In our analysis of the two specific semidirect sums, we have seen that there is always an arbitrary modified term $\Delta_{n,a}$. This indicates that higher order matrix spectral problems have more degrees of freedom in generating integrable systems. On the other hand, in all additional spectral submatrices such as U_{a_i}, one can take their dependence on the spectral parameter into consideration, and this will bring much more diverse integrable couplings.

There are also other questions about integrable properties of the resulting enlarged lattice equations, even in the case where additional spectral submatrices are independent of the spectral parameter. For example, can we solve the enlarged lattice equations by the inverse scattering transform? The class of Lie algebras in (2.8) provides a few realizations of semidirect sums of Lie algebras. Other possible realizations are still interesting, especially those which could carry significant information about integrable properties. Reductions of the presented cases of semidirect sums, which keep the uniqueness property of discrete spectral problems (see Ref. 17), could be good examples.

We would especially like to emphasize that we have been considering the problem of integrable couplings and the key is semidirect sums of Lie algebras. The initial Lie algebras G associated with given integrable systems in our construction can be simple (e.g., see Refs. 29 and 30), but semidirect sums of Lie algebras $\overline{G}$ are normally nonsimple (see Ref. 15). Our examples in Sec. II are all nonsimple, since the Killing forms on those semidirect sums of Lie algebras $\overline{G}$ are degenerate. However, there still exist specific nondegenerate bilinear forms on the Lie algebras $\overline{G}$, with nice invariance properties, and their corresponding generalized trace identities, which present Hamiltonian structures of the enlarged lattice equations.

To conclude, semidirect sums of Lie algebras provide a good source of matrix spectral problems for generating integrable systems, and thus the study of integrable couplings using semidirect sums of Lie algebras will enhance our understanding of classification of integrable systems. We are expecting to see more research on related topics.

Tzitzéica transformation is a dressing action

Erxiao Wang[a)]
University of Texas, Austin, Texas 78712

(Received 17 January 2006; accepted 15 March 2006; published online 4 May 2006)

We classify the simplest rational elements in a twisted loop group, and prove that dressing actions of them, on proper indefinite affine spheres, give the classical Tzitzéica transformation and its dual. We also give the group point of view of the permutability theorem, construct complex Tzitzéica transformations, and discuss the group structure for these transformations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2195527]

I. INTRODUCTION

In 1910, Tzitzéica published a classical paper[21] on hyperbolic surfaces in $\mathbb{R}^3$ whose Gauss curvature at any point p is proportional to the fourth power of the distance from a fixed point to the tangent plane at p. He proved

$$w_{xy} = e^{w} - e^{-2w} \tag{1.1}$$

is the structure equation, and also constructed a geometric transformation of such surfaces that is similar to the well-known Bäcklund transformation of surfaces with constant negative curvature. These surfaces are invariant under affine transformations, and they are now known as (proper) affine spheres in affine differential geometry.

The classical Tzitzéica equation (1.1) was rediscovered in many mathematical and physical contexts afterwards (see, e.g., Refs. 5, 7, and 8). In recent years, techniques from soliton theory have been applied to this equation extensively by, e.g., Rogers and Schief in the context of gas dynamics,[15] Kaptsov and Shan'ko on multisoliton formulas,[11] Dorfmeister and Eitner on Weierstrass-type representation,[6] and Bobenko and Schief on its discretizations.[3,4] Terng and Uhlenbeck[20] gave a systematic method to construct Bäcklund-type transformations via dressing actions of simple rational loop group elements. It is natural to ask whether the classical Tzitzéica transformation is a dressing action of some loop element, whether there are new transformations of affine spheres, and what is the group structure of these transformations. This paper answers these questions.

In Sec. II, we give a brief review of classical results and provide the Lax pair of the structure equations. In Sec. III, we review the reality conditions for this Lax pair and give the loop group description of indefinite affine spheres. We then classify the simplest rational elements in this loop group and compute their dressing actions on affine spheres in Sec. IV. These rational elements cannot be constructed by projections as in Ref. 20 and the computation is harder. It turns out that one class of dressing action provides exactly the Tzitzéica transformation and the other provides the dual transformation. In Sec. V, we present the group point of view of the classical permutability theorem, construct complex Tzitzéica transformations and discuss the group structure of these transformations. Some examples are presented in the last section.

II. INDEFINITE AFFINE SPHERE AND ITS LAX REPRESENTATION

Classical affine differential geometry studies the properties of surfaces in $\mathbb{R}^3$ invariant under the (equi) affine transformations $x \to Ax+v$, where $A \in \mathrm{SL}(3,\mathbb{R})$ and $x,\ v \in \mathbb{R}^3$. There are three fundamental affine invariants: the affine (or Blaschke) metric, the Fubini-Pick cubic form, and the third fundamental form (or the affine shape operator). These invariants satisfy certain compatibility equations and the fundamental theorem states that they then determine a surface uniquely up to affine transformations. Let us first review the definitions of these invariants (for more details see, e.g., Refs. 2, 13, and 18). The reader may also refer to Refs. 2–4 or 17 for an elementary description of affine spheres.

Let $X: M \hookrightarrow \mathbb{R}^3$ be an immersed surface with nondegenerate second fundamental form. Let $E=(e_1,e_2,e_3)$ be a local $\mathrm{SL}(3,\mathbb{R})$-frame on M such that e_1,e_2 are tangent to M, and e_3 is transversal to M. Let ω_1,ω_2 denote the dual coframe of e_1,e_2, i.e.,

$$\mathrm{d}X = e_1 \otimes \omega_1 + e_2 \otimes \omega_2.$$

Let (ω_{AB}) denote the $\mathrm{sl}(3,\mathbb{R})$-valued 1-form $E^{-1}\,\mathrm{d}E$, i.e.,

$$\mathrm{d}e_A = \sum_{B=1}^{3} e_B \otimes \omega_{BA}.$$

Then we have the structure equation

$$\begin{aligned} \mathrm{d}\omega_A &= -\sum\nolimits_B \omega_{AB} \wedge \omega_B, \\ \mathrm{d}\omega_{AB} &= -\sum\nolimits_C \omega_{AC} \wedge \omega_{CB}. \end{aligned} \tag{2.1}$$

Since $\omega_3=0$ on M, (2.1) implies that for $i=1,2$,

$$\omega_{3,i} = h_{i1}\omega_1 + h_{i2}\omega_2, \quad \text{with } h_{ij} = h_{ji}. \tag{2.2}$$

A direct computation shows that the quadratic form

$$g := |\det(h_{ij})|^{-1/4} \sum_{i,j=1}^{2} h_{ij}\omega_i\omega_j \tag{2.3}$$

is invariant under change of affine frames, and it is called the *affine metric* of M. M is said to be *definite* or *indefinite* if the affine metric is definite or indefinite, respectively.

The *affine normal* is $\xi := \triangle X/2$, where $\triangle$ is the Laplacian of g. It satisfies two natural geometric conditions,

(i) $\mathrm{d}\xi(\cdot) \in \mathrm{T}M$,
(ii) $i_\xi\,\mathrm{d}V = \mathrm{dvol}_g$ (the volume form of g);

and is essentially determined by them.

Take the exterior differentiation of (2.2) to get

$$\sum_j (\mathrm{d}h_{ij} + h_{ij}\omega_{3,3} - h_{ik}\omega_{kj} - h_{kj}\omega_{ki}) \wedge \omega^j = 0, \tag{2.4}$$

and define h_{ijk} by

$$\sum_k h_{ijk}\omega_k = \mathrm{d}h_{ij} + h_{ij}\omega_{3,3} - h_{ik}\omega_{kj} - h_{kj}\omega_{ki}. \tag{2.5}$$

Then (2.2) and (2.4) imply that h_{ijk} is symmetric in i,j,k. *The Fubini-Pick cubic form* is defined as

$$J := \sum_{i,j,k} h_{ijk}\omega_i\omega_j\omega_k,$$

which is an affine invariant.

We choose $e_3=\xi$. Then $\omega_{3,3}=0$. Exterior differentiate it to get

$$\omega_{13}\wedge\omega_{31}+\omega_{23}\wedge\omega_{32}=0.$$

Thus the following form

$$\mathrm{III} := |\det(h_{ij})|^{1/4}(\omega_{13}\omega_{31}+\omega_{23}\omega_{32})$$

is symmetric. This is the *third fundamental form*. Equivalently, we can first define the *affine shape operator* S,

$$S(u) := \mathrm{d}\xi(u), \quad \forall\, u\in T_pM,$$

then $\mathrm{III}(u,v)=g(S(u),v)=g(u,S(v))$. The *affine mean curvature* H and the *affine Gauss curvature* K are defined as $H=\mathrm{Tr}\,S/2$, $K=\det S$.

Definition 2.1: An *affine sphere* is a surface all of whose affine normals meet at a common point.

An equivalent definition is $S=H\cdot\mathrm{Id}$, i.e., the shape operator is a scalar multiple of the identity map and H is then the affine mean curvature. It follows from the structure equations that H must be constant. When $H=0$, all affine normals are parallel and the center is at infinity. Such surface is called *improper affine sphere* and has been completely classified in Ref. 2. When $H\neq 0$, it is called *proper affine sphere* and we can move the center to the origin and normalize H to 1 by scaling the ambient space and changing the orientation if necessary. Then $e_3=\xi=X$.

From now on we will only consider proper indefinite affine spheres in $\mathbb{R}^3$ with $\xi=X$. First note that there exists local asymptotic coordinate system (x,y) and a smooth function $w(x,y)$ such that the affine metric is

$$g = e^w(\mathrm{d}x\otimes\mathrm{d}y+\mathrm{d}y\otimes\mathrm{d}x).$$

We choose a frame $e_1=X_x$, $e_2=e^{-w}X_y$, and $e_3=\xi=X$. Then $\det(e_1,e_2,e_3)=1$, and

$$\omega_1=\mathrm{d}x=\omega_{13}=\omega_{32}, \qquad \omega_2=e^w\,\mathrm{d}y=\omega_{23}=\omega_{31},$$
$$\omega_{33}=0, \qquad (h_{ij})=\begin{pmatrix}0&1\\1&0\end{pmatrix}.$$

A direct computation using the formula (2.5) shows

$$\omega_{21}=a\,\mathrm{d}x, \quad \omega_{12}=be^{-2w}\,\mathrm{d}y \quad \text{for some functions } a,\ b;$$
$$J=-2a\,\mathrm{d}x^3-2b\,\mathrm{d}y^3.$$

Finally from $\mathrm{d}\omega_A+\Sigma_B\omega_{AB}\wedge\omega_B=0$ we get

$$\omega_{11}=-\omega_{22}=w_x\,\mathrm{d}x.$$

We have obtained the flat $\mathrm{sl}(3,\mathbb{R})$-valued 1-form

$$\omega = E^{-1}\,\mathrm{d}E=\begin{pmatrix} w_x\,\mathrm{d}x & be^{-2w}\,\mathrm{d}y & \mathrm{d}x\\ a\,\mathrm{d}x & -w_x\,\mathrm{d}x & e^w\,\mathrm{d}y\\ e^w\,\mathrm{d}y & \mathrm{d}x & 0\end{pmatrix}.$$

The compatibility equations are

$$d\omega + \omega \wedge \omega = 0 \Leftrightarrow \begin{cases} w_{xy} = e^w - abe^{-2w}, \\ a_y = 0, \quad b_x = 0. \end{cases} \tag{2.6}$$

When $ab \neq 0$ we may reparametrize the asymptotic coordinates to make $a=b=1$. Then (2.6) is simplified to the classical Tzitzéica equation.

Remark 2.2: It is known that ruled proper indefinite affine spheres correspond to the case $ab=0$ and they have been well understood (see Ref. 13). For nonruled case, the points at which $ab=0$ are called *planar points*.

The following observation is crucial for the integrability of proper indefinite affine spheres: The system (2.6) is invariant under the transformation

$$a \to \gamma a, \quad b \to \gamma^{-1} b$$

with $\gamma \in \mathbb{C}\backslash\{0\}$. Thus a family of flat connections is obtained,

$$\omega_\gamma = \begin{pmatrix} w_x\, dx & \gamma^{-1} b e^{-2w}\, dy & dx \\ \gamma a\, dx & -w_x\, dx & e^w\, dy \\ e^w\, dy & dx & 0 \end{pmatrix}.$$

The zero curvature equation of ω_γ is called the *Lax representation* of (2.6).

When we solve E_γ from

$$E_\gamma^{-1}\, dE_\gamma = \omega_\gamma \tag{2.7}$$

for any $\gamma \in \mathbb{R}\backslash\{0\}$, the last column of E_γ gives a family of affine spheres, whose affine fundamental invariants are

$$g = 2e^w\, dx\, dy, \quad S = \mathrm{Id}, \quad J = -2\gamma a\, dx^3 - \frac{2}{\gamma} b\, dy^3.$$

Let us recall the classical *duality relation* for indefinite affine spheres. Let $h=e^\omega$. Then Tzitzéica equation becomes

$$(\ln h)_{xy} = h - \frac{1}{h^2}, \quad \text{or } h_{xy}h - h_x h_y = h^3 - 1. \tag{2.8}$$

Classically (2.7) with $a=b=1$ was written as a linear system for X,

$$\begin{aligned} X_{xx} &= \frac{h_x}{h} X_x + \frac{\gamma}{h} X_y, \\ X_{xy} &= hX, \\ X_{yy} &= \frac{1}{\gamma h} X_x + \frac{h_y}{h} X_y. \end{aligned} \tag{2.9}$$

If X solves (2.9), then we can check that

$$X^* := \frac{1}{h} X_x \times X_y$$

is a solution of (2.9) with γ replaced by $-\gamma$. Here $\times$ is the vector cross product in $\mathbb{R}^3$. This is clearly a duality relation $(X^*)^* = X$.

Finally let us recall the classical Tzitzéica transformation.

Theorem 2.3 (Ref. 21). *Given a solution* (h, X) *of* (2.8) and (2.9), *and* ϕ_1 *any scalar solution of* (2.9) *with parameter* γ_1, *then the following transformation produces a new solution* (h_1, X_1) *of* (2.8) and (2.9):

$$h_1 := h - 2(\ln \phi_1)_{xy},$$
$$X_1 := \frac{(\gamma - \gamma_1)hX - 2\gamma(\ln \phi_1)_x X_y + 2\gamma_1(\ln \phi_1)_y X_x}{(\gamma + \gamma_1)h}. \tag{2.10}$$

III. THE REALITY CONDITIONS AND LOOP GROUP DESCRIPTION

Henceforth we assume $a=b=1$. To further reveal the hidden symmetry, let $\lambda = \sqrt[3]{\gamma}$ and change the frame E_γ to

$$F_\lambda = E_\gamma \operatorname{diag}(1/\lambda, \lambda, 1).$$

The gauged family of flat connections is then

$$\theta_\lambda = F_\lambda^{-1}\, dF_\lambda = \begin{pmatrix} w_x & 0 & \lambda \\ \lambda & -w_x & 0 \\ 0 & \lambda & 0 \end{pmatrix} dx + \lambda^{-1} \begin{pmatrix} 0 & e^{-2w} & 0 \\ 0 & 0 & e^{w} \\ e^{w} & 0 & 0 \end{pmatrix} dy. \tag{3.1}$$

For any $g \in \mathrm{SL}(3,\mathbb{C})$, we need to define $\tau(g) := \bar{g}$ and define σ by

$$\sigma(g) := T(g^t)^{-1}T^{-1}, \quad \text{where } T = \begin{pmatrix} 0 & 1 & 0 \\ -\epsilon & 0 & 0 \\ 0 & 0 & \epsilon^2 \end{pmatrix}, \quad \epsilon = e^{\pi i/3}.$$

The automorphism σ has order 6 and induces the following automorphism (still denoted by σ) on the Lie algebra $\mathrm{sl}(3,\mathbb{C})$: $\sigma(A) = -TA^tT^{-1}$. Therefore σ gives the eigenspace decomposition: $\mathrm{sl}(3,\mathbb{C}) = \oplus_{j=0}^{5}\mathcal{G}_j$, where $\mathcal{G}_j$ is of eigenvalue ϵ^j. We compute that $X_j \in \mathcal{G}_j$ if and only if

$$X_0 = \begin{pmatrix} x_{11} & 0 & 0 \\ 0 & -x_{11} & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad X_1 = \begin{pmatrix} 0 & 0 & x_{13} \\ x_{21} & 0 & 0 \\ 0 & x_{13} & 0 \end{pmatrix},$$

$$X_2 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & x_{23} \\ -x_{23} & 0 & 0 \end{pmatrix}, \quad X_3 = \begin{pmatrix} x_{11} & 0 & 0 \\ 0 & x_{11} & 0 \\ 0 & 0 & -2x_{11} \end{pmatrix},$$

$$X_4 = \begin{pmatrix} 0 & 0 & x_{13} \\ 0 & 0 & 0 \\ 0 & -x_{13} & 0 \end{pmatrix}, \quad X_5 = \begin{pmatrix} 0 & x_{12} & 0 \\ 0 & 0 & x_{23} \\ x_{23} & 0 & 0 \end{pmatrix}.$$

Note that $\sigma\tau = \tau^{-1}\sigma^{-1}$ implies that $\oplus_{j=0}^{5}(\mathrm{sl}(3,\mathbb{R}) \cap \mathcal{G}_j)$ is the corresponding eigenspace decomposition of $\mathrm{sl}(3,\mathbb{R})$.

The θ_λ in (3.1) satisfies two reality conditions (first given in Ref. 12),

$$\tau(\theta_\lambda) = \theta_{\bar{\lambda}}, \quad \sigma(\theta_\lambda) = \theta_{\epsilon\lambda}. \tag{3.2}$$

When we solve F_λ in (3.1) uniquely with the initial condition $F(0,0,\lambda) = I$, it is easy to show that F_λ also satisfies the reality conditions (3.2).

Let $\mathbb{C}_* := \mathbb{C}\backslash\{0\}$. We adopt the following notations for loop groups:

$$\Lambda G = \{\text{holomorphic maps from } \mathbb{C}_* \cap (\mathcal{O}_r \cup \mathcal{O}_{1/r}) \text{ to } G\},$$

$$\Lambda_+ G = \{\text{holomorphic maps from } \mathbb{C}_* \text{ to } G\},$$

$$\Lambda_{-}G = \{\text{holomorphic maps } f \text{ from } \mathcal{O}_r \cup \mathcal{O}_{1/r} \text{ to } G \text{ with } f(\infty) = I\},$$

where $0 < r < 1$ is sufficiently small and

$$\mathcal{O}_r = \{\lambda \in \mathbb{C} : |\lambda| < r\}, \quad \mathcal{O}_{1/r} = \{\lambda \in \mathbb{C} \cup \{\infty\} : |\lambda| > 1/r\}.$$

Similar notations also apply to their Lie algebras. Let $\Lambda^{\tau,\sigma}G$ denote the subgroup of $g \in \Lambda G$ satisfying the reality conditions (3.2). Then θ_λ in (3.1) is a $\Lambda_+^{\tau,\sigma}\mathrm{sl}(3,\mathbb{C})$-valued flat connection, and the corresponding frame F_λ for indefinite affine spheres lies in $\Lambda_+^{\tau,\sigma}\mathrm{SL}(3,\mathbb{C})$. Conversely, given any smooth map F from a domain in $\mathbb{R}^2$ to $\Lambda_+^{\tau,\sigma}\mathrm{SL}(3,\mathbb{C})$ satisfying

$$F^{-1}F_x = A\lambda + B, \quad F^{-1}F_y = C\lambda^{-1} + D \tag{3.3}$$

with $A_{32}C_{31} \neq 0$, the last column of F then gives an affine sphere with $h = A_{32}C_{31}$ and F differs from F_λ in (3.1) by a simple gauge. This is the loop group description for indefinite affine spheres (for details, see Refs. 3 and 6).

IV. DRESSING ACTIONS OF SIMPLE RATIONAL ELEMENTS

Let us briefly review the method of dressing action (the original idea went back to Ref. 22 but see Refs. 9 or 19 for an elementary introduction). Let $G = \mathrm{SL}(3,\mathbb{C})$, $g(\lambda) \in \Lambda_-^{\tau,\sigma}G$, and $F(x,y,\lambda) \in \Lambda_+^{\tau,\sigma}G$ the frame of an associated family of indefinite affine spheres. Assume we can do the following factorization for each fixed (x,y):

$$g(\lambda)F(x,y,\lambda) = \widetilde{F}(x,y,\lambda)\widetilde{g}(x,y,\lambda), \tag{4.1}$$

with $\widetilde{F} \in \Lambda_+^{\tau,\sigma}G$ and $\widetilde{g} \in \Lambda_-^{\tau,\sigma}G$. Then $\widetilde{F}$ also satisfies (3.3) and generates new affine spheres. We sketch the proof here. It suffices to prove that $\widetilde{F}^{-1}(\widetilde{F})_x$ and $\widetilde{F}^{-1}(\widetilde{F})_y$ are linear in λ and λ^{-1}, respectively. But

$$\widetilde{F}^{-1}(\widetilde{F})_x = \widetilde{g}F^{-1}g^{-1}(gF\widetilde{g}^{-1})_x = \widetilde{g}(F^{-1}F_x)\widetilde{g}^{-1} + \widetilde{g}(\widetilde{g}^{-1})_x = \widetilde{g}(A\lambda + B)\widetilde{g}^{-1} - \widetilde{g}_x\widetilde{g}^{-1}.$$

On the left-hand side, $\widetilde{F}^{-1}(\widetilde{F})_x$ is holomorphic in $\lambda \in \mathbb{C}\backslash\{0\}$; on the right it has a simple pole at ∞ since $g(\infty) = \widetilde{g}(\infty) = I$. So

$$\widetilde{F}^{-1}(\widetilde{F})_x = \widetilde{A}\lambda + \widetilde{B}.$$

Similarly, $\widetilde{F}^{-1}(\widetilde{F})_y$ is linear in $1/\lambda$. This completes the proof.

Furthermore, $g * F := \widetilde{F}$ defines a group action of $\Lambda_-^{\lambda,\sigma}G$ on the frames of affine spheres, which is called the *dressing action*.

The factorization (4.1) can indeed be done on a dense open subset of $\Lambda^{\tau,\sigma}G$ (see Refs. 1 and 14). There is no explicit construction for general g, but when g is a rational element, the factorization can be carried out using residue calculus (see Ref. 20). In search of simple rational elements in $\Lambda_-^{\tau,\sigma}\mathrm{SL}(3,\mathbb{C})$, it helps to write $\sigma = \nu \circ \mu$ as the composition of two commuting automorphisms, where

$$\nu(g) := QgQ^{-1} \quad \text{with } Q = \mathrm{diag}(\epsilon^4, \epsilon^2, 1),$$

$$\mu(g) := P(g^t)^{-1}P \quad \text{with } P = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Here ν has been called the Coxeter-Killing automorphism, and the involution μ is the unique outer automorphism of $\mathrm{SL}(3,\mathbb{C})$ modulo inner ones. We observe that an element $g(\lambda) \in \Lambda G$ lies in $\Lambda^{\tau,\sigma}G$ if and only if

$$\tau(g_\lambda^-) = g_\lambda, \quad \nu(g_\lambda) = g_{\epsilon^4\lambda}, \quad \mu(g_\lambda) = g_{-\lambda}. \tag{4.2}$$

Remark 4.1: τ and μ define a symmetric space $\mathrm{SL}(3,\mathbb{R})/\mathrm{SO}(2,1)$. Here $\mathrm{SO}(2,1)$ is the isometry group of the quadratic form given by the symmetric matrix P, i.e., $2x_1x_2+x_3^2$ on $\mathbb{R}^3$. It was proved in Ref. 19 that if F_λ is the frame of an associated family of indefinite affine spheres, then $F_{-1}F_1^{-1}$ is a harmonic map from $\mathbb{R}^{1,1}$ to the symmetric space $\mathrm{SL}(3,\mathbb{R})/\mathrm{SO}(2,1)$.

We will first study rational elements in $\Lambda_-^\sigma G$. Due to the ν-reality condition in (4.2), the simplest rational element in $\Lambda_-^\sigma G$ may have only three simple poles $\{\alpha, \epsilon^2\alpha, \epsilon^4\alpha\}$ with $\alpha \in \mathbb{C}_*$. The element can always take the following special form:

$$g(\lambda) = I + \frac{2\alpha}{\lambda-\alpha}A + \frac{2\epsilon^2\alpha}{\lambda-\epsilon^2\alpha}B + \frac{2\epsilon^4\alpha}{\lambda-\epsilon^4\alpha}C. \tag{4.3}$$

Plug it into (ν,μ)-reality conditions in (4.2) and compare the residues, at each pole, we obtain that $g \in \Lambda_-^\sigma G$ if and only if

$$\begin{gathered} B = Q^{-1}AQ, \quad C = QAQ^{-1}, \\ A^tP(I - A - 2\epsilon B + 2\epsilon^2 C) = 0. \end{gathered} \tag{4.4}$$

Write $A=(a_{ij})$, and we compute that

$$(I - A - 2\epsilon B + 2\epsilon^2 C) = \begin{pmatrix} 1-3a_{11} & -3a_{12} & 3a_{13} \\ 3a_{21} & 1-3a_{22} & -3a_{23} \\ -3a_{31} & 3a_{32} & 1-3a_{33} \end{pmatrix}. \tag{4.5}$$

If the rank of A is 3, we get $A=I/3$ and $g(\lambda)$ is trivial. So there are two types left for A: rank 1 type and rank 2 type. A long but not hard computation implies that the **rank** 1 **type** is as follows:

$$A = \frac{1}{3}\begin{pmatrix} \dfrac{b}{2ab-1} \\ a \\ 1 \end{pmatrix}(a \quad b \quad 1) = \frac{1}{3}\begin{pmatrix} \dfrac{ab}{2ab-1} & \dfrac{b^2}{2ab-1} & \dfrac{b}{2ab-1} \\ a^2 & ab & a \\ a & b & 1 \end{pmatrix}, \tag{4.6}$$

with the corresponding loop group element

$$g(\lambda) = I + \frac{2}{\lambda^3-\alpha^3}\begin{pmatrix} \dfrac{\alpha^3 ab}{2ab-1} & \dfrac{\alpha\lambda^2 b^2}{2ab-1} & \dfrac{\alpha^2\lambda b}{2ab-1} \\ \alpha^2\lambda a^2 & \alpha^3 ab & \alpha\lambda^2 a \\ \alpha\lambda^2 a & \alpha^2\lambda b & \alpha^3 \end{pmatrix}; \tag{4.7}$$

and the rank 2 type [*thus the matrix* (4.5) *has rank* 1] is as follows:

$$A = \frac{1}{3}\begin{pmatrix} \dfrac{ab-1}{2ab-1} & \dfrac{-b^2}{2ab-1} & \dfrac{b}{2ab-1} \\ a^2 & 1-ab & -a \\ -a & b & 0 \end{pmatrix}, \tag{4.8}$$

with the corresponding loop group element

$$g(\lambda) = I + \frac{2}{\lambda^3 - \alpha^3}\begin{pmatrix} \frac{\alpha^3(ab-1)}{2ab-1} & \frac{-\alpha\lambda^2 b^2}{2ab-1} & \frac{\alpha^2\lambda b}{2ab-1} \\ \alpha^2\lambda a^2 & \alpha^3(1-ab) & -\alpha\lambda^2 a \\ -\alpha\lambda^2 a & \alpha^2\lambda b & 0 \end{pmatrix}. \tag{4.9}$$

Both types must meet the constraint $2ab \neq 1$.

Remark 4.2: We compute that $\det g$ is $[(\lambda^3+\alpha^3)/(\lambda^3-\alpha^3)]^{\mathrm{rank}(A)}$, i.e., only depending on the poles and the rank of the residues. A scaling by $(\det g)^{-1/3}$ will make them lie in $\mathrm{SL}(3,\mathbb{C})$, though not rational any more. Since the scaling does not affect the factorization and the dressing action, we will ignore this step henceforth.

Let $l := (a,b,1)$, ℓ be the line $\mathbb{C}\cdot l$, and introduce the following cone:

$$\Delta := \{(z_1,z_2,z_3) \in \mathbb{C}^3 \mid 2z_1z_2 = z_3^2, \text{ or } z_3 = 0\}.$$

Then $2ab \neq 1$ is equivalent to $\ell \subsetneq \Delta$. We observe that $\ell^t = \mathrm{Image}(\mathrm{Res}_\alpha g^t)$ for rank 1 type and $\ell^t = \mathrm{Kernel}(\mathrm{Res}_\alpha g\, P)$ for rank 2 type (here ℓ^t means $\mathbb{C}\cdot l^t$). Conversely, a line ℓ not in Δ determines the residue A and thus the simple element g uniquely in both types. Henceforth we always use $g_{\alpha,\ell}$ to denote the rank 1 type element (4.7) and use $h_{\alpha,\ell}$ to denote the rank 2 type element (4.9). We have proved the following theorem.

Theorem 4.3: *The simplest rational element in* $\Lambda_-^\sigma \mathrm{GL}(3,\mathbb{C})$ *is either* $g_{\alpha,\ell}$ *of rank* 1 *type* (4.7) *or* $h_{\alpha,\ell}$ *of rank* 2 *type* (4.9), *where* $\alpha \in \mathbb{C}_*$ *and* $\ell \subsetneq \Delta$.

Imposing the τ-reality condition $g(\bar{\lambda}) = g(\lambda)$ on both types, we obtain that one pole, say α, must be real and so is the residue A there. It is convenient in this case to let ℓ denote the real line $\mathbb{R}\cdot(a,b,1)$ in $\mathbb{R}^3$ and let Δ_0 denote $\Delta \cap \mathbb{R}^3$. We then have the following.

Corollary 4.4: The simplest rational element in $\Lambda_-^{\tau,\sigma}\mathrm{GL}(3,\mathbb{C})$ *is either* $g_{\alpha,\ell}$ *of rank* 1 *type or* $h_{\alpha,\ell}$ *of rank* 2 *type*, *where* $\alpha \in \mathbb{R}_*$ *and the real line* $\ell \subsetneq \Delta_0$.

We are ready to compute the dressing action of these simple elements.

Lemma 4.5: Let $g_{\alpha,\ell} \in \Lambda_-^{\tau,\sigma}\mathrm{GL}(3,\mathbb{C})$ *as in* (4.7), *and* $F \in \Lambda_+^{\tau,\sigma}\mathrm{SL}(3,\mathbb{C})$. *If* $\ell := \ell F(\alpha) \subsetneq \Delta_0$, *then* $g_{\alpha,\ell}\cdot F$ *can be factored uniquely as*

$$g_{\alpha,\ell}\cdot F = \widetilde{F}\cdot g_{\alpha,\widetilde{\ell}} \in \Lambda_+^{\tau,\sigma}\mathrm{SL}(3,\mathbb{C}) \times \Lambda_-^{\tau,\sigma}\mathrm{GL}(3,\mathbb{C}).$$

Proof: It suffices to prove that $\widetilde{F} := g_{\alpha,\ell}\cdot F\cdot g_{\alpha,\widetilde{\ell}}^{-1}$ lies in $\Lambda_+^{\tau,\sigma}\mathrm{SL}(3,\mathbb{C})$. Since $\widetilde{F}$ satisfies the reality conditions (4.2) and is holomorphic in $\mathbb{C}_*$ except for possible simple poles coming from the poles of $g_{\alpha,\ell}$ and $g_{\alpha,\widetilde{\ell}}^{-1}$, we only need to prove that the residues of $\widetilde{F}$ are zero at both α and $-\alpha$. But

$$\mu(g_{\alpha,\ell}(\lambda)) = g_{\alpha,\ell}(-\lambda) \Leftrightarrow P = g_{\alpha,\ell}(\lambda)Pg_{\alpha,\ell}(-\lambda)^t,$$

whose residue is zero at α implies that $\ell P g_{\alpha,\ell}(-\alpha)^t = 0$, or equivalently $g_{\alpha,\ell}(-\alpha)P\ell^t = 0$. These two equations are also true for $\widetilde{\ell}$. Therefore $(a,b,1)F(\alpha) \in \widetilde{\ell}$ and the special form of A in (4.6) imply that

$$\mathrm{Res}_\alpha \widetilde{F} = 2\alpha A F(\alpha) P g_{\alpha,\widetilde{\ell}}(-\alpha)^t P = 0,$$

and $F(-\alpha)P(\widetilde{a},\widetilde{b},1)^t \in [F(-\alpha)PF(\alpha)^t]\ell^t = P\ell^t$ implies that

$$\mathrm{Res}_{-\alpha} \widetilde{F} = 2\alpha g_{\alpha,\ell}(-\alpha)F(-\alpha)P\widetilde{A}^t P = 0.$$

The proof is completed once we notice that $\det \widetilde{F} = 1$ by Remark 4.2. □

Theorem 4.6: *The dressing action of rank* 1 *type* $g_{\alpha,\ell}$ *on the affine frames* $F(x,y,\lambda)$ *of proper indefinite affine spheres gives the classical Tzitzéica transformation*, *provided an open condition that* $\ell F(x,y,\alpha) \subsetneq \Delta_0$. *The dressing action of rank* 2 *type* $h_{\alpha,\ell}$ *gives the dual transformation.*

Proof: By Lemma 4.5, for fixed (x,y), we have the factorization

$$g_{\alpha,\ell}(\lambda)\cdot F(x,y,\lambda)=\tilde{F}(x,y,\lambda)\cdot g_{\alpha,\tilde{\ell}}(\lambda)$$

with $\tilde{\ell}=\ell F(x,y,\alpha)$. From $F(x,y,\alpha)=((X_\alpha)_x/\alpha,\alpha(X_\alpha)_y/h,X_\alpha)$, we get

$$(a,b,1)F(x,y,\alpha)=(\phi_x/\alpha,\alpha\phi_y/h,\phi)\in\tilde{\ell},$$

where $\phi:=(a,b,1)X_\alpha$ is a scalar solution of (2.9) with parameter α. Note that a constant scaling of ϕ does not change Tzitzéica transformation (2.10), and the solution space of the linear system (2.9) has dimension 3. Therefore, by varying ℓ,ϕ can be a generic scalar solution up to a constant multiple.

By the discussion at the beginning of this section, the third column of $\tilde{F}$ produces new affine sphere, so does the affine transformation of it by $g_{\alpha,\ell}^{-1}$,

$$\begin{aligned}\hat{X}&:=g_{\alpha,\ell}^{-1}(\tilde{F})_3=(F(\lambda)g_{\alpha,\tilde{\ell}}(\lambda)^{-1})_3\\&=(F(\lambda)Pg_{\alpha,\tilde{\ell}}(-\lambda)^tP)_3\\&\overset{(4.7)}{=}(X_x/\lambda,\lambda X_y/h,X)\cdot\frac{1}{\lambda^3+\alpha^3}\cdot\begin{pmatrix}2\alpha^3\lambda\phi_y/(h\phi)\\-2\lambda^2\phi_x/\phi\\\lambda^3-\alpha^3\end{pmatrix}\\&=\frac{(\lambda^3-\alpha^3)hX-2\lambda^3(\ln\phi)_xX_y+2\alpha^3(\ln\phi)_yX_x}{(\lambda^3+\alpha^3)h}.\end{aligned}$$

The corresponding solution to Tzitzéica equation is given by

$$\hat{h}=\hat{X}_{xy}/\hat{X}=h-2(\ln\phi)_{xy}.$$

This is exactly the classical Tzitzéica transformation (2.10) with

$$\gamma=\lambda^3,\quad \gamma_1=\alpha^3,\quad \phi_1=\phi.$$

In rank 2 type case, there is a similar factorization $h_{a,\ell}\cdot F=\tilde{F}\cdot h_{\alpha,\tilde{\ell}}$ when $\tilde{\ell}:=\mathrm{Kernel}^t(AF(\alpha)P)\subsetneq\Delta_0$. We omit the details and present the corresponding transformation on affine spheres

$$\tilde{X}=\frac{(\lambda^3+\alpha^3)hX-2\lambda^3(\ln\phi)_xX_y-2\alpha^3(\ln\phi)_yX_x}{(\lambda^3-\alpha^3)h},$$

where ϕ is the same scalar solution as the rank 1 type case. We see that

$$\hat{X}_\lambda=-\tilde{X}_{-\lambda},$$

i.e., $-\tilde{X}$ gives the dual of $\hat{X}$. This completes the proof. □

V. PERMUTABILITY THEOREM AND COMPLEX TZITZÉICA TRANSFORMATIONS

Let us briefly review the classical description of the permutability theorem. In Theorem 2.3, let ϕ_1,ϕ_2 be the scalar solution of (2.9) with parameter γ_1,γ_2, respectively. Then using ϕ_1 to apply Tzitzéica transformation on h, we get a new solution to Tzitzéica equation,

$$h_1:=h-2(\ln\phi_1)_{xy}.$$

Applying Tzitzéica transformation (2.10) to (ϕ_2,γ_2), we obtain

$$\phi_{12} := \frac{(\gamma_2 - \gamma_1)h\phi_2 - 2\gamma_2(\ln \phi_1)_x(\phi_2)_y + 2\gamma_1(\ln \phi_1)_y(\phi_2)_x}{(\gamma_2 + \gamma_1)h} \tag{5.1}$$

as a scalar solution to (2.9) with new h_1 and parameter γ_2. Therefore we can use ϕ_{12} to apply Tzitzéica transformation again on the new h_1, i.e.,

$$h_{12} = h_1 - 2(\ln \phi_{12})_{xy}$$

will give another solution to Tzitzéica equation. In this two step iteration, we may interchange the roles of ϕ_1 and ϕ_2 to obtain h_{21} as another new solution. The permutability theorem claims $h_{12} = h_{21}$. Similarly we can apply this two step iteration to the affine sphere X to obtain X_{12} and X_{21}, respectively, and the equality $X_{12} = X_{21}$ still holds.

We will give a group point of view to this permutability theorem.

Lemma 5.1: Let $g_{\alpha_i,\ell_i}(\lambda)(i=1,2)$ *be of rank* 1 *type with* $\alpha_1^3 \neq \pm\alpha_2^3$. *If both* $\tilde{\ell}_1 := \ell_1 g_{\alpha_2,\ell_2}(\alpha_1)^{-1}$ *and* $\tilde{\ell}_2 := \ell_2 g_{\alpha_1,\ell_1}(\alpha_2)^{-1}$ *are not in* Δ, *then*

$$g_{\alpha_2,\tilde{\ell}_2} g_{\alpha_1,\ell_1} = g_{\alpha_1,\tilde{\ell}_1} g_{\alpha_2,\ell_2}. \tag{5.2}$$

Proof: It is equivalent to prove that $f := g_{\alpha_1,\tilde{\ell}_1} g_{\alpha_2,\ell_2} g_{\alpha_1,\ell_1}^{-1}$ equals $g_{\alpha_2,\tilde{\ell}_2}$. First of all, they both are rational elements in the group $\Lambda^{\sigma}_{-}\mathrm{GL}(3,\mathbb{C})$. It suffices to prove that their poles and residues are the same.

Let $l_i=(a_i,b_i,1)$ and $\tilde{l}_i=(\tilde{a}_i,\tilde{b}_i,1)$ span ℓ_i and $\tilde{\ell}_i$, respectively. Similar to the proof of Lemma 4.5, we compute that

$$\mathrm{Res}_{\alpha_1} f = 2\alpha_1 \tilde{A}_1 g_{\alpha_2,\ell_2}(\alpha_1) P g_{\alpha_1,\ell_1}(-\alpha_1)^t P = 0$$

since $\tilde{l}_1 g_{\alpha_2,\ell_2}(\alpha_1) \in \ell_1$, and

$$\mathrm{Res}_{-\alpha_1} f = -2\alpha_1 g_{\alpha_1,\tilde{\ell}_1}(-\alpha_1) g_{\alpha_2,\ell_2}(-\alpha_1) P A_1^t P = 0$$

since $g_{\alpha_2,\ell_2}(-\alpha_1) P l_1^t \in [g_{\alpha_2,\ell_2}(-\alpha_1) P g_{\alpha_2,\ell_2}(\alpha_1)^t]\tilde{\ell}_1^t = P\tilde{\ell}_1^t$. Thus f has only three simple poles $\{\alpha_2, \epsilon^2\alpha_2, \epsilon^4\alpha_2\}$, same as $g_{\alpha_2,\tilde{\ell}_2}$.

Now due to the ν reality condition in (4.2), we only need to prove that their residues at α_2 are the same. But

$$\mathrm{Image}(\mathrm{Res}_{\alpha_2} f^t) = \mathrm{Image}(g_{\alpha_1,\ell_1}(\alpha_2)^{-1})^t A_2^t g_{\alpha_1,\tilde{\ell}_1}(\alpha_2)^t = (g_{\alpha_1,\ell_1}(\alpha_2)^{-1})^t \ell_2^t = \tilde{\ell}_2^{\,t} = \mathrm{Image}(\mathrm{Res}_{\alpha_2} g^t_{\alpha_2,\tilde{\ell}_2}).$$

Then $\mathrm{Res}_{\alpha_2} f$ must be the same as $\mathrm{Res}_{\alpha_2}(g_{\alpha_2,\tilde{\ell}_2})$ since rank 1 type residue is uniquely determined by the above image. This completes the proof. □

Example 5.2: Choose two nonzero poles α_1, α_2 such that $\alpha_1^3 \neq \pm\alpha_2^3$, and let $\ell_i = \mathbb{C}\cdot(0,b_i,1)$ for $i=1,2$. Then $g_{\alpha_2,\tilde{\ell}_2} g_{\alpha_1,\ell_1} = g_{\alpha_1,\tilde{\ell}_1} g_{\alpha_2,\ell_2}$ holds for $\tilde{\ell}_i = \mathbb{C}\cdot(0,\tilde{b}_i,1)$ with

$$\tilde{b}_1 = \frac{(\alpha_1^3 + \alpha_2^3)b_1 - 2\alpha_1\alpha_2^2 b_2}{(\alpha_1^3 - \alpha_2^3)}, \quad \tilde{b}_2 = \frac{2\alpha_1^2\alpha_2 b_1 - (\alpha_1^3 + \alpha_2^3)b_2}{(\alpha_1^3 - \alpha_2^3)}.$$

Theorem 5.3: *Use the same notation and the factorization formula* (5.2) *in Lemma 5.1. Let all* α_i, ℓ_i *be real. Let* $F_1 := g_{\alpha_1,\ell_1} * F$ *and* $F_2 := g_{\alpha_2,\ell_2} * F$, *where* * *is the dressing action on the frames* $F(x,y,\lambda)$ *of affine spheres. Then the following holds and implies the classical permutability theorem*:

$$(g_{\alpha_2,\tilde{\ell}_2} g_{\alpha_1,\ell_1}) * F = g_{\alpha_2,\tilde{\ell}_2} * F_1 (=: F_{12}) = (g_{\alpha_1,\tilde{\ell}_1} g_{\alpha_2,\ell_2}) * F = g_{\alpha_1,\tilde{\ell}_1} * F_2 (=: F_{21}). \tag{5.3}$$

Proof: Because the dressing action is a group action, (5.3) certainly holds by (5.2). Let $l_i = (a_i,b_i,1)$ and $\tilde{l}_i=(\tilde{a}_i,\tilde{b}_i,1)$ span ℓ_i and $\tilde{\ell}_i$, respectively. From the proof of Theorem 4.6, F_1:

$=g_{\alpha_1,\ell_1}*F$ means in classical terms the following: Tzitzéica transformation via $\phi_1:=l_1(F(\alpha_1))_3$ on $X=(F)_3$ gives a new affine sphere $X_1:=g^{-1}_{\alpha_1,\ell_1}(F_1)_3$. Therefore $F_{12}:=g_{\alpha_2,\tilde{\ell}_2}*F_1$ implies that Tzitzéica transformation via $\phi_{12}:=\tilde{l}_2(F_1(\alpha_2))_3$ on $(F_1)_3=g_{\alpha_1,\ell_1}X_1$ gives a new affine sphere $g^{-1}_{\alpha_2,\tilde{\ell}_2}(F_{12})_3$. We observe that

$$\phi_{12}:=\tilde{l}_2(F_1(\alpha_2))_3=c_0 l_2 g_{\alpha_1,\ell_1}(\alpha_2)^{-1}(F_1(\alpha_2))_3=c_0 l_2 X_1(\alpha_2),$$

which coincides with the classical formula (5.1) except for a negligible constant c_0 when we plug in $\phi_2:=l_2X(\alpha_2)$.

So Tzitzéica transformation via ϕ_{12} on $X_1=g^{-1}_{\alpha_1,\ell_1}(F_1)_3$ produces

$$X_{12}=g^{-1}_{\alpha_1,\ell_1}(g^{-1}_{\alpha_2,\bar{\ell}_2}F_{12})_3=(g^{-1}_{\alpha_1,\ell_1}g^{-1}_{\alpha_2,\bar{\ell}_2}F_{12})_3.$$

Similarly $X_{21}=(g^{-1}_{\alpha_2,\ell_2}g^{-1}_{\alpha_1,\tilde{\ell}_1}F_{21})_3$. Therefore, by (5.2) and (5.3) we obtain the classical permutability theorem: $X_{12}=X_{21}$, which automatically implies $h_{12}=h_{21}$ for the corresponding affine metrics.□

There is some rational element in $\Lambda^{\tau,\sigma}_{-}\mathrm{GL}(3,\mathbb{C})$ which has six simple poles but none of them are real. The poles must form two conjugate triples as $\{\alpha,\epsilon^2\alpha,\epsilon^4\alpha\}$ and $\{\bar{\alpha},\epsilon^2\bar{\alpha},\epsilon^4\bar{\alpha}\}$, where we may assume $0<\arg(\alpha)<\pi/3$ without loss of generality. So such element is not a product of *real* rank 1 or 2 type elements. In fact, we can use Lemma 5.1 to construct them.

Proposition 5.4: Let $\alpha\in\mathbb{C}_*$ *with* $\arg(\alpha)\in(0,\pi/6)\cup(\pi/6,\pi/3)$. *Let* $\ell\subsetneq\Delta$. If $\ell^*:=\ell\cdot g_{\alpha,\ell}(\bar{\alpha})^{-1}\subsetneq\Delta$, *then* $f_{\alpha,\ell}:=g_{\bar{\alpha},\ell^*}g_{\alpha,\ell}\in\Lambda^{\tau,\sigma}_{-}\mathrm{GL}(3,\mathbb{C})$.

Proof: We first observe that $f_{\alpha,\ell}$ lies in $\Lambda^{\sigma}_{-}\mathrm{GL}(3,\mathbb{C})$. It suffices to verify $f(\bar{\lambda})=f(\lambda)$, which is

$$g_{\alpha,\bar{\ell}^*}g_{\bar{\alpha},\bar{\ell}}=g_{\bar{\alpha},\ell^*}g_{\alpha,\ell}.$$

Since $\ell^*=\bar{\ell}\cdot g_{\alpha,\ell}(\bar{\alpha})^{-1}\subsetneq\Delta$ implies $\bar{\ell}^*=\ell\cdot g_{\bar{\alpha},\bar{\ell}}(\alpha)^{-1}\subsetneq\Delta$ and $\arg(\alpha)\neq\pi/6$ implies $\alpha^3\neq-\bar{\alpha}^3$, the above factorization holds by Lemma 5.1. □

The dressing action of $f_{\alpha,\ell}$ on affine spheres can be viewed as the composition of two conjugate complex Tzitzéica transformations, which produces a real solution in the end. The permutability Theorem 5.3 can be applied to compute this action. Solutions from this construction are often called breather type solutions.

It is not hard to show, by a similar residue calculus as before, that any rational element with six simple poles as above can be constructed from Proposition 5.4. What would be much messier, if not harder, to prove is that the subgroup of all rational elements in $\Lambda^{\tau,\sigma}_{-}\mathrm{GL}(3,\mathbb{C})$ is generated by $g_{\alpha,\ell}$'s, $f_{\alpha,\ell}$'s, and their rank 2 type brothers. This subgroup can then be regarded as the group of Tzitzéica transformations on affine spheres. We will leave this interesting problem for future study.

VI. BASIC EXAMPLES

In this section, we use x,y,z as the standard $\mathbb{R}^3$ coordinates to represent the immersion X, and use u,v to denote the asymptotic coordinates of the affine spheres.

Example 6.1 (*the vacuum solution):* The vacuum solution to Tzitzéica equation (see also Refs. 6 and 15) is $\omega_0\equiv0$ (or $h_0\equiv1$). One can integrate (3.1) to obtain the whole family of frames. The Cartesian equation of the surface is then obtained by the determinant

$$x^3+y^3+z^3-3xyz=1.$$

Note that it is independent of the parameter λ. So this family is really a family of parametrizations of the same affine sphere.

A general scalar solution of system (2.9) with parameter $\gamma=\lambda^3$ is

$$\phi(\lambda)=c_0R(\lambda)+c_1R(\epsilon^2\lambda)+c_2R(\epsilon^4\lambda),\tag{6.1}$$

where $R(\lambda):=\exp(\lambda u+\lambda^{-1}v)$.

Therefore we may choose the following asymptotic parametrizations of the vacuum affine sphere after certain affine transformations:

$$X_0(u,v,\lambda)=\begin{pmatrix}\exp[-(\lambda u+\lambda^{-1}v)/2]\cos[\sqrt{3}(\lambda u-\lambda^{-1}v)/2]\\ \exp[-(\lambda u+\lambda^{-1}v)/2]\sin[\sqrt{3}(\lambda u-\lambda^{-1}v)/2]\\ \frac{2}{3\sqrt{3}}\exp(\lambda u+\lambda^{-1}v)\end{pmatrix},$$

which is a surface of revolution (Note that Jonas has classified all affine spheres of revolution in Ref. 10 using elliptic functions).

Example 6.2 (*the one-soliton solution):* Apply Tzitzéica transformation to the vacuum solution we obtain the one-soliton solution h_1. By (6.1), $\phi_1=\phi(\lambda_1)$ is a scalar solution of system (2.9) with parameter $\gamma_1=\lambda_1^3$. It is real when $c_0\in\mathbb{R}$, $c_1=\overline{c_2}$, and $\lambda_1\in\mathbb{R}_*$. Compute $h_1=1-2\ (\ln\phi_1)_{uv}$:

$$h_1=1-\frac{6\beta_0\exp(3s_1/2)\cos(\sqrt{3}t_1/2+\theta_0)+1.5}{[\beta_0\exp(3s_1/2)+\cos(\sqrt{3}t_1/2+\theta_0)]^2},$$

where $c_1=\rho_0 e^{i\theta_0}$, $\beta_0=c_0/(2\rho_0)$, $s_1=\lambda_1 u+\lambda_1^{-1}v$, and $t_1=\lambda_1 u-\lambda_1^{-1}v$. The family of affine spheres $X_1(u,v,\lambda)$ has a long expression given by (2.10).

When $\beta_0=0$ (i.e., $c_0=0$), we have the special solution

$$h_1=1-1.5\sec^2[\sqrt{3}(\lambda_1 u-\lambda_1^{-1}v)/2+\theta_0]. \tag{6.2}$$

We give explicit formula for this family of affine spheres,

$$\begin{aligned}X_1(u,v,\lambda)=&\frac{(\lambda^3-\lambda_1^3)}{(\lambda^3+\lambda_1^3)}X_0(u,v,\lambda)\\&+\frac{\sqrt{3}\lambda\lambda_1\tan(\sqrt{3}t_1/2+\theta_0)}{(\lambda^3+\lambda_1^3)}.\begin{pmatrix}e^{-s/2}[\lambda\cos(\sqrt{3}t/2+4\pi/3)+\lambda_1\cos(\sqrt{3}t/2+2\pi/3)]\\ e^{-s/2}[\lambda\sin(\sqrt{3}t/2+4\pi/3)+\lambda_1\sin(\sqrt{3}t/2+2\pi/3)]\\ 2e^{s}(\lambda+\lambda_1)/(3\sqrt{3}).\end{pmatrix}\end{aligned} \tag{6.3}$$

Note that ϕ_1 need not be real to produce real h_1. For example, (6.2) will be a real hyperbolic function solution when λ_1 and θ_0 are pure imaginary. In this case the real (or imaginary) part of (6.3) still produces affine spheres, among which are the stationary and traveling one-soliton affine sphere shown in Ref. 16. Some pictures have already been shown in Refs. 15 and 16. In terms of dressing action, λ_1 is the pole of some rank 1 type simple element $g_{\lambda 1,\ell}$. So dressing actions of $g_{\lambda 1,\ell}$ with a pure imaginary pole (or a pole whose argument is $\pm\pi/6$) may also produce new real affine spheres sometime.

ACKNOWLEDGMENTS

Part of this paper was in the author's thesis at Northeastern University and he would like to express the deepest gratitude to his advisor Chuu-Lian Terng, for her help and encouragement. The author would like to thank Franz Pedit for pointing out an error about the associated family of affine spheres, when the author presented a draft of this paper in the 2005 AMS meeting at Lubbock, Texas. Thanks also go to the organizers of this meeting Josef F. Dorfmeister and Hongyou Wu for the invitation and helpful discussions. The research was supported in part by Postdoctoral Fellowship of the Mathematical Sciences Research Institute.

Assimilating the physical space-time with a fractal, a general theory is built. For a fractal dimension $D=2$, the virtual geodesics of this space-time implies a generalized Schrödinger type equation. Subsequently, a geometric formulation of the gravitation theory on a fractal space-time is given. Then, a connection is introduced on a tangent bundle, the connection coefficients, the Riemann curvature tensor and the Einstein field equation are calculated. It results, by means of a dilation operator, the equivalence of this model with quantum Einstein gravity. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2196747]

I. INTRODUCTION

A fractal structure is a manifestation of the universality of self-organization processes, a result of a sequence of spontaneous symmetry breaking. Space-time itself may be a fractal. Some arguments in favor of the universality of a fractal structure of space-time and matter at small and large scales are given in Refs. 1 and 2: "(i) Fractal trajectories in space with Hausdorff dimension two (a Peano-Moore curve) exhibit both an uncertainty principle and a de Broglie relation. Quantum particles move statistically on such a fractal (Feynman) paths. Thus, the Schrödinger equation may be interpreted as a fractal signature of space-time; (ii) The formal analytic continuation ($t \rightarrow it$) which relates the Schrödinger and diffusion equations has a physical alternative: there is a (classical and quantum) stochastic fluid which can be either a fluid of probability for a unique element or a real fluid composed of elements undergoing quasi-Brownian motion. A (composite) particle (corpuscle with internal structure) may be one or a small cluster of stochastic elements. There is a sort of democracy (statistical self-similarity) between the stochastic element constituting the particle. As regards the cause of the randomness, the parton model involves a fragmentation of the partons. The diffusion may be considered as a Brownian (random) motion which is superimposed on the Hamiltonian time development. This leads to a Langevin equation which is equivalent to a Fokker-Planck equation for distribution function $\rho(\xi,t)$ in the phase space, $\partial\rho/\partial t + \{H,\rho\} - (D/2)\Delta^H\rho = 0$, where $-\Delta^H\rho$ is a positive semidefinite second order differential operator which is determined by the Hamiltonian dynamics and a sympletic metric $g^{\alpha\beta} = \langle \Delta\xi^\alpha \Delta\xi^\beta \rangle$ on phase space; (iii) Nature does not 'fractalize' (and quantize); it is intrinsically fractal (and quantum). Wave function of the Universe is a solution of the Weller-DeWitt equation of quantum cosmology and corresponds to the Schrödinger equation. This can be related to the fact that observations of the galaxy-galaxy and cluster-cluster correlations, as well as other large-scale structure can be fit with a fractal with $D_f \approx 1.2$ which may have grown from two-dimensional sheet-like objects such as domain walls or string wakes. The fractal dimension D_f can serve as a constraint on the properties of the stochastic motion responsible for limiting the fractal structure; (iv) The non-

linear (soliton) equation corresponds to a (linear) Schrödinger equation coupled to a medium with specific nonlocal response. Physically, this model is similar to a simple case of linear propagation of thin beams in a wave-guide. Thus, a free photon in (fractal) space represents in fact a "bouncing ball" in a wave-guide. In other words, space-time is structured as a (fractal) web if optical fibers (channels) which represents a skeleton of space-time; (v) The proper wave-function $(\psi_1, \psi_2, \psi_3, \ldots)$ describing the hydrogen-like atom are similar to the electromagnetic models $(\mathrm{TEM}_0, \mathrm{TEM}_1, \mathrm{TEM}_2, \ldots)$ in optical resonating cavities; (vi) It is known that in quasi-crystalline phase there exists atomic clusters with hierarchical and quasi-periodic packing which display a scale-invariance under appropriate inflation/deflation transformation. In the case of a one-dimensional quasi-periodic chain there appears a new type of electronic ('critical') state which manifests a multifractal nature."

In particular, $\epsilon^{(\infty)}$ Cantorian fractal space-time is constructed as an infinite numbers of elementary Cantor sets with all conceivable Hausdorff dimension. This space has three dimensions, the formal dimension $n_f=\infty$, the topological dimension $n_T=4$, and the Hausdorff dimension $\langle d_c \rangle = 4 + \phi^3 = 4.236\,067\,977$.[3] A fractal path in the Cantorian space time has always a fractal Hausdorff dimension of $d_H=2$, and can be considered a two-dimensional projection of a fractal string [in three-dimensional (3D) space] which may represent a cosmic string. Then, the stability of the solitonic objects (strings and vortices) in quantum fields theory implies instantons.[4,5] An instanton may be interpreted as a tunneling transition and it is effectively an unusual transition between the energy levels of Dirac's sea. This remarkable construction was subsequently used by 't Hooft to resolve the $U(I)$ problem of the standard model and to explain the mass of the η meson. However, seen from the $\epsilon^{(\infty)}$ symplictic vacuum point of view, such "event," are completely natural and go on all the time to ensure the symplictic topology of the vacuum (VAK) as the ultimate source of all of the physics particles.[4] It might be possible to interpret supersymmetry (SUSY) and exotic particles in an analogous way.[4,5]

The Cantorian gravity is effectively the quantum gravity of $\epsilon^{(\infty)}$ theory (El Naschie's Cantorian gravity).[4,6] In turn Cantorian-fractal gravity is an effect that is, in essence, analogous to the van der Waals forces and may therefore be understood in terms of what has been termed the Feynman—El Naschie conjecture.[4] In short, the idea is the following[4]: It is well known that the speed at which "time flows" could be slowed down by a gravitational field. If this is true, and it is true according to Einstein's theory, then the converse is also true. This means that by changing the "speed" of the passing of time, one can "create" a gravitational effect. Put in a different way, a fluctuation in time creates a fluctuation in gravity and vice versa. Now the fundamental idea in the El Naschie's theory is that space-time is a random Cantorian fractal, which means that "time" is also a fractal. Since even a regular fractal possesses an "intrinsic fluctuation" which may clearly be seen from a parametric representation of say a Peano curve, the random fractal nature of Cantorian time must be seen as the cause for gravitational fluctuation. Similar to van der Waals forces the expectation or mean value of this fluctuation at the VAK level is a nonzero quantity and is that the origin of "fractal" gravity which we can now link to mass via Einstein's equivalence principle. The preceding discussion could be summarized in one single sentence; the fractalness of space-time is the origin of massiveness. A simple logical consequence of the previous discussion seems to be that "particles" for which times does not pass could not possibly have any rest mass. Thus the photon for which times does not pass as far as our classical theories tell us, must be "massless".

In this article we give a geometric formulation of the gravitation theory in a fractal space-time.

II. A MATHEMATICAL MODEL OF THE FRACTAL SPACE-TIME

Let us suppose that the motion of the various physical objects takes place on continuous, but nowhere differentiable, curves, hence on fractals. In order to save the differential equations of physics, we consider, for a real fractalic function $f(x)$,[5] its approximation obtained from smoothing it or averaging at various resolutions

$$f(x,\epsilon) = \int_{-\infty}^{+\infty} \phi(x,y,\epsilon) f(y) \mathrm{d}y, \tag{1}$$

where $\phi(x,y,\epsilon)$ is a smoothing function centered on x. Now we impose $\lim_{\epsilon\to 0} \phi(x,y,\epsilon) = \delta_{x-y}$ hence

$$\lim_{\epsilon\to 0} f(x,\epsilon) = f(x). \tag{2}$$

$f(x,\epsilon)$ can be everywhere differentiable and $f(x)$ is the so-called *fractal function*.[5] In this treatment we have a new variable (a new dimension), the *resolution* ϵ.

Let us consider an infinitesimal dilatation

$$\epsilon \to \epsilon' = \epsilon(1 + \mathrm{d}\rho) = \epsilon + \epsilon\, \mathrm{d}\rho \tag{3}$$

to the resolution. Omitting the x dependence of a function $\mathcal{L}$ (e.g., the length) we have

$$\mathcal{L}(\epsilon') = \mathcal{L}(\epsilon + \epsilon\, \mathrm{d}\rho) = \mathcal{L}(\epsilon) + \epsilon \frac{\partial \mathcal{L}(\epsilon)}{\partial \epsilon} \mathrm{d}\rho, \tag{4}$$

or

$$\mathcal{L}(\epsilon') = (1 + D\, \mathrm{d}\rho)\mathcal{L}(\epsilon). \tag{5}$$

Here

$$D = \epsilon\, \partial/\partial\epsilon = \partial/\partial \ln \epsilon \tag{6}$$

as

$$\partial/\partial\epsilon = (\partial \ln \epsilon/\partial\epsilon)(\partial/\partial \ln \epsilon) = (1/\epsilon)\, \partial/\partial \ln \epsilon \tag{7}$$

with D the dilation operator.

From the previous equations it is obvious that the intrinsic variable of resolution is not ϵ, but $\ln \epsilon$. This claim has an important consequence. Since both the argument of the logarithm and the exponent of the exponential function must be nondimensional, the same feature must have the variables of the fractal functions (in the aforementioned case x and ϵ). It does not mean that we cannot work with variables like distance, or time, but they are divided as constants of the same physical dimension, having the unitary dimension. For example, the time t measured in seconds is in fact divided by $t_0 = 1$ s.

The nondifferentiable nature of space-time implies some dramatic consequences.

(i) A breaking of differential time reflection invariance. Let us consider indeed the usual definition of the derivative of a given function with respect to time

$$\left(\frac{\mathrm{d}f}{\mathrm{d}t}\right) = \lim_{\mathrm{d}t\to 0} \frac{f(t + \mathrm{d}t) - f(t)}{\mathrm{d}t} = \lim_{\mathrm{d}t\to 0} \frac{f(t) - f(t - \mathrm{d}t)}{\mathrm{d}t}. \tag{8}$$

The two definitions are equivalent in the differentiable case. One passes from one to the other by the transformation $dt \to -dt$ (time reflection invariance at the infinitesimal level). In the nondifferentiable situation considered here, both definitions fail, since the limits are no longer defined. The fractal method solves this problem in the following way: we attribute to the differential element $\mathrm{d}t$ the new meaning of a variable, identified with a time resolution, $\mathrm{d}t = \delta t$. The passage to the limit $dt \to 0$ is actually devoid of physical meaning (an infinite energy would be needed to really perform a measurement at zero time resolution interval). The physics is now in the behavior of the function during the "zoom" operation on $\mathrm{d}t$. The two functions f'_+ and f'_- are now defined as explicit functions of t and of $\mathrm{d}t$:

$$f'_+(t,\mathrm{d}t)=\frac{f(t+\mathrm{d}t,\mathrm{d}t)-f(t,\mathrm{d}t)}{\mathrm{d}t}, \tag{9a}$$

$$f'_-(t,\mathrm{d}t)=\frac{f(t,\mathrm{d}t)-f(t-\mathrm{d}t,\mathrm{d}t)}{\mathrm{d}t}. \tag{9b}$$

(ii) We can write:

$$\mathrm{d}X^i_\pm=\mathrm{d}x^i_\pm+\mathrm{d}\xi^i_\pm \tag{10}$$

for the forward process (+) and backward process (−), respectively. Here $\mathrm{d}x^i_\pm$ are the right and left differentials of the classical variables, and $\mathrm{d}\xi^i_\pm$ describe the fractal behavior. So that

$$\langle dX^i_\pm\rangle=dx^i_\pm, \tag{11a}$$

$$\langle d\xi^i_\pm\rangle=0. \tag{11b}$$

If a point like body along a fractal curve moves, the parameter t of the time could establish the place where the moving object is at a given moment. Since $d\xi^i_\pm$ describes the fractal properties of the considered curve which has the fractal dimension D,[5] it is natural to impose $(d\xi^i_\pm)^D$ to be proportional to $\mathrm{d}t$, i.e.,

$$(\mathrm{d}\xi^i_\pm)^D\sim\mathrm{d}t, \tag{12a}$$

or

$$(\mathrm{d}\xi^i_\pm)^D=\mathcal{D}\,\mathrm{d}t, \tag{12b}$$

where $\mathcal{D}$ is a coefficient of proportionality. From our earlier discussion, the fluctuation $d\xi_\pm$ is written:

$$\langle \mathrm{d}\xi^i_\pm \mathrm{d}\xi^j_\pm\rangle=\pm\,\delta^{ij}(\mathcal{D}\,\mathrm{d}t)^{2/D}. \tag{13}$$

This relation is invariant under translations and rotations in space between Cartesian coordinate systems. If $i\neq j$ relation (13) is zero, due to the independence of $d\xi^i$ on $d\xi^j$.

(iii) We must introduce two velocities (v_+,v_-) instead of one even when going back to the classical domain. Such a two valuedness of the velocity vector is a new, specific consequence of nondifferentiability that has no standard counterpart (in the sense of differential physics), since it finds its origin in a breaking of the symmetry $(\mathrm{d}t\rightarrow-\mathrm{d}t)$. Such a symmetry was considered self-evident up to now in physics (since the differential element $\mathrm{d}t$ disappears when passing to the limit), so that it has not been analyzed on the same footing as the other well-known symmetries. Note that it is actually different from the time reflection symmetry T, even though infinitesimal irreversibility implies global irreversibility. Now, at the level of our description, we have no way to favor v_+ rather than v_-. Both choices are equally qualified for the description of the laws on nature. The only solution to this problem is to consider both the forward $(\mathrm{d}t>0)$ and backward $(\mathrm{d}t<0)$ processes together. The number of degrees of freedom is doubled with respect to the classical, differentiable description (six velocity components instead of three).

We define average forward (+) and backward (−) derivatives, which, once applied to x^i, yield the above-mentioned forward and backward mean velocities

$$\frac{\mathrm{d}_+x^i(t)}{\mathrm{d}t}=v^i_+, \tag{14a}$$

$$\frac{\mathrm{d}_- x^i(t)}{\mathrm{d}t} = v_-^i, \tag{14b}$$

where $v_\pm^i$ are the components of the "forward" velocity, and v_-^i the components of the "backward" velocity. The average of the fractal velocities $\langle \mathrm{d}\xi_\pm^i/\mathrm{d}t\rangle$ is zero. Yet, if $(v_+^i+v_-^i)/2$ may be considered as classical velocity, the difference between them, more precisely $(v_+^i-v_-^i)/2$ is due to the fractal movement. In order to emphasize the latter from the former, we introduce a complex velocity

$$\mathcal{V}^i = \frac{v_+^i + v_-^I}{2} - i\frac{v_+^i - v_-^i}{2} = \frac{dx_+^i + dx_-^i}{2dt} - i\frac{dx_+^i - dx_-^i}{2dt}. \tag{15}$$

Such procedures are quite often in the theoretical physics (see, e.g., the dumping factor of the oscillations).

Let us make now a change in our parameters. Instead of $\mathrm{d}x_\pm$, we put $\mathrm{d}_\pm x$. Then (15) becomes

$$\mathcal{V}^i = \left(\frac{\mathrm{d}_+ + \mathrm{d}_-}{2\mathrm{d}t} - i\frac{\mathrm{d}_+ - \mathrm{d}_-}{2\mathrm{d}t}\right)x^i, \tag{16}$$

which justifies the definition of the operator

$$d = \frac{\mathrm{d}_+ + \mathrm{d}_-}{\mathrm{d}t} - i\frac{\mathrm{d}_+ - \mathrm{d}_-}{2\mathrm{d}t}. \tag{17}$$

(iv) Let us assume now that the fractal curve[5] is immersed in a 3D space, and $\boldsymbol{X}$ of components $X^i(i=\overline{1,3})$ is the position vector of a point on the curve. Let us consider now a function $f(\boldsymbol{X},t)$ and the following Taylor series expansion up to the second order. This second order term we consider rest term; without entering into deep mathematics, we have

$$\mathrm{d}f = f(X^i + \mathrm{d}X^i, t + \mathrm{d}t) - f(X^i, \mathrm{d}t)$$

$$= \nabla f \cdot d\boldsymbol{X} + \frac{\partial f}{\partial t}\mathrm{d}t + \frac{1}{2}\frac{\partial^2 f}{\partial X^i\,\partial X^j}\mathrm{d}X^i\mathrm{d}X^j + \frac{\partial^2 f}{\partial X^i\,\partial t}\mathrm{d}X^i dt + \frac{1}{2}\frac{\partial^2 f}{\partial t^2}(\mathrm{d}t)^2. \tag{18}$$

The right and left average values of this equation reads

$$\langle \mathrm{d}_\pm f\rangle = \langle \nabla f \cdot \mathrm{d}_\pm \boldsymbol{X}\rangle + \left\langle \frac{\partial f}{\partial t}\mathrm{d}t \right\rangle + \frac{1}{2}\left\langle \frac{\partial^2 f}{\partial X^i\,\partial X^j}\mathrm{d}X_\pm^i \mathrm{d}X_\pm^j \right\rangle + \left\langle \frac{\partial^2 f}{\partial X^i\,\partial t}\mathrm{d}X_\pm^i \mathrm{d}t \right\rangle + \frac{1}{2}\left\langle \frac{\partial^2 f}{\partial t^2}(\mathrm{d}t^2) \right\rangle. \tag{19}$$

We make now the following stipulations: the mean values of the function f and its derivatives coincide with themselves, and the differentials $\mathrm{d}X_\pm^i$ and $\mathrm{d}t$ are independent, therefore the averages of their products coincide with the product of averages. Thus (19) becomes

$$\mathrm{d}_\pm f = \frac{\partial f}{\partial t}\mathrm{d}t + \nabla f \cdot \langle \mathrm{d}_\pm \boldsymbol{X}\rangle + \frac{1}{2}\frac{\partial^2 f}{\partial X^i\,\partial X^j}\langle \mathrm{d}X_\pm^i \mathrm{d}X_\pm^j\rangle + \frac{\partial^2 f}{\partial X^i\,\partial t}\langle \mathrm{d}X_\pm^i\rangle\langle \mathrm{d}t\rangle + \frac{1}{2}\frac{\partial^2 f}{\partial t^2}\langle (\mathrm{d}t)^2\rangle. \tag{20}$$

In what follows we use (11a). Consequently it results

$$\mathrm{d}_\pm f = \frac{\partial f}{\partial t}\mathrm{d}t + \nabla f \cdot \mathrm{d}x_\pm + \frac{1}{2}\frac{\partial^2 f}{\partial X^i\,\partial X^j}\left\{\mathrm{d}x_\pm^i \mathrm{d}x_\pm^j + \langle \mathrm{d}\xi_\pm^i \mathrm{d}\xi_\pm^j\rangle\right\} + \frac{\partial^2 f}{\partial X^i\,\partial t}\mathrm{d}x^i\mathrm{d}t + \frac{1}{2}\frac{\partial^2 f}{\partial t^2}(\mathrm{d}t)^2, \tag{21}$$

where we took into account the fact that $\langle d\xi^i\rangle = 0$ [see (11b)].

Now we make a choice and a specification. The choice concerns the dimension $D=2$ of the fractal curve, i.e., of the Peano type curves. Now (13) becomes

$$\langle \mathrm{d}\xi_{\pm}^{i}\mathrm{d}_{\pm}^{j}\rangle = \pm \delta^{ij}\mathcal{D}\,\mathrm{d}t. \tag{22}$$

The specification relates to the sign: since $\langle \mathrm{d}\xi_{\pm}^{i}\mathrm{d}\xi_{\pm}^{j}\rangle \geqslant 0$, and $\mathrm{d}t$ is negative for the vectors taken to the left, we have put $\pm$ in front of $\mathrm{d}t$ for the two cases.

Now (21) becomes

$$\mathrm{d}_{\pm}f = \frac{\partial f}{\partial t}\mathrm{d}t + \nabla f\cdot \mathrm{d}x_{\pm} + \frac{1}{2}\frac{\partial^2 f}{2\,\partial X^i\,\partial X^j}\mathrm{d}x_{\pm}^{i}\mathrm{d}x_{\pm}^{j} \pm \frac{\partial^2 f}{\partial X^i\,\partial X^j}\delta^{ij}\mathcal{D}\,\mathrm{d}t + \frac{\partial^2 f}{\partial X^i\,\partial t}\mathrm{d}x^i\mathrm{d}t + \frac{1}{2}\frac{\partial^2 f}{\partial t^2}\langle(\mathrm{d}t)^2\rangle. \tag{23}$$

If we now divide by $\mathrm{d}t$ and neglect the terms which still contain differential factors, (23) is reduced to

$$\frac{\mathrm{d}_{\pm}f}{\mathrm{d}t} = \frac{\partial f}{\partial t} + \nabla f\cdot\frac{\mathrm{d}\boldsymbol{X}}{\mathrm{d}t} \pm \frac{\mathcal{D}}{2}\Delta f. \tag{24}$$

The last term is specific to fractality. Let us calculate, under these circumstances $df/\mathrm{d}t$. Taking into account (24), we have

$$\frac{df}{\mathrm{d}t} = \frac{1}{2}\left\{\frac{\mathrm{d}_{+}f}{\mathrm{d}t} + \frac{\mathrm{d}_{-}f}{\mathrm{d}t} - i\left[\frac{\mathrm{d}_{+}f}{\mathrm{d}t} - \frac{\mathrm{d}_{-}f}{\mathrm{d}t}\right]\right\}$$

$$= \frac{1}{2}\left\{\left(\frac{\partial f}{\partial t} + \nabla f\cdot\boldsymbol{v}_{+} + \frac{\mathcal{D}}{2}\Delta f\right) + \left(\frac{\partial f}{\partial t} + \nabla f\cdot + \boldsymbol{v}_{-} - \frac{\mathcal{D}}{2}\Delta f\right)\right.$$

$$\left. - i\left[\left(\frac{\partial f}{\partial t} + \nabla f\cdot\boldsymbol{v}_{+} + \frac{\mathcal{D}}{2}\Delta f\right) - \left(\frac{\partial f}{\partial t} + \nabla f\cdot\boldsymbol{v}_{-} - \frac{\mathcal{D}}{2}\Delta f\right)\right]\right\}$$

$$= \frac{\partial f}{\partial t} + \nabla f\cdot\frac{\boldsymbol{v}_{+}+\boldsymbol{v}_{-}}{2} - i\left(\nabla f\cdot\frac{\boldsymbol{v}_{+}-\boldsymbol{v}_{-}}{2} + \frac{\mathcal{D}}{2}\Delta f\right),$$

or using (15)

$$\frac{df}{dt} = \frac{\partial f}{\partial t} + \boldsymbol{\mathcal{V}}\cdot\nabla f - i\mathcal{D}\Delta f. \tag{25}$$

This relation allows us to also give the definition of the fractal operator

$$\frac{d}{\mathrm{d}t} = \frac{\partial}{\partial t} + \boldsymbol{\mathcal{V}}\cdot\nabla - i\mathcal{D}\Delta. \tag{26}$$

We now apply the principle of scale covariance, and postulate that the passage from classical (differentiable) mechanics to the new nondifferentiable mechanics that is considered here can be implemented by replacing the standard time derivative $\mathrm{d}/\mathrm{d}t$ by the new complex operator $d/\mathrm{d}t$. As a consequence, we are now able to write the equation of geodesics of the fractal space under its covariant form $d\boldsymbol{\mathcal{V}}/dt=0$. Equivalent results was given in Refs. 4–6.

III. A GENERALIZED SCHRÖDINGER EQUATION

Now, let us consider the covariant derivative (26) and the following $\boldsymbol{\mathcal{V}}$ complex velocity concretization

$$\boldsymbol{\mathcal{V}} = -2i\mathcal{D}\,\nabla\,\ln\psi. \tag{27}$$

Applying the $d/\mathrm{d}t$ covariant derivative to the $\boldsymbol{\mathcal{V}}$ complex velocity, we obtain

$$(d/\mathrm{d}t)\boldsymbol{\mathcal{V}} = \partial_t \boldsymbol{\mathcal{V}} + \nabla\left[(\boldsymbol{\mathcal{V}}^2/2) - i\mathcal{D}\,\nabla\cdot\boldsymbol{\mathcal{V}}\right]$$

$$= -2i\mathcal{D}\left[\partial_t(\nabla \ln \psi) - 2i\mathcal{D}(\nabla \ln \psi\cdot\nabla)(\nabla \ln \psi) - i\mathcal{D}\Delta(\nabla \ln \psi)\right] \tag{28}$$

or still, considering the identity

$$\nabla(\Delta\psi/\psi) = \Delta(\nabla \ln \psi) + 2(\nabla \ln \psi\cdot\nabla)(\nabla \ln \psi),$$

we have

$$(d/\mathrm{d}t)\boldsymbol{\mathcal{V}} = -2\mathcal{D}\,\nabla\,[i(\partial_t, \psi/\psi) + \mathcal{D}(\Delta\psi/\psi)]. \tag{29}$$

Now, Newton's second principle takes the form

$$m(d/\mathrm{d}t)\boldsymbol{\mathcal{V}} = -\nabla U \tag{30}$$

or explicitly

$$\nabla U = \nabla\left[2im\mathcal{D}(\partial_t\psi/\psi) + 2m\mathcal{D}^2(\Delta\psi/\psi)\right] \tag{31}$$

with U the potential. Integrating this equation yields

$$\mathcal{D}^2\Delta\psi + i\mathcal{D}\partial_t\psi = \frac{U}{2m}\psi \tag{32}$$

up to an arbitrary phase factor $\alpha(t)$ which may be set to zero by a suitable choice of the phase of ψ. If there is no external field, $U=0$, the covariance is explicit, since Newton's equation of inertial motion is $(d/\mathrm{d}t)\boldsymbol{\mathcal{V}}=0$. The statistical meaning of the wave function (Born postulate) can now be deduced from the very construction of the theory.[4] Even in the case of only one particle, the virtual geodesic family is infinite (this remains true even in the zero particle case, i.e., for the vacuum field). The particle properties are assimilated to those of a random subset of the geodesics in the family, and its probability to be found at a given position must be proportional to the density of the geodesic fluid. This density can easily be calculated in our formalism, since the imaginary part of Eq. (32) writes in terms of $\rho=\psi\psi^*, \partial_t\rho+\nabla\cdot[\rho(\boldsymbol{\mathcal{V}}+\boldsymbol{\mathcal{V}}^*)/2=0]$, where $(\boldsymbol{\mathcal{V}}+\boldsymbol{\mathcal{V}}^*)/2$ is the real part of the complex velocity, which is identified, at the classical limit, with the classical velocity.

IV. A COVARIANT MECHANICAL MODEL

We assume that any mechanical system can be characterized by a Lagrange function $L(x, \boldsymbol{\mathcal{V}}, t)$ from which an action S is defined

$$S = \int_1^2 L(x, \mathcal{V}, t)\mathrm{d}t. \tag{33}$$

In a general way, the Lagrange function is expected to be a function of the variables x and their derivatives $\dot{x}=v$. We have found that the number of velocity components v is doubled, so that we led to write $L=L(x, v_+, v_-, t)$. Instead, we have made the choice to write the Lagrange function as $L=L(x, \mathcal{V}, t)$. We now justify this choice by the covariance principle. Re-expressed in terms of v_+ and v_- the Lagrange function writes

$$L = L\left(x, \frac{1-i}{2}v_+ + \frac{1+i}{2}v_-, t\right). \tag{34}$$

Therefore we obtain

$$\frac{\partial L}{\partial v_+} = \frac{1-i}{2}\frac{\partial L}{\partial \mathcal{V}}, \tag{35a}$$

$$\frac{\partial L}{\partial v_-} = \frac{1+i}{2}\frac{\partial L}{\partial \boldsymbol{\mathcal{V}}}, \tag{35b}$$

whereas the new covariant time derivative operator writes

$$d/\mathrm{d}t = \frac{1-i}{2}\frac{\mathrm{d}_+}{\mathrm{d}t} + \frac{1+i}{2}\frac{\mathrm{d}_-}{\mathrm{d}t}. \tag{36}$$

Let us write the stationary action principle in terms of the Lagrange function $\delta S = \delta\int_1^2 L(x, \boldsymbol{\mathcal{V}}, t)\mathrm{d}t = 0$. It becomes

$$\int_1^2 \left(\frac{\partial L}{\partial x}\delta x + \frac{\partial L}{\partial v_+}\delta v_+ + \frac{\partial L}{\partial v_-}\delta v_-\right)\mathrm{d}t = 0. \tag{37}$$

As $\delta v_+ = \mathrm{d}_+(\delta x)/\mathrm{d}t$ and $\delta v_- = \mathrm{d}_-(\delta x)/\mathrm{d}t$ it takes the form

$$\int_1^2 \left(\frac{\partial L}{\partial x}\delta x + \frac{\partial L}{\partial \mathcal{V}}\left[\frac{1-i}{2}\frac{\mathrm{d}_+}{\mathrm{d}t} + \frac{1+i}{2}\frac{\mathrm{d}_-}{\mathrm{d}t}\right]\delta x\right)\mathrm{d}t = 0, \tag{38}$$

i.e.,

$$\int_1^2 \left(\frac{\partial L}{\partial x}\delta x + \frac{\partial L}{\partial \mathcal{V}}\frac{d}{\mathrm{d}t}\delta x\right)\mathrm{d}t = 0 \tag{39}$$

The subsequent demonstration of the Lagrange equations relies on an integration by parts. Now such an operation involves the Leibniz rule for the covariant derivative operator $d/\mathrm{d}t$. As $d/\mathrm{d}t = \partial/\partial t + \boldsymbol{\mathcal{V}}\cdot\nabla - iD\Delta$ is a linear combination of first and second order derivatives, the same is true of its Leibniz rule. This implies the appearance of an additional term in the expression for the derivative of a product:

$$\frac{d}{\mathrm{d}t}\left[\frac{\partial L}{\partial \mathcal{V}}\cdot\delta x\right] = \frac{d}{\mathrm{d}t}\frac{\partial L}{\partial \boldsymbol{\mathcal{V}}}\cdot\delta x + \frac{\partial L}{\partial \boldsymbol{\mathcal{V}}}\frac{d}{\mathrm{d}t}\delta x - 2iD\,\nabla\frac{\partial L}{\partial \boldsymbol{\mathcal{V}}}\cdot\nabla\delta x. \tag{40}$$

As $\delta x(t)$ is not a function of x, the additional term vanishes. After having defined a new integration as the inverse of the covariant derivation, i.e. $\int df = f$, the integral reduces to

$$\int_1^2 \left(\frac{\partial L}{\partial x} - \frac{d}{\mathrm{d}t}\frac{\partial L}{\partial \boldsymbol{\mathcal{V}}}\right)\delta x\,\mathrm{d}t = 0. \tag{41}$$

Finally the Euler-Lagrange equations write

$$\frac{d}{\mathrm{d}t}\frac{\partial L}{\partial \boldsymbol{\mathcal{V}}} = \frac{\partial}{\partial x}. \tag{42}$$

Therefore, thanks to the transformation $\mathrm{d}/\mathrm{d}t \to d/\mathrm{d}t$, they take exactly their standard classical form. This results reinforced the identification of our tool with a "quantum-covariant" representation, since, as we have shown in previous paragraph and as we recall in what follows, this Euler-Lagrange equation can be integrated in the form of a Schrödinger equation.

Assuming homogeneity of space in the mean lead to define a generalized complex momentum given by $P = \partial L/\partial \boldsymbol{\mathcal{V}}$. If we consider the action as a functional of the upper limit of integration in Eq. (41), the variation of the action from a trajectory to another nearby trajectory yields a generalization of another well-known relation of standard mechanics $P = \nabla S$.

V. THE GEOMETRY OF THE FRAME

Physics, both experimental and theoretical, is in fact based on the referential concept. The position, or more general, the motion of a body cannot be described but relative to certain referential. From the experimental point of view, the referential is given by a system of bodies or, with a certain degree of abstraction, by points "relatively fixed" one from each other, system which is the core of the measurements of distance and direction. The intervention of speculative thinking subsequently led to the detaching of the notion of coordinates of a point in a given referential: spatially speaking, the point is localized by three real numbers—its coordinates—if it is moving, also by means of the time when it is localized, i.e., by the moment of time read by a clock attached to the referential.

Theoretically speaking the events or phenomena may be described by coordinates which ease up most of the computations. Usually, the system of coordinates are chosen as to satisfy a certain type of symmetry, or as to the results of the computations to be able to be reported in terms directly testable by experiments.

In principle, the computations may be performed in any coordinate system, the result being equivalent: the geometry found here has an entire arsenal of formula of transformation from one system of coordinates to another. This reciprocal transformability led subsequently to the detachment of the notion of referential from the pure experimental one mentioned above. A referential frequently used in geometry is the referential of the vectors tangent to the lines of coordinates (the so-called natural referential.[7]) Due to the fact that the crossings between several such referentials are easy to be expressed through derivatives of some unknown functions, the referential transformations are called "olonomous." Related to such referentials, pure mathematical, the physical one defined previously, is marked by a high degree of arbitrariness: not always its abstract defining elements—the basis vectors—may define lines of coordinates relatively to where they must be tangent. As a result, it is said that the basis of such referentials is nonolonomous.[8,9] However, clearly, these referentials are those used in the experimental physics, the olonomous being in general, only abstractions necessary to the calculus, as we will try to show in what follows.

Physically speaking, for a system of coordinates to correspond to reality: it is necessary to be measurable or interpretable in terms of measurable parameters. Although, in the quasitotality of the cases the coordinates are not measurable. For example, in astronomy, the position of a star may be reported in spherical or Cartesian coordinates: azimuth, height, and distance from the star. In both cases we deal with parameters with unknown significance, or effectively measured value. For example, the Cartesian coordinates are not measurable even if we consider the space absolutely Euclidian. The manner of work in astronomy consists of a second set of coordinates, for which the radial distance, deduced from physical considerations, is affected by a large arbitrariness, quantitatively speaking. Then even qualitatively, if the space is non-Euclidian, it has not the significance which was given. In this last case, even the angles do not give the real direction anymore, but a local, apparent one. Nevertheless, they keep a certain significance—as we tried to mention to emphasize in—which is not related to translations, but only to rotations of the moving referential or of some portions of it (which to play, eventually, the part of "theodolite"). Let us not forget this fact, since we will use it in what follows.

This, because, among all the other notions used in physics, the notion of direction is endowed apparently with a certain transcendence. For example, in quantum mechanics, the experimental device must obey with enough accuracy, to the classical laws. This refers to the fact that the difference between the classical laws [applicable to the measurement gauges and the quantum laws (applicable to the microobjects)], is extended in what concerns the measuring scale of masses, lengths and times and, in general, over any parameters which imply displacements, not over the directions, which implies only rotations. This has here two aspects: the first one concerns the intuitive fact that a direction, no matter how it has been established, may serve as referential both for microscopic, and for macroscopic ones, and the second one, concerns the fact that the imprecision relations which complies angular variables and associated operators, need a plus of precautions in definition,[10] which might indicate a certain "classicism" of the respective variables.

The indiscernability of the coordinate systems, as well as the fact that in measurements one

uses the nonolonomous physical referentials indicate, clearly, the necessity of reporting the calculus to these last ones. Hence, only these are used, e.g., in the operational definition of the space-time metric element or, as it is underlined in Refs. 11–13, even the models of universe defined by ingenious operational methods, as is the kinematic model of Milne, may be reformulated with the help of the notion of metrics. For the metric theories there is a strong basis: the general relativity theory of Einstein. In our opinion, what lacks in order to overcome the state of fact in physics (or in cosmology, with a higher restraint) is the physical interpretation, i.e., a physical referential, of the coordinates which enter in metrics. In other words, if usually a coordinates system may determine a referential (of the tangent vectors), the problem which arises is exactly inverse: given a referential, one has to detect a coordinate system compatible with it. The theory of the complex potential[9,14,15] allows us to reach to some extent the solving of this problem, as from here, it is clear that the only olonomous coordinates cannot be but the three-dimensional ambient metrics, which could be a working hypothesis.

Therefore, these coordinates have a relation with what is measuring (which is e.g., a potential), only through a certain function solution of a partial derivative equation. This supposes yet an extension of the operational processes beyond the ones used habitually: the distance measurement, even by light signals, and the watch synchronization by the same signals. These being intrinsically linked to each other, since synchronization is marked by a high degree of arbitrariness, the same will happen with the definition of the distance.

A first way of defining a measurement process related to the physical referential, as it was accepted previously, resides in a speculation which has at its basis the quantum measurability, i.e., by means of hermitic operators, whose eigenvalues represent values measured of the parameters which has operators attached. In order to explain such a point of view, we must first accept that on a physical referential one can establish directions independent of the phenomenological frame where we are fixed (micro- or macro-cosmos). Specifically we admit that, artificially (with rational intervention) or intrinsically, a physical referential is endowed with "theodolitic apparatus," which may be oriented anyhow independently on the referential and, mostly, of the way this is taken into consideration (e.g., indifferently of the orientation of the three Cartesian axis attached to it). Obviously, such a theodolitic apparatus "points to" something. Rising to some degree of abstraction, in its interior some interactions happen, due to the fields captured from the pointing direction, interactions through which one measures some parameters related to this field. Pointing to various directions, the apparatus "measures" in the same way: what it measures (what it evidences) does not depend in its nature on the direction it is pointing to, or on the parameters associated to this direction in the considered physical referential. In one word, the internal process through which the measurement is achieved is independently on the direction. Under these circumstances, a theodolit must be characterized by a hermitic operator which may depend on the direction, but which—in any case—has eigenvalues, independent on it. One may build such operators using the S^3 sphere.

The S^3 sphere can be parameterized in terms of either Cartesian coordinates $x^m (m=1,2,3,4)$, complex variables (u,v), or ρ and angles (θ,α,β). If the radius of S^3 is equal to ρ, then

$$(x^1)^2 + (x^2)^2 + (x^3)^2 + (x^4)^2 = \rho^2. \tag{43}$$

We will set ρ equal to unity $(\rho=1)$ wherever possible. The inverse radius ρ^{-1} can be considered as a mass scale in this space.[16] The connection between different variables is of the form

$$u = x^1 + ix^2 = \rho \cos\theta e^{i\alpha}, \tag{44a}$$

$$\mathcal{V} = x^3 + ix^4 = \rho \sin\theta e^{i\beta}, \tag{44b}$$

with the angular volume element

$$d\Omega = \frac{1}{2\pi^2} \sin\theta \cos\theta \, d\theta \, d\alpha \, d\beta. \tag{45}$$

The manifold S^3 has an $O(4)$ symmetry, whose algebra is $SU(2) \times SU(2)$. S^3 is itself the manifold of the group SU(2), and the two subgroups correspond to left and right multiplications acting on the manifold. As a consequence, there are two independent frames $e_i^{(1)}$ and $e_i^{(2)}$ ($i = 1,2,3$) possible on S^3, each of which is smooth everywhere and can be used to define the spatial derivatives. The particular choice of one or another of these frames has no physical consequences.

Throughout this article we choose the frame $e_i^{(1)}$, and the corresponding derivatives will be denoted by ∂_i ($i=1,2,3$):

$$\partial_1 = \frac{i}{\rho}\left(u\frac{\partial}{\partial \nu^*} - \nu\frac{\partial}{\partial u^*} + \nu^*\frac{\partial}{\partial u} - u^*\frac{\partial}{\partial \nu}\right)$$

$$= \frac{1}{\rho}\left[-\sin(\alpha+\beta)\frac{\partial}{\partial\theta} + \cos(\alpha+\beta)\left(\tan\theta\frac{\partial}{\partial\alpha} - \cot\theta\frac{\partial}{\partial\beta}\right)\right], \tag{46a}$$

$$\partial_2 = \frac{1}{\rho}\left(u\frac{\partial}{\partial \nu^*} - \nu\frac{\partial}{\partial u^*} - \nu^*\frac{\partial}{\partial u} + u^*\frac{\partial}{\partial \nu}\right)$$

$$= \frac{1}{\rho}\left[\cos(\alpha+\beta)\frac{\partial}{\partial\theta} + \sin(\alpha+\beta)\left(\tan\theta\frac{\partial}{\partial\alpha} - \cot\theta\frac{\partial}{\partial\beta}\right)\right], \tag{46b}$$

$$\partial_3 = \frac{i}{\rho}\left(u^*\frac{\partial}{\partial u^*} - u\frac{\partial}{\partial u} + \nu^*\frac{\partial}{\partial u^*} - \nu\frac{\partial}{\partial \nu}\right) = -\frac{1}{\rho}\left(\frac{\partial}{\partial\alpha} - \frac{\partial}{\partial\beta}\right). \tag{46c}$$

Note that these derivatives do not commute

$$[\partial_i, \partial_j] = \frac{2}{\rho}\varepsilon_{ijk}\partial_k, \tag{47}$$

where ε_{ijk} is the antisymmetric tensor of rank 3 with $\varepsilon_{123}=1$. If we consider the derivatives

$$\partial_\mu = \left(\partial_i, \partial_4 = \left(\frac{\partial}{\partial\xi_\pm}\right)^D = \frac{1}{\mathcal{D}}\frac{\partial}{\partial t}\right),$$

then we have

$$[\partial_\mu, \partial_\nu] = C^\gamma_{\mu\nu}\partial_\gamma = -\frac{2}{\rho}\varepsilon^\gamma_{\mu\nu 4}\partial_\gamma, \tag{48a}$$

$$\varepsilon_{1234} = -1, \tag{48b}$$

$$\mu = 1,2,3,4. \tag{48c}$$

The quantities $C^\gamma_{\mu\nu}$ are the structure constants for the Lie algebra of the group $SU(2) \times T$, were T is the group of fractal time translations. In the works of Carmeli and Marlin[17–22] one uses the angular momentum components $L_i (i=1,2,3)$ as derivatives in S^3. They satisfy the commutation relations

$$[L_i, L_j] = -\varepsilon_{ijk}L_k \tag{49}$$

which are equivalent up to a factor with (47). In this case we have $C^\gamma_{\mu\nu} = (2/\rho)\varepsilon^\gamma_{\mu\nu 4}$

VI. THE LINEAR CONNECTION ON THE FRACTAL SPACE-TIME

Let $\bar{T}$ be the tangent bundle over the fractal space-time and ∇ a linear connection on this manifold. It is known that ∇ is a derivative on the bundle $\bar{T}$. We define then a Riemannian structure on the fractal space-time by introducing a metric form on $\bar{T}$ (Ref. 23)

$$g:(X,Y) \to g(X,Y), \tag{50}$$

which is symmetric, nondegenerate, and positive. Here X and Y are vector fields over the fractal space-time.

If we use the derivatives $\partial_\mu, \mu=0,1,2,3$, then the vector fields X,Y can be written under the form[23]

$$X = X^\mu \partial_\mu, \quad Y = Y^\mu \partial_\mu. \tag{51}$$

In this case the metric form g becomes

$$g(X,Y) = g(X^\mu \partial_\mu, Y^\nu \partial_\nu) = X^\mu Y^\nu g(\partial_\mu, \partial_\nu). \tag{52}$$

If we introduce the metric coefficients

$$g_{\mu\nu} = g(\partial_\mu, \partial_\nu) \tag{53}$$

then relation (52) can be written as

$$g(X,Y) = g_{\mu\nu} X^\mu Y^\nu. \tag{54}$$

Because g is symmetric, the metric coefficient has the property

$$g_{\mu\nu} = g_{\nu\mu}. \tag{55}$$

To describe the gravitational field, we suppose that the connection ∇ is Riemannian, i.e., the covariant derivative of g is null:

$$(\nabla_x g)(Y,Z) = 0. \tag{56}$$

This condition combined with the property of null torsion for Riemannian manifold yields:

$$2g(\nabla_x Y,Z) = X(g(Y,Z)) - Y(g(Z,X)) - Z(g(X,Y)) + g([X,Y],Z) + g([Z,X],Y) - g([Y,Z],X). \tag{57}$$

In a local chart we choose the vector fields X,Y, and Z to be ∂_μ, ∂_ν, and ∂_γ, respectively. Then, using, (48a)–(48c) Eq. (57) becomes

$$2g(\nabla_{\partial_\mu} \partial_\nu, \partial_\gamma) = \partial_\mu g_{\nu\gamma} + \partial_\nu g_{\gamma\mu} - \partial_\gamma g_{\mu\nu} + g([\partial_\mu, \partial_\nu], \partial_\gamma) + g([\partial_\gamma, \partial_\mu]\partial_\nu) - g([\partial_\nu, \partial_\gamma]\partial_\mu). \tag{58}$$

We introduce now the connection coefficient $\Gamma^\omega_{\mu\nu}$ by the definition

$$\nabla_{\partial_\mu} \partial_\nu = \Gamma^\omega_{\mu\nu} \partial_\omega. \tag{59}$$

Then, using (48a)–(48c) and (53), we can write (58) in the form

$$2\Gamma^\omega_{\mu\nu} g_{\omega\gamma} = \partial_\mu g_{\nu\gamma} + \partial_\nu g_{\gamma\mu} - \partial_\gamma g_{\mu\nu} + C^\rho_{\mu\nu} g_{\rho\gamma} + C^\rho_{\gamma\nu} g_{\rho\nu} - C^\rho_{\nu\gamma} g_{\rho\mu}. \tag{60}$$

Finally, if we observe that $g_{\omega\gamma}g^{\gamma\lambda}=\partial^{\omega}_{\lambda}$, then from Eq. (60) we obtain

$$\Gamma^{\lambda}_{\mu\nu}=\tfrac{1}{2}g^{\gamma\lambda}(\partial_{\mu}g_{\nu\gamma}+\partial_{\nu}g_{\gamma\mu}-\partial_{\gamma}g_{\mu\nu})+\tfrac{1}{2}g^{\gamma\,\lambda}(C^{\rho}_{\mu\nu}g_{\rho\gamma}+C^{\rho}_{\gamma\nu}g_{\rho\nu}-C^{\rho}_{\nu\gamma}g_{\rho\mu}). \tag{61}$$

This result differs from the result of Carmeli and Malin[22] by the last three terms on the right-hand side. These terms, containing the structure constants $C^{\gamma}_{\mu\nu}$ are determined by the noncommutativity of the derivatives ∂_{μ}.

It is easy to verify that

$$\Gamma^{\lambda}_{\mu\nu}-\Gamma^{\lambda}_{\nu\mu}-C^{\lambda}_{\mu\nu}=0. \tag{62}$$

This result shows that the torsion of the Riemannian connection ∇ introduced in fractal space-time is null. Indeed, from the definition of torsion[23] we have

$$T(\partial_{\mu},\partial_{\nu})=\nabla_{\partial_{\mu}}\partial_{\nu}-\nabla_{\partial_{\nu}}\partial_{\mu}-\lfloor\partial_{\mu},\partial_{\nu}\rfloor$$

$$=(\Gamma^{\lambda}_{\mu\nu}-\Gamma^{\lambda}_{\nu\mu}-C^{\lambda}_{\mu\nu})\partial_{\lambda} \tag{63}$$

and, by using the definition of the torsion tensor components

$$T^{\lambda}_{\mu\nu}\partial_{\lambda}=T(\partial_{\mu},\partial_{\nu})$$

we obtain

$$T^{\lambda}_{\mu\nu}=\Gamma^{\lambda}_{\mu\nu}-\Gamma^{\lambda}_{\nu\mu}-C^{\lambda}_{\mu\nu}=0. \tag{64}$$

Now, we can write the covariant derivative of a covariant vector by using the property

$$\nabla_{X}(fY)=f\nabla_{X}Y+(Xf)Y, \tag{65}$$

where f is a differentiable function defined on the fractal space-time. If we choose X as ∂_{μ} and put $Y=\partial_{\nu}$ and $f=V^{\nu}$, then

$$\nabla_{\partial_{\mu}}(V^{\nu}\partial_{\nu})=V^{\nu}\nabla_{\partial_{\mu}}\partial_{\nu}+(\partial_{\mu}V^{\nu})\partial_{\nu}=(\partial_{\mu}V^{\nu}+\Gamma^{\nu}_{\mu\rho}V^{\rho})\partial_{\nu}$$

or

$$\nabla_{\mu}V^{\nu}=\partial_{\mu}V^{\nu}+\Gamma^{\nu}_{\mu\rho}V^{\rho}. \tag{66}$$

This result coincides with that given in Ref. 22 for the covariant derivative.

We calculated now the Riemann curvature tensor $R^{\sigma}_{\rho\mu\nu}$ by using the definition of the curvature two-form $R(X,Y)$.[23] If we choose X,Y, and Z as $\partial_{\mu},\partial_{\nu}$, and ∂_{γ}, respectively, then

$$R(\partial_{\mu},\partial_{\nu})\partial_{\gamma}=\nabla_{\partial_{\mu}}\nabla_{\partial_{\nu}}\partial_{\gamma}-\nabla_{\partial_{\nu}}\nabla_{\partial_{\mu}}\partial_{\gamma}-\nabla_{[\partial_{\mu},\partial_{\nu}]}\partial_{\gamma}. \tag{67}$$

Using (48a)–(48c) and (59), we write expression (67) as

$$R(\partial_{\mu},\partial_{\nu})\partial_{\gamma}=\nabla_{\partial_{\mu}}(\Gamma^{\sigma}_{\nu\gamma}\partial_{\sigma})-\nabla_{\partial_{\nu}}(\Gamma^{\sigma}_{\mu\gamma}\partial_{\sigma})-C^{\sigma}_{\mu\nu}\nabla_{\partial_{\sigma}}\partial_{\gamma}. \tag{68}$$

If we define now the Riemann curvature tensor $R^{\sigma}_{\rho\mu\nu}$ by

$$R(\partial_{\mu},\partial_{\nu})\partial_{\gamma}=R^{\sigma}_{\gamma\mu\nu}\partial_{\sigma} \tag{69}$$

then from Eq. (68) we obtain

$$R^{\sigma}_{\gamma\mu\nu}=\partial_{\mu}\Gamma^{\sigma}_{\nu\gamma}-\partial_{\nu}\Gamma^{\sigma}_{\mu\gamma}+\Gamma^{\sigma}_{\mu\rho}\Gamma^{\rho}_{\nu\gamma}-\Gamma^{\sigma}_{\nu\rho}\Gamma^{\sigma}_{\mu\gamma}-C^{\sigma}_{\mu\nu}\Gamma^{\sigma}_{\rho\gamma}. \tag{70}$$

This result differs also from that of Ref. 22 by the term $C^{\rho}_{\mu\nu}\Gamma^{\sigma}_{\rho\gamma}$, and is determined by the noncommutativity of the derivative ∂_{μ}.

VII. EINSTEIN'S FIELD EQUATIONS

The parametrization (44a) and (44b) is consistent, leading to the metric

$$d\sigma^2 = \rho^2\left[\cos^2\theta\, d\alpha^2 + \sin^2\theta\, d\beta^2 + d\theta^2\right] \tag{71}$$

and to the everywhere continuous right-handed triad $e_i=\partial_i$—see (46a)–(46c) whose corresponding dual base is[24]

$$\omega^1 = (\rho/2)\cos(\alpha+\beta)\sin(2\theta)(d\alpha - d\beta) - \rho\sin(\alpha+\beta)d\theta, \tag{72a}$$

$$\omega^2 = (\rho/2)\sin(\alpha+\beta)\sin(2\theta)(d\alpha - d\beta) - \rho\cos(\alpha+\beta)d\theta, \tag{72b}$$

$$\omega^3 = -\rho(\cos^2\theta\, d\alpha + \sin^2\theta\, d\beta). \tag{72c}$$

The Lorentzian metric for the $S^3\times T$ space-time being

$$ds^2 = d\sigma^2 - dt^2, \tag{73}$$

the orthonormal frame is defined by $\{\partial_\mu\}=\{\partial_1,\partial_2,\partial_3,\partial_4=\partial/\mathcal{D}\partial t\}$, whereas the corresponding dual orthonormal base consists of $\{\omega^\mu\}=\{\omega^1,\omega^2,\omega^3,\omega^4=\mathcal{D}\,dt\}$.

The above-introduced pseudo-orthonormal tetradic fields satisfy the $SU(2)\times T$ algebra (48a)–(48c). Using the tetradic field one-forms $\{\omega^\mu\}$ one can obtain the line element as[12,25]

$$ds^2 = g_{\mu\nu}\omega^\mu\omega^\nu, \tag{74}$$

where $g_{\mu\nu}=\mathrm{diag}(1,1,1,-1)=\eta_{\mu\nu}$ denotes the usual "flat" metric. In this choice of the tetrad, exploiting the group properties of the manifold, the Cartan formalism leads to important results which will be presented in the sequel.

Thus, the algebraically essential coefficients of the Levi-Civita connection are easily obtained as

$$\Gamma_{ijk} = -\varepsilon_{ijk}, \tag{75a}$$

$$\Gamma_{4ij} = 0, \tag{75b}$$

$$i,j,k = \overline{1,3}. \tag{75c}$$

Considering $\rho=f(\mathcal{D}t)$ to be a function of time alone, we generalize the previous results to a time-dependent radius of curvature. With this assumption, the structure constants for the algebra (48a)–(48c) read

$$C_{ijk} = (2/f)\varepsilon_{ijk}, \tag{76a}$$

$$C_{ii4} = -C_{i4i} = f'/f, \tag{76b}$$

$$C_{4ii} = 0, \tag{76c}$$

where prime marks fractal time derivatives.

Using the first torsionless Cartan equation[12,25]

$$d\omega^\mu = -\Gamma^\mu_\nu \wedge \omega^\nu \tag{77}$$

we obtain the connection coefficients as

$$\Gamma^i_{jk} = -(1/f)\varepsilon^i_{jk}, \quad \Gamma^i_{41} = \Gamma^4_{ii} = -f'/f, \quad \Gamma^i_{i4} = 0. \tag{78}$$

From the second Cartan equation[12,25]

$$\mathrm{d}\Gamma_{\mu\nu} + \Gamma_{\mu\alpha} \wedge \Gamma^{\alpha}_{\nu} = (1/2) R_{\mu\nu\alpha\beta} \omega^{\alpha} \wedge \omega^{\beta} \tag{79}$$

we get the following essential Riemann tensor components:

$$\begin{gathered} R_{1212} = R_{1313} = R_{2323} = 1/f^2 + (f'/f)^2, \\ R_{1414} = R_{2424} = R_{3434} = -f''/f^2, \end{gathered} \tag{80}$$

which enable us to compute the Ricci tensor

$$\begin{gathered} R_{11} = R_{22} = R_{33} = 2/f^2 + f''/f + 2(f'/f)^2, \\ R_{44} = -3f''/f, \end{gathered} \tag{81}$$

and the scalar curvature

$$R = \eta^{\mu\nu} R_{\mu\nu} = 6[1/f^2 + f''/f + (f'/f)^2]. \tag{82}$$

For $f(\mathcal{D}t) = \rho = \text{const.}$, one can obtain from (82) the well-known geometrical result $R = 6/\rho^2$.[13]

Using (81) and (82), we compute the components of the Einstein tensor $G_{\mu\nu} = R_{\mu\nu} - (1/2)\eta_{\mu\nu} R$, obtaining

$$G_{ii} = -[1/f^2 + 2f''/f + (f'/f)^2], \tag{83a}$$

$$G_{44} = (3/f^2)(1 + f'^2). \tag{83b}$$

In the following we analyze the Einstein equations, for the dynamized metric, in two physically important cases. The exact solutions are derived and some considerations on particular cases are made.

Considering the Einstein field equations

$$G_{\mu\nu} = kT_{\mu\nu} \tag{84}$$

with the matter-energy-momentum tensor of an ideal fluid

$$T_{\mu\nu} = (w + p) u_{\mu} u_{\nu} + p \eta_{\mu\nu}, \tag{85}$$

where p is the pressure and w is the energy density. The concrete expressions for the components (83a) and (83b) suggest the use of the well-known relation $w = 3p$. So, the ideal fluid may be identified with an electromagnetic field of pure radiation, and (85) can be written in the form

$$T_{\mu\nu} = (w/3)(4\delta^4_{\mu}\delta^4_{\nu} + \eta_{\mu\nu}). \tag{86}$$

Introducing (83a), (83b), and (86) in (84), we get

$$1/f^2 + 2f''/f + (f'/f)^2 = -kw/3, \tag{87a}$$

$$(3/f^2)(1 + f'2) = kw. \tag{87b}$$

which lead to the following different equation for f:

$$f''f + f'2 + 1 = 0 \tag{88}$$

with the general solution

$$f(\mathcal{D}t) = \pm [f_0^2 - (\mathcal{D}t - \mathcal{D}t_0)^2]^{1/2}, \tag{89}$$

where f_0 and t_0 are integration constants.

The (88) result in the form

$$\frac{\partial \mathcal{L}}{\partial \ln \varepsilon} = -2,$$

where

$$\mathcal{L} = \ln(p^2 + 1), p = f' \text{ and } \varepsilon = f$$

leads to a continuous scale invariance—see Refs. 4 and 5. In this case, the scale dimension is given by the eigenvalues of the dilation operator (6)

$$\mathcal{D}\mathcal{L} = \lambda \mathcal{L}$$

and indicates, according to the general theory of the fractal space-time—see Refs. 4 and 5 that it is valuable at the microscopic scale since $\lambda = -2$. Moreover, the fractalic dimension $D = -\lambda = 2$ show that this model becomes the quantum Einstein gravity.[26,27]

Replacing (89) in (87a) and (87b), we obtain the energy density for the electromagnetic field of pure radiation as

$$w = \pm (3\rho/k)[f_0^2 - (\mathcal{D}t - \mathcal{D}t_0)^2]^{1/2}. \tag{90}$$

For comparison, it is worthwhile analyzing the simplest case of a cosmological dust whose energy-momentum tensor is $T_{\mu\nu} = w u_\mu u_\nu$ [derived from (85) for $p = 0$] and possesses, with respect to the co-moving frame $u_i = 0$, a single nonvanishing component, $T_{44} = w$. Under these hypotheses, the Einstein's field equations (84) concretely become

$$l/f^2 + 2f''/f + (f'/f)^2 = 0, \tag{91a}$$

$$(3/f^2)(1 + f'^2) = kw, \tag{91b}$$

whose general solution is expressed through the transcendent dependence of the sphere radius on time

$$\mathcal{D}t = \mathcal{D}t_0 \pm \lfloor f_0 \sqrt{(f/f_0)(1 - f/f_0)} + (\sqrt{f_0}/2)\arcsin\sqrt{1 - f/f_0} \rfloor, \tag{92}$$

where t_0 and f_0 are integration constants.

Equation (91b) provides the energy density

$$w = 3f_0/(kf^3) \tag{93}$$

in perfect agreement with Ref. 13.

VIII. CONCLUSIONS

The main conclusions of the present paper are the following: (i) Assimilating the physical space-time with a fractal, a general theory is built. For a fractal dimension $D = 2$, the virtual geodesics of this space-time impliesh a generalized Schrödinger type equation and (ii) A geometric formulation of the gravitation theory on a fractal space-time is given. Then, a connection is introduced on a tangent bundle, the connection coefficients, the Riemann curvature tensor and the Einstein field equation are calculated. It results, by means of the a dilation operator, the equivalence of this model with quantum Einstein gravity.

We develop a Hilbert-space framework for a number of general multiscale problems from dynamics. The aim is to identify a spectral theory for a class of systems based on iterations of a non-invertible endomorphism. We are motivated by the more familiar approach to wavelet theory which starts with the two-to-one endomorphism $r:z\mapsto z^2$ in the one-torus $\mathbb{T}$, a wavelet filter, and an associated transfer operator. This leads to a scaling function and a corresponding closed subspace V_0 in the Hilbert space $L^2(\mathbb{R})$. Using the dyadic scaling on the line $\mathbb{R}$, one has a nested family of closed subspaces V_n, $n\in\mathbb{Z}$, with trivial intersection, and with dense union in $L^2(\mathbb{R})$. More generally, we achieve the same outcome, but in different Hilbert spaces, for a class of non-linear problems. In fact, we see that the geometry of scales of subspaces in Hilbert space is ubiquitous in the analysis of multiscale problems, e.g., martingales, complex iteration dynamical systems, graph-iterated function systems of affine type, and subshifts in symbolic dynamics. We develop a general framework for these examples which starts with a fixed endomorphism r (i.e., generalizing $r(z)=z^2$) in a compact metric space X. It is assumed that $r:X\to X$ is onto, and finite-to-one. © *2006 American Institute of Physics.*

I. INTRODUCTION

We study a class of endomorphisms $r:X\to X$, where X is a metric space. The endomorphism is assumed onto, and finite-to-one. We build a spectral theory on a Hilbert space associated naturally with (X,r). Our focus is on the case when X is assumed to carry a certain strongly invariant measure ρ, see (2.3).

Continuing our earlier work[13] we consider basis constructions in a general context of dynamical systems; the case of endomorphisms, i.e., non-reversible dynamics. Our framework will include wavelet bases, as well as algorithmic basis constructions in Hilbert spaces built on fractals or on Julia sets of rational functions in one complex variable. In fact, these examples motivated our results.

First recall that in the real variable case of standard wavelets (in one or several variables, i.e., the d-dimensional Lebesgue measure), there is a separate generalizations of standard dyadic wavelets, again based on translation and scaling: See for example Ref. 1 for such an approach to the construction of generalized wavelet bases in the Hilbert space $L^2(\mathbb{R}^d)$, i.e., of orthogonal bases in $L^2(\mathbb{R}^d)$, or just frame wavelet bases, but still in $L^2(\mathbb{R}^d)$.

[a)]Electronic mail: ddutkay@math.rutgers.edu
[b)]Electronic mail: jorgen@math.uiowa.edu

It is the purpose of this paper to develop a geometric context of this viewpoint which applies to any kind of dynamics which is based on an iterated scale of selfsimilarity. Hence our paper will offer a Hilbert-space framework which goes beyond the setting of scale similarity, and our results will offer a new viewpoint even in the case of the more familiar selfsimilarity which is based on a cascade of affine scales.

The best know instance of this is $d=1$, and dyadic wavelets.[10] In that case, the two operations on the real line $\mathbb{R}$ are translation by the group $\mathbb{Z}$ of the integers, and scaling by powers of 2, i.e., $x\mapsto 2^j x$, as j runs over $\mathbb{Z}$. This is the approach to wavelet theory which is based on multiresolutions and filters from signal processing. In higher dimensions d, the scaling is by a fixed matrix, and the translations by the rank-d lattice $\mathbb{Z}^d$. Again we will need scaling by all integral powers. We view points x in $\mathbb{R}^d$ as column vectors, and we then consider the group of scaling transformations, $x\mapsto A^j x$ as j ranges over $\mathbb{Z}$.

Suitable spectral conditions will be imposed on A. In particular we note that if A is integral, i.e., the entries in A are in $\mathbb{Z}$, then $x\mapsto Ax$ passes to the quotient $\mathbb{R}^d/\mathbb{Z}^d$. Since $\mathbb{R}^d/\mathbb{Z}^d$ is a copy of the compact d-torus $\mathbb{T}^d$ via a familiar identification, we see that A induces an endomorphism r_A in $\mathbb{T}^d$. If further A is invertible, then r_A is finite-to-one, and maps $\mathbb{T}^d$ onto itself. In fact, for every x in $\mathbb{T}^d$, the inverse image $r_A^{-1}(x)$ has cardinality $=|\det A|=:N$,

$$\frac{1}{\sqrt{\det A}}\varphi(A^{-1}x)=\sum_{k\in\mathbb{Z}^d} a_k\varphi(x-k)\quad (x\in\mathbb{R}^d). \tag{1.1}$$

So our starting point is a given finite-to-one endomorphism $r: X\to X$ in a compact space X. Our aim is threefold: (1) to build an associated Hilbert space which admits wavelet decompositions; (2) to show that the corresponding computations can be done with a geometric algorithm; and finally (3) we offer concrete examples from dynamics where our approach leads to new insight. So in addition to the endomorphism (X,r), our initial setup will include a scalar function m_0; an analog of the function from wavelet theory which determines low-pass filters.

Details: Set $W(x):=|m_0|^2/\#r^{-1}(x)$. We say that m_0 satisfies a *low-pass* condition if $W(0)=1$. (In the special case of (1.1) above, the relationship between the function m_0 and the coefficients $\{a_k\}$ is that the a_k numbers will be the d-Fourier coefficients of m_0 when m_0 is viewed as a function on the compact quotient $X=\mathbb{R}^d/\mathbb{Z}^d$. This explains the summation over $\mathbb{Z}^d$ in (1.1).)

Suppose for some p, and $x\in X$, that $r^p(x)=x$. Then we say that the finite set of points $C=\{x,r(x),\ldots,r^{p-1}(x)\}$ is a *cycle*. A cycle C is called a *W-cycle* if $W(y)=1$ for all $y\in C$.

We will extend to the context of endomorphisms the following general principle from wavelets in the Hilbert space $L^2(\mathbb{R}^d)$: A generalized wavelet basis (also called a Parseval-frame, see e.g., Ref. 1) will have the stronger orthonormal basis (ONB)property when the only one W-cycle is $C=\{0\}$. On the other hand, the presence of non-trivial W-cycles is consistent with wavelet systems that form frame-bases. The reader is referred to Ref. 6 for details regarding these more general wavelet bases. It was proved in Ref. 6 that the presence of W-cycles is consistent with a class of certain *super-wavelets*. This wavelet basis involves an additional cyclic structure which we will develop in the paper.

This setup arose earlier for the familiar linear multiresolution analysis (MRA) approach to wavelets: Recall[10] that dyadic wavelets represent a special basis for the Hilbert space $L^2(\mathbb{R})$, but they are generated by a subspace V_0 in $L^2(\mathbb{R})$ which is the closed linear span of a single function φ and its translates by the integers $\mathbb{Z}$. The function φ satisfies a certain scaling identity

$$\frac{1}{\sqrt{2}}\varphi(x/2)=\sum_{k\in\mathbb{Z}} a_k\varphi(x-k)\quad (x\in\mathbb{R}), \tag{1.2}$$

which implies that the scaling operator $Uf(x):=1/\sqrt{2}f(x/2)$ maps V_0 into itself. A solution φ is called a scaling function. Using a terminology from optics, we say that functions on $\mathbb{R}$ represent signals or images, and that the subspace V_0 initializes a fixed resolution.

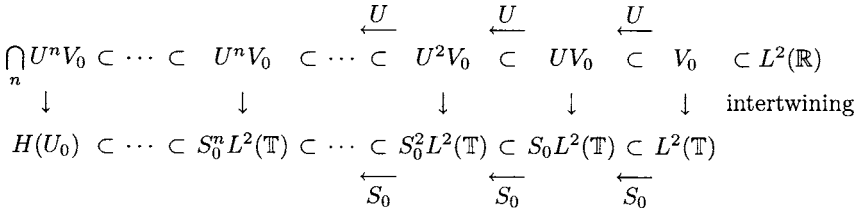

FIG. 1. Multiresolutions.

A special case: $X=\mathbb{T}=\{z\in\mathbb{C}\,|\,|z|=1\}=\mathbb{R}/\mathbb{Z}$, $r(z)=z^2$, and m_0 is the function on $\mathbb{T}$ with Fourier coefficients equal to the masking coefficients a_k from (1.2), i.e., $m_0(z)=\Sigma_{k\in\mathbb{Z}}a_k z^k$. The function m_0 is called a filter function because of an analogy to a setting in signal processing. One of the axioms for m_0 (the *quadrature-mirror-filter* axiom) from wavelet theory amounts to the fact that the associated linear operator, $S_0h(z):=m_0(z)h(z^2)$ is isometric in $L^2(\mathbb{T},$ Haar measure); see Fig. 1,

In this paper, we state a version of the scaling identity (1.2), for the case of an endomorphism $r:X\to X$, and we show that it admits a solution in certain Hilbert spaces built on (X,r). It turns out that the variant of (1.2) which arises by the Fourier transform, i.e.,

$$\sqrt{2}\hat{\varphi}(t)=m_0(e^{it/2})\hat{\varphi}(t/2)\quad(t\in\mathbb{R}),\tag{1.3}$$

is more suggestive of the generalization we have in mind; see Theorem 2.14 for details.

While the standard MRA approach to wavelets (see Ref. 17) restricts the functions m_0 in (1.3) by assuming that m_0 is in some regularity class, e.g., is Lipschitz, we shall not do this here. Moreover, there is a rich class of wavelet systems where m_0 is typically only known *a priori* to be L^∞. This is the case, for example, for the frequency localized wavelets studied in Refs. 1 and 21. (In this last case, m_0 is in fact matrix-valued.)

The scaling identity (1.2) implies that there is a natural intertwining of the isometry S_0 on $L^2(\mathbb{T})$ with the restriction of U to the subspace V_0 in $L^2(\mathbb{R})$. A second axiom for m_0 from wavelet theory (called *low-pass*) implies that S_0 is a *pure* shift isometry, i.e., that the intersection $S_0^n(L^2(\mathbb{T}))$, for n in $\mathbb{N}$ is $\{0\}$, see Fig. 1. Because of the intertwining relation, this fact guarantees that the standard functions that make up a wavelet basis really do form a basis for the whole Hilbert space $L^2(\mathbb{R})$. See Fig. 1. And the purity of S_0 is also what yields a certain martingale system, i.e., a nested family of spaces, or of sigma-algebras.

It is the purpose of this paper to generalize this setting to that of endomorphisms, and to realize a natural scaling function, as a generating vector in a Hilbert space which corresponds to $L^2(\mathbb{R})$ for the special case of wavelets. For this purpose we introduce a solenoid X_∞ built on X, and a family of repelling cycles for the system (X,r,m_0). Our Hilbert space is built as an L^2-space on certain infinite paths starting at X. In Theorem 2.14, we solve the corresponding scaling identity, and write the scaling function as an infinite product. As one should expect by analogy to wavelets, a central theme in our present analysis is a characterization of those filter functions m_0 on X for which the scaling identity has non-trivial solutions in a Hilbert space of functions of X_∞.

A concrete example of this wavelet technique used on a particular graph dynamical system (The Golden mean shift) is presented in Proposition 2.18 below. Our aim is to present this as a systematic tool for dynamics outside the traditional context of wavelets in $L^2(\mathbb{R})$.

In recent papers,[11,13] the co-authors have adapted this MRA technique to a related but different problem, the problem of creating a spectral theory for a class of non-linear iterated function systems (IFS), but in those cases, there is not a direct analog to the scaling identity. Our construction here parallels the one we outlined briefly for the standard dyadic MRA wavelet constructions.[17] (We have sketched the standard wavelet construction only in the dyadic case, and only in one dimension, i.e., for $\mathbb{R}$, but it is known that this construction carries over *mutatis mutandis* to $\mathbb{R}^d$ with $d>1$, and when $x\mapsto 2x$, is replaced with matrix scaling $x\mapsto Ax$ in $\mathbb{R}^d$ where A is a d by d matrix over $\mathbb{Z}$ with eigenvalues λ such that $|\lambda|>1$. Moreover our results apply to the kind of multiwavelets studied recently in Ref. 1.)

Our present paper is not about $\mathbb{R}^d$-wavelets but instead about a class of non-linear dynamics $r:X\to X$. Specifically, now we start with $r:X\to X$, and the function m_0 is defined on X. We will also call m_0 a *filter function* because of known analogy to subband filtering in signal processing. When m_0 is given then S_0 given by $S_0h(x):=m_0(x)h(r(x))$ is isometric in $L^2(X)$, subject to a technical condition on m_0. So by Wold's theorem,[31] it is then the orthogonal sum of a shift operator S and a unitary operator U_0; i.e., the Hilbert space $L^2(X)$ on which S_0 acts is the direct sum of two Hilbert spaces $H(S)$ and $H(U_0)$ such that (i) each space invariant for S_0, (ii) the restriction to $H(S)$ is a shift S, and the restriction to $H(U_0)$ a unitary operator. We say that S_0 is *pure* if $H(U_0)=\{0\}$. (See Fig. 1.) This will be equivalent to the fact that the intersection of the multiresolution subspaces is trivial.

This means that S_0 is itself a shift operator on $L^2(X)$. Our Theorem 3.9 gives a simple condition for the isometry S_0 to be pure.

The first step in our construction is an extension from the initial endomorphism $r:X\to X$, to a new invertible system $\hat{r}:X_\infty\to X_\infty$, i.e., with $\hat{r}$ invertible on X_∞. When r is assumed finite-to-one, this can be done such that there is a quotient X_∞/X which becomes a Cantor space. The extension space X_∞ is called a solenoid. For the case when (X,r) is a one-sided subshift,[24] we work out (in Sec. II D) an explicit model for this solenoid.

In fact the notion of a solenoid (for the study of dynamics of an endomorphism and extension to an automorphism) was used already in a pioneering paper by Lawton[19] in 1973. Lawton considered groups with expansive automorphisms; see also Ref. 20. Motivated by applications, we note that our present analysis is not restricted to groups.

The use of solenoids in the study of particular systems with scale similarity was initiated in Ref. 8, and was continued in Ref. 7. The context of Ref. 8 is a class of algebraic irrational numbers and an associated C^*-algebraic crossed product. In a general context of non-linear dynamics, this work was continued in Refs. 11 and 13.

II. COVARIANT REPRESENTATIONS

Let X be a compact metric space with a non-invertible endomorphism $r:X\to X$ such that r is measurable, onto and finite to one, i.e., $0<\#r^{-1}(x)<\infty$ for all $x\in X$.

We have shown in Refs. 12 and 13 that, for certain filter functions m_0 on X, one can construct multiresolutions and scaling functions in Hilbert spaces of functions on X_∞ (see (2.1)).

In Ref. 13 we proved that to get useful multiresolutions, the function m_0 must have certain extreme cycles (see Definition 2.10). In this case the measure on X_∞ is actually supported on a smaller set $\mathbf{N}_C$ (see (2.4) below).

A. The ground space

An (infinite) *path* starting at x is a sequence $(z_1,z_2,\dots)$ of points in X such that $r(z_1)=x$, $r(z_{n+1})=z_n$ for $n\geqslant 1$. We denote by Ω_x the set of paths starting at x. We denote by X_∞ the set of all paths,

$$X_\infty=\cup_{x\in X}\Omega_x. \tag{2.1}$$

Note that a path $(z_1,z_2,\dots)$ in Ω_x can be identified with the doubly infinite sequence $(z_n)_{n\in\mathbb{Z}}$, where $z_0:=x$ and $z_{-n}=r^n(x)$ for $n\geqslant 0$.

$X_\infty\subset X^{\mathbb{Z}}$ inherits the usual Tychonoff topology from $X^{\mathbb{Z}}$.

The maps $\theta_n:X_\infty\to X$ are defined for all $n\in\mathbb{Z}$, by

$$\theta_n((z_k)_{k\in\mathbb{Z}})=z_n.$$

The endomorphism r can be extended to the automorphism $\hat{r}$ defined on X_∞ by

$$\hat{r}(z_n)_{n\in\mathbb{Z}}=(z_{n-1})_{n\in\mathbb{Z}}.$$

These maps satisfy the following relations:

$$\theta_n \circ \hat{r} = \theta_{n-1} \quad \theta_0 \circ \hat{r} = r \circ \theta_0.$$

For a function g on X we define

$$g^{(n)}(x) := g(x)g(r(x)) \cdots g(r^{n-1}(x)) \quad (n \geqslant 1). \tag{2.2}$$

For a function ξ on X_∞, we define $\xi^{(0)}=1$,

$$\xi^{(n)} := \xi\xi \circ \hat{r} \cdots \xi \circ \hat{r}^{n-1},$$

and if ξ is not vanishing on X_∞, then

$$\xi^{(-n)} = \frac{1}{\xi \circ \hat{r}^{-1}\xi \circ \hat{r}^{-2} \cdots \xi \circ \hat{r}^{-n}} \quad (n \geqslant 1).$$

We can identify functions g on X with functions on X_∞ by $g \leftrightarrow g \circ \theta_0$. (Note that the two definitions for $g^{(n)}$ will coincide.)

Consider $r: X \to X$ and suppose ρ is a *strongly invariant* probability measure on X, i.e.,

$$\int_X f(x)d\rho(x) = \int_X \frac{1}{\#r^{-1}(x)} \sum_{y \in r^{-1}(x)} f(y)d\rho(x) \quad (f \in L^\infty(\rho)). \tag{2.3}$$

Let $C=\{x_0, x_1, \ldots, x_{p-1}\} \subset X$ be a *cycle* of length p, i.e., the points x_i are distinct and $r(x_{i+1}) = x_i$, $r(x_0)=x_{p-1}$.

We define the set

$$\mathbf{N}_C(x) := \{\omega = (z_1, z_2, \ldots) \in \Omega_x | \lim_{n\to\infty} z_{pn} \in C\}. \tag{2.4}$$

For each $x \in X$ and $\omega=(z_1, z_2, \ldots) \in \mathbf{N}_C(x)$, define $i(\omega) \in \{0, \ldots, p-1\}$ by $i(\omega) := i$ if $\lim_{k\to\infty} z_{kp} = x_i$.

An inspection reveals that each $\mathbf{N}_C(x)$ is countable.

Define the measure λ_C on X_∞ by

$$\int_{X_\infty} f d\lambda_C = \int_X \sum_{\omega \in \mathbf{N}_C(x)} f(\omega)d\rho(x). \tag{2.5}$$

To simplify the notation we write $\mathfrak{c}(x) = \# r^{-1}(r(x))$.

Proposition 2.1: For all $\xi \in L^1(X_\infty, \lambda_C)$ and $n \in \mathbb{Z}$, we have

$$\int_{X_\infty} \mathfrak{c}^{(n)} \xi \circ \hat{r}^n d\lambda_C = \int_{X_\infty} \xi d\lambda_C.$$

Proof: It is enough to prove this for $n=1$, the rest follows by induction,

$$\begin{aligned}
\int_{X_\infty} \mathfrak{c}\xi \circ \hat{r} d\lambda_C &= \int_X \# r^{-1}(r(x)) \sum_{\omega \in \mathbf{N}_C(x)} \xi(\hat{r}(x,\omega))d\rho(x) \\
&= \int_X \frac{1}{\#r^{-1}(x)} \sum_{y \in r^{-1}(x)} \# r^{-1}(r(y)) \sum_{\omega \in \mathbf{N}_C(y)} \xi(\hat{r}(y,\omega))d\rho(x) \\
&= \int_X \sum_{\omega \in \mathbf{N}_C(x)} \xi(x,\omega)d\rho(x) = \int_{X_\infty} d\lambda_C.
\end{aligned}$$

□

B. The operators

In this section we show that when (X,r) is given as above, there is a natural covariant representation (U,π) acting on the Hilbert space $L^2(X_\infty,\lambda_C)$, i.e., with r inducing a unitary operator U, and π a representation of $L^\infty(X)$ by multiplication operators, such that the relation (2.8) is satisfied on $L^2(X_\infty,\lambda_C)$. (The operators on $L^2(X_\infty,\lambda_C)$ are equipped with the strong operator topology (SOT).)

Let $\alpha_0,\ldots,\alpha_{p-1}$ be a set of complex numbers of absolute value 1.

Let U be the operator on $L^2(X_\infty,\lambda_C)$ defined by

$$U\xi(x,\omega)=\alpha_{i(\omega)}\sqrt{\#r^{-1}(r(x))}\,\xi\circ\hat{r}(x,\omega)\quad(\xi\in L^2(X_\infty,\lambda_C),x\in X,\omega\in\Omega_x). \tag{2.6}$$

For $f\in L^\infty(X,\rho)$ define the operator $\pi(f)$ on $L^2(X_\infty,\lambda_C)$ by

$$\pi(f)\xi(x,\omega)=f(x)\xi(x,\omega)\quad(\xi\in L^2(X_\infty,\lambda_C),x\in X,\omega\in\Omega_x). \tag{2.7}$$

Proposition 2.2: The operator U is unitary, π is a representation of the algebra $L^\infty(X,\rho)$ and the following covariance relation is satisfied:

$$U\pi(f)U^{-1}=\pi(f\circ r)\quad(f\in L^\infty(X,\rho)). \tag{2.8}$$

For any function $f\in L^\infty(X,\rho)$ and $n\geqslant 1$, the operator $U^{-n}\pi(f)U^n$ is the operator of multiplication by $f\circ\theta_n$. The union of the algebras $\{U^{-n}\pi(f)U^n|f\in L^\infty(X,\rho)\}$ is SOT-dense in the algebra $L^\infty(X_\infty,\lambda_C)$ (seen as multiplication operators on $L^2(X_\infty,\lambda_C)$). An operator S on $L^2(X_\infty,\lambda_C)$ commutes with U and $\pi(f)$ for all $f\in L^\infty(X,\rho)$ if and only if there exists a function $F\in L^\infty(X_\infty,\lambda_C)$ such that $F=F\circ\hat{r}$ and S is the operator of multiplication by F.

Proof: The fact that U is an isometry follows form Proposition 2.1.

The inverse of U is

$$U^{-1}\xi(x,\omega)=\alpha^{-1}_{i(\hat{r}(\omega))}\frac{1}{\sqrt{\#r^{-1}(x)}}\xi\circ\hat{r}^{-1}(x,\omega).$$

Some simple computations prove the other relations.

Note that the algebra $\{U^{-n}\pi(f)U^nf\in L^\infty(X,\rho)\}$ is the algebra of operators of multiplication by functions which depend only on the first n coordinates. Since any function in $L^\infty(X,\rho)$ can be pointwise and uniformly boundedly approximated by such functions, it follows that the union of these algebras is dense in $L^\infty(X_\infty,\lambda_C)$.

Since $L^\infty(X_\infty,\lambda_C)$ is maximal Abelian, if S commutes with U and π then S commutes with the multiplication operators, so it is a multiplication operator itself, $S=M_F$. Since S commutes with U, it follows that $F=F\circ\hat{r}$. □

Our formula for the measure λ_C in (2.5) shows that the Hilbert space $L^2(X_\infty,\lambda_C)$ fibers over functions on X as follows: for a dense space of functions $\xi,\eta\in L^2(X_\infty,\lambda_C)$, the sum

$$\langle\xi|\eta\rangle(x):=\sum_{\omega\in\mathbf{N}_C(x)}\xi(\omega)\overline{\eta}(\omega)$$

defines a $C(X)$-valued inner product as in Refs. 28 and 16 and

$$\int_X\langle\xi|\eta\rangle(x)d\rho(x)=\langle\xi|\eta\rangle_{L^2(X_\infty,\lambda_C)}.$$

C. A direct integral decomposition

We now resume our discussion of cycles C for the endomorphism.

The cycle $C=\{x_0,\ldots,x_{p-1}\}$ generates p points in X_∞:

$$\omega_C := (x_0,x_1,\ldots,x_{p-1},x_0,\ldots) \quad \text{and} \quad \hat{r}^k(\omega_C), k \in \{1,\ldots,p-1\},$$

i.e., ω_C is the path that goes through the cycle infinitely many times. We may write $\omega_C := CC\cdots = C^\infty$.

Definition 2.3: A fixed point x_0 for r is called repelling if there is $0<c<1$ and $\delta>0$ such that for all $x \in X$ with $d(x,x_0)<\delta$, one has $d(r(x),x_0)>c^{-1}d(x,x_0)$.

A cycle $C=\{x_0,\ldots,x_{p-1}\}$ is called repelling if each point x_i is repelling for r^p.

Definition 2.4: A subset A of X_∞ is called a *cross section* if for every path $\omega \in \cup_{x\in X}\mathbf{N}_C(x)\backslash\{\hat{r}^k(\omega_C)\,|\,k\in\{0,\ldots,p-1\}\}$, the intersection $A\cap\{\hat{r}^k(\omega)\ k\in\mathbb{Z}\}$ contains exactly one point.

Proposition 2.5: If C is repelling, and r is continuous at the points in C, then there exists a cross section.

Proof: Using the continuity of r and the fact that the cycle is repelling, we can find a small $\delta>0$ and $0<c<1$ such that $r^i(B(x_0,\delta))\cap B(x_0,\delta)=\emptyset$, for $i\in\{1,\ldots,p-1\}$, $r^{-p}(x_0)\cap B(x_0,\delta)=\{x_0\}$, and such that $d(r^p(x),x_0)\geq c^{-1}d(x,x_0)$ for $x\in B(x,\delta)$.

Define

$$A := \{(z_k)_{k\in\mathbb{Z}} \in X_\infty | z_0 \in r^p(B(x_0,\delta))\setminus B(x_0,\delta), \quad \text{and} \quad z_{kp}\in B(x_0,\delta) \text{ for } k\geq 1\}.$$

It is enough to prove that, for every path $(z_k)_{k\in\mathbb{Z}}$ in $\mathbf{N}_C(x)$, except the special ones ω_C and the others, there is a unique $k_0\in\mathbb{Z}$ such that

$$z_{k_0}\in r^p(B(x_0,\delta))\setminus B(x_0,\delta), \quad \text{and} \quad z_{kp}\in B(x_0,\delta) \quad \text{for } k\geq 1. \tag{2.9}$$

Since ω is in $\mathbf{N}_C(x)$, the sequence $\{z_{kp}\}$ converges to one of the points x_i. Then, using the continuity of r, $\{z_{kp+p-i}\}$ converges to x_0.

Take the first $k_0\in\mathbb{Z}$ such that $z_{kp+k_0}\in B(x_0,\delta)$, for all $k\geq 1$. We still have to justify why there is a first one.

If not, then $z_{-kp+k_0}\in B(x_0,\delta)$ for all $k\geq 0$. Then, using the fact that x_0 is repelling for r^p, there is a c such that $0<c<1$, and for all $k\geq 0$,

$$\delta > d(z_{-kp+k_0},x_0) = d(r^{kp}(z_{k_0}),x_0) \geq c^{-k}d(z_{k_0},x_0).$$

But then let $k\to\infty$, and obtain that $z_{k_0}=x_0$. So, $z_{k_0-l}=r^l(x_0)=x_{l \bmod p}$ for all $l\geq 0$. Also, since $z_{k_0+p}\in B(x_0,\delta)\cap r^{-p}(x_0)$, we get $z_{k_0+p}=x_0$. By induction we obtain then that ω is one of the special points in the orbit of ω_C, which yields the contradiction.

Since $z_{k_0+p}\in B(x_0,\delta)$, $z_{k_0}=r^p(z_{k_0+p})$ is in $r^p(B(x_0,\delta))$ but not in $B(x_0,\delta)$.

Since $z_{k_0+kp}\in B(x_0,\delta)$ for $k\geq 1$, this proves that k_0+kp does not have the property (2.9).

Since $z_{k_0}\notin B(x_0,\delta)$, this proves that k_0-kp does not have the property (2.9) for $k\geq 1$.

Since for $k\geq 0$, $z_{k_0+kp+p}\in B(x_0,\delta)$, it follows that for $i\in\{1,\ldots,p-1\}$, one has $z_{k_0+kp+i}\in r^{p-i}(B(x_0,\delta))$ so it is not in $B(x_0,\delta)$, and therefore k does not satisfy (2.9) when $k\not\equiv k_0 \bmod p$.

This proves that A is a cross section. □

Our present notion of cross section, and our next theorem are motivated in part by an earlier theorem of Lim, Packer, and Taylor[21] on direct integral decompositions of a class of wavelet representations: This is the class of wavelets for which the Fourier transform $\hat{\psi}$ of the wavelet mother-function ψ is the indicator function of a measurable subset in $\mathbb{R}^d$. Both our present direct integral decomposition theorem, and that in Ref. 21 are motivated by Mackey's theory of unitary representations of non-Abelian groups. In fact, our representation of the covariant system (U,π) may be viewed as a single representation of a certain non-Abelian crossed product $\mathfrak{A}_{\hat{r}}$

$:= C(X_\infty) \ltimes_{\hat{r}} \mathbb{Z}$ (see Ref. 8), and our simultaneous direct integral decomposition of U and π in Theorem 2.6 below, is also a direct integral decomposition of a single representation of the crossed product group.

Assume now that A is a cross section. For each $\omega \in A$, define the operators U_ω and $\pi_\omega(f)$, $f \in L^\infty(X,\rho)$ on $l^2(\mathbb{Z})$ by

$$U_\omega \xi(k) = \alpha_{i(r^k(\omega))} \xi(k+1) \quad (\xi \in l^2(\mathbb{Z}), k \in \mathbb{Z}),$$

$$\pi_\omega(f)\xi(k) = f(z_{-k})\xi(k) \quad (\xi \in l^2(\mathbb{Z}), k \in \mathbb{Z}).$$

The representation π_ω extends to a representation of $C(X_\infty)$ defined by

$$\pi_\omega(f)\xi(k) = f(\hat{r}^k(\omega))\xi(k) \quad (f \in C(X_\infty), \xi \in l^2(\mathbb{Z}), k \in \mathbb{Z}).$$

The covariance relation is satisfied:

$$U_\omega \pi_\omega(f) U_\omega^{-1} = \pi_\omega(f \circ \hat{r}) \quad (f \in C(X_\infty)).$$

Theorem 2.6: *Let A be a cross section, and assume that $\rho(C)=0$. The map $\Phi: L^2(X_\infty, \lambda_C) \to L^2(A, \lambda_C) \otimes l^2(\mathbb{Z})$ defined by*

$$(\Phi(f))(\omega,k) = \sqrt{\mathfrak{c}^{(k)}(z_0)} f(\hat{r}^k(\omega)) \quad (f \in L^2(X_\infty, \lambda_C), \omega = (z_k)_{k\in\mathbb{Z}} \in A, k \in \mathbb{Z})$$

is an isometric isomorphism which intertwines the operators U and $\int_A^\oplus U_\omega d\lambda_C(\omega)$, and also the representations π and $\int_A^\oplus \pi_\omega d\lambda_C(\omega)$. The representations (U_ω, π_ω) on $l^2(\mathbb{Z})$ are irreducible for all $\omega \in A$.

Proof: The fact that Φ is isometric follows from Proposition 2.1. The inverse of Φ is defined as follows: for each $\omega \in \cup_x \mathbf{N}_C(x)$, (except the special ones which have measure 0, so do not matter), there exists a unique $k(\omega) \in \mathbb{Z}$ and $\eta(\omega) \in A$ such that $\omega = \hat{r}^{k(\omega)}(\eta(\omega))$. Then

$$\Phi^{-1}(f)(\omega) = \frac{1}{\sqrt{\mathfrak{c}^{(k(\omega))}(\eta(\omega)_0)}} f(\eta(\omega), k(\omega)).$$

Everything follows by direct computation.

We prove now that the representation (U_ω, π_ω) is irreducible for all $\omega = (z_k)_{k\in\mathbb{Z}} \in A$.

Note first that $\pi_\omega(f)$ is a diagonal operator F with entries $F_{kk} = f(z_{-k})$, $k \in \mathbb{Z}$.

We claim that for $k \neq l$ big enough, we have $z_k \neq z_l$. Since ω is in $\mathbf{N}_C(z_0)$, it follows that z_{kp} converges to one of the points of the cycle. Also, for k big enough, the points z_k cannot be in C, because, this path ω_C was removed from A. Suppose now that for any m we can find $k, l \geqslant m$, such that $k > l$ and $z_k = z_l$. Then this implies that z_k is periodic, therefore also $z_{k-1} = r(z_k), z_{k-2}, \ldots, z_l$ are periodic, and since m is arbitrary, it follows that all the points z_m are periodic. The orbit of the two periodic points z_0 and z_k intersect, because $r^k(z_k) = z_0$, therefore the two orbits must be the same. Thus the path $(z_k)_{k\in\mathbb{Z}}$ is an infinite repetition of the periodic orbit of z_0: $(z_0, z_1, \ldots, z_{p_0-1}, z_0, z_1, \ldots)$. However, this cannot converge to the cycle C.

Take now $k \neq l$ small enough. Then $z_{-k} \neq z_{-l}$ so we can pick a function continuous function f such that $F_{kk} = f(z_{-k}) \neq f(z_{-l}) = F_{ll}$. If $T = (T_{ij})_{i,j\in\mathbb{Z}}$ is an operator on $l^2(\mathbb{Z})$ that commutes with U_ω and π_ω, then $T_{kl}F_{ll} = F_{kk}T_{kl}$. So $T_{kl} = 0$ for $k \neq l$ small enough.

Note that $(U_\omega^{-1}\pi_\omega(f)U_\omega\xi)(k) = f(z_{-k+1})\xi(k)$, so the conjugation with U_ω shifts the diagonal entries of $\pi_\omega(f)$. Therefore, with the previous argument, we obtain that $T_{kl} = 0$ for all $k \neq l$. So T is a diagonal operator. Since, T commutes with U_ω, we obtain that $T_{kk} = T_{k+1,k+1}$. So T is a constant multiple of the identity. This proves that the representation (U_ω, π_ω) is irreducible. □

We show in Theorem 2.7 below that the harmonic analysis of covariant systems (U, π) as in (2.8) is completely equivalent to that of single representations $\hat{\pi}$ of a certain C^*-algebraic crossed product $\mathfrak{A}_{\hat{r}}$. With this identification $(U, \pi) \leftrightarrow \hat{\pi}$, we note in particular that the operators in the

commutant of the pair (U,π) coincide with the commutant of the representation $\hat{\pi}$. Our main conclusion in Theorem 2.7 is that the representation $\hat{\pi}$ of $\mathfrak{A}_{\hat{r}}$ is faithful, i.e., that the kernel of $\hat{\pi}$ is trivial.

Theorem 2.7: *Assume that for every $x \in X$, there exists a path $(z_i)_{i\geqslant 1}$ that starts at x and with $\lim_{i\to\infty} z_{pi} \in C$, (i.e., $\mathbf{N}_C(x)$ is non-empty). Then the operators U and M_f, $(f \in C(X_\infty))$ on $L^2(X_\infty,\lambda_C)$ form a faithful representation of the crossed-product $\mathfrak{A}_{\hat{r}} := C(X_\infty) \ltimes_{\hat{r}} \mathbb{Z}$.*

Proof: The C^*-algebraic crossed product $\mathfrak{A}_{\hat{r}}$ (Ref. 29) is the C^*-algebraic completion of formal symbols $\{(f,k)\,|\,f \in C(X_\infty), k \in \mathbb{Z}\}$ with product

$$(f,k)\cdot(g,l) = (fg\circ \hat{r}^k, k+l) \quad (f,g \in C(X_\infty), k,l \in \mathbb{Z}).$$

The representation is defined by

$$\hat{\pi}:(f,k) \mapsto \pi(f)U^k.$$

We saw in Proposition 2.2 and its proof that the covariance relation is satisfied, so we have to check only that this representation is faithful. If not, using a result from Ref. 32, we see that there is a non-zero element in $\mathfrak{A}_{\hat{r}}$ of the form $(\Sigma_{k\in\mathbb{Z}} c_k(f,k))$ with $\Sigma_{k\in\mathbb{Z}}|c_k| < \infty$, $f \in C(X_\infty)$ such that this element is mapped to 0 under $\hat{\pi}$.

This means that $\pi(f)\Sigma_{k\in\mathbb{Z}} c_k U^k = 0$. With Theorem 2.6 it follows that for almost all $\omega \in A$ and all $\xi \in l^2(\mathbb{Z})$, $l \in \mathbb{Z}$, one has

$$f(\hat{r}^l(\omega)) \sum_{k\in\mathbb{Z}} c_k \xi(k+l) = 0.$$

Take $\xi = \delta_i$ and get $f(\hat{r}^l(\omega))c_{i-l} = 0$ which implies that either $f(\hat{r}^l(\omega)) = 0$ for all l, or $c_l = 0$ for all l. But, if $c_l = 0$ for all l then this contradicts that the element in the crossed-product is non-zero.

Thus, for almost all $\omega = (z_i)_{i\in\mathbb{Z}} \in A$, we have that $f(\hat{r}^l(\omega)) = 0$ for all l.

This implies that f is 0 on almost all $\cup_x \mathbf{N}_C(x)$. We know that non-empty open sets in X have positive ρ-measure (see Ref. 13). Hence, since the measure on each $\mathbf{N}_C(x)$ is atomic, every non-empty open set in $\cup_x \mathbf{N}_C(x)$ has positive measure. This implies that f has to be 0 on all $\cup_x \mathbf{N}_C(x)$. We claim that this set is dense in X_∞.

Take $\omega := (z_1, z_2, \ldots) \in X_\infty$ and $n \geqslant 1$ fixed. Since $\mathbf{N}_C(z_n)$ is not empty, there exists a path $(y_1, y_2, \ldots)$ that starts at z_n and is convergent to the cycle. Then, $(z_1, z_2, \ldots, z_n, y_1, y_2, \ldots)$ is in $\mathbf{N}_C(x)$ and coincides with the initial path on the first n components. Thus, the path ω can be approximated with paths in $\mathbf{N}_C(x)$.

Hence $\cup_x \mathbf{N}_C(x)$ is dense in X_∞, and this implies that $f = 0$. The contradiction yields the result. □

Remark 2.8: [Iteration of rational functions]

Let $r: \mathbb{S}^2 \to \mathbb{S}^2$ be a rational function viewed as an endomorphism of the Riemann sphere $\mathbb{S}^2$, or $\mathbb{C}^\infty = \mathbb{C} \cup \{\infty\}$; and suppose the degree of r is bigger than 2. Let $X = X(r)$ be the *Julia set* of r, i.e., X is the complement of the largest open subset $\mathcal{U}$ such that $\{r^n|_{\mathcal{U}} \,|\, n \geqslant 1\}$ is a normal family. It is known that X is non-empty, compact, and that (X,r) carries a unique strongly invariant probability measure; see Refs. 5 and 9.

Our present general result for cycles is motivated by the following specific theorems for rational mappings:

Let r be a rational mapping of degree at least 2.

- Let C be a p-cycle for r. Then C is repelling if and only if $|(r^p)'(z)| > 1$ for all $z \in C$. Moreover, $(r^p)'(z) = \Pi_{w\in C} r'(w)$, $z \in C$, so $(r^p)'$ has the same value for all points z on the cycle C.
- Every repelling cycle C lies in the Julia set X.
- The Julia set X is the closure of the repelling periodic points, see Ref. 25.

D. The scaling function

We now turn to a theorem which is analogous to the existence theorem for the scaling function in the classical theory of wavelets. As outlined in Ref. 10, the wavelet scaling function φ in $L^2(\mathbb{R})$ depends on a filter function m_0 with m_0 defined on $\mathbb{T}=\mathbb{R}/\mathbb{Z}$. In fact, in the wavelet theory, it is the Fourier transform $\hat{\varphi}$ which is an infinite product of scaled versions of m_0. As is well known, this representation requires that the function m_0 satisfies two conditions: one is called the *quadrature condition*, and the second is called the *low-pass* condition. Both of these conditions are motivated directly from the probabilistic interpretation that $|m_0|^2$ enjoys in signal processing.

In our theorem below we identify the analog of these two conditions for the function $m_0: X \to \mathbb{C}$ which is associated to an endomorphism $r: X \to X$. The quadrature condition takes the form (2.10), and the low-pass condition takes the form (2.11). The reason for the name quadrature is that $r(z)=z^2$ in the wavelet case, and the reason for the name low-pass, is that points on $\mathbb{T}=\mathbb{R}/\mathbb{Z}$ correspond to frequencies, and $x=0$ is the lowest frequency.

In the general setting of the endomorphism r, the analog of low frequencies are points in cycles C for r, and in this setting low-pass means that $|m_0|^2$ attains its maximum on C. This is exactly what condition (2.11) is saying.

In the case of endomorphism, we will therefore expect to represent a scaling function as an infinite product built out of m_0 and iterated shifts applied to m_0. The fact that this can be done is the main conclusion in the theorem.

Definition 2.9: A complex valued function f on a metric space X is called β-Lipschitz at a point x_0 if there is a non-decreasing function $\beta: [0,\infty) \to [0,\infty)$ such that for all $A>0$ and $c<1$,

$$\sum_{k=1}^{\infty} \beta(Ac^k) < \infty,$$

and

$$|f(x) - f(x_0)| \leq \beta(d(x,x_0)),$$

for all x in some neighborhood of x.

Definition 2.10: Let $W: X \to [0,1]$ be a given function, and set

$$R_W f(x) := \sum_{r(y)=x} W(y) f(y) \quad (x \in X).$$

We say that R_W is a *transfer operator*, or a *Ruelle operator*. A function h on X is said to be *harmonic* with respect to R_W if $R_W h = h$. A cycle C for r is said to be a W-cycle if $W(x)=1$ for all $x \in C$.

The operator in Definition 2.10 plays a role in many areas of mathematics and physics. Some of its recent uses are highlighted in Ref. 30, where it is key to Ruelle's thermodynamical formalism.

Lemma 2.11: There is a unique family of measures P_x supported on Ω_x, $x \in X$, satisfying the following relation: for all measurable sets $E \subset X_\infty$ and all $x \in X$,

$$\sum_{r(y)=x} W(y) P_y(\Omega_y \cap \hat{r}^{-1}(E)) = P_x(\Omega_x \cap E).$$

Proof: It is enough to define P_x on cylinder sets: for a fixed $(a_1, a_2, \ldots, a_n, \ldots) \in \Omega_x$ and $n \geq 2$,

$$E := \{(z_1, z_2, \ldots) \in \Omega_x | z_1 = a_1, \ldots, z_n = a_n\}.$$

Then $P_x(E \cap \Omega_x) = \prod_{k=1}^{n} W(a_k)$.

The extension of P_x to the sigma-algebra generated by the cylinder sets now follows from Kolmogorov's theorem. See Ref. 13 for more details.

Also, for $y \in r^{-1}(x)$, one has that $\hat{r}^{-1}(E) \cap \Omega_y$ is empty unless $y = a_1$, in which case $P_y(\hat{r}^{-1}(E) \cap \Omega_y) = \Pi_{k=2}^{n} W(a_k)$. The lemma follows. □

Lemma 2.12: The function $h_C(x) := P_x(\mathbf{N}_C(x))$ is harmonic with respect to R_W.

Proof: We have the following disjoint union $\cup_{r(y)=x} \mathbf{N}_C(y) = \hat{r}^{-1}(\mathbf{N}_C(x))$. The lemma follows then from Lemma 2.11. Indeed,

$$(R_W h_C)(x) = \sum_{r(y)=x} W(y) h_C(y) = \sum_{r(y)=x} W(y) P_y(\Omega_y \cap \mathbf{N}_C(y))$$

$$= \sum_{r(y)=x} W(y) P_y(\Omega_y \cap \hat{r}^{-1}\mathbf{N}_C(x)) = P_x(\Omega_x \cap \mathbf{N}_C(x)) = h_C(x).$$

□

Definition 2.13: We call $h_C(x) := P_x(\mathbf{N}_C(x))$ the harmonic function associated to the cycle C. See also Ref. 13 for more details.

In our next theorem, we prove that each repelling cycle C generates a covariant operator system on the corresponding Hilbert space $L^2(X_\infty, \lambda_C)$. Moreover, under two conditions on a given filter function m_0, we show that the corresponding scaling equation has a natural solution $\hat{\varphi}_C$ in $L^2(X_\infty, \lambda_C)$.

Theorem 2.14: *Assume now that the cycle C is repelling and the functions r and $x \mapsto \# r^{-1}(x)$ are continuous at the points in C. Let $m_0 \in L^\infty(X, \rho)$ be a function which is β-Lipschitz at the points in C and which satisfies the conditions*

$$\frac{1}{\# r^{-1}(x)} \sum_{y \in r^{-1}(x)} |m_0(y)|^2 = 1, \quad (x \in X), \tag{2.10}$$

and

$$m_0(x_i) = \alpha_i \sqrt{\# r^{-1}(r(x_i))}, \quad (i \in \{0, \ldots, p-1\}). \tag{2.11}$$

Define the function $\hat{\varphi}$ by

$$\hat{\varphi}(x, (z_k)_{k \geqslant 1}) := \prod_{k=1}^{\infty} \frac{\alpha_{i(\omega)+k}^{-1} m_0(z_k)}{\sqrt{\# r^{-1}(r(z_k))}}, \quad (x \in X, (z_k)_{k \geqslant 1} \in \mathbf{N}_C(x)). \tag{2.12}$$

Then $\hat{\varphi}$ is in $L^2(X_\infty, \lambda_C)$ and it satisfies the following relation:

$$U\hat{\varphi} = \pi(m_0)\hat{\varphi}. \tag{2.13}$$

If $W(x) := |m_0(x)|^2 / \# r^{-1}(r(x))$, then C is a W-cycle, and if h_C is the harmonic function associated to this W-cycle, then

$$\langle \pi(f)\hat{\varphi} | \hat{\varphi} \rangle = \int_X f h_C d\rho. \tag{2.14}$$

Set $V_0 := \overline{\{\pi(f)\hat{\varphi} | f \in L^\infty(X, \rho)\}}^{L^2}$, and $V_n := U^{-n} V_0$, for $n \in \mathbb{Z}$. Then $V_n \subset V_{n+1}$,

$$\overline{\cup_{n \in \mathbb{Z}} V_n} = L^2(X_\infty, \lambda_C), \quad \cap_{n \in \mathbb{Z}} V_n = \{0\}.$$

Proof: First we check that the infinite product (2.12) is convergent. Take $x \in X$, $\omega = (z_1, z_2, \ldots) \in \mathbf{N}_C(x)$. Then the sequence $\{z_{kp}\}$ converges to one of the points of the cycle C,

namely $x_{i(\omega)}$. Applying r, which is continuous at these points, we obtain that, for all l, the sequence $\{z_{kp+l}\}$ is convergent to $x_{i(\omega)+l}$.

Now we use the fact that the cycle is repelling. For k large enough, the path ω enters the neighborhood where the cycle is repelling (see Definition 2.3). Therefore, there are constants $0<c_l<1$, $0\leqslant m_l<\infty$ such that for k large enough $d(z_{kp+l},x_{i(\omega)+l})\leqslant c_l^k m_l$, for all $l\in\{0,\dots,p-1\}$. Take $c=\max\{\sqrt[p]{c_l}\}\in(0,1)$ and $M:=c^{-p}\max\{m_l\}$. Then for k large enough

$$d(z_k,x_{i(\omega)+k})\leqslant c^k M.$$

Since the function $\#r^{-1}(r(\cdot))$ is continuous at the points of the cycle, we get that for k large, $\#r^{-1}(r(z_k))=\#r^{-1}(r(x_{i(\omega)+k}))=:A_k\geqslant 1$.

Let β be the function given by the β-Lipschitz condition for m_0 at all the points of the cycle (Take the minimum of these functions over all the points of the cycle). Using the condition (2.11), we have

$$\left|\frac{\alpha_{i(\omega)+k}^{-1}m_0(z_k)}{\sqrt{\#r^{-1}(r(z_k))}}-1\right|=\frac{1}{\sqrt{A_k}}|m_0(z_k)-m_0(x_{i(\omega)+k})|$$

$$\leqslant\beta(d(z_k,x_{i(\omega)+k}))\leqslant\beta(c^kM).$$

This implies that the sum over the terms on the left-hand side of this inequality is convergent, which in turn implies that the infinite product is absolutely convergent.

Next we check (2.14). It is clear that C is a W-cycle. Also note that

$$|\hat{\varphi}(x,(z_k)_{k\geqslant 1})|^2=\prod_{k=1}^{\infty}W(z_k)=P_x(\{(z_k)_{k\geqslant 1}\}).$$

(See Ref. 13). Then

$$h_C(x)=P_x(\mathbf{N}_C(x))=\sum_{\omega\in\mathbf{N}_C(x)}|\hat{\varphi}(x,\omega)|^2, \tag{2.15}$$

and Eq. (2.14) follows. Since $h_C\leqslant 1$, this also implies that $\hat{\varphi}$ is in $L^2(X_\infty,\lambda_C)$.

We check Eq. (2.13). For $\omega=(z_1,z_2,\dots)\in\mathbf{N}_C(x)$,

$$U\hat{\varphi}(x,\omega)=\sqrt{\#r^{-1}(r(x))}\,\alpha_{i(\omega)}\prod_{k=1}^{\infty}\frac{\alpha_{i(\hat{r}(\omega))+k}^{-1}m_0(z_{k-1})}{\sqrt{\#r^{-1}(r(z_{k-1}))}}$$

$$=\sqrt{\#r^{-1}(r(x))}\,\alpha_{i(\omega)}\frac{\alpha_{i(\omega)}^{-1}m_0(x)}{\sqrt{\#r^{-1}(r(x))}}\prod_{k=2}^{\infty}\frac{\alpha_{i(\omega)+k-1}^{-1}m_0(z_{k-1})}{\sqrt{\#r^{-1}(r(z_{k-1}))}}=m_0(x)\hat{\varphi}(x,\omega).$$

The scaling equation (2.13) and the covariance equation (2.8) imply that $V_{-1}\subset V_0$. This implies that the sequence of subspaces $\{V_n\}$ is increasing.

To check that their union is dense, we note that the closure of this union is invariant for U and for $\pi(f)$, $f\in L^\infty(X,\rho)$. Therefore the projection P onto this space is in the commutant $\{U,\pi\}'$. But, then, with Proposition 2.2, we obtain a function F in $L^\infty(X_\infty,\lambda_C)$ such that $F=F\circ\hat{r}$ and $P=M_F$. In particular, $F\hat{\varphi}=\hat{\varphi}$ and F is the characteristic function of some set $\mathcal{F}$ which is invariant for $\hat{r}$.

However, the previous argument shows that, if $\omega=(z_1,z_2,\dots)\in\mathbf{N}_C(x)$ has z_i close enough to the cycle C, for all $i\geqslant 1$, then $\hat{\varphi}(x,\omega)$ is close to 1. Now, take $\omega=(z_1,z_2,\dots)\in\mathbf{N}_C(x)\setminus\mathcal{F}$. Then $\hat{r}^{-n}(\omega)$ is outside $\mathcal{F}$. Because $\omega\in\mathbf{N}_C(x)$, for n large enough, all the points $z_{n+1},z_{n+2},\dots$ are close to the cycle, so $\hat{\varphi}(\hat{r}^{-n}(\omega))$ is close to 1. But $\hat{\varphi}(\hat{r}^{-n}(\omega))=\hat{\varphi}(\hat{r}^{-n}(\omega))\chi_{\mathcal{F}}(\hat{r}^{-n}(\omega))=0$, a contradiction. It follows that $\mathcal{F}$ has complement of measure 0 so $P=M_F$ is the identity, and therefore the union of the multiresolution subspaces is dense.

It remains to check that the intersection $\cap V_n$ is trivial. We use the following lemma:

Lemma 2.15: Define $\mathcal{J}: L^2(X, h_C d\rho) \to V_0$ *by*

$$\mathcal{J}(f) = \pi(f)\hat{\varphi}, \quad (f \in L^\infty(X,\rho)).$$

Define the operator S_0 *on* $L^2(X, h_C d\rho)$ *by* $S_0 f = m_0 f \circ r$. *Then* $\mathcal{J}$ *is an isometric isomorphism such that* $U\mathcal{J} = \mathcal{J}S_0$.

The proof of the lemma requires just some simple computations. The fact that S_0 is an isometry is proved in Theorem 3.9.

With this lemma, the assertion follows from Theorem 3.9. □

Let $(X, \mathfrak{B}, \rho)$ be a measure space with ρ some fixed probability measure defined on the sigma-algebra $\mathfrak{B}$ on X. Let π be a representation of $L^\infty(X, \mathfrak{B})$ on a Hilbert space $\mathcal{H}$, and suppose that the measure $f \mapsto \langle \pi(f)\psi | \psi \rangle$ is absolutely continuous with respect to ρ for all $\psi \in \mathcal{H}$, i.e., there exists $h_\psi \in L^1(X, \mathfrak{B})$ such that $\langle \pi(f)\psi | \psi \rangle = \int_X f h_\psi d\rho$, $f \in L^\infty(X, \mathfrak{B})$.

By the spectral multiplicity theorem (Refs. 2, 15, and 31), there is a measurable function $d: X \to \{1, 2, \ldots, \infty\}$ such that if $X_k := \{x \in X | d(x) \geqslant k\}$, then the spectral representation of π takes the form of an isometric isomorphism $\mathcal{J}: \mathcal{H} \to \Sigma^{\oplus}_{k \in \mathbb{N}} L^2(X_k, \mathfrak{B}, \rho)$, such that $\mathcal{J}_k \pi(f)\psi = f \mathcal{J}_k \psi = M_f \mathcal{J}_k \psi$ for all $f \in L^\infty(X, \mathfrak{B})$ and all $\psi \in \mathcal{H}$.

We say that d is the *multiplicity function* of the representation π.

Corollary 2.16: Let $V_0 \subset L^2(X_\infty, \lambda_C)$, *be the subspace from Lemma 2.15 and Theorem 2.14, and let* π_n, $n \in \mathbb{N}$, *be the restriction of the representation* π *of* $L^\infty(X, \mathfrak{B})$ *to* $U^{-n}V_0$. *Then*

$$d_{U^{-n}V_0}(x) = \#\left(r^{-n}(x) \cap \{z \in X | h_C(z) \neq 0\}\right) \quad (x \in X).$$

Proof: Since $\langle \pi(f)\hat{\varphi} | \hat{\varphi} \rangle = \int_X f h_C d\rho$, it follows that $d_{V_0}(x) = \chi_{\{z \in X | h_C(z) \neq 0\}} =: \chi_{E_C}$.

From Ref. 12, we know that

$$d_{U^{-n}V_0}(x) = \sum_{r^n(y)=x} d_{V_0}(y) = \sum_{r^n(y)=x} \chi_{E_C}(y) = \#\left(r^{-n}(x) \cap E_C\right).$$

□

Example 2.17: Let A be a square matrix with $0-1$ entries. Suppose every column of A contains at least one entry 1. Then we show that the two systems $(X_\infty, \hat{r})$ and (X, r) may be realized as two-sided, respectively one-sided subshifts.

Let I be the index set for the rows and columns of A. Let

$$X_\infty(A) := \{(x_i)_{i \in \mathbb{Z}} \in I^{\mathbb{Z}} | A(x_i, x_{i+1}) = 1\}.$$

Let

$$\hat{r}((x_i)_{i \in \mathbb{Z}}) = (x_{i+1})_{i \in \mathbb{Z}}.$$

Define $\theta_0((x_i)_{i \in \mathbb{Z}}) = (x_i)_{i \geqslant 0}$, and set $X(A) = \theta_0(X_\infty(A))$.

Then there is an endomorphism $r = r_A: X(A) \to X(A)$ such that $r \circ \theta_0 = \theta_0 \circ \hat{r}$.

Specifically,

$$x = (x_i)_{i \in \mathbb{Z}} = \ldots x_{-2}x_{-1}x_0x_1x_2 \ldots$$

with $x_i \in I$;

$$\theta_0((x_i)_{i \in \mathbb{Z}}) = (x_i)_{i \geqslant 0} = x_0x_1x_2 \ldots;$$

and $r(x_0x_1x_2\ldots) = (x_1x_2x_3\ldots)$ for $x \in X(A)$.

For $x, y \in X(A)$, let $x \wedge y$ be the longest initial block in $I \times I \times \cdots$ common to both x and y, and let $|x \wedge y|$ be the length of this block. Let $0 < c < 1$, and set $d_c(x, y) = c^{|x \wedge y|}$. Then d_c is a metric, and $(X(A), d_c)$ is a compact metric space whose open sets are generated by the cylinder sets in $X(A)$.

Moreover, $d_c(r(x),r(y)) \leqslant c^{-1}d_c(x,y)$ holds for all $x,y \in X(A)$. If $x \in X(A)$, then $r^{-1}(x) = \{(ix) \mid A(i,x_0)=1\}$, and for the transfer operator $\mathcal{L}_A : C(X(A)) \to C(X(A))$,

$$(\mathcal{L}_A f)(x) = \frac{1}{\#r^{-1}(x)} \sum_{r(y)=x} f(y),$$

we have

$$(\mathcal{L}_A f)(x) = \frac{1}{\#\{i \mid A(i,x_0)=1\}} \sum_{A(i,x_0)=1} f(ix).$$

By Ref. 24, Chap. 2, there is a unique probability measure $\rho=\rho_A$ on $X(A)$ such that $\rho(\mathcal{L}_A f) = \rho(f)$ for all $f \in C(X(A))$; i.e., $\rho=\rho_A$ is the unique strongly invariant probability measure on $X(A)$.

It follows that all the results in this setting apply; in particular, if $C \subset X(A)$ is a cycle, then $L^2(X_\infty(A),\lambda_C)$ is defined by

$$\int_{X_\infty(A)} |f|^2 d\lambda_C = \int_{X(A)} \sum_{\omega \in \mathbf{N}_C(x)} |f(\omega)|^2 d\rho(x) < \infty .$$

Note also that $\mathbf{N}_C(x)$ consists of doubly infinite words in $X_\infty(A)$ that start with an infinite repetition of the cycle C. Specifically, for $x=(x_0x_1x_2\ldots) \in X(A)$, $\mathbf{N}_C(x)=\{(\omega_i)_{i\in\mathbb{Z}} \in X_\infty(A) \mid \exists k \in \mathbb{N}$ such that $(\omega_I)_{i\leqslant -k}$ is C^∞, $(\omega_i)_{-k<i\leqslant -1}$ is some finite word, and $\omega_i=x_i$ for $i \geqslant 0\}$.

We now turn to a concrete example. Let the index set I be $\{1,2\}$ and let $A=\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$. This is called the golden mean shift (see Ref. 22, p. 37).

Proposition 2.18: Let m_0 be the function on $X(A)$ determined by

$$m_0(11\ldots)=\sqrt{2}, \quad m_0(21\ldots)=0, \quad m_0(12\ldots)=1, \tag{2.16}$$

and C be the cycle $\{111\ldots\}$. Then m_0 satisfies (2.10) *and* (2.11) *and defines a scaling vector $\hat{\varphi} \in L^2(X_\infty,\lambda_C)$ with $h_C=1$.*

Proof: It is easy to verify the two conditions (2.10) and (2.11). The scaling function $\hat{\varphi}$ is defined by the infinite product (2.12). (We set $\alpha_i=1$.) If ω is in $\mathbf{N}_C(x_0x_1\ldots)$, then it has the form $\ldots 111x_{-n}x_{-n+1}\ldots x_{-1}x_0x_1\ldots$. Note that if one of the letters x_{-k} is 2 ($k \geqslant 1$) then the next one has to be 1. Therefore, shifting the word to the right will bring the 21 to the central position, and m_0 is 0 on words that start with 21. Therefore the infinite product is non-zero only when $x_{-k}=1$ for all $k \geqslant 1$. Then, an analysis of the possibilities for x_0 shows that $\hat{\varphi}$ is 1 in this case.

Therefore $\hat{\varphi}(\omega)=1$, if $x_{-k}=1$ for all $k \geqslant 1$, and $\hat{\varphi}(\omega)=0$ otherwise.

Then by (2.15)

$$h_C(x_0x_1\ldots) = \sum_{\omega \in \mathbf{N}_C(x_0x_1\ldots)} |\hat{\varphi}(\omega)|^2 = 1.$$

An interesting consequence of (2.10) and (2.11) for this example is that an admissible m_0 cannot be of the form $m_0=\sqrt{2}\chi_E$ for a subset E of $X(A)$ (because $|m_0(21\ldots)|^2=1$). This contrasts a known wavelet, the Shannon wavelet, see Refs. 17 and 1. □

III. ERGODIC PROPERTIES AND THE WOLD DECOMPOSITION

In our analysis of the intersection of the multiresolution spaces V_n, we are forced to study some convergence properties for the measure ρ and the filter m_0. The main tool in this study will be Doob's convergence theorems for reversed martingales, see e.g., Ref. 27.

Even though we are mainly interested in the strongly invariant measure ρ, our analysis works in the following more general case.

Definition 3.1: Let $V \geqslant 0$ be a measurable function on X such that

$$\sum_{r(y)=x} V(y) = 1 \quad (x \in X).$$

A probability measure ν on X such that

$$\int_X f d\nu = \int_X \sum_{r(y)=x} V(y) f(y) d\nu(x) \quad (f \in L^1(X,\nu)) \tag{3.1}$$

is called a Perron-Frobenius measure for the corresponding Ruelle operator

$$(R_V f)(x) := \sum_{r(y)=x} V(y) f(y) \quad (x \in X).$$

For example, when $V(x) = 1/\#r^{-1}(r(x))$, then (3.1) is equivalent to the strong invariance of ν.

Note that a Perron-Frobenius measure ν is also invariant for r, because

$$\int_X f \circ r d\nu = \int_X \sum_{r(y)=x} V(y) f(r(y)) d\nu(x) = \int_X f(x) \sum_{r(y)=x} V(y) d\nu(x) = \int_X f d\nu.$$

Let $\mathfrak{B}$ be the sigma-algebra of measurable subsets of X.

Definition 3.2: Let $\mathfrak{B}$ be a sigma-algebra on X and let ν be a probability measure on $(X,\mathfrak{B})$. Let $\mathfrak{C} \subset \mathfrak{B}$ be a sub-sigma-algebra. Then the $\mathfrak{C}$-conditional expectation $E_{\mathfrak{C}}$ is defined by

$$\int_X E_{\mathfrak{C}} f g d\nu = \int_X f g d\nu,$$

for $f \in L^1(\mathfrak{B},\nu)$, $g \in L^\infty(\mathfrak{C})$; and $E_{\mathfrak{C}} L^1(\mathfrak{B},\nu) = L^1(\mathfrak{C},\nu)$.

Proposition 3.3: The operator E_n^V defined on $L^1(X,\nu)$ by

$$E_n^V(f)(x) = \sum_{r^n(y)=r^n(x)} V^{(n)}(y) f(y) \quad (x \in X),$$

defines the conditional expectation of $\mathfrak{B}$ with respect to $r^{-n}(\mathfrak{B})$.

Proof: First note that if a function g on X is $r^{-n}(\mathfrak{B})$-measurable, then $g(x) = g(y)$ whenever $r^n(x) = r^n(y)$. Take now $g \in L^2(r^{-n}(\mathfrak{B}))$ and $f \in L^1(\mathfrak{B})$. Using the invariance of ν and (3.1), we have

$$\int_X E_n^V(f) g d\nu = \int_X \sum_{r^n(x)=r^n(y)} V^{(n)}(y) f(y) g(x) d\nu(x)$$

$$= \int_X \sum_{r^n(y)=x} V^{(n)}(y) f(y) g(y) d\nu(x) = \int_X f g d\nu.$$

This shows that E_n^V is the conditional expectation. □

We note the relation between the Ruelle operator R_V and the conditional expectation E_n^V:

$$E_n^V(f) = (R_V^n) \circ r^n \quad (n \geqslant 1, f \in L^1(X,\nu)). \tag{3.2}$$

The sigma-algebras $r^{-n}(\mathfrak{B})$ form a decreasing sequence, and we denote their intersection by $\mathfrak{B}_\infty$. Denote by E_∞^V the conditional expectation of $\mathfrak{B}$ with respect to $\mathfrak{B}_\infty$. Doob's theorems for reverse martingales can be applied now directly and we obtain the following theorem:

Theorem 3.4: *If $f \in L^p(X,\nu)$, $(1 \leqslant p < \infty)$, then $E_n^V(f)$ converges pointwise ν-a.e. and in $L^p(X,\rho)$ to $E_\infty^V(f)$.*

Definition 3.5: We say that r is *averaging* (with respect to the measure ν), if $L^1(\mathfrak{B}_\infty)$ contains only functions which are constant ν-a.e., (or, equivalently, the sigma-algebra $\mathfrak{B}_\infty$ contains only sets of ν-measure 0 or 1).

Proposition 3.6: If r is averaging with respect to ν then it is also ergodic with respect to ν.

Proof: If A is a completely invariant set for r then, for any two points x,y such that $r^n(x)=r^n(y)$ for some $n\geqslant 0$ $\chi_A(x)=\chi_A(r^n(x))=\chi_A(r^n(y))=\chi_A(y)$, so $\chi_A\in L^1(\mathfrak{B}_\infty)$, therefore $\nu(A)$ is 0 or 1. □

Corollary 3.7: If r is averaging with respect to ν, then for all $f\in L^p(X,\nu)$, $1\leqslant p<\infty$, the sequence $E_n^V(f)$ converges pointwise ν-a.e. and in $L^p(X,\nu)$ to $\int_X f d\nu$.

Next, we will derive an ergodic property for a function m_0 satisfying (2.10).

Theorem 3.8: *Assume that the strongly invariant measure ρ is ergodic with respect to r. Let $m_0\in L^\infty(X,\rho)$ be a function that satisfies* (2.10) *and such that $|m_0|\neq 1$ on a set of positive measure. Then*

$$A := \int_X \ln|m_0(x)|d\rho(x) \in [-\infty,0).$$

Then

$$\lim_{n\to\infty}|m_0(x)\cdots m_0(r^{n-1}(x))|^{\frac{1}{n}}=e^A \quad \textit{for } \rho\text{-a.e. } x\in X.$$

Proof: We have, using the strong invariance of ρ:

$$\begin{aligned}\int_X \ln|m_0(x)|d\rho(x)&=\frac{1}{2}\int_X \ln|m_0(x)|^2 d\rho(x)=\int_X \frac{1}{\#r^{-1}(x)}\sum_{r(y)=x}\ln|m_0(y)|^2 d\rho(x)\\&=\int_X \ln\Big(\prod_{r(y)=x}|m_0(y)|^2\Big)^{1/\#r^{-1}(x)}d\rho(x)\\&\leqslant\int_X \ln\Big(\frac{1}{\#r^{-1}(x)}\sum_{r(y)=x}|m_0(y)|^2\Big)d\rho(x)=\int_X \ln(1)=0.\end{aligned}$$

If we have equality in this chain, then we get that for ρ-a.e., $x\in X$, $|m_0(y)|=|m_0(y')|$ for all $y,y'\in r^{-1}(x)$, which implies that

$$1=\frac{1}{\#r^{-1}(r(x))}\sum_{r(y)=r(x)}|m_0(y)|^2=|m_0(x)|,\quad \text{for a.e. } x.$$

This contradicts the hypothesis. Thus $A\in[-\infty,0)$.

Assume now, that $A>-\infty$. Then, using Birkhoff's ergodic theorem, we obtain that

$$\lim_{n\to\infty}\ln\Big(\frac{|m_0(x)\cdots m_0(r^{n-1}(x))|^{1/n}}{e^A}\Big)=\lim_{n\to\infty}\frac{1}{n}\sum_{k=0}^{n-1}\ln|m_0(r^k(x))|-A$$

$$=\int_X \ln|m_0(x)|d\rho(x)-A=0.$$

This yields the conclusion in the case $A>-\infty$.

When $A=-\infty$, take $0>B>-\infty$ arbitrary and choose a bounded measurable function f, with $|f|\geqslant|m_0|$ and such that $-\infty<\int_X\ln|f(x)|\,d\rho(x)=B$. Then apply the previous argument to conclude that $|f(x)f(r(x))\cdots f(r^{n-1}(x))|^{1/n}$ converges a.e. to e^B. Then

$$\limsup_n|m_0(x)\cdots m_0(r^{n-1}(x))|^{1/n}\leqslant e^B$$

and, as B is arbitrary this implies that the limit is $e^{-\infty}=0$. □

With these results, we are now able to derive the result about the Wold decomposition[31] of the isometry S_0 associated to m_0.

Theorem 3.9: *Let ρ be a strongly invariant measure for r. Let $m_0 \in L^\infty(X,\rho)$ be a function that satisfies* (2.10). *Let $h \in L^\infty(X,\rho)$ be a function such that $h \geqslant 0$ and*

$$\frac{1}{\#r^{-1}(x)} \sum_{r(y)=x} |m_0(y)|^2 h(y) = h(x) \quad (x \in X). \tag{3.3}$$

Then the operator S_0 on $L^2(X,hd\rho)$ defined by

$$S_0 f = m_0 f \circ r$$

is an isometry.

Assume in addition that r is averaging with respect to ρ, and that $|m_0| \neq 1$ on a set of positive measure ρ. Then

$$\cap_{k \geqslant 1} S_0^k (L^2(X,hd\rho)) = \{0\}.$$

Proof: The fact that S_0 is an isometry follows from the fact that ρ is strongly invariant and from the relation (3.3):

$$\int_X |m_0(x)|^2 |f(r(x))|^2 h(x) d\rho(x) = \int_X \frac{1}{\#r^{-1}(x)} \sum_{r(y)=x} |m_0(y)|^2 |f(r(y))|^2 h(y) d\rho(x)$$

$$= \int_X |f(y)|^2 d\rho(x).$$

Denote by

$$c(x) := \frac{1}{\#r^{-1}(r(x))} \quad (x \in X).$$

Note that

$$R_{m_0}^k f(x) = \sum_{r^k(y)=x} c^{(k)}(y) |m_0^{(k)}(y)|^2 f(y),$$

where R_{m_0} is the Ruelle operator associated to $W(x) := |m_0(x)|^2 / \#r^{-1}(r(x))$.

In particular

$$\sum_{r^k(y)=x} c^{(k)}(y) |m_0^{(k)}(y)|^2 = 1.$$

Take now $\xi \in \cap_k S_0^k (L^2(X,hd\rho))$. Then for all $k \geqslant 1$, there exists $f_k \in L^2(X,hd\rho)$ such that $\xi = m_0^{(k)} f_k \circ r^k$. This implies that for all $x \in X$:

$$|\xi(x)|^2 = |m_0^{(k)}(x)|^2 |f_k(r^k(x))|^2 \sum_{r^k(y)=r^k(x)} c^{(k)}(y) |m_0^{(k)}(y)|^2$$

$$= |m_0^{(k)}(x)|^2 \sum_{r^k(y)=r^k(x)} c^{(k)}(y) |m_0^{(k)}(y) f_k(r^k(y))|^2$$

$$= |m_0^{(k)}(x)|^2 \sum_{r^k(y)=r^k(x)} c^{(k)}(y) |\xi(y)|^2$$

$$= |m_0^{(k)}(x)|^2 E_k^c(|\xi|^2).$$

With Theorem 3.8 and Corollary 3.7, if we let $k \to \infty$, we can conclude that $\xi = 0$, ρ-a.e. This proves the theorem. □

Remark 3.10: It is conceivable that the last conclusion in Theorem 3.9 above may hold slightly more generally; possibly when only ergodicity is assumed for (X, r, ρ). But for the applications we have in mind, our present assumption of strong invariance is appropriate, i.e., the averaging assumption we place on the system (X, r, ρ).

Some conditions for r to be averaging. We will give some necessary conditions for r to averaging. For this we will relate the expectation E_V^n to the Ruelle operator R_V.

Just as before, assume $V \geqslant 0$ is a measurable function such that

$$\sum_{r(y)=x} V(y) = 1 \quad (x \in X),$$

and let ν be a measure such that

$$\int_X R_V f d\nu = \int_X f d\nu.$$

Proposition 3.11: Suppose there exists a family of functions $\mathcal{F}$ which is dense in $L^1(X, \nu)$ such that for all $f \in \mathcal{F}$,

$$\lim_{n\to\infty} \left\| R_V^n(f) - \int_X f d\nu \right\|_1 = 0.$$

Then, for all $f \in L^1(X, \nu)$.

$$\lim_{n\to\infty} R_V^n(f) = \int_X f d\nu = E_\infty^V(f).$$

In particular r is averaging with respect to ν.

Proof: Take $f \in L^1(X, \nu)$, and $\epsilon > 0$. There exists $g \in \mathcal{F}$, such that $\|f - g\|_1 < \epsilon$. Then, using the fact that ν is invariant for r, and also for R_V, we have, with the aid of (3.2):

$$\left\| E_n^V(f) - \int_X f d\nu \right\|_1 = \left\| R_V^n f - \int_X f d\nu \right\|_1$$

$$\leqslant \|R_V^n(f-g)\|_1 + \left\| R_V^n g - \int_X g d\nu \right\|_1 + \left\| \int_X (g-f) d\nu \right\|_1$$

$$\leqslant 2\|f-g\|_1 + \left\| R_V^n g - \int_X g \right\|_1 < 3\epsilon,$$

for n large enough. This proves the first assertion. Since $E_\infty^V(f)$ is constant for all $f \in L^1(X, \nu)$, it follows that $L^1(\mathfrak{B}_\infty)$ contains only constant functions so r is averaging. □

Remark 3.12: The conditions of Proposition 3.11 are satisfied in many cases of interest. This is a consequence of Ruelle's theorem (see Refs. 3 and 14). For example, if r is locally expanding (i.e., there exists $b > 0$ and $\lambda > 1$ such that $d(r(x), r(y)) \geqslant \lambda d(x, y)$ when $d(x, y) < b$), and mixing (i.e., for every open set U in X, there exists n such that $r^n(U) = X$), and if $V > 0$ and is Lipschitz, then $\mathcal{F}$ can be taken to be the set of continuous functions, and $R_V^n f$ converges uniformly to $\int_X f d\nu$, where ν is the unique probability measure invariant for R_V.

In particular, this is satisfied, for subshifts of finite type.

Also, consider the case when r is a rational map on $\mathbb{C}$ and X is its Julia set. Take $V=1/N$ where N is the degree of the map r. Then $\nu=\rho$ is the unique strongly invariant measure and we may take again $\mathcal{F}$ to be the set of continuous functions (see Ref. 23).

Given our assumptions above, the existence and the uniqueness of the measure ν follows from the conclusion in Ruelle's theorem, applied to R_V.

(Received 6 February 2006; accepted 21 March 2006; published online 9 May 2006)

Vertex algebras in higher dimensions, introduced previously by Nikolov, provide an algebraic framework for investigating axiomatic quantum field theory with global conformal invariance. We develop further the theory of such vertex algebras by introducing formal calculus techniques and investigating the notion of polylocal fields. We derive a Jacobi identity which together with the vacuum axiom can be taken as an equivalent definition of vertex algebra. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2197687]

I. INTRODUCTION

Two-dimensional conformal field theory is important in physics as providing models of quantum field theory (QFT). It also plays a role in other areas of mathematical physics as well as in statistical physics and condensed matter physics. A *vertex algebra* is essentially the same as a *chiral algebra* in conformal field theory (see Refs. 7 and 20 and Ref. 12). In more details, the field content in two-dimensional conformal field theories splits into two chiral parts consisting of fields that depend separately on one of the two light-cone variables. Observable chiral fields have commutators supported on the diagonal, i.e., vanishing for noncoinciding arguments. It turns out that chiral fields form a purely algebraic structure under their *operator product expansion*, which is called a vertex algebra. Axiomatically, the notion of vertex algebra was first introduced by Borcherds.[8] Vertex algebras arose naturally in the representation theory of infinite-dimensional Lie algebras and in the construction of the "moonshine module" for the Monster finite simple group.[8,19] Now the theory of vertex algebras is a rapidly developing area of mathematics (see Refs. 19, 21, 17, and 24). "Multidimensional" generalizations of vertex algebras were considered in Refs. 9, 23, 26, and 28.

The vertex algebras introduced in Ref. 28 for higher space–time dimension arose naturally within a one-to-one correspondence with axiomatic QFT models satisfying the additional symmetry condition of *global conformal invariance* (GCI). The incorporation of GCI within the framework of axiomatic QFT, together with the problem of finding (nonperturbatively) such models in higher dimensions, has been studied previously in, e.g., Refs. 31, 30, 32, and 29 [see also the groundbreaking early work (Ref. 34)]. In this way constructing models of higher-dimensional QFT with GCI becomes a purely algebraic problem. Let us point out that even for general QFT (without GCI) there are not any known models that satisfy the Wightman axioms in space–time dimension greater or equal to 4, which cannot be realized by free or generalized free (Heisenberg) fields. In fact, this problem has remained open for more than 50 years.

On the other hand, even in dimension one (i.e., in chiral conformal field theory), vertex algebras are far from full classification and are quite intricate in general. A different algebraic structure known as a *vertex Lie algebra* has been introduced by Kac[21] (see also Refs. 33, 17, and 14) (it is also called a "conformal algebra" but we will not use this terminology here since it can be confused with the usual conformal Lie algebra in higher dimensions). This is the structure formed by the commutators of fields, i.e., by the singular part of their operator product expansion. Thus the relationship between vertex Lie algebras and vertex algebras is somewhat similar to the relationship between Lie algebras and associative algebras. It turns out that this new algebraic structure is more tractable and, in particular, classification results for vertex Lie (super)algebras can be obtained[11,15] (see also Refs. 21 and 22). The theory of vertex Lie algebras was further developed in, e.g., Refs. 10 and 4, and a "multidimensional" generalization was considered in Ref. 1.

In the present paper we initiate an investigation of the notion of vertex Lie algebra for the vertex algebras in higher dimensions of Ref. 28. In dimension one, the main axiom for vertex Lie algebras is the so-called *Jacobi identity*, which is related to the Jacobi identity of Ref. 19 for vertex algebras (and the Borcherds identity of Ref. 21). Recall that in dimension one vertex algebras can be defined in terms of the Jacobi identity (see Refs. 19, 18, 21, and 24). The main result of the present paper is a generalization of this Jacobi identity to higher dimensions. In addition, we show that together with the vacuum axiom this identity can be taken as a definition of vertex algebra equivalent to the definition of Ref. 28.

As in dimension one, we derive our Jacobi identity from certain "commutativity" and "associativity" identities (cf. Refs. 18, 25, 2, and 24). However, in the one-dimensional case the Jacobi identity can be simplified so that it does not involve external sufficiently large parameters. This is no longer the case in higher dimensions, and our Jacobi identity entails the same degree of difficulty as the "associativity" identity. The main difference with the one-dimensional case is that now the singular part of the operator product expansion contains infinitely many terms. Nevertheless, it follows from our Jacobi identity that the singular modes close an algebraic structure under the commutator, which would be the higher-dimensional analog of vertex Lie algebra.

The paper is organized as follows. The next two sections are devoted to an important technical preparation, which can be useful not only for this work but also for future investigations of vertex algebras in higher dimensions. This includes an introduction of several spaces of *formal series* in Sec. II and a higher-dimensional *residue functional* in Sec. III (additional material is contained in the Appendix). In Sec. IV we recall the notions of fields, locality and operator product expansion in higher dimensions, mainly following Ref. 28, but extending our considerations also to *polylocal fields*. Our main result, the *Jacobi identity*, is contained in Sec. V, together with several integral versions and a *commutator formula*. Concluding remarks are presented in Sec. VI.

II. SPACES OF FORMAL SERIES

In this section we introduce various spaces of formal series, which will be used throughout the paper. In particular, we define the notion of a formal distribution, and we discuss formal series expansions.

A. Notation

In this section we fix some notation to be used throughout the paper, mostly following the notation of Ref. 28. We fix a positive integer D, which will play the role of *space–time dimension*, and we denote by z, z_i, w, etc., D-component variables,

$$\mathrm{z} = (z^1, \dots, z^D), \quad \mathrm{z}_i = (z_i^1, \dots, z_i^D), \quad \mathrm{w} = (w^1, \dots, w^D). \tag{2.1}$$

We will denote by z_{ij} the difference

$$\mathrm{z}_{ij} := \mathrm{z}_i - \mathrm{z}_j = (z_i^1 - z_j^1, \dots, z_i^D - z_j^D), \tag{2.2}$$

and not a new variable. We introduce the standard scalar product,

$$\mathrm{z}_1 \cdot \mathrm{z}_2 := \sum_{\alpha=1}^{D} z_1^\alpha z_2^\alpha, \quad \mathrm{z}^2 := \mathrm{z} \cdot \mathrm{z}. \tag{2.3}$$

Note that z^2 stands for the Euclidean square of the vector z, while z^2 is its second component.

For concreteness we will work over the field $\mathbb{C}$ of complex numbers, even though all of our results hold over an arbitrary field of characteristic 0. For a vector space V, let $V[\mathrm{z}]$ (respectively, $V[\![\mathrm{z}]\!]$) be the space of polynomials (respectively, formal power series) in z with coefficients in V. For a one-component variable ϱ, we denote by $V[\![\varrho, \varrho^{-1}]\!]$ the space of formal power series in ϱ and ϱ^{-1} with coefficients in V, and by $V[\![\varrho]\!]_\varrho \equiv V[\![\varrho]\!][\varrho^{-1}]$ the space of formal Laurent series involving finitely many negative powers of ϱ.

Note that $V[\mathrm{z}]$ is a $\mathbb{C}[\mathrm{z}]$-module and $V[\![\mathrm{z}]\!]$ is a $\mathbb{C}[\![\mathrm{z}]\!]$-module. We denote by $\mathbb{C}[\mathrm{z}]_{\mathrm{z}^2}$ (respectively, $\mathbb{C}[\![\mathrm{z}]\!]_{\mathrm{z}^2}$) the localization of $\mathbb{C}[\mathrm{z}]$ (respectively, $\mathbb{C}[\![\mathrm{z}]\!]$) with respect to the multiplicative system $\{(\mathrm{z}^2)^k\}_{k=1,2,\ldots}$. Let $V[\mathrm{z}]_{\mathrm{z}^2}$ and $V[\![\mathrm{z}]\!]_{\mathrm{z}^2}$ be the localizations of the corresponding modules. Then $V[\mathrm{z}]_{\mathrm{z}^2}$ (respectively, $V[\![\mathrm{z}]\!]_{\mathrm{z}^2}$) is a module over $\mathbb{C}[\mathrm{z}]_{\mathrm{z}^2}$ (respectively, $\mathbb{C}[\![\mathrm{z}]\!]_{\mathrm{z}^2}$).

We introduce the formal derivatives on $V[\mathrm{z}]$ and $V[\![\mathrm{z}]\!]$,

$$\partial_{\mathrm{z}} := (\partial_{z^1}, \ldots, \partial_{z^D}), \quad \partial_{z^\alpha} := \frac{\partial}{\partial z^\alpha}, \tag{2.4}$$

and the Euler and Laplace operators

$$\mathrm{z} \cdot \partial_{\mathrm{z}} = \sum_{\alpha=1}^{D} z^\alpha \partial_{z^\alpha}, \quad \partial_{\mathrm{z}}^2 = \sum_{\alpha=1}^{D} (\partial_{z^\alpha})^2. \tag{2.5}$$

Then a polynomial $f(\mathrm{z}) \in V[\mathrm{z}]$ is **homogeneous** of degree m iff $(\mathrm{z}\cdot\partial_{\mathrm{z}} - m)f(\mathrm{z}) = 0$; it is **harmonic** iff $\partial_{\mathrm{z}}^2 f(\mathrm{z}) = 0$. We denote by $V[\mathrm{z}]^{\mathrm{har}}$ (respectively, $V[\![\mathrm{z}]\!]^{\mathrm{har}}$) the spaces of harmonic polynomials (respectively, formal power series). Note that a formal power series is harmonic if and only if each of its homogeneous components is a harmonic polynomial.

Finally, we denote by $\mathbb{Z}_+$ the set of non-negative integers, and by $\mathbb{N}$ the set of positive integers. The notation $N \gg 0$ means that $N > 0$ is sufficiently large.

B. Harmonic decomposition

The classical harmonic decomposition is the fact that every polynomial of $\mathrm{z} \in \mathbb{C}^D$ can be divided by z^2 with a unique harmonic remainder. One can view this in a more abstract way as follows. Let V be an arbitrary vector space. It is easy to see that the linear operators ∂_{z}^2, z^2 and $\mathrm{z}\cdot\partial_{\mathrm{z}} + D/2$ generate a representation of $\mathfrak{sl}_2$ on $V[\mathrm{z}]$, namely

$$[\partial_{\mathrm{z}}^2, \mathrm{z}^2] = 2\mathrm{z} \cdot \partial_{\mathrm{z}} + D, \quad [\mathrm{z} \cdot \partial_{\mathrm{z}}, \partial_{\mathrm{z}}^2] = -2\partial_{\mathrm{z}}^2, \quad [\mathrm{z} \cdot \partial_{\mathrm{z}}, \mathrm{z}^2] = 2\mathrm{z}^2. \tag{2.6}$$

In particular, we have the following useful formula:

$$[\partial_{\mathrm{z}}^2, (\mathrm{z}^2)^n] = 4n(\mathrm{z}^2)^{n-1}(n - 1 + \mathrm{z} \cdot \partial_{\mathrm{z}} + D/2). \tag{2.7}$$

It follows from the representation theory of $\mathfrak{sl}_2$ that every homogeneous polynomial $\phi(\mathrm{z}) \in V[\mathrm{z}]$ of degree k can be written uniquely in the form

$$\phi(\mathrm{z}) = \sum_{2n+m=k} (\mathrm{z}^2)^n h_m(\mathrm{z}), \tag{2.8}$$

where $h_m(\mathrm{z})$ are harmonic homogeneous polynomials of degree m (see, e.g., Ref. 28, Lemma 1.1 for a direct proof). There is a similar harmonic decomposition for elements $\phi(\mathrm{z})$ of the localized space $V[\mathrm{z}]_{\mathrm{z}^2}$; the only difference is that we allow k and n to be negative (and the sum is still finite).

If we allow infinite sums, the largest space that we get is the space $V[\![\mathrm{z}, 1/\mathrm{z}^2]\!]$ of formal series (see Ref. 28)

$$\phi(\mathrm{z}) = \sum_{n\in\mathbb{Z}} \sum_{m=0}^{\infty} \sum_{\sigma=1}^{\mathfrak{h}_m} \phi_{\{n,m,\sigma\}} (\mathrm{z}^2)^n h_{m,\sigma}(\mathrm{z}), \quad \phi_{\{n,m,\sigma\}} \in V. \tag{2.9}$$

Here $\{h_{m,\sigma}(\mathrm{z})\}_{\sigma=1,\ldots,\mathfrak{h}_m}$ is a basis of the space of harmonic homogeneous polynomials of degree m and

$$\mathfrak{h}_m = \binom{m+D-1}{D-1} - \binom{m+D-3}{D-1}. \tag{2.10}$$

Note that the localized space $V[\![\mathrm{z}]\!]_{\mathrm{z}^2}$ introduced in Sec. II A can be naturally embedded in $V[\![\mathrm{z}, 1/\mathrm{z}^2]\!]$ as the set of elements (2.9) for which the sum over n is bounded from below.

Elements (2.9) are called V-valued **formal distributions**, and the coefficients $\phi_{\{n,m,\sigma\}}$ in expansion (2.9) are called modes of $\phi(\mathrm{z})$. The space $V[\![\mathrm{z}, 1/\mathrm{z}^2]\!]$ has a natural structure of a **differential module** over the algebra $\mathbb{C}[z]_{\mathrm{z}^2}$ (see Ref. 28 Sec. 1), i.e., a $\mathbb{C}[z]_{\mathrm{z}^2}$-module equipped with a compatible action of $\mathbb{C}[\partial_z]$ so that the Leibniz rule for differentiation is satisfied. We will review and generalize this in the next section.

C. Differential module structure

In this section we will describe the algebraic structure of the space $V[\![\mathrm{z}, 1/\mathrm{z}^2]\!]$ in a way that can be generalized to more general vector spaces of "formal functions."

As a consequence of harmonic decomposition (2.8), the vector space $V[\mathrm{z}]$ is naturally isomorphic to $V[\varrho][\mathrm{z}]^{\mathrm{har}}$, the vector spaces of harmonic polynomials with coefficients polynomials in a one-component variable $\varrho \equiv \mathrm{z}^2$. Similarly, we have $V[\mathrm{z}]_{\mathrm{z}^2} \cong V[\varrho, \varrho^{-1}][\mathrm{z}]^{\mathrm{har}}$ and

$$V[\![\mathrm{z}]\!]_{\mathrm{z}^2} \cong V[\![\varrho]\!]_{\varrho}[\mathrm{z}]^{\mathrm{har}}, \quad V[\![\mathrm{z}, 1/\mathrm{z}^2]\!] \cong V[\![\varrho, \varrho^{-1}]\!][\![\mathrm{z}]\!]^{\mathrm{har}}, \tag{2.11}$$

using the notation of Secs. II A and II B.

We will now describe the differential module structures of the spaces $V[\mathrm{z}]$ and $V[\mathrm{z}]_{\mathrm{z}^2}$ (over the algebras $\mathbb{C}[\mathrm{z}]$ and $\mathbb{C}[\mathrm{z}]_{\mathrm{z}^2}$, respectively) in a way that is applicable to the space $V[\![\mathrm{z}, 1/\mathrm{z}^2]\!]$ and is suitable for generalization. Set $R = V[\varrho]$ or $V[\varrho, \varrho^{-1}]$, respectively. Let $f(\varrho) \in R$ and let $h(\mathrm{z}) \in R[\mathrm{z}]^{\mathrm{har}}$ be a harmonic homogeneous polynomial of degree m. Then for each $\alpha = 1, \ldots, D$, the polynomials $\partial_{z^\alpha} h(\mathrm{z})$ and

$$(A_\alpha h)(\mathrm{z}) := z^\alpha h(\mathrm{z}) - (D + 2m - 2)^{-1} \mathrm{z}^2 \partial_{z^\alpha} h(\mathrm{z}) \tag{2.12}$$

are harmonic as well. Indeed, for $(A_\alpha h)(\mathrm{z})$ this follows from (2.7). Note that the right-hand side of (2.12) is well defined for $m = 0$ since in this case $\partial_{z^\alpha} h(\mathrm{z}) = 0$. We deduce that the action of z^α and ∂_{z^α} on $R[\mathrm{z}]^{\mathrm{har}}$ is given by the formulas

$$z^\alpha (f(\varrho) h(\mathrm{z})) = f(\varrho)(A_\alpha h)(\mathrm{z}) + (D + 2m - 2)^{-1} \varrho f(\varrho)(\partial_{z^\alpha} h)(\mathrm{z}), \tag{2.13}$$

$$\partial_{z^\alpha} (f(\varrho) h(\mathrm{z})) = f(\varrho)(\partial_{z^\alpha} h)(\mathrm{z}) + 2 z^\alpha (f'(\varrho) h(\mathrm{z})), \tag{2.14}$$

where $\varrho \equiv \mathrm{z}^2$ and $f'(\varrho)$ denotes the derivative $\mathrm{d}f(\varrho)/\mathrm{d}\varrho$, and in the right-hand side of (2.14) one must apply (2.13) in order to get a result in $R[\mathrm{z}]^{\mathrm{har}}$.

Now we observe that by linearity Eqs. (2.13), (2.14) give rise to a well-defined action of z^α and ∂_{z^α} on the space of harmonic formal power series $R[\![\mathrm{z}]\!]^{\mathrm{har}}$. This follows from the fact that the linear operators A_α and ∂_{z^α} on $R[\![\mathrm{z}]\!]^{\mathrm{har}}$ are *graded* (of degree +1 and −1, respectively) with respect to the polynomial degree in z. We also notice that the right-hand sides of Eqs. (2.13) and (2.14) involve only the differential $\mathbb{C}[\varrho]$-module structure of R. These observations are summarized in the following statement.

