_2} y_3, \quad z_3 \to e^{-i\phi_2} z_3, \tag{34}$$

$$S_2, \quad \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} \to e^{i\phi_3} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix}, \quad z_4 \to e^{-i\phi_3}, \tag{35}$$

$$S_3, \quad \begin{pmatrix} z_1 \\ z_2 \\ z_3 \\ z_4 \end{pmatrix} \to e^{i\phi_4} \begin{pmatrix} z_1 \\ z_2 \\ z_3 \\ z_4 \end{pmatrix}. \tag{36}$$

In this case there are six invariant phases. These may be chosen as

$$\omega_1 = \phi(x_2) - \phi(x_1),$$

$$\omega_2 = \phi(y_2) - \phi(y_1),$$

$$\omega_3 = \phi(z_2) - \phi(z_1),$$

$$\omega_4 = \phi(x_2) + \phi(y_3) - \phi(y_2), \tag{37}$$

$$\omega_5 = \phi(x_2) + \phi(z_3) - \phi(z_2),$$

$$\omega_6 = \phi(y_3) + \phi(z_4) - \phi(z_3).$$

As before, we may use S_1 to remove the phase of x_2 followed by S_2 and S_3 to rotate the ensuing y_3 and z_4 to be real and say positive. The invariant phases are then the phases of x_1, y_1, y_2, z_1, z_2, and z_3. Note that, from the very beginning we chose the angle θ_2 not to be accompanied by a phase, i.e., $|A^{(2)}\rangle = 1$. One can, of course, leave the phase of $|A^{(2)}\rangle$ arbitrary. This will introduce an extra symmetry which we have not bothered to write down as it is trivial.

The above procedure may be generalized to arbitrary order n. Without loss of generality, we may take, for example, the last component of all the characteristic vectors $|A^{(k)}\rangle$ to be real. The invariant phases are then the phases of the remaining components. For an n-by-n matrix there are then $1+2+\cdots+(n-2)=(n-1)(n-2)/2$ such independent phases as expected.

C. The "panel" approach to invariant phases

Another approach to constructing the invariant phases of a matrix is to consider the latter as a lattice. For the case of $n=4$, considered from now on, the matrix can be visualized as shown

$$\begin{array}{ccccccc}
\bullet & & \bullet & & \bullet & & \bullet \\
 & P_{11} & & P_{12} & & P_{13} & \\
\bullet & & \bullet & & \bullet & & \bullet \\
 & P_{21} & & P_{22} & & P_{23} & \\
\bullet & & \bullet & & \bullet & & \bullet \\
 & P_{31} & & P_{32} & & P_{33} & \\
\bullet & & \bullet & & \bullet & & \bullet
\end{array} . \tag{38}$$

The bullets denote the sites where the matrix elements are situated. For example, the bullets on the first row stand for V_{11}, V_{12}, V_{13}, and V_{14} and so on. The P's denote minipanels of the matrix, to be described here below. The invariants of interest to us are again

$$(\alpha\beta;jk) \equiv \mathrm{Im}[V_{\alpha j} V_{\beta k} V^{\star}_{\alpha k} V^{\star}_{\beta j}], \tag{39}$$

$$\langle\alpha\beta;jk\rangle \equiv \mathrm{Re}[V_{\alpha j} V_{\beta k} V^{\star}_{\alpha k} V^{\star}_{\beta j}]. \tag{40}$$

As mentioned before, there are 36 quantities $(\alpha\beta;jk)$ (six possible combinations of α,β multiplied by as many combinations of j,k) and we are looking for a set of three of them such that all the others can be expressed as functions of them and the real parts $\langle\alpha\beta;jk\rangle$. This problem was treated long time ago[8] and was found to be rather involved. Here we provide some simplification. Nine of these invariants (the nearest neighbors) are explicitly exhibited on our lattice. Their analytic form may easily be read off from their locations. For example,

$$P_{11} \equiv V_{11} V_{22} V^{\star}_{12} V^{\star}_{21},$$

$$P_{12} \equiv V_{12} V_{23} V^{\star}_{13} V^{\star}_{22},$$

$$P_{22} \equiv V_{22} V_{33} V^{\star}_{23} V^{\star}_{32},$$

$$P_{32} \equiv V_{32}V_{43}V_{33}^{\star}V_{42}^{\star},$$

and so on. Furthermore

$$P_{ab} = R_{ab} + iJ_{ab}, \tag{41}$$

where R and J denote the real and imaginary parts of the corresponding P. Thus the imaginary parts, in the notation employed earlier, are given by

$$J_{11} = (12;12), \quad J_{12} = (12;23), \quad J_{22} = (23;23), \quad J_{32} = (34;23) \tag{42}$$

and so forth. Similar expressions may be written down for the real parts.

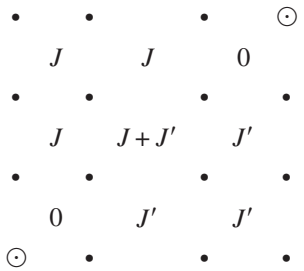
Suppose that none of the matrix elements vanishes. Using unitarity conditions we then find

$$\begin{aligned}
J_{13} - \left(1 + \frac{R_{11}}{|V_{12}V_{22}|^2}\right)J_{12} &= \frac{R_{12}}{|V_{12}V_{22}|^2}J_{11}, \\
J_{13} - \left(1 + \frac{R_{33}}{|V_{33}V_{34}|^2}\right)J_{23} &= \frac{R_{23}}{|V_{33}V_{34}|^2}J_{33}, \\
J_{31} - \left(1 + \frac{R_{11}}{|V_{21}V_{22}|^2}\right)J_{21} &= \frac{R_{21}}{|V_{21}V_{22}|^2}J_{11}, \\
J_{31} - \left(1 + \frac{R_{33}}{|V_{33}V_{43}|^2}\right)J_{32} &= \frac{R_{32}}{|V_{33}V_{43}|^2}J_{33}, \\
J_{12} - \frac{R_{22}}{|V_{32}V_{33}|^2}J_{32} &= \left(1 + \frac{R_{32}}{|V_{32}V_{33}|^2}\right)J_{22}, \\
J_{21} - \frac{R_{22}}{|V_{23}V_{33}|^2}J_{23} &= \left(1 + \frac{R_{23}}{|V_{23}V_{33}|^2}\right)J_{22}.
\end{aligned} \tag{43}$$

In principle, we may take the set J_{11}, J_{22}, J_{33} to constitute a basis and determine the remaining six J's in terms of them. These equations are rather complicated and need further thought concerning special cases. For example, if the matrix is symmetric we only have three equations but, of course, also only three unknown, say J_{12}, J_{13}, and J_{23}. We are not allowed to divide by vanishing matrix elements and so forth. Here below, we shall consider a simple and yet nontrivial example to demonstrate the technique and to compare it with the recursive approach which is much simpler and does not require thinking about the possible pitfalls.

D. A simple example

For simplicity we consider the case where two of the elements of the four-by-four matrix are zero, and where these elements are neither on the same row nor on the same column. All other elements of the matrix are assumed to be nonzero. Without loss of generality we may take the two vanishing elements to be V_{14} and V_{41} which in particle physics would correspond to the case where the mixing of the first and the fourth families is negligible. Our lattice, with its nine minipanels, now looks as follows:



(44)

Here the ⊙'s indicate where the vanishing matrix elements are situated and we have defined

$$J = J_{11} \equiv (12,12), \quad J' = J_{33} \equiv (34,34). \tag{45}$$

A simple computation, using unitarity relations, gives the imaginary parts of the minipanels as marked in the lattice. Computing all the imaginary parts, we find that 19 of the 36 invariants $(\alpha\beta, jk)$ vanish. The nonvanishing ones, in addition to J and J' defined in Eq. (45), are

$$\begin{aligned} &-(12,13) = (12,23) = -(13,12) = (13,13) = -(13,23) = (23,12) = -(23,13) = J, \\ &-(23,24) = (23,34) = -(24,23) = (24,24) = -(24,34) = (34,23) = -(34,24) = J', \end{aligned} \tag{46}$$

and

$$(23,23) = J + J' \tag{47}$$

as exhibited in the corresponding panel. Moreover, we find

$$\frac{J'^2}{J^2} = \left|\frac{V_{24}V_{34}}{V_{21}V_{31}}\right|^2 = \left|\frac{V_{42}V_{43}}{V_{12}V_{13}}\right|^2 = \left(\frac{|V_{24}|^2 + |V_{34}|^2}{|V_{12}|^2 + |V_{13}|^2}\right)^2 = \left(\frac{|V_{42}|^2 + |V_{43}|^2}{|V_{21}|^2 + |V_{31}|^2}\right)^2. \tag{48}$$

It is amusing to note that the unitarity relations for the above matrix define eight triangles. Using the method in Ref. 7 one finds that four of these have each an area equal to $J/2$ while the area of the other four is $J'/2$.

We would now like to compute J and J'. For this purpose we turn to the recursive parametrization. It turns out that the calculations are simpler if we take $V_{34}=V_{43}=0$ instead of the above choice $V_{14}=V_{41}=0$. The two choices are equivalent as they are related to one another by interchanges in rows and columns. This amounts to a relabeling of the matrix elements which obviously cannot affect the results. After finishing the computations we can simply revert to the former case by interchanging rows one and three as well as columns one and three.

In the recursive parametrization, Eq. (29), the conditions $V_{34}=V_{43}=0$ give

$$y_3 = x_1 y_1^\star + x_2 y_2^\star = 0. \tag{49}$$

These conditions tell us that $|y_1|=|x_2|$, $|y_2|=|x_1|$ and that x_1 and y_1 are relatively real in the frame where x_2 and y_2 are taken to be real. Therefore, there is only one invariant phase, in this example. We introduce the lattice again

$$
\begin{array}{cccccc}
\bullet & & \bullet & & \bullet & & \bullet \\
& \hat{J} & & \hat{J} & & 0 & \\
\bullet & & \bullet & & \bullet & & \bullet \\
& \hat{J} & & \hat{J} & & 0 & \\
\bullet & & \bullet & & \bullet & & \odot \\
& 0 & & 0 & & 0 & \\
\bullet & & \bullet & & \odot & & \bullet
\end{array}
\quad . \tag{50}
$$

$\odot$'s indicate where the vanishing matrix elements are situated. Furthermore, we have exhibited the imaginary parts of the minipanels starting with the definition

$$\hat{J} = (12,12). \tag{51}$$

Taking into account the permutations, we find that $\hat{J}$ here is identical with our previous J that we wanted to compute. Using the recursive parametrization we find

$$
\begin{aligned}
J &= c_2 c_3 c_4 s_2 s_3^2 \,\mathrm{Im}(x_1^\star x_2), \\
J' &= -\, c_2 c_3 c_4 s_2 s_4^2 \,\mathrm{Im}(x_1^\star x_2).
\end{aligned} \tag{52}
$$

Thus

$$\frac{J'}{J} = -\,\frac{s_4^2}{s_3^2}. \tag{53}$$

For comparison, note that for a general three-by-three matrix [which we may obtain from Eq. (29) by setting $\theta_4 = 0$] the unique invariant is given by $J^{(3\text{-fam})} = c_2 c_3 s_2 s_3^2 \,\mathrm{Im}(x_1^\star x_2)$.

The recursive parametrization allows us to compute all the imaginary parts for the most general case, i.e., irrespectively of whether the matrix has zeros or not. We find, for the general four-by-four matrix, parametrized as in Eq. (29),

$$
\begin{aligned}
(34,34) &= c_3 c_4 s_3 s_4^2 |y_3| \{ |x_2 y_2| \sin\omega_3 + |x_1 y_1| \sin(\omega_3 + \omega_2 - \omega_1) \}, \\
(34,24) &= c_4 s_3 s_4^2 |x_2 y_2| \{ s_3 |x_1 y_1| \sin(\omega_1 - \omega_2) - c_3 |y_3| \sin\omega_3 \},
\end{aligned} \tag{54}
$$

where the angles ω_j are as defined in Eq. (32). We thus see that, as expected, only the invariant phases appear in these relations. We do not quote the remaining imaginary parts $(\alpha\beta, jk)$. The important point is that all of them are functions of $|x_j|$, $|y_j|$ and the three ω's, as expected.

IV. CONCLUSIONS

In this paper, we have presented further properties of the recursive parametrization of unitary matrices proposed in Ref. 2, where the matrix is written as a product of $n-1$ matrices each with its own angle θ and characteristic vector $|A\rangle$. We have found that the factors in the recursive formula may be introduced in any desired order.

Encouraged by the convenience of the recursive method, we have taken a fresh look at the issue of invariant phases of unitary matrices. After having exhibited the symmetries of the parametrization, we have shown how the invariant phases of n-by-n matrices can be identified. Subsequently, we have paid particular attention to the case $n=4$ and have compared the results with those of an earlier approach based on "panels" of the matrix.

The recursive parametrization has some really nice features because in some cases it allows the "new physics" to be introduced in a gentle manner through the last factor in the recursion formula, a topic which we are currently studying.

In an earlier study,[9] we found that there is a parametrization that allows one to introduce, in a simple way, any desired angle of any of the so-called unitarity triangles as one of the parameters in the quark mixing matrix for three families in the standard model of particle physics. The same parametrization allowed us to choose the expansion parameter in this matrix to be λ^2 instead of λ that one usually uses.[5] Indeed λ is not so small ($\lambda=0.2$). Therefore, the recursive parametrization may be convenient whenever expansion in the above parameter is required, for example, in model building or for construction of quark and lepton mass matrices. It turned out that the parametrization found in Ref. 9, with the above nice features, is indeed nothing but the order $n=3$ version of the recursive parametrization discussed in this paper and in Ref. 2.

Finally, in the Appendix of this paper, we deal with the question of how to construct manifestly symmetric unitary matrices in the recursive framework.

APPENDIX: SYMMETRIC UNITARY MATRICES

A matrix X is defined to be symmetric if $X_{ij}=X_{ji}$. We write the symmetric unitary matrix in the form

$$X^{(n)\mathrm{sym}} = \Phi^{(n)}(\vec{\alpha}) V^{(n)\mathrm{sym}} \Phi^{(n)}(\vec{\alpha}) \tag{A1}$$

requiring $V^{(n)\mathrm{sym}}$ to be symmetric, as indicated by its superscript, and that the external matrices be the same [see Eq. (1)]. A general symmetric unitary matrix has $n(n+1)/2$ real parameters. The external matrix Φ takes care of n of them. Thus $n(n-1)/2$ real parameters reside in $V^{(n)\mathrm{sym}}$.

For a general $V^{(n)}$, we have (see Sec. II B) that the factors in the recursion formula Eq. (3) may be written as

$$A_{n,k} = e^{i\theta_k \mathbb{G}_{n,k}}, \tag{A2}$$

where the generating matrix $\mathbb{G}_{n,k}$ is Hermitian. In order to obtain a symmetric $A_{n,k}$ we must impose the additional requirement that the generating matrix be symmetric. This means that the corresponding characteristic vector is purely imaginary. For example, for $k=2$ we obtain

$$V^{(2)\mathrm{sym}} \equiv A^{\mathrm{sym}}_{n,2} = \begin{pmatrix} c_2 & is_2 & 0 \\ is_2 & c_2 & 0 \\ 0 & 0 & I_{n-2} \end{pmatrix} \tag{A3}$$

and for $k=3$,

$$A^{\mathrm{sym}}_{n,3} \begin{pmatrix} 1-(1-c_3)x_1^2 & -(1-c_3)x_1x_2 & is_3x_1 & 0 \\ -(1-c_3)x_1x2_1 & 1-(1-c_3)x_2^2 & is_3x_2 & 0 \\ is_3x_1 & is_3x_2 & c_3 & 0 \\ 0 & 0 & 0 & I_{n-3} \end{pmatrix}. \tag{A4}$$

We have set $|A\rangle = i|x\rangle$, where the x's are real. Thus, the construction of symmetric factors in the recursion formula is a trivial task. But, of course, the product of these factors will not be symmetric. This defect is easily remedied by invoking the reordering procedure described in Sec. II A in which we showed that the reordering of the factors in the recursion formula only amounts to a redefinition of the characteristic vectors. Therefore, we may write

$$V^{(n)\mathrm{sym}} = A^{\mathrm{sym}}_{n,2} A^{\mathrm{sym}}_{n,3} \cdots A^{\mathrm{sym}}_{n,n-1} A^{\mathrm{sym}}_{n,n} A^{\mathrm{sym}}_{n,n-1} \cdots A^{\mathrm{sym}}_{n,3} A^{\mathrm{sym}}_{n,2}, \tag{A5}$$

$V^{(n)\mathrm{sym}}$ thus obtained is manifestly unitary and symmetric. We must now count the number of its independent parameters. Each order k introduces $k-1$ real parameters, these being the angle θ_k and $k-2$ components of the corresponding characteristic vector (one component being redundant because the vector is normalized). Therefore the total number of parameters in $V^{(n)\mathrm{sym}}$ is

$$\sum_{k=2}^{n}(k-1)=n(n-1)/2 \tag{A6}$$

as expected. Adding into this number the n parameters coming from the external matrices amounts to the total of $n(n+1)/2$ real parameters, as required.

Note that it would be somewhat more elegant to call the angles in the above factors $\theta_k/2$ instead of θ_k, except the angle θ_n of the factor $A^{\mathrm{sym}}_{n,n}$. The reason being that $A^{\mathrm{sym}}_{n,n}$ appears only once while the others appear twice.

The chain in Eq. (A5) looks long and perhaps a bit frightening. However, if needed for practical applications, it can be somewhat simplified as we shall now describe.

Consider the case $n=3$, where we introduce

$$V^{(3)\mathrm{sym}}\equiv V^{(2)\mathrm{sym}}(\theta_2/2)A^{(3)\mathrm{sym}}V^{(2)\mathrm{sym}}(\theta_2/2), \tag{A7}$$

where $V^{(2)\mathrm{sym}}$ is as defined in Eq. (A3), for $n=3$. Multiplying the factors, we find

$$V^{(3)\mathrm{sym}}=\begin{pmatrix} c_2-(1-c_3)u_1^2 & is_2-(1-c_3)u_1u_2 & is_3u_1 \\ is_2-(1-c_3)u_1u_2 & c_2-(1-c_3)u_2^2 & is_3u_2 \\ is_3u_1 & is_3u_2 & c_3 \end{pmatrix}. \tag{A8}$$

Here

$$u_1=c_2'x_1+is_2'x_2,\quad u_2=c_2'x_2+is_2'x_1 \tag{A9}$$

$c_2'=\cos(\theta_2/2)$ and $s_2'=\sin(\theta_2/2)$. Moreover, the x's are as introduced in Eq. (A4).

The essential point is that we may set aside the question of the origin of the u's and their relationship with the x's and simply consider them as our new variables, as two complex numbers that satisfy

$$|u_1|^2+|u_2|^2=1 \tag{A10}$$

and, of course, $c_2'u_1-is_2'u_2$ as well as $c_2'u_2-is_2'u_1$ must be real as these are x_1 and x_2 in the above equations. Going to the next order, $n=4$, we may use the identity

$$A_2^{\mathrm{sym}}A_3^{\mathrm{sym}}A_4^{\mathrm{sym}}A_3^{\mathrm{sym}}A_2^{\mathrm{sym}}=A_2^{\mathrm{sym}}A_3^{\mathrm{sym}}A_2^{\mathrm{sym}}[(A_2^{\mathrm{sym}})^{-1}A_4^{\mathrm{sym}}(A_2^{\mathrm{sym}})^{-1}]A_2^{\mathrm{sym}}A_3^{\mathrm{sym}}A_2^{\mathrm{sym}}=V^{(3)\mathrm{sym}}[A_4'^{\mathrm{sym}}]V^{(3)\mathrm{sym}},$$

$$A_4'^{\mathrm{sym}}\equiv(A_2^{\mathrm{sym}})^{-1}A_4^{\mathrm{sym}}(A_2^{\mathrm{sym}})^{-1}. \tag{A11}$$

Here $V^{(3)\mathrm{sym}}$ is as found in Eq. (A8). From our earlier results, we have

$$A_4^{\mathrm{sym}}=\begin{pmatrix} 1-(1-c_4)y_1^2 & -(1-c_4)y_1y_2 & -(1-c_4)y_1y_3 & is_4y_1 \\ -(1-c_4)y_1y_2 & 1-(1-c_4)y_2^2 & -(1-c_4)y_2y_3 & is_4y_2 \\ -(1-c_4)y_1y_3 & -(1-c_4)y_2y_3 & 1-(1-c_4)y_3^2 & is_4y_3 \\ is_4y_1 & is_4y_2 & is_4y_3 & c_4 \end{pmatrix}, \tag{A12}$$

where y's are real. Therefore, we may immediately write down the factor $A_4'^{\mathrm{sym}}$, without having to do any calculations. The first two components of the vector y get "rotated" but y_3 is untouched. We find

$$A_4^{\mathrm{sym}\prime}=\begin{pmatrix} c_2-(1-c_4)v_1^2 & -is_2-(1-c_4)v_1v_2 & -(1-c_4)v_1v_3 & is_4v_1 \\ -is_2-(1-c_4)v_1v_2 & c_2-(1-c_4)v_2^2 & -(1-c_4)v_2v_3 & is_4v_2 \\ -(1-c_4)v_1v_3 & -(1-c_4)v_2v_3 & 1-(1-c_4)v_3^2 & is_4v_3 \\ is_4v_1 & is_4v_2 & is_4v_3 & c_4 \end{pmatrix}, \tag{A13}$$

where

$$v_1 = c_2' y_1 - i s_2' y_2, \quad v_2 = c_2' y_2 - i s_2' y_1, \quad v_3 = y_3. \tag{A14}$$

Again the vector v has unit norm and we may, as before, forget about the y's and just use v's, keeping in mind that v_1 and v_2 are complex numbers.

As a final example, we wish to compute the quantity J for the case of a three-by-three symmetric matrix, where

$$(\alpha\beta;jk) \equiv J \sum_{\gamma,i} \epsilon_{\gamma\alpha\beta}\epsilon_{ijk} \tag{A15}$$

and $V^{(3)\mathrm{sym}}$ is as given in Eq. (A8). A glance at this matrix yields

$$J = c_2 c_3 s_3^2 \,\mathrm{Im}\,(u_2)^2 = c_2 c_3 s_2 s_3^2 x_1 x_2. \tag{A16}$$

This resembles our earlier result in Sec. III D where we found $J^{(3-\mathrm{fam})} = c_2 c_3 s_2 s_3^2 \,\mathrm{Im}(x_1^\star x_2)$. The meaning of the x's in the two cases are, of course, different. Note that a general $V^{(3)}$ has four parameters while $V^{(3)\mathrm{sym}}$ has one less. Equation (A16) is telling us that the symmetry requirement does not remove the invariant phase of the matrix. In the language of Euler rotations, where $V^{(3)}$ would be parametrized with three rotation angles and one phase, the requirement that the matrix be symmetric keeps the phase but removes one of the rotation angles. Note that the new phase and angles will be functions of the former phase and angles.

Distributed Gaussian polynomials as *q*-oscillator eigenfunctions

Hasan Karabulut
Rize Faculty of Arts and Sciences, Physics Department, Karadeniz Technical University, 53100 Rize, Turkey

(Received 25 July 2005; accepted 18 November 2005; published online 19 January 2006)

Karabulut and Sibert [J. Math. Phys. **38**, 4815 (1997)] have constructed an orthogonal set of functions from linear combinations of equally spaced Gaussians. In this paper we show that they are actually eigenfunctions of a *q*-oscillator in coordinate representation. We also reinterpret the coordinate representation example of *q*-oscillator given by Macfarlane as the functions orthogonal with respect to an unusual inner product definition. It is shown that the eigenfunctions in both *q*-oscillator examples are infinitely degenerate. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2161022]

I. INTRODUCTION

Distributed Gaussians are a set of equally spaced Gaussians, $g_n(x)=e^{-c^2(x-n)^2}$ where $(n=-\infty,\ldots,\infty)$. A finite chain of them is often used in variational calculations as a basis set. They are a very flexible and efficient basis set often yielding very accurate variational results. Calculating the potential matrix elements are often the most difficult part of a variational calculation. Because of their compactness it is very easy to calculate potential energy matrix elements with a few point Gauss-Hermite quadrature very accurately which is a major advantage of using this basis.

We need orthogonal functions for variational calculations and the distributed Gaussians are not orthogonal. In a 1997 paper Karabulut and Sibert[1] constructed a set of orthogonal functions from distributed Gaussians and they studied the underlying Gaussian quadrature. They called these functions distributed Gaussian polynomials (DG polynomials briefly). Their motivation was entirely practical and they were not looking for an algebraic structure behind these functions. Later Karabulut[2] showed how to normalize them and used these functions to construct a Wannier function set from distributed Gaussians.

While searching for an operator that admits the DG polynomials as eigenfunctions the author came across a seminal paper by Macfarlane[3] in which he constructed a coordinate representation of his *q*-oscillator algebra (the same *q*-oscillator was also studied by Biederharn[4] but he did not have the explicit coordinate representation example that Macfarlene gave). Eigenfunctions of Macfarlene were a linear combination of distributed Gaussians and it involved the *q*-binomial coefficients just like the DG polynomials. They looked similar to the DG polynomials but they were not the same. Following his example, the author constructed another coordinate representation of the *q*-oscillator algebra that yields the DG polynomials as eigenfunctions. The *q*-oscillator turns out to be a coordinate representation example of the Arik-Coon oscillator.[5] Macfarlane gave an inner product definition for his functions in term of Rogers-Szegö polynomials. The author of this paper also found a simpler inner product definition for the Macfarlane functions and reinterpreted his results.

The outline of the paper is the following. Section II gives a summary of the basic results about the DG polynomials and discusses its links to Rogers-Szegö polynomials. Section III derives the DG polynomials from the *q*-oscillator algebra. Section IV discusses Macfarlane's example to his *q*-oscillator and reinterprets its eigenfunctions. Finally, Sec. V gives a summary and discussion.

II. DISTRIBUTED GAUSSIAN POLYNOMIALS AND THEIR PROPERTIES

We will mostly denote the Gaussians $e^{-c^2x^2}$ as q^{x^2} where $q=e^{-c^2}$ and c^{-1} is related to the width of the Gaussians. DG polynomials are defined as

$$\Phi_n(x) = \sum_{k=0}^{n} C_k^n (-1)^k q^{-k/2} q^{(x-k)^2}. \tag{1}$$

The C_k^n are the well-known q-binomial coefficients

$$C_k^n = \frac{(q,q)_n}{(q,q)_k (q,q)_{n-k}}, \tag{2}$$

where $(q,q)_n$ is defined as

$$(q,q)_n = (1-q)(1-q^2)\cdots(1-q^n), \tag{3}$$

and $(q,q)_0=1$. They satisfy the following orthogonality relation:[2]

$$\int_{-\infty}^{\infty} \Phi_n(x)\Phi_m(x)\mathrm{d}x = \|\Phi_n(x)\|^2 \delta_{nm}, \tag{4}$$

where the norm $\|\Phi_n(x)\|$ is given as

$$\|\Phi_n(x)\| = \left(\frac{\pi}{2c^2}\right)^{1/4} q^{-n/2}\sqrt{(q,q)_n}. \tag{5}$$

We will denote the normalized functions with lowercase ϕ,

$$\phi_n = \frac{\Phi_n(x)}{\|\Phi_n(x)\|} = \frac{\alpha}{\sqrt{(q,q)_n}} \sum_{k=0}^{n} C_k^n (-1)^k q^{(n-k)/2} q^{(x-k)^2}, \tag{6}$$

where

$$\alpha = \left(\int_{-\infty}^{\infty} q^{2x^2}\,\mathrm{d}x\right)^{-1/2} = \left(\frac{2c^2}{\pi}\right)^{1/4}. \tag{7}$$

We defined α this way for later convenience.

Karabulut and Sibert[1] also found that the DG polynomials yield harmonic oscillator eigenfunctions in a particular limit as

$$\lim_{c\to 0} \frac{\Phi_n(s/\sqrt{2}c)}{(-c/\sqrt{2})^n} = e^{-s^2/2} h_n(s), \tag{8}$$

where $h_n(s)$ are the standard Hermite polynomials. We will refer to this limit later.

DG polynomials are related Stieltjes-Wigert polynomials. Let us write the orthogonality relation as follows:

$$\int_{-\infty}^{\infty} \Phi_n(x-s)\Phi_m(x-s)\mathrm{d}x = 0, \quad (n \neq m). \tag{9}$$

If we denote $u=q^{-2x}$ then $\Phi_n(x-s)$ is written as

$$\Phi_n(x-s) = e^{-(\ln u)^2/(-4\ln q)} u^s P_n(u;s), \tag{10}$$

where the polynomials $P_n(u;s)$ are

$$P_n(u;s)=\sum_{k=0}^{n} C_k^n(-1)^k q^{(k+s)^2-k/2}u^k. \tag{11}$$

Then the orthogonality relation becomes

$$\int_{-\infty}^{\infty} e^{-(\ln u)^2/(-2\ln q)}u^{2s-1}P_n(u;s)P_m(u;s)\mathrm{d}x=0, \quad (n\neq m). \tag{12}$$

Evidently the polynomials $P_n(u;s)$ are orthogonal with respect to the weight function

$$W(u)=e^{-(\ln u)^2/(-2\ln q)}u^{2s-1}. \tag{13}$$

For $s=1/2$ the weight function is the lognormal distribution and the corresponding polynomials are known as the Stieltjes-Wigert polynomials. So the $P_n(u;1/2)$ are proportional to Stieltjes-Wigert polynomials.

The above connection to the Stieltjes Wigert polynomials were noted in Karabulut and Sibert.[1] Later Atakishiyev and Nagiyev[6] found a connection between the Stieltjes-Wigert polynomials and Rogers-Szegö polynomials through the Fourier transform which implied that DG polynomials are also connected to the Rogers-Szegö polynomials. Here we note this connection.

We take the convention for the Fourier transform as

$$f(\theta)=\int_{-\infty}^{\infty} e^{i2\pi\theta x}f(x)\mathrm{d}x. \tag{14}$$

Using the Parseval relation of the Fourier transforms

$$\int_{-\infty}^{\infty} F^*(x)G(x)\mathrm{d}x=\int_{-\infty}^{\infty} F^*(\theta)G(\theta)\mathrm{d}\theta, \tag{15}$$

we write Eq. (4) as

$$\int_{-\infty}^{\infty} \Phi_n^*(\theta)\Phi_m(\theta)\mathrm{d}\theta=\left(\frac{\pi}{2c^2}\right)^{1/2} q^{-n}(q,q)_n\delta_{nm}, \tag{16}$$

where $\Phi_n(\theta)$ is the Fourier transform of $\Phi_n(x)$ given as

$$\Phi_n(\theta)=\left(\frac{\pi}{c^2}\right)^{1/2} e^{-(\pi/c)^2\theta^2}\sum_{k=0}^{n} C_k^n(-q^{-1/2}e^{i2\pi\theta})^k. \tag{17}$$

The polynomials

$$H_n(x)=\sum_{k=0}^{n} C_k^n x^k \tag{18}$$

are known as Rogers-Szegö polynomials.[6–8] Using them the orthogonality relation is written as

$$\int_{-\infty}^{\infty} H_n(-q^{-1/2}e^{-i2\pi\theta})H_n(-q^{-1/2}e^{i2\pi\theta})e^{-2(\pi/c)^2\theta^2}\,\mathrm{d}\theta=\left(\frac{c^2}{2\pi}\right)^{1/2} q^{-n}(q,q)_n\delta_{nm}. \tag{19}$$

A form of the Poisson summation formula reads

$$\int_{-\infty}^{\infty} f(x)\mathrm{d}x=\int_0^1\left(\sum_{k=-\infty}^{\infty} f(x+k)\right)\mathrm{d}x, \tag{20}$$

which is valid when $\Sigma_{k=-\infty}^{\infty} f(x+k)$ exists (in our case it does). Using this, Eq. (19) is expressed as

$$\int_0^1 H_n(-q^{-1/2}e^{-i2\pi\theta})H_n(-q^{-1/2}e^{i2\pi\theta})\left(\sum_{k=-\infty}^{\infty} e^{-2(\pi/c)^2(\theta+k)^2}\right)\mathrm{d}\theta = \left(\frac{c^2}{2\pi}\right)^{1/2} q^{-n}(q,q)_n \delta_{nm}. \quad (21)$$

The sum in parentheses is periodic with period unity and it is a form of theta function. We can expand it in Fourier series. The Fourier coefficients can be calculated using the Poisson summation formula as

$$\sum_{k=-\infty}^{\infty} e^{-2(\pi/c)^2(\theta+k)^2} = \sqrt{\frac{c^2}{2\pi}} \sum_{k=-\infty}^{\infty} q^{n^2/2} e^{i2\pi n\theta}. \quad (22)$$

Using the Jacobi ϑ_3 function[9] defined as

$$\vartheta_3(\theta;q) = \sum_{n=-\infty}^{\infty} q^{n^2/2} e^{in\theta}, \quad (23)$$

the orthogonality is written as follows:

$$\int_0^1 H_n(-q^{-1/2}e^{-i2\pi\theta})H_m(-q^{-1/2}e^{i2\pi\theta})\,\vartheta_3(2\pi\theta;q)\mathrm{d}\theta = q^{-n}(q,q)_n \delta_{nm}. \quad (24)$$

This relation is the well-known orthogonality of the Rogers-Szegö polynomials on the unit circle. Clearly it is the same thing as the orthogonality of the DG polynomials and one can be expressed in terms of the other. This is also of interest because Macfarlane[3] expressed orthogonality of his q-oscillator eigenfunctions in terms of orthogonality of Rogers-Szegö polynomials on the unit circle.

III. DG POLYNOMIALS AS A q-OSCILLATOR EIGENFUNCTIONS

A. Algebraic derivation of DG polynomials

Let us define the translation operator T^s as $T^s = e^{s(\partial/\partial x)}$. It has the effect of shifting a function to the left by s, $T^s f(x) = f(x+s)$. We define the creation and destruction operators $\hat{a}$ and $\hat{a}^\dagger$ as

$$\hat{a} = \frac{1}{\sqrt{1-q}} T^{1/2}[q^{x+1/4} - T^{1/2}], \quad (25)$$

$$\hat{a}^\dagger = \frac{1}{\sqrt{1-q}} [q^{x+1/4} - T^{-1/2}]T^{-1/2}. \quad (26)$$

Our inner product is the usual one

$$(f,g) = \int_{-\infty}^{\infty} f^*(x)g(x)\mathrm{d}x, \quad (27)$$

and the conjugate operator is defined as $(f,\hat{O}g) = (\hat{O}^\dagger f, g)$. According to this $(q^x)^\dagger = q^x$ and $(\partial/\partial x)^\dagger = -(\partial/\partial x)$ and $\hat{a}^\dagger$ given above is the right one. The $\hat{a}$ and $\hat{a}^\dagger$ satisfy the commutation relation

$$\hat{a}\hat{a}^\dagger - q\hat{a}^\dagger\hat{a} = 1. \quad (28)$$

This is the commutation relation satisfied by the Arik-Coon oscillator.[5]

We look for the eigenstates of the $\hat{a}^\dagger\hat{a}$,

$$\hat{a}^\dagger \hat{a} A_n(x) = \lambda_n A_n(x). \tag{29}$$

We start from a ground state $A_0(x)$ that satisfies $\hat{a}A_0(x)=0$ which yields the functional equation,

$$A_0(x+1/2) = q^{(x+1/4)} A_0(x). \tag{30}$$

If we set $A_0(x)=(\text{const})w(x)q^{x^2}$ in this equation we get $w(x+1/2)=w(x)$. Therefore the normalized ground state is

$$A_0(x) = \alpha_w w(x) q^{x^2}, \tag{31}$$

where $w(x)$ is any (in general complex) function satisfying $w(x+1/2)=w(x)$ periodicity condition and α_w is the normalization coefficient,

$$\alpha_w = \left(\int_{-\infty}^{\infty} |w(x)|^2 q^{2x^2} \, dx \right)^{-1/2}. \tag{32}$$

For $w(x)=1$ we denote α_w as just α whose value is given in Eq. (7). We choose normalization of our eigenfunctions as $(A_n,A_n)=1$ and taking $w(x)=1$ with this normalization will lead us to the normalized DG polynomials.

Next we build the states $(\hat{a}^\dagger)^n A_0(x)$. Using the commutation relation one can easily show that if $(\hat{a}^\dagger)^n A_0(x)$ is an eigenfunction of $\hat{a}^\dagger\hat{a}$ with the eigenvalue λ_n then the $(\hat{a}^\dagger)^{n+1} A_0(x)$ is an eigenfunction of the $\hat{a}^\dagger\hat{a}$ with eigenvalue λ_{n+1} and one obtains a recursion relation for the eigenvalues

$$\lambda_{n+1} = q\lambda_n + 1. \tag{33}$$

Since $\hat{a}A_0(x)=0$, then $A_0(x)$ is an eigenfunction of $\hat{a}^\dagger\hat{a}$ with the eigenvalue $\lambda_0=0$ and by induction it follows that all $(a^\dagger)^n A_0(x)$ are eigenfunctions. Using the recursion relation in Eq. (33) and $\lambda_0=0$ we get the eigenvalues as

$$\lambda_n = \frac{1-q^n}{1-q}. \tag{34}$$

In exactly the same way that we do in solving the harmonic oscillator algebraically, we can easily obtain the following relations:

$$\hat{a}A_n(x) = \sqrt{\lambda_n} A_{n-1}(x), \tag{35}$$

$$\hat{a}^\dagger A_n(x) = \sqrt{\lambda_{n+1}} A_{n+1}(x). \tag{36}$$

Then $A_n(x)$ can be written as

$$A_n(x) = \sqrt{\frac{(1-q)^n}{(q,q)_n}} (\hat{a}^\dagger)^n A_0(x). \tag{37}$$

Instead of applying $\hat{a}^\dagger$ n times, the following recursive relation is easier. Define $A_n(x)$ as

$$A_n(x) = \frac{\alpha_w w(x)}{\sqrt{(q,q)_n}} \sum_{k=0}^{n} D_k^n (-1)^k q^{(n-k)/2} q^{(x-k)^2}. \tag{38}$$

Then if we apply $\hat{a}^\dagger/\sqrt{\lambda_{n+1}}$ to obtain $A_{n+1}(x)$ and compare the coefficients we get the recursion relation for the D_k^n coefficients. In this process $w(x)$ completely commutes with $\hat{a}^\dagger$ because of periodicity, $T^{-1/2}w(x)=w(x-1/2)=w(x)$. The recursion relation we obtain is

$$D_k^{n+1} = q^k D_k^n + D_{k-1}^n. \tag{39}$$

Together with the conditions $D_0^0=1$ and $D_{-1}^n=D_{n+1}^n=0$ this completely determines the D_k^n. As can be shown easily, the q-binomial coefficients C_k^n satisfy this recursion relation and the boundary conditions and therefore

$$D_k^n = C_k^n = \frac{(q,q)_n}{(q,q)_k(q,q)_{n-k}}. \tag{40}$$

This shows that

$$A_n(x) = \frac{\alpha_w w(x)}{\sqrt{(q,q)_n}} \sum_{k=0}^{n} C_k^n (-1)^k q^{(n-k)/2} q^{(x-k)^2}, \tag{41}$$

are the normalized eigenfunctions and they reduce to the normalized DG polynomials $\phi_n(x)$ when $w(x)=1$.

Now let us see how the q-oscillator algebra reduces to harmonic oscillator algebra in the limit $q\to 0 (c\to 0)$. The limit in Eq. (8) shows us how to do it. First define the new variable $z=cx$. With this variable, the $\hat{a}$ will look like

$$\hat{a} = \frac{1}{\sqrt{1-e^{-c^2}}} e^{(c/2)(\partial/\partial z)} [e^{-c^2/4} e^{-cz} - e^{(c/2)(\partial/\partial z)}], \tag{42}$$

and in the limit $c\to 0$ this reduces to

$$\hat{a} \to -\frac{1}{2}\frac{\partial}{\partial z} - z. \tag{43}$$

Similarly, $\hat{a}^\dagger$ reduces to

$$\hat{a}^\dagger \to \frac{1}{2}\frac{\partial}{\partial z} - z, \tag{44}$$

which, together with $\hat{a}$, are the destruction and creation operators for the harmonic oscillator problem

$$\left(-\frac{1}{4}\frac{\partial}{\partial z^2} + z^2\right)\psi(z) = E\psi(z). \tag{45}$$

B. Further discussion on $w(x)$ degeneracy

Although the algebraic solution seems flawless, it is still very surprising that the $A_n(x)$ are orthogonal for all the functions $w(x)$ satisfying $w(x+1/2)=w(x)$. Here we give a separate proof of it.

When we multiply two of our parent Gaussians $g_n(x)=q^{(x-n)^2}$ we get daughter Gaussians $G_n(x)=q^{2(x-n/2)^2}$ as

$$g_n(x)g_m(x) = q^{(n-m)^2/2} G_{n+m}(x). \tag{46}$$

The parent Gaussians are centered at integers whereas the daughter Gaussians are centered at both integers and half-integers. Therefore the $\phi_n(x)\phi_m(x)$ product of the normalized DG polynomials

$$\phi_n(x) = \frac{\alpha}{\sqrt{(q,q)_n}} \sum_{k=0}^{n} C_k^n (-1)^k q^{(n-k)/2} q^{(x-k)^2}, \tag{47}$$

can be written as a linear combination of daughter polynomials as

$$\phi_n^*(x)\phi_m(x) = \alpha^2 \sum_{k=0}^{n+m} d_k^{nm} q^{2(x-k/2)^2}. \tag{48}$$

If we integrate this we should get δ_{nm} due to the orthogonality of normalized DG polynomials. The integrals $\int_{-\infty}^{\infty} q^{2(x-k/2)^2}\,dx$ are independent of k (just shift the integral by $k/2$) and have the value $1/\alpha^2$. Therefore we get the relation

$$\sum_{k=0}^{n+m} d_k^{nm} = \delta_{nm}. \tag{49}$$

Now, the $A_n^*(x)A_m(x)$ product of the $A_n(x)$ functions

$$A_n(x) = \frac{\alpha_w w(x)}{\sqrt{(q,q)_n}} \sum_{k=0}^{n} C_k^n (-1)^k q^{(n-k)/2} q^{(x-k)^2}, \tag{50}$$

can be expressed as

$$A_n^*(x)A_m(x) = |\alpha_w|^2 \sum_{k=0}^{n+m} d_k^{nm} (|w(x)|^2 q^{2(x-k/2)^2}). \tag{51}$$

If we integrate this we get

$$\int_{-\infty}^{\infty} A_n^*(x)A_m(x)\,dx = \sum_{k=0}^{n+m} d_k^{nm} \left(|\alpha_w|^2 \int_{-\infty}^{\infty} |w(x)|^2 q^{2(x-k/2)^2}\,dx \right). \tag{52}$$

The integral in parentheses can be shifted by $k/2$ as

$$\int_{-\infty}^{\infty} |w(x)|^2 q^{2(x-k/2)^2}\,dx = \int_{-\infty}^{\infty} |w(x+k/2)|^2 q^{2x^2}\,dx. \tag{53}$$

Because of the periodicity of $w(x)$, we have $w(x+k/2)=w(x)$ and all the integrals are independent of k and they have the value $1/|\alpha_w|^2$. This yields

$$\int_{-\infty}^{\infty} A_n^*(x)A_m(x)\,dx = \sum_{k=0}^{n+m} d_k^{nm} = \delta_{nm}, \tag{54}$$

which follows from Eq. (49). Therefore the orthogonality holds for any $w(x)$ satisfying the periodicity requirement.

We actually found more than the DG polynomials from the algebraic treatment. We found an infinite set of orthogonal functions.

IV. A DIFFERENT INTERPRETATION OF q-OSCILLATOR EXAMPLE OF MACFARLANE

In a seminal and widely cited paper Macfarlane constructed a different coordinate representation of the q-oscillator. His definition of the creation and destruction operators are

$$\hat{b} = e^{2x} - e^x e^{s(\partial/\partial x)}, \tag{55}$$

$$\hat{b}^{\dagger} = e^{-2x} - e^{s(\partial/\partial x)}e^{-x}. \tag{56}$$

Obviously, according to the usual definition of the inner product in Eq. (27) the $\hat{b}^{\dagger}$ is not right. Macfarlane himself goes on to construct eigenstates of $\hat{b}^{\dagger}\hat{b}$ without discussing the inner product and orthogonality relation first. After finding the eigenfunctions he states inner product and orthogonality relations in terms of orthogonality of Rogers-Szegö polynomials on the unit circle. The functions we find do not agree with the functions he found and apparently his formula for the eigenfunctions contains some error. Therefore we redo the problem with a different inner product definition here.

We define the inner product as

$$(f,g) = \int_{-\infty}^{\infty} (\hat{P}f^{*}(x))g(x)\mathrm{d}x. \tag{57}$$

$$= \int_{-\infty}^{\infty} f^{*}(-x)g(x)\mathrm{d}x, \tag{58}$$

where $\hat{P}$ is the usual parity operator. For an operator $\hat{O}$, its conjugate $\hat{O}^{\dagger}$ is defined by the relation

$$(f,\hat{O}g) = (\hat{O}^{\dagger}f,g), \tag{59}$$

The $\hat{b}^{\dagger}$ expression in Eq. (56) is right if one defines the inner product this way because $(e^{x})^{\dagger} = e^{-x}$ and $(d/\mathrm{d}x)^{\dagger} = d/\mathrm{d}x$. Notice that this definition of the inner product does not satisfy $(f,f) \geqslant 0$ condition. But we will not use this property of the inner product in our development. We will use the conjugacy definition in Eq. (59) in a few places.

In order to obtain functions as a linear combination of the Gaussians centered at non-negative integers we change the variable $x=-c^2(y+1/4)$ and $s=-c^2/2$ and we take $q=e^{-c^2}$ as before. We will also divide $\hat{b}$ and $\hat{b}^{\dagger}$ by $\sqrt{q(1-q)}$ which does not change the eigenfunctions (only eigenvalues), but in the limit of the harmonic oscillator $(q\to 1)$ it helps to get the right results. The new $\hat{b}$ and $\hat{b}^{\dagger}$ are

$$\hat{b} = (q^{2y+1/2} - q^{y+1/4}T^{1/2})/\sqrt{q(1-q)}, \tag{60}$$

$$\hat{b}^{\dagger} = (q^{-2y+1/2} - T^{1/2}q^{-y+1/4})/\sqrt{q(1-q)}, \tag{61}$$

where $T^{1/2} = e^{\frac{1}{2}(\partial/\partial y)}$. They satisfy the commutation relation

$$\hat{b}^{\dagger}\hat{b} - q\hat{b}\hat{b}^{\dagger} = 1. \tag{62}$$

Note that this is somewhat different than the commutation relation in Eq. (28).

Again we want to find the eigenfunctions of the operator $\hat{b}^{\dagger}\hat{b}$,

$$\hat{b}^{\dagger}\hat{b}B_n(y) = \lambda_n B_n(y). \tag{63}$$

We again start from a ground state that satisfies $\hat{b}B_0(y)=0$ (hence $\lambda_0=0$). $\hat{b}B_0(y)=0$ yields the same functional equation that $A_0(x)$ satisfy

$$B_0(y+1/2) = q^{y+1/4}B_0(y), \tag{64}$$

which we already know has the solution $B_0(y)=\alpha_w w(y)q^{y^2}$ where $w(y)$ satisfies the $w(y+1/2) = w(y)$ periodicity condition. The infinite degeneracy of the states appear here too. Note that this time α_w is defined as

$$\alpha_w = \left(\int_{\infty}^{-\infty} w^*(-y) w(y) q^{2y^2} \mathrm{d}y \right)^{-1/2}. \tag{65}$$

Next we build the unnormalized states $(\hat{b}^\dagger)^n B_0(y)$. Using the commutation relation we can easily show that if the $(\hat{b}^\dagger)^n B_0$ is an eigenfunction of $\hat{b}^\dagger \hat{b}$ with an eigenvalue λ_n then $(\hat{b}^\dagger)^{n+1} B_0$ is an eigenfunction with the eigenvalue λ_{n+1} where λ_{n+1} is related to the λ_n as

$$q\lambda_{n+1} = \lambda_n - 1. \tag{66}$$

Since $B_0(y)$ is an eigenfunction, by induction all $(\hat{b}^\dagger)^n B_0$ are eigenfunctions too. Starting from $\lambda_0 = 0$, this recursion relation yields

$$\lambda_n = -q^{-n} \left(\frac{1-q^n}{1-q} \right). \tag{67}$$

Notice that the eigenvalues are negative.

To obtain relations similar to Eqs. (35) and (36). We form the inner product

$$\lambda_n (B_n, B_n) = (B_n, \hat{b}^\dagger \hat{b} B_n) = (\hat{b} B_n, \hat{b} B_n). \tag{68}$$

Taking $\hat{b} B_n = \mu_n B_{n-1}$ we get

$$\lambda_n = |\mu_n|^2 \frac{(B_{n-1}, B_{n-1})}{(B_n, B_n)}. \tag{69}$$

Since $|\mu_n|^2$ is positive and λ_n is negative, the (B_{n-1}, B_{n-1}) and (B_n, B_n) must have opposite signs. This looks surprising but we should remember that in our definition of the inner product the (f, f) can be negative. Therefore we will take our normalization as

$$(B_n, B_n) = (-1)^n. \tag{70}$$

With this normalization we obtain $\mu_n = \sqrt{-\lambda_n}$,

$$\hat{b} B_n = \sqrt{-\lambda_n} B_{n-1}. \tag{71}$$

Starting from

$$\lambda_{n+1} B_{n+1} = \hat{b}^\dagger \hat{b} B_{n+1} = \sqrt{-\lambda_{n+1}} \hat{b}^\dagger B_n, \tag{72}$$

we also obtain

$$\hat{b}^\dagger B_n = -\sqrt{-\lambda_{n+1}} B_{n+1}. \tag{73}$$

This result is also a little unusual because of the sign in front. It is a consequence of negative λ_n eigenvalues.

Since we started from an unusual inner product definition there might be doubts on orthogonality of the B_n. Consider the inner product

$$(B_m, \hat{b}^\dagger \hat{b} B_n) = (\hat{b}^\dagger \hat{b} B_m, B_n). \tag{74}$$

Using $\hat{b}^\dagger \hat{b} B_k = \lambda_k B_k$ we get

$$(\lambda_n - \lambda_m)(B_m, B_n) = 0, \tag{75}$$

which yields $(B_m, B_n) = 0$ when $m \neq n$. We added this common proof to emphasize that the orthogonality does not depend on the $(f, f) \geqslant 0$ property of the usual inner products. We just used the conjugacy relation Eq. (59) in this proof of orthogonality. But unlike the case of usual definition

inner product given in Eq. (27), $(f,f)=0$ does not imply $f=0$ when we do not have $(f,f)\geqslant 0$ property.

To complete the discussion we obtain the eigenfunctions $B_n(y)$. It makes things easier to figure out the coefficient of Gaussian centered at zero (q^{y^2}) first. The $\hat{b}^\dagger$

$$\hat{b}^\dagger = (q^{-2y+1/2} - T^{1/2}q^{-y+1/4})/\sqrt{q(1-q)}, \tag{76}$$

has two parts that do different things. When $q^{-2y+1/2}$ acts on $q^{(y-k)^2}$ it produces the next Gaussian $q^{(y-k-1)^2}$ and multiplies it with a constant. When $T^{1/2}q^{-y+1/4}$ act on $q^{(y-k)^2}$ it gives $q^{(y-k)^2}$ back and multiplies with a constant. Here are the precise relations

$$q^{-2y+1/2}q^{(y-k)^2} = q^{-2k-1/2}q^{(y-k-1)^2}, \tag{77}$$

$$T^{1/2}q^{-y+1/4}q^{(y-k)^2} = q^{-k}q^{(y-k)^2}. \tag{78}$$

From the second relation we have $T^{1/2}q^{-y+1/4}q^{y^2}=q^{y^2}$ which means this operator leaves q^{y^2} as it is. The other operator $q^{-2y+1/2}$ creates $k=1$ Gaussian $(q^{(y-1)^2})$ from it. Since we produce higher eigenfunctions by applying $-\hat{b}^\dagger/\sqrt{-\lambda_n}$ successively, after each application the coefficient of $k=0$ Gaussian changes by a factor $1/\sqrt{q(1-q)(-\lambda_n)}$. We denote the coefficient of $k=0$ Gaussian in $B_n(y)$ by ζ_n and it should be

$$\zeta_n = \alpha_w \frac{1}{\sqrt{q^n(1-q)^n}} \frac{1}{\sqrt{(-\lambda_1)(-\lambda_2)\cdots(-\lambda_n)}} = \alpha_w \frac{q^{n(n-1)/4}}{\sqrt{(q,q)_n}}. \tag{79}$$

Now let us take the $B_n(y)$ of the form

$$B_n(y) = w(x)\zeta_n \sum_{k=0}^{n} E_k^n q^{(y-k)^2}, \tag{80}$$

where $E_0^n=1$ by construction. We can use Eq. (72) to generate a recursion relation for E_k^n as before. To show a different and easier way of doing things we will use Eq. (70) relation this time. The $\hat{b}$ has the effect of shifting each Gaussian to the left by one unit

$$\hat{b}q^{(y-k)^2} = -\frac{q^{k-1/2}(1-q^k)}{\sqrt{q(1-q)}} q^{(y-k+1)^2}, \tag{81}$$

and it also destroys the leftmost Gaussian (the $k=0$ Gaussian centered at zero). Therefore the equality

$$\hat{b}[(\zeta_n E_k^n)q^{(y-k)^2}] = \sqrt{-\lambda_n}[(\zeta_{n-1}E_{k-1}^{n-1})q^{(y-k+1)^2}] \tag{82}$$

should hold for each Gaussian. This yields the recursion relation for the E_k^n as

$$E_k^n = -E_{k-1}^{n-1}\left(\frac{1-q^n}{1-q^k}\right)q^{-n-k+3/2}. \tag{83}$$

Together with the condition $E_0^n=1$ this is enough information to solve the E_k^n. The quotient in parentheses tells us that the q binomial coefficients C_k^n are involved. If we set $E_k^n=(-1)^k C_k^n q^{u(n,k)}$ we get the recursion relation for $u(n,k)$ as

$$u(n,k) - u(n-1,k-1) = -n-k+3/2. \tag{84}$$

Together with the condition $u(n,0)=0$ (which follows from $E_0^n=1$) this is uniquely solved as $u(n,k)=-nk+k/2$. Therefore the $B_n(y)$ should be

$$B_n(y) = \alpha_w w(x) \frac{q^{n(n-1)/4}}{\sqrt{(q,q)_n}} \sum_{k=0}^{n} C_k^n (-1)^k q^{-(n-1/2)k} q^{(y-k)^2}. \tag{85}$$

This formula does not agree with the result of Macfarlane even after setting $c^2=-2s$ and $y=-1/4+x/2s$ back in $B_n(y)$ above. To be sure that we have the right formula we have checked numerically if the $B_n(y)$ satisfy the orthogonality relation

$$\int_{-\infty}^{\infty} B_n(-y) B_m(y) \mathrm{d}y = (-1)^n \delta_{nm}. \tag{86}$$

They satisfy it perfectly and we are sure that we have the right formula. Apparently Macfarlane's paper contains an error.

The harmonic oscillator limit is as straightforward as it is in the DG polynomials case. We change variable $y=z/c$ and take the limit $c \to 0$ which yields

$$\hat{b} \to z - \frac{1}{2} \frac{\partial}{\partial z}, \tag{87}$$

$$\hat{b}^\dagger \to -z - \frac{1}{2} \frac{\partial}{\partial z}. \tag{88}$$

Then $\hat{b}^\dagger \hat{b} B_n = \lambda_n B_n$ reduces to ($\lambda_n \to -n$ in this limit)

$$\left(-\frac{1}{4} \frac{\partial^2}{\partial z^2} + z^2 \right) \Psi_n = (n + 1/2) \Psi_n. \tag{89}$$

The fact that the inner product is defined differently makes no difference in this limit because the harmonic oscillator eigenfunctions are either even or odd. The harmonic oscillator eigenfunctions satisfy the normalization condition

$$\int \Psi_n^*(-y) \Psi_m(y) \mathrm{d}y = (-1)^n \delta_{nm} \tag{90}$$

as can be verified easily using parity of the wave functions.

Now, just as the DG polynomials, the orthogonality of the $B_n(y)$ can be expressed as an orthogonality relation of the Rogers-Szegö polynomials on the unit circle. We will take $w(x)=1$ and $\alpha_w = \alpha$ for this. By Fourier transforming the orthogonality relation Eq. (85) we get the relation

$$\int_{-\infty}^{\infty} B_n^*(-\theta) B_m(\theta) \mathrm{d}\theta = (-1)^n \delta_{nm}, \tag{91}$$

where $B_n(\theta)$ is the Fourier transform of the $B_n(y)$,

$$B_n(\theta) = \left(\frac{\pi}{c^2} \right)^{1/2} \zeta_n e^{-(\pi/c)^2 \theta^2} \sum_{k=0}^{n} C_k^n (-q^{-(n-1/2)} e^{i2\pi\theta})^k. \tag{92}$$

Here θ is the Fourier transform variable just as before. Using the Poisson summation formula in Eq. (20) the orthogonality relation can be expressed as

$$\int_0^1 H_n(-q^{-(n-1/2)} e^{i2\pi\theta}) H_m(-q^{-(m-1/2)} e^{i2\pi\theta}) \left(\sum_{k=-\infty}^{\infty} e^{-2(\pi/c)^2(\theta+k)^2} \right) \mathrm{d}\theta = \frac{c^2}{\pi} \frac{(-1)^n}{\zeta_n^2} \delta_{nm}. \tag{93}$$

Setting the sum in parentheses from Eqs. (22) and (23) we obtain

$$\int_0^1 H_n(-q^{-(n-1/2)}e^{i2\pi\theta})H_m(-q^{-(m-1/2)}e^{i2\pi\theta})\vartheta_3(2\pi\theta;q)\mathrm{d}\theta = q^{-n(n-1)/2}(q,q)_n(-1)^n\delta_{nm}. \quad (94)$$

This is again some form of the orthogonality relation of the Rogers-Szegö polynomials on the circle. This is a new set of orthogonality relations and we are not aware of its existence in mathematical literature.

V. SUMMARY

In this study we found that the DG polynomials that Karabulut and Sibert discovered before are actually eigenfunctions of coordinate representation of the Arik-Coon q-oscillator. We derived the DG polynomials from q-oscillator algebra. We also indicated that orthogonality of the DG polynomials can be cast into orthogonality of the Rogers-Szegö polynomials on the unit circle and the two are equivalent.

We showed that the example given by Macfarlane can be interpreted with an unusual inner product definition and we constructed the corresponding orthogonal functions. Their orthogonality can be recast into a form of orthogonality relation for the Rogers-Szegö polynomials on the unit circle. We were not able to find this result in mathematical literature and it is probably a new result.

A very interesting result of this work is that the eigenstates of the q-oscillators we solved turned out to be infinitely degenerate. We know that algebraic solution of the one dimensional harmonic oscillator is nondegenerate. In the usual algebraic solution of the harmonic oscillator we base our arguments on the commutation relations and the algebra has nothing in it that implies nondegenerate states. But the ground state $\hat{a}\phi_0=0$ yields a unique solution for the harmonic oscillator because it is a differential equation and nondegeneracy of the excited states follows from this. For our q-oscillator examples we have a first order difference equation for the $\hat{a}\phi_0=0$ and such equations together with the boundary conditions do not uniquely define a function. It defines a function on all real axis if its values in a $1/2$ wide interval are known.

Finally, the freedom to choose $w(x)$ arbitrarily gives us possibility of constructing orthogonal function sets more general than the DG polynomials. Consider a set of functions $w_0(x), w_1(x), w_2(x), \ldots$ satisfying the periodicity condition $w_n(x+1/2)=w_n(x)(n=0,1,2,\ldots)$ and the orthogonality relation

$$\int_{-\infty}^{\infty} w_n^*(x)w_m(x)q^{2x^2}\,\mathrm{d}x = \delta_{nm}. \quad (95)$$

Then the set of functions

$$\Gamma_{nm}(x) = \frac{\alpha(w_n)}{\alpha} w_n(x)\phi_m(x) \quad (96)$$

will satisfy an orthogonality relation of the form

$$\int_{-\infty}^{\infty} \Gamma_{nm}^*(x)\Gamma_{ij}(x)\mathrm{d}x = \delta_{ni}\delta_{mj}. \quad (97)$$

Here $\alpha(w_n)$ is the α_w for $w=w_n(x)$ given in Eq. (32) and α is given in Eq. (7). This gives us much freedom to construct orthogonal function sets useful as basis sets in variational calculations. This possibility should be investigated in future research.

ACKNOWLEDGMENTS

In a private communication Professor R. G. Littlejohn suggested to the author that there must be an operator that admits the DG polynomials as eigenfunctions, or equivalently, there must be an algebraic structure behind them. Although his insightful comments and suggestions are entirely

responsible for the creation of the work presented here, he kindly declined to coauthor this paper on the grounds that his contribution was minimal. The author is indebted to Professor Robert G. Littlejohn for suggesting the problem addressed in this paper.

In this work, an algorithm to decompose a given orthogonal transformation as a product of reflections through hyperplanes is presented. This in fact constitutes a constructive proof of a Cartan theorem, valid over any field $K=\mathbb{Q}$, $\mathbb{R}$ or $\mathbb{C}$. Clifford algebras are used to explicitly calculate the reflections that decompose a given orthogonal transformation. Our algorithm may have application in fields such as computer graphics or crystallography, and can also play an important role in orthogonal elimination and the solution of equations systems. An explicit example is provided and we apply our results to the crystallographic problem of coincidence lattices. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2161072]

I. INTRODUCTION

This work is concerning the decomposition of a given orthogonal transformation in $\mathbb{R}^n$ as a product of simple reflections (reflections by hyperplanes). This problem is directly related to a Cartan theorem,[1] which asserts that every orthogonal transformation can be written as the product of at most n reflections with respect to hyperplanes. The original proofs of this theorem, of around 70 years ago, were nonconstructive; for a given orthogonal transformation the existence of such reflections was demonstrated. In Ref. 2, for instance, a proof based on the Raleigh quotient is presented. Constructive ways by the induction method have been given in different contexts; when computing over $\mathbb{R}$ or $\mathbb{C}$, and by using Householder matrices, it was proved that any real (or complex) orthogonal (or unitary) matrix can be written as the product of at most n Householder matrices, derived constructively from the original matrix.[3] The importance of this proof relies in the fact that Householder matrices are relevant in numerical linear algebra.[3,4] Also, there exists a constructive derivation of the analog of the Cartan theorem for symplectic matrices.[5]

Here, we present a constructive proof of the Cartan theorem, valid for n-dimensional linear spaces with inner product over any field $K=\mathbb{Q}$, $\mathbb{R}$ or $\mathbb{C}$, which produces an algorithm for the factorization of a given orthogonal transformation into a product of simple reflections. We have found that this factorization is greatly simplified by using Clifford algebras, where reflections and rotations are handled in a convenient way. These algebras have proved to be a powerful mathematical language for expressing geometric ideas and have been relevant not only in several mathematical areas but also in physics, engineering and computer science (see, for example, Ref. 6 and references therein). The use of Clifford algebras to prove the Cartan theorem do not obscure but enhances the geometrical meaning, yielding an algorithm which can be relevant in several

fields since it offers a simple way to decompose any arbitrary orthogonal transformation as a product of simple reflections. In particular, we have shown that Clifford algebras are suitable for calculations in n-dimensional crystallographic lattices.[7,8] In these works, it was conjectured that any coincidence transformation of the lattice $\mathbb{Z}^n$ (see Sec. V) can be written as the product of coincidence reflections. The conjecture was proved in two dimensions[8] and here, as an application of our results, we prove the conjecture for $\mathbb{Z}^n$ (Sec. V, Theorem 20).

This paper is organized as follows. In Sec. II we provide a brief introduction to real orthogonal spaces and Clifford algebras. In Sec. III, we present a constructive proof of the Cartan theorem that produces an algorithm to calculate the simple reflections that decompose a given orthogonal transformation. An explicit example is given in Sec. IV and applications to coincidence transformation are presented in Sec. V. Section VI is devoted to conclusions and discussions.

II. REAL ORTHOGONAL SPACES AND CLIFFORD ALGEBRAS

To set the background and fix notation, in this section we first introduce several basic concepts and the basis of Clifford algebras. Most of the results are presented without proofs, and interested readers are referred to Refs. 9 and 10.

Definition 1: The pair $(\mathcal{X},\mathcal{B})$ *is called a n-dimensional real orthogonal space if* $\mathcal{X}$ *is a n-dimensional vector space and* $\mathcal{B}$: $\mathcal{X}\times\mathcal{X}\to\mathbb{R}$ *is an inner product.*

If $\mathcal{W}\subset\mathcal{X}$ is a vector subspace of $\mathcal{X}$ ($\mathcal{W}<\mathcal{X}$), the orthogonal complement of $\mathcal{W}$ in $\mathcal{X}$ is the set

$$\mathcal{W}^{\perp}=\{u\in\mathcal{X}|\mathcal{B}(v,u)=0,\ \text{for all } v\in\mathcal{W}\}.$$

Clearly $\mathcal{W}^{\perp}<\mathcal{X}$. Furthermore, we have the following.

Proposition 2: Let $(\mathcal{X},\mathcal{B})$ *be a n-dimensional real orthogonal space and let* $\mathcal{W}<\mathcal{X}$. *Then* $\mathcal{X}=\mathcal{W}\oplus\mathcal{W}^{\perp}$.

In particular, for a given $a\in\mathcal{X}$ such that $\mathcal{B}(a,a)\neq 0$ we have that $\mathcal{X}=\mathbb{R}a\oplus(\mathbb{R}a)^{\perp}$, and the element $a\in\mathcal{X}$ is called *invertible*. Moreover,

$$a^{-1}=\frac{a}{a^2}=\frac{a}{\mathcal{B}(a,a)}.$$

The $(n-1)$-dimensional subspace $H_a=(\mathbb{R}a)^{\perp}<\mathcal{X}$ is called the hyperplane associated with the invertible element $a\in\mathcal{X}$. Now, since each $v\in\mathcal{X}$ allows a unique decomposition $v=\lambda a+b$, where $\lambda\in\mathbb{R}$ and $b\in(\mathbb{R}a)^{\perp}=H_a$, then the map $\varphi_a(v)=-\lambda a+b$ is orthogonal. Thus φ_a represents a reflection with respect to the hyperplane H_a, which is called a simple reflection.

To end this brief section, we introduce some basic concepts of Clifford algebra. It is important to remark that there are several constructions of Clifford algebras[11–14] and here we choose the approach by Porteous.[10]

Definition 3: Let $(\mathcal{X},\mathcal{B})$ *be a n-dimensional real orthogonal space and let* $\mathcal{A}$ *be a real associative algebra with identity* 1 *such that*

(*C*1) $\mathcal{A}$ *contains copies of* $\mathbb{R}$ *and* $\mathcal{X}$ *as linear subspaces.*

(*C*2) *For all* $v\in\mathcal{X}$ *we have that* $v^2=\mathcal{B}(v,v)$.

(*C*3) $\mathcal{A}$ *is generated as a ring by the copies of* $\mathbb{R}$ *and* $\mathcal{X}$ *or, equivalently as a real algebra by* $\{1\}$ *and* $\mathcal{X}$.

Then $\mathcal{A}$ *is said to be a real Clifford algebra for* $(\mathcal{X},\mathcal{B})$ *and it is denoted by* $\mathcal{A}=\mathcal{C}(\mathcal{X})$.

Axiom (C2) contains the relationship between Clifford algebras and bilinear forms thus holding, as we shall see below, the geometrical interpretation of the Clifford algebra.

If $e=\{e_1,e_2,\ldots,e_n\}$ is an orthonormal basis of $(\mathcal{X},\mathcal{B})$, from the condition (C2) it follows that

$$e_i^2=1,\quad i=1,2,\ldots,n$$

$$e_ie_j+e_je_i=0,\quad i\neq j.$$

In general, for all v, $w\in\mathcal{X}$ we have that

$$\mathcal{B}(v,w) = \tfrac{1}{2}(vw + wv), \tag{1}$$

as it is inferred from $\mathcal{B}(v+w,v+w)=(v+w)^2$. Notice that from (1) it readily follows that two vectors u, $v \in \mathcal{X}$ anticommute if and only if they are orthogonal.

If u, $v \in \mathcal{X}$, then we have

$$uv = \tfrac{1}{2}(uv + vu) + \tfrac{1}{2}(uv - vu) = \mathcal{B}(u,v) + u \wedge v,$$

where

$$u \wedge v = \tfrac{1}{2}(uv - vu)$$

is called the *exterior* product. Moreover, it turns out that $u \wedge v = 0$ if and only if u, v are parallel or linearly dependent vectors.

Notice that since $\mathcal{C}(\mathcal{X})$ is generated by $\{1\}$ and $\mathcal{X}$ then, in terms of the orthonormal basis e, a typical element a of $\mathcal{C}$ is

$$a = \sum_A \lambda_A e_{\alpha_1}^{n_1} e_{\alpha_2}^{n_2} \cdots e_{\alpha_s}^{n_s},$$

where $\lambda_A \in \mathbb{R}$ and $n_j = 1, 0$.

There is an obvious upper bound to the linear dimension of a Clifford algebra for a n-dimensional real orthogonal space. More specifically, $\dim \mathcal{C}(\mathcal{X}) = 2^{n-1}$ or $\dim \mathcal{C}(\mathcal{X}) = 2^n$. In this work, we shall restrict ourselves to Clifford algebras of dimension 2^n, which are called *universal* Clifford algebras.

III. THE CARTAN THEOREM

Before formulating the Cartan theorem, it is useful to first briefly discuss how the algebraic properties of Clifford algebra provide us with a convenient framework for representing orthogonal transformations (linear transformations that preserve the bilinear form).

Suppose $a \in \mathcal{X}$ is a nonzero vector and let H_a be its orthogonal complement.

Lemma 4: Let $\mathcal{C}(\mathcal{X})$ be a Clifford algebra for a n-dimensional real orthogonal space $(\mathcal{X},\mathcal{B})$. If $a \in \mathcal{X}$ is invertible, then the map $T_a: \mathcal{X} \to \mathcal{X}$, defined by

$$T_a(x) = -axa^{-1},$$

is an orthogonal transformation. Moreover, T is a simple reflection.

Proof: T_a is linear, as a consequence of the distributive property of the algebra. To see that T_a is a reflection by the hyperplane H_a it is enough to prove that $T_a(a) = -a$ and $T_a(w) = w$ for all $w \in H_a$. Indeed,

$$T_a(a) = -aaa^{-1} = -a,$$

$$T_a(w) = -awa^{-1} = -(-wa)a^{-1} = w,$$

where we use the fact that $aw = -wa$ since $\mathcal{B}(a,w) = 0$. T_a is an orthogonal transformation since $T_a(v)^2 = v^2$ for all $v \in \mathcal{X}$.

■

Clearly the inverse of a simple reflection is a simple reflection itself

$$T_a(x) = -axa^{-1} = -ax\frac{a}{a^2} = -\frac{a}{a^2}xa = a^{-1}x(a^{-1})^{-1} = T_{a^{-1}}(x).$$

The following Lemma not only displays a simple geometrical fact discussed below, but turns out to be fundamental for the proof of the Cartan theorem proposed here (cf. with Ref. 10, p. 34).

Lemma 5: Let $\mathcal{C}(\mathcal{X})$ be a Clifford algebra for a n-dimensional real orthogonal space $(\mathcal{X},\mathcal{B})$.

If $a,b \in \mathcal{X}$ *are invertible vectors and* $a^2=b^2 \neq 0$, *then there exists a simple reflection* $\varphi:\mathcal{X}\to\mathcal{X}$ *such that*

$$\varphi(a) = b.$$

Proof: For the trivial case $a=b$, it is enough to take $\varphi=I$, where $I:\mathcal{X}\to\mathcal{X}$ is the identity transformation. If $a \neq b$ we shall first prove that the vectors $a-b$ and $a+b$ are orthogonal. Indeed,

$$2\mathcal{B}(a-b,a+b) = (a-b)(a+b) + (b+a)(a-b) = (a^2 - ba + ab - b^2) + (ba + a^2 - ab - b^2) = 0.$$

Now, since

$$(a+b)^2 + (a-b)^2 = (a^2 + ab + ba + b^2) + (a^2 - ab - ba + b^2) = 4a^2 \neq 0,$$

we conclude that $a-b$ is invertible. We can thus define the following orthogonal transformation:

$$\varphi_{a-b}(x) = -(a-b)x(a-b)^{-1},$$

which satisfies $\varphi_{a-b}(a)=b$, as it can be easily verified:

$$\varphi_{a-b}(a) = -(a-b)\left(\frac{1}{2}(a-b) + \frac{1}{2}(a+b)\right)(a-b)^{-1}$$

$$= -\frac{1}{2}(a-b)(a-b)(a-b)^{-1} - \frac{1}{2}(a-b)(a+b)(a-b)^{-1} = -\frac{1}{2}(a-b) + \frac{1}{2}(a+b) = b.$$

Thus, $\varphi(x)$ can be expressed as

$$\varphi(x) = \begin{cases} I & \text{if } a = b, \\ \varphi_{a-b}(x) & \text{if } a \neq b. \end{cases}$$

■

The geometric meaning of the previous lemma can be explained if we consider two vectors, a and b, such that $a^2=b^2\neq 0$. The diagonals of the rhombuses ($a+b$ and $a-b$) are perpendicular and thus the orthogonal complement of $a-b$ is $a+b$ and vice versa. Consequently, if we construct the reflection by using the vector $a-b$, the operation $\varphi_{a-b}(a)$ produces the reflection of a through the hyperplane H_{a-b}, which obviously gives b. The recurrent application of Lemma 5 produces an algorithm to decompose any given orthogonal transformation as the composition of simple reflections. For this goal, it is enough to adequately choose the vectors a and b at each step of the algorithm. This constitutes the Cartan theorem and therefore a constructive proof can now be given.

Theorem 6 (Cartan): *Any orthogonal transformation, in a n-dimensional real orthogonal space* $(\mathcal{X},\mathcal{B})$, *can be written as the product of at most n simple reflections*.

Proof: Let $T:\mathcal{X}\to\mathcal{X}$ be an orthogonal transformation in a n-dimensional real orthogonal space $(\mathcal{X},\mathcal{B})$, and assume that $\{w_1,\ldots,w_n\}$ is an orthogonal basis of $(\mathcal{X},\mathcal{B})$ such that $w_i^2 \neq 0$ for $i=1,\ldots,n$.

Consider w_1, $T(w_1)$ (which play the role of a and b, respectively, in the proof of Lemma 5) and the transformation $\varphi_1:\mathcal{X}\to\mathcal{X}$ defined by

$$\varphi_1(x) = \begin{cases} I & \text{if } T(w_1) = w_1, \\ -c_1 x c_1^{-1} & \text{if } T(w_1) \neq w_1, \end{cases}$$

where $c_1=T(w_1)-w_1$. As it follows from Lemma 5, $\varphi_1(x)$ has the following properties:

$$\varphi_1 T(w_1) = w_1,$$

$$\varphi_1 T(w_l) \in \mathrm{Span}\{w_2,\ldots,w_n\} \quad \text{for } l = 2,\ldots,n.$$

Now, consider w_2, $\varphi_1 T(w_2)$ and the transformation $\varphi_2: \mathcal{X} \to \mathcal{X}$ defined by

$$\varphi_2(x) = \begin{cases} I & \text{if } \varphi_1 T(w_2) = w_2, \\ -c_2 x c_2^{-1} & \text{if } \varphi_1 T(w_2) \neq w_2, \end{cases}$$

where $c_2 = \varphi_2 T(w_2) - w_2$. We already know that $\varphi_2 \varphi_1 T(w_2) = w_2$, and since $c_1 \in \mathrm{Span}\{w_2, w_3, \ldots, w_n\}$, it can be verified that $\varphi_2 \varphi_1 T(w_1) = w_1$. Then we have that

$$\varphi_2 \varphi_1 T(w_i) = w_i \quad \text{for } i = 1,2,$$

$$\varphi_2 \varphi_1 T(w_l) \in \mathrm{Span}\{w_3, w_4, \ldots, w_n\}, \quad \text{for } l = 3,4, \ldots, n.$$

Accordingly, now consider w_3, $\varphi_2 \varphi_1 T(w_3)$ and $\varphi_3: \mathcal{X} \to \mathcal{X}$ defined by

$$\varphi_3(x) = \begin{cases} I & \text{if } \varphi_2 \varphi_1 T(w_3) = w_3, \\ -c_3 x c_3^{-1} & \text{if } \varphi_2 \varphi_1 T(w_3) \neq w_3, \end{cases}$$

where $c_3 = \varphi_2 \varphi_1 T(w_3) - w_3$. We also already know that $\varphi_3 \varphi_2 \varphi_1 T(w_2) = w_2$, and since $c_3 \in \mathrm{Span}\{w_3, \ldots, w_n\}$, it follows that $\varphi_2 \varphi_1 T(w_i) = w_i$, $i = 1,2$. Thus we have that

$$\varphi_3 \varphi_2 \varphi_1 T(w_i) = w_i \quad \text{for } i = 1,2,3,$$

$$\varphi_3 \varphi_2 \varphi_1 T(w_l) \in \mathrm{Span}\{w_4, \ldots, w_n\} \quad \text{for } l = 4, \ldots, n.$$

This procedure can be straightforwardly continued up to n steps, to obtain $\varphi_1, \varphi_2, \ldots, \varphi_n$ orthogonal transformations such that

$$\varphi_n \varphi_{n-1} \cdots \varphi_1 T(w_i) = w_i \quad \text{for } i = 1, \ldots, n, \tag{2}$$

where

$$\varphi_{k+1}(x) = \begin{cases} I & \text{if } \varphi_k \varphi_{k-1} \cdots \varphi_1 T(w_{k+1}) = w_{k+1}, \\ -c_{k+1} x c_{k+1}^{-1} & \text{if } \varphi_k \varphi_{k-1} \ldots \varphi_1 T(w_{k+1}) \neq w_{k+1}, \end{cases}$$

and

$$c_{k+1} = \varphi_k \varphi_{k-1} \cdots \varphi_1 T(w_{k+1}) - w_{k+1}.$$

Notice that

$$\varphi_{k+1}^{-1}(x) = \begin{cases} I & \text{if } \varphi_k \varphi_{k-1} \cdots \varphi_1 T(w_{k+1}) = w_{k+1}, \\ -c_{k+1} x c_{k+1}^{-1} & \text{if } \varphi_k \varphi_{k-1} \ldots \varphi_1 T(w_{k+1}) \neq w_{k+1}. \end{cases}$$

By (2) we obtain

$$T(x) = \varphi_1^{-1} \cdots \varphi_n^{-1}(x),$$

and since each $\varphi_k^{-1}(x)$ is a simple refelction, then the orthogonal transformation T is written as the product of at most n reflections by hyperplanes. Moreover, we can find $a_1, a_2, \ldots, a_s \in \mathcal{X}$ such that

$$T(x) = (-1)^s a_1 a_2 \cdots a_s x a_s^{-1} \cdots a_2^{-1} a_1^{-1},$$

where $s \leqslant n$.

■

IV. EXAMPLE

The following example illustrates the procedure to decompose a particular orthogonal transformation in $\mathbb{R}^3$ as a product of simple reflections. The computations were done with a *Mathematica* Clifford algebra package.[15]

Let $T:\mathbb{R}^3\to\mathbb{R}^3$ be an orthogonal transformation with the following associated matrix, with respect to the canonical basis $\{e_1,e_2,e_3\}$:

$$\mathcal{T}=\begin{pmatrix} \frac{6}{7} & \frac{2}{7} & \frac{3}{7} \\ \frac{2}{7} & \frac{3}{7} & -\frac{6}{7} \\ -\frac{3}{7} & \frac{6}{7} & \frac{2}{7} \end{pmatrix}.$$

By following step by step the procedure used in the proof of the Cartan theorem (Theorem 6), we have that

$$c_1 = T(e_1) - e_1 = \begin{pmatrix} -\frac{1}{7} \\ \frac{2}{7} \\ -\frac{3}{7} \end{pmatrix},$$

and thus $\phi_1(x)=-c_1xc_1^{-1}$. Now

$$c_2 = \phi_1(T(e_2)) - e_2 = -c_1T(e_2)c_1^{-1} - e_2 = 0,$$

that is, $\phi_2(x)=x$, the identity. Finally

$$c_3 = \phi_2(\phi_1(T(e_3))) - e_3 = -c_1T(e_3)c_1^{-1} - e_3 = \begin{pmatrix} 0 \\ 0 \\ -2 \end{pmatrix},$$

and $\phi_3(x)=-c_3xc_3^{-1}$. Consequently, T is decomposed as

$$T(x) = \phi_1(\phi_2(\phi_3(x))) = a_1a_3xa_3^{-1}a_1.$$

If Φ_i denotes the matrix associated to ϕ_i, with respect to the canonical basis, these are given by

$$\Phi_1 = \frac{1}{7}\begin{pmatrix} -6 & -2 & 3 \\ -2 & -3 & -6 \\ 3 & -6 & 2 \end{pmatrix}, \quad \Phi_2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \Phi_3 = \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

and we can easily verify that $\mathcal{T}=\Phi_1\Phi_2\Phi_3$.

V. AN APPLICATION TO THE COINCIDENCE SITE LATTICE THEORY

Coincidence site lattice theory has provided partial answers to the complex problems that arise in the description of grain and twin boundaries.[16] Mathematically, the problem can be stated as follows:

Let Λ be a lattice in $\mathbb{R}^n$ and let $T\in O(\mathbb{R}^n)$, T is called a coincidence transformation if $\Lambda\cap T\Lambda$ is a sublattice of Λ. The problem is therefore to identify and characterize coincidence transformations of a given lattice Λ.

Here, by considering simple reflections as primitive transformation, we analyze this problem by finding conditions under which a given transformation is of coincidence. In a previous work,[7] it was conjectured that any arbitrary coincidence transformation can be decomposed as product of coincidence reflections by vectors of the lattice Λ. This conjecture was proved in two dimensions[8] and here, as an application of our results, we prove the conjecture for $\mathbb{Z}^n$ (Theorem 20).

We first introduce the basic concepts related to lattices and coincidence lattices, by following the formalization of the coincidence problem given by Baake.[17] Henceforth $\mathcal{B}(x,y)$ represents the canonical scalar product in $\mathbb{R}^n$, denoted by $x\cdot y$.

Definition 7: A discrete subset $\Lambda\subset\mathbb{R}^n$ is called a lattice, of dimension n, if it is spanned as $\Lambda=\oplus_{i=1}^{n}\mathbb{Z}a_i$, with $\{a_1,\ldots,a_1\}$ a set linearly independent vectors of $\mathbb{R}^n$. These vectors form a basis of the lattice.

The lattice Λ is isomorphic to the free Abelian group of order n. It allows us to define the concept of sublattice.

Definition 8: Let $\Lambda\subset\mathbb{R}^n$ be a lattice. A subset $\Lambda_1\subset\Lambda$ is called a sublattice of Λ if it is a subgroup of finite order, i.e., $[\Lambda,\Lambda_1]<\infty$ (the number of the right cosets is finite).

The following two definitions are central for the coincidence problem.

Definition 9: Two lattices Λ_1 and Λ_2 are called commensurate, denoted by $\Lambda_1\sim\Lambda_2$ if and only if $\Lambda_1\cap\Lambda_2$ is a sublattice of both Λ_1 and Λ_2.

Definition 10: An orthogonal transformation $T\in O(\mathbb{R}^n)$ is called a coincidence transformation if and only if $T\Lambda\sim\Lambda$. The integer $\Sigma(T)=[\Lambda:T\Lambda\cap\Lambda]$ is called the coincidence index of T with respect to Λ. If T is not a coincidence transformation then $\Sigma(T):=\infty$. Two useful sets are also defined,

$$OC(\Lambda) := \left\{T\in O(n)\middle|\sum(T)<\infty\right\},$$

$$SOC(\Lambda) := \{T\in O(n)|\det T=1\}.$$

Coincidence transformations are usually worked out using matrices. In what follows, we recall this approach in order to state a result that will be used later.

Definition 11: Let Λ be a lattice in $\mathbb{R}^n$ with basis $\{a_1,\ldots,a_n\}$. The structure matrix N of Λ is defined through the relation $a_i=Ne_i=\Sigma_{j=1}^{n}N_{ji}e_j$, where $\{e_1,\ldots,e_n\}$ is the canonical basis of $\mathbb{R}^n$.

Theorem 12 (Grimmer): *Let Λ_1 and Λ_2 be two lattices in $\mathbb{R}^n$, with structure matrices N_1 and N_2, respectively. Then, $\Lambda_1\sim\Lambda_2$ if and only if $N_1^{-1}N_2$ has rational entries.*

Theorem 13: *Let $\Lambda\subset\mathbb{R}^n$ be a lattice and let T be an orthogonal transformation. Then, $T\in OC(\Lambda)$ if and only if its associated matrix, with respect to the basis of the lattice, has rational entries.*

A consequence of this theorem is the following.

Proposition 14: Let $\Lambda=\oplus_{i=1}^{n}\mathbb{Z}a_i$ and T be a lattice and an orthogonal transformation in $\mathbb{R}^n$, respectively. Then $T\in OC(\Lambda)$ if and only if for any a_i there exists $m_i\in\mathbb{N}$ such that $m_ia_i\in T(\Lambda)$.

With this background, we can formulate the problem of coincidences between two lattices by using the language of Clifford algebras. By simplicity, in some cases we restrict our treatment to the case of hypercubic lattices $\mathbb{Z}^n$.

Let $\mathbb{Z}^n=\oplus_{i=1}^{n}\mathbb{Z}e_i$ be a n-dimensional hypercubic lattice equipped with a canonical basis $\{e_1,\ldots,e_n\}$. As we have seen, the simple reflection R of a vector x can be written as

$$R(x)=-sxs^{-1}=-\lambda sx(\lambda s)^{-1},$$

where $\lambda\neq 0$ and the reflection hyperplane is $H_s=\{s\}^{\perp}$. We shall find conditions under which R is a coincidence reflection.

Proposition 15: Let $\Lambda=\oplus_{i=1}^{n}\mathbb{Z}a_i$ be a lattice in $\mathbb{R}^n$ and consider a vector $s\in\mathbb{R}^n$. If the transformation $R(x)=-sxs^{-1}$ is a coincidence reflection, i.e., *$R(x)\in OC(\Lambda)$, then there exists a vector $t\in\Lambda$ such that $R(x)=-sxs^{-1}=-txt^{-1}$.*

Proof: Let R be a reflection and assume $R\in OC(\Lambda)$. Given this last assumption, for a given $a\in\Lambda$ we can always find $m\in\mathbb{N}$ such that $mR(a)=R(ma)\in\Lambda$. Thus, for a given $x\in\Lambda$ the vector $y=R(x)$ belongs to the lattice Λ, that is, for some $s\in\mathbb{R}^n$ we have that

$$y=-sxs^{-1}\in\Lambda.$$

Now, since $ys=-sx$,

$$y \cdot s = -s \cdot x$$

$$y \wedge s = -s \wedge x = x \wedge s,$$

and therefore

$$(y - x) \wedge s = 0.$$

Consequently, since $x, y \in \Lambda$, there exists $\lambda \in \mathbb{R}$ such that $y - x = \lambda s \in \Lambda$. By taking $t = \lambda s \in \Lambda$, we conclude that $R(x) - sxs^{-1} = -txt^{-1}$.

■

The contrary is true for hypercubic lattices $\Lambda = \mathbb{Z}^n$.

Proposition 16: Consider $c \in \mathbb{Z}^n$ with $c \neq 0$. Then $R(x) = -cxc^{-1} \in OC(\mathbb{Z}^n)$.

Proof: If $c, x \in \mathbb{Z}^n$ then

$$R(x) = -cxc^{-1} = -2\frac{x \cdot c}{c^2}c + x,$$

since $B(x,c)/c^2 \in \mathbb{Q}$. Then by taking $m = c^2 \in \mathbb{N}$ we obtain

$$mR(x) = -2(x \cdot c)c + mx,$$

which belongs to $\mathbb{Z}^n$ and thus $R(x) \in OC(\mathbb{Z}^n)$.

■

Consequently, for hypercubic lattices the previous results can be summarized as follows.

Theorem 17: *Let R be a reflection by a hyperplane in $\mathbb{R}^n$. Then $R \in OC(\mathbb{Z}^n)$ if and only if it can be written as*

$$R(x) = -cxc^{-1},$$

where $c \in \mathbb{Z}^n$.

Now, we are interested in decomposing any arbitrary coincidence orthogonal transformation into a product of coincidence reflections. First consider the following.

Lemma 18: Let $T \in OC(\mathbb{Z}^n)$ be a coincidence orthogonal transformation. Let also $a \in \mathbb{Z}^n$ and $b \in T(Z^n)$ be two lattice vectors of the same length, that is $a^2 = b^2$. Then, there exists a map $S \in OC(\mathbb{Z}^n)$ such that $S(a) = b$.

Proof: Let $a \in \mathbb{Z}^n$ be a lattice vector and let $T \in OC(\mathbb{Z}^n)$ be a coincidence orthogonal transformation. If $b \in T(\mathbb{Z}^n)$ is a vector in the transformed lattice, then there exists an integer m such that $m(a-b) \in \mathbb{Z}^n$. Thus, the reflection defined by

$$S(x) = -(ma - mb)x(ma - mb)^{-1} = -(a - b)x(a - b)^{-1},$$

belongs to $OC(\mathbb{Z}^n)$, and then it follows that

$$S(a) = b.$$

■

An immediate consequence is the following.

Corollary 19: Consider the hypercubic lattice $\mathbb{Z}^n$ and let $T \in OC(\mathbb{Z}^n)$ be a coincidence orthogonal transformation. Let also $a \in \mathbb{Z}^n$ and $b \in T(\mathbb{Z}^n)$ be vectors of the same length $(a^2 = b^2)$ belonging to the lattice and to the transformed lattice, respectively. Then there exists $c \in \mathbb{Z}^n$ such that $S(a) = b$, where $S(x) = -cxc^{-1}$.

The following theorem allows us to formulate our main result, namely that any arbitrary coincidence transformation can be written as product of coincidence reflections by vectors of the lattice $\mathbb{Z}^n$.

Theorem 20: *Let $\mathbb{Z}^n$ be a hypercubic lattice, and consider $T \in OC(\mathbb{Z}^n)$. Then, for some integer*

l, $0<l\leqslant n$, *there exist reflections* $R_1,R_2,\ldots,R_l\in OC(\mathbb{Z}^n)$ *such that* T *can be written as* $T=R_1R_2\cdots R_l$.

Proof: We will proceed by induction by first considering $n=1$. In this case, the only available orthogonal transformations in $\mathbb{Z}$ are $I(x)=x$ and $S(x)=-x$. If $b\in\mathbb{Z}$ and $b\neq 0$, we have that $S(x)=-bxb^{-1}$ and $I(x)=S^2(x)$. These transformations belong to $OC(\mathbb{Z})$, as follows from Theorem 16, and thus the theorem is valid for $n=1$.

Assume now that the theorem is valid for $n=k$. Let $\mathbb{Z}^k$ be a k-dimensional hypercubic lattice and let $T\in OC(\mathbb{Z}^{k+1})$ be an orthogonal coincidence transformation. Suppose that $\{e_1,\ldots,e_n\}$ is an orthonormal basis of $\mathbb{Z}^n$ and consider the vectors $T(e_{k+1})$ and e_{k+1}. According to Lemma 18, there exists a reflection $S\in OC(\mathbb{Z}^{k+1})$, such that $S(T(e_{k+1}))=e_{k+1}$. Clearly $ST\in OC(\mathbb{Z}^{k+1})$ but $ST|_{\mathbf{Z}^k}\in OC(\mathbb{Z}^n)$. Then, for some integer $l>0$, by the induction hypothesis we have that $ST=R_1R_2\cdots R_l$, where $R_1,R_2,\ldots,R_l\in OC(\mathbb{Z}^k)$ are reflections. Consequently

$$T=S^{-1}R_1R_2\cdots R_l.$$

■

Theorem 21: *Let* $\mathbb{Z}^n=\oplus_{i=1}^n\mathbb{Z}e_i$ *be a hypercubic lattice. Then an orthogonal transformation* T *is of coincidence*, i.e., $T\in OC(\mathbb{Z}^n)$, *if and only if there exist lattice vectors* $c_1,c_2,\ldots,c_k\in\mathbb{Z}^n$ *such that*

$$T(x)=(-1)^k(c_1c_2\cdots c_k)x(c_1c_2\cdots c_k)^{-1},$$

where $k\leqslant n$.

VI. CONCLUSIONS

In this work we provide a simple algorithm to explicitly calculate the reflections in which a particular orthogonal transformation is decomposed. This algorithm constitutes a constructive proof of the Cartan theorem. Albeit we have assumed that the underlying field is $\mathbb{R}$, the proofs of and theorems are also valid for $\mathbb{Q}$ or $\mathbb{C}$.

The approach given here can also be useful for solving equations systems and orthogonal elimination. In this case, Householder matrices replaces the reflections through hyperplanes derived from the Cartan theorem here presented. Also we can generalize the proof of this theorem to the Cartan-Dieudonné theorem.[18] This work is under way.

As an application, the crystallographic problem of coincidence lattices is formulated in terms of reflections. We show that any arbitrary coincidence transformation for the lattice $\mathbb{Z}^n$ can be written as product of coincidence reflections in vectors of the lattice.

(Received 29 July 2005; accepted 28 November 2005; published online 23 January 2006)

We compute the Lie symmetry algebra of the generalized Davey-Stewartson (GDS) equations and show that under certain conditions imposed on parameters in the system it is infinite-dimensional and isomorphic to that of the standard integrable Davey-Stewartson equations which is known to have a very specific Kac-Moody-Virasoro loop algebra structure. We discuss how the Virasoro part of this symmetry algebra can be used to construct new solutions, which are of vital importance in demonstrating existence of blow-up profiles, from known ones using Lie subgroup of transformations generated by three-dimensional subalgebras, namely $\mathrm{sl}(2,\mathbb{R})$. We further discuss integrability aspects of GDS equations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2162147]

I. INTRODUCTION

A system of nonlinear partial differential equations in $2+1$ dimensions as a model of wave propagation in a bulk medium composed of an elastic material with couple stresses has recently been derived in Ref. 1, namely

$$\begin{aligned} &i\psi_t+\delta\psi_{xx}+\psi_{yy}=\chi|\psi|^2\psi+\gamma(w_x+\phi_y)\psi,\\ &w_{xx}+n\phi_{xy}+m_2w_{yy}=(|\psi|^2)_x,\\ &nw_{xy}+\lambda\phi_{xx}+m_1\phi_{yy}=(|\psi|^2)_y, \end{aligned} \tag{1.1}$$

with the condition $(\lambda-1)(m_1-m_2)=n^2$. Here $\psi(t,x,y)$ is a complex function, $w(t,x,y)$ and $\phi(t,x,y)$ are real functions and $\delta,n,m_1,m_2,\lambda,\chi,\gamma$ are real constants. The authors of Ref. 1 showed that if the parameters are related by

$$n=1-\lambda=m_1-m_2, \tag{1.2}$$

then (1.1) can be reduced to the standard Davey-Stewartson (DS) equations (in general not integrable) by a noninvertible point transformation of dependent variables. Therefore, they called (1.1) the generalized Davey-Stewartson (GDS) equations. Below, we justify this naming from a group-theoretical point of view. Also, in Ref. 1 some travelling type solutions of (1.1) in terms of elementary and elliptic functions are obtained. Based on some physically obvious Noetherian symmetries (time-space translations and constant change of phase), global existence and nonexistence results are given in Ref. 2. In another recent work,[3] under some constraints on the physical parameters, the so-called hyperbolic-elliptic-elliptic case of the system (1.1) [in Ref. 3 the system is classified into different types according to the signs of parameters (δ,m_1,m_2,λ)] was shown to

[a]Electronic mail: gungorf@itu.edu.tr
[b]Electronic mail: aykanato@itu.edu.tr

admit singular solutions that blow up in a finite time. To do this, inspired by the (pseudo) conformal invariance of the DS system, they used the fact that time-dependent $\mathrm{SL}(2,\mathbb{R})$ invariant solutions can be generated from stationary radial solutions for an appropriate choice of coefficients.

The purpose of this paper is to study GDS equations from a group theoretical point of view. For our purposes, we find it more convenient to consider the differentiated form of (1.1). Thus, differentiating the last two equations of (1.1) with respect to x and y, respectively, and then making the substitution $w_x \to w$, $\phi_y \to \phi$ and rewriting the corresponding system in a real form by separating $\psi = u + iv$ into real and imaginary parts, we obtain a system of four real partial differential equations,

$$\begin{aligned} u_t + \delta v_{xx} + v_{yy} &= \chi v(u^2 + v^2) + \gamma v(w + \phi), \\ -v_t + \delta u_{xx} + u_{yy} &= \chi u(u^2 + v^2) + \gamma u(w + \phi), \\ w_{xx} + n\phi_{xx} + m_2 w_{yy} &= 2(u_x^2 + uu_{xx} + v_x^2 + vv_{xx}), \\ nw_{yy} + \lambda\phi_{xx} + m_1\phi_{yy} &= 2(u_y^2 + uu_{yy} + v_y^2 + vv_{yy}). \end{aligned} \tag{1.3}$$

In the sequel, we shall call (1.3) the GDS equations.

The main result of the paper is to show that, when some conditions on physical parameters $\delta, n, m_1, m_2, \lambda$ are imposed, the Lie algebra of the symmetry group of the GDS system has a Kac-Moody-Virasoro (KMV) loop structure which is shared by the symmetry algebras of all known integrable equations in $2+1$ dimensions such as the Kadomtsev-Petviashvilli (KP) equation[4,5] and the usual integrable DS equations.[6] The corresponding special case is a candidate for being integrable. Moreover, we show that this algebra is isomorphic to that of DS equations[6]

$$\begin{aligned} i\psi_t + \delta_1\psi_{xx} + \psi_{yy} &= \delta_2|\psi|^2\psi + w\psi, \\ \varepsilon_1 w_{xx} + w_{yy} &= \varepsilon_2(|\psi|^2)_{yy}, \end{aligned} \tag{1.4}$$

with $\delta_1 = \pm 1$, $\delta_2 = \pm 1$. In the special case when $\delta_1 + \varepsilon_1 = 0$, this system which is one of the rare systems in more than $1+1$ dimensions for which the Cauchy initial value problem is solvable by the inverse spectral transform (IST) technique becomes completely integrable. The Lie algebra of the symmetry group of the integrable DS system is referred to as the DS algebra. This isomorphism (a necessary condition for two different systems to be transformable into each other) should motivate one to look for point transformations taking the Lie algebras into each other. We expect such transformations to transform the systems into each other as well.

In Sec. II we compute the Lie symmetry algebra of (1.3) and identify its structure. In particular, we show that for a special choice of parameters it is a centerless Kac-Moody-Virasoro algebra.

II. THE SYMMETRY GROUP OF THE GDS EQUATIONS AND STRUCTURE OF ITS LIE ALGEBRA

We apply the standard infinitesimal procedure[7] to find the symmetry algebra L and hence the symmetry group G of (1.3). We write the GDS equations as a system $\Delta_i(t,x,y,u,v,w,\phi) = 0$, $i = 1,2,3,4$. A general element of the algebra is represented by a vector field

$$\mathbf{V} = \tau\partial_t + \xi\partial_x + \eta\partial_y + \varphi_1\partial_u + \varphi_2\partial_v + \varphi_3\partial_w + \varphi_4\partial_\phi, \tag{2.1}$$

where the coefficients $\tau, \xi, \eta, \varphi_i, i = 1,2,3,4$ are functions of t,x,y,u,v,w,ϕ. According to the general theory for symmetries of differential equations, to find these functions we prolong the vector field (2.1) to second order derivatives and require that the second prolonged vector field annihilates Δ_i on the solution manifold of the system, namely

$$\mathrm{pr}^{(2)}\,\mathbf{V}(\Delta_i(t,x,y,u,v,w,\phi))\big|_{\Delta_i=0}=0,\quad i=1,2,3,4, \tag{2.2}$$

where $\mathrm{pr}^{(2)}\,\mathbf{V}$ is the second prolongation of the vector field $\mathbf{V}$. This condition provides us with a quite complicated system of determining equations (a system of linear partial differential equations) for the coefficients. This step is entirely algorithmic and is implemented on several computer algebra packages like REDUCE, MATHEMATICA, MAPLE (see Ref. 8 for a survey of symbolic softwares for symmetry). The final step of integrating the determining equations is less algorithmic. Solving these huge numbers of determining equations we find that the general element can be written as

$$\mathbf{V}=T(f)+X(g)+Y(h)+W(m), \tag{2.3}$$

where

$$\begin{aligned}
T(f)&=f(t)\partial_t+\frac{1}{2}f'(t)(x\partial_x+y\partial_y-u\partial_u-v\partial_v-2w\partial_w-2\phi\partial_\phi)\\
&\quad-\frac{(x^2+\delta y^2)}{8\delta}\left[f''(t)(v\partial_u-u\partial_v)+\frac{f'''(t)}{2\gamma}(\partial_w+\partial_\phi)\right],\\
X(g)&=g(t)\partial_x-\frac{x}{2\delta}\left[g'(t)(v\partial_u-u\partial_v)+\frac{g''(t)}{2\gamma}(\partial_w+\partial_\phi)\right],\\
Y(h)&=h(t)\partial_y-\frac{y}{2}\left[h'(t)(v\partial_u-u\partial_v)+\frac{h''(t)}{2\gamma}(\partial_w+\partial_\phi)\right],\\
W(m)&=m(t)(v\partial_u-u\partial_v)+\frac{m'(t)}{2\gamma}(\partial_w+\partial_\phi).
\end{aligned} \tag{2.4}$$

The functions $g(t)$, $h(t)$, and $m(t)$ are arbitrary functions of class $C^\infty(I)$, $I\subseteq\mathbb{R}$. The function $f(t)$ is arbitrary if

$$m_2\delta+n+1=0,\quad m_1\delta+n\delta+\lambda=0, \tag{2.5}$$

otherwise $f(t)=c_2t^2+c_1t+c_0$. We mention that these conditions come from the fact that two of the determining equations are

$$(m_2\delta+n+1)f'''(t)=0,\quad (m_1\delta+n\delta+\lambda)f'''(t)=0,$$

whereas the remaining ones are solved without any constraints on g, h, and m.

We mainly focus on the case when $f(t)$ is allowed to be arbitrary. The symmetry algebra realized by the vector fields (2.3) and (2.4) is then infinite dimensional and more important has the structure of a Kac-Moody-Virasoro algebra as we shall see below. More interestingly, it is generic among the symmetry algebras of a few 2+1-dimensional integrable partial differential equations (the KP equation, the modified KP equation, the potential KP equation, the integrable three-wave resonant equations and the integrable DS equations). Henceforth, we shall call this the GDS symmetry algebra and the corresponding system the GDS system.

Note that sometimes it is more convenient to use the polar decomposition $u+iv=\mathrm{Re}^{i\sigma}$ so that in (2.4) we can write

$$u\partial_u+v\partial_v=R\partial_R,\quad -(v\partial_u-u\partial_v)=\partial_\sigma.$$

The commutation relations for the GDS algebra are easily obtained as follows:

$$[T(f_1),T(f_2)]=T(f_1f_2'-f_1'f_2),$$

$$[T(f),X(g)] = X\left(fg' - \tfrac{1}{2}f'g\right),$$

$$[T(f),Y(h)] = Y\left(fh' - \tfrac{1}{2}f'h\right),$$

$$[T(f),W(m)] = W(fm'), \tag{2.6}$$

$$[X(g_1),X(g_2)] = -\frac{1}{2\delta}W(g_1g_2' - g_1'g_2),$$

$$[Y(h_1),Y(h_2)] = -\tfrac{1}{2}W(h_1h_2' - h_1'h_2),$$

$$[X(g),Y(h)] = [X(g),W(m)] = [Y(h),W(m)] = [W(m_1),W(m_2)] = 0.$$

From (2.6) we see that the GDS system has a Lie symmetry algebra L isomorphic to that of the DS symmetry algebra.[6] Indeed, it allows a Levi decomposition

$$L = S \oplus N, \tag{2.7}$$

where $S=\{T(f)\}$ is a simple infinite-dimensional Lie algebra and

$$N = \{X(g),Y(h),W(m)\}$$

is a nilpotent ideal (nilradical). Here, $\oplus$ denotes a semidirect sum. The algebra $\{T(f)\}$ is isomorphic to the Lie algebra corresponding to the Lie group of diffeomorphisms of a real line.

We remark that a similar isomorphism between the symmetry algebras of a class of (integrable) generalized cylindrical KP (GCKP) equation and of the KP equation was pointed out in Ref. 9.

Expanding the arbitrary functions f, g, h, and m into Laurent polynomials and considering each monomial t^n (n not necessarily positive integer) separately, we obtain a realization of a KMV algebra without central extension. Here the factor subalgebra S is the Virasoro part, the nilpotent subalgebra N is the Kac-Moody part of the GDS algebra.[10] We refer for different realizations of the Virasoro algebras to Ref. 11. Furthermore, just as the DS algebra[6] it can be shown that the GDS algebra with (2.5) can be imbedded into a Kac-Moody-type loop algebra.

Theorem 2.1: *The system* (1.3) *is invariant under an infinite-dimensional Lie point symmetry group, the Lie algebra of which has a Kac-Moody-Virasoro structure isomorphic to the DS algebra if and only if the conditions* (2.5) *hold.*

Let us mention that the GDS equations are also invariant under a group of discrete transformations generated by

$$t \to t, \quad x \to -x, \quad y \to y, \quad \psi \to \psi, \quad w \to w, \quad \phi \to \phi,$$

$$t \to t, \quad x \to x, \quad y \to -y, \quad \psi \to \psi, \quad w \to w, \quad \phi \to \phi,$$

$$t \to t, \quad x \to x, \quad y \to y, \quad \psi \to -\psi, \quad w \to w, \quad \phi \to \phi,$$

$$t \to -t, \quad x \to x, \quad y \to y, \quad \psi \to \psi^*, \quad w \to w, \quad \phi \to \phi. \tag{2.8}$$

The obvious physical symmetries L_p of the GDS equations are obtained by restricting all the functions f, g, h, and m to be first order polynomials. Indeed, we have

$$T = T(1) = \partial_t, \quad P_1 = X(1) = \partial_x, \quad P_2 = Y(1) = \partial_y,$$

$$W_0 = W(1) = v\partial_u - u\partial_v,$$

$$D = T(t) = t\partial_t + \tfrac{1}{2}(x\partial_x + y\partial_y - u\partial_u - v\partial_v - 2w\partial_w - 2\phi\partial_\phi), \tag{2.9}$$

$$B_1 = X(t) = t\partial_x - \frac{x}{2\delta}(v\partial_u - u\partial_v), \quad B_2 = Y(t) = t\partial_y - \frac{y}{2}(v\partial_u - u\partial_v),$$

$$W_1 = W(t) = t(v\partial_u - u\partial_v) + \frac{1}{2\gamma}(\partial_w + \partial_\phi).$$

We see that T, P_1, P_2 generate translations, D dilations, B_1 and B_2 Galilei boosts in the x and y directions, respectively. Finally, W_0 and W_1 generate a constant change of phase of ψ and a change of phase of ψ, linear in t, plus constant shifts in w and ϕ, respectively.

The generators (2.9) form a basis of an eight-dimensional solvable Lie algebra $L_p = \{D, T, P_1, P_2, B_1, B_2, W_0, W_1\}$. It has a seven-dimensional nilpotent ideal (the nilradical) $N = \{T, P_1, P_2, B_1, B_2, W_0, W_1\}$.

Another finite-dimensional algebra, not contained in L_p is obtained by restricting $f(t)$ to quadratic polynomials. We obtain $T=T(1)$, $D=T(t)$ as in (2.9), and in addition

$$C = T(t^2) = t^2\partial_t + tD - \frac{(x^2 + \delta y^2)}{4\delta}(v\partial_u - u\partial_v). \tag{2.10}$$

The commutation relations are

$$[T,D] = T, \quad [T,C] = 2D, \quad [D,C] = C,$$

so that we have obtained the algebra $\mathrm{sl}(2,\mathbb{R})$ with C generating conformal type of transformations

$$\tilde{t} = \frac{t}{1-pt}, \quad \tilde{x} = \frac{x}{1-pt}, \quad \tilde{y} = \frac{y}{1-pt},$$

$$\tilde{R} = (1-pt)R, \quad \tilde{\sigma} = \frac{p(x^2 + \delta y^2)}{4\delta(1-pt)} + \sigma, \tag{2.11}$$

$$\tilde{w} = (1-pt)^2 w, \quad \tilde{\phi} = (1-pt)^2\phi,$$

where p is the group parameter. Further, composing (2.11) with time translations generated by T and dilations generated by D we obtain the $\mathrm{SL}(2,\mathbb{R})$ group generated by actions on the space of independent and depend variables. It should be mentioned that any finite-dimensional subalgebra of the Virasoro algebra of 2+1 dimensional integrable equations is isomorphic to $\mathrm{sl}(2,\mathbb{R})$ or one of its subalgebras. The transformed variables and the new solution in terms of the original ones are given by the formulas

$$\tilde{t} = \frac{c+dt}{a+bt}, \quad \tilde{x} = \frac{x}{a+bt}, \quad \tilde{y} = \frac{y}{a+bt}, \quad ad - bc = 1,$$

$$\tilde{\psi} = (a+bt)^{-1} \exp\left\{\frac{ib(x^2 + \delta y^2)}{4\delta(a+bt)}\right\}\psi(\tilde{t},\tilde{x},\tilde{y}),$$

$$\tilde{w} = (a+bt)^{-2} w(\tilde{t},\tilde{x},\tilde{y}),$$

$$\tilde{\phi} = (a+bt)^{-2}\phi(\tilde{t},\tilde{x},\tilde{y}). \tag{2.12}$$

Here a,b,c are the group parameters of $\mathrm{SL}(2,\mathbb{R})$. These are exactly the formulas which played an essential role in the construction of analytic blow-up profiles[3] in which the authors made use of stationary radial solutions (ψ,w,ϕ) to generate new solutions (time dependent) $(\tilde{\psi},\tilde{w},\tilde{\phi})$ of the GDS equations. More generally, the elements of the connected part of the full symmetry group of the GDS equations can be obtained by integrating the vector fields (2.3) and (2.4). We refer the reader to Ref. 6 for the general Lie group of transformations of DS algebra.

Let us now return to the isomorphic GDS and DS symmetry algebras, and transform the GDS vector fields (2.1) by the point transformation $q=w+\phi-|\psi|^2$. It is easy to see that the component $\frac{1}{2}(\partial_w+\partial_\phi)$ transforms to ∂_q, and $D\to x\partial_x+y\partial_y-u\partial_u-v\partial_v-2q\partial_q$, and the rest remains unaltered, namely the DS symmetry algebra is obtained. This means that the functions (ψ,q) satisfy the DS equations whenever (ψ,w,ϕ) satisfy the GDS equations, but not vice versa. At this time, it remains open whether it is possible to construct an invertible point transformation relating these two systems.

We conclude by making several comments. As is well illustrated by the results of this paper, knowing that a nonlinear partial differential equation (or system) admits a KMV algebra as a symmetry algebra can serve as a useful criterion of identifying integrable equations. In particular, this fact can be used to pick out an integrable equation from a class of generically nonintegrable ones. For instance, for all values of parameters not satisfying (2.5), the Virasoro part $T(f)$ of the GDS algebra is not present. The first author of the present paper and Winternitz[12] used the same approach to identify all subclasses invariant under a KMV algebra and its subalgebras containing up to three arbitrary functions of time from a rather general class of KP-type equations involving nine arbitrary functions of one or two variables. On the other hand, a classification of all one- and two-dimensional subalgebras of the DS algebra into conjugacy classes under the adjoint action of the DS group (including the discrete transformations) is performed in Ref. 6. The GDS algebra will have the same conjugacy classes of subalgebras as the DS algebra. Depending on which of the functions $g(t)$, $h(t)$, and $m(t)$ are nonzero, precisely six conjugacy classes of one-dimensional subalgebras exist,

$$L_{1,1}=\{T(1)\},\quad L_{1,2}^{a}=\{X(1)+aY(1)\},\quad L_{1,3}(h)=\{X(1)+Y(h)\},\quad a\geqslant 0,$$

$$L_{1,4}=\{Y(1)\},\quad L_{1,5}=\{W(t)\},\quad L_{1,6}=\{W(1)\}.$$

They can be used to reduce the integrable GDS system to integrable one in two variables and thus to obtain subgroup invariant solutions. There will be four type of reductions since only the first four subgroups corresponding to $(L_{1,1},L_{1,2}^{a},L_{1,3}(h),L_{1,4})$ will generate actions on the coordinate space (t,x,y). The remaining two $(L_{1,5},L_{1,6})$ generate purely vertical (or gauge) transformations changing phases only and thus lead to no reductions. For example, one can show that all the travelling wave solutions obtained in Ref. 1 can be extracted from those of representative reduced equations by applying appropriate symmetry group transformations. We note that these types of physically important solutions are invariant under translational subgroups alone.

This paper is the first in a series revisiting the Faraday effect, or more generally, the theory of electronic quantum transport/optical response in bulk media in the presence of a constant magnetic field. The independent electron approximation is assumed. At zero temperature and zero frequency, if the Fermi energy lies in a spectral gap, we rigorously prove the Widom-Streda formula. For free electrons, the transverse conductivity can be explicitly computed and coincides with the classical result. In the general case, using magnetic perturbation theory, the conductivity tensor is expanded in powers of the strength of the magnetic field B. Then the linear term in B of this expansion is written down in terms of the zero magnetic field Green function and the zero field current operator. In the periodic case, the linear term in B of the conductivity tensor is expressed in terms of zero magnetic field Bloch functions and energies. No derivatives with respect to the quasimomentum appear and thereby all ambiguities are removed, in contrast to earlier work. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2162148]

I. INTRODUCTION

In sharp contrast with the zero magnetic field case, the analysis of properties of electrons in periodic or random potentials subjected to external magnetic fields is a very challenging problem. The difficulty is rooted in the singular nature of the magnetic interaction: due to a linear increase of the magnetic vector potential, the naive perturbation theory breaks down even at arbitrarily small fields.

To our best knowledge, only the periodic case has been considered in connection with the Faraday effect for bulk systems. The first full scale quantum computation was done by Roth[30] (for a review of earlier attempts[4–6] we direct the reader to this paper). The physical experiment starts by sending a monochromatic light wave, parallel to the $0z$ direction and linearly polarized in the plane $x0z$. When the light enters the material, the polarization plane can change; in fact, there exists a linear relation between the angle θ of rotation of the plane of polarization per unit length and the transverse component of the conductivity tensor σ_{xy} [see formula (1) in Ref. 30]. The material is chosen in such a way that when the magnetic field is zero, this transverse component

a)Electronic mail: cornean@math.aau.dk
b)Electronic mail: gheorghe.nenciu@imar.ro
c)Electronic mail: tgp@physics.aau.dk

vanishes. When the magnetic field B is turned on, the transverse component is no longer zero. For weak fields one expands the conductivity tensor to first order in B and obtains a formula for the Verdet constant.