Proposition 2.1: Let R be a differential module over $\mathbb{C}[\varrho]$ *with a derivation* $f \mapsto f'$. *Then Eqs.* (2.13) and (2.14) *define on* $R[\mathrm{z}]^{\mathrm{har}}$ *and* $R[\![\mathrm{z}]\!]^{\mathrm{har}}$ *structures of differential modules over* $\mathbb{C}[\mathrm{z}]$ *with derivations* ∂_{z^α}. *If R is a differential* $\mathbb{C}[\varrho, \varrho^{-1}]$*-module, then* $R[\mathrm{z}]^{\mathrm{har}}$ *and* $R[\![\mathrm{z}]\!]^{\mathrm{har}}$ *are differential*

$\mathbb{C}[z]_{z^2}$*-modules*.

Proof: We must check that for every $\phi(z) \in R[z]^{\mathrm{har}}$ or $R[\![z]\!]^{\mathrm{har}}$, the following relations are satisfied:

$$z^\alpha z^\beta \phi(z) = z^\beta z^\alpha \phi(z), \quad \sum_{\alpha=1}^{D} (z^\alpha)^2 \phi(z) = z^2 \phi(z),$$

$$\partial_{z^\alpha}\partial_{z^\beta}\phi(z) = \partial_{z^\beta}\partial_{z^\alpha}\phi(z), \quad \partial_{z^\alpha}(z^\beta \phi(z)) = z^\beta \partial_{z^\alpha}\phi(z) + \delta^\beta_\alpha \phi(z),$$

$$\partial_{z^\alpha}((z^2)^{-1}\phi(z)) = (z^2)^{-1}\partial_{z^\alpha}\phi(z) - 2(z^2)^{-2} z^\alpha \phi(z).$$

This can be verified by a straightforward computation, or can be deduced from the fact that these relations hold for $R = V[\varrho]$ and $V[\varrho, \varrho^{-1}]$. □

In particular, using isomorphism (2.11) and taking $R = V[\![\varrho, \varrho^{-1}]\!]$ in the above proposition, we obtain a structure of a differential $\mathbb{C}[z]_{z^2}$-module on the space $V[\![z, 1/z^2]\!]$ of formal distributions (cf. Ref. 28). Note that $V[\![z]\!]$ is also a $\mathbb{C}[z]$-module, and $V[\![z]\!]_{z^2}$ is a $\mathbb{C}[z]_{z^2}$-module. However, $V[\![z, 1/z^2]\!]$ is *not* a $\mathbb{C}[z]$-module because $V[\![\varrho, \varrho^{-1}]\!]$ is not a $\mathbb{C}[\varrho]$-module. Although obvious, the next remark plays an important role in the theory.

Remark 2.1: The action of $\mathbb{C}[\![z]\!]_{z^2}$ on $V[\![z]\!]_{z^2}$ does not have zero divisors. In other words, if $p(z)\,\phi(z) = 0$ for $p(z) \in \mathbb{C}[\![z]\!]_{z^2}$, $\phi(z) \in V[\![z]\!]_{z^2}$, then either $p(z) = 0$ or $\phi(z) = 0$. Note that this is not the case for the $\mathbb{C}[z]_{z^2}$-module $V[\![z, 1/z^2]\!]$ (see Ref. 28, Example 1.1).

D. Generalized formal distributions

As another application of Proposition 2.1, we will define spaces of formal distributions that involve nonintegral powers of z^2. We will take R to be a space of formal series in real powers of ϱ,

$$R = V[\![\varrho^\Gamma]\!] := \left\{ f(\varrho) = \sum_{\gamma \in \Gamma} f_\gamma \varrho^\gamma \,\middle|\, f_\gamma \in V \right\}, \tag{2.15}$$

where Γ is a $\mathbb{Z}$-invariant subset of $\mathbb{R}$, i.e., such that

$$\Gamma + \mathbb{Z} := \{\gamma + m \,|\, \gamma \in \Gamma, m \in \mathbb{Z}\} \subseteq \Gamma. \tag{2.16}$$

Then R is a differential $\mathbb{C}[\varrho, \varrho^{-1}]$-module [with $(\varrho^\gamma)' = \gamma \varrho^{\gamma-1}$], and $R[\![z]\!]^{\mathrm{har}}$ is a differential $\mathbb{C}[z]_{z^2}$-module, which we denote as $V[\![z, (z^2)^\Gamma]\!]$. We can view the elements of $V[\![z, (z^2)^\Gamma]\!]$ as infinite series [cf. (2.9) and (2.11)]

$$\phi(z) = \sum_{\gamma \in \Gamma} \sum_{m=0}^{\infty} \sum_{\sigma=1}^{\mathfrak{h}_m} \phi_{\{\gamma,m,\sigma\}} (z^2)^\gamma h_{m,\sigma}(z), \quad \phi_{\{n,m,\sigma\}} \in V. \tag{2.17}$$

For $\Gamma = \mathbb{Z}$, the above-defined module $V[\![z, (z^2)^{\mathbb{Z}}]\!]$ coincides with $V[\![z, 1/z^2]\!]$. We will call elements (2.17) (generalized) **formal distributions**. Note that this construction works also for subsets $\Gamma \subseteq \mathbb{C}$ but we will restrict our considerations to $\mathbb{R}$. We define inductively the vector spaces

$$V[\![z_1, (z_1^2)^{\Gamma_1}; \ldots; z_n (z_n^2)^{\Gamma_n}]\!] := (V[\![z_1, (z_1^2)^{\Gamma_1}; \ldots; z_{n-1}, (z_{n-1}^2)^{\Gamma_{n-1}}]\!])[\![z_n, (z_n^2)^{\Gamma_n}]\!] \tag{2.18}$$

of formal distributions in several D-dimensional vector variables $z_1, \ldots, z_n$. When all $\Gamma_i = \mathbb{Z}$, we will denote the space (2.18) as $V[\![z_1, 1/z_1^2; \ldots; z_n, 1/z_n^2]\!]$.

Remark 2.2: Choosing instead $R = V[\varrho^\Gamma]$ in the above construction, we obtain a differential $\mathbb{C}[z]_{z^2}$-module $R[z]^{\mathrm{har}}$ denoted as $V[z, (z^2)^\Gamma]$; it consists of all finite sums of the form (2.17).

Remark 2.3: Note that Eq. (2.7) is valid for $n \in \Gamma$, and it implies

$$\partial_z^2((z^2)^\gamma h_{m,\sigma}(z)) = 4\gamma\left(\gamma + m + \frac{D}{2} - 1\right)(z^2)^{\gamma-1} h_{m,\sigma}(z). \tag{2.19}$$

In particular, $(z^2)^\gamma h_{m,\sigma}(z)$ is harmonic if and only if $\gamma=0$ or $\gamma=-(D/2)+1-m$.

Example 2.1: Let us consider the case $D=1$. Then $z=z$ is a one-component variable and the harmonic polynomials are just the affine polynomials $a+bz$. Thus, every element of $V[\![z,(z^2)^\Gamma]\!]$ has the form

$$\phi(z) = \sum_{\gamma\in\Gamma} (z^2)^\gamma (a_\gamma + b_\gamma z), \quad a_\gamma, b_\gamma \in V. \tag{2.20}$$

It is easy to see that when Γ is an additive subgroup of $\mathbb{R}$ containing $\frac{1}{2}\mathbb{Z}$, we have the following direct sum of differential $\mathbb{C}[z]_{z^2}$-modules:

$$V[\![z,(z^2)^\Gamma]\!] = (1+(z^2)^{-1/2}z)V[\![z,(z^2)^\Gamma]\!] \oplus (1-(z^2)^{-1/2}z)V[\![z,(z^2)^\Gamma]\!]. \tag{2.21}$$

Note that here $(z^2)^{-1/2}z$ is viewed as an element of $V[\![z,(z^2)^\Gamma]\!]$, and is not equal to 1.

E. Γ-Localization

The vector space of localized formal power series $V[\![z]\!]_{z^2}$ can be embedded in $V[\![z, 1/z^2]\!]$ as the subspace of all elements (2.9) for which the sum over n is bounded from below. This space is a (differential) module over the localized algebra $\mathbb{C}[\![z]\!]_{z^2}$. We will later need the following generalizations of these spaces.

Let $\Gamma_1,\dots,\Gamma_s$ be additive subgroups of $\mathbb{R}$ containing $\mathbb{Z}$; then each Γ_i is automatically $\mathbb{Z}$-invariant [see (2.16)]. Let A be a commutative associative algebra, and let $f_1,\dots,f_s$ be some fixed elements of A. Then we define

$$A_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}} := (\mathbb{C}[\Gamma_1]\otimes_{\mathbb{C}}\cdots\otimes_{\mathbb{C}}\mathbb{C}[\Gamma_s]\otimes_{\mathbb{C}}A)/J, \tag{2.22}$$

where $\mathbb{C}[\Gamma_i]$ is the group algebra of Γ_i (with elements denoted as e^γ) and J is the ideal generated by elements of the form

$$e^{\gamma_1'}\otimes\cdots\otimes e^{\gamma_s'}\otimes g - e^{\gamma_1''}\otimes\cdots\otimes e^{\gamma_s''}\otimes g \tag{2.23}$$

for which there exist $\gamma_i\in\Gamma_i$ such that $\gamma_i+\gamma_i', \gamma_i+\gamma_i''\in\mathbb{Z}_+$ $(i=1,\dots,s)$ and

$$f_1^{\gamma_1+\gamma_1'}\cdots f_s^{\gamma_s+\gamma_s'} g = f_1^{\gamma_1+\gamma_1''}\cdots f_s^{\gamma_s+\gamma_s''} g \tag{2.24}$$

in the algebra A. The so-defined commutative associative algebra $A_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}}$ will be called the $(\Gamma_1,\dots,\Gamma_s)$-**localization** of A with respect to $f_1,\dots,f_s$. When all groups Γ_i are equal to Γ, we will just call it Γ-localization. The image in $A_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}}$ of an element $e^{\gamma_1}\otimes\cdots\otimes e^{\gamma_s}\otimes g$ will be denoted as $f_1^{\gamma_1}\cdots f_s^{\gamma_s} g$.

Obviously, the $\mathbb{Z}$-localization of A with respect to $f_1,\dots,f_s$ coincides with the localized algebra $A_{f_1\cdots f_s}$. In this case the localization with respect to a set $\{f_1,\dots,f_s\}$ is naturally isomorphic to the localization with respect to the product $f_1\cdots f_s$. For general Γ this is not true.

If M is an A-module, then in the same way one defines the localization $M_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}}$ as an $A_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}}$-module. In addition, if M is a differential A-module, then the localization $M_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}}$ is a differential $A_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}}$-module with the same set of derivations. Indeed, every derivation of A extends by the Leibniz rule to $A_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}}$ since J is an invariant subspace. We note also that if M has no zero divisors the same is true for $M_{f_1^{\Gamma_1}\dots f_s^{\Gamma_s}}$(cf. Remark 2.1).

As a special case of the above construction, we get a differential $\mathbb{C}[\![z]\!]_{(z^2)^\Gamma}$-module $V[\![z]\!]_{(z^2)^\Gamma}$. The latter can be identified with the $\mathbb{C}[z]_{z^2}$-submodule of $V[\![z,(z^2)^\Gamma]\!]$ consisting of all elements (2.17) for which the sum over γ is over the union of *finitely* many sets of the form $\{\gamma_i+\mathbb{Z}_+\}$.

F. Formal expansions

Let Γ be an additive subgroup of $\mathbb{R}$ containing $\mathbb{Z}$, and let V be a vector space. Recall the Γ-localizations defined in Sec. II E and the spaces of formal series defined by (2.17), (2.18). There are obvious embeddings

$$\mathbb{C}[\![z,w]\!]_{(z^2)^\Gamma(w^2)^\Gamma} \subsetneqq \mathbb{C}[\![z]\!]_{(z^2)^\Gamma}[\![w]\!]_{(w^2)^\Gamma} \subsetneqq \mathbb{C}[\![z,(z^2)^\Gamma;w,(w^2)^\Gamma]\!]. \tag{2.25}$$

We emphasize that the spaces $\mathbb{C}[\![z]\!]_{z^2}[\![w]\!]_{w^2}$ and $\mathbb{C}[\![w]\!]_{w^2}[\![z]\!]_{z^2}$ are different, because elements of the former space have only finitely many negative powers of w^2 but possibly infinitely many negative powers of z^2. Note also that the first two spaces in (2.25) are rings, and hence the second one is a module over the first.

For $\gamma\in\Gamma$, we define $\iota_{z,w}((z-w)^2)^\gamma$ as the Taylor expansion of $((z-w)^2)^\gamma$ in w around 0, to wit

$$\iota_{z,w}((z-w)^2)^\gamma := e^{-w\cdot\partial_z}(z^2)^\gamma = \sum_{k=0}^{\infty}\frac{(-w\cdot\partial_z)^k}{k!}(z^2)^\gamma \in \mathbb{C}[\![z]\!]_{(z^2)^\Gamma}[\![w]\!]. \tag{2.26}$$

One defines $\iota_{z,w}((z+w)^2)^\gamma$ in the same way, while $\iota_{w,z}((z-w)^2)^\gamma$ is defined using the identifications

$$((z-w)^2)^\gamma \equiv ((w-z)^2)^\gamma, \quad ((-z)^2)^\gamma \equiv (z^2)^\gamma. \tag{2.27}$$

More generally, for $\psi(z,w)\in V[\![z,w]\!]_{(z^2)^\Gamma(w^2)^\Gamma}$ we set

$$\iota_{z,w}(\psi(z,w)((z-w)^2)^\gamma) := \psi(z,w)\iota_{z,w}((z-w)^2)^\gamma, \tag{2.28}$$

thus obtaining a $\mathbb{C}[\![z,w]\!]_{(z^2)^\Gamma(w^2)^\Gamma}$-linear map

$$\iota_{z,w}: V[\![z,w]\!]_{(z^2)^\Gamma(w^2)^\Gamma((z-w)^2)^\Gamma} \to V[\![z]\!]_{(z^2)^\Gamma}[\![w]\!]_{(w^2)^\Gamma}. \tag{2.29}$$

Note that the map $\iota_{z,w}$ commutes with all partial derivatives ∂_{z^α} and ∂_{w^α}.

We define another version of $\iota_{z,w}$ as follows:

$$\begin{gathered}\iota_{z,w}: V[\![z-w]\!]_{((z-w)^2)^\Gamma}[\![w]\!]_{(w^2)^\Gamma} \to V[\![z]\!]_{(z^2)^\Gamma}[\![w]\!]_{(w^2)^\Gamma},\\ \phi(z-w,w)\mapsto e^{-w'\cdot\partial_z}\phi(z,w)\big|_{w'=w},\end{gathered} \tag{2.30}$$

where on the left-hand side $z-w$ is viewed as an independent variable. Equation (2.30) is well defined because $e^{-w'\cdot\partial_z}\phi(z,w)\in V[\![z]\!]_{(z^2)^\Gamma}[\![w,w']\!]_{(w^2)^\Gamma}$ (while an analogous formal expansion $\iota_{z,w}$ on $V[\![w]\!]_{(w^2)^\Gamma}[\![z-w]\!]_{((z-w)^2)^\Gamma}$ does not make sense). Obviously, maps (2.29) and (2.30) agree with each other on the intersection of their domains. The two versions of $\iota_{z,w}$ can be related to each other by the following statement.

Proposition 2.2: (Taylor's formula) *For every* $\phi(z,w)\in V[\![z,w]\!]_{(z^2)^\Gamma(w^2)^\Gamma((z-w)^2)^\Gamma}$ *we have*

$$\iota_{z,w}\iota_{z-w,w}\phi((z-w)+w,w) = \iota_{z,w}\phi(z,w). \tag{2.31}$$

Proof: It suffices to prove (2.31) for $\phi(z,w)=(z^2)^\gamma$, $\gamma\in\Gamma$. Then, according to Eqs. (2.26) and (2.30), we have

$$\iota_{z,w}\iota_{z-w,w}(((z-w)+w)^2)^\gamma = \iota_{z,w}\left(e^{w'\cdot\partial_z}((z-w)^2)^\gamma\big|_{w'=w}\right)$$

$$= e^{-w''\cdot\partial_z}e^{w'\cdot\partial_z}(z^2)^\gamma\big|_{w'=w''=w} = (z^2)^\gamma,$$

which completes the proof. □

We define the spaces of successively localized formal series

$$V[\![z_1]\!]_{(z_1^2)^\Gamma}\cdots[\![z_1]\!]_{(z_n^2)^\Gamma} := (V[\![z_1]\!]_{(z_1^2)^\Gamma}\cdots[\![z_{n-1}]\!]_{(z_{n-1}^2)^\Gamma})[\![z_n]\!]_{(z_n^2)^\Gamma}, \tag{2.32}$$

which will be used in the sequel. The space (2.32) is a module over the algebra $\mathbb{C}[\![z_1]\!]_{(z_1^2)^\Gamma}\cdots[\![z_1]\!]_{(z_n^2)^\Gamma}$. Again, one should keep in mind that in (2.32) one would get a different space if the variables are put in different order.

III. RESIDUE FUNCTIONAL

In this section we introduce an important linear functional on the spaces of formal distributions, which we call the residue functional. We discuss its fundamental properties and we prove an analog of the Cauchy formula. A geometric interpretation of the residue is given in the Appendix.

A. Definition and main properties

In this section we introduce, for an arbitrary vector space V, an important linear map $V[\![z,(z^2)^{\mathbb{R}}]\!]\to V$, which will be denoted as $\phi(z)\mapsto \mathrm{Res}_z\,\phi(z)$ and will be called the residue. Observing that every element of $V[\![z,(z^2)^{\mathbb{R}}]\!]$ can be uniquely represented as a formal series of the form

$$\phi(z)=\sum_{\gamma\in\mathbb{R}}(z^2)^\gamma\phi_\gamma(z)\quad \text{with } \phi_\gamma(z)\in V[\![z]\!]^{\mathrm{har}}, \tag{3.1}$$

we define

$$\mathrm{Res}_z\sum_{\gamma\in\mathbb{R}}(z^2)^\gamma\phi_\gamma(z) := \phi_{-D/2}(0). \tag{3.2}$$

Theorem 3.1: (a) *The linear map* (3.2) *is* ∂_z-invariant *in the sense that*

$$\mathrm{Res}_z\,\partial_{z^\alpha}\phi(z)=0 \tag{3.3}$$

for all $\phi(z)\in V[\![z,(z^2)^{\mathbb{R}}]\!]$ *and* $\alpha=1,\dots,D$.

(b) *The bilinear form*

$$\langle f,g\rangle := \mathrm{Res}_z f(z)g(z),\quad f,g\in\mathbb{C}[z,(z^2)^{\mathbb{R}}], \tag{3.4}$$

is nondegenerate.

(c) *Let* $h_m(z)$ *and* $h'_{m'}(z)$ *be harmonic homogeneous polynomials of degrees* m *and* m', *respectively. Then*

$$\langle (z^2)^\gamma h_m(z),h'_{m'}(z)\rangle=0\quad \textit{if}$$

$$m\neq m'\quad \textit{or}\quad 2\gamma+m+m'\neq -D, \tag{3.5}$$

and in the opposite case this coincides with the unique, up to a multiplicative constant, $\mathrm{O}(D)$*-invariant scalar product on the vector space of harmonic homogeneous polynomials of degree* $m(=m')$ *given by*

$$\langle (z^2)^{-m-(D/2)}h_m(z),h'_m(z)\rangle. \tag{3.6}$$

Proof: (a) Let $h(z)$ be a harmonic homogeneous polynomial of degree m. From Eqs. (2.12)–(2.14) we deduce the harmonic decomposition

$$\partial_{z^\alpha}((z^2)^\gamma h(z)) = 2\gamma(z^2)^{\gamma-1}(A_\alpha h)(z) + (1+2\gamma(D+2m-2)^{-1})(z^2)^\gamma\partial_{z^\alpha}h(z).$$

Now let us apply Res_z to the right-hand side of this equation. The first term will give zero, because

$(A_\alpha h)(0)=0$. Similarly, the second term can give a nonzero result only if $m=1$ and $\gamma=-D/2$ but then the coefficient vanishes.

(b), (c) Property (3.5) follows from the harmonic decomposition

$$h_m(\mathrm{z})h'_{m'}(\mathrm{z}) = \sum_{n=0}^{\min(m,m')} (\mathrm{z}^2)^n h''_{m+m'-2n}(\mathrm{z}),$$

where $h''_{m''}(\mathrm{z})$ are uniquely determined harmonic homogeneous polynomials of degree $m''=|m-m'|,\ldots,m+m'$. It is known that for $m=m'$, the constant polynomial $h''_0 \in \mathbb{C}$ defines an $\mathrm{O}(D)$-invariant nondegenerate scalar product on the space of harmonic polynomials of degree m. This proves the remaining statements. □

From now on, we will assume that the bases $\{h_{m,\sigma}(\mathrm{z})\}_{\sigma=1,\ldots,\mathfrak{h}_m}$ of harmonic homogeneous polynomials of degree m are *orthonormal*, so that

$$\mathrm{Res}_{\mathrm{z}}(\mathrm{z}^2)^\gamma h_{m,\sigma}(\mathrm{z})h_{m',\sigma'}(\mathrm{z}) = \delta_{\gamma,-(D/2)-m}\delta_{m,m'}\delta_{\sigma,\sigma'}, \tag{3.7}$$

in accord with Theorem 3.1(c). Consequently, the modes of a formal series $\phi(\mathrm{z})$ given by (2.17) can be recovered as residues,

$$\phi_{\{\gamma,m,\sigma\}} = \mathrm{Res}_{\mathrm{z}}\, \phi(\mathrm{z})(\mathrm{z}^2)^{-(D/2)-\gamma-m}h_{m,\sigma}(\mathrm{z}). \tag{3.8}$$

This justifies the name "formal distributions."

Corollary 3.2: Let Γ *be a* $\mathbb{Z}$*-invariant subset of* $\mathbb{R}$ (*i.e.*, $\Gamma+\mathbb{Z}\subseteq\Gamma$), *and set*

$$\Gamma' = -\Gamma + \frac{D}{2} \coloneqq \left\{ -\gamma + \frac{D}{2} \,\middle|\, \gamma \in \Gamma \right\}. \tag{3.9}$$

Then

$$V[\![\mathrm{z},(\mathrm{z}^2)^\Gamma]\!] \cong \mathrm{Hom}_{\mathbb{C}}(\mathbb{C}[\mathrm{z},(\mathrm{z}^2)^{\Gamma'}],V) \tag{3.10}$$

as differential $\mathbb{C}[\mathrm{z}]_{\mathrm{z}^2}$*-modules. In particular,* $\mathbb{C}[\![\mathrm{z},(\mathrm{z}^2)^\Gamma]\!]$ *is the dual* $\mathbb{C}[\mathrm{z}]_{\mathrm{z}^2}$*-module of* $\mathbb{C}[\mathrm{z},(\mathrm{z}^2)^{\Gamma'}]$.

Note that by the recursive definition (2.18) the residue functional is defined also on formal distributions in several D-dimensional variables. For instance, we have

$$V[\![\mathrm{z},(\mathrm{z}^2)^{\mathbb{R}};\mathrm{w},(\mathrm{w}^2)^{\mathbb{R}}]\!] \xrightarrow{\mathrm{Res}_{\mathrm{w}}} V[\![\mathrm{z},(\mathrm{z}^2)^{\mathbb{R}}]\!] \xrightarrow{\mathrm{Res}_{\mathrm{z}}} V. \tag{3.11}$$

Then under the natural isomorphism

$$V[\![\mathrm{z},(\mathrm{z}^2)^{\mathbb{R}};\mathrm{w},(\mathrm{w}^2)^{\mathbb{R}}]\!] \cong V[\![\mathrm{w},(\mathrm{w}^2)^{\mathbb{R}};\mathrm{z},(\mathrm{z}^2)^{\mathbb{R}}]\!] \tag{3.12}$$

the "Fubini theorem" is satisfied, namely,

$$\mathrm{Res}_{\mathrm{z}}\,\mathrm{Res}_{\mathrm{w}}\,\phi(\mathrm{z},\mathrm{w}) = \mathrm{Res}_{\mathrm{w}}\,\mathrm{Res}_{\mathrm{z}}\,\phi(\mathrm{z},\mathrm{w}) \tag{3.13}$$

for $\phi(\mathrm{z},\mathrm{w}) \in V[\![\mathrm{z},(\mathrm{z}^2)^{\mathbb{R}};\mathrm{w},(\mathrm{w}^2)^{\mathbb{R}}]\!]$.

The following proposition describes all ∂_{z}-invariant linear functionals $V[\![\mathrm{z},(\mathrm{z}^2)^\Gamma]\!] \to V$ [cf. (3.3)].

Proposition 3.3: Let Γ *be a* $\mathbb{Z}$*-invariant subset of* $\mathbb{R}$, *and let* $\Omega: V[\![\mathrm{z},(\mathrm{z}^2)^\Gamma]\!] \to V$ *be a linear map that is* ∂_{z}*-invariant, i.e., such that* $\Omega(\partial_{\mathrm{z}^\alpha}\phi)=0$ *for all* $\phi \in V[\![\mathrm{z},(\mathrm{z}^2)^\Gamma]\!]$ *and* $\alpha=1,\ldots,D$.

(a) *If* $D\geqslant 2$, *then there exists a complex constant* C *such that* $\Omega(\phi)=C\,\mathrm{Res}_{\mathrm{z}}\,\phi$ *for all* $\phi \in V[\![\mathrm{z},(\mathrm{z}^2)^\Gamma]\!]$. *In particular, if* $D/2 \notin \Gamma$ *then* $\Omega=0$.

(b) *If* $D=1$, *then there exist complex constants* C *and* C' *such that* $\Omega(\phi)=C\,\mathrm{Res}_z\,\phi + C'\,\mathrm{Res}'_z\,\phi$ *for all* $\phi \in V[\![z,(z^2)^\Gamma]\!]$ (z *is now one-component variable*), *where* Res'_z *is defined by*

$$\mathrm{Res}'_z \sum_{\gamma\in\mathbb{R}} (z^2)^\gamma (a_\gamma + b_\gamma z) := b_{-1} \tag{3.14}$$

(*see Example 2.1*).

Proof: The space of all ∂_z-invariant linear maps $\Omega: V[\![z,(z^2)^\Gamma]\!] \to V$ is isomorphic to the vector space

$$\mathrm{Hom}_{\mathbb{C}}(V[\![z,(z^2)^\Gamma]\!]/\partial_z V[\![z,(z^2)^\Gamma]\!], V),$$

where

$$\partial_z V[\![z,(z^2)^\Gamma]\!] := \partial_{z^1} V[\![z,(z^2)^\Gamma]\!] + \cdots + \partial_{z^D} V[\![z,(z^2)^\Gamma]\!].$$

Fix $\gamma \in \Gamma$ and a harmonic homogeneous polynomials $h(z)$ of degree m. We will prove that for $D \geqslant 2$ one has

$$(z^2)^\gamma h(z) \in \partial_z V[\![z,(z^2)^\Gamma]\!] \quad \text{if } (\gamma,m) \neq \left(-\frac{D}{2},0\right), \tag{3.15}$$

while for $D=1$ one has

$$(z^2)^\gamma h(z) \in \partial_z V[\![z,(z^2)^\Gamma]\!] \quad \text{if} \quad (\gamma,m) \neq \left(-\frac{1}{2},0\right) \quad \text{or } (\gamma,m) \neq (-1,1). \tag{3.16}$$

Indeed, using the equalities [see (2.19)]

$$\partial_z^2((z^2)^{\gamma+1}h(z)) = 4(\gamma+1)\left(\gamma+m+\frac{D}{2}\right)(z^2)^\gamma h(z)$$

and

$$\sum_{\alpha=1}^{D} \partial_{z^\alpha}((z^2)^{\gamma+1}\partial_{z^\alpha}h(z)) = 2m(\gamma+1)(z^2)^\gamma h(z),$$

we conclude that $(z^2)^\gamma h(z) \in \partial_z V[\![z,(z^2)^\Gamma]\!]$ if $\gamma \neq -1$ and $(\gamma,m) \neq (-D/2,0)$. Finally, in the case $\gamma=-1$, we have

$$\sum_{\alpha=1}^{D} \partial_{z^\alpha}((z^2)^{-1}z^\alpha h(z)) = (D+m-2)(z^2)^{-1}h(z).$$

This proves (3.15) and (3.16).

Now observing that by Theorem 3.1(a) we have $(z^2)^{-D/2} \notin \partial_z V[\![z,(z^2)^\Gamma]\!]$, we complete the proof of part (a). To prove part (b), it remains to check that Res'_z is ∂_z-invariant, which is straightforward. □

Example 3.1: Let $D=1$; then elements of $V[\![z,(z^2)^\Gamma]\!]$ have the form (2.20). In particular, for $\Gamma=\mathbb{Z}$, we can write every element $\phi(z) \in V[\![z,1/z^2]\!]$ uniquely as

$$\phi(z) = \sum_{n\in\mathbb{Z}} c_n z^n, \quad c_n \in V. \tag{3.17}$$

In other words, $V[\![z,1/z^2]\!]$ can be identified with the space of formal series $V[\![z,z^{-1}]\!]$. The functional Res_z vanishes on a series (3.17), while the functional Res'_z coincides with the usual residue, $\mathrm{Res}'_z\, \phi(z) = c_{-1}$.

B. Translation invariance and Cauchy formula

Let V be a vector space, as before. One of the most important properties of the residue map (3.2) is its translation invariance.

Proposition 3.4: (Formal translation invariance)

$$\mathrm{Res}_z\, \iota_{z,w}\phi(z+w) = \mathrm{Res}_z\, \phi(z), \quad \phi(z) \in V[\![z]\!]_{(z^2)^{\mathbb{R}}}. \tag{3.18}$$

This equation is also valid for elements of $V[\![z,(z^2)^{\mathbb{R}}]\!]$.

Proof: Recall that, by definition [cf. (2.26)], $\iota_{z,w}\phi(z+w)=e^{w\cdot\partial_z}\phi(z)$. Then Eq. (3.18) follows from Theorem 3.1(a). □

We proceed to finding an analog of the Cauchy kernel for our residue functional.

Proposition 3.5: For $\psi(z) \in V[\![z]\!]$, $\gamma \in \mathbb{R}$, $n \in \mathbb{N}$, *we have*

$$\mathrm{Res}_z (z^2)^{\gamma}\psi(z) = 0 \quad \textit{if } \gamma + \frac{D}{2} > 0 \quad \textit{or } \gamma + \frac{D}{2} \notin \mathbb{Z}, \tag{3.19}$$

$$\mathrm{Res}_z (z^2)^{-D/2}\psi(z) = \psi(0), \tag{3.20}$$

and

$$\mathrm{Res}_z (z^2)^{-(D/2)-n}\psi(z) = K_n^{-1}((\partial_z^2)^n\psi)(0), \tag{3.21}$$

where

$$K_n := 2^{2n}\prod_{k=1}^{n} k\left(k + \frac{D}{2} - 1\right). \tag{3.22}$$

Proof: Equations (3.19) and (3.20) are straightforward from the definition of the residue functional. To prove (3.21), it is enough to assume that $\psi(z)$ is a homogeneous polynomial of degree $2n$. Then we apply induction on n, starting with (3.20), and using the ∂_z-invariance (3.3) and the relation

$$\sum_{\alpha=1}^{D} \partial_{z^\alpha}((z^2)^{-(D/2)-n+1}(\partial_{z^\alpha}\psi)(z)) = -4n\left(n + \frac{D}{2} - 1\right)(z^2)^{-(D/2)-n}\psi(z) + (z^2)^{-(D/2)-n+1}(\partial_z^2\psi)(z).$$

This completes the proof. □

As a corollary of Proposition 3.5, for *even D* we have a local formula for the residue of an element $\phi(z) \in V[\![z]\!]_{z^2}$,

$$\mathrm{Res}_z\, \phi(z) = K_N^{-1}(\partial_z^2)^N((z^2)^{N+D/2}\phi(z))|_{z=0}, \quad N \gg 0. \tag{3.23}$$

Proposition 3.6: (Higher-dimensional "Cauchy formula")

$$\mathrm{Res}_z\, \iota_{z,w}((z-w)^2)^{-D/2}\psi(z) = \psi(w) \quad \textit{for } \psi(z) \in V[\![z]\!]. \tag{3.24}$$

Proof: Consider the formal series

$$\phi(z,w) := \iota_{z,w}((z-w)^2)^{-D/2}\psi(z) \in V[\![z]\!]_{z^2}[\![w]\!].$$

By (3.18), we have

$$\mathrm{Res}_z\, \phi(z,w) = \mathrm{Res}_z\, \iota_{z,w'}\phi(z+w',w).$$

We can set $w'=w$ on the right-hand side and obtain

$$\mathrm{Res}_z\, \iota_{z,w}\phi(z+w,w) = \mathrm{Res}_z\, \iota_{z,w}(z^2)^{-D/2}\psi(z+w) = \psi(w),$$

using (3.20). □

C. Harmonic decomposition of $\iota_{z,w}((z-w)^2)^\gamma$

As before, let $\{h_{m,\sigma}(z)\}$ be an *orthonormal* basis of the space of harmonic homogeneous polynomials of degree m [see (3.7)]. Introduce the polynomials

$$H_m(z,w) := \sum_{\sigma=1}^{\mathfrak{h}_m} h_{m,\sigma}(z)h_{m,\sigma}(w). \tag{3.25}$$

Note that $H_m(z,w)$ is the unique, up to a multiplicative constant, $O(D)$-invariant polynomial that is separately harmonic and homogeneous in z and w of degree m. Combining Eq. (3.7) with the Cauchy formula (3.24), we obtain that

$$\iota_{z,w}((z-w)^2)^{-D/2} = \sum_{m,n=0}^{\infty} (z^2)^{-(D/2)-m-n}(w^2)^n H_m(z,w). \tag{3.26}$$

Recall that for every $\gamma \in \mathbb{R}$ and $n \in \mathbb{Z}_+$ the binomial coefficient $\binom{\gamma}{n}$ is defined as $\gamma(\gamma-1)\cdots(\gamma-n+1)/n!$ and is a polynomial of γ of degree n.

Proposition 3.7: For every $\gamma \in \mathbb{R}$, we have

$$\iota_{z,w}((z-w)^2)^\gamma = \sum_{m,n=0}^{\infty} K_{m,n}(\gamma)(z^2)^{\gamma-m-n}(w^2)^n H_m(z,w), \tag{3.27}$$

where

$$K_{m,n}(\gamma) := \frac{(-1)^n}{\binom{-\frac{D}{2}}{m+n}} \binom{\frac{D}{2}-1+\gamma}{n} \binom{\gamma}{m+n}. \tag{3.28}$$

Proof: It follows from definition (2.26) and the $O(D)$-invariance that $\iota_{z,w}((z-w)^2)^\gamma$ has the form (3.27). Moreover, it is clear from (2.26) that for each fixed $m,n \in \mathbb{Z}_+$, the coefficient $K_{m,n}(\gamma)$ is a polynomial of γ. Then to establish (3.28) it will suffice to prove it for infinitely many values of γ.

We will prove by induction that formula (3.28) holds for all γ such that $-(D/2)-\gamma \in \mathbb{Z}_+$. For $\gamma=-D/2$ it gives $K_{m,n}(-D/2)=1$, which agrees with (3.26). Next, assume that (3.27) and (3.28) hold for some γ. Apply the Laplace operator ∂_z^2 to both sides of (3.27) and use (2.19) to find

$$\gamma\left(\gamma+\tfrac{D}{2}-1\right)\iota_{z,w}((z-w)^2)^{\gamma-1} = \sum_{m,n=0}^{\infty} K_{m,n}(\gamma)(\gamma-m-n)\left(\gamma-n+\tfrac{D}{2}-1\right)(z^2)^{\gamma-1-m-n}(w^2)^n H_m(z,w).$$

Comparing this to (3.27) with $\gamma-1$ instead of γ, we obtain that (3.28) holds for $\gamma-1$. This completes the proof. □

For $\gamma=-(D/2)+1$, expansion (3.27) takes the particularly simple form

$$\iota_{z,w}((z-w)^2)^{-(D/2)+1} = \sum_{m=0}^{\infty} \frac{\frac{D}{2}-1}{\frac{D}{2}-1+m}(z^2)^{-(D/2)+1-m}H_m(z,w). \tag{3.29}$$

Note that both sides of this equation are harmonic with respect to both z and w (see Remark 2.3). Let us also point out that for fixed $\gamma \in \mathbb{Z}_+$, the coefficient $K_{m,n}(\gamma)$ vanishes whenever $m+n>\gamma$. Using (3.27) for $\gamma=0,1,2,\ldots$, one can find the polynomials $H_m(z,w)$ recursively; for example,

$$H_0(z,w)=1,\quad H_1(z,w)=Dz\cdot w,$$
$$H_2(z,w)=\left(\tfrac{D}{2}+1\right)(D(z\cdot w)^2-z^2w^2). \tag{3.30}$$

D. Formal delta-function

In this section we define a formal distribution in two variables, which plays the role of the delta distribution. Let us consider the $\mathbb{Z}$-invariant set $\mathbb{Z}'\coloneqq(D/2)+\mathbb{Z}$ [cf. (3.9)], which coincides with $\mathbb{Z}$ when D is even. We define the following formal distribution in two variables:

$$\delta(z,w)\coloneqq\sum_{n\in\mathbb{Z}}\sum_{m=0}^{\infty}(z^2)^{-(D/2)-m-n}(w^2)^nH_m(z,w)\in\mathbb{C}[[z,(z^2)^{\mathbb{Z}'};w,(w^2)^{\mathbb{Z}}]]. \tag{3.31}$$

Proposition 3.8: The above-defined $\delta(z,w)$ *is the unique element of* $\mathbb{C}[[z,(z^2)^{\mathbb{Z}'};w,(w^2)^{\mathbb{Z}}]]$ *with the property that*

$$\mathrm{Res}_z\,\phi(z)\delta(z,w)=\phi(w)\quad \textit{for all}\ \phi(z)\in\mathbb{C}[z]_{z^2}. \tag{3.32}$$

In addition, it satisfies

$$\phi(z)\delta(z,w)=\phi(w)\delta(z,w),\quad \phi(z)\in\mathbb{C}[z]_{z^2} \tag{3.33}$$

and

$$\partial_{z^\alpha}\delta(z,w)=-\partial_{w^\alpha}\delta(z,w),\quad \alpha=1,\dots,D. \tag{3.34}$$

Proof: Property (3.32) and the uniqueness of $\delta(z,w)$ follow from the orthogonality relation (3.7) (cf. Corollary 3.2). Then Eq. (3.32) and the ∂_z-invariance of the residue (3.3) imply that, for every $\phi(z)\in\mathbb{C}[z]_{z^2}$,

$$\mathrm{Res}_z\,\phi(z)(\partial_{z^\alpha}+\partial_{w^\alpha})\delta(z,w)=-\mathrm{Res}_z(\partial_{z^\alpha}\phi(z))\delta(z,w)+\partial_{w^\alpha}\mathrm{Res}_z\,\phi(z)\delta(z,w)=0.$$

This proves (3.34). Similarly, (3.33) follows from the equalities:

$$\mathrm{Res}_z\,\psi(z)\phi(z)\delta(z,w)=\psi(w)\phi(w)=\mathrm{Res}_z\,\psi(z)\phi(w)\delta(z,w),$$

for all $\psi(z),\phi(z)\in\mathbb{C}[z]_{z^2}$. □

Remark 3.1: Let Γ be any $\mathbb{Z}$-invariant subset of $\mathbb{R}$, and let $\Gamma'=-\Gamma+\frac{D}{2}$ [see (3.9)]. Corollary 3.2 implies that there exists a unique element $\delta_\Gamma(z,w)\in\mathbb{C}[[z,(z^2)^{\Gamma'};w,(w^2)^{\Gamma}]]$ such that Eq. (3.32) holds for $\delta_\Gamma(z,w)$ and all $\phi(z)\in\mathbb{C}[z]_{(z^2)\Gamma}$. Then (3.34) is satisfied as well, while the analog of (3.33) holds only when Γ is a subgroup of $\mathbb{R}$ (this is needed for $\mathbb{C}[z]_{(z^2)\Gamma}$ to be a ring). Finally, note that $\delta_\Gamma(z,w)=\delta_\Gamma(w,z)$ when $\Gamma=\Gamma'$.

Observe that $\delta(z,w)$ is symmetric, i.e., $\delta(z,w)=\delta(w,z)$, if and only if D is even. Switching z and w in (3.26) and using (2.27), we obtain that for even D we have

$$\delta(z,w)=\iota_{z,w}((z-w)^2)^{-D/2}+\iota_{w,z}((z-w)^2)^{-D/2}+\sum_{m=0}^{\infty}\sum_{n=1}^{(D/2)-1+m}(z^2)^{-(D/2)-m+n}(w^2)^{-n}H_m(z,w). \tag{3.35}$$

This splitting of $\delta(z,w)$ as a sum of three terms suggests the introduction of a natural partition of the space of formal distributions (without assuming that D is even). For a formal distribution $\phi(z)\in V[[z,1/z^2]]$, written as in (2.9), we define its parts $\phi(z)_+$, $\phi(z)_-$, and $\phi(z)_\sim$, as follows. We let $\phi(z)_+$ be given by (2.9) with the sum over $n\in\mathbb{Z}$ restricted to $n\geqslant 0$, $n\in\mathbb{Z}$. For $\phi(z)_-$ we restrict

the sum to $n \leqslant -(D/2)-m$, $n \in \mathbb{Z}$ (we first sum over m and then over n). For $\phi(z)_\sim$ we restrict the sum to $-(D/2)+1-m \leqslant n \leqslant -1$, $n \in \mathbb{Z}$. We call $\phi(z)_+$ the regular part of $\phi(z)$, and we define the singular part as

$$\phi(z)_{s.p.} := \phi(z)_- + \phi(z)_\sim. \tag{3.36}$$

Then, obviously, $\phi(z)_+ \in V[[z]]$ and

$$\phi(z) = \phi(z)_+ + \phi(z)_- + \phi(z)_\sim = \phi(z)_+ + \phi(z)_{s.p.}. \tag{3.37}$$

It is important that the above partition of the space of formal distributions is $\mathbb{C}[\partial_z]$-invariant, i.e.,

$$(\partial_z{}^{(\alpha)}\phi(z))_\star = \partial_z{}^{(\alpha)}\phi(z)_\star \quad \text{for } \star = +, -, \sim, \text{s.p.} \quad \text{and } \alpha = 1, \ldots, D. \tag{3.38}$$

Let us point out that the product $\phi(z)\iota_{z,w}((z-w)^2)^{-D/2}$ is well defined and belongs to the space $V[[z,1/z^2]][[w]]$. Then we can generalize Cauchy formula (3.24), using Eq. (3.26), to obtain

$$\mathrm{Res}_z\, \phi(z)\iota_{z,w}((z-w)^2)^{-D/2} = \phi(w)_+, \quad \phi(z) \in V[[z,1/z^2]]. \tag{3.39}$$

Thus, $\iota_{z,w}((z-w)^2)^{-D/2}$ may be called $\delta^+(z,w)$, and one can also introduce formal distributions $\delta^-(z,w)$ and $\delta^\sim(z,w)$ that give the $-$ and $\sim$ parts of $\phi(w)$, respectively, and such that $\delta(z,w) = \delta^+(z,w)+\delta^-(z,w)+\delta^\sim(z,w)$. In the case when D is even, this splitting of $\delta(z,w)$ coincides with the one in Eq. (3.35).

Remark 3.2: Introduce the formal distribution [cf. (3.26)]

$$\delta^+_{\mathrm{har}}(z,w) := (z^2-w^2)\iota_{z,w}((z-w)^2)^{-D/2} = \sum_{m=0}^{\infty} (z^2)^{-(D/2)+1-m} H_m(z,w).$$

It is harmonic with respect to both z and w, and has the property that

$$\mathrm{Res}_z\, h(z)\delta^+_{\mathrm{har}}(z,w) = h(w) \quad \text{for all } h(z) \in \mathbb{C}[z]^{\mathrm{har}}.$$

It follows from (3.31) that $\delta(z,w) = \delta_1(z^2-w^2)\delta^+_{\mathrm{har}}(z,w)$, where

$$\delta_1(x-y) := \sum_{n\in\mathbb{Z}} x^{-1-n}y^n \in \mathbb{C}[[x,x^{-1};y,y^{-1}]]$$

is the formal delta distribution in the usual $D=1$ theory of vertex algebras (see, e.g., Refs. 19, 21, and 24). Notice that, even though $(z^2-w^2)\delta_1(z^2-w^2)=0$, one cannot conclude from here that $\delta(z,w)=0$, because the product $\delta_1(z^2-w^2)\iota_{z,w}((z-w)^2)^{-D/2}$ is not well defined [see the discussion in Ref. 24, Sec. 2.1 and in particular Eq. (2.1.17)].

E. Transformation properties

For completeness, in this section we will investigate the transformation properties of the residue functional and the ι-operation under the *conformal inversion* $z \mapsto z/z^2$.

We observe that the substitution $\phi(z) \mapsto \phi(z/z^2)$ is a well-defined involution of $V[[z,(z^2)^{\mathbb{R}}]]$ if we set $((z/z^2)^2)^\gamma := (z^2)^{-\gamma}$. Explicitly, if $\phi(z)$ is given by (2.17), then

$$\phi\left(\frac{z}{z^2}\right) := \sum_{\gamma\in\Gamma}\sum_{m=0}^{\infty}\sum_{\sigma=1}^{\mathfrak{h}_m} \phi_{\{\gamma,m,\sigma\}}(z^2)^{-\gamma-m}h_{m,\sigma}(z), \tag{3.40}$$

because $h_{m,\sigma}(z/z^2) = (z^2)^{-m}h_{m,\sigma}(z)$. Clearly, under this isomorphism, the $\mathbb{C}[z]_{z^2}$-module $V[[z,(z^2)^\Gamma]]$ is mapped onto $V[[z,(z^2)^{-\Gamma}]]$.

Now let Γ be an additive subgroup of $\mathbb{R}$ containing $\mathbb{Z}$. For $\gamma \in \Gamma$, we define

$$\left(\left(\frac{z}{z^2}-\frac{w}{w^2}\right)^2\right)^{\gamma} := (z^2)^{-\gamma}(w^2)^{-\gamma}((z-w)^2)^{\gamma}, \tag{3.41}$$

which agrees with the usual formula for $\gamma=1$. Then the substitution $\psi(z,w)\mapsto\psi(z/z^2,w/w^2)$ defines an automorphism of $V[z,w]_{(z^2)^{\Gamma}(w^2)^{\Gamma}((z-w)^2)^{\Gamma}}$.

Proposition 3.9: Let $\phi(z)\in V[\![z,(z^2)^{\mathbb{R}}]\!]$ *and* $\psi(z,w)\in V[z,w]_{(z^2)^{\Gamma}(w^2)^{\Gamma}((z-w)^2)^{\Gamma}}$. *Then we have*

$$\mathrm{Res}_z\,\phi\left(\frac{z}{z^2}\right)=\mathrm{Res}_z(z^2)^{-D}\phi(z) \tag{3.42}$$

and

$$\iota_{z,w}\left(\psi\left(\frac{z}{z^2},\frac{w}{w^2}\right)\right)=(\iota_{w',z'}\psi(z',w'))\Big|_{z'=z/z^2,w'=w/w^2}. \tag{3.43}$$

Proof: Equation (3.42) is immediate from the definition of the residue [cf. (2.17), (3.40)]. To prove (3.43), it suffices to check it for $\psi(z,w)=((z-w)^2)^{\gamma}$, in which case the statement follows from (2.27), (3.27), and (3.41). □

One can define involutive automorphisms

$$\phi(z)\mapsto\phi(-z),\quad \psi(z,w)\mapsto\psi(-z,-w) \tag{3.44}$$

of $V[\![z,(z^2)^{\mathbb{R}}]\!]$ and $V[z,w]_{(z^2)^{\Gamma}(w^2)^{\Gamma}((z-w)^2)^{\Gamma}}$ by setting [cf. (2.27)]

$$(z^2)^{\gamma_1}(w^2)^{\gamma_2}((z-w)^2)^{\gamma_3}f(z,w)\mapsto(z^2)^{\gamma_1}(w^2)^{\gamma_2}((z-w)^2)^{\gamma_3}f(-z,-w) \tag{3.45}$$

for $f(z,w)\in V[\![z,w]\!]$. By the definition of $\iota_{z,w}$ and $\iota_{w,z}$ (see Sec. II F), the so-defined operation commutes with both of them. It is also clear that it anticommutes with all partial derivatives ∂_{z^α}, ∂_{w^α}, and satisfies

$$\mathrm{Res}_z\,\phi(-z)=\mathrm{Res}_z\,\phi(z),\quad \phi(z)\in V[\![z,(z^2)^{\mathbb{R}}]\!]. \tag{3.46}$$

Remark 3.3: In analogy with the above automorphism (3.45), one can define an automorphism Θ by setting

$$\Theta:(z^2)^{\gamma_1}(w^2)^{\gamma_2}((z-w)^2)^{\gamma_3}f(z,w)\mapsto e^{2\pi i(\gamma_1+\gamma_2+\gamma_3)}(z^2)^{\gamma_1}(w^2)^{\gamma_2}((z-w)^2)^{\gamma_3}f(z,w)$$

for $f(z,w)\in V[\![z,w]\!]$. Then Θ commutes with the ι-operations and with the partial derivatives, and instead of (3.46) one has $\mathrm{Res}_z(\Theta\phi)(z)=(-1)^D\,\mathrm{Res}_z\,\phi(z)$.

IV. FIELDS AND LOCALITY

In this section we investigate the notions of fields, locality, and operator product expansion in higher dimensions, mainly following Ref. 28. We give the definition of vertex algebra and we provide two examples of vertex algebras.

A. Polylocal fields

In this section we introduce the notion of a field of several variables, and we generalize the results of Ref. 28, Sec. 2 about the existence of operator product expansion.

Let $V=V_{\bar{0}}\oplus V_{\bar{1}}$ be a $\mathbb{Z}_2$-graded vector space (i.e., a *superspace*). Then $\mathrm{End}\,V=(\mathrm{End}\,V)_{\bar{0}}\oplus(\mathrm{End}\,V)_{\bar{1}}$ is a $\mathbb{Z}_2$-graded associative algebra, and we will denote its Lie super bracket by

$$[A,B]:=AB-(-1)^{pq}BA,\quad \text{for } A\in(\mathrm{End}\,V)_p,\quad B\in(\mathrm{End}\,V)_q. \tag{4.1}$$

We will suppose that V is endowed with an action of mutually commuting even endomorphisms $T_1,\ldots,T_D$ (called **translation endomorphisms**) and with an even vector $|0\rangle$ (called **vacuum**), such that $T_1|0\rangle=\cdots=T_D|0\rangle=0$.

Let $A(z_1,\dots,z_m)$ be an (End V)-valued formal distribution; in other words, let

$$A(z_1,\dots,z_m) \in (\mathrm{End}\ V)[[z_1,1/z_1^2;\dots;z_m,1/z_m^2]]. \tag{4.2}$$

It is called a **field** in $z_1,\dots,z_m$ (or just an m-field) iff for every $v \in V$ one has

$$A(z_1,\dots,z_m)v \in V[[z_1,\dots,z_m]]_{z_1^2\cdots z_m^2}. \tag{4.3}$$

This means that for every $v \in V$ there is a non-negative integer $N_{A,v}$ such that

$$A(z_1,\dots,z_m)v = (z_1^2\cdots z_m^2)^{-N_{A,v}}\psi_{A,v}(z_1,\dots,z_m) \tag{4.4}$$

for some $\psi_{A,v}(z_1,\dots,z_m) \in V[[z_1,\dots,z_m]]$.

If A is an m-field, then for every partition

$$\{1,\dots,m\} = J_1 \sqcup \cdots \sqcup J_r \quad \text{(disjoint union)}, \tag{4.5}$$

the restriction

$$\widetilde{A}(u_1,\dots,u_r)v := ((z_1^2\cdots z_m^2)^{-N_{A,v}}\psi_{A,v}(z_1,\dots,z_m))\big|_{z_j:=u_s \text{ for } j\in J_s} \tag{4.6}$$

makes sense and defines again a field.

An m-field [or, more generally, an (End V)-valued formal distribution] A is called **translation invariant** iff

$$[T_\alpha, A(z_1,\dots,z_m)] = \sum_{k=1}^{m} \partial_{z_k^\alpha} A(z_1,\dots,z_m) \tag{4.7}$$

for every $\alpha = 1,\dots,D$.

Let us point out that a product $A(z_1,\dots,z_m)B(w_1,\dots,w_n)$ of two fields is *not* a field in general. Indeed, by the above definition, for every $v \in V$ we have

$$A(z_1,\dots,z_m)B(w_1,\dots,w_n)v \in V[[z_1,\dots,z_m]]_{z_1^2\cdots z_m^2}[[w_1,\dots,w_n]]_{w_1^2\cdots w_n^2}, \tag{4.8}$$

and it may contain infinitely many negative powers of $z_1^2,\dots,z_m^2$. As a consequence, the restriction of the product (4.8) for coinciding arguments is not well defined in general. We will show below that one can "regularize" this product to make a field if the following definition is satisfied.

Two fields [or, more generally, (End V)-valued formal distributions] A and B are called **mutually local** iff there exists a non-negative integer $N_{A,B}$ such that

$$\left(\prod_{j=1}^{m}\prod_{k=1}^{n}(z_j-w_k)^2\right)^{N_{A,B}} [A(z_1,\dots,z_m),B(w_1,\dots,w_n)] = 0. \tag{4.9}$$

A 1-field that is local with respect to itself is usually called a **local** field; a 2-field that is local with respect to itself is called a **bilocal** field. An m-field, for general m, which is local with respect to itself, is called a **polylocal** field.

In the following statement we sum up some consequences of the above definitions.

Theorem 4.1: *Let* $A(z_1,\dots,z_m)$ *and* $B(z_1,\dots,z_n)$ *be an m-field and an n-field, respectively, which are mutually local as above.*

(a) *Every restriction* (4.6) *of A is also a field and is mutually local with respect to B.*
(b) *If the field A is translation invariant, then its restrictions* (4.6) *are also translation invariant fields.*
(c) *If A is translation invariant, then* $A(z_1,\dots,z_m)|0\rangle \in V[[z_1,\dots,z_m]]$.
(d) *Every partial derivative* $\partial_{z_k^\alpha}A$ *is a field and is mutually local with respect to B. If the field A is translation invariant, then* $\partial_{z_k^\alpha}A$ *is also translation invariant.*
(e) *The formal distribution*

$$F_{A,B}(\mathrm{z}_1,\dots,\mathrm{z}_m,\mathrm{w}_1,\dots,\mathrm{w}_n) := \left(\prod_{j=1}^{m}\prod_{k=1}^{n}(\mathrm{z}_j-\mathrm{w}_k)^2\right)^{N_{A,B}} A(\mathrm{z}_1,\dots,\mathrm{z}_m)B(\mathrm{w}_1,\dots,\mathrm{w}_n) \quad (4.10)$$

is an $(m+n)$-field. If the fields A and B are local with respect to a p-field $C(\mathrm{z}_1,\dots,\mathrm{z}_p)$, then $F_{A,B}$ is also local with respect to C. If both fields A and B are translation invariant, then $F_{A,B}$ is also translation invariant.

Proof: Statements (a) and (b) follow easily from definitions.

Statement (c) for $m=1$ is proved in Ref. 32, Proposition 3.2(a), and that proof can be straightforwardly generalized for general m (note that one can take $h_2=h_1$ there).

To prove (d), one "commutes" the derivative $\partial_{\mathrm{z}_k}^{\alpha}$ through the polynomial $((\mathrm{z}_k-\mathrm{w}_j)^2)^N$, as it is done in a more general case in Ref. 28, Lemma 2.3.

(e) Note that, by (4.8) and (4.9), for every $v\in V$ the series $F_{A,B}(\mathrm{z}_1,\dots,\mathrm{z}_m,\mathrm{w}_1,\dots,\mathrm{w}_n)v$ belongs to the intersection

$$V[\![\mathrm{z}_1,\dots,\mathrm{z}_m]\!]_{\mathrm{z}_1^2\cdots\mathrm{z}_m^2}[\![\mathrm{w}_1,\dots,\mathrm{w}_n]\!]_{\mathrm{w}_1^2\cdots\mathrm{w}_n^2} \cap V[\![\mathrm{w}_1,\dots,\mathrm{w}_n]\!]_{\mathrm{w}_1^2\cdots\mathrm{w}_n^2}[\![\mathrm{z}_1,\dots,\mathrm{z}_m]\!]_{\mathrm{z}_1^2\cdots\mathrm{z}_m^2}$$

which is exactly $V[\![\mathrm{z}_1,\dots,\mathrm{z}_m,\mathrm{w}_1,\dots,\mathrm{w}_n]\!]_{\mathrm{z}_1^2\cdots\mathrm{z}_m^2\mathrm{w}_1^2\cdots\mathrm{w}_n^2}$. But this means, by definition, that $F_{A,B}$ is an $(m+n)$-field. The remaining part of the statement is straightforward. □

As a corollary of Theorem 4.1, every m-field $A(\mathrm{z}_1,\dots,\mathrm{z}_m)$ can be expanded in 1-fields as follows. Consider for $v\in V$ the formal expansion

$$\begin{aligned}&\iota_{\mathrm{z},\mathrm{w}_1}\cdots\iota_{\mathrm{z},\mathrm{w}_{m-1}}A(\mathrm{z}+\mathrm{w}_1,\dots,\mathrm{z}+\mathrm{w}_{m-1},\mathrm{z})v\\ &\quad := \exp(\mathrm{w}_1\cdot\partial_{\mathrm{z}_1}+\cdots+\mathrm{w}_{m-1}\cdot\partial_{\mathrm{z}_{m-1}})A(\mathrm{z}_1,\dots,\mathrm{z}_m)v\big|_{\mathrm{z}_1=\cdots=\mathrm{z}_m=\mathrm{z}}\\ &\quad \in V[\![\mathrm{z}]\!]_{\mathrm{z}^2}[\![\mathrm{w}_1,\dots,\mathrm{w}_{m-1}]\!].\end{aligned} \quad (4.11)$$

This is a formal power series in $\mathrm{w}_1,\dots,\mathrm{w}_{m-1}$ with coefficients of the form $\psi_i(\mathrm{z})v\in V[\![\mathrm{z}]\!]_{\mathrm{z}^2}$ for some uniquely defined fields $\psi_i(\mathrm{z})$ (i running over some index set). All $\psi_i(\mathrm{z})$ are fields because they are obtained from $A(\mathrm{z}_1,\dots,\mathrm{z}_m)$ by the operations of differentiation and restriction. If, in addition, A is translation invariant and is local with respect to some other fields B, C, etc., then all the fields $\psi_i(\mathrm{z})$ are also translation invariant and local with respect to B, C, etc.

The formal expansion (4.11) is called the **operator expansion** of $A(\mathrm{z}_1,\dots,\mathrm{z}_m)$. Applying this expansion to the field $F_{A,B}$ (4.10), we get what is called the **operator product expansion** (OPE) of two mutually local fields A and B.

Example 4.1: Let us consider, for comparison, the $D=1$ case of OPE. Recall from Example 3.1 that now $\mathrm{z}=z$ is a one-component variable and the space of (End V)-valued formal distributions is identified with (End V)$[\![z,z^{-1}]\!]$. Then our notions of *fields* and *locality* coincide with the ones used in vertex algebra theory (see Refs. 20, 13, 25, 21, and 24). For two mutually local fields $a(z)$ and $b(z)$ with parities p_a and p_b, respectively, one introduces their nth product for $n\in\mathbb{Z}$ by

$$(a(w)_{(n)}b(w))c := \mathrm{res}_z\, a(z)b(w)c\iota_{z,w}(z-w)^n-(-1)^{p_ap_b}\mathrm{res}_z\, b(w)a(z)c\iota_{w,z}(z-w)^n, \quad (4.12)$$

where $\mathrm{res}_z\, z^k := \delta_{k,-1}$ is the usual residue functional (it corresponds to our Res'_z; see Example 3.1). By the Cauchy theorem for res_z (see Refs. 19, 21, and 24), one gets an equivalent definition

$$(a(w)_{(n)}b(w))c = \frac{1}{N!}\partial_z^N((z-w)^{N+n+1}a(z)b(w)c)\big|_{z=w}, \quad N\gg 0, \quad (4.13)$$

where the right-hand side is independent of N. Our approach to the OPE of $a(z)$ and $b(z)$ corresponds precisely to definition (4.13). Then *Dong's lemma*, the fact that the field $a(z)_{(n)}b(z)$ is local with respect to every field $c(z)$ local with respect to a and b, is a simple corollary of Theorem 4.1 (e), (d), (a).

B. Completeness and state-field correspondence: Definition of vertex algebra

The translation invariance and locality properties allow us to introduce a state-field correspondence for a vertex algebra in higher dimensions, as in Secs. 3 and 4 of Ref. 28. Here we will reproduce these results in a more concise way.

As in the previous section, let V be a superspace endowed with an action of mutually commuting even endomorphisms T_α ($\alpha=1,\dots,D$) and a vacuum vector $|0\rangle$. A system of fields $\{\phi_i(z)\}_{i\in\mathcal{I}}$ is called **local** iff $\phi_i(z)$ and $\phi_j(z)$ are mutually local for every $i,j\in\mathcal{I}$. The system $\{\phi_i(z)\}$ is called **translation invariant** iff every $\phi_i(z)$ is translation invariant. Finally, the system $\{\phi_i(z)\}$ is called **complete** (with respect to the vacuum $|0\rangle$) iff the coefficients of all formal series $\phi_{i_1}(z_1)\cdots\phi_{i_n}(z_n)|0\rangle$ ($n\in\mathbb{N}$)together with $|0\rangle$ span the whole vector space V. In other words, the system $\{\phi_i(z)\}$ is complete iff the vacuum $|0\rangle$ is a cyclic vector for the associative subalgebra of End V generated by the modes of all fields $\phi_i(z)$.

Theorem 4.2: Let $\{\phi_i(z)\}_{i\in\mathcal{I}}$ *be a translation invariant, local, and complete system of fields. Then for every* $a\in V$ *there exists a unique field, denoted as* $Y(a,z)$, *which is translation invariant, local with respect to all* $\phi_i(z)$, *and such that*

$$Y(a,z)|0\rangle\big|_{z=0}=a. \tag{4.14}$$

Proof: Let us consider the vector space $\mathcal{F}$ of all translation invariant 1-fields that are local with respect to $\phi_i(z)$ for all $i\in\mathcal{I}$. By Theorem 4.1(c), there is a well-defined linear map

$$\mathcal{F}\to V,\quad \chi(z)\mapsto\chi(z)|0\rangle\big|_{z=0}. \tag{4.15}$$

It follows from translation invariance that

$$\chi(z)|0\rangle=e^{z\cdot T}(\chi(w)|0\rangle\big|_{w=0}),\quad z\cdot T:=z^1T_1+\cdots+z^DT_D.$$

Then Theorem 3.1 from Ref. 28 implies that map (4.15) is injective. The theorem will be proved as soon as we show that map (4.15) is surjective.

Consider for every fixed $m=1,2,\dots$ and $i_1,\dots,i_m\in\mathcal{I}$ the m-field

$$A(z_1,\dots,z_m):=\Bigg(\prod_{1\le k<l\le m}(z_{kl}^2)^{N_{kl}}\Bigg)\phi_{i_1}(z_1)\cdots\phi_{i_m}(z_m),$$

where $z_{kl}=z_k-z_l$ and N_{kl} are the integers fulfilling the locality condition (4.9) for ϕ_{i_k} and ϕ_{i_l}. We then claim that all coefficients of $A(z_1,\dots,z_m)|0\rangle$ belong to the image of (4.15). To prove this, first note that by Theorem 4.1(e) A is a translation invariant m-field that is local with respect to $\phi_i(z)$ for all $i\in\mathcal{I}$. Then all coefficients $\psi_i(z)$ in the operator expansion of A are contained in $\mathcal{F}$ [see (4.11)]. It follows from Theorem 4.1(c) that for $v=|0\rangle$ the right-hand side of (4.11) is simply the Taylor expansion of

$$A(z+w_1,\dots,z+w_{m-1},z)|0\rangle\in V[\![z,w_1,\dots,w_{m-1}]\!].$$

Then it is clear that all coefficients of $A(z_1,\dots,z_m)|0\rangle$ belong to the image of (4.15).

On the other hand, iterating (4.8) we obtain that [cf. (2.32)]:

$$\phi_{i_1}(z_1)\cdots\phi_{i_m}(z_m)|0\rangle\in V[\![z_1]\!]_{z_1^2}\cdots[\![z_m]\!]_{z_m^2}. \tag{4.16}$$

The right-hand side of (4.16) is a module over the algebra $\mathbb{C}[\![z_1]\!]_{z_1^2}\cdots[\![z_m]\!]_{z_m^2}$, in which the polynomial $\Pi_{k<l}(z_{kl}^2)^{N_{kl}}$ is invertible: its inverse is given by applying the expansion $\Pi_{k<l}\,\iota_{z_k,z_l}$ (see Sec. II F). Therefore,

$$\phi_{i_1}(z_1)\cdots\phi_{i_m}(z_m)|0\rangle=\Bigg(\prod_{1\le k<l\le m}\iota_{z_k,z_l}(z_{kl}^2)^{-N_{kl}}\Bigg)A(z_1,\dots,z_m)|0\rangle\,.$$

This implies that every coefficient of (4.16) can be expressed as a linear combination of coefficients of $A(\mathrm{z}_1,\ldots,\mathrm{z}_m)|0\rangle$, and hence belongs to the image of map (4.15). But by completeness the coefficients of (4.16) span V; therefore, (4.15) is surjective. □

Corollary 4.3: Let $\chi(\mathrm{z})$ *be a translation invariant field, which is local with respect to a translation invariant, local, and complete system of fields* $\{\phi_i(\mathrm{z})\}$. *Then* $\chi(\mathrm{z})$ *is a local field and* $\chi(\mathrm{z})=Y(a,\mathrm{z})$ *for* $a=\chi(\mathrm{z})|0\rangle|_{\mathrm{z}=0}$.

Theorem 4.2 leads naturally to the following definition.[28]

Definition 4.1: A **vertex algebra** V over $\mathbb{C}^D$ is a superspace V endowed with

(a) an action of mutually **commuting, even** endomorphisms $T_1,\ldots,T_D$ (translation endomorphisms),
(b) an **even** vector $|0\rangle$ (vacuum) such that $T_1|0\rangle=\cdots=T_D|0\rangle=0$,
(c) a **parity preserving** linear map (state-field correspondence)

$$V\to(\mathrm{End}\,V)[\![\mathrm{z},1/\mathrm{z}^2]\!],\quad a\mapsto Y(a,\mathrm{z}),$$

such that $\{Y(a,\mathrm{z})\}_{a\in V}$ is a **translation invariant, local** system of **fields** and $a=Y(a,\mathrm{z})|0\rangle|_{\mathrm{z}=0}$ for all $a\in V$.

Corollary 4.4: Every translation invariant, local, and complete system of fields $\{\phi_i(\mathrm{z})\}$ *generates on V a unique structure of a vertex algebra.*

Note that when $D=1$, Definition 4.1 is equivalent to the definition of a usual (chiral) vertex algebra (see, e.g., Refs. 21 and 24). We will use the notation

$$a(\mathrm{z})\equiv Y(a,\mathrm{z}) \tag{4.17}$$

as it is customary in the usual $D=1$ theory of vertex algebras. For a vertex algebra V and elements $a,b\in V$, we denote by $N(a,b)$ the smallest non-negative integer fulfilling the locality condition for $a(\mathrm{z})$ and $b(\mathrm{z})$, i.e.,

$$N(a,b):=\min\{N\in\mathbb{Z}_+|((\mathrm{z}-\mathrm{w})^2)^N[a(\mathrm{z}),b(\mathrm{w})]=0\}. \tag{4.18}$$

Remark 4.1: One can introduce a more general notion of vertex algebra that involves nonintegral powers of z^2 in the definition of a field and in the notion of locality. For $D=1$ this would correspond to the "generalized vertex algebras" of Refs. 16, 13, and 27, as explained in Ref. 3. For $D=2$, a related notion was introduced in Ref. 23.

C. Examples of vertex algebras

For completeness, in this section we present two simple examples of vertex algebras. We refer to Refs. 28, 32, 5, and 6 for additional examples.

Our first example shows that the notion of a vertex algebra includes as a special case that of a (super)commutative associative algebra (cf. Ref. 8). We call a vertex algebra V over $\mathbb{C}^D$ holomorphic if $Y(a,\mathrm{z})\in(\mathrm{End}\,V)[\![\mathrm{z}]\!]$ for all $a\in V$. The following statement is a straightforward generalization of the corresponding one in the case $D=1$ (see Refs. 8, 21, and 24).

Proposition 4.5: (a) *If V is a holomorphic vertex algebra over* $\mathbb{C}^D$, *then* $a\star b:=Y(a,z)b|_{\mathrm{z}=0}$ *defines on V the structure of supercommutative associative algebra with a unit* $|0\rangle$ *and even derivations* $T_1,\ldots,T_D$.

(b) *Conversely, given a supercommutative associative algebra V with a product* $\star$, *a unit* $|0\rangle$, *and with mutually commuting even derivations* $T_1,\ldots,T_D$, *then* $Y(a,\mathrm{z})b:=(e^{\mathrm{z}\cdot\mathrm{T}}a)\star b$ *defines the structure of a holomorphic vertex algebra on V.*

Our second example is the vertex algebra generated by a harmonic scalar free field $\varphi(\mathrm{z})$ in *even* space–time dimensions $D>2$ (see Ref. 28 Sec. 5 for a more general construction). Consider a new formal variable $\mathrm{p}:=(p_1,\ldots,p_D)$ and introduce the vector spaces

$$P := \mathbb{C}[\mathrm{p}]/\mathrm{p}^2\mathbb{C}[\mathrm{p}] \cong \mathbb{C}[\mathrm{p}]^{\mathrm{har}}, \quad V := \mathbb{C}[P]. \tag{4.19}$$

Here V is defined as the algebra of all polynomials of the elements of P, i.e., it is the symmetric algebra of P. We will denote by $[f(\mathrm{p})]$ the equivalence class of a polynomial $f(\mathrm{p}) \in \mathbb{C}[\mathrm{p}]$ in P. Then V is the linear span over $\mathbb{C}$ of all monomials of the form $[f_1(\mathrm{p})]\cdots[f_n(\mathrm{p})]$ (note that $[f_1(\mathrm{p})][f_2(\mathrm{p})] \neq [f_1(\mathrm{p})f_2(\mathrm{p})]$ in V).

We define an (End V)-valued formal distribution $\varphi(\mathrm{z})$ by the formula

$$\varphi(\mathrm{z})[f_1(\mathrm{p})]\cdots[f_n(\mathrm{p})] := \sum_{k=0}^{\infty} \frac{1}{k!}[(\mathrm{z}\cdot\mathrm{p})^k][f_1(\mathrm{p})]\cdots[f_n(\mathrm{p})] + \sum_{l=1}^{n} f_l(-\partial_{\mathrm{z}})(\mathrm{z}^2)^{-\frac{D}{2}+1}[f_1(\mathrm{p})]\cdots\widehat{[f_l(\mathrm{p})]}\cdots[f_n(\mathrm{p})], \tag{4.20}$$

where a hat over a term means that it is omitted in the product. This does not depend on the choice of representatives $f_l(\mathrm{p})$ because $\partial_{\mathrm{z}}^2(\mathrm{z}^2)^{-(D/2)+1}=0$. Since the right-hand side of (4.20) contains only finitely many negative powers of z^2, it follows that $\varphi(\mathrm{z})$ is a field. After a straightforward computation, one finds

$$\varphi(\mathrm{z}_1)\varphi(\mathrm{z}_2)[f_1(\mathrm{p})]\cdots[f_n(\mathrm{p})] = e^{-\mathrm{z}_2\cdot\partial_{\mathrm{z}_1}}(\mathrm{z}_1^2)^{-(D/2)+1}[f_1(\mathrm{p})]\cdots[f_n(\mathrm{p})] + \cdots, \tag{4.21}$$

where the remaining terms are symmetric under the exchange of z_1 and z_2. Hence,

$$[\varphi(\mathrm{z}_1),\varphi(\mathrm{z}_2)] = (\iota_{\mathrm{z}_1,\mathrm{z}_2}(\mathrm{z}_{12}^2)^{-(D/2)+1} - \iota_{\mathrm{z}_2,\mathrm{z}_1}(\mathrm{z}_{12}^2)^{-(D/2)+1})\mathrm{id}_V, \tag{4.22}$$

where $\mathrm{z}_{12}=\mathrm{z}_1-\mathrm{z}_2$. Therefore, $\varphi(\mathrm{z})$ is a *local field*, since

$$(\mathrm{z}_{12}^2)^{(D/2)-1}[\varphi(\mathrm{z}_1),\varphi(\mathrm{z}_2)] = 0. \tag{4.23}$$

We define endomorphisms $T_1,\ldots,T_D$ of V by the formula

$$T_\alpha[f_1(\mathrm{p})]\cdots[f_n(\mathrm{p})] := \sum_{l=1}^{n} [p_\alpha f_l(\mathrm{p})][f_1(\mathrm{p})]\cdots\widehat{[f_l(\mathrm{p})]}\cdots[f_n(\mathrm{p})] \tag{4.24}$$

for $\alpha=1,\ldots,D$. In particular, $T_\alpha|0\rangle=0$, where $|0\rangle$ is the constant polynomial $1\in V$. One can easily verify that the endomorphisms $T_1,\ldots,T_D$ commute with each other, and the field $\varphi(\mathrm{z})$ is *translation invariant*. Let us point out that $\varphi(\mathrm{z})|0\rangle=[e^{\mathrm{z}\cdot\mathrm{p}}]=e^{\mathrm{z}\cdot\mathrm{T}}[1]$, and $\varphi(\mathrm{z})|0\rangle|_{\mathrm{z}=0}=[1]\neq 1=|0\rangle$.

Using (4.20), one can prove by induction on n that every monomial $[f_1(\mathrm{p})]\cdots[f_n(\mathrm{p})]$ is a linear combination of the coefficients of $\varphi(\mathrm{z}_1)\cdots\varphi(\mathrm{z}_n)|0\rangle$. Therefore, the field $\varphi(\mathrm{z})$ is *complete*, and one can apply Corollary 4.4 to generate on V the structure of a vertex algebra over $\mathbb{C}^D$. Finally, we note that the field $\varphi(\mathrm{z})$ is *harmonic*, i.e., it satisfies the Laplace equation $\partial_{\mathrm{z}}^2\varphi(\mathrm{z})=0$. This follows from (4.19), (4.20) and the fact that the function $(\mathrm{z}^2)^{-(D/2)+1}$ is harmonic.

V. JACOBI IDENTITY

This section contains the main results of the paper. We first prove certain "formal commutativity and associativity" relations, and then use them to derive our Jacobi identity. Integral versions of the Jacobi identity are also presented. We show that together with a partial vacuum axiom it can be taken as an equivalent definition of the notion of vertex algebra over $\mathbb{C}^D$. We derive a formula for the commutator of two fields, and we prove that the singular parts of fields close a substructure under the commutator.

A. Commutativity and associativity

In this section we will extend the "associativity" of Ref. 28, Theorem 4.3 by giving a connection between the degrees of the poles in a product $a(z)b(w)$ of two fields and the integers $N(a,b)$ introduced in (4.18). In the case of usual $D=1$ vertex algebras our results agree with the "formal commutativity and associativity" of Refs. 17 and 24.

Theorem 5.1: ("Formal commutativity and associativity.") *Let V be a vertex algebra, and let $a,b,c \in V$, where a and b have parities p_a and p_b, respectively. Then there exists a localized formal series*

$$\mathcal{Y}_{a,b,c}(z_1,z_2) = \frac{\psi_{a,b,c}(z_1,z_2)}{(z_1^2)^{N(a,c)}(z_2^2)^{N(b,c)}(z_{12}^2)^{N(a,b)}}, \tag{5.1}$$

where

$$\psi_{a,b,c}(z_1,z_2) \in V[[z_1,z_2]], \quad z_{12} = z_1 - z_2,$$

such that

$$\mathcal{Y}_{a,b,c}(z_1,z_2) = (-1)^{p_a p_b}\mathcal{Y}_{b,a,c}(z_2,z_1) \tag{5.2}$$

and

$$a(z_1)b(z_2)c = \iota_{z_1,z_2}\mathcal{Y}_{a,b,c}(z_1,z_2), \tag{5.3}$$

$$b(z_2)a(z_1)c = (-1)^{p_a p_b}\iota_{z_2,z_1}\mathcal{Y}_{a,b,c}(z_1,z_2), \tag{5.4}$$

$$(a(z_3)b)(z_2)c = \iota_{z_2,z_3}\mathcal{Y}_{a,b,c}(z_2+z_3,z_2). \tag{5.5}$$

Proof: Equations (5.2)–(5.5) follow from Proposition 4.2 and Theorem 4.3 of Ref. 28. The explicit form (5.1) of $\mathcal{Y}_{a,b,c}(z_1,z_2) \in V[[z_1,z_2]]_{z_1^2 z_2^2 z_{12}^2}$ follows from Eq. (4.18) and the following lemma, which provides another description of the numbers $N(a,b)$. □

Lemma 5.2: For any two elements a and b in a vertex algebra V, we have

$$N(a,b) = \min\{N \in \mathbb{Z}_+ | (z^2)^N a(z)b \in V[[z]]\}. \tag{5.6}$$

Proof: Denote the right-hand side of (5.6) by $N'(a,b)$, and consider the formal distribution

$$F_{a,b}(z_1,z_2) := (z_{12}^2)^{N(a,b)}a(z_1)b(z_2).$$

Due to Theorem 4.1(e), (c), $F_{a,b}$ is a translation invariant, bilocal field and $F_{a,b}(z_1,z_2)|0\rangle \in V[[z_1,z_2]]$. Therefore, setting $z_2=0$ we find from $b(z_2)|0\rangle|_{z_2=0}=b$ that $N'(a,b) \leqslant N(a,b)$.

Consider now the formal distribution

$$F'_{a,b}(z_1,z_2) := (z_{12}^2)^{N'(a,b)}a(z_1)b(z_2).$$

As in the proof of Theorem 4.1(e), $F'_{a,b}$ is translation invariant and local (as a formal distribution) with respect to all fields $c(z)$ for $c \in V$. It follows from translation invariance that

$$F'_{a,b}(z_1,z_2)|0\rangle = e^{z_2\cdot T}((z_{12}^2)^{N'(a,b)}a(z_{12})b) \in V[[z_{12},z_2]] \equiv V[[z_1,z_2]]. \tag{5.7}$$

On the other hand, by locality (assuming that $c \in V$ has a fixed parity p_c) we get

$$((z_1-w)^2(z_2-w)^2)^N F'_{a,b}(z_1,z_2)c(w)|0\rangle = ((z_1-w)^2(z_2-w)^2)^N(-1)^{(p_a+p_b)p_c}c(w)F'_{a,b}(z_1,z_2)|0\rangle$$

for $N \gg 0$. It follows from Eq. (5.7) and Theorem 4.1 that both sides of the above equation belong to the intersection of $V[[z_1, 1/z_1^2; z_2, 1/z_2^2]][[w]]$ and $V[[w]]_{w^2}[[z_1,z_2]]$. But the latter space is exactly $V[[z_1,z_2,w]]$. Therefore,

$$((z_1-w)^2(z_2-w)^2)^N F'_{a,b}(z_1,z_2)c(w)|0\rangle \in V[[z_1,z_2,w]],$$

and setting $w=0$ we find that $F'_{a,b}$ is a field.

In the same way one proves that

$$F'_{b,a}(z_1,z_2) := (z_{12}^2)^{N'(a,b)} b(z_2)a(z_1)$$

is a field; note that $N'(a,b)=N'(b,a)$ because of the "quasisymmetry" relation

$$a(z)b = (-1)^{p_a p_b} e^{z\cdot T}(b(-z)a), \quad a,b \in V \tag{5.8}$$

(see Ref. 28, Proposition 4.4). Locality for $a(z)$ and $b(z)$ implies that

$$(z_{12}^2)^N (F'_{a,b}(z_1,z_2) - (-1)^{p_a p_b} F'_{b,a}(z_1,z_2))c = 0, \quad N \gg 0.$$

On the other hand, since $F'_{a,b}$ and $F'_{b,a}$ are fields,

$$(F'_{a,b}(z_1,z_2) - (-1)^{p_a p_b} F'_{b,a}(z_1,z_2))c \in V[[z_1,z_2]]_{z_1^2 z_2^2},$$

which is a $\mathbb{C}[z_1,z_2]_{z_1^2 z_2^2}$-module with *no zero divisors*. Hence, $F'_{a,b}=(-1)^{p_a p_b}F'_{b,a}$ and $N(a,b) \leqslant N'(a,b)$. □

From the proof of Lemma 5.2 and from Theorem 4.1, we deduce the following corollary.

Corollary 5.3: Let V be a vertex algebra, and let $A(z_1,\dots,z_m)$ be an (End V)*–valued formal distribution, which is translation invariant and local with respect to all fields $Y(c,z)(c \in V)$. Then A is an m-field if and only if $A(z_1,\dots,z_m)|0\rangle \in V[[z_1,\dots,z_m]]$.*

Next, we will derive from Theorem 5.1 an "associativity" property, which generalizes Eqs. (4.2) and (7.3) from Ref. 2 (see also Refs. 13 and 24).

Proposition 5.4: ("Associativity") *For every three elements a,b,c in a vertex algebra V and for $L \geqslant N(a,c)$, we have*

$$((z+w)^2)^L (a(z)b)(w)c = ((z+w)^2)^L \iota_{z,w} a(z+w)b(w)c, \tag{5.9}$$

$$(z^2)^L a(z)b(w)c = [((u+z-w)^2)^L \iota_{z,w}(a(z-w)b)(u)c]_{u=w}, \tag{5.10}$$

where the expression under the substitution on the right-hand side of (5.10) *belongs to $\iota_{z,w}V[[z,w,u]]_{(z-w)^2u^2}$ and setting $u=w$ makes sense.*

Proof: We can assume without loss of generality that $L=N(a,c)$. Then, by Theorem 5.1, the left-hand side of (5.9) is equal to

$$\frac{\psi_{a,b,c}(z+w,w)}{(z^2)^{N(a,b)}(w^2)^{N(b,c)}} \in V[[z,w]]_{z^2w^2},$$

while the right-hand side is

$$\iota_{z,w}\iota_{z+w,w}\frac{\psi_{a,b,c}(z+w,w)}{(((z+w)-w)^2)^{N(a,b)}(w^2)^{N(b,c)}}.$$

Then Eq. (5.9) follows from Taylor's formula (2.31). The proof of Eq. (5.10) is simpler: its sides are equal to

$$\iota_{z,w}\frac{\psi_{a,b,c}(z,w)}{((z-w)^2)^{N(a,b)}(w^2)^{N(b,c)}} \quad \text{and} \quad \iota_{z,w}\frac{\psi_{a,b,c}(u+z-w,u)}{((z-w)^2)^{N(a,b)}(u^2)^{N(b,c)}},$$

respectively, and obviously they become equal after the substitution $u=w$. □

B. Jacobi identity

In this section, for any three elements in a vertex algebra over $\mathbb{C}^D$, we derive an identity that generalizes the Jacobi identity of Ref. 19 (and the Borcherds identity of Ref. 21) for usual $D=1$ vertex algebras.

Theorem 5.5: ("Jacobi identity") *Let V be a vertex algebra, and let $a,b,c \in V$, where a and b have fixed parities p_a and p_b, respectively. Then for $L \geqslant N(a,c)$ and for every $F(\mathrm{z},\mathrm{w}) \in \mathbb{C}[[\mathrm{z},\mathrm{w}]]_{(\mathrm{z}^2)^{\mathbb{R}}(\mathrm{w}^2)^{\mathbb{R}}((\mathrm{z}-\mathrm{w})^2)^{\mathbb{R}}}$, we have*

$$\begin{aligned} &a(\mathrm{z})b(\mathrm{w})c\iota_{\mathrm{z},\mathrm{w}}F(\mathrm{z},\mathrm{w}) - (-1)^{p_a p_b}b(\mathrm{w})a(\mathrm{z})c\iota_{\mathrm{w},\mathrm{z}}F(\mathrm{z},\mathrm{w}) \\ &\quad = (\mathrm{z}^2)^{-L}[((\mathrm{u}+\mathrm{z}-\mathrm{w})^2)^L(\iota_{\mathrm{z},\mathrm{w}} - \iota_{\mathrm{w},\mathrm{z}})(a(\mathrm{z}-\mathrm{w})b)(\mathrm{u})cF(\mathrm{z},\mathrm{w})]_{\mathrm{u}=\mathrm{w}}, \end{aligned} \tag{5.11}$$

where the expression under the substitution on the right-hand side belongs to $(\iota_{\mathrm{z},\mathrm{w}}-\iota_{\mathrm{w},\mathrm{z}})V[[\mathrm{z},\mathrm{w},\mathrm{u}]]_{(\mathrm{z}^2)^{\mathbb{R}}(\mathrm{w}^2)^{\mathbb{R}}((\mathrm{z}-\mathrm{w})^2)^{\mathbb{R}}\mathrm{u}^2}$ and setting $\mathrm{u}=\mathrm{w}$ makes sense.

Proof: By the same argument as in the proof of Eq. (5.10) above, one finds separately

$$a(\mathrm{z})b(\mathrm{w})c\iota_{\mathrm{z},\mathrm{w}}F(\mathrm{z},\mathrm{w}) = (\mathrm{z}^2)^{-L}[((\mathrm{u}+\mathrm{z}-\mathrm{w})^2)^L\iota_{\mathrm{z},\mathrm{w}}(a(\mathrm{z}-\mathrm{w})b)(\mathrm{u})cF(\mathrm{z},\mathrm{w})]_{\mathrm{u}=\mathrm{w}}, \tag{5.12}$$

$$(-1)^{p_a p_b}b(\mathrm{w})a(\mathrm{z})c\iota_{\mathrm{w},\mathrm{z}}F(\mathrm{z},\mathrm{w}) = (\mathrm{z}^2)^{-L}[((\mathrm{u}+\mathrm{z}-\mathrm{w})^2)^L\iota_{\mathrm{w},\mathrm{z}}(a(\mathrm{z}-\mathrm{w})b)(\mathrm{u})cF(\mathrm{z},\mathrm{w})]_{\mathrm{u}=\mathrm{w}} \tag{5.13}$$

for $L \geqslant N(a,c)$. Taking the difference we obtain (5.11). □

The main subtlety of Eq. (5.11) is that on the right-hand side one cannot make the substitution $\mathrm{u}=\mathrm{w}$ in each of the factors separately. It is only after we multiply them that this substitution makes sense. The reason is that, in contrast to the case $D=1$, the expression $(\iota_{\mathrm{z},\mathrm{w}}-\iota_{\mathrm{w},\mathrm{z}})a(\mathrm{z}-\mathrm{w})b$ involves an infinite sum, and hence in general $(\iota_{\mathrm{z},\mathrm{w}}-\iota_{\mathrm{w},\mathrm{z}})(a(\mathrm{z}-\mathrm{w})b)(\mathrm{w})c$ is not well defined. We refer to Secs. V D and V E below for additional discussion.

It is clear from the proof of Eq. (5.10) that if we multiply the right-hand sides of Eqs. (5.12) and (5.13) by $(\mathrm{u}^2)^M$ for $M \geqslant N(b,c)$, they will become regular in u (i.e., not containing negative powers of u^2). Then we will be able to represent the substitution $\mathrm{u}=\mathrm{w}$ by Cauchy formula (3.24). Thus we obtain the following equivalent integral form of Jacobi identity (5.11).

Corollary 5.6: For every element a,b,c in a vertex algebra V, a and b having fixed parities p_a and p_b, respectively, and for every $L \geqslant N(a,c)$, $M \geqslant N(b,c)$, we have

$$\begin{aligned} &a(\mathrm{z})b(\mathrm{w})c\iota_{\mathrm{z},\mathrm{w}}F(\mathrm{z},\mathrm{w}) - (-1)^{p_a p_b}b(\mathrm{w})a(\mathrm{z})c\iota_{\mathrm{w},\mathrm{z}}F(\mathrm{z},\mathrm{w}) \\ &\quad = \mathrm{Res}_{\mathrm{u}}(\mathrm{z}^2)^{-L}(\mathrm{w}^2)^{-M}((\mathrm{u}+\mathrm{z}-\mathrm{w})^2)^L(\mathrm{u}^2)^M\iota_{\mathrm{u},\mathrm{w}}((\mathrm{u}-\mathrm{w})^2)^{-D/2} \\ &\qquad \times (\iota_{\mathrm{z},\mathrm{w}} - \iota_{\mathrm{w},\mathrm{z}})((a(\mathrm{z}-\mathrm{w})b)(\mathrm{u})cF(\mathrm{z},\mathrm{w})) \end{aligned} \tag{5.14}$$

for $F(\mathrm{z},\mathrm{w}) \in \mathbb{C}[[\mathrm{z},\mathrm{w}]]_{(\mathrm{z}^2)^{\mathbb{R}}(\mathrm{w}^2)^{\mathbb{R}}((\mathrm{z}-\mathrm{w})^2)^{\mathbb{R}}}$.

Proof: It remains to note that the right-hand side of (5.14) makes sense. Indeed, the product of the Cauchy kernel $\iota_{\mathrm{u},\mathrm{w}}((\mathrm{u}-\mathrm{w})^2)^{-D/2}$ and the third line in (5.14) is well defined in the space $(\iota_{\mathrm{z},\mathrm{w}} - \iota_{\mathrm{w},\mathrm{z}})V[[\mathrm{u}]]_{\mathrm{u}^2}[[\mathrm{z},\mathrm{w}]]_{(\mathrm{z}^2)^{\mathbb{R}}(\mathrm{w}^2)^{\mathbb{R}}((\mathrm{z}-\mathrm{w})^2)^{\mathbb{R}}}$. □

Remark 5.1: One can give an alternative proof of Theorem 5.5 by using "associativity" relation (5.9), "quasisymmetry" relation (5.8), and generalizing the arguments of Ref. 2, Sec. 7 to the case of arbitrary D (see also Refs. 18, 25, and 24). With obvious modifications, Eq. (5.11) remains valid for generalized vertex algebras (see Remark 4.1 and Refs. 16, 13, 27, and 3).

We will show in Sec. V D below that Jacobi identity (5.11), together with a partial vacuum axiom, can be taken as an equivalent definition of vertex algebra over $\mathbb{C}^D$.

C. Integral Borcherds formula

In this section we will derive an integral version of Jacobi identity (5.11), which in particular gives a formula for the commutator of modes that generalizes the Borcherds commutator formula from Ref. 8 (see also Refs. 19, 18, 21, and 24).

Let us introduce the following additive subgroup of $\mathbb{R}$:

$$\hat{\mathbb{Z}} := \mathbb{Z} + \tfrac{D}{2}\mathbb{Z} = \begin{cases} \mathbb{Z} & \text{if } D \text{ is even,} \\ \frac{1}{2}\mathbb{Z} & \text{if } D \text{ is odd.} \end{cases} \tag{5.15}$$

As a consequence of Corollary 3.2, every $(\mathrm{End}\, V)$–valued formal distribution $\phi(z) \in (\mathrm{End}\, V)[[z, 1/z^2]]$ can be considered as a linear map

$$\mathbb{C}[z]_{(z^2)\hat{z}} \to \mathrm{End}\, V, \quad f(z) \mapsto \mathrm{Res}_z \phi(z) f(z). \tag{5.16}$$

Thus $\mathbb{C}[z]_{(z^2)\hat{z}}$ plays the role of a vector space of *test functions*, and for even space–time dimension D it is exactly $\mathbb{C}[z]_{z^2} \equiv \mathbb{C}[z]_{(z^2)\mathbb{Z}}$. According to Eq. (3.8), the modes of $\phi(z)$ can be obtained by integrating $\phi(z)$ (with Res_z) against appropriate test functions.

Now let us take $\mathrm{Res}_z \mathrm{Res}_w$ of both sides of Eqs. (5.12) and (5.13) for $F(z,w) \in \mathbb{C}[[z,w]]_{(z^2)\hat{z}(w^2)\hat{z}((z-w)^2)\hat{z}}$, and represent the substitution $u=w$ as Res_u as done in Eq. (5.14). We are going to rewrite the resulting identities in the form

$$\mathrm{Res}_z \mathrm{Res}_w\, a(z)b(w)c\iota_{z,w}F(z,w) = \mathrm{Res}_z \mathrm{Res}_w\, \mathcal{K}^+_{L,M}(z,w;F)(a(z)b)(w)c, \tag{5.17}$$

$$\mathrm{Res}_z \mathrm{Res}_w\, b(w)a(z)c\iota_{w,z}F(z,w) = (-1)^{p_a p_b}\mathrm{Res}_z \mathrm{Res}_w \mathcal{K}^-_{L,M}(z,w;F)(a(-z)b)(w)c, \tag{5.18}$$

where $\mathcal{K}^{\pm}_{L,M}$ are to be determined. To arrive at the above formulas, we will use translation invariance of the residue to replace z with $z+w$ in (5.12) and w with $w+z$ in (5.13). More precisely, we have the following lemma.

Lemma 5.7: For every $G(z,w) \in V[[z,w]]_{(z^2)\hat{z}(w^2)\hat{z}((z-w)^2)\hat{z}}$ we have

$$\mathrm{Res}_z \mathrm{Res}_w\, \iota_{z,w}G(z,w) = \mathrm{Res}_z \mathrm{Res}_w\, \iota_{z,w}G(z+w,w). \tag{5.19}$$

Proof: Translation invariance of the residue [see (3.18)] implies the identity

$$\mathrm{Res}_z \mathrm{Res}_w\, \iota_{z,w}G(z,w) = \mathrm{Res}_z \mathrm{Res}_w\, \iota_{z,u}\iota_{z+u,w}G(z+u,w).$$

Then since the expression under the residue on the right-hand side belongs to the space $V[[z]]_{(z^2)\hat{z}}[[w,u]]_{(w^2)\hat{z}}$, we can set there $u=w$. But

$$\iota_{z,w}\iota_{z+w,w}G(z+w,w) = \iota_{z,w}G(z+w,w)$$

by "Taylor formula" (2.31). □

Applying Lemma 5.7 to the right-hand side of (5.12), we obtain (5.17) with

$$\mathcal{K}^+_{L,M}(z,w;F) := \mathrm{Res}_u\, \iota_{z,u}F(u+z,u)((u+z)^2)^{-L}(u^2)^{-M}\iota_{w,u}((w-u)^2)^{-D/2}((z+w)^2)^L(w^2)^M. \tag{5.20}$$

Similarly, after a renaming of the variables, (5.13) leads to (5.18) with

$$\mathcal{K}^-_{L,M}(z,w;F) := \mathrm{Res}_u\, \iota_{z,u}F(u,u+z)((u+z)^2)^{-M}(u^2)^{-L}\iota_{w,u+z}((w-(u+z))^2)^{-D/2}((w-z)^2)^L(w^2)^M. \tag{5.21}$$

Notice that the expressions after Res_u on the right-hand sides of (5.20) and (5.21) are well-defined elements of $\mathbb{C}[[w]]_{(w^2)\hat{z}}[[z]]_{(z^2)\hat{z}}[[u]]_{(u^2)\hat{z}}$, and in fact the former belongs to $\mathbb{C}[[z,w]]_{(z^2)\hat{z}(w^2)\hat{z}}[[u]]_{(u^2)\hat{z}}$. Then (5.20) and the formula

$$\mathcal{K}^-_{L,M}(z,w;F) = \iota_{w,z}\mathcal{K}^+_{L,M}(z,w-z;F^{\mathrm{op}}), \quad F^{\mathrm{op}}(z,w) := F(w,z) \tag{5.22}$$

imply that

$$\mathcal{K}^+_{L,M}(z,w;F) \in \mathbb{C}[[z,w]]_{(z^2)\hat{z}(w^2)\hat{z}}, \quad \mathcal{K}^-_{L,M}(z,w;F) \in \mathbb{C}[[w]]_{(w^2)\hat{z}}[[z]]_{(z^2)\hat{z}}. \tag{5.23}$$

Taking the difference of Eqs. (5.17) and (5.18), and using (3.46), we obtain the following result.

Theorem 5.8: *With the above notation, in any vertex algebra, we have*

$$\begin{aligned}&\mathrm{Res}_{\mathrm{z}}\,\mathrm{Res}_{\mathrm{w}}\, a(\mathrm{z})b(\mathrm{w})c\,\iota_{\mathrm{z,w}}F(\mathrm{z},\mathrm{w}) - (-1)^{p_a p_b}\,\mathrm{Res}_{\mathrm{z}}\,\mathrm{Res}_{\mathrm{w}} b(\mathrm{w})a(\mathrm{z})c\,\iota_{\mathrm{w,z}}F(\mathrm{z},\mathrm{w})\\ &\quad=\mathrm{Res}_{\mathrm{z}}\,\mathrm{Res}_{\mathrm{w}}\,\mathcal{K}_{L,M}(\mathrm{z},\mathrm{w};F)(a(\mathrm{z})b)(\mathrm{w})c,\end{aligned}\tag{5.24}$$

where

$$\mathcal{K}_{L,M}(\mathrm{z},\mathrm{w};F) := \mathcal{K}^{+}_{L,M}(\mathrm{z},\mathrm{w};F) - \mathcal{K}^{-}_{L,M}(-\mathrm{z},\mathrm{w};F).\tag{5.25}$$

In particular, when $F(\mathrm{z},\mathrm{w})=f(\mathrm{z})g(\mathrm{w})$ is a product of two test functions, Eq. (5.24) gives a formula for the commutator of modes, generalizing the Borcherds formula.

D. The Jacobi identity as alternative axiom and the case $D=1$

In this section we derive some consequences of our Jacobi identity (5.11). We prove that together with a partial vacuum axiom it can be taken as an equivalent definition of vertex algebra over $\mathbb{C}^D$. We also show that for $D=1$ it reduces to (an equivalent form of) the Jacobi identity of Ref. 19.

First of all, it is clear from the definitions that if $(\mathrm{z}^2)^N a(\mathrm{z})b \in V[\![\mathrm{z}]\!]$, then $(\iota_{\mathrm{z,w}}-\iota_{\mathrm{w,z}})a(\mathrm{z}-\mathrm{w})b((\mathrm{z}-\mathrm{w})^2)^N=0$. Therefore, Jacobi identity (5.11) implies locality. Our next step is to show that it also implies "associativity."

Lemma 5.9: Let V be a vector space, let c be an element of V, and let $a(\mathrm{z})$, $b(\mathrm{w})$ be two fields on V. Assume that Eq. (5.11) *holds for some fixed p_a, p_b, L and for all $F(\mathrm{z},\mathrm{w}) \in \mathbb{C}[\![\mathrm{z},\mathrm{w}]\!]_{\mathrm{z}^2\mathrm{w}^2((\mathrm{z}-\mathrm{w})^2)\hat{\mathrm{z}}}$ [see* (5.15)*]. Then Eq.* (5.9) *holds for some $L' \geqslant L$.*

Proof: Let $L' \geqslant L$ be large enough so that $(\mathrm{z}^2)^{L'} a(\mathrm{z})c \in V[\![\mathrm{z}]\!]$. Obviously, if Eq. (5.11) holds for some L then it holds for all $L' \geqslant L$, so let us just assume $L'=L$. Applying $\mathrm{Res}_{\mathrm{z}}$ to both sides of (5.11) with $F(\mathrm{z},\mathrm{w})=(\mathrm{z}^2)^L f(\mathrm{z}-\mathrm{w})$, where $f(\mathrm{z}) \in \mathbb{C}[\![\mathrm{z}]\!]_{(\mathrm{z}^2)\hat{\mathrm{z}}}$ is an arbitrary test function, we obtain

$$\mathrm{Res}_{\mathrm{z}}(\mathrm{z}^2)^L a(\mathrm{z})b(\mathrm{w})c\,\iota_{\mathrm{z,w}} f(\mathrm{z}-\mathrm{w}) = \mathrm{Res}_{\mathrm{z}}[((\mathrm{u}+\mathrm{z}-\mathrm{w})^2)^L \iota_{\mathrm{z,w}}(a(\mathrm{z}-\mathrm{w})b)(\mathrm{u})c f(\mathrm{z}-\mathrm{w})]_{\mathrm{u}=\mathrm{w}}.$$

Now using the translation invariance of the residue [see (3.18)], we get

$$\mathrm{Res}_{\mathrm{z}}((\mathrm{z}+\mathrm{w})^2)^L \iota_{\mathrm{z,w}} a(\mathrm{z}+\mathrm{w})b(\mathrm{w})c f(\mathrm{z}) = [\mathrm{Res}_{\mathrm{z}}((\mathrm{u}+\mathrm{z})^2)^L (a(\mathrm{z})b)(\mathrm{u})c f(\mathrm{z})]_{\mathrm{u}=\mathrm{w}}.$$

After the substitution $\mathrm{u}=\mathrm{w}$, this gives exactly Eq. (5.9) [cf. (5.16)]. □

Now we can prove the following statement, which shows that a vertex algebra can be defined in terms of Jacobi identity as in Ref. 19 for the $D=1$ case (see also Refs. 21 and 24).

Theorem 5.10: *Let V be a vector superspace endowed with an even vector $|0\rangle$ and with a parity preserving linear map $Y: V \mapsto Y(a,\mathrm{z}) \equiv a(\mathrm{z})$ to the space of fields on V. Assume that Jacobi identity* (5.11) *holds for every fixed $a,b,c \in V$ with parities p_a, p_b of a and b, respectively, for some $L \geqslant 0$ and for all $F(\mathrm{z},\mathrm{w}) \in \mathbb{C}[\![\mathrm{z},\mathrm{w}]\!]_{\mathrm{z}^2\mathrm{w}^2((\mathrm{z}-\mathrm{w})^2)\hat{\mathrm{z}}}$. Finally, let the following "partial vacuum axiom" be satisfied:*

$$Y(|0\rangle,\mathrm{z})a = a, \quad \mathrm{Res}_{\mathrm{z}}(\mathrm{z}^2)^{-D/2} Y(a,\mathrm{z})|0\rangle = a \quad \text{for all } a \in V.\tag{5.26}$$

Then there exist uniquely determined mutually commuting even endomorphisms $T_1,\ldots,T_D$ of V, which make V a vertex algebra over $\mathbb{C}^D$.

Proof: We have already pointed out that locality of $a(\mathrm{z})$ and $b(\mathrm{w})$ follows from Jacobi identity for $F(\mathrm{z},\mathrm{w})=((\mathrm{z}-\mathrm{w})^2)^N$ with $N \gg 0$. We will derive the rest of the axioms of vertex algebra (Definition 4.1) from Eqs. (5.9) and (5.26) (cf. Lemma 5.9).

Setting in Eq. (5.9) $b=|0\rangle$ and $L \gg 0$ such that $(\mathrm{z}^2)^L a(\mathrm{z})c \in V[\![\mathrm{z}]\!]$, we obtain that

$$((z+w)^2)^L(a(z)|0\rangle)(w)c \in V[[z,w]].$$

Since $(a(z)|0\rangle)(w)c \in V[[w]]_{w^2}[[z]]_{z^2}$, it makes sense to multiply the above equation by $\iota_{w,z}((z+w)^2)^{-L}$ and get

$$(a(z)|0\rangle)(w)c \in \iota_{w,z}V[[z,w]]_{(z+w)^2} \subset V[[w]]_{w^2}[[z]].$$

Then letting $c=|0\rangle$ and using the second equality in (5.26) (with respect to w), we deduce from here that $a(z)|0\rangle \in V[[z]]$ for all $a \in V$. Thus the second equality in (5.26) can be restated as $a(z)|0\rangle|_{z=0}=a$.

We define the translation endomorphisms $T_1, \ldots, T_D$ of V by the formula

$$T_\alpha a := \partial_{z^\alpha} a(z)|0\rangle\,|_{z=0}, \quad \alpha = 1, \ldots, D,$$

which should hold if V is a vertex algebra. Then setting $c=|0\rangle$ in Eq. (5.9), we deduce that

$$T_\alpha(a(z)b) - a(z)(T_\alpha b) = \partial_{z^\alpha} a(z)b,$$

while the substitution $b=|0\rangle$ in Eq. (5.9) implies $(T_\alpha a)(z)=\partial_{z^\alpha} a(z)$. The remaining axioms [Definition 4.1(a), (b)] are then immediate. □

Remark 5.2: With obvious modifications, Theorem 5.5 and Theorem 5.10 hold also for modules over vertex algebras (see Ref. 28, Sec. 6 for the definition of module).

The main subtlety of Jacobi identity (5.11) is that one cannot make the substitution u=w in each of the factors separately. However, in the next proposition we will show that this can be done if the field $a(z)$ has a special form. Recall that the regular and singular parts of a formal distribution were defined in Sec. III D.

Proposition 5.11: Let a,b be elements in a vertex algebra V, with parities p_a and p_b, respectively. Assume that for some $n \in \mathbb{Z}$ the singular part of $(z^2)^n a(z)b$ belongs to $V[z]_{z^2}$. Then we have:

$$\begin{aligned} &a(z)b(w)\iota_{z,w}((z-w)^2)^n - (-1)^{p_a p_b} b(w)a(z)\iota_{w,z}((z-w)^2)^n \\ &\quad = (\iota_{z,w} - \iota_{w,z})((a(z-w)b)(w)((z-w)^2)^n), \end{aligned} \tag{5.27}$$

and the right-hand side is well defined.

Proof: For an arbitrary fixed $c \in V$ and $L \gg 0$, set $F(z,w)=((z-w)^2)^n$ in Eq. (5.11). Because the regular part of $((z-w)^2)^n a(z-w)$ is killed by $\iota_{z,w}-\iota_{w,z}$, we can replace $((z-w)^2)^n a(z-w)$ by its singular part in the right-hand side of (5.11). But by assumption the coefficients of the singular part of $(z^2)^n a(z)b$ span a finite-dimensional subspace of V. Therefore, in (5.11) one can substitute u=w in each factor separately, and the right-hand side of (5.27) makes sense. After setting u=w in the other factor in (5.11) it cancels with $(z^2)^L$. □

Remark 5.3: When $D=1$, the assumption of Proposition 5.11 is satisfied for every pair of elements $a,b \in V$ and every $n \in \mathbb{Z}$. In this case, the collection of identities (5.27) is equivalent to the Jacobi identity of Ref. 19.

Let us note that for $D>1$ the assumption of Proposition 5.11 is in fact quite restrictive. For $n=0$ it holds for the scalar free field $\varphi(z)$ discussed in Sec. IV C [because $\varphi(z)$ is harmonic] but it does not hold for the Wick square $:\varphi(z)^2:$. Furthermore, it does not hold for $\varphi(z)$ itself when $n<0$. On the other hand, the assumption is satisfied for $n=0$ and any "generalized free field" (see Ref. 28, Sec. 5), thus providing a version of the *Wick theorem* (note that the element b is arbitrary).

E. Degree cutoffs and commutator formula

In this section, we derive a commutator formula, which shows in particular that the singular modes of fields close an algebraic structure under the commutator.

We have remarked at the end of the preceding section that the main difficulty for $D>1$ as opposed to $D=1$ is that the singular part of $a(z)b$ involves an infinite sum in general. To circumvent this problem we introduce "degree cutoffs" as follows. For a formal distribution $\phi(z)$, written as in (2.17), and for any $N \in \mathbb{R}$, we define the cutoff $\phi(z)^{\leqslant N}$ by restricting the sums over m and γ

in (2.17) to indices with $m+2\gamma \leqslant N$. In other words, we restrict the sum to terms with degrees in z less than or equal to N. We denote the remaining part of $\phi(z)$ by $\phi(z)^{>N} := \phi(z) - \phi(z)^{\leqslant N}$. In the same way, we define cutoffs $\phi(z)^{\leqslant N}_{s.p.}$ of the singular part of $\phi(z)$ [see (3.36)]. Note that all these operations are commuting projections on the space of formal distributions.

Even though the singular part $a(z)_{s.p.}b$ may involve infinitely many terms with arbitrarily high degrees in z, it is important that for fixed $N \in \mathbb{Z}$ the cutoff of the singular part $a(z)^{\leqslant N}_{s.p.}b$ is *finite*, i.e., it belongs to $V[z]_{z^2}$. Then the same argument as in the proof of Proposition 5.11 gives the following result.

Lemma 5.12: Let a,b,c be elements in a vertex algebra V, where a and b have parities p_a and p_b, respectively. Then for every $n,N \in \mathbb{Z}$ and every $L \geqslant N(a,c)$, we have

$$\begin{aligned} &a(z)b(w)\iota_{z,w}((z-w)^2)^n - (-1)^{p_a p_b} b(w)a(z)\iota_{w,z}((z-w)^2)^n \\ &\quad = (\iota_{z,w} - \iota_{w,z})((a(z-w)^{\leqslant N}b)(w)((z-w)^2)^n) \\ &\qquad + (z^2)^{-L}[((u+z-w)^2)^L(\iota_{z,w} - \iota_{w,z})(a(z-w)^{>N}b)(u)c((z-w)^2)^n]_{u=w}. \end{aligned}$$

We will now apply this lemma in the case $n=0$ when it reduces to a formula for the commutator of the fields $a(z)$, $b(w)$. Then, because of the presence of $\iota_{z,w} - \iota_{w,z}$, on the right-hand side of the above equation one can replace $a(z-w)^{\leqslant N}$ and $a(z-w)^{>N}$ by their singular parts and obtain

$$\begin{aligned} [a(z),b(w)]c = &(\iota_{z,w} - \iota_{w,z})(a(z-w)^{\leqslant N}_{s.p.}b)(w) \\ &+ [(z^2)^{-L}((u+z-w)^2)^L(\iota_{z,w} - \iota_{w,z})(a(z-w)^{>N}_{s.p.}b)(u)c]_{u=w}. \end{aligned} \tag{5.28}$$

The next result shows that the singular parts of fields themselves close a structure with respect to the commutator.

Proposition 5.13: For every three elements a,b,c in a vertex algebra V and for every $L \geqslant N(a,c)$, one has

$$[a(z)_{s.p.},b(w)_{s.p.}]c = ([(z^2)^{-L}((u+z-w)^2)^L(\iota_{z,w} - \iota_{w,z})(a(z-w)_{s.p.}b)(u)_{s.p.}c]_{u=w})_{s.p.}, \tag{5.29}$$

where the outer s.p. *on the right-hand side designates taking the singular part with respect to both* z *and* w.

Note that for $D>1$ a product of two singular terms may contain a regular part; that is why in (5.29) we must include the outer projection onto the singular parts.

Proof of Proposition 5.13: We will prove that (5.29) holds for all terms with total degree in z and w up to N, for every fixed $N \in \mathbb{Z}$. For this purpose, we consider all terms of total degree $\leqslant N$ in (5.28), and take the singular parts with respect to both z and w. We will consider separately the resulting two terms on the right-hand side.

In the first term, the expansion $\iota_{w,z}$ will not contribute because it produces terms regular in z. Since $\iota_{z,w}(a(z-w)^{\leqslant N}_{s.p.}b)(w)_+$ is regular in w, it will not contribute either, and we will obtain

$$(\iota_{z,w}(a(z-w)^{\leqslant N}_{s.p.}b)(w)_{s.p.}c)_{s.p.}.$$

Reversing the above reasoning, this expression can be rewritten as

$$((\iota_{z,w} - \iota_{w,z})(a(z-w)^{\leqslant N}_{s.p.}b)(w)_{s.p.}c)_{s.p.}.$$

Then, as in the derivation of Lemma 5.12, it is equal to

$$([(z^2)^{-L}((u+z-w)^2)^L(\iota_{z,w} - \iota_{w,z})(a(z-w)^{\leqslant N}_{s.p.}b)(u)_{s.p.}c]_{u=w})_{s.p.}.$$

It remains to prove that the second term resulting from the right-hand side of (5.28) is equal to

$$([(z^2)^{-L}((u+z-w)^2)^L(\iota_{z,w}-\iota_{w,z})(a(z-w)^{>N}_{s.p.}b)(u)_{s.p.}c]_{u=w})_{s.p.}.$$

This follows from the fact that

$$[(z^2)^{-L}((u+z-w)^2)^L(\iota_{z,w}-\iota_{w,z})(a(z-w)^{>N}_{s.p.}b)(u)_+c]_{u=w}$$

contains only terms with total degree in z and w strictly greater than N. □

VI. CONCLUDING REMARKS

In this paper we develop further the theory of vertex algebras in higher dimensions. We start by introducing useful formal calculus techniques including various spaces of formal series and a formal residue functional. This residue functional is uniquely determined (up to a multiplicative constant) by the property that it is translation invariant (Theorem 3.1), and so it plays the role of the integral. In addition, it satisfies an analog of the Cauchy formula [Eq. (3.24)]. The modes of fields can be obtained by integrating the fields (with respect to our residue functional) against certain test functions.

Our main goal was to understand the algebraic structure obeyed by the modes of local fields with respect to the commutator. For this purpose we derived an analog of the Jacobi identity for vertex algebras in higher dimensions (Theorem 5.5). Since the commutator of two local fields is expressed in terms of the singular part of their operator product expansion, a natural question arises whether the singular parts of fields close a structure under the commutator. Utilizing a certain degree cutoff technique we proved that this is indeed the case (Proposition 5.13).

Thus, if we denote by $a[z]b$ the singular part $a(z)_{s.p.}b$, we find that it closes the following structure. The map $a,b\mapsto a[z]b\in(V[\![z]\!]_{z^2})_{s.p.}$ is parity preserving and bilinear on a superspace V endowed with an action of mutually commuting even endomorphisms $T_1,\dots,T_D$, and the following axioms are satisfied:

(a) (*translation invariance*) $[T_\alpha,a[z]]b=(T_\alpha a)[z]b=\partial_{z^\alpha}a[z]b$;
(b) (*skew-symmetry*) $a[z]b=(-1)^{p_ap_b}(e^{z\cdot T}(b[-z]a))_{s.p.}$;
(c) (*Jacobi identity*)

$$[a[z],b[w]]c=((z^2)^{-L}[((u+z-w)^2)^L(\iota_{z,w}-\iota_{w,z})(a[z-w]b)[u]c]_{u=w})_{s.p.}$$

for $L\gg 0$, and the expression under the substitution on the right-hand side belongs to the space $(\iota_{z,w}-\iota_{w,z})V[\![z,w,u]\!]_{(z-w)^2u^2}$ where setting $u=w$ makes sense. It is expected that the obtained algebraic structure will play in higher dimensions the same role as vertex Lie algebras do in dimension one.

APPENDIX: GEOMETRIC REALIZATION OF THE RESIDUE

In this appendix we will provide a geometric definition of the residue functional introduced in Sec. III A. We will suppose that the space–time dimension D is *even*.

Let us introduce the following one-parameter family $\{\bar{M}_r\}_{r>0}$ of D-dimensional real submanifolds of $\mathbb{C}^D$:

$$\bar{M}_r := \{\mathrm{z} \in \mathbb{C}^D | \mathrm{z} = \lambda \mathrm{u}, \quad \lambda \in \mathbb{C}, \quad |\lambda| = r, \quad \mathrm{u} \in \mathbb{S}^{D-1} \subset \mathbb{R}^D\}, \tag{A1}$$

where $\mathbb{S}^{D-1}$ denotes the unit sphere in $\mathbb{R}^D$. Note that $\bar{M}_1$ is exactly the *conformally compactified Minkowski space* (see Refs. 31 and 28).

We introduce a parametrization of $\bar{M}_r$,

$$\bar{M}_r \ni \mathrm{z} = re^{i\zeta}\mathrm{u} \quad \text{for } \zeta \in [0, \pi), \quad \mathrm{u} \in \mathbb{S}^{D-1}, \tag{A2}$$

which shows that $\bar{M}_r$ is diffeomorphic to $(\mathbb{S}^1 \times \mathbb{S}^{D-1})/\mathbb{Z}_2$, with the points $(e^{i\zeta}, \mathrm{u})$ and $(-e^{i\zeta}, -\mathrm{u})$ being identified. In particular, all $\bar{M}_r$ are orientable for even D. Thus, the volume form $\mathrm{d}z^1 \wedge \cdots \wedge \mathrm{d}z^D$ on $\mathbb{C}^D$ can be restricted to $\bar{M}_r$ and gives rise to a complex measure there. In parametrization (A2), we have

$$\mathrm{d}z^1 \wedge \cdots \wedge \mathrm{d}z^D \big|_{\bar{M}_r} = ir^D e^{iD\zeta}\, \mathrm{d}\zeta \wedge \mathrm{d}\sigma(\mathrm{u}), \tag{A3}$$

where $\mathrm{d}\sigma(\mathrm{u})$ is the $\mathrm{O}(D)$-invariant volume form $\mathrm{d}z^1 \wedge \cdots \wedge \mathrm{d}z^D|_{\mathbb{S}^{D-1}}$ on the unit sphere $\mathbb{S}^{D-1}$.

An important property of the family $\{\bar{M}_r\}$ is that if $\mathrm{z} \in \bar{M}_r$ and $\mathrm{w} \in \bar{M}_{r'}$ for $r \neq r'$ then $(\mathrm{z} - \mathrm{w})^2 \neq 0$. Indeed, writing

$$\mathrm{z} = re^{i\zeta}\mathrm{u}, \quad \mathrm{w} = r'e^{i\zeta'}\mathrm{u}', \quad \mathrm{u} \cdot \mathrm{u}' = \cos\alpha = (e^{i\alpha} + e^{-i\alpha})/2, \tag{A4}$$

we find that

$$(\mathrm{z} - \mathrm{w})^2 = (re^{i\zeta} - r'e^{i(\zeta'+\alpha)})(re^{i\zeta} - r'e^{i(\zeta'-\alpha)}). \tag{A5}$$

This shows that for $n \in \mathbb{Z}$ the formal Taylor expansion $\iota_{\mathrm{z},\mathrm{w}}((\mathrm{z}-\mathrm{w})^2)^n$ [see (2.26)] in the above parametrization corresponds to a geometric series expansion for $r > r'$. Note also that the conformal inversion $\mathrm{z} \mapsto \mathrm{z}/\mathrm{z}^2$ maps $\bar{M}_r$ onto $\bar{M}_{r^{-1}}$.

Proposition A.1: For $f(\mathrm{z}) \in \mathbb{C}[\mathrm{z}]_{\mathrm{z}^2}$ *and* $g(\mathrm{z},\mathrm{w}) \in \mathbb{C}[\mathrm{z},\mathrm{w}]_{\mathrm{z}^2\mathrm{w}^2(\mathrm{z}-\mathrm{w})^2}$, *we have*

$$\mathrm{Res}_{\mathrm{z}} f(\mathrm{z}) = (i\pi\mathcal{V}_{D-1})^{-1} \int_{\bar{M}_r} f(\mathrm{z})\mathrm{d}z^1 \wedge \cdots \wedge \mathrm{d}z^D, \tag{A6}$$

$$\mathrm{Res}_{\mathrm{z}}\, \iota_{\mathrm{z},\mathrm{w}} g(\mathrm{z},\mathrm{w}) = (i\pi\mathcal{V}_{D-1})^{-1} \int_{\bar{M}_r} g(\mathrm{z},\mathrm{w})\mathrm{d}z^1 \wedge \cdots \wedge \mathrm{d}z^D \quad \textit{for } \mathrm{w} \in \bar{M}_{r'}, \quad r' < r, \tag{A7}$$

$$\mathrm{Res}_{\mathrm{z}}\, \iota_{\mathrm{w},\mathrm{z}} g(\mathrm{z},\mathrm{w}) = (i\pi\mathcal{V}_{D-1})^{-1} \int_{\bar{M}_r} g(\mathrm{z},\mathrm{w})\mathrm{d}z^1 \wedge \cdots \wedge \mathrm{d}z^D \quad \textit{for } \mathrm{w} \in \bar{M}_{r'}, \quad r' > r, \tag{A8}$$

where $\mathcal{V}_{D-1} = \int_{\mathbb{S}^{D-1}} \mathrm{d}\sigma(\mathrm{u})$.

Proof: It is enough to check (A6) for the functions $(\mathrm{z}^2)^n h(\mathrm{z})$, where $n \in \mathbb{Z}$ and $h(\mathrm{z})$ is a harmonic homogeneous polynomial of degree m. Then (A6) follows from (A3) and the formulas

$$\int_{\mathbb{S}^{D-1}} h(\mathrm{u})\mathrm{d}\sigma(\mathrm{u}) = \delta_{m,0} h(0)\mathcal{V}_{D-1}, \quad \int_0^{\pi} e^{iD\zeta + 2in\zeta}\, \mathrm{d}\zeta = \pi\delta_{n,-(D/2)}.$$

Equation (A7) follows from (A6) because the expansion $\iota_{\mathrm{z},\mathrm{w}} g(\mathrm{z},\mathrm{w})$ converges uniformly to $g(\mathrm{z},\mathrm{w})$ for $\mathrm{z} \in \bar{M}_r$, $\mathrm{w} \in \bar{M}_{r'}$ and fixed $r > r'$ [see (A5)]. Finally, (A8) is proved in the same way as (A7) but for $r < r'$. □

Finite dimensional representations of the Euclidean algebra $\mathfrak{e}(2)$ having two generators

Andrew Douglas
Department of Mathematics, University of Toronto, Toronto, Ontario, Canada M5S 2E4

(Received 17 February 2006; accepted 22 March 2006; published online 16 May 2006)

The Euclidean algebra $\mathfrak{e}(2)$ is the Lie algebra of the group E(2) of Euclidean transformations of the plane. This paper examines finite dimensional representations of $\mathfrak{e}(2)$ having two generators. To each representation with two generators we associate a graph. In term of graphs, we give a criterion for the indecomposability of such representations and describe an invariant for indecomposable representations. We also classify the indecomposable representations of dimensions 5 and 6, regardless of the number of generators (dimensions less than 5 have been classified). In each case there are finitely many such representations. Next, we show that for each dimension $\geqslant 8$ there are infinitely many nonequivalent indecomposable representations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2197688]

I. INTRODUCTION

The group E(2) of Euclidean motions of the plane is the noncompact semidirect product group $\mathbb{R}^2 \rtimes \mathrm{SO}(2)$. The complexification of its Lie algebra, $\mathfrak{e}(2)$, has basis $\{p_+, p_-, l\}$ with commutation relations given by

$$[p_+, p_-] = 0, \quad [l, p_\pm] = \pm p_\pm. \tag{1}$$

Let V be a complex representation of E(2); then V decomposes into weight spaces according to the action of $\mathfrak{so}(2)$,

$$V = \oplus V_k, \quad \text{where } V_k = \{v \in V : l \cdot v = kv\} \text{ and } k \in \mathbb{Z}. \tag{2}$$

Further, we have

$$p_+ V_k \subseteq V_{k+1}, \quad p_- V_k \subseteq V_{k-1}. \tag{3}$$

Henceforth, all representations will be over the complex numbers.

Since $\mathfrak{e}(2)$ is solvable, its finite dimensional, irreducible representations are all one dimensional (see Ref. 11), and thus of limited interest. Considerable research has been done investigating the infinite dimensional, unitary irreducible representations of $\mathfrak{e}(2)$ (see, for example, 1, 3, and 4). However, much less is known about the finite dimensional, indecomposable representations of $\mathfrak{e}(2)$. These representations play a significant role in the representation theory of the Poincaré group (see Refs. 2, 5, 8, and 9).

Given a finite dimensional representation V, a set of elements $v_1, \ldots, v_n \in V$ is defined to be a set of *generators* if each element is a weight vector, $V = \langle v_1, \ldots, v_n \rangle$, and fewer than n weight vectors will not generate V. A representation of $\mathfrak{e}(2)$ with one generator is necessarily indecomposable (see Ref. 6) and their classification is trivial. They are classified according to the dimensions of the weight spaces since $\langle v \rangle \cong \langle w \rangle$ if and only if $\dim(\langle v \rangle_k) = \dim(\langle w \rangle_k)$, for all k.

In this paper, we will investigate the finite dimensional representations of $\mathfrak{e}(2)$ with two generators. In Sec. II we describe how we may associate to a representation V with generators v_1 and v_2 a graph $\mathcal{G}(V, v_1, v_2)$. Section III contains necessary notation, terminology, and preliminaries.

The graph of a representation is dependent on the choice of generators. In Sec. IV we describe

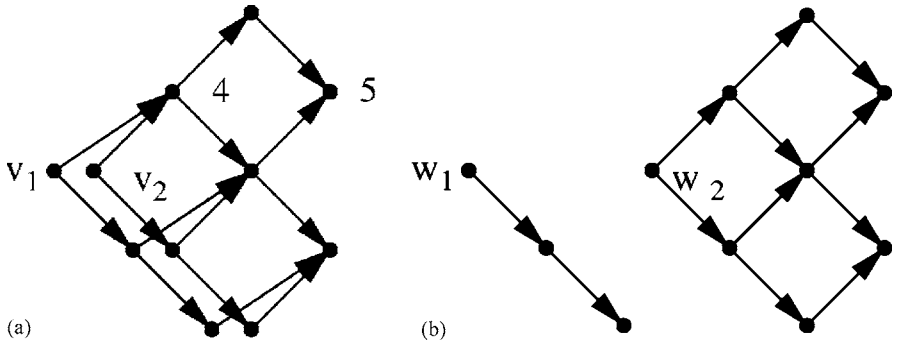

FIG. 1. Graphs (a) $\mathcal{G}(V,v_1,v_2)$, and (b) $\mathcal{G}(v,w_1,w_2)$.

an important type of graph of a representation called the *maximal form graph*. In Sec. V we present a criterion for the indecomposability of representations with two generators in terms of their maximal form graphs. In Sec. VI we derive a formula, the *generator change formula*, that describes how changing generators of a representation with two generators changes its graph. We then determine an invariant for indecomposable representations using the generator change formula and maximal form graphs.

In Sec. VII we classify the finite dimensional, indecomposable representations of dimensions 5 and 6 (regardless of the number of generators); in each case there are finitely many such representations (up to isomorphism). Those representations of dimension less than 5 were considered in Ref. 5. Next, we show that there are infinitely many nonequivalent indecomposable representations for all dimensions $\geqslant 8$.

II. THE GRAPH OF A REPRESENTATION OF $\mathfrak{e}(2)$

A representation of $\mathfrak{e}(2)$ may be completely described in term of generators and relations. Using this property, Repka and de Guise[10] introduced a method for graphically describing some finite dimensional representations of $\mathfrak{e}(2)$. According to this method, a finite dimensional representation is described by a graph with vertices and directed edges (or arrows); vertices at the same height form a basis of a weight space. Arrows pointing diagonally upwards represent the action of p_+ and arrows pointing diagonally downwards represent the action of p_-.

For example, the representation whose graph is in Fig. 1(a) has generators v_1 and v_2. We denote the graph $\mathcal{G}(V,v_1,v_2)$. The scalars, which can be any complex numbers, describe relations between v_1 and v_2. The relation in Fig. 1(a) is

$$p_+v_1 - 4p_+v_2 - 5p_+^2p_-v_2 = 0. \tag{4}$$

The scalars in the graph will always be associated with the generator with index 2.

Define $wt(v_i)$ to be the weight of v_i. Thus, in the case of Fig. 1(a), $wt(v_1)=wt(v_2)$.

Note that the graph of a representation is dependent on the choice of generators. For example, both Figs. 1(a) and 1(b) are graphs of the same representation. In Fig. 1(a) we have the graph $\mathcal{G}(V,v_1,v_2)$, and in Fig. 1(b) we have the graph $\mathcal{G}(V,w_1,w_2)$, where $w_1=v_1-4v_2-5p_+p_-v_2$, and $w_2=v_2$. $\mathcal{G}(V,w_1,w_2)$ is disconnected, reflecting the fact that the representation is decomposable with decomposition $\langle w_1\rangle \oplus \langle w_2\rangle$.

III. NOTATION, TERMINOLOGY AND PRELIMINARIES

Before we continue, we will introduce further notation and terminology and make preliminary remarks. Let V be a representation with generators v_1 and v_2. The generators will be indexed such that $wt(v_1) \geqslant wt(v_2)$. Define

$$H = wt(v_1) - wt(v_2). \tag{5}$$

Consider the relation

$$\sum_{i=0}^{N} p_+^{k+i} p_-^{l+i} W_i v_1 - \sum_{i=0}^{N} p_+^{m+i} p_-^{n+i} Z_i v_2 = 0, \tag{6}$$

where $Z_i, W_i \in \mathbb{C}$ and $Z_0, W_0 \neq 0$. Define invertible matrices

$$W = \begin{pmatrix} W_0 & W_1 & W_2 & \cdots & W_N \\ 0 & W_0 & W_1 & \cdots & W_{N-1} \\ 0 & 0 & W_0 & \cdots & W_{N-2} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & W_0 \end{pmatrix}, \quad Z = \begin{pmatrix} Z_0 & Z_1 & Z_2 & \cdots & Z_N \\ 0 & Z_0 & Z_1 & \cdots & Z_{N-1} \\ 0 & 0 & Z_0 & \cdots & Z_{N-2} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & Z_0 \end{pmatrix}. \tag{7}$$

We shall write the relation in (6) as

$$p_+^k p_-^l W v_1 - p_+^m p_-^n Z v_2 = 0. \tag{8}$$

Writing relations in this form allows us to manipulate them easily. For example, multiplying both sides of (8) by W^{-1} gives

$$p_+^k p_-^l v_1 - p_+^m p_-^n W^{-1} Z v_2 = 0. \tag{9}$$

Let $\rho = gcd(p_+^k p_-^l, p_+^m p_-^n)$. Then Eq. (9) becomes

$$\rho(p_+^{k'} p_-^{l'} v_1 - p_+^{m'} p_-^{n'} W^{-1} Z v_2) = 0, \quad \text{for appropriate } k', m', l', n' \in \mathbb{N}. \tag{10}$$

Suppose we have a relation R of the form $\rho(p_+^{h_Z(1)} v_1 - p_+^{h_Z(0)} Z v_2) = 0$ where $h_Z(0), h_Z(1) \geqslant 0$ and by assumption $Z_0 \neq 0$. By a slight abuse of notation we shall often write the relation $\rho(p_-^{h_Z(1)} v_1 - p_+^{h_Z(0)} Z v_2) = 0$ as

$$R = \rho(p_-^{h_Z(1)} v_1 - p_+^{h_Z(0)} Z v_2). \tag{11}$$

The matrix Z of the relation is called a *relation matrix*. And, $h_Z(0)$ is called the *height* of the relation matrix Z. Of course, $h_Z(0)$ determines $h_Z(1)$ and vice versa since $H = h_Z(0) + h_Z(1)$.

Suppose $wt(v_1) > wt(v_2)$. Then, the relation in (11) is of *type 1* if $h_Z(1) > 0$ and $h_Z(0) > 0$; *type 2* if $h_Z(1) = 0$ and $h_Z(0) > 0$; *type 3* if $h_Z(1) > 0$ and $h_Z(0) = 0$.

Given relation matrices Z and W of the same height, define $\Delta(Z, W)$ to be the index of the first entries of Z and W that differ. The *gluing scalar* of a relation matrix is the leading entry (that is, the entry with index 0). A nonzero weight element $v \in V$ is *terminal* if $p_+ v = 0$ and $p_- v = 0$.

Given a matrix W as in (7), we will define a matrix $W[k]$ to be the matrix obtained by inserting k zero-columns on the left of W and removing the k rightmost columns of W. To illustrate this concept consider the following example:

$$\text{If } W = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 0 & 1 & 2 & 3 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad \text{then } W[2] = \begin{pmatrix} 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{12}$$

Matrices of the form in (7) are called upper triangular Toeplitz matrices. For any such matrices W and Z, we have $(WZ)[k] = W[k]Z = WZ[k]$. Also note that $W[0] = W$.

IV. THE MAXIMAL FORM

As was mentioned above, the graph of a representation depends on the choice of generators. In this section we describe a particular choice of generators that will be used in the indecomposability criterion and for the invariant of indecomposable representations.

Let v_1 and v_2 be generators of a representation V such that $wt(v_1) \geqslant wt(v_2)$. Consider an arbitrary pair of generators w_1, w_2 of V such that $wt(v_1)=wt(w_1)$ and $wt(v_2)=wt(w_2)$. Recall $H=wt(v_1)-wt(v_2)$ and suppose

$$\dim(\langle v_1\rangle_k) \geqslant \max\{\dim(\langle w_1\rangle_k), \dim(\langle p_+^H w_2\rangle_k)\}, \tag{13}$$

$$\dim(\langle v_2\rangle_k) \geqslant \max\{\dim(\langle w_2\rangle_k), \dim(\langle p_-^H w_1\rangle_k)\}, \quad \forall\, k \in \mathbb{N}. \tag{14}$$

Then $\mathcal{G}(V, v_1, v_2)$ is in *maximal form*.

Note that every representation has a graph which is in maximal form; suppose that a representation V has generators v_1, v_2. Then, it is straightforward to show that $\mathcal{G}(V, v_1 - \lambda p_+^H v_2, p_-^H v_1 - \eta v_2)$ is in maximal form if λ and η are not zero, are not gluing scalars and $\lambda \neq \eta$.

The following lemma and Proposition 1 below establish several important properties of the maximal form that will be important in subsequent sections.

Lemma 1: Let V be a representation with generators v_1 and v_2 such that $wt(v_1) \geqslant wt(v_2)$. Suppose that $\mathcal{G}(V, v_1, v_2)$ is in maximal form. Then all relations are of type 1, 2, *or* 3.

Proof: Suppose there is a relation that is not of type 1, 2, or 3. We then have a relation

$$R_1 = \rho_1(v_1 - Z p_+^{H+l} p_-^l v_2), \tag{15}$$

or

$$R_2 = \rho_2(p_+^l p_-^{H+l} v_1 - Z v_2), \tag{16}$$

where $Z_0 \neq 0$ and $l > 0$. Assume there is a relation as in (15). Then

$$\langle \rho_1 v_1\rangle \cong \langle \rho_1 Z p_+^{H+l} p_-^l v_2\rangle. \tag{17}$$

Let

$$w_1 = v_1 - \lambda p_+^H v_2 \quad \text{and } w_2 = v_2, \tag{18}$$

where $\lambda \neq 0$ and if there are relation of the form $R=\rho(v_1 - W p_+^H v_2)$ such that $W_0 \neq 0$, then $\lambda \neq W_0$. Let $\rho_1 = p_+^s p_-^t$ and define $k = wt(v_1) + s - t$. Then, by (17) and (18),

$$\dim(\langle w_1\rangle_k) > \dim(\langle v_1\rangle_k). \tag{19}$$

This, however, contradicts the hypothesis that $\mathcal{G}(V, v_1, v_2)$ is maximal. Thus, we cannot have a relation as in (15) and we may show in a similar manner that we cannot have a relation as in (16). □

Consider graphs $\mathcal{G}(V, v_1, v_2)$ and $\mathcal{G}(U, u_1, u_2)$ in maximal form such that $wt(v_i)=wt(u_i)$ and $\langle v_i\rangle \cong \langle u_i\rangle$, for $i \in \{1,2\}$. A relation in $\mathcal{G}(U, u_1, u_2)$ is said to *correspond* to a relation in $\mathcal{G}(V, v_1, v_2)$ if they have the same weight.

Let the graphs $\mathcal{G}(V, v_1, v_2)$ and $\mathcal{G}(U, u_1, u_2)$ be in maximal form and $wt(v_i)=wt(u_i)$ for $i \in \{1,2\}$. Then, define

$$\mathcal{G}(V, v_1, v_2) \sim \mathcal{G}(U, u_1, u_2) \tag{20}$$

if

(1) $\langle v_i\rangle \cong \langle u_i\rangle$, for $i \in \{1,2\}$.
(2) There is a relation $R=\rho(p_-^{h_Z(1)} v_1 - Z p_+^{h_Z(0)} v_2)$ in $\mathcal{G}(V, v_1, v_2)$.

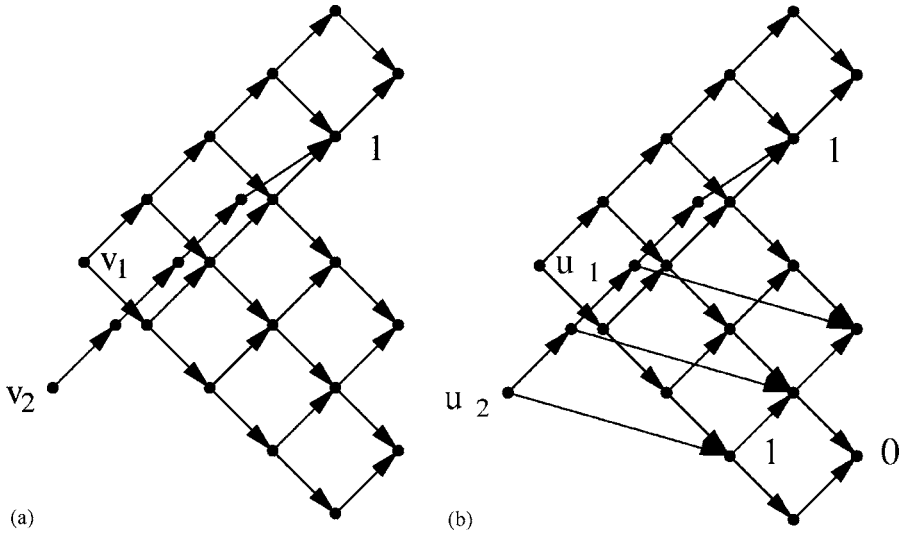

FIG. 2. Graphs of a representation (a) not in maximal form and (b) in maximal form.

($\Leftrightarrow$) There is a relation $S=\rho(p_-^{h_W(1)}u_1-Wp_+^{h_W(0)}u_2)$ in $\mathcal{G}(U,u_1,u_2)$, where R and S are corresponding relations.

Note that it is not necessary that $W=Z$, but if R and S correspond then necessarily $h_Z(0)=h_W(0)$ and $h_Z(1)=h_W(1)$ If $\mathcal{G}(V,v_1,v_2)\sim\mathcal{G}(U,u_1,u_2)$, then these graphs are identical up to the scalar values in the relations.

Proposition 1: Let the graphs $\mathcal{G}(V,v_1,v_2)$ and $\mathcal{G}(U,u_1,u_2)$ be in maximal form. Then,

$$V\cong U\Rightarrow\mathcal{G}(V,v_1,v_2)\sim\mathcal{G}(U,u_1,u_2). \tag{21}$$

Proof: Let $wt(v_1)=wt(u_1)\geqslant wt(u_2)=wt(v_2)$. Let w_1,w_2 be another set of generators of V such that $\mathcal{G}(V,w_1,w_2)$ is in maximal form, then we must have $\langle v_i\rangle_k=\langle w_i\rangle_k$ for $i=1,2$ and all $k\in\mathbb{N}$ by maximality. Hence, $\langle v_i\rangle\cong\langle w_i\rangle$ for $i=1,2$. It follows that

$$\langle v_i\rangle\cong\langle u_i\rangle,\quad i=1,2. \tag{22}$$

By Lemma 1, a relation of V must be of the form

$$R=\rho(p_-^{h_Z(1)}v_1-Zp_+^{h_Z(0)}v_2),\quad 0\leqslant h_Z(i)\leqslant H,\quad i\in\{1,2\}. \tag{23}$$

It suffices to show that if V has a relation as in (23) then U has a corresponding relation

$$S=\rho(p_-^{h_Z(1)}v_1-Wp_+^{h_Z(0)}v_2). \tag{24}$$

However, this follows from (22), consideration of dimensions and maximality. □

Unfortunately, if $\mathcal{G}(V,v_1,v_2)\sim\mathcal{G}(U,u_1,u_2)$, then it is not necessarily true that $V\cong U$ (see Ref. 6). Further, if $V\cong U$ with $\mathcal{G}(V,v_1,v_2)$ and $\mathcal{G}(U,u_1,u_2)$ in maximal form then it is not necessarily true that $\mathcal{G}(V,v_1,v_2)=\mathcal{G}(U,u_1,u_2)$.

We end the section with an example of a maximal and a nonmaximal graph. Let V be a representation with generators v_1 and v_2 such that $wt(v_1)>wt(v_2)$ and graph as shown in Fig. 2(a). The graph is not in maximal form. But, if we let $u_1=v_1$ and $u_2=p_-^2v_1-v_2$ the graph is in maximal form [see Fig. 2(b)]. It will follow from the indecomposability criterion that V is indecomposable.

V. INDECOMPOSABILITY CRITERION

Let V be a representation with graph $\mathcal{G}(V,v_1,v_2)$ in maximal form. In this section we give a precise criterion under which V does or does not decompose. Equivalently, the criterion establishes when there exists a choice of generators u_1,u_2 for V such that $\mathcal{G}(V,u_1,u_2)$ is disconnected.

Let

$$w_1 = Av_1 + Bp_+^H v_2, \quad w_2 = Cp_-^H v_1 + Dv_2, \tag{25}$$

where $A=[a_i]$, $B=[b_i]$, $C=[c_i]$ and $D=[d_i]$ are upper triangular Toeplitz matrices. Then w_1 and w_2 generate V if and only if $a_0d_0 \neq b_{-H}c_{-H}$, where we define $b_i=0$, if $i<0$ (we similarly define a_i,c_i and d_i for $i<0$).

The indecomposability criterion is expressed in the following proposition.

Proposition 2: (a) *V is decomposable $\Leftrightarrow$ there is a generator change w_1,w_2 such that for each relation $\rho(p_-^{h(1)}v_1 - p_+^{h(0)}Zv_2)=0$ in the maximal graph $\mathcal{G}(V,v_1,v_2)$ either $\rho w_1=0$ or $\rho w_2=0$.*

(b) *Further, in the case of decomposability, $V=\langle w_1\rangle \oplus \langle w_2\rangle$.*

Proof: We first consider (a) ($\Leftarrow$) We will show that $V=\langle w_1\rangle \oplus \langle w_2\rangle$ [this will also establish (b)]. Consider the relation $\rho(p_-^{h(1)}v_1 - Zp_+^{h(0)}v_2)=0$. Since either $\rho w_1=0$ or $\rho w_2=0$ we have either $h(1)=0$ or $h(0)=0$, respectively.

Since $\mathcal{G}(V,v_1,v_2)$ is in maximal form, dimension considerations imply that no relations may be created as we change generators from v_1, v_2 to w_1, w_2; and no relation may be increased in length. Thus, it suffices to show that that for each relation of the form $\rho(v_1 - Zp_+^H v_2)=0$ or $\rho(p_-^H v_1 - Zv_2)=0$ we no longer have a relation between w_1 and w_2 of weight $wt(\rho w_1)$ or $wt(\rho w_2)$, respectively. This, however, follows from the fact that $\rho w_1=0$ or $\rho w_2=0$.

($\Rightarrow$) Suppose that V decomposes. Then for some generator change $w_1=Av_1+Bp_+^H v_2, w_2 = Cp_-^H v_1 + Dv_2$ we have $V=\langle w_1\rangle \oplus \langle w_2\rangle$. The generator change from v_1, v_2 to w_1, w_2 and the relation $\rho(p_-^{h(1)}v_1 - Zp_+^{h(0)}v_2)=0$ imply, via straightforward algebraic manipulation, that

$$\rho(C[h(0)]Z + D)p_-^{h(1)}w_1 = \rho(AZ + B[h(1)])p_+^{h(0)}w_2. \tag{26}$$

If both $C[h(0)]Z+D=0$ and $AZ+B[h(1)]=0$ then $a_0d_0=c_{-H}d_{-H}$ which is impossible since w_1,w_2 are generators. If both $C[h(0)]Z+D\neq 0$ and $AZ+B[h(1)]\neq 0$ then $\langle w_1\rangle \cap \langle w_2\rangle \neq 0$ which is impossible since $V=\langle w_1\rangle \oplus \langle w_2\rangle$.

Thus exactly one of $C[h(0)]Z+D=0$ or $AZ+B[h(1)]=0$. If $C[h(0)]Z+D=0$ then $h(0)=0$ and $a_0Z_0+b_{-H}\neq 0$ to satisfy $a_0d_0\neq c_{-H}d_{-H}$. Then $AZ+B[h(1)]$ is invertible so that (26) implies $\rho w_2=0$. Similarly if $AZ+B[h(1)]=0$ then $\rho w_1=0$ as required. □

Note that if a representation V is decomposable, its decomposition is unique up to isomorphism and permutation of components by the Krull-Schmidt theorem.[7]

The following corollaries express special cases of Proposition 2 which are often useful in practice.

Corollary 1: If $\mathcal{G}(V,v_1,v_2)$ has a type 1 relation then V is indecomposable.

Proof: Suppose that V were decomposable and let $\rho(p_-^{h(1)}v_1 - Zp_+^{h(0)}v_2)=0$ be a type 1 relation of $\mathcal{G}(V,v_1,v_2)$. Then, by Proposition 2, there would exist a generator change $w_1=Av_1 + Bp_+^H v_2, w_2=Cp_-^H v_1+Dv_2$ such that $\rho w_1=0$ or $\rho w_2=0$. However, since $h(0)>0$ and $h(1)>0$, this implies $a_0d_0=0=b_{-H}c_{-H}$, which contradicts the fact that w_1,w_2 is a set of generators. Hence, it must be the case that V is indecomposable. □

Corollary 2: If $H=0$ and $\mathcal{G}(V,v_1,v_2)$ has $\geqslant 3$ gluing scalars then V is indecomposable.

Proof: There are relations $R_i=\rho_i(v_1-\lambda_i v_2)$ for $i=1,2,3$ such that the λ_i are distinct. Suppose that V were to decompose. Then there would exist a generator change $w_1=Av_1+Bp_+^H v_2, w_2 = Cp_-^H v_1 + Dv_2$ as in Proposition 2. Then, by the above proposition, there must be two relations, say R_1 and R_2, such that either $\rho_1 w_1=0$ and $\rho_2 w_1=0$ or $\rho_1 w_2=0$ and $\rho_2 w_2=0$. Without loss of generality, assume the former. $\rho_1 w_1=0$ implies $\lambda_1=-b_0/a_0$ while $\rho_2 w_1=0$ implies $\lambda_2=-b_0/a_0$. This is impossible since then $\lambda_1\neq\lambda_2$. Hence it must be the case that V is indecomposable. □

Example: The graph in Fig. 3(a) is in maximal form. The relations in $\mathcal{G}(V,v_1,v_2)$ are

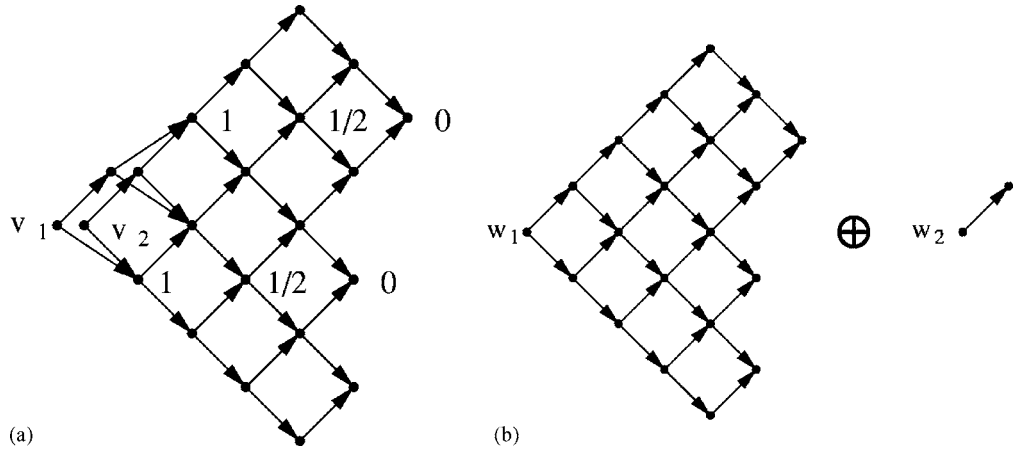

FIG. 3. (a) A decomposable graph and (b) its decomposition.

$$p_+^2\left(v_1-\begin{pmatrix}1 & \frac{1}{2}\\ 0 & 1\end{pmatrix}v_2\right)=0 \quad \text{and} \quad p_-\left(v_1-\begin{pmatrix}1 & \frac{1}{2}\\ 0 & 1\end{pmatrix}v_2\right)=0. \tag{27}$$

Consider the generator change $w_1=v_1$, and $w_2=v_1-v_2-\frac{1}{2}p_+p_-v_2$. Then $p_+^2w_2=0$ and $p_-w_2=0$. Thus, by Proposition 2, V decomposes as $\langle w_1\rangle\oplus\langle w_2\rangle$, as in Fig. 3(b).

Example: The graph $\mathcal{G}(V,v_1,v_2)$ in Fig. 4, which is in maximal form, has relations

$$\begin{gathered}p_+^5\left(v_1-\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}p_+v_2\right)=0, \quad p_+^3p_-^2\left(v_1-\begin{pmatrix}1 & 2\\ 0 & 1\end{pmatrix}p_+v_2\right)=0,\\ p_-^5\left(p_-v_1-\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}v_2\right)=0.\end{gathered} \tag{28}$$

By Proposition 2, if V were to decompose there would be a generator change $w_1=Av_1+Bp_+v_2$, $w_2=Cp_-v_1+Dv_2$ such that $p_+^5w_1=0, p_+^3p_-^2w_1=0$ and $p_-^5w_2=0$. However, if $p_+^5w_1=0$, then $p_+^3p_-^2w_1=p_+^3p_-^2\left(v_1-\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}p_+v_2\right)=p_+^5p_-^3v_2\neq 0$. Hence it must be the case that V is indecomposable.

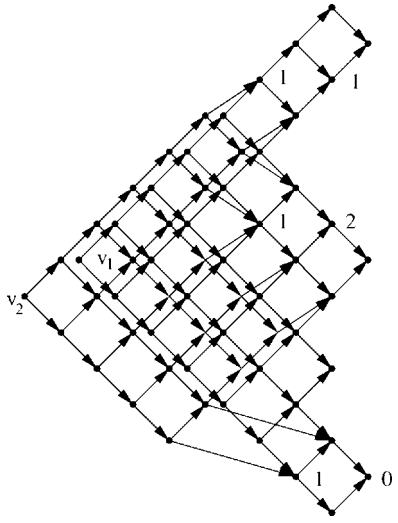

FIG. 4. An indecomposable graph.

VI. THE GENERATOR CHANGE TRANSFORMATION AND AN INVARIANT FOR INDECOMPOSABLE REPRESENTATIONS

In this section we describe an invariant for indecomposable representations. First we introduce a transformation on pairs of generators. Let

$$w_1 = Av_1 + Bp_+^H v_2, \quad w_2 = Cp_-^H v_1 + Dv_2 \tag{29}$$

be a generator change. The generator change from v_1, v_2 to w_1, w_2 induces a change of graphs from $\mathcal{G}(V, v_1, v_2)$ to $\mathcal{G}(V, w_1, w_2)$ which in turn induces a change in the relations and relation matrices. To this generator change we will also associate the transformation

$$\Gamma_{\{v_1,v_2\},\{w_1,w_2\}}(Z) = \frac{AZ + B[h(1)]}{C[h(0)]Z + D}, \tag{30}$$

where Z is an upper triangular Toeplitz matrix. In place of $\Gamma_{\{v_1,v_2\},\{w_1,w_2\}}$ we shall write Γ when no ambiguity arises. The transformation Γ is called the *generator change transformation*. After establishing preliminary results for generator change transformations we will construct an indecomposability criterion in Proposition 3 below.

Lemma 2: Suppose that V is an indecomposable representation with generators v_1, v_2 and $w_1 = Av_1 + Bp_+^H v_2, w_2 = Cp_-^H v_1 + Dv_2$ such that $\mathcal{G}(V, v_1, v_2)$ and $\mathcal{G}(V, w_1, w_2)$ are in maximal form. Then, $\mathcal{G}(V, v_1, v_2) \sim \mathcal{G}(V, w_1, w_2)$. Further, given a relation

$$\rho(p_-^{h(1)} v_1 - Z p_+^{h(0)} v_2) = 0 \tag{31}$$

in $\mathcal{G}(V, v_1, v_2)$, where $H = h(0) + h(1)$, the corresponding relation in $\mathcal{G}(V, w_1, w_2)$ is

$$\rho(p_-^{h(1)} w_1 - \Gamma(Z) p_+^{h(0)} w_2) = 0. \tag{32}$$

Note that by maximality, all relations are in the form of (31).

Proof: That $\mathcal{G}(V, v_1, v_2) \sim \mathcal{G}(V, w_1, w_2)$ follows from Proposition 1. And, as was mentioned above, the generator change $w_1 = Av_1 + Bp_+^H v_2, w_2 = Cp_-^H v_1 + Dv_2$ and the relation in (31), via straightforward algebraic manipulation, imply

$$\rho(C[h(0)]Z + D) p_-^{h(1)} w_1 = \rho(AZ + B[h(1)]) p_+^{h(0)} w_2. \tag{33}$$

If both $a_0 Z_0 + b_{-h(1)} = 0$ and $c_{-h(0)} Z_0 + d_0 = 0$ then we contradict $a_0 d_0 \neq c_{-H} d_{-H}$ which is a necessary condition for w_1, w_2 to be generators. If one of $a_0 Z_0 + b_{-h(1)} = 0$ or $c_{-h(0)} Z_0 + d_0 = 0$ then (33) contradicts Lemma 1. Thus $a_0 Z_0 + b_{-h(1)} \neq 0$ and $c_{-h(0)} Z_0 + d_0 \neq 0$, so that $C[h(0)]Z + D$ and $AZ + B[h(1)]$ are invertible, and

$$\rho p_-^{h(1)} w_1 = \rho \frac{AZ + B[h(1)]}{C[h(0)]Z + D} p_+^{h(0)} w_2 = \rho \Gamma(Z) p_+^{h(0)} w_2. \tag{34}$$

□

Lemma 3: Let v_1, v_2 and $w_1 = Av_1 + Bp_+^H v_2, w_2 = Cp_-^H v_1 + Dv_2$ be generators of a representation V. Further, let $\mathcal{G}(V, v_1, v_2)$ be in maximal form. If $a_0 Z_0 + b_{-h_Z(1)} \neq 0$ and $c_{-h_Z(0)} Z_0 + d_0 \neq 0$ for all relation matrices Z, then $\mathcal{G}(V, w_1, w_2)$ is also in maximal form.

Proof: Since $\mathcal{G}(V, v_1, v_2)$ is in maximal form, dimension considerations imply that no relations may be created as we change generators from v_1, v_2 to w_1, w_2. Hence to show that $\mathcal{G}(V, w_1, w_2)$ is in maximal form it suffices to show that no relations are shortened in length (they may not be lengthened by dimension considerations).

Consider the relation

$$\rho(p_-^{h(1)} v_1 - Z p_+^{h(0)} v_2) = 0. \tag{35}$$

As above we have,

$$\rho(C[h(0)]Z+D)p_-^{h(1)}w_1=\rho(AZ+B[h(1)])p_+^{h(0)}w_2. \tag{36}$$

Since $a_0Z_0+b_{-h_Z(1)}\neq 0$ and $c_{-h_Z(0)}Z_0+d_0\neq 0$, the matrices $C[h(0)]Z+D$ and $AZ+B[h(1)]$ are invertible thus the relation in (35) becomes

$$\rho p_-^{h(1)}w_1-\rho\frac{AZ+B[h(1)]}{C[h(0)]Z+D}p_+^{h(0)}w_2=0 \tag{37}$$

with the leading entry of $(AZ+B[h(1)])/(C[h(0)]Z+D)$ in $\mathbb{C}-\{0\}$, as required. □

The converse of Lemma 3 also holds, but will not be proved here. The next proposition determines an invariant for indecomposable representations.

Proposition 3: Let V and U be indecomposable representation with generators v_1,v_2 *and* u_1,u_2, *respectively, such that* $\mathcal{G}(V,v_1,v_2)$ *and* $\mathcal{G}(U,u_1,u_2)$ *are in maximal form. Then*

$$V\cong U\Leftrightarrow \mathcal{G}(V,v_1,v_2)\sim\mathcal{G}(U,u_1,u_2), \tag{38}$$

and there exists a generator change Γ *such that* $\Gamma(Z)=W$ *for all corresponding relation matrices Z and W.*

Proof: ($\Rightarrow$) Suppose $V\cong U$, then Proposition 1 implies $\mathcal{G}(V,v_1,v_2),\sim\mathcal{G}(U,u_1,u_2)$. By equivalence, there must exist a generator change $w_1=Av_1+Bp_+^Hv_2, w_2=Cp_-^Hv_1+Dv_2$ such that $\mathcal{G}(V,w_1,w_2)=\mathcal{G}(U,u_1,u_2)$. Hence, by Lemma 2 we have a generator change transformation $\Gamma(Z)=(AZ+B[h(1)])/(C[h(0)]Z+D)=W$ for all corresponding relation matrices Z and W of $\mathcal{G}(V,v_1,v_2)$ and $\mathcal{G}(U,u_1,u_2)$, respectively.

($\Leftarrow$) Assume $\mathcal{G}(V,v_1,v_2)\sim\mathcal{G}(U,u_1,u_2)$ and let Γ be a generator change such that $\Gamma(Z)=(AZ+B[h(1)])/(C[h(0)]Z+D)=W$, for all corresponding relation matrices Z and W.

Then, $w_1=Av_1+Bp_+^Hv_2, w_2=Cp_-^Hv_1+Dv_2$ are generators of V and the hypothesis of Lemma 3 is satisfied. Thus $\mathcal{G}(V,w_1,w_2)$ is in maximal form. Hence, by Proposition 1 $\mathcal{G}(V,v_1,v_2)\sim\mathcal{G}(V,w_1,w_2)$. It follows that $\mathcal{G}(V,w_1,w_2)\sim\mathcal{G}(U,u_1,u_2)$.

We have that $\Gamma(Z)=W$ is the relation in $\mathcal{G}(V,w_1,w_2)$ and in $\mathcal{G}(U,u_1,u_2)$ corresponding to Z in $\mathcal{G}(V,v_1,v_2)$. Hence $\mathcal{G}(V,w_1,w_2)\sim\mathcal{G}(U,u_1,u_2)$ with equal corresponding relations. That is, $\mathcal{G}(V,w_1,w_2)=\mathcal{G}(U,u_1,u_2)$. Thus $V\cong U$. □

Note that showing the existence of a generator change Γ such that $\Gamma(Z)=W$ for all corresponding relation matrices Z and W amounts to solving a system of linear equations in variables a_i,b_i,c_i, and d_i subject to the constraint $a_0d_0\neq b_{-H}c_{-H}$.

VII. CLASSIFICATION IN SMALL DIMENSION

In this section we classify the indecomposable representations of dimensions 5 and 6, regardless of the number of generators. In each case there are finitely many such representations (up to isomorphism). Next, we show that for all dimensions $\geqslant 8$ there are infinitely many nonequivalent indecomposable representations.

Any indecomposable representation V may be tensored with a character χ_r for $r\in\mathbb{Z}$ so that a weight space V_k with weight k becomes a weight space $V_k\otimes\chi_r$ of weight $k+r$. From here onward we shall assume that all indecomposable representations are renormalized so that their lowest weight is 0.

In Ref. 5, Cassinelli *et al.* describe a class $\mathcal{C}$ of indecomposable representations and classify the representations in this class of dimension $\leqslant 4$. The representations in $\mathcal{C}$ can be characterized as follows: $V\in\mathcal{C}$ if there exists a set of generators $v_1,v_2,\ldots,v_n$ such that $wt(v_i)>wt(v_{i+1})$ and $p_-^{\alpha_i}v_i=p_+^{\beta_i}v_{i+1}$ for $1\leqslant i\leqslant n-1$ and $\alpha_i,\beta_i\in\mathbb{N}_{>0}$.

The indecomposable representations in $\mathcal{C}$ of a given dimension are found by considering the connected graphs of the required dimension satisfying the characterization of the representations in $\mathcal{C}$ (and of course satisfying the requirement that $[p_-,p_+]=0$). These graphs are shown to be indecomposables and it is straightforward to show that two such representations are equivalent if and only if they have the same graph.[5]

Cassinelli *et al.* remark that they are uncertain whether or not all finite dimensional indecomposable representations are in $\mathcal{C}$. We illustrate below that there are indecomposable representations not in $\mathcal{C}$ for all dimensions $\geqslant 6$. In fact the most complicated representations (complicated in terms of creating an indecomposability criterion and classifying) are not contained in $\mathcal{C}$.

A. Classification in dimension 5

Figure 6 lists all five-dimensional representations in $\mathcal{C}$ and Proposition 4 below shows that all indecomposable representations of this dimension are contained in $\mathcal{C}$. In fact all indecomposable representation of dimension $\leqslant 5$ are in $\mathcal{C}$.

Figure 8 lists the indecomposable representations of dimension 6 in $\mathcal{C}$. There are two additional isomorphism classes which are not in $\mathcal{C}$; they are shown in Fig. 7. Figures 7 and 8 form a complete list of indecomposable, nonequivalent representations (Proposition 5 below).

The method described to assign graphs to representations with two generators may be generalized in a natural way to representations with an arbitrary number of generators, provided all relations among generators can be generated by pairwise relations between generators. We call such representations *graphical*. We will use the following lemma about graphical representations below.

Lemma 4: If V is indecomposable and dim$(V)\leqslant 6$ *then V is graphical.*

Proof: We consider just the case $\dim(V)=6$ and 3 generators since all other cases are similar and easier. Let v_1, v_2, and v_3 generate V with $wt(v_1)\geqslant wt(v_2)\geqslant wt(v_3)$.

Suppose that V is not graphical. Then we would have $\dim\{\rho_i v_i\}_{i=1,2,3}=2$ for some $\rho_i=p_+^{a_i}p_-^{b_i}$. It follows, by dimension considerations, that $p_+p_-v_i=0$ for all i. Hence, for each $i, \rho_i=p_+^{a_i}$ or $p_-^{b_i}$.

Suppose $a_i>0$ for all i. We would then have a relation $\Sigma_{i=1}^3\lambda_i p_+^{a_i}v_i=0$ with $\lambda_i\neq 0$ for all i. If this were the only relation required to describe all relations among the generators then $V=\langle v_3\rangle \oplus\langle v_1, \lambda_2 v_2+\lambda_3 p_+^{a_3-a_2}v_3\rangle$.

Suppose there is another relation among the generators. There is at most one other relation and it must be of the form $\eta_1 p_-^{c_1}v_1+\eta_2 p_-^{c_2}v_2+\eta_3 p_-^{c_3}v_3=0$ with exactly two of $\eta_i\neq 0$ (considering dimensions and $p_+p_-v_i=0$). Assume $\eta_1=0$ (other cases are similar). By dimension considerations, $wt(v_1)=wt(v_2)=wt(v_3)$ so that $a_1=a_2=a_3=1$. We have either $\dim\{p_+v_1, \eta_2 p_+v_2+\eta_3 p_+v_3\}=1$ or 2. If $\dim\{p_+v_1, \eta_2 p_+v_2+\eta_3 p_+v_3\}=1$ then $\langle \eta_2 v_2+\eta_3 v_3\rangle=\langle \lambda_2 v_2+\lambda_3 v_3\rangle$ and $V=\langle v_1, \eta_2 v_2+\eta_3 v_3\rangle\oplus\langle v_3\rangle$. If $\dim\{p_+v_1, \eta_2 p_+v_2+\eta_3 p_+v_3\}=2$ then $V=\langle \eta_2 v_2+\eta_3 v_3\rangle\oplus\langle v_1, \lambda_2 v_2+\lambda_3 v_3\rangle$.

Similarly, if $b_i>0$ for all i then V would decompose. Now suppose that exactly two of $a_i>0$. Then we must have $b_1>0, a_2>0$ and $a_3>0$. Then we have a relation $\lambda_1 p_-^{b_1}v_1+\Sigma_{i=1}^2\lambda_i p_+^{a_i}v_i=0$ with $\lambda_i\neq 0$ for all i. If this is the only relation required to describe all relations among the generators then $V=\langle v_3\rangle\oplus\langle v_1, \lambda_2 v_2+\lambda_3 p_+^{a_3-a_2}v_3\rangle$.

Suppose there is another relation among the generators. There is at most one other relation and it must be of the form $\eta_2 p_-^{c_2}v_2+\eta_3 p_-^{c_3}v_3=0$ with $\eta_i\neq 0$ for all i (considering dimensions and $p_+p_-v_i=0$). By dimension considerations, $wt(v_2)=wt(v_3)$ and $a_1=b_2=b_3=1$. We have either $\dim\{p_-v_1, \eta_2 p_+v_2+\eta_3 p_+v_3\}=1$ or 2. If $\dim\{p_-v_1, \eta_2 p_+v_2+\eta_3 p_+v_3\}=1$ then $\langle \eta_2 v_2+\eta_3 v_3\rangle=\langle \lambda_2 v_2+\lambda_3 v_3\rangle$ and $V=\langle v_1, \eta_2 v_2+\eta_3 v_3\rangle\oplus\langle v_3\rangle$. If $\dim\{p_-v_1, \eta_2 p_+v_2+\eta_3 p_+v_3\}=2$ then $V=\langle \eta_2 v_2+\eta_3 v_3\rangle\oplus\langle v_1, \lambda_2 v_2+\lambda_3 v_3\rangle$.

Similarly, if exactly two of $b_i>0$ then V would decompose. Thus V, being indecomposable, is graphical. □

Proposition 4: Let V be an indecomposable representation with dim $(V)\leqslant 5$, *then* $V\in\mathcal{C}$.

Proof: Certainly there can be no more than five generators. If there were five generators, v_i for $i=1,2,3,\ldots,5$, then $\dim(V)=5$ and $V=\oplus_{i=1}^5\langle v_i\rangle$. If there is one generator then trivially $V\in\mathcal{C}$.

Suppose there were four generators. Let v_1, v_2, v_3, v_4 be a set of generators. If $\dim(V)=4$ then V would decompose as $V=\oplus_{i=1}^4\langle v_i\rangle$. Thus we must have $\dim(V)=5$.

By dimension considerations and indecomposability, for all i, $p_-v_i=0$, or $p_+v_i=0$; and p_-v_i, or p_+v_i is terminal. Thus, we must have $wt(v_i)=wt(v_j)$ for some $i\neq j$. Let $wt(v_1)=wt(v_2)$. We have either $p_+v_1-\lambda p_+v_2=0$ or $p_-v_1-\lambda p_-v_2=0$ for some $\lambda\in\mathbb{C}-\{0\}$. In either case, $V\cong\langle v_1-\lambda v_2\rangle \oplus\langle v_1, v_3, v_4\rangle$. Hence, V, being indecomposable, cannot have four generators.

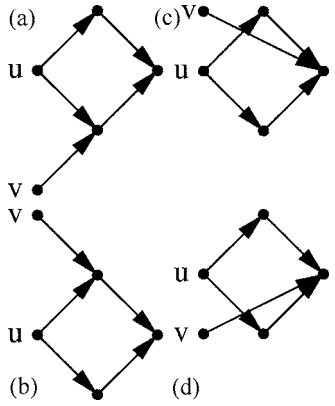

FIG. 5. The graphs $\mathcal{G}(V,u,v)$ of five dimensions such that $p_+p_-u\neq 0$.

Suppose that V has two generators. Let u and v generate V and suppose that $p_+p_-u\neq 0$. By dimension consideration we must then have $p_+p_-v=0, p_+^2p_-u=0$, and $p_+p_-^2u=0$. Then, V must be equivalent to one of the four graphs in Fig. 5.

The graphs in Figs. 5(a) and 5(b) are in $\mathcal{C}$. The graphs in Figs. 5(c) and 5(d) are decomposable; $V=\langle v-p_+u\rangle\oplus\langle u\rangle$ or $V=\langle v-p_-u\rangle\oplus\langle u\rangle$, respectively.

Now suppose that V has generators v_1,v_2 with $wt(v_1)\geqslant wt(v_2)$ such that $p_+p_-v_i=0$ for $i=1,2$. First let $wt(v_1)=wt(v_2)$. Then we may have relations of the form $p_+^av_1-\lambda p_+^av_2=0$ or $p_-^bv_1-\eta p_-^bv_2=0$.

If we have just the first relation then $V=\langle v_1-\lambda v_2\rangle\oplus\langle v_1\rangle$. If just the second then $V=\langle v_1-\eta v_2\rangle\oplus\langle v_1\rangle$. If we have both relations and $\lambda\neq\eta$ then $V=\langle v_1-\lambda v_2\rangle\oplus\langle v_1-\eta v_2\rangle$ while if $\lambda=\eta$ then $V=\langle v_1-\lambda v_2\rangle\oplus\langle v_2\rangle$.

Now suppose that $wt(v_1)>wt(v_2)$. If we have a relation $p_-^av_1-\lambda p_+^bv_2=0$ then we have no other relations and $V\in\mathcal{C}$. Otherwise we just have relations $p_-^av_1-\lambda p_-^bv_2=0$ or $p_+^cv_1-\eta p_+^dv_2=0$. If we have just the first relation then $V=\langle p_-^{a-b}v_1-\lambda v_2\rangle\oplus\langle v_1\rangle$. If just the second then $V=\langle v_1-\eta p_+^{d-c}v_1\rangle\oplus\langle v_2\rangle$. If both then $V=\langle v_1-\lambda p_+^{d-c}v_2\rangle\oplus\langle p_+^{a-b}v_1-\lambda v_2\rangle$.

Hence, if V has two generators than either $V\in\mathcal{C}$ or V is decomposable. The remaining case were V has three generators follows in an analogous manner to the two generator case and thus will not be considered. □

Figure 6 is a complete list of indecomposable, nonequivalent representations of dimension 5 in $\mathcal{C}$. Hence by Proposition 4 it is a complete list of all indecomposable, nonequivalent representations of this dimension.

B. Classification in dimension 6

Proposition 5: Let V be an indecomposable representation such that dim$(V)=6$ *then V is equivalent to one of the graphs in Fig.* 8 *or one of the six dimensional graphs in Fig.* 7 (*i.e.*, $k=0$ *in Fig.* 7).

Proof: Checking that $V\in\mathcal{C}$ if V does not have two generators follows as in the previous proof. Hence we will only show that if V has two generators then it is equivalent to one of the graphs in Fig. 8 or one of the six dimensional graphs in Fig. 7.

We first establish that we cannot have $wt(v_1)=wt(v_2)$. We may assume that $\mathcal{G}(V,v_1,v_2)$ is in maximal form so that $\langle v_1\rangle\cong\langle v_2\rangle$. Let T_i be the terminal space of $\langle v_i\rangle$ (i.e., $T_i=\{v\in\langle v_i\rangle : p_+v=0,\ p_-v=0\}$). By dimension considerations $\dim(T_i)\leqslant 2$ for $i=1,2$. Also by dimension considerations all relation matrices must be 1×1. Hence there can be at most two gluing scalars λ_1,λ_2 and all relations are in the form $\rho(v_1-\lambda_iv_2)=0$ for $i=1$ or 2. Hence, $V=\langle v_1\rangle\oplus\langle v_1-\lambda_1v_2\rangle$ in the case of one gluing scalar or $V=\langle v_1-\lambda_1v_2\rangle\oplus\langle v_1-\lambda_2v_2\rangle$ in the case of two gluing scalars.

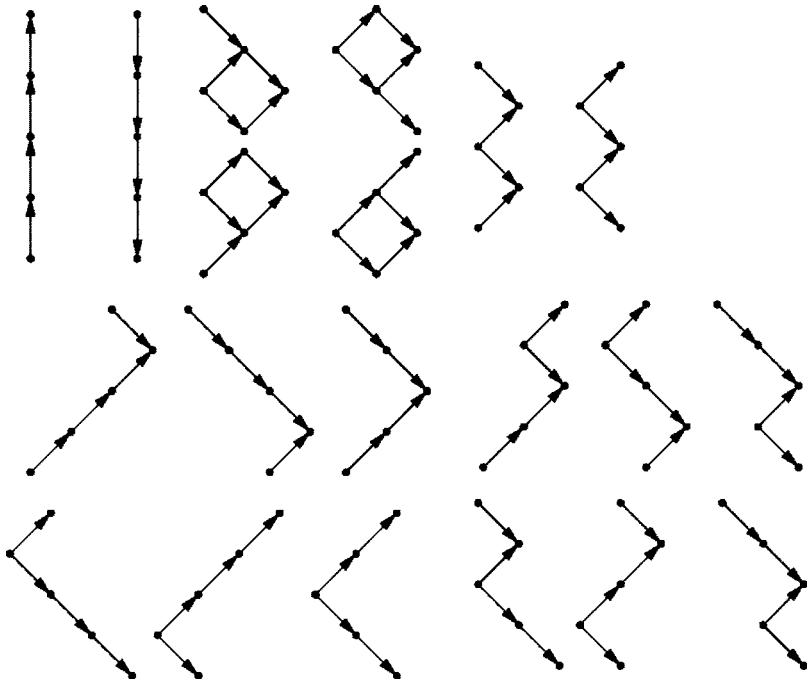

FIG. 6. The indecomposable representation of dimension 5.

Next we consider $wt(v_1) > wt(v_2)$. First suppose that $p_+p_-v_i=0$ for $i=1,2$. Then, we have only three possible relations; $p_+^{a_1}v_1-\lambda p_+^{a_2}v_2=0, p_-^{b_1}v_1-\lambda p_-^{b_2}v_2=0$ or $p_-^{c_1}v_1-\lambda p_+^{c_2}v_2=0$ for $\lambda \in \mathbb{C}-\{0\}$. If we have the last relation than we cannot have either of the other two and $V \in \mathcal{C}$. If we have one or both of $p_+^{a_1}v_1-\lambda_a p_+^{a_2}v_2=0, p_-^{b_1}v_1-\lambda_b p_-^{b_2}v_2=0$ then V decomposes. For instance if we have both then $V=\langle v_1-\lambda_a p_+^{a_2-a_1}v_2\rangle \oplus \langle p_-^{b_1-b_2}v_1-\lambda_b v_2\rangle$.

Now suppose that $p_+p_-v_1 \neq 0$. By dimension considerations $p_+^2p_-v_1=0$ and $p_+p_-^2v_1=0$. If V is not in $\mathcal{C}$ then the only possibility is that $p_+^2v_2-\lambda p_+p_-v_1=0$ for some $\lambda \in \mathbb{C}-\{0\}$ describes the relation between v_1 and v_2. We can always change generators to $w_1=v_1, w_2=\lambda v_2$ to get the first graph in Fig. 7. (By Corollary 1, it is indecomposable since it has a relation of type 1). The case where $p_+p_-v_2 \neq 0$ is similar. Hence we have shown that if $\dim(V)=6$ then either V decomposes or is equivalent to one of the graphs in Fig. 8 or one of the six-dimensional graphs in Fig. 7. □

The two graphs in Fig. 7 are clearly nonequivalent for any k. Figure 8 is a complete list of indecomposable, nonequivalent representations of dimension 6 in $\mathcal{C}$. Hence by Proposition 5, Figs. 8 and 7 form a complete list of all indecomposable, nonequivalent representations of this dimension.

Proposition 5 shows that not all indecomposable representations are in $\mathcal{C}$ for $\dim(V)=6$. In fact, for each dimension $\geqslant 6$ there are indecomposable representations not in $\mathcal{C}$. For example, the

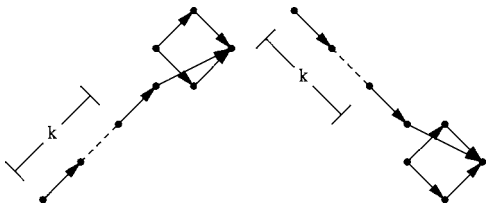

FIG. 7. Indecomposable representations of dimension $6+k$, for $k \in \mathbb{N}$, not in $\mathcal{C}$.

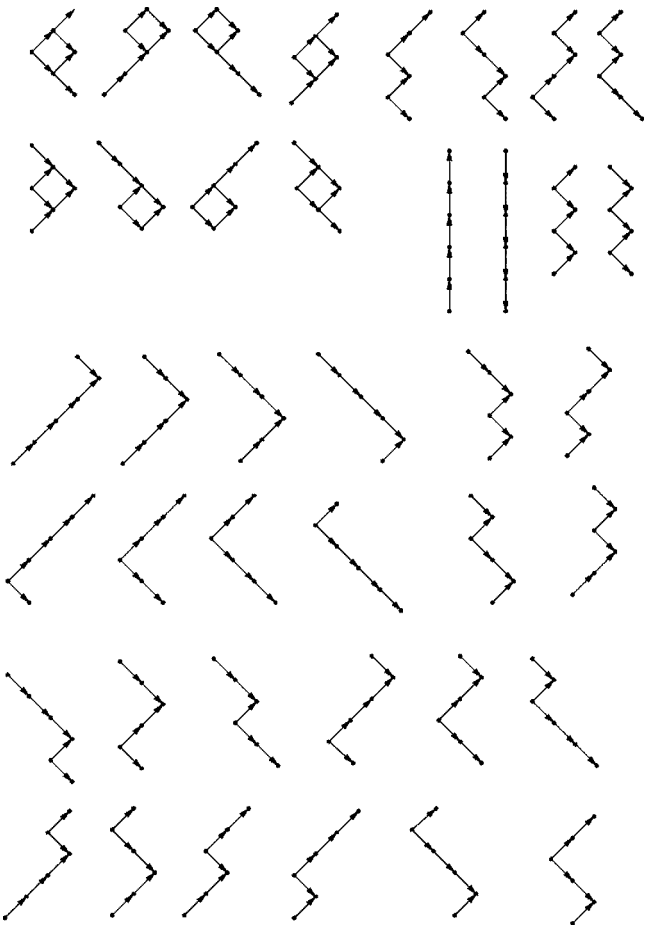

FIG. 8. The indecomposable representations of dimension 6 in $\mathcal{C}$.

representations in Fig. 7, which each have two generators, are $6+k$ dimensional for $k \in \mathbb{N}$. By Corollary 1, they are indecomposable since they have either a relation $p_+(p_-v_1 - p_+^{k+1}v_2)=0$ or $p_-(p_-^{k+1}v_1 - p_+v_2)=0$.

C. Higher dimensional representations

For each dimension $\geqslant 8$ there are infinitely many nonequivalent, indecomposable representations. The graph in Fig. 9 is from a representation V_z of dimension $8+k$ for $k \in \mathbb{N}$. The maximal graph $\mathcal{G}(V_z, v_1, v_2)$ has relations $p_+(p_-v_1 - p_+v_2)=0$ and $p_-(p_-v_1 - zp_+v_2)=0$. These relations are both type 1 and thus the representation is indecomposable (Corollary 1).

Proposition 6: $V_z \cong V_w \Leftrightarrow z=w$.

Proof: If $z=w$ then $\mathcal{G}(V_z, v_1, v_2)=\mathcal{G}(V_w, v_1, v_2)$ which implies $V_z \cong V_w$. Let $z \neq w$ and suppose that $V_z \cong V_w$. Then, by Proposition 3, we would have a generator change Γ such that $\Gamma(1)=1$ and $\Gamma(z)=w$. However, $\Gamma(1)=a_0 1/d_0=1$ thus $\Gamma(z)=a_0 z/d_0=z \neq w$; a contradiction. Hence, $z \neq w$ implies $V_z \ncong V_w$. □

Proposition 6 establishes that there are infinitely many nonequivalent indecomposable representations of dimension $8+k$ for $k \in \mathbb{N}$. We are uncertain if there are only finitely many indecomposable representations of dimension 7, but we conjecture that there are.

In a subsequent paper we will generalize the results of this paper pertaining to two generators to all graphical representations of $\mathfrak{e}(2)$. We will also classify all indecomposable representations having two generators.

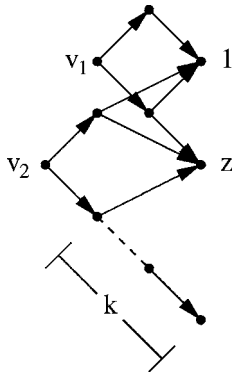

FIG. 9. The graph $\mathcal{G}(V_z, v_1, v_2)$ of dimension $8+k$ for $k \in \mathbb{N}$ and $z \in \mathbb{C}-\{0\}$.

We investigate the link between a periodic box-ball system (PBBS) and a solvable lattice model. Introducing a PBBS with an integer parameter corresponding to the dimensionality of the auxiliary space for the lattice model, we prove an important relationship between the conserved quantities of states of the PBBS and eigenvectors constructed through the string hypothesis. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2200142]

I. INTRODUCTION

A periodic box-ball system (PBBS) is a dynamical system of balls in a one-dimensional array of boxes with a periodic boundary condition. It can be obtained from the zero temperature limit of solvable lattice models which are generalizations of the six-vertex model.[1] In Ref. 2, we explained why the fundamental cycle of PBBS is obtained from the eigenvalues of the transfer matrix of the lattice model and conjectured an important relation between the string hypothesis of Bethe ansatz equation and the conserved quantities of PBBS. In this article, we prove this relation (Theorem 1.1) by introducing a positive integer parameter to the evolution rule of PBBS. As for the PBBS obeying this rule, we will shown the following properties: the time evolution rule is equivalent to an action of the transfer matrix of the solvable lattice model at the zero temperature limit (Theorem 2.1); the conserved quantities under the original time evolution rule of the PBBS are conserved under the new rule (Proposition 2.1).

In the rest of this section, we give definitions of the PBBS and the vertex models, and present the main theorem (Theorem 1.1). In Sec. II, we introduce yet another PBBS with the time evolution rule characterized by a positive integer, and we investigate its properties. In Sec. III, we prepare a proposition about eigenvalues of the transfer matrix in the zero temperature limit of the solvable lattice model, and prove Theorem 1.1. Section IV is devoted to the concluding remarks.

A. A periodic box-ball system

There may be many ways to describe the update rule of a periodic box-ball system.[1,3] Here we shall give yet another one. This is done in order that we may define a generalized model in Sec.

II. We hope that the readers feel that things are clearly stated in the following description. The equivalent definition adopted in previous work is shown in the Appendix .

Let N and M be non-negative integers. Let $\Omega(N)$ be the set of all sequences of zeros and ones of length N, and let $\Omega_M(N)$ be the subset of $\Omega(N)$ consisting of sequences having exactly M 1's. That is,

$$\Omega(N) = \mathrm{Map}([N],\{0,1\}),$$

$$\Omega_M(N) = \{\boldsymbol{\alpha} | \boldsymbol{\alpha} \in \Omega(N), \# \boldsymbol{\alpha}^{-1}(\{1\}) = M\},$$

where $[N]=\{1,2,\ldots,N\}$, $\mathrm{Map}(A,B)$ denotes the set of all mappings of A into B, and $\#A$ the number of elements in a finite set A. We use $\boldsymbol{\alpha}$ to denote both the mapping $\boldsymbol{\alpha}:[N]\to\{0,1\}$ and a finite sequence $(\boldsymbol{\alpha}(1),\boldsymbol{\alpha}(2),\ldots,\boldsymbol{\alpha}(N))$.

In what follows, we always assume that $M<N/2$.

Let $\boldsymbol{\alpha}=(\alpha_1,\alpha_2,\ldots,\alpha_N)\in\Omega_M(N)$. Let $\boldsymbol{\alpha}^{(0)}=\boldsymbol{\alpha}$, $N^{(0)}=N$, and $M^{(0)}=M$. For each $j=1,2,3,\ldots$, let $W^{(j)}$ be the set of all pairs of positions in $\boldsymbol{\alpha}^{(j-1)}$ where 0 follows 1. Because of the periodic boundary condition, this includes the case $\alpha_N=1$ and $\alpha_1=0$. By definition, $\#W^{(j)}$ is even; thus, define

$$p_j = \tfrac{1}{2}\# W^{(j)} \quad \text{and} \quad N^{(j)} = N^{(j-1)} - 2p_j;$$

let $n^{(j)}\in\mathrm{Map}([N^{(j)}],[N^{(j-1)}])$ be defined by

$$\{n^{(j)}(1),n^{(j)}(2),\ldots,n^{(j)}(N^{(j)})\} = [N^{(j-1)}]\setminus W^{(j)},$$

where $n^{(j)}(1)<n^{(j)}(2)<\cdots<n^{(j)}(N^{(j)})$; let $M^{(j)}=M^{(j-1)}-p_j$, and define a subsequence $\boldsymbol{\alpha}^j\in\Omega_{M^{(j)}}(N^{(j)})$ of $\boldsymbol{\alpha}^{(j-1)}$ by

$$\boldsymbol{\alpha}^{(j)} = \boldsymbol{\alpha}^{(j-1)}\circ n^{(j)}.$$

Let L be the integer uniquely determined by the condition

$$N^{(j-1)} > N^{(j)} \quad (j\le L) \quad \text{and} \quad N^{(j)} = N^{(L)} \quad (j\ge L).$$

Then we have

$$[N] = W^{(1)} \cup \left(\bigcup_{j=2}^{L} n^{(1)}(n^{(2)}(\cdots n^{(j-1)}(W^{(j)})\cdots)) \right)$$

$$\cup n^{(1)}(n^{(2)}(\cdots n^{(L-1)}(n^{(L)}([N^{(L)}]))\cdots)) \quad \text{(disjoint union)}.$$

For example, let $N=28$, $M=9$, and

$$\boldsymbol{\alpha} = (0,0,0,0,0,1,1,1,1,0,0,0,1,1,0,1,1,0,0,0,1,0,0,0,0,0,0,0).$$

Then we have

(1) $W^{(1)}=\{9,10,14,15,17,18,21,22\}$, $p_1=\frac{1}{2}\#W^{(1)}=4$,

$$N^{(1)} = N-2p_1 = 20, \quad M^{(1)} = M-p_1 = 5,$$

$$n^{(1)} = (1,2,3,4,5,6,7,8,11,12,13,16,19,20,23,24,25,26,27,28),$$

$$\boldsymbol{\alpha}^{(1)} = \boldsymbol{\alpha}\circ n^{(1)} = (0,0,0,0,0,1,1,1,0,0,1,1,0,0,0,0,0,0,0,0);$$

(2) $W^{(2)}=\{8,9,12,13\}$, $p_2=\frac{1}{2}\#W^{(2)}=2$,

$$N^{(2)} = N^{(1)}-2p_2 = 16, \quad M^{(2)} = M^{(1)}-p_2 = 3,$$

$$n^{(2)} = (1,2,3,4,5,6,7,10,11,14,15,16,17,18,19,20),$$

$$\boldsymbol{\alpha}^{(2)} = \boldsymbol{\alpha}^{(1)} \circ n^{(2)} = (0,0,0,0,0,1,1,0,1,0,0,0,0,0,0,0);$$

(3) $W^{(3)}=\{7,8,9,10\}$, $p_3=\frac{1}{2}\#W^{(3)}=2$,

$$N^{(3)} = N^{(2)} - 2p_3 = 12, \quad M^{(3)} = M^{(2)} - p_3 = 1,$$

$$n^{(3)} = (1,2,3,4,5,6,11,12,13,14,15,16),$$

$$\boldsymbol{\alpha}^{(3)} = \boldsymbol{\alpha}^{(2)} \circ n^{(3)} = (0,0,0,0,0,1,0,0,0,0,0,0);$$

(4) $W^{(4)}=\{6,7\}$, $p_4=\frac{1}{2}\#W^{(4)}=1$,

$$N^{(4)} = N^{(3)} - 2p_4 = 10, \quad M^{(4)} = M^{(3)} - p_4 = 0,$$

$$n^{(4)} = (1,2,3,4,5,8,9,10,11,12),$$

$$\boldsymbol{\alpha}^{(4)} = \boldsymbol{\alpha}^{(3)} \circ n^{(4)} = (0,0,0,0,0,0,0,0,0,0);$$

(5) For $k=5,6,7,\ldots$, $W^{(k)}=0$, $p_k=\frac{1}{2}\#W^{(k)}=0$,

$$N^{(k)} = N^{(k-1)} - 2p_k = 10, \quad M^{(k)} = M^{(k-1)} - p_k = 0,$$

$$n^{(k)} = (1,2,3,4,5,6,7,8,9,10),$$

$$\boldsymbol{\alpha}^{(k)} = \boldsymbol{\alpha}^{(k-1)} \circ n^{(k)} = (0,0,0,0,0,0,0,0,0,0);$$

hence, we obtain $L=4$ and the decomposition of $[28]=\{1,2,\ldots,28\}$

$$W^{(1)} \cup n^{(1)}(W^{(2)}) \cup n^{(1)}(n^{(2)}(W^{(3)}))$$

$$\cup n^{(1)}(n^{(2)}(n^{(3)}(W^{(4)}))) \cup n^{(1)}(n^{(2)}(n^{(3)}(n^{(4)}([N^{(4)}]))))$$

$$=\{9,10,14,15,17,18,21,22\} \cup \{8,11,16,19\} \cup \{7,12,13,20\}$$

$$\cup\{6,23\} \cup \{1,2,3,4,5,24,25,26,27,28\}.$$

Let $\bar{\mathbb{N}}=\mathbb{N}\cup\{\infty\}=\{1,2,3,\ldots\}\cup\{\infty\}$, and assume that $\infty > m$ for any number $m \in \mathbb{N}$. Define $\boldsymbol{\lambda}=(\lambda_1,\lambda_2,\ldots,\lambda_N) \in \mathrm{Map}([N],\bar{\mathbb{N}})$ as follows:

$$\lambda_k = \begin{cases} 1 & \text{for } k \in W^{(1)} \\ j & \text{for } k \in n^{(1)}(n^{(2)}(\cdots n^{(j-1)}(W^{(j)})\cdots)) \quad (j=2,3,\ldots,L) \\ \infty & \text{otherwise.} \end{cases}$$

A *periodic box-ball system* (PBBS) is defined by the set $\Omega_M(N)$ whose elements are called *states* and a mapping T of $\Omega_M(N)$ into (in fact, onto) itself, which is called *time evolution*. For $\boldsymbol{\alpha} \in \Omega_M(N)$ and $k \in [N]$, we define

$$T(\boldsymbol{\alpha}) = (\alpha'_1, \alpha'_2, \ldots, \alpha'_N)$$

where

$$\alpha'_k = \begin{cases} 1-\alpha_k & \text{if } \lambda_k < \infty \\ \alpha_k & \text{if } \lambda_k = \infty \end{cases}.$$

For the above example,

$$\boldsymbol{\lambda} = (\infty, \infty, \infty, \infty, \infty, 4,3,2,1,1,2,3,3,1,1,2,1,1,2,3,1,1,4, \infty, \infty, \infty, \infty, \infty),$$

$$T(\boldsymbol{\alpha}) = (0,0,0,0,0,0,0,0,0,0,1,1,1,0,0,1,0,0,1,1,1,0,1,1,0,0,0,0,0).$$

Thus, the PBBS is a type of discrete dynamical system. The number N is called the number of boxes (or length of the system), and M is called the number of balls. We shall say that a state $\boldsymbol{\alpha} \in \Omega_M(N)$ has (or consists of) M balls.

It is convenient to write $\boldsymbol{\alpha}=(\alpha_1, \alpha_2, \ldots, \alpha_N) \in \Omega_M(N)$ as

$$\alpha_1 \alpha_2 \cdots \alpha_N;$$

for example

$$0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 1\ \ 1\ \ 1\ \ 1\ \ 0\ \ 0\ \ 0\ \ 1\ \ 1\ \ 0\ \ 1\ \ 1\ \ 0\ \ 0\ \ 0\ \ 1\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0.$$

In a similar manner, we shall express $(\boldsymbol{\alpha}, \boldsymbol{\lambda})=(\alpha_1, \lambda_1), (\alpha_2, \lambda_2), \ldots, (\alpha_N, \lambda_N))$ as

$$\alpha_1^{\lambda_1}\ \alpha_2^{\lambda_2} \cdots \alpha_N^{\lambda_N};$$

for example

$$0^{\infty}0^{\infty}0^{\infty}0^{\infty}0^{\infty}1^4 1^3 1^2 1^1 0^1 0^2 0^3 1^3 1^1 0^1 1^2 1^1 0^1 0^2 0^3 1^1 0^1 0^4 0^{\infty}0^{\infty}0^{\infty}0^{\infty}0^{\infty},$$

or more simply

$$0\ 0\ 0\ 0\ 0\ 1^4 1^3 1^2 1^1 0^1 0^2 0^3 1^3 1^1 0^1 1^2 1^1 0^1 0^2 0^3 1^1 0^1 0^4 0\ 0\ 0\ 0\ 0$$

where ∞'s in the upper suffix are omitted.

The numbers p_j determined for a state $\boldsymbol{\alpha}$ by the above-noted procedure are conserved quantities of the PBBS;[3] that is, if we write $p_j(\boldsymbol{\alpha})$ for these numbers for a state $\boldsymbol{\alpha}$, then

$$p_j(T(\boldsymbol{\alpha})) = p_j(\boldsymbol{\alpha}) \quad \text{for } j = 1,2,3, \ldots, \text{ and for any } \boldsymbol{\alpha} \in \Omega_M(N).$$

Since, by definition,

$$p_1 \geq p_2 \geq p_3 \geq \ldots, \quad \text{and} \quad \sum_j p_j = M,$$

the sequence of conserved quantities $\boldsymbol{p}=(p_1, p_2, p_3, \ldots)$ is a partition of the integer M.

We shall not distinguish a partition $\boldsymbol{p}$ and a Young diagram, the array of squares left justified in decreasing order (p_1 squares in the top row, p_2 in the second row, and so on). The *conjugate* of a partition $\boldsymbol{p}$ is the partition $\boldsymbol{p}'=(p'_1, p'_2, p'_3, \ldots)$ defined by

$$p'_j = \#\{i | i \geq 1 \text{ and } p_i \geq j\};$$

or equivalently, in terms of Young diagrams, $\boldsymbol{p}'$ is the transpose of the diagram $\boldsymbol{p}$. An example is shown in Fig. 1.

Let Y be a Young diagram; we define a subset $\Omega_M^Y(N)$ of $\Omega_M(N)$ by

$$\Omega_M^Y(N) = \{\boldsymbol{\alpha} \in \Omega_M(N) | \boldsymbol{p}(\boldsymbol{\alpha}) \text{ is the conjugate of } Y\}.$$

In what follows, we shall often write $\Omega_M, \Omega_M^Y, \ldots$ for $\Omega_M(N), \Omega_M^Y(N), \ldots$, respectively, when their N-dependence is apparent.

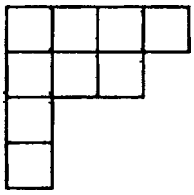

FIG. 1. Young diagram whose conjugate corresponds to the partition (4,2,2,1).

B. The vertex models

The six-vertex model and its higher spin generalizations are defined by the so-called R-matrices $R^{(\ell,\ell')}:\mathbb{C}^{\ell+1}\otimes\mathbb{C}^{\ell'+1}\to\mathbb{C}^{\ell+1}\otimes\mathbb{C}^{\ell'+1}$,

$$R^{(\ell,\ell')}(|i'\rangle\otimes|j'\rangle)=\sum_{i=0}^{\ell}\sum_{j=0}^{\ell'}\langle i,j|R^{(\ell,\ell')}|i',j'\rangle(|i\rangle\otimes|j\rangle),$$

where $\{|i\rangle|i=0,1,\ldots,\ell\}$ and $\{|j\rangle|j=0,1,\ldots,\ell'\}$ are bases of $\mathbb{C}^{\ell+1}$ and $\mathbb{C}^{\ell'+1}$, respectively. The R-matrices are parametrized by two parameters, x and q. We follow the parametrization given in Ref. 4. For $\ell'=1$, the parametrization of $R^{(\ell,1)}=R^{(\ell,1)}[x;q]$ we need is given by

(i) for $k=0,1,\ldots,\ell$,

$$\langle k,1|R^{(\ell,1)}[x;q]|k,1\rangle=\frac{q^{\ell-k}x-q^{k+1}x^{-1}}{x-q^{\ell+1}x^{-1}},$$

$$\langle k,0|R^{(\ell,1)}[x;q]|k,0\rangle=\frac{q^{k}x-q^{\ell-k+1}x^{-1}}{x-q^{\ell+1}x^{-1}};$$

(ii) for $k=1,2,\ldots,\ell$,

$$\langle k-1,1|R^{(\ell,1)}[x;q]|k,0\rangle=\langle k,0|R^{(\ell,1)}[x;q]|k-1,1\rangle$$

$$=\frac{\sqrt{(1-q^{2k})(1-q^{2(\ell-k+1)})}}{x-q^{\ell+1}x^{-1}};$$

(iii) otherwise, $\langle i,j|R^{(\ell,1)}[x;q]|i',j'\rangle=0$,

where x and q are called the spectral parameter and the deformation parameter, respectively. The matrix $R^{(1,\ell)}[x;q]$ is related to $R^{(\ell,1)}[x;q]$ by

$$R^{(1,\ell)}[x;q]=P^{(\ell,1)}R^{(\ell,1)}[x;q]P^{(1,\ell)},$$

where $p^{(m,n)}:\mathbb{C}^{m+1}\otimes\mathbb{C}^{n+1}\to\mathbb{C}^{n+1}\otimes\mathbb{C}^{m+1}$ is the permutation

$$P^{(m,n)}(|i\rangle\otimes|j\rangle)=|j\rangle\otimes|i\rangle.$$

For $\ell=1,2,3,\ldots$, we define the transfer matrix $\hat{t}_\ell[x;q]:V\to V(V:=\underbrace{\mathbb{C}^2\otimes\mathbb{C}^2\otimes\ldots\otimes\mathbb{C}^2}_{N})$ by

$$\hat{t}_\ell[x;q](|i_1'\rangle\otimes|i_2'\rangle\otimes\ \ldots\ \otimes|i_N'\rangle)$$

$$=\sum_{i_1,i_2,\ldots,i_N\in\{0,1\}}\langle i_1,i_2,\ldots,i_N|\hat{t}_\ell[x;q]|i_1',i_2',\ldots,i_N'\rangle(|i_1\rangle\otimes|i_2\rangle\otimes\ \ldots\ \otimes|i_N\rangle),$$

$$\langle i_1, i_2, \ldots, i_N | \hat{t}_\ell[x;q] | i'_1, i'_2, \ldots, i'_N \rangle$$

$$:= \sum_{j_1, j_2, \ldots, j_N = 0}^{\ell} \langle i_N, j_1 | R^{(1,\ell)}[x;q] | i'_N, j_N \rangle \langle i_{N-1}, j_N | R^{(1,\ell)}[x;q] | i'_{N-1}, j_{N-1} \rangle$$

$$\ldots \langle i_2, j_3 | R^{(1,\ell)}[x;q] | i'_2, j_2 \rangle \cdot \langle i_1, j_2 | R^{(1,\ell)}[x;q] | i'_1, j_1 \rangle .$$

The transfer matrices for different x's and ℓ's commute with each other by virtue of the Yang-Baxter relation which the R matrices obeys; that is,

$$\hat{t}_\ell[x;q]\hat{t}_{\ell'}[x';q] = \hat{t}_{\ell'}[x';q]\hat{t}_\ell[x;q] \quad \text{for any } \ell, \ell', x, \text{ and } x' .$$

Let $V_M := \mathrm{span}\{|i_1\rangle \otimes |i_2\rangle \otimes \ldots \otimes |i_N\rangle \in V \,|\, i_1 + i_2 + \ldots i_N = M\}$. Since the R-matrix obeys the so-called ice condition

$$\langle i, j | R^{(1,\ell)} | i', j' \rangle = 0 \quad \text{unless } i + j = i' + j' ,$$

$\hat{t}_\ell[x;q]$ maps V_M into itself.

Let $|\varphi\rangle$ be a vector in V of the form

$$|\varphi\rangle = |\varphi; \{x_j\}_{j=1}^M\rangle = C[x_1;q]C[x_2;q]\cdots C[x_M;q](|0\rangle \otimes |0\rangle \otimes \cdots \otimes |0\rangle),$$

where $C[x;q]: V \to V$ is a creation operator in the algebraic Bethe ansatz method.[5] Assume that the additional parameters $x_1, x_2, \ldots, x_M$ are mutually distinct and satisfy the so-called Bethe ansatz equation (BAE),

$$\left(\frac{q^{-1}x_k - q x_k^{-1}}{x_k - x_k^{-1}} \right)^N = \prod_{\substack{j=1 \\ j \neq k}}^{M} \frac{q^{-1}x_k x_j^{-1} - q x_k^{-1} x_j}{q x_k x_j^{-1} - q^{-1} x_k^{-1} x_j} \quad (k = 1, 2, \ldots, M). \tag{1}$$

Then it follows that $\hat{t}_\ell[x;q]|\varphi\rangle = \Lambda_\ell[x;\{x_j\};q]|\varphi\rangle$, where

$$\Lambda_\ell[x;\{x_j\};q] = \sum_{k=0}^{\ell} \left(\frac{q^k x - q^{\ell-k+1}x^{-1}}{x - q^{\ell+1}x^{-1}} \right)^N \prod_{j=1}^{M} \frac{(q^{-1}x_j^2)x^{-2} - q^{-\ell-2} - q^\ell + q^{-2}(q^{-1}x_j^2)^{-1}x^2}{q^{\ell-2k}(q^{-1}x_j^2)x^{-2} - 1 - q^{-2} + q^{2k-\ell-2}(q^{-1}x_j^2)^{-1}x^2}. \tag{2}$$

We are interested in these solutions at $q = 0$. We make use of the string hypothesis:[6]

Definition 1.1: *Let Y be the Young diagram, which represents a partition of M*

$$(\underbrace{m_1, m_1, \ldots, m_1}_{K_1}, \underbrace{m_2, m_2, \ldots, m_2}_{K_2}, \ldots, \underbrace{m_s, m_s, \ldots, m_s}_{K_s}), \tag{3}$$

where $m_1 < m_2 < \cdots < m_s$ and $K_i > 0 (i = 1, 2, \ldots, s)$ (Fig. 2). Then, the string hypothesis is the assumption that any solution $\{x_j\}_{j=1}^M$ to the BAE (1) is expressed as $\{x_{i\alpha k}\}$ of the form

$$(x_{i\alpha k}(q))^2 = q^{m_i - 2k + 2}(z_{i\alpha}^0 + O(q))$$

$$(i = 1, 2, \ldots, s;\ \alpha = 1, 2, \ldots, K_i;\ k = 1, 2, \ldots, m_i).$$

If all the eigenvectors can be obtained by the string hypothesis, the space V_M decomposes into subspaces $V_M^Y(q)$:

$$V_M = \bigoplus_Y V_M^Y(q),$$

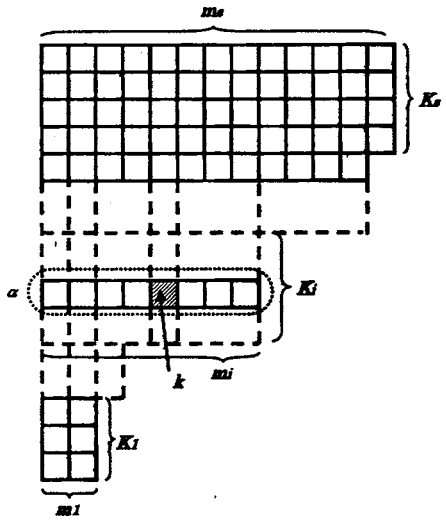

FIG. 2. The Young diagram corresponding to (3).

$$V_M^Y(q) = \mathrm{span}\{|\varphi;\{x_{i\alpha k}\}\rangle | \{x_{i\alpha k}\} \in S_Y\},$$

where S_Y is the set of all solutions to the BAE under the string hypothesis for a given Young diagram Y.

C. A statement of the main theorem

Let $V_M^Y := \lim_{q\to 0} V_M^Y(q)$. A 0,1 sequence $\boldsymbol{\alpha} \in \Omega_M$ corresponds to a monomial in V_M by the mapping $\iota: \Omega_M \to V_M$ defined by

$$\iota(\boldsymbol{\alpha}) = |\alpha_1\rangle \otimes |\alpha_2\rangle \otimes \ \ldots \ \otimes |\alpha_N\rangle,$$

and so we can identify V_M with the space spanned by vectors in $\iota(\Omega_M)$:

$$V_M = \mathrm{span}\ \iota(\Omega_M).$$

In this article, we prove the following theorem concerning this identification.

Theorem 1.1: *If the string hypothesis in Definition 1.1 is true, then*

(i) $V_M^Y \subset \mathrm{span}\iota(\Omega_M^Y)$.
Furthermore, if all the eigenvectors can obtained by the string hypothesis, the stronger condition
(ii) $V_M^Y = \mathrm{span}\ \iota(\Omega_M^Y)$
holds.

The above statements were conjectured in Ref. 2.

II. A PBBS WITH CARRIER AND THE VERTEX MODEL

In this section, we consider a class of PBBSs which obey different time evolution rules characterized by a positive integer parameter.

Let ℓ be a positive integer. A *periodic box-ball system with carrier (PBBSC) of capacity* ℓ is defined again by the set $\Omega_M(N)$ and a mapping $T_\ell: \Omega_M(N) \to \Omega_M(N)$ whose definition is given in the following.

In Sec. I we defined a sequence $\mathbf{\lambda}$ in $\bar{\mathbb{N}}$ for each state $\boldsymbol{\alpha} \in \Omega(N)$ and in this section we will define another sequence $\bar{\mathbf{\lambda}}$ in $\bar{\mathbb{N}}$. Both $\mathbf{\lambda}$ and $\bar{\mathbf{\lambda}}$ will be necessary to define the time evolution T_ℓ.

Still we are assuming that $M<N/2$. Let $\boldsymbol{\alpha}\in\Omega_M(N)$. Let $\bar{\boldsymbol{\alpha}}^{(0)}=\boldsymbol{\alpha}$, $N^{(0)}=N$, and $M^{(0)}=M$. For each $j=1,2,3,\ldots$, let $\bar{W}^{(j)}$ be the set of all pairs of positions in $\bar{\boldsymbol{\alpha}}^{(j-1)}$ where 1 follows 0; note that $\#\bar{W}^{(j)}=\#W^{(j)}=2p_j$; let $N^{(j)}=N^{(j-1)}-2p_j$ as before; let $\bar{n}^{(j)}\in\mathrm{Map}(N^{(j)},N^{(j-1)})$ be defined by

$$\{\bar{n}^{(j)}(1),\bar{n}^{(j)}(2),\ldots,\bar{n}^{(j)}(N^{(j)})\}=[N^{(j-1)}]\setminus\bar{W}^{(j)},$$

where $\bar{n}^{(j)}(1)<\bar{n}^{(j)}(2)<\cdots<\bar{n}^{(j)}(N^{(j)})$; define a subsequence $\bar{\boldsymbol{\alpha}}^{(j)}\in\Omega_{M^{(j)}}(N^{(j)})$ of $\bar{\boldsymbol{\alpha}}^{(j-1)}$ by

$$\bar{\boldsymbol{\alpha}}^{(j)}=\bar{\boldsymbol{\alpha}}^{(j-1)}\circ\bar{n}^{(j)}.$$

We again have a decomposition of $[N]$ into a disjoint union

$$[N]=\bar{W}^{(1)}\cup\left(\bigcup_{j=2}^{L}\bar{n}^{(1)}(\bar{n}^{(2)}(\cdots\bar{n}^{(j-1)}(\bar{W}^{(j)})\cdots))\right)\cup\bar{n}^{(1)}(\bar{n}^{(2)}(\cdots\bar{n}^{(L-1)}(\bar{n}^{(L)}([N^{(L)}]))\cdots)).$$

Define $\bar{\boldsymbol{\lambda}}\in\mathrm{Map}([N],\bar{\mathbb{N}})$ by

$$\bar{\lambda}_k=\begin{cases}1 & \text{for } k\in\bar{W}^{(1)}\\ j & \text{for } k\in\bar{n}^{(1)}(\bar{n}^{(2)}(\cdots\bar{n}^{(j-1)}(\bar{W}^{(j)})\cdots)) \quad (j=2,3,\ldots,L)\\ \infty & \text{otherwise.}\end{cases}$$

Then the time evolution T_ℓ is defined by

$$T_\ell(\boldsymbol{\alpha})=(\alpha'_1,\alpha'_2,\ldots,\alpha'_N),$$

where

$$\alpha'_k=\begin{cases}1 & \text{if } \alpha_k=0 \text{ and } \lambda_k\le\ell\\ 0 & \text{if } \alpha_k=1 \text{ and } \bar{\lambda}_k\le\ell\\ \alpha_k & \text{otherwise}\end{cases}$$

for $\bar{\boldsymbol{\alpha}}\in\Omega_M(N)$ and $k\in[N]$.

As before, we shall express $(\boldsymbol{\alpha},\boldsymbol{\lambda},\bar{\boldsymbol{\lambda}})=((\alpha_1,\lambda_1,\bar{\lambda}_1),(\alpha_2,\lambda_2,\bar{\lambda}_2),\ldots,(\alpha_N,\lambda_N,\bar{\lambda}_N))$ as

$$\alpha_{1\,\bar{\lambda}_1}^{\lambda_1}\alpha_{2\,\bar{\lambda}_2}^{\lambda_2}\cdots\alpha_{N\,\bar{\lambda}_N}^{\lambda_N};$$

for example,

$$0_\infty^\infty 0_4^\infty 0_3^\infty 0_2^\infty 0_1^\infty 1_1^4 1_2^3 1_3^2 1_4^1 0_3^1 0_2^2 0_1^3 1_1^3 1_2^1 0_1^1 1_1^2 1_3^1 0_\infty^1 0_\infty^2 0_1^3 1_1^1 0_\infty^1 0_\infty^4 0_\infty^\infty 0_\infty^\infty 0_\infty^\infty 0_\infty^\infty, \tag{4}$$

or more simply

$$0\ 0\ 0\ 0\ 0\ 0\ 1_1 1_2 1_3 1_4 0^1 0^2 0^3 1_1 1_2 0^1 1_1 1_3 0^1 0^2 0^3 1_1 0^1 0^4 0\ 0\ 0\ 0\ 0,$$

where only upper suffices of 0's and lower suffices of 1's are indicated.

From the definition of $\hat{t}_\ell[x;q]$ in the previous section, the action of $\hat{t}_\ell[x]:=\lim_{q\to0}\hat{t}_\ell[x;q]$ ($\ell=1,2,3,\ldots$) on a monomial $|\psi\rangle:=|i_1\rangle\otimes|i_2\rangle\otimes\cdots\otimes|i_N\rangle$ is

$$\hat{t}_\ell[x]|\psi\rangle=\sum_{\substack{i'_1,i'_2,\ldots\\ \ldots,i'_N\in\{0,1\}}}\sum_{y_0=0}^{\ell}\sum_{y_1=0}^{\ell}\cdots\sum_{y_N=0}^{\ell}(R^{i_1 i'_1}_{y_0 y_1}[x]R^{i_2 i'_2}_{y_1 y_2}[x]\cdots R^{i_N i'_N}_{y_{N-1} y_N}[x])$$

$$\times \delta_{y_0,y_N}|i_1'\rangle \otimes |i_2'\rangle \otimes \cdots \otimes |i_N'\rangle,$$

where

$$R_{yy'}^{ii'}[x] = \begin{cases} 1 & (i,y;i',y') = (1,\ell\,;1,\ell\,) \text{ or } (0,0;0,0) \\ 1/x & (i,y;i',y') = (1,k;0,k+1\ell) \text{ or } (0,k+1;1,k) \\ & (k=0,1,\ldots,\ell-1) \\ 0 & \text{otherwise.} \end{cases} \tag{5}$$

Hereafter, for simplicity, we write $\hat{t}_\ell := \hat{t}_\ell[1]$ and $R_{yy'}^{ii'} := R_{yy'}^{ii'}[1]$.

Proposition 2.1:

$$\iota(T_\ell(\boldsymbol{\alpha})) = \hat{t}_\ell(\iota(\boldsymbol{\alpha})) \quad (\boldsymbol{\alpha} \in \Omega_M).$$

The following lemma guarantees that the vector $\hat{t}_\ell(\iota(\boldsymbol{\alpha}))$ is a monomial.

Lemma 2.1: *If $|\psi\rangle \in V$ is a monomial, then $\hat{t}_\ell|\psi\rangle$ is a monomial.*

Proof. From (5), we find that, for given i and y, there is one and only one pair (i',y') which satisfies $R_{yy'}^{ii'}=1$. Hence, for a given $(N+1)-\text{tuple}(y_0;i_1,i_2,\ldots,i_N)$, there exists one and only one $2N$-tuple $(y_1,y_2,\ldots,y_N;i_1',i_2',\ldots,i_N')$ which satisfies

$$R_{y_0y_1}^{i_1i_1'} R_{y_1y_2}^{i_2i_2'} R_{y_2y_3}^{i_3i_3'} \cdots R_{y_{N-1}y_N}^{i_Ni_N'} = 1. \tag{6}$$

Thus $(y_N;i_1',i_2',\ldots,i_N')$ is determined uniquely from the condition (6). Denote the induced mapping $(y_0;i_1,i_2,\ldots,i_N) \mapsto (y_N;i_1',i_2',\ldots,i_N')$ by

$$(y_0;\boldsymbol{i}) \mapsto (\tilde{y}(y_0;\boldsymbol{i});\tilde{\boldsymbol{i}}(y_0;\boldsymbol{i})) \tag{7}$$

where $\boldsymbol{i}=(i_1,i_2,\ldots i_N)$. [Furthermore, from a symmetry property of $R: R_{yy'}^{ii'} = R_{y'y}^{i'i}$ (for any i,i',y and y'), we can show that (7) is one-to-one.] If $|\boldsymbol{i}\rangle$ denotes a monomial $|i_1\rangle \otimes |i_2\rangle \otimes \cdots \otimes |i_N\rangle$ then we have

$$\hat{t}_\ell|\boldsymbol{i}\rangle = \sum_{y_0=0}^{\ell} \delta_{y_0\tilde{y}(y_0;\boldsymbol{i})}|\tilde{\boldsymbol{i}}(y_0;\boldsymbol{i})\rangle$$

where $|\tilde{\boldsymbol{i}}(y_0;\boldsymbol{i})\rangle = |i_1'\rangle \otimes |i_2'\rangle \otimes \cdots \otimes |i_N'\rangle$. Hence it is enough to show that there is one and only one $y_0 (0 \le y_0 \le \ell\,)$ which satisfies $y_0=\tilde{y}(y_0;\boldsymbol{i})$.

Noticing the fact that the condition (5) determines $y_1,y_2,\ldots,y_N$ successively from y_0, we can easily find that there exist integers $a,b,c (0 \le a < b \le c \le \ell\,)$ such that

$$\tilde{y}(y_0;\boldsymbol{i}) = \begin{cases} a & (0 \le y_0 \le b) \\ y_0 + a - b & (b \le y_0 \le c) \\ a - b + c & (c \le y_0 \le \ell\,); \end{cases}$$

see Figs. 3 and 4. Therefore $y_0=\tilde{y}(y_0;\boldsymbol{i})$ if and only if $y_0=a$, which completes the proof. □

Corollary 2.1: *The operator $\hat{t}_\ell$ is invertible.*

Proof: In this proof, $\tilde{y}$ and $\tilde{\boldsymbol{i}}$ are as defined (7). For a given $\boldsymbol{i}$, let $y_0=a^{[\boldsymbol{i}]}$ denote the unique solution of $y_0=\tilde{y}(y_0;\boldsymbol{i})$. Then, Lemma 2.1 says that $\hat{t}_\ell(|\boldsymbol{i}\rangle) = |\tilde{\boldsymbol{i}}(a^{[\boldsymbol{i}]};\boldsymbol{i})\rangle$. Since it is sufficient to show that the mapping $\hat{t}_\ell$ is one-to-one on the set of all monomial, what is to be proved is that

$$\boldsymbol{i} \neq \boldsymbol{j} \text{ means } \tilde{\boldsymbol{i}}(a^{[\boldsymbol{i}]};\boldsymbol{i}) \neq \tilde{\boldsymbol{i}}(a^{[\boldsymbol{j}]};\boldsymbol{j}).$$

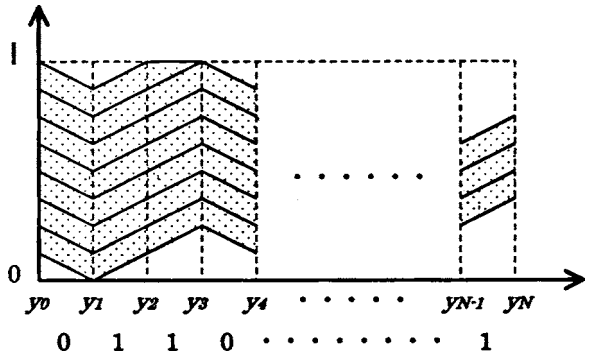

FIG. 3. Successive maps $y_i \mapsto y_{i+1} (i=0,1,2,\ldots,N-1)$.

So suppose that $\boldsymbol{i} \neq \boldsymbol{j}$. Since the mapping (7) is one-to-one, $(a^{[i]}; \tilde{\boldsymbol{i}}(a^{[i]}; \boldsymbol{i})) \neq (a^{[j]}; \tilde{\boldsymbol{i}}(a^{[j]}; \boldsymbol{j}))$. Hence, if $a^{[i]}=a^{[j]}$ then $\tilde{\boldsymbol{i}}(a^{[i]}; \boldsymbol{i}) \neq \tilde{\boldsymbol{i}}(a^{[j]}; \boldsymbol{j})$ follows. Now suppose that $a^{[i]} \neq a^{[j]}$ and assume that $\tilde{\boldsymbol{i}}(a^{[i]}; \boldsymbol{i}) \neq \tilde{\boldsymbol{i}}(a^{[j]}; \boldsymbol{j})$. Since R is symmetric ($R^{ii'}_{yy'} = R^{i'i}_{y'y}$), the mapping (7) gives

$$(a^{[i]}; \tilde{\boldsymbol{i}}(a^{[i]}; \boldsymbol{i})) \mapsto (a^{[i]}; \boldsymbol{i}) \quad \text{and} \quad (a^{[j]}; \tilde{\boldsymbol{i}}(a^{[i]}; \boldsymbol{i})) \mapsto (a^{[j]}; \boldsymbol{j});$$

then, as in the proof of Lemma 2.1, $a^{[i]}$ and $a^{[j]}$ must be equal, contrary to our assumption. □

Proof of Propostion 2.1: Let $\iota(\boldsymbol{\alpha}) = |a_1\rangle \otimes |\alpha_2\rangle \otimes \cdots \otimes |\alpha_N\rangle$, and $\hat{t}_\ell(\iota(\boldsymbol{\alpha})) = |\alpha'_1\rangle \otimes |\alpha'_2\rangle \otimes \cdots \otimes |\alpha'_N\rangle$. From Lemma 2.1, there exists one and only one y_0 $(N+1)$-tuple $(y_0, y_1, \ldots, y_{N-1}, y_N = y_0)$ which satisfies (6) for $\iota(\boldsymbol{\alpha})$ and $\hat{t}_\ell(\iota(\boldsymbol{\alpha}))$.

When $\alpha_n = 0$, from (5), it holds that

$$\alpha'_n = \begin{cases} 0 & (y_{n-1} = 0) \\ 1 & (y_{n-1} \geq 1). \end{cases}$$

Suppose that $\lambda_n = j$, that is, ${\alpha_n}^{\lambda_n} = 0^j$. From the definition of $\boldsymbol{\lambda}$, there is a subsequence

$${\alpha_m}^{\lambda m} {\alpha_{m+1}}^{\lambda m+1} \cdots {\alpha_n}^{\lambda n} (\subset {\alpha_1}^{\lambda 1} {\alpha_2}^{\lambda 2} \cdots {\alpha_N}^{\lambda N})$$

where ${\alpha_m}^{\lambda m} = 1^j$ and $1 \leq \lambda_{m+1}, \lambda_{m+2}, \ldots, \lambda_{n-1} \leq j-1$. Among the subsequence, there exists at least one pair ${\alpha_s}^{\lambda s} {\alpha_{s+1}}^{\lambda s+1}$ which satisfies ${\alpha_s}^{\lambda s} {\alpha_{s+1}}^{\lambda s+1} = 1^1 0^1$ and

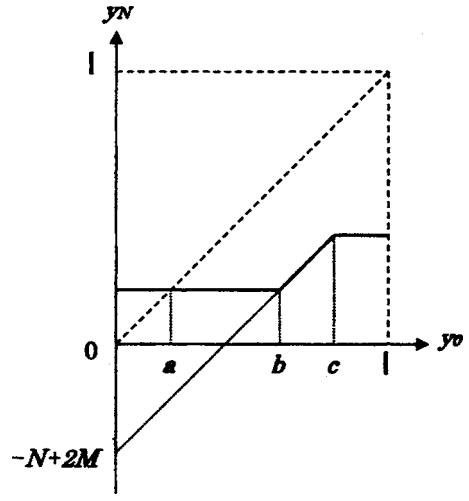

FIG. 4. A graph of $y_0 \mapsto y_N$.

$$\begin{cases} 1^k \in \{\alpha_{m+1}{}^{\lambda m+1}, \alpha_{m+2}{}^{\lambda m+2}, \ldots, \alpha_{s-1}{}^{\lambda s-1}\} \\ 0^k \in \{\alpha_{s+2}{}^{\lambda s+2}, \alpha_{s+3}{}^{\lambda s+3}, \ldots, \alpha_{n-1}{}^{\lambda n-1}\} \end{cases} \quad (k = 2,3,\ldots,j-1).$$

Note that the number of 1's in $\alpha_m\alpha_{m+1}\ldots\alpha_s$ is larger than that of 0's by j. Similarly the number of 0's in $\alpha_{s+1}\alpha_{s+2}\ldots\alpha_n$ is larger than that of 1's by j. Hence, using the action of R matrix, it holds that

$$\begin{aligned} &y_s = \ell \quad (j > \ell) \\ &j \le y_s \le \ell \quad (j \le \ell), \end{aligned} \tag{8}$$

and

$$y_{n-1} = \max[y_s - (j-1), 0]. \tag{9}$$

From (8) and (9), we find that

$$\begin{aligned} &y_{n-1} = 0 \qquad (j > \ell), \\ &y_{n-1} \ge 1 \qquad (j \le \ell), \end{aligned}$$

which implies

$$\alpha_n' = \begin{cases} 0 & (j > \ell) \\ 1 & (j \le \ell). \end{cases}$$

Furthermore, for 0^∞, it is immediately seen that $y_{n-1}=0$. Therefore the action of $\hat{t}_\ell$ is equivalent to the time evolution rule of T_ℓ for 0's.

The proof for 1's is carried out in a similar manner. □

Hereafter we fix a partition $\boldsymbol{p}=(p_1,p_2,p_3,\ldots)$ of M, that is, an integer sequence which satisfies $p_1,p_2,p_3,\ldots$ which satisfies $p_1 \ge p_2 \ge p_3 \ge \cdots \ge 0$ and $\Sigma_{j\ge 1} p_j = M$. Let Y be the Young diagram whose conjugate corresponds to the partition $\boldsymbol{p}$. Then we have the following corollary.

Corollary 2.2

$$\boldsymbol{\alpha} \in \Omega_M^Y \Leftrightarrow \hat{t}_\ell([\iota(\boldsymbol{\alpha})]) = x^{-2\Sigma_{i=1}^{\ell} p_i} \hat{t}_\ell(\iota(\boldsymbol{\alpha})) \quad (\ell = 1,2,3,\ldots).$$

Proof: In the proof of Lemma 2.1, we see

$$R^{i_1 i_1'}_{a y_1}[x] R^{i_2 i_2'}_{y_1 y_2}[x] R^{i_3 i_3'}_{y_2 y_3}[x] \cdots R^{i_N i_N'}_{y_{N-1} a}[x] = x^{-K(a)}$$

with a non-negative integer $K(a)$. Hence we have

$$\hat{t}_\ell[x](\iota(\boldsymbol{\alpha})) = x^{-K(a)} \hat{t}_\ell(\iota(\boldsymbol{\alpha})).$$

From (5) and Propostion 2.1, $K(a)$ is equal to the number of 0^j's and 1_j's $(1 \le j \le \ell)$.

Therefore,

$$K(a) = 2\sum_{i=1}^{\ell} p_i.$$

On the other hand, when $\boldsymbol{\alpha} \notin \Omega_M^Y$, clearly there exist ℓ_0 such that

$$\hat{t}_{\ell_0}[x](\iota(\boldsymbol{\alpha})) \ne x^{-2\Sigma_{i=1}^{\ell_0} p_i} \hat{t}_{\ell_0}(\iota(\boldsymbol{\alpha})),$$

which completes the proof. □

Next we show that the vector space spanned by the vectors in $\iota(\Omega_M^Y)$ is invariant under the action $\hat{t}_\ell$. For a monomial $|\psi\rangle \in \iota(\Omega_M^Y)$, we define

$$\pi_\ell(|\psi\rangle) := -2\sum_{i=1}^{\ell} p_i \quad (\ell = 1,2,3,\dots).$$

Lemma 2.2: *For an arbitrary monomial* $|\psi\rangle$ *and* $\ell=1,2,3,\dots,$

(a) $\pi_\ell(|\psi\rangle)=\pi_\ell(\hat{t}_1|\psi\rangle)$
and
(b) $\pi_1(|\psi\rangle)=\pi_1(\hat{t}_\ell|\psi\rangle)$.

Proof:

(a) For a state $\boldsymbol{\alpha}=(\alpha_1,\alpha_2,\alpha_3\dots,\alpha_N)\in\Omega_M$, it holds that

$$T_1(\boldsymbol{\alpha})=(\alpha_N,\alpha_1,\alpha_2,\dots,\alpha_{N-1}),$$

and each conserved quantity does not change. Hence, from Proposition 2.1, we have $\pi_\ell(|\psi\rangle)=\pi_\ell(\hat{t}_1|\psi\rangle)$.

(b) From Corollary 2.2,

$$\hat{t}_1[x](\hat{t}_\ell[x]|\psi\rangle)=x^{\pi_\ell(|\psi\rangle)}\hat{t}_1[x](\hat{t}_\ell|\psi\rangle)=x^{\pi_\ell(|\psi\rangle)+\pi_1(\hat{t}_\ell|\psi\rangle)}\hat{t}_1\hat{t}_\ell|\psi\rangle\,,$$

$$\hat{t}_\ell[x](\hat{t}_1[x]|\psi\rangle)=x^{\pi_1(|\psi\rangle)}\hat{t}_\ell[x](\hat{t}_1|\psi\rangle)=x^{\pi_1(|\psi\rangle)+\pi_\ell(\hat{t}_1|\psi\rangle)}\hat{t}_\ell\hat{t}_1|\psi\rangle\,.$$

Since transfer matrices are commutative $\hat{t}_1[x]\hat{t}_\ell[x]=\hat{t}_\ell[x]\hat{t}_1[x]$, we obtain

$$\pi_\ell(|\psi\rangle)+\pi_1(\hat{t}_\ell|\psi\rangle)=\pi_1(|\psi\rangle)+\pi_\ell(\hat{t}_1|\psi\rangle).$$

Thus, from (a), $\pi_1(\hat{t}_\ell|\psi\rangle)=\pi_1(|\psi\rangle)$. □

For $\boldsymbol{\alpha}=(\alpha_1,\alpha_2,\dots,\alpha_N)\in\Omega_M$ and $\boldsymbol{\beta}=(\beta_1,\beta_2,\dots,\beta_N)\in\Omega_M$, we write $\boldsymbol{\alpha}\simeq\boldsymbol{\beta}$ when $\boldsymbol{\alpha}$ coincides with $\boldsymbol{\beta}$ up to shift, that is, $^{\exists}k\in\mathbb{Z},(\beta_1,\beta_2,\dots,\beta_N)=(\alpha_k,\alpha_{k+1},\dots,\alpha_N,\alpha_1,\alpha_2\dots,\alpha_{k-1})$. We also define $\hat{E}_{10}(\boldsymbol{\alpha})$ as the reduced 0,1 sequence with length $N-2p_1$ which is obtained by eliminating 1_1's and 0^1's from $(\boldsymbol{\alpha},\boldsymbol{\lambda},\bar{\boldsymbol{\lambda}})$.

Proposition 2.2: *For a state* $\boldsymbol{\alpha}\in\Omega_M$,

$$T_{\ell-1}\circ\hat{E}_{10}(\boldsymbol{\alpha})\simeq\hat{E}_{10}\circ T_\ell(\boldsymbol{\alpha})\quad(\ell=2,3,4,\dots).$$

Proof: A state consists of alternating sequences of consecutive 1's and of consecutive 0's. We call these sequences *domains of* 1's and *domains of* 0's. Note that the action of $\hat{E}_{10}$ is equivalent to removing one element from each domain.

By the definition of $T_{\ell-1}$ and $\hat{E}_{10}$, the operator $T_{\ell-1}\circ\hat{E}_{10}$ acts on a state as follows: Eliminate 1_1's and 0^1's, and replace $1_2,1_3,1_4,\dots$ and $0^2,0^3,0^4,\dots$ with $1_1,1_2,1_3,\dots$ and $0^1,0^2,0^3,\dots$ respectively; then replace 1_i and 0^i $(i=1,2,\dots,\ell-1)$ with 0 and 1, respectively. For example, in case of $\ell=2$,

$$0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 1_1 1_2 1_3 1_4 0^1 0^2 0^3 1_1 1_2 0^1 1_1 1_3 0^1 0^2 0^3 1_1 0^1 0^4\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0$$

$$\overset{\hat{E}_{10}}{\mapsto}\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 1_1 1_2 1_3 0^1 0^2 1_1 1_2 0^1 0^2 0^3 0\ \ 0\ \ 0\ \ 0\ \ 0$$

$$\overset{T_{\ell-1}}{\mapsto}\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 1\ \ 1\ \ 1\ \ 0\ \ 0\ \ 1\ \ 1\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0.$$

It is equivalent to the action: Replace 1_i and 0^i $(i=1,2,\dots,\ell)$ with 0 and 1, respectively, and eliminate 0's and 1's corresponding to 1_1 and 0^1. For example, in case of $\ell=2$,

$$0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 1_1 1_2 1_3 1_4 0^1 0^2 0^3 1_1 1_2 0^1 1_1 1_3 0^1 0^2 0^3 1_1 0^1 0^4 0\ \ 0\ \ 0\ \ 0\ \ 0$$

$$\overset{\text{Replacement}}{\mapsto}\ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 1\ \ 1\ \ 1\ \ 1\ \ 0\ \ 0\ \ 0\ \ 1\ \ 0\ \ 1\ \ 1\ \ 1\ \ 0\ \ 0\ \ 1\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0$$

$$\overset{\text{Elimination}}{\mapsto}\ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 1\ \ 1\ \ 1\ \ 0\ \ 0\ \ 1\ \ 1\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0\ \ 0.$$

In this process, we eliminate p_1 0's and the same number of 1's which are arranged alternately in the sequence. Since from Lemma 2.2(b), the number of each domain does not change in the time evolution, we eliminate an element in each domain. Thus this action is equivalent to the action of $\hat{E}_{10} \circ T_\ell$. Therefore, we find

$$T_{\ell-1} \circ \hat{E}_{10}(\boldsymbol{\alpha}) \simeq \hat{E}_{10} \circ T_\ell(\boldsymbol{\alpha}).$$

Theorem 2.1: If $\alpha \in \Omega_M^Y$, *then* $T_\ell(\boldsymbol{\alpha}) \in \Omega_M^Y (\ell = 1,2,3,\ldots)$.

Proof: By the definition of $\hat{E}_{10}$, we have

$$\pi_{\ell-1}(\iota(\hat{E}_{10}(\boldsymbol{\alpha}))) = \pi_\ell(\iota(\boldsymbol{\alpha})) - \pi_1(\iota(\boldsymbol{\alpha})). \tag{10}$$

From Proposition II.1 and Lemma II.2(b),

$$\pi_1(\iota(\boldsymbol{\alpha})) = \pi_1(\iota(T_\ell(\boldsymbol{\alpha}))). \tag{11}$$

Hence, from (10), (11) and Proposition 2.2, it follows that

$$\begin{aligned}\pi_2(\iota(\boldsymbol{\alpha})) &= \pi_1(\iota(\hat{E}_{10}(\boldsymbol{\alpha}))) + \pi_1(\iota(\boldsymbol{\alpha})) \\ &= \pi_1(\iota(T_{\ell-1} \circ \hat{E}_{10}(\boldsymbol{\alpha}))) + \pi_1(\iota(T_\ell(\boldsymbol{\alpha}))) \\ &= \pi_1(\iota(\hat{E}_{10} \circ T_\ell(\boldsymbol{\alpha}))) + \pi_1(\iota(T_\ell(\boldsymbol{\alpha}))) \\ &= \pi_2(\iota(T_\ell(\boldsymbol{\alpha}))).\end{aligned}$$

Repeating a similar procedure for $\pi_3(\iota(\boldsymbol{\alpha})), \pi_4(\iota(\boldsymbol{\alpha})), \pi_5(\iota(\boldsymbol{\alpha})), \ldots$, we obtain

$$\pi_m(\iota(\boldsymbol{\alpha})) = \pi_m(\iota(T_\ell(\boldsymbol{\alpha}))) \quad (m = 1,2,3,\ldots).$$

Therefore the conserved quantities of $T_\ell(\boldsymbol{\alpha})$ are $p_1, p_2, p_3, \ldots$.

Corollary 2.3: *If* $|\varphi\rangle \in$ span $\iota(\Omega_M^Y)$, *then* $\hat{t}_\ell |\varphi\rangle \in$ span $\iota(\Omega_M^Y) (\ell = 1,2,3,\ldots)$.

Proof: This is a direct consequence of Proposition 2.1 and Theorem 2.1. □

III. PROOF OF THEOREM 1.1

In this section, we prove Theorem 1.1. we fix a Young diagram Y with M squares as in the previous section. The corresponding partition of M is given in Definition 1.1. We also denote by $p_j = (j = 1,2,3,\ldots)$ the jth column length of Y. Note that the following relation holds:

$$\sum_{i=1}^{s} \min[m_i, \ell\,] K_i = \sum_{i=1}^{\ell} p_i \quad (\ell = 1,2,3,\ldots). \tag{12}$$

In order to consider the eigenvalues $\Lambda_\ell[x;\{x_j\};q]$ of $\hat{t}_\ell[x]$ in (2), we put

$$\tilde{\Lambda}_\ell^{\langle k\rangle}[x;\{z_{i\alpha}^0\};q] := (q^k x^2 - q^{\ell-k+1})^N x^{-2N} \prod_{i=1}^{s} \prod_{\alpha=1}^{K_i} \prod_{h=1}^{m_i} Q_\ell^{\langle k\rangle}[x, z_{i\alpha}^0, r_{ih}; q]$$

where $r_{ih} := m_i - 2h + 1$ and

$$Q_\ell^{\langle k\rangle}[x,z,r;q] := \frac{q^{\ell+2r+2z^2} - q^r z x^2 + q^\ell x^4}{q^{2\ell-2k+2r+2z^2} - q^{\ell+r} z x^2 + q^{2k} x^4}.$$

By direct calculation, we see that

$$\Lambda_\ell[x] := \lim_{q\to 0} \Lambda_\ell[x;\{x_j\};q] = \lim_{q\to 0} \sum_{k=0}^{\ell} \tilde{\Lambda}_\ell^{\langle k\rangle}[x;\{z_{i\alpha}^0\};q].$$

When a function $f(q)$ is expressed as $f(q) = q^a(f_0 + f_1 q + f_2 q^2 + \cdots)(f_0 \neq 0)$, we write $\mathrm{ord}_q(f) = a$ and $f \sim q^a f_0$.

Lemma 3.1: *For* $k \neq 0$,

$$\mathrm{ord}_q(\tilde{\Lambda}_\ell^{\langle k\rangle}[x;\{z_{i\alpha}^0\};q]) \geq N - 2M.$$

Proof: For each $k (k = 1, 2, \ldots, \ell)$, we put

$$\eta_\ell^{\langle k\rangle}(r) := \mathrm{ord}_q(Q_\ell^{\langle k\rangle}[x, z_{i\alpha}^0; r; q]).$$

Then we have

$$\eta_\ell^{\langle k\rangle}(r) = \begin{cases} \ell - 2k & (\ell \leq r) \\ r - 2k & (2k - \ell \leq r \leq \ell) \\ -\ell & (2k - \ell - 2 \leq r \leq 2k - \ell) \\ -r - 2(\ell - k) - 2 & (-\ell - 2 \leq r \leq 2k - \ell - 2) \\ 2k - \ell & (r \leq -\ell - 2). \end{cases}$$

Since

$$\mathrm{ord}_q((q^k x^2 - q^{\ell-k+1})^N) = N \min[k, \ell - k + 1],$$
$$q^{N \min[k,\ell-k+1]} = q^{(N-2M)\min[k,\ell-k+1]} \cdot q^{2M \min[k,\ell-k+1]}$$

and $M = \sum_{i=1}^{s} m_i K_i$, we get

$$\mathrm{ord}_q(\tilde{\Lambda}_\ell^{\langle k\rangle}[x;\{z_{i\alpha}^0\};q]) = (N - 2M)\min[k, \ell - k + 1] + \sum_{i=1}^{s} \sum_{\alpha=1}^{Ki} \sum_{h=1}^{m_i} (\eta_\ell^{\langle k\rangle}(r_{ih}) + 2 \min[k, \ell - k + 1]).$$

Furthermore we obtain the following inequality immediately:

$$\eta_\ell^{\langle k\rangle}(r) + \eta_\ell^{\langle k\rangle}(-r) + 4 \min[k, \ell - k + 1] \geq 0 \quad (r \in \mathbb{Z}_{\geq 0}).$$

Therefore, for each $k (k = 1, 2, \ldots, \ell)$, we have

$$\mathrm{ord}_q(\tilde{\Lambda}_\ell^{\langle k\rangle}[x;\{z_{i\alpha}^0\};q]) \geq (N - 2M)\min[k, \ell - k + 1]$$
$$\geq N - 2M.$$

Proposition 3.1: *For* $\ell = 1, 2, 3, \ldots,$

$$\Lambda_\ell[x] = x^{-2\Sigma_{k=1}^{s}\min[m_k,\ell]K_k}\prod_{i=1}^{s}\prod_{\alpha=1}^{K_i}(-z_{i\alpha}^0)^{\min[m_i,\ell]}.$$

Proof: From Lemma 3.1, terms $\tilde{\Lambda}_\ell^{\langle k\rangle}$ for $k\geq 1$ would not contribute to $\Lambda_\ell[x]$ since we have assumed $N-2M>0$. For $Q_\ell^{\langle 0\rangle}[x,z_{i\alpha}^0,r;q]$, we have

$$Q_\ell^{\langle 0\rangle}[x,z_{i\alpha}^0,r;q]\sim\begin{cases} q^\ell & (\ell<r)\\ q^\ell(-z_{i\alpha}^0x^{-2}+1) & (r=\ell)\\ -q^r z_{i\alpha}^0x^{-2} & (-\ell<r<\ell)\\ \dfrac{-q^{-\ell}z_{i\alpha}^0}{-z_{i\alpha}^0+x^2} & (r=-\ell)\\ q^{-\ell} & (r<-\ell). \end{cases}$$

(i) If $m_i\equiv \ell \bmod 2$, then

$$Q_\ell^{\langle 0\rangle}[x,z_{i\alpha}^0,r;q]\sim\begin{cases} q^\ell & (r=\ell+1,\ell+3,\ell+5,\dots)\\ -q^r z_{i\alpha}^0x^{-2} & (r=-\ell+1,-\ell+3,\dots,\ell-1)\\ -q^{-\ell} & (r=-\ell-1,-\ell-3,-\ell-5,\dots). \end{cases}$$

(ii) If $m_i\not\equiv \ell \bmod 2$, then

$$Q_\ell^{\langle 0\rangle}[x,z_{i\alpha}^0,r;q]\sim\begin{cases} q^\ell & (r=\ell+2,\ell+4,\ell+6,\dots)\\ q^\ell(-z_{i\alpha}^0x^{-2}+1) & (r=\ell)\\ -q^r z_{i\alpha}^0x^{-2} & (r=-\ell+2,-\ell+4,\dots,\ell-2)\\ \dfrac{-q^{-\ell}z_{i\alpha}^0}{-z_{i\alpha}^0+x^2} & (r=-\ell)\\ q^{-\ell} & (r=-\ell-2,-\ell-4,-\ell-6,\dots). \end{cases}$$

Hence we obtain

$$\lim_{q\to 0}\prod_{h=1}^{m_i}Q_\ell^{\langle 0\rangle}[x,z_{i\alpha}^0,r_{ih};q] = x^{-2\,\min[m_i,\ell]}(-z_{i\alpha}^0)^{\min[m_i,\ell]},$$

which completes the proof.

Proof of Theorem 1.1(i): For an eigenvector $|\varphi\rangle\in V_M^Y$ of $\hat{t}_\ell[x]$ $(\ell=1,2,3,\dots)$, from Proposition 3.1 and (12), we have

$$\begin{aligned}\hat{t}_\ell[x]|\varphi\rangle &= x^{-2\Sigma_{k=1}^{s}\min[m_k,\ell]K_k}\prod_{i=1}^{s}\prod_{\alpha=1}^{K_i}(-z_{i\alpha}^0)^{\min[m_i,\ell]}|\varphi\rangle\\ &= x^{-2\Sigma_{k=1}^{s}\min[m_k,\ell]K_k}\hat{t}_\ell|\varphi\rangle\\ &= x^{-2\Sigma_{k=1}^{\ell}pk}\hat{t}_\ell|\varphi\rangle. \end{aligned}\tag{13}$$

On the other hand, $|\varphi\rangle$ can be expanded as

$$|\varphi\rangle=\sum_j C_j|\psi_j\rangle,$$

where $|\psi_j\rangle$ are monomials in V_M^Y and $C_j(\neq 0)$ are coefficients. Let $|\psi_j\rangle=\iota(\boldsymbol{\alpha}_j)(\boldsymbol{\alpha}_j\in\Omega_M)$.

Then, from Corollary 2.2,

$$\hat{t}_\ell[x]|\varphi\rangle = \hat{t}_\ell[x]\sum_j C_j|\psi_j\rangle = \sum_j C_j\hat{t}_\ell[x]|\psi_j\rangle$$
$$= \sum_j C_j\hat{t}_\ell[x](\iota(\boldsymbol{\alpha}_j)) = \sum_j C_j x^{-2\Sigma_{k=1}^{\ell} p_k^{\langle j\rangle}}\hat{t}_j(\iota(\boldsymbol{\alpha}_j)) = \sum_j C_j x^{2\Sigma_{k=1}^{\ell} p_k^{\langle j\rangle}}\hat{t}_\ell|\psi_j\rangle\,, \tag{14}$$

where $p_k^{\langle j\rangle}(k=1,2,\ldots,\ell)$ are conserved quantities of $\boldsymbol{\alpha}_j$. Since $|\psi_j\rangle$'s are linearly independent and $\hat{t}_\ell$ is invertible on V_M (Corollary 2.1), the vectors $\hat{t}_\ell|\psi_j\rangle$ are also linearly independent. Hence, from (13) and (14), we have

$$x^{-2\Sigma_{k=1}^{\ell} p_k^{\langle j\rangle}}\hat{t}_\ell|\psi_j\rangle = x^{-2\Sigma_{k=1}^{\ell} pk}\hat{t}_\ell|\psi_j\rangle\,,$$

that is,

$$\hat{t}_\ell[x]|\psi_j\rangle = x^{-2\Sigma_{k=1}^{\ell} pk}\hat{t}_\ell|\psi_j\rangle\,.$$

Thus, from Corollary 2.2, it follows that $|\psi_j\rangle \in \iota(\Omega_M^Y)$ for each j and $|\varphi\rangle \in \mathrm{span}\iota(\Omega_M^Y)$.

Therefore, if $|\psi\rangle$ is a vector in V_M^Y then it is also a vector in span $\iota(\Omega_M^Y)$. □

Proof of Theorem 1.1(ii): The completeness implies that

$$\bigoplus_Y V_M^Y = V_M.$$

On the other hand

$$\bigoplus_Y \mathrm{span}\iota(\Omega_M^Y) = V_M.$$

Therefore, it must be that

$$V_M^Y = \mathrm{span}\iota(\Omega_M^Y).$$

□

IV. CONCLUDING REMARKS

In this paper, we have showed an important relationship between the string hypothesis of BAE and the conserved quantities of PBBS (Theorem 1.1). In the limit that $q\to 0$, for a given Young diagram one may obtain eigenvectors from string hypothesis in terms of monomials. These monomials correspond exactly with the states of PBBS whose conserved quantities are given by exactly the same Young diagram. Although our result elucidates an aspect of the string solutions, it does not justify the string hypothesis or prove the completeness of Bethe vectors. However, we hope that our approach with PBBS may give some pieces of information about these problems.

APPENDIX: EQUIVALENT DEFINITION OF PBBS

In this appendix, we give the equivalent definition of PBBS in previous work.[2,3] Consider a one-dimensional array of boxes each with a capacity of one ball. A periodic boundary condition is imposed by assuming that the last box is adjacent to the first one. We denote the number of boxes by N and the number of balls by M and we assume $M<N/2$. An arrangement of M balls in N boxes is called a state of the PBBS.

Denoting a vacant box by 0 and a filled box by 1, a state of the PBBS is represented as a 0,1 sequence of length N. For example, in a case of $N=8$ and $M=3$,

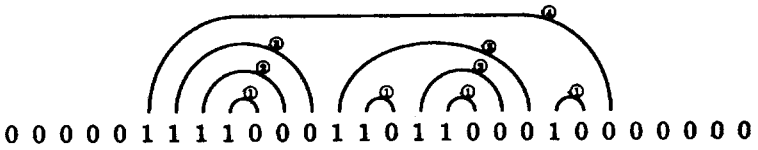

FIG. 5. A state of PBBS with $j^{\cap}$ arc lines.

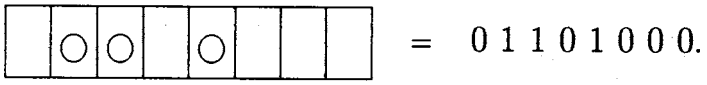

If we think of this state at time t, the mapping T described in Sec. I A corresponds to incrementing time t to $t+1$. The time evolution rule from time step t to $t+1$ is also described as follows:

1. For a given state, connect all 10 pairs in the sequence with arc lines. We call them "$1^{\cap}$ arc lines."
2. Neglecting the 10 pairs which are connected in the first step, connect all the remaining 10's with arc lines. We call them "$2^{\cap}$ arc lines."
3. Repeat the above procedure until all 1's are connected to 0's with arc lines.
4. Exchange all the 1's and 0's which are connected with arc lines.

If we denote by $p_j(t)$ the number of $j^{\cap}$arc lines, we obtain a nonincreasing sequence of integers, $p_j(t)(j=1,2,3,\ldots)$. Then, this sequence is conserved in time, that is,

$$p_j(t) = p_j(t+1) \equiv p_j \quad (j = 1,2,3, \ldots).$$

For example, for the state considered in Sec. I A

$$0\ 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1\ 0\ 0\ 0\ 1\ 1\ 0\ 1\ 1\ 0\ 0\ 0\ 1\ 0\ 0\ 0\ 0\ 0\ 0\ 0,$$

we draw arc lines as shown in Fig. 5 and evolve it by one time step according to the above procedure; then we obtain a new state

$$0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 1\ 1\ 1\ 0\ 0\ 1\ 0\ 0\ 1\ 1\ 1\ 0\ 1\ 1\ 0\ 0\ 0\ 0\ 0.$$

In this case, the conserved quantities are $p_1=4$, $p_2=2$, $p_3=2$, $p_4=1$, $p_j=0$ $(j=5,6,7,\ldots)$. These results are in agreement with those obtained by the other definition.

Next, we consider a class of PBBSs which obey different time evolution rules characterized by a positive integer parameter. Let ℓ be a positive integer.

1. For a given state, draw the arc lines in the same way as in the original time evolution rule of the PBBS.
2. For 01 pairs, we also draw arc lines by a similar procedure to that for 10 pairs. We call the arc lines drawn at jth step by "$j_{\cup}$ arc lines."
3. Replace with 0's all the 1's connected by $i_{\cup}$ arc lines $(i=1,2,\ldots,\ell)$ and replace with 1's all the 0's connected by $j^{\cap}$arc lines $(j=1,2,\ldots,\ell)$.

For example, for $\ell=2$, the state given in Fig. 6 evolves into

$$0\ 0\ 0\ 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1\ 0\ 0\ 0\ 1\ 0\ 1\ 1\ 1\ 0\ 0\ 1\ 0\ 0\ 0\ 0\ 0\ 0$$

at the next time step. When the system size is infinite and the number of 1's is finite, this rule coincides with the rule of a BBS with carrier of capacity ℓ introduced in Ref. 7. So we call the PBBS with the above rule a PBBS with carrier (PBBSC).

To see the state at the next time step, it is convenient to express a state as a 0,1 sequence with subscripts, where 1 and 0 connected by $i_{\cup}$ and $j^{\cap}$ arc lines are replaced 1_i and 0^j, respectively. For example, the state in Fig. 6 is expressed as

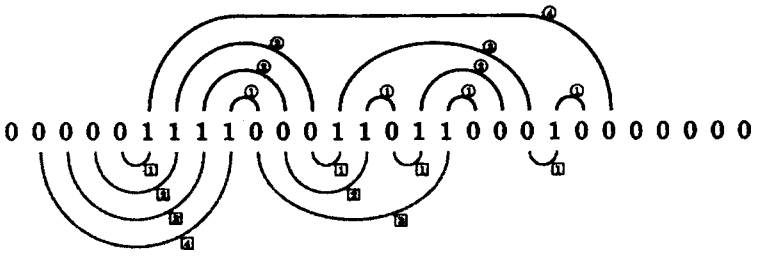

FIG. 6. A configuration with $j^{\cap}$ and $i^{\cup}$ arc lines.

$$0\ 0\ 0\ 0\ 0\ 1_1\ 1_2\ 1_3\ 1_4\ 0^1\ 0^2\ 0^3\ 1_1\ 1_2\ 0^1\ 1_1\ 1_3\ 0^1\ 0^2\ 0^3\ 1_1\ 0^1\ 0^4\ 0\ 0\ 0\ 0\ 0,$$

which coincides with (4). The time evolution rule of PBBSC of capacity ℓ is given as follows: replace 1_i and 0^i $(i=1,2,\ldots,\ell)$ with 0 and 1, respectively.

(Received 24 February 2006; accepted 24 March 2006; published online 24 May 2006)

Our starting point is a class of braid matrices, presented in a previous paper, constructed on a basis of a nested sequence of projectors. Statistical models associated to such $N^2\times N^2$ matrices for odd N are studied here. Presence of $\frac{1}{2}(N+3)\times(N-1)$ free parameters is the crucial feature of our models, setting them apart from other well-known ones. There are N possible states at each site. The trace of the transfer matrix is shown to depend on $\frac{1}{2}(N-1)$ parameters. For order r, N eigenvalues constitute the trace and the remaining (N^r-N) eigenvalues involving the full range of parameters come in zero-sum multiplets formed by the rth roots of unity, or lower dimensional multiplets corresponding to factors of the order r when r is not a prime number. The modulus of any eigenvalue is of the form $e^{\mu\theta}$, where μ is a linear combination of the free parameters, θ being the spectral parameter. For r a prime number an amusing relation of the number of multiplets with a theorem of Fermat is pointed out. Chain Hamiltonians and potentials corresponding to factorizable S-matrices are constructed starting from our braid matrices. Perspectives are discussed. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2197690]

I. INTRODUCTION

The most salient feature of the class of braid matrices presented in Ref. 1, setting it apart from other known examples, is the number of free parameters. This class was obtained for $N^2\times N^2$ braid matrices for *odd*

$$N=(2p-1)\quad (p=1,2,\ldots). \tag{1.1}$$

Such matrices, depending on a spectral parameter θ and satisfying the braid equation

$$\hat{R}_{12}(\theta-\theta')\hat{R}_{23}(\theta)\hat{R}_{12}(\theta')=\hat{R}_{23}(\theta')\hat{R}_{12}(\theta)\hat{R}_{23}(\theta-\theta') \tag{1.2}$$

have $\frac{1}{2}(N+3)(N-1)$ free parameters when the overall normalization is fixed. Thus for $N=3,5,7,\ldots$, the respective number of parameters are $6,16,30,\ldots$. These parameters appear in the coefficients of the N^2 projectors (the "*nested sequence*" defined in Ref. 1) providing the basis of $\hat{R}(\theta)$.

[a)]This work was carried out at the Centre de Physique Théorique de l'Ecole Polytechnique, Palaiseau.
[b)]Electronic mail: boucif@cpht.polytechnique.fr and boucif@yahoo.fr
[c)]Electronic mail: chakra@cpht.polytechnique.fr

The projectors are defined as follows. Let (ij) be the $N\times N$ matrix with a single nonzero element 1 on row i and column j. Then N^2 projectors are defined, with $\epsilon=\pm$ and $\bar{i}=N-i+1$, as

$$P_{pp}=(pp)\otimes(pp),$$

$$2P_{pi(\epsilon)}=(pp)\otimes[(ii)+(\bar{i}\bar{i})+\epsilon((i\bar{i})+(\bar{i}i))],$$

$$2P_{ip(\epsilon)}=[(ii)+(\bar{i}\bar{i})+\epsilon((i\bar{i})+(\bar{i}i))]\otimes(pp), \tag{1.3}$$

$$2P_{ij(\epsilon)}=(ii)\otimes(jj)+(\bar{i}\bar{i})\otimes(\bar{j}\bar{j})+\epsilon[(i\bar{i})\otimes(j\bar{j})+(\bar{i}i)\otimes(\bar{j}j)],$$

$$2P_{i\bar{j}(\epsilon)}=(ii)\otimes(\bar{j}\bar{j})+(\bar{i}\bar{i})\otimes(jj)+\epsilon[(i\bar{i})\otimes(\bar{j}j)+(\bar{i}i)\otimes(j\bar{j})],$$

where, from (1.1),

$$i=1,2,\ldots,p-1,\quad \bar{i}=N-i+1=2p-1,2p-2\ldots,p+1,\quad p=\tfrac{1}{2}(N+1). \tag{1.4}$$

The projectors satisfy [with α, β standing for triplets (i,j,ϵ)]

$$P_\alpha P_\beta=\delta_{\alpha\beta}P_\alpha,\quad \sum_\alpha P_\alpha^2=I_{N^2\times N^2}. \tag{1.5}$$

Their total number is

$$1+4(p-1)+4(p-1)^2=(2p-1)^2=N^2. \tag{1.6}$$

For our class of solutions, normalizing to 1 the coefficient of P_{pp},

$$\hat{R}(\theta)=P_{pp}+\sum_{i,\epsilon}(e^{m_{pi}^{(\epsilon)}\theta}P_{pi(\epsilon)}+e^{m_{ip}^{(\epsilon)}\theta}P_{ip(\epsilon)})+\sum_{i,j,\epsilon}(e^{m_{ij}^{(\epsilon)}\theta}P_{ij(\epsilon)}+e^{m_{i\bar{j}}^{(\epsilon)}\theta}P_{i\bar{j}(\epsilon)}), \tag{1.7}$$

with the crucial constraint,

$$m_{ij}^{(\epsilon)}=m_{i\bar{j}}^{(\epsilon)},\quad (\bar{j}=N-j+1=2p-j). \tag{1.8}$$

This sufficient and necessary constraint concerning the coefficient of θ in the exponents, leaves

$$\tfrac{1}{2}(N+3)(N-1) \tag{1.9}$$

free parameters. For $N=3$ one thus obtains, with six free parameters,

$$\hat{R}(\theta)=\begin{vmatrix} a_+ & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_- \\ 0 & b_+ & 0 & 0 & 0 & 0 & 0 & b_- & 0 \\ 0 & 0 & a_+ & 0 & 0 & 0 & a_- & 0 & 0 \\ 0 & 0 & 0 & c_+ & 0 & c_- & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & c_- & 0 & c_+ & 0 & 0 & 0 \\ 0 & 0 & a_- & 0 & 0 & 0 & a_+ & 0 & 0 \\ 0 & b_- & 0 & 0 & 0 & 0 & 0 & b_+ & 0 \\ a_- & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a_+ \end{vmatrix}, \tag{1.10}$$

where

$$a_{\pm} = \tfrac{1}{2}(e^{m_{11}^{(+)}\theta} \pm e^{m_{11}^{(-)}\theta}), \quad b_{\pm} = \tfrac{1}{2}(e^{m_{12}^{(+)}\theta} \pm e^{m_{12}^{(-)}\theta}), \quad c_{\pm} = \tfrac{1}{2}(e^{m_{21}^{(+)}\theta} \pm e^{m_{21}^{(-)}\theta}). \tag{1.11}$$

The parameters $a_{\pm}$ are each repeated in (1.10) according to (1.8), since

$$m_{1\bar{1}}^{(\pm)} = m_{11}^{(\pm)} \quad (\bar{1} = 3). \tag{1.12}$$

This is the case we will study mostly in the following sections. The corresponding results for $N > 3$ will be indicated briefly. For example, the generalization of the considerations below in this section for $N > 3$ is entirely straightforward. To explore the statistical model associated to (1.10) one starts by constructing explicit representations of the monodromy matrices $t_{ij}^{(r)}(\theta)$ of successive orders ($r = 1, 2, 3, \ldots$) obtained by taking coproducts of the fundamental 3×3 blocks (with the same θ for each factor)

$$t_{ij}^{(r)} = \sum_{j_1, \ldots, j_{r-1}} t_{ij_1} \otimes t_{j_1 j_2} \otimes \cdots \otimes t_{j_{r-1} j}. \tag{1.13}$$

For $N = 3$,

$$t^{(r)} = \begin{vmatrix} t_{11}^{(r)} & t_{12}^{(r)} & t_{1\bar{1}}^{(r)} \\ t_{21}^{(r)} & t_{22}^{(r)} & t_{2\bar{1}}^{(r)} \\ t_{\bar{1}1}^{(r)} & t_{\bar{1}2}^{(r)} & t_{\bar{1}\bar{1}}^{(r)} \end{vmatrix}. \tag{1.14}$$

If the $\hat{R}tt$ equation for the blocks $t_{ij}^{(r)}$ (Appendix C),

$$\hat{R}(\theta - \theta')(t^{(r)}(\theta) \otimes t^{(r)}(\theta')) = (t^{(r)}(\theta') \otimes t^{(r)}(\theta))\hat{R}(\theta - \theta') \tag{1.15}$$

is satisfied for $r = 1$, then the coproduct construction (1.13) ensures that (1.15) is satisfied for all higher values $r = 2, 3, \ldots$. The solution for $r = 1$ is given by

$$t^{(1)}(\theta) \equiv t(\theta) = P\hat{R}(\theta) = R(\theta), \tag{1.16}$$

where P is the permutation matrix

$$p = \sum_{ij} (ij) \otimes (ji) \tag{1.17}$$

and $R(\theta)$ is the Yang-Baxter (YB) matrix. This is a standard result valid generally for solutions of (1.2). (See Appendix B of Ref. 1 for sources cited.)

The transfer matrix, for each order r, is defined to be the trace (with argument θ)

$$T^{(r)} = t_{11}^{(r)} + t_{22}^{(r)} + t_{\bar{1}\bar{1}}^{(r)}. \tag{1.18}$$

The properties of the model depend crucially on the eigenvalues of $T^{(r)}$. References 2–4 provide ample information citing numerous basic sources.

So our basic task will be to construct the eigenstates and eigenvalues of $T^{(r)}(\theta)$. Remarkable feature following from (1.10) [and more generally from (1.7)] will be presented in the following sections and appendixes.

We will also construct chain Hamiltonians and potentials leading to factorizable S-matrices starting from our class of $\hat{R}(\theta)$.

Concerning each aspect we will try to display the role of our multiple parameters. For all

$$m_{ij}^{(+)}\theta \geqslant m_{ij}^{(-)}\theta \tag{1.19}$$

the elements of $\hat{R}(\theta)$ and hence the Boltzmann weights are non-negative, consistent with physical interpretations. For *definiteness* we consider the sector, say

$$m_{11}^{(+)} > m_{11}^{(-)} > m_{12}^{(+)} > m_{12}^{(-)} > m_{21}^{(+)} > m_{21}^{(-)}, \quad \theta \geqslant 0. \tag{1.20}$$

of (1.10). The eigenvalues will be ordered differently for other sectors. They can be considered separately.

II. TRANSFER MATRIX, EIGENVECTORS, EIGENVALUES ($N=3$): CRUCIAL FEATURES

We start by signalling some crucial features to be encountered below in the explicit constructions restricted (in this section) to $N=3$.

(1) The trace of the transfer matrix (1.17) of order r will turn out to be

$$\mathrm{tr}(T^{(r)}(\theta)) = 2e^{rm_{11}^{(+)}\theta} + 1. \tag{2.1}$$

Of the six parameters $(m_{11}^{(\pm)}, m_{12}^{(\pm)}, m_{21}^{(\pm)})$ of (1.11) *only* $m_{11}^{(+)}$ appears in the trace. A simple explanation of this fact will be given after discussing the generalization for $N>3$.

(2) The eigenvalue $e^{rm_{11}^{(+)}\theta}$ is obtained exactly *twice* for each r and the value 1 only *once*.

(3) The remaining (3^r-3) eigenvalues occur in multiplets of *zero sum* due to the presence of *roots of unity*. Hence they do not contribute to the trace. For r a prime number there will be "r-plets" (and possibly "nr-plets," n being an integer)

$$e^{\mu\theta}(1, e^{(2\pi i/r)}, e^{(2\pi i/r)\cdot 2}, \ldots, e^{(2\pi i/r)\cdot(r-1)}), \tag{2.2}$$

where μ is a *linear* combination of the parameters $m_{ij}^{(\pm)}$. When r is factorizable lower order multiplets can be present corresponding to the factors. Thus for $r=4$ one obtains both doublets and quadruplets

$$e^{\mu_2\theta}(1,-1), \quad e^{\mu_4\theta}(1, i, -1, -i), \tag{2.3}$$

with appropriate linear combinations μ_2, μ_4 to be displayed below.

(4) Apart from possible roots of unity phase factors the modulus of each eigenvalue is a simple exponential of the type $e^{\mu\theta}$ of (2.2). For $r=3$, for example, one obtains for μ the values (Appendix A)

$$\begin{gathered} 3m_{11}^{(+)}, \quad (m_{11}^{(+)} + 2m_{11}^{(-)}), \\ (m_{11}^{(+)} + m_{12}^{(+)} + m_{21}^{(+)}), \quad (m_{11}^{(+)} + m_{12}^{(-)} + m_{21}^{(-)}), \\ (m_{11}^{(-)} + m_{12}^{(+)} + m_{21}^{(-)}), \quad (m_{11}^{(-)} + m_{12}^{(-)} + m_{21}^{(+)}), \\ (m_{12}^{(+)} + m_{21}^{(+)}), \quad (m_{12}^{(-)} + m_{21}^{(-)}), \\ 0. \end{gathered} \tag{2.4}$$

Along with roots of unity factors these provide all the 27 eigenvalues as will be shown below.

(5) The values of μ depend crucially on the subspaces, to be introduced below, which are invariant under the action of $T^{(r)}(\theta)$, the transfer matrix.

A. Construction of $T^{(r)}(\theta)$ for $N=3$

The standard construction of the fundamental 3×3 block matrices $t_{ij}(\theta)$ implementing (1.15), (1.16), (1.10), (1.11), leads to [for $t^{(1)}(\theta) \equiv t(\theta)$ with $\bar{1}=3$]

$$t_{11}(\theta)=\begin{vmatrix} a_+ & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & a_- \end{vmatrix},\quad t_{12}(\theta)=\begin{vmatrix} 0 & 0 & 0 \\ c_+ & 0 & c_- \\ 0 & 0 & 0 \end{vmatrix},\quad t_{1\bar{1}}(\theta)=\begin{vmatrix} 0 & 0 & a_- \\ 0 & 0 & 0 \\ a_+ & 0 & 0 \end{vmatrix},$$

$$t_{21}(\theta)=\begin{vmatrix} 0 & b_+ & 0 \\ 0 & 0 & 0 \\ 0 & b_- & 0 \end{vmatrix},\quad t_{22}(\theta)=\begin{vmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{vmatrix},\quad t_{2\bar{1}}(\theta)=\begin{vmatrix} 0 & b_- & 0 \\ 0 & 0 & 0 \\ 0 & b_+ & 0 \end{vmatrix}, \tag{2.5}$$

$$t_{\bar{1}1}(\theta)=\begin{vmatrix} 0 & 0 & a_+ \\ 0 & 0 & 0 \\ a_- & 0 & 0 \end{vmatrix},\quad t_{\bar{1}2}(\theta)=\begin{vmatrix} 0 & 0 & 0 \\ c_- & 0 & c_+ \\ 0 & 0 & 0 \end{vmatrix},\quad t_{\bar{1}\bar{1}}(\theta)=\begin{vmatrix} a_- & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & a_+ \end{vmatrix},$$

where, from (1.11),

$$(a_+ \pm a_-)=e^{m_{11}^{(\pm)}\theta},\quad (b_+ \pm b_-)=e^{m_{12}^{(\pm)}\theta},\quad (c_+ \pm c_-)=e^{m_{21}^{(\pm)}\theta}. \tag{2.6}$$

One now must implement these in (1.13), (1.14), and (1.18) to obtain $T^{(r)}(\theta)$. Then one proceeds to construct eigenvalues of $T^{(r)}(\theta)$.

B. Subspaces invariant under the action of $T^{(r)}(\theta)$

We start by introducing convenient, compact notations. The state vectors of the fundamental representation (2.5) are denoted as

$$\left(\begin{vmatrix} 1 \\ 0 \\ 0 \end{vmatrix}\right\rangle, \begin{vmatrix} 0 \\ 1 \\ 0 \end{vmatrix}\right\rangle, \begin{vmatrix} 0 \\ 0 \\ 1 \end{vmatrix}\right\rangle) \equiv (|1\rangle,|2\rangle,|\bar{1}\rangle). \tag{2.7}$$

Tensor products for higher orders are constructed as

$$(|1\rangle\otimes|1\rangle,|1\rangle\otimes|2\rangle,|1\rangle\otimes|\bar{1}\rangle,\dots) \equiv (|11\rangle,|12\rangle,|1\bar{1}\rangle,\dots) \tag{2.8}$$

and so on in evident continuation. The *order* of the labels $(1,2,\bar{1})$ will indicate the tensor product structure. Thus, for example,

$$|1\rangle\otimes|1\rangle\otimes|2\rangle\otimes|\bar{1}\rangle\otimes|1\rangle \equiv |112\bar{1}1\rangle. \tag{2.9}$$

Corresponding to the rth order coproduct, $T^{(r)}(\theta)$ acts on a space spanned by 3^r states (for $N=3$). Let

$$S(r,k)\quad (k=0,1,\dots,r) \tag{2.10}$$

denote the subspaces labeled by k, the *multiplicity* of the index 2. The coefficients of different power of x in the expansion

$$(x+2)^r = 1\cdot x^r + 2rx^{r-1} + \cdots + 2^{r-k}\binom{r}{r-k}x^k + \cdots + 2^r \tag{2.11}$$

give the number of states in the respective subspaces. Setting $x=1$ one obtains the total number

$$(1+2)^r = 3^r. \tag{2.12}$$

For example, for $r=3$, one obtains the subspaces,

$$
\begin{aligned}
S(3,3):&\quad |222\rangle;\\
S(3,2):&\quad |221\rangle,|22\bar{1}\rangle,|212\rangle,|2\bar{1}2\rangle,|122\rangle,|\bar{1}22\rangle;\\
S(3,1):&\quad |211\rangle,|21\bar{1}\rangle,|2\bar{1}1\rangle,|2\overline{11}\rangle,\\
&\quad |121\rangle,|12\bar{1}\rangle,|\bar{1}21\rangle,|\bar{1}2\bar{1}\rangle,\\
&\quad |112\rangle,|1\bar{1}2\rangle,|\bar{1}12\rangle,|\overline{11}2\rangle;\\
S(3,0):&\quad |111\rangle,|11\bar{1}\rangle,|1\bar{1}1\rangle,|\bar{1}11\rangle,\\
&\quad |\overline{111}\rangle,|\overline{11}1\rangle,|\bar{1}1\bar{1}\rangle,|1\overline{11}\rangle.
\end{aligned}
\tag{2.13}
$$

A striking and most helpful consequence of the structure of the matrices (2.5) and their coproducts is *each subspace $S(r,k)$ is invariant under the action of $T^{(r)}(\theta)$*. This facilitates considerably the construction of eigenstates. One works on lower dimensional spaces.

One possible approach is as follows: One selects any one state from the $2^{r-k}\binom{r}{r-k}$ states of $S(r,k)$ and computes the action of $T^{(r)}(\theta)$ on it. One gets on the right-hand side (rhs) a linear combination of states belonging to $S(r,k)$. Thus, for example,

$$
\begin{aligned}
T^{(4)}(\theta)|1111\rangle &= (a_+^4 + a_-^4)|1111\rangle + 2a_+^2a_-^2(|\overline{1111}\rangle + |1\bar{1}1\bar{1}\rangle + |\bar{1}1\bar{1}1\rangle)\\
&\quad + (a_+^2 + a_-^2)a_+a_-(|1\overline{11}\rangle + |\overline{11}1\rangle + |\bar{1}11\bar{1}\rangle + |1\overline{11}\rangle),
\end{aligned}
\tag{2.14}
$$

where $a_\pm = \frac{1}{2}(e^{m_{11}^{(+)}\theta} \pm e^{m_{11}^{(-)}\theta})$ as noted before. Next, one computes the action of $T^{(4)}$ successively on the other states appearing on the right-hand side. This continues until one obtains the coefficients for a closed subsystem. Then one searches for linear combinations such that under $T^{(4)}$ it is reproduced to within a factor. Thus one systematically obtains all eigenvectors and eigenvalues, for the subspace $S(r,k)$. For our class one must solve systems of *linear* equations with fairly simple coefficient. Even the 81 eigenstates and eigenvalues for $r=4$ were obtained directly without using a computer program and without any real difficulties.

We have thus obtained exhaustive solutions for $r=1,2,3,4$. The corresponding 3, 9, 27, and 81 eigenvalues are presented in Appendix A. We have also obtained explicitly all the corresponding eigenstates. For brevity they are not presented here. The eigenvalues of Appendix A fully illustrate the crucial properties (1)–(5) signalled at the start of this section. In the following section we indicate a related but somewhat differently formulated approach for various comparisons.

III. LINEAR CONSTRAINTS FOR EIGENVECTORS FOR $N=3$ AND COMPARISION WITH ALGEBRAIC BETHE ANSATZ

In Sec. II we have noted how, exploiting the invariance of the subspaces $S(r,k)$ defined by (2.10) one can construct step by step all the eigenstates. The comments following (2.14) indicate how the relevant linear equations are obtained. We formulate below the approach in a systematic, explicit fashion.

Starting with (2.5) and (2.6) for $t_{ij}^{(1)}(\theta)=t_{ij}(\theta)$ we define the operators

$$
U = b_+(-\theta)t_{21}(\theta) + b_-(-\theta)t_{2\bar{1}}(\theta) = \begin{pmatrix} 0 & 1 & 0\\ 0 & 0 & 0\\ 0 & 0 & 0 \end{pmatrix},
$$

$$
A = t_{22}(\theta) = \begin{pmatrix} 0 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 0 \end{pmatrix},
\tag{3.1}
$$

$$D = b_-(-\theta)t_{21}(\theta) + b_+(-\theta)t_{2\bar{1}}(\theta) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}.$$

Then (suppressing arguments θ of t_{ij})

$$\begin{aligned}
t_{11}(A,U,D) &= (0,a_+U,a_-D),\\
t_{12}(A,U,D) &= (0,c_+A,c_-A),\\
t_{1\bar{1}}(A,U,D) &= (0,a_+D,a_-U),\\
t_{21}(A,U,D) &= (b_+U + b_-D,0,0),\\
t_{22}(A,U,D) &= (A,0,0),\\
t_{2\bar{1}}(A,U,D) &= (b_-U + b_+D,0,0),\\
t_{\bar{1}1}(A,U,D) &= (0,a_-D,a_+U),\\
t_{\bar{1}2}(A,U,D) &= (0,c_-A,c_+A),\\
t_{\bar{1}\bar{1}}(A,U,D) &= (0,a_-U,a_+D).
\end{aligned} \tag{3.2}$$

Also from (2.7) and (3.1)

$$U|2\rangle = |1\rangle, \quad A|2\rangle = |2\rangle, \quad D|2\rangle = |\bar{1}\rangle. \tag{3.3}$$

For any r, starting with $S(r,r)$ one obtains the basic eigenstate [trivially since $S(r,r)$ is of dimension 1],

$$T^{(r)}(\theta)|22\cdots 2\rangle = 1|22\cdots 2\rangle. \tag{3.4}$$

Now one moves up in $(r-k)$ stepwise.

$S(r,r-1)(\dim 2r)$: With $2r$ coefficients $(u_i,d_i)(i=1,\ldots,r)$ one can label the states as

$$\begin{pmatrix} (u_1U + d_1D)\otimes A\otimes\cdots\otimes A \\ +A\otimes(u_2U+d_2D)\otimes A\otimes\cdots\otimes A \\ \vdots \\ +A\otimes A\otimes\cdots\otimes A\otimes(u_rU+d_rD) \end{pmatrix}|22\cdots 2\rangle. \tag{3.5}$$

The action of $T^{(r)}(\theta)$ on these leads to a linear system of equations in (u_i,d_i) corresponding to eigenstates. For $S(r,r-1)$ the solution is particularly simple. Define

$$|\omega,\epsilon\rangle = \begin{pmatrix} A\otimes A\otimes\cdots\otimes A\otimes(U+\epsilon D) \\ +\omega A\otimes A\otimes\cdots\otimes(U+\epsilon D)\otimes A \\ +\omega^2 A\otimes A\otimes\cdots\otimes(U+\epsilon D)\otimes A\otimes A \\ \vdots \\ +\omega^{r-1}(U+\epsilon D)\otimes A\otimes A\otimes\cdots\otimes A \end{pmatrix}|22\cdots 2\rangle, \tag{3.6}$$

where $\epsilon=\pm$ and ω can have r values (as a rth root of unity)

$$\omega = (1, e^{i2\pi/r}, \ldots, e^{(i2\pi/r)\cdot(r-1)}). \tag{3.7}$$

One obtains

$$T^{(r)}(\theta)|\omega, \epsilon\rangle = \omega^{r-1} e^{(m_{12}^{(\epsilon)} + m_{21}^{(\epsilon)})\theta} |\omega, \epsilon\rangle. \tag{3.8}$$

The $2r$ eigenvalues are

$$e^{(m_{12}^{(\epsilon)} + m_{21}^{(\epsilon)})\theta} (1, e^{i2\pi/r}, \ldots, e^{(i2\pi/r)(r-1)}). \tag{3.9}$$

The next step is $k=r-2$.

$S(r, r-2)$ $(\dim 2r(r-1))$: A set of states spanning this subspace is given by

$$\sum_{i \neq j} (A \otimes \cdots \otimes A \otimes (u_i U + d_i D) \otimes A \otimes \cdots \otimes (u_j U + d_j D) \otimes A \otimes \cdots \otimes A) |22 \cdots 2\rangle. \tag{3.10}$$

The parameters (u, d) must be constrained to obtain eigenstates. At each step one obtains sets of linear constraints. The pattern is now evident. At each step one inserts, as in (3.10), $(r-k)$ factors of the type $(u_i U + d_i D)$ excluding their coincidence.

Finally for $k=0$, one has $S(r,0)$ of dimension 2^r. Here a basis spanning the subspace can be labeled as

$$\left(\sum_i (u_1^{(i)} U + d_1^{(i)} D) \otimes (u_2^{(i)} U + d_2^{(i)} D) \otimes \cdots \otimes (u_r^{(i)} U + d_r^{(i)} D) \right) |22 \cdots 2\rangle. \tag{3.11}$$

Since there are no label $|2\rangle$ left, it can be shown from (3.2) that $T^{(r)}(\theta)$, acting on $S(r,0)$ simplifies to

$$T^{(r)} \approx t_{11}^{(r)} + t_{\bar{1}\bar{1}}^{(r)} \approx t_{11} \otimes t_{11}^{(r-1)} + t_{1\bar{1}} \otimes t_{\bar{1}1}^{(r-1)} + t_{\bar{1}1} \otimes t_{1\bar{1}}^{(r-1)} + t_{\bar{1}\bar{1}} \otimes t_{\bar{1}\bar{1}}^{(r-1)}. \tag{3.12}$$

In successive steps ($t^{(r-1)} \to t \otimes t^{(r-2)}$ and so on) only the indices $(1, \bar{1})$ need be retained. They only give nonzero contributions. From (3.2),

$$\begin{aligned}
t_{11}(u_s^{(i)} U + d_s^{(i)} D) &= (a_+ u_s^{(i)} U + a_- d_s^{(i)} D) \equiv X_{11}^{(i)}(s), \\
t_{1\bar{1}}(u_s^{(i)} U + d_s^{(i)} D) &= (a_- d_s^{(i)} U + a_+ u_s^{(i)} D) \equiv X_{1\bar{1}}^{(i)}(s), \\
t_{\bar{1}1}(u_s^{(i)} U + d_s^{(i)} D) &= (a_+ d_s^{(i)} U + a_- u_s^{(i)} D) \equiv X_{\bar{1}1}^{(i)}(s), \\
t_{\bar{1}\bar{1}}(u_s^{(i)} U + d_s^{(i)} D) &= (a_- u_s^{(i)} U + a_+ d_s^{(i)} D) \equiv X_{\bar{1}\bar{1}}^{(i)}(s).
\end{aligned} \tag{3.13}$$

Define, with indices taking values $(1, \bar{1})$ only,

$$X_{ab}^{(i)}(1,2,\ldots,r) = \sum_{b_1,\ldots,b_{r-1}} X_{ab_1}^{(i)}(1) \otimes X_{b_1 b_2}^{(i)}(2) \otimes \cdots \otimes X_{b_{r-1} b}^{(i)}(r). \tag{3.14}$$

The action of $T^{(r)}(\theta)$ on the generic state (3.11) finally reduces to

$$\left(\sum_{i=1}^{r} (X_{11}^{(i)}(1,2,\ldots,r) + X_{\bar{1}\bar{1}}^{(i)}(1,2,\ldots,r)) \right) |22 \cdots 2\rangle. \tag{3.15}$$

It is of particular interest to see what parametrizations in (3.11) corresponds to the *two* eigenstates (and two only for any r) that contribute to the trace.

For $r=2$,

$$T^{(2)}(\theta)(|11\rangle + |\overline{11}\rangle) = e^{2m_{11}^{(+)}\theta}(|11\rangle + |\overline{11}\rangle),$$
$$T^{(2)}(\theta)(|1\bar{1}\rangle + |\bar{1}1\rangle) = e^{2m_{11}^{(+)}\theta}(|1\bar{1}\rangle + |\bar{1}1\rangle). \tag{3.16}$$

Along with

$$T^{(2)}(\theta)|22\rangle = |22\rangle \tag{3.17}$$

the two states of (3.16) yield

$$\mathrm{tr}(T^{(2)}(\theta)) = 2e^{2m_{11}^{(+)}\theta} + 1. \tag{3.18}$$

For other six states provide the three zero sum doublets of (A4), (A5), (A6).

For $r=3$. Apart from eight zero sum triplets of eigenvalues (see Appendix A) and the corresponding eigenstates one obtains for

$$V_1 = |111\rangle + |1\overline{11}\rangle + |\bar{1}1\bar{1}\rangle + |\overline{1}\overline{1}1\rangle, \tag{3.19}$$

$$V_2 = |\overline{111}\rangle + |\bar{1}11\rangle + |1\bar{1}1\rangle + |11\bar{1}\rangle, \tag{3.20}$$

$$T^{(3)}(\theta)(V_1, V_2) = e^{3m_{11}^{(+)}\theta}(V_1, V_2). \tag{3.21}$$

Along with $|222\rangle$ these assure

$$\mathrm{tr}(T^{(3)}(\theta)) = 2e^{3m_{11}^{(+)}\theta} + 1. \tag{3.22}$$

For $r=4$, the two corresponding combinations are

$$V_1 = |1111\rangle + |11\overline{11}\rangle + |1\overline{11}1\rangle + |1\bar{1}1\bar{1}\rangle + |\overline{1111}\rangle + |\overline{11}11\rangle + |\bar{1}1\bar{1}1\rangle + |\bar{1}11\bar{1}\rangle,$$
$$V_2 = |111\bar{1}\rangle + |11\bar{1}1\rangle + |1\bar{1}11\rangle + |\bar{1}111\rangle + |\overline{111}1\rangle + |\overline{11}1\bar{1}\rangle + |\bar{1}1\overline{11}\rangle + |1\overline{111}\rangle, \tag{3.23}$$

with

$$T^{(4)}(\theta)(V_1, V_2) = e^{4m_{11}^{(+)}\theta}(V_1, V_2). \tag{3.24}$$

Along with $|2222\rangle$ these assure

$$\mathrm{tr}(T^{(4)}(\theta)) = 2e^{4m_{11}^{(+)}\theta} + 1. \tag{3.25}$$

The general pattern is now visible. Indeed the general result is that (with relative coefficients in the sums below being all unity as in the example above)

$$V_e = (\text{sum of states with } \textit{even} \text{ number of } |1\rangle),$$
$$V_0 = (\text{sum of states with } \textit{odd} \text{ number of } |1\rangle), \tag{3.26}$$

give

$$T^{(r)}(\theta)(V_e, V_0) = e^{rm_{11}^{(+)}\theta}(V_e, V_0). \tag{3.27}$$

Along with $|22\cdots2\rangle$ they assure

$$\mathrm{tr}(T^{(r)}(\theta)) = 2e^{rm_{11}^{(+)}\theta} + 1. \tag{3.28}$$

All the reaming (3^r-3) states are grouped unto subsets giving "zero-trace" multiplets of eigenvalues involving roots of unity.

This is as far as we propose to go in explicitly constructing the eigenstates. We repeat that, as mentioned in Appendix A, we could obtain the complete sets for $r=1,2,3,4$ the $3,3^2,3^3,3^4$ eigenstates exhaustively.

Let us now compare our approach with that via algebraic Bethe ansatz (Refs. 3, 5, and 6 provide a considerable number of references). For ready comparison we recapitulate the essential results for the relatively simple and well studied case of 6-vertex models. We follow the notation of Ref. 3 for the *ferroelectric regime* in particular. Starting with the 4×4 6-vertex braid matrix and denoting the Nth order transfer matrix blocks as (N, r having *different* significance here as compared to our notations)

$$T^{(N)}(\theta) = \begin{pmatrix} A(\theta) & B(\theta) \\ C(\theta) & D(\theta) \end{pmatrix} \tag{3.29}$$

with

$$\mathrm{tr}(T^{(N)}(\theta)) = A(\theta) + D(\theta). \tag{3.30}$$

The eigenvalues of this trace are extracted from the ansatz

$$\psi(\theta_1,\theta_2,\ldots,\theta_r) = B(\theta_1)B(\theta_2)\cdots B(\theta_r)\left(\left|\begin{matrix}1\\0\end{matrix}\right\rangle_1 \otimes \left|\begin{matrix}1\\0\end{matrix}\right\rangle_2 \otimes \cdots \otimes \left|\begin{matrix}1\\0\end{matrix}\right\rangle_N\right). \tag{3.31}$$

For the chosen regime, denoting

$$\lambda_j = i\left(\theta_j + \frac{\gamma}{2}\right) \tag{3.32}$$

(where γ is the single free parameter of $\hat{R}$) the constraints on the parameters $(\theta_1,\ldots,\theta_r)$ for (3.31) to give eigenstates reduce (due to the Rtt algebra) to

$$\left[\frac{\sin(\lambda_j + i\gamma/2)}{\sin(\lambda_j - i\gamma/2)}\right]^N = -\prod_{k=1}^{r}\frac{\sin(\lambda_j - \lambda_k + i\gamma)}{\sin(\lambda_j - \lambda_k - i\gamma)}. \tag{3.33}$$

One must find the solutions (in general complex) for $(\theta_1,\ldots,\theta_r)$ from these set of nonlinear constraints.

For our case the invariance of the subspaces $S(r,k)$ defined in (2.10) under the action of $T^{(r)}(\theta)$ [our r being N of (3.29)] clearly indicates the choice of

$$|22\cdots 2\rangle = \left|\begin{matrix}0\\1\\0\end{matrix}\right\rangle \otimes \left|\begin{matrix}0\\1\\0\end{matrix}\right\rangle \otimes \cdots \otimes \left|\begin{matrix}0\\1\\0\end{matrix}\right\rangle \tag{3.34}$$

with eigenvalue 1 (for all successive orders r) as the starting point. This is the subspace $S(r,r)$ with only one state.

From (3.1) to (3.28) we have defined and implemented operators which acting on (3.34) moves stepwise through the subspaces

$$S(r,r), S(r,r-1), \ldots, S(r,1), S(r,0). \tag{3.35}$$

For our class of higher dimensional structures, already for $N=3$, the state-labels $(1,2,\bar{1})$ necessitate different types of actions on the index 2. Instead of a single complex θ-dependent matrix [like $B(\theta)$ of (3.31)] we have chosen and systematically implemented the operators (U,A,D) to move

through the sequence (3.35). At each step our formalism leads to relatively simple *linear* constraints, (3.6) giving the complete results for $S(r,r-1)$ being the simplest example. The results (3.26)–(3.28) give the complete trace. The results in Appendix A (for $r=1,2,3,4$ for spaces of 3,9,27,81 dimensions, respectively) give a fair idea of the structure of the eigenvalues.

The fact that one finally solves only sets of linear equations with simple constant coefficients is not evident directly from (3.13)–(3.15), for example. But the fact that one ends up only with eigenvalues of the form $e^{\mu\theta}$ (where, as in Appendix A, μ is a linear function of the parameters $m_{ij}^{(\pm)}$) leads finally to such constraints. For the 3^r-3 eigenvalues of zero total trace one searches for multiplets formed by roots unity and hence summing to zero. This also is very helpful in constructing eigenstates. The eigenvalues, for each r, are known to a certain extent (through certainly not entirely) beforehand.

IV. HAMILTONIANS AND CONSERVED QUANTITIES ($N=3$)

We study here the role of our parameters in the sequence of conserved quantities, the first one in the sequence being chain Hamiltonian.[3,4] (Many source are cited in Ref. 3.) Define

$$H_n = \left.\frac{\partial^n}{\partial\theta^n}\ln T^{(r)}(\theta)\right|_{\theta=0}. \tag{4.1}$$

The commutativity of the transfer matrices $T(\theta)$, $T(\theta')$ implies

$$[H_n,H_m]=0. \tag{4.2}$$

If H_1 is regarded as the Hamiltonian of the system, there is infinite set of conserved quantities.

Using standard results[3,4] and taking account of our normalization and the regularity, i.e.,

$$\hat{R}(0)=PR(0)=I, \tag{4.3}$$

one obtains [since $(P\hat{R}(0))^{-1}(P\partial_\theta\hat{R}(\theta))_{\theta=0}=(\partial_\theta\hat{R}(\theta))_{\theta=0}$]

$$H_1 = (T^{(r)}(0))^{-1}\frac{\partial}{\partial\theta}T^{(r)}(\theta)\bigg|_{\theta=0} = \sum_{k=1}^{r} I\otimes\cdots\otimes\dot{\hat{R}}(0)_{k,k+1}\otimes\cdots\otimes I. \tag{4.4}$$

Note that due to the trace (circular boundary) constraint $k+1=r+1\approx 1$. Indeed starting with $r=2$, evaluating directly and explicitly

$$(T^{(2)}(0))^{-1}\frac{\partial}{\partial\theta}T^{(2)}(\theta)\bigg|_{\theta=0} \tag{4.5}$$

and setting

$$x_\pm=\tfrac{1}{2}(m_{11}^{(+)}\pm m_{11}^{(-)}),\quad y_\pm=\tfrac{1}{2}(m_{12}^{(+)}\pm m_{12}^{(-)}),\quad z_\pm=\tfrac{1}{2}(m_{21}^{(+)}\pm m_{21}^{(-)}), \tag{4.6}$$

one obtains (writing H for H_1 when $r=2$)

$$H = \begin{pmatrix} 2x_+ & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2x_- \\ 0 & y_+ + z_+ & 0 & 0 & 0 & 0 & 0 & y_- + z_- & 0 \\ 0 & 0 & 2x_+ & 0 & 0 & 0 & 2x_- & 0 & 0 \\ 0 & 0 & 0 & y_+ + z_+ & 0 & y_- + z_- & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & y_- + z_- & 0 & y_+ + z_+ & 0 & 0 & 0 \\ 0 & 0 & 2x_- & 0 & 0 & 0 & 2x_+ & 0 & 0 \\ 0 & y_- + z_- & 0 & 0 & 0 & 0 & 0 & y_+ + z_+ & 0 \\ 2x_- & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2x_+ \end{pmatrix}$$

$$= \dot{\hat{R}}(0) + P\dot{\hat{R}}(0)P = \dot{\hat{R}}(0)_{12} + \dot{\hat{R}}(0)_{21}, \tag{4.7}$$

where, in evident notations,

$$\dot{\hat{R}}(0)_{12} = (x_+, y_+, x_+, z_+, 0, z_+, x_+, y_+, x_+)_{\text{diag}} + (x_-, y_-, x_-, z_-, 0, z_-, x_-, y_-, x_-)_{\text{antidiag}} \tag{4.8}$$

and

$$\dot{\hat{R}}(0)_{21} = (x_+, z_+, x_+, y_+, 0, y_+, x_+, z_+, x_+)_{\text{diag}} + (x_-, z_-, x_-, y_-, 0, y_-, x_-, z_-, x_-)_{\text{antidiag}}. \tag{4.9}$$

The expressions for (12) and (21) are related through the interchanges

$$(y_\pm, z_\pm) \to (z_\pm, y_\pm). \tag{4.10}$$

The appearance of (21) in (4.7) is consistent with the remark below (4.4).

For higher derivatives one has

$$\frac{d^l}{\mathrm{d}\theta^l}\hat{R}(\theta)\bigg|_{\theta=0} = (x_+^l, y_+^l, x_+^l, z_+^l, 0, z_+^l, x_+^l, y_+^l, x_+^l)_{\text{diag}} + (x_-^l, y_-^l, x_-^l, z_-^l, 0, z_-^l, x_-^l, y_-^l, x_-^l)_{\text{antidiag}}. \tag{4.11}$$

For H_2 one now obtains, as compared to (4.4),

$$H_2 = \sum_{j\neq k} I \otimes \cdots \otimes I \otimes \dot{\hat{R}}(0)_{jj+1} \otimes I \cdots \otimes I \otimes \dot{\hat{R}}(0)_{k,k+1} \otimes I \cdots \otimes I$$

$$+ \sum_k I \cdots \otimes I \otimes \ddot{\hat{R}}(0)_{k,k+1} \otimes I \cdots \otimes I. \tag{4.12}$$

Generalization to higher orders are carried out in evident fashion.

In Sec. 5 of Ref. 1 in constructing θ-expansions the H defined in (5.1) is *precisely* $\dot{\hat{R}}(0)$ of (4.8) above generalized to all odd N, namely $N=3,5,7,\ldots$. There it was noted [Eq. 5.9 of Ref. 1],

$$[H_{12} + H_{23}, [H_{12}, H_{23}]] = 0, \tag{4.13}$$

where $H_{12}=H\otimes I$ and $H_{23}=I\otimes H$. This vanishing double commutator is the simplest version of the Reshetikhin condition given in Eqs. 3.20 of Ref. 2 as

$$[H_{12} + H_{23}, [H_{12}, H_{23}]] = X_{12} - X_{23}, \tag{4.14}$$

the rhs being the difference of two two-point-quantities. In (4.13) the rhs is simply zero.

V. POTENTIAL FOR FACTORIZABLE *S*-MATRICES AND CAYLEY TRANSFORMS (*N*=3)

Potentials for scattering of bosons or fermions with quadratic interaction terms (Sec. 3 of Ref. 2 and Sec. 1 of Ref. 3 provide more references) can correspond to factorizable *S*-matrices (factorizable into two particle scatterings, independently of the chosen order of the latter ones) provided that such potentials are inverse Cayley transforms of Yang-Baxter matrices of appropriate dimensions, i.e., V being the potential (for a chosen helicity fixing the sign of θ)

$$-iV=(R(\theta)-\lambda(\theta)I)^{-1}(R(\theta)+\lambda(\theta)I). \tag{5.1}$$

As compared to Refs. 2 and 3 we display explicitly a free normalization factor

$$(\lambda(\theta))^{-1}R(\theta). \tag{5.2}$$

Our multiparametric case shows clearly that though the normalization (if well-defined) trivially cancels in the YB or the braid equation it must be compatible with the existence of the inverse of

$$(\lambda^{-1}(\theta)R(\theta)-I). \tag{5.3}$$

We will find that

$$\lambda(\theta)\neq(1,e^{m_{11}^{(\pm)}\theta},\pm e^{m_{11}^{(-)}\theta},\pm e^{(1/2)(m_{12}^{(\pm)}+m_{21}^{(\pm)})\theta}). \tag{5.4}$$

The inverse [when $\hat{R}(\theta)$ is given by (1.10)]

$$(\hat{R}(\theta)-\lambda'(\theta)I)^{-1} \tag{5.5}$$

can be shown to exist for

$$\lambda'(\theta)\neq(1,e^{m_{11}^{(\pm)}\theta},e^{m_{12}^{(\pm)}\theta},e^{m_{21}^{(\pm)}\theta}). \tag{5.6}$$

The significance of (5.6) is simple, the rhs exhibiting simply the coefficients of the projectors

$$(P_{22},P_{11}^{(\pm)},P_{12}^{(\pm)},P_{21}^{(\pm)}) \tag{5.7}$$

in (1.10).

Diagonalizing $\hat{R}(\theta)$ the situation becomes particularly transparent [Eqs. (3.4), (3.5) of Ref. 1]. M being given by (3.5) of Ref. 1,

$$M(\hat{R}(\theta)-\lambda'(\theta)I)M^{-1}=(e^{m_{11}^{(+)}\theta},e^{m_{12}^{(+)}\theta},e^{m_{11}^{(+)}\theta},e^{m_{21}^{(+)}\theta},1,e^{m_{21}^{(-)}\theta},e^{m_{11}^{(-)}\theta},e^{m_{12}^{(-)}\theta},e^{m_{11}^{(-)}\theta})_{\mathrm{diag}}-\lambda'(\theta)I. \tag{5.8}$$

When $\lambda'(\theta)$ is equal to any one of the eigenvalues (including 1) the determinant of $[\hat{R}(\theta)-\lambda'(\theta)I]$ vanishes. Hence (5.6).

For (5.1) one requires invertibility of

$$P\hat{R}(\theta)-\lambda(\theta)I. \tag{5.9}$$

The action of P finally leads to (5.4) rather than (5.6).

Defining X through

$$(R(\theta)-\lambda(\theta)I)X=I, \tag{5.10}$$

we present below the explicit form of X for our $N=3$ case,

$$X=\begin{pmatrix} x_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & x_8 \\ 0 & x_2 & 0 & x_6 & 0 & x_7 & 0 & x_4 & 0 \\ 0 & 0 & x_3 & 0 & 0 & 0 & x_9 & 0 & 0 \\ 0 & x_{10} & 0 & x_2 & 0 & x_4 & 0 & x_{11} & 0 \\ 0 & 0 & 0 & 0 & x_5 & 0 & 0 & 0 & 0 \\ 0 & x_{11} & 0 & x_4 & 0 & x_2 & 0 & x_{10} & 0 \\ 0 & 0 & x_9 & 0 & 0 & 0 & x_3 & 0 & 0 \\ 0 & x_4 & 0 & x_7 & 0 & x_6 & 0 & x_2 & 0 \\ x_8 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & x_1 \end{pmatrix}, \tag{5.11}$$

where [writing λ for $\lambda(\theta)$]

$$x_1=\frac{1}{2}\left(\frac{1}{e^{m_{11}^{(+)}\theta}-\lambda}+\frac{1}{e^{m_{11}^{(-)}\theta}-\lambda}\right),\quad x_8=\frac{1}{2}\left(\frac{1}{e^{m_{11}^{(+)}\theta}-\lambda}-\frac{1}{e^{m_{11}^{(-)}\theta}-\lambda}\right),$$

$$x_2=\frac{\lambda}{2}\left(\frac{1}{e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta}-\lambda^2}+\frac{1}{e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta}-\lambda^2}\right),$$

$$x_4=\frac{\lambda}{2}\left(\frac{1}{e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta}-\lambda^2}-\frac{1}{e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta}-\lambda^2}\right),$$

$$x_3=\frac{1}{2}\left(\frac{1}{e^{m_{11}^{(+)}\theta}-\lambda}-\frac{1}{e^{m_{11}^{(-)}\theta}+\lambda}\right),\quad x_9=\frac{1}{2}\left(\frac{1}{e^{m_{11}^{(+)}\theta}-\lambda}+\frac{1}{e^{m_{11}^{(-)}\theta}+\lambda}\right),$$

$$x_5=\frac{1}{1-\lambda}, \tag{5.12}$$

$$x_6=\frac{1}{2}\left(\frac{e^{m_{21}^{(+)}\theta}}{e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta}-\lambda^2}+\frac{e^{m_{21}^{(-)}\theta}}{e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta}-\lambda^2}\right),$$

$$x_7=\frac{1}{2}\left(\frac{e^{m_{21}^{(+)}\theta}}{e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta}-\lambda^2}-\frac{e^{m_{21}^{(-)}\theta}}{e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta}-\lambda^2}\right),$$

$$x_{10}=\frac{1}{2}\left(\frac{e^{m_{12}^{(+)}\theta}}{e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta}-\lambda^2}+\frac{e^{m_{12}^{(-)}\theta}}{e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta}-\lambda^2}\right),$$

$$x_{11}=\frac{1}{2}\left(\frac{e^{m_{12}^{(+)}\theta}}{e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta}-\lambda^2}-\frac{e^{m_{12}^{(-)}\theta}}{e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta}-\lambda^2}\right).$$

Now, from (5.1), (5.10), and (5.11),

$$\begin{aligned} -iV &= (R(\theta)-\lambda(\theta)I)^{-1}(R(\theta)+\lambda(\theta)I) \\ &= (R(\theta)-\lambda(\theta)I)^{-1}(R(\theta)-\lambda(\theta)I+2\lambda(\theta)I) \\ &= X(X^{-1}+2\lambda(\theta)I), \end{aligned}$$

$$-iV = I + 2\lambda(\theta)X. \tag{5.13}$$

From (5.12) it is evident that X is well-defined only when (5.4) is satisfied. We have thus obtained explicitly, for $N=3$, the potential leading to a factorizable S-matrix. The role played by our parameters is now displayed.

Note that any $\lambda(\theta)$ satisfying (5.4) can be implemented. One many choose to display this dependence on λ by denoting the potential as $V(\lambda)$. With our $V(\lambda)$ one now considers the fermionic Lagrangian

$$\mathcal{L} = \int \mathrm{d}x(i\bar{\psi}_a\gamma_v\partial_v\psi_a - g(\bar{\psi}_a\gamma_v\psi_c)V_{ab,cd}(\bar{\psi}_b\gamma_v\psi_d)), \tag{5.14}$$

where

$$V = \sum_{ab,cd}(V_{ab,cd})(ab)\otimes(cd). \tag{5.15}$$

There is an analogous, simpler, formulation for bosons. We will not further analyze the consequences of our V. But it should be compared to the detailed studies of the solutions obtained in Refs. 7 and 8.

VI. $N>3$

So far we have studied the case $N=3$ in detail. Now we indicate briefly the crucial new features arising for $N>3$. Many aspects are conserved also, as will be pointed out.

The first major feature is the generalization of (2.1). For $N=2p-1$, one obtains

$$\mathrm{tr}(T^{(r)}(\theta)) = 2(e^{rm_{11}^{(+)}\theta} + e^{rm_{22}^{(+)}\theta} + \cdots + e^{rm_{p-1,p-1}^{(+)}\theta}) + 1, \quad p = 2,3,4,\ldots. \tag{6.1}$$

There are

$$2(p-1)+1 = 2p-1 = N \tag{6.2}$$

terms. An explanation, promised below (2.1), is as follows. *Only the diagonal blocks $t_{ii}(\theta)$ have diagonal terms*. Thus in (2.5) only $t_{11}(\theta)$, $t_{22}(\theta)$, $t_{\bar{1}\bar{1}}(\theta)$, has nonzero elements on the diagonal, their sum being

$$\mathrm{tr}(T^{(1)}(\theta)) = 2(a_+ + a_-) + 1 = 2e^{m_{11}^{(+)}\theta} + 1 \quad (r=1). \tag{6.3}$$

For $r=2$ (and $N=3$) one obtains from the coproduct structure

$$\begin{aligned}\mathrm{tr}(T^{(2)}(\theta)) &= \mathrm{tr}((a_+a_+,0,a_+a_-)_{\mathrm{diag}} + (0,1,0)_{\mathrm{diag}} + (a_-a_-,0,a_-a_+)_{\mathrm{diag}} + (a_-a_+,0,a_-a_-)_{\mathrm{diag}} \\ &\quad + (a_+a_-,0,a_+a_+)_{\mathrm{diag}}) + \mathrm{tr}(\text{blocks with nondiagonal terms only}) = 2(a_+ + a_-)^2 + 1, \\ &\mathrm{tr}(T^{(2)}(\theta)) = 2e^{2m_{11}^{(+)}\theta} + 1,\end{aligned} \tag{6.4}$$

and so on.

For $N>3$ the basic features persist. Along with the crucial constraint (1.8)

$$m_{ij}^{(\epsilon)} = m_{\bar{i}\bar{j}}^{(\epsilon)} \quad (\bar{j} = 2p-j) \tag{6.5}$$

which symmetrizes the blocks on the diagonal [generalizing (1.10)], the final result is

$$\mathrm{tr}(T^{(r)}(\theta)) = 2\sum_{i=1}^{p-1}(a_{ii}^{(+)} + a_{ii}^{(-)})^r + 1 \tag{6.6}$$

$$=2\sum_{i=1}^{p-1} e^{rm_{ii}^{(+)}\theta}+1. \tag{6.7}$$

The result is obtained directly by looking closely at the structure of the matrices concerned, *without constructing eigenstates and their eigenvalues*. We have checked (6.7) directly and explicitly for arbitrary p (Appendix A). But this result has profound consequence on the spectrum of the eigenvalues for each r. Given (N,r) and the coproduct rule,

(1) the number of eigenvalues for $T^{(r)}(\theta)=N^r$,
(2) the number of eigenvalues contributing in the trace$=N$,
(3) the remaining (N^r-N) eigenvalues must sum to give zero contribution in the trace.

For $N=3$ we have shown (Appendix A) how this constraint is satisfied via the multiplet structures

$$e^{\mu\theta}(1,\omega_{(l)},\omega_{(l)}^{(2)},\ldots,\omega_{(l)}^{l-1}),\quad \omega_{(l)}=e^{2\pi i/l},$$
$$1+\omega_{(l)}+\omega_{(l)}^2+\cdots+\omega_{(l)}^{(l-1)}=0, \tag{6.8}$$

where μ is linear in $m_{ij}^{(\pm)}$ and for

$$r=2,\quad l=2,$$
$$r=3,\quad l=3, \tag{6.9}$$
$$r=4,\quad l=2,4,$$

and so on.

This multiplet structure involving roots of unity can also be shown to be carried over for $N>3$ explicitly. But apart from the fact that the number of eigenstates and the number of states in the linear combinations giving eigenstates increase very fast there are no other basic difficulties.

For $N=5$, for example, generalizing the basis (2.7), for $p=3$, to

$$\left\langle \begin{pmatrix}1\\0\\0\\0\\0\end{pmatrix}, \begin{pmatrix}0\\1\\0\\0\\0\end{pmatrix}, \begin{pmatrix}0\\0\\1\\0\\0\end{pmatrix}, \begin{pmatrix}0\\0\\0\\1\\0\end{pmatrix}, \begin{pmatrix}0\\0\\0\\0\\1\end{pmatrix} \right\rangle \equiv (|1\rangle,|2\rangle,|3\rangle,|\bar{2}\rangle,|\bar{1}\rangle,) \tag{6.10}$$

one again obtains subspaces stable under the action of $T^{(r)}(\theta)$,

$$S(r,k)\quad (k=0,1,\ldots,r), \tag{6.11}$$

where k is now the multiplicity of the index 3. The operator structures (3.1), (3.2), (3.3) are now generalized, in terms of operators $(t_{31}(\theta),t_{3\bar{1}}(\theta))$, $(t_{32}(\theta),t_{3\bar{2}}(\theta))$, $t_{33}(\theta)$ to construct

$$U_1|3\rangle=|1\rangle,\quad U_2|3\rangle=|2\rangle,$$
$$D_1|3\rangle=|\bar{1}\rangle,\quad D_2|3\rangle=|\bar{2}\rangle, \tag{6.12}$$
$$A|3\rangle=|3\rangle.$$

The subspace $S(r,r)$ is still given by a single state

$$T^{(r)}(\theta)|33\cdots3\rangle = |33\cdots3\rangle. \tag{6.13}$$

The subspace $S(r,r-1)$ is now spanned by $4r$ (instead of $2r$ for $N=3$) states and is easily diagonalized.

The stepwise generalization for $N=7,9,\ldots$ is now fairly evident. The dimensions of $S(r,k)$ is given by a generalization of (2.11) by the successive coefficients in

$$(x+2(p-1))^r = 1\cdot x^r + 2r(p-1)x^{r-1} + \cdots + (2(p-1))^{r-k}\binom{r}{r-k}x^k + \cdots + (2(p-k))^r. \tag{6.14}$$

For $x=1$, one gets the total dimension

$$(2p-1)^r = N^r. \tag{6.15}$$

The generalization of (3.26) is also fairly direct. When the order r of $T^r(\theta)$ is a prime number there is an amusing encounter with a theorem of Fermat in considering our multiplet structures. This is discussed in Appendix B.

The generalization of the structure of the Hamiltonian of Sec. IV involving $\dot{\hat{R}}(0)$ of (4.8) is particulary straightforward. But even for $N=5$ we have 24 nonzero terms on the diagonal and as many on the antidiagonal.

The potential (5.1) for $N=5,7,\ldots$ now involve inversions of N^2 dimensional matrices $(R(\theta)-\lambda(\theta)I)$. This is again straightforward, given our specific structure of $\hat{R}(\theta)$, but evidently lengthly.

Apart from such general indications as presented above systematic studies for cases $N>3$ are beyond the scope of this work. In particular possible substructures in each subspace $S(r,k)$ corresponding to multiplicities of different indices [say $(1,\bar{1})$ and $(2,\bar{2})$ for $N=5$] should be formulated with care.

VII. GENERALIZATION OF THE NESTED SEQUENCE OF PROJECTORS

The sequence of projectors (1.3), forming a complete orthonormalized basis admits the more general parametrization displayed below (for odd N)

$$P_{pp} = (pp)\otimes(pp),$$

$$(u_{pi}+u_{pi}^{-1})P_{pi(\pm)} = (pp)\otimes[u_{pi}^{\pm1}(ii)+u_{pi}^{\mp1}(\bar{i}\bar{i})\pm(v_{pi}(i\bar{i})+v_{pi}^{-1}(\bar{i}i))],$$

$$(u_{ip}+u_{ip}^{-1})P_{ip(\pm)} = [u_{ip}^{\pm1}(ii)+u_{ip}^{\mp1}(\bar{i}\bar{i})\pm(v_{ip}(i\bar{i})+v_{ip}^{-1}(\bar{i}i))]\otimes(pp), \tag{7.1}$$

$$(u_{ij}+u_{ij}^{-1})P_{ij(\epsilon)} = u_{ij}^{\pm1}(ii)\otimes(jj)+u_{ij}^{\mp1}(\bar{i}\bar{i})\otimes(\bar{j}\bar{j})\pm[v_{ij}(i\bar{i})\otimes(j\bar{j})+v_{ij}^{-1}(\bar{i}i)\otimes(\bar{j}j)],$$

$$(u_{i\bar{j}}+u_{i\bar{j}}^{-1})P_{i\bar{j}(\epsilon)} = u_{i\bar{j}}^{\pm1}(ii)\otimes(\bar{j}\bar{j})+u_{i\bar{j}}^{\mp1}(\bar{i}\bar{i})\otimes(jj)\pm[v_{i\bar{j}}(i\bar{i})\otimes(\bar{j}j)+v_{i\bar{j}}^{-1}(\bar{i}i)\otimes(j\bar{j})],$$

where the supplementary parameters introduced are compatible with the orthonormality and completeness conditions (1.5). For even N also an analogues pammetrization can be introduced. Thus 6-vertex and 8-vertex projector basis [given in (6.1) of Ref. 1] can be generalized to

$$(u_{11}+u_{11}^{-1})P_{11(\pm)}=\begin{pmatrix} u_{11}^{\pm 1} & 0 & 0 & \pm v_{11} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \pm v_{11}^{-1} & 0 & 0 & u_{11}^{\mp 1} \end{pmatrix},$$

$$(u_{1\bar{1}}+u_{1\bar{1}}^{-1})P_{1\bar{1}(\pm)}=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & u_{1\bar{1}}^{\pm 1} & \pm v_{1\bar{1}} & 0 \\ 0 & \pm v_{1\bar{1}}^{-1} & u_{1\bar{1}}^{\mp 1} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{7.2}$$

Braid matrices on such bases of projectors and associated statistical models can be studied systematically. Such a study will be presented elsewhere with suitable restrictions on parameters for specific solutions. Setting $u_{ab}=v_{ab}=1$ for all values of the indices one recovers the projectors of (1.3).

VIII. DISCUSSION

Our results presented above, are limited to formal study of the transfer matrix, construction of chain Hamiltonians and potentials corresponding to factorizable S-matrices. Adequate study of the, consequences of the features obtained, of their deeper significance remains to be done. The role of our parameters should be analyzed in various domains for comparison with corresponding features of well-known statistical models.[3,9–11] Our braid matrices encode star-triangle relations.

Certain features are, of course, immediately available for our case. Thus the free energy (defined with the opposite sign in Ref. 10), is given by the maximum eigenvalue ($\theta>0$) as

$$f=-\lim_{r\to\infty}\frac{1}{r}\ln e^{rm_{11}^{(+)}\theta}=-m_{11}^{(+)}\theta \tag{8.1}$$

if we choose, say, the order

$$m_{11}^{(+)}>m_{22}^{(+)}>\cdots>m_{p-1,p-1}^{(+)}. \tag{8.2}$$

In our case results depend on the sector of the parameters selected (their ordering). The second largest eigenvalue, also of particular interest, is again directly obtained once the ordering is fixed.

Correlation functions are of major interest and a domain of intense activity.[12,13] Here our model can have quite interesting consequences. This aspect also remains to be explored.

We intend to continue our study elsewhere. But we consider the series of remarkable features presented here to be sufficiently rich in content. They open up a significantly different domain, as compared to standard, well known cases.

ACKNOWLEDGMENTS

It is a pleasure to thank Jean Lascoux and Alain Lascoux for discussions concerning the theme of Appendix B. One of us (B.A.) thanks Patrick Mora for a kind invitation at Ecole Polytechnique. The author (B.A.) is also very grateful to the members of the group for their warm hospitality. This work is supported by a grant of "La Fondation Charles de Gaulle."

APPENDIX A: EIGENVALUES OF $T^{(r)}(\theta)$ FOR $N=3$, $r=1,2,3,4$ AND DIRECT CONSTRUCTION OF TRACE FOR $N>3$

For each r, the eigenvalues of $T^{(r)}(\theta)$ are given systematically for the subspaces $S(r,k)$ defined in (2.10), for $k=0,1,\ldots,r$.

$r=1$(dim 3):

$$S(1,0)(\dim 2): \quad \begin{matrix} \text{eigenvalues} \\ e^{m_{11}^{(+)}\theta}(1,1), \end{matrix} \tag{A1}$$

$$S(1,1)(\dim 1): \quad 1, \tag{A2}$$

$$\mathrm{tr}(T^{(1)}(\theta)) = 2e^{m_{11}^{(+)}\theta} + 1. \tag{A3}$$

r=2(dim 9):

$$S(2,0)(\dim 4): \quad \begin{matrix} e^{2m_{11}^{(+)}\theta}(1,1), \\ e^{2m_{11}^{(-)}\theta}(1,-1); \end{matrix} \tag{A4}$$

$$S(2,1)(\dim 4): \quad \begin{matrix} e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta}(1,-1), \\ e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta}(1,-1); \end{matrix} \tag{A5}$$

$$S(2,2)(\dim 1): \quad 1; \tag{A6}$$

$$\mathrm{tr}(T^{(2)}(\theta)) = 2e^{2m_{11}^{(+)}\theta} + 1. \tag{A7}$$

r=3(dim 27):

$$S(3,0)(\dim 8): \quad \begin{matrix} e^{3m_{11}^{(+)}\theta}(1,1), \\ e^{(m_{11}^{(+)}+2m_{11}^{(-)})\theta}(1,e^{2\pi i/3},e^{(2\pi i/3)2}) \quad [2 \text{ times}]; \end{matrix} \tag{A8}$$

$$S(3,1)(\dim 12): \quad \begin{pmatrix} e^{(m_{11}^{(+)}+m_{12}^{(+)}+m_{21}^{(+)})\theta} \\ e^{(m_{11}^{(+)}+m_{12}^{(-)}+m_{21}^{(-)})\theta} \\ e^{(m_{11}^{(-)}+m_{12}^{(+)}+m_{21}^{(-)})\theta} \\ e^{(m_{11}^{(-)}+m_{12}^{(-)}+m_{21}^{(+)})\theta} \end{pmatrix} (1,e^{2\pi i/3},e^{(2\pi i/3)2}); \tag{A9}$$

$$S(3,2)(\dim 6): \quad \begin{pmatrix} e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta} \\ e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta} \end{pmatrix} (1,e^{2\pi i/3},e^{(2\pi i/3)2}); \tag{A10}$$

$$S(3,3)(\dim 1): \quad 1; \tag{A11}$$

$$\mathrm{tr}(T^{(3)}(\theta)) = 2e^{3m_{11}^{(+)}\theta} + 1. \tag{A12}$$

r=4(dim 81):

$$S(4,0)(\dim 16): \quad \begin{matrix} e^{4m_{11}^{(+)}\theta}(1,1), \\ e^{2(m_{11}^{(+)}+m_{11}^{(-)})\theta}(1,e^{2\pi i/4},e^{(2\pi i/4)\cdot 2},e^{(2\pi i/4)\cdot 3}) \quad [3 \text{ times}]; \\ e^{4m_{11}^{(-)}\theta}(1,-1), \end{matrix} \tag{A13}$$

$$
\begin{aligned}
S(4,1)(\dim 32): \quad & e^{(m_{11}^{(+)}+m_{11}^{(-)}+m_{12}^{(+)}+m_{21}^{(-)})\theta}(1,e^{2\pi i/4},e^{(2\pi i/4)\cdot 2},e^{(2\pi i/4)\cdot 3},) \quad [2 \text{ times}],\\
& e^{(m_{11}^{(+)}+m_{11}^{(-)}+m_{12}^{(-)}+m_{21}^{(+)})\theta}(1,e^{2\pi i/4},e^{(2\pi i/4)\cdot 2},e^{(2\pi i/4)\cdot 3},) \quad [2 \text{ times}];\\
& \begin{pmatrix} e^{(2m_{11}^{(+)}+m_{12}^{(+)}+m_{21}^{(+)})\theta}\\ e^{(2m_{11}^{(+)}+m_{12}^{(-)}+m_{21}^{(-)})\theta}\\ e^{(2m_{11}^{(-)}+m_{12}^{(+)}+m_{21}^{(+)})\theta}\\ e^{(2m_{11}^{(-)}+m_{12}^{(-)}+m_{21}^{(+)})\theta} \end{pmatrix}(1,e^{2\pi i/4},e^{(2\pi i/4)\cdot 2},e^{(2\pi i/4)\cdot 3},),
\end{aligned} \tag{A14}
$$

$$
\begin{aligned}
S(4,2)(\dim 24): \quad & \begin{pmatrix} e^{2(m_{12}^{(+)}+m_{21}^{(+)})\theta}\\ e^{2(m_{12}^{(-)}+m_{21}^{(-)})\theta} \end{pmatrix}(1,-1),\\
& e^{(m_{12}^{(+)}+m_{12}^{(-)}+m_{21}^{(+)}+m_{21}^{(-)})\theta}(1,e^{2\pi i/4},e^{(2\pi i/4)\cdot 2},e^{(2\pi i/4)\cdot 3}),\\
& \begin{pmatrix} e^{(m_{11}^{(+)}+m_{12}^{(+)}+m_{21}^{(+)})\theta}\\ e^{(m_{11}^{(+)}+m_{12}^{(-)}+m_{21}^{(-)})\theta}\\ e^{(m_{11}^{(-)}+m_{12}^{(+)}+m_{21}^{(-)})\theta}\\ e^{(m_{11}^{(-)}+m_{12}^{(-)}+m_{21}^{(+)})\theta} \end{pmatrix}(1,e^{2\pi i/4},e^{2\pi i/4\cdot 2},e^{2\pi i/4\cdot 3});
\end{aligned} \tag{A15}
$$

$$
S(4,3)(\dim 8): \quad \begin{pmatrix} e^{(m_{12}^{(+)}+m_{21}^{(+)})\theta}\\ e^{(m_{12}^{(-)}+m_{21}^{(-)})\theta} \end{pmatrix}(1,e^{2\pi i/4},e^{2\pi i/4\cdot 2},e^{2\pi i/4\cdot 3}); \tag{A16}
$$

$$
S(4,4)(\dim 1): \quad 1; \tag{A17}
$$

$$
\operatorname{tr}(T^{(4)}(\theta)) = 2e^{4m_{11}^{(+)}\theta} + 1. \tag{A18}
$$

Now we indicate briefly the direct construction of trace for all N, without constructing the full set of eigenvalues explicitly.

Set, for the coefficients on the diagonal and the antidiagonal, respectively,

$$
d_{ij} = \tfrac{1}{2}(e^{m_{ij}^{(+)}\theta} + e^{m_{ij}^{(-)}\theta}) = d_{i\bar{j}}, \quad a_{ij} = \tfrac{1}{2}(e^{m_{ij}^{(+)}\theta} + e^{m_{ij}^{(-)}\theta}) = a_{i\bar{j}}, \tag{A19}
$$

where

$$
i = 1,2,\ldots,p-1, \quad \bar{i} = (2p-1),\ldots,(p+1), \quad p = \tfrac{1}{2}(N+1). \tag{A20}
$$

From (1.7) and (1.15)

$$
\begin{aligned}
t(\theta) = & \sum_i ((pi)\otimes(d_{ip}(ip)+a_{ip}(\bar{i}\bar{p})) + (p\bar{i})\otimes(a_{ip}(ip)+d_{ip}(\bar{i}\bar{p})) + (ip)\otimes(d_{pi}(pi)+a_{pi}(p\bar{i}))\\
& + (\bar{i}\bar{p})\otimes(a_{pi}(pi)+d_{pi}(p\bar{i}))) + \sum_{ij}((ji)\otimes(d_{ij}(ij)+a_{ij}(\bar{i}\bar{j})) + (\bar{j}\bar{i})\otimes(a_{ij}(ij)+d_{ij}(\bar{i}\bar{j})) + (j\bar{i})\\
& \otimes(d_{ij}(\bar{i}j)+a_{ij}(i\bar{j})) + (\bar{j}i)\otimes(d_{ij}(\bar{i}j)+a_{ij}(i\bar{j}))) + \sum_i((i\bar{i})\otimes(d_{ii}(\bar{i}\bar{i})+a_{ii}(ii)) + (\bar{i}\bar{i})\otimes(a_{ii}(\bar{i}\bar{i})\\
& + d_{ii}(i\bar{i}))) + \sum_i((ii)\otimes(d_{ii}(ii)+a_{ii}(\bar{i}\bar{i})) + (\bar{i}\bar{i})\otimes(a_{ii}(ii)+d_{ii}(\bar{i}\bar{i}))) + (pp)\otimes(pp).
\end{aligned} \tag{A21}
$$

Crucial features to be noted are the following:

(1) Only the diagonal blocks have nonzero terms on the diagonal.
(2) In each such block there are only two nonzero terms (with only one for the pth).

(3) These features are iterated under successive coproducts.

Thus

$$\mathrm{tr}(T(\theta)) = \mathrm{tr}\left(\sum_i (t_{ii}(\theta) + t_{\bar{i}\bar{i}}(\theta)) + t_{pp}(\theta)\right) = 2\sum_i (d_{ii} + a_{ii}) + 1 = 2\sum_i e^{m_{ii}^{(+)}\theta} + 1, \tag{A22}$$

$$\mathrm{tr}(T^{(2)}(\theta)) = 2\sum_i (d_{ii}(d_{ii} + a_{ii}) + a_{ii}(d_{ii} + a_{ii})) + 1 = 2\sum_i (d_{ii} + a_{ii})^2 + 1 = 2\sum_i e^{2m_{ii}^{(+)}\theta} + 1, \tag{A23}$$

and continuing stepwise

$$\mathrm{tr}(T^{(r)}(\theta)) = 2\sum_{i=1}^{p-1} (d_{ii} + a_{ii})^r + 1 = 2\sum_{i=1}^{p-1} e^{rm_{ii}^{(+)}\theta} + 1. \tag{A24}$$

This is how the structure of our projector basis leads to a direct evaluation of $\mathrm{tr}(T^{(r)}(\theta))$ for the general case without the full list of eigenvalues. The trace is given by $2(p-1)+1=2p-1=N$ eigenvalues. The remaining (N^r-N) eigenvalues give zero trace, as we have seen, due to multiplet structures corresponding to roots of unity.

APPENDIX B: ENCOUNTER WITH A THEOREM OF FERMAT

A well-known theorem of Fermat states

$$N^r = N \bmod r, \tag{B1}$$

where (N, r) are positive integers and r is a prime number. Writing it as

$$N^r - N = rM, \tag{B2}$$

we try to obtain the integer M explicitly with the following purpose.

In Sec. VI we noted that out of N^r eigenvalues of the transfer matrix $T^{(r)}(\theta)$ of order $r(N^r - N)$ eigenvalues must give zero trace when summed. We have also seen how such a zero trace constraint is implemented in our case through multiplets corresponding to roots of unity as explained in (6.8)–(6.10). When r is a prime number the minimal multiplets can be consistently "r-plets" (or "nr-plets") only if (B2) is satisfied. But precisely this is guaranteed by (B1). This is the link of our multiplet structure with (B1). When r is factorizable one can have lower multiplets $(r_1, r_2, \ldots)$ for, say, $r = r_1 \cdot r_2 \cdots r_n$. This is already seen for $r=4$ in (6.10). We are interested here in odd integers N, but (B2) holds also for even N. We now construct M giving the number of r-plets.

Different constructions of M are certainly possible. The one particularly suitable for our purpose is as follow. One has for $r = 1, 3, 5, 7, 11, \ldots$, respectively,

$$N - N = 0,$$

$$N^3 - N = (N-1)N(N+1),$$

$$N^5 - N = (N-2)(N-1)N(N+1)(N+2) + 5(N-1)N(N+1),$$

$$N^7 - N = (N-3)(N-2)(N-1)N(N+1)(N+2)(N+3)$$

$$+ 7(2(N-2)(N-1)N(N+1)(N+2) + 3(N-1)N(N+1)).$$

Continuing thus with product of consecutive factors

$$N^{11}-N=(N-5)\cdots N\cdots(N+5)+11[5(N-4)\cdots N\cdots(N+4)+57(N-3)\ldots N\ldots(N+3)$$
$$+128(N-2)\cdots N\cdots(N+2)+31(N-1N(N+1))]. \tag{B3}$$

Thus for $N=3$, $r=3,5,7,\ldots$, one has, respectively, eight triplets, 48 5-plets, 312 7-plets, and so on (unless 10-plets, 14-plets, and so on are also obtained).

The first term is

$$\left(N-\frac{r-1}{2}\right)\cdots\left(N+\frac{r-1}{2}\right) \tag{B4}$$

and being a product of r consecutive integers, evidently divisible by r. The lower order products all have r as a factor. Hence the result. When $N\leqslant(r-1)/2$ one or more higher order products vanish. Although now N^r is not directly, visibly present on the right-hand side, the results still hold. Thus though $(N-3)$ vanishes in the leading term,

$$3^7-3=0+7\times(312). \tag{B5}$$

For completeness we give the general result below

$$N^r-N=\sum_{p=1}^{(r-1)/2}A_p(r)\prod_{k=-p}^{p}(N+k)\equiv\sum_{p=0}^{(r-1)/2}A_p(r)B(N,p), \tag{B6}$$

where

$$A_{(r-1)/2}(r)=1,$$

$$A_{(r-2k+1)/2}(r)=\sum_{m_1=1}^{k-1}\sum_{m_2=1}^{m_1-1}\cdots\sum_{m_{k-1}=1}^{m_{k-2}-1}\left[-\frac{H_{m_1}^{2k-2m_1}(r)}{(2k-2m_1)!}\right]\times\left[-\frac{H_{m_2}^{2m_1-2m_2}(r)}{(2m_1-2m_2)!}\right]\times\cdots$$

$$\times\left[-\frac{H_{m_{k-1}}^{2m_{k-2}-2m_{k-1}}(r)}{(2m_{k-2}-2m_{k-1})!}\right],\quad k=2,3,\ldots,\frac{r-1}{2}. \tag{B7}$$

The elements H_k^m are given by

$$H_k^m(r)=\left(\sum_{p_1=-(r-2k+1)/2}^{(r-2k+1)/2}p_1\right)\left(\sum_{\substack{p_2=-(r-2k+1)/2\\ p_2\neq p_1}}^{(r-2k+1)/2}p_2\right)\cdots\left(\sum_{\substack{p_m=-(r-2k+1)/2\\ p_m\neq p_1,\ldots,p_{m-1}}}^{(r-2k+1)/2}p_m\right),\quad m\neq 0,$$
$$H_k^0(r)=1. \tag{B8}$$

For example,

$$H_k^2(r)=-\tfrac{1}{12}(r-2k+1)(r-2k+2)(r-2k+3),$$

$$H_k^4(r)=\tfrac{1}{240}(5r+17-10k)(r+3-2k)(r-2k+2)(r-2k+1)(r-2k)(r-1-2k),$$

$$H_{(r-2k+1)/2}^{2k}(r)=(-1)^k(2k)!\,(k!)^2,\quad k=0,\ldots,\frac{r-1}{2},$$

$$H_{(r-2p+1)/2}^{2p+2k-r-1}(r)=(2p+2k-r-1)!\left.\frac{d^{r-2k+2}B(N,p)}{dN^{r-2k+2}}\right|_{N=0},\quad p=\frac{r-2k+1}{2},\ldots,\frac{r-1}{2},$$

$$H_{m_1}^{2k-2m_1}(r) = (2k-2m_1)!\ \left.\frac{d^{2m_1+1}B\left(N,\frac{r-2m_1+1}{2}\right)}{\mathrm{d}N^{2m_1+1}}\right|_{N=0}, \quad m_1 = k, \ldots, \frac{r-1}{2}. \tag{B9}$$

The above formula gives the general expression for the coefficients. But, as A. Lascoux has pointed out, the symmetric form of Newton's interpolation formula relevant for our case leads to complete functions as coefficients. These can be obtained systematically and conveniently. Thus one obtains, for example

$$\begin{aligned} N^{11} - N = {} & (N-5)\cdots N\cdots(N+5) \\ & + (N-4)\cdots N\cdots(N+4)(1^2+2^2+3^2+4^2+5^2) \\ & + (N-3)\cdots N\cdots(N+3)(1^4+2^4+3^4+4^4+1^2\times 2^2+1^2\times 3^2 \\ & + 1^2\times 4^2+2^2\times 3^2+2^2\times 4^2+3^2\times 4^2) \\ & + (N-2)\cdots N\cdots(N+2)(1^6+2^6+3^6+1^4\times 3^2+2^4\times 3^2 \\ & + 2^4\times 1^2+3^4\times 1^2+3^4\times 2^2+1^4\times 2^2+1^2\times 2^2\times 3^2) \\ & + (N-1)N(N+1)(1^8+2^8+1^6\times 2^2+2^6\times 1^2+1^4\times 2^4). \end{aligned} \tag{B10}$$

This gives (B3) in which 11 is already factorized.

APPENDIX C: $\hat{R}tt$-ALGEBRA

We present below a canonical formulation of the $\hat{R}tt$ algebra[14] specifically adapted to our case. The Baxterized form with N^2 blocks of $N\times N$ matrices $t_{ij}(\theta)$ must satisfy

$$\hat{R}(\theta-\theta')(t(\theta)\otimes t(\theta')) = (t(\theta')\otimes t(\theta))\hat{R}(\theta-\theta'), \tag{C1}$$

where (since $P^2=I$)

$$t(\theta)\otimes t(\theta') = (t(\theta)\otimes I)(I\otimes t(\theta)) \equiv t_1(\theta)t_2(\theta) = (t_1(\theta)P)(Pt_2(\theta)). \tag{C2}$$

But $t_1(\theta)=Pt_2(\theta)P$, hence

$$t_1(\theta)P = t_2(\theta)P \equiv \hat{t}(\theta). \tag{C3}$$

Thus

$$\hat{R}(\theta-\theta')\hat{t}(\theta)\hat{t}(\theta') = \hat{t}(\theta')\hat{t}(\theta)\hat{R}(\theta-\theta'), \tag{C4}$$

where one has just matrix multiplication of the same matrix $\hat{t}$ with arguments (θ,θ').

Now suppose that one has obtained explicitly the diagonalizer M of $\hat{R}(\theta)$. When

$$\hat{R}(\theta) = \sum_{\alpha,\beta} f_{\alpha,\beta}(\theta)P_{\alpha,\beta}, \tag{C5}$$

where $P_{\alpha\beta}$ form a complete basis of θ-independent projectors (and the minimal polynomial equation satisfied by $\hat{R}(\theta)$ has no multiple roots for consistency) one can construct a θ-independent M to diagonalize each $P_{\alpha\beta}$ simultaneously. For our nested sequence of projectors (1.3) the diagonalizer is given in Sec. III of Ref. 1 as

$$\begin{aligned}\sqrt{2}M = \sqrt{2}M^{-1} &= \sqrt{2}(pp)\otimes(pp)\\ &+ (pp)\otimes\left(\sum_i ((ii)-(\bar{i}\bar{i})+(i\bar{i})+(\bar{i}i))\right)\\ &+ \left(\sum_i ((ii)-(\bar{i}\bar{i})+(i\bar{i})+(\bar{i}i))\right)\otimes(pp)\\ &+ \sum_{ij}(((ii)-(\bar{i}\bar{i}))\otimes((jj)+(\bar{j}\bar{j}))+((i\bar{i})+(\bar{i}i))\otimes((j\bar{j})+(\bar{j}j))),\end{aligned} \tag{C6}$$

where

$$i = 1,2,\ldots,p-1,\quad \bar{i} = 2p-1,\ldots,p+1,\quad N = 2p-1. \tag{C7}$$

For $N=3$ ($p=2$), one obtains [see (3.5) of Ref. 1]

$$\sqrt{2}M = \sqrt{2}M^{-1} = (1,1,1,1,\sqrt{2},-1,-1,-1,-1)_{\text{diag}} + (1,1,1,1,\sqrt{2},1,1,1,1)_{\text{antidiag}} \tag{C8}$$

($\sqrt{2}$ being the common element of diag and antidiag).

The general case is now evident. Defining

$$M\hat{R}(\theta)M^{-1} = D(\theta) \tag{C9}$$

a diagonal matrix and

$$M\hat{t}(\theta)M^{-1} = K(\theta) \tag{C10}$$

quite generally

$$D(\theta-\theta')K(\theta)K(\theta') = K(\theta')K(\theta)D(\theta-\theta'). \tag{C11}$$

This is our canonical formulation.[15] For our present case (3.3), (3.4) of Ref. 1,

$$D(\theta) = \left(e^{m_{11}^{(+)}\theta}, e^{m_{12}^{(+)}\theta}, \ldots, e^{m_{11}^{(-)}\theta}\right). \tag{C12}$$

From (C11)

$$D_{aa}(\theta-\theta')K_{ac}(\theta)K_{cb}(\theta') = K_{ac}(\theta')K_{cb}(\theta)D_{bb}(\theta-\theta'). \tag{C13}$$

For $N=3$, for our case, defining the 3×3 diagonal blocks

$$\begin{aligned} d_{11}(\theta) &= (e^{m_{11}^{(+)}\theta}, e^{m_{12}^{(+)}\theta}, e^{m_{11}^{(+)}\theta})_{\text{diag}},\\ d_{22}(\theta) &= (e^{m_{21}^{(+)}\theta}, 1, e^{m_{21}^{(-)}\theta})_{\text{diag}},\\ d_{\bar{1}\bar{1}}(\theta) &= (e^{m_{11}^{(-)}\theta}, e^{m_{12}^{(-)}\theta}, e^{m_{11}^{(-)}\theta})_{\text{diag}},\end{aligned} \tag{C14}$$

and denoting $(K(\theta),K(\theta'),D(\theta-\theta'))\equiv(K,K',D'')$ when $d_{11}(\theta-\theta')\equiv d''_{11}$ and so on

$$\begin{pmatrix} d''_{11}(KK')_{11} & d''_{11}(KK')_{12} & d''_{11}(KK')_{1\bar{1}} \\ d''_{22}(KK')_{21} & d''_{22}(KK')_{22} & d''_{22}(KK')_{2\bar{1}} \\ d''_{\bar{1}\bar{1}}(KK')_{\bar{1}1} & d''_{\bar{1}\bar{1}}(KK')_{\bar{1}2} & d''_{\bar{1}\bar{1}}(KK')_{\bar{1}\bar{1}} \end{pmatrix} = \begin{pmatrix} (K'K)_{11}d''_{11} & (K'K)_{12}d''_{22} & (K'K)_{1\bar{1}}d''_{\bar{1}\bar{1}} \\ (K'K)_{21}d''_{11} & (K'K)_{22}d''_{22} & (K'K)_{2\bar{1}}d''_{\bar{1}\bar{1}} \\ (K'K)_{\bar{1}1}d''_{11} & (K'K)_{\bar{1}2}d''_{22} & (K'K)_{\bar{1}\bar{1}}d''_{\bar{1}\bar{1}} \end{pmatrix}. \tag{C15}$$

Substituting the explicit form of $(KK')_{ij}$ one obtains the full set of 81 relations (for $N=3$) of the $\hat{R}tt$-algebra. Each K_{ij} is a 3×3 block whose elements are the blocks of t_{ij}. Thus

$$2K_{11}=\begin{pmatrix} t_{11}+t_{\bar{1}\bar{1}} & t_{12}+t_{\bar{1}2} & t_{1\bar{1}}+t_{\bar{1}1} \\ 0 & 0 & 0 \\ t_{1\bar{1}}+t_{\bar{1}1} & t_{12}+t_{\bar{1}2} & t_{11}+t_{\bar{1}\bar{1}} \end{pmatrix} = (t_{11}+t_{\bar{1}\bar{1}})((11)+(\bar{1}\bar{1}))+(t_{12}+t_{\bar{1}2})((12)+(\bar{1}2))+(t_{1\bar{1}}+t_{\bar{1}1}) \times((1\bar{1})+(\bar{1}1)). \tag{C16}$$

In such a notation

$$2K_{\bar{1}\bar{1}}=(t_{11}+t_{\bar{1}\bar{1}})(-(11)+(\bar{1}\bar{1}))+(t_{12}+t_{\bar{1}2})(-(12)+(\bar{1}2))+(t_{1\bar{1}}+t_{\bar{1}1})(-(1\bar{1})+(\bar{1}1)), \tag{C17}$$

$$2K_{1\bar{1}}=(t_{11}-t_{\bar{1}1})((11)-(\bar{1}\bar{1}))+(t_{12}-t_{\bar{1}2})((12)-(\bar{1}2))+(t_{11}-t_{\bar{1}\bar{1}})((1\bar{1})-(\bar{1}1)), \tag{C18}$$

$$2K_{\bar{1}1}=(t_{1\bar{1}}-t_{\bar{1}1})((11)+(\bar{1}\bar{1}))+(t_{12}-t_{\bar{1}2})((12)+(\bar{1}2))+(t_{11}-t_{\bar{1}\bar{1}})((1\bar{1})+(\bar{1}1)), \tag{C19}$$

$$2K_{12}=(t_{11}+t_{1\bar{1}}+t_{\bar{1}1}+t_{\bar{1}\bar{1}})(21)+\sqrt{2}(t_{12}+t_{\bar{1}2})(22)+(t_{11}-t_{\bar{1}\bar{1}}+t_{\bar{1}1}-t_{\bar{1}\bar{1}})(2\bar{1}), \tag{C20}$$

$$2K_{\bar{1}2}=(t_{11}+t_{1\bar{1}}-t_{\bar{1}1}-t_{\bar{1}\bar{1}})(21)+\sqrt{2}(t_{12}-t_{\bar{1}2})(22)+(t_{11}-t_{\bar{1}\bar{1}}-t_{\bar{1}1}+t_{\bar{1}\bar{1}})(2\bar{1}), \tag{C21}$$

$$2K_{21}=(t_{21}+t_{2\bar{1}})((11)+(\bar{1}\bar{1}))+2t_{22}(12)+(t_{21}-t_{2\bar{1}})((\bar{1}1)-(\bar{1}\bar{1})), \tag{C22}$$

$$2K_{2\bar{1}}=(t_{21}-t_{2\bar{1}})(-(11)+(1\bar{1}))+2t_{22}(\bar{1}2)+(t_{21}+t_{2\bar{1}})((\bar{1}1)+(\bar{1}\bar{1})), \tag{C23}$$

$$2K_{22}=\sqrt{2}(t_{21}+t_{2\bar{1}})(21)+2t_{22}(22)+\sqrt{2}(t_{21}-t_{2\bar{1}})(2\bar{1}). \tag{C24}$$

We have not directly utilized the $\hat{R}tt$ constraints in constructing eigenstates. But since (C1) is the basic equation providing the starting point we present here the most compact approach to the full set of 81 constraints for $N=3$.

Time minimal trajectories for a spin 1/2 particle in a magnetic field

Ugo Boscain[a] and Paolo Mason[b]
SISSA, via Beirut 2-4 34014 Trieste, Italy

(Received 22 December 2005; accepted 12 April 2006; published online 2 June 2006)

In this paper we consider the minimum time population transfer problem for the z component of the spin of a (spin 1/2) particle, driven by a magnetic field, that is constant along the z axis and controlled along the x axis, with bounded amplitude. On the Bloch sphere (i.e., after a suitable Hopf projection), this problem can be attacked with techniques of optimal syntheses on two-dimensional (2-D) manifolds. Let $(-E,E)$ be the two energy levels, and $|\Omega(t)| \leq M$ the bound on the field amplitude. For each couple of values E and M, we determine the time optimal synthesis starting from the level $-E$, and we provide the explicit expression of the time optimal trajectories, steering the state one to the state two, in terms of a parameter that can be computed solving numerically a suitable equation. For $M/E \ll 1$, every time optimal trajectory is bang-bang and, in particular, the corresponding control is periodic with frequency of the order of the resonance frequency $\omega_R = 2E$. On the other side, for $M/E > 1$, the time optimal trajectory steering the state one to the state two is bang-bang with exactly one switching. For fixed E, we also prove that for $M \to \infty$ the time needed to reach the state two tends to zero. In the case $M/E > 1$ there are time optimal trajectories containing a singular arc. Finally, we compare these results with some known results of Khaneja, Brockett, and Glaser and with those obtained by controlling the magnetic field both on the x and y directions (or with one external field, but in the rotating wave approximation). As a byproduct we prove that the qualitative shape of the time optimal synthesis presents different patterns that cyclically alternate as $M/E \to 0$, giving a partial proof of a conjecture formulated in a previous paper. © *2006 American Institute of Physics.*

I. INTRODUCTION

A. Preliminaries

The issue of designing an efficient transfer of population between different atomic or molecular levels is crucial in atomic and molecular physics (see, e.g., Refs. 1–4). In the experiments, excitation and ionization are often induced by means of a sequence of laser pulses. The transfer should be as efficient as possible in order to minimize the effects of relaxation or decoherence that are always present. In the recent past years, people started to approach the design of laser pulses by using Geometric Control Techniques (see, for instance, Refs. 5–9). Finite-dimensional closed quantum systems are in fact left (or right) invariant control systems on $SU(n)$, or on the corresponding Hilbert sphere $S^{2n-1} \subset \mathbb{C}^n$, where n is the number of atomic or molecular levels. For these kinds of systems very powerful techniques were developed, both for what concerns controllability[10–13] and optimal control.[14–16]

[a]Electronic mail: boscain@sissa.it
[b]Electronic mail: mason@sissa.it

The dynamics of an n-level quantum system is governed by the time dependent Schrödinger equation (in a system of units such that $\hbar=1$),

$$i\dot{x}(t)=\left(H_0+\sum_{j=1}^{m}\Omega_j(t)H_j\right)x(t), \tag{1}$$

where $x(\cdot)$, defined on $[0,T]$, is a function taking values on the *state space* that is $SU(n)$ (if we formulate the problem for a time evolution operator) or the sphere S^{2n-1} (if we formulate the problem for the wave function). The quantity H_0 called the *drift Hamiltonian* is a Hermitian matrix, that is natural to assume diagonalized, i.e., $H_0=\mathrm{diag}(E_1,\ldots,E_n)$, where $E_1,\ldots,E_n$ are real numbers representing the *energy levels*. With no loss of generality we can assume $\Sigma_{j=1}^{n}E_j=0$. The real valued *controls* $\Omega_1(.),\ldots,\Omega_m(.)$, represent the *external pulsed field*, while the matrices H_j $(j=1,\ldots,m)$ are Hermitian matrices describing the coupling between the external fields and the system. The time dependent Hamiltonian $H(t):=H_0+\Sigma_{j=1}^{m}\Omega_j(t)H_j$ is called the *controlled Hamiltonian*.

The first problem that usually one would like to solve is the *controllability problem*, i.e., proving that for every couple of points in the state space one can find controls steering the system from one point to the other. For applications, the most interesting initial and final states are of course the *eigenstates of* H_0.

If $x\in SU(n)$, thanks to the fact that the control system (1) is a left invariant control system on the compact Lie group $SU(n)$, this occurs if and only if

$$\mathrm{Lie}\{iH_0,iH_1,\ldots,iH_m\}=su(n), \tag{2}$$

(see, for instance, Ref. 13). If the problem is formulated for the wave function, i.e., $x\in S^{2n-1}$, one can have controllability, with less restrictive conditions on the Lie algebra $\mathrm{Lie}\{iH_0,iH_1,\ldots,iH_m\}$, see Ref. 17. The problem of finding easily verifiable conditions under which (2) is satisfied has been deeply studied in the literature (see, for instance, Refs. 18 and 13). Here we just recall that the condition (2) is generic in the space of Hermitian matrices.

Once that controllability is proved, one would like to steer the system between two fixed points in the state space, in the most efficient way. Typical costs that are interesting to minimize for applications are as follows.

- Energy transferred by the controls to the system. $\int_0^T\Sigma_{j=1}^{m}\Omega_j^2(t)dt$,
- Time of transfer. In this case one can attack two different problems: one with *bounded* and one with *unbounded* controls.

The problem of minimizing time with unbounded controls has been deeply investigated in Refs. 19 and 8. The problems of minimizing time or energy with bounded controls are very difficult in general, and one can hope to find a complete solution in low dimension only.

In Refs. 5 and 20–22 a special class of systems, for which the analysis can be pushed much further, was studied, namely systems such that the drift term H_0 disappear in the interaction picture (by a unitary change of coordinates and a change of controls). For these systems the controlled Hamiltonian reads as

$$H(t)=\begin{pmatrix} E_1 & \mu_1\mathbf{\Omega}_1(t) & 0 & \cdots & 0 \\ \mu_1\mathbf{\Omega}_1^*(t) & E_2 & \mu_2\mathbf{\Omega}_2(t) & \ddots & \vdots \\ 0 & \mu_2\mathbf{\Omega}_2^*(t) & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & E_{n-1} & \mu_{n-1}\mathbf{\Omega}_{n-1}(t) \\ 0 & \cdots & 0 & \mu_{n-1}\mathbf{\Omega}_{n-1}^*(t) & E_n \end{pmatrix}. \tag{3}$$

Here $(^*)$ denotes the complex conjugation involution. The controls $\mathbf{\Omega}_1,\ldots,\mathbf{\Omega}_{n-1}$ are complex [they play the role of the real controls $\Omega_1,\ldots,\Omega_m$ in (1) with $m=2(n-1)$] and $\mu_j>0$ $(j$

$=1,\ldots,n-1$) are real constants describing the couplings (intrinsic to the quantum system) that we have restricted to couple only levels j and $j+1$ by pairs.

For $n=2$ the dynamics (3) describes the evolution of the z component of the spin of a (spin 1/2) particle driven by a magnetic field that is constant along the z axis and controlled both along the x and y axes, while for $n\geq 2$ it represents the first n levels of the spectrum of a molecule in the *rotating wave approximation* (see, for instance, Ref. 23), and assuming that each external fields couples only close levels. The complete solution to the optimal control problem between eigenstates of $H_0=\mathrm{diag}(E_1,\ldots,E_n)$ has been constructed for $n=2$ and $n=3$, for the minimum time problem with bounded controls (i.e., $|\mathbf{\Omega}_j|\leq M_j$) and for the minimum energy problem $\int_0^T\sum_{j=1}^{n-1}|\mathbf{\Omega}_j(t)|^2\,dt$ (with a fixed final time).

Remark 1: For the simplest case $n=2$ (studied in Refs. 5 and 7), the minimum time problem with bounded control and the minimum energy problem actually coincide. In this case the controlled Hamiltonian is

$$H(t)=\begin{pmatrix} -E & \mathbf{\Omega}(t) \\ \mathbf{\Omega}^*(t) & E \end{pmatrix}, \quad |\mathbf{\Omega}|\leq M, \tag{4}$$

and the optimal trajectories, steering the system from the first to the second eigenstate of $H_0=\mathrm{diag}(-E,E)$, correspond to controls in *resonance* with the energy gap $2E$, and with maximal amplitude, i.e., $\mathbf{\Omega}(t)=Me^{i[(2E)t+\phi]}$, where $\phi\in[0,2\pi[$ is an arbitrary phase. The quantity $\omega_R=2E$ is called the *resonance frequency*. In this case, the time of transfer T_C is proportional to the inverse of the laser amplitude. More precisely (see, for instance, Ref. 5), $T_C=\pi/(2M)$.

For $n=3$ the problem has been studied in Refs. 20 and 22, and it is much more complicated (in particular, when the coupling constants μ_1 and μ_2 are different). In the case of minimum time with bounded controls, it requires some nontrivial technical tools of 2-D syntheses theory for distributional systems that have been developed in Ref. 22.

For $n\geq 4$ the problem is very hard and still unsolved, but in Ref. 21, it has been proved that the optimal controls steering the system from any couple of eigenstates of H_0 are in *resonance*, i.e., they oscillate with a frequency equal to the difference of energy between the levels that the control is coupling. More precisely,

$$\mathbf{\Omega}_j=A_j(t)e^{i[(E_{j+1}-E_j)t+\phi_j]}, \quad j=1,\ldots,n-1, \tag{5}$$

where $A_j(.)$ are real functions describing the amplitude of the external fields and ϕ_j are arbitrary phases. Actually, this result holds for more general systems, initial and final conditions, and costs (see Ref. 21).

The problem of minimizing time with bounded controls or energy is even more difficult if it is not possible to eliminate the drift H_0. This occurs, for instance, in a system in the form (3) with real controls $\mathbf{\Omega}_j(t)=\mathbf{\Omega}_j^*(t)$, $j=1,\ldots,n-1$, as we are going to discuss now. (For more details on the elimination of the drift see Refs. 5, 20, and 21.)

B. A spin 1/2 particle in a magnetic field

In this paper we attack the simplest quantum mechanical model interesting for applications for which it is not possible to eliminate the drift, namely a *two-level quantum system* driven by a *real control*. This system describes the evolution of the z-component of the spin of a (spin 1/2) particle driven by a magnetic field, which is constant along the z axis and controlled along the x axis. Equivalently, it describes the first two levels of a molecule driven by an external field without the rotating wave approximation. The dynamics is governed by the time dependent Schrödinger equation (in a system of units such that $\hbar=1$):

$$i\frac{d\psi(t)}{dt} = H(t)\psi(t), \tag{6}$$

where $\psi(.)=[\psi_1(.),\psi_2(.)]^T:[0,T]\to\mathbb{C}^2$, $\Sigma_{j=1}^2|\psi_j(t)|^2=1$ [i.e., $\psi(t)$ belongs to the sphere $S^3\subset\mathbb{C}^2$], and

$$H(t)=\begin{pmatrix}-E & \Omega(t)\\ \Omega(t) & E\end{pmatrix}, \tag{7}$$

where $E>0$ and the control $\Omega(.)$, is assumed to be a real function. With the notation of formula (1), the drift Hamiltonian is

$$H_0=\begin{pmatrix}-E & 0\\ 0 & E\end{pmatrix},$$

while

$$H_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},$$

and the controllability condition (2) is satisfied.

Notice that for a spin 1/2 system, it is equivalent to treat the problem for the wave function or for the time evolution operator since S^3 is diffeomorphic to $SU(2)$. The aim is to induce a transition from the first eigenstate of H_0 (i.e., $|\psi_1|^2=1$) to any other *physical state*. We recall that two states $\psi,\psi'\in S^3$ are physically equivalent if they differ by a factor of phase. More precisely, by the physical state we mean a point of the two dimensional sphere (called the *Bloch sphere*) $\mathbf{S}_B:=S^3/\sim$ where the equivalence relation $\sim$ is defined as follows: $\psi\sim\psi'$ (where $\psi,\psi'\in S^3$) if and only if $\psi=\exp(i\Phi)\psi'$, for some $\Phi\in[0,2\pi[$. The projection from S^3 to $\mathbf{S}_B$ is called the *Hopf projection*, and it is given explicitly in the next section. A particularly interesting transition is of course from the first to the second eigenstates of H_0 (i.e., from $|\psi_1|^2=1$ to $|\psi_2|^2=1$).

Due to the presence of the drift, in this case the minimum time problem with bounded control and the minimum energy problem are different. In Ref. 7 the authors studied the minimum energy problem (in that case, optimal solutions can be expressed in terms of elliptic functions), while here we minimize the time of transfer, with a bounded field amplitude:

$$|\Omega(t)|\le M, \quad \text{for every } t\in[0,T], \tag{8}$$

where T is the time of the transition and $M>0$ represents the maximum amplitude available. This problem requires completely different techniques with respect to those used in Ref. 7.

Thanks to the reduction to a two dimensional problem (on the Bloch sphere), this problem can be attacked with the techniques of optimal syntheses on 2-D manifolds developed by Sussmann, Bressan, Piccoli, and the first author; see, for instance, Refs. 24–27 and recently rewritten in Ref. 15. We make a brief recall of these techniques in Appendix A.

C. The control problem on the Bloch sphere $\mathbf{S_B}$

An explicit Hopf projection from S^3 to $\mathbf{S}_\mathrm{B}$ is given by

$$\Pi:\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}\in S^3\subset\mathbb{C}^2\mapsto y=\begin{pmatrix}y_1\\ y_2\\ y_3\end{pmatrix}=\begin{pmatrix}-2\,\mathrm{Re}(\psi_1^*\psi_2)\\ 2\,\mathrm{Im}(\psi_1^*\psi_2)\\ |\psi_1|^2-|\psi_2|^2\end{pmatrix}\in\mathbf{S}_\mathrm{B}\subset\mathbb{R}^3. \tag{9}$$

Notice that Π maps the first eigenstate of H_0 (i.e., $|\psi_1|^2=1$) to the *North Pole* $P_N:=(0,0,1)^T$ of $\mathbf{S}_\mathrm{B}$, and the second eigenstate (i.e., $|\psi_2|^2=1$) to the *South Pole* $P_S:=(0,0,-1)^T$.

After setting $u(t)=\Omega(t)/M$, the Schrödinger equation (6), (7) projects to the following single input affine system (clarified below, after normalizations),

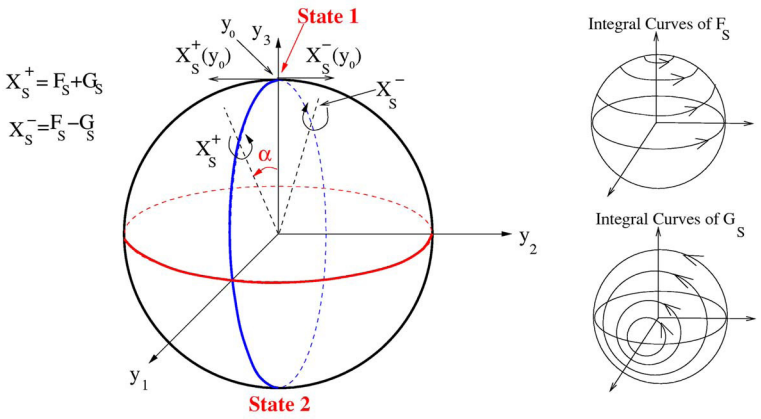

FIG. 1. (Color online) The Bloch sphere.

$$\dot{y} = F_S(y) + uG_S(y), \quad |u| \leq 1, \tag{10}$$

where

$$y \in \mathbf{S}_B := \left\{ (y_1, y_2, y_3) \in \mathbb{R}^3, \sum_{j=1}^{3} y_j^2 = 1 \right\}, \tag{11}$$

$$F_S(y) := k\cos(\alpha)\begin{pmatrix} -y_2 \\ y_1 \\ 0 \end{pmatrix}, \quad G_S(y) := k\sin(\alpha)\begin{pmatrix} 0 \\ -y_3 \\ y_2 \end{pmatrix}, \tag{12}$$

$$\alpha := \arctan\left(\frac{M}{E}\right) \in \left]0, \pi/2\right[, \quad k := 2E/\cos(\alpha) = 2\sqrt{M^2 + E^2}. \tag{13}$$

Remark 2 (**normalizations**)*:* In the following, to simplify the notations, we normalize $k=1$. This normalization corresponds to a reparametrization of the time. More precisely, if T is the minimum time to steer the state $\tilde{y}$ to the state $\bar{y}$ for the system with $k=1$, the corresponding minimum time for the original system is $T/(2\sqrt{M^2+E^2})$. Sometimes we need also the original system (6), (7) on S^3, with the normalization made in this remark, i.e., the system

$$i\frac{d\psi(t)}{dt} = \tilde{H}(t)\psi(t), \quad \text{where } \tilde{H}(t) = \frac{1}{2}\sin\alpha\begin{pmatrix} -\cot\alpha & u(t) \\ u(t) & \cot\alpha \end{pmatrix}. \tag{14}$$

We come back to the original value of k only in Sec. III C, where we compare our results with those of other authors.

We refer to Fig. 1. The vector fields $F_S(y)$ and $G_S(y)$ (that play the role, respectively, of H_0 and H_1) describe rotations, respectively, around the axes y_3 and y_1. Let us define the vector fields corresponding to constant control ± 1,

$$X_S^{\pm}(y) := F_S(y) \pm G_S(y). \tag{15}$$

The parameter $\alpha \in \left]0, \pi/2\right[$ (that is the only parameter of the problem) is the angle between the axes of rotations of F_S and X_S^+. The case $\alpha \geq \pi/4$ (resp., $\alpha < \pi/4$) corresponds to $M \geq E$ (resp., $M < E$).

Definition 1: An admissible control $u(.)$ *for the system* (10)–(13) *is a measurable function* $u(.):[a,b]\to[-1,1]$, *while an admissible trajectory is a Lipschitz functions* $y(.):[a,b]\to\mathbf{S}_B$ *sat-*

isfying (10), *a.e., for some admissible control* $u(.)$. *If* $y(.)$ *is an admissible trajectory and* $u(.)$ *the corresponding control, we say that* $[y(.),u(.)]$ *is an admissible pair.*

For every $\bar{y} \in \mathbf{S}_B$, our minimization problem is then to find the admissible pair steering the North Pole to $\bar{y}$ in minimum time. More precisely, we have the following.

Problem (P): *Consider the control system* (10)–(13). *For every* $\bar{y} \in \mathbf{S}_B$, *find an admissible pair* $[y(.),u(.)]$ *defined on* $[0,T]$ *such that* $y(0)=P_N$, $y(T)=\bar{y}$, *and* $y(.)$ *is time optimal.*

For us an optimal synthesis is the collection of all the solutions to the problem (**P**). More precisely we have the following.

Definition 2 (*optimal synthesis*)*: An optimal synthesis for the problem* (**P**) *is the collection of all time optimal trajectories* $\Gamma=\{y_{\bar{y}}(.):[0,b_{\bar{y}}]\mapsto \mathbf{S}_B,\ \bar{y} \in \mathbf{S}_B : y_{\bar{y}}(0)=P_N,\ y_{\bar{y}}(b_{\bar{y}})=\bar{y}\}$.

For more elaborated definitions of optimal synthesis see Refs. 15 and 28 and references therein.

Definition 3 [bang, singular for the problem (10)–(13)]: A control $u(.):[a,b]\to[-1,1]$ *is said to be a bang control if* $u(t)=+1$, *a.e., in* $[a,b]$ *or* $u(t)=-1$, *a.e., in* $[a,b]$. *A control* $u(.):[a,b]\to[-1,1]$ *is said to be a singular control if* $u(t)=0$, *a.e., in* $[a,b]$. *A finite concatenation of bang controls is called a bang-bang control. A switching time of* $u(.)$ *is a time* $\bar{t} \in [a,b]$ *such that, for every* $\varepsilon>0$, u *is not bang or singular on* $(\bar{t}-\varepsilon,\bar{t}+\varepsilon)\cap[a,b]$. *A trajectory of the control system (A4) is said a bang trajectory (or arc), singular trajectory (or arc), bang-bang trajectory, if it corresponds, respectively, to a bang control, singular control, bang-bang control. If* $\bar{t}$ *is a switching time, the corresponding point on the trajectory* $y(\bar{t})$ *is called a switching point.*

Remark 3: The definitions of singular trajectory and control, given above are very specific to our problem (10)–(13). For the definition of singular trajectories for more general systems see Definition 8, Appendix A.1.

In Ref. 29 it was proved that, for the same problem (10)–(13), but in which $y \in \mathbb{R}P^2$, for every couple of points there exists a time optimal trajectory joining them. Moreover it was proved that every time optimal trajectory is a finite concatenation of bang and singular trajectories. Repeating exactly the same arguments and recalling that S^2 is a double covering of $\mathbb{R}P^2$, one easily gets the same result on $\mathbf{S}_B$. More precisely we have the following.

Proposition 1: For the problem (10)–(13), *for each pair of points* p *and* q *belonging to* $\mathbf{S}_B$, *there exists a time optimal trajectory joining* p *to* q. *Moreover, every time the optimal trajectory for the problem* (10)–(13) *is a finite concatenation of bang and singular trajectories.*

Notice that the previous proposition does not apply if $\alpha=0$ or $\alpha=\pi/2$, since in these cases the controllability property is lost.

D. Purpose of the paper

Our aim is to study problem (**P**) for every possible value of the parameter α, giving a particular relief to the case in which $\bar{y}=P_S$ (i.e., to the optimal trajectory steering the North to the South Pole).

We will not be able to give a complete solution to the problem (**P**), without the help of numerical simulations. However, thanks to the theory developed in Ref. 15 we give a satisfactory description of the optimal trajectories. In the following we describe the main results and the structure of the paper.

For $\alpha<\pi/4$, every time optimal trajectory is bang-bang and, in particular, the corresponding control is periodic, in the sense that for every fixed optimal trajectory the time between two consecutive switchings is constant. Moreover, it tends to π as α goes to 0. For the original non-normalized problem this means that for $M/E \ll 1$, the optimal control oscillates with frequency of the order of the resonance frequency $\omega_R=2E$. In this case it is possible to give a satisfactory description of the optimal synthesis, excluding a neighborhood of the South Pole, in which we are able to find the optimal synthesis only numerically (such results were already given in Ref. 29, as we see later).

On the other side, if $\alpha \geq \pi/4$ the computation of the optimal trajectories is simpler since the number of switchings needed to cover the whole sphere is small (less than or equal than 2). In this

case, for α big enough, we are also able to give the exact value of the time needed to cover the whole sphere. However, there is a new difficulty, namely, the presence of singular arcs. Moreover, the qualitative shape of the optimal synthesis is rather different if α is close to $\pi/4$ or to $\pi/2$. A relevant fact is that this synthesis contains a singularity (the so called $(S,K)_3$) that is predicted by the general theory (see Ref. 15, pp. 61 and 82), and was never observed out from *ad hoc* examples.

The problem of finding explicitly the optimal trajectories from the North Pole P_N to the South Pole P_S, can be easily solved in the case $\alpha \geq \pi/4$ as a consequence of the construction of the time optimal synthesis. (Coming back to the original non-normalized problem, we also prove that at fixed E, for $M \to \infty$, the time of transfer from P_N to P_S tends to zero.)

For $\alpha < \pi/4$ the problem is more complicated. However, we are able to prove that if $u(t)$ is an optimal control steering the North Pole P_N to the South Pole P_S in time T, then $u(T-t)$ is as well (see Lemma 4 in Appendix B). Thanks to this fact, we can prove that the optimal trajectories steering the North to the South Pole belong to a set Ξ, containing, at most eight trajectories (half starting with control $+1$ and half starting with control -1, and switching exactly at the same times). These trajectories are determined in terms of a parameter (the first switching time) that can be easily computed numerically solving suitable equations. Once these trajectories are identified, one can check by hands which are the optimal ones.

The analysis can be pushed much forward. We also prove that the cardinality of Ξ depends on the so called *normalized remainder*,

$$\mathsf{R} := \frac{\pi}{2\alpha} - \left[\frac{\pi}{2\alpha}\right] \in [0,1[, \tag{16}$$

where $[.]$ denotes the integer part. In particular, for α small, we prove that if R is close to zero then Ξ contains exactly eight trajectories (and, in particular, there are four optimal trajectories), while if R is close to 1 then Ξ contains only four trajectories (two of them are optimal). The precise description of these facts is contained in Proposition 6, Sec. III B. As a consequence, the qualitative shape of the time optimal synthesis presents different patterns, that cyclically alternate, in the noncontrollability limit $\alpha \to 0$, giving a partial proof of a conjecture formulated in a previous paper (Ref. 29), that was supported by numerical simulations; see Remark 11. This is probably the most interesting byproduct of this paper.

Finally, we compare these results with some known results of Khaneja, Brockett, and Glaser and with those obtained by controlling the magnetic field both on the x and y directions.

The structure of the paper is as follows. In Sec. II we briefly resume the results of paper[29] that are connected to our problem and the conjectures formulated therein. The main results of the paper are described in Sec. III, while the proofs are postponed to Appendix B. In Appendix A we recall the main tools of the theory of optimal synthesis. In Appendix C we determine the last point reached by trajectories starting at P_N and the time needed to cover the whole sphere.

II. HISTORY OF THE PROBLEM AND KNOWN FACTS

The problem (**P**) (although with different purposes) was already partially studied in Ref. 29, in the case $\alpha < \pi/4$. In that paper the aim was to give an estimate on the maximum number of switchings for time optimal trajectories on $SO(3)$ (this problem was first studied by Agrachev and Gamkrelidze in Ref. 30, using index theory).

In Ref. 29 it has been proved that, for the problem (**P**) in the case $\alpha < \pi/4$, every optimal trajectory is bang-bang. More precisely, it was proved that in the case $\alpha < \pi/4$, if $y(.)$ is a time optimal trajectory starting at the North Pole, then it should satisfy the following properties.

(i) $y(.)$ is bang bang.
(ii) The duration s_i of the first bang arc satisfies $s_i \in [0, \pi]$.
(iii) The time duration between two consecutive switchings is the same for all *interior bang arcs* (i.e., excluding the first and the last bang), and it is the following function of s_i defined in the interval $[0, \pi]$,

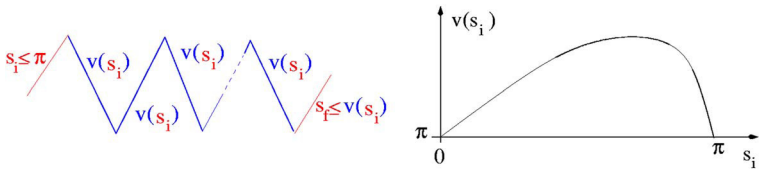

FIG. 2. (Color online) Time optimal trajectories for $\alpha < \pi/4$.

$$v(s_i) = \pi + 2\arctan\left(\frac{\sin(s_i)}{\cos(s_i) + \cot^2(\alpha)}\right). \tag{17}$$

One can immediately check that this function satisfies $v(0)=v(\pi)=\pi$ and $v(s_i)>\pi$ for every $s_i \in]0,\pi[$,

(iv) The time duration of the last arc is $s_f \in [0, v(s_i)]$.

Properties (i)–(iv) are illustrated in Fig. 2. Moreover, thanks to the analysis given in Ref. 29, one easily gets (always in the case $\alpha < \pi/4$).

(v) The number of switchings N_y of $y(.)$ satisfies the following inequality:

$$N_y \leq N_M := \left[\frac{\pi}{2\alpha}\right] + 1. \tag{18}$$

Conditions (i)–(v) define a set of candidate optimal trajectories. Notice that conditions (i)–(v) are just necessary conditions for optimality and one is faced with the problem of selecting, among them, those that are really optimal. In particular, given a trajectory satisfying conditions (i)–(v), one would like to find the time after which it is no more optimal. In the following we say that at this time the trajectory loses optimality.

The way in which these candidate optimal trajectories cover the whole sphere is shown in the top of Fig. 3.

Consider the following curves, made by points where the control switches from +1 to −1 or *vice versa*, called *switching curves*, defined by induction,

$$C_1^\varepsilon(s) = e^{X_S^\varepsilon v(s)} e^{X_S^{-\varepsilon} s} P_N, \quad C_k^\varepsilon(s) = e^{X_S^\varepsilon v(s)} C_{k-1}^{-\varepsilon}(s) \quad (\text{where } \varepsilon = \pm 1 \text{ and } k = 2, \ldots, N_M - 1). \tag{19}$$

See the top of Fig. 3.

Even if the analysis made in Ref. 29 was sufficient for the purpose of giving a bound on the maximum number of switchings for time optimal trajectories on $SO(3)$, some questions remained unsolved, in particular, questions about *local optimality* of the switching curves. Roughly speaking, we say that a switching curve is locally optimal if it never "reflects" the trajectories [see Fig. 4(A)]. [More precisely, consider a smooth switching curve C between two smooth vector field Y_1 and Y_2 on a smooth two-dimensional manifold. Let $C(s)$ be a smooth parametrization of C. We say that C is *locally optimal* if, for every $s \in \mathrm{Dom}(C)$, we have $\dot{C}(s) \neq \alpha_1 Y_1(C(s)) + \alpha_2 Y_2(C(s))$, for every α_1, α_2 s.t. $\alpha_1 \alpha_2 \geq 0$. The points of a switching curve on which this relation is not satisfied are usually called "conjugate points." See Fig. 4. The terminology "conjugate points" and "cut locus" comes from Riemannian Geometry.] When a family of trajectories is reflected by a switching curve, then local optimality is lost and some *cut locus* appear in the optimal synthesis.

Definition 4: A cut locus for the problem (**P**) *is a set of points reached at the same time by two* (*or more*) *optimal trajectories. A subset of a cut locus that is a connected* $\mathcal{C}^1$ *manifold is called the overlap curve*.

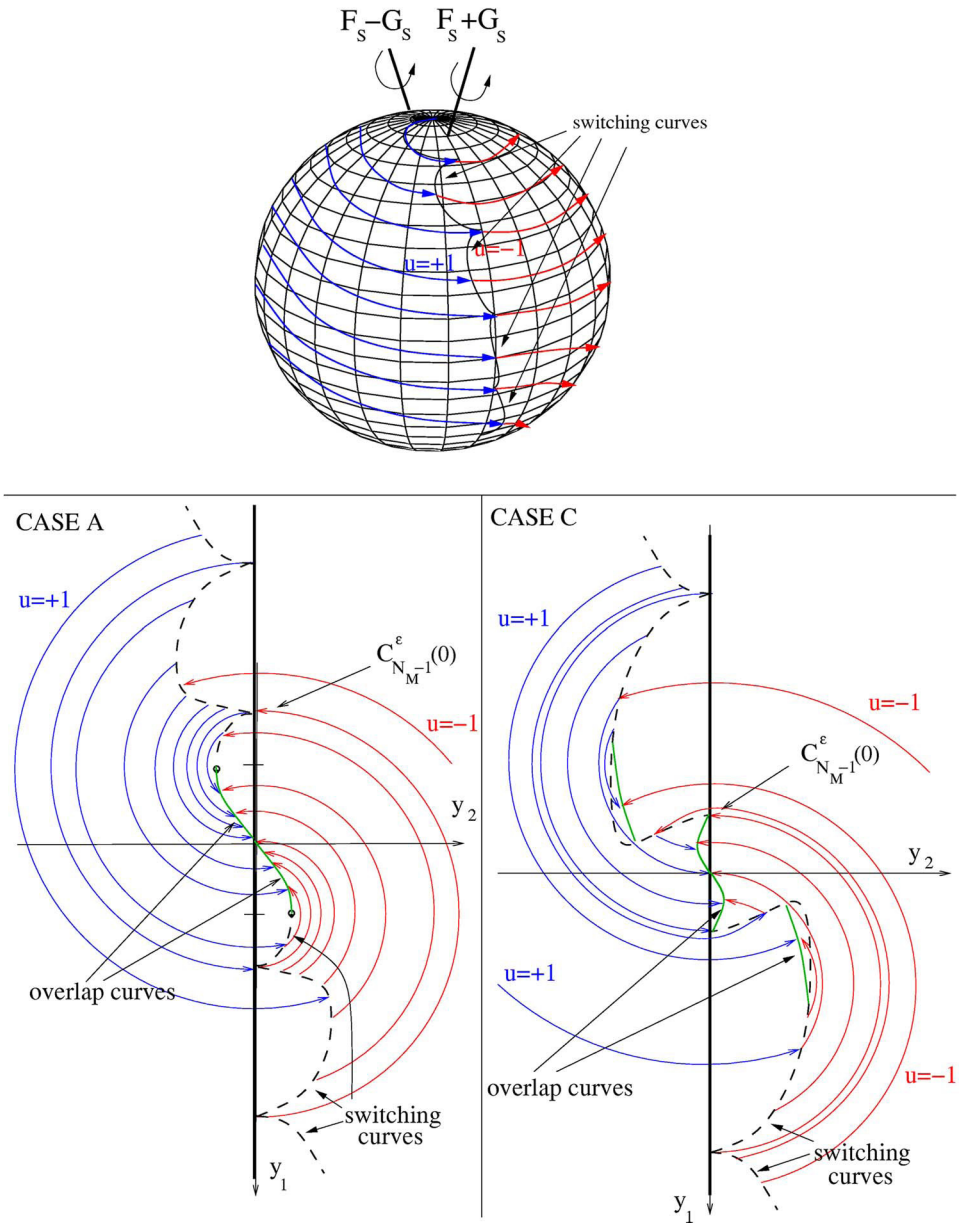

FIG. 3. (Color online) Synthesis on the sphere for $\alpha < \pi/4$ and a conjectured shape in a neighborhood of the South Pole.

An example showing how a "reflection" on a switching curves generate a cut locus is portrayed in Figs. 4(B) and 4(C). More details are given later. In Ref. 29, the following questions remain unsolved.

Question 1: Are the switching curves C_k^ε, $k=1,\ldots,N_M-1$, locally optimal? More precisely, one would like to understand how the candidate optimal trajectories previously described are going to lose optimality.

Question 2: What is the shape of the optimal synthesis in a neighborhood of the South Pole?

Numerical simulations suggested some conjectures regarding the previous questions. More precisely, we have the following

C1: Define $k_{\text{last}}=[(\pi-\alpha)/2\alpha]-1$. Then the curves $C_k^\varepsilon(s)$, $(k=1,\ldots,N_M-1)$ are locally optimal if and only if $k \leq k_{\text{last}}$. Notice that $k_{\text{last}} \in \{N_M-3, N_M-2\}$.

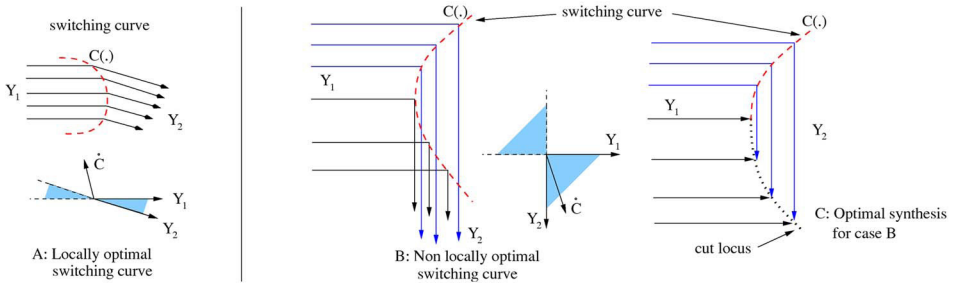

FIG. 4. (Color online) Locally optimal switching curves and nonlocally optimal switching curves with the corresponding synthesis.

Analyzing the evolution of the minimum time wave front in a neighborhood of the South Pole, it is reasonable to conjecture the following.

C2: The shape of the optimal synthesis in a neighborhood of the South Pole depends on the so called *remainder* $r := \pi - 2\alpha[\pi/2\alpha]$. [Notice that $r = 2\alpha\mathsf{R}$, where R has been defined in formula (16). In conjecture **C2**, we use the remainder r to keep the same notation of Ref. 29.] Notice that r belongs to the interval $[0, 2\alpha[$. More precisely, we conjecture that for $\alpha \in]0, \pi/4[$, there exist two positive numbers α_1 and α_2 such that $0 < \alpha_1 < \alpha < \alpha_2 < 2\alpha$ and the following:

CASE A: $r \in]\alpha_2, 2\alpha[$. The switching curve $C^{\varepsilon}_{N_M-1}$ glues to an overlap curve that passes through the origin (Fig. 3, Case A).

CASE B: $r \in [\alpha_1, \alpha_2]$. The switching curve $C^{\varepsilon}_{N_M-1}$ is not reached by optimal trajectories in the interval $]0, \pi]$. At the point $C^{\varepsilon}_{N_M-1}(0)$ an overlap curve starts and passes through the origin.

CASE C: $r \in]0, \alpha_1[$. The situation is more complicated and it is depicted in the bottom of Fig. 3, Case C.

For $r = 0$, the situation is the same as in CASE A, but for the switching curve starting at $C^{\varepsilon}_{N_M-2}(0)$.

III. MAIN RESULTS

We give here a brief description of the main results of the paper. The corresponding proofs are given in Appendix B. From now on we use the following conventions.

Remark 4 (*notation*)*:* Recall Definition 3. The letter B refers to a bang trajectory and the letter S refers to a singular trajectory. A concatenation of bang and singular trajectories is labeled by the corresponding letter sequence, written in order from left to right. Sometimes, we use a subscript to indicate the time duration of a trajectory so that we use B_t to refer to a bang trajectory defined on an interval of length t and, similarly, S_t for a singular trajectory defined on an interval of length t. Moreover, we indicate by γ^+ (resp., γ^-) the trajectory of (10)–(13) starting at the North Pole at time zero and corresponding to control $u \equiv 1$ (resp., $u \equiv -1$). Notice that $\gamma^{\pm}$ are defined for every time, and are periodic. Finally, we use the following subsets of $\mathbf{S}_{\mathrm{B}}$: the circle of equation $y_3 = 0$ called the *equator*, the set $y_3 > 0$, called *northern hemisphere* and the set $y_3 < 0$, called *southern hemisphere*.

From Sec. II, recall the definitions of switching curves, cut loci, and overlap curves.

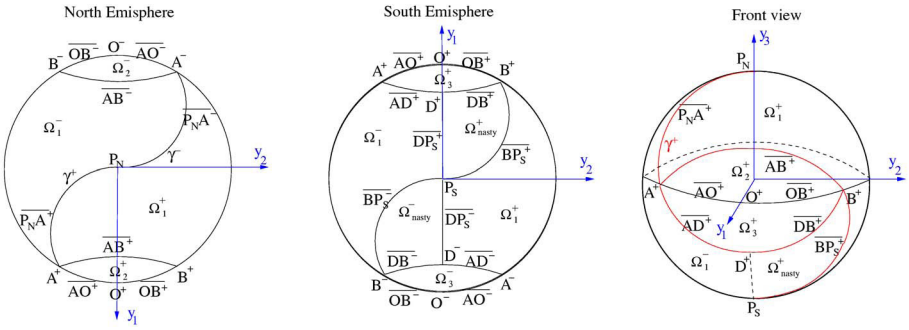

FIG. 5. (Color online) Definition 5.

A. Optimal synthesis for $\alpha \geq \pi/4$

In this section we describe the time optimal synthesis for $\alpha \geq \pi/4$. We divide $\mathbf{S}_B$ in 8 open regions called $\Omega_1^{\pm}, \ldots, \Omega_3^{\pm}$, $\Omega_{\text{nasty}}^{\pm}$ and in 16 arcs (see Definition 5, and Fig. 5). For every point $\bar{y} \in \mathbf{S}_B \setminus (\Omega_{\text{nasty}}^{+} \cup \Omega_{\text{nasty}}^{-})$, Theorem 1 gives the optimal trajectories reaching $\bar{y}$.

Unlike the $\alpha < \pi/4$ case, here it is possible to detect the presence of singular trajectories that are optimal, and also of cut loci (even not only in a neighborhood of the South Pole).

The region $\Omega_{\text{nasty}}^{+}$ (and similarly $\Omega_{\text{nasty}}^{-}$) is more difficult to analyze. It contains a cut locus that should be determined numerically. Even if we are not able to provide an analytic characterization of this locus, we are able to prove the following.

(i) $\alpha = \arcsin(1/\sqrt[4]{2})$ is a bifurcation point for the optimal synthesis, i.e., the qualitative shape is different if $\alpha \in [\pi/4, \arcsin(1/\sqrt[4]{2})[$ (called **Case 1**) or $\alpha \in [\arcsin(1/\sqrt[4]{2}), \pi/2[$ (called **Case 2**). More precisely, from the point $D^+ := \gamma^+(\pi)$, in **Case 1** it starts an optimal switching curve, while in **Case 2** it starts an overlap curve (see Proposition 3). The situation in $\Omega_{\text{nasty}}^{-}$ is symmetric.

(ii) The South Pole belongs to the cut locus and it is reached exactly by four optimal trajectories (see Proposition 2).

Numerical computations show that in **Case 2** the cut locus in $\Omega_{\text{nasty}}^{+}$ is an overlap curve connecting D^+ with the South Pole, while in **Case 1**, the switching curve starting from D^+ loses local optimality at a point of $\Omega_{\text{nasty}}^{+}$ and connects to an overlap curve that reaches the South Pole (see Fig. 6). Remark 9 explains that in **Case 2** it is not necessary to compute the cut locus lying

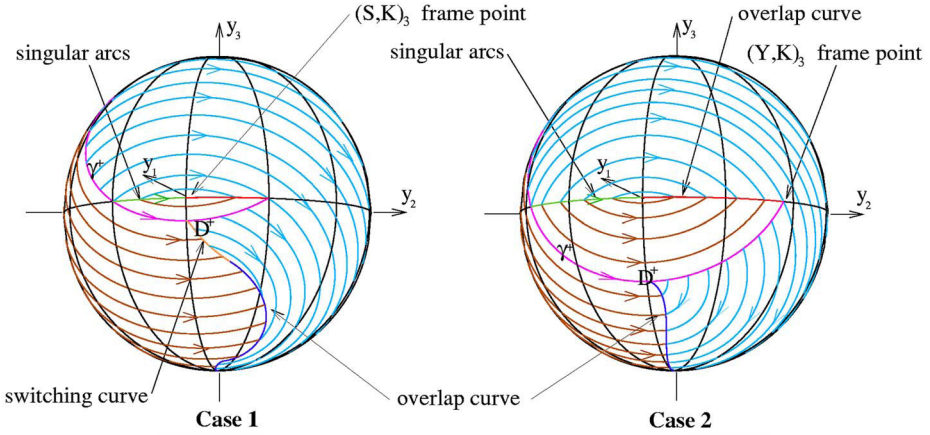

FIG. 6. (Color online) Optimal synthesis for $\alpha = \pi/3$ and α slightly larger than $\pi/4$.

in Ω^+_{nasty} to get the expression of the optimal trajectory connecting P_N to a point of Ω^+_{nasty}. The situation in Ω^-_{nasty} is symmetric.

Let us start with the description of the optimal synthesis in $\mathbf{S}_{\mathrm{B}}\backslash(\Omega^+_{\text{nasty}}\cup\Omega^-_{\text{nasty}})$. Even if Definition 5 and Theorem 1 look complicated, the shape of the optimal synthesis is quite simple, as it is shown in Fig. 6.

Definition 5: *According to Fig.* 5, *let us define the following curves on* $\mathbf{S}_{\mathrm{B}}$.

- *Let* t_1 *be the first time at which* γ^+ *intersects the equator and let* $A^+ := \gamma^+(t_1)$ [*notice that* $t_1=\pi-\arccos(\cot^2(\alpha))$]. *Define* $\overline{P_NA^+}=Supp(\gamma^+|_{[0,t_1]})$.
- *Let* ξ^- *be the trajectory corresponding to control* -1, *starting at time zero from* A^+. *Let* t_2 *be the first positive time at which* ξ^- *intersects the equator* [*notice that* $t_2=2\arccos(\cot^2(\alpha))$]. *Define* $B^+ := \xi^-(t_2)$ *and* $\overline{AB^+}=Supp(\xi^-|_{[0,t_2]})$.
- *Let* $O^+=(1,0,0)$. *Define* $\overline{AO^+}$ (*resp.*, $\overline{OB^+}$) *as the support of the trajectory corresponding to control zero, starting at* A^+ (*resp.*, O^+) *and ending at* O^+ (*resp.*, B^+).
- *Recall that* $D^+=\gamma^+(\pi)$, *and define* $\overline{AD^+}=Supp(\gamma^+|_{[t_1,\pi]})$, $\overline{DB^+}=Supp(\gamma^+|_{[\pi,t_3]})$, *where* t_3 *is the second intersection time of* γ^+ *with the equator* [*notice that* $t_3=\pi+\arccos(\cot^2(\alpha))=t_1+t_2$].
- *Let* $\overline{BP^+_S}$ *the support of the trajectory corresponding to control* -1, *starting at* B^+ *and ending at the South Pole*.
- *Let* $\overline{DP^+_S}$ *the connected subset of the meridian* $y_2=0$, *lying in the southern hemisphere and connecting the point* D^+ *to the South Pole*.

Similarly, define A^-, B^-, O^-, D^-, $\overline{P_NA^-}$, $\overline{AB^-}$, $\overline{AO^-}$, $\overline{OB^-}$, $\overline{AD^-}$, $\overline{DB^-}$, $\overline{BP^-_S}$, $\overline{DP^-_S}$.

According to Fig. 5, *define* $\Omega^\pm_1,\dots,\Omega^\pm_4,\Omega^\pm_{\text{nasty}}$ *as the open connected components of the open set obtained subtracting from* $\mathbf{S}_{\mathrm{B}}$ *all the arcs previously defined.*

The following theorem holds for every $\alpha\in\,]\pi/4,\pi/2[$. For the particular value $\alpha=\pi/4$, the claims of the theorem must be modified. Such changes are reported in Remark 5.

Theorem 1: *Let* $\gamma_{\bar y}$ *be the set of time optimal trajectories steering the North Pole to* $\bar y$. *We have the following*:

T1. *If* $\bar y\in\overline{P_NA^+}$, *then* $\gamma_{\bar y}$ *is made by a unique trajectory corresponding to control* $+1$ *of the form* B_t, *with* $t\le t_1$.
T2. *If* $\bar y\in\overline{AB^+}\backslash B^+$, *then* $\gamma_{\bar y}$ *is made by a unique trajectory of the form* $B_{t_1}B_t$ (*with the first bang corresponding to control* $+1$).
T3. *If* $\bar y\in\overline{AO^+}$, *then* $\gamma_{\bar y}$ *is made by a unique trajectory of the form* $B_{t_1}S_s$ (*with the first bang corresponding to control* $+1$).
T4. *If* $\bar y\in\overline{OB^+}\backslash O^+$, *then* $\gamma_{\bar y}$ *is made by two trajectories of the form* $B_{t_1}S_sB_t$, *both starting with control* $+1$ *and ending, respectively, with control* $+1$ *and* -1. *These two trajectories have the same values of* $s\ge 0$ *and* $t>0$.
T5. *If* $\bar y\in\overline{AD^+}$, *then* $\gamma_{\bar y}$ *is made by a unique trajectory corresponding to control* $+1$ *of the form* B_t, *with* $t\in[t_1,\pi]$.
T6. *If* $\bar y\in\overline{DB^+}\backslash B^+$, *then* $\gamma_{\bar y}$ *is made by a unique trajectory corresponding to control* $+1$ *of the form* B_t, *with* $t\in[\pi,t_3[$.
T7. *If* $\bar y\in\overline{BP^+_S}$ *then* $\gamma_{\bar y}$ *is made by two trajectories, respectively, of the form* $B_{t_1}B_t$ *and* $B_{t_3}B_{t-t_2}$ *and starting with control* $+1$.
T8. *If* $\bar y\in\Omega^+_1\cup(\overline{DP^-_S}\backslash P_S)$, *then* $\gamma_{\bar y}$ *is made by a unique trajectory of the form* $B_tB_{t'}$, *with* $0\le t<t_1$ *and the first bang corresponding to control* $+1$.
T9. *If* $\bar y\in\Omega^+_2$, *then* $\gamma_{\bar y}$ *is made by a unique trajectory of the form* $B_{t_1}S_sB_t$, *with* $s>0$, *the first bang arc and the last bang arc corresponding respectively to control* $+1$ *and* -1.
T10. *If* $\bar y\in\Omega^+_3$, *then* $\gamma_{\bar y}$ *is made by a unique trajectory of the form* $B_{t_1}S_sB_t$, *with* $s>0$ *and both bang arcs corresponding to control* $+1$.
T11. *If* $\bar y=P_S$ *then* $\gamma_{\bar y}$ *is made by the four trajectories of the form* $B_{t_1}B_{t_3}$ *and* $B_{t_3}B_{t_1}$.
T12. *If* $\bar y\in\Omega^+_{\text{nasty}}$ *then every trajectory of* $\gamma_{\bar y}$ *is bang-bang with, at most, two switchings.*

If $\bar y$ *belongs to one of the remaining sets defined previously, the description of the optimal*

strategy is analogous, by symmetry.

Remark 5: In the case $\alpha=\pi/4$, some changes in the previous statement are required. In particular, the points A^+, B^+, O^+, and D^+ coincide (also the points A^-, B^-, O^-, and D^- coincide) and, consequently, there are no optimal trajectories containing singular arcs. Another immediate consequence of this fact is that there are only two optimal trajectories reaching the South Pole, of the form $B_\pi B_\pi$.

Remark 6: Notice that every point of $\overline{OB^+}\backslash O^+$, $\overline{OB^-}\backslash O^-$, $\overline{BP_S^+}$, $\overline{BP_S^-}$ is reached by more than one optimal trajectory, i.e., it belongs to the cut locus. Other points of the cut locus can be identified numerically in Ω^+_{nasty} and Ω^-_{nasty}, as explained in the next section.

Remark 7: In Theorem 1 we do not specify all the durations of the bang arcs. However, the missing ones can be obtained simply by following the switching strategy backward.

Remark 8: Note that the region reached by optimal trajectories containing a singular arc $\Omega_2^\pm\cup\Omega_3^\pm\cup\overline{AO^\pm}\cup\overline{OB^\pm}$ become bigger and bigger as α tends to $\pi/2$. Moreover, in this limit, since the modulus of the drift F_S becomes smaller and smaller, the time needed to cover such a region tends to infinity. Notice, however, that the time needed to reach P_S is always 2π. The time needed to reach every point of the sphere for α big enough, and the last point reached by an optimal trajectory containing a singular arc, can be computed explicitly. This is done in Appendix C.

Since the case $\bar{y}=P_S$ is important also for the determination of the cut locus in $\Omega^+_{\text{nasty}}\cup\Omega^-_{\text{nasty}}$, it is reported in the next section as a separate proposition (see Proposition 2).

1. The time optimal synthesis in $\Omega^\pm_{\text{nasty}}$ and optimal trajectories reaching P_S for $\alpha\geq\pi/4$

From the next proposition, T11 of Theorem 1 follows. More precisely, Proposition 2 shows that in the case $\alpha\geq\pi/4$, there are exactly four optimal trajectories steering P_N to P_S, and it characterizes them. As a consequence, the South Pole belongs to the cut locus.

Proposition 2: Consider the control system (10)–(13), *and assume* $\alpha\geq\pi/4$. *Then the optimal trajectories steering the North Pole to the South Pole are bang-bang with only one switching. More precisely, they are the four trajectories corresponding to the four controls*:

$$u^{(1)}=\begin{cases} u=1,\ t\in[0,t_1],\\ u=-1,\ t\in\,]\,t_1,T],\end{cases}\qquad u^{(2)}=\begin{cases} 1,\ t\in[0,t_3],\\ -1,\ t\in\,]\,t_3,T],\end{cases}$$

$$u^{(3)}=\begin{cases} -1,\ t\in[0,t_1],\\ 1,\ t\in\,]\,t_1,T],\end{cases}\qquad u^{(4)}=\begin{cases} -1,\ t\in[0,t_3],\\ 1,\ t\in\,]\,t_3,T],\end{cases}$$

where t_1 *and* t_3 *are defined in Definition 5, and* $T=2\pi$.

One can easily check that the switchings described in Proposition 2 occur on the equator ($y_3=0$).

The following proposition describes the optimal synthesis in $\Omega^\pm_{\text{nasty}}$, in a neighborhood of the points $D^\pm$ and the bifurcation occurring at $\alpha=\arcsin(1/\sqrt[4]{2})$.

Proposition 3: Let $\alpha\geq\pi/4$. *In a neighborhood of the point* D^+ *in* Ω^+_{nasty}, *there exists a switching curve starting at* D^+ *of the form* $e^{v(s)X_S^+}e^{sX_S^-}P_N$. *If* $\alpha>\pi/4$, *this curve is tangent to the equator at* D^+. *Moreover, if* $\alpha<\arcsin(1/\sqrt[4]{2})$ (*called* **Case 1**), *then the switching curve is optimal near* D^+, *while if* $\alpha\geq\arcsin(1/\sqrt[4]{2})$ (*called* **Case 2**) *then the switching curve is not locally optimal near* D^+ *and an overlap curve starts at the point* D^+. *A symmetric result holds in a neighborhood of* D^- *in* Ω^-_{nasty}.

The region Ω^+_{nasty} contains a cut locus that should be determined numerically. In **Case 2**, numerical simulations show that the switching curve starting at D^+ is never optimal, i.e., every point of Ω^+_{nasty} is reached by an optimal trajectory of the form $e^{tX_+}e^{sX_-}P_N$, with $s\in\,]0,t_1[$ or an optimal trajectory of the form $e^{tX_-}e^{sX_+}P_N$, with $s\in\,]\pi,t_3[$.

Remark 9: Notice, however, that, in **Case 2**, given a point $\bar{y}\in\Omega^+_{\text{nasty}}$, to find the time optimal trajectory reaching $\bar{y}$, it is not necessary to compute the cut locus. Indeed it is sufficient to compare

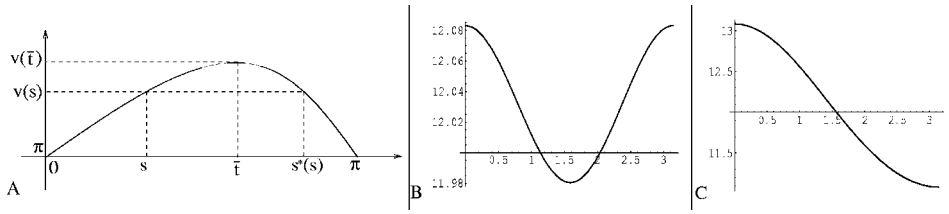

FIG. 7. Graph of $v(.)$ when $\alpha=\pi/6$ (A). Graph of the functions $\mathcal{F}$ and $\mathcal{G}$ when $\alpha=0.13$ (B) and (C).

the final times, corresponding to the two switching strategies given previously, and to chose the quickest one. The situation in Ω^-_{nasty} is symmetric.

In **Case 1**, the situation is more complicated. The switching curve described by Proposition 3 has the expression $C_1^+(s)=e^{X_S^+v(s)}e^{X_S^-s}P_N$, $s\in]0,t_1[$ where the function $v(.)$ is given by the same formula of the $\alpha<\pi/4$ case, i.e. $v(s)=\pi+2\arctan[(\sin s)/(\cos s+\cot^2\alpha)]$. (To verify such a formula, it is enough to repeat the computations done in Ref. 29.) As described by Proposition 3, this switching curve is optimal near D^+ and numerical simulations show that there exists $\bar{s}\in]0,t_1[$ such that there is an optimal trajectory switching on $C_1^+(s)$ if and only if $s\in[0,\bar{s}[$, and an overlap curve connecting $C_1^+(\bar{s})$ to the South Pole appears. The optimal synthesis for **Case 1** and **Case 2** is depicted in Fig. 6.

B. Optimal trajectories reaching the South Pole for $\alpha<\pi/4$

In this section we characterize the time optimal trajectories reaching the South Pole, in the case $\alpha<\pi/4$. This characterization is more complicated with respect to the case $\alpha\geq\pi/4$, due to the fact that the optimal trajectories have many switchings. The time optimal synthesis for $\alpha<\pi/4$ was already (partially) studied in Ref. 29, and it has been described in Sec. II.

From conditions (i)–(iv) in Sec. II, we know that every optimal trajectory starting at the North Pole has the form $B_{s_i}B_{v(s_i)}\cdots B_{v(s_i)}B_{s_f}$, where the function $v(s_i)$ is given by formula (17). [In the following we do not specify if the first bang corresponds to control $+1$ or -1, since, as a consequence of the symmetries of the problem, if $u(t)$ is an optimal control steering the North Pole to the South Pole, $-u(t)$ steers the North Pole to the South Pole as well.] It remains to identify one or more values of s_i,s_f and the corresponding number of switchings n for this trajectory to reach the South Pole.

Notice that $\bar{t}=\arccos(-\tan^2(\alpha))$ is the maximum of the function $v(.)$ on the interval $[0,\pi]$, $v(.)$ is increasing on $[0,\bar{t}]$ and decreasing on $[\bar{t},\pi]$ and $v(0)=v(\pi)=\pi$. Then, given $s\in[0,\pi]$ such that $s\neq\bar{t}$, there is a unique solution $s^*(s)\in[0,\pi]$, $s^*(s)\neq s$, to the equation $v(s^*)=v(s)$. The function $s^*(.)$ is extended to the whole interval $[0,\pi]$, setting $s^*(\bar{t})=\bar{t}$ [see Fig. 7(A)]. Thanks to the symmetries of the problem, we prove that if $\alpha<\pi/4$, s_f is equal either to s_i or to $s^*(s_i)$. This fact is described by Lemma 4 stated and proved in Appendix B.

The following two propositions describe how to identify candidate triples (s_i,s_f,n) for which the corresponding trajectory steers the North Pole to the South Pole in minimum time. From now on, all along the paper, we say that a bang-bang trajectory, solution of the system (10)–(13), is a *candidate optimal trajectory* if it is an extremal trajectory for problem (**P**) reaching the South Pole and it has a number n of switchings satisfying $n\leq N_M$ [defined in Formula (18)]. From Lemma 4, there are two kinds of candidate optimal trajectories:

- $s_f=s^*(s_i)$, called TYPE-1-candidate optimal trajectories
- $s_f=s_i$ called TYPE-2-candidate optimal trajectories

Define the following functions, whose geometric meaning is clarified in Appendix B.2:

$$\theta(s)=2\arccos\left(\sin^2\left(\frac{v(s)}{2}\right)\cos(2\alpha)-\cos^2\left(\frac{v(s)}{2}\right)\right), \tag{20}$$

$$\beta(s) = 2\arccos(\sin(\alpha)\cos(\alpha)(1-\cos(s))). \tag{21}$$

Proposition 4 (TYPE-1-trajectories): Fixed $\alpha < \pi/4$, *the equation for the couple* $(s,n) \in [0,\pi]\times\mathbb{N}$:

$$\mathcal{F}(s) := \frac{2\pi}{\theta(s)} = n, \tag{22}$$

has either two or zero solutions. More precisely, if (s,n) *is a solution to Eq.* (22), *then* $(s^*(s),n)$ *is the second one. The trajectories* $B_s\underbrace{B_{v(s)}\cdots B_{v(s)}}_{n-1}B_{s^*(s)}$ *and* $B_{s^*(s)}\underbrace{B_{v(s)}\cdots B_{v(s)}}_{n-1}B_s$ *are the TYPE-1-candidate optimal trajectories.*

Proposition 5 (TYPE-2-trajectories): Fixed $\alpha < \pi/4$, *the equation for the couple* $(s,n) \in [0,\pi]\times\mathbb{N}$:

$$\mathcal{G}(s) := \frac{2\beta(s)}{\theta(s)} + 1 = n, \tag{23}$$

has exactly two solutions. More precisely these solutions have the form (s_1,n), $(s_2,n+1)$. *The trajectories* $B_{s_1}\underbrace{B_{v(s_1)}\cdots B_{v(s_1)}}_{n-1}B_{s_1}$ *and* $B_{s_2}\underbrace{B_{v(s_2)}\cdots B_{v(s_2)}}_{n}B_{s_2}$ *are the TYPE-2-candidate optimal trajectories.*

In Figs. 7(B) and 7(C), the graphs of the functions (22) and (23) are drawn for a particular value of α, namely $\alpha=0.13$. Propositions 4 and 5 select a set of (possibly coinciding) four or eight candidate optimal trajectories (half of them starting with control +1 and the other half with control −1) corresponding to triples (s_i,s_f,n). Such triples can be easily computed numerically solving Eqs. (22) and (23). Then the optimal trajectories can be selected by comparing the times needed to reach the South Pole for each of the candidate optimal trajectory. Notice that there are at least two optimal trajectories steering the North to the South Pole (one starting with control +1 and the other with control −1).

If $\pi/(2\alpha)$ is an integer number $\bar{n}$, then TYPE-1 candidate optimal trajectories coincide with the TYPE-2 candidate optimal trajectories of the form $B_\pi\underbrace{B_\pi\ldots B_\pi}_{\bar{n}-2}B_\pi$. The remaining trajectories of TYPE-2 are of the form $B_s\underbrace{B_{v(s)}\ldots B_{v(s)}}_{\bar{n}-1}B_s$ for some $s\in]0,\pi[$. Otherwise, if $\pi/(2\alpha)$ is not an integer number, define the following:

$$m := \left[\frac{\pi}{2\alpha}\right], \quad \text{and the normalized remainder} \quad \mathsf{R} := \frac{\pi}{2\alpha} - \left[\frac{\pi}{2\alpha}\right] \in [0,1[.$$

where $[.]$ denotes the integer part. The following proposition determines precisely the time optimal trajectories for particular values of the parameter R:

Proposition 6: *For m large enough, there exist* $r_1(m) \le r_2(m) \in]0,1[$ *such that the following occurs*

A. *If* $\mathsf{R}\in]0,r_1(m)]$, *then Eq.* (22) *admits exactly two solutions that are both optimal, while TYPE-2 candidate optimal trajectories are not.*
B. *If* $\mathsf{R}\in]r_1(m),r_2(m)[$, *then Eq.* (22) *admits two solutions that are not optimal.*
C. *If* $\mathsf{R}\in]r_2(m),1[$ *then Eq.* (22) *does not admit any solution. Moreover,* $r_2(m)\to 0$ *for* $m\to\infty$.

Remark 10: The function $r_2(m)$ can be determined explicitly (see Appendix B2.1), while for $r_1(m)$ we are just able to prove the existence, and we conjecture that it can be taken equal to $r_2(m)$.

Remark 11: An important consequence of Proposition 6 is that for α small, the number of optimal trajectories reaching the South Pole is not fixed with respect to α. Indeed, such a number

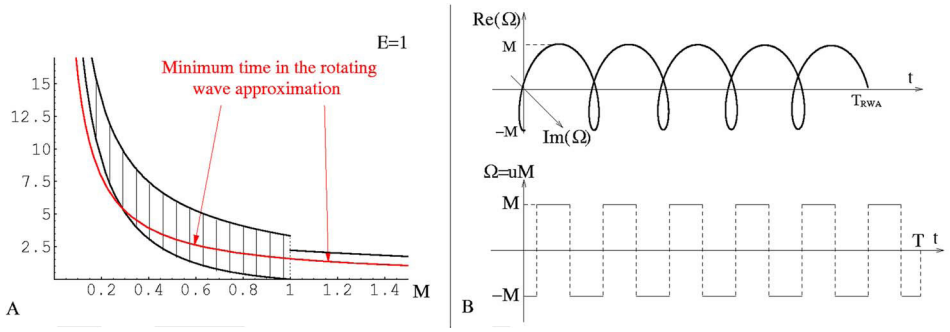

FIG. 8. (Color online) (A) Estimate of the minimum time to reach the state two and comparison with the time needed with two controls or in the rotating wave approximation (B) A comparison between the optimal strategy for our system and in the rotating wave approximation.

alternates as $\alpha \to 0$, according to Proposition 6: in particular, it is equal to 4 if $\mathsf{R} \in]0, r_1(m)]$ and it is equal to 2 if $\mathsf{R} \in]r_2(m), 1[\cup \{0\}$. This is enough to conclude that also the qualitative shape of the optimal synthesis in a neighborhood of the South Pole alternates, giving a partial proof to conjecture **C2** of Sec. II (originally stated in Ref. 29). In particular, it is a proof of the first assertion (on the dependence of the synthesis on the remainder $r=2\alpha\mathsf{R}$). Moreover, notice that the results of Proposition 6 perfectly fit with all the other statements of conjecture **C2**, with $r_2(m)$ playing the role of $\alpha_1/(2\alpha)$. One can apply the definition of locally equivalent syntheses given in Ref. 15 (see Definition 32, p. 59), to make rigorous the statement that the qualitative shape of the optimal synthesis changes with α.

Using the previous analysis one can easily show the following result (of which we skip the proof).

Proposition 7: If N is the number of switchings of an optimal trajectory joining the North to the South Pole, then

$$\frac{\pi}{2\alpha} - 1 \leq N < \frac{\pi}{2\alpha} + 1.$$

Using these inequalities and the fact that, for $\alpha < \pi/6$, the function $2s + (\pi/2\alpha - 1)v(s)$ is increasing on $[0, \pi]$, one can give a rough estimate of the time needed to reach the South Pole:

Proposition 8: The total time T of an optimal trajectory joining the North to the South Pole satisfies the inequalities:

$$\frac{\pi^2}{2\alpha} - 2\pi < T < \frac{\pi^2}{2\alpha} + \pi.$$

C. Comparison with results in the rotating wave approximation and with Ref. 8

In this section we come back to the original value of k, i.e., $k = 2E/\cos(\alpha) = 2\sqrt{M^2+E^2}$, and we compare the time necessary to steer the state one to the state two for our model and the model (4), described in Remark 1, in which we control the magnetic field both along the x and y directions, or we consider a two-level molecule in the rotating wave approximation. We recall that $-E, E$ are the energy levels and M is the bound on the control. For our model, the time of transfer T satisfies the following:

- for $\alpha \geq \pi/4$ (i.e., for $M \geq E$) then $T = 2\pi/k = \pi/\sqrt{M^2+E^2}$;
- for $\alpha < \pi/4$ (i.e., for $M < E$) then T is estimated by $1/k(\pi^2/2\alpha - 2\pi) < T < \frac{1}{k}(\pi^2/2\alpha + \pi)$.

On the other hand, for the model (4), the time of transfer is $T_C = \pi/(2M)$ (cf. Remark 1).

Fixed $E=1$, in Fig. 8(A) the times T and T_C as function of M are compared. Notice that

although T_C is bigger than the lower estimate of T in some interval, we always have $T_C \leq T$. This is due to the fact that the admissible velocities of our model are a subset of the admissible velocities of the model (4).

Notice that, fixed $E=1$, for $M \to 0$ we have $T \sim \pi^2/(4M) = (\pi/2)T_C$, while for $M \to \infty$, we have $T \sim \pi/M = 2T_C$.