Therefore the central object is $\sigma_{xy}(B)$, which depends among other things on temperature, density of the material, and frequency of light. Using a modified Bloch representation, Roth was able to obtain a formula for $(\mathrm{d}\sigma_{xy}/\mathrm{d}B)(0)$, and studied how this first order term behaves as a function of frequency, both for metals and semiconductors.

However, the theory in Ref. 30 is not free of difficulties. First, it seems almost hopeless to estimate errors or to push the computation to higher orders in B. Second, even the first order formula contains terms which are singular at the crossings of the Bloch bands. Accordingly, at the practical level this theory only met a moderate success and alternative formalisms have been used, as for example the celebrated Kohn-Luttinger effective many band Hamiltonian (see Refs. 17, 31, and 28 and references therein), or tight-binding models.[25] Since all these methods have limited applicability, a more flexible approach was still needed.

In the zero magnetic field case, a very successful formalism (see, e.g., Refs. 2, 9, 16, and 27 and references therein) is to use the Green function method. This is based on the fact that the traces involved in computing various physical quantities can be written as integrals involving Green functions. The main aim of our paper is to develop a Green function approach to the Faraday effect, i.e., for the conductivity tensor when a magnetic field is present. Let us point out that the use of Green functions (albeit different from the ones used below) goes back at least to Sondheimer and Wilson[33] in their theory of diamagnetism of Bloch electrons. Aside from the fact that the Green function (i.e., the integral kernel of the resolvent or the semigroup) is easier to compute and control, the main point is that by factorizing out the so-called nonintegrable phase factor (or magnetic holonomy) from the Green function, one can cope with the singularities introduced by the increase at infinity of the magnetic vector potentials. In addition (as it has already been observed by Schwinger[32] in a QED context), after factorizing out the magnetic holonomy one remains with a gauge invariant quantity which makes the problem of gauge fixing irrelevant. The observation (going back at least to Peierls[26]) that one can use these magnetic phases in order to control the singularity of the magnetic perturbation has been used many times in various contexts (see, e.g., Refs. 19 and 33). We highlight here the results of Nedoluha[20] where a Green function approach for the magneto-optical phenomena at zero temperature and with the Fermi level in a gap has been investigated.

But the power of this method has only recently been fully exploited in Refs. 11 and 12 and developed as a general gauge invariant magnetic perturbation theory in Ref. 22. Applied to the case at hand, this theory gives an expansion of the conductivity tensor in terms of the zero magnetic field Green functions. Moreover, it is free of any divergences. A key ingredient in controlling divergences is the exponential decrease of the Green functions with the distance between the arguments, for energies outside the spectrum.[10,21] We stress the fact that since no basis is involved, periodicity is not needed and the theory can also be applied to random systems. Finite systems and/or special geometries (layers) are also allowed. The content of the paper is as follows.

In Sec. II we give a derivation of the conductivity tensor from first principles in the linear response theory. We include it to point out that it coincides with various formulas used before. Although in physics establishing the Kubo formula is considered somehow a triviality, from a mathematical point of view it remains a serious challenge (see Ref. 7).

Section III contains the precise formulation of the thermodynamic limit, stated in Theorem 3.1. We do not give its proof here, but we try to explain why it is true.

Section IV shows that at the thermodynamic limit, at zero temperature, zero frequency, and for the Fermi energy in a spectral gap, we reobtain a formula of Streda[34] for the transverse component of the conductivity tensor, known from the integral quantum Hall effect (IQHE). A precise statement and its proof are contained in Theorem 4.1. Moreover, under the proviso that exponentially localized Wannier function exist (see Theorem 4.2), this transverse component vanishes (see also Refs. 35 and 3 for related results). We stress that this result holds for the *whole* $\sigma_{xy}(B)$ as long as

the magnetic field is not too large, not just for $(\mathrm{d}\sigma_{xy}/\mathrm{d}B)(0)$. The vanishing of its first order correction was in fact claimed in formula (50) in Ref. 30.

Section V contains the exact quantum computation of $\sigma_{xy}(B)$ for free electrons; in spite of the fact that such a result might be known (and it is known at zero frequency), we were not able to find it in the literature. Interestingly enough, the quantum computation gives the same result as the well-known classical computation (when the relaxation time is infinite).

Section VI contains the core of the paper, which includes the derivation of $(\mathrm{d}\sigma_{xy}/\mathrm{d}B)(0)$ for general Bloch electrons. As in the zero magnetic field case, its formula only contains zero magnetic field Green functions and current operators.

Section VII deals with periodic systems, and the result of the preceding section is written down in terms of zero magnetic field Bloch functions and bands.

At the end we have some conclusions.

The main goal of this paper is to present the strategy, state the results concerning the Verdet constant, and to outline future theoretical and practical problems. Detailed proofs of the thermodynamic limit and of other technical estimates will be given elsewhere.

II. PRELIMINARIES: THE CONDUCTIVITY TENSOR IN THE LINEAR RESPONSE REGIME

We begin by fixing the notation used in the description of independent electrons subjected to a constant magnetic field. The units are chosen so that $\hbar=1$. Since we consider spin $1/2$ particles, the one particle Hilbert space for a nonconfined particle is

$$\mathcal{H}_\infty = L^2(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3)$$

with the standard scalar product. Accordingly, all operators below and their integral kernels are 2×2 matrices in the spin variable. We choose the constant magnetic field of strength B to be oriented along the z axis. Then the one particle Hamiltonian with the spin-orbit coupling included is (see, e.g., Ref. 30)

$$H_\infty(B) = \frac{1}{2m}\mathbf{P}(B)^2 + V + g\mu_b B\sigma_3, \tag{2.1}$$

with

$$\mathbf{P}(B) = -i\nabla - b\mathbf{a} + \frac{1}{2mc^2}\mathbf{s}\wedge(\nabla V) = \mathbf{P}(0) - b\mathbf{a}, \tag{2.2}$$

where

$$b = -\frac{e}{c}B$$

and $\mathbf{a}(\mathbf{x})$ is an arbitrary smooth magnetic vector potential which generates a magnetic field of intensity $B=1$, i.e., $\nabla\wedge\mathbf{a}(\mathbf{x})=(0,0,1)$. The most frequently used magnetic vector potential is the symmetric gauge,

$$\mathbf{a}_0(\mathbf{x}) = \tfrac{1}{2}\mathbf{n}_3\wedge\mathbf{x}, \tag{2.3}$$

where $\mathbf{n}_3$ is the unit vector along z axis.

In the periodic case we denote by $\mathcal{L}$ the underlying Bravais lattice, by Ω its elementary cell and by Ω^* the corresponding Brillouin zone. $|\Omega|$ and $|\Omega^*|$ stand for the volumes of the elementary cell and Brillouin zone, respectively. In the absence of the magnetic field one has the well-known Bloch representation in terms of Bloch functions,

$$\Psi_j(\mathbf{x},\mathbf{k}) = \frac{1}{\sqrt{|\Omega^*|}} e^{i\mathbf{k}\cdot\mathbf{x}} u_j(\mathbf{x},\mathbf{k}), \quad \mathbf{x} \in \mathbb{R}^3, \tag{2.4}$$

where $u_j(\mathbf{x},\mathbf{k})$ are the normalized to one eigenfunctions of the operator

$$h(\mathbf{k})u_j(\mathbf{x},\mathbf{k}) = \lambda_j(\mathbf{k})u_j(\mathbf{x},\mathbf{k}), \tag{2.5}$$

$$h(\mathbf{k}) = \frac{1}{2m}\left(-i\nabla_p + \frac{1}{2mc^2}\mathbf{s}\wedge(\nabla V) + \mathbf{k}\right)^2 + V = \frac{1}{2m}(\mathbf{p}+\mathbf{k})^2 + V, \quad \mathbf{k} \in \Omega^*,$$

$$\mathbf{p} = -i\nabla_p + \frac{1}{2mc^2}\mathbf{s}\wedge(\nabla V), \tag{2.6}$$

defined in $L^2(\Omega)\oplus L^2(\Omega)$ with periodic boundary conditions. We label $\lambda_j(\mathbf{k})$ in increasing order. We have to remember that, as functions of $\mathbf{k}$, $\lambda_j(\mathbf{k})$, and $u_j(\mathbf{x},\mathbf{k})$ are not differentiable at the crossing points. Since the $\Psi_j(\mathbf{x},\mathbf{k})$'s form a basis of generalized eigenfunctions, the Green function (i.e., the integral kernel of the resolvent) writes as

$$G_\infty^{(0)}(\mathbf{x},\mathbf{y};z) = \int_{\Omega^*}\sum_{j\geqslant 1}\frac{|\Psi_j(\mathbf{x},\mathbf{k})\rangle\langle\Psi_j(\mathbf{y},\mathbf{k})|}{\lambda_j(\mathbf{k})-z}\mathrm{d}\mathbf{k}, \tag{2.7}$$

and it is seen as a matrix in the spin variables. The above formula must be understood in the formal sense since the series on the right-hand side is typically not absolutely convergent, and care is to be taken when interchanging the sum with the integral. Notice however that $G_\infty^{(0)}(\mathbf{x},\mathbf{x}';z)$ is a well behaved matrix valued function.

We consider a system of noninteracting electrons in the grand-canonical ensemble. More precisely, we consider a box $\Lambda_1 \subset \mathbb{R}^3$, which contains the origin, and a family of scaled boxes

$$\Lambda_L = \{\mathbf{x} \in \mathbb{R}^3 : \mathbf{x}/L \in \Lambda_1\}. \tag{2.8}$$

The thermodynamic limit will mean $L\to\infty$, that is when Λ_L tends to fill out the whole space. The one particle Hilbert space is $\mathcal{H}_L := L^2(\Lambda_L)\oplus L^2(\Lambda_L)$. The one particle Hamiltonian is denoted by $H_L(B)$ and is given by (2.1) with Dirichlet boundary conditions [i.e., the wave functions in the domain of $H_L(B)$ vanish at the surface $\partial\Lambda_L$]. More precisely, we first define it on $C_0^\infty(\Lambda_L)\oplus C_0^\infty(\Lambda_L)$, and then $H_L(B)$ will be the Friedrichs extension of this minimal operator. This is indeed possible, because our operator can be written as (up to some irrelevant constants) $-\Delta_D I_2 + W$, where Δ_D is the Dirichlet Laplacian and W is a first order differential operator, relatively bounded to $-\Delta_D I_2$ (remember that $L<\infty$) with relative bound zero. The form domain of $H_L(B)$ is the Sobolev space $H_0^1(\Lambda_L)\oplus H_0^1(\Lambda_L)$, while the operator domain is

$$\mathrm{Dom}(H_L(B)) = D_L \oplus D_L, \quad D_L := H^2(\Lambda_L)\cap H_0^1(\Lambda_L). \tag{2.9}$$

Moreover, $H_L(B)$ is essentially self-adjoint on $C_{(0)}^\infty(\overline{\Lambda_L})$, i.e., functions with support in $\overline{\Lambda_L}$ and indefinitely differentiable in Λ_L up to the boundary.

We assume that the temperature $T=1/(k\beta)$ and the chemical potential μ are fixed by a reservoir of energy and particles. We work in a second quantized setting with an antisymmetric Fock space denoted by $\mathcal{F}_L$. Denote the operators in the Fock space with a hat and borrow some notation from the book of Bratelli and Robinson,[8] if A is an operator defined in $\mathcal{H}_L$, we denote by $\hat{A}=\mathrm{d}\Gamma(A)$ its second quantization in the Fock space. At $t=-\infty$ the system is supposed to be in the grand-canonical equilibrium state of temperature T and chemical potential μ, i.e., the density matrix is

$$\hat{\rho}_e = \frac{1}{\mathrm{Tr}(e^{-\beta\hat{K}_\mu})} e^{-\beta\hat{K}_\mu}, \tag{2.10}$$

where

$$\hat{K}_\mu = \mathrm{d}\Gamma(H_L(B) - \mu \cdot \mathrm{Id}) \tag{2.11}$$

is the "grand-canonical Hamiltonian."

The interaction with a classical electromagnetic field is described by a time-dependent electric potential

$$V(\mathbf{x},t) := (e^{i\omega t} + e^{-i\bar{\omega}t}) e\mathbf{E} \cdot \mathbf{x}, \quad t \leqslant 0, \quad \mathbf{x} \in \Lambda_L. \tag{2.12}$$

so the total time-dependent one-particle Hamiltonian is

$$H(t) = H_L(B) + V(t). \tag{2.13}$$

Notice that e near $\mathbf{E}$ is the positive elementary charge. Here we take $\mathrm{Im}\ \omega < 0$ which plays the role of an adiabatic parameter, and insures that there is no interaction in the remote past. Finally, the one-particle current operator is as usual

$$\mathbf{J} = -ei[H_L(B), \mathbf{X}] = -\frac{e}{m}\mathbf{P}(B), \tag{2.14}$$

where $\mathbf{X}$ is the multiplication by $\mathbf{x}$. Note that $\mathbf{J}$ is a well-defined operator on the domain of $H_L(B)$, because multiplication by any component of $\mathbf{X}$ leaves this domain invariant [see (2.9)]. Moreover, since $L < \infty$, $\mathbf{X}$ is a bounded operator. In fact, $\mathbf{X}$ is the true physical self-adjoint observable, while $\mathbf{P}(B)$ (or $\mathbf{J}$) appear when one differentiates the map $t \mapsto e^{itH_L(B)}\mathbf{X}e^{-itH_L(B)}$ in the strong sense on the domain of $H_L(B)$.

We assume that the state of our system is now described by a time-dependent density matrix, $\hat{\rho}(t)$, obtained by evolving $\hat{\rho}_e$ from $-\infty$ up to the given time, i.e.,

$$i\partial_t \hat{\rho}(t) = [\hat{H}(t), \hat{\rho}(t)], \quad \hat{\rho}(-\infty) = \hat{\rho}_e. \tag{2.15}$$

Going to the interaction picture and using the Dyson expansion up to the first order, one gets

$$\hat{\rho}(t=0) = \hat{\rho}_e - i\int_{-\infty}^{0} [\mathrm{d}\Gamma(\widetilde{V}(s), \hat{\rho}_e\ ]\mathrm{d}s + \mathcal{O}(\mathbf{E}^2), \tag{2.16}$$

where

$$\widetilde{V}(s) := e^{isH_L(B)} V(s) e^{-isH_L(B)}. \tag{2.17}$$

The current density flowing through our system at $t=0$ is given by [see (2.16)]:

$$\mathbf{j} = \frac{1}{|\Lambda_L|}\mathrm{Tr}_{\mathcal{F}_L}(\hat{\rho}(0)\hat{\mathbf{J}}) = \frac{1}{|\Lambda_L|}\mathrm{Tr}_{\mathcal{F}_L}(\hat{\rho}_e\hat{\mathbf{J}}) - \frac{i}{|\Lambda_L|}\mathrm{Tr}_{\mathcal{F}_L}\left(\int_{-\infty}^{0} [\mathrm{d}\Gamma(\widetilde{V}(s)), \hat{\rho}_e]\hat{\mathbf{J}}\,\mathrm{d}s\right) + \mathcal{O}(\mathbf{E}^2). \tag{2.18}$$

In evaluating the right-hand side (rhs) of (2.18) we use the well-known fact that traces over the Fock space can be computed in the one-particle space (see Proposition 5.2.23 in Ref. 8),

$$\mathrm{Tr}_{\mathcal{F}_L}\{\hat{\rho}_e\,\mathrm{d}\Gamma(A)\} = \mathrm{Tr}_{\mathcal{H}_L}\{f_{\mathrm{FD}}(H_L(B))A\}, \tag{2.19}$$

where f_{FD} is the Fermi-Dirac one-particle distribution function,

$$f_{\mathrm{FD}}(x) := \frac{1}{e^{\beta(x-\mu)}+1}, \quad x \in \mathbb{R}, \quad \beta > 0, \quad \mu \in \mathbb{R}. \tag{2.20}$$

Plugging (2.19) into (2.18), the identity $[\mathrm{d}\Gamma(A),\mathrm{d}\Gamma(B)]=\mathrm{d}\Gamma([A,B])$, the invariance of trace under cyclic permutations and ignoring the quadratic correction in $\mathbf{E}$ one arrives at

$$\mathbf{j} = \frac{1}{|\Lambda_L|}\mathrm{Tr}_{\mathcal{H}_L}\{f_{\mathrm{FD}}(H_L(B))\mathbf{J}\} - \frac{i}{|\Lambda_L|}\frac{e}{m}\mathrm{Tr}_{\mathcal{H}_L}\left(\int_{-\infty}^{0}[\tilde{V}(s),\mathbf{P}(B)]f_{\mathrm{FD}}(H_L(B))\mathrm{d}s\right). \tag{2.21}$$

The first term in (2.21) is always zero because of the identity (trace cyclicity again)

$$\mathrm{Tr}_{\mathcal{H}_L}\{[H_L(B),\mathbf{X}]f_{\mathrm{FD}}(H_L(B))\} = \mathrm{Tr}_{\mathcal{H}_L}\{[f_{\mathrm{FD}}(H_L(B)),H_L(B)]\mathbf{X}\} = 0 \tag{2.22}$$

which is nothing but the fact that the current vanishes on an equilibrium state. Note that these operations under the trace sign are quite delicate, since unbounded operators are involved. Let us for once give a complete proof to (2.22). We have the identity between bounded operators (consider the first component X_1),

$$[H_L(B),X_1]f_{\mathrm{FD}}(H_L(B)) = H_L(B)X_1 f_{\mathrm{FD}}(H_L(B)) - X_1 H_L(B) f_{\mathrm{FD}}(H_L(B)). \tag{2.23}$$

Remember that X_1 is a bounded operator in the box, and preserves the domain of $H_L(B)$. This means that the operator $O_L=(H_L(B)+i)X_1(H_L(B)+i)^{-1}$ is bounded. Hence we can write

$$H_L(B)X_1 f_{\mathrm{FD}}(H_L(B)) = [1 - i(H_L(B)+i)^{-1}]O_L[H_L(B)+i]f_{\mathrm{FD}}(H_L(B)).$$

Now the operator $[H_L(B)+i]f_{\mathrm{FD}}(H_L(B))$ still is trace class due to the exponential decay of f_{FD}, while $[1-i(H_L(B)+i)^{-1}]$ and O_L are bounded. Thus $H_L(B)X_1 f_{\mathrm{FD}}(H_L(B))$ is trace class and we can compute its trace using the complete eigenbasis of $H_L(B)$, which gives the same result as for the other operator $X_1 H_L(B) f_{\mathrm{FD}}(H_L(B))$. Thus (2.22) is proved.

Using (2.12) and (2.17) one can write

$$j_\alpha = \sum_{\beta=1}^{3}\{\sigma_{\alpha\beta}(\omega) + \sigma_{\alpha\beta}(-\bar{\omega})\}E_\beta, \quad \alpha \in \{1,2,3\}, \quad \Im(\omega) < 0, \tag{2.24}$$

where the conductivity tensor is given by

$$\sigma_{\alpha\beta}(B,\omega) = -\frac{i}{|\Lambda_L|}\frac{e^2}{m}\mathrm{Tr}_{\mathcal{H}_L}\int_{-\infty}^{0}[e^{isH_L(B)}x_\beta e^{-isH_L(B)},P_\alpha(B)]f_{\mathrm{FD}}(H_L(B))e^{is\omega}\,\mathrm{d}s. \tag{2.25}$$

Performing an integration by parts, using the formulas $i[H_L(B),x_\beta]=P_\beta(B)/m$ and $i[P_\alpha(B),x_\beta]=\delta_{\alpha\beta}$ one arrives at

$$\sigma_{\alpha\beta}(B,\omega) = \frac{1}{|\Lambda_L|}\frac{e^2}{im\omega}\left\{\delta_{\alpha\beta}\,\mathrm{Tr}(f_{\mathrm{FD}}(H_L(B))) + \frac{i}{m}\mathrm{Tr}\int_{-\infty}^{0} e^{is(\omega+H_L(B))}P_\beta(B)e^{-isH_L(B)} \times[P_\alpha(B),f_{\mathrm{FD}}(H_L(B))]\mathrm{d}s\right\}, \tag{2.26}$$

and this coincides (at least at the formal level) with formula (5) in Ref. 30. Notice that from now on, we write just Tr when we perform the trace, since we only work in the one-particle space.

Since we are interested in the Faraday effect, and we assume that the magnetic field $\mathbf{B}$ is parallel with the z axis, we will only consider the transverse conductivity $\sigma_{12}(B,\omega)$. Hence the first term vanishes. We now perform the integral over s with the help of Stone's formula followed by a deformation of the contour [paying attention not to hit the singularities of $f_{\mathrm{FD}}(z)$ or to make the integral over s divergent]

$$f_{\mathrm{FD}}(H_L(B))e^{is(H_L(B)+\eta)} = \frac{i}{2\pi}\int_{\Gamma_\omega} f_{\mathrm{FD}}(z)e^{is(z+\eta)}(H_L(B)-z)^{-1}\,\mathrm{d}z, \tag{2.27}$$

where η is either 0 or ω, the contour is counter-clockwise oriented and given by

$$\Gamma_\omega = \{x \pm i\mathrm{d}: a \leqslant x < \infty\} \cup \{a + iy: -\mathrm{d} \leqslant y \leqslant \mathrm{d}\} \tag{2.28}$$

with

$$\mathrm{d} = \min\left\{\frac{\pi}{2\beta}, \frac{|\mathrm{Im}\ \omega|}{2}\right\}, \tag{2.29}$$

and $a+1$ lies below the spectrum of $H_L(B)$. As a final result one gets

$$\sigma_{12}(B,\omega) = -\frac{e^2}{2\pi m^2 \omega|\Lambda_L}\mathrm{Tr}\int_{\Gamma_\omega} f_{\mathrm{FD}}(z)\{P_1(B)(H_L(B)-z)^{-1}P_2(B)(H_L(B)-z-\omega)^{-1}$$
$$+ z \to z-\omega\}\mathrm{d}z =: \frac{e^2}{m^2\omega}a_L(B,\omega), \tag{2.30}$$

where "$z \to z-\omega$" means a similar term where we exchange z with $z-\omega$. Now one can see that by inserting the eigenbasis of $H_L(B)$ one obtains the well-known formula derived from semiclassical radiation theory [see, e.g., formula (4) in Ref. 30].

III. GAUGE INVARIANCE AND EXISTENCE OF THE THERMODYNAMIC LIMIT

Up to now the system was confined in a box Λ_L. As is well known (see, e.g., Ref. 30) a direct evaluation of (2.30) [or previous formulas equivalent to it including formula (4) in Roth's paper] is out of reach: the eigenvalues and eigenstates of $H(B)$ are rather complicated (even in the thermodynamic limit $\Lambda_L \to \mathbb{R}^3$) and at the same time the Bloch representation is plagued by singular matrix elements of the magnetic vector potential. Roth used a modified magnetic Bloch representation in Ref. 29 and derived a formula for the linear term in B of (2.30) in terms of the zero magnetic field Bloch representation. Still, her procedure is not free of difficulties since it involves $\nabla_{\mathbf{k}} u_j(\mathbf{x},\mathbf{k})$ which might not exist at crossing points. In addition, it seems almost hopeless to control the errors or to push computations to the second order in B which would describe the Cotton-Mouton effect for example.

In what follows, we shall outline another route of evaluating (2.30) which is mathematically correct, systematic, and completely free of the above difficulties. There are two basic ideas involved. The first one (going back at least to Sondheimer and Wilson[33] in their theory of diamagnetism) consists in writing the trace in (2.30) as integrals over Λ_L of corresponding integral kernels. This is nothing but the well-known Green function approach (see, e.g., Ref. 15) which has been very successful in computing optical and magneto-optical properties of solids (see, e.g., Refs. 2, 16, and 27) in the absence of an external magnetic field. The point is that the integral kernels are on the one hand easier to control and compute, and on the other hand they do not require periodicity. Moreover, this approach proved to be essential in deriving rigorous results concerning the diamagnetism of free electrons[1,11] and actually we expect the methods of the present paper to simplify the theory of diamagnetism of Bloch electrons as well.

However, when applying Green function approach in the presence of an external magnetic field one hits again the divergences caused by the linear increase of the magnetic vector potential: naively, at the first sight $a_L(B,\omega)$ is not bounded in the thermodynamic limit $L \to \infty$ but instead grows like the second power of L. It was already observed in Ref. 1 that these divergent terms vanish identically due to some identities coming from gauge invariance.

This is indeed the case and the main point of this paper is to show, following the developments in Refs. 11, 12, and 22 that factorizing the so-called nonintegrable phase factor from the Green function [the integral kernel of $(H_L(B)-\zeta)^{-1}$] allows, at the same time, to eliminate the

divergences coming from the increase of the magnetic vector potential and to obtain a controlled expansion in powers of B. In addition, this leads to expressions of $a_L(B,\omega)$ which are manifestly gauge invariant.

For an arbitrary pair of points $\mathbf{x}$, $\mathbf{y} \in \Lambda_L$ consider the "magnetic phase" associated with the magnetic vector potential $\mathbf{a}(\mathbf{u})$ defined as the path integral on the line linking $\mathbf{y}$ and $\mathbf{x}$,

$$\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y}) = \int_{\mathbf{y}}^{\mathbf{x}} \mathbf{a}(\mathbf{u}) \cdot \mathrm{d}\mathbf{u}. \tag{3.1}$$

The magnetic phase satisfies the following crucial identity: for every fixed $\mathbf{c}$,

$$e^{-ib\phi_{\mathbf{a}}(\mathbf{x},\mathbf{c})}\mathbf{P}(B)e^{ib\phi_{\mathbf{a}}(\mathbf{x},\mathbf{c})} = \mathbf{P}(0) - b\mathbf{A}(\mathbf{x}-\mathbf{c}), \tag{3.2}$$

where $\mathbf{A}(\mathbf{x}) = \frac{1}{2}\mathbf{n}_3 \wedge \mathbf{x}$, i.e., irrespective of the choice of $\mathbf{a}(\mathbf{x})$,

$$\mathbf{A}(\mathbf{x}-\mathbf{c}) = \tfrac{1}{2}\mathbf{n}_3 \wedge (\mathbf{x}-\mathbf{c}) \tag{3.3}$$

is the symmetric (transverse, Poincaré) gauge with respect to $\mathbf{c}$.

Write now the Green function (as a 2×2 matrix in the spin space)

$$G_L(\mathbf{x},\mathbf{y};\zeta) = (H_L - \zeta)^{-1}(\mathbf{x},\mathbf{y}) \tag{3.4}$$

in the factorized form

$$G_L(\mathbf{x},\mathbf{y};\zeta) = e^{ib\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})}K_L(\mathbf{x},\mathbf{y};\zeta). \tag{3.5}$$

It is easy to check that while $G_L(\mathbf{x},\mathbf{y};\zeta)$ is gauge dependent, $K_L(\mathbf{x},\mathbf{y};\zeta)$ is gauge independent, i.e., the whole gauge dependence of $G_L(\mathbf{x},\mathbf{y};\zeta)$ is contained in the phase factor $e^{ib\phi_{\mathbf{a}}(\mathbf{x},\mathbf{y})}$. Plugging the factorization (3.5) into the integrand of the rhs of (2.30), using (3.2) and (3.3), one obtains that its integral kernel writes as

$$\begin{aligned}\mathcal{A}^L_{s,s'}(\mathbf{x},\mathbf{x}') = e^{ib\phi_{\mathbf{a}}(\mathbf{x},\mathbf{x}')}\int_{\Gamma_\omega} \mathrm{d}z\, f_{\mathrm{FD}}(z)\sum_{\sigma=1}^{2}\int_{\Lambda_L}\mathrm{d}\mathbf{y}\, e^{ib\Phi(\mathbf{x},\mathbf{y},\mathbf{x}')}\{[(P_{1,\mathbf{x}}(0) - bA_1(\mathbf{x}-\mathbf{y}))K_L(\mathbf{x},\mathbf{y};z)]_{s,\sigma}\\ \times [(P_{2,\mathbf{y}}(0) - bA_2(\mathbf{x}-\mathbf{y}))K_L(\mathbf{y},\mathbf{x}';z+\omega)]_{\sigma,s'} + z \to z-\omega\},\end{aligned} \tag{3.6}$$

where

$$\Phi(\mathbf{x},\mathbf{y},\mathbf{x}') = \phi_{\mathbf{a}}(\mathbf{x},\mathbf{y}) + \phi_{\mathbf{a}}(\mathbf{y},\mathbf{x}') + \phi_{\mathbf{a}}(\mathbf{x}',\mathbf{x})$$

is the flux of the magnetic field (0, 0, 1) through the triangle $\Delta(\mathbf{x},\mathbf{y},\mathbf{x}')$. Now the fact that there are no long range divergences in the formula for $\mathcal{A}_{s,s'}(\mathbf{x},\mathbf{x}')$ follows from the exponential decay of Green functions[10] (see also Ref. 21): for ζ outside the spectrum of H there exists $m(\zeta)>0$ such that as $|\mathbf{x}-\mathbf{y}|\to\infty$

$$|K_L(\mathbf{x},\mathbf{y};\zeta)| = |G_L(\mathbf{x},\mathbf{y};\zeta)| \sim e^{-m(\zeta)|\mathbf{x}-\mathbf{y}|}. \tag{3.7}$$

It can be proved (the technical details which are far from being simple will be given elsewhere) that $\mathcal{A}^L_{s,s'}(\mathbf{x},\mathbf{x}')$ is jointly continuous and moreover outside a thin region near the surface of Λ_L one can replace it by the integral kernel $\mathcal{A}^\infty_{s,s'}(\mathbf{x},\mathbf{x}')$ of the corresponding operator on the whole $\mathbb{R}^3$. Accordingly, up to surface corrections,

$$a_L(B,\omega) \approx -\frac{1}{2\pi|\Lambda_L|}\sum_{s=1}^{2}\int_{\Lambda_L}\mathcal{A}^\infty_{s,s}(\mathbf{x},\mathbf{x})\mathrm{d}\mathbf{x}. \tag{3.8}$$

Notice that due to the fact that $\Phi(\mathbf{x},\mathbf{y},\mathbf{x}) = \phi_{\mathbf{a}}(\mathbf{x},\mathbf{x}) = 0$ the phase factors appearing in (3.6) reduce to unity in (3.8).

In the periodic case, from the fact that in the symmetric gauge the Hamiltonian $H_\infty(B)$ commutes with the magnetic translations [actually one can define magnetic translations for an arbitrary gauge, just first make the gauge transformation relating $\mathbf{a}(\mathbf{x})$ to $\mathbf{A}(\mathbf{x})$] generated by $\mathcal{L}$, it follows that for $\vec{\gamma} \in \mathcal{L}$ we have

$$K_\infty(\mathbf{x}+\vec{\gamma},\mathbf{y}+\vec{\gamma};\zeta) = K_\infty(\mathbf{x},\mathbf{y};\zeta),$$

which implies that

$$\mathcal{A}^\infty_{s,s}(\mathbf{x}+\vec{\gamma},\mathbf{x}+\vec{\gamma}) = \mathcal{A}^\infty_{s,s}(\mathbf{x},\mathbf{x})$$

is periodic with respect to $\mathcal{L}$, hence up to surface corrections

$$a_L(B,\omega) \approx a(B,\omega) = -\frac{1}{2\pi|\Omega|}\sum_{s=1}^{2}\int_\Omega \mathcal{A}^\infty_{s,s}(\mathbf{x},\mathbf{x})\mathrm{d}\mathbf{x}. \tag{3.9}$$

Therefore, the transverse conductivity writes as

$$\sigma_{12}(B,\omega) = \frac{e^2}{m^2\omega}a(B,\omega) \tag{3.10}$$

with $a(B,\omega)$ given by the rhs of (3.9).

A precise formulation of this result is contained in the following theorem.

Theorem 3.1: *Assume for simplicity that* Ω *is the unit cube in* $\mathbb{R}^3$. *The above defined transverse component of the conductivity tensor admits the thermodynamic limit; more precisely* as follows.

(i) *The following operator defined by a* $B(L^2\oplus L^2)$*-norm convergent Riemann integral*,

$$F_L := -\frac{1}{2\pi}\int_{\Gamma_\omega} f_{\mathrm{FD}}(z)\{P_1(B)(H_L(B)-z)^{-1}P_2(B)(H_L(B)-z-\omega)^{-1} + z\to z-\omega\}\mathrm{d}z, \tag{3.11}$$

is in fact trace-class, and $\sigma^{(L)}_{12}(B,\omega) = (e^2/m^2\omega|\Lambda_L|)\mathrm{Tr}(F_L)$.

(ii) *Consider the operator* F_∞ *defined by the same integral but with* $H_\infty(B)$ *instead of* $H_L(B)$, *and defined on the whole space. Then* F_∞ *is an integral operator, with a kernel* $\mathcal{A}^\infty_{s,s'}(\mathbf{x},\mathbf{x}')$ *jointly continuous on its spatial variables. Moreover, the function defined by* $\mathbb{R}^3 \ni \mathbf{x} \to s_B(\mathbf{x}) := \Sigma^2_{s=1}\mathcal{A}^\infty_{s,s}(\mathbf{x},\mathbf{x}) \in \mathbb{C}$ *is continuous and periodic with respect to* $\mathbb{Z}^3$.

(iii) *The thermodynamic limit exists*,

$$\sigma^{(\infty)}_{12}(B,\omega) := \lim_{L\to\infty}\sigma^{(L)}_{12}(B,\omega) = \frac{e^2}{m^2\omega|\Omega|}\int_\Omega s_B(\mathbf{x})\mathrm{d}\mathbf{x}. \tag{3.12}$$

The proof of this theorem will be given elsewhere.[13]

IV. THE ZERO FREQUENCY LIMIT AT $T=0$: A RIGOROUS PROOF OF THE WIDOM-STREDA FORMULA FOR SEMICONDUCTORS

Doing some very formal computations one can show that at $T=0$ and $\omega=0$, $\sigma_{12}(B,\omega)$ as given by (3.9) and (3.10) coincide with the formula for the quantized Hall conductivity [see, e.g., formulas (5) and (6) in Ref. 34] which in turn gives (again at the heuristic level) the well-known Widom-Streda formula. The original derivation has little mathematical rigor, in particular because it assumes some very strong assumptions on the existence and regularity of $(H_\infty(B)-\lambda+i0)^{-1}$ as a function of $\lambda\in\mathbb{R}$. These assumptions are clearly not true in many situations.

Here we will show how the Widom-Streda formula can be rigorously obtained when the Fermi energy lies in a spectral gap. The problem in which the Fermi energy is in the spectrum, remains

open. Now assume that for some B, the chemical potential μ lies in a spectral gap of $H_\infty(B)$. More precisely, throughout this section we suppose that $(d_1,d_2)\subset\rho(H_\infty(B))$ with $d_1<d_2$, and take $\mu\in(d_1,d_2)$. For simplicity, assume that $\mu=(d_1+d_2)/2$. This is the typical situation for semiconductors and/or isolators. In the absence of spin, the Widom-Streda formula roughly states that

$$\sigma_{12}(B,T=0,\omega=0)=ec\left.\frac{\partial N(B,E)}{\partial B}\right|_{E=\mu}, \tag{4.1}$$

where $N(B,E)$ is the integrated density of states up to the energy E. When the spin is present (this was not considered by Streda), this formula is slightly changed. If we denote by B_1 the B multiplying the spin matrix σ_3 in our Hamiltonian (2.1), and with B_2 the B near $\mathbf{A}$, then in fact we have

$$\sigma_{12}(B,T=0,\omega=0)=ec\left.\frac{\partial N(B_1,B_2,E)}{\partial B_2}\right|_{E=\mu,B_1=B_2=B}. \tag{4.2}$$

In the rest of this section we give a rigorous (but still not fully technical) proof of (4.2).

Theorem 4.1: *Consider the conductivity at the thermodynamic limit given in* (3.12), *and drop the superscript* ∞. *Then if we first take the limit* $T\searrow 0$, *and after that* $\omega\to 0$, *we get*

$$\lim_{\omega\to 0}\lim_{T\to 0}\sigma_{12}(B,T,\omega)=ec\frac{\partial}{\partial B_2}\left.\frac{1}{|\Omega|}\sum_{s=1}^{2}\int_\Omega \Pi^B_{s,s}(\mathbf{x},\mathbf{x})\mathrm{d}\mathbf{x}\right|_{B_1=B_2=B}, \tag{4.3}$$

where

$$\Pi^B=\frac{i}{2\pi}\int_\Gamma\frac{1}{H_\infty(B)-z}\mathrm{d}z \tag{4.4}$$

with a positively oriented contour Γ *enclosing the spectrum of* $H_\infty(B)$ *below* μ, *i.e.*, Π^B *is the Fermi projection onto the subspace of "occupied" states at* $T=0$.

Remarks:

(1) Streda did not consider spin in his work[34] and in this case the derivative with respect to the magnetic field appears on the rhs of (4.3).

(2) While it is not clear that $\Pi^B(\mathbf{x},\mathbf{x})$ is well defined $[(H_\infty(B)-z)^{-1}(\mathbf{x},\mathbf{x})$ does not exist] this can be seen by writing for some $a\in\rho(H_\infty(B))$,

$$\begin{aligned}\Pi^B&=\frac{1}{2\pi}\int_\Gamma((H_\infty(B)-z)^{-1}\ -(H_\infty(B)-a)^{-1}\,\mathrm{d}z\\&=\frac{1}{2\pi}\int_\Gamma(z-a)(H_\infty(B)-z)^{-1}(H_\infty(B)-a)^{-1}\,\mathrm{d}z.\end{aligned} \tag{4.5}$$

Each resolvent has a polar integral kernel with a $1/|\mathbf{x}-\mathbf{x}'|$ singularity, and the product of two resolvents will have a continuous kernel. In fact we can repeat this trick and obtain products of as many resolvents as we want, thus further improving the regularity of the integral kernel. Technical details will be given elsewhere. Actually this kind of argument can be used to show that all operators defined by integrals over complex contours have jointly continuous integral kernels.

(3) Although the order of limits in (4.3) is important for the argument below, it might be possible [at least under additional conditions on the spectrum of $H_\infty(B)$] to interchange the order of limits. The important fact is that the thermodynamic limit must be taken first: great care is to be taken when defining currents in the static limit for finite systems (for a discussion of this point in a related context see Ref. 24).

(4) The result is valid for arbitrary magnetic field B and establishes the connection between the Hall conductivity and the Faraday effect. However, the quantum Hall effect requires high magnetic fields while the Faraday effect is usually considered at low magnetic fields.

Proof: We start from the conductivity in the thermodynamic limit as given by Theorem 3.1,

$$\sigma_{12}(B,T,\omega) = -\frac{e^2}{2\pi m^2 \omega |\Omega|} \sum_{s=1}^{2} \int_{\Omega} \left[\int_{\Gamma_{\beta,\omega}} f_{\mathrm{FD}}(z) \Sigma(z,\omega) \mathrm{d}z \right]_{s,s} (\mathbf{x},\mathbf{x}) \mathrm{d}\mathbf{x}, \tag{4.6}$$

where

$$\Sigma(z,\omega) := P_1(B)(H_\infty(B)-z)^{-1} P_2(B)(H_\infty(B)-z-\omega)^{-1} + (z \to z-\omega). \tag{4.7}$$

Since we made the assumption that $(d_1,d_2) \subset \rho(H_\infty(B))$, then for $|\omega| < (d_2-d_1)/4$ the integral over z on the contour $\Gamma_{\beta,\omega}$ can be replaced with the integral on the contour $\Gamma^1_{\beta,\omega} \cup \Gamma^2_{\beta,\omega}$ where [see also (2.28) and (2.29)],

$$\Gamma^1_{\beta,\omega} = \left\{ x \pm id : a \leqslant x \leqslant d_1 + \frac{d_2-d_1}{4} \right\} \cup \{ a+iy : -d \leqslant y \leqslant d \} \cup \left\{ d_1 + \frac{d_2-d_1}{4} + iy : -d \leqslant y \leqslant d \right\} \tag{4.8}$$

and

$$\Gamma^2_{\beta,\omega} = \left\{ x \pm id : x \geqslant d_2 - \frac{d_2-d_1}{4} \right\} \cup \left\{ d_2 - \frac{d_2-d_1}{4} + iy : -d \leqslant y \leqslant d \right\}. \tag{4.9}$$

Accordingly, one can rewrite $\sigma_{12}(B,T,\omega)$ as

$$\begin{aligned} \sigma_{12}(B,T,\omega) = -\frac{e^2}{2\pi m^2 \omega |\Omega|} \sum_{s=1}^{2} \int_{\Omega} \Bigg\{ & \int_{\Gamma^1_{\beta,\omega}} \Sigma(z,\omega) \mathrm{d}z + \int_{\Gamma^1_{\beta,\omega}} (f_{\mathrm{FD}}(z)-1) \Sigma(z,\omega) \mathrm{d}z \\ & + \int_{\Gamma^2_{\beta,\omega}} f_{\mathrm{FD}}(z) \Sigma(z,\omega) \mathrm{d}z \Bigg\}_{s,s} (\mathbf{x},\mathbf{x}) \mathrm{d}\mathbf{x}. \end{aligned} \tag{4.10}$$

Note that since the singularities of $f_{\mathrm{FD}}(z)$ lie on $(c+d)/2+iy, y \in (-\infty,\infty)$, one can take $\Gamma^j_{\beta,\omega}$ independent of β, i.e., one can take $d = |\Im(\omega)|/2$ in (2.29). At this point we take the limit $\beta \to \infty$. Since on Γ^2_ω we have $|f_{\mathrm{FD}}(z)| \leqslant 2\exp[-\beta(x-(d_1+d_2)/2)]$, and on Γ^1_ω we have that $|f_{\mathrm{FD}}(z)-1| \leqslant 2\exp[-\beta((d_1+d_2)/2-x)]$, the last two terms in (4.10) vanish in the zero temperature limit (full details about the control of various integral kernels will be given elsewhere). Hence we get

$$\sigma_{12}(B,T=0,\omega) = -\frac{e^2}{2\pi m^2 \omega |\Omega|} \sum_{s=1}^{2} \int_{\Omega} \left\{ \int_{\Gamma^1_\omega} \Sigma(z,\omega) \mathrm{d}z \right\}_{s,s} (\mathbf{x},\mathbf{x}) \mathrm{d}\mathbf{x}. \tag{4.11}$$

An application of the Cauchy residue theorem shows that the two terms of $\Sigma(z,\omega)$ [see (4.7)] will combine in the above integral and give

$$\begin{aligned} \sigma_{12}(B,T=0,\omega) = -\frac{e^2}{2\pi m^2 \omega} \frac{1}{|\Omega|} \sum_{s=1}^{2} \int_{\Omega} \Bigg[& \int_{\Gamma} P_1(B)(H_\infty(B) \\ & - z + \omega/2)^{-1} P_2(B)(H_\infty(B) - z - \omega/2)^{-1} \Bigg]_{s,s} (\mathbf{x},\mathbf{x}) \mathrm{d}\mathbf{x}, \end{aligned} \tag{4.12}$$

where Γ is any finite contour such that $\Gamma \subset \rho(H_\infty(B)+\omega)$ for all $|\omega| < |d_2-d_1|/4$ and only enclosing the spectrum of $H_\infty(B)$ below $(d_1+d_2)/2$. Now the integrand in (4.12) is analytic in ω in a neighborhood of the origin. By expanding the resolvents one obtains

$$\sigma_{12}(B,T=0,\omega)=-\frac{e^2}{2\pi m^2}\frac{1}{|\Omega|}\sum_{s=1}^{2}\int_{\Omega}\left\{\int_{\Gamma}\frac{1}{\omega}P_1(B)(H_\infty(B)-z)^{-1}P_2(B)(H_\infty(B)-z)^{-1}\right.$$
$$+\frac{1}{2}[P_1(B)(H_\infty(B)-z)^{-1}P_2(B)(H_\infty(B)-z)^{-2}$$
$$\left.-P_1(B)(H_\infty(B)-z)^{-2}P_2(B)(H_\infty(B)-z)^{-1}]\right\}_{s,s}(\mathbf{x},\mathbf{x})\mathrm{d}\mathbf{x}+\mathcal{O}(\omega). \tag{4.13}$$

Apparently we have a first order pole at $\omega=0$. But we now prove that the singular term on the rhs of (4.13) is identically zero. Namely (when no spin variables appear the integral kernels below must be understood as matrices in the spin space):

$$\left\{\int_{\Gamma}P_1(B)(H_\infty(B)-z)^{-1}P_2(B)(H_\infty(B)-z)^{-1}\,\mathrm{d}z\right\}(\mathbf{x},\mathbf{x})=0. \tag{4.14}$$

Using the magnetic perturbation theory and the trick from (4.5) one can prove that even though the integrand in (4.14) has a quite singular kernel, after integration with respect to z one gets a smooth kernel, exponentially localized near the diagonal (details will be given elsewhere).

Let us notice an operator equality which makes sense on compactly supported functions,

$$\frac{1}{m}(H_\infty(B)-z)^{-1}P_2(B)(H_\infty(B)-z)^{-1}=i[X_2,(H_\infty(B)-z)^{-1}], \tag{4.15}$$

because the resolvent $(H_\infty(B)-z)^{-1}$ sends compactly supported functions into exponentially decaying functions [see (3.7)], which are in the domain of X_2. In fact, the operator on the right-hand side has a nice integral kernel, given by

$$\{i[X_2,(H_\infty(B)-z)^{-1}]\}(\mathbf{x},\mathbf{y})=i(x_2-y_2)G_\infty(\mathbf{x},\mathbf{y};z), \tag{4.16}$$

which is no longer singular at the diagonal and still exponentially localized near the diagonal, thus defining a bounded operator on the whole Hilbert space. After integration we get

$$\frac{i}{2\pi}\int_{\Gamma}P_1(B)(H_\infty(B)-z)^{-1}P_2(B)(H_\infty(B)-z)^{-1}\,\mathrm{d}z=\frac{im}{2\pi}\int_{\Gamma}P_1(B)[(H_\infty(B)-z)^{-1},X_2]\mathrm{d}z$$
$$=m[P_1(B)\Pi^B,X_2], \tag{4.17}$$

where we used that $P_1(B)$ and X_2 commute. Note that the magnetic perturbation theory states that the integral kernel of $P_1(B)\Pi^B$ is smooth and exponentially localized near the diagonal. Therefore $[P_1(B)\Pi^B,X_2]$ will have the integral kernel

$$\{[P_1(B)\Pi^B,X_2]\}(\mathbf{x},\mathbf{y})=(y_2-x_2)\{P_1(B)\Pi^B\}(\mathbf{x},\mathbf{y}) \tag{4.18}$$

which is identically zero at the diagonal and proves (4.14). We can conclude at this point that

$$\lim_{\omega\to 0}\sigma_{12}(B,T=0,\omega)=-\frac{e^2}{4\pi m^2}\frac{1}{|\Omega|}\sum_{s=1}^{2}\int_{\Omega}\{P_1(B)(H_\infty(B)-z)^{-1}P_2(B)(H_\infty(B)-z)^{-2}$$
$$-P_1(B)(H_\infty(B)-z)^{-2}P_2(B)(H_\infty(B)-z)^{-1}\}_{s,s}(\mathbf{x},\mathbf{x})\mathrm{d}\mathbf{x}. \tag{4.19}$$

Now consider the rhs of (4.3). Since the magnetic field multiplying the spin will not change, our notation will only refer to B_2. Due to the stability of the spectrum against small variations of the magnetic field, for sufficiently small ΔB, $\Pi^{B_2+\Delta B}$ still exists and

$$\Pi^{B_2+\Delta B} - \Pi^{B_2} = \frac{i}{2\pi}\int_\Gamma ((H_\infty(B_2+\Delta B) - z)^{-1} - (H_\infty(B_2) - z)^{-1})\mathrm{d}z. \tag{4.20}$$

By using the magnetic perturbation theory[22] with respect to ΔB [see also the discussion around (6.2)] one obtains

$$[\Pi^{B_2+\Delta B} - \Pi^{B_2}](\mathbf{x},\mathbf{x}) = \frac{ie\Delta B}{2\pi mc}\int_\Gamma \left\{ \int_{\mathbb{R}^3} \mathrm{d}\mathbf{y}(H_\infty(B_2) - z)^{-1}(\mathbf{x},\mathbf{y}) \right.$$
$$\left. \times[\mathbf{P}_\mathbf{y}(B_2)\cdot\mathbf{A}(\mathbf{y}-\mathbf{x})](H_\infty(B_2) - z)^{-1}(\mathbf{y},\mathbf{x}) \right\}\mathrm{d}z + \mathcal{O}((\Delta B)^2). \tag{4.21}$$

Now a very important identity is [see (3.3), (4.15), and (4.16)]

$$\mathbf{A}(\mathbf{y}-\mathbf{x})(H_\infty(B_2) - z)^{-1}(\mathbf{y},\mathbf{x}) = -\frac{i}{2m}\mathbf{n}_3 \wedge [(H_\infty(B_2) - z)^{-1}\mathbf{P}(B_2)(H_\infty(B_2) - z)^{-1}](\mathbf{y},\mathbf{x}). \tag{4.22}$$

The remainder in $(\Delta B)^2$ will have a smooth integral kernel after the integration with respect to z, hence we obtain

$$\frac{\partial}{\partial B_2}\frac{1}{|\Omega|}\int_\Omega \Pi^B(\mathbf{x},\mathbf{x})\mathrm{d}\mathbf{x} = -\frac{e}{4\pi m^2 c}$$
$$\times \int_\Omega \left\{ \int_\Gamma [(H_\infty(B) - z)^{-1}P_1(B)(H_\infty(B) - z)^{-1}P_2(B)(H_\infty(B) - z)^{-1} \right.$$
$$\left. - (H_\infty(B) - z)^{-1}P_2(B)(H_\infty(B) - z)^{-1}P_1(B)\ (H_\infty(B) - z)^{-1})\mathrm{d}z] \right\}(\mathbf{x},\mathbf{x}). \tag{4.23}$$

From (4.23) and (4.19) we see that (4.3) follows if we can prove that one can circularly permute the operators under the integral sign in (4.23). One can prove this by interpreting (4.23) as the thermodynamic limit of the corresponding expression on finite volume and then using the invariance of the trace under cyclic permutations. Alternatively one can prove it directly and in what follows we outline the proof.

Due to the smoothing effect of the integral with respect to z, we can always restrict ourselves to considering a product of only two integral operators which commute with the discrete magnetic translations, and have kernels $e^{ib\phi_\mathbf{a}(\mathbf{x},\mathbf{y})}K_1(\mathbf{x},\mathbf{y})$ and $e^{ib\phi_\mathbf{a}(\mathbf{y},\mathbf{x}')}K_2(\mathbf{y},\mathbf{x}')$. We therefore look at an absolutely convergent integral of the form [the antisymmetric magnetic phases disappear when we look at the diagonal, see (3.1)]

$$\int_\Omega \mathrm{d}\mathbf{x}\int_{\mathbb{R}^3}\mathrm{d}\mathbf{y}\ K_1(\mathbf{x},\mathbf{y})K_2(\mathbf{y},\mathbf{x}) \tag{4.24}$$

with

$$K_{1,2}(\mathbf{x},\mathbf{y}) = K_{1,2}(\mathbf{x}+\vec{\gamma},\mathbf{y}+\vec{\gamma}).$$

Then

$$\int_\Omega d\mathbf{x}\int_{\mathbb{R}^3} d\mathbf{y}\, K_1(\mathbf{x},\mathbf{y})K_2(\mathbf{y},\mathbf{x}) = \sum_{\vec{\gamma}\in\mathcal{L}}\int_\Omega d\mathbf{x}\int_\Omega d\mathbf{y}\, K_1(\mathbf{x},\mathbf{y}+\vec{\gamma})K_2(\mathbf{y}+\vec{\gamma},\mathbf{x})$$

$$= \sum_{\vec{\gamma}\in\mathcal{L}}\int_\Omega d\mathbf{x}\int_\Omega d\mathbf{y}\, K_1(\mathbf{x}-\vec{\gamma},\mathbf{y})K_2(\mathbf{y},\mathbf{x}-\vec{\gamma})$$

$$= \int_\Omega d\mathbf{y}\int_{\mathbb{R}^3} d\mathbf{x}\int_{\mathbb{R}^3} K_2(\mathbf{y},\mathbf{x})K_1(\mathbf{x},\mathbf{y}) \tag{4.25}$$

which gives the needed "trace cyclicity" and the theorem is proved. □

We now turn to the question whether the limit in (4.3) actually vanishes as is suggested by some heuristic arguments (see, e.g., Ref. 30). We start by recalling some results about Wannier functions. Let $\sigma_0(B_0)$ be an isolated part of the spectrum of $H_\infty(B_0)$ and $\Pi_0^{B_0}$ the corresponding spectral projection. We say that $\Pi_0^{B_0}$ has a basis of exponentially localized (magnetic) Wannier functions if there exist $\alpha>0$, $w_j\in L^2(\mathbb{R}^3)\oplus L^2(\mathbb{R}^3)$, $j=1,2,\ldots,p<\infty$ satisfying [we denote by $w_j(\mathbf{x},s)\in\mathbb{C}$ the values of w_j in $\mathbf{x}\in\mathbb{R}^3$ and $s\in\{1,2\}$]

$$\sum_{s=1}^{2}\int_{\mathbb{R}^3}|w_j(\mathbf{x},s)|^2 e^{2\alpha|\mathbf{x}|}\,d\mathbf{x}\leqslant M<\infty, \tag{4.26}$$

such that the set of functions $\{w_{j,\vec{\gamma}}\}_{j=1,2,\ldots,p,\vec{\gamma}\in\mathcal{L}}$ with

$$w_{j,\vec{\gamma}}(\mathbf{x},s) = e^{ib\phi_{\mathbf{a}}(\mathbf{x},\vec{\gamma})}w_j(\mathbf{x}-\vec{\gamma},s)$$

is a basis in the range of the projection $\Pi_0^{B_0}(L^2(\mathbb{R}^3)\oplus L^2(\mathbb{R}^3))$. If the spin is neglected, it has been proved in Ref. 21 that the existence of bases of exponentially localized Wannier functions is stable against small values of the magnetic field (i.e., $B_0=0$). More precisely, if σ_0 is an isolated part of the spectrum of $-\Delta+V$ and the corresponding subspace has a basis of exponentially localized Wannier functions then, for sufficiently small B, $\sigma_0(B)$ is still isolated and the corresponding spectral subspace has a basis of exponentially localized magnetic Wannier functions. The methods in Ref. 23 together with the magnetic perturbation theory[11,12,22] allow one to generalize the above result to arbitrary B_0 and presence of the spin (as far as the spin-orbit term is sufficiently small).[14] Now the existence of exponentially localized magnetic Wannier functions for an isolated part of the spectrum and for the value of the magnetic field B_2 in an interval around B_0 allows one to write

$$\sum_{s=1}^{2}\int_\Omega \Pi^B_{0;s,s}(\mathbf{x},\mathbf{x})d\mathbf{x} = \int_\Omega \sum_{j,\vec{\gamma}}\sum_{s=1}^{2}|w_{j,\vec{\gamma}}(\mathbf{x},s)|^2\,d\mathbf{x}$$

$$= \sum_{j,\vec{\gamma}}\sum_{s=1}^{2}\int_\Omega d\mathbf{x}|w_j(\mathbf{x}-\vec{\gamma},s)|^2 = \sum_{j=1}^{p}\sum_{s=1}^{2}\int_{\mathbb{R}^3}d\mathbf{x}|w_j(\mathbf{x},s)|^2 = p. \tag{4.27}$$

Thus the integrated density of states corresponding to the Fermi projection is constant in B_2 in a small interval around B_0, hence this band gives no contribution on the rhs of (4.3).

For small fields, the above discussion can be summarized in the following.

Theorem 4.2: *Suppose* $(d_1,d_2)\subset\rho(-\Delta+V)$, $d_2>d_1$, *and that the spectral subspace corresponding to* $(-\infty,d_1]$ *admits a basis of exponentially localized Wannier functions. Suppose that the spin-orbit interaction* [*see* (2.2)] *is small enough such that as* c^2 *decreases from* ∞ *to its actual value, we have that* $(d_1+d_2)/2\in\rho(H_\infty(0))$. *Then for sufficiently small* B,

$$\lim_{\omega\to 0}\lim_{T\to 0}\sigma_{12}(B,T,\omega)=0. \tag{4.28}$$

In particular all the derivatives of $\sigma_{12}(B,0)$ vanish for $B=0$, and this substantiates Roth's result [formula (50) in Ref. 30] for the first-order correction in B at zero frequency.

V. A CLOSED FORMULA FOR FREE ELECTRONS

If $V=0$ it turns out that the conductivity tensor can be explicitly computed for all values of B and ω. The formula does not depend on whether we work in two or three dimensions. More precisely, we will show in this section that

$$\sigma_{12}(B,\omega)=\frac{e^3 n}{m^2 c}\frac{B}{\omega^2-\dfrac{B^2e^2}{m^2c^2}}, \tag{5.1}$$

where $n=n(T,\mu,B)$ is the grand-canonical density. The formula (5.1) is well known in classical physics and goes back at least to Drude but we are not aware of a known fully quantum derivation. The coincidence of classical and quantum formulas can be understood taking into account that the Hamiltonians involved (choose the symmetric gauge) are quadratic and it is known that for this class of operators classical and quantum computations coincide in many instances. While it is possible to derive (5.1) by using the explicit form of the Green function or alternatively of eigenvalues and eigenprojections for the Landau Hamiltonian (see, e.g., Ref. 18) we shall obtain it below only using resolvent and commutation identities.

Let us only notice that when $\omega=0$ we reobtain formula (18) in Ref. 34, while for a fixed frequency we get

$$\frac{\partial\sigma_{12}}{\partial B}(0,\omega)=\frac{e^3 n}{m^2 c\omega^2}$$

which is "the high frequency limit" or what Roth also calls "the free electron Faraday effect" in formula (51) from Ref. 30.

We begin by listing a few identities which are valid for a free electron on the entire space,

$$\begin{aligned}
i[P_1(B),P_2(B)]&=\frac{Be}{c},\\
i[H_\infty(B),P_1(B)]&=-\frac{Be}{mc}P_2(B),\\
i[H_\infty(B),P_2(B)]&=\frac{Be}{mc}P_1(B),\\
[H_\infty(B),[H_\infty(B),P_1(B)]]&=\frac{B^2e^2}{m^2c^2}P_1(B),\\
[H_\infty(B),[H_\infty(B),P_2(B)]]&=\frac{B^2e^2}{m^2c^2}P_2(B).
\end{aligned} \tag{5.2}$$

Next, since in this case $\mathcal{A}^{\infty}_{s,s}(\mathbf{x},\mathbf{x})$ does not depend upon $\mathbf{x}$ one has

$$\begin{aligned}
a(B,\omega)=-\frac{1}{2\pi}\sum_{s=1}^{2}\left\{\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z)[P_1(B)(H_\infty(B)-z)^{-1}P_2(B)(H_\infty(B)-z-\omega)^{-1}+z\to z-\omega]\right\}\\
\times(\vec{0},s;\vec{0},s).
\end{aligned} \tag{5.3}$$

Commuting $(H_\infty(B)-z-\omega)^{-1}$ with $P_2(B)$ in the first term, and $P_1(B)$ with $(H_\infty(B)-z+\omega)^{-1}$ in the second one, we obtain

$$a(B,\omega) = -\frac{1}{2\pi|\Omega|}\sum_{s=1}^{2}\left\{\int_{\Gamma_\omega} \mathrm{d}z\, f_{\mathrm{FD}}(z)[P_1(B)(H_\infty(B)-z)^{-1}(H_\infty(B)-z-\omega)^{-1}P_2(B)+P_1(B)\right.$$
$$\times (H_\infty(B)-z)^{-1}(H_\infty(B)-z-\omega)^{-1}[H_\infty(B),P_2(B)](H_\infty(B)-z-\omega)^{-1}+(H_\infty(B)$$
$$-z+\omega)^{-1}P_1(B)P_2(B)(H_\infty(B)-z)^{-1}+(H_\infty(B)-z+\omega)^{-1}[H_\infty(B),P_1(B)]$$
$$\left.\times (H_\infty(B)-z+\omega)^{-1}P_2(B)(H_\infty(B)-z)^{-1}]\right\}(\vec{0},s;\vec{0},s) = \mathrm{I}+\mathrm{II}+\mathrm{III}+\mathrm{IV}. \tag{5.4}$$

Now I+III can easily be computed. Indeed, by cyclic permutations [see (4.25)] one can cluster the two resolvents and then by the resolvent identity

$$(A-z_1)^{-1}(A-z_2)^{-1} = (z_1-z_2)^{-1}[(A-z_1)^{-1}-(A-z_2)^{-1}], \tag{5.5}$$

one obtains four terms. Two of them vanish after the integration over z due to the analyticity of the integrand while the other two give

$$\mathrm{I}+\mathrm{III} = \frac{1}{2\pi}\sum_{s=1}^{2}\left\{\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z)\frac{1}{\omega}[P_2(B),P_1(B)](H_\infty(B)-z)^{-1}\right\}(\vec{0},s;\vec{0},s) \tag{5.6}$$

$$= \frac{Be}{\omega}\sum_{s=1}^{2}\{f_{\mathrm{FD}}(H_\infty(B))\}(\vec{0},s;\vec{0},s) =: \frac{Be}{\omega}n(T,\mu,B). \tag{5.7}$$

In an analogous manner

$$\mathrm{III}+\mathrm{IV} = \frac{1}{2\pi\omega}\sum_{s=1}^{2}\left\{\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z)\{(H_\infty(B)-z)^{-1}[H_\infty(B),P_2(B)](H_\infty(B)-z-\omega)^{-1}P_1(B)\right.$$
$$\left.-(H_\infty(B)-z)^{-1}[H_\infty(B),P_1(B)](H_\infty(B)-z+\omega)^{-1}P_2(B)\}\right\}(\vec{0},s;\vec{0},s). \tag{5.8}$$

At this point we commute $[H_\infty(B),P_2(B)]$ with $(H_\infty(B)-z-\omega)^{-1}$ in the first term, and $[H_\infty(B),P_1(B)]$ with $(H_\infty(B)-z+\omega)^{-1}$ in the second term and use (3.3) again. Some of the terms vanish after performing the integration over z and the remaining ones write as

$$-\frac{1}{\omega}(H_\infty(B)-z)^{-1}[H_\infty(B),P_2(B)]P_1(B)-\frac{1}{\omega}(H_\infty(B)-z)^{-1}[H_\infty(B),[H_\infty(B),P_2(B)]](H_\infty(B)$$
$$-z-\omega)^{-1}P_1(B)-\frac{1}{\omega}(H_\infty(B)-z)^{-1}[H_\infty(B),P_1(B)]P_2(B)$$
$$-\frac{1}{\omega}(H_\infty(B)-z)^{-1}[H_\infty(B),[H_\infty(B),P_1(B)]](H_\infty(B)-z+\omega)^{-1}P_2(B). \tag{5.9}$$

Taking into account (5.2) the first and the third terms in (5.9) combine to

$$-\frac{1}{\omega}(H_\infty(B)-z)^{-1}[H_\infty(B),P_1(B)P_2(B)]$$

which after integration over z is proportional to

$$f_{\mathrm{FD}}(H_\infty(B))i[H_\infty(B),P_1(B)P_2(B)]=\frac{Be}{mc}\{f_{\mathrm{FD}}(H_\infty(B))P_1(B)^2-f_{\mathrm{FD}}(H_\infty(B))P_2(B)^2\}, \quad (5.10)$$

where we used the second and third identities in (5.2). Consider the unitary operator U which implements the coordinate change $(Uf)(x_1,x_2,x_3)=f(x_2,-x_1,x_3)$. Then one can prove that $UP_1(B)U^*=-P_2(B)$, $UP_2(B)U^*=P_1(B)$, and $UH_\infty(B)U^*=H_\infty(B)$. This implies that

$$Uf_{\mathrm{FD}}(H_\infty(B))P_1(B)^2U^*=f_{\mathrm{FD}}(H_\infty(B))P_2(B)^2.$$

Since both operators have a smooth integral kernel, and because the rotation with U does not change the diagonal value of the integral kernel on the left-hand side, it means that the contribution given by (5.10) is zero.

Therefore we only remain with the second and fourth terms in (5.9). Using (5.2), they become

$$\begin{aligned}&-\frac{B^2e^2}{m^2c^2\omega}(H_\infty(B)-z)^{-1}P_2(B)(H_\infty(B)-z-\omega)^{-1}P_1(B),\\&-\frac{B^2e^2}{m^2c^2\omega}(H_\infty(B)-z)^{-1}P_1(B)(H_\infty(B)-z+\omega)^{-1}P_2(B).\end{aligned} \quad (5.11)$$

Using once more the cyclicity of the trace and comparing with the starting point (5.3), we obtain the remarkable identity

$$\mathrm{II}+\mathrm{IV}=\frac{B^2e^2}{m^2c^2\omega^2}a(B,\omega). \quad (5.12)$$

Setting together (5.4), (5.6), and (5.12), we obtain the equation

$$a(B,\omega)=\frac{Be}{c\omega}n+\frac{B^2e^2}{m^2c^2\omega^2}a(B,\omega),$$

which gives (5.1) [see (3.10)].

VI. MAGNETIC PERTURBATION THEORY AND THE LINEAR TERM IN *B*

When $V\neq 0$ it is no longer possible to obtain a closed formula for $\sigma_{12}(B,\omega)$. Since in most physical applications the external magnetic field can be considered weak, an expansion in B up to the first or second order would be sufficient. In this section we show that $a_L(B,\omega)$ has an expansion in B to any order and write down the expressions of the first two terms. The first one gives the transverse conductivity at zero magnetic field and the second which is linear in B provides the Verdet constant. From (3.6) and (3.8) (in what follows by tr we mean the trace over the spin variable),

$$\begin{aligned}a_L(B,\omega)=-\frac{1}{2\pi|\Lambda_L|}\int_{\Lambda_L}\mathrm{d}\mathbf{x}\ \Bigg\{\mathrm{tr}\int_{\Gamma_\omega}\mathrm{d}z\,f_{\mathrm{FD}}(z)\int_{\Lambda_L}\mathrm{d}\mathbf{u}\{[(P_{\mathbf{x},1}(0)-bA_1(\mathbf{x}-\mathbf{u}))K_L(\mathbf{x},\mathbf{u};z)]\\\times[(P_{\mathbf{u},2}(0)-bA_2(\mathbf{u}-\mathbf{x}'))K_L(\mathbf{u},\mathbf{x}';z+\omega)]+[(P_{\mathbf{x},1}(0)-bA_1(\mathbf{x}-\mathbf{u}))K_L(\mathbf{x},\mathbf{u};z-\omega)]\\\times[(P_{\mathbf{u},2}(0)-bA_2(\mathbf{u}-\mathbf{x}'))K_L(\mathbf{u},\mathbf{x}';z)]\}\Bigg\}\Bigg|_{\mathbf{x}=\mathbf{x}'}.\end{aligned} \quad (6.1)$$

Let us mention here that one cannot interchange the order of the above integrals. First one performs the integral with respect to $\mathbf{u}$, then the integral in z, then we can set $\mathbf{x}=\mathbf{x}'$ since the resulting kernel is smooth, and finally one integrates with respect to $\mathbf{x}$ over Λ_L.

When considering the expansion in b of $a_L(B,\omega)$ we are left with the problem of the expansion of $K_{\Lambda_L}(\mathbf{x},\mathbf{y};\zeta)$. This expansion is provided by the magnetic perturbation theory as developed in Ref. 22. Following the steps in Ref. 22 in the case at hand one obtains

$$\begin{aligned} K_L(\mathbf{x},\mathbf{y};z) &= G_L^{(0)}(\mathbf{x},\mathbf{y};z) + \frac{b}{m}\int_{\Lambda_L} G_L^{(0)}(\mathbf{x},\mathbf{u};z)[\mathbf{P}_\mathbf{u}(0)\mathbf{A}(\mathbf{u}-\mathbf{y})G_L^{(0)}(\mathbf{u},\mathbf{y};z)]\mathrm{d}\mathbf{u} \\ &\quad + b\frac{gc\mu_b}{e}\int_{\Lambda_L} G_L^{(0)}(\mathbf{x},\mathbf{u};z)\sigma_3 G_L^{(0)}(\mathbf{u},\mathbf{y};z)\mathrm{d}\mathbf{u} + \mathcal{O}(b^2) \\ &= G_L^{(0)}(\mathbf{x},\mathbf{y};z) + bG_L^{(\mathrm{orbit})}(\mathbf{x},\mathbf{y};z) + bG_L^{(\mathrm{spin})}(\mathbf{x},\mathbf{y};z) + \mathcal{O}(b^2). \end{aligned} \tag{6.2}$$

The above integrands are matrices in the spin variable, that is why the spin does not appear explicitly. The error term $\mathcal{O}(b^2)$ can also be fully controlled with the magnetic perturbation theory (actually arbitrary order terms can be computed; see Ref. 22 for details). Plugging the expansion into (6.2) and collecting the terms of zero and first order one obtains

$$a_L(B,\omega) = a_L(0,\omega) + ba_{L,1}(\omega) + \mathcal{O}(b^2), \tag{6.3}$$

where the zeroth order term is

$$\begin{aligned} a_L(0,\omega) = -\frac{1}{2\pi|\Lambda_L|}\int_{\Lambda_L}\mathrm{d}\mathbf{x}\ \Bigg\{\mathrm{tr}\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z)\{P_1(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z+\omega)^{-1} \\ + (z\to z-\omega)\}\Bigg\}\Bigg|_{\mathbf{x}=\mathbf{x}'}, \end{aligned} \tag{6.4}$$

while the first order correction reads as

$$a_{L,1}(\omega) = a_{L,1}^{\mathrm{orbit}}(\omega) + a_{L,1}^{\mathrm{spin}}(\omega), \tag{6.5}$$

where

$$\begin{aligned} a_{L,1}^{\mathrm{orbit}}(\omega) = -\frac{1}{2\pi|\Lambda_L|}\int_{\Lambda_L}\mathrm{d}\mathbf{x}\ \Bigg\{\mathrm{tr}\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z)\int_{\Lambda_L}\mathrm{d}\mathbf{u}\{-[A_1(\mathbf{x}-\mathbf{u})G_L^{(0)}(\mathbf{x},\mathbf{u};z)] \\ \times[P_{\mathbf{u},2}(0)G_L^{(0)}(\mathbf{u},\mathbf{x}';z+\omega)] - [P_{\mathbf{x},1}(0)G_L^{(0)}(\mathbf{x},\mathbf{u};z)][A_2(\mathbf{u}-\mathbf{x}')G_L^{(0)}(\mathbf{u},\mathbf{x}';z+\omega)] \\ + [P_{\mathbf{x},1}(0)G_L^{(\mathrm{orbit})}(\mathbf{x},\mathbf{u};z)][P_{\mathbf{u},2}(0)G_L^{(0)}(\mathbf{u},\mathbf{x}';z+\omega)] + [P_{\mathbf{x},1}(0)G_L^{(0)}(\mathbf{x},\mathbf{u};z)] \\ \times[P_{\mathbf{u},2}(0)G_L^{(\mathrm{orbit})}(\mathbf{u},\mathbf{x}';z+\omega)] + (z\to z-\omega)\}\Bigg\}\Bigg|_{\mathbf{x}=\mathbf{x}'}, \end{aligned} \tag{6.6}$$

$$\begin{aligned} a_{L,1}^{\mathrm{spin}}(\omega) = -\frac{1}{2\pi|\Lambda_L|}\int_{\Lambda_L}\mathrm{d}\mathbf{x}\ \Bigg\{\mathrm{tr}\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z)\int_{\Lambda_L}\mathrm{d}\mathbf{u}\{[P_{\mathbf{x},1}(0)G_L^{(\mathrm{spin})}(\mathbf{x},\mathbf{u};z)][P_{\mathbf{u},2}(0)G_L^{(0)}(\mathbf{u},\mathbf{x}';z \\ + \omega)] + [P_{\mathbf{x},1}(0)G_L^{(0)}(\mathbf{x},\mathbf{u};z)][P_{\mathbf{u},2}(0)G_L^{(\mathrm{spin})}(\mathbf{u},\mathbf{x}';z+\omega)] + (z\to z-\omega)\}\Bigg\}\Bigg|_{\mathbf{x}=\mathbf{x}'}. \end{aligned} \tag{6.7}$$

Now consider the expression $\mathbf{A}(\mathbf{x}-\mathbf{y})G_L^{(0)}(\mathbf{x},\mathbf{y};z)$ appearing in the formula for $a_{L,1}(\omega)$. Observing that it represents a commutator [see (3.3)] one has the identity

$$\begin{aligned}\mathbf{A}(\mathbf{x}-\mathbf{y})G_L^{(0)}(\mathbf{x},\mathbf{y};z) &= \left(\frac{1}{2}\mathbf{n}_3 \wedge (\mathbf{x}-\mathbf{y})\right) G_L^{(0)}(\mathbf{x},\mathbf{y};z) \\ &= \left(\frac{1}{2}\mathbf{n}_3 \wedge [\mathbf{X},(H_L(0)-z)^{-1}]\right)(\mathbf{x},\mathbf{y}) \\ &= -\frac{i}{2m}\{(H_L(0)-z)^{-1}(\mathbf{n}_3 \wedge P)(H_L(0)-z)^{-1}\}(\mathbf{x},\mathbf{y}), \end{aligned} \tag{6.8}$$

where $\mathbf{X}$ denotes the multiplication operator with $\mathbf{x}$. By a straightforward (but somewhat tedious) computation one arrives at

$$a_{L,1}(\omega) = a_{L,1}^{\text{orbit},1}(\omega) + a_{L,1}^{\text{orbit},2}(\omega) + a_{L,1}^{\text{spin}}(\omega), \tag{6.9}$$

where

$$\begin{aligned} a_{L,1}^{\text{orbit},1}(\omega) = \frac{i}{4m\pi\omega|\Lambda_L|}\int_{\Lambda_L} d\mathbf{x}\Bigg\{ \text{tr}\int_{\Gamma_\omega} dz\, f_{\text{FD}}(z)\Bigg[&\sum_{\alpha=1}^{2} P_\alpha(0)(H_L(0)-z)^{-1}P_\alpha(0)(H_L(0)-z-\omega)^{-1} \\ &+ \sum_{\alpha=1}^{2} P_\alpha(0)(H_L(0)-z)^{-1}P_\alpha(0)(H_L(0)-z+\omega)^{-1} \\ &- \sum_{\alpha=1}^{2} P_\alpha(0)(H_L(0)-z)^{-1}P_\alpha(0)(H_L(0)-z)^{-1}\Bigg]\Bigg\}(\mathbf{x},\mathbf{x}), \end{aligned} \tag{6.10}$$

$$\begin{aligned} a_{L,1}^{\text{orbit},2}(\omega) = \frac{i}{4\pi m^2|\Lambda_L|}\int_{\Lambda_L} d\mathbf{x}\Bigg\{ \text{tr}\int_{\Gamma_\omega} dz\, f_{\text{FD}}(z)\{ &- P_1(0)(H_L(0)-z)^{-1}P_1(0)(H_L(0)-z)^{-1} \\ &\times P_2(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z-\omega)^{-1} + P_1(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z)^{-1} \\ &\times P_1(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z-\omega)^{-1} - P_1(0)(H_L(0)-z+\omega)^{-1}P_1(0) \\ &\times (H_L(0)-z+\omega)^{-1}P_2(0)(H_L(0)-z+\omega)^{-1}P_2(0)(H_L(0)-z)^{-1} \\ &+ P_1(0)(H_L(0)-z+\omega)^{-1}P_2(0)(H_L(0)-z+\omega)^{-1}P_1(0)(H_L(0)-z+\omega)^{-1}P_2(0)(H_L(0) \\ &- z)^{-1} - P_1(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z-\omega)^{-1}P_1(0)(H_L(0)-z-\omega)^{-1}P_2(0)(H_L(0) \\ &- z-\omega)^{-1} + P_1(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z-\omega)^{-1}P_2(0)(H_L(0)-z-\omega)^{-1}P_1(0) \\ &\times (H_L(0)-z-\omega)^{-1} - P_1(0)(H_L(0)-z+\omega)^{-1}P_2(0)(H_L(0)-z)^{-1} \\ &\times P_1(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z)^{-1} + P_1(0)(H_L(0)-z+\omega)^{-1} \\ &\times P_2(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z)^{-1}P_1(0)(H_L(0)-z)^{-1}\}\Bigg\}(\mathbf{x},\mathbf{x}), \end{aligned} \tag{6.11}$$

and

$$a^{\mathrm{spin}}_{L,1}(\omega) = -\frac{gc\mu_b}{2e\pi|\Lambda_L|}\int_{\Lambda_L} \mathrm{d}\mathbf{x}\Bigg\{ \mathrm{tr}\int_{\Gamma_\omega} \mathrm{d}z\, f_{\mathrm{FD}}(z)\{[P_1(0)(H_L(0)-z)^{-1}\sigma_3(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z-\omega)^{-1}] + [P_1(0)(H_L(0)-z)^{-1}P_2(0)(H_L(0)-z-\omega)^{-1}\sigma_3(H_L(0)-z-\omega)^{-1}] + [P_1(0)(H_L(0)-z+\omega)^{-1}\sigma_3(H_L(0)-z+\omega)^{-1}P_2(0)(H_L(0)-z)^{-1}] + [P_1(0)(H_L(0)-z+\omega)^{-1}P_2(0)(H_L(0)-z)^{-1}\sigma_3(H_L(0)-z)^{-1}]\}\Bigg\}(\mathbf{x},\mathbf{x}). \tag{6.12}$$

VII. THE PERIODIC CASE

Now consider the case when V is periodic. In this case, after taking the thermodynamic limit one can replace [see (3.9)] $(1/|\Lambda_L|)\int_{\Lambda_L}$ with $(1/|\Omega|)\int_\Omega$ and rewrite (6.10)–(6.12) as integrals over the Brillouin zone,

$$\begin{aligned} a^{\mathrm{orbit},1}_{\infty,1}(\omega) = \frac{i}{4m\pi\omega|\Omega|}\int_{\Omega^*}\mathrm{d}\mathbf{k}\int_\Omega \mathrm{d}\mathbf{x}\Bigg\{ \mathrm{tr}\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z) \\ \times\sum_{\alpha=1}^{2}(p_\alpha+k_\alpha)(h(\mathbf{k})-z)^{-1}(p_\alpha+k_\alpha)(h(\mathbf{k})-z-\omega)^{-1} \\ +\sum_{\alpha=1}^{2}(p_\alpha+k_\alpha)(h(\mathbf{k})-z)^{-1}(p_\alpha+k_\alpha)(h(\mathbf{k})-z+\omega)^{-1} \\ -\sum_{\alpha=1}^{2}(p_\alpha+k_\alpha)(h(\mathbf{k})-z)^{-1}P_\alpha(0)(h(\mathbf{k})-z)^{-1}\Bigg\}(\mathbf{x},\mathbf{x}), \end{aligned} \tag{7.1}$$

$$\begin{aligned} a^{\mathrm{orbit},2}_{\infty,1}(\omega) = \frac{i}{4\pi m^2|\Omega|}\int_{\Omega^*}\mathrm{d}\mathbf{k}\int_\Omega \mathrm{d}\mathbf{x}\Bigg\{ \mathrm{tr}\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z) \\ \times\{-(p_1+k_1)(h(\mathbf{k})-z)^{-1}(p_1+k_1)(h(\mathbf{k})-z)^{-1}\times(p_2+k_2)(h(\mathbf{k})-z)^{-1} \\ \times(p_2+k_2)(h(\mathbf{k})-z-\omega)^{-1}+(p_1+k_1)(h(\mathbf{k})-z)^{-1}(p_2+k_2)(h(\mathbf{k})-z)^{-1} \\ \times(p_1+k_1)(h(\mathbf{k})-z)^{-1}(p_2+k_2)(h(\mathbf{k})-z-\omega)^{-1}-(p_1+k_1)(h(\mathbf{k})-z+\omega)^{-1}(p_1+k_1) \\ \times(h(\mathbf{k})-z+\omega)^{-1}(p_2+k_2)(h(\mathbf{k})-z+\omega)^{-1}(p_2+k_2)(h(\mathbf{k})-z)^{-1}+(p_1+k_1)(h(\mathbf{k})-z \\ +\omega)^{-1}(p_2+k_2)(h(\mathbf{k})-z+\omega)^{-1}(p_1+k_1)(h(\mathbf{k})-z+\omega)^{-1}(p_2+k_2)(h(\mathbf{k})-z)^{-1}-(p_1+k_1) \\ \times(h(\mathbf{k})-z)^{-1}(p_2+k_2)(h(\mathbf{k})-z-\omega)^{-1}(p_1+k_1)(h(\mathbf{k})-z-\omega)^{-1} \\ \times(p_2+k_2)(h(\mathbf{k})-z-\omega)^{-1}+(p_1+k_1)(h(\mathbf{k})-z)^{-1}(p_2+k_2)(h(\mathbf{k})-z-\omega)^{-1}(p_2+k_2) \\ \times(h(\mathbf{k})-z-\omega)^{-1}(p_1+k_1)(h(\mathbf{k})-z-\omega)^{-1}-(p_1+k_1)(h(\mathbf{k})-z+\omega)^{-1}(p_2+k_2) \\ \times(h(\mathbf{k})-z)^{-1}(p_1+k_1)(h(\mathbf{k})-z)^{-1}(p_2+k_2)(h(\mathbf{k})-z)^{-1}+(p_1+k_1)(h(\mathbf{k})-z+\omega)^{-1} \\ \times(p_2+k_2)(h(\mathbf{k})-z)^{-1}(p_2+k_2)(h(\mathbf{k})-z)^{-1}(p_1+k_1)(h(\mathbf{k})-z)^{-1}\}\Bigg\}(\mathbf{x},\mathbf{x}), \end{aligned} \tag{7.2}$$

and

$$a_{\infty,1}^{\mathrm{spin}}(\omega) = -\frac{gc\mu_b}{2e\pi|\Omega|}\int_{\Omega^*}\mathrm{d}\mathbf{k}\int_{\Omega}\mathrm{d}\mathbf{x}\Bigg\{\mathrm{tr}\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z)\{[(p_1+k_1)(h(\mathbf{k})-z)^{-1}\sigma_3(h(\mathbf{k})-z)^{-1}(p_2+k_2)$$
$$\times(h(\mathbf{k})-z-\omega)^{-1}] + [(p_1+k_1)(h(\mathbf{k})-z)^{-1}(p_2+k_2)(h(\mathbf{k})-z-\omega)^{-1}\sigma_3(h(\mathbf{k})-z-\omega)^{-1}]$$
$$+ [(p_1+k_1)(h(\mathbf{k})-z+\omega)^{-1}\sigma_3(h(\mathbf{k})-z+\omega)^{-1}(p_2+k_2)(h(\mathbf{k})-z)^{-1}]$$
$$+ [(p_1+k_1)(h(\mathbf{k})-z+\omega)^{-1}(p_2+k_2)(h(\mathbf{k})-z)^{-1}\sigma_3(h(\mathbf{k})-z)^{-1}]\}\Bigg\}(\mathbf{x},\mathbf{x}). \tag{7.3}$$

Finally, for the convenience of the reader only interested in applying the theory to the case when one assumes that the Bloch bands and functions are known (as, for example, from Kohn-Luttinger type models), we write (7.1)–(7.3) in terms of Bloch functions and energies. The important thing here is that no derivatives with respect to the quasimomentum appear. With the usual notation (here $\langle,\rangle$ denotes the scalar product over the spin variables)

$$\hat{\pi}_{ij}(\alpha,\mathbf{k}) = \int_{\Omega}\langle u_i(\mathbf{x},\mathbf{k}),(p_\alpha+\mathbf{k}_\alpha)u_j(\mathbf{x},\mathbf{k})\rangle\mathrm{d}\mathbf{x}, \tag{7.4}$$

and after some rearrangements, the terms coming from the orbital magnetism are

$$a_{\infty,1}^{\mathrm{orbit},1}(\omega) = \frac{1}{2m\omega(2\pi)^3}\sum_{\alpha=1}^{2}\int_{\Omega^*}\mathrm{d}\mathbf{k}\Bigg\{\sum_{j\geqslant 1}|\hat{\pi}_{jj}(\alpha,\mathbf{k})|^2 f'_{\mathrm{FD}}(\lambda_j(\mathbf{k}))$$
$$-\omega^2\sum_{j\neq l}|\hat{\pi}_{lj}(\alpha,\mathbf{k})|^2\frac{f_{\mathrm{FD}}(\lambda_j(\mathbf{k}))-f_{\mathrm{FD}}(\lambda_l(\mathbf{k}))}{[(\lambda_j(\mathbf{k})-\lambda_l(\mathbf{k}))^2-\omega^2](\lambda_j(\mathbf{k})-\lambda_l(\mathbf{k}))}\Bigg\}, \tag{7.5}$$

$$a_{\infty,1}^{\mathrm{orbit},2}(\omega) = \frac{1}{2m^2(2\pi)^3}\int_{\Omega^*}\mathrm{d}\mathbf{k}\sum_{n_1,n_2,n_3,n_4\geqslant 1}\frac{1}{2\pi i}\int_{\Gamma_\omega}\mathrm{d}z\, f_{\mathrm{FD}}(z)$$
$$\times\Bigg\{\frac{\hat{\pi}_{n_4n_1}(1,\mathbf{k})\hat{\pi}_{n_1n_2}(1,\mathbf{k})\hat{\pi}_{n_2n_3}(2,\mathbf{k})\hat{\pi}_{n_3n_4}(2,\mathbf{k})}{(z-\lambda_{n_1}(\mathbf{k}))(z-\lambda_{n_2}(\mathbf{k}))(z-\lambda_{n_3}(\mathbf{k}))(z+\omega-\lambda_{n_4}(\mathbf{k}))}$$
$$-\frac{\hat{\pi}_{n_4n_1}(1,\mathbf{k})\hat{\pi}_{n_1n_2}(2,\mathbf{k})\hat{\pi}_{n_2n_3}(1,\mathbf{k})\hat{\pi}_{n_3n_4}(2,\mathbf{k})}{(z-\lambda_{n_1}(\mathbf{k}))(z-\lambda_{n_2}(\mathbf{k}))(z-\lambda_{n_3}(\mathbf{k}))(z+\omega-\lambda_{n_4}(\mathbf{k}))}$$
$$+\frac{\hat{\pi}_{n_4n_1}(1,\mathbf{k})\hat{\pi}_{n_1n_2}(1,\mathbf{k})\hat{\pi}_{n_2n_3}(2,\mathbf{k})\hat{\pi}_{n_3n_4}(2,\mathbf{k})}{(z-\omega-\lambda_{n_1}(\mathbf{k}))(z-\omega-\lambda_{n_2}(\mathbf{k}))(z-\omega-\lambda_{n_3}(\mathbf{k}))(z-\lambda_{n_4}(\mathbf{k}))}$$
$$-\frac{\hat{\pi}_{n_4n_1}(1,\mathbf{k})\hat{\pi}_{n_1n_2}(2,\mathbf{k})\hat{\pi}_{n_2n_3}(1,\mathbf{k})\hat{\pi}_{n_3n_4}(2,\mathbf{k})}{(z-\omega-\lambda_{n_1}(\mathbf{k}))(z-\omega-\lambda_{n_2}(\mathbf{k}))(z-\omega-\lambda_{n_3}(\mathbf{k}))(z-\lambda_{n_4}(\mathbf{k}))}$$
$$+\frac{\hat{\pi}_{n_4n_1}(1,\mathbf{k})\hat{\pi}_{n_1n_2}(2,\mathbf{k})\hat{\pi}_{n_2n_3}(1,\mathbf{k})\hat{\pi}_{n_3n_4}(2,\mathbf{k})}{(z-\lambda_{n_1}(\mathbf{k}))(z+\omega-\lambda_{n_2}(\mathbf{k}))(z+\omega-\lambda_{n_3}(\mathbf{k}))(z+\omega-\lambda_{n_4}(\mathbf{k}))}$$
$$-\frac{\hat{\pi}_{n_4n_1}(1,\mathbf{k})\hat{\pi}_{n_1n_2}(2,\mathbf{k})\hat{\pi}_{n_2n_3}(2,\mathbf{k})\hat{\pi}_{n_3n_4}(1,\mathbf{k})}{(z-\lambda_{n_1}(\mathbf{k}))(z+\omega-\lambda_{n_2}(\mathbf{k}))(z+\omega-\lambda_{n_3}(\mathbf{k}))(z+\omega-\lambda_{n_4}(\mathbf{k}))}$$
$$+\frac{\hat{\pi}_{n_4n_1}(1,\mathbf{k})\hat{\pi}_{n_1n_2}(2,\mathbf{k})\hat{\pi}_{n_2n_3}(1,\mathbf{k})\hat{\pi}_{n_3n_4}(2,\mathbf{k})}{(z-\omega-\lambda_{n_1}(\mathbf{k}))(z-\lambda_{n_2}(\mathbf{k}))(z-\lambda_{n_3}(\mathbf{k}))(z-\lambda_{n_4}(\mathbf{k}))}$$

$$- \frac{\hat{\pi}_{n_4 n_1}(1,\mathbf{k})\hat{\pi}_{n_1 n_2}(2,\mathbf{k})\hat{\pi}_{n_2 n_3}(2,\mathbf{k})\hat{\pi}_{n_3 n_4}(1,\mathbf{k})}{(z-\omega-\lambda_{n_1}(\mathbf{k}))(z-\lambda_{n_2}(\mathbf{k}))(z-\lambda_{n_3}(\mathbf{k}))(z-\lambda_{n_4}(\mathbf{k}))} \Bigg\}. \tag{7.6}$$

As for the spin contribution, with the notation

$$\hat{s}_{ij}(\mathbf{k}) := \int_\Omega \langle u_i(\mathbf{x},\mathbf{k}), \sigma_3 u_j(\mathbf{x},\mathbf{k})\rangle \mathrm{d}\mathbf{x}, \tag{7.7}$$

one has

$$\begin{aligned} a^{\mathrm{spin}}_{\infty,1}(\omega) = & -\frac{gc\mu_b}{(2\pi)^4 e}\int_{\Omega^*} \mathrm{d}\mathbf{k} \sum_{n_1,n_2,n_3\geqslant 1} \frac{1}{2\pi i}\int_{\Gamma_\omega} \mathrm{d}z\, f_{\mathrm{FD}}(z) \\ & \times \Bigg\{ \frac{\hat{\pi}_{n_1 n_2}(1,\mathbf{k})\hat{s}_{n_2 n_3}(\mathbf{k})\hat{\pi}_{n_3 n_1}(2,\mathbf{k})}{(\lambda_{n_2}(\mathbf{k})-z)(\lambda_{n_3}(\mathbf{k})-z)(\lambda_{n_1}(\mathbf{k})-z-\omega)} \\ & + \frac{\hat{\pi}_{n_1 n_2}(1,\mathbf{k})\hat{\pi}_{n_2 n_3}(2,\mathbf{k})\hat{s}_{n_3 n_1}(\mathbf{k})}{(\lambda_{n_2}(\mathbf{k})-z)(\lambda_{n_3}(\mathbf{k})-z-\omega)(\lambda_{n_1}(\mathbf{k})-z-\omega)} \\ & + \frac{\hat{\pi}_{n_1 n_2}(1,\mathbf{k})\hat{s}_{n_2 n_3}(\mathbf{k})\hat{\pi}_{n_3 n_1}(2,\mathbf{k})}{(\lambda_{n_2}(\mathbf{k})-z+\omega)(\lambda_{n_3}(\mathbf{k})-z+\omega)(\lambda_{n_1}(\mathbf{k})-z)} \\ & + \frac{\hat{\pi}_{n_1 n_2}(1,\mathbf{k})\hat{\pi}_{n_2 n_3}(2,\mathbf{k})\hat{s}_{n_3 n_1}(\mathbf{k})}{(\lambda_{n_2}(\mathbf{k})-z+\omega)(\lambda_{n_3}(\mathbf{k})-z)(\lambda_{n_1}(\mathbf{k})-z)} \Bigg\}. \end{aligned} \tag{7.8}$$

VIII. CONCLUSIONS

We presented in the present paper a method which shed new light on the quantum dynamics/optical response in bulk media in the presence of a constant magnetic field. We applied the gauge invariant magnetic perturbation theory and gave a clear and very general way of dealing with long range magnetic perturbations.

The formal connection with the integer quantum Hall effect was established in (4.2). Equations (6.9)–(6.12) and (7.4)–(7.8) contain our main result concerning the Verdet constant and the Faraday effect: it gives the linear term in B of the transverse conductivity in terms of the zero magnetic field Green function. They open the way of using the recently developed Green function techniques for the calculation of optical and magneto-optical properties of solids, to the case when an external magnetic field is present. Our method can be applied to ordered, as well as to random systems (with the appropriate average over configurations). Of course, in the last case one must assume ergodicity properties in order to insure convergence of results in the thermodynamic limit. Layers or other geometries can also be considered.

There are many subtle and difficult mathematical questions left aside in this paper, as those related to the thermodynamic limit, the convergence of infinite series over Bloch bands, and the low frequency limit when the Fermi energy lies in the spectrum. Another open problem is to consider self-interacting electrons and to investigate the exciton influence on the Faraday effect. These questions will be addressed elsewhere.

Our results are not only theoretical. In a future presentation we will use the residue theorem in Eqs. (7.4)–(7.8) to calculate the Verdet constant for various finite band models, and compare our results with the existing experimental data. Moreover, our results will be shown to imply those of Roth[30] and Nedoluha.[20]

Study of the normalizer of the MAD-group corresponding to a fine grading offers the most important tool for describing symmetries in the system of nonlinear equations connected with contraction of a Lie algebra. One fine grading that is always present in any Lie algebra $\mathrm{sl}(n,\mathbb{C})$ is the Pauli grading. The MAD-group corresponding to it is generated by generalized Pauli matrices. For such MAD-group, we already know its normalizer; its quotient group is isomorphic to the Lie group $\mathrm{SL}(2,\mathbb{Z}_n)\times\mathbb{Z}_2$. In this paper, we deal with a more complicated situation, namely that the fine grading of $\mathrm{sl}(p^2,\mathbb{C})$ is given by a tensor product of the Pauli matrices of the same order p, p being a prime. We describe the normalizer of the corresponding MAD-group and we show that its quotient group is isomorphic to $\mathrm{Sp}(4,\mathbb{F}_p)\times\mathbb{Z}_2$, where $\mathbb{F}_p$ is the finite field with p elements. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2162149]

I. INTRODUCTION

A grading Γ of a Lie algebra L is a decomposition $\Gamma: L=\oplus_{i\in J}L_i$ into nontrivial subspaces L_i such that, for each pair of indices $i,j\in J$, there exists an index $k\in J$ fulfilling the property $[L_i,L_j]\subset L_k$. Among all the gradings of a Lie algebra, the most important ones are fine gradings, since any grading is created from some fine grading.

It was shown in Ref. 10 that there is a one-to-one correspondence between fine gradings of a simple Lie algebra over $\mathbb{C}$ and maximal Abelian groups of diagonalizable automorphisms (so-called MAD-groups) in Aut L. Each fine grading of a simple Lie algebra over $\mathbb{C}$ is obtained as a decomposition of L into eigensubspaces of automorphisms from a MAD group. In Ref. 4, all MAD-groups of Aut $\mathrm{sl}(n,\mathbb{C})$ were described.

Let us recall that the Lie algebra $\mathrm{sl}(n,\mathbb{C})$ has inner and outer automorphisms. An inner automorphism is given by a nonsingular matrix A of order n by the prescription

$$\mathrm{Ad}_A X := A^{-1}XA \quad \text{for } X\in \mathrm{sl}(n,\mathbb{C}).$$

An outer automorphism is connected with a nonsingular matrix A of order n as well, and it is given by the prescription

$$\mathrm{Out}_A X := -(A^{-1}XA)^{\mathsf{T}} \quad \text{for } X\in \mathrm{sl}(n,\mathbb{C}),$$

where A^{T} denotes the transposed matrix.

An important role in the description of MAD-groups without outer automorphism is played by generalized Pauli matrices. They were introduced in Ref. 11.

Definition 1.1: For a given $n\in\mathbb{N}$, set $\omega=\omega_n=e^{2\pi i/n}$. A group of matrices

$$\mathcal{P}_n := \{\omega^j P_n^k Q_n^l | j,k,l\in\{0,1,\ldots,n-1\}\}, \quad \text{where}$$

$$P_n = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 \\ 0 & \omega & 0 & \dots & 0 \\ 0 & 0 & \omega 2 & \dots & 0 \\ \vdots & & & \ddots & \\ 0 & 0 & 0 & \dots & \omega^{n-1} \end{pmatrix} \in \mathbb{C}^{n\times n} \quad \text{and } Q_n = \begin{pmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & 0 & 1 & \dots & 0 \\ \vdots & & & \ddots & \\ 0 & 0 & 0 & \dots & 1 \\ 1 & 0 & 0 & \dots & 0 \end{pmatrix} \in \mathbb{C}^{n\times n},$$

is called the Pauli group of order n; P_n and Q_n are the generalized Pauli matrices of order n.

Let us note that the matrices P_n and Q_n do not commute, since $Q_nP_n=\omega P_nQ_n$. Nevertheless, the inner automorphisms corresponding to these matrices do commute, $\mathrm{Ad}_{Q_n}\mathrm{Ad}_{P_n}=\mathrm{Ad}_{P_n}\mathrm{Ad}_{Q_n}$.

In order to describe MAD-groups of the algebra $\mathrm{sl}(n,\mathbb{C})$, we need further notation:

The group of nonsingular diagonal matrices of order n will be denoted by $\mathcal{D}_n$, i.e.,

$$\mathcal{D}_n = \{\mathrm{diag}(\alpha_1,\alpha_2,\dots,\alpha_n)|\alpha_1,\alpha_2,\dots,\alpha_n \in \mathbb{C}\setminus\{0\}\}.$$

If G_1 and G_2 are groups of matrices, then $G_1\otimes G_2$ denotes the group of all tensor products $A\otimes B$, where $A\in G_1$ and $B\in G_2$. [If $A\in\mathbb{C}^{n\times n}$ and $B\in\mathbb{C}^{m\times m}$, then the tensor product $A\otimes B\in\mathbb{C}^{nm\times nm}$ is defined by $(A\otimes B)_{IJ}=A_{i_1i_2}B_{j_1j_2}$, where $i_1,i_2\in\{0,1,\dots,n-1\}$, $j_1,j_2\in\{0,1,\dots,m-1\}$, $I,J\in\{0,1,\dots,mn-1\}$ and $I=i_1m+j_1$, $J=i_2m+j_2$.]

The MAD-groups of $\mathrm{Aut}\,\mathrm{sl}(n,\mathbb{C})$ can be divided into two classes, depending whether or not they contain an outer automorphism. It is proved in Ref. 4 that any MAD-group in the automorphism group $\mathrm{Aut}\,\mathrm{sl}(n,\mathbb{C})$ containing only inner automorphisms is isomorphic to a group of the following form:

$$\mathcal{G} = \{\mathrm{Ad}_A|A \in \mathcal{P}_{n_1}\otimes\mathcal{P}_{n_2}\otimes\cdots\otimes\mathcal{P}_{n_{r-1}}\otimes\mathcal{D}_{n_r}\},$$

where $n_1n_2\cdots n_r=n$ and n_{i-1} divides n_i for any $i=2,3,\dots,r-1$.

A grading $\Gamma: L=\oplus_{i\in J}L_i$ of a Lie algebra L is a starting point for searching for graded contractions of the Lie algebra. This method for finding contractions of Lie algebras was used by several authors.[1,3,7] In this type of contraction, we define new Lie brackets by prescription

$$[x,y]_{\mathrm{new}} := \varepsilon_{jk}[x,y], \quad \text{where } x\in L_j,\ y\in L_k.$$

The complex or real parameters ε_{jk}, for $j,k\in J$, must be determined in such way that the vector space L with the binary operation $[.,.]_{\mathrm{new}}$ forms again a Lie algebra. Antisymmetry of Lie brackets demands that $\varepsilon_{jk}=\varepsilon_{kj}$. Compliance with the Jacobi identity, however, already implies that the coefficients ε_{jk} fulfill a complicated system of quadratic equations, which is in general difficult to solve. For description of symmetries of this system, it is important to know the symmetries of the original grading Γ. By a symmetry of a grading of the Lie algebra L we mean such an automorphism $g\in\mathrm{Aut}\,L$ that

$$\text{for each } j\in J \text{ there exists } k\in J \text{ fulfilling } gL_j=L_k. \tag{1}$$

Let us suppose that a fine grading $\Gamma:\mathrm{sl}(n,\mathbb{C})=\oplus_{j\in J}L_j$ corresponds to a MAD-group $\mathcal{G}\subset\mathrm{Aut}\,\mathrm{sl}(n,\mathbb{C})$. It means that

$$hL_k=L_k \quad \text{for all } h\in\mathcal{G} \quad \text{and } k\in J. \tag{2}$$

Combining (2) and (1), we obtain

$$ghg^{-1}L_j=L_j \quad \text{for any } j\in J.$$

The maximality of $\mathcal{G}$ implies that $ghg^{-1}\in\mathcal{G}$ for any $h\in\mathcal{G}$. This means, in other words, that the symmetries of the grading Γ corresponding to the MAD-group $\mathcal{G}$ form a group

$$\mathcal{N}(\mathcal{G}) = \{g \in \mathrm{Aut}\,\mathrm{sl}(n,\mathbb{C}) | g\mathcal{G}g^{-1} \subseteq \mathcal{G}\}.$$

This group is usually called the normalizer of the subgroup $\mathcal{G}$ in $\mathrm{Aut}\,\mathrm{sl}(n,\mathbb{C})$.

The definition of the normalizer $\mathcal{N}(\mathcal{G})$ implies that $\mathcal{G} \subset \mathcal{N}(\mathcal{G})$. Moreover, $\mathcal{G}$ is a normal subgroup of $\mathcal{N}(\mathcal{G})$. Thus, when describing $\mathcal{N}(\mathcal{G})$, it is sufficient to inspect the quotient group $\mathcal{N}(\mathcal{G})/\mathcal{G}$.

Reference 5 shows the study of the normalizer of one MAD-group of $\mathrm{sl}(n,\mathbb{C})$, namely

$$\mathcal{G} = \{\mathrm{Ad}_A | A \in \mathcal{P}_n\}.$$

It was shown that $\mathcal{N}(\mathcal{G})/\mathcal{G}$ is isomorphic to the matrix group $\{A \in \mathbb{Z}_n^{2\times 2} | \det A = \pm 1\}$, $\mathbb{Z}_n$ being a cyclic group of order n. This result was used for obtaining all the graded contractions (see Ref. 6) of Lie algebra $\mathrm{sl}(3,\mathbb{C})$ that arise from the Pauli grading

$$\mathrm{sl}(3,\mathbb{C}) = \oplus_{(j,k)\in J}\{P_3^j Q_3^k\}_{\mathrm{lin}}, \quad J = \mathbb{Z}_3 \times \mathbb{Z}_3 \setminus \{(0,0)\}.$$

In this paper, we are going to study the symmetries of the grading corresponding to the MAD-group,

$$\mathcal{G} = \{\mathrm{Ad}_A | A \in \mathcal{P}_n \otimes \mathcal{P}_n\} \subset \mathrm{Aut}\,\mathrm{sl}(n^2,\mathbb{C}), \quad n \text{ prime}. \tag{3}$$

In the sequel we will use notation P and Q instead of P_n and Q_n, and by the letter $\mathcal{G}$ we will denote only the group given by (3).

If n and m are coprime integers, then the tensor product $\mathcal{P}_n \otimes \mathcal{P}_m$ of the Pauli groups $\mathcal{P}_n$ and $\mathcal{P}_m$ is isomorphic to the Pauli group $\mathcal{P}_{nm}$, therefore it is a natural step in investigation of symmetries of gradings to devote attention to the MAD-group given by $\mathcal{P}_n \otimes \mathcal{P}_n$.

II. THE NORMALIZER OF THE MAD-GROUP CORRESPONDING TO THE TENSOR PRODUCT $\mathcal{P}_n \otimes \mathcal{P}_n$

If $(g_i)_{i\in I}$ is a set of generators of a group $\mathcal{H} \subset \mathrm{Aut}\,L$, then $\varphi \in \mathrm{Aut}\,L$ belongs to the normalizer $\mathcal{N}(\mathcal{H})$ if and only if $\varphi g_i \varphi^{-1} \in \mathcal{H}$ for all the generators g_i. Since $\mathcal{P}_n \otimes \mathcal{P}_n = \{P^i Q^j \otimes P^k Q^l\}$, our MAD-group

$$\mathcal{G} = \{\mathrm{Ad}_{P^i Q^j \otimes P^k Q^l} | i,j,k,l \in \mathbb{Z}_n\}$$

has four generators (we use the letter I for unit matrix of order n),

$$\mathrm{Ad}_{A_1}, \quad \text{where } A_1 = P \otimes I,$$

$$\mathrm{Ad}_{A_2}, \quad \text{where } A_2 = Q \otimes I,$$

$$\mathrm{Ad}_{A_3}, \quad \text{where } A_3 = I \otimes P,$$

$$\mathrm{Ad}_{A_4}, \quad \text{where } A_4 = I \otimes Q.$$

Any element of the MAD-group $\mathcal{G}$ is characterized by a quadruple of indices in $\mathbb{Z}_n$. We know that an automorphism $\varphi \in \mathrm{Aut}\,\mathrm{sl}(n^2,\mathbb{C})$ belongs to $\mathcal{N}(\mathcal{G})$ if and only if $\varphi \mathrm{Ad}_{A_i} \varphi^{-1} \in \mathcal{G}$ for $i = 1,2,3,4$. Thus each $\varphi \in \mathcal{N}(\mathcal{G})$ is characterized by a set of 16 coefficients $(a_{ij})_{i,j=1}^4$ such that

$$\varphi\, \mathrm{Ad}_{A_j}\, \varphi^{-1} = \mathrm{Ad}_{P^{a_{1j}} Q^{a_{2j}} \otimes P^{a_{3j}} Q^{a_{4j}}} = \mathrm{Ad}_{A_1^{a_{1j}} A_2^{a_{2j}} A_3^{a_{3j}} A_4^{a_{4j}}} \quad \text{for } j = 1,2,3,4.$$

We order these 16 parameters into a matrix $C(\varphi) \in \mathbb{Z}_n^{4\times 4}$ as follows:

$$\varphi \mapsto C(\varphi) = \begin{pmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{pmatrix}. \tag{4}$$

Remark 2.1: Obviously, the assignment $\varphi \mapsto C(\varphi)$ implies that $C(\varphi)=I_4$ if and only if φ commutes with each generator of the MAD-group $\mathcal{G}$, and thus with the whole MAD-group. This means that φ necessarily belongs to $\mathcal{G}$ (due to the maximality of $\mathcal{G}$). Shortly, we have

$$C(\varphi) = I_4 \Leftrightarrow \varphi \in \mathcal{G}. \tag{5}$$

The advantage of such ordering of the 16 coefficients corresponding to $\varphi \in \mathcal{N}(\mathcal{G})$ is obvious from the following statement.

Proposition 2.2: Let $\varphi, \psi \in \mathcal{N}(\mathcal{G})$. *Then* $C(\varphi\psi)=C(\varphi)C(\psi)$.

Proof: We denote the coefficient matrices by $C(\varphi)=(a_{ij})_{i,j=1}^4$, and $C(\psi)=(b_{ij})_{i,j=1}^4$. Let us apply the automorphism $\varphi\psi$ on an element $\mathrm{Ad}_{A_p} \in \mathcal{G}$ as follows:

$$\begin{aligned}(\varphi\psi)\mathrm{Ad}_{A_p}(\varphi\psi)^{-1} &= \varphi(\psi\,\mathrm{Ad}_{A_p}\psi^{-1})\varphi^{-1} = \varphi(\mathrm{Ad}_{A_1^{b_{1p}}A_2^{b_{2p}}A_3^{b_{3p}}A_4^{b_{4p}}})\varphi^{-1} \\ &= (\varphi\,\mathrm{Ad}_{A_4}\,\varphi^{-1})^{b_{4p}}(\varphi\,\mathrm{Ad}_{A_3}\,\varphi^{-1})^{b_{3p}}(\varphi\,\mathrm{Ad}_{A_2}\,\varphi^{-1})^{b_{2p}}(\varphi\,\mathrm{Ad}_{A_1}\,\varphi^{-1})^{b_{1p}} \\ &= (\mathrm{Ad}_{A_1^{a_{14}}A_2^{a_{24}}A_3^{a_{34}}A_4^{a_{44}}})^{b_{4p}}(\mathrm{Ad}_{A_1^{a_{13}}A_2^{a_{23}}A_3^{a_{33}}A_4^{a_{43}}})^{b_{3p}}(\mathrm{Ad}_{A_1^{a_{12}}A_2^{a_{22}}A_3^{a_{32}}A_4^{a_{42}}})^{b_{2p}}(\mathrm{Ad}_{A_1^{a_{11}}A_2^{a_{21}}A_3^{a_{31}}A_4^{a_{41}}})^{b_{1p}}.\end{aligned}$$

Since $A_jA_k=\mathrm{const}\,A_kA_j$, we have $\mathrm{Ad}_{A_jA_k}=\mathrm{Ad}_{A_kA_j}$ for any $j,k=1,2,3,4$. Therefore

$$(\varphi\psi)\mathrm{Ad}_{A_p}(\varphi\psi)^{-1} = \mathrm{Ad}_{A_1^{c_{1p}}A_2^{c_{2p}}A_3^{c_{3p}}A_4^{c_{4p}}},$$

where

$$c_{1p} = a_{11}b_{1p} + a_{12}b_{2p} + a_{13}b_{3p} + a_{14}b_{4p},$$

$$c_{2p} = a_{21}b_{1p} + a_{22}b_{2p} + a_{23}b_{3p} + a_{24}b_{4p},$$

$$c_{3p} = a_{31}b_{1p} + a_{32}b_{2p} + a_{33}b_{3p} + a_{34}b_{4p},$$

$$c_{4p} = a_{41}b_{1p} + a_{42}b_{2p} + a_{43}b_{3p} + a_{44}b_{4p}.$$

This means, in brief notation, that $C(\varphi\psi)=C(\varphi)C(\psi)$. □

We prove below that the matrix $C(\varphi)$ assigned to the element φ of the normalizer $\mathcal{N}(\mathcal{G})$ characterizes a coset belonging to the quotient group $\mathcal{N}(\mathcal{G})/\mathcal{G}$.

Proposition 2.3: Let φ, ψ *belong to the normalizer* $\mathcal{N}(\mathcal{G})$ *of the MAD-group* $\mathcal{G}$. *Then* $C(\varphi)=C(\psi)$ *if and only if there exists* $h \in \mathcal{G}$ *such that* $\varphi=h\psi$.

Proof: Let $\varphi, \psi \in \mathcal{N}(\mathcal{G})$ such that $C(\varphi)=C(\psi)$. Since $\psi^{-1} \in \mathcal{N}(\mathcal{G})$ as well, we obtain from Proposition 2.2,

$$C(\varphi\psi^{-1}) = C(\varphi)C(\psi^{-1}) = C(\psi)C(\psi^{-1}) = C(\psi\psi^{-1}) = C(Id) = I_4.$$

By Remark 2.1, $\varphi\psi^{-1}$ commutes with all elements of $\mathcal{G}$, which is only possible when $\varphi\psi^{-1} \in \mathcal{G}$.

The opposite implication follows directly from Remark 2.1. □

Lemma 2.4: The outer automorphism Out_I *belongs to the normalizer* $\mathcal{N}(\mathcal{G})$, *and*

$$C(\mathrm{Out}_I) = \mathrm{diag}(-1,1,-1,1).$$

Proof: Let us denote $\varphi_0=\mathrm{Out}_I$. As φ_0 is given by the prescription $\varphi_0 X=-X^{\mathsf{T}}$, clearly $\varphi_0^{-1}=\varphi_0$. We can derive for any inner automorphism Ad_A that

$$(\varphi_0 \operatorname{Ad}_A \varphi_0^{-1})(X) = (\varphi_0 \operatorname{Ad}_A)(-X^{\mathsf{T}}) = \varphi_0(-A^{-1}X^{\mathsf{T}}A)$$
$$= (A^{-1}X^{\mathsf{T}}A)^{\mathsf{T}} = A^{\mathsf{T}}XA^{-\mathsf{T}} = (A^{-\mathsf{T}})^{-1}XA^{-\mathsf{T}} = \operatorname{Ad}_{A^{-\mathsf{T}}}(X),$$

where we used abbreviated notation $A^{-\mathsf{T}}$ instead of $(A^{-1})^{\mathsf{T}}$. This notation is used in the sequel as well.

Thus we have shown that the action of Out_I on any inner automorphism Ad_A is

$$\mathrm{Out}_I \operatorname{Ad}_A \mathrm{Out}_I^{-1} = \operatorname{Ad}_{A^{-\mathsf{T}}}. \tag{6}$$

Now, for each generator Ad_{A_j}, $j=1,2,3,4$, of the MAD-group $\mathcal{G}$, we prove that $\varphi_0 \operatorname{Ad}_{A_j} \varphi_0^{-1}$ belongs to $\mathcal{G}$:

Let us recall the following trivial properties of matrices P and Q and the properties of tensor product:

(i) $(A\otimes B)^{-1}=A^{-1}\otimes B^{-1}$;
(ii) $(A\otimes B)^{\mathsf{T}}=A^{\mathsf{T}}\otimes B^{\mathsf{T}}$;
(iii) $P^{\mathsf{T}}=P$, as P is diagonal;
(iv) $Q^{-1}=Q^{\mathsf{T}}$, as Q is a permutation matrix.

Using these relations, we obtain

(1) $A_1^{-\mathsf{T}}=(P\otimes I)^{-\mathsf{T}}=P^{-\mathsf{T}}\otimes I=P^{-1}\otimes I=(P\otimes I)^{-1}=A_1^{-1}$;
(2) $A_2^{-\mathsf{T}}=(Q\otimes I)^{-\mathsf{T}}=Q^{-\mathsf{T}}\otimes I=Q\otimes I=A_2$;
(3) $A_3^{-\mathsf{T}}=(I\otimes P)^{-\mathsf{T}}=I\otimes P^{-\mathsf{T}}=I\otimes P^{-1}=(I\otimes P)^{-1}=A_3^{-1}$;
(4) $A_4^{-\mathsf{T}}=(I\otimes Q)^{-\mathsf{T}}=I\otimes Q^{-\mathsf{T}}=I\otimes Q=A_4$.

Statements (1)–(4) together with Eq. (6) already prove the lemma. □

Remark 2.5: Product of two outer automorphisms is an inner automorphism. Thus, when describing the set of all automorphisms in $\mathcal{N}(\mathcal{G})$, we can focus on the subgroup $\mathcal{N}_{\mathrm{in}}(\mathcal{G})$ containing all the inner automorphisms in $\mathcal{N}(\mathcal{G})$. The whole $\mathcal{N}(\mathcal{G})$ can then be described as

$$\mathcal{N}(\mathcal{G}) = \mathcal{N}_{\mathrm{in}}(\mathcal{G}) \cup \mathrm{Out}_I \mathcal{N}_{\mathrm{in}}(\mathcal{G}).$$

The following theorem shows the connection between normalizers of these MAD-groups and the symplectic groups over finite field which were introduced in Ref. 2.