Remark 12: For $M \ll E$ (i.e., for α small) the difference between two switching times is $v(s)/k \sim \pi/(2E)$. It follows that a time optimal trajectory connecting the North to the South Pole (in the interval between the first and the last bang) is periodic with period $P \sim \pi/E$, i.e., with a frequency of the order of the resonance frequency $\omega_R = 2E$ [see Fig. 8(B)]. On the other side, if $M > E$, then the time optimal trajectory connecting the North with the South Pole is the concatenation of two pulses. Notice that if $M \gg E$, the time of transfer is of the order of π/M and therefore tends to zero as $M \to \infty$. It is interesting to compare this result with a result of Khaneja, Brockett, and Glaser, for a two level system, but with no bound on controls (see Ref. 8). They estimate the infimum time to reach every point of the whole group $SU(2)$ in π/E. On the other side, in Appendix C it is proved that the time needed to cover the whole sphere $\mathbf{S}_B = SU(2)/S^1$ goes to $\pi/(4E)$ as M goes to infinity (however, this does not contradict the fact that the state two can be reached in an arbitrary small time, as we previously discussed).

Notice that our optimal control has the same "qualitative form" of the control computed in Ref. 8, i.e., a pulse (bang) followed by an evolution with the drift (singular) followed by a pulse (bang).

D. Some possible extensions

It is very easy to see that if $\{u_{\bar{y}}\}_{\bar{y} \in \mathbf{S}_B}$ is the collection of all time optimal controls steering the North Pole to all the points of $\mathbf{S}_B$, then the same set is also the collection of all time optimal controls starting from the South Pole.

Notice that nothing is changing if the controlled magnetic field is in any direction in the x-y plane. If this is not the case, the problem is different. However, the same techniques of this paper could be used to deal with this case, but the solution is probably more complicated.

Another interesting problem could be the variant of (**P**) in which one considers a different initial condition. In this case, generically, one loses the local controllability property (i.e., for small time, the trajectories do not cover a neighborhood of the starting point), but the structure of extremal trajectories (i.e., trajectories satisfying the Pontryagin Maximum Principle; cf. Appendix A) is very similar.

APPENDIX A: AN OVERVIEW ON OPTIMAL SYNTHESIS ON 2-D MANIFOLDS

In this section we briefly recall the theory of optimal syntheses on 2-D manifolds for a system of the kind $\dot{y} = F(y) + uG(y)$, $|u| \leq 1$, developed by Sussmann, Bressan, Piccoli, and the first author in Refs. 24–27 and recently rewritten in15. This appendix is written to be as much self-consistent as possible.

For every coordinate chart on the manifold it is possible to introduce the following three functions:

$$\Delta_A(y) := \mathrm{Det}(F(y), G(y)) = F_1(y)G_2(y) - F_2(y)G_1(y), \tag{A1}$$

$$\Delta_B(y) := \mathrm{Det}(G(y), [F,G](y)) = G_1(y)[F,G]_2(y) - G_2(y)[F,G]_1(y), \tag{A2}$$

$$f_S(y) := -\Delta_B(y)/\Delta_A(y). \tag{A3}$$

The sets $\Delta_A^{-1}(0), \Delta_B^{-1}(0)$ of zeros of Δ_A, Δ_B are, respectively, the set of points where F and G are parallel, and the set of points where G is parallel to $[F,G]$. These loci are fundamental in the construction of the optimal synthesis. In fact, assuming that they are a smooth embedded one-dimensional submanifold of M, we have the following:

- In each connected region of $M\backslash(\Delta_A^{-1}(0)\cup\Delta_B^{-1}(0))$, every extremal trajectory is bang-bang with, at most, one switching. Moreover, for every switching of the extremal trajectory, the value of the control passes from -1 to $+1$ if $f_S>0$ and from $+1$ to -1 if $f_S<0$.
- The support of singular trajectories (that are trajectories for which the switching function identically vanishes; see Definition 7) is always contained in the set $\Delta_B^{-1}(0)$.
- A trajectory not switching on the set of zeros of G is an abnormal extremal (i.e., a trajectory for which the Hamiltonian given by the Pontryagin Maximum Principle vanishes; see later) if and only if it switches on the locus $\Delta_A^{-1}(0)$.

Then the synthesis is built recursively on the number of switchings of extremal trajectories, canceling at each step the nonoptimal trajectories (see Ref. 15, Chap. 1).

Remark 13: Notice that, although the functions Δ_A and Δ_B depend on the coordinate chart, the sets $\Delta_A^{-1}(0)$, $\Delta_B^{-1}(0)$ and the function f_S do not, i.e., they are intrinsic objects of the control equation $\dot{y}=F(y)+uG(y)$.

1. Basic definitions and Pontryagin Maximum Principle on an *n*-dimensional manifold

In this section we define our optimization problem, we state the Pontryagin Maximum Principle (that is a key tool to compute optimal trajectories) and we give some basic definitions in the more general case of a n-dimensional manifold. We do this, since in Appendix B1 we stated some result for the original problem (14), on $S^3\sim SU(2)$.

Problem (Q): Consider the control system:

$$\dot{y}=F(y)+uG(y),\quad y\in M,\quad |u|\leq 1, \tag{A4}$$

where the following occurs.

(**H0**) *M is a smooth n-dimensional manifold. The vector fields $F(y)$ and $G(y)$ are $\mathcal{C}^\infty$.*

We are interested in the problem of reaching every point of M in minimum time from a point $y_0\in M$.

Definition 6: An admissible control $u(.)$ for the system (A4) *is a measurable function $u(.):[a,b]\to[-1,1]$, while an admissible trajectory is a Lipschitz functions $y(.):[a,b]\to M$ satisfying $\dot{y}(t)=F(y(t))+u(t)G(y(t))$, a.e., for some admissible control $u(.)$*

In the following we assume that the control system is *complete*, i.e., for every measurable control function $u(.):[a,b]\to[-1,1]$ and every initial state $\bar{y}$, there exists a trajectory $y(.)$ corresponding to $u(.)$, which is defined on the whole interval $[a,b]$ and satisfies $y(a)=\bar{y}$.

The main tool to compute time optimal trajectories is the Pontryagin Maximum Principle (PMP for short; see Refs. 14–16).

Theorem [Pontryagin maximum principle for the problem (Q)]: *Consider the control system* (A4) *subject to* (**H0**). *Define for every $(y,\lambda,u)\in T^*M\times[-1,1]$ the function*

$$\mathcal{H}(y,\lambda,u):=\langle\lambda,F(y)\rangle+u\langle\lambda,G(y)\rangle.$$

If the couple $(y(.),u(.)):[0,T]\to M\times[-1,1]$ is time optimal then there exist a never vanishing Lipschitz continuous covector $\lambda(.):t\in[0,T]\mapsto\lambda(t)\in T^*_{y(t)}M$ and a constant $\lambda_0\leq 0$ such that for, a.e., $t\in[0,T]$:

(i) $\dot{y}(t)=\frac{\partial\mathcal{H}}{\partial\lambda}(y(t),\lambda(t),u(t))$,
(ii) $\dot{\lambda}(t)=-\frac{\partial\mathcal{H}}{\partial y}(y(t),\lambda(t),u(t))=-\lambda(t)(\nabla F(y(t))+u(t)\nabla G(y(t)))$,
(iii) $\mathcal{H}(y(t),\lambda(t),u(t))=\mathcal{H}_M(y(t),\lambda(t))$ *where* $\mathcal{H}_M(y,\lambda):=\max\{\mathcal{H}(y,\lambda,u):u\in[-1,1]\}$,
(iiii) $\mathcal{H}_M(y(t),\lambda(t))+\lambda_0=0$.

Remark 14: The PMP is just a necessary condition for optimality. A trajectory $y(.)$ [resp., a couple $(y(.),\lambda(.))$] satisfying the conditions given by the PMP is said to be an *extremal* (resp., an *extremal pair*). An extremal corresponding to $\lambda_0=0$ is said to be an *abnormal extremal*, otherwise we call it a *normal extremal*.

We are now interested in determining the extremal trajectories satisfying the conditions given by the PMP. A key role is played by the following.

Definition 7 (switching function): Let $(y(.),\lambda(.))$ *be an extremal pair. The corresponding switching function is defined as* $\phi(t) := \langle \lambda(t), G(y(t)) \rangle$.

Notice that $\phi(.)$ is continuously differentiable [indeed $\dot{\phi}(t) = \langle \lambda(t), [F,G](y(t)) \rangle$, which is continuous].

Definition 8 (bang, singular): Let γ, *defined in* $[a,b]$, *be an extremal trajectory and* $u(.):[a,b] \to [-1,1]$ *the corresponding control. We say that* $u(.)$ *is a bang control if* $u(t) = +1$, *a.e., in* $[a,b]$ *or* $u(t) = -1$, *a.e., in* $[a,b]$. *We say that* $u(.)$ *is singular if the corresponding switching function* $\phi(t) = 0$ *in* $[a,b]$. *A finite concatenation of bang controls is called a bang-bang control. A switching time of* $u(.)$ *is a time* $\bar{t} \in [a,b]$ *such that, for every* $\varepsilon > 0$, u *is not bang or singular on* $(\bar{t}-\varepsilon, \bar{t}+\varepsilon) \cap [a,b]$. *An extremal trajectory of the control system* (A4) *is said abang extremal, singular extremal, bang-bang extremal, respectively, if it corresponds to a bang control, singular control, bang-bang control, respectively. If* $\bar{t}$ *is a switching time, the corresponding point on the trajectory* $y(\bar{t})$ *is called a switching point.*

The switching function is important because it determines where the controls may switch. In fact, using the PMP, one easily gets the following.

Proposition 9: A necessary condition for a time t to be a switching is that $\phi(t) = 0$. *Therefore, on any interval where* ϕ *has no zeroes* (*respectively, finitely many zeros*), *the corresponding control is bang* (*respectively, bang-bang*). *In particular,* $\phi > 0$ (*resp,* $\phi < 0$) *on* $[a,b]$ *implies* $u = 1$ (*resp.*, $u = -1$) *a.e. on* $[a,b]$. *On the other hand, if* ϕ *has a zero at t and* $\dot{\phi}(t)$ *is different from zero, then t is an isolated switching.*

2. More on singular extremals and predicting switchings for 2-D systems

Now we come back to the case in which M is two dimensional. In this section we compute the control corresponding to singular extremals and we would like to predict which kind of switchings can occur, using properties of the vector fields F and G. The following two lemmas illustrate the role of the functions $\Delta_A^{-1}(0)$, $\Delta_B^{-1}(0)$ in relation with singular and abnormal extremals. The proofs can be found in Refs. 24, 15, and 26.

Lemma 1: Let $y(.)$ *be an extremal trajectory that is singular in* $[a,b] \subset Dom(y(.))$. *Then* $y(.)|_{[a,b]}$ *corresponds to the so called singular control* $\varphi(y(t))$, *where*

$$\varphi(y) = -\frac{\nabla \Delta_B(y) \cdot F(y)}{\nabla \Delta_B(y) \cdot G(y)}, \tag{A5}$$

with Δ_A *and* Δ_B *defined in Eqs.* (A1) and (A2). *Moreover, on* $Supp(y(.))$, $\varphi(y)$ *is always well defined and its absolute value is less than or equal to one. Finally,* $Supp(y(.)|_{[a,b]}) \subset \Delta_B^{-1}(0)$.

Lemma 2: Let $y(.)$ *be a bang-bang extremal for the control problem* (A4), $t_0 \in Dom(y(.))$ *be a time such that* $\phi(t_0) = 0$ *and* $G(y(t_0)) \neq 0$. *Then, the following conditions are equivalent:* (i) $y(.)$ *is an abnormal extremal*; (ii) $y(t_0) \in \Delta_A^{-1}(0)$; and (iii) $y(t) \in \Delta_A^{-1}(0)$, *for every time* $t \in Dom(y(.))$, *such that* $\phi(t) = 0$.

The following lemma describes what happens when Δ_A and Δ_B are different from zero.

Lemma 3: Let $\Omega \subset M$ *be an open set such that* $\Omega \cap (\Delta_A^{-1}(0) \cup \Delta_B^{-1}(0)) = \emptyset$. *Then all connected components of* $Supp(y(.)) \cap \Omega$, *where* $y(.)$ *is an extremal trajectory of* (A4), *are bang-bang with, at most, one switching. Moreover, if* $f_S > 0$ *throughout* Ω, *then* $y(.)|_\Omega$ *is associated to a constant control equal to* $+1$ *or* -1 *or has a switching from* -1 *to* $+1$. *If* $f_S < 0$ *throughout* Ω, *then* $y(.)|_\Omega$ *is associated to a constant control equal to* $+1$ *or* -1 *or has a switching from* $+1$ *to* -1.

Remark 15: For the problem **(Q)**, under generic conditions on the vector fields F and G, one can make the complete classification of synthesis singularities, stable synthesis, singularities of the minimum time wave fronts. We refer to Ref. 15 for the general theory. For some extensions to higher dimension, see Refs. 31 and 32.

APPENDIX B: PROOF OF THE MAIN RESULTS

In this section we give the proof of our main results. We start with a lemma, stating a property of optimal trajectories, that is a consequence of the symmetries of the problem. It is used to identify the time optimal trajectories steering the North to the South Pole both for $\alpha \geq \pi/4$ and $\alpha < \pi/4$.

Lemma 4: Let $\alpha \in]0, \pi/2[$. *Every optimal bang-bang trajectory, connecting the North to the South Pole, with more than one switching is such that* $v(s_i)=v(s_f)$ *where* s_i *is the first switching time,* s_f *is the time needed to steer the last switching point to the South Pole and* $v(s_i)$ *is the time between two consecutive switchings.*

Proof of Lemma 4: Consider the problem of connecting P_S with P_N in minimum time for the system $\dot{z}=F'_S(z)+uG'_S(z)$, where $z \in S^2$ and $F'_S(z)=-F_S(z)$, $G'_S(z)=-G_S(z)$. The trajectories of this system coincide with those of the system (10)–(13), but the velocity is reversed. Therefore the optimal trajectories for the new problem coincide with the optimal ones for the system (10)–(13) connecting P_N to P_S, and the time between two switchings is the same. Since performing the change of coordinates $(z_1, z_2, z_3) \to (y_1, y_2, y_3)=(-z_1, z_2, -z_3)$, the new problem becomes exactly the original problem, we deduce that, if we have more than one switching, it must be $v(s_i)=v(s_f)$. ■

1. Time optimal synthesis for the two level quantum system for $\alpha \geq \pi/4$

In this section, we apply the theory of optimal syntheses on 2-D manifolds recalled in Appendix A, to the system (10)–(13). Our aim is to describe the time optimal synthesis for $\alpha \geq \pi/4$, i.e., to prove Theorem 1 and Propositions 2 and 3. First, we state some general results, holding for $\alpha \in]0, \pi/2[$, regarding time optimal trajectories of the system (14), on $S^3 \sim SU(2)$, analogous to those obtained in Ref. 29 for $SO(3)$ (in particular, the proofs can be repeated using the same arguments).

A. General results on S^3

In this section $\alpha \in]0, \pi/2[$. The first proposition states that singular extremals, defined as extremals for which the switching function vanishes (see Definitions 7 and 8) correspond to zero control. This fact is very specific for our problem.

Proposition 10: For the normalized minimum time problem on S^3 (14), *singular extremals are integral curves of the drift, i.e., they must correspond to a control almost everywhere vanishing.*

Since for a fixed $u \in [-1, 1]$ every trajectory of (14) is periodic with period $4\pi/\sqrt{u^2 \sin^2 \alpha + \cos^2 \alpha}$, we have the following.

Proposition 11: Given an extremal trajectory γ *of type* B_t (*resp.*, S_t), *then* $t < 4\pi$ (*resp.*, $t < 4\pi/\cos \alpha$).

The following proposition describes the switching behavior of abnormal and bang-bang normal extremals (see Sec. A 1 for the definition).

Proposition 12: Let γ *be an abnormal extremal of* (14). *Then it is bang-bang and the time duration between two consecutive switchings is always equal to* π. *In other words,* γ *is of kind* $B_s B_\pi \ldots B_\pi B_t$ *with* $s, t \leq \pi$.

On the other hand, if γ *is a bang-bang normal extremal, then the time duration* $\mathcal{T}$ *along an interior bang arc is the same for all interior bang arcs and verifies* $\pi < \mathcal{T} < 2\pi$ (*i.e.,* γ *is of kind* $B_s B_\mathcal{T} \ldots B_\mathcal{T} B_t$ *with* $s, t \leq \mathcal{T}$).

For the optimal trajectories containing a singular arc we have the following.

Proposition 13: Let γ *be a time optimal trajectory containing a singular arc. Then* γ *is of the type* $B_t S_s B_{t'}$, *with* $s \leq 2\pi/\cos \alpha$ *if* $t > 0$ *or* $t' > 0$ *and* $s < 4\pi/\cos \alpha$ *otherwise.*

These results on $S^3 \sim SU(2)$ are useful to determine the optimal synthesis on $\mathbf{S}_\mathrm{B}$, since every optimal trajectory on $\mathbf{S}_\mathrm{B}$ is the projection of an optimal trajectory on S^3. This is a simple consequence of the fact that $\mathbf{S}_\mathrm{B}$ is a homogeneous space of $SU(2)$.

Proposition 14: A time optimal trajectory γ *for the system* (10)–(13) *on* $\mathbf{S}_\mathrm{B}$ *starting at* P_N *is*

the projection of a time optimal trajectory of (14), *starting from a point satisfying* $|\psi_1|^2=1$ [*recall that* $\psi=(\psi_1,\psi_2)^T\in S^3\subset\mathbb{C}^2$].

Remark 16: Notice that, since two opposite points on S^3 project on the same point on $\mathbf{S}_\mathrm{B}$, it is easy to see from Proposition 11 that the projection on $\mathbf{S}_\mathrm{B}$ of an optimal trajectory of (14) of type B_t (resp., S_t), must be such that $t<2\pi$ (resp., $t<2\pi/\cos\alpha$). More precisely, for a fixed $u\in[-1,1]$ every trajectory of (10)–(13) is periodic with period $2\pi/\sqrt{u^2\sin^2\alpha+\cos^2\alpha}$ (the period divides by two after projection).

B. Construction of the synthesis on $\mathbf{S}_\mathrm{B}$

In this section we assume $\alpha\geq\pi/4$. Following Appendix A, we first need to determine the sets $\Delta_A^{-1}(0)$, $\Delta_B^{-1}(0)$, and the function f_S. Checking where F_S is parallel to G_S and where G_S is parallel to $[F_S,G_S]$, one gets $\Delta_A^{-1}(0)=\{y\in\mathbf{S}_\mathrm{B}:y_2=0\}$ and $\Delta_B^{-1}(0)=\{y\in\mathbf{S}_\mathrm{B}:y_3=0\}$. To find the function f_S we can choose for instance, the coordinate chart defined on each hemisphere by the projection on the plain $\{(y_1,y_2)\in\mathbb{R}^2\}$, obtaining $f_S=(\sin\alpha)y_3/y_2$. Then Lemma 3 says that every optimal trajectory belonging to one of the regions $\{y\in\mathbf{S}_\mathrm{B}:y_3>0,y_2>0\}$, $\{y\in\mathbf{S}_\mathrm{B}:y_3<0,y_2<0\}$ is bang-bang with, at most, one switching. Moreover only the switching from control -1 to control $+1$ is allowed. On the contrary, on the regions $\{y\in\mathbf{S}_\mathrm{B}:y_3>0,y_2<0\}$, $\{y\in\mathbf{S}_\mathrm{B}:y_3<0,y_2>0\}$, the control can switch only from $+1$ to -1. Moreover, thanks to Lemma 1, every singular extremal must lie on the equator. The following lemma characterizes the structure of the bang-bang extremals for the problem (**P**).

Lemma 5: Recall that $t_1=\pi-\arccos(\cot^2\alpha)$ *and* $t_3=\pi+\arccos(\cot^2\alpha)$ *and consider a bang-bang extremal for the problem* (**P**). *Then it is of the form* $B_sB_{v(s)}B_{v(s)}\ldots$ *with* $s\in[0,t_1]\cup[\pi,t_3]$, *where, on the set* $[0,t_1[\cup[\pi,t_3[$, $v(.)$ *is defined as follows:*

$$v(s):=\pi+2\arctan\left(\frac{\sin s}{\cos s+\cot^2\alpha}\right).$$

If $\alpha=\pi/4$ *then* $t_1=t_3=\pi$ *and* $v(\pi):=\pi$, *while if* $\alpha>\pi/4$ *we set* $v(t_1):=v(t_3):=2\pi$.

Notice that the function $v(.)$ has the same expression (17) obtained in the case $\alpha<\pi/4$ (excepted at the points t_1 and t_3). However, its interval of definition is different.

Proof of Lemma 5: As shown previously, the meridian $\Delta_A^{-1}(0)$ and the equator $\Delta_B^{-1}(0)$ divide the sphere in four parts and in each of them the sign of the function f_S is constant and changes when passing through $\Delta_A^{-1}(0)$ or $\Delta_B^{-1}(0)$. In particular, following γ^+ or γ^- (cf. Remark 4) in the case in which $\alpha>\pi/4$ this happens at the times t_1 (where the equator is crossed), at time π (where $\Delta_A^{-1}(0)$ is crossed) and at time t_3 (again is the equator to be crossed). Applying Lemma 3, we obtain that for an extremal trajectory the first switching may occur only on the intervals $[0,t_1]$ and $[\pi,t_3]$. Exactly as in,[29] one shows that the extremal must have the form $B_sB_{v(s)}B_{v(s)}\ldots$ with $s\in[0,t_1]\cup[\pi,t_3]$. The case $\alpha=\pi/4$ is similar. ■

Remark 17: One can also show that every trajectory starting from P_N, of the form $B_sB_{v(s)}B_{v(s)}\ldots$ with $s\in[0,t_1]\cup[\pi,t_3]$, is extremal, i.e., for every s in such a set, there exists an initial value of the covector λ such that the switching function $\phi(.)$ vanishes for the first time at time s.

Unlike the case in which $\alpha<\pi/4$, in the case $\alpha>\pi/4$ it is possible to establish the presence of optimal trajectories containing a singular arc, whose switching behavior is described by the following proposition, illustrated in Fig. 9(A).

Proposition 15: Let $\alpha\geq\pi/4$. *A trajectory* γ *of* (10)–(13) *starting with control* $u=1$ *and containing a singular arc is a solution of* (**P**) *if and only if it is of the form* $B_tS_sB_{t'}$ *and satisfies the following conditions.*

- $t=t_1=\pi-\arccos(\cot^2\alpha)$, *i.e., γ coincides with* γ^+ *until it reaches the equator.*
- $s\leq\arccos(\cot\alpha)/\cos\alpha$, *i.e., the singular arc is optimal until it reaches the point* $O^+=(1,0,0)^T$.
- *If* $s=\arccos(\cot\alpha)/\cos\alpha$, *then the trajectory is of type* B_tS_s, (*i.e., the time duration of the*

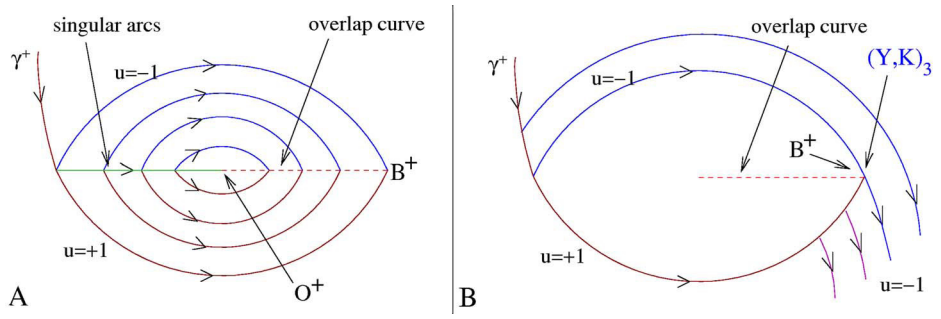

FIG. 9. (Color online) The region covered by optimal trajectories with singular arcs and the $(Y,K)_3$ frame point.

last bang arc reduces to zero). *If* $s<\arccos(\cot\alpha)/\cos\alpha$, *then* γ *is optimal until the last bang arc reaches the equator* [*i.e., it does not exist* $\bar{t}\in]0,t'[$ *such that* $\gamma(t+s+\bar{t})$ *is contained in the equator*].

An analogous result holds for trajectories, starting with control -1.

Remark 18: Notice that in the case $\alpha=\pi/4$, Proposition 15 provides a singular trajectory degenerated to a point. In other words, for $\alpha=\pi/4$ there are no singular trajectories that are optimal.

Remark 19: Notice that the previous result completely characterizes the optimal synthesis in some neighborhoods of the points $O^{\pm}=(\pm1,0,0)^T$, namely $\Omega_2^{\pm}\cup\Omega_3^{\pm}$, and moreover it determines the presence of two symmetric overlap curves contained inside the equator. The synthesis around the point O^+ is represented in Fig. 9(A).

Proof of Proposition 15: Consider a trajectory, solution of (**P**), starting with $u=+1$ and containing a singular arc. Using Propositions 13 and 14, this trajectory must be of the form $B_tS_sB_{t'}$, and, since the singular arc is contained inside the equator, we have $t=t_1$ (the case $t=t_3$ can be easily excluded). Consider a singular arc containing in its interior the point O^+. This arc contains two points of the form $(y_1^0,-y_2^0,0)^T$ and $(y_1^0,y_2^0,0)^T$, with both y_1^0, y_2^0 positive, that can be connected by a bang arc. Using classical comparison theorems for second order ODEs, one can easily compare the time needed to follow such a trajectory with the time needed to steer the two points along the singular arc finding that the bang arc is quicker than the singular arc. Therefore a singular arc containing O^+ cannot be optimal. By symmetry, the extremal trajectories that have the same singular arc, but the last bang arc corresponding to opposite control, must meet on a point of the equator. Therefore the arc of the equator that is comprised between the point O^+ (resp., O^-) and the second intersection point with γ^+ (resp., γ^-) is an overlap curve. It remains now to verify that the trajectories previously described are optimal (until the last bang arc reaches the equator). This is a straightforward consequence of the fact that the quickest bang-bang trajectories that enter the region spanned by such trajectories (i.e., the closure of the regions $\Omega_2^{\pm}\cup\Omega_3^{\pm}$) are not extremal because of Lemma 3 (see also Lemma 5). ■

Remark 20: Notice the trivial fact that, if a trajectory γ defined on the interval $[a,b]$ is optimal between $\gamma(a)$ and $\gamma(b)$, then the restriction of γ in $[c,d]$, $c,d\in[a,b]$, $c<d$, is optimal between $\gamma(c)$ and $\gamma(d)$.

Using Remark 20, we have that Proposition 15 characterizes completely the time optimal synthesis on $\overline{P_NA^{\pm}}$, and in the closure of $\Omega_2^{\pm}\cup\Omega_3^{\pm}$, i.e., it proves items **T1**–**T6**, **T9**, and **T10**, of Theorem 1.

Remark 21: From Lemma 5 we obtain that there are four families of bang-bang trajectories. In particular, the families starting with control $+1$ and switching, respectively, in $[0,t_1]$ and $[\pi,t_3]$ join at the point B^+, generating an amazing $(Y,K)_3$ frame point, in the framework of the classification of Ref. 15. See Fig. 9(B).

Next we give the proof of Proposition 2, from which it follows **T11** of Theorem 1, and, using again Remark 20, also **T7**.

Proof of Proposition 2: By Proposition 15, there are no optimal trajectories containing a singular arc joining P_N with P_S. One can easily see that the only possible trajectories steering P_N to P_S with only one switching are those described in the statement of the proposition, that we have to compare with trajectories having more than one switching. Trajectories having two switchings with the first or the last bang longer than π and trajectories with more than two switchings are excluded, since from Lemma 5 their total time is larger than 2π. Trajectories having two switchings and the length of the first arc s_i and the length of the last arc s_f satisfying $s_i, s_f < \pi$ are excluded, since by Lemma 4 they must satisfy $s_i = s_f$. For these trajectories the total time can be easily computed and it is $2\pi + 2\arcsin(1/2\sin(\alpha)) > 2\pi$. ■

Item **T8** is proved by the following.

Proposition 16: If $\bar{y} \in \Omega_1^+ \cup (\overline{DP_S^-} \backslash P_S)$, *then* $\gamma_{\bar{y}}$ *is made by a unique trajectory of the form* $B_t B_{t'}$, *with* $0 \le t < t_1$ *and the first bang corresponding to control* $+1$. *A similar result holds if* $\bar{y} \in \Omega_1^- \cup (\overline{DP_S^+} \backslash P_S)$. *As a consequence there is not a cut locus in the region,* $\Omega_1^+ \cup \Omega_1^-$. *On the other hand,* $\Omega_{\text{nasty}}^+ \cup \Omega_{\text{nasty}}^-$ *contains a cut locus.*

Proof of Proposition 16: Define the following three families of extremal trajectories:

$$\gamma_s^A(t) := e^{tX_S^+} e^{sX_S^-} P_N, \quad \text{with } s \in \,]0, t_1[\text{ and } t \le v(s),$$

$$\gamma_s^B(t) := e^{tX_S^-} e^{sX_S^+} P_N, \quad \text{with } s \in [\pi, t_3[\text{ and } t \le v(s),$$

$$\gamma_s^C(t) := e^{tX_S^-} e^{v(s)X_S^+} e^{sX_S^-} P_N, \quad \text{with } s \in \,]0, t_1[\text{ and } t \le v(s).$$

First, notice that from Proposition 2 that there are no optimal trajectories of kind γ_s^A reaching the arc $\overline{BP_S^+}$. Now for every point $x \in \overline{DP_S^+}$ the following occurs: (i) there exist s_A, t_A such that $x = \gamma_{s_A}^A(t_A)$, and they are unique; (ii) if there exist s_B, t_B (resp., s_C, t_C) such that $x = \gamma_{s_B}^B(t_B)$, [resp., $x = \gamma_{s_C}^C(t_C)$], then they are unique. By direct computation, one can compare the times the three trajectories need to reach x, i.e. $s_A + t_A, s_B + t_B, s_C + v(s_C) + t_C$, finding that the optimal trajectory is of kind γ^A (these computations are long, not very instructive, and we omit them). From this fact, the first part of the claim immediately follows. Moreover, it implies that there is not a cut locus in Ω_1^+, since the only trajectories entering such a region are those of the form γ^A. The existence of a cut locus in Ω_{nasty}^+ is evident, since no optimal trajectories belonging to the families γ^A, γ^B, γ^C leave Ω_{nasty}^+. The reasoning in Ω_1^- and in Ω_{nasty}^- is similar. ■

End of the proof of Theorem 1: To conclude the proof of Theorem 1, it remains to prove **T12**. Consider by contradiction an optimal bang-bang trajectory γ defined in $[0, t_\gamma]$ steering P_N to a point of Ω_{nasty}^+, with at least three switchings. Define $\bar{t} = \max\{t \in [0, t_\gamma] : \gamma(t) \notin \Omega_{\text{nasty}}^+\}$. Then, by Remark 20, $\gamma|_{[0,\bar{t}]}$ must be optimal between P_N and $\gamma(\bar{t})$. Then, from the results proved previously, we deduce that $\gamma|_{[0,\bar{t}]}$ can have, at most, one switching. Therefore γ switches at least two times in Ω_{nasty}^+, and the arc between them must be completely contained in Ω_{nasty}^+, and this leads to a contradiction since the sign of f_S is constant in Ω_{nasty}^+ (see Lemma 3). ■

Before proving Proposition 3, notice that the point D^+, which is obtained following the trajectory γ^+ for a time π (see Fig. 6), belongs to two different families of bang-bang trajectories at time π, one given by trajectories starting with control -1 and switching at time $s \le t_1$, the other one given by trajectories that start with control 1 and switching at time $s \in [\pi, t_3]$. Moreover, since $v(0) = \pi$, there must be a switching curve starting at D^+ and therefore we deduce that there are two possible behaviors of the optimal synthesis around this point: either this switching curve is optimal or the two fronts continue to intersect generating an overlap curve.

Observe that if $\alpha \ge \pi/3$ the trajectories of the type $B_s B_{v(s)} B_t$ with s small cannot be optimal since the vector fields X_S^+ and X_S^- point to opposite sides on the switching curve (i.e., the switching curve "reflects the trajectories," and therefore it is not locally optimal, by the definition given in Sec. II). In this case the two families of bang-bang trajectories described previously must intersect, giving rise to an overlap curve. Therefore to prove Proposition 3 we assume $\alpha < \pi/3$.

Proof of Proposition 3: First we parametrize the switching curve with respect to the first switching time (assuming without loss of generality that this curve starts with $u=-1$):

$$C(s) = e^{v(s)X_S^+} e^{sX_S^-} P_N.$$

We consider the functions $\xi_1(s)=\det(C(s), C'(s), X_S^+(C(s)))$ (here the superscript $'$ denotes the derivative with respect to s) and $\xi_2(s)=\det(C(s), C'(s), X_S^-(C(s)))$. It is easy to see that the optimality of $C(.)$, for s small, depends on the signs of such functions. Indeed $C(.)$ is locally optimal near the point $D^+=C(0)$ if and only if for every positive and small enough s, and given a neighborhood of $C(s)$ that is divided in two connected components U_1, U_2 by the trajectory $C(.)$, both $X_S^-(C(s))$ and $X_S^+(C(s))$ point toward U_1 or toward U_2. It is easy to see that this occurs if $\xi_1(s)$ and $\xi_2(s)$ have the same sign. Notice that $\xi_1(0)=\xi_2(0)=0$ and that $\xi_1(s) = \det(P_N, X_S^-(P_N), e^{-sX_S^-} X_S^+(e^{sX_S^-} P_N)) = 2\cos\alpha \sin^2\alpha \sin s$, which is positive for every $\alpha < \pi/2$ and $s \in]0, \pi[$. To determine the sign of $\xi_2(s)$ near 0, it is enough to look at the sign of the derivative $\xi_2'(0)$ that can be computed directly: $\xi_2'(0) = 4\cos\alpha \sin^2\alpha(1-2\sin^4\alpha)$. We deduce that, if $\alpha < \arcsin(1/\sqrt[4]{2})$, the switching curve $C(.)$ is optimal for s small enough. For the particular value $\alpha = \arcsin(1/\sqrt[4]{2})$, one can easily check that the function $\xi_2(.)$ is negative for $s>0$ small, and then $C(.)$ is no more optimal for $\alpha \geq \arcsin(1/\sqrt[4]{2})$. The tangency of the switching curve starting at D^+ if $\alpha > \pi/4$, is a consequence of the fact that, in this case, the bang-bang trajectory switching at D^+ is an abnormal extremal (see Proposition 2 and Ref. 15, Proposition 23, pp. 177). ■

2. Time optimal trajectories reaching the South Pole for $\alpha < \pi/4$

Our purpose of this section is to characterize the optimal trajectories steering P_N to P_S in the case $\alpha < \pi/4$, i.e., to prove Propositions 4 and 5. A key tool is Lemma 4. Recall the shape of the function $v(s)$, in the case $\alpha < \pi/4$ [see Fig. 7(A)]. Given $\alpha < \pi/4$ and $s \in [0, \pi]$ with $s \neq \arccos(-\tan^2\alpha)$, there exists one and only one time $s^*(s) \in [0, \pi]$ different from s, such that $v(s) = v(s^*(s))$. From Sec. III B, recall the following definition of candidate optimal trajectories:

- $s_f = s^*(s_i)$ (i.e., TYPE-1-candidate optimal trajectories),
- $s_f = s_i$ (i.e., TYPE-2-candidate optimal trajectories).

A useful relation between s and $s^*(s)$ is given by the following.

Lemma 6: For $\alpha < \pi/4$ and $s \in [0, \pi]$, it holds that $s + s^*(s) = v(s)$.

Proof of Lemma 6: Both s and $s^*(s)$ satisfy the following equation in $t \in [0, \pi]$:

$$\cot\left(\frac{1}{2}v(s)\right) = -\frac{\sin(t)}{\cos(t)+\cot^2(\alpha)} \Rightarrow \cos\left(\frac{1}{2}v(s)-t\right) = -\cos\left(\frac{1}{2}v(s)\right)\cot^2(\alpha).$$

Therefore, since $\frac{1}{2}v(s) - t \in [-\pi, \pi]$, $\forall s, t \in [0, \pi]$ and $s^*(s) \neq s$, it must be $s^*(s) - \frac{1}{2}v(s) = \frac{1}{2}v(s) - s \Rightarrow s + s^*(s) = v(s)$. ■

The description of candidate optimal trajectories is simplified by the following lemma, of which we skip the proof.

Lemma 7: Set

$$Z(s) = \frac{1}{\rho}\begin{pmatrix} 0 & \cot\left(\frac{1}{2}v(s)\right) & -\sin(\alpha) \\ -\cot\left(\frac{1}{2}v(s)\right) & 0 & 0 \\ \sin(\alpha) & 0 & 0 \end{pmatrix},$$

where $\rho = \sqrt{\cot^2\left(\frac{1}{2}v(s)\right) + \sin^2(\alpha)}$. *Then, if* $\theta(s)$ *is defined as in* (20), *we have* $e^{\theta(s)Z(s)} = e^{v(s)X_S^-} e^{v(s)X_S^+}$. Notice that the matrix $Z(s) \in so(3)$ is normalized in such a way that the map $t \mapsto e^{tZ(s)} \in SO(3)$ represents a rotation around the axes $R(s) = \left(0, \sin(\alpha), \cot\left(\frac{1}{2}v(s)\right)\right)^T$ with angular velocity equal to one.

To prove the results stated in Sec. III B we study separately the two possible cases previously listed.

Proof of Proposition 4: In this case we consider TYPE-1-candidate optimal trajectories. Assume that the optimal trajectory starts with $u=-1$ (the case $u=1$ is symmetric) and has an even number n of switchings. Then it must be

$$P_S = e^{s_f X_S^-} \underbrace{e^{v(s_i)X_S^+} \dots e^{v(s_i)X_S^+}}_{n-1 \text{ times}} e^{s_i X_S^-} P_N \tag{B1}$$

where P_N and P_S denote, respectively, the North and the South Pole, and we have that

$$e^{s_i X_S^-} P_S = e^{v(s_i)X_S^-} e^{v(s_i)X_S^+} \dots e^{v(s_i)X_S^+} e^{s_i X_S^-} P_N = e^{(1/2)n\theta(s_i)Z(s_i)} e^{s_i X_S^-} P_N,$$

from which we deduce that s_i must satisfy

$$\frac{1}{2} n\theta(s_i) = \pi + 2p\pi, \quad \text{for some integer} p.$$

It is easy to see that a value of s_i that satisfies a previous equation with $p>0$ does not give rise to a candidate optimal trajectory since the corresponding number of switchings is larger than N_M. Therefore in a previous equation it must be $p=0$. If n is odd, instead than (B1) we have

$$P_S = e^{s_f X_S^+} \underbrace{e^{v(s_i)X_S^-} \dots \dots e^{v(s_i)X_S^+}}_{n-1 \text{ times}} e^{s_i X_S^-} P_N \tag{B2}$$

and, moreover, by symmetry,

$$P_N = e^{s_f X_S^-} e^{v(s_i)X_S^+} \dots \dots e^{v(s_i)X_S^-} e^{s_i X_S^+} P_S.$$

Then, combining with (B2) and using the relation Lemma 6, we find

$$P_N = e^{-s_i X_S^-} \underbrace{e^{v(s_i)X_S^-} \dots \dots e^{v(s_i)X_S^+}}_{2n \text{ times}} e^{s_i X_S^-} P_N = e^{-s_i X_S^-} e^{n\theta(s_i)Z(s_i)} e^{s_i X_S^-} P_N.$$

Since $e^{s_i X_S^-} P_N$ is orthogonal to the rotation axis $R(s_i)$ corresponding to $Z(s_i)$, the previous identity is satisfied if and only if $n\theta(s_i)=2m\pi$ with m a positive integer. As in the previous case, for a candidate optimal trajectory, it must be $m=1$. ■

Proof of Proposition 5: Here we consider TYPE-2-candidate optimal trajectories. For simplicity call $s_i=s_f=s$. Assume, as before, that the optimal trajectory starts with $u=-1$. If this trajectory has $n=2q+1$ switchings then it must be

$$P_S = e^{sX_S^+} e^{q\theta(s)Z(s)} e^{sX_S^-} P_N.$$

In particular, the points $e^{-sX_S^+} P_S$ and $e^{sX_S^-} P_N$ must belong to a plane invariant with respect to rotations generated by $Z(s)$, and therefore the difference $e^{sX_S^-} P_N - e^{-sX_S^+} P_S$ must be orthogonal to the rotation axis $R(s)$. Actually it is easy to see that this is true for every value $s \in [0, \pi]$, since both $e^{-sX_S^+} P_S$ and $e^{sX_S^-} P_N$ are orthogonal to $R(s)$. Since the integral curve of $Z(s)$ passing through $e^{sX_S^-} P_N$ and $e^{-sX_S^+} P_S$ is a circle of radius 1, it is easy to compute the angle $\beta(s)$ between these points. In particular, the distance between $e^{sX_S^-} P_N$ and $e^{-sX_S^+} P_S$ coincides with $2\sin(\beta(s)/2)$, and so one easily gets the expression $\beta(s)=2\arccos(\sin(\alpha)\cos(\alpha))(1-\cos(s))$. Then Proposition 5 is proved when n is odd.

Assume now that the optimal trajectory has $n=2q+2$ switchings; then we can assume without loss of generality that $P_S = e^{sX_S^-} e^{v(s)X_S^+} e^{q\theta(s)Z(s)} e^{sX_S^-} P_N$. First of all, it is possible to see that $e^{-v(s)X_S^+} e^{-sX_S^-} P_S$ is orthogonal to $R(s)$. So it remains to compute the angle $\tilde{\beta}(s)$ between the point $e^{sX_S^-} P_N$ and the point $e^{-v(s)X_S^+} e^{-sX_S^-} P_S$ on the plane orthogonal to $R(s)$. As before, the distance

between these points coincides with $2\sin(\tilde{\beta}(s)/2)$. Instead of computing directly $\tilde{\beta}(s)$, we compute the difference between the angle $\tilde{\beta}(s)$ and the angle $\beta(s)$ previously defined above. We know that

$$2\sin\left(\frac{\beta(s)}{2}-\tilde{\beta}(s)\right)=\left|e^{-v(s)X_S^+}e^{-sX_S^-}P_S-e^{-sX_S^+}P_S\right|=\left|e^{-sX_S^-}P_S-e^{v(s)X_S^+}e^{-sX_S^+}P_S\right|=\left|e^{-sX_S^-}P_S-e^{s^*(s)X_S^+}P_S\right|.$$

Using the fact that s and $s^*(s)$ satisfy the relation $v(s)=v(s^*(s))$, one can easily find that

$$\left|e^{-sX_S^-}P_S-e^{s^*(s)X_S^+}P_S\right|=2\sqrt{1-\cos^2(\alpha)\sin^2\left(\frac{1}{2}v(s)\right)}.$$

Therefore $\beta(s)=\tilde{\beta}(s)+2\arccos\left(\cos(\alpha)\sin\left(\frac{1}{2}v(s)\right)\right)$. This leads to $\beta(s)-\tilde{\beta}(s)=\theta(s)/2$, and the proposition is proved also in the case n is even. ■

A. Proof of Proposition 6, on the alternating behavior of the optimal synthesis

In this section we need to consider also the dependence on α of the functions $v(s),\theta(s),\beta(s),\mathcal{F}(s),\mathcal{G}(s)$. Therefore we switch to the notation $v(s,\alpha),\theta(s,\alpha),\beta(s,\alpha),\mathcal{F}(s,\alpha),\mathcal{G}(s,\alpha)$.

The claims about the existence of solutions in Proposition 6 come from the fact that $\mathcal{F}(0)=\mathcal{F}(\pi)=\pi/2\alpha$ and the only minimum point of $\mathcal{F}$ occurs at $\bar{s}=\pi-\arccos(\tan^2(\alpha))$. It turns out that the image of $\mathcal{F}$ is a small interval whose length is of order α and therefore equation (22) has a solution only if α is close enough to $\pi/2m$ for some integer number m. This proves **C** with $r_2(m)$ satisfying $r_2(m)=O(1/m)$.

On the other hand, it is possible to estimate the derivative of $\mathcal{G}$ with respect to s, showing that it is negative in the open interval $]0,\pi[$. Therefore, since $\mathcal{G}(0)=\pi/2\alpha+1$ and $\mathcal{G}(\pi)=\pi/2\alpha-1$, Eq. (23) has always two positive solutions.

For the particular values $\alpha=\pi/2m$, where $m>1$ is an integer number, the solutions to Eqs. (22) and (23) give rise to two candidate optimal trajectories: the first one has exactly m bang arcs, all of length π (TYPE-1 and TYPE-2 candidate optimal trajectory at the same time), while the second one has one more switching and is a TYPE-2 candidate optimal trajectory. We want to see that the optimal trajectory is the first one. For this purpose, we need to estimate the time needed to reach the South Pole by the second candidate optimal trajectory, showing that it is greater than $m\pi=\pi^2/2\alpha$.

First, using the Taylor expansions with respect to α and centered at 0 of $\beta(\pi/2,\alpha)$ and $\theta(\pi/2,\alpha)$, one obtains

$$\mathcal{G}\left(\frac{\pi}{2},\alpha\right)=\frac{\pi}{2\alpha}-\alpha\frac{\pi}{4}+o(\alpha). \tag{B3}$$

We want now to estimate the solution $s(\alpha)$ of the equation $\mathcal{G}(s,\alpha)=\pi/2\alpha$. This can be done using (B3) and the following estimate on the derivative of $\mathcal{G}(.)$, with respect to s, near $s=\pi/2$:

$$\frac{\mathrm{d}}{\mathrm{d}s}\mathcal{G}(s,\alpha)=-1+o\left(|\alpha|+\left|\frac{\pi}{2}-s\right|\right).$$

Then it is easy to find that $s(\alpha)=\pi/2-\alpha(\pi/4)+o(\alpha)$, and, consequently, $v(s(\alpha),\alpha)=\pi+2\alpha^2+o(\alpha^2)$. Therefore $2s(\alpha)+(\pi/2\alpha-1)v(s(\alpha),\alpha)=\pi^2/2\alpha+\alpha(\pi/2)+o(\alpha)$. In particular, for $\alpha=\pi/2m$ this expression gives the time needed to reach the South Pole by the candidate optimal trajectory, and, since for m large enough it is larger than $m\pi=\pi^2/2\alpha$, we conclude that this trajectory cannot be optimal. Since the solutions to the equations (22), (23) change continuously with respect to α for each fixed number of switchings n, we easily deduce that, if we slightly decrease α starting from the value $\pi/2m$, the solution of (22) for $n=m$ does not give rise to an optimal trajectory.

For α slightly smaller than $\bar{\alpha} := \pi/2m$ there is a TYPE-2 candidate optimal trajectory corresponding to a solution $(s_1(\alpha), m+1)$ of (23), where $s_1(.)$ is continuous (on $[\bar{\alpha}-\varepsilon, \bar{\alpha}]$) and $s_1(\bar{\alpha}) = 0$, and there is also a TYPE-1 candidate optimal trajectory corresponding to a solution $(s_2(\alpha), m)$ of (22), where $s_2(.)$ is continuous (on $[\bar{\alpha}-\varepsilon, \bar{\alpha}]$) and $s_2(\bar{\alpha})=0$. Clearly for $\alpha=\bar{\alpha}$ these trajectories coincide. So we have to compare the time to reach the South Pole for such trajectories with α close to $\bar{\alpha}$.

We start with the TYPE-1 candidate optimal trajectory. From Eq. (22) we have that $(\mathrm{d}/\mathrm{d}\alpha)\theta(s_2(\alpha), \alpha)=0$. We use a subscript s, α to denote the partial differentiation with respect to such variables. Since $\theta_s(0, \alpha)=0$ we cannot apply directly the implicit function theorem near $(0, \bar{\alpha})$. However, if we set $\tilde{s}_2(\alpha)=s_2^2(\alpha)$ we find that $\tilde{s}_2'(\alpha)=2s_2(\alpha)\theta_\alpha(s_2(\alpha), \alpha))/\theta_s(s_2(\alpha), \alpha))$ (the superscript $'$ denotes differentiation with respect to α), and then, passing to the limit as $(s_2(\alpha), \alpha)$tends to $(0, \bar{\alpha})$, one easily finds that $\tilde{s}_2'(\bar{\alpha})=-2/\sin(\bar{\alpha})^3 \cos(\bar{\alpha})$.

Now we want to determine the way in which the total time $T_2(\alpha)=mv(s_2(\alpha), \alpha)$ changes. It is easy to see that $T_2(\alpha)$ is not differentiable at $\bar{\alpha}$, therefore we introduce the function $F(\alpha) = (T_2(\alpha)-T_2(\bar{\alpha}))^2 = m^2(v(s_2(\alpha), \alpha)-\pi)^2$.

Then $F'(\alpha)=2m^2(\mathrm{d}/\mathrm{d}\alpha)v(s_2(\alpha), \alpha)(v(s_2(\alpha), \alpha)-\pi)=2m^2(v_s(s_2(\alpha), \alpha)s_2'(\alpha)+v_\alpha(s_2(\alpha), \alpha))$ and, after the substitution $s_2'(\alpha)=\tilde{s}_2'(\alpha)/2s_2(\alpha)$ we can pass to the limit as α converges to $\bar{\alpha}$ obtaining

$$F'(\bar{\alpha}) = m^2 v_s^2(0, \bar{\alpha})\tilde{s}_2'(\bar{\alpha}) = -8m^2 \tan \bar{\alpha}.$$

Now we consider the TYPE-2 candidate optimal trajectory and we want to estimate $s_1(\alpha)$. From Eq. (23) we have that $s_1(.)$ is implicitly defined by the equation $\Phi(s_1(\alpha), \alpha) := 2\beta(s_1(\alpha), \alpha)-m\theta(s_1(\alpha), \alpha)=0$. As before, it is easy to see that $s_1(.)$ is not differentiable at $\bar{\alpha}$, and therefore we introduce the parameter $\tilde{s}_1(\alpha)=s_1^2(\alpha)$. As before, it is possible to compute the derivative $\tilde{s}_1'(\alpha)$:

$$\tilde{s}_1'(\bar{\alpha}) = -\lim_{\alpha\to\bar{\alpha}} \frac{2s_1(\alpha)\Phi_\alpha(s_1(\alpha), \alpha)}{\Phi_s(s_1(\alpha), \alpha)} = -\frac{2m}{\sin\bar{\alpha}\cos\bar{\alpha}(1+m\sin^2\bar{\alpha})}.$$

We have now to estimate the total time $T_1(\alpha)=2s_2(\alpha)+mv(s_2(\alpha), \alpha)$ for α close to $\bar{\alpha}$. After defining

$$G(\alpha) = (T_1(\alpha) - T_1(\bar{\alpha}))^2 = (2s_2(\alpha) + m(v(s_2(\alpha), \alpha) - \pi))^2,$$

we can compute the derivative of $G(.)$ as follows:

$$G'(\bar{\alpha}) = \lim_{\alpha\to\bar{\alpha}}\left[2(2s_2(\alpha) + m(v(s_2(\alpha), \alpha) - \pi))\left(\frac{\tilde{s}_2'(\alpha)}{s_2(\alpha)} + m\left(\frac{v_s(s_2(\alpha), \alpha)\tilde{s}_2'(\alpha)}{2s_2(\alpha)} + v_\alpha(s_2(\alpha), \alpha)\right)\right)\right]$$

$$= \lim_{\alpha\to\bar{\alpha}}\left[2\left(2 + m\frac{v(s_2(\alpha), \alpha) - v(0, \alpha)}{s_2(\alpha)}\right)\right]\lim_{\alpha\to\bar{\alpha}}\left[\tilde{s}_2'(\alpha) + m\left(\frac{1}{2}v_s(s_2(\alpha), \alpha)\tilde{s}_2'(\alpha) + v_\alpha(s_2(\alpha), \alpha)s_2(\alpha)\right)\right]$$

$$= (2 + mv_s(0, \bar{\alpha}))^2 s_2'(\bar{\alpha}) = -(2 + 2m\sin^2\bar{\alpha})^2 \frac{2m}{\sin\bar{\alpha}\cos\bar{\alpha}(1+m\sin^2\bar{\alpha})} = -\frac{8m(1+m\sin^2\bar{\alpha})}{\sin\bar{\alpha}\cos\bar{\alpha}}.$$

Since

$$\frac{8m(1+m\sin^2\bar{\alpha})}{\sin\bar{\alpha}\cos\bar{\alpha}} > m\tan\bar{\alpha},$$

we deduce that $G(\alpha)$ decreases faster than $F(\alpha)$ as α goes to $\bar{\alpha}$ and, since $T_1(\alpha)$ and $T_2(\alpha)$ are decreasing for α close to $\bar{\alpha}$, we have that $T_2(\alpha) > T_1(\alpha)$, i.e., the TYPE-1 trajectory is optimal for $\alpha \in [\bar{\alpha}-\varepsilon, \bar{\alpha}]$.

APPENDIX C: THE TIME NEEDED TO REACH EVERY POINT OF THE BLOCH SPHERE STARTING FROM THE NORTH POLE IN THE CASE $\alpha \in [\pi/4, \pi/2[$

In this section we assume $\alpha \in [\pi/4, \pi/2[$. If α is close to $\pi/4$, it is easy to verify that the South Pole is not the last point reached by bang-bang trajectories (the last point reached belongs to the cut locus present in the region $\Omega^{\pm}_{\text{nasty}}$), and the time needed to cover the whole sphere is slightly larger than 2π.

On the other hand, if α is large enough then the velocity along a singular arc is small and therefore the time needed to move along trajectories containing singular arcs is larger than 2π. The following proposition gives the asymptotic behavior of the total time needed to reach every point from the North Pole and determines the last point reached by the optimal synthesis for α large enough.

Proposition 17: Let $T(\alpha)$ the time needed to cover the whole sphere. Then, if α is large enough

$$T(\alpha) = \frac{\pi}{2\cos\alpha} + \pi - \frac{2\arcsin(\cot\alpha)}{\cos\alpha} + 2\arcsin(\cot^2\alpha) = \frac{\pi}{2\cos\alpha} + \pi - 2 + O\left(\frac{\pi}{2} - \alpha\right), \tag{C1}$$

and the last points reached for a fixed value of α are $\pm(\sqrt{1-\cot^2\alpha}, \cot\alpha, 0)^T$.

Proof of Proposition 17: From Proposition 2 the last points reached by optimal trajectories of the form $B_t S_s B_{t'}$ must lie on overlap curves that are subsets of the equator. Therefore it is enough to estimate the maximum time to reach these overlap curves. Assume that the first bang arc corresponds to the control $u=1$ and denote by β the angle corresponding to the arc of the equator between the last point of the singular arc and the point $O^+=(1,0,0)^T$. Notice that $\beta \in]0, \arccos(\cot\alpha)[$. Then it is easy to find the expression $T(\alpha,\beta)$ of the time needed to reach the overlap curve along that optimal trajectory:

$$T(\alpha,\beta) = \pi - \arccos(\cot^2\alpha) + \frac{\arccos(\cot\alpha)}{\cos\alpha} - \frac{\beta}{\cos\alpha} + \arccos\left(\frac{\cos^2\alpha - \tan^2\beta}{\cos^2\alpha + \tan^2\beta}\right).$$

The conclusion follows finding the maximum with respect to β of the previous quantity, which corresponds to the value $\bar{\beta} = \arcsin(\cot\alpha)$. Notice that $\bar{\beta}$ belongs to the interval of definition of β only if $\alpha > \operatorname{arccot}(\sqrt{2}/2)$. ■

Remark 22: Notice that, if $\alpha > \operatorname{arccot}(\sqrt{2}/2)$, then the set of points of the sphere reached within time t, with t in a left neighborhood of $T(\alpha)$, is not simply connected. More precisely there are two symmetric neighborhoods of the points $\pm(\sqrt{1-\cot^2\alpha}, \cot\alpha, 0)^T$ that are not reached in time less than or equal than t.

Remark 23: Recall that for system (6) the time needed to cover the whole sphere for α close enough to $\pi/2$ is obtained dividing by $k = 2E/\cos\alpha$ the expression (C1). Therefore, if we fix E it turns out that this quantity converges to $\pi/4E$ as M goes to infinity.

(Received 16 January 2006; accepted 26 April 2006; published online 7 June 2006)

We consider solutions of the one-dimensional equation $-u''+(Q+\lambda V)u=0$ where $Q:\mathbb{R}\to\mathbb{R}$ is locally integrable, $V:\mathbb{R}\to\mathbb{R}$ is integrable with $\mathrm{supp}(V)\subset[0,1]$, and $\lambda\in\mathbb{R}$ is a coupling constant. Given a family of solutions $\{u_\lambda\}_{\lambda\in\mathbb{R}}$ which satisfy $u_\lambda(x)=u_0(x)$ for all $x<0$, we prove that the zeros of $b(\lambda):=W[u_0,u_\lambda]$, the Wronskian of u_0 and u_λ, form a discrete set unless $V\equiv 0$. Setting $Q(x):=-E$, one sees that a particular consequence of this result may be stated as: if the fixed energy scattering experiment $-u''+\lambda Vu=Eu$ gives rise to a reflection coefficient which vanishes on a set of couplings with an accumulation point, then $V\equiv 0$. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2206691]

I. INTRODUCTION

The purpose of this paper is to prove a result concerning perturbations of one-dimensional Schrödinger-type equations. Let $Q:\mathbb{R}\to\mathbb{R}$ be locally integrable and let $u_0:\mathbb{R}\to\mathbb{C}$ be a solution of

$$-u_0''(x)+Q(x)u_0(x)=0 \tag{1}$$

that is not identically zero. The perturbation is a second (real-valued) potential, $V\in L^1(\mathbb{R})$ of compact support which, for simplicity, we assume satisfies $\mathrm{supp}(V)\subseteq[0,1]$. Define u_λ as the solution of

$$-u_\lambda''(x)+Q(x)u_\lambda(x)+\lambda V(x)u_\lambda(x)=0 \tag{2}$$

that obeys $u_\lambda(x)=u_0(x)$ for all $x<0$. The parameter λ is known as the coupling constant. In the problems of interest to us, it is real; however, we will allow it to vary over the complex plane as this does not affect our results.

The question we wish to discuss is the following: for how many values of λ is it possible that $u_\lambda(x)$ is a multiple of $u_0(x)$ in the region $x>1$? An equivalent formulation is to study the zeros of the Wronskian between u_0 and u_λ,

$$b(\lambda):=W[u_0,u_\lambda](x)=u_0'(x)u_\lambda(x)-u_0(x)u_\lambda'(x) \tag{3}$$

for any $x>1$.

Theorem 1.1: *The zeros of $b(\lambda)$ form a discrete set unless $V\equiv 0$.*

Furthermore, if b has infinitely many zeros, they must approach infinity rather rapidly.

Theorem 1.2: *If $V\not\equiv 0$, then the number of roots of $b(\lambda)=0$ in the disk $|\lambda|\le r$ (counted by multiplicity) is $O(r^{1/2})$ as $r\to\infty$.*

[a)]Electronic mail: killip@math.ucla.edu
[b)]Electronic mail: rjsims@math.ucdavis.edu

When V is sign definite and $Q \equiv 0$, Chadan has shown that the zeros of $b(\lambda)$ determine V precisely in a slightly different scenario; see Ref. 2. A Liouville transformation is used to reduce the problem to the well-known uniqueness problem in the energy parameter.

The proof of Theorems 1 and 2 consist of using some classical analysis to reduce the problem to one treated by Stolz.[13] (We repeat his solution for the convenience of the reader.) As with this paper, Stolz was interested in such matters for their relation to localization for the Anderson model. Before elaborating this point, let us first explain the connection of our results to scattering theory.

Consider the time-independent Schrödinger equation with potential $q(x)$:

$$-\psi''(x) + q(x)\psi(x) = E\psi(x), \tag{4}$$

which describes the wave function of a quantum particle with energy E. For certain choices of q and E, this equation admits a solution, u_0, that corresponds to the particle travelling from right to left (the complex conjugate solution represents left-to-right motion). For example, when $q \equiv 0$ and $E = k^2$ with $k > 0$, we have $\psi(x) = e^{-ikx}$. The Floquet-Bloch waves form another example when q is periodic.

If a perturbation λV is introduced, this may cause the particle to be reflected back with nonzero probability. This situation can be analyzed by looking at the solution u_λ of (2) with $Q(x) = q(x) - E$. For $x > 1$, we may write $u_\lambda(x) = \alpha u_0(x) + \beta \overline{u_0}(x)$ for some complex numbers α and β. In this way, we obtain a formula for the probability of reflection, $|\beta/\alpha|^2$. We also see that there will be no reflection if and only if u_λ and u_0 are linearly dependent on the interval $[0,1]$. That is, there will be no reflection if and only if $b(\lambda) = 0$.

Our interest in this question stems from its relevance to the one-dimensional Anderson model. Consider solutions of (2) in the situation where the coupling constant λ is a random variable. As was first observed in the context of the random dimer model,[6,7] it is possible for the localization length to diverge (i.e., Lyapunov exponent vanish) at a fixed energy. In particular, this happens at positive energies when the reflection coefficient associated to the single site potential vanishes almost surely for a particular choice of random coupling constant. The presence of these exceptional energies leads to interesting transport phenomena (see Refs. 3 and 8 and references therein), while away from them one may prove exponential and dynamical localization (see Refs. 4 and 5). A consequence of Theorem 1.1 is that these divergences cannot occur unless the distribution of the couplings is purely discrete.

We assumed from the very beginning that V was an L^1 function. The theorems above are false if V is permitted to be a measure as the following example shows: see Ref. 5 for an analogous example in the discrete setting.

Example 1.3: Consider $Q(x) = -k^2$ and $u_0(x) = e^{ikx}$. For $V(x) = \delta(x) - \delta(x-1)$, a simple calculation reveals

$$b(\lambda) = \lambda\left(1 + \tfrac{\lambda}{2ik}\right)(e^{2ik} - 1). \tag{5}$$

Thus we see that $b \equiv 0$ whenever $k = n\pi$, $n \in \mathbb{Z}$. (The case $k = 0$ follows by a limiting argument.) The same is true for any other choice of u_0. This is particularly evident when $u_0 = \sin(n\pi x)$ for in this case, $u_\lambda(x) = \sin(n\pi x)$, which vanishes on the support of V.

One may ask for analogues of the theorems given above when V is not of compact support. In this case, one would define $u_\lambda(x)$ by the constraint $u_\lambda(x) - u_0(x) \to 0$ as $x \to -\infty$ and define $b(\lambda)$ as the limit of $W[u_0, u_\lambda](x)$ as $x \to +\infty$. Naturally, one would need to ensure that V decays fast enough so that these limits exist; moreover the choice of decay rate cannot be made without knowledge of the behavior of Q at infinity. We haven chosen not to pursue this matter.

II. PROOFS

Let us choose a solution v_0 of (1), linearly independent of u_0, normalized by the requirement $W[u_0,v_0]\equiv 1$. As $u_\lambda(x)$ is also a solution of (1) in the region $x>1$, we may write

$$u_\lambda(x) = a(\lambda)u_0(x) + b(\lambda)v_0(x) \quad \text{for all } x > 1;$$

moreover, by computing Wronskians, we see that $b(\lambda)$ is the same function defined in (3).

First we show that $a(\lambda)$ and $b(\lambda)$ are analytic functions of order one-half. This allows us to deduce Theorem 1.2 from Theorem 1.1. Moreover, it shows that if the zeros of b are not discrete, then b must vanish identically. These two applications require us only to treat b; however when u_0 is complex valued, we will need to invoke properties of a when we prove Theorem 1.1.

Proposition 2.1: The functions $a(\lambda)$ and $b(\lambda)$ are entire and obey

$$|a(\lambda)| \le C\exp\{c|\lambda|^{1/2}\}, \quad |b(\lambda)| \le C\exp\{c|\lambda|^{1/2}\} \tag{6}$$

for some positive constants c and C, which depend on u_0 and $\|V\|_{L^1}$.

Proof: As in the preceding paragraphs, let v_0 be a solution of (1) which satisfies $W[u_0,v_0]\equiv 1$. We define

$$K(x,t) = [u_0(x)v_0(t) - v_0(x)u_0(t)]V(t)$$

so $u_\lambda(x)$ can be constructed as the solution of the Volterra integral equation

$$u_\lambda(x) = u_0(x) + \lambda\int_0^x K(x,t)u_\lambda(t)\mathrm{d}t \tag{7}$$

acting on $C^0([0,\infty))$. While this equation arises naturally from variation of parameters, it is quicker to check it by differentiating both sides twice. The key observations are

$$K(x,x) = 0, \quad \frac{\partial K}{\partial x}(x,x) = V(x), \quad \text{and } \frac{\partial^2 K}{\partial x^2}(x,t) = Q(x)K(x,t).$$

One can solve (7) by repeated substitution, which gives rise to an infinite series for u_λ,

$$u_\lambda(x) = u_0(x) + \sum_{n=1}^{\infty}\lambda^n\int\cdots\int K(x,t_1)\cdots K(t_{n-1},t_n)u_0(t_n)\mathrm{d}t_1\cdots\mathrm{d}t_n, \tag{8}$$

where integration takes place over the region $0<t_n<\cdots<t_1<x$. Convergence of this series is a well-known property of Volterra operators (cf. Ref. 14, Sec. 36) and can be deduced from the estimates below.

From (8) we obtain power series for a and b,

$$a(\lambda) = 1 + \sum_{n=1}^{\infty}\lambda^n\int\cdots\int_{\Delta_n} v_0(t_1)V(t_1)K(t_1,t_2)\cdots K(t_{n-1},t_n)u_0(t_n)\mathrm{d}t_1\cdots\mathrm{d}t_n,$$

$$b(\lambda) = -\sum_{n=1}^{\infty}\lambda^n\int\cdots\int_{\Delta_n} u_0(t_1)V(t_1)K(t_1,t_2)\cdots K(t_{n-1},t_n)u_0(t_n)\mathrm{d}t_1\cdots\mathrm{d}t_n,$$

where Δ_n is the simplex $0<t_n<\cdots<t_1<1$. Our bound on the size of these functions will follow by estimating the individual terms in these series. We only give details for $b(\lambda)$ because the argument for $a(\lambda)$ is almost identical.

As u_0 and v_0 are C^1, one may choose a constant M so that

$$|u_0(t)| \le M \quad \text{and } |K(s,t)| \le M|s-t||V(t)| \quad \forall\, t,s \in [0,1].$$

Second, by the arithmetic/geometric mean inequality,

$$\prod_{j=1}^{n-1} |t_j - t_{j+1}| \le (n-1)^{-(n-1)}.$$

Combining these two observations, we can deduce

$$\begin{aligned} |b(\lambda)| &\le \sum_{n=1}^{\infty} \frac{|\lambda|^n M^{n+1}}{(n-1)^{n-1}} \int \cdots \int_{\Delta_n} |V(t_1)| \cdots |V(t_n)| \mathrm{d}t_1 \cdots \mathrm{d}t_n \\ &\le \sum_{n=1}^{\infty} \frac{|\lambda|^n M^{n+1}}{n\,!\,(n-1)^{n-1}} \|V\|_{L^1}^n. \end{aligned}$$

The resulting bound on $|b(\lambda)|$ can now be deduced either through the properties of the Bessel function

$$\sum_{n=0}^{\infty} \frac{r^{2n}}{(n\,!\,)^2} = I_0(2r) = \frac{1}{\pi} \int_0^{\pi} e^{2r\cos\theta}\, \mathrm{d}\theta \le e^{2|r|},$$

or by brute force. □

The one-half power appearing in (6) is the smallest possible; see Example 2.3 below.

In the proof of Theorem 1.1 will specifically consider only $\lambda \in \mathbb{R}$ in order to be able to use some facts about self-adjoint operators. When u_0 is real-valued, Theorem 1.1 follows by the argument presented in Lemma 3 of Ref. 13. Of course the problem is unchanged if u_0 is a complex multiple of a real solution. However, when $\operatorname{Re} u_0$ and $\operatorname{Im} u_0$ are linearly independent solutions, one needs to make some modifications. The approach we take is to show that one may replace u_0 by $\operatorname{Re} u_0$.

Proposition 2.2: Suppose $\operatorname{Re} u_0$ *and* $\operatorname{Im} u_0$ *are linearly independent and* $b(\lambda) \equiv 0$. *Then* $W[\operatorname{Re} u_0, \operatorname{Re} u_\lambda](x) = 0$ *for all* $x > 1$ *and all* $\lambda \in \mathbb{R}$.

Proof: By assumption, $u_\lambda(x) = a(\lambda) u_0(x)$ for all $x > 1$. For $\lambda \in \mathbb{R}$, both u_λ and $\overline{u_\lambda}$ are solutions of (2). Therefore,

$$W[u_0, \overline{u_0}] = W[u_\lambda, \overline{u_\lambda}] = |a(\lambda)|^2 W[u_0, \overline{u_0}],$$

which is nonzero because we assumed linear independence. Thus it follows that $a(\lambda)$ is unimodular for $\lambda \in \mathbb{R}$.

By the Schwarz reflection principle, the complex conjugate of any zero of a must be a pole; however, a is an entire function so we may conclude that it is zero-free. This means that $\log[a(\lambda)]$ is an entire function, but then by the estimate in Proposition 2.1, it must be constant. By taking $\lambda = 0$, we learn that $a(\lambda) \equiv 1$.

We have just seen that for all λ (real or complex) and all $x > 1$, $u_\lambda(x) = u_0(x)$. By taking real parts, we immediately obtain the conclusion sought. □

Proof of Theorem 1.1: In light of Proposition 2.2 we may assume that u_0 is real-valued. We now essentially repeat the argument from Lemma 3 of Ref. 13. Let us choose θ_0 and θ_1 so that

$$\cos(\theta_0) u_0(0) + \sin(\theta_0) u_0'(0) = 0 = \cos(\theta_1) u_0(1) + \sin(\theta_1) u_0'(1)$$

and consider the self-adjoint operators $H_\lambda u = -u'' + Qu + \lambda V u$ on $[0,1]$ with the boundary conditions

$$\cos(\theta_x) u(x) + \sin(\theta_x) u'(x) = 0 \quad \text{for } x \in \{0,1\}.$$

Suppose $V \neq 0$ and the set of λ for which $b(\lambda)=0$ has an accumulation point. In this case, $b(\lambda) \equiv 0$, and in particular, 0 is an eigenvalue of H_λ for every $\lambda \in \mathbb{R}$. As the spectrum of H_λ is simple, discrete, and bounded from below, this implies that the number of negative eigenvalues of H_λ is finite and independent of λ. We will derive a contradiction by using a very weak form of Weyl's law. (When Q and V obey some mild regularity hypotheses, full Weyl-law asymptotics are known, cf. Ref. 10 Theorem XIII.79.)

As $V \neq 0$, it must happen that either V is positive on a set of positive measure, or V is negative on a set of positive measure. We will treat the former case, the latter follows with obvious modifications.

For each $\epsilon > 0$, let us define

$$\phi_\epsilon(x) = \begin{cases} \sqrt{\frac{3}{2}}\epsilon^{-3/2}(\epsilon - |x|) & |x| < \epsilon, \\ 0 & |x| \geq \epsilon. \end{cases}$$

By the Lebesgue differentiation theorem, $\int \phi(x-t)^2 V(t) \mathrm{d}t \to V(x)$ as $\epsilon \downarrow 0$ for a.e. $x \in \mathbb{R}$. Therefore, given any integer $N > 0$, one can find N distinct points $x_1, \ldots, x_N \in (0,1)$ and ϵ sufficiently small, so that $\phi_\epsilon(x-x_j)$ are supported in disjoint subsets of $(0,1)$ and obey $\int V(x)\phi_\epsilon(x-x_j)\mathrm{d}x > \epsilon$. Thus, by the minimax principle (cf. Ref. 10, Sec. XIII.1) one can see that H_λ has at least N negative eigenvalues when λ is a sufficiently large negative number. □

An alternate approach to proving that $a(\lambda) \equiv 1$ implies $V \equiv 0$, is through recent work on the large-λ asymptotics of the spectral shift function $\arg[a(\lambda)]$; see Refs. 9 and 11, for example. The authors thank Pushnitski for explaining some of this material to us.

Proof of Theorem 1.2: The conclusion of this theorem holds for any nonzero entire function of order one-half and finite type; see Ref. 1, Theorem 2.5.13 or Ref. 12, Theorem 5.2.1. □

Theorem 1.2 is optimal with regard to the power of r. This is to be expected from Weyl's law and can be seen with an elementary example.

Example 2.3: Consider $Q \equiv -\pi^2$, $u_0(x) = \sin(\pi x)$, and $V = -\chi_{[0,1]}$. In this case,

$$b(\lambda) = -\cos(\sqrt{\lambda + \pi^2}).$$

As cosine is an even function, both branches of the square root lead to the same answer.

(Received 15 February 2006; accepted 19 April 2006; published online 8 June 2006)

We obtain several new results for the complex generalized associated Lamé potential $V(x)=a(a+1)m\,\mathrm{sn}^2(y,m)+b(b+1)m\,\mathrm{sn}^2(y+K(m),m)+f(f+1)m\,\mathrm{sn}^2(y+K(m)+iK'(m),m)+g(g+1)m\,\mathrm{sn}^2(y+iK'(m),m)$, where $y\equiv x-K(m)/2-iK'(m)/2$, $\mathrm{sn}(y,m)$ is the Jacobi elliptic function with modulus parameter m, and there are four real parameters a,b,f,g. First, we derive two new duality relations which, when coupled with a previously obtained duality relation, permit us to relate the band edge eigenstates of the 24 potentials obtained by permutations of the parameters a,b,f,g. Second, we pose and answer the question: how many independent potentials are there with a finite number "a" of band gaps when a,b,f,g are integers and $a\geqslant b\geqslant f\geqslant g\geqslant 0$? For these potentials, we clarify the nature of the band edge eigenfunctions. We also obtain several analytic results when at least one of the four parameters is a half-integer. As a by-product, we also obtain new solutions of Heun's differential equation. © *2006 American Institute of Physics.*

I. INTRODUCTION

In a recent paper,[1] hereafter referred to as paper I, we discussed the generalized associated Lamé (GAL) potential given by

$$\begin{aligned}\hat{V}(x) &= a(a+1)m\,\mathrm{sn}^2(x,m)+b(b+1)m\,\mathrm{sn}^2(x+K(m),m)\\ &\quad+f(f+1)m\,\mathrm{sn}^2(x+K(m)+iK'(m),m)+g(g+1)m\,\mathrm{sn}^2(x+iK'(m),m)\\ &= a(a+1)m\,\mathrm{sn}^2(x,m)+b(b+1)m\frac{\mathrm{cn}^2(x,m)}{\mathrm{dn}^2(x,m)}+f(f+1)\frac{\mathrm{dn}^2(x,m)}{\mathrm{cn}^2(x,m)}+g(g+1)\frac{1}{\mathrm{sn}^2(x,m)},\end{aligned} \tag{1}$$

which involves four real parameters a,b,f,g. Here, sn (x,m), cn (x,m), dn (x,m) are Jacobi elliptic functions with elliptic modulus parameter $m(0\leqslant m\leqslant 1)$. They are doubly periodic functions with periods $[4K(m),i2K'(m)]$, $[4K(m),2K(m)+i2K'(m)]$, $[2K(m),i4K'(m)]$ respectively,[2] where $K(m)\equiv\int_0^{\pi/2}d\theta[1-m\sin^2\theta]^{-1/2}$ denotes the complete elliptic integral of the first kind, and $K'(m)\equiv K(1-m)$. From now on, unless essential, we will not explicitly display the modulus parameter m as an argument of Jacobi elliptic functions. It may be noted here that the four terms in the GAL potential (1) correspond to complex translations of the independent variable x by 0, $K(m),K(m)+iK'(m),iK'(m)$. Although the GAL potential is real, it does have singularities on the real axis coming from the zeros of the Jacobi elliptic functions sn (x) and cn (x) in the last two terms. One way to avoid these singularities is to make a complex change of variables $y=ix+\beta$,

a)Electronic mail: sukhatme@buffalo.edu

with β being an arbitrary real, nonzero constant, chosen so as to avoid the singularities arising from the zeros of Jacobi elliptic functions on the real axis.[3] This procedure was used in paper I, and we studied many of the properties of the resulting PT-invariant complex periodic potential.[4] However, consistent with the practice in the mathematics literature, in this paper we use an alternative approach of avoiding singularities by simply translating the independent variable x by an arbitrary nonzero amount in the complex plane. In fact, for simplicity, from symmetry considerations, we take the translated variable to be $x-K(m)/2-iK'(m)/2$. Note that the potential still is a PT-invariant complex periodic potential. One very important consequence of this choice is that the energy eigenvalues which we shall obtain here will be opposite in sign from the values obtained in paper I. This point should be kept in mind while comparing the results from the two papers. Thus explicitly, we consider the potential

$$\begin{aligned} V(x) &= \hat{V}(y) \\ &= a(a+1)m\,\mathrm{sn}^2(y,m) + b(b+1)m\,\mathrm{sn}^2(y+K(m),m) + f(f+1)m\,\mathrm{sn}^2(y+K(m)+iK'(m),m) \\ &\quad + g(g+1)m\,\mathrm{sn}^2(y+iK'(m),m) \\ &= a(a+1)m\,\mathrm{sn}^2(y,m) + b(b+1)m\frac{\mathrm{cn}^2(y,m)}{\mathrm{dn}^2(y,m)} + f(f+1)\frac{\mathrm{dn}^2(y,m)}{\mathrm{cn}^2(y,m)} \\ &\quad + g(g+1)\frac{1}{\mathrm{sn}^2(y,m)} \equiv [a,b,f,g], \end{aligned} \tag{2}$$

where

$$y = x - \frac{K(m)}{2} - \frac{iK'(m)}{2}. \tag{3}$$

It may be noted here that in paper I we used the notation $[a(a+1),b(b+1),f(f+1),g(g+1)]$ to denote this potential. However, for consistency with the prevailing practice in the mathematics literature, in this paper we use the notation $[a,b,f,g]$. In this notation, ordinary Lamé potentials are denoted by $[a, 0, 0, 0]$, and associated Lamé (AL) potentials are denoted by $[a,b, 0, 0]$. Note that the potential (2) remains unchanged when any one or more of the parameters a,b,f,g change to $-a-1,-b-1,-f-1,-g-1$ respectively.

There is one important observation which permits us to construct many supersymmetric partner potentials corresponding to a given potential.[5] Although this point was previously made in paper I, it is worth restating here. Normally, in supersymmetric quantum mechanics,[6] given a potential $V_-(x)$, the ground state wave function $\psi_0(x)$ is used to construct the superpotential $W(x)=-\psi_0'(x)/\psi_0(x)$, which then yields the supersymmetric (SUSY) partner potential $V_+(x)=W^2+W'$. If one uses any excited state wave function $\psi(x)$ of $V_-(x)$ to construct a superpotential $W(x)$, then the original potential $V_-(x)$ is recovered correctly (by construction), but the corresponding partner potential $V_+(x)$ turns out to be singular on the real x axis due to the zeros of the excited state wave function $\psi(x)$. However, for the complex potential (2), the singularities are not on the real axis.[7] Thus in this case one could also use any of the excited state wave functions to obtain the superpotential $W(x)$ and hence discover several supersymmetric partner potentials with the same energy spectrum.

In paper I we showed that several GAL potentials with specific integer values of a,b,f,g have a finite number of band gaps. Further, looking at the symmetry of these potentials, we conjectured that all GAL potentials with integer values of a,b,f,g also have a finite number of band gaps. Some results of this type are available in the mathematics literature, and it is worthwhile to present a brief review of what is already known about the GAL potential.

The GAL potential (2), expressed in terms of Weierstrass functions, was discussed in a brief note by Darboux in 1882,[8] as well as in two subsequent articles in 1914 and 1915. He mentioned that some results had already been presented by Hermite in 1872 in unpublished lectures at Ecole Polytechnique. In 1883, Sparre[9] wrote two long papers on the GAL potential expressed in terms of

Jacobi elliptic functions. Unfortunately, the mathematics community was largely unaware of these papers, and the GAL potential was "rediscovered" by Treibich and Verdier in 1990.[10] Nowadays, the GAL potential, expressed in terms of Weierstrass functions, is known as the Treibich-Verdier potential. Several investigators have shown that when a,b,f,g are integers, these potentials have a finite number of band gaps. In particular, the number of band gaps p is given by[11]

$$p = \tfrac{1}{2}\max\Big[2\max[a,b,f,g], 1+N-\{1+(-1)^N\}\Big\{\min[a,b,f,g]+\tfrac{1}{2}\Big\}\Big], \tag{4}$$

where $N=a+b+f+g$. It was also shown that finite band gap potentials are solutions of higher order KdV equations.[12] In recent times, several people have also discussed the connection between Heun's equation and the Treibich-Verdier potential.[13] Finally, some authors have studied other general potentials (different from GAL potentials) which have a finite number of band gaps.[14]

In paper I using supersymmetry we showed that the band edge eigenvalues of the Lamé and the AL potentials [2, 0, 0, 0], [3, 0, 0, 0], $[a,(a-3),0,0]$ are the same as those of the GAL potentials [1, 1, 1, 0], [2, 1, 1, 1], $[a,a-1,1,0]$, respectively. We had also conjectured in paper I that for integer a,b, Lamé and AL potentials have the same band edge eigenvalues as some GAL potentials—the explicit relationship being

$$\begin{aligned}
[a,0,0,0] &\equiv \left[\frac{a}{2},\frac{a}{2},\frac{a}{2},\frac{a-2}{2}\right], \quad a=\text{even integer},\\
[a,0,0,0] &\equiv \left[\frac{a+1}{2},\frac{a-1}{2},\frac{a-1}{2},\frac{a-1}{2}\right], \quad a=\text{odd integer},\\
[a,b,0,0] &\equiv \left[\frac{a+b}{2},\frac{a+b}{2},\frac{a-b}{2},\frac{a-b-2}{2}\right], \quad a+b=\text{even integer},\\
[a,b,0,0] &\equiv \left[\frac{a+b+1}{2},\frac{a+b-1}{2},\frac{a-b-1}{2},\frac{a-b-1}{2}\right], \quad a+b=\text{odd integer}.
\end{aligned} \tag{5}$$

Note that we are using the notation "≡" to denote "same band edge eigenvalues," but not identical potentials. It is interesting to note that recently, Takemura[15] has verified the conjectures expressed in (5). Further, more generally, he has proved that the GAL potential $[a,b,f,g]$ for integer a,b,f,g has the same band edge eigenvalues as another GAL potential, with the explicit relationship depending on whether $N\equiv a+b+f+g$ is an even or an odd integer. If N is an even integer, the relationship is

$$[a,b,f,g] \equiv \left[\frac{a+b+f-g}{2},\frac{a+b+g-f}{2},\frac{a+f+g-b}{2},\frac{b+f+g-a}{2}\right], \tag{6}$$

while if N is an odd integer, then the relationship is

$$[a,b,f,g] \equiv \left[\frac{a+b+f+g+1}{2},\frac{a+b-f-g-1}{2},\frac{a+f-b-g-1}{2},\frac{a+g-b-f-1}{2}\right]. \tag{7}$$

He has also shown that if a,b,f,g are all half-integers and their sum is an even integer, then the band edge energy eigenvalues of the potential $[a,b,f,g]$ are the same as two other GAL potentials where also all four parameters are half-integers with their sum being an even integer. In particular, the explicit relationships are

$$\left[a=k+\frac{1}{2},b=l+\frac{1}{2},f=n+\frac{1}{2},g=p+\frac{1}{2}\right]$$
$$\equiv\left[\frac{k+l+n+p+3}{2},\frac{k+l-n-p-1}{2},\frac{k+n-l-p-1}{2},\frac{k+p-n-l-1}{2}\right]$$
$$\equiv\left[\frac{k+l+n-p+1}{2},\frac{k+l+p-n+1}{2},\frac{k+n+p-l+1}{2},\frac{l+n+p-k+1}{2}\right]. \quad (8)$$

The above-mentioned results, when combined with our work in paper I, raise several questions. For example, while it is clear from relation (4) that all 24 potentials obtained by permutation of the four parameters a,b,f,g have the same number of band gaps, what is the precise relationship between the band edge eigenstates of these 24 potentials? Second, a very interesting question is to ask how many independent GAL potentials there are with say a band gaps. Third, is it possible to further generalize the results of Takemura?[15] Besides, what is the nature of the band edge eigenfunctions for a general GAL potential in case a,b,f,g are all integers? Finally, in view of the connection between the GAL potentials and Heun's equation,[9,13] it is worth inquiring about the implications of these results in the context of solutions to Heun's equation.

In this paper, we address all the above-raised issues. Further, we also consider GAL potentials in which at least one of the four parameters is a half-integer while the other parameters are arbitrary numbers and show that both relations (6) and (7) are valid in all these cases. As a consequence, we conjecture that relations (6) and (7) are in fact simultaneously valid even when all four parameters a,b,f,g are integers with their band edge eigenvalues being the same as the quasi-exactly solvable (QES) eigenvalues of potentials where all four parameters are half-integers (with their sum being an odd integer). Further, knowing the QES eigenvalues of the GAL potentials $[a,1/2,f,g]$, $[a,b,1/2,g]$, $[a,b,f,1/2]$ (where a,b,f,g are arbitrary numbers), and using the connection between the Schrödinger equation for the GAL potentials and Heun's equation, we show that the corresponding eigenfunctions can be obtained by directly solving the algebraic form of Heun's equation.

The plan of this paper is as follows. In Sec. II, we derive new duality relations and examine some consequences. In particular, using these duality relations we obtain the precise connection between the energy eigenvalues and eigenfunctions of the 24 potentials obtained by permuting the four parameters a,b,f,g. In Sec. III, we discuss the GAL potential (2) in some detail when the four parameters a,b,f,g are all integers. First, we find various GAL potentials which are related to each other in the sense that they have identical band edge energy eigenvalues. We also find a large number of self-isospectral potentials as well as self-dual but non-self-isospectral potentials. Using all these results, we obtain the number of independent potentials with say a band gaps. We also clarify the nature of the band edge eigenfunctions for these potentials. In Sec. IV we discuss the GAL potential when either one or more of the four parameters take half-integer values while the remaining parameters are arbitrary. In this case, in general one expects to obtain QES mid-band states, by which we mean any energy state lying inside an energy band and thus not a band edge. Quite remarkably, by generalizing Takemura's results[15] we obtain GAL potentials which have the same band edge eigenvalues as the mid-band energy values of the potentials with one or more of the parameters being half-integers. In Sec. V we discuss the GAL potential in case the parameters a,b,f,g take arbitrary values and obtain the corresponding GAL potentials with the same band edge and mid-band energy values when $a+b+f+g$ [or any other combination obtained by replacing one or more of these parameters by $-a-1,-b-1,-f-1,-g-1$, respectively] is an even integer. In Sec. VI we discuss the implications of all these results in the context of Heun's equation. In particular, we show that in view of the connection between the different GAL potentials, given a periodic solution of Heun's equation, one immediately obtains four periodic and three quasi-periodic solutions of the same equation. We also show that in many cases, knowing the QES energy values of a GAL potential, it is much easier to solve the algebraic form of Heun's equation and obtain the corresponding eigenfunctions of the GAL potential. Finally, in Sec. VII we summarize the results obtained in this paper and spell out some open problems.

II. DUALITY RELATIONS FOR GAL POTENTIALS

In this paper our main focus is on the Schrödinger equation

$$-\frac{\mathrm{d}^2}{\mathrm{d}x^2}\psi(x)+\hat{V}(x)\psi(x)=E\psi(x), \tag{9}$$

where $\hat{V}(x)$ is the GAL potential given by Eq. (1), and we have chosen units with $\hbar=2m=1$. Displaying parameters more explicitly, Eq. (9) states that the potential $\hat{V}(a,b,f,g,m;x)$ has band edge eigenvalues $E(a,b,f,g,m)$ and eigenfunctions $\psi(a,b,f,g,m;x)$. Of course, this means that the translated potential $V(x)\equiv V(a,b,f,g,m;x)=\hat{V}(a,b,f,g,m;x-K(m)/2-iK'(m)/2)$ given in Eq. (2) has the same eigenvalues $E(a,b,f,g,m)$ and eigenfunctions $\psi(a,b,f,g,m;x-K(m)/2-iK'(m)/2)$.

First we want to show that the band edge eigenstates of the 24 potentials [obtained via permutations of the 4 parameters, a,b,f,g in $V(x)$] are all related, so that once the band edge eigenstates of any one permutation are known, the complete band edge eigenstates of all 24 potentials are also known. Actually, these relations are valid for both band edges as well as mid-band states.

The first relation is simple—in view of the invariance of the Schrödinger Eq. (9) under the translation $x\to x+K(m)$ followed by the interchanges $a\leftrightarrow b$ and $f\leftrightarrow g$, one gets[1]

$$E(b,a,g,f,m)=E(a,b,f,g,m),\quad \psi(b,a,g,f,m;x)\propto\psi(a,b,f,g,m;x+K(m)). \tag{10}$$

Similarly, the translations $x\to x+iK'(m)$ and $x\to x+K(m)+iK'(m)$ followed by suitable interchanges of parameters yield

$$E(g,f,b,a,m)=E(a,b,f,g,m),\quad \psi(g,f,b,a,m;x)\propto\psi(a,b,f,g,m;x+iK'(m)), \tag{11}$$

$$E(f,g,a,b,m)=E(a,b,f,g,m),\quad \psi(f,g,a,b,m;x)\propto\psi(a,b,f,g,m;x+K(m)+iK'(m)). \tag{12}$$

Thus, once we obtain the eigenvalues and eigenfunctions of a given potential $[a,b,f,g]$, then we immediately know the eigenvalues and eigenfunctions of three other potentials: $[b,a,g,f]$, $[g,f,b,a]$, and $[f,g,a,b]$. Note that relations (10)–(12) all involve the same modulus parameter m.

We now derive three remarkable duality relations, which connect the energy states of different GAL potentials, and involve changes in the modulus parameter from m to $1-m$, $1/m$ and $-m/(1-m)$.

Duality Relation I: This was already derived in paper I and is given by

$$\begin{gathered}E(a,b,f,g,m)=[a(a+1)+b(b+1)+f(f+1)+g(g+1)]-E(a,g,f,b,1-m),\\ \psi(a,b,f,g,m;x)\propto\psi(a,g,f,b,1-m;x+K'(m)+iK(m)).\end{gathered} \tag{13}$$

Duality Relation II: Using the formulas[2]

$$\mathrm{sn}(x,m)=\frac{1}{k}\mathrm{sn}\left(kx,\frac{1}{m}\right),\quad \mathrm{cn}(x,m)=\mathrm{dn}\left(kx,\frac{1}{m}\right),\quad \mathrm{dn}(x,m)=\mathrm{cn}\left(kx,\frac{1}{m}\right),\quad k^2\equiv m, \tag{14}$$

and redefining a new variable $z=kx$, the Schrödinger equation (9) takes the form

$$-\frac{\mathrm{d}^2}{\mathrm{d}z^2}\psi(z)+\left[\frac{a(a+1)}{m}\mathrm{sn}^2\left(z,\frac{1}{m}\right)+\frac{f(f+1)}{m}\frac{\mathrm{cn}^2\left(z,\frac{1}{m}\right)}{\mathrm{dn}^2\left(z,\frac{1}{m}\right)}+b(b+1)\frac{\mathrm{dn}^2\left(z,\frac{1}{m}\right)}{\mathrm{cn}^2\left(z,\frac{1}{m}\right)}+g(g+1)\frac{1}{\mathrm{sn}^2\left(z,\frac{1}{m}\right)}\right]\psi(z)=\frac{E(m)}{m}\psi(z). \tag{15}$$

On comparing Eqs. (9) and (15) we then have the duality relation

$$E(a,b,f,g,m)=mE\left(a,f,b,g,\frac{1}{m}\right),\quad \psi(a,b,f,g,m;x)\propto\psi\left(a,f,b,g,\frac{1}{m};kx\right). \tag{16}$$

Duality Relation III: We again start from the Schrödinger equation (9) and now use the formulas[2]

$$\mathrm{sn}(x,m)=\frac{\mathrm{sn}[\sqrt{1-m}x,-m/(1-m)]}{\sqrt{1-m}\,\mathrm{dn}[\sqrt{1-m}x,-m/(1-m)]},$$

$$\mathrm{cn}(x,m)=\frac{\mathrm{cn}[\sqrt{1-m}x,-m/(1-m)]}{\mathrm{dn}[\sqrt{1-m}x,-m/(1-m)]}, \tag{17}$$

$$\mathrm{dn}(x,m)=\frac{1}{\mathrm{dn}[\sqrt{1-m}x,-m/(1-m)]}.$$

On defining a new variable $z=\sqrt{1-m}x$, the Schrödinger equation (9) takes the form

$$-\frac{d^2}{dz^2}\psi(z)+\left[-\frac{mb(b+1)}{1-m}\mathrm{sn}^2\left(z,\frac{-m}{1-m}\right)-\frac{ma(a+1)}{1-m}\frac{\mathrm{cn}^2\left(z,\frac{-m}{1-m}\right)}{\mathrm{dn}^2\left(z,\frac{-m}{1-m}\right)}+f(f+1)\frac{\mathrm{dn}^2\left(z,\frac{-m}{1-m}\right)}{\mathrm{cn}^2\left(z,\frac{-m}{1-m}\right)}+g(g+1)\frac{1}{\mathrm{sn}^2\left(z,\frac{-m}{1-m}\right)}\right]\psi(z)$$

$$=\frac{1}{1-m}E\psi(z)-\frac{m}{1-m}[a(a+1)+b(b+1)+f(f+1)+g(g+1)]\psi(z). \tag{18}$$

On comparing Eqs. (9) and (18) one gets the duality relation

$$E(a,b,f,g,m)=(1-m)E\left(b,a,f,g,\frac{-m}{1-m}\right)+m[a(a+1)+b(b+1)+f(f+1)+g(g+1)],$$

$$\psi(a,b,f,g,m;x)\propto\psi\left(b,a,f,g,\frac{-m}{1-m};\sqrt{1-m}x\right). \tag{19}$$

Using the three duality relations [Eqs. (13), (16), and (19)] along with the translation results [Eqs. (10)–(12)], it is easily shown that once the eigenstates of a given potential are known, we

can immediately obtain the energy eigenstates of all 24 potentials obtained by permuting the 4 parameters a,b,f,g. Hence, out of these 24 potentials, there is only one independent potential and without loss of any generality, throughout this paper we only consider the potential $[a,b,f,g]$ with $a \geqslant b \geqslant f \geqslant g$ (unless stated otherwise).

The duality relations are very powerful and have many interesting consequences. For example, we find that for arbitrary integer values of a,f, the potential $[a,0,f,0]$ has only a finite number of band gaps. This follows because Eq. (16) gives

$$E(a,0,f,0,m) = mE\left(a,f,0,0,\frac{1}{m}\right), \tag{20}$$

so that both the potentials $[a,f,0,0]$ and $[a,0,f,0]$ must have the same number of band edges. Since one knows[16] that the AL potential $[a,f,0,0]$ has a finite number of band gaps, the same statement holds for the potential $[a,0,f,0]$.

III. INDEPENDENT GAL POTENTIALS WITH *a* BAND GAPS [*a*,*b*,*f*,*g*=integers]

In this section, we want to answer the following interesting question: given a potential of the form $[a,b,f,g]$ with $a \geqslant b \geqslant f \geqslant g \geqslant 0$, how many independent GAL potentials are there with exactly a band gaps?

To begin, for a given integer a, let us calculate the total number of possible GAL potentials with $a \geqslant b \geqslant f \geqslant g \geqslant 0$. The number of such potentials is

$$\sum_{b=0}^{a}\sum_{f=0}^{b}\sum_{g=0}^{f} 1 = (a+1)(a+2)(a+3)/6. \tag{21}$$

Now due to the Landen transformations,[2,17] potentials of the form $[a,a,b,b]$ with $a \neq b$ are essentially the same as the potentials $[a,b,0,0]$ and hence are not really distinct. There are a such potentials (for any given value of a). Similarly, it is easy to show that the potential $[a,a,a,a]$ is related to the potential $[a,0,0,0]$ and hence not distinct. In particular, on using the relations[2]

$$\mathrm{sn}^2(x,m) = \frac{1-\mathrm{cn}(2x,m)}{1+\mathrm{dn}(2x,m)}, \quad m\,\mathrm{sn}^2(x+iK'(m),m) = \frac{1}{\mathrm{sn}^2(x,m)}, \tag{22}$$

one obtains

$$\mathrm{sn}^2(x,m) + \mathrm{sn}^2(x+K(m),m) + \mathrm{sn}^2(x+iK'(m),m) + \mathrm{sn}^2(x+K(m)+iK'(m),m) = 4\mathrm{sn}^2(2x+iK'(m),m). \tag{23}$$

Thus the number of distinct GAL potentials of the form $[a,b,f,g]$ with $a \geqslant b \geqslant f \geqslant g \geqslant 0$ is given by

$$N_{\mathrm{dist}} = a(a+1)(a+5)/6. \tag{24}$$

In view of formula (4) for the number of band gaps, it is obvious that these distinct potentials are of two types—there are those with exactly a band gaps and those with more than a band gaps. Using Eqs. (6) and (4) and (4) it follows that in case $a+b+f+g$ is an even integer and if $a+g \geqslant b+f$ then the potential has a band gaps while if $a+g<b+f$ then it has $(a+b+f-g)/2$ band gaps. Similarly, using Eqs. (7) and (4) it follows that in case $a+b+f+g$ is an odd integer and if $a \geqslant b+f+g$ then the potential has a band gaps while if $a<b+g+f$ then it has $(a+b+f+g+1)/2$ band gaps.

It is now straightforward to count the number of independent GAL potentials $[a,b,f,g]$ with a band gaps and show that

$$N_a = \frac{1}{18}[a^3+9a^2+6a+2], \quad a = 1(\mathrm{mod}\ 3),$$

$$N_a = \frac{1}{18}[a^3 + 9a^2 + 6a - 2], \quad a = 2(\text{mod } 3),$$

$$N_a = \frac{a}{18}[a^2 + 9a + 6], \quad a = 0(\text{mod } 3). \tag{25}$$

Several comments are in order at this stage.

1. There is only one independent potential with one band gap but there are three independent potentials with two band gaps and seven independent potentials with three band gaps. This then implies[12] that while there is only one independent KdV equation of third order, there should be three such equations of fifth order and seven such equations of seventh order. It is worth pointing out that indeed there are three such independent KdV equations of fifth order already known in the literature, called standard, Sawada-Kotera, and Kupershmidt (fifth-order) KdV equations. It may be interesting to explicitly obtain all seven independent KdV equations of seventh order.

2. On subtracting the number of independent potentials with a band gaps [as given by Eq. (25)] from the total number of allowed potentials as given by Eq. (24), we immediately find that the number of independent potentials of the form $[a,b,f,g]$ having more than a band gaps is given by

$$N_{>a} = \tfrac{1}{18}(a+2)(2a^2 + 5a - 1), \quad a = 1(\text{mod } 3),$$

$$N_{>a} = \tfrac{1}{18}(a+1)(2a^2 + 7a + 2), \quad a = 2(\text{mod } 3), \tag{26}$$

$$N_{>a} = \tfrac{1}{18}a(a+3)(2a+3), \quad a = 0(\text{mod } 3).$$

For example there are four potentials of the form $[a,b,f,g]$ with $a=2$ having more than two band gaps given by

$$N_{>2} = [2,2,2,0],[2,2,2,1],[2,2,1,0],[2,1,1,1], \tag{27}$$

while for $a=3$ there are nine such potentials with more than three band gaps, given by

$$N_{>3} = [3,3,3,0],[3,3,3,1],[3,3,3,2],[3,3,2,0],[3,3,2,1],[3,3,1,0],[3,2,1,1],[3,2,2,0],[3,2,2,2]. \tag{28}$$

3. If $a+b+f+g$ is an even integer and further if $a+g=b+f$, then both sides of Eq. (6) are identical and the corresponding potential is self-dual. Similarly, if $a+b+f+g$ is an odd integer and $a=b+f+g+1$, then both sides of Eq. (7) are identical, and one has a self-dual potential. As an illustration, the AL potential $[a,a-1,0,0]$ is self-dual, a fact we already knew from Ref. 18 But we now get a large number of additional self-dual GAL potentials, like [2,1,1,0], [4,2,2,0], and [4,2,1,0], for example.

4. A related question is, out of the above self-dual potentials how many are also self-isospectral?[18,19] It is easy to see that the most general form of (at least one of) the eigenfunction for the self-isospectral potentials is

$$\psi = \frac{\text{dn}^a(x,m)\text{sn}^b(x,m)}{\text{cn}^b(x,m)} \tag{29}$$

and that the corresponding self-isospectral potential has the form

$$[a,a-1,b,b-1], \quad b > 0, \quad [a,a-1,0,0], \quad b = 0. \tag{30}$$

The fact that the AL potentials of the form $[a,a-1,0,0]$ are self-isospectral was established many years ago.[18] However, what is new is the realization that the potentials $[a,a-1,b,b-1]$ are also self-isospectral potentials. Note that here a,b can be any integers. Some examples of self-

isospectral potentials are [1,0,0,0], [2,1,0,0], [3,2,2,0], [3,2,1,1], and [3,2,0,0]. Thus out of all the self-dual potentials, those which are of form (30) are also self-isospectral while the rest are self-dual but not self-isospectral. One can show that the number of self-dual potentials N_{sd} which are not self-isospectral is given by

$$N_{\mathrm{sd}} = \tfrac{1}{3}(a-1)^2, \quad a = 1,4,7,\ldots,$$
$$N_{\mathrm{sd}} = \tfrac{1}{3}a(a-2), \quad a = 2,3,5,6,\ldots. \tag{31}$$

On the other hand, it is easy to see that the number of self-isospectral potentials is $N_{\mathrm{si}}=a$. As an illustration, the self-isospectral potentials with two band gaps are [2,1,0,0] and [2,1,1,0] while there are no self-dual (but non-self-isospectral) potentials with two band gaps. On the other hand, the self-isospectral potentials with three band gaps are [3,2,2,1], [3,2,1,0], and [3,2,0,0], while the only self-dual (but non-self-isospectral) potential with three band gaps is [3,1,1,0].

5. Clearly all potentials with $a+g>b+f$ or $a>b+f+g+1$ depending on if $a+b+f+g$ is an odd or an even integer, have partner potentials as given by Eq. (6) or (7), respectively. Now out of these, some are SUSY partner potentials while the rest are merely partner potentials. So let us count both types of potentials. Now if two GAL potentials are SUSY partners, then one of their eigenfunctions must be related to each other by $\psi_{\mathrm{II}}=\psi_{\mathrm{I}}^{-1}$. Further, these two eigenfunctions must have the form

$$\mathrm{dn}^{\alpha}(x)\mathrm{cn}^{\beta}(x)\mathrm{sn}^{\gamma}(x). \tag{32}$$

Besides, from paper I we know that if the QES eigenfunction is of the form (32), then $b=-\alpha$, $f=-\beta$, $g=-\gamma$, and $a+b+f+g=0$. From here it is easy to show that the potential $[a,b,f,g]$ with a band gaps has a SUSY GAL partner provided either $a+g=b+f+2$ or $a=b+f+g+3$ depending on if $a+b+f+g$ is an even or an odd integer, respectively. Hence, all potentials of the form $[a,b,f,g]$ with a band gaps and satisfying $a+g>b+f+2$ or $a>b+g+f+3$ have merely partner potentials of the form (6) and (7), respectively. It is worth emphasizing that while these partner potentials have the same band edge eigenvalues, none of them are SUSY partner potentials. For example, [2,0,0,0] and [1,1,1,0] are SUSY partner GAL potentials with two band gaps. Similarly [3,1,0,0] and [2,2,1,0] are SUSY partner GAL potentials with three band gaps. On the other hand, [4,0,0,0] and [2,2,2,1] are merely partner potentials with four band gaps.

6. One can count the number of potentials (N_{su}) of the form $[a,b,f,g]$ with a band gaps having another GAL potential as its SUSY partner and it is easy to show that

$$N_{\mathrm{su}} = \tfrac{1}{3}[a^2-1], \quad a \neq 0(\mathrm{mod}\ 3),$$
$$N_{\mathrm{su}} = \tfrac{1}{3}a^2, \quad a = 0(\mathrm{mod}\ 3). \tag{33}$$

Finally, it is not difficult to show that the number of potentials of the form $[a,b,f,g]$ with a band gaps and having merely a (non-SUSY) partner potential of the form as given by Eqs. (6) and (7), respectively, is given by

$$N_{\mathrm{nsu}} = \tfrac{1}{18}(a-1)(a^2-2a-2), \quad a = 1(\mathrm{mod}\ 3),$$
$$N_{\mathrm{nsu}} = \tfrac{1}{18}(a-2)(a^2-a-2), \quad a = 2(\mathrm{mod}\ 3), \tag{34}$$
$$N_{\mathrm{nsu}} = \tfrac{1}{18}a^2(a-3), \quad a = 0(\mathrm{mod}\ 3).$$

7. On adding the number of self-dual (but non-self-isospectral), self-isospectral, SUSY partner and (non-SUSY) merely partner potentials as given by Eqs. (30)–(34) respectively, as expected, we find that the number of independent potentials with a band gaps is as given by Eq. (25).

8. One obvious interesting question is whether there are non-GAL potentials with a finite number of band gaps. The answer to this question is yes. In particular, since the general form of the eigenfunction for any GAL potential is of the form[1]

$$\psi_{\mathrm{GAL}}(x) = \mathrm{dn}^{-b}(x)\mathrm{cn}^{-f}(x)\mathrm{sn}^{-g}(x)\sum_{k=0}^{N} A_k \mathrm{sn}^{2k}(x), \tag{35}$$

it follows that non-GAL potentials of the form

$$V_+(x) = V_{\mathrm{GAL}}(x) - 2\frac{\mathrm{d}^2}{\mathrm{d}x^2}\ln \psi_{\mathrm{GAL}}(x) \tag{36}$$

are also finite gap potentials. In this context it is worth mentioning that some people[14] have recently obtained potentials with a finite number of band gaps which are more general than the GAL potentials. It is not clear if those potentials and the potentials (36) have any overlap.

The nature of band edge eigenstates. In paper I we showed that if $a+b+f+g=2n$, then $n+1$ QES states can be obtained for GAL potentials (2) and they are of the form given in Eq. (35). On using this key result as well as the fact that the GAL potential $[a,b,f,g]$ remains unchanged when any one (or more) of the four parameters a,b,f,g is changed to $-a-1$, $-b-1$, $-f-1$, $-g-1$, respectively, it is easy to specify the nature of the band edge eigenfunctions for any potential $[a,b,f,g]$ with a band gaps. The nature as well as the number of eigenstates crucially depend on whether $a+b+f+g$ is an even or an odd integer—so we will discuss these situations separately.

$a+b+f+g=$*even integer:* In this case it is easy to show that one has $(a+b+f+g+2)/2$ eigenstates of the form

$$\mathrm{sn}^{-g}(x)\mathrm{cn}^{-f}(x)\mathrm{dn}^{-b}(x)F_{(a+b+f+g)/2}[\mathrm{sn}^2(x)], \tag{37}$$

$(a+b-f-g)/2$ eigenstates of the form

$$\mathrm{sn}^{g+1}(x)\mathrm{cn}^{f+1}(x)\mathrm{dn}^{-b}(x)F_{(a+b-f-g-2)/2}[\mathrm{sn}^2(x)], \tag{38}$$

$(a+f-b-g)/2$ eigenstates of the form

$$\mathrm{sn}^{g+1}(x)\mathrm{cn}^{-f}(x)\mathrm{dn}^{b+1}(x)F_{(a+f-b-g-2)/2}[\mathrm{sn}^2(x)], \tag{39}$$

and $(a+g-b-f)/2$ eigenstates of the form

$$\mathrm{sn}^{-g}(x)\mathrm{cn}^{f+1}(x)\mathrm{dn}^{b+1}(x)F_{(a+g-b-f-2)/2}[\mathrm{sn}^2(x)]. \tag{40}$$

If instead $b+g>a+f$, then one has $(b+f-a-g)/2$ eigenstates of the form

$$\mathrm{sn}^{g+1}(x)\mathrm{cn}^{-f}(x)\mathrm{dn}^{-b}(x)F_{(b+f-a-g-2)/2}[\mathrm{sn}^2(x)]. \tag{41}$$

$a+b+f+g=$*odd integer:* In this case it is easy to show that one has $(a+b+f-g+1)/2$ eigenstates of the form

$$\mathrm{sn}^{g+1}(x)\mathrm{cn}^{-f}(x)\mathrm{dn}^{-b}(x)F_{(a+b+f-g-1)/2}[\mathrm{sn}^2(x)], \tag{42}$$

$(a+b+g-f+1)/2$ eigenstates of the form

$$\mathrm{sn}^{-g}(x)\mathrm{cn}^{f+1}(x)\mathrm{dn}^{-b}(x)F_{(a+b+g-f-1)/2}[\mathrm{sn}^2(x)], \tag{43}$$

$(a+f+g-b+1)/2$ eigenstates of the form

$$\mathrm{sn}^{-g}(x)\mathrm{cn}^{-f}(x)\mathrm{dn}^{b+1}(x)F_{(a+f+g-b-1)/2}[\mathrm{sn}^2(x)], \tag{44}$$

$(a-b-f-g-1)/2$ eigenstates of the form

$$\mathrm{sn}^{g+1}(x)\mathrm{cn}^{f+1}(x)\mathrm{dn}^{b+1}(x)F_{(a-b-f-g-3)/2}[\mathrm{sn}^2(x)]. \tag{45}$$

If instead $b+f+g>a-1$ then one has $(b+f+g-a+1)/2$ eigenstates of the form

$$\mathrm{sn}^{-g}(x)\mathrm{cn}^{-f}(x)\mathrm{dn}^{-b}(x)F_{(b+f+g-a-1)/2}[\mathrm{sn}^2(x)]. \tag{46}$$

Here $F_n[\mathrm{sn}^2(x)]$ denotes a polynomial of order n in $\mathrm{sn}^2(x)$. It is worth pointing out that not only the QES band edge eigenvalues are identical for the two partner potentials as given either by Eq. (6) or by (7), even the nature of the band edge eigenfunctions in the two cases is also similar. For example, the potential $[(a+b+f-g)/2,(a+b+g-f)/2,(a+f+g-b)/2,(b+f+g-a)/2]$ as given by Eq. (6) has the same band edge eigenvalues and further the corresponding eigenfunction is simply obtained from Eqs. (37)–(41) by replacing a,b,f,g with $(a+b+f-g)/2,(a+b+g-f)/2,(a+f+g-b)/2,(b+f+g-a)/2$, respectively. Exactly the same is also true about the equivalent potential given by Eq. (7) in case $a+b+f+g$ is an odd integer and the corresponding eigenfunctions are exactly as given by Eqs. (42)–(46) but with the replacement of a,b,f,g by $(a+b+f+g+1)/2,(a+b-f-g-1)/2,(a+f-b-g-1)/2,(a+g-b-f-1)/2$, respectively. It follows from here that irrespective of whether $a+b+f+g$ is an odd or an even integer, there are precisely a bound bands, same a number of band gaps and $2a+1$ number of band edges all of which are analytically known in principle, beyond which there is a continuum band extending up to $E=\infty$. Further, irrespective of whether $a+b+f+g$ is an odd or an even integer, if $a+b$ is an even (odd) integer, then there are $a+b+1$ band edges of period $2K(4K)$ and $a-b$ band edges of period $4K(2K)$.

Thus in general the band structure of the GAL potentials is unusual in that if $a+b$ is an even (odd) integer, then b band gaps of period $4K(2K)$ must be of zero width, i.e., there must be b doubly degenerate states of period $4K(2K)$. Unfortunately, till today we do not know either the eigenvalue or the nature of the eigenfunction of even one of these doubly degenerate states. One exception is the case of pure Lamé (and their GAL partners) potentials, i.e., when $b=f=g=0$, as in that case depending on if a is even or odd integer, one has $a+1$ band edges of period $2K(4K)$ and a band edges of period $4K(2K)$ and the band structure is normal one, with no doubly degenerate states.

As an illustration, consider the GAL potentials with two band gaps. As seen earlier, there are three distinct potentials with two band gaps out of which we have already discussed the band structure of the two potentials [2, 0, 0, 0] and [2, 1, 0, 0].[16,18] Thus it would be interesting to know the band edges and the band structure of the remaining potential with two band gaps, i.e., [2, 1, 1, 0]. Since $a+b=3$, it follows from the above discussion that in this case there must be four band edges of period $4K$ and 1 band edge of period $2K$. Using Table 4 of paper I it is easily seen that the eigenstate with period $2K$ is given by

$$\psi=\mathrm{dn}^2(x)\mathrm{sn}(x)\mathrm{cn}^{-1}(x),\quad E=9m, \tag{47}$$

while out of the four band edges of period $4K$, one eigenstate has the form

$$\psi=\mathrm{dn}^{-1}(x)\mathrm{sn}(x)\mathrm{cn}^2(x),\quad E=9. \tag{48}$$

The three other eigenstates of period $4K$ have the form

$$\psi=\mathrm{dn}^{-1}(x)\mathrm{cn}^{-1}(x)[A+B\,\mathrm{sn}^2(x)+D\,\mathrm{sn}^4(x)], \tag{49}$$

and the corresponding three eigenvalues satisfy the cubic equation

$$r^3+8(1+m)r^2+80mr+64m(1+m)=0,\quad E=-r+1+m. \tag{50}$$

Further, it is clear that there must be one doubly degenerate state of period $2K$ whose eigenvalue and eigenfunctions are not known analytically.

IV. GAL POTENTIALS [WITH AT LEAST ONE PARAMETER a,b,f,g=HALF-INTEGER]

So far, we have discussed GAL potentials when all four parameters a,b,f,g take integer values. We have seen that these are problems with a finite number of band gaps. We now consider the case when at least one of the parameters a,b,f,g is a half-integer. In general, all such problems have an infinite number of band gaps and one has only a few QES states.

A. a=half-integer

As mentioned in Sec. I, we conjecture that the relations (6) and (7) are simultaneously valid when at least one of the four parameters a,b,f,g is a half-integer. In particular, in case $a=k+\frac{1}{2}$ and b,f,g are arbitrary numbers, we assert that $k+1$ QES energy values are identical for three GAL potentials, that is

$$\begin{aligned}&\left[a=k+\frac{1}{2},b,f,g\right]\\&\equiv\left[\frac{2(k+b+f+g)+3}{4},\frac{2(k+b-f-g)-1}{4},\frac{2(k+f-b-g)-1}{4},\frac{2(k+g-b-f)-1}{4}\right]\\&\equiv\left[\frac{2(k+b+f-g)+1}{4},\frac{2(k+b+g-f)+1}{4},\frac{2(k+f+g-b)+1}{4},\frac{2(b+f+g-k)-1}{4}\right].\end{aligned}\tag{51}$$

This relation needs some clarification. What is being conjectured here is that there are $k+1$ QES mid-band energy values of the potential with $a=k+1/2$ and b,f,g being arbitrary numbers, which are the same as the band edge energy eigenvalues of the two other potentials given in (51). For these two potentials, we can always obtain $k+1$ QES band edges, since for both of them the sum of the four parameters characterizing the potentials is $2k$.[1]

We have explicitly verified our conjecture in the following cases: (i) Lamé potentials with $a=1/2,3/2$ (and $b=f=g=0$); (ii) AL potentials[16] with $a=1/2,3/2$, $b=1,2,3$ (and $f=g=0$); (iii) GAL potentials with $a=1/2,3/2$, and either b or f or g is arbitrary while the remaining two parameters take any integer values. For example, we know that the mid-band state of the $a=1/2$ Lamé potential is at $(1+m)/4$. Using Eq. (51), we predict that both the potentials $[\frac{3}{4},-\frac{1}{4},-\frac{1}{4},-\frac{1}{4}]$ and $[\frac{1}{4},\frac{1}{4},\frac{1}{4},-\frac{3}{4}]$ must have a QES band edge eigenvalue at $E=(1+m)/4$. Using Table 4 of paper I it is easily checked that this is indeed so, with the corresponding band edge eigenfunctions being $\psi=[\mathrm{dn}(x)\mathrm{cn}(x)\mathrm{sn}(x)]^{1/4}$ and $\psi=\mathrm{dn}^{-1/4}(x)\mathrm{cn}^{-1/4}(x)\mathrm{sn}^{3/4}(x)$, respectively. Similarly, it is well known that the QES mid-band states of the $a=3/2$ Lamé potential are at

$$E=\frac{5(1+m)}{4}\pm\sqrt{1-m+m^2}.\tag{52}$$

Using Eq. (51) we then predict that both the potentials $[\frac{5}{4},\frac{1}{4},\frac{1}{4},\frac{1}{4}]$ and $[\frac{3}{4},\frac{3}{4},\frac{3}{4},\frac{-1}{4}]$ must have QES band-edge eigenvalues as given by Eq. (52). Using Table 4 of paper I it is easily checked that this is indeed so, with the corresponding band edge eigenfunctions being respectively given by

$$\psi=[\mathrm{dn}(x)\mathrm{cn}(x)\mathrm{sn}(x)]^{-1/4}(1+[-(1+m)\pm\sqrt{1-m+m^2}]\mathrm{sn}^2(x)),\tag{53}$$

$$\psi=[\mathrm{dn}^{-3/4}(x)\mathrm{cn}^{-3/4}(x)\mathrm{sn}^{1/4}(x)](3+[-(1+m)\pm\sqrt{1-m+m^2}]\mathrm{sn}^2(x)).\tag{54}$$

We have similarly checked the equivalence in all the above-mentioned cases. For example, using the results[16] for the AL potential [3/2, 1, 0, 0], we find (and verify using Table 4 of paper I) that the GAL potentials $[7/4,3/4,-1/4,-1/4]$ and $[5/4,5/4,1/4,-1/4]$ have QES band edges at $E=(13+5m)/4\pm\sqrt{9-9m+m^2}$. The corresponding band edge eigenfunctions are

$$\psi = [\mathrm{dn}^{-3}(x)\mathrm{cn}(x)\mathrm{sn}(x)]^{-1/4}(3 + [-(3+m) \pm \sqrt{9 - 9m + m^2}]\mathrm{sn}^2(x)), \tag{55}$$

$$\psi = [\mathrm{dn}^{-5/4}(x)\mathrm{cn}^{-1/4}(x)\mathrm{sn}^{3/4}(x)](5 + [-(3+m) \pm \sqrt{9 - 9m + m^2}]\mathrm{sn}^2(x)), \tag{56}$$

respectively. Similarly, using the results in paper I for the mid-band states of the GAL potential $[\frac{1}{2}, t-\frac{1}{2}, 1, 0]$ we verify that the potentials $[t/2+1, t/2-1, (1-t)/2, -(1+t)/2]$ and $[(1+t)/2, -(1-t)/2, 1-t/2, t/2]$ indeed have a QES band edge eigenvalue $E=t^2+9m/4$, for any noninteger t and the corresponding eigenfunctions are $\psi = \mathrm{dn}^{(2-t)/2}(x)\mathrm{cn}^{(t-1)/2}(x)\mathrm{sn}^{(1+t)/2}(x)$ and $\psi = \mathrm{dn}^{(1-t)/2}(x)\mathrm{cn}^{(t-2)/2}(x)\mathrm{sn}^{(2+t)/2}(x)$.

Thus one is fairly confident that the remarkable relationship (51) is indeed valid. We now turn around and use (51) to predict new results for the mid-band states of GAL potentials with half-integer values of a in case b, f, g take arbitrary values. As an illustration, we predict that the potential $[1/2, b, f, g]$, where b, f, g are arbitrary numbers must have a QES state at energy

$$E = (b + 1/2)^2 + (f + 1/2)^2 m, \tag{57}$$

while the potential $[3/2, b, f, g]$ with b, f, g being arbitrary numbers must have two QES states with energies

$$E = [(b + 1/2)^2 + 1] + [1 + (f + 1/2)^2]m \pm 2\sqrt{[(b + 1/2) + (f + 1/2)m]^2 - (b + f + g + 3/2)(b + f - g + 1/2)m}. \tag{58}$$

Perhaps some clarification is required as to when the QES state is a band edge and when it is a mid-band state. We believe that only those states correspond to band edges for which $a+b+f+g$ [or any other combination obtained by changing one or more of these parameters to $-a-1$, $-b-1, -f-1, -g-1$, respectively] is equal to an even integer (including zero). All other QES states should correspond to mid-band states. We thus believe that the QES energy values as given above for the potentials $[1/2, b, f, g]$ and $[3/2, b, f, g]$ with arbitrary b, f, g are in most cases the energies for the mid-band states of these potentials. In Sec. VI we shall obtain the QES eigenstates corresponding to some of these QES eigenvalues by using the connection of the GAL potential problem and Heun's equation.

We can also predict the QES energy values when $a=5/2$ and b, f, g are arbitrary numbers, by computing the band edges of either of the two potentials given in (51). In this way, we predict that the mid-band energy values for the three QES states of the GAL potential $[5/2, b, f, g]$ are solutions of the cubic equation

$$r^3 + 2[1 + 6b + (1 + 6f)m]r^2 + 4[2(4b^2 - 1) + 2(4f^2 - 1)m^2 + (4b^2 + 4f^2 - 4g^2 + 24bf + 8b + 8f - 2g + 3)m]r + 8m[2b + 1 + (2f + 1)m][4(b + f)^2 - (2g + 1)^2] = 0, \tag{59}$$

where $r = -E + (3/2 - b)^2 + (3/2 - f)^2 m$. For the special cases (i) $b=f=g=0$ as well as (ii) $b=1, f=g=0$, it is easily checked that Eq. (59) agrees with well-known results,[16] thereby providing a powerful check on our calculations. Generalization to higher half-integer values is straightforward (in principle) and it is easy to see that energy values for $a+1/2$ QES mid-band states can be predicted (at least in principle) when b, f, g are arbitrary numbers and a is a half-integer.

B. a, b = half-integers

Let us now discuss the case when both a and b are half-integers while f and g are arbitrary numbers using our conjecture that Eqs. (6) and (7) are both simultaneously valid. In particular, for $a = k + \frac{1}{2}$, $b = l + \frac{1}{2}$ while f, g are any numbers, we assert that the three potentials

$$\left[a=k+\frac{1}{2},b=l+\frac{1}{2},f,g\right]$$
$$\equiv\left[\frac{k+l+f+g+2}{2},\frac{k+l-f-g}{2},\frac{k+f-l-g-1}{2},\frac{k+g-l-f-1}{2}\right]$$
$$\equiv\left[\frac{k+l+f-g+1}{2},\frac{k+l+g-f+1}{2},\frac{k+f+g-l}{2},\frac{l+f+g-k}{2}\right], \tag{60}$$

have the same $k+l+2$ QES energy values. This means that the QES mid-band energy values of the potential with $a=k+1/2$, $b=l+1/2$ are the same as the band edge eigenvalues of the two other potentials in (60). For these two potentials, we can obtain $k+l+2=a+b+1$ QES states since, for both of them, the sum of the four numbers characterizing the potentials is either $2k$ or $2l$. This is possible because the GAL potential $[a,b,f,g]$ remains unchanged when any one (or more) of the four parameters a,b,f,g changes to $[-a-1,-b-1,-f-1,-g-1]$, respectively.

As an illustration, consider the potential $[3/2,1/2,f,g]$ with f,g being arbitrary numbers. It is then easily shown that this potential must have three QES mid-band states at

$$E_1=4+(g+1/2)^2m, \tag{61}$$

$$E_{2,3}=2+[(f+1/2)^2+1]m\pm\sqrt{[2-(2f+1)m]^2+[(2g+1)^2-(2f-1)^2m]}. \tag{62}$$

The point is, from Eq. (60) it follows that the potential $[3/2,1/2,f,g]$ has the same QES mid-band states as the potentials

$$\left[\frac{3+f+g}{2},\frac{1-f-g}{2},\frac{f-g}{2},\frac{g-f}{2}\right] \text{ and } \left[\frac{2+f-g}{2},\frac{2+g-f}{2},\frac{1+f+g}{2},-\frac{1+f+g}{2}\right].$$

Now, using Table 4 of paper I, it is easily shown that these potentials indeed have these three QES eigenvalues. Further, corresponding to the eigenvalue E_1 in Eq. (61) the corresponding eigenfunctions for these two potentials, respectively, are

$$\mathrm{dn}^{(g+f-1)/2}(x)\mathrm{cn}^{(2+f-g)/2}(x)\mathrm{sn}^{(2+g-f)/2}(x),\quad \mathrm{dn}^{(f-2-g)/2}(x)\mathrm{cn}^{(3+f+g)/2}(x)\mathrm{sn}^{(1-f-g)/2}(x). \tag{63}$$

The eigenfunctions corresponding to the eigenvalues $E_{2,3}$ in Eq. (62) can similarly be written down using Table 4 of paper I.

Note that out of the $k+l+2$ QES states, the energies for the $k+1$ states can also be obtained by considering the previous case of $a=k+1/2$ and b,f,g arbitrary and putting $b=l+1/2$ at the end of the calculation. As an illustration, consider the case $[3/2,b,f,g]$ where b is any arbitrary number. As shown in the last section, there are two QES energies given by Eq. (58). On putting $b=1/2$ we find that the two QES energy values of the potential $[3/2,1/2,f,g]$ are precisely as given by Eq. (62). For the special case $f=g=0$, these eigenvalues agree with well-known results for the AL potential.[16] Similarly, consider the case $[5/2,b,0,0]$. As shown in Sec. IV A, there are three QES energy values as given by Eq. (59). On putting $b=1/2$, it is easily seen that the three eigenvalues are $E=(1+9m/4),(1+25m/4),(9+m/4)$, in agreement with the eigenvalues obtained by us previously.[16]

C. a,b,f=half-integers

We shall now discuss the case when three out of the four parameters (say a,b,f) are half-integers while g is any number (not a half-integer), and obtain the energies of the QES mid-band states. Our argument is again based on the assertion that relations (6) and (7) are simultaneously valid. In particular, we assert that for $a=k+\frac{1}{2}$, $b=l+\frac{1}{2}$, $f=n+\frac{1}{2}$ the three potentials

$$\left[a=k+\frac{1}{2},b=l+\frac{1}{2},f=n+\frac{1}{2},g\right]$$
$$\equiv\left[\frac{2(k+l+n+g)+5}{4},\frac{2(k+l-n-g)-1}{4},\frac{2(k+n-l-g)-1}{4},\frac{2(l+n-k-g)-1}{4}\right]$$
$$\equiv\left[\frac{2(k+l+n-g)+3}{4},\frac{2(k+l+g-n)+1}{4},\frac{2(k+n+g-l)+1}{4},\frac{2(l+n+g-k)+1}{4}\right] \tag{64}$$

have identical $k+l+n+3$ QES energy values. What is being asserted here is that the $k+l+n+3$ QES mid-band energies of the potential with half-integer values of a,b,f and arbitrary g are the same as the band edge energy eigenvalues of the two other potentials in (64). This happens because for arbitrary values of g, for the two potentials

$$\left[\frac{2(k+l+n+g)+5}{4},\frac{2(k+l-n-g)-1}{4},\frac{2(k+n-l-g)-1}{4},\frac{2(l+n-k-g)-1}{4}\right], \tag{65}$$

$$\left[\frac{2(k+l+n-g)+3}{4},\frac{2(k+l+g-n)+1}{4},\frac{2(k+n+g-l)+1}{4},\frac{2(l+n+g-k)+1}{4}\right], \tag{66}$$

we can always obtain $k+l+n+3=a+b+f+3/2$ QES band edges, since for both potentials the sum of the four numbers characterizing the potentials is either $2k$ or $2l$ or $2n$. This is possible because the GAL potential $[a,b,f,g]$ remains unchanged when any one (or more) of the four parameters a,b,f,g change to $-a-1,-b-1,-f-1,-g-1$, respectively. Thus we conjecture that the potential $[k+1/2,l+1/2,n+1/2,g]$, for arbitrary g has $k+l+n+3$ QES mid-band states. As an illustration, consider the case $k=l=n=0$ with g arbitrary. We assert that the potential $\left[\frac{1}{2},\frac{1}{2},\frac{1}{2},g\right]$ must have three QES states, being a partner of the potentials

$$\left[\frac{2g+5}{4},-\frac{(2g+1)}{4},-\frac{(2g+1)}{4},-\frac{(2g+1)}{4}\right]$$

and

$$\left[\frac{3-2g}{4},\frac{(2g+1)}{4},\frac{(2g+1)}{4},\frac{(2g+1)}{4}\right].$$

Using Table 4 of paper I it is easily checked that these two potentials have three QES energy eigenstates which are:
(i) $E=1+m$ with the two corresponding eigenfunctions respectively being

$$\psi=[\mathrm{cn}(x)\mathrm{dn}(x)]^{(2g+1)/4}\mathrm{sn}^{(3-2g)/4}(x),\quad \psi=[\mathrm{cn}(x)\mathrm{dn}(x)]^{-(2g+1)/4}\mathrm{sn}^{(2g+5)/4}(x). \tag{67}$$

(ii) $E=1+\left(g+\frac{1}{2}\right)^2 m$ with the two corresponding eigenfunctions being

$$\psi=[\mathrm{sn}(x)\mathrm{dn}(x)]^{(2g+1)/4}\mathrm{cn}^{(3-2g)/4}(x),\quad \psi=[\mathrm{sn}(x)\mathrm{dn}(x)]^{-(2g+1)/4}\mathrm{cn}^{(2g+5)/4}(x). \tag{68}$$

(iii) $E=\left(g+\frac{1}{2}\right)^2+m$ with the two corresponding eigenfunctions being

$$\psi=[\mathrm{sn}(x)\mathrm{cn}(x)]^{(2g+1)/4}\mathrm{dn}^{(3-2g)/4}(x),\quad \psi=[\mathrm{sn}(x)\mathrm{cn}(x)]^{-(2g+1)/4}\mathrm{dn}^{(2g+5)/4}(x). \tag{69}$$

We now make a number of predictions for the energy eigenvalues of the mid-band states for GAL potentials of the form $[k+1/2,l+1/2,n+1/2,g]$.

1. We predict that the potential $[1/2,1/2,1/2,g]$ has three QES mid-band states with energy values

$$E_1=(1+m),\quad E_2=1+(g+1/2)^2 m,\quad E_3=(g+1/2)^2+m. \tag{70}$$

2. The potential $[3/2,1/2,1/2,g]$ has four QES mid-band states with energy values

$$E_1=(4+m),\quad E_2=(g+1/2)^2+4m,\quad E_{3,4}=2(1+m)\pm\sqrt{4(1-m)^2+(2g+1)^2m}. \tag{71}$$

3. The potential $[3/2,3/2,1/2,g]$ has five QES mid-band states with energy values

$$\begin{gathered}E_1=(g+1/2)^2+4m,\quad E_{2,3}=5+2m\pm\sqrt{4(2-m)^2+(2g+1)^2m-4m},\\ E_{4,5}=5+[(g+1/2)^2+1]m\pm\sqrt{[4-(2g+1)m]^2-(2g-3)^2m+4m}.\end{gathered} \tag{72}$$

4. The potential $[3/2,3/2,3/2,g]$ has six QES mid-band states with energy values

$$\begin{gathered}E_{1,2}=(5+m)\pm\sqrt{16(1-m)^2+(2g+1)^2m},\\ E_{3,4}=5+[(g+1/2)^2+1]m\pm\sqrt{16-(2g+1)^2m(1-m)},\\ E_{5,6}=[(g+1/2)^2+1]+5m\pm\sqrt{16m^2+(2g+1)^2(1-m)}.\end{gathered} \tag{73}$$

5. One can readily obtain some QES mid-band energy values when (i) k is an arbitrary integer while l and/or n are either 0 or 1; (ii) k,l are arbitrary integers with $n=0$ or 1 and g being any arbitrary number. It would be nice to prove (or disprove) these conjectures and more importantly, try to obtain the corresponding energy eigenfunctions. We shall have something to say about this point when we discuss the implications of these results in the context of Heun's equation.

6. Note that out of the $k+l+n+3$ QES states, the energy values for $k+l+2$ states can also be obtained by considering the previous case $[a=k+1/2,\ b=l+1/2,f,\ g=\text{arbitrary}]$ and putting $f=n+1/2$ at the end of the calculation. As an illustration, consider the case $[3/2,1/2,f,g]$ where f,g are arbitrary numbers. As shown in Sec. IV B, there are three QES energy values and they are given by Eqs. (61) and (62). On putting $f=1/2$ in these equations, we find that three (out of four) QES eigenvalues of $[3/2,1/2,1/2,g]$ as given by Eq. (72) are correctly obtained.

D. a,b,f,g=half-integers

Finally, let us consider the case when all four parameters are half-integers. The potential is of the form $[k+1/2,l+1/2,n+1/2,p+1/2]$, where k,l,n,p are integers and we take $k\geqslant l\geqslant n\geqslant p$. We shall discuss the two cases when the sum $k+l+n+p$ is an even or an odd integer separately.

1. $k+l+n+p$=even-integer

As shown in paper I, for the GAL potential (2), QES energies are obtained when the sum of the four parameters is an even integer including zero. In this case, as already shown by Takemura,[15] both the relations (6) and (7) are simultaneously valid. We would like to assert here that in this case, in general there should be $k+n+l+p+4$ QES states, since the sum of the four numbers characterizing the potentials is either $2k$ or $2l$ or $2n$ or $2p$. This is possible because the GAL potential $[a,b,f,g]$ remains unchanged when any one (or more) of the four parameters a,b,f,g change to $-a-1,-b-1,-f-1,-g-1$, respectively. Unfortunately, in the several specific cases that we have examined, we find that some of the eigenvalues simply get repeated. Thus the true number of QES states may be much less than $k+l+n+p+4$. For example, consider the case of $[5/2,\ 1,\ 2,\ 1/2,1/2]$. Using Eqs. (6) and (7) it follows that this potential must have the same QES eigenvalues as the potential $[3/2,3/2,3/2,-1/2]$. While naively we expect six QES states for these potentials, we only find three QES levels. The three QES energy eigenstates for the two potentials are:

(i) $E=1+m$ with the two corresponding eigenfunctions being

$$\psi=[\mathrm{cn}(x)\mathrm{dn}(x)]^{-3/2}\mathrm{sn}^{1/2}(x),\quad \psi=[\mathrm{cn}(x)\mathrm{dn}(x)]^{3/2}\mathrm{sn}^{-1/2}(x). \tag{74}$$

(ii) $E=9+m$ with the two corresponding eigenfunctions being

$$\psi = \mathrm{dn}^{-3/2}(x)\mathrm{cn}^{5/2}(x)\mathrm{sn}^{1/2}(x), \quad \psi = [\mathrm{sn}(x)\mathrm{cn}(x)]^{3/2}\mathrm{dn}^{-1/2}(x). \tag{75}$$

(iii) $E=1+9m$ with the two corresponding eigenfunctions being

$$\psi = \mathrm{dn}^{5/2}(x)\mathrm{cn}^{-3/2}(x)\mathrm{sn}^{1/2}(x), \quad \psi = [\mathrm{sn}(x)\mathrm{dn}(x)]^{3/2}\mathrm{cn}^{-1/2}(x). \tag{76}$$

Similarly, for the potential $[9/2,1/2,1/2,1/2]$, while naively we expect eight QES states, we only find four QES levels at $E=(1+m)$, $(1+25m)$, $(25+m)$, $9(1+m)$.

2. $k+l+n+p$=odd integer

Let us now discuss perhaps the most intriguing case when all four parameters are half-integers and their sum is an odd integer. While it is clear from paper I that no QES band edges can be obtained when $k+l+n+p$ is an odd integer, it is not obvious whether mid-band states can be obtained in this case. In fact we shall now obtain energy values for several QES mid-band states for these potentials. As argued in Sec. I, while Takemura has shown that relations (6) or (7) are valid when $a+b+f+g$ is an even or an odd integer, respectively (and all are integers), we conjecture that irrespective of whether $a+b+f+g$ is an odd or an even integer, both relations are always valid. Using Eqs. (6) and (7), it then follows that irrespective of whether $a+b+f+g$ is an even or an odd integer, they always have a partner potential of the form $[k+1/2,l+1/2,n+1/2,p+1/2]$ where k,l,n,p are all integers and their sum is an odd integer. We thus conjecture that when $a+b+f+g$ is an even integer, then the QES mid-band energy values of the potential $[(a+b+f+g+1)/2, (a+b-f-g-1)/2, (a+f-b-g-1)/2, (a+g-b-f-1)/2]$ are the same as the band edge eigenvalues of the potential $[a,b,f,g]$. Similarly, when $a+b+f+g$ is an odd integer, then we conjecture that the QES mid-band energy values of the potential $[(a+b+f-g)/2, (a+b+g-f)/2, (a+f+g-b)/2, (b+f+g-a)/2]$ are the same as the band edge eigenvalues of the potential $[a,b,f,g]$. This is rather remarkable. Since the band edges of the GAL potentials $[a,b,f,g]$ with integer a,b,f,g are all known (at least in principle), hence one has a prediction for $k+l+n+p+4$ QES mid-band states of the GAL potentials of the type $[k+1/2,l+1/2,n+1/2,p+1/2]$ when $k+l+n+p$ is an odd integer. To be precise, we predict that the potential $[k+1/2,l+1/2,n+1/2,p+1/2]$ has $k+l+n+p+4$ QES mid-band states in case $k+l+n+p$ is an odd integer and these eigenvalues are identical to the band edges of the potential $[(k+l+n+p+3)/2, (k+l-n-p-1)/2, (k+n-l-p-1)/2, (k+p-l-n-1)/2]$. As an illustration, knowing the band edges of the Lamé potential $2m\mathrm{sn}^2(x)$ we predict that the three QES mid-band state energy values of the potential $[1/2,1/2,1/2,-1/2]$ must be at $E=m,1,1+m$. Similarly, we predict that the five mid-band QES energies of the potential $[3/2,1/2,1/2,1/2]$ are at

$$E_2 = 1+m, \quad E_3 = (1+4m), \quad E_4 = (4+m), \quad E_{1,5} = 2(1+m) \pm 2\sqrt{1-m+m^2}. \tag{77}$$

The validity of our conjecture and in a way the consistency of our whole approach can be checked by extrapolating the results obtained in the previous subsection. In particular, in the last subsection we have discussed the case when the potential is of the form $[k+1/2,l+1/2,n+1/2,g]$ where g is any arbitrary number and we have seen that in that case one obtains energies for $k+l+n+3$ QES mid-band states. On choosing $g=p+1/2$ and choosing k,l,n,p such that their sum is an odd integer, we have verified in many cases the validity of our conjectures.

We thus predict that the potentials $[3/2,1/2,1/2,1/2]$, $[5/2,1/2,1/2,-1/2]$ and $[3/2,3/2,1/2,-1/2]$ have exactly the same (five) QES mid-band energies as the band edge energy eigenvalues of the potentials [2, 0, 0, 0], [2, 1, 1, 0], [2, 1, 0, 0], respectively. It is worth observing that there are exactly three ways of obtaining $k+l+n+p=1$ given that $k\geqslant l\geqslant n\geqslant p$ and that while k,l,n are non-negative integers, p is $\geqslant -1$. It may be noted here that in case n is also -1 then the corresponding partner potentials as given by Eqs. (6) and (7) are potentials of the type $[a,a,b.b]$ and similarly if both $n=l=-1$ then the partner potentials are of type $[a,a,a,a]$ which, as explained in Sec. II, are not included in our analysis. Thus, put another way, the problem of finding the number of independent potentials with say a band gaps reduces to finding four integers k,l,n,p with $k\geqslant l\geqslant n\geqslant p$ (with $n\geqslant 0, p\geqslant -1$) such that their sum equals $2a-3$.

V. GAL POTENTIALS [a,b,f,g=ARBITRARY NUMBERS]

So far, we have discussed the cases when the four parameters a,b,f,g take integer values or at least one of them is half-integer. Now we want to extend this discussion to the general case when a,b,f,g take arbitrary values.

As seen in Sec. IV, when either one, two, or three of the parameters are half-integer while the remaining parameters are arbitrary, then clearly the corresponding partners indeed correspond to the case where a,b,f,g are arbitrary numbers. We therefore conjecture that the relations (6) and (7) are valid even when the four parameters a,b,f,g take any arbitrary values, the only restriction being that either $a+b+f+g$ or any other combination obtained by replacing one or more of these parameters by $-a-1,-b-1,-f-1,-g-1$, respectively, is a non-negative even integer. Further, in that case the two partner potentials have the same band-edge eigenvalues as the QES mid-band energies of the potentials where either one, two, or three of the parameters are half-integers.

A few illustrative examples are in order here. Consider the potential $[4/5,2/5,2/5,2/5]$. In this case while $a+b+f+g=2$, no other combination characterizing relations (38)–(46) gives an even integer. Using Eq. (6) we find that this potential has a GAL partner $[3/5,3/5,3/5,1/5]$. Using Table 4 of paper I it is easily shown that both these potentials have two (identical) QES band edge energy eigenvalues

$$E=\tfrac{26}{25}(1+m)\pm\tfrac{2}{5}\sqrt{1-m+m^2}. \tag{78}$$

If instead we consider the potential $[17/5,8/5,7/5,6/5]$, then only $a+f-b-g$ is an integer and the corresponding GAL partner potential is $[13/5,12/5,11/5,2/5]$ and both have one (identical) QES energy. Of course it can happen that a,b,f,g are such that more than one of the relations (37)–(46) are satisfied. In that case one has more QES band edge eigenvalues. For example, if the potential parameters are such that $a+b-g-f-1,a+f-b-g-1$ as well as $a+g-f-b-1$ are non-negative integers, then using Eqs. (38)–(40) it is easily seen that the number of QES energy eigenvalues is equal to $(3a-b-f-g)/2$. One illustration of this is the potential $[11/5,1/5,1/5,1/5]$ which has three QES energies $(1+m)$, $144/25+m$, $1+(144/25)m$. We might add here that the above-presented discussion is valid even if the numbers a,b,f,g are irrational numbers but such that $a+b+f+g$ or any other combination obtained by replacing one or more of a,b,f,g to $-a-1,-b-1,-f-1,-g-1$, respectively, is an even integer (including zero).

We would like to restate here that when all four parameters a,b,f,g are integers, one has a finite number of band gaps. In all other cases one expects to have an infinite number of bands and band gaps out of which only a few are QES states.

VI. IMPLICATIONS FOR HEUN'S EQUATION

Heun's equation, a second-order linear differential equation with four regular singular points has been extensively discussed in the mathematics literature.[20–22] The intimate connection between Heun's equation and GAL potentials is well known.[9] In recent years, this equation has also proven very useful in the context of a number of physical problems, like quasi-exactly solvable systems,[23] sphaleron stability,[24] Calogero-Sutherland models,[25] higher dimensional correlated systems,[26] Kerr-de Sitter black holes,[27] and finite lattice Bethe ansatz systems.[28]

The canonical form of Heun's equation is given by[20]

$$\left[\frac{\mathrm{d}^2}{\mathrm{d}x^2}+\left(\frac{\gamma}{x}+\frac{\delta}{x-1}+\frac{\epsilon}{x-c}\right)\frac{\mathrm{d}}{\mathrm{d}x}+\frac{\alpha\beta x-q}{x(x-1)(x-c)}\right]G(x)=0, \tag{79}$$

where $\alpha,\beta,\gamma,\delta,\epsilon,q,c$ are parameters, except that $c\neq 0,1$ and the first five parameters are related by

$$\gamma+\delta+\epsilon=\alpha+\beta+1. \tag{80}$$

The four regular singular points of Eq. (79) are located at $x=0,1,c$ and the point at infinity.

If we make the transformation $x=\mathrm{sn}^2(y,m)$, then Heun's equation takes the form[20]

$$F''(y)+\left[(1-2\epsilon)m\frac{\mathrm{sn}(y,m)\mathrm{cn}(y,m)}{\mathrm{dn}(y,m)}+(1-2\delta)\frac{\mathrm{sn}(y,m)\mathrm{dn}(y,m)}{\mathrm{cn}(y,m)}+(2\gamma-1)\frac{\mathrm{cn}(y,m)\mathrm{dn}(y,m)}{\mathrm{sn}(y,m)}\right]F'(y)$$
$$-[4mq-4\alpha\beta m\mathrm{sn}^2(y,m)]F(y)=0, \tag{81}$$

where $c=1/m$, $G(x)\equiv F(y)$. The periodic solutions of Eq. (81) correspond to the polynomial solutions of Eq. (79) while the quasiperiodic solutions correspond to nonpolynomial solutions of (79).

The interesting point is that after a transformation, the Schrödinger equation (9) for the GAL potential (2) is in fact Heun's Eq. (81). In particular, let us start from the Schrödinger equation (9) for the GAL potential (2). On substituting

$$\psi(y)=\mathrm{dn}^{-b}(y)\mathrm{cn}^{-f}(y)\mathrm{sn}^{-g}(y)\phi(y), \tag{82}$$

one can show that $\phi(y)$ satisfies the differential equation

$$\phi''(y)+2\left[mb\frac{\mathrm{sn}(y,m)\mathrm{cn}(y,m)}{\mathrm{dn}(y,m)}+f\frac{\mathrm{sn}(y,m)\mathrm{dn}(y,m)}{\mathrm{cn}(y,m)}-g\frac{\mathrm{cn}(y,m)\mathrm{dn}(y,m)}{\mathrm{sn}(y,m)}\right]\phi'(y)$$
$$-[R-Qm\mathrm{sn}^2(y,m)]\phi(y)=0, \tag{83}$$

where

$$R=-E+m(g+b)^2+(f+g)^2,\quad Q=(b+f+g)(b+f+g-1)-a(a+1). \tag{84}$$

Thus once we obtain solutions of the Schrödinger equation for the GAL potential (2), then we can immediately write the solutions for the periodic form of Heun's Eq. (81) and the solutions of the original Heun's Eq. (79) with the identification

$$\gamma=\tfrac{1}{2}-g,\quad \delta=\tfrac{1}{2}-f,\quad \epsilon=\tfrac{1}{2}-b,$$
$$\alpha+\beta=\tfrac{1}{2}-(b+f+g),\quad 4\alpha\beta=Q,\quad 4mq=R, F(y)\equiv\phi(y). \tag{85}$$

We now make a crucial observation. From Eq. (84), it follows that if under any transformation, the parameters b_1,f_1,g_1 change to b_2,f_2,g_2 and the energy E remains invariant, then the corresponding values of R are related by

$$R_1-m(b_1+g_1)^2-(f_1+g_1)^2=R_2-m(b_2+g_2)^2-(f_2+g_2)^2. \tag{86}$$

Making use of Eq. (86) and the connection between GAL potentials as given by Eqs. (6) and (7), we can obtain interesting relations for Heun's equation. Using the fact that the two GAL potentials given by Eq. (6) have the same band edge energy eigenvalues and the eigenfunctions for both the partners as are given by Eqs. (37)–(41), one can obtain the connection between the two corresponding solutions of Heun's equation. For example, consider the solution (37) and the corresponding solution of the GAL partner obtained by the above-noted substitution. Using Eq. (86) it then follows that corresponding to a given periodic (i.e., polynomial) solution of Heun's equation with parameter set (α, β, δ, ϵ, γ, q) there always exists another periodic solution with the *same* q provided the other parameters change as follows:

$$\gamma\to\alpha,\quad \alpha\to\gamma,\quad \beta\to\beta,\quad \epsilon\to 1+\beta-\delta,\quad \delta\to 1+\beta-\epsilon. \tag{87}$$

Similarly, on considering the other three periodic solutions as given by Eqs. (38)–(40) and the corresponding solutions of the GAL partner potential with the same energy, we find that corresponding to a given periodic solution of Heun's equation, there exist the following three (periodic) solutions with the change of parameters given by (note that $R=4mq$ and $c=1/m$)

$$\gamma\to 1+\beta-\epsilon,\quad \alpha\to\delta,\quad \beta\to\beta,\quad \epsilon\to 1+\beta-\gamma,\quad \delta\to\alpha,\quad q\to q-\beta(\delta-\alpha), \tag{88}$$

$$\epsilon \to \alpha, \quad \alpha \to \epsilon, \quad \beta \to \beta, \quad \gamma \to 1+\beta-\delta, \quad \delta \to 1+\beta-\gamma, \quad q \to q-\beta(\epsilon-\alpha)c, \tag{89}$$

$$\gamma \to 1+\beta-\gamma, \quad \alpha \to 1+\beta-\alpha, \quad \beta \to \beta, \quad \epsilon \to 1+\beta-\epsilon, \quad \delta \to 1+\beta-\delta,$$
$$q \to q+\beta[(\alpha-\delta)+(\alpha-\epsilon)c]. \tag{90}$$

Thus given a periodic solution of Heun's equation, one immediately has four other periodic solutions as given by Eqs. (87)–(90). We have checked that if instead we consider the two partner GAL potentials given by Eq. (7) and consider the corresponding eigenfunctions given by Eqs. (42)–(46) (and those of the corresponding GAL partner potentials with the same energy), then we again obtain the *same* relations [Eqs. (87)–(90)]. As an additional check, we have looked at the partner GAL potentials as given by Eqs. (51), (65), (66), (60), and (8) and in all these cases we get back the relations (87)–(90), which to the best of our knowledge, are new results. Several comments are in order:

1. In Sec. IV we have shown that the QES mid-band energy values of the GAL potential $[a=k+1/2, b, f, g]$ are the same as the QES energies of the two GAL potentials given in (51). What does this imply in the context of Heun's equation? It is easily shown that as a consequence of the discussion in Sec. IV, ven a periodic solution of Heun's equation with the set of parameters α, β, γ, δ, ϵ, q, one has a corresponding quasiperiodic solution with changed parameters:

$$\gamma \to 2-\alpha, \quad \alpha \to 1+\gamma-\alpha, \quad \beta \to 1+\beta-\alpha, \quad \epsilon \to 1+\beta-\delta, \quad \delta \to 1+\beta-\epsilon,$$
$$q \to q+(\alpha-1)[(1+\beta-\delta)+(1+\beta-\epsilon)c]. \tag{91}$$

An additional check on this relation is obtained by using the connection between the mid-band states of the GAL potentials $[a=k+1/2,\ b=l+1/2,\ f,\ g]$ and $[a=k+1/2,\ b=l+1/2,\ f=n+1/2,\ g]$ and the QES energies of the potentials (60), (65), and (66) and we again obtain the *same* connection between the periodic and quasiperiodic solutions of Heun's equation.

2. Using the results in Sec. IV regarding the case when three of the four parameters a, b, f, g are half-integers, we also obtain two more relations connecting the periodic and quasiperiodic solutions of Heun's equation. In particular, given a periodic solution of Heun's equation with the set of parameters α, β, γ, δ, ϵ, q, it implies the following two quasiperiodic solutions of Heun's equation:

$$\gamma \to \alpha, \quad \alpha \to 1+\alpha-\epsilon, \quad \beta \to \delta, \quad \epsilon \to 1+\delta-\beta, \quad \delta \to 1+\beta-\epsilon, \quad q \to q+\alpha(\beta-\delta), \tag{92}$$

$$\gamma \to \alpha, \quad \alpha \to 1+\alpha-\delta, \quad \beta \to \epsilon, \quad \epsilon \to 1+\beta-\delta, \quad \delta \to 1+\epsilon-\beta, \quad q \to q+4\alpha(\beta-\epsilon)c. \tag{93}$$

3. Needless to say that if instead, a quasiperiodic solution of Heun's equation is given, then by inverting Eqs. (91)–(93), we immediately obtain three periodic solutions of Heun's equation.

So far we have discussed how the connections between different GAL potentials can help in finding new solutions of Heun's equation. It may happen that in some cases it may be simpler to solve the algebraic Heun's equation (79) rather than its periodic variant. We now show that this is indeed so in the case of several quasiperiodic mid-band eigenfunctions. Consider for example the GAL potentials when either b or f or g is $1/2$ while the other three parameters are arbitrary. Using arguments of Sec. IV, we can easily obtain the eigenvalues for mid-band states for these potentials. We shall now show that using these eigenvalues we can easily solve the algebraic form of Heun's equation (79) and hence using the connection as explained earlier, obtain the eigenfunctions for the mid-band states of these GAL potentials.

Consider the GAL potential $[a, 1/2, f, g]$ where a, f, g are arbitrary numbers, Note that using the relations (6) and (7) and Table 4 of I, it is easily shown that the QES mid-band eigenvalue of

the GAL potential $[a,1/2,f,g]$ is at $E=(a+1/2)^2+m(g+1/2)^2$. On using the connection formulas (84) and (85) it is easily shown that the corresponding parameters for Heun's equation (79) are

$$\gamma = 1/2 - g, \quad \delta = 1/2 - f, \quad \epsilon = 0, \quad \alpha = (a - f - g + 1/2)/2,$$

$$\beta = -(a + f + g + 1/2)/2, \quad q = (a + f + g + 1/2)(f + g - a - 1/2)(c/4). \tag{94}$$

Remarkably, for these parameters, it is straightforward to obtain the solution of the algebraic Heun's equation (79) and show that

$$G(x) = F[(a - f - g + 1/2)/2, -(a + f + g + 1/2)/2, 1/2 - g; x], \tag{95}$$

where $F(a,b,c;x)$ is the hypergeometric function. The corresponding mid-band state eigenfunction for the GAL potential $[a,1/2,f,g]$ is then immediately written down. We have verified that this is indeed the correct eigenfunction in the following cases (i) $a=f=g=0$, (ii) a integral, $f=g=0$, (iii) a arbitrary while f, g are integral.

Similarly, for the GAL potential $[a,b,1/2,g]$, with arbitrary a, b, g, the QES mid-band energy eigenvalue is $E=(g+1/2)^2+(a+1/2)^2m$ and proceeding as above, it is easily shown that the solution of the algebraic Heun's equation (79) is given by

$$G(x) = F[(a - b - g + 1/2)/2, -(a + b + g + 1/2)/2, 1/2 - g; mx]. \tag{96}$$

Finally, for the GAL potential $[a,b,f,1/2]$, with arbitrary a, b, f, the QES energy is $E=(f+1/2)^2+(b+1/2)^2m$ and proceeding as above, it is easily shown that the solution of the algebraic Heun's equation (79) is given by

$$G(x) = F[(a - b - f + 1/2)/2, -(a + b + f + 1/2)/2, 1/2 - b; (1 - mx)/(1 - m)]. \tag{97}$$

On using the solutions (95)–(97) it follows that for the potential $[a,1/2,1/2,1/2]$ one knows three QES mid-band energy eigenstates. In the special case when $a=2k+3/2$ these eigenstates are the mid-band QES eigenstates for the potential $[2k+3/2,1/2,1/2,1/2]$ where the sum of the four parameters characterizing the potential is an odd integer.

VII. SUMMARY AND OPEN QUESTIONS

In this paper, we have addressed many issues regarding GAL potentials with a number of choices for the parameters a, b, f, g. The most interesting case is when all four parameters are integers. This is a potential with a finite number of band gaps. We have been able to count the number of independent GAL potentials with a given number of band gaps and completely specify the nature of the band edge eigenfunctions. We have introduced the new concept of self-dual potentials which are not self-isospectral. We are also able to specify how many of the independent potentials with a given number of band gaps have supersymmetric partner potentials and how many have nonsupersymmetric partner potentials. Finally, using the results for the GAL potentials, we have shown that given any one periodic solution of Heun's equation, one can obtain four more periodic solutions.

We have also discussed several issues related with GAL potentials when one or more of the parameters take half-integer values. In particular, while nothing is known so far about GAL potentials when three of the parameters take half-integer values, we have been able to obtain the QES energy values for several of these potentials. Further, using these eigenvalues and the algebraic form of Heun's equation, we have also been able to obtain the corresponding eigenfunctions for potentials of the form $[a,1/2,f,g]$, $[a,b,1/2,g]$, $[a,b,f,1/2]$ where a, b, f, g are arbitrary numbers. The key point to make while addressing these questions is that the relations (6) and (7) are not only valid when the four parameters a, b, f, g are integers but also when one or more of these parameters take half-integer values. This in turn immediately implies that these relations are also valid when the four parameters a, b, f, g take arbitrary values so long as either their sum $a+b+f+g$ [or one or more of the combinations obtained by changing one or more of the param-

eters to $-a-1$, $-b-1$, $-f-1$, $-g-1$, respectively] is a nonnegative even integer. We have also conjectured that both relations (6) and (7) are simultaneously valid when a, b, f, g are integers and that the energy eigenvalues for the band edges of these potentials are the same as mid-band QES energy values of GAL potentials in which all four parameters are half-integers and their sum is an odd integer. Finally, using these results we have also shown that given a periodic solution of Heun's equation, one can immediately obtain three quasiperiodic solutions of the same equation.

This work raises several issues which we have not been able to address satisfactorily:

1. Can one explicitly write down all seven KdV equations of seventh order?
2. What are the QES eigenfunctions for GAL potentials when one or more of the parameters is half-integral ($\geqslant 3/2$) while the remaining parameters are arbitrary?
3. The problem when two of the four parameters are half-integers needs further study. In particular, it is still not clear how many QES energy eigenvalues can be obtained, in general, in that case.
4. When the sum of all the four parameters is an even integer, it is clear that the QES states correspond to band edges. However, a complete understanding is still lacking regarding the number of QES states for various values of a, b, f, g. Further, when the sum of the four parameters is an odd integer, the form of the QES eigenfunctions is not clear when the half-integer parameters are $>1/2$.

A geometrical characterization of commutative positive operator valued measures

Roberto Beneduci[a)]

(Received 14 March 2006; accepted 27 April 2006; published online 14 June 2006)

We show that a POV measure F on the Borel σ-algebra of the reals $\mathcal{B}(\mathbb{R})$ is commutative if and only if there exists a PV measure E on $\mathcal{B}(\mathbb{R})$ and, for every λ in the spectrum of E, a probability measure $\gamma_{(\cdot)}(\lambda)$ on $\mathcal{B}(\mathbb{R})$ such that the effect $F(\Delta)$ coincides with $\gamma_\Delta(A)$, where A is the self-adjoint operator associated to E. The relevance of this result to the theory of the sharp reconstruction is analyzed.
 [DOI: 10.1063/1.2206879]

I. INTRODUCTION

POV (positive operator valued) measures have been used to define generalized observables in quantum mechanics,[1–8] and are a consequence of the probabilistic structure of quantum mechanics. Their introduction can also be justified by the analysis of some ideal experiments which show that there are physical events which cannot be described by projection operators.[6] POV measures were also used to generalize Mackey's imprimitivity theorem[8] and to study the problem of the joint measurement of incompatible observables.[9,10]

As shown in Refs. 1–3 there exists a one-to-one correspondence between POV measures and affine maps $S\mapsto\mu_S^F(\cdot)$ from the set of states $\mathcal{S}$ into the set of probability measures on $\mathcal{B}(\mathbb{R})$. Moreover, this correspondence is determined by the relation $\mu_S^F(\Delta)=\mathrm{Tr}[SF(\Delta)]$. This allows one to interpret the number

$$\mu_S^F(\Delta)=\mathrm{Tr}[SF(\Delta)]$$

as the probability that the outcomes of a measurement of the observable F (corresponding to a POV measure F) is in Δ when the physical system is in the state $S\in\mathcal{S}$. We recall that an analogous relation holds for standard observables $E:\mathcal{B}(\mathbb{R})\to\mathcal{E}(\mathcal{H})$, that is:

$$\mu_S^E(\Delta)=\mathrm{Tr}[SE(\Delta)].$$

Therefore POV measures are a generalization of the standard quantum observables and the problem of giving them a clear physical meaning should be dealt with. In order to address this problem several characterizations of commutative POV measures were found.[11–16]

In Ref. 13 it is proved that for each commutative POV measure F, there exists a unique Baire probability measure $\mu:\mathcal{P}(\mathbb{R},\mathcal{A}(F))\to[0,1]$ [defined on the space of all the PV measures with values in the commutative von Neumann algebra $\mathcal{A}(F)$ generated by the set $\{F(\Delta)\}_{\Delta\in\mathcal{B}(\mathbb{R})}$] such that $F(\Delta)=\int_{\mathcal{P}(X,\mathcal{A}(F))}E(\Delta)\mathrm{d}\mu(E)$.

Naimark theorem[16] establishes that every POV measure F in a Hilbert space $\mathcal{H}$ can be dilated to a PV measure E^+ in an extended Hilbert space $\mathcal{H}^+$ such that F is the projection of E^+ on $\mathcal{H}$.

In Refs. 11 and 12 it is shown that: if $F:\mathcal{B}(\mathbb{R})\to\mathcal{F}(\mathcal{H})$ is a commutative POV measure, then there exists a unique PV measure $E:\mathcal{P}_\mathbb{R}\to\mathcal{E}(\mathcal{H})$, where $\mathcal{P}_\mathbb{R}$ is the space of the probability measures on $\mathcal{B}(\mathbb{R})$, such that

a)Electronic mail: rbeneduci@unical.it

$$F(\Delta) = \int_{\mathcal{P}_{\mathbb{R}}} p(\Delta) E(\mathrm{d}p). \tag{1}$$

Here we follow a different approach, which stems from Refs. 14 and 15. In these papers, the outcomes of the measurement of a commutative POV measure are interpreted as deriving from a stochastic diffusion of the outcomes of the measurement of a particular PV measure. The starting point of this approach is a theorem due to von Neumann, which states that for any given set $\{F_i\}_{i\in I}$ of commuting self-adjoint operators there exists a self-adjoint operator A and a family of measurable functions $f_i(\lambda)$ such that $f_i(A)=F_i$ (see Theorem 1 below). von Neumann's theorem implies that a POV measure F is commutative if and only if there exists a self-adjoint operator A (corresponding to a PV measure E) and a family of functions $\{\mu_\Delta\}_{\Delta\in\mathcal{B}(\mathbb{R})}$ such that $F(\Delta)=\mu_\Delta(A)$.

In Ref. 14, starting from a commutative POV measure with spectrum in $[0, 1]$, the authors constructed explicitly a self-adjoint operator A with spectrum $\sigma(A)\subset[0,1]$ and, for every set $\Delta \in \mathcal{B}([0,1])$, a measurable function $\omega_\Delta(\lambda):\sigma(A)\to[0,1]$ such that $F(\Delta)=\omega_\Delta(A)$. Their construction uses a procedure analogous to the one used by Riesz and Nagy to prove von Neumann's theorem (see Ref. 21, Sec. 130).

In Ref. 15 it was shown that, for every real number λ, the application $\omega_{(\cdot)}(\lambda):\mathcal{B}([0,1]) \to[0,1]$, corresponding to the family of functions $\{\omega_\Delta(\lambda)\}_{\Delta\in\mathcal{B}([0,1])}$, defines an *additive* set function on a particular ring $\mathcal{R}(\mathcal{S})$ which generates $\mathcal{B}([0,1])$.

This result suggests to interpret the outcomes of the measurement of F as deriving from a randomization of the outcomes of the measurement of E. Indeed let us consider a pure state $S=P_\psi$. From $F(\Delta)=\omega_\Delta(A)$ we get

$$\mu_S^F(\Delta) = \int w_\Delta(\lambda)\|E((\lambda-\mathrm{d}\lambda,\lambda])\psi\|^2 = \int w_\Delta(\lambda)\mathrm{d}\mu_S^E, \tag{2}$$

where E is the PV measure corresponding to the operator A.

This relation shows that $w_\Delta(\lambda)$ could be interpreted, quoting from Ref. 15, "*as the probability that the outcome* λ *of* E *turns into an outcome in* Δ *for* F." The physical source of randomization could be the imprecision of the measuring apparatus, or some other cause.

The above interpretation is satisfactory if the application $\omega_{(\cdot)}(\lambda)$ is σ-additive on $\mathcal{B}([0,1])$. However, the problem of the σ-additivity of $\omega_{(\cdot)}(\lambda)$ was left open by the authors.

In this paper we follow a novel approach and give a general geometrical characterization of POV measures, without using constructive procedures. Specifically, we show that a POV measure $F:\mathcal{B}(\mathbb{R})\to\mathcal{F}(\mathcal{H})$ is commutative if and only if there exists a PV measure $E:\mathcal{B}(\mathbb{R})\to\mathcal{E}(\mathcal{H})$ (corresponding to a self-adjoint operator A) and, for every $\lambda\in\sigma(A)$, a *probability measure* $\gamma_{(\cdot)}(\lambda):\mathcal{B}(\mathbb{R})\to[0,1]$ such that $F(\Delta)=\gamma_\Delta(A)$ (see Theorem 2). This result is founded on the ground of von Neumann's theorem. Its relevance to the interpretation of the commutative POV measures proposed in Refs. 14 and 15 is that, repeating the reasoning used to get Eq. (2), we get

$$\mu_S^F(\Delta) = \int \gamma_\Delta(\lambda)\mathrm{d}\mu_S^E$$

so that the sharp reconstruction E and the POV measure F are related by a probability measure.

It is worth mentioning that this result is close to the one obtained by Holevo[11,12] but, at variance with Theorem 2, the PV measure in (1) is not defined on $\mathcal{B}(\mathbb{R})$ but on the space of the probability measures on $\mathcal{B}(\mathbb{R})$. It would be interesting to check if there are relationships between the two characterizations.

The paper is organized as follows. In Sec. II we give some basic definitions and state the classical von Neumann's theorem. Then, in Sec. III, we prove the main result of the paper, Theorem 2. In Sec. IV we prove Proposition 2 which will be used in the last section where we discuss the relevance of Theorem 2 to the theory of the sharp reconstruction. In the appendices we give some technical results which are used in the paper.

II. PRELIMINARIES

In this section we fix the basic notation and terminology, and state von Neumann's theorem, which will be the starting point of the paper.

We denote by $\mathcal{B}(\mathbb{R})$ the Borel σ-algebra of $\mathbb{R}$, and by $\mathcal{F}(\mathcal{H})$ the space of bounded, positive self-adjoint operators acting on the Hilbert space $\mathcal{H}$. A POV measure is defined as follows:

Definition 1: A POV (positive operator valued) measure is a mapping $F:\mathcal{B}(\mathbb{R})\to\mathcal{F}(\mathcal{H})$ *such that:*

1. $F(\Delta)\geqslant 0$ *for all* $\Delta\in\mathcal{B}(\mathbb{R})$*;*
2. *if* $\{\Delta_n\}$ *is a countable family of disjoint sets in* $\mathcal{B}(\mathbb{R})$ *then*

$$F\left(\bigcup_{n=1}^{\infty}\Delta_n\right)=\sum_{n=1}^{\infty}F(\Delta_n),$$

where the series converges in the weak operator topology;
The POV measure is said to be normalized if one has also

3. $F(\mathbb{R})=1$.

Definition 2: A PV (projection valued) measure is a normalized POV measure which is orthogonal, that is, such that

4. $F(\Delta_1)F(\Delta_2)=0$ *if* $\Delta_1\cap\Delta_2=\emptyset$.

If this is the case we have $F(\Delta)=F(\Delta)^2$. Then, $F(\Delta)$ is a projection operator for every $\Delta\in\mathcal{B}(\mathbb{R})$ and the PV measure is denoted by $E:\mathcal{B}(\mathbb{R})\to\mathcal{E}(\mathcal{H})$, where $\mathcal{E}(\mathcal{H})$ is the space of all the projection operators of the Hilbert space $\mathcal{H}$. We recall that to each PV measure it is possible to associate a measure $\langle E(\Delta)x,x\rangle$ for every $x\in\mathcal{H}$.

Definition 3: A POV measure F is said to be commutative if the following relations are valid:

$$[F(\Delta_1),F(\Delta_2)]=0;\quad \forall\,\Delta_1,\Delta_2\in\mathcal{B}(\mathbb{R}).$$

We recall that PV measures are also named *sharp* or *standard* observables and, by the spectral theorem,[17] they are in a one to one correspondence with the self-adjoint operators, while nonorthogonal normalized POV measures are also named *unsharp* observables.

In what follows we shall always refer to normalized POV measures defined on $\mathcal{B}(\mathbb{R})$.

Next we proceed to define the spectrum of a POV measure.

Definition 4, see Ref. 18: Given a POV measure F we define the co-spectrum of F as the open set

$$\rho(F)=\cup\{\Delta:\Delta\ \textit{is open},\ F(\Delta)=0\}$$

and the spectrum $\sigma(F)$ *of F as the complement of* $\rho(F)$.

The spectrum of a POV measure is characterized by the following proposition:

Proposition 1: The spectrum $\sigma(F)$ of *F is closed and coincides with the set* $\{\lambda\in\mathbb{R}:\forall\,\delta>0,F((\lambda-\delta,\lambda+\delta))\neq 0\}$.

Proof: Let us suppose $\lambda\in\sigma(F)$. Then, $\lambda\notin\rho(F)$ and $F(\Delta)\neq\mathbf{0}$ for every open set Δ. In particular,

$$F((\lambda-\delta,\lambda+\delta))\neq 0$$

for every $\delta>0$. On the converse, let us suppose that λ is so that $F((\lambda-\delta,\lambda+\delta))\neq 0$ for every $\delta>0$. For every open set Δ containing λ it must exist a number $\delta>0$ such that the open interval $(\lambda-\delta,\lambda+\delta)$ is contained in Δ. By items 1 and 2 of definition 1 we get

$$0<F((\lambda-\delta,\lambda+\delta))\leqslant F(\Delta)$$

then, $\lambda\notin\rho(F)$, hence $\lambda\in\sigma(F)$. □

We shall use the term "measurable" for the Borel measurable functions and consider the class $\mathcal{M}([0,1])$ of measurable functions defined on $[0, 1]$ which are bounded or are equal almost everywhere (a.e.), with respect to a PV measure E, to a bounded measurable function. Thus $\mathcal{M}([0,1])$ is the set of functions such that

$$E\text{-ess}\sup_{t\in[0,1]}|f(t)| = \inf_{E(\Delta)=I_{t\in\Delta}}\sup|f(t)| < +\infty.$$

The norm in $\mathcal{M}([0,1])$ is $\|f\|=E-\text{ess}\sup_{t\in[0,1]}|f(t)|$. Moreover we shall always consider equivalence classes of measurable functions. We say that two functions f and g are equivalent if $f=g$ a.e. with respect to a PV measure E, that is a.e. with respect to all the measures $\langle E(\Delta)x,x\rangle$, where x runs through all the vectors of the space $\mathcal{H}$.

As it is well known,[17,22] if a measurable function f is defined on the spectrum $\sigma(A)$ of a self-adjoint operator A, one has $f(A)=\int f(\lambda)E((\lambda-\mathrm{d}\lambda,\lambda])$ where E is the PV measure corresponding to A.

We shall denote by **0** and **1** the null and the identity operators, respectively.

Theorem 1 (von Neumann[19–21]): *For any family $\{F_i\}_{i\in\mathcal{I}}$ of self-adjoint operators acting on a Hilbert space $\mathcal{H}$ such that $[F_i,F_j]=\mathbf{0}$ for all $i,j\in\mathcal{I}$, there exist*

a) a bounded self-adjoint operator A;
b) a family of measurable functions $\{f_i:\mathbb{R}\to R\}_{i\in\mathcal{I}}$ such that for every $i\in\mathcal{I}$,

$$F_i = f_i(A) = \int_{-\infty}^{\infty} f_i(\lambda)E((\lambda - d\lambda,\lambda]) = \int_{-\infty}^{\infty} f_i(\lambda)\mathrm{d}E_\lambda$$

where E is the PV measure corresponding to A.

It follows that an unsharp observable $F:\mathcal{B}(\mathbb{R})\to\mathcal{F}(\mathcal{H})$ is commutative if and only if there exist:[14]

- *a sharp observable $E:\mathcal{B}(\mathbb{R})\to\mathcal{E}(\mathcal{H})$ (which corresponds to a self-adjoint operator $\mathbf{0}<A<\mathbf{1}$),*
- *a family of set functions*

$$\omega_{(\cdot)}(\lambda):\mathcal{B}(\mathbb{R})\to[0,1],\quad \Delta\mapsto\omega_\Delta(\lambda),\quad \lambda\in\sigma(A)$$

such that $F(\Delta)=\omega_\Delta(A)$.

Indeed the family $\{F(\Delta),\Delta\in\mathcal{B}(\mathbb{R})\}$ is a commutative family of bounded positive operators and von Neumann's theorem can be applied. Conversely, if a self-adjoint operator A exists such that all the operators $F(\Delta)$ are functions of A, then the family $\{F(\Delta),\Delta\in\mathcal{B}(\mathbb{R})\}$ is commutative (see Ref. 19, theorem 2, Sec. 75).

In what follows whenever a POV measure F, a self-adjoint operator A and an application $\mu_{(\cdot)}(\lambda)$ are such that $F(\Delta)=\mu_\Delta(A)$ we shall say that the triple $(F,A,\mu_{(\cdot)}(\lambda))$ satisfies the thesis of von Neumann's theorem.

III. A CHARACTERIZATION OF COMMUTATIVE POV MEASURES

Let us consider a family of functions $\mathcal{F}=\{\mu_\Delta(\lambda):[0,1]\to[0,1]\}_{\Delta\in\mathcal{B}(\mathbb{R})}$ and the corresponding family of set functions $\mathcal{F}_S=\{\mu_{(\cdot)}(\lambda):\mathcal{B}(\mathbb{R})\to[0,1],\lambda\in\sigma(A)\}$ and assume that the triple $(F,A,\mu_{(\cdot)}(\lambda))$ satisfies the thesis of von Neumann's theorem. The aim of the present section is to show that the family of functions $\{\mu_\Delta(\lambda):[0,1]\to[0,1]\}_{\Delta\in\mathcal{B}(\mathbb{R})}$ can always be chosen in such a way that the corresponding set functions $\mu_{(\cdot)}(\lambda)\in\mathcal{F}_S$ are probability measures.

Theorem 2 (Main result): *A normalized POV measure $F:\mathcal{B}(\mathbb{R})\to\mathcal{F}(\mathcal{H})$ is commutative if and only if there exist an application $\mu_{(\cdot)}(\lambda):\mathcal{B}(\mathbb{R})\to[0,1]$ and a PV measure $E:\mathcal{B}(\mathbb{R})\to\mathcal{E}(\mathcal{H})$ such that:*

1. *the application* $\mu_{(\cdot)}(\lambda):\mathcal{B}(\mathbb{R})\rightarrow[0,1]$ *is a probability measure for every* $\lambda\in\sigma(A)$*;*
2. $F(\Delta)=\mu_{\Delta}(A)=\int\mu_{\Delta}(\lambda)E((\lambda-\mathrm{d}\lambda,\lambda])$*,*

where A is the self-adjoint operator associated to the PV measure E.

To prove this theorem we need two lemmas:

Lemma 1: For any commutative POV measure F, it is possible to find a couple $(A,\omega_{(\cdot)}(\lambda))$ *such that the triple* $(F,A,\omega_{(\cdot)}(\lambda))$ *satisfies the thesis of von Neumann theorem and* $\omega_{(\cdot)}(\lambda)$ *is additive on an appropriate ring which generates the Borel* σ*-algebra* $\mathcal{B}(\mathbb{R})$.

Proof: Following Ref. 14 we shall consider, without loss of generality, POV measures with a bounded spectrum contained in [0, 1] so that $\Delta\in\mathcal{B}([0,1])$ (see Appendix A). To prove the lemma let us consider a family of set functions

$$\gamma_{(\cdot)}(\lambda):\mathcal{B}([0,1])\rightarrow[0,1],\quad \Delta\mapsto\mu_{\Delta}(\lambda),\quad \lambda\in\sigma(A)$$

such that the triple $(F,A,\gamma_{(\cdot)}(\lambda))$ satisfies the thesis of von Neumann's theorem. We have that $\gamma_{[0,1]}(A)=\mathbf{1}$. Moreover the function $\omega_{[0,1]}(\lambda):=1$ is such that $\omega_{[0,1]}(A)=F([0,1])$ so that we can replace $\gamma_{[0,1]}(\lambda)$ with $\omega_{[0,1]}(\lambda)$.

We proceed by showing that it is possible to replace the functions $\gamma_{[0,1/2]}(\lambda)$ and $\gamma_{(1/2,1]}(\lambda)$ with two measurable functions $\omega_{[0,1/2]}(\lambda)$ and $\omega_{(1/2,1]}(\lambda)$ such that:

1) $\omega_{[0,1/2]}(\lambda)+\omega_{(1/2,1]}(\lambda)=\omega_{[0,1]}(\lambda)$ for all λ;
2) $\omega_{[0,1/2]}(A)=F([0,1/2])$ and $\omega_{(1/2,1]}(A)=F((1/2,1])$.

We have

$$\int\omega_{[0,1]}(\lambda)\mathrm{d}E_{\lambda}=F([0,1])=F([0,1/2])+F((1/2,1])$$

$$=\int\gamma_{[0,1/2]}(\lambda)\mathrm{d}E_{\lambda}+\int\gamma_{(1/2,1]}(\lambda)\mathrm{d}E_{\lambda}=\int[\gamma_{[0,1/2]}(\lambda)+\gamma_{(1/2,1]}(\lambda)]\mathrm{d}E_{\lambda}$$

so that, by Ref. 22, Corollary 9 (see also Ref. 21, Chap. IX),

$$\gamma_{[0,1/2]}(\lambda)+\gamma_{(1/2,1]}(\lambda)=\omega_{[0,1]}(\lambda)\ \text{a.e. with respect to } E.$$

By setting

$$\omega_{(1/2,1]}(\lambda)=\omega_{[0,1]}(\lambda)-\gamma_{[0,1/2]}(\lambda)$$

$$\omega_{[0,1/2]}(\lambda)=\gamma_{[0,1/2]}(\lambda)$$

we get two measurable functions $\omega_{[0,1/2]}(\lambda)$ and $\omega_{(1/2,1]}(\lambda)$ such that items 1) and 2) are satisfied and which differ from functions $\gamma_{[0,1/2]}(\lambda)$ and $\gamma_{(1/2,1]}(\lambda)$ only in a set of zero E-measure.

We proceed by showing that it is possible to replace the functions $\gamma_{[0,1/4]}(\lambda)$ and $\gamma_{(1/4,1/2]}(\lambda)$ with two measurable functions $\omega_{[0,1/4]}(\lambda)$ and $\omega_{(1/4,1/2]}(\lambda)$ such that:

1′) $\omega_{[0,1/4]}(\lambda)+\omega_{(1/4,1/2]}(\lambda)=\omega_{[0,1/2]}(\lambda)$ for all λ;
2′) $\omega_{[0,1/4]}(A)=F([0,1/4])$ and $\omega_{(1/4,1/2]}(A)=F((1/4,1/2])$.

We have

$$\int \omega_{[0,1/2]}(\lambda)\mathrm{d}E_\lambda = F([0,1/2]) = F([0,1/4]) + F((1/4,1/2])$$

$$= \int \gamma_{[0,1/4]}(\lambda)\mathrm{d}E_\lambda + \int \gamma_{(1/4,1/2]}(\lambda)\mathrm{d}E_\lambda = \int [\gamma_{[0,1/4]}(\lambda) + \gamma_{(1/4,1/2]}(\lambda)]\mathrm{d}E_\lambda,$$

so that

$$\gamma_{[0,1/4]}(\lambda) + \gamma_{(1/4,1/2]}(\lambda) = \omega_{[0,1/2]}(\lambda) \text{ a.e. with respect to } E.$$

Let us consider the set $N \subset [0,1]$ such that $\gamma_{[0,1/4]}(\lambda) > \omega_{[0,1/2]}(\lambda)$. Since N is a null set, there exists a Borel set $\bar{\Delta}$ such that $N \subset \bar{\Delta}$ and $E(\bar{\Delta})=0$. Now we define the function

$$\bar{\gamma}_{[0,1/4]}(\lambda) := \begin{cases} \gamma_{[0,1/4]}(\lambda) & \text{if } \lambda \notin \bar{\Delta} \\ 0 & \text{if } \lambda \in \bar{\Delta}, \end{cases}$$

which is less than or equal to $\omega_{[0,1/2]}(\lambda)$. Moreover $\bar{\gamma}_{[0,1/4]}(\lambda)$ is measurable. Indeed by the measurability of $\gamma_{[0,1/4]}(\lambda)$ we have that, for every $x \in [0,1]$,

$$\{\lambda \in [0,1] | \bar{\gamma}_{[0,1/4]}(\lambda) \leqslant x\} = \{\lambda \in [0,1] \setminus \bar{\Delta} | \gamma_{[0,1/4]}(\lambda) \leqslant x\} \cup \bar{\Delta}$$

$$= [\{\lambda \in [0,1] | \gamma_{[0,1/4]}(\lambda) \leqslant x\} \cap \{[0,1] \setminus \bar{\Delta}\}] \cup \bar{\Delta} \in \mathcal{B}([0,1]).$$

By setting

$$\omega_{[0,1/4]}(\lambda) = \bar{\gamma}_{[0,1/4]}(\lambda),$$

$$\omega_{(1/4,1/2]}(\lambda) = \omega_{[0,1/2]}(\lambda) - \bar{\gamma}_{[0,1/4]}(\lambda),$$

we get two functions such that items 1′) and 2′) are satisfied and which differ from the functions $\gamma_{[0,1/4]}(\lambda)$ and $\gamma_{(1/4,1/2]}(\lambda)$ only in a set of zero E-measure.

Analogously, starting from the functions $\gamma_{(1/2,3/4]}(\lambda)$ and $\gamma_{(3/4,1]}(\lambda)$, we can define two measurable functions $\omega_{(1/2,3/4]}(\lambda)$ and $\omega_{(3/4,1]}(\lambda)$ such that

1″) $\omega_{(1/2,3/4]}(\lambda) + \omega_{(3/4,1]}(\lambda) = \omega_{(1/2,1]}(\lambda)$;

2″) $\omega_{(1/2,3/4]}(A) = F((1/2,3/4])$, and $\omega_{(3/4,1]}(A) = F((3/4,1])$.

Iterating the procedure we shall finally obtain a family of functions $\{\omega_\Delta(\lambda):[0,1] \to [0,1]\}_{\Delta \in \mathcal{S}}$ where $\mathcal{S}$ is the semi-ring:

$$\mathcal{S} = \{[0,1/2^{n-1}], (k/2^{n-1}, k+1/2^{n-1}]], k = 1,2,\ldots,2^{n-1}-1, n \in \mathbb{N}\}.$$

Moreover, for every given λ, the set function $\omega_{(\cdot)}(\lambda):\mathcal{S} \to [0,1]$ is additive on the semi-ring $\mathcal{S}$.

Now, for any λ, it is possible to extend $\omega_{(\cdot)}(\lambda):\mathcal{S} \to [0,1]$ to the ring $\mathcal{R}(\mathcal{S})$ generated by $\mathcal{S}$. The extension $\omega_{(\cdot)}(\lambda):\mathcal{R}(\mathcal{S}) \to [0,1]$ is an additive set function on $\mathcal{R}(\mathcal{S})$ such that $\omega_\Delta(A) = F(\Delta)$ (see Ref. 24). □

The following lemma concerns the definition and the monotonicity property of $\omega_{[0,t)}(\lambda)$ as a function of t. In particular it will be proved that $\omega_{[0,t)}(\lambda)$ is nondecreasing with respect to t and such that $\omega_{[0,t)}(A) = F[0,t)$.

In order to define $\omega_{[0,t)}(\lambda)$ we use the fact that it is always possible to decompose $[0,t)$ into the union of a disjoint sequence of intervals from $\mathcal{S}$.

Definition 5: For every $t \in (0,1]$ *we define* $\omega_{[0,t)}(\lambda) = \Sigma_{j=1}^{\infty} \omega_{\Delta_j}(\lambda)$ *where* $\{\Delta_j : \Delta_j \in \mathcal{S}\}_{j \in \mathbb{N}}$ *is a decomposition of the interval* $[0,t)$ *with the following property: for every* $x \in (0,t)$ *there is a closed interval* $[0,a]$: $a \geqslant x$ *such that* $[0,a] = \cup_{j=1}^{n} \Delta_j$. *The set of the decompositions so defined is denoted by* $\mathcal{D}$.

The series $\Sigma_{j=1}^{\infty}\omega_{\Delta_j}(\lambda)$ used to define the function $\omega_{[0,t)}(\lambda)$ is convergent. Indeed for every $p \in \mathbb{N}$, $\cup_{j=1}^{p}\Delta_j \subset [0,t) \subset [0,1]$ and then, using the additivity of the measure on $\mathcal{R}(\mathcal{S})$, $\Sigma_{j=1}^{p}\omega_{\Delta_j}(\lambda) \leqslant \omega_{[0,1]}$. Moreover, as shown in Appendix B, $\omega_{[0,t)}(\lambda)$ is well defined.

Lemma 2. The set function $\omega_{[0,t)}(\lambda)$, *is nondecreasing with respect to* t *and* $\omega_{[0,t)}(A) = F([0,t))$.

Proof. Let us consider the two intervals $[0,t)$ and $[0,t')$ where $t<t'$ and let us decompose them as $\{\Delta_k;\Delta_k \in \mathcal{S}\}_{k\in\mathbb{N}}$ and $\{\Delta'_k;\Delta'_k \in \mathcal{S}\}_{k\in\mathbb{N}}$, respectively. Following Definition 5 it is possible to find $m \in \mathbb{N}$ so that

$$[0,t) \subset [0,b] = \bigcup_{k=1}^{m}\Delta'_k \subset [0,t'),$$

with $[0,b] \in \mathcal{R}(\mathcal{S})$. We can write:

$$[0,t') = \left[\bigcup_{k=1}^{m}\Delta'_k\right] \cup \left[\bigcup_{k=m+1}^{\infty}\Delta'_k\right].$$

By the additivity of $\omega_{(\cdot)}(\lambda)$ on $\mathcal{R}(\mathcal{S})$ we get:

$$\omega_{[0,t')}(\lambda) = \sum_{k=1}^{m}\omega_{\Delta'_k}(\lambda) + \sum_{k=m+1}^{\infty}\omega_{\Delta'_k}(\lambda) = \omega_{[0,b]}(\lambda) + \sum_{k=m+1}^{\infty}\omega_{\Delta'_k}(\lambda) \geqslant \omega_{[0,b)}(\lambda).$$

Using again the additivity of the measure and the relation

$$\bigcup_{k=1}^{p}\Delta_k \subset \bigcup_{k=1}^{\infty}\Delta_k = [0,t) \subset [0,b]; \quad \forall\, p \in \mathbb{N},$$

we finally have

$$\omega_{(\cup_{k=1}^{p}\Delta_k)}(\lambda) \leqslant \omega_{[0,b]}(\lambda), \quad \forall\, p \in \mathbb{N},$$

$$\omega_{[0,b]}(\lambda) \geqslant \omega_{[0,t)}(\lambda),$$

which ends the proof of the first part of the proposition. The second assertion is proved as follows: $F([0,t)) = F(\cup_j\Delta_j) = \Sigma_j F(\Delta_j) = \Sigma_j \int \omega_{\Delta_j}(\lambda)dE_\lambda$ and, by Theorem VII.2.d in Ref. 17, we get

$$F([0,t)) = \int \sum_j \omega_{\Delta_j}(\lambda)\mathrm{d}E_\lambda = \omega_{[0,t)}(A).$$

□

Now we are ready to prove the main theorem of this paper.

Proof of Theorem 2. Let $(F,A,\omega_{(\cdot)}(\lambda))$ satisfy the thesis of von Neumann's theorem. By Lemma 1, the family of set functions $\{\omega_{(\cdot)}(\lambda), \lambda \in \sigma(A)\}$ can be chosen in such a way that, for each $\lambda \in \sigma(A)$, $\omega_{(\cdot)}(\lambda)$ is an additive set function. Moreover, Lemma 2 allows us to define a function $\omega_{[0,t)}(\lambda)$ which is nondecreasing with respect to t and such that $\omega_{[0,t)}(A) = F([0,t))$.

Now, starting from $\omega_t := \omega_{[0,t)}(\lambda)$, it is possible to define a distribution function $\mu_t(\lambda)$ continuous from the left as follows:

$$\mu_t(\lambda) = \begin{cases} \omega_{t^-}(\lambda) & \text{if } 0 < t \leqslant 1 \\ 0 & \text{if } t \leqslant 0 \\ 1 & \text{if } t > 1, \end{cases}$$

where $\omega_{t^-}(\lambda) = \lim_{x\to t^-}\omega_{[0,t)}(\lambda)$.

In its turn, for every λ, starting from the left continuous function $\mu_t(\lambda)$ it is possible to define the set function $\mu_{[a,b)}(\lambda)=\mu_b-\mu_a$, $[a,b)\subset(-\infty,\infty)$ which can be extended to a σ-additive probability measure (see Ref. 23, p. 97) $\mu_{(.)}(\lambda):\mathcal{B}(\mathbb{R})\to[0,1]$ such that

$$\mu_\Delta(\lambda)=0 \quad \text{if } \Delta\cap[0,1]=\emptyset.$$

We want to prove that:

$$\mu_t(A)=F([0,1]\cap(-\infty,t)) \tag{3}$$

and that the probability measure $\mu_{(.)}(\lambda):\mathcal{B}([0,1])\to[0,1]$, which is the restriction of $\mu_{(.)}\times(\lambda):\mathcal{B}(\mathbb{R})\to[0,1]$ to $\mathcal{B}([0,1])$, is such that

$$\mu_\Delta(A)=F(\Delta), \quad \Delta\in\mathcal{B}([0,1]). \tag{4}$$

First we prove (3). If $t\in(0,1]$, we have:

$$\mu_t(A)=\int\mu_t(\lambda)\mathrm{d}E_\lambda=\int[\lim_{x\to t^-}\omega_x(\lambda)]\mathrm{d}E_\lambda.$$

Notice that the integral exists thanks to the measurability of $\mu_t(\lambda)$ as a function of λ (see Remark 2 below). Let us consider a sequence $\{x_n\}$ such that $x_n\to t$ from the left. We have $\mu_t(A)=\int[\lim_{x\to t^-}\omega_x(\lambda)]\mathrm{d}E_\lambda=\int[\lim_{n\to\infty}\omega_{x_n}(\lambda)]\mathrm{d}E_\lambda$. By the continuity of F and theorem 11 in Ref. 18 we get

$$\mu_t(A)=\int[\lim_{n\to\infty}\omega_{x_n}(\lambda)]\mathrm{d}E_\lambda=\lim_{n\to\infty}\int\omega_{x_n}(\lambda)\mathrm{d}E_\lambda=\lim_{n\to\infty}F([0,x_n))=F([0,t))=F([0,1]\cap(-\infty,t)).$$

Moreover, if $t\leqslant 0$ then $\mu_t(A)=\mathbf{0}=F(\emptyset)=F([0,1]\cap(-\infty,t))$, while, if $t>1$ then $\mu_t(A)=\mathbf{1}=F([0,1])=F([0,1]\cap(-\infty,t))$.

It remains to prove that the probability measure $\mu_{(.)}(\lambda):\mathcal{B}(\mathbb{R})\to[0,1]$ generated by $\mu_t(\lambda)$ is such that $\mu_\Delta(A)=F(\Delta)$, $\Delta\in\mathcal{B}([0,1])$. Let us consider the POV measure $F':\mathcal{B}(\mathbb{R})\to\mathcal{F}(\mathcal{H})$ such that $F'(\Delta)=F(\Delta\cap[0,1])$. Notice that F is the restriction of F' to $\mathcal{B}([0,1])$ and $F'(\Delta)=\mathbf{0}$ if $\Delta\cap[0,1]=\emptyset$.

As a consequence of (3),

$$\begin{aligned}F'([t,\bar{t}))&=F'((-\infty,\bar{t}))-F'((-\infty,t))=F([0,1]\cap(-\infty,\bar{t}))-F([0,1]\cap(-\infty,t))\\&=\mu_{\bar{t}}(A)-\mu_t(A)=\mu_{[t,\bar{t})}(A)\end{aligned}$$

so that $F'(\Delta)=\mu_\Delta(A)$ for every set Δ in the ring $\mathcal{P}$ generated by sets of the kind $[t,\bar{t})\subset(-\infty,\infty)$. Moreover by the uniqueness of the extensions of $F':\mathcal{P}\to\mathcal{F}(\mathcal{H})$ to the σ-algebra $\mathcal{B}(\mathbb{R})$ (see Ref. 18, theorem 7), it follows that the probability measure $\mu_{(.)}(\lambda):\mathcal{B}(\mathbb{R})\to[0,1]$ generated by the distribution function $\mu_t(\lambda)$ and the POV measure $F':\mathcal{B}(\mathbb{R})\to\mathcal{F}(\mathcal{H})$ are such that $F'(\Delta)=\mu_\Delta(A)$ for every $\Delta\in\mathcal{B}(\mathbb{R})$, hence $\mu_\Delta(A)=F(\Delta)$ for every $\Delta\in\mathcal{B}([0,1])$. □

Remark 1: The argument used to prove Theorem 2, applies to every pair $(B,\omega^B_{(.)}(\lambda))$ *such that the triple* $(F,B,\omega^B_{(.)}(\lambda))$ *satisfies the thesis of von Neumann's theorem. Therefore we can state the following corollary:*

Corollary 1: If the triple $(F,B,\omega^B_{(.)}(\lambda))$ *satisfies the thesis of von Neumann theorem then there exists a probability measure* $\mu^B_{(.)}(\lambda)$, *equivalent to* $\omega^B_{(.)}(\lambda)$ (*that is, for every* $\Delta\in\mathcal{B}([0,1])$, $\mu^B_\Delta(\lambda)=\omega^B_\Delta(\lambda)$ *a.e.*), *such that the triple* $(F,B,\mu^B_{(.)}(\lambda))$ *satisfies the thesis of von Neumann's theorem.*

Remark 2: The function $\mu_t(\cdot)$ *defined in the proof of Theorem 2 is measurable because it is the limit of a monotone sequence of measurable functions.*[17,23–25] *Indeed, for each* λ, *the function* $\omega_x(\lambda)$ *is bounded and nondecreasing with respect to* x, *then the limit* $\omega_{t^-}(\lambda)$ *exists and we have*

$\mu_t(\lambda)=\omega_{t^-}(\lambda)=\lim_{x\to t^-}\omega_x(\lambda)=\lim_{n\to\infty}\omega_{x_n}(\lambda)$ *where* $\{x_n\}$ *is an increasing sequence of numbers such that* $x_n\to t$ *from the left.*

IV. A NECESSARY AND SUFFICIENT CONDITION FOR THE σ-ADDITIVITY OF $\omega_{(\cdot)}(\lambda)$

In the proof of Theorem 2 we started from the *additive* set function $\omega_{(\cdot)}(\lambda):\mathcal{R}(\mathcal{S})\to[0,1]$ such that $\omega_\Delta(A)=F(\Delta)$, $\Delta\in\mathcal{R}(\mathcal{S})$ and proved the existence of a probability measure $\mu_{(\cdot)}(\lambda):\mathcal{B}([0,1])\to[0,1]$ such that the triple $(F,A,\mu_{(\cdot)}(\lambda))$ satisfies the thesis of von Neumann's theorem. Clearly, if $\omega_{(\cdot)}(\lambda):\mathcal{R}(\mathcal{S})\to[0,1]$ were σ-additive on $\mathcal{R}(\mathcal{S})$ it could be directly extended to a probability measure $\mu_{(\cdot)}(\lambda)$ on $\mathcal{B}([0,1])$ such that $\mu_\Delta(A)=F(\Delta)$. Now we want to show that the additive set function $\omega_{(\cdot)}(\lambda):\mathcal{R}(\mathcal{S})\to[0,1]$ is σ-additive if and only if $\omega_\Delta(\lambda)=\mu_\Delta(\lambda)$ for every $\Delta\in\mathcal{R}(\mathcal{S})$.

Proposition 2: The additive set function $\omega_{(\cdot)}(\lambda):\mathcal{R}(\mathcal{S})\to[0,1]$ *is* σ*-additive on* $\mathcal{R}(\mathcal{S})$ *if and only if* $\omega_\Delta(\lambda)=\mu_\Delta(\lambda)$ *for every* $\Delta\in\mathcal{R}(\mathcal{S})$, *where* $\mu_{(\cdot)}(\lambda)$ *is the probability measure introduced in the proof of Theorem 2.*

Proof: Let us assume that, for any λ, $\omega_{(\cdot)}(\lambda)$ is σ-additive on the ring $\mathcal{R}(\mathcal{S})$. Then, by Caratheodory theorem (see Ref. 24 p. 88, and Ref. 25), it can be uniquely extended to a σ-additive measure $\nu_{(\cdot)}(\lambda)$ on $\mathcal{B}([0,1])$. Now, we can define (see Theorem 4.8 of Ref. 24 and p. 88 of Ref. 23), a distribution function continuous from the left (see Definition 9 in Appendix D) as follows:

$$\nu_t(\lambda)=\begin{cases}\nu_{([0,t))}(\lambda) & t\in(0,1]\\ 1 & t>1\\ 0 & t\leqslant 0.\end{cases}$$

By Theorem 4 in Appendix D, it follows that the measure $\nu_{(\cdot)}(\lambda):\mathcal{B}(\mathbb{R})\to[0,1]$ generated by $\nu_t(\lambda)$ coincides with $\nu_{(\cdot)}(\lambda):\mathcal{B}([0,1])\to[0,1]$ on $\mathcal{B}([0,1])$ so that it is an extension of $\omega_{(\cdot)}(\lambda)$ to $\mathcal{B}(\mathbb{R})$. Moreover $\nu_\Delta(\lambda)=0$ if $\Delta\cap[0,1]=\emptyset$. Therefore, by the σ-additivity of the measure and by Definition 5, we have

$$\nu_{[0,t)}(\lambda)=\sum_{k=1}^{\infty}\nu_{\Delta_k}(\lambda)=\sum_{k=1}^{\infty}\omega_{\Delta_k}(\lambda)$$

for every decomposition

$$\cup_k\Delta_k=[0,t),\quad \Delta_k\in\mathcal{S}.$$

Hence,

$$\omega_{[0,t)}(\lambda)=\nu_{[0,t)}(\lambda),\quad t\in(0,1]$$

and $\omega_{[0,t)}(\lambda)$ is continuous from the left in (0,1]. Therefore we get

$$\nu_t(\lambda)=\mu_t(\lambda)=\begin{cases}\omega_{([0,t))}(\lambda) & t\in(0,1]\\ 1 & t>1\\ 0 & t\leqslant 0,\end{cases}\tag{5}$$

which means that the probability measure $\mu_{(\cdot)}(\lambda)$ corresponding to $\mu_t(\lambda)$ coincides with the probability measure $\nu_{(\cdot)}(\lambda)$ corresponding to $\nu_t(\lambda)$. Hence, $\mu_\Delta(\lambda)=\nu_\Delta(\lambda)=\omega_\Delta(\lambda)$ on $\mathcal{R}(\mathcal{S})$. The converse is obvious because if it were $\mu_\Delta(\lambda)=\omega_\Delta(\lambda)$ for every $\Delta\in\mathcal{R}(\mathcal{S})$, then $\omega_{(\cdot)}(\lambda)$ would be σ-additive on $\mathcal{R}(\mathcal{S})$. □

V. SHARP RECONSTRUCTION AND UNIQUENESS OF THE CHARACTERIZATION

This section is devoted to the analysis of the implications of Theorem 2 to the theory of the sharp reconstruction. Moreover we show (Theorem 3) that the result obtained in Ref. 15 implies the uniqueness (in a sense specified below) of the characterization in Theorem 2.

In Ref. 14, starting from a commutative POV measure F, the authors constructed a PV measure E (corresponding to a self-adjoint operator A) called the sharp reconstruction of F, and an application $\omega_{(.)}(\lambda):\mathcal{B}([0,1])\rightarrow[0,1]$ which connects A and F by means of relation $\omega_{\Delta}(A)=F(\Delta)$, proving that the triple $(F,A,\omega_{(.)}(\lambda))$ satisfies the thesis of von Neumann's theorem. In Ref. 15 it was proven that for every given $\lambda\in\sigma(A)$ the set function $\omega_{(.)}(\lambda)$ is *additive* on $\mathcal{R}(S)$. By Corollary 1 it follows that, for every given $\lambda\in\sigma(A)$, there exists a probability measure $\mu_{(.)}(\lambda):\mathcal{B}([0,1])\rightarrow[0,1]$ such that the triple $(F,A,\mu_{(.)}(\lambda))$ satisfies the thesis of von Neumann's theorem. Indeed, thanks to the additivity of $\omega_{(.)}(\lambda)$ on $\mathcal{R}(S)$, it is sufficient to apply the reasoning in the proof of Theorem 2 to the functions $\omega_{\Delta}(\lambda)$, $\Delta\in\mathcal{R}(S)$.

Moreover, by proposition 2, $\omega_{(.)}(\lambda)$ is σ-additive on $\mathcal{R}(S)$ if and only if $\omega_{\Delta}(\lambda)=\mu_{\Delta}(\lambda)$ for every $\Delta\in\mathcal{R}(S)$ so that if $\omega_{(.)}(\lambda)$ is not σ-additive on $\mathcal{R}(S)$ it would be interesting to check whether there are conditions, on the construction of the functions $\omega_{\Delta}(\lambda)$, $\Delta\in\mathcal{R}(S)$, which, added to conditions C and D in Ref. 14, imply the σ-additivity of $\omega_{(.)}(\lambda)$ on $\mathcal{R}(S)$. In Ref. 15 it was proven that the sharp reconstruction A is unique in the following sense: if the triples $(F,A,\omega_{(.)}\times(\lambda))$ and $(F,B,\omega^{B}_{(.)}(\lambda))$ satisfy the thesis of von Neumann's theorem then there exists a function $g:[0,1]\rightarrow[0,1]$ such that $A=g(B)$, so that, among the set of all sharp observables which satisfy the thesis of von Neumann's theorem, the sharp reconstruction A is the only one (modulo a bijection) which is related to the others by means of a relation of the kind $A=g(B)$. Due to the last relation, the operators A and B commute. This allowed the authors to consistently interpret the outcomes of measurements of the unsharp observable F as deriving from a randomization of the outcomes of measurements of the sharp reconstruction A (see Ref. 15). By Theorem 2 of the present work and by the main result of Ref. 15 we get the following theorem:

Theorem 3: *A POV measure $F:\mathcal{B}(\mathbb{R})\rightarrow\mathcal{F}(\mathcal{H})$ is commutative if and only if there exist a PV measure $E^{B}:\mathcal{B}(\mathbb{R})\rightarrow\mathcal{E}(\mathcal{H})$ (corresponding to a self-adjoint operator B) and, for every $\lambda\in\sigma(B)$, a probability measure $\mu^{B}_{(.)}(\lambda):\mathcal{B}(R)\rightarrow[0,1]$ such that the triple $(F,B,\mu^{B}_{(.)}(\lambda))$ satisfies the thesis of von Neumann's theorem. The sharp reconstruction A is the only one (modulo a bijection) which is related to the others as follows:*

for every triple $(F,B,\mu^{B}_{(.)}(\lambda))$ satisfying the thesis of von Neumann's theorem there exists a function $g:[0,1]\rightarrow[0,1]$ such that $A=g(B)$.

APPENDIX A: POV MEASURES WITH SPECTRUM IN [0, 1]

In this appendix we show[14] that, without loss of generality, we can restrict ourselves to POV measures with spectrum in [0, 1].

Definition 6: Given the POV measure F, the application $\omega_{(.)}(\lambda):\mathcal{B}(\mathbb{R})\rightarrow[0,1]$ and a bijective function $f:(0,1)\rightarrow\mathbb{R}$ we denote by $\bar{F}$ the POV measure $\Delta\in\mathcal{B}([0,1])\rightarrow F(f(\Delta))$ and by $\bar{\omega}_{(.)}(\lambda)$ the application $\Delta\in\mathcal{B}([0,1])\rightarrow\omega_{f(\Delta)}(\lambda)$.

Notice that the POV measure $\bar{F}$ has spectrum in [0, 1].

Proposition 3: Given a POV measure F and a self-adjoint operator A, the triple $(F,A,\omega_{(.)}\times(\lambda))$ satisfies the thesis of von Neumann's theorem if and only if the triple $(\bar{F},A,\bar{\omega}_{(.)}(\lambda))$ satisfies the thesis of von Neumann's theorem too.

Proof: If $(F,A,\omega_{(.)}(\lambda))$ satisfies the thesis of von Neumann's theorem then $\bar{F}(f^{-1}(\Delta))=F(\Delta)=\omega_{(\Delta)}(A)=\bar{\omega}_{f^{-1}(\Delta)}(A)$ for every $\Delta\in\mathcal{B}(\mathbb{R})$. Notice that f establishes a one to one correspondence between Borel sets in $\mathcal{B}([0,1])$ and Borel set in $\mathcal{B}(\mathbb{R})$. Therefore the triple $(\bar{F},A,\bar{\omega}_{(.)}(\lambda))$ satisfies the thesis of von Neumann theorem. Now let us suppose that the triple $(\bar{F},A,\bar{\omega}_{(.)}(\lambda))$ satisfies the thesis

of von Neumann theorem. Then we have $F(f(\Delta))=\bar{F}(\Delta)=\bar{\omega}_{(\Delta)}(A)=\omega_{f(\Delta)}(A)$ for every $\Delta \in \mathcal{B}([0,1])$ which means that $(F,A,\omega_{(\cdot)}(\lambda))$ satisfies the thesis of von Neumann's theorem. □

APPENDIX B: THE NONDECREASING REAL FUNCTION $\omega_{[0,t)}(\lambda)$

In this appendix we prove the following lemma:

Lemma 3: The sum in Definition 5 does not depend on the decomposition of the interval $[0,t)$.

In order to prove Lemma 3 the following simple facts will be used:

1) if the interval $((k'-1)/2^{q-1},k'/2^{q-1}=b]$ is an element of the decomposition $\{\Delta_j\}_{j\in\mathbb{N}}$ of $[0,t)$ it is not possible that intervals of the kind $((j-1)/2^{p-1},j/2^{p-1}=b]$ with $p\neq q$ be elements of the decomposition too. Otherwise $\{\Delta_j\}_{j\in\mathbb{N}}$ would not be a disjoint family of sets;
2) the extrema of the sets $\Delta \in \mathcal{S}$ define the set of points:

$$A=\left\{\frac{k}{2^{n-1}}k,n \in \mathbb{N}:k \leqslant 2^{n-1}\right\};$$

if $a \in A$ and $a \in ((i-1)/2^{n-1},i/2^{n-1}] \in \mathcal{S}$ it follows that $a=r/2^{l-1}$ for some $r,l \in \mathbb{N}$ such that $r \leqslant 2^{l-1}$ and $n \leqslant l$. Therefore every set $\Delta \in \mathcal{S}$ having $a=r/2^{l-1}$ as one of its extrema must be contained in $((i-1)/2^{n-1},i/2^{n-1}]$;
3) every point $a \in A$, with the exception of 0, is contained in [0, 1] as the right extreme of one interval $\Delta \in \mathcal{S}$

Definition 7: For any decomposition $d_t=\{\Delta_j\}_{j\in\mathbb{N}} \in \mathcal{D}$ *of* $[0,t)$ *and for any* $x \in (0,t)$ *we define the set*

$$\mathcal{M}_{d_t}(x)=\left\{b|x \in [0,b]=\bigcup_{l=1}^{m}\Delta_l,\Delta_l \in d_t\right\}.$$

Proposition 4: Let us consider two decompositions $d_t=\{\Delta_l\}_{l\in\mathbb{N}}$, $\tilde{d}_t=\{\tilde{\Delta}_k\}_{k\in\mathbb{N}} \in \mathcal{D}$ *of* $[0,t)$. *If for any* $0<x<t$ *it is* $\mathcal{M}_{d_t}(x)\cap\mathcal{M}_{\tilde{d}_t}(x)\neq\emptyset$ *then sequences* $\{\Sigma_{l=1}^{n}\omega_{\Delta_l}(\lambda)\}_{n\in\mathbb{N}}$ *and* $\{\Sigma_{k=1}^{n}\omega_{\tilde{\Delta}_k}(\lambda)\}_{n\in\mathbb{N}}$ *converge to the same limit*.

Proof: Let us choose a sequence of numbers $\{x_i;0\leqslant x_i<t\}$ such that $x_i\to t$. For every x_i there exists a number $b_i \in \mathcal{M}_{d_t}(x_i)\cap\mathcal{M}_{\tilde{d}_t}(x_i)$ such that $x_i\leqslant b_i<t$, hence a sequence $\{b_i\}$ such that $b_i \to t$ is defined. We have

$$\lim_{i\to\infty} b_i = t,$$

$$\lim_{i\to\infty} n(i) = \lim_{i\to\infty} m(i) = \infty,$$

$$[0,b_i]=\bigcup_{l=1}^{m_i}\Delta_l=\bigcup_{k=1}^{n_i}\tilde{\Delta}_k,$$

$$\sum_{l=1}^{m_i}\omega_{\Delta_l}(\lambda)=\sum_{k=1}^{n_i}\omega_{\tilde{\Delta}_k}(\lambda)\ \forall\, i,$$

hence

$$\lim_{i\to\infty}\sum_{l=1}^{m_i}\omega_{\Delta_l}(\lambda)=\lim_{i\to\infty}\sum_{k=1}^{n_i}\omega_{\tilde{\Delta}_k}(\lambda)$$

which proves the existence of two subsequences $\{\Sigma_{l=1}^{m_i}\omega_{\Delta_l}(\lambda)\}_{m_i\in\mathbb{N}}$ and $\{\Sigma_{k=1}^{n_i}\omega_{\tilde{\Delta}_k}(\lambda)\}_{n_i\in\mathbb{N}}$ of sequences $\{\Sigma_{l=1}^{n}\omega_{\Delta_l}(\lambda)\}_{n\in\mathbb{N}}$ and $\{\Sigma_{k=1}^{n}\omega_{\tilde{\Delta}_k}(\lambda)\}_{n\in\mathbb{N}}$, respectively, converging to the same limit. □

Now we are ready to prove Lemma 3.

Proof of Lemma 3: Let us consider two decompositions $\{\Delta_l\}_{l\in\mathbb{N}},\{\tilde{\Delta}_k\}_{k\in\mathbb{N}}\in\mathcal{D}$ of $[0,t)$. The proposition is proved if we prove that for every $0<x<1$ it is $\mathcal{M}_{d_t}(x)\cap\mathcal{M}_{\tilde{d}_t}(x)\neq\emptyset$.

For any x, with $0<x<t$, we denote by b the minimum of $\mathcal{M}_{d_t}(x)$ and by $\tilde{b}$ the minimum of $\mathcal{M}_{\tilde{d}_t}(x)$. The existence of the minimum comes from the definition of the class $\mathcal{D}$. If $b\neq\tilde{b}$ we suppose (without loss of generality) $b<\tilde{b}$.

Let $((k'-1)/2^{q-1},k'/2^{q-1}=\tilde{b}]\in\{\tilde{\Delta}_k\}_{k\in\mathbb{N}}$ be the interval of decomposition $\{\tilde{\Delta}_k\}_{k\in\mathbb{N}}$ having $\tilde{b}$ as the right extreme. Then, considering that $\tilde{b}$ is the minimum of set $\mathcal{M}_{\tilde{d}_t}(x)$ and that sets $\tilde{\Delta}_k$ are disjoint, we get $x\in((k'-1)/2^{q-1},k'/2^{q-1}=\tilde{b}]$. Let us consider the number $\bar{a}=\max\{a\in\mathcal{M}_{d_t}(x):[0,a]\subset[0,\tilde{b}]\}$. We have $x\leqslant\bar{a}<\tilde{b}$ and then $\bar{a}\in((k'-1)/2^{q-1},k'/2^{q-1}=\tilde{b}]$. Following item 2), we have that every interval of decomposition $\{\Delta_l\}_{l\in\mathbb{N}}$ having $\bar{a}$ as the left extreme is contained in $((k'-1)/2^{q-1},k'/2^{q-1}=\tilde{b}]$. In other words for every $\Delta_l\in\{\Delta_l\}_{l\in\mathbb{N}}\subset\mathcal{S}$ such that $\Delta_l=(\bar{a},y]$ $(y\in[0,1))$ it must be $y\leqslant\tilde{b}$. Considering that $\bar{a}$ is the maximum of $\mathcal{M}_{d_t}(x)$, that $\tilde{b}\in[0,1]$ and by item 3), we get $y=\tilde{b}$. This proves that $\mathcal{M}_{d_t}(x)\cap\mathcal{M}_{\tilde{d}_t}(x)\neq\emptyset$. The thesis derives from Proposition 4. □

Spectral geometry of κ-Minkowski space

Francesco D'Andrea[a)]
International School for Advanced Studies (SISSA), I–34014, Trieste, Italy

(Received 11 November 2005; accepted 19 April 2006; published online 22 June 2006)

After recalling Snyder's idea [Phys. Rev. **71**, 38 (1947)] of using vector fields over a smooth manifold as "coordinates on a noncommutative space," we discuss a two-dimensional toy-model whose "dual" noncommutative coordinates form a Lie algebra: this is the well-known κ-Minkowski space [Phys. Lett. B **334**, 348 (1994)]. We show how to improve Snyder's idea using the tools of quantum groups and noncommutative geometry. We find a natural representation of the coordinate algebra of κ-Minkowski as linear operators on an Hilbert space (a major problem in the construction of a physical theory), study its "spectral properties," and discuss how to obtain a Dirac operator for this space. We describe two Dirac operators. The first is associated with a spectral triple. We prove that the cyclic integral of Dimitrijevic *et al.* [Eur. Phys. J. C **31**, 129 (2003)] can be obtained as Dixmier trace associated to this triple. The second Dirac operator is equivariant for the action of the quantum Euclidean group, but it has unbounded commutators with the algebra. © *2006 American Institute of Physics.*

I. INTRODUCTION

In classical mechanics, Legendre transformation in the Hamiltonian formalism exhibits an evident symmetry between coordinate space and momentum space.

The same holds in quantum mechanics on a flat space ($\mathbb{R}^n$ or a quotient by a discrete subgroup), with Fourier transform/series replacing the Legendre transformation.

Dealing with quantum mechanics on a curved space M (a smooth manifold), the situation changes. While coordinate functions on M are elements of a commutative algebra, "momenta" (we mean, vector fields over M) no longer commute. A basic example is the 3-sphere, whose vector fields generate $su(2)$, the algebra of angular momenta of quantum mechanics.

Snyder's idea was to use momenta, i.e., vector fields over a smooth manifold M, as "coordinates on a noncommutative space" dual to M.

He applied this idea to the four-dimensional deSitter space, and was led to study the algebra generated by ten operators $\{x_\mu, J_{\mu\nu}\}$ satisfying the commutation rules (Greek letters run over $0,1,2,3$):

$$[x_\mu, x_\nu] = i\lambda^2 J_{\mu\nu}, \tag{1}$$

where $J_{\mu\nu}$ is an element of $so(3,1)$ with suitable commutators with the "coordinates" x_μ. One can notice that this algebra [isomorphic to $so(3,2)$] has too many generators to represent a four-dimensional "noncommutative space," while the elements x_μ alone are correct in number, but do not close an algebra.

A characteristic feature is the presence in (1) of an invariant length λ, whose role is to provide the correct physical dimensions and to allow us to recover $\mathbb{R}^4$ as λ goes to zero ("long distance" or "low energy" limit).

a)Electronic mail: dandrea@sissa.it

The purpose of this article is to show how to modify Snyder's idea in such a way as to obtain an algebra that can be studied with noncommutative-geometric tools.

In Sec. II, we discuss Snyder's model in full detail in the two-dimensional version, and realize that Snyder's coordinates do not close an algebra, either in two dimensions, or in four.

In Sec. III, we retry in three dimensions, and realize a fundamental difference from the original Snyder example: in the three-dimensional case the "dual" of the deSitter space is an algebra. This is a basic property, if we want to study noncommutative geometry.[1–3]

The geometrical reason at the base of the difference between Snyder's model in three and in $n \neq 3$ dimensions is clear: the deSitter space in three dimensions is a Lie group, hence the tangent bundle trivialize and vector fields form a Lie algebra isomorphic to the Lie algebra of the group.

In Sec. IV, we search for a two-dimensional example and realize that there is only one, the spacetime studied in literature under the name of κ-Minkowski,[4] whose coordinate algebra is isomorphic to $U(sb(2,\mathbb{R}))$.

As a by-product of this section, we find a natural representation of the algebra as linear operators on a Hilbert space (the choice of a representation on a Hilbert space is a major problem in the construction of a physical theory). Another main point of this section is the realization of Poincaré as a symmetry of κ-Minkowski, in the spirit of Snyder's idea.

In Sec. V we adopt a different point of view and, applying Weyl quantization, construct a C^*-algebra encoding information on the "topology" of the underlying κ-Minkowski space.

We then focus attention on the construction of a spectral triple over κ-Minkowski space. A proposal for a Dirac operator on κ-Minkowski has already appeared in Ref. 5, although the Dirac operator they found does not satisfy Connes' axioms for a spectral triple (the same holds for the one in Ref. 6, as well as the one parametric family of Dirac operators in Ref. 7). For the generalization of such axioms to the noncompact case we refer to the original paper of Connes[2] (see also Refs. 8 and 9 for a comprehensive presentation).

In Sec. V C, we construct a Dirac operator that fulfills all axioms of a spectral triple, and prove that the Dixmier trace associated with the spectral triple is just the cyclic integral discussed in Ref. 10.

Then, we compute a Dirac operator imposing equivariance for the action of the quantum Euclidean group. This turns out to be very similar to the one in Refs. 5 and 6, and has not bounded commutators with the algebra.

II. THE TWO-DIMENSIONAL ANALOGUE OF SNYDER'S SPACETIME

In his original article, Snyder considers the deSitter space $SO(3,2)/SO(3,1)$ and identifies the spacetime "coordinate functions" with a basis of the vector subspace of $so(3,2)$ orthogonal to $so(3,1)$. The (connected component of the) $SO(3,1)$ subgroup provides the Lorentz symmetries and, with a suitable choice of the momenta, it can be extended to a Poincaré symmetry. For the sake of simplicity, we will study, in full detail, the two-dimensional version. Interested readers can find the four-dimensional model discussed in Snyder's original article.[11]

In the two-dimensional version, the deSitter space is $SO(2,1)/SO(1,1)$. If η_0, η_1, η_2 are coordinates of $\mathbb{R}^3$, the deSitter spacetime is the $SO(2,1)$-orbit with equation

$$\eta_0^2 - \eta_1^2 - \eta_2^2 = -1. \tag{2}$$

The (three-dimensional Lorentz) Lie algebra $so(2,1)$ has generators $\{J, K_1, K_2\}$ (a rotation and two boosts) given by

$$J = i(\eta_2 \partial_1 - \eta_1 \partial_2),$$

$$K_1 = i(\eta_0 \partial_1 + \eta_1 \partial_0),$$

$$K_2 = i(\eta_0\partial_2 + \eta_2\partial_0),$$

where $\partial_\mu = \partial/\partial\eta_\mu$. So, the commutation rules are

$$[J,K_1] = iK_2, \quad [J,K_2] = -iK_1, \quad [K_1,K_2] = -iJ. \tag{3}$$

Emulating Snyder, we call $N=K_2$ the generator of the $so(1,1)$ subalgebra (the one-dimensional Lorentz Lie-algebra, isomorphic to $\mathbb{R}$) that leaves fixed the point $m_0=(0,0,1)$, and $x=\lambda J$, $t=\lambda K_1$ the remaining generators [whose span is the subspace of vector fields over $SO(2,1)$ that are tangent to M at m_0]. The length λ provides the correct physical dimensions. By (3), the coordinates satisfy the commutation rule

$$[x,t] = i\lambda^2 N,$$

and clearly do not form a subalgebra of $so(2,1)$.

The higher-dimensional analogue is the commutator $[x_\mu,x_\nu]=i\lambda^2 J_{\mu\nu}$ anticipated in Sec. I.

The action of the Lorentz algebra $so(1,1)$ on the coordinates is via commutator, and by (3) is undeformed:

$$N \triangleright x = it, \quad N \triangleright t = ix.$$

Since the action is undeformed, the invariant is the classical quadratic element x^2-t^2.

We still need to introduce translations.

Let us recall the idea of Snyder: to start with a commutative spacetime, in which translations do not commute, and define a noncommutative spacetime with commutative momenta. Half of this idea was already applied, to find the noncommutative spacetime "dual" to deSitter.

To complete the picture, following Snyder, we define momenta as $P=\lambda^{-1}\eta_1$ and $E=\lambda^{-1}\eta_0$ (the presence of λ ensures the correct physical dimensions). Together with N they form the classical Poincaré algebra:

$$[E,P] = 0, \quad [N,P] = -iE, \quad [N,E] = -iP.$$

The momenta act on the coordinates via commutators. For example:

$$P \triangleright x = [P,x] = -i\lambda(\eta_2\partial_1 - \eta_1\partial_2)\lambda^{-1}\eta_1 = -i\eta_2 = -i\sqrt{\lambda^2(E^2-P^2)-1}.$$

In the last step we used Eq. (2), defining the deSitter space.

With a straightforward calculation we derive the (deformed) action of momenta on coordinates

$$P \triangleright x = -i\sqrt{\lambda^2(E^2-P^2)-1} = E \triangleright t, \quad P \triangleright t = E \triangleright x = 0,$$

while the associated phase-space is defined by

$$[x,P] = i\sqrt{\lambda^2(E^2-P^2)-1} = [t,E], \quad [t,P] = [x,E] = 0.$$

In the $\lambda \to 0$ limit, the spacetime reduces to a commutative one, phase space becomes the Heisenberg algebra, and the action of the Poincaré algebra reduces to the standard one; so for $\lambda=0$ we recover the classical scenario.

III. THE THREE-DIMENSIONAL ANALOGUE OF SNYDER'S SPACETIME

In two dimensions, we have just seen that "Snyder's coordinates" do not form a complete set of generators for an algebra. Let us try in three dimensions.

The space we consider here is the $SO(2,2)$-orbit $M \subset \mathbb{R}^4$ with equation

$$\eta_0^2+\eta_1^2-\eta_2^2-\eta_3^2=-1, \quad \eta_\mu\in\mathbb{R}^4. \tag{4}$$

The stability group of the point $m_0=(0,0,0,1)$ is $SO(2,1)$, so the orbit is the quotient $M\simeq SO(2,2)/SO(2,1)$. Being an homogeneous $SO(2,2)$-space, elements of the Lie algebra $so(2,2)$ [i.e., vector fields over $SO(2,2)$] correspond to derivatives of $C^\infty(M)$. Vectors of the subspace $so(2,1)\subset so(2,2)$ are orthogonal to M, so the "naive" approach would be to take a basis of $so(2,1)^\perp$, the orthogonal of $so(2,1)$ in $so(2,2)$, as coordinates of the noncommutative spacetime dual to M. But $so(2,1)^\perp$ is not a subalgebra of $so(2,2)$, this because M is not a group with the quotient structure [$SO(2,1)$ is not a *normal* subgroup of $SO(2,2)$].

Despite this, we can put a Lie group structure on M. Writing

$$g=\begin{pmatrix}\eta_0+\eta_3 & \eta_1+\eta_2\\ \eta_1-\eta_2 & -\eta_0+\eta_3\end{pmatrix}, \quad \eta_\mu\in\mathbb{R}^4, \tag{5}$$

we have the obvious (smooth manifold) isomorphism $M\simeq SL(2,\mathbb{R})$, the equation $\det g=1$ [that identifies $SL(2,\mathbb{R})$ inside $\mathrm{Mat}(2,\mathbb{R})$] being equivalent to (4). Thus, M is a double cover of the Lorentz group $SO(2,1)$.

This is the pseudo-Euclidean analogue of the fibration $SO(4)\overset{SO(3)}{\longrightarrow}S^3\simeq SU(2)$, i.e. $SO(2,2)\overset{SO(2,1)}{\longrightarrow}SL(2,\mathbb{R})$.

Since M is a Lie group, its tangent bundle is trivial. The Lie algebra of global vector fields on M, isomorphic to $sl(2,\mathbb{R})$, will be identified with the algebra "coordinate functions on the noncommutative spacetime," three-dimensional analogue of the Snyder's spacetime. Let us compute it explicitly.

We take $\widetilde{L}\in sl(2,\mathbb{R})$ (real traceless matrices) and call L the associated vector field on M, defined by

$$(Lf)(g)=\left.\frac{\mathrm{d}}{\mathrm{d}\tau}\right|_{\tau=0} f(\exp\{\tau L\}\cdot g), \tag{6}$$

for all $f\in C^\infty(M)$, $g\in SL(2,\mathbb{R})$. We fix a basis for $sl(2,\mathbb{R})$:

$$\widetilde{t}=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, \quad \widetilde{x}=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, \quad \widetilde{y}=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix},$$

compute the exponentials

$$\exp\{\tau\widetilde{t}\}=\begin{pmatrix}e^\tau & 0\\ 0 & e^{-\tau}\end{pmatrix},$$

$$\exp\{\tau\widetilde{x}\}=\begin{pmatrix}\cosh\tau & \sinh\tau\\ \sinh\tau & \cosh\tau\end{pmatrix},$$

$$\exp\{\tau\widetilde{y}\}\begin{pmatrix}\cos\tau & \sin\tau\\ -\sin\tau & \cos\tau,\end{pmatrix},$$

and their action via left multiplication on (5), the generic element of $SL(2,\mathbb{R})$. Then, through (6), we determine the associated vector fields. For example:

$$\exp\{\tau\widetilde{t}\}g=\begin{pmatrix}(\eta_0+\eta_3)e^\tau & (\eta_1+\eta_2)e^\tau\\ (\eta_1-\eta_2)e^{-\tau} & (-\eta_0+\eta_3)e^{-\tau}\end{pmatrix}.$$

So $\exp\{\tau\widetilde{t}\}$ maps η to the point $\eta^{(\tau)}$, with coordinates

$$\begin{pmatrix} \eta_0^{(\tau)} \\ \eta_1^{(\tau)} \\ \eta_2^{(\tau)} \\ \eta_3^{(\tau)} \end{pmatrix} = \begin{pmatrix} \eta_0 \cosh \tau + \eta_3 \sinh \tau \\ \eta_1 \cosh \tau + \eta_2 \sinh \tau \\ \eta_1 \sinh \tau + \eta_2 \cosh \tau \\ \eta_0 \sinh \tau + \eta_3 \cosh \tau \end{pmatrix},$$

and by (6):

$$(-i\lambda^{-1} t \cdot f)(\eta) = \left. \frac{\mathrm{d}}{\mathrm{d}\tau} \right|_{\tau=0} f(\eta^{(\tau)}),$$

where λ is a parameter with the dimensions of a length.

We have called $-i\lambda^{-1}t$ the derivation associated with $\tilde{\tau}$ because we like to work with symmetric operators, and we want a t with the dimension of a length.

Thus,

$$-i\lambda^{-1} t = \sum_{\mu} \left. \frac{\mathrm{d}\eta_\mu^{(\tau)}}{\mathrm{d}\tau} \right|_{\tau=0} \frac{\partial}{\partial \eta_\mu} = \eta_3 \partial_0 + \eta_2 \partial_1 + \eta_1 \partial_2 + \eta_0 \partial_3.$$

On the same line, one can compute x and y. The full list of vector fields is

$$t = i\lambda(\eta_3 \partial_0 + \eta_2 \partial_1 + \eta_1 \partial_2 + \eta_0 \partial_3),$$

$$x = i\lambda(-\eta_2 \partial_0 + \eta_3 \partial_1 - \eta_0 \partial_2 + \eta_1 \partial_3),$$

$$y = i\lambda(\eta_1 \partial_0 - \eta_0 \partial_1 + \eta_3 \partial_2 - \eta_2 \partial_3),$$

and the commutation rules are those of "$i \cdot sl(2,\mathbb{R})$:"

$$[t,x] = 2i\lambda y, \quad [t,y] = 2i\lambda x, \quad [x,y] = -2i\lambda t.$$

In contrast with the two-dimensional Snyder's model, now $\{t,x,y\}$ is the basis of a Lie algebra. Furthermore, this algebra has the correct number of generators to represent a three-dimensional noncommutative space, dual to the three-dimensional deSitter space.

This idea can easily be generalized: starting with a Lie group M, one can consider $U(\mathrm{Lie}\, M)$ as noncommutative space dual to M, and eventually study it with tools of noncommutative geometry.

A celebrated (compact, Riemannian) example is the *fuzzy sphere*,[12] quotient of $U(su(2))$ for the ideal generated by $J^2 - c$, with J^2 the Casimir and c a suitable constant.

In the next section we consider a simple, two-dimensional example.

IV. A TWO-DIMENSIONAL MODEL: κ-MINKOWSKI

In two dimensions, the unique (real connected) non-Abelian Lie group is the matrix group of elements (Ref. 13, Sec. 10.1)

$$\begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix}, \quad (a,b) \in \mathbb{R}^+ \times \mathbb{R}.$$

That is (the connected component of) the group of affine transformations of the real line:

$$\begin{pmatrix} y \\ 1 \end{pmatrix} \mapsto \begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix} \begin{pmatrix} y \\ 1 \end{pmatrix} = \begin{pmatrix} ay + b \\ 1 \end{pmatrix}, \quad y \in \mathbb{R}.$$

The map

$$\begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix} \mapsto \begin{pmatrix} a & a^{-1}b \\ 0 & a^{-1} \end{pmatrix}$$

gives an isomorphism with $Sb(2,\mathbb{R})$, the group of special upper-triangular real matrices, so the variety $M \simeq Sb(2,\mathbb{R})$ is the starting point.

We want to compute the vector fields and identify them with noncommutative coordinates. Let $L=\left(\begin{smallmatrix} a & b \\ 0 & 0 \end{smallmatrix}\right)$ be the generic element of the Lie algebra, $a,b \in \mathbb{R}$, and $-i\tilde{L}$ the associated vector field:

$$(-i\tilde{L}f)(m) = \left.\frac{\mathrm{d}}{\mathrm{d}\tau}\right|_{\tau=0} f(\exp\{\tau L\}m), \quad f \in C^\infty(M).$$

We use physicists' habit of working with self-adjoint operators. Since

$$L^n = \begin{pmatrix} a^n & a^{n-1}b \\ 0 & 1 \end{pmatrix}, \quad \exp\{\tau L\} = \begin{pmatrix} e^{\tau a} & \dfrac{e^{\tau a}-1}{a}b \\ 0 & 1 \end{pmatrix},$$

if we indicate with $m=\begin{pmatrix} \eta_0 & \eta_1 \\ 0 & 1 \end{pmatrix}$ the generic point of M, $(\eta_0,\eta_1) \in \mathbb{R}^+ \times \mathbb{R}$, it is easy to compute

$$(\tilde{L}f)(\eta_0,\eta_1) = i(a\eta_0\partial_0 + (a\eta_1 + b)\partial_1)f(\eta_0,\eta_1),$$

with $\partial_\mu = \partial/\partial\eta_\mu$. We fix the basis

$$x = i\lambda\partial_1, \quad t = i\lambda(\eta_0\partial_0 + \eta_1\partial_1),$$

for vector fields on M, and define the algebra of "functions on the noncommutative spacetime" to be the algebra of polynomials generated by x and t. The presence of the length λ guarantees the correct physical dimensions, and enables us to recover $\mathbb{R}^2$ as $\lambda \to 0$ limit.

Thus, the algebra is generated by x and t modulo

$$[x,t] = i\lambda x. \tag{7}$$

This is just $U(sb(2,\mathbb{R}))$, the two-dimensional version of the so-called κ-Minkowski, introduced in Ref. 4 as homogeneous space for κ-Poincaré.[14]

The same Lie algebra, but with different real structure, emerges in the Weyl quantization of $S^1 \times \mathbb{R}$. In that case x is unitary, thus the space is "compact" in the x direction.

Now, let μ be the (left) Haar measure on M. Explicitly, for an integrable function f on M:

$$\int_M f\mathrm{d}\mu = \int_{\mathbb{R}^+\times\mathbb{R}} f(\eta_0,\eta_1)\,\eta_0^{-1}\mathrm{d}\eta_0\mathrm{d}\eta_1.$$

You can easily verify the invariance with respect to the left regular action, i.e., $\int_M f\mathrm{d}\mu = \int_M f'\mathrm{d}\mu$ with $f'(\eta_0,\eta_1) = f(a\eta_0, a\eta_1 + b)$ and for all $(a,b) \in \mathbb{R}^+ \times \mathbb{R}$.

With this measure, we can define the Hilbert space $\mathcal{H} = \mathcal{L}^2(M,\mu)$ with inner product $\langle\varphi,\psi\rangle = \int_M \varphi^* \psi \mathrm{d}\mu$.

The measure being invariant, it means that finite transformations of the group M act as isometries on the associated Hilbert space, i.e., as unitary operators. Thus, the vector fields x and t, the generators of these transformations, are represented by (unbounded) self-adjoint linear operators. I mean:

$$\langle x^*\varphi,\psi\rangle := \langle\varphi, x\psi\rangle \equiv \langle x\varphi,\psi\rangle,$$

$$\langle t^{*}\varphi,\psi\rangle := \langle \varphi, t\psi\rangle \equiv \langle t\varphi,\psi\rangle,$$

for all $\varphi,\psi\in\mathcal{H}$ and in the domain of x, respectively, t (it is an easy check to verify these equations). The self-adjointness of x and t allows us to interpret them as quantum-mechanical observables.

A. κ-Minkowski more in depth

Following Snyder's idea, we interpret vector fields on M as "coordinates," and define momenta as the following functions in $C(M)$:

$$P=\lambda^{-1}\eta_1, \quad E=\lambda^{-1}\log\ \eta_0.$$

Again, the presence of λ is for dimensional reasons and we choose E as a logarithm because we want it in $\mathbb{R}$, and not in $\mathbb{R}^{+}$.

The commutators defining phase-space are

$$[x,E]=0, \quad [x,P]=i=[t,E], \quad [t,P]=i\lambda P, \tag{8}$$

and reduce to the classical Heisenberg algebra for $\lambda=0$ (physically, this can be interpreted as a "low-energy limit," i.e., as an approximation for $|\lambda E|,|\lambda P|\ll 1$).

To complete the picture, we want to define the analogue of a boost generator: the generator of a transformation of M with a fixed point [of course, we choose the unit element $(\eta_0,\eta_1)=(1,0)$ as fixed point].

If we define

$$iN=E\partial_P+P\partial_E\equiv\ \eta_0\eta_1\partial_0+\log\ \eta_0\partial_1,$$

N acts on E and P as a classical boost, and $\{E,P,N\}$ generate the (undeformed) Poincaré algebra:

$$[N,E]=-iP, \quad [N,P]=-iE.$$

Since $N\equiv -Pt-(E-\lambda P^2)x$, the action on coordinates is

$$[N,x]=i(t-\lambda Px), \quad [N,t]=i(1-\lambda E-\lambda^2P^2)x+i\lambda Pt.$$

Thus, the action on coordinates is nonlinear and reduces to a classical boost for $\lambda\to 0$.

Like in Snyder's case, we have deformed $\mathbb{R}^2$ into a noncommutative space without breaking the Poincaré symmetry.

In the Snyder case, the coordinates are vector fields on $SO(2,1)$ orthogonal to the submanifold $SO(1,1)$, they are a G-algebra module for Poincaré and do not close an algebra.

In the κ-Minkowski case, the Lie group associated with $\{E,P,N\}$ is Poincaré, isomorphic to $SO(1,1)\ltimes Sb(2,\mathbb{R})$, where $SO(1,1)\simeq\mathbb{R}$ is the subgroup generated by N. Coordinates are vector fields on $M=Sb(2,\mathbb{R})\simeq\{SO(1,1)\ltimes Sb(2,\mathbb{R})\}/SO(1,1)$, and close a Lie algebra isomorphic to "$i\cdot sb(2,\mathbb{R})$." The boosts $SO(1,1)$ are the isotropy transformations of M, which we identify with momentum space. The Poincaré symmetry of spacetime is obtained by dualizing the action of $SO(1,1)$ and taking the cross-product with momenta.

All that has been done in this section can be generalized to $n+1$ dimensions. Just substitute M with the matrix group of elements

$$\begin{pmatrix} e^{a} & b \\ 0 & \mathbb{1} \end{pmatrix}$$

$$\text{with } a\in\mathbb{R}, b\in\mathbb{R}^n, \quad \text{and} \quad \mathbb{1} \text{ the } n\times n \text{ identity matrix.}$$

The associated Lie algebra is again called κ-Minkowski[4] and arises in quantum group theory as a quantum homogeneous space.

B. Quantum group of symmetries for κ-Minkowski

One could object that the action of the boost N on κ-Minkowski coordinates depends on momenta. In more mathematical terms: spacetime is not an algebra module for Poincaré, although phase-space is.

It is obvious that a noncommutative space cannot be a quantum homogeneous space for a Lie group (I mean "embeddable," see, e.g., Ref. 15 for the definition of homogeneous space in a noncommutative framework). Or, in other words, that the algebra of functions on a Lie group has only commutative subalgebras.

It results that κ-Minkowski is embeddable in a quantum group, κ-Poincaré, whose $\lambda \to 0$ limit is the classical Poincaré group. Or, from a dual point of view, it carries a covariant action of an Hopf algebra whose $\lambda \to 0$ limit is the universal enveloping algebra (UEA) of the classical Poincaré Lie algebra.

By using the tools of Hopf algebras,[16] it is not difficult to produce such a deformation. As algebra of momenta one takes the dual of κ-Minkowski Lie algebra, and as covariant action the left canonical one. Then, one adds a "boost" generator and determines the full Hopf algebra of symmetries and its action on coordinates using a bi-cross-product.[16]

The result is the Hopf algebra generated by three real elements $\{N,E,P\}$ (for notational convenience we continue to use the same symbols as in Sec. IV A, but we remark that the Hopf algebra is different) with commutation relations:

$$[E,P]=0, \quad [N,P]=\tfrac{i}{2\lambda}(1-e^{2\lambda E})-\tfrac{i\lambda}{2}P^2, \quad [N,E]=-iP,$$

coproduct:

$$\Delta E = E\otimes 1 + 1\otimes E, \tag{9a}$$

$$\Delta P = P\otimes 1 + e^{\lambda E}\otimes P, \tag{9b}$$

$$\Delta N = N\otimes 1 + e^{\lambda E}\otimes N, \tag{9c}$$

and counit/antipode:

$$\epsilon(E)=\epsilon(P)=\epsilon(N)=0, \quad S(E)=-E, \quad S(P)=-Pe^{-\lambda E}, \quad S(N)=-Ne^{-\lambda E}. \tag{9d}$$

This is the two-dimensional version of κ-Poincaré algebra, obtained for the first time in Ref. 14 by contraction of $U_q(so(3,2))$.

The action on coordinates is undeformed:

$$\begin{aligned} &N\triangleright x = it, \qquad P\triangleright x = -i, \qquad E\triangleright x = 0,\\ &N\triangleright t = ix, \qquad P\triangleright t = 0, \qquad E\triangleright t = -i. \end{aligned}$$

On the other hand, the coproduct is deformed. For this reason, one can calculate, for example:

$$N\triangleright x^2 = (N\triangleright x)x + x(N\triangleright x) = i(tx+xt),$$

$$N\triangleright t^2 = (N\triangleright t)t + (e^{\lambda E}\triangleright t)(N\triangleright t) = i(tx+xt)+\lambda x = N\triangleright x^2 - i\lambda N\triangleright t,$$

and prove that the quadratic invariant is deformed into $x^2-t(t+i\lambda)$, that is:

$$N\triangleright\{x^2 - t(t+i\lambda)\}=0.$$

Finally, a phase space can be obtained as a cross product of momenta and coordinates. The relations defining the phase space are

$$fg = (f_{(1)} \triangleright g) f_{(2)},$$

for f a generic function of the momenta, g a function of the coordinates, and $\Delta T = T_{(1)} \otimes T_{(2)}$ the Sweedler notation.[16] Thus:

$$[x,P] = [t,E] = i, \quad [t,P] = i\lambda P, \quad [x,E] = 0.$$

This is the same algebra defined by Eq. (8).

A second (different) phase space can be constructed via a cross product using the right canonical action of momenta on coordinates, instead of the left one.

The construction of phase space as a cross product (in 3+1 dimensions) was performed in Refs. 17 and 18, an analysis of physical consequences is in Ref. 19.

V. SPECTRAL GEOMETRY OF κ-MINKOWSKI

Let us quote from Ref. 2 the definition of spectral triple, noncommutative generalization of the notion of Riemannian spin^c manifold.

Definition 1: *A spectral triple* $(\mathcal{A},\mathcal{H},D)$ *is given by an involutive algebra* $\mathcal{A}$, *a representation* $\pi:\mathcal{A}\to\mathcal{B}(\mathcal{H})$ *by bounded operators on a Hilbert space* $\mathcal{H}$, *and a self-adjoint operator* $D=D^*$ *with dense domain in* $\mathcal{H}$, *such that*:

(S1) $\pi(a)(D^2+1)^{-1/2}$ *is a compact operator for all* $a\in\mathcal{A}$;
(S2) $[D,\pi(a)]$ *is a bounded operator for all* $a\in\mathcal{A}$.

A commutative example is the canonical spectral triple associated with the spin structure of $\mathbb{R}^2$: $(C_0^\infty(\mathbb{R}^2),\mathcal{H},\not{D})$, with $C_0^\infty(\mathbb{R}^2)$ smooth functions vanishing at infinity on $\mathbb{R}^2$, $\mathcal{H}=L^2(\mathbb{R}^2)\otimes\mathbb{C}^2$ the Hilbert space of L^2-spinors and $\not{D}$ the Dirac operator:

$$\not{D} = i(\sigma_1\partial_0 + \sigma_2\partial_1) = \begin{pmatrix} 0 & i\partial_0+\partial_1 \\ i\partial_0-\partial_1 & 0 \end{pmatrix}.$$

Here σ_j are the Pauli matrices, η_μ coordinates in $\mathbb{R}^2$ and $\partial_\mu := \partial/\partial\eta_\mu$ the corresponding derivatives. Greek letters run over 0,1. We define also $\vec{\eta}=(\eta_0,\eta_1)$.

$C_0^\infty(\mathbb{R}^2)$ is a Frechét pre-C^*-algebra. The supremum norm is equivalent to the operator norm on $\mathcal{H}$, and the C^*-algebra completion is $C_0(\mathbb{R}^2)$, the algebra of continuous functions vanishing at infinity.

Definition 2: *A spectral triple* $(\mathcal{A},\mathcal{H},D)$ *is even if there exists a grading* $\gamma\in\mathcal{B}(\mathcal{H})$, $\gamma=\gamma^*$ *and* $\gamma^2=1$, *such that* $\gamma D=-D\gamma$ *and* $a\gamma=\gamma a\ \forall\ a\in\mathcal{A}$.

The operator:

$$\gamma := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \tag{10}$$

is a grading for the canonical spectral triple on $\mathbb{R}^2$.

We quote also the notion of equivariance with respect to the action of a Lie group.

Definition 3: *Let* H *be Lie group*, $\rho:H\to\mathcal{B}(\mathcal{H})$ *a representation and* $\triangleright:H\times\mathcal{A}\to\mathcal{A}$ *a covariant action. An even spectral triple* $(\mathcal{A},\mathcal{H},D,\gamma)$ *is H-equivariant if*:

(E1) $\rho(h)\pi(a)\rho(h)^{-1}=\pi(h\triangleright a)$ *for all* $a\in\mathcal{A}$, $h\in H$;
(E2) $\rho(h)D\rho(h)^{-1}=D$ *and* $\rho(h)\gamma\rho(h)^{-1}=\gamma$ *for all* $h\in H$.

The spin structure of $\mathbb{R}^2$ is equivariant with respect to the spin representation of $H:=ISO(2)\simeq SO(2)\ltimes\mathbb{R}^2$, the group of isometries of the Euclidean plane $\mathbb{R}^2$.

If $(R,\vec{v}),(R',\vec{v}')\in SO(2)\times\mathbb{R}^2$, the multiplication law of $ISO(2)$ is

$$(R,\vec{v})\cdot(R',\vec{v}')=(RR',\vec{v}+R\vec{v}'),$$

and the spin representation $\rho: H\to\mathcal{B}(\mathcal{H})$ is defined by

$$\{\rho(R,\vec{v})\psi\}(\vec{\eta}):=R\cdot\psi(R^{-1}(\vec{\eta}-\vec{v})),\quad \forall\,\psi\in\mathcal{H}. \tag{11}$$

The representation π of the algebra satisfies (E1) if we define $\triangleright$ to be the pull-back of the natural action on $\mathbb{R}^3$:

$$\{(R,\vec{v})\triangleright f\}(\vec{\eta})=f(R^{-1}(\vec{\eta}-\vec{v})),\quad \forall\, f\in C_0^\infty(\mathbb{R}^2).$$

Differentiating the action of the group, we arrive at the equivalent notion of $U(\mathrm{Lie}\,H)$-equivariance. This notion can be generalized to a generic Hopf-algebra.

Definition 4: *Let $\mathcal{U}$ be an Hopf-algebra, $\rho:\mathcal{U}\to\mathcal{B}(\mathcal{H})$ a representation and $\triangleright:\mathcal{U}\times\mathcal{A}\to\mathcal{A}$ a covariant action. An even spectral triple $(\mathcal{A},\mathcal{H},D,\gamma)$ is $\mathcal{U}$-equivariant if*:

(E1′) $\rho(u_{(1)})\pi(a)\rho(Su_{(2)})=\pi(u\triangleright a)$ *for all* $a\in\mathcal{A}$, $u\in\mathcal{U}$,
(E2′) $\rho(u)D=D\rho(u)$ *and* $\rho(u)\gamma=\gamma\rho(u)$ *for all* $u\in\mathcal{U}$.

In the following we construct the algebras replacing continuous and smooth functions vanishing at infinity associated with κ-Minkowski, and describe the spinor representation.

Since the metric properties of the space depend on the Dirac operator, at this point there is no difference between Euclidean and Lorenzian version.

We then analyze the problem of constructing an Euclidean Dirac operator. We exhibit an operator that is essentially the Dirac operator on the commutative subspace $\mathbb{R}$ of κ-Minkowski, and prove that it defines a spectral triple. We search also for an equivariant Dirac operator and find that there is just one, and does not satisfy the axioms of a spectral triple.

A. The algebra of polynomials of the "noncommutative coordinates"

Let us recall the construction of the algebra of coordinates on κ-Minkowski.

We call $G:=(\mathbb{R}^2,\dot{+})$ the space $\mathbb{R}^2$ with deformed sum:

$$(p_0,p_1)\dot{+}(p_0',p_1')=(p_0+p_0',p_1+p_1'e^{\lambda p_0}),\quad \forall\,(p_0,p_1),(p_0',p_1')\in\mathbb{R}^2.$$

The map:

$$(p_0,p_1)\mapsto g:=\begin{pmatrix}e^{\lambda p_0} & p_1\\ 0 & 1\end{pmatrix}$$

is an isomorphism between G and $\mathrm{Aff}_0(\mathbb{R})$, (the connected component of) the group of affine transformation of $\mathbb{R}$. We will identify G and $\mathrm{Aff}_0(\mathbb{R})$.

There is only one unitary irreducible infinite-dimensional representation of the group $\mathrm{Aff}(\mathbb{R})$, defined on the Hilbert space $L^2(\mathbb{R}^*,\mathrm{d}\eta_1/|\eta_1|)$ by:[20]

$$\{g\cdot\varphi\}(\eta_1):=e^{ib\eta_1}\varphi(a\eta_1),\quad \varphi\in L^2(\mathbb{R}^*,\mathrm{d}\eta_1/|\eta_1|),\quad g=\begin{pmatrix}a & b\\ 0 & 1\end{pmatrix}\in\mathrm{Aff}(\mathbb{R}).$$

We take the tensor product of this representation with the trivial representation $g\mapsto e^{i\eta_0 p_0}$ of the Abelian subgroup $\mathbb{R}$. Then we take the direct integral on $\eta_0\in\mathbb{R}$ with an arbitrary measure $\mathrm{d}\mu(\eta_0)$ on $\mathbb{R}$.

The result is a unitary representation of G on the space:

$$\mathcal{H}_\mu:=L^2(\mathbb{R}\times\mathbb{R}^*,\mathrm{d}\mu(\eta_0)|\eta_1|^{-1}\mathrm{d}\eta_1)\otimes\mathbb{C}^2, \tag{12}$$

defined by

$$\pi: G \to \mathcal{B}(\mathcal{H}_\mu), \quad \vec{p} \mapsto \pi(\vec{p}),$$

$$\{\pi(\vec{p})\psi\}(\vec{\eta}) = e^{i\vec{p}\cdot\vec{\eta}}\psi(\eta_0, \eta_1 e^{\lambda p_0}), \tag{13}$$

where $\psi \in \mathcal{H}_\mu$. One can explicitly check that it is an homomorphism:

$$\pi(\vec{p})\pi(\vec{p}') = \pi(p_0 + p_0', p_1 + p_1' e^{\lambda p_0}).$$

We indicate with $\mathcal{H}_0$ the Hilbert space obtained taking as $\mathrm{d}\mu(\eta_0)$ the Lebesgue measure $\mathrm{d}\eta_0$.

In the previous section, we defined the noncommutative coordinates on κ-Minkowski as the vector fields associated with the generators of $U(\mathfrak{g})$:

$$\begin{pmatrix} \lambda & 0 \\ 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},$$

where $\mathfrak{g}$ is the Lie algebra of G.

We can obtain a representation of these coordinates on $\mathcal{H}_\mu$ using the differential of π:

$$\hat{x}_0 = i\mathrm{d}\pi\begin{pmatrix} \lambda & 0 \\ 0 & 0 \end{pmatrix} = \eta_0 - i\lambda\,\eta_1\partial_1,$$

$$\hat{x}_1 = i\mathrm{d}\pi\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} = \eta_1.$$

The operators $(\hat{x}_0, \hat{x}_1)$ generate an algebra isomorphic to the κ-Minkowski algebra:

$$[\hat{x}_0, \hat{x}_1] = -i\lambda\hat{x}_1. \tag{14}$$

We indicate with $\mathbb{R}^2_\lambda$ the virtual "quantum space" associated with the algebra $U(\mathfrak{g})$, and call elements of $U(\mathfrak{g})$ the "polynomial functions" on κ-Minkowski space.

When $\lambda = 0$, the representation $\mathrm{d}\pi$ reduces to the ordinary (unbounded) representation of polynomial functions on $\mathbb{R}^2$ via pointwise multiplication on $\mathcal{H}_\mu$.

B. Continuous and smooth "functions" on κ-Minkowski space

To construct a spectral triple with the polynomial algebra $U(\mathfrak{g})$ is problematic, since $\hat{x}_\mu$ cannot be represented by bounded operators, and (14) can be satisfied only on a dense domain in $\mathcal{H}_\mu$. It is the same problem one encounters in the canonical quantization of phase-space in quantum mechanics. A possible solution is to shift the attention from $\hat{x}_\mu$ to complex exponentials, that is, from the Lie algebra $\mathfrak{g}$ to the Lie group G. This is Weyl quantization, defined as a map associating complex exponentials on $\mathbb{R}^2$ to elements of G, represented by unitary operators on $\mathcal{H}_\mu$. The quantization map can be extended to an involutive subalgebra of $C_0(\mathbb{R}^2)$ using Fourier transform.

We call $\mathrm{Fun}(\mathbb{R}^2)$ the following class of functions:

$$\mathrm{Fun}(\mathbb{R}^2) := C_0(\mathbb{R}^2) \cap \mathcal{H}_0,$$

and define the following quantization map:

$$\Omega: \mathrm{Fun}(\mathbb{R}^2) \to \mathcal{B}(\mathcal{H}_\mu),$$

$$f \mapsto \Omega(f) = \int_{\mathbb{R}^2} \mathrm{d}^2 p \tilde{f}(\vec{p})\,\pi(\vec{p}),$$

where π is the representation (13) and $\tilde{f}$ is the Fourier transform of f:

$$\widetilde{f}(\vec{p}) = \frac{1}{(2\pi)^2}\int_{\mathbb{R}^2} f(\vec{\eta})e^{-i\vec{p}\vec{\eta}}\mathrm{d}^2\eta.$$

Although $f = e^{i\vec{p}\vec{\eta}} \notin C_0(\mathbb{R}^2)$, one can formally verify taking $\widetilde{f}(\vec{p}\,') = \delta^{(2)}(\vec{p}-\vec{p}\,')$ that

$$\Omega(e^{i\vec{p}\vec{\eta}}) = \pi(\vec{p}),$$

and since

$$\eta_\mu = -i\ \frac{\partial}{\partial p_\mu}\bigg|_{\vec{p}=0} e^{i\vec{p}\vec{\eta}},$$

$$\Omega(\eta_\mu) = -i\frac{\partial}{\partial p_\mu}\big|_{\vec{p}=0}\pi(\vec{p}) \equiv \hat{x}_\mu.$$

The explicit expression of the quantization map is

$$\{\Omega(f)\psi\}(\vec{\eta}) = \int_{\mathbb{R}^2}\widetilde{f}(\vec{p})e^{i\vec{p}\vec{\eta}}\psi(\eta_0, \eta_1 e^{\lambda p_0})\mathrm{d}^2p, \quad f \in \mathrm{Fun}(\mathbb{R}^2), \quad \psi \in \mathcal{H}_\mu, \tag{15}$$

and we need to verify that it defines a bounded operator.

Proposition 5: *The quantization map* Ω, *defined by* (15), *sends* $\mathrm{Fun}(\mathbb{R}^2)$ *into bounded operators* $\mathcal{B}(\mathcal{H}_\mu)$. *For this class of functions*, *the operator norm is bounded by*

$$\|\Omega(f)\|^2 := \sup_{\psi\in\mathcal{H}_\mu,\psi\neq 0}\frac{\|\Omega(f)\psi\|^2_{\mathcal{H}_\mu}}{\|\psi\|^2_{\mathcal{H}_\mu}} \leq \frac{1}{2\pi}\|f\|^2_{\mathcal{H}_0}, \tag{16}$$

where $\|_{\mathcal{H}_\mu}$ *indicate the norm in the Hilbert space* $\mathcal{H}_\mu$.

Proof: Let $a = e^{\lambda p_0}$ and call:

$$F(\vec{\eta}, a) = \frac{1}{2\pi}\int_{\mathbb{R}}\mathrm{d}\eta_0' f(\eta_0', \eta_1)e^{ip_0(\eta_0-\eta_0')} = \int_{\mathbb{R}}\mathrm{d}\eta_1\widetilde{f}(\vec{p})e^{i\vec{p}\vec{\eta}}.$$

Then:

$$\{\Omega(f)\psi\}(\vec{\eta}) = \int_{\mathbb{R}}\mathrm{d}p_0 F(\vec{\eta}, a)\psi(\eta_0, a\eta_1) = \int_{\mathbb{R}^+}\frac{\mathrm{d}a}{\lambda a}F(\vec{\eta}, a)\psi(\eta_0, a\eta_1).$$

Since (partial) Fourier transform is an isometry of L^2, then $F \in L^2(\mathbb{R}, \mathrm{d}p_0) = L^2(\mathbb{R}^+, \mathrm{d}a/\lambda a)$ for each fixed $\vec{\eta}$. Using Schwartz inequality:

$$|\Omega(f)\psi(\vec{\eta})|^2 \leq \left(\int_{\mathbb{R}^+}\frac{\mathrm{d}a}{\lambda a}\left|F(\vec{\eta}, a)\psi(\eta_0, a\eta_1)\right|\right)^2 \leq \left(\int_{\mathbb{R}^+}\frac{\mathrm{d}a}{\lambda a}|F(\vec{\eta}, a)|^2\right)\left(\int_{\mathbb{R}^+}\frac{\mathrm{d}a}{a}|\psi(\eta_0, a\eta_1)|^2\right). \tag{17}$$

Now:

$$\begin{aligned}\int_{\mathbb{R}^+}\frac{\mathrm{d}a}{\lambda a}|F(\vec{\eta}, a)|^2 &= \frac{1}{(2\pi)^2}\int_{\mathbb{R}^+}\frac{\mathrm{d}a}{\lambda a}\left|\int_{\mathbb{R}}\mathrm{d}\eta_0' f(\eta_0', \eta_1)e^{ip_0(\eta_0-\eta_0')}\right|^2 \\ &= \frac{1}{(2\pi)^2}\int_{\mathbb{R}}\mathrm{d}p_0\int_{\mathbb{R}^2}\mathrm{d}\eta_0'\mathrm{d}\eta_0''\overline{f(\eta_0', \eta_1)}f(\eta_0'', \eta_1)e^{ip_0(\eta_0'-\eta_0'')} = \frac{1}{2\pi}\int_{\mathbb{R}}\mathrm{d}\eta_0'|f(\eta_0', \eta_1)|^2,\end{aligned} \tag{18a}$$

$$\int_{\mathbb{R}^+} \frac{\mathrm{d}a}{a} |\psi(\eta_0, a\eta_1)|^2 \leq \int_{\mathbb{R}^*} \frac{\mathrm{d}a}{|a|} |\psi(\eta_0, a\eta_1)|^2 = \int_{\mathbb{R}^*} \frac{\mathrm{d}\eta_1'}{|\eta_1'|} |\psi(\eta_0, \eta_1')|^2, \tag{18b}$$

where $\eta_1' = a\eta_1$ and in the last step we used dilatation invariance of the measure. Using the inequalities (17) and (18) we arrive at

$$\|\Omega(f)\psi\|_{\mathcal{H}_\mu}^2 = \int_{\mathbb{R}\times\mathbb{R}^*} \frac{\mathrm{d}\mu(\eta_0)\mathrm{d}\eta_1}{|\eta_1|} |\Omega(f)\psi(\vec{\eta})|^2 \leq \frac{1}{2\pi} \left(\int_{\mathbb{R}\times\mathbb{R}^*} \frac{\mathrm{d}\eta_0'\mathrm{d}\eta_1}{|\eta_1|} |f(\eta_0', \eta_1)|^2 \right)$$
$$\times \left(\int_{\mathbb{R}\times\mathbb{R}^*} \frac{\mathrm{d}\mu(\eta_0)\mathrm{d}\eta_1'}{|\eta_1'|} |\psi(\eta_0, \eta_1')|^2 \right) = \frac{1}{2\pi} \|f\|_{\mathcal{H}_0}^2 \cdot \|\psi\|_{\mathcal{H}_\mu}^2.$$

Using the last inequality, we find the upper bound (16) for the operator norm. □

We define the following $*$-product on $\mathrm{Fun}(\mathbb{R}^2)$:

$$f_1 * f_2 := \Omega(f_1) f_2, \quad \forall f_{1,2} \in \mathrm{Fun}(\mathbb{R}^2). \tag{19}$$

Let $\mathrm{Fun}^\infty(\mathbb{R}^2)$ be the subspace of smooth functions of $\mathrm{Fun}(\mathbb{R}^2)$.

Proposition 6: $\mathcal{A} := (\mathrm{Fun}(\mathbb{R}^2), *)$ *and* $\mathcal{A}^\infty := (\mathrm{Fun}^\infty(\mathbb{R}^2), *) \subset \mathcal{A}$ *are involutive algebras* (*associative without unit*). $\Omega : \mathcal{A} \to \mathcal{B}(\mathcal{H}_\mu)$ *is a unitary representation*.

Proof: Since $\Omega(f_1)$ is a bounded operator on $\mathcal{H}_\mu$, for all μ, and $f_2 \in \mathcal{H}_0$, the product $f_1 * f_2$ is in $\mathcal{H}_0$. Moreover, $f_1 * f_2 \in C_0(\mathbb{R}^2)$ and is smooth if f_1 and f_2 are.

By construction:

$$\Omega(f_1 * f_2) = \Omega(f_1)\Omega(f_2).$$

This guarantees associativity of the product, and proves that Ω is a representation.

Finally, $\Omega(\bar{f}_1) = \Omega(f_1)^+$ is the adjoint of $\Omega(f_1)$, since the representation π of the group $\mathrm{Aff}_0(\mathbb{R})$ is unitary. So we have a unitary representation of $\mathcal{A}$. □

We call $\mathcal{A}$ the algebra of continuous functions on κ-Minkowski space, and $\mathcal{A}^\infty$ the subalgebra of "smooth functions." Since $1 \notin \mathcal{A}$, the space is not compact.

From (15), using Leibniz rule and the property $ip_\mu \widetilde{f} = \widetilde{\partial_\mu f}$, we deduce the following "deformed" Leibniz rule:

$$\partial_0\{\Omega(f_1)f_2\} = \Omega(\partial_0 f_1) f_2 + \Omega(f_1)\partial_0 f_2, \tag{20a}$$

$$\partial_1\{\Omega(f_1)f_2\} = \Omega(\partial_1 f_1) f_2 + \Omega(e^{-i\lambda\partial_0} f_1)\partial_1 f_2, \tag{20b}$$

or equivalently:

$$\partial_0(f_1 * f_2) = (\partial_0 f_1) * f_2 + f_1 * (\partial_0 f_2),$$

$$\partial_1(f_1 * f_2) = (\partial_1 f_1) * f_2 + (e^{-i\lambda\partial_0} f_1) * (\partial_1 f_2),$$

for all $f_1, f_2 \in \mathrm{Fun}^\infty(\mathbb{R}^2)$.

C. A Dirac operator for κ-Minkowski space

The first attempt to define a Dirac operator would be to use the classical one $\not{D}$.

Properties (20) means that $\not{D}$ has not bounded commutator with the algebra. Indeed:

$$[\partial_0, \Omega(f)] = \Omega(\partial_0 f), \quad f \in \mathcal{A}^\infty$$

is bounded, but $[\partial_1, \Omega(f)]$ is not, due to the presence of the unbounded operator $e^{-i\lambda\partial_0}$.

$D := i\partial_0$ has nontrivial sign (it is not positive), has dense domain in $\mathcal{H}$ and bounded commutators with $\mathcal{A}$. Geometrically, the evaluation at $\eta_1 = 0$:

$$\Omega(f) \mapsto f(\eta_0, 0)$$

is an algebra morphism $\mathcal{A} \to C_0(\mathbb{R})$, and tells us that $\mathbb{R}$ is a commutative subspace. D is just the Dirac operator on this subspace.

Let $\Delta := -\partial_0^2 + 1$. Intuitively, one would expect that the axiom (S1) in the definition of spectral triple is not satisfied. For $\lambda = 0$, $f \cdot \Delta^{-1/2}$ is not a compact operator on $L^2(\mathbb{R}^2)$. Surprisingly if $\lambda \neq 0$, $\Omega(f)\Delta^{-1/2}$ is a compact operator on $\mathcal{H}_\mu$, if μ is a finite measure on $\mathbb{R}$ [i.e., $\int_{\mathbb{R}} \mathrm{d}\mu(\eta_0) < \infty$] and absolutely continuous with respect to the Lebesgue measure.

Proposition 7: *Let μ be a finite measure on $\mathbb{R}$, absolutely continuous with respect to the Lebesgue measure, and let $\lambda \neq 0$. Then, $(\mathcal{A}^\infty, \mathcal{H}_\mu, i\partial_0)$ is a 1^+-summable spectral triple. The associated Dixmier trace is just the cyclic integral of*[10]

$$\fint \Omega(f)\Delta^{-1/2} := \mathrm{Res}_{z=1}\mathrm{Trace}_{\mathcal{H}_\mu}\Omega(f)\Delta^{-z/2} \propto \int_{\mathbb{R}\times\mathbb{R}^*} f(\vec{x})\frac{\mathrm{d}x_0\mathrm{d}x_1}{|x_1|}, \tag{21}$$

where $\Delta := -\partial_0^2 + 1$.

Proof: We decompose $\mathcal{H}_\mu = \mathcal{V}_0 \otimes \mathcal{V}_1$, with $\mathcal{V}_0 := L^2(\mathbb{R}, \mathrm{d}\mu(\eta_0))$ and $\mathcal{V}_1 := L^2(\mathbb{R}^*, \mathrm{d}\eta_1/|\eta_1|)$.

Let us recall some facts from Ref. 21 (see also Ref. 22 for a pedagogical presentation and Ref. 9 for considerations on the noncompact case).

Let $\mu'(\eta_0) = \mathrm{d}\mu(\eta_0)/\mathrm{d}\eta_0$. By hypothesis $\mu' \in C_0(\mathbb{R}^2)$.

$i\partial_0$ being the Dirac operator on $\mathbb{R}$, $f\Delta^{-1/2}$ is compact on $L^2(\mathbb{R}, \mathrm{d}\eta_0)$ for all $f \in C_0(\mathbb{R}^2)$. In particular, taking $f = \mu'$, we prove that $\Delta^{-1/2}$ is compact on $\mathcal{V}_0$.

From the formula:

$$\mathrm{Res}_{z=1}\mathrm{Trace}_{L^2(\mathbb{R},\mathrm{d}\eta_0)} f\Delta^{-z/2} \propto \int_{\mathbb{R}} f(\eta_0)\mathrm{d}\eta_0$$

(we do not care about the proportionality constant, which is independent on f) we deduce

$$\mathrm{Res}_{z=1}\mathrm{Trace}_{\mathcal{V}_0}\Delta^{-z/2} = \mathrm{Res}_{z=1}\mathrm{Trace}_{L^2(\mathbb{R},\mathrm{d}\eta_0)}\mu'\Delta^{-z/2} \propto \int_{\mathbb{R}} \mathrm{d}\mu(\eta_0) < \infty .$$

The operator $\Delta^{-z/2}$ is traceclass on $\mathcal{V}_0$ if $z > 1$, and in the Dixmier class $\mathcal{L}^{1+}(\mathcal{V}_0)$ if $z = 1$.

On $\mathcal{H}_\mu$, if $f \in \mathcal{A}$, the kernel of the operator $\Omega(f)\Delta^{-z/2}$ is the distribution:

$$K_f(\vec{\eta}, \vec{\eta}') = \frac{1}{2\pi}\int_{\mathbb{R}^2} \mathrm{d}^2 p \tilde{f}(\vec{p}) e^{i\vec{p}\vec{\eta}} \delta(\eta_1' - \eta_1 e^{\lambda p_0}) \int_{\mathbb{R}} \mathrm{d}\xi (1+\xi^2)^{-z/2} e^{i\xi(\eta_0 - \eta_0')},$$

where the integral in $\mathrm{d}\xi$ is the resolvent of $\Delta^{z/2}$.

We consider first the case in which f is integrable ($f \in L^1(\mathbb{R}^*, \mathrm{d}\eta_0 \mathrm{d}\eta_1/|\eta_1|)$).

The partial trace of $\Omega(f)\Delta^{-z/2}$ on $\mathcal{V}_1$ is the operator with kernel:

$$\begin{aligned}\hat{K}_f(\vec{\eta}, \vec{\eta}') &= \int_{\mathbb{R}^*} \frac{\mathrm{d}\eta_1}{|\eta_1|} K_f(\eta_0, \eta_1; \eta_0', \eta_1) = \frac{\lambda^{-1}}{2\pi}\int_{\mathbb{R}^*}\frac{\mathrm{d}\eta_1}{|\eta_1|}\int_{\mathbb{R}} \mathrm{d}p_1 \tilde{f}(0, p_1) e^{ip_1\eta_1} \int_{\mathbb{R}} \mathrm{d}\xi (1+\xi^2)^{-z/2} e^{i\xi(\eta_0 - \eta_0')} \\ &= \frac{\lambda^{-1}}{2\pi}\left(\int_{\mathbb{R}\times\mathbb{R}^*} \frac{\mathrm{d}x_0\mathrm{d}x_1}{|x_1|} f(\vec{x})\right)\int_{\mathbb{R}} \mathrm{d}\xi (1+\xi^2)^{-z/2} e^{i\xi(\eta_0 - \eta_0')}.\end{aligned}$$

Then, as operators on $\mathcal{V}_0$:

$$\mathrm{Trace}_{\mathcal{V}_1}\{\Omega(f)\Delta^{-z/2}\} = \frac{\lambda^{-1}}{2\pi}\left(\int_{\mathbb{R}\times\mathbb{R}^*} f(\vec{x})\frac{\mathrm{d}x_0\mathrm{d}x_1}{|x_1|}\right)\Delta^{-z/2}. \tag{22}$$

From what was said above about $\Delta^{-z/2}$, we see that $\Omega(f)\Delta^{-z/2}$ is traceclass on $\mathcal{H}_\mu$ if $z > 1$, and in the Dixmier class $\mathcal{L}^{1+}(\mathcal{H}_\mu)$ if $z = 1$.

Taking the trace on $\mathcal{V}_0$ of (22) and then the residue in $z=1$ we prove (21).

Now, since $\mathrm{Fun}(\mathbb{R}^2)\subset L^2$, integrable functions are dense in the algebra $\mathcal{A}$. So, $\Omega(f)\Delta^{-1/2}$ is in the closure of $\mathcal{L}^{1+}(\mathcal{H}_\mu)$ for all $f\in\mathcal{A}$. The closure of the Dixmier class are the compact operators $\mathcal{K}$, and this concludes the proof. □

Remark: The spectral triple constructed in this section does not have a commutative analogue. Axiom (S1) is not satisfied for $\lambda=0$.

D. Equivariance properties of the representation

Let $\mathcal{A}$ be the involutive algebra defined in Proposition 6, $\mathcal{H}$ the Hilbert space:

$$\mathcal{H}:=\mathcal{H}_0\otimes\mathbb{C}^2=L^2(\mathbb{R}\times\mathbb{R}^*,|\eta_1|^{-1}\mathrm{d}\eta_0\mathrm{d}\eta_1)\otimes\mathbb{C}^2,$$

and γ the grading in (10). We lift trivially the representation (15) of $\mathcal{A}$ from $\mathcal{H}_0$ to $\mathcal{H}$.

We postpone the problem of constructing an equivariant Dirac operator and study the equivariance properties of the data $(\mathcal{A},\mathcal{H},\gamma)$. Clearly $\mathcal{A}$ commutes with γ, and so γ is a natural candidate for the grading.

The space $\mathcal{H}_0$ carries a representation of an Hopf-algebra, which we indicate with $U_\kappa(iso(2))$, that is the Euclidean analogue of κ-Poincaré. It is generated by three real operators, which we continue to denote with E,P,N, with commutation relations:

$$[E,P]=0,\quad [N,P]=\tfrac{i}{2\lambda}(1-e^{2\lambda E})+\tfrac{i\lambda}{2}P^2,\quad [N,E]=iP,$$

while coproduct, counit, and antipode are defined by (9), as for κ-Poincaré algebra.

Notice that in the basis

$$P_x=E,\quad P_y=Pe^{-\lambda E/2},\quad J=Ne^{-\lambda E/2},$$

the Hopf-algebra is just the *quantum Euclidean group* derived in Ref. 23 by contraction of $U_q(su(2))$.

There is a natural representation of the (E,P) sub-Hopf-algebra of $U_\kappa(iso(2))$ on a space dense in $\mathcal{H}_0$, defined by

$$\rho(E)=-i\partial_0,\quad \rho(P)=-i\partial_1.$$

This extends to a representation of the full Hopf-algebra if we define:

$$\rho(N)=\eta_0\rho(P)+\eta_1\rho\left(\frac{1-e^{2\lambda E}}{2\lambda}+\frac{\lambda}{2}P^2\right)=-i\eta_0\partial_1+\frac{1}{2\lambda}\eta_1(1-e^{-2i\lambda\partial_0})-\frac{\lambda}{2}\eta_1\partial_1^2. \tag{23}$$

On the space $\mathbb{C}^2$, we call σ the representation of the commutative $\mathbb{R}$ subalgebra, defined by

$$\sigma(N):=\frac{1}{2}\gamma=\frac{1}{2}\begin{pmatrix}1&0\\0&-1\end{pmatrix},\quad \sigma(E)=\sigma(P)=0.$$

On the space $\mathcal{H}=\mathcal{H}_0\otimes\mathbb{C}^2$ we consider the representation $\rho\otimes\sigma$ defined through the (opposite) coproduct:

$$(\rho\otimes\sigma)(h)=\rho(h_{(2)})\otimes\sigma(h_{(1)}),\quad \forall\, h\in U_\kappa(iso(2)).$$

This representation commutes with the grading γ, since the image through σ of the algebra is in the subspace of $\mathrm{Mat}_2(\mathbb{C})$ spanned by 1 and γ.

Before discussing the $U_\kappa(iso(2))$-equivariance of $(\mathcal{A},\mathcal{H},\gamma)$ we need to define a covariant action of the Hopf algebra on $\mathcal{A}$. If we define:

$$h\triangleright\Omega(f):=\Omega(\rho(h)f),\quad \forall\, h\in U_\kappa(iso(2)),\quad \Omega(f)\in\mathcal{A},$$

this is a representation of the Hopf-algebra. We want to prove that it is covariant, that is:

$$h \triangleright \Omega(f_1)\Omega(f_2) = \{h_{(1)} \triangleright \Omega(f_1)\}\{h_{(2)} \triangleright \Omega(f_2)\},$$

or equivalently using the $*$-product:

$$\rho(h)(f_1 * f_2) = \{\rho(h_{(1)})f_1\} * \{\rho(h_{(2)})f_2\}.$$

Proposition 8: *The action* $\triangleright$ *of* $U_\kappa(iso(2))$ *on* $\mathcal{A}$ *is covariant. Moreover*:

$$h \triangleright a = \rho(h_{(1)})a\rho(Sh_{(2)}),$$

for all $h \in U_\kappa(iso(2))$ *and* $a \in \mathcal{A}$ (*on a subspace dense in* $\mathcal{H}_0$).

Proof: Using (19), we deduce that the covariance condition is equivalent to

$$\rho(h)\Omega(f_1)f_2 = \Omega(\rho(h_{(1)})f_1) \cdot \{\rho(h_{(2)})f_2\}. \tag{24}$$

Since on both sides appear representations of $U_\kappa(iso(2))$, it is sufficient to do the check for the generators E, P, N.

We can rewrite (20a) as

$$\rho(E)\Omega(f_1)f_2 = \Omega(\rho(E)f_1)f_2 + \Omega(f_1)\{\rho(E)f_2\},$$

$$\rho(P)\Omega(f_1)f_2 = \Omega(\rho(P)f_1)f_2 + \Omega(\rho(e^{\lambda E})f_1)\{\rho(P)f_2\},$$

and then the action of E and P is covariant.

In the same way, using (20) and (23), it is a straightforward computation to prove the covariance of the action of N.

If in Eq. (24) we replace h with $h_{(1)}$, call $a=\Omega(f_1) \in \mathcal{A}$, $f_2=\rho(Sh_{(2)})\psi$, and recall that $\Omega(\rho(h_{(1)})f_1)=h_{(1)} \triangleright a$, we obtain

$$\rho(h_{(1)})a\rho(Sh_{(2)})\psi = (h_{(1)} \triangleright a)\rho(h_{(2)}S(h_{(3)}))\psi = \{\epsilon(h_{(2)})h_{(1)} \triangleright a\}\psi = (h \triangleright a)\psi.$$

This concludes the proof. □

Since the representation of $\mathcal{A}$ is lifted diagonally from $\mathcal{H}_0$ to $\mathcal{H}=\mathcal{H}_0 \otimes \mathbb{C}^2$, $\sigma(h)a=a\sigma(h)$ for all $h \in U_\kappa(iso(2))$ and $a \in \mathcal{A}$. Then, as a corollary:

$$h \triangleright a = (\rho \otimes \sigma)(h_{(1)})a(\rho \otimes \sigma)(Sh_{(2)}).$$

This means that:

Corollary 9: $(\mathcal{A}, \mathcal{H}, \gamma)$ *is* $U_\kappa(iso(2))$*-equivariant.*

E. An $U_\kappa(iso(2))$-equivariant Dirac operator

To have an equivariant spectral triple on κ-Minkowski space, it remains to find a Dirac operator D that is equivariant for the action of the quantum Euclidean group.

We write D as a formal pseudo-differential operator:

$$D\psi(\vec{\eta}) = \int_{\mathbb{R}^2} e^{i\vec{p}\vec{\eta}} \begin{pmatrix} 0 & T(\vec{\eta},\vec{p}) \\ T(\vec{\eta},\vec{p})^* & 0 \end{pmatrix} \tilde{\psi}(\vec{p}) \mathrm{d}^2p, \quad \psi \in \mathcal{H},$$

and determine the symbol T imposing equivariance. The matrix form of the symbol is a consequence of the grading and formal self-adjointness.

Since $(\rho\otimes\sigma)(E)=\rho(E)$, $(\rho\otimes\sigma)(P)=\rho(P)$ and $(\rho\otimes\sigma)(N)=\sigma(N)+\rho(N)\sigma(e^{\lambda E})=\rho(N)+\frac{1}{2}\gamma$, the equivariance conditions become

$$[\rho(E),D]=0, \quad [\rho(P),D]=0, \quad [\rho(N),D]=-\tfrac{1}{2}[\gamma,D] \equiv -\gamma D.$$

The first two conditions are equivalent to

$$\partial_0 T(\vec{\eta},\vec{p}) = \partial_1 T(\vec{\eta},\vec{p}) = 0.$$

Then, $T(\vec{\eta},\vec{p}) = T(\vec{p})$. The last condition can be written as

$$[\chi(N), T(\vec{p})] = -T(\vec{p}), \quad [\chi(N), T(\vec{p})^*] = T(\vec{p})^*, \tag{25}$$

where

$$\chi(N) := ip_1 \frac{\partial}{\partial p_0} + i\left(\frac{1-e^{2\lambda p_0}}{2\lambda} + \frac{\lambda}{2}p_1^2\right)\frac{\partial}{\partial p_1}.$$

If we define $\chi(E)=p_0$ and $\chi(P)=p_1$, then the map χ extends to a representation of the $U_\kappa(iso(2))$ Hopf algebra.

In Ref. 24 it was constructed for the first time a (formal) isomorphism between κ-Poincaré and the Poincaré algebra. The Euclidean counterpart is the change of coordinates:

$$e^{-\lambda p_0} p_1 =: r \sin\theta, \quad \frac{1}{\lambda}\sinh(\lambda p_0) + \frac{\lambda}{2}p_1^2 e^{-\lambda p_0} =: r\cos\theta,$$

with $r \in \mathbb{R}_0^+$ and $\theta \in S^1$. The Casimir of the quantum Euclidean group is:

$$m^2 := \left(\frac{2}{\lambda}\sinh\frac{\lambda E}{2}\right)^2 + e^{-\lambda E}P^2.$$

It is related to r^2 by

$$r^2 = \chi\left(m^2\left(1+\frac{\lambda^2 m^2}{4}\right)\right), \tag{26}$$

and then r^2 is central and $[\chi(N), r^2]=0$. So, $\chi(N)=\tilde{N}(r,\theta)\partial_\theta$ is a derivation in the θ direction, with $\tilde{N}$ defined by $\tilde{N}(r,\theta)re^{i\theta} = -i[\chi(N), re^{i\theta}]$.

With a straightforward computation we arrive at $[\chi(N), re^{i\theta}] = re^{i\theta}$, and prove that

$$\chi(N) = -i\frac{\partial}{\partial\theta}.$$

The general solution of (25) is $T(\vec{p}) = R(r)e^{-i\theta}$, with R an arbitrary function. If we want the classical Dirac operator as $\lambda=0$ limit, we are forced to choose $R(r)=-r$, and the final solution is

$$\begin{aligned} D &= -\rho\begin{pmatrix} 0 & \frac{1}{\lambda}\sinh(\lambda E) + e^{-\lambda E}P\left(\frac{\lambda}{2}P - i\right) \\ \frac{1}{\lambda}\sinh(\lambda E) + e^{-\lambda E}P\left(\frac{\lambda}{2}P + i\right) & 0 \end{pmatrix} \\ &= \begin{pmatrix} 0 & \frac{1}{\lambda}\sinh(i\lambda\partial_0) + e^{i\lambda\partial_0}\left(1+\frac{\lambda}{2}\partial_1\right)\partial_1 \\ \frac{1}{\lambda}\sinh(i\lambda\partial_0) - e^{i\lambda\partial_0}\left(1-\frac{\lambda}{2}\partial_1\right)\partial_1 & 0 \end{pmatrix}. \end{aligned} \tag{27}$$

This Dirac operator is very similar to the one constructed in Refs. 5–7, but for Euclidean signature instead of Lorentzian one, and $1+1$ dimension instead of $3+1$.

A deformed Leibniz rule for D comes from the coproduct of E, P, and tells us that commutators with the algebra are not bounded, due to the presence of the $e^{\lambda E}$ factor.

Using Eq. (2.5) of Ref. 7 one can reach the same conclusion for the Dirac operators in Refs. 5–7.

From (26) we derive the following relation:

$$D^2 = \rho\left(m^2\left(1 + \frac{\lambda^2 m^2}{4} \right) \right),$$

that is the same as Eq. (12) in Ref. 5.

VI. CONCLUSION

In quantum mechanics over $\mathbb{R}^n$, it is usual to work in momentum space by means of Fourier transform. If the physical system under consideration lives in a curved manifold, with trivial tangent bundle, momenta are globally defined as vector fields on the manifold, and in general do not commute. We have illustrated this situation with an example that is recurrent in physics, the deSitter space in three dimensions. In such a situation, if we want to work in "momentum space," we need the tools of noncommutative geometry.

In these notes, we have studied the lowest dimensional nontrivial (i.e., noncommutative) example, when the manifold M is the connected component of the group of affine transformations of the real line, and found that the "dual" space is κ-Minkowski. This is the unique two-dimensional noncommutative example coming from a Lie group.

We have found a natural representation of κ-Minkowski on $L^2(M,\mu)$, with μ the (left) Haar measure on the group M.

Usually this spacetime is studied from an Hopf-algebra point of view, considering $U(\mathrm{Lie}\, M)$ as the polynomial algebra of coordinates on some virtual space.[4] We have argued how, using Weyl quantization, it is possible to define the associated C^*-algebra. The definition of the C^*-algebra allows one to study the topology of the space, following the general philosophical viewpoint that C^*-algebra theory may be regarded as a kind of noncommutative topology.

In the last section, we have constructed a spectral triple associated with the cyclic integral of Ref. 10, and an $U_\kappa(iso(2))$-equivariant Dirac operator which does not satisfy the axioms for a spectral triple.

About the Dirac operator $i\partial_0$, it could be interesting to construct pure states of the algebra and investigate the properties of the distance defined by the celebrated Connes formula (see, e.g., Refs. 2 and 3). Since it only involves time derivatives, it is natural to expect that, in some way, it provides information only about the time distance between two events.

Apart from its intrinsic interest, κ-Minkowski is a simple nontrivial example in which to compare Connes' approach to noncommutative geometry with the Hopf-algebraic one.

Let $|\Psi\rangle$ be an arbitrary stabilizer state distributed between three remote parties, such that each party holds several qubits. Let S be a stabilizer group of $|\Psi\rangle$. We show that $|\Psi\rangle$ can be converted by local unitaries into a collection of singlets, GHZ states, and local one-qubit states. The numbers of singlets and GHZs are determined by dimensions of certain subgroups of S. For an arbitrary number of parties m we find a formula for the maximal number of m-partite GHZ states that can be extracted from $|\Psi\rangle$ by local unitaries. A connection with earlier introduced measures of multipartite correlations is made. An example of an undecomposable four-party stabilizer state with more than one qubit per party is given. These results are derived from a general theoretical framework that allows one to study interconversion of multipartite stabilizer states by local Clifford group operators. As a simple application, we study three-party entanglement in two-dimensional lattice models that can be exactly solved by the stabilizer formalism. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2203431]

I. INTRODUCTION

Many quantum cryptographic protocols such as quantum key distribution,[1] coin flipping,[2] or other quantum games[3] operate with a single copy of a pure quantum state shared by three or more parties. Each party has complete control of its subsystem, so the states which can be converted to each other by local unitary (LU) operators may be regarded as equivalent. Unfortunately, in general, LU-equivalence classes lack any known concise analytical description. For tripartite pure states (or, equivalently, bipartite mixed states), substantial progress has been achieved only for Gaussian states of fermions[4] and bosons[5] with some additional symmetry properties.

In the present paper we study LU-equivalence classes of *stabilizer states*. A stabilizer state of n qubits can be thought of as an irreducible representation of an Abelian *stabilizer group* generated by n pairwise commuting operators in the Pauli group (i.e., tensor products of the identity I and the Pauli matrices σ^x, σ^y, σ^z). Important applications of stabilizer states include measurement-based schemes of quantum computation[6] and quantum error correction using ancillas.[7] They also provide exactly solvable models of condensed-matter systems.[8]

In the special case when each party holds exactly one qubit (so that a local operator means a one-qubit operator), LU-equivalence classes of stabilizer states have been already studied by Van den Nest, Dehaene, and De Moor in Refs. 9–11.

We assume that n qubits are distributed between a finite set of parties M. Each party may hold an arbitrary number of qubits. Our main results are summarized below.

Result 1: Three-party entanglement.

We prove that an arbitrary stabilizer state shared by three parties A,B,C is LU equivalent to a collection (tensor product) of states from a set $E_3=\{|0\rangle,|\Psi^+\rangle,|\Psi_3^+\rangle\}$, where

$$|\Psi^+\rangle = \frac{1}{\sqrt{2}}(|0,0\rangle + |1,1\rangle),$$
$$|\Psi_3^+\rangle = \frac{1}{\sqrt{2}}(|0,0,0\rangle + |1,1,1\rangle) \tag{1}$$

are the EPR state and the GHZ state. The set E_3 thus can be called an entanglement generating set (EGS) for three-party systems, as far as stabilizer states are concerned. LU-equivalence classes are completely specified by four integers (a,b,c,p), where a,b,c are the numbers of EPR states $|\Psi^+\rangle$ shared by BC, AC, and AB, respectively, while p is the number of GHZ states $|\Psi_3^+\rangle$ shared by all three parties. A prerequisite to this result is the work in Ref. 12, where a set $E_2=\{|0\rangle,|\Psi^+\rangle\}$ was shown to be an EGS for bipartite systems. It should be emphasized that the set E_3 is not an EGS for arbitrary tripartite states, even if one allows arbitrary local manipulation and classical communication (see Ref. 13).

Result 2: Multipartite entanglement.

Let $|\Psi\rangle$ be an n-qubit stabilizer state shared by a set of parties M, $|M|=m\geq 3$, and let S be its stabilizer group. We are interested in the maximal number of m-party GHZ states

$$|\Psi_m^+\rangle = \frac{1}{\sqrt{2}}(|0^{\otimes m}\rangle + |1^{\otimes m}\rangle)$$

that can be extracted from $|\Psi\rangle$ by local unitaries. Denote this number by p. We prove that

$$p = \dim(S) - \dim(S_{\mathrm{loc}}), \tag{2}$$

where S_{loc} is a subgroup of S generated by all stabilizer operators that act trivially on at least one party. [For bipartite systems the answer is slightly different, $p=(1/2)(\dim(S)-\dim(S_{loc}))$, see Ref. 12.]

In particular, p can be computed in polynomial time in the number of qubits. Interestingly, we will give below a constructive proof of Eq. (2), which translates naturally into an efficient algorithm to perform the GHZ extraction. An implementation of this algorithm will be available online soon.

It should be mentioned that Eq. (2) provides a simple upper bound on p. Indeed, if one can find l independent generators of S, such that each of them acts trivially on at least one party, then $\dim(S_{\mathrm{loc}})\geq l$ and thus $p\leq \dim(S)-l$.

Also, we show that the GHZ extraction yield p, considered as a functional of $|\Psi\rangle$, coincides with an entanglement measure introduced by Linden, Popescu, and Wootters in Ref. 14 to quantify irreducible multipartite correlations.

To illustrate the usefulness of Results 1 and 2, we consider two-dimensional lattice models that can be exactly solved by the stabilizer formalism. Well-known examples of such models include the cluster state used in one-way quantum computation[6] and Kitaev's toric code state.[8,15] In general, the ground state of such models can be specified as an eigenvector of local stabilizer operators. We study tripartite entanglement of the ground state with respect to a partition of the lattice into three angular segments with a common junction point (see Fig. 1 in Sec. VII). We show that the number of GHZ states extractable from the ground state is bounded from above by a constant that depends only upon the structure of stabilizers near the junction point (and does not depend upon the size of the lattice). This is a natural generalization of the entanglement saturation phenomenon found for 1D spin chains (see Ref. 16 and references therein).

The rest of the paper is organized as follows. Section II introduces notation and terminology. Our main technical theorems are proved in Sec. III. In Sec. IV we consider multipartite stabilizer states and prove Eq. (2). Section V establishes a connection between GHZ extraction yield and measures of multipartite correlations. LU-equivalence classes of tripartite states are discussed in

Sec. VI. We apply the developed technique to spin lattices in Sec. VII. The goal of Sec. VIII is to convince the reader that four-party stabilizer states are likely to lack a simple entanglement generating set.

II. PRELIMINARIES AND NOTATION

A. Stabilizer states

The goal of this section is to introduce convenient terminology. Whenever it is possible, we use the notation of Ref. 17, Chap. 15.

The Pauli operators σ^x, σ^y, σ^z, and the identity operator I will be labeled by elements of two-dimensional binary linear space $G=\{00,01,10,11\}$, such that

$$\sigma_{00}=I, \quad \sigma_{10}=\sigma^x, \quad \sigma_{01}=\sigma^z, \quad \sigma_{11}=\sigma^y.$$

For any integer n and $f=(\alpha_1,\beta_1,\ldots,\alpha_n,\beta_n)\in G^n$, define a *σ-operator*

$$\sigma(f)=\sigma_{\alpha_1\beta_1}\otimes\cdots\otimes\sigma_{\alpha_n\beta_n}.$$

For all $f,g\in G^n$, one has $\sigma(f)\sigma(g)=e^{i\theta}\sigma(f+g)$ for some phase factor $e^{i\theta}$. The commutation rules for σ-operators can be written as

$$\sigma(f)\sigma(g)=(-1)^{\omega(f,g)}\sigma(g)\sigma(f).$$

Here $\omega: G^n\otimes G^n\to\{0,1\}$ is a symplectic form,

$$\omega(f,f')=\sum_{j=1}^{n}\alpha_j\beta_j'+\beta_j\alpha_j' \bmod 2.$$

For any subspace $S\subseteq G^n$ define a dual subspace $S^\perp$ as

$$S^\perp=\{f\in G^n:\omega(f,g)=0 \text{ for all } g\in S\}.$$

A subspace S is called *isotropic* iff $S\subseteq S^\perp$, i.e., $\omega(f,g)=0$ for any $f,g\in S$. A subspace S is called self-dual iff $S^\perp=S$. For any isotropic (self-dual) subspace $S\subset G^n$ one has $\dim(S)\leq n$ ($\dim(S)=n$).

The Hilbert space of n qubits will be denoted $\mathcal{B}^n$. A unitary operator $U:\mathcal{B}^n\to\mathcal{B}^n$ belongs to the *Clifford group*, $U\in\mathrm{Cl}(n)$, iff it maps σ-operators to σ-operators (up to a sign) under the conjugation. In other words, $U\in\mathrm{Cl}(n)$ iff there exists a map $u:G^n\to G^n$ and a function $\epsilon:G^n\to\{+1,-1\}$, such that

$$U\sigma(f)U^\dagger=\epsilon(f)\sigma(u(f)) \tag{3}$$

for any $f\in G^n$. Unitarity of U implies that u is a linear invertible map preserving the inner product ω, i.e.,

$$\omega(f,g)=\omega(u(f),u(g))$$

for all $f,g\in G^n$. Such linear maps constitute a binary symplectic group $\mathrm{Sp}_2(n)$. In fact, all $u\in\mathrm{Sp}_2(n)$ can be realized through an appropriate choice of $U\in\mathrm{Cl}(n)$.

A *stabilizer state* $|\Psi\rangle\in\mathcal{B}^n$ is an irreducible representation of a group $\{\epsilon(f)\sigma(f):f\in S\}$, where $S\subset G^n$ is a self-dual subspace and $\epsilon:S\to\{+1,-1\}$ is a function that accounts for a phase in a product of σ operators. In other words,

$$\sigma(f)|\Psi\rangle=\epsilon(f)|\Psi\rangle, \quad f\in S. \tag{4}$$

The state $|\Psi\rangle$ is uniquely specified by Eq. (4). The subspace S is referred to as a *stabilizer group* of $|\Psi\rangle$. Two stabilizer states have the same stabilizer group iff they can be mapped to each other

by a σ operator, see Ref. 17. Any stabilizer state can be represented as $|\Psi\rangle = U|0^{\otimes n}\rangle$ for some operator $U \in \mathrm{Cl}(n)$.

B. Local Clifford equivalence

A state $|\Psi\rangle \in \mathcal{B}^n$ is called *M-partite* iff the n qubits are distributed between a finite set of parties M, i.e.,

$$n = \sum_{\alpha \in M} n_\alpha, \quad n_\alpha \geq 0. \tag{5}$$

We shall be interested in equivalence classes (orbits) of stabilizer states under local Clifford unitary (LCU) operators.

Definition 1: M-partite stabilizer states $|\Psi\rangle, |\Psi'\rangle \in \mathcal{B}^n$ *are called LCU-equivalent iff there exist Clifford unitaries* $\{U_\alpha \in \mathrm{Cl}(n_\alpha)\}_{\alpha \in M}$ *such that*

$$|\Psi'\rangle = \bigotimes_{\alpha \in M} U_\alpha |\Psi\rangle .$$

For any vector $f \in G^n$ and party α denote by $f_\alpha \in G^{n_\alpha}$ a projection of f onto the party α (if one regards f as a binary string, f_α is a substring that includes all qubits owned by a party α). In particular, $f_\alpha = 0$ iff $\sigma(f)$ acts trivially on the party α.

Definition 2: Suppose n qubits are distributed among a set of parties M. Let $S \subseteq G^n$ *be a linear subspace. For each* $\alpha \in M$ *define a local subspace* $S_\alpha \subseteq S$ *and a colocal subspace* $S_{\hat{\alpha}} \subseteq S$ *as*

$$S_\alpha = \{g \in S : g_\beta = 0 \text{ for all } \beta \in M \setminus \alpha\},$$

and

$$S_{\hat{\alpha}} = \{g \in S : g_\alpha = 0\}.$$

In other words, $f \in S_{\hat{\alpha}}$ iff $\sigma(f)$ acts as the identity on the party α; $f \in S_\alpha$ iff $\sigma(f)$ acts as the identity on all parties $\beta \neq \alpha$. In the case $n_\alpha = 0$ we shall use a convention $S_\alpha = 0$ and $S_{\hat{\alpha}} = S$. If S is a stabilizer group of some state, we shall use the terms local (colocal) subspace and local (colocal) subgroup interchangeably.

Consider an M-party stabilizer state $|\Psi\rangle$. Let ρ_α be the reduced state of the party α. To simplify the discussion we shall assume that $\mathrm{Rk}(\rho_\alpha) = 2^{n_\alpha}$ for all $\alpha \in M$, that is, that all states under consideration have the maximal possible local ranks. Let S be a stabilizer group of $|\Psi\rangle$. One can easily check that the requirement $\mathrm{Rk}(\rho_\alpha) = 2^{n_\alpha}$ is equivalent to the local subgroup S_α being trivial.

Definition 3: An M-party stabilizer state $|\Psi\rangle$ *with a stabilizer group S has full local ranks iff all local subgroups of S are trivial*:

$$S_\alpha = 0 \quad \text{for all } \alpha \in M.$$

In general case, if $\mathrm{Rk}(\rho_\alpha) = 2^k$, one has $\dim(S_\alpha) = n_\alpha - k$. Equivalently, $n_\alpha - k$ copies of the one-qubit state $|0\rangle$ can be extracted from $|\Psi\rangle$ for each $\alpha \in M$ by local Clifford unitaries (this will follow from Theorem 2 with $S' = S_\alpha$). After such local extractions we arrive at a state with full local ranks. A necessary and sufficient criterion for LCU equivalence is given below.

Theorem 1: *Let* $|\Psi\rangle, |\Psi'\rangle \in \mathcal{B}^n$ *be M-party stabilizer states with full local ranks. Let* $S, S' \subset G^n$ *be their stabilizer groups. The state* $|\Psi\rangle$ *is LCU equivalent to* $|\Psi'\rangle$ *iff there exists a linear invertible map* $T : S \to S'$ *such that*

$$\omega(T(f)_\alpha, T(g)_\alpha) = \omega(f_\alpha, g_\alpha) \quad \text{for all } f, g \in S, \alpha \in M.$$

We shall prove Theorem 1 in the next section.

III. LOCAL EXTRACTION

Let $|\Psi\rangle \in \mathcal{B}^n$ be an M-party stabilizer state. The most interesting stabilizer states are *LCU-irreducible* ones (which in this paper we simply refer to as *irreducible*), which are not LCU equivalent to a collection of stabilizer states of smaller dimension. For example, if one considers the finest partition, $M=\{1,2,\ldots,n\}$, a state $|\Psi\rangle$ is irreducible iff it is entangled with respect to any bipartition. On the other hand, we shall see that for bipartite and tripartite systems ($|M|=2$ or $|M|=3$), the only irreducible states are the EPR and GHZ states. If $|\Psi\rangle$ is not irreducible, one can *extract* some simpler stabilizer state from it by LCU operators. Given two M-party states $|\Psi\rangle$ and $|\Psi'\rangle$, one can ask under what circumstances $|\Psi'\rangle$ is extractable from $|\Psi\rangle$. The goal of this section is to answer this question. Note that LCU-equivalence of states is just a special case of extraction, when $|\Psi'\rangle$ and $|\Psi\rangle$ are composed from the same number of qubits.

Definition 4: Let $|\Psi\rangle \in \mathcal{B}^n$ and $|\Psi'\rangle \in \mathcal{B}^k$ be M-party stabilizer states, such that

$$n=\sum_{\alpha\in M} n_\alpha, \quad k=\sum_{\alpha\in M} k_\alpha, \quad 0\le k_\alpha \le n_\alpha.$$

The state $|\Psi'\rangle$ is extractable from $|\Psi\rangle$ iff $|\Psi\rangle$ is LCU-equivalent to $|\Psi'\otimes\Psi''\rangle$ for some M-party stabilizer state $|\Psi''\rangle$.

Remark: An equality $k_\alpha=0$ means that the party α owns no qubits of the state $|\Psi'\rangle$. Analogously, $k_\alpha=n_\alpha$ implies that the party α owns no qubits of the state $|\Psi''\rangle$.

A necessary and sufficient criterion for a state $|\Psi'\rangle$ to be extractable from $|\Psi\rangle$ is given below.

Theorem 2: *Let $|\Psi\rangle \in \mathcal{B}^n$ and $|\Psi'\rangle \in \mathcal{B}^k$ be M-party stabilizer states with stabilizer groups $S\subset G^n$ and $S'\subset G^k$. The state $|\Psi'\rangle$ is extractable from $|\Psi\rangle$ iff there exists a linear injective map $T:S'\to S$ such that*

(i) $\omega(T(f)_\alpha, T(g)_\alpha)=\omega(f_\alpha,g_\alpha)$ *for all* $f,g\in S'$ *and* $\alpha\in M$;
(ii) $(T\cdot S')_{\hat{\alpha}}=T\cdot(S'_{\hat{\alpha}})$ *for all* $\alpha\in M$.

This theorem is a simple consequence of the following lemma.

Lemma 1: Suppose n qubits are distributed among a set of parties M. Let $S,S'\subset G^n$ be linear subspaces. The following statements are equivalent:

(1) *There exist local operators $\{u_\alpha\in \mathrm{Sp}_2(n_\alpha)\}_{\alpha\in M}$ such that*

$$S'=\left(\bigoplus_{\alpha\in M} u_\alpha\right)\cdot S,$$

(2) *There exists a linear invertible map $T:S\to S'$ such that*

(i) $\omega(T(f)_\alpha, T(g)_\alpha)=\omega(f_\alpha,g_\alpha)$ *for all* $f,g\in S$ *and* $\alpha\in M$;
(ii) $T\cdot S_{\hat{\alpha}}=S'_{\hat{\alpha}}$ *for all* $\alpha\in M$.

Here the direct sum $\oplus_{\alpha\in M}u_\alpha$ corresponds to a decomposition of G^n into its local subspaces, i.e., $G^n=\oplus_{\alpha\in M}G^n_\alpha$. A proof of the lemma is presented in Appendix B.

Proof of Theorem 2: The nontrivial part is to prove that existence of T with the properties (i), (ii) implies that $|\Psi'\rangle$ is extractable from $|\Psi\rangle$. Let us split the n_α qubits owned by the party $\alpha\in M$ into two subsets

$$\{1,2,\ldots,n_\alpha\}=A_\alpha\cup B_\alpha,$$

such that $|A_\alpha|=k_\alpha$. We shall refer to a qubit as an A-qubit (B-qubit) if it belongs to one of the subsets A_α (B_α). Any vector $f\in G^n$ can be represented as a direct sum $f=f_A\oplus f_B$, where f_A and f_B are projections of f onto A-qubits and B-qubits, respectively.

Let us define a linear subspace $R'\subset G^n$ that is equal to a direct sum of S' on A-qubits and the zero space on B-qubits, i.e.,

$$R' = \{f \in G^n : f_B = 0 \text{ and } f_A \in S'\}.$$

Define also a subspace $R = T \cdot S' \subseteq S$, i.e.,

$$R = \{f \in G^n : f = T(g) \text{ for some } g \in S'\}. \tag{6}$$

The map T regarded as a map from R' to R obviously satisfies condition (2) of Lemma 1. We conclude that there exists a linear symplectic operator $u : G^n \to G^n$ such that

$$R' = u \cdot R, \quad u = \bigoplus_{\alpha \in M} u_\alpha, \tag{7}$$

where $u_\alpha \in \mathrm{Sp}_2(n_\alpha)$.

Consider a linear subspace

$$Q = u \cdot S \subset G^n. \tag{8}$$

The fact that $u \in \mathrm{Sp}_2(n)$ implies that Q is self-dual. Let $|\Phi\rangle \in \mathcal{B}^n$ be a stabilizer state with the stabilizer group Q. ($|\Phi\rangle$ is unique up to multiplication by a σ operator.) Since u is a direct sum of local symplectic operators, $|\Phi\rangle$ is LCU equivalent to $|\Psi\rangle$.

We still must show that $|\Phi\rangle$ is a tensor product of two stabilizer states, $|\Phi\rangle = |\Phi_A \otimes \Phi_B\rangle$, that live on the A-qubits and B-qubits, respectively. Indeed, since R is a subgroup of S, it follows from Eqs. (7) and (8) that

$$R' \subseteq Q.$$

Thus the state $|\Phi\rangle$ satisfies stabilizer equations

$$\sigma(f)|\Phi\rangle = \epsilon(f)|\Phi\rangle, \quad f \in R', \tag{9}$$

for some function $\epsilon : R' \to \{+1, -1\}$. By the definition of R', any operator $\sigma(f)$, $f \in R'$ acts trivially on B-qubits. If we restrict our attention to A-qubits only, R' is a self-dual subspace (since $R \cong S'$). Thus the stabilizer equations (9) completely specify the state of the A-qubits [see the remarks following Eq. (4)]. Denote this state $|\Phi_A\rangle$. Since the states $|\Phi_A\rangle$ and $|\Psi'\rangle$ have the same stabilizer group, they coincide up to a σ operator. Thus $|\Phi\rangle$ is LCU equivalent to $|\Psi' \otimes \Phi_B\rangle$ for some stabilizer state $|\Phi_B\rangle$. On the other hand, $|\Phi\rangle$ is LCU equivalent to $|\Psi\rangle$. We have proved that $|\Psi'\rangle$ is extractable from $|\Psi\rangle$.

Conversely, suppose $|\Psi\rangle$ is LCU equivalent to $|\Psi' \otimes \Psi''\rangle$. This means that $S = u \cdot (S' \oplus S'')$, where S'' is a self-dual subspace, $u = \oplus_{\alpha \in M} u_\alpha$ is a local symplectic operator, and the direct sum corresponds to the bipartition of all qubits in the state $|\Psi' \otimes \Psi''\rangle$. One can easily check that a map

$$T(f) = u \cdot (f \oplus 0)$$

from S' to S satisfies conditions (i) and (ii). The theorem is proved. □

Remark: Condition (ii) in Theorem 2 cannot be dropped. Indeed, consider as an example three-party states, $M = \{A, B, C\}$. Let $|\Psi\rangle = |\Psi_3^+\rangle$ be the GHZ state and $|\Psi'\rangle = |\Psi^+\rangle$ be the EPR state shared by A and B. Obviously, $|\Psi'\rangle$ cannot be extracted from $|\Psi\rangle$ without classical communication. However, the linear injective map T satisfying condition (i) exists. Indeed, consider a mapping

$$\sigma^x \otimes \sigma^x \to \sigma^x \otimes \sigma^x \otimes \sigma^x,$$

$$\sigma^z \otimes \sigma^z \to \sigma^z \otimes \sigma^z \otimes I$$

between stabilizer generators of $|\Psi'\rangle$ and $|\Psi\rangle$. It can be easily converted to a map $T : S' \to S$ between the stabilizer groups. This map preserves local commutation rules, so condition (i) is satisfied.

Proof of Theorem 1: Consider a special case of Theorem 2 with $k_\alpha = n_\alpha$ for all $\alpha \in M$, i.e., with

the state $|\Psi''\rangle$ being a complex number. In this case $S,S' \subset G^n$ are self-dual subspaces, so that $\dim(S)=\dim(S')=n$. Thus T is a linear invertible map and $T\cdot S'=S$. On the other hand, the statement "$|\Psi'\rangle$ is extractable from $|\Psi\rangle$" translates into "$|\Psi'\rangle$ is LCU equivalent to $|\Psi\rangle$." What we obtain is exactly Theorem 1 with T replaced by T^{-1} and with the extra condition (ii). We will show now that (ii) can be derived from (i), the equality $T\cdot S'=S$, and the maximal local rank assumption.

Indeed, consider some particular α and take any vector $f \in S'_{\hat{\alpha}}$, so $f_\alpha=0$. Denote $h=T(f) \in S$. Condition (i) tells us that

$$\omega(h_\alpha, g_\alpha) = \omega(f_\alpha, (T^{-1}(g))_\alpha) = 0 \quad \text{for any } g \in S.$$

Consider a vector $\tilde{h} \in G^n_\alpha$ such that $\tilde{h}_\alpha=h_\alpha$. Then $\omega(\tilde{h},g)=0$ for any $g \in S$, that is $\tilde{h} \in S^\perp$. Since $S^\perp=S$ we have $\tilde{h} \in S \cap G^n_\alpha=S_\alpha=0$. We conclude that $h_\alpha=0$, that is $h \in S_{\hat{\alpha}}$. This proves that

$$T \cdot S'_{\hat{\alpha}} \subseteq S_{\hat{\alpha}}.$$

Applying the same arguments to the map $T^{-1}: S \to S'$ [which, of course, also satisfies condition (i)] one gets

$$T^{-1} \cdot S_{\hat{\alpha}} \subseteq S'_{\hat{\alpha}}.$$

Therefore $S'_{\hat{\alpha}}$ and $S_{\hat{\alpha}}$ have the same dimension, and thus $T\cdot S'_{\hat{\alpha}}=S_{\hat{\alpha}}$. □

Remark: In fact, a little bit more work shows that the full local ranks assumption in Theorem 1 can be dropped. We sacrifice some generality for the sake of readability.

IV. GHZ-EXTRACTION FORMULA

Given a set of parties M, $|M|=m$, consider an M-party analogue of the GHZ state

$$|\Psi^+_m\rangle = \frac{1}{\sqrt{2}}(|0^{\otimes m}\rangle + |1^{\otimes m}\rangle) \in \mathcal{B}^m.$$

It is a stabilizer state with a stabilizer group generated by a vector $\bar{f} \in G^m$ such that

$$\sigma(\bar{f}) = \sigma^x_1 \otimes \sigma^x_2 \otimes \cdots \otimes \sigma^x_m, \tag{10}$$

and vectors $\{f_{\alpha\beta} \in G^m\}_{\alpha,\beta \in M}$ such that

$$\sigma(f_{\alpha\beta}) = \sigma^z_\alpha \otimes \sigma^z_\beta \tag{11}$$

(the identity factors are suppressed). The vectors $\bar{f}$, $f_{\alpha\beta}$ constitute an overcomplete basis of the stabilizer group.

Given an M-party stabilizer state $|\Psi\rangle \in \mathcal{B}^n$, one can ask how many copies of $|\Psi^+_m\rangle$ can be extracted from $|\Psi\rangle$ by local Clifford unitaries. The goal of this section is to answer this question. Let S be a stabilizer group of $|\Psi\rangle$, and $S_{\hat{\alpha}} \subseteq S$, $\alpha \in M$, be its colocal subgroups (see Definition 2). Define a subgroup

$$S_{\text{loc}} = \sum_{\alpha \in M} S_{\hat{\alpha}} \tag{12}$$

generated by all colocal subgroups. The sum above is generally not a direct one, since the colocal subgroups may overlap. By definition, $S_{\text{loc}} \subseteq S$, and, in general, $S_{\text{loc}} \subset S$. In the latter case one has a deficit of local stabilizer elements, meaning that for any choice of a basis in S there will be at least $n-\dim(S_{\text{loc}})$ basis vectors having support on all m parties $\alpha \in M$. We will see that each of these nonlocal basis vectors can be identified with the $\bar{f}$ element of the stabilizer of a state $|\Psi^+_m\rangle$ [see Eq. (10)].

It was pointed out in Ref. 12 that a functional

$$\Delta(\Psi) = n - \dim(S_{\mathrm{loc}}) = \dim(S) - \dim(S_{\mathrm{loc}}) \tag{13}$$

can be used as an entanglement measure that quantifies truly multipartite correlations in $|\Psi\rangle$. In the present paper we go further and prove the following theorem.

Theorem 3: *Let $|\Psi\rangle \in \mathcal{B}^n$ be an M-party stabilizer state with a stabilizer group S. Suppose that $m=|M| \geq 3$. The maximal number of states $|\Psi_m^+\rangle$ extractable from $|\Psi\rangle$ by local Clifford unitaries is equal to $\Delta(\Psi)$.*

Remarks: (1) Note that the functional $\Delta(\Psi)$ is invariant under extraction of local $|0\rangle$ states. Thus we can safely assume that $|\Psi\rangle$ has full local ranks. (2) The generalization of the theorem to arbitrary LU operators is discussed in Sec. V. (3) A shorter but less constructive proof of the theorem is given in Appendix A.

Proof: For each $\alpha \in M$ define a subspace $\mathcal{L}_\alpha \in G^n$ as

$$\mathcal{L}_\alpha = \{f \in G_\alpha^n : \omega(f,g) = 0 \text{ for all } g \in S_{\mathrm{loc}}\}.$$

Here G_α^n is the local subspace of G^n corresponding to the party α (see Definition 2). To illustrate the usefulness of this definition, consider as an example $|\Psi\rangle = |\Psi_m^+\rangle$. Then the subgroup S_{loc} is generated by vectors $\{f_{\alpha\beta}\}$ [see Eq. (11)], while $\mathcal{L}_\alpha$ is a one-dimensional subspace generated by σ_α^z. The remaining stabilizer generator of the GHZ state $\bar{f}$ anticommutes with σ_α^z for any $\alpha \in M$. Thus any product $\sigma_\alpha^z \otimes \sigma_\beta^z$ commutes with both $\bar{f}$ and stabilizer elements from S_{loc}. Therefore, $\sigma_\alpha^z \otimes \sigma_\beta^z$ is in the stabilizer of $|\Psi\rangle$. Similarly, in the general case, we shall use the subspaces $\mathcal{L}_\alpha$ to construct 2-local stabilizer elements of $|\Psi\rangle$ that are analogous to $\sigma_\alpha^z \otimes \sigma_\beta^z$ stabilizer elements of the GHZ state.

Our first goal is to prove that

$$\dim(\mathcal{L}_\alpha) = \Delta(\Psi) \quad \text{for any } \alpha \in M. \tag{14}$$

Choose an arbitrary subgroup $S_{\mathrm{ent}} \subseteq S$ such that

$$S = S_{\mathrm{loc}} \oplus S_{\mathrm{ent}}. \tag{15}$$

By definition of S_{loc}, any nonzero vector $f \in S_{\mathrm{ent}}$ has support on all parties, i.e., $f_\alpha \neq 0$ for all $\alpha \in M$. Define a bilinear form

$$\eta_\alpha : \mathcal{L}_\alpha \otimes S_{\mathrm{ent}} \to \{0,1\}, \quad \eta_\alpha(f,g) = \omega(f_\alpha, g_\alpha).$$

We claim that the form η_α is nonsingular, that is

$$\eta_\alpha(f,g) = 0 \quad \text{for all } g \in S_{\mathrm{ent}} \text{ iff } f = 0, \tag{16}$$

and

$$\eta_\alpha(f,g) = 0 \quad \text{for all } f \in \mathcal{L}_\alpha \quad \text{iff } g = 0. \tag{17}$$

Indeed, suppose $f \in \mathcal{L}_\alpha$ and $\omega(f,g)=0$ for all $g \in S_{\mathrm{ent}}$. By definition of $\mathcal{L}_\alpha$, we have $\omega(f,g)=0$ for all $g \in S_{\mathrm{loc}}$. Thus the decomposition Eq. (15) implies that $f \in S^\perp$. But since $S^\perp = S$, one has $f \in S$. Since the state $|\Psi\rangle$ has full local ranks (see the remark after the theorem), $\mathcal{L}_\alpha \cap S \subseteq S_\alpha = 0$, that is $f=0$. The property Eq. (16) is proved.

Suppose $g \in S_{\mathrm{ent}}$ and $\omega(f,g)=0$ for all $f \in \mathcal{L}_\alpha$ (for some particular $\alpha \in M$), that is $g \in \mathcal{L}_\alpha^\perp$. The definition of $\mathcal{L}_\alpha$ implies that

$$g \in \mathcal{L}_\alpha^\perp \text{ iff } g_\alpha = h_\alpha \quad \text{for some } h \in S_{\mathrm{loc}}.$$

[Here we use the fact that $(\mathcal{L}^\perp)^\perp = \mathcal{L}$ for any binary subspace $\mathcal{L}$.] Thus there exists a vector $h \in S_{\mathrm{loc}}$ such that $(h+g)_\alpha = 0$, i.e., $h+g \in S_{\mathrm{loc}}$. But this means that $g \in S_{\mathrm{loc}}$. Since decomposition Eq. (15) is a direct sum, the inclusion $g \in S_{\mathrm{ent}} \cap S_{\mathrm{loc}}$ implies $g=0$. The property Eq. (17) is proved.

The fact that η_α is nonsingular implies that the subspaces $\mathcal{L}_\alpha$ and S_{ent} have the same dimension. But from Eq. (15) we infer that $\dim(S_{\text{ent}})=\Delta(\Psi)$. The formula Eq. (14) is proved.

Denote $p=\Delta(\Psi)$ and choose an arbitrary basis $\bar{g}_1,\bar{g}_2,\ldots,\bar{g}_p$ in the subspace S_{ent}. For each $\alpha\in M$ choose the dual basis $g_{\alpha 1},g_{\alpha 2},\ldots,g_{\alpha p}$ in the subspace $\mathcal{L}_\alpha$ with respect to the form η_α. That is, the set of vectors $\{g_{\alpha j}\}_j$ must satisfy equations

$$\eta_\alpha(g_{\alpha j},\bar{g}_k)=\delta_{jk} \quad \text{for all } 1\le j,k\le p \quad \text{and } \alpha\in M. \tag{18}$$

Define vectors $g_{\alpha\beta j}\in G^n$ by

$$g_{\alpha\beta j}=g_{\alpha j}+g_{\beta j}, \quad j=1,\ldots,p.$$

It follows from Eq. (18) that

$$\omega(g_{\alpha\beta j},\bar{g}_k)=\eta_\alpha(g_{\alpha j},\bar{g}_k)+\eta_\beta(g_{\beta j},\bar{g}_k)=\delta_{jk}+\delta_{jk}=0.$$

Thus $g_{\alpha\beta j}\in S_{\text{ent}}^{\perp}$. On the other hand, by definition of the subspaces $\mathcal{L}_\alpha$, one has $\mathcal{L}_\alpha\subseteq S_{\text{loc}}^{\perp}$ for all $\alpha\in M$, that is $g_{\alpha\beta j}\in S_{\text{loc}}^{\perp}$. We infer from Eq. (15) that $g_{\alpha\beta j}\in S^{\perp}$. Since S is self-dual, we conclude that $g_{\alpha\beta j}\in S$.

All arguments above apply equally well to $m=2$ and $m\ge 3$. From now on we shall focus on the case $m\ge 3$.

We would like to show that the subspaces $\mathcal{L}_\alpha$ are isotropic, i.e.,

$$\omega(f,g)=0 \quad \text{for all } f,g\in\mathcal{L}_\alpha, \quad \alpha\in M. \tag{19}$$

Indeed, it suffices to show that $\omega(g_{\alpha j},g_{\alpha k})=0$ for any j,k. Assuming that $m\ge 3$, choose an arbitrary triple $\alpha,\beta,\gamma\in M$, such that $\alpha\ne\beta\ne\gamma$. Taking into account that $g_{\alpha\beta j}\in S$, $g_{\alpha\gamma k}\in S$, we obtain that

$$0=\omega(g_{\alpha\beta j},g_{\alpha\gamma k})=\omega(g_{\alpha j},g_{\alpha k}).$$

The property Eq. (19) is proved.

By definition, a vector $g_{\alpha\beta j}$ has a support only on two parties. If $m\ge 3$ it means that

$$g_{\alpha\beta j}\in S_{\text{loc}} \tag{20}$$

for all pairs of parties $\alpha,\beta\in M$ and $j=1,\ldots,p$.

Our next goal is to adjust the subspace S_{ent} to make it "locally isotropic," i.e., to fulfill the following property:

$$\omega(f_\alpha,g_\alpha)=0 \quad \text{for all } f,g\in S_{\text{ent}}, \quad \alpha\in M.$$

This adjustment can be achieved by adding a proper "local shift" taken from the subspaces $\mathcal{L}_\alpha$. Namely, the basis vectors $\bar{g}_j\in S_{\text{ent}}$ must be replaced by new basis vectors according to

$$\bar{g}_j\to\bar{g}_j+\sum_{\alpha\in M}\sum_{l=1}^{j-1}\Gamma_{jl}^{\alpha}g_{\alpha l}, \quad j=1,\ldots,p, \tag{21}$$

where

$$\Gamma_{jl}^{\alpha}=\omega((\bar{g}_j)_\alpha,(\bar{g}_l)_\alpha).$$

One can easily check that after this replacement we end up with

$$\omega((\bar{g}_j)_\alpha,(\bar{g}_k)_\alpha)=0$$

for all $\alpha\in M$ and all j,k. In addition, the fact that S_{ent} is an isotropic subspace, i.e., $\omega(\bar{g}_j,\bar{g}_k)=0$, implies that

$$\sum_{\alpha\in M}\Gamma^{\alpha}_{jl}=0$$

for any fixed j,l. This means that the vector added to $\bar{g}_j$ in Eq. (21) belongs to the stabilizer group S. Accordingly, the adjusted $S_{\rm ent}$ is still a subspace of S. Moreover, Eq. (20) implies that the added vector belongs to $S_{\rm loc}$, so the decomposition $S=S_{\rm loc}\oplus S_{\rm ent}$ remains a direct sum.

Summarizing, after the adjustment described above we can assume that

$$\omega(g_{\alpha j},g_{\alpha k})=0,\quad \omega((\bar{g}_j)_\alpha,(\bar{g}_k)_\alpha)=0,\quad \omega(g_{\alpha j},\bar{g}_k)=\delta_{jk}, \tag{22}$$

for all $\alpha\in M$. Here j and k are arbitrary integers in the range $1,\ldots,p$.

Denote by $S_{\rm ghz}\subset G^{m\cdot p}$ a stabilizer group of p copies of the GHZ state $|\Psi^+_m\rangle$. As generators of $S_{\rm ghz}$ let us choose p copies of the canonical GHZ generators [see Eqs. (10) and (11)]. Denote them as $\bar{f}_j$ and $f_{\alpha\beta j}$, where $j=1,\ldots,p$ refers to different copies of $|\Psi^+_m\rangle$. Define a linear map $T:S_{\rm ghz}\to S$ such that its action on the generators is as follows:

$$T(\bar{f}_j)=\bar{g}_j,\quad T(f_{\alpha\beta j})=g_{\alpha\beta j},$$

where $j=1,\ldots,p$ and $\alpha,\beta\in M$. We would like to prove that T satisfies all conditions of Theorem 2.

Using the fact that the vectors $\{\bar{g}_j,g_{\alpha k}\}$, $j,k=1,\ldots,p$, $\alpha\in M$ are linearly independent, one can easily show that T is a linear injection. Taking into account that $\bar{g}_1,\ldots,\bar{g}_p$ span the subspace $S_{\rm ent}$ that has no intersection with $S_{\rm loc}$, we conclude that $(T\cdot S_{\rm ghz})_{\hat{\alpha}}=T\cdot(S_{\rm ghz})_{\hat{\alpha}}$. Condition (i) of Theorem 2 follows from the local commutation relations Eq. (22). Thus one can extract *at least* p copies of the state $|\Psi^+_m\rangle$ from $|\Psi\rangle$.

Conversely, to prove the upper bound, assume that one can extract q copies of $|\Psi^+_m\rangle$ from $|\Psi\rangle$. Denote by $S_{\rm ghz}$ the stabilizer group of $|q\cdot\Psi^+_m\rangle$ and let $\bar{f}_1,\ldots,\bar{f}_q$ be the canonical σ^x-type stabilizers [see Eq. (10)]. Let $T:S_{\rm ghz}\to S$ be the linear injective map whose existence is guaranteed by Theorem 2. Clearly, a linear span of $\bar{f}_1,\ldots,\bar{f}_q$ has no intersection with colocal subspaces $(S_{\rm ghz})_{\hat{\alpha}}$. According to Theorem 2, vectors $T(\bar{f}_1),\ldots,T(\bar{f}_q)$ are linearly independent and their linear span has no intersection with $S_{\rm loc}$. This means that $\dim(S_{\rm loc})\le n-q$. Therefore $p\ge q$, i.e., one can extract *at most* p copies of $|\Psi^+_m\rangle$. □

V. BEYOND STABILIZER STATES

In this section we argue that the functional $\Delta(\Psi)$ defined in Eq. (13) for stabilizer states can be naturally extended to arbitrary multipartite states. Namely, it coincides with a measure of multipartite correlations introduced by Linden, Popescu, and Wootters in Ref. 14. A similar measure has been introduced also for multipartite probability distributions in Ref. 18. It will allow us to show that $\Delta(\Psi)$ is equal to the number of GHZ states extractable from $|\Psi\rangle$ by *arbitrary* local unitaries.

Denote by $D(\mathcal{B}^n)$ a set of all mixed n-qubit states. Assume that n qubits are distributed between a set of parties M. Let $|\Psi\rangle\in\mathcal{B}^n$ be an arbitrary M-party state. Define a set

$$\Gamma(\Psi)=\{\rho\in D(\mathcal{B}^n):{\rm Tr}_\alpha(\rho)={\rm Tr}_\alpha(|\Psi\rangle\langle\Psi|)\ \alpha\in M\},$$

where Tr_α is the partial trace. In other words, $\rho\in\Gamma(\Psi)$ iff ρ agrees with $|\Psi\rangle$ on any subset of $|M|-1$ parties. Following Ref. 14, define a functional

$$\Omega(\Psi)=\max_{\rho\in\Gamma(\Psi)}S(\rho), \tag{23}$$

where $S(\rho)=-{\rm Tr}\,\rho\log(\rho)$ is the von Neumann entropy. For bipartite states $\Omega(\Psi)$ coincides with the entanglement entropy (except for a factor 2) (see Ref. 14). The main result of this section is the following.

Theorem 4: *For any M-party stabilizer state $|\Psi\rangle$ with a stabilizer group S one has*

$$\Omega(\Psi) = \dim(S) - \dim(S_{\mathrm{loc}}),$$

where $S_{\mathrm{loc}} = \Sigma_{\alpha \in M} S_{\hat{\alpha}}$.

The proof is based on the following observation.

Lemma 2: *Let* $|\Psi\rangle$ *be an M-party stabilizer state with a stabilizer group S. If S is generated by its colocal subgroups*, $S = S_{\mathrm{loc}}$, *then* $|\Psi\rangle\langle\Psi|$ *is the only state that belongs to the set* $\Gamma(\Psi)$.

In other words a state $|\Psi\rangle$ with $S = S_{\mathrm{loc}}$ is the unique (mixed) state compatible with partial traces of $|\Psi\rangle$.

Proof: We shall use stabilizer equations $\sigma(f)|\Psi\rangle = \epsilon(f)|\Psi\rangle$, $f \in S$, uniquely specifying $|\Psi\rangle$ [see Eq. (4)]. Take any state $\rho \in \Gamma(\Psi)$. For any $f \in S_{\hat{\alpha}}$ one has

$$\mathrm{Tr}(\sigma(f)\rho) = \langle\Psi|\sigma(f)|\Psi\rangle = \epsilon(f).$$

Now consider a projector $\Pi = (1/2)(I + \epsilon(f)\sigma(f))$. Then $\mathrm{Tr}(\Pi\rho) = 1$. This is possible only if the range of ρ coincides with the range of Π. Thus, $\Pi\rho = \rho$, i.e.,

$$\sigma(f)\rho = \rho\sigma(f) = \epsilon(f)\rho \quad \text{for any } f \in S_{\hat{\alpha}}, \quad \alpha \in M. \tag{24}$$

Since S is generated by the subgroups $S_{\hat{\alpha}}$, the equalities Eq. (24) actually hold for any $f \in S$. But equations $\sigma(f)\rho = \epsilon(f)\rho$, $f \in S$, mean that ρ has support on the subspace stabilized by S, that is $\rho = |\Psi\rangle\langle\Psi|$. □

Corollary 1: *Let* $|\Psi\rangle = |\Psi' \otimes \Phi\rangle$ *be a collection of two M-party stabilizer states*, *such that* $|\Phi\rangle$ *satisfies the conditions of Lemma 2. Then*

$$\Gamma(\Psi) = \Gamma(\Psi') \otimes |\Phi\rangle\langle\Phi|. \tag{25}$$

To prove the corollary, take any state $\rho \in \Gamma(\Psi)$ and apply Lemma 2 to the partial trace of ρ over the first subsystem. Now we are ready to prove Theorem 4.

Proof: Let $p = \dim(S) - \dim(S_{\mathrm{loc}})$ and $m = |M|$. Obviously, $\Omega(\Psi)$ is invariant under local unitaries. As we know from Theorem 3, $|\Psi\rangle$ is LCU equivalent to a collection of p M-party GHZ states, $|p \cdot \Psi_m^+\rangle$, and some M-party stabilizer state $|\Phi\rangle$ satisfying the conditions of Lemma 2. Taking into account the factorization property Eq. (25), we obtain

$$\Omega(\Psi) = \Omega(p \cdot \Psi_m^+).$$

It remains to be shown that

$$\Omega(p \cdot \Psi_m^+) = p. \tag{26}$$

First of all, consider a mixed version of the GHZ state,

$$\rho = (1/2)|0^{\otimes m}\rangle\langle 0^{\otimes m}| + (1/2)|1^{\otimes m}\rangle\langle 1^{\otimes m}|. \tag{27}$$

It is clear that $\rho \in \Gamma(\Psi_m^+)$. Thus

$$\Omega(p \cdot \Psi_m^+) \geq S(\rho^{\otimes p}) = pS(\rho) = p. \tag{28}$$

To get an upper bound, take any $\rho \in \Gamma(\Psi)$. Divide M into three nonempty subsets by an arbitrary way: $M = M_1 \cup M_2 \cup M_3$. Let ρ_j and ρ_{jk} be the reduced states of the subset M_j and $M_j \cup M_k$ (with respect to ρ). The strong subadditivity inequality shows that

$$S(\rho) + S(\rho_1) \leq S(\rho_{12}) + S(\rho_{13}).$$

But the condition $\rho \in \Gamma(p \cdot \Psi_m^+)$ implies that all the states ρ_1, ρ_{12}, and ρ_{13} are the mixed versions of the GHZ state [Eq. (27)], that is $S(\rho_1) = S(\rho_{12}) = S(\rho_{13}) = p$. Thus we get $S(\rho) \leq p$. Combining it with the lower bound Eq. (28) we get Eq. (26). □

Corollary 2: *Theorem 3 gives the GHZ extraction yield from a stabilizer state for arbitrary local unitary operators*.

Proof: Let $p = \Delta(\Psi)$ and q be the number of GHZ states extractable from $|\Psi\rangle$ by local

unitaries. Obviously, $q \geq p$. Since the functional $\Omega(\Psi)$ is LU invariant, we infer from Eq. (26) that $\Omega(\Psi) \geq \Omega(q \cdot \Psi_m^+) = q$. It follows from Theorem 4 that $p \geq q$. Thus $p = q$. □

VI. TRIPARTITE STABILIZER STATES

As a simple application of Theorem 3 let us show that any tripartite stabilizer state is LCU equivalent to a collection of states from the set $E_3 = \{|0\rangle, |\Psi^+\rangle, |\Psi_3^+\rangle\}$. After extraction of all local $|0\rangle$ states one can consider only states with full local ranks.

Theorem 5: *Let $|\Psi\rangle \in \mathcal{B}^n$ be a stabilizer state with full local ranks shared by a set of parties $M = \{A, B, C\}$. Let S be a stabilizer group of $|\Psi\rangle$ and $S_{\mathrm{loc}} = \Sigma_{\alpha \in M} S_{\hat{\alpha}}$. Denote $p = \dim(S) - \dim(S_{\mathrm{loc}})$ and $d(\alpha) = \dim(S_{\hat{\alpha}})$. The state $|\Psi\rangle$ is LCU equivalent to a collection of*

(i) $(d(A) - p)/2$ *copies of* $|\Psi^+\rangle$ *shared by B and C*,
(ii) $(d(B) - p)/2$ *copies of* $|\Psi^+\rangle$ *shared by C and A*,
(iii) $(d(C) - p)/2$ *copies of* $|\Psi^+\rangle$ *shared by A and B*,
(iv) p *copies of the GHZ state* $|\Psi_3^+\rangle$.

Proof: As we already know from Theorem 3, one can extract p copies of $|\Psi_3^+\rangle$ from $|\Psi\rangle$. This allows us to consider only the case $p = 0$. Equivalently, we can assume that S is equal to the sum of its colocal subgroups, $S = S_{\mathrm{loc}}$. The full local ranks assumption means that the colocal subgroups do not overlap, i.e., $S_{\hat{\alpha}} \cap S_{\hat{\beta}} = 0$ for $\alpha \neq \beta$. Thus S can be represented as a direct sum,

$$S = S_{\hat{A}} \oplus S_{\hat{B}} \oplus S_{\hat{C}}. \tag{29}$$

Let us prove that $|\Psi\rangle$ is LCU equivalent to a collection of EPR states $|\Psi^+\rangle$. The proof consists of applying the same arguments to each pair of parties, so let us focus on the pair AB.

Denote $R \equiv S_{\hat{C}}$ and consider a bilinear form

$$\eta : R \otimes R \to \{0,1\}, \quad \eta(f,g) = \omega(f_A, g_A),$$

for any $f, g \in R$. We claim that η is a nonsingular form. Indeed, suppose that

$$\eta(f,g) = 0 \quad \text{for all } g \in R \tag{30}$$

and prove that $f = 0$. Indeed, Eq. (30) and decomposition Eq. (29) imply that $\omega(f_A, h_A) = 0$ for any $h \in S$. We can rewrite this as $\omega(\tilde{f}, h) = 0$ for any $h \in S$, where $\tilde{f} \in G_A^n$ is chosen such that $\tilde{f}_A = f_A$. It means that $\tilde{f} \in S^{\perp}$, that is $\tilde{f} \in S \cap G_A^n = S_A = 0$. Therefore, $f_A = 0$ and so $f \in S_B = 0$. We conclude that $f = 0$ and η is nonsingular.

Applying the Gram-Schmidt orthogonalization procedure, one can check that R must have an even dimension, $\dim(R) = 2l$, and that there exists a symplectic basis $\{g_j, \bar{g}_j\}_{j=1,\ldots,l}$ of R such that

$$\eta(g_j, g_k) = 0, \quad \eta(\bar{g}_j, \bar{g}_k) = 0, \quad \eta(g_j, \bar{g}_k) = \delta_{jk}. \tag{31}$$

(For a proof see Dickson's theorem in Ref. 19, Chap. 15.)

Denote by $S_{\mathrm{EPR}} \subset G^{2l}$ a stabilizer group of l copies of the EPR state, $|l \cdot \Psi^+\rangle$. We consider $|l \cdot \Psi^+\rangle$ as a tripartite state, such that C holds no qubits at all, and there are l EPR states shared by A and B. The group S_{EPR} has independent generators $\{f_j, \bar{f}_j\}_{j=1,\ldots,l}$ such that

$$\sigma(f_j) = \sigma_j^z \otimes \sigma_j^z, \quad \sigma(\bar{f}_j) = \sigma_j^x \otimes \sigma_j^x,$$

where j labels the copies of $|\Psi^+\rangle$, i.e., $j = 1, \ldots, l$. Define a linear map $T : S_{\mathrm{EPR}} \to S$ such that

$$T(f_j) = g_j, \quad T(\bar{f}_j) = \bar{g}_j, \quad j = 1, \ldots, l.$$

Obviously, $T(S_{\mathrm{EPR}}) = R$. We would like to check that T satisfies all the conditions of Theorem 2. Indeed, it is a linear injection because the images of the basis vectors of S_{EPR} are linearly independent. Condition (i) follows directly from Eq. (31). Condition (i) holds because S_{EPR} has trivial

colocal subgroup and so does R. Thus l copies of $|\Psi^+\rangle$ shared between A and B can be extracted from $|\Psi\rangle$.

Applying the same arguments to other pairs of parties, we conclude that AB, BC, and AC can extract $d(C)/2$, $d(A)/2$, and $d(B)/2$ EPR states, respectively. The total number of qubits in the extracted EPR states is $d(A)+d(B)+d(C)$ which coincides with $\dim(S)=n$, see Eq. (29). Thus no qubits are left after the extraction.

To conclude the proof it is sufficient to note that extraction of a single GHZ state $|\Psi_3^+\rangle$ reduces each of the dimensions $\dim(S_{\hat{\alpha}})$ by one. □

A simple corollary of Theorem 5 is that two tripartite stabilizer states $|\Psi\rangle, |\Psi'\rangle$ are LU-equivalent iff their decompositions into $|\Psi^+\rangle$, $|\Psi_3^+\rangle$, and local $|0\rangle$ states coincide. Indeed, make use of the fact that a partial trace of $|\Psi_3^+\rangle$ over any qubit is a separable state. LU equivalence of $|\Psi\rangle$ and $|\Psi'\rangle$ implies that all partial traces of $|\Psi\rangle$ and $|\Psi'\rangle$ are LU equivalent; that is, the number of singlets $|\Psi^+\rangle$ extractable by each pair of parties is the same for $|\Psi\rangle$ and $|\Psi'\rangle$. By counting the remaining dimensions we conclude that the numbers of GHZ's $|\Psi_3^+\rangle$ extractable from $|\Psi\rangle$ and $|\Psi'\rangle$ are the same. Thus LU-equivalence classes of tripartite stabilizer states are completely specified by the numbers of $|\Psi^+\rangle$ and $|\Psi_3^+\rangle$ in the decomposition of Theorem 5.

Remark: One could prove Theorem 5 by making use of mixed stabilizer states. A mixed stabilizer state is a maximally mixed state encoded by some stabilizer code. Bipartite mixed stabilizer states can be classified using the techniques of the paper.[12] It turns out that any bipartite mixed stabilizer state is LCU equivalent to a collection of (i) local pure states; (ii) local maximally mixed states; (iii) EPR states; (iv) two-qubit mixed states $(1/2)|0,0\rangle\langle 0,0|+(1/2)|1,1\rangle\langle 1,1|$. Combining this fact with the purification theorem one immediately gets Theorem 5. We refrain from pushing this approach further, because it is less symmetric than the one presented above.

VII. SATURATION OF MULTIPARTITE ENTANGLEMENT ENTROPY IN SPIN LATTICES

As was mentioned in the introduction, characterization of multipartite entangled states might be useful for quantum cryptography and quantum game theory. Another natural area to look for applications is condensed matter physics. It has been realized recently that ground states of d-dimensional spin lattices with spatially uniform short-range interactions are distinguished among all other states by obeying the *entropic area law* (see Ref. 16 and references therein). According to this law, entanglement entropy of a block of spins with a spatial size L (thus containing about L^d spins) scales as $E(L)=b\cdot L^{d-1}+o(L^{d-1})$, where b is a constant (critical systems are set aside). This law can be understood, at least very roughly, if one regards the ground state as a collection of short-range EPR states. Then $E(L)$ is equal to the number of EPR states that stretch between the interior and exterior of the block. It is obviously proportional to the area of the boundary. From this standpoint (which is of course only a rude approximation) $E(L)$ can be regarded as the maximal number of EPR states extractable from the ground state by local unitaries.

To get more insight into the structure of entanglement of the ground state, one can consider a partition of the lattice into several blocks of spins (which may or may not have junction points), and ask how many multipartite GHZ states can be extracted from the ground state by local unitaries. In this section we shall try to follow this program.

Let us first set the problem more strictly. We shall focus on the two-dimensional case (a generalization to an arbitrary d is trivial). Suppose that the system under consideration consists of n qubits that are assigned to sites of a 2D regular lattice. Let $|\Psi_0\rangle \in \mathcal{B}^n$ be the ground state of the system. Consider a partition of the lattice into three segments A, B, and C which have a common junction point O, while pairwise intersections are one-dimensional rays incident to O (see Fig. 1). The problem is to compute the quantity

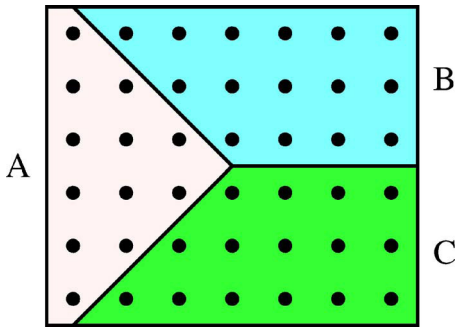

FIG. 1. (Color online) A junction point.

$$E_3(n) = \Omega(\Psi_0),$$

defined by Eq. (23). As was argued in Sec. V, the quantity $\Omega(\Psi_0)$ is a natural generalization of the GHZ extraction yield beyond stabilizer states. We are particularly interested in the asymptotic behavior of $E_3(n)$ when n goes to infinity (the thermodynamic limit).

It is natural to expect that $E_3(n)$ does not diverge as $n \to \infty$, since tripartite correlations must be formed by interactions acting on spins near the junction point O. As long as the Hamiltonian of the system is short ranged, there is only a finite number of such interactions. In other words, a natural conjecture is that

$$\sup_n E_3(n) < \infty . \tag{32}$$

This inequality says that $E_3(n)$ can be bounded from above by a constant that does not depend on the size of the system (this constant may depend upon the details of the system's Hamiltonian, however). The conjecture Eq. (32), if it is true, would generalize the entanglement saturation phenomenon found for one-dimensional spin chains[16] to higher dimensions.

In the rest of this section we prove Eq. (32) for a special case when (i) $|\Psi_0\rangle$ is a stabilizer state; (ii) the stabilizer group of $|\Psi_0\rangle$ has a set of geometrically local generators. Well-known examples of such states are the 2D cluster state[6] or the planar analogue of Kitaev's toric code state.[15]

Let $|\Psi_0\rangle \in \mathcal{B}^n$ be a stabilizer state and $S \subset G^n$ be its stabilizer group. Let us say that S has an *interaction length* l, iff there exists a family of vectors $f_1, \ldots, f_p \in S$, such that (i) S is generated by $f_1, \ldots, f_p$; (ii) for any j, the support of the vector f_j can be covered by a $l \times l$ rectangular block. We do not assume that the f_j are linearly independent, so in general $p > n$. However we assume that any vector $u \in G^n$ appears in the list $f_1, \ldots, f_p$ with multiplicity at most one (which, of course, is not a restriction at all). For example, one can easily check that the 2D cluster state and Kitaev's state have interaction length $l=3$ and $l=2$, respectively.

Consider a subgroup $S' \subseteq S$ generated by vectors f_j that have support on all three parties A, B, and C. Obviously, f_j is supported on all three parties only if the $l \times l$ block representing the support of f_j covers the junction point O. Since there are only l^2 different blocks that cover O and each block can represent at most l^2 independent vectors f_j, we conclude that

$$\dim(S') \leq l^4.$$

Consider now a subgroup $S_{\mathrm{loc}} \subseteq S$ generated by colocal subgroups of S [see Eq. (12)]. Since each f_j belongs to at least one of the subgroups S', S_{loc}, we infer that

$$S = S_{\mathrm{loc}} + S' \quad \text{and} \quad \dim(S_{\mathrm{loc}}) \geq \dim(S) - \dim(S').$$

Taking into account Theorem 4, one gets

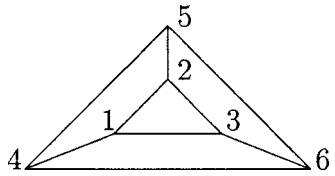

FIG. 2. Graph $\mathcal{G}$ used in the definition of $|\mathcal{G}\rangle$.

$$\Omega(\Psi_0) = \dim(S) - \dim(S_{\text{loc}}) \leq \dim(S') \leq l^4$$

which gives us an upper bound on the number of GHZ states $|\Psi_3^+\rangle$ that can be extracted from $|\Psi_0\rangle$. This bound does not depend upon n—only upon the interaction length l. Therefore Eq. (32) is proved.

Remark: Since the state $|\Psi_0\rangle$ is uniquely specified by stabilizer equations $\sigma(f)|\Psi_0\rangle = \epsilon(f)|\Psi_0\rangle$, $f \in S$ [see Eq. (4)], it can be regarded as the nondegenerate ground state of a Hamiltonian

$$H = -\sum_{j=1}^{p} \epsilon(f_j)\sigma(f_j).$$

This Hamiltonian is a sum of local interactions each of which affects the qubits inside some $l \times l$ block.

VIII. FOUR-PARTY STABILIZER STATES

As we learned from Sec. VI, there exists essentially one irreducible tripartite stabilizer state—the GHZ state $|\Psi_3^+\rangle$. What about four-party states? As the simplest example, consider a system of four qubits distributed between four parties. As was pointed out in Ref. 20, there exist only two irreducible four-qubit stabilizer states: the GHZ state $|\Psi_4^+\rangle$ and a state

$$|C_4\rangle = (1/2)(|0000\rangle + |0011\rangle + |1100\rangle - |1111\rangle),$$

such that $|C_4\rangle = \Lambda(\sigma^z)[2,3]|\Psi^+ \otimes \Psi^+\rangle$ (one can check that $|C_4\rangle$ is LCU equivalent to the cluster state of a four-qubit linear chain).

Is it true that a set $E_4 = \{|0\rangle, |\Psi^+\rangle, |\Psi_3^+\rangle, |\Psi_4^+\rangle, |C_4\rangle\}$ is an entanglement generating set for four-party stabilizer states? In this section we give an example of a state that is not LCU equivalent to any collection of states from E_4, thus answering this question in the negative.

Consider a graph $\mathcal{G} = (V,E)$ with six vertices shown in Fig. 2. For each vertex $u \in V$ define a stabilizer $f_u \in G^6$ such that

$$\sigma(f_u) = \sigma_u^x \bigotimes_{(u,v)\in E} \sigma_v^z. \tag{33}$$

The vectors $\{f_u\}_{u\in V}$ generate a self-dual subspace $S \subset G^6$. Let $|\mathcal{G}\rangle \in \mathcal{B}^6$ be the corresponding stabilizer state [it is known as a *graph state* associated with the graph $\mathcal{G}$; one can also define $|G\rangle$ using a classical GF(4)-linear code known as *hexacode*, see Ref. 21]. This state has the following curious property.

Proposition: A partial trace of $|\mathcal{G}\rangle$ over any triple of qubits is maximally mixed:

$$\text{Tr}_{uvw}\big(|\mathcal{G}\rangle\langle\mathcal{G}|\big) = \tfrac{1}{8}I, \quad \text{for any } u \neq v \neq w. \tag{34}$$

For a proof see Ref. 22.

Suppose now that $|\mathcal{G}\rangle$ is shared by a set of parties $M = \{A,B,C,D\}$ such that

$$A = \{1,4\}, \quad B = \{3,6\}, \quad C = \{2\}, \quad D = \{5\}.$$

Lemma 3: *If* $|\mathcal{G}\rangle$ *is shared by the set of parties* $M=\{A,B,C,D\}$ *as above*, *it is irreducible*, *i.e.*, *no stabilizer state can be extracted from* $|\mathcal{G}\rangle$.

(Here we talk about extraction in the sense of Definition 4 and ignore the trivial possibility of extracting $|\mathcal{G}\rangle$ from itself.)

Proof: We shall first show that neither of the states $|\Psi^+\rangle$, $|\Psi_3^+\rangle$ can be extracted from $|\mathcal{G}\rangle$.

(a) $|\Psi_3^+\rangle$ *extraction*: Suppose one can extract one copy of $|\Psi_3^+\rangle$ which is shared by a subset of parties $M' \subset M$, $|M'|=3$. Obviously, M' contains at least one of A, B, and at least one of C, D. By the symmetry, assume that $A \in M'$ and $D \in M'$. Then the reduced state of the qubits $1,4,5$ has a rank at most 4, contradicting Eq. (34).

(b) $|\Psi^+\rangle$ *extraction*: Obviously, $|\Psi^+\rangle$ cannot be shared by C and D (the reduced state of any pair of qubits is maximally mixed). Thus there are only two possibilities: (i) $|\Psi^+\rangle$ is shared by one of $\{A,B\}$ and one of $\{C,D\}$. Then one of the triple of qubits AC, AD, BC, BD has a rank at most 2, contradicting Eq. (34). (ii) $|\Psi^+\rangle$ is shared by A and B. Then there must be two vectors $f,\bar{f} \in S$ such that

$$f_C = f_D = \bar{f}_C = \bar{f}_D = 0, \tag{35}$$

$$\omega(f_A,\bar{f}_A) = \omega(f_B,\bar{f}_B) = 1. \tag{36}$$

Taking into account the explicit form of the stabilizer generators Eq. (33), one can check that the only nontrivial stabilizer elements having a support on A and B are the following:

$$\sigma_1^y \otimes \sigma_4^z \otimes \sigma_3^y \otimes \sigma_6^z, \quad \sigma_1^z \otimes \sigma_4^y \otimes \sigma_3^z \otimes \sigma_6^y, \quad \sigma_1^x \otimes \sigma_4^x \otimes \sigma_3^x \otimes \sigma_6^x.$$

(All identity factors are suppressed.) Any pair of them commute locally on A and B. Thus the equations Eqs. (35) and (36) have no solutions and we get a contradiction.

Extraction of a four-party state from $|\mathcal{G}\rangle$ is impossible, since it leaves a bipartite (or a local pure state) which would also be extractable from $|\mathcal{G}\rangle$. As we already know, this would lead to a contradiction. □

This observation means that we must add the state $|\mathcal{G}\rangle$ to the entanglement generating set E_4. It raises a question: Is there a *finite* EGS for four-party stabilizer states? (Note that we allow an arbitrary number of qubits per party, so the total number of stabilizer states is infinite.) To the authors' best knowledge, the answer is unknown.

A closely related problem is to find LCU-equivalence classes of *bipartite* unitary operators from the Clifford group (it suffices to take two copies of a maximally entangled state and apply a unitary operator to one-half of each state, see Ref. 23 for more details).

Another open question is the relation between LU equivalence and LCU equivalence of stabilizer states. To the authors' best knowledge, there are no known examples of LU-equivalent stabilizer states which are not LCU equivalent. On the other hand, it was shown by Van den Nest, Dehaene, and De Moor in Ref. 11, extending the work of Rains,[24] that for a large class of stabilizer states, including the states specified by GF(4) linear codes, LCU equivalence coincides with LU equivalence (this statement applies only to one-qubit-per-party partitions).

ACKNOWLEDGMENTS

The authors acknowledge Ike Chuang for fruitful discussion. One of the authors (S.B.) received support from the National Science Foundation under Grant No. EIA-0086038. One of the authors (D.G.) is supported by CIAR and by NSERC of Canada.

APPENDIX A

In this section we give a shorter (but less constructive) proof of the GHZ extraction formula, see Theorem 3.

Denote p the maximal number of states $|\Psi_m^+\rangle$ extractable from $|\Psi\rangle$. Clearly, $p>0$ implies $S \neq S_{\mathrm{loc}}$, and thus $\Delta(\Psi)>0$. Since $\Delta(\Psi)$ is additive under a tensor product of states, and $\Delta(\Psi_m^+)=1$ (for $m\geq 3$), it suffices to prove that $\Delta(\Psi)>0$ implies $p>0$.

(1) Consider a linear map $\Pi_\alpha: S\to G^{n_\alpha}$ that sends $f\in S$ to f_α (a projection onto party α). By definition of a colocal subspace, $\mathrm{Ker}(\Pi_\alpha)=S_{\hat{\alpha}}$. The fact that $|\Psi\rangle$ has full local ranks (see the remark after the statement of Theorem 3) implies that $\mathrm{Im}(\Pi_\alpha)=G^{n_\alpha}$. Therefore $\dim(S)=n_\alpha+\dim(S_{\hat{\alpha}})$ for any $\alpha\in M$. Thus any linear function $\lambda: S\to\{0,1\}$ such that $\lambda(S_{\hat{\alpha}})=0$ can be uniquely represented as $\lambda(f)=\omega(x_\alpha,f)$for some $x_\alpha\in G_\alpha^n$.

(2) Choose a nonzero linear function $\lambda: S\to\{0,1\}$ such that $\lambda(S_{\mathrm{loc}})=0$. As shown above, for any $\alpha\in M$ we can choose $x_\alpha\in G_\alpha^n$ such that $\lambda(f)=\omega(x_\alpha,f)$ for all $f\in S$. Then $\omega(x_\alpha+x_\beta,f)=0$ for all $f\in S$ and thus $x_\alpha+x_\beta\in S$ (recall that S is self-dual).

(3) Choose $\bar{g}\in S$ such that $\lambda(\bar{g})=1$. Define a linear subspace $V\subseteq S$, such that V is spanned by vectors $g_{\alpha,\beta}=x_\alpha+x_\beta$, $\alpha,\beta\in M$, and $\bar{g}$. From $\lambda(\bar{g})=1$ we infer that $\bar{g}\notin S_{\mathrm{loc}}$, and thus that $\bar{g}_\alpha\neq 0$ for all $\alpha\in M$. Besides, the fact that $\omega(x_\alpha,g)=\lambda(g)=1$ implies that x_α and g_α are linearly independent. Thus a colocal subspace $V_{\mathrm{loc}}\subset V$ is spanned by vectors $g_{\alpha,\beta}$.

(4) Let $S_{\mathrm{ghz}}\subset G^m$ be a stabilizer group of $|\Psi_m^+\rangle$ with canonical generators $f_{\alpha,\beta}$ and $\bar{f}$, see Eqs. (10) and (11). Define a linear map $T: S_{\mathrm{ghz}}\to S$ according to $T(f_{\alpha,\beta})=g_{\alpha,\beta}$ and $T(\bar{f})=\bar{g}$. Let us verify that T obeys conditions of Theorem 2. Indeed, T is the injective map since x_α and g_α are linearly independent. The property (i) follows from equality $\omega(x_\alpha,g_\alpha)=\lambda(g)=1$. The property (ii) follows from equality $T((S_{\mathrm{ghz}})_{\mathrm{loc}})=V_{\mathrm{loc}}$. Thus$|\Psi_m^+\rangle$ is extractable from $|\Psi\rangle$, i.e., $p>0$.

APPENDIX B

The goal of this section is to prove Lemma 1. We start by stating one more lemma.

Lemma 4: *Let $f_1,\ldots,f_p$ and $f_1',\ldots,f_p'$ be two families of vectors in G^n satisfying the following conditions*:

$$\omega(f_j,f_k)=\omega(f_j',f_k') \quad \textit{for all } 1\leq j,k\leq p, \tag{B1}$$

$$\sum_{j=1}^{p} x_j f_j=0 \quad \textit{iff} \sum_{j=1}^{p} x_j f_j'=0. \tag{B2}$$

Here $x_1,\ldots,x_p\in\{0,1\}$ are arbitrary binary coefficients. Then there exists a symplectic operator $u\in \mathrm{Sp}_2(n)$ such that

$$f_j'=u(f_j) \quad \textit{for all } j=1,\ldots,p.$$

Proof: Let us call a basis $e_1,\bar{e}_1,\ldots,e_n,\bar{e}_n$ of the space G^n canonical iff the following relations hold:

$$\omega(e_j,e_k)=0, \quad \omega(\bar{e}_j,\bar{e}_k)=0, \quad \omega(e_j,\bar{e}_k)=\delta_{jk}. \tag{B3}$$

One can extend the family $f_1,\ldots,f_p$ to a canonical basis $\{e_j,\bar{e}_j\}$ using the Gram-Schmidt orthogonalization algorithm. After that one can write

$$f_j = \sum_{k=1}^{n} F_{jk} e_k + \bar{F}_{jk} \bar{e}_k, \quad j = 1, \ldots, p,$$

where F and $\bar{F}$ are some binary $p \times n$ matrices. It is a property of the Gram-Schmidt algorithm that the coefficients F_{jk} and $\bar{F}_{jk}$ depend only upon the inner products Eq. (B1) and upon the set of linear dependencies Eq. (B2). Thus if we apply the same algorithm in parallel to the family $f'_1, \ldots, f'_p$, we shall end up with a canonical basis $\{e'_1, \bar{e}'_1, \ldots, e'_n, \bar{e}'_n\}$ such that

$$f'_j = \sum_{k=1}^{n} F_{jk} e'_k + \bar{F}_{jk} \bar{e}'_k, \quad j = 1, \ldots, p.$$

The symplectic group $\mathrm{Sp}_2(n)$ acts transitively on the set of canonical bases. Thus

$$e'_j = u(e_j), \quad \bar{e}'_j = u(\bar{e}_j), \quad j = 1, \ldots, n,$$

for some $u \in \mathrm{Sp}_2(n)$. This implies that $f'_j = u(f_j)$ for all $j = 1, \ldots, p$. □

Now we are ready to prove Lemma 1. The nontrivial part is to prove that statement 1 follows from statement 2. Choose an arbitrary basis $f_1, \ldots, f_p$ of the subspace S. Denote $f'_j = T(f_j) \in S'$. The condition that T is an invertible map implies that $f'_1, \ldots, f'_p$ is a basis of S'. For each $\alpha \in M$, consider projections $f_{\alpha j} = (f_j)_\alpha$ and $f'_{\alpha j} = (f'_j)_\alpha$. The condition (2-i) is equivalent to

$$\omega(f_{\alpha j}, f_{\alpha k}) = \omega(f'_{\alpha j}, f'_{\alpha k}) \quad \text{for all } \alpha \in M \tag{B4}$$

and any j, k in the range $1, \ldots, p$.

In addition, we have the following chain of implications: $\Sigma_{j=1}^{p} x_j f_{\alpha j} = 0$ iff $\Sigma_{j=1}^{p} x_j f_j \in S_{\hat{\alpha}}$ iff $T(\Sigma_{j=1}^{p} x_j f_j) \in S'_{\hat{\alpha}}$ iff $\Sigma_{j=1}^{p} x_j f'_{\alpha j} = 0$. The second implication is the condition (2-ii) of the lemma, while all others follow from the definition of the colocal subspace. Summarizing, we have

$$\sum_{j=1}^{p} x_j f_{\alpha j} = 0 \quad \text{iff} \sum_{j=1}^{p} x_j f'_{\alpha j} = 0. \tag{B5}$$

Now, for each $\alpha \in M$, let us apply Lemma 4 to the families of vectors $f_{\alpha 1}, \ldots, f_{\alpha p} \in G^{n_\alpha}$ and $f'_{\alpha 1}, \ldots, f'_{\alpha p} \in G^{n_\alpha}$. The conditions of Lemma 4 are equivalent to Eqs. (B4) and (B5). Thus there exist operators $u_\alpha \in \mathrm{Sp}_2(n_\alpha)$ such that

$$f'_{\alpha j} = u_\alpha(f_{\alpha j}), \quad \alpha \in M, \quad j = 1, \ldots, p.$$

This means that

$$f'_j = \left(\bigoplus_{\alpha \in M} u_\alpha \right)(f_j), \quad j = 1, \ldots, p.$$

This is equivalent to statement 1 of Lemma 1.

(Received 30 December 2005; accepted 1 April 2006; published online 26 June 2006)

For the largest class of physical systems having a classical analog, a new rigorous, but not probabilistic, Lagrangian version of nonrelativistic quantum mechanics is given, in terms of a notion of regularized action function. As a consequence of the study of the symmetries of this action, an associated Nœther theorem is obtained. All the quantum symmetries resulting from the canonical quantization procedure follow in this way, as well as a number of symmetries which are new even for the case of the simplest systems. The method is based on the study of a corresponding Lie algebra and an analytical continuation in the time parameter of the probabilistic construction given in paper I of this work. Generically, the associated quantum first integrals are time dependent and the probabilistic model provides a natural interpretation of the new symmetries. Various examples illustrate the physical relevance of our results. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2199087]

I. INTRODUCTION

This paper is the continuation of the one, referred hereafter simply as paper I, whose subtitle was the "Theorem of Nœther in Schrödinger's Euclidean quantum mechanics."[1] There, a probabilistic (i.e., "Euclidean") generalization of Nœther's theorem of classical mechanics was presented, for a class of Lagrangians quadratic in the velocities, and involving a special family of time-symmetric $\mathbb{R}^3$-valued diffusion processes. At the end of paper I, our physical motivation was indicated: after an appropriate analytic continuation in the time parameters, the main conclusion of the construction was preserved as a theorem on quantum symmetries, in the Heisenberg picture. In other words, although the probabilistic content of the theorem of Nœther was destroyed by this continuation in time, its geometrical one survived.

The purpose of this second paper is to describe in a detailed way the reason of this apparently surprising conclusion. This will provide us with a new Lagrangian version of the quantum theory of such a class of systems. The symmetries of the associated new concept of regularized action functional will be expressed as a quantum version of the theorem of Nœther. All the unusual regularizations introduced on the quantum side will correspond to the ones given for free with the underlying diffusion process, whose probability measures make sense only in the Euclidean setting. In point of fact, it will be shown that the corresponding symbolic "quantum diffusions" in real time have all the properties of the heuristic ones manipulated by Feynman in his famous path integral method.[2] In this sense, our indirect method is very much along the line of Feynman's space–time approach. It will be shown that we obtain many more quantum symmetries in this way than using the usual theorems on quantum symmetries, even for the simplest class of elementary integrable systems. Those "new" quantum symmetries are the keys of basic relations with stochastic analysis. A general argument of Lie group theory assures us, in fact, that all quantum symmetries arise in this way.

The organization of this work is as follows.

Section II introduces the notions (implicit in Feyman's approach) of (complex-valued) space–time observables associated with a family of regular quantum observables and of quantum derivatives along a state. Although these quantum derivatives are not observables in the sense of Von Neumann, they constitute a key tool of our construction. Under the quantum expectation, such differential operators behave like derivations.

Then, we define the concept of quantum conditional expectation in a state, given a space–time point. In spite of the fact that this concept shares a number of properties with its counterpart in probability theory, we show why it is not a conditional expectation in the probabilistic sense. The associated "quantum diffusions" are precisely the ones introduced by Feynman in time discretized manner.

Section III is devoted to the definition of the regularized action function for this class of systems and its relations with quantum dynamics.

The study of the symmetries of this quantum action is the subject of Sec. IV. In particular, the definition of the invariance of the action corresponds to a natural regularization of the classical notion. The symmetry group of the underlying Schrödinger equation is used in an essential way here, and the regular concept of constant observable of the motion is adapted to our calculus on space–time observable (or *quantum calculus*, for short).

In Sec. V the construction is specialized to the case of Hamiltonians which are polynomials of degrees ≤ 2 in the position and momentum observables. This is the case where all the calculations are explicit. Although this class is supposed to be completely known, our method provides, even for the most elementary systems, more symmetries than the traditional approach. For general Hamiltonians the main results hold true; but no explicit basis of the symmetry algebra can be found, in general and, therefore, the method is more indirect.

Section VI is devoted to the analysis of the content of our Nœther theorem in a Riemannian manifold.

In Sec. VII we come back to the relation of what we did with the ideas of Feynman and show in what sense the content of the present paper is a natural counterpart of paper I, where stochastic analysis is involved in an essential way.

Finally, the last section is devoted to a short collection of explicit examples of quantum symmetries with some emphasis on those not directly accessible to regular methods. Of course, as soon as we know it, the theorem of Nœther in quantum mechanics can be verified without any use of our detour via probability theory and stochastic analysis. However, it is argued in favor of this detour for the intuition it provides, in the same sense as Feynman's path integral approach has proved to be very useful for the discovery of many new aspects of quantum theory. A short Errata for paper I will conclude the present work.

II. THE CONCEPT OF QUANTUM MECHANICAL CONDITIONAL EXPECTATION

Let H be a self-adjoint, lower bounded Hamiltonian operator in the Hilbert space $\mathcal{H} = L^2(\mathbb{R}^n, \mathrm{d}x)$ of square integrable complex-valued function over $\mathbb{R}^n$. Consider the one-parameter, strongly continuous groups of unitary operators $U_t: \mathcal{H} \to \mathcal{H}, t \in \mathbb{R}$,

$$U_t = e^{-(i/\hbar)tH},$$

with the reduced Planck constant $\hbar$. Then for any ψ in the definition domain $\mathcal{D}_H \subset \mathcal{H}$ of H,

$$\psi_t = U_t \psi, \tag{2.1}$$

solves the Schrödinger equation with the initial condition ψ:

$$\begin{aligned} i\hbar \frac{\partial \psi_t}{\partial t} &= H\psi_t, \\ \psi_0 &= \psi. \end{aligned} \tag{2.2}$$

Let consider a one-parameter family $A(t), t \in \mathbb{R}$, of self-adjoint operators in $\mathcal{H}$. Assume that $\mathcal{D}_{A(t)} \supset H\mathcal{D}_H$ and $A(t)\mathcal{D}_H \subset \mathcal{D}_H$, so that the commutators $[A(t),H]=A(t)H-HA(t)$ are well defined on $\mathcal{D}_H$. Let $0<T\leq\infty$ and define $\mathcal{D}_T^A(t) \equiv \mathcal{D}^A(t)$ by $\mathcal{D}^A(t)=\cap_{T\geq\Delta t\geq 0}\mathcal{D}_{A(t+\Delta t)}$. In particular we have $\mathcal{D}^A(t) \subset \mathcal{D}_{A(t)}$. If $A(t)$ is weakly differentiable on $\mathcal{D}^A(t)$ with respect to the time parameter $t \in [0,T)$,then we can compute

$$\lim_{\Delta t \downarrow 0}\left(\psi, \frac{A(t+\Delta t)-A(t)}{\Delta t}\varphi\right) \equiv \dot{\varepsilon_t^A}(\psi,\varphi).$$

It exists for any $\psi \in \mathcal{H}, \varphi \in \mathcal{D}^A(t)$, where $(\cdot,\cdot)$ denotes the scalar product in $\mathcal{H}$, and is linear in the second vector. Provided that $\mathcal{D}^{\dot{A}}(t)$ is dense in $\mathcal{H}, \dot{\varepsilon_t^A}: \mathcal{H}\times\mathcal{D}^A(t) \to \mathbb{C}$ is a densely defined sesquilinear form.

Now let us define, for $\psi_t \in \mathcal{H}$ and $\varphi_t \in \mathcal{D}_{A(t)}, I_{\psi,\varphi}(t)=(\psi_t,A(t)\varphi_t)$.

When $\varphi_t \in \mathcal{D}^A(t)$ and ψ_t is the solution of (2.2) with $\psi_t \in D_{A(t)}, T>t\geq 0$ and $\Delta t>0$, we can compute the relative time increment of $I_{\psi,\varphi}(t)$ as follows:

$$\begin{aligned} I_{\psi,\varphi}(t,\Delta t) &\equiv \frac{I_{\psi,\varphi}(t+\Delta t)-I_{\psi,\varphi}(t)}{\Delta t} \\ &= \frac{1}{\Delta t}[(\psi_{t+\Delta t},A(t+\Delta t)\varphi_{t+\Delta t})-(\psi_t,A(t+\Delta t)\varphi_{t+\Delta t}) \\ &\quad +(\psi_t,A(t+\Delta t)\varphi_{t+\Delta t})-(\psi_t,A(t)\varphi_{t+\Delta t}) \\ &\quad +(\psi_t,A(t)\varphi_{t+\Delta t})-(\psi_t,A(t)\varphi_t)]. \end{aligned}$$

If, in addition, $\varphi_t=U_t\varphi$ with $\varphi_0 \equiv \varphi \in \mathcal{D}(H)$ then the strong derivative $\dot{\varphi}_t$ of φ_t with respect to t exists and $\dot{\varphi_t}=(1/i\hbar)H\varphi_t$. But, by assumption, $H\varphi_t \in D_{A(t)}$. This, inserted in the above relative increment of $I_{\psi,\varphi}(t)$ gives, when $\Delta t \downarrow 0$, using the strong differentiability of ψ_t, φ_t, the strong continuity of $A(t)\varphi_t$ on $\mathcal{D}^A(t)$, the fact that $\varphi_{t+\Delta t} \in \mathcal{D}^A(t)$ and that $A(t)$ is weakly differentiable on $\mathcal{D}^A(t)$,

$$\lim_{\Delta t\downarrow 0} I_{\psi,\varphi}(t,\Delta t) = (\dot{\psi}_t,A(t)\varphi_t)+\dot{\varepsilon_t^A}(\psi_t,\varphi_t)+(\psi_t,A(t)\dot{\varphi}_t).$$

By (2.2), the corresponding equation for φ_t and the further assumption $\mathcal{D}^A(t) \supset H\mathcal{D}_H$, we see that the latter relation can be rewritten as

$$\lim_{\Delta t\downarrow 0} I_{\psi,\varphi}(t,\Delta t) = \left(\frac{1}{i\hbar}H\psi_t,A(t)\varphi_t\right)+\dot{\varepsilon_t^A}(\psi_t,\varphi_t)+\left(\psi_t,\frac{1}{i\hbar}A(t)H\varphi_t\right).$$

Since $A(t)\mathcal{D}_H \subset \mathcal{D}_H$ by assumption, and so $A(t)\varphi_t \in \mathcal{D}_H$, this reduces, by the self-adjointness of H, to

$$\frac{1}{i\hbar}(\psi_t,[A(t),H]\varphi_t)+\dot{\epsilon_t^A}(\psi_t,\varphi t)=\frac{d}{dt}(\psi_t,A(t)\varphi_t), \tag{2.3}$$

where we used the definitions of $I_{\psi,\varphi}(t,\Delta t)$, $I_{\psi,\varphi}(t)$, and $\dot{\epsilon_t^A}(\psi_t,\varphi_t)$.

We shall denote by $\varepsilon_D(\psi_t,\varphi_t)$ the sesquilinear form on left-hand side (lhs) of (2.3). So

$$\varepsilon_D(\psi_t,\varphi_t)=\frac{d}{dt}(\psi_t,A(t)\varphi_t). \tag{2.4}$$

We recall that for $T>t\geq 0$, $\varepsilon_D(\psi_t,\varphi_t)$ is well defined if $\varphi_t \in \mathcal{D}^A(t)$ and $A(t)\mathcal{D}_H \subset \mathcal{D}_H$.

Definition II.1: Let φ be in $\mathcal{H}$ and such that $\varphi_t \in \mathcal{D}_{A(t)}$. The complex-valued space–time observable $a_{\varphi_t}^A(x,t)$ associated with the family of quantum observable $A(t)$ in the state φ_t is defined

for all $x \in \mathbb{R}^n, t \in \mathbb{R}, s.t. \varphi_t(x) \neq 0$, *by*

$$a^A_{\varphi_t}(x,t) \equiv \frac{(A(t)\varphi_t)(x)}{\varphi_t(x)}. \tag{2.5}$$

We shall consider, for any x,t, versions of $\varphi_t(x)$ jointly measurable in $t \in \mathbb{R}$, $x \in \mathbb{R}^n$, and denote them again by $\varphi_t(x)$. For x,t such that $\varphi_t(x)=0$ we set $a^A_{\varphi_t}(x,t) \equiv 0$. Therefore, for any ψ_t in $\mathcal{H}$ and φ_t in $\mathcal{D}_{A(t)}$ we have

$$(\psi_t, A(t)\varphi_t) = \int_{(N_t^\varphi)^c} \bar{\psi}_t A(t)\varphi_t \, \mathrm{d}x + \int_{N_t^\varphi} \bar{\psi}_t A(t)\varphi_t \, \mathrm{d}x = \int_{(N_t^{\dot{\varphi}})^c} \bar{\psi}_t A(t)\varphi_t \, \mathrm{d}x,$$

where $\mathcal{N}_t^\varphi = \{x \in \mathbb{R}^n \,|\, \varphi_t(x)=0\}, (N_t^\varphi)^c = \mathbb{R}^n - N_t^\varphi$.

Using (2.5), it is clear that, by construction,

$$(\psi_t, A(t)\varphi_t) = \int \bar{\psi}_t \varphi_t a^A_{\varphi_t} \, \mathrm{d}x. \tag{2.6}$$

Assumption on the zeroes of the wave function

We shall need that $\mathcal{N}_t^\varphi$ has zero Lebesgue measure. Sufficient conditions for this are known in terms of assumption on H. See Sec. V.

Using (2.3) and (2.4) and our assumption that $\mathcal{N}_t^\varphi$ has zero Lebesgue measure, we get

$$\varepsilon_D(\psi_t,\varphi_t) = \frac{1}{i\hbar}(\psi_t,[A(t),H]\varphi_t) + \varepsilon_t^{\dot{A}}(\psi_t,\varphi_t) = \frac{1}{i\hbar}\int_{(N_t^\varphi)^c} \bar{\psi}_t \varphi_t \frac{1}{\varphi_t}[A(t),H]\varphi_t \, \mathrm{d}x + \varepsilon_t^{\dot{A}/\varphi_t}(\psi_t\bar{\varphi}_t, \varphi_t), \tag{2.7}$$

where we have defined $\varepsilon_t^{\dot{A}/\varphi_t}$, for $f/\bar{\varphi}_t \in \mathcal{H}$ and $g \in \mathcal{D}^A(t)$, by

$$\varepsilon_t^{\dot{A}/\varphi_t}(f,g) \equiv \lim_{\Delta t \downarrow 0}\left(f, \frac{1}{\varphi_t}\left[\frac{A(t+\Delta t)-A(t)}{\Delta t}\right]g\right).$$

Now suppose that, in the strong sense on $\mathcal{D}^A(t)$, there exist a linear operator $\partial A(t)/\partial t$ such that

$$\lim_{\Delta t \downarrow 0} \frac{A(t+\Delta t)-A(t)}{\Delta t}\varphi_t = \frac{\partial A}{\partial t}(t)\varphi_t, \quad 0 \leq t < T.$$

Then, for $\psi \in \mathcal{H}, \varphi_t \in \mathcal{D}^A(t)$, using the definition of $\varepsilon_t^{\dot{A}}(\psi_t,\varphi_t)$,

$$\left(\psi_t, \frac{\partial A}{\partial t}(t)\varphi_t\right) = \varepsilon_t^{\dot{A}}(\psi_t,\varphi_t).$$

Also, for any $\varphi_t \in \mathcal{D}^A(t)$,

$$\left(\frac{\partial A}{\partial t}(t) + \frac{1}{i\hbar}[A(t),H]\right)\varphi_t$$

is well defined [recall that we have assumed $H\mathcal{D}_H \subset \mathcal{D}_{A(t)}$ and $A(t)\mathcal{D}_H \subset \mathcal{D}_H$]. According to the definition (2.5), $a^A_{\varphi_t}.\varphi_t = A(t)\varphi_t$ is also well defined. Therefore in the sense of the identification of the corresponding Bochner integrals,

$$\frac{\partial}{\partial t}(a^A_{\varphi t}\cdot\varphi_t)=\frac{\partial A}{\partial t}(t)\varphi_t+\frac{1}{i\hbar}A(t)H\varphi_t,$$

for any $\varphi_t\in\mathcal{D}^A(t)$ and Lebesgue a.e. $t\in[0,T)$ [recalling our assumption that $\mathcal{D}^A(t)\supset H\mathcal{D}_H$]. From this it follows that

$$\left(\frac{\partial}{\partial t}-\frac{1}{i\hbar}H\right)(a^A_{\varphi_t}\cdot\varphi_t)$$

is well defined and coincides, for Lebesgue a.e. t, with

$$\left(\frac{\partial A}{\partial t}+\frac{1}{i\hbar}[A(t),H]\right)\varphi_t.$$

Now for any $x\in(\mathcal{N}^\varphi_t)^c$ we defined $D_t a^A_{\varphi_t}$ by

$$(D_t a^A_{\varphi_t})(x)=\frac{1}{\varphi_t}\left(\frac{\partial}{\partial t}-\frac{1}{i\hbar}H\right)(a^A_{\varphi_t}\cdot\varphi_t)(x). \tag{2.8}$$

Using the relation above, we get first on $(N^\varphi_t)^c$ but then in the $L^2(\mathbb{R}^n)$-sense

$$D_t a^A_{\varphi_t}=\frac{1}{\varphi_t}\left(\frac{\partial A}{\partial t}+\frac{1}{i\hbar}[A(t),H]\right)\varphi_t. \tag{2.9}$$

From this, for all $\psi_0=\psi\in D_H$ we obtain

$$(\psi_t,(D_t a^A_{\varphi_t})\varphi_t)=\left(\psi_t,\left(\frac{\partial A}{\partial t}+\frac{1}{i\hbar}[A(t),H]\right)\varphi_t\right)=\frac{d}{dt}(\psi_t,A(t)\varphi_t),$$

where (2.7) and (2.9) have been used. All equalities hold first for Lebesgue a.e. t but can be extended to all t if both sides of the equalities are continuous in t.

In summary, we have proved the following:

Proposition II.2:

Let H be a self-adjoint operator in $\mathcal{H}=L^2(\mathbb{R}^n,dx)$ and $A(t)$ a one-parameter family of self-adjoint operators in $\mathcal{H}$ with $A(t)\mathcal{D}_H\subset\mathcal{D}_H$ and $\mathcal{D}^A(t)\supset H\mathcal{D}_H$. For $\varphi\in\mathcal{D}_H$, consider $\varphi_t=e^{-(i/\hbar)tH}\varphi$ and assume that $\mathcal{N}^\varphi_t$ has a zero Lebesgue measure. Suppose that $\partial A(t)/\partial t$ exists in the strong sense on $\mathcal{D}^A(t)$. Define $\mathcal{D}_t a^A_{\varphi_t}$ by equations (2.8) and (2.9). *Then, for any $\varphi\in\mathcal{D}_H$ and $\psi_t\in\mathcal{D}_{A(t)}$, with ψ_t satisfying* (2.2), *we have*

$$\frac{d}{dt}(\psi_t,A(t)\varphi_t)=(\psi_t,(D_t a^A_{\varphi_t})\varphi_t), \tag{2.10}$$

for Lebesgue a.e. $t\in\mathbb{R}$. If both sides of (2.10) *are continuous in t, then* (2.10) *holds for all $t\in\mathbb{R}$.*

Corollary II.3:

If $A(t)$ is a quantum constant of motion *of the system with Hamiltonian H, defined on a dense domain $\mathcal{D}\subset\mathcal{H}$, in the sense that*

$$\left(\frac{\partial A}{\partial t}(t)+\frac{1}{i\hbar}[A(t),H]\right)\mathcal{X}=0\quad\text{for any }\mathcal{X}\in\mathcal{D},$$

then the space–time observable associated with $A(t)$ satisfies

$$D_t a^A_{\varphi_t}=0,$$

for all $\varphi_t\in\mathcal{D}^A(t)$.

Proof: By (2.9) we have $D_t a^A_{\varphi_t} = (1/\varphi_t)\dot{A}(t)\varphi_t = 0$, for

$$\dot{A}(t) \equiv \frac{\partial A}{\partial t}(t) + \frac{1}{i\hbar}[A(t), H].$$

$\dot{A}(t)$ is a closable operator since $A(t)$, $(\partial A/\partial t)(t)$ and H are all symmetric, defined on a common domain.

By approximation of $\varphi_t \in \mathcal{D}^A(t)$ through vectors in $\mathcal{D}$, and since $A(t)$ is a quantum constant of motion, we see that $\bar{\dot{A}}(t)\varphi_t = 0$, where the overbar denotes the closure. Since φ_t is in the domain of $\dot{A}(t)$, the conclusion follows. □

Remarks:

(1) If we call *quantum space–time observable* any operator-valued map $(x,t) \to g(x,t)$ measurable in the sense that $(x,t) \to (\phi, g(x,t)\varphi)$ is measurable for $\phi \in \mathcal{H}, \varphi \in \mathcal{D}$ a dense domain and $g(x,t)$ self-adjoint in $\mathcal{H}$, we can define D_t, $t \in \mathbb{R}$, on the set of such observables g by

$$D_t g \equiv \frac{1}{\varphi_t}\left(\frac{\partial}{\partial t} - \frac{1}{i\hbar}H\right)(g\varphi_t), \tag{2.11}$$

whenever the right-hand side (rhs) makes sense [with $(g\varphi_t)(x) \equiv (g(x,t)\varphi_t)(x)$]. Then, for $g = a^A_{\varphi_t}$, $D_t a^A_{\varphi_t}$ coincides with (2.9). If $g\varphi_t \in \mathcal{D}_H$, $\partial g/\partial t$ exists in the strong sense on $\mathcal{D}_H$ and $\mathcal{D}_{\partial g/\partial t} \supset \mathcal{D}_H$, then the rhs of (2.11) is well defined (for $\varphi_t \in \mathcal{D}_H$). However, we are going to show that there is a more natural definition of D_t regarded as differential operator densely defined in an associated Hilbert space.

(2) D_t, acting on space–time functions $a^A_{\varphi_t}$, for example, should not be confused with the familiar Heisenberg derivative D acting on the family of self-adjoint operators $A(t)$ and defined heuristically by

$$DA(t) = \frac{\partial A}{\partial t}(t) + \frac{1}{i\hbar}[A(t), H].$$

Indeed, according to (2.9), the relation between these two derivatives is $D_t a^A_{\varphi_t} = (1/\varphi_t)(DA(t)\varphi_t)$. In particular, Heisenberg's derivative D does not depend on the state φ_t. In order to avoid any confusion, from now on we shall call D_t the *quantum derivative* along φ_t.

(3) Consider two arbitrary observables A and H, time independent and with $\mathcal{D}_A = \mathcal{D}_H = \mathcal{D}$, a common dense domain in $\mathcal{H}$, invariant under A and H. We say that A and H commute, and write $[A,H]=0$ whenever for any f, g bounded and Borel measurable one has $f(A)g(H) - g(H)f(A) = 0$.

A necessary and sufficient condition for this property is, for example, that

$$[e^{i(\alpha/\hbar)A}, e^{i(t/\hbar)H}] = 0 \quad \forall\ \alpha,\ t \in \mathbb{R}.$$

(cf., for example, Ref. 3). If A is essentially self-adjoint on a domain $\mathcal{D}$, invariant under $e^{i(t/\hbar)H}$, $\forall t \in \mathbb{R}$, then A and H commute if

$$A(t)\chi \equiv e^{i(t/\hbar)H} A e^{-i(t/\hbar)H}\chi = A\chi, \quad \forall\ \chi \in \mathcal{D} \text{ and } t \in \mathbb{R}.$$

So it suffices indeed to show that

$$\frac{d}{dt}(\phi, e^{i(t/\hbar)H}Ae^{-i(t/\hbar)H}\chi) = \frac{d}{dt}(\phi_t, A\chi_t)$$
$$= \left(\phi_t, \frac{1}{i\hbar}[A(t), H]\chi_t\right)$$
$$= 0$$

with

$$\phi_t \equiv e^{-i(t/\hbar)H}\phi, \quad \mathcal{X}_t \equiv e^{-i(t/\hbar)H}\chi, \quad \text{and } \forall\, \chi, \phi \text{ in } \mathcal{D} = \mathcal{D}_H \cap \mathcal{D}_A,$$

in order to prove that A and H commute (in the sense of the above-mentioned sufficient condition) and therefore that $A(t)$ is a constant of motion. According to the Corollary II.3, when this holds, we have $D_t a^A_{\varphi_t} = 0$.

Lemma II.4:

Let φ_t be the solution of the Schrödinger equation (2.2) *with initial condition φ in $L^2(\mathbb{R}^n)$ and let $\mathcal{N}_t^\varphi$ be a zero Lebesgue measure set. Then the quantum derivative D_t along the solution φ_t of the Schrödinger equation* (2.2) *with initial condition φ is a densely defined differential operator in $L^2(\mathbb{R}^n, |\varphi_t(x)|^2\, dx)$.*

Proof: Let φ_t be the solution of the Schrödinger equation (2.2) with the initial condition $\varphi \in L^2(\mathbb{R}^n, dx) \equiv \mathcal{H}$ and consider the weighted Hilbert space $L^2(\mathbb{R}^n, |\varphi_t(x)|^2\, dx)$. Since, by assumption, $\mathcal{N}_t^\varphi$ has zero Lebesgue measure, the two Hilbert spaces are unitarily equivalent through the transformation

$$U_{\varphi_t}: \quad L^2(\mathbb{R}^n, |\varphi_t(x)|^2\, dx) \to L^2(\mathbb{R}^n, dx),$$
$$g \mapsto g\varphi_t.$$

Let $\mathcal{K}$ be the space of $\mathbb{R}$-indexed families of functions $f = (f^{(t)})_{t\in\mathbb{R}}$ with each $f^{(t)}$ strongly continuously differentiable from $\mathbb{R}$ into $\mathcal{H}$, such that

$$\frac{\partial}{\partial t} f^{(t)} \equiv \lim_{\Delta t \downarrow 0} \frac{f^{(t+\Delta t)} - f^{(t)}}{\Delta t} \in \mathcal{H},$$

where the limit is taken in the strong $\mathcal{H}$ sense. Let us define the partial differential operator

$$\mathcal{Q} = \frac{\partial}{\partial t} - \frac{1}{i\hbar}H$$

on the subset $\mathcal{K}_H$ of $\mathcal{K}$ consisting of those $(f^{(t)})_{t\in\mathbb{R}}$ such that the mapping $x \in \mathbb{R}^n \mapsto f^{(t)}(x)$ belongs to $\mathcal{D}_H$ for all $t \in \mathbb{R}$. We can also define the Hilbert space $W_1^2(\mathbb{R}, \mathcal{H})$, consisting of the functions $f = (f^{(t)})_{t\in\mathbb{R}}$, with $f \in \mathcal{K}$ such that $f^{(t)}(x), (\partial/\partial t) f^{(t)}(x) \in L^2(\mathbb{R}, dt)$ for dx a.e., $x \in \mathbb{R}^n$. The operator $i\mathcal{Q}$ is well defined on $\mathcal{K}_H^0 \equiv \{f^{(t)} \in \mathcal{K}_H, t \mapsto f^{(t)} \in C_0^1(\mathbb{R})\}$. This operator is symmetric in $W_1^2(\mathbb{R}^n, \mathcal{H})$, on a dense domain $\mathcal{K}_H^S \equiv \mathcal{D}_S$ (S for "Schrödinger"), independent of time.

Let $\mathcal{K}_t$ be the "tth copy" of $L^2(\mathbb{R}^n, dx)$ so that $f^{(t)} \in \mathcal{K}_t$ for any $t \in \mathbb{R}$. Let us consider the image under $U_{\varphi_t}^{-1}$ of $\mathcal{K}_t$. $U_{\varphi_t}^{-1}\mathcal{K}_t$ is made of all functions of the form $f^{(t)}(x)/\varphi_t(x)$, with $f^{(t)} \in \mathcal{K}_t$ and $(x, t) \notin \mathcal{N}_t^\varphi$.

$U_{\varphi_t}^{-1}$ can be extended to an operator $\tilde{U}_{\varphi_t}^{-1}$ from $\mathcal{K}$ into $L^2(\mathbb{R}^n, |\varphi_t(x)|^2\, dx)$, defined by

$$(\tilde{U}_{\varphi_t}^{-1} f^{(s)})(x) = \frac{f^{(s)}(x)}{\varphi_t(x)}, \quad (x,t) \notin \mathcal{N}_t^\varphi, \quad s \in \mathbb{R}.$$

Restricted to $L^2(\mathbb{R}^n, |\varphi_t(x)|^2\, dx)$, $\tilde{U}_{\varphi_t}^{-1}$ is unitary from $L^2(\mathbb{R}^n, |\varphi_t(x)|^2\, dx)$ to $L^2(\mathbb{R}^n, dx)$, since

$$\|\tilde{U}_{\varphi_t}^{-1} f^{(s)}\|_{L^2(\mathbb{R}^n,|\varphi_t(x)|^2\,\mathrm{d}x)} = \|f^{(s)}\|_{L^2(\mathbb{R}^n,\mathrm{d}x)}, \quad \forall\, s,t \in \mathbb{R},$$

and its inverse is $\tilde{U}_{\varphi_t} f^{(s)} = \varphi_t f^{(s)}$.

We can look at the image of the operator $\mathcal{Q}_t$ in $\mathcal{K}$ under $\tilde{U}_{\varphi_t}^{-1}$ as an operator $\hat{\mathcal{Q}}_t$ whose action on elements of $L^2(\mathbb{R}^n,|\varphi_t(x)|^2\,\mathrm{d}x)$ is given by $\tilde{U}_{\varphi_t}^{-1}\mathcal{Q}_t\tilde{U}_{\varphi_t} = \hat{\mathcal{Q}}_t$ on $D \subset L^2(\mathbb{R}^n,|\varphi_t(x)|^2\,\mathrm{d}x), D$ being such that $\tilde{U}_{\varphi_t} D \in \mathcal{D}_{\mathcal{Q}t}$. Since $i\mathcal{Q}_t = i\partial/\partial t - (1/\hbar)H$ is symmetric on the dense domain $\mathcal{D}_S$ of $W_1^2(\mathbb{R},\mathcal{H})$, this means that $i\mathcal{Q}_t$ is symmetric on the dense domain $\tilde{U}_{\varphi_t}^{-1}\mathcal{D}_S$ in $L^2(\mathbb{R}^n \times \mathbb{R}, \mathrm{d}x\,\mathrm{d}t)$. On this domain, $\hat{\mathcal{Q}}_t$ is given by

$$\hat{\mathcal{Q}}_t \tilde{U}_{\varphi_t}^{-1} f = \frac{1}{\varphi_t}\left(\frac{\partial}{\partial t} - \frac{1}{i\hbar}H\right) f,$$

with $f = (f^{(t)})_{t\in\mathbb{R}} \in \mathcal{D}_S$.

$\mathcal{D}_S$ contains, for example, the subset $\mathcal{D}_S^0$ consisting of all families $f = (f^{(t)})_{t\in\mathbb{R}}$ such that $f^{(t)}(\cdot)$ as well as $(\partial/\partial t) f^{(t)}(\cdot)$ are both in $C_0^\infty(\mathbb{R}^n)$ [if $\mathcal{D}_H \supset C_0^\infty(\mathbb{R}^n)$].

Setting $h = \tilde{U}_{\varphi_t}^{-1} f$ for $f \in \mathcal{D}_S^0$ we see that

$$\hat{\mathcal{Q}}_t h = \frac{1}{\varphi t}\left(\frac{\partial}{\partial t} - \frac{1}{i\hbar}H\right)(\varphi_t h).$$

Comparing with (2.11), this means that, on $\tilde{U}_{\varphi_t}^{-1}\mathcal{D}_S^0$ we have indeed

$$\hat{\mathcal{Q}}_t = D_t. \tag{2.12}$$

□

Remarks:

(1) Suppose that H is the Hamiltonian for a unit mass and charged particle in an electromagnetic field, i.e., $H = -(\hbar^2/2)[\nabla - (i/\hbar)A]^2 + V$ on $C_0^\infty(\mathbb{R}^n)$ or

$$H = -\frac{\hbar^2}{2}\Delta + i\hbar\, A\cdot\nabla + \frac{i\hbar}{2}\nabla\cdot A + \frac{1}{2}\|A\|^2 + V, \tag{2.13}$$

where $A:\mathbb{R}^n \mapsto \mathbb{R}^n$ is the vector potential and $V:\mathbb{R}^n \mapsto \mathbb{R}$ the scalar potential, both continuous, A being C^1, and such that H has a unique self-adjoint extension, also denoted by H (cf., for example, Ref. 4 for sufficient conditions such that this holds). In this case, using (2.11), we obtain explicitly a quantum derivative along φ_t (in the sense of Lemma II.4) given by

$$D_t = \frac{\partial}{\partial t} + \left(-i\hbar\,\frac{\nabla\varphi_t}{\varphi_t} - A\right)\cdot\nabla - \frac{i\hbar}{2}\Delta \tag{2.14}$$

on the domain of functions of the form $\varphi\cdot\mathcal{D}_S$, which is dense in $L^2(\mathbb{R}^n,|\varphi_t(x)|^2\,\mathrm{d}x)$. According to our Remark 1 after Corollary II.3, D_t is also defined on a larger set of functions in $L^2(\mathbb{R}^n,|\varphi_t(x)|^2\,\mathrm{d}x)$. For example, denoting by q the function

$$\begin{aligned}\mathbb{R}^n \times \mathbb{R} &\to \mathbb{R}^n, \quad \forall\, t, \quad \text{we have } D_t q = i\hbar\,\frac{\nabla\varphi_t}{\varphi_t} - A\\ (x,t) &\mapsto x\end{aligned}$$

which is well defined, provided

$$\int \bar{\varphi}_t(x)x(H\varphi_t)(x)\mathrm{d}x < \infty\,.$$

This is the case under weak restrictions on the vector and scalar potentials A and V.

(2) We shall also need the complex conjugate of the operator D_t, denoted by $\bar{D}_t$. On complex space–time observables of the form $a^A_{\varphi_t}$, one has, by definition,

$$\bar{D}_t a^A_{\bar{\varphi}_t} = \frac{1}{\bar{\varphi}_t}\left(\frac{\partial}{\partial t} + \frac{1}{i\hbar}H\right)(\bar{\varphi}_t a^A_{\bar{\varphi}_t}).$$

Proceeding as before in connection with (2.12), i.e., considering vectors h of the form $\tilde{U}^{-1}_{\bar{\varphi}_t} f$, with $f \in \mathcal{D}^0_S$, we have

$$\bar{D}_t h = \frac{1}{\bar{\varphi}_t}\left(\frac{\partial}{\partial t} + \frac{1}{i\hbar}H\right)(\bar{\varphi}_t h). \tag{2.15}$$

In particular, when the Hamiltonian H is of the form (2.13), $\bar{D}_t$ reduces on $\tilde{U}^{-1}_{\bar{\varphi}_t}\mathcal{D}^0_S$ to the differential operator

$$\bar{D}_t = \frac{\partial}{\partial t} + \left(i\hbar\frac{\nabla\bar{\varphi}_t}{\bar{\varphi}_t} - A\right)\cdot\nabla + \frac{i\hbar}{2}\Delta \tag{2.16}$$

defined on the elements $\{\tilde{U}^{-1}_{\bar{\varphi}_t}\mathcal{D}^0_S\}_{t\in\mathbb{R}}$ of $W^2_1(\mathbb{R}^n,\mathcal{H})$. These elements form a dense domain of $W^2_1(\mathbb{R}^n,\mathcal{H})$, as discussed in the proof of the Lemma II.4. Using the terminology introduced there, $\bar{D}_t$ will simply be called the *quantum derivative along* $\bar{\varphi}_t$.

(3) It follows clearly from (2.11) and (2.15) that

$$\overline{D_t g} = \bar{D}_t \bar{g},$$

where the lhs denotes the complex conjugate of $D_t g$.

Motivated by Born's probabilistic interpretation of the wave function, let us introduce the natural definition.

Definition II.5: Let $f=(f^{(t)})_{t\in\mathbb{R}}$, *with* $f^{(t)}(\cdot)$ *in* $L^1(\mathbb{R}^n,|\varphi_t(x)|^2\,\mathrm{d}x)$ *and* $f^{(t)}$ *measurable in* t. *The* quantum (absolute) expectation of f in the state φ_t *solving* (2.1), *denoted by* $\langle f\rangle_{\varphi_t}$, *is the integral*

$$\langle f\rangle_{\varphi_t} = \int f^{(t)}(x)|\varphi_t(x)|^2\,\mathrm{d}x \tag{2.17}$$

and we shall refer to $|\varphi_t(x)|^2$ *as the density* (*with respect to* $\mathrm{d}x$) *of the quantum probability in the state* φ_t.

The terminology chosen for D_t and $\bar{D}_t$ is due to the crucial observation that, under this quantum expectation, these differential operators behave like derivations.

Proposition II.6:

Let $f=(f^{(t)})_{t\in\mathbb{R}}$, $g=(g^{(t)})_{t\in\mathbb{R}}$ *be in the domains of the quantum derivatives* D_t *and* $\bar{D}_t$ *and with compact support in the space variables. Then* $\langle f\cdot g\rangle_{\varphi_t}$ *is differentiable with respect to the time variable and the following Leibniz rule holds:*

$$\frac{d}{\mathrm{d}t}\langle f\cdot g\rangle_{\varphi_t} = \langle D_t f\cdot g + f\cdot\bar{D}_t g\rangle_{\varphi_t}. \tag{2.18}$$

In particular,

$$\frac{d}{\mathrm{d}t}\langle f\rangle_{\varphi_t} = \langle D_t f\rangle_{\varphi_t} = \langle \bar{D}_t f\rangle_{\varphi_t}. \tag{2.19}$$

Corollary II.7:

If f, g *have supports with respect to the time variable strictly contained in the interior of an interval* $[t_0,t_1]$ *for some* $t_0,t_1\in\mathbb{R}$, *then* $\mathcal{D}^+_t=-\bar{D}_t$ *where* $^+$ *denotes the adjoint with respect to* $|\varphi_t(x)|^2\,\mathrm{d}x\,\mathrm{d}t$ *on* $\mathbb{R}^n\times[t_0,t_1]$.

Proof: Integrating (2.18), we obtain

$$\int_{t_0}^{t_1} \langle D_t f \cdot g \rangle_{\varphi_t} \, \mathrm{d}t = - \int_{t_0}^{t_1} \langle f \cdot \bar{D}_t g \rangle_{\varphi_t} \, \mathrm{d}t.$$

□

Proof of Proposition II.6: By definition, $(d/\mathrm{d}t)\langle f \cdot g \rangle_{\varphi_t}$ denotes

$$\lim_{\Delta t \downarrow 0} \frac{\langle f^{(t+\Delta t)} g^{(t+\Delta t)} \rangle_{\varphi_{t+\Delta t}} - \langle f^{(t)} g^{(t)} \rangle_{\varphi_t}}{\Delta t}.$$

The term under $\lim_{\Delta t \downarrow 0}$ means explicitly

$$\begin{aligned}
&\frac{1}{\Delta t}\left[\int f^{(t+\Delta t)} g^{(t+\Delta t)} |\varphi_{t+\Delta t}(x)|^2 \, \mathrm{d}x - \int f^{(t)} g^{(t)} |\varphi_t(x)|^2 \, \mathrm{d}x \right] \\
&\quad = \frac{1}{\Delta t}\left[\int (f^{(t+\Delta t)} - f^{(t)}) g^{(t+\Delta t)} |\varphi_{t+\Delta t}(x)|^2 \, \mathrm{d}x \right. \\
&\qquad + \int f^{(t)} (g^{(t+\Delta t)} - g^{(t)}) |\varphi(x)_{t+\Delta t}|^2 \, \mathrm{d}x \\
&\qquad \left. + \int f^{(t)} g^{(t)} (|\varphi_{t+\Delta t}(x)|^2 - |\varphi_t(x)|^2) \mathrm{d}x \right].
\end{aligned}$$

The first term on the rhs converges, when $\Delta t \downarrow 0$, to $\int (\dot{f}^{(t)} g^{(t)})(x) \, |\varphi_t(x)|^2 \, \mathrm{d}x$ by the dominated convergence theorem and the hypothesis that $f^{(t)}$ is strongly differentiable in $L^2(\mathbb{R}^n, \mathrm{d}x)$ [here we denote $(\partial/\partial t) f^{(t)}$ by $\dot{f}^{(t)}$ for simplicity]. Similarly we see that the second term of the rhs converges to $\int f^{(t)} \dot{g}^{(t)} |\varphi_t(x)|^2 \, \mathrm{d}x$.

For the third term we use again the dominated convergence theorem and the fact that, in the strong $L^2(\mathbb{R}^n, \mathrm{d}x)$ sense,

$$\frac{d}{\mathrm{d}t} |\varphi_t|^2 = \frac{d}{\mathrm{d}t} \bar{\varphi}_t \cdot \varphi_t = - \frac{1}{i\hbar} H \bar{\varphi}_t \cdot \varphi_t + \dot{\bar{\varphi}}_t \frac{1}{i\hbar} H \varphi_t,$$

where the Schrödinger equation has been used, together with the fact that $\dot{\bar{\varphi}}_t \cdot H\varphi_t$ as well as $H\bar{\varphi}_t \cdot \varphi_t$ are in $L^1(\mathbb{R}^n, \mathrm{d}x)$ and $f^{(t)}, g^{(t)}$ have compact support as functions of the space variable. In other words the rhs above becomes

$$\begin{aligned}
&\int \left\{ \dot{f}^{(t)} g^{(t)} + f^{(t)} \dot{g}^{(t)} + f^{(t)} g^{(t)} \left(\frac{1}{i\hbar} \frac{H\varphi_t}{\varphi_t} - \frac{1}{i\hbar} \frac{H\bar{\varphi}_t}{\bar{\varphi}_t} \right) \right\} (x) |\varphi_t(x)|^2 \, \mathrm{d}x \\
&\quad = \int (D_t f^{(t)} \cdot g^{(t)} + f^{(t)} \bar{D}_t g^{(t)})(x) |\varphi_t(x)|^2 \, \mathrm{d}x,
\end{aligned}$$

where the definition of $D_t, \bar{D}_t$ have been used together with the self-adjointness of H, in order to simplify the term involving $H(f^{(t)}\varphi_t)$.

The second part of the calculation follows from the first one by approaching in the $L^2(\mathbb{R}^n, |\varphi_t(x)|^2 \, \mathrm{d}x)$-norm $f^{(t)} = 1$, respectively, $g^{(t)} = 1$ through $C_0^\infty(\mathbb{R}^n)$ functions. □

Remarks:

(1) When the Hamiltonian H is of the explicit form (2.13), the relation (2.18) can be given a more illuminating form if we use exclusively one of the quantum derivatives,

$$\frac{d}{dt}\langle f\cdot g\rangle_{\varphi_t}=\langle (D_tf)\cdot g+f(D_tg)\rangle_{\varphi_t}-i\hbar\,\langle \nabla f\cdot\nabla g\rangle_{\varphi_t} \tag{2.20}$$

$$=\langle (\bar{D}_tf)\cdot g+f(\bar{D}_tg)\rangle_{\varphi_t}+i\hbar\,\langle \nabla f\cdot\nabla g\rangle_{\varphi_t}. \tag{2.21}$$

Proof: This follows directly from Proposition II.6, using the explicit expressions (2.14) and (2.16) of D_t and $\bar{D}_t$ available for the Hamiltonian (2.13). □

(2) Relations like (2.20) and (2.21) hold, in fact, also without integration with respect to $|\varphi_t(x)|^2\,dx$.

Proposition II.8:

For f,g in a dense domain of the form $\varphi_t\cdot\mathcal{D}_S\subset L^2(\mathbb{R}^n,|\varphi_t(x)|^2\,dx)$ (cf. Lemma II.4) and an Hamiltonian of the form (2.13), *one has*

$$D_t(f\cdot g)=(D_tf)\cdot g+f(D_tg)-i\hbar\,\nabla f\cdot\nabla g, \tag{2.20′}$$

$$\bar{D}_t(f\cdot g)=(\bar{D}_tf)\cdot g+f(\bar{D}_tg)+i\hbar\,\nabla f\cdot\nabla g, \tag{2.21′}$$

for any (t,x) such that $\varphi_t(x)\neq 0$.

Proof: Equations (2.20) and (2.21) can be written, for any $\varphi_t=U_t\varphi$, and any (t,x) s.t. $\varphi(t,x)\neq 0, \int A(x,t)|\varphi_t(x)|^2\,dx=0$ with $A(x,t)=\bar{D}(f\cdot g)-(\bar{D}_tf)g-f(\bar{D}_tg)-i\hbar\nabla f\cdot\nabla g$, and so equations (2.20′) and (2.21′) hold a.e. with respect to dx. Alternatively, one can use directly the definitions (2.14) and (2.16) to show that the conclusion holds. □

Equations (2.20′) and (2.21′) show that the quantum derivatives behave, in fact, like quantum *deformations* of derivatives in the (commutative) algebra of families of functions $f=(f^{(t)})_{t\in\mathbb{R}}$ with $f^{(t)}\in C_0(\mathbb{R}^n)$. To regard D_t and $\bar{D}_t$ as quantum deformations of derivations will prove, later on, to be a very natural interpretation.

Now we are going to introduce the quantum counterpart of the probabilistic concept of conditional expectation given a space point $x\in\mathbb{R}^n$ in the past time $t\geq 0$.

Definition II.9:

Let $g=(g^{(\tau)})_{\tau\in\mathbb{R}}$ be complex valued, measurable functions defined on $\mathbb{R}^n$ and such that $g^{(\tau)}\times(\cdot)\psi_\tau(\cdot)\in L^2(\mathbb{R}^n,dx)$ where, as before, $\psi_\tau=U_\tau\psi$. For $0\leq t\leq\tau$ and (t,x) such that $\psi_t(x)\neq 0$ [or, for short, (t,x) "ψ-admissible"] let us define the quantum conditional expectation $M^{\psi}_{t,x}$ in the state ψ, given (t,x) and evaluated at $g^{(\tau)}$ *by*

$$M^{\bar{\psi}}_{t,x}[g^{(\tau)}]=(\bar{\psi}_t(x))^{-1}(U_{\tau-t}(g^{(\tau)}\bar{\psi}_\tau))(x). \tag{2.22}$$

Let us first assume that the Hamiltonian H is time-independent and that the evolution group $U_{\tau-t}$ has an integral kernel, denoted by

$$k(x,\tau-t,q)=(e^{-(i/\hbar)(\tau-t)H})(x,q),\quad x,q\in\mathbb{R}^n,\ \tau>t.$$

Then the definition (2.22) means

$$M^{\bar{\psi}}_{t,x}[g^{(\tau)}]=(\bar{\psi}_t(x))^{-1}\int k(x,\tau-t,q)g^{(\tau)}(q)\bar{\psi}_\tau(q)dq, \tag{2.22′}$$

which is well defined for any ψ-admissible $(t,x)\in\mathbb{R}^+\times\mathbb{R}^n$. We shall denote by

$$\hat{p}(t,x,\tau,dq)=(\bar{\psi}_t(x))^{-1}k(x,\tau-t,q)\bar{\psi}_\tau(q)dq,\quad t\leq\tau,\ x,q\in\mathbb{R}^n, \tag{2.23}$$

the integral kernel associated with (2.22′) and refer to it as the *forward quantum transition* kernel ["forward" because the conditioning x is in the past $t\leq\tau$ and also because the initial quantum

probability density $|\psi_t(x)|^2$ is propagated towards the future by $\hat{p}$]. More precisely since, for $\tau > t$ the kernel $k(x,\tau-t,q)$ coincides with the retarded (or "casual") propagator

$$k_+(x,\tau-t,q) = \theta(\tau-t)(e^{-(i/\hbar)(\tau-t)H})(x,q),$$

(where θ is Heaviside's distribution) i.e., the distribution solving

$$\left(-i\hbar\frac{\partial}{\partial\tau}+H\right)k_+(x,\tau-t,q) = -i\hbar\,\delta(q-x)\delta(\tau-t),$$

Eq. (2.23) means that

$$\hat{p}(t,x,\tau,\mathrm{d}q) = (\bar{\psi}_t(x))^{-1}k_+(x,\tau-t,q)\bar{\psi}_\tau(q)\mathrm{d}q. \tag{2.23′}$$

Let us observe that sufficient conditions for the existence of k and therefore $\hat{p}$ as continuous functions in all the variable are known; cf., e.g., Refs. 5, 6, and 60.

We remark that when H is time dependent, Eq. (2.23) still holds with k replaced by the integral kernel of the two-parameter family of unitary operators $U(t,\tau)$, $t,\tau\in\mathbb{R}$ defining the corresponding time evolution.