Theorem 2.6: *Let* Ad_A *be an inner automorphism contained in the normalizer* $\mathcal{N}(\mathcal{G})$ *of the MAD-group* $\mathcal{G}$, *and let* $C(\mathrm{Ad}_A)$ *be the coefficient matrix corresponding to* Ad_A. *Then*

$$C(\mathrm{Ad}_A) \in \mathrm{Sp}(4,\mathbb{Z}_n) := \{X \in \mathbb{Z}_n^{4\times 4} | X^{\mathsf{T}}JX = J\}, \tag{7}$$

where

$$J = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix} = I_2 \otimes \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

Proof: Let us denote $C(\mathrm{Ad}_A)=(a_{ij})_{i,j=1}^4$. The definition of the matrix $C(\mathrm{Ad}_A)$ implies that

$$\operatorname{Ad}_A \operatorname{Ad}_{A_p}(\operatorname{Ad}_A)^{-1} = \operatorname{Ad}_{A^{-1}A_pA} = \operatorname{Ad}_{A_1^{a_{1p}}A_2^{a_{2p}}A_3^{a_{3p}}A_4^{a_{4p}}} \quad \text{for } p=1,2,3,4. \tag{8}$$

As $\mathrm{Ad}_K=\mathrm{Ad}_H$ if and only if $K=\alpha H$ for some $\alpha\in\mathbb{C}-\{0\}$, we obtain from (8) existence of four nonzero constants $\alpha_p, p=1,2,3,4$, such that

$$A_p = \alpha_p A A_1^{a_{1p}} A_2^{a_{2p}} A_3^{a_{3p}} A_4^{a_{4p}} A^{-1}. \tag{9}$$

We derive easily from the basic relation $QP=\omega PQ$ that

$$A_1A_2 = \omega^{-1}A_2A_1, \tag{10}$$

$$A_3A_4 = \omega^{-1}A_4A_3. \tag{11}$$

The remaining pairs A_i, A_j commute

$$A_1A_3 = A_3A_1, \tag{12}$$

$$A_1A_4 = A_4A_1, \tag{13}$$

$$A_2A_3 = A_3A_2, \tag{14}$$

$$A_2A_4 = A_4A_2. \tag{15}$$

By inputting A_1, A_2 expressed in the form (9) into the relation (10), we obtain

$$\alpha_1 A A_1^{a_{11}} A_2^{a_{21}} A_3^{a_{31}} A_4^{a_{41}} A^{-1} \alpha_2 A A_1^{a_{12}} A_2^{a_{22}} A_3^{a_{32}} A_4^{a_{42}} A^{-1}$$
$$= \omega^{-1} \alpha_2 A A_1^{a_{12}} A_2^{a_{22}} A_3^{a_{32}} A_4^{a_{42}} A^{-1} \alpha_1 A A_1^{a_{11}} A_2^{a_{21}} A_3^{a_{31}} A_4^{a_{41}} A^{-1},$$

and, after simplification and using relations (10)–(15),

$$\omega^{a_{21}a_{12}+a_{41}a_{32}} A_1^{a_{11}+a_{12}} A_2^{a_{21}+a_{22}} A_3^{a_{31}+a_{32}} A_4^{a_{41}+a_{42}} = \omega^{-1+a_{22}a_{11}+a_{42}a_{31}} A_1^{a_{11}+a_{12}} A_2^{a_{21}+a_{22}} A_3^{a_{31}+a_{32}} A_4^{a_{41}+a_{42}}.$$

This implies that $\omega^{a_{21}a_{12}+a_{41}a_{32}} = \omega^{-1+a_{22}a_{11}+a_{42}a_{31}}$, and therefore

$$1 = a_{11}a_{22} - a_{21}a_{12} + a_{31}a_{42} - a_{41}a_{32} \pmod{n}. \tag{16}$$

Analogously, the equations (11)–(15) result in

$$1 = a_{13}a_{24} - a_{14}a_{23} + a_{33}a_{44} - a_{34}a_{43} \pmod{n}, \tag{17}$$

$$0 = a_{11}a_{23} - a_{13}a_{21} + a_{31}a_{43} - a_{33}a_{41} \pmod{n}, \tag{18}$$

$$0 = a_{11}a_{24} - a_{14}a_{21} + a_{31}a_{44} - a_{34}a_{41} \pmod{n}, \tag{19}$$

$$0 = a_{12}a_{23} - a_{13}a_{22} + a_{32}a_{43} - a_{33}a_{42} \pmod{n}, \tag{20}$$

$$0 = a_{12}a_{24} - a_{14}a_{22} + a_{32}a_{44} - a_{34}a_{42} \pmod{n}. \tag{21}$$

It can be easily verified (by a direct calculation) that the matrix $(a_{ij})_{i,j=1}^4$ belongs to the group $\mathrm{Sp}(4,\mathbb{Z}_n)$ if and only if the matrix elements a_{ij} fulfill equations (16)–(21). □

Remark 2.7: We were notified[9] that the set $\mathrm{Sp}(4,\mathbb{Z}_n)$ defined analogously to (7) is a group even in the case when $\mathbb{Z}_n$ is not a field. All our previous considerations hold therefore for any positive integer n. But our deductions in the sequel already need n to be a prime number.

We are going to prove that the mapping given by (4) is in fact the mapping on the whole symplectic group $\mathrm{Sp}(4,\mathbb{F}_n)$. To show it we need to find for any element of $\mathrm{Sp}(4,\mathbb{F}_n)$ its preimage, or equivalently for any generator of $\mathrm{Sp}(4,\mathbb{F}_n)$ its preimage.

To simplify the proof we need to find the smallest possible set of generators of $\mathrm{Sp}(4,\mathbb{F}_n)$. In Ref. 8 a set of generators of the group $\mathrm{Sp}(2m,K)$ over a finite field K is described. In case $m=2$, the set of generators contains n^4-n^2+n+1 elements, where n is the cardinality of K. As we show in Appendix B, it is possible to reduce the number of generators of the group $\mathrm{Sp}(4,\mathbb{F}_n)$ to four matrices. In formal notation

$$\mathrm{Sp}(4,\mathbb{F}_n)=\langle D_1,D_2,D_3,D_4\rangle,$$

where

$$D_1=\begin{pmatrix}1&1&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix},\quad D_2=\begin{pmatrix}0&1&0&0\\-1&0&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix},$$

$$D_3=\begin{pmatrix}0&0&1&0\\0&0&0&1\\1&0&0&0\\0&1&0&0\end{pmatrix},\quad \text{and}\quad D_4=\begin{pmatrix}1&0&0&0\\0&1&0&-1\\1&0&1&0\\0&0&0&1\end{pmatrix}. \tag{22}$$

(We recall that for elements $k_1,k_2,\ldots,k_s$ of a group G, the notation $\langle k_1,k_2,\ldots,k_s\rangle$ means the smallest subgroup of the group G containing $k_1,k_2,\ldots,k_s$.) We show that these four matrices are images of inner automorphisms which belong to the normalizer of the group $\mathcal{G}$.

Proposition 2.8: Let n be a prime. Then for the four matrices D_j as introduced in (22), there exist inner automorphisms $\varphi_j=\mathrm{Ad}_{B_j}\in\mathcal{N}_{\mathrm{in}}(\mathcal{G})$ such that $D_j=C(\varphi_j)=C(\mathrm{Ad}_{B_j})$.

The proof is postponed to the Appendix A since it is rather technical and we do not want to interrupt coherency in the content of the paper.

The immediate consequence of the previous proposition is the following main result of the paper.

Theorem 2.9: *Let n be a prime. The mapping $\varphi\mapsto C(\varphi)$ defined in (4) is an isomorphism between groups*

$$\mathcal{N}_{\mathrm{in}}(\mathcal{G})/\mathcal{G}\simeq\mathrm{Sp}(4,\mathbb{F}_n)=\{X\in\mathbb{Z}_n^{4\times4}|X^{\mathsf{T}}JX=J\},$$

and

$$\mathcal{N}(\mathcal{G})/\mathcal{G}\simeq\{X\in\mathbb{Z}_n^{4\times4}|X^{\mathsf{T}}JX=\pm J\},$$

where

$$J=\begin{pmatrix}0&1&0&0\\-1&0&0&0\\0&0&0&1\\0&0&-1&0\end{pmatrix}=I_2\otimes\begin{pmatrix}0&1\\-1&0\end{pmatrix}.$$

Proof:

(i) The mapping $\varphi\mapsto C(\varphi)$ from $\mathcal{N}_{\mathrm{in}}(\mathcal{G})/\mathcal{G}$ to $\mathrm{Sp}(4,\mathbb{F}_n)$ is a homomorphism, as $C(\varphi\psi)=C(\varphi)C(\psi)$, which was proved in Proposition 2.2.

(ii) The mapping $\varphi\mapsto C(\varphi)$ from $\mathcal{N}_{\mathrm{in}}(\mathcal{G})/\mathcal{G}$ to $\mathrm{Sp}(4,\mathbb{F}_n)$ is injective, as shown in Proposition 2.3.

(iii) The group $\mathrm{Sp}(4,\mathbb{F}_n)$ is generated by four matrices D_1,D_2,D_3,D_4 (see Theorem 3.1 in Appendix B).

(iv) All the matrices D_j, $j=1,2,3,4$, have their inverse images $\varphi_j\in\mathcal{N}_{\mathrm{in}}(\mathcal{G})/\mathcal{G}$, such that $C(\varphi_j)=D_j$ (see Proposition 2.8). This implies that the mapping $\varphi\mapsto C(\varphi)$ is also surjective.

In total, we see that the mapping $\varphi\mapsto C(\varphi)$ is an isomorphism from $\mathcal{N}_{\mathrm{in}}(\mathcal{G})/\mathcal{G}$ onto $\mathrm{Sp}(4,\mathbb{F}_n)$.

To show isomorphism between $\mathcal{N}(\mathcal{G})/\mathcal{G}$ and $\mathrm{Sp}(4,\mathbb{F}_n)\otimes\mathbb{Z}_2$, it is enough to use Remark 2.5 and the fact that the matrix $M:=C(\mathrm{Out}_I)=\mathrm{diag}(-1,1,-1,1)$ corresponding to the outer automorphisms $\mathrm{Out}_I\in\mathcal{N}(\mathcal{G})$ satisfies the equality $M^{\mathsf{T}}JM=-J$. □

III. CONCLUSIONS

Let us summarize the content of the paper:

(1) The normalizer $\mathcal{N}(\mathcal{G})$ of the MAD-group $\mathcal{G}=\{\mathrm{Ad}_{P^iQ^j\otimes P^kQ^l} | i,j,k,l\in\mathbb{Z}_n\}\subset \mathrm{Aut}\ \mathrm{sl}(n^2,\mathbb{C})$ consists of two subsets,

$$\mathcal{N}_{\mathrm{in}}(\mathcal{G}) \quad \text{the group of all inner automorphisms in } \mathcal{N}(\mathcal{G}),$$

$$\mathrm{Out}_I\mathcal{N}_{\mathrm{in}}(\mathcal{G}) \quad \text{the set of all outer automorphisms in } \mathcal{N}(\mathcal{G}).$$

(2) We provide an explicit expression of the four generators of $\mathcal{N}_{\mathrm{in}}(\mathcal{G})/\mathcal{G}$, namely the inner automorphisms Ad_{B_j}, $j=1,2,3,4$ (see Proposition 2.8).

(3) Altogether, we can write the set of generators

$$\mathcal{G}=\langle \mathrm{Ad}_{P\otimes I},\mathrm{Ad}_{Q\otimes I},\mathrm{Ad}_{I\otimes P},\mathrm{Ad}_{I\otimes Q}\rangle,$$

$$\mathcal{N}_{\mathrm{in}}(\mathcal{G})/\mathcal{G}=\langle \mathrm{Ad}_{B_1},\mathrm{Ad}_{B_2},\mathrm{Ad}_{B_3},\mathrm{Ad}_{B_4}\rangle,$$

$$\mathcal{N}(\mathcal{G})=\mathcal{N}_{\mathrm{in}}(\mathcal{G})\cup \mathrm{Out}_I\mathcal{N}_{\mathrm{in}}(\mathcal{G}).$$

(4) Thus, one can generate each element of the normalizer from the set $\{\mathrm{Ad}_{B_1},\mathrm{Ad}_{B_2},\mathrm{Ad}_{B_3},\mathrm{Ad}_{B_4},\mathrm{Out}_I,\mathrm{Ad}_{P\otimes I},\mathrm{Ad}_{Q\otimes I},\mathrm{Ad}_{I\otimes P},\mathrm{Ad}_{I\otimes Q}\}$. In formal notation,

$$\mathcal{N}(\mathcal{G})=\langle \mathrm{Ad}_{B_1},\mathrm{Ad}_{B_2},\mathrm{Ad}_{B_3},\mathrm{Ad}_{B_4},\mathrm{Out}_I,\mathrm{Ad}_{P\otimes I},\mathrm{Ad}_{Q\otimes I},\mathrm{Ad}_{I\otimes P},\mathrm{Ad}_{I\otimes Q}\rangle,$$

where the matrices B_j were defined in the proof of Proposition 2.8.

The description of the normalizer as done in this article was only possible for n prime. For n nonprime, the problem is still open.

It was shown previously that for the Pauli grading, the normalizer of the respective MAD-group is isomorphic to $\mathrm{SL}(2,\mathbb{Z}_n)$, which is isomorphic to $\mathrm{Sp}(2,\mathbb{Z}_n)$, for any positive integer $n>1$. This suggests that in the case of a MAD-group formed by inner automorphisms generated by

$$\underbrace{\mathcal{P}_n\otimes\mathcal{P}_n\otimes\ \ldots\ \otimes\mathcal{P}_n}_{k\text{–times}},$$

the normalizer may be isomorphic to $\mathrm{Sp}(2k,\mathbb{Z}_n)$.

Let us mention that the normalizer has not yet been described for any MAD-group containing outer automorphisms.

APPENDIX A

This section contains a proof of Proposition 2.8. The matrices D_j's considered in the proof are defined by (22).

Proof: In order to prove that an automorphism $\varphi_j=\mathrm{Ad}_{B_j}$ is an inverse image of D_j, we must express the action of φ_j on the basis elements $P\otimes I,Q\otimes I,I\otimes P,I\otimes Q$ of $\mathcal{G}$ again in terms of $P\otimes I,Q\otimes I,I\otimes P,I\otimes Q$. The coefficients a_{kl} describing the action of φ_j [as introduced in (4)] then form the matrix D_j. In the following we set the four matrices B_j, and verify that each satisfies the equation $D_j=C(\mathrm{Ad}_{B_j})$.

Throughout the proof, we use the coefficient ω, which is, as defined previously, the nth root of unity, $\omega=\omega_n=e^{2\pi i/n}$. We also shorten the notation of I_n to I.

And, finally, the elements of matrices P,Q (whose indices are also counted modulo n) can be written in terms of the Kronecker symbol as

$$P_{ij}=\delta_{ij}\omega^j,\quad Q_{ij}=\delta_{i(j-1)},\quad Q^{\mathsf{T}}_{ij}=\delta_{i(j+1)}. \tag{A1}$$

(1) We define $\varphi_1=\mathrm{Ad}_{B_1}$, where

$$B_1=\widetilde{B}_1\otimes I,\quad \widetilde{B}_1=\mathrm{diag}(b_0,b_1,\ldots,b_{(n-1)}),\quad b_j=\varepsilon^j\omega^{j(j-1)/2},\quad \varepsilon=\omega^{-(n-1)/2}.$$

As $\widetilde{B}_1$, $\widetilde{B}_1^{-1}$, and P are diagonal, they all mutually commute, and thus $B_1^{-1}(P\otimes I)B_1=(\widetilde{B}_1\otimes I)^{-1}(P\otimes I)(\widetilde{B}_1\otimes I)=(\widetilde{B}_1^{-1}\otimes I)(P\widetilde{B}_1\otimes I)=(\widetilde{B}_1^{-1}P\widetilde{B}_1)\otimes I=(\widetilde{B}_1^{-1}\widetilde{B}_1P)\otimes I=P\otimes I$. In other words,

$$\varphi_1\,\mathrm{Ad}_{P\otimes I}\,\varphi_1^{-1}=\mathrm{Ad}_{B_1}\,\mathrm{Ad}_{P\otimes I}\,\mathrm{Ad}_{B_1^{-1}}=\mathrm{Ad}_{B_1^{-1}(P\otimes I)B_1}=\mathrm{Ad}_{P\otimes I},$$

which means, according to the definition of $C(\varphi_1)$, that the first column of the matrix $C(\varphi_1)$ is

$$(a_{11},a_{21},a_{31},a_{41})^{\mathsf{T}}=(1,0,0,0)^{\mathsf{T}}.$$

Now we apply φ_1 on the second generator of the group $\mathcal{G}$, which is the inner automorphism defined by the matrix $Q\otimes I$. In fact, we need to express $B_1^{-1}(Q\otimes I)B_1$ in terms of the basis matrices $P\otimes I,Q\otimes I,I\otimes P,I\otimes Q$. Using the notation of elements of P and Q introduced in (A1), we obtain

$$\begin{aligned}(\widetilde{B}_1^{-1}Q\widetilde{B}_1)_{ij}&=\sum_{k=0}^{n-1}\sum_{l=0}^{n-1}(\widetilde{B}_1^{-1})_{ik}Q_{kl}(\widetilde{B}_1)_{lj}\\&=\sum_{k=0}^{n-1}\sum_{l=0}^{n-1}\delta_{ik}\varepsilon^{-k}\omega^{-k(k-1)/2}\delta_{k(l-1)}\delta_{lj}\varepsilon^j\omega^{j(j-1)/2}\\&=\sum_{k=0}^{n-1}\delta_{ik}\varepsilon^{j-k}\omega^{[j(j-1)-k(k-1)]/2}\delta_{k(j-1)}\\&=\varepsilon\,\delta_{i(j-1)}\omega^{j-1}\end{aligned}$$

$$(PQ)_{ij}=\sum_{k=0}^{n-1}P_{ik}Q_{kj}=\sum_{k=0}^{n-1}\delta_{ik}\omega^k\delta_{k(j-1)}=\delta_{i(j-1)}\omega^{j-1}.$$

We see that the matrix $B_1^{-1}(Q\otimes I)B_1$ is just an ε multiple of PQ, and it follows that

$$\varphi_1\,\mathrm{Ad}_{Q\otimes I}\,\varphi_1^{-1}=\mathrm{Ad}_{B_1}\,\mathrm{Ad}_{Q\otimes I}\,\mathrm{Ad}_{B_1^{-1}}=\mathrm{Ad}_{B_1^{-1}(Q\otimes I)B_1}=\mathrm{Ad}_{(\tilde{B}_1^{-1}Q\tilde{B}_1)\otimes I}=\mathrm{Ad}_{(\varepsilon PQ)\otimes I}=\mathrm{Ad}_{PQ\otimes I}.$$

The second column of the matrix $C(\varphi_1)$ is thus equal to

$$(a_{12},a_{22},a_{32},a_{42})^{\mathsf{T}}=(1,1,0,0)^{\mathsf{T}}.$$

By simple matrix multiplication, we see that $B_1^{-1}(I\otimes P)B_1=(\widetilde{B}_1^{-1}\otimes I)(I\otimes P)(\widetilde{B}_1\otimes I)=(\widetilde{B}_1^{-1}\widetilde{B}_1)\otimes P=I\otimes P$; which means $\varphi_1\,\mathrm{Ad}_{I\otimes P}\,\varphi_1^{-1}=\mathrm{Ad}_{B_1}\,\mathrm{Ad}_{I\otimes P}\,\mathrm{Ad}_{B_1^{-1}}=\mathrm{Ad}_{B_1^{-1}(I\otimes P)B_1}=\mathrm{Ad}_{I\otimes P}$, and therefore

$$(a_{13},a_{23},a_{33},a_{43})^{\mathsf{T}}=(0,0,1,0)^{\mathsf{T}}.$$

Analogously, setting Q on the place of P, we have $B_1^{-1}(I\otimes Q)B_1=(\widetilde{B}_1^{-1}\otimes I)(I\otimes Q)(\widetilde{B}_1\otimes I)=(\widetilde{B}_1^{-1}\widetilde{B}_1)\otimes Q=I\otimes Q$; which means $\varphi_1\,\mathrm{Ad}_{I\otimes Q}\,\varphi_1^{-1}=\mathrm{Ad}_{B_1}\,\mathrm{Ad}_{I\otimes Q}\,\mathrm{Ad}_{B_1^{-1}}=\mathrm{Ad}_{B_1^{-1}(I\otimes Q)B_1}=\mathrm{Ad}_{I\otimes Q}$, and therefore

$$(a_{14},a_{24},a_{34},a_{44})^{\mathsf{T}} = (0,0,0,1)^{\mathsf{T}}.$$

Thus, we have shown that

$$C(\varphi_1) = D_1 = \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

(2) We define $\varphi_2 = \mathrm{Ad}_{B_2}$, where

$$B_2 = \widetilde{B}_2 \otimes I, \quad (\widetilde{B}_2)_{ij} = \omega^{ij}, \quad i,j = 0,1,\ldots,n-1.$$

Note that $\widetilde{B}_2$ is the famous Sylvester matrix.

In preparation for describing the action of Ad_{B_2}, we apply the matrix $\widetilde{B}_2$ on P, Q, and Q^{T} from both right and left,

$$(P\widetilde{B}_2)_{ij} = \sum_{k=0}^{n-1} P_{ik}(\widetilde{B}_2)_{kj} = \sum_{k=0}^{n-1} \delta_{ik}\omega^k\omega^{kj} = \omega^i\omega^{ij} = \omega^{i(j+1)},$$

$$(\widetilde{B}_2Q^{\mathsf{T}})_{ij} = \sum_{k=0}^{n-1} (\widetilde{B}_2)_{ik}(Q^{\mathsf{T}})_{kj} = \sum_{k=0}^{n-1} \omega^{ik}\delta_{k(j+1)} = \omega^{i(j+1)},$$

$$(Q\widetilde{B}_2)_{ij} = \sum_{k=0}^{n-1} Q_{ik}(\widetilde{B}_2)_{kj} = \sum_{k=0}^{n-1} \delta_{i(k-1)}\omega^{kj} = \omega^{(i+1)j},$$

$$(\widetilde{B}_2P)_{ij} = \sum_{k=0}^{n-1} (\widetilde{B}_2)_{ik}P_{kj} = \sum_{k=0}^{n-1} \omega^{ik}\delta_{kj}\omega^j = \omega^{ij}\omega^j = \omega^{(i+1)j}.$$

We easily conclude that

$$P\widetilde{B}_2 = \widetilde{B}_2Q^{\mathsf{T}} \Rightarrow \widetilde{B}_2^{-1}P\widetilde{B}_2 = Q^{\mathsf{T}} = Q^{-1},$$

$$Q\widetilde{B}_2 = \widetilde{B}_2P \Rightarrow \widetilde{B}_2^{-1}Q\widetilde{B}_2 = P.$$

Using these relations, the way to find the coefficients of $C(\varphi_2) = C(\mathrm{Ad}_{B_2})$ is quite straightforward as follows:

$$B_2^{-1}(P\otimes I)B_2 = (\widetilde{B}_2\otimes I)^{-1}(P\otimes I)(\widetilde{B}_2\otimes I) = (\widetilde{B}_2^{-1}\otimes I)(P\widetilde{B}_2\otimes I) = (\widetilde{B}_2^{-1}P\widetilde{B}_2)\otimes I = Q^{-1}\otimes I.$$

Therefore, $\varphi_2\,\mathrm{Ad}_{P\otimes I}\,\varphi_2^{-1} = \mathrm{Ad}_{B_2^{-1}(P\otimes I)B_2} = \mathrm{Ad}_{(Q\otimes I)^{-1}}$, and we have found the coefficients

$$(a_{11},a_{21},a_{31},a_{41})^{\mathsf{T}} = (0,-1,0,0)^{\mathsf{T}};$$

$$B_2^{-1}(Q\otimes I)B_2 = (\widetilde{B}_2\otimes I)^{-1}(Q\otimes I)(\widetilde{B}_2\otimes I) = (\widetilde{B}_2^{-1}\otimes I)(Q\widetilde{B}_2\otimes I) = (\widetilde{B}_2^{-1}Q\widetilde{B}_2)\otimes I = P\otimes I.$$

Therefore, $\varphi_2\,\mathrm{Ad}_{Q\otimes I}\,\varphi_2^{-1}=\mathrm{Ad}_{B_2^{-1}(Q\otimes I)B_2}=\mathrm{Ad}_{(P\otimes I)}$, and the respective coefficients of D_2 are

$$(a_{12},a_{22},a_{32},a_{42})^{\mathsf{T}}=(1,0,0,0)^{\mathsf{T}};$$

$B_2^{-1}(I\otimes P)B_2=(\tilde{B}_2\otimes I)^{-1}(I\otimes P)(\tilde{B}_2\otimes I)=(\tilde{B}_2^{-1}\otimes I)(\tilde{B}_2\otimes P)=(\tilde{B}_2^{-1}\tilde{B}_2)\otimes P=I\otimes P$. In this case, $\varphi_2\,\mathrm{Ad}_{I\otimes P}\,\varphi_2^{-1}=\mathrm{Ad}_{B_2^{-1}(I\otimes P)B_2}=\mathrm{Ad}_{(I\otimes P)}$, and the respective coefficients of D_2 are

$$(a_{13},a_{23},a_{33},a_{43})^{\mathsf{T}}=(0,0,1,0)^{\mathsf{T}};$$

$B_2^{-1}(I\otimes Q)B_2=(\tilde{B}_2\otimes I)^{-1}(I\otimes Q)(\tilde{B}_2\otimes I)=(\tilde{B}_2^{-1}\otimes I)(\tilde{B}_2\otimes Q)=(\tilde{B}_2^{-1}\tilde{B}_2)\otimes Q=I\otimes Q$. So lastly, we obtain $\varphi_2\,\mathrm{Ad}_{I\otimes Q}\,\varphi_2^{-1}=\mathrm{Ad}_{B_2^{-1}(I\otimes Q)B_2}=\mathrm{Ad}_{(I\otimes Q)}$, and obviously,

$$(a_{14},a_{24},a_{34},a_{44})^{\mathsf{T}}=(0,0,0,1)^{\mathsf{T}}.$$

Thus, the matrix $C(\varphi_2)$ is equal to

$$C(\varphi_2)=D_2=\begin{pmatrix}0&1&0&0\\-1&0&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix}.$$

(3) We define $\varphi_3=\mathrm{Ad}_{B_3}$, where

$$(B_3)_{pq}=\delta_{p_1q_2}\delta_{p_2q_1},\quad p=p_1n+p_2,\quad q=q_1n+q_2,\quad p_1,p_2,q_1,q_2\in\{0,1,\ldots,n-1\}.$$

(One can easily verify by a direct calculation that $B_3^{-1}=B_3$.)

In order to satisfy the relation $C(\varphi_3)=C(\mathrm{Ad}_{B_3})=D_3$, it is sufficient to show that the matrix B_3 fulfills the following equations:

$$B_3^{-1}(P\otimes I)B_3=I\otimes P,\quad B_3^{-1}(I\otimes P)B_3=P\otimes I,$$

$$B_3^{-1}(Q\otimes I)B_3=I\otimes Q,\quad B_3^{-1}(I\otimes Q)B_3=Q\otimes I.$$

In fact, we have found B_3 such that even a more general relation is satisfied,

$$B_3^{-1}(K\otimes L)B_3=L\otimes K\ \text{for any matrices}\ K,L\in\mathbb{C}^{n\times n}. \tag{A2}$$

The matrix elements of B_3 are $\delta_{p_1q_2}\delta_{p_2q_1}$ as introduced above. In order to prove Eq. (A2), it is sufficient to express the (pq)th element of the tensor product $K\otimes L$ as $(K\otimes L)_{pq}=K_{p_1q_1}L_{p_2q_2}$, and proceed by

$$\begin{aligned}[B_3^{-1}(K\otimes L)B_3]_{pq}&=[B_3^{-1}(K\otimes L)B_3]_{(p_1n+p_2)(q_1n+q_2)}\\&=\sum_{r_1,r_2=0}^{n-1}(B_3^{-1})_{(p_1n+p_2)(r_1n+r_2)}[(K\otimes L)B_3]_{(r_1n+r_2)(q_1n+q_2)}\\&=\sum_{r_1,r_2=0}^{n-1}\sum_{s_1,s_2=0}^{n-1}(B_3^{-1})_{(p_1n+p_2)(r_1n+r_2)}(K\otimes L)_{(r_1n+r_2)(s_1n+s_2)}(B_3)_{(s_1n+s_2)(q_1n+q_2)}\\&=\sum_{r_1,r_2=0}^{n-1}\sum_{s_1,s_2=0}^{n-1}\delta_{p_1r_2}\delta_{p_2r_1}K_{r_1s_1}L_{r_2s_2}\delta_{s_1q_2}\delta_{s_2q_1}\\&=K_{p_2q_2}L_{p_1q_1}=L_{p_1q_1}K_{p_2q_2}=(L\otimes K)_{pq}.\end{aligned}$$

(4) We define $\varphi_4=\mathrm{Ad}_{B_4}$, where

$$(B_4)_{pq} = \delta_{(p_1-p_2)q_1}\delta_{p_2q_2}, \quad p = p_1 n + p_2, \quad q = q_1 n + q_2, \quad p_1,p_2,q_1,q_2 \in \{0,1,\ldots,n-1\}.$$

Remember that, with the matrix coefficients p_1, p_2, q_1, q_2, we count modulo n.

We first express the matrices relevant for the proof by means of their pqth elements,

$$(P \otimes I)_{pq} = \omega^{p_1}\delta_{p_1q_1}\delta_{p_2q_2},$$

$$(P \otimes P)_{pq} = \omega^{p_1+p_2}\delta_{p_1q_1}\delta_{p_2q_2},$$

$$(I \otimes P)_{pq} = \omega^{p_2}\delta_{p_1q_1}\delta_{p_2q_2},$$

$$(Q \otimes I)_{pq} = \delta_{(p_1+1)q_1}\delta_{p_2q_2},$$

$$(Q^{-1} \otimes Q)_{pq} = \delta_{p_1(q_1+1)}\delta_{(p_2+1)q_2},$$

$$(I \otimes Q)_{pq} = \delta_{p_1q_1}\delta_{(p_2+1)q_2}.$$

Then, we proceed by showing that the elements of matrix D_4 indeed reflect the action of the automorphism $\varphi_4 = \mathrm{Ad}_{B_4}$,

$$\begin{aligned}
[(P \otimes I)B_4]_{pq} &= \sum_{r_1,r_2=0}^{n-1} (P \otimes I)_{(p_1n+p_2)(r_1n+r_2)}(B_4)_{(r_1n+r_2)(q_1n+q_2)} \\
&= \sum_{r_1,r_2=0}^{n-1} \omega^{p_1}\delta_{p_1r_1}\delta_{p_2r_2}\delta_{(r_1-r_2)q_1}\delta_{r_2q_2} \\
&= \omega^{p_1}\delta_{(p_1-p_2)q_1}\delta_{p_2q_2},
\end{aligned}$$

$$\begin{aligned}
[B_4(P \otimes P)]_{pq} &= \sum_{r_1,r_2=0}^{n-1} (B_4)_{(p_1n+p_2)(r_1n+r_2)}(P \otimes P)_{(r_1n+r_2)(q_1n+q_2)} \\
&= \sum_{r_1,r_2=0}^{n-1} \delta_{(p_1-p_2)r_1}\delta_{p_2r_2}\omega^{r_1+r_2}\delta_{r_1q_1}\delta_{r_2q_2} \\
&= \delta_{(p_1-p_2)q_1}\delta_{p_2q_2}\omega^{q_1+q_2} = \omega^{p_1}\delta_{(p_1-p_2)q_1}\delta_{p_2q_2}.
\end{aligned}$$

Thus we have shown that $(P \otimes I)B_4 = B_4(P \otimes P)$, and consequently, $B_4^{-1}(P \otimes I)B_4 = P \otimes P$, which gives the coefficients

$$(a_{11},a_{21},a_{31},a_{41})^{\mathsf{T}} = (1,0,1,0)^{\mathsf{T}},$$

$$\begin{aligned}
[(Q \otimes I)B_4]_{pq} &= \sum_{r_1,r_2=0}^{n-1} (Q \otimes I)_{(p_1n+p_2)(r_1n+r_2)}(B_4)_{(r_1n+r_2)(q_1n+q_2)} \\
&= \sum_{r_1,r_2=0}^{n-1} \delta_{(p_1+1)r_1}\delta_{p_2r_2}\delta_{(r_1-r_2)q_1}\delta_{r_2q_2} \\
&= \delta_{p_2q_2}\delta_{(p_1+1)(q_1+q_2)},
\end{aligned}$$

$$[B_4(Q\otimes I)]_{pq} = \sum_{r_1,r_2=0}^{n-1} (B_4)_{(p_1n+p_2)(r_1n+r_2)}(Q\otimes I)_{(r_1n+r_2)(q_1n+q_2)}$$
$$= \sum_{r_1,r_2=0}^{n-1} \delta_{(p_1-p_2)r_1}\delta_{p_2r_2}\delta_{(r_1+1)q_1}\delta_{r_2q_2}$$
$$= \delta_{p_2q_2}\delta_{(p_1-p_2)(q_1-1)} = \delta_{p_2q_2}\delta_{(p_1+1)(q_1+q_2)}.$$

Combining the two equations, we obtain $(Q\otimes I)B_4=B_4(Q\otimes I)$, and $B_4^{-1}(Q\otimes I)B_4$. In terms of the matrix coefficients of D_4, it writes as

$$(a_{12},a_{22},a_{32},a_{42})^{\mathsf{T}} = (0,1,0,0)^{\mathsf{T}},$$

.

$$[(I\otimes P)B_4]_{pq} = \sum_{r_1,r_2=0}^{n-1} (I\otimes P)_{(p_1n+p_2)(r_1n+r_2)}(B_4)_{(r_1n+r_2)(q_1n+q_2)}$$
$$= \sum_{r_1,r_2=0}^{n-1} \omega^{p_2}\delta_{p_1r_1}\delta_{p_2r_2}\delta_{(r_1-r_2)q_1}\delta_{r_2q_2}$$
$$= \omega^{p_2}\delta_{(p_1-p_2)q_1}\delta_{p_2q_2},$$

$$[B_4(I\otimes P)]_{pq} = \sum_{r_1,r_2=0}^{n-1} (B_4)_{(p_1n+p_2)(r_1n+r_2)}(I\otimes P)_{(r_1n+r_2)(q_1n+q_2)}$$
$$= \sum_{r_1,r_2=0}^{n-1} \delta_{(p_1-p_2)r_1}\delta_{p_2r_2}\omega^{r_2}\delta_{r_1q_1}\delta_{r_2q_2}$$
$$= \omega^{p_2}\delta_{(p_1-p_2)q_1}\delta_{p_2q_2}.$$

From $(I\otimes P)B_4=B_4(I\otimes P)$ we obtain $B_4^{-1}(I\otimes P)B_4=I\otimes P$, i.e., the matrix $I\otimes P$ remains intact by the action of Ad_{B_4}, which means that

$$(a_{13},a_{23},a_{33},a_{43})^{\mathsf{T}} = (0,0,1,0)^{\mathsf{T}},$$

$$[(I\otimes Q)B_4]_{pq} = \sum_{r_1,r_2=0}^{n-1} (I\otimes Q)_{(p_1n+p_2)(r_1n+r_2)}(B_4)_{(r_1n+r_2)(q_1n+q_2)}$$
$$= \sum_{r_1,r_2=0}^{n-1} \delta_{p_1r_1}\delta_{(p_2+1)r_2}\delta_{(r_1-r_2)q_1}\delta_{r_2q_2}$$
$$= \delta_{(p_2+1)q_2}\delta_{p_1(q_1+q_2)},$$

$$[B_4(Q^{-1}\otimes Q)]_{pq} = \sum_{r_1,r_2=0}^{n-1} (B_4)_{(p_1n+p_2)(r_1n+r_2)}(Q^{-1}\otimes Q)_{(r_1n+r_2)(q_1n+q_2)}$$
$$= \sum_{r_1,r_2=0}^{n-1} \delta_{(p_1-p_2)r_1}\delta_{p_2r_2}\delta_{r_1(q_1+1)}\delta_{(r_2+1)q_2}$$
$$= \delta_{(p_2+1)q_2}\delta_{(p_1-p_2)(q_1+1)}$$

$$= \delta_{(p_2+1)q_2}\delta_{p_1(q_1+q_2)}.$$

Here, we see the action of Ad_{B_4} on the last of the four matrices generating $\mathcal{G}$: $(I\otimes Q)B_4 = B_4(Q^{-1}\otimes Q)$ is equivalent to $B_4^{-1}(I\otimes Q)B_4 = Q^{-1}\otimes Q$. As a result,

$$(a_{14},a_{24},a_{34},a_{44})^{\mathsf{T}} = (0,-1,0,1)^{\mathsf{T}}.$$

Thus, we have shown that

$$C(\varphi_4) = D_4 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & -1 \\ 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

□

APPENDIX B

Theorem 3.1: *Let n be a prime. Then the four matrices*

$$D_1 = \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad D_2 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

$$D_3 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \quad \text{and} \quad D_4 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & -1 \\ 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

generate the group $\mathrm{Sp}(4,\mathbb{F}_n)$.

For a better overview, we first sketch the main framework of the proof, and only afterwards we prove the individual steps in detail.

Remark 3.2: The fact that n is a prime ensures that $\mathbb{Z}_n$ is a field $\mathbb{F}_n$, and consequently that the set $\mathrm{Sp}(4,\mathbb{F}_n)=\{X\in\mathbb{Z}_n^{4\times 4} \mid X^{\mathsf{T}}JX=J\}$, where $J=\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)\oplus\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, is a group.

Remark 3.3: It is a well known fact that, for any integer n, the two matrices $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ generate the group $\mathrm{SL}(2,\mathbb{Z}_n)=\{A\in\mathbb{Z}_n^{2\times 2} \mid \det A=1\}$ (see Ref. 5).

Remark 3.4: It is easy to verify that D_1, D_2, D_3, and D_4 belong to $\mathrm{Sp}(4,\mathbb{F}_n)$.

For a group $\mathcal{K}$ and any group elements $k_1,k_2,\ldots,k_r\in\mathcal{K}$, we denote by $\langle k_1,\ldots,k_r\rangle$ the smallest subgroup of $\mathcal{K}$ containing $k_1,\ldots,k_r$.

Under the framework of this notation and Remark 3.3, we have

$$\langle D_1,D_2\rangle = \left\{ \begin{pmatrix} A & 0 \\ 0 & I_2 \end{pmatrix} \middle| A \in \mathrm{Sl}(2,\mathbb{Z}_n) \right\},$$

$$\langle D_1,D_2,D_3\rangle = \left\{ \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}, \begin{pmatrix} 0 & A \\ B & 0 \end{pmatrix} \middle| A,B \in \mathrm{Sl}(2,\mathbb{Z}_n) \right\}.$$

Our aim is to prove that $\langle D_1,D_2,D_3,D_4\rangle=\mathrm{Sp}(4,\mathbb{Z}_n)$. For this purpose, it is enough to verify statements of the next two steps.

Step 1: Let us note $\mathcal{H}:=\langle D_1,D_2,D_3\rangle$ and $M\in\mathrm{Sp}(4,\mathbb{F}_n)$, $M\notin\mathcal{H}$. There exist $k\in\mathbb{Z}_n$ and matrices $G_1,G_2\in\mathcal{H}$ such that $G_1MG_2=S(k)$, where

$$S(k) := \begin{pmatrix} 1 & 0 & 1 & 0 \\ 0 & k & 0 & 1-k \\ k-1 & 0 & k & 0 \\ 0 & -1 & 0 & 1 \end{pmatrix}.$$

Step 2: The matrix $S(k)$ belongs to $\langle D_1, D_2, D_3, D_4 \rangle$ for any $k \in \mathbb{Z}_n$.

Lemma 3.5: Let n be a prime and $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathbb{Z}_n^{2\times 2}$, $A \neq \left(\begin{smallmatrix} 0 & 0 \\ 0 & 0 \end{smallmatrix}\right)$. *Then there exist*

(i) *matrices* $B, C \in \mathrm{SL}(2, \mathbb{Z}_n)$ *such that* $BAC = \left(\begin{smallmatrix} 1 & 0 \\ 0 & k \end{smallmatrix}\right)$, *where* $k = \det A$;

(ii) *matrices* $D, E \in \mathrm{SL}(2, \mathbb{Z}_n)$ *such that* $DAE = \left(\begin{smallmatrix} k & 0 \\ 0 & 1 \end{smallmatrix}\right)$, *where* $k = \det A$.

Moreover, if $\det A = k \neq 0$, *then we have* $C = E = I_2$.

Proof: (a) First, we consider the case $\det A = k \neq 0$.

(i) We assume, without loss of generality, that $a \neq 0$ [otherwise, we would consider matrix $A\left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} -b & a \\ -d & c \end{smallmatrix}\right) = \left(\begin{smallmatrix} -b & 0 \\ -d & c \end{smallmatrix}\right)$, as $b \neq 0$ when $a = 0$]. The desired matrices B and C are as follows:

$$B = B_3 B_2 B_1 = \begin{pmatrix} 1 & -ba^{-1}k^{-1} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -ac & 1 \end{pmatrix} \begin{pmatrix} a^{-1} & 0 \\ 0 & a \end{pmatrix},$$

$$C = I_2,$$

$$BAC = B_3 B_2 \begin{pmatrix} a^{-1} & 0 \\ 0 & a \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} = B_3 \begin{pmatrix} 1 & 0 \\ -ac & 1 \end{pmatrix} \begin{pmatrix} 1 & a^{-1}b \\ ac & ad \end{pmatrix}$$
$$= \begin{pmatrix} 1 & -ba^{-1}k^{-1} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & a^{-1}b \\ 0 & k \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & k \end{pmatrix}.$$

(ii) Alternatively, we multiply the result by one more matrix, in order to obtain the desired matrix $\left(\begin{smallmatrix} k & 0 \\ 0 & 1 \end{smallmatrix}\right)$,

$$D = \begin{pmatrix} k & 0 \\ 0 & k^{-1} \end{pmatrix} B,$$

$$E = C = I_2,$$

$$DAE = \begin{pmatrix} k & 0 \\ 0 & k^{-1} \end{pmatrix} BAC = \begin{pmatrix} k & 0 \\ 0 & k^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & k \end{pmatrix} = \begin{pmatrix} k & 0 \\ 0 & 1 \end{pmatrix}.$$

(b) Second, we have the situation $\det A = k = 0$, but still $A \neq 0$.

(i) If $a \neq 0$, we set

$$B = B_2 B_1,$$

$$C = \begin{pmatrix} 1 & -a^{-1}b \\ 0 & 1 \end{pmatrix},$$

$$BAC = B_2\begin{pmatrix} a^{-1} & 0 \\ 0 & a \end{pmatrix}\begin{pmatrix} a & b \\ c & d \end{pmatrix}C = \begin{pmatrix} 1 & 0 \\ -ac & 1 \end{pmatrix}\begin{pmatrix} 1 & a^{-1}b \\ ac & ad \end{pmatrix}C$$
$$= \begin{pmatrix} 1 & a^{-1}b \\ 0 & k \end{pmatrix}\begin{pmatrix} 1 & -a^{-1}b \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & k \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

If $a=0$, then at least one of the remaining three matrix elements is nonzero. Thus, we can analogously work with one of the matrices

$$A\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}A, \quad \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}A\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \tag{B1}$$

namely with the one whose element in the first row and first column is nonzero.

(ii) Again, without loss of generality, we assume that $d \neq 0$ [otherwise we would transform A into one of the three matrices given in (B1); one of which would have a nonzero element in its second row and second column]. We set

$$D = D_2D_1 = \begin{pmatrix} 1 & -bd \\ 0 & 1 \end{pmatrix}\begin{pmatrix} d & 0 \\ 0 & d^{-1} \end{pmatrix},$$

$$E = \begin{pmatrix} 1 & 0 \\ -cd^{-1} & 1 \end{pmatrix},$$

$$DAE = D_2\begin{pmatrix} d & 0 \\ 0 & d^{-1} \end{pmatrix}\begin{pmatrix} a & b \\ c & d \end{pmatrix}E = \begin{pmatrix} 1 & -bd \\ 0 & 1 \end{pmatrix}\begin{pmatrix} da & db \\ d^{-1}c & 1 \end{pmatrix}E$$
$$= \begin{pmatrix} k & 0 \\ d^{-1}c & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ -cd^{-1} & 1 \end{pmatrix} = \begin{pmatrix} k & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}.$$

□

Proof of Step 1: Let us express a matrix $M \in \mathrm{Sp}(4,\mathbb{F}_n)$ in blocks:

$$M = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix}, \quad \text{where } M_{ij} \in \mathbb{Z}_n^{2\times 2}.$$

The equality (17) means that $\det M_{12} + \det M_{22} = 1$. We denote $\det M_{22} = k$, and consequently $\det M_{12} = 1-k$.

(i) Let us assume that $k \neq 0$. We take matrices $B, C \in \mathrm{SL}(2,\mathbb{Z}_n)$ as described in Lemma 3.5, so as to obtain $BM_{12}C = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1-k \end{smallmatrix}\right)$. Afterwards, we apply Lemma 3.5 on matrix $M_{22}C$, whose determinant is $\det(M_{22}C) = (\det M_{22})(\det C) = k \cdot 1 = k \neq 0$. Thus, we find $D \in \mathrm{SL}(2,\mathbb{Z}_n)$ such that $DM_{22}C = \left(\begin{smallmatrix} k & 0 \\ 0 & 1 \end{smallmatrix}\right)$. At this moment, we are able to transform M by means of matrices $F_1 = \left(\begin{smallmatrix} B & 0 \\ 0 & D \end{smallmatrix}\right)$, $F_2 = \left(\begin{smallmatrix} I_2 & 0 \\ 0 & C \end{smallmatrix}\right)$ into the following:

$$F_1MF_2 = \begin{pmatrix} B & 0 \\ 0 & D \end{pmatrix}\begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix}\begin{pmatrix} I_2 & 0 \\ 0 & C \end{pmatrix} = \begin{pmatrix} BM_{11} & BM_{12} \\ DM_{21} & DM_{22} \end{pmatrix}\begin{pmatrix} I_2 & 0 \\ 0 & C \end{pmatrix}$$
$$= \begin{pmatrix} BM_{11} & BM_{12}C \\ DM_{21} & DM_{22}C \end{pmatrix} = \begin{pmatrix} \tilde{m}_{11} & \tilde{m}_{12} & 1 & 0 \\ \tilde{m}_{21} & \tilde{m}_{22} & 0 & 1-k \\ \tilde{m}_{31} & \tilde{m}_{32} & k & 0 \\ \tilde{m}_{41} & \tilde{m}_{42} & 0 & 1 \end{pmatrix} = \tilde{M},$$

where we denote matrices $BM_{11}=\left(\begin{smallmatrix}\tilde{m}_{11} & \tilde{m}_{12}\\ \tilde{m}_{21} & \tilde{m}_{22}\end{smallmatrix}\right)$ and $DM_{21}=\left(\begin{smallmatrix}\tilde{m}_{31} & \tilde{m}_{32}\\ \tilde{m}_{41} & \tilde{m}_{42}\end{smallmatrix}\right)$ by $\tilde{M}_{11},\tilde{M}_{21}$, respectively. As the matrix $\tilde{M}$ is a multiple of F_1, F_2, and M, which all belong to $\mathrm{Sp}(4,\mathbb{F}_n)$, then also $\tilde{M}$ is an element of $\mathrm{Sp}(4,\mathbb{F}_n)$, and so its elements fulfill equations (18)–(21),

$$0=-\tilde{m}_{21}-k\tilde{m}_{41} \pmod{n},$$

$$0=(1-k)\tilde{m}_{11}+\tilde{m}_{31} \pmod{n},$$

$$0=-\tilde{m}_{22}-k\tilde{m}_{42} \pmod{n},$$

$$0=(1-k)\tilde{m}_{12}+\tilde{m}_{32} \pmod{n}.$$

These relations ensure that we can transform $\tilde{M}$ into $S(k)$ by means of matrix $N=\left(\begin{smallmatrix}\tilde{m}_{11} & \tilde{m}_{12}\\ -\tilde{m}_{41} & -\tilde{m}_{42}\end{smallmatrix}\right)$,

$$\begin{pmatrix}1 & 0\\ 0 & k\end{pmatrix}N=\begin{pmatrix}\tilde{m}_{11} & \tilde{m}_{12}\\ -k\tilde{m}_{41} & -k\tilde{m}_{42}\end{pmatrix}=\begin{pmatrix}\tilde{m}_{11} & \tilde{m}_{12}\\ \tilde{m}_{21} & \tilde{m}_{22}\end{pmatrix}=\tilde{M}_{11},$$

$$\begin{pmatrix}k-1 & 0\\ 0 & -1\end{pmatrix}N=\begin{pmatrix}(k-1)\tilde{m}_{11} & (k-1)\tilde{m}_{12}\\ \tilde{m}_{41} & \tilde{m}_{42}\end{pmatrix}=\begin{pmatrix}\tilde{m}_{31} & \tilde{m}_{32}\\ \tilde{m}_{41} & \tilde{m}_{42}\end{pmatrix}=\tilde{M}_{21}.$$

Therefore, $\tilde{M}_{11}N^{-1}=\left(\begin{smallmatrix}1 & 0\\ 0 & k\end{smallmatrix}\right)$, $\tilde{M}_{21}N^{-1}=\left(\begin{smallmatrix}k-1 & 0\\ 0 & -1\end{smallmatrix}\right)$, and consequently

$$\tilde{M}\begin{pmatrix}N^{-1} & 0\\ 0 & I_2\end{pmatrix}=\begin{pmatrix}\tilde{m}_{11} & \tilde{m}_{12} & 1 & 0\\ \tilde{m}_{21} & \tilde{m}_{22} & 0 & 1-k\\ \tilde{m}_{31} & \tilde{m}_{32} & k & 0\\ \tilde{m}_{41} & \tilde{m}_{42} & 0 & 1\end{pmatrix}\begin{pmatrix}N^{-1} & 0\\ 0 & I_2\end{pmatrix}=S(k).$$

As an element of $\mathrm{Sp}(4,\mathbb{F}_n)$, the matrix $\tilde{M}$ also fulfills Eq. (16), which implies that $\det\tilde{M}_{11}+\det\tilde{M}_{21}=1=k\det N+(1-k)\det N=\det N$, and thus $N\in\mathrm{SL}(2,\mathbb{Z}_n)$. Hence, we have found the desired matrices $G_1=F_1=B\oplus D$, $G_2=F_2(N^{-1}\oplus I_2)=N^{-1}\oplus C$, transforming M into $G_1MG_2=S(k)$.

(ii) The case when $k=0$, we treat as follows. First, we find D, $E\in\mathrm{SL}(2,\mathbb{Z}_n)$ such that $DM_{22}E=\left(\begin{smallmatrix}k & 0\\ 0 & 1\end{smallmatrix}\right)$ and $B\in\mathrm{SL}(2,\mathbb{Z}_n)$ such that $BM_{21}E=\left(\begin{smallmatrix}1 & 0\\ 0 & 1-k\end{smallmatrix}\right)$, according to Lemma 3.5. Analogously to the case $k\neq 0$, we set $G_1=F_1=B\oplus D$, $G_2=F_2(N^{-1}\otimes I_2)=N^{-1}\oplus E$, and we reach the result $G_1MG_2=S(k)$.

Proof of Step 2: We need to express each matrix $S(k)$ as an element of $\langle D_1,D_2,D_3,D_4\rangle$. We begin by showing (by induction) that

$$D_4^j=\begin{pmatrix}1 & 0 & 0 & 0\\ 0 & 1 & 0 & -j\\ j & 0 & 1 & 0\\ 0 & 0 & 0 & 1\end{pmatrix}=\begin{pmatrix}1 & 0 & 0 & 0\\ 0 & 1 & 0 & -1\\ 1 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\end{pmatrix}\begin{pmatrix}1 & 0 & 0 & 0\\ 0 & 1 & 0 & -j+1\\ j-1 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\end{pmatrix}=D_4D_4^{j-1}.$$

We make use of the fact that $J=\left(\begin{smallmatrix}0 & 1\\ -1 & 0\end{smallmatrix}\right)\oplus\left(\begin{smallmatrix}0 & 1\\ -1 & 0\end{smallmatrix}\right)\in\mathcal{H}$, $J^{\mathsf{T}}\in\mathcal{H}$, and $D_4^{\mathsf{T}}=D_3D_4D_3\in\mathrm{Sp}(4,\mathbb{F}_n)$ (this can be verified by a simple matrix multiplication); and we generate $S(k)$ from D_4 and elements from $\mathcal{H}$,

$$J^{\mathsf{T}}(D_4^{1-k})^{\mathsf{T}}JD_4^{\mathsf{T}} = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 & 1-k & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & k-1 & 0 & 1 \end{pmatrix}\begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}\begin{pmatrix} 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{pmatrix}$$

$$= \begin{pmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 1-k & 0 \\ 0 & 1-k & 0 & -1 \\ 0 & 0 & 1 & 0 \end{pmatrix}\begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & -1 & 0 \\ 0 & -1 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 1 & 0 \\ 0 & k & 0 & 1-k \\ k-1 & 0 & k & 0 \\ 0 & -1 & 0 & 1 \end{pmatrix} = S(k).$$

(Received 13 October 2005; accepted 28 November 2005; published online 26 January 2006)

We study the problem of quadruple extensions of simple Lie algebras. We find that, adding a new simple root α_{+4}, it is not possible to have an extended Kac-Moody algebra described by a Dynkin-Kac diagram with simple links and no loops between the dots, while it is possible if α_{+4} is a Borcherds imaginary simple root. We also comment on the root lattices of these new algebras. The folding procedure is applied to the simply laced triple extended Lie algebras, obtaining all the non-simply laced ones. Nonstandard extension procedures for a class of Lie algebras are proposed. It is shown that the two-extensions of E_8, with a dot simply linked to the Dynkin-Kac diagram of E_9, are rank 10 subalgebras of E_{10}. Finally the simple root systems of a set of rank 11 subalgebras of E_{11}, containing as sub-algebra E_{10}, are explicitly written. © *2006 American Institute of Physics.*

I. INTRODUCTION

It has been conjectured by Peter West[1] that the still elusive M-Theory possesses a rank 11 Kac-Moody symmetry algebra, called E_{11}, that is the triple extended or very extended E_8 algebra. Very extended algebras can be defined for any finite-dimensional Lie algebra $\mathcal{G}$.[2] So it is tempting to argue that other theories, which are associated with other triple extensions of Lie algebras, may exist. Indeed the same analysis was applied to a conjectured extension of the eleven dimensional supergravity.[3,4] More generally, it has been proposed that the closed bosonic string in D dimensions and type I supergravity and pure gravity theories exhibit a Kac-Moody symmetry algebra, respectively, identified as the triple extensions of the D and A series.[5–7] This conjecture is supported by dimensional reduction and by the so-called cosmological billiards.[8–10] Then it is natural to look for a more general symmetry algebra which can include all these Kac-Moody algebras as particular cases. So we address the question of how to go beyond $\mathcal{G}^{+++}$ algebras; we find that the adjoint of a new simple root α_{+4} introduces multiple links and loops in the structure of the 4-extended algebra, if α_{+4} is an ordinary Kac-Moody simple root, while the "simple-links" structure is preserved if we allow α_{+4} is a Borcherds (imaginary) simple root.

The (first) extension of a finite-dimensional Lie algebra is the construction of (untwisted) affine Kac-Moody algebras, which are obtained adding to the simple roots of any finite-dimensional Lie algebra $\mathcal{G}$ a root α_0 that is the opposite of the highest root (h.r.) plus a light-like vector k_+, in order to make α_0 linearly independent from the system of the simple roots of $\mathcal{G}$, keeping unchanged its length, and are denoted as $\mathcal{G}^+$ or $\hat{\mathcal{G}}$ or $\mathcal{G}^1$. This procedure for the simply laced algebras of the D_N and E_N series can be formulated as the addition to the simple root system of $\mathcal{G}$ of another root α_0, that is the opposite of the unique fundamental weight of length 2, which is in the root lattice of the algebra, plus a light-like vector k_+. The light-like vector can be considered to belong to a 2-dim. Lorentzian lattice, usually denoted $\mathrm{II}^{1,1}$, and the double extension or overextension of $\mathcal{G}$, denoted $\mathcal{G}^{++}$, is obtained by adding a new simple root, of length 2, which

[a]Electronic mail: forte@na.infn.it
[b]Electronic mail: sciarrino@na.infn.it

is formed by the sum of the two light like vectors $k_{\pm}$, $(k_+,k_-)=1$, spanning $\mathrm{II}^{1,1}$. The triple extended or very extended $\mathcal{G}$, denoted $\mathcal{G}^{+++}$, is obtained adding a new simple root of length 2, which belongs to a new copy of the lattice $\mathrm{II}^{1,1}$, plus k_+. In this way, an indefinite Kac-Moody or Lorentzian algebra of rank $r+3$ is obtained whose roots belong to a Lorentzian lattice of dimension $r+4$, so it is natural to wonder if an indefinite Kac-Moody algebra of rank $r+4$ can be obtained by a further extension. Moreover, let us notice that in the lattice $\mathrm{II}^{1,1}$ vectors of negative length do exist (see Appendix A). From this remark one can make an extension of $\mathcal{G}$ adding a new root, that is the opposite of any fundamental weight, that can be written as linear combination with integer coefficients of the simple roots of the algebra, plus a suitable element of the lattice $\mathrm{II}^{1,1}$ in order to have an independent new simple root of length 2. This construction will be discussed in the following. It has been pointed out in Ref. 11 that the structure of subalgebras of hyperbolic Kac-Moody, in general of two-extended (overextended) Lie algebras, is very rich and surprising. Some of the results of that paper can be generalized to more general extensions and we comment on this point in the following. This paper is organized as follows. In Sec. II, to make the paper self-contained, we recall the well-known construction of the three-extended Lie algebras. We show that the four-extended algebras are described by Dynkin-Kac diagrams with loops and multiple links (so their structure is quite different from that of the one-, two-, and three-extended algebras). In particular, we show that we cannot have a situation in which the new (fourth) simple root α_{+4} is simply linked to α_{+3}, unless we let α_{+4} be a Borcherds simple root (with squared norm zero or negative). So we also study the possibility to have a Borcherds extension of the $\mathcal{G}^{+++}$ algebras, but this extension has sense only when the algebra $\mathcal{G}$ is simply-laced (see Appendix B for the definition of a Borcherds algebra[12]). In Sec. III, we show that all the nonsimply laced three-extended Lie algebras can be obtained by *folding* the simply-laced ones. In Sec. IV, we discuss nonstandard extension procedures, discussing in detail a few examples which may be of physical interest. In Sec. V, we show that the algebras obtained by some general nonstandard procedure, but not for all the procedures, are indeed subalgebras, of the same rank, of the standard triple extended algebras. In particular we prove that any nonstandard one-extension of E_9, with a root simply linked to a simple roots of E_9, is a subalgebra of E_{10}. The simple root systems of a set of rank 11 subalgebras of E_{11}, containing as subalgebra E_{10}, are explicitly written. Finally we present a few conclusions and perspectives. To make the paper self-contained two very short Appendices are added to recall the main features of the 2-dim Lorentzian lattice $\mathrm{II}^{1,1}$ and of Borcherds algebras.

II. ON EXTENSIONS OF $\mathcal{G}^{+++}$ ALGEBRAS

An excellent discussion of the mechanism of standard extensions of Lie algebras can be found in Ref. 2, here we briefly recall the essential points, mainly to introduce the notation and to make the paper self-consistent. [Let us remember that the standard extension for G_2 does not work, because G_2 is the only finite Lie algebra for which it is not possible to normalize the highest root θ such that $(\theta,\theta)=2$. However, it's possible to extend G_2 with the following choice of the extended roots: $\alpha_{+1}=k_+-\theta$, $\alpha_{+2}=-(k_++3k_-)$ and $\alpha_{+3}=-(l_++3l_-)+k_+$. Anyway, G_2^{+++} can be obtained by folding D_4^{+++} (see Sec. III).] Let $\mathcal{G}$ be a simple Lie algebra of rank r, with simple root system α_i $(i=1,\ldots,r)$ and root lattice $\Lambda_{\mathcal{G}}=\oplus_{i=1}^{r}\mathbb{Z}\alpha_i$ (for the roots and fundamental weights we use the notation of Ref. 13). Let us consider also two copies of the lattice $\mathrm{II}^{1,1}$, which we indicate with $\mathrm{II}^{1,1}_{k_\pm}$ and $\mathrm{II}^{1,1}_{l_\pm}$. In the following, we consider indefinite Kac-Moody algebras with root lattice included in the direct sum $\Lambda_{\mathcal{G}}\oplus\mathrm{II}^{1,1}_{k_\pm}\oplus\mathrm{II}^{1,1}_{l_\pm}$.

Let $\mathcal{G}^+$ be the extended Lie algebra (or affine Kac-Moody algebra), with simple root system $\{\alpha_i,\alpha_0\equiv\alpha_{r+1}\equiv\alpha_{+1}=-\mathrm{h.r.}+k_+\}$ $(i=1,\ldots,r)$, where h.r. denotes the highest root of $\mathcal{G}$ (which is $\theta\equiv\mathrm{h.r.}=\Sigma_{i=1}^{r}a_i\alpha_i$ where a_i are Kac marks, see Ref. 13), and

$$(k_+,k_+)=(k_+,\alpha_i)=0. \tag{1}$$

Let $\mathcal{G}^{++}$ be the double extended or overextended Lie algebra (actually a Lorentzian Kac-Moody algebra), with simple root system $[\alpha_j,\alpha_{r+2}\equiv\alpha_{+2}=-(k_++k_-)\}$ $(j=1,\ldots,r+1)$, where

$$(k_+,k_-)=1, \quad (k_-,k_-)=(k_-,\alpha_i)=0. \tag{2}$$

Let us note that the root lattice of $\mathcal{G}^+$ is properly contained in the direct sum $\Lambda_{\mathcal{G}}\oplus \mathrm{II}^{1,1}_{k_\pm}$, whereas the root lattice of $\mathcal{G}^{++}$ coincides with the direct sum. To see this, it is enough to obtain k_+ and k_- from the other roots α_j $(j=1,\ldots,r+2)$. In fact,

$$k_+=\theta+\alpha_{+1}=\sum_{i=1}^{r} a_i\alpha_i+\alpha_{+1}, \tag{3}$$

$$k_-=-k_+-\alpha_{+2}=-\theta-\alpha_{+1}-\alpha_{+2} \tag{4}$$

so k_+ and k_- are linear combinations (with integer coefficients) of the $r+2$ simple roots of the $\mathcal{G}^{++}$ algebra. This means that with a change of basis (in the lattice), we can pass from $\{\alpha_j\ (j=1,\ldots,r+2)\}$ to $\{\alpha_i\ (i=1,\ldots,r);k_+,k_-\}$, that is the lattice $\Lambda_{\mathcal{G}}\oplus\mathbb{Z}\alpha_{+1}\oplus\mathbb{Z}\alpha_{+2}$ coincides with $\Lambda_{\mathcal{G}}\oplus \mathrm{II}^{1,1}_{k_\pm}$.

Now, let $\mathcal{G}^{+++}$ be the triple extended Lie algebra (still a Lorentzian Kac-Moody algebra), with simple root system $\{\alpha_k,\alpha_{r+3}\equiv\alpha_{+3}=-(l_++l_-)+k_+\}$ $(k=1,\ldots,r+2)$, where

$$(\alpha_i,l_\pm)=(k_\pm,l_\pm)=(k_\mp,l_\pm)=(l_\pm,l_\pm)=0, \quad (l_\mp,l_\pm)=1. \tag{5}$$

In this way starting from the r-dim. Euclidean lattice $\Lambda_{\mathcal{G}}$, we have build up a $(r+4)$-dim. Lorentzian lattice $\mathbf{\Lambda}\equiv\Lambda_{\mathcal{G}}\oplus \mathrm{II}^{1,1}_{k_\pm}\oplus \mathrm{II}^{1,1}_{l_\pm}$, with signature $+\ldots+--$ ($r+2$ plus signs). The simple root system of $\mathcal{G}^{+++}$ clearly spans a $(r+3)$-dim sublattice of $\mathbf{\Lambda}$ (because α_{+3} only takes the direction l_++l_- in the second lattice $\mathrm{II}^{1,1}$, so the orthogonal direction is lacking), so it is natural to wonder if it is possible to extend further the $\mathcal{G}^{+++}$ algebra and *fill in* $\mathbf{\Lambda}$.

Motivated by the previous steps, one would just add another node at the Dynkin diagram of a $\mathcal{G}^{+++}$ algebra, with a simple link to the root α_{+3}; in this way, as it happens in the case of the $\mathcal{G}^{++}$ algebra, one would expect that this construction fills the root lattice $\Lambda_{\mathcal{G}}\oplus \mathrm{II}^{1,1}_{k_\pm}\oplus \mathrm{II}^{1,1}_{l_\pm}$. In the following, we show that actually this is not the case. (Our discussion does not account for the introduction of another lattice $\mathrm{II}^{1,1}$, which solves the question only partially, because it moves the problem to fill this new lattice.)

As we already mentioned, the simple root α_{+3} contains only the combination l_++l_-, so if we want to span completely also the second lattice $\mathrm{II}^{1,1}$, we need a new simple root α_{+4} which allows us to obtain l_+ and l_- separately. In this way, we are guaranteed that the root lattice of the new algebra also contains all vectors which are integer multiples of l_+ or l_-, so this lattice coincides with $\mathbf{\Lambda}$. In the following, let us choose for α_{+4} the more general form:

$$\alpha_{+4}\equiv al_++bl_-+ck_++dk_-, \tag{6}$$

which allows us to make many considerations about the possible extensions of the $\mathcal{G}^{+++}$ algebras. (As it happens also for α_{+2} and α_{+3}, here we do not consider the situation in which α_{+4} is also linked with the simple roots α_i of $\mathcal{G}$. However this simple choice does not really change the conclusions of our analysis.) First of all, let us obtain the expression for l_+ and l_- using the definition of α_{+3} and α_{+4}:

$$(a-b)l_+=(d-b-c)\theta+(d-b-c)\alpha_{+1}+d\alpha_{+2}+b\alpha_{+3}+\alpha_{+4}, \tag{7}$$

$$(b-a)l_-=(d-a-c)\theta+(d-a-c)\alpha_{+1}+d\alpha_{+2}+a\alpha_{+3}+\alpha_{+4}. \tag{8}$$

We see then that it is possible to obtain l_+ and l_- as linear combinations (over $\mathbb{Z}$) of the simple roots if and only if $|a-b|=1$. Only in this case we are guaranteed that we actually catch all the vectors in the lattice $\mathrm{II}^{1,1}_{l_\pm}$. With this in mind, let us find the other relations a,b,c,d have to satisfy, that is let us compute the norm of α_{+4} and the scalar products with the other simple roots (here we write only the relevant elements a_{ij} of the generalized Cartan matrix):

$$(\alpha_{+4})^2 = 2(ab + cd), \tag{9}$$

$$a_{+4,+1} \equiv 2\frac{(\alpha_{+4}, \alpha_{+1})}{(\alpha_{+4}, \alpha_{+4})} = \frac{d}{ab + cd}, \quad a_{+4,+2} \equiv 2\frac{(\alpha_{+4}, \alpha_{+2})}{(\alpha_{+4}, \alpha_{+4})} = \frac{-c - d}{ab + cd}, \tag{10}$$

$$a_{+4,+3} \equiv 2\frac{(\alpha_{+4}, \alpha_{+3})}{(\alpha_{+4}, \alpha_{+4})} = \frac{d - a - b}{ab + cd}. \tag{11}$$

Let us limit ourselves to consider the case $(\alpha_{+4})^2=2$ (to look for a "natural extension") and let all four coefficients be different from zero; we must have

$$ab + cd = 1, \tag{12}$$

$$d < 0, \quad c \geqslant -d > 0, \quad d \leqslant a + b, \tag{13}$$

because only with these constraints α_{+4} is an acceptable simple root (à la Kac-Moody). In particular, the product cd must be negative, and as Eq. (12) holds, the product ab must be positive (actually, it must be at least 2), that is a and b must have the same sign. A simple solution, pointed out to us by C. Helfgott, to Eqs. (12) and (13) is the following:

$$a = 2, \quad b = 1, \quad c = 1, \quad d = -1, \tag{14}$$

where α_{+4} has norm 2 and the scalar products are $(\alpha_{+4}, \alpha_{+1})=-1$, $(\alpha_{+4}, \alpha_{+2})=0$ and $(\alpha_{+4}, \alpha_{+3})=-4$. Furthermore, this solution verifies also the condition $a-b=1$, so its root lattice is precisely $\mathbf{\Lambda}$, but it presents one loop and a multiple link with the (last) root α_{+3}, so its structure is very different from the other previous extensions. [A. Kleinschmidt suggested another solution to us $\alpha_{+4}=\alpha+3k_+-2k_--2l_+-3l_-$ in which α_{+4} is also linked to the only simple root α of su(2); this solution too presents loops and multiple links.] This situation is common to all solutions of Eqs. (12) and (13): it is not possible (we stress: without adding any $\mathrm{II}^{1,1}$ or different lattice) to have a simple link with α_{+4} and no loops (for example the equation $d-a-b=-1$ is never satisfied if a and b are both positive, because d is at least -1, and goes in contradiction with the other relations if a and b are both negative). In this sense, the procedure of standard extension stops at the third step ($\mathcal{G}^{+++}$).

It is clear that there exist infinite solutions to Eqs. (12) and (13) [for example, it is enough to take a, b both positive, $d=-1$ and an opportune value of c to satisfy Eq. (12) and the second equation of Eq. (13)], but only those with $|a-b|=1$ have the property that their root lattice coincides with $\mathbf{\Lambda}$. We can also try (in α_{+4}) to put one coefficient equal to zero and to explore more specific cases. An investigation, case by case, shows that:

- $d=0$: the scalar products imply $ab=1$ and $a+b>0$, that is $a=b=1$, but the case $a=b$ is not acceptable because, in this case, α_{+4} is a linear combination of the other simple roots.
- $c=0$: the scalar products with α_{+1} and α_{+2} are, respectively, proportional to d and $-d$, so one of the two is positive and has the wrong sign, or $d=0$ and then α_{+4} is a linear combination of the other simple roots.
- $a=0$: this case implies $c=-1$, but then $d=-1$ too and the scalar product with α_{+2} is positive.
- $b=0$: it has the same problem as the case $a=0$.

If we put equal to zero two coefficients, the only possibility is to have $c=d=0$ (we cannot take equal to zero a coefficient of l_+ or l_- and a coefficient of k_+ or k_-, because α_{+4} would have vanishing norm), but in this case, as already discussed, we have problems.

So far, we have seen that it is never possible to add a (Kac-Moody) simple root in order to have a simple link with α_{+3}; besides this, the possible solutions which span the whole lattice $\mathbf{\Lambda}$ are

restricted to the condition $|a-b|=1$. Yet, if we abandon the condition that α_{+4} is a Kac-Moody simple root and let it be a Borcherds (imaginary) simple root, the situation changes. In fact, we can easily find an imaginary root of the kind:

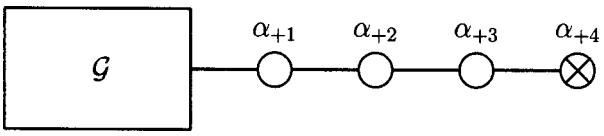
$$\alpha_{+4} = al_+ + bl_-, \tag{15}$$

which has scalar product equal to -1 with α_{+3}: it is only necessary that $b=1-a$, that is $\alpha_{+4}=al_+ +(1-a)l_-$, with norm $2a(1-a)$. Then if $a=0$ or $a=1$, α_{+4} has norm zero, in all the other cases its norm is negative, that is α_{+4} is a good Borcherds simple root. If we want to fill in $\mathbf{\Lambda}$ with the introduction of a Borcherds simple root, we have always to fulfill the condition $|a-b|=1$ (this condition is independent from the norm of α_{+4}), but now it is possible to have both $(\alpha_{+4},\alpha_{+3})=-1$ and, at the same time, to span the whole lattice $\mathbf{\Lambda}$. In fact the values $a=1$, $b=0$ (and vice versa $a=0$, $b=1$), which correspond to $\alpha_{+4}=l_+$ ($\alpha_{+4}=l_-$), are the only ones which allow one to have

$$\Lambda_{\text{roots}}(\mathcal{BG}^{+++}) \equiv \Lambda_{\text{roots}}(\mathcal{G}^{++}) \oplus \text{II}^{1,1}_{l_\pm} = \mathbf{\Lambda}, \tag{16}$$

$$(\alpha_{+4},\alpha_{+3}) = -1, \tag{17}$$

as opposite to the Kac-Moody case, where, as we already said, it is never possible to satisfy Eq. (17) and only some solutions allow one to fill in $\mathbf{\Lambda}$ (we have called $\mathcal{BG}^{+++}$ the Borcherds extension of $\mathcal{G}^{+++}$ corresponding to $\alpha_{+4}=l_+$ or $\alpha_{+4}=l_-$). Denoting by a crossed dot the Borcherds simple root α_{+4}, we can draw the Dynkin diagram of this Borcherds algebra in the following way:



Actually, this construction makes sense if $\mathcal{G}$ is simply laced, because otherwise the Cartan matrix is not well-defined. In fact, if α_{+4} is an imaginary (isotropic) root, we cannot define the extended Cartan matrix as $2(\alpha_i,\alpha_j)/(\alpha_i,\alpha_i)$ for all α_i because $\alpha_{+4}^2=0$. We have the same problem if we add an imaginary simple root with negative squared norm (as previously recalled, in $\text{II}^{1,1}$ there are infinite vectors whose squared norm is negative), because we shall have positive elements out of the principal diagonal. The solution is then to consider a $\mathcal{G}$ simply laced and define the extended Cartan matrix by the scalar products between all the simple roots: $b_{i,j}:=(\alpha_i,\alpha_j)$. So, while the extension of $\mathcal{G}$ is possible up to $\mathcal{G}^{+++}$ for any finite $\mathcal{G}$, in the case of a Borcherds extension it is necessary to choose for $\mathcal{G}$ a simply laced algebra (in fact, a Borcherds algebra is defined only on a symmetric Cartan matrix). To summarize our result, we have proven the following.

Proposition 1: The extension of $\mathcal{G}^{+++}$ algebra, whose simple root system spans completely $\mathbf{\Lambda}$ and whose Dynkin-Kac diagram has no loops and only simple links between the dots, is the Borcherds algebra $\mathcal{BG}^{+++}$ (with $\mathcal{G}$ simply laced).

The particular solution $a=1$, $b=0$ (or vice versa) looks like the same construction of $\mathcal{G}^+$ and $\mathcal{G}^{++}$, as the role of $k_\pm$ is now played by $l_\pm$, with the difference that α_{+1} contains also a root of a simple Lie algebra, while α_{+4} does not. This observation suggests that it is possible to fuse together two (finite) simple Lie algebras, let's say $\mathcal{G}$ and $\mathcal{G}'$, adding the highest root θ' of $\mathcal{G}'$ to α_{+4}. In this way, $\alpha'_{+4}\equiv\alpha_{+4}-\theta'$ is again a Kac-Moody simple root, indeed the affine root of $\mathcal{G}'^{+}$. Anyway, we do not insist on this point, because there are many possible ways to fuse together two (or more) finite dimensional simple Lie algebras (with or without the introduction of intermediate Kac-Moody or Borcherds algebras).

Remark: In this section, we have seen that triple extended Lie algebras $\mathcal{G}^{+++}$ have their root lattice properly included in $\mathbf{\Lambda}=\Lambda_{\mathcal{G}}\oplus\text{II}^{1,1}\oplus\text{II}^{1,1}$ (in particular, their root lattice is Lorentzian with just one negative eigenvalue). Among the four-extensions we considered in this section, we have shown that there are many algebras (of Kac-Moody or generalized Kac-Moody type) whose root

lattice coincides with $\mathbf{\Lambda}$, which is Lorentzian in a more general sense (it has two negative eigenvalues). These seem to be the first algebras obtained in literature with this kind of lattice, together with some similar algebras studied by Harvey and Moore in Refs. 14 and 15 (strictly speaking, their algebras are not Borcherds algebras, because they could not satisfy some grading conditions in the characterization of generalized Kac-Moody algebras, while our Borcherds algebras are *true* Borcherds algebras because we have constructed them from an acceptable generalized Cartan matrix). Our result is not in contrast with the statement of Ref. 16, according to which algebras of physical states, whose root lattices are of the kind $\Gamma^{p,q}$, i.e., with a signature with more than one negative sign (obtained through a vertex operator construction) cannot be described in terms of generators and relations of Kac-Moody or Borcherds algebras and belong to a new class of Lie algebras. Indeed our algebras are defined by a Cartan matrix and do not satisfy the root structure and multiplicities of the physical state algebra; this last condition seems, indeed, too strong and incompatible with the algebras constructed by us.

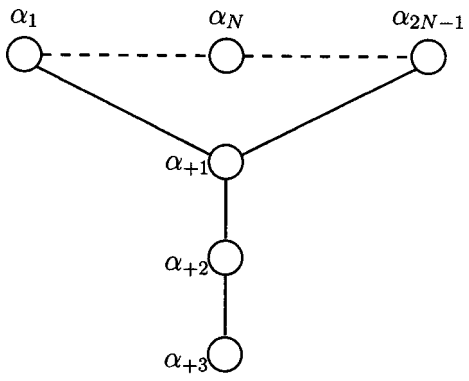
III. FOLDING OF TRIPLE EXTENDED LIE ALGEBRAS

The *folding* technique is a simple and powerful method to find class of singular subalgebras of finite Lie algebras as well as of affine or indefinite Kac-Moody algebras. The starting point is to use the symmetry τ of the Dynkin diagram, corresponding to an exterior automorphism of the algebra $\mathcal{G}$. In the finite case all the Dynkin diagrams of simply laced algebras show an automorphism of order $k=2$, except the case of D_4 where the order is 3. Let α_i be a simple root of $\mathcal{G}$. Using the automorphism τ of order k, we obtain

$$\beta_i := \alpha_i + \tau(\alpha_i) + \cdots + \tau^{k-1}(\alpha_i), \tag{18}$$

which form the simple root system of a singular subalgebra $\mathcal{H}$ of $\mathcal{G}$. The generators of $\mathcal{G}$, corresponding to the simple roots α_i, left unchanged by τ, become generators of $\mathcal{H}$, while the other ones transform according to a relation analogous to Eq. (18). In the following we apply the folding method to the triple extended Lie algebras, obtaining all the nonsimply laced triple extended algebras, as in the finite case. The automorphism of the three-extended Dynkin diagram acts on the standard way upon the roots of the finite classical subalgebras and trivially on the extended roots $\alpha_{+1}, \alpha_{+2}, \alpha_{+3}$. This property has to hold if we want to preserve the structure of the triple extension of the nonsimply laced algebras. (Indeed, also the nonsimply laced G^{++} algebras can be obtained with the same folding technique from the simply laced $\mathcal{G}^{++}$, while a different kind of folding applied to the $\mathcal{G}^{+}$ algebras allows one to get all the twisted affine algebras.) Let us enumerate all the cases.

A. $A^{+++}_{2N-1} \to C^{+++}_{N}$



The Cartan matrix of A^{+++}_{2N-1} can be written, in block form, as

$$A = (a_{ij}) = (\alpha_i, \alpha_j) = \begin{pmatrix} & & & -1 & 0 & 0 \\ & A_{A_{2N-1}} & & \vdots & \vdots & \vdots \\ & & & -1 & 0 & 0 \\ -1 & \cdots & -1 & 2 & -1 & 0 \\ 0 & \cdots & 0 & -1 & 2 & -1 \\ 0 & \cdots & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{19}$$

The not trivial action of τ on the simple roots gives

$$\beta_1 := \alpha_1 + \tau(\alpha_1) = \alpha_1 + \alpha_{2N-1}, \tag{20}$$

$$\beta_2 := \alpha_2 + \tau(\alpha_2) = \alpha_2 + \alpha_{2N-2} \ldots, \tag{21}$$

$$\beta_{N-1} := \alpha_{N-1} + \tau(\alpha_{N-1}) = \alpha_{N-1} + \alpha_{N+1}, \tag{22}$$

$$\beta_N := \alpha_N + \tau(\alpha_N) = 2\alpha_N, \tag{23}$$

$$\beta_{+1} := \alpha_{+1} + \tau(\alpha_{+1}) = 2\alpha_{+1}, \tag{24}$$

$$\beta_{+2} := \alpha_{+2} + \tau(\alpha_{+2}) = 2\alpha_{+2}, \tag{25}$$

$$\beta_{+3} := \alpha_{+3} + \tau(\alpha_{+3}) = 2\alpha_{+3}, \tag{26}$$

the length of the simple roots is

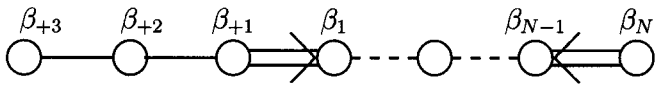
$$\beta_1^2 = \ldots = \beta_{N-1}^2 = 4, \tag{27}$$

$$\beta_{+3}^2 = \beta_{+2}^2 = \beta_{+1}^2 = \beta_N^2 = 8. \tag{28}$$

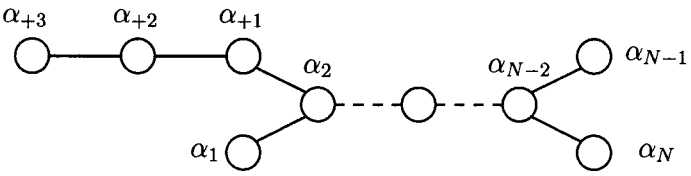
The corresponding Cartan matrix is

$$B = (b_{ij})_{i,j} = 2\frac{(\beta_i, \beta_j)}{(\beta_i, \beta_i)} = \begin{pmatrix} & & & -2 & 0 & 0 \\ & A_{C_N} & & \vdots & \vdots & \vdots \\ & & & 0 & 0 & 0 \\ -1 & \cdots & 0 & 2 & -1 & 0 \\ 0 & \cdots & 0 & -1 & 2 & -1 \\ 0 & \cdots & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{29}$$

So we get the three-extended Lie algebra C_N^{+++} with Dynkin diagram



B. $\mathbf{D}_N^{+++} \longrightarrow \mathbf{B}_{N-1}^{+++}$



The Cartan matrix can be written as

$$A=(a_{ij})_{i,j}=(\alpha_i,\alpha_j)=\begin{pmatrix} & & & & 0 & 0 & 0 \\ & & & & -1 & \vdots & \vdots \\ & & A_{D_N} & & \vdots & \vdots & \vdots \\ & & & & 0 & 0 & 0 \\ 0 & -1 & \cdots & 0 & 2 & -1 & 0 \\ 0 & \cdots & \cdots & 0 & -1 & 2 & -1 \\ 0 & \cdots & \cdots & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{30}$$

The nontrivial action of τ is

$$\tau(\alpha_{N-1})=\alpha_N, \quad \tau(\alpha_N)=\alpha_{N-1}. \tag{31}$$

The new simple roots are

$$\beta_{N-1}:=\alpha_{N-1}+\tau(\alpha_{N-1})=\alpha_{N-1}+\alpha_N, \tag{32}$$

$$\beta_{N-2}:=\alpha_{N-2}+\tau(\alpha_{N-2})=2\alpha_{N-2}\ldots, \tag{33}$$

$$\beta_1:=\alpha_1+\tau(\alpha_1)=2\alpha_1, \tag{34}$$

$$\beta_{+1}:=\alpha_{+1}+\tau(\alpha_{+1})=2\alpha_{+1}, \tag{35}$$

$$\beta_{+2}:=\alpha_{+2}+\tau(\alpha_{+2})=2\alpha_{+2}, \tag{36}$$

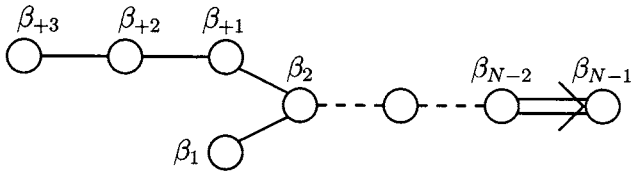
$$\beta_{+3}:=\alpha_{+3}+\tau(\alpha_{+3})=2\alpha_{+3}, \tag{37}$$

where

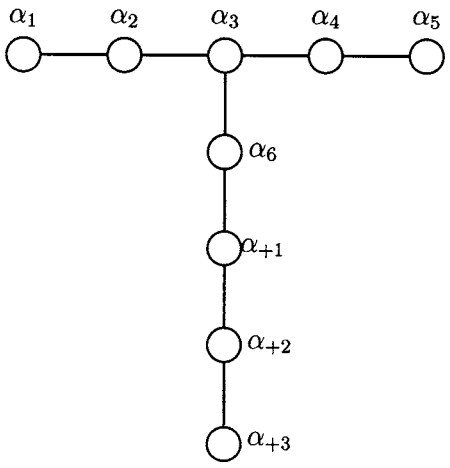
$$\beta_{N-1}^2=4, \quad \beta_{+3}^2=\beta_{+2}^2=\ldots=\beta_{N-2}^2=8. \tag{38}$$

The Cartan matrix and the corresponding Dynkin diagram of B_{N-1}^{+++} are

$$B=(b_{ij})_{i,j}=2\frac{(\beta_i,\beta_j)}{(\beta_i,\beta_i)}=\begin{pmatrix} & & & & 0 & 0 & 0 \\ & & & & -1 & \vdots & \vdots \\ & & A_{B_{N-1}} & & \vdots & \vdots & \vdots \\ & & & & 0 & 0 & 0 \\ 0 & -1 & \cdots & 0 & 2 & -1 & 0 \\ 0 & \cdots & \cdots & 0 & -1 & 2 & -1 \\ 0 & \cdots & \cdots & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{39}$$



c. $\mathbf{E}_6^{+++} \longrightarrow \mathbf{F}_4^{+++}$



The Cartan matrix of E_6^{+++} is

$$A = (a_{ij})_{i,j} = (\alpha_i, \alpha_j) = \begin{pmatrix} & & & 0 & 0 & 0 \\ & A_{E_6} & & \vdots & \vdots & \vdots \\ & & & -1 & 0 & 0 \\ 0 & \cdots & -1 & 2 & -1 & 0 \\ 0 & \cdots & 0 & -1 & 2 & -1 \\ 0 & \cdots & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{40}$$

The simple roots are given by

$$\beta_1 := \alpha_1 + \tau(\alpha_1) = \alpha_1 + \alpha_5, \tag{41}$$

$$\beta_2 := \alpha_2 + \tau(\alpha_2) = \alpha_2 + \alpha_4, \tag{42}$$

$$\beta_3 := \alpha_3 + \tau(\alpha_3) = 2\alpha_3, \tag{43}$$

$$\beta_4 := \alpha_6 + \tau(\alpha_6) = 2\alpha_6 \tag{44}$$

$$\beta_{+1} := 2\alpha_{+1}, \quad \beta_{+2} := 2\alpha_{+2} \tag{45}$$

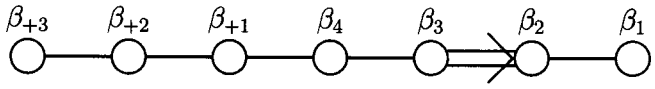
$$\beta_{+3} := 2\alpha_{+3}, \tag{46}$$

and

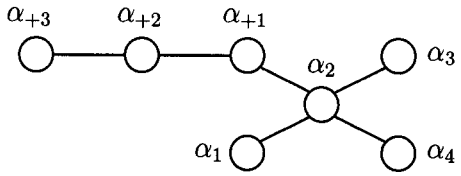
$$\beta_1^2 = \beta_2^2 = 4, \quad \beta_{+3}^2 = \beta_{+2}^2 = \ldots = \beta_3^2 = 8. \tag{47}$$

One gets the three-extended algebra F_4^{+++}, with Cartan matrix and Dynkin diagram

$$B = (b_{ij})_{i,j} = 2\frac{(\beta_i,\beta_j)}{(\beta_i,\beta_i)} = \begin{pmatrix} & & & 0 & 0 & 0 \\ & A_{F_4} & & \vdots & \vdots & \vdots \\ & & & -1 & 0 & 0 \\ 0 & \cdots & -1 & 2 & -1 & 0 \\ 0 & \cdots & 0 & -1 & 2 & -1 \\ 0 & \cdots & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{48}$$



D. $D_4^{+++} \longrightarrow G_2^{+++}$



The Cartan matrix of D_4^{+++} is

$$A = (a_{ij})_{i,j} = (\alpha_i,\alpha_j) = \begin{pmatrix} 2 & -1 & 0 & 0 & 0 & 0 & 0 \\ -1 & 2 & -1 & -1 & -1 & 0 & 0 \\ 0 & -1 & 2 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 2 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 2 & -1 & 0 \\ 0 & 0 & 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{49}$$

The action of τ on the simple roots gives

$$\beta_1 := \alpha_1 + \tau(\alpha_1) + \tau^2(\alpha_1) = \alpha_1 + \alpha_3 + \alpha_4, \tag{50}$$

$$\beta_2 := 3\alpha_2, \tag{51}$$

$$\beta_{+1} := 3\alpha_{+1}, \quad \beta_{+2} := 3\alpha_{+2}, \tag{52}$$

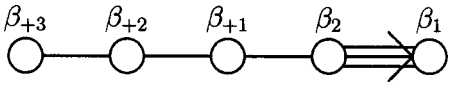
$$\beta_{+3} := 3\alpha_{+3} \tag{53}$$

and

$$\beta_1^2 = 6, \quad \beta_{+3}^2 = \ldots = \beta_2^2 = 18. \tag{54}$$

One gets the extended algebra G_2^{+++} with Cartan matrix and Dynkin diagram:

$$B = (b_{ij})_{i,j} = 2\frac{(\beta_i,\beta_j)}{(\beta_i,\beta_i)} = \begin{pmatrix} 2 & -3 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 \\ 0 & -1 & 2 & -1 & 0 \\ 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & -1 & 2 \end{pmatrix}. \tag{55}$$



Let us remark that, in general, by applying the folding procedure to an algebra $\mathcal{G}$, defined by the Cartan matrix A and Dynkin diagram $S(A)$, we obtain the Cartan matrix B and the corresponding Dynkin diagram $S(B)$ of another algebra $\mathcal{H}$. However we have to check that the new generators, defined in function of the generators of $\mathcal{G}$ satisfy all the defining relations of the algebra $\mathcal{H}$. Let us see how the new generators are obtained. Let α_i be a simple root of $\mathcal{G}$ and h_i, e_i, f_i the associated generators. Let us denote by β_i, respectively, h_i', e_i', f_i', the roots and the associated generators transformed under the action of τ, which we identify, respectively, as the simple roots and the associated generators of $\mathcal{H}$. If the action of τ is trivial, that is $\beta_i = k\alpha_i$ (where k is the order of the automorphism τ, $\tau^k = 1$) then the generators are not transformed $h_i' = h_i$, $e_i' = e_i$ and $f_i' = f_i$. If the action of τ is not trivial, that is $\beta_i = \alpha_i + \tau(\alpha_i) + \ldots + \tau^{k-1}(\alpha_i)$, we obtain $h_i' = h_i + h_{\tau(\alpha_i)} + \ldots + h_{\tau^{k-1}(\alpha_i)}$, $e_i' = e_i + e_{\tau(\alpha_i)} + \ldots + e_{\tau^{k-1}(\alpha_i)}$ and $f_i' = f_i + f_{\tau(\alpha_i)} + \ldots + f_{\tau^{k-1}(\alpha_i)}$. We have to verify that the generators h_i', e_i', f_i' satisfy the defining relations

$$[e_i', f_j'] = \delta_{ij} h_j',$$

$$[h_i', e_j'] = b_{ij} e_j', \quad [h_i', f_j'] = -b_{ij} f_j',$$

$$[h_i', h_j'] = 0,$$

$$(\text{ad } e_i')^{1-b_{ij}} e_j' = 0, \quad (\text{ad } f_i')^{1-b_{ij}} f_j' = 0, \quad (i \neq j).$$

We do not report here the explicit calculations, but everything works nicely. Finally it should be remarked that the folding procedure for indefinite Kac-Moody algebra, when applicable, always gives rise to indefinite Kac-Moody algebra, as it happens for the finite, affine, hyperbolic Kac-Moody algebras. On the contrary other reduction procedures, as the orbifolding, do not preserve the kind of algebras. Indeed as remarked in Ref. 17, the orbifolding of E_{10}, to which the folding procedure cannot be applied, gives rise to non Kac-Moody algebras.

IV. NONSTANDARD EXTENSIONS OF LIE ALGEBRAS

In this section we present a nonstandard construction of extended Lie algebras; as stated in Sec. I, the idea of the nonstandard extension is to add to the simple root system $\{\alpha_i\}$ of a simple Lie algebra $\mathcal{G}$ new roots, which are formed by those fundamental weights of the algebra that are linear combinations with integer coefficients of α_i, plus a suitable combination of vectors belonging to the Lorentzian lattice $\text{II}^{1,1}_{k_\pm}$ and/or $\text{II}^{1,1}_{l_\pm}$. The new roots have to satisfy the requirements that their squared norms are equal to 2 and that are suitably linked with the previous ones. Let us remark that the roots of the nonstandard extension do not generally span the whole lattice $\mathbf{\Lambda} = \Lambda_{\mathcal{G}} \oplus \text{II}^{1,1}_{k_\pm} \oplus \text{II}^{1,1}_{l_\pm}$ and that, moreover, the structure of the added simple root is, by no way, unique. Of course one can add more than two 2-dim. Lorentzian lattices, but these extensions will not be considered in the present paper, where we add at most three new roots. Also we shall not discuss the case where the squared norm of the added roots is not equal to 2. So, given a simple Lie algebra $\mathcal{G}$, we add to the root lattice $\Lambda_{\mathcal{G}}$ a new simple root $\alpha_{r+1} \equiv \alpha_{+1}$, which is formed by the opposite of a fundamental weight $-\Lambda_i$ and by a suitable linear combination, with integer coefficients, of the vectors $k_\pm$, in order to have $\alpha_{+1}^2 = 2$, as Λ_i^2 is not necessarily 2. Let us remember that the fundamental weights have the property $2(\Lambda_i, \alpha_j)/(\alpha_j, \alpha_j) = \delta_{i,j}$; they span the weight lattice $P = \oplus_{i=1}^r \mathbb{Z}\Lambda_i$, which is dual to the coroot lattice $\Lambda_{\mathcal{G}}^\vee = \oplus_{i=1}^r \mathbb{Z}\alpha_i^\vee$ where $\alpha_i^\vee = 2\alpha_i/(\alpha_i, \alpha_i)$ are the coroots. So while it is always true that $P = (\Lambda_{\mathcal{G}}^\vee)^*$, in general we have $\Lambda_{\mathcal{G}} \subseteq P$. This means that for each $\mathcal{G}$, only some Λ_i belong to the root lattice; so, in defining α_{+1} we choose the $\Lambda_i \in \Lambda_{\mathcal{G}}$. Since Λ_i is only linked with the simple root α_i, we have $(\alpha_{+1}, \alpha_j) = -\delta_{+1,i}$. So the first extension is made by adding the root $\alpha_{r+1} \equiv \alpha_{+1} \equiv := -\Lambda_i + k_+ - ak_-$, where $a \in \mathbf{Z}_+$ is fixed by the condition $\alpha_{+1}^2 = \Lambda_i^2$

$-2a=2$. At this point, we add the simple root $\alpha_{r+2}\equiv\alpha_{+2}:=-\theta+bk_--l_-$, where θ is the highest root of $\mathcal{G}$ and $b\in\mathbf{Z}$ is a coefficient chosen in order to have $(\alpha_{+2},\alpha_{+1})=(\Lambda_i,\theta)-b=0$. In this way, we have $\alpha_{+2}^2=2$ and α_{+2} behaves like an affine root (that is, it is linked with the simple roots of $\mathcal{G}$ in a way completely analogous as the affine root of the algebras $\hat{\mathcal{G}}$). At the end, we add the third simple root $\alpha_{r+3}\equiv\alpha_{+3}:=l_++l_-$ with the property that $(\alpha_{+3},\alpha_{+2})=-1$ and $(\alpha_{+3},\alpha_i)=0$ for $i=1,\ldots,r,r+1$. As $(\Lambda_i,\Lambda_j)\in\mathbf{Z}_>$ for the Lie algebra $\mathcal{G}$ below considered, this procedure is completely general and the extended algebra contains as subalgebra the affine extension of $\mathcal{G}$ (so sometimes we shall call this a *nonstandard affine extension*). Clearly the lightlike vector l_- can be hanged up to any other simple root, producing another indefinite Kac-Moody. We shall comment on this point in Sec. V. This construction leads to indefinite Kac-Moody algebras, one-, two-, and three-extended, whose (symmetric) Cartan matrix $2(\alpha_i,\alpha_j)/(\alpha_i,\alpha_i)$ (for $i,j=1,\ldots,r+3$) has Lorentzian signature $(+\ldots+-)$ with $r+2$ plus signs and 1 minus sign. The root lattice of the three-extended algebra is properly contained in $\Lambda_{\mathcal{G}}\oplus\mathrm{II}^{1,1}_{k_\pm}\oplus\mathrm{II}^{1,1}_{l_\pm}$. For these algebras, one can make similar discussions as those in Sec. II on eventual further extensions. Now we want to discuss another possible extension, which cannot be performed for any fundamental weight Λ_i belonging to the root lattice of $\mathcal{G}$. The first extension is performed as before, but as second extension we add the root $\alpha_{+2}:=-\Lambda_j+k_+-bk_--l_-$ $(i\neq j)$, where $b\in\mathbf{Z}_+$ is such that $\alpha_{+2}^2=2$ and $(\alpha_{+1},\alpha_{+2})=(\Lambda_i,\Lambda_j)-a-b=0$. In the following we shall show that, for $\mathcal{G}\neq E_6$, for any i $(\Lambda_i\neq\theta)$, at least one j exists which satisfies the above condition. In the following, we discuss only some examples of the general construction, we called *affine extension*; in particular we concentrate on the simply laced algebras, but it is possible to consider also the other cases paying attention at the choice of the fundamental weight.

Looking at the fundamental weights of simply laced-Lie algebras, see Ref. 13, one realizes that the fundamental weights which can be written as

$$\Lambda_i=\sum_n c_n\alpha_n,\quad c_n\in\mathbf{Z} \tag{56}$$

are

1. for $D_N=so(2N)$ $(N\geqslant 4)$, the weights Λ_i with i even number $(N-2\geqslant i\geqslant 2)$,
2. for E_6, only the weights Λ_i $(i=3,6)$,
3. for E_7, only the weights Λ_i $(i=1,2,3,5)$,
4. for E_8, all the weights Λ_i, which is just a consequence of the E_8-lattice being a self-dual one.

In the following we discuss some of the possible nonstandard extensions, with the aim to illustrate the procedure in a few examples which may be relevant for their subalgebras content. Let us emphasize that the discussed extensions as well their subalgebras content are not at all exhaustive, being the choice of the extended simple roots not unique, in general.

A. $D_N=so(2N)$

In order to illustrate the general procedure, we discuss in some detail the case of $D_6=so(12)$, which is the first algebra of the even orthogonal series which admits a nonstandard extension. We add the simple root

$$\alpha_{+1}:=-\Lambda_4+k_+-k_-,\quad \alpha_{+1}^2=2, \tag{57}$$

where Λ_4 is the fundamental weight (the ε_i are unit ortho-normal vectors in $\mathbb{R}^6$)

$$\Lambda_4=\varepsilon_1+\varepsilon_2+\varepsilon_3+\varepsilon_4,\quad \Lambda_3^2=4, \tag{58}$$

Clearly we have

$$(\alpha_{+1},\alpha_i)=-\delta_{4,i}. \tag{59}$$

We add now the root

$$\alpha_{+2} := -\text{h.r.} - 2k_- - l_- = -(\varepsilon_1 + \varepsilon_2) - 2k_- - l_-, \tag{60}$$

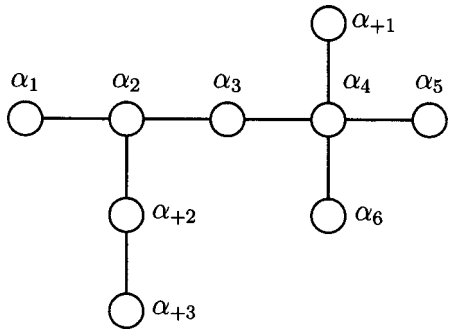
$$(\alpha_{+2}, \alpha_j) = -\delta_{2,j}, \tag{61}$$

and

$$\alpha_{+3} := l_+ + l_-, \tag{62}$$

$$(\alpha_{+3}, \alpha_k) = -\delta_{+2,k}, \tag{63}$$

with Dynkin diagram:



Let's observe that the first extension of D_6 is the same algebra as D_4^{+++}, so folding α_{+1}, α_5, and α_6 we re-obtain G_2^{+++}. Clearly the choice of the extended simple roots is not unique. One can easily see that:

- A nonstandard extension of $so(4N)$ admits as subalgebra the affine extension of $so(4N)$ and $so(4(N-1))$. Indeed one adds to the roots of $so(4N)$ the root of the affine extension

  $$\alpha_{+1} := -\Lambda_2 + k_+ \tag{64}$$

  and the new nonstandard root

  $$\alpha_{+2} := -\Lambda_4 + l_+ - l_-. \tag{65}$$

  Taking away the roots α_{+1}, α_j $(j=1,2)$ one gets the algebra $so(4(N-1))^{(1)}$. Let us remark that if we add the root

  $$\alpha_{+2} := -\Lambda_6 + l_+ - 2l_- \tag{66}$$

  and then we take away the roots α_{+1}, α_j $(j=1,\ldots,4)$ one gets the algebra $so(4(N-2))^{(1)}$.
- The nonstandard extension of $so(24)$ is the smallest extension of the orthogonal series which contains as subalgebra E_{11}. Indeed adding to the roots of $so(24)$ the nonstandard root

  $$\alpha_{+1} := -\Lambda_8 + k_+ - 3k_- \tag{67}$$

  and deleting α_{11}, α_{12} one gets E_{11}.

Let us call $\hat{\Lambda}_{2n} = -\Lambda_{2n} + k_+ - (n-1)k_-$, where $n \in \mathbb{Z}_+$ and $\Lambda_{2n} = \Sigma_{i=1}^{2n} \varepsilon_i$ is a fundamental weight. Clearly we have

$$\hat{\Lambda}_{2n}^2 = 2 \quad (\hat{\Lambda}_{2n}, \hat{\Lambda}_{2n+2}) = 0. \tag{68}$$

B. E_6

Let us add to the simple root system of E_6 the root

$$\alpha_{+1} := -\Lambda_3 + k_+ - 2k_-, \quad \alpha_{+1}^2 = 2, \tag{69}$$

where Λ_3 is the fundamental weight

$$\Lambda_3 = \varepsilon_3 + \varepsilon_4 + \varepsilon_5 + \varepsilon_8 - \varepsilon_7 - \varepsilon_6, \quad \Lambda_3^2 = 6. \tag{70}$$

Clearly we have

$$(\alpha_{+1}, \alpha_i) = -\delta_{3,i}. \tag{71}$$

We add now the root

$$\alpha_{+2} := -\text{h.r.} - 3k_- - l_- = -\tfrac{1}{2}(\varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4 + \varepsilon_5 - \varepsilon_6 - \varepsilon_7 + \varepsilon_8) - 3k_- - l_-, \tag{72}$$

$$(\alpha_{+2}, \alpha_j) = -\delta_{6,j}, \tag{73}$$

and

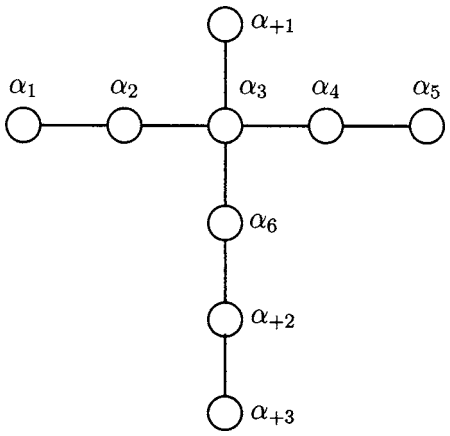
$$\alpha_{+3} := l_+ + l_-, \quad (\alpha_{+3}, \alpha_k) = -\delta_{+2,k}. \tag{74}$$

Alternatively we can add the roots

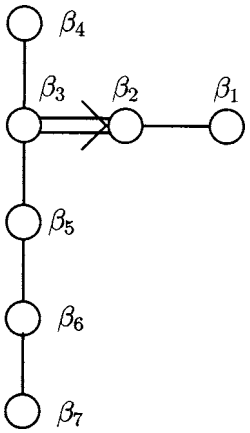
$$\alpha_{+2} := k_- + k_+ - l_-, \quad (\alpha_{+2}, \alpha_j) = -\delta_{+1,j}, \tag{75}$$

$$\alpha_{+3} := l_+ + l_-, \quad (\alpha_{+3}, \alpha_k) = -\delta_{+2,k}, \tag{76}$$

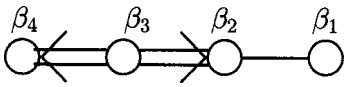
and we obtain the same Dynkin diagram:



where in the second construction the roles of α_{+1} and α_6 are exchanged. Let's observe that many nonstandard (simply laced) Dynkin diagrams can be folded to obtain other (nonsimply laced) Dynkin diagrams. For example, in the case of E_6, we can identify the roots α_1 and α_2 with α_5 and α_4, respectively (so the new simple roots are $\beta_1 = \alpha_1 + \alpha_5$, $\beta_2 = \alpha_2 + \alpha_4$ and $\beta_i = 2\alpha_i$ for $i = 3, +1, +2, +3$), obtaining the following folded Dynkin diagram:



Actually, if we consider only the first extension of E_6, then we can identify also α_{+1} with α_6 and we obtain:



C. E_7

In this case we could use the fundamental weights Λ_1, Λ_2, Λ_3, and Λ_5. To illustrate the procedure, let's consider the weight Λ_5 $((\Lambda_5,\Lambda_5)=4)$ and add the simple roots:

$$\alpha_{+1} := -\Lambda_5 + k_+ - k_-, \quad \alpha_{+1}^2 = 2, \quad (\alpha_{+1},\alpha_i) = -\delta_{5,i}, \tag{77}$$

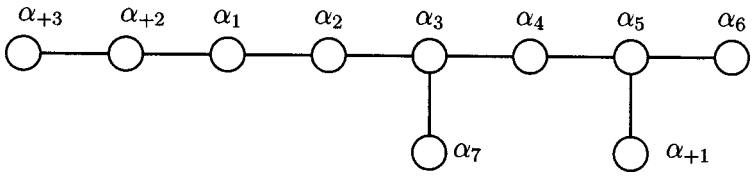
with

$$\Lambda_5 = \varepsilon_5 + \varepsilon_6 - \varepsilon_7 + \varepsilon_8, \quad \Lambda_5^2 = 4. \tag{78}$$

Then

$$\alpha_{+2} := -\text{h.r.} - 2k_- - l_- = \varepsilon_7 - \varepsilon_8 - 2k_- - l_-, \quad \alpha_{+3} = l_+ + l_-, \tag{79}$$

with $(\alpha_{+2},\alpha_k)=-\delta_{k,1}$ and $(\alpha_{+3},\alpha_j)=-\delta_{j,+2}$. In this way we obtain the Dynkin diagram:



Let us call $\hat{\Lambda}_i := -\Lambda_i + k_+ - ak_-$, where $a \in \mathbb{Z}_+$ and Λ_i, $i=1,2,3,5$, is a fundamental weight. We have

$$\hat{\Lambda}_i^2 = 2 \quad (\hat{\Lambda}_3,\hat{\Lambda}_5) = 0. \tag{80}$$

D. E_8

E_8 root lattice is self-dual, so it coincides with the weight lattice. The nonstandard extension can be made adding to the simple root system a root equal to the opposite of any weight Λ_i ($i=1,\ldots,8$) plus some combination of k_+ and k_-. In this way we have eight different extensions of E_8, with the nodes +2, +3 always in the same position (that is $(\alpha_{+2},\alpha_7)=-1$ and $(\alpha_{+3},\alpha_{+2})=-1$), while the node +1 moves from the node 1 to the node 8, when i runs from 1 to 8, respectively. Actually, this situation is general for the nonstandard extensions.

Let us emphasize again that the choice of the extended simple roots is not unique at all. Motivated by this consideration, we observe that classically we have $E_6 \subset E_7 \subset E_8$, while this inclusion is lost when we consider the corresponding affine algebras (and the same thing is true for the double and the triple extensions). So we look for an algebra that may contain all the E series and the $E^{(1)}$ series. This is possible considering the following nonstandard extension of E_8 (in which the new simple roots are linked to those of E_8 using different fundamental weights). We add the new simple root:

$$\alpha_{+1} := -\text{h.r.} + k_+ + l_+ = -(\varepsilon_7 + \varepsilon_8) + k_+ + l_+, \quad \alpha_{+1}^2 = 2, \tag{81}$$

Then we add the two simple roots:

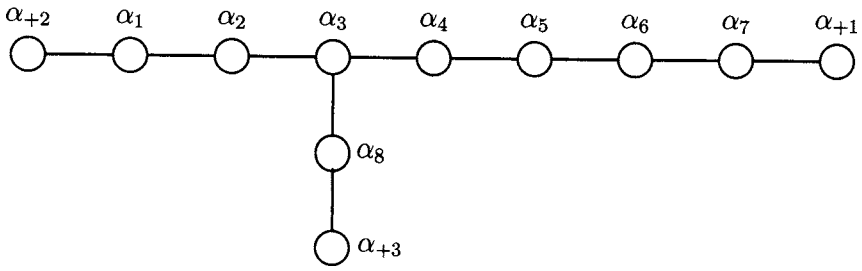
$$\Lambda_1 = 2\varepsilon_8, \quad \Lambda_8 = \frac{1}{2}\left(\sum_{i=1}^{7} \varepsilon_i + 5\varepsilon_8\right), \tag{82}$$

$$\alpha_{+2} := -\Lambda_1 - k_- + l_+ - l_-, \quad \alpha_{+1}^2 = 2, \tag{83}$$

and

$$\alpha_{+3} := -\Lambda_8 + k_+ + l_+ - 3l_-, \quad \alpha_{+3}^2 = 2, \tag{84}$$

so that the only nonzero scalar products are: $(\alpha_{+1}, \alpha_7) = -1$, $(\alpha_{+2}, \alpha_1) = -1$ and $(\alpha_{+3}, \alpha_8) = -1$ and we have the following Dynkin diagram:



This algebra contains E_8 (then also E_7 and E_6) and all the affinizations $E_{6,7,8}^{(1)}$, so it seems to be interesting for its content in subalgebras. Let us call $\hat{\Lambda}_i = -\Lambda_i + k_+ - ak_-$, where $a \in \mathbb{Z}_+$ and Λ_i, is any fundamental weight. We have $(\hat{\Lambda}_i^2 = 2)$

$$(\hat{\Lambda}_1, \hat{\Lambda}_2) = (\hat{\Lambda}_1, \hat{\Lambda}_5) = 0,$$

$$(\hat{\Lambda}_4, \hat{\Lambda}_8) = 0 (\hat{\Lambda}_2, \hat{\Lambda}_3) = (\hat{\Lambda}_2, \hat{\Lambda}_4) = (\hat{\Lambda}_2, \hat{\Lambda}_5) = (\hat{\Lambda}_2, \hat{\Lambda}_6) = 0,$$

$$(\hat{\Lambda}_2, \hat{\Lambda}_3) = (\hat{\Lambda}_2, \hat{\Lambda}_4) = (\hat{\Lambda}_2, \hat{\Lambda}_5) = (\hat{\Lambda}_2, \hat{\Lambda}_6) = 0. \tag{85}$$

We have proposed a procedure to build nonstandard triple extended Lie algebras, which we have illustrated with a number of relevant examples. As already recalled, Kac-Moody or Borcherds extensions can be defined for these Lie algebras too. On the light of the remarks of Ref. 11, it is natural to wonder if these or some of these algebras are not really subalgebras of the standard triple extended Lie algebras. This point will be discussed in the next section, where we discuss also a few examples of subalgebras which point out the intriguing and surprising structure of the subalgebras.

V. SUBALGEBRAS OF EXTENDED LIE ALGEBRAS

First of all, let us discuss another nonstandard procedure to extend a Lie algebras of rank r. If one adds to the simple roots of $\mathcal{G}$ the opposite of the h.r. $\alpha_0 \equiv \alpha_{r+1}$ and, to recover the linear independence of the simple root system, one glues the light like vector k_+ to a simple root α_i $(1 \leqslant i \leqslant r)$, one gets exactly the affine $\mathcal{G}$. As next step one adds the new root, which belongs to $\mathrm{II}_k^{1,1}$, $\alpha_{r+2} = -(k_+ + k_-)$. From the Feingold-Nicolai theorem,[11] it is easy to realize that in this way one obtains a generalized Kac-Moody algebra which is really a subalgebra of the standard overextended Lie algebra $\mathcal{G}^{++}$. Things may be different if one considers simple root systems, obtained by analogous procedure, in the lattice $\Lambda_{\mathcal{G}} \oplus \mathrm{II}_k^{1,1} \oplus \mathrm{II}_l^{1,1}$. Indeed indefinite Kac-Moody algebras are obtained which, in general, are described by Dynkin-Kac diagrams not equivalent to the ones obtained by the standard and not standard procedure described in the previous section. A general discussion of these algebras is beyond the aim of this paper and we limit ourselves to state a few properties and to present some examples. Let us start with the following

Proposition 2: The roots $\hat{\Lambda}_i$ defined in Sec. IV are roots of the standard overextended $\mathcal{G}^{++}$.

Proof: We shall explicitly write $\hat{\Lambda}_i$ in terms of the simple roots of $\mathcal{G}^{++}$. Let us remark that, by construction, $\mathcal{G}^{++}$ contains two affine $\mathcal{G}$, i.e., $\mathcal{G}^{+}$, whose real root system is formed by the roots of $\mathcal{G}$ plus nk_+, respectively, nk_-, $(n \in \mathbf{Z})$. Clearly the following decomposition in roots is not all unique.