The main properties of the quantum conditional expectation of Definition 2.9 are expressed by the following:

Proposition II.10:

For all ψ-admissible $(t,x)\in\mathbb{R}\times\mathbb{R}^n$ and $g=(g^{(\tau)})_{\tau\in\mathbb{R}}$ as in (2.22′), *with $\tau\geq t$,*

(1) *the quantum mechanical conditional expectation is linear*: *if $\alpha_i\in\mathbb{C}$ and $g_i=(g_i^{(\tau)})_{\tau\in\mathbb{R}}$, $i=1,2$ as above*,

$$M^{\bar{\psi}}_{t,x}[\alpha_1 g_1^{(\tau)}+\alpha_2 g_2^{(\tau)}] = \alpha_1 M^{\bar{\psi}}_{t,x}[g_1^{(\tau)}]+\alpha_2 M^{\bar{\psi}}_{t,x}[g_2^{(\tau)}];$$

(2) $M^{\bar{\psi}}_{t,x}[\alpha]=\alpha,\ \alpha\in\mathbb{C}$;

(3) $M^{\bar{\psi}}_{t,x}[g^{(\tau)}]=g^{(t)}(x),\ \tau\geq t$;

(4) $\langle M^{\bar{\psi}}_t[g^{(\tau)}]\rangle_{\psi_\tau}=\langle g^{(\tau)}\rangle_{\psi_\tau},\ \tau\geq t$;

(5) *when $M^{\bar{\psi}}_{s,x}[g_1^{(s)}g_2^{(t)}]$, $s\leq t$, is well defined, then*

$$M^{\bar{\psi}}_{s,x}[g_1^{(s)}g_2^{(t)}] = g_1^{(s)}(x)M^{\bar{\psi}}_{s,x}[g_2^{(t)}].$$

Proof: This follows from direct computations using the definitions (2.17) and (2.22). □

Remarks:

(1) We shall also need, for the same class of $g=(g^{(\tau)})_{\tau\in\mathbb{R}}$ as in Proposition II.10, and any ψ-admissible $(t,x)\in\mathbb{R}\times\mathbb{R}^n$, the definition (2.22) with ψ replaced by $\bar{\psi}$ and $U_{\tau-t}$ replaced by $U_{\tau-t}$, $0<\tau\leq t$, i.e.,

$$M^{t,x}_{\psi}[g^{(\tau)}] = (\psi_t(x))^{-1}(U_{t-\tau}(g^{(\tau)}\psi_\tau))(x). \tag{2.24}$$

The properties of $M^{t,x}_{\psi}$ are, of course, similar to the ones of $M^{\bar{\psi}}_{t,x}$.

Let us stress that, for the latter quantum conditional expectation in the state ψ, the conditioning x is lying in the future of the time interval under consideration [i.e., $t\geq\tau$; this justifies our alteration of notation with respect to (2.22)]. For this reason, we shall occasionally call backward (respectively, forward) the conditional expectation (2.24) [respectively (2.22)] when a confusion is possible between these two concepts. When needed, we shall denote by $p(\tau,\mathrm{d}q,t,x)$ the *backward quantum transition* kernel associated with (2.24), i.e.,

$$p(\tau,\mathrm{d}q,t,x) = \psi_\tau(q)k_-(q,t-\tau,x)(\psi_\tau(x))^{-1}\,\mathrm{d}q,\quad \tau\leq t, \tag{2.25}$$

for any (t,x) ψ-admissible. Here, we denote by k_- the advanced propagator defined in terms of the causal one by

$$k_-(x_1,s-u,x_2)=\overline{k_+(x_2,u-s,x_1)}. \tag{2.26}$$

(2) Comparing the definitions (2.23′) and (2.25), it is clear that the relation between the forward and backward quantum transition kernels can be expressed as

$$\overline{\hat{p}(t,x,s,y)}=p(s,y,t,x), \quad s\le t,\ x,y\in\mathbb{R}^n. \tag{2.27}$$

Definition II.11:

Let $f=(f^{(t)})_{t\in\mathbb{R}}$, $(g^{(s)})_{s\in\mathbb{R}}$ *as in the definitions* (2.22′) and (2.23). *The* quantum (absolute) expectation of their product $f^{(t)}\cdot g^{(s)}$ *in the state* ψ, *for* $t\ge s$, *is defined by*

$$\langle f^{(t)}g^{(s)}\rangle_\psi=\langle M^{\bar{\psi}}_{s,\cdot}[f^{(t)}]\cdot g^{(s)}\rangle_{\psi_s} \tag{2.28}$$

$$=\langle f^{(t)}M^{t,\cdot}_{\psi}[g^{(s)}]\rangle_{\psi_t}, \tag{2.28′}$$

when $M^{\bar{\psi}}_{s,\cdot}[f^{(t)}]\cdot g^{(s)}\in L^2(|\psi_s(x)|^2\,\mathrm{d}x)$ *and* $f^{(t)}M^{t,\cdot}_{\psi}[g^{(s)}]\in L^2(|\psi_t(q)|^2\,\mathrm{d}q)$.

The consistency of this definition is verified by observing that equation (2.28) reduces, after simplification, to

$$\int\int \psi_s(x)g^{(s)}(x)k(x,t-s,q)f^{(t)}(q)\bar{\psi}_t(q)\mathrm{d}q\,\mathrm{d}x,$$

when the integral kernel (2.23′) exists (since $t\ge s$). On the other hand, using the forward conditional expectation of (2.28′), this absolute expectation in the state ψ_t reduces to

$$\int\int \psi_s(x)g^{(s)}(x)k_-(x,t-s,q)f^{(t)}(q)\bar{\psi}_t(q)\mathrm{d}q\,\mathrm{d}x,$$

i.e., to the same expression as before, by definition of the advanced propagator k_- when $t\ge s$.

This duality with respect to the time parameter suggests to introduce the following two-parameters family of operators $P^*_{s,t}, s\le t$ associated with quantum conditional expectations:

$$\begin{aligned} &P^*_{s,t}:L^2(|\psi_s(x)|^2\,\mathrm{d}x)\to L^2(|\psi_t(q)|^2\,\mathrm{d}q)\\ &g^{(s)}(\cdot)\mapsto\int g^{(s)}(x)p(s,\mathrm{d}x,t,q)\equiv M^{t,q}_{\psi}[g^{(s)}], \end{aligned} \tag{2.29}$$

where the backward transition kernel (2.25) has been introduced and its "time reversed" family $P_{t,s}$, $s\le t$,

$$\begin{aligned} &P_{t,s}:L^2(|\psi_t(q)|^2\,\mathrm{d}q)\to L^2(|\psi_s(x)|^2\,\mathrm{d}x),\\ &f^{(t)}(\cdot)\mapsto\int f^{(t)}(q)\hat{p}(s,x,t,\mathrm{d}q)\equiv M^{\bar{\psi}}_{s,x}[f^{(t)}], \end{aligned} \tag{2.29′}$$

so that the equality between (2.28) and (2.28′) can be rewritten as

$$\langle(P_{t,s}f^{(t)})\cdot g^{(s)}\rangle_{\psi_s}=\langle f^{(t)}\cdot(P^*_{s,t}g^{(s)})\rangle_{\psi_t}. \tag{2.30}$$

The properties of the operators $P^*_{s,t}$ (or $P_{t,s}$) for $s\le t$ are as follows:

(a) $P^*_{s,t}$ are linear operators; as a map from $\mathbb{R}_+\times\mathbb{R}_+$ into densely defined, bounded operators from $L^2(|\psi_s(x)|^2\,\mathrm{d}x)$ into $L^2(|\psi_t(q)|^2\,\mathrm{d}q)$, $(s,t)\mapsto P^*_{s,t}$ is continuous;

(b) $\|P^*_{s,t}g^{(s)}\|_{L^2(|\psi_t(q)|^2\,dq)}=\|g^{(s)}\|_{L^2(|\psi_s(x)|^2\,dx)}$;
(c) $P^*_{s,t}1_{(s)}=1_{(t)}$ where $1_{(s)}$ is the function identically 1 in $L^2(|\psi_s(x)|^2\,dx)$ [with $1_{(t)}$ the same in $L^2(|\psi_t(q)|^2\,dq)$] and $P_{t,s}1_{(t)}=1_{(s)}$;
(d) $P^*_{s,s}=\mathrm{Id}$, the identity operator from $L^2(|\psi_s(x)|^2\,dx)$ into $L^2(|\psi_s(x)|^2\,dx)$;
(e) $P^*_{t,u}\cdot P^*_{s,t}=P^*_{s,u}$, $\quad s\le t\le u$;
(f) $P^*_{s,t}\cdot P_{t,s}=1_{(t)}$ and $P_{t,s}\cdot P^*_{s,t}=1_{(s)}$.

We may summarize the situation as follows:

Proposition II.12:

The two-parameters family of bounded operators $P^*_{s,t}$ and $P_{t,s}$ are dual from $L^2(|\psi_s(x)|^2\,dx)$ into $L^2(|\psi_t(q)|^2\,dq)$ in the sense that for any $f^{(t)}\in\mathcal{D}_{P_{t,s}}$ and $g^{(s)}\in\mathcal{D}_{P^*_{s,t}}$, the relation (2.30) *holds. Moreover, the properties* (*a*) *to* (*f*) *are satisfied* [*where* (*a*) *to* (*e*) *have their natural counterparts for $P_{t,s}$*].

The proof follows directly from the definitions (2.23′) and (2.25) of the forward and backward quantum transition kernels.

Remarks:

(1) Let $f^{(s)}(\cdot)$ be non-negative in $L^2(|\psi_s(x)|^2\,dx)$. Then, clearly $P^*_{s,t}$ does not, in general, transform $f^{(s)}(\cdot)$ into a non-negative element of $L^2(|\psi_t(q)|^2\,dq)$ since the backward quantum transition kernel p is not even real. In particular, $p(s,\cdot,t,q)$ is not a measure, although it shares manifestly a number of properties with probability measures.
(2) The equality between (2.28) and (2.28′) can be rewritten infinitesimally using the quantum derivatives D_t and $\bar{D}_t$. To do this, we need another property of these derivatives, which will be the first result of the next section.

Let $P^*_{s,t}$ and $P_{t,s}$ a pair of 2-parameters family of operators satisfying the properties of Proposition II.12 and $p,\bar{p}$, respectively, their associated quantum transition kernels.

Definition II.13:

The two dual kernels define a quantum diffusion if $\forall s<t, x\in\mathbb{R}^n, \varepsilon>0$, we have

(1) $\hat{p}(s,x,t,S_\varepsilon(x)^c)=o(t-s)$, *where $S_\varepsilon(x)^c$ is the complement of the sphere $S_\varepsilon(x)$ of radius ε and center x.*
(2) *There is a $\mathbb{C}^n$-valued function $\hat{B}(x,s)$ s.t.,*

$$\int_{S_\varepsilon(x)}(q-x)\hat{p}(s,x,t,dq)=\hat{B}(x,s)(t-s)+o(t-s).$$

There is an $n\times n$ complex-valued function $\hat{C}(x,s)$ s.t.

$$\int_{S_\varepsilon(x)}(q-x)(q-x)^T\hat{p}(s,x,t,dq)=\hat{C}(x,s)(t-s)+o(t-s).$$

$\hat{C}$ will be called the quantum diffusion matrix *and $\hat{B}$ the* (forward) drift of the quantum diffusion.

(3) *There is a $\mathbb{C}^n$-valued function $B(x,t)$ s.t.*

$$\int_{S_\varepsilon(x)}(q-x)p(s,dx,t,q)=B(q,t)(t-s)+o(t-s),$$

and an $n\times n$ complex-valued function $C(x,s)$ s.t.

$$\int_{S_\varepsilon(x)}(q-x)(q-x)^Tp(s,dx,t,q)=C(q,t)(t-s)+o(t-s).$$

These properties are satisfied, e.g., for the kernels associated with the Hamiltonians (2.13) Compare also Refs. 5 and 6. Indeed we have the following.

Proposition II.14:

Let H be of the form (2.13) *and its associated kernel k be such that*

$$\lim_{\Delta s \downarrow 0} \frac{1}{\Delta s} \int (q-x) R(q,x,\Delta s) k(x,\Delta s,q) \mathrm{d}q = 0,$$

where $R(q,x,\Delta s)=0((q-x)^2)+0(\Delta s)^2$ *is a term in the Taylor expansion of the integrand of* $\hat{B}(x,s)$ *in the proof below. Let* $(q,t) \in \mathbb{R}^n \times \mathbb{R}$ *be* ψ*-admissible, where* ψ_t *is a regular solution of the Schrödinger equation for H, admitting a Taylor expansion in powers of the space and time variables around* $\psi_t(q)$. *Then a quantum diffusion corresponds to this solution, whose drifts and diffusion matrix are, respectively, given by*

$$\hat{B}(q,t) = i\hbar \frac{\nabla \bar{\psi}_t}{\bar{\psi}_t}(q) - A(q),$$

$$B(q,t) = -i\hbar \frac{\nabla \psi_t}{\psi_t}(q) - A(q), \tag{2.31}$$

$$C(q,t) = \hat{C}(q,t) = i\hbar \mathbb{1},$$

where $\mathbb{1}$ *denotes the* $n \times n$ *identity matrix.*

Proof: By (3) and (2.23),

$$\begin{aligned}
\hat{B}(x,s) &= \lim_{\Delta s \downarrow 0} \frac{1}{\Delta s} \int_{s_\varepsilon(x)} (q-x) \hat{p}(s,x,s+\Delta s,q) \mathrm{d}q \\
&= \lim_{\Delta s \downarrow 0} \frac{1}{\Delta s} \int_{s_\varepsilon(x)} (q-x) (\bar{\psi}_s(x))^{-1} k(x,\Delta s,q) \bar{\psi}_{s+\Delta s}(q) \mathrm{d}q \\
&= \lim_{\Delta s \downarrow 0} \frac{1}{\Delta s} \int_{s_\varepsilon(x)} (q-x) \left[1 + \frac{\nabla \bar{\psi}_s}{\bar{\psi}_s}(x)(q-x) + \frac{\dot{\bar{\psi}}_s}{\bar{\psi}_s}(x)\Delta s + O((q-x)^2) + O(\Delta s^2) \right] k(x,\Delta s,q) \mathrm{d}q.
\end{aligned}$$

We can easily verify the following properties of the integral kernel $k(x,\tau,q)$ of the evolution group U_τ for the Hamiltonian (2.13):

$$\lim_{\tau \downarrow 0} \frac{1}{\tau} \left[1 - \int_{\mathbb{R}^n} k(x,\tau,q) \mathrm{d}q \right] = \frac{1}{2} \nabla \cdot A(x) + \frac{i}{2\hbar} \|A(x)\|^2 + \frac{i}{\hbar} V(x),$$

$$\lim_{\tau \downarrow 0} \frac{1}{\tau} \int_{\mathbb{R}^n} (q-x) k(x,\tau,q) \mathrm{d}q = A(x),$$

$$\lim_{\tau \downarrow 0} \frac{1}{\tau} \int_{\mathbb{R}^n} (q-x)(q-x)^T k(x,\tau,q) \mathrm{d}q = i\hbar \mathbb{1}.$$

Using these in the above rhs of the expression of $\hat{B}(x,s)$ we obtain the expected result. The other results follow in a similar way. □

Proposition II.15:

Let $\nabla \psi_t / \psi_t$ *and* $A(q)$ *be given and continuous, for a Hamiltonian of the form* (2.13). *Assume*

that, in the representations (2.29) and (2.29′), *the partial derivatives with respect to* (t,q) [*respectively* (s,x)] *of the quantum conditional expectations are well defined and continuous, and can be exchanged with the integrals. Then the quantum equation of Kolmogorov for the transition kernel* $\hat{p}$ *for* $s \leq t \in \mathbb{R}$, $x,y \in \mathbb{R}^n$, *is given by*

(a)

$$-\frac{\partial \hat{p}}{\partial s}(s,x,t,q) = \frac{i\hbar}{2}\frac{\partial^2 \hat{p}}{\partial x^j\, \partial x^j}(s,x,t,q) + \left(i\hbar\, \frac{\nabla^j \bar{\psi}_t}{\bar{\psi}_t}(q) - A^j(q) \right) \frac{\partial}{\partial x^j}\hat{p}(s,x,t,q) \tag{2.32}$$

(*with the usual summation convention over the indices j*). *Equivalently, regarded as a function of the past variable,* $\hat{p}$ *is the fundamental solution of*

$$\bar{D}_s u = 0, \quad for \quad u \in \mathcal{D}_{\bar{D}_s}, \tag{2.33}$$

with $\bar{D}_s$ *defined in* (2.16).

(b) *If all the involved partial derivatives exist and are continuous,* $\hat{p}$, *regarded as a function of the future variables, solves the quantum Fokker-Planck equation*

$$\frac{\partial \hat{p}}{\partial t}(s,x,t,q) = \frac{i\hbar}{2}\frac{\partial^2 \hat{p}}{\partial q^j\, \partial q^j}(s,x,t,q) - \frac{\partial}{\partial q^j}\left[\left(i\hbar\, \frac{\nabla^j \bar{\psi}_t}{\bar{\psi}_t}(q) - A^j(q) \right) \hat{p}(s,x,t,q) \right]. \tag{2.34}$$

Similarly, the transition kernel $p(s,x,t,q)$ *solves*

(c)

$$-\frac{\partial p}{\partial s}(s,x,t,q) = -\frac{i\hbar}{2}\frac{\partial^2 p}{\partial x^j\, \partial x^j}(s,x,t,q) + \left(-i\hbar\, \frac{\nabla^j \psi_t}{\psi_t}(q) - A^j(q) \right) \frac{\partial}{\partial x^j} p(s,x,t,q). \tag{2.35}$$

So that p *is the fundamental solution of*

$$D_s v = 0 \quad for \quad v \in \mathcal{D}_{D_s}, \tag{2.36}$$

with D_s *given by* (2.14) *and the following backward quantum Fokker-Planck equation holds*:

(d)

$$\frac{\partial p}{\partial t}(s,x,t,y) = -\frac{i\hbar}{2}\frac{\partial^2 p}{\partial q^j\, \partial q^j}(s,x,t,y) - \frac{\partial}{\partial q^j}\left[\left(-i\hbar\, \frac{\nabla^j \psi_t}{\psi_t}(q) - A^j(q) \right) p(s,x,t,y) \right]. \tag{2.37}$$

Proof: (*a*) Let us consider (2.29′)

$$(P_{t,s} f^{(t)})(x) = \int f^{(t)}(q)\hat{p}(s,x,t,\mathrm{d}q) \equiv u(s,x), \quad s < t,$$

for any $f^{(t)}$ of compact support in the class used to define (2.22). By hypothesis, we can differentiate with respect to (s,x) under the integral sign. Using Proposition II.12 (c) and the properties of the quantum transition kernels before Proposition II.14,

$$
\begin{aligned}
u(s_1,x)-u(s_2,x) &= \int_{S_\varepsilon(x)} [u(s_2,q)-u(s_2,x)]\hat{p}(s_1,x,s_2,q)\mathrm{d}q + o(s_2-s_1) \\
&= \int_{S_\varepsilon(x)} \left\{ (q-x)\,\nabla\, u(s_2,x) + (q-x)(q-x)^T \frac{1}{2}\nabla^2 u(s_2,x) + R \right\} \hat{p}\,\mathrm{d}q + o(s_2-s_1) \\
&= \left[\nabla u(s_2,x) \int_{S_\varepsilon(x)} (q-x)\hat{p}(s_1,x,s_2,q)\mathrm{d}q \right. \\
&\quad \left. + \frac{1}{2}\nabla^2 u(s_2,x) \int_{S_\varepsilon(x)} (q-x)(q-x)^T \hat{p}(s_1,x,s_2,q)\,\mathrm{d}q + R \right] (s_2-s_1) + o(s_2-s_1) \\
&= \left[\hat{B}(x,s_2)\,\nabla\, u(s_2,x) + \frac{1}{2}\hat{C}(s_2,x)\nabla^2 u(s_2,x) + R \right] (s_2-s_1) + o(s_2-s_1),
\end{aligned}
$$

where $\hat{B}$ and $\hat{C}$ have been computed in Proposition II.14 and $R \equiv R(s_1,s_2,q,x)$ is a remainder $O(|q-x|^2)$. Dividing by (s_2-s_1) and taking $\lim_{s_2\downarrow s}$, $\lim_{s_1\uparrow s}$ one verifies that $u(s,x)$ solves the quantum Fokker-Planck equation (2.34).

According to (2.29′), the boundary condition of this equation is provided by

$$
u(s,x) - f^{(s)}(x) = \int_{S_\varepsilon(x)} [f^{(t)}(q) - f^{(s)}(x)]\hat{p}(s,x,t,q)\mathrm{d}q + o(t-s).
$$

So

$$
\lim_{s\uparrow t} u(s,x) \equiv \lim_{s\uparrow t} M^{\bar{\psi}}_{s,x}[f^{(t)}] = f^{(t)}(x). \tag{2.33′}
$$

(b) Let $f^{(t)}$ be of compact support, twice continuously differentiable in the class used to define (2.22). As before, one verifies that

$$
\lim_{s_1\uparrow s, s_2\downarrow s} \frac{1}{s_2-s_1} \left[\int f^{(s_2)}(q)\hat{p}(s_1,x,s_2,q)\mathrm{d}q - f^{(s)}(x) \right] = \hat{B}(x,s)\,\nabla\, f^{(s)}(x) + \frac{1}{2}\hat{C}(x,s)\nabla^2 f^{(s)}(x). \tag{2.38}
$$

Now let us write

$$
\begin{aligned}
\frac{\partial}{\partial t}\int f^{(t)}(q)\hat{p}(s,x,t,q)\mathrm{d}q &= \lim_{s_1\uparrow t, s_2\downarrow t} \frac{1}{s_2-s_1} \int [\hat{p}(s,x,s_2,q) - \hat{p}(s,x,s_1,q)] f^{(t)}(q)\mathrm{d}q \\
&= \lim_{s_1\uparrow t, s_2\downarrow t} \int \hat{p}(s,x,s_1,q) \left[\frac{1}{s_2-s_1} \int f^{(s_2)}(z)\hat{p}(s_1,q,s_2,z)\mathrm{d}z - f^{(s_2)}(q) \right] \mathrm{d}q.
\end{aligned}
$$

Using (2.38) this reduces to

$$
\int \hat{p}(s,x,t,q) \left[\hat{B}(q,t)\,\nabla\, f^{(t)}(q) + \frac{1}{2}\hat{C}(q,t)\nabla^2 f^{(t)}(q) \right] \mathrm{d}q.
$$

After integration by parts, we get

$$
\int \frac{\partial}{\partial t}\hat{p}(s,x,t,q)\cdot f^{(t)}(q)\mathrm{d}q = \int \mathrm{d}q\, f^{(t)}(q) \left[-\nabla_q \left(\hat{p}(s,x,t,q)\hat{B}(q,t) - \frac{1}{2}\nabla_q \left(\hat{C}(q,t)\hat{p}(s,x,t,q) \right) \right) \right].
$$

□

Introducing $\hat{B}$, $\hat{C}$ of Proposition II.14, (2.34) holds since $f^{(t)}$ is arbitrary in the chosen dense class.

Starting from (2.29), one proves (c) and (d) in the same way.

Proposition II.16:

Under the same conditions as in Proposition II. 15, the density of the quantum probability in the state $\psi_t, \rho(x,t)\,\mathrm{d}x=|\psi_t(x)|^2\,\mathrm{d}x$, *solves the continuity equation*

$$\frac{\partial \rho}{\partial t}+\nabla_j\left[\frac{i\hbar}{2}(\psi_t\nabla^j\bar{\psi}_t-\bar{\psi}_t\nabla^j\psi_t)-A^j\rho\right]=0,$$

or

$$\frac{\partial \rho}{\partial t}+\nabla_j\left[\frac{i\hbar}{2}\left(\frac{\nabla^j\bar{\psi}_t}{\bar{\psi}_t}-\frac{\nabla^j\psi_t}{\psi_t}-A^j\right)\rho\right]=0. \tag{2.39}$$

Proof: It follows from the definition (2.23′) of the forward quantum transition kernel $\hat{p}(s,x,t,q)$ that, if $\rho^{(s)}(\mathrm{d}x)$ denotes the quantum probability density at time $s<t$, then

$$\rho(q,t)=\int \rho^{(s)}(\mathrm{d}x)\hat{p}(s,x,t,q). \tag{2.40}$$

Applying the integration with respect to $\rho^{(s)}(\mathrm{d}x)$ to the quantum Fokker-Planck equation (2.34) one can see that $\rho(q,t)$ satisfies the same equation, namely

$$\frac{\partial \rho}{\partial t}=-\nabla_j\left[\left(i\hbar\frac{\nabla^j\bar{\psi}_t}{\bar{\psi}_t}-A\right)\rho\right]+\frac{i\hbar}{2}\Delta\rho. \tag{2.41}$$

But the quantum probability density ρ is also propagated backward in time by the transition kernel p solving (2.37). This means that ρ solves as well

$$\frac{\partial \rho}{\partial t}=-\nabla_j\left[\left(-i\hbar\frac{\nabla^j\psi_t}{\psi_t}-A\right)\rho\right]-\frac{i\hbar}{2}\Delta\rho. \tag{2.42}$$

It follows that ρ also solves the average of (2.41) and (2.42), i.e., the usual quantum continuity equation (2.39), as claimed. □

III. THE QUANTUM ACTION FUNCTION AND ITS DYNAMICAL CONTENT

Let us show first why, in relation with the quantum conditional expectation in a given state, it is legitimate to call $\bar{D}_\tau$ a quantum (time) derivative. The next proposition can be regarded as a quantum version of the fundamental theorem of calculus.

Proposition III.1: Let $f=(f^{(\tau)})_{\tau\in\mathbb{R}}$ *be any function continuous in the time variable* τ, *and in the domain of* $\bar{D}_\tau$. *Then, for any* $t\leq u$ *we have*

$$M^{\bar{\psi}}_{t,x}\left[\int_t^u \bar{D}_\tau f^{(\tau)}\,\mathrm{d}\tau\right]=M^{\bar{\psi}}_{t,x}[f^{(u)}]-f^{(t)}(x), \tag{3.1}$$

where $\bar{D}_\tau$ *is defined by* (2.15), *for* φ *replaced by* ψ.

Proof: By the definition (2.22) of $M^{\bar{\psi}}_{t,x}$, the lhs of (3.1), for (t,x) ψ-admissible, is

$$(\bar{\psi}_t(x))^{-1}\left(\int_t^u U_{\tau-t}[\bar{D}_\tau f^{(\tau)}\cdot\bar{\psi}_\tau]\mathrm{d}\tau\right)(x).$$

Introducing the definition (2.15) of $\bar{D}_\tau$, this means

$$(\bar{\psi}_t(x))^{-1}\left(\int_t^u U_{\tau-t}\cdot\left[\frac{1}{\bar{\psi}}\left(\frac{\partial}{\partial\tau}+\frac{1}{i\hbar}H\right)(\bar{\psi}_\tau f^{(\tau)})\cdot\bar{\psi}_\tau\right]\mathrm{d}\tau\right)(x)$$
$$=[\bar{\psi}_t(x)]^{-1}\left(\int_t^u U_{\tau-t}\left[\left(\frac{\partial}{\partial\tau}+\frac{1}{i\hbar}H\right)(\bar{\psi}_\tau\cdot f^{(\tau)})\right]\mathrm{d}\tau\right](x).$$

By an integration by parts with respect to $\mathrm{d}\tau$ and using the self-adjointness of H in $L^2(\mathbb{R}^n,\mathrm{d}x)$ we obtain

$$(\bar{\psi}_t(x))^{-1}\left\{-\int_t^u\left(\frac{\partial}{\partial\tau}U_{\tau-t}\right)(\bar{\psi}_\tau f^{(\tau)})\mathrm{d}\tau+U_{\tau-t}(\bar{\psi}_\tau f^{(\tau)})\Big|_t^u(x)+\frac{1}{i\hbar}\int_t^u(HU_{\tau-t})(\bar{\psi}_\tau f^{(\tau)})\mathrm{d}\tau\right\}.$$

Since $U_{\tau-t}$ solves, for $\tau>t$, $(\partial/\partial\tau)U_{\tau-t}\chi=(1/i\hbar)HU_{\tau-t}\chi$ for all χ in $\mathcal{D}_H$, this reduces to

$$(\bar{\psi}_t(x))^{-1}U_{\tau-t}(\bar{\psi}_\tau f^{(\tau)})\Big|_t^u=(\bar{\psi}_t(x))^{-1}\{U_{u-t}(\bar{\psi}_u f^{(t)})(x)-\bar{\psi}_t(x)f^{(t)}(x)\}.$$

By definition of the quantum conditional expectation, this is the rhs of Eq. (3.1). □

Remark:

When U_τ admits an integral kernel k, as in Sec. II, then the lhs of Eq. (3.1) becomes

$$(\bar{\psi}_t(x))^{-1}\int_t^T\int k(x,\tau-t,q)\bar{D}_\tau f^{(\tau)}(q)\bar{\psi}_\tau(q)\mathrm{d}q\,\mathrm{d}\tau.$$

The integration by parts with respect to $\mathrm{d}\tau$ mentioned in Proposition III.1 is done using the fact that k coincides with the retarded (or causal) distribution k_+ solving, for $\tau\geq t$, in the sense of distributions

$$\left(-i\hbar\frac{\partial}{\partial\tau}+H\right)k_+(x,\tau-t,q)=-i\hbar\,\delta(q-x)\delta(\tau-t).$$

□

Corollary III.2:

Let $f=(f^{(t)})_{t\in\mathbb{R}}$ strongly continuously differentiable from $\mathbb{R}$ into $L^2(\mathbb{R}^n,\mathrm{d}x)$, with $f^{(t)}(\cdot)\in\mathcal{D}_H$, $\forall t$. Assume that $(Hf^{(t)})_{t\in\mathbb{R}}$ is continuous in the time variable t. Then

$$\bar{D}_t f^{(t)}(x)=\lim_{\Delta t\downarrow 0}M^{\bar{\psi}}_{t,x}\left[\frac{f^{(t+\Delta t)}(\cdot)-f^{(t)}(x)}{\Delta t}\right]. \tag{3.2}$$

Proof: By Proposition III.1 for $u=t+\Delta t$ and property (3) of Proposition II.10,

$$\Delta t M^{\bar{\psi}}_{t,x}[\bar{D}_{t^*}f^{(t^*)}]=M^{\bar{\psi}}_{t,x}[f^{(t+\Delta t)}(\cdot)-f^{(t)}(x)], \tag{3.3}$$

for some $t^*\geq t$. The lhs is

$$\Delta t(\bar{\psi}_t(x))^{-1}U_{t^*-t}\left[\left(\frac{\partial}{\partial t^*}+\frac{1}{i\hbar}H\right)(\bar{\psi}_{t^*}f^{(t^*)})\right].$$

Now $f^{(t^*)}\in\mathcal{D}_H$ and $H(\bar{\psi}_{t^*}f^{(t^*)})=\bar{\psi}_{t^*}Hf^{(t^*)}\to_{t^*\to t}\bar{\psi}_tHf^{(t)}=H(\bar{\psi}_tf^{(t)})$. By Lemma II.4 $(\partial/\partial t^*)f^{(t^*)}$ is continuous in time, thus $\lim_{t^*\to t}M^{\bar{\psi}}_{t,x}[\bar{D}_{t^*}f^{(t^*)}]$ exists. After division by Δt, the rhs limit of (3.3) is the rhs of (3.2).

Corollary III.2 provides another proof of Proposition II.14 regarding the forward quantum transition kernel $\hat{p}$.

Corollary III.3:

Let us assume that $f=(f^{(\tau)})_{\tau\in\mathbb{R}}$ is as before and, moreover, admits a Taylor expansion up to the second order around a ψ-admissible $(t,x)\in\mathbb{R}\times\mathbb{R}^n$. Then if the Hamiltonian H is of the form

(2.13), *equation* (3.2) *implies, for* $f^{(t)}(x)=x$,

$$\bar{D}_t x = \lim_{\Delta t \downarrow 0} M^{\bar{\psi}}_{t,x}\left[\frac{f^{(t+\Delta t)}(\cdot)-x}{\Delta t}\right] = i\hbar\,\frac{\nabla\bar{\psi}_t}{\bar{\psi}_t}(x) - A(x), \tag{3.4}$$

and

$$\lim_{\Delta t \downarrow 0} M^{\bar{\psi}}_{t,x}\left[\frac{(f^{(t+\Delta t)}(\cdot)-x)^2}{\Delta t}\right] = i\hbar\,\mathbb{1}, \tag{3.5}$$

where $(f^{(t+\Delta t)}(\cdot)-x)^2$ *refers to the tensor product* $(f^{(t+\Delta t)}(\cdot)-x)\otimes(f^{(t+\Delta t)}(\cdot)-x)$ *and* $\mathbb{1}$ *is the* $n\times n$ *identity matrix.*

In equations (3.4) and (3.5) *the dummy variable* $(\cdot)$ *is the one denoted by* q *in* (2.23′). *All such "quantum moments" of order higher than 2 vanish.*

Proof: Let us consider the Taylor expansion up to the second order,

$$M^{\bar{\psi}}_{t,x}[f^{(t+\Delta t)}(q)-f^{(t)}(x)] = M^{\bar{\psi}}_{t,x}\left[\frac{\partial f}{\partial t}(x,t)\,\nabla t + (q-x)\cdot\Delta f(x,t) + \frac{1}{2}\sum_{i,j}((q_i-x_i)(q_j-x_j))\frac{\partial^2 f}{\partial x^i\,\partial x^j}(x,t) + o(\Delta t)\right].$$

Using the linearity of the quantum conditional expectation, as well as the properties (3) and (5) of Proposition II.15, the conclusion follows from the comparison with the explicit form (2.16) of $\bar{D}_t$ (with ψ replacing φ) for the Hamiltonian (2.13). □

In a similar way one proves the following.

Proposition III.4:

Let $f=(f^{(\tau)})_{\tau\in\mathbb{R}}$ *be continuous in the time variable* τ *and in the domain of* D_τ. *Then,* $\forall t\geq s$,

$$M^{t,x}_{\psi}\left[\int_s^t D_\tau f^{(\tau)}\,\mathrm{d}\tau\right] = f^{(t)}(x) - M^{t,x}_{\psi}[f^{(s)}], \tag{3.6}$$

where D_τ *is defined by* (2.11), *with* φ *replaced by* ψ.

Corollary III.5:

Under the same conditions as in Corollary III.2 we have

$$D_t f^{(t)}(x) = \lim_{\Delta t\downarrow 0} M^{t,x}_{\psi}\left[\frac{f^{(t)}(x)-f^{(t-\Delta t)}(\cdot)}{\Delta t}\right]. \tag{3.7}$$

If f *admits a Taylor expansion up to the second order around a* ψ*-admissible* $(t,x)\in\mathbb{R}\times\mathbb{R}^n$, *with* H *as in* (2.13) *we have, for* $f^{(t)}(x)=x$,

$$D_t x = \lim_{\Delta t\downarrow 0} M^{t,x}_{\psi}\left[\frac{x-f^{(t-\Delta t)}(\cdot)}{\Delta t}\right] = -\,i\hbar\,\frac{\nabla\psi_t}{\psi_t}(x) - A(x), \tag{3.8}$$

and

$$\lim_{\Delta t\downarrow 0} M^{t,x}_{\psi}\left[\frac{(x-f^{(t-\Delta t)}(\cdot))^2}{\Delta t}\right] = i\hbar\,\mathbb{1}, \tag{3.9}$$

where $(\cdot)$ *is the dummy space variable of the definition* (2.24). *As before, all such moments of order higher than 2 vanish.*

As mentioned in Remark 2 after Proposition II.12, in the conditions of Propositions III.1 and III.4, the definitions of the quantum (absolute) expectation of $f^{(t)}\cdot g^{(s)}$ in the state ψ, $t\geq s$, given in (2.28) and (2.28′) can be reexpressed in terms of the quantum derivatives D_t and $\bar{D}_t$ as follows.

Corollary III.6:

$$\langle f^{(t)}g^{(s)}\rangle_\psi = \left\langle M^{\bar{\psi}}_{s,\cdot}\left[\int_s^t \bar{D}_\tau f^{(\tau)}\,\mathrm{d}\tau\right]\cdot g^{(s)} + f^{(s)}g^{(s)}\right\rangle_{\psi_s}$$
$$= \left\langle f^{(t)}g^{(t)} - f^{(t)}M^{t,\cdot}_{\psi}\left[\int_s^t D_\tau g^{(\tau)}\,\mathrm{d}\tau\right]\right\rangle_{\psi_t}, \quad t \geq s.$$

This relation could define, actually, the proper concept of time-dependent Dirichlet form relevant to quantum dynamics (or its Euclidean counterpart—cf. Ref. 7).

Let us apply the Proposition III.1 to a $f=(f^{(\tau)})_{\tau\in\mathbb{R}}$ in the domain of $\bar{D}_\tau$ which is, in fact, time independent and of the form $f^{(\tau)}(\cdot)=F(\cdot)$ for some regular F. Then the lhs of (3.1) can be made explicit using (2.16) for the Hamiltonian (2.13), as well as (3.4),

$$M^{\bar{\psi}}_{t,x}\int_t^T \bar{D}_\tau F\,\mathrm{d}\tau = M^{\bar{\psi}}_{t,x}\int_t^T \left(\bar{D}_\tau q\cdot\nabla F + \frac{i\hbar}{2}\Delta F\right)\mathrm{d}\tau = M^{\bar{\psi}}_{t,x}[F(\cdot)] - F(x). \tag{3.10}$$

This relation clearly displays a quantum deformation of the fundamental theorem of calculus for line integrals along C^1 trajectories

$$\gamma:[t,T]\subset\mathbb{R}\to\mathbb{R}^n$$
$$\tau\mapsto q(\tau).$$

We shall henceforth denote the lhs of (3.10) by

$$M^{\bar{\psi}}_{t,x}\int_t^T \nabla F\circ \mathrm{d}q \tag{3.11}$$

in order to remind ourselves that it coincides simply with the rhs of (3.10) but involves the mentioned deformation of the classical calculus.

Using (3.6) instead of (3.1), we shall write as well, when $s\leq t$,

$$M^{t,x}_{\psi}\int_s^t \nabla F\circ \mathrm{d}q = F(x) - M^{t,x}_{\psi}[F(\cdot)], \tag{3.11$'$}$$

understanding now the lhs as

$$M^{t,x}_{\psi}\int_s^t \left(D_\tau q\cdot\nabla F - \frac{i\hbar}{2}\Delta F\right)\mathrm{d}\tau. \tag{3.10$'$}$$

More generally, for any $A:\mathbb{R}^n\to\mathbb{R}^n$ regular such that

$$M^{\bar{\psi}}_{t,x}\int_t^T \left(\bar{D}_\tau q\cdot A + \frac{i\hbar}{2}\nabla A\right)\mathrm{d}\tau \tag{3.12}$$

makes sense, we shall denote the expression (3.12) simply by

$$M^{\bar{\psi}}_{t,x}\int_t^T A\circ \mathrm{d}q. \tag{3.13}$$

We preserve, however, the boundary value in the time variable, in order to stress that (3.13) is only a short notation for (3.12) and that, in particular, *no* assumption on the existence of some underlying continuous trajectories $\tau\mapsto q(\tau)$ is made. The same remark applies to

$$M_{\psi}^{t,x}\left[\int_s^t A\circ \mathrm{d}q\right] = M_{\psi}^{t,x}\int_s^t \left(D_\tau q\cdot A - \frac{i\hbar}{2}\nabla\cdot A\right)\mathrm{d}\tau, \tag{3.13$'$}$$

so, with the conventions (3.13) and (3.13′), this "quantum calculus" satisfies the rules of the classical (Riemann-Stieltjes) calculus.

Let us come back to the special Lagrangian system whose quantum Hamiltonian is (2.13), i.e., a unit mass and charge particle in an electromagnetic field. Its associated classical action S_L with initial condition $S^{(s)}$ is defined by

$$S_L(x,t) = S^{(s)}(q(s)) + \int_\gamma \left(\frac{1}{2}|\dot{q}|^2 + \dot{q}\cdot A - V(q)\right)\mathrm{d}\tau, \tag{3.14}$$

for $s<t$. It is a real valued function of $x\in\mathbb{R}^n$, $t\in\mathbb{R}$ and a functional along a bundle of solutions γ in $C^2([s,t];\mathbb{R}^n):\tau\mapsto q(\tau)$ of the classical Lagrangian equations of motion, with the mixed boundary conditions on $[s,t]$,

$$\dot{q}(s) = \left.\frac{\partial S^{(s)}}{\partial q}\right|_{q(s)} \quad \text{and} \quad q(t)=x.$$

It is well known (cf., e.g., Ref. 8) that for $|t-s|$ small enough [and A and V as in (2.13)], S_L is a well-defined function. Notice that the Lagrangian L of S_L [i.e., the integrand of (3.14)] can be rewritten as

$$\int_\gamma L\,\mathrm{d}\tau = \int_\gamma \left(\frac{1}{2}|\dot{q}|^2 - V(q)\right)\mathrm{d}\tau + \int_\gamma A\,\mathrm{d}q. \tag{3.15}$$

We are going to show that, using various regularizations provided by the quantum mechanical conditional expectation, we can define a quantization of the above classical action functional S_L which will prove to be natural later on.

For any $(\tau,q)\psi$-admissible, let us define

$$S(q,\tau) = -i\hbar\,\ln\psi_\tau(q), \tag{3.16}$$

where ψ_τ is a regular solution of the Schrödinger equation (2.2) with Hamiltonian (2.1), such that $S=(S^{(\tau)})_{\tau\in\mathbb{R}}$ is continuous in the domain of D_τ. [We may choose the principal determination of the logarithm in the definition (3.16).]

According to (3.8), we observe that

$$D_\tau q = \nabla S(q,\tau) - A(q) \tag{3.17}$$

is an element of $L^2(\mathbb{R}^n,|\psi_\tau(q)|^2\,\mathrm{d}q)$ when $\int|\nabla\psi_\tau|^2\,\mathrm{d}q<\infty$ as well as $\int A^2(q)\,|\psi_\tau(q)|^2\,\mathrm{d}q<\infty$. Using the definition (2.14) for our situation, we compute

$$D_\tau S(q,\tau) = \frac{\partial S}{\partial\tau} + \left(-i\hbar\,\frac{\nabla\psi_\tau}{\psi_\tau} - A\right)\cdot\nabla S - \frac{i\hbar}{2}\Delta S = \frac{1}{2}(D_\tau q)^2 - \frac{i\hbar}{2}\nabla\cdot A + A\cdot D_\tau q - V(q), \tag{3.18}$$

where the relation (3.16) and the fact ψ_i solves the Schrödinger equation with H as in (2.13) have been used. The rhs of (3.18) is interpreted as the Lagrangian $L(D_\tau q,q)$ of our quantum system. Then, by Proposition III.4,

$$M_{\psi}^{t,x}\left[\int_s^t\left(\frac{1}{2}(D_\tau q)^2 - V(q)\right)\mathrm{d}\tau + \int_s^t\left(A\cdot D_\tau q - \frac{i\hbar}{2}\nabla\cdot A\right)\mathrm{d}\tau\right] = S(x,t) - M_{\psi}^{t,x}[S^{(s)}(\cdot)].$$

With the convention (3.13), this means that we have defined a regularized action function by

$$S(x,t) = M_{\psi}^{t,x}[S^{(s)}(\cdot)] + M_{\psi}^{t,x}\left[\int_s^t \left(\frac{1}{2}(D_\tau q)^2 - V(q)\right) \mathrm{d}\tau\right] + M_{\psi}^{t,x}\left[\int_s^t A \circ \mathrm{d}q\right], \tag{3.19}$$

to be compared with the corresponding classical action (3.14) and (3.15). The relation (3.19) provides us with an exact representation of the solution ψ_t of the Schrödinger equation.

Theorem III.7:

Let ψ_t be the solution of the Cauchy problem in $L^2(\mathbb{R}^n, \mathrm{d}x), t \geq s$,

$$i\hbar \frac{\partial \psi_t}{\partial t} = H\psi_t,$$

$$\psi_s(x) = e^{(i/\hbar)S^{(s)}(x)} \in \mathcal{D}_H, \quad \textit{with } S^{(s)} \textit{ such that } S^{(s)} = -i\hbar \ \ln \psi_s(x) \textit{ exists},$$

for $H = -(\hbar^2/2)[\nabla - (i\hbar)A]^2 + V$, with A,V continuous as in Remark 1 after Lemma II.4. We also assume that $\int |\nabla \psi_\tau(q)|^2 \, \mathrm{d}q < \infty$ and $\int A^2 |\psi_\tau(q)|^2 \, \mathrm{d}q < \infty$, $\forall \tau \geq s$. Then the following exact integral representation of the solution ψ_t holds:

$$\psi_t(x) = \exp\left(\frac{i}{\hbar} M_{\psi}^{t,x}\left[\int_s^t \left(\frac{1}{2}(D_\tau q)^2 - V(q)\right) \mathrm{d}\tau + \int_s^t A \circ \mathrm{d}q + S^{(s)}(\cdot)\right]\right) = e^{(i/\hbar)S(x,t)}, \tag{3.20}$$

$\forall (t,x)$ ψ-admissible, where S is the (complex-valued) solution of the quantum Hamilton Jacobi equation on $\mathbb{R}^n \times [s, \infty[$

$$\frac{\partial S}{\partial t} + \frac{1}{2}(\nabla S - A)^2 + V + \frac{i\hbar}{2} \nabla \cdot A - \frac{i\hbar}{2}\Delta S = 0,$$

$$S^{(s)}(x) = -i\hbar \ \ln \psi_s(x). \tag{3.21}$$

Remark: The kinetic energy term in (3.20) (i.e., the term with $V=0, A=0$) involves the scalar product of real vectors and not an Hermitian product. So, since $D_\tau q$ is a complex function, the kinetic energy term is, in general, a complex function, denoted here by $(D_\tau q)^2$.

Proof: When $t=s$ the representation (3.20) holds trivially, according to the property (3) of Proposition II.10 of the quantum mechanical conditional expectation. When $t>s$, using the relation (3.17), Eq. (3.18) means

$$\frac{\partial S}{\partial t} + (\nabla S - A) \cdot \nabla S - \frac{i\hbar}{2}\Delta S = \frac{1}{2}(\nabla S - A)^2 - \frac{i\hbar}{2} \nabla \cdot A + A \cdot (\nabla S - A) - V.$$

After simplification, this reduces to (3.21). The integral representation (3.20) follows from the definition (3.16) and the relation (3.19).

Remarks: We shall interpret (3.20) as a rigorous substitute for Feynman's path integral representation of the wave function ψ_t.[2] Like this one, (3.20) is built in term of the Lagrangian of the underlying classical system. We are going to need this for our study of quantum symmetries. However, the mathematical status of (3.20) is quite distinct from Feynman's heuristic (and, in some cases, rigorous[9,10] sum over a path space, as it involves in an essential way the regularizations provided by the quantum conditional expectation and no underlying path space whatsoever (cf. Sec. VII).

Corollary III.8:

Let $\bar{\psi}_t$ be the solution of the boundary problem in $L^2(\mathbb{R}^n, \mathrm{d}x)$ which is complex conjugate to the one of Theorem III.7,

$$\begin{cases} -i\hbar\,\dfrac{\partial\bar{\psi}_t}{\partial t} = H\bar{\psi}_t, \quad 0 \le t \le T, H \text{ as in Theorem III.7}, \\ \bar{\psi}_T(x) = e^{(i/\hbar)S^{(T)}(x)}. \end{cases}$$

Then the following representation holds under the same assumptions as Theorem III.7:

$$\bar{\psi}_t(x) = \exp\left(\frac{i}{\hbar}M^{\bar{\psi}}_{(t,x)}\left[\int_t^T\left(\frac{1}{2}(\bar{D}_\tau q)^2 - V(q)\right)\mathrm{d}\tau + \int_t^T A\circ \mathrm{d}q + S^{(T)}(\cdot)\right]\right) = e^{(i/\hbar)\hat{S}(x,t)}, \tag{3.22}$$

where $\hat{S}$ *solves the equation adjoint to* (3.21) *on* $\mathbb{R}^m\times[-\infty, T]$,

$$\begin{gathered} -\frac{\partial\hat{S}}{\partial t} + \frac{1}{2}(-\nabla\hat{S} - A)^2 + V - \frac{i\hbar}{2}\nabla\cdot A - \frac{i\hbar}{2}\Delta\hat{S} = 0, \\ \hat{S}(x,T) = \hat{S}^{(T)}(x) = -i\hbar\,\ln\bar{\psi}_T(x). \end{gathered} \tag{3.23}$$

Proof: Starting from the logarithmic transformation of (3.22), Eq. (2.16) shows that $\bar{D}_\tau q = -\nabla\hat{S} - A$. Also $\bar{D}_i\hat{S}(q,\tau) = -(1/2)(\bar{D}_\tau q)^2 + V(q) - \bar{D}_\tau q\cdot A - (i\hbar/2)\nabla$. A reduces to (3.23). The conclusion follows from the definition (3.10) and Proposition III.1. □

Notice the change of signs in the two Hamilton-Jacobi equation (3.21) and (3.23). In the heuristic classical limit $\hbar = 0$, this is a well-known observation when the action is computed as a function of the future or past configurations (Ref. 11). This limit could be computed rigorously using, e.g., the methods of Ref. 12.

Also notice that, up to the convention (3.10) and (3.11) and the fact that the classical norm $|\dot{q}|^2$ of (3.14) is replaced by the square of a complex-valued quantum derivative, the Lagrangian of (3.22) is indeed the classical one, but evaluated on regularized variables.

The regularized action (3.19) used in our integral representation (3.20) satisfies the following additivity property along an admissible family of states ψ_τ, $s \le \tau \le u$.

Corollary III.9:

For any $t \in [s,u]$ *and under the conditions of Theorem III.7*,

$$M^{u,z}_\psi\left[\int_s^t L\,\mathrm{d}\tau + A\circ\mathrm{d}q\right] + M^{u,z}_\psi\left[\int_t^u L\,\mathrm{d}\tau + A\circ\mathrm{d}q\right] = M^{u,z}_\psi\left[\int_s^t L\,\mathrm{d}\tau + A\circ\mathrm{d}q\right].$$

Proof: According to the property (c) of the operator P^* defined by (2.29), using (3.19), and for $S^{(s)}$ like in the definition (3.21),

$$\begin{aligned} P^*_{t,u}\cdot P^*_{s,t}[S^{(s)}] &= M^{u,z}_\psi[M^{t,\cdot}_\psi[S^{(s)}]] \\ &= M^{u,z}_\psi\left[S^{(t)}(\cdot) - M^{t,\cdot}_\psi\left[\int_s^t L\mathrm{d}\tau + A\circ\mathrm{d}q\right]\right] \\ &= M^{u,z}_\psi[S^{(t)}(\cdot)] - M^{u,z}_\psi\left[M^{t,\cdot}_\psi\left[\int_s^t L\mathrm{d}\tau + A\circ\mathrm{d}q\right]\right] \\ &= S^{(u)}(z) - M^{u,z}_\psi\left[\int_t^u L\,\mathrm{d}\tau + A\circ\mathrm{d}q\right] - M^{u,z}_\psi\left[\int_s^t L\,\mathrm{d}\tau + A\circ\mathrm{d}q\right] \\ &= P^*_{s,u}[S^{(s)}] \\ &= S^{(u)}(z) - M^{u,z}_\psi\left[\int_s^u L\,\mathrm{d}\tau + A\circ\mathrm{d}q\right]. \end{aligned}$$

□

Let us see what the fundamental gauge invariance of quantum mechanics means in the context of our integral representation (3.20).

Proposition III.10:

Let ψ_t be the solution of the Cauchy problem of Theorem III.7. Let $\chi=(\chi^{(\tau)})_{\tau\in\mathbb{R}}$ be real continuous and differentiable in the domain of D_τ. Then the gauge transformation

$$A \mapsto A' = A + \nabla\chi,$$
$$V \mapsto V' = V - \frac{\partial\chi}{\partial\tau} \tag{3.24}$$

leaves the form of the Schrödinger equation invariant provided that the integral representation (3.20) *becomes*

$$\psi_t(x) \mapsto \psi'_t(x) = \exp\left(\frac{i}{\hbar}M_\psi^{t,x}\left[\int_s^t\left(\frac{1}{2}(D_\tau q)^2 - V(q)\right)\mathrm{d}\tau + \int_s^t A\circ\mathrm{d}q + \int_s^t D_\tau\chi^{(\tau)}\mathrm{d}\tau + (S^{(s)}+\chi^{(s)})(\cdot)\right]\right). \tag{3.25}$$

Proof: According to (2.14), for φ_t replaced by ϕ_t, and (3.11),

$$M_\psi^{t,x}\left[\int_s^t D_\tau\chi^{(\tau)}\,\mathrm{d}\tau\right] = M_\psi^{t,x}\left[\int_s^t \nabla\chi\circ\mathrm{d}q + \int_s^t\frac{\partial\chi}{\partial\tau}\,\mathrm{d}\tau\right] = \chi^{(t)}(x) - M_\psi^{t,x}[\chi^{(t)}(\cdot)]. \tag{3.26}$$

Using the representation of $\psi_t(x)$ in Theorem III.7 and (3.26), the representation (3.25) reduces to

$$\psi'_t(x) = \psi_t(x)e^{(i/\hbar)\chi^{(t)}(x)}. \tag{3.27}$$

When the starting wave function ψ_t is subject to the phase transformation (3.27), it is well know that the Schrödinger equation is form invariant under the gauge transformation (3.24). And indeed, (3.25) coincides with the representation (3.20) of $\psi'_t(x)$ in term of V' and A' defined by (3.24). □

We shall need, later on, a dynamical characterization of what plays, for our regularized action (3.19), the role of the critical points of the classical action (3.15), regarded as a functional of the C^2 path $\gamma\colon\tau\mapsto q(\tau)$.

Proposition III.11:

For the action (3.19), *the regularized equations of motion and conservation of energy in the admissible state ψ_τ solving the Schrödinger equation* (2.2) *with Hamiltonian H* (2.13) *in $L^2(\mathbb{R}^3,\mathrm{d}q)$ are, respectively, when $D_\tau q$ is in the domain of D_τ,*

$$D_\tau D_\tau q = -\operatorname{rot}A\wedge D_\tau Z - \frac{i\hbar}{2}\operatorname{rot}(\operatorname{rot}A) - \nabla V, \tag{3.28}$$

when $\wedge$ denotes the exterior product in $\mathbb{R}^n$ and

$$D_\tau h^H_{\psi_\tau}(q,\tau) = \frac{\partial h^H_{\psi_\tau}}{\partial\tau}, \tag{3.29}$$

where $h^H_{\psi_\tau}$ is the space–time observable associated by (2.5) *with the Hamiltonian* (2.13), *i.e.,*

$$h^H_{\psi_\tau} = \frac{1}{2}p^2 - p\cdot A + \frac{i\hbar}{2}\nabla\cdot(A-p) + \frac{1}{2}A^2 + V$$

for p the vector $p^j=-i\hbar(\nabla^j\psi_\tau/\psi_\tau)=B^j-A^j, j=1,2,3$ and $B(q,\tau)=D_\tau q$. In (3.29), *$\partial h^H_{\psi_\tau}/\partial\tau$ denotes the space–time observable associated with $\partial H/\partial\tau$, i.e., here, $\partial V/\partial\tau$. In particular, for V time independent, $h^H_{\psi_\tau}$ is a quantum martingale along ψ_τ, i.e., $D_\tau h^H_{\psi_\tau}=0$.*

Proof: According to (2.14), we have $D_\tau q=-i\hbar(\nabla\psi_\tau/\psi_\tau)-A$. If $D_\tau q$ is in the domain of $\mathcal{D}_\tau$ we can compute $D_\tau D_\tau q$. Using the fact that ψ_τ solves the Schrödinger equation of Theorem III.7 one gets, after some simplification, the rhs of (3.28). Alternatively, taking the gradient ∇ of the quantum Hamilton-Jacobi equation (3.21) and, by (3.17),

$$D_\tau q=\nabla S(q,\tau)-A(q)\equiv B(q,\tau),$$

where we introduced the notation $B=-i\hbar(\nabla\psi_\tau/\psi_\tau)-A$ for the space–time observable $a_{\psi_\tau}^{P-A}$ associated by (2.5) with the quantum velocity observable $P-A(Q)$ (P being the momentum and Q the position observable). We verify that the resulting equation coincides with (3.28). The additional "quantum" deformation on the rhs of (3.28) comes from the vector identity in $\mathbb{R}^3$: $\nabla(\nabla\cdot A)=\mathrm{rot}(\mathrm{rot}\,A)+\Delta A$ for the potential vector A. Besides this extra term, the rhs of (3.28) is the quantum regularization of the classical Lorentz force acting, at the singular limit $\hbar=0$, on the system with Hamiltonian (2.13) (cf. remark below). Concerning (3.29), the space–time energy function h associated with the Hamiltonian (2.13) is, by (2.5), $(H\psi_\tau/\psi_\tau)$ for $\psi_\tau\in\mathcal{D}_H$. After substitution in (2.11) and using the fact that $i\hbar(\partial\psi_\tau/\partial\tau)=H\psi_\tau$, we obtain the conclusion. □

Remark: Using $\bar{D}_\tau$, as defined in (3.2), instead of D_τ, we would find that

$$\bar{D}_\tau\bar{D}_\tau q=\bar{D}_\tau q\wedge\mathrm{rot}\,A+\frac{i\hbar}{2}\mathrm{rot}(\mathrm{rot}\,A)-\nabla V, \tag{3.30}$$

instead of (3.28). In particular, only the average of $D_\tau D_\tau q$ and $\bar{D}_\tau\bar{D}_\tau q$ can provide a regularization of the classical Lorentz force free of quantum corrections but involving, instead, the symmetric velocity $(1/2)(D_\tau q+\bar{D}_\tau q)$, namely

$$\tfrac{1}{2}(D_\tau D_\tau q+\bar{D}_\tau\bar{D}_\tau q)=\tfrac{1}{2}(D_\tau q+\bar{D}_\tau q)\wedge\mathrm{rot}\,A-\nabla V. \tag{3.31}$$

Let us stress that our quantum calculus over space–time observables is perfectly commutative. For example, $-\mathrm{rot}\,A\wedge D_\tau q=D_\tau q\wedge\mathrm{rot}\,A$ in contrast with its operator counterpart,

$$-\mathrm{rot}\,A\wedge(P-A)=(P-A)\wedge\mathrm{rot}\,A+i\hbar\ \mathrm{rot}(\mathrm{rot}\,A), \tag{3.32}$$

but the quantum correction associated with the noncommutativity of the operators reappears now in (3.28) as a consequence of the definition (2.14) of D_τ. Also we remark that the use of both $\bar{D}_\tau$ and D_τ is really necessary for our quantum calculus. For example, as expressed by (3.32), $-\mathrm{rot}\,A\wedge q$ and $q\wedge\mathrm{rot}\,A$ differ after canonical quantization and, in fact, they do not even define, individually, symmetric operators. So our symmetrization leading to (3.31) is the space–time counterpart of the canonical (symmetrized) Lorentz equations of motion[13]

$$\frac{d^2Q}{\mathrm{d}\tau^2}=\frac{1}{2}[(P-A)\wedge\mathrm{rot}\,A-\mathrm{rot}\,A\wedge(P-A)]-\nabla V, \tag{3.33}$$

for Q and P, respectively, the position and momentum quantum observables in the sense of Heisenberg.

IV. SYMMETRIES OF THE QUANTUM ACTION FUNCTION AND THE THEOREM OF NŒTHER

Let $\mathbb{R}^n$ be the configuration manifold of the classical system associated with the quantum Hamiltonian H of (2.2). The corresponding Lagrangian is

$$\begin{gathered}L:\mathbb{R}^n\times\mathbb{R}^n\times\mathbb{R}\to\mathbb{R}\\(q,\dot{q},t)\mapsto L(q,\dot{q},t).\end{gathered} \tag{4.1}$$

Let us consider a one-parameter local Lie group of transformations of the extended configuration space $\mathbb{R}^n \times \mathbb{R}$, of the form

$$U_\alpha : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n \times \mathbb{R}$$

$$(q,t) \mapsto (Q,\tau),$$

where

$$Q = q + \alpha X(q,t) + o(\alpha); \quad \tau = t + \alpha T(t) + o(\alpha); \tag{4.2}$$

the generators $X : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ and $T : \mathbb{R} \to \mathbb{R}$ are real analytical functions and α is a real parameter.

Let us write the action function (3.19) associated with the special Hamiltonian H of Theorem III.7. With an appropriate choice of the gauge $\chi^{(t)}(x)$ (Proposition III.10), we can get rid of the initial condition in the representation (3.19) for, say, $s = t_0$ and $t = t_1$,

$$S_L(x,t_1) = M_\psi^{t_1,x}\left[\int_{t_0}^{t_1}\left(\frac{1}{2}(D_t q)^2 - V(q)\right)\mathrm{d}t + \int_{t_0}^{t_1} A \circ \mathrm{d}q\right] \tag{4.3}$$

where ψ denotes the underlying solution of the associated Cauchy problem of Theorem III.7.

In analogy with the concept of invariance of the action involved in the classical Theorem of Nœther[14] we want to use the change of space–time variables, defined by (4.2), for defining the invariance of our regularized action (4.3).

Let us assume the existence of a further, complex analytic, generator $\varphi^{(t)}$ in the domain of D_τ, called the "divergence."

Definition IV.1: The action (4.3) *is divergence invariant under the one-parameter group of transformations* (4.2) *if, any interval* $[t_0, t_1]$, *we have*

$$M_\psi^{t_1,x_1}\left[\int_{t_0}^{t_1}\left(\frac{1}{2}(D_\tau q)^2 - V(q)\right)\mathrm{d}t + \int_{t_0}^{t_1} A \circ \mathrm{d}q\right] + \alpha M_\psi^{t_1,x_1}\left[\int_{t_0}^{t_1} D_\tau \varphi^{(t)} \mathrm{d}t\right]$$
$$= M_{\tilde{\psi}}^{\tau_1,Q_1}\left[\int_{\tau_0}^{\tau_1}\left(\frac{1}{2}(D_\tau Q)^2 - V(Q)\right)\mathrm{d}\tau + \int_{\tau_0}^{\tau_1} A \circ dQ\right] + o(\alpha), \tag{4.4}$$

where $\tilde{\psi}$ *denotes the associated solution of the same Cauchy problem as in Theorem III.7 but for the new space–time variables* (Q,τ) *resulting from the transformation* U_α.

We remark that the definition (4.2) implies, up to the first order in α,

$$q + \alpha X(q,t) = Q, \tag{4.5}$$

where Q refers to the new configuration at the new time τ (we do not denote Q by Q_τ only to avoid the suggestion that paths $\tau \mapsto Q_\tau$ are involved).

Clearly, the invariance condition (4.4) can only hold under severe restrictions on the generations X, T, and φ. These conditions are easier to find in terms of the two solutions ψ and $\tilde{\psi}$ of the underlying Cauchy problem.

First, Proposition III.10 suggests that the addition in (4.4) of the divergence term $D_t \varphi^{(t)}$ to the given Lagrangian should correspond to a relation similar to (3.27) between ψ and $\tilde{\psi}$. So, to the first order in the parameter α, it should hold that

$$\tilde{\psi} = \psi - \alpha \frac{i}{\hbar} \varphi \cdot \psi. \tag{4.6}$$

Now let us consider (4.2) and (4.6) together with the linear generator of the associated local group of transformations of the Schrödinger equation (2.2) (as before, Einstein's sum convention is used)

$$\mathcal{L} = X^j \frac{\partial}{\partial x^j} + T\frac{\partial}{\partial t} + \frac{i}{\hbar}\varphi, \quad j = 1, \ldots, n.$$

For further purposes, it will be more natural to consider, instead, the formal symmetry generator

$$\hat{N}(t) = -i\hbar\,\mathcal{L} = X^j(x,t)\left(-i\hbar\,\frac{\partial}{\partial x^j}\right) - T(t)\left(i\hbar\,\frac{\partial}{\partial t}\right) + \varphi(x,t), \tag{4.7}$$

as well as the Schrödinger partial differential operator [cf. (2.2)], already used in Lemma II.4 (up to a factor i),

$$\mathbb{Q} = i\frac{\partial}{\partial t} - \frac{1}{\hbar}H. \tag{4.8}$$

Definition IV.2: $\hat{N}(t)$ *is a symmetry operator for the Schrödinger* equation (2.2) *provided*

$$[\hat{N}(t), \mathbb{Q}] = \lambda_{\hat{N}}(x,t)\mathbb{Q}, \tag{4.9}$$

where the complex analytic function $\lambda_{\hat{N}}(x,t)$ *will depend, in general, on* $\hat{N}(t)$ *and is s.t.* $\lambda_{\hat{N}}\mathbb{Q}D_{\mathbb{Q}} \subset L^2(\mathbb{R}^n \times \mathbb{R}, \mathrm{d}x\,\mathrm{d}t)$.

The domain $\mathcal{D}_{\mathbb{Q}}$ of $\mathbb{Q}$ has been defined in Lemma II.4. For the time being, we assume that $\mathcal{D}_{\mathbb{Q}} \supset \mathbb{Q}\mathcal{D}_{\mathbb{Q}}$ and $\hat{N}(t)\mathcal{D}_{\mathbb{Q}} \subset \mathcal{D}_{\mathbb{Q}}$ so that the lhs commutator of (4.9) is well defined on $\mathcal{D}_{\mathbb{Q}}$. We shall be more specific about $\mathcal{D}_{\hat{N}}$ in Sec. V.

In Refs. 15 and 67 it was shown that, in the algebraic sense, we have the following:

A symmetry operator $\hat{N}(t)$ generates a group, mapping solutions of the Schrödinger equation (2.2) into other solutions. The collection $\mathfrak{g}$ of such symmetry operators $\hat{N}(t)$ is a complex Lie algebra, i.e., if $\hat{N}_1, \hat{N}_2 \in \mathfrak{g}$, then (1) $\beta_1\hat{N}_1 + \beta_2\hat{N}_2 \in \mathfrak{g}$, $\forall\,\beta_1,\ \beta_2 \in \mathbb{C}$, (2) $[\hat{N}_1, \hat{N}_2] \in \mathfrak{g}$.

The formal symmetry group $G \equiv \exp\mathfrak{g}$ of Eq. (2.2) results from products of formal exponentials of symmetry operators; it is a local Lie group.

Let us stress that, in order to make this claim analytical rigorous, we have first to define the symmetrization $N(t)$ of such a formal generator $\hat{N}(t)$ then a self-adjoint extension $\hat{N}(t)$ and finally the unitary group generated by $\hat{N}(t)$. This will be done in Sec. V.

For a given Hamiltonian H, the property (4.9) implies the explicit conditions on the coefficients X, T, and φ that we are looking for.

Proposition IV.3:

$\hat{N}(t)$ *is a symmetry operator for the Schrödinger equation in* $L^2(\mathbb{R}^n)$, *with Hamiltonian* (2.13) *(where V may depend on time), if and only if*

(1)

$$\frac{\mathrm{d}T}{\mathrm{d}t}\delta^{jk} = \frac{\partial X^k}{\partial x^j} + \frac{\partial X^j}{\partial x^k}, \quad 1 \le j, \quad k \le n,$$

(2)

$$\frac{\partial X^j}{\partial t} = -\frac{\partial \varphi}{\partial x^j} - \frac{1}{2}\frac{\mathrm{d}T}{\mathrm{d}t}A^j - X^k\frac{\partial A^j}{\partial x^k},$$

(3)

$$\frac{\partial \varphi}{\partial t} - A^j\frac{\partial \varphi}{\partial x^j} - \frac{i\hbar}{2}\Delta\varphi = X^j\frac{\partial}{\partial x^j}\left(\frac{i\hbar}{2}\nabla\cdot A + \frac{1}{2}|A|^2 + V\right) + \frac{\mathrm{d}T}{\mathrm{d}t}\left(\frac{i\hbar}{2}\nabla\cdot A + \frac{1}{2}|A|^2 + V\right) + T\frac{\partial V}{\partial t},$$

where Einstein's sum convention has been used, $\nabla\cdot A$ *denotes the divergence of the vector field A*

and n is the dimension of the configuration space of the underlying classical system.

Remark: If we allow space–dependent time transformation $\tau=t+\alpha T(q,t)+o(\alpha)$ in (4.2) then, for the associated $\hat{N}(t)$ to be a symmetry operator it is necessary, in addition to (1), (2), (3), that

$$\frac{\partial T}{\partial x^j}=0, \quad j=1,\ldots,n.$$

In other words, our initial choice of $T=T(t)$ was not a restriction.

Proof: Using the definitions (4.7) and (4.8), the conclusion follows from (4.9), after a laborious computation. One verifies that the coefficient $\lambda_{\hat{N}}(x,t)$ in (4.9) is

$$\lambda_{\hat{N}}(x,t)=-\frac{\mathrm{d}T}{\mathrm{d}t}(t). \tag{4.10}$$

In particular $\lambda_{\hat{N}}$ is not space dependent. □

Notice that the "determining equations" (1)–(4) (Ref. 16) for the coefficients X^j, T, and φ of the symmetry operator (4.7) are linear. We shall come back later to discuss their integrability conditions.

According to Theorem III.7, when $\hat{N}$ is a symmetry operator for (2.2) with Hamiltonian H of the form (2.13), $\tilde{\psi}$ solves the same Schrödinger equation but in the new variables (Q,τ). Therefore it follows from (3.16) and (3.19) that

$$-i\hbar\ \ln\tilde{\psi}(Q,\tau)=M_{\tilde{\psi}}^{\tau,Q}\left[\int_{\tau_0}^{\tau}\left(\frac{1}{2}(D_sQ)^2-V(Q)\right)\mathrm{d}s+\int_{\tau_0}^{\tau}A\circ\mathrm{d}Q\right].$$

On the other hand, taken together, the relations (4.2) and (4.6) defining the Lie groups of transformation around the identity $\alpha=0$ mean that ψ and $\tilde{\psi}$ are related, up to the first order in α, by

$$\psi(q,t)\exp\left(-\frac{i\alpha}{\hbar}\varphi(q,t)\right)=\tilde{\psi}(q+\alpha X(q,t),t+\alpha T(t)).$$

By considering $(-i\hbar\ \ln)$ of this equality for the principal determination of ln, taking into account the relation (4.5), valid for α small enough, as well as the representations (3.20) and (3.26), we verify that the invariance condition (4.4) of the action (4.3) is satisfied. In other words, the following proposition holds.

Proposition IV.4:

When the determining equations (1)–(3) *are satisfied for the Schrödinger equation with Hamiltonian* (2.13) *i.e., when the operator* $\hat{N}$ *of* (4.7) *is a symmetry operator for this equation, the associated action* (4.3) *is divergence invariant under the Lie groups of transformations defined by* (4.2) *and* (4.6).

We shall need:

Proposition IV.5:

Let us denote by $L=L(D_tq,q,t)$ *the Lagrangian involved in* (3.18)–(3.20). *Then, a necessary condition for the divergence invariance* (4.4) *of the action is that*

$$\frac{\partial L}{\partial t}T+\frac{\partial L}{\partial q^j}X^j+\frac{\partial L}{\partial(D_tq)^j}\left(D_tX^j-(D_tq)^j\frac{\mathrm{d}T}{\mathrm{d}t}\right)+L\frac{\mathrm{d}T}{\mathrm{d}t}=-D_t\varphi. \tag{4.11}$$

Proof: For the Hamiltonian of Theorem III.7 we have, according to the definition (2.14) of D_t, densely defined in $L^2(\mathbb{R}^n,|\psi_t(x)|^2\,\mathrm{d}x)$,

$$D_t X^j = \frac{\partial X^j}{\partial t} + B^k \frac{\partial X^j}{\partial q^k} - \frac{i\hbar}{2}\Delta X^j, \tag{4.12}$$

where

$$B^k = -i\hbar \frac{\nabla^k \psi_t}{\psi_t} - A^k, \quad k = 1, \ldots, n.$$

By (1) and (2) of Proposition IV.3,

$$D_t X^j = -\frac{\partial \varphi}{\partial q^j} - \frac{1}{2}\frac{\mathrm{d}T}{\mathrm{d}t}A^j - X^k \frac{\partial A^j}{\partial q^k} + B^k \frac{\partial X^j}{\partial q^k}.$$

In particular,

$$D_t X^j = -(D_t q)^j \frac{\mathrm{d}T}{\mathrm{d}t} = i\hbar \frac{\nabla^j \psi_t}{\psi_t} \cdot \frac{1}{2}\frac{\mathrm{d}T}{\mathrm{d}t} - \frac{\partial \varphi}{\partial q^j} - X^k \frac{\partial A^j}{\partial q^k} + \frac{1}{2} B^k \left(\frac{\partial X^j}{\partial q^k} - \frac{\partial X^k}{\partial q^j} \right).$$

After substitution of $L(D_t q, q, t) = (1/2)(D_t q)^2 + A \cdot D_t q - (i\hbar/2)\nabla \cdot A - V$ in (4.11) we verify that this relation reduces to the condition (3) of Proposition IV.3 and therefore to one of the conditions ensuring that the generator $\hat{N}$ of (4.7) is a symmetry operator for the Schrödinger equation of Theorem III.7. □

Proposition IV.6:

When the generator $\hat{N}(t)$ is a symmetry operator for the Schrödinger equation (2.2) *s.t.* $(\varphi_t, \hat{N}(t)\varphi_t)$ *is well defined and the assumption for* (4.9) *is satisfied, then we have* $\forall \varphi_t \in \mathcal{D}_{\hat{N}(t)}$,

$$\frac{d}{\mathrm{d}t}(\varphi_t, \hat{N}(t)\varphi_t) = 0.$$

Proof: The equation (2.3) for $A(t) = \hat{N}(t)$ holds even when the members of the one-parameter family of operators $\hat{N}(t)$ are not self-adjoint as long as H is, and if the $\hat{N}(t)$ are densely defined and such that $(\varphi_t, \hat{N}(t)\varphi_t)$ makes sense.

Then, for any $\varphi_t \in D_{\hat{N}(t)}$, using (2.3) for $\psi_t = \varphi_t$,

$$\begin{aligned} \frac{d}{\mathrm{d}t}(\varphi_t, \hat{N}(t)\varphi_t) &= \int \bar{\varphi}_t \left(\frac{\partial \hat{N}(t)}{\partial t} + \frac{i}{\hbar}[H, \hat{N}(t)] \right) \varphi_t \, \mathrm{d}x \\ &= -i \int \bar{\varphi}_t \{ \mathbb{Q}(\hat{N}(t)\varphi_t) - \hat{N}(t)\mathbb{Q}\varphi_t \} \mathrm{d}x, \end{aligned}$$

where the operator $-i\mathbb{Q} = [(\partial/\partial t) - (1/i\hbar)H]$ of Lemma II.4 has been introduced.

On the other hand, it follows from the definition (4.9) that when $\hat{N}$ is a symmetry operator for (2.2) then $\mathbb{Q}\varphi_t = 0 \Rightarrow \mathbb{Q}(\hat{N}(t)\varphi_t) = 0$. So the conclusion follows. □

Let us prove a stronger version of Proposition IV.6 (without expectation) in terms of space–time observables.

Theorem IV.7 (Theorem of Nœther):

When $\hat{N}(t)$ is a symmetry operator for the Schrödinger equation (2.2) *with Hamiltonian* (2.13), *and when the action* (4.3) *is divergence invariant under the Lie group of transformations generated by $\hat{N}(t)$, the associated space–time observable $n^{\hat{N}}_{\psi_t}$ in the state ψ_t satisfies $D_t n^{\hat{N}}_{\psi_t} = 0$,* for all *$\psi_t$-admissible elements in $\mathcal{D}_{\hat{N}(t)}$. In this case we shall say that $n^{\hat{N}}_{\psi_t}$ is a* quantum martingale *for this Schrödinger equation.*

Proof: According to the definition (4.7), writing n instead of $n^{\hat{N}}_{\psi_t}$ for simplicity, we have

$$D_t n(x,t) = D_t(X^j p_j - Th + \varphi)(x,t), \tag{4.13}$$

where the space–time functions associated with $\hat{N}$, the momentum observable P_j and the Hamiltonian observable H of (2.13) have been introduced.

Using the relation (4.12) and Proposition II.8, the derivative of the scalar product in (4.13) can be written as

$$D_t(X^j p_j) = (D_t X^j)p_j + X^j(D_t p_j) - i\hbar \frac{\partial X^j}{\partial x^k}\frac{\partial p_j}{\partial x^k}, \tag{4.14}$$

where we notice the quantum deformation of Leibniz rule. Since $p_j = -i\hbar(\nabla_j \psi_t/\psi_t)$, $\partial p_j/\partial x^k$ is symmetric in j and k, so

$$\begin{aligned} D_t(X^j p_j) &= (D_t X^j)p_j + X^j(D_t p_j) - i\hbar \frac{1}{2}\left(\frac{\partial X^k}{\partial x^j} + \frac{\partial X^j}{\partial x^j}\right)\frac{\partial p^j}{\partial x^k} \\ &= (D_t X^j)p_j + X^j(D_t p_j) - \frac{\hbar^2}{2}\frac{\mathrm{d}T}{\mathrm{d}t}\left(\frac{\Delta\psi_t}{\psi_t} - \left(\frac{\nabla\psi_t}{\psi_t}\right)^2\right), \end{aligned}$$

since, by (1) of Proposition IV.3,

$$\frac{\partial X^k}{\partial x^j} + \frac{\partial X^j}{\partial x^k} = \frac{\mathrm{d}T}{\mathrm{d}t}\delta^{jk}. \tag{4.15}$$

On the other hand, coming back to (4.13), we have

$$h = -\frac{\hbar^2}{2}\frac{\Delta\psi_t}{\psi_t} + i\hbar\frac{\nabla\psi}{\psi}\cdot A + \frac{i\hbar}{2}\nabla\cdot A + \frac{1}{2}|A|^2 + V. \tag{4.16}$$

Using (2.11) it is easy to verify (cf. also Proposition III.11) that

$$D_t h = \frac{\partial V}{\partial t}. \tag{4.17}$$

We have already found, in Proposition IV.5, that

$$D_t X^j = (D_t q)^i \frac{\mathrm{d}T}{\mathrm{d}t} + i\hbar\frac{\nabla^j\psi_t}{\psi_t}\cdot\frac{1}{2}\frac{\mathrm{d}T}{\mathrm{d}t} - \frac{\partial\varphi}{\partial x^j} - X^k\frac{\partial A^j}{\partial x^k}.$$

Also, by (3) of Proposition IV.3,

$$\begin{aligned} D_t\varphi &= \left(\frac{\partial\varphi}{\partial t} - A^j\frac{\partial\varphi}{\partial x^j} - \frac{i\hbar}{2}\Delta\varphi\right) - i\hbar\frac{\nabla^j\psi_t}{\psi_t}\frac{\partial\varphi}{\partial x^j} \\ &= X^j\frac{\partial}{\partial x^j}\left(\frac{i\hbar}{2}\nabla\cdot A + \frac{1}{2}|A|^2 + V\right) + \frac{\mathrm{d}T}{\mathrm{d}t}\left(\frac{i\hbar}{2}\nabla\cdot A + \frac{1}{2}|A|^2 + V\right) + T\frac{\partial V}{\partial t} - i\hbar\frac{\nabla^j\psi_t}{\psi_t}\frac{\partial\varphi}{\partial x^j}. \end{aligned}$$

By (3.28), we also have, since $p_j = (D_t q)_j + A_j$,

$$D_t p_j = (D_t q \wedge \mathrm{rot}\, A)_j - \frac{i\hbar}{2}\mathrm{rot}(\mathrm{rot}\, A)_j - \nabla_j V + D_t A_j,$$

where

$$D_t A_j = \left(-i\hbar\frac{\nabla\psi_t}{\psi_t}\cdot\nabla\right)A_j - (A\cdot\nabla)A_j - \frac{i\hbar}{2}\Delta A_j.$$

After substitution of all this in

$$D_t n = (D_t X^j) p_j + X^j (D_t p_j) - \frac{\hbar^2}{2}\left[\frac{\Delta\psi_t}{\psi_t} - \left(\frac{\nabla\psi_t}{\psi_t}\right)^2\right] - hD_t T - D_t h \cdot T + D_t\varphi,$$

we obtain, indeed, zero. □

Let us come back to the explicit definition (4.7) of a symmetry operator $\hat{N}(t)$ for the Schrödinger equation (2.2). Introducing the definitions of the momentum and energy quantum observables P and H (in Heisenberg's picture) we observe that

$$\hat{N}(t) = X^j P_j - TH + \varphi, \tag{4.18}$$

where the coefficients X^j, T, and φ solve the partial differential equations of Proposition IV.3.

Let us denote by $Q(t)$ the time (Heisenberg) evolution of the position observable under an Hamiltonian H of the form (2.13). Then we define the following symmetrization of $\hat{N}(t)$:

$$N(t) = X^j(Q(t),t) \circ P_j(t) - T(t)H(t) + \hat{\varphi}(Q(t),t), \tag{4.19}$$

where $\circ$ denotes Jordan's multiplication of operators, i.e., $C \circ B = (1/2)(CB+BC)$. Then the phase φ should be redefined by

$$\hat{\varphi} = \varphi + \frac{i\hbar}{2}\nabla \cdot X. \tag{4.20}$$

Proceeding heuristically, without worrying about domains (cf. Sec. V for precise definitions), we see that by the Corollary II.3 and Theorem IV.7, $n_{\varphi_t}^{\hat{N}}$ satisfies

$$D_t n_{\varphi_t}^{\hat{N}} = \frac{1}{\varphi_t}\left(\frac{\partial\hat{N}}{\partial t} + \frac{1}{i\hbar}[\hat{N},H]\right)\varphi_t = 0, \tag{4.21}$$

or, equivalently, for $n_{\varphi_t}^{N}$. So we can also verify, using the definition (4.19) of $N(t)$, the following Heisenberg equations of motion for the Hamiltonian (2.13):

$$\frac{\mathrm{d}Q}{\mathrm{d}t} = P - A(Q),$$

$$\frac{\mathrm{d}P}{\mathrm{d}t} = [P,H] = \frac{1}{2}\{(P-A)\wedge \mathrm{rot}\,A - \mathrm{rot}\,A \wedge (P-A)\} - \nabla V + \frac{1}{i\hbar}[A,H], \tag{4.22}$$

$$\frac{\mathrm{d}H}{\mathrm{d}t} = \frac{\partial H}{\partial t},$$

and the equations (1), (2), and (3) of Proposition IV.3, that $N(t)$ is indeed a constant of motion, i.e., satisfies

$$\frac{\partial N(t)}{\partial t} + \frac{1}{i\hbar}[N(t),H] = 0. \tag{4.23}$$

So we have heuristically checked that the family of operators $N(t)$ defined by (4.19) in terms of any solution $\{X^j, T, \varphi_s\}$ of the system of determining equations of Proposition IV.3 are constants of motion of the system with Hamiltonian H (2.13), associated with the Lie groups of space–time transformations generated by $\hat{N}(t)$.

From now on, we shall refer to $N(t)$ as above as a Nœtherian operator. We must now prove that any Nœtherian operator is indeed a respectable quantum observable, in the sense of Von Neumann.

V. STUDY OF THE NŒTHERIAN OPERATORS

A. Quadratic Hamiltonians

We shall start from the special class of Hamiltonian observables used in Theorem III.7, i.e., of the form

$$H(Q,P,t) = \tfrac{1}{2}[P - A(Q)]^2 + V(Q,t) \quad \text{on } C_0^\infty(\mathbb{R}^n) \tag{5.1}$$

but where, in addition, H is a real-valued polynomial of degree ≤ 2 in Q and P, which may be time dependent.

Let us denote by H_c the classical observable (or symbol) on the phase space $\mathbb{R}^{2n}\times\mathbb{R}$ to which $H \equiv H^W$ is associated by the Weyl calculus[17] of pseudodifferential operators. The set of quadratic inhomogeneous polynomials in q,p on $\mathbb{R}^{2n}$, denoted by $IQ(2n)$, constitutes a Lie algebra under the classical Poisson bracket of observables

$$\{F_c, G_c\} = \sum_{j=1}^{n} \frac{\partial F_c}{\partial q^j}\frac{\partial G_c}{\partial p_j} - \frac{\partial F_c}{\partial p_j}\frac{\partial G_c}{\partial q^j}. \tag{5.2}$$

Since the algebra generated under (5.2) by $IQ(2n)$ and any additional polynomial of order >2 is the set of all polynomials, $IQ(2n)$ will be maximal for our purpose.

Let us consider a smooth family of initial conditions $\psi^\alpha \in \mathcal{D}_H \subset L^2(\mathbb{R}^n, dx)$, $\alpha \in \mathbb{R}$, for the Schrödinger equation of a quadratic Hamiltonian (5.1), such that $\psi^0 = \psi$. The infinitesimal generator $\mathcal{N}$ of the associated one-parameter group in $\mathcal{D}_H$ is defined formally by

$$\mathcal{N}\psi = \frac{d}{d\alpha}\psi^\alpha\bigg|_{\alpha=0}. \tag{5.3}$$

Using the notation (4.7) for the symmetry operator $\hat{N}(t)$ of this Schrödinger equation, we consider the family of transformations $\mathcal{N}$ of the initial conditions ψ such that, under the quantum evolution generated by the quadratic Hamiltonian H,

$$(\mathcal{N}\psi)_t(x) = \hat{N}(t)\psi_t(x), \tag{5.4}$$

where, as before, ψ_t denotes the solution of the above-mentioned Cauchy problem of Schrödinger with initial condition $\psi \in \mathcal{D}_H$.

On the other hand, the ("Weyl") quantization $(-i/\hbar)F^W(Q,P)$ of any observable $F(q,p) \in IQ(2n)$ provides a linear map between Lie algebras, preserving the Lie bracket operation, i.e., a *representation* of such quadratic polynomials by skew-symmetric operators, such that Dirac's correspondence holds,

$$[F^W(Q,P), G^W(Q,P)] = \frac{i}{\hbar}\{F_c, G_c\}^W(Q,P) \tag{5.5}$$

for Q and P the quantum position and momentum observables, respectively. We consider first the simplest quadratic Hamiltonian (5.1), i.e., the free case $A=V=0$. This will prove to be sufficient for any quadratic case (cf. Proposition V.4).

Proposition V.1:

The above (faithful) representation of $IQ(2n)$ can be exponentiated to a representation of a Lie group, called the inhomogeneous (or extended) metaplectic group and denoted $iMp(n)$, which is the semidirect product of $Mp(n)$, the ("metaplectic") group generated by the quadratic observables and W_n, the Heisenberg group generated by the linear and constant observables. In particular, any generator $\mathcal{N}$ satisfying (5.4) *belongs to the inhomogeneous metaplectic algebra, denoted by $imp(n)$.*

Proof: Let us denote by $k_0(q,t,x)$ the propagator of the free Schrödinger equation (2.2) [i.e.,

with $H=H_0$ in (5.1), where $A=V=0$]. Using the definition (4.7) of $\hat{N}(t)$, the rhs of Eq. (5.4) can be written as

$$\int_{\mathbb{R}^n} \psi(q)\left\{X^j(x,t)\left(-i\hbar\frac{\partial k_0}{\partial x^j}\right)-T(t)i\hbar\frac{\partial k_0}{\partial t}+\varphi(x,t)k_0\right\}(q,t,x)\mathrm{d}q$$
$$=\int_{\mathbb{R}^n}\left\{i\hbar X^j(x,t)\frac{\partial\psi(q)}{\partial q^j}+T(t)\frac{\hbar^2}{2}\frac{\partial^2\psi(q)}{\partial(q^j)^2}+\varphi(x,t)\right\}k_0(q,t,x)\mathrm{d}q,$$

where the space translation invariance of k_0 has been used. Taking $\lim_{t\downarrow 0}$, this provides the following explicit form of $\mathcal{N}$ defined on $C_0^\infty(\mathbb{R}^n)$ by (5.4):

$$\mathcal{N}=-X^j(Q,0)P_j-\tfrac{1}{2}T(0)P_j^2+\varphi(Q,0). \tag{5.6}$$

□

Clearly, the maximal Lie algebra generated by such infinitesimal operators is a subalgebra, denoted by $\mathcal{G}_s(n)$, of the above-mentioned Weyl quantization of $IQ(2n)$.

Equivalently, each $X^j(x,0)$ can be an inhomogeneous polynomial of degree 1, $T(0)$ is a constant and $\varphi(x,0)$ an inhomogeneous polynomial of degree 2. Taking into account the restrictions imposed by (5.4) and the special form of our free Schrödinger equation, one computes that the dimension of this ("symmetry") Lie algebra $\mathcal{G}_s(n)$ of skew-symmetric operators is $(n/2)(n+3)+4=l$.

Here is a basis of $\mathcal{G}_s(n)$, for $j,k=1,2,\ldots,n$:

$$B_s(n)=\left\{i, iq^k, \hbar\frac{\partial}{\partial q^k}, i\sum_k (q^k)^2, i\frac{\hbar^2}{2}\sum_k\frac{\partial^2}{\partial(q^k)^2}\quad,\quad \hbar\sum_k q^k\frac{\partial}{\partial q^k}+\frac{\hbar}{2}n,\ \hbar\left(q^j\frac{\partial}{\partial q^k}-q^k\frac{\partial}{\partial q^j}\right)\right\}. \tag{5.7}$$

We shall denote by $\mathcal{N}_j, j=1,2,\ldots,(n/2)(n+3)+4\equiv l$, the skew-Hermitian operators of $B_s(n)$ on $L^2(R^n)$. A necessary condition for exponentiating this representation of the Lie algebra $\mathcal{G}_s(n)$ is that all the generators $\mathcal{N}_j$ should be essentially skew-adjoint on a common domain in the Hilbert spaces. We shall use the following general result of Nelson[18] (cf. also Ref. 19):

Let G be a simply connected Lie group with an ℓ-dimensional Lie algebra $\mathcal{G}$, and a given representation of $\mathcal{G}$ by unbounded skew-Hermitian operators $\mathcal{N}_j, j=1,\ldots,\ell$, on a Hilbert space $\mathcal{H}$. Then this representation of $\mathcal{G}$ arises by differentiation of a unique unitary representation of $\mathcal{G}$ if there is dense set vectors ψ in the domain of any product $\mathcal{N}_{j_1},\ldots,\mathcal{N}_{j_m}$ and such that

$$\frac{\|\mathcal{N}_{j_1}\cdots\mathcal{N}_{j_m}\psi\|_{\mathcal{H}}}{m!}\le CK^m, \tag{5.8}$$

$\forall m\in\mathbb{N}$ and $\forall j_i\in\{1,\ldots,\ell\}$, for C,K two positive constants. Such a $\psi\in\mathcal{H}$ is called "analytic for $\{\mathcal{N}_j\}_{j=1}^{\ell}$."

In our case we have the following.

Lemma V.2:

The finite linear combinations of the Hermite functions on $\mathbb{R}^n$ (i.e., the products of one-dimensional Hermite functions) are analytic vectors for any products $\mathcal{N}_{j_1}\ldots\mathcal{N}_{j_m}$ of the generators listed in the basis (5.7) *of $\mathcal{G}_s(n)$.*

Proof: Since the set of finite linear combinations of Hermite functions is dense in $L^2(\mathbb{R}^n)$, one needs only to show that each Hermite function is an analytic vector for any $\mathcal{N}_{j1}\cdots\mathcal{N}_{jm}$. Instead of the standard basic $\{i, iq^k, \hbar\partial/\partial q^k\}, k=1,\ldots,n$, used in (5.7) for the Heisenberg algebra (of constant and linear observables in q and p), consider the linear combinations called creation and annihilation operators:

$$\left\{ i, A_k \equiv \frac{1}{\sqrt{2}}\left(q^k + \hbar \frac{\partial}{\partial q^k} \right), \quad A_k^+ \equiv \frac{1}{\sqrt{2}}\left(q^k - \hbar \frac{\partial}{\partial q^k} \right) \right\}. \tag{5.9}$$

Expressing the Hermite function in terms of A_k^+, one shows that those functions are analytical vectors for q^k and $-i\hbar(\partial/\partial q^k)$ (see, e.g., Ref. 4, p. 204). On the other hand, the operators of $B_s(n)$ quadratic in q and p are generated by all possible double products of creation and annihilation operators and it is known that the Hermite functions are analytic vectors as well for such quadratic observables (Ref. 19, p. 190). □

So there is indeed a unique representation of a Lie group $G_s(n)$ whose infinitesimal version (or differential) is the symmetry algebra $\mathcal{G}_s(n)$. The representation is included in the so-called extended metaplectic representation[19] which is the semidirect product of the $n(2n+1)$-dimensional metaplectic group $Mp(n)$, generated by all quadratic observables, and the $(2n+1)$-dimensional Heisenberg group W_n generated by the constant and liner observable.

In particular, let us consider matrices D in the symplectic Lie algebra $\mathcal{S}p(2n)$, i.e., of the form

$$D = \begin{pmatrix} W^T & Z \\ Y & -W \end{pmatrix}, \tag{5.10}$$

where Y and Z are $n \times n$ real matrices of the form $Y = \gamma \mathbb{1}, Z = \beta \mathbb{1}$, with γ, β two real constants, $\mathbb{1}$ the $n \times n$ identity matrix, and W is a $n \times n$ real matrix of the form

$$W = \begin{pmatrix} \delta & -W_{21} & -W_{31} & \cdots & \cdots & -W_{n1} \\ W_{21} & \delta & -W_{32} & \cdots & \cdots & -W_{n2} \\ W_{32} & W_{32} & \delta & \cdots & \cdots & -W_{n3} \\ \vdots & & & \ddots & & \vdots \\ \vdots & & & & \ddots & -W_{nn-1} \\ W_{n1} & W_{n2} & \cdots & \cdots & W_{nn-1} & \delta \end{pmatrix} \tag{5.11}$$

for δ a constant. Then we use the faithful representation of $\mathcal{S}p(2n)$ by skew-Hermitian quadratic operators associated with the names of Segal, Shale, and Weil,[20]

$$D \mapsto -iP_D^W(Q,P) \equiv \beta \frac{i\hbar^2}{2} \frac{\partial^2}{\partial q_k^2} - \hbar\, q_k W_{jk} \frac{\partial}{\partial q^j} - \frac{\hbar}{2} n\delta + \gamma \frac{i}{2} q_k^2, \tag{5.12}$$

which is the infinitesimal version of the representation of some elements M_α of the symplectic groups $\mathcal{S}p(2n)$ by unitary groups $U_\alpha, \alpha \in R$, on $L^2(R^n)$,

$$M_\alpha = e^{\alpha D} \mapsto U_\alpha = e^{\alpha P_D^W(Q,P)}.$$

On the classical side, each M_α is a one-parameter group of linear difeomorphisms of the classical phase space $\mathbb{R}^{2n}$, whose associated quadratic Hamiltonian vector field v_D is defined by

$$\begin{aligned} v_D(F_c) &= \frac{\mathrm{d}}{\mathrm{d}\alpha} F_c(M_\alpha(q,p))\big|_{\alpha=0} = (W^T q + \beta p)\nabla_q F_c + (\gamma q - Wp)\nabla_p F_c \\ &= \nabla_p P_D^c \cdot \nabla_q F_c - \nabla_q P_D^c \cdot \nabla_p F_c \\ &= \{F_c, P_D^c\} \end{aligned} \tag{5.13}$$

on any F^c in the Schwartz space of smooth and rapidly decreasing functions, which are C^∞ vectors for the metaplectic representation. Equation (5.13) holds since the classical observable P_D^c in $IQ(2n)$ associated with $D \in \mathcal{S}p(2n)$ is

$$P_D^c(q,p) = \frac{\beta}{2}p^2 + qWp - \frac{\gamma}{2}q^2. \tag{5.14}$$

Notice that the only additional constant term in the representation (5.12) with respect to (5.14) is due to the Weyl (Jordan) symmetrization of the classical qWp term in (5.14).

The relation $D \in \mathcal{S}p(2n) \mapsto v_D$ preserves the respective Lie parentheses, i.e., is a Lie algebra homomorphism. As mentioned before, the Heisenberg algebra W_n adds to the previous picture the representation of the linear observable on $\mathbb{R}^{2n}$,

$$ap - bq + c \mapsto -i\hbar\, a_k \frac{\partial}{\partial qk} - b_k q^k + c, \tag{5.15}$$

where $a, b \in \mathbb{R}^n$ and $c \in \mathbb{R}$, so that, finally, the classical quadratic observable

$$P_D^c(q,p) = \frac{\beta}{2}p^2 + qWp - \frac{\gamma}{2}q^2 + ap - bq + c \tag{5.16}$$

of Hamiltonian vector field v_P associated with the (affine) equation of Hamilton,

$$\begin{pmatrix} \dot{q} \\ \dot{p} \end{pmatrix} = \begin{pmatrix} \nabla_p P^c \\ -\nabla_q P^c \end{pmatrix} = \begin{pmatrix} W^T & \beta\mathbb{1} \\ \gamma\mathbb{1} & -W \end{pmatrix} \begin{pmatrix} q \\ p \end{pmatrix} + \begin{pmatrix} a \\ b \end{pmatrix},$$

is quantized, according to Weyl, by

$$P_D^W(Q,P) = -\frac{\beta}{2}\hbar^2 \frac{\partial^2}{\partial q_k^2} - i\hbar\, q_k W_{jk} \frac{\partial}{\partial q_j} - \frac{\gamma}{2} q_k^2 - i\hbar\, a_k \frac{\partial}{\partial q_k} - b_k q^k + \left(c - \frac{i\hbar}{2} n\delta \right) \tag{5.17}$$

(with the usual convention of summing over repeated indices). We can now be more specific about the comments at the beginning of this section: The Lie algebra $IQ(2n)$ associated with the semidirect product of the metaplectic group $Mp(n)$ and the Heisenberg group W_n is isomorphic to the algebra of all polynomial observables of degree ≤ 2 on $\mathbb{R}^{2n}$ equipped with the Poisson bracket (5.2) and the representation of the classical observables is Weyl quantization procedure.

Let us observe that some subgroups of $S_p(2n)$ have, under this representation, explicit integral formulations. We will not need them here. See Ref. 19 for some particular cases.

In particular, let us consider $D = \begin{pmatrix} 0 & \mathbb{1} \\ 0 & 0 \end{pmatrix} \in \mathcal{S}p(2n)$, i.e., the case $\beta = 1, \gamma = 0, W = 0$ in (5.14). So the associated classical observable reduces to our free Hamiltonian

$$P_A^c(q,p) = \tfrac{1}{2}p^2 \equiv H_0(p),$$

and its Weyl quantization is, of course,

$$P_A^W(Q,P) = -\frac{i}{\hbar} H_0(P)$$

or $i\mathcal{N}_{(2n+3)}$ in term of the $(2n+3)$th element of the basis $B_s(n)$ (5.7). Denoting the associated parameter α by t, let us consider

$$U_t = e^{tP_A^W} = e^{-(i/\hbar)tH_0}, \quad t \in \mathrm{R},$$

i.e., the strongly continuous unitary group evolution in $L^2(\mathbb{R}^n)$, solving the free Schrödinger equation, and defined on $\mathcal{D}_{H_0}$. This groups acts on the symmetry algebra $\mathcal{G}_s(n)$ generated by the symmetry operators $\mathcal{N}_j, j = 1, \cdots (n/2)(n+3)+4$ via the adjoint representation

$$\mathcal{N} \mapsto U_t \mathcal{N} U_t \equiv \hat{N}(t). \tag{5.18}$$

Since this representation sends analytic vectors into analytic vectors, the domains are preserved, $\mathcal{D}_{\mathcal{N}} = \mathcal{D}_{\hat{N}(t)}$. In other words, although H_0 and the operators $-i\mathcal{N}$ are unbounded symmetric operators, they are essentially self-adjoint and defined on a common dense invariant domain of analytic vectors in $L^2(\mathbb{R}^n)$. By a variant of the commutator theorem,[4] the Baker-Campbell-Hausdorff formula still holds. The image of the basis $B_s(n)$ under (5.18) is, therefore, computed as follows:

$$\left\{ i, iq^k - t\hbar \frac{\partial}{\partial q^k}, \hbar \frac{\partial}{\partial q^k}, i\sum_k (q^k)^2 - 2t\left(\sum_k q^k \hbar \frac{\partial}{\partial q^k} + \frac{\hbar}{2} n \right) - 2t^2 \hbar \frac{\partial}{\partial t}, \hbar \frac{\partial}{\partial t}, \right.$$
$$\left. \hbar \sum_k q^k \frac{\partial}{\partial q^k} + \frac{\hbar}{2} n + 2t\hbar \frac{\partial}{\partial t}, \hbar \left(q^j \frac{\partial}{\partial q^k} - q^k \frac{\partial}{\partial q^j} \right) \right\}, \tag{5.19}$$

where $j,k = 1, \cdots, n$. We shall denote by $\hat{N}_j(t), j = 1, \cdots, \ell$, any of those $\ell = (n/2)(n+3)+4$ resulting skew-symmetric operators.

Theorem V.3:

For fixed $t \in \mathbb{R}$, let us define by $U_t V_0^j(\alpha) U_{-t} = V_t^j(\alpha)$, $\alpha \in \mathbb{R}$, a one-parameter family of operators in $L^2(\mathbb{R}^n)$, with $V_0^j(\alpha) = e^{(\alpha/\hbar)\mathcal{N}_j}$ and $V_t^j(\alpha) = e^{(\alpha/\hbar)\hat{N}_j(t)}$, $\hat{N}_j(t)$ being any of the skew-symmetric operators of (5.19), *image under the adjoint representation* (5.18) *of the one-parameter group of operators $V_0^j(\alpha)$, $j = 1, \ldots, \ell$, generated by the basis* (5.7) *of the symmetry algebra $\mathcal{G}_s(n)$. Then, the $V_t^j(\alpha)$ are symmetry operators of the free, Schrödinger equation $i\hbar(\partial/\partial t)\psi_t = H_0\psi_t$ in $L^2(\mathbb{R}^n)$, i.e., they map any regular solution ψ_t of this equation in another solution of the same equation $\tilde{\psi}_t = V_t^j(\alpha)\psi_t$, and the $i\hat{N}_j(t)$ are constant observables of the free quantum system.*

Proof: Let us consider $\psi_t = U_t\psi$, $\psi \in \mathcal{D}_H$ for $U_t = e^{-(i/\hbar)tH_0}$, $t \in \mathbb{R}$. Then $V_t^j(\alpha)\psi_t \equiv e^{-(i/\hbar)tH_0}\psi^\alpha$, $\alpha \in \mathbb{R}$, is, by construction, solution of the same free Schrödinger equation, for the one-parameter family of initial conditions in $\mathcal{D}_H \subset L^2(\mathbb{R}^n)$ defined by $\psi^\alpha \equiv e^{(\alpha/\hbar)\mathcal{N}_j}\psi$.

It follows from the definition of $V_t^j(\alpha)$ and the computation of $(\partial/\partial\alpha)|_{\alpha=0}$ in the relation above that

$$(\mathcal{N}_j\psi)_t(x) = \hat{N}_j(t)\psi_t(x), \quad j = 1, \ldots, \frac{n}{2}(n+3)+4, \tag{5.20}$$

is the infinitesimal version of this relation, as required by the definition (5.4) of a symmetry operator.

Now by (5.18), $U_t \mathcal{N}_j U_t^{-1} = \hat{N}_j(t)$. Proceeding like in Sec. II (or observing, as before, that the Baker-Campbell-Hausdorff formula holds here), we see that

$$\frac{\mathrm{d}}{\mathrm{d}t}(\psi_t, \hat{N}_j(t)\varphi_t) = \left(\psi_t, \left(\frac{\partial \hat{N}_j}{\partial t} + \frac{1}{i\hbar}[\hat{N}_j, H_0] \right) \varphi_t \right).$$

But, by definition (4.9) of a symmetry operator $\hat{N}(t)$ for the free Schrödinger operator

$$\mathbb{Q}\varphi_t \equiv \left(i\frac{\partial}{\partial t} - \frac{1}{\hbar}H_0 \right)\varphi_t, \tag{5.21}$$

we had

$$[\hat{N}(t), \mathbb{Q}]\varphi_t = \lambda_N \mathbb{Q}\varphi_t = 0 \tag{5.22}$$

for any $\varphi_t \in \mathcal{D}^{\hat{N}}(t)$ (in the notations of Proposition II.2). In particular, for any $\hat{N}_j(t)$ as before we find, by Proposition IV.6,

$$i\frac{\mathrm{d}}{\mathrm{d}t}(\varphi_t,\hat{N}_j(t)\varphi_t)=0, \tag{5.23}$$

i.e., that $i\hat{N}_j(t)$ is a constant observable of the free Schrödinger equation. □

Any quadratic Hamiltonian H of the form (5.1) can, in fact, be handled in the same way since the infinitesimal generators of $B_s(n)$ [cf. (5.7)] form a vector space. Let us see how, in the special case $n=2$ for the simplicity of the illustration (and notations).

Proposition V.4:

All Schrödinger equations in $L^2(\mathbb{R}^2)$, *of the form*

$$i\hbar\frac{\partial}{\partial t}\psi_t=\left[-\frac{\hbar^2}{2}\Delta+c_1((x^1)^2+(x^2)^2)+c_2\left(-i\hbar\frac{\partial}{\partial x^1}\right)+c_3\left(-i\hbar\frac{\partial}{\partial x^2}\right)+c_4\left(-i\hbar\left(x^1\frac{\partial}{\partial x^2}-x^2\frac{\partial}{\partial x^1}\right)\right)\right.$$
$$\left.+c_5x^1+c_6x^2+c_7\left(-i\hbar\left(x^1\frac{\partial}{\partial x^1}+x^2\frac{\partial}{\partial x^2}\right)\right)+c_8\right]\psi_t, \tag{5.24}$$

with $c_k\in\mathbb{R}$ *such that the Hamiltonian is essentially self-adjoint on* $C_0^\infty(\mathbb{R}^2)$, *have isomorphic symmetry algebras and are equivalent to the free equation*

$$i\hbar\frac{\partial}{\partial t}\psi_t=H_0\psi_t, \tag{5.25}$$

where H_0 *is the two-dimensional free Hamiltonian*

$$H_0=-\frac{\hbar^2}{2}\left(\frac{\partial^2}{\partial(x^1)^2}+\frac{\partial^2}{\partial(x^2)^2}\right).$$

Proof: Given in Ref. 15. □

In order to illustrate this isomorphism, let us consider the following linear combination of elements of $\mathcal{G}_s(2)$ [using the notations of (5.7)]:

$$\mathcal{N}=-\mathcal{N}_6+\frac{1}{2}\mathcal{N}_7=i\left(-\frac{\hbar^2}{2}\Delta+\frac{1}{2}((x^1)^2+(x^2)^2)\right)\equiv iH_{0s}. \tag{5.26}$$

H_{0s} is the Hamiltonian observable of the isotropic two-dimensional harmonic oscillator. So, for any $\psi\in\mathcal{D}_{H_{0s}}$,

$$\psi_t(x)=\left(e^{-(i/\hbar)tH_{0s}}\psi\right)(x) \tag{5.27}$$

solves in $L^2(\mathbb{R}^2)$

$$i\hbar\frac{\partial\psi_t}{\partial t}=H_{0s}\psi_t,$$
$$\psi_0(x)=\psi(x). \tag{5.28}$$

Now pick any $\mathcal{N}_j$, $j=1,\ldots,9$ in $B_s(2)$, the basis (5.7) of the free symmetry algebra $\mathcal{G}_s(2)$. Then, according to (5.18), but now for $U_t^{0s}=\exp(-(i/\hbar)tH_{0s})$,

$$\hat{N}_j^{0s}(t)=U_t^{0s}\mathcal{N}_j(U_t^{0s})^{-1} \tag{5.29}$$

is a symmetry generator of the harmonic oscillator, for the same reason as in Theorem V.3. Therefore $i\hat{N}_j^{0s}(t)$ is a constant observable of the quantum harmonic oscillator (5.28). All such harmonic symmetry operators $\hat{N}_j^{0s}(t)$, $j=1,\ldots,9$, are linear combinations of the $\mathcal{N}_j$ in $B_s(2)$, with time-dependent coefficients denoted by $X^k(x,t)$, $k=1,2,T(t)$ and $\varphi(x,t)$ in (4.7).

By Proposition IV.3, we already know the system of partial differential equations solved by these coefficients X^k, T, and φ regarded as functions. In our case, since $V(q)=\frac{1}{2}((x^1)^2+(x^2)^2)$ and the vector field A in (5.26) vanishes, they reduce to

$$\frac{\partial X^1}{\partial x^2}+\frac{\partial X^2}{\partial x^1}=0, \quad \frac{\partial X^1}{\partial x^1}+\frac{\partial X^2}{\partial x^2}=\frac{\mathrm{d}T}{\mathrm{d}t},$$
$$\frac{\partial X^j}{\partial t}=-\frac{\partial \varphi}{\partial x^j}, \quad j=1,2, \tag{5.30}$$
$$\frac{\partial \varphi}{\partial t}-\frac{i\hbar}{2}\Delta\varphi=X^1x^1+X^2x^2+\frac{\mathrm{d}T}{\mathrm{d}t}\cdot\frac{1}{2}((x^1)^2+(x^2)^2).$$

In particular, instead of solving (5.30), we could use the Baker-Campbell-Hausdorff formula in (5.29), for $\mathcal{N}_j$ any explicit element of the free basis $B_s(2)$ of (5.7). Let us take, for example, $\mathcal{N}_4=\hbar\,\partial/\partial x^1$. According to (5.19) this generator is invariant under (5.18), i.e., $\hat{N}_4(t)=\hbar\,\partial/\partial x^1$. On the other hand, under (5.29) we obtain, on $C_0^\infty(\mathbb{R}^2)$,

$$\hat{N}_4^{0s}(t)=\exp\left(-\frac{i}{\hbar}tH_{0s}\right)\mathcal{N}_4\exp\left(\frac{i}{\hbar}tH_{0s}\right)=\left(1-\frac{t^2}{2!}+\frac{t^4}{4!}-\cdots\right)\left(\hbar\frac{\partial}{\partial x^1}\right)-x^1\left(t-\frac{t^3}{3!}+\frac{t^5}{5!}-\cdots\right).$$

Comparing with the general form (4.7), this means that the coefficients of $\hat{N}_4^{0s}(t)$ are, respectively,

$$X^1(x,t)=\cos t, \quad X^2(x,t)=0, \quad T(t)=0, \quad \varphi(x,t)=x^1\sin t. \tag{5.31}$$

One verifies easily that (5.31) makes up a solution of the system (5.30). In other words,

$$\cos t\cdot P_1(t)+\sin t\cdot Q^1(t) \tag{5.32}$$

is a constant of motion of the quantum harmonic oscillator. This can also be easily verified otherwise: Consider the solution of the equation of motion of this system, in the Heisenberg picture. Those (linear) equations are, for $j=1,2$,

$$\begin{pmatrix}Q^j(t)\\P_j(t)\end{pmatrix}=\Omega(t)\begin{pmatrix}Q^j\\P_j\end{pmatrix}, \quad \text{with } \Omega(t)=\begin{pmatrix}\cos t & \sin t\\ -\sin t & \cos t\end{pmatrix}\in \mathrm{SO}(2). \tag{5.33}$$

In particular, the (constant) operators which are initial conditions of this solution are given by

$$\begin{pmatrix}Q^j\\P_j\end{pmatrix}=\begin{pmatrix}\cos t & -\sin t\\ \sin t & \cos t\end{pmatrix}\begin{pmatrix}Q^j(t)\\P_j(t)\end{pmatrix}, \quad j=1,2. \tag{5.34}$$

So the constant of motion (5.32) provided by Nœther's theorem coincides, in this elementary case, with the initial momentum P_1 of the solution (5.33). Another trivial example of symmetry generator is

$$\cos tQ^2(t)-\sin tP_2(t)\equiv Q^2, \tag{5.35}$$

associated with the following solution of the system (5.30)

$$X^1(x,t)=0, \quad X^2(x,t)=-\sin t, \quad T(t)=0, \quad \varphi(x,t)=x^2\cos t.$$

Fortunately, many nontrivial examples follow as well from this constructions (cf. Sec. VIII). In this way, the free basis $B_s(2)$ allows us to compute the basis of the symmetry Lie algebra of any quadratic Hamiltonian of the form (5.24) and then their associated symmetry operators $\hat{N}(t)$. We summarize this result (in two dimensions, for simplicity) as follows.

Proposition V.5:

Let us consider any essentially self-adjoint quadratic Hamiltonian H_Q in $L^2(\mathbb{R}^2)$, as in the rhs of equation (5.24), *i.e., resulting from a linear combination of elements of $\mathcal{G}_s(2)$. For any ψ*

$\in \mathcal{D}_{H_Q}$, $\psi_t = (e^{-(i/\hbar)tH_Q}\psi)(x)$ *solves the Cauchy problem for the associated Schrödinger equation. If* $\mathcal{N}_j$, $j=1,\ldots,9$, *denotes any element of the basis* $B_s(2)$ *of the free symmetry algebra* $\mathcal{G}_s(2)$ *then, on the dense invariant domain of analytic vectors of Lemma V.2*,

$$\hat{N}_j^{H_Q}(t) = U_t^Q \mathcal{N}_j (U_t^Q)^{-1} \tag{5.36}$$

is a symmetry generator of the H_Q*-system, where* U_t^Q, $t \in \mathbb{R}$, *denotes the one-parameter strongly continuous group of unitary operators*

$$U_t^Q = e^{-(i/\hbar)tH_Q} : L^2(\mathbb{R}^2) \to L^2(\mathbb{R}^2).$$

In particular, $i\hat{N}_j^{H_Q}(t)$ *is a constant of the motion of the* H_Q*-system. By construction, the time-dependent coefficients* $X^j(x,t), T(t)$ *and* $\varphi(x,t)$ *of this constant observable solve the system of equations of Proposition IV.3, for the quadratic Hamiltonian* H_Q.

Moreover, if W_t *denotes the one-parameter, strongly continuous, group of unitary operators in* $L^2(\mathbb{R}^2)$ *defined by*

$$W_t = U_t^Q \cdot e^{(i/\hbar)tH_0} \tag{5.37}$$

on the invariant domain of Lemma V.2, and for H_0 *as in* (5.25), *then* W_t *provides the time-dependent canonical transformation from the free system* (5.25) *to the one of Hamiltonian* H_Q. *In particular, we have*

$$H_Q = W_t H_0 W_t^{-1} + i\hbar \frac{\mathrm{d}W_t}{\mathrm{d}t} W_t^{-1}. \tag{5.38}$$

Proof: The Hamiltonian defined by the rhs of (5.24) is of the general quadratic form (5.18) with

$$\begin{gathered} \beta = 1, \quad W_{21} = -c_4, \quad \gamma = -2c_1, \quad a_1 = c_2, \quad a_2 = c_3, \\ b_1 = -c_5, \quad b_2 = -c_6, \quad \delta = c_7, \quad c - i\hbar\, c_7 = c_8 \end{gathered} \tag{5.39}$$

and results indeed from a linear combination of elements of $\mathcal{G}_s(2)$. Let H_Q denote a self-adjoint extension of this (lower-bounded) operator in $L^2(\mathbb{R}^2)$. By Stone's theorem, $U_t^Q = e^{-(i/\hbar)tH_Q}$ is a strongly continuous unitary group of evolution in $L^2(\mathbb{R}^n)$ solving the associated Schrödinger equation. Using (5.36), any $\mathcal{N}_j \in B_s(2), j=1,\ldots,9$, evolves into a symmetry generator $\hat{N}_j^{H_Q}(t)$ of the H_Q-system, as in the above-mentioned example.

Let us define a time-dependent unitary operator W_t on the invariant domain of Lemma V.2 by

$$W_t = U_t^Q e^{(i/\hbar)tH_0}.$$

Clearly, if ψ_t is a solution of the free Schrödinger equation (5.25) with initial condition $\psi_0 = \psi \in \mathcal{D}_{H_0}$ then $\phi_t = W_t\psi_t$ solves the Schrödinger equation with quadratic potential H_Q and the same initial condition. Equivalently, an H_Q-solution ϕ_t is given by a quadrature from a solution ψ_t of the free equation. (One could also introduce an extra unitary generator M acting as well on the initial condition ψ, so that

$$W_t' = U_t^Q M e^{(i/\hbar)tH_0}$$

is unitary.)

Then, it is well known that such a time-dependent unitary transformation W_t the Hamiltonian H_0 is transformed into H_Q given by (5.38). Precisely, this goes as follows.

Let us write $H_Q = H_0 + (H_Q - H_0)$ and denoted by $\mathcal{D}_Q$ the above-mentioned common dense domain of analytic vectors of H_0 and H_Q. Then $H_Q = U_t^Q H_0 (U_t^Q)^{-1} + U_t^Q (H_Q - H_0)(U_t^Q)^{-1}$ on $\mathcal{D}_Q$. By the definition (5.37) of W_t this is also $H_Q = W_t H_0 W_t^{-1} + U_t^Q (H_Q - H_0)(U_t^Q)^{-1}$ on $\mathcal{D}_Q$. Now on $\mathcal{D}_Q$ [in the strong $L^2(\mathbb{R}^n)$ sense]

$$
\begin{aligned}
i\hbar\frac{dW_t}{dt}\cdot W_t^{-1} &= ih\frac{d}{dt}(U_t^Q e^{(i/\hbar)tH_0})e^{-(i/\hbar)tH_0}(U_t^Q)^{-1}\\
&= H_Q - U_t^Q H_0 (U_t^Q)^{-1}\\
&= U_t^Q (H_Q - H_0)(U_t^Q)^{-1},
\end{aligned}
$$

so $H_Q = W_t H_0 W_t^{-1} + i\hbar(dW_t/dt)W_t^{-1}$ on $\mathcal{D}_Q$.

Since $\mathcal{D}_Q$ is a domain of essential self-adjointness, this implies (5.38). □

Let us make a remark on the problem of the zeroes set $\mathcal{N}_t^\psi = \{x \in \mathbb{R}^n \,|\, \psi_t(x) = 0\}$.

As mentioned in Sec. II, our construction [see the definitions (2.5) and (2.14), for example] requires to consider (t,x)-admissible states ψ, i.e., such that $\psi_t(x) \neq 0$.

The study of the zeroes of $\psi_t(x)$ amounts to investigate the wave front set WF of the integral kernel of Schrödinger,

$$k(x,t,y) = \text{kernel}(e^{-(i/\hbar)tH})(x,y)$$

for fixed initial configuration x and time t. This problem has been considered by Zelditch[21] and Weinstein[22] for H slight perturbations of a quadratic Hamiltonian H_Q.

For example, in the case of the classical harmonic oscillator Hamiltonian $P_A^c(q,p) = (1/2)p^2 + (\omega^2/2)q^2$ [i.e., the case $\beta = 1$, $\gamma = -\omega^2$ and $W = 0$ in (5.14)] the initial zero (cf. Mehler formula) of the associated ψ_t reappears at times $k\pi/\omega$ and positions $(-1)^k x = y, k \in \mathbb{Z}$.

For more about this, see also Fujiwara (Ref. 23).

Under bounded perturbations with bounded derivative, the singularities of ψ_t behave as if H was the harmonic Hamiltonian, i.e., the wave front sets are stable under these weak perturbations.

The study of these singularities is made using the geometry of the underlying Hamiltonian flow on the classical phase space.

B. General Hamiltonians

When the Hamiltonian H of our given quantum system is not of the quadratic form H_Q considered in Sec. V A (cf., for example, Proposition V.5), the symmetry operators $N(t)$ defined formally in (4.19) with coefficients X, T, φ solving the PDE of Proposition IV.3 are still quantum constants of motion.

However, Dirac's correspondence (5.5) does not hold anymore and the metaplectic representation used in Sec. V B is of no help. In general, no explicit basis of the associated symmetry algebra can be found. But since, by hypothesis, the coefficients X, T, and φ of the symmetry operator $N(t)$ are analytic functions, it is easy to show that $N(t)$ is well defined for a large class of Hamiltonians H.

Proposition V.6: *Let us consider* $H = -(\hbar^2/2)\Delta + V$, *with* $V: \mathbb{R}^n \to \mathbb{R}$ *as in the Kato-Rellich theorem, so that* H *is self-adjoint in* $L^2(\mathbb{R}^2)$. *Let* $X: \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n, \varphi: \mathbb{R}^n \times \mathbb{R} \to \mathbb{C}$ *and* $T: \mathbb{R} \to \mathbb{R}$ *be analytic functions, respectively, of the form* $X(q,t) = \sum_{n=0}^\infty \alpha_n(t) q^n$, *with* α_n *real-valued smooth functions,* $\varphi(q,t) = \sum_{n=0}^\infty \gamma_n(t) q^n$ *with* γ_n *complex-valued and smooth. If* $\sum_{n=0}^\infty |\alpha_n(t)| \|Q^n P \varphi\| < \infty$ *and* $\sum_{n=0}^\infty |\gamma_n(t)| \, \|Q^n \varphi\| < \infty$, $\forall \varphi \in \mathcal{A}(H)$, *the set of analytic vectors for* H, *then the Nœtherian symmetry operator*

$$N(t) = X^j(Q(t),t) \circ P_j(t) - T(t)H(t) + \hat{\varphi}(Q(t),t) \tag{5.40}$$

is a densely defined operator in $L^2(\mathbb{R}^n)$.

VI. THE QUANTUM THEOREM OF NŒTHER IN A RIEMANNIAN MANIFOLD

Let us consider now a classical system like the one of Sec. IV but with a configuration space which is, instead of $\mathbb{R}^n$, any n-dimensional smooth Riemannian manifold M, with positive-definite metric tensor $g_{i,j}$.

The state ψ of the associated quantum system evolves in $L^2(M,\mathrm{d}\mathcal{M})$, with volume element $\mathrm{d}\mathcal{M}(q)=\sqrt{g}\,\mathrm{d}q$, where $g=\det(g_{ij})$, according to

$$i\hbar\frac{\partial\psi_t}{\partial t}=H\psi_t \tag{6.1}$$

for the Hamiltonian of the form (2.13)

$$H=-\frac{\hbar^2}{2}\nabla^j\nabla_j+i\hbar A^j\nabla_j+\frac{i\hbar}{2}\nabla_k A^k+\frac{1}{2}\|A\|^2+V, \tag{6.2}$$

where $\|\cdot\|$ denotes the Riemannian norm and ∇_j is the covariant derivative with respect to the Levi-Civita connection. Let us recall that for this connection, the Christoffel symbols are symmetric: $\Gamma^i_{jk}=\Gamma^i_{kj}$, i.e., we are in the torsion-free case.

Conditions on the vector and scalar potentials V and A ensuring the self-adjointness of H on a dense domain of $L^2(M,\sqrt{g}\mathrm{d}q)$ are known; see, e.g., Refs. 24–27.

The relevant one-parameter group $U_\alpha, \alpha\in\mathbb{R}$, of transformations of the extended configuration space will be denoted, like in the flat case, by

$$U_\alpha: M\times\mathbb{R},(q^i,t)\mapsto(Q^i_\alpha=q^i+\alpha X^i(q,t)+o(\alpha),\tau_\alpha=t+\alpha T(t)+o(\alpha)), \tag{6.3}$$

where q^i are local configuration coordinates and

$$X: M\times\mathbb{R}\to M,\quad T:\mathbb{R}\to\mathbb{R},$$

are real analytic. For g any scalar field on $M\times\mathbb{R}$ such that $g\psi_t\in\mathcal{D}_H$ and such that $\dot{g}$ exists, let us define, like in (2.11), the quantum derivative along ψ_t by

$$D_t g=\frac{1}{\psi_t}\left(\frac{\partial}{\partial t}-\frac{1}{i\hbar}H\right)(g\psi_t). \tag{6.4}$$

Introducing (6.1) and (6.2), this means that

$$D_t g=\left(\frac{\partial}{\partial t}+\left(-i\hbar\frac{\nabla^j\psi_t}{\psi_t}-A^j\right)\nabla_j-\frac{i\hbar}{2}\nabla^j\nabla_j\right)g. \tag{6.5}$$

Since this can be interpreted as a quantum deformation of the classical "absolute" (or "intrinsic") derivative of the scalar g along a smooth continuous curve $q^j=q^j(t)$, we shall define $D_t q^j$ by the vector

$$D_t q^j=-i\hbar\frac{\nabla^j\psi_t(q)}{\psi_t(q)}-A^j(q)\equiv B^j(q,t), \tag{6.6}$$

in analogy with what we have done in the proof of Theorem III.7 of Sec. III. Choosing, like in Eq. (3.16), $g(q,\tau)=S(q,\tau)$, with

$$S(q,\tau)=-i\hbar\,\ln\psi_\tau(q) \tag{6.7}$$

for any τ,q ψ-admissible solution of the Schrödinger equation (6.1), we can compute

$$D_\tau S(q,\tau)=\frac{1}{2}D_\tau q^j D_\tau q_j-\frac{i\hbar}{2}\nabla_j A^j+A_j D_\tau q^j-V(q). \tag{6.8}$$

The rhs of (6.8) defines the Lagrangian $L(D_\tau q,q)$ associated with the quantum system (6.1). Defining, for any $g=(g^{(s)})_{s\in\mathbb{R}}$ complex-valued, measurable and such that $g^{(s)}(\cdot)\psi_s(\cdot)\in L^2(M,\mathrm{d}\mathcal{M})$, the (forward) quantum conditional expectation in the state ψ by

$$E_{\psi}^{t,x}[g^{(s)}] = \int g^{(s)}(\xi)p(s,\xi,t,x)\mathrm{d}\mathcal{M}(\xi), \tag{6.9}$$

where, for any (t,x) ψ-admissible, $s \leq t$,

$$p(s,\xi,t,x)\mathrm{d}\mathcal{M}(\xi) = \psi_s(\xi)k_-(\rho,t-s,x)(\psi_t(x))^{-1}\,\mathrm{d}\mathcal{M}(\xi) \tag{6.10}$$

with k_- the advanced propagator of the Schrödinger equation (6.1), one verifies that Theorem III.7 still holds. So, canceling the boundary term without loss of generality, the regularized action functional (6.3) becomes

$$\begin{aligned} S_L(x,t_1) &= M_{\psi}^{t_1,x}\left[\int_{t_0}^{t_1}\left(\frac{1}{2}(D_t q)^2 - V(q)\right)\mathrm{d}t + \int_{t_0}^{t_1}\left(A_j Dq^j - \frac{i\hbar}{2}\nabla_j A^j\right)\mathrm{d}t\right] \\ &= M_{\psi}^{t_1,x}\left[\int_{t_0}^{t_1}\left(\frac{1}{2}(D_t q)^2 - V(q)\right)\mathrm{d}t + \int_{t_0}^{t_1} A \circ \mathrm{d}q\right], \end{aligned} \tag{6.11}$$

where we have used on M the same notations as in the Euclidean case of equations (3.10) and (3.11).

Given an additional analytic generator $\varphi: M \times \mathbb{R} \to \mathcal{C}$, called the divergence, the invariance of the action (6.11) (up to this divergence term) is defined as in (4.4).

The formal symmetry operator on M becomes, instead of (4.7),

$$\hat{N}(t) = X^j(x,t)(-i\,\hbar\,\nabla_j) - T(t)\left(i\,\hbar\,\frac{\partial}{\partial t}\right) + \varphi(x,t), \tag{6.12}$$

and it is defined by the same commutation property (4.9) with the Schrödinger equation as in the Euclidean case. This property implies the following conditions on X, T, and φ.

Proposition VI.1:

$\hat{N}(t)$ is a symmetry operator for the Schrödinger equation (6.1) *in* $L^2(M,\mathrm{d}\mathcal{M})$, *with Hamiltonian* (6.2) (*where V may depend smoothly on time*) *if and only if the following determining equations hold*:

(1)

$$\frac{\mathrm{d}T}{\mathrm{d}t}g^{jk} = \nabla^j X^k + \nabla^k X^j,$$

(2)

$$\frac{\partial X^j}{\partial t} = -\nabla^j\varphi - \frac{1}{2}\frac{\mathrm{d}T}{\mathrm{d}t}A^j - X^k\nabla_k A^j,$$

(3)

$$\begin{aligned} \frac{\partial\varphi}{\partial t} - A^j\nabla_j\varphi - \frac{i\hbar}{2}\nabla_j\nabla^j\varphi &= X^j\nabla_j\left(\frac{i\hbar}{2}\nabla_k A^k + \frac{1}{2}\|A\|^2 + V\right) \\ &\quad + \frac{\mathrm{d}T}{\mathrm{d}t}\left(\frac{i\hbar}{2}\nabla_k A^k + \frac{1}{2}\|A\|^2 + V\right) + T\frac{\partial V}{\partial t}. \end{aligned}$$

Proof: This is based on a simple computation of $[\hat{N}(t),\mathbb{Q}] = \lambda_{\hat{N}}(x,t)\mathbb{Q}$, where $\mathbb{Q} = (\partial/\partial t) - (i/\hbar)H$ with the Hamiltonian (6.2). Like in the flat Euclidean case, one finds that

$$\lambda_{\hat{N}}(x,t) = -\frac{\mathrm{d}T}{\mathrm{d}t}(t). \tag{6.13}$$

□

Remark: As in the flat Euclidean case, if we allow space-dependent time transformations in (6.3), a further condition is needed for $\hat{N}(t)$ to be a symmetry operator for (6.1). This is

$$\nabla_j T = 0. \tag{6.14}$$

In other words (6.3) is indeed the most general space–time transformation for our purpose.

The integrability conditions of the determining equations (1)–(3) are not as obvious as in the flat Euclidean case, but they have already been investigated.[28]

When the determining equations (1)–(3) hold, the divergence invariance of the action (6.11) [in the sense of the relation (4.4)] is guaranteed by construction.

In order to obtain the general form of the invariance of the Lagrangian under our groups of transformations (Proposition IV.5) we need first to define the quantum derivative along ψ_t of a vector field Y^j on $M \times \mathbb{R}$.

In classical mechanics on a Riemannian manifold M, it is well known that the time derivative of the velocity field is, in general, not a tensor. In consequence, the acceleration is defined as the "absolute" (or "intrinsic") derivative of the velocity.[29] The result is indeed a contravariant tensor of rank one.

Definition VI.2: *Let R^j_k be the Ricci tensor of the Riemannian manifold M. Then the quantum ("absolute") derivative of the complex-valued vector field Y, on $M \times \mathbb{R}$ is defined by*

$$D_t Y^j = \frac{\partial Y^j}{\partial t} + B^k \nabla_k Y^j - \frac{i\hbar}{2}(\nabla^k \nabla_k Y^j + R^j_k Y^k), \tag{6.15}$$

where B^k is given by (6.6).

To be short, we shall denote simply by Δ the operator $\nabla^k \nabla_k + R$, so that

$$D_t Y^j = \frac{\partial Y^j}{\partial t} + B^k \nabla_k Y^j - \frac{i\hbar}{2} \triangle Y^j. \tag{6.15'}$$

On scalars and covariant vectors, the Laplacian $\triangle$ coincides with the Laplace-Kodaira-de Rham operator.[30] One easily shows that this Laplacian commutes with the gradient and the divergence, i.e., for g a scalar field as before,

$$\nabla_j \triangle g = \triangle \nabla_j g,$$

and for Y a vector field,

$$\nabla_j \triangle Y^j = \triangle \nabla_j Y^j.$$

Notice, in contrast, that $[\nabla^j \nabla_j, \nabla_i]$ is not zero, in general.

Proposition VI.3:

Let $L(D_t q, q, t)$ be the Lagrangian, defined by the rhs of (6.8), *of the quantum system, when the potential V is allowed to be a smooth function of the time. A necessary condition for the divergence invariance of the action functional* (6.11) *is*

$$\frac{\partial L}{\partial t} T + \frac{\partial L}{\partial q^j} X^j + \frac{\partial L}{\partial (D_t q)^j} \left(D_t X^j - (D_t q)^j \frac{\mathrm{d}T}{\mathrm{d}t} \right) + L \frac{\mathrm{d}T}{\mathrm{d}t} = -D_t \varphi. \tag{6.16}$$

Proof:

$$D_t X^j = \frac{\partial X^j}{\partial t} + B^k \nabla_k X^j - \frac{i\hbar}{2}(\nabla^k \nabla_k X^j + R^j_k X^k). \tag{6.17}$$

From the determining equation (1) (Proposition VI.1) and $(\mathrm{d}T/\mathrm{d}t) = (2/n)\nabla_j X^j$ (where $n = \dim M$) we have

$$\nabla_l \nabla_k X_j + \nabla_l \nabla_j X_k = 0.$$

Using this in the Ricci identity we get

$$\nabla_l \nabla_k X_j = R^m_{kjl} X_m, \tag{6.18}$$

where R^m_{kjl} denotes the Riemannian-Christoffel curvature tensor. The rhs of (6.18) coincides with $R_{kn,jl}X^n$, so

$$\nabla^n \nabla_k X_j = g^{n,l} R_{kn,jl} X^n$$

and

$$\nabla^k \nabla_k X^j = -R^j_k X^k. \tag{6.19}$$

After introduction of the determining equation (2) (Proposition VI.1) and of (6.19) in the definition (6.17) we obtain

$$D_t X^j = -\nabla^j \varphi - \frac{1}{2}\frac{\mathrm{d}T}{\mathrm{d}t} \cdot A^j - X^k \nabla_k A^j + B^j \nabla_k X^j.$$

In particular,

$$D_t X^j - (D_t q)^j \frac{\mathrm{d}T}{\mathrm{d}t} = -\nabla^j \varphi - \frac{1}{2}\frac{\mathrm{d}T}{\mathrm{d}t} \cdot A^j - X^k \nabla_k A^j - \frac{1}{2} B^j \frac{\mathrm{d}T}{\mathrm{d}t} + \frac{1}{2} B^k (\nabla_k X^j - \nabla^j X_k). \tag{6.20}$$

Now consider the invariance condition (6.16). Using the rhs of (6.8) as a definition of the Lagrangian (for V smoothly time dependent) this condition means explicitly, after simplification,

$$\frac{\partial \varphi}{\partial t} - A^j \nabla_j \varphi - \frac{i\hbar}{2} \nabla_j \nabla^j \varphi = X^j \nabla_j \left[\frac{i\hbar}{2} \nabla_k A^k + \frac{1}{2}\|A\|^2 + V \right] + \frac{\mathrm{d}T}{\mathrm{d}t} \left(\frac{i\hbar}{2} \nabla_k A^k + \frac{1}{2}\|A\|^2 + V \right) + T \frac{\partial V}{\partial t}.$$

This is the determining equation (3) of Proposition VI.1 and, therefore, the invariance condition (6.16) constitutes indeed a necessary condition for the divergence invariance of the action (6.11) under the Lie group of transformations (6.13). □

The main results of the flat case are, now, easily generalized. Using the definition of the quantum derivative along ψ_t of the scalar field $\boldsymbol{S}$ defined by (6.7), one verifies that S solves the quantum Hamilton-Jacobi equation on $M \times \mathbb{R}$,

$$\frac{\partial S}{\partial t} + \frac{1}{2}(\nabla S - A)^2 + V + \frac{i\hbar}{2} \nabla_j A^j - \frac{i\hbar}{2} \nabla^j \nabla_j S = 0, \tag{6.21}$$

where the same remark as after (3.21) applies, as far as our notations are concerned. The quantum Hamilton-Jacobi equation (6.21) provides us with a direct derivation of the regularized equation of motion generalizing (3.28) and the Riemannian version of conservation of energy (3.29).

Let us compute

$$\nabla_j S = B_j + A_j. \tag{6.22}$$

We first notice that

$$\nabla_j \tfrac{1}{2}(\nabla S - A)^2 = \tfrac{1}{2}\nabla_j(B^k B_k) = B^k \nabla_k B_j + (\nabla_j B_k - \nabla_k B_j)B^k.$$

Since, for the Levi-Civita connection, there is no torsion, $\nabla_j B_k - \nabla_k B_j$ is the exterior derivative of B_k, generalizing the curl operator of Proposition III.11. By (6.22) this coincides with $-(\nabla_j A_k - \nabla_k A_j)$ so

$$\nabla_j \tfrac{1}{2}(\nabla S - A)^2 = B^k \nabla_k B_j - (\nabla_j A_k - \nabla_k A_j)B^k. \tag{6.23}$$

On the other hand, as observed after (6.15′), $[\Delta, \nabla_j]S = 0$ implies that

$$\nabla_j \nabla^k \nabla_k S = \nabla^k \nabla_k \nabla_j S + R^k_j \nabla_k S.$$

Finally, using (6.15) and (6.22), the covariant derivative of the quantum Hamilton-Jacobi equation (6.21) reduces to

$$D_t D_t q_j = -(\nabla_j A_k - \nabla_k A_j)B^k - \frac{i\hbar}{2}(\nabla_j \nabla_k A^k - \nabla A_j) - \nabla_j V. \tag{6.24}$$

Now let us consider the space–time observable of energy $h^H_{\psi_t}$ associated with (6.2), namely

$$h^H_{\psi_t} = \frac{H\psi_t}{\psi_t} = -\frac{\hbar^2}{2}\frac{\nabla^j \psi_t}{\psi_t}\frac{\nabla_j \psi_t}{\psi_t} - \frac{\hbar^2}{2}\nabla^j\left(\frac{\nabla_j \psi_t}{\psi_t}\right) + i\hbar A^j \frac{\nabla_j \psi_t}{\psi_t} + \frac{i\hbar}{2}\nabla_k A^k + \frac{1}{2}||A||^2 + V. \tag{6.25}$$

According to (6.6), it is consistent to denote the space–time momentum by

$$p^j = B^j + A^j, \tag{6.26}$$

so that the energy becomes

$$h^H_{\psi_t} = \frac{1}{2}p^2 - A^j p_j + \frac{i\hbar}{2}\nabla^j A_j - \frac{i\hbar}{2}\nabla^j p_j + \frac{1}{2}A^2 + V. \tag{6.25′}$$

Associated with the quantum Hamilton-Jacobi equation (6.21) we notice the following integrability condition:

$$\nabla_j h^H_{\psi_t} = -\frac{\partial B_j}{\partial t}. \tag{6.27}$$

Indeed, from the definition (2.5) and Schrödinger equation (6.1), $h^H_{\psi_t} = -(\partial/\partial t)S$, where the relation (6.7) has been used. In other words, according to (6.6), the relation (6.27) holds. Since the energy space–time observable is a scalar, its quantum derivative along ψ_t is given by (6.5),

$$D_t h^H_{\psi_t} = \frac{\partial h}{\partial t} - B^j \frac{\partial B_j}{\partial t} + \frac{i\hbar}{2}\nabla^j \frac{\partial B_j}{\partial t}, \tag{6.28}$$

where the integrability condition (6.27) was used. On the other hand, by the definition (6.25′) of $h^H_{\psi_t}$,

$$\frac{\partial H^H_{\psi_t}}{\partial t} = B^j \frac{\partial B_j}{\partial t} - \frac{i\hbar}{2}\nabla^j \frac{\partial B_j}{\partial t} + \frac{\partial V}{\partial t}.$$

After substitution in (6.28) we obtain the conservation of the energy

$$D_t h^H_{\psi_t} = \frac{\partial V}{\partial t}. \tag{6.29}$$

Let us collect this information in the

Proposition VI.4:

For the action functional S_L defined by (6.11), *the regularized equation of motion and conservation of energy in an admissible state ψ_t, solution of the Schrödinger equation* (6.1) *in* $L^2(M,\sqrt{g}\mathrm{d}q)$, *are given respectively by*

$$D_t D_t q_j = -(\nabla_j A_k - \nabla_k A_j)B^k - \frac{i\hbar}{2}(\nabla_j \nabla_k A^k - \triangle A_j) - \nabla_j V \tag{6.30}$$

and

$$D_t h^H_{\psi_t} = \frac{\partial V}{\partial t}. \tag{6.31}$$

In particular, when the scalar potential V is time independent, the energy space–time observable is a quantum martingale.

More generally, one shows, like in the flat case (cf. Ref. 31 and 32 for the probabilistic case), the following.

Theorem VI.5 (Theorem of Nœther):

Let us consider the Jordan symmetrization of the formal symmetry operator $\hat{N}(t)$ in $L^2(M,d\mathcal{M})$ defined in (6.12), *i.e., the Nœtherian operator*

$$N(t) = X^j(Q(t),t) \circ P_j(t) - T(t)H(t) + \hat{\varphi}(Q(t),t), \tag{6.32}$$

where $\circ$ denotes Jordan's multiplication of operators,

$$\hat{\varphi} = \varphi + \frac{i\hbar}{2}\nabla_j X^j \tag{6.33}$$

and X, T, and φ are solutions of the determining equations (1), (2), *and* (3) *of Proposition VI.1, for the symmetry groups of the Schrödinger equation* (6.1). *In* (6.32) *P_j and H are, respectively, the momentum and Hamiltonian observable in Heisenberg's picture [cf.* (6.26) *and* (6.2)*].*

Then $N(t)$ is a quantum constant observable, densely defined on $\mathcal{D}_{N(t)} \subset L^2(M,\mathrm{d}\mathcal{M})$ and the associated space–time (scalar) observable $n^N_{\psi_t}$ is a quantum martingale, i.e., $D_t n^N_{\psi_t} = 0$, $\forall\, \psi_t$ admissible.

VII. QUANTUM PHYSICS, FEYNMAN PATH INTEGRAL AND STOCHASTIC ANALYSIS

Von Neumann axiomatization of quantum mechanics in Hilbert space is the mathematical form of the original version of this theory.[33] It can be regarded as a generalization of classical Hamiltonian mechanics, where the commutative algebra of the (real) observables in phase space is replaced by a noncommutative one.

It is well known that there is no mathematically rigorous Lagrangian version of quantum theory. To construct such a framework was precisely one of Feynman's original motivations.[2] But, in spite of its success (founded on its extraordinary heuristic power), Feynman's path integral theory still cannot be regarded as such a satisfactory framework, from the mathematical point of view. Let us recall that Feynman represents the solution of the initial value problem (2.2) by the symbolic expression

$$\psi_t(x) = \int_{\Omega^{t,x}} \psi(\omega(0)) e^{(i/\hbar)S[\omega;t]} \mathcal{D}\omega, \tag{7.1}$$

where $\Omega^{t,x}$ denotes the path space $\{\omega \in C([0,t],\mathbb{R}^n) \,|\, \omega(t)=x\}$. $S[\omega;t]$ is the action functional of the underlying classical Lagrangian system. For example, when H is as in (2.13), with $A=0$,

$$S[\omega;t] = \int_0^t \left(\frac{1}{2}|\dot{\omega}(\tau)|^2 - V(\omega(\tau))\right)\mathrm{d}\tau \equiv S_0[\omega;t] - \int_0^t V(\omega(\tau))\mathrm{d}\tau, \tag{7.2}$$

$\mathcal{D}\omega$ is the heuristic "flat measure" on the path space $\Omega^{t,x}$ (used as a Lebesgue measure)

$$\mathcal{D}\omega = \prod_{0\le\tau\le t} \mathrm{d}\omega(\tau),$$

and

$$e^{(i/\hbar)S[\omega;t]} \equiv e^{-(i/\hbar)\int_0^t V(\omega(\tau))\mathrm{d}\tau} e^{(i/\hbar)S_0[\omega;t]}$$

is a complex weight.

Note that to make sense of the kinetic energy term in S_0 one should *a priori* assume that the paths $\tau \mapsto \omega(\tau)$ are absolutely continuous and in the Cameron-Martin Hilbert space $\mathcal{H}_{\mathrm{CM}}$ with (finite) norm

$$(\omega,\omega)_{\mathcal{H}} = \int_0^t |\dot{\omega}(\tau)|^2 \mathrm{d}\tau. \tag{7.3}$$

Using Lie-Trotter's formula, Nelson has shown that the rhs of (7.1) can be reinterpreted as the strong limit $j\to\infty$ in $L^2(\mathbb{R}^n)$ of a discretization of the time interval $0<t_1<t_2<\cdots<t_j=t$ along polygonal paths interpolating linearly between the corresponding configurations $\omega(t_k)=x_k$, $k=1,\ldots,j,\omega(t)=x$. But the heuristic expression for the limit of

$$e^{(i/\hbar)S_0[\omega,t]} \prod_{\tau\in\{t_1,\ldots,t_j=t\}} \mathrm{d}\omega(\tau) \tag{7.4}$$

is not σ-additive (cf. Ref. 18) and therefore cannot be used for the construction of a basic complex measure on $\Omega^{t,x}$. However, it is possible, but very hard, to construct a rigorous (nonprobabilistic) functional calculus on path space, using the time discretization approximation (cf. Ref. 34). For various other approaches, cf. also Ref. 35. Let us see (in the free case, for simplicity) how the lack of complex measure is reinterpreted in our distinct construction.

We consider a finite product of complex-valued functions like the ones used in our definition (2.28),

$$F = f_n^{(t)} \cdot f_{n-1}^{(t_j-1)} \cdots f_1^{(t_1)}, \quad n\in\mathbb{N}, \quad t > t_{j-1} > t_{j-2} > \cdots > t_1. \tag{7.5}$$

By iteration of the argument used there for only two such functions, the quantum (absolute) expectation of F in the state ψ becomes

$$\langle f_j^{(t)} \cdots f_1^{(t_1)}\rangle_\psi = \int \psi_{t_1}(x_1) f_1^{(t_1)}(x_1) k_0(x_1,t_2-t_1,x_2) f_2^{(t_2)}(x_2) k_0(x_2,t_3-t_2,x_3)\cdots k_0(x_{j-1},t-t_{j-1},x_j)$$
$$f_j^{(t)}(x_j)\bar{\psi}_t(x_j)\mathrm{d}x_1\cdots\mathrm{d}x_j, \tag{7.6}$$

where $k_0(x,t-s,y)$ denotes the integral kernel of the evolution group U_{t-s} when $V=0$.

The rhs of (7.6) is a multilinear functional of $f_1^{(t_1)},\ldots,f_j^{(t)}$ which is well defined. But the corresponding finite additive measure is not σ-additive (the proof goes back to Cameron.[36] See also Ref. 37) and, therefore, there is no way to look at such an additive measure as the path space measure of some diffusion process, i.e., a Markovian stochastic process with continuous sample paths $\tau\to\omega(\tau)$.

What we have called the forward quantum transition kernel $\hat{p}$ in (2.23), for example, is not positive in contrast with a crucial requirement of the existence proof of such a probability measure.[38] However, regarded only as defining a continuous complex-valued functional on a

reasonable domain of integrable functions and satisfying some basic properties needed otherwise for quantum theory, the limit of (7.4) makes sense and allows to obtain a number of results (see Refs. 39, 40, 37, 41, 42, and 61).

If we are insistent about interpreting Feynman's type of formula (7.1) as an integral over a space of continuous paths, the traditional way, in mathematical physics, is to appeal to Kac's approach (but cf. also Refs. 62–66). First one replaces Schrödinger's initial value problem (2.2) by its "Euclidean" (or "imaginary time") counterpart, say

$$-\hbar \frac{\partial \eta^*}{\partial t} = H\eta^* \tag{7.7}$$

with a bounded continuous initial condition χ in $L^2(\mathbb{R}^n)$. Then the counterpart of (7.4), i.e.,

$$e^{-(1/\hbar)\mathcal{S}_0[\omega;t]} \prod_{\tau\in\{t_1,\cdots,t_j=t\}} \mathrm{d}\omega(\tau), \tag{7.8}$$

converges to the Wiener measure with diffusion coefficient $\hbar$, denoted by $\mathrm{d}\mathcal{M}_W^\hbar$, on the path space $\Omega^{t,x}$ (cf., e.g., Ref. 38). The measure $\mathcal{M}_W^\hbar$ has support on continuous but not differentiable paths [in particular $\mathcal{M}_W^\hbar(\mathcal{H}_{\mathrm{CM}})=0$] so neither the first factor in (7.8) nor the second one are well defined but their product is. After a discrete absorption of the a.s. singular kinetic energy term in the measure, the probabilistic counterpart of (7.1) is Feynman-Kac formula,[43]

$$\eta_t^*(x) = \int_{\Omega^{t,x}} \chi(\omega(0)) e^{-(1/\hbar)\int_0^t V(\omega(\tau))\mathrm{d}\tau} \mathrm{d}\mathcal{M}_W(\omega) = E^{t,x}\left[\chi(W(0)) e^{-(1/\hbar)\int_0^t V(W(\tau))\mathrm{d}\tau}\right], \tag{7.9}$$

where the last expression adopts the probabilities notation for the conditional expectation given that the Wiener process satisfies $W(t)=x$ (our superscript t,x indicates that the condition lies in the future of the time interval of integration), as well as another notation η_χ^* for the solution of (7.7) stressing its dependence on the initial condition χ.

The process $W(\tau)$ is used exclusively as a technical tool in (7.9). We shall not insist here on the fact, underlined time and time again[44,45] that its (irreversible) dynamical properties have little to do with the (reversible) ones of free quantum dynamics. There is no surprise here: the way probability theory enters in (7.7)–(7.9) has nothing to do with the way it enters in quantum dynamics, where, in particular, no direct probabilistic concept of conditional expectation is defined but Born interpretation of ψ_t is fundamental to the absolute expectation.

The above-mentioned support of $\mathcal{M}_W^\hbar$ makes rather tricky the construction of any "stochastic (Euclidean) Lagrangian calculus" along the line suggested by Feynman in Ref. 2, since the irregularities of the "quantum paths" turn any classical action functional into a divergent one.

Any quantum observable should be defined as a function of the basic underlying "stochastic process." It is easy to check (see Chap. 7 of Ref. 2) that Feynman's implicit relation between self-adjoint operators in Hilbert space and associated "random variables" is precisely of our form (2.5) (although formulated by the authors in the time discretized context, i.e., before taking $\lim_{j\to\infty}$ in the above-mentioned construction, in order to avoid flagrant singularities). But the specific rules for handling these "random variables" are not established at all in Ref. 2. Their calculus seems to be plagued by the same kind of singularities as in naive computations along the paths of diffusion processes before the advent of Itô's calculus.

The first problem is, of course, that the precise nature of the underlying formal stochastic process itself (for a given H) is never specified. This may be due to the fact that, after the above-mentioned nonexistence proof of the "Feynman's process," the specific properties it should have were not, understandably, investigated. Is it clear, for example, that this process should be the one associated with the real time version of the Wiener measure or, instead, of the counterpart of some measure absolutely continuous with respect to the Wiener measure?

Also even if, given a quantum observable A, one admits (2.5) as a rule for the associated space–time observable, there are, of course, many other candidates providing the same quantum mechanical expectation $\langle\psi_t, A(t)\psi_t\rangle$. For example, Feynman gives two distinct space–time observ-

ables for the Hamiltonian H of the form (2.13) with zero vector potential (Ref. 2, p. 194). He does not indicate any way to choose which of those is more natural, for instance as defining the proper space–time counterpart of the quantum constant of motion. It is also worthwhile to observe here that Feynman's path integral approach does not provide, curiously, any Nœther Theorem although its whole point is to be a Lagrangian approach.

Nevertheless, Feynman's formal computations suggest that the abelian nature of the classical algebra of observables should be preserved under quantization but that other basic rules of Newtonian calculus should be "deformed in $\hbar$" so as to preserve the compatibility with regular (noncommutative) quantum mechanics in Hilbert space.

The point of our present work has been to investigate systematically the properties of the above-mentioned "process," beyond what Feynman did, without ever using what it certainly cannot provide, a well-defined probability measure on the path space, compatible with Born interpretation of the wave function ψ_t and all quantum mechanical predictions.

Our main improvement with respect to Feynman's original framework is the introduction of the quantum version(s) of conditional expectation(s) for his heuristic process. Indeed, this supplies us with a natural regularization of the many divergent terms in his formal computation, for example the kinetic energy term [cf. (3.20)] of the classical action function.

Introducing the quantum derivatives along an L^2-state associated with this quantum conditional expectation, our calculus of space–time observables follows directly, as well as the definition of quantum martingale, underlying Nœther theorem.

The key deformations of the rules of the classical calculus are, therefore, the ones of the derivations, given by Proposition II.8.

With this procedure, we have embedded regular quantum mechanics (more precisely, the class of elementary systems considered here) into a framework which, we claim, is much closer to probability theory and stochastic analysis than Feynman's path integral approach and, a fortiori, than quantum theory in Hilbert space.

Let us now recall why this claim is justified.

A solution of the Cauchy problems for Schrödinger's equation can be regarded as the value on the imaginary axis of a solution of the heat equation (7.7). This is the famous "Euclidean" relation (or "Wick rotation")

$$\psi_\chi(x,-it) = \eta^*_\chi(x,t) \tag{7.10}$$

for any $\chi \in \mathcal{D}_H \subset L^2(\mathbb{R}^n)$.

Let us restrict ourselves, for a fixed $T>0$, to χ in the dense set of vectors in $L^2(\mathbb{R}^n)$, denoted by $\mathcal{D}(e^{(T/2)H})$, such that

$$\sum_{n=0}^{\infty} \frac{1}{n!} \|H^n \chi\|_2 |t|^n < \infty, \quad \forall\, t \in I = \left[-\frac{T}{2}, \frac{T}{2}\right].$$

Then, together with the solution of (7.7), we can consider the solution, in the strong L^2-sense of the adjoint equation with respect to the time parameter

$$\begin{aligned} \hbar \frac{\partial \eta_{\bar\chi}}{\partial t} &= H \eta_{\bar\chi}, \quad t \in I \\ \eta_{\bar\chi}(\cdot,0) &= \bar\chi(\cdot), \end{aligned} \tag{7.11}$$

where the overbar denotes, now, the complex conjugate.

Clearly we have

$$\int_{\mathbb{R}^n} \eta_{\bar{\chi}} \eta_{\chi}^*(x,t)\mathrm{d}x = \|\chi\|_2^2, \tag{7.12}$$

in a striking analogy with Born's "probabilistic" interpretation of the associated wave function ψ_t [cf. definition (2.17)]. This observation is due to Schrödinger (cf. Refs. 44 and 45) and lies at the foundations of Euclidean quantum mechanics.

The identity (7.12) suggests the introduction of various Hilbert spaces associated with the pair of heat equations (7.7)–(7.11) and allowing to mimic what happens in regular quantum mechanics. For each $t \in I$, consider the solution space of (7.7), namely

$$\widetilde{\vartheta}_t^* \equiv \widetilde{\vartheta}_t^*(\mathbb{R}^n) = \left\{ \eta_{\chi}^*(t), \chi \in \mathcal{D}(e^{(T/2)H}) \right\},$$

and define

$$\begin{aligned} U_t^{-1} &: \widetilde{\vartheta}_t^* \to \mathcal{D}(e^{(T/2)H}), \\ \eta_{\chi}^*(t) &\mapsto \chi. \end{aligned} \tag{7.13}$$

Equation (7.12) suggests as well the definition of the following scalar product in $\widetilde{\vartheta}_t^*$:

$$(\eta_{\chi_1}^*(t)|\eta_{\chi_2}^*(t))_t = \langle U_t^{-1}\eta_{\chi_1}^*(t)|U_t^{-1}\eta_{\chi_2}^*(t)\rangle_2 = \langle \chi_1|\chi_2\rangle_2, \tag{7.14}$$

and to complete $\widetilde{\vartheta}_t^*$ with respect to $(\cdot|\cdot)_t$. The resulting space, denoted by ϑ_t^*, is called forward Hilbert space. As a matter of fact, $(\vartheta_t^*, (\cdot|\cdot)_t)$ is unitarily equivalent to $(L^2, \langle\cdot|\cdot\rangle_2)$ since U_t^{-1} can be extended unitarily from ϑ_t^* onto L^2. Using U_t, the Euclidean version of Heisenberg time evolution of observables will be, for any densely defined A,

$$A_{-t}^F = U_t A U_t^{-1}, \quad t \in I, \tag{7.15}$$

where F stands for forward (space).

So the familiar (Heisenberg's) quantum formulas will be valid, but without the factor $i = \sqrt{-1}$. For the same reason, the observables, in this framework, are densely defined normal operators (not necessarily self-adjoint). For example, the momentum observable in $\vartheta_0^*(\mathbb{R}^n) = L^2(\mathbb{R}^n)$ is defined as $-\hbar\nabla$ on its usual domain. A symmetric construction for equation (7.11) would introduce another one-parameter family of ("backward") Hilbert space, ϑ_t.

Before continuing, it is worth stressing that the "reciprocal" analytical continuation in time of the above construction adds nothing to regular quantum theory. Since the analytical vectors are dense in $L^2(\mathbb{R}^n)$ and $e^{-(i/\hbar)tH}(L^2(\mathbb{R}^n)) = L^2(\mathbb{R}^n)$ $\forall t$, the real time version of the key restriction $\chi \in \mathcal{D}(e^{(T/2)H})$ disappears since

$$\mathcal{D}(e^{i(T/2)H}) = L^2(\mathbb{R}^n), \quad \forall T \in \mathbb{R}.$$

Let us see that the probabilistic interpretation suggested by (7.12) and (7.14) is indeed fully justified on positive vectors in ϑ_t^*, if $e^{-(t/\hbar)H}$ is positively preserving. For H as in Theorem III.7, with $A=0$, this is the case when V belongs to a subset of a class of potentials introduced by Kato (cf. Ref. 45). The integral kernel of $e^{-(1/\hbar)(t-s)H}$ in $L^2(\mathbb{R}^n)$, denoted by

$$h(x, t-s, q), \tag{7.16}$$

is, then, known to be jointly continuous and strictly positive.

For $\chi > 0$ fixed as before, and $\eta_s^*(\cdot) = \eta_{\chi}^*(\cdot, s)$, the Euclidean counterpart of the quantum transition kernel (2.25) becomes

$$q^*(\tau, \mathrm{d}q, t, x) = \eta_{\tau}^*(q) h(q, t-\tau, x)(\eta_t^*(x))^{-1}\,\mathrm{d}q, \quad \tau \le t \text{ in } I. \tag{7.17}$$

In contrast with (2.25), q^* satisfies all the properties of the backward transition probability of a real-valued Markov process in I, for a given final probability distribution $p_{T/2}(y)\mathrm{d}y$.

For another fixed $\chi' > 0$, and $\eta_t(\cdot) = \eta_{\chi'}(\cdot, t)$ in $\vartheta_t(\mathbb{R}^n)$ one gets the Euclidean version of the quantum transition kernel (2.23), i.e.,

$$q(t,x,\tau,\mathrm{d}q) = \eta_t^{-1}(x) h(x,\tau-t,q)\,\eta_\tau(q)\mathrm{d}q, \quad t \le \tau \text{ in I}, \tag{7.18}$$

namely the (forward) transition probability of a Markov process for a given initial probability distribution $p_{-T/2}(x)\mathrm{d}x$. The existence of this Markov process $Z_t, t \in I$, introduced in 1984–1985 under the name of Bernstein diffusion[45] has been proved since then in more general settings (see Ref. 46 for a recent review, using the tools of statistical physics).

Notice that the quantum problem of the zeroes of the wave function disappears here since, by hypothesis on the potential V, $\exp(-(1/\hbar)(t-s)H)$ is positivity preserving. Using (7.17) and (7.18), one verifies easily that Z_t, $t \in I$, is a real valued inhomogeneous diffusion process whose drifts and diffusion matrix are given by the Euclidean version of Proposition II.14, i.e.,

$$B^*(q,t) = -\,\hbar\,\frac{\nabla \eta_t^*}{\eta_t^*}(q),$$

$$B(q,t) = \hbar\,\frac{\nabla \eta_t}{\eta_t}(q), \tag{7.19}$$

$$C(q,t) = C^*(q,t) = \hbar\,\mathbb{1},$$

with $\mathbb{1}$ the $n \times n$ identity matrix.

The particularity of such diffusions is that, in contrast with the traditional one-sided notion of Markov processes, they take seriously the fact that the Markov property itself is invariant under time reversal. If $\mathcal{P}_t$ denotes the σ-algebra generated by the past of Z_t, i.e., $\mathcal{P}_t = \sigma\{Z_s, s \in I, s \le t\}$ and $\mathcal{F}_t$ the future, $\mathcal{F}_t = \{Z_u, u \epsilon I, u \ge t\}$, then, for any events $A \in \mathcal{P}_t$ and $B \in \mathcal{F}_t$,[38]

$$P(AB|\mathcal{N}_t) = P(A|\mathcal{N}_t) \cdot P(B|\mathcal{N}_t) \tag{7.20}$$

almost surely, where $\mathcal{N}_t$ denotes the present $\sigma\{Z_t\}$ and $P(\cdot|\mathcal{N}_t)$ is the conditional probability given $\mathcal{N}_t$.

The time symmetry of $Z_t, t \in I$, shows up in the multiplicative aspect of the integrand of (7.12), for a pair of positive analytic vectors χ, χ', since Eqs. (7.7) and (7.11) are formally time reversed of each other.

The Euclidean version of the relation (2.5) between operators in Hilbert space and space–time observables provides us with well-defined random variables, functions of Z_t. For example, the above-mentioned momentum observable at time t corresponds to $-\hbar(\nabla \eta_t^* / \eta_t^*)(Z_t)$, i.e., the drift $B_*(z_k, t)$ already known by (7.19).

It follows that the Euclidean counterparts of the quantum derivatives (2.14) and (2.16) along the quantum state ψ_t and $\bar{\psi}_t$ are given, respectively, by

$$D_t^* = \frac{\partial}{\partial t} + \mathcal{L}^*, \tag{7.21}$$

$$D_t = \frac{\partial}{\partial t} + \mathcal{L}, \tag{7.22}$$

where $\mathcal{L}^*$ and $\mathcal{L}$ are backward and forward generators of $Z_t, t \in I$, namely the elliptic operators

$$\mathcal{L}^* = -\,\hbar\,\frac{\nabla \eta_t^*}{\eta_t^*} \cdot \nabla - \frac{\hbar}{2}\Delta, \tag{7.21$'$}$$

and

$$\mathcal{L} = \hbar \frac{\nabla \eta_t}{\eta_t} \cdot \nabla + \frac{\hbar}{2} \Delta. \tag{7.22'}$$

The derivatives (7.21) and (7.22) are better defined as limits (whenever they exist) of conditional expectations, for f smooth real valued with compact support on $\mathbb{R}^{n+1}$, namely

$$D_t^* f(Z_t,t) = \lim_{\Delta t \downarrow 0} E_t \left[\frac{f(Z_t,t) - f(Z_{t-\Delta t}, t-\Delta t)}{\Delta t} \right] \tag{7.23}$$

and

$$D_t f(Z_t,t) = \lim_{\Delta t \downarrow 0} E_t \left[\frac{f(Z_{t+\Delta t}, t+\Delta t) - f(Z_t,t)}{\Delta t} \right], \tag{7.24}$$

where E_t denotes the conditional expectation given Z_t in the future or in the past of the time interval, computed in terms of the kernels (7.17) or (7.18), respectively. These conditional expectations make sense from the probabilistic viewpoint, since the process Z_t does, in contrast with our quantum definitions (2.24) and (2.22).

Let us stress that, although the definitions (7.23) and (7.24) coincide with Nelson's ones in Ref. 47, the processes Z_t have little in common with the ones introduced by him in order to interpret probabilistically (2.2) (cf. Ref. 44 for more about that).

By definition of D_t^* and D_t, notice that $f(Z_t,t)$ is an $\mathcal{F}_t$ (respectively, $\mathcal{P}_t$) martingale if and only if $D_t^* f(Z_t,t)=0$ [respectively, $D_t f(Z_t,t)=0$].

The probabilistic counterpart of Proposition III.1, involving the derivative (7.24), is generally known in stochastic analysis, as Dynkin's formula (cf., e.g., Ref. 48). The fact that the counterpart of (3.4), using (7.23), holds as well is due to the time symmetry of Bernstein measures.

The infinitesimal operators D_t and D_t^* are keystones of Itô's stochastic calculus.[49,68] Although it is not as widely known in mathematical physics as it should, this calculus can indeed be formulated in a time-symmetric way as well as with respect to the usual increasing filtration $\mathcal{P}_t$. This requires the introduction of the time-reversed filtration $\mathcal{F}_t$, (Refs. 45, 47, and 50), used here. The quantum deformations (2.20′) and (2.21′) of Leibniz rule (for our class of Hamiltonians) become, respectively, in stochastic analysis, for f,g smooth and real valued,

$$D_t(f \cdot g) = (D_t f) \cdot g + f(D_t g) + \hbar \nabla f \cdot \nabla g, \tag{7.25}$$

$$D_t^*(f \cdot g) = (D_t^* f) \cdot g + f(D_t^* g) - \hbar \nabla f \cdot \nabla g, \tag{7.26}$$

The relations (3.13) and (3.13′) are the quantum counterparts of the relations between Itô and Stratonovich stochastic integrals [also denoted by $\circ$ (Ref. 50)] with respect to $\mathcal{P}_t$ and $\mathcal{F}_t$. It is well known that the latter relation had already been discovered by Feynman in his path integral approach to quantum theory.[2,44]

Using this, one shows that positive solutions of the two adjoint heat equations (7.7) and (7.11) admit two path integral representations in terms of $Z_t, t \in I$. These are the probabilistic counterparts of the integral representations (3.20) and (3.22).

The study of the symmetries of the action functionals involved in these path integrals results in the probabilistic version of the quantum theorem of Nœther, proved in paper I, which is in fact the origin of the present Lagrangian formulation of quantum theory for elementary systems.

One can further develop Feynman's ideas using the rigorous tools of stochastic analysis.[69] For example, his functional calculus[2] is well defined for the class of Bernstein diffusions and allows to prove the Euclidean version of his heuristic results.[51] The aim of Euclidean quantum mechanics, in the sense of Refs. 44 and 45 and for the present paper, is to transfer along this line, as much as possible of mathematical structures from stochastic analysis to regular quantum theory. The point of this indirect approach is to make the best of the irreducible probabilistic content of this theory

and discover more easily new conceptual and technical aspects of quantum dynamics which have been muddled along the years by the superficial role of probability in the traditional Hilbert space framework.

VIII. SOME CONCRETE EXAMPLES

A. One-dimensional free fall

Let the configuration manifold M of Sec. VI be simply $\mathbb{R}$ and consider the free fall Hamiltonian,

$$H = -\frac{\hbar^2}{2}\frac{\partial^2}{\partial q^2} + gq, \tag{8.1}$$

where g is a real constant. This is the (one dimensional) case $A=0, V(q,t)=gq$ of (6.2). In particular, H belongs to the quadratic class (5.1) and it follows from Sec. V that it is sufficient to compute the free case $V=0$. The basis $\mathcal{B}_s(1)$ of the symmetry Lie algebra $\mathfrak{g}_s(1)$ is six dimensional and, according to (5.7), given by

$$\mathcal{B}_s(1) = \left\{ i, iq, \hbar\frac{\partial}{\partial q}, iq^2, i\frac{\hbar^2}{2}\frac{\partial^2}{\partial q^2}, \hbar\, q\frac{\partial}{\partial q} + \frac{\hbar}{2} \right\} \equiv \{\mathcal{N}_j, j = 1, \ldots, 6\}. \tag{8.2}$$

We observe that the free fall Hamiltonian (8.1) results from a linear combination of elements of $\mathcal{B}_s(1)$.

By (5.19) we know that the constant observables of the one-dimensional free system are

$$\left\{ i, i\left(q + i\hbar\, t\frac{\partial}{\partial q}\right), \hbar\frac{\partial}{\partial q}, iq^2 - 2t\left[iq\left(-i\hbar\frac{\partial}{\partial q}\right) + \frac{\hbar}{2}\right] + 2it^2\left(i\hbar\frac{\partial}{\partial t}\right), \right.$$
$$\left. \hbar\frac{\partial}{\partial t}, q\hbar\frac{\partial}{\partial q} + \frac{\hbar}{2} - 2it\left(i\hbar\frac{\partial}{\partial t}\right) \right\} \tag{8.3}$$

Equivalently the coefficients of the symmetry generator defined in (4.18) for the one-dimensional free case are

X	T	φ
0	0	1
$-t$	0	q
1	0	0
$-qt$	$-t^2$	$\frac{1}{2}(i\hbar\, t + q^2)$
0	1	0
q	$2t$	$-\frac{i\hbar}{2}$.

(8.4)

According to the method of Proposition V,5 each of these generators is unitarily equivalent to one generator of the free fall Hamiltonian H via the strongly continuous one parameter groups of unitary operators in $L^2(\mathbb{R})$ defined by

$$W_t = e^{-(i/\hbar)tH} \cdot e^{(i/\hbar)tH_0}. \tag{8.5}$$

Using this, one computes the corresponding coefficients for the free fall symmetry generators. The results are

$$\begin{array}{ccc} X & T & \varphi \\ \hline 0 & 0 & 1 \\ -t & 0 & q-\frac{g}{2}t^2 \\ 1 & 0 & gt \\ -qt+\frac{g}{2}t^3 & -t^2 & \frac{1}{2}(i\hbar\, t+q^2)-\frac{3g}{2}t^2q+\frac{g^2}{8}t^4 \\ 0 & 1 & 0 \\ q-\frac{3g}{2}t^2 & 2t & -\frac{i\hbar}{2}+3gtq-\frac{g^2}{2}t^3. \end{array} \tag{8.6}$$

As they should, the constant observables of the free fall system reduce clearly to the ones of the pure free case (8.4) when the constant g vanishes.

We also observe that the second and third of those constants are "trivial" (although consistently forgotten) since they correspond to the initial position and momentum observables expressed, in the Heisenberg picture, in terms of $Q(t)$ and $P(t)$. On the other hand, the fourth and last observables are nontrivial constants for this elementary system with purely continuous spectrum σ_H.

B. The free particle on the sphere $S^2 \subset \mathbb{R}^3$

Now take for the configuration manifold M of Sec. VI the sphere S^2 of radius R in $\mathbb{R}^3$.

It is natural to introduce the spherical coordinates $(q^j)=(\theta,\phi)$ in $]0,\pi[\times[0,2\pi]$. Then, since $A=V=0$ here, the Lagrangian of the classical system reduces to the kinetic part

$$L(\dot\theta,\dot\phi,\theta,\phi)=\frac{R^2}{2}(\dot\theta^2+\sin^2\theta\dot\phi^2), \tag{8.7}$$

since the metric of S^2 is of the form

$$\mathrm{d}s^2=R^2(\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\phi^2), \tag{8.8}$$

or, equivalently,

$$g_{ij}=\begin{pmatrix} R^2 & 0 \\ 0 & R^2\sin^2\theta \end{pmatrix}. \tag{8.9}$$

The associated Christoffel symbols and covariant derivatives are easily computed,

$$\begin{gathered} \Gamma^1_{11}=\Gamma^1_{12}=\Gamma^1_{21}=\Gamma^2_{11}=\Gamma^2_{22}=0, \\ \Gamma^2_{12}=\Gamma^2_{21}=\operatorname{cotg}\theta, \\ \Gamma^1_{22}=-\sin\theta\cos\phi, \end{gathered} \tag{8.10}$$

and

$$\begin{gathered} \nabla_\theta=\frac{\partial}{\partial\theta},\quad \nabla_\phi=\frac{\partial}{\partial\phi}, \\ \nabla^\theta=\frac{1}{R^2}\frac{\partial}{\partial\theta},\quad \nabla^\phi=\frac{1}{R^2\sin^2\theta}\frac{\partial}{\partial\phi}. \end{gathered} \tag{8.11}$$

The quantum momentum observables in $L^2(S^2,R^2\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi)$ are

$$P_\theta = -i\hbar\nabla_\theta - i\hbar\ \cot g\,\theta,$$
$$P_\phi = -i\hbar\nabla_\phi, \tag{8.12}$$

and the Hamiltonian observable is

$$H = -\frac{\hbar^2}{2R^2}\left[\left(\frac{\partial^2}{\partial\theta^2} + \text{cotg}\ \theta\frac{\partial}{\partial\theta}\right) + \frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2}\right]. \tag{8.13}$$

It is known that for this case with constant curvature $K=R^{-2}>0$ and potentials $A=V=0$ the dimension of the symmetry algebra is maximal; here this is five. The table of the coefficients of the symmetry generator $\hat{N}(t)$ for the Schrödinger equation with Hamiltonian (8.13) is the following:

$X=(X^\theta,X^\phi)$	T	φ
$(0,0)$	1	0
$(0,0)$	0	1
$\left(\sin\phi,\frac{\cos\phi}{tg\ \theta}\right)$	0	0
$\left(-\cos\phi,\frac{\sin\phi}{tg\ \theta}\right)$	0	0
$(0,-1)$	0	0.

(8.14)

Given the definition (6.12) of the symmetry generator $\hat{N}(t)$, it is clear that the first symmetry corresponds to the conservation of the energy observable. The three last ones are interesting, but also of a purely classical origin.

$(X_j^\theta,X_j^\phi), j=1,2,3$ form a basis of the Killing vector field Lie algebra for S^2, an homogeneous manifold. Those vectors X_j are proportionals to the quantum angular momenta, known to be a basis of SO(3), the group of isometries (rotations) of S^2:

$$L_x = i\hbar\left(\sin\phi\frac{\partial}{\partial\theta} + \frac{\cos\phi}{\text{tg}\ \theta}\frac{\partial}{\partial\phi}\right) \equiv i\hbar\left(\sin\phi,\frac{\cos\phi}{\text{tg}\ \theta}\right) \equiv i\hbar X_1, \tag{8.15}$$

and correspondingly for L_y, L_z. The three vectors X_j solve the determining equation (1) of Proposition VI.1 which reduces here to Killing's equation

$$\nabla^\theta X_j^\phi + \nabla^\phi X_j^\theta = 0, \quad j=1,2,3. \tag{8.16}$$

The last symmetry of the table (8.14) corresponds to the conservation of the angular momentum P_ϕ.

The integrability of the underlying classical system is built on the existence of the two constants of motion H and P_ϕ allowing to foliate the data space by a two parameter family of two-dimensional tori.

C. An example of Goldstein

In Goldstein's *Classical Mechanics* (1980), (p. 430), the problem 2a) consists in showing that, for a one-dimensional classical system with Hamiltonian

$$H(q,p) = \frac{p^2}{2} - \frac{1}{2}q^{-2}, \tag{8.17}$$

there is a time-dependent constant of motion of the form

$$n = \frac{q}{2}p - tH. \tag{8.18}$$

This is the case where $M=\mathbb{R}, A(q)=0$, $V(q)=-\frac{1}{2}q^{-2}$and (8.18) shows that

$$X(q,t) = \frac{q}{2}, \quad T(t) = t, \quad \varphi(q,t) = 0.$$

The determining equations (1) and (2) of Proposition IV.3 are trivially satisfied and the "classical limit $\hbar=0$" of (3) holds as well, so n is indeed a (classical) constant of motion. Let us recall that there is nothing exotic about time-dependent classical first integrals, as shown by the ones associated with Galilean boosts.

D. Lewis and Riesenfeld invariant

This is a quantum invariant, discovered in 1969 (Ref. 52) for the harmonic oscillator with time-dependent frequency, i.e., with classical Hamiltonian ($M=\mathbb{R}$)

$$H(q,p,t) = \frac{1}{2}p^2 + \frac{\omega^2(t)}{2}q^2. \tag{8.19}$$

It can be shown that this invariant is of the form (6.32), with

$$X(q,t) = \frac{\dot{T}}{2}q, \quad \hat{\varphi}(q,t) = -\frac{\ddot{T}}{4}q^2, \quad T(t) = \rho^2(t),$$

where $\rho(t)$ solves the nonlinear equation

$$\ddot{\rho} + \omega^2(t)\rho - \frac{1}{\rho^3} = 0.$$

Details can be found in Ref. 53.

IX. CONCLUSIONS

Our framework is founded on a dynamic reinterpretation of the symmetry group of the Schrödinger equation, itself very close to the one of the associated heat equation.

Given the fact that this group was computed by Lie around 1890, a number of the tools we used here are, indeed, quite old. The free Lie algebra can be found in most of the textbooks on Lie groups analysis of PDE published since 1970 (for example Refs. 15, 16, and 54), often with commentaries about the obscure physical interpretation of most explicitly time-dependent transformations, notably those presented as trivial in our Section V. Kuwabara's result[28] (1984) (discovered by us after the redaction of the present work was almost finished) is especially relevant, as it shows that the Lie algebraic structure for quantum (and classical) symmetries is time-dependent. He found, in particular, the form (6.12) of the symmetry operator, without regarding it as a consequence of a Nœther theorem or trying to relate it with a Lagrangian framework. Although we could not find a clear statement that the associated quantum first integrals should be understood in the sense of the Heisenberg picture of quantum dynamics, such a statement may well already exist in the vast literature on the subject, but is certainly not common knowledge in mathematical or theoretical physics.

The specific contribution of our indirect Euclidean approach lies, curiously, in the physical interpretation it provides of many time-dependent symmetries, through their elementary meaning in stochastic analysis.[69]

The simplest illustration is provided by the one-dimensional ($n=1$) free case ($A=V=0$) and the symmetry associated with the coefficients $X=-t, T=0, \varphi=x$ of the symmetric generator $\hat{N}(t)$ in (4.7), corresponding to a simple solution of the system of equations of Proposition IV.3. This symmetry corresponds to the one-parameter family of solutions

$$\psi_\alpha(x,t) = e^{(i/\hbar)(\alpha x-(\alpha^2/2)t)}\psi(x-\alpha t,t), \quad \alpha \in \mathbb{R} \tag{9.1}$$

of the free equation $i\hbar(\partial\psi/\partial t)=-(\hbar^2/2)\Delta\psi$, quite familiar in the context of the Galilean invariance of this equation.[55]

Let us rewrite (9.1) as

$$\psi_\alpha(x,t) = (e^{\alpha\hat{N}(t)}\psi)(x,t), \tag{9.2}$$

and expand in α this expression when ψ is the trivial (unnormalizable) free solution if $\psi_t=1$. On this "state," the space–time observables of momentum and energy vanish and the one associated with $\hat{N}(t)$ reduces to the phase φ [cf. (4.18)]. We find

$$\psi_\alpha(x,t) = 1 + \alpha x + \frac{\alpha^2}{2!}(x^2 + i\hbar t) - \frac{\alpha^3}{3!}(x^3 + 3i\hbar tx) + \cdots. \tag{9.3}$$

By successive taking of $(\partial/\partial\alpha)$ at $\alpha=0$ we obtain a collection of constant space–time observables $n_1^{\hat{N}^n}(x,t)\equiv\varphi_n(x,t), n\in\mathbb{N}$, each, indeed, solution of $D_t\varphi_n=0$.

Now $\hat{N}(t)=(-tP(t)+Q(t))$ itself is certainly a trivial quantum first integral, namely the initial position observable [since $Q(t)$ and $P(t)$ are solutions of the free Heisenberg equation of motion] and the $\hat{N}^n(t), n\in\mathbb{N}$, reduce to the successive powers of this trivial dynamical information on the free quantum system.

On the Euclidean side, we are dealing instead of (9.1) with the one parameter family

$$\eta_\alpha(q,t) = e^{(1/\hbar)(\alpha q-(\alpha^2/2)t)}\eta(q-\alpha t,t), \quad \alpha \in \mathbb{R} \tag{9.4}$$

of (positive) solutions of the free heat equation (7.11). It corresponds to the Euclidean counterpart (cf. paper I)

$$N_E(t) = t\frac{\partial}{\partial q} - q \tag{9.5}$$

of the real time symmetry generator $\hat{N}(t)$. The above unphysical state ψ_t turns into the trivial solution $\eta_t=1$ of the free equation (7.11) whose probabilistic role becomes fundamental. Indeed, according to (7.19) and (7.22′) the associated well-defined diffusion Z_t reduces to the one-dimensional Wiener process with diffusion coefficient $\hbar$. Notice that the corresponding solution of the free adjoint heat equation (7.7) is, then, the integral kernel $\eta_t^*=h_0(x,t,q)$ of this equation. Since the relation between η_t and η_t^* is manifestly not the Euclidean counterpart of a complex conjugacy, this means that for the Wiener process itself, the time invariance of the lhs of (7.12) (with an appropriate pair of positive boundary conditions) is the basis of our probabilistic interpretation of a complex quantum probability amplitude.

Now let us consider

$$h_\alpha(q,t) = \frac{\eta_\alpha}{\eta}(q,t). \tag{9.6}$$

If Z_t is the diffusion, of law P, built from η using (7.19), it is easy to show that h_α is a strictly positive $\mathcal{P}_t$-martingale of Z_t, i.e., satisfies $D_t h_\alpha(Z_t,t)=0$. Denoting by Z_t^α the new diffusion, of law P_α, built from η_α, one shows easily that P_α is absolutely continuous with respect to P, with Radon-Nikodym derivative $\mathrm{d}P_\alpha/\mathrm{d}P=h_\alpha$. In the case of the Wiener process, h_α is the exponential martingale of this process, a basic tool dating[44,49] back to the foundations of stochastic analysis.

The family of $\mathcal{P}_t$-martingales resulting from the successive taking of derivatives $\partial/\partial\alpha$ at $\alpha=0$, namely $\{1,q,q^2-\hbar t,q^3-3\hbar tq,\ldots\}$, coincides with the familiar Wick product of the Brownian motion[56] which is, therefore, reinterpreted as the probabilistic counterpart of the above-mentioned trivial dynamical information on the free quantum system provided by Nœther's theorem.

Thus stochastic analysis may help, indeed, to understand some conventional aspects of quantum dynamics.

The version of Euclidean quantum mechanics advocated in paper I is known to be valid for a class of Hamiltonians much larger than the one considered here (cf. Ref. 57) and it is expected that many ideas expressed here will survive in more general contexts (cf. Refs. 70 and 71).

Although, as shown here, the Riemannian formulation of our results is quite natural, the proper geometrical framework of this method is distinct. It should be regarded, in fact, as deformation of classical contact geometry.[58] This viewpoint also has serious computational advantages when adopted in the Euclidean context where the probability measures make sense, and quantum symmetries are reinterpreted as symmetries of families of diffusion processes.

X. ERRATA FOR PAPER I

(1) In Proposition 3.6 of Ref. 1 (cf. also Ref. 59), the term $\nabla\phi - X_q\cdot B$, i.e., the variation of the drift, is ambiguous. It should be understood as

$$\frac{\partial\phi}{\partial q^i}-\frac{\partial X^k}{\partial q^i}B^k$$

(where the summation convention is used).

(2) The "illustration of the central role of time symmetry," mentioned in p. 331 of Ref. 1 is wrong: the function $n(q,t)$ [respectively $n_*(q,t)$] solves our heat equation (7.11) [respectively, (7.7)] and so are $\mathcal{P}_t$ (respectively, $\mathcal{F}_t$) martingales of the starting process Z_t, $t\in I$. But they are not strictly positive and so cannot be used as h-functions, in the sense of Doob's h-transform. However, when the Nœtherian symmetry operator $\hat{N}$ is positivity preserving, $\eta_\alpha(q,t)=e^{-\alpha\hat{N}}\eta(q,t)$, where η is the positive solution of (7.11) associated with Z_t, is a one-parameter family of solutions of the same equation. Then $h_\alpha(q,t)=(\eta_\alpha/\eta)(q,t)$ is, indeed, the positive martingale needed for the h-transform producing the family of Bernstein diffusions Z_t^α associated with this symmetry (cf. Conclusion here, Sec. 6, Part 2 of Ref. 44, and Refs. 31, 32, and 58 for much more).

The weak Hopf algebras related to generalized Kac-Moody algebra

Wu Zhixiang[a)]
Mathematics Department, Zhejiang University, Hangzhou, 310027, People's Republic of China

(Received 20 March 2006; accepted 11 May 2006; published online 28 June 2006)

We define a kind of quantized enveloping algebra of a generalized Kac-Moody algebra $\mathcal{G}$ by adding a generator J satisfying $J^m=J^{m-1}$ for some integer m. We denote this algebra by $wU_q^\tau(\mathcal{G})$. This algebra is a weak Hopf algebra if and only if $m=2$. In general, it is a bialgebra, and contains a Hopf subalgebra. This Hopf subalgebra is isomorphic to the usually quantum envelope algebra $U_q(\mathcal{G})$ of a generalized Kac-Moody algebra $\mathcal{G}$. © *2006 American Institute of Physics.*

I. INTRODUCTION

In his study of Monstrous moonshine,[3–5] Borcherds introduced a new class of infinite dimensional Lie algebras called generalized Kac-Moody algebras. These generalized Kac-Moody algebra have a contravariant bilinear form which is almost positive definite. The fixed point algebra of any Kac-Moody algebra under a diagram automorphism is a generalized Kac-Moody algebra. A generalized Kac-Moody algebra can be regarded as a Kac-Moody algebra with imaginary simple roots. More explicitly, a generated Kac-Moody algebra is determined by a Borcherds-Cartan matrix $A=(a_{ij})_{(i,j)\in I\times I}$, where either $a_{ii}=2$, or $a_{ii}\leq 0$. If $a_{ii}\leq 0$, then the index i is called imaginary, and the corresponding simple root α_i is called imaginary root. In this paper, the set $\{i\in I|a_{ii}=2\}$ is denoted by I^+. Set $I^{im}=I\backslash I^+$. The structure and the representation theory of generalized Kac-Moody algebras are very similar to those of Kac-Moody algebras, and many basic facts about Kac-Moody algebras can be extended to generalized Kac-Moody algebras. For example, the Kac-Weyl formula about an irreducible representation over a Kac-Moody algebra is generalized to a formula about an irreducible representation over a generalized Kac-Moody algebra as follows:

$$chV(\lambda)=\frac{\sum_{w\in W}\sum_{F\subseteq T,F\perp\lambda}(-1)^{l(w)+|F|}e^{w(\lambda+\rho-s(F))}}{\sum_{w\in W,F\subseteq T}(-1)^{l(w)+|F|}e^{w(\rho-s(F))}},$$

where T is the set of all imaginary simple roots, F runs all over finite subsets of T such that any two elements in F are mutually perpendicular. We denote by $s(F)$ the sum of the roots in F. We call the above formula Borcherds-Kac-Weyl formula.

On the other hand, many mathematicians are interested in generalization of Hopf algebras, of which importance has been recognized in both mathematics and physics. One way to do this is to introduce a kind of weak coproduct such that $\Delta(1)\neq 1\otimes 1$ in Ref. 1. The face algebras[7] and generalized Kac algebras[14] are examples of this class of weak Hopf algebras. Li and Duplij have defined and studied another kind of weak Hopf algebras.[11] A bialgebra $(H,\mu,\eta,\Delta,\varepsilon)$ is called a weak Hopf algebra if there is an antiautomorphism T such that $T*\mathrm{id}_H*T=\mathrm{id}_H$ and $\mathrm{id}_H*T*\mathrm{id}_H=T$, where id_H is the identity map and * is the convolution product. Hopf algebras, and left or right Hopf[12,13] algebras are weak Hopf algebras in this sense. In the presented paper a weak Hopf

[a)]Electronic mail: wzx@zju.edu.cn

algebra is always a mean weak Hopf algebra in this sense. The weak quantized enveloping algebras of semisimple Lie algebras are also weak Hopf algebras.[15] Our aim is to give more nontrivial examples of weak Hopf algebras. Thanks to the definition of quantized enveloping algebra $U_q(\mathcal{G})$ associated a generalized Kac-Moody algebra $\mathcal{G}$ defined in Ref. 7, we can also replace the group $G(U_q(\mathcal{G}))$of grouplike elements by some regular monoid as in Ref. 15, we use a generator J instead of the projector in Ref. 13. Our generator J satisfies $J^m=J^{m-1}$ for some integer $m\geq 2$. By this way, we obtain a subclass of bialgebra $wU_q(\mathcal{G})$. This bialgebra contains a subbialgebra $U^\tau(\mathcal{G})$, which is a weak Hopf algebra in the sense of Ref. 11. Moreover, the quotient algebra $wU_q(\mathcal{G})/(1-J^m)$ is isomorphic to a sub-Hopf algebra of the quantized enveloping algebra $U_q(\mathcal{G})$ as Hopf algebras. As in the case of the classic quantum group $U_q(\mathcal{G})$, we try to determine irreducible representation of $wU_q(\mathcal{G})$.

Finally, let us outline the structure of this paper. In Sec. II, we recall some basic facts related to the quantized enveloping algebra of a generalized Kac-Moody algebra. In Sec. III, we give the definition of $wU_q(\mathcal{G})$. We study the bialgebra structure of $wU_q(\mathcal{G})$ in Sec. IV. In the final section, we study the irreducible representation of $wU_q(\mathcal{G})$.

II. NOTATIONS AND PRELIMINARIES

In this section, we fix notations and recall fundamental results about generalized Kac-Moody algebras.

Let $I=\{1,\ldots,n\}$ or the set of positive integers, and $A=(a_{ij})_{I\times I}$, a Borcherds-Cartan matrix, i.e., it satisfies

(1) $a_{ii}=2$ or $a_{ii}\leq 0$ for all $i\in I$,
(2) $a_{ij}\leq 0$ for all $i\neq j$,
(3) $a_{ij}\in \mathbf{Z}$,
(4) $a_{ij}=0$ if only if $a_{ji}=0$.

We say that an index i is real if $a_{ii}=2$ and imaginary if $a_{ii}\leq 0$. We denote $I^+=\{i\in I\,|\,a_{ii}=2\}$ and $I^{im}=I-I^+$. Kang considered the generalized Kac-Moody algebras associated with Borcherds-Cartan matrices with charge[10]

$$\mathbf{m}=\{(m_i\in \mathbf{Z}_{\geq 0})\,|\,i\in I, m_i=1 \text{ for } i\in I\}.$$

The charge m_i is the multiplicity of the simple root corresponding to $i\in I$. In this paper, we follow Ref. 9, and assume that $m_i=1$ for all $i\in I$. However, we do not lose generality by this hypothesis. Indeed, if we take Borcherds-Cartan matrices with some of the rows and columns identical, then the generalized Kac-Moody algebras with charge introduced in Ref. 10 can be recovered from the ones in the present paper by identifying the h_i's and d_i's (and hence the α_i's) corresponding to these identical rows and columns.

Moreover, we also assume that A is symmetrizable; that is, there is a diagonal matrix $D=\mathrm{diag}\{s_i>0\,|\,i\in I\}$ such that DA is a symmetric matrix.

Let $P=(\oplus_{i\in I}\mathbf{Z}h_i)\oplus(\oplus_{i\in I}\mathbf{Z}d_i)$ be a free Abelian group generated by the set $\{h_i,d_i\,|\,i\in I\}$. This free Abelian group is called the coweight lattice of A. The element h_i in $\Pi^\vee=\{h_i\,|\,i\in I\}$ is called a simple coweight. We call $\Pi^\vee$ the set of all simple coweights. The space $\mathcal{H}=\mathbf{Q}\otimes_{\mathbf{Z}}P^\vee$ over the rational number field $\mathbf{Q}$ is said to be a Cartan subalgebra. The weight lattice is defined to be $P:=\{\lambda\in\mathcal{H}^*\,|\,\lambda(P^\vee)\subseteq\mathbf{Z}\}$, where $\mathcal{H}^*$ is the dual space of the Cartan subalgebra $\mathcal{H}=\mathbf{Q}\otimes_{\mathbf{Z}}P^\vee$. We denote by P^+ the set $\{\lambda\in P\,|\,\lambda(h_i)\geq 0,\ \textit{for every } i\in I\}$ of dominant integral weights.

Define $\alpha_i,\Lambda_i\in\mathcal{H}^*$ by

$$\alpha_i(h_j)=a_{ji},\quad \alpha_i(d_j)=\delta_{ij},$$

$$\Lambda_i(h_j)=\delta_{ij},\quad \Lambda_i(d_j)=0.$$

Then $\alpha_i, i\in I$ are called simple roots of A. Let $\Pi=\{\alpha_i\,|\,i\in I\}\subset P$ be the set of simple roots. The free Abelian group $Q=\oplus_{i\in I}\mathbf{Z}\alpha_i$ is called the root lattice. Set $Q_+=\Sigma_{i\in I}\mathbf{Z}_{\geq 0}\alpha_i$ and $Q_-=-Q_+$. For any

$\alpha \in Q_+$, we can write $\alpha = \Sigma_{k=1}^{n} \alpha_{i_k}$ for $i_1, i_2, \ldots, i_n \in I$. We set $ht(\alpha) = n$ and call it the height of α.

Let $(.|.)$ be the bilinear form on $(\oplus_i(\mathbf{Q}\alpha_i \oplus \mathbf{Q}\Lambda_i)) \times \mathcal{H}^*$ defined by

$$(\alpha_i|\lambda) = s_i\lambda(h_i), (\Lambda_i|\lambda) = s_i\lambda(d_i).$$

Since it is symmetric on $(\oplus_i(\mathbf{Q}\alpha_i \oplus \mathbf{Q}\Lambda_i)) \times (\oplus_i(\mathbf{Q}\alpha_i \oplus \mathbf{Q}\Lambda_i))$, one can extend this to a symmetric bilinear form on $\mathcal{H}^*$. Then such a form is nondegenerated.

We always assume that $\mathbf{K}$ is a field of characteristic 0. Let $q \in \mathbf{K}$ and $q_i = q^{d_i}$. It is assumed that $q_i \neq \pm 1, 0$ for all $i \in i$. For an indeterminant ν and an integer m, let

$$[m]_\nu = \frac{\nu^m - \nu^{-m}}{\nu - \nu^{-1}}, \quad [m]!_\nu = [m]_\nu \cdots [1]_\nu, \quad [0]_\nu = 1,$$

and

$$\begin{bmatrix} m \\ s \end{bmatrix}_\nu = \frac{[m]!_\nu}{[s]!_\nu [m-s]!_\nu}.$$

Definition: The quantized enveloping generalized Kac-Moody algebra $U_q(\mathcal{G})$ associated with a Borcherds-Cartan datum $(A, P^\vee, P, \Pi^\vee, \Pi)$ is the associated algebra with unit 1 over a field $\mathbf{K}$ *of characteristic* 0, *generated by the symbols e_i, f_i $(i \in I)$ and $P^\vee$ subject to the following defining relations:*

$$q^0 = 1, q^h q^{h'} = q^{h+h'} \quad \forall\, h, h' \in P^\vee,$$

$$q^h e_i q^{-h} = q^{\alpha_i(h)} e_i, \quad q^h f_i q^{-h} = q^{-\alpha_i(h)} f_i,$$

$$e_i f_j - f_j e_i = \delta_{ij} \frac{k_i - k_i^{-1}}{q_i - q_i^{-1}}, \quad \text{where } k_i = q^{s_i h_i},$$

$$\sum_{r=0}^{1-a_{ij}} (-1)^r \begin{bmatrix} 1-a_{ij} \\ r \end{bmatrix}_i e_i^{1-a_{ij}-r} e_j e_i^r = 0 \quad \text{if } a_{ii} = 2,\ i \neq j,$$

$$\sum_{r=0}^{1-a_{ij}} (-1)^r \begin{bmatrix} 1-a_{ij} \\ r \end{bmatrix}_i f_i^{1-a_{ij}-r} f_j f_i^r = 0 \quad \text{if } a_{ii} = 2,\ i \neq j,$$

$$e_i e_j - e_j e_i = f_i f_j - f_j f_i = 0 \quad \text{if } a_{ij} = 0.$$

The quantum generalized Kac-Moody algebra $U_q(\mathcal{G})$ has a Hopf algebra structure with the comultiplication Δ, the counit ε, and antipode S defined by

$$\Delta(q^h) = q^h \otimes q^h,$$

$$\Delta(e_i) = e_i \otimes k_i^{-1} + 1 \otimes e_i,$$

$$\Delta(f_i) = k_i \otimes f_i + f_i \otimes 1,$$

$$\varepsilon(q^h) = 1, \quad \varepsilon(e_i) = \varepsilon(f_i) = 0,$$

$$S(q^h) = q^{-h}, \quad S(e_i) = -e_i k_i, \quad S(f_i) = -k_i^{-1} f_i$$

for all $h \in P^\vee$ and $i \in I$.

Let $U_q^+(\mathcal{G})$ and $U_q^-(\mathcal{G})$ be the subalgebras of $U_q(\mathcal{G})$ generated by elements e_i and f_i, respectively, for $i \in I$, and let $U_q^0(\mathcal{G})$ be the subalgebra of $U_q(\mathcal{G})$ generated by $q^h (h \in P^\vee)$. Then we have the triangular decomposition[1,8]

$$U_q(\mathcal{G}) = U_q^-(\mathcal{G}) \otimes U_q^0(\mathcal{G}) \otimes U_q^+(\mathcal{G}).$$

Finally, let us use $U_q'(\mathcal{G})$ to denote a subalgebra of $U_q(\mathcal{G})$ generated by e_i, f_i, q^h, where $h \in \oplus_{i\in I}\mathbf{Z}s_i h_i \oplus \oplus_{i\in I}\mathbf{Z}d_i$. It is obvious that $U_q'(\mathcal{G})$ is a Hopf algebra.

III. WEAK QUANTUM ALGEBRAS $wU_q^T(\mathcal{G})$

Let m be a fixed positive integer. To generalize the invertibility condition $k_i k_i^{-1} = 1$ in $U_q(\mathcal{G})$, let us introduce some generators J, K_i, and $\bar{K}_i$, which subject the following relations:

$$J^m = J^{m-1} = K_i\bar{K}_i = \bar{K}_i K_i = D_i\bar{D}_i = \bar{D}_i D_i. \tag{3.1}$$

Moreover, we assume that $J^r \neq J^{r-1}$ for any $r < m$. Suppose K_i and $\bar{K}_i$ are not zero divisors. Then

$$K_i J = JK_i = K_i, \quad \bar{K}_i J = J\bar{K}_i = \bar{K}_i. \tag{3.2}$$

$$D_i J = JD_i = D_i, \quad \bar{D}_i J = J\bar{D}_i = \bar{D}_i. \tag{3.3}$$

In this paper we always assume that (3.2) and (3.3) hold. We call an element E_i of type one if it satisfies

$$K_j E_i = q_i^{a_{ij}} E_i K_j, \quad \bar{K}_j E_i = q_i^{-a_{ij}} E_i \bar{K}_j. \tag{3.4}$$

Similarly, if

$$K_j F_i = q_i^{-a_{ij}} F_i K_j, \quad \bar{K}_j F_i = q_i^{-a_{ij}} F_i \bar{K}_j, \tag{3.5}$$

then F_i is said to be type one. Suppose

$$K_j E_i \bar{K}_j = q^{a_{ij}} E_i. \tag{3.6}$$

Then we say that E_i is type zero. Similarly, F_i is type zero if it satisfies the following:

$$K_j F_i \bar{K}_j = q^{-a_{ij}} F_i. \tag{3.7}$$

Proposition III.1: E_i (*respectively,* F_i) *is type zero if and only if* E_i *is type one and* $E_i J^{m-1} = J^{m-1} E_i = E_i$ (*respectively*, $F_i J^{m-1} = J^{m-1} F_i = F_i$).

Proof: If E_i is type zero, then we obtain from (3.6),

$$K_j E_i \bar{K}_j K_j = K_j E_i J^m = q_i^{a_{ij}} E_i K_j.$$

On the other hand, since $J^m K_j = K_j$,

$$K_j E_i \bar{K}_j = K_j E_i J^m \bar{K}_j = q_i^{a_{ij}} E_i K_j \bar{K}_j = q_i^{a_{ij}} E_i J^{m-1}.$$

So $E_i = E_i J^{m-1}$. Similarly, we can prove that $E_i = J^{m-1} E_i$. Then

$$K_j E_i = K_j E_i J^m = q_i^{a_{ij}} E_i K_j$$

and

$$E_i \bar{K}_j = J^m E_i \bar{K}_j = q_i^{a_{ij}} \bar{K}_j E_i.$$

That is, E_i is type one. On the other hand, if E_i is type one, and $E_i J^m = J^m E_i = E_i$, then

$$q_i^{a_{ij}}E_i = q_i^{a_{ij}}E_iK_j\bar{K}_j = K_jE_i\bar{K}_j.$$

Similarly,we can prove the statement about F_i is true. By now, we complete the proof.

The types of E_i and F_i are denoted by κ_i, κ', respectively. Let $\tau=(\{\kappa_i\}_{i\in I}|\{\kappa_i'\}_{i\in I})$. By now, we can give the definition for the weak quantum algebra of type τ as follows.

Definition: The type τ weak quantum algebra $wU_q^\tau(\mathcal{G})$ associated with the generalized Kac-Moody algebra $\mathcal{G}$ is an associated algebra with unit 1 *over a field* **K** *of characteristic* 0, *generated by* J, $E_i,F_i(i\in I)$ *and* $K_i,D_i(i\in I)$ *subjecting with the following defining relations*:

$$J^m = J^{m-1} = K_i\bar{K}_i = D_i\bar{D}_i, \tag{3.8}$$

$$K_i\bar{K}_j = \bar{K}_jK_i, \quad K_iK_j = K_jK_i, \quad \bar{K}_i\bar{K}_j = \bar{K}_j\bar{K}_i, \tag{3.9}$$

$$D_i\bar{D}_j = \bar{D}_jD_i, \quad D_iD_j = D_jD_i, \quad \bar{D}_i\bar{D}_j = \bar{D}_j\bar{D}_i, \tag{3.10}$$

$$D_i\bar{K}_j = \bar{K}_jD_i, \quad K_iD_j = D_jK_i, \quad \bar{D}_iK_j = K_j\bar{D}_i, \quad \bar{D}_i\bar{K}_j = \bar{K}_j\bar{D}_i, \tag{3.11}$$

$$D_iJ = JD_i = D_i, \quad K_iJ = JK_i = K_i, \tag{3.12}$$

$$J\bar{D}_i = \bar{D}_iJ = D_i, \quad J\bar{K}_i = \bar{K}_iJ = \bar{K}_i, \tag{3.13}$$

$$E_i \quad F_i \quad \textit{are type } \tau, \tag{3.14}$$

$$E_iF_j - F_jE_i = \delta_{ij}\frac{K_i - \bar{K}_i}{q_i - q_i^{-1}}, \tag{3.15}$$

$$\sum_{r=0}^{1-a_{ij}} (-1)^r \begin{bmatrix} 1-a_{ij} \\ r \end{bmatrix}_i E_i^{1-a_{ij}-r}E_jE_i^r = 0 \quad \textit{if } a_{ii}=2, i\neq j, \tag{3.16}$$

$$\sum_{r=0}^{1-a_{ij}} (-1)^r \begin{bmatrix} 1-a_{ij} \\ r \end{bmatrix}_i F_i^{1-a_{ij}-r}F_jF_i^r = 0 \quad \textit{if } a_{ii}=2, i\neq j, \tag{3.17}$$

$$E_iE_j - E_jE_i = F_iF_j - F_jF_i = 0, \quad \textit{if } a_{ij}=0. \tag{3.18}$$

If $m=1$, and the Borcherds-Cartan matrix A is symmetric, then $wU_q^T(\mathcal{G})=U_q(\mathcal{G})$ provided that we identify K_i with q^{h_i}, $\bar{K}_i$ with q^{-h_i}, D_i with q^{d_i} and $\bar{D}_i$ with q^{-d_i}. If $m=2$ and $\mathcal{G}$ is a semisimple Lie algebra, then $wU_q^T(\mathcal{G})$ has been defined and studied by Yang in Ref. 14. Notice that the type zero was called type two by Yang.

Lemma III.1: J^m is a center idempotent element of $wU_q^\tau(\mathcal{G})$.

Proof: If E_i is type one, then $J^mE_i=K_j\bar{K}_jE_i=E_iK_j\bar{K}_j=E_iJ^m$. Similarly, we can prove that $F_iJ^m=J^mF_i$ provided F_i is type one. Hence this lemma follows from Proposition III.1.

In the following corollary, the subalgebra of $U_q(\mathcal{G})$ generated by $E_i,F_i,s_ih_i,d_i(i\in I)$ is denoted by $U_q'(\mathcal{G})$. It is a Hopf subalgebra of $U_q(\mathcal{G})$.

Corollary III.1:

(1) $wU_q^\tau(\mathcal{G})=wU_q^\tau(\mathcal{G})J^m\oplus wU_q^\tau(\mathcal{G})(1-J^m)$ *is a direct sum of algebras.*
(2) $wU_q^\tau(\mathcal{G})/(1-J)$ *is isomorphic to the algebra* $U_q'(\mathcal{G})$.
(3) $wU_q^\tau(\mathcal{G})J^m$ *is isomorphic to the algebra* $U_q'(\mathcal{G})$.

Proof: The proof of (1) and (2) is easy. To prove (3), let us define a map ψ from $U_q'(\mathcal{G})$ to $wU_q^\tau(\mathcal{G})J^m$ as follows.

$$\psi(q^{s_i h_i}) = K_i, \quad \psi(q^{d_i}) = D_i, \quad \psi(e_i) = E_i J^m, \quad \psi(f_i) = F_i J^m, \quad \psi(1) = J^m.$$

Then one can show that ψ is an algebra homomorphism. Similarly we can define an algebra homomorphism a map φ from $wU_q^\tau(\mathcal{G})J^m$ to $U_q'(\mathcal{G})$ as follows:

$$\varphi(K_i) = q^{s_i h_i}, \quad \varphi(D_i) = q^{d_i}, \quad \varphi(E_i J^m) = e_i, \quad \varphi(F_i J^m) = f_i, \quad \varphi(J^m) = 1.$$

It is easy to check that $\varphi\psi$=id and $\psi\varphi$=id. This proves (3).

Remark 1: *By Proposition III.1*, $wU_q^\tau(\mathcal{G})(1-J^m)$ *is generated by* $J^r - J^{m-1}$ *for* $0 \le r \le m-2$, $E_i(1-J^m)$ *and* $F_i(1-J^m)$, *where* E_i *and* F_i *are type one*. *Since* (3.15) *holds in* $wU_q^\tau(\mathcal{G})$, $E_i(1-J^m)F_j(1-J^m) = F_j(1-J^m)E_i(1-J^m)$. *If all* $\kappa_i = \bar{\kappa}_i = 0$, *then* $wU_q^\tau(\mathcal{G})(1-J^m)$ *is isomorphic to the group algebra* $\mathbf{K}[\mathbf{Z}_{m-2}]$.

IV. THE BIALGEBRA STRUCTURE OF $wU_q^\tau(\mathcal{G})$

The algebras $wU_q^\tau(\mathcal{G})J^m$ and $wU_q^\tau(\mathcal{G})(1-J^m)$ are denoted by w and $\bar{w}$, respectively, in the following. By Corollary III.1, w is isomorphic to the quantum group $U_q(\mathcal{G})$ provided $s_i = 1$. Thus the comultiplication and counit of $U_q(\mathcal{G})$ transplant to the algebra $wU_q^\tau(\mathcal{G})J^m$, and $wU_q^\tau(\mathcal{G})J^m$ becomes a Hopf algebra. Moreover, we can define three maps:

$$\Delta: wU_q^\tau(\mathcal{G}) \to wU_q^\tau(\mathcal{G}) \otimes wU_q^\tau(\mathcal{G}),$$

$$\varepsilon: wU_q^\tau(\mathcal{G}) \to \mathbf{K},$$

$$T: wU_q^\tau(\mathcal{G}) \to wU_q^\tau(\mathcal{G}),$$

as follows:

$$\Delta(K_i) = K_i \otimes K_i, \quad \Delta(\bar{K}_i) = \bar{K}_i \otimes \bar{K}_i, \tag{4.1}$$

$$\Delta(D_i) = D_i \otimes D_i, \quad \Delta(\bar{D}_i) = \bar{D}_i \otimes \bar{D}_i, \tag{4.2}$$

$$\Delta(J) = J \otimes J, \tag{4.3}$$

$$\Delta(E_i) = \begin{cases} 1 \otimes E_i + E_i \otimes K_i, & E_i \text{ is type one}, \\ J^{m-1} \otimes E_i + E_i \otimes K_i, & E_i \text{ is type zero}, \end{cases} \tag{4.4}$$

$$\Delta(F_i) = \begin{cases} F_i \otimes 1 + \bar{K}_i \otimes F_i, & F_i \text{ is type one}, \\ F_i \otimes J^{m-1} + \bar{K}_i \otimes F_i, & F_i \text{ is type zero}, \end{cases} \tag{4.5}$$

$$\varepsilon(K_i) = \varepsilon(\bar{K}_i) = 1, \quad \varepsilon(D_i) = \varepsilon(\bar{D}_i) = 1, \quad \varepsilon(J) = 1, \tag{4.6}$$

$$\varepsilon(E_i) = \varepsilon(F_i) = 0, \tag{4.7}$$

while the map T is defined as follows:

$$T(1) = 1, \quad T(K_i) = \bar{K}_i, \quad T(\bar{K}_i) = K_i, \tag{4.8}$$

$$T(J) = J, \quad T(D_i) = \bar{D}_i, \quad T(\bar{D}_i) = D_i, \tag{4.9}$$

$$T(E_i) = -E_i\bar{K}_i, \quad T(F_i) = -K_iF_i. \tag{4.10}$$

Then we extend them to the whole $wU_q^\tau(\mathcal{G})$. Thus we obtain the following lemma.

Lemma IV.1: *$wU_q^\tau(\mathcal{G})$ is a bialgebra with comultiplication Δ and counit ε.*

Proof: It can be shown by direct calculation that the following relations hold:

$$\Delta(K_i)\Delta(\bar{K}_j) = \Delta(\bar{K}_j)\Delta(K_i), \quad \Delta(D_i)\Delta(\bar{D}_j) = \Delta(\bar{D}_j)\Delta(D_i),$$

$$\Delta(J^{m-1}) = \Delta(K_i)\Delta(\bar{K}_i) = \Delta(D_i)\Delta(\bar{D}_i),$$

$$\Delta(JK_i) = \Delta(K_i), \quad \Delta(J\bar{K}_i) = \Delta(\bar{K}_i),$$

$$\Delta(JD_i) = \Delta(D_i), \quad \Delta(J\bar{D}_i) = \Delta(\bar{D}_i),$$

$$\varepsilon(K_i\bar{K}_j) = \varepsilon(K_i)\varepsilon(\bar{K}_j), \quad \varepsilon(D_i\bar{D}_j) = \varepsilon(D_i)\varepsilon(\bar{D}_j),$$

$$\varepsilon(JK_i) = \varepsilon(K_i), \quad \varepsilon(J\bar{K}_j) = \varepsilon(\bar{K}_j),$$

$$\varepsilon(J\bar{D}_i) = \varepsilon(D_i), \quad \varepsilon(J\bar{D}_j) = \varepsilon(\bar{D}_j),$$

$$\varepsilon(K_j)\varepsilon(E_i) = q_i^{a_{ij}}\varepsilon(E_i)\varepsilon(K_j), \quad \varepsilon(F_i)\varepsilon(\bar{K}_j) = q_i^{a_{ij}}\varepsilon(F_j)\varepsilon(\bar{K}_j),$$

$$\varepsilon(E_i)\varepsilon(F_j) - \varepsilon(F_j)\varepsilon(E_i) = \delta_{ij}\frac{\varepsilon(K_i) - \varepsilon(\bar{K}_i)}{q_i - q_i^{-1}}.$$

If E_i is type one, then

$$\Delta(K_j)\Delta(E_i) = (K_j \otimes K_j)((1 \otimes E_i + E_i \otimes K_i) = K_j \otimes K_jE_i + K_jE_i \otimes K_jK_i = q_i^{a_{ij}}\Delta(E_i)\Delta(K_j).$$

If E_i is type zero, then

$$\begin{aligned}\Delta(K_j)\Delta(E_i)\Delta(\bar{K}_j) &= (K_j \otimes K_j)(J^{m-1} \otimes E_i + E_i \otimes K_i)(\bar{K}_j \otimes \bar{K}_j) = K_j\bar{K}_j \otimes K_jE_i\bar{K}_j + K_jE_i\bar{K}_j \otimes K_jK_i\bar{K}_j \\ &= q_i^{a_{ij}}\Delta(E_i).\end{aligned}$$

Next we prove that

$$\Delta(E_i)\Delta(F_j) - \Delta(F_j)\Delta(E_i) = \delta_{ij}\frac{\Delta(K_i) - \Delta(\bar{K}_i)}{q_i - q_i^{-1}}. \tag{4.11}$$

For any integers $0 \le r, s \le m$, if $J^{m-r}F_j = F_jJ^{m-r}$ and $J^{m-s}E_i = E_iJ^{m-s}$, then

$$(J^{m-r} \otimes E_i + E_i \otimes K_i)(F_j \otimes J^{m-s} + \bar{K}_j \otimes F_j)$$

$$-(F_j \otimes J^{m-s} + \bar{K}_j \otimes F_j)(J^{m-r} \otimes E_i + E_i \otimes K_i)$$

$$= J^{m-r}F_j \otimes E_iJ^{m-s} + \bar{K}_j \otimes E_iF_j + E_iF_j \otimes K_i + E_i\bar{K}_j \otimes K_iF_j$$

$$
\begin{aligned}
&- F_j J^{m-r} \otimes J^{m-s} E_i - F_j E_i \otimes K_i - \bar{K}_j \otimes F_j E_i - \bar{K}_j E_i \otimes F_j K_i \\
&= \bar{K}_j \otimes (E_i F_j - F_j E_i) + (E_i F_j - F_j E_i) \otimes K_i \\
&= \delta_{ij} \frac{\Delta(K_i) - \Delta(\bar{K}_i)}{q_i - q_i^{-1}}.
\end{aligned}
$$

Thus (4.11) holds for all i, j.

Finally, we prove that Δ satisfies the quantum Serre relations, i.e., the relations from (3.16) to (3.18).

From $a_{ij}=0$, we obtain $E_iE_j=E_jE_i$, and $K_iE_j=q_j^{a_{ji}}E_jK_i=E_jK_i$. Hence

$$
\begin{aligned}
&(J^{m-r} \otimes E_i + E_i \otimes K_i)(J^{m-s} \otimes E_j + E_j \otimes K_j) \\
&- (J^{m-s} \otimes E_j + E_j \otimes K_j)(J^{m-r} \otimes E_i + E_i \otimes K_i) \\
&= J^{2m-r-s} \otimes E_iE_j + J^{m-r}E_j \otimes E_iK_j + E_iJ^{m-s} \otimes K_iE_j + E_iE_j \otimes K_iK_j \\
&- J^{2m-r-s} \otimes E_jE_i - J^{m-s}E_i \otimes E_jK_i - E_jJ^{m-r} \otimes K_jE_i - E_jE_i \otimes K_jK_i \\
&= J^{m-r}E_j \otimes E_iK_j + E_iJ^{m-s} \otimes K_iE_j - J^{m-s}E_i \otimes E_jK_i - E_jJ^{m-r} \otimes K_jE_i = 0,
\end{aligned}
$$

for any $1 \le r, s \le m$. So

$$\Delta(E_i)\Delta(E_j) - \Delta(E_j)\Delta(E_i) = 0.$$

Similarly, we can prove

$$\Delta(F_i)\Delta(F_j) - \Delta(F_j)\Delta(F_i) = 0.$$

By now we have proven that Δ satisfies the relation (3.18).

To prove that Δ satisfies the relation (3.16), we must consider the following cases:

(1) Both E_i and E_j are type one.
(2) Only one of the E_i and E_j is type one.
(3) Both E_i and E_j are type zero.

For the case (3). Since E_i is type zero,

$$\Delta(E_i) = J^m \otimes E_i + E_i \otimes K_i = (J^m \otimes 1)(1 \otimes E_i + E_i \otimes K_i) = (1 \otimes E_i + E_i \otimes K_i)(J^m \otimes 1).$$

Let us introduce notations. $(1 \otimes E_i + E_i \otimes K_i)$ is denoted by $\Delta'(E_i)$. Set $s = 1 - a_{ij}$. Then

$$
\begin{aligned}
&\sum_{r=0}^{s} (-1)^r \begin{bmatrix} s \\ r \end{bmatrix} \Delta(E_i)^{s-r} \Delta(E_j) \Delta(E_i)^r \\
&= (J^m \otimes 1)^{(s+1)} \sum_{r=0}^{s} (-1)^r \begin{bmatrix} s \\ r \end{bmatrix} \Delta'(E_i)^{s-r} \Delta'(E_j) \Delta'(E_i)^r = 0,
\end{aligned}
$$

by the discussion in Ref. 8, pp. 67 and 68. Hence Δ satisfies (3.16) in this case. For the other cases, the argument is more or less the same as case (3).

Similarly, we can prove that Δ satisfies (3.17). Therefore Δ and ε can be extended to an algebra morphism from $wU_q^\tau(\mathcal{G})$ to $wU_q^\tau(\mathcal{G}) \otimes wU_q^\tau(\mathcal{G})$, and from $wU_q^\tau(\mathcal{G})$ to $\mathbf{K}$, respectively.

It is easy to prove that

$$(\Delta \otimes 1)\Delta(X) = (1 \otimes \Delta)\Delta(X), \tag{4.12}$$

$$(\varepsilon \otimes 1)\Delta(X) = (1 \otimes \varepsilon)\Delta(X) \tag{4.13}$$

for any $X = E_i, F_i, K_i\bar{K}_i, D_i\bar{D}_i, J$. Since Δ, ε are algebra morphisms, (4.12) and (4.13) hold for any $X \in wU_q^\tau(\mathcal{G})$. By now we have completed the proof.

Next we prove that the map T, defined by (4.8), (4.9), (4.10), is a weak antipode of the subalgebra of a subbialgebra of the bialgebra $wU_q^\tau(\mathcal{G})$ generated by $E_i, F_i, K_i, \bar{K}_i, D_i, \bar{D}_i, J^m$. First we prove that T can be extended to an antiautomorphism of $wU_q^\tau(\mathcal{G})$. It is easy to prove the following relations are true:

$$T(K_i)T(\bar{K}_j) = T(\bar{K}_j)T(K_i), \quad T(D_i)T(\bar{D}_j) = T(\bar{D}_j)T(D_i),$$

$$T(D_i)T(\bar{K}_j) = T(\bar{K}_j)T(D_i), \quad T(K_i)T(\bar{D}_j) = T(\bar{D}_j)T(K_i),$$

$$T(\bar{D}_i)T(\bar{K}_j) = T(\bar{K}_j)T(\bar{D}_i), \quad T(J)T(\bar{K}_i) = T(\bar{K}_i), \quad T(J)T(K_i) = T(K_i)$$

$$T(J)T(\bar{D}_i) = T(\bar{D}_i), \quad T(J)T(D_i) = T(D_i),$$

$$T(E_i)T(E_j) = T(E_j)T(E_i), \quad T(F_i)T(F_j) = T(F_j)T(F_i) \quad \text{if } a_{ij} = 0.$$

If E_i is type one, then

$$T(E_i)T(K_j) = -E_i\bar{K}_i\bar{K}_j = -q_i^{a_{ij}}\bar{K}_jE_i\bar{K}_i = q_i^{a_{ij}}T(K_j)T(E_i).$$

If E_i is type zero, then

$$T(\bar{K}_j)T(E_i)T(K_j) = -K_jE_iK_i\bar{K}_j = -q_i^{a_{ij}}E_iK_i = q_i^{a_{ij}}T(E_i).$$

Similarly, we can prove

$$T(F_i)T(K_j) = q_i^{-a_{ij}}T(K_j)T(F_i)$$

if F_i is type one, and

$$T(\bar{K}_j)T(F_i)T(K_j) = q_i^{-a_{ij}}T(F_i)$$

if F_i is type zero. Moreover,

$$T(F_j)T(E_i) - T(E_i)T(F_j) = K_j(F_jE_i)\bar{K}_i - E_i\bar{K}_iK_jF_j = q_j^{-a_{jj}}q_i^{a_{ij}}F_jE_iK_j\bar{K}_i - q_j^{-a_{jj}}q_j^{a_{ji}}F_jE_iK_j\bar{K}_i$$
$$= \delta_{ij}\frac{\bar{K}_i - K_i}{q_i - q_i^{-1}}K_j\bar{K}_i = \delta_{ij}\frac{T(K_i) - T(\bar{K}_i)}{q_i - q_i^{-1}}.$$

Similarly to Ref. 15, p. 8, we can prove the following antirelations to the quantum Serre relations hold:

$$\sum_{r=0}^{s}(-1)^r\begin{bmatrix} s \\ r \end{bmatrix}T(E_i)^rT(E_j)T(E_i)^{s-r} = 0 \quad \text{if } a_{ii} = 2,$$

$$\sum_{r=0}^{s}(-1)^r\begin{bmatrix}s\\r\end{bmatrix}T(F_i)^rT(F_j)T(F_i)^{s-r}=0 \quad \text{if } a_{ii}=2,$$

where $s=1-a_{ij}$.

From the above discussion, we get that T is an antiautomorphism of $wU_q^\tau(\mathcal{G})$. Let U^τ be a subalgebra of $wU_q^\tau(\mathcal{G})$ generated by $K_i,\bar{K}_i,D_i,\bar{D}_i,E_i,F_i,J^m$.

Theorem IV.2: *T is a weak antipode of $U^\tau(\mathcal{G})$ and $U^\tau(\mathcal{G})$ is a weak Hopf algebra.*

Proof: It is easy to verify that the following relations hold:

$$(\mathrm{id} * T * \mathrm{id})(X) = X,$$

$$(T * \mathrm{id} * T)(X) = T(X),$$

for $X=K_i,\bar{K}_i,D_i,\bar{D}_i,E_i,F_i,J^m$.

Since

$$\mathrm{id} * T * \mathrm{id} = (\mu\otimes 1)\mu(\mathrm{id}\otimes T\otimes \mathrm{id})(\Delta\otimes 1)\Delta,$$

$\mathrm{id}*T*\mathrm{id}$ is a linear automorphism of $wU_q^\tau(\mathcal{G})$. To prove $(\mathrm{id}*T*\mathrm{id})(X)=X$, for any $X\in U^\tau(\mathcal{G})$, we only need to prove that

$$(\mathrm{id} * T * \mathrm{id})(xy) = xy \tag{4.14}$$

provided that $(\mathrm{id}*T*\mathrm{id})(x)=x$, and y is one of the generators $K_i,\bar{K}_i,D_i,\bar{D}_i,E_i,F_i,J^m$. Suppose $(\Delta\otimes 1)\Delta(x)=\Sigma x_{(1)}\otimes x_{(2)}\otimes x_{(3)}$. Then $(\Delta\otimes 1)\Delta(xJ^m)=\Sigma x_{(1)}J^m\otimes x_{(2)}J^m\otimes x_{(3)}J^m$ and hence

$$\mathrm{id} * T * \mathrm{id}(xJ^m) = \sum x_{(1)}T(x_{(2)})x_{(3)}J^m = xJ^m.$$

Similarly

$$\begin{aligned}\mathrm{id} * T * \mathrm{id}(xE_i) &= \sum x_{(1)}J^mT(x_{(2)}J^m)x_{(3)}E_i + \sum x_{(1)}J^mT(x_{(2)}E_i)x_{(3)}K_i + \sum x_{(1)}E_iT(x_{(2)}K_i)x_{(3)}K_i\\ &= \sum x_{(1)}T(x_{(2)})x_{(3)}E_i - \sum x_{(1)}E_i\bar{K}_iT(x_{(2)})x_{(3)}K_i + \sum x_{(1)}E_i\bar{K}_iT(x_{(2)})x_{(3)}K_i = xE_i,\end{aligned}$$

if E_i is type zero. We can prove (4.14) is true for other generators of $U^\tau(\mathcal{G})$. So $\mathrm{id}*T*\mathrm{id}(x)=x$ for any $x\in U^\tau(\mathcal{G})$ by induction.

Similarly, we can prove $T*\mathrm{id}*T(x)=T(x)$ for any $x\in U^\tau(\mathcal{G})$. So T is a weak antipode of $U^\tau(\mathcal{G})$, and $U^\tau(\mathcal{G})$ is a weak Hopf algebra.

Corollary IV.1: *$wU_q^\tau(\mathcal{G})$ is a weak Hopf algebra if and only if $m=2$. Moreover, if $m=2$, then $wU_q^\tau(\mathcal{G})$ is a noncommutative and noncocommutative weak Hopf algebra with the weak antipode T, but not a Hopf algebra.*

Proof: Since $m=2$, $J^{m-1}=J^m=J$. Thus $U^\tau(\mathcal{G})=wU_q^\tau(\mathcal{G})$. So it is a weak Hopf algebra. Suppose it is a Hopf algebra with antipode S. Then $J^m=S(J^m)J^m=1$. On the other hand, since $J^m=J^{m-1}$, $J^{m-1}(J-1)=0$ implies that $J=1$. This is impossible. So $wU_q^\tau(\mathcal{G})$ is not a Hopf algebra.

If $wU_q^\tau(\mathcal{G})$ is a weak Hopf algebra, then $\mathrm{id}*T*\mathrm{id}(J)=J^3=J$. From this and $J^m=J^{m-1}$, we can obtain $J^2=J$. Thus $m=2$ by our assumption.

Corollary IV.2: *$U^\tau(\mathcal{G})$ is a noncommutative and noncocommutative weak Hopf algebra with the weak antipode T, but not a Hopf algebra. Moreover, $wU_q^\tau(\mathcal{G})J^m=U^\tau(\mathcal{G})J^m$ is isomorphic to $U_q'(\mathcal{G})$ as Hopf algebras.*

Proof: It follows from Corollary III.1, Theorem IV.2.

Let H be a coalgebra. The set of grouplike elements of H is denoted by $G(H)$ in the next proposition.

Proposition IV.1: $G(U^\tau(\mathcal{G}))=G(U^\tau(\mathcal{G})J^m)\cup\{1\}$.

Proof: If $g\in G(U^\tau(\mathcal{G}))$, then $g=gJ^m+g(1-J^m)$. Let $g_1=gJ^m, g_2=g(1-J^m)$. Then $g\otimes g=\Delta(g)$

$=g_1\otimes g_1+g_1\otimes g_2+g_2\otimes g_1+g_2\otimes g_2$. Since $\Delta(g_1)=g_1\otimes g_1$ is a grouplike element, $\Delta(g_2)=g_1\otimes g_2+g_2\otimes g_1+g_2\otimes g_2$. So

$$(1\otimes\Delta)\Delta(g_2)=g_1\otimes g_1\otimes g_2+g_1\otimes g_2\otimes g_1+g_1\otimes g_2\otimes g_2+g_2\otimes g_1\otimes g_1+g_2\otimes g_1\otimes g_2+g_2\otimes g_2\otimes g_1+g_2\otimes g_2\otimes g_2.$$

Then

$$(T*\mathrm{id}*T)(g_2)=T(g_2)g_2T(g_2)=T(g_2),$$

$$(\mathrm{id}*T*\mathrm{id})(g_2)=g_2T(g_2)g_2=g_2. \tag{4.15}$$

Because $U^\tau(\mathcal{G})(1-J^m)$ is generated by $E_i(1-J^m),F_j(1-J^m),1-J^m$ and $T(E_i(1-J^m))=T(F_j(1-J^m))=0$, $T(g_2)=k(1-J^m)$ for some $k\in\mathbf{K}$. From (4.15), we obtain the following:

$$k^2g_2=k^2(1-J^m)^2g_2=k(1-J^m),$$

$$kg_2^2(1-J^m)=kg_2^2=g_2. \tag{4.16}$$

If $k=0$, then $g=g_1\in G(U^\tau(\mathcal{G}))$. If $k\neq 0$, then $g_2=(1/k)(1-J^m)$. Thus

$$\frac{1}{k}(1\otimes 1-J^m\otimes J^m)=\frac{1}{k}g_1\otimes(1-J^m)+\frac{1}{k}(1-J^m)\otimes g_1+\frac{1}{k^2}(1-J^m)\otimes(1-J^m).$$

Multiplying by $k(J^m\otimes 1)$ on both sides of the above equation, we get

$$J^m\otimes 1-J^m\otimes J^m=g_1\otimes(1-J^m).$$

Similarly, we have

$$1\otimes J^m-J^m\otimes J^m=(1-J^m)\otimes g_1.$$

Then

$$1\otimes 1-J^m\otimes J^m=J^m\otimes 1+1\otimes J^m-2J^m\otimes J^m+\frac{1}{k}(1-J^m)\otimes(1-J^m).$$

Hence

$$(1-J^m)\otimes(1-J^m)=\frac{1}{k}(1-J^m)\otimes(1-J^m).$$

Consequently, $k=1$. Notice that the set of grouplike elements of $U^\tau(\mathcal{G})J^m$ is a monoid generated by $K_i,\bar{K}_i,D_i,\bar{D}_i$ and J^m, and the elements from this monoid are linearly independent over $\mathbf{K}$. So we get $g_1=J^m$ from $1\otimes J^m-J^m\otimes J^m=(1-J^m)\otimes J^m=(1-J^m)\otimes g_1$. Hence $g=1$.

Proposition IV.2: Suppose φ is an automorphism of the bialgebra $wU_q^\tau(\mathcal{G})$. Then $\varphi(J)=J$ and the restriction of φ on w (respectively, $\bar{w}$) is an isomorphism of w (respectively, $\bar{w}$).

Proof: From $J^m=J^{m-1}$, we obtain $\varphi(J)^m=\varphi(J)^{m-1}$. Thus $\varphi(J)^mJ^m=\varphi(J)^{m-1}J^m$ is a grouplike element in $wU_q^\tau(\mathcal{G})\subseteq U_q(\mathcal{G})$. Hence $\varphi(J)J^m=J^m$. Suppose $\varphi(J)=J^m+x$, where $x=\varphi(J)(1-J^m)\in\bar{w}$. Since $T\varphi(J)=\varphi(T(J))=\varphi(J)$, $Tx=x$. Consequently, $x=\sum_{i=0}^{m-2}k_i(J^i-J^m)$. Then

$$\Delta(\varphi(J))=(J^m+x)\otimes(J^m+x)=J^m\otimes J^m+\sum_{i=0}^{m-2}k_i(J^i\otimes J^i)-\sum_{i=0}^{m-2}k_i(J^m\otimes J^m)$$

$$=J^m\otimes J^m+\sum_{i=0}^{m-2}k_i(J^i\otimes J^m)+\sum_{i=0}^{m-2}k_i(J^m\otimes J^i)+\sum_{i=0}^{m-2}k_iJ^i\otimes\sum_{j=0}^{m-2}k_jJ^j. \tag{4.17}$$

From (4.17), we obtain that $\varphi(J)=J^m+(J^r-J^m)=J^r$ for some $0\leq r\leq m-2$. If $r\geq 2$, then $\varphi(J^{m-2}-J^{m-1})=J^{r(m-2)}-J^{r(m-1)}=0$. This is a contradiction to the fact that φ is an isomorphism. So $r=1$.

Since $\varphi(J)=J$, $\varphi(w)=\varphi(wJ^m)=\varphi(w)J^m=w$. Consequently, the restriction of φ on w is a Hopf algebra isomorphism of w. Similarly, we can prove the restriction of φ on $\bar{w}$ is an algebra isomorphism of $\bar{w}$.

Similarly to Ref. 15, we can prove the following:

Corollary IV.3: Suppose $\mathcal{G}$ is a semisimple Lie algebra. Then the automorphism group of the bialgebra of $wU_q^\tau(\mathcal{G})$ is the semidirect product of N and H, where H is the group of diagram automorphism, and N is the group of diagonal automorphism and it is a normal subgroup of the automorphism group of $wU_q^\tau(\mathcal{G})$.

Remark: If $\mathcal{G}$ is a semisimple Lie algebra, then $U^\tau(\mathcal{G})$ is isomorphic to the weak quantum algebra defined by Yang in Ref 15.

V. THE REPRESENTATIONS OF $wU_q^\tau(\mathcal{G})$

In this section, we try to determine the irreducible representations of $wU_q^\tau(\mathcal{G})$. Suppose V is a simple module over the bialgebra $wU_q^\tau(\mathcal{G})$. Then $V=J^mV\oplus(1-J^m)V$. Since both J^mV and $(1-J^m)V$ are modules over $wU_q^\tau(\mathcal{G})$, either $V=J^mV$ or $V=(1-J^m)V$.

If $V=J^mV$, then $Jv=v$ for any $v\in V$. Suppose $v\in V$ satisfying $K_iv=\lambda_iv$, then $\lambda_i\neq 0$. In this case, $K_i\bar{K}_iK_iv=\lambda_i^2\bar{K}_iv=\lambda_iv$. So $\bar{K}_iv=(1/\lambda_i)v$.

If $V=(1-J^m)V$, then $J^mv=0$ $v\in V$, $K_iv=K_iJ^mv=0$ and $\bar{K}_iv=\bar{K}_iJ^mv=0$ for any $v\in V$.

By now we have completed the proof of the following proposition.

Proposition V.1: Let V be simple $wU_q^\tau(\mathcal{G})$-module. Then either $Jv=v$ for all $v\in V$, or $J^mv=0$ for any $v\in V$. Suppose there exists an $i\in I$ such that $K_iv=\lambda_iv$ for some nonzero vector v. Then $\bar{K}_iv=\bar{\lambda}_iv$ for λ_i, where

$$\bar{\lambda}_i=\begin{cases}\lambda_i^{-1} & \text{if } \lambda_i\neq 0,\\ 0 & \text{if } \lambda_i=0.\end{cases}$$

Moreover, $\lambda_i\neq 0$ *if and only if* $Jv=v$.

Suppose $V=J^mV$. Then V can be viewed as a module over $wU_q^\tau(\mathcal{G})/(1-J)$ by Proposition V.1. Notice that $wU_q^\tau(\mathcal{G})/(1-J)$ is isomorphic to $U_q'(\mathcal{G})$ by Corollary III.1(2). In this case, V has been studied by Kang.[10] For example, the limit of highest weight simple module is a highest weight simple module over the generalized Kac-Moody algebra $\mathcal{G}$ with the same weight λ. Then this simple module is unique determined by its formally Borcherd-Kac-Weyl character formula (see Sec. I).

Suppose $V=(1-J^m)V$. Then $J^mV=0$ and $K_iV=\bar{K}_iV=0$ for any $i\in I$ by Proposition V.1. Similarly, we can prove that $D_iV=\bar{D}_iV=0$ for all $i\in I$. Hence $E_iF_jV=F_jE_iV$ for all $i,j\in I$. Moreover, V can be viewed as a module over $\bar{w}$. Recall that $\bar{w}$ is generated by $J^r-J^m(0\leq r\leq m-2)$, $E_i(1-J^m)$, and $F_j(1-J^m)$, where E_i,F_j are type one. Hence $E_i(1-J^m)F_j(1-J^m)V=F_j(1-J^m)E_i(1-J^m)V$ for all $i,j\in I$. In the following, we try to determine the structure of V in some special case.

Proposition V.2: For any $wU_q^\tau(\mathcal{G})$ module V, if $V=(1-J^m)V$, then $JV=0$.

Proof: Consider the subalgebra B of $\bar{w}$ generated by J^i-J^m for $0\leq r\leq m-2$. Since $(J^i-J^m)\times(J^j-J^m)=J^r-J^m$, where $r\equiv i+j \bmod(m-2)$, B is isomorphic to $\mathbf{K}[\mathbf{Z}_{m-2}]$. Because char $\mathbf{K}=0$, B is a semisimple algebra. Hence V is a semisimple module over B. Let S be a simple B-module contained in V and v be a nonzero element of S. Then there exists r such that $J^rv=0$ and $J^{r-1}v\neq 0$. So S is equal to a vector space spanned by $v,Jv,\ldots,J^{r-1}v$ over $\mathbf{K}$. Since $\mathbf{K}J^{r-1}v$ is a nonzero module of S, $S=\mathbf{K}J^{r-1}v$ and $JS=0$. Consequently $JV=0$.

The above proposition also characterizes the simple $\bar{w}$ module when all E_i,F_j are type zero. In the general case, let $X_i=E_i(1-J^m),Y_i=F_i(1-J^m)$. Then every simple module V over $\bar{w}$ is a module over the algebra generated by $\{X_i,Y_j|$ for $i\in I_1,J\in I_2\}$, where $I_1=\{i\in I|E_i$ is type one$\}$, $I_2=\{j\in I|F_j$ is type one$\}$. The generators X_i,Y_j satisfy the following relation:

$$X_iY_j=Y_jX_i,$$

$$\sum_{r=0}^{1-a_{ij}} (-1)^r \begin{bmatrix} 1-a_{ij} \\ r \end{bmatrix}_i X_i^{1-a_{ij}-r} X_j X_i^r = 0 \quad \text{if} \quad a_{ii} = 2,\ i \neq j,$$

$$\sum_{r=0}^{1-a_{ij}} (-1)^r \begin{bmatrix} 1-a_{ij} \\ r \end{bmatrix}_i Y_i^{1-a_{ij}-r} Y_j Y_i^r = 0 \quad \text{if } a_{ii} = 2,\ i \neq j,$$

$$X_i X_j - X_j X_i = Y_i Y_j - Y_j Y_i = 0, \quad \text{if } a_{ij} = 0.$$

This simple module V satisfies $JV=0$. From the above discussion, we obtain the following result.

Corollary V.1: If $a_{ij}=0$ for any $i \in (I_1 \cup I_2) \cap I^+$, then every simple module over $\bar{w}$ is isomorphic to $\bar{w}/M$, where M is a maximal ideal of $\bar{w}$.

By Corollary V.1, the only simple over $\bar{w}$ is $\mathbf{K}[x]/(p(x))$ if $|I_1 \cup I_2| = 1$, where $p(x)$ is an irreducible polynomial in $\mathbf{K}[x]$. Suppose $\mathbf{K}$ is an algebraically closed field. If $a_{ij}=0$ for any $i \in (I_1 \cup I_2) \cap I^+$, and $|I_1 \cup I_2| = n$, then the simple module V over $\bar{w}$ is isomorphic to $\mathbf{K}[X_i, Y_j | i \in I_1, J_j \in I_2]/(\{X_i - a_i, Y_j - b_j | i \in I_1, j \in I_2\})$ for some $((a_i)_{i \in I_1}, (b_j)_{j \in I_2}) \in \mathbf{K}^n$. (See Refs. 2, 6, and 10.)

Ground state energies and wave functions of quartic and pure quartic oscillators are calculated by first casting the Schrödinger equation into a nonlinear Riccati form and then solving that nonlinear equation analytically in the first iteration of the quasilinearization method (QLM). In the QLM the nonlinear differential equation is solved by approximating the nonlinear terms by a sequence of linear expressions. The QLM is iterative but not perturbative and gives stable solutions to nonlinear problems without depending on the existence of a smallness parameter. Our explicit analytic results are then compared with exact numerical and also with WKB solutions and it is found that our ground state wave functions, using a range of small to large coupling constants, yield a precision of between 0.1 and 1 percent and are more accurate than WKB solutions by two to three orders of magnitude. In addition, our QLM wave functions are devoid of unphysical turning point singularities and thus allow one to make analytical estimates of how variation of the oscillator parameters affects physical systems that can be described by the quartic and pure quartic oscillators. © *2006 American Institute of Physics.*

I. INTRODUCTION

A basic nonrelativistic quantum mechanics problem is to solve the Schrödinger equation with a potential $V(x)$ that governs motion of a given physical system. The first two terms of the power expansion of a one-dimensional, even potential around an equilibrium position are

$$\frac{g^2x^2}{2}+\lambda x^4, \tag{1}$$

where x is the deviation from an equilibrium position. The above potential describes the dynamics of a great many systems that deviate from the idealized picture of pure harmonic motion. When both g and λ are nonzero, we call this potential a "quartic" or quartic anharmonic oscillator; whereas, when $g=0$ with nonzero λ it is dubbed a "pure quartic" oscillator. In addition to providing an excellent description of spectroscopic molecular vibrational data (see Ref. 1 and references therein), the quartic anharmonic oscillator (1) also serves as a basic tool for checking various approximate and perturbative methods in quantum mechanics. Such an application appears in several recent field theoretical model studies.[2–14]

It is well known[15,16] that for the quartic anharmonic oscillator the perturbation expansion diverges even for small couplings and becomes completely useless for strong coupling. In view of this divergence of perturbation theory, we have adopted[17,18] the general and very powerful quasilinearization method (QLM),[19–23] which although iterative is not a perturbative method. In QLM the pth order solution of a nonlinear differential equation with N variables is obtained by first approximating the nonlinear aspect by a sequence of linear terms and then iteratively solving the

associated linear equations. This iterative process converges to a solution without requiring the existence of a smallness parameter. Properties and applications of the quasilinearization method were reviewed recently in Ref. 24.

To apply the quasilinearization method, one first casts the Schrödinger equation into the nonlinear Riccati form and then solves that nonlinear equation by the QLM iterations. In a series of presentations,[17,18,25–27] we have shown that for a range of anharmonic and other physical potentials (with both weak and strong couplings), the QLM iterates display very fast quadratic convergence. Indeed, after just a few QLM iterations, energies and wave functions are obtained with extremely high accuracy, reaching 20 significant figures for the energy of the sixth iterate even in the case of very large coupling constants.

Although numerical solutions using either the QLM or direct numerical solution of the differential equations can be very accurate, it is important to also provide analytic solutions. Analytic solutions allow one to gauge the role of different potential parameters, and explore the influence of such variations on the properties of the quantum system under study. However, in contrast to the harmonic oscillator, the anharmonic oscillator cannot be solved analytically, and thus one usually has to resort to approximations.

The goal of this paper is to obtain and test approximate analytic solutions for the quartic and pure quartic oscillators using the explicit analytic equation for the first QLM iterate. We will show that both energies and wave functions will be represented by closed analytic expressions with the accuracy of the wave functions being between 0.1 and 1 percent for both small and large coupling constants. Various accurate analytic expressions for the *energies* have already appeared in the literature based on using convergent, strong coupling expansions generated by rearrangement of the usual divergent weak coupling expansion[28] or by some variational requirement.[29] Variational anharmonic oscillator wave functions have also been obtained.[30,31] However, accurate nonvariational analytic expressions representing *wave functions* have not hitherto been known. That result is provided here.

II. MAIN FORMULAS

The usual WKB substitution $y(x)=\psi'(x)/\psi(x)$ converts the Schrödinger equation to the nonlinear Riccati form

$$\frac{dy(x)}{dx}+[k^2(x)+y^2(x)]=0. \tag{2}$$

Here $k^2(x)=2[E-V(x)]$, where we use $m=1$, $\hbar=1$ units. The quasilinearization[21–24] of Eq. (2) leads to the recurrence differential equation

$$\frac{dy_p(x)}{dx}+(2y_{p-1}(x))y_p(x)=y_{p-1}^2(x)-k^2(x), \tag{3}$$

where $y_p(x)$ is the subsequent pth QLM iterate, which have the same boundary condition as $y(x)$ of Eq. (2). Note that Eq. (3) is a linear equation of the form $dy_p(x)/dx+f(x)y_p(x)=q(x)$, with $f(x)=2y_{p-1}(x)$ and $q(x)=y_{p-1}^2(x)-k^2(x)$.

Let us use Eq. (3) to estimate the ground state wave function and energy of the quartic oscillator. Excited states will be considered elsewhere.

The ground state wave function is nodeless and for an even potential (1) should therefore be an even function. Its logarithmic derivative is necessarily odd, and therefore the boundary condition obviously is $y(0)=0$ and correspondingly $y_p(0)=0$.

A. Linear initial condition

The zero iterate should be based on physical considerations. Let us consider first an initial guess $y_0(x)=-gx$. This linear initial condition completely neglects the anharmonic term containing λ compared with the harmonic term and thus this initial guess is expected to be reasonable only for relatively small values of λ.

Solution of the first order linear differential Eq. (3) with the above zero boundary condition at the origin can always be found analytically. For $p=1$ the solution is

$$y_1(x) = 2e^{gx^2}\int_0^x e^{-gs^2}(g^2s^2 + \lambda s^4 - E_1)\mathrm{d}s. \tag{4}$$

Integration by parts, yields an expression for $y_1(x)$ that involves the error function $\mathrm{Erf}(x) \equiv (2/\sqrt{\pi})\int_0^x e^{-t^2}\,\mathrm{d}t$,

$$y_1(x) = \frac{1}{4g^{5/2}}\{-2x\sqrt{g}(2g^3 + 3\lambda + 2g\lambda x^2) + e^{gx^2}\sqrt{\pi}\,\mathrm{Erf}(x\sqrt{g})[2g^2(g-2E_1)+3\lambda]\}. \tag{5}$$

The asymptotic expression $\mathrm{Erf}(x) \simeq [1-(e^{-x^2}/\sqrt{\pi}x)]$ for $|x|\to\infty$, indicates that $y_1(x)$ will be exponentially large for very large x unless the second term in Eq. (5) is made zero. Correspondingly, invoking the condition $2g^2(g-2E_1)+3\lambda=0$ yields the energy and the logarithmic derivative in the first iteration: $E_1=a/2$ and $y_1(x)=-ax-bx^3$, where $a=g+3\lambda/2g^2$; $b=\lambda/g$. This leads to the first QLM iteration wave function $\psi(x)=C\exp\left[-\frac{gx^2}{2}-\lambda\left(\frac{3x^2}{4g^2}+\frac{x^4}{4g}\right)\right]$. This QLM result for the energy coincides with the perturbative result, as well as with the result obtained by Friedberg, Lee, and Zhao[32] who used their recently developed iterative method for solving the Schrödinger equation.

The wave functions we obtained above obviously have incorrect asymptotic behavior. Also, the energies E_1 calculated for different λ, as displayed in Table I ($g=1$), are far from being precise. Therefore, to improve the result one is tempted to go to the second QLM iteration, using $y_1(x)$ as an input.

Equation (3) then yields the second iterate

$$y_2(x) = e^{ax^2+(b/2)x^4}\int_0^x \{[a^2+g^2+2(ab+\lambda)t^2+b^2t^4]t^2 - 2E_2\}e^{-at^2-(b/2)t^4}\,\mathrm{d}t. \tag{6}$$

Since $y_2(x)e^{-[ax^2+(b/2)x^4]}$ approaches a constant when x goes to infinity, $y_2(x)$ and consequently the corresponding wave function grows exponentially at infinity, unless the integral in Eq. (6) equals zero when its upper limit equals infinity. This condition yields the following expression for the energy E_2 in the second iteration:

$$E_2 = \frac{\int_0^\infty [a^2 + g^2 + 2(ab + \lambda)t^2 + b^2 t^4] t^2 e^{-at^2 - (b/2)t^4}\, dt}{2\int_0^\infty e^{-at^2 - (b/2)t^4}\, dt}. \tag{7}$$

Values of E_2, for this initial linear form, are compared to exact values E calculated numerically in Table I (g=1). It is seen that E_2 approximates the exact E reasonably well only for small λ, as we anticipated would result from using an initial linear condition. We now turn to another choice for the initial form.

B. Quadratic initial condition

To ensure a proper wave function asymptotically, one needs an adequate initial guess. Our second condition is based on the asymptotic behavior of the quartic potential. The zeroth iterate of the logarithmic derivative, $y_0(x)$, is for example, now obtained by taking an initial iterate of quadratic form $y_0(x) = -\sqrt{2\lambda}x^2$. This choice for the first iterate automatically satisfies the asymptotic and $x=0$ boundary conditions, but is based on neglecting the harmonic term compare with the anharmonic one.

With this quadratic initial condition, the solution $y_1(x)$ of Eq. (3) satisfying $y_1(0)=0$ is then given by

$$y_1(x) = e^{(2/3)\sqrt{2\lambda}x^3} \int_0^x e^{-(2/3)\sqrt{2\lambda}s^3} [4\lambda s^4 + g^2 s^2 - 2E_1] ds. \tag{8}$$

Note, that $y_1(x)e^{-(2/3)\sqrt{2\lambda}x^3}$ approaches a constant, C_∞, as x goes to infinity, and consequently $y_1(x)$ grows exponentially at infinity unless the above limit C_∞, is set to zero. The latter condition yields another expression for the energy based on the quadratic initial condition:

$$E_1 = \frac{\int_0^\infty e^{-(2/3)\sqrt{2\lambda}s^3} \left[2\lambda s^4 + \frac{g^2 s^2}{2} \right] ds}{\int_0^\infty e^{-(2/3)\sqrt{2\lambda}s^3}\, ds}. \tag{9}$$

The integrals in Eq. (9) can be expressed in terms of the Euler gamma function $\Gamma(x)$.[33] The final expression for the first iterate energy based on a quadratic initial condition reads

$$E_1 = \frac{\lambda^{1/6}}{3^{1/3}\Gamma\left(\frac{1}{3}\right)} \left[\frac{3g^2}{4\sqrt{\lambda}} + \lambda^{1/6} 3^{2/3} \Gamma\left(\frac{2}{3}\right) \right]. \tag{10}$$

This result should be proper for large λ when the second term of the quartic potential $(g^2x^2/2) + \lambda x^4$ dominates over the harmonic term and thus a term containing g in initial guess $y_0(x)$ could be neglected. The above expression for the energy is not expected to be suitable for small λ. Indeed, one can see that for the $\lambda \to 0$, the energy in Eq. (10) diverges.

C. Linear plus quadratic initial condition

To obtain a result accommodating arbitrary values of both g and λ, one must start from an initial choice $y_0(x)$ that takes into account the asymptotic behavior of both the harmonic and the anharmonic parts of the potential. Let us choose, for example, $y_0(x) = -gx - \sqrt{2\lambda}x^2$ which is a linear combination of our two previous initial guesses. This yields

$$y_1(x) = 2e^{gx^2 + (2\sqrt{2\lambda}/3)x^3} \int_0^x [t^2(g^2 + g\sqrt{2\lambda}t + 2\lambda t^2) - E_1] e^{-gt^2 - (2\sqrt{2\lambda}/3)t^3}\, dt, \tag{11}$$

with

$$E_1 = \frac{\int_0^\infty t^2(g^2 + g\sqrt{2\lambda}t + 2\lambda t^2)e^{-gt^2-(2\sqrt{2\lambda}/3)t^3}\,dt}{\int_0^\infty e^{-gt^2-(2\sqrt{2\lambda}/3)t^3}\,dt}. \tag{12}$$

Another possible initial guess, which also accounts for the asymptotic behavior of both harmonic and anharmonic parts of the potential is $y_0(x) = -\sqrt{g^2x^2 + 2\lambda x^4}$. This guess is easy to justify by assuming that $y'(x)$ in Eq. (2) at large x becomes negligible compared with $y^2(x)$ and therefore $y^2(x)$ can be set equal to $k^2(x) = g^2x^2 + 2\lambda x^4 - 2E \approx g^2x^2 + 2\lambda x^4$ since in this expression we can neglect E for sufficiently large x.

The solution of Eq. (3) using the initial condition $y_0(x) = -\sqrt{g^2x^2 + 2\lambda x^4}$, is only slightly more complicated than in when one uses the initial guess $y_0(x) = -gx - \sqrt{2\lambda}x^2$, and is given by the expression

$$y_1(x) = 2e^{(g^2 + 2\lambda x^2)^{3/2}/3\lambda} \int_0^x e^{-(g^2 + 2\lambda t^2)^{3/2}/3\lambda}[g^2t^2 + 2\lambda t^4 - E_1]dt. \tag{13}$$

The condition to avoid exponential behavior of the logarithmic derivative at infinity now yields the following expression for the ground state energy:

$$E_1 = \frac{\int_0^\infty t^2(g^2 + 2\lambda t^2)e^{-(g^2 + 2\lambda t^2)^{3/2}/3\lambda}\,dt}{\int_0^\infty e^{-(g^2 + 2\lambda t^2)^{3/2}/3\lambda}\,dt}. \tag{14}$$

For a pure quartic oscillator with $g=0$, both Eqs. (11) and (13) reduce to

$$y_1(x) = 2e^{2\sqrt{2\lambda}x^3/3} \int_0^x e^{-2\sqrt{2\lambda}t^3/3}[2\lambda t^4 - E_1]dt \tag{15}$$

with E_1 given by

$$E_1 = \frac{2\lambda\int_0^\infty e^{-(2\sqrt{2\lambda}/3)s^3}s^4\,ds}{\int_0^\infty e^{-(2\sqrt{2\lambda}/3)s^3}\,ds} = \lambda^{1/3}3^{1/3}\frac{\Gamma\left(\frac{2}{3}\right)}{\Gamma\left(\frac{1}{3}\right)} \simeq 0.729\,011\lambda^{1/3}. \tag{16}$$

In view of Eq. (16) $y_1(x)$ of Eq. (15) can be expressed in terms of a special function, namely, the exponential integral[33] $\mathbf{EI}_\mu(z) = \int_1^\infty e^{-zt}t^{-\mu}\,dt$,

$$y_1(x) = -\sqrt{2\lambda}x^2 + \frac{2}{3}e^{(2\sqrt{2\lambda}/3)x^3}\left\{-\sqrt{2\lambda}x^2\mathbf{EI}_{1/3}\left(\frac{2\sqrt{2\lambda}}{3}x^3\right) + \lambda^{1/3}3^{1/3}\frac{\Gamma\left(\frac{2}{3}\right)}{\Gamma\left(\frac{1}{3}\right)}x\mathbf{EI}_{2/3}\left(\frac{2\sqrt{2\lambda}}{3}x^3\right)\right\}. \tag{17}$$

This expression for the log derivative yields a first iterate QLM wave function, based on the initial condition $y_0(x) = -\sqrt{g^2x^2 + 2\lambda x^4}$, that is the main result of our paper.

The exact dependence of E_1 on λ for the pure quartic oscillator has the same form, but with a factor of 0.667 986 259 before $\lambda^{1/3}$,[28] so that the accuracy of the QLM prediction for the energy is about 9.1 percent. The WKB energy can be easily estimated and gives $E_{\mathrm{WKB}} \simeq 0.546\,267\lambda^{1/3}$, an accuracy of 18.2 percent.

III. RESULTS AND DISCUSSION

The ground state energies for the quartic oscillator in the first QLM approximation for different initial guesses and for values of $g=1$ and λ between zero and 1000 and their comparison with the numerically calculated exact and WKB values are given in Tables I and II ($g=1$). One can see that the values computed using explicit equations (12) and (14) for the QLM energy are significantly more accurate than the WKB values or than values obtained in the first and second QLM iterations with the initial guess $y_0(x) = -gx$. They have a precision of 0.4 to 9 percent for values of λ varying between 0.1 and 1000, respectively.

However, the main results of our work, are not the expressions for the energy. As mentioned in the introduction, such expressions were already given in different forms by others. Our major results are the analytic expressions for the wave functions given by Eqs. (11) and (13), which are based on using the first QLM iterate with the initial conditions $y_0=-gx-\sqrt{2\lambda}x^2$ and $y_0=-\sqrt{g^2x^2+2\lambda x^4}$, respectively.

The graphs of the wave functions for the quartic oscillator with $g=1$ and for different λ together with the correspondent exact and WKB wave functions, are presented in Figs. 1, 3 and 5, while Figs. 2, 4, and 6 display the logarithm of the absolute value of the differences between the WKB or QLM wave functions and the exact solution for λ being equal to 0.1, 1, and 10, respectively. The same graphs for the pure quartic oscillator ($g=0$) are presented in Figs. 7, 9, 11 and in Figs. 8, 10, 12, respectively. One can see that in Figs. 1–12 the differences between the exact and QLM solutions are two to three orders of magnitude smaller than the differences between the exact and the WKB solutions and that the QLM wave functions expressed analytically by Eqs. (11), (13) have an accuracy of between 0.1 and 1 percent. The order of magnitude better accuracy of the wave function compared to the poorer accuracy of the energies is explained by the fact that the general theorems[19–24] for the QLM iterates show that the solutions converge quadratically with each iteration, while no such convergence theorem has been proven for the energy iterates. Note, that the dips in the figures are artifacts of the logarithmic scale, since the logarithm of the absolute

value of the difference of two solutions goes to $-\infty$ at points where the difference changes sign. The overall accuracy of the solution can therefore be inferred only at x values not too close to the dips.

IV. CONCLUSION

We calculated analytically the ground state energy and wave function of the quartic and pure quartic oscillators by casting the Schrödinger equation into the nonlinear Riccati form, which is then solved in the first iteration of the quasilinearization method (QLM), which approaches the solution of the nonlinear differential equation by approximating nonlinear terms with a sequence of linear ones and does not rely on the existence of a smallness parameter. Comparison of our results with exact numerical solutions and the WKB solutions shows that the explicit analytic expressions we obtain (12) and (14) for the ground state energy have a precision of only a few percent while the analytically expressed wave functions (11) and (13) have an accuracy of between 0.1 and 1 percent and are more accurate by two to three orders of magnitude than those

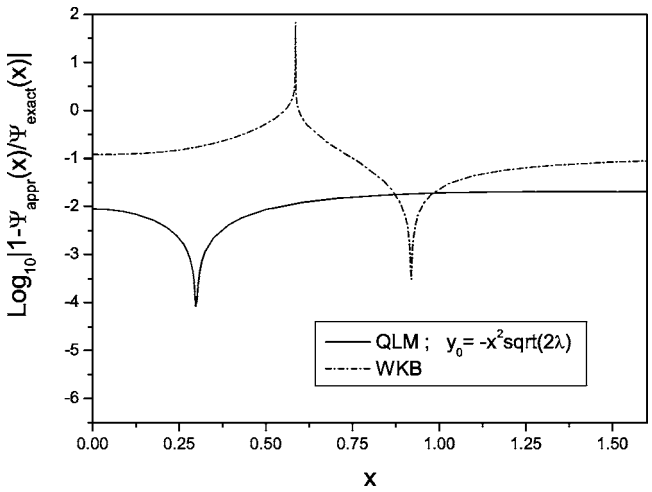

FIG. 12. Logarithm of the differences of the WKB and QLM wave functions with exact wave function for the ground state of the pure quartic oscillator for $g=0$, $\lambda=10$.

given in the WKB approximation. The QLM wave function in addition possess no unphysical turning point singularities which allows one to use these wave functions to make analytical estimates of the effects of variation of the oscillator parameters on the properties of systems described by quartic and pure quartic oscillators.

The next QLM iterations could be evaluated numerically.[17,18,25–27] These further QLM iterates for the different anharmonic and other physical potentials with both strong and weak couplings also display very fast quadratic convergence so that the accuracy of energies and wave functions obtained after a few iterations is extremely high, reaching 20 significant figures for the energy of the sixth iterate even in the case of very large coupling constants.

Extension of this approach to excited states and to other potentials is underway.

(Received 9 February 2005; accepted 11 May 2006; published online 30 June 2006)

We introduce a Bargmann transform for the space $L^2(S^n)$ of square integrable functions on the $n=2,3,5$ dimensional unit sphere S^n inmersed in $\mathbb{R}^{n+1}$. This is done on base of the Hopf fibration for the spheres $S^k \mapsto S^d$ with $(k,d)=(1,1),(3,2),(7,4)$ and a suitable canonical transformation relating two different ways to regularize the $n=2,3,5$ dimensional Kepler problem (with fixed negative energy) involving the null complex quadric Q^n inmersed in $\mathbb{C}^{n+1}$. We prove the unitarity of the Bargmann transform onto a suitable space of analytical functions. We give reproducing kernels for these spaces of analytical functions which, for the cases $n=3,5$, are defined as the kernel of quantizations of restrictions for regularizations of the classical Kepler problem. We give an inversion formula for our Bargmann transform. We also give a set of coherent states for $L^2(S^n)$, $n=2,3,5$ and their semiclassical asymptotics $(\hbar \to 0)$. Our Bargmann transform is actually a coherent states transform. Additionally, we use the moment map technique in order to construct a map with values in Q^n that gives the base to define our canonical transformation. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2209556]

I. INTRODUCTION

In 1961, Bargmann[4] introduced the so called Bargmann transform as a unitary operator from $L^2(\mathbb{R}^n)$ onto a Hilbert space $\mathcal{B}_n$ of analytical functions which are square integrable with respect to a Gaussian measure on $\mathbb{C}^n$. This alternative representation of quantum mechanics through operators acting on spaces of analytical functions has shown to be very useful in semiclassical analysis (see Refs. 29, 23, and 26).

The main goal of this paper is to introduce and study a Bargmann transform when the configuration space is the unit n-sphere S^n (the set of all vectors of unit length in $\mathbb{R}^{n+1}$) in the special cases $n=2,3,5$. The reason to study this particular sphere is motivated by the physical fact that it is in this special dimension that the duality between the Kepler problem and harmonic oscillators holds: for fixed negative energy, the $n=2,3,5$ dimensional Kepler problem is transformed into $m=2,4,8$ harmonic oscillators with the same frequency, respectively. Here we are regarding the $n=2,3,5$ dimensional Kepler problem as the Hamiltonian system with phase space $T^*(\mathbb{R}^n-\{0\})$, symplectic form $d\mathbf{p}\wedge d\mathbf{x}$ (where $\mathbf{p}$ and $\mathbf{x}$ denote the momentum and position vectors of the particle, respectively) and Hamiltonian

$$H=\frac{|\mathbf{p}|^2}{2}-\frac{1}{|\mathbf{x}|}. \tag{1}$$

The duality between the Kepler problem and harmonic oscillators in the dimensions specified above has its roots, from the mathematical viewpoint, in the Hopf fibration between the spheres $S^k \mapsto S^d$ with $(k,d)=(1,1),(3,2),(7,4)$. By extending the Hopf fibrations $S^1 \mapsto S^1$ and $S^3 \mapsto S^2$ one

a)Electronic mail: villegas@matcuer.unam.mx

obtains maps of the type used by Levi-Civita[25] and Kustaanheimo-Stiefel[19] to regularize the Kepler problem. Namely we can find new position variables where, for fixed negative energy E and after a time reparametrization, $[d/\mathrm{d}s=|\mathbf{x}|(d/\mathrm{d}t)$ with t and s the old and new time parameters, respectively] the equation of motion for the $n=2,3$ Kepler problem (1) appears as the equation of motion for $m=2,4$ harmonic oscillators, respectively, without any singularity. The oscillators have the same frequency which depends on the energy E. The same can be done for the case of the Hopf fibration $S^7\mapsto S^4$ and the $n=5$ dimensional Kepler problem obtaining $m=8$ harmonic oscillators. For this last case, the first reference we are aware of is Ref. 7. We will refer to these maps as Kustaanheimo-Stiefel-type maps and denote them by $\mathcal{H}_{(n,m)}$. Here and in the sequel, whenever we write (n,m) we mean the three possible cases $(n,m)=(2,2),(3,4),(5,8)$ unless a particular value of (n,m) is specified.

There is another way to regularize the Kepler problem which works for any dimension $n\geqslant 1$. This regularization was introduce by Moser.[22] The main idea here lies on the physical fact that the orbits of the Kepler problem for fixed negative energy and nonzero angular momentum when projected into the momentum space are circles. By a standard stereographic projection, those circles correspond to great circles on the n-sphere S^n not passing through the north pole. Moser extended this stereographic projection to a canonical transformation $\mathcal{M}_n$ from the phase space of the Kepler problem onto the cotangent bundle of S^n with the north pole removed in order that the one form $\mathbf{x}\cdot\mathrm{d}\mathbf{p}$ transforms into the one form $\xi\cdot\mathrm{d}\mathbf{w}$ with $\mathbf{w}\in S^n$ and ξ in the cotangent space of S^n at $\mathbf{w}$. Thus Moser shows, after the same time reparametrization $d/\mathrm{d}s=|\mathbf{x}|(d/\mathrm{d}t)$ considered above for the other type of regularization and for fixed negative energy $E=-1/2$, the equivalence between the Hamiltonian flow of the n-dimensional Kepler problem with the geodesic flow of the punctured n-sphere. The regularization of the Kepler problem is achieved when we add the north pole. This allows us to include the collision states (negative energy orbits with zero angular momentum) corresponding to geodesics passing through the north pole of S^n.

The relationship between the two different ways to regularize the Kepler problem mentioned above plays a crucial role in our definition of the Bargmann transform for the spaces $L^2(S^2)$, $L^2(S^3)$, and $L^2(S^5)$. We are denoting by $L^2(S^n)$, $n\geqslant 1$, the Hilbert space of square-integrable functions with respect to the normalized surface measure $\mathrm{d}S$ on the n-sphere S^n and endowed with the inner product

$$\langle\boldsymbol{\Psi}_1,\boldsymbol{\Psi}_2,\rangle_{L^2(S^n)}=\int_{\mathbf{w}\in S^n}\boldsymbol{\Psi}_1(\mathbf{w})\overline{\boldsymbol{\Psi}_2}(\mathbf{w})\mathrm{d}S(\mathbf{w}). \tag{2}$$

Kummer[18] showed how to relate the two regularizations in the case $n=3$ by using the moment map for the group SU(2,2). In Ref. 28 it is shown how a canonical transformation (denoted here by $\mathcal{C}_{(3,4)}$) between a suitable reduction of the space $\mathbb{C}^4-\{0\}$ and the cotangent bundle of the 3-sphere with the zero section removed $T^*S^3-\{0\}$ also links the two regularizations for $n=3$. This canonical transformation was actually obtained from the integral kernel of a Bargmann transform that we introduced in Ref. 27 for $L^2(S^3)$ by following the symmetries of the negative energy hydrogen atom problem given by the rotations group SO(4). The canonical transformation we are mentioning is actually the composition of two maps involving the null complex quadric $Q^3-\{0\}$ of four complex variables (for $n\geqslant 1$, a vector belongs to the null complex quadric Q^n if and only if the addition of the squares of the components of the vector is zero). Namely, the composition of a map $\rho_{(3,4)}$ from $\mathbb{C}^4-\{0\}$ onto the null complex quadric $Q^3-\{0\}$ and a map σ_3 from $Q^3-\{0\}$ onto $T^*S^3-\{0\}$. It is also shown that the function given by the inner product $(\rho_{(3,4)}(\mathbf{z})\cdot\mathbf{w})$ is a generating function of the canonical transformation $\mathcal{C}_{(3,4)}$ with $\mathbf{z}\in\mathbb{C}^4$ and $\mathbf{w}\in S^3$.

In order to build the Bargmann transform for $L^2(S^5)$, the key point for our approach is to consider a canonical transformation $\mathcal{C}_{(5,8)}$ from a reduced phase space of eight complex variables $\mathbb{C}^8-\{0\}$ onto the cotangent bundle of the 5-sphere $T^*S^5-\{0\}$ (with the zero section removed) and involving the null complex quadric Q^5. We take this canonical transformation as the composition of two maps $\rho_{(5,8)}$ and σ_5 involving the null complex quadric $Q^5-\{0\}$. Again, the function

$(\rho_{(5,8)}(\mathbf{z})\cdot\mathbf{w})$ (with $\mathbf{z}\in\mathbb{C}^8$ and $\mathbf{w}\in S^5$) is a generating function of the canonical transformation $\mathcal{C}_{(5,8)}$. More precisely, for the three cases we are considering we define a canonical transformation $\mathcal{C}_{(n,m)}$ as

$$\begin{array}{ccc} & \overset{\mathcal{C}_{(n,m)}}{\longrightarrow} & \\ \mathbb{C}^m-\{0\} & & T^*S^n-\{0\} \\ \Big\downarrow{\scriptstyle \rho_{(n,m)}} & \nearrow{\scriptstyle \sigma_n} & \\ Q^n-\{0\} & & \end{array}$$

and the following diagram holds:

$$\begin{array}{ccc} K_m & \xrightarrow{\mathcal{C}_{(n,m)}} & T^*S_0^n-\{0\} \\ \Big\downarrow{\scriptstyle \mathcal{T}_m^{-1}} & & \Big\downarrow{\scriptstyle \mathcal{M}_n^{-1}} \\ J_m & \xrightarrow{\mathcal{H}_{(n,m)}} & T^*(\mathbb{R}^n-\{0\}) \end{array}$$

where S_0^n denotes the n-sphere S^n with the north pole removed, $\mathcal{T}_m: T^*\mathbb{R}^m\mapsto\mathbb{C}_m$ is a complexification of $T^*\mathbb{R}^m$. For the cases $m=4,8$, the manifolds K_m and J_m are obtained from the inverse image of the zero value of moment maps $\mathcal{K}_m$ and $\mathcal{J}_m$ acting on $\mathbb{C}^m$ and $T^*(\mathbb{R}^m-\{0\})$ and related to the action of the groups S^1 and SU(2) for $m=2$ and $m=8$, respectively. In both cases we remove the inverse image of the cotangent space of S^n at the north pole under the map $\mathcal{C}_{(n,m)}$ and the origin from $\mathbb{C}^m$. In the case $m=2$, $J_2=T^*(\mathbb{R}^2-\{0\})$ and $K_2=\mathbb{C}^2-\{0\}$ (see Sec. V for details).

We remark that even though the map $\mathcal{C}_{(n,m)}$ is not injective, we still call it a canonical transformation as people in the physics literature do. In order to get an injective map, we need to consider the quotient (symplectic reduction in the cases $m=4,8$) of J_m and K_m by the action of the groups $\mathbb{Z}_2$, S^1 or SU(2) corresponding to the cases $m=2,4,8$, respectively.

For $m=4,8$, the map $\rho_{(n,m)}$ appearing in the first diagram is obtained by considering the moment map $\mathcal{I}$ of the action on $\mathbb{C}^m$ of the group F of matrices that leave invariant the moment map $\mathcal{K}_m$. Thus the map $\rho_{(n,m)}$ is invariant under the action of the groups S^1 and SU(2) for $m=4,8$, respectively. The map $\rho_{(2,2)}$ is obtained by considering a basis of the vector space of homogeneous polynomials in two complex variables of degree two (and then invariant under the action of the group $\mathbb{Z}_2$). The map σ_n appearing in the same diagram identifies $Q^n-\{0\}$ and $T^*S^n-\{0\}$ in a natural way (see Secs. V and VI for details).

Thus based on our experience on Bargmann transforms for $L^2(S^2)$ and $L^2(S^3)$ (see Refs. 27 and 28), we define a Bargmann transform for $L^2(S^n)$, $n=2,3,5$, as a suitable power series in the generating function $(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})$ of the canonical transformation $\mathcal{C}_{(n,m)}$. We choose the coefficients of the power series in such a way that our transform is an isometry and then we prove that our Bargmann transform is unitary. The Bargmann transform that we define in the present paper for the cases $n=2,3$ is actually the same as the one introduced in Ref. 27 (with the exception of nonrelevant changes in the definition of the map $\rho_{(n,m)}$). However the Bargmann transform in Ref. 27 is introduced as the linear extension of an assignment between corresponding orthonormal basis of its domain and range. This idea is hard to implement in the case $n=5$ since an explicit description of a basis of the range is quite complicated. So we present in this paper the three cases $n=2,3,5$ all together in the same framework. The nontrivial part for our present approach is now to prove that our Bargmann transform is well defined and unitary. We show those facts by following the method of Bargmann in his original paper.[4]

We show in detail that our Bargmann transform for $L^2(S^2)$, $L^2(S^3)$, and $L^2(S^5)$ is a unitary

operator and give a reproducing kernel for the corresponding range. This reproducing kernel is obtained by averaging the usual reproducing kernel for the Bargmann spaces over the groups $\mathbb{Z}_2$, S^1 and SU(2) appearing in the corresponding Hopf fibrations. The range of our Bargmann transforms for $L^2(S^3)$ and $L^2(S^5)$ is actually given by the kernel of suitable operators which are quantizations of restrictions appearing in the Kepler problem. We also give an inversion formula for our Bargmann transform.

We finally show that our Bargmann transform is actually a coherent states transform, i.e., when applied to a function $\Psi \in L^2(S^n)$ we obtain the inner product of Ψ with a coherent state labeled by a point in the cotangent bundle of S^n. Our coherent states for $L^2(S^n)$ have the property that their Bargmann transform give us the reproducing kernel of the range of the Bargmann transform. Moreover, our set of coherent states gives a resolution of the identity for $L^2(S^n)$, i.e., any element of $L^2(S^n)$ can be written as the limit (in the norm sense) of integrals involving projections of $\boldsymbol{\Psi}$ onto each coherent state with respect to a measure on the null complex quadric Q^n (the cotangent bundle $T^*S^n - \{0\}$ with the zero section removed can be identified with $Q^n - \{0\}$ through the map σ_n). Our coherent states are infinite linear combinations of states that concentrate on great circles of S^n in the large quantum numbers regime. In order to study the semiclassical behavior of our coherent states, we introduce the Planck's constant $\hbar$ in the definition of our Bargmann transforms. Based on the work of Thomas and Wassell,[26] we provide an asymptotic expression for our coherent states showing that they concentrate at points of the sphere S^n for $\hbar$ small.

We remark that the $n=5$ dimensional Kepler problem has been studied before in the classical mechanics setting (see Refs. 7 and 14) and its quantization (see Refs. 7 and 20). The work of Mladenov[20] about geometric quantization of the $n=5$ dimensional Kepler problem is quite relevant and connected with our work. The definition of the range of our Bargmann transform for $L^2(S^5)$ is actually described in Mladenov's paper. However, our Bargmann transform is not mentioned there.

We finally mention that other Bargmann-type transforms for spheres have been introduced in the literature before. We comment on this point in the discussion section of this paper.

The paper is organized as follows. Section II is devoted to describe the Hopf fibration and to obtain its explicit equations. We also show the action of the groups $\mathbb{Z}_2$, S^1 and SU(2) in the corresponding fibers. In Sec. III we extend the Hopf fibration and obtain a regularization of the $n=2,3,5$ dimensional Kepler problem of the type obtained by Levi-Civita and Kustaanheimo-Stiefel for the $n=2$ and $n=3$ dimensional problems, respectively. The restrictions appearing in the cases $n=3,5$ are introduced via a moment map. In Sec. III we describe the Moser regularization of the $n \geqslant 1$ dimensional Kepler problem. Despite the fact that the content of Secs. II–IV is known in the literature, we include these sections in the present paper in order to introduce notation and to try to make it as self-contained as possible. In Sec. V and following Kummer[18] in his work about the $n=3$ dimensional Kepler problem, we obtain the maps $\rho_{(n,m)}$ appearing in the diagram above through the moment map of the group of linear transformations which leave the moment map $\mathcal{K}_m$ invariant. Then in Sec. VI we present our canonical transformation $\mathcal{C}_{(n,m)}$ linking the two regularizations mentioned above and explain the second diagram above.

In Sec. VII we introduce and study our Bargmann transform for $L^2(S^n)$, $n=2,3,5$ and prove its unitarity. We also show the reproducing kernel for the range of our Bargmann transform and show that our Bargmann transform is actually a coherent states transform providing $L^2(S^n)$ with a set of coherent states. Then we introduce the parameter $\hbar$ into the definition of both the Bargmann transform and coherent states and show the localization property of our coherent states for $\hbar$ small. We conclude in Sec. VIII with a discussion concerning the possible use of our coherent states for $L^2(S^n)$ to define coherent states for the hydrogen atom problem (with negative energy) in dimensions $n=2,3,5$. We also include Appendix A about representations in $\mathbb{C}^m$, $m=2,4,8$, of the covering groups of rotations in $\mathrm{SO}(n+1)$, $n=2,3,5$ and Appendix B about an explicit expression for orthogonal projectors on eigenspaces of the Laplacian on S^n. Appendix A is used in Appendix B and to show the invariance of certain measures on the null complex quadric Q^n with respect to

rotations in SO($n+1$). However, we think that Appendix A is interesting on its own because it provides a nontrivial and specific representation of the covering group of SO(6) on the space $\mathbb{C}^8$.

II. THE HOPF FIBRATION

In this section we define the Hopf fibration $S^1 \mapsto S^1$, $S^3 \mapsto S^2$, $S^7 \mapsto S^4$ by following Ref. 24. We give explicit equations of these maps. We also describe the action of the corresponding group on the fibers.

A. Stereographic projection

In this section we give the equations of the stereographic projection $\mathbf{T}_k$ from $\mathbb{R}^k \cup \{\infty\}$, $k \geqslant 1$, onto the k-sphere,

$$S^k = \left\{ (x_1, \ldots, x_{k+1}) \in \mathbb{R}^{k+1} \Big| \sum_{i=1}^{k+1} x_i^2 = 1 \right\}. \tag{3}$$

Let us consider a point $\mathbf{x}=(x_1,\ldots,x_k) \in \mathbb{R}^k$ and the straight line joining this point with the north pole of S^k. This line intersects S^k at the point $\mathbf{w}=(w_1,\ldots,w_{k+1})$ given by

$$w_i = \frac{2x_i}{|\mathbf{x}|^2+1}, \quad i=1,\ldots,k,$$

$$w_{k+1} = \frac{|\mathbf{x}|^2-1}{|\mathbf{x}|^2+1}, \quad |\mathbf{x}|^2 = \sum_{i=1}^{k} x_i^2.$$

Then we can assign the north pole of S^k to ∞ if we need to.

B. The Hopf fibration $S^1 \mapsto S^1$, $S^3 \mapsto S^2$, $S^7 \mapsto S^4$

Our presentation of the definition of the Hopf fibration follows.[24] Let $\mathbb{F}$ denote either the field of real $\mathbb{R}$, complex $\mathbb{C}$ or quaternion $\mathbb{H}$ numbers. Let us define $\mathbb{F}^2=\mathbb{F}\times\mathbb{F}$ (the Cartesian product of $\mathbb{F}$ with itself). Let $\mathbb{F}P_1$ be the $\mathbb{F}$-projective space defined as the set of equivalence classes of $\mathbb{F}^2 - \{(0,0)\}$ (i.e., $\mathbb{F}^2$ with the origin removed) under the following equivalence relation: $(q_1',q_2') \sim (q_1,q_2)$ if and only if there exists $\lambda \in \mathbb{F}-\{0\}$ such that $(q_1',q_2')=(q_1,q_2)\lambda$.

For $k=1,3,7$, let us regard the k-sphere S^k as the set of points (q_1,q_2) where $q_1,q_2 \in \mathbb{F}$ and $|q_1|^2+|q_2|^2=1$, with $\mathbb{F}=\mathbb{R},\mathbb{C},\mathbb{H}$, respectively. Then consider the map D_k from S^k onto $\mathbb{F}P_1$ which assigns to (q_1,q_2) its equivalence class $[(q_1,q_2)]$ in $\mathbb{F}P_1$. Notice that elements of S^k of the form $(q,0)$ with $q \in \mathbb{F}-\{0\}$ are sent to the same equivalence class $[(q,0)]$. Any other element of S^k of the form (q_1,q_2) with $q_2 \neq 0$ (and $q_1 \in \mathbb{F}$ arbitrary) is equivalent to $(q_1 q_2^{-1},1)$. Thus, if we identify the equivalence class $[(q,0)]$ with ∞, then the map D_k can be seen as a map from S^k onto $\mathbb{F}\cup\{\infty\}$ under the identification of $\mathbb{F}P_1$ with $\mathbb{F}\cup\{\infty\}$.

The Hopf fibration $\mathbf{H}_{(k,d)}$ is the map from S^k onto S^d, with $(k,d)=(1,1),(3,2),(7,4)$, defined as the composition of the map D_k and the stereographic projection from the field $\mathbb{F}\cup\{\infty\}$ (with $\mathbb{F}$ identified with $\mathbb{R}$, $\mathbb{C}$ or $\mathbb{H}$) onto the sphere S^1,S^2,S^4, respectively.

Let us give the equations of the Hopf fibration for the cases we are considering. Let us regard the domain and range of the Hopf fibration as the sets $\{(u_1,\ldots,u_{k+1}) \in \mathbb{R}^{k+1} | u_1^2+\cdots+u_{k+1}^2=1\}$ and $\{(x_1,\ldots,x_{d+1}) \in \mathbb{R}^{d+1} | x_1^2+\cdots+x_{d+1}^2=1\}$ (with $k=1,3,7$ and $d=1,2,4$), respectively.

(i) *Case* $S^1 \mapsto S^1$:

$$x_1 = 2u_1u_2,$$

$$x_2 = u_1^2 - u_2^2. \tag{4}$$

(ii) *Case* $S^3 \mapsto S^2$: Here we regard a point $(u_1,\ldots,u_4) \in S^3$ as $(u_1+\imath u_2, u_3+\imath u_4)$.

$$x_1 = 2(u_1u_3 + u_2u_4),$$

$$x_2 = 2(u_2u_3 - u_1u_4), \tag{5}$$

$$x_3 = u_1^2 + u_2^2 - u_3^2 - u_4^2.$$

(iii) *Case* $S^7 \mapsto S^4$: Here we regard a point $(u_1,\ldots,u_8) \in S^7$ as (a_1,a_2) with a_1,a_2 quaternions given by the 2×2 matrices

$$a_1 = \begin{pmatrix} u_1 + \imath u_2 & u_3 + \imath u_4 \\ -u_3 + \imath u_4 & u_1 - \imath u_2 \end{pmatrix}, \quad a_2 = \begin{pmatrix} u_5 + \imath u_6 & u_7 + \imath u_8 \\ -u_7 + \imath u_8 & u_5 - \imath u_6 \end{pmatrix}. \tag{6}$$

Then the equations for the Hopf fibration are

$$x_1 = 2(u_1u_5 + u_2u_6 + u_3u_7 + u_4u_8),$$

$$x_2 = 2(-u_1u_6 + u_2u_5 - u_3u_8 + u_4u_7),$$

$$x_3 = 2(-u_1u_7 + u_2u_8 + u_3u_5 - u_4u_6), \tag{7}$$

$$x_4 = 2(-u_1u_8 - u_2u_7 + u_3u_6 + u_4u_5),$$

$$x_5 = u_1^2 + u_2^2 + u_3^2 + u_4^2 - u_5^2 - u_6^2 - u_7^2 - u_8^2.$$

The Hopf fibration map $\mathbf{H}_{(k,d)}$ that we have defined in the three cases above is onto but not one to one. The inverse image of a point $\mathbf{x}$ in the range of the Hopf fibration (the fiber of the Hopf fibration map at $\mathbf{x}$) is the set of points $(q_1,q_2) \in \mathbb{F}^2 - \{(0,0)\}$ (with $|q_1|^2+|q_2|^2=1$) such that $q_2q_1^{-1}$ is equal to the inverse image of $\mathbf{x}$ under the corresponding stereographic projection. The points $(q_1,q_2),(q_1',q_2') \in (\mathbb{F}^2-\{0,0\})$ such that $q_2q_1^{-1}=q_2'q_1'^{-1}$ are related to each other by the action of an element of the group $G=\mathbb{Z}^2$, S^1 or SU(2) for the Hopf fibration $S^1 \mapsto S^1$, $S^3 \mapsto S^2$ or $S^7 \mapsto S^4$, respectively. More explicitly, let us introduce the following equivalence relations in the spheres S^1, S^3 and S^7 given by $\mathbf{u}' \sim \mathbf{u},\mathbf{v}$ iff $\mathbf{u}' = \mathbf{T}(g)\mathbf{u}$ for some g in $\mathbb{Z}^2$, S^1 or SU(2), respectively, and $\mathbf{T}(g)$ defined in the following way.

(i) *Case* S^1:

$$\mathbf{T}(g) = \pm 1. \tag{8}$$

(ii) *Case* S^3. For $g=\exp(\imath\psi) \in S^1$,

$$\mathbf{T}(g) = \mathbf{C}^\dagger \mathbf{U} \mathbf{C}, \tag{9}$$

where $\mathbf{C}^\dagger$ denotes the adjoint of the following unitary matrix:

$$\mathbf{C} = \frac{1}{\sqrt{2}} \begin{pmatrix} -\imath & -1 & 0 & 0 \\ 0 & 0 & 1 & -\imath \\ 0 & 0 & 1 & \imath \\ -\imath & 1 & 0 & 0 \end{pmatrix} \tag{10}$$

and

$$\mathbf{U}=\begin{pmatrix}\exp(-\imath\psi) & 0 & 0 & 0\\ 0 & \exp(-\imath\psi) & 0 & 0\\ 0 & 0 & \exp(\imath\psi) & 0\\ 0 & 0 & 0 & \exp(\imath\psi)\end{pmatrix}. \tag{11}$$

(iii) *Case* S^7: For $g\in \mathrm{SU}(2)$,

$$\mathbf{T}(g)=\mathbf{D}^{\dagger}\mathbf{V}\mathbf{D}, \tag{12}$$

where $\mathbf{D}$ is the following unitary matrix:

$$\mathbf{D}=\frac{1}{\sqrt{2}}\begin{pmatrix}-\imath & -1 & 0 & 0 & 0 & 0 & 0 & 0(25)\\ 0 & 0 & 1 & -\imath & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & -\imath & -1 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & -\imath\\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & -\imath\\ 0 & 0 & 0 & 0 & \imath & -1 & 0 & 0\\ 0 & 0 & 1 & \imath & 0 & 0 & 0 & 0\\ -\imath & 1 & 0 & 0 & 0 & 0 & 0 & 0\end{pmatrix} \tag{13}$$

and

$$\mathbf{V}=\begin{pmatrix}g & 0 & 0 & 0\\ 0 & g & 0 & 0\\ 0 & 0 & g & 0\\ 0 & 0 & 0 & g\end{pmatrix}. \tag{14}$$

Thus the fibers of the Hopf fibration are the equivalence classes described above with the group $G=\mathbb{Z}^2$, S^1 or SU(2) (respectively) acting on them.

III. REGULARIZATION OF THE KEPLER PROBLEM IN $n=2,3,5$ DIMENSIONS

In this section we extend the Hopf fibration maps introduced above in order to get a regularization of the Kepler problem in $n=2,3,5$ dimensions.

First, let us extend the domain and range of the Hopf fibration maps. We do this by considering Eqs. (4), (5), and (7) and then regarding (u_1,u_2), $(u_1,\ldots,u_4)$ or $(u_1,\ldots,u_8)$ in $\mathbb{R}^2$, $\mathbb{R}^4$ or $\mathbb{R}^8$, respectively. Thus we obtain maps $\mathbb{R}^2\mapsto\mathbb{R}^2$, $\mathbb{R}^4\mapsto\mathbb{R}^3$, and $\mathbb{R}^8\mapsto\mathbb{R}^5$. All of these maps can be written as

$$\mathbf{x}=\mathbf{A}\mathbf{u} \tag{15}$$

in the following way (for each case that we are considering):

$$\begin{pmatrix}x_1\\ x_2\end{pmatrix}=\begin{pmatrix}u_2 & u_1\\ u_1 & -u_2\end{pmatrix}\begin{pmatrix}u_1\\ u_2\end{pmatrix}, \tag{16}$$

$$\begin{pmatrix}x_1\\ x_2\\ x_3\\ 0\end{pmatrix}=\begin{pmatrix}u_3 & u_4 & u_1 & u_2\\ -u_4 & u_3 & u_2 & -u_1\\ u_1 & u_2 & -u_3 & -u_4\\ u_2 & -u_1 & u_4 & -u_3\end{pmatrix}\begin{pmatrix}u_1\\ u_2\\ u_3\\ u_4\end{pmatrix}, \tag{17}$$

$$\begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} u_5 & u_6 & u_7 & u_8 & u_1 & u_2 & u_3 & u_4 \\ -u_6 & u_5 & -u_8 & u_7 & u_2 & -u_1 & u_4 & -u_3 \\ -u_7 & u_8 & u_5 & -u_6 & u_3 & -u_4 & -u_1 & u_2 \\ -u_8 & -u_7 & u_6 & u_5 & u_4 & u_3 & -u_2 & -u_1 \\ u_1 & u_2 & u_3 & u_4 & -u_5 & -u_6 & -u_7 & -u_8 \\ u_2 & -u_1 & -u_4 & u_3 & u_6 & -u_5 & -u_8 & u_7 \\ u_3 & u_4 & -u_1 & -u_2 & u_7 & u_8 & -u_5 & -u_6 \\ u_4 & -u_3 & u_2 & -u_1 & u_8 & -u_7 & u_6 & -u_5 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \\ u_3 \\ u_4 \\ u_5 \\ u_6 \\ u_7 \\ u_8 \end{pmatrix}, \tag{18}$$

where in the last two cases we have completed the matrix $\mathbf{A}$ such that the Eqs. (17) and (18) hold.

Notice that the rows of the matrix $\mathbf{A}$ are orthogonal among them (the same happens with the columns). It is here where the special dimensions $(n,m)=(2,2),(3,4),(5,8)$ appear. The rows of the matrix $\mathbf{A}$ give a frame for the spheres S^1, S^3, and S^7 that changes smoothly (notice that first row vector is actually the position vector in the corresponding sphere). This is possible because the k-sphere S^k is a parallelizable manifold only when $k=1,3,7$.

Since the matrix $\mathbf{A}$ satisfies the relation

$$\mathbf{A}^t\mathbf{A} = |\mathbf{u}|^2\mathbf{I} \tag{19}$$

(with $\mathbf{A}^t$ the transpose matrix of $\mathbf{A}$ and $\mathbf{I}$ the identity matrix) then $\mathbf{A}$ is invertible with inverse $\mathbf{A}^{-1}=\mathbf{A}^t/|\mathbf{u}|^2$ when $|\mathbf{u}|\neq 0$.

We will consider the Kepler problem in dimensions 2, 3, 5 by regarding the vector $\mathbf{x}$ [appearing on the left-hand side of Eqs. (16)–(18)] as a vector describing the position of a particle in $\mathbb{R}^2$, $\mathbb{R}^3$ or $\mathbb{R}^5$, respectively, under the influence of the gravitational force

$$\mathbf{F} = -\frac{\mathbf{x}}{|\mathbf{x}|^3} \tag{20}$$

and obeying the Newton's law $\mathbf{F}=-d^2\mathbf{x}/d^2t$.

The singularity of the force vector $\mathbf{F}$ at the origin $\mathbf{x}=0$ has been studied and regularized before. Two different ways to achieve this regularization are the following.

(a) By considering maps of the type appearing in Eqs. (16)–(18), Levi-Civita studied the first case $n=2$, Kustaanheimo and Stiefel[19] considered the second case $n=3$ and the third case $n=5$ can be solved via a Hurwitz transformation, Refs. 7 and 20. See Ref. 25 for a nice description of the first two cases.

(b) By considering an extension of the stereographic projection between $\mathbb{R}^n$ and the n-sphere S^n, Moser[22] regularized the Kepler problem for any dimension $n\geqslant 1$. This regularization will be presented in Sec. IV.

The two regularizations mentioned above use as a key idea to consider a reparametrization of time t in the following way: when the particle moves in a straight line towards the origin (a collision orbit) the speed of the particle goes to infinity. However the product $|\mathbf{x}|(d\mathbf{x}/dt)$ tends to a finite limit (zero) when $|\mathbf{x}|$ approaches the origin [this is a consequence of the conservation of energy $E=\frac{1}{2}|(d\mathbf{x}/dt)|^2-(1/|\mathbf{x}|)$]. Thus a new time parameter s is introduced via the following equation:

$$\frac{d}{\mathrm{d}s} = |\mathbf{x}|\frac{d}{\mathrm{d}t}. \tag{21}$$

In this way, the speed of the particle when it reaches the origin is finite and equal to zero with respect to time s.

In order to show the regularization indicated in (a), let us consider the symplectic spaces $N=(T^*(\mathbb{R}^n-\{0\}),\omega)$ and $M=(T^*(\mathbb{R}^m-\{0\}),\nu)$ with symplectic forms $\omega=\mathrm{d}\mathbf{p}\wedge\mathrm{d}\mathbf{x}$ and $\nu=4\,\mathrm{d}\mathbf{v}\wedge\mathrm{d}\mathbf{u}$,

respectively. We will show a canonical transformation that transforms the Hamiltonian system of the $n=2,3,5$ dimensional Kepler problem $\left[N, H=\frac{1}{2}|\mathbf{p}|^2-(1/|\mathbf{x}|)\right]$ into a suitable reduction of the Hamiltonian system $[M, H'=(1/|\mathbf{u}|^2)(2|\mathbf{v}|^2-1)]$ with $m=2,4,8$, respectively. Moreover, we will show that, for fixed negative energy $H=E$ and after the time reparametrization Eq. (21), the Hamiltonian flow of H is transformed into the Hamiltonian flow of the reduction of an isotropic harmonic oscillator $K=\frac{1}{2}(|\mathbf{v}|^2+k|\mathbf{u}|^2)$ with strength $k=-E/2$ and obtained from the Hamiltonian flow of H'. Since the Hamiltonian flow of K does not have any singularity, we will say that we have achieved a regularization of the $n=2,3,5$ dimensional Kepler problem.

Let us consider the following action of the group G on the symplectic manifold M: given $g \in G$ we define $(\mathbf{u}', \mathbf{v}')=(\mathbf{T}(g)\mathbf{u}, \mathbf{T}(g)\mathbf{v})$ where $\mathbf{T}(g)$ is defined by Eqs. (8)–(14). Since $\mathbf{T}(g)$ is an orthogonal matrix for all $g \in G$, then the action we are defining is symplectic.

In order to find the reduction of the symplectic manifold M under the action of the group G defined above, we need to find the moment map for the cases $m=4$ and $m=8$. First we introduce some notation.

Let $\mathcal{G}$ denote the Lie algebra of the group G. That is, $\mathcal{G}$ is the vector space $\mathbb{R}$ when $m=4$ or the real vector space su(2) of 2×2 self-adjoint and traceless complex matrices when $m=8$.

Let Υ denote the representation of the Lie algebra $\mathcal{G}$ obtained from the representation of G given by the matrices $\mathbf{T}(g)$. Let us denote the elements of Υ by $\mathcal{T}(\xi)$ with $\xi \in \mathcal{G}$. More specifically, for the case $m=4$,

$$\mathcal{T}(\xi) = \mathbf{C}^{\dagger}\mathcal{U}\mathbf{C}, \tag{22}$$

where $\mathbf{C}$ is given by Eq. (10) and

$$\mathcal{U} = \begin{pmatrix} -\psi & 0 & 0 & 0 \\ 0 & -\psi & 0 & 0 \\ 0 & 0 & \psi & 0 \\ 0 & 0 & 0 & \psi \end{pmatrix} \tag{23}$$

(for some $\xi=\psi \in \mathbb{R}$) and for the case $m=8$,

$$\mathcal{T}(\xi) = \mathbf{D}^{\dagger}\mathcal{V}\mathbf{D}, \tag{24}$$

where $\mathbf{D}$ is given by Eq. (13) and

$$\mathcal{V} = \begin{pmatrix} \xi & 0 & 0 & 0 \\ 0 & \xi & 0 & 0 \\ 0 & 0 & \xi & 0 \\ 0 & 0 & 0 & \xi \end{pmatrix} \tag{25}$$

with $\xi \in \mathrm{su}(2)$.

Let us introduce the following inner product in the Lie algebra $\mathbf{\Upsilon}$: for $\mathcal{T}(\xi_1)$ and $\mathcal{T}(\xi_2)$ in $\mathbf{\Upsilon}$, let us define

$$\langle \mathcal{T}(\xi_1), \mathcal{T}(\xi_2) \rangle = \tfrac{1}{8}\mathrm{tr}(\mathcal{T}(\xi_1)\mathcal{T}(\xi_2)) = \tfrac{1}{2}\mathrm{tr}(\xi_1\xi_2) \tag{26}$$

Let $\widetilde{\mathbf{\Upsilon}}$ be the representation of the Lie algebra $\mathcal{G}$ given by matrices of the form

$$\widetilde{\mathcal{T}}(\xi) = \begin{pmatrix} \mathcal{T}(\xi) & 0 \\ 0 & \mathcal{T}(\xi) \end{pmatrix} \tag{27}$$

with $\mathcal{T}(\xi) \in \mathbf{\Upsilon}$.

The moment map is defined as the function $\mathcal{J}_m: M \mapsto \tilde{\mathbf{Y}}^*$, where $\tilde{\mathbf{Y}}^*$ denotes the dual vector space of $\tilde{\mathbf{Y}}$, such that $\mathcal{J}_m(\mathbf{u},\mathbf{v})$ evaluated at $\tilde{\mathcal{T}}(\xi) \in \tilde{\mathbf{Y}}$ is equal to the infinitesimal generator of the action corresponding to $\tilde{\mathcal{T}}(\xi)$ at the point $(\mathbf{u},\mathbf{v})$. Namely, we want the following equation to hold:

$$\langle \mathcal{J}_m(\mathbf{u},\mathbf{v}), \tilde{\mathcal{T}}(\xi) \rangle = \left. \frac{d}{\mathrm{d}s} \right|_{s=0} \exp(is\tilde{\mathcal{T}}(\xi)) \begin{pmatrix} \mathbf{u} \\ \mathbf{v} \end{pmatrix}, \tag{28}$$

where we have used the Riez representation theorem and denoted the element of $\tilde{\mathbf{Y}}$ which represents $\mathcal{J}_m(\mathbf{u},\mathbf{v})$ by the same symbol.

The result is that the element $\xi(\mathbf{u},\mathbf{v}) \in \mathcal{G}$ determining $\mathcal{J}_m(\mathbf{u},\mathbf{v})$ is the following.

For the case $m=4$,

$$\xi(\mathbf{u},\mathbf{v}) = -u_2v_1 + u_1v_2 - u_4v_3 + u_3v_4. \tag{29}$$

For the case $m=8$,

$$\xi(\mathbf{u},\mathbf{v}) = \begin{pmatrix} \lambda & \alpha + i\beta \\ \alpha - i\beta & -\lambda \end{pmatrix} \tag{30}$$

with

$$\alpha(\mathbf{u},\mathbf{v}) = -u_3v_1 - u_4v_2 + u_1v_3 + u_2v_4 - u_7v_5 - u_8v_6 + u_5v_7 + u_6v_8,$$

$$\beta(\mathbf{u},\mathbf{v}) = u_4v_1 - u_3v_2 + u_2v_3 - u_1v_4 + u_8v_5 - u_7v_6 + u_6v_7 - u_5v_8,$$

$$\lambda(\mathbf{u},\mathbf{v}) = u_2v_1 - u_1v_2 - u_4v_3 + u_3v_4 + u_6v_5 - u_5v_6 - u_8v_7 + u_7v_8. \tag{31}$$

The equations $\lambda=0$ and $\alpha=\beta=\lambda=0$ are known in the physics literature as the restrictions of the Kepler problem in the variables $\mathbf{u}$ and $\mathbf{v}$ for the $n=3$ (see Ref. 19) and $n=5$ (see Ref. 7) dimensional Kepler problem, respectively. The geometrical meaning of them is that the momentum vector $\mathbf{v}$ is orthogonal to the fiber of the point $\mathbf{u}$ at the point $\mathbf{u}$ (see Ref. 25 for the $n=3$ dimensional case).

Thus we want to restrict ourselves to the submanifold $\mathcal{J}_m^{-1}(0)$ of M given by the inverse image of the zero element 0 of $\tilde{\mathbf{Y}}^*$. Since 0 is a regular value of $\mathcal{J}_m$, The Marsden-Weinstein reduction method (see Ref. 1) implies that we can take the reduction of M by the action of the Lie group G and consider the symplectic manifold $\mathcal{J}_m^{-1}(0)/G$ with a well-defined symplectic form $\tilde{\nu}$ acting on it and coming from the initial symplectic form $\nu = 4\,\mathrm{d}\mathbf{v} \wedge \mathrm{d}\mathbf{u}$.

Let us consider the map $\mathcal{H}_{(n,m)}: \mathcal{J}_m^{-1}(0) \mapsto N$ given by

$$\mathbf{x} = \mathbf{A}(\mathbf{u})\mathbf{u}, \quad \mathbf{p} = \frac{2}{|\mathbf{u}|^2}\mathbf{A}(\mathbf{u})\mathbf{v}, \tag{32}$$

where $\mathbf{A}(\mathbf{u})$ denotes the matrix $\mathbf{A}$ as a function of $\mathbf{u}$ as it appears in Eqs. (17) and (18). Notice that if $(\mathbf{u},\mathbf{v}) \in \mathcal{J}_m^{-1}(0)$ then $(\mathbf{v},\mathbf{u}) \in \mathcal{J}_m^{-1}(0)$, and the matrix $\mathbf{A}$ has the following property:

$$\mathbf{A}(\mathbf{u})\mathbf{v} = \mathbf{A}(\mathbf{u})\mathbf{v}, \tag{33}$$

where $\mathbf{A}(\mathbf{v})$ is the matrix $\mathbf{A}$ with entries for the components of the vector $\mathbf{v}$ instead of $\mathbf{u}$ (the importance of having this equation is emphasized in Ref. 25 for $m=2,4$). This property in particular implies that $\mathrm{d}\mathbf{x} = 2\mathbf{A}(\mathbf{u})\mathrm{d}\mathbf{u}$.

Since $\mathbf{A}^t(\mathbf{u})\mathbf{A}(\mathbf{u}) = |\mathbf{u}|^2\mathbf{I}$, then $\mathbf{p}\,\mathrm{d}\mathbf{x} = 4\mathbf{v}\,\mathrm{d}\mathbf{u}$, which in turn implies that $\mathcal{H}_{(n,m)}{}^*\omega = \nu$. Thus we can obtain a canonical transformation $\tilde{\mathcal{H}}_{(n,m)}$ from the symplectic manifold $(\mathcal{J}_m^{-1}(0)/G, \tilde{\nu})$ onto the symplectic manifold (N,ω).

The analog of the situation described in the last paragraph holds in the case $m=2$ as well. In this case the canonical transformation $\tilde{\mathcal{H}}_{(2,2)}$ goes from $T^*(\mathbb{R}^2-\{0\})/\mathbb{Z}_2$ onto $T^*(\mathbb{R}^2-\{0\})$ with corresponding symplectic forms $\tilde{\nu}$ and ω.

Since the Hamiltonian system $(\mathcal{J}_m^{-1}(0),\nu,H'=(1/|\mathbf{u}|^2)(2|\mathbf{v}|^2-1))$ is invariant under the action of G, the equations of motion of the corresponding reduced Hamiltonian system associated to $(\mathcal{J}_m^{-1}(0)/G,\tilde{\nu},\tilde{H})$ [with $\tilde{H}$ being the Hamiltonian H' acting on the reduced manifold $\mathcal{J}_m^{-1}(0)/G$] are determined by the equations of motion of $(\mathcal{J}_m^{-1}(0),\nu,H')$ which in turn are

$$\frac{d\mathbf{u}}{dt}=\frac{1}{4}\frac{\partial H'}{\partial \mathbf{v}}=\frac{\mathbf{v}}{|\mathbf{u}|^2},$$
$$\frac{d\mathbf{v}}{dt}=-\frac{1}{4}\frac{\partial H'}{\partial \mathbf{u}}=\frac{\mathbf{u}}{2|\mathbf{u}|^4}(2|\mathbf{v}|^2-1). \tag{34}$$

Thus on each surface of constant negative energy $H'=E$, and after the time reparametrization $d/dt=(1/|\mathbf{x}|)(d/ds)$, we obtain the equations of motion of an isotropic harmonic oscillator (with strength $k=-E/2$),

$$\frac{d\mathbf{u}}{ds}=\mathbf{v},$$
$$\frac{d\mathbf{v}}{ds}=\frac{E}{2}\mathbf{u}. \tag{35}$$

The Hamiltonian H' is mapped to the Hamiltonian of the Kepler problem $H=\frac{1}{2}|\mathbf{p}|^2-(1/|\mathbf{x}|)$ through the transformation $\mathcal{H}_{(n,m)}$ defined in Eq. (32) (i.e., $H'=H\circ\mathcal{H}_{(n,m)}$). Since $\mathcal{H}_{(n,m)}^*\omega=\nu$, the Hamilton equations of H' indicated in Eqs. (34) are mapped to the Hamilton equations of the Kepler problem:

$$\frac{d\mathbf{x}}{dt}=\frac{\partial H}{\partial \mathbf{p}}=\mathbf{p},$$
$$\frac{d\mathbf{p}}{dt}=-\frac{\partial H}{\partial \mathbf{x}}=-\frac{\mathbf{x}}{|\mathbf{x}|^3}. \tag{36}$$

We conclude that, for fixed negative energy $H=H'=E$, the Hamiltonian flow of the Kepler problem given by Eqs. (36) is equivalent, after a time reparametrization, to the reduction of the Hamiltonian flow of an isotropic harmonic oscillator $K=\frac{1}{2}(|\mathbf{v}|^2+k|\mathbf{u}|^2)$ with strength $k=-E/2$ under the corresponding action of $\mathbb{Z}_2$, S^1 or SU(2).

We remark that the study of the above moment map $\mathcal{J}_m$ has already been considered by Iwai[14] and Mladenov.[20]

IV. THE MOSER REGULARIZATION

Moser[22] introduced a different way to regularize the Kepler problem for fixed negative energy than the one described in the preceding section. The Moser regularization actually works for any dimension and not only for $n=2,3,5$. The Moser map that we describe below is usually associated to the fixed energy $E=-1/2$. Other negative values of the energy can be considered by taking the corresponding dilations (see Ref. 22).

In this section we briefly present the Moser regularization. The main idea goes as follows: The orbits corresponding to nonzero angular momentum (where the initial position and momentum vectors are linearly independent) are circles when projected into the momentum space. These circles correspond, under a stereographic projection $\mathbf{T}_n:\mathbb{R}^n\mapsto S_o^n$ and fixed energy $E=-1/2$, to

great circles on the punctured n-sphere S_o^n. The idea is to consider an extension of this stereographic projection $\mathbf{T}_n$ from the phase space $T^*\mathbb{R}^n$ onto the tangent bundle $T^*S_o^n$ of the punctured n-sphere S^n under the restriction: $\mathbf{T}_n^*\xi\cdot d\mathbf{w}=\mathbf{x}\cdot d\mathbf{p}$ where $(\mathbf{w},\xi)\in T^*S_o^n$, $\mathbf{w}\in S_o^n$. Thus we obtain a map $\mathcal{M}_n: T^*\mathbb{R}^n \mapsto T^*S_o^n$. The explicit equations are the following:

$$w_j = \frac{2}{|p|^2+1}p_j, \quad j=1,2,\ldots,n,$$

$$w_{n+1} = \frac{|p|^2-1}{|p|^2+1}, \tag{37}$$

$$\xi_j = \frac{|p|^2+1}{2}x_j - (\mathbf{x}\cdot\mathbf{p})p_j, \quad j=1,2,\ldots,n,$$

$$\xi_4 = \mathbf{x}\cdot\mathbf{p} = \sum_{j=1}^{n} x_j p_j. \tag{38}$$

The equations for the inverse transformation are

$$p_j = \frac{w_j}{1-w_4}, \quad j=1,2,\ldots,n,$$

$$x_j = (1-w_4)\xi_j + \xi_4 w_j, \quad j=1,2,\ldots,n. \tag{39}$$

The Moser map $\mathcal{M}_n$ is actually a symplectomorphism from the phase space $T^*\mathbb{R}^n$ endowed with its canonical symplectic form $\omega=d\mathbf{p}\wedge d\mathbf{x}$ onto $T^*S_o^n$ endowed with the symplectic form $\kappa=d\mathbf{w}\wedge d\xi$ obtained from the restriction to $T^*S_o^n$ of the canonical symplectic form of the ambient $T^*\mathbb{R}^{n+1}$. Moreover, for fixed negative energy $E=-1/2$, the Moser map $\mathcal{M}_n$ and the time reparametrization Eq. (21) transform the Hamiltonian flow of the n-dimensional Kepler problem $[(\mathbb{R}^n-\{0\})\times\mathbb{R}^n, d\mathbf{p}\wedge d\mathbf{x}, H=(|p|^2/2)-(1/|\mathbf{x}|)]$ onto the geodesic flow of the punctured n-sphere with the zero section of $T^*S_o^n$ removed [note that $|\xi|=[(|\mathbf{p}|^2+1)/2]|\mathbf{x}|$ which implies $\xi=0$ iff $\mathbf{x}=0$]. The collision orbits (orbits with zero angular momentum) are sent to geodesics passing through the north pole but not including the north pole itself.

The north pole can be included into the picture in the following way: it can be shown that, after the time reparametrization, a collision orbit of the n-dimensional Kepler problem corresponds to a particle moving on a segment with one of its ends at the origin and reaching the origin with zero speed. Thus, if we make the convention that after the collision with the center of attraction the particle goes back to its motion on the segment, then we have an oscillatory motion with respect to the time s. Note that we are now including the point $\mathbf{x}=0$. Moreover, since the total energy is conserved then $|\mathbf{x}|\to 0$ iff $|\mathbf{p}|\to\infty$ then we include the case $|\mathbf{p}|=\infty$ in the stereographic projection by assigning to $|\mathbf{p}|=\infty$ the north pole of S^n. The oscillatory motion corresponds to motion on a geodesic passing through the north pole including this point. Thus we say that, for fixed negative energy $E=-1/2$, the Hamiltonian flow of the n-dimensional Kepler problem is regularized by the geodesic flow of the whole n-sphere S^n after the time reparametrization. We will refer to this fact as the Moser regularization of the n-dimensional Kepler problem.

V. MAPPING A COMPLEXIFICATION OF $T^*\mathbb{R}^m$ ONTO A NULL QUADRIC THROUGH A MOMENT MAP

In this section we set up a map $\rho_{n,m}(\mathbf{z})$ from a complexification of $T^*\mathbb{R}^m$ onto a quadric Q^n that will play a key role when we define the Bargmann transform acting on $L^2(S^n)$. In the case of $m=4$ and $m=8$, such a map will be obtained through a moment map $\mathcal{I}$ of a suitable defined group

F acting on a related space to the above-mentioned complexification. The group F is defined as the set of $m\times m$ complex matrices that leave the moment map $\mathcal{K}_m$ [defined in (29)–(31)] invariant. This section is motivated by the work of Kummer[20] where he considers the case $m=4$.

Let us introduce the following complexification of $T^*\mathbb{R}^m$ (similar to the one considered by Mladenov[20]) $\mathcal{T}_m: T^*\mathbb{R}^m \mapsto \mathbb{C}^m$,

$$\mathbf{z} = \mathbf{M}\mathbf{u} + 2\imath\mathbf{M}\mathbf{v}, \tag{40}$$

where we take the following particular expression for the unitary matrix $\mathbf{M}$.

(i) *The case* $m=2$:

$$\mathbf{M} = \frac{1}{\sqrt{2}}\begin{pmatrix} -\imath & -1 \\ -\imath & 1 \end{pmatrix}. \tag{41}$$

(ii) *The case* $m=4$:

$$\mathbf{M} = \frac{1}{\sqrt{2}}\begin{pmatrix} -\imath & -1 & 0 & 0 \\ 0 & 0 & 1 & -\imath \\ 0 & 0 & 1 & \imath \\ -\imath & 1 & 0 & 0 \end{pmatrix}. \tag{42}$$

(iii) *The case* $m=8$:

$$\mathbf{M} = \frac{1}{\sqrt{2}}\begin{pmatrix} -\imath & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & -\imath & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -\imath & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & \imath \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & -\imath \\ 0 & 0 & 0 & 0 & \imath & -1 & 0 & 0 \\ 0 & 0 & 1 & -\imath & 0 & 0 & 0 & 0 \\ -\imath & 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{43}$$

Since $\mathbf{M}$ is unitary, we have

$$\theta := -\imath\, d\mathbf{z}\wedge d\underline{\mathbf{z}} = 4\, d\mathbf{v}\wedge d\mathbf{u}. \tag{44}$$

Given k a positive integer number, we define the null quadric by

$$Q^k = \{\boldsymbol{\alpha}\in\mathbb{C}^{k+1} \mid \alpha_1^2 + \cdots + \alpha_{k+1}^2 = 0\}. \tag{45}$$

Let us first define the map $\rho(\mathbf{z})$ in the case $m=2$. In this case we have the action $\mathbf{z}'\mapsto\pm\mathbf{z}$ of the group $\mathbb{Z}_2$ on the complex manifold $\mathbb{C}^2$. The set of monomials $\{z_1^2, z_2, z_1z_2\}$ give a basis of the vector space V of all the homogeneous polynomials of degree 2 (all the elements of V are invariant under the $\mathbb{Z}_2$ action). Thus, we define the map $\rho(\mathbf{z})_{(2,2)}=(\rho_1(\mathbf{z}),\rho_2(\mathbf{z}),\rho_3(\mathbf{z}))$ by

$$\rho_1 = (z_2^2 - z_1^2)/2, \quad \rho_2 = \imath(z_1^2 + z_2^2)/2, \quad \rho_3 = z_1z_2. \tag{46}$$

The map $\rho(\mathbf{z})$ defined by Eq. (46) has values in the null quadric Q^2.

In order to consider the cases $m=4,8$, let us introduce the variable $\boldsymbol{\eta}\in\mathbb{C}^m$ and write it as $\boldsymbol{\eta}=(\boldsymbol{\eta}_{\mathrm{I}},\boldsymbol{\eta}_{\mathrm{II}})$ with $\boldsymbol{\eta}_{\mathrm{I}},\boldsymbol{\eta}_{\mathrm{II}}\in\mathbb{C}^{m/2}$. Let us consider the following change of variables from the variable $\mathbf{z}$ to the variable $\boldsymbol{\eta}$:

$$\boldsymbol{\eta}_{\mathrm{I}} = \mathbf{z}_{\mathrm{I}}, \quad \boldsymbol{\eta}_{\mathrm{II}} = \overline{\mathbf{z}}_{\mathrm{II}}. \tag{47}$$

Thus the symplectic form θ written in terms of $\boldsymbol{\eta}$ is

$$\theta = -\imath(\mathrm{d}\boldsymbol{\eta}_{\mathrm{I}} \wedge \mathrm{d}\overline{\boldsymbol{\eta}}_{\mathrm{I}} - \mathrm{d}\boldsymbol{\eta}_{\mathrm{II}} \wedge \mathrm{d}\overline{\boldsymbol{\eta}}_{\mathrm{II}}). \tag{48}$$

Let us denote by $\mathcal{K}_m$ the moment map associated to the action of the group G on the space $\mathbb{C}^m$ in terms of the variable $\boldsymbol{\eta}$.

The moment map $\mathcal{K}_m$ written in terms of $\boldsymbol{\eta}$ and $\overline{\boldsymbol{\eta}}$ is determined by the following equations [see Eqs. (29)–(31) and the definition of the complexification $\mathcal{T}_m$ in Eqs. (40)–(43))].

For the case $m=4$,

$$\xi(\boldsymbol{\eta}, \overline{\boldsymbol{\eta}}) = \frac{1}{4}\boldsymbol{\eta}^{\dagger}\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}\boldsymbol{\eta}, \tag{49}$$

where I denotes the 2×2 unit matrix and $\boldsymbol{\eta}^{\dagger}$ the adjoint of $\boldsymbol{\eta}$.

For the case $m=8$,

$$\alpha(\boldsymbol{\eta}, \overline{\boldsymbol{\eta}}) = -\frac{1}{4}\Re\left[\boldsymbol{\eta}^{t}\begin{pmatrix} 0 & J \\ J & 0 \end{pmatrix}\boldsymbol{\eta}\right],$$

$$\beta(\boldsymbol{\eta}, \overline{\boldsymbol{\eta}}) = \frac{1}{4}\Im\left[\boldsymbol{\eta}^{t}\begin{pmatrix} 0 & J \\ J & 0 \end{pmatrix}\boldsymbol{\eta}\right],$$

$$\lambda(\boldsymbol{\eta}, \overline{\boldsymbol{\eta}}) = -\frac{1}{4}\boldsymbol{\eta}^{\dagger}\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}\boldsymbol{\eta}, \tag{50}$$

where I denotes the 4×4 unit matrix and J is

$$J = \begin{pmatrix} 0 & \sigma_1 \\ \sigma_1 & 0 \end{pmatrix}, \quad \boldsymbol{\sigma}_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{51}$$

Let us define the group F as the group of linear transformations which leave the moment map $\mathcal{K}_m$ invariant. Namely, F is the Lie group of $m\times m$ matrices $\mathbf{S}$ which satisfy the condition

$$\mathbf{S}^{\dagger}\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}\mathbf{S} = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \tag{52}$$

and additionally the following condition for the case $m=8$:

$$\mathbf{S}^{t}\begin{pmatrix} 0 & J \\ J & 0 \end{pmatrix}\mathbf{S} = \begin{pmatrix} 0 & J \\ J & 0 \end{pmatrix}, \tag{53}$$

where $\mathbf{S}^t$ denotes the transpose matrix of $\mathbf{S}$.

We will also require the condition that the elements of F have unit determinant in both cases. Notice that $F=\mathrm{SU}(2,2)$ for $m=4$ and F is a subgroup of $\mathrm{SU}(4,4)$ for $m=8$.

From the definition of the group F [Eq. (52)] and the expression of the symplectic form θ in terms of the variables $\boldsymbol{\eta}$ and $\overline{\boldsymbol{\eta}}$ [Eq. (48)], we have that the action of F on $\mathbb{C}^8$ is symplectic. Therefore we can consider the moment map $\mathcal{I}$ of the action of F on $\mathbb{C}^8$. We will obtain from this moment map a map $\rho(\mathbf{z})$ from $\mathbb{C}^8$ to T^*S^n which is invariant under the following action [obtained from the action of the group G in the last section and acting on the variables $(\mathbf{u},\mathbf{v})$].

Case $m=4$,

$$\mathbf{z}' = \begin{pmatrix} \exp(-\imath\psi) & 0 & 0 & 0 \\ 0 & \exp(-\imath\psi) & 0 & 0 \\ 0 & 0 & \exp(\imath\psi) & 0 \\ 0 & 0 & 0 & \exp(\imath\psi) \end{pmatrix}\mathbf{z}. \tag{54}$$

Case $m=8$,

$$\mathbf{z}' = \mathbf{L}^{\dagger}\mathbf{V}\mathbf{L}\mathbf{z}, \tag{55}$$

where $\mathbf{V}$ has the form indicated in Eq. (14) and

$$\mathbf{L} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}. \tag{56}$$

The Lie algebra $\mathcal{F}$ of F is the real vector space of $m \times m$ traceless complex matrices ζ which have the following form.

Case $m=4$,

$$\begin{pmatrix} \mathbf{a} & \mathbf{b} \\ -\mathbf{b}^{\dagger} & \mathbf{d} \end{pmatrix} \tag{57}$$

with the 2×2 matrices $\mathbf{a}$ and $\mathbf{d}$ restricted to be self-adjoint.

Case $m=8$,

$$\zeta = \begin{pmatrix} \mathbf{a} & \mathbf{b} \\ -\mathbf{b}^{\dagger} & -J\mathbf{a}^{t}J \end{pmatrix}, \tag{58}$$

where the 4×4 matrices $\mathbf{a}$ and $\mathbf{b}$ satisfy

$$\mathbf{a}^{\dagger} = \mathbf{a}, \quad J\mathbf{b}^{t} = -\mathbf{b}J \tag{59}$$

or, equivalently, the matrix $\mathbf{b}$ must have the form

$$\mathbf{b} = \begin{pmatrix} \mathbf{b}_{11} & \mathbf{b}_{12} \\ \mathbf{b}_{21} & -\boldsymbol{\sigma}_3\mathbf{b}_{11}^{t}\boldsymbol{\sigma}_3 \end{pmatrix} \tag{60}$$

with $\mathbf{b}_{11}$ any 2×2 complex matrix, $\mathbf{b}_{12}$ and $\mathbf{b}_{21}$ any two complex multiples of the 2×2 matrix $\boldsymbol{\sigma}_3$ defined in Eq. (51).

Notice that the dimension of $\mathcal{F}$ is 15 and 28 when $m=4$ and $m=8$, respectively.

Let us introduce the following real valued inner product in $\mathcal{F}$:

$$\langle \zeta_1, \zeta_2 \rangle = \mathrm{tr}\left(\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \zeta_1 \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \zeta_2 \right). \tag{61}$$

Given a Hamiltonian system (H, ω), with $H=H(\boldsymbol{\eta}, \overline{\boldsymbol{\eta}})$, the associated Hamiltonian vector field X_H is

$$X_H = \imath \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix} \frac{\partial}{\partial \overline{\boldsymbol{\eta}}} H. \tag{62}$$

The infinitesimal generator $\zeta_{\boldsymbol{\eta}}$ associated to a given element ζ of the Lie algebra $\mathcal{F}$ at the point $\boldsymbol{\eta}$ is equal to $\imath\zeta\boldsymbol{\eta}$. Thus we want the moment map $\mathcal{I}$ to satisfy the following equation for all $\zeta \in \mathcal{F}$:

$$\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}\zeta\boldsymbol{\eta} = \frac{\partial}{\partial\bar{\boldsymbol{\eta}}}\mathrm{tr}\left(\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}\mathcal{I}(\boldsymbol{\eta},\bar{\boldsymbol{\eta}})\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}\zeta\right). \tag{63}$$

The solution to Eq. (63) is the following.

Case $m=4$,

$$\mathcal{I}(\boldsymbol{\eta},\bar{\boldsymbol{\eta}}) = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}\boldsymbol{\eta}\boldsymbol{\eta}^{\dagger}. \tag{64}$$

Case $m=8$,

$$\mathcal{I}(\boldsymbol{\eta},\bar{\boldsymbol{\eta}}) = \frac{1}{2}\left[\begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}\boldsymbol{\eta}\boldsymbol{\eta}^{\dagger} + \begin{pmatrix} 0 & J \\ J & 0 \end{pmatrix}(\boldsymbol{\eta}\boldsymbol{\eta}^{\dagger})^{t}\begin{pmatrix} 0 & -J \\ J & 0 \end{pmatrix}\right]. \tag{65}$$

We are now ready to introduce the map $\rho(\mathbf{z})=(\rho_1,\ldots,\rho_{n+1})$. The real and imaginary parts of the components of $\rho(\mathbf{z})$ are defined as the Hamiltonians $\langle\mathcal{I}(\boldsymbol{\eta},\bar{\boldsymbol{\eta}}),\zeta\rangle$ written in terms of $\mathbf{z}$ with the following particular choices for $\zeta\in\mathcal{F}$.

Case $m=4$: Denote the elements of $\mathcal{F}$ by $\zeta=\zeta(\mathbf{a},\mathbf{b},\mathbf{d})$ as indicated in Eq. (57). Let us define

$$\begin{gathered}
\Re\rho_1 = \langle\mathcal{I},\zeta(0,\boldsymbol{\sigma}_0,0)\rangle, \quad \Im\rho_1 = \langle\mathcal{I},\zeta(0,\imath\boldsymbol{\sigma}_0,0)\rangle, \\
\Re\rho_2 = \langle\mathcal{I},\zeta(0,-\imath\boldsymbol{\sigma}_3,0)\rangle, \quad \Im\rho_2 = \langle\mathcal{I},\zeta(0,\boldsymbol{\sigma}_3,0)\rangle, \\
\Re\rho_3 = \langle\mathcal{I},\zeta(0,-\imath\boldsymbol{\sigma}_1,0)\rangle, \quad \Im\rho_3 = \langle\mathcal{I},\zeta(0,\boldsymbol{\sigma}_1,0)\rangle, \\
\Re\rho_4 = \langle\mathcal{I},\zeta(0,\imath\boldsymbol{\sigma}_2,0)\rangle, \quad \Im\rho_4 = \langle\mathcal{I},\zeta(0,\boldsymbol{\sigma}_2,0)\rangle,
\end{gathered} \tag{66}$$

where the matrix $\boldsymbol{\sigma}_0$ is the 2×2 identity matrix and $\boldsymbol{\sigma}_j$, $j=1,2,3$, are the Pauli matrices given by

$$\boldsymbol{\sigma}_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \boldsymbol{\sigma}_2 = \begin{pmatrix} 0 & -\imath \\ \imath & 0 \end{pmatrix}, \quad \boldsymbol{\sigma}_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{67}$$

More explicitly, we define the components of $\rho_{(3,4)}$ by

$$\begin{gathered}
\rho_1(\mathbf{z}) = z_1z_3 + z_2z_4, \quad \rho_2(\mathbf{z}) = \imath(z_1z_3 - z_2z_4), \\
\rho_3(\mathbf{z}) = \imath(z_1z_4 + z_2z_3), \quad \rho_4(\mathbf{z}) = z_1z_4 - z_2z_3.
\end{gathered} \tag{68}$$

Case $m=8$: Denote the elements of $\mathcal{F}$ by $\zeta=\zeta(\mathbf{a},\mathbf{b}_{11},\mathbf{b}_{12},\mathbf{b}_{21})$ as indicated in Eqs. (58)–(60). Let us define then

$$\begin{gathered}
\Re\rho_1 = \langle\mathcal{I},\zeta(0,-\boldsymbol{\sigma}_2,0,0)\rangle, \quad \Im\rho_1 = \langle\mathcal{I},\zeta(0,-\imath\boldsymbol{\sigma}_2,0,0)\rangle, \\
\Re\rho_2 = \langle\mathcal{I},\zeta(0,\boldsymbol{\sigma}_1,0,0)\rangle, \quad \Im\rho_2 = \langle\mathcal{I},\zeta(0,\imath\boldsymbol{\sigma}_1,0,0)\rangle, \\
\Re\rho_3 = \langle\mathcal{I},\zeta(0,-\boldsymbol{\sigma}_3,0,0)\rangle, \quad \Im\rho_3 = \langle\mathcal{I},\zeta(0,-\imath\boldsymbol{\sigma}_3,0,0)\rangle, \\
\Re\rho_4 = \langle\mathcal{I},\zeta(0,\imath\boldsymbol{\sigma}_0,0,0)\rangle, \quad \Im\rho_4 = \langle\mathcal{I},\zeta(0,-\boldsymbol{\sigma}_0,0,0)\rangle, \\
\Re\rho_5 = \langle\mathcal{I},\zeta(0,0,\imath\boldsymbol{\sigma}_1,\imath\boldsymbol{\sigma}_1)\rangle, \quad \Im\rho_5 = \langle\mathcal{I},\zeta(0,0,-\boldsymbol{\sigma}_1,-\boldsymbol{\sigma}_1)\rangle, \\
\Re\rho_6 = \langle\mathcal{I},\zeta(0,0,\boldsymbol{\sigma}_1,-\boldsymbol{\sigma}_1)\rangle, \quad \Im\rho_6 = \langle\mathcal{I},\zeta(0,0,\imath\boldsymbol{\sigma}_1,-\imath\boldsymbol{\sigma}_1)\rangle.
\end{gathered} \tag{69}$$

More explicitly, we define the components of $\rho_{5,8}$ by

$$\begin{aligned}
\rho_1(\mathbf{z}) &= \imath(-z_1z_6 + z_3z_8 + z_2z_5 - z_4z_7),\\
\rho_2(\mathbf{z}) &= z_1z_6 + z_3z_8 + z_2z_5 + z_4z_7,\\
\rho_3(\mathbf{z}) &= z_2z_6 + z_3z_7 - z_1z_5 - z_4z_8,\\
\rho_4(\mathbf{z}) &= \imath(-z_1z_5 + z_4z_8 - z_2z_6 + z_3z_7),\\
\rho_5(\mathbf{z}) &= \imath(-z_1z_8 - z_2z_7 - z_3z_6 - z_4z_5),\\
\rho_6(\mathbf{z}) &= z_1z_8 + z_2z_7 - z_3z_6 - z_4z_5.
\end{aligned} \tag{70}$$

We remark that in each case ($m=4$ and $m=8$) the particular matrices $\zeta \in \mathcal{F}$ that we have chosen are orthogonal among them. Moreover, we can extend this particular subset of $\mathcal{F}$ to an orthonormal basis (as shown by Kummer[20] in the case $m=4$) obtaining Hamiltonians $\langle \mathcal{I}(\boldsymbol{\eta}, \bar{\boldsymbol{\eta}}), \zeta \rangle$ which give the six generators of the SO(4) group and the 15 generators of the SO(6) group for $m=4$ and $m=8$, respectively. Moreover, in both cases we can choose one of the basis elements such that we obtain the Hamiltonian $H=\sum_{k=1}^{k=m}|z_k|^2$. Thus we can obtain $8+6+1=15$ and $12+15+1=28$ elements of the basis of $\mathcal{F}$ when $m=4$ and $m=8$, respectively. Note that in both cases $m=4,8$ the moment map $\mathcal{I}$ is invariant under the action of G defined by Eqs. (54)–(56). Therefore, the map $\rho_{(n,m)}(\mathbf{z})$ enjoys that invariance property too and it is well defined on the reduced symplectic manifold $\mathcal{K}_m^{-1}(0)/G$. Moreover, the map $\rho(\mathbf{z})$ is onto and takes values in the null quadric Q^3 or Q^5 corresponding to the cases $m=4$ or $m=8$.

VI. CANONICAL TRANSFORMATION

In this section we provide a canonical transformation $\tilde{\mathcal{C}}_{(n,m)}$ from $(\mathcal{K}_m^{-1}(0)-\{0\})/G$ (with $\{0\}$ denoting the origin of $\mathbb{C}^m$) onto $T^*S^n-\{0\}$ (here $\{0\}$ denotes the zero section of T^*S^n). This transformation comes from a map $\mathcal{C}_{(n,m)}$ defined as the composition of the map $\rho_{(n,m)}$ defined in the preceding section (and restricted to $\mathbb{C}^m-\{0\}$) and a map σ which identifies the null quadric $Q^n-\{0\}$ with $T^*S^n-\{0\}$. The map $\tilde{\mathcal{C}}_{(n,m)}$ has the remarkable property that relates the two different ways to regularize the Kepler problem that we have explained in the preceding sections (the Moser and $\mathcal{H}_{(n,m)}$ maps). Moreover, the Bargmann transform for $L^2(S^n)$, $n=2,3,5$, that we will define in the next section can be regarded as the quantization of the canonical transformation $\mathcal{C}_{(n,m)}$.

Let us define the map σ_n in the following way. Since $\boldsymbol{\alpha} \in Q^n$ if and only if the real and imaginary parts of $\boldsymbol{\alpha}$ are orthogonal and have the same norm (as vectors in $\mathbb{R}^{n+1}$), then we can identify $Q^n-\{0\}$ with $T^*S^n-\{0\}$ through the map

$$\begin{aligned}
&\sigma_n: Q^n - \{0\} \mapsto T^*S^n - \{0\},\\
&\sigma_n(\boldsymbol{\alpha}) = \left(\frac{\Re\boldsymbol{\alpha}}{|\boldsymbol{\alpha}|}, -\Im\boldsymbol{\alpha}\right).
\end{aligned} \tag{71}$$

Thus we define the map $\mathcal{C}_{(n,m)}$ as composition of the maps $\rho_{(n,m)}$ and σ_n,

$$\begin{aligned}
&\mathcal{C}_{(n,m)}: \mathbb{C}^m - \{0\} \mapsto T^*S^n - \{0\},\\
&\mathcal{C}_{(n,m)} = \rho_{(n,m)} \circ \sigma_n.
\end{aligned} \tag{72}$$

The map $\mathcal{C}_{(n,m)}$ makes the following diagram commute:

$$\begin{array}{ccc} \mathcal{K}_m^{-1}(0)-(\{0\}\cup P) & \xrightarrow{\mathcal{C}_{(n,m)}} & T^*S_0^n-\{0\} \\ \Big\downarrow \mathcal{T}_m^{-1} & & \Big\downarrow \mathcal{M}_n^{-1} \\ \mathcal{J}_m^{-1}(0) & \xrightarrow{\mathcal{H}_{(n,m)}} & T^*(\mathbb{R}^n-\{0\}) \end{array}$$

where the set P denotes the inverse image of the cotangent space of S^n at the north pole under the map $\mathcal{C}_{(n,m)}$ and $\mathcal{T}_m: T^*\mathbb{R}^m \mapsto \mathbb{C}_m$ denotes the complexification indicated in Eq. (40). Note that the set P is actually given by the inverse image of the real number one under the function $\Re\rho_{n+1}$ which is invariant under the action of the group G and therefore we can consider the quotient $\widetilde{P} := P/G$.

To check that the last diagram holds, we can make use of the relations $|\Re\rho_{(n,m)}| = |\rho_{(n,m)}|/\sqrt{2}$, $|\rho_{(n,m)}| = |\mathbf{z}|^2/\sqrt{2}$ and the equations

$$\begin{aligned} p_j &= \frac{\Re\rho_j(\mathbf{z})}{|\Re\rho_{(n,m)}(\mathbf{z})| - \Re\rho_{n+1}(\mathbf{z})}, \\ x_j &= \frac{-|\Re\rho_{(n,m)}(\mathbf{z})|\Im\rho_j(\mathbf{z}) + \Im\{\overline{\rho_{n+1}(\mathbf{z})}\rho_j(\mathbf{z})\}}{|\Re\rho_{(n,m)}(\mathbf{z})|}, \quad j=1,\ldots,n. \end{aligned} \tag{73}$$

where the components of $\rho_{(n,m)}$ are denoted by $\rho_j(\mathbf{z})$ as above. Then a long computation follows.

Moreover, when $\mathcal{C}_{(n,m)}$ is considered as in the last diagram, we can check through a direct computation that $\mathbf{w}\,\mathrm{d}\boldsymbol{\xi} = \Im\{\overline{\mathbf{z}}\,\mathrm{d}\mathbf{z}\}$, which in turn implies that $\mathcal{C}^*_{(n,m)}\kappa = \theta$.

Since $\mathcal{C}_{(n,m)}$ is invariant under the action of the group G, we can define our canonical transformation $\widetilde{\mathcal{C}}_{(n,m)}$ as the reduction of $\mathcal{C}_{(n,m)}$ and with domain $(\mathcal{K}_m^{-1}(0)-\{0\})/G-\widetilde{P}$. As indicated in the introduction of this paper, we still call $\mathcal{C}_{(n,m)}$ a canonical transformation even though it is not injective.

VII. BARGMANN TRANSFORM

In this section we define a Bargmann transform for the space $L^2(S^n)$ with $n=2,3,5$. We do this by following the ideas in Refs. 27 and 28. Namely, we regard the Bargmann transform as an integral operator from $L^2(S^n)$ onto a suitable Hilbert space of analytical functions of the complex variable $\mathbf{z}\in\mathbb{C}^m$ ($m=2,4,8$) with an integral kernel given as a power series of a function which in turn is the inner product of $\rho_{(n,m)}(\mathbf{z})$ with the variable $\mathbf{w}$ in S^n.

In order to define the range of the Bargmann transform for $L^2(S^n)$, let us recall the usual Bargmann spaces $\mathcal{B}_k$ introduced by Bargmann in Ref. 4.

A. Bargmann transform for $L^2(\mathbb{R}^k)$

For $k\in\mathbb{N}$, let $\mathcal{B}_k$ be the space of analytical functions in k complex variables [denoted by $\mathbf{z}=(z_1,z_2,\ldots,z_k)$] which are square integrable with respect to the Gaussian measure

$$\mathrm{d}\nu_k(\mathbf{z}) = \frac{1}{\pi^k}\exp(-|\mathbf{z}|^2)\prod_{j=1}^{k}\mathrm{d}x_j\,\mathrm{d}y_j, \tag{74}$$

where $|\mathbf{z}|^2 = |z_1|^2+|z_2|^2+\cdots+|z_k|^2$ and $z_j = x_j+\imath y_j$, $x_j,y_j\in\mathbf{R}$, with $j=1,2,\ldots,k$.

The space $\mathcal{B}_k$ is a Hilbert space endowed with the inner product

$$\langle F,G\rangle_{\mathcal{B}_k} = \int_{\mathbb{C}^k} F(\mathbf{z})\bar{G}(\mathbf{z})\mathrm{d}\nu_k(\mathbf{z}). \tag{75}$$

The norm of a function $F \in \mathcal{B}_k$ will be denoted by $\|F\|_{\mathcal{B}_k} = \sqrt{\langle F, F\rangle_{\mathcal{B}_k}}$.

The set of all monomials $z_1^{a_1} z_2^{a_2} \cdots z_k^{a_k} / \sqrt{a_1! a_2! \cdots a_k!}$, with $a_1, a_2, \ldots, a_k$ non-negative integers, is an orthonormal basis of $\mathcal{B}_k$.

The space $\mathcal{B}_k$ has a reproducing kernel. Let us denote by

$$\mathbf{\Psi}_{\mathbf{a}}(\mathbf{z}) = \exp(\bar{\mathbf{a}}\mathbf{z}), \quad \text{with } \mathbf{a} \in \mathbb{C}^k. \tag{76}$$

Then for all $\mathbf{\Phi} \in \mathcal{B}_k$ the following equation holds:

$$\mathbf{\Phi}(\mathbf{z}) = \langle \mathbf{\Phi}, \mathbf{\Psi}_{\mathbf{z}} \rangle_{\mathcal{B}_k} = \int_{\mathbb{C}^k} \exp(\mathbf{z}\bar{\eta}) \mathbf{\Phi}(\eta) \mathrm{d}\nu_k(\eta). \tag{77}$$

The Bargmann transform for $\mathrm{L}^2(\mathbb{R}^k)$ is defined as the operator $\mathbf{B}_{\mathbb{R}^k}: L^2(\mathbb{R}^k) \mapsto \mathcal{B}_k$ given by

$$\mathbf{B}_{\mathbb{R}^k} \mathbf{\Psi}(\mathbf{z}) = \frac{1}{\pi^{k/4}} \int_{\mathbb{R}^k} A(\mathbf{x}, \mathbf{z}) \Psi(\mathbf{x}) \mathrm{d}\mathbf{x}, \quad \mathbf{\Psi} \in L^2(\mathbb{R}^k), \tag{78}$$

where $\mathrm{d}\mathbf{x}$ is the usual Lebesgue measure on $\mathbb{R}^k$ and

$$A(\mathbf{x}, \mathbf{z}) = \exp\left(-\tfrac{1}{2}(\mathbf{z}^2 + \mathbf{x}^2) + \sqrt{2}\mathbf{z} \cdot \mathbf{x}\right), \tag{79}$$

with $\mathbf{z}^2 = z_1^2 + z_2^2 + \cdots + z_k^2$, $\mathbf{x} = (x_1, x_2, \ldots, x_k)$, $\mathbf{x}^2 = x_1^2 + x_2^2 + \cdots + x_k^2$ and $\mathbf{z} \cdot \mathbf{x} = z_1 x_1 + z_2 x_2 + \cdots + z_k x_k$. The Bargmann transform $\mathbf{B}_{R^k}$ is a unitary operator with $\mathrm{L}^2(\mathbb{R}^k)$ endowed with the usual inner product,

$$\langle \mathbf{\Psi}_1, \mathbf{\Psi}_2 \rangle_{L^2(\mathbb{R}^k)} = \int_{\mathbf{x} \in \mathbb{R}^k} \mathbf{\Psi}_1(\mathbf{x}) \overline{\mathbf{\Psi}_2}(\mathbf{x}) \mathrm{d}\mathbf{x}. \tag{80}$$

The inverse $\mathbf{B}_{\mathbb{R}^k}^{-1}$ is given by

$$\mathbf{B}_{\mathbb{R}^k}^{-1} F(\mathbf{x}) = \lim_{M \mapsto \infty} \int_{|\mathbf{z}| \leq M} \overline{A(\mathbf{x}, \mathbf{z})} F(\mathbf{z}) \mathrm{d}\nu_k(\mathbf{z}). \tag{81}$$

Here we need to take the limit because the integral over all the space $\mathbf{C}^k$ might not exist [note that, for fixed $\mathbf{x}$, $A(\mathbf{x}, \mathbf{z}) \notin \mathcal{B}_k$].

B. Bargmann transform for $L^2(S^n)$ with $n = 2, 3, 5$

The range of the Bargmann transform for $L^2(S^n)$ with $n = 2$, 3 or 5 will be defined as a closed subspace of the Bargmann space $\mathcal{B}_2$, $\mathcal{B}_4$ or $\mathcal{B}_8$, respectively.

(i) *Case* $L^2(S^2)$: Let us define the space $\mathcal{F}_2$ as the closed subspace of the Bargmann space $\mathcal{B}_2$ generated by the monomials $z_1^{a_1} z_2^{a_2}$ with $a_1 + a_2$ an even non-negative integer number.

(ii) *Case* $L^2(S^3)$: Let $\mathcal{F}_4 \subset \mathcal{B}_4$ be the kernel of the following operator:

$$\mathcal{L} \equiv z_1 \frac{\partial}{\partial z_1} + z_2 \frac{\partial}{\partial z_2} - z_3 \frac{\partial}{\partial z_3} - z_4 \frac{\partial}{\partial z_4}. \tag{82}$$

The domain of $\mathcal{L}$ is defined as $\{f \in \mathcal{B}_4 \,|\, \mathcal{L}f \in \mathcal{B}_4\}$.

(iii) *Case* $L^2(S^5)$: Let $\mathcal{F}_8 \subset \mathcal{B}_8$ be the intersection of the kernel of the following three operators:

$$\mathcal{R}_1 \equiv z_1 \frac{\partial}{\partial z_1} + z_2 \frac{\partial}{\partial z_2} + z_3 \frac{\partial}{\partial z_3} + z_4 \frac{\partial}{\partial z_4} - z_5 \frac{\partial}{\partial z_5} - z_6 \frac{\partial}{\partial z_6} - z_7 \frac{\partial}{\partial z_7} - z_8 \frac{\partial}{\partial z_8},$$

$$\mathcal{R}_2 \equiv z_7 \frac{\partial}{\partial z_1} - z_8 \frac{\partial}{\partial z_2} + z_5 \frac{\partial}{\partial z_3} - z_6 \frac{\partial}{\partial z_4} - z_1 \frac{\partial}{\partial z_7} + z_2 \frac{\partial}{\partial z_8} - z_3 \frac{\partial}{\partial z_5} + z_4 \frac{\partial}{\partial z_6},$$

$$\mathcal{R}_3 \equiv z_7\frac{\partial}{\partial z_1} - z_8\frac{\partial}{\partial z_2} + z_5\frac{\partial}{\partial z_3} - z_6\frac{\partial}{\partial z_4} + z_1\frac{\partial}{\partial z_7} - z_2\frac{\partial}{\partial z_8} + z_3\frac{\partial}{\partial z_5} - z_4\frac{\partial}{\partial z_6}. \tag{83}$$

The domains of $\mathcal{R}_q, q=1,2,3$ are defined in a similar way as the domain of $\mathcal{L}$. The definition of the operators $\mathcal{L}$ and $\mathcal{R}_q$ is motivated by the quantization of the restrictions given by $\mathcal{K}_m^{-1}\{0\}$ [see Eqs. (49) and (50) with the change of variables (47)] taking z_j and $\bar{z}_j$ to the operators of multiplication by the complex variable z_j and to partial derivation with respect to z_j, respectively, with $j=1,\ldots,m$.

Notice that, since the operators $\mathcal{L}$, $\mathcal{R}_1$, and $\mathcal{R}_2$ are closed (see Sec. 3d of Ref. 4), the spaces $\mathcal{F}_4$ and $\mathcal{F}_8$ are actually Hilbert spaces.

Following Refs. 27 and 28, we define the Bargmann transform in the three cases we are considering, initially in a formal way, as the following integral operator: For $\Psi \in L^2(S^n)$,

$$\mathbf{B}_{S^n}\boldsymbol{\Psi}(\mathbf{z}) = \int_{S^n}\left(\sum_{k=0}^{\infty} c_k(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k\right)\boldsymbol{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w}), \quad \mathbf{z}\in\mathbb{C}^m, \tag{84}$$

where the inner product of two vectors in $\mathbb{C}^{n+1}$ is given by $\boldsymbol{\alpha}\cdot\boldsymbol{\beta}=\Sigma_{j=1}^{n+1}\alpha_j\bar{\beta}_j$.

The coefficients c_k appearing in Eq. (84) are determined in such a way that $\mathbf{B}_{S^n}$ is an isometry. Thus let us consider the function $\boldsymbol{\Psi}_\ell(\mathbf{w})=d_\ell((\mathbf{e}_1+\imath\mathbf{e}_2)\cdot\mathbf{w})^\ell$ where ℓ is a non-negative integer, $\mathbf{e}_1=(1,0,\ldots,0)$ and $\mathbf{e}_2=(0,1,0,\ldots,0)$ are two unit vectors in $\mathbb{R}^{n+1}$ and d_ℓ is a normalization constant such that $\|\boldsymbol{\Psi}_\ell\|_{L^2(S^n)}=1$. Since the integral

$$\begin{aligned}\int_{S^n}(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k((\mathbf{e}_1+\imath\mathbf{e}_2)\cdot\mathbf{w})^\ell\,\mathrm{d}S(\mathbf{w}) = \delta_{k,\ell}\Bigg\{&\frac{(2k)!!}{(2k+1)!!}\left(\frac{\alpha_1(\mathbf{z})+\imath\alpha_2(\mathbf{z})}{2}\right)^k \quad \text{for } n=2,\\ &\times\frac{1}{k}\left(\frac{\alpha_1(\mathbf{z})+\imath\alpha_2(\mathbf{z})}{2}\right)^k \quad \text{for } n=3,\\ &\times\frac{2}{(k+2)(k+1)}\left(\frac{\alpha_1(\mathbf{z})+\imath\alpha_2(\mathbf{z})}{2}\right)^k \quad \text{for } n=5\Bigg\},\end{aligned} \tag{85}$$

where $(2k)!!$ is the product of all positive even numbers lesser or equal than $2k$ [a similar definition for $(2k+1)!!$].

Then by demanding Ψ_ℓ to be sent to the function $\Phi_\ell=b_\ell([\alpha_1(\mathbf{z})+\imath\alpha_2(\mathbf{z})]/2)^\ell$ (with b_ℓ a normalization constant such that $\|\Phi_\ell\|_{\mathcal{B}_m}=1$) we can evaluate the constant c_k obtaining

$$c_k = \left\{\frac{\sqrt{2k+1}}{k!} \quad \text{for } n=2, \quad \frac{\sqrt{k+1}}{k!} \quad \text{for } n=3, \quad \sqrt{\frac{k+2}{2}}\frac{1}{k!} \quad \text{for } n=5\right\}. \tag{86}$$

Since the series $\Sigma_{k=0}^{\infty}c_k(\eta)^k$ is an analytic function in the complex variable η on the whole complex plane, and $|(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})|\leqslant|\rho_{(n,m)}(\mathbf{z})|$ then the integral appearing in Eq. (84) is well defined for $\boldsymbol{\Psi}\in L^2(S^n)$ [and therefore in $L^1(S^n)$] and $\mathbf{z}\in\mathbb{C}^m$. Moreover, $\mathbf{B}_{S^n}\boldsymbol{\Psi}$ has the following properties.

Proposition 1: Let $\boldsymbol{\Psi}\in L^2(S^n)$.

(i) *The function* $\mathbf{B}_{S^n}\boldsymbol{\Psi}$ *[defined by Eq. (84)] is an analytical function on the whole complex space* $\mathbb{C}^m$.
(ii) *The Bargmann transform* $\mathbf{B}_{S^n}$ *is an isometry,* $\|\mathbf{B}_{S^n}\boldsymbol{\Psi}\|_{\mathcal{B}_m}=\|\boldsymbol{\Psi}\|_{L^2(S^n)}$.
(iii) *The function* $\mathbf{B}_{S^n}\boldsymbol{\Psi}$ *is in the space* $\mathcal{F}_m$.

Note that from (ii) we have that the Bargmann transform $\mathbf{B}_{S^n}$ is one-to-one and that the function $\mathbf{B}_{S^n}\boldsymbol{\Psi}$ belongs to the space $\mathcal{B}_m$.

Proof:(i) Let $\mathbf{z}$ be a fixed element of $\mathbb{C}^m$. We will show that $(\partial/\partial z_j)\mathbf{B}_{S^n}\boldsymbol{\Psi}(\mathbf{z})$ exist for any j

$=1,2,\ldots,m$. Let $\mathbf{q}=(0,\ldots,h,\ldots,0)\in\mathbb{C}^m$ with the complex variable h in the jth entry and $|h|<\delta$ (for some positive number δ). Since

$$\frac{1}{h}[\mathbf{B}_{S^n}\mathbf{\Psi}(\mathbf{z}+\mathbf{q})-\mathbf{B}_{S^n}\mathbf{\Psi}(\mathbf{z})]=\int_{S^n}\sum_{k=0}^{\infty}c_k\left[\frac{(\rho_{(n,m)}(\mathbf{z}+\mathbf{q})\cdot\mathbf{w})^k-(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k}{h}\right]\mathbf{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w}) \tag{87}$$

then, on base of the dominated convergence theorem, it will be enough to prove that the sequence of functions

$$f_h(\mathbf{w})\equiv\sum_{k=0}^{\infty}c_k\left[\frac{(\rho_{(n,m)}(\mathbf{z}+\mathbf{q})\cdot\mathbf{w})^k-(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k}{h}\right],\quad \mathbf{w}\in S^n \tag{88}$$

is uniformly bounded by a constant. Namely, from the Cauchy's integral formula we have

$$\left|\frac{(\rho_{(n,m)}(\mathbf{z}+\mathbf{q})\cdot\mathbf{w})^k-(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k}{h}\right|\leqslant\frac{1}{2\pi}\oint_{\mathcal{C}}\frac{|(\rho_{(n,m)}(\eta)\cdot\mathbf{w})^k|}{|(\eta-(\mathbf{z}+\mathbf{q}))||(\eta-\mathbf{z})|}d|\eta| \tag{89}$$

with $\mathcal{C}=\{(z_1,\ldots,z_j+r\exp(\imath 2\pi\theta),\ldots,z_m)\,|\,0\leqslant\theta\leqslant 1\}$ and $\delta<r$. Therefore,

$$|f_h(\mathbf{w})|\leqslant\frac{1}{r(r-\delta)}\sum_{k=0}^{\infty}c_k(\max\{|\rho_{(n,m)}(\eta)||\,\eta\in\mathcal{C}\})^k. \tag{90}$$

Thus we conclude that $\partial/\partial z_j\mathbf{B}_{S^n}\mathbf{\Psi}(\mathbf{z})$ exist and

$$\begin{aligned}\frac{\partial}{\partial z_j}\mathbf{B}_{S^n}\mathbf{\Psi}(\mathbf{z})&=\int_{S^n}\frac{\partial}{\partial z_j}\left(\sum_{k=0}^{\infty}c_k(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k\right)\mathbf{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w})\\&=\int_{S^n}\left(\sum_{k=0}^{\infty}c_k\frac{\partial}{\partial z_j}(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k\right)\mathbf{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w}).\end{aligned} \tag{91}$$

(ii) We will use the following criterion (see Sec. 1g of Ref. 4): an analytical function F on $\mathbb{C}^m$ is in the Bargmann space $\mathcal{B}_m$ if and only if for $0<\lambda<1$ the functions F_λ defined as $F_\lambda(\mathbf{z})=F(\lambda\mathbf{z})$ belong to $\mathcal{B}_m$ and their norms $\|F_\lambda\|_{\mathcal{B}_m}$ are uniformly bounded. Moreover, if $F\in\mathcal{B}_m$ then $F_\lambda\to F$ as $\lambda\to 1$ in the norm of $\mathcal{B}_m$.

Thus let us consider the functions $\mathbf{B}_{S^n}\mathbf{\Psi}(\lambda\mathbf{z})$. The main point in the following calculations is that $0<\lambda<1$ and then we can use Fubini's theorem.

Let us define

$$\begin{aligned}I=&\int_{\mathbb{C}^m}\int_{S^n\times S^n}\left(\sum_{k=0}^{\infty}c_k\lambda^{2k}(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k\right)\\&\times\left(\sum_{\ell=0}^{\infty}c_\ell\lambda^{2\ell}\overline{(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{v})}^{\ell}\right)\mathbf{\Psi}(\mathbf{w})\overline{\mathbf{\Psi}(\mathbf{v})}\mathrm{d}S(\mathbf{w})\mathrm{d}S(\mathbf{v})\mathrm{d}\nu_m(\mathbf{z}).\end{aligned} \tag{92}$$

Let us define the following function:

$$f(\mathbf{z},(\mathbf{w},\mathbf{v}))=\left(\sum_{k=0}^{\infty}c_k\lambda^{2k}(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k\right)\left(\sum_{\ell=0}^{\infty}c_\ell\lambda^{2\ell}\overline{(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{v})}^{\ell}\right). \tag{93}$$

Since $|\Re\rho_{(n,m)}(\mathbf{z})|=|\Im\rho_{(n,m)}(\mathbf{z})|$ and $|\Re\rho_{(n,m)}(\mathbf{z})|=(1/\sqrt{2})|\rho_{(n,m)}(\mathbf{z})|=\frac{1}{2}|\mathbf{z}|^2$ in all of the cases we are considering, then

$$\left|\sum_{k=0}^{\infty} c_k\lambda^{2k}(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k\right| \leqslant \sum_{k=0}^{\infty} c_k\lambda^{2k}\left|\frac{\Re\rho_{(n,m)}(\mathbf{z})}{|\Re\rho_{(n,m)}(\mathbf{z})|}\cdot\mathbf{w}+\imath\frac{\Im\rho_{(n,m)}(\mathbf{z})}{|\Im\rho_{(n,m)}(\mathbf{z})|}\cdot\mathbf{w}\right|^k|\Re\rho_{(n,m)}(\mathbf{z})|^k$$
$$\leqslant \sum_{k=0}^{\infty} c_k\lambda^{2k}|\mathbf{w}|^k\left(\frac{|\mathbf{z}|^2}{2}\right)^k \leqslant \sum_{k=0}^{\infty} d_k\lambda^k\frac{1}{k!}\left(\frac{\lambda|\mathbf{z}|^2}{2}\right)^k \tag{94}$$

with $d_k=c_k k!$

Now notice that given $0<\lambda<1$, there exist N_λ such that $d_k\lambda^k<1$ for $k\geqslant N_\lambda$. Therefore,

$$\sum_{k=0}^{\infty} d_k\lambda^k\frac{1}{k!}\left(\frac{\lambda|\mathbf{z}|^2}{2}\right)^k \leqslant P(|\mathbf{z}|^2)+\exp\left(\frac{\lambda|\mathbf{z}|^2}{2}\right) \tag{95}$$

for some polynomial P which degree depends on λ. Since a polynomial times $\exp(\lambda|\mathbf{z}|^2)$ is integrable with respect to the Gaussian measure $\mathrm{d}\nu_m(\mathbf{z})$, then the integral of $|f(\mathbf{z},(\mathbf{w},\mathbf{v}))|$ is finite with respect to $\mathrm{d}\nu_m(\mathbf{z})$. Moreover, since $\mathbf{\Psi}\in L^2(S^n)$ and then $\mathbf{\Psi}\in L^1(S^n)$, we can use Fubini's theorem in order to interchange the two integrals appearing in Eq. (92). Thus we have

$$I=\int_{S^n}\sum_{k=0}^{\infty}\int_{S^n}\int_{\mathbb{C}^m} c_k^2\lambda^{4k}(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k\overline{(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{v})}^k\,\mathrm{d}\nu_m(\mathbf{z})\mathbf{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w})\overline{\mathbf{\Psi}(\mathbf{v})}\mathrm{d}S(\mathbf{v}), \tag{96}$$

where we have used the orthogonality of two given homogeneous polynomials of different degree in the Bargmann space $\mathcal{B}_m$.

Let us denote by P_k the projector onto the kth eigenspace of the Laplacian. In Appendix B we prove that the first two integrals in Eq. (96) give an expression of P_k acting on Ψ. Namely,

$$P_k\mathbf{\Psi}(\mathbf{v})=\int_{S^n} J_k(\mathbf{w},\mathbf{v})\mathbf{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w}) \tag{97}$$

with

$$J_k(\mathbf{w},\mathbf{v})=c_k^2\int_{\mathbb{C}^m}(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k\overline{(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{v})}^k\,\mathrm{d}\nu_m(\mathbf{z}). \tag{98}$$

Thus we have

$$\int_{\mathbb{C}^m}\mathbf{B}_{S^n}\mathbf{\Psi}(\lambda\mathbf{z})\overline{\mathbf{B}_{S^n}\mathbf{\Psi}(\lambda\mathbf{z})}\mathrm{d}\nu_m(\mathbf{z})=\int_{S^n}\sum_{k=0}^{\infty}\lambda^{4k}P_k\mathbf{\Psi}(\mathbf{v})\overline{\mathbf{\Psi}(\mathbf{v})}\mathrm{d}S(\mathbf{v}). \tag{99}$$

Let

$$f_\lambda(\mathbf{v})=\sum_{k=0}^{\infty}\lambda^{4k}P_k\mathbf{\Psi}(\mathbf{v})\overline{\mathbf{\Psi}(\mathbf{v})} \tag{100}$$

By following the same procedure as in Eq. (94) we obtain

$$|J_k(\mathbf{w},\mathbf{v})|\leqslant\frac{c_k^2}{2^{2k}}\int_{\mathbb{C}^m}(|\mathbf{z}|^2)^{2k}\,\mathrm{d}\nu_m(\mathbf{z}). \tag{101}$$

Since $c_k^2\lambda^{2k}(2k)!/2^{2k+1}$ is bounded, then we obtain from the bounded dominated convergence theorem

$$|f_\lambda(\mathbf{v})| \leqslant C|\mathbf{\Psi}(\mathbf{v})| \int_{\mathbb{C}^m} (\exp(\lambda|\mathbf{z}|^2) + \exp(-\lambda|\mathbf{z}|^2)) \mathrm{d}\nu_m(\mathbf{z}) \tag{102}$$

for some constant involving the integral of $|\mathbf{\Psi}|$ on S^n.

Since $0<\lambda<1$ then $|f_\lambda(\mathbf{v})| \leqslant C|\mathbf{\Psi}(\mathbf{v})|$ (for some other finite constant C) which allows us to use the dominated convergence theorem in Eq. (99) to obtain

$$\int_{\mathbb{C}^m} \mathbf{B}_{S^n}\mathbf{\Psi}(\lambda\mathbf{z})\overline{\mathbf{B}_{S^n}\mathbf{\Psi}(\lambda\mathbf{z})}\mathrm{d}\nu_m(\mathbf{z}) = \sum_{k=0}^{\infty} \lambda^{4k}\langle P_k\mathbf{\Psi}, \mathbf{\Psi}\rangle = \sum_{k=0}^{\infty} \lambda^{4k}\|P_k\mathbf{\Psi}\|^2. \tag{103}$$

Since the right-hand side is finite then we have proved that, for $0<\lambda<1$, $\mathbf{B}_{S^n}\mathbf{\Psi}(\lambda\mathbf{z})$ are in $\mathcal{B}_m$ and their norms are uniformly bounded, therefore $\mathbf{B}_{S^n}\mathbf{\Psi}(\mathbf{z})$ is in $\mathcal{B}_m$. Moreover,

$$\|\mathbf{B}_{S^n}\mathbf{\Psi}\|^2 = \lim_{\lambda\to 1} \sum_{k=0}^{\infty} \lambda^{4k}\|P_k\mathbf{\Psi}\|^2 = \sum_{k=0}^{\infty} \|P_k\mathbf{\Psi}\|^2 = \|\mathbf{\Psi}\|^2 \tag{104}$$

which proves that $\mathbf{B}_{S^n}$ is an isometry.

(iii) The case $(n,m)=(2,2)$ is immediate because the function $\rho_{(2,2)}$ is homogeneous of degree 2 in the variables (z_1,z_2). The cases $(n,m)=(3,4)$ and $(n,m)=(5,8)$, are consequence of Eq. (91) and the fact that each entry of the function $\rho_{(n,m)}(\mathbf{z})$ is in the kernel of the corresponding operators defining $\mathcal{F}_m$. □

C. Reproducing kernel for the spaces $\mathcal{F}_m$

by following Ref. 5 we will find the reproducing kernel of the spaces $\mathcal{F}_m$ by taking the average of the reproducing kernel of the corresponding Bargmann space (where $\mathcal{F}_m$ is contained) with respect to the action and Haar measures of the groups $\mathbb{Z}_2, S^1$, SU(2) for the cases $m=2,4,8$, respectively.

Let us consider the action of the group $G=\mathbb{Z}_2$, S^1, SU(2) on the space $\mathbb{C}^m$ for $m=2,4,8$, respectively, given by Eqs. (54)–(56).

Proposition 2. For $m=2,4,8$, the elements of the Hilbert spaces $\mathcal{F}_m$ are given by the invariant functions in $\mathcal{B}_m$ under the group actions of $\mathbb{Z}_2$, S^1, SU(2) described above. Namely, $\mathcal{F}_2=\{f \in \mathcal{B}_2 | f(T_g(z))=f(z)\ \forall\, g\in\mathbb{Z}_2\}$, $\mathcal{F}_4=\{f\in\mathcal{B}_4|f(T_g(z))=f(z)\ \forall\, g\in S^1\}$ and $\mathcal{F}_8=\{f\in\mathcal{B}_8|f(T_g(z))=f(z)\ \forall\, g\in \mathrm{SU}(2)$.

Proof: Since the set of monomials $z_1^{a_1}z_2^{a_2}/a_1!a_2!$ (with a_1 and a_2 non-negative integer numbers) is an orthonormal basis of $\mathcal{B}_2$, then the case $m=2$ is immediate.

Let us now consider a similar basis of monomials for the Bargmann space $\mathcal{B}_4$. One can show that $f\in\mathcal{B}_4$ is in $\mathcal{F}_4$ if and only if f is a linear combination of monomials of the type $z_1^{a_1}z_2^{a_2}z_3^{a_3}z_4^{a_4}$ with $a_1+a_2-a_3-a_4=0$ (see the proof of Proposition 2.1 of Ref. 27). Thus if $f\in\mathcal{F}_4$ then f is clearly invariant under the action of S^1 described above. Conversely, if $f\in\mathcal{B}_4$ is invariant, then by considering the expansion of f in terms of all of the monomials $z_1^{a_1}z_2^{a_2}z_3^{a_3}z_4^{a_4}$ (i.e., with $a_j, j=1,2,3,4$ arbitrary non-negative integer numbers) we conclude that $\exp(\imath(-a_1-a_2+a_3+a_4)\psi)=1\ \forall\,\psi\in\mathbb{R}$ which it is possible only if $a_1+a_2-a_3-a_4=0$. Thus f must belong to $\mathcal{F}_4$.

Let us assume that $f\in\mathcal{B}_8$ is invariant under the action of SU(2), that is

$$f(T_g(z)) = f(z)\ \forall\ g\in \mathrm{SU}(2). \tag{105}$$

Let us consider the following parametrization of $g\in\mathrm{SU}(2)$:

$$g = \begin{pmatrix} \cos(\theta)\exp(\imath\alpha) & \sin(\theta)\exp(\imath\beta) \\ -\sin(\theta)\exp(-\imath\beta) & \cos(\theta)\exp(-\imath\alpha) \end{pmatrix} \tag{106}$$

with $\theta\in[0,\pi/2]$ and $\alpha,\beta\in[-\pi,\pi]$

By considering the partial derivative of both sides in Eq. (105) with respect to α and evaluating the resulting equation at the point $(\theta,\beta,\alpha)=(0,0,0)$, we obtain that f must belong to the

kernel of the operator $\mathcal{R}_1$. In a similar way, we can prove that f is in the kernel of the operators $\mathcal{R}_2$ and $\mathcal{R}_3$ by considering the partial derivatives with respect to θ and β, respectively, and then evaluating at the point $(\theta,\beta,\alpha)=(0,0,0)$ (we actually need to take the limit $\theta\to 0$ in the last case).

Conversely, let us assume $\mathcal{R}_1 f=\mathcal{R}_2 f=\mathcal{R}_3 f=0$ and consider the function $h(\theta,\beta,\alpha)=f(T_g(\mathbf{z}))-f(\mathbf{z})$ regarding $\mathbf{z}\in\mathbb{C}^8$ as fixed. By considering the inverse transformation of Eq. (55), it is possible to show that the gradient of h with respect to the variables θ,β,α must be equal to zero. Since $h(0,0,0)=0$, then $h(\theta,\beta,\alpha)=0$ for all θ,β,α and then f must be invariant under the SU(2) action. □

Theorem 3: *The Hilbert space $\mathcal{F}_m$, $m=2,4,8$, has the following reproducing kernel (respectively):*

$$\mathbf{Q}_2(\mathbf{z},\mathbf{w})=\frac{1}{2}(\exp(z_1\bar{w}_1+z_2\bar{w}_2)+\exp(-z_1\bar{w}_1-z_2\bar{w}_2)),$$

$$\mathbf{Q}_4(\mathbf{z},\mathbf{w})=\frac{1}{2\pi}\int_{\psi=0}^{2\pi}\exp(z_1\bar{w}_1\exp(\imath\psi)+z_2\bar{w}_2\exp(\imath\psi)+z_3\bar{w}_3\exp(-\imath\psi)+z_4\bar{w}_4\exp(-\imath\psi))\mathrm{d}\psi,$$

$$\mathbf{Q}_8(\mathbf{z},\mathbf{w})=\frac{1}{2\pi^2}\int_{\theta=0}^{\pi/2}\int_{\alpha=0}^{2\pi}\int_{\beta=0}^{2\pi}\exp(z_1'\bar{w}_1+\cdots+z_8'\bar{w}_8)\mathrm{d}m(\theta,\alpha,\beta), \tag{107}$$

where $\mathbf{z}'=T_g(\mathbf{z})$ is given by the action of SU(2) defined in Eq. (55) and $\mathrm{d}m(\theta,\alpha,\beta)=(1/2\pi^2)\sin(\theta)\cos(\theta)\mathrm{d}\theta\,\mathrm{d}\alpha\,\mathrm{d}\beta$ is the Haar measure of SU(2).

Proof: We just need to use the previous Proposition and the fact that $\exp(z_1\bar{w}_1+\cdots+z_m\bar{w}_m)$ is the reproducing kernel of the Bargmann space $\mathcal{B}_m$. □

D. The reproducing kernel for $\mathcal{F}_m$ and the Bargmann transform $\mathbf{B}_{S^n}$

The purpose of this section is to introduce a set of states $\{\mathbf{\Phi}_{\boldsymbol{\alpha}}|\,\boldsymbol{\alpha}\in Q^n-\{0\}\}$ in $L^2(S^n)$, $n=2,3,5$ with the property that their Bargmann transform give us the reproducing kernel $\mathbf{Q}_m$ of the space $\mathcal{F}_m$ when we take $\boldsymbol{\alpha}=\rho_{(n,m)}(\mathbf{w})$, with $m=2,4,8$, respectively.

Following Refs. 27 and 28, let us define the following functions in $L^2(S^n)$, $n=2,3,5$:

$$\mathbf{\Phi}_{\bar{\boldsymbol{\alpha}}}(\mathbf{x})=\sum_{k=0}^{\infty}c_k(\bar{\boldsymbol{\alpha}}\cdot\mathbf{x})^k,\quad \bar{\boldsymbol{\alpha}}\in Q^n-\{0\} \tag{108}$$

with c_k given by Eq. (86).

Our first goal is to obtain an explicit expression for the Bargmann transform of $\mathbf{\Phi}_{\alpha}$. Let R be a rotation in $\mathrm{SO}(n+1)$ such that, for some $\mu>0$, $R\boldsymbol{\alpha}=\mu(\mathbf{e_1}+\imath\mathbf{e_2})$ with $\mathbf{e_1}=(1,0,\ldots,0)$ and $\mathbf{e_2}=(0,1,0,\ldots,0)$ two unit vectors in $\mathbb{R}^{n+1}$. Since $|(\mathbf{x}\cdot\boldsymbol{\alpha})|\leqslant|\Re\boldsymbol{\alpha}|$ for all $\mathbf{x}\in S^n$ and $\boldsymbol{\alpha}\in Q^n$ we obtain the following equation by using the dominated convergence theorem:

$$\begin{aligned}\mathbf{B}_{S^n}\mathbf{\Phi}_{\boldsymbol{\alpha}}(\mathbf{z})&=\sum_{k=0}^{\infty}\sum_{\ell=0}^{\infty}c_kc_\ell\int_{S^n}(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{x})^k(\mathbf{x}\cdot\boldsymbol{\alpha})^\ell\,\mathrm{d}S(\mathbf{x})\\&=\sum_{k=0}^{\infty}\sum_{\ell=0}^{\infty}\mu^\ell c_kc_\ell\int_{S^n}(R\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{y})^k(\mathbf{y}\cdot(\mathbf{e_1}+\imath\mathbf{e_2}))^\ell\,\mathrm{d}S(\mathbf{w}),\end{aligned} \tag{109}$$

where we have made the change of variable $\mathbf{y}=R\mathbf{x}$ and made use of the orthogonality of the rotation R.

The integral appearing in the last equation is equal to zero when $k \neq \ell$ because $(R\rho_{(n,m)} \times(\mathbf{z})\cdot\mathbf{y})^k$ and $(\mathbf{y}\cdot(\mathbf{e_1}+\imath\mathbf{e_2}))^\ell$ are eigenfunctions of the spherical Laplacian on S^n and therefore they are orthogonal (they are harmonic homogeneous polynomials of degree k and ℓ, respectively, in the components of the vector $\mathbf{y} \in \mathbb{R}^{n+1}$).

In order to evaluate the integral in Eq. (109) when $k=\ell$, let us introduce spherical coordinates $(\theta_1, \ldots, \theta_n)$ for the variable $\mathbf{y}=(y_1, \ldots, y_{n+1}) \in S^n$:

$$\begin{aligned} y_1 &= \sin(\theta_n)\cdots\sin(\theta_2)\sin(\theta_1), \\ y_2 &= \sin(\theta_n)\cdots\sin(\theta_2)\cos(\theta_1), \\ &\cdots, \\ y_n &= \sin(\theta_n)\cos(\theta_{n-1}), \\ y_{n+1} &= \cos(\theta_n). \end{aligned} \tag{110}$$

Since $\int_0^{2\pi} \exp(\_k\theta_1)\mathrm{d}\theta_1$ is equal to zero when $k \neq 0$ then we find after some computation,

$$\mathbf{B}_{S^n}\mathbf{\Phi}_{\boldsymbol{\alpha}}(\mathbf{z}) = \sum_{k=0}^{\infty} \mu^k f_k (R\rho_{(n,m)}(\mathbf{z})\cdot(\mathbf{e_1}+\imath\mathbf{e_2}))^k = 2\pi\sum_{k=0}^{\infty} f_k(\rho_{(n,m)}(\mathbf{z})\cdot\boldsymbol{\alpha})^k, \tag{111}$$

where

$$f_k = \left\{ \frac{1}{k!(2k-1)!!} \quad \text{for } n=2 \quad \frac{1}{2^k(k!)^2} \quad \text{for } n=3 \quad \frac{1}{2^k k!(k+1)!} \quad \text{for } n=5 \right\}. \tag{112}$$

By using the explicit expressions for the map $\rho_{(n,m)}$ [see Eqs. (46), (68), and (70)] in the expression $\rho_{(n,m)}(\mathbf{z})\cdot\boldsymbol{\alpha}$ with $\boldsymbol{\alpha}=\rho_{(n,m)}(\mathbf{w})$ we get the following equations:

$$\mathbf{B}_{S^2}\mathbf{\Phi}_{\rho_{(2,2)}(\mathbf{w})}(\mathbf{z}) = \sum_{k=0}^{\infty} \frac{1}{(2k)!}(z_1\bar{w}_1 + z_2\bar{w}_2)^{2k},$$

$$\mathbf{B}_{S^3}\mathbf{\Phi}_{\rho_{(3,4)}(\mathbf{w})}(\mathbf{z}) = \sum_{k=0}^{\infty} \frac{1}{(k!)^2}(z_1\bar{w}_1 + z_2\bar{w}_2)^k(z_3\bar{w}_3 + z_4\bar{w}_4)^k,$$

$$\begin{aligned} \mathbf{B}_{S^5}\mathbf{\Phi}_{\rho_{(5,8)}(\mathbf{w})}(\mathbf{z}) = \sum_{k=0}^{\infty} \frac{1}{k!(k+1)!}&([z_1\bar{w}_1 + z_2\bar{w}_2 + z_3\bar{w}_3 + z_4\bar{w}_4][z_5\bar{w}_5 + z_6\bar{w}_6 + z_7\bar{w}_7 + z_8\bar{w}_8] \\ &+ [z_7\bar{w}_1 - z_8\bar{w}_2 + z_5\bar{w}_3 - z_6\bar{w}_4][-z_3\bar{w}_5 + z_4\bar{w}_6 - z_1\bar{w}_7 + z_2\bar{w}_8])^k. \end{aligned} \tag{113}$$

We now establish the relation between the Bargmann transform of the functions $\mathbf{\Phi}_{\rho_{(n,m)}(\mathbf{w})}$ with the reproducing kernel of $\mathcal{F}_m$ in the following.

Theorem 4: *The Bargmann transform* $\mathbf{B}_{S^n}$ *of the functions* $\mathbf{\Phi}_{\rho_{(n,m)}(\mathbf{w})}$ *coincides with the reproducing kernel of the spaces* $\mathcal{F}_m$,

$$\mathbf{B}_{S^n}\mathbf{\Phi}_{\rho_{(n,m)}(\mathbf{w})}(\mathbf{z}) = \mathbf{Q}_m(\mathbf{z},\mathbf{w}). \tag{114}$$

Proof: Use the Taylor series expansion for the exponential function in the expression for $\mathbf{Q}_m(\mathbf{z},\mathbf{w})$ [see Eqs. (107)]. The last case $(n,m)=(5,8)$ requires a more elaborated calculation. For this case, integrate first with respect to α and then with respect to β. To perform the integration with respect

to θ use the identity $\int_0^{\pi/2} \sin^{2(k-\ell)+1}\cos^{2\ell+1} d(\theta)=(k-\ell)!\ell!/2(k+1)!$. □

In addition to having the property indicated in the last proposition, the set of functions $\{\mathbf{\Phi}_{\boldsymbol{\alpha}}|\,\boldsymbol{\alpha}\in Q^n-\{0\}\}$ provides a resolution of the identity which will be explained in the next section of this paper. Moreover, we will introduce in Section VII H the Planck's constant $\hbar$ into the definition of the states $\mathbf{\Phi}_{\boldsymbol{\alpha}}$ showing that they have a concentration property in the semi-classical limit $\hbar\to 0$. Thus, in analogy with some of the properties in the definition of coherent states for the harmonic oscillator (see Ref. 15 and Ref. 2 for different types of definitions of coherent states existing in the literature depending on the property to be emphasized), we will refer to $\{\mathbf{\Phi}_{\boldsymbol{\alpha}}|\,\boldsymbol{\alpha}\in Q^n-\{0\}\}$ as a set of coherent states for $L^2(S^n)$, $n=2,3,5$.

E. Unitarity of the Bargmann transform $\mathbf{B}_{S^n}$

In this section we show the following.

Theorem 5: *The Bargmann transform* $\mathbf{B}_{S^n}$, $n=2,3,5$, *is a unitary operator from* $L^2(S^n)$ *onto* $\mathcal{F}_m$, $m=2,4,8$.

Proof: We already have shown that $\mathbf{B}_{S^n}$ is an isometry [see Eq. (104)] which implies that $\mathbf{B}_{S^n}$ is a one-to-one operator and preserves the inner product (as a consequence of the polarization identity). Thus we only need to show that $\mathbf{B}_{S^n}$ is onto, i.e., that the range of $\mathbf{B}_{S^n}$ is the whole space $\mathcal{F}_m$.

From the preceding section we know that the reproducing kernel $\mathbf{Q}_m(\mathbf{z},\mathbf{w})$ is in the range of the Bargmann transform [think of $\mathbf{Q}_m(\mathbf{z},\mathbf{w})$ as a function of $\mathbf{z}$ for $\mathbf{w}$ fixed]. Therefore, the orthogonal complement in $\mathcal{F}_m$ of the range of $\mathbf{B}_{S^n}$ is the trivial vector space. Since $\mathcal{F}_m$ is a Hilbert space, then the range of $\mathbf{B}_{S^n}$ is dense in $\mathcal{F}_m$. Thus $\mathbf{B}_{S^n}$ is an isometry with dense range, which implies that it is onto. □

F. The inverse of the Bargmann transform $\mathbf{B}_{S^n}$

In this section we give an inversion formula for the Bargmann transform $\mathbf{B}_{S^n}$. Motivated by the expression for the inverse Segal-Bargmann transform introduced in Ref. 8 for $L^2(K)$ with K a compact Lie group, we state the following.

Theorem 6: *Let* $\{E_q|\,q\in\mathbb{N}\}$ *be an increasing sequence of bounded measurable sets in* $\mathbb{C}^m$ *such that* $\cup_{q=1}^{\infty}E_q=\mathbb{C}^m$. *Let* $f\in\mathcal{F}_m$. *Then the inverse Bargmann transform of* f *is given by*

$$\mathbf{B}_{S^n}^{-1}f(\mathbf{x})=\lim_{q\to\infty}\int_{E_q}\sum_{k=0}^{\infty}c_k\overline{(\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{x})^k}f(\mathbf{z})\mathrm{d}\nu_m(\mathbf{z}). \tag{115}$$

The proof of this proposition follows a standard procedure as in Ref. 8.

G. Coherent states for $L^2(S^n)$, $n=2,3,5$

In this section we show that the set of coherent states $\{\mathbf{\Phi}_{\boldsymbol{\alpha}}|\,\boldsymbol{\alpha}\in Q^n-\{0\}\}$ provides a resolution of the identity for the space $L^2(S^n)$. This resolution of the identity will be a consequence of the expression for the inverse of the Bargmann transform $\mathbf{B}_{S^n}$ that we obtained in the preceding section. We also include a description of the resolution of the identity for the eigenspaces of the Laplacian on S^n given by great-circle states that we define below.

Let $\mathbf{\Psi}\in L^2(S^n)$. From the inversion formula for the Bargmann transform obtained in the preceding section we have

$$\mathbf{\Psi}(x)=\lim_{q\mapsto\infty}\int_{E_q}\mathbf{\Phi}_{\rho_{(n,m)}(\mathbf{z})}\mathbf{B}_{S^n}\mathbf{\Psi}(\mathbf{z})\mathrm{d}\nu_m(\mathbf{z}). \tag{116}$$

Notice that $\mathbf{B}_{S^n}\mathbf{\Psi}(\mathbf{z})$ is equal to the inner product in $L^2(S^n)$ of $\mathbf{\Psi}$ with the coherent state $\mathbf{\Phi}_{\rho_{(n,m)}(\mathbf{z})}$:

$$\mathbf{B}_{S^n}\mathbf{\Psi}(\mathbf{z})=\langle\mathbf{\Psi},\mathbf{\Phi}_{\rho_{(n,m)}(\mathbf{z})}\rangle. \tag{117}$$

Thus we conclude from Eq. (117) that

$$\mathbf{\Psi}(x) = \lim_{q\mapsto\infty} \int_{E_q} \langle \mathbf{\Psi}, \mathbf{\Phi}_{\rho_{(n,m)}(\mathbf{z})} \rangle \mathbf{\Phi}_{\rho_{(n,m)}(\mathbf{z})} \, \mathrm{d}\nu_m(\mathbf{z}). \tag{118}$$

Let us now consider the map $\rho_{(n,m)}$ from $\mathbb{C}^m$ onto the null quadric Q^n. Let us denote by $\mathrm{d}\mu(\alpha)$ the measure on Q^n obtained from the measure $\mathrm{d}\nu_m(\mathbf{z})$ through the map $\rho_{(n,m)}$. Thus we can rewrite Eq. (118) as

$$\mathbf{\Psi}(\mathbf{x}) = \lim_{q\to\infty} \int_{E_q} \langle \mathbf{\Psi}, \mathbf{\Phi}_{\boldsymbol{\alpha}} \rangle \mathbf{\Phi}_{\boldsymbol{\alpha}} \, \mathrm{d}\mu_m(\boldsymbol{\alpha}). \tag{119}$$

We will refer to Eq. (119) as the resolution of the identity for $L^2(S^n)$.

Remark 7: *From Appendix A, it follows that the measure* $\mathrm{d}\mu_m$ *is* $\mathrm{SO}(n+1)$ *invariant. Namely, for all* $f \in L^1(\mathrm{d}\mu_m)$ *and* $R \in \mathrm{SO}(n+1)$ *we have*

$$\begin{aligned} \int f(R\boldsymbol{\alpha})\mathrm{d}\mu_m(\boldsymbol{\alpha}) &= \int f(R\rho_{(n,m)}(\mathbf{z}))\mathrm{d}\nu_m(\mathbf{z}) \\ &= \int f(\rho_{(n,m)}(U\mathbf{z}))\mathrm{d}\nu_m(\mathbf{z}) = \int f(\rho_{(n,m)}(\mathbf{z}'))\mathrm{d}\nu_m(\mathbf{z}') = \int f(\boldsymbol{\alpha})\mathrm{d}\mu_m(\boldsymbol{\alpha}), \end{aligned} \tag{120}$$

where we made the change of variables $\mathbf{z}' = U\mathbf{z}$ *and used the invariance of the Gaussian measure* $\mathrm{d}\nu_m$ *with respect to the action of* U.

Notice that the coherent states $\mathbf{\Phi}_{\boldsymbol{\alpha}}$ [see Eq. (108)] are infinite linear combinations of the states $\mathbf{\Phi}_{\boldsymbol{\alpha},k}(\mathbf{x}) \equiv (\boldsymbol{\alpha}\cdot\mathbf{x})^k$. These states $\mathbf{\Phi}_{\boldsymbol{\alpha},k}$ have in turn the following interesting properties (see Ref. 27).

Proposition 8: (i) The states $\mathbf{\Phi}_{\boldsymbol{\alpha},k}$ *are eigenfunctions of the Laplacian on* S^n, *i.e., for each* k, *the state* $\mathbf{\Phi}_{\boldsymbol{\alpha},k}$ *belongs to the eigenspace* $\mathcal{E}_k$ *of the Laplacian on* S^n.

(ii) For $|\Re\boldsymbol{\alpha}| = 1$ *and* k *large, the state* $\mathbf{\Phi}_{\alpha,k}$ *concentrates around the great circle in* S^n *generated by the two orthogonal unit vectors* $\Re\boldsymbol{\alpha}$ and $\Im\boldsymbol{\alpha}$.

(iii) For each k, *the set of states* $\mathbf{\Phi}_{\boldsymbol{\alpha},k}$ *provides a resolution of the identity in the eigenspace* $\mathcal{E}_k$. *Namely, for* $\mathbf{\Psi} \in \mathcal{E}_k$ we have

$$\mathbf{\Psi}(\mathbf{x}) = c_k^2 \int_{\mathbf{z}\in\mathbb{C}^m} \langle \mathbf{\Psi}, \mathbf{\Phi}_{\boldsymbol{\alpha},k} \rangle \mathbf{\Phi}_{\boldsymbol{\alpha},k}(\mathbf{x}) \mathrm{d}\nu_m(\mathbf{z}) = c_k^2 \int_{\boldsymbol{\alpha}\in Q^n} \langle \mathbf{\Psi}, \mathbf{\Phi}_{\boldsymbol{\alpha},k} \rangle \mathbf{\Phi}_{\boldsymbol{\alpha},k}(\mathbf{x}) \mathrm{d}\mu(\boldsymbol{\alpha}). \tag{121}$$

Since property (ii) of the previous proposition is satisfied, we will refer to the functions $\mathbf{\Phi}_{\boldsymbol{\alpha},k}$ as great-circle states (as suggested to us by Hall). Since these states provide a resolution of the identity for the space $\mathcal{E}_k$, we can also think of the great-circle states as coherent states for the space $\mathcal{E}_k$.

We end this section by giving an explicit expression for the inner product of two great-circle states.

Proposition 9:

$$\langle \mathbf{\Phi}_{\boldsymbol{\alpha},k}, \mathbf{\Phi}_{\beta,k} \rangle = \mathrm{d}_k \langle \boldsymbol{\alpha}, \beta \rangle \tag{122}$$

with

$$d_k = \left\{ \frac{k!}{(2k+1)!!} \quad \text{for } n=2, \quad \frac{1}{2^k(k+1)} \quad \text{for } n=3, \quad \frac{1}{2^{k-1}(k+2)(k+1)} \quad \text{for } n=5 \right\}. \tag{123}$$

Proof: Since the surface measure on S^n is $\mathrm{SO}(n+1)$ invariant we only need to show Eq. (122) when $\boldsymbol{\alpha} = (\mathbf{e}_1 + \imath\mathbf{e}_2)$. To that end, introduce spherical coordinates on S^n [see Eq. (110)] to evaluate

the inner product. □

Notice that the Bargmann transform $\mathbf{B}_{S^n}$ of the great-circle states can be easily obtained from the preceding equation,

$$\mathbf{B}_{S^n}\mathbf{\Phi}_{\boldsymbol{\alpha},k}(\mathbf{z}) = d_k\langle\rho_{(n,m)}(\mathbf{z}),\boldsymbol{\alpha}\rangle. \tag{124}$$

H. Asymptotic behavior of coherent states

In this section we introduce the Planck's constant $\hbar$ in the definition of the Bargmann transform and provide an asymptotic expression for the coherent states for $L^2(S^n)$, $n=2,3,5$ that we have introduced above.

By scaling the expression for the Bargmann transform in Eq. (84) and using Theorem 5 we obtain that the operator

$$\mathbf{B}^{\hbar}_{S^n}\mathbf{\Psi}(\mathbf{z}) = \int_{S^n}\left(\sum_{k=0}^{\infty} c_k\left(\frac{\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w}}{\hbar}\right)^k\right)\mathbf{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w}), \quad \mathbf{z}\in\mathbb{C}^m \tag{125}$$

is a unitary transformation from $L^2(S^n)$ onto the Hilbert space $\mathcal{F}^{\hbar}_m$ with the space $\mathcal{F}^{\hbar}_m$ having the same elements as $\mathcal{F}_m$ but endowed with the inner product

$$\langle f,g\rangle = \int_{\mathbb{C}^m} f(\mathbf{z})\bar{g}(\mathbf{z})\mathrm{d}\nu^{\hbar}_m(\mathbf{z}) \tag{126}$$

with the measure

$$\mathrm{d}\nu^{\hbar}_m(\mathbf{z}) := \frac{1}{(\pi\hbar)^n}\exp\left(-\frac{|\mathbf{z}|^2}{\hbar}\right)\prod_{j=1}^{k}\mathrm{d}x_j\,\mathrm{d}y_j. \tag{127}$$

Let us denote the coefficients c_k given by Eq. (86) as $c_k=\sqrt{ak+b}/k!$. Define the analytical function $g(z)=\Sigma_{k=0}^{\infty}c_kz^k$ with domain $\mathbb{C}$. Thomas and Wassel[26] have described an asymptotic expansion for $g(z)$ in the case $m=2$. Their proof can be adapted easily to the other cases $m=4,8$. Thus we have the following.

Proposition 10: For $\Re z\mapsto\infty$ and $|\Im z|\leqslant C\Re z$ and C a positive constant,

$$g(z) = \frac{2z^{1/2}}{\sqrt{a}}\exp(z)\left(1+\frac{a_1}{z}+\frac{a_2}{z^2}+\cdots\right). \tag{128}$$

Therefore we obtain an asymptotic expansion for the coherent states (with $\hbar$ included)

$$\mathbf{\Phi}^{\hbar}_{\boldsymbol{\alpha}}(\mathbf{w}) = \sum_{k=0}^{\infty} c_k\left(\frac{\boldsymbol{\alpha}\cdot\mathbf{x}}{\hbar}\right)^k, \quad \boldsymbol{\alpha}\in Q^n-\{0\} \tag{129}$$

in the following way.

Proposition 11: Let $\boldsymbol{\alpha}\in\mathbf{Q}^n-\{0\}$. Then for $\hbar\mapsto 0$ and $|\mathbf{x}\cdot\Im\boldsymbol{\alpha}|\leqslant C\mathbf{x}\cdot\Re\alpha$ we have

$$\mathbf{\Phi}^{\hbar}_{\boldsymbol{\alpha}}(\mathbf{x}) = \frac{2(\mathbf{x}\cdot\boldsymbol{\alpha})^{1/2}}{\sqrt{a\hbar}}\exp\left(\frac{\mathbf{x}\cdot\boldsymbol{\alpha}}{\hbar}\right)\left(1+\frac{a_1\hbar}{\mathbf{x}\cdot\boldsymbol{\alpha}}+\frac{a_2\hbar^2}{(\mathbf{x}\cdot\boldsymbol{\alpha})^2}+\cdots\right). \tag{130}$$

This proposition describes asymptotically the coherent state $\mathbf{\Phi}^{\hbar}_{\boldsymbol{\alpha}}$ on a neighborhood around the point $\mathbf{a}=\Re\boldsymbol{\alpha}/|\Re\boldsymbol{\alpha}|$ in the sphere S^n when $\hbar$ is very small. In particular, it indicates concentration of the coherent states $\mathbf{\Phi}^{\hbar}_{\boldsymbol{\alpha}}$ around $\mathbf{a}$ for $\hbar$ small in the sense that the magnitude of the function $\mathbf{\Psi}^{\hbar}_{\boldsymbol{\alpha}}(\mathbf{x})\equiv[2(\mathbf{x}\cdot\boldsymbol{\alpha})^{1/2}/\sqrt{a\hbar}]\exp(\mathbf{x}\cdot\boldsymbol{\alpha}/\hbar)$ achieves its maximum value at $\mathbf{x}=\mathbf{a}$ and the relative quotient $|\mathbf{\Psi}^{\hbar}_{\boldsymbol{\alpha}}(\mathbf{x})/\mathbf{\Psi}^{\hbar}_{\boldsymbol{\alpha}}(\mathbf{a})|$ goes to zero (with $\mathbf{x}\neq\mathbf{a}$ fixed) as a constant times $\exp((\mathbf{x}\cdot\Re\boldsymbol{\alpha}-|\Re\boldsymbol{\alpha}|)/\hbar)$.

The phase of the function $\mathbf{\Psi}^{\hbar}_{\boldsymbol{\alpha}}(\mathbf{x})$ contains information too. To see that, let us write the function

$$\mathbf{\Psi}^{\hbar}_{\boldsymbol{\alpha}}(\mathbf{x}) = \frac{2}{\sqrt{a}} \sqrt{\frac{\mathbf{x}\cdot\Re\boldsymbol{\alpha}}{\hbar}} \exp\left(\frac{\mathbf{x}\cdot\Re\boldsymbol{\alpha}}{\hbar}\right) \sqrt{1+\imath\frac{\mathbf{x}\cdot\Im\boldsymbol{\alpha}}{\mathbf{x}\cdot\Re\boldsymbol{\alpha}}} \exp\left(\frac{\imath\mathbf{x}\cdot\Im\boldsymbol{\alpha}}{\hbar}\right). \tag{131}$$

Thus for $\mathbf{x}\in S^n$ in a small neighborhood around the point $\mathbf{a}$ (and therefore the quotient $\mathbf{x}\cdot\Im\boldsymbol{\alpha}/\mathbf{x}\cdot\Re\boldsymbol{\alpha}$ a small number) the phase of $\Psi^{\hbar}_{\boldsymbol{\alpha}}(\mathbf{x})$ is mainly determined by the factor $\exp(\imath\mathbf{x}\cdot\Im\boldsymbol{\alpha}/\hbar)$. This is similar to what occurs in the case of the canonical coherent states [labeled by $\mathbf{z}=(\mathbf{q}-\imath\mathbf{p})/\sqrt{2}$] of the n-dimensional harmonic oscillator [see Eq. (5.1) of Ref. 28 for instance] having as a consequence in this last case that the Fourier transform of the coherent state is concentrated around $\mathbf{p}$ in momentum space. We remind the reader that a point $\boldsymbol{\alpha}$ in $Q^n-\{0\}$ corresponds under the map σ_n to a point in T^*S^n with momentum $\Im\boldsymbol{\alpha}$.

VIII. DISCUSSION

We have introduced a Bargmann transform $\mathbf{B}_{S^n}$ for $L^2(S^n)$, $n=2,3,5$, i.e., a unitary transformation from $L^2(S^n)$ onto a suitable Hilbert space of analytical functions $\mathcal{F}_m$, $m=2,4,8$, inmersed in the usual Bargmann space $\mathcal{B}_m$. The key point to build such a Bargmann transform is to consider the function $(\rho_{(n,m)}\cdot\mathbf{w})$ in its integral kernel. The relevant property of the function $(\rho_{(n,m)}\cdot\mathbf{w})$ is that it is a generating function of a canonical transformation which links the Moser map and the map $\mathcal{H}_{(n,m)}$ concerning the regularization of the $n=2,3,5$ dimensional Kepler problem. Thus our Bargmann transform can be regarded as the quantization of such a canonical transformation. We have proved in detail the unitarity of $\mathbf{B}_{S^n}$ and provided its range with an explicit reproducing kernel. We have also provided the inversion formula for $\mathbf{B}_{S^n}$ and given a set of coherent states for $L^2(S^n)$ including their semiclassical asymptotics. We also point out that the map $\rho_{(n,m)}$ is constructed via a moment map for a suitable defined group F [this construction has been done just in the case $(n,m)=(3,4)$ by Kummer[18]].

We comment that other Bargmann-type transforms have been introduced by Hall and Mitchell[10] for the n-sphere (with $n\geqslant 1$) and by Kowalski and Rembielínski[17] for the circle and the 2-sphere. However, theses Bargmann-type transforms are different than ours. The work of Hall and Mitchell is based on properties of heat kernel functions whereas the work of Kowalski and Rembielínski is based on the construction of certain types of coherent states defined as eigenstates of a vector operator whose addition of the squares of its components is one. In both of the cases the non-null complex quadric appears.

We also comment on the interesting work of Mladenov[20] on the geometric quantization of the $n=5$ dimensional Kepler problem. By following the technique of geometric quantization, Mladenov builds a Hilbert space $\widetilde{\mathcal{K}}$ of analytical functions called physically admissible states. The space $\widetilde{\mathcal{K}}$ is determined by considering the Hilbert space generated by the bound states of eight harmonic oscillators (with the same frequency) subject to the restrictions $\mathcal{R}_1\Psi=0$, $\mathcal{R}_2\Psi=0$, and $\mathcal{R}_3\Psi=0$ [see Eqs. (83)]. This is the same space $\mathcal{F}_8$ that we are considering and that we defined motivated by our previous work on the Bargmann transform for $L^2(S^3)$ (see Ref. 28). The Hilbert space $\widetilde{\mathcal{K}}$ is seen as quantization of the phase space $(\mathbb{C}^m-\{0\},-\imath\,\mathrm{d}\mathbf{z}\wedge\mathrm{d}\overline{\mathbf{z}})$ and then imposing the aforementioned conditions. The phase space $(\mathbb{C}^m-\{0\},-\imath\,\mathrm{d}\mathbf{z}\wedge\mathrm{d}\overline{\mathbf{z}})$ comes out from a complexification of $((\mathbb{R}^m-\{0\})\times\mathbb{R}^m,4\,\mathrm{d}\mathbf{v}\wedge\mathrm{d}\mathbf{u})$ considered by Mladenov. We remark that Mladenov's way to consider such a complexification was very inspiring for our present paper and useful in order to construct our canonical transformation. Mladenov uses the Hilbert space $\widetilde{\mathcal{K}}$ representation as an alternative method to the canonical quantization in order to find the eigenvalues and their multiplicities of the $n=5$ dimensional hydrogen atom.

On the other hand, the coherent states for $L^2(S^n)$, $n=2,3,5$, that we have introduced can be used to construct coherent states for the $n=2,3,5$ hydrogen atom problem. This can be done via a known unitary transformation between $L^2(S^n)$ and the Hilbert space generated by the bound states of the $n=2,3,5$ hydrogen atom problem (see Ref. 3). The development of this work and the

comparison of the coherent states obtained in this way with already known and proposed sets of coherent states for the hydrogen atom (like the coherent states of Klauder,[16] and the ones proposed by Horowski and Odzijewicz[13]) is part of future work.

We finally remark that Hilbert spaces of analytical functions on the null complex quadric Q^n endowed with the measure $d\mu_m(\boldsymbol{\alpha})$ can also be considered in the framework of our work. These Hilbert spaces are related with the ones introduced by Bargmann and Todorov.[5]

For the case $L^2(S^2)$, Thomas and Wassell have used the Bargmann transform presented in this paper in order to obtain approximations of eigenvalues of Schrödinger operators on the 2-sphere S^2. Our work could be also useful in semiclassical analysis like in the work done by Helffer *et al.* (see Refs. 11 and 12) about Schrödinger operators with a Coulomb type singularity where the Kustaanheimo-Stiefel regularization was implemented in the quantum mechanical setting.

ACKNOWLEDGMENTS

It is a pleasure to thank I. M. Mladenov for very interesting comments and for mentioning the existence of his papers (Refs. 20 and 21) and the work of Iwai[14] about the $n=5$ dimensional Kepler problem. The author also thanks Alberto Verjovsky-Solá for illustrative conversations concerning the null complex quadric and the spin groups. The author thanks Alejandro Uribe-Ahumada and Brian Hall for their permanent interest and comments. This work was partially supported by CONACYT, Grant No. 32146-E.

APPENDIX A: SO($n+1$) AND ITS COVERING GROUP ACTING ON THE QUADRIC Q^n AND $\mathbb{C}^m$, RESPECTIVELY

In this appendix we give the explicit relation between the SO($n+1$) action of rotations on the quadric Q^n and the corresponding action of its universal covering group on $\mathbb{C}^m$. Namely, we give representations of the groups SU(2), SU(2)$\times$SU(2) and SU(4) acting on $\mathbb{C}^2$, $\mathbb{C}^4$, and $\mathbb{C}^8$, respectively, and then, by using the maps $\rho_{(n,m)}$ [see Eqs. (46), (68), and (70)], we map these representations through a map Φ into the representations of the rotation groups SO(3), SO(4), and SO(6) acting on the quadric Q^2, Q^3, and Q^5, respectively. We show that the map $\boldsymbol{\Phi}$ is onto, two-to-one, and a homomorphism between the corresponding Lie groups.

We remark that the universal covering group of SO($n+1$) is also known as the spin group spin ($n+1$) (see Ref. 6).

The action of SO($n+1$) on the quadric Q^n is defined as follows: let R be a rotation in SO($n+1$) and $\boldsymbol{\alpha}$ in Q^n. Then we define

$$R\boldsymbol{\alpha} = R\Re\boldsymbol{\alpha} + \imath R\Im\boldsymbol{\alpha}, \tag{A1}$$

where $R\Re\boldsymbol{\alpha}$ and $R\Im\boldsymbol{\alpha}$ denote the usual action of R on the real and imaginary parts of $\boldsymbol{\alpha}$, respectively (regarded as elements of $\mathbb{R}^{n+1}$).

Let us consider the map $\rho_{(n,m)}$ [see Eqs. (46), (68), and (70)]. This map will give us the relation between the action defined in Eq. (A1) and the corresponding action of the covering group of SO($n+1$) on $\mathbb{C}^m$. The main idea is the same for the three cases $n=2,3,5$. We describe in detail the most complicated case $n=5$. The cases $n=2,3$ follow in a similar way and we do not include their description in order not to make this appendix too long.

The case $n=5$: let us write the map $\rho_{(5,8)}(\mathbf{z})=(\alpha_1(\mathbf{z}),\ldots,\alpha_6(\mathbf{z}))$ in matrix form

$$\alpha_j = (z_1,z_2,z_3,z_4)A_j\begin{pmatrix} z_5 \\ z_6 \\ z_7 \\ z_8 \end{pmatrix}, \quad j=1,\ldots,6, \tag{A2}$$

where the matrices A_j, $j=1,\ldots,6$ are defined as follows:

$$A_1 = \begin{pmatrix} 0 & -\imath & 0 & 0 \\ \imath & 0 & 0 & 0 \\ 0 & 0 & 0 & \imath \\ 0 & 0 & -\imath & 0 \end{pmatrix}, \quad A_2 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix},$$

$$A_3 = \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \quad A_4 = \begin{pmatrix} -\imath & 0 & 0 & 0 \\ 0 & -\imath & 0 & 0 \\ 0 & 0 & \imath & 0 \\ 0 & 0 & 0 & \imath \end{pmatrix}, \tag{A3}$$

$$A_5 = \begin{pmatrix} 0 & 0 & 0 & -\imath \\ 0 & 0 & -\imath & 0 \\ 0 & -\imath & 0 & 0 \\ -\imath & 0 & 0 & 0 \end{pmatrix}, \quad A_6 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}.$$

In order to find the action of SU(4) on $\mathbb{C}^8$, the key point is to consider the following transformation: let $U \in \mathrm{SU}(4)$ and define

$$\begin{pmatrix} z_1' \\ z_2' \\ z_3' \\ z_4' \end{pmatrix} = U \begin{pmatrix} z_1 \\ z_2 \\ z_3 \\ z_4 \end{pmatrix}, \quad \begin{pmatrix} z_5' \\ z_6' \\ z_7' \\ z_8' \end{pmatrix} = EUE \begin{pmatrix} z_5 \\ z_6 \\ z_7 \\ z_8 \end{pmatrix}, \tag{A4}$$

where the matrix E is defined by

$$E = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}. \tag{A5}$$

Let us denote by α_j', $j=1,\ldots,6$, the components of the vector $\rho_{(8,5)}(\mathbf{z}')$. Then

$$\alpha_j' = (z_1, z_2, z_3, z_4) U^t A_j EUE \begin{pmatrix} z_5 \\ z_6 \\ z_7 \\ z_8 \end{pmatrix}, \tag{A6}$$

where U^t denotes the transpose matrix of U.

Let V denote the real vector space generated by the matrices A_j, $j=1,\ldots,6$. The vector space V is the set of complex matrices of the form

$$A = \begin{pmatrix} -\mu & \bar{\delta} & 0 & \gamma \\ \delta & \bar{\mu} & \gamma & 0 \\ 0 & -\bar{\gamma} & \mu & \delta \\ -\bar{\gamma} & 0 & \bar{\delta} & -\bar{\mu} \end{pmatrix}, \tag{A7}$$

with $\mu, \delta, \gamma \in \mathbb{C}$.

We now claim that, for $U \in \mathrm{SU}(4)$, the matrix $U^t A_j EUE$ is in the vector space V. To prove this fact, let us denote by $U_{j,k}$ the matrix elements of U. Since $U^\dagger = U^{-1}$ and $\det(U)=1$ then by considering the explicit expression for the inverse matrix U^{-1} we find that the matrix elements of U must satisfy the following six relations:

$$\bar{U}_{11}\bar{U}_{33} - \bar{U}_{31}\bar{U}_{13} = U_{22}U_{44} - U_{42}U_{24}, \bar{U}_{21}\bar{U}_{43} - \bar{U}_{41}\bar{U}_{23} = U_{12}U_{34} - U_{32}U_{14},$$

$$\bar{U}_{31}\bar{U}_{23} - \bar{U}_{21}\bar{U}_{33} = U_{12}U_{44} - U_{42}U_{14}, \bar{U}_{11}\bar{U}_{43} - \bar{U}_{41}\bar{U}_{13} = U_{32}U_{24} - U_{22}U_{34}, \tag{A8}$$

$$\bar{U}_{11}\bar{U}_{23} - \bar{U}_{21}\bar{U}_{13} = U_{42}U_{34} - U_{32}U_{44}, \bar{U}_{41}\bar{U}_{33} - \bar{U}_{31}\bar{U}_{43} = U_{12}U_{24} - U_{22}U_{14}.$$

Then by using Eqs. (A8) and computing the explicit expression for the matrix $U^t A_j EUE$, we find that $U^t A_j EUE$ has the form indicated in Eq. (A7).

The vector space V is endowed with the real valued inner product

$$\langle A, B\rangle_V = \tfrac{1}{2}(\mathrm{trace}(AB^\dagger) + \mathrm{trace}(BA^\dagger)). \tag{A9}$$

The set of matrices $\{\frac{1}{2}A_j \,|\, j=1,\ldots,6\}$ gives an orthonormal basis for the space V. Thus $U^t A_j EUE$ must be the following linear combination of the basis elements (summation over repeated indexes):

$$U^t A_j EUE = \tfrac{1}{4}\langle U^t A_j EUE, A_k\rangle_V A_k, \quad j=1,\ldots,6. \tag{A10}$$

Therefore we have

$$\alpha'_j = (z_1, z_2, z_3, z_4) R_{jk} A_k \begin{pmatrix} z_5 \\ z_6 \\ z_7 \\ z_8 \end{pmatrix} = R_{jk}\alpha_k \tag{A11}$$

with the real numbers R_{jk}, $j,k=1,2,3$, given by

$$R_{jk} = \tfrac{1}{4}\langle U^t A_j EUE, A_k\rangle_V. \tag{A12}$$

Thus to each element $U \in \mathrm{SU}(4)$ we associate a 6×6 matrix R whose matrix elements are R_{jk} given by Eq. (A12). Since the matrix R satisfies the relation $R_{jk}R_{sk} = \delta_{js}$ (thus R must be an orthogonal matrix) then we have a continuous map $U \mapsto R$ from SU(4) into O(6). Since SU(4) is a connected manifold, then its image under the map we are considering must be the connected component of the identity matrix in O(6) [notice that from Eq. (A12) the identity element of SU(4) goes to the identity element of O(6)]. Thus the assignment $U \mapsto R$ gives us a map $\mathbf{\Phi}$ from SU(4) into SO(6). Moreover, since the set $\{\frac{1}{2}A_j \,|\, j=1,\ldots,6\}$ is an orthonormal basis for the space V, we obtain from Eq. (A12) that $\mathbf{\Phi}$ is a Lie group homomorphism.

We now claim that the map $\mathbf{\Phi}$ is onto. Let us consider an element $U \in \mathrm{SU}(4)$. Since SU(4) is a compact connected Lie group, the exponential map is onto and therefore there is a matrix σ in the Lie algebra of SU(4) [denoted by su(4)] such that $U = \exp(\imath\sigma)$. Consider the one-parameter group $U(s) = \exp(\imath s\sigma)$ with parameter $s \in \mathbb{R}$.

Let $\{\sigma_\ell \,|\, \ell = 1,\ldots,15\}$ be an orthonormal basis of SU(4) under the inner product $\langle A, B\rangle_{\mathrm{su}(4)} = \mathrm{trace}(AB)$. Thus we obtain a one-parameter group of rotations $R(s)$ whose matrix elements are given by

$$R(s)_{jk} = \tfrac{1}{4}\langle U^t(s)A_jEU(s)E, A_k\rangle_V, \quad j,k = 1, \ldots, 6 \tag{A13}$$

with $U(s)=\exp(\imath s h_j \sigma_j)$ and $h_\ell = \langle \sigma, \sigma_\ell\rangle_{\mathrm{su}(4)}$, $\ell = 1, \ldots, 15$. Let us now consider the element $\mathcal{A}$ of so(3) [the Lie algebra of SO(3)] obtained by taking the $-\imath$ times the derivative of $R(s)$ at $s=0$. Thus we have

$$\mathcal{A}_{jk} = \frac{1}{8}\left.\frac{d}{\mathrm{d}s}\right|_{s=0} \mathrm{trace}(U^t(s)A_jEU(s)EA_k + A_k(U^t(s)A_jEU(s)E)^\dagger) = h_\ell(\beta_\ell)_{jk}, \quad j,k = 1, \ldots, 6, \tag{A14}$$

where $(\beta_\ell)_{jk}$ denotes the (j,k) matrix element of the matrix β_ℓ defined by

$$(\beta_\ell)_{jk} = \tfrac{1}{8}\,\mathrm{trace}(\sigma_\ell^t(A_jA_k^\dagger - A_kA_j^\dagger) + \sigma_\ell E(A_k^\dagger A_j - A_j^\dagger A_k)E), \tag{A15}$$

where we have used the property $\sigma_\ell^\dagger = \sigma_\ell$.