1. $so(2N)$

$$\begin{aligned}\hat{\Lambda}_{2m} &= -(-\varepsilon_1 - \varepsilon_2 + k_+) + (-\varepsilon_3 - \varepsilon_4 - k_-) + \ \ldots \ + (-\varepsilon_{2m-1} - \varepsilon_{2m} - k_-) \\ &= -\Lambda_{2m} + k_+ - (m-1)k_-. \end{aligned} \tag{86}$$

2. E_6

$$\begin{aligned}\hat{\Lambda}_3 &= \frac{1}{2}\left[-\sum_{i\neq 6,7} \varepsilon_i + \varepsilon_6 + \varepsilon_7 + k_+\right] + \frac{1}{2}[\varepsilon_1 + \varepsilon_2 - \varepsilon_3 - \varepsilon_4 - \varepsilon_5 + \varepsilon_6 + \varepsilon_7 - \varepsilon_8 - 2k_-] \\ &= -\Lambda_3 + k_+ - 2k_-. \end{aligned} \tag{87}$$

3. E_7

$$\hat{\Lambda}_2 = \frac{1}{2}[\varepsilon_1 - \varepsilon_2 - \varepsilon_3 - \varepsilon_4 - \varepsilon_5 - \varepsilon_6 + \varepsilon_7 - \varepsilon_8 + k_+] + (\varepsilon_7 - \varepsilon_8 - 2k_-) = -\Lambda_2 + k_+ - 2k_-, \tag{88}$$

$$\begin{aligned}\hat{\Lambda}_3 &= (-\varepsilon_3 + \varepsilon_7 + k_+) + (-\varepsilon_4 + \varepsilon_7 - 2k_-) + (-\varepsilon_5 - \varepsilon_8 - k_-) + (-\varepsilon_6 - \varepsilon_8 - 2k_-) \\ &= -\Lambda_3 + k_+ - 5k_-, \end{aligned} \tag{89}$$

$$\hat{\Lambda}_5 = (-\varepsilon_3 - \varepsilon_6 + k_+) + (-\varepsilon_7 + \varepsilon_8 - k_-) = -\Lambda_5 + k_+ - k_-. \tag{90}$$

4. E_8

$$\hat{\Lambda}_1 = (-\varepsilon_i - \varepsilon_8 + k_+) + (\varepsilon_i - \varepsilon_8 - k_-) = -\Lambda_1 + k_+ - k_- \quad (i \neq 8),$$

$$\begin{aligned}\hat{\Lambda}_2 &= \frac{1}{2}[(\varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4 - \varepsilon_5 - \varepsilon_6 - \varepsilon_7 - \varepsilon_8) + k_+] + (-\varepsilon_3 - \varepsilon_8 - k_-) + (-\varepsilon_4 - \varepsilon_8 - 2k_-) \\ &\quad + (-\varepsilon_5 - \varepsilon_8 - 3k_-) = -\Lambda_2 + k_+ - 6k_-, \end{aligned}$$

$$\hat{\Lambda}_3 = (-\varepsilon_3 - \varepsilon_8 + k_+) + (-\varepsilon_4 - \varepsilon_8 - 2k_-) + (-\varepsilon_5 - \varepsilon_8 - 3k_-) + (-\varepsilon_6 - \varepsilon_8 - 4k_-) + (-\varepsilon_7 - \varepsilon_8 - 5k_-) = -\Lambda_3 + k_+ - 14k_-,$$

$$\hat{\Lambda}_4 = (-\varepsilon_4 - \varepsilon_8 + k_+) + (-\varepsilon_5 - \varepsilon_8 - 2k_-) + (-\varepsilon_6 - \varepsilon_8 - 3k_-) + (-\varepsilon_7 - \varepsilon_8 - 4k_-) = -\Lambda_4 + k_+ - 9k_-,$$

$$\hat{\Lambda}_5 = (-\varepsilon_5 - \varepsilon_8 + k_+) + (-\varepsilon_6 - \varepsilon_8 - 2k_-) + (-\varepsilon_7 - \varepsilon_8 - 3k_-) = -\Lambda_5 + k_+ - 5k_-,$$

$$\hat{\Lambda}_6 = (-\varepsilon_6 - \varepsilon_8 + k_+) + (-\varepsilon_7 - \varepsilon_8 - 2k_-) = -\Lambda_6 + k_+ - 2k_-,$$

$$\hat{\Lambda}_8 = \frac{1}{2}[(-\varepsilon_1 - \varepsilon_2 - \varepsilon_3 - \varepsilon_4 - \varepsilon_5 - \varepsilon_6 + \varepsilon_7 + \varepsilon_8) + k_+] + (-\varepsilon_6 - \varepsilon_8 - k_-) + (-\varepsilon_7 - \varepsilon_8 - 2k_-) = -\Lambda_8 + k_+ - 3k_-. \tag{91}$$

Therefore, the considered combinations of the fundamental weights with the vectors of the Lorentzian lattices $\mathrm{II}^{1,1}_k$ do belong to the root system of the overextended Lie algebras, even if the considered fundamental weights do not belong to the root system of the native Lie algebra. (One can recover the generators by the change $\alpha \to E_\alpha$ and $\alpha+\beta \to [E_\alpha, E_\beta]$.) It follows that the double nonstandard extensions (called previously *affine extensions*) are all subalgebras, of the same rank, of $\mathcal{G}^{++}$. Indeed it is easy to verify that the differences $\beta_i - \beta_j$ $(\forall i,j; i \neq j)$ of the simple roots β_i of the nonstandard double extension of $\mathcal{G}$ do not belong to the root system, therefore satisfying the conditions of the Feingold-Nicolai theorem. In particular we have

Proposition 3: The indefinite Kac-Moody algebras of rank 10 described by the Dynkin-Kac diagrams, obtained by adding to the diagram of the affine algebra E_8, i.e., E_9, a dot, connected with a simple link to the jth dot of E_9 $(1 \leqslant j \leqslant 9)$, is a subalgebra of E_{10}.

The simple root systems of these subalgebras is formed by the simple roots of E_8, by a root $\hat{\Lambda}_i$ given by Eq. (91) and by the root $-\theta + ak_-$ where a is a positive integer such that $(\hat{\Lambda}_i, -\theta + ak_-) = 0$.

One can naturally ask if an analogous theorem holds for E_{11}, that is if the triple nonstandard extensions of E_8 form Lorentzian algebras of rank 11, subalgebra of E_{11}. We have:

Proposition 4: The indefinite Kac-Moody algebras of rank 11 obtained by adding to the simple root system of the algebra E_8 three roots: $\alpha_{+1} = \hat{\Lambda}_j$, connected with a simple link to the jth dot of E_8 $(1 \leqslant j \leqslant 8, j \neq 7)$; $\alpha_{+2} = -\theta - ak_-$, where a is a positive integer such that $(\alpha_{+2}\alpha_{+1}) = 0$ and $\alpha_{+3} = l_+ + l_- - k_-$, simply linked with α_{+1}, is a subalgebra of E_{11}.

The proof is straightforward using the explicit expressions of $\hat{\Lambda}_j$, given in Eq. (91). Let us remark that these subalgebras do not have as subalgebra E_{10}. In the following we give the simple roots systems of a set (not exhaustive) of rank eleven subalgebra E_{11}, which contains as subalgebra E_{10}. Let us consider the following simple root system of E_{11}: α_i $(1 \leqslant i \leqslant 8)$ are the simple roots of E_8, $\alpha_9 = -\alpha_0 - k_+$, $\alpha_{10} = k_+ + k_-$ and $\alpha_{11} = (l_+ + l_-) - k_+$. We follow the convention of Ref. 13 and, for the reader convenience, we explicitly write here the E_8 simple root system and the root system Δ:

$$\alpha_1 = \frac{1}{2}\left(\varepsilon_1 + \varepsilon_8 - \sum_{j=2}^{7} \varepsilon_j\right), \quad \alpha_i = \varepsilon_i - \varepsilon_{i-1} \; i = 2, \ldots, 7$$

$$\alpha_8 = \varepsilon_1 + \varepsilon_2, \quad \text{h.r.} := \alpha_0 = \varepsilon_7 + \varepsilon_8, \tag{92}$$

$$\Delta = \left\{ \tfrac{1}{2}(\pm\varepsilon_1 \pm \varepsilon_2 \pm \varepsilon_3 \pm \varepsilon_4 \pm \varepsilon_5 \pm \varepsilon_6 \pm \varepsilon_7 \pm \varepsilon_8), \pm\varepsilon_i \pm \varepsilon_j \right\}, \tag{93}$$

where the total number of + signs (or − signs) in the first expression is an even number. Let us consider the E_{10} Dynkin-Kac diagram obtained by the E_{11} diagram, deleting the dot corresponding to 11th simple root. Let us denote by $E_{10}^{(j)}$ the algebra of rank 11 whose Dynkin-Kac diagram is obtained by the E_{10} diagram adding a dot (in the following denoted by +1) with a simple link to the jth dot ($1 \leqslant j \leqslant 10$) and by $\beta_i^{(j)}$ ($i = 1, \ldots, 10, +1$) the simple roots of $E_{10}^{(j)}$. In the following we do not explicitly write the upper label j in the roots. Clearly $E_{10}^{(10)} = E_{11}$ and, in this case, $\beta_{+1} = \alpha_{11}$. We make the following (not unique) choice for the simple root system of $E_{10}^{(j)}$ ($1 \leqslant j \leqslant 9$):

- $j=9$)

$$\beta_1 = \alpha_1 - k_+, \quad \beta_i = \alpha_i, \quad i = 2, \ldots, 7, 8,$$

$$\beta_9 = -\varepsilon_7 + \varepsilon_8 + k_-, \quad \beta_{10} = -\alpha_0 - k_+, \quad \beta_{+1} = \alpha_{11}. \tag{94}$$

- $j=7$)

$$\beta_i = \alpha_i, \quad i = 1, \ldots, 6, 8, \quad \beta_7 = \alpha_7 - k_+,$$

$$\beta_9 = \alpha_{10}, \quad \beta_{10} = \alpha_{11}, \quad \beta_{+1} = -\alpha_0. \tag{95}$$

- $j=6$)

$$\beta_i = \alpha_i, \quad i = 1, \ldots, 5, 7, 8, \quad \beta_6 = \alpha_6 + k_-,$$

$$\beta_9 = -\alpha_0, \quad \beta_{10} = \varepsilon_7 + \varepsilon_6 - k_+, \quad \beta_{+1} = \alpha_{11}. \tag{96}$$

- $j=5$)

$$\beta_i = \alpha_i, \quad i = 1,2,3,4,6,7,8, \quad \beta_5 = \alpha_5 + k_-,$$

$$\beta_9 = -\alpha_0, \quad \beta_{10} = \varepsilon_5 + \varepsilon_8 - k_+, \quad \beta_{+1} = \alpha_{11}. \tag{97}$$

- $j=4$)

$$\beta_i = \alpha_i, \quad i = 1,2,3,5,6,7,8, \quad \beta_4 = \alpha_4 + k_-,$$

$$\beta_9 = -\alpha_0, \quad \beta_{10} = \varepsilon_4 + \varepsilon_8 - k_+, \quad \beta_{+1} = \alpha_{11}. \tag{98}$$

- $j=3$)

$$\beta_i = \alpha_i, \quad i = 1,2, \ldots, 7, 8, \quad \beta_3 = \alpha_3 + k_-,$$

$$\beta_9 = -\alpha_0, \quad \beta_{10} = \varepsilon_3 + \varepsilon_8 - k_+, \quad \beta_{+1} = \alpha_{11}. \tag{99}$$

- $j=2$)

$$\beta_i = \alpha_i, \quad i = 1,3, \ldots, 7, 8, \quad \beta_2 = \alpha_2 + k_-,$$

$$\beta_9 = -\alpha_0, \quad \beta_{10} = -\varepsilon_1 + \varepsilon_8 - k_+, \quad \beta_{+1} = \alpha_{11}. \tag{100}$$

- $j=1$)

$$\beta_1 = -\frac{1}{2}\sum_{i=i}^{8} \varepsilon_i + k_-, \quad \beta_2 = \alpha_8, \quad \beta_i = \alpha_i, \quad i = 3, \ldots, 6, \quad \beta_8 = \alpha_2,$$

$$\beta_7 = \alpha_7, \quad \beta_9 = -\varepsilon_7 + \varepsilon_8, \quad \beta_{10} = -\alpha_1 + k_+, \quad \beta_{+1} = \alpha_{11}. \tag{101}$$

- $j=8$)

$$\beta_i = \alpha_i, \quad i = 1, \ldots, 7, \quad \beta_8 = \alpha_8 + k_-,$$

$$\beta_9 = -\alpha_0, \quad \beta_{10} = \frac{1}{2}\sum_{i=1}^{8} \varepsilon_i - k_+, \quad \beta_{+1} = \alpha_{11}. \tag{102}$$

It is easy to verify that the roots β_i belong to the roots systems of E_{11}. Actually they belong, except for α_{11}, to the root system of affine $E_8=E_9$ which is a regular subalgebra of E_{11}—while the differences $\beta_i-\beta_j$ $(\forall i,j;i\neq j)$ $(|\beta_i-\beta_j|^2\geqslant 4)$ do not belong, therefore satisfying the conditions of the Feingold-Nicolai theorem. The Dynkin-Kac diagrams describing these algebras contain loops except for $j=7$. This algebra has been considered in Ref. 14, where it has been denoted EE_{11}, and it has been shown to be a subalgebra of E_{11} by explicitly constructing the generators by commutation of the E_{11} generators. The Dynkin-Kac diagrams for these algebras are easily drawn by adding to the E_{10} diagram a dot simply connected with the jth dot and then connecting, with a simple link, the following dots: $j=9$) 7–10; $j=6$) 1–10; $j=5$) 6–10; $j=4$) 5–10; $j=3$) 4–10; $j=2$) 8–10; $j=1$) 7–10, 8–10; $j=8$) 1–10. Of course, these subalgebras do not exhaust the set of 11 dimensional indefinite Kac-Moody subalgebras of E_{11}. In particular we have not considered the subalgebras which do appear as invariant algebras with respect to an involution of the generators of E_{11}, see Refs. 18 and 19.

VI. CONCLUSIONS AND FUTURE DEVELOPMENTS

In studying four-extended Lie algebras, we have seen that Borcherds algebras seem to emerge naturally. This remark raises the question: which are the fingerprints of a theory which exhibits a symmetry under a Borcherds algebra? This question is indeed interesting on the light of the remark that many dualities have a group-theoretical origin in the Weyl group of the algebra. The Weyl group of the Borcherds algebra has peculiar properties as the reflection with respect to the imaginary vanishing roots is not defined. Some particular properties related to this kind of algebras have already been discussed in Ref. 20. The nonstandard extension introduced in this paper has peculiar features, which deserve further investigation, on both their mathematical structure and their possible physical relevance. A classification of these algebras is beyond the aim of this paper, where we present only a few representative examples. As, however, very little is known on Lorentzian Kac-Moody algebras, we believe that any new information is interesting. In the cited literature on the physical role of the very extended Lie algebras, nonlinear realizations of the indefinite Kac-Moody algebras are used. How does a Chevalley realization of this algebra look like? In Ref. 21 a procedure to build up vertex realization of Lorentzian algebra with only a lattice $\mathrm{II}^{1,1}$ has been proposed and applied to the very simple case of the overextended A_1 algebra. It seems possible to generalize that procedure to the triple extended Lie algebras. Moreover, it has also been argued by West[22] that $sl(32)$ is contained in the Cartan invariant subalgebra of E_{11}. At first sight the rank of $sl(32)$ is too large to be a subalgebra, so it seems that very extended algebras, at least in the nonlinear realization, admit finite dimensional subalgebras which naively could not be there. The investigation of the finite Lie subalgebras of the indefinite Kac-Moody algebras requires new methods beyond the very familiar ones used in the case of finite Lie algebra, which are essentially based on the Dynkin methods. This feature is not completely unrelated with the property, noted in Ref. 11, that the set of infinite dimensional subalgebras of Lorentzian algebras is quite rich and surprising. We have illustrated this feature in Sec. V iscussing a class of subalgebras of E_{11}, but it would be useful to dispose of techniques to build up explicitly or to identify classes of these subalgebras or to dispose of further examples.

We thank C. Helfgott, A. Kleinschmidt, and I. Schnakenburg for pointing out a mistake in the previous version and for useful comments.

APPENDIX A: SOME FACTS ABOUT THE LATTICE $II^{1,1}$

We review some basic facts about the lattice $II^{1,1}$, which is the only Lorentzian even self-dual lattice in dimension two. The points in this lattice can be described as the vectors:

$$(n,m) \tag{A1}$$

with $n,m \in \mathbb{Z}$ and Gram matrix $\left(\begin{smallmatrix} 0 & -1 \\ -1 & 0 \end{smallmatrix}\right)$, with eigenvalues ± 1. In this way, the scalar product between two vectors $a=(a_+,a_-)$ and $b=(b_+,b_-)$ can be written as: $a\cdot b=-a_+b_--a_-b_+$. We can take $k_+ \equiv (1,0)$ and $k_- \equiv (0,-1)$ as basis vectors in $II^{1,1}$; with this choice, we have

$$k_\pm \cdot k_\pm = 0, \quad k_\pm \cdot k_\mp = 1. \tag{A2}$$

All the vectors in $II^{1,1}$ can be written as $v=pk_+ + qk_-$ (with $p,q \in \mathbb{Z}$); in particular there are only two vectors of squared norm 2, $\pm(k_+ + k_-)$, but infinite vectors of positive ($\geqslant 4$) and negative ($\leqslant -2$) squared norm, being $v^2=2pq$.

APPENDIX B: DEFINITION OF BORCHERDS ALGEBRAS

The best way to think of a Borcherds algebra is to consider it as a generalization of a finite-dimensional simple Lie algebra. The definition is based on the Serre-Chevalley construction of finite-dimensional algebras; we follow Ref. 12. These algebras always have a symmetric matrix and their structure is very similar to that of ordinary Kac-Moody algebras, the only major difference is that generalized Kac-Moody algebras allow the presence of imaginary simple roots. Let $A=(a_{i,j})$ a $n \times n$ (real) symmetric matrix satisfying the following properties:

- $a_{ii}=2$ or $a_{ii} \leqslant 0$,
- $a_{ij} \leqslant 0$ if $i \neq j$,
- $a_{ij} \in Z$ if $a_{ii}=2$.

Then the Borcherds algebra $\mathcal{G}(A)$ associated with the Cartan matrix A is the Lie algebra given by the following generators and relations.

$3n$ *Generators*: e_i, f_i and h_i

Relations:

- $[h_i,h_j]=0$,
- $[e_i,f_j]=\delta_{ij}h_i$,
- $[h_i,e_j]=a_{ij}e_j$, $[h_i,f_j]=-a_{ij}e_j$,
- $e_{ij} := (\mathrm{ad}e_i)^{1-a_{ij}}e_j=0$, $f_{ij} := (\mathrm{ad}f_i)^{1-a_{ij}}f_j=0$ if $a_{ii}=2$ and $i \neq j$,
- $e_{ij} := [e_i,e_j]=0$, $f_{ij} := [f_i,f_j]=0$ if $a_{ii} \leqslant 0$, $a_{jj} \leqslant 0$ and $a_{ij}=0$.

The elements h_i form a basis for an abelian subalgebra of $\mathcal{G}(A)$, called Cartan subalgebra $\mathcal{H}(A)$; as it happens for Kac-Moody algebras, $\mathcal{G}(A)$ has the triangular decomposition:

$$\mathcal{G}(A) = \mathcal{N}_- \oplus \mathcal{H}(A) \oplus \mathcal{N}_+ \tag{B1}$$

and has many of the properties of the usual Kac-Moody algebras (real and imaginary roots, etc.). In particular, in this paper, we have considered Borcherds algebras with just one imaginary simple root (with squared norm 0), which we have added by hand. A rank 2 Borcherds algebra in the lattice $II^{1,1}$ can be constructed as follows: the Cartan matrix is given by

$$A = \begin{pmatrix} 0 & -1 \\ -1 & 2 \end{pmatrix}. \tag{B2}$$

A possible choice for the simple roots is

$$\alpha_1 = k_+, \quad \alpha_2 = -(k_+ + k_-), \tag{B3}$$

with Weyl vector $\rho = -k_+$ (defined by $(\rho, \alpha_i) = 1/2(\alpha_i, \alpha_i)$).

(Received 22 November 2005; accepted 5 December 2005; published online 27 January 2006)

Although it is well known that the Seiberg-Witten equations do not admit nontrivial L^2 solutions in flat space, singular solutions to them have been previously exhibited—either in $\mathbb{R}^3$ or in the dimensionally reduced spaces $\mathbb{R}^2$ and $\mathbb{R}^1$—which have physical interest. In this work, we employ an extension of the Hopf fibration to obtain an iterative procedure to generate particular singular solutions to the Seiberg-Witten and Freund equations on flat space. Examples of solutions obtained by such method are presented and briefly discussed. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2162823]

I. INTRODUCTION

Given a physical system defined on a configuration space M, there are various instances where it is useful to employ (extensions of) fibrations $P \to M$ to lift the corresponding equations of motion from M to P. For instance, the natural extension of the Hopf fibration $S^3 \to S^2$ to $\mathbb{R}^4 \to \mathbb{R}^3$ (defining the so-called Kustaanheimo-Stiefel transformation[1,2]) can be used to map the Kepler problem in $\mathbb{R}^3$ to a harmonic oscillator problem in $\mathbb{R}^4$. This construction has been recurrently employed to regularize and calculate orbits of celestial objects, besides giving rise to various applications in atomic physics (see, e.g., Ref. 3, and references therein). In this work, we apply this idea to the case when M, instead of representing the configuration space of a particle, is the target space of a given field theory. Specifically, we show that by lifting the equations of magnetostatics (in the sense above), it is possible to obtain the Seiberg-Witten equations (SWE) on $\mathbb{R}^3$ provided that a certain constraint is imposed on the resulting fields. Moreover, we show that such constraint naturally gives rise to an iterative method to generate particular solutions to the SWE and Freund equations on $\mathbb{R}^3$ and its dimensionally reduced spaces.

It should be kept in mind that the SWE do not admit nontrivial L^2 solutions in flat space[4] (the same is not true for the Freund equations[5]). However, singular solutions to the SWE in flat space do exist,[5,6] with physical interest. Another point to be emphasized is that the lifting procedure considered here (Sec. II) is not new since it is implicit in the pioneer work of Loss and Yau on zero modes of the three-dimensional Dirac operator[7] (it is also known that, by applying the Kustaanheimo-Stiefel transformation to the vector potential coupled to a Dirac spinor, one recovers the *ansatz* of Loss and Yau[8]). In fact, our formulas for the relevant Abelian potential A_k and wave function $|\psi\rangle$ are the same as those of Ref. 7, where A_k and $|\psi\rangle$ are given in terms of a generating vector field, but with the differences that, in our case, such generating vector field satisfies a certain constraint and that, due to the singular nature of the present problem, we do not demand that the associated fields be square integrable.

It is precisely such constraint that gives rise, in our approach, to the aforementioned iterative method to the SWE and Freund equations on $\mathbb{R}^3$. This is considered in Sec. III, where we also show that application of such method recovers some known solutions to the SWE and Freund

[a)]Electronic mail: mosna@ime.unicamp.br

equations and yields, to the best of our knowledge, previously unnoticed solutions to the SWE. In particular, we obtain an axisymmetric singular solution to the SWE on $\mathbb{R}^3$. We conclude by presenting some final remarks in Sec. IV.

II. LIFTING THE MAGNETOSTATICS EQUATIONS

We start from the equations of magnetostatics,

$$\nabla \cdot \boldsymbol{H} = 0, \tag{1a}$$

$$\nabla \times \boldsymbol{H} = \boldsymbol{J}, \tag{1b}$$

where $\boldsymbol{J}$ is the steady current associated with the magnetic field $\boldsymbol{H}$ (we use Heaviside-Lorentz units with $c=1$). Let $|\psi\rangle$ be a two-component spinor such that

$$H^k = \langle\psi|\sigma^k|\psi\rangle, \quad k=1,2,3, \tag{2}$$

where $\sigma^1,\sigma^2,\sigma^3$ are the Pauli matrices. For each $\boldsymbol{r}\in\mathbb{R}^3$, $\boldsymbol{H}(\boldsymbol{r})$ can be formally regarded as the "polarization vector" or "spin density" associated with $|\psi(\boldsymbol{r})\rangle\in\mathbb{C}^2$, as in quantum mechanics textbooks.[9] The general solution of Eq. (2) for $|\psi\rangle$ in terms of $\boldsymbol{H}$ is given by

$$|\psi\rangle = e^{-i\chi}\frac{1}{\sqrt{2(H+H^3)}}\begin{pmatrix} H+H^3 \\ H^1+iH^2 \end{pmatrix}, \tag{3}$$

where $H=\|\boldsymbol{H}\|$ and $e^{-i\chi}$ is an arbitrary phase factor. In spherical coordinates, Eq. (3) assumes the familiar form

$$|\psi\rangle = e^{-i\chi}\sqrt{H}\begin{pmatrix} \cos(\alpha/2) \\ e^{i\beta}\sin(\alpha/2) \end{pmatrix},$$

where $\boldsymbol{H}=H(\sin\alpha\cos\beta,\sin\alpha\sin\beta,\cos\alpha)$. It is interesting to note that this is a (trivial) application of what has been termed the inversion theorem,[11] an useful result (especially in four dimensions[12,13]) when one wants to reconstruct a given spinor, apart from arbitrary phases, from its bilinear covariants.

Before transferring the dynamics (Eq. (1)) from $\boldsymbol{H}$ to $|\psi\rangle$, we briefly consider the geometry underlying Eqs. (2) and (3). Let S^n_a denote the n-sphere of radius a in $\mathbb{R}^{n+1}$, and consider the map $\pi_a: S^3_a \to S^2_{a^2}$ taking a two-component spinor $|\phi\rangle\in S^3_a\subset\mathbb{C}^2$ into the vector $\boldsymbol{s}\in S^2_{a^2}$ with components $s^k=\langle\phi|\sigma^k|\phi\rangle$. Here $|\phi\rangle=\binom{z_1}{z_2}\in S^3_a\subset\mathbb{C}^2$ means that $|z_1|^2+|z_2|^2=a^2$. This defines a principal fiber bundle $U(1)\cdots S^3_a\to S^2_{a^2}$ which is essentially the first Hopf bundle (where one usually takes $a=1$).[10] More generally, one can drop the requirement that $|\phi\rangle$ belongs to a sphere of fixed radius and consider the map $\pi:\mathbb{R}^4\to\mathbb{R}^3$ taking $|\phi\rangle\in\mathbb{C}^2\cong\mathbb{R}^4$ into $s^k=\langle\phi|\sigma^k|\phi\rangle$. In this way, π is a natural extension of the Hopf map $S^3\to S^2$ to $\mathbb{R}^4\to\mathbb{R}^3$, in which each sphere of radius $a>0$ in $\mathbb{R}^4$ is mapped into the sphere $S^2_{a^2}\subset\mathbb{R}^3$, and the origin of $\mathbb{R}^4$ is mapped into the origin of $\mathbb{R}^3$. Such map defines the so-called Kustaanheimo-Stiefel transformation[1,2] (this no longer gives rise to a principal fiber bundle, since the fiber over the origin is just a point). Note that, in our case, Eq. (2) defines a Kustaanheimo-Stiefel transformation on the corresponding *target spaces*, relating, for each $\boldsymbol{r}$, the vector $\boldsymbol{H}(\boldsymbol{r})\in\mathbb{R}^3$ to the spinor $|\psi(\boldsymbol{r})\rangle\in\mathbb{C}^2\cong\mathbb{R}^4$. We also note that Eq. (3) yields, for each fixed $\boldsymbol{r}$, a local section of the bundle $U(1)\cdots S^3_H\to S^2_{H^2}$ over $S^2_{H^2}\backslash\{\text{south pole}\}$. A related local section over $S^2_{H^2}\backslash\{\text{north pole}\}$ can be similarly obtained.

Going back to Eq. (3), it is easy to see that the density matrix associated with $|\psi\rangle$ is given by

$$|\psi\rangle\langle\psi| = \tfrac{1}{2}(H\mathbb{1} + H^k\sigma_k), \tag{4}$$

where $\mathbb{1}$ is the identity 2×2 matrix (notice that we are working with Cartesian coordinates in Euclidean flat space, so that indices can be freely raised and lowered). For what follows, it is useful to define the following matrix-valued functions:

$$\mathsf{H}(\boldsymbol{r}) = H^k(\boldsymbol{r})\sigma_k, \tag{5a}$$

$$\mathsf{J}(\boldsymbol{r}) = J^k(\boldsymbol{r})\sigma_k. \tag{5b}$$

Then, it is easily seen that Eq. (1) can be equivalently written, in terms of H and J, as

$$\partial\mathsf{H} = i\mathsf{J}, \tag{6}$$

where $\partial = \sigma^k\partial_k$ (this follows at once from the relationship $\sigma^i\sigma^j = \delta^{ij}\mathbb{1} + i\epsilon^{ijk}\sigma_k$ satisfied by the Pauli matrices, where ϵ^{ijk} is the totally antisymmetric symbol with $\epsilon^{123}=1$).

We now transfer the dynamics defined by Eq. (1) from $\boldsymbol{H}$ to $|\psi\rangle$. From Eq. (4):

$$\mathsf{H} = 2|\psi\rangle\langle\psi| - H\mathbb{1},$$

which leads, upon substitution into Eq. (6), to

$$\sigma^k\left[\partial_k|\psi\rangle\langle\psi| + |\psi\rangle\partial_k\langle\psi| - \frac{1}{2}\partial_k H - \frac{i}{2}J_k\right] = 0.$$

Our aim is to obtain a differential equation governing the dynamics of $|\psi\rangle$. To that end, we right-multiply the above equation by $|\psi\rangle$ and use the fact that $\langle\psi|\psi\rangle = H$. This yields

$$\sigma^k\left[\partial_k + \frac{1}{2H}\partial_k H - \frac{1}{H}\langle\psi|\partial_k|\psi\rangle - \frac{i}{2H}J_k\right]|\psi\rangle = 0. \tag{7}$$

The term $\langle\psi|\partial_k|\psi\rangle$ can be computed by a straightforward calculation; it follows from Eq. (2) that

$$\langle\psi|\partial_k|\psi\rangle = \frac{1}{2}\partial_k H + \frac{i}{2(H+H^3)}(H^1\partial_k H^2 - H^2\partial_k H^1) - iH\partial_k\chi.$$

Upon substitution into Eq. (7), this leads to

$$\sigma^k\left[\partial_k + i\left(\partial_k\chi - \frac{1}{2H(H+H^3)}(H^1\partial_k H^2 - H^2\partial_k H^1) - \frac{1}{2H}J_k\right)\right]|\psi\rangle = 0.$$

Defining

$$A_k := -\frac{1}{2H(H+H^3)}(H^1\partial_k H^2 - H^2\partial_k H^1) - \frac{1}{2H}J_k, \tag{8}$$

which can be fully expressed in terms of $\boldsymbol{H}$ (through Eq. (1b)) as

$$A_k = -\frac{1}{2H(H+H^3)}(H^1\partial_k H^2 - H^2\partial_k H^1) - \frac{1}{2H}(\nabla\times\boldsymbol{H})_k, \tag{9}$$

we finally get

$$i\sigma^k(\partial_k + iA_k + i\partial_k\chi)|\psi\rangle = 0. \tag{10}$$

Therefore, $|\psi\rangle$ satisfies the Weyl equation with the Abelian potential A_k (i.e., the massless Dirac equation for two-component spinors representing states of definite chirality). Note that χ enters Eqs. (3) and (9) simply as a gauge parameter.

It is interesting to note that Eq. (1b) enters the derivation above merely as a bookkeeping device. In fact, Eq. (10) follows as long as $\boldsymbol{H}$ satisfies Eq. (1a), regardless of any interpretation of the right-hand side of Eq. (1b) as an external current. In any case, it should be noted that Eq. (1b) does affect the form of Eq. (10) through A_k.

An important observation for what follows is that the field strength B_k associated with A_k,

$$\boldsymbol{B} := \nabla \times \boldsymbol{A}, \tag{11}$$

does not have to bear any relation to the magnetic field $\boldsymbol{H}$ we started with.

III. SEIBERG-WITTEN AND FREUND EQUATIONS

Let us summarize what has been done above. We started from the equations of magnetostatics, expressed the magnetic field $\boldsymbol{H}$ in terms of the associated spinor field $|\psi\rangle$, and then lifted the dynamics from $\boldsymbol{H}$ to $|\psi\rangle$. As a result, the following set of equations (Eqs. (2), (10), and (11)) was obtained:

$$\langle\psi|\sigma^k|\psi\rangle = H^k, \tag{12a}$$

$$i\sigma^k(\partial_k + iA_k)|\psi\rangle = 0, \tag{12b}$$

$$\epsilon^{ijk}\partial_i A_j = B^k, \tag{12c}$$

where we chose to suppress the terms associated with the gauge parameter χ. The SWE and Freund equations in three dimensions have been discussed in detail in Ref. 5 (see especially its Eqs. (3.5) and (3.6)) from where we note a remarkable similarity with Eq. (12). More precisely:

1. Eqs. (12a)–(12c) are the Seiberg-Witten equations on $\mathbb{R}^3$ *provided that* $H_k = +B_k$;
2. Eqs. (12a)–(12c) are the Freund equations on $\mathbb{R}^3$ *provided that* $H_k = -B_k$.

Therefore, the constraint

$$\boldsymbol{H} = \pm \boldsymbol{B} \tag{13}$$

yields a natural *ansatz* for obtaining solutions to the Seiberg-Witten and Freund equations for $\boldsymbol{A}$, $\boldsymbol{B}$, and $|\psi\rangle$ on $\mathbb{R}^3$. Using Eq. (9), this amounts to solving

$$\boldsymbol{H} = \pm \nabla \times \left(-\frac{1}{2H(H+H^3)}(H^1 \nabla H^2 - H^2 \nabla H^1) - \frac{1}{2H} \nabla \times \boldsymbol{H} \right) \tag{14}$$

for $\boldsymbol{H}$. This equation has been recently studied from a group-theoretical perspective in Ref. 14 to examine the Lie symmetries of the SWE and Freund equations on $\mathbb{R}^3$.

It is interesting to note that, given a solution of Eq. (14), with the + or − sign, respectively, one immediately obtains $|\psi\rangle$, A_k, and B_k from Eqs. (3), (9), and (13):

$$|\psi\rangle = \frac{1}{\sqrt{2(H+H^3)}} \begin{pmatrix} H+H^3 \\ H^1 + iH^2 \end{pmatrix}, \tag{15a}$$

$$\boldsymbol{A} = -\frac{1}{2H(H+H^3)}(H^1 \nabla H^2 - H^2 \nabla H^1) - \frac{1}{2H} \nabla \times \boldsymbol{H}, \tag{15b}$$

$$\boldsymbol{B} = \pm \boldsymbol{H}. \tag{15c}$$

As noted in Sec. I, the above expressions for $|\psi\rangle$ and $\boldsymbol{A}$ in terms of a generating vector field (which is given, in this case, by $\boldsymbol{H}$) were first obtained in the study of zero modes of the massless Dirac operator in Ref. 7.

A. An iterative procedure.

We now show how Eq. (14) can serve as a basis for an iterative procedure for obtaining $\boldsymbol{H}$, and thus $|\psi\rangle$, $\boldsymbol{A}$ and $\boldsymbol{B}$ satisfying the SWE or Freund equations on flat space. The procedure goes as follows. Choose an initial guess $\boldsymbol{H}_{(0)}$ for $\boldsymbol{H}$; substitute $\boldsymbol{H}_{(0)}$ into the right-hand side of Eq. (14) and consider the result as a second estimate $\boldsymbol{H}_{(1)}$ for $\boldsymbol{H}$; then substitute $\boldsymbol{H}_{(1)}$ into the right-hand side of Eq. (14), and so on. If the sequence $\boldsymbol{H}_{(k)}$ converges, its limit is a solution to Eq. (14). It is important to note that this procedure does fail in most cases, either by computational or mathematical difficulties (we come back to this point in Sec. IV). Nevertheless, when it succeeds, we end up with a solution to the Seiberg-Witten or Freund equations. In the remainder of this section, we show representative results of a limited experiment in algebraic computation, performed with the software MATHEMATICA, implementing such iterative procedure.

Example 1: Starting with $\boldsymbol{H}_{(0)}=\pm(x,y,z)$, we obtain the solution

$$\boldsymbol{B}=\mp\frac{1}{2r^3}(x,y,z), \tag{16a}$$

$$\boldsymbol{A}=\frac{1}{2r(r\pm z)}(y,-x,0), \tag{16b}$$

$$|\psi\rangle=\frac{1}{2r\sqrt{r(r\pm z)}}\begin{pmatrix} r\pm z \\ \pm(x+iy)\end{pmatrix} \tag{16c}$$

to the Freund equations, where $r=\sqrt{x^2+y^2+z^2}$. A monopole solution of this kind was first obtained in Ref. 15 (see also Ref. 5, where the authors discuss in detail how the Freund equations are related to the SWE on $\mathbb{R}^3$).

Example 2: Starting with $\boldsymbol{H}_{(0)}=\pm(\sinh\kappa y,0,0)$, we obtain the solution

$$\boldsymbol{B}=\mp\frac{\kappa^2}{\sinh^2\kappa y}\mathbf{e}_x, \tag{17a}$$

$$\boldsymbol{A}=\pm\kappa\coth\kappa y\mathbf{e}_z, \tag{17b}$$

$$|\psi\rangle=\frac{\kappa}{\sqrt{2}\sinh\kappa y}\begin{pmatrix} 1 \\ \mp 1\end{pmatrix} \tag{17c}$$

to the Seiberg-Witten equations (in order to avoid dealing with the absolute value function in the algebraic computation procedure of Examples 2 and 3, it is useful to first restrict attention to the domain given by $x>0$, $y>0$, and $z>0$, and later extend the obtained solution to any nonzero x, y, and z). This solution is essentially the same as the effectively one-dimensional solution to the SWE found in Ref. 6. On the other hand, if we start with $\boldsymbol{H}_{(0)}=\pm(\cosh\kappa y,0,0)$, we obtain the solution

$$\boldsymbol{B}=\pm\frac{\kappa^2}{\cosh^2\kappa y}\mathbf{e}_x,$$

$$\boldsymbol{A}=\pm\kappa\tanh\kappa y\mathbf{e}_z,$$

$$|\psi\rangle = \frac{\kappa}{\sqrt{2}\cosh \kappa y}\begin{pmatrix} 1 \\ \mp 1 \end{pmatrix}$$

to the Freund equations. We note that similar expressions were also obtained in Ref. 6 through analytic continuation of the aforementioned one-dimensional solution to the SWE.

Example 3: Starting with $\boldsymbol{H}_{(0)} = \pm(xyz, 0, 0)$, we obtain the solution

$$\boldsymbol{B} = \mp\left(\frac{1}{y^2} + \frac{1}{z^2}, 0, 0\right), \tag{18a}$$

$$\boldsymbol{A} = \pm\frac{1}{y^2 + z^2}\left(0, -\frac{y^2}{z}, \frac{z^2}{y}\right), \tag{18b}$$

$$|\psi\rangle = \sqrt{\frac{1}{2y^2} + \frac{1}{2z^2}}\begin{pmatrix} 1 \\ \mp 1 \end{pmatrix} \tag{18c}$$

to the Seiberg-Witten equations.

For solutions of this kind, in which $\boldsymbol{B}(\boldsymbol{r})$ is always parallel to some fixed vector $\mathbf{n}$ and only depends on coordinates (u, v) of a plane orthogonal to $\mathbf{n}$, the quantity $\omega = \frac{1}{2}\ln B$ is known[6] to satisfy the Liouville equation $4\partial_z\partial_{\bar{z}}\omega = e^{2\omega}$, where z now denotes the complex coordinate $z = u + iv$ and $B = \|\boldsymbol{B}\|$ [it should be clear from the context when z refers to the complex coordinate $z = u + iv$ or to the Cartesian coordinate in (x, y, z)]. Using the *ansatz*

$$\omega = \frac{1}{2}\ln\frac{4(\mathrm{d}g/\mathrm{d}z)(\mathrm{d}\bar{g}/\mathrm{d}\bar{z})}{(1 - g\bar{g})^2}, \tag{19}$$

with $g(z)$ an arbitrary analytic function, the authors of Ref. 6 construct a family of effectively two-dimensional solutions to the SWE with interesting properties. We note, however, that the above solution (18a) apparently does not belong to such family, obtained via *ansatz* (19). In any case, we show in the Appendix that the alternative *ansatz*

$$\omega = \frac{1}{2}\ln\frac{(\mathrm{d}g/\mathrm{d}z)(\mathrm{d}\bar{g}/\mathrm{d}\bar{z})}{[\Im(g)]^2}, \tag{20}$$

where $\Im(g)$ denotes the imaginary part of g, does yield the above solution. In fact, as discussed in the Appendix, (18a) is the $n = 2$ case of a family of two-dimensional singular solutions generated by the choice $g(z) = z^n$ in (20), with $n = \frac{1}{2}, 1, \frac{3}{2}, \ldots$ [it should be noted that both (19) and (20) are particular cases of the well-known general solution of the Liouville equation[16] (see Appendix)].

Example 4: Starting with $\boldsymbol{H}_{(0)} = \pm(y, -x, 0)$, we obtain the axisymmetric solution

$$\boldsymbol{B} = \pm\frac{1}{2\rho^2}\mathbf{e}_\phi, \tag{21a}$$

$$\boldsymbol{A} = -\frac{1}{2\rho}\mathbf{e}_\phi \pm \frac{1}{2\rho}\mathbf{e}_z, \tag{21b}$$

$$|\psi\rangle = \frac{1}{2\rho}\begin{pmatrix} 1 \\ \pm ie^{i\phi} \end{pmatrix} \tag{21c}$$

to the Seiberg-Witten equations, where cylindrical coordinates ρ, ϕ, z, with $\rho = \sqrt{x^2 + y^2}$ and $\phi = \arctan(y/x)$, were used. Such $\boldsymbol{B}$ is similar (but different in the ρ-dependence) to the magnetic field $\boldsymbol{B} \propto (1/\rho)\mathbf{e}_\phi$ produced by a steady current along the z axis. The integral curves of $\boldsymbol{A}$ are

helices of constant ρ going upward (downward) with respect to the z axis. We note that the first term $\boldsymbol{A}_{AB}=-(1/2\rho)\mathbf{e}_{\phi}$ of $\boldsymbol{A}$ is in fact an Aharonov-Bohm potential, with holonomy given by

$$\int_{\gamma} \boldsymbol{A}_{\mathrm{AB}}(\boldsymbol{r}) \cdot \mathrm{d}\boldsymbol{r} = -\pi, \tag{22}$$

where γ is any loop winding once around the z axis. Note that the Aharonov-Bohm term $\boldsymbol{A}_{\mathrm{AB}}$ is actually *implied* by $\boldsymbol{B}$ [through Eq. (15b)] even though $\boldsymbol{B}$ in Eq. (21a) does not receive any contribution from the curl of $\boldsymbol{A}_{\mathrm{AB}}$ (which is actually zero for $\rho \neq 0$). In this way, the purely azimuthal magnetic field of Eq. (21a), defined away from the z axis, unavoidably gives rise, through $\boldsymbol{A}_{\mathrm{AB}}$, to the "additional" singular magnetic field $-\pi\delta(x)\delta(y)\mathbf{e}_z$ along the z axis (which is the same as the magnetic field of an infinitely long and infinitesimally thin solenoid at the z axis).

It is also interesting to note that, although the two solutions to the SWE in Eq. (21a) (given, respectively, by its plus and minus signs) wind in opposite directions with respect to the xy plane, their associated potentials both wind clockwise, with identical Aharonov-Bohm terms, the only difference residing in their z components.

IV. CLOSING REMARKS

In all the examples above, the final solution for $\boldsymbol{H}$ is obtained in *exact form* after very few iterations. On the other hand, some experience with the above computational experiment shows that a generic initial condition for $\boldsymbol{H}$ typically leads to an increasingly complicated algebraic expression at each iteration, thereby requiring further investigation on convergence issues related to such method. A natural question to ask is what are the initial conditions under which the sequence $\boldsymbol{H}_{(k)}$ may be guaranteed to converge since, under such circumstances, the approach presented here could be used to define classes of solutions to the SWE and Freund equations iteratively.

Finally, we note that the approach presented here suggests a natural generalization to the four-dimensional case, where one may try to lift the whole set of (Euclidean) Maxwell equations to obtain (singular) solutions to the SWE on $\mathbb{R}^4$. This is the subject of work in progress.

APPENDIX

The general solution to the Liouville equation,

$$4\partial_z\partial_{\bar{z}}\omega = e^{2\omega},$$

was first given by Liouville in Ref. 16 (where the author considers, in fact, the corresponding equation for $\lambda=e^{2\omega}$, and with real variables). It is given by

$$\omega(z,\bar{z}) = \frac{1}{2}\ln\frac{4(\mathrm{d}g(z)/\mathrm{d}z)(\mathrm{d}h(\bar{z})/\mathrm{d}\bar{z})}{[1-g(z)h(\bar{z})]^2}, \tag{A1}$$

where $g(z)$ and $h(\bar{z})$ are arbitrary analytic and antianalytic functions, respectively. The *ansatz* of Ref. 6, given by Eq. (19), is recovered from Eq. (A1) if the natural choice $h(\bar{z})=\overline{g(z)}$ is made. However, as mentioned in Example 3 of Sec. III, the solution given by $B=1/u^2+1/v^2$ is apparently not recovered by such *ansatz* (recall that B is related to ω by $B=e^{2\omega}$, where $B=\|\boldsymbol{B}\|$ and now z denotes the complex coordinate $z=u+iv$). This motivates the search for an alternative *ansatz* for such B. Generalizing the above choice of h in terms of g to $h(\bar{z})=\overline{g(z)}^{\nu}$, it is not hard to show that,

in general, the requirement that ω be real restricts ν to $+1$ or -1, which yield Eq. (19) and Eq. (20), respectively. Therefore, the alternative *ansatz* (20) is given by the choice $h(\bar{z})=1/\overline{g(z)}$ in (A1). The solution of Example 3 is recovered from such *ansatz* for $g(z)=z^2$, as a direct calculation shows.

More generally, choosing $g(z)=z^n$ in Eq. (20) leads to the solution $B=n^2/(\rho^2 \sin^2 n\phi)$, where polar coordinates $z=\rho e^{i\phi}$ were used. The requirement that B be single-valued restricts n to $n=\frac{1}{2},1,\frac{3}{2},\ldots$ (note that B is insensitive to the change $n\to -n$). In this way, the solution of Example 3 is the $n=2$ case of such family of two-dimensional singular solutions. Note that the solution corresponding to a given n is singular along $2n$ lines starting at the origin and passing through the roots of unity of order $2n$.

(Received 27 October 2005; accepted 6 December 2005; published online 30 January 2006)

This paper sets out to study the spectral minimum for an operator belonging to the family of random Schrödinger operators of the form $H_{\lambda,\omega}=-\Delta+W_{\text{per}}+\lambda V_\omega$, where we suppose that V_ω is of Anderson type and the single site is assumed to be with an indefinite sign. Under some assumptions we prove that there exists $\lambda_0>0$ such that for any $\lambda\in[0,\lambda_0]$, the minimum of the spectrum of $H_{\lambda,\omega}$ is obtained by a given realization of the random variables. © *2006 American Institute of Physics.*

I. INTRODUCTION

Among the most investigated and dealt with operators in the field of mathematical physics problems are random Schrödinger operators of the form

$$H_\omega=-\Delta+W_{\text{per}}+V_\omega=H_0+V_\omega, \tag{1.1}$$

where W_{per} is a $\mathbb{Z}^d$-periodic function and V_ω is a random potential having the Anderson form, i.e., $V_\omega(\cdot)=\Sigma_{\gamma\in\mathbb{Z}^d}\omega_\gamma f(\cdot-\gamma)$. See Refs. 2 and 12 for the physical motivations.

Here we consider H_ω as a family of self-adjoint operators in $L^2(\mathbb{R}^d)$ with some appropriate domain. In fact, we are not dealing with a single Schrödinger operator, but with rather large family of operators H_ω, indexed by the random parameter $\omega\in\Omega$. Nevertheless, from the general theory of ergodic operators, which applies to H_ω, it is known[9] that the spectrum of H_ω is *almost surely deterministic*, i.e., there exists a set $\Sigma\subset\mathbb{R}$ such that the spectrum $\sigma(H_\omega)$ coincides with Σ for $\mathbb{P}$-almost every $\omega\in\Omega$. (Here $\mathbb{P}$ is the probability measure on the probability space Ω.)

The study of the spectral theory of operators of the form (1.1) has drawn the attention of many researchers for the importance of the related results. In fact, it is linked to the systems evolutions for which the Hamiltonian is described by (1.1). The goal of this paper is to discuss one of the problems that remain unsolved: the spectrum location of H_ω, precisely the spectrum infimum. This will be carried out in the case when the single site f does not have a definite sign.

As the main object is to study the location of the spectrum, let us recall the following basic results already known on this subject and stated by Kirsch and Martinelli:[2,3]

Theorem 1.1:

$$\Sigma(H_\omega)=\overline{\bigcup_{(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}\in\mathcal{P}}\Sigma\left(-\Delta+W_{\text{per}}+\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma f(x-\gamma)\right)}. \tag{1.2}$$

Here $\mathcal{P}$ is the set of all periodic sequences $\{\omega_\gamma\}_{\gamma\in\mathbb{Z}^d}$, with an arbitrary period such that ω_γ is in the support of μ for all γ and $\Sigma(H)$ is the spectrum of H.

As has been said above the proof of Theorem 1.1 exists in Refs. 2 and 3 and is based on Weyl sequences and probabilistic arguments. Notice that this theorem reduces the determination of the

[a)]Electronic mail: hatem.najar@ipeim.rnu.tn

spectra of random Schrödinger operators for the case of periodic Schrödinger operators. As it is well known[10] that the spectrum of periodic operators have a band structure, this will be the case for $\Sigma(H_\omega)$ with the possibility to close gaps.

Under additional assumptions on f more is known:

Theorem 1.2: *If f has a fixed sign, i.e., $f\leqslant 0$ or $f\geqslant 0$ and if μ is supported in $[\omega^-,\omega^+]$, then*

$$\Sigma(H_\omega)=\bigcup_{\omega\in[\omega^-,\omega^+]}\Sigma\left(-\Delta+W_{\mathrm{per}}+\omega\sum_{\gamma\in\mathbb{Z}^d}f(x-\gamma)\right). \tag{1.3}$$

In particular,

$$\inf\Sigma(H_\omega)=\begin{cases}\inf\Sigma\left(-\Delta+W_{\mathrm{per}}+\omega^+\sum_{\gamma\in\mathbb{Z}^d}f(x-\gamma)\right) & \text{if } f\leqslant 0\\ \inf\Sigma\left(-\Delta+W_{\mathrm{per}}+\omega^-\sum_{\gamma\in\mathbb{Z}^d}f(x-\gamma)\right) & \text{if } f\geqslant 0.\end{cases} \tag{1.4}$$

Theorem 1.2 is a simple consequence of Theorem 1.1. Indeed, using (1.2) and the fact that constant sequences $\{\omega_\gamma=\omega\in\operatorname{supp}\mu\}\subset\mathcal{P}$, we get that the right-hand side of (1.3) is naturally contained in $\Sigma(H_\omega)$. For the inverse inclusion, let $(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}\in\mathcal{P}$ be k-periodic and let $[a,b]$ be the nth band of the k periodic operator $H_{\omega,k}=-\Delta+W_{\mathrm{per}}+\Sigma_{\gamma\in\mathbb{Z}^d}\omega_\gamma f(x-\gamma)$. Let $[a_1,b_2]$ and $[a_2,b_2]$ be the nth bands of, respectively, $-\Delta+W_{\mathrm{per}}+\omega^-\Sigma_{\gamma\in\mathbb{Z}^d}f(x-\gamma)$ and $-\Delta+W_{\mathrm{per}}+\omega^+\Sigma_{\gamma\in\mathbb{Z}^d}f(x-\gamma)$ (both seen as k-periodic operators). By the min-max principle we have $a_1\leqslant a\leqslant a_2$ and $b_1\leqslant b\leqslant b_2$. As the bands of $-\Delta+W_{\mathrm{per}}+\omega\Sigma_{\gamma\in\mathbb{Z}^d}f(x-\gamma)$ depend continuously on ω, we deduce that $\Sigma(-\Delta+W_{\mathrm{per}}+\Sigma_{\gamma\in\mathbb{Z}^d}\omega_\gamma f(x-\gamma))$ is contained in the r.h.s of (1.3). The proof of (1.3) is ended by taking into account the fact that these sets are closed.

For (1.4) it is a simple consequence of monotonicity of the model, it is increasing when $f\geqslant 0$ and decreasing when $f\leqslant 0$. indeed if $f\leqslant 0$, and $\widetilde{\omega}_\gamma\leqslant\hat{\omega}_\gamma$ for any $\gamma\in\mathbb{Z}^d$ then in the sense form we have

$$-\Delta+W_{\mathrm{per}}+\sum_{\gamma\in\mathbb{Z}^d}\hat{\omega}_\gamma f(x-\gamma)\leqslant-\Delta+W_{\mathrm{per}}+\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma f(x-\gamma).$$

The situation is more complicated and different when the single site f changes the sign, as the monotonicity property is not true in this case. We notice that recently Lott and Stolz have conjectured[6] that in dimension one, the spectral minimum of random displacement models is realized through the pair formation of the single site.

A. The model

Our basic object of study is the so-called *Anderson model*, a random Schrödinger operator of the form

$$H_{\lambda,\omega}=-\sum_{i=1}^{d}\frac{\partial^2}{\partial x_i^2}+W_{\mathrm{per}}+\lambda\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma f(x-\gamma), \tag{1.5}$$

where

- W_{per} is a $\mathbb{Z}^d$-periodic and bounded function.
- λ is a positive parameter
- $(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}$ is a family of independent, identically distributed random variables taking values in $[\omega^-,\omega^+]$. We denote by μ the probability distribution.
- For $C_0=\left[-\frac{1}{2},\frac{1}{2}\right]^d$, the single site potential $f\in C_0^\infty(C_0)$ such that $f\in l^1(L^p(\mathbb{R}^d))$, with $p=2$ if $d\leqslant 3$, $p>2$ if $d=4$ and $p=d/2$ if $d\geqslant 5$ and $f=f^+ +f^-$, with $f^+\geqslant 0$, $f^-\leqslant 0$, and $f^+\cdot f^-=0$.

By Refs. 2 and 9, we know that $H_{\lambda,\omega}$ is an essentially self-adjoint operator on $L^2(\mathbb{R}^d)$ with the domain $C_0^\infty(\mathbb{R}^d)$, we denote by $H_{\lambda,\omega}$ its self-adjoint extension.

It is an ergodic operator so, according to Refs. 2 and 9, we know that there exist $\Sigma_\lambda, \Sigma_{\lambda,\mathrm{pp}}, \Sigma_{\lambda,\mathrm{ac}}$, and $\Sigma_{\lambda,\mathrm{sc}}$ closed and nonrandom sets of $\mathbb{R}$ such that Σ_λ is the spectrum of $H_{\lambda,\omega}$ with probability one and such that if σ_{pp} (respectively, σ_{ac} and σ_{sc}) design the pure point spectrum (the absolutely continuous and singular continuous spectrum, respectively) of $H_{\lambda,\omega}$, then $\Sigma_{\lambda,\mathrm{pp}} = \sigma_{\mathrm{pp}}, \Sigma_{\lambda,\mathrm{ac}} = \sigma_{\mathrm{ac}}$ and $\Sigma_{\lambda,\mathrm{sc}} = \sigma_{\mathrm{sc}}$ with probability one.

B. The result

Let us introduce the following operators:

$$H_{\lambda,\omega^-} = -\sum_{i=1}^{d} \frac{\partial^2}{\partial x_i^2} + W_{\mathrm{per}} + \lambda \sum_{\gamma\in\mathbb{Z}^d} \omega^- f(x-\gamma),$$

and

$$H_{\lambda,\omega^+} = -\sum_{i=1}^{d} \frac{\partial^2}{\partial x_i^2} + W_{\mathrm{per}} + \lambda \sum_{\gamma\in\mathbb{Z}^d} \omega^+ f(x-\gamma).$$

We denote by $\Sigma_{\lambda,\omega^-}$ and $\Sigma_{\lambda,\omega^+}$ the spectrum of H_{λ,ω^-} and H_{λ,ω^+}, respectively.

As we will see (Sec. II A) $H_{\lambda,\omega}$ can be considered as a perturbation of the periodic operator H_{λ,ω^-}. Let $\varphi_{\lambda,1}(x,\theta(\lambda))$ be the Floquet eigenfunction associated to the first Floquet eigenvalue $E_1(\lambda,\theta)$ of H_{λ,ω^-}. Let $(\theta_k(\lambda))_{1\leqslant k\leqslant m}$ be the points where $E_1(\lambda,\theta)$ attains its minimum. We set

$$A(0) = (\langle f\varphi_{0,1}(\cdot,\theta_k(0)), \varphi_{0,1}(\cdot,\theta_{k'}(0))\rangle_{L^2(C_0)})_{1\leqslant k,k'\leqslant m}.$$

We prove that

Theorem 1.3: *Let $H_{\lambda,\omega}$ be the operator defined by* (1.5).

If the matrix $A(0)$ is positive-definite, then there exists $\lambda_0>0$ such that for any $\lambda\in[0,\lambda_0]$ we have

$$\inf(\Sigma_\lambda) = \inf(\Sigma_{\lambda,\omega^-}).$$

If the matrix $A(0)$ is negative-definite, then there exists $\lambda_0>0$ such that for any $\lambda\in[0,\lambda_0]$ we have

$$\inf(\Sigma_\lambda) = \inf(\Sigma_{\lambda,\omega^+}).$$

Remark 1.4: *Theorem* 1.3 *is stated for the infimum of the spectrum. Under some additional assumptions the same result is still true for the internal edges of the spectrum.*

The result remains true if we replace $\mathbb{Z}^d$ by any nondegenerate d-dimensional lattice $\Gamma = \oplus_{i=1}^d \mathbb{Z}e_i$, with $(e_1,\ldots,e_d)$ some basis of $\mathbb{R}^d$.

The analogous problem for the random magnetic Schrödinger operator is considered and studied in Ref. 1.

Theorem 1.3 *can be considered as a first step toward the physically motivated applications. One of them is the study of the so-called Lifshitz tails of the integrated density of states. This could be done under some additional assumptions on the behavior of the random variables in the vicinity of ω^- or ω^+.*[4,7,8] *Another one is the spectral localization.*[12,13]

The proof of Theorem 1.3, is given in Sec. III. It is based on the reduction procedure. This powerful technique was predicted by Klopp[4] and used in several works.[1,7,8]

As stated the proof of Theorem 1.3 can be divided naturally into two parts, we shall discuss them separately.

Indeed, if $A(0)$ is positive-definite we will conjugate H_ω with $\Pi_{\lambda,0}$, the spectral projection for H_{λ,ω^-} on the first band. Then we prove that

$$\Pi_{\lambda,0} H_{\lambda,\omega} \Pi_{\lambda,0} \geqslant E_{\lambda,\omega^-} \Pi_{\lambda,0}.$$

Here E_{λ,ω^-} is the bottom of the spectrum of the periodic operator H_{λ,ω^-}.

If $A(0)$ is negative-definite we will conjugate H_ω with $\Pi_{\lambda,0}$, the spectral projection for H_{λ,ω^+} on the first band. Then we prove

$$\Pi_{\lambda,0} H_{\lambda,\omega} \Pi_{\lambda,0} \geqslant E_{\lambda,\omega^+} \Pi_{\lambda,0}.$$

Here E_{λ,ω^+} is the bottom of the spectrum of the periodic operator H_{λ,ω^+}.

II. PRELIMINARY

Let us consider the following periodic operator:

$$H_{\lambda,\omega^-} = -\Delta + W_{\text{per}} + \lambda \sum_{\gamma \in \mathbb{Z}^d} \omega^- f(\cdot - \gamma). \tag{2.1}$$

For this, it is convenient to consider $H_{\lambda,\omega}$ as a perturbation of H_{λ,ω^-}. Indeed, we have

$$H_{\lambda,\omega} = H_{\lambda,\omega^-} + \lambda \sum_{\gamma \in \mathbb{Z}^d} (\omega_\gamma - \omega^-) f(\cdot - \gamma).$$

For this for $\gamma \in \mathbb{Z}^d$, we set $\widetilde{\omega}_\gamma = \omega_\gamma - \omega^-$ and $V_{\widetilde{\omega}}(\cdot) = \Sigma_{\gamma \in \mathbb{Z}^d} \widetilde{\omega}_\gamma f(\cdot - \gamma)$. We notice that according to the definition of $(\omega_\gamma)_{\gamma \in \mathbb{Z}^d}$ we get that $(\widetilde{\omega}_\gamma)_{\gamma \in \mathbb{Z}^d}$ is a family of random positive and bounded variables.

A. Some Floquet theory

For $\gamma \in \mathbb{Z}^d$, we denote by τ_γ the translation by γ operator, i.e., $(\tau_\gamma \varphi)(x) = \varphi(x - \gamma)$. We have, for any $\gamma \in \mathbb{Z}^d$,

$$\tau_\gamma H_{\lambda,\omega^-} \tau_\gamma^* = \tau_\gamma^* H_{\lambda,\omega^-} \tau_\gamma = H_{\lambda,\omega^-}.$$

Then the so-called Floquet Theory can be used to study H_{λ,ω^-}. For this, we review some standard facts from the Floquet theory for periodic operators. Basic references for this material are Refs. 5, 10, and 11. Let $\mathbb{T}^* = \mathbb{R}^d / (2\pi\mathbb{Z}^d)$. We define $\mathcal{H}$ by

$$\mathcal{H} = \{u(x,\theta) \in L^2_{\text{loc}}(\mathbb{R}^d) \otimes L^2(\mathbb{T}^*);\ \forall\ (x,\theta,\gamma) \in \mathbb{R}^d \times \mathbb{T}^* \times \mathbb{Z}^d; u(x+\gamma,\theta) = e^{i\gamma\theta} u(x,\theta)\}.$$

$\mathcal{H}$ is equipped with the norm

$$\frac{1}{\text{vol}(\mathbb{T}^*)} \int_{\mathbb{T}^*} \|u(x,\theta)\|^2_{L^2(C_0)} \mathrm{d}\theta.$$

For $\theta \in \mathbb{R}^d$ and $u \in \mathcal{S}(\mathbb{R}^d)$; the Schwartz space of rapidly decreasing functions we define

$$(Uu)(x,\theta) = \sum_{\gamma \in \mathbb{Z}^d} e^{i\gamma\cdot\theta} u(x-\gamma).$$

U can be extended as a unitary isometry from $L^2(\mathbb{R}^d)$ to $\mathcal{H}$. Its inverse is given by the formula,

$$\text{for } u \in \mathcal{H}, \quad (U^* u)(x) = \frac{1}{\text{vol}(\mathbb{T}^*)} \int_{\mathbb{T}^*} u(x,\theta) \mathrm{d}\theta.$$

U is a unitary isometry from $L^2(\mathbb{R}^d)$ to $\mathcal{H}$ and $H_{\lambda,\omega}$ admits the Floquet decomposition[5,11]

$$UH_{\lambda,\omega^-}U^* = \int_{\mathbb{T}^*}^{\oplus} H_{\lambda,\omega^-}(\theta)\mathrm{d}\theta.$$

Here $H_{\lambda,\omega^-}(\theta)$ is the operator H_{λ,ω^-} acting on $\mathcal{H}_\theta$, defined by

$$\mathcal{H}_\theta = \{u \in L^2_{\mathrm{loc}}(\mathbb{R}^d);\ \forall\ \gamma \in \mathbb{Z}^d, u(x+\gamma) = e^{i\gamma\theta}u(x)\}.$$

As H_{λ,ω^-} is elliptic, we know that, $H_{\lambda,\omega^-}(\theta)$ has a compact resolvent; hence its spectrum is discrete.[10] We denote its eigenvalues, called Floquet eigenvalues of H_{λ,ω^-}, by

$$E_1(\lambda,\theta) \leqslant E_2(\lambda,\theta) \leqslant \cdots \leqslant E_n(\lambda,\theta) \leqslant \cdots .$$

The corresponding Floquet eigenfunctions are denoted by $(\varphi_{\lambda,j}(x,\cdot))_{j\in\mathbb{N}^*}$. The functions $(\theta \to E_n(\lambda,\theta))_{n\in\mathbb{N}^*}$ are Lipshitz-continuous, and we have

$$E_n(\lambda,\theta) \to +\infty \quad \text{as } n \to +\infty \text{ uniformly in } \theta.$$

The spectrum $\Sigma_{\lambda,\omega^-}$ of H_{λ,ω^-} is made of bands (i.e., $\Sigma_{\lambda,\omega^-} = \cup_{n\in\mathbb{N}^*} E_n(\lambda,\mathbb{T}^*)$.)

Let us note by E_{λ,ω^-} the bottom of the spectrum of $\Sigma_{\lambda,\omega^-}$, i.e., $E_{\lambda,\omega^-} = \inf_{\theta\in\mathbb{T}^d} E_1(\lambda,\theta)$.

It is a well-known fact that, in any dimension, the bottom (the first band) of the spectrum of periodic Schrödinger operators is given by a simple Floquet eigenvalue and that the minimum of this Floquet eigenvalue is nondegenerate and quadratic. More precisely let $\theta(\lambda)$ be an element of

$$Z_\lambda = \{\theta \in \mathbb{T}^*;\ E_1(\lambda,\theta) = E_{\lambda,\omega^-}\}.$$

Then there exist $C>0$ and $\delta>0$ such that

$$\forall |\theta-\theta(\lambda)| \leqslant \delta, \quad \frac{1}{C}|\theta-\theta(\lambda)|^2 \leqslant E_1(\lambda,\theta) - E_{\lambda,\omega^-} \leqslant C|\theta-\theta(\lambda)|^2.$$

Hence, the points where $E_1(\lambda,\theta)$ reaches E_{λ,ω^-} are isolated and as $\mathbb{T}^*$ is compact, one concludes that Z_λ contains only finitely many of the elements. Let m be the cardinal of Z_λ and let us denote them by $(\theta_k(\lambda))_{1\leqslant k\leqslant m}$. One can check that $\theta_k(\lambda)$ depends continuously on λ. For the sake of brevity, we use the notation $\theta_k = \theta_k(\lambda)$.

For $1 \leqslant k \leqslant m$ and $\theta \in \mathbb{T}^*$, we set

$$\zeta_{k,\lambda}(\theta) = \sum_{1\leqslant i\leqslant d} (\theta_i - \theta_{k,i})^2. \tag{2.2}$$

We notice that for any $1 \leqslant k \leqslant m$,

$$\theta \mapsto \varphi_{\lambda,1}(x,\theta)$$

is analytic in a neighborhood of θ_k.

B. Wannier basis

We recall concepts used in Ref. 4. Let $\mathcal{E} \subset L^2(\mathbb{R}^d)$ be a closed subspace invariant by the $\mathbb{Z}^d$-translations, i.e., such that $\Pi^{\mathcal{E}}$, the orthogonal projection on $\mathcal{E}$, satisfies

$$\forall\ \gamma \in \mathbb{Z}^d, \quad \Pi^{\mathcal{E}} = \tau_{-\gamma}\Pi^{\mathcal{E}}\tau_\gamma.$$

Following the computations done in Sec. I B of Ref. 4, we see that there exists an orthonormal system of vectors $(\widetilde{\varphi}_{j,0})_{j\in N}$ such that for $\widetilde{\varphi}_{j,\gamma} = \tau_\gamma(\widetilde{\varphi}_{j,0})$; $(\widetilde{\varphi}_{j,\gamma})_{(j\in N;\gamma\in\mathbb{Z}^d)}$ is an orthonormal basis of $\mathcal{E}$. Such a system is called the ***Wannier basis*** of $\mathcal{E}$. The vectors $(\widetilde{\varphi}_{n,0})_{n\in N}$ are called ***Wannier generators*** of $\mathcal{E}$.

Let $\mathcal{E} \subset L^2(\mathbb{R}^d)$ be a space which is translation-invariant. $\mathcal{E}$ is said to be of finite energy for $H_{\lambda,\omega}$ if $\Pi^{\mathcal{E}}H_{\lambda,\omega}\Pi^{\mathcal{E}}$ is a bounded operator. In this case, $\mathcal{E}$ admits a finite set of Wannier generators.

Let $\Pi_{\lambda,0}(\theta)$ (respectively, $\Pi_{\lambda,+}(\theta)$) be the orthogonal projection in $\mathcal{H}_\theta$ on the vector space generated by $\varphi_{\lambda,1}(\cdot,\theta)$ (respectively by $(\varphi_{\lambda,j}(\cdot,\theta))_{j\geqslant 2}$). These projections are two-by-two orthogonal and their sum is the identity for all $\theta\in\mathbb{T}^*$. One defines

$$\Pi_{\lambda,\alpha}=U^{-1}\left(\int_{\mathbb{T}^*}\Pi_{\lambda,\alpha}(\theta)\mathrm{d}\theta\right)U:L^2(\mathbb{R}^d)\to L^2(\mathbb{R}^d),$$

where $\alpha\in\{0,+\}$. $\Pi_{\lambda,\alpha}$ is an orthogonal projection on $L^2(\mathbb{R}^d)$ and for all $\gamma\in\mathbb{Z}^d$, we have $\tau_\gamma^*\Pi_{\lambda,\alpha}\tau_\gamma=\Pi_{\lambda,\alpha}$.

For $\alpha\in\{0,+\}$, we set $\mathcal{E}_{\lambda,\alpha}=\Pi_{\lambda,\alpha}(L^2(\mathbb{R}^d))$. These spaces are translation-invariant. Moreover $\mathcal{E}_{\lambda,0}$ is of finished energies for H_{λ,ω^-}. The reduction procedure consists in decomposing the operator H_{λ,ω^-} according to various translation-invariants subspaces. The random operators thus obtained are reference operators.

III. THE PROOF OF THEOREM 1.3

As we have indicated, our aim in this section is to prove Theorem 1.3, but first, let us introduce some notations and useful lemma.

For $u\in L^2(\mathbb{T}^*)$, let

$$\mathcal{T}_{\varphi_{\lambda,1}}(u)=U^*(u\varphi_{\lambda,1}(x,\theta))=\int_{\mathbb{T}^*}u(\theta)\varphi_{\lambda,1}(x,\theta)\mathrm{d}\theta. \tag{3.1}$$

So, $\mathcal{T}_{\varphi_{\lambda,1}}$ define a unitary transformation from $L^2(\mathbb{T}^*)$ to $\mathcal{E}_{\lambda,0}$ and if to simplify the computation we set $\mathrm{vol}(\mathbb{T}^*)=1$, then for $v\in\mathcal{E}_{\lambda,0}$ we have

$$\mathcal{T}^*_{\varphi_{\lambda,1}}(v)=\langle(Uv)(\cdot,\theta),\varphi_{\lambda,1}(\cdot,\theta)\rangle.$$

For $1\leqslant k\leqslant m$ and $(x,\theta)\in\mathbb{R}^d\times\mathbb{T}^*$, let

$$\widetilde{\varphi}_{\lambda,1,k}(x,\theta)=\varphi_{\lambda,1}(\theta_k(\lambda),x)e^{(\theta-\theta_k)\cdot x}.$$

We set,

$$\delta\varphi_{\lambda,1,k}(x,\theta)=\frac{1}{\sqrt{\zeta_{k,\lambda}(\theta)}}(\varphi_{\lambda,1}-\widetilde{\varphi}_{\lambda,1,k}(x,\theta)).$$

By this, for any $u\in L^2(\mathbb{T}^*)$, we have

$$\mathcal{T}_{\varphi_{\lambda,1}}(u)=\mathcal{T}_{\widetilde{\varphi}_{\lambda,1,k}}(u)+\mathcal{T}_{\delta\varphi_{\lambda,1,k}}(\sqrt{\zeta_{k,\lambda}}u). \tag{3.2}$$

For $v\in\mathcal{H}^2_\theta=\{v\in H^2_{\mathrm{loc}}(\mathbb{R}^d);v(\cdot-\gamma)=e^{-i\gamma\cdot\theta}u(\cdot)\}$ one defines the following norms:

$$\sup_{\theta\in\mathbb{T}^*}\{\|v(\cdot,\theta)\|^2_{L^2(C_0)}\}=\|v\|^2_{1,\infty},$$

and

$$\sup_{\theta\in\mathbb{T}^*}(\|H_{\lambda,\omega^-}(\theta)u(\cdot,\theta)\|^2_{L^2(C_0)}+\|v(\cdot,\theta)\|^2_{L^2(C_0)})=\|v\|_{H_{\lambda,\omega^-},\infty}.$$

Remark 3.1: *The functions* $\widetilde{\varphi}_{\lambda,1,k}$ *and* $\delta\varphi_{\lambda,1,k}$ *are well defined and*

$$\|\widetilde{\varphi}_{\lambda,1,k}\|_{1,\infty},\quad \|\widetilde{\varphi}_{\lambda,1,k}\|_{H_{\lambda,\omega^-},\infty}\|\delta\widetilde{\varphi}_{\lambda,1,k}\|_{1,\infty},\quad \textit{and}\quad \|\delta\widetilde{\varphi}_{\lambda,1,k}\|_{H_{\lambda,\omega^-},\infty}$$

are finished (*see Ref.* 4).

The following Lemma is of use. It will be proven at the end of this section.

Lemma 3.2: *For* $\theta_k,\theta_{k'}\in\mathbb{T}^*$ *and* $\varphi\in L^2(\mathbb{T}^*,\mathcal{H}^2)$ *let* $\varphi_k=e^{i(\theta-\theta_k)x}\varphi(x,\theta_k)$, $\varphi_{k'}=e^{i(\theta-\theta_{k'})x}$

$\varphi(x,\theta_{k'})$, *and* $a_{\varphi,k,k'}(x)=f(x)\varphi(x,\theta_k)\varphi(x,\theta_{k'})$. *If* $\|\varphi\|_{1,\infty}<\infty$ (*respectively*, $\|\varphi\|_{H_{\lambda,\omega^-},\infty}<\infty$) *then* $\mathcal{T}_\varphi \in \mathcal{L}(L^2(\mathbb{T}^*),L^2(\mathbb{R}^d))$ (*respectively*, $V_{\tilde{\omega}}\cdot\mathcal{T}_\varphi \in \mathcal{L}(L^2(\mathbb{T}^*),L^2(\mathbb{R}^d))$) *and there exist* $C,\beta>0$ *such that for all* $u,v\in L^2(\mathbb{T}^*)$, *we have*

$$\left|\langle V_{\tilde{\omega}}\mathcal{T}_{\varphi_k}(u),\mathcal{T}_{\varphi_{k'}}(v)\rangle - \left(\int_{C_0} a_{\varphi,k,k'}(x)\mathrm{d}x\right)\cdot\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma\hat{u}(\gamma)\overline{\hat{v}(\gamma)}\right| \leqslant C\beta\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma(|\hat{u}(\gamma)|^2+|\hat{v}(\gamma)|^2)$$
$$+C(1+1/\beta)(\langle\zeta_{k,\lambda}u,u\rangle_{L^2(\mathbb{T}^*)}+\langle\zeta_{k',\lambda}v,v\rangle_{L^2(\mathbb{T}^*)}), \tag{3.3}$$

$$\|V_{\tilde{\omega}}\mathcal{T}_{\varphi_k}(u)\|^2_{L^2(\mathbb{R}^d)} \leqslant C\left(\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma|\hat{u}(\gamma)|^2+\langle\zeta_{k,\lambda}u,u\rangle_{L^2(\mathbb{T}^*)}\right). \tag{3.4}$$

A. If $A(0)$ is positive-definite

We set

$$H^0_{\lambda,\omega}=\Pi_{\lambda,0}H_{\lambda,\tilde{\omega}}\Pi_{\lambda,0}=\Pi_{\lambda,0}H_{\lambda,\omega^-}\Pi_{\lambda,0}+\Pi_{\lambda,0}V_{\tilde{\omega}}\Pi_{\lambda,0}.$$

Theorem 3.3: *Assume that the matrix* $A(0)$ *is positive-definite. Then there exists* $\lambda_0>0$ *such that for any* $\lambda\in[0,\lambda_0]$ *we have*

$$\Pi_{\lambda,0}(H_{\lambda,\omega}-E_{\lambda,\omega^-})\Pi_{\lambda,0} \quad \textit{is a positive operator}.$$

The proof of Theorem 3.3 is the object of the following section.

1. The proof of Theorem 3.3

Using (3.1), we get that $H^0_{\lambda,\omega}$ is unitarily equivalent to the operator

$$h^0_{\lambda,\omega}=\mathcal{T}^*_{\varphi_{\lambda,1}}H^0_{\lambda,\omega}\mathcal{T}_{\varphi_{\lambda,1}},$$

acting on $L^2(\mathbb{T}^*)$ and written as

$$h^0_{\lambda,\omega}=h^0_{\lambda,\omega^-}+\lambda V^0_{\lambda,\tilde{\omega}}.$$

h^0_{λ,ω^-} is the multiplication operator by $E_1(\lambda,\theta)$ and $V^0_{\lambda,\tilde{\omega}}$ is an integral operator with the kernel

$$V_{\lambda,\tilde{\omega}}(\theta,\theta')=\langle V_{\tilde{\omega}}\varphi_{\lambda,1}(\cdot,\theta),\varphi_{\lambda,1}(\cdot,\theta')\rangle.$$

Let V_k be a neighborhood of θ_k, such that if $\theta_{k'}\in Z$ and $k\neq k'$ then $\theta\notin\overline{V_k}$ and $V_k\cap V_{k'}=\emptyset$. As $\mathbb{T}^*$ is compact, one can cover it by $(V_k)_{1\leqslant k\leqslant m}$ (i.e., $\cup_{1\leqslant k\leqslant m}V_k=\mathbb{T}^*$). For $1\leqslant k\leqslant m$ let χ_k be the characteristic function of V_k.

For simplicity for $u\in L^2(\mathbb{T}^*)$, we will denote $\chi_k u$ as u_k in the following. We consider u as a system of m columns denoted by $(u_k)_{1\leqslant k\leqslant m}$. We endow $L^2(\mathbb{T}^*)\otimes\mathbb{C}^m$ with the scalar product generating the following Euclidean norm:

$$\|u\|^2_{L^2(\mathbb{T}^*)\otimes\mathbb{C}^m}=\sum_{k=1}\|u_k\|^2_{L^2(\mathbb{T}^*)}.$$

2. The lower bound of h^0_{λ,ω^-}

Proposition 3.4: *There exists* $C>0$ *such that for any* $u\in L^2(\mathbb{T}^*)$, *we have*

$$\langle h^0_{\lambda,\omega^-}u,u\rangle \geqslant \sum_{1\leqslant k\leqslant m}E_1(\lambda,\theta_k(\lambda))\|u_k\|^2_{L^2(\mathbb{T}^*)}+\frac{1}{C}\sum_{1\leqslant k\leqslant m}\langle\zeta_{k,\lambda}u_k,u_k\rangle_{L^2(\mathbb{T}^*)}. \tag{3.5}$$

Proof: For $u \in L^2(\mathbb{T}^*)$, one computes

$$\langle h^0_{\lambda,\omega^-} u,u\rangle = \int_{\mathbb{T}^*} E_1(\lambda,\theta)|u(\theta)|^2 \mathrm{d}\theta = \sum_{1\leqslant k\leqslant m} \int_{\mathbb{T}^*} E_1(\lambda,\theta)\chi_k(\theta)|u(\theta)|^2 \mathrm{d}\theta.$$

As for any θ in V_k the support of χ_k, there exists $C>0$ such that we have

$$E_1(\lambda,\theta_k(\lambda)) + \frac{1}{C}\zeta_{k,\lambda}(\theta) \leqslant E_1(\lambda,\theta),$$

we get the result. □

3. The lower bound of $V^0_{\lambda,\widetilde{\omega}}$

Proposition 3.5: *There exists* $C_1, C_2 > 0$, *and* λ_0 *such that for all* $\lambda \in [0,\lambda_0]$ *and* $u \in L^2(\mathbb{T}^*)$ *we have*

$$\langle V^0_{\lambda,\widetilde{\omega}} u,u\rangle \geqslant C_1 \sum_{1\leqslant k\leqslant m,\,\gamma\in\mathbb{Z}^d} \widetilde{\omega}_\gamma |(\hat{u_k})(\gamma)|^2 - C_2 \sum_{1\leqslant k\leqslant m} \langle \zeta_{k,\lambda} u_k, u_k\rangle_{L^2(\mathbb{T}^*)}. \tag{3.6}$$

Proof of Theorem 3.3: Let us notice that, by combining the results of Propositions 3.4 and 3.5, one gets that there exists $\lambda_0>0$ such that for any $\lambda \in [0,\lambda_0]$ and for any $u \in L^2(\mathbb{T}^*)$ we have

$$\langle h^0_{\lambda,\omega} u,u\rangle \geqslant \sum_{1\leqslant k\leqslant m} E_1(\lambda,\theta_k(\lambda))\|u_k\|^2_{L^2(\mathbb{T}^*)} + \frac{1}{C}\left(\sum_{1\leqslant k\leqslant m} \langle \zeta_{k,\lambda} u_k, u_k\rangle_{L^2(\mathbb{T}^*)} + \lambda \sum_{1\leqslant k\leqslant m} \sum_{\gamma\in\mathbb{Z}^d} \widetilde{\omega}_\gamma |\hat{u_k}(\gamma)|^2 \right)$$

$$\geqslant E_{\lambda,\omega^-}\|u\|^2_{L^2(\mathbb{T}^*)} + \frac{1}{C}\left(\sum_{1\leqslant k\leqslant m} \langle \zeta_{k,\lambda} u_k, u_k\rangle_{L^2(\mathbb{T}^*)} + \lambda \sum_{1\leqslant k\leqslant m} \sum_{\gamma\in\mathbb{Z}^d} \widetilde{\omega}_\gamma |\hat{u_k}(\gamma)|^2 \right).$$

This gives that

$$\langle (h^0_{\lambda,\widetilde{\omega}} - E_{\lambda,\omega^-})u,u\rangle \geqslant \frac{1}{C}\left(\sum_{1\leqslant k\leqslant m} \langle \zeta_{k,\lambda} u_k, u_k\rangle_{L^2(\mathbb{T}^*)} + \lambda \sum_{1\leqslant k\leqslant m} \sum_{\gamma\in\mathbb{Z}^d} \widetilde{\omega}_\gamma |\hat{u_k}(\gamma)|^2 \right). \tag{3.7}$$

This ends the proof of Theorem 3.3. □

Remark 3.6: *We notice that even if we know that the bottom of the spectrum of* H_ω *coincides with the bottom of the spectrum of* H_{λ,ω^-} *we cannot consider* $\Pi_{\lambda,0}(H_{\lambda,\omega} - H_{\lambda,\omega^-})\Pi_{\lambda,0}$ *as a positive operator*.

Proof of Proposition 3.5: Let us start by expanding $\langle V^0_{\lambda,\widetilde{\omega}} u,u\rangle$,

$$\langle V^0_{\lambda,\widetilde{\omega}} u,u\rangle = \sum_{1\leqslant k,k'\leqslant m} \langle V^0_{\lambda,\omega} \mathcal{T}_{\widetilde{\varphi}_{\lambda,1,k}}(u_k), \mathcal{T}_{\widetilde{\varphi}_{\lambda,1,k'}}(u_{k'})\rangle_{L^2(\mathbb{R}^d)}$$

$$+ \sum_{1\leqslant k,k'\leqslant m} \langle V^0_{\lambda,\widetilde{\omega}} \mathcal{T}_{\delta\widetilde{\varphi}_{\lambda,1,k}}(\sqrt{\zeta_{k,\lambda}}u_k), \mathcal{T}_{\delta\widetilde{\varphi}_{\lambda,1,k'}}(\sqrt{\zeta_{k',\lambda}}u_{k'})\rangle_{L^2(\mathbb{R}^d)}$$

$$+ 2 \sum_{1\leqslant k,k'\leqslant m} \Re(\langle V^0_{\lambda,\widetilde{\omega}} \mathcal{T}_{\widetilde{\varphi}_{\lambda,1,k}}(u_k), \mathcal{T}_{\delta\widetilde{\varphi}_{\lambda,1,k'}}(\sqrt{\zeta_{k',\lambda}}u_{k'})\rangle_{L^2(\mathbb{R}^d)}).$$

We start by estimating the three sums of the last equation.

For the second sum, using Cauchy Schwartz inequality and Lemma 3.2, we get that for any $1\leqslant k,k'\leqslant m$, there exists $C>0$ such that we have

$$|\langle V^0_{\lambda,\tilde{\omega}}\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k}}(\sqrt{\zeta_{k,\lambda}}u_k),\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k'}}(\sqrt{\zeta_{k',\lambda}}u_{k'})\rangle_{L^2(\mathbb{R}^d)}| \leqslant \tfrac{1}{2}(\|V^0_{\lambda,\tilde{\omega}}\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k}}(\sqrt{\zeta_{k,\lambda}}u_k)\|^2_{L^2(\mathbb{R}^d)} + \|\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k'}}(\sqrt{\zeta_{k',\lambda}}u_{k'})\|^2_{L^2(\mathbb{R}^d)}) \leqslant C\cdot(\langle\zeta_{k,\lambda}u_k,u_k\rangle_{L^2(\mathbb{T}^*)} + \langle\zeta_{k',\lambda}u_{k'},u_{k'}\rangle_{L^2(\mathbb{T}^*)}).$$

So there exists $C>0$ such that we have

$$\sum_{1\leqslant k,k'\leqslant m}|\langle V^0_{\lambda,\tilde{\omega}}\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k}}(\sqrt{\zeta_{k,\lambda}}u_k),\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k'}}(\sqrt{\zeta_{k',\lambda}}u_{k'})\rangle_{L^2(\mathbb{R}^d)}| \leqslant C\sum_{1\leqslant k\leqslant m}\langle\zeta_{k,\lambda}u_k,u_k\rangle_{L^2(\mathbb{T}^*)}. \tag{3.8}$$

For the third sum, using the Cauchy-Schwartz inequality once more, we get that for $1\leqslant k\leqslant m$ there exists $\beta>0$ such that we have

$$|\langle V^0_{\lambda,\tilde{\omega}}\mathcal{T}_{\tilde{\varphi}_{\lambda,1,k}}(u_k),\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k'}}(\sqrt{\zeta_{k',\lambda}}u_{k'})\rangle_{L^2(\mathbb{R}^d)}| \leqslant \beta\|V^0_{\tilde{\omega}}\mathcal{T}_{\tilde{\varphi}_{\lambda,1,k}}(u_k)\|^2_{L^2(\mathbb{R}^d)} + 1/(4\beta)\|\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k'}}(\sqrt{\zeta_{k,\lambda}}u_{k'})\|^2_{L^2(\mathbb{R}^d)}. \tag{3.9}$$

Using Eq. (3.4), one gets that there exist $\widetilde{C}_1,\widetilde{C}_2,\beta>0$ such that

$$\sum_{1\leqslant k,k'\leqslant m}|\langle V^0_{\lambda,\tilde{\omega}}\mathcal{T}_{\tilde{\varphi}_{\lambda,1,k}}(u_k),\mathcal{T}_{\delta\tilde{\varphi}_{\lambda,1,k'}}(\sqrt{\zeta_{k',\lambda}}u_{k'})\rangle_{L^2(\mathbb{R}^d)}| \leqslant \widetilde{C}_1\beta\sum_{1\leqslant k\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma|\hat{u_k}(\gamma)|^2 + \widetilde{C}_2(\beta+1/\beta)\sum_{1\leqslant k\leqslant m}\langle\zeta_{k,\lambda}u_k,u_k\rangle_{L^2(\mathbb{T}^*)}. \tag{3.10}$$

For the first sum, using (3.3), we get that there exist $C_1',C_2',\beta>0$ such that

$$\left|\sum_{1\leqslant k,k'\leqslant m}\langle V^0_{\tilde{\omega}}\mathcal{T}_{\tilde{\varphi}_{\lambda,1,k}}(u_k),\mathcal{T}_{\tilde{\varphi}_{\lambda,1,k'}}(u_{k'})\rangle_{L^2(\mathbb{R}^d)} - \sum_{1\leqslant k,k'\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma\left(\int_{C_0}a_{\varphi_{\lambda,1},k,k'}(x)\mathrm{d}x\right)(\hat{u_k})(\gamma)\overline{(\hat{u_{k'}})(\gamma)}\right| \leqslant C_1'\beta\sum_{1\leqslant k\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma|\hat{u_k}(\gamma)|^2 + C_2'(1+1/\beta)\sum_{1\leqslant k\leqslant m}\langle\zeta_{k,\lambda}u_k,u_k\rangle_{L^2(\mathbb{T}^*)}. \tag{3.11}$$

Now Eqs. (3.8), (3.10), and (3.11) give that there exist $K_1,K_2,\beta>0$ such that

$$\left|\langle V^0_{\lambda,\tilde{\omega}}u,u\rangle - \sum_{1\leqslant k,k'\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma\left(\int_{C_0}a_{\varphi_{\lambda,1},k,k'}(x)\mathrm{d}x\right)(\hat{u_k})(\gamma)\overline{(\hat{u_{k'}})(\gamma)}\right| \leqslant K_1\beta\sum_{1\leqslant k\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma|(\hat{u_k})(\gamma)|^2 + K_2(1+1/\beta)\sum_{1\leqslant k\leqslant m}\langle\zeta_{k,\lambda}u_k,u_k\rangle_{L^2(\mathbb{T}^*)}. \tag{3.12}$$

Now, if the matrix

$$A(0)=\left(\int_{C_0}a_{\varphi_{0,1},k,k'}(x)\mathrm{d}x\right)_{1\leqslant k,k'\leqslant m}$$

is positive-definite, one gets that $\inf\sigma(A(0))=C>0$ satisfies

$$CI_m\leqslant A.$$

Let $A(\lambda)$ be the matrix,

$$\left(\int_{C_0}a_{\varphi_{\lambda,1},k,k'}(x)\mathrm{d}x\right)_{1\leqslant k,k'\leqslant m}.$$

Notice that for any $1\leqslant k,k'\leqslant m$, the functions

$$f_{k,k'}:\lambda \to \int_{C_0} a_{\varphi_{\lambda,1},\theta_k(\lambda),\theta_{k'}(\lambda)}(x)\mathrm{d}x$$

are continuous in λ. So there exists $\lambda_0>0$ such that for any $\lambda \in [0,\lambda_0]$,

$$\frac{C}{2} I_m \leqslant A(\lambda).$$

This gives that for any $u \in L^2(\mathbb{T}^*)$,

$$\frac{C}{2} \sum_{1\leqslant k\leqslant m} \sum_{\gamma\in\mathbb{Z}^d} \tilde{\omega}_\gamma |(\hat{u_k})(\gamma)|^2 \leqslant \sum_{1\leqslant k,k'\leqslant m} \sum_{\gamma\in\mathbb{Z}^d} \tilde{\omega}_\gamma \left(\int_{C_0} a_{\varphi_{\lambda,1},k,k'}(x)\mathrm{d}x\right)(\hat{u_k})(\gamma)\overline{(\hat{u_{k'}})(\gamma)}. \quad (3.13)$$

Now using the expanation of $\langle V^0_{\lambda,\tilde{\omega}} u,u\rangle$ and Eq. (3.12), we get that there exist $K_1,K_2>0$ and $\beta>0$ such that

$$\langle V^0_{\lambda,\tilde{\omega}} u,u\rangle \geqslant \left(\frac{C_1'}{2} - K_1\beta\right) \sum_{1\leqslant k\leqslant m;\gamma\in\mathbb{Z}^d} \tilde{\omega}_\gamma |(\hat{u_k})(\gamma)|^2 - K_2(1+1/\beta) \sum_{1\leqslant k\leqslant m} \langle \zeta_{k,\lambda} u_k,u_k\rangle_{L^2(\mathbb{T}^*)}. \quad (3.14)$$

So, for $\beta>0$ well chosen we get that there exist constants $C_1,C_2>0$ such that

$$\langle V^0_{\lambda,\tilde{\omega}} u,u\rangle \geqslant \frac{C_1}{3} \sum_{1\leqslant k\leqslant m;\gamma\in\mathbb{Z}^d} \tilde{\omega}_\gamma |(\hat{u_k})(\gamma)|^2 - C_2 \sum_{1\leqslant k\leqslant m} \langle \zeta_{k,\lambda} u_k,u_k\rangle_{L^2(\mathbb{T}^*)}. \quad (3.15)$$

This ends the proof of Proposition 3.5. □

B. If $A(0)$ is negative-definite

We recall that H_{λ,ω^+} is the following operator:

$$H_{\lambda,\omega^+} = -\Delta + W_{\mathrm{per}} + \lambda \sum_{\gamma\in\mathbb{Z}^d} \omega^+ f(\cdot-\gamma).$$

As H_{λ,ω^+} is a $\mathbb{Z}^d$-periodic operator, the analysis given in Sec. II A for H_{λ,ω^-} is still true in the present case. For $(E_j(\lambda,\theta))_{j\in\mathbb{N}^*}$, the Floquet eigenvalue of H_{λ,ω^+} let us set $E_{\lambda,\omega^+}=\inf_{\theta\in\mathbb{T}^*} E_1(\lambda,\theta)$.

Theorem 3.7: *Assume that the matrix $A(0)$ is negative-definite. Then there exists $\lambda_0>0$ such that for any $\lambda\in[0,\lambda_0]$ we have*

$$\Pi_{\lambda,0}(H_{\lambda,\omega} - E_{\lambda,\omega^+})\Pi_{\lambda,0} \quad \textit{is a positive operator}.$$

The result of Theorem 3.7 can be proved in the same way as we did for Theorem 3.3 in the previous section. Indeed, $H_{\lambda,\omega}$ can be seen as a perturbation of H_{λ,ω^+} as follows:

$$H_{\lambda,\omega} = H_{\lambda,\omega^+} + V_{\bar{\omega}}.$$

With $V_{\bar{\omega}}(\cdot)=\Sigma_{\gamma\in\mathbb{Z}^d}\bar{\omega}_\gamma f(\cdot-\gamma)$ and for any $\gamma\in\mathbb{Z}^d$, $\bar{\omega}_\gamma=\omega_\gamma-\omega^+$. Notice that in this case $(\bar{\omega}_\gamma)_{\gamma\in\mathbb{Z}^d}$ is a family of bounded and negative random variables. Using an analogous unitary transformation to (3.1), one gets that $H^0_{\lambda,\omega}$ is unitarily equivalent to

$$h^0_{\lambda,\omega} = h^0_{\lambda,\omega^+} + V^0_{\lambda,\bar{\omega}}.$$

The lower bound of h_{λ,ω^+} can be derived easily. As all arguments used to lower bound $V^0_{\tilde{\omega}}$ remain valid, we lower bound $V^0_{\lambda,\bar{\omega}}$ using the same computation done in Sec. III A.

So we get that there exist $K_1,K_2,\beta>0$ such that

$$\left|\langle V^0_{\lambda,\bar{\omega}}u,u\rangle - \sum_{1\leqslant k,k'\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}\bar{\omega}_\gamma\left(\int_{C_0}a_{\varphi_{\lambda,1},k,k'}(x)\mathrm{d}x\right)(\hat{u_k})(\gamma)\overline{(\hat{u_{k'}})(\gamma)}\right|$$

$$\leqslant K_1\beta(\omega^+-\omega^-)\sum_{1\leqslant k\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}|(\hat{u_k})(\gamma)|^2+K_2(1+1/\beta)\sum_{1\leqslant k\leqslant m}\langle\zeta_{k,\lambda}u_k,u_k\rangle_{L^2(\mathbb{T}^*)}. \tag{3.16}$$

When $A(0)$ is negative-definite, there exists $C<0$ and $\lambda_0>0$ such that for any $\lambda\in[0,\lambda_0]$, we have

$$A(\lambda)\leqslant CI_m.$$

As the random variables $(\bar{\omega}_\gamma)_{\gamma\in\mathbb{Z}^d}$ are negative, we get that

$$C\sum_{1\leqslant k\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}\bar{\omega}_\gamma|(\hat{u_k})(\gamma)|^2\leqslant\sum_{1\leqslant k,k'\leqslant m}\sum_{\gamma\in\mathbb{Z}^d}\bar{\omega}_\gamma\left(\int_{C_0}a_{\varphi_{\lambda,1},k,k'}(x)\mathrm{d}x\right)(\hat{u_k})(\gamma)\overline{(\hat{u_{k'}})(\gamma)}. \tag{3.17}$$

This and Eq. (3.16) give the desired result on the lower bound of $V_{\bar{\omega}}$. This ends the proof of Theorem 3.7. □

Proof of Lemma 3.2: As $V_{\tilde{\omega}}$ is H_{λ,ω^-}-relatively bound uniformly on $\tilde{\omega}_\gamma$, there exists $c>0$ such that for any $u\in L^2(\mathbb{T}^*)$ we have

$$\|V_{\tilde{\omega}}\mathcal{T}_\varphi(u)\|\leqslant c(\|H_{\lambda,\omega^-}\mathcal{T}_\varphi(u)\|^2+\|\mathcal{T}_\varphi(u)\|^2)$$

$$\leqslant c\int_{\mathbb{T}^*}(\|H_{\lambda,\omega^-}(\theta)\varphi(\cdot,\theta)\|^2_{L^2(C_0)}+\|\varphi(\cdot,\theta)\|^2_{L^2(C_0)})|u(\theta)|^2\mathrm{d}\theta$$

$$\leqslant c\|\varphi\|^2_{H_{\lambda,\omega^-,\infty}}\cdot\|u\|^2_{L^2(\mathbb{T}^*)}.$$

One computes

$$\begin{aligned}&\langle V^0_{\tilde{\omega}}\mathcal{T}_{\varphi_k}(u),\mathcal{T}_{\varphi_{k'}}(v)\rangle_{L^2(\mathbb{R}^d)}\\&=\int_{\mathbb{R}^d}V_{\tilde{\omega}}(x)\varphi_k(x,\theta_k)\overline{\varphi_{k'}(x,\theta_{k'})}\cdot\left(\int_{\mathbb{T}^*}e^{(\theta-\theta_k)x}u(\theta)\mathrm{d}\theta\cdot\overline{\int_{\mathbb{T}^*}e^{(\theta-\theta_{k'})x}v(\theta)\mathrm{d}\theta}\right)\mathrm{d}x\\&=\sum_{\gamma\in\mathbb{Z}^d}\tilde{\omega}_\gamma\int_{C_0}f(x)\varphi_k(x,\theta_k)\overline{\varphi_{k'}(x,\theta_{k'})}\cdot\left(\int_{\mathbb{T}^*}e^{(\theta-\theta_k)x}e^{i\gamma\cdot\theta}u(\theta)\mathrm{d}\theta\cdot\overline{\int_{\mathbb{T}^*}e^{(\theta-\theta_{k'})x}e^{i\gamma\cdot\theta}v(\theta)\mathrm{d}\theta}\right)\mathrm{d}x.\end{aligned}$$

Let

$$\hat{u}(\gamma)=\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}u(\theta)\mathrm{d}\theta.$$

For any $(x,\theta)\in\mathbb{R}^d\times\mathbb{T}^*$ and $1\leqslant k\leqslant m$, we set

$$g_k(x,\theta)=\frac{e^{i(\theta-\theta_k)\cdot x}-1}{\sqrt{\zeta_{k,\lambda}(\theta)}}. \tag{3.18}$$

As $\theta_k(\lambda)$ is the only zero of $\zeta_{k,\lambda}$ and as it is nondegenerate, there exist $C>0$ such that, for $(x,\theta)\in\mathbb{R}^d\times\mathbb{T}^*$, and $1\leqslant k\leqslant m$, we have

$$|g_k(x,\theta)|\leqslant C(1+|x|). \tag{3.19}$$

We have $e^{i(\theta-\theta_k)x}=\sqrt{\zeta_{k,\lambda}}g_k(x,\theta)+1$. So using this and expanding $\langle V_{\widetilde{\omega}}\mathcal{T}_{\varphi_k}(u),\mathcal{T}_{\varphi_{k'}}(v)\rangle_{L^2(\mathbb{R}^d)}$, we get

$$\begin{aligned}
&\langle V_{\widetilde{\omega}}\mathcal{T}_{\varphi_k}(u),\mathcal{T}_{\varphi_{k'}}(v)\rangle_{L^2(\mathbb{R}^d)}-\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma\left(\int_{C_0}a_{\varphi,k,k'}(x)\mathrm{d}x\right)\cdot u(\gamma)\cdot\overline{v(\gamma)}\\
&=\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma\int_{C_0}a_{\varphi,k,k'}(x)\cdot\left(\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}g_k(x,\theta)\sqrt{\zeta_{k,\lambda}(\theta)}u(\theta)\mathrm{d}\theta\cdot\overline{\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}g_{k'}(x,\theta)\sqrt{\zeta_{k',\lambda}(\theta)}v(\theta)\mathrm{d}\theta}\right)\mathrm{d}x\\
&\quad+\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma\hat{u}(\gamma)\int_{C_0}a_{\varphi,k,k'}(x)\cdot\left(\overline{\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}g_{k'}(x,\theta)\sqrt{\zeta_{k',\lambda}(\theta)}v(\theta)\mathrm{d}\theta}\right)\mathrm{d}x\\
&\quad+\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma\overline{\hat{v}(\gamma)}\int_{C_0}a_{\varphi,k,k'}(x)\cdot\left(\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}g_k(x,\theta)\sqrt{\zeta_{k,\lambda}(\theta)}u(\theta)\mathrm{d}\theta\right)\mathrm{d}x. \qquad (3.20)
\end{aligned}$$

Now using the fact that the family $(\widetilde{\omega}_\gamma)_{\gamma\in\mathbb{Z}^d}$ is bounded, Cauchy-Schwartz inequality and Perseval identity and Eq. (3.19), we get that there exists $C,\beta>0$ such that

$$\begin{aligned}
&\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma\int_{C_0}a_{\varphi,k,k'}(x)\cdot\left(\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}g_k(x,\theta)\sqrt{\zeta_{k,\lambda}(\theta)}u(\theta)\mathrm{d}\theta\cdot\overline{\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}g_{k'}(x,\theta)\sqrt{\zeta_{k',\lambda}(\theta)}v(\theta)\mathrm{d}\theta}\right)\mathrm{d}x\\
&\quad\leqslant C\langle\zeta_{k,\lambda}u,u\rangle_{L^2(\mathbb{T}^*)}+\langle\zeta_{k',\lambda}v,v\rangle_{L^2(\mathbb{T}^*)}, \qquad (3.21)
\end{aligned}$$

and

$$\begin{aligned}
&\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma\hat{u}(\gamma)\int_{C_0}a_{\varphi,k,k'}(x)\cdot\overline{\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}g_{k'}(x,\theta)\sqrt{\zeta_{k',\lambda}(\theta)}v(\theta)\mathrm{d}\theta}\mathrm{d}x\leqslant C\beta\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma|\hat{u}(\gamma)|^2\\
&\qquad+\frac{C}{4\beta}\langle\zeta_{k',\lambda}v,v\rangle_{L^2(\mathbb{T}^*)}. \qquad (3.22)
\end{aligned}$$

The same argument gives

$$\begin{aligned}
&\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma\overline{\hat{v}(\gamma)}\int_{C_0}a_{\varphi,k,k'}(x)\cdot\int_{\mathbb{T}^*}e^{i\gamma\cdot\theta}g_k(x,\theta)\sqrt{\zeta_{k,\lambda}(\theta)}u(\theta)\mathrm{d}\theta\,\mathrm{d}x\leqslant C\beta\sum_{\gamma\in\mathbb{Z}^d}\widetilde{\omega}_\gamma|\hat{v}(\gamma)|^2\\
&\qquad+\frac{C}{4\beta}\langle\zeta_{k,\lambda}u,u\rangle_{L^2(\mathbb{T}^*)}. \qquad (3.23)
\end{aligned}$$

So from (3.20)–(3.23) we get (3.3).

The proof of (3.4) follows by changing $\mathcal{T}_{\varphi_{\lambda,1}}(u)$ using (3.2) and following the same steps as (3.3).

This ends the proof of Lemma 3.2. □

Remarkable identities related to the (quantum) elliptic Calogero-Sutherland model

Edwin Langmann
Mathematical Physics, Physics KTH, AlbaNova, SE-106 91 Stockholm, Sweden

(Received 12 July 2005; accepted 19 December 2005; published online 16 February 2006)

We present remarkable functional identities related to the elliptic Calogero-Sutherland (eCS) system. We derive them from a second quantization of the eCS model within a quantum field theory model of anyons on a circle and at finite temperature. The identities involve two eCS Hamiltonians with arbitrary and, in general, different particle numbers N and M, and a particular function of $N+M$ variables arising as anyon correlation function of N particles and M antiparticles. In addition to identities obtained from anyons with the same statistics parameter λ, we also obtain "dual" relations involving "mixed" correlation functions of anyons with two different statistics parameters λ and $1/\lambda$. We also give alternative, elementary proofs of these identities by direct computations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2167807]

I. BACKGROUND AND RESULT

The elliptic Calogero-Sutherland (eCS) system is a quantum mechanical model of an arbitrary number, N, of particles moving on a circle of length 2π and interacting with two-body potentials given by the Weierstrass elliptic functions $\wp$.[2,15,13] More specifically, this model is defined by the differential operator

$$H = -\sum_{j=1}^{N} \frac{\partial^2}{\partial x_j^2} + 2\lambda(\lambda-1) \sum_{1\leqslant j<k\leqslant N} V(x_j - x_k), \tag{1}$$

where $-\pi \leqslant x_j \leqslant \pi$ are coordinates on the circle, $\lambda > 0$ is a real parameter determining the coupling strength, and

$$V(r) = \sum_{m\in\mathbb{Z}} \frac{1}{4\sin^2[(r+i\beta m)/2]}, \quad \beta > 0 \tag{2}$$

is essentially the Weierstrass elliptic function $\wp$ with periods 2π and $i\beta$,

$$V(z) = \wp(z) + c_0, \quad c_0 = \frac{1}{12} - \sum_{m=1}^{\infty} \frac{1}{2\sinh^2[(\beta m)/2]} \tag{3}$$

(see Appendix A 1. in Ref. 12, for example).

In this paper we obtain and prove various remarkable identities involving eCS Hamiltonians and special functions of many variables constructed from the following building block:

$$\theta(z) = \sin(z/2)\prod_{n=1}^{\infty}(1-2q^{2n}\cos(z)+q^{4n}), \quad q = e^{-\beta/2}, \tag{4}$$

which is essentially the Jacobi theta function ϑ_1,

$$\theta(z) = \frac{1}{2q^{1/4}\prod_{n=1}^{\infty}(1-q^{2n})}\vartheta_1\left(\frac{1}{2}z\right) \tag{5}$$

(see Sec. 21.3 in Ref. 17, for example). We derive these results from the quantum field theory construction in Ref. 11 We collect all these identities in the following theorem.

Theorem: *Let*

$$F_{N,M}(\mathbf{x};\mathbf{y}) = \frac{\prod_{1\leqslant j<k\leqslant N}\theta(x_k-x_j)^{\lambda}\prod_{1\leqslant j<k\leqslant M}\theta(y_j-y_k)^{\lambda}}{\prod_{j=1}^{N}\prod_{k=1}^{M}\theta(x_j-y_k)^{\lambda}} \tag{6}$$

with $\mathbf{x}\in\mathbb{C}^N$ *and* $\mathbf{y}\in\mathbb{C}^M$ *and* $\theta(z)$ *defined in Eq. (4). This function obeys the identity*

$$\left[H_{\lambda,N}(\mathbf{x}) - H_{\lambda,M}(\mathbf{y}) + 2(N-M)\lambda\frac{\partial}{\partial\beta} - c_{N,M}\right]F_{N,M}(\mathbf{x};\mathbf{y}) = 0 \tag{7}$$

with $H=H_{\lambda,N}(\mathbf{x})$ *the eCS Hamiltonian in Eq. (1) and the constant*

$$c_{N,M} = \lambda^2[N(N-1)-M(M-1)]c_0 + (N-M)\lambda^2[N(N-1)+M(M-1)-2NM]c_1, \tag{8}$$

where

$$c_0 = \frac{1}{12} - \sum_{n=1}^{\infty}\frac{2q^{2n}}{(1-q^{2n})^2}, \quad c_1 = \frac{1}{12}. \tag{9}$$

Moreover, a similar identity holds true for the function

$$\widetilde{F}_{N,M}(\mathbf{x};\mathbf{y}) = \prod_{1\leqslant j<k\leqslant N}\theta(x_k-x_j)^{\lambda}\prod_{1\leqslant j<k\leqslant M}\theta(y_j-y_k)^{1/\lambda}\prod_{j=1}^{N}\prod_{k=1}^{M}\theta(x_j-y_k), \tag{10}$$

namely

$$\left[H_{\lambda,N}(\mathbf{x}) + \lambda H_{1/\lambda,M}(\mathbf{y}) + 2(\lambda N+M)\frac{\partial}{\partial\beta} - \widetilde{c}_{N,M}\right]\widetilde{F}_{N,M}(\mathbf{x};\mathbf{y}) = 0 \tag{11}$$

with

$$\begin{aligned}\widetilde{c}_{N,M} = {}& [\lambda^2 N(N-1) + M(M-1)/\lambda + (1+\lambda)NM]c_0 \\ & + (\lambda N+M)[\lambda N(N-1) + M(M-1)/\lambda + 2NM]c_1.\end{aligned} \tag{12}$$

It is interesting to note that there are corresponding identities for the first order differential operators

$$P_N(\mathbf{x}) = \sum_{j=1}^{N} i\frac{\partial}{\partial x_j} \tag{13}$$

equal to the total momentum operator for the eCS system, namely

$$[P_N(\mathbf{x}) + P_M(\mathbf{y})]F_{N,M}(\mathbf{x};\mathbf{y}) = 0 \tag{14}$$

[this is easily proven by observing that $F_{N,M}(\mathbf{x};\mathbf{y})$ is invariant under common shifts $(x_j,y_k) \to (x_j+a,y_k+a)$ for arbitrary real a], and similarly

$$[P_N(\mathbf{x}) + P_M(\mathbf{y})]\widetilde{F}_{N,M}(\mathbf{x};\mathbf{y}) = 0. \tag{15}$$

It is natural to conjecture that similar identities hold true for all commuting differential operators $H^{(j)}=H_N^{(j)}(\mathbf{x})$, $j=1,2,,\ldots$, which are known to exist for the eCS model[13] (since $H^{(j)}$ for $j=1$ and 2 are equal to the total momentum operator and the Hamiltonian of the eCS system, respectively).

Remark 1.1: Note that the constant c_0 in Eq. (9) is identical to the one in Eq. (3). Moreover, the constant c_1 appears in the following from:

$$c_1 = \frac{1}{8} - \sum_{n=1}^{\infty} \frac{nq^{2n}}{1-q^{2n}} - \frac{c_0}{2},$$

but due to the identity

$$\sum_{n=1}^{\infty} \frac{nq^{2n}}{1-q^{2n}} = \sum_{m=1}^{\infty} \frac{q^{2m}}{(1-q^{2m})^2} \tag{16}$$

one gets $c_1=1/12$.

Remark 1.2: It is interesting to note that by redefining the elliptic functions by β-dependent constants as follows:

$$V(r) \to V(r) + b_0,$$

$$\theta(r) \to B_1\theta(r) \quad \text{with } \frac{\partial \ln(B_1)}{\partial\beta} = b_1,$$

the constants in our identities are changed as follows:

$$c_{N,M} \to c_{N,M} - \lambda(\lambda-1)[N(N-1) - M(M-1)]b_0 - (N-M)\lambda^2[N(N-1) + M(M-1) - 2NM]b_1$$

and

$$\widetilde{c}_{N,M} \to \widetilde{c}_{N,M} - [\lambda(\lambda-1)N(N-1) + (1/\lambda - 1)M(M-1)]b_0 + (\lambda N + M)[\lambda N(N-1) + M(M-1)/\lambda + 2NM]b_1.$$

In particular, choosing $b_0=c_0$ and $b_1=c_1$ we can simplify these constants significantly,

$$\begin{aligned} c_{N,M} &\to \lambda[N(N-1) - M(M-1)]c_0, \\ \widetilde{c}_{N,M} &\to [\lambda N(N-1) + M(M-1) + (1+\lambda)MN]c_0. \end{aligned} \tag{17}$$

This latter simple choice amounts to replacing

$$\begin{aligned} V(r) &\to \wp(r), \\ \theta(r) &\to \vartheta_1\left(\tfrac{1}{2}r\right). \end{aligned} \tag{18}$$

This shows that if one uses the standard elliptic functions one gets somewhat simpler formulas. However, our choice has the advantage that the trigonometric limit $q=0$ is not singular. Moreover, it removes a trivial contribution from the eigenvalues of the eCS model.[12] □

It is useful to write the constants above as follows:

$$c_{N,M} = \tfrac{1}{12}\lambda^2(N-M)[(N-M)^2-1] + 2\lambda^2(N-M)(N+M-1)c_2 \tag{19}$$

and

$$\widetilde{c}_{N,M} = \tfrac{1}{12}[\lambda^2 N^3 + M^3/\lambda + 3NM(\lambda N + M) - (\lambda^2 N + M/\lambda)] - 2[\lambda^2 N^2 + M^2/\lambda - (\lambda^2 N + M/\lambda) + (\lambda + 1)MN]c_2 \tag{20}$$

with

$$c_2 = \sum_{n=1}^{\infty} \frac{nq^{2n}}{1-q^{2n}}. \tag{21}$$

In Refs. 9 and 11 we obtained the special case $N=M$ of the identity in Eq. (7) using a second quantization of the eCS model in a quantum field theory (QFT) of anyons on a circle and at finite temperature $1/\beta$, and in Ref. 12, Appendix A 3, we gave an alternative, elementary proof by straightforward but rather tedious computations. In this paper we show that the QFT results in Ref. 11 naturally imply all the identities in the theorem above. To be convincing also for readers not familiar with QFT we will also give elementary proofs by direct computations which are, however, not so illuminating. These direct proofs are based on three functional identities of the functions $V(r)$ and $\theta(r)$ introduced above: First,

$$V(r) = -\frac{d^2}{dr^2} \ln \theta(r), \tag{22}$$

second,

$$\phi(x)\phi(y) + \phi(x)\phi(z) + \phi(y)\phi(z) = f(x) + f(y) + f(z) \quad \text{if } x+y+z=0, \tag{23}$$

where

$$\phi(x) = \frac{d}{dx} \ln \theta(x), \quad f(x) = \frac{1}{2}[V(x) - \phi(x)^2 - c_0], \tag{24}$$

and third,

$$f(x) = -\frac{\partial}{\partial\beta} \ln \theta(x) + c_1 \tag{25}$$

with the constants c_0 and c_1 in Eq. (9). The (elementary) proofs (22) and (23) can be found in Ref. 12, Appendix A 1 and A 2, respectively; (25) follows readily from

$$\vartheta_1(x/2) = \sum_{n=1}^{\infty} (-1)^{n-1} q^{(n-1/2)^2} \sin[(n-1/2)x]$$

(see Section 21.22 in Ref. 17, for example) and Eq. (5), using the observation made in Remark 1.1 above. To avoid misunderstanding we stress that the functional identities needed to prove our results are classical and known for a long time.

An interesting special case of our result is for $M=0$ in which case the identities reduce to

$$H_{\lambda,N}(\mathbf{x})\Psi_0(\mathbf{x}) = \left[c_{N,0} - 2N\lambda\frac{\partial}{\partial\beta}\right]\Psi_0(\mathbf{x}), \tag{26}$$

where $\Psi_0(\mathbf{x}) = F_{N,0}(\mathbf{x},\mathbf{y})$, i.e.,

$$\Psi_0(\mathbf{x}) = \prod_{1\leqslant j<k\leqslant N} \theta(x_k - x_j)^{\lambda}. \tag{27}$$

In the limiting case $\beta\to\infty$ the β-derivative term disappears, and we recover the well-known eigenvalue equation for the ground state of the Sutherland model. It is interesting to note that the elliptic generalization of this identity which we find here does *not* give the ground state of the eCS

model, which is why Sutherland's solution[15] of the Sutherland model does not generalize to the elliptic case. For $N=2$, $M=0$ our identities reduce to

$$\left[-2\frac{\partial^2}{\partial x^2}+4\lambda\frac{\partial}{\partial\beta}-c_{2,0}\right]\theta(x)^\lambda=0,$$

which for $\lambda=1$ is (essentially) the heat equation obeyed by ϑ_1 ($x=x_1-x_2$). Other interesting special cases will be discussed in Sec. III.

It is worth noting that original motivation to study the QFT model of anyons in Ref. 3 was its relation to the fractional quantum Hall effect,[16] and it is remarkable that this physics relation proved to be helpful for finding the generalization in Refs. 9 and 11. However, one can regard this construction also pragmatically as a useful generating function technique for deriving interesting identities which, once found, can also be proven by direct computations. Since we believe that there are other identities to be found along similar lines, we hope it is nevertheless of some interest to not only give the direct proof but also the detailed QFT derivation.

We also mention that the QFT construction in Ref. 11 seems closely related to earlier work on conformal field theory on the torus[1,5,4,6,7] also finding and exploiting interesting relations to the eCS model. The approach in Ref. 11 and here is, however, rather different in spirit and technique.

The plan of this paper is as follows. In Sec. II we give an outline of how to derive our identities from the QFT results in Refs. 9 and 11, emphasizing the physical interpretation and deferring computational details to Appendix A. In this discussion we clarify this QFT construction, in particular the interpretation of the representation we use as finite temperature representation (which, since not needed there, was only discussed in an Appendix in Ref. 11). Section III contains our conclusions, including a comparison with previous results and a short discussion of possible applications of our identities. The elementary, alternative proofs can be found in Appendix B.

II. QUANTUM FIELD THEORY DERIVATION

In this section we explain how the identities in our theorem are obtained from our results in Refs. 9 and 11. Some computational details are deferred to Appendix A.

1. Second quantization of the eCS model

We first briefly summarize the construction of anyons.[11]

Anyons (for us) are operator valued distributions $\phi_\nu(x)$ parametrized by a coordinate on the unit circle, $-\pi\leqslant x\leqslant\pi$, and depending on a real parameter ν determining their commutator relations as follows:

$$\phi_\nu(x)\phi_\nu(y)=e^{\pm i\pi\nu^2}\phi_\nu(y)\phi_\nu(x)\quad\text{for } x\neq y \tag{28}$$

[see the Definition in Sec. 2.2 in Ref. 11; note that what we denote as $\phi_\nu(x)$ here is identical with $\lim_{\varepsilon\downarrow}\phi^1_\varepsilon(x)$ there; we ignore the regularization parameter ε here but indicate the parameter ν determining the statistics instead: see also Remark 2.1 below]. We constructed a particular representation of these anyons on a Fock space $\mathcal{F}$ generated from a "vacuum" Ω such that

$$\langle\Omega,\phi_\nu(x)^*\phi_\nu(y)\Omega\rangle=\text{const }\theta(x-y)^{-\nu^2} \tag{29}$$

where $\theta(r)$ is the elliptic function in Eq. (4); $\langle\cdot,\cdot\rangle$ is the Hilbert space inner product and $*$ the Hilbert space adjoint. This representation is characterized by a parameter $\beta>0$ which determines the modulus of the elliptic functions as $q=\exp(-\beta/2)$ and which, as we showed, has a natural physical interpretation as inverse temperature. We then constructed a self-adjoint operator $\mathcal{H}$ in $\mathcal{F}$ which has remarkable commutator relations with products of an arbitrary number N of anyon fields

$$\Phi_\nu^N(\mathbf{x}) := \phi_\nu(x_1)\cdots\phi_\nu(x_N), \tag{30}$$

namely

$$[\mathcal{H},\Phi_\nu^N(\mathbf{x})]\Omega = H_{N,\lambda}(\mathbf{x})\Phi_\nu^N(\mathbf{x})\Omega, \tag{31}$$

where $H=H_{\lambda,N}(\mathbf{x})$ is the eCS Hamiltonian given in Eq. (1) with the coupling determined by the statistic parameter as follows:

$$\lambda = \nu^2. \tag{32}$$

These relations suggest to regard $\mathcal{H}$ as a second quantization of the eCS Hamiltonian. Another important property of $\mathcal{H}$ is the following:

$$\langle\Omega,[A,\mathcal{H}]\Omega\rangle = 0, \tag{33}$$

which is true for a large class of operators A on $\mathcal{F}$ (see Lemma 4 in Ref. 11 for the precise statement), including arbitrary products of anyons.

Remark 2.1: A main technical point in Ref. 11 was to give precise mathematical meaning to this operator valued distributions $\phi_\nu(x)$ by introducing approximate anyons depending on a regularization parameter $\varepsilon>0$ such that, for $\varepsilon>0$, they are well-defined operator, and the anyons are obtained as a limit $\varepsilon\downarrow 0$ (see Sec. 2.2 in Ref. 11). This is a useful method to treat QFT divergences. However, in the present paper we can ignore this technicality except for one instance in Appendix A.

Remark 2.2: It is worth noting that, at zero temperature, the "vacuum" is a highest weight state annihilated by $\mathcal{H}$, but this property is lost at finite temperature. The relation in Eq. (33) is a weaker substitute for this highest weight conditions which holds true also at finite temperature. A similar remark applies to the operator $\check{W}^2$ discussed below.

2. Identities: a special case

In Refs. 9 and 11 we observed that the relations above imply that the anyon correlation function

$$G_{N,N}(\mathbf{x},\mathbf{y}) \equiv \langle\Omega,\Phi_\nu^N(\mathbf{x})^*\Phi_\nu^N(\mathbf{y})\Omega\rangle \tag{34}$$

satisfies the following remarkable identity:

$$[H_{\lambda,N}(\mathbf{x}) - H_{\lambda,N}(\mathbf{y})]G_{N,N}(\mathbf{x},\mathbf{y}) = 0. \tag{35}$$

The argument is simple: using Eq. (33) for $A=\Phi_\nu^N(\mathbf{x})^*\Phi_\nu^N(\mathbf{y})$ we get

$$\langle[\mathcal{H},\Phi_\nu^N(\mathbf{x})]\Omega,\Phi_\nu^N(\mathbf{y})\Omega\rangle - \langle\Omega,\Phi_\nu^N(\mathbf{x})^*[\mathcal{H},\Phi_\nu^N(\mathbf{y})]\Omega\rangle = 0, \tag{36}$$

where we used $[\Phi_\nu^N(\mathbf{x})^*,\mathcal{H}]=[\mathcal{H},\Phi_\nu^N(\mathbf{x})]^*$ which holds true since $\mathcal{H}$ is self-adjoint. Inserting Eq. (31) twice, moving the eCS Hamiltonians in front of the Hilbert inner product, and using (34) we get Eq. (35). Computing $G_{N,N}(\mathbf{x},\mathbf{y})$ one finds that it is equal to $F_{N,N}(\mathbf{x},\mathbf{y})$ in Eq. (6) [see Proposition 1 in Ref. 11 or Eqs. (42) and (43) below], and we thus obtain the special case $N=M$ of the identity in Eq. (7).

3. Other correlation functions

It is natural to try to generalize this identity by considering generalized anyon correlation functions which are vacuum expectation values of

$$\Phi_\nu^N(\mathbf{x})^* \Phi_\mu^M(\mathbf{y}),$$

allowing also for different particle numbers in $\mathbf{x}$ and $\mathbf{y}$ and/or different anyon parameters ν and μ. To construct and compute nontrivial such functions we need to recall a few more details of the anyon construction in Ref. 11

The explicit form of the anyons is

$$\phi_\nu(x) = {}^{\times}_{\times} R \exp\left(- i\nu^2 Q x - \nu \sum_{n\neq 0} \frac{1}{n} \rho(n) e^{inx} \right)^{\times}_{\times}, \tag{37}$$

where the $\rho(n)$, $n \in Z$, and R are generators of the Heisenberg algebra defined by the following relations:

$$[\rho(n), \rho(m)] = n\delta_{n,-m}, \quad [\rho(n), R] = \delta_{n,0} R \tag{38}$$

and

$$\rho(n)^* = \rho(-n), \quad R^* = R^{-1}, \tag{39}$$

where

$$\rho(0) = Q \tag{40}$$

has the physical interpretation of a *charge operator*. A important point here is the definition of normal ordering ${}^{\times}_{\times} \cdot {}^{\times}_{\times}$ which is not the standard one; see Lemma 1 in Ref. 11 for a detailed characterization. The operator Q satisfies, by definition,

$$Q\Omega = 0, \tag{41}$$

and this has important consequences: we say that an operator A on $\mathcal{F}$ has charge q iff $[Q, A] = qA$, and the definitions above imply that only operators A with charge zero can have a nonzero vacuum expectation value, and that $R^{\pm 1}$ changes the charge by ± 1. We therefore need to insert an appropriate power of R to get a nontrivial vacuum expectation value, and the natural correlation function to consider is

$$G_{\nu,\mu;N,M}(\mathbf{x};\mathbf{y}) = \langle \Omega, \Phi_\nu^N(\mathbf{x})^* R^{N-M} \Phi_\mu^M(\mathbf{y}) \Omega \rangle. \tag{42}$$

By straightforward computations we obtain (for details see Appendix A 1)

$$G_{\nu,\mu;N,M}(\mathbf{x};\mathbf{y}) = e^{i(p_1 X - p_2 Y)} \frac{\prod_{1\leq j<k\leq N} \theta(x_j - x_k)^{\nu^2} \prod_{1\leq j<k\leq M} \theta(y_k - y_j)^{\mu^2}}{\prod_{j=1}^N \prod_{k=1}^M \theta(x_j - y_k)^{\nu\mu}}, \tag{43}$$

where the exponential factor gives the dependence of the center-of-mass coordinates,

$$X = \sum_{j=1}^N x_j, \quad Y = \sum_{j=1}^M y_j, \tag{44}$$

and the center-of-mass momenta are determined by the statistics parameters of the anyons as follows:

$$p_1 = \tfrac{1}{2}(\nu^2 N - \nu\mu M), \quad p_2 = \tfrac{1}{2}(\mu^2 M - \nu\mu N). \tag{45}$$

Note that, up to the exponential factors, these correlation functions for $\mu = \nu = \sqrt{\lambda}$ and $\nu = -1/\mu = \sqrt{\lambda}$ are equal to the functions in Eq. (6) and (10), respectively.

In the following we give a simplified derivation of Eqs. (7) and (11), ignoring less interesting terms which only contribute to the constants $c_{N,M}$ and $\tilde{c}_{N,M}$, respectively, and which we indicate by dots. This simplifies the argument considerably. The complete equations including all terms are given in Appendix A 3 and A 4, respectively.

4. Derivation of the identity in Eq. (7)

We now consider the function

$$G_{N,M}(\mathbf{x};\mathbf{y}) \equiv G_{\nu,\nu;N,M}(\mathbf{x};\mathbf{y}), \quad \nu = \sqrt{\lambda} \tag{46}$$

and try to use a similar argument as above. If we now use the identity in Eq. (33) for $A = \Phi_\nu^N(\mathbf{x})^* R^{N-M} \Phi_\nu^M(\mathbf{y})$ and use Eq. (31) twice we obtain

$$[H_{\lambda,N}(\mathbf{x}) - H_{\lambda,M}(\mathbf{y})] G_{N,M}(\mathbf{x},\mathbf{y}) = \langle \Omega, \Phi_\nu^N(\mathbf{x})^* [\mathcal{H}, R^{N-M}] \Phi_\nu^M(\mathbf{y}) \Omega \rangle, \tag{47}$$

where we now get an additional term. It is a rather surprising that it is possible to compute this term in a simple manner: this is due to a "miracle" which we now describe.

For that we need to recall the explicit form of the second quantized eCS Hamiltonian $\mathcal{H}$,

$$\mathcal{H} = \nu \breve{W}^3 + (1-\nu^2)\mathcal{C} + 2\nu^2 \breve{W}^2 Q + \tfrac{1}{3}\nu^4 Q^3 - \nu^4 c_0 Q, \tag{48}$$

with the constant c_0 in Eq. (9),

$$\breve{W}^s = \frac{1}{s}\int_0^{2\pi} \frac{\mathrm{d}x}{2\pi} {}^{\times}_{\times} \left(\sum_{n\neq 0} \rho(n) e^{inx} \right)^s {}^{\times}_{\times} \quad \text{for } s = 2,3, \tag{49}$$

and $\mathcal{C}$ is some (known) operator satisfying

$$[\mathcal{C}, R] = 0, \quad \mathcal{C}\Omega = 0 \tag{50}$$

[see Proposition 2 in Ref. 11; the formula given there looks different but is equivalent, as is seen by a simple computation and the identity in Eq. (16)].

Remark 2.3: The charge operator Q [equal to the zero mode $\rho(0)$] plays an even more important role here than in Ref. 11, and it is therefore more natural now to write $\mathcal{H}$ in terms of the operators $\breve{W}^s$ with all zero modes removed: since these operators obviously commute with the charge-rising operator R,

$$\breve{W}^2 = \frac{1}{2}{\sum_n}' {}^{\times}_{\times} \rho(n)\rho(-n) {}^{\times}_{\times},$$

$$\breve{W}^3 = \frac{1}{3}{\sum_{n,m}}' {}^{\times}_{\times} \rho(n)\rho(m)\rho(-n-m) {}^{\times}_{\times} \tag{51}$$

with the prime on the sums indicating that all terms with at least one factor $\rho(0)$ are left out, it thus becomes easier to compute the commutator of $\mathcal{H}$ with R. It is gratifying to see that this also simplifies the formula for $\mathcal{H}$ [compare Eq. (48) above with Eq. (57) in Ref. 11].

We thus get

$$[\mathcal{H}, R^{N-M}] = 2(N-M)\lambda R^{N-M} \breve{W}^2 + \cdots, \tag{52}$$

with the dots less interesting terms which we ignore for simplicity (they are given in Appendix 2.3). The "miracle" is that this commutator is proportional to the operator $\breve{W}^2$ which plays an important twofold role in the anyon QFT: first, $\breve{W}^2$ is (essentially) the second quantization of the total momentum operator,

$$[\breve{W}^2, \Phi_\nu^N(\mathbf{x})] = P_N(\mathbf{x})\Phi_\nu^N(\mathbf{x}) + \cdots \tag{53}$$

with $P_N(\mathbf{x})$ defined in Eq. (13) is the generator of translations [see Eq. (68) in Ref. 11], and second, $\breve{W}^2$ is (essentially) identical with the many-body Hamiltonian used to construct the temperature representation (see Proposition 4 in Appendix B.2 of Ref. 11) which implies

$$\langle \Omega, A\breve{W}^2\Omega\rangle = -\frac{\partial}{\partial\beta}\langle\Omega, A\Omega\rangle + \cdots . \tag{54}$$

Remark 2.4: Equation (54) is the key to our identities. While the first term on the right-hand-side (rhs) is easy to understand from what we said above, the computation of the terms "$\cdots$" proportional to $\langle A\rangle$ is somewhat subtle. This computation clarifies some interesting aspects of our finite temperature representation not mentioned in Ref. 11. They are discussed in Appendix A 2.

Using Eqs. (53) and (54) we can compute

$$\begin{aligned}\langle \Omega, \Phi_\nu^N(\mathbf{x})^*[\mathcal{H}, R^{N-M}]\Phi_\nu^M(\mathbf{y})\Omega\rangle &= 2\lambda(N-M)\langle\Omega, \Phi_\nu^N(\mathbf{x})^* R^{N-M}([\breve{W}^2, \Phi_\nu^M(\mathbf{y})] + \Phi_\nu^M(\mathbf{y})\breve{W}^2)\Omega\rangle + \cdots \\ &= 2\lambda(N-M)\left(P_M(\mathbf{y}) - \frac{\partial}{\partial\beta}\right)G_{N,M}(\mathbf{x};\mathbf{y}) + \cdots ,\end{aligned}$$

and inserting this in Eq. (47) we obtain

$$[H_{\lambda,N}(\mathbf{x}) - H_{\lambda,M}(\mathbf{y})]G_{N,M}(\mathbf{x},\mathbf{y}) = 2\lambda(N-M)\left(P_M(\mathbf{y}) - \frac{\partial}{\partial\beta}\right)G_{N,M}(\mathbf{x};\mathbf{y}) + \cdots . \tag{55}$$

From Eqs. (46), (43), and (6) we see that $G_{N,M}(\mathbf{x};\mathbf{y})$ is equal to $F_{N,M}(\mathbf{x};\mathbf{y})$ up to a phase factor depending only on center-of-mass coordinates X and Y, and using

$$e^{-ipX}H_N(\mathbf{x})e^{ipX} = H_N(\mathbf{x}) + Np^2 - 2pP_N(\mathbf{x})$$

$$e^{-ipX}P_N(\mathbf{x})e^{ipX} = P_N(\mathbf{x}) - Np \tag{56}$$

the identity in Eq. (55) turns into a similar identity for $F_{N,M}(\mathbf{x};\mathbf{y})$. Remarkably we can use Eq. (14) to cancel all terms involving $P_N(\mathbf{x})$ and $P_M(\mathbf{y})$. This proves the identity in Eq. (7) up to the precise value of the constant $c_{N,M}$.

As mentioned, the missing details to also compute the constant $c_{N,M}$ are given in Appendices A 2 and A 3.

5. Derivation of the identity in Eq. (11)

In general, the argument above does not work for correlation functions in Eq. (42) if the anyon parameters ν and μ are different. However, there is one such case where it does work: from the explicit formula for the second quantization of the eCS Hamiltonian in Eq. (48) we observe that replacing ν by $-1/\nu$ gives back essentially the same operator up to a constant factor,

$$\mathcal{H}^{(\nu)} = -\lambda\mathcal{H}^{(-1/\nu)} + 2(\lambda+1)\breve{W}^2Q + (\lambda^2 + 1/\lambda)\left(\tfrac{1}{3}Q^3 - c_0Q\right), \quad \lambda = \nu^2, \tag{57}$$

where we now indicate also the anyon parameter ν. This suggests that we should be able to also get an identity for the correlation functions

$$\widetilde{G}_{N,M}(\mathbf{x};\mathbf{y}) \equiv G_{\nu,-1/\nu;N,M}(\mathbf{x};\mathbf{y}), \quad \nu = \sqrt{\lambda} \tag{58}$$

defined in Eq. (42). Indeed, by a similar computation as above we obtain

$$0 = \langle \Omega, [\Phi_\nu^N(\mathbf{x})^* R^{N-M} \Phi_{-1/\nu}^M(\mathbf{y}), \mathcal{H}^{(\nu)}]\Omega\rangle = [H_{\lambda,N}(\mathbf{x}) + \lambda H_{1/\lambda,M}(\mathbf{y})]\widetilde{G}_{N,M}$$
$$- \langle \Omega, \Phi_\nu^N(\mathbf{x})^* ([\mathcal{H}^{(\nu)}, R^{N-M}] - 2(\lambda+1)MR^{N-M}\check{W}^2)\Phi_{-1/\nu}^M(\mathbf{y})\Omega\rangle + \cdots ,$$

where we used Eqs. (33) and (57) and twice Eq. (31). As mentioned, the dots indicate less interesting terms specified in Appendix A 4. Inserting Eqs. (52) and (53) we get, similarly as above,

$$(H_{\lambda,N}(\mathbf{x}) + \lambda H_{1/\lambda,M}(\mathbf{y}))\widetilde{G}_{N,M}(\mathbf{x};\mathbf{y}) = \left(2(N-M)P_M(\mathbf{y}) - 2(\lambda N + M)\frac{\partial}{\partial\beta}\right)\widetilde{G}_{N,M}(\mathbf{x};\mathbf{y}) + \cdots . \tag{59}$$

Since $\widetilde{G}_{N,M}(\mathbf{x};\mathbf{y})$ is equal to $\widetilde{F}_{N,M}(\mathbf{x};\mathbf{y})$ up to the center-of-mass phase factor [cf. Eqs. (58), (43), and (10)] we can use Eq. (56) to obtain a similar identity for $\widetilde{F}_{N,M}(\mathbf{x};\mathbf{y})$. Again all terms involving $P_N(\mathbf{x})$ and $P_M(\mathbf{y})$ cancel due to Eq. (15), and we obtain the identity in Eq. (11) up to the value of the constant $\widetilde{c}_{N,M}$.

The details of this computation can be found in Appendix A 4.

III. CONCLUSIONS

It is interesting to note that by introducing the operators

$$L_{N,\lambda}(\mathbf{x}) = 2\lambda N\frac{\partial}{\partial\beta} + H_{N,\lambda}(\mathbf{x}) \tag{60}$$

one can write the identities in Eqs. (7) and (11) as follows:

$$(L_{\lambda,N}(\mathbf{x}) - L_{M,\lambda}(\mathbf{y}) - c_{N,M})F_{N,M}(\mathbf{x};\mathbf{y}) = 0 \tag{61}$$

and

$$(L_{\lambda,N}(\mathbf{x}) + \lambda L_{1/\lambda,M}(\mathbf{y}) - \widetilde{c}_{N,M})\widetilde{F}_{N,M}(\mathbf{x};\mathbf{y}) = 0, \tag{62}$$

respectively. The operator L_N seems to be a special case of one introduced by Bernard;[1] see Eq. (6.1) in Ref. 5. The results in Ref. 1 suggests that it should be possible to interpret Eqs. (61) and (62) as Ward identities of some conformal field theory on the torus; see Refs. 6 and 7. We also note that the special case $M=0$ of Eq. (7) seems to be identical with an identity given in the Remark after Theorem 4.1 in Ref. 7.

We finally discuss possible applications of these identities. We first discuss the trigonometric limit $\beta\to\infty$ in which case the derivative terms proportional to $\partial/\partial\beta$ in Eqs. (7) and (11) are absent. In particular, for $M=0$ we recover the well-known eigenvalue equation for the ground state of the Sutherland model which is the starting point of Sutherland's solution of this model,[15] as already mentioned in Sec. I. Another interesting special case is the identity in Eq. (7) for $N=M$: it seems to give an alternative construction of the Q-operator playing a central role in Ref. 8 deriving interesting explicit results for the solution of the Sutherland system. Moreover, this very identity is also the starting point of an alternative solution algorithm for the Sutherland model.[10] Our generalization of this identity to $M\neq N$ might allow to construct a generalized Q-operator relating eigenfunctions of the Sutherland model for different particle numbers and/or different coupling parameters λ and $1/\lambda$. For the general elliptic case $\beta<\infty$ the identity $N=M$ in Eq. (7) was used as a starting point for a perturbative algorithm to solve the eCS model as a formal power series in q^2.[12] We speculate that it might be possible to also find elliptic generalizations of the results in Ref. 8 using our identities (this is suggested to us by the interesting results on the 3-particle eCS system in Sec. 7 of Ref. 14).

APPENDIX A: QFT DERIVATION. DETAILS

In this Appendix we provide the details of the quantum field theory derivation of the identities summarized in our theorem.

1. Computation of the anyon correlation functions

Here we give more details of how to compute $G_{\nu,\mu;N,M}(\mathbf{x};\mathbf{y})$ defined in Eq. (42) and obtain Eq. (43).

We know that

$$\Phi_\nu^N(\mathbf{y}) = b_N(\mathbf{x})^{\nu^2 \times}_{\times} \Phi_\nu^N(\mathbf{x})^{\times}_{\times}, \quad b_N(\mathbf{x}) = \prod_{1\leqslant j<k\leqslant N} \theta(x_j - x_k) \tag{A1}$$

and thus

$$\begin{aligned}\left\langle \Omega, {}^{\times}_{\times}\Phi_\nu^N(\mathbf{x})^{*\times}_{\times} R^{N-M} {}^{\times}_{\times}\Phi_\mu^M(\mathbf{y})^{\times}_{\times}\Omega \right\rangle &= \langle \Omega, e^{i\nu^2 X/2} R^{-N} e^{i\nu^2 X/2} R^N R^{-M} e^{-i\mu^2 Y/2} R^M e^{-i\mu^2 Y/2}\Omega\rangle(*) \\ &= e^{i(N\nu^2 X - M\mu^2 Y)/2}(*)\end{aligned} \tag{A2}$$

[see Eqs. (50), (16), and (17) and in Ref. 11 we also used $R^{-1}QR = Q+1$ following from Eqs. (11) in Ref. 11] where

$$(*) = \prod_{j,k} e^{\nu\mu C(x_j - y_k)} = \prod_{j,k} \theta(x_j - x_k)^{-\nu\mu} e^{-i\nu\mu(x_j - y_k)/2} = e^{-i\nu\mu(MX - NY)/2} \prod_{j,k} \theta(x_j - x_k)^{-\nu\mu}$$

are the other contributions [see Eq. (44) in Ref. 11]. By simple computations this yields Eq. (43).

2. Finite temperature correlations functions

Equation (54) is a crucial step in the QFT derivation of our identities. As discussed in the main text, it is a consequence of β being equal to the inverse temperature and $\breve{W}^2$ being (essentially) the Hamiltonian used to construct the finite temperature representation of our QFT model. We now discuss this relation in more detail.

In Ref. 11 Appendix B.1, we proved that the vacuum expectation value of (essentially) any operator A is equal to its thermal expectation as follows:

$$\langle \Omega, A\Omega\rangle = \frac{1}{\mathcal{Z}} \lim_{a\to\infty} \mathrm{Tr}(e^{-\beta H_0} A_0), \tag{A3}$$

where

$$H_0 = aQ_0^2 + \sum_{n=1}^{\infty} \rho_0(n)\rho_0(-n) \tag{A4}$$

and the subscripts 0 are to indicate that these operators are in the standard (=zero temperature) representation;

$$\mathcal{Z} = \prod_{n=1}^{\infty} \frac{1}{(1-q^{2n})}, \quad q = e^{-\beta/2} \tag{A5}$$

is the partition function [see Proposition 4 and Eq. (B16) in Ref. 11]. Remarkably,

$$\frac{1}{\mathcal{Z}} \frac{\partial \mathcal{Z}}{\partial \beta} = -c_2 \tag{A6}$$

with c_2 the constant in Eq. (21), and thus Eq. (A3) implies

$$\langle\Omega,AH\Omega\rangle = -\left(\frac{\partial}{\partial\beta} - c_2\right)\langle\Omega,A\Omega\rangle \tag{A7}$$

with $H=aQ^2+\Sigma_{n=1}^{\infty}\rho(-n)\rho(n)$. Since H is (essentially) equal to $aQ^2+\breve{W}^2$ this implies Eq. (54).

However, there is a subtle point we need to take into account to make this relation precise: the normal ordering prescription used in Ref. 11 is β-dependent, and $aQ^2+\breve{W}^2$ is therefore *not* equal to H (which is defined by zero temperature normal ordering) but differs from it by a constant. This difference can be computed as follows: by definition of the normal ordering in the thermal state [see Eq. (25) in Ref. 11], $\langle\Omega,\breve{W}^2\Omega\rangle=0$, whereas Eq. (A7) for $A=\mathbf{1}$ gives $\langle\Omega,H\Omega\rangle=c_2$. We conclude that $\breve{W}^2=H-aQ^2-c_2$, and thus

$$\langle\Omega,A\breve{W}^2\Omega\rangle = -\frac{\partial}{\partial\beta}\langle\Omega,A\Omega\rangle \tag{A8}$$

with the normal ordering difference taking away precisely the constant c_2 in Eq. (A7).

It is also important to note that also the anyon operators are defined using normal ordering. More explicitly, as explained in Remark 2.6 after Eq. (46) in Ref. 11, normal ordering of the anyon field $\phi_\nu(x)$ amounts to a multiplication with the constant

$$\left[(1-e^{-2\varepsilon})\prod_{m=1}^{\infty}(1-q^{2m}e^{-2\varepsilon})^2\right]^{-\nu^2/2}$$

in the limit $\varepsilon\downarrow 0$ [see Eq. (A4) in Ref. 11]; since the divergent factor is β independent, the factor accounting for the difference in normal ordering has a finite limit as $\varepsilon\downarrow 0$ which is identical with $\mathcal{Z}^{\nu^2}$. Thus

$$\langle\Omega,\Phi_\nu^N(\mathbf{x})^* R^{N-M}\Phi_\mu^M(\mathbf{y})\Omega\rangle = \mathcal{Z}^{N\nu^2+M\mu^2-1}\lim_{a\to\infty}\mathrm{Tr}(e^{-\beta H_0}\Phi_{\nu,0}^N(\mathbf{x})^* R_0^{N-M}\Phi_{\mu,0}^M(\mathbf{y})). \tag{A9}$$

We conclude that

$$\langle\Omega,\Phi_\nu^N(\mathbf{x})^* R^{N-M}\Phi_\mu^M(\mathbf{y})\breve{W}^2\Omega\rangle = -\left(\frac{\partial}{\partial\beta} + (N\nu^2+M\mu^2)c_2\right)G_{\nu,\mu;N,M}(\mathbf{x};\mathbf{y}) \tag{A10}$$

[we used Eq. (42)] which is the equation we need.

3. Detailed derivation of Eq. (7)

In our derivation of Eq. (7) in the main text we ignored terms proportional to $G_{N,M}(\mathbf{x};\mathbf{y})$ (indicated by dots), to simplify the argument. Here we give the full derivation, with all terms included.

Using Eq. (48) we obtain

$$[\mathcal{H},R^{N-M}] = (2\lambda\breve{W}^2 - c_0\lambda^2)(N-M)R^{N-M} + \tfrac{1}{3}\lambda^2[Q^3,R^{N-M}], \tag{A11}$$

implying

$$\begin{aligned}\langle\Omega,\Phi_\nu^N(\mathbf{x})^*[\mathcal{H},R^{N-M}]\Phi_\nu^M(\mathbf{y})\Omega\rangle &= 2\lambda(N-M)\langle\Omega,\Phi_\nu^N(\mathbf{x})^*\breve{W}^2 R^{N-M}\Phi_\nu^M(\mathbf{y})\Omega\rangle \\ &\quad + \lambda^2\left[\tfrac{1}{3}(N^3-M^3) - c_0(N-M)\right]G_{N,M}(\mathbf{x},\mathbf{y}).\end{aligned} \tag{A12}$$

We now use

$$\left[\breve{W}^2+\tfrac{1}{2}\lambda Q^2,\Phi_\nu^N(\mathbf{x})\right]=P_N(\mathbf{x})\Phi_\nu^N(\mathbf{x}) \tag{A13}$$

with $P_N(\mathbf{x})$ defined in Eq. (13) [see Eqs. (68) in Ref. 11; there is an error in this latter formula: $(\nu-1)(\nu-3)$ should be replaced by (ν^2-1)]. Using that and (A10) for $\nu=\mu$ [recall Eq. (49)] we obtain

$$\langle\Omega,\Phi_\nu^N(\mathbf{x})^*\breve{W}^2R^{N-M}\Phi_\nu^M(\mathbf{y})\Omega\rangle=\left(P_M(\mathbf{y})-\tfrac{1}{2}\lambda M^2-\frac{\partial}{\partial\beta}-\lambda(N+M)c_2\right)G_{N,M}(\mathbf{x},\mathbf{y}). \tag{A14}$$

Putting the equations above together we obtain

$$\left[H_{\lambda,N}(\mathbf{x})-H_{\lambda,M}(\mathbf{y})+2\lambda(N-M)\frac{\partial}{\partial\beta}\right]G_{N,M}(\mathbf{x},\mathbf{y})=\left(\lambda^2\left[\tfrac{1}{3}(N^3-M^3)-c_0(N-M)\right]+2\lambda(N-M)\times\left[P_M(\mathbf{y})-\tfrac{1}{2}\lambda M^2-\lambda(N+M)c_2\right]\right)G_{N,M}(\mathbf{x},\mathbf{y}). \tag{A15}$$

To get from this an identity for $F_{N,M}(\mathbf{x},\mathbf{y})$ we recall Eqs. (42), (43), (46), and (6), implying

$$G_{N,M}(\mathbf{x},\mathbf{y})=e^{ip(X+Y)}F_{N,M}(\mathbf{x},\mathbf{y}),\quad p=\tfrac{1}{2}(N-M)\lambda. \tag{A16}$$

Using the identities in Eq. (56) this gives

$$\left[H_{\lambda,N}(\mathbf{x})-H_{\lambda,M}(\mathbf{y})+2\lambda(N-M)\frac{\partial}{\partial\beta}\right]F_{N,M}(\mathbf{x},\mathbf{y})=\left(\lambda^2\left[\tfrac{1}{3}(N^3-M^3)-c_0(N-M)\right]+2\lambda(N-M)\times\left[P_M(\mathbf{y})-Mp-\tfrac{1}{2}\lambda M^2-\lambda(N+M)c_2\right]-(N-M)p^2+2p[P_N(\mathbf{x})-P_M(\mathbf{y})]\right)F_{N,M}(\mathbf{x},\mathbf{y}).$$

Inserting $p=\frac{1}{2}\lambda(N-M)$ and using Eq. (15) we see that all terms involving $P_N(\mathbf{x})$ and $P_M(\mathbf{y})$ on the rhs cancel, and we obtain the identity in Eq. (7) with

$$c_{N,M}=\lambda^2\left(\tfrac{1}{3}(N^3-M^3)-c_0(N-M)\right)-\lambda(N-M)(M\lambda(N-M)+\lambda M^2+2\lambda(N+M)c_2)-\tfrac{1}{4}(N-M)^3\lambda^2, \tag{A17}$$

identical with the constant in Eq. (8).

4. Detailed derivation of Eq. (11)

We now consider the functions defined in Eq. (58). Equations (42), (43), and (10) imply

$$\widetilde{G}_{N,M}(\mathbf{x},\mathbf{y})=e^{i(p_1X-p_2Y)}\widetilde{G}_{N,M}(\mathbf{x},\mathbf{y}),\quad p_1=\tfrac{1}{2}(\lambda N+M),\quad p_2=\tfrac{1}{2}(N+M/\lambda). \tag{A18}$$

Using Eq. (57) we can compute

$$\begin{aligned}0=&\langle\Omega,[\Phi_\nu^N(\mathbf{x})^*R^{N-M}\Phi_{-1/\nu}^M(\mathbf{y}),\mathcal{H}^{(\nu)}]\Omega\rangle=\langle[\mathcal{H}^{(\nu)},\Phi_\nu^N(\mathbf{x})]^*\Omega,R^{N-M}\Phi_M^{-1/\nu}(\mathbf{y})\Omega\rangle\\&+\langle\Omega,\Phi_{\nu,N}(\mathbf{x})^*[R^{N-M},\mathcal{H}^{(\nu)}]\Phi_M^{-1/\nu}(\mathbf{y})\Omega\rangle+\left\langle\Omega,\Phi_{\nu,N}(\mathbf{x})^*R^{N-M}\left[\lambda\mathcal{H}^{(-1/\nu)}-2(\lambda+1)\breve{W}^2Q\right.\right.\\&\left.\left.-(\lambda^2+1/\lambda)\left(\tfrac{1}{3}Q^3-c_0Q\right),\Phi_M^{-1/\nu}(\mathbf{y})\Omega\right\rangle=\left[H_{\lambda,N}(\mathbf{x})+\lambda H_{1/\lambda,M}(\mathbf{y})-(\lambda^2+1/\lambda)\left(\tfrac{1}{3}M^3-Mc_0\right)\right]\widetilde{G}_{N,M}\\&-\langle\Omega,\Phi_{\nu,N}(\mathbf{x})^*[\mathcal{H}^{(\nu)},R^{N-M}]\Phi_M^{-1/\nu}(\mathbf{y})\Omega\rangle-2(\lambda+1)M\langle\Omega,\Phi_{\nu,N}(\mathbf{x})^*\breve{W}^2R^{N-M}\Phi_M^{-1/\nu}(\mathbf{y})\Omega\rangle.\end{aligned}$$

As above,

$$\langle\Omega,\Phi_\nu^N(\mathbf{x})^*[\mathcal{H}^{(\nu)},R^{N-M}]\Phi_{-1/\nu}^M(\mathbf{y})\Omega\rangle = 2\lambda(N-M)\langle\Omega,\Phi_\nu^N(\mathbf{x})^*R^{N-M}\breve{W}^2\Phi_{-1/\nu}^M(\mathbf{y})\Omega\rangle + \lambda^2\left[\tfrac{1}{3}(N^3-M^3)-c_0(N-M)\right]\widetilde{G}_{N,M}(\mathbf{x},\mathbf{y})$$

which yields

$$\left[H_{\lambda,N}(\mathbf{x})+\lambda H_{1/\lambda,M}(\mathbf{y})-\lambda^2\left(\tfrac{1}{3}N^3-Nc_0\right)-\left(\tfrac{1}{3}M^3-Mc_0\right)/\lambda\right]\widetilde{G}_{N,M}(\mathbf{x},\mathbf{y}) = 2(\lambda N+M)\langle\Omega,\Phi_\nu^N(\mathbf{x})^*\breve{W}^2R^{N-M}\Phi_{-1/\nu}^M(\mathbf{y})\Omega\rangle. \tag{A19}$$

Moreover, Eq. (A10) gives

$$\langle\Omega,\Phi_\nu^N(\mathbf{x})^*\breve{W}^2R^{N-M}\Phi_{-1/\nu}^M(\mathbf{y})\Omega\rangle = \left(P_M(\mathbf{y})-\tfrac{1}{2}M^2/\lambda-\frac{\partial}{\partial\beta}-(\lambda N+M/\lambda)c_2\right)\widetilde{G}_{N,M}(\mathbf{x},\mathbf{y}), \tag{A20}$$

and with that we obtain

$$\left[H_{\lambda,N}(\mathbf{x})+\lambda H_{1/\lambda,M}(\mathbf{y})+2(N\lambda+M)\frac{\partial}{\partial\beta}\right]\widetilde{G}_{N,M}(\mathbf{x},\mathbf{y}) = \left[\lambda^2\left(\tfrac{1}{3}N^3-c_0N\right)+\left(\tfrac{1}{3}M^3-Mc_0\right)/\lambda + 2(N\lambda+M)\left[P_M(\mathbf{y})-\tfrac{1}{2}M^2/\lambda-(\lambda N+M/\lambda)c_2\right]\right]\widetilde{G}_{N,M}(\mathbf{x},\mathbf{y}),$$

or equivalently

$$\left[H_{\lambda,N}(\mathbf{x})+\lambda H_{1/\lambda,M}(\mathbf{y})+2(N\lambda+M)\frac{\partial}{\partial\beta}\right]\widetilde{F}_{N,M}(\mathbf{x},\mathbf{y}) = \left[\lambda^2\left(\tfrac{1}{3}N^3-c_0N\right)+\left(\tfrac{1}{3}M^3-Mc_0\right)/\lambda + 2(N\lambda+M)\left[P_M(\mathbf{y})+Mp_2-\tfrac{1}{2}M^2/\lambda-(\lambda N+M/\lambda)c_2\right]-Np_1^2+2p_1P_N(\mathbf{x})-\lambda Mp_2^2 - 2\lambda p_2P_M(\mathbf{y})\right]\widetilde{F}_{N,M}(\mathbf{x},\mathbf{y}), \tag{A21}$$

where we used Eqs. (A18) and (56). Using Eq. (15) we see that, again, all derivative terms involving $P_N(\mathbf{x})$ and $P_M(\mathbf{y})$ cancel, and we obtain the identity in Eq. (11) with

$$\widetilde{c}_{N,M} = \lambda^2\left(\tfrac{1}{3}N^3-c_0N\right)+\left(\tfrac{1}{3}M^3-Mc_0\right)/\lambda+(N\lambda+M)[M(N+M/\lambda)-M^2/\lambda-2(\lambda N+M/\lambda)c_2] - \tfrac{1}{4}N(N\lambda+M)^2-\tfrac{1}{4}\lambda M(N+M/\lambda)^2 \tag{A22}$$

identical with the constant in Eq. (12).

APPENDIX B: ELEMENTARY PROOFS OF THE IDENTITIES

We define the function

$$G(\mathbf{x};\mathbf{y}) = \frac{\prod_{1\le j<k\le N}\theta(x_k-x_j)^{\lambda_1}\prod_{1\le J<K\le M}\theta(y_J-y_K)^{\lambda_2}}{\prod_{j=1}^N\prod_{K=1}^M\theta(x_j-y_K)^{\lambda_3}} \tag{B1}$$

and compute

$$W := \frac{1}{G}\left(\sum_{j=1}^N\frac{\partial^2}{\partial x_j^2}-A\sum_{J=1}^M\frac{\partial^2}{\partial y_J^2}\right)G \tag{B2}$$

with parameters λ_1, λ_2, λ_3, and A to be determined. We find it convenient to use in this appendix two different kinds of indices: small letters $j,k,\ell=1,2,\ldots,N$ and capital letters $J,K,L=1,2,\ldots,M$. Obviously,

$$\frac{\partial G}{\partial x_j} = \left[\sum_{j \neq k} \lambda_1 \phi(x_j - x_k) - \sum_K \lambda_3 \phi(x_j - y_K) \right] G \tag{B3}$$

and

$$\frac{1}{G} \frac{\partial^2}{\partial x_j^2} G = \sum_{k \neq j} \lambda_1 \phi'(x_j - x_k) + \sum_{k,\ell \neq j} \lambda_1^2 \phi(x_j - x_k) \phi(x_j - x_\ell) - \sum_K \lambda_3 \phi'(x_j - y_K) + \sum_{K,L} \lambda_3^2 \phi(x_j - y_K) \phi(x_j - y_L) - 2 \sum_{k \neq j, K} \lambda_1 \lambda_3 \phi(x_j - x_k) \phi(x_j - y_K), \tag{B4}$$

and similarly for the y_J-derivatives. We collect the terms in eight different groups as follows:

$$W = W_1 + W_2 + W_3 + W_4, \quad W_s = W_s^{(1)} - W_s^{(2)} \tag{B5}$$

with

$$W_1^{(1)} = \sum_{j,k \neq j} [\lambda_1 \phi'(x_j - x_k) + \lambda_1^2 \phi(x_j - x_k)^2], \tag{B6}$$

$$W_1^{(2)} = A \sum_{J,K \neq J} [\lambda_2 \phi'(y_J - y_K) + \lambda_2^2 \phi(y_J - y_K)^2], \tag{B7}$$

$$W_2^{(1)} = \sum_{j \neq k \neq \ell} \lambda_1^2 \phi(x_j - x_k) \phi(x_j - x_\ell), \tag{B8}$$

where $\Sigma_{j \neq k \neq \ell}$ is short for the sum over all j, k, ℓ with the constraints $j \neq k$ and $j \neq \ell$ and $k \neq \ell$,

$$W_2^{(2)} = A \sum_{J \neq K \neq L} \lambda_2^2 \phi(y_J - y_K) \phi(y_J - y_L), \tag{B9}$$

$$W_3 = (1 - A) \sum_{j,K} [-\lambda_3 \phi'(x_j - y_K) + \lambda_3^2 \phi(x_j - y_K)^2], \tag{B10}$$

since obviously $W_3^{(2)} = -A W_3^{(1)}$, and the rest

$$W_4 = \sum_{j,K \neq L} \lambda_3^2 \phi(x_j - y_K) \phi(x_j - y_L) - A \sum_{J,k \neq \ell} \lambda_3^2 \phi(y_J - x_k) \phi(y_J - x_\ell) - \sum_{j,k \neq j,K} 2\lambda_1 \lambda_3 \phi(x_j - x_k) \phi(x_j - y_K) + A \sum_{J,K \neq J,k} 2\lambda_2 \lambda_3 \phi(y_J - y_K) \phi(y_J - x_k). \tag{B11}$$

We insert $\phi'(x) = -V(x)$ and $\phi(x)^2 = V(x) - c_0 - 2f(x)$ [see Eqs. (23) and (24)] in Eq. (B6) and obtain

$$\begin{aligned} W_1^{(1)} &= \sum_{j,k \neq j} [\lambda_1(\lambda_1 - 1) V(x_j - x_k) - \lambda_1^2 c_0 - 2\lambda_1^2 f(x_j - x_k)] \\ &= -N(N-1)\lambda_1^2 c_0 + \sum_{j<k} [2\lambda_1(\lambda_1 - 1) V(x_j - x_k) - 4\lambda_1^2 f(x_j - x_k)], \end{aligned}$$

where we used that the functions V and f are even, and similarly

$$W_1^{(2)} = -AM(M-1)\lambda_2^2 c_0 + A \sum_{J<K} [2\lambda_2(\lambda_2 - 1) V(y_J - y_K) - 4\lambda_2^2 f(y_J - y_K)].$$

Renaming summation indices and using that ϕ is odd we then write

$$W_2^{(1)} = \sum_{j\neq k\neq \ell} \frac{1}{3}(-\lambda_1^2)[\phi(x_k - x_j)\phi(x_j - x_\ell) + \phi(x_j - x_\ell)\phi(x_\ell - x_k) + \phi(x_\ell - x_k)\phi(x_k - x_j)].$$

Inserting the identity in Eq. (23) with $x=x_k-x_j$, $y=x_j-x_\ell$, and $z=x_\ell-x_k$ gives

$$W_2^{(1)} = \sum_{j\neq k\neq \ell} \frac{1}{3}(-\lambda_1^2)[f(x_k - x_j) + f(x_j - x_\ell) + f(x_\ell - x_k)] = -2\lambda_1^2(N-2)\sum_{j<k} f(x_j - x_k),$$

where we again renamed summation indices and used that f is even. Similarly,

$$W_2^{(2)} = -2A\lambda_2^2(M-2)\sum_{J<K} f(y_J - y_K).$$

Inserting Eq. (23) in Eq. (B10) we obtain

$$W_3 = (1-A)\lambda_3(\lambda_3+1)\sum_{j,K} V(x_j - y_K) - (1-A)\lambda_3^2\left(NMc_0 + 2\sum_{j,K} f(x_j - y_K)\right).$$

The first term in this expression mixes $\mathbf{x}$ and $\mathbf{y}$ in a intolerable way, and in order to get a useful relation it must disappear. This leads to the following important restriction on parameters:

$$(1-A)\lambda_3(\lambda_3+1) = 0. \tag{B12}$$

Next we try to simplify W_4. We write $W_4 = W_4^{(1)} - W_4^{(2)}$ with

$$W_4^{(1)} = \sum_{j,K\neq L} [-\lambda_3^2\phi(y_K - x_j)\phi(x_j - y_L) - A\lambda_2\lambda_3\phi(y_K - y_J)\phi(y_J - x_j) - A\lambda_2\lambda_3\phi(y_J - y_K)\phi(y_K - x_j)],$$

where we used that ϕ is odd and wrote the same term in two different ways renaming summation indices. Similarly,

$$W_4^{(2)} = \sum_{J,k\neq \ell} [-A\lambda_3^2\phi(x_k - y_J)\phi(y_J - x_\ell) - \lambda_1\lambda_3\phi(x_k - x_j)\phi(x_j - y_K) - \lambda_1\lambda_3\phi(x_j - x_k)\phi(x_k - y_K)].$$

We now see that we can use the identity in Eq. (23) to simplify W_4 provided the parameters obey the following conditions:

$$\lambda_3 = A\lambda_2 \quad \text{and } A\lambda_3 = \lambda_1, \tag{B13}$$

and this is another important restriction on parameters. If and only if this holds true we get

$$\begin{aligned} W_4^{(1)} &= \sum_{j,K\neq L} (-\lambda_3^2)[f(y_K - x_j) + f(y_J - y_K) + f(x_j - y_J)] \\ &= -2(M-1)\lambda_3^2\sum_{j,K} f(y_K - x_j) - 2N\lambda_3^2\sum_{J<K} f(y_J - y_K), \end{aligned}$$

and similarly

$$W_4^{(2)} = -2A(N-1)\lambda_3^2\sum_{J,k} f(x_k - y_J) - 2MA\lambda_3^2\sum_{j<k} f(x_j - x_k).$$

Assuming the conditions in Eqs. (B12) and (B13) hold true we thus obtain

$$W = 2\lambda_1(\lambda_1 - 1)\sum_{j<k} V(x_j - x_k) - A2\lambda_2(\lambda_2 - 1)\sum_{J<K} V(y_J - y_K) - [N(N-1)\lambda_1^2 - AM(M-1)\lambda_2^2 + (1-A)\lambda_3^2 NM]c_0 + 2(-N\lambda_1^2 + AM\lambda_3^2)\sum_{j<k} f(x_j - x_k) + 2(AM\lambda_2^2 - N\lambda_3^2)\sum_{J<K} f(y_J - y_K) + 2[-(1-A) - (M-1) + A(N-1)]\lambda_3^2\sum_{j,K} f(x_j - y_K), \tag{B14}$$

or equivalently,

$$\left[H_{\lambda_1,N}(\mathbf{x}) - AH_{\lambda_2,M}(\mathbf{x}) - C_0 - C_1\sum_{j<k} f(x_j - x_k) - C_2\sum_{J<K} f(x_J - x_K) + C_3\sum_{j,K} f(x_j - y_K)\right]G = 0 \tag{B15}$$

with

$$C_1 = 2(N\lambda_1^2 - AM\lambda_3^2), \quad C_2 = 2(N\lambda_3^2 - AM\lambda_2^2), \quad C_3 = 2[AN - M] \tag{B16}$$

and

$$C_0 = [N(N-1)\lambda_1^2 - AM(M-1)\lambda_2^2 + (1-A)\lambda_3^2 NM]c_0. \tag{B17}$$

Using the identity in (25) we now compute

$$\frac{1}{G}\frac{\partial G}{\partial \beta} = \lambda_1\sum_{j<k}[c_1 - f(x_j - x_k)] + \lambda_2\sum_{J<K}[c_1 - f(y_J - y_K)] - \lambda_3\sum_{j,K}[c_1 - f(x_j - y_K)] = \frac{1}{2}[N(N-1)\lambda_1 + M(M-1)\lambda_2 - 2NM\lambda_3]c_1 - \lambda_1\sum_{j<k} f(y_J - y_K) - \lambda_2\sum_{J<K} f(y_J - y_K) + \lambda_3\sum_{j,K} f(x_j - y_K). \tag{B18}$$

We thus see that we can write Eq. (B15) in the following form:

$$\left[H_{\lambda_1,N}(\mathbf{x}) - AH_{\lambda_2,M}(\mathbf{y}) - \tilde{C}_0 + C\frac{\partial}{\partial \beta}\right]G = 0 \tag{B19}$$

provided that

$$C_i = C\lambda_i \quad \text{for } i = 1,2,3. \tag{B20}$$

In this case

$$\tilde{C}_0 = C_0 + C\tfrac{1}{2}[N(N-1)\lambda_1 + M(M-1)\lambda_2 - 2NM\lambda_3]c_1. \tag{B21}$$

Interestingly, the conditions in (B12), (B13), and (B20) have two nontrivial solutions. First,

$$A = 1, \quad \lambda_1 = \lambda_2 = \lambda_3 \equiv \lambda, \tag{B22}$$

with $C=2(N-M)\lambda$ and $\tilde{C}_0=c_{N,M}$ given in Eq. (8), and second,

$$A = -\lambda, \quad \lambda_1 = \lambda, \quad \lambda_2 = 1/\lambda, \quad \lambda_3 = -1 \tag{B23}$$

with $C=2(\lambda N+M)$ and $\tilde{C}_0=\tilde{c}_{N,M}$ in Eq. (12). Obviously these two cases correspond to the identities given in Eqs. (6)–(11), and we have completed our proof. □

(Received 24 October 2005; accepted 3 January 2006; published online 21 February 2006)

We consider the problem of estimating the ensemble average of an observable on an ensemble of equally prepared identical quantum systems. We show that, among all kinds of measurements performed jointly on the copies, the optimal unbiased estimation is achieved by the usual procedure that consists in performing independent measurements of the observable on each system and averaging the measurement outcomes. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2168122]

I. INTRODUCTION

The astonishing precision of measurements currently available in quantum optics[1] along with the growing demand of quantum devices of the new information technology[2,3] have revived the interest in the theory of quantum measurements.[4] The outcome statistics of a quantum measurement for all possible input states is described by a positive operator valued measure (POVM). The general optimization approach of quantum estimation theory[5] is to maximize over all possible POVM's an appropriate cost function, which depends on the context and on the specific use of the measurement. The output statistics can then be improved by using multiple copies of the same quantum system, all prepared in the same state, and performing a suitable *ensemble measurement* over the copies.

The experimental complexity of ensemble measurements is roughly classified by dividing them into three main categories: (a) *independent*, (b) *separable*, and (c) *entangled* measurements. Category (a) is described by tensor products of independent POVM's; (b) by POVM's with separable elements only; (c) by POVM's where some elements are entangled. Notice that the separability of POVM's generally does not correspond to a physical separability of measuring apparatuses [there exist separable measurements that cannot be performed by separate measuring apparatuses, i.e., by local operations and classical communication (LOCC)], and this classification remains essentially mathematical in nature. However, at least one can say that category (b) contains all *adaptive* measurements (in which the choice of the measuring apparatus on the nth copy depends on the outcomes of previous measurements), whereas category (c) contains those measurements that need quantum interactions between copies, implying that all copies during the measuring time must be at the same physical location, or, otherwise, that a "quantum memory" is available.

Among the three categories of ensemble measurements, the category (c) of entangled POVM's discloses the full exponential growth of the Hilbert space dimension versus the number of copies N for a virtually unlimited optimization of the statistical efficiency of the measurement, with the

[a)]Electronic mail: dariano@unipv.it
[b)]Electronic mail: v.giovannetti@sns.it
[c)]Electronic mail: perinotti@fisicavolta.unipv.it

possibility of largely surpassing the performance of categories (a) and (b).[6–9] Indeed, over the last few years, it has been recognized that entangled measurements are usually more efficient than independent measurements, and the optimal measurement scheme is almost always entangled.[10–13] However, in some situations it has been also shown that asymptotically for $N\to\infty$ an equivalently optimal estimation may be achieved using just independent measurements over the copies.[14–17]

In the above scenario it is natural to ask if the *canonical procedure* of averaging the outcomes of repeated measurements of an observable A over equally prepared systems is the best way of estimating the ensemble average $\langle A\rangle$ of A, or, instead, if a joint entangled measurement over the copies can improve the estimation. As we will see it turns out that the canonical procedure is indeed optimal, however, the derivation of this result is nontrivial, and offers a general warning against easy assumptions and generalizations when evaluating statistical efficiencies of ensemble measurements.

Let us be more precise, and fix precisely the scenario of the quantum estimation. Suppose one has a finite number N of equally prepared distinguishable identical d-dimensional quantum systems, which are described by the state $\rho^{\otimes N}$, and one wants to estimate the ensemble average $\langle A\rangle_\rho \equiv \mathrm{Tr}[\rho A]$ of the observable A. Suppose now that one has unlimited technology at one's disposal, including measuring apparatus that can achieve any desired entangled POVM on all N systems jointly. The question is which is the best measuring apparatus to choose in order to estimate $\langle A\rangle_\rho$ with the minimum statistical error? What we will prove in the present paper is that the best estimation strategy is just the canonical procedure, which consists in averaging the outcomes of repeated measurements of the observable A over the equally prepared quantum systems.

II. PERMUTATIONALLY INVARIANT POLARIZATION IDENTITIES

In the derivation of our main result the following lemma will play a crucial role.

Lemma 1: Any permutationally invariant operator X on $\mathsf{H}^{\otimes N}$ is completely determined by all ensemble averages $\mathrm{Tr}[X\rho^{\otimes N}]$ on identical equally prepared systems.

Proof: The statement of the lemma is equivalent to the following logical implication:

$$X\in\mathcal{P}_N(\mathsf{H}),\quad \forall\,\rho\in\mathcal{S}(H),\quad \mathrm{Tr}[X\rho^{\otimes N}]=0\Rightarrow X=0, \tag{1}$$

where $\mathcal{S}(H)$ denotes the set of states on H, and $\mathcal{P}_N(\mathsf{H})$ the algebra of permutationally invariant operators on $\mathsf{H}^{\otimes N}$. Indeed, statement (1) is equivalent to the statement that if $\mathrm{Tr}[X\rho^{\otimes N}]=\mathrm{Tr}[Y\rho^{\otimes N}]$ for all states ρ, then $X\equiv Y$.

Consider the following special states of the form

$$\rho_\lambda=\sum_{j=1}^{N}\lambda_j|\psi_j\rangle\langle\psi_j|,\quad \lambda_j>0,\lambda_j\neq\lambda_i,i\neq j, \tag{2}$$

with $\{\psi_j\}_N$ any set of N unequal states (not necessarily orthogonal). The trace $\mathrm{Tr}[X\rho_\lambda^{\otimes N}]$ is a polynomial in $\Pi_{j=1}^N\lambda_j^{x_j}$, with $\Sigma_{j=1}^N x_j=N$ and $x_j\geqslant 0$ integers. Now, in order to have $\mathrm{Tr}[X\rho_\lambda^{\otimes N}]=0$ for arbitrary ρ_λ, all coefficients of the polynomial must vanish. In particular, the coefficient of $\Pi_{j=1}^N\lambda_j$ is given by

$$\sum_\sigma\langle\psi_1|\ldots\langle\psi_N|\Pi_\sigma X\Pi_\sigma^\dagger|\psi_1\rangle\ldots|\psi_N\rangle\equiv 0, \tag{3}$$

where Π_σ are the permutations of the N systems. By hypothesis we have $\Pi_\sigma X\Pi_\sigma^\dagger=X$, then the vanishing of $\mathrm{Tr}[X\rho_\lambda^{\otimes N}]$ for all states ρ_λ implies

$$\langle\psi_1|\ldots\langle\psi_N|X|\psi_1\rangle\ldots|\psi_N\rangle=0, \tag{4}$$

for all sets $\{\psi_j\}_N$. If we take $|\psi_k\rangle=\alpha|\phi\rangle+\beta|\phi_\perp\rangle$, by arbitrariness of α and β we have

$$\begin{aligned}\langle\psi_1|\cdots\langle\phi|\cdots\langle\psi_N|X|\psi_1\rangle\cdots|\phi\rangle\cdots|\psi_N\rangle &= \langle\psi_1|\cdots\langle\phi|\cdots\langle\psi_N|X|\psi_1\rangle\cdots|\phi_\perp\rangle\cdots|\psi_N\rangle \\ &= \langle\psi_1|\cdots\langle\phi_\perp|\cdots\langle\psi_N|X|\psi_1\rangle\cdots|\phi\rangle\cdots|\psi_N\rangle \\ &= \langle\psi_1|\cdots\langle\phi_\perp|\cdots\langle\psi_N|X|\psi_1\rangle\cdots|\phi_\perp\rangle\cdots|\psi_N\rangle = 0. \quad (5)\end{aligned}$$

By repeating the same argument for different values of k and choosing ϕ and $\phi_\perp$ as all possible elements of an orthonormal basis $\{\phi_j\}$ we get

$$\langle\phi_{j_1}|\cdots\langle\phi_{j_N}|X|\phi_{k_1}\rangle\cdots|\phi_{k_N}\rangle = 0, \quad \forall\,\{j_i\},\{k_i\}. \quad (6)$$

Since all the matrix elements of X on an orthonormal basis are null, one has that $X\equiv 0$. ■

Notice that the proof of the previous lemma contains the following interesting corollary.

Corollary 1: For any operator X on $\mathsf{H}^{\otimes N}$ the diagonal elements on factorized states completely determine X.

This is a kind of *factorized* polarization identity for permutation invariant operators.

III. THE MAIN RESULT

Let us now come back to the original problem of determining the optimal measurement for estimating the ensemble average of an observable. Consider a generic joint POVM $P(r)$ on $\mathsf{H}^{\otimes N}$, with outcome r providing an estimate of the expectation $\langle A\rangle_\rho$ of the observable A on N identical systems all in the same state ρ. Clearly, one has $\lambda_m \leqslant r \leqslant \lambda_M$, with λ_m and λ_M minimum and maximum eigenvalues of A, respectively. The POVM $P(r)$ provides an estimate of the expectation $\langle A\rangle_\rho$ if the conditional probability $p(r|\rho)$ of estimating expectation value r for actual value $\mathrm{Tr}[A\rho]$ is expressed via the Born rule as follows:

$$p(r|\rho)\mathrm{d}r = \mathrm{Tr}[P(r)\rho^{\otimes N}]\mathrm{d}r. \quad (7)$$

Since the state $\rho^{\otimes N}$ is permutation invariant, we can consider permutation invariant POVM's. Indeed, using invariance of $\rho^{\otimes N}$ under permutations, one has

$$p(r|\rho)\mathrm{d}r = \frac{1}{N!}\sum_\sigma \mathrm{Tr}[\Pi_\sigma\rho^{\otimes N}\Pi_\sigma^\dagger P(r)]\mathrm{d}r = \mathrm{Tr}\left[\rho^{\otimes N}\frac{1}{N!}\sum_\sigma(\Pi_\sigma^\dagger P(r)\Pi_\sigma)\right]\mathrm{d}r = \mathrm{Tr}[\Pi'(r)\rho^{\otimes N}]\mathrm{d}r, \quad (8)$$

where the POVM

$$P'(r) \equiv \frac{1}{N!}\sum_\sigma \Pi_\sigma^\dagger P(r)\Pi_\sigma \quad (9)$$

is permutation invariant by construction. This means that for any POVM there is a permutation invariant one giving the same probability distributions for all states $\rho^{\otimes N}$. Therefore, without loss of generality, in the following we can assume that $P(r)$ is permutation invariant. We will consider now the case in which the POVM is *unbiased*, that is the averaging over r coincides with the value to be estimated. Mathematically this means that for all states ρ the following identity holds:

$$\int_{\lambda_m}^{\lambda_M}\mathrm{d}r\, rp(r|\rho) = \mathrm{Tr}[A\rho]. \quad (10)$$

The statistical error in the estimate is given by the rms of the probability distribution

$$\epsilon_N(A) \doteq \left[\int_{\lambda_m}^{\lambda_M}\mathrm{d}r(r-\langle A\rangle_\rho)^2 p(r|\rho)\right]^{1/2}, \quad (11)$$

which for unbiased estimation equals

$$\epsilon_N(A) \doteq \left[\int_{\lambda_m}^{\lambda_M} \mathrm{d}r[r^2 p(r|\rho)] - \langle A \rangle_\rho^2 \right]^{1/2}. \tag{12}$$

Since the only part which depends on the POVM is the conditional probability $p(r|\rho)$, the optimization of the error resorts to minimize the quantity

$$\int_{\lambda_m}^{\lambda_M} \mathrm{d}r\, r^2 \,\mathrm{Tr}[P(r)\rho^{\otimes N}], \tag{13}$$

with the constraints

$$\int_{\lambda_m}^{\lambda_M} \mathrm{d}r\, P(r) = I, \tag{14}$$

$$\int_{\lambda_m}^{\lambda_M} \mathrm{d}r\, r\, \mathrm{Tr}[P(r)\rho^{\otimes N}] = \langle A \rangle_\rho. \tag{15}$$

Using the following identity:

$$\langle A \rangle_\rho = \mathrm{Tr}\left[\rho^{\otimes N} \frac{1}{N!} \sum_\sigma \Pi_\sigma (A \otimes I^{\otimes (N-1)}) \Pi_\sigma^\dagger \right] = \mathrm{Tr}\left[\rho^{\otimes N} \frac{1}{N} \sum_{k=1}^N A^{(k)} \right] \tag{16}$$

with $A^{(k)} \doteq I^{\otimes (k-1)} \otimes A \otimes I^{\otimes N-k}$, by virtue of Lemma 1 we can recast Eq. (15) as follows:

$$\int_{\lambda_m}^{\lambda_M} \mathrm{d}r\, rP(r) = \frac{1}{N} \sum_{k=1}^N A^{(k)} \doteq \Theta. \tag{17}$$

The operator $\Delta \geqslant 0$ defined as

$$\Delta \doteq \int_{\lambda_m}^{\lambda_M} \mathrm{d}r\, r^2 P(r), \tag{18}$$

allows to reexpress the statistical error as follows:

$$\epsilon_N(A)^2 = \mathrm{Tr}[\Delta \rho^{\otimes N}] - \langle A \rangle_\rho^2. \tag{19}$$

In the representation in which Δ is diagonal, the constraints (14) and (15) become

$$\int_{\lambda_m}^{\lambda_M} \mathrm{d}r\, P(r)_{lk} = \delta_{lk}, \tag{20}$$

$$\int_{\lambda_m}^{\lambda_M} \mathrm{d}r\, rP(r)_{lk} = \Theta_{lk}, \tag{21}$$

whereas the error (12) becomes

$$\epsilon_N(A)^2 = \sum_n (\rho^{\otimes N})_{nn} \int_{\lambda_m}^{\lambda_M} \mathrm{d}r\, r^2 P(r)_{nn} - \langle A \rangle_\rho^2. \tag{22}$$

From Eqs. (20) and (21) it follows that the diagonal elements $P(r)_{nn}$ are probability densities in r over $[\lambda_m, \lambda_M]$, with average Θ_{nn}. Denoting the variance of $P(r)_{nn}$ by σ_n^2, we can write

$$\epsilon_N(A)^2 = \sum_n (\rho^{\otimes N})_{nn}(\sigma_n^2 + \Theta_{nn}^2) - \langle A\rangle_\rho^2. \tag{23}$$

Therefore, $\epsilon_N(A)^2$ is minimized by taking $\sigma_n^2=0$, corresponding to $P(r)_{nn} \equiv \delta(\Theta_{nn}-r)$. This implies that the outcomes of the optimal POVM are actually discrete, corresponding to $r_n=\Theta_{nn}$. In this discrete version, the POVM has $P(r_n)_{nm}=\delta_{nm}$ [which also implies that $\Theta_{nm}=\delta_{nm}\Theta_{nn}$ via Eq. (21)], that is $P(r_n)$ is projection valued on the nth eigenvector of Δ (when it happens that $\Theta_{nn}=\Theta_{mm}$ for some $m \neq n$, then the projector has rank equal to the number of equal diagonal elements). We have finally

$$\epsilon_N(A)^2 = \sum_n (\rho^{\otimes N})_{nn}\Theta_{nn}^2 - \langle A\rangle_\rho^2. \tag{24}$$

Moreover, we have

$$I = \sum_n P(r_n), \tag{25}$$

$$\Theta = \sum_n \Theta_{nn} P(r_n), \tag{26}$$

$$\Delta = \sum_n \Theta_{nn}^2 P(r_n). \tag{27}$$

Since optimization makes Θ and Δ jointly diagonal, one has $\Sigma_n \Theta_{nn}^2(\rho^{\otimes N})_{nn}=\mathrm{Tr}[\Theta^2\rho^{\otimes N}]$, and using Eqs. (17) and (24) we can write the following expression for the minimal error:

$$\epsilon_N(A)^2 = \frac{1}{N^2}\sum_{i,j=1}^{N} \mathrm{Tr}[A^{(i)}A^{(j)}\rho^{\otimes N}] - \langle A\rangle_\rho^2. \tag{28}$$

Notice that the sum in the first term contains N terms with $i=j$ equal to $\mathrm{Tr}[A^2\rho]$ and $N(N-1)$ with $i \neq j$ equal to $\langle A\rangle_\rho^2$, resulting in

$$\epsilon_N(A) = \sqrt{\frac{\langle A^2\rangle_\rho - \langle A\rangle_\rho^2}{N}}, \tag{29}$$

that is the optimal error equals the statistical error occurring when measuring A separately on all the identical quantum systems in the state ρ, and then averaging. Indeed, the optimal POVM coincides with the spectral resolution of $\Theta=(1/N)\Sigma_n A^{(n)}$ on $\mathsf{H}^{\otimes N}$.

I. INTRODUCTION

As is well known one of the central roles in high energy physics plays Regge concept[1–4] based on the analytical extension of the scattering amplitudes in the complex angular momentum plane. One of the most distinctive features of this technique are the Regge trajectories. Regge trajectories are very generic in hadronic physics. For example, they are well established for mesons, baryons, and soft Pomeron.[5–8] Recently a lot of activity has been dedicated to various studies of the Regge trajectories.[7,9,10]

In recent years a revival interest to the Regge approach in the high energy physics is seen.[11,12] At present time, Regge approach is applied with success for description of the hadrons at high energies.[13–15] We note that, in the series of the works the idea of the generalized Pomeron (vacuum Regge trajectory which determine asymptotic behavior of the scattering amplitudes at high energies)—the BFKL (Balitsky-Fadin-Kuraev-Lipatov) Pomeron is applied with success for description of the processes at high energy.[16] Recently, the Regge concept is applied to astrophysics problems.[17,18] For example, in cosmology it is demonstrated[17] that the use of the Regge trajectories makes it possible to explain the problem of the rotation of cosmic objects.[19,20]

Also in recent years the quantum-mechanical models based on the geometry of spaces of constant curvature have attracted considerable attention due to their interesting mathematical features[21–24] as well as the possibility of applications to physical problems.[25] For example, these models are used for the description of the bound states in nuclear and elementary particle physics[24] Thus, Kepler problem on the sphere S_3 has been used as a model for description of quarkonium spectrum,[26] also it was used as a model for description of the spectra electrons, holes, and excitons confined in semiconductor quantum dots.[27,28] Also, integrable models on a sphere S_3 are used for construction of model potential for quantum dots.[29]

In this paper we apply the Regge analysis to the Coulomb scattering problem in the space of constant negative curvature ${}^1S_3$. The analytic properties of the scattering amplitude for Coulomb potential in the complex angular momentum plane in the three-dimensional space of constant negative curvature ${}^1S_3$ are discussed. In Refs. 4 and 30 the analytic properties of the Coulomb scattering amplitude in the complex angular momentum plane for flat space are discussed. Special attention is given to the comparison of the Regge trajectories for curved and flat spaces.

II. REGGE ANALYSIS OF THE COULOMB PROBLEM IN THE SPACE OF CONSTANT NEGATIVE CURVATURE

As is known in the case of space of constant negative curvature, both finite and infinite motions of a particle are possible. The corresponding Schrödinger equation has both discrete and continuous spectra. Therefore it is possible to formulate the Coulomb scattering problem.

We use embedding of the space of constant negative curvature in four-dimensional pseudo-Euclidean space with coordinates $x_\mu, \mu=1,2,3,4$, given by the formulas

$$x_\mu x_\mu = \mathbf{x}^2 + x_4^2 = \mathbf{x}^2 - x_0^2 = -\rho^2,$$
$$\mathbf{x} = \{x_1, x_2, x_3\}, \quad x_4 = ix_0. \tag{1}$$

The Coulomb potential in the ${}^1S_3$ space reads

$$U = -\frac{\alpha}{\rho}\frac{x_0}{|\mathbf{x}|}, \tag{2}$$

where $\alpha > 0$ for the attractive potential.

The Schrödinger equation for the attractive Coulomb potential (2) is

$$H\Psi = E\Psi, \quad H = \frac{1}{4\rho^2}M_{\mu\nu}M_{\mu\nu} - \frac{\alpha}{\rho}\frac{x_0}{|\mathbf{x}|},$$
$$M_{\mu\nu} = x_\mu\partial_\nu - x_\nu\partial_\mu. \tag{3}$$

We use the system of units such that $\hbar = m = 1$.

The exact solution of the Coulomb scattering problem in the space of constant negative curvature was found in the work.[31] The S-matrix element for energy E, angular momentum l and curvature ρ in the ${}^1S_3$ space is given by

$$S(E,l,\rho) = \frac{\Gamma(1 - i\gamma_+ + i\gamma_- + l)}{\Gamma(1 + i\gamma_+ - i\gamma_- + l)}, \tag{4}$$

where

$$\gamma_\pm = \sqrt{\frac{(E\rho^2 \pm \alpha\rho)}{2} - \frac{1}{4}}. \tag{5}$$

The S-matrix element for the Coulomb problem in the flat space is

$$S(E,l) = \frac{\Gamma\left(1 + l - \frac{i}{\sqrt{2E}}\right)}{\Gamma\left(1 + l + \frac{i}{\sqrt{2E}}\right)}. \tag{6}$$

We note that in the limit of the flat space, i.e., when $\rho \to \infty$ we have

$$\lim_{\rho\to\infty}(\gamma_+ - \gamma_-) = \frac{\alpha}{\sqrt{2E}}, \tag{7}$$

and expression for the S matrix in the ${}^1S_3$ space (4) transforms to (6).

It is well known from quantum mechanics that the scattering amplitude may be expanded in Legendre polynomials. This is called partial wave expansion. In our case partial wave expansion of the scattering amplitude[31] is given by

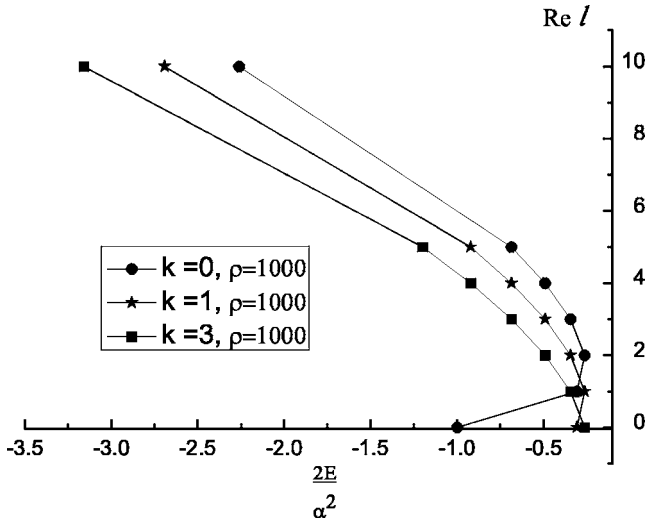

FIG. 1. The first three Regge trajectories in the space of constant negative curvature. The symbols on the plot correspond to bound states of the system.

$$f(\theta,\rho) = \frac{\rho}{2i(\gamma_+ + \gamma_-)} \times \sum_l (2l+1)\frac{\Gamma(1 - i\gamma_+ + i\gamma_- + l)}{\Gamma(1 + i\gamma_+ - i\gamma_- + l)} P_l(\cos\theta), \tag{8}$$

where θ is the scattering angle.

As is known, the Regge poles are determined by the position of singularities of the scattering amplitude at complex plane of angular momentum. Since $\Gamma(z)$ is a meromorphic function in the finite z plane with poles at $z=0,-1,-2,\ldots$, therefore the Regge poles are the poles of the gamma function $\Gamma(1-i\gamma_+ + i\gamma_- + l)$.

Thus, the position of kth Regge pole $l=\alpha_k(E,\rho)$ is given by

$$\alpha_k(E,\rho) = -k + \alpha_0(E,\rho) \quad (\text{for } k = 0,1,2,\ldots), \tag{9}$$

where

$$\alpha_0(E,\rho) = -1 + i\gamma_+ - i\gamma_-. \tag{10}$$

When we vary the energy, the poles $\alpha_k(E)$ move in the l plane along Regge trajectories. The first three Regge trajectories are shown in Fig. 1.

We see from Figs. 2 and 3 there exist differences in the Regge trajectories for curved and flat spaces. From these figures it follows that there are such values of the angular momentum l and quantum number k for which no differences exist. But with the increase of l and k considerable differences in the Regge trajectories appear.

The plot of the dependence $\mathrm{Im}[\alpha_k(E,\rho)]$ on $\mathrm{Re}[\alpha_k(E,\rho)]$ is also called Regge trajectory. We can now trace the Regge trajectory of that type in the l plane as we vary the energy along the real axis (see Figs. 4 and 5). Also from these figures we can observe that with the growth of the radius of curvature ρ we have the plane case.

The energy at which the kth Regge pole crosses a physical l value is given by

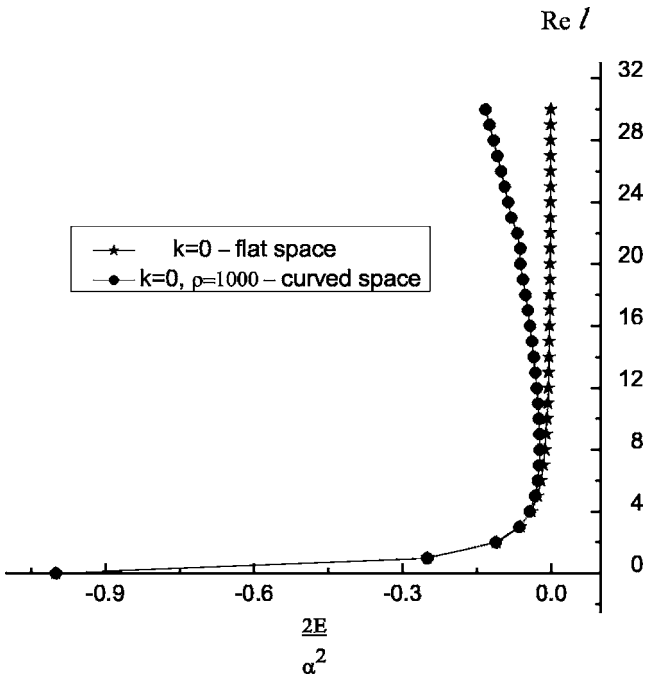

FIG. 2. The comparison of the Regge trajectories for $k=0$.

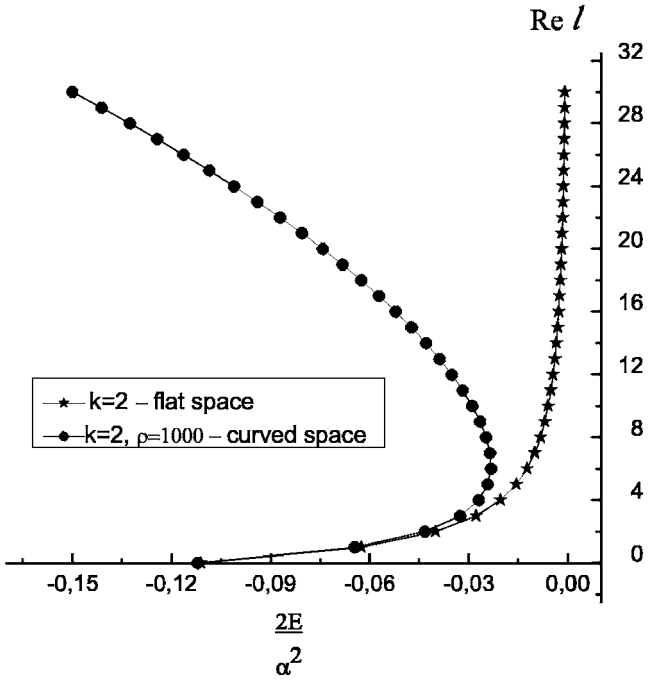

FIG. 3. The comparison of the Regge trajectories for $k=2$.

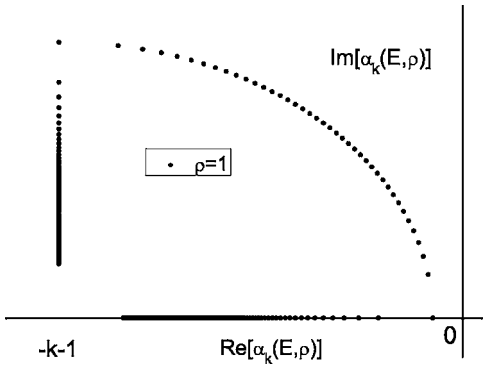

FIG. 4. The trajectory with energy (real) of the kth Regge pole for attractive Coulomb potential in the space of constant negative curvature for $\rho=1$.

$$E=-\frac{1}{2}\left[\frac{\alpha^2}{(k+l+1)^2}+\frac{(k+l+1)^2-1}{\rho^2}\right]. \tag{11}$$

These values are just the energies of the bound states for the attractive Coulomb field in the ${}^1S_3$ space.

As is known, the function $\alpha_k(E)=l+1-i/\sqrt{2E}$ in the flat space is a real analytical in E with a branch point at $E=0$. From (9) it follows

$$\alpha_m(0,\rho)=-k-1+i\left(\sqrt{\frac{\alpha\rho}{2}-\frac{1}{4}}-\sqrt{\frac{-\alpha\rho}{2}-\frac{1}{4}}\right),$$

that is in the space of constant negative curvature the function $\alpha_k(E,\rho)$ has not a branch point at $E=0$. Instead, in the space of constant negative curvature the function $\alpha_k(E,\rho)$ has two branch points in E,

$$E_1(\rho)=\frac{1-2\alpha\rho}{2\rho^2} \text{ and } E_2(\rho)=\frac{1+2\alpha\rho}{2\rho^2}. \tag{12}$$

The branch points move as the curvature ρ varies. For any ρ the value $E_2(\rho)>0$, if $\rho<1/2\alpha$ then $E_1(\rho)>0$ too. When $\rho-\to\infty$ the branch points $E_1(\rho)$ and $E_2(\rho)$ transform to $E=0-\epsilon$ and $E=0+\epsilon$, respectively.

In Ref. 31 the explicit expression for the scattering amplitude

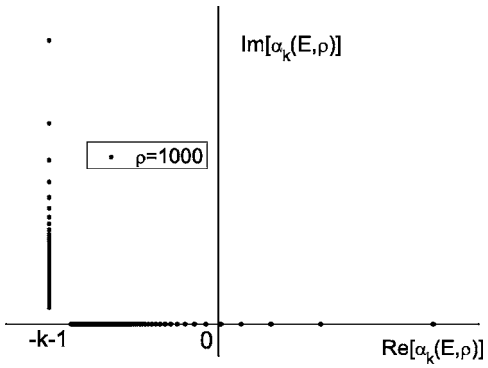

FIG. 5. The trajectory with energy (real) of the kth Regge pole for attractive Coulomb potential in the space of constant negative curvature for $\rho=1000$.

$$f(\theta,\rho)=\frac{\rho(\gamma_+-\gamma_-)}{(\gamma_++\gamma_-)}\frac{\Gamma(1-i\gamma_++i\gamma_-)}{\Gamma(1+i\gamma_+-i\gamma_-)}\times 2^{-i(\gamma_+-\gamma_-)}(1-\cos\theta)^{i\gamma_+-i\gamma_--1} \tag{13}$$

was found.

Using the recurrence formula $\Gamma(1+z)=z\Gamma(z)$ and (10) we may rewrite the scattering amplitude (13) in the Regge representation

$$f(\theta,\rho)=\frac{\rho}{2i(\gamma_++\gamma_-)}\frac{\Gamma[-\alpha_0(E,\rho)]}{\Gamma[1+\alpha_0(E,\rho)]}\times\left(\frac{1-\cos\theta}{2}\right)^{\alpha_0(E,\rho)}. \tag{14}$$

With the use of the variable

$$t=-2E(1-\cos\theta), \tag{15}$$

Eq. (14) can be written as

$$f(t,E,\rho)=\frac{\rho}{2i(\gamma_++\gamma_-)}\frac{\Gamma[-\alpha_0(E,\rho)]}{\Gamma[1+\alpha_0(E,\rho)]}\times\left(-\frac{t}{4E}\right)^{\alpha_0(E)}. \tag{16}$$

We see from (16) that the asymptotic of the scattering amplitude $f(t,E,\rho)$ when $t\to\infty$ is determined of the poles (9) and has behavior of the Regge type

$$f(t,E,\rho)\big|_{t\to\infty}\approx g(E,\rho)t^{\alpha_0(E,\rho)}. \tag{17}$$

Thus, at the very high energies the scattering amplitude is determined mainly by the zero Regge pole.

III. CONCLUSION

The Regge analysis for Coulomb problem in the space of constant negative curvature has been given. We have the following results:

(a) As in the case of the three-dimensional Euclidean space for the Coulomb scattering problem in the space of constant negative curvature to each value of energy corresponds to the finite number of the Regge trajectories. This fact is underlaid by the existence of additional conserved quantity, the Runge-Lentz vector.

(b) The Regge poles considered as a function of energy E in the ${}^1S_3$ space has two branch points and are directly proportional to the square from the energy. While in the three-dimensional Euclidean space the Regge trajectories are inversely proportional to the square from the energy and has a branch point at $E=0$.

In conclusion, we note that the Regge trajectories are nonlinear trajectories for potential scattering in the flat space. At that time, when we vary the radius of curvature ρ the Regge trajectories may be a straight line in the entire energy interval in the curved space. This fact can be used for description of the bound states in particle physics and will be a subject of further study. In this approach the radius of curvature ρ will be connected with the size of particles.[32,33]

Quantum and Fisher information from the Husimi and related distributions

Paul B. Slater[a)]
ISBER, University of California, Santa Barbara, California 93106

(Received 9 November 2005; accepted 3 January 2006; published online 24 February 2006)

The two principal/immediate influences—which we seek to interrelate here—upon the undertaking of this study are papers of Życzkowski and Słomczyński [J. Phys. A **34**, 6689 (2001)] and of Petz and Sudár [J. Math. Phys. **37**, 2262 (1996)]. In the former work, a metric (the Monge one, specifically) over generalized Husimi distributions was employed to define a distance between two arbitrary density matrices. In the Petz-Sudár work (completing a program of Chentsov), the quantum analog of the (classically unique) Fisher information (monotone) metric of a probability simplex was extended to define an uncountable infinitude of Riemannian (also monotone) metrics on the set of positive definite density matrices. We pose here the questions of what is the specific/*unique* Fisher information metric for the (classically defined) Husimi distributions and how does it relate to the *infinitude* of (quantum) metrics over the density matrices of Petz and Sudár? We find a highly proximate (small relative entropy) relationship between the probability distribution (the quantum Jeffreys' prior) that yields quantum universal data compression, and that which (following Clarke and Barron) gives its classical counterpart. We also investigate the Fisher information metrics corresponding to the *escort* Husimi, positive-*P* and certain Gaussian probability distributions, as well as, in some sense, the discrete Wigner *pseudoprobability*. The *comparative noninformativity* of prior probability distributions—recently studied by Srednicki [Phys. Rev. A **71**, 052107 (2005)]—formed by normalizing the volume elements of the various information metrics, is also discussed in our context. © *2006 American Institute of Physics.*

I. INTRODUCTION

The two-level quantum systems (TLQS) are describable (nonclassically) in terms of 2×2 density matrices (ρ)—Hermitian non-negative definite matrices of trace unity. These matrices can be parametrized by points in the unit ball [Bloch ball/sphere (Ref. 1, p. 10244)] in Euclidean 3-space. On the other hand, the TLQS can be described in a *classical* manner using a generalization of the Husimi distribution[2] (Ref. 3, Sec. 4.1) (cf. Refs. 4–9). "The Husimi function is a function on phase space, and takes only non-negative values while the Wigner function can be negative and is usually violently oscillating. Hence the Husimi function can be regarded as a probability distribution in phase space, and its order of delocalization can be a measure of chaoticity of quantum states."[10] (Note that the original Husimi distribution was defined only for density operators in *separable* Hilbert space—one which admits a countable orthonormal basis—while the distribution studied here is defined over a finite-dimensional Hilbert space.)

There is an (uncountable) *infinitude* (Ref. 11, Sec. 16.7) of (quantum monotone) Riemannian metrics that can be attached to the Bloch ball of TLQS. Contrastingly, in the classical context of the Husimi distribution, there is not an infinitude, but rather a *single* distinguished (up to a constant multiple) monotone Riemannian metric—the *Fisher information* metric.[12–14] ["In the

a)Electronic mail: slater@kitp.ucsb.edu

classical case, decision theory provides a unique monotone metric, namely, the Fisher information. In the quantum case, there are infinitely many monotone metrics on the state space" (Ref. 15, p. 2672).] So, it appears to be an question of obvious interest—which we seek to address here—of how one reconciles/deals with this phenomenon of classical uniqueness and quantum nonuniqueness, as applied to essentially the *same* objects (that is, the TLQS).

II. MONOTONE METRICS

The monotone metrics are all *stochastically monotone*.[15] That is, geodesic distances (as well as relative entropies) between density matrices *decrease* under coarse-grainings [completely positive trace-preserving maps, satisfying the Schwarz inequality: $T(a^*a) \geqslant T(a)^*T(a)$]. These metrics can be used for purposes of statistical distinguishability.[15] The monotone metrics for the TLQS have been found to be rotationally invariant over the Bloch ball, depending only on the radial coordinate r, that is the distance of the state in question from the origin (0,0,0)—corresponding to the fully mixed state. They are splittable into radial and tangential components of the form [Ref. 15, Eq. (3.17),

$$\mathrm{d}s^2_{\mathrm{monotone}} = \frac{1}{1-r^2}\mathrm{d}r^2 + \left((1+r)f\left(\frac{1-r}{1+r}\right)\right)^{-1}\mathrm{d}n^2. \tag{1}$$

Here, using spherical coordinates (r,θ_1,θ_2), one has $\mathrm{d}n^2 = r^2\,\mathrm{d}\theta_1^2 + r^2\sin^2\theta_1\,\mathrm{d}\theta_2^2$. Further, $f:\mathbb{R}^+ \to \mathbb{R}^+$ is an operator monotone function such that $f(t)=tf(t^{-1})$ for every $t>0$. [A function is operator monotone if the relation $0 \leqslant K \leqslant H$, meaning that $H-K$ is nonnegative definite, implies $0 \leqslant f(K) \leqslant f(H)$ for any such matrices K and H of any order.] The radial component is *independent* of the function f, and in the case of the Bures (minimal monotone) metric [corresponding to the particular choice $f_{\mathrm{Bures}}(t)=(1+t)/2$], the tangential component is independent of r.[16]

In the classical context of the Husimi distribution, there is not an infinitude, but rather a *single* distinguished (to a constant multiple) monotone metric—the *Fisher information* metric.[12–14] (The counterpart here to stochastic mappings—which are the appropriate morphisms in the category of quantum state spaces—are stochastic *matrices*.[15]) The ij entry of the Fisher information matrix (tensor) is the expected value with respect to the probability distribution in question of the product of the *first* derivative of the logarithm of the probability with respect to its ith parameter times the analogous first derivative with respect to its jth parameter. [Under certain regularity conditions, the Fisher information matrix is equal to the "second derivative matrix for the informational divergence (relative entropy)" (Ref. 17, pp. 455–456, Ref. 18, p. 43).] The volume element of the Fisher information metric can be considered—in the framework of Bayesian theory—as a prior distribution (Jeffreys' prior[17,19,20]) over, for our purposes here, the Bloch ball of TLQS.

Fisher information metric for the Husimi distribution: We have found (having to make use of numerical, as well as symbolic MATHEMATICA procedures in our quest) that for the Husimi distribution over the TLQS, the Fisher information metric takes the specific form [cf. (2)],

$$\mathrm{d}s^2_{\mathrm{Fisher_{Hus}}} = \frac{-2r - \ln\left(\frac{1-r}{1+r}\right)}{2r^3}\mathrm{d}r^2 + \left((1+r)f_{\mathrm{Hus}}\left(\frac{1-r}{1+r}\right)\right)^{-1}\mathrm{d}n^2. \tag{2}$$

Here,

$$f_{\mathrm{Hus}}(t) = \frac{(t-1)^3}{t^2 - 2t\ln t - 1}. \tag{3}$$

Now, a plot (Fig. 1) shows $f_{\mathrm{Hus}}(t)$ to be, in fact, a *monotone* function. [$f_{\mathrm{Hus}}(t)$ is "almost" equal to $(t-1)^3/(t^2-2t-1) = t-1$.] It has a singularity at $t=1$, corresponding to the fully mixed state ($r=0$), where $f_{\mathrm{Hus}}(1+\Delta t) \approx 3+3\Delta t/2$, though we have not attempted to confirm its *operator* monotonicity. Also, $f_{\mathrm{Hus}}(t)$ fulfills the self-adjointness condition $f(t)=tf(t^{-1})$ of Petz and Sudár (Ref. 15, p. 2667), at least at $t \neq 1$. For the pure states, that is $t=0$, $r=1$, we have $\lim_{t\to 0} f_{\mathrm{Hus}}(t)=1$.

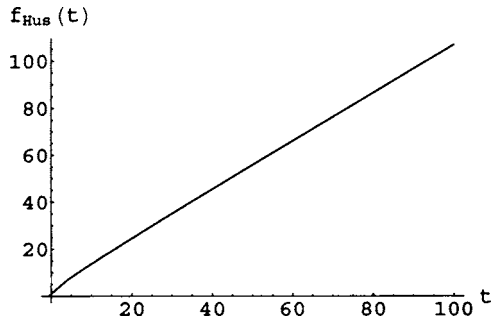

FIG. 1. The monotone function $f_{\mathrm{Hus}}(t)$ that yields the *tangential* component of the Fisher information metric over the trivariate Husimi probability distributions for the two-level quantum systems.

We further have the relation,

$$c_{\mathrm{Hus}}(p,q) = \frac{1}{q f_{\mathrm{Hus}}\left(\frac{p}{q}\right)} = \frac{q^2 - p^2 - 2pq \ln \frac{q}{p}}{(q-p)^3}, \tag{4}$$

where $c_{\mathrm{Hus}}(p,q)$ is a specific "Morozova-Chentsov" function. There exist one-to-one correspondences between Morozova-Chentsov functions, monotone metrics and operator means (Ref. 21, Corollary 6). "Operator means are binary operations on positive operators which fulfill the main requirements of monotonicity and the transformer inequality."[21]

We can write (1) more explicitly as

$$\mathrm{d}s^2_{\mathrm{Fisher}_{\mathrm{Hus}}} = \frac{-2r - \ln\left(\frac{1-r}{1+r}\right)}{2r^3}\mathrm{d}r^2 + \frac{2r + (1-r^2)\ln\left(\frac{1-r}{1+r}\right)}{4r^3}\mathrm{d}n^2. \tag{5}$$

Certainly, $\mathrm{d}s^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$ does not have—in terms of the radial component—the specific form (1) required of a monotone metric (cf. Ref. 22). In Fig. 2 we show both the *radial* components of (any) $\mathrm{d}s^2_{\mathrm{monotone}}$ and of $\mathrm{d}s^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$. Petz (Ref. 23, p. 934) attributes the unvarying nature $[1/(1-r^2)]$ of the radial component of the (quantum) monotone metrics to the (classical) Chentsov uniqueness (of Fisher information) theorem.[12,13] "Loosely speaking, the unicity [sic] result in the [probability] simplex case survives along the diagonal and the off-diagonal provides new possibilities for the definition of a stochastically invariant metric" (Ref. 15, p. 2664).

If we (counterfactually) equate the volume element of $\mathrm{d}s^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$ to that of a generic monotone

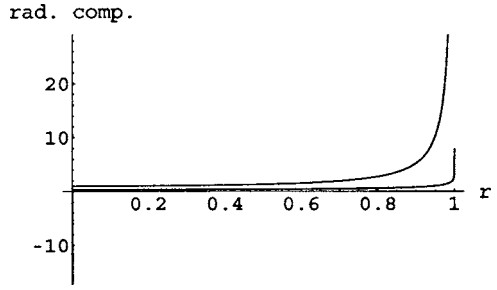

FIG. 2. The radial components of *any* monotone metric and that of the Fisher information metric derived from the family of trivariate Husimi distributions over the TLQS. The one for the (nondenumerably infinite) class $\mathrm{d}s^2_{\mathrm{monotone}}$ dominates that for $\mathrm{d}s^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$.

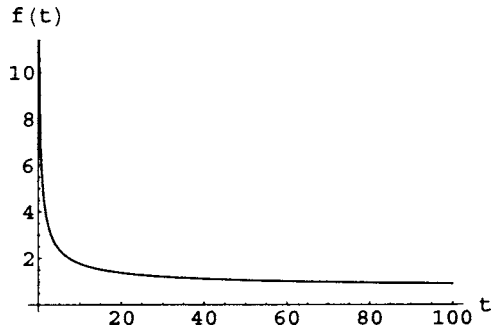

FIG. 3. Monotonically *decreasing* function $f_{\text{counter factual}}$ obtained by equating the volume element of $ds^2_{\text{Fisher}_{\text{Hus}}}$ to that of a generic monotone metric (1).

metric (1), and solve for $f(t)$, we obtain a monotonically *decreasing* function (Fig. 3) (cf. Ref. 22),

$$f_{\text{counter factual}}(t) = \frac{\sqrt{2}(-1+t)^{9/2}}{t(1+t)\sqrt{(-1+t^2-2t\ln(t))^2(2-2t+(1+t)\ln(t))}}. \tag{6}$$

Converting to (Cartesian coordinates (x,y,z), the *trace* of $ds^2_{\text{Fisher}_{\text{Hus}}}$ can be simply expressed as $-\ln[(1-R)/(1+R)]/(2R)$, where $R=\sqrt{x^2+y^2+z^2}$ (cf. Refs. 14 and 24). Also, at the fully mixed state $(x=y=z=0)$, the metric is simply *flat*, that is

$$ds^2_{\text{Fisher}_{\text{Hus}}} = \tfrac{1}{3}(dx^2+dy^2+dz^2). \tag{7}$$

(The Riemann and Ricci tensors evaluated at the fully mixed state have no nonzero entries.)

Numerical evidence indicates that the Fisher information matrix for the Husimi distribution over the TLQS is bounded by the corresponding information matrices for the (quantum) monotone metrics, in the sense that the monotone metric tensors minus the Fisher-Husimi information tensor are positive definite.

We can normalize the volume element of $ds^2_{\text{Fisher}_{\text{Hus}}}$ to a probability distribution p_{Hus} by dividing by the Fisher information metric volume $\approx 1.393\,509\,893\,676\,60$. If we generate a "hybridized-Husimi" (quantum[15]) monotone metric, $ds^2_{\text{HYB}_{\text{Hus}}}$, *via* the formula (1), using $f_{\text{Hus}}(t)$, then the volume of the Bloch ball of TLQS in terms of this newly generated monotone metric is $\frac{1}{2}\pi^2(4-\pi)\approx 4.236\,07 > 1.393\,51$. Using this as a normalization factor, we obtain a probability distribution $(p_{\text{HYB}_{\text{Hus}}})$ of interest over the TLQS.

III. COMPARATIVE NONINFORMATIVITIES

Let us compare p_{Hus}—in the manner employed in Refs. 25 and 26 (cf. Refs. 27 and 28, Sec. VI)—with the prior probability distribution (p_{Bures}). The latter is obtained by normalizing the volume element of the well-studied *minimal* monotone (Bures) metric [Ref. 29, Eq. (7)] [Ref. 30, Eq. (16)], that is,

$$p_{\text{Bures}} = \frac{r^2 \sin\theta_1}{\pi^2\sqrt{1-r^2}}, \tag{8}$$

generated from (1) using the operator monotone function $f_{\text{Bures}}(t)=(1+t)/2$. (We avoid the specific designations $f_{\min}(t)$ and $f_{\max}(t)$ because these are usually, confusingly, considered to generate the maximal and minimal monotone metrics, respectively [Ref. 15, Eq. (3.21)]. Our integrations of probability distributions are conducted over $r\in[0,1]$, $\theta_1\in[0,\pi]$ and $\theta_2\in[0,2\pi]$.)

The *relative entropy* (Kullback-Leibler distance) of p_{Bures} with respect to p_{Hus} [which we denote $S_{\text{KL}}(p_{\text{Bures}},p_{\text{Hus}})$]—that is, the *expected* value with respect to p_{Bures} of $\ln p_{\text{Bures}}/p_{\text{Hus}}$—is 0.130 845 "nats" of information. (We use the *natural* logarithm, and not 2 as a base, with one nat

equalling 0.531 bits.) Let us note that the Shannon entropy (S_{Shannon}) of the Husimi distribution is the Wehrl entropy (S_{Wehrl}) of the corresponding quantum state. Explicitly implementing [Ref. 31, Eq. (6)], we have for the TLQS,

$$S_{\text{Wehrl}} = \frac{1}{4r}\left(2r + 4r\ln 2 + (1+r^2)\ln\left(\frac{1-r}{1+r}\right) - 2r\ln(1-r^2)\right). \tag{9}$$

S_{Wehrl} is always greater than the von Neumann entropy, $S_{\text{vN}} = -\text{Tr}\,\rho\ln\rho$, which for the TLQS is expressible as

$$S_{\text{vN}} = \frac{1}{2}\left(2\ln 2 + r\ln\left(\frac{1-r}{1+r}\right) - \ln(1-r^2)\right). \tag{10}$$

[We, of course, notice the omnipresence in these last two formulas, as well as in (5) and further formulas below of the term $W \equiv \ln[(1-r)/(1+r)]$. The two eigenvalues $(\lambda_1, \lambda_2 = 1-\lambda_1)$ of ρ are $(1\pm r)/2$, so W is expressible as $\ln(\lambda_1/\lambda_2)$.] Each monotone metric can be obtained in the form of a "contrast functional" for a certain convex subset of relative entropies.[32,33]

A. Bures prior

Now, let us convert p_{Bures} to a *posterior* probability distribution ($\text{post}_{\text{Bures}}$) by assuming the performance of *six* measurements, *two* (with one outcome "up" and the other "down") in each of the x, y, and z directions. Normalizing the product of the prior p_{Bures} and the *likelihood* function corresponding to the six measurement outcomes (Ref. 25, p. 3),

$$\text{post}_{\text{Bures}} = \frac{192\,p_{\text{Bures}}(1-x^2)(1-y^2)(1-z^2)}{71}, \tag{11}$$

we find $S_{\text{KL}}(\text{post}_{\text{Bures}}, p_{\text{Hus}}) = 0.091\,2313 < 0.130\,845$. [The Cartesian coordinates in (11) are transformed to the spherical ones employed in our analysis.] So, in this sense p_{Bures} is *more* noninformative than p_{Hus}, the relative entropy being *reduced* by *adding* information to p_{Bures}. On the other hand, p_{Bures}—corresponding to the *minimal* monotone metric—is itself the *least* noninformative of the monotone-metric priors (p_{monotone}).[25] (Luo has established an inequality between the [monotone metric] Wigner-Yanase *skew information* and its minimal monotone counterpart.[34])

Reversing the arguments of the relative entropy functional, we obtain $S_{\text{KL}}(p_{\text{Hus}}, p_{\text{Bures}}) = 0.081\,8197$. But now, following the same form of posterior construction, we find $S_{\text{KL}}(\text{post}_{\text{Hus}}, p_{\text{Bures}}) = 0.290\,405 > 0.081\,8197$, further supportive of the conclusion that p_{Bures} is *more* noninformative than p_{Hus}. In some sense, then, p_{Bures} assumes *less* about the data than p_{Hus}. But this diminishability of the relative entropy is limited. If we convert p_{Bures} to a new posterior $\text{Post}_{\text{Bures}}$ using the *square* of the likelihood function above—that is, assuming 12 measurements, *four* (with two outcomes "up" and the other two "down") in each of the x, y, and z directions, giving

$$\text{Post}_{\text{Bures}} = \frac{21\,504\,p_{\text{Bures}}[(1-x^2)(1-y^2)(1-z^2)]^m}{3793}, \quad m = 2, \tag{12}$$

then $S_{\text{KL}}(\text{Post}_{\text{Bures}}, p_{\text{Hus}}) = 0.292\,596 > 0.130\,845$. To much the same effect, if we use a likelihood based on the *optimal/nonseparable* set of measurements for *two* qubits, consisting of five possible measurement outcomes, given in Ref. 35, Eq. (8), to convert p_{Bures} to a new posterior, then the relative entropy reaches higher still, that is from 0.130 845 to 0.623 855. (Employing a likelihood based on the optimal/nonseparable set of measurements for *three* qubits, consisting of eight possible measurement outcomes [Ref. 35, Eq. (9)], the relative entropy with respect to p_{Hus} increases further to 1.513 65.) Actually, if we *formally* take $m = \frac{1}{2}$ in Eq. (12), and renormalize to a new posterior, we obtain a superior reduction, that is, to $0.071\,67 < 0.091\,2313$. (Further, with $m = \frac{5}{8}$, we get 0.070 2389 and 0.073 2039, with $m = \frac{3}{4}$.)

B. Morozova-Chentsov prior

In Ref. 25, it was found that the ("Morozova-Chentsov") prior distribution,

$$p_{\mathrm{MC}} = \frac{0.005\,132\,99\left[\ln\left(\frac{1-r}{1+r}\right)\right]^2 \sin\theta_1}{\sqrt{1-r^2}}, \tag{13}$$

that is, the normalized volume element of the monotone metric (1) based on the operator monotone function,

$$f_{\mathrm{MC}}(t) = \frac{2(t-1)^2}{(1+t)(\ln t)^2}, \tag{14}$$

was apparently the *most* noninformative of those (normalizable) priors based on the operator monotone functions that had been explicitly discussed in the literature. Now, $S_{\mathrm{KL}}(p_{\mathrm{MC}}, p_{\mathrm{Hus}}) = 1.379\,91$, that is, quite large. This can be reduced to 0.893 996 if, into p_{MC}, one incorporates $m=6$ measurements of the type described above; diminished further to 0.561 901 with $m=12$; and further still to 0.471 852—the greatest reduction of this type—with $m=18$. (For $m=24$, it starts to rise to 0.652 441.)

But, if we again use the likelihood based on the optimal nonseparable measurement of two qubits [Ref. 25, Eq. (8)], with just five measurements, the relative entropy of the corresponding posterior form of p_{MC} with respect to p_{Hus} is reduced to 0.342 124, which is the *smallest* we have achieved so far along these lines. (For the mentioned optimal nonseparable measurement scheme for *three* qubits, the reduction is quite minor, only to 1.334 92 nats.) We obtained intermediate-sized reductions to 0.455 24 and 0.492 979, respectively, by using for our measurements, 20 projectors oriented to the vertices (Ref. 36, Secs. 9 and 10) of a dodecahedron and of an icosahedron. (The primary measurement scheme used above, and in Ref. 25, with six measurements oriented along three orthogonal directions, is tantamount to the use of an *octahedron*.)

C. Hilbert-Schmidt prior

The prior distribution generated by normalizing the volume element of the Hilbert-Schmidt metric over the Bloch sphere is [Ref. 25, Eq. (10)] [Ref. 16, Eq. (31)]

$$p_{\mathrm{HS}} = 3\frac{r^2 \sin\theta_1}{4\pi}, \tag{15}$$

which is simply the uniform distribution over the unit ball. The Hilbert-Schmidt volume element can be reproduced using the formula (1) for a quantum monotone metric, making use of $f_{\mathrm{HS}} = (1+t)^2/\sqrt{t}$, but this function is neither monotone increasing nor decreasing over $t \in [0,1]$ (cf. Ref. 37).

We have that $S_{\mathrm{KL}}(p_{\mathrm{Hus}}, p_{\mathrm{HS}}) = 0.057\,9239$ and $S_{\mathrm{KL}}(p_{\mathrm{HS}}, p_{\mathrm{Hus}}) = 0.054\,43$. Now, in terms of our usual posterior distributions based on six measurements, $S_{\mathrm{KL}}(\mathrm{post}_{\mathrm{Hus}}, p_{\mathrm{HS}}) = 0.023\,6596$ and $S_{\mathrm{KL}}(\mathrm{post}_{\mathrm{HS}}, p_{\mathrm{Hus}}) = 0.278\,953$, so we can conclude that the Husimi prior p_{Hus} is more noninformative than the Hilbert-Schmidt prior p_{HS}.

IV. UNIVERSAL DATA COMPRESSION

Employing p_{Hus} as a prior distribution (Jeffreys' prior) over the family (Riemannian manifold) of Husimi qubit probability distributions, the (classical) *asymptotic minimax/maximin redundancy of universal data compression* is equal to [Ref. 18, Eq. (2.4)],[17]

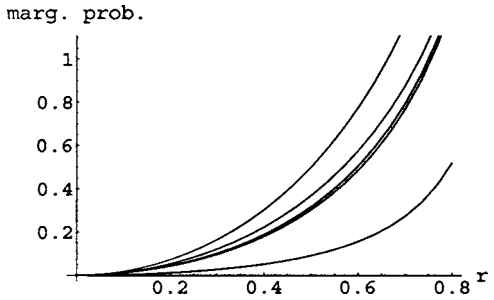

FIG. 4. Plots of one-dimensional marginal probability distributions over the radial coordinate r of p_{Bures}, $p_{\mathrm{HYB}_{\mathrm{Hus}}}$, p_{GKS}, p_{Hus}, and p_{MC}. The order of dominance of the curves is $p_{\mathrm{Hus}} > p_{\mathrm{Bures}} > p_{\mathrm{GKS}} > p_{\mathrm{HYB}_{\mathrm{Hus}}} > p_{\mathrm{MC}}$. The marginal distributions of $p_{\mathrm{HYB}_{\mathrm{Hus}}}$ and p_{GKS} are quite close, as reflected in their small relative entropy (≈ 0.0004).

$$\frac{3}{2}\ln\frac{n}{2\pi e}+\ln 1.393\,509\,893\,676\,60=\frac{3}{2}\ln\frac{n}{2\pi e}+0.331\,826=\frac{3}{2}\ln n-3.924\,99, \tag{16}$$

where n is the sample size (the number of qubits [TLQS]) and we used the before-mentioned volume of $\mathrm{d}s^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$. ["Suppose that X is a discrete random variable whose distribution is in the parametric family $\{P_\theta : \theta \in \Theta\}$ and we want to encode a block of data for transmission. It is known that a lower bound on the expected codeword length is the entropy of the distribution. Moreover, this entropy bound can be achieved, within one bit, when the distribution is known. Universal codes have expected length near the entropy no matter which member of the parametric family is true. The redundancy of a code is defined to be the difference between its expected length and its entropy" (Ref. 17, p. 459).]

For the *quantum*/nonclassical counterpart[38] (cf. Refs. 39–41), let us consider the use of the "Grosse-Krattenthaler-Slater" ("quasi-Bures") probability distribution [Ref. 35, Eq. (33)],

$$p_{\mathrm{GKS}}=\frac{0.083\,2258e}{1-r^2}\left(\frac{1-r}{1+r}\right)^{1/2r} r^2\sin\theta_1. \tag{17}$$

This is the normalized form of the monotone metric (1) associated with the (presumably operator) monotone function,

$$f_{\mathrm{GKS}}(t)=\frac{t^{t/(t-1)}}{e}. \tag{18}$$

[Taking limits, we have for the fully mixed state, $f_{\mathrm{GKS}}(1)=1$ and for the pure states, $f_{\mathrm{GKS}}(0)=e^{-1}$.] It appears[42] (though not yet fully rigorously established) that the (quantum) asymptotic minimax/maximin redundancy, employing p_{GKS} as a prior probability distribution over the 2×2 density matrices [*and* their n-fold tensor products (cf. Ref. 43)], is $\frac{3}{2}\ln n - 1.770\,62$. This is *greater* than the classical (Husimi-Fisher-information-based) analog (16) by 2.200 95 nats of information. It would seem that this difference is attributable to the greater dimensionality (2^n) of an n-qubit Hilbert space, as opposed to a dimensionality of $3n$ for n trivariate Husimi probability distributions over the TLQS.

We further note that $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{\mathrm{Hus}}})=0.006\,360\,46$ and $S_{\mathrm{KL}}(p_{\mathrm{HYB}_{\mathrm{Hus}}}, p_{\mathrm{Bures}})=0.006\,2714$, both being very small. Smaller still, $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{GKS}})=0.003\,590\,93$ and $S_{\mathrm{KL}}(p_{\mathrm{GKS}}, p_{\mathrm{Bures}})=0.003\,545\,79$—whence the designation $p_{\text{quasi-Bures}} \equiv p_{\mathrm{GKS}}$. But then, even more strikingly, we computed that $S_{\mathrm{KL}}(p_{\mathrm{GKS}}, p_{\mathrm{HYB}_{\mathrm{Hus}}})=0.000\,397\,852$ and $S_{\mathrm{KL}}(p_{\mathrm{HYB}_{\mathrm{Hus}}}, p_{\mathrm{GKS}})=0.000\,396\,915$. In Fig. 4 we show the *one*-dimensional marginal probability distributions over the radial coordinate r of the five distributions p_{Bures}, $p_{\mathrm{HYB}_{\mathrm{Hus}}}$, p_{Hus}, p_{GKS}, and p_{MC}, with those for $p_{\mathrm{HYB}_{\mathrm{Hus}}}$ and p_{GKS} being—as indicated—particularly proximate.

Substitution of $p_{\mathrm{HYB}_{\mathrm{Hus}}}$ for p_{GKS} into the quantum asymptotic (maximin) redundancy formula that has to be *maximized* over all possible prior probability distributions [Ref. 42, Eq. (4.3)],

$$\frac{3}{2}\ln n-\frac{1}{2}-\frac{3}{2}\ln 2-\frac{3}{2}\ln\pi+4\pi\int_0^1\left(-\ln(1-r^2)+\frac{1}{2r}\ln\left(\frac{1-r}{1+r}\right)-\ln w(r)\right)r^2w(r)\mathrm{d}r, \tag{19}$$

leads to a very slightly decreased (and hence suboptimal) redundancy, $\frac{3}{2}\ln n-1.771\,01$ vs $\frac{3}{2}\ln n-1.770\,62$. (Use of p_{Bures} as a quantum prior over the 2×2 density matrices gives us a constant term of $-1.774\,21$, use of p_{Hus}, $-1.882\,79$ and use of p_{MC}, $-2.156\,67$.) To obtain the appropriate form of $w(r)$ to use in (19), we take our probability distributions [such as (8) and (13)], divide them by $4\pi r^2$ and integrate the results over $\theta_1\in[0,\pi]$ and $\theta_2\in[0,2\pi]$. [Thus, we must have $4\pi\int_0^1 w(r)r^2\,\mathrm{d}r=1$.] The *minimax* objective function is

$$\min_w\max_{0\leqslant r\leqslant 1}\left(\frac{3}{2}\ln n-\frac{1}{2}-\frac{3}{2}\ln 2-\frac{3}{2}\ln\pi-\ln(1-r^2)+\frac{1}{2r}\ln\left(\frac{1-r}{1+r}\right)-\ln w(r)\right). \tag{20}$$

The minimax is also achieved using the $w(r)$ formed from p_{GKS}.

We can, additionally, achieve an extremely good fit to p_{Hus} by proceeding in somewhat an *opposite* fashion to that above—*reversing* our hybridization procedure. Employing $f_{\mathrm{GKS}}(t)$, rather than $f_{\mathrm{Hus}}(t)$ in the expression (2) for $\mathrm{d}s^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$ and obtaining the corresponding normalized (dividing by 4.002 77) volume element ($p_{\mathrm{H\tilde{Y}B}_{\mathrm{GKS}}}$), we find $S_{\mathrm{KL}}(p_{\mathrm{H\tilde{Y}B}_{\mathrm{GKS}}},p_{\mathrm{Hus}})=0.000\,316\,927$. (Interchanging the arguments of the relative entropy functional, we get 0.000 317 754.) It is quite surprising, then, that a joint plot of $f_{\mathrm{GKS}}(t)$ and $f_{\mathrm{Hus}}(t)$ readily shows them to be substantially *different* in character [for example, $f_{\mathrm{Hus}}(50)=55.8161$ and $f_{\mathrm{GKS}}(50)=19.9227$], since they have been shown here to generate two pairs of such highly similar probability distributions, one pair composed of (quantum) monotone (p_{GKS} and $p_{\mathrm{HYB}_{\mathrm{Hus}}}$), and the other pair of (quantum) nonmonotone metrics ($p_{p_{\mathrm{H\tilde{Y}B}_{\mathrm{GKS}}}}$ and p_{Hus}).

V. ESCORT-HUSIMI DISTRIBUTIONS

For the *escort*-Husimi distributions,[44] we raise the probability element of the Husimi distribution to the qth power, and renormalize to a new probability distribution. (Of course, the Husimi distribution itself corresponds to $q=1$. If we set $\alpha=2q-1$, we recover the α-family of Amari.[33,45,46]) To normalize the qth power of the Husimi distribution, one must divide by

$$\frac{2^{-q}(-(1-r)^{1+q}+(1+r)^{1+q})}{r+qr}. \tag{21}$$

A. The case $q=2$

For (entropic index) $q=2$, the Fisher information metric takes the form

$$\mathrm{d}s^2_{\mathrm{Fisher}_{q=2}}=\frac{2}{(3+r^2)^2}\mathrm{d}r^2+\left((1+r)f_{q=2}\left(\frac{1-r}{1+r}\right)\right)\mathrm{d}n^2, \tag{22}$$

where

$$f_{q=2}(t)=\frac{t^2+t+1}{2(t+1)}. \tag{23}$$

We have $f_{q=2}(1)=\frac{3}{4}$ and $f_{q=2}(0)=\frac{1}{2}$.

Relative entropies: Further, the relative entropies $S_{\mathrm{KL}}(p_{\mathrm{Hus}},p_{\mathrm{Esc}_{q=2}})=0.011\,4308$ and $S_{\mathrm{KL}}(p_{\mathrm{Bures}},p_{\mathrm{Esc}_{q=2}})=0.429\,64$, So, it appears that $p_{\mathrm{Esc}_{q=2}}$ is even less noninformative than p_{Hus} [recalling that $S_{\mathrm{KL}}(p_{\mathrm{Bures}},p_{\mathrm{Hus}})=0.130\,845<0.429\,64$], which in turn we found above was less noninformative than the prior probabilities formed from any of the (quantum) monotone metrics. We also note that $S_{\mathrm{KL}}(\mathrm{post}_{\mathrm{Bures}},p_{\mathrm{Esc}_{q=2}})=0.125\,159<0.429\,64$. If we "hybridize" $\mathrm{d}s^2_{\mathrm{Fisher}_{q=2}}$ by

modifying its radial component into that required of a (quantum) monotone metric, then we find that $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{q=2}}) = 0.002\,460\,31 (< (S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{\mathrm{Hus}}}) = 0.006\,360\,46)$ is quite small.

B. The cases $q>2$

For the escort-Husimi probability distribution with $q=3$, the Fisher information metric takes the form

$$\mathrm{d}s^2_{\mathrm{Fisher}_{q=3}} = \frac{3-r^2}{(1+r^2)^2}\mathrm{d}r^2 + \left((1+r) f_{q=3}\left(\frac{1-r}{1+r}\right)\right)\mathrm{d}n^2, \tag{24}$$

where

$$f_{q=3}(t) = \frac{t^2+1}{3(t+1)}. \tag{25}$$

Now, $f_{q=3}(1) = f_{q=3}(0) = \frac{1}{3}$ and a plot of $f_{q=3}(t)$ clearly manifests monotonic behavior also. (The monotonically decreasing scalar curvature of $\mathrm{d}s^2_{\mathrm{Fisher}_{q=3}}$ equals $\frac{4}{3}$ at $r=0$.) We have that $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{Esc}_{q=3}}) = 0.637\,05 > S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{Esc}_{q=2}}) = 0.429\,64$, so the informativity (noninformativity) of the escort-Husimi prior probabilities *appears* to increase (decrease) with q.

For $q=4$,

$$\mathrm{d}s^2_{\mathrm{Fisher}_{q=4}} = \frac{80(5-2r^2+r^4)}{3(5+10r^2+r^4)^2}\mathrm{d}r^2 + \left((1+r) f_{q=4}\left(\frac{1-r}{1+r}\right)\right)^{-1}\mathrm{d}n^2, \tag{26}$$

where

$$f_{q=4}(t) = \frac{3(t^4+t^3+t^2+t+1)}{4(t+1)(3t^2+4t+3)}. \tag{27}$$

For $q=5$,

$$\mathrm{d}s^2_{\mathrm{Fisher}_{q=5}} = \frac{3(5-r^2)(5+3r^4)}{(3+10r^2+3r^4)^2}\mathrm{d}r^2 + \left((1+r) f_{q=5}\left(\frac{1-r}{1+r}\right)\right)^{-1}\mathrm{d}n^2, \tag{28}$$

where

$$f_{q=5}(t) = \frac{2(t^4+t^2+1)}{5(t++1)(2t^2+t+2)}. \tag{29}$$

We have (as found by Krattenthaler, making use of explicit MATHEMATICA computations of ours for $q=2,3,\ldots,40$) (cf. Ref. 47, Sec. 3.2, Ref. 48),

$$f_q(t) = \frac{(q-1)\sum_{i=0}^{q} t^i}{q(t+1)\sum_{i=0}^{q-1} i(q-i)t^{i-1}}. \tag{30}$$

[For *odd* q some simplification in the resulting expression occurs due to cancellation by a factor of $(t+1)$.]

In Fig. 5 we plot $f_{q=i}(t)$, $i=1,\ldots,30$, revealing their common monotonically increasing behavior. [Of course, we have $f_{q=1}(t) \equiv f_{\mathrm{Hus}}(t)$, shown already in Fig. 1. The steepness of the curves *decreases* with increasing q.]

Let us further note that in addition to $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{\mathrm{Hus}}}) = 0.006\,360\,46$ and $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{q=2}}) = 0.002\,460\,43$, we have $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{q=3}}) = 0.013\,2258$, $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{q=4}}) = 0.023\,8858$ and $S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{q=5}}) = 0.032\,7578$. [We have also been able to compute that

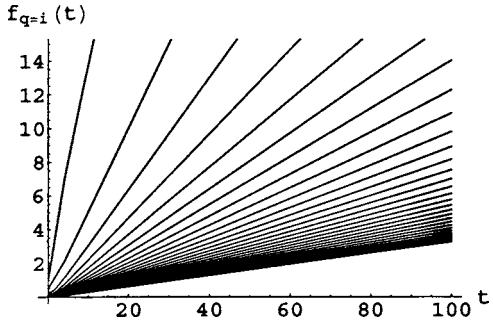

FIG. 5. The monotone functions $f_{q=i}(t)$, $i=1,\ldots,30$ that yield the *tangential* components of the Fisher information metric over the escort-Husimi ($q=i$) probability distributions. The steepness of the graphs decreases as q increases.

$S_{\mathrm{KL}}(p_{\mathrm{Bures}}, p_{\mathrm{HYB}_{q=1000}})=0.096\,9315$ and $S_{\mathrm{KL}}(p_{\mathrm{GKS}}, p_{\mathrm{HYB}_{q=1000}})=0.127\,027$.] So, the best of these fits of p_{Bures} to the prior probabilities for the hybridized-escort-Husimi probability distributions is for $q=2$.

C. Tangential components

Now, we can reexpress the formula (30) *without* summations, making use of the binomial theorem, as

$$f_q(t)=\frac{(-1+q)(-1+t)^2(-1+t^{1+q})}{q(1+t)(1-q+t+qt-t^q-qt^q-t^{1+q}+qt^{1+q})}. \tag{31}$$

So, we could study hybridized escort-Husimi metrics based on *non*integral q using this formula. [We note that (31), in fact, yields $\lim_{q\to 1} f_q(t)\equiv f_{\mathrm{Hus}}(t)$.] For example,

$$f_{q=1/2}(t)=6+6\sqrt{t}+2t-\frac{4}{1+t}. \tag{32}$$

Thus, (31) gives us [following the formulation (1)] the tangential components of the escort-Husimi Fisher information metrics for arbitrary q. (Pennini and Plastino[44] have argued, though, that in a *quantal* regime, q can be no less than 1. Tsallis statistics with an entropic index of $q=\frac{3}{2}$, Beck has contended, correctly describes the small-scale statistics of Lagrangian turbulence.[49])

D. Radial components

We do not have, at this point, a comparable complete formula for the *radial* components. However, Krattenthaler has shown—making use of explicit computations of ours for the cases $q=2,3,\ldots,18$—that the *denominators* of the functions giving the radial components are simply proportional to

$$u(q)=\left(\sum_{i=0}^{q}\frac{\mathrm{Pochhammer}[q-2i+1,2i+1]r^{2i}}{2(2i+1)!}\right)^2. \tag{33}$$

(The Pochhammer symbol is synonymous with the rising or ascending factorial. The obtaining of comparable formulas for the *numerators* of the radial components might be possible using the "Rate.m" program available from the website of Krattenthaler [http://www.mat.univie.ac.at/kratt/], if we had available additional explicit computations beyond the $q=18$.) As way of illustration, the radial component of $\mathrm{d}s^2_{\mathrm{Fisher}_{q=8}}$ is expressible as

$$\frac{144(21+42r^2+135r^4+28r^6+35r^8-6r^{10}+r^{12})}{7u(8)}. \tag{34}$$

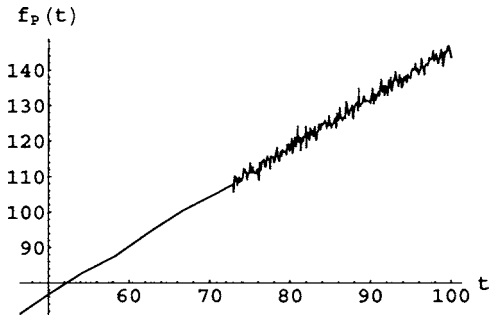

FIG. 6. *Approximation* to the presumed operator monotone function $f_P(t)$ yielding the *tangential* component of $\mathrm{d}s^2_{\mathrm{Fisher}_P}$ for the positive P representation over the two-level quantum systems.

VI. POSITIVE *P*-REPRESENTATION FOR TLQS

Braunstein, Caves, and Milburn focused on a specific choice of *positive P*-representation which they called the canonical form and which is always well defined [Ref. 50, Eq. (3.3)] (cf. Ref. 51, Sec. 6.4):

$$P_{\mathrm{can}}(\alpha,\beta^*) \equiv \frac{1}{4\pi^2}\exp\left(-\frac{1}{4}|\alpha+\beta|^2\right)\left\langle \frac{1}{2}(\alpha+\beta)\left|\hat{\rho}\right|\frac{1}{2}(\alpha+\beta)\right\rangle$$
$$= \frac{1}{4\pi^2}\exp\left(-\frac{1}{4}|\alpha-\beta|^2\right)Q\left(\frac{1}{2}(\alpha+\beta)\right). \tag{35}$$

"The canonical form is clearly positive, and…it is essentially the Q-function [Husimi distribution]."[50]

We sought to implement this model, choosing for α and β *independent* two-dimensional representations of the spin-$\frac{1}{2}$ coherent states (while for the Husimi distribution or Q-function, only, say α, need be employed). [The "positive P representation achieves [its] considerable success by doubling the number of degrees of freedom of the system, i.e., doubling the number of dimensions of the phase space" (Ref. 50, p. 1153). More typically, in the positive P representation, α and β are allowed to vary independently over the *entire* complex plane.] However, then our result—using this choice of α and β—was *not* normalized to a probability distribution in the manner indicated in (35).

We noted that Braunstein, Caves, and Milburn had commented that a "positive P representation can be defined for a large class of operators. We restrict ourselves here to those that are built up from the standard annihilation and creation operators of a harmonic oscillator. In particular, our work does not apply to generalizations of the positive P representation that include spin or pseudospin operators often used to describe a two-level atom" (Ref. 50, p. 1155). [We are not aware, however, of any specific applications reported in the literature of the positive P representation to n-level (finite-dimensional) quantum systems.]

We did not perceive how to exactly (re)normalize the distribution (35) for our particular choices of α and β. So, we expanded just the exponential term of (35) into a power series in third order in the four *phase* variables and exactly normalized the product of this series with the remaining unmodified factor (the Q-function or Husimi distribution) to obtain a new (presumed) probability distribution. We then fit (numerically) the resultant tangential component of the associated Fisher information metric to the form (1) required of a monotone metric. In Fig. 6 we show what we (gratifyingly) obtained in this manner for $f_P(t)$. In Fig. 7 we show an approximation to the radial component of $\mathrm{d}s^2_{\mathrm{Fisher}_P}$, similarly obtained. [The positive P function "seems to possess some interesting properties and may deserve close inspection" (Ref. 52, p. 175).] It would be of interest to see how near the associated probability distributions (p_P and p_{HYB_P}) would be to the probability distributions (already discussed above) p_{GKS}, p_{Hus}, $p_{\mathrm{HYB}_{\mathrm{Hus}}}$, and $p_{\mathrm{H\tilde{Y}B}_{\mathrm{GKS}}}$. Most press-

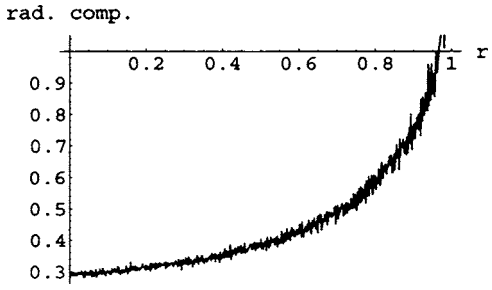

FIG. 7. *Approximation* to the *radial* component of $ds^2_{\mathrm{Fisher}_P}$ for the positive P-representation over the two-level quantum systems.

ing, though, is the question of whether or not the concept of a positive P representation does, in fact, have a meaningful and natural theoretical application to the n-level quantum systems.

VII. GAUSSIAN DISTRIBUTION

An approach quite distinct from that of the Husimi probability distributions, but still *classical* in nature, to modeling quantum systems has been presented in Refs. 4–8 (cf. Ref. 9). Here the family of probability distributions is taken as that of the Gaussian (complex multivariate normal distributions) having covariance matrix equal to the density matrix. For the TLQS, Slater [Ref. 53, Eq. (13)] [Ref. 54, Eq. (16)] derived the corresponding Fisher information metric. This is representable as

$$ds^2_{\mathrm{Fisher}_{\mathrm{Gauss}}} = \frac{2(1+r^2)}{(1-r^2)^2}dr^2 + \frac{2}{1-r^2}dn^2. \tag{36}$$

The tangential component can be reproduced, following the basic formula (1), by choosing $f_{\mathrm{Gauss}}(t)=t/(1+t)$. This is simply *one-half* of that—$f_{\mathrm{YL}}(t)=2f_{\mathrm{Gauss}}(t)=2t/(1+t)$—associated with the *maximal* monotone (Yuen-Lax) metric.[55] Like that metric, the metric (36) yields a *non*-normalizable volume element (so one cannot immediately apply—without some preliminary truncation—the comparative noninformativity/relative entropy test we have used above[25,26]). Of course, the radial component of (36) is also not consistent with the requirement for a monotone metric. In fact, it rises much *more* steeply than $1/(1-r^2)$, in opposite behavior to that for $ds^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$. In Fig. 8 we show this phenomenon.

VIII. DISCRETE WIGNER FUNCTION FOR A QUBIT

The discrete Wigner function (pseudoprobability) W, in the simplest case of a qubit, is defined on a 2×2 array, with four components $W_{i,j}$, $i, j=1,2$ [Ref. 56, Eqs. (14)–(17)]. The sum of W_{ij} in each "line" λ is the probability p_{ij} of projecting the state onto the basis vector $|\alpha_{ij}\rangle$, where i

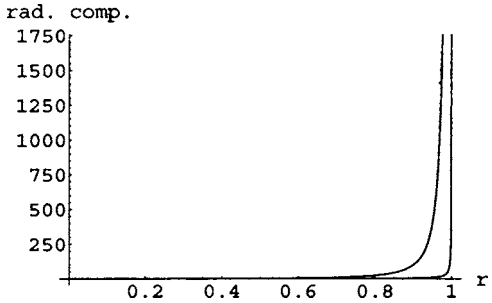

FIG. 8. Radial components of ds^2_{monotone} and $ds^2_{\mathrm{Fisher}_{\mathrm{Gauss}}}$. The latter dominates the former.

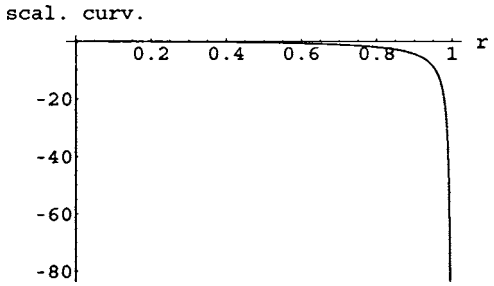

FIG. 9. Scalar curvature of the Fisher information metric for the family of Husimi distributions.

$\in\{1,2,3\}$ indexes a set of three mutually unbiased bases (MUB) for a qubit and $j\in\{1,2\}$ indexes the basis vector in each MUB. Choosing the MUB to be the eigenstates of the three Pauli operators, and using our cartesian coordinates, one can obtain three one-dimensional *marginal* (binomial) probability distributions over the x, y, and z axes, of the form $((1+x)/2,(1-x)/2),\ldots$(cf. Refs. 57 and 58). Now, the corresponding Jeffreys' prior for the one-dimensional family of such binomial distribution is simply the *beta* distribution $p_\beta(x)=1/\pi\sqrt{1-x^2}$. (Let us note that the one-dimensional marginal distributions obtained for p_{Bures} are of another form, that is, $2\sqrt{1-x^2}/\pi$.)

Let us take the product of $p_\beta(x)$, $p_\beta(y)$, and $p_\beta(z)$, which naturally forms a (prior) probability distribution,

$$p_{\text{product}}=\frac{1}{\pi^3\sqrt{(1-x^2)(1-y^2)(1-z^2)}},\tag{37}$$

over the hypercube with vertices $(\pm1,\pm1,\pm1)$ and renormalize/truncate it to a probability distribution over the Bloch sphere,

$$p_{\text{Wigner}}=\frac{1}{6.614\,555\,161\,01\sqrt{(1-x^2)(1-y^2)(1-z^2)}}.\tag{38}$$

(Thus, the quantum-mechanically *inaccessible* region lying outside the Bloch ball, but within the hypercube is disregarded—assigned null measure—in the new normalization.)

Now, we found—strictly following the notation, formulas and line of argument above in Sec. III—that $S_{\text{KL}}(p_{\text{Wigner}},p_{\text{Hus}})=0.014\,9831$ and $S_{\text{KL}}(p_{\text{Hus}},p_{\text{Wigner}})=0.015\,6225$, so these two distributions are rather close in nature. Of course, p_{Hus} is rotationally symmetric over the Bloch sphere, while p_{Wigner} is not, so it seems to make little sense to try to compute some function $f_{\text{Wigner}}(t)$ to generate the tangential component. We found it problematical, using our usual (relative entropy) approach, to designate either p_{Hus} or p_{Wigner} as more or less noninformative. [The "Husimi function is a kind of...coarse-grained Wigner function" (Ref. 48, p. 3).]

IX. SCALAR CURVATURE

In Fig. 9, we plot the *scalar curvature* of $\mathrm{d}s^2_{\text{Fisher}_{\text{Hus}}}$. The formula for this scalar curvature is

$$K^{n=2}_{\text{Hus}}=\frac{r(-6r+W(-3+r^2))(-4r^2(-3+r^2)+6Wr(2-3r^2+r^4)+W^2(3-8r^2+5r^4))}{(W+2r)^2(-1+r^2)(-2r+W(-1+r^2))^2},\tag{39}$$

where $W=\ln(1-r)/(1+r)$. Also, expanding about $r=0$,

$$K^{n=2}_{\text{Hus}}\approx\frac{-6r^2}{5}-\frac{138r^4}{125}-\frac{32\,094r^6}{30\,625}-\frac{154\,474r^8}{153\,125}-\frac{57\,710\,054r^{10}}{58\,953\,125}.\tag{40}$$

The *nonpositive* monotonically *decreasing* scalar curvature (Fig. 9) has its *maximum* at $r=0$, corresponding to the fully mixed state, indicative of a *flat* metric there [cf. (7)] (and is $-\infty$ at the pure states, $r=1$). For the minimal monotone (Bures) metric, the *non-negative* scalar curvature is *constant*, that is $K^{n=2}_{\min}=6$, over the Bloch ball, and for the (n^2-1)-dimensional convex set of $n \times n$ density matrices, $n>2$, achieves its *minimum* of $K^{n}_{\min}=(5n^2-4)(n^2-1)/8$ at the fully mixed state $[\rho=(1/n)I]$.[59] [In Ref. 59, the metric used is one-quarter of that corresponding to (1), used here, so the results we compute here differ from those there by such a factor. For the *maximal* monotone metric, $K^{n=2}_{\max}=8(r^2-6)/(1-r^2)$, which is monotonically *decreasing* as r increases, as is $K^{n=2}_{\mathrm{Hus}}$.]

For the two-level quantum systems, Andai[60] has constructed a family of monotone metrics with *non*monotone scalar curvature, and given a condition for a monotone metric to have a local minimum at the maximally mixed state.

Metrics of constant scalar curvature: The metric $\mathrm{d}s^2_{\mathrm{Fisher}_{q=2}}$ has *constant* scalar curvature, $K^{n=2}_{q=2}=\frac{3}{2}$ while, as previously noted, $K^{n=2}_{\min}=6$. Let us note that $K^{n}_{\mathrm{WY}}=\frac{1}{4}(n^2-1)(n^2-2)$, which is also $\frac{3}{2}$ for $n=2$. Here, WY denotes the Wigner-Yanase metric—the only pull-back metric among the quantum monotone metrics—and $f_{\mathrm{WY}}(t)=\frac{1}{4}(\sqrt{t}+1)^2$, which is the only *self-dual* operator monotone function.[61] "It is not known at the moment if there are other monotone metrics of constant sectional and scalar curvature" (Ref. 61, p. 3760). It is a theorem that the "set of two-dimensional normalized density matrices equipped with the Bures metric is isometric to one closed-half of the three-sphere with radius $\frac{1}{2}$."[62] The WY-metric "looks locally like a sphere of radius 2 of dimension (n^2-1)" (Ref. 61, p. 3759). If we transform to spherical coordinates on the 3-sphere, then, the metric tensor for $\mathrm{d}s^2_{\min}$ is diagonal in character, while the two other (constant scalar curvature) metrics are not (cf. Ref. 63).

The three metrics $\mathrm{d}s^2_{\min}$, $\mathrm{d}s^2_{\mathrm{WY}}$, and $\mathrm{d}s^2_{\mathrm{Fisher}_{q=2}}$ are *Einstein*. If we *scale* these metrics so that they are all of *unit* volume,[64] then $K^{n=2}_{\mathrm{min/scaled}}=6\pi^2\approx 59.2176$, $K^{n=2}_{\mathrm{WY/scaled}}=6\pi(\pi-2)\approx 21.5185$ and $K^{n=2}_{q=2/\mathrm{scaled}}=4\pi^2-6\sqrt{3}\pi\approx 6.830\,03$. The constant scalar curvatures of (unit-volume) *Yamabe* metrics are bounded above, and their least upper bound is a real number equal to $n(n-1)V_n^{2/n}$, where V_n is the volume of the standard metric on S^n, and in our (Bloch sphere) case, $n=3$, so the bound is $242^{1/3}\pi^{4/3}\approx 139.13$.[64]

X. DISCUSSION

Luo[24] (cf. Ref. 44, Sec. 2.4 and Refs. 19, 20, and 65) has calculated the Fisher information matrix of the Husimi distribution in the Fock-Bargmann representation of the quantum harmonic oscillator with one degree of freedom. He found that the Fisher information of the position and that of the momentum move in opposite directions, and that a weighted trace of the Fisher information matrix is a constant independent of the wave function, and thus has an upper bound. (Luo did not consider the possibility of generating prior probability distributions by normalizing the volume element of the Fisher information metric.)

Gnutzmann and Życzkowski noted that one "is tempted to think of the Husimi function as a probability density on the phase space. However, the rules for calculating expectation values of some observable using the Husimi function are nonclassical" (Ref. 47, Sec. 2.1) (cf. Ref. 66, p. 548). Gardiner and Zoller remarked that the "main problem of the Q-function is that not all positive normalizable Q-functions correspond to positive normalizable density operators" (Ref. 51, p. 109).

Further, the comparison of distances between Husimi distributions for arbitrary quantum states based on the Fisher information metric with those employing the Monge distance,[3] might be investigated. For the TLQS studied here, the Monge distance is, in fact, "consistent with the geometry of the Bloch ball induced by the Hilbert-Schmidt or the trace distance" (Ref. 3, p. 6716). [The trace distance is monotone, but *not* Riemannian, while the Hilbert-Schmidt distance, contrastingly, is Riemannian, but *not* monotone (Ref. 67, p. 10083).[37]] For n-dimensional quantum systems ($n>2$), unlike the trace, Hilbert-Schmidt or Bures distance, the Monge distance of ρ to the fully mixed state—which provides information concerning the *localization* of ρ in the classical

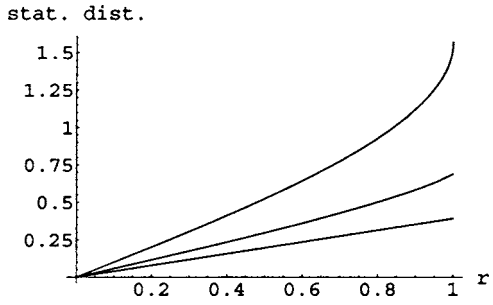

FIG. 10. Statistical distance as a function of distance from the origin of the Bloch ball—corresponding to the fully mixed state—for any monotone metric, for $ds^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$, and for the Monge (or equivalently, for $n=2$, Hilbert-Schmidt) metric. The monotone-metric curve dominates that for $ds^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$, which dominates the linear curve for the Monge metric.

phase space—is *not* the same for all pure states.[3] The only monotone metrics for which explicit distance formulas are so-far available are the Bures (minimal monotone) and Wigner-Yanase ones.[61]

In Fig. 10 we show how the distance from the fully mixed state ($r=0$) increases as r increases, for any monotone metric and for $ds^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$, and (linearly) for the Monge (or Hilbert-Schmidt) metric. The first-mentioned distance—taking the functional form $\arcsin r$ (equalling $\pi/2$ for $r=1$)—dominates the second-mentioned distance (equalling $\pi/4.555\,153\,216\,7057$ for $r=1$), which in turns dominates the third [Ref. 3, Eq. (4.10)], which takes the value $\pi/8$ for $r=1$.

Let us bring to the attention of the reader, a recent preprint, which introduces a concept of escort *density operators* and a related one of *generalized* Fisher information[68] (cf. Refs. 46 and 69).

We have been consistently able above to find (apparently operator) monotone functions to generate the tangential components of (classical) Fisher information metrics for (rotationally symmetric) probability distributions over the TLQS. We suspect the existence of some (yet not formally demonstrated) theorem to this effect. Also, it would be of interest to formally test the various monotone functions presented above for the property (requisite for a *quantum* monotone metric[15,21] of *operator* monotonicity.

We have "hybridized" $ds^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$ above to a (quantum) monotone metric $ds^2_{\mathrm{HYB}_{\mathrm{Hus}}}$ by replacing its radial component by that required $[1/(1-r^2)]$ while retaining its tangential component [formed from $f_{\mathrm{Hus}}(t)$]. But it appears that we could also convert it by appropriately scaling (a *conformal* transformation) the entire metric (tangential *and* radial components) by some suitable function. If we do so, we find that—by explicit construction—the new metric ($ds^2_{\mathrm{conformal}_{\mathrm{Hus}}}$) has the required radial component, while the tangential component is generated by a function

$$f_{\mathrm{conformal}_{\mathrm{Hus}}}(t) = f_{\mathrm{Hus}}(t) - t - 1, \tag{41}$$

which also appears to be operator monotone. [We note that $f_{\mathrm{conformal}_{\mathrm{Hus}}}(1)=1$ and $\lim_{t\to 0} f_{\mathrm{conformal}_{\mathrm{Hus}}}(t)=0$.] But now, we have the large relative entropies $S_{\mathrm{KL}}(p_{\mathrm{GKS}}, p_{\mathrm{conformal}_{\mathrm{Hus}}}) = 50.4636$ and $S_{\mathrm{KL}}(p_{\mathrm{conformal}_{\mathrm{Hus}}}, p_{\mathrm{GKS}}) = 54.2601$. At $r=0$, $ds^2_{\mathrm{conformal}_{\mathrm{Hus}}}$ is not flat, as is $ds^2_{\mathrm{Fisher}_{\mathrm{Hus}}}$, but has a (limiting) scalar curvature of $-\frac{24}{5}$.

Further questions: Motivated by the analyses above, we would like to pose the question of whether there exists a family of trivariate *probability* distributions parametrized by the points of the Bloch ball, for which the associated [classically *unique* (up to a constant multiple)] Fisher information metric *fully*—both in terms of tangential *and* radial components—has the requisite form (1) for a monotone metric. Also, the *volume elements* (and hence associated prior probabilities) of the monotone metrics are expressible as the *product* of Haar measure and measures over the eigenvalues.[16] To what extent, if any, does this hold true for prior probabilities *not* arising from monotone metrics? Are there any nonmonotone metrics which give rise to prior probabilities *more* noninformative than (at the very least) the minimal monotone (Bures) one? What are suitable

counterparts to formula (1) for n-level quantum systems ($n>2$)? Are there any monotone metrics which are flat at the fully mixed state, as is $ds^2_{\text{Fisher}_{\text{Hus}}}$ (7)?

XI. SUMMARY

In a *classical* context, for the family of Husimi *probability* distributions over the three-dimensional Bloch ball of two-level quantum systems (TLQS), we derived the (flat-at-the-fully-mixed-state) Fisher information metric [$ds^2_{\text{Fisher}_{\text{Hus}}}$, given by (2)]. Its tangential—but *not* its radial (r)—component conformed to that of one of the (uncountably) *infinite* class of (quantum) monotone metrics. The *prior* probability distribution (p_{Hus}) formed by normalizing the volume element of $ds^2_{\text{Fisher}_{\text{Hus}}}$ was found (Sec. III) to be considerably *less* noninformative than the priors formed from *any* of the (quantum) monotone metrics, even that (p_{Bures}) based on the (relatively informative) *minimal* monotone (Bures) metric. However, if we replaced the radial component of $ds^2_{\text{Fisher}_{\text{Hus}}}$ by that required $[1/(1-r^2)]$ of *all* (quantum) monotone metrics, the resultant "hybridized-Husimi" prior probability ($p_{\text{HYB}_{\text{Hus}}}$) became very close (in the sense of relative entropy ≈ 0.006 "nats") to p_{Bures}, and thus comparably informative in nature, but even nearer (≈ 0.0004) to another quantum-monotone-metric-based ("Grosse-Krattenthaler-Slater" or "quasi-Bures") probability distribution (p_{GKS}) that has been conjectured to yield the asymptotic minimax/maximin redundancy for universal *quantum* coding. The analogous (Bayesian) role in universal (classical) coding—by a well-known result of Clarke and Barron[17,18]—is played by Jeffreys' prior (cf. Refs. 19 and 20). This takes the specific (original, nonhybridized) form p_{Hus} for the family (manifold) of trivariate Husimi qubit probability distributions under study. We also studied the Fisher information metric for the *escort*-Husimi (Sec. V), positive-P (Sec. VI) and certain Gaussian probability distributions (Sec. VII), as well as, in some sense, the discrete Wigner pseudoprobability (Sec. VIII). Additionally, we applied the Clarke comparative noninformativity test[25,26] to quantum priors (Sec. III). Evidence that this test is consistent with the recently stated criterion of "biasedness to pure states" of Srednicki[27] has been presented.[28]

ACKNOWLEDGMENTS

The author expresses gratitude to the Kavli Institute for Theoretical Physics (KITP) for computational support in this research and to C. Krattenthaler for deriving the expressions (30) and (33) and to M. Trott for assistance with certain MATHEMATICA computations.

Rigorous bra-ket formalism and wave function operator for one particle quantum mechanics

H. Bergeron[a)]
LURE Bat. 209D, Centre Universitaire Paris-Sud, BP34, 91898 Orsay, Cedex, France

(Received 6 July 2005; accepted 7 October 2005; published online 27 February 2006)

Following previous works dedicated to the mathematical meaning of the "bra-ket" formalism [I. M. Gel'fand and G. E. Shilov, Generalized Functions (Academic, New York, 1964), Vol. I; J. P. Antoine, J. Math. Phys. **10**, 53 (1969); Yu. M. Berezanskii, Expansions of Self-adjoint Operators (American Mathematical Society, Providence, RI 1968); E. Prugovečki, J. Math. Phys. **14**, 1410 (1973); J. P. Antoine and A. Grossmann, J. Funct. Anal. **23**, 369 (1976); **23**, 379 (1976)], we develop a new rigorous mathematical approach, based on an operator representation of bras and kets. This leads to a formalism very similar to second quantization. Well-defined operators associated with local observables can be exhibited, intimately related to previous works of E. Prugovečki [Stochastic Quantum Mechanics and Quantum Space-Time (Reidel, Dordrecht, 1986)]. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2157053]

I. INTRODUCTION

Since the early years of quantum mechanics, different mathematical studies have been led to give a rigorous meaning to the symbolic "bra-ket" formalism used in most quantum mechanical papers. Quantum mechanics (for a spinless particle) is mathematically represented on the Hilbert space $\mathcal{H}=L^2(\mathbb{R}^3)$ over position space equipped with the inner product $(\phi|\psi)=\int_{\mathbb{R}^3}d^3\vec{q}\ \phi^*(\vec{q})\psi(\vec{q})$; but most of quantum mechanics books also introduce "the states $|\vec{q}\rangle$, $|\vec{p}\rangle$," the "inner product" $\langle\vec{q}|\psi\rangle$ or use the formula $|\phi\rangle=\int_{\mathbb{R}^3}d^3\vec{q}\ \phi(\vec{q})|\vec{q}\rangle$, while "the vectors $|\vec{q}\rangle$" do not belong to $\mathcal{H}$. So different structures have been developed to give a right mathematical meaning to these objects. We can quote two different procedures. The first one is based on the construction of "super-Hilbert" spaces, such as the rigged,[1,2] equipped,[3] extended,[4] or nested[5] Hilbert spaces. The second approach is essentially the reverse of the previous ones and is based on the definition of a new mathematical structure: the partial inner product spaces,[6] that unifies the previous constructions.

In this paper we study how the symbolic expressions and calculations of the bra-ket formalism are justified, if we represent bras and kets by operators. Our approach is practical: we do not start from a general abstract structure, and we study the concrete case of a spinless particle in standard nonrelativistic quantum mechanics. Of course our construction crosses the previous works by several ways.

First of all, we focus on the "basis" $\{|\vec{q}\rangle\}$ and then we assign a special role to the position operator. In the abstract context of previous works, this means that the position coordinates correspond to *labeled observables*.[2,7] To give a right mathematical meaning to the vectors $|\vec{q}\rangle$, we map them into bounded operators $\mathbf{\Phi}_{\vec{q}}$ on $\mathcal{H}$, and the symbolic integral $\int_{\mathbb{R}^3}d^3\vec{q}\phi(\vec{q})|\vec{q}\rangle$ over $\mathbb{R}^3$ becomes a true (operator valued) integral (Sec. II). The $\mathbf{\Phi}_{\vec{q}}$ are obtained thanks to the introduction of a C^∞ function ξ of compact support that we call the *dressing function*: it plays a central role in our procedure. Then we show that bounded bras and kets are realized as Hilbert-Schmidt operators, and the standard inner product is mapped into the Hilbert-Schmidt inner product (Secs. III and IV). Moreover this bra-ket representation can be extended to a large family of "unbounded"

[a)]Electronic mail: herve.bergeron@lure.u-psud.fr

bras and kets corresponding to possibly unbounded operators (Sec. V). The representation of all objects in terms of operators is an old idea that can be found in Foias's papers.[8] More precisely, he defined the concept of an integral decomposition of some vector space in terms of eigenoperators associated with a self-adjoint operator. In the symbolic language of the bra-ket formalism, these eigenoperators correspond to distributions as $\delta(\mathbf{P}-p)=|\vec{p}\rangle\langle\vec{p}|$. We recover this formalism with the representation of unbounded bra-kets and the properties of the momentum observable (Secs. V and X). Moreover the definition of a generalized inner product for unbounded bras and kets leads us to the definition of a partial inner product (Sec. V).

Then we look at how to represent observables and symmetries with our formalism (Secs. VI–XI). In fact quantum observables are represented as self-adjoint operators acting on the standard Hilbert space $\mathcal{H}$ or as superoperators acting on the Hilbert space $\mathcal{L}_{\mathrm{HS}}$ of Hilbert-Schmidt operators. This representation gives a right mathematical representation for the symbolic objects $|\vec{q}_1\rangle\langle\vec{q}_2|$. We analyze in Sec. VIII the physical meaning of these representations and the role of the dressing function ξ.

Furthermore, we find that the operator $\mathbf{\Phi}_{\vec{q}}$ can be interpreted as a "wave function operator," and the quantum mechanical observables (for one particle) are expressed in a very similar way to second quantization. Nevertheless we do not think that this similarity hides some deeper direct connection, but rather that it is a consequence of the common mathematical structure shared by both formalisms, kets (creating operators), bras (annihilating operators), and observables (one particle observables) are elements of the same algebra, moreover in both cases we have a linear mapping from the initial Hilbert space into some algebra.

Finally the "wave function operator" allows us to define local observables, and we show that these operators are intimately related to previous works of Prugovečki[9] (positive operator valued measures). We also recover "the proper wave function" of a particle that cannot be pointlike. This special point was also derived in our previous paper.[10]

In the remainder we call the $\mathcal{H}$ Hilbert space $L^2(\mathbb{R}^3)$ over position space, $\mathcal{L}_{\mathcal{H}}$ the set of bounded operators on $\mathcal{H}$, and $\mathcal{L}_{\mathcal{HS}}$ the Hilbert space of Hilbert-Schmidt operators and the paper is organized as follows:

(i) First, we define the "wave function operator" $\mathbf{\Phi}_{\vec{q}}$ and the representation of $\mathcal{H}$ into $\mathcal{L}_{\mathcal{H}}$, allowing us to give a precise mathematical definition of "kets" in the q-basis (Sec. II). Then we show that "bounded kets" are in fact represented by Hilbert-Schmidt operators and we show that the representation of $\mathcal{H}$ into $\mathcal{L}_{\mathcal{HS}}$ is in fact an isometry (Sec. III). This allows us to give the representation of "bras." We also study the reverse mapping from $\mathcal{L}_{\mathcal{HS}}$ onto $\mathcal{H}$ (Sec. IV). In Sec. V, we generalize the previous definitions to "unbounded kets and bras."
(ii) We continue with the representation of symmetries and quantum observables in this new framework (Secs. VI and VII).
(iii) In Sec. VIII, we summarize the mathematical results and their physical meanings.
(iv) Then we study in details different observables, the position (Sec. IX), the momentum (Sec. X), and local observables (Sec. XI). Section XII is devoted to the Schrödinger equation.
(v) Finally we conclude this paper by Sec. XIII.

Remark: We specify that operator valued integrals are defined in the weak operator topology and bold letters stand for operators.

II. MAPPING $\mathcal{H}$ INTO $\mathcal{L}_{\mathcal{H}}$

In this section we introduce the operators $\mathbf{\Phi}_{\vec{q}}$ that allow us to map $\mathcal{H}$ into $\mathcal{L}_{\mathcal{H}}$. We call $\mathbf{\Phi}_{\vec{q}}$ the "wave function operator."

A. Definition of the wave function operator and first properties

We define the operators $\mathbf{\Phi}_{\vec{q}}$ on $\mathcal{H}$ as

$$\forall \varphi \in \mathcal{H}, \quad \forall \vec{q},\vec{x} \in \mathbb{R}^3, \quad \mathbf{\Phi}_{\vec{q}}(\varphi)(\vec{x}) = \xi(\vec{x}-\vec{q})\varphi(\vec{x}-\vec{q}), \tag{1}$$

where ξ is a given radial real function $\xi(\vec{x})=F(\|\vec{x}\|)$; and we assume ξ to be a C^∞ function with compact support.

Moreover ξ is normalized as

$$\int_{\mathbb{R}^3} d^3\vec{x}\ \xi(\vec{x})^2 = 1. \tag{2}$$

If we introduce the quantum operators $\vec{\mathbf{Q}}$ and $\vec{\mathbf{P}}=-i\hbar\,\partial_{\vec{q}}$, the operators $\mathbf{\Phi}_{\vec{q}}$ can be written

$$\mathbf{\Phi}_{\vec{q}} = \exp[-(i/\hbar)\vec{\mathbf{P}}\cdot q]\xi(\vec{\mathbf{Q}}), \tag{3}$$

so

$$\|\mathbf{\Phi}_{\vec{q}}\|_\infty \leqslant \|\xi\|_\infty. \tag{4}$$

We deduce that the adjoint $\mathbf{\Phi}_{\vec{q}}^\dagger$ verifies

$$\forall \varphi \in \mathcal{H}, \quad \forall \vec{q},\vec{x} \in \mathbb{R}^3, \quad \mathbf{\Phi}_{\vec{q}}^\dagger(\varphi)(\vec{x}) = \xi(\vec{x})\varphi(\vec{x}+\vec{q}),$$

$$\mathbf{\Phi}_{\vec{q}}^\dagger = \xi(\vec{\mathbf{Q}})\exp[(i/\hbar)\mathbf{P}\cdot\vec{q}]. \tag{5}$$

Finally, we conclude this part with the following important property.

Theorem: For any vectors φ and ψ of $\mathcal{H}$, the functions $\vec{q}\to\|\mathbf{\Phi}_{\vec{q}}^\dagger(\psi)\|_{\mathcal{H}}$ and $\vec{q}\to(\varphi|\mathbf{\Phi}_{\vec{q}}\psi)$ belong to $\mathcal{H}$.

Proof: We have

$$\|\mathbf{\Phi}_{\vec{q}}^\dagger(\psi)\|_{\mathcal{H}}^2 = \int_{\mathbb{R}^3} d^3\vec{x}\ \xi(\vec{x})^2|\psi(\vec{x}+\vec{q})|^2, \tag{6}$$

so

$$\int_{\mathbb{R}^3} d^3\vec{q}\|\mathbf{\Phi}_{\vec{q}}^\dagger(\psi)\|_{\mathcal{H}}^2 = \|\psi\|_{\mathcal{H}}^2\int_{\mathbb{R}^3} d^3\vec{x}\ \xi(\vec{x})^2 = \|\psi\|_{\mathcal{H}}^2. \tag{7}$$

Moreover we can write $(\varphi|\mathbf{\Phi}_{\vec{q}}\psi)$ as being $(\psi|\mathbf{\Phi}_{\vec{q}}^\dagger\varphi)^*$, then using the Schwarz inequality and the previous result we find

$$\int_{\mathbb{R}^3} d^3\vec{q}|(\varphi|\mathbf{\Phi}_{\vec{q}}\psi)|^2 \leqslant \|\varphi\|_{\mathcal{H}}^2\|\psi\|_{\mathcal{H}}^2. \tag{8}$$

B. The representation of kets in the *q*-basis

The previous theorem shows that for any $f\in\mathcal{H}$, the quantity $B_f(\varphi,\psi)=\int_{\mathbb{R}^3}d^3\vec{q}\ f(\vec{q})(\varphi|\mathbf{\Phi}_{\vec{q}}\psi)$ defines a continuous sesquilinear form on $\mathcal{H}$, so we know[11] that there exists some bounded operator $\hat{\mathbf{f}}$ on $\mathcal{H}$ such that $B_f(\varphi,\psi)=(\varphi|\hat{\mathbf{f}}\psi)$. By construction $\hat{\mathbf{f}}$ is the operator valued integral,

$$\hat{\mathbf{f}} = \int_{\mathbb{R}^3} d^3\vec{q}\ f(\vec{q})\mathbf{\Phi}_{\vec{q}}. \tag{9}$$

$\hat{\mathbf{f}}$ is a bounded operator, moreover we find

$$\|\hat{\mathbf{f}}^{\dagger}(\varphi)\|_{\mathcal{H}} \leqslant \int_{\mathbb{R}^3} d^3\vec{q}\,|f(\vec{q})|\|\mathbf{\Phi}^{\dagger}_{\vec{q}}(\varphi)\|_{\mathcal{H}} \leqslant \|f\|_{\mathcal{H}}\|\varphi\|_{\mathcal{H}}, \tag{10}$$

so

$$\|\hat{\mathbf{f}}\|_{\infty} = \|\hat{\mathbf{f}}^{\dagger}\|_{\infty} \leqslant \|f\|_{\mathcal{H}}. \tag{11}$$

We deduce that the mapping $\mathcal{U}: f \to \hat{\mathbf{f}}$ from $\mathcal{H}$ into the set $\mathcal{L}_{\mathcal{H}}$ of bounded operators on $\mathcal{H}$ is a continuous linear mapping.

Then we have the following correspondence between the ket formalism and its operator representation on $\mathcal{L}_{\mathcal{H}}$:

$$\text{for } f \in \mathcal{H}, \quad \begin{cases} |\vec{q}\rangle \mapsto \mathbf{\Phi}_{\vec{q}}, \\ |f = \int_{\mathbb{R}^3} d^3\vec{q}\, f(\vec{q})|\vec{q} \mapsto \hat{\mathbf{f}} = \int_{\mathbb{R}^3} d^3\vec{q}\, f(\vec{q})\mathbf{\Phi}_{\vec{q}}. \end{cases} \tag{12}$$

The same correspondence is formally used in second quantization (up to the replacement $\mathbf{\Phi}_{\vec{q}} \to \mathbf{\Phi}^{\dagger}_{\vec{q}}$). So we can think that $\mathbf{\Phi}_{\vec{q}}$ (or $\mathbf{\Phi}^{\dagger}_{\vec{q}}$) represents in our formalism some analogous of the "wave function operator," but in the unusual framework of one particle equations. This idea is confirmed by our first theorem, since the expectation value $f(\vec{q}) = (\varphi|\mathbf{\Phi}_{\vec{q}}\varphi)$ defines a vector of $\mathcal{H}$. We will see in the following that a great number of results agrees with this interpretation of $\mathbf{\Phi}_{\vec{q}}$.

III. INNER PRODUCT AND BRAS

We call $\mathcal{L}_{\mathcal{HS}}$ the Hilbert space of Hilbert-Schmidt operators on $\mathcal{H}$ equipped with the inner product $(\mathbf{A}|\mathbf{B})_{\mathcal{HS}} = \mathrm{Tr}(\mathbf{A}^{\dagger}\mathbf{B})$.

A. Isometric mapping from $\mathcal{H}$ into $\mathcal{L}_{\mathcal{HS}}$

We have the following theorem that specifies the isometry.

Theorem: For any $\phi \in \mathcal{H}$, $\hat{\boldsymbol{\phi}} \in \mathcal{L}_{\mathcal{HS}}$, and $\|\hat{\boldsymbol{\phi}}\|_{\mathcal{HS}} = \|\phi\|_{\mathcal{H}}$. So $(\hat{\boldsymbol{\varphi}}|\hat{\boldsymbol{\psi}})_{\mathcal{HS}} = \mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\hat{\boldsymbol{\psi}}) = (\varphi|\psi)_{\mathcal{H}}$.

Proof: First we remark from Eq. (5) that $\hat{\boldsymbol{\phi}}$ is defined by a kernel K_{ϕ},

$$\forall \varphi \in \mathcal{H}, \quad \forall \vec{x} \in \mathbb{R}^3, \quad \hat{\boldsymbol{\phi}}(\varphi)(\vec{x}) = \int_{\mathbb{R}^3} d^3\vec{q}\; \phi(\vec{q})\xi(\vec{x}-\vec{q})\varphi(\vec{x}-\vec{q}), \tag{13}$$

then

$$\hat{\boldsymbol{\phi}}(\varphi)(\vec{x}) = \int_{\mathbb{R}^3} d^3\vec{q}\; K_{\phi}(\vec{x},\vec{q})\varphi(\vec{q}),$$

$$K_{\phi}(\vec{x},\vec{q}) = \phi(\vec{x}-\vec{q})\xi(\vec{q}). \tag{14}$$

Moreover $K_{\phi} \in L^2(\mathbb{R}^6)$ since

$$\int_{\mathbb{R}^3\times\mathbb{R}^3} d^3\vec{x}\, d^3\vec{q}\,|K_{\phi}(\vec{x},\vec{q})|^2 = \|\phi\|^2_{\mathcal{H}}, \tag{15}$$

where we use the condition of normalization on the field ξ.

This shows that $\hat{\boldsymbol{\phi}}$ is a Hilbert-Schmidt operator and

$$\|\hat{\boldsymbol{\phi}}\|_{\mathcal{HS}} = \|\phi\|_{\mathcal{H}}. \tag{16}$$

Then, from the polarization identity we deduce that

$$\forall \varphi, \quad \psi \in \mathcal{H}, \quad (\hat{\boldsymbol{\varphi}}|\hat{\boldsymbol{\psi}})_{\mathcal{HS}} = \mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\hat{\boldsymbol{\psi}}) = (\varphi|\psi)_{\mathcal{H}}. \tag{17}$$

We have shown that the linear mapping $\mathcal{U}$: $\phi \to \hat{\boldsymbol{\phi}}$ is an isometry from the Hilbert space $\mathcal{H}$ into a closed subspace $\hat{\mathcal{H}} = \mathcal{U}(\mathcal{H})$ of $\mathcal{L}_{\mathrm{HS}}$.

B. The bra representation in the *q*-basis

From the relation $\mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\hat{\boldsymbol{\psi}}) = (\varphi|\psi)_{\mathcal{H}}$, we deduce that we have the following correspondence between the bra formalism and its operator representation on $\mathcal{L}_{\mathcal{H}}$:

$$\text{for } f \in \mathcal{H}, \quad \begin{cases} \langle \vec{q}| \mapsto \boldsymbol{\Phi}_{\vec{q}}^{\dagger} \\ \langle f| = \displaystyle\int_{\mathbb{R}^3} d^3\vec{q} f(\vec{q})^* \langle \vec{q}| \mapsto \hat{\mathbf{f}}^{\dagger} = \int_{\mathbb{R}^3} d^3\vec{q} f(\vec{q})^* \boldsymbol{\Phi}_{\vec{q}}^{\dagger}. \end{cases} \tag{18}$$

Then the set of bras and the set of kets are represented as two different subspaces of bounded (or Hilbert-Schmidt) operators and the symmetry bra-ket is given by the conjugate antilinear mapping $\mathbf{A} \to \mathbf{A}^{\dagger}$. So, in this formalism bras and kets are elements of a same space of operators.

IV. REVERSE MAPPING FROM $\mathcal{L}_{\mathcal{HS}}$ ONTO $\mathcal{H}$

Since $\hat{\mathcal{H}} = \mathcal{U}(\mathcal{H})$ is a closed subspace of the Hilbert space $\mathcal{L}_{\mathcal{HS}}$, we can formally define the superprojector Π from $\mathcal{L}_{\mathcal{HS}}$ onto $\hat{\mathcal{H}}$ as Π: $\mathbf{K} \in \mathcal{L}_{\mathcal{HS}} \to \Pi(\mathbf{K}) = \int_{\mathbb{R}^3} d^3\vec{q}\, \boldsymbol{\Phi}_{\vec{q}} \mathrm{Tr}(\boldsymbol{\Phi}_{\vec{q}}^{\dagger}\mathbf{K})$, where it is assumed that $\mathrm{Tr}(\boldsymbol{\Phi}_{\vec{q}}^{\dagger}\hat{\boldsymbol{\phi}}) = \phi(\vec{q})$ and then $\Pi(\hat{\boldsymbol{\phi}}) = \hat{\boldsymbol{\phi}}$. Unfortunately $\boldsymbol{\Phi}_{\vec{q}}^{\dagger}\mathbf{K}$ for $\mathbf{K} \in \mathcal{L}_{\mathcal{HS}}$ is not always (for any $\vec{q}$) a trace class operator, so $\mathrm{Tr}(\boldsymbol{\Phi}_{\vec{q}}^{\dagger}\mathbf{K})$ is not a well-defined mathematical quantity. Nevertheless, we will see with the following theorem that the kernel integral deduced from the symbolic expression of $\mathrm{Tr}(\boldsymbol{\Phi}_{\vec{q}}^{\dagger}\mathbf{K})$ is almost everywhere defined.

Theorem: For $\mathbf{K} \in \mathcal{L}_{\mathcal{HS}}$ represented by its kernel $K(\vec{x},\vec{y})$, we define the function $\breve{\mathbf{K}}: \vec{q} \to \int_{\mathbb{R}^3} d^3\vec{x}\, \xi(\vec{x}) K(\vec{x}+\vec{q},\vec{x})$ [corresponding to the symbolic expression $\mathrm{Tr}(\boldsymbol{\Phi}_{\vec{q}}\mathbf{K})$]. $\breve{\mathbf{K}}$ is an almost everywhere defined function that belongs to $\mathcal{H}$, and $\mathbf{K} \to \breve{\mathbf{K}}$ corresponds to a continuous linear extension to $\mathcal{L}_{\mathcal{HS}}$ of the reverse mapping $\mathcal{U}^{-1}$ from $\hat{\mathcal{H}}$ onto $\mathcal{H}$.

Proof: So let us prove that $\breve{\mathbf{K}}$ is an almost everywhere defined square integrable function. From the Scharwz inequality and the normalization of ξ we have

$$\int_{\mathbb{R}^3} d^3\vec{q} \left(\int_{\mathbb{R}^3} d^3\vec{x} |\xi(\vec{x})| |K(\vec{x}+\vec{q},\vec{x})| \right)^2 \leqslant \|\mathbf{K}\|_{\mathcal{HS}}^2. \tag{19}$$

This shows that $\breve{\mathbf{K}}(\vec{q})$ is almost everywhere defined and that $\breve{\mathbf{K}} \in \mathcal{H}$. Moreover

$$\|\breve{\mathbf{K}}\|_{\mathcal{H}} \leqslant \|\mathbf{K}\|_{\mathcal{HS}}, \tag{20}$$

then $\mathbf{K} \to \breve{\mathbf{K}}$ is continuous.

Finally, the kernel K_{ϕ} corresponding to $\hat{\boldsymbol{\phi}} \in \hat{\mathcal{H}}$ is given by

$$K_{\phi}(\vec{x},\vec{y}) = \phi(\vec{x}-\vec{y})\xi(\vec{y}), \tag{21}$$

so

$$\breve{\hat{\boldsymbol{\phi}}} = \phi. \tag{22}$$

Conclusion: We deduce that the superprojector Π previously mentioned from $\mathcal{L}_{\mathcal{HS}}$ onto $\hat{\mathcal{H}}$ possesses the well-defined expression

$$\forall \mathbf{K} \in \mathcal{L}_{\mathcal{HS}}, \quad \Pi(\mathbf{K}) = \int_{\mathbb{R}^3} d^3\vec{q}\, \breve{\mathbf{K}}(\vec{q})\mathbf{\Phi}_{\vec{q}}. \tag{23}$$

V. GENERALIZED BRAS, KETS AND THEIR INNER PRODUCT

In this section we extend the definition of bras and kets to be able to define the kets $|\vec{p}\rangle$, for example.

A. Generalized bras and kets

The previous representation of bounded kets and bras suggests that we can define generalized objects by relaxing the condition on f in the operator valued integral $\hat{\mathbf{f}}=\int_{\mathbb{R}^3} d^3\vec{q}\, f(\vec{q})\mathbf{\Phi}_{\vec{q}}$. The simplest way is to use a complex Baire measure μ and to define $\hat{\boldsymbol{\mu}}=\int_{\mathbb{R}^3} \mathrm{d}\mu(\vec{q})\mathbf{\Phi}_{\vec{q}}$. Generally $\hat{\boldsymbol{\mu}}$ is an unbounded operator on $\mathcal{H}$.

We introduce the Gel'fand triplet $\mathcal{H}_+ \subset \mathcal{H} \subset \mathcal{H}_-$, where $\mathcal{H}_+=\{f \in L^\infty(\mathbb{R}^3)$ with a compact support$\}$ and $\mathcal{H}_-$ is the Frechet space of locally summable functions on $\mathbb{R}^3$ with its directed family of seminorms $\|f\|_n=\int_{\|\vec{q}\|\leq n} d^3\vec{q}\,|f(\vec{q})|$. $\mathcal{H}_+$ is a dense subset of $\mathcal{H}$ and is related to $\mathcal{H}_-$ by the duality $\mathcal{H}_-^*=\mathcal{H}_+$.

Theorem: For any Baire measure μ, the operator valued integral $\hat{\boldsymbol{\mu}}=\int_{\mathbb{R}^3} \mathrm{d}\mu(\vec{q})\mathbf{\Phi}_{\vec{q}}$ is a continuous linear mapping from $\mathcal{H}$ into $\mathcal{H}_-$. Moreover, the operator $\hat{\boldsymbol{\mu}}^\dagger$ defined as $\hat{\boldsymbol{\mu}}^\dagger = \int_{\mathbb{R}^3} \mathrm{d}\mu^*(\vec{q})\mathbf{\Phi}_{\vec{q}}^\dagger$ is a linear mapping from $\mathcal{H}_+$ into $\mathcal{H}$. Then $\hat{\boldsymbol{\mu}}$ and $\hat{\boldsymbol{\mu}}^\dagger$ are special cases of mappings from $\mathcal{H}_+$ into $\mathcal{H}_-$.

Proof: Since any complex measure μ can be split into $\mu=\mu_1+i\mu_2$ where μ_1 and μ_2 are real, and since any real measure μ can be written as $\mu=\mu_+-\mu_-$ where μ_+ and μ_- are positive, we only need to analyze the case of positive Baire measures. So, let μ be a positive measure and $\varphi \in \mathcal{H}$. We study the function $\psi(\vec{x})=\hat{\mu}(\varphi)(\vec{x})=\int_{\mathbb{R}^3} \mathrm{d}\mu(\vec{q})\mathbf{\Phi}_{\vec{q}}(\varphi)(\vec{x})$.

From the Eq. (5) we have

$$\psi(\vec{x}) = \int_{\mathbb{R}^3} \mathrm{d}\mu(\vec{q})\xi(\vec{x}-\vec{q})\varphi(\vec{x}-\vec{q}). \tag{24}$$

Let us prove that ψ is an almost everywhere defined, locally summable function.

We call K_n the compact set $K_n=\{\vec{q}/\|\vec{q}\| \leq n\}$; using the Schwarz inequality we have

$$\int_{K_n} d^3\vec{x} \int_{\mathbb{R}^3} \mathrm{d}\mu(\vec{q})|\xi(\vec{x}-\vec{q})\varphi(\vec{x}-\vec{q})| \leq C_n\|\varphi\|_{\mathcal{H}} \tag{25}$$

with

$$C_n = \int_{\mathbb{R}^3} \mathrm{d}\mu(\vec{q}) \left(\int_{K_n} d^3\vec{x}\, \xi(\vec{x}-\vec{q})^2 \right)^{1/2}. \tag{26}$$

Since ξ is a C^∞ function with a compact support, $F(\vec{q})=\int_{K_n} d^3\vec{x}\, \xi(\vec{x}-\vec{q})^2$ is a continuous function with compact support, then $\int_{\mathbb{R}^3} \mathrm{d}\mu(\vec{q})\sqrt{F(\vec{q})}$ is finite (μ is a Baire measure). This shows that ψ is a locally summable function, and

$$\|\hat{\mu}(\varphi)\|_n \leq C_n\|\varphi\|. \tag{27}$$

So $\hat{\boldsymbol{\mu}}$ is a continuous linear mapping from $\mathcal{H}$ into $\mathcal{H}_-$.

Moreover, since functions of $\mathcal{H}_+$ define continuous linear functionals on $\mathcal{H}_-$, we have for any $\eta \in \mathcal{H}_+$ and any $\varphi \in \mathcal{H}$,

$$<\eta^*, \hat{\boldsymbol{\mu}}(\varphi)> = \int_{\mathbb{R}^3} d^3\vec{x}\, \eta^*(\vec{x})\hat{\boldsymbol{\mu}}(\varphi)(\vec{x}) = \int_{\mathbb{R}^3} \mathrm{d}\mu_{\vec{q}}(\eta|\mathbf{\Phi}_{\vec{q}}\varphi)_{\mathcal{H}}. \tag{28}$$

By duality, we deduce that the operator $\hat{\boldsymbol{\mu}}^\dagger = \int_{\mathbf{R}^3} d\mu^*(\vec{q}) \boldsymbol{\Phi}_{\vec{q}}^\dagger$ is a well-defined linear mapping from $\mathcal{H}_+ = \mathcal{H}_-^*$ into $\mathcal{H} = \mathcal{H}^*$, and

$$\forall\, \eta \in \mathcal{H}_+,\ \hat{\boldsymbol{\mu}}^\dagger(\eta)(\vec{x}) = \xi(\vec{x}) \int_{\mathbb{R}^3} \mathrm{d}\mu^*(\vec{q})\, \eta(\vec{x}+\vec{q}),$$

$$\forall\, \eta \in \mathcal{H}_+,\ \forall\, \varphi \in \mathcal{H}, \quad (\varphi | \hat{\boldsymbol{\mu}}^\dagger \eta)_{\mathcal{H}} = \int_{\mathbb{R}^3} \mathrm{d}\mu^*(\vec{q}) (\varphi | \boldsymbol{\Phi}_{\vec{q}}^\dagger \eta)_{\mathcal{H}}. \tag{29}$$

B. Generalized inner product

For any complex Baire measures μ and ν, the above paragraph shows that $\hat{\boldsymbol{\mu}} \cdot \hat{\boldsymbol{\nu}}^\dagger$ is a well-defined operator from $\mathcal{H}_+$ into $\mathcal{H}_-$; but $\hat{\boldsymbol{\nu}}^\dagger \cdot \hat{\boldsymbol{\mu}}$ is generally undefined. So, if M is the set of complex Baire measures, we define the subset Ω of $M \times M$ as being the set of pairs (ν, μ) such that $\hat{\boldsymbol{\nu}}^\dagger \cdot \hat{\boldsymbol{\mu}}$ is a well-defined trace class operator on $\mathcal{H}$. We define a generalized inner product on Ω as

$$\forall (\nu, \mu) \in \Omega, \quad (\hat{\boldsymbol{\nu}} | \hat{\boldsymbol{\mu}}) = \mathrm{Tr}(\hat{\boldsymbol{\nu}}^\dagger \cdot \hat{\boldsymbol{\mu}}). \tag{30}$$

By construction, this definition generalized the Hilbert-Schmidt inner product $(\hat{\boldsymbol{\varphi}} | \hat{\boldsymbol{\psi}})_{\mathcal{HS}}$ previously defined and this structure corresponds to a partial inner product.[6]

C. Practical examples

We introduce the Dirac measure $\delta_{\vec{q}}$ and the Fourier measure $\mu_{\vec{k}}$ such that $\mathrm{d}\mu_{\vec{k}}(\vec{x}) = \phi_{\vec{k}}(\vec{x}) d^3\vec{x}$ with $\phi_{\vec{k}}(\vec{x}) = \exp(i\vec{k} \cdot \vec{x})$; we also define the correspondent operators $\hat{\boldsymbol{\delta}}_{\vec{q}}$ and $\hat{\boldsymbol{\phi}}_{\vec{k}}$. Obviously we have

$$\hat{\boldsymbol{\delta}}_{\vec{q}} = \boldsymbol{\Phi}_{\vec{q}} \quad \text{and} \quad \hat{\boldsymbol{\delta}}_{\vec{q}}^\dagger = \boldsymbol{\Phi}_{\vec{q}}^\dagger \tag{31}$$

then $\hat{\boldsymbol{\delta}}_{\vec{q}}$ and $\hat{\boldsymbol{\delta}}_{\vec{q}}^\dagger$ define bounded operators on $\mathcal{H}$. Moreover

$$\forall\, \varphi \in \mathcal{H}, \quad \hat{\boldsymbol{\phi}}_{\vec{k}}(\varphi)(\vec{x}) = \int_{\mathbb{R}^3} d^3\vec{q}\, \exp(i\vec{k} \cdot \vec{q}) \xi(\vec{x} - \vec{q}) \varphi(\vec{x} - \vec{q}), \tag{32}$$

so

$$\forall\, \varphi \in \mathcal{H}, \quad \begin{cases} \hat{\boldsymbol{\phi}}_{\vec{k}}(\varphi)(\vec{x}) = F(\vec{k}) \phi_{\vec{k}}(\vec{x}), \\ F(\vec{k}) = \displaystyle\int_{\mathbb{R}^3} d^3\vec{q}\, \exp(-i\vec{k} \cdot \vec{q}) \xi(\vec{q}) \varphi(\vec{q}). \end{cases} \tag{33}$$

But $\vec{x} \to \boldsymbol{\Phi}_{\vec{q}}(\phi_{\vec{k}})(\vec{x}) = \exp(i\vec{k} \cdot \vec{q}) \xi(\vec{x}) \exp(i\vec{k} \cdot \vec{x})$ is a well-defined function of $\mathcal{H}$, then the operator $\hat{\boldsymbol{\delta}}_{\vec{q}}^\dagger \cdot \hat{\boldsymbol{\mu}}_{\vec{k}}$ is a bounded operator on $\mathcal{H}$ defined by the kernel K,

$$K(\vec{x}, \vec{y}) = \exp(i\vec{k} \cdot \vec{q}) \psi^*(\vec{x}) \psi(\vec{y}),$$

$$\psi(\vec{y}) = \xi(\vec{y}) \exp(-i\vec{k} \cdot \vec{y}). \tag{34}$$

This corresponds to a trace class operator and we have the generalized inner product,

$$(\hat{\boldsymbol{\delta}}_{\vec{q}} | \hat{\boldsymbol{\phi}}_{\vec{k}}) = \int_{\mathbb{R}^3} d^3\vec{x}\, K(\vec{x}, \vec{x}) = \exp(i\vec{k} \cdot \vec{q}). \tag{35}$$

We can easily check that $\hat{\boldsymbol{\phi}}_{\vec{k}}^\dagger \cdot \hat{\boldsymbol{\delta}}_{\vec{q}}$ also is a trace class operator and

$$(\hat{\boldsymbol{\phi}}_{\vec{k}}|\hat{\boldsymbol{\delta}}_{\vec{q}}) = \exp(-i\vec{k}\cdot\vec{q}). \tag{36}$$

This reasoning can be extended to any $\hat{\mathbf{f}}$ where f is a bounded continuous function,

$$(\hat{\boldsymbol{\delta}}_{\vec{q}}|\hat{\mathbf{f}}) = f(\vec{q}) \quad \text{and} \quad (\hat{\mathbf{f}}|\hat{\boldsymbol{\delta}}_{\vec{q}}) = f(\vec{q})^*. \tag{37}$$

Furthermore, let us assume ϕ to be a C^∞ function of rapid decrease, then $\hat{\boldsymbol{\delta}}^\dagger_{\vec{q}}\cdot\hat{\boldsymbol{\phi}}$ and $\hat{\boldsymbol{\phi}}^\dagger_{\vec{k}}\cdot\hat{\boldsymbol{\phi}}$ are trace class operators and

$$(\hat{\boldsymbol{\delta}}_{\vec{q}}|\hat{\boldsymbol{\phi}}) = \phi(\vec{q}),$$

$$(\hat{\boldsymbol{\phi}}_{\vec{k}}|\hat{\boldsymbol{\phi}}) = \int_{\mathbb{R}^3} d^3\vec{x}\,\exp(-i\vec{k}\cdot\vec{x})\,\phi(\vec{x}). \tag{38}$$

After this study on the representation of bras and kets, we can look for the representation of operators used in the bra-ket formalism.

VI. LOWERING AND RAISING THE BRA-KET FORMALISM

The bra-ket formalism used on $\mathcal{H}$ can be also employed on $\mathcal{L}_{\mathcal{HS}}$. Let us analyze in this section the symbolic expressions resulting from this simultaneous utilization.

We write down $|\varphi\rangle$ for the kets of $\mathcal{H}$ and $|\hat{\boldsymbol{\varphi}}\rangle$ for the kets of $\hat{\mathcal{H}}$. This notation extends to operators from $\mathcal{H}$ to $\mathcal{H}_-$ and the formula,

$$|\hat{\boldsymbol{\varphi}}\rangle = \int_{\mathbb{R}^3} d^3\vec{q}\;\varphi(\vec{q})|\boldsymbol{\Phi}_{\vec{q}} \tag{39}$$

becomes meaningful. Moreover we have seen that $\langle\boldsymbol{\Phi}_{\vec{q}}|\hat{\boldsymbol{\varphi}}\rangle = \mathrm{Tr}(\boldsymbol{\Phi}^\dagger_{\vec{q}}\hat{\boldsymbol{\varphi}})$ is an almost everywhere defined function and $\langle\boldsymbol{\Phi}_{\vec{q}}|\hat{\boldsymbol{\varphi}}\rangle = \varphi(\vec{q})$ (almost everywhere) then the symbolic closure relation $\int_{\mathbb{R}^3} d^3\vec{q}\,|\boldsymbol{\Phi}_{\vec{q}}\rangle\langle\boldsymbol{\Phi}_{\vec{q}}| = \mathbf{1}$ is justified. Now let us investigate more symbolic expressions.

We can write $|\hat{\boldsymbol{\varphi}}\rangle = \int_{\mathbb{R}^3} d^3\vec{q}\langle\vec{q}\,|\,\varphi\rangle|\boldsymbol{\Phi}_{\vec{q}}\rangle$, then our mapping $\mathcal{U}$ is $\mathcal{U} = \int_{\mathbb{R}^3} d^3\vec{q}\,|\boldsymbol{\Phi}_{\vec{q}}\rangle\langle\vec{q}|$ and $\mathcal{U}^{-1} = \int_{\mathbb{R}^3} d^3\vec{q}\,|\vec{q}\rangle\langle\boldsymbol{\Phi}_{\vec{q}}|$. If we are interested in the representation of operators different possibilities appear.

Let us assume that $\mathbf{A}$ is an operator, given in the bra-ket formalism of $\mathcal{H}$ by $\mathbf{A} = \int d^3\vec{q}\;d^3\vec{q}\,'\langle\vec{q}\,|\mathbf{A}\,|\vec{q}\,'\rangle|\vec{q}\rangle\langle\vec{q}\,'|$.

We can first lift up $\mathbf{A}$ in a superoperator

$$\mathbf{A}^{(S)} = \mathcal{U}\mathbf{A}\mathcal{U}^{-1} = \int d^3\vec{q}\;d^3\vec{q}\,'\langle\vec{q}|\mathbf{A}|\vec{q}\,'\rangle|\boldsymbol{\Phi}_{\vec{q}}\rangle\langle\boldsymbol{\Phi}_{\vec{q}\,'}|. \tag{40}$$

This corresponds to the isometric representation. But this is not the unique solution.

$\mathbf{A}$ possesses a natural action on the operators $\hat{\boldsymbol{\varphi}} \in \hat{\mathcal{H}}$ by $\hat{\boldsymbol{\varphi}} \to \mathbf{A}\cdot\hat{\boldsymbol{\varphi}}$, but $\mathbf{A}\cdot\hat{\boldsymbol{\varphi}}$ is not an element of $\hat{\mathcal{H}}$. If we remark that the matrix elements $(\hat{\boldsymbol{\psi}}|\,\mathbf{A}\cdot\hat{\boldsymbol{\varphi}})_{\mathcal{HS}}$ are the only important quantities, we find another (nonequivalent) representation of $\mathbf{A}$ as a new superoperator,

$$\hat{\mathbf{A}} = \int d^3\vec{q}\;d^3\vec{q}\,'\;\mathrm{Tr}(\boldsymbol{\Phi}^\dagger_{\vec{q}}\mathbf{A}\boldsymbol{\Phi}_{\vec{q}\,'})|\boldsymbol{\Phi}_{\vec{q}}\rangle\langle\boldsymbol{\Phi}_{\vec{q}\,'}|. \tag{41}$$

The interesting point of this representation is the relation

$$\langle\hat{\boldsymbol{\psi}}|\hat{\mathbf{A}}|\hat{\boldsymbol{\varphi}}\rangle = \mathrm{Tr}(\hat{\boldsymbol{\psi}}^\dagger\mathbf{A}\hat{\boldsymbol{\varphi}}) \tag{42}$$

that reproduces the symmetric notation of the bra-ket formalism.

Finally we have a third representation. The symbolic expression $|\vec{q}\rangle\langle\vec{q}'|$ represents an operator by some "tensorial product," but if we do the substitutions $|\vec{q}\rangle \to \mathbf{\Phi}_{\vec{q}}$ and $\langle\vec{q}'| \to \mathbf{\Phi}^{\dagger}_{\vec{q}'}$ the quantity $\mathbf{\Phi}_{\vec{q}}\mathbf{\Phi}^{\dagger}_{\vec{q}'}$ is well defined as a product of operators. Then we deduce a new representation on $\mathcal{H}$ by

$$\widetilde{\mathbf{A}} = \int d^3\vec{q}'\ d^3\vec{q}\langle\vec{q}|\mathbf{A}|\vec{q}'\rangle\mathbf{\Phi}_{\vec{q}}\,\mathbf{\Phi}^{\dagger}_{\vec{q}'}. \tag{43}$$

The interest of this representation is the substitution of the ket-bra tensorial product by the usual operator product $|\varphi\rangle\langle\psi| \to \hat{\boldsymbol{\varphi}}\hat{\boldsymbol{\psi}}^{\dagger}$.

In the following we study in details the representations $\hat{\mathbf{A}}$ and $\widetilde{\mathbf{A}}$.

VII. BOUNDED OPERATORS IN THE NEW REPRESENTATION

A. Representation of symmetries

1. Definition

Symmetries on $\mathcal{H}$ are given by unitary operators $\mathbf{U}$ and they represent, either a change of mathematical basis, or the change of state associated with a physical change of frame. So it is natural to lift up directly the action of $\mathbf{U}$ on $\mathcal{H}$ into an unitary superoperator $\mathbf{U}^{(S)}$ acting on $\hat{\mathcal{H}} = \mathcal{U}(\mathcal{H})$ as

$$\mathbf{U}^{(S)} = \mathcal{U}\mathbf{U}\mathcal{U}^{-1}. \tag{44}$$

Then

$$\forall\,\varphi \in \mathcal{H}, \quad \mathbf{U}^{(S)}(\hat{\boldsymbol{\varphi}}) = \widehat{\mathbf{U}(\varphi)}. \tag{45}$$

Moreover,

$$\forall\,\varphi, \quad \psi \in \mathcal{H}, \quad (\hat{\boldsymbol{\varphi}}|\mathbf{U}^{(S)}(\hat{\boldsymbol{\psi}}))_{\mathrm{HS}} = (\varphi|\mathbf{U}(\psi))_{\mathcal{H}}. \tag{46}$$

Another equivalent definition is obtained by postulating that symmetries are superunitary operators on $\mathcal{L}_{\mathcal{HS}}$ that have $\hat{\mathcal{H}}$ invariant.

2. Geometrical symmetries: Rotations, translations, and parity

The unitary transforms $\mathbf{R}_{\vec{\omega}}, \mathbf{T}_{\vec{a}}$, and $\mathbf{K}_P$ of rotation, translation, and parity are defined on $\mathcal{H}$ as

$$\mathbf{R}_{\vec{\omega}}(\varphi)(\vec{x}) = \varphi(\mathcal{R}^{-1}_{\vec{\omega}}(\vec{x})),$$

$$\mathbf{T}_{\vec{a}}(\varphi)(\vec{x}) = \varphi(\vec{x} - \vec{a}),$$

$$\mathbf{K}_P(\varphi)(\vec{x}) = \varphi(-\vec{x}), \tag{47}$$

where $\mathcal{R}_{\vec{\omega}}$ is a geometric rotation.

Since the function ξ is radial, we find

$$\mathbf{R}_{\vec{\omega}}\mathbf{\Phi}_{\vec{q}}\mathbf{R}^{\dagger}_{\vec{\omega}} = \mathbf{\Phi}_{\mathcal{R}_{\vec{\omega}}(\vec{q})},$$

$$\mathbf{T}_{\vec{a}}\,\mathbf{\Phi}_{\vec{q}} = \mathbf{\Phi}_{\vec{q}-\vec{a}},$$

$$\mathbf{K}_P\mathbf{\Phi}_{\vec{q}}\mathbf{K}_P = \mathbf{\Phi}_{-\vec{q}}. \tag{48}$$

From the expression $\hat{\boldsymbol{\varphi}}=\int_{\mathbb{R}^3} d^3\vec{q}\ \varphi(\vec{q})\boldsymbol{\Phi}_{\vec{q}}$, we deduce that for any $\varphi\in\mathcal{H}$, we have

$$\widehat{\mathbf{R}_{\vec{\omega}}(\varphi)}=\mathbf{R}_{\vec{\omega}}\cdot\hat{\boldsymbol{\varphi}}\cdot\mathbf{R}_{\vec{\omega}}^{\dagger},$$

$$\widehat{\mathbf{T}_{\vec{a}}(\varphi)}=\mathbf{T}_{\vec{a}}\cdot\hat{\boldsymbol{\varphi}},$$

$$\widehat{\mathbf{K}_P(\varphi)}=\mathbf{K}_P\cdot\hat{\boldsymbol{\varphi}}\cdot\mathbf{K}_P. \tag{49}$$

So, the superunitary operators $\mathbf{R}_{\vec{\omega}}^{(S)}$, $\mathbf{T}_{\vec{a}}^{(S)}$, and $\mathbf{K}_P^{(S)}$ on $\hat{\mathcal{H}}$ are defined as

$$\mathbf{R}_{\vec{\omega}}^{(S)}(\hat{\boldsymbol{\varphi}})=\mathbf{R}_{\vec{\omega}}\cdot\hat{\boldsymbol{\varphi}}\cdot\mathbf{R}_{\vec{\omega}}^{\dagger},$$

$$\mathbf{T}_{\vec{a}}^{(S)}(\hat{\boldsymbol{\varphi}})=\mathbf{T}_{\vec{a}}\cdot\hat{\boldsymbol{\varphi}},$$

$$\mathbf{K}_P^{(S)}(\hat{\boldsymbol{\varphi}})=\mathbf{K}_P\cdot\hat{\boldsymbol{\varphi}}\cdot\mathbf{K}_P. \tag{50}$$

3. Kinematical symmetry: Galilei boost

This symmetry $\mathbf{G}_{\vec{k}}$ is defined on $\mathcal{H}$ as

$$\mathbf{G}_{\vec{k}}(\varphi)(\vec{x})=\exp(i\vec{k}\cdot\vec{x})\varphi(\vec{x}), \tag{51}$$

so

$$\mathbf{G}_{\vec{k}}\boldsymbol{\Phi}_{\vec{q}}\mathbf{G}_{\vec{k}}^{\dagger}=\exp(i\vec{k}\cdot\vec{q})\boldsymbol{\Phi}_{\vec{q}}. \tag{52}$$

From the expression $\hat{\boldsymbol{\varphi}}=\int_{\mathbb{R}^3} d^3\vec{q}\ \varphi(\vec{q})\boldsymbol{\Phi}_{\vec{q}}$, we deduce that for any $\varphi\in\mathcal{H}$, we have

$$\widehat{\mathbf{G}_{\vec{k}}(\varphi)}=\mathbf{G}_{\vec{k}}\cdot\hat{\boldsymbol{\varphi}}\cdot\mathbf{G}_{\vec{k}}^{\dagger}. \tag{53}$$

So the superunitary operator $\mathbf{G}_{\vec{k}}^{(S)}$ is defined as

$$\mathbf{G}_{\vec{k}}^{(S)}(\hat{\boldsymbol{\varphi}})=\mathbf{G}_{\vec{k}}\cdot\hat{\boldsymbol{\varphi}}\cdot\mathbf{G}_{\vec{k}}^{\dagger}. \tag{54}$$

4. The special case of antiunitary transform: Time reversal

This antiunitary symmetry $\mathbf{K}_T$ is defined on $\mathcal{H}$ as

$$\mathbf{K}_T(\varphi)(\vec{x})=\varphi(\vec{x})^*. \tag{55}$$

Since ξ is real, we find

$$\mathbf{K}_T\cdot\boldsymbol{\Phi}_{\vec{q}}\cdot\mathbf{K}_T=\boldsymbol{\Phi}_{\vec{q}},$$

$$\mathbf{K}_T\cdot\boldsymbol{\Phi}_{\vec{q}}^{\dagger}\cdot\mathbf{K}_T=\boldsymbol{\Phi}_{\vec{q}}^{\dagger}. \tag{56}$$

From the expression $\hat{\boldsymbol{\varphi}}=\int_{\mathbb{R}^3} d^3\vec{q}\ \varphi(\vec{q})\boldsymbol{\Phi}_{\vec{q}}$, we deduce that for any $\varphi\in\mathcal{H}$, we have

$$\widehat{\mathbf{K}_T(\varphi)}=\mathbf{K}_T\cdot\hat{\boldsymbol{\varphi}}\cdot\mathbf{K}_T. \tag{57}$$

We deduce that $\mathbf{K}_T$ can be lifted into an antiunitary superoperator $\mathbf{K}_T^{(S)}$ acting on $\hat{\mathcal{H}}$ as

$$\mathbf{K}_T^{(S)}(\hat{\boldsymbol{\varphi}})=\mathbf{K}_T\cdot\hat{\boldsymbol{\varphi}}\cdot\mathbf{K}_T. \tag{58}$$

B. Representation of observables

1. Definition and first properties

Since $\mathcal{L}_{\mathcal{HS}}$ is an ideal of $\mathcal{L}_{\mathcal{H}}$, we have a natural representation of $\mathcal{L}_{\mathcal{H}}$, on $\mathcal{L}_{\mathcal{HS}}$, as $L_{\mathbf{A}}:\mathbf{B} \in \mathcal{L}_{\mathcal{HS}} \rightarrow \mathbf{A}\cdot\mathbf{B} \in \mathcal{L}_{\mathcal{HS}}$ for bounded operator $\mathbf{A}$. Moreover if Π is the superprojector on the closed subspace $\hat{\mathcal{H}}=\mathcal{U}(\mathcal{H})$ of $\mathcal{L}_{\mathcal{HS}}$, we can define the superoperator $\hat{\mathbf{A}}$ on $\mathcal{L}_{\mathcal{HS}}$ that maps $\hat{\mathcal{H}}$into $\hat{\mathcal{H}}$ as

$$\hat{\mathbf{A}} = \Pi L_{\mathbf{A}} \Pi. \tag{59}$$

Obviously

$$(\hat{\mathbf{A}})^{\dagger} = \widehat{\mathbf{A}^{\dagger}},$$

$$\mathbf{A} \geqslant \mathbf{0} \Rightarrow \hat{\mathbf{A}} \geqslant 0. \tag{60}$$

Moreover we have the following relation for inner product:

$$\forall\, \varphi, \psi \in \mathcal{H}, \quad (\hat{\boldsymbol{\varphi}}|\hat{\mathbf{A}}(\hat{\boldsymbol{\psi}}))_{\mathcal{HS}} = (\hat{\boldsymbol{\varphi}}|\mathbf{A}\hat{\boldsymbol{\psi}})_{\mathcal{HS}} = \mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\mathbf{A}\hat{\boldsymbol{\psi}}). \tag{61}$$

Since results of experiments are given by expectation values, the previous equation gives a very natural way to represent observables in the new representation. Moreover we recover in $\mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\mathbf{A}\hat{\boldsymbol{\psi}})$ the complete symmetric expression $\langle\varphi|\,\mathbf{A}\,|\psi\rangle$ used in the bra-ket formalism.

Furthermore, we can build the sesquilinear form B_A on $\mathcal{H}$ as

$$\forall\, \varphi,\ \psi \in \mathcal{H}, \quad B_A(\varphi,\psi) = (\hat{\boldsymbol{\varphi}}|\hat{\mathbf{A}}(\hat{\boldsymbol{\psi}}))_{\mathcal{HS}} = \mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\mathbf{A}\hat{\boldsymbol{\psi}}). \tag{62}$$

B_A is continuous since

$$B_A(\varphi,\psi) \leqslant \|\mathbf{A}\|_{\infty}\|\varphi\|_{\mathcal{H}}\|\psi\|_{\mathcal{H}}. \tag{63}$$

So for any operator $\mathbf{A} \in \mathcal{L}_{\mathcal{H}}$, there exists some bounded operator $\widetilde{\mathbf{A}}$ on $\mathcal{H}$ such that

$$(\hat{\boldsymbol{\varphi}}|\mathbf{A}\hat{\boldsymbol{\psi}})_{\mathcal{HS}} = \mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\mathbf{A}\hat{\boldsymbol{\psi}}) = (\varphi|\widetilde{\mathbf{A}}\psi)_{\mathcal{H}}. \tag{64}$$

This shows that

$$\hat{\mathbf{A}}(\hat{\boldsymbol{\varphi}}) = \widehat{\widetilde{\mathbf{A}}(\varphi)}. \tag{65}$$

Since we know that

$$\|\widetilde{\mathbf{A}}\|_{\infty} = \sup_{\varphi,\psi\in\mathcal{H}} \frac{|(\varphi|\widetilde{\mathbf{A}}\psi)_{\mathcal{H}}|}{\|\varphi\|_{\mathcal{H}}\|\psi\|_{\mathcal{H}}} \tag{66}$$

and

$$|(\hat{\boldsymbol{\varphi}}|\mathbf{A}\hat{\boldsymbol{\psi}})_{\mathrm{HS}}| \leqslant \|\mathbf{A}\|_{\infty}\|\hat{\boldsymbol{\varphi}}\|_{\mathrm{HS}}\|\hat{\boldsymbol{\psi}}\|_{\mathrm{HS}}, \tag{67}$$

we find

$$\|\widetilde{\mathbf{A}}\|_{\infty} \leqslant \|\mathbf{A}\|_{\infty}. \tag{68}$$

We deduce a new continuous mapping $\mathcal{V}:\mathbf{A}\rightarrow\widetilde{\mathbf{A}}$ from $\mathcal{L}_{\mathcal{H}}$ into itself. Moreover,

$$(\widetilde{\mathbf{A}})^\dagger = \widetilde{\mathbf{A}^\dagger},$$

$$\mathbf{A} \geqslant \mathbf{0} \Rightarrow \widetilde{\mathbf{A}} \geqslant 0. \tag{69}$$

Finally, using the functional calculus, the Eq. (65) implies that for any bounded Borel function f, we have

$$f(\hat{\mathbf{A}})(\hat{\boldsymbol{\varphi}}) = \widehat{f(\widetilde{\mathbf{A}})(\varphi)}. \tag{70}$$

2. Analytical expression of $\tilde{\mathbf{A}}$ for Hilbert-Schmidt operators

(a) Kernel representation: Let us assume that $\mathbf{A} \in \mathcal{L}_{\mathcal{HS}}$ is represented by its kernel $A(\vec{x},\vec{y}), [A(\vec{x},\vec{y}) \in L^2(\mathbb{R}^6)]$, and that $\hat{\boldsymbol{\psi}}, \hat{\boldsymbol{\varphi}}^\dagger$ are defined by their kernels K_ψ and $K_{\varphi^\dagger}$,

$$K_\psi(\vec{x},\vec{y}) = \xi(\vec{y})\psi(\vec{x}-\vec{y}),$$

$$K_{\varphi^\dagger}(\vec{x},\vec{y}) = \xi(\vec{x})\varphi^*(\vec{y}-\vec{x}). \tag{71}$$

Then $\hat{\boldsymbol{\varphi}}^\dagger \mathbf{A} \hat{\boldsymbol{\psi}}$ is given by the kernel K,

$$K(\vec{x},\vec{y}) = \xi(\vec{x})\xi(\vec{y}) \int_{\mathbb{R}^3\times\mathbb{R}^3} d^3\vec{q}\, d^3\vec{q}_1\, \varphi^*(\vec{q}-\vec{x}) A(\vec{q},\vec{q}_1)\psi(\vec{q}_1-\vec{y}), \tag{72}$$

or

$$K(\vec{x},\vec{y}) = \xi(\vec{x})\xi(\vec{y}) \int_{\mathbb{R}^3\times\mathbb{R}^3} d^3\vec{q}\, d^3\vec{q}_1\, \varphi^*(\vec{q})\psi(\vec{q}_1) A(\vec{q}+\vec{x},\vec{q}_1+\vec{y}). \tag{73}$$

So

$$(\varphi|\widetilde{\mathbf{A}}\psi)_{\mathcal{H}} = \mathrm{Tr}(\hat{\boldsymbol{\varphi}}^\dagger \mathbf{A} \hat{\boldsymbol{\psi}}) = \int_{\mathbb{R}^3} d^3\vec{x}\, K(\vec{x},\vec{x}). \tag{74}$$

From Eqs. (73) and (74), we find that $\widetilde{\mathbf{A}}$ is given by a kernel $\widetilde{A}(\vec{x},\vec{y})$,

$$\widetilde{A}(\vec{x},\vec{y}) = \int_{\mathbb{R}^3} d^3\vec{q}\, \xi(\vec{q})^2 A(\vec{q}+\vec{x},\vec{q}+\vec{y}). \tag{75}$$

If $\mathbf{A}$ is a trace class operator, then

$$\widetilde{A}(\vec{x},\vec{y}) = \mathrm{Tr}(\boldsymbol{\Phi}_{\vec{x}}^\dagger \mathbf{A} \boldsymbol{\Phi}_{\vec{y}}). \tag{76}$$

(The previous expression cannot be defined for any $\vec{x}$ and $\vec{y}$ if $\mathbf{A}$ is only a Hilbert-Schmidt operator.)

Remark: Using the Schwarz inequality and the normalization of ξ we have

$$\int_{\mathbb{R}^3\times\mathbb{R}^3} d^3\vec{x}\, d^3\vec{y} |\widetilde{A}(\vec{x},\vec{y})|^2 \leqslant \|\mathbf{A}\|^2_{\mathcal{HS}}. \tag{77}$$

This shows that $\mathcal{V}: \mathbf{A} \to \widetilde{\mathbf{A}}$ maps $\mathcal{L}_{\mathcal{HS}}$ into $\mathcal{L}_{\mathcal{HS}}$.

(b) Explicit formula with operator valued integral: We notice that

$$(\varphi|\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{y}}^{\dagger}\psi)_{\mathcal{H}}=\int_{\mathbb{R}^3}d^3\vec{q}\;\xi(\vec{q})^2\varphi^*(\vec{q}+\vec{x})\psi(\vec{q}+\vec{y}),\tag{78}$$

and since ξ is radial, we have $\xi(\vec{q})=\xi(-\vec{q})$, so

$$(\varphi|\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{y}}^{\dagger}\psi)_{\mathcal{H}}=\int_{\mathbb{R}^3}d^3\vec{q}\;\xi(\vec{q})^2\varphi^*(\vec{x}-\vec{q})\psi(\vec{y}-\vec{q}).\tag{79}$$

Moreover using the Scharwz inequality we find

$$\int_{\mathbb{R}^3\times\mathbb{R}^3}d^3\vec{x}\,d^3\vec{y}|(\varphi|\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{y}}^{\dagger}\psi)|^2\leqslant\|\varphi\|_{\mathcal{H}}^2\|\psi\|_{\mathcal{H}}^2.\tag{80}$$

So the function $(\vec{x},\vec{y})\to(\varphi|\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{y}}^{\dagger}\psi)$ belongs to $L^2(\mathbb{R}^6)$.

From Eqs. (72), (74), and (79) we find

$$(\varphi|\widetilde{\mathbf{A}}\psi)=\int_{\mathbb{R}^3\times\mathbb{R}^3}d^3\vec{x}\,d^3\vec{y}\,A(\vec{x},\vec{y})(\varphi|\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{y}}^{\dagger}\psi).\tag{81}$$

We deduce that the operator $\widetilde{\mathbf{A}}$ is given by the following operator valued integral (well-defined for Hilbert-Schmidt operators)

$$\widetilde{\mathbf{A}}=\int_{\mathbb{R}^3\times\mathbb{R}^3}d^3\vec{x}\,d^3\vec{y}\,A(\vec{x},\vec{y})\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{y}}^{\dagger}.\tag{82}$$

(c) Correspondence with the bra-ket formalism: When $\mathbf{A}$ belongs to $\mathcal{L}_{\mathcal{HS}}$, $\mathbf{A}$ allows to define a correspondence between the bra-ket symbolic formula and its well-defined mathematical representation,

$$|\vec{x}\rangle\langle\vec{y}|\mapsto\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{y}}^{\dagger},$$

$$\int_{\mathbb{R}^3\times\mathbb{R}^3}d^3\vec{x}\,d^3\vec{y}\,A(\vec{x},\vec{y})|\vec{x}\rangle\langle\vec{y}|\mapsto\widetilde{\mathbf{A}}=\int_{\mathbb{R}^3\times\mathbb{R}^3}d^3\vec{x}\,d^3\vec{y}\,A(\vec{x},\vec{y})\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{y}}^{\dagger}.\tag{83}$$

Moreover if $\mathbf{A}$ is a trace class operator, we have the correspondence

$$\langle\vec{x}|\mathbf{A}|\vec{y}\rangle\to\widetilde{\mathbf{A}}(\vec{x},\vec{y})=\mathrm{Tr}(\mathbf{\Phi}_{\vec{x}}^{\dagger}\mathbf{A}\mathbf{\Phi}_{\vec{y}}).\tag{84}$$

Finally we notice

$$\mathbf{A}=\text{“}|\varphi\rangle\langle\psi|\text{”}\mapsto\widetilde{\mathbf{A}}=\hat{\boldsymbol{\varphi}}\cdot\hat{\boldsymbol{\psi}}^{\dagger}.\tag{85}$$

We will see in the next section how to generalize Eq. (83).

3. The representation of bounded operators and the closure relation

We start from the preceding section with $\mathbf{A}\in\mathcal{L}_{\mathcal{HS}}$. The kernel representation of Eq. (75) gives the following relation for any $\varphi,\psi\in\mathcal{H}$:

$$(\varphi|\widetilde{\mathbf{A}}\psi)=\int_{\mathbb{R}^3}d^3\vec{q}\;\xi(\vec{q})^2(\varphi|\exp[(i/\hbar)\vec{\mathbf{P}}\cdot\vec{q}]\mathbf{A}\exp[-(i/\hbar)\vec{\mathbf{P}}\cdot\vec{q}]\psi).\tag{86}$$

We deduce that for any $\mathbf{A}\in\mathcal{L}_{\mathcal{HS}}$,

$$\widetilde{\mathbf{A}} = \int_{\mathbb{R}^3} d^3\vec{q}\ \xi(\vec{q})^2 \exp[(i/\hbar)\vec{\mathbf{P}}\cdot\vec{q}]\mathbf{A}\exp[-(i/\hbar)\vec{\mathbf{P}}\cdot\vec{q}]. \tag{87}$$

Since ξ is square integrable, this relation can be extended to all bounded operators $\mathbf{A}\in\mathcal{L}_{\mathcal{H}}$. Moreover $\widetilde{\mathbf{A}}\to\mathbf{A}$ if $\xi^2\to\delta$.

Remark: ξ is a radial function, then $\xi(\vec{q})=\xi(-\vec{q})$ and the previous equation becomes

$$\widetilde{\mathbf{A}} = \int_{\mathbb{R}^3} d^3\vec{q}\ \xi(\vec{q})^2 \exp[-(i/\hbar)\vec{\mathbf{P}}\cdot\vec{q}]\mathbf{A}\exp[(i/\hbar)\vec{\mathbf{P}}\cdot\vec{q}]. \tag{88}$$

Now we can explain the relation $\mathrm{Tr}(\hat{\boldsymbol{\varphi}}^\dagger\mathbf{A}\hat{\boldsymbol{\psi}})=(\varphi|\widetilde{\mathbf{A}}\psi)_{\mathcal{H}}$. From Eqs. (87) and (88), we find $\mathrm{Tr}(\widetilde{\mathbf{A}}\mathbf{B})=\mathrm{Tr}(\mathbf{A}\widetilde{\mathbf{B}})$. If we choose $\mathbf{B}=$"$|\psi\rangle\langle\varphi|$," taking into account Eq. (85), we recover $\mathrm{Tr}(\hat{\boldsymbol{\varphi}}^\dagger\mathbf{A}\hat{\boldsymbol{\psi}})=(\varphi|\widetilde{\mathbf{A}}\psi)_{\mathcal{H}}$.

Now, if $\{\phi_n\}$ is an orthonormal basis of $\mathcal{H}$, and if we call π_n the orthogonal projector "$|\phi_n\rangle\langle\phi_n|$," we have the closure relation on $\mathcal{H}$,

$$\sum_{n=0}^{\infty}\pi_n = \mathbf{1}_{\mathcal{H}}, \tag{89}$$

where the limit holds in the weak operator topology.

The mapping $\mathbf{A}\to\widetilde{\mathbf{A}}$ is continuous, so

$$\sum_{n=0}^{\infty}\widetilde{\pi}_n = \widetilde{\mathbf{1}}_{\mathcal{H}} = \mathbf{1}_{\mathcal{H}} \tag{90}$$

in the weak operator topology.

From Eq. (85) we deduce

$$\sum_{n=0}^{\infty}\hat{\phi}_n\hat{\phi}_n^\dagger = \mathbf{1}_{\mathcal{H}}. \tag{91}$$

We recover the symbolic notation $\Sigma_{n=0}^{\infty}|\phi_n\rangle\langle\phi_n| = \mathbf{1}_{\mathcal{H}}$.

This reasoning naturally extends to bounded self-adjoint operators $\mathbf{A}=\Sigma_{n=0}^{\infty}a_n\pi_n$ where $\{a_n\}$ are the (bounded) eigenvalues,

$$\widetilde{\mathbf{A}} = \sum_{n=0}^{\infty}a_n\hat{\phi}_n\hat{\phi}_n^\dagger. \tag{92}$$

But generally $\widetilde{\mathbf{A}}\neq\mathbf{A}$, and the eigenvalues (eigenvectors) of $\widetilde{\mathbf{A}}$ are not a_n (ϕ_n).

The physical meaning of this last result seems obscure, so let us return to quantum axiomatic.

VIII. QUANTUM AXIOMATIC IN THE NEW FRAMEWORK

We summarize in this paragraph the results previously obtained and their connection with quantum axiomatic:

(i) From the usual quantum framework on $\mathcal{H}$, we have developed a new mathematical framework that supports the symbolic manipulations of bras and kets as elements of an algebra of operators.

(ii) A particle must be associated with $\varphi\in\mathcal{H}$ or with $\hat{\boldsymbol{\varphi}}\in\hat{\mathcal{H}}$, and the bra-ket formalism on $\hat{\mathcal{H}}$ possesses a well-defined mathematical representation as seen above [Eqs. (12) and (18)]. Unbounded states are realized as operators that do not belong to $\hat{\mathcal{H}}$.

(iii) Symmetries are represented by unitary operators on $\mathcal{H}$ or by superunitary operators on $\hat{\mathcal{H}}$ [Eq. (45)] and the practical cases of geometrical symmetries and Galilei boosts are given in Eqs. (50) and (54).

(iv) We have a natural method to lift up observables $\mathbf{A}$ as superoperators $\hat{\mathbf{A}}$ [Eq. (59)] such that the symmetric bra-ket notation $\langle\varphi|\mathbf{A}|\psi\rangle$ can be mapped into the well-defined symmetric expression $\mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\mathbf{A}\hat{\boldsymbol{\psi}})$. Furthermore this procedure leads to the definition of a new operator $\tilde{\mathbf{A}}$ on $\mathcal{H}$ such that $\mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\mathbf{A}\hat{\boldsymbol{\psi}})=(\varphi|\tilde{\mathbf{A}}\psi)_{\mathcal{H}}$, where $\tilde{\mathbf{A}}$ possesses a well-defined integral representation [Eqs. (82) and (87)] very similar to the bra-ket expression of $\mathbf{A}$ [Eqs. (83)]. But the eigenvalues and eigenvectors of $\mathbf{A}$ are not those of $\tilde{\mathbf{A}}$.

The physical interpretation: A simple picture of these results can be given if we introduce the idea of two categories of objects in our quantum formalism: "the bare objects" and "the dressed ones." Usual objects introduced by the bra-ket formalism of quantum mechanics are in fact "bare objects" that have to be dressed. A state $\varphi\in\mathcal{H}$ is a bare wave function, while $\hat{\boldsymbol{\varphi}}\in\hat{\mathcal{H}}$ is its dressed version. In the same way, we must think about the definition of all usual quantum observables $\mathbf{A}$ in the bra-ket formalism as being "bare objects" that have to be dressed into new observables $\tilde{\mathbf{A}}$ acting on $\mathcal{H}$ (or superoperators $\hat{\mathbf{A}}$ acting on $\hat{\mathcal{H}}$).

In fact we have a duality of frameworks for physical calculations (expectation values):

(i) On $\hat{\mathcal{H}}$ we must use dressed wave functions $\hat{\boldsymbol{\varphi}}$ to represent states and standard self-adjoint operators $\mathbf{A}$ (bare) for observables, $\langle\mathbf{A}\rangle=\mathrm{Tr}(\hat{\boldsymbol{\varphi}}^{\dagger}\mathbf{A}\hat{\boldsymbol{\varphi}})$. This corresponds to the rigorous form of the symmetric bra-ket notation.

(ii) On $\mathcal{H}$ we must use standard wave functions φ (bare) and dressed observables $\tilde{\mathbf{A}}$: $\langle\mathbf{A}\rangle=(\varphi|\tilde{\mathbf{A}}\varphi)_{\mathcal{H}}$.

This reasoning implies that the physical eigenvalues and eigenvectors are those of $\tilde{\mathbf{A}}$ on $\mathcal{H}$ (or $\hat{\mathbf{A}}$ on $\hat{\mathcal{H}}$).

We obtain the same result differently from the relation $\mathrm{Tr}(\tilde{\mathbf{A}}\mathbf{B})=\mathrm{Tr}(\mathbf{A}\tilde{\mathbf{B}})$ (Sec. VI). Let us assume that $\boldsymbol{\rho}$ is any statistical density operator and $\mathbf{A}$ an observable, usual quantum mechanics says that the expectation value of $\mathbf{A}$ is $\langle\mathbf{A}\rangle=\mathrm{Tr}(\boldsymbol{\rho}\mathbf{A})$. Our formalism says that we must modify this formula according to $\langle\mathbf{A}\rangle=\mathrm{Tr}(\boldsymbol{\rho}\tilde{\mathbf{A}})=\mathrm{Tr}(\tilde{\boldsymbol{\rho}}\mathbf{A})$. Moreover $\tilde{\boldsymbol{\rho}}$ also is a density operator (for a pure state φ, $\tilde{\boldsymbol{\rho}}=\hat{\boldsymbol{\varphi}}\hat{\boldsymbol{\varphi}}^{\dagger}$) and $\tilde{\mathbf{A}}$ is an observable. So, with purely mathematical arguments, we cannot choose between the modification of $\boldsymbol{\rho}$ and the modification of $\mathbf{A}$. But this is not true on the physical level, because the mapping $\boldsymbol{\rho}\rightarrow\tilde{\boldsymbol{\rho}}$ is not "onto:" $\tilde{\boldsymbol{\rho}}$ cannot be a pure state ($\hat{\boldsymbol{\varphi}}\hat{\boldsymbol{\varphi}}^{\dagger}$ is not a projector). If we say that the physical observable is $\mathbf{A}$, then the particle can never be in a pure state: this is a too strong modification. If we say that the physical observable is $\tilde{\mathbf{A}}$, of course the "bare" observable $\mathbf{A}$ is possibly modified, but all statistical properties of usual quantum mechanics are preserved.

The physical meaning of the dressing function: Let us start with an observable $\mathbf{A}$ and a density operator $\boldsymbol{\rho}$ defined with the bra-ket formalism. From the previous paragraph the usual formula for expectation value must be modified according to $\langle\mathbf{A}\rangle=\mathrm{Tr}(\boldsymbol{\rho}\tilde{\mathbf{A}})=\mathrm{Tr}(\tilde{\boldsymbol{\rho}}\mathbf{A})$, and the symmetry $\mathrm{Tr}(\boldsymbol{\rho}\tilde{\mathbf{A}})=\mathrm{Tr}(\tilde{\boldsymbol{\rho}}\mathbf{A})$ allows us to preserve the set of all possible densities (and then the Hilbert space structure) by choosing to change $\mathbf{A}$ in $\tilde{\mathbf{A}}$. However, this choice could be a simple technical trick that allows us to bypass a supplementary difficulty (the disappearance of pure states), while preventing us to see the real physical meaning of the transformation $\boldsymbol{\rho}\rightarrow\tilde{\boldsymbol{\rho}}$. So let us analyze what kind of physical process can produce this modification. In fact since $\tilde{\boldsymbol{\rho}}$ is a true density operator, there exists a unique well-known process: a *decoherence* one. Furthermore if the transformation $\boldsymbol{\rho}\rightarrow\tilde{\boldsymbol{\rho}}$ is real, it must be applied in all circumstances; this means that we are looking for an *intrinsic decoherence process*. Of course we cannot find the origin of such a phenomenon in the framework of nonrelativistic quantum mechanics, but an explanation exists in the framework of quantum field theory.

We know that any particle (quantum field) possesses at least one way to interact with other ones and this interaction is described by a coupling with another quantum field. So the complete quantum description of a free particle is in fact some intricate state that describes the degrees of freedom of the particle and the vacuum of some associated quantum field. Looking at the degrees of freedom of the particle (and only them) is obtained by some partial trace on the degrees of freedom of the quantum field, and this corresponds to a decoherence process. The decoherence is intrinsic in the sense that the coupling with an external quantum field is intrinsic. Moreover since field interactions always take place in space-time (and not in momentum space), we can understand that this decoherence effect essentially acts on the position operator and then on the states $|\vec{q}\rangle$. Of course this effect cannot be measured in the framework of nonrelativistic quantum mechanics, but this does not mean that the mathematical structure of the theory is not sensitive to this effect. This is exactly what we find through the dressing function ξ that introduces some length scale λ: λ can be as small as you want but it cannot be removed everywhere in the formalism. In fact the limit $\lambda \to 0$ is only possible for the computation of expectation values, because these quantities are in fact weighted integrals depending on the function ξ^2 (ξ^2 is similar to a point spread function). The limit $\lambda \to 0$ corresponds to $\xi^2 \to \delta$.

In conclusion, the dressing function ξ can be related to some decoherence effect that transforms bare operators into dressed ones; but thanks to the symmetry $\langle \mathbf{A} \rangle = \mathrm{Tr}(\boldsymbol{\rho}\widetilde{\mathbf{A}}) = \mathrm{Tr}(\tilde{\boldsymbol{\rho}}\mathbf{A})$ we can preserve the Hilbert space structure by modifying observables (dressed observables) rather than densities.

The following section analyzes the effect of the dressing function on the position operator.

IX. THE POSITION OPERATOR

A. The projection valued measure

The projection valued measure (pvm) associated with the quantum operator $\vec{\mathbf{Q}}$ of position is given by the family of orthogonal projectors $\{\chi_A(\vec{\mathbf{Q}})\}_{A \in \mathcal{B}(\mathbb{R}^3)}$ [where $\mathcal{B}(\mathbb{R}^3)$ is the family of Borel sets and χ_A is characteristic function of A].

Computing $(\hat{\boldsymbol{\varphi}}|\chi_A(\vec{\mathbf{Q}})\hat{\boldsymbol{\psi}})_{\mathcal{HS}} = \mathrm{Tr}(\hat{\boldsymbol{\varphi}}^\dagger \chi_A(\vec{\mathbf{Q}})\hat{\boldsymbol{\psi}})$ with the kernel method previously seen, we obtain

$$(\hat{\boldsymbol{\varphi}}|\chi_A(\vec{\mathbf{Q}})\hat{\boldsymbol{\psi}})_{\mathrm{HS}} = \int_{\mathbb{R}^3} d^3\vec{q}\ \varphi^*(\vec{q})\psi(\vec{q}) \int_{\mathbb{R}^3} d^3\vec{x}\ \chi_A(\vec{x})\xi(\vec{q}-\vec{x})^2. \tag{93}$$

We deduce that the operator $\widetilde{\chi_A(\vec{\mathbf{Q}})}$ is given by

$$\widetilde{\chi_A(\vec{\mathbf{Q}})} = F_A(\vec{\mathbf{Q}}),$$

$$F_A(\vec{q}) = \int_A d^3\vec{x}\ \xi(\vec{q}-\vec{x})^2. \tag{94}$$

But using Eqs. (93) and (79) we also find

$$(\hat{\boldsymbol{\varphi}}|\chi_A(\vec{\mathbf{Q}})\hat{\boldsymbol{\psi}})_{\mathcal{HS}} = \int_{\mathbb{R}^3} d^3\vec{x}\ \chi_A(\vec{x})(\varphi|\boldsymbol{\Phi}_{\vec{x}}\boldsymbol{\Phi}_{\vec{x}}^\dagger\psi)_{\mathcal{H}}. \tag{95}$$

So

$$\widetilde{\chi_A(\vec{\mathbf{Q}})} = \int_A d^3\vec{x}\, \mathbf{\Phi}_{\vec{x}} \mathbf{\Phi}_{\vec{x}}^\dagger. \tag{96}$$

Moreover $\chi_{\mathbf{R}^3}(\vec{\mathbf{Q}}) = \mathbf{1}$ and $(\hat{\boldsymbol{\varphi}}|\hat{\boldsymbol{\psi}})_{\mathcal{HS}} = (\varphi|\psi)_{\mathcal{H}}$, so

$$\widetilde{\mathbf{1}}_{\mathcal{H}} = \mathbf{1}_{\mathcal{H}} = \int_{\mathbb{R}^3} d^3\vec{x}\, \mathbf{\Phi}_{\vec{x}} \mathbf{\Phi}_{\vec{x}}^\dagger. \tag{97}$$

We deduce that the family of operators $\{\widetilde{\chi_A(\vec{\mathbf{Q}})}\}_{A \in \mathcal{B}(\mathbb{R}^3)}$ corresponds to a positive operator valued measure (pov). This pov is used in different works of Prugovečki.[9,12] Moreover these studies show that the mathematical field ξ must be interpreted as the "proper wave function" of the particle (the particle cannot be pointlike). This idea was previously introduced by Landé[13] and Born.[14]

B. Related operators

From functional calculus, we can generalize the previous result to a real bounded or unbounded function of $\vec{\mathbf{Q}}$ as

$$\widetilde{F(\vec{\mathbf{Q}})} = \int_{\mathbb{R}^3} d^3\vec{x}\, F(\vec{x}) \mathbf{\Phi}_{\vec{x}} \mathbf{\Phi}_{\vec{x}}^\dagger,$$

$$\widetilde{F(\vec{\mathbf{Q}})} = \widetilde{F}(\vec{\mathbf{Q}}),$$

$$\widetilde{F}(\vec{q}) = \int_{\mathbb{R}^3} d^3\vec{x}\, \xi(\vec{q} - \vec{x})^2 F(\vec{x}). \tag{98}$$

In the particular case $F(\vec{x}) = \vec{x}$, we have

$$\widetilde{F}(\vec{q}) = \int_{\mathbb{R}^3} d^3\vec{x}\, \xi(\vec{x})^2 (\vec{x} + \vec{q}). \tag{99}$$

Since ξ is a (normalized) radial function, ξ is even, so

$$\widetilde{F}(\vec{q}) = \vec{q}. \tag{100}$$

We deduce

$$\widetilde{\vec{\mathbf{Q}}} = \vec{\mathbf{Q}} = \int_{\mathbb{R}^3} d^3\vec{x}\, \vec{x} \mathbf{\Phi}_{\vec{x}} \mathbf{\Phi}_{\vec{x}}^\dagger. \tag{101}$$

We see that the well-defined bounded operator $\mathbf{\Phi}_{\vec{x}} \mathbf{\Phi}_{\vec{x}}^\dagger = \xi(\vec{\mathbf{Q}} - \vec{x})^2$ represents the symbolic expression $|\vec{x}\rangle\langle\vec{x}|$ used in the bra-ket formalism. Moreover the Eq. (101) shows that the observable $\vec{\mathbf{Q}}$ is unchanged in our framework.

Furthermore, the expression $|\vec{x}\rangle\langle\vec{x}| = \delta(\vec{\mathbf{Q}} - \vec{x})$ corresponds to the "density operator" (or the probability density). So we find that $\mathbf{\Phi}_{\vec{x}} \mathbf{\Phi}_{\vec{x}}^\dagger = \delta_{\vec{x}}(\vec{\mathbf{Q}})$ is the mathematically well-defined observable (dressed operator) associated with the probability density. This interpretation is consistent with the fact that $\int_{\mathbb{R}^3} d^3\vec{x} (\varphi|\mathbf{\Phi}_{\vec{x}} \mathbf{\Phi}_{\vec{x}}^\dagger \varphi)_{\mathcal{H}} = 1$ if φ is a normalized vector of $\mathcal{H}$. Moreover since $(\varphi|\mathbf{\Phi}_{\vec{x}} \mathbf{\Phi}_{\vec{x}}^\dagger \varphi)_{\mathcal{H}} = ||\mathbf{\Phi}_{\vec{x}}^\dagger(\varphi)||_{\mathcal{H}}^2 \leqslant ||\xi||_\infty^2$ [Eq. (4)], we see that the probability density is always bounded; then the particle cannot be localized "at the point $\vec{x}$." A punctual localization corresponds to the limit $\xi(\vec{x})^2 \to \delta(\vec{x})$.

Finally, if $(\varphi|\mathbf{\Phi}_{\vec{x}}\mathbf{\Phi}_{\vec{x}}^{\dagger}\varphi)_{\mathcal{H}}$ is the effective probability density, it is natural to say that $(\varphi|\mathbf{\Phi}_{\vec{x}}\varphi)_{\mathcal{H}}$ is the "wave function expectation value," and then we recover that $\mathbf{\Phi}_{\vec{x}}$ is the "wave function operator." We also remark that the expression of the density operator is formally the same in second quantization. Of course all this reasoning cannot be induced from usual quantum mechanical axioms.

X. THE MOMENTUM OPERATOR

We are interested in the family of operators $\{\chi_A(\vec{\mathbf{P}})\}_{A\in\mathcal{B}(\mathbb{R}^3)}$. Using Eq. (87) and the normalization of ξ we find

$$\widetilde{\chi_A(\vec{\mathbf{P}})} = \chi_A(\vec{\mathbf{P}}). \tag{102}$$

By extension, this equation remains valid for any Borel function f,

$$\widetilde{f(\vec{\mathbf{P}})} = f(\vec{\mathbf{P}}). \tag{103}$$

This last result can be reformulated on $\hat{\mathcal{H}}$ as

$$\forall\,\varphi\in\mathcal{H},\quad \widehat{f(\vec{\mathbf{P}})}(\hat{\varphi}) = f(\vec{\mathbf{P}})\cdot\hat{\varphi}. \tag{104}$$

Now using Eq. (33), we find that the unbounded kets $\hat{\boldsymbol{\phi}}_{\vec{k}}$ are the eigenstates of $\vec{\mathbf{P}}$,

$$\vec{\mathbf{P}}\hat{\boldsymbol{\phi}}_{\vec{k}} = \hbar\,\vec{k}\hat{\boldsymbol{\phi}}_{\vec{k}}. \tag{105}$$

Moreover if φ and ψ are two C^{∞} functions of rapid decrease $(\varphi|\,\hat{\boldsymbol{\phi}}_{\vec{k}}\hat{\boldsymbol{\phi}}_{\vec{k}}^{\dagger}\psi)$ is well-defined and we have

$$\int_{\mathbb{R}^3}\frac{d^3\vec{k}}{(2\pi)^3}(\varphi|\,\hat{\boldsymbol{\phi}}_{\vec{k}}\hat{\boldsymbol{\phi}}_{\vec{k}}^{\dagger}\psi) = (\varphi|\psi) \tag{106}$$

and

$$\int_{\mathbb{R}^3}\frac{d^3\vec{k}}{(2\pi)^3}\,\hbar\,\vec{k}(\varphi|\,\hat{\boldsymbol{\phi}}_{\vec{k}}\hat{\boldsymbol{\phi}}_{\vec{k}}^{\dagger}\psi) = (\varphi|\vec{\mathbf{P}}\psi). \tag{107}$$

In fact $\hat{\boldsymbol{\phi}}_{\vec{k}}\hat{\boldsymbol{\phi}}_{\vec{k}}^{\dagger}$ is the distribution $2\pi\hbar\,\delta(\vec{\mathbf{P}}-\hbar\vec{\mathbf{k}})$ corresponding to $|\vec{k}\rangle\langle\vec{k}|$. In Foias's approach[8] these distributions are the eigenoperators of $\vec{\mathbf{P}}$ and Eq. (106) represents the spectral decomposition of the space of C^{∞} functions of rapid decrease. But in our formalism the true eigenoperators (eigenstates) are the $\hat{\boldsymbol{\phi}}_{\vec{k}}$ in agreement with the bra-ket formalism. The dressing function ξ explains this difference. In terms of distributions, we can write $\hat{\boldsymbol{\phi}}_{\vec{k}}=2\pi\hbar\,\delta(\vec{\mathbf{P}}-\hbar\vec{\mathbf{k}})\xi(\vec{\mathbf{Q}})$ or $\hat{\boldsymbol{\phi}}_{\vec{k}}=|\vec{k}\rangle\langle\vec{k}|\,\xi(\vec{\mathbf{Q}})$ and then $\hat{\boldsymbol{\phi}}_{\vec{k}}\hat{\boldsymbol{\phi}}_{\vec{k}}^{\dagger}=2\pi\hbar\,\delta(\vec{\mathbf{P}}-\hbar\vec{\mathbf{k}})F(\vec{\mathbf{k}})$ with $F(\vec{\mathbf{k}})=\langle\vec{k}|\,\xi(\vec{\mathbf{Q}})^2\,|\vec{k}\rangle$. But the normalization of ξ gives $F(\vec{\mathbf{k}})=1$ and then $\hat{\boldsymbol{\phi}}_{\vec{k}}\hat{\boldsymbol{\phi}}_{\vec{k}}^{\dagger}=2\pi\hbar\,\delta(\vec{\mathbf{P}}-\hbar\vec{\mathbf{k}})$. So the dressing function allows us to define some "square root" of the distribution $\delta(\vec{\mathbf{P}}-\hbar\vec{\mathbf{k}})$ that gives the true eigenstates of $\vec{\mathbf{P}}$ corresponding to the bra-ket formula.

XI. LOCAL OBSERVABLES

We have shown that the probability density is $\boldsymbol{\rho}_{\vec{q}}=\mathbf{\Phi}_{\vec{q}}\mathbf{\Phi}_{\vec{q}}^{\dagger}$. Now we are interested in the current density.

Let us call $\mathcal{S}$ the dense subset of $\mathcal{H}$ of C^∞ functions of rapid decrease. The operators $\mathbf{\Phi}_{\vec{q}}$ and $\mathbf{\Phi}^\dagger_{\vec{q}}$ map $\mathcal{S}$ into $\mathcal{S}$, and the unbounded operators $\partial_{\vec{q}}\mathbf{\Phi}_{\vec{q}}$ and $\partial_{\vec{q}}\mathbf{\Phi}^\dagger_{\vec{q}}$ are defined on $\mathcal{S}$,

$$-i\hbar\,\partial_{\vec{q}}\mathbf{\Phi}^\dagger_{\vec{q}} = \mathbf{\Phi}^\dagger_{\vec{q}}\vec{\mathbf{P}},$$

$$i\hbar\,\partial_{\vec{q}}\mathbf{\Phi}_{\vec{q}} = \vec{\mathbf{P}}\mathbf{\Phi}_{\vec{q}}. \tag{108}$$

Using Eq. (97) we deduce that

$$\vec{\mathbf{P}} = \int_{\mathbb{R}^3} d^3\vec{q}\;\mathbf{\Phi}_{\vec{q}}(-i\hbar\,\partial_{\vec{q}}\mathbf{\Phi}^\dagger_{\vec{q}}) = \int_{\mathbb{R}^3} d^3\vec{q}(i\hbar\,\partial_{\vec{q}}\mathbf{\Phi}_{\vec{q}})\mathbf{\Phi}^\dagger_{\vec{q}}. \tag{109}$$

The same arguments show that

$$\vec{\mathbf{P}}^2 = \int_{\mathbb{R}^3} d^3\vec{q}\;\mathbf{\Phi}_{\vec{q}}(-\hbar^2\Delta_{\vec{q}}\mathbf{\Phi}^\dagger_{\vec{q}}) = \int_{\mathbb{R}^3} d^3\vec{q}(-\hbar^2\Delta_{\vec{q}}\mathbf{\Phi}_{\vec{q}})\mathbf{\Phi}^\dagger_{\vec{q}}. \tag{110}$$

(where $\Delta_{\vec{q}}$ is the Laplacian), or in a symmetric form

$$\vec{\mathbf{P}}^2 = \int_{\mathbb{R}^3} d^3\vec{q}\;\hbar^2(\partial_{\vec{q}}\mathbf{\Phi}_{\vec{q}})\cdot(\partial_{\vec{q}}\mathbf{\Phi}^\dagger_{\vec{q}}). \tag{111}$$

Moreover, starting from Eq. (109) and if we call m the mass of the particle, we can define the local (unbounded) observable of current density $\vec{\mathbf{J}}(\vec{q})$ as

$$\vec{\mathbf{J}}(\vec{q}) = \frac{i\hbar}{2m}((\partial_{\vec{q}}\mathbf{\Phi}_{\vec{q}})\mathbf{\Phi}^\dagger_{\vec{q}} - \mathbf{\Phi}_{\vec{q}}(\partial_{\vec{q}}\mathbf{\Phi}^\dagger_{\vec{q}})). \tag{112}$$

From Eq. (108) we find

$$\vec{\mathbf{J}}(\vec{q}) = \frac{1}{2m}(\mathbf{\Phi}_{\vec{q}}\mathbf{\Phi}^\dagger_{\vec{q}}\vec{\mathbf{P}} + \vec{\mathbf{P}}\mathbf{\Phi}_{\vec{q}}\mathbf{\Phi}^\dagger_{\vec{q}}) \tag{113}$$

and

$$\vec{\mathbf{P}} = m\int_{\mathbb{R}^3} d^3\vec{q}\;\vec{\mathbf{J}}(\vec{q}). \tag{114}$$

We recover in formula (109) and (112) the expressions used in second quantization, $\mathbf{\Phi}^\dagger_{\vec{q}}$ being the wave function operator. This parallel leads us to study the integral $m\int d^3\vec{q}\;\vec{q}\wedge\vec{\mathbf{J}}(\vec{q})$ that usually gives the field angular momentum. Using Eqs. (113) and (101) we find

$$m\int_{\mathbb{R}^3} d^3\vec{q}\;\vec{q}\wedge\vec{\mathbf{J}}\cdot(\vec{q}) = \vec{\mathbf{Q}}\wedge\vec{\mathbf{P}} = \vec{\mathbf{L}}. \tag{115}$$

So the observable of angular momentum $\vec{\mathbf{L}}$ is really obtained as in second quantization. Moreover we can verify that $\vec{\mathbf{L}} = \vec{\mathbf{L}}$.

These definitions of local observables for one particle can be also found in Prugovečki's monograph,[9] but they are not build with this formalism.

XII. THE SCHRÖDINGER EQUATION

A. The evolution operator

The evolution with time of a vector $\varphi \in \mathcal{H}$ is given by $\varphi(t)=\mathbf{U}_t(\varphi_0)$ where $\mathbf{U}_t$ is the unitary operator $\mathbf{U}_t=\exp(-(i/\hbar)\mathbf{H}t)$, where $\mathbf{H}$ is the standard quantum Hamiltonian. So the evolution on $\mathcal{H}$ is naturally defined as $\hat{\boldsymbol{\varphi}}(t)=\widehat{\varphi(t)}$. This implies that $\mathbf{U}_t$ must be lifted up into the superunitary operator $\mathbf{U}_t^{(S)}$ acting on $\hat{\mathcal{H}}$ as defined in Sec. VII A 1

$$\hat{\boldsymbol{\varphi}}(t) = \mathbf{U}_t^{(S)}(\hat{\boldsymbol{\varphi}}_0) = \widehat{\mathbf{U}_t(\varphi_0)}. \tag{116}$$

Furthermore, the standard quantum Hamiltonian $\mathbf{H}$ is a physical observable, so following our general point of view $\mathbf{H}$ "has to be dressed" into $\widetilde{\mathbf{H}}$ that represents the "true" physical observable on $\mathcal{H}$. Consequently, if the true physical observable is $\widetilde{\mathbf{H}}$, we must use $\widetilde{\mathbf{H}}$ and not $\mathbf{H}$ into the definition of $\mathbf{U}_t$, so we define in fact

$$\mathbf{U}_t = \exp(-(i/\hbar)\widetilde{\mathbf{H}}t), \tag{117}$$

where $\mathbf{H}$ is the standard Hamiltonian; $\hat{\boldsymbol{\varphi}}(t)$ is defined as in Eq. (116). Now, from Eq. (70), we deduce that

$$\mathbf{U}_t^{(S)} = \exp(-(i/\hbar)\hat{\mathbf{H}}t). \tag{118}$$

B. The Schrödinger equation

On the dense subset $\mathcal{S}$ of functions of rapid decrease, Eqs. (116) and (118) lead to the Schrödinger equation,

$$i\hbar\frac{\partial\hat{\boldsymbol{\varphi}}}{\partial t} = \hat{\mathbf{H}}(\hat{\boldsymbol{\varphi}}) = \widetilde{H(\vec{\varphi})}. \tag{119}$$

C. The free particle

The standard Hamiltonian is $\mathbf{H}_0=\vec{\mathbf{P}}^2/2m$ and from Eq. (103) we know that $\widetilde{\mathbf{H}}_0=\mathbf{H}_0$ because $\mathbf{H}_0$ only depends on $\vec{\mathbf{P}}$. Moreover using Eqs. (110) and (111) we find

$$\widetilde{\mathbf{H}}_0 = \mathbf{H}_0 = \int_{\mathbb{R}^3} d^3\vec{q}\,\boldsymbol{\Phi}_{\vec{q}}\left(-\frac{\hbar^2}{2m}\Delta_{\vec{q}}\,\boldsymbol{\Phi}_{\vec{q}}^{\dagger}\right) = \frac{\hbar^2}{2m}\int_{\mathbb{R}^3} d^3\vec{q}(\partial_{\vec{q}}\,\boldsymbol{\Phi}_{\vec{q}})\cdot(\partial_{\vec{q}}\,\boldsymbol{\Phi}_{\vec{q}}^{\dagger}), \tag{120}$$

and we formally recover the expression used in second quantization.

Furthermore, always from Eq. (103), the superunitary operator $\mathbf{U}_t^{(S)}$ acts on $\hat{\mathcal{H}}$ as

$$\mathbf{U}_t^{(S)}(\hat{\boldsymbol{\varphi}}) = \mathbf{U}_t\hat{\boldsymbol{\varphi}},$$

$$\mathbf{U}_t = \exp((-i/\hbar)\mathbf{H}_0t). \tag{121}$$

Remark: The observables that generate the Galilei group $(\vec{\mathbf{Q}},\vec{\mathbf{P}},\vec{\mathbf{L}},\mathbf{H}_0)$ verify $\mathbf{A}=\mathbf{A}$. Then the dressing function ξ introduces no modification of quantum equations for the natural observables of the free particle.

XIII. CONCLUSION

This procedure shows how the definition of a dressing function ξ for a particle and the associated wave function operator $\boldsymbol{\Phi}_{\vec{q}}$, can be related to a rigorous development of the bra-ket formalism. Moreover we show that the new quantum framework contains "bare" and "dressed"

quantities and we find that local observables are now well defined, while these objects are singular in the usual quantum context. Finally the function ξ can be seen as a perturbative effect that "regularizes" the bra-ket formalism in such a way that all standard formula correspond to the limit $\xi^2 \to \delta$.

(Received 15 November 2005; accepted 5 January 2006; published online 27 February 2006)

Large-order behavior for the perturbation energies of the hydrogen atom in magnetic field is derived. By means of the dispersion relations, the large-order behavior of the series is determined by calculating the lifetime of the quasistationary states in an imaginary magnetic field. This problem is treated by means of the modified multidimensional WKB method. The asymptotic formula for the perturbation energies derived by Avron is generalized to the states with an arbitrary degeneracy. The first order correction to the resulting formula is also found. Thus, the multidimensional WKB method is for the first time explicitly carried out beyond the leading approximation. The analytical results are verified numerically and an excellent agreement between the two is found. The connection between our and conventional semiclassical approximation is also briefly discussed. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2168689]

I. INTRODUCTION

The problem of the hydrogen atom in the magnetic field is elementary but difficult and great deal of effort has been devoted to its solution over the years (see, e.g., Refs. 1–21and references given therein). Except for its own importance, it has been used as a relatively simple problem to answer some more general questions, as for example determination of the large-order behavior of the perturbation energies and related problem of the multidimensional WKB approximation,[1,3,4] summation of the divergent perturbation series,[2,7,21] application of the perturbation theory in the degenerate case,[8] determination of the lower bounds to the eigenvalues[9,14] and so on.

In this paper, we are interested in the problem of the hydrogen atom in magnetic field mainly from the point of view of the multidimensional WKB approximation and related problem of the asymptotic behavior of the corresponding divergent perturbation series. The multidimensional WKB method is important in many areas of physics ranging from the theory of chemical reactions to cosmology, for review see Ref. 22. Knowledge of the large-order behavior of the divergent perturbation series can be used in the summation of the series[1,2,21,23] and checking correctness of calculated perturbation energies. The latter application is especially important when treating the degenerate states where the perturbation theory is difficult to apply.

Schrödinger equation for the hydrogen atom in a constant magnetic field $\vec{B}=(0,0,B)$ with fixed nucleus and neglecting the spin effects reads

$$\left[-\frac{\nabla^2}{2}-\frac{1}{r}+\frac{BL_z}{2}+\frac{B^2}{8}(x^2+y^2)\right]\psi=E\psi, \tag{1}$$

where the atomic units are used. The Hamiltonian commutes with the projection of the angular momentum operator $\vec{L}$ onto the direction of the magnetic field and with the parity operator. In the following, we shall restrict ourselves to the states of the zero projection of the angular momentum onto the z axis and even parity.

The energy E has the following perturbation expansion:

$$E = \sum_{n=0}^{\infty} E_n \left(\frac{B^2}{8} \right)^n . \tag{2}$$

This perturbation series is divergent. The reason is that the energy E is not an analytic function in the vicinity of point $B=0$. This can be understood as follows. We consider analytic continuation of the energy E for complex magnetic fields $E=E(B^2)$. In the upper half of the complex plane we take $B^2=|B^2|e^{i\ \arg(B^2)}$ and in the lower half of the complex plane we take $B^2=|B^2|e^{-i\ \arg(B^2)}$, $\arg(B^2) \in (0,\pi)$. For real magnetic fields, Eq. (1) is solved with the boundary condition $\psi(\rho \to \infty) \to e^{-(B^2/8)^{1/2}\rho^2}$, where $\rho^2=x^2+y^2$. For complex magnetic fields, Eq. (1) is solved with the analytic continuation of this boundary condition. Now, approaching the value $-|B^2|$ from the upper half of the complex plane leads to the boundary condition $\psi(\rho \to \infty) \to e^{-i|B^2/8|^{1/2}\rho^2}$,while approaching this value from the lower half of the complex plane leads to the boundary condition $\psi(\rho \to \infty) \to e^{+i|B^2/8|^{1/2}\rho^2}$. These different boundary conditions yield different signs of the imaginary part of the energy $\Im[E(B^2)]$. Therefore, the energy E has for real negative values of B^2 the discontinuity $2i\Im[E(-|B^2|+i\varepsilon)]$, $\varepsilon>0$. Using Cauchy theorem one can show that the perturbation energies E_n are related to the imaginary part of the energy for the imaginary values of the magnetic fields via the dispersion relation[1,24–26]

$$E_n = \frac{(-1)^{n+1}(2N^2)^n}{\pi} \int_0^{\infty} \mathrm{d}\lambda \frac{\Im[E(\lambda)]}{\lambda^{n+1}}, \tag{3}$$

where a new coupling constant λ has been introduced via equation

$$\frac{B^2}{8} = -\frac{\lambda}{2N^2}. \tag{4}$$

Here, $N=1,2,3,\ldots$ denotes the principal quantum number of the hydrogen atom. The imaginary part of the energy is one-half of the inverse lifetime of the quasistationary states in the potential in Eq. (1) with the imaginary magnetic field B.

It is seen from Eq. (3) that the behavior of the perturbation energies E_n for very large n is given by the lifetime of the quasistationary states for small values of the coupling constant λ. Thus, provided we are able to calculate this lifetime, Eq. (3) enables precise determination of the degree of the divergence of the series (2).

Expression for the imaginary part of the energy can be derived as follows. First, since Eq. (1) has an axial symmetry we introduce the cylindric coordinates $x=\rho\cos\varphi$, $y=\rho\sin\varphi$, $z=z$. Since the states with the zero projection of the angular momentum are independent of the coordinate φ, Eq. (1) reads

$$\left[\frac{\partial^2}{\partial\rho^2} + \frac{1}{\rho}\frac{\partial}{\partial\rho} + \frac{\partial^2}{\partial z^2} \right] \psi = [V(\rho,z) - 2E]\psi, \tag{5}$$

where

$$V(\rho,z) = -\frac{2}{(\rho^2+z^2)^{1/2}} - \frac{\lambda}{N^2}\rho^2. \tag{6}$$

Equation (5) is solved with the boundary condition $\psi(\rho \to \infty) \to e^{-i\lambda^{1/2}\rho^2/N}$. Further, we multiply Eq. (5) by $\rho\psi^*$. We take complex conjugate of Eq. (5) and multiply it by $\rho\psi$. Then we subtract the two equations and integrate the resulting equation over the whole space, i.e., over z from $-\infty$ to ∞ and over ρ from 0 to ∞. Finally, we integrate this equation by parts and obtain the time-independent version of the continuity equation for the probability density

$$\Im[E] = \frac{J}{2\langle\psi|\psi\rangle}, \tag{7}$$

where the probability flux J in the ρ direction equals

$$J = -\frac{1}{2i}\int_{-\infty}^{\infty} \mathrm{d}z \lim_{\rho\to\infty}\rho\left[\psi^*\frac{\partial}{\partial\rho}\psi - \psi\frac{\partial}{\partial\rho}\psi^*\right] \tag{8}$$

and the norm of the wave function reads

$$\langle\psi|\psi\rangle = \int_0^{\infty}\mathrm{d}\rho\int_{-\infty}^{\infty}\mathrm{d}z\,\rho|\psi|^2. \tag{9}$$

To calculate the imaginary part of the energy from Eq. (7) we proceed as follows.[24] Inside the potential well, we approximate the wave function by means of the Rayleigh-Schrödinger perturbation theory (RSPT). Since the dominant contribution to the norm of the wave function describing the quasistationary state comes from the interior of the well we replace the exact wave function in the denominator of Eq. (7) by the perturbation wave function. In the tunneling region and outside the potential well we approximate the wave function by the WKB wave function. Since the dominant contribution to the probability current comes from the tunneling, classically forbidden region we replace the exact wave function in Eq. (8) by the WKB wave function. The same normalization of the RSPT and the WKB wave functions is guaranteed by the asymptotic matching of these functions in the overlap region of their mutual validity.

The main obstacle in carrying out the program described above is the construction of the WKB wave function. The standard formulation of the WKB approximation as applied to Eq. (5) leads to the nonseparable nonlinear partial differential equation that is difficult to solve.

The simplification of the problem used here comes out from the fact that the tunneling of the particle takes place in the neighborhood of the line $z=0$, see Eq. (5). Consequently, we do not need to know the wave function in all space, but only in the neighborhood of this line. The situation is further greatly simplified by the fact that the minimum of the potential is the straight line (compare it with the case of the curved lines[27,28]). This simplification was for the first time realized in Ref. 29 for the problem of the coupled oscillators and later used in Ref. 1 to derive the imaginary part of the energy in Eq. (5) at the leading approximation. However, it seems that the full content of the simplification was not appreciated so far. Indeed, none from the multidimensional WKB calculations for the straight escape paths performed so far[1,4,29,30] shows how to extend the calculation beyond the leading approximation.

In this paper we show how the WKB wave function for Eq. (5) and the outgoing probability flux can be obtained to the desired accuracy. Our method is not bound to the problem considered here and with appropriate modifications it can be extended to all problems involving multidimensional tunneling along the straight escape paths.

The paper is organized as follows. In Sec. II the modified multidimensional WKB method is suggested and used to calculate the outgoing probability flux, Eq. (8), with accuracy to the order $\lambda^{1/2}$. In Sec. III the calculation of the perturbation energies in Eq. (2) is described. The perturbation wave function is used to calculate the norm of the wave function (9). In Sec. IV the results of the preceding two sections are put together and inserted into Eq. (3) to get the asymptotics of the perturbation energies. Numerical verification of the derived formula is made and an excellent agreement between the analytical and numerical calculation is found. In the Conclusions the perspectives of further applications of the proposed WKB approximation are briefly outlined. In the Appendix the connection between the suggested and conventional WKB method is discussed.

II. WKB METHOD

There are two facts stressed in the next two paragraphs that simplify the calculations enormously and that were not explicitly realized so far. The first one is the approximation of the wave function in the coordinate z by the wave function of the anharmonic oscillator, Eq. (11). The second one is the scaling in the coordinate ρ, Eq. (15).

A. Approximation of the wave function in the transversal direction

First, in the vicinity of the ρ axis the potential $V(\rho,z)$ given by Eq. (6) can be expanded as

$$V(\rho,z) = V_0(\rho) + V_2(\rho)z^2 + V_4(\rho)z^4 + \cdots . \tag{10}$$

Then, the wave function of the particle in the direction transversal to tunneling can be written as

$$\psi(\rho,z) = e^{f(\rho)+h(\rho)z^2+q(\rho)z^4+\cdots} . \tag{11}$$

Physically, this says nothing else than close to the minimum of the potential in the direction perpendicular to tunneling we can approximate the exact wave function by the wave function of the harmonic oscillator. This approximation can be further improved by considering anharmonic terms.

Inserting the expansions (10) and (11) into Eq. (5) and comparing the terms of the same order of z we get

$$f'(\rho)^2 + f''(\rho) + \frac{f'(\rho)}{\rho} + 2h(\rho) = -2E - \frac{\lambda}{N^2}\rho^2 - \frac{2}{\rho} \tag{12}$$

at the zeroth order,

$$2f'(\rho)h'(\rho) + h''(\rho) + \frac{h'(\rho)}{\rho} + 4h(\rho)^2 + 12q(\rho) = \frac{1}{\rho^3} \tag{13}$$

at the second order and

$$2f'(\rho)q'(\rho) + h'(\rho)^2 + q''(\rho) + \frac{q'(\rho)}{\rho} + 16h(\rho)q(\rho) = -\frac{3}{4\rho^5} \tag{14}$$

at the fourth order of z. Here, the prime denotes the differentiation with respect to ρ.

B. Approximation of the wave function in the longitudinal direction

Second, in the direction of the tunneling we approximate the wave function as follows. In the classically forbidden region the terms $-2E_0$ and $-(\lambda/N^2)\rho^2$ are of the same order of magnitude.[31] To make these terms of the same order in λ we make the scaling in the coordinate ρ,

$$\rho = \lambda^{-1/2}u, \tag{15}$$

and expand the real part of the energy in the series (2). Equations (12)–(14) then read

$$\lambda\left(f'(u)^2 + f''(u) + \frac{f'(u)}{u}\right) + 2h = \frac{1-u^2}{N^2} - \frac{2\lambda^{1/2}}{u} - 2\sum_{n=1}^{\infty} E_n\left(-\frac{\lambda}{2N^2}\right)^n, \tag{16}$$

$$\lambda\left(2f'(u)h'(u) + h''(u) + \frac{h'(u)}{u}\right) + 4h(u)^2 + 12q(u) = \frac{\lambda^{3/2}}{u^3} \tag{17}$$

and

$$\lambda\left(2f'(u)q'(u)+h'(u)^2+q''(u)+\frac{q'(u)}{u}\right)+16h(u)q(u)=-\frac{3\lambda^{5/2}}{4u^5}, \tag{18}$$

where the prime denotes now differentiation with respect to u. To get a clue how to expand the functions $f(u)$, $h(u)$, and $q(u)$ in the powers of $\lambda^{1/2}$ we use the fact that for $u\to 0$ we must recover the wave function of the hydrogen atom. For example, it reads for the ground state

$$\psi_{1s}=e^{-r}=e^{-\sqrt{\rho^2+z^2}}=e^{-\rho-z^2/(2\rho)-z^4/(8\rho^3)+\cdots}=e^{-u/\lambda^{1/2}-\lambda^{1/2}z^2/(2u)-\lambda^{3/2}z^4/(8u^3)+\cdots}. \tag{19}$$

Therefore we expand the functions $f(u)$, $h(u)$, and $q(u)$ as follows:

$$f(u)=\frac{f_0(u)}{\lambda^{1/2}}+f_1(u)+f_2(u)\lambda^{1/2}+\cdots, \tag{20}$$

$$h(u)=h_0(u)\lambda^{1/2}+h_1(u)\lambda+\cdots, \tag{21}$$

and

$$q(u)=q_0(u)\lambda^{3/2}+\cdots. \tag{22}$$

C. Equations for the WKB wave function

Comparing the terms of the order λ^0 in Eq. (16), of the order λ in Eq. (17) and of the order $\lambda^{1/2}$ in Eq. (16) we get equations for the functions $f_0(u)$, $h_0(u)$, and $f_1(u)$,

$$f_0'(u)=\frac{\pm\sqrt{1-u^2}}{N}, \tag{23}$$

$$2f_0'(u)h_0'(u)+4[h_0(u)]^2=0 \tag{24}$$

and

$$2f_0'(u)f_1'(u)+f_0''(u)+\frac{1}{u}f_0'(u)+2h_0(u)=-\frac{2}{u}, \tag{25}$$

respectively. Since we want to calculate the imaginary part of the energy beyond the leading approximation, we have to determine also the functions $q_0(u)$, $h_1(u)$, and $f_2(u)$. Comparing the terms of the order λ^2 in Eq. (18), of the order $\lambda^{3/2}$ in Eq. (17) and of the order λ in Eq. (16) we get equations for the functions $q_0(u)$, $h_1(u)$, and $f_2(u)$,

$$2f_0'(u)q_0'(u)+[h_0'(u)]^2+16h_0(u)q_0(u)=0, \tag{26}$$

$$2f_0'(u)h_1'(u)+2f_1'(u)h_0'(u)+h_0''(u)+\frac{1}{u}h_0'(u)+8h_0(u)h_1(u)+12q_0(u)=\frac{1}{u^3}, \tag{27}$$

and

$$2f_0'(u)f_2'(u)+[f_1'(u)]^2+f_1''(u)+\frac{1}{u}f_1'(u)+2h_1(u)=\frac{E_1}{N^2}, \tag{28}$$

respectively. The solution of the above equations is determined uniquely by requirement that for u going to zero, the WKB wave function must match the bound state function. This will be discussed in detail below. Before actual solution of the equations given above, let us show that the proposed approximation to the wave function yields systematic approximation to the outgoing probability flux.

D. Approximation to the outgoing probability flux

To calculate the outgoing probability flux from Eq. (8) we need to know the behavior of the wave function for large ρ. Integration of Eq. (25) yields

$$f_1(u) = -\tfrac{1}{2}\ln(uf_0'(u)) + F_1(u), \tag{29}$$

where the second term is given as

$$F_1(u) = -\frac{N}{2}\ln\frac{1+(1-u^2)^{1/2}}{1-(1-u^2)^{1/2}} + \frac{1}{2}\ln(h_0(u)) - A_1. \tag{30}$$

The integration constant A_1 is determined from the requirement of the matching of the WKB and bound state functions. Here, we took the solution of Eq. (23) with the minus sign, see discussion after Eq. (37) below.

Thus, the behavior of the wave function (11) for large ρ is given as

$$\psi(\rho,z) = \frac{\exp\{f_0(\rho)/\lambda^{1/2} + F_1(\rho) + \lambda^{1/2}f_2(\rho) + \cdots + h(\rho)z^2 + q(\rho)z^4 + \cdots\}}{[\rho f_0'(\rho)]^{1/2}}, \tag{31}$$

where we inserted the expansion (20). Differentiation of the function (31) with respect to ρ yields

$$\frac{\partial\psi(\rho,z)}{\partial\rho} \sim \frac{[f_0'(\rho)]^{1/2}}{[\rho\lambda]^{1/2}}\exp\left\{\frac{f_0(\rho)}{\lambda^{1/2}} + F_1(\rho) + \lambda^{1/2}f_2(\rho) + + h(\rho)z^2 + q(\rho)z^4 + \cdots\right\}. \tag{32}$$

Differentiation of the terms $F_1(\rho)$, $\lambda^{(1/2)}f_2(\rho)$ and so on yields the contribution to the probability flux that vanishes for ρ approaching infinity. For large ρ the particle moves in the classically allowed region and $f_0'(\rho)$ is purely imaginary, see Eq. (23). Thus it follows from Eqs. (8), (31), and (32) that the nonvanishing contribution to the probability flux for ρ going to infinity is given as[29,30]

$$\begin{aligned} J = {} & \frac{1}{\lambda^{1/2}}\exp\{2\Re[f_0(u\to\infty)/\lambda^{1/2} + F_1(u\to\infty) + \lambda^{1/2}f_2(u\to\infty) + \cdots]\} \\ & \times\int_{-\infty}^{\infty} dz\,\exp\{2z^2\Re[\lambda^{1/2}h_0(u\to\infty) + \lambda h_1(u\to\infty)] + 2z^4\Re[\lambda^{3/2}q_0(u\to\infty)] + \cdots\}, \end{aligned} \tag{33}$$

where $\Re$ denotes the real part. Here we inserted the expansions (21) and (22) and made the substitution (15). This can be done since the real parts of the functions $f_i(u)$, $h_i(u)$ and so on, goes to the constants for u going to infinity. Therefore, it does not matter if we calculate it in the variable u or ρ.

The integration over the transversal direction can be performed easily. Expanding the above equation in the powers of $\lambda^{1/2}$ as

$$\begin{aligned} J = {} & \frac{1}{\lambda^{1/2}}\exp\{2\Re[f_0(u\to\infty)/\lambda^{1/2} + F_1(u\to\infty)]\}(1 + 2\lambda^{1/2}\Re[f_2(u\to\infty)] + \cdots) \\ & \times\int_{-\infty}^{\infty} dz\,\exp\{2z^2\Re[\lambda^{1/2}h_0(u\to\infty)]\}(1 + 2z^2\lambda\Re[h_1(u\to\infty)] + 2z^4\lambda^{3/2}\Re[q_0(u\to\infty)] + \cdots) \end{aligned} \tag{34}$$

we are left with the Gaussian integrals. The outgoing probability flux accurate up to the first order of $\lambda^{1/2}$ then reads

$$J = \exp\{2\Re[f_0(u \to \infty)/\lambda^{1/2} + F_1(u \to \infty)]\} \frac{\sqrt{\pi}}{\lambda^{3/4}(\Re[-2h_0(u \to \infty)])^{1/2}} (1 + \lambda^{1/2} R_1 + \lambda R_2 + \cdots), \tag{35}$$

where the first correction coefficient R_1 equals

$$R_1 = 2\Re[f_2(u \to \infty)] + \frac{\Re[h_1(u \to \infty)]}{\Re[-2h_0(u \to \infty)]} + \frac{3\Re[q_0(u \to \infty)]}{2(\Re[-2h_0(u \to \infty)])^2}. \tag{36}$$

It is clear from the above equations that the suggested approximation of the wave function provides systematic approximation to the outgoing probability flux in the form of the series in powers of $\lambda^{1/2}$. It is well known that the WKB approximation fails in the vicinity of the turning point corresponding here to $u=1$, see Eq. (23). There is a number of papers dealing with the approximation of the wave function in the neighborhood of the turning points, see, e.g., Refs. 32–36. It is clear from the above equations that what we actually need is the behavior of the WKB approximation for u going to infinity. The proper normalization of the WKB wave function is guaranteed by matching it to the bound state function for u going to zero. In this region the WKB wave function is valid as an asymptotic expansion. Therefore, we do not have to care at all about the divergence of the WKB approximation at the turning point, see also Ref. 31.

E. Solution of equations

1. Boundary conditions

As becomes apparent during the calculation it is possible and advantageous to normalize the bound state wave function in such a way that it behaves in the overlap region as

$$\psi_0(\rho \to \infty, z \to 0) \sim e^{-\rho/N - z^2/(2N\rho) - z^4/(8N\rho^3) - \cdots} \rho^{N-1} \left(1 + \frac{Cz^2}{\rho^2} + \cdots\right), \tag{37}$$

where C is a constant depending on the form of the bound state wave function and it will be precisely determined in Sec. III. It is seen from Eq. (19) that for the ground state

$$C_{1s} = 0. \tag{38}$$

The solution of Eqs. (23)–(28) is determined uniquely by the requirement that the WKB wave function has this behavior for small u.

2. Calculation of the first approximation

Since for $u>1$ the integrand in Eq. (23) is purely imaginary we can stop the integration at the turning point $u=1$. We start the integration at the point $u=0$ and take the minus sign in Eq. (23) to get the first term in the argument of exponential function on the right-hand side of Eq. (37) for small u

$$\Re[f_0(u \to \infty)] = -\int_0^1 du \frac{\sqrt{1-u^2}}{N} = -\frac{\pi}{4N}. \tag{39}$$

Equation (24) is nonlinear first order differential equation whose solution reads

$$h_0(u) = -\frac{1}{2N \arcsin u}, \tag{40}$$

where the integration constant was set to zero to get the second term in the argument of exponential function on the right-hand side of Eq. (37) for small u. We note that for $u>1$, the function $\arcsin(u)$ is complex and two-valued with the branch point at $u=1$,

$$\arcsin(u) = \frac{\pi}{2} + i \ln(u \pm \sqrt{u^2 - 1}). \tag{41}$$

These two values correspond to the incoming (+) and outgoing (−) waves. Taking the solution with the minus sign we get

$$\Re[h_0(u \to \infty)] = h_0(u = 1) = -\frac{1}{N\pi}. \tag{42}$$

For u going to zero the function $f_1(u)$ given by Eq. (29) behaves as

$$f_1(u \to 0) \to -\frac{2N+1}{2} \ln 2 + (N-1)\ln(u) - A_1 = -\frac{2N+1}{2} \ln 2 + \frac{N-1}{2} \ln \lambda + (N-1)\ln \rho - A_1, \tag{43}$$

where we substituted for u from Eq. (15). To get the leading power term in Eq. (37) we obviously must set

$$A_1 = -\frac{2N+1}{2} \ln 2 + \frac{N-1}{2} \ln \lambda. \tag{44}$$

Using Eqs. (40) and (41) in Eq. (30) we get

$$\Re[F_1(u \to \infty)] = -\frac{1}{2} \ln N\pi - A_1 = -\frac{1}{2} \ln N\pi - \frac{N-1}{2} \ln \lambda + \frac{2N+1}{2} \ln 2. \tag{45}$$

Now we are ready to calculate the outgoing probability flux at the leading order of $\lambda^{1/2}$ from Eq. (35). By inserting Eqs. (39), (42), and (45) into Eq. (35) we obtain

$$J = \frac{2^{2N+1}}{\lambda^{N-1/4}(2N)^{1/2}} e^{-\pi/(2N\lambda^{1/2})}(1 + R_1\lambda^{1/2} + \cdots). \tag{46}$$

3. Calculation of the second approximation

To calculate the coefficient R_1 we must determine the functions $q_0(u)$, $h_1(u)$, and $f_2(u)$.

Equation (26) is inhomogenous linear differential equation for $q_0(u)$. We first solve the homogenous part and then use the variation of a constant. We obtain the function $q_0(u)$ as

$$q_0(u) = [h_0(u)]^4 Q_0(u), \tag{47}$$

where

$$Q_0(u) = N^3 \frac{2u}{(1-u^2)^{1/2}}. \tag{48}$$

The integration constant was set to zero to get the third term in the argument of the exponential function on the right-hand side of Eq. (37). By virtue of Eqs. (42) and (48) the real part of the function $q_0(u)$ vanishes for u going to infinity

$$\Re[q_0(u \to \infty)] = \Re[Q_0(u \to \infty)] = 0. \tag{49}$$

The function $h_1(u)$ is obtained similarly as the function $q_0(u)$,

$$h_1(u) = [h_0(u)]^2 H_1(u), \tag{50}$$

where for the function $H_1(u)$ we obtain using Eqs. (24), (25), (47), (48) and integrating by parts

$$H_1'(u) = -\frac{2}{[f_0'(u)]^3} + \frac{1}{2u^3 f_0'(u)[h_0(u)]^2} + \left(3Q_0(u)h_0(u) + \frac{1}{[f_0'(u)]^2}\right)'. \tag{51}$$

Inserting now the explicit form of the functions $f_0'(u)$ and $h_0(u)$, Eqs. (23) and (40), the integration of the last equation yields

$$H_1(u) = 3Q_0(u)h_0(u) + \frac{1}{[f_0'(u)]^2} + 2N^3\left[\frac{1}{(1-u^2)^{1/2}} + \frac{(1-u^2)^{1/2}}{2u^2}\arcsin^2(u) + \frac{\arcsin(u)}{u} - \int_0^u \frac{\arcsin^2(t)}{t(1-t^2)^{1/2}}dt\right] - A_2. \tag{52}$$

To determine the integration constant A_2 we note that for u going to zero we get from Eqs. (48), (50), and (52),

$$\lambda h_1(u \to 0) \to \frac{\lambda}{(2N)^2u^2}(5N^3 - 2N^2 - A_2) = \frac{1}{(2N)^2\rho^2}(5N^3 - 2N^2 - A_2), \tag{53}$$

where we substituted for u from Eq. (15). To get the last term on the right-hand side of Eq. (37), we obviously must set

$$A_2 = 4N^2\left(\frac{5N-2}{4} - C\right). \tag{54}$$

The real part of the asymptotics of the function $h_1(u)$ is by virtue of Eqs. (42) and (48) given as

$$\Re[h_1(u \to \infty)] = h_0(u=1)\Re[H_1(u \to \infty)] = h_0(u=1)\left\{-A_2 - 2N^3\Re\left[\int_0^u \frac{\arcsin^2(t)}{t(1-t^2)^{1/2}}\mathrm{d}t\right]\right\}. \tag{55}$$

Finally, the integration of Eq. (28) is substantially simplified by the identity

$$\frac{f_1''(u)}{2f_0'(u)} = \left(\frac{f_1'(u)}{2f_0'(u)}\right)' + \frac{f_1'(u)f_0''(u)}{2[f_0'(u)]^2}. \tag{56}$$

We note that this identity substantially simplifies the calculation of the higher orders of the WKB approximation in general. Further, it is useful to separate the part of $f_2(u)$ denoted as $F_2(u)$ that depends on the function $h_0(u)$ and the part denoted as $\phi_2(u)$ that is independent of it,

$$f_2(u) = F_2(u) + \phi_2(u). \tag{57}$$

The function $\phi_2(u)$ is integrated easily without any tricks. The real part of its asymptotics is given as

$$\Re[\phi_2(u \to \infty)] = -\frac{E_1\pi}{4N}. \tag{58}$$

For the part $F_2(u)$ we find using Eqs. (24), (25), and (51) and integrating by parts

$$F_2'(u) = -\frac{1}{4u^3 f_0'(u)h_0(u)} + \left(\frac{H_1(u)h_0(u)}{2} - \frac{3Q_0(u)h_0(u)^2}{4}\right)'. \tag{59}$$

The real part of the asymptotics of the function $F_2(u)$ is by virtue of Eqs. (23), (40), and (48) given as

$$\Re[F_2(u\to\infty)]=h_0(u=1)\frac{H_1(u\to\infty)}{2}+\lim_{u\to\infty}\frac{N^2}{4}\left\{\frac{(1-u^2)^{1/2}\arcsin(u)}{u^2}+\frac{1}{u}-\Re\left[\int_0^u\frac{\mathrm{d}t\arcsin(t)}{t(1-t^2)^{1/2}}\right]\right\}. \tag{60}$$

By inserting Eqs. (49), (54), (55), (57), (58), and (60) into Eq. (36) we obtain

$$R_1=-\frac{E_1\pi}{2N}+\frac{A_2}{2N\pi}+\frac{N^2}{2\pi}\int_0^1\frac{\arcsin^2(u)-\pi\arcsin(u)}{u(1-u^2)^{1/2}}\mathrm{d}u=-\frac{E_1\pi}{2N}+\frac{2N}{\pi}\left(\frac{5N-2}{4}-C\right)-N^2\frac{7\zeta(3)}{4\pi}, \tag{61}$$

where $\zeta(z)$ denotes Riemann zeta function. The first order perturbation energy E_1 as well as the constant C will be determined in the next section.

III. PERTURBATION METHOD

To calculate the norm of the wave function in Eq. (9) accurate up to the first order in $\lambda^{1/2}$ it is sufficient to take the wave function of the unperturbed hydrogen atom. For the excited states, the unperturbed wave function is degenerate and we must use the first order perturbation theory to determine the correct linear combination of the unperturbed functions. Since we need to calculate the perturbation energies up to the large order for numerical verification of the analytic formulas we describe the application of the perturbation method to Eq. (1) in greater detail.

The method described here is an extension of the method suggested in Ref. 29 for the coupled oscillators. The alternative way of calculation of the perturbation energies for the problem considered here is described for example in Ref. 10 for the ground state energy and in Refs. 8 and 37 for the excited states.

A. Derivation of difference equations

We transform Eq. (1) into the spherical coordinates, $x=r\sin\theta\cos\varphi$, $y=r\sin\theta\sin\varphi$ and $z=r\cos\theta$, multiply it by r, write the wave function in the form

$$\psi(r,\theta)=e^{-r/n}\sum_{k=0}\varphi_k(r,\theta)\left(\frac{B^2}{8}\right)^k, \tag{62}$$

insert the expansion (2) for the energy and compare the terms of the same order of $(B^2/8)$. Equation (1) then reads

$$\left\{-\frac{r}{2}\left[\frac{\partial^2}{\partial r^2}+\frac{2}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\left(\frac{\cos\theta}{\sin\theta}\frac{\partial}{\partial\theta}+\frac{\partial^2}{\partial\theta^2}\right)\right]+\frac{r}{N}\frac{\partial}{\partial r}+\frac{1-N}{N}\right\}\varphi_k+r^3\sin^2\theta\varphi_{k-1}=r\sum_{l=1}^{k}E_l\varphi_{k-l}. \tag{63}$$

Further, we expand the perturbation functions φ_k in the form of the double series

$$\varphi_k=\sum_{i=0}\sum_{j=0}g_{i,j}^{(k)}r^i\sin^{2j}\theta, \tag{64}$$

where the upper bounds of the summations will be determined later, insert it into Eq. (63) and compare the terms of the same order of r and $\sin^2\theta$. As a result we get the difference equations for the coefficients $g_{i,j}^{(k)}$,

$$-\frac{1}{2}g^{(k)}_{i+1,j}[(i+1)(i+2)-2j(j+1)]-2(j+1)^2 g^{(k)}_{i+1,j+1}+\frac{i+1-N}{N}g^{(k)}_{i,j}+g^{(k-1)}_{i-3,j-1}=\sum_{l=1}^{k}E_l g^{(k-l)}_{i-1,j}. \tag{65}$$

These equations can be used for the calculation of the perturbation energies as follows. The calculation for the ground state is not difficult and does not differ from that described in Refs. 2 and 29. In the first order of the perturbation theory we get

$$E_1^{1s}=2. \tag{66}$$

For the excited states, the situation is a bit more complicated because the unperturbed state is degenerate. We describe calculation of the perturbation energies for the $3s$-$3d$ state in detail.

B. Solution of equations for the 3*s*-3*d* state

The unperturbed wave function of the $3s$-$3d$ state reads

$$\psi_{3s\text{-}3d}=s\psi_{3s}+d\psi_{3d}, \tag{67}$$

where s and d denotes the coefficients of the linear combination and the unperturbed wave functions of $3s$ and $3d$ states read

$$\psi_{3s}=e^{-r/3}\left(1-\frac{2r}{3}+\frac{2r^2}{27}\right) \tag{68}$$

and

$$\psi_{3d}=e^{-r/3}r^2(1-3\cos^2\theta), \tag{69}$$

respectively. Thus, we set $g^{(0)}_{0,0}=s$, $g^{(0)}_{1,0}=-2s/3$, $g^{(0)}_{2,0}=(2s/27)-2d$, $g^{(0)}_{2,1}=3d$, and $g^{(0)}_{i,j}=0$ otherwise. We express the third term in Eq. (65), $g^{(k)}_{i,j}$, set $g^{(k)}_{i,k+2}=0$, $g^{(k)}_{3k+3,j}=0$ and solve Eq. (65) with $N=3$ for k starting from 1. For given k we solve Eq. (65) for j descending from $k+1$ to 0 and for i descending from $3k+2$ to 3. For $i=2$ the third term in Eq. (65) vanishes. Therefore, for $i=2$ we solve Eq. (65) for j descending from k to 1 to get equations for the coefficients $g^{(k)}_{2,k-1}$. For $i=2$ and $j=0$ we get the equation for the perturbation energies E_k. Finally, for i descending from 1 to 0 we again express $g^{(k)}_{i,j}$ and solve Eqs. (65) for j descending from $k+1$ to 0. The perturbation coefficients calculated in this way agree with those given in Ref. 8.

For the sake of transparency we illustrate this procedure of solving Eqs. (65) for $i=2$ on the first two orders of the perturbation theory. In the first order, $k=1$, we get for $j=1$,

$$30s+(1620-27E_1)d=0 \tag{70}$$

and for $j=0$

$$(72-2E_1/3)s+18E_1 d=0. \tag{71}$$

From Eq. (70) we get

$$d=\frac{10s}{9(E_1-60)}. \tag{72}$$

By inserting this value into Eq. (71) we obtain a quadratic equation for E_1. Two roots of this equation equal

$$(E_1^{3s\text{-}3d})_{1,2}=99\pm 9\sqrt{41}. \tag{73}$$

In the second order of the perturbation theory, $k=2$, we get for $j=2$,

$$g_{2,2}^{(1)} = 0, \tag{74}$$

for $j=1$,

$$766\,908s + 15\,549\,570d - (5616s + 167\,670d)E_1 + 1701/2E_1^2 d - 405g_{2,0}^{(1)} + (9E_1 - 810)g_{2,1}^{(1)} + 27E_2 d = 0 \tag{75}$$

and finally for $j=0$,

$$1\,308\,798s + 1\,296\,4536d - (14\,310s + 29\,160d)E_1 + (57s - 567d)E_1^2 + (9E_1 - 972)g_{2,0}^{(1)} - 648g_{2,1}^{(1)} + (2s/3 - 18d)E_2 = 0. \tag{76}$$

We solve Eq. (75) to get the coefficient $g_{2,1}^{(1)}$ and insert it into Eq. (76) to get E_2. We note that the values of the coefficients s and $g_{2,0}^{(1)}$ are not given by the perturbation theory. We also note that Eq. (76) for E_2 is linear. It means that after splitting of the degenerate energy level at the first order, there is only one solution for given E_1 for higher order perturbation energies E_2, E_3, and so on.

Since the coefficient s is not given by the perturbation theory, it can be used to normalize the bound state function to behave as in Eq. (37) for large ρ and small z. The function (67) behaves in this region as

$$\psi_{3s\text{-}3d} \sim e^{-\rho/3 - z^2/(6\rho)}\rho^2\left\{\frac{2s}{27} + d + \frac{z^2}{\rho^2}\left(\frac{2s}{27} - 2d\right) + \cdots\right\}. \tag{77}$$

It is seen that to get required behavior (37) we must set

$$\frac{2s}{27} + d = 1 \tag{78}$$

and that the constant C in Eq. (37) equals

$$C_{3s\text{-}3d} = \frac{2s}{27} - 2d. \tag{79}$$

C. Solution of equations for the state 5*s*-5*d*-5*g*

Only slight modifications of the above procedure are necessary for the $5s$-$5d$-$5g$ state. The unperturbed wave function in this case equals

$$\psi_{5s\text{-}5d\text{-}5g} = \mathrm{s}\psi_{5s} + \mathrm{d}\psi_{5d} + g\psi_{5g}, \tag{80}$$

where the wave functions of the $5s$, $5d$, and $5g$ states read

$$\psi_{5s} = e^{-r/5}\left(1 - \frac{4r}{5} + \frac{4r^2}{25} - \frac{4r^3}{375} + \frac{2r^4}{9375}\right), \tag{81}$$

$$\psi_{5d} = e^{-r/5}r^2\left(1 - \frac{2r}{15} + \frac{2r^2}{525}\right)(1 - 3\cos^2\theta) \tag{82}$$

and

$$\psi_{5g} = e^{-r/5}r^4\left(1 - 10\cos^2\theta + \frac{35}{3}\cos^4\theta\right), \tag{83}$$

respectively.

In the first order of the perturbation theory we get from Eqs. (65) the following three energies:

$$(E_1^{5s\text{-}5d\text{-}5g})_{1,2,3} = 550,775 \pm 25\sqrt{481}. \tag{84}$$

Further we get the expression for the coefficients d and g,

$$d = \frac{2s(7E_1 - 2850)}{(E_1 - 300)(E_1 - 750)} \tag{85}$$

and

$$g = \frac{12s}{7(E_1 - 300)(E_1 - 750)}. \tag{86}$$

To get required behavior (37) we set

$$\frac{2s}{9375} + \frac{2d}{525} + g = 1 \tag{87}$$

and the constant C equals

$$C_{5s\text{-}5d\text{-}5g} = \frac{4s}{9375} - \frac{2d}{525} - 8g. \tag{88}$$

D. Calculation of the norm of the wave function

The norm of the function (19) is calculated from Eq. (9):

$$\langle \psi_{1s} | \psi_{1s} \rangle = \int_0^\infty \mathrm{d}r \int_0^\pi \mathrm{d}\theta r^2 \sin\theta |\psi_{1s}|^2 = 1/2, \tag{89}$$

where we made change of the variables $\rho = r \sin\theta$ and $z = r\cos\theta$. Further, the norm of the wave functions (67) and (80) equals

$$\langle \psi_{3s\text{-}3d} | \psi_{3s\text{-}3d} \rangle = 19\,683d^2 + \frac{27s^2}{2} \tag{90}$$

and

$$\langle \psi_{5s\text{-}5d\text{-}5g} | \psi_{5s\text{-}5d\text{-}5g} \rangle = \frac{125s^2}{2} + \frac{390\,625d^2}{7} + 136\,718\,750\,000g^2, \tag{91}$$

respectively.

IV. LARGE-ORDER BEHAVIOR OF THE PERTURBATION SERIES

By inserting Eq. (46) into Eq. (7) and the latter equation into Eq. (3) we obtain the large-order behavior of the perturbation energies,

$$E_n = E_n^{\mathrm{asy}} \left(1 + \frac{R_1 \pi}{2N\left(2n + 2N - \frac{3}{2}\right)} + \cdots \right), \tag{92}$$

where the leading term of the large-order behavior reads

TABLE I. Comparison of the numerical and analytical values of the coefficient R_1. See the text after Eq. (94) for details.

State	E_1	R_1, Eq. (94)	R_1, Eq. (61)
$1s$	2	−3.333 724 367 368 66	−3.333 724 367 368 65
$3s$-$3d$	$99+9\sqrt{41}$	−82.969 565 723 945	−82.969 565 723 942
$3s$-$3d$	$99-9\sqrt{41}$	−47.079 674 497 78	−47.079 674 497 77
$5s$-$5d$-$5g$	550	−273.083 854 65	−273.083 854 64
$5s$-$5d$-$5g$	$775+25\sqrt{481}$	−417.562 256 273	−417.562 256 272
$5s$-$5d$-$5g$	$775-25\sqrt{481}$	−212.681 342 928	−212.681 342 920

$$E_n^{\mathrm{asy}} = \frac{2^{4N}N^{2N-1}}{\pi^{2N+1/2}\langle\psi|\psi\rangle}(-1)^{n+1}\left(\frac{2^{3/2}N^2}{\pi}\right)^n \Gamma\left(2n+2N-\frac{1}{2}\right). \tag{93}$$

Here, the norm of the wave function $\langle\psi|\psi\rangle$ is given by Eqs. (89)–(91) for $1s$, $3s$-$3d$, and $5s$-$5d$-$5g$ states, respectively. The coefficients s and d in Eq. (90) are given by Eqs. (72) and (78), respectively. The coefficients s, d, and g in Eq. (91) are given by Eqs. (85)–(87), respectively.

The coefficient R_1 in Eq. (92) is given by Eq. (61). The first order perturbation energies in this equation are given by Eqs. (66), (73), and (84) for $1s$, $3s$-$3d$, and $5s$-$5d$-$5g$ states, respectively. The constant C in Eq. (61) is given by Eqs. (38), (79), and (88) for $1s$, $3s$-$3d$, and $5s$-$5d$-$5g$ states, respectively.

Formula (93) for $N=1$ and $N=3$ was for the first time given in Ref. 1 and for $N=1$ rederived in Refs. 3 and 4. The first correction (61) is given here for the first time. To check its correctness we calculated numerically

$$R_1 = \left(\frac{E_n}{E_n^{\mathrm{asy}}} - 1\right)\frac{2N\left(2n+2N-\frac{3}{2}\right)}{\pi}, \tag{94}$$

where E_n are the exact perturbation energies calculated from Eqs. (65) by means of the language MAPLE and E_n^{asy} is the leading term of the large-order behavior given by Eq. (93). For $1s$ state we calculated first 80 perturbation coefficients in the rational form. Numerical values in Eq. (94) were extrapolated by means of the Thiele-Padé extrapolation from the interval $n=70-80$ to infinity. For $3s$-$3d$ and $5s$-$5d$-$5g$ states we calculated first 100 coefficients in 200 digits accuracy for both energies in Eq. (73) and all three energies in Eq. (84). Numerical values were extrapolated from the interval $n=90-100$ to infinity. The extrapolated values are compared with the values given by Eq. (61) in Table I. Agreement between numerical and WKB results is excellent and confirms soundness of both the perturbation and WKB methods suggested in this paper.

V. CONCLUSIONS

In this paper the large-order behavior of the perturbation series for the energy of the hydrogen atom in the magnetic field was derived by means of the modified WKB approximation. The asymptotic formula derived by Avron in Ref. 1 was generalized to describe the states of higher than twofold degeneracies. On the other hand, we restricted ourselves to the states of zero projection of the angular momentum and even parity, while in Ref. 1 this restriction was not done. The first correction to the asymptotic formula was given here for the first time. The analytic results were compared with numerical ones and an excellent agreement between the two was found. The calculation of further terms in the expansions (35) and (92), though straightforward in principle, is very tedious. We note that in this case we must take also the correction to the norm of the wave function.[24,31,33,34] On the basis of the experience with one-dimensional problems[33,34] we expect that the series (35) and (92) are only asymptotic, i.e., hold for sufficiently small λ and large n only.

The most immediate further application of the WKB method suggested in this paper is the calculation of the ionization rate of the atoms in the weak electric field. The standard calculation of this rate for the many-electron atoms is based on the calculation for the hydrogen atom.[38] The latter is based on the separability of the Schrödinger equation in the parabolic coordinates.[33,35,36,39] However, the separation of the Schrödinger equation for the motion of the electron in the binding potential and applied electric field holds only in the case of a purely Coulombic binding potential. Arbitrarily small perturbation from the other electrons destroys the separability of Schrödinger equation. Even for the hydrogen atom, the separability is lost once the relativistic effects are considered. Only slight modifications of the procedure described here are necessary to derive the ionization rate of the hydrogen atom in the weak electric field without invoking the separability of the Schrödinger equation.

Finally, we note that the WKB approximation suggested here is not bound to the problem of the calculation of the lifetime of quasistationary states. It is a local approximation of the wave function and it can be used, for example, to describe motion of the bound electron in the intense laser field or to estimate forward scattering amplitude for the elastic scattering of the electrons on the atoms.

APPENDIX

In this Appendix we discuss the relation between the WKB method suggested in Sec. II and the usual semiclassical approximation.

Let us consider the Schrödinger equation where we included the reduced Planck constant $\hbar$,

$$\hbar^2\left[\frac{\partial^2}{\partial\rho^2}+\frac{\partial^2}{\partial z^2}\right]\psi=[V(\rho,z)-E]\psi, \tag{A1}$$

and let us assume that the potential behaves in the vicinity of ρ axis as in Eq. (10). Then we can write the wave function of the particle in the vicinity of ρ axis in the form of Eq. (11). In general case there is no parameter λ associated with the external field driving the particle out of the potential well. Nevertheless, by the scaling

$$z=\hbar\,\eta \tag{A2}$$

the WKB approximation, very similar to that suggested for Eq. (5), can be obtained. Physically, the scaling (A2) implies that while the longitudinal motion is treated semiclassicaly, the transversal motion is treated in fully quantum manner. Proceeding then in accordance with the considerations leading to Eq. (35), it can be shown that the expansion of Eq. (A1) in the powers of η and $\hbar$ provides systematic approximations to the probability flux in the ρ direction in form of the series in the reduced Planck constant $\hbar$.

Bohr proposed in 1913 a model for atoms and molecules by synthesizing Planck's quantum hypothesis with classical mechanics. When the atom number Z is small, his model provides good accuracy for the ground-state energy. When Z is large, his model is not as accurate in comparison with the experimental data but still provides a good trend agreeing with the experimental values of the ground-state energy of atoms. The main objective of this paper is to provide a rigorous mathematical analysis for the Bohr atom model. We have established the following: (1) An existence proof of the global minimizer of the ground-state energy through scaling. (2) A careful study of the critical points of the energy function. Such critical points include both the stable steady-state electron configurations as well as unstable saddle-type configurations. (3) Coplanarity of certain electron configurations. Numerical examples and graphics are also illustrated. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2168396]

I. INTRODUCTION

In 1913, Bohr presented a series of three papers[1–3] describing his approach for modeling atoms and molecules by synthesizing Planck's quantum hypothesis with classical mechanics. Bohr tried to explain the hydrogen spectral lines with a radical "planetary" model of electrons orbiting around a nucleus. He made a set of assumptions to quantify his model, leading to the existence in the atom a discrete set of stable, stationary orbits for electrons:

(1) The dynamical equilibrium of the stationary orbits is achieved by balancing the electrostatic Coulomb forces of attraction against the centrifugal effect and the interelectronic repelling of the orbital motion in classical mechanics.
(2) Stationary states satisfy the quantization condition that the ratio of the total kinetic energy of the electron to its orbital frequency be an integral multiple of $\pi\hbar$. For circular orbits, this signifies that the angular momentum of the electron is restricted to integral multiples of $\hbar$.

[a)]Work completed while on sabbatical leave from National Tsing Hua University. Supported in part by an NSC grant of Republic of China.

(3) Energy is emitted only when an electron makes a "jump" (i.e., noncontinuous) transition between two stationary orbits, and the frequency of such a radiation emission is determined by $\Delta E/2\pi\hbar$, where ΔE is the energy difference between the two orbits where the transition occurs.

From now on, vectors will be denoted by bold letters. For the hydrogen atom, Bohr's assumptions work as follows. The total energy of the electron on a circular orbit with radius r and velocity $\mathbf{v}$ is

$$E = \text{kinetic energy} + \text{potential energy} = \frac{m_e v^2}{2} - \frac{Ze^2}{r}, \tag{1.1}$$

where

$$m_e = \text{the mass of the electron},$$

$$e = \text{the charge of the electron},$$

$$Ze = \text{the positive charge of the nucleus}.$$

Since

$$\mathbf{L} = \text{the angular momentum} = \mathbf{r} \times \mathbf{p} \quad (\mathbf{p} \equiv \text{the linear momentum} = m_e \mathbf{v}),$$

$$|\mathbf{L}| = L = m_e v r, \tag{1.2}$$

which, in turn, by Bohr's quantization assumption, satisfies

$$L = n\hbar. \tag{1.3}$$

From (1.1)–(1.3), we now have

$$E = \frac{m_e^2 v^2 r^2}{2m_e r^2} - \frac{Ze^2}{r} = \frac{L^2}{2m_e r^2} - \frac{Ze^2}{r} = \frac{n^2\hbar^2}{2m_e r^2} - \frac{Ze^2}{r} = \frac{1}{2}\frac{n^2}{r^2} - \frac{Z}{r}, \tag{1.4}$$

in atomic units (by setting $e=1$, $\hbar^2/m_e=1$).

Minimizing $E=E(r,n,Z)$ with respect to r for $n=1,2,3,\ldots$, for fixed Z, we obtain

$$\hat{E}_n \equiv \min_{r>0} E(r,n,Z) = -\frac{1}{2}\frac{Z^2}{n^2}, \quad n = 1,2,3, \ldots . \tag{1.5}$$

These values and their differences totally determine the hydrogen atom's spectral lines.

Sommerfeld later in 1916 generalized Bohr's theory by allowing noncircular orbits and by incorporating relativistic effects, leading to the Bohr-Sommerfeld (old) quantum theory of the hydrogen atom. However, for other atoms, including the simple helium, there are difficulties unaccountable by the Bohr-Sommerfeld theory; see, e.g., Refs. 6 and 7. Heisenberg worked under both Bohr and Sommerfeld trying to resolve such difficulties, eventually he gave up but in the process invented the matrix mechanics during the 1920s.

The objective of the present paper is to analyze, mathematically, a Bohr atom model for the ground states of general atoms. Such a general Bohr model seems to be well understood by atomic physicists (see, e.g., the pictorials on the website of Patton[11]) but we could not provide an exact citation. The model that we are going to describe below is communicated to us by our colleague, Dr. S. A. Chin.[4] Consider a neutral atom with atom number Z. There are Z electrons. The kinetic energy of an electron i moving around a circular orbit of radius r_i on the nth shell, $n_i = 1,2,3,\ldots$, is

TABLE I. Assignment of quantum numbers n_i for the ground state of an atom with atom number Z from $Z=1$ to 108.

Electron numbers i	Electron shells names	Assigned quantum numbers n_i
$1 \leqslant i \leqslant 2$	K	1
$3 \leqslant i \leqslant 8$	L	2
$9 \leqslant i \leqslant 18$	M	3
$19 \leqslant i \leqslant 36$	N	4
$37 \leqslant i \leqslant 54$	O	5
$55 \leqslant i \leqslant 86$	P	6
$87 \leqslant i \leqslant 108$	Q	7

$$T_i = -\tfrac{1}{2} n_i^2 / r_i^2 \quad [r_i = |\mathbf{r}_i|, \mathbf{r}_i = (x_i, y_i, z_i) \in \mathbb{R}^3 \text{ is the position vector of electron } i]. \tag{1.6}$$

For a heuristic derivation of (1.6), see Ref. 6, Appendix. The potential energy is attributed to the Coulomb interactions of electron j with the nucleus and electrons j for $j \neq i$,

$$P_i = -\frac{Z}{r_i} + \sum_{\substack{j=1 \\ j \neq i}}^{Z} \frac{1}{r_{ij}} \quad (r_{ij} = |\mathbf{r}_i - \mathbf{r}_j|). \tag{1.7}$$

Thus the total energy of the atom is

$$E = E(\mathbf{r}_1, \mathbf{r}_2, \ldots, \mathbf{r}_Z) = \sum_{j=1}^{Z} (T_j + P_j) = \sum_{i=1}^{Z} \left(\frac{n_i^2}{2r_i^2} - \frac{Z}{r_i} \right) + \sum_{\substack{i,j=1 \\ i \neq j}}^{Z} \frac{1}{2r_{ij}}. \tag{1.8}$$

We now pack these Z electrons into the various "electron shells" by the *Aufbau principle* by assigning the values of n_i according to Table I. (The packing of electrons into electron shells by the Aufbau principle involves also *subshells* p, d, f, etc. Since here we are only dealing with ground states of atoms, we pack electrons only into the *principal s* shells.) These designated integral values of n_i give us the Bohr atom model in this paper.

The stable stationary orbit or electron configuration, denoted as $(\mathbf{r}_1^*, \mathbf{r}_2^*, \ldots, \mathbf{r}_Z^*)$, and the associated ground state energy $E(\mathbf{r}_1^*, \mathbf{r}_2^*, \ldots, \mathbf{r}_Z^*)$, can now be obtained by

$$\min_{\mathbf{R} \in \mathbb{R}^{3Z}} E(\mathbf{R}) \equiv E(\mathbf{R}^*), \quad \mathbf{R}^* \equiv (\mathbf{r}_1^*, \mathbf{r}_2^*, \ldots, \mathbf{r}_Z^*). \tag{1.9}$$

In Table II, we have listed the ground-state energy of all the atoms calculated from (1.9) as well as the known ("exact") experimental values. The reader may find some agreement between these two sets of values, especially when Z is small.

The Bohr model of atoms was derived by Bohr in an *ad hoc* way at first. The rigorous, wave-mechanical model is the following Schrödinger-Born-Oppenheimer equation describing the many-particle quantum-mechanical behavior

$$\left(-\frac{1}{2} \sum_{k=1}^{Z} \nabla_k^2 + \frac{1}{2} \sum_{\substack{k,k'=1 \\ k \neq k'}}^{Z} \frac{1}{r_{kk'}} - \sum_{k=1}^{Z} \frac{Z}{r_k} \right) \phi(\mathbf{R}) = E \phi(\mathbf{R}). \tag{1.10}$$

As Bohr's model appears to be something of the history, why does it still warrant any attention? The reasons that motivate our study here are threefold:

(i) Recently, through the *dimensional scaling* (D-scaling) method,[9] Svidzinsky, Scully, and

TABLE II. Comparison of ground-state energies of atoms' ground-state energies in hartrees (htr) with atom number Z: $2 \leqslant Z \leqslant 30$, between experimental values and Bohr's energies. When Z is small, there is a better agreement, and the trend is basically sound. But none of Bohr's energies are within the *chemical accuracy* of five decimal places.

Hershbach[12,13] have arrived at Bohr's model from the totally quantum-mechanical (Schrödinger-Born-Oppenheimer) model via asymptotics. This has stirred surprise, excitement, and interests,[15] especially among the researchers in the Institute for Quantum Studies at Texas A&M and has rekindled efforts in trying to understand the synergism between D-scaling, the Schrödinger-Born-Oppenheimer model and the Bohr model for atoms and molecules.

(ii) The Schrödinger-Born-Oppenheimer model (1.10) involves large-scale numerical computation and is rather theoretically intractable, while the Bohr model (1.8) and (1.9) requires only desk-top computing, producing outcomes of electron configurations highly valuable and intuitive for atomic experiments and molecular modeling, especially with the incorporation of the Hartree-Fock and other refinement techniques (e.g., Refs. 6, 7, 5, 8, and 14).

(iii) Mathematically speaking, even though Bohr's atom model is nearly 90 years old, historically it has not attracted due attention in the mathematics community and, thus, has not undergone rigorous mathematical analysis it rightfully deserves. Many relevant interesting mathematical problems are worth investigation. We hope our mathematical analysis carried out here will improve the understanding of Bohr's atomic model and that of atoms in

general at a more fundamental level, with an ultimate goal of improving the modeling and compution of molecules or even building new molecular models.

II. EXISTENCE AND ALGORITHM FOR THE GLOBAL MINIMIZER

The following problems are of significant mathematical interests, which also have physical importance:

(i) a rigorous existence proof of ground-state energies;
(ii) *stable* as well as *unstable* electron steady-state orbits;
(iii) geometric configurations: coplanarity and symmetries of electron locations.

We discuss them through a sequence of lemmas and theorems.

From now on, to simplify notation, we often write

$$\sum_{i=1}^{n} \text{ as } \sum_{i}, \quad \sum_{\substack{i,j=1 \\ i\neq j}}^{n} \text{ as } \sum_{i\neq j},$$

unless more clarity of the summation index is deemed necessary.

We begin by letting Z be a positive number and n be a positive integer; $n=1,2,3,\ldots$, define

(1) For $n=1$,

$$E_1^Z:\mathbb{R}^3 \to \mathbb{R}, \quad E_1^Z(\mathbf{r}_1) = \frac{n_1^2}{2r_1^2} - \frac{Z}{r_1}, \quad \mathbf{r}_1 \in \mathbb{R}^3.$$

(2) For $n \geqslant 2$ and $Z \geqslant n$, $E_n^Z:\mathbb{R}^{3n} \to \mathbb{R}$,

$$E_n^Z(\mathbf{R}) = \sum_{i=1}^{n} \left(\frac{n_i^2}{2r_i^2} - \frac{Z}{r_i} \right) + \sum_{\substack{i,j=1 \\ i\neq j}}^{n} \frac{1}{2r_{ij}}, \tag{2.1}$$

where $\mathbf{R}=(\mathbf{r}_1,\ldots,\mathbf{r}_n)$, $\mathbf{r}_i \in \mathbb{R}^3$, r_i and r_{ij} are defined as in (1.6) and (1.7). The domain of E_n^Z is then given by $\mathbb{R}^{3n}\backslash\mathcal{S}_n$, where $\mathcal{S}_n$ is the singularity manifold of E_n^Z given by

$$\mathcal{S}_n = \{\mathbf{R}=(\mathbf{r}_1,\ldots,\mathbf{r}_n) \in \mathbb{R}^{3n} | \mathbf{r}_j = \mathbf{0} \text{ or } \mathbf{r}_j - \mathbf{r}_k = 0, \quad \text{for some } j,k, 1 \leqslant j,k \leqslant n, j \neq k\}.$$

E_n^Z is obviously in $C^\infty(\mathbb{R}^{3n}\backslash\mathcal{S}_n)$. We are interested in the existence of $\mathbf{R}^* \in \mathbb{R}^{3n}\backslash\mathcal{S}_n$ such that

$$E_n^Z(\mathbf{R}^*) = \inf_{\mathbf{R}\in\mathbb{R}^{3n}\backslash\mathcal{S}_n} E_n^Z(\mathbf{R}), \quad \text{for } n \geqslant 2.$$

Note that the case of $n=1$ is already solved in (1.6). From now on, we will abbreviate E_n^Z as E if no ambiguities should arise. Throughout the rest of the section, the reader may find that in all of the proofs given, as long as $n_i>0$ for $i=1,2,\ldots,n$, the proofs go through without any problem, i.e., n_i's do not have to follow the designated values as in Table I. We further define

$$\mathcal{S}_Z^n = \left\{ \mathbf{R} \in \mathbb{R}^{3n}\backslash\mathcal{S}_n \middle| \sum_i \frac{Z}{r_i} - \sum_{i\neq j} \frac{1}{2r_{ij}} > 0 \right\}.$$

Lemma 1 (scaling along a ray): Let $\mathbf{R} \in \mathcal{S}_Z^n$. The function $g:\mathbb{R}_+ \equiv (0,\infty) \to \mathbb{R}$, $g(t) \equiv E(t\mathbf{R})$ has a unique global minimum at

$$t^* = t^*(\mathbf{R}) = \arg \min_{t\neq 0, t\in\mathbb{R}} E(t\mathbf{R}), \tag{2.2}$$

where

$$t^* > 0, g'(t^*) = 0, \quad g''(t^*) > 0, \tag{2.3}$$

$$E(t^*\mathbf{R}) = -\frac{1}{2}\sum_i \frac{n_i^2}{r_i^2}\frac{1}{t^{*2}} = -\frac{1}{2}\left(\sum_i \frac{Z}{r_i} - \sum_{i\neq j}\frac{1}{r_{ij}}\right)^2 \Bigg/ \left(\sum_i \frac{n_i^2}{r_i^2}\right) < 0. \tag{2.4}$$

Proof: First, we note that $\mathcal{S}_Z^n$ is a nonempty unbounded open set of $\mathbb{R}^{3Z}$. It is easy to see that if $\mathbf{R} \in \mathcal{S}_Z^n$, then $t\mathbf{R} \in \mathcal{S}_Z^n$ for any $t \neq 0$, i.e., $\mathcal{S}_Z^n$ is star shaped. For $t > 0$, we have

$$g(t) = \frac{1}{t^2}\sum_i \left(\frac{n_i^2}{2r_i^2}\right) + \frac{1}{t}\left(-\sum_i \frac{Z}{r_i} + \sum_{i\neq j}\frac{1}{2r_{ij}}\right), \tag{2.5}$$

$$g'(t) = -\frac{2}{t^3}\sum_i \frac{n_i^2}{2r_i^2} + \frac{1}{t^2}\left(\sum_i \frac{Z}{r_i} - \sum_{i\neq j}\frac{1}{2r_{ij}}\right). \tag{2.6}$$

Set $g'(t^*)=0$ to get the *only* zero of g' at

$$t^* = \frac{\sum_i n_i^2/r_i^2}{\sum_i Z/r_i - \sum_{i\neq j} 1/2r_{ij}}. \tag{2.7}$$

Note that the denominator in (2.7) is positive since $\mathbf{R} \in \mathcal{S}_Z^n$. So t^* is well defined. Next, we have

$$g''(t) = \frac{6}{t^4}\sum_i \frac{n_i^2}{2r_i^2} - \frac{2}{t^3}\left(\sum_i \frac{Z}{r_i} - \sum_{i\neq j}\frac{1}{2r_{ij}}\right),$$

$$g''(t^*) = \frac{1}{t^{*4}}\sum_i \frac{n_i^2}{r_i^2} > 0.$$

Therefore $g(t)$ has only a global minimum at $t^* > 0$, and $\phi(t^*) = E(t^*\mathbf{R})$ is given as in (2.4). □

Remark 1: If $\mathbf{R} \notin \mathcal{S}_n \cup \mathcal{S}_Z^n$, then for $t > 0$,

$$g(t) = E(t\mathbf{R}) = \frac{1}{t^2}\sum_i \frac{n_i^2}{r_i^2} + \frac{1}{t}\left(-\sum_i \frac{Z}{r_i} + \sum_{i\neq j}\frac{1}{2r_{ij}}\right).$$

This function $g(t)$ is always *positive* and monotonic for $t \in (0,\infty)$ such that $g'(t)=0$ has no solution $t \in \mathcal{R}_+$. In fact, $g'(t) < 0$ on $\mathbb{R}_+$, i.e., g is strictly decreasing. Since $g(t)$ is smooth on $\mathbb{R}_+$, $\lim_{t\to 0} g(t) = +\infty$ and $\lim_{t\to\infty} g(t) = 0$, we have $g(t) \geqslant 0$ for any $t \in \mathbb{R}_+$. □

From (2.1), by completing the square we have

$$E(\mathbf{R}) = \sum_i \left(\frac{n_i}{\sqrt{2}r_i} - \frac{\sqrt{2}Z}{n_i}\right)^2 + \sum_{i\neq j}\frac{1}{2r_{ij}} - \sum_i \frac{2Z^2}{n_i^2} \geqslant -\sum_i \frac{2Z^2}{n_i^2},$$

therefore $E(\mathbf{R})$ is bounded from below, its infimum exists and we have

$$\mu_n^Z := \inf_{\mathbf{R}\in\mathbb{R}^{3n}\setminus\mathcal{S}_n} E_n^Z(\mathbf{R}) = \inf_{\mathbf{R}\in\mathcal{S}_Z^n} E_n^Z(\mathbf{R}) < 0. \tag{2.8}$$

We introduce the following gradient notation: Let $f(x_1, x_2, \ldots, x_n)$ be any scalar valued function of n variables. For any variables $x_{i_1} x_{i_2}, \ldots, x_{i_k}$, where $1 \leqslant i_1 < i_2 < \cdots < i_k \leqslant n$, we denote the gradient of f with respect to these variables as

$$D_{(x_{i_1}x_{i_2},\ldots,x_{i_k})}f(x_1,x_2,\ldots,x_n)=\left[\frac{\partial f}{\partial x_{i_1}}(x_1,x_2,\ldots,x_n),\frac{\partial f}{\partial x_{i_2}}(x_1,x_2,\ldots,x_n),\ldots,\frac{\partial f}{\partial x_{i_k}}(x_1,x_2,\ldots,x_n)\right]^T,$$

(where T means transpose) which is regarded as a column vector. If $(x_{i_1},x_{i_2},\ldots,x_{i_k})=(x_1,x_2,\ldots,x_n)$, i.e., all the variables $x_1,x_2,\ldots,x_n$ are included, then we simply write the above as Df, i.e.,

$$Df=[\partial f/\partial x_1\ \partial f/\partial x_2\cdots\partial f/\partial x_n]^T.$$

A point $\mathbf{y}\in\mathbb{R}^n$ is said to be a *critical point* of f if $Df(y)=\mathbf{0}$. Obviously, any local maximum or minimum of E is a critical point, but many critical points of E may be of the saddle type which are *physically unstable*.

Later, we will also need to utilize the *Hessian matrix* of f,

$$D^2f=\left[\frac{\partial^2 f}{\partial x_i\partial x_j}\right]_{1\leqslant i,j\leqslant n}. \tag{2.9}$$

A critical point $\mathbf{R}^\dagger\in\mathbb{R}^{3Z}$ of $E(\mathbf{R})$ is defined by $DE(\mathbf{R}^\dagger)=0$. Thus, at a critical point we obtain the set of gradient (vector) equations

$$D_{\mathbf{r}_j}E(\mathbf{R}^\dagger)=\mathbf{0}\quad\text{for } j=1,2,\ldots,n, \tag{2.10}$$

i.e.,

$$\left(\frac{n_j^2}{r_j^{\dagger 4}}-\frac{Z}{r_j^{\dagger 3}}\right)\mathbf{r}_j^\dagger+\sum_{\substack{k=1\\k\neq j}}^{n}\frac{1}{2r_{kj}^{\dagger 3}}\mathbf{r}_{kj}^\dagger=\mathbf{0}\in\mathbf{R}^3,\quad j=1,2,\ldots,n. \tag{2.11}$$

Using $\mathbf{r}_{kj}^\dagger=\mathbf{r}_k^\dagger-\mathbf{r}_j^\dagger$, we can write (2.11) alternatively as

$$\left(\frac{n_j^2}{r_j^{\dagger 4}}-\frac{Z}{r_j^{\dagger 3}}+\sum_{\substack{k=1\\k\neq j}}^{n}\frac{1}{2r_{kj}^{\dagger 3}}\right)\mathbf{r}_j^\dagger-\sum_{\substack{k=1\\k\neq j}}^{n}\frac{1}{2r_{kj}^{\dagger 3}}\mathbf{r}_k^\dagger=\mathbf{0},\quad j=1,2,\ldots,n. \tag{2.12}$$

These constitute the equations for the *steady states* of electron orbits, based on the Bohr model. In particular, if $\mathbf{R}^*$ is a global minimum of E established in the preceding section, then $\mathbf{R}^*$ is necessarily a critical point and so the equations in (2.11) or (2.12) hold, with the "†" signs therein replaced by "*."

Theorem 1 (Virial): *Let* $\mathbf{R}^\dagger=(\mathbf{r}_1^\dagger,\mathbf{r}_2^\dagger,\ldots,\mathbf{r}_n^\dagger)$ *be a critical point of E satisfying* $DE(\mathbf{R}^\dagger)=\mathbf{0}\in\mathbb{R}^{3n}$, *then so is* $\mathcal{R}\mathbf{R}^\dagger$ *for any 3D rotation* $\mathcal{R}$, *and* $\mathbf{R}^\dagger\in\mathcal{S}_Z^n$. *The ground-state energy value is given by*

$$E(\mathbf{R}^\dagger)=-\sum_{i=1}^{n}\frac{n_i^2}{2r_i^{\dagger 2}}<0. \tag{2.13}$$

In addition, along the ray $t\mathbf{R}^\dagger$ *for* $t>0$, $E(t\mathbf{R}^\dagger)$ *attains its global minimum at* $t=1$.

Proof: The energy $E(\mathbf{R})$ is invariant under any 3D rotation $\mathcal{R}$, where for $\mathbf{R}=(\mathbf{r}_1,\mathbf{r}_2,\ldots,\mathbf{r}_n)$, $\mathcal{R}\mathbf{R}=(\mathcal{R}\mathbf{r}_1,\mathcal{R}\mathbf{r}_2,\ldots,R\mathbf{r}_n)$. Thus, if $\mathbf{R}^\dagger$ is a critical point, so is $\mathcal{R}\mathbf{R}^\dagger$.

Consider, for $t\neq 0$,

$$E(t\mathbf{R}^\dagger)=\sum_{i=1}^{n}\left(\frac{n_i^2}{2t^2r_i^{\dagger 2}}-\frac{Z}{tr_i^\dagger}\right)+\sum_{\substack{i,j=1\\i\neq j}}^{2}\frac{1}{2tr_{ij}^\dagger}.$$

Then, because $DE(\mathbf{R}^\dagger)=\mathbf{0}$, we have

$$\frac{d}{dt}E(t\mathbf{R}^\dagger)\big|_{t=1} = DE(\mathbf{R}^\dagger)\cdot\mathbf{R}^\dagger = 0,$$

i.e.,

$$\sum_i \left(-\frac{n_i^2}{r_i^{\dagger 2}} + \frac{Z}{r_i^\dagger}\right) - \sum_{i\neq j}\frac{1}{2r_{ij}^\dagger} = 0, \tag{2.14}$$

and

$$\sum_i \frac{Z}{r_i^\dagger} - \sum_{i\neq j}\frac{1}{2r_{ij}^\dagger} = \sum_i \frac{n_i^2}{r_i^{\dagger 2}} > 0,$$

and, hence, $\mathbf{R}^\dagger \in S_Z^n$. Therefore

$$E(\mathbf{R}^\dagger) = \sum_i \left(\frac{n_i^2}{2r_i^{\dagger 2}} - \frac{Z}{r_i^\dagger}\right) + \sum_{i\neq j}\frac{1}{2r_{ij}^\dagger} = \left[\sum_i \left(\frac{n_i^2}{r_i^{\dagger 2}} - \frac{Z}{r_i^\dagger}\right) + \sum_{i\neq j}\frac{1}{2r_{ij}}\right] - \sum_i \frac{n_i^2}{2r_i^{\dagger 2}} = -\sum_{i=1}^{Z}\frac{n_i^2}{2r_i^{\dagger 2}}.$$

But from the proof of Lemma 1, the derivative of function $g(t)=E(t\mathbf{R}^\dagger)$, $g'(t)$, has only one zero t^* satisfying $g'(t^*)=0$. Thus $t^*=1$, and $t^*=1$ necessarily corresponds to the global minimum of $g(t)$.

The proof is complete. □

Corollary 1: Let $R^\dagger=(\mathbf{r}_1^\dagger,\ldots,\mathbf{r}_n^\dagger)$ *be a critical point of E satisfying Theorem 1. Define an* $n\times n$ *matrix* $M^\dagger$ whose (j,k)*-entries* M_{jk} *are given by*

$$M_{jk}^\dagger = \begin{cases} -\dfrac{1}{2r_{kj}^{\dagger 3}}, & k\neq j, \\ \dfrac{n_k^2}{r_k^{\dagger 4}} - \dfrac{Z}{r_k^{\dagger 3}} + \displaystyle\sum_{\substack{i=1\\ i\neq k}}^{Z}\frac{1}{2r_{ki}^{\dagger 3}}, & j=k. \end{cases} \tag{2.15}$$

Then $\det M^\dagger = 0$.

Proof: Note that these $M_{jk}^\dagger$'s are the coefficients appearing in (2.12). As the matrix equation $M^\dagger\boldsymbol{\alpha}=\mathbf{0}\in\mathbb{R}^n$ has at least a nontrivial solution $\boldsymbol{\alpha}\in\mathbb{R}^n$, $\boldsymbol{\alpha}\neq 0$, where $\boldsymbol{\alpha}$ is a vector formed by all of the ith components of the vectors in $(\mathbf{r}_1^\dagger,\mathbf{r}_2^\dagger,\ldots,\mathbf{r}_n^\dagger)$, with $i=1$, or 2, or 3, we must have the determinant of $M^\dagger$ equal to 0. □

From (2.14), we obtain that the set

$$\mathcal{N}_Z^n = \left\{\mathbf{R}=(\mathbf{r}_1,\ldots,\mathbf{r}_n)\in\mathbb{R}^{3n}\setminus\mathcal{S}_n \Big| \sum_{k=1}^{n}\left[\frac{Z}{r_k} - \frac{n_i^2}{r_k^2}\right] = \sum_{\substack{j,k=1\\ j\neq k}}^{n}\frac{1}{2r_{jk}}\right\}, \tag{2.16}$$

contains all critical points of E_n^Z. $\mathcal{N}_Z^n$ is a closed nonempty subset of $\mathbb{R}^{3n}$, and $\mathcal{N}_Z^n\subset S_Z^n$. We then have

$$\inf_{\mathbf{R}\in\mathcal{S}_Z^n} E_n^Z(\mathbf{R}) = \inf_{\mathbf{R}\in\mathcal{N}_Z^n} E_n^Z(\mathbf{R}). \tag{2.17}$$

Furthermore, we obtain from (2.4)

$$E_n^Z(\mathbf{R}) = -\frac{1}{2}\sum_{i=1}^{n}\frac{n_i^2}{r_i^2} < 0, \quad \forall\,\mathbf{R}=(\mathbf{r}_1,\ldots,\mathbf{r}_n)\in\mathcal{N}_Z^n. \tag{2.18}$$

When $n=1$, define $\mathcal{N}_Z^1=\{\mathbf{r}_1\in\mathbb{R}^3 | r_1=n_1^2/Z\}$. For any $\mathbf{r}\in\mathcal{N}_Z^1$,

$$E_1^Z(\mathbf{r}) = -\frac{Z^2}{2n_1^2} = \inf_{\mathbf{r}_1 \in \mathbb{R}^3 \setminus \mathcal{S}_1} E_1^Z(\mathbf{r}_1).$$

Lemma 2: Let $n \geqslant 2$ and $Z=n$, then

$$\mu_n^Z \leqslant \mu_k^Z, \quad \forall\, k\colon 1 \leqslant k \leqslant n-1.$$

If $\mu_k^Z = E_k^Z(\mathbf{r}_1^*, \ldots, \mathbf{r}_k^*)$ for some $(\mathbf{r}_1^*, \ldots, \mathbf{r}_k^*) \in (\mathbb{R}^3)^k$, then

$$\mu_n^Z < \mu_k^Z, \quad \forall\, 1 \leqslant k \leqslant n-1.$$

Proof: For any $(\mathbf{r}_1, \ldots, \mathbf{r}_k) \in S_Z^k$ and $(\mathbf{r}_{k+1}, \ldots, \mathbf{r}_n) \in S_{Z-k}^{n-k}$, we have

$$\begin{aligned} E_n^Z(\mathbf{r}_1, \ldots, \mathbf{r}_k, t\mathbf{r}_{k+1}, \ldots, t\mathbf{r}_n) &= \left\{ \sum_{j=1}^{k} \left[\frac{n_j^2}{2r_j^2} - \frac{Z}{r_j} \right] + \sum_{\substack{j,i=1 \\ j \neq i}}^{k} \frac{1}{2r_{ij}} \right\} \\ &\quad + \left\{ \sum_{j=k+1}^{n} \left[\frac{n_j^2}{2t^2 r_j^2} - \frac{Z}{t r_j} \right] + \sum_{\substack{j,i=k+1 \\ j \neq i}}^{n} \frac{1}{2tr_{ij}} + \sum_{j=k+1}^{n} \sum_{i=1}^{k} \frac{1}{|t\mathbf{r}_j - \mathbf{r}_i|} \right\} \\ &\equiv \Delta_1 + \frac{1}{t}\Delta_2. \end{aligned}$$

Note that

$$\lim_{t\to\infty} \Delta_2 = \lim_{t\to\infty} \left\{ \sum_{j=k+1}^{n} \left[\frac{n_j^2}{2tr_j^2} - \frac{Z}{r_j} \right] + \sum_{\substack{j,i=k+1 \\ j \neq i}}^{n} \frac{1}{2r_{ij}} + \sum_{j=k+1}^{n} \sum_{i=1}^{k} \frac{t}{|t\mathbf{r}_j - \mathbf{r}_i|} \right\} = -\left(\sum_{j=k+1}^{n} \frac{Z-k}{r_j} - \sum_{\substack{j,i=k+1 \\ j \neq i}}^{n} \frac{1}{2r_{ij}} \right).$$

In the special case when $k=n-1$, we have $\mathbf{r}_n \in S_{Z-n+1}^1$ and then

$$\lim_{t\to\infty} \Delta_2 = -\frac{Z-n+1}{r_n} < 0;$$

but if $1 \leqslant k \leqslant n-2$, which occurs only when $n \geqslant 3$, then $(\mathbf{r}_{k+1}, \ldots, \mathbf{r}_n) \in S_{Z-k}^{n-k}$ implies

$$\lim_{t\to\infty} \Delta_2 = -\left(\sum_{j=k+1}^{n} \frac{Z-k}{r_j} - \sum_{\substack{j,i=k+1 \\ j \neq i}}^{n} \frac{1}{2r_{ij}} \right) < 0. \tag{2.19}$$

Thus we obtain, for any $(\mathbf{r}_{k+1}, \ldots, \mathbf{r}_n) \in S_{Z-k}^{n-k}$,

$$\frac{1}{t}\Delta_2 < 0, \quad \text{for } t \text{ sufficiently large.}$$

Hence, we have for any $(\mathbf{r}_1, \ldots, \mathbf{r}_k) \in S_Z^k$, for t sufficiently large,

$$\mu_n^Z \leqslant E_n^Z(\mathbf{r}_1, \ldots, \mathbf{r}_k, t\mathbf{r}_{k+1}, \ldots, t\mathbf{r}_n) < \left(\sum_{j=1}^{k} \left[\frac{n_j^2}{2r_j^2} - \frac{Z}{r_j} \right] + \sum_{\substack{j,i=1 \\ j \neq i}}^{k} \frac{1}{2r_{ij}} \right). \tag{2.20}$$

Thus

$$\mu_n^Z \leqslant \mu_k^Z.$$

If $\mu_k^Z = E_k^Z(\mathbf{r}_1^*, \ldots, \mathbf{r}_k^*)$ for some $(\mathbf{r}_1^*, \ldots, \mathbf{r}_k^*) \in (\mathbb{R}^3)^k$, then (2.19) and (2.20) leads to

$$\mu_n^Z < \mu_k^Z.$$

□

Theorem 2: *Let $Z=n$. There exists an $\mathbf{R}^*=(\mathbf{r}_1^*,\ldots,\mathbf{r}_n^*)\in\mathbb{R}^{3n}$ such that*

$$E_n^Z(\mathbf{R}^*) = \inf_{\mathbf{R}\in\mathbb{R}^{3n}\setminus\mathcal{S}_n} E_n^Z(\mathbf{R}).$$

Proof: Since the case of $n=1$ is trivial, we assume $n\geqslant 2$. From (2.8) and (2.17), we only need to prove that there exists an $\mathbf{R}^*=(\mathbf{r}_1^*,\ldots,\mathbf{r}_n^*)\in\mathcal{N}_Z^n$ such that

$$E_n^Z(\mathbf{R}^*) = \inf_{\mathbf{R}\in\mathcal{N}_Z^n} E_n^Z(\mathbf{R}) = \mu_n^Z.$$

Let $\{\mathbf{R}_m\}\subset\mathcal{N}_Z^n$ be a minimizing sequence such that $E_n^Z(\mathbf{R}_m)\to\mu_n^Z$ as $m\to\infty$. We first show that $\{\mathbf{R}_m\}$ is bounded.

Suppose $\{\mathbf{R}_m\}$ is unbounded. Let $\mathbf{R}_m=(\mathbf{r}_1^m,\ldots,\mathbf{r}_n^m)$. By replacing $\{\mathbf{R}_m\}$ with its subsequence, if necessary, essentially two cases need to be considered:

(a) $|\mathbf{r}_k^m|\to+\infty$, $1\leqslant k\leqslant n$; and
(b) there exist $M>0$ and k_0: $1\leqslant k_0\leqslant n-1$, such that

$$r_k^m\to+\infty,\quad 1\leqslant k\leqslant k_0,$$

$$r_k^m\leqslant M,\quad k_0+1\leqslant k\leqslant n.$$

In general, the index set $\{1,2,\ldots,n\}$ has two disjoint subsets such that $r_k^m\to\infty$ and $r_k^m<M$, respectively, as $m\to\infty$ for k in each of these two index subsets. But the proof is the same.

For case (a), since $\{\mathbf{R}_m\}\subset\mathcal{N}_Z^n$ and (2.18), we have

$$\mu_n^Z = \lim_{m\to\infty} E_n^Z(\mathbf{R}_m) = \lim_{m\to\infty}\left\{-\frac{1}{2}\sum_{i=1}^n \frac{n_i^2}{r_i^m}\right\} = 0.$$

This contradicts $\mu_n^Z<0$ from (2.8). Thus, case (a) is impossible.

For case (b), we can further assume that $\mathbf{r}_k^m\to\mathbf{r}_k^*$ for $k_0+1\leqslant k\leqslant n$. Then we have

$$\begin{aligned}\mu_n^Z &= \lim_{m\to\infty} E_n^n(\mathbf{R}_m) = \lim_{m\to\infty}\left\{\sum_{i=1}^n\left(\frac{n_i^2}{2(r_i^m)^2}-\frac{Z}{r_i^m}\right)+\sum_{\substack{i,j=1\\ i\neq j}}^n\frac{1}{2r_{ij}^m}\right\}\\ &= \left\{\sum_{k=k_0+1}^n\left[\frac{n_k^2}{2(r_k^*)^2}-\frac{Z}{r_k^*}\right]+\sum_{\substack{j,k=k_0+1\\ j\neq k}}^n\frac{1}{2r_{jk}^*}\right\}+\lim_{m\to\infty}\sum_{\substack{j,k=1\\ j\neq k}}^{k_0}\frac{1}{2r_{jk}^m}\geqslant\mu_{n-k_0}^Z+\lim_{m\to\infty}\sum_{\substack{j,k=1\\ j\neq k}}^{k_0}\frac{1}{2r_{jk}^m}\geqslant\mu_{n-k_0}^Z.\end{aligned}$$

By applying the first part of Lemma 2, we must have

$$\lim_{m\to\infty}\sum_{\substack{j,k=1\\ j\neq k}}^{k_0}\frac{1}{r_{jk}^m}=0$$

and

$$\mu_n^Z = \mu_{n-k_0}^Z = \sum_{k=k_0+1}^{n} \left[\frac{n_i^2}{2(r_k^*)^2} - \frac{Z}{r_k^*} \right] + \sum_{\substack{j,k=k_0+1 \\ j\neq k}}^{n} \frac{1}{2r_{jk}^*},$$

which contradicts the second part of Lemma 2. Thus, case (b) is also impossible.

Therefore $\{\mathbf{R}_m\}$ is bounded and contains a convergent subsequence, denoted by $\{\mathbf{R}_m\}$ again, such that $\mathbf{R}_m \to \mathbf{R}^* \in \mathbb{R}^{3n}$. Since $\mathcal{N}_Z^n$ is a closed subset of $\mathbb{R}^{3n}$, we have $\mathbf{R}^* \in \mathcal{N}_Z^n$, and

$$E_n^n(\mathbf{R}^*) = \mu_n^Z = \inf_{\mathbf{R}\in\mathbb{R}^{3n}\setminus\mathcal{S}_n} E_n^Z(\mathbf{R}).$$

□

Corollary 2: Let $Z=n$. For any nontrivial subspace V of $\mathbb{R}^3$, the energy function E_n^Z defined in (2.1) attains a minimum in V^n. □

III. CRITICAL POINTS OF THE ENERGY E: STABLE AND UNSTABLE ELECTRON CONFIGURATIONS

From here throughout the rest of the paper for all practical interest we assume $n=Z$ for E_n^Z, which will be written simply as E.

In order to distinguish any global (or, possibly local) minimizer $\mathbf{R}^*$ from a saddle-type critical point $\mathbf{R}^\wedge$ of E, we need to examine whether the $(3Z)\times(3Z)$ Hessian matrix D^2E [cf. (2.9)] is (semi-) positive-definite at $\mathbf{R}^*$, as the second order Taylor approximation gives

$$E(\mathbf{R}) = E(\mathbf{R}^*) + DE(\mathbf{R}^*)\cdot(\mathbf{R}-\mathbf{R}^*) + \frac{1}{2}(\mathbf{R}-\mathbf{R}^*)^T\cdot D^2E(\mathbf{R}^*)\cdot(\mathbf{R}-\mathbf{R}^*) + \mathcal{O}(|\mathbf{R}-\mathbf{R}^*|^3)$$

$$= E(\mathbf{R}^*) + \frac{1}{2}(\mathbf{R}-\mathbf{R}^*)^T\cdot D^2E(\mathbf{R}^*)\cdot(\mathbf{R}-\mathbf{R}^*) + \mathcal{O}(|\mathbf{R}-\mathbf{R}^*|^3), \quad \text{for } |\mathbf{R}-\mathbf{R}^*| \text{ small},$$

requiring that

$$\mathbf{R}^T\cdot D^2E(\mathbf{R}^*)\cdot\mathbf{R} \geqslant 0 \quad \text{for any } \mathbf{R}\in\mathbb{R}^{3Z},$$

for $\mathbf{R}^*$ to be a local or global minimum.

Following the terminology of calculus of variations, we say that a critical point $\mathbf{R}^\wedge$ is *nondegenerate* if $D_{\mathbf{R}}^2E(\mathbf{R}^\wedge)$ is an invertible (i.e., nonsingular) $(3Z)\times(3Z)$ matrix. Otherwise, $\mathbf{R}^\wedge$ is said to be a *degenerate* critical point. Thus, a critical point is degenerate if and only if $D_{\mathbf{R}}^2E(\mathbf{R}^\wedge)$ has 0 as its eigenvalue. Here all the critical points are degenerate according to the following, due to the rotational invariance of the critical points (Theorem 1).

Theorem 3 (degeneracy of critical points): *Any critical point $\mathbf{R}^\wedge$ of $E(\mathbf{R})$ is degenerate. The dimension of degeneracy is at least 2.*

Proof: Any critical point $\mathbf{R}_0^\wedge$ satisfies (2.10) and, according to Theorem 1, $\mathcal{R}\mathbf{R}^\wedge$ is also a critical point for any 3D rotation $\mathcal{R}$,

$$DE(\mathcal{R}\mathbf{R}_0^\wedge) = \mathbf{0} \in \mathbb{R}^{3Z}. \tag{3.1}$$

From the theory of Lie groups in $\mathbb{R}^3$, we know that the rotation group SO(3) (i.e., the special orthogonal group) in $\mathbb{R}^3$ can be (essentially) parametrized by two independent parameters (θ_1,θ_2). So we may write $\mathcal{R}=\mathcal{R}(\theta_1,\theta_2)$ and define

$$\mathbf{R}^\wedge(\theta_1,\theta_2) \equiv \mathcal{R}(\theta_1,\theta_2)\mathbf{R}_0^\wedge. \tag{3.2}$$

Then by (3.1),

$$DE(\mathbf{R}^{\wedge}(\theta_1,\theta_2))=\mathbf{0} \quad \text{for all } \theta_1 \text{ and } \theta_2. \tag{3.3}$$

Thus, by the chain rule,

$$\frac{\partial}{\partial\theta_j}DE(\mathbf{R}^{\wedge}(\theta_1,\theta_2))=D^2E(\mathbf{R}^{\wedge}(\theta_1,\theta_2))\cdot\left[\frac{\partial}{\partial\theta_j}\mathbf{R}^{\wedge}(\theta_1,\theta_2)\right]=\mathbf{0}, \quad j=1,2. \tag{3.4}$$

Since

$$\frac{\partial}{\partial\theta_j}\mathbf{R}^{\wedge}(\theta_1,\theta_2)\neq\mathbf{0} \quad \text{for } j=1,2, \tag{3.5}$$

and $(\partial/\partial\theta_1)\mathbf{R}^{\wedge}(\theta_1,\theta_2)$ and $(\partial/\partial\theta_2)\mathbf{R}^{\wedge}(\theta_1,\theta_2)$ are linearly independent, because by holding $\theta_1=\theta_1^0$ and $\theta_2=\theta_2^0$, $\mathbf{R}^{\wedge}(\theta_1,\theta_2^0)$ and $\mathbf{R}^{\wedge}(\theta_1^0,\theta_2)$ form two independent trajectories when only one of θ_1 and θ_2 is allowed to vary, and $(\partial/\partial\theta_1)\mathbf{R}^{\wedge}(\theta_1,\theta_2^0)$ and $(\partial/\partial\theta_2)\mathbf{R}^{\wedge}(\theta_1^0,\theta_2)$ are the tangent vectors along these two independent trajectories. We conclude from (3.4) that the Hessian matrix $D^2E(\mathbf{R}^{\wedge})$ has two linearly independent eigenvectors corresponding to the eigenvalue 0. The proof is complete. □

The determination of *all* critical point $\mathbf{R}^{\dagger}$ from either (2.11) or analytically is no easy task. The following two theorems provide a systematic way to construct (unstable) saddle-type critical points which are not global minima.

Define a subset $\mathbb{R}_x^{3Z}$ of $\mathbb{R}^{3Z}$ by

$$\mathbb{R}_x^{3Z}=\{\mathbf{R}=(\mathbf{r}_1,\mathbf{r}_2,\ldots,\mathbf{r}_Z)\in\mathbb{R}^{3Z}|\mathbf{r}_j=(x_j,y_j,z_j)^T=(x_j,0,0), \text{ for } j=1,2,\ldots,Z;x_j\in\mathbb{R}\}. \tag{3.6}$$

So $\mathbb{R}_x^{3Z}$ is a Z-dimensional subspace of $\mathbb{R}^{3D}$. The subspaces $\mathbb{R}_y^{3Z}$ and $\mathbb{R}_z^{3Z}$ can be defined likewise.

Theorem 4: *The minimization problem*

$$\min_{\mathbf{R}\in\mathbb{R}_x^{3Z}} E(\mathbf{R}) \tag{3.7}$$

has at least a (global) minimizer $\mathbf{R}_x^*\in\mathbf{R}_x^{3Z}$. *This* $\mathbf{R}_x^*$ *is also a critical point of* E *in* $\mathbb{R}^{3Z}$, *i.e.*, $DE(\mathbf{R}_x^*)=\mathbf{0}$. *In fact, any critical point* $\mathbf{R}_x^{\dagger}$ *of* $E(\mathbf{R})$ *in* $\mathbb{R}_x^{3Z}$ *is also a critical point of* E *in* $\mathbb{R}^{3Z}$, *i.e.*, $DE(\mathbf{R}_x^{\dagger})=\mathbf{0}$. *The same is true if* $\mathbb{R}_x^{3Z}$ *is replaced by* $\mathbb{R}_y^{3Z}$ *or* $\mathbb{R}_z^{3Z}$.

Proof: Because $\mathbb{R}_x^{3Z}$ is a closed subspace of $\mathbb{R}^{3Z}$, we can establish that (3.7) has a minimizer $\mathbf{R}_x^*$ in $\mathbb{R}_x^{3Z}$ by Corollary 2. The same conclusion follows for $\mathbb{R}_{y_x}^{3Z}$ and $\mathbb{R}_y^{3Z}$.

We now show how $\mathbf{R}_x^*$ satisfies $DE(\mathbf{R}_x^*)=\mathbf{0}$. Since $\mathbf{R}_x^*$ solves (3.7), we have the gradient equations

$$\frac{\partial}{\partial x_j}E(\mathbf{R})\big|_{\mathbf{R}=\mathbf{R}_x^*}=0, \quad \text{for } j=1,2,\ldots,Z; \text{ cf. (3.6) for } x_j.$$

The above gives

$$\left(\frac{n_j^2}{x_j^{*4}}-\frac{Z}{x_j^{*3}}+\sum_{\substack{k=1\\k\neq j}}^{Z}\frac{1}{2|x_k^*-x_j^*|^3}\right)x_j^*-\sum\frac{1}{2|x_k^*-x_j^*|^3}x_k^*=0, \quad j=1,2,\ldots,Z, \tag{3.8}$$

where x_j^*'s are the first components of $\mathbf{r}_j^*$, with $\mathbf{R}_x^*=(\mathbf{r}_1^*,\mathbf{r}_2^*,\ldots,\mathbf{r}_Z^*)$. Note that (3.8) just represents the first component (i.e., related to x) of the vector equations (2.12), with "†" therein replaced by "*." But the second and third components (related to y and z) are automatically satisfied because $y_j=z_j=0$ for $j=1,2,\ldots,Z$. □

Next, define the following subsets of $\mathbb{R}^{3Z}$:

$$\mathbb{R}_{x,y}^{3Z}=\{\mathbf{R}=(\mathbf{r}_1,\mathbf{r}_2,\ldots,\mathbf{r}_Z)\in\mathbb{R}^{3Z}|\mathbf{r}_j=(x_j,y_j,z_j)=(x_j,y_j,0), \text{ for } j=1,2,\ldots,Z;x_j,y_j\in\mathbb{R}\},$$

$$\mathbb{R}^{3Z}_{x,z} = \{\mathbf{R} = (\mathbf{r}_1, \mathbf{r}_2, \ldots, \mathbf{r}_z) \in \mathbb{R}^{3Z} | \mathbf{r}_j = (x_j, y_j, z_j) = (x_j, 0, z_j), \text{ for } j = 1,2, \ldots, Z; x_j, z_j \in \mathbb{R}\},$$

$$\mathbb{R}^{3Z}_{y,z} = \{\mathbb{R} = (\mathbf{r}_1, \mathbf{r}_2, \ldots, \mathbf{r}_Z) \in \mathbb{R}^{3Z} | \mathbf{r}_j = (x_j, y_j, z_j) = (0, y_j, z_j), \text{ for } j = 1,2, \ldots, Z; y_j, z_j \in \mathbb{R}\}.$$

Theorem 5: *The minimization problem*

$$\min_{\mathbf{R} \in \mathbb{R}^{3Z}_{x,y}} E(\mathbf{R})$$

has at least a (global) minimizer $\mathbf{R}^*_{x,y} \in \mathbb{R}^{3Z}_{x,y}$. *This* $\mathbf{R}^*_{x,y}$ *is a critical point of* $E(\mathbf{R})$ *in* $\mathbb{R}^{3Z}$, *i.e.*, $DE(\mathbf{R}^*_{x,y}) = \mathbf{0}$. *In fact, any critical point* $\mathbf{R}^\dagger_{x,y}$ *of* $E(\mathbf{R})$ *in* $\mathbb{R}^{3Z}_{x,y}$ *is also a critical point of* $E(\mathbf{R})$ *in* $\mathbb{R}^{3Z}$, *i.e.*, $DE(\mathbf{R}^\dagger_{x,y}) = \mathbf{0}$. *The same theorem holds if we replace* $\mathbb{R}^{3D}_{x,y}$ *above by* $\mathbb{R}^{3D}_{x,z}$ *or* $\mathbb{R}^{3D}_{y,z}$.

Proof: Same as that for Theorem 4. □

Corollary 3: Let V be a (coordinate) subspace of $\mathbb{R}^3$ *with dimension 1 or 2. Then any critical point of E on* V^Z *is a critical point of E on* $\mathbb{R}^{3Z}$.

Proof: Any such V can be obtained by a rotation from $\mathbb{R}^{3Z}_x$ or $\mathbb{R}^{3Z}_{x,y}$, respectively, if V has dimension of, respectively, 1 and 2. The corollary follows because E is rotationally invariant. □

Remark 2:

(i) Due to the rotational invariance of the critical points, there is *nonuniqueness* of the global minimum of $E(\mathbf{R})$. Thus, a *quotient space* needs to be used (or considered) if one wishes to have any uniqueness of the global minimum of E. Computationally, this 3D rotational congruence is avoided by setting up a coordinate frame using (5.1) in Sec. V.

(ii) According to Lemma 1, for any critical point $\mathbf{R}^\wedge$, the direction along the ray $\mathbf{R}^\wedge$ is a direction of increase for E. Therefore, $D^2_{\mathbf{R}} E(\mathbf{R}^\wedge)$ has *at least one positive eigenvalue*.

(iii) According to the numerical computation in Examples 2 and 3 in Sec. V, critical points computed by utilizing Theorems 4 and 5 and Corollary 3 all have some *negative eigenvalues* for the Hessian $D^2_R(E)$ at those critical points. Thus, in view of (ii) above, those critical points are all *saddle-type* unstable critical points. □

We conjecture that the energy function E as defined in Table I and (1.6) and (1.9) has only finitely many critical points $\mathbf{R}^\dagger$ satisfying $DE(\mathbf{R}^\dagger) = \mathbf{0}$, which are not rotationally equivalent. But we do not yet have a proof.

IV. COPLANARITY OF STABLE OR UNSTABLE ELECTRON CONFIGURATIONS

Numerical results (see Example in Sec. V) indicate that for $Z=3$ and 4, the stable electron configuration (corresponding to a global minimizer of E) has all electrons coplanar with the origin. For $Z=1$ and 2, the coplanarity is trivial. For $Z \geqslant 5$, numerical evidence suggests that coplanarity no longer holds.

Theorem 6 (co-planarity of the electrons with the origin, $Z=3$): Let $Z=3$. If $\mathbf{R}^\dagger = (\mathbf{r}^\dagger_1, \mathbf{r}^\dagger_2, \mathbf{r}^\dagger_3)$ *is a critical point of* $E(\mathbf{R})$ (*including the global minimizer* $\mathbf{R}^*$), *then* $\mathbf{r}^\dagger_1, \mathbf{r}^\dagger_2, \mathbf{r}^\dagger_3$, and $\mathbf{0}$ *are coplanar in* $\mathbb{R}^3$.

Proof: For clarity, we write out the system of equations (2.12),

$$\left(\frac{1}{r^{\dagger 4}_1} - \frac{3}{r^{\dagger 3}_1} + \frac{1}{r^{\dagger 3}_{12}} + \frac{1}{r^{\dagger 3}_{13}}\right)\mathbf{r}^\dagger_1 - \frac{1}{r^{\dagger 3}_{12}}\mathbf{r}^\dagger_2 - \frac{1}{r^{\dagger 3}_{13}}\mathbf{r}^\dagger_3 = \mathbf{0},$$

$$\left(\frac{1}{r^{\dagger 4}_2} - \frac{3}{r^{\dagger 3}_2} + \frac{1}{r^{\dagger 3}_{12}} + \frac{1}{r^{\dagger 3}_{23}}\right)\mathbf{r}^\dagger_2 - \frac{1}{r^{\dagger 3}_{12}}\mathbf{r}_1 - \frac{1}{r^{\dagger 3}_{23}}\mathbf{r}^\dagger_3 = \mathbf{0},$$

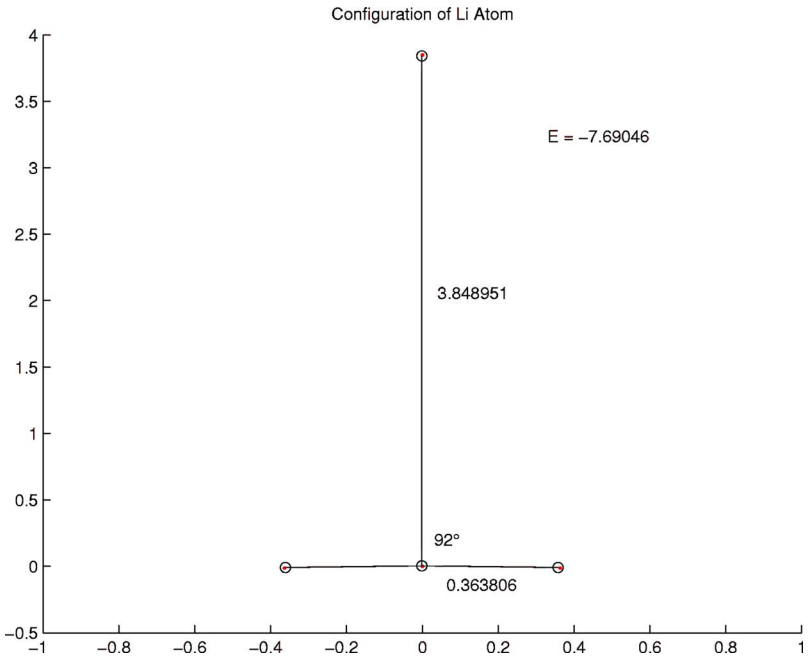

FIG. 1. For lithium (Li), $Z=3$. The electron configuration is shown. We have $r_1=r_2=0.363\,806$, $r_3=3.848\,951$, $\theta_2=1.605\,660=91.997\,541\,43^\circ\neq\pi/2$, $\theta_3=1.605\,660=91.997\,541\,31^\circ\neq\pi/2$, $\phi_3=\pi$, $E=-7.690\,46$(htr); htr=hartree.

$$\left(\frac{4}{r_3^{\dagger 4}}-\frac{3}{r_3^{\dagger 3}}+\frac{1}{r_{13}^{\dagger 3}}+\frac{1}{r_{23}^{\dagger 3}}\right)\mathbf{r}_3^{\dagger}-\frac{1}{r_{13}^{3}}\mathbf{r}_1^{\dagger}-\frac{1}{r_{23}^{\dagger 3}}\mathbf{r}_2^{\dagger}=\mathbf{0}. \tag{4.1}$$

If any single equation in (4.1) has all three coefficients of $\mathbf{r}_1^{\dagger}$, $\mathbf{r}_2^{\dagger}$, and $\mathbf{r}_3^{\dagger}$ to be nonzero, then any one vector in $\{\mathbf{r}_1^{\dagger},\mathbf{r}_2^{\dagger},\mathbf{r}_3^{\dagger}\}$ can be expressed as a linear combination of the other two vectors, and

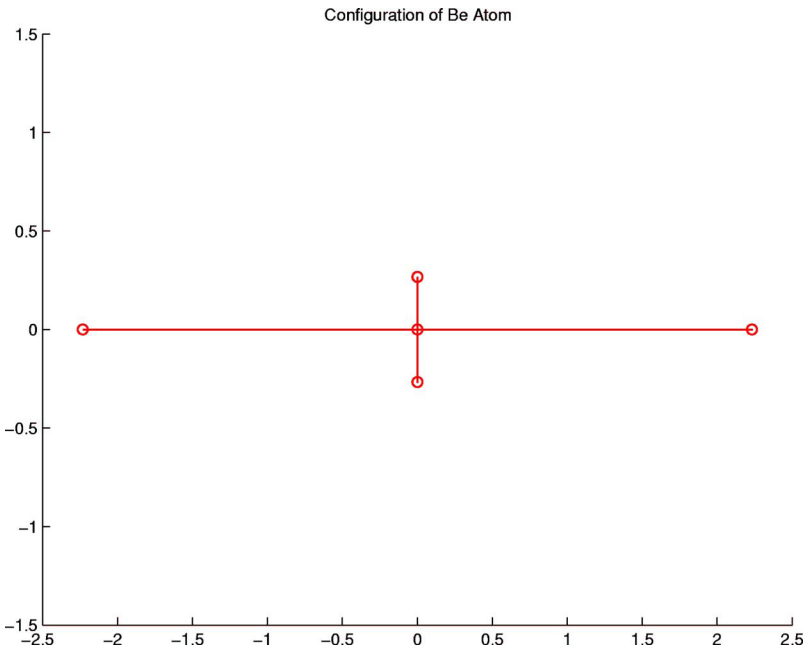

FIG. 2. (Color online) For beryllium (Be), $Z=4$. We have $r_1=r_2=0.266\,90$, $\theta_2=3.141\,59=\pi$, $r_3=r_4=2.231\,96$, $\theta_3=\theta_4=1.570\,80=\pi/2$, $\phi_3=\phi_4=3.141\,59=\pi$, $E=-14.840\,35$(htr).

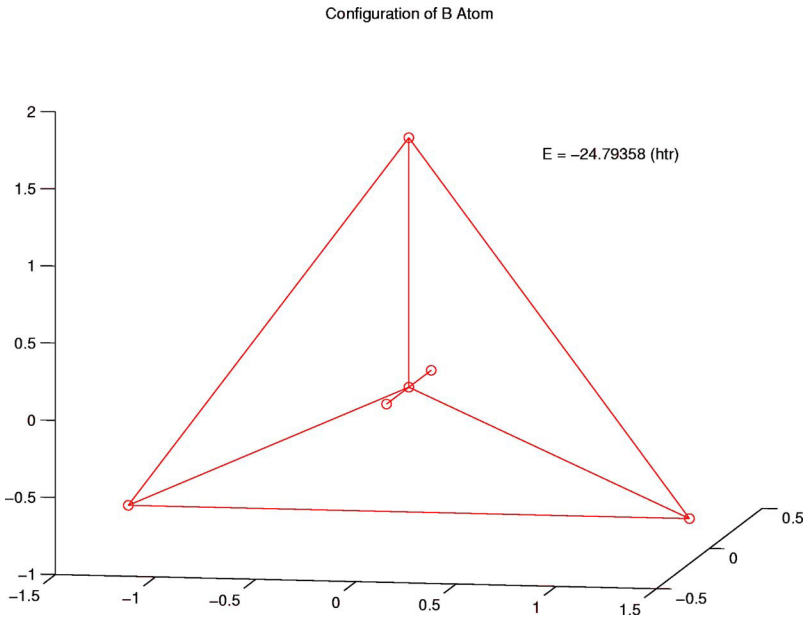

FIG. 3. (Color online) For boron (B), $Z=5$. We have $r_1=r_2=0.210\,81$, $r_3=r_4=r_5=1.617\,77$, $\theta_2=2.094\,40=2\pi/3$, $\theta_3=2.094\,40=2\pi/3$, $\phi_3=3.141\,59=\pi$, $\theta_4=1.570\,80=\pi/2$, $\phi_4=1.570\,80=\pi/2$, $\theta_5=1.570\,80=\pi/2$, $\phi_5=-1.570\,80=-\pi/2$, $E=-24.793\,58$(htr).

thus the proof follows. Therefore, the only possibility that $\mathbf{r}_1^\dagger$, $\mathbf{r}_2^\dagger$, $\mathbf{r}_3^\dagger$ and $\mathbf{0}$ are not coplanar is when

$$\frac{n_i^2}{r_i^{\dagger 4}} - \frac{3}{r_i^{\dagger 3}} - \sum_{\substack{j=1 \\ j\neq i}}^{3} \frac{1}{r_{ij}^\dagger} = 0 \quad \text{for } i = 1,2,3. \tag{4.2}$$

But the above implies, from (4.2), that

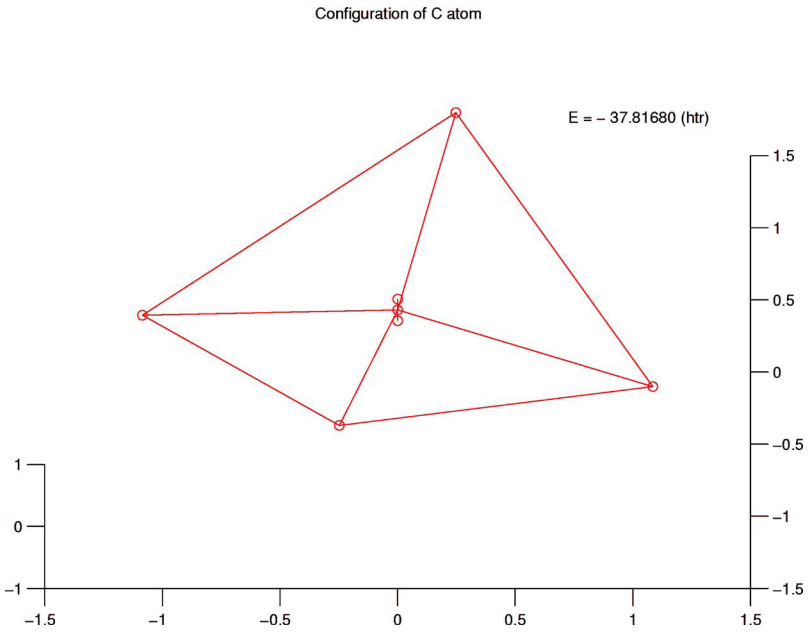

FIG. 4. (Color online) For carbon (C), $Z=6$. We have $r_1=r_2=0.173\,98$, $r_3=r_4=r_5=r_6=1.293\,53$, $\theta_2=3.141\,59=\pi$, $\theta_3=2.106\,38$, $\phi_3=-0.224\,66$, $\theta_4=1.035\,22$, $\phi_4=1.346\,14$, $\theta_5=2.106\,38$, $\phi_5=2.916\,93$, $\theta_6=1.035\,22$, $\phi_6=-1.795\,46$, $E=-37.816\,80$(htr).

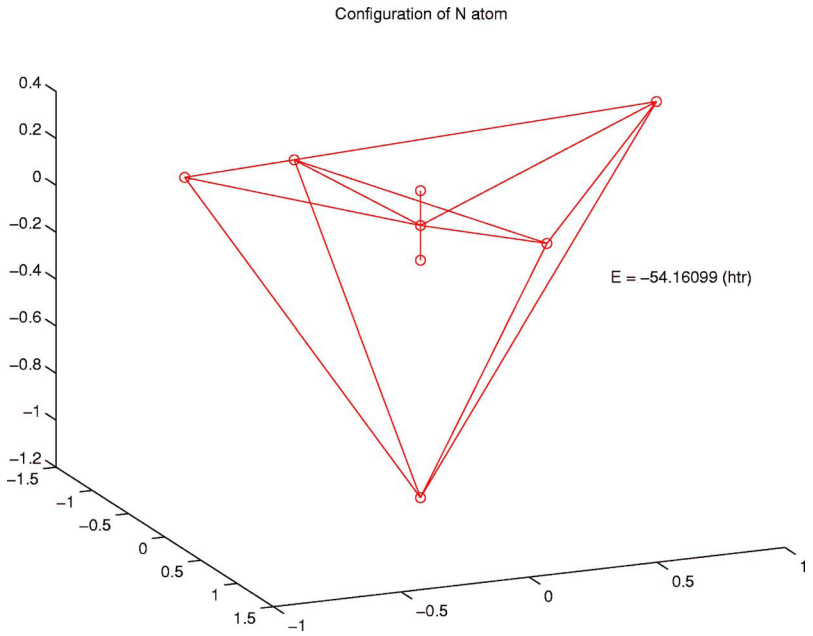

FIG. 5. (Color online) For nitrogen (N), $Z=7$. We have $r_1=r_2=0.148\,22$, $r_3=r_6=1.060\,95$, $r_4=r_5=1.051\,75$, $r_7=1.158\,87$, $\theta_2=3.141\,59=\pi$, $\theta_3=-\theta_6=1.218\,01$, $\phi_3=\phi_6=-0.195\,28$, $\theta_4=\theta_5=1.474\,08$, $\phi_4=1.375\,51$, $\phi_5=-1.766\,08$, $\theta_7=3.141\,59=\pi$, $\phi_7=0.328\,85$, $E=-54.160\,99$(htr).

$$\frac{1}{r_{12}^{\dagger 3}}\mathbf{r}_2^{\dagger}+\frac{1}{r_{13}^{\dagger 3}}\mathbf{r}_3^{\dagger}=\mathbf{0},\quad \frac{1}{r_{12}^{\dagger 3}}\mathbf{r}_1^{\dagger}+\frac{1}{r_{23}^{\dagger 3}}\mathbf{r}_3^{\dagger}=\mathbf{0},\quad \frac{1}{r_{12}^{\dagger 3}}\mathbf{r}_1^{\dagger}+\frac{1}{r_{23}^{\dagger 3}}\mathbf{r}_2^{\dagger}=\mathbf{0}.$$

Adding up the three equations in (4.2), we have

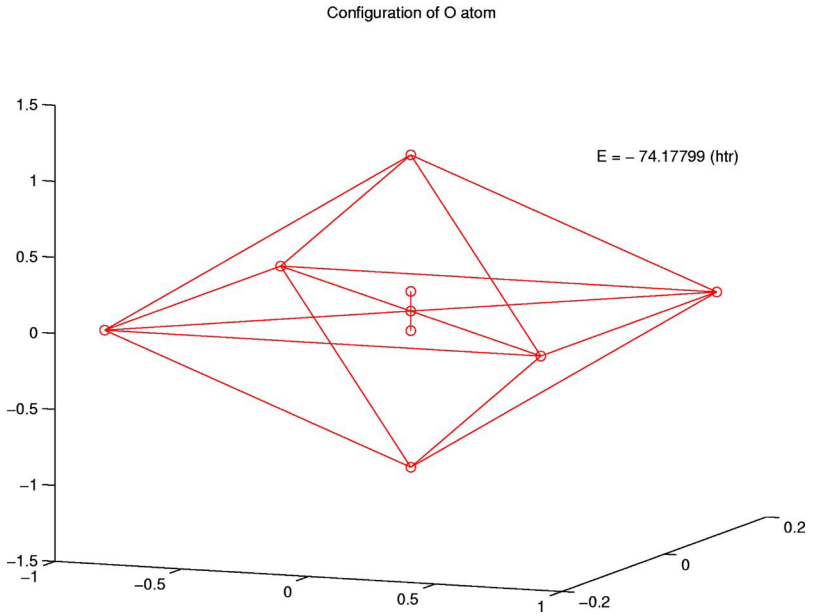

FIG. 6. (Color online) For oxygen (O), $Z=8$. We have $r_1=r_2=0.129\,10$, $r_3=r_4=r_5=r_6=0.877\,70$, $r_7=r_8=1.026\,74$, $\theta_2=\theta_8=\pi$, $\theta_3=\theta_4=\theta_5=\theta_6=\pi/2$, $\theta_7=0$, $\phi_3=-0.197\,20$, $\phi_4=1.373\,60$, $\phi_5=2.944\,40$, $\phi_6=-1.768\,00$, $\phi_7=-0.482\,03$, $\phi_8=-0.737\,23$, $E=-74.177\,99$(htr).

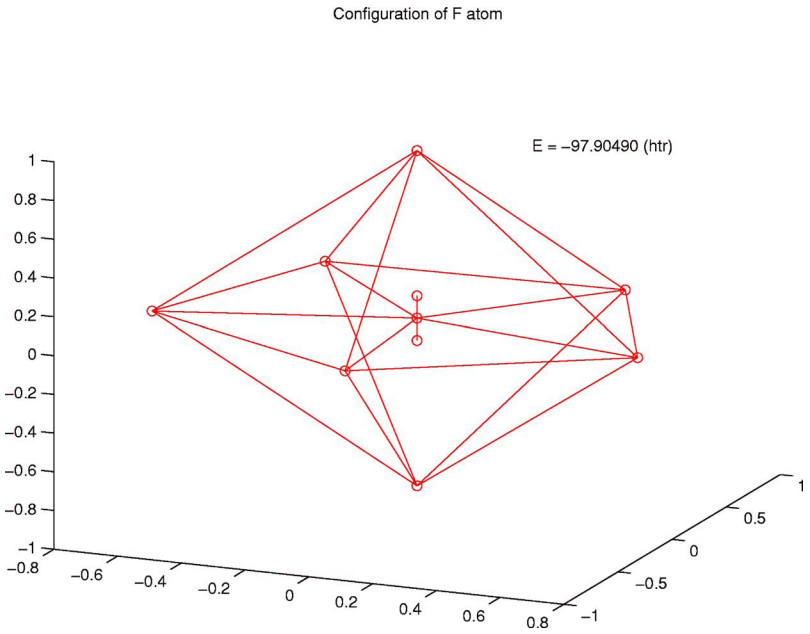

FIG. 7. (Color online) For fluorine (F), $Z=9$. We have $r_1=r_2=0.114\,35$, $r_3=r_4=r_5=r_6=r_7=0.78\,23$, $r_8=r_9=0.865\,58$, $\theta_2=\theta_9=\pi$, $\theta_3=\theta_4=\theta_5=\theta_6=\theta_7=\pi/2$, $\theta_8=0$, $\phi_3=-0.261\,52$, $\phi_4=0.995\,12$, $\phi_5=2.251\,76$, $\phi_6=3.508\,39$, $\phi_7=4.765\,03$, $\phi_8=-0.213\,56$, $\phi_9=-0.021\,96$, $E=-97.904\,90$(htr).

$$\sum_{i=}^{3}\left(\sum_{\substack{j=1\\ j\neq i}}^{3}\frac{1}{r_{ij}^{\dagger 3}}\right)\mathbf{r}_i^{\dagger}=\mathbf{0}.$$

Once again, any $\mathbf{r}_i^{\dagger}$ can be expressed as a linear combination of $\mathbf{r}_j^{\dagger}$ for $j\neq i$. Therefore, $\mathbf{r}_1^{\dagger}$, $\mathbf{r}_2^{\dagger}$, $\mathbf{r}_3^{\dagger}$ and $\mathbf{0}$ are coplanar. □

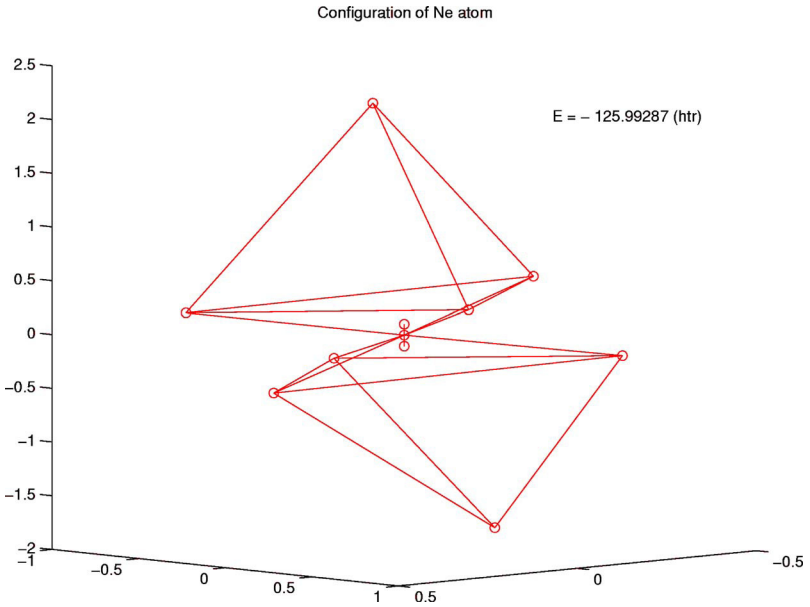

FIG. 8. (Color online) For neon (NE), $Z=10$. We have $r_1=r_2=0.102\,63$, $r_3=2.146\,17$, $r_4=0.637\,26$, $r_5=0.632\,88$, $r_6=0.633\,87$, $r_7=0.633\,55$, $r_8=0.630\,08$, $r_9=0.624\,96$, $r_{10}=1.870\,83$, $\theta_2=3.139\,87(\neq\pi)$, $\theta_3=-0.063\,17$, $\theta_4=0.990\,93$, $\theta_5=1.069\,46$, $\theta_6=0.985\,91$, $\theta_7=2.138\,22$, $\theta_8=2.114\,86$, $\theta_9=2.040\,94$, $\theta_{10}=3.016\,75$, $\phi_3=-0.168\,95$, $\phi_4=0.141\,27$, $\phi_5=2.172\,93$, $\phi_6=4.253\,46$, $\phi_7=1.110\,58$, $\phi_8=3.258\,05$, $\phi_9=-0.948\,26$, $\phi_{10}=-1.325\,32$, $E=-125.992\,87$(htr).

TABLE III. Locations of four critical points of problem (5.4). Note that only $\mathbf{R}_2^\dagger$ and $\mathbf{R}_3^\dagger$ are true minimizers for (5.4), while $\mathbf{R}_1^\dagger$, $\mathbf{R}_4^\dagger$, and $\mathbf{R}_5^\dagger$ are just local minima for (5.4).

	Coordinates [cf. (5.3)] (set $\phi_2=\pi$)					
Critical points	r_1	r_2	r_3	θ_1	θ_2	Energies
$\mathbf{R}_1^\dagger$	1.0334	0.3133	7.2778	0	0	−5.5985
$\mathbf{R}_2^\dagger$	0.3622	0.3647	4.1865	0	π	−7.6837
$\mathbf{R}_3^\dagger$	0.3647	0.3622	4.1865	π	0	−7.6837
$\mathbf{R}_4^\dagger$	1.0967	0.3174	2.2462	π	π	−5.7752
$\mathbf{R}_5^\dagger$	0.3174	1.0967	2.2462	π	π	−5.7752

At this time, we are not yet able to prove the coplanarity property for the case $Z=4$, which as Fig. 2 in the next section indicates, is true from numerical computation.

V. NUMERICAL EXAMPLES AND DATA

We first list in Table II the comparison between the experimental values of atoms' ground-state energies and those of the Bohr energies, for atom numbers between 2 and 30. There is a reasonable agreement between these values when Z is small. When the value of Z increases, the deviations also grow. Nevertheless, the *trend* of Bohr's atom energies look good.

We now provide several examples to illustrate stable as well as unstable electron configurations according to Bohr's model, by utilizing Theorems 4 and 5 and Corollary 3.

Example 1 (*stable electron configurations for the ground state of the Bohr atom model, with* $Z: 3 \leqslant Z \leqslant 10$): We set up the problem as follows. In order to avoid the 3D rotational congruence as stated in Theorem 1, we fix the direction of $\mathbf{r}_1$ along the positive z axis and that of $\mathbf{r}_2$ on the (x,z)-plane, as follows:[10]

$$\mathbf{r}_1 = r_1\mathbf{k},$$

$$\mathbf{r}_2 = r_2 \sin\theta_2\mathbf{i} + r_2\cos\theta_2\mathbf{k},$$

$$\mathbf{r}_i = r_i \sin\theta_i\cos\phi_i\mathbf{i} + r_i\sin\theta_i\sin\phi_i\mathbf{j} + r_i\cos\theta_i\mathbf{k}, \quad i \geqslant 3,$$

$$0 \leqslant \theta_i \leqslant \pi, \quad 0 \leqslant \phi_i \leqslant 2\pi, \quad i \geqslant 2. \tag{5.1}$$

Then the relative distances become

$$r_{1i} = (r_1^2 - r_i^2 - 2r_1r_i\cos\theta_i)^{1/2}, \quad 2 \leqslant i \leqslant Z,$$

$$r_{2i} = [r_2^2 + r_i^2 - 2r_2r_i(\sin\theta_2\sin\theta_i\cos\phi_i + \cos\theta_2\cos\phi_i)]^{1/2}, \quad 3 \leqslant i \leqslant Z,$$

TABLE IV. Eigenvalues of the Hessian with respect to the angular variables θ_1 and θ_2.

Point	Two eigenvalues of Hessian $[\partial^2 E/\partial\theta_i\partial\theta_j]$	Eigenvectors
$\mathbf{R}_1^\dagger$	−1.7530, −0.0187	$(-0.7120,-0.7022)^T$, $(0.7022,-0.7120)^T$
$\mathbf{R}_2^\dagger$	−0.0061, 0.6831	$(-0.7290,0.685)^T$, $(0.6845,0.7290)^T$
$\mathbf{R}_3^\dagger$	−0.0061, 0.6831	$(0.6845,-0.7290)^T$, $(-0.7290,-0.6845)^T$
$\mathbf{R}_4^\dagger$	−1.4170, 0.0542	$(0.7014,0.7128)^T$, $(-0.7128,0.7014)^T$
$\mathbf{R}_5^\dagger$	−1.4170, 0.0542	$(0.7014,0.7128)^T$, $(-0.7128,0.7014)$

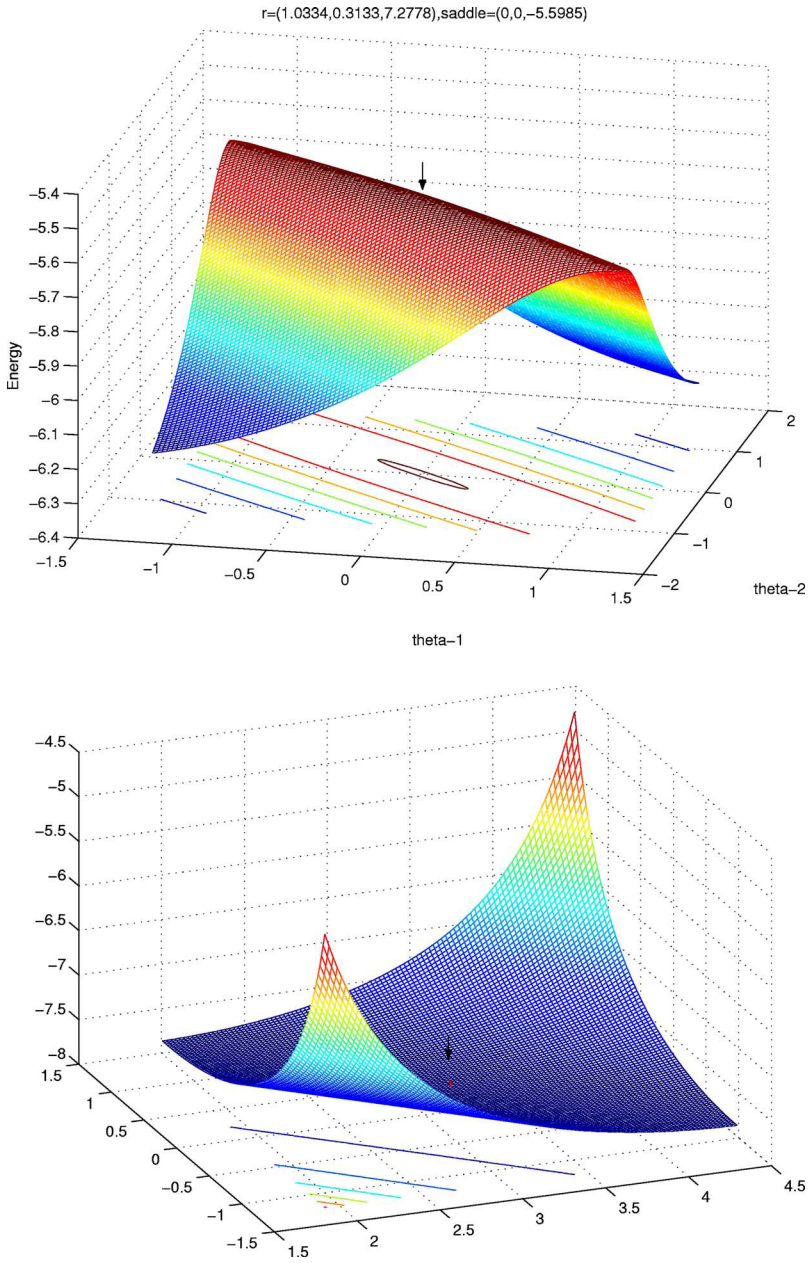

FIG. 9. (Color online) The energy surface E plotted against the angular variables θ_1 and θ_2 [cf. (5.3)] near the critical points $\mathbf{R}_i^{\dagger}$, $i=1,2,3,4,5$ (cf. Table III) in sequential order, whose locations are pin-pointed by an arrow. These surfaces are all of the saddle type.

$$r_{ij}=[r_i^2+r_j^2-2r_ir_j(\sin\,\theta_i\sin\,\theta_j\cos(\phi_i-\phi_j)+\cos\,\theta_i\cos\,\theta_j)]^{1/2},\quad 3\leqslant i<j<Z. \tag{5.2}$$

The stable electron configurations corresponding to minimal ground-state energy are shown in Figs. 1–8, along with the data given in the captions.

Example 2 (*saddle-type unstable colinear electron configurations,* $Z=3$): Consider the case of Li, $Z=3$. Write

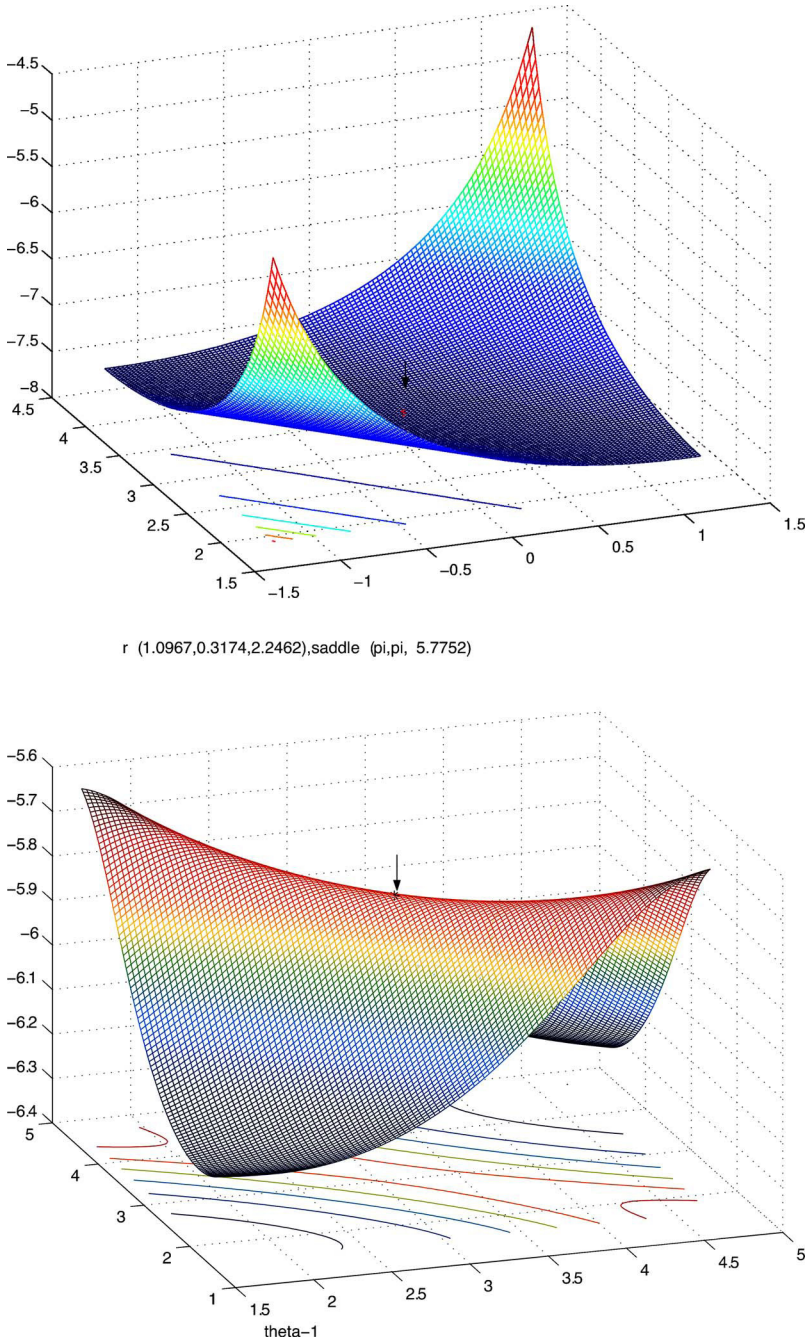

FIG. 9. (*Continued*).

$$\mathbf{r}_3 = r_3\mathbf{k}, \mathbf{r}_1 = r_1 \sin\theta_1\mathbf{i} + r_1 \cos\theta_1\mathbf{k},$$

$$\mathbf{r}_2 = r_2 \cos\theta_2\mathbf{k} + r_2 \sin\theta_2 \cos\phi_2\mathbf{i} + r_2 \sin\theta_2 \sin\phi_2\mathbf{j}. \tag{5.3}$$

We consider

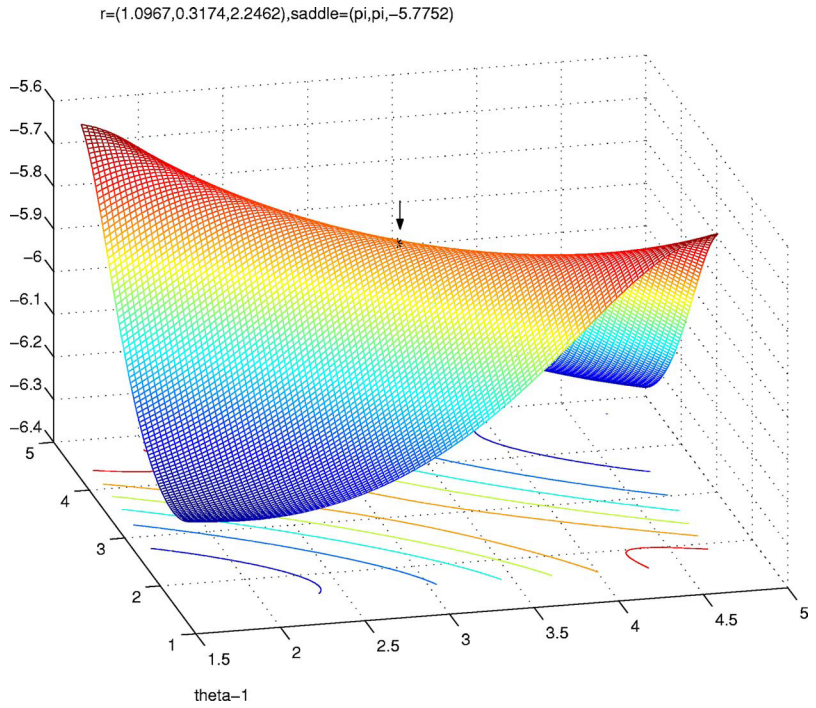

FIG. 9. (*Continued*).

$$\min_{\mathbf{R}\in\mathbb{R}^9_z} E(\mathbf{R}), \quad \mathbf{R}=(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)=\left(\begin{bmatrix}0\\0\\r_1\end{bmatrix},\begin{bmatrix}0\\0\\r_2\end{bmatrix},\begin{bmatrix}0\\0\\r_3\end{bmatrix}\right), \tag{5.4}$$

i.e., all three vectors $\mathbf{r}_1$, $\mathbf{r}_2$, and $\mathbf{r}_3$ are required to be colinear on the z axis. This can be done by setting $\phi_2=\pi$ and by requiring θ_1 and θ_2 to be equal to either 0 or π in (5.3).

For problem (5.4), we have found five critical points $\mathbf{R}_i^\dagger$, $i=1,2,3,4,5$, with respect to the three scalar variables r_1, r_2, and r_3. See Table III.

Note that by Theorem 4, all these points $\mathbf{R}_i^\dagger$, $i=1,2,3,4,5$, are critical points of E on $\mathbb{R}^{3Z}$. On the other hand, fix $\phi_2=\pi$ only. Then $\mathbf{r}_1$, $\mathbf{r}_2$, and $\mathbf{r}_3$ are coplanar and

$$E(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)=\frac{1}{2r_1}+\frac{1}{2r_2}+\frac{4}{2r_3}-\sum_{i=1}^{3}\frac{3}{r_i}+\left(\frac{1}{|\mathbf{r}_1-\mathbf{r}_2|}+\frac{1}{|\mathbf{r}_1-\mathbf{r}_3|}+\frac{1}{|\mathbf{r}_2-\mathbf{r}_3|}\right)\equiv E(r_1,r_2,r_3,\theta_1,\theta_2). \tag{5.5}$$

Numerical computations of the Hessian matrix $H=[\partial^2 E/\partial\theta_i\partial\theta_j]_{1\leqslant i,j\leqslant 2}$ and Lemma 1 show that, indeed, these $\mathbf{R}_i^\dagger$ are saddle-type critical points. See Table IV.

In Fig. 9, we plot the energy surfaces of E with respect to the angular variables θ_1 and θ_2 in a neighborhood of these critical points $\mathbf{R}_i^\dagger$.

It is quite interesting to note from Fig. 1 earlier that the global minimum value of E on $\mathbb{R}^9$ is −7.690 46 htr, while the global minimum value of E in (5.4) by restricting all $\mathbf{r}_i$, $i=1,2,3$, to lie on the z axis is −7.6837 htr (cf. Table III), which differs from −7.690 46 by less than 0.1%. □

Example 3 (*saddle type unstable coplanar electron configurations*, $Z=5$): In order to find unstable coplanar electron configurations, Z must be greater than or equal to 5, as Sec. IV has proved that $Z=3$ can only have stable configurations and Fig. 1 has provided a numerical evidence that $Z=4$ also has stable coplanar electron configurations. For $Z=5$, we apply Theorem 6 to find

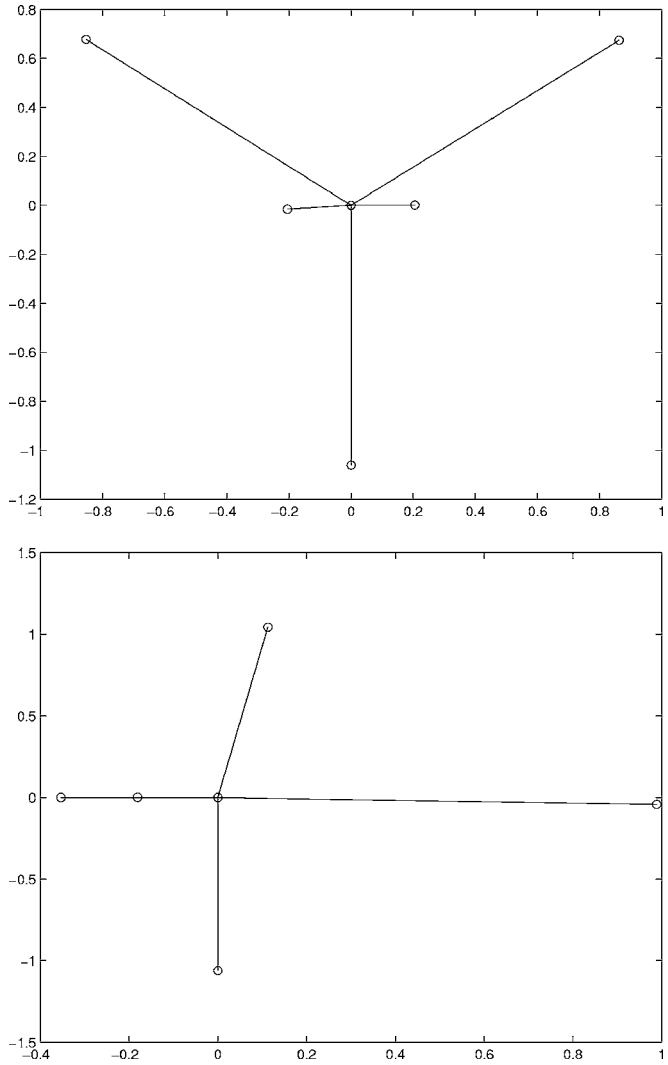

FIG. 10. For $Z=5$ (boron), the above three configurations are obtained according to Theorem 6 by finding critical points of E on the (x,y)-plane numerically. They should be contrasted with the one in Fig. 3. Coordinates of the five vectors, as well as the corresponding energy values, given from top to bottom for these three configurations, are $(-0.2045, -0.0156, 0)$, $(0.2050, 0.0014, 0)$, $(0.8625, 0.6741, 0)$, $(-0.8524, 0.6777, 0)$, $(0., -1.0604, 0)$ with $E_{\min}=-28.9146$; $(-0.3532, 0, 0)$, $(-0.1808, 0.0011, 0)$, $(0.9884, -0.0419, 0)$, $(0.1128, 1.0034, 0)$, $(0., -1.0610, 0)$ with $E_{\min}=-24.9439$; $(0.0661, 0.1942, 0)$, $(0.0628, -0.1781, 0)$, $(-6.4876, 0.3784, 0)$, $(-0.9024, 0.2594, 0)$, $(0., -1.5647, 0)$ with $E_{\min}=-27.5713$.

coplanar configurations, which must be of the saddle type and unstable, as Fig. 3 shows that a stable configuration cannot be coplanar. Several unstable configurations can be seen in Fig. 10.

VI. CONCLUSIONS

In this paper, we have conducted basic mathematical analysis for existence of minimal energy configurations and certain properties of critical points for the Bohr energy function. Relevant numerical results are also developed and presented.

There are still interesting problems remaining open. One among them is the *coplanarity* of the stable electron configuration for $Z=4$, which we have not yet been able to prove in Sec. IV. Also, the determination of the many symmetries manifested in Figs. 1–8 has not been achieved.

Bohr's original model for *molecules*[3] (which generalized the atomic case studied here) had

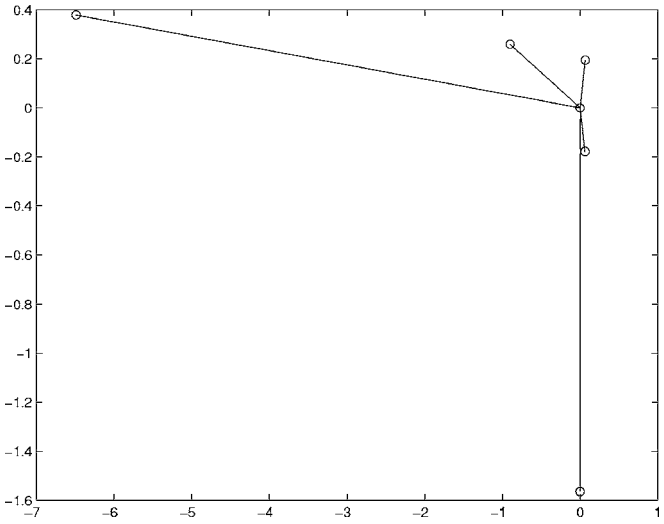

FIG. 10. (*Continued*).

some difficulties which has recently been improved by Svidzinsky, Scully, and Hershbach.[13] It has many interesting mathematical features therein worth investigation and we hope to be able to do it in the near future.

(Received 12 October 2005; accepted 11 January 2006; published online 28 February 2006)

In the present paper we study the following problem: how to construct a coherent orthoalgebra which has only a finite number of elements, but at the same time does not admit a bivaluation (i.e., a morphism with a codomain being an orthoalgebra with just two elements). This problem is important in the perspective of Bell-Kochen-Specker theory, since one can associate such an orthoalgebra to every saturated noncolorable finite configuration of projective lines. The first result obtained in this paper provides a general method for constructing finite orthoalgebras. This method is then applied to obtain a new infinite family of finite coherent orthoalgebras that do not admit bivaluations. The corresponding proof is combinatorial and yields a description of the groups of symmetries for these orthoalgebras. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2171691]

I. INTRODUCTION

Mackey formulated in his book[7] the axiomatics of nonrelativistic quantum mechanics based on the notion of an *orthomodular poset*. That is just a partially ordered set equipped with an involution, such that certain axioms hold. These axioms are chosen such that the elements of this poset may be identified with binary observables of a quantum system. Compared to the traditional axiomatics in terms of linear operators on Hilbert spaces,[11] this system focuses on the *logical* aspects of quantum theory. In fact, the Hilbert space is introduced only at the final stage in a completely *ad hoc* manner.

In alternative terminology, an orthomodular poset is called a *coherent orthoalgebra*, and an orthoalgebra is a particular case of an *effect algebra*. Let us provide some motivation for the introduction of these notions. Consider a Hilbert space $\mathcal{H}$ over $\mathbb{C}$, and denote by $L(\mathcal{H})$ a collection of closed linear manifolds in it. For every $U \in L(\mathcal{H})$, we have an orthogonal projector $\hat{\pi}_U$ on U, which represents an observable with two possible values, 0 and 1. Two observables represented by $\hat{\pi}_U$ and $\hat{\pi}_{U_1}$, $U, U_1 \in L(\mathcal{H})$, are *compatible* iff their commutator $[\hat{\pi}_U, \hat{\pi}_{U_1}]=0$. The first step towards the notion of an effect algebra is based on the following remark. The mentioned commutator vanishes iff $\mathcal{H}$ splits into an orthogonal sum $\mathcal{H}=Z\oplus V\oplus V_1\oplus W$, such that $Z\oplus V=U$ and $Z\oplus V_1=U_1$. The idea is to reformulate everything in terms of orthogonal decomposition.

Consider $\cdot\oplus\cdot$ as a partially defined binary operation on $L(\mathcal{H})$ with domain of definition consisting of all pairs (U, U_1) such that $U_1 \subset U^\perp$. Note that $U_1 \subset U^\perp$ is equivalent to $U \subset U_1^\perp$. Consider $L(\mathcal{H})$ as a partially ordered set with respect to inclusion $\subset$. Then the map $U \mapsto U^\perp$ is an involution on $L(\mathcal{H})$, since $U^{\perp\perp}=U$ and for all U and U_1 we have $U \subset U_1 \Leftrightarrow U^\perp \supset U_1^\perp$. Note, that it is possible to express the partial order $\subset$ in terms of the $\cdot\oplus\cdot$ operation: $U \subset U_1$ iff $\exists V: V\oplus U = U_1$. The involution $(\cdot)^\perp: L(\mathcal{H}) \to L(\mathcal{H})$, admits a similar characterization. For every U, there exists a unique U_1, such that $U_1 \oplus U = \mathcal{H}$; this U_1 is precisely $U^\perp$.

Take any $U, U_1 \in L(\mathcal{H})$. If the corresponding two observables are compatible, then the following formulas are valid:

$$\inf\{U,U_1\}\oplus U^{\perp}=U_1\oplus\sup\{U,U_1\}^{\perp},$$
$$\inf\{U,U_1\}\oplus U_1^{\perp}=U\oplus\sup\{U,U_1\}^{\perp}. \tag{1}$$

Moreover, it is not difficult to prove that $\hat{\pi}_U$ and $\hat{\pi}_{U_1}$ are compatible exactly when these two equalities (1) are valid. Which properties of $\cdot\oplus\cdot$ are actually needed in this proof? It turns out that it is convenient to capture these properties within the notion of an *effect algebra*.

Let S be a set, and $R\subset S\times S$ a relation on S. Let $\cdot\oplus\cdot:R\to S$, $(x,y)\mapsto x\oplus y$, be a map. Let $\mathbf{0}$ and $\mathbf{1}$ be two elements in S, such that $\mathbf{1}\neq\mathbf{0}$. The algebraic structure $(S,\oplus,\mathbf{0},\mathbf{1})$ is called an *effect algebra* if for all $x,y,z\in S$ the following conditions are satisfied:

(1) if $x\oplus y$ is defined, then $y\oplus x$ is defined and $y\oplus x=x\oplus y$;
(2) if $(x\oplus y)\oplus z$ is defined, then $x\oplus(y\oplus z)$ is defined and $x\oplus(y\oplus z)=(x\oplus y)\oplus z$;
(3) $x\oplus\mathbf{0}=x$;
(4) if $x\oplus y=x\oplus z$, then $y=z$;
(5) there exists $x^*\in S$, such that $x^*\oplus x=\mathbf{1}$;
(6) if $x\oplus\mathbf{1}$ is defined, then $x=\mathbf{0}$.

Note that for each x, the element x^* is uniquely defined. Hence, to every effect algebra $X=(S,\oplus,\mathbf{0},\mathbf{1})$ one associates a map $(\cdot)^*:S\to S$, $x\mapsto x^*$. The set S is termed the *ground* set of X.

An effect algebra is called an *orthoalgebra*, if for any element x of the ground set, such that $x\oplus x$ is defined, we have $x=\mathbf{0}$. Note that this property together with the first five axioms, implies the sixth axiom. An othoalgebra is called *coherent* if for all x, y, and z in the ground set, such that $x\oplus y$, $y\oplus z$, and $z\oplus x$ are defined, the $x\oplus y\oplus z$ is defined.

The basic example of an effect algebra is, of course, the following: $S=L(\mathcal{H})$, $\oplus$ is the orthogonal sum defined for all (U,U_1) such that $U_1\subset U^{\perp}$, $\mathbf{0}=\theta_{\mathcal{H}}$ is the trivial subspace of $\mathcal{H}$, and $\mathbf{1}=\mathcal{H}$. Denote this effect algebra by $\mathbb{L}(\mathcal{H})$. In fact, it is a coherent orthoalgebra. Just as for $\mathbb{L}(\mathcal{H})$, one can define for every effect algebra $X=(S,\oplus,\mathbf{0},\mathbf{1})$ a partial order $\preccurlyeq$ on the ground set S (termed the *standard* partial order): $\forall x,y\in S: x\preccurlyeq y:\Leftrightarrow\exists x_1: x_1\oplus x=y$. The map $(\cdot)^*$ is an involution with respect to $\preccurlyeq$. It is possible to imitate the notion of compatibility on any effect algebra as follows: call two elements $U,U_1\in S$ *compatible*, if the set $\{U,U_1\}$ has infimum and supremum (with respect to the standard partial order), and the formulas of the form (1) (with $\perp$ replaced by *) are valid. Such a definition of compatibility, is additionally justified by the following fact: for any compatible U and U_1, there exists a decomposition of $\mathbf{1}$ of the form $\mathbf{1}=Z\oplus V\oplus V_1\oplus W$, such that $Z\oplus V=U$ and $Z\oplus V_1=U_1$.

Since the notion of a coherent orthoalgebra captures up to certain extent the essential properties of $L(\mathcal{H})$, it presents special interest to investigate the case when the ground set is *finite*. By that one may try to imitate quantum mechanics on a finite set. The latter is not only conceptually interesting, but also can be important for the computational methods. Of course, it is necessary to have a "complicated enough" example for this case.

It is natural to introduce a category of effect algebras $\mathcal{E}$ with morphisms $f:(S,\oplus,\mathbf{0},\mathbf{1})\to(S',\oplus',\mathbf{0}',\mathbf{1}')$ being the maps $\bar{f}:S\to S'$ such that $\bar{f}(\mathbf{0})=\mathbf{0}'$, $\bar{f}(\mathbf{1})=\mathbf{1}'$, and $\bar{f}(x\oplus y)=\bar{f}(x)\oplus'\bar{f}(y)$, whenever $x\oplus y$ is defined. The composition of morphisms is defined by the composition of the corresponding maps. Consider the most simple effect algebra that can be—the effect algebra with only two elements—$\mathbf{0}$ and $\mathbf{1}$. This is an initial object in the category of effect algebras. There is only one way to define $\oplus$ in this case $\mathbf{0}\oplus\mathbf{0}:=\mathbf{0}$, $\mathbf{0}\oplus\mathbf{1}=\mathbf{1}\oplus\mathbf{0}:=\mathbf{1}$, and $\mathbf{1}\oplus\mathbf{1}$—undefined. Denote this object by $\mathbb{B}$ and call it the *minimal Boolean* effect algebra. The other example of an effect algebra that has been described above is $\mathbb{L}(\mathcal{H})$. Call it the *Hilbert* effect algebra. Is it possible to have an arrow from $\mathbb{L}(\mathcal{H})$ to $\mathbb{B}$ in the category $\mathcal{E}$? The answer is well known from functional analysis (Gleason's theorem) and is negative. At the same time there is another important example of an effect algebra $(S,\oplus,\mathbf{0},\mathbf{1})$, for which such an arrow exists. Let $S=\mathcal{F}$, where $\mathcal{F}$ is some σ-algebra of subsets of a set Ω. Define $U\oplus U_1$ as $U\cup U_1$ for all *disjoint* $U,U_1\in\mathcal{F}$. Set $\mathbf{0}=\varnothing$ and $\mathbf{1}=\Omega$. This defines an effect algebra, denoted by $\mathbb{W}(\mathcal{F})$ and called *Kolmogorov* effect algebra. Any

$\mathbb{W}(\mathcal{F})$ admits a morphism f to $\mathbb{B}$: one may fix any $\omega \in \Omega$ and for each $U \in \mathcal{F}$ set $\bar{f}(U)=\mathbf{1}$ if $U \ni \omega$, and $\mathbf{0}$—otherwise.

The Kolmogorov and Hilbert effect algebras, $\mathbb{W}(\mathcal{F})$ and $\mathbb{L}(\mathcal{H})$, are different, and this is clear if one looks at all morphisms ending in the minimal Boolean effect algebra $\mathbb{B}$. This motivates the following mathematical problem. For any $X \in \mathcal{E}$, let us call an arrow $f: X \to \mathbb{B}$ (if it exists) a *bivaluation*. Denote by *for* the forgetful functor from $\mathcal{E}$ to the category of sets, $for: \mathcal{E} \to \mathbf{Sets}$. One is required to find in $\mathcal{E}$ such objects X, which do not admit a bivaluation, but have a finite ground set *for* (X). In the present paper an infinite family of such objects is constructed.

Let us make several bibliographical remarks to conclude the introduction. The analysis of logical foundations of quantum mechanics has been initiated in the famous paper by Birkhoff and von Neumann.[1] The new wave of interest to this subject is motivated by the recent developments in quantum computing technology. For an up to date discussion of effect algebras, orthoalgebras, and similar structures, one should refer to the monograph.[2] The terms effect algebra and orthoalgebra were suggested in Refs. 3 and 4, respectively. The importance of orthoalgebras is also clear in the perspective of the consistent histories approach to quantum theory.[5]

The results obtained in the present paper are related to the results of Refs. 10 and 11, and may be viewed as their generalization. The orthoalgebras described below yield a family of "indeterministic objects" in the terminology of Ref. 9. Every saturated (in the sense of Ref. 10) Kochen-Specker-type configuration of projective lines naturally yields a finite orthoalgebra not admitting a bivaluation.

II. GENERAL CONSTRUCTION

How to construct a *finite* orthoalgebra, which will look "similar" to the Hilbert orthoalgebra? The starting point can be the following. Consider a Hilbert space $\mathcal{H}$ over $\mathbb{C}$ of finite dimension d. Let $\mathbb{P}(\mathcal{H})$ denote the set of projective lines in $\mathcal{H}$. Consider the set $\mathcal{P}_\perp(\mathbb{P}(\mathcal{H}))$ consisting of all subsets $U \subset \mathbb{P}(\mathcal{H})$ satisfying the condition $\forall l, l_1 \in U: l_1 \neq l \Rightarrow l \perp l_1$. Note, that the empty set and any subset with only one element, belong to $\mathcal{P}_\perp(\mathbb{P}(\mathcal{H}))$. There is a natural equivalence relation $\sim$ on this set: $U \sim U_1 :\Leftrightarrow \operatorname{span} U_1 = \operatorname{span} U$ (the span of the empty set is $\theta_\mathcal{H}$ by definition). It is clear, that the set $\mathcal{L}(\mathcal{H}) := \mathcal{P}_\perp(\mathbb{P}(\mathcal{H}))/\sim$ is in natural bijection with $L(\mathcal{H})$. Hence, the structure of orthoalgebra on $L(\mathcal{H})$ induces a structure of orthoalgebra on $\mathcal{L}(\mathcal{H})$. For $[U],[U_1] \in \mathcal{L}(\mathcal{H})$ ($[\cdot]$ denotes the equivalence class with respect to $\sim$), the value of $[U] \oplus [U_1]$ is defined iff $U \cap U_1 = \varnothing$ and $U \cup U_1 \in \mathcal{P}_\perp(\mathbb{P}(\mathcal{H}))$, and it is equal to $[U \cup U_1]$.

This leads to the first (naive) idea of how to construct examples of finite orthoalgebras. Take a *finite* set A equipped with some relation $T \subset A \times A$, which is thought to imitate the orthogonality relation $\perp$. In analogy with $\mathcal{L}(\mathcal{H})$, consider the set

$$\mathcal{P}_T(A) := \{U \subset A \mid \forall\, l, l_1 \in U: l_1 \neq l \Rightarrow (l, l_1) \in T\},$$

and try to find an equivalence relation $\sim$ on it, such that the formula $[U] \oplus [U_1] := [U \cup U_1]$ yields the structure of an orthoalgebra. It is necessary to describe this equivalence relation in terms of T. After that one faces the difficulty to find some reasonable conditions on T, entailing the axioms of an effect algebra.

It turns out that there is a better idea. For *any* $B \subset A$, denote

$$B^T := \{l \in A \mid \forall\, l_1 \in A: l_1 \in B \Rightarrow (l_1, l) \in T\}.$$

Consider a map $\tau: \mathcal{P}_T(A) \to \mathcal{P}(A)$, $U \mapsto U^T$, and look at the image of this map,

$$\mathcal{P}^T(A) := \operatorname{Im}(\mathcal{P}_T(A) \ni U \mapsto U^T). \tag{2}$$

Take it as a ground set for the future orthoalgebra. Note, that if one specializes A to $\mathbb{P}(\mathcal{H})$, and T to the orthogonality relation $\perp$, then for $U, U_1 \in \mathcal{P}_T(A)$ one has $\tau(U) = \tau(U_1)$, whenever $\operatorname{span} U_1 = \operatorname{span} U$. It is natural to try to define the $\oplus$ operation by the formula

$$Q \oplus Q_1 := (Q \cup Q_1)^{TT}, \tag{3}$$

for all $Q, Q_1 \in \mathcal{P}^T(A)$, such that $Q_1 \subset Q^T$. Of course, it is necessary to impose some conditions on T, which ensure that $\oplus$ is well defined, since the right-hand side is not *a priori* in $\mathcal{P}^T(A)$. The axioms of an orthoalgebra will induce the other conditions on T.

First, since T is supposed to imitate the orthogonality relation $\perp$, one needs to require for all $l, l_1 \in A$, $l_1 \neq l$, the following:

$$(l, l_1) \in T \Leftrightarrow (l_1, l) \in T, \tag{4}$$

$$(l, l) \in T. \tag{5}$$

Impose one more condition,

$$\forall M \in \mathrm{Max}(\mathcal{P}_T(A); \subset)\ \forall B \subset M: B^T = (M \setminus B)^{TT}, \tag{6}$$

where Max(−) means taking the *set* of all maximal subsets of the partially ordered set. Note that this condition is valid for the case $A = \mathbb{P}(\mathcal{H})$ and $T = \perp$. Let us say that T is *saturated* if it satisfies (6).

Theorem 1: *Let A be a finite nonempty set and T be a relation on A. Let $\mathcal{P}^T(A)$ be defined by* (2). *If T satisfies the three conditions* (4)–(6), *then*

(1) *A and $\varnothing$ belong to $\mathcal{P}^T(A)$;*
(2) *$\oplus$ is well-defined by the formula* (3);
(3) *$(\mathcal{P}^T(A), \oplus, \varnothing, A)$ is a coherent orthoalgebra.*

Proof: (1) Since $\varnothing \in \mathcal{P}_T(A)$, and $\varnothing^T = A$, one has $A \in \mathcal{P}^T(A)$. Now, take any $M \in \mathrm{Max}(\mathcal{P}_T(A); \subset)$, set $B = M$, and apply the third condition on T above. This yields $M^T = (M \setminus M)^{TT} = \varnothing^{TT} = A^T$. If A^T is not empty, then one can take any $l \in A^T$ and applying the definition of $(\cdot)^T$ claim, that $(l, l) \in T$. But this contradicts the first condition on T above. Hence, $A^T = \varnothing$. Therefore, $\varnothing = M^T \in \mathcal{P}^T(A)$.

(2) Take any $Q, Q_1 \in \mathcal{P}_T(A)$, such that $Q_1 \subset Q^T$. It is necessary to show that $(Q \cup Q_1)^{TT} \in \mathcal{P}^T(A)$. Invoking the main condition on T, represent Q and Q_1 in the form $Q = U^T = (M \setminus U)^{TT}$, and $Q_1 = U_1^T = (M_1 \setminus U_1)^{TT}$, where $U, U_1 \in \mathcal{P}_T(A)$, $M, M_1 \in \mathrm{Max}(\mathcal{P}_T(A); \subset)$, and $M \supset U$, $M_1 \supset U_1$. Since $Q_1 \subset Q^T$, for any $l \in (M \setminus U)^{TT}$ and any $l_1 \in (M_1 \setminus U_1)^{TT}$, one has $(l, l_1) \in T$. Note, that due to the symmetry of T, for all $B \subset A$ there is an inclusion $B^{TT} \supset B$. Indeed, take any $\lambda_0 \in B$. In order to show, that $\lambda_0 \in B^{TT}$, one must show that $\forall \lambda_1 \in B^T: (\lambda_1, \lambda_0) \in T$. But the definition of B^T implies that $\forall \lambda \in B\, \forall \lambda_1 \in B^T: (\lambda, \lambda_1) \in T$. Since T is symmetric, the order of appearance of λ and λ_1 in $(\lambda, \lambda_1) \in T$ is unimportant, and one obtains $B \subset B^{TT}$. Now, return to Q and Q_1. One has $Q = U^T = (M \setminus U)^{TT}$, and $Q_1 = U_1^T = (M_1 \setminus U_1)^{TT}$. Take any $l \in M \setminus U$, and any $l_1 \in M_1 \setminus U_1$. Since $M \setminus U \subset (M \setminus U)^{TT}$, and $M_1 \setminus U_1 \subset (M_1 \setminus U_1)^{TT}$, the elements l and l_1 are in Q and Q_1, respectively. From $Q_1 \subset Q^T$, one obtains $(l, l_1) \in T$. Therefore, $(M \setminus U) \cup (M_1 \setminus U_1) \in \mathcal{P}_T(A)$. Now note, that for any $B, B_1 \subset A$, the definition of $(\cdot)^T$, without any assumptions on T, implies $(B \cup B_1)^T = B^T \cap B_1^T$. This together with the main condition, yields

$$(Q \cup Q_1)^{TT} = (Q^T \cap Q_1^T)^T = (U^{TT} \cap U_1^{TT})^T = ((M \setminus U)^T \cap (M_1 \setminus U_1)^T)^T = ((M \setminus U) \cup (M_1 \setminus U_1))^{TT}.$$

Before proceeding further, let us prove two simple auxiliary facts. Recall, that $A, \varnothing \in \mathcal{P}^T(A)$, and we have $\varnothing^T = A$, $A^T = \varnothing$. Therefore $\varnothing^{TT} = \varnothing$, $A^{TT} = A$. Let us show that for any $Q_0 \in \mathcal{P}^T(A)$, the element $Q_0^T \in \mathcal{P}^T(A)$, and $Q_0^{TT} = Q_0$. Indeed, take any Q_0 and represent it in the form $Q_0 = U_0^T$, $U_0 \in \mathcal{P}_T(A)$. For any $M_0 \supset U_0$, $M_0 \in \mathrm{Max}(\mathcal{P}_T(A); \subset)$, the main condition implies $Q_0^T = U_0^{TT} = (M_0 \setminus U_0)^T$. Since $M_0 \setminus U_0 \in \mathcal{P}_T(A)$, one has $Q_0^T \in \mathcal{P}^T(A)$. Now, for Q_0^{TT}, we have $Q_0^{TT} = (U_0^{TT})^T = ((M_0 \setminus U_0)^T)^T = (M_0 \setminus U_0)^{TT} = U_0^T = Q_0$ (we have used the main condition once more).

Specializing $Q_0 \in \mathcal{P}^T(A)$ to $((M \setminus U) \cup (M_1 \setminus U_1))^T = (M \setminus U)^T \cap (M_1 \setminus U_1)^T = U^{TT} \cap U_1^{TT} = (U^T \cup U_1^T)^T = (Q \cup Q_1)^T$, we obtain $\mathcal{P}^T(A) \ni Q_0^T = (Q \cup Q_1)^{TT}$, i.e., $\oplus$ is well defined.

(3) Let us start with the axioms of an effect algebra. Consider the first axiom. Take any $Q,Q_1\in\mathcal{P}^T(A)$ such that $Q_1\subset Q^T$. The latter inclusion means, that for any $l\in Q$ and any $l_1\in Q_1$, the pair $(l,l_1)\in T$. Since T is symmetric, $(l_1,l)\in T$. Hence, $Q_1\subset Q^T$ is equivalent to $Q\subset Q_1^T$, i.e., $Q\oplus Q_1$ is defined iff $Q_1\oplus Q$ is defined. We have $Q\oplus Q_1=(Q\cup Q_1)^{TT}=(Q_1\cup Q)^{TT}=Q_1\oplus Q$.

Next, let us verify the second axiom. Take any $Q,Q_1,Q_2\in\mathcal{P}^T(A)$, and assume that $(Q\oplus Q_1)\oplus Q_2$ is defined. We have

$$(Q\oplus Q_1)\oplus Q_2=((Q\cup Q_1)^{TT}\cup Q_2)^{TT}=((Q\cup Q_1)^{TTT}\cap Q_2^T)^T=((Q\cup Q_1)^T\cap Q_2^T)^T$$
$$=(Q^T\cap Q_1^T\cap Q_2^T)^T=(Q\cup Q_1\cup Q_2)^{TT}.$$

Hence, if we can prove that $Q\oplus(Q_1\oplus Q_2)$ is defined as well, then $Q\oplus(Q_1\oplus Q_2)=(Q_1\oplus Q_2)\oplus Q=(Q_1\cup Q_2\cup Q)^{TT}$, and then the second axiom is established. So, we assume $Q_1\subset Q^T$ and $Q_2\subset(Q\oplus Q_1)^T$, and need to verify two inclusions, $Q_2\subset Q_1^T$ and $Q\subset(Q_1\oplus Q_2)^T$. Recall that whenever $Q\oplus Q_1$ is defined, we know that $(Q\cup Q_1)^T\in\mathcal{P}^T(A)$. Derive, $Q_2\subset(Q\oplus Q_1)^T=((Q\cup Q_1)^{TT})^T=(Q\cup Q_1)^T=Q^T\cap Q_1^T$. In particular $Q^T\cap Q_1^T\subset Q_1^T$ and therefore $Q_2\subset Q_1^T$, i.e., the first inclusion is valid, i.e., $Q_1\oplus Q_2$ is defined. Note, that we also have $Q_2\subset Q^T$, or, what is the same, $Q\subset Q_2^T$. Now, invoke the assumption $Q_1\subset Q^T$, or, equivalently, $Q\subset Q_1^T$. Combining this with the previous fact, we obtain $Q\subset Q_1^T\cap Q_2^T=(Q_1\cup Q_2)^T=(Q_1\cup Q_2)^{TTT}=(Q_1\oplus Q_2)^T$. Hence, the second inclusion is valid and by that the second axiom is established.

Consider the third axiom. The candidate for $\mathbf{0}$ is $\varnothing$. For any $Q\in\mathcal{P}^T(A)$, $Q\oplus\mathbf{0}$ is defined, since $\varnothing\subset Q^T$. We have $Q\oplus\mathbf{0}=(Q\cup\varnothing)^{TT}=Q^{TT}=Q$. The third axiom is established.

Before considering the fourth axiom, let us prove another general auxiliary fact. We know, that any $Q\in\mathcal{P}^T(A)$ can be represented in the form $Q=V^{TT}$, where $V\in\mathcal{P}_T(A)$ [take $U\in\mathcal{P}_T(A)$ and $M\in\mathrm{Max}(\mathcal{P}_T(A);\subset)$ such that $M\supset U$, and set $V=M\backslash U$]. The element Q^T is in $\mathcal{P}^T(A)$ as well. Hence, $Q^T=W^{TT}$, for some $W\in\mathcal{P}_T(A)$. Claim, that $V\cup W\in\mathrm{Max}(\mathcal{P}_T(A);\subset)$. Indeed, since $Q^{TT}=Q$, we have, in particular, $Q\subset(Q^T)^T$, and so $Q\oplus Q^T$ is defined. Next, $Q\oplus Q^T=(V^{TT}\cup W^{TT})^{TT}=(V^{TTT}\cap W^{TTT})^T=(V^T\cap W^T)^T=(V\cup W)^{TT}$. If $V\cup W$ is not maximal, then there exists $l_0\in(V\cup W)^T$. At the same time, $(V\cup W)^T=(V\cup W)^{TTT}=(Q\oplus Q^T)^T=(Q\cup Q^T)^{TTT}=(Q\cap Q^T)^{TT}$. But $Q\cap Q^T=\varnothing$, due to the first condition on T. Therefore, we continue, $(Q\cap Q^T)^{TT}=\varnothing^{TT}=\varnothing$. Hence, l_0 cannot exist, and $V\cup W$ is maximal. Note, that we also have $(Q\oplus Q^T)^T=\varnothing$, and as a corollary $Q\oplus Q^T=(Q\oplus Q^T)^{TT}=\varnothing^T=A$.

Now for the fourth axiom, take any $Q,Q_1,Q_2\in\mathcal{P}^T(A)$, and assume that $Q\oplus Q_1=Q\oplus Q_2$. It is necessary to show, that $Q_1=Q_2$. Represent Q, Q_1, and Q_2 in the form $Q=V^{TT}$, $Q_1=V_1^{TT}$, and $Q_2=V_2^{TT}$, where $V,V_1,V_2\in\mathcal{P}_T(A)$. Denote $Q_0:=Q\oplus Q_1=Q\oplus Q_2$, and write it in the form $Q_0=U_0^T$, where $U_0\in\mathcal{P}_T(A)$. Hence, $Q_0^T=U_0^{TT}$. We claim that both $(V\cup V_1)\cup U_0$ and $(V\cup V_2)\cup U_0$ are in $\mathrm{Max}(\mathcal{P}_T(A);\subset)$. Since $V\subset V^{TT}=Q\subset Q_1^T=V_1^{TTT}=V_1^T$, due to the first condition, the sets V and V_1 are disjoint. Similarly, $V\cap V_2=\varnothing$. We also have $Q_0=Q\oplus Q_1=(V^{TT}\cup V_1^{TT})^{TT}=(V^{TTT}\cap V_1^{TTT})^T=(V^T\cap V_1^T)^T=(V\sqcup V_1)^{TT}$, and $Q_0^T=U_0^{TT}$. Since $Q_0\oplus Q_0^T$ is defined, we similarly conclude that $V\sqcup V_1$ and U_0 are disjoint. Moreover, we already know, that in this case $(V\sqcup V_1)\sqcup U_0$ is maximal. Similarly, $(V\sqcup V_2)\sqcup U_0$ is maximal. Applying the main condition, one obtains $V_1^{TT}=(V\cup U_0)^T=V_2^{TT}$, i.e., $Q_1=Q_2$. Hence the fourth axiom is established.

Consider the fifth axiom. The candidate for $\mathbf{1}$ is A. It is easy to guess, that for $Q\in\mathcal{P}^T(A)$ it is necessary to set $Q^*:=Q^T$. We already know, that $Q^T\oplus Q=A$, and since A plays the role of $\mathbf{1}$, we obtain $Q^*\oplus Q=\mathbf{1}$. The fifth axiom is established.

Finally, it remains to consider the sixth axiom. Note, that since $\mathbf{1}=A$, $\mathbf{0}=\varnothing$, and A is not empty, one has $\mathbf{1}\neq\mathbf{0}$. Take any $Q\in\mathcal{P}^T(A)$, and assume that $Q\oplus\mathbf{1}$ is defined. This implies, that $Q\subset\mathbf{1}^T=A^T=\varnothing$. Hence, $Q=\varnothing$, i.e., $Q=\mathbf{0}$. The last axiom is established, and we have an effect algebra.

It is not difficult to verify, that in fact this effect algebra is an orthoalgebra, and, moreover, a coherent orthoalgebra. Indeed, if we take any $Q\in\mathcal{P}^T(A)$, and assume, that $Q\oplus Q$ is defined, then this implies $Q\subset Q^T$. Hence, $Q=Q\cap Q^T$. But $Q\cap Q^T=\varnothing$ due to the first condition. Therefore $Q=\mathbf{0}$ ($\mathbf{0}:=\varnothing$), i.e., our effect algebra is an orthoalgebra. Now, consider $Q,Q_1,Q_2\in\mathcal{P}^T(A)$, and assume, that $Q\oplus Q_1$, $Q_1\oplus Q_2$, and $Q_2\oplus Q$ are defined. We have $Q\subset Q_1^T$ and $Q\subset Q_2^T$. Hence,

$Q \subset Q_1^T \cap Q_2^T$. Apply the $(\cdot)^T$ operation, $Q^T \supset (Q_1^T \cap Q_2^T)^T = (Q_1 \cup Q_2)^{TT} = Q_1 \oplus Q_2$. Therefore $Q \oplus (Q_1 \oplus Q_2)$ is defined. The orthoalgebra is coherent. □

III. THE GROUP OF SYMMETRY

We have just three conditions on $T \subset A \times A$, which, when valid, allow to construct a coherent orthoalgebra. The first two are very simple, but the verification of the third one (the main condition), may be nontrivial. The main problem is, that there can be many elements in $\mathrm{Max}(\mathcal{P}_T(A); \subset)$. First, it is necessary to *characterize* them all, and then, for every $M \in \mathrm{Max}(\mathcal{P}_T(A); \subset)$ and every $B \subset M$ verify the property $B^T = (M \backslash B)^{TT}$. A straightforward computation can become very complicated.

The general approach to deal with this problem is to find some group of symmetry of A. Look at all bijections $\beta: A \xrightarrow{\sim} A$, which respect the T relation on A, i.e., $\forall l, l_1 \in A: (l_1, l) \in T \Rightarrow (\beta(l_1), \beta(l)) \in T$. Denote the group of all such bijections as $Bij_T(A)$. Every $\beta \in Bij_T(A)$ induces a bijective map from $\mathrm{Max}(\mathcal{P}_T(A); \subset)$ to itself. Suppose, we are able to describe some subgroup $\mathcal{G} \subset Bij_T(A)$, such that its natural action on $\mathrm{Max}(\mathcal{P}_T(A); \subset)$ has "large" orbits. Since it suffices to pick from each orbit just one representative, and verify the main condition on T only for these, the verification of the main condition becomes more feasible.

Let us now describe A, T, and $\mathcal{G}$ for the examples given below. Note, that these constructions clarify the combinatorics of the formulas present in Ref. 10. Let V be a finite set, such that $N := \#V$ is divisible by 4. Our construction will involve two collections of parameters with values in $\mathbb{Z}/2$. The first collection is indexed by $U \in \mathcal{P}(V)$ and the corresponding parameters are denoted as $b_U \in \mathbb{Z}/2$. The second collection is indexed by $U, U_1 \in \mathcal{P}(V)$, $U \neq U_1$, and the parameters are denoted by c_{U,U_1}. It is assumed that $c_{U,U_1} = c_{U_1,U}$. Look at all maps $V \to \mathbb{Z}/2$, and for every $U \in \mathcal{P}(V)$ denote

$$L_b(U) := \left\{ \phi: V \to \mathbb{Z}/2 \,\middle|\, \sum_{v \in V} \phi(v) = b_U \right\}, \tag{7}$$

where the index b in the notation $L_b(\cdot)$ stands for $b := \{b_U\}_U$. Set

$$A_b := \bigsqcup_{U \in \mathcal{P}(V)} L_b(U). \tag{8}$$

Denote by $i_U^b: L_b(U) \rightarrowtail A_b$, $U \in \mathcal{P}(V)$, the canonical injections. Now define some relation T_c on A_b, making use of the second collection of parameters $c := \{c_{U,U_1}\}_{U,U_1}$. For any $U, U_1 \in \mathcal{P}(V)$, $U \neq U_1$, and any $\phi, \phi' \in L(U)$ and $\phi_1 \in L(U_1)$, set

$$\begin{aligned} (i_U^b(\phi), i_U^b(\phi')) \in T_c &:\Leftrightarrow \phi \neq \phi', \\ (\phi, \phi_1) \in T_c &:\Leftrightarrow \sum_{s \in U \Delta U_1} (\phi(z) + \phi_1(z)) \neq c_{U,U_1}, \end{aligned} \tag{9}$$

where Δ denotes the symmetric difference of two subsets.

We are going to apply with respect to (A_b, T_c) the general construction of the preceding section, i.e., substitute $A = A_b$, $T = T_c$, and try to adjust the parameters b_U and c_{U,U_1} in order to satisfy the three conditions. The main result of the present paper can now be outlined as follows: if the number of points N in V is divisible by 4, then it is possible to choose the parameters b_U and c_{U,U_1} in such a way, that the assumptions of the proposition above are satisfied. Hence a new family of orthoalgebras is constructed. Moreover, it is possible to choose c_{U,U_1} and b_U in such a way, that the corresponding orthoalgebras do not admit bivaluations. It is interesting to stress the observed periodicity by 4. Without $4 \mid N$, the construction does not work.

Let us describe the group $\mathcal{G}$. Note, that the set of functions from V to $\mathbb{Z}/2$ may be viewed as a N-dimensional vector space over a field with two elements $\mathbb{F}_2$. Denote this vector space by $\mathbb{F}_2^N$. The number of elements in $\mathbb{F}_2^N$ is 2^N. The sum of two vectors corresponds to a symmetric differ-

ence of two subsets. Look at the group of all automorphisms of this vector space, i.e., the general linear group $\mathrm{GL}(N,\mathbb{F}_2)$ of $N\times N$ matrices with coefficients in $\mathbb{F}_2$. Let us describe a system of generators of this group (not a minimal one). For every $S\in\mathcal{P}(V)$, define a map $T_S:\mathcal{P}(V)\to\mathcal{P}(V)$,

$$T_S(U) := \begin{cases} U & \text{if } \#(U\cap S) \text{ is even,} \\ \overline{U\Delta S} & \text{if } \#(U\cap S) \text{ is odd,} \end{cases} \tag{10}$$

where U varies over $\mathcal{P}(V)$. Note, that these maps in the case of $N=4$ have been introduced in Ref. 10. Hence, in order to compute $T_S(U)$, one needs to look at $S\cap U$. Observe, that $S\cap T_S(U)=S\cap U$. This implies, that $T_S^2=\mathrm{id}$. In particular, T_S is a bijection. Moreover, for all $S,U,U_1\in\mathcal{P}(V)$, we have

$$T_S(U\Delta U_1)=T_S(U)\Delta T_S(U_1).$$

In order to prove the latter formula, note, that

$$\#(S\cap(U\Delta U_1))=\#(S\cap U)+\#(S\cap U_1)-2\#(S\cap U\cap U_1).$$

Therefore $\#_2(S\cap(U\Delta U_1))$ ($\#_2$ denotes the cardinality of a set viewed in $\mathbb{Z}/2$) is determined by $\#_2(S\cap U)$ and $\#_2(S\cap U_1)$. Hence the T_S correspond to *linear* bijective maps of $\mathbb{F}_2^N$, i.e., T_S corresponds to an element $\hat{T}_S\in\mathrm{GL}(N,\mathbb{F}_2)$. The range of possible values of S—the set $\mathcal{P}(V)$—may be identified with $\mathbb{F}_2^N$. We denote by $|S\rangle$ an element of $\mathbb{F}_2^N$ corresponding to S. Note, that there exists a formula $\hat{T}_S|U\rangle=|T_S(U)\rangle$, where $U,S\in\mathcal{P}(V)$.

Proposition 1: Let T_S, $|S\rangle\in\mathbb{F}_2^N$, *be the set of reflections defined by the formula* (10). *Then* $\{\hat{T}_S\}_S$ *generates the whole group* $\mathrm{GL}(N,\mathbb{F}_2)$.

Proof: For particular N small enough it is easy to verify the statement on computer in GAP. Let us provide a proof for all N. Note, that $T_\varnothing=T_V=\mathrm{id}$. Take any $S\in\mathcal{P}(V)$, $S\neq\varnothing,V$, and select $w\in\overline{S}:=V\backslash S$. There is a useful formula:

$$(T_S T_{S\cup\{w\}} T_S)(\{v\}) = \begin{cases} \{v\} & \text{if } v\neq w, \\ \overline{S} & \text{if } v\neq w. \end{cases} \tag{11}$$

It allows to prove (by induction) that the standard basis in $\mathbb{F}_2^N$ transforms into any other basis by a sequence of $\hat{T}_S$. Hence, the group is indeed $\mathrm{GL}(N,\mathbb{F}_2)$. □

Note, that the fact that $\hat{T}_S$ are reflections, and the fact that they generate the whole general linear group, is obtained without using the assumption $4|N$.

We shall describe some bijections $A_b\xrightarrow{\sim}A_b$, which respect the relation $T_c\subset A_b\times A_b$. The group $\mathcal{G}$ will be generated by these bijections. Before considering the general case, first look at the case where all the parameters b_U and c_{U,U_1} are set to $0\in\mathbb{Z}/2$. Write A_0 and T_0 in this case instead of A_b and T_c, respectively. For every $S\in\mathcal{P}(V)$, define the maps $\theta_S:\mathrm{Maps}(V,\mathbb{Z}/2)\to\mathrm{Maps}(V,\mathbb{Z}/2)$ by the formulas,

$$\theta_S(\varphi)(v) := \begin{cases} \varphi(v) & \text{if } v\in\overline{S}, \\ \varphi(v)+\displaystyle\sum_{w\in\overline{S}}\varphi(w) & \text{if } v\in S, \end{cases} \tag{12}$$

where $\varphi:V\to\mathbb{Z}/2$, $\overline{S}:=V\backslash S$. The latter can be expressed more compactly by $\theta_S(\varphi)(v)=\Sigma_{z\in T_S(\{v\})}\varphi(z)$. A straightforward computation shows, that

$$\theta_S^2=\mathrm{id},$$

and that for any $S,U\in\mathcal{P}(V)$, and any $\varphi:V\to\mathbb{Z}/2$, the following formula is valid:

$$\sum_{v\in T_S(U)} \theta_S(\varphi)(v) = \sum_{v\in U} \varphi(v). \tag{13}$$

This implies for any $U,S\in\mathcal{P}(V)$, that $\varphi\in L_0(U)$ yields $\theta_S(\varphi)\in L_0(T_S(U))$. It means that there exist induced maps

$$\theta_{S,U}: L_0(U)\to L_0(T_S(U)).$$

For every $S\in\mathcal{P}(V)$, the collection $\{\theta_{S,U}\}_U$, $U\in\mathcal{P}(V)$, defines a bijective map

$$\hat{\theta}_S: A_0 \xrightarrow{\sim} A_0,$$

[recall, $A_0=\sqcup_{U\in\mathcal{P}(V)}L_0(U)$]. The bijectivity follows from $\theta_S^2=\mathrm{id}$. Of course, $\hat{\theta}_S^2=\mathrm{id}$ itself as well. Invoking that for any $S,U,U_1\in\mathcal{P}(V)$, we have $T_S(U\Delta U_1)=T_S(U)\Delta T_S(U_1)$, it is not difficult to verify that all $\hat{\theta}_S$ respect the relation $T_0\subset A_0\times A_0$, or, equivalently, the relation $(A_0\times A_0)\backslash T_0$. Consider $U,U_1\in\mathcal{P}(V)$ and $\varphi\in L_0(U)$, $\varphi_1\in L_0(U_1)$, such that $(i^0_U(\varphi), i^0_{U_1}(\varphi_1))\notin T_0$ (i^0_U and $i^0_{U_1}$ denote the canonical injections into A_0). If $U_1=U$, then the fact mentioned is implied by the bijectivity of $\hat{\theta}_S$. If $U\neq U_1$, then we have $\Sigma_{v\in U\Delta U_1}(\varphi(v)+\varphi_1(v))=0$. Therefore, $\Sigma_{v\in T_S(U\Delta U_1)}\times(\theta_S(\varphi)(v)+\theta_S(\varphi_1)(v))=0$. Since $T_S(U\Delta U_1)=T_S(U)\Delta T_S(U_1)$, the pair of elements in A_0 that correspond to $\theta_S(\varphi)\in L_0(T_S(U))$ and $\theta_S(\varphi_1)\in L_0(T_S(U_1))$, is in relation $(A_0\times A_0)\backslash T_0$.

Now let us generalize the construction of the maps $\hat{\theta}_S$. We have the collections of parameters $b=\{b_U\}_U$, and $c=\{c_{U,U_1}\}_{U,U_1}$. For every $U,S\in\mathcal{P}(V)$, we need to describe some maps $L_b(U)\to L_b(T_S(U))$. In the case considered above, these were the maps $\theta_{S,U}$. For every fixed S, the whole collection $\{\theta_{S,U}\}_U$ stemmed just from one "global" function θ_S. Now, let us not assume this property. Take an arbitrary collection of $\mathbb{Z}/2$-valued parameters $\{a_{S,U}(v)\}_{S,U,v}$, $S,U\in\mathcal{P}(V)$, $v\in V$, and try to define some maps $\theta^{(a)}_{S,U}: L_b(U)\to L_b(T_S(U))$ by the formula

$$\theta^{(a)}_{S,U}(\varphi)(v) := \theta_S(\varphi)(v) + a_{S,U}(v), \tag{14}$$

where $\varphi\in L_b(U)$, $v\in V$. The case considered above corresponds to all $a_{S,U}(v)=0$. It is necessary to ensure, that $\theta^{(a)}_{S,U}(\varphi)(v)\in L_b(T_S(U))$. This yields a condition on $a_{S,U}(v)$,

$$\sum_{v\in U}\theta^{(a)}_{S,U}(\varphi)(v) = b_{T_S(U)},$$

where $\varphi\in L_b(U)$. Expanding the definitions of $L_b(U)$ and $\theta^{(a)}_{S,U}$, one reduces this equality just to $0=b_{T_S(U)}$, if $\#(S\cap U)$ is even, and to $b_U+\Sigma_{v\in\overline{U\Delta S}}a_{S,U}(v)=b_{T_S(U)}$, if $\#(S\cap U)$ is odd. Both cases are captured by one formula,

$$\sum_{v\in T_S(U)} a_{S,U}(v) = b_{T_S(U)} + b_U, \tag{15}$$

where S and U vary over $\mathcal{P}(V)$. Assume, that this condition is satisfied. Hence, we have well-defined maps $\theta^{(a)}_{S,U}: L_b(U)\to L_b(T_S(U))$. Since $\theta_{S,U}$ are bijections, so are $\theta^{(a)}_{S,U}$. For every fixed $S\in\mathcal{P}(V)$, the collection $\{\theta^{(a)}_{S,U}\}_U$ defines a bijective map

$$\hat{\theta}^{(a)}_S: A_b \xrightarrow{\sim} A_b.$$

Impose a requirement, that $\hat{\theta}^{(a)}_S$ respects the relation $T_c\subset A_b\times A_b$. This yields another condition on the parameters $a_{S,U}(v)$. Take any $U,U_1\in\mathcal{P}(V)$. Since $\hat{\theta}^{(a)}_S$ is bijective, the requirement is satisfied if $U_1=U$. Let $U_1\neq U$. Take any $\varphi\in L_b(U)$, $\varphi_1\in L_b(U_1)$, and assume that $\Sigma_{v\in U\Delta U_1}(\varphi(v)+\varphi_1(v))=c_{U,U_1}$. This should imply $\Sigma_{v\in T_S(U)\Delta T_S(U_1)}(\theta^{(a)}_{S,U}(\varphi)(v)+\theta^{(a)}_{S,U_1}(\varphi_1)(v))=c_{T_S(U),T_S(U_1)}$. Taking into account, that $T_S(U)\Delta T_S(U_1)=T_S(U\Delta U_1)$, expanding the definitions (14) of $\theta^{(a)}_{S,U}$ and $\theta^{(a)}_{S,U_1}$, and taking into account the mentioned formula (13) for θ_S, one reduces this requirement to the form

$$\sum_{v \in T_S(U \Delta U_1)} (a_{S,U}(v) + a_{S,U_1}(v)) = c_{U,U_1} + c_{T_S(U),T_S(U_1)}, \tag{16}$$

where S, U, and U_1 vary over $\mathcal{P}(V)$, and $U_1 \neq U$.

We have an overdetermined system of linear equations (15) and (16), with respect to the indeterminates $a_{S,U}(v) \in \mathbb{Z}/2$. The quantities b_U and c_{U,U_1} are parameters. It is necessary to solve this system of equations, and then obtain a condition of solvability in terms of b_U and c_{U,U_1}. After that b_U and c_{U,U_1} become indeterminates themselves, and one needs to find at least some solutions of the solvability equations. Assume all this is accomplished. Then we obtain a collection of bijective maps $\hat{\theta}_S^{(a)}: A_b \xrightarrow{\sim} A_b$, which respect the relation T_c. They generate some group $\mathcal{G}_a \subset Bij_{T_c}(A_b)$. In what follows, it is this group that will be used to establish the main condition on T_c, that allows to construct the orthoalgebra. Moreover, that parameters b_U and c_{U,U_1} can be chosen in such a way, that the corresponding orthoalgebra does not admit a bivaluation (this is the easy part).

IV. THE SOLUTIONS

Let us rewrite Eq. (16) as follows. This equation contains a sum over $v \in T_S(U \Delta U_1)$. This is the same as the sum over $v \in T_S(U) \Delta T_S(U_1)$. Since the terms in this sum are $\mathbb{Z}/2$-valued, it can be split as $\Sigma_{v \in T_S(U)} + \Sigma_{v \in T_S(U_1)}$. Perform this action upon Eq. (16), and then use twice Eqs. (15) corresponding to $U_0 = U$ and $U_0 = U_1$. It is convenient to denote

$$c_{U,U_1}^{(S)} := c_{U,U_1} + b_U + b_{U_1} + c_{T_S(U),T_S(U_1)} + b_{T_S(U)} + b_{T_S(U_1)},$$

$$b_{U_0}^{(S)} := b_{U_0} + b_{T_S(U_0)}.$$

The system of Eqs. (15) and (16), is equivalent to

$$\sum_{v \in T_S(U_1)} a_{S,U}(v) + \sum_{v \in T_S(U)} a_{S,U_1}(v) = c_{U,U_1}^{(S)}, \tag{17}$$

$$\sum_{v \in T_S(U_0)} a_{S,U_0}(v) = b_{U_0}^{(S)}. \tag{18}$$

Let us express all $a_{S,Q}(v)$ with $\#Q \geqslant 2$ via the indeterminates of the form $a_{S,\{z\}}(v)$. Let $Q \in \mathcal{P}(V)$ be any subset such that $\#Q \geqslant 2$, and $u \in S$ and $w \in \bar{S}$ be any points. Look at the equation (17). Set $U = Q$ and $U_1 = \{w\}$. This allows to find $a_{S,Q}(w)$,

$$a_{S,Q}(w) = \sum_{v \in T_S(Q)} a_{S,\{w\}}(v) + c_{Q,\{w\}}^{(S)}, \quad w \in \bar{S}.$$

Next, set $U = Q$ and $U_1 = \{u\}$. Since $T_S(\{u\}) = \{u\} \cup \bar{S}$, the resulting expression on the left-hand side will contain a sum of $a_{S,Q}(v)$ over $v \in \{u\} \cup \bar{S}$. For all values of v, except $v = u$, we already can express $a_{S,Q}(v)$. Hence, it is possible to find $a_{S,Q}(u)$,

$$a_{S,Q}(u) = \sum_{w' \in \bar{S}} a_{S,Q}(w') + \sum_{v \in T_S(Q \Delta \{u\})} a_{S,\{u\}}(v) + c_{Q,\{u\}}^{(S)}, \quad u \in S.$$

Now consider the case where the sets U_0, U, and U_1, are singletons. Let $u, u_1 \in S$ and $w, w_1 \in \bar{S}$ be any points. Equations (18) corresponding to $U_0 = \{w\}$ and $U_0 = \{u\}$, respectively, yield

$$a_{S,\{w\}}(w) = 0,$$

$$a_{S,\{u\}}(u) = b^{(S)}_{\{u\}} + \sum_{w' \in \bar{S}} a_{S,\{u\}}(w').$$

For the c-equations, it is necessary to consider the following three cases: (1) $U=\{w\}$, $U_1=\{w_1\}$; (2) $U=\{u\}$, $U_1=\{w\}$; (3) $U=\{u\}$, $U_1=\{u_1\}$. They yield

$$a_{S,\{w\}}(w_1) + a_{S,\{w_1\}}(w) = 0,$$

$$a_{S,\{u\}}(w) + a_{S,\{w\}}(u) = c^{(S)}_{\{u\},\{u_1\}} + \sum_{w' \in \bar{S}} a_{S,\{w\}}(w'),$$

$$a_{S,\{u\}}(u_1) + a_{S,\{u_1\}}(u) = c^{(S)}_{\{u\},\{u_1\}} + \sum_{w' \in \bar{S}} (a_{S,\{u\}}(w') + a_{S,\{u_1\}}(w')).$$

For every fixed $S \in \mathcal{P}(V)$, one may view the latter five equalities as a system of linear equations with respect to $a_{S,\{z\}}(v) \in \mathbb{Z}/2$, $v, z \in V$. It is not difficult to verify, that the corresponding *homogeneous* system of equations has many solutions. Redenote the indeterminates in this system as $\alpha_{S,\{z\}}(v)$, $v, z \in V$. Denote $\mathcal{E}(V) := \{U \subset V \mid \#U=2\}$. Write vz instead of $\{v, z\}$ for the elements of $\mathcal{E}(V)$. Take any function $\mu: \mathcal{E}(V) \to \mathbb{Z}/2$, and denote

$$\chi^{Q}_{\mu}(v) := \sum_{z \in Q \setminus \{v\}} \mu(vz),$$

where $Q \in \mathcal{P}(V)$, $v \in V$. It is not difficult to verify in a straightforward manner, that $\alpha_{\{z\}}(v) = \chi^{T_S(\{z\})}_{\mu}(v)$ defines a solution of the homogeneous system. We just remark, that $\chi^{T_S(\{w\})}_{\mu}(v) = \mu(vw)$ for $w \in \bar{S}$, $\chi^{T_S(\{u\})}_{\mu}(v) = \mu(uv) + \Sigma_{w' \in \bar{S}} \mu(vw')$ for $u \in S$, and it is convenient to accept a formal agreement $\mu(vv)=0$ in order to perform this computation.

We need a solution of the nonhomogeneous system. Let $u, u_1 \in S$ and $w, w_1 \in \bar{S}$ be any points. Set

$$\bar{a}_{S,\{w\}}(w_1) := \begin{cases} 0 & \text{if } w \prec w_1, \\ c^{(S)}_{\{w\},\{w_1\}} & \text{if } w_1 \prec w, \\ b^{(S)}_{\{w\}} & \text{if } w_1 = w; \end{cases}$$

$$\bar{a}_{S,\{u\}}(u_1) := \begin{cases} 0 & \text{if } u \prec u_1, \\ c^{(S)}_{\{u\},\{u_1\}} & \text{if } u_1 \prec u, \\ b^{(S)}_{\{u\}} & \text{if } u_1 = u; \end{cases}$$

$$\bar{a}_{S,\{w\}}(u) := b^{(S)}_{\{w\}} + c^{(S)}_{\{u\},\{w\}} + \sum_{\substack{w' \in \bar{S}, \\ w' \prec w}} c^{(S)}_{\{w'\},\{w\}},$$

$$\bar{a}_{s,\{u\}}(w) := 0.$$

A straightforward computation shows that $a_{S,\{z\}}(v) = \bar{a}_{S,\{z\}}(v)$ is a solution. Moreover, any other solution $a_{S,\{z\}}(v) = \hat{a}_{S,\{z\}}(v)$ can be represented in the form

$$\hat{a}_{S,\{z\}}(v) = \bar{a}_{S,\{z\}}(v) + \chi_{\hat{\mu}}^{T_S(\{z\})}(v),$$

for some $\hat{\mu}: \mathcal{E}(V) \to \mathbb{Z}/2$. For any $u, u \in S$, $u \neq u_1$, and $w, w_1 \in \bar{S}$, $w \neq w_1$, the values of $\hat{\mu}(ww_1)$, $\hat{\mu}(uu_1)$, and $\hat{\mu}(uw)$ are given by the formulas

$$\hat{\mu}(ww_1) := \begin{cases} \hat{a}_{S,\{w\}}(w_1) & \text{if } w \prec w_1, \\ \hat{a}_{S,\{w_1\}}(w) & \text{if } w_1 \prec w, \end{cases}$$

$$\hat{\mu}(uu_1) := \begin{cases} \hat{a}_{S,\{u\}}(u_1) & \text{if } u \prec u_1, \\ \hat{a}_{S,\{u_1\}}(u) + \sum\limits_{w' \in \bar{S}} \hat{a}_{S,\{u\}}(w') & \text{if } u_1 \prec u, \end{cases}$$

and

$$\hat{\mu}(uw) := \hat{a}_{S,\{u\}}(w) + \sum_{\substack{w' \in \bar{S}, \\ w' \prec w}} \hat{a}_{S,\{w'\}}(w) + \sum_{\substack{w' \in \bar{S}, \\ w' \succ w}} \hat{a}_{S,\{w\}}(w').$$

The verification is straightforward. Therefore, *any* solution of the homogeneous system is of the form $\alpha_{S,\{z\}}(v) = \chi_{\mu}^{T_S(\{z\})}(v)$, μ is some function. One can now take a solution for $a_{S,\{z\}}(v)$, and compute the rest of the $a_{S,Q}(v)$ according to the formulas derived above. Note, that the transformation $\alpha_{\{z\}}(v) = \chi_{\mu}^{T_S(\{z\})}(v) \to \alpha_{\{z\}}(v) = \chi_{\mu}^{T_S(\{z\})}(v) + \chi_{\mu}^{T_S(\{z\})}(v)$ induces the transformation of $a_{S,Q}(v)$ of the form $a_{S,Q}(v) \to a_{S,Q}(v) + \chi_{\mu}^{T_S(Q)}(v)$, i.e., there is a gauge symmetry group of transformations for the system of equations for $a_{S,Q}(v)$.

We have the expressions for all $a_{S,Q}(v)$, but we did not use all the equations of the system. Take any $S \in \mathcal{P}(V)$, and any $Q, Q_1 \in \mathcal{P}(V)$, $Q_1 \neq Q$. Substituting these expressions into the equations, one obtains the conditions,

$$c_{Q,Q_1}^{(S)} + \sum_{z_1 \in Q_1} c_{Q,\{z_1\}}^{(S)} + \sum_{z \in Q} c_{\{z\},Q_1}^{(S)} = \sum_{z_1 \in Q_1} \sum_{v \in T_S(Q)} a_{S,\{z_1\}}(v) + \sum_{z \in Q} \sum_{v_1 \in T_S(Q_1)} a_{S,\{z\}}(v_1)$$

and

$$b_Q^{(S)} + \sum_{z \in Q} c_{Q,\{z\}}^{(S)} = \sum_{z \in Q} \sum_{v \in T_S(Q)} a_{S,\{z\}}(v).$$

Denote the right-hand sides of these equalities by $X_a(S,Q,Q_1)$ and $Y_a(S,Q,Q_1)$, respectively. Note, that these two quantities are invariant under the gauge transformation $a_{S,\{z\}}(v) \to a_{S,\{z\}}(v) + \chi_{\mu}^{T_S(\{z\})}(v)$, ($\mu$ is any function). It remains to substitute $a_{S,\{z\}}(v) = \bar{a}_{S,\{z\}}(v)$ and compute the corresponding $X_{\bar{a}}$ and $Y_{\bar{a}}$.

In order to compute $Y_{\bar{a}}$ it is necessary to consider two cases, $\#(Q \cap S)$ is even, and $\#(Q \cap S)$ is odd. The computation in the first case is a little bit easier, but it turns out, that in both cases the result is the same

$$Y_{\bar{a}}(S,Q,Q_1) = \sum_{z \in Q} b_{\{z\}}^{(S)} + \sum_{\substack{z,z' \in Q, \\ z \prec z'}} c_{\{z\},\{z'\}}^{(S)}.$$

The value of the sum on the right-hand side does not depend on $\prec$, due to the symmetry $c_{U,U_1}^{(S)} = c_{U_1,U}^{(S)}$, which is implied by the assumption $c_{U,U_1} = c_{U_1,U}$.

In order to compute $X_{\bar{a}}(S,Q,Q_1)$, it is necessary to investigate the following three cases: (1) both $\#(Q \cap S)$ and $\#(Q_1 \cap S)$ are even; (2) $\#(Q \cap S)$ is odd, and $\#(Q_1 \cap S)$ is even; (3) both $\#(Q \cap S)$ and $\#(Q_1 \cap S)$ are odd. In all three cases, one obtains the same expression,

$$X_{\bar{a}}(S,Q,Q_1) = \sum_{\substack{z\in Q, z_1\in Q_1,\\ z\neq z_1}} c^{(S)}_{\{z\},\{z_1\}}.$$

Therefore, we obtain the following conditions:

$$c^{(S)}_{Q,Q_1} + \sum_{z_1\in Q_1} c^{(S)}_{Q,\{z_1\}} + \sum_{z\in Q} c^{(S)}_{\{z\},Q_1} + \sum_{\substack{z\in Q, z_1\in Q_1,\\ z\neq z_1}} c^{(S)}_{\{z\},\{z_1\}} = 0 \tag{19}$$

and

$$\sum_{z\in Q} c^{(S)}_{Q,\{z\}} + \sum_{\substack{z,z'\in Q,\\ z<z'}} c^{(S)}_{\{z'\},\{z\}} = b^{(S)}_{Q} + \sum_{z\in Q} b^{(S)}_{\{z\}}. \tag{20}$$

Recall that S, Q, and Q_1 vary over $\mathcal{P}(V)$, $Q_1 \neq Q$. By definition, we set formally $c^{(S)}_{Q,Q}=0$. Note, that if $\#Q=1$, then the second condition (20) turns into an identity. Similarly, if at least one of the sets Q or Q_1 has cardinality 1, then the first condition (19) trivializes as well. These two conditions are the conditions of the solvability of the system of equations for $\{a_{S,U}(v)\}_{v,U,S}$.

V. PERIODICITY BY FOUR

Is it possible to satisfy the obtained solvability conditions (20) and (19)? We shall not try to describe all the solutions, but construct some. The crucial assumption is the following. Let us search for c_{U,U_1} and b_U in the form

$$\begin{aligned} c_{U,U_1} &= c(\#_4(U\Delta U_1)),\\ b_U &= b(\#_4 U), \end{aligned} \tag{21}$$

where $U, U_1 \in \mathcal{P}(V)$, $U_1 \neq U$, $\#_4(\cdot)$ denotes the cardinality of the subset viewed in $\mathbb{Z}/4$, and $c(\cdot):\mathbb{Z}/4\to\mathbb{Z}/2$ and $b(\cdot):\mathbb{Z}/4\to\mathbb{Z}/2$ are unknown functions. A not quite trivial property of the solvability system of equations (19) and (20), is that it admits such an anzats if the number of points N in V is divisible by 4.

Take any S, and look at the quantity $b^{(S)}_{\{z\}}$, $z\in V$. Observe, that since $b_U=b(\#_4 U)$, its value depends only on whether $z\in S$ or $z\notin S$. In other words, one may take *any* $u_0\in S$ and $w_0\in\bar{S}$, and claim that $b^{(S)}_{\{z\}}=b^{(S)}_{\{u_0\}}$, if $z\in S$, and $b^{(S)}_{\{z\}}=b^{(S)}_{\{w_0\}}$, if $z\in\bar{S}$. Similar statements may be made about the quantities of the form $c^{(S)}_{Q,\{z_1\}}$, $c^{S}_{\{z\},Q_1}$, and $c^{(S)}_{\{z\},\{z_1\}}$.

Choose any S, and Q, Q_1 such that $Q_1\neq Q$. Look at the set S. It gets partitioned into four subsets,

$$S = (S\cap Q\cap Q_1)\sqcup(S\cap\bar{Q}\cap Q_1)\sqcup(S\cap Q\cap\bar{Q}_1)\sqcup(S\cap\bar{Q}\cap\bar{Q}_1).$$

In each of the subsets, if nonempty, choose a point (it does not matter which one): $\xi_0 \in S\cap Q\cap Q_1$, $\xi_1\in S\cap\bar{Q}\cap Q_1$, $\xi_2\in S\cap Q\cap\bar{Q}_1$, and $\xi_3\in S\cap\bar{Q}\cap\bar{Q}_1$. Denote the cardinalities of these four subsets by m_0, m_1, m_2, and m_3, respectively. Next, perform a similar process with respect to $\bar{S}$, i.e., choose arbitrary four points η_0, η_1, η_2, and η_3, such that $\eta_0\in\bar{S}\cap Q\cap Q_1$, $\eta_1 \in\bar{S}\cap\bar{Q}\cap Q_1$, $\eta_2\in\bar{S}\cap Q\cap\bar{Q}_1$, and $\eta_3\in\bar{S}\cap\bar{Q}\cap\bar{Q}_1$. (If a set is empty, the corresponding point will not be needed.) Denote the cardinalities of these subsets as n_0, n_1, n_2, and n_3, respectively. Note, that $c^{(S)}_{\{z\},\{z_1\}}=0$, if both z and z_1 are in S, or both are in $\bar{S}$. With this remark, the solvability equation (19) after the described anzats, acquires the form,

$$c^{(S)}_{Q,Q_1} + (m_0 c^{(S)}_{Q,\{\xi_0\}} + n_0 c^{(S)}_{Q,\{\eta_0\}} + m_1 c^{(S)}_{Q,\{\xi_1\}} + n_1 c^{(S)}_{Q,\{\eta_1\}}) + [m_0 c^{(S)}_{Q_1,\{\xi_0\}} + n_0 c^{(S)}_{Q_1,\{\eta_0\}} + m_2 c^{(S)}_{Q_1,\{\xi_2\}} + n_2 c^{(S)}_{Q_1,\{\eta_2\}}]$$
$$+ \{m_0 n_1 + n_0 m_1 + m_0 n_2 + n_0 m_2 + m_1 n_2 + n_1 m_2\} c^{(S)}_{\{\xi_3\},\{\eta_3\}} = 0.$$

Note, that the values of m_i and n_i $(i=0,1,2,3)$ depend on the sets S, Q, and Q_1. Of course, $\Sigma_{i=0}^{3}(m_i+n_i)=N$. Note, that it suffices to know only the images of m_i and n_i $(i=0,1,2,3)$ in $\mathbb{Z}/2$.

The solvability condition (20) is reduced in a similar way. This time we do not need the set Q_1. Take any S and Q, choose any points $\zeta \in Q \cap S$, $\omega \in Q \cap \bar{S}$, and then any $\zeta' \in Q \cap S$, $\zeta' \neq \zeta$, and $\omega' \in Q \cap \bar{S}$, $\omega' \neq \omega$ (if some of these points cannot be chosen, they are not needed). Denote $k := \#(Q \cap S)$ and $l := \#(Q \cap \bar{S})$. The condition reduces to the form

$$k c^{(S)}_{Q,\{\zeta\}} + l c^{(S)}_{Q,\{\omega\}} + \frac{k(k-1)}{2} c^{(S)}_{\{\zeta\},\{\zeta'\}} + \frac{l(l-1)}{2} c^{(S)}_{\{\omega\},\{\omega'\}} + kl c^{(S)}_{\{\zeta\},\{\omega\}} = b^{(S)}_{Q} + k b^{(S)}_{\{\zeta\}} + l b^{(S)}_{\{\omega\}}.$$

Note, that each time, when the corresponding points cannot be chosen, the term that contains this point contains a factor equal to zero. The values of k and l depend on the sets S and Q. Note that it suffices to know only the image of l in $\mathbb{Z}/2$, and the image of k in $\mathbb{Z}/4$ (not $\mathbb{Z}/2$)!

It remains to perform the mentioned anzats in these equations and simplify them. It is convenient to use the following formulas:

$$\#_4(U \Delta U_1) = \#_4 U + \#_4 U_1 - 2\#_4(U \cap U_1),$$

$$\forall i \in \mathbb{Z}/4 : [i]_2 = 0 \Rightarrow 2i = 0,$$

$$\forall i \in \mathbb{Z}/4 : [i]_2 = 1 \Rightarrow 2i = 2,$$

where $[i]_2$ denotes the canonical image of i in $\mathbb{Z}/2$, U and U_1 are any subsets of V. We shall also need the assumption that the number N of points in V is divisible by 4. In this case, for all $U \in \mathcal{P}(V)$, the following formula is valid:

$$\#_4 \bar{U} = -\#_4 U.$$

First look at Eq. (20). Recall, that $\zeta \in S \cap Q$, and $\omega \in \bar{S} \cap Q$. We have

$$b^{(S)}_{Q} = b(\#_4 Q) + b(\#_4 T_S(Q)),$$

$$b^{(S)}_{\{\zeta\}} = b(\#_4\{\zeta\}) + b(\#_4 T_S(\{\zeta\})) = b(1) + b(-\#_4 S + 1),$$

$$b^{(S)}_{\{\omega\}} = b(\#_4\{\omega\}) + b(\#_4 T_S(\{\omega\})) = 0.$$

Similar computations yield

$$c^{(S)}_{Q,\{\zeta\}} = b^{(S)}_{Q} + b^{(S)}_{\{\zeta\}} + c(\#_4 Q - 1) + c(\#_4 T_S(Q \Delta \{\zeta\})),$$

$$c^{(S)}_{Q,\{\omega\}} = b^{(S)}_{Q} + b^{(S)}_{\{\omega\}} + c(\#_4 Q - 1) + c(\#_4 T_S(Q \Delta \{\omega\})),$$

$$c^{(S)}_{\{\zeta\},\{\zeta'\}} = 0,$$

$$c^{(S)}_{\{\zeta\},\{\omega\}} = b(1) + b(-\#_4 S + 1) + c(2) + c(-\#_4 S),$$

$$c^{(S)}_{\{\omega\},\{\omega'\}} = 0.$$

We need to compute $\#_4 T_S(Q)$, $\#_4 T_S(Q\Delta\{\zeta\})$, and $\#_4 T_S(Q\Delta\{\omega\})$. Set

$$s := \#_4 S, \quad q := \#_4 Q, \quad t := \#_4(Q \cap S).$$

If $\#(Q \cap S)$ is even, (i.e., $t=0,2$), then

$$\#_4 T_S(Q) = q,$$

$$\#_4 T_S(Q\Delta\{\zeta\}) = -s - q - 1,$$

$$\#_4 T_S(Q\Delta\{\omega\}) = q - 1.$$

If $\#(Q \cap S)$ is odd, (i.e., $t=1,3$), then

$$\#_4 T_S(Q) = -s - q + 2,$$

$$\#_4 T_S(Q\Delta\{\zeta\}) = q - 1,$$

$$\#_4 T_S(Q\Delta\{\omega\}) = -s - q - 1.$$

Hence, it suffices to know the values of these parameters $s,q,t \in \mathbb{Z}/4$ in order to compute the left-hand and right-hand expressions of Eq. (20). (Of course, $[k]_4 = t$, and $[l]_4 = q - t$.) It turns out (this can be easily verified on a computer in Maple, or by a straightforward computation), that for each of the 4^3 possible variants of (s,q,t), the reduced equation acquires only one of the following types: either it becomes an identity $0=0$, or one of the two equations,

$$\begin{aligned} c(0) + c(2) &= b(0) + b(2), \\ c(1) + c(3) &= b(1) + b(3), \end{aligned} \tag{22}$$

or their sum $\Sigma_{i=0}^{3}(c(i)+b(i))=0$. One may assign arbitrary values, say to all $c(i)$ and to $b(0)$, $b(1)$, and then determine $b(2)$ and $b(3)$.

Equations (19) are reduced in a similar way, and in the final stage it is best to compute in Maple. Let us describe all the preparatory work. Look at $c^{(S)}_{Q,Q_1}$. We have $c^{(S)}_{Q,Q_1} = b^{(S)}_{Q} + b^{(S)}_{Q_1} + c(\#_4(Q\Delta Q_1)) + c(\#_4 T_S(Q\Delta Q_1))$. In particular, it is necessary to know $\#_2 S \cap (Q\Delta Q_1)$. Since $\#S \cap (Q\Delta Q_1) = \#(S \cap Q) + \#(S \cap Q_1) - 2\#(S \cap Q \cap Q_1)$, and the latter term is even, one has

$$\#_2 S \cap (Q\Delta Q_1) = \#_2(S \cap Q) + \#_2(S \cap Q_1).$$

Denote

$$s := \#_4 S, \quad q := \#_4 Q, \quad q_1 := \#_4 Q_1,$$

$$t := \#_4(S \cap Q), \quad t_1 := \#_4(S \cap Q_1),$$

$$p := \#_4(Q \cap Q_1), \quad r := \#_4(S \cap Q \cap Q_1).$$

With this notation, $\#_2 S \cap (Q\Delta Q_1) = [t + t_1]_2$. Therefore $\#_4(Q\Delta Q_1) = q + q_1 - 2p$, and

$$\#_4 T_S(Q\Delta Q_1) = \begin{cases} q+q_1-2p & \text{if } [t+t_1]_2 = 0, \\ -s-(q+q_1-2p)+2 & \text{if } [t+t_1]_2 = 1. \end{cases}$$

Taking into account these formulas, one can reduce $c^{(S)}_{Q,Q_1}$ to the following form. If $[t]_2=0$ and $[t_1]_2=0$, then $c^{(S)}_{Q,Q_1}=0$. If $[t]_2=1$ and $[t_1]_2=0$, then $c^{(S)}_{Q,Q_1}=b(q)+b(-q-s+2t)+c(q+q_1-2p)+c(-s-(q+q_1-2p)+2)$. Similarly, if $[t]_2=0$ and $[t_1]_2=1$, then $c^{(S)}_{Q,Q_1}=b(q_1)+b(-q_1-s+2t_1)+c(q+q_1-2p)+c(-s-(q+q_1-2p)+2)$. Finally, if $[t]_2=1$ and $[t_1]_2=1$, then $c^{(S)}_{Q,Q_1}=b(q)+b(-q-s+2t)+b(q_1)+b(-q_1-s+2t_1)$. The other computations are easier.

If $\#(Q\cap S)$ is even, i.e., $t=0,2$, then

$$c^{(S)}_{Q,\{\xi_0\}} = b(1)+b(-s+1)+c(q-1)+c(-s-q+2t-1),$$

$$c^{(S)}_{Q,\{\eta_0\}} = 0,$$

$$c^{(S)}_{Q,\{\xi_1\}} = b(1)+b(-s+1)+c(q+1)+c(-s-q+2t+1),$$

$$c^{(S)}_{Q,\{\eta_1\}} = 0.$$

If $t=1,3$, then

$$c^{(S)}_{Q,\{\xi_0\}} = b(q)+b(-s-q+2t)+b(1)+b(-s+1),$$

$$c^{(S)}_{Q,\{\eta_0\}} = b(q)+b(-s-q+2t)+c(q-1)+c(-s-q+2t+1),$$

$$c^{(S)}_{Q,\{\xi_1\}} = b(q)+b(-s-q+2t)+b(1)+b(-s+1),$$

$$c^{(S)}_{Q,\{\eta_1\}} = b(q)+b(-s-q+2t)+c(q+1)+c(-s-q+2t-1).$$

There are similar expressions corresponding to Q_1. If $\#(Q_1\cap S)$ is even, i.e., $t_1=0,2$, then

$$c^{(S)}_{Q_1,\{\xi_0\}} = b(1)+b(-s+1)+c(q_1-1)+c(-s-q_1+2t_1-1),$$

$$c^{(S)}_{Q_1,\{\eta_0\}} = 0,$$

$$c^{(S)}_{Q_1,\{\xi_2\}} = b(1)+b(-s+1)+c(q_1+1)+c(-s-q_1+2t_1+1),$$

$$c^{(S)}_{Q_1,\{\eta_2\}} = 0.$$

If $t_1=1,3$, then

$$c^{(S)}_{Q_1,\{\xi_0\}} = b(q_1)+b(-s-q_1+2t_1)+b(1)+b(-s+1),$$

$$c^{(S)}_{Q_1,\{\eta_0\}} = b(q_1)+b(-s-q_1+2t_1)+c(q_1-1)+c(-s-q_1+2t_1+1),$$

$$c^{(S)}_{Q_1,\{\xi_2\}} = b(q_1)+b(-s-q_1+2t_1)+b(1)+b(-s+1),$$

$$c^{(S)}_{Q_1,\{\eta_2\}} = b(q_1) + b(-s-q_1+2t_1) + c(q_1+1) + c(-s-q_1+2t_1-1).$$

Finally, $c^{(S)}_{\{\xi_3\},\{\eta_3\}}$ reduces to the form

$$c^{(S)}_{\{\xi_3\},\{\eta_3\}} = b(1) + b(-s+1) + c(2) + c(-s).$$

For the cardinalities m_0, m_1, m_2, and m_3, we have

$$[m_0]_4 = r, \quad [m_1]_4 = t_1 - r, \quad [m_2]_4 = t - r, \quad [m_3]_4 = s - t - t_1 + r,$$

where $[\cdot]_4$ denotes the canonical image of an integer number in $\mathbb{Z}/4$. Similarly, for the cardinalities n_0, n_1, n_2, and n_3, we have

$$[n_0]_4 = p - r, \quad [n_1]_4 = (q_1 - t_1) - (p - r), \quad [n_2]_4 = (q - t) - (p - r),$$

$$[n_3]_4 = (-s) - (q - t) - (q_1 - t_1) + (p - r).$$

Therefore it remains to investigate what happens to Eq. (19) as the parameters s, q, q_1, t, t_1, p, and r, vary over $\mathbb{Z}/4$. There are finitely many options, and the corresponding computation is easily implemented in Maple. In fact, it is possible to perform it manually, if one uses some symmetry of Eq. (19). The result is similar to the case of Eq. (20), i.e., every variant reduces to a linear combination of the simple equalities (22) mentioned above. It means, that we have established the fact that the solvability system of Eqs. (19) and (20), has solutions, and we have identified at least some of them (21).

VI. THE ORBITS

We are able to construct the group $\mathcal{G}_a$ in two steps. First, verify the main condition on T_c for some of the elements of $\mathrm{Max}(\mathcal{P}_{T_c}(A_b), \subset)$, and then compute the orbits of these elements under the action of $\mathcal{G}_a$. One needs enough such elements, so that the orbits cover the whole set $\mathrm{Max}(\mathcal{P}_{T_c}(A_b), \subset)$. The proof is essentially combinatorial.

Recall, that for every $U, S \in \mathcal{P}(V)$ we have defined the maps $\theta^U_S : L_b(U) \to L_b(T_S(U))$:

$$\theta^U_S(\varphi)(v) = \sum_{z \in T_S(\{v\})} \varphi(z) + a^U_S(v),$$

where $\varphi \in L_b(U)$, $v \in V$. There is also a collection of maps $I^U_\mu : L_b(U) \to L_b(U)$, $U \in \mathcal{P}(V)$, corresponding to the gauge transformation with function $\mu : \mathcal{E}(V) \to \mathbb{Z}/2$, defined by the formula

$$I^U_\mu(\varphi)(v) \coloneqq \varphi(v) + \chi^U_\mu(v),$$

where $\varphi \in L_b(U)$, $v \in V$, and $\chi^U_\mu(\cdot)$ is as in the preceding section.

Look at the diagram (in **Sets**),

$$\begin{array}{ccc} L_b(U) & \xrightarrow{\theta^U_S} & L_b(T_S(U)) \\ {\scriptstyle I^U_\nu}\,\vdots & & \downarrow{\scriptstyle I^{T_S(U)}_\mu} \\ L_b(U) & \xrightarrow{\theta^U_S} & L_b(T_S(U)) \end{array}$$

It turns out, that for every $U, S \in \mathcal{P}(V)$ and every $\mu : \mathcal{E}(V) \to \mathbb{Z}/2$, there exists a unique $\nu : \mathcal{E}(V) \to \mathbb{Z}/2$, rendering this diagram commutative. Denote this ν by $\tau_S(\mu)$. We have

$$I^{T_S(U)}_\mu \circ \theta^U_S = \theta^U_S \circ I^U_{\tau_S(\mu)},$$

where

$$\tau_S(\mu)(vv_1) := \mu(vv_1) + \sum_{z\in T_S(\{v\})} \mu(zv_1) + \sum_{z_1\in T_S(\{v_1\})} \mu(vz_1),$$

for vv_1 varying over $\mathcal{E}(V)$.