Since the matrices A_j, $j=1, \ldots, 6$ satisfy the following equation:

$$E(A_k^\dagger A_j - A_j^\dagger A_k)E = -\overline{(A_jA_k^\dagger - A_kA_j^\dagger)}, \quad j,k = 1, \ldots, 6 \tag{A16}$$

and the matrices $\imath(A_jA_k^\dagger - A_kA_j^\dagger)$ are in su(4) (they are self-adjoint and traceless) then we find after some computation

$$(\beta_\ell)_{jk} = \frac{-\imath}{4}\langle \sigma_\ell, \imath(A_jA_k^\dagger - A_kA_j^\dagger)\rangle_{\mathrm{su}(4)}. \tag{A17}$$

From the last equation we see that the matrices $(1/\sqrt{2})\beta_\ell$ are in so(6) (they are of the form $\imath$ times an antisymmetric matrix with real entries) and they actually give an orthonormal set of so(6) under the inner product $\langle A, B\rangle_{\mathrm{so}(6)} = \mathrm{trace}(AB)$ because the set of matrices $\{(\imath/4)(A_jA_k^\dagger - A_kA_j^\dagger) \,|\, j,k = 1, \ldots, 6, j<k\}$ is an orthonormal set of SU(4).

Let $S \in \mathrm{SO}(6)$. Since $S \in \mathrm{SO}(6)$ is a compact connected group, there exist $\mathcal{D} \in \mathrm{so}(6)$ such that $S=\exp(\imath\mathcal{D})$. Since $\{(1/\sqrt{2})\beta_\ell\}$ is an orthonormal basis of so(6), then $\mathcal{D} = c_\ell(1/\sqrt{2})\beta_\ell$ with $c_\ell = \langle \mathcal{D}, (1/\sqrt{2})\beta_\ell\rangle_{\mathrm{so}(6)}$. Consider the matrix $U=\exp[\imath(c_\ell/\sqrt{2})\sigma_\ell[$ in SU(4). From Eq. (A14) we find that $\mathbf{\Phi}(U)=S$ and therefore Φ is onto.

Let us denote by $\phi: \mathrm{su}(4) \mapsto \mathrm{so}(6)$ the associated Lie algebra homomorphism of $\mathbf{\Phi}$. From Eq. (A14) we obtain that $\phi(\sigma) = \langle \sigma, \sigma_\ell\rangle_{\mathrm{su}(4)}\beta_\ell$ for all $\sigma \in \mathrm{su}(4)$. It is easy to check that ϕ is a linear bijection. Moreover ϕ is a Lie algebra isomorphism because of the way it is defined and Theorem 2.21 of Ref. 9.

Finally, $\mathbf{\Phi}$ is two-to-one. Since $\mathbf{\Phi}$ is an homomorphism, it is enough to show that the only two solutions of the equation $\mathbf{\Phi}(U)=I$ are the matrices $U=I$ or $U=-I$. Thus suppose that $\mathbf{\Phi}(U)=I$. From Eq. (A14) we must have that $U^tA_kEUE = A_k$ for all $k=1, \ldots, 6$. By performing the analysis of these equations we find that $U=I$ or $U=-I$ are the only two solutions.

APPENDIX B: ORTHOGONAL PROJECTORS ON EIGENSPACES OF THE LAPLACIAN

Let P_k denote the orthogonal projector onto the kth eigenspace $\mathcal{E}_k$ of the Laplacian on S^n ($n=2,3,5$). The finite dimensional vector space $\mathcal{E}_k$ is the space of restrictions of harmonic homogeneous polynomials of degree k in $n+1$ variables. The Hilbert space $L^2(S^n)$ is equal to the direct sum of all the spaces $\mathcal{E}_k$ (k a non-negative integer number). In particular, two elements of different eigenspaces of the Laplacian are orthogonal with respect to the usual inner product of $L^2(S^n)$.

Let us define the operator $S_k: L^2(S^n) \mapsto L^2(S^n)$ by the following expression:

$$S_k\mathbf{\Psi}(\mathbf{v}) = \int_{S^n} J_k(\mathbf{w}, \mathbf{v})\mathbf{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w}) \tag{B1}$$

with

$$J_k(\mathbf{w},\mathbf{v}) = c_k^2 \int_{\mathbb{C}^m} (\rho_{(m,n)}(\mathbf{z})\cdot\mathbf{w})^k \overline{(\rho_{(m,n)}(\mathbf{z})\cdot\mathbf{v})}^k \, \mathrm{d}\nu_m(\mathbf{z}). \tag{B2}$$

Proposition 12: The operator S_k is equal to the orthogonal projector P_k.

Proof: Since, $\overline{J_k(\mathbf{w},\mathbf{v})}$ is in the space $\mathcal{E}_k$ as a function of $\mathbf{w}$ and $\mathbf{v}$ fixed, then $S_k\Psi=0$ for $\boldsymbol{\Psi}$ in the orthogonal complement of $\mathcal{E}_k$. Thus we only need to show that S_k is the identity operator when acting on the eigenspace $\mathcal{E}_k$. We will use the Schur's lemma for that purpose.

Let us define the following representation of the rotation group $\mathrm{SO}(n+1)$ on the eigenspace $\mathcal{E}_k$. Given $R\in\mathrm{SO}(n+1)$, define the operator $T_R:\mathcal{E}_k\mapsto\mathcal{E}_k$ by $T_R\boldsymbol{\Psi}(\mathbf{w})=\boldsymbol{\Psi}(R^{-1}\mathbf{w})$. The set of operators $\{T_R|R\in\mathrm{SO}(n+1)\}$ gives an irreducible representation of the group $\mathrm{SO}(n+1)$. By Schur's lemma we just need to prove that the operator S_k restricted to $\mathcal{E}_k$ commutes with T_R for all $R\in\mathrm{SO}(n+1)$ and that $S_k\boldsymbol{\Psi}=\boldsymbol{\Psi}$ for a particular nontrivial function in $\mathcal{E}_k$.

Notice that for $\boldsymbol{\Psi}$ in $\mathcal{E}_k$,

$$S_kT_R\boldsymbol{\Psi}(\mathbf{v}) = \int_{S^n} J_k(\mathbf{w},\mathbf{v})\boldsymbol{\Psi}(R^{-1}\mathbf{w})\mathrm{d}S(\mathbf{w}). \tag{B3}$$

On the other hand, we have

$$T_RS_k\boldsymbol{\Psi}(\mathbf{v}) = S_k\boldsymbol{\Psi}(R^{-1}\mathbf{v}) = \int_{S^n} J_k(\mathbf{w},R^{-1}\mathbf{v})\boldsymbol{\Psi}(\mathbf{w})\mathrm{d}S(\mathbf{w}) = \int_{S^n} J_k(R^{-1}\mathbf{w},R^{-1}\mathbf{v})\boldsymbol{\Psi}(R^{-1}\mathbf{w})\mathrm{d}S(\mathbf{w}), \tag{B4}$$

where we have made the change of variable $\mathbf{w}\mapsto R\mathbf{w}$ and used the invariance of the $\mathrm{SO}(n+1)$ surface measure $\mathrm{d}S(\mathbf{w})$. We now claim that $J_k(R^{-1}\mathbf{w},R^{-1}\mathbf{v})=J_k(\mathbf{w},\mathbf{v})$:

$$\begin{aligned} J_k(R^{-1}\mathbf{w},R^{-1}\mathbf{v}) &= c_k^2 \int_{\mathbb{C}^m} (\rho_{(n,m)}(\mathbf{z})\cdot R^{-1}\mathbf{w})^k \overline{(\rho_{(n,m)}(\mathbf{z})\cdot R^{-1}\mathbf{v})}^k \, \mathrm{d}\nu_m(\mathbf{z}) \\ &= c_k^2 \int_{\mathbb{C}^m} (R\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{w})^k \overline{(R\rho_{(n,m)}(\mathbf{z})\cdot\mathbf{v})}^k \, \mathrm{d}\nu_m(\mathbf{z}), \end{aligned} \tag{B5}$$

where we have used the orthogonality of the matrix $R\in\mathrm{SO}(n+1)$.

From Appendix A, we know that, given $R\in\mathrm{SO}(n+1)$, there exist a transformation U acting on $\mathbb{C}^m$ such that $R\rho_{(n,m)}(\mathbf{z})=\rho_{(n,m)}(U\mathbf{z})$ and $\mathrm{d}\nu_m(\mathbf{z})$ is invariant under the action of the matrix U. By considering the change of variables $\mathbf{z}\mapsto U\mathbf{z}$ we conclude that $J_k(R^{-1}\mathbf{w},R^{-1}\mathbf{v})=J_k(\mathbf{w},\mathbf{v})$ Using this fact in Eq. (B3) we obtain $S_kT_R\boldsymbol{\Psi}(\mathbf{v})=T_RS_k\boldsymbol{\Psi}(\mathbf{v})$ and therefore the operator S_k commutes with all of the operators T_R.

Now consider the particular function $\boldsymbol{\Upsilon}(\mathbf{w})=(\,(\mathbf{e}_1+\imath\mathbf{e}_2)\cdot\mathbf{w})^k$ in the eigenspace $\mathcal{E}_k$. From the expression for the inner product of two coherent states Eq. (122) and Fubini's theorem we conclude that $S_k\boldsymbol{\Upsilon}(\mathbf{z})=\boldsymbol{\Upsilon}(\mathbf{z})$.

(Received 20 January 2006; accepted 13 April 2006; published online 5 June 2006)

A simple exact analytical solution of the relativistic Duffin-Kemmer-Petiau equation within the framework of the asymptotic iteration method is presented. Exact bound state energy eigenvalues and corresponding eigenfunctions are determined for the relativistic harmonic oscillator as well as the Coulomb potentials. As a nontrivial example, the anharmonic oscillator is solved and the energy eigenvalues are obtained within the perturbation theory using the asymptotic iteration method. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2203429]

I. INTRODUCTION

Exact analytical solutions to relativistic wave equations are important in relativistic quantum mechanics since the wave function contains all the necessary information to describe a quantum system fully. There are only a few potentials for which the relativistic Dirac, Klein-Gordon, and Duffin-Kemmer-Petiau (DKP) equations can be solved analytically. So far, many methods such as the supersymmetric (SUSY),[1] shape invariance,[2,3] factorization and path integral,[4–7] etc., have been developed to solve the relativistic wave equations exactly, or quasiexactly, for potentials like Coulomb, harmonic oscillator, Pösch Teller and exponential type ones. In recent years, an asymptotic iteration method for solving second-order homogeneous linear differential equations has been proposed by Ciftci *et al.*[8–10] This method has been applied to solve the nonrelativistic radial Schrödinger and Dirac equations for various potentials.[10]

Since the DKP equation is being increasingly used to describe the interactions of relativistic spin-0 and spin-1 bosons,[11–19] it would be interesting to probe whether the DKP equation is amenable to exact solutions in the framework of the asymptotic iteration method (AIM). This is precisely the aim of this paper.

In the next section, we explain the AIM briefly and show how to solve a second-order homogeneous differential equation. Then, we introduce the DKP oscillator and Coulomb problems and obtain their exact eigenvalues and eigenfunctions. In Sec. V, we present the solution of the anharmonic oscillator as a nontrivial example within the perturbation theory. Finally, in the last section, we provide our summary and conclusion.

II. BASIC EQUATIONS OF THE ASYMPTOTIC ITERATION METHOD (AIM)

We briefly outline the asymptotic iteration method here; the details can be found in Refs. 8–10. The asymptotic iteration method was proposed to solve second-order differential equations of the form

$$y'' = \lambda_0(x)y' + s_0(x)y, \tag{1}$$

where $\lambda_0(x) \neq 0$ and $s_0(x)$, $\lambda_0(x)$ are in $C_\infty(a,b)$. The variables, $s_0(x)$ and $\lambda_0(x)$, are sufficiently differentiable. The differential equation (1) has a general solution[8]

$$y(x) = \exp\left(-\int^{x} \alpha \mathrm{d}x'\right)\left[C_2 + C_1 \int^{x} \exp\left(\int^{x'} \lambda_0(x'') + 2\alpha(x'')\mathrm{d}x''\right)\mathrm{d}x'\right] \tag{2}$$

if $n>0$, for sufficiently large n,

$$\frac{s_n}{\lambda_n} = \frac{s_{n-1}}{\lambda_{n-1}} = \alpha, \tag{3}$$

where

$$\lambda_n = \lambda_n' + s_{n-1} + \lambda_0\lambda_{n-1} \quad \text{and } s_n = s_{n-1}' + s_0\lambda_{n-1}. \tag{4}$$

The quantization condition of the method together with Eq. (4) can also be written as follows:

$$\delta(x) = \lambda_{n+1}(x)s_n(x) - \lambda_n(x)s_{n+1}(x) = 0. \tag{5}$$

For a given potential, the idea is to convert the relativistic wave equation to the form of Eq. (1). Then, s_0 and λ_0 are determined and s_n and λ_n parameters are calculated. The energy eigenvalues are then obtained by the condition given by Eq. (5). However, the wave functions are determined by using the wave function generator, namely $\exp(-\int^x \alpha\, dx')$.

In this study, we seek the exact solution of DKP equation for which the relevant second-order homogeneous linear differential equation takes the following general form:

$$y'' = 2\left(\frac{ax^{N+1}}{1-bx^{N+2}} - \frac{(m+1)}{x}\right)y' - \frac{wx^N}{1-bx^{N+2}}y. \tag{6}$$

If this equation is compared to Eq. (1), it entails the following expressions:

$$\lambda_0 = 2\left(\frac{ax^{N+1}}{1-bx^{N+2}} - \frac{(m+1)}{x}\right), \quad s_0(x) = -\frac{wx^N}{1-bx^{N+2}} \tag{7}$$

while the condition (3) yields for $N=-1,0,1,2,3,\ldots$,

$$w_n^m(-1) = n(2a + 2bm + (n+1)b), \tag{8}$$

$$w_n^m(0) = 2n(2a + 2bm + (2n+1)b), \tag{9}$$

$$w_n^m(1) = 3n(2a + 2bm + (3n+1)b), \tag{10}$$

$$w_n^m(2) = 4n(2a + 2bm + (4n+1)b), \tag{11}$$

$$w_n^m(3) = 5n(2a + 2bm + (5n+1)b), \tag{12}$$

etc. Hence, these formulas are easily generalized as

$$w_n^m(N) = b(N+2)^2 n\left(n + \frac{(2m+1)b + 2a}{(N+2)b}\right). \tag{13}$$

The exact eigenfunctions can be derived from the following generator:

$$y_n(x) = C_2 \exp\left(-\int^{x} \alpha_k \mathrm{d}x'\right). \tag{14}$$

Using Eq. (3) and Eq. (7), the eigenfunctions are obtained as follows:

$$y_0(x) = 1,$$

$$y_1(x) = -C_2(N+2)\sigma\left(1 - \frac{b(\rho+1)}{\sigma}x^{N+2}\right),$$

$$y_2(x) = C_2(N+2)^2\sigma(\sigma+1)\left(1 - \frac{2b(\rho+2)}{\sigma}x^{N+2} + \frac{b^2(\rho+2)(\rho+3)}{\sigma(\sigma+1)}x^{2(N+2)}\right),$$

$$y_3(x) = -C_2\frac{\sigma(\sigma+1)(\sigma+2)}{(N+2)^{-3}}\left(1 - \frac{3b(\rho+3)}{\sigma}x^{N+2} + \frac{3b^2(\rho+3)(\rho+4)}{\sigma(\sigma+1)}x^{2(N+2)} - \frac{b^3(\rho+3)(\rho+4)(\rho+5)}{\rho(\rho+1)(\rho+2)}x^{3(N+2)}\right),$$

etc. Finally, the following general formula for the exact solutions $y_n(x)$ is acquired as:

$$y_n(x) = (-1)^n C_2(N+2)^n(\sigma)_{n2}F_1(-n,\rho+n;\sigma;bx^{N+2}), \tag{15}$$

where

$$(\sigma)_n = \frac{\Gamma(\sigma+n)}{\Gamma(\sigma)}, \quad \sigma = \frac{2m+N+3}{N+2}, \quad \text{and } \rho = \frac{(2m+1)b+2a}{(N+2)b}.$$

.

III. DKP HARMONIC OSCILLATOR

In this section, the Duffin-Kemmer-Petiau formalism[11,13] is briefly sketched and the DKP oscillator is solved using AIM. Generally, the first-order relativistic Duffin-Kemmer-Petiau equation for a free spin zero or spin one particle of mass m is

$$(c\beta\,.\,\mathbf{p} + mc^2)\psi = i\hbar\beta^0\frac{\mathrm{d}\psi}{\mathrm{d}t}, \tag{16}$$

where $\beta^\mu(\mu=0,1,2,3)$ matrices satisfy the commutation relation

$$\beta^\mu\beta^\nu\beta^\lambda + \beta^\lambda\beta^\nu\beta^\mu = g^{\mu\nu}\beta^\lambda + g^{\nu\lambda}\beta^\mu \tag{17}$$

which defines the so-called Duffin-Kemmer-Petiau algebra. The algebra generated by the four β matrices has three irreducible representations: a 10-dimensional one that is related to $S=1$, a five-dimensional one relevant for $S=0$ (spinless particles), and a one-dimensional one which is trivial.

In the spin-0 representation, β^μ are 5×5 matrices defined as $(i=1,2,3)$

$$\beta^0 = \begin{pmatrix} \theta & \tilde{0} \\ \overline{0}_T & \mathbf{0} \end{pmatrix}, \quad \beta^i = \begin{pmatrix} \tilde{0} & \rho^i \\ -\rho^i_T & \mathbf{0} \end{pmatrix} \tag{18}$$

with $\tilde{0}$, $\overline{0}$, $\mathbf{0}$ as 2×2, 2×3, 3×3 zero matrices, respectively, and

$$\theta = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \rho^1 = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \rho^2 = \begin{pmatrix} 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \rho^3 = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \end{pmatrix}. \tag{19}$$

For spin one particles, β^μ are 10×10 matrices given by

$$\beta^0 = \begin{pmatrix} 0 & \overline{0} & \overline{0} & \overline{0} \\ \overline{0}^T & \mathbf{0} & \mathbf{I} & \mathbf{I} \\ \overline{0}^T & \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \overline{0}^T & \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix}, \quad \beta^i = \begin{pmatrix} 0 & \overline{0} & e_i & \overline{0} \\ \overline{0}^T & \mathbf{0} & \mathbf{0} & -is_i \\ e_i^T & \mathbf{0} & \mathbf{0} & 0 \\ \overline{0}^T & -is_i & \mathbf{0} & 0 \end{pmatrix}, \tag{20}$$

where s_i are the usual 3×3 spin one matrices

$$\overline{0} = (0\ 0\ 0), \quad e_1 = (1\ 0\ 0), \quad e_2 = (0\ 1\ 0), \quad e_3 = (0\ 0\ 1). \tag{21}$$

I and **0** are the identity and zero matrices, respectively. While the dynamical state ψ_{DKP} is a five component spinor for spin zero particles, it has 10 component spinors for $S=1$ particles.

For the external potential introduced with the nonminimal substitution

$$\mathbf{p} \to \mathbf{p} - im\omega\eta^0\mathbf{r}, \tag{22}$$

where ω is the oscillator frequency and $\eta^0 = 2\beta^{0^2} - 1$, the DKP equation for the system is

$$[c\beta\cdot(\mathbf{p} - im\omega\eta^0\mathbf{r}) + mc^2]\psi = i\hbar\beta^0\frac{\mathrm{d}\psi}{\mathrm{d}t}. \tag{23}$$

In the spin zero representation, the five component DKP spinor

$$\psi(\mathbf{r}) = \begin{pmatrix} \psi_{\mathrm{upper}} \\ i\psi_{\mathrm{lower}} \end{pmatrix} \quad \text{with } \psi_{\mathrm{upper}} \equiv \begin{pmatrix} \phi \\ \varphi \end{pmatrix} \quad \text{and } \psi_{\mathrm{lower}} \equiv \begin{pmatrix} A_1 \\ A_2 \\ A_3 \end{pmatrix}, \tag{24}$$

so that for stationary states the DKP equation can be written as

$$mc^2\phi = E\varphi + ic(\mathbf{p} + im\omega\mathbf{r})\cdot\mathbf{A},$$

$$mc^2\varphi = E\phi,$$

$$mc^2\mathbf{A} = ic(\mathbf{p} - im\omega\mathbf{r})\phi, \tag{25}$$

where **A** is the vector (A_1, A_2, A_3).

The five-component wave function ψ is simultaneously an eigenfunction of J^2 and J_3,

$$J^2\begin{pmatrix} \psi_{\mathrm{upper}} \\ \psi_{\mathrm{lower}} \end{pmatrix} = \begin{pmatrix} L^2\psi_{\mathrm{upper}} \\ (L+S)^2\psi_{\mathrm{lower}} \end{pmatrix} = J(J+1)\begin{pmatrix} \psi_{\mathrm{upper}} \\ \psi_{\mathrm{lower}} \end{pmatrix}, \tag{26}$$

$$J_3\begin{pmatrix} \psi_{\mathrm{upper}} \\ \psi_{\mathrm{lower}} \end{pmatrix} = \begin{pmatrix} L_3\psi_{\mathrm{upper}} \\ (L_3+s_3)\psi_{\mathrm{lower}} \end{pmatrix} = M\begin{pmatrix} \psi_{\mathrm{upper}} \\ \psi_{\mathrm{lower}} \end{pmatrix}, \tag{27}$$

where the total angular momentum $J=L+S$ which commutes with β^0, is a constant of the motion.

For $S=0$ DKP oscillator eigenstates problem, the most general solution for a central problem[11] is presented as follows:

$$\psi_{JM}(r) = \begin{pmatrix} F_{nJ}(r)Y_{JM}(\Omega) \\ G_{nJ}(r)Y_{JM}(\Omega) \\ i\sum\limits_L H_{nJL}(r)Y^M_{JL1}(\Omega) \end{pmatrix}, \tag{28}$$

where

$$\alpha_J = \sqrt{(J+1)/(2J+1)}, \quad \zeta_J = \sqrt{J/(2J+1)}, \tag{29}$$

$$F_{nJ}(r) = F(r), \quad G_{nJ} = G(r), \quad H_{n,J,J\pm1}(r) = H_{\pm1}(r), \tag{30}$$

ψ_{JM} of parity $(-1)^J$ is inserted into Eq. (23) and the following equations are found:

$$EF = mc^2 G, \tag{31}$$

$$\hbar c\left(\frac{d}{\mathrm{d}r} - \frac{J+1}{r} + \frac{m\omega r}{\hbar}\right)F = -\frac{1}{\alpha_J} mc^2 H_1, \tag{32}$$

$$\hbar c\left(\frac{d}{\mathrm{d}r} - \frac{J}{r} + \frac{m\omega r}{\hbar}\right)F = -\frac{1}{\zeta_J} mc^2 H_{-1}, \tag{33}$$

$$-\alpha_J\left(\frac{d}{\mathrm{d}r} + \frac{J+1}{r} - \frac{m\omega r}{\hbar}\right)H_1 + \zeta_J\left(\frac{d}{\mathrm{d}r} - \frac{J}{r} - \frac{m\omega r}{\hbar}\right)H_{-1} = \frac{1}{\hbar c}(mc^2 F - EG). \tag{34}$$

From the above equations, if Eqs. (31)–(33) are inserted into Eq. (34), the homogeneous second-order differential equation for the DKP harmonic oscillator[11] is obtained as

$$\left(\frac{d^2}{\mathrm{d}r^2} + \frac{(E^2 - m^2c^4)}{(\hbar c)^2} + \frac{3m\omega}{\hbar} - \frac{m^2\omega^2 r^2}{\hbar^2} - \frac{J(J+1)}{r^2}\right)F(r) = 0. \tag{35}$$

If we define $E_{\mathrm{eff}}=[(E^2-m^2c^4)/(\hbar c)^2]+(3m\omega/\hbar)$ and $k=m\omega/\hbar$, Eq. (35) becomes

$$\left(\frac{d^2}{\mathrm{d}r^2} + E_{\mathrm{eff}} - k^2 r^2 - \frac{J(J+1)}{r^2}\right)F(r) = 0. \tag{36}$$

The asymptotic iteration method requires selecting the wave function as follows:

$$F(r) = r^{J+1} e^{(-1/2)kr^2} f(r) \tag{37}$$

equating it into Eq. (36) leads to

$$\frac{d^2 f(r)}{\mathrm{d}r^2} - 2\left(kr - \frac{J+1}{r}\right)\frac{\mathrm{d}f(r)}{\mathrm{d}r} + (E_{\mathrm{eff}} - 3k - 2kJ)f(r) = 0, \tag{38}$$

where $\lambda_0=2\{kr-[(J+1)/r]\}$ and $s_0=3k+2kJ-E_{\mathrm{eff}}$. By means of Eq. (4), we may calculate $\lambda_n(r)$ and $s_n(r)$. This gives

$$\lambda_0 = 2\left(kr - \frac{J+1}{r}\right),$$

$$s_0 = 3k + 2kJ - E_{\mathrm{eff}},$$

$$\lambda_1 = 5k + 2\frac{J+1}{r^2} + 2kJ - E_{\mathrm{eff}} + 4\left(kr - \frac{J+1}{r}\right)^2,$$

$$s_1 = 2(3k + 2kJ - E_{\mathrm{eff}})\left(kr - \frac{J+1}{r}\right),$$

$$\lambda_2 = -4\frac{J+1}{r^3} + 2\left(kr - \frac{J+1}{r}\right)\left[4\left(k + \frac{J+1}{r^2}\right) + (3k - 2kJ - E_{\text{eff}}) + 2\left(kr - \frac{J+1}{r}\right)\right],$$

$$s_2 = (3k + 2kJ - E_{\text{eff}})\left[7k + 4\frac{J+1}{r^2} + 2kJ - E_{\text{eff}} + 4\left(kr - \frac{J+1}{r}\right)^2\right], \tag{39}$$

etc. Combining these results with the quantization condition given by Eq. (5) yields

$$\frac{s_0}{\lambda_0} = \frac{s_1}{\lambda_1} \Rightarrow (E_{\text{eff}})_0 = 3k + 2kJ, \tag{40}$$

$$\frac{s_1}{\lambda_1} = \frac{s_2}{\lambda_2} \Rightarrow (E_{\text{eff}})_1 = 7k + 2kJ, \tag{41}$$

$$\frac{s_2}{\lambda_2} = \frac{s_3}{\lambda_3} \Rightarrow (E_{\text{eff}})_2 = 11k + 2kJ, \tag{42}$$

etc.

When the above expressions are generalized, the DKP oscillator eigenvalues turn out as

$$(E_{\text{eff}})_n = k(4n + 3 + 2J). \tag{43}$$

If one inserts the values of k and E_{eff} into Eq. (43), the relativistic energy spectrum of DKP oscillator becomes

$$\frac{1}{2mc^2}(E_{NJ}^2 - m^2c^4) = N\hbar\omega, \tag{44}$$

where N is the principal quantum number defined as $N=2n+J$. Our result is in agreement with the result of Ref. 11 for the same potential.

As indicated in Sec. II, we can construct the corresponding eigenfunctions by using the wave function generator given by Eq. (14) and Eq. (39) where we obtain λ and s values. Therefore, similar to Eq. (15), the wave function $f_n(r)$ can be written

$$f_n(r) = (-1)^n C_2 2^n (\sigma)_n \, {}_1F_1(-n, \sigma; kr^2). \tag{45}$$

$F(r)$ ensues right away in the following form:

$$F(r) = r^{J+1} e^{-(1/2)kr^2}[(-1)^n C_2 2^n (\sigma)_n \, {}_1F_1(-n, \sigma; kr^2)], \tag{46}$$

where

$$\sigma = \frac{2J+3}{2} \quad \text{and } (\sigma)_n = \frac{\Gamma(\sigma + n)}{\Gamma(\sigma)}. \tag{47}$$

Using the wave function $F(r)$, the wave functions $G(r)$, $H_1(r)$, and $H_{-1}(r)$ can be easily obtained by using Eqs. (31)–(34).

IV. DKP COULOMB POTENTIAL

We now apply the AIM method to the bound state problem of a spinless charged pion (π^-) in the Coulomb field of a nucleus. If we use the following *ansatz*:

$$a_{\pm}=\frac{mc^2\pm E}{\hbar c},\quad \gamma=\alpha Z,\quad \lambda_{\pi}=\frac{\hbar}{mc},\quad \kappa=\frac{2}{\hbar c}\sqrt{m^2c^4-E^2},\quad \xi=\frac{2\gamma E}{\kappa\hbar c},\quad \rho=\kappa r \tag{48}$$

the system of coupled equations for the Coulomb potential becomes

$$\alpha_J\left(\frac{\mathrm{d}F}{\mathrm{d}\rho}-\frac{J+1}{\rho}F\right)=-\frac{1}{\kappa\lambda_{\pi}}H_1, \tag{49}$$

$$\zeta_J\left(\frac{\mathrm{d}F}{\mathrm{d}\rho}+\frac{J}{\rho}F\right)=\frac{1}{\kappa\lambda_{\pi}}H_{-1}, \tag{50}$$

$$-\alpha_J\left(\frac{\mathrm{d}H_1}{\mathrm{d}\rho}+\frac{J+1}{\rho}H_1\right)+\zeta_J\left(\frac{\mathrm{d}H_{-1}}{\mathrm{d}\rho}-\frac{J}{\rho}H_{-1}\right)=\kappa\lambda_{\pi}\left(\frac{a_+}{\kappa}+\frac{\gamma}{\rho}\right)\left(\frac{a_-}{\kappa}-\frac{\gamma}{\rho}\right)F. \tag{51}$$

Eliminating H_1 and H_{-1} in favor of F, the second-order differential equation for the Coulomb potential becomes

$$\frac{d^2F(\rho)}{\mathrm{d}\rho^2}+\left(\frac{\xi}{\rho}-\frac{1}{4}-\frac{J(J+1)-\gamma^2}{\rho^2}\right)F(\rho)=0. \tag{52}$$

Let the radial wave function be factorized as

$$F(\rho)=\rho^{\Lambda+1}e^{-(1/2)\rho}f(\rho), \tag{53}$$

where

$$\Lambda=-\tfrac{1}{2}+\sqrt{\left(J+\tfrac{1}{2}\right)^2-\gamma^2}. \tag{54}$$

Equation (52) becomes

$$\frac{d^2f(\rho)}{\mathrm{d}\rho^2}-\frac{(\rho-2\Lambda-2)}{\rho}\frac{\mathrm{d}f(\rho)}{\mathrm{d}\rho}-\frac{(\Lambda+1-\xi)}{\rho}f(\rho)=0 \tag{55}$$

which is now amenable to an AIM solution. In order to find the exact energy eigenvalues, we define λ_0 and s_0 as

$$\lambda_0=-\frac{(\rho-2\Lambda-2)}{\rho},\quad s_0=-\frac{(\Lambda+1-\xi)}{\rho}. \tag{56}$$

Using the quantization condition given by Eq. (5), the ξ values take the form

$$\xi_1=\Lambda+1,\quad \xi_2=\Lambda+2,\quad \xi_3=\Lambda+3,\quad \text{etc.}, \tag{57}$$

which can be generalized as

$$\xi_n=\Lambda+n'. \tag{58}$$

Inserting ξ and Λ in Eq. (48) and defining the principal quantum number as $n=n'+J$, we obtain the exact bound state eigenenergies,

$$E_{nJ}=mc^2\left[1+\frac{(\alpha Z)^2}{\left(n-J-\frac{1}{2}+\sqrt{\left(J+\frac{1}{2}\right)^2-(\alpha Z)^2}\right)^2}\right]^{-1/2}, \tag{59}$$

which is in agreement with the results of Refs. 12 and 13 for the same potential. The binding energy B_{nJ} can be calculated from $B_{nJ}=mc^2-E_{nJ}$.

We can also construct the corresponding eigenfunctions using AIM as

$$f_n(\rho) = (-1)^n C_2(\sigma)_n \, {}_1F_1(-n, \sigma; \rho) \tag{60}$$

which gives

$$F(\rho) = \rho^{\Lambda+1} e^{-(1/2)\rho} [(-1)^n C_2(\sigma)_n \, {}_1F_1(-n, \sigma; \rho)], \tag{61}$$

where

$$\sigma = 2\Lambda + 2 \quad \text{and} \quad (\sigma)_n = \frac{\Gamma(\sigma + n)}{\Gamma(\sigma)}. \tag{62}$$

Other components of the the wave functions $[G(\rho)$, $H_1(\rho)$, and $H_{-1}(\rho)]$ can be obtained through Eqs. (49) and (50) using $F(\rho)$.

V. ANHARMONIC OSCILLATOR

In this section, we present the application of the asymptotic iteration method to nontrivial problems. We have thus chosen a vector potential of the type

$$U_V = r^{2\xi}, \quad \xi = 2, 3, \ldots . \tag{63}$$

Taking $\xi=2$, the second-order DKP equation becomes as follows:

$$\frac{d^2}{dr^2} F(r) + \left(\frac{E^2 - 2Er^4 + r^8 - m^2c^4}{h^2c^2} - \frac{J(J+1)}{r^2} \right) F(r) = 0. \tag{64}$$

In order to solve this equation with AIM, we propose the following wave function to transform it to an equation similar to Eq. (1):

$$F(r) = e^{-1/2\beta r^2} f(r), \tag{65}$$

where β is an arbitrarily introduced constant to improve the convergence speed of the method. We take $\beta=5$ as in Ref. 20 to compare with their nonrelativistic results for a similar problem. By taking $\hbar=c=m=1$ and $J=0$ (s state) for simplicity and inserting this wave function into Eq. (64), we obtain

$$\frac{d^2}{dr^2} f(r) = (-E^2 + 2Er^4 + \beta + 1 - \beta^2 r^2 - r^8) f(r) + 2\beta r \frac{d}{dr} f(r) \tag{66}$$

which can be now solved by AIM. Here, the $s_0(r)$ and $\lambda_0(r)$ are as follows:

$$s_0(r) = (-E^2 + 2Er^4 + \beta + 1 - \beta^2 r^2 - r^8), \quad \lambda_0(r) = 2\beta r. \tag{67}$$

In order to obtain the energy eigenvalues from Eq. (66), using Eq. (4), we obtain the $s_k(r)$ and $\lambda_k(r)$ in terms of $s_0(r)$ and $\lambda_0(r)$. Then, using the quantization condition of the method given by Eq. (5), we obtain the energy eigenvalues. This straightforward application of AIM gives us the energy eigenvalues, however, we have observed that the energy eigenvalues oscillate and do not converge within a reasonable number of iterations. The sequence appears to converge when the number of iterations $k \leqslant \simeq 30$, but then it begins to oscillate as the iteration number k increases. This result violates the principle behind the AIM; as the number of iteration increases, the method should converge and should not oscillate. We have noticed that the first reason for the oscillatory behavior is the r^8 term and the second but less serious reason is the E^2 term.

Therefore, in order to overcome this problem, we have used a perturbation approach within the framework of the AIM, similar to Ref. 21. In order to apply the perturbation, we introduce a parameter γ for $s_0(r)$ in Eq. (67),

TABLE I. Ground state energy of the anharmonic oscillator where k is the iteration number [$n=0$, $\hbar=c=m=1$, and $J=0$ (s state)].

k	E_0^0	E_0^1	E_0^2	E_0^3	E_0^4	E_0^5	E_0	E_0 (Ref. 20)
5	2.478 891	−0.481 521	−0.171 317	−0.087 565	−0.038 408	−0.030 214	1.669 866	
10	2.477 792	−0.485 884	−0.158 642	−0.080 739	−0.054 255	−0.036 055	1.662 217	1.325 073 435
15	2.477 837	−0.485 459	−0.159 187	−0.082 888	−0.052 218	−0.035 973	1.662 112	1.147 766 154
20	2.477 839	−0.485 450	−0.159 249	−0.083 021	−0.051 830	−0.035 991	1.662 298	1.072 223 000
25	2.477 838	−0.485 452	−0.159 247	−0.082 987	−0.051 875	−0.036 052	1.662 225	1.062 711 298
30			−0.159 246	−0.082 983	−0.051 885	−0.036 069	1.662 203	1.060 482 716
35			−0.159 246	−0.082 984	−0.051 885	−0.036 062	1.662 209	1.060 372 025
40					−0.051 884	−0.036 060	1.662 212	1.060 362 059
45						−0.036 061	1.662 211	1.060 362 077
50								1.060 362 091
55								1.060 362 091
60								1.060 362 090
65								
70								

$$s_0(r) = (-E^2 + 2Er^4 + \beta + 1 + \gamma(-\beta^2 r^2 - r^8)), \tag{68}$$

γ is an artificially introduced perturbation expansion parameter and at the end of the calculations, it will be seen that it is equal to 1. After this, Eq. (5) becomes

$$\delta_k(x,\gamma) = \lambda_{k+1}(x,\gamma)s_k(x,\gamma) - \lambda_k(x,\gamma)s_{k+1}(x,\gamma) = 0. \tag{69}$$

If we expand $\delta(x,\gamma)$ near $\gamma=0$, we obtain the following series:

$$\delta_k(x,\gamma) = \delta_k(x,0) + \frac{\gamma}{1!}\left.\frac{\partial\delta_k(x,\gamma)}{\partial\gamma}\right|_{\gamma=0} + \frac{\gamma^2}{2!}\left.\frac{\partial^2\delta_k(x,\gamma)}{\partial\gamma^2}\right|_{\gamma=0} + \frac{\gamma^3}{3!}\left.\frac{\partial^3\delta_k(x,\gamma)}{\partial\gamma^3}\right|_{\gamma=0} + \cdots . \tag{70}$$

According to AIM, the quantization condition $\delta_k(x,\gamma)$ must be equal to zero,

$$\delta_k^{(j)}(x,\gamma) = \frac{\gamma^j}{j!}\left.\frac{\partial^j\delta_k(x,\gamma)}{\partial\gamma^j}\right|_{\gamma=0}, \quad j = 0,1,2,\ldots . \tag{71}$$

It is also suitable to expand the energy eigenvalue E,

$$E_n = E_n^0 + \gamma E_n^1 + \gamma^2 E_n^2 + \gamma^3 E_n^3 + \gamma^4 E_n^4 + \cdots . \tag{72}$$

E_n expansion terms can be obtained by comparing the terms with the same order of γ in Eqs. (71) and (72). Hence, it is clear that the roots of $\delta_k^{(0)}(x,0)=0$ give us the main contribution energy terms E_n^0 and the roots of $\delta_k^{(1)}(x,0)=0$ give us the first correction E_n^1 and so on.

After we apply this perturbation approach, we have obtained the ground and the first even excited state energy eigenvalues. The results are presented in Tables I and II, respectively, for the ground and the first even excited state eigenvalues. In the first column of Table I, we present the E_0^0 (unperturbed), the second column E_0^1 which is the first correction and so on. We have used the perturbation up to fifth term, but one can use higher terms to improve the results. However, the effect becomes smaller as it can be seen from tables. In the last column of Table I, we show the nonrelativistic results of Fernandez[20] for the same potential to compare with our results. For these calculations, we have observed that the first term (E_0^0) in the expansion (72) converges around $k=30$ iterations, however, the correction terms require higher iterations and start to converge around $k=50$.

TABLE II. First even excited state energy of the anharmonic oscillator where k is the iteration number [$n=2$, $\hbar=c=m=1$, and $J=0$ (s state)].

k	E_2^0	E_2^1	E_2^2	E_2^3	E_2^4	E_2^5	E_2
5	5.698 344	−1.478 344	0.027 555	−2.574 579	−1.656 472	3.568 314	3.584 818
10	5.370 588	−0.911 718	−0.040 349	−0.433 823	−0.040 637	−0.068 883	3.875 178
15	5.413 951	−0.974 055	−0.267 240	−0.202 274	−0.037 847	−0.001 956	3.930 579
20	5.415 995	−0.992 837	−0.286 535	−0.104 029	−0.066 451	−0.078 990	3.887 153
25	5.415 458	−0.991 076	−0.277 803	−0.121 674	−0.072 980	−0.054 753	3.897 172
30	5.415 453	−0.990 550	−0.276 740	−0.127 545	−0.073 126	−0.040 145	3.907 347
35	5.415 460	−0.990 604	−0.277 153	−0.126 693	−0.071 566	−0.043 842	3.905 602
40	5.415 460	−0.990 626	−0.277 226	−0.126 297	−0.071 080	−0.046 266	3.903 965
45	5.415 460	−0.990 623	−0.277 201	−0.126 333	−0.071 315	−0.045 760	3.904 228
50	5.415 460	−0.990 622	−0.277 194	−0.126 358	−0.071 409	−0.045 369	3.904 508

In Table II, we show the first even excited state energy eigenvalues. Again, the perturbation is calculated up to fifth and the first term (E_0^0) converges around $k=35$ iterations, however, the correction terms require higher iterations and we have run them up to $k=50$ iteration.

VI. CONCLUSION

This paper has presented a different approach, the asymptotic iteration method, to the calculation of the nonzero angular momentum solutions of the relativistic Duffin-Kemmer-Petiau equation. Exact eigenvalues and eigenfunction for the relativistic Duffin-Kemmer-Petiau oscillator and Coulomb problems are derived easily. The advantage of the asymptotic iteration method is that it gives the eigenvalues directly by transforming the second-order differential equation into a form of $y''=\lambda_0(r)y'+s_0(r)y$. The exact wave functions are easily constructed by iterating the values of s_0 and λ_0. We have also shown how to solve the nontrivial problems with the help of the perturbation theory within the framework of the asymptotic iteration method. The method presented in this study is general and worth extending to the solution of other interaction problems.

(Received 3 February 2006; accepted 4 May 2006; published online 27 June 2006)

We construct a huge number of anomaly free models of six-dimensional $\mathcal{N}=(1,0)$ gauged supergravity. The gauge groups are products of U(1) and SU(2), and every hyperino is charged under some of the gauge groups. It is also found that the potential may have flat directions when the *R*-symmetry is diagonally gauged together with another gauge group. In an Appendix, we determine the contribution to the global SU(2) anomaly from symplectic Majorana Weyl fermions in six dimensions. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2209767]

I. INTRODUCTION

Six-dimensional $\mathcal{N}=(1,0)$ supergravity[1,2] has many interesting features. The ungauged version has been useful in uncovering the interesting dynamics of string theory in six dimensions. The gauged one is particularly interesting, because it does not allow the flat six-dimensional Minkowski space-time as a solution. Their solutions typically describe space–times which are spontaneously compactified to lower dimensions.[3,4] They can also be used to build various higher-dimensional models of particle phenomenology and cosmology. See e.g., Refs. 5 and 6.

Any higher dimensional theory of gravity should be considered as a low energy approximation of some unknown quantized theory, and there are several consistency conditions that any low energy approximation should satisfy. Anomaly freedom is one of the most important criteria. The search for anomaly free models in six dimensions is more difficult and at the same time richer than in 10 dimensions. It is because in six dimensions we can include hypermultiplets, which contribute to perturbative anomalies.[7]

The $d=6$, $\mathcal{N}=(1,0)$ ungauged supergravity can be obtained from heterotic strings on *K*3, and many anomaly free models are known,[8–12] with the help of the Green-Schwarz mechanism[13] in six dimensions. For $d=6$, $\mathcal{N}=(1,0)$ gauged supergravity, however, only a handful of consistent models have been found so far. Furthermore, if we impose the constraint that all hyperini should be charged under some of the gauge groups, the number of consistent models is very small.[14–16]

In $d=10$, $\mathcal{N}=1$ supergravity the anomaly cancels only for a few models, namely SO(32), $E_8\times E_8$, $E_8\times \mathrm{U}(1)^{248}$ and $\mathrm{U}(1)^{496}$. Moreover, the discovery of anomaly freedom of $E_8\times E_8$ inspired the construction of heterotic string theories. It is thus quite interesting to study how many anomaly free models there are in $d=6$, $\mathcal{N}=(1,0)$ gauged supergravity, and it might suggest the existence of some totally novel quantum completion of those theories within superstring theory or outside of it. No consistent way to derive it from the compactification of string or *M* theory is not known yet, although some progress is being made.[17,18] This is also interesting from the point of view of its phenomenological or cosmological applications.

[b)]Electronic mail: yujtach@hep-th.phys.s.u-tokyo.ac.jp

In this paper, we investigate the models whose gauge groups are products of U(1) and SU(2). This choice makes the condition for anomaly cancellation relatively simple. It will be shown that there are enormously many models which are free of both perturbative and global anomaly.

The paper is organized as follows. First we recall basic knowledge on $d=6$, $\mathcal{N}=(1,0)$ gauged supergravity in Sec. II. In Sec. III, we describe the general form of both perturbative and global anomaly free conditions, and we carry out the search and give our results in Sec. IV. Section V is the summary and discussion. In Appendix A we collect our notations concerning the group representations. Appendix B discusses the global gauge anomaly from the symplectic Majorana-Weyl fermion charged under SU(2) gauge group.

II. GAUGED $\mathcal{N}=(1,0)$ SUPERGRAVITY IN SIX DIMENSIONS

A. The spectrum

$\mathcal{N}=(1,0)$ supergravity in six dimensions contains the following multiplets:

$$\begin{aligned} &\text{supergravity multiplet,} && (e_\mu{}^m,\ B^-_{\mu\nu},\ \psi_\mu{}^{A-});\\ &\text{tensor multiplet,} && (B^+_{\mu\nu},\ \chi^{A+},\ \varphi);\\ &\text{vector multiplet,} && (A_\mu,\ \lambda^{A-});\\ &\text{hypermultiplet,} && (4\phi,\ \psi^+); \end{aligned}$$

where $\mu,\nu=0,\ldots,5$ label space–time, $m=0,\ldots,5$ labels tangent space, $A=1,2$ labels the fundamental representation of $\mathrm{Sp}(1)_R$, and $\pm$ denotes the chirality of Weyl spinors or the self-duality of the field strength of antisymmetric two-forms.

Weyl spinors of SO(1,5) and the fundamental representation of $\mathrm{Sp}(1)_R$ are both pseudoreal. By combining two antilinear involutions, we can impose a reality condition to get symplectic Majorana-Weyl spinors. Gravitini, tensorini, and gaugini are symplectic Majorana-Weyl under $\mathrm{Sp}(1)_R$. Hyperini are inert under $\mathrm{Sp}(1)_R$ and are Weyl spinors in general. If some of the hypermultiplets form a pseudoreal representation under the gauge groups, then we can impose the symplectic reality condition on them. Such a hypermultiplet is called a half-hypermultiplet.

Hereafter we assume the number of tensor multiplet n_T is one. This is because only in this case Lorentz- and gauge-covariant Lagrangian exist at the classical level.

B. Gauging hyperscalar manifold

The $d=6,\mathcal{N}=(1,0)$ rigid supersymmetry requires the scalar fields in the hypermultiplets to parametrize a hyperkähler manifold. If we couple hypermultiplets to gravity, then it must be a quaternionic manifold with negative curvature. For simplicity we assume the target space of the hyperscalars to be the manifold

$$\mathcal{M}_H := \frac{\mathrm{Sp}(1,n_H)}{\mathrm{Sp}(1)_R \times \mathrm{Sp}(n_H)}, \tag{2.1}$$

where n_H is the number of hypermultiplets.

We introduce vector multiplets which gauge some part of the isometry group $\mathrm{Sp}(1)_R \times \mathrm{Sp}(n_H)$ of $\mathcal{M}_H$. Arbitrary subgroups of $\mathrm{Sp}(1)_R \times \mathrm{Sp}(n_H)$ can be gauged. Let us write the gauge groups as $G_R \times G_H \subset \mathrm{Sp}(1)_R \times \mathrm{Sp}(n_H)$, where $G_R \subset \mathrm{Sp}(1)_R \times \mathrm{Sp}(n_H)$ gauges some part of the R-symmetry and $G_H \subset \mathrm{Sp}(n_H)$ acts only on the hypermultiplets. The closure of Lie algebra requires that G_R be one of the following possibilities: $\mathrm{U}(1)_R$, $\mathrm{Sp}(1)_R$, $\mathrm{U}(1)_{R+}$, and $\mathrm{Sp}(1)_{R+}$, where in the latter two cases we take U(1) or Sp(1) subgroup of $\mathrm{Sp}(n_H)$ and gauge the diagonal combination of them with $\mathrm{U}(1)_R$ or $\mathrm{Sp}(1)_R$, respectively. We call these latter two choices as diagonal gaugings. When G_H is made out of several factors $G_{H1} \times G_{H2} \times \cdots$, we use the label $z=1,2,\ldots$ to distinguish different factors.

Gauging hyperscalar manifold brings an additional potential term to the Lagrangian, which is required by supersymmetry. Here we will write the general form of the potential, citing the results

of Refs. 1 and 2. We denote hyperscalars parametrizing the manifold $\mathcal{M}_H$ by ϕ^α, $\alpha=1,\ldots,4n_H$. Since $\mathcal{M}_H$ is a symmetric space, its tangent space is spanned by the coset of the Lie algebras. Let $L(\phi)$ be a representative of the coset $\mathrm{Sp}(1,n_H)/[\mathrm{Sp}(1)_R\times\mathrm{Sp}(n_H)]$ so that $L(\phi)=\mathbf{1}_{\mathrm{Sp}(1,n_H)}+\mathcal{O}(\phi)$, and define C-functions as (the C-function is known under various names: P function, Killing prepotential, triholomorphic moment map, etc.)

$$C^{AB}{}_{CD} := (L^{-1}T^{AB}L)_{CD}, \quad C_z{}^{ab}{}_{CD} := (L^{-1}T_z^{ab}L)_{CD}, \tag{2.2}$$

where T^{AB} and T_z^{ab} are the generators of G_R and G_{Hz}, respectively. Then, the potential is given by

$$V(\phi)=\frac{1}{4}e^{-\varphi}\left(g_R^2 C^{AB}{}_{CD}C^{ABCD}+\sum_z g_{Hz}^2 C_z{}^{ab}{}_{CD}C_z{}^{abCD}\right), \tag{2.3}$$

where g_R, g_{Hz} are the coupling constants [we normalize the gauge kinetic term as $-(e^{\pm\varphi}/4g_k^2)\mathrm{tr}_k F_{\mu\nu}F^{\mu\nu}$, with $k=R,H_z$] of G_R, G_{Hz}.

The potential (2.3) is non-negative, because it is the sum of the squares of C-functions. One important feature is that $C^{AB}{}_{CD}=T^{AB}{}_{DC}+\mathcal{O}(\phi)$ and $C_z{}^{ab}{}_{CD}=\mathcal{O}(\phi)$, hence the potential is positive at $\phi^\alpha=0$ if we gauge R-symmetry. It provides a positive cosmological constant in a six-dimensional sense. For a nondiagonal gauging, explicit calculations of Refs. 1, 15, and 19 show that $\phi^\alpha=0$ is the minimum of the potential and there is no possibility of Higgsing. If we take a diagonal gauging, however, the potential may have flat or tachyonic directions. In this case, one can spontaneously break R-symmetry and possibly it leads to ungauged supergravity theories. The physics of models with diagonal gauging is relatively unexplored, and we hope to revisit this problem in the future.

Another important feature is that in the examples discussed so far, quadratic terms of $V(\phi)$ are only from the R coupling. Thus, the mass of hyperscalars is determined by their R charges.

The way how hyperini acquire four-dimensional mass depends on the details of compactification. Consider, for example, a space–time $\mathbb{R}^{1,3}\times S^2$ with monopoles in the internal S^2. If we embed the field strength of the monopole in $G_R=\mathrm{U}(1)_R$, $d=4$, $\mathcal{N}=1$ supersymmetry can remain unbroken.[3] Other choices of monopole charges generically break all the supersymmetry and many of them induce instability. [See Ref. 20 for the models with monopoles sitting in the U(1) factor, and Ref. 21 for those with monopoles sitting in the non-Abelian factor.]

III. GENERAL ANOMALY FREE CONDITIONS

Any six-dimensional gauge theory must satisfy two constraints concerning its gauge groups and representations. They are the freedom from the local and the global gravitational, gauge and mixed anomaly. The local or the global anomaly measures the change in the fermion determinant, induced by a gauge transformation which can or cannot be continuously deformed to identity. One must choose the gauge groups and the representations carefully so that both kinds of anomaly will cancel.

A. Local anomaly

It is well known that the Green-Schwarz mechanism can cancel the local gravitational, gauge and mixed anomaly if anomaly polynomial factorizes. (Note that in six dimensions the consistency of the Green-Schwarz mechanism is rather subtle, because we need to modify the lowest-derivative terms in the Lagrangian in order to introduce the Green-Schwarz counterterm. More details can be found in Refs. 2 and 22, including the generalization to $n_T>1$.)

Anomaly polynomial can be explicitly calculated by summing up the contributions from fermions and (anti-) self-dual tensors. Fermions of positive chirality or antisymmetric tensor with self-dual field strength contribute to it positively, while fermions of negative chirality or antisymmetric tensor with anti-self-dual field strength do negatively. Hence in our case, the total anomaly polynomial P_{total} is of the form

$$P_{\text{total}} = -(I_{3/2} + I_A) + \sum_{\text{tensor}} (I_A + I_{1/2}) - \sum_{\text{vector}} I_{1/2} + \sum_{\text{hyper}} I_{1/2}, \tag{3.1}$$

where each term comes from the supergravity multiplet, tensor multiplets, vector multiplets, and hypermultiplets, respectively.

In six dimensions, the anomaly polynomials for spin 3/2 fermions and spin 1/2 fermions in the representation r are known to be[7,23]

$$I_{3/2} = \left(\tfrac{245}{360}\text{tr}\, R^4 - \tfrac{43}{288}(\text{tr}\, R^2)^2\right)\text{tr}_r\, 1 + \tfrac{19}{6}\,\text{tr}\, R^2\,\text{tr}_r\, F^2 + \tfrac{10}{3}\,\text{tr}_r\, F^4, \tag{3.2}$$

$$I_{1/2} = \left(\tfrac{1}{360}\,\text{tr}\, R^4 + \tfrac{1}{288}(\text{tr}\, R^2)^2\right)\text{tr}_r\, 1 - \tfrac{1}{6}\,\text{tr}\, R^2\,\text{tr}_r\, F^2 + \frac{2}{3}\,\text{tr}_r\, F^4, \tag{3.3}$$

and that for a real self-dual antisymmetric tensor to be

$$I_A = \tfrac{28}{360}\,\text{tr}\, R^4 - \tfrac{8}{288}(\text{tr}\, R^2)^2. \tag{3.4}$$

We will study what conditions are necessary for (3.1) to factorize into the product of four-forms.

First of all, the coefficients of $\text{tr}\, R^4$ and $\text{tr}_r\, F^4$ must vanish. Using (3.2) and (3.3), the $\text{tr}\, R^4$ condition gives

$$n_H = 273 - 29n_T + n_V. \tag{3.5}$$

To satisfy the $\text{tr}_r\, F^4$ condition, we restrict our analysis to particular representations for which $\text{tr}\, F^4$ is a multiple of $(\text{tr}\, F^2)^2$. We call such representations exceptional type. All finite dimensional irreducible representations of A_1, A_2, E_6, E_7, E_8, F_4, and G_2 are of exceptional type, which we call Lie algebras of exceptional type. Further studies on exceptional-type representations can be found in Refs. 24 and 25. Casimir invariants of exceptional-type Lie algebras are summarized in Appendix A.

When $\text{tr}\, R^4$ and $\text{tr}_r\, F^4$ vanish, we can rewrite the total anomaly polynomial as

$$P_{\text{total}} = \sum_{jk} \beta_{jk} K^j K^k, \tag{3.6}$$

where K^k is

$$\vec{K} := (\text{tr}\, R^2, \text{tr}_f\, F_{G_R}^2, \text{tr}_f\, F_{G_1}^2, \text{tr}_f\, F_{G_2}^2, \ldots, \text{tr}_f\, F_{G_n}^2), \tag{3.7}$$

where G_i is shorthand notation for G_{Hi} and f is the smallest nontrivial irreducible representation of G_i.

It is convenient to regard β_{ij} as a $(n+1)\times(n+1)$ matrix. We call β_{ij} as anomaly matrix of the model. The condition for factorization of P_{total} is equivalent to $\beta_{ij} = (\alpha_i\gamma_j + \alpha_j\gamma_i)/2$ for some α_i, γ_j. It is clear that the columns of β are linear combination of $\vec{\alpha}$ and $\vec{\gamma}$, so we must have

$$\text{rank}\, \beta \leq 2. \tag{3.8}$$

Besides, the two vectors $\vec{\alpha}$ and $\vec{\gamma}$ must be real, because they enter into Lagrangian through the Green-Schwarz counterterm. Elementary calculation shows that β has two real nonzero eigenvectors (and thus real $\vec{\alpha}$ and $\vec{\gamma}$) if and only if

$$\lambda^+\lambda^- \leq 0. \tag{3.9}$$

We call (3.8) and (3.9) the first and the second factorization condition, respectively.

As a preparation for the actual search for anomaly free models in the next section, we describe the anomaly matrix more explicitly in each case of $G_R=\mathrm{U}(1)_{R(+)}$ and $\mathrm{Sp}(1)_{R(+)}$. Throughout the paper, we write the representation of hyperini as ρ^H and use tr_H as the abbreviation for the trace over ρ^H.

For $G_R=\mathrm{U}(1)_R$, the gravitini, tensorini, and gaugini all have charge one under $\mathrm{U}(1)_R$. The gaugini are the adjoints of the gauge groups. The anomaly polynomial is given by (we normalize the total anomaly polynomial so that $\alpha_1=\gamma_1=1$)

$$P=(\mathrm{tr}\,R^2)^2+\frac{\mathrm{tr}\,R^2}{6}\left((-20+n_V)F_{\mathrm{U}(1)R}^2+\sum_{i=1}^{n}\mathrm{tr}_{\mathrm{ad}}\,F_{G_i}^2-\mathrm{tr}_H\,F^2\right)$$
$$+\frac{2}{3}\left\{-(4+n_V)F_{\mathrm{U}(1)R}^4-\sum_{i=1}^{n}\mathrm{tr}_{\mathrm{ad}}\,F_{G_i}^4-6F_{\mathrm{U}(1)R}^2\sum_{i=1}^{n}\mathrm{tr}_{\mathrm{ad}}\,F_{G_i}^2+\mathrm{tr}_H\,F^4\right\}. \tag{3.10}$$

For $G_R=\mathrm{U}(1)_{R+}$, the anomaly polynomial is almost the same as (3.10), except that hyperini are charged under $\mathrm{U}(1)_{R+}$ in this case.

For $G_R=\mathrm{Sp}(1)_R$, recall that the symplectic Majorana-Weyl condition is imposed on gravitini, tensorini, and gaugini. Another important point to notice is that the gaugini of the $\mathrm{Sp}(1)_R$ symmetry transforms in the $\mathbf{2}\otimes\mathbf{3}$ representation. The anomaly polynomial is given by

$$P=(\mathrm{tr}\,R^2)^2+\frac{\mathrm{tr}\,R^2}{6}\left(\left(\frac{-12+n_V}{2}\right)\mathrm{tr}_2\,F_{\mathrm{Sp}(1)}^2+\sum_{i=1}^{n}\mathrm{tr}_{\mathrm{ad}}\,F_{G_i}^2-\mathrm{tr}_H\,F^2\right)$$
$$+\frac{2}{3}\left\{-\left(\frac{84+n_V}{4}\right)(\mathrm{tr}_2\,F_{\mathrm{Sp}(1)R}^2)^2-\sum_{i=1}^{n}\mathrm{tr}_{\mathrm{ad}}\,F_{G_i}^4-3\,\mathrm{tr}_2\,F_{\mathrm{Sp}(1)R}^2\sum_{i=1}^{n}\mathrm{tr}_{\mathrm{ad}}\,F_{G_i}^2+\mathrm{tr}_H\,F^4\right\}. \tag{3.11}$$

For $G_R=\mathrm{Sp}(1)_{R+}$, we need to take it into account that hyperini are charged under $\mathrm{Sp}(1)_{R+}$.

B. Global anomaly

Once one finds a perturbatively anomaly free model, one needs to check whether the global anomaly vanishes. Global gauge anomaly in six dimensions may appear if the gauge group G has the nonvanishing sixth homotopy group, $\pi_6(G)\neq 0$.[26] There are three simple Lie groups with $\pi_6(G)\neq 0$, namely $\pi_6(\mathrm{SU}(2))=\mathbb{Z}_{12}$, $\pi_6(\mathrm{SU}(3))=\mathbb{Z}_6$, and $\pi_6(\mathsf{G}_2)=\mathbb{Z}_3$. Abelian gauge groups do not cause global anomaly because $\pi_6(\mathrm{U}(1))=0$.

The conditions for the cancellation of global gauge anomaly have been investigated through the works of Refs. 27–31 for the case of Weyl spinors. The conditions with symplectic Majorana-Weyl spinors in six dimensions seem to be absent in the literature, so we will give the derivation in Appendix B. The results are

$$1-4C_4(\rho^H;\mathsf{G}_2)\equiv 0 \pmod 3 \quad \text{for } \mathsf{G}_2, \tag{3.12}$$

$$8-D_4(\rho^H;\mathrm{SU}(2))\equiv 0 \pmod{12} \quad \text{for } \mathrm{SU}(2), \tag{3.13}$$

$$-2C_4(\rho^H;\mathrm{SU}(3))\equiv 0 \pmod 6 \quad \text{for } \mathrm{SU}(3), \tag{3.14}$$

$$n_V-D_4(\rho^H;\mathrm{Sp}(1))\equiv 0 \pmod{12} \quad \text{for } \mathrm{Sp}(1)_{R(+)}, \tag{3.15}$$

where the quantity C_4 is defined in Appendix A and the quantity D_4 for $\mathrm{SU}(2)\simeq\mathrm{Sp}(1)$ is defined in Appendix B. If there are no half-hypermultiplets, the relation $D_4\equiv 4C_4 (\mathrm{mod}\ 12)$ holds. Then the condition (3.13) reduces to

$$4 - 2C_4(\rho^H;\mathrm{SU}(2)) \equiv 0 \pmod 6, \tag{3.16}$$

which is precisely the condition found in Ref. 31.

Assuming the vanishing of global gauge anomaly, one can show that there is no global gravitational anomaly in six dimensions if the space–time is S^6, by slightly generalizing the argument in Ref. 32. Furthermore, it means that any six-dimensional theory is free of global anomaly on a coordinate patch, because any large diffeomorphism or large gauge transformation on a small patch can be done likewise on S^6. There might be other global anomalies coming from the nontrivial topology of space–time, but it is beyond the scope of our present work.

IV. EXAMPLES OF MODELS

We performed an extensive computer-aided search of anomaly free models whose gauge groups are of the form $G_{R(+)} \times G_H$ where $G_{R(+)}$ and G_H are U(1) or SU(2). And then we discovered enormously many anomaly free models. In what follows, we describe the details of our search and show several examples of the models.

A. Abelian gauge groups

Let $\{h_i\}$ be the basis of Cartan subalgebra $\mathrm{u}(1)^{n_H}$ of $\mathrm{sp}(n_H)$, then the generator of a $\mathrm{u}(1) \subset \mathrm{u}(1)^{n_H}$ is written as

$$T := \sum_{i=1}^{n_H} q^i h_i. \tag{4.1}$$

We assume q^i's to be quantized in integers.

When there are more than one Abelian factor within the gauge groups under which hyperini are charged, the anomaly polynomial, in general, contains terms of the form

$$\mathrm{tr}\, F_{\mathrm{U}(1)_1} \mathrm{tr}\, F^3_{\mathrm{U}(1)_2}, \quad \mathrm{tr}\, F_{\mathrm{U}(1)_1} \mathrm{tr}\, F_{\mathrm{U}(1)_2} \mathrm{tr}\, F^2_{\mathrm{U}(1)_3}, \quad \mathrm{tr}\, F_{\mathrm{U}(1)_1} \mathrm{tr}\, F_{\mathrm{U}(1)_2} \mathrm{tr}\, F_{\mathrm{U}(1)_3} \mathrm{tr}\, F_{\mathrm{U}(1)_4}.$$

The presence of traces of odd powers of F necessitates the generalization of the procedure outlined in the preceding sections. Therefore, in such situations we assume the presence of a symmetry among U(1) charges which forbids the appearances of the trace of odd powers of $F_{\mathrm{U}(1)_i}$'s.

Before giving our calculation and results, let us explain what kind of solutions we seek. First, if one finds an anomaly free model, one can rescale the unit charge of any U(1) and obtain another solution. This operation is rather trivial, so we regard two charge vectors related in this way as the same solution.

Second, in the literature, solutions with so-called drones are considered to be unrealistic and uninteresting, and thus we search for anomaly free models without drones. By drones we mean hypermultiplets which are not charged under $G_R \times G_H$, and U(1) vector multiplets with no charged scalars or fermions.

$\mathrm{U}(1)_R$: One needs $n_H = 245$ neutral hypermultiplets to cancel $\mathrm{tr}\, R^4$ terms. Then the anomaly polynomial automatically factorizes into

$$(\mathrm{tr}\, R^2 - 4F^2_{\mathrm{U}(1)R})\left(\mathrm{tr}\, R^2 + \tfrac{5}{6}F^2_{\mathrm{U}(1)R}\right). \tag{4.2}$$

Thus, there is one anomaly free model, albeit lots of singlet hyperini entering into it.

$\mathrm{U}(1)_R \times \mathrm{U}(1)$: We have found more than 40 million solutions to (3.8), (3.9) without drones. Some of them are listed as follows:

$$(n_1,n_2,n_3,n_4) = (243,0,3,0), \quad (173,70,3,0), \quad (138,96,12,0), \quad (123,102,21,0),$$
$$(112,109,24,1), \quad (108,96,42,0), \quad (108,54,84,0), \quad (123,0,123,0),$$

where n_q is the number of hypermultiplets with charge q. We set $n_q = 0$ for $q > 4$.

We also found some infinite series of anomaly free solutions with drone U(1) vector multiplets. For example, if $n_V=2+n_{\text{drone}}$ and $n_H=246+n_{\text{drone}}$, the combinations

$$(n_1,n_2,n_3,n_4)=(243,0,3+n_{\text{drone}},0), \tag{4.3}$$

$$(n_1,n_2,n_3,n_4)=(173,70,3,n_{\text{drone}}) \tag{4.4}$$

solve the factorization conditions for any $n_{\text{drone}}\geq 1$. There might be a deeper reason why such infinite series exist.

$U(1)_{R+}$: In this case, β_{jk} is a two-by-two matrix and the anomaly polynomial immediately factorizes. We also need to check the constraint (3.9), of which one can easily find an enormous amount of solutions with no singlet hypers.

$U(1)_{R+}\times U(1)_H$: Now hyperini can have charges under two Abelian groups, so the term $\operatorname{tr} F_{U(1)_{R+}}\operatorname{tr} F^3_{U(1)_H}$ may appear. Let us denote by n_{ab} the number of hyperini whose $U(1)_{R+}$ charge is $\pm a$ and whose $U(1)_H$ charge is $\pm b$. We restrict n_{ab} to be even so that one-half of them have charge (a,b) and the other one-half $(a,-b)$. Then the terms containing $\operatorname{tr} F_{U(1)}$, $\operatorname{tr} F^3_{U(1)}$ are removed.

We have found thousands of anomaly free choices of n_{ab}, some of which are

$$\begin{pmatrix} n_{11} & n_{12} & n_{13} \\ n_{21} & n_{22} & n_{23} \\ n_{31} & n_{32} & n_{33} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 \\ 114 & 12 & 2 \\ 22 & 66 & 30 \end{pmatrix}, \quad \begin{pmatrix} 2 & 4 & 6 \\ 150 & 4 & 2 \\ 6 & 62 & 10 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 & 0 \\ 190 & 14 & 30 \\ 10 & 2 & 0 \end{pmatrix},$$

where other n_{ab} are all zero.

B. Non-Abelian gauge groups

In addition to (3.8), (3.9), one must also check the vanishing of global gauge anomaly for $\mathrm{Sp}(1)_R$ and SU(2) when dealing with non-Abelian gauge groups. These conditions altogether are quite lengthy and therefore it becomes far rarer to find the solutions than in Abelian cases. Still, we are able to discover hundreds or thousands of anomaly free models. To be concrete, we will describe some of them in this section.

As explained in Sec. II A, we can impose symplectic Majorana-Weyl condition to the fermions which transform in a pseudoreal representation. A half-hypermultiplet contributes to the anomaly polynomial (3.3) half as much as a hypermultiplet. Thus, once half-hypermultiplets are taken into account, n_H should be decomposed as

$$n_H=\sum_r n_r \dim r, \tag{4.5}$$

where n_r is the number of hypermultiplets in the representation r, and we allow n_r to be half-integers if r is pseudoreal. The group-theoretical constants defined in Appendix A then become

$$C_2(\rho^H;G)=\sum_r n_r C_2(r;G), \quad C_4(\rho^H;G)=\sum_r n_r C_4(r;G), \tag{4.6}$$

where G is a non-Abelian simple Lie group.

$U(1)_R\times \mathrm{SU}(2)$: Anomaly free choices of ρ^H are listed as follows:

$$\begin{aligned}(n_2,n_3,n_4,n_5,n_6,n_7,n_8) = {} & (0,4,1,11,26,3,0), \quad (0,7,0,2,0,31,0), \\ & (1,0,12,0,33,0,0), \quad (1,3,1,3,7,24,1), \\ & (2,1,29,25,0,0,0), \quad (3,0,0,0,11,0,22), \\ & (5,0,0,0,37,0,2), \quad (124,0,0,0,0,0,0).\end{aligned}$$

$U(1)_{R+}\times SU(2)$: Let $n_{i,r}$ be the number of hypermultiplets with $U(1)_{R+}$ charge i and in the $SU(2)$ representation r. Let us list some solutions of anomaly free conditions,

$$\begin{pmatrix} n_{1,2} & n_{1,3} & n_{1,4} \\ n_{2,2} & n_{2,3} & n_{2,4} \\ n_{3,2} & n_{3,3} & n_{3,4} \end{pmatrix} = \begin{pmatrix} 1 & 0 & 12 \\ 66 & 0 & 9 \\ 9 & 0 & 3 \end{pmatrix}, \quad \begin{pmatrix} 2 & 6 & 9 \\ 46 & 4 & 5 \\ 28 & 2 & 1 \end{pmatrix}, \quad \begin{pmatrix} 3 & 1 & 5 \\ 28 & 6 & 1 \\ 65 & 1 & 2 \end{pmatrix}, \quad \begin{pmatrix} 4 & 5 & 8 \\ 59 & 1 & 8 \\ 15 & 2 & 1 \end{pmatrix}.$$

$Sp(1)_R$, $Sp(1)_R\times U(1)$ and $Sp(1)_R\times SU(2)$: There are no consistent models, because the $Sp(1)_R$ part has global gauge anomaly.

$Sp(1)_{R+}$: A few examples of anomaly free spectrum are

$$\begin{aligned}(n_2,n_3,n_4,n_5) &= (107+1/2,0,8,0), \quad (109+1/2,8,1,0), \\ &\quad (117+1/2,1,1,1), \quad (119+1/2,0,2,0).\end{aligned}$$

$Sp(1)_{R+}\times U(1)$: Let us denote by $n_{r,i}$ the number of hypermultiplets with $U(1)$ charge i and in $Sp(1)_R$ representation r. Hypermultiplets like

$$\begin{pmatrix} n_{2,1} & n_{2,2} & n_{2,3} \\ n_{3,1} & n_{3,2} & n_{3,3} \\ n_{4,1} & n_{4,3} & n_{4,3} \end{pmatrix} = \begin{pmatrix} 0 & 22 & 56 \\ 0 & 0 & 0 \\ 0 & 4 & 19 \end{pmatrix}, \quad \begin{pmatrix} 15 & 28 & 11 \\ 0 & 0 & 0 \\ 5 & 11 & 19 \end{pmatrix}, \quad \begin{pmatrix} 23 & 0 & 9 \\ 23 & 8 & 1 \\ 0 & 18 & 4 \end{pmatrix}, \quad \begin{pmatrix} 32 & 24 & 0 \\ 28 & 0 & 4 \\ 6 & 2 & 2 \end{pmatrix}$$

give anomaly free models.

$Sp(1)_{R+}\times SU(2)$: Let us denote by $n_{r,s}$ the number of hypermultiplets in the representation (r,s) of $Sp(1)_R\times SU(2)$. Examples of solutions are

$$\begin{pmatrix} n_{1,1} & n_{1,2} & n_{1,3} \\ n_{2,1} & n_{2,2} & n_{2,3} \\ n_{3,1} & n_{3,2} & n_{3,3} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 \\ 2 & 6 & 5 \\ 26 & 16 & 2 \end{pmatrix}, \quad \begin{pmatrix} 0 & 35 & 0 \\ 49 & 7 & 0 \\ 9 & 3 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 56 & 1 \\ 3 & 0 & 2 \\ 12 & 12 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 92 & 5 \\ 9 & 6 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

We set $n_{1,1}=0$ to exclude singlet hyperini.

Before closing this section, we would like to mention an extra anomaly free model with the gauge groups $U(1)_R\times SU(3)$. The hypermultiplets behave as a totally symmetric tensor of $SU(3)$ with 21 indices. And this model is free from the global $SU(3)$ anomaly.

V. SUMMARY AND DISCUSSION

We discussed consistency conditions of six-dimensional gauged supergravity coming from anomaly cancellation. By performing a computer-aided search for consistent models, we found an enormous number of anomaly free models where the one-loop anomaly from the fermions is cancelled via the Green-Schwarz mechanism.

In the literature, it has often been considered that anomaly free models of six-dimensional gauged supergravity are quite rare. Our results suggest that there are a huge number of other perturbatively anomaly free models in six-dimensional gauged supergravity. However, our search was limited to the cases where the gauge group is a product of $U(1)$ and/or $SU(2)$. In fact, it is still very hard to find consistent models whenever the gauge groups consist of more than two simple Lie groups. Thus, the existence of $E_7\times E_6\times U(1)_R$, $E_7\times G_2\times U(1)_R$, and $F_4\times Sp(9)\times U(1)_R$ models found in Refs. 14–16 is indeed miraculous.

If one incorporates several tensor multiplets at the cost of covariant Lagrangian formulation, one can employ the generalized Green-Schwarz mechanism. Then, if rank $\beta\leq n_T+1$, one can successfully cancel the local anomaly. Thus, we might be able to find enormously many consistent models with the gauge groups like $G_R\times G_1\times\cdots\times G_{n_H}$ in a similar manner. The need for the quantum formulation is much more pressing with $n_T>1$, since in this case we cannot tell anything about the effective action in a strict sense.

We would like to comment on possible applications of our results. We have shown several examples of anomaly free models of $d=6,\mathcal{N}=(1,0)$ gauge supergravity. And some of them look very simple compared to the consistent models known so far. We hope that they will help to study various aspects of six-dimensional supergravity.

For example, when one wants to derive six-dimensional gauged supergravity from the compactifications of type II theory on a smooth space, we often have only Abelian gauge groups except for R-symmetry, as well as lots of drone U(1)'s. If such compactification is consistent as type II string theory, then it should be automatically anomaly free. Thus, our solutions with local R-symmetry $\times$ Abelian factors seem to be a good step in this direction. However, how to obtain a large number of charged hypermultiplets from string theory and how to make gravitini charged still remain as big problems.

Compactification to four dimensions is worth a further investigation. Our models might find a use in constructing higher-dimensional models of phenomenology and cosmology.[5,6,33–35] Moreover, if we compactify the theory down to four dimensions with branes,[34] new anomaly possibly arises on the branes. Then one should take care of anomaly inflow[36,37] in that framework.

Furthermore, our results may also be interesting in building solutions of $d=6,\mathcal{N}=(1,0)$ gauged supergravity. For example, see the recent paper.[38]

Finally, the physics of diagonally gauged models can be studied more thoroughly. We may find interesting generalization of the aforementioned applications. We hope to revisit this problem in the future.

APPENDIX A: REPRESENTATION THEORETICAL CONSTANTS

Let $F_G=F_G^i T_r^i$ be the field strength of gauge group G, acting on fermions in the representation r. When G is a simple non-Abelian gauge group, we define group-theoretical constants $C_2(R;G)$, $A(R;G)$, and $B(R;G)$ as

$$\mathrm{tr}_R F_G^2 \coloneqq C_2(R;G)\mathrm{tr}_f F_G^2, \quad \mathrm{tr}_R F_G^4 \coloneqq A(R;G)\mathrm{tr}_f F_G^4 + B(R;G)(\mathrm{tr}_R F_G^2)^2, \tag{A1}$$

where f is the smallest nontrivial irreducible representation of G. For exceptional-type representations which has no fourth-order Casimir invariants, we also define $C_4(R;G)$ as

$$\mathrm{tr}_R F_G^4 \coloneqq C_4(R;G)(\mathrm{tr}_f F_G^2)^2 = B(R;G)C_2(R;G)^2(\mathrm{tr}_f F_G^2)^2. \tag{A2}$$

We will omit G if it causes no ambiguity.

Some comments on the group-theoretical constants defined here: First, the ratio $\mathrm{tr}_r(F_G)^n/\mathrm{tr}_{r'}(F_G)^n$ is independent of the normalization of T_r^i. Thus the quantities $A(R;G)$, $B(R;G)$, and $C_i(R;G)$ are determined only by the representation R of G. Second, when R is the direct sum of irreducible representations $R=\oplus_i R_i$, then $C_2(R)$ and $C_4(R)$ are equal to the sums $\Sigma_i C_2(R_i)$ and $\Sigma_i C_4(R_i)$, respectively. Third, for an irreducible exceptional-type representation R, we have a formula[24]

$$C_4(R;G) = \frac{\dim G}{2\dim R(2+\dim G)}\left(6 - \frac{C_2(\mathrm{ad})}{\dim G}\cdot\frac{\dim R}{C_2(R)}\right)C_2(R;G)^2. \tag{A3}$$

APPENDIX B: GLOBAL GAUGE ANOMALY FOR MAJORANA-WEYL FERMIONS

If $\pi_6(H)=\mathbb{Z}_p$ for some gauge group H, global anomaly may exist. Then we must check whether the global gauge anomaly cancels.

1. Weyl fermions

First let us review the calculation for Weyl fermions.[27–31] The basic strategy is to embed H into G such that $\pi_7(G)=\mathbb{Z}$ and $\pi_6(G)=0$. Then, because the gauge group G has no global gauge anomaly in six dimensions, the global gauge transformation in H can be deformed continuously to identity in G. In this way we can reduce the calculation of global anomaly for H to that of perturbative anomaly for G.

The embedding

$$0 \to H \overset{\iota}{\to} G \overset{p}{\to} G/H \to 0 \tag{B1}$$

induces the homotopy exact sequence

$$\cdots \overset{\iota_*}{\to} \pi_7(G) \overset{p_*}{\to} \pi_7(G/H) \overset{\partial_*}{\to} \pi_6(H) \to \pi_6(G) = 0. \tag{B2}$$

Let us denote by g, g' the generators of $\pi_7(G)$ and $\pi_7(G/H)$, respectively. Then, $\tilde{g} \equiv \partial_* g'$ is a generator of $\pi_6(H)$ and there is an integer s such that $p_*(g)=(g')^s$ in our cases.

Let us embed the fermion in the representation r_L of H in the representation $R_L \ominus R_R$ of G (here the subscripts L and R denote the chirality), so that $R_L \ominus R_R$ decompose under H to r_L plus some fermions which can be massive. Then, following the argument of Ref. 27, the H gauge transformation corresponding to $\tilde{g}$ produces a phase $e^{i\theta(r)}$, with $\theta(r)$ given by

$$\theta(r) = \frac{1}{s}\int_{S^7} \gamma(g,A,F;R_L \ominus R_R), \tag{B3}$$

where $\gamma(g,A,F;R)$ is the change under g of the non-Abelian Chern-Simons terms in the representation R. We can easily show that $\int_{S^7}\gamma(g,A,F;R)=2\pi A(R;G)$ if $G=\mathrm{SU}(n)$. Thus we have

$$\theta(r) = 2\pi A(R;G)/s. \tag{B4}$$

For $H=\mathrm{SU}(2)$, $\mathrm{SU}(3)$, and G_2, we can choose G as $\mathrm{SU}(4)$, $\mathrm{SU}(4)$, $\mathrm{SU}(7)$, respectively.[28] We claim that, for the representation R of $\mathrm{SU}(4)$ or $\mathrm{SU}(7)$, $A(R;G)$ is given by

$$A(R;\mathrm{SU}(4)) \equiv 2\sum_i C_4(r_i;H) \pmod 6 \quad \text{for } H=\mathrm{SU}(2) \text{ or } \mathrm{SU}(3), \tag{B5}$$

$$A(R;\mathrm{SU}(7)) \equiv 4\sum_i C_4(r_i;H) \pmod 3 \quad \text{for } H=\mathsf{G}_2, \tag{B6}$$

provided that the representation R decomposes as $R=\oplus_i r_i$ under H.

To prove them, we evaluate $\mathrm{tr}_G F_R^4$ in two ways. Using (A1), it can be rewritten as

$$\mathrm{tr}_G F_R^4|_{\mathrm{on}\ H} = A(R;G)\mathrm{tr}_G F_f^4|_{\mathrm{on}\ H} + B(R;G)(\mathrm{tr}_G F_f^2|_{\mathrm{on}\ H})^2 = \{B(f;H)A(R;G) + B(R;G)\}(\mathrm{tr}_G F_f^2|_{\mathrm{on}\ H})^2, \tag{B7}$$

where f is the fundamental representation of G, and in the last line we evaluate the trace after restricting it on H. Using the direct product decomposition $R=\oplus_i r_i$, the trace is

$$\mathrm{tr}_G F_R^4|_{\mathrm{on}\ H} = \mathrm{tr}_H\left(\sum_i F_{r_i}\right)^4 = \sum_i \mathrm{tr}_H F_{r_i}^4 = \sum_i C_4(r_i;H)(\mathrm{tr}_H F_f^2)^2. \tag{B8}$$

By comparing the two, we get

$$B(f;H)A(R;G) + B(R;G) = \sum_i C_4(r_i;H). \tag{B9}$$

We have $B(f;H)=1/2$ for $H=\mathsf{A}_1,\mathsf{A}_2$ and $1/4$ for $H=\mathsf{G}_2$. Furthermore, one can show that $B(R;G)\equiv 0 \pmod 3$ by mathematical induction,[39] and the claims (B5) and (B6) immediately follow. It is easy to derive the equations (3.12), (3.14), and (3.16) from these results.

2. Majorana-Weyl fermions

Let us now move on to the case with Majorana-Weyl fermions. As discussed in Sec. II A, in six dimensions we can halve the degrees of freedom of Weyl spinors when they form a pseudoreal representation of the gauge groups. Such Majorana-Weyl fermions are more specifically called symplectic Majorana-Weyl fermions, though we use the two words interchangeably.

If we carry out this procedure for a hypermultiplet, the resulting multiplet is called a half-hypermultiplet. The gravitini, tensorini, and gaugini of $d=6,\mathcal{N}=(1,0)$ supergravity are all Majorana-Weyl, where we use the fact the **2** of $\mathrm{Sp}(1)_R$ is pseudoreal.

Of the gauge groups which have global anomaly in $d=6$, only SU(2) has pseudoreal irreducible representations. So hereafter we restrict our attention to global SU(2) [or Sp(1)] anomaly. We assume that the perturbative anomaly is already canceled by the Green-Schwarz mechanism. As we saw in the preceding section, the Weyl fermions in **2** produces the phase $e^{2\pi i/6}$ under the generator of $\pi_6(\mathrm{SU}(2))$. Let α be the phase produced by Majorana-Weyl fermions in **2**. Because $\alpha^2=e^{2\pi i/6}$, α must be either $e^{2\pi i/12}$ or $e^{2\pi i 7/12}$. Now we are going to determine which is the case.

To do it, we need to embed a symplectic Majorana-Weyl fermion in **2** of SU(2) in a Majorana-Weyl fermion in a larger gauge group without global anomaly. Thus **4** in Sp(2) is a good choice. Let it decompose into $\mathbf{2}\oplus\mathbf{1}\oplus\mathbf{1}$ under SU(2). We write the change of the Chern-Simons seven-form by $\gamma(g,A,F)$, as in the preceding section.

The phase change for Weyl fermions in the fundamental of SU(4) is $\int\gamma(g,A,F)=2\pi$ under the generator g of $\pi_7(\mathrm{SU}(4))$. Consider the homotopy exact sequence

$$\begin{aligned}\pi_8(S^5) = \mathbb{Z}_{24} \xrightarrow{\partial_*} \pi_7(\mathrm{Sp}(2)) = \mathbb{Z} \xrightarrow{\iota_*} \\ \pi_7(\mathrm{SU}(4)) = \mathbb{Z} \xrightarrow{p_*} \pi_7(S^5) = \mathbb{Z}_2 \xrightarrow{\partial_*} \pi_6(\mathrm{Sp}(2)) = 0.\end{aligned} \tag{B10}$$

[A considerable knowledge of algebraic topology is required for the actual calculation of homotopy groups. A concise table for the higher homotopy groups of the compact Lie groups can be found in the Appendix A of Ref. 40. Interested readers can consult the textbooks (Refs. 41 and 42) and references therein.]

It implies that the generator g' of $\pi_7(\mathrm{Sp}(2))$ is mapped to g^2. Thus, the phase change for Weyl fermions in **4** of Sp(2) under g' is 4π. Therefore it is 2π for Majorana-Weyl fermions in **4**.

Now consider another sequence

$$\begin{aligned}\pi_7(\mathrm{Sp}(1)) = \mathbb{Z}_2 \xrightarrow{\iota_*} \pi_7(\mathrm{Sp}(2)) \\ = \mathbb{Z} \xrightarrow{p_*} \pi_7(\mathrm{Sp}(2)/\mathrm{Sp}(1)) = \mathbb{Z} \xrightarrow{\partial_*} \pi_6(\mathrm{Sp}(1)) = \mathbb{Z}_{12} \xrightarrow{\iota_*} \pi_6(\mathrm{Sp}(2)) = 0.\end{aligned} \tag{B11}$$

Denote the generator of $\pi_7(\mathrm{Sp}(2)/\mathrm{Sp}(1))$ by h'. Then h' satisfies $p_*(g')=(h')^{12}$, and $\tilde{h}:=\partial_* h'$ is one of the generators of $\pi_6(\mathrm{Sp}(1))$. Thus, the phase change under $\tilde{h}$ for Majorana-Weyl fermions in **2** is $e^{2\pi i/12}$.

Let us go on to other representations. Let $[k]$ be the k-index symmetric tensor representation of Sp(1) or Sp(2). Let us bear in mind that $\mathbf{k}=[k-1]$ in Sp(1). Then, for Sp(2),

$$\mathrm{tr}_{[k]} F^4 = A(k)\mathrm{tr}_{[1]} F^4 + \cdots, \tag{B12}$$

where $A(k)=k(k+1)(k+2)(k+3)(k+4)(k^2+4k+2)/840$. Furthermore,

$$[k] \to [k] + 2[k-1] + 3[k-2] + 4[k-3] + \cdots . \tag{B13}$$

under the restriction of groups from Sp(2) to Sp(1). Thus, $[k-1]_L - 2[k-2]_R + [k-3]_L$ of Sp(2) reduces to $\mathbf{k}_L$ of Sp(1), and hence the phases under the global gauge transformation $\tilde{h}$ for Majorana-Weyl $\mathbf{k}$ is $2\pi D_4(\mathbf{k})/12$, where

$$D_4(\mathbf{k}) = A(k-1) - 2A(k-2) + A(k-3). \tag{B14}$$

Specifically, Majorana-Weyl fermions in **4** contribute $e^{-\pi i/3}$, and Weyl fermions in **3** contribute $e^{4\pi i/3}$ to the global anomaly phase.

Finally, by considering

$$I_{3/2} = \cdots + \tfrac{10}{3}\,\mathrm{tr}\,F^4, \quad I_{1/2} = \cdots + \tfrac{2}{3}\,\mathrm{tr}\,F^4,$$

and the embedding of gravitini into **4** of Sp(2) with the symplectic Majorana-Weyl condition, we see that a gravitino contributes five times as much as that of a spin 1/2 fermion.

Suppose we gauge the Sp(1) *R*-symmetry, then the contributions from various fermions are summarized as

$$\begin{aligned} &\text{gravitini in a supergravity multiplet,} && 5 \bmod 12;\\ &\text{tensorini in a tensor multiplet,} && -1 \bmod 12;\\ &\text{the } \mathrm{Sp}(1)_R \text{ gaugini,} && -1 \bmod 12;\\ &\text{other gaugini in a vector multiplet,} && 1 \bmod 12. \end{aligned} \tag{B15}$$

Thus, the condition for the cancellation of global $\mathrm{Sp}(1)_{R(+)}$ anomaly is

$$n_V - D_4(\rho^H; \mathrm{Sp}(1)) \equiv 0 \pmod{12}. \tag{B16}$$

Character formulas and partition functions in higher dimensional conformal field theory

F. A. Dolan[a)]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Cambridge CB3 0WA, England

(Received 21 December 2005; accepted 21 March 2006; published online 28 June 2006)

A discussion of character formulas for positive energy, unitary irreducible representations of the conformal group is given, employing Verma modules and Weyl group reflections. Product formulas for various conformal group representations are found. These include generalizations of those found by Flato and Fronsdal for SO(3,2). In even dimensions the products for free representations split into two types depending on whether the dimension is divisible by four or not. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2196241]

I. INTRODUCTION

Motivated by the AdS/CFT correspondence, which relates string theory in an AdS space to a conformal field theory on the boundary character formulas for groups associated with conformal symmetry have received greater attention recently.[1–4] In Refs. 1, 2, and 4 the way in which character formulas encode the spectrum of operators allowed in a conformal Yang-Mills theory has been their main use. We hope that the present discussion might be similarly useful for conformal Yang-Mills theories in higher dimensions.

It is well known that character formulas provide an elegant way of decomposing tensor products of Lie algebra representations—the Racah-Speiser algorithm for decomposing tensor products of finite dimensional irreducible representations of simple Lie algebras may be easily proved in terms of Weyl characters, see Ref. 5 for a summary. In conformal field theories the method of characters was used by Flato and Fronsdal[6] to decompose products of certain massless representations, called "Di" and "Rac," in three dimensions. Oscillator and other methods have been used by various authors to generalize this to higher dimensions.[7–10] Here we follow a more direct approach using character formulas for the conformal group to decompose products of positive energy unitary irreducible representations of the conformal group which *inter alia* provides a generalization of the Flato-Fronsdal results. These formulas may also be relevant to operator product expansions.

The layout of the paper is as follows. We rewrite the conformal algebra in terms of the orthonormal basis of $SO^*(d+2)$, the complexification of the conformal group in d dimensions, in Sec. II.

In Sec. III we construct the characters of any positive energy unitary irreducible representation of the conformal group. The problem is related to finding characters of certain infinite dimensional representations of $SO^*(d+2)$ and we make use of a result in Ref. 11, employing Verma module characters, for solving it. The main part of the task consists, in this approach, of finding sub-Verma modules of an original one. This is more straightforward in the orthonormal basis of $SO^*(d+2)$ due to simplifications in the Weyl group action on weights in this basis. In this section we also show how these formulas are equivalent to ones obtained as follows. The basis for the original $SO^*(d+2)$ Verma module is reduced in a way determined by Appendix C which discusses unitary representations of the conformal group. We write down the character of the reduced $SO^*(d+2)$

[a)]Address for correspondence: Trinity College, Cambridge, CB2 1TQ, England; Electronic mail: fad20@damtp.cam.ac.uk

Verma module and then simply act on it with the Weyl symmetry operator of SO(d). The formula obtained agrees with the character formula for the corresponding irreducible representation of $SO^*(d+2)$. We also give the three- and four-dimensional results explicitly and these match known results.[4,6,24,25]

In Sec. IV we discuss products of the unitary irreducible representations. As a simple example we first discuss the case of $d=4$. This is made simpler by the fact that the SO(4) character may be rewritten as a product of two SO(3) characters. We then go on to discuss higher dimensional cases which correspond to products of free representations. Crucial in this approach are expansion formulas of the characters in the following form, namely,

$$\sum_N s^{\Delta+N} F_N(x), \tag{1.1}$$

where Δ denotes the canonical conformal dimension, $F_N(x)$ is some linear combination of the SO(d) characters and with s and $\underline{x}=(x_1,\ldots,x_r)$, $r=\left[\frac{1}{2}d\right]$ being some variables. We give expansion formulas of the type (1.1) for all character formulas of interest.

In even dimensions the product formulas obtained divide into two forms depending on whether the dimension d is divisible by 4 or not.

While we do not find all such product formulas, we feel that the method presented generalizes easily when used in conjunction with expansion formulas of the type (1.1).

Expansions of the form (1.1) are used in Sec. V then to correlate our results for character formulas with one-particle partition functions which have been found by various authors[12–14] for the free scalar, Weyl fermion and $(d/2)$-form field strengths. We also discuss an expansion formula given for the character for conserved symmetric traceless tensor currents in the main text. A simple argument is given which explains the behavior of the character formula [in the form (1.1)] when $\underline{x}=(1,\ldots,1)$. Also it is found that the character for the free scalar obtained here matches the one particle partition function for a scalar field on the boundary of AdS in Ref. 15 when the spin of descendants is taken into account.

Various useful formulas and proofs are left in the remaining appendixes. In Appendix A results for character formulas for infinite dimensional representations of semisimple Lie groups are discussed. In Appendix B standard formulas for SO(d) Weyl characters are given. In Appendix C unitarity bounds are discussed. While unitarity bounds have been discussed in great detail by other authors, see, for example, Refs. 16–18, we feel that this attention is merited in that it determines which combination of generators are to be omitted from the full Verma module for $SO^*(d+2)$ when character formulas for unitary irreducible representations of the conformal group are analyzed. Appendix D contains proofs of certain product and expansion formulas for conformal group characters.

II. THE CONFORMAL ALGEBRA IN THE ORTHONORMAL BASIS

Starting from the Lie algebra for SO($d,2$),

$$[M_{AB},M_{CD}]=i(g_{AC}M_{BD}-g_{AD}M_{BD}-g_{BC}M_{AD}+g_{BD}M_{AC}), \tag{2.1}$$

for $A,B=1,\ldots,d+2$, $g_{AB}=\text{diag}\,(1,\ldots,1,-1,-1)$ and where $M_{AB}=-M_{BA}$ are Hermitian, then (2.1) may be related to the standard form of the conformal algebra by defining $M_{ab},\mathcal{P}_a,\mathcal{K}_a,H$, for $a,b=1,\ldots,d$ through

$$[M_{AB}]=\begin{pmatrix} M_{ab} & -M_{at} \\ M_{sb} & \epsilon_{st}H \end{pmatrix}, \tag{2.2}$$

where $s,t=d+1,d+2$, $\epsilon_{dd+1}=1$, $\epsilon_{st}=-\epsilon_{ts}$, and

$$\mathcal{P}_a=M_{ad+1}+iM_{ad+2}, \quad \mathcal{K}_a=M_{ad+1}-iM_{ad+2}. \tag{2.3}$$

Then

$$[M_{ab},M_{cd}] = i(\delta_{ac}M_{bd} - \delta_{ad}M_{bc} - \delta_{bc}M_{ad} + \delta_{bd}M_{ac}),$$

$$[M_{ab},\mathcal{P}_c] = i(\delta_{ac}\mathcal{P}_b - \delta_{bc}\mathcal{P}_a), \quad [M_{ab},\mathcal{K}_c] = i(\delta_{ac}\mathcal{K}_b - \delta_{bc}\mathcal{K}_a), \tag{2.4}$$

$$[H,\mathcal{P}_a] = \mathcal{P}_a, \quad [H,\mathcal{K}_a] = -\mathcal{K}_a, \quad [\mathcal{K}_a,\mathcal{P}_b] = -2iM_{ab} + 2\delta_{ab}H,$$

with all other commutators not mentioned in (2.4) vanishing. As usual, $M_{ab}=-M_{ba}$ are Hermitian generators of SO(d) rotations. Here H, the conformal Hamiltonian, is required to have a positive definite spectrum of eigenvalues for positive energy representations.

In (2.4) M_{ab} of course satisfy the Lie algebra of SO(d). For what follows we will use the orthonormal basis for SO(d) whereby the Cartan subalgebra is defined by

$$H_i = M_{2i-12i}, \quad i = 1,\ldots,r, \quad [H_i,H_j] = 0, \tag{2.5}$$

with raising and lowering operators formed from

$$E_{ij}^{\varepsilon\eta} = -E_{ji}^{\eta\varepsilon} = M_{2i-12j-1} + i\varepsilon M_{2i2j-1} + i\eta M_{2i-12j} - \varepsilon\eta M_{2i2j}, \quad i \neq j, \quad \varepsilon,\eta = \pm, \tag{2.6}$$

augmented by

$$E_i^{\pm} = M_{2i-12r+1} \pm iM_{2i2r+1}, \tag{2.7}$$

for SO($2r+1$).

In $2r$ dimensions the commutation relations among the SO($2r$) generators in the orthonormal basis are given by

$$[H_i,E_{jk}^{\varepsilon\eta}] = (\varepsilon\delta_{ij} + \eta\delta_{ik})E_{jk}^{\varepsilon\eta},$$

$$[E_{ij}^{\varepsilon\eta},E_{ij}^{\varepsilon'\eta'}] = (\varepsilon - \varepsilon')(1 - \eta\eta')H_i + (\eta - \eta')(1 - \varepsilon\varepsilon')H_j, \tag{2.8}$$

$$[E_{ij}^{\varepsilon\eta},E_{jk}^{\varepsilon'\eta'}] = i(\varepsilon'\eta - 1)E_{ik}^{\varepsilon\eta'}, \quad i \neq k,$$

where $i,j,k=1,\ldots,r$ and $\varepsilon,\varepsilon',\eta,\eta'=\pm$ with other commutators, that cannot be obtained through the symmetry $E_{ij}^{\varepsilon\eta}=-E_{ji}^{\eta\varepsilon}$, vanishing.

Using standard orthogonal unit vectors $e_i \in \mathbb{R}^r$ then E_{ij}^{++} for $1 \leqslant i < j \leqslant r$ correspond to the set of positive roots $e_i \pm e_j$ while E_{ij}^{--} correspond to the set of negative roots $-e_i \pm e_j$. The simple roots $e_i - e_{i+1}, e_{r-1} + e_r$ for $1 \leqslant i \leqslant r-1$ correspond to the linearly independent set of raising operators $E_{ii+1}^{+-}, E_{r-1r}^{++}$. Similarly the linearly independent set of lowering operators is $E_{ii+1}^{-+}, 1 \leqslant i \leqslant r-1, E_{r-1r}^{--}$.

In $2r+1$ dimensions we have additionally the following commutation relations involving the extra generators (2.7), namely,

$$[H_i,E_j^{\pm}] = \pm\delta_{ij}E_j^{\pm},$$

$$[E_i^{\varepsilon},E_i^{\eta}] = (\varepsilon - \eta)H_i, \quad [E_i^{\varepsilon},E_j^{\eta}] = iE_{ij}^{\varepsilon\eta}, \quad i \neq j, \tag{2.9}$$

$$[E_{ij}^{\varepsilon\eta},E_j^{\varepsilon'}] = -[E_{ji}^{\eta\varepsilon},E_j^{\varepsilon'}] = i(\varepsilon'\eta - 1)E_i^{\varepsilon},$$

for $i,j=1,\ldots,r$ with all other such vanishing.

For SO($2r+1$) E_i^+ corresponds to the extra positive roots e_i while E_i^- corresponds to the extra negative roots $-e_i$. The simple roots $e_i - e_{i+1}, 1 \leqslant i \leqslant r-1$ and e_r correspond to the linearly independent set of raising operators E_{ii+1}^{+-}, E_r^+. The linearly independent set of lowering operators is $E_{ii+1}^{-+}, 1 \leqslant i \leqslant r-1$ along with E_r^-.

In the orthonormal basis of SO($2r$), the $2r$ dimensional vector representation has highest weight e_1 and all other weights in the weight system are given by $\pm e_i, 1 \leqslant i \leqslant r$. The weight system may be represented diagrammatically by

$$\begin{array}{ccccccccccccccc} & & & & & & & & \mathrm{e}_r & & & & & & \\ & & & & & & & E^{-+}_{r-1\,r} \nearrow & & \searrow E^{--}_{r-1\,r} & & & & & \\ \mathrm{e}_1 & \xrightarrow{E^{-+}_{12}} & \mathrm{e}_2 & \cdots & \mathrm{e}_{r-2} & \xrightarrow{E^{-+}_{r-2\,r-1}} & \mathrm{e}_{r-1} & & & & -\,\mathrm{e}_{r-1} & \xrightarrow{E^{-+}_{r-2\,r-1}} & -\,\mathrm{e}_{r-2} & \cdots & -\,\mathrm{e}_2 \xrightarrow{E^{-+}_{1\,2}} -\,\mathrm{e}_1 \\ & & & & & & & E^{--}_{r-1\,r} \searrow & & \nearrow E^{-+}_{r-1\,r} & & & & & \\ & & & & & & & & -\mathrm{e}_r & & & & & & \end{array} \tag{2.10}$$

which also indicates the action of the lowering operators $E^{-+}_{ii+1}, 1 \leqslant i \leqslant r, E^{--}_{r-1r}$. As a convenient basis for the $\mathcal{P}_a, \mathcal{K}_a$ operators, which of course transform in the vector representation, we define

$$\mathcal{P}_{i\pm} = \mathcal{P}_{2i-1} \pm i\mathcal{P}_{2i}, \quad \mathcal{K}_{i\pm} = \mathcal{K}_{2i-1} \pm i\mathcal{K}_{2i}, \tag{2.11}$$

for which $[E^{+-}_{ii+1}, \mathcal{P}_{1+}] = [E^{++}_{r-1r}, \mathcal{P}_{1+}] = [E^{+-}_{ii+1}, \mathcal{K}_{1+}] = [E^{++}_{r-1r}, \mathcal{K}_{1+}] = 0$ and

$$[H_i, \mathcal{P}_{j\pm}] = \pm\,\delta_{ij}\mathcal{P}_{j\pm}, \quad [H_i, \mathcal{K}_{j\pm}] = \pm\,\delta_{ij}\mathcal{K}_{j\pm}, \tag{2.12}$$

so that $\mathcal{P}_{i\pm}, \mathcal{K}_{i\pm}$ correspond to the weights $\pm e_i$. In terms of explicit action of lowering operators, we have that

$$\begin{aligned} \mathcal{P}_{i\pm} &= -\frac{i}{2}[E^{-\pm}_{1i}, \mathcal{P}_{1+}], \quad i = 2, \ldots, r-1, \quad \mathcal{P}_{1-} = \tfrac{1}{4}[E^{-+}_{12}, [E^{--}_{12}, \mathcal{P}_{1+}]], \\ \mathcal{K}_{i\pm} &= -\frac{i}{2}[E^{-\pm}_{1i}, \mathcal{K}_{1+}], \quad i = 2, \ldots, r-1, \quad \mathcal{K}_{1-} = \tfrac{1}{4}[E^{-+}_{12}, [E^{--}_{12}, \mathcal{K}_{1+}]], \end{aligned} \tag{2.13}$$

which may be easily unravelled in terms of the action of the linearly independent set of lowering operators $E^{-+}_{ii+1}, 1 \leqslant i \leqslant r, E^{--}_{r-1r}$.

In fact the entire conformal algebra in this basis may be written in terms of the orthonormal basis of the SO$^*(2r+2)$ algebra. Making the definitions

$$H_0 = -H, \quad E^{-\pm}_{0i} = -E^{\pm-}_{i0} = \mathcal{P}_{i\pm}, \quad E^{\pm+}_{i0} = -E^{+\pm}_{0i} = \mathcal{K}_{i\pm}, \quad i = 1, \ldots, r \tag{2.14}$$

(so that $-H$ is the extra Cartan subalgebra element and $\mathcal{K}_{i\pm}/\mathcal{P}_{i\pm}$ form the extra raising/lowering operators) then the conformal algebra may be shown to be equivalent to (2.8) for the range of the indices i, j, k being extended to $0, 1, \ldots, r$. The linearly independent set of raising/lowering operators in this case is extended to include $\mathcal{K}_{1-}/\mathcal{P}_{1+}$.

The $2r+1$ dimensional vector representation of SO($2r+1$) has highest weight e_1 and the weight system is $\pm e_i$ and 0. Diagrammatically the weight system is given by

$$\begin{array}{ccccccccccccc} & E^{-+}_{12} & & & & E^{-+}_{r-1r} & E^{-}_{r} & E^{-}_{r} & & E^{-+}_{r-1r} & & & E^{-+}_{12} \\ e_1 \rightarrow & e_2 & \cdots & e_{r-1} & \rightarrow & e_r & \rightarrow 0 \rightarrow & -\,e_r & \rightarrow & -\,e_{r-1} & \cdots & -\,e_2 \rightarrow & -\,e_1, \end{array} \tag{2.15}$$

where we have indicated the action of lowering operators. In addition to (2.11) we may also choose

$$\mathcal{P}_0 = \mathcal{P}_{2r+1}, \quad \mathcal{K}_0 = \mathcal{K}_{2r+1}, \tag{2.16}$$

as extra elements of the basis for $\mathcal{P}_a, \mathcal{K}_a$ operators and these commute with $H_i, 1 \leqslant i \leqslant r$, so that they have weight 0.

Again, in this basis the conformal algebra may be written in terms of the orthonormal basis of SO$^*(2r+3)$. In addition to (2.14) in this case we define

$$E_0^- = \mathcal{P}_0, \quad -E_0^+ = \mathcal{K}_0, \tag{2.17}$$

and along with (2.8) the extra commutation relations are given by (2.9) for the range of the indices i,j being extended to $0,1,\ldots,r$. Again, the linearly independent set of raising/lowering operators in this case is extended to include $\mathcal{K}_{1-}/\mathcal{P}_{1+}$.

In terms of the orthonormal basis, unitarity requires that

$$H^\dagger = H, \quad H_i^\dagger = H_i, \quad E_{ij}^{\varepsilon\eta\dagger} = E_{ij}^{-\varepsilon-\eta}, \quad E_i^{\varepsilon\dagger} = E_i^{-\varepsilon}, \quad \mathcal{P}_{i\varepsilon}^\dagger = \mathcal{K}_{i-\varepsilon}, \quad \mathcal{P}_0^\dagger = \mathcal{K}_0. \tag{2.18}$$

III. CHARACTER FORMULAS FOR POSITIVE ENERGY UNITARY IRREDUCIBLE REPRESENTATIONS

Essential in our approach to finding the character formulas for positive energy irreducible representations of the conformal group are $\mathrm{SO}^*(d+2)$ Verma modules. These have basis generated by the arbitrary action of lowering operators on the conformal highest weight state $|\Delta,\ell\rangle^{\mathrm{hw}}$ corresponding to the $\mathrm{SO}^*(d+2)$ weight $\underline{\Lambda}=(-\Delta,\ell_1,\ldots,\ell_r)$, $r=\left[\frac{1}{2}d\right]$ (where for $a=0,1,\ldots,r$ then Λ_a are $H_a=-H,H_i$ eigenvalues). In what follows we assume that ℓ is a dominant integral highest weight with respect to $\mathrm{SO}(d)$, so that in the orthonormal basis $\ell_i=\ell\cdot e_i\in\frac{1}{2}\mathbb{Z}$ and (the Dynkin labels for even d are given by $\Lambda_i'=\ell_i-\ell_{i+1}, 1\leqslant i\leqslant r-2$ and $\Lambda_{r-1}'=\ell_{r-1}+\ell_r, \Lambda_r'=\ell_{r-1}-\ell_r$ while for odd d they are $\Lambda_i'=\ell_i-\ell_{i+1}, 1\leqslant i\leqslant r-1$ and $\Lambda_r'=2\ell_r$ and these are the conditions for them to be non-negative integers)

$$\ell_1 \geqslant \cdots \geqslant \ell_{r-1} \geqslant |\ell_r|, \tag{3.1}$$

for $\mathrm{SO}(2r)$ while for $\mathrm{SO}(2r+1)$

$$\ell_1 \geqslant \cdots \geqslant \ell_r \geqslant 0, \tag{3.2}$$

these being the respective dominant Weyl chambers (or boundaries thereof).

The highest weight state $|\Delta,\ell\rangle^{\mathrm{hw}}$ satisfies

$$H_a|\Delta,\underline{\ell}\,\rangle^{\mathrm{hw}} = \Lambda_a|\Delta,\underline{\ell}\,\rangle^{\mathrm{hw}}, \quad \mathcal{K}_{1-}|\Delta,\underline{\ell}\,\rangle^{\mathrm{hw}} = E_\alpha|\Delta,\underline{\ell}\,\rangle^{\mathrm{hw}} = 0, \tag{3.3}$$

for α being the simple roots of $\mathrm{SO}(d)$ so that

$$\{E_\alpha\} \to \{E_{ii+1}^{++}, 1\leqslant i\leqslant r-1, E_{r-1r}^{++}\}, \tag{3.4}$$

for $\mathrm{SO}(2r)$ while

$$\{E_\alpha\} \to \{E_{ii+1}^{++}, 1\leqslant i\leqslant r-1, E_r^{+}\}, \tag{3.5}$$

for $\mathrm{SO}(2r+1)$.

The Verma module $\mathcal{V}_\Lambda$ with highest weight Λ therefore has basis

$$\prod_{\substack{v=i\varepsilon,0\\ 1\leqslant i\leqslant r,\varepsilon=\pm}} \mathcal{P}_v^{n_v} \prod_{\alpha\in\Phi_-} E_\alpha^{n_\alpha}|\Delta,\underline{\ell}\,\rangle^{\mathrm{hw}}, \tag{3.6}$$

for Φ_- denoting the set of negative roots of $\mathrm{SO}(d)$ and with n_v,n_α all positive or zero integers, with $n_0=0$ for $\mathrm{SO}(2r)$. As mentioned before, for $\mathrm{SO}(2r)$ then $\{E_\alpha\}\to\{E_{ij}^{-\pm}\}$ while for $\mathrm{SO}(2r+1)$ then $\{E_\alpha\}\to\{E_{ij}^{-\pm},E_i^-\}$. Corresponding to the basis (3.6) the weights Λ' in the Verma module are given by

$$\Lambda_0' = -\Delta - \sum_{\substack{v=i\varepsilon,0 \\ 1\leqslant i\leqslant r,\varepsilon=\pm}} n_v, \quad \ell' = \ell - \sum_{\alpha\in\Phi_-} n_\alpha \alpha + \sum_{i=1}^{r} (n_{i+} - n_{i-}) e_i. \tag{3.7}$$

In (3.6) we assume some fixed ordering of $\mathcal{P}_v$, E_α. This ordering may be arbitrarily chosen since if a different ordering is assumed then the resulting Verma module basis can be expressed in terms of that in (3.6) due to $\mathcal{P}_v, E_\alpha$ having commutators which are closed among themselves.

In Appendix C we will use the form of the algebra in the last section, in terms of the orthonormal basis, to derive conditions necessary for conformal group representations to be unitary. These results are summarized by

$$\begin{gathered} \Delta \geqslant \Delta_p = \ell_1 + d - p - 1, \quad p = 1, \ldots, \left[\tfrac{1}{2}d\right] \quad \text{for } \ell_1 = \ell_2 = \cdots = \ell_p > \ell_{p+1}, \\ \Delta \geqslant \tfrac{1}{2}d - 1 \quad \text{or } \Delta = 0 \quad \text{for } \underline{\ell} = 0, \end{gathered} \tag{3.8}$$

while for odd d we have in addition that

$$\Delta \geqslant \left[\tfrac{1}{2}d\right] \quad \text{for } \ell_1 = \cdots = \ell_{\left[\frac{1}{2}d\right]} = \tfrac{1}{2}. \tag{3.9}$$

It has been proven elsewhere that these conditions are sufficient[16] (in order for states in irreducible representations of the conformal group to have strictly positive norm). We impose these conditions on the representations we are interested in.

Along with the highest weight Λ the weight system for $\mathcal{V}_\Lambda$ may contain other highest weights Λ^w being, for certain w in the relevant Weyl group $\mathcal{W}$, shifted (or affine) Weyl reflections given by

$$\Lambda^w = w(\Lambda + \rho) - \rho, \tag{3.10}$$

for ρ being the Weyl vector, $\rho = -\frac{1}{2}\Sigma_{\alpha\in\Phi_-}\alpha$. (A simple example is for the $\mathcal{V}_\ell$ Verma module of SO(d) whereby the state $|\underline{\ell}^{\sigma_{12}}\rangle = (E_{12}^{-+})^{\ell_1-\ell_{2+1}}|\underline{\ell}\rangle^{\text{hw}}$, for $\sigma_{12}(\ell_1,\ell_2,\ldots) = (\ell_2,\ell_1,\ldots)$, characterizes a sub-Verma-module $\mathcal{V}_{\ell^{\sigma_{12}}}$, for $|\underline{\ell}\rangle^{\text{hw}}$ being annihilated by all SO(d) raising operators. To see this it suffices to use that $[E_{12}^{+-},(E_{12}^{-+})^n] = 4n(H_1 - H_2 + n - 1)(E_{12}^{-+})^{n-1}$. For unitary representations $E_{ij}^{\varepsilon\eta\dagger} = E_{ij}^{-\varepsilon-\eta}$ and $|\underline{\ell}^{\sigma_{12}}\rangle$ is null.) As described more in Appendix A, $\mathcal{V}_{\Lambda^w}$ is a sub-Verma module if and only if the w can be made to satisfy condition (A9). A necessary conditions is that $\Lambda - \Lambda^w$ be expressible as a linear combination of positive roots with non-negative integer coefficients. This is equivalent to demanding that the state with weight Λ^w can be reached by applying lowering operators on the highest weight state with weight Λ. If the highest weight Λ is dominant integral then all $\mathcal{V}_\Lambda w$ are sub-Verma modules of $\mathcal{V}_\Lambda$.

As described in Appendix A, in order to find the character of $\mathcal{I}_\Lambda$ the first step is to find all Λ^w which are highest weights of sub-Verma modules. Below we give necessary conditions for SO$^*(d+2)$ weights to satisfy this for the highest weight having orthonormal basis labels $\underline{\Lambda} = (-\Delta, \ell_1, \ldots, \ell_r)$. We show how each such weight may be written as Λ'^w where $w \in \mathcal{W}_d$, the Weyl group of SO(d), and $\underline{\Lambda}' = (-\Delta', \underline{\ell}')$ has $\underline{\ell}'$ satisfying (3.1) and (3.2), so that ℓ' is a dominant integral weight of SO(d), or else such that the weight ℓ' has a Dynkin label equal to -1 in which case such contributions vanish in χ_Λ. Using the results of Appendix A we may then write the character as

$$\chi_\Lambda = \sum_{w\in\mathcal{W}_d} \operatorname{sgn}(w) \mathcal{C}_{\Lambda^w} + \sum_{w\in\mathcal{W}_d,\Lambda'} \gamma_{\Lambda'} \operatorname{sgn}(w) \mathcal{C}_{\Lambda' w}, \tag{3.11}$$

where $\mathcal{C}_{\Lambda'}$ are SO$^*(d+2)$ Verma module characters and $\gamma_{\Lambda'}$ is determined by a recurrence relation. To solve this recurrence relation requires knowing in more detail which submodules are contained in which and so condition (A9) applies here.

The Weyl group $\mathcal{W}_{d+2}$ acts in a particularly simple way on weights of the Verma module $\mathcal{V}_\Lambda$ of SO$^*(d+2)$ in the orthonormal basis. Choosing any $w \in \mathcal{W}_{d+2}$ then we may write

$$w(\Lambda_0, \ldots, \Lambda_r) = (\varepsilon_0 \Lambda_{\sigma(0)}, \ldots, \varepsilon_r \Lambda_{\sigma(r)}), \tag{3.12}$$

for $\sigma \in \mathcal{S}_{r+1}$ and $\varepsilon_a = \pm 1$ with $\Pi_a \varepsilon_a = 1$ for $d = 2r$. In the present case the relevant-Weyl vector has components

$$\rho_a = \tfrac{1}{2}d - a, \quad a = 0, \ldots, r, \tag{3.13}$$

in the orthonormal basis of $\mathrm{SO}^*(d+2)$. Notice that the last r components are the components of the Weyl vector for $\mathrm{SO}(d)$. From (3.10) we have that the components of Λ^w in the orthonormal basis are

$$\Lambda^w_a = \varepsilon_a \Lambda_{\sigma(a)} + (\varepsilon_a - 1)\tfrac{1}{2}d - \varepsilon_a \sigma(a) + a. \tag{3.14}$$

Now for $\mathrm{SO}^*(d+2)$ the weights $\underline{\Lambda} = (-\Delta, \ell_1, \ldots, \ell_r)$ are clearly not dominant integral unless $\Delta = \ell_i = 0$ which corresponds to the trivial representation. Sub-Verma-module weights must satisfy (3.7). Thus, for any Λ^w to be the highest weight of a sub-Verma-module then $\Lambda^w_0 = -\Delta - n$, $n \in \mathbb{N}$. Also the minimum value of Λ^w_0 is that for $\varepsilon_0 = -1$, $\sigma(0) = 1$ so that sub-Verma-modules exist for

$$-\ell_1 - d + 1 \leqslant \Lambda^w_0 = -\Delta - n. \tag{3.15}$$

Notice that for $\varepsilon_0 = 1$, $\sigma(0) = 0$ so that $\Lambda^w_0 = -\Delta$ then all $\mathcal{V}_{\Lambda^w}$, $w \in \mathcal{W}_d$ are sub-Verma-modules as ℓ is a dominant integral highest weight with respect to the $\mathrm{SO}(d)$ subgroup. For any other $\varepsilon_0, \sigma(0)$ then this corresponds to a definite action of $\mathcal{P}_v$ on the highest weight state so that for these cases $n \geqslant 1$.

Using the formula (3.11) and the results of Appendix A with condition (3.15) we now discuss the even and odd dimension character formulas separately.

A. Character formulas: even dimensions

For application of the results of Appendix A we need to specify what condition (A9) demands for $\mathrm{SO}^*(d+2)$ Weyl group elements in $d = 2r$ dimensions. For $S_{ab}, T_{(ab)}$ being the $\mathcal{W}_d$ element for the respective positive roots $e_a + e_b$, $e_a - e_b$, $0 \leqslant a < b \leqslant r$ then clearly

$$\begin{aligned} S_{ab}(\Lambda_0, \ldots, \Lambda_a, \ldots, \Lambda_b, \ldots, \Lambda_r) &= (\Lambda_0, \ldots, -\Lambda_b, \ldots, -\Lambda_a, \ldots, \Lambda_r), \\ T_{(ab)}(\Lambda_0, \ldots, \Lambda_a, \ldots, \Lambda_b, \ldots, \Lambda_r) &= (\Lambda_0, \ldots, \Lambda_b, \ldots, \Lambda_a, \ldots, \Lambda_r). \end{aligned} \tag{3.16}$$

$T_{(ab)}$ corresponds to the transposition (ab) and below we use the short-hand notation $T_\sigma = T_{(a_1 b_1)} \ldots T_{(a_j b_j)}$ for $\sigma = (a_1 b_1) \ldots (a_j b_j)$. Applying S_{ab}, respectively, $T_{(ab)}$, to some weight $\underline{\Lambda}' = (\Lambda'_0, \ldots, \Lambda'_r)$ then clearly condition (A9) allows only those S_{ab}, respectively, $T_{(ab)}$, for which $\Lambda'_a + \Lambda'_b \in \mathbb{N}$, respectively, $\Lambda'_a - \Lambda'_b \in \mathbb{N}$.

We may easily write the character formula for the $\mathrm{SO}^*(2r+2)$ Verma module with highest weight Λ, for $\underline{\Lambda} = (-\Delta, \underline{\ell})$, and weights Λ' given by (3.7) as

$$C^{(2r+2)}_{\underline{\Lambda}}(s,x) = \sum_{\Lambda'} e^{\Lambda'}(\mu) = s^\Delta C^{(2r)}_{\underline{\ell}}(x) P^{(2r)}(s,x), \tag{3.17}$$

where, for some general $\mathrm{SO}^*(d+2)$ weight μ,

$$s = e^{-e_0}(\mu) = e^{-\mu_0}, \quad x_i = e^{e_i}(\mu) = e^{\mu_i}, \tag{3.18}$$

$C^{(2r)}_{\underline{\ell}}(x)$ denotes the character of the $\mathrm{SO}(2r)$ Verma module with highest weight ℓ (given in Appendix B) and

$$P^{(2r)}(s,x)=\prod_{1\leqslant i\leqslant r}(1-sx_i)^{-1}(1-sx_i^{-1})^{-1}. \tag{3.19}$$

[$P^{(2r)}(s,x)$ comes from the summation over $n_{i\pm}$ implicit in (3.17).]

For $\Delta>\ell_1+d-2$ or Δ lying between two any of Δ_p and Δ_{p+1} in (3.8) then (3.15) implies that the only sub-Verma-modules are at most those having highest weights for $\varepsilon_0=1$, $\sigma(0)=0$ in (3.14). However, since ℓ is a dominant integral weight of SO(d) then all $\mathcal{V}_{\Lambda^w}$, $w\in\mathcal{W}_d$ are sub-Verma-modules of $\mathcal{V}_\Lambda$ in this case. Thus from (3.11) the corresponding character is

$$\mathcal{A}^{(2r)}_{[\Delta;\underline{\ell}]}(s,x)=\sum_{w\in\mathcal{W}_{2r}}\operatorname{sgn}(w)C^{(2r+2)}_{\underline{\Lambda}^w}(s,x)=s^\Delta\chi^{(2r)}_{\underline{\ell}}(x)P^{(2r)}(s,x). \tag{3.20}$$

Let us assume that $\ell_1=\ell_2=\cdots=\ell_p>|\ell_{p+1}|$, $p\leqslant r-1$, $\Delta=\Delta_p$. In this case only Λ_0^w for $\varepsilon_0=1,\sigma(0)=0$ and $\varepsilon_0=-1$, $\sigma(0)=1,\ldots,p$ in (3.14) satisfy (3.15). For $\varepsilon_0=1$, $\sigma(0)=0$ then all $\mathcal{V}_{\Lambda^w}$, $w\in\mathcal{W}_d$ are sub-Verma-modules. Let us assume $\varepsilon_0=-1$, $\sigma(0)=j$, $1\leqslant j\leqslant p$ for which $\Lambda_0^w=-\ell_1-d+j$ then it is not difficult to show that the rest of the components may be written as

$$(\ell_1,\ldots,\ell_1,\ell_{p+1},\ldots)^w=(\ell_1,\ldots,\ell_1,\underset{\substack{\uparrow\\ j\text{th position}}}{\ell_1-1},\ldots,\ell_1-1,\ell_{p+1},\ldots)^{w'},\quad w'\in\mathcal{W}_d; \tag{3.21}$$

whereby if in the original $w\in\mathcal{W}_{d+2}$ then $\sigma(k_a)=a,k_a\neq 0$, $a\neq j$ then w' is defined in terms of w by

$$\varepsilon_0'=-\varepsilon_0=1,\quad \varepsilon_{k_0}'=-\varepsilon_{k_0},\quad \varepsilon_{k_i}'=\varepsilon_{k_i},\quad \sigma'=(0pp-1\cdots j)\sigma, \tag{3.22}$$

so that $\sigma'(0)=0$ and σ' exhausts all members of $\mathcal{S}_r$. Thus we have shown that all weights for the case of $w\in\mathcal{W}_{d+2}$ having $\varepsilon_0=-1$, $\sigma(0)=j$ in (3.14) may be written as $\Lambda^{(j,p)w'}$, $w'\in\mathcal{W}_d$ with

$$\underline{\Lambda}^{(j,p)}=(-\ell_1-d+j,\ell_1,\ldots,\ell_1,\underset{\substack{\uparrow\\ (j+1)\text{th position}}}{\ell_1-1},\ldots,\ell_1-1,\ell_{p+1},\ldots). \tag{3.23}$$

[Also $\Pi_a\varepsilon_a'=\Pi_a\varepsilon_a$ and $\operatorname{sgn}(w')=(-1)^{p+j+1}\operatorname{sgn}(w)$. During the course of this work we noticed that, at this point, simply using the following formula:

$$\chi_\Lambda=\mathcal{C}_\Lambda+\sum_{\substack{w\in\mathcal{W},w\neq 1\\ \Lambda^w<\Lambda}}\operatorname{sgn}(w)\mathcal{C}_{\Lambda^w},$$

where the sum runs over all w satisfying condition (A9), gives exactly the same result for the character as we find here by a more laborious procedure. It would be interesting to know whether or not this formula holds for more general Lie algebras and highest weights. We have not been able to find such a simple formula in the literature.]

We may now easily show that $\Lambda^{(j,p)w'}$, $w'\in\mathcal{W}_d$ exhaust all other highest weights of sub-Verma-modules of $\mathcal{V}_\Lambda$ in this case. To see this notice that if condition (A9) of Appendix A is satisfied for the weight $\Lambda^{(j,p)}$ then it is satisfied for $\Lambda^{(j,p)w'}$, $w'\in\mathcal{W}_d$ since the $(\ell_1,\ldots,\ell_1,\ell_1-1,\ldots,\ell_1-1,\ell_{p+1},\ldots)$ corresponds to a dominant integral weight of SO(d). For $\Lambda^{(j,p)}$ itself we may show that $\Lambda^{(j,p)}=\Lambda^w$ where $w=S_{0p}T_\sigma$ for $\sigma=(pp-1\ldots j)$ satisfies condition (A9). We see this as $(pp-1\cdots j)=(pp-1)(p-1p-2)\cdots(j+1j)$ and $T_{(i+1i)}T_{(ii-1)}\cdots T_{(j+1j)}(\underline{\Lambda}+\rho)\cdot(\underline{e}_{i+2}-\underline{e}_{i+1})\in\mathbb{N}$ for $i<p$ and $T_\sigma(\underline{\Lambda}+\underline{\rho})\cdot(\underline{e}_0+\underline{e}_p)\in\mathbb{N}$.

It now remains to determine $\gamma_{\Lambda^{(j,p)}}\to\gamma_{j,p}$ in (3.11) for the weight $\Lambda^{(j,p)}$ by the recurrence relation in Appendix A. The first observation which is not difficult to show (in a similar fashion as above) is that among $\mathcal{V}_{\Lambda^{(k,p)}}$ the only such modules which contain $\mathcal{V}_{\Lambda^{(j,p)}}$ as a submodule are those for $j<k\leqslant p$ or none such if $j=p$. In fact it is possible to show that no proper submodule of $\mathcal{V}_\Lambda$ contains $\mathcal{V}_{\Lambda^{(p,p)}}$ so that in this case $\gamma_{p,p}=-1$.

To describe which submodules contain other $\mathcal{V}_{\Lambda^{(j,p)}}$ we first define a subset of the permutation group $\mathcal{T}_n \subset \mathcal{S}_n$ so that every $\tau \in \mathcal{T}_n$ has $1 \leqslant c \leqslant n$ cycles, where the first cycle consists of the first n_1 of the integers $n, n-1, \ldots, 2, 1$, preserving this ordering, the second consists of the next n_2 such integers, again preserving this ordering, and so on and where $n_1, \ldots, n_c \geqslant 1$ satisfy $\Sigma_{i=1}^{c} n_i = n$. For example, for $n=3$ then $\mathcal{T}_n = \{(321), (32)(1) = (32), (3)(21) = (21), (3)(2)(1) = 1\}$. It is not difficult to see that the number of such permutations with c cycles (counting trivial one cycles) is $\binom{n-1}{c-1}$ so that the total number of such permutations is 2^{n-1}. Further we have that for $n > 1$ there are 2^{n-2} of these permutations with signature 1 or -1 so that $\Sigma_{\tau \in \mathcal{T}_n} \operatorname{sgn}(\tau) = 0$.

With the above definition of $\mathcal{T}_n$ we have found that the submodules $\mathcal{V}_{\Lambda^{w'}}$, $w' \in \mathcal{W}_d, w' \neq 1$ contain $\mathcal{V}_{\Lambda^{(j,p)}}$ as a submodule only for $w' \in \mathcal{T}_{p+1-j}$ so that for $j > p$ then $\Sigma_{w'} \operatorname{sgn}(w') = -1$ is the contribution to $\gamma_{j,p}$ coming from these. Also we have found that the submodules $\mathcal{V}_{\Lambda^{(k,p)w'}}, j < k \leqslant p, w' \in \mathcal{W}_d$ containing $\mathcal{V}_{\Lambda^{(j,p)}}$ have $w' \in \mathcal{T}_{k-j}$ so that for $j+1 < k \leqslant p$ then $\Sigma_{w'} \operatorname{sgn}(w') = 0$ so that the contribution to $\gamma_{j,p}$ coming from these vanishes while for $k = j+1$ then $w' = 1$ and this contributes $\gamma_{j+1,p} \operatorname{sgn}(w') = \gamma_{j+1,p}$ to $\gamma_{j,p}$. With these results we may then easily find that

$$\gamma_{j,p} = (-1)^{p+j+1}, \tag{3.24}$$

solves the recurrence relation $\gamma_{j,p} = -\gamma_{j+1,p}, \gamma_{p,p} = -1$.

It is possible to show that for such w' as described above (essentially belonging to $\mathcal{T}_n$ for various n) then for $w \in \mathcal{W}_{d+2}$ so that $\Lambda^{(j,p)} = \Lambda^{ww'}$ or $\Lambda^{(j,p)} = \Lambda^{(k,p)ww'}$ the only w which satisfy condition (A9) are expressible as products of $S_{0l}, T_{(mn)}, 1 \leqslant l, m, n \leqslant p$.

Now applying (3.11) and the Weyl character formula for SO($2r$) in terms of (3.17) (Appendix B) we find that the corresponding character is

$$\begin{aligned} &\mathcal{D}^{(2r)}_{[\ell_1+2r-p-1;\ell_1,\ell_{p+1},\ldots,\ell_r]}(s,x) \\ &\quad = s^{\ell_1+2r-p-1}\left(\chi^{(2r)}_{\underline{\ell}}(x) + \sum_{1 \leqslant j \leqslant p} (-s)^{p+1-j} \chi^{(2r)}_{\underline{\ell}-\underline{e}_p-\cdots-\underline{e}_j}(x)\right) P^{(2r)}(s,x) \end{aligned} \tag{3.25}$$

for $\underline{\ell} = (\ell_1, \ldots, \ell_1, \ell_{p+1}, \ldots, \ell_r)$.

Notice that for even dimensions we also have the possibility of $\ell_1 = \cdots = \ell_{r-1} = \pm \ell_r, \Delta = \ell_1 + \frac{1}{2}d - 1$. Here the Λ_0^w satisfying (3.15) are those for $\varepsilon_0 = 1$, $\sigma(0) = 0$, $\varepsilon_0 = \mp 1$, $\sigma(0) = r$ along with $\varepsilon_0 = -1$, $\sigma(0) = 1, \ldots, r-1$. By an argument very similar to the previous we find that, for $\underline{\ell} = (\ell, \ldots, \ell, \pm \ell)$,

$$\begin{aligned} &\mathcal{D}^{(2r)}_{[\ell+r-1;\ell]_\pm}(s,x) \\ &\quad = s^{\ell+r-1}\left(\chi^{(2r)}_{\underline{\ell}}(x) + \sum_{1 \leqslant j \leqslant r} (-s)^{r+1-j} \chi^{(2r)}_{\underline{\ell}\mp\underline{e}_r-\cdots-\underline{e}_j}(x)\right) P^{(2r)}(s,x), \end{aligned} \tag{3.26}$$

is the corresponding character in this case.

The free scalar case, for which $\underline{\Lambda} = (-r+1, 0, \ldots, 0)$ is the highest SO($2r+2$) weight, is accounted for by (3.26) for $\ell = 0$ and has character

$$\mathcal{D}^{(2r)}_{[r-1;0]}(s,x) \equiv \mathcal{D}^{(2r)}_{[r-1;0]_\pm}(s,x) = s^{r-1}(1-s^2)P^{(2r)}(s,x), \tag{3.27}$$

since the SO($2r$) characters obey $\chi_{(0,\ldots,0,-1,\pm 1)}(x) = -1$ with $\chi_{(0,\ldots,0\pm 1)}(x) = 0$ and $\chi_{(0,\ldots,0,-1,\ldots,-1,\pm 1)} \times (x) = 0$ otherwise.

B. Character formulas: odd dimensions

Considerations for odd $d = 2r+1$ dimensions are very similar to those above for even $d = 2r$ dimensions and we will not go into as much detail here. Along with (3.16) $\mathcal{W}_{2r+1}$ has extra elements corresponding to the extra positive roots $e_i, 1 \leqslant i \leqslant r$ given by

$$S_a(\Lambda_0,\ldots,\Lambda_a,\ldots,\Lambda_r)=(\Lambda_0,\ldots,-\Lambda_a,\ldots,\Lambda_r). \tag{3.28}$$

Acting on some weight $\underline{\Lambda}'=(\Lambda_0',\ldots,\Lambda_r')$ then condition (A9) only allows those S_a for which $\Lambda_a'\in\frac{1}{2}\mathbb{N}$.

We may easily write the character formula for the $SO^*(2r+3)$ Verma module with highest weight Λ and weights Λ' given by (3.7) as

$$C_{\underline{\Lambda}}^{(2r+3)}(s,x)=\sum_{\Lambda'}e^{\Lambda'}(\mu)=s^{\Delta}C_{\underline{\ell}}^{(2r+1)}(x)P^{(2r+1)}(s,x), \tag{3.29}$$

where $C_{\underline{\ell}}^{(2r+1)}(x)$ denotes the character of the $SO(2r+1)$ Verma module with highest weight ℓ (given in Appendix B) and

$$P^{(2r+1)}(s,x)=(1-s)^{-1}\prod_{1\leqslant i\leqslant r}(1-sx_i)^{-1}(1-sx_i^{-1})^{-1}. \tag{3.30}$$

[$P^{(2r+1)}(s,x)$ comes from the summation over $n_{i\pm},n_0$ implicit in (3.29).]

For $\Delta>\ell_1+d-2$ or Δ lying between two any of Δ_p and Δ_{p+1} in (3.8) then character for positive energy unitary irreducible representations is

$$\mathcal{A}_{[\Delta;\underline{\ell}]}^{(2r+1)}(s,x)=\sum_{w\in\mathcal{W}_{2r+1}}\mathrm{sgn}(w)C_{\underline{\Lambda}^w}^{(2r+3)}(s,x)=s^{\Delta}\chi_{\underline{\ell}}^{(2r+1)}(x)P^{(2r+1)}(s,x), \tag{3.31}$$

where $\chi_{\underline{\ell}}^{(2r+1)}(x)$ is the character of the $SO(2r+1)$ irreducible representation with highest weight ℓ.

For $\bar{\Delta}=\Delta_p$ in (3.8) we may go through the same procedure as for the even dimensional case and find that the extra Weyl reflections (3.28) lead to nothing new as far as condition (A9) is concerned. Thus for odd d and with $\underline{\ell}=(\ell_1,\ldots,\ell_1,\ell_{p+1},\ldots,\ell_r)$ corresponding character for these representations is

$$\begin{aligned}&\mathcal{D}_{[\ell_1+2r-p;\ell_1,\ell_{p+1},\ldots,\ell_r]}^{(2r+1)}(s,x)\\&\quad=s^{\ell_1+2r-p}\left(\chi_{\underline{\ell}}^{(2r+1)}(x)+\sum_{1\leqslant j\leqslant p}(-s)^{p+1-j}\chi_{\underline{\ell}-\underline{e}_p-\cdots-\underline{e}_j}^{(2r+1)}(x)\right)P^{(2r+1)}(s,x).\end{aligned} \tag{3.32}$$

For the free scalar case, for which $\underline{\Lambda}=\left(-r+\frac{1}{2},0,\ldots,0\right)$ is the highest $SO(2r+3)$ weight, we have that the corresponding character is given by

$$\mathcal{D}_{[r-\frac{1}{2};0]}^{(2r+1)}(s,x)=s^{r-\frac{1}{2}}(1-s^2)P^{(2r+1)}(s,x). \tag{3.33}$$

For odd dimensions we also have the possibility of the highest weight Λ having components $\underline{\Lambda}=\left(-r,\frac{1}{2},\ldots,\frac{1}{2}\right)$. This time the Λ_0^w satisfying (3.15) are those for $\varepsilon_0=\pm1$, $\sigma(0)=0$, $\varepsilon_0=-1$, $\sigma(0)=j$, $1\leqslant j\leqslant r$. For $\varepsilon_0=-1$, $\sigma(0)=0$ then $\Lambda_0^w=-r-1$ and the remaining components may be rewritten as $\ell^w=\ell^{w'}$ where $w'\in\mathcal{W}_{2r+1}$ is identical to w save for $\varepsilon_0'=-\varepsilon_0=1$ so that $\Pi_a\varepsilon_a'=-\Pi_a\varepsilon_a$ and $\mathrm{sgn}(w')=-\mathrm{sgn}(w)$. The cases of $\varepsilon_0=-1$, $\sigma(0)=j$, $1\leqslant j\leqslant r$ are accounted for similarly as for even dimensions for $p=r$. However these cases have highest weights which are shifted $\mathcal{W}_{2r+1}$ Weyl group reflections of $(-\Delta',\underline{\ell}')=\left(-2r-1+j,-\frac{1}{2},\ldots,-\frac{1}{2},\frac{1}{2},\ldots\right)$. For these weights at least one of the Dynkin labels $\ell_{i+1}'-\ell_i'$ is equal to -1 so that contributions from all these Verma modules vanish from the character formula (by a result of Appendix A).

The only cases we must consider are for the Verma modules $\mathcal{V}_{\Lambda'w'},w'\in\mathcal{W}_{2r+1}$ for $\underline{\Lambda}'=\left(-r-1,\frac{1}{2},\ldots,\frac{1}{2}\right)$. By similar arguments as before all $\mathcal{V}_{\Lambda'w'}$ for $w'\neq1$ are submodules of $\mathcal{V}_{\Lambda'}$. Due to $\underline{\Lambda}'+\underline{\rho}=S_0(\underline{\Lambda}+\underline{\rho})$, where S_a is defined in (3.28) then condition (A9) [which is satisfied due to $e_0\cdot(\underline{\Lambda}+\underline{\rho})=\frac{1}{2}$] implies that all $\mathcal{V}_{\Lambda'w'},w'\in\mathcal{W}_{2r+1}$ are submodules of $\mathcal{V}_{\Lambda}$]. Further we may show that $\mathcal{V}_{\Lambda'}$ is contained only in $\mathcal{V}_{\Lambda}$, and no submodules of $\mathcal{V}_{\Lambda}$, and so $\gamma_{\Lambda'}=-1$.

Taking into account these considerations, we have that the character is, from (3.11),

$$\mathcal{D}^{(2r+1)}_{[r;\frac{1}{2}]}(s,x)=\sum_{w\in\mathcal{W}_{2r+1}}\mathrm{sgn}(w)(\mathcal{C}_{\Lambda^w}-\mathcal{C}_{\Lambda' w})=s^r(x_1^{1/2}+x_1^{-1/2})\cdots(x_r^{1/2}+x_r^{-1/2})(1-s)P^{(2r+1)}(s,x), \tag{3.34}$$

and where we have used that

$$\chi^{(2r+1)}_{(1/2,\ldots,1/2)}(x)=(x_1^{1/2}+x_1^{-1/2})\cdots(x_r^{1/2}+x_r^{-1/2}). \tag{3.35}$$

C. Relation with reduced Verma module bases

We wish to show here that omitting certain of $\mathcal{P}_v$ from the original Verma module basis (3.6) leads to formulas for characters which are equivalent to those obtained in the last sections.

Descendant states (i.e., those obtained by definite action of $\mathcal{P}_v$ on the highest weight state) are SO(d) representations belonging to the decomposition of $\mathbf{e}_1\otimes\cdots\otimes\mathbf{e}_1\otimes\ell$ in terms of irreducible representations. From Appendix C, these states are null for either of two reasons. One reason is that ℓ may lie on the boundary of the dominant Weyl chamber (3.1) (i.e., that some $\ell_1=\ell_2=\cdots$) so that certain descendant states are null with respect to the SO(d) subgroup. The other reason is that Δ may lie on a unitarity bound. By omitting the correct $\mathcal{P}_v$ from (3.6) we effectively discard states in the original Verma module which are null due to the value of Δ. Acting with the Weyl symmetry operator on the character of the reduced Verma module is equivalent to projecting out of the reduced module states which are null by virtue of which SO(d) representation they belong to. We may show that this prescription gives the same formulas for characters as found earlier.

For definiteness we consider the case where $\ell_1=\cdots=\ell_p>|\ell_{p+1}|$, $\Delta\geqslant\ell_1+d-p-1$, in even dimensions, $d=2r$, although the other cases of interest are similar.

For this case and in the notation of Appendix C, consider the SO($2r$) highest weight state $|\Delta+1,\underline{\ell}-\underline{e}_p\rangle$. The construction of such a state is nontrivial and in Appendix C only the simplest such states have been constructed. Nevertheless we may write down the state in principle as

$$|\Delta+1,\underline{\ell}-\underline{e}_p\rangle=\mathcal{A}_{\underline{\ell}}\mathcal{P}_{p-}|\Delta,\underline{\ell}\,\rangle^{\mathrm{hw}}+\sum_{v',\underline{\ell}'}\mathcal{B}_{v',\underline{\ell}'}\mathcal{P}_{v'}|\Delta,\underline{\ell}'\,\rangle\,, \tag{3.36}$$

where $\mathcal{P}_{v'}\leftrightarrow v'\in\{\pm e_i\}$ is the subset of $\mathcal{P}_{i\pm}$ which may be reached by applying SO($2r$) raising operators to $\mathcal{P}_{p-}$ and $\underline{\ell}'+\underline{v}'=\underline{\ell}-\underline{e}_p$. The subset $\mathcal{P}_{v'}$ may be easily determined from (2.10) to be given by $\mathcal{P}_{i+},\mathcal{P}_{j-}$ for $1\leqslant i\leqslant r$ and $p+1\leqslant j\leqslant r$. The complex numbers $\mathcal{A}_{\underline{\ell}},\mathcal{B}_{v',\underline{\ell}'}$ are determined by the condition that (3.36) be a highest weight state with respect to SO($2r$), i.e., that all SO($2r$) raising operators annihilate it. By the results of Appendix C, for Δ above the unitarity bound this state is not null however when $\Delta=\ell_1+d-p-1$ then $|\Delta+1,\underline{\ell}-\underline{e}_p\rangle=0$. This is equivalent to a conservation equation for the highest weight state $|\Delta,\underline{\ell}\rangle^{\mathrm{hw}}$.

Now the modulus of $\mathcal{A}_{\underline{\ell}}$ is nonzero despite $\ell_1=\cdots=\ell_p>|\ell_{p+1}|$. When $\Delta=\ell_1+d-p-1$, so that (3.36) vanishes, then $\mathcal{P}_{p-}|\bar{\Delta},\underline{\ell}\rangle^{\mathrm{hw}}$ may be expressed in terms of $\mathcal{P}_{i+}|\Delta,\ell'\rangle$, $\mathcal{P}_{j-}|\Delta,\ell'\rangle$ for $1\leqslant i\leqslant r$ and $p+1\leqslant j\leqslant r$. Also, as

$$E^{-+}_{ii+1}|\Delta,\ell_1,\ldots,\ell_1,\ell_{p+1},\ldots,\ell_r\rangle^{\mathrm{hw}}=0,\quad i=1,\ldots,p-1, \tag{3.37}$$

then applying such E^{-+}_{ii+1} to (3.36) and using (2.10), we have that for Δ on the unitarity bound then $\mathcal{P}_{i-}|\Delta,\underline{\ell}\rangle^{\mathrm{hw}}$, $1\leqslant i\leqslant p-1$ may be similarly expressed in terms of $\mathcal{P}_{i+}|\Delta,\ell'\rangle$, $\mathcal{P}_{j-}|\Delta,\ell'\rangle$ for $1\leqslant i\leqslant r$ and $p+1\leqslant j\leqslant r$. Thus, effectively the Verma module basis (3.6) becomes reduced so as to exclude $\mathcal{P}_{i-}$, $1\leqslant i\leqslant p$.

Acting with the SO(d) Weyl symmetry operator $\mathfrak{W}_d$ (see Appendixes A and B) on the character for the reduced Verma module yields the following formula:

$$\sum_{\Lambda',w\in\mathcal{W}_{2r}} e^{w(\Lambda')}(\mu) = s^{\ell_1+2r-p-1}\mathfrak{W}_d(C^{(2r)}_{\underline{\ell}}(x)(1-sx_1^{-1})\cdots(1-sx_p^{-1}))P^{(2r)}(s,x)$$
$$= s^{\ell_1+2r-p-1}\left(\chi^{(2r)}_{\underline{\ell}}(x) + \sum_{\substack{1\leqslant n\leqslant p\\ i_j\in(1,\ldots,p),i_j\neq i_k}} (-s)^n \chi^{(2r)}_{\underline{\ell}-\underline{e}_{i_1}-\cdots-\underline{e}_{i_n}}(x)\right)P^{(2r)}(s,x), \tag{3.38}$$

for $\underline{\ell}=(\ell_1,\ldots,\ell_1,\ell_{p+1},\ldots,\ell_r)$ and where now $\Lambda'=(-\Lambda'_0,\underline{\ell}')$ are specified by

$$\Lambda'_0 = -\Delta' = -\ell_1 - d + p + 1 - \sum_{1\leqslant i\leqslant r} n_{i+} - \sum_{p+1\leqslant j\leqslant r} n_{j-},$$
$$\ell' = \ell - \sum_{\alpha\in\Phi_-}\alpha + \sum_{1\leqslant i\leqslant r} n_{i+}e_i - \sum_{p+1\leqslant j\leqslant r} n_j - e_j. \tag{3.39}$$

It is easy to see that (3.38) reduces to (3.25). To see this note that $\chi_{\underline{\ell}'}(x)$ in (3.38) is nonzero only for $\underline{\ell}'=(\ell_1,\ldots,\ell_1,\ell_1-1,\ldots,\ell_1-1,\ell_{p+1},\ldots,\ell_r)$, i.e., for $i_j=k,k+1,\ldots,p$ for some $1\leqslant k\leqslant p$.

To summarize: when the conformal dimension Δ saturates a unitarity bound the Verma module basis is reduced so as to exclude certain of the $\mathcal{P}_{i\pm}$, $\mathcal{P}_0$ from (3.6). This is equivalent to conservation equations constraining the highest weight state. This subset may be determined in terms of the results of Appendix C. Acting with the SO(d) Weyl symmetry operator on the character of the reduced Verma module then leads to the characters for the corresponding unitary irreducible representation. Explicitly, for (3.25) and (3.32) the subset to be omitted from (3.6) is $\mathcal{P}_{i-}, 1\leqslant i\leqslant p$, for (3.26) the subset is $\mathcal{P}_{i-}, 1\leqslant i\leqslant r-1$ along with $\mathcal{P}_{r-}$ for $\mathcal{D}^{(2r)}_{[\ell+r-1;\ell]_+}$ or $\mathcal{P}_{r+}$ for $\mathcal{D}^{(2r)}_{[\ell+r-1;\ell]_-}$ while for (3.34) the subset is $\mathcal{P}_{i-}, 1\leqslant i\leqslant r$ along with $\mathcal{P}_0$.

D. Special cases

We here illustrate these character formulas for the simplest cases of the SO(3,2) and SO(4,2) conformal groups and mention how special cases relate to conformal field representations.

We have that,

$$C_\ell(x) \equiv C^{(3)}_\ell(x) = \frac{x^\ell}{1-x^{-1}}, \tag{3.40}$$

is the character of SO(3) Verma modules and

$$\chi_\ell(x) \equiv \chi^{(3)}_\ell(x) = C_\ell(x) + C_\ell(x^{-1}) = \frac{x^{\ell+(1/2)} - x^{-\ell-(1/2)}}{x^{1/2}-x^{-1/2}}, \tag{3.41}$$

is the usual character for SO(3) irreducible representations. We have therefore that,

$$\mathcal{A}^{(3)}_{[\Delta;\ell]}(s,x) = s^\Delta \chi_\ell(x)P^{(3)}(s,x),$$
$$\mathcal{D}^{(3)}_{[\ell+1;\ell]}(s,x) = s^{\ell+1}(\chi_\ell(x) - s\chi_{\ell-1}(x))P^{(3)}(s,x),$$
$$\mathcal{D}^{(3)}_{[1;1/2]}(s,x) = s(x^{1/2}+x^{-1/2})(1-sx)^{-1}(1-sx^{-1})^{-1}, \tag{3.42}$$
$$\mathcal{D}^{(3)}_{[1/2;0]}(s,x) = s^{1/2}(1+s)(1-sx)^{-1}(1-sx^{-1})^{-1},$$

exhaust all characters of the unitary irreducible representations of SO(3,2). (In terms of the notation employed in Ref. 6 these character formulas agree for $x\to\beta^2$, $s\to\alpha^2$. In the nomenclature

of Ref. 6, the representations $\mathcal{D}^{(3)}_{[1;1/2]}$ and $\mathcal{D}^{(3)}_{[1/2;0]}$ correspond to the "Di" and "Rac" singleton representations, respectively.)

For $SO(4)\simeq SU(2)\otimes SU(2)$ we have that

$$C^{(4)}_{(\ell_1,\ell_2)}(x_1,x_2)=C_j(x)C_{\bar{J}}(y) \quad \text{for } \ell_1=j+\bar{J}, \quad \ell_2=j-\bar{J}, \quad x_1=x^{1/2}y^{1/2}, \quad x_2=x^{1/2}y^{-1/2} \tag{3.43}$$

i.e., the Verma module character with dominant highest weight (ℓ_1,ℓ_2) may be expressed as a product of two SU(2) Verma module characters with highest weights $j,\bar{J}$. The characters of unitary irreducible representations of $SO(4,2)$ are given by

$$\mathcal{A}^{(4)}_{[\Delta;j,\bar{J}]}(s,x,y)=s^{\Delta}\chi_{\bar{J}}(x)\chi_{\bar{J}}(y)P^{(4)}(s,x,y),$$

$$\begin{aligned}
\mathcal{D}^{(4)}_{[j+\bar{J}+2;j,\bar{J}]}(s,x,y)&=s^{j+\bar{J}+2}(\chi_j(x)\chi_{\bar{J}}(y)-s\chi_{j-(1/2)}(x)\chi_{\bar{J}-(1/2)}(y))P^{(4)}(s,x,y),\\
\mathcal{D}^{(4)}_{[j+1;j]_+}(s,x,y)&=s^{j+1}(\chi_j(x)-s\chi_{j-(1/2)}(x)\chi_{1/2}(y)+s^2\chi_{j-1}(x))P^{(4)}(s,x,y),\\
\mathcal{D}^{(4)}_{[\bar{J}+1;\bar{J}]_-}(s,x,y)&=s^{\bar{J}+1}(\chi_{\bar{J}}(y)-s\chi_{\bar{J}-(1/2)}(y)\chi_{1/2}(x)+s^2\chi_{\bar{J}-1}(y))P^{(4)}(s,x,y).
\end{aligned} \tag{3.44}$$

Here we have written $P^{(4)}(s,x_1,x_2)\to P^{(4)}(s,x,y)$ for x_1,x_2 as in (3.43). This reproduces the results for character formulas in four dimensions found in Ref. 4.

Free fields have conformal dimension $\ell+\frac{1}{2}d-1$ and belong to the $(\ell,\ldots,\ell,\pm\ell)$ representation of $SO(2r)$ for any $\ell\in\frac{1}{2}\mathbb{N}$ in $d=2r$, dimensions and the $(\ell,\ldots,\ell,\ell)$ representation of $SO(2r+1)$ for $\ell=0,\frac{1}{2}$ in $d=2r+1$ dimensions.[19] The corresponding characters for even dimensions are $\mathcal{D}^{(2r)}_{[\ell+r-1;\ell]_\pm}(s,x)$ in (3.26) along with $\mathcal{D}^{(2r)}_{[r-1;0]}(s,x)$ in (3.27) for the scalar case. For odd dimensions the corresponding characters are $\mathcal{D}^{(2r+1)}_{[r;1/2]}(s,x)$of (3.34) and $\mathcal{D}^{(2r+1)}_{[r-(1/2);0]}(s,x)$ in (3.33).

The characters (3.25), (3.32) for the special case of $p=1$ and $\ell_1\equiv\ell,\ell_2=\cdots=\ell_r=0$ correspond to conserved symmetric traceless tensor-field representations of the conformal group, $T_{\mu_1\cdots\mu_\ell}=T_{(\mu_1\cdots\mu_\ell)}$, $T^{\mu}_{\mu\mu_2\cdots\mu_\ell}=\partial^{\mu_1}T_{\mu_1\cdots\mu_\ell}=0$. These have conformal dimension $d+\ell-2$ in d dimensions and examples are the conserved vector current for $\ell=1$ and energy momentum tensor for $\ell=2$.

IV. PRODUCT FORMULAS

We now turn to the determination of the decomposition of products of unitary irreducible representations of the conformal group into other unitary irreducible representations.

A. Product formulas: four dimensions

We illustrate for the $SO(4,2)$ case first. For these purposes we first note a useful identity, namely,

$$P^{(4)}(s,x,y)=\sum_{p,q=0}^{\infty}s^{2p+q}\chi_{(1/2)q}(x)\chi_{(1/2)q}(y). \tag{4.1}$$

With (4.1) we may now easily determine the products of unitary irreducible representations of the conformal group. Using the usual decomposition of products of SU(2) characters,

$$\chi_{j\otimes j'}(x)\equiv\chi_j(x)\chi_{j'}(x)=\sum_{q=|j-j'|}^{j+j'}\chi_q(x), \tag{4.2}$$

and (4.1), we notice that

$$\mathcal{D}^{(4)}_{[j+1;j]+}(s,x,y)=\sum_{q=0}^{\infty}s^{q+j+1}\chi_{j+(1/2)q}(x)\chi_{(1/2)q}(y). \tag{4.3}$$

Thus we may straightforwardly, determine that

$$\begin{aligned}&\mathcal{D}^{(4)}_{[j+1,j]+}(s,x,y)\mathcal{D}^{(4)}_{[j'+1;j']+}(s,x,y)\\&\quad=s^{j+j'+2}P(s,x,y)\left(\chi_{j\otimes j'}(x)+\sum_{q=1}^{\infty}s^q(\chi_{j+j'+(1/2)q}(x)\chi_{(1/2)q}(y)-s\chi_{j+j'+(1/2)q-(1/2)}(x)\chi_{(1/2)q-(1/2)}(y))\right)\\&\quad=\mathcal{A}^{(4)}_{[j+j'+2;j\otimes j',0]}(s,x,y)+\sum_{q=1}^{\infty}\mathcal{D}^{(4)}_{[j+j'+q+2;j+j'+(1/2)q,(1/2)q]}(s,x,y).\end{aligned} \tag{4.4}$$

Similarly, using (4.2), (4.3), we may easily determine that

$$\begin{aligned}&\mathcal{D}^{(4)}_{[j+1,j]+}(s,x,y)\mathcal{D}^{(4)}_{[\bar{J}+1;\bar{j}]-}(s,x,y)\\&\quad=s^{j+\bar{J}+2}P(s,x,y)\sum_{q=0}^{\infty}s^q(\chi_{j+(1/2)q}(x)\chi^{-}_{\bar{J}+(1/2)q}(y)-s\chi_{j+(1/2)q-(1/2)}(x)\chi^{-}_{\bar{J}+(1/2)q-(1/2)}(y))\\&\quad=\sum_{q=0}^{\infty}\mathcal{D}^{(4)}_{[j+\bar{J}+q+2;j+(1/2)q,\bar{J}+(1/2)q]}(s,x,y).\end{aligned} \tag{4.5}$$

Using (4.2), (4.3), we may also find that

$$\begin{aligned}&\mathcal{D}^{(4)}_{[j+\bar{J}+2;j,\bar{J}]+}(s,x,y)\mathcal{D}^{(4)}_{[j'+1,j']+}(s,x,y)\\&\quad=\sum_{q=0}^{\infty}(\mathcal{A}^{(4)}_{[\Delta_q,j+j'+(1/2)q,\bar{J}+(1/2)q]}(s,x,y)+\mathcal{A}_{[\Delta_q,[j-(1/2)]\otimes[j'+(1/2)q-(1/2)],\bar{J}+(1/2)q]}(s,x,y)\\&\qquad+\mathcal{A}^{(4)}_{[\Delta_q,j+j'+(1/2)q,(\bar{J}-(1/2))\otimes[(1/2)q-(1/2)]]}(s,x,y)),\quad \Delta_q=j+j'+\bar{J}+q+3,\end{aligned} \tag{4.6}$$

and

$$\mathcal{A}^{(4)}_{[\Delta;j,\bar{J}]}(s,x,y)\mathcal{D}^{(4)}_{[j'+1,j']+}(s,x,y)=\sum_{q=0}^{\infty}\mathcal{A}^{(4)}_{[\Delta+j'+q+1;j\otimes[j'+(1/2)q],\bar{J}\otimes 1/2q]}(s,x,y), \tag{4.7}$$

which exhausts all products involving $\mathcal{D}^{(4)}_{[j+1;j]+}(s,x,y)$. Those involving $\mathcal{D}^{(4)}_{[\bar{J}+1;J]-}(s,x,y)$ may be obtained by the exchange $x\leftrightarrow y$ above noting

$$\begin{gathered}\mathcal{D}^{(4)}_{[\bar{J}+1;\bar{j}]-}(s,x,y)=\mathcal{D}^{(4)}_{[\bar{J}+1;\bar{j}]+}(s,y,x),\quad \mathcal{D}^{(4)}_{[j+\bar{J}+2;j,\bar{J}]}(s,x,y)=\mathcal{D}^{(4)}_{[j+\bar{J}+2;\bar{J},j]}(s,y,x),\\ \mathcal{A}^{4}_{[\Delta;j,\bar{J}]}(s,x,y)=\mathcal{A}^{(4)}_{[\Delta;\bar{J},j]}(s,y,x).\end{gathered} \tag{4.8}$$

Similarly, using (4.1) directly, we have that

$$\mathcal{A}^{(4)}_{[\Delta;j,\bar{J}]}(s,y,x)\mathcal{A}_{[\Delta';j',\bar{J}']}(s,y,x)=\sum_{p,q=0}^{\infty}\mathcal{A}^{(4)}_{[\Delta+\Delta'+2p+q;j\otimes j'\otimes(1/2)q,\bar{J}\otimes\bar{J}'\otimes(1/2)q]}(s,x,y). \tag{4.9}$$

We may note that each of these product formulas is compatible with the blind partition functions,

$$\mathcal{A}^{(4)}_{[\Delta;j,\bar{J}]}(s,1,1)=\frac{s^{\Delta}}{(s-1)^4}(2j+1)(2\bar{J}+1),$$

$$\mathcal{D}^{(4)}_{[j+\bar{J}+2;j,\bar{J}]}(s,1,1)=\frac{s^{j+\bar{J}+2}}{(s-1)^4}((2j+1)(2\bar{J}+1)-4sj\bar{J}), \tag{4.10}$$

$$\mathcal{D}^{(4)}_{[j+1;j]_+}(s,1,1)=\mathcal{D}^{(4)}_{[j+1;j]_-}(s,1,1)=\frac{s^{j+1}}{(s-1)^3}(-(2j+1)+s(2j-1)).$$

As we see, the $d=4$ cases are relatively simple when we use expansion formulas of the type (4.1), (4.3) to expand one of the characters in the product of two. The general cases which we consider now are also made simpler with analogous expansion formulas.

B. Product formulas: even dimensions

Useful for finding product formulas for the $\mathrm{SO}(2r,2)$ conformal group is the following expansion of $P(s,x)$ in terms of $\mathrm{SO}(2r)$ characters, namely,

$$P^{(2r)}(s,x)=\sum_{p,q=0}^{\infty}s^{2p+q}\chi^{(2r)}_{(q,0,\ldots,0)}(x), \tag{4.11}$$

where

$$\chi^{2r}_{(q,0,\ldots,0)}(x)=\tfrac{1}{2}\det[x_i^{k_j}+x_i^{-k_j}]\Delta(x_1+x_1^{-1},\ldots,x_r+x_r^{-1})^{-1}, \tag{4.12}$$

with $k_1=q+r-1$, $k_j=r-j$, $j>1$, for $\Delta(x)$ being the Vandermonde determinant,

$$\Delta(x_1,\ldots,x_n)=\prod_{1\leqslant i<j\leqslant n}(x_j-x_i). \tag{4.13}$$

The latter expression for the character comes from Appendix B where also expressions for more general characters of $\mathrm{SO}(d)$ in even and odd dimensions are given.

Analogously to (4.3) we have for (3.26) that

$$\mathcal{D}^{(2r)}_{[\ell+r-1;\ell]_\pm}(s,x)=\sum_{q=0}^{\infty}s^{\ell+r+q-1}\chi^{(2r)}_{(\ell+q,\ell,\ldots,\ell,\pm\ell)}(x), \tag{4.14}$$

which we prove in Appendix D.

More generally for the $p=r-j$ case of (3.25) [note that (4.14) encapsulates the $p=r$ case] we have, for $\ell>\ell_1>\cdots>|\ell_j|$,

$$\begin{aligned}&\mathcal{D}^{(2r)}_{[\ell+r+j-1;\ell,\ell_1,\ldots,\ell_j]}(s,x)\\&\quad=\sum_{p_1,\ldots,p_j,q=0}^{\infty}\sum_{i_1=-\frac{1}{2}p_1}^{\frac{1}{2}p_1}\cdots\sum_{i_j=-\frac{1}{2}p_j}^{\frac{1}{2}p_j}s^{\ell+r+j+q+p_1+\cdots+p_j-1}\chi^{(2r)}_{(\ell+q,\ell,\ldots,\ell,\ell_1+2i_1,\ldots,\ell_j+2i_j)}(x),\end{aligned} \tag{4.15}$$

which we also prove in Appendix D. Note that the weights $(\ell+q,\ell,\ldots,\ell,\ell_1,+2i_1,\ldots,\ell_j+2i_j)$ may lie outside the dominant Weyl chamber, i.e., not satisfy (3.1) for particular ℓ,ℓ_i. However for such weights we may use that $\chi^{(2r)}_{\ell'}(x)=\mathrm{sgn}(w)\chi^{(2r)}_{\ell' w}(x)$, for some $w\in\mathcal{W}_{2r}$, to relate such characters to the character with dominant integral highest weight $\ell' w$.

A notable simplification to (4.15) occurs for the $p=1$ case of (3.25) for $\ell_1\equiv\ell,\ell_2=\cdots=\ell_r=0$ which corresponds to conserved symmetric traceless tensor representations of the conformal group. In this case we obtain that, for $d>4$,

$$\mathcal{D}^{(2r)}_{[\ell+2r-2;\ell,0\ldots,0]}(s,x)=\sum_{p,q=0}^{\infty}\sum_{k=0}^{\ell}s^{\ell+2r+2p+q-2}\chi^{(2r)}_{(q+k,\ell-k,0,\ldots,0)}(x). \tag{4.16}$$

We now discuss products involving the representations in (4.14) which contain the truncated representations in (3.25) for $p=1$ namely, $\mathcal{D}^{(2r)}_{[\ell_1+2r-2,\ell_1,\ldots,\ell_r]}$.

For $d=6$, for example, we may find using (4.14), (3.25) for $p=1$ and (3.26) that

$$\begin{aligned}&\mathcal{D}^{(6)}_{[\ell+2;\ell]_+}(s,x)\mathcal{D}^{(6)}_{[\ell'+2;\ell']_-}(s,x)\\&\quad=\mathcal{A}^{(6)}_{[\ell+\ell'+4;(\ell,\ell,\ell)\otimes(\ell',\ell',-\ell')]}(s,x)+\sum_{q=1}^{\infty}\mathcal{D}^{(6)}_{[\ell+\ell'+q+4;\ell+\ell'+q,\ell+\ell',\ell-\ell']}(s,x),\end{aligned} \tag{4.17}$$

and that

$$\mathcal{D}^{(6)}_{[\ell+2;\ell]_\pm}(s,x)\mathcal{D}^{(6)}_{[\ell'+2;\ell']_\pm}(s,x)=\sum_{q=0}^{\infty}\sum_{t=|\ell-\ell'|}^{\ell+\ell'}\mathcal{D}^{(6)}_{[\ell+\ell'+q+4;\ell+\ell'+q,t,\pm t]}(s,x). \tag{4.18}$$

Here and in the following we are using the short-hand notation, for $r=\left[\frac{1}{2}d\right]$,

$$\chi^{(d)}_{(\ell_1,\ldots,\ell_r)\otimes(\ell'_1,\ldots,\ell'_r)}(x)\equiv\chi^{(d)}_{(\ell_1,\ldots,\ell_r)}(x)\chi^{(d)}_{(\ell'_1,\ldots,\ell'_r)}(x), \tag{4.19}$$

in $\mathcal{A}_{[\Delta;\ell]}(s,x)$. Of course (4.19) may be decomposed in terms of SO(d) characters once we know how $\ell\otimes\ell'$ decomposes into irreducible representations.

More generally there is a distinction in such product formulas between the cases where the dimension is divisible by four or not so.

Explicitly, we have for $d=4m$ that

$$\begin{aligned}&\mathcal{D}^{(4m)}_{[\ell+2m-1;\ell]_+}(s,x)\mathcal{D}^{(4m)}_{[\ell'+2m-1;\ell']_-}(s,x)\\&\quad=\sum_{q=0}^{\infty}\sum_{\substack{t_i\geqslant t-\ell'\\ t_i\geqslant t_{i+1}}}\mathcal{D}^{(4m)}_{[\ell+\ell'+q+4m-2;\ell+\ell'+q,t_1,t_1,t_2,t_2,\ldots,t_{m-1},t_{m-1},\ell-\ell']}(s,x)\end{aligned} \tag{4.20}$$

and

$$\begin{aligned}&\mathcal{D}^{(4m)}_{[\ell+2m-1;\ell]_\pm}(s,x)\mathcal{D}^{(4m)}_{[\ell'+2m-1;\ell']_\pm}(s,x)\\&\quad=\mathcal{A}^{(4m)}_{[\ell+\ell'+4m-2;(\ell,\ldots,\pm\ell)\otimes(\ell',\ldots,\pm\ell')]}(s,x)\\&\qquad+\sum_{q=1}^{\infty}\sum_{\substack{t_i\geqslant|\ell-\ell'|\\ t_i\geqslant t_{i+1}}}^{\ell+\ell'}\mathcal{D}^{(4m)}_{[\ell+\ell'+q+4m-2;\ell+\ell'+q,\ell+\ell',t_1,t_1,t_2,t_2,\ldots,t_{m-1},\pm t_{m-1}]}(s,x),\end{aligned} \tag{4.21}$$

while for $d=4m+2$ we have that

$$\mathcal{D}^{(4m+2)}_{[\ell+2m;\ell]_+}(s,x)\mathcal{D}^{(4m+2)}_{[\ell'+2m;\ell']_-}(s,x)$$
$$=\mathcal{A}^{(4m+2)}_{[\ell+\ell'+4m;(\ell,\ldots,\ell)\otimes(\ell',\ldots,-\ell')]}(s,x)$$
$$+\sum_{q=1}^{\infty}\sum_{\substack{t_i\geqslant|\ell-\ell'|\\ t_i\geqslant t_{i+1}}}^{\ell+\ell'}\mathcal{D}^{(4m+2)}_{[\ell+\ell'+q+4m;\ell+\ell'+q,\ell+\ell',t_1,t_1,t_2,t_2,\ldots,t_{m-1},t_{m-1},\ell-\ell']}(s,x), \tag{4.22}$$

and

$$\mathcal{D}^{(4m+2)}_{[\ell+2m;\ell]_\pm}(s,x)\mathcal{D}^{(4m+2)}_{[\ell'+2m;\ell']_\pm}(s,x)=\sum_{q=0}^{\infty}\sum_{\substack{t_i\geqslant|\ell-\ell'|\\ t_i\geqslant t_{i+1}}}^{\ell+\ell'}\mathcal{D}^{(4m+2)}_{[\ell+\ell'+q+4m;\ell+\ell'+q,t_1,t_1,t_2,t_2,\ldots,t_m,\pm t_m]}(s,x). \tag{4.23}$$

A special case of the previous is the product involving the character $\mathcal{D}^{(2r)}_{[r-1;0]}$ in (3.27), corresponding to a free scalar field, for which we have

$$\mathcal{D}^{(2r)}_{[r-1;0]}(s,x)\mathcal{D}^{(2r)}_{[\ell+r-1;\ell]_\pm}(s,x)=\sum_{q=0}^{\infty}\mathcal{D}^{2r}_{[\ell+q+2r-2;\ell+q,\ell,\ldots,\pm\ell]}(s,x). \tag{4.24}$$

Another special case of the above contains a result first found by Vasiliev[10] which generalizes a well-known result by Flato and Fronsdal[6] in three dimensions to even dimensions $d=2r$. This result involves products of the representation corresponding to the free Dirac spinor,

$$Di^{(2r)}(s,x)\equiv\mathcal{D}^{(2r)}_{[r-(1/2),(1/2)]_+}(s,x)+\mathcal{D}^{(2r)}_{[r-(1/2),(1/2)]_-}(s,x)$$
$$=s^{r-(1/2)}(1-s)(\chi^{(2r)}_{(1/2,\ldots,1/2,1/2)}(x)+\chi^{(2r)}_{(1/2,\ldots,1/2,-1/2)}(x))P(s,x)$$
$$=s^{r-(1/2)}(1-s)(x_1^{(1/2)}+x_1^{-(1/2)})\cdots(x_r^{(1/2)}+x_r^{-(1/2)})P(s,x). \tag{4.25}$$

Using the above product formulas we may show that

$$Di^{(2r)}(s,x)Di^{(2r)}(s,x)=2\mathcal{A}^{(2r)}_{[2r-1,0,\ldots,0]}+2\sum_{q=0}^{\infty}(\mathcal{D}^{(2r)}_{[2r+q-1,q+1,1,1,\ldots,1,0]}(s,x)+\mathcal{D}_{[2r+q-1,q+1,1,1,\ldots,1,0,0]}(s,x)$$
$$+\cdots+\mathcal{D}^{(2r)}_{[2r+q-1,q+1,1,0,\ldots,0,0]}(s,x)+\mathcal{D}^{(2r)}_{[2r+q-1,q+1,0,0,\ldots,0,0]}(s,x))$$
$$+\sum_{q=0}^{\infty}(\mathcal{D}^{(2r)}_{[2r+q-1,q+1,11,\ldots,1,1]}(s,x)+\mathcal{D}^{(2r)}_{[2r+q-1,q+1,1,1,\ldots,1,-1]}(s,x)), \tag{4.26}$$

regardless of whether $d=2r$ is divisible by 4 or not so. The latter matches Vasiliev's result.

C. Product formulas: odd dimensions

For SO$(2r+1,2)$ we have that

$$P^{(2r+1)}(s,x)=\sum_{p,q=0}^{\infty}s^{2p+q}\chi^{(2r+1)}_{(q,0,\ldots,0)}(x), \tag{4.27}$$

where

$$\chi^{(2r+1)}_{(q,0,\ldots,0)}(x)=\tfrac{1}{2}\det[x_i^{k_j}-x_i^{-k_j}]\Delta(x_1+x_1^{-1},\ldots,x_r+x_r^{-1})^{-1}(x_1^{(1/2)}-x_1^{-(1/2)})^{-1}\cdots(x_r^{1/2}-x_r^{-(1/2)})^{-1}, \tag{4.28}$$

with $k_1=q+\frac{1}{2}+r-1$, $k_j=\frac{1}{2}+r-j$, $j>1$.

From the results of Appendix D, we have the following expansions for the free spinor case of (3.34) and the free scalar case of (3.33), namely,

$$\mathcal{D}^{(2r+1)}_{[r;1/2]}(s,x)=\sum_{q=0}^{\infty}s^{r+q}\chi^{(2r+1)}_{((1/2)+q,(1/2),\ldots,(1/2))}(x), \tag{4.29}$$

for the free spinor case and

$$\mathcal{D}^{(2r+1)}_{[r-(1/2);0]}(s,x)=\sum_{q=0}^{\infty}s^{r+q-(1/2)}\chi^{(2r+1)}_{(q,0,\ldots,0)}(x), \tag{4.30}$$

for the free scalar case.

For (3.32) and $p=r-j$ we have that, for $\ell>\ell_1>\cdots>\ell_j$,

$$\mathcal{D}^{(2r+1)}_{[\ell+r+j;\ell,\ell_1,\ldots,\ell_j]}(s,x)=\sum_{p_1,\ldots,p_j,q,t=0}^{\infty}\sum_{i_1=-\frac{1}{2}p_1}^{\frac{1}{2}p_1}\cdots\sum_{i_j=-\frac{1}{2}p_j}^{\frac{1}{2}p_j}s^{\ell+r+j+q+t+p_1+\cdots+p_j}\chi^{(2r+1)}_{(\ell+q,\ell,\ldots,\ell,\ell_1+2i_1,\ldots,\ell_j+2i_j)}(x), \tag{4.31}$$

which we show in Appendix D. Again, the weights $(\ell+q,\ell,\ldots,\ell,\ell_1+2i_1,\ldots,\ell_j,+2i_j)$ may lie outside the dominant Weyl chamber, i.e., not satisfy (3.2), for particular ℓ,ℓ_i. For such weights we may use that $\chi^{(2r+1)}_{\ell'}(x)=\mathrm{sgn}(w)\chi^{(2r+1)}_{\ell' w}(x)$, some $w\in\mathcal{W}_{2r+1}$, to relate such characters to those with dominant integral highest weights $\ell' w$.

Just as for even dimensions in (4.16) a simplification to (4.31) occurs for the $p=1$ case of (3.32) for $\ell_1\equiv\ell,\ell_2=\cdots=\ell_r=0$ for which,

$$\mathcal{D}^{(2r+1)}_{[\ell+2r-1;\ell,0,\ldots,0]}(s,x)=\sum_{p,q=0}^{\infty}\sum_{k=0}^{\ell}s^{\ell+2r+2p+q-1}\chi^{(2r+1)}_{(q+k,\ell-k,0,\ldots,0)}(x). \tag{4.32}$$

Regarding products of free representations, we may determine that, using (3.32) for $p=1$,

$$\begin{aligned}\mathcal{D}^{(2r+1)}_{[r;1/2]}(s,x)\mathcal{D}^{(2r+1)}_{[r;1/2]}(s,x)=\mathcal{A}_{[2r;0,\ldots,0]}(s,x)+\sum_{q=0}^{\infty}(&\mathcal{D}^{(2r+1)}_{[2r+q;q+1,1,\ldots,1]}(s,x)+\mathcal{D}^{(2r+1)}_{[2r+q;q+1,1,\ldots,1,0]}(s,x)\\&+\cdots+\mathcal{D}^{(2r+1)}_{[2r+q;q+1,0,\ldots,0]}(s,x)),\end{aligned} \tag{4.33}$$

and

$$\mathcal{D}^{(2r+1)}_{[r;1/2]}(s,x)\mathcal{D}^{(2r+1)}_{[r-(1/2);0]}(s,x)=\sum_{q=0}^{\infty}\mathcal{D}^{(2r+1)}_{[2r+q-(1/2);q+(1/2),(1/2),\ldots,(1/2)]}(s,x), \tag{4.34}$$

along with

$$\mathcal{D}^{(2r+1)}_{[r-(1/2);0]}(s,x)\mathcal{D}^{(2r+1)}_{[r-(1/2);0]}(s,x)=\sum_{q=0}^{\infty}\mathcal{D}^{(2r+1)}_{[2r+q-1;q,0,\ldots,0]}(s,x), \tag{4.35}$$

which generalize similar formulas obtained in Ref. 6 to odd dimensions.

V. PARTITION FUNCTIONS

As a partial check of the character formulas corresponding to free fields, we will compare them to partition functions which have been obtained by various authors in conformally invariant theories on $S^1 \times S^{d-1}$. For these cases, the single particle partition function for a local free operator F may expressed by

$$Y_F^{(d)}(s) = \sum_{q=0}^{\infty} n_{F,q}^{(d)} s^{\Delta_0+q}, \tag{5.1}$$

where $n_{F,q}^{(d)}$ enumerates the descendants of F in the flat background $\mathbb{R}^d$. For even d, the form (4.14) for the character formula corresponding to such free fields allows us to obtain $Y_F^{(d)}(s)$ directly when we set $x_1, \ldots, x_{(1/2)d}=1$. Thus we easily find that

$$Y_{F_\pm}^{(d)}(s) = \sum_{q=0}^{\infty} n_{F_\pm,q}^{(d)} s^{\ell+(1/2)d+q-1}, \tag{5.2}$$

where for $\ell \neq 0$ (from Appendix B)

$$\begin{aligned} n_{F_\pm,q}^{(d)} = \chi_{(\ell+q,\ell,\ldots,\ell+\pm\ell)}^{(d)}(1,\ldots,1) &= \dim(\mathcal{I}_{(\ell+q,\ell,\ldots,\ell)}^{(d)}) \\ &= 2^{(1/2)d-1} \prod_{i=1}^{\frac{1}{2}d-1} \frac{1}{(d-2i)!}(q+i)(2\ell+q+d-2-i) \\ &\quad \times \prod_{2\leqslant k<j\leqslant \frac{1}{2}d} (j-k)(2\ell+d-j-k), \end{aligned} \tag{5.3}$$

while for the scalar field

$$n_{S,q}^{(d)} = \chi_{(q,0,\ldots,0)}^{(d)}(1,\ldots,1) = \frac{2q+d-2}{q+d-2}\binom{q+d-2}{q}, \tag{5.4}$$

which is the dimension of the rank-q symmetric traceless tensor representation of SO(d). (This agrees with a similar formula in Ref. 12.) For chiral Weyl fermions we find, from (5.3) for $\ell=\frac{1}{2}$.

$$n_{f_{\pm},q}^{(d)} = 2^{(1/2)d}\frac{1}{q!}(q+1)(q+2)\cdots(q+d-2). \tag{5.5}$$

Similarly for the $\frac{1}{2}d$-form field strength, from (5.3) for $\ell=1$,

$$n_{V_{\pm},q}^{(d)} = \frac{d}{2(2q+d)}\binom{d}{\frac{1}{2}d}\binom{q+d-1}{q}. \tag{5.6}$$

Note that it may be easily checked that these occupancy numbers agree with those obtained in Ref. 13. For $d=4,6$ [where for $d=4$ then $Y_{V^+}^{(4)}(s)+Y_{V^-}^{(4)}(s)$ is the single particle partition function of the Maxwell field].

For bosonic F the multiparticle partition function is given by

$$Z_F^{(d)}(s) = \exp\left(\sum_{n=1}^{\infty}\frac{1}{n}Y_F^{(d)}(s^n)\right) = \prod_{q=0}^{\infty}(1-s^{\Delta_0+q})^{-n_{F,q}^{(d)}}, \tag{5.7}$$

while for fermionic F it is given by

$$Z_F^{(d)}(s) = \exp\left(\sum_{n=1}^{\infty} \frac{1}{n}(-1)^{n+1} Y_F^{(d)}(s^n)\right) = \prod_{q=0}^{\infty} (1+s^{\Delta_0+q})^{n_{F,q}^{(d)}}. \tag{5.8}$$

It is easy to check that (5.7), (5.8) for the scalar, Weyl fermion and field strength cases above match the results Ref. 13 for $d=4,6$.

Performing the summation in (5.2) for the scalar, Weyl fermion and $\frac{1}{2}d$-form field-strength cases we find

$$Y_S^{(d)}(s) = (s+1)\frac{s^{(1/2)d-1}}{(1-s)^{d-1}},$$

$$Y_{f\pm}^{(d)}(s) = 2^{(1/2)d}\frac{s^{(1/2)(d-1)}}{(1-s)^{d-1}}, \tag{5.9}$$

$$Y_{V_\pm}^{(d)}(s) = \frac{d!}{2\left(\frac{1}{2}d\right)!^2}\frac{s^{(1/2)d}}{(1-s)^{d-1}}F\left(1,-\tfrac{1}{2}d+1;\tfrac{1}{2}d+1;s\right),$$

[where $F(a,b;c;x)$ is the usual hypergeometric function] which may be read off directly from (3.26), (3.27) for $x_i=1$. This form may be directly compared to similar results in Ref. 14 whereby the formulas agree for the scalar and Weyl fermion cases.

It is not difficult to compute the first couple of numbers (5.6) for the self-dual $r=\frac{1}{2}d$ form field strength which we denote by $F_{\mu_1\cdots\mu_r}=*F_{\mu_1\cdots\mu_r}$. For $q=0$ this number just counts the number of independent components in $F_{\mu_1\cdots,\mu_r}$. Antisymmetry in the indices implies $\binom{2r}{r}$ independent components which is reduced by a factor of one-half due to self-duality. For $q=1$ (5.6) counts the number of first-order descendants, $\partial_\mu F_{\mu_1\cdots\mu_r}$. This will be $r\binom{2r}{r}$ less the number of constraint equations $\partial^{\mu_1}F_{\mu_1\cdots\mu_r}=0$ which is $\binom{2r}{r-1}$.

As a further example and check of our formulas, we consider the single particle partition function for rank-ℓ symmetric traceless tensor fields $T_{\mu_1\cdots\mu_\ell}$ satisfying the constraint equation $\partial^{\mu_1}T_{\mu_1\cdots\mu_\ell}=0$. The appropriate character formula in this case is given by (4.16). The corresponding occupation numbers, for $n_{F,q}^{(d)}\to N_{q,\ell}$ in (5.2), are given by

$$N_{q,\ell} = (q(d-2)(2\ell+d-3)+(d-1)(\ell+d-3)(2\ell+d-2)) \times\frac{1}{(d-1)(d-2)(d-3)}\binom{\ell+d-4}{\ell}\binom{q+d-2}{q}. \tag{5.10}$$

To see this we may use (4.16) to write

$$N_{q,\ell} = \sum_{i=0}^{\left[\frac{1}{2}q\right]} t_{q-2i,\ell} \quad \text{for } t_{q,\ell} = \sum_{k=0}^{\ell} \dim(\mathcal{I}^{(d)}_{(q+k,\ell-k,0,\ldots,0)}). \tag{5.11}$$

Using the dimension formula in Appendix B we may find that

$$t_{q,\ell} = (\ell+q+d-3)(4\ell q+(d-3)(2\ell+2q+d-2))\frac{1}{(d-2)(d-3)^2}\binom{\ell+d-4}{\ell}\binom{q+d-4}{q}, \tag{5.12}$$

and thence obtain (5.10) from (5.11).

Again it is not difficult to check that the first couple of numbers agree with expectations. We may easily show that $N_{\ell,0}=\dim(\mathcal{I}^{(d)}_{(\ell,0,\ldots,0)})$ given in (5.4) as expected. Also we may easily show that $N_{\ell,1}=d\,\dim(\mathcal{I}^{(d)}_{(\ell,0,\ldots,0)})-\dim(\mathcal{I}^{(d)}_{(\ell-1,0,\ldots,0)})$ which is the number of first-order descendants $\partial_\mu T_{\mu_1\cdots\mu_\ell}$ reduced by the number of constraint equations coming from the conservation condition. More generally

$$N_{\ell,q}=\binom{q+d-1}{q}\dim(\mathcal{I}^{(d)}_{(\ell,0,\ldots,0)})-\binom{q+d-2}{q-1}\dim(\mathcal{I}^{(d)}_{(\ell-1,0,\ldots,0)}), \tag{5.13}$$

which may be easily seen as the descendants at level q are given by $\partial_{\nu_1}\partial_{\nu_2}\cdots\partial_{\nu_q}T_{\mu_1\cdots\mu_\ell}$ whose number of independent components, is given by the first term in (5.13) which is reduced by the number of independent components in $\partial_{\nu_1}\partial_{\nu_2}\cdots\partial_{\nu_{q-1}}\partial^{\mu_1}T_{\mu_1\cdots\mu_\ell}$ which vanishes by conservation.

More generally, we may use (4.15) in even dimensions and (4.29), (4.30), (4.31) in odd dimensions for $x_i=1$ to determine the occupation numbers in the single particle partition function corresponding to fields whose conformal dimension saturates the unitarity bounds (3.8), (3.9). As mentioned before these are fields which satisfy certain conservation conditions which determines the particular unitarity bound.

Rotating quantum fields in an AdS_{d+1} background have been considered in Ref. 15. Here the modes of a quantum field are supposed to have energies E and angular momenta j_i where $i=1,\ldots,\lfloor\frac{1}{2}d\rfloor$. For the boundary conformal field theory on $\mathbb{R}\times S^{d-1}$ the energies are related to the conformal dimension of conformal fields and their descendants via $E=\Delta$ assuming that the sphere has unit radius while j_i correspond to $\mathrm{SO}(d)$ eigenvalues. Making the identification

$$s=e^{-\beta},\quad x_i=e^{\beta\Omega_i}, \tag{5.14}$$

where $\beta=T^{-1}$ for T being the temperature and Ω_i denote chemical potentials for angular momenta, then it can be shown that the one particle boundary partition function $\Sigma_{E,j_i}e^{-\beta(E-\Omega_i j_i)}$ and character formula for the conformal field coincide. For instance, for a free scalar field, the character formula (3.27) obtained here agrees with the corresponding single particle partition function for the boundary conformal field theory obtained in Ref. 15 when we make the identification (5.14).

APPENDIX A: CHARACTER FORMULAS FOR INFINITE DIMENSIONAL IRREDUCIBLE MODULES OF SEMISIMPLE LIE ALGEBRAS

In this appendix we outline some results on character formulas of relevance for the main text. First we give basic definitions and notation.

The Weyl group $\mathcal{W}$ is generated by mappings w_α, for α being a root, which on weight space give

$$w_\alpha(\Lambda)=\Lambda-(\alpha^\vee,\Lambda)\alpha,\quad \alpha^\vee=2\alpha/(\alpha,\alpha). \tag{A1}$$

For $\Lambda=\beta$, another root, then $w_\alpha(\beta)$ is a reflection of β with respect to the hyperplane through the origin and perpendicular to α. Here (λ,μ) denotes the usual inner product on weight space between λ and μ. [In the Dynkin basis this is given by $(\lambda,\mu)=\Sigma_{i,j}\lambda_i G_{ij}\mu_j$ where λ_i,μ_i are Dynkin labels and $[G_{ij}]$ is the quadratic form matrix]. Any $w\in\mathcal{W}$ may be decomposed in terms of simple Weyl reflections $w_i\equiv w_{\alpha_i}$, for α_i being the simple roots, as $w=w_{i_1}\cdots w_{i_n}$ for some n which is generally not unique. However the signature of w defined, in the present case, by $\mathrm{sgn}(w)=(-1)^n$ is uniquely defined. We denote by $\ell(w)$ the minimum number of w_i in the composition of w. Clearly $\mathrm{sgn}(w)=(-1)^{\ell(w)}$.

The Weyl group divides the weight space into a family of open sets called Weyl chambers. These are simplicial cones defined by

$$\mathcal{H}_w = \{\lambda : (\alpha_i^\vee, w(\lambda)) > 0, \quad 1 \leqslant i \leqslant r\}, \tag{A2}$$

for $w \in \mathcal{W}$. The number of such equals the order of $\mathcal{W}$, $|\mathcal{W}|$. The weights lying on the boundary of the Weyl chambers are the points on the hyperplanes perpendicular to the roots $(\alpha_i^\vee, w(\lambda))=0$. In terms of Dynkin labels these are the weights having at least one vanishing Dynkin label.

The Weyl chamber corresponding to the identity of the Weyl group $\mathcal{H}_1$ is the fundamental or dominant Weyl chamber. In terms of Dynkin labels the weights in this chamber have strictly positive Dynkin labels. If all the Dynkin labels are non-negative and/or integers then we say the weight is dominant and/or integral.

Suppose we have some Lie algebra module V_Λ having highest weight Λ. The definition of the corresponding character we use is[5]

$$\mathrm{Char}_\Lambda \equiv \sum_{\lambda \in V_\Lambda} \mathrm{mult}_{V_\Lambda}(\lambda) e^\lambda, \tag{A3}$$

where $\mathrm{mult}_{V_\Lambda}(\lambda)$, $\mathrm{mult}_{V_\Lambda}(\Lambda)=1$, denotes the multiplicity of the weight λ in the weight system of V_Λ. This is to be interpreted as a function on weight space satisfying

$$e^\lambda e^\mu = e^{\lambda+\mu}, \quad e^\lambda(\mu) = e^{(\lambda,\mu)}. \tag{A4}$$

Under the action of the Weyl group, for $w \in \mathcal{W}$,

$$w(e^\lambda) = e^{w(\lambda)}. \tag{A5}$$

For a unitary group and with $\mathrm{mult}_{V_\Lambda}(\lambda)$ always finite we may recover a trace formula for the character by normalizing each vector $v_\lambda \in V_\Lambda$ corresponding to the weight λ so that $\langle v_\lambda | v_\lambda \rangle = 1$. Then we may write,

$$\mathrm{Char}_\Lambda(\mu) = \sum_{v_\lambda \in \tilde{V}_\Lambda} \langle v_\lambda | v_\lambda \rangle e^{(\lambda,\mu)} = \mathrm{Tr}(e^{(H,\mu)}), \tag{A6}$$

where $(H,\mu)=\Sigma_{i,j} H_i G_{ij} \mu_j$ in the Dynkin basis, for example, for H_i being Cartan subalgebra elements with $H_i|v_\lambda\rangle = \lambda_i |v_\lambda\rangle$.

As an example, consider a Verma module $\mathcal{V}_\Lambda$ with basis $\Pi_{\alpha\in\Phi_-} E_\alpha^{n_\alpha} |\underline{\Lambda}\rangle^{\mathrm{hw}}$ for Φ_- being negative roots and n_α being non-negative integers. For fixed n_α then the corresponding weight $\lambda_{(n_\alpha)} = \Lambda + \Sigma_{\alpha\in\Phi_-} n_\alpha \alpha$ has unit multiplicity in the weight system of $\mathcal{V}_\Lambda$. Thus we may write the character for the Verma module as

$$\mathcal{C}_\Lambda = \sum_{n_\alpha \geqslant 0} e^{\lambda(n_\alpha)} = e^\Lambda \prod_{\alpha\in\Phi_-} (1 - e^\alpha)^{-1}. \tag{A7}$$

Note that a given weight λ has multiplicity given by $\mathcal{P}(\Lambda - \lambda)$ where $\mathcal{P}(\mu)$ counts the number of ways in which the weight μ may be written as a linear combination of positive roots with non-negative integer coefficients.

We may easily also show that

$$w(\mathcal{C}_\Lambda) = \mathrm{sgn}(w) \mathcal{C}_{\Lambda^w}, \quad \Lambda^w = w(\Lambda + \rho) - \rho, \tag{A8}$$

for any $w \in \mathcal{W}$.

The character χ_Λ of an infinite dimensional irreducible module $\mathcal{I}_\Lambda$ of a semisimple Lie algebra has been written down long ago.[11] For the highest weight Λ not being dominant integral then $\mathcal{I}_\Lambda$ is infinite dimensional. Otherwise $\mathcal{I}_\Lambda$ is finite dimensional and the character is given by the well-known Weyl character formula. Before we give the result of Ref. 11 we quote a number of results which give insight into the structure of infinite dimensional irreducible modules.

Concerning Verma modules (which in Ref. 11 are called elementary representations), the first result we recount is that if Λ^w, $w \in \mathcal{W}$ is not a weight of $\mathcal{V}_\Lambda$ then $\mathcal{V}_\Lambda$ itself is irreducible. This is the simplest case and an example is $\mathcal{V}_\ell$ for SO(3) with ℓ being a negative half integer. We now give the conditions for $\mathcal{V}_\Lambda$ to contain submodules $\mathcal{V}_{\Lambda'}$ and so to be reducible.

We define a partial ordering on weights so that $\Lambda' \prec \Lambda$ if and only if $\Lambda - \Lambda' = \Pi$ for some $\Pi = \Sigma_{\alpha \in \Phi_+} p_\alpha \alpha$ for p_α being non-negative integers, not all zero. A necessary condition for a Verma module $\mathcal{V}_\Lambda$ to contain a submodule $\mathcal{V}_{\Lambda'}$ is that $\Lambda' = \Lambda^w \prec \Lambda$ for some $w \in \mathcal{W}$, $w \neq 1$. A crucial result is a theorem in Ref. 20 which proves that a necessary and sufficient condition for $\mathcal{V}_{\Lambda^w}$ to be a submodule of $\mathcal{V}_\Lambda$ is that there exist a sequence of positive roots $\beta_1, \ldots, \beta_K$ such that

$$w = w_{\beta_1} w_{\beta_2} \cdots w_{\beta_k}, \quad (w^\vee_{\beta_k}, w_{\beta_{k+1}} w_{\beta_{k+2}} \cdots w_{\beta_K}(\Lambda + \rho)) \in \mathbb{N}, \quad k = 1, \cdots, K, \tag{A9}$$

where we define $w_{\beta_{K+1}} \equiv 1$. For Λ being a dominant integral weight then condition (A9) holds for all Λ^w, $w \in \mathcal{W}$. This justifies the claim made in this paper that for Λ being dominant integral then Λ^w is a highest weight in $\mathcal{V}_\Lambda$ for every $w \in \mathcal{W}$.

A key result proved by Verma[21] and recounted in Ref. 11 is the following. A Verma module contains those and only those irreducible representations $\mathcal{I}_{\Lambda'}$ for which $\mathcal{V}_{\Lambda'}$ is a submodule of $\mathcal{V}_\Lambda$. Furthermore it contains $\mathcal{I}_{\Lambda'}$ at most once.

This results in the following formula for characters:

$$\mathcal{C}_\Lambda = \chi_\Lambda + \sum_{\substack{w \in \mathcal{W} \\ \Lambda^w \prec \Lambda}} \chi_{\Lambda^w}, \tag{A10}$$

where the sum runs over all w for which (A9) holds.

Using these results and formulas for multiplicities of weights determined for Verma modules in terms of the function $\mathcal{P}(\mu)$ above a formula has been given for χ_Λ in Ref. 11. This may be rewritten in the equivalent form

$$\chi_\Lambda = \mathcal{C}_\Lambda + \sum_{\substack{w \in \mathcal{W} \\ \Lambda^w \prec \Lambda}} \gamma_{\Lambda^w} \mathcal{C}_{\Lambda^w}, \tag{A11}$$

where each w satisfies condition (A9) and where the integers γ_{Λ^w} are determined by a recurrence relation as follows.

Consider a submodule $\mathcal{V}_{\Lambda^w}$ of $\mathcal{V}_\Lambda$ so that there is no other submodule $\mathcal{V}_{\Lambda^{w'}}$ of $\mathcal{V}_\Lambda$ containing $\mathcal{V}_{\Lambda^w}$ in turn as a submodule. Then in this case $\gamma_{\Lambda^w} = -1$.

For a submodule $\mathcal{V}_{\Lambda^w}$ of $\mathcal{V}_\Lambda$ which is in turn contained in the submodules $\mathcal{V}_{\Lambda^{w'}}$ of $\mathcal{V}_\Lambda$, then in this case

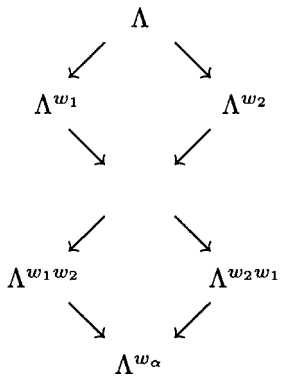
$$\gamma_{\Lambda^w} = -\sum_{w'} \gamma_{\Lambda^{w'}} - 1, \tag{A12}$$

which determines γ_{Λ^w} in (A11) recursively.

A simple example illustrates this formula. Consider Sl_3 whereby, for a weight $\Lambda = [a, b]$ with Dynkin labels a, b, the simple Weyl reflections are given by

$$w_1([a,b]) = [-a, a+b], \quad w_2([a,b]) = [a+b, -b]. \tag{A13}$$

The $\mathcal{S}_3$ Weyl group elements consist of $\{1, w_1, w_2, w_1 w_2, w_2 w_1, w_\alpha\}$ where $w_\alpha = w_1 w_2 w_1 = w_2 w_1 w_2$ is the Weyl reflection corresponding to the root $\alpha = \alpha_1 + \alpha_2$. The shifted Weyl reflections are given by $\Lambda^1 = \Lambda$, $\Lambda^{w_1} = \Lambda - (a+1)\alpha_1$, $\Lambda^{w_2} = \Lambda - (b+1)\alpha_2$, $\Lambda^{w_2 w_1} = \Lambda - (a+1)\alpha_1 - (a+b+2)\alpha_2$, $\Lambda^{w_1 w_2} = \Lambda - (a+b+2)\alpha_1 - (b+1)\alpha_2$, $\Lambda^{w_\alpha} = \Lambda - (a+b+2)\alpha$. For $\swarrow$ denoting a vector in the $-\alpha_1$ direction of length $a+1$ and $\searrow$ denoting such in the $-\alpha_2$ direction of length $b+1$ then we may represent the weight system of the Verma module $\mathcal{V}_\Lambda$ diagrammatically as follows:



(A14)

assuming Λ is dominant integral and where we have omitted any other weights occurring. In computing $\chi_{\Lambda^{w_1}}$, for example, we have that $\mathcal{V}_{\Lambda^{w_1 w_2}}$ and $\mathcal{V}_{\Lambda^{w_2 w_1}}$ are both sub-Verma modules of $\mathcal{V}_{\Lambda^{w_1}}$ with $\gamma_{\Lambda^{w_1 w_2}}=\gamma_{\Lambda^{w_2 w_1}}=-1$. Also $\mathcal{V}_{\Lambda^{w_\alpha}}$ is a sub-verma-module of both the latter and so $\gamma_{\Lambda^{w_\alpha}}=-(\gamma_{\Lambda^{w_1 w_2}}+\gamma_{\Lambda^{w_2 w_1}})-1=1$. Thus $\chi_{\Lambda^{w_1}}=\mathcal{C}_{\Lambda^{w_1}}-\mathcal{C}_{\Lambda^{w_2 w_1}}-\mathcal{C}_{\Lambda^{w_1 w_2}}+C_{\Lambda^{w_\alpha}}$ In fact for all $\Lambda'=\Lambda^{w'}$ it is easy to check that $\chi_{\Lambda'}=\mathcal{C}_{\Lambda'}+\sum_{\substack{w\in\mathcal{S}_3\\ \Lambda' w<\Lambda'}}\mathrm{sgn}(w)=\mathcal{C}_{\Lambda' w}$.

Other properties of $\mathcal{I}_\Lambda$ which are useful for what follows concern symmetry under Weyl group reflections. For all Dynkin labels Λ_i of the weight Λ which are non-negative integers then the subgroup $\mathcal{W}'$ generated by the corresponding simple Weyl reflections w_i is the maximal symmetry group of the weight system of $\mathcal{I}_\Lambda$. Furthermore $\mathcal{V}_{\Lambda^{w'}}$ is a submodule of $\mathcal{V}_\Lambda$ for all $w'\in\mathcal{W}', w'\neq 1$ [since all w' satisfy condition (A9)]. In terms of characters we have that $w'(\chi_\Lambda)=\chi_\Lambda$ for every $w'\in\mathcal{W}'$.

For Λ being dominant integral then this symmetry group is of course the Weyl group itsetf and $\mathcal{W}'=\mathcal{W}$. In this case we from (A11) that

$$\chi_\Lambda=\sum_{w\in\mathcal{W}}\mathrm{sgn}(w)\mathcal{C}_{\Lambda^w}=\prod_{\alpha\in\Phi_-}(1-e^\alpha)^{-1}\sum_{w\in\mathcal{W}}\mathrm{sgn}(w)e^{w(\Lambda+\rho)-\rho}, \tag{A15}$$

the usual Weyl character formula. This follows as symmetry under $\mathcal{W}$ determines $\gamma_{\Lambda^w}=\mathrm{sgn}(w)$ in this case. Using (A8) we may find that the Weyl character may be rewritten as

$$\chi_\Lambda=\sum_{w\in\mathcal{W}}w(\mathcal{C}_\Lambda)\equiv\mathfrak{W}(\mathcal{C}_\Lambda). \tag{A16}$$

Due to the invariance of $\mathcal{I}_\Lambda$ under the action of any $w\in\mathcal{W}$ then the Weyl symmetry operator $\mathfrak{W}$ defined by (A16) is obviously linear and idempotent on the vector space spanned by the characters of the Verma modules, $\mathfrak{W}^2=|\mathcal{W}|\mathfrak{W}$.

Denoting by I the subset of labels for which Λ_i, $i\in I$, are non-negative integers, supposing we find that every sub-Verma-module highest weight $\Lambda^{w''}$, $w''\in\mathcal{W}$ may be written in the form $\Lambda^{w''}=\Lambda^{w'w}$, $w\in\mathcal{W}$, $w'\in\mathcal{W}'$ for Λ_i^w, $i\in I$ being non-negative integers or $\Lambda_i^w=-1$ for some $i\in I$. We claim that the weights $\Lambda^{w''}<\Lambda$ are given by the disjoint union of the weights $\Lambda^{w'w}$ for every $w'\in\mathcal{W}'$. For the cases of $\Lambda_i^w=-1$ then the $\mathcal{C}_{\Lambda^{w'w}}$, $w'\in\mathcal{W}'$ cancel among themselves in χ_Λ.

Under this assumption (which holds in the cases considered in this paper) then using (A11) we may write for the character

$$\chi_\Lambda=\mathcal{C}_\Lambda+\sum_{\substack{w'\in\mathcal{W}'\\ w'\neq 1}}\gamma_{\Lambda^{w'}}\mathcal{C}_{\Lambda^{w'}}+\sum_{\substack{w'\in\mathcal{W}'\\ w\in\mathcal{W},w\neq 1}}\gamma_{\Lambda^{w'w}}\mathcal{C}_{\Lambda^{w'w}}, \tag{A17}$$

where the sum runs over only those $w\in\mathcal{W}$ which satisfy (A9) and for which Λ_i^w, $i\in I$, is a non-negative integer or -1. Using (A8) and $w'(\chi_\Lambda)=\chi_\Lambda$, $w'\in\mathcal{W}'$ and the claims proved below we may show that $\gamma_{\Lambda^{w'}}=\mathrm{sgn}(w')$, $\gamma_{\Lambda^{w'w}}=\gamma_{\Lambda^w}\mathrm{sgn}(w')$ and that the $\mathcal{C}_{\Lambda^{w'w}}$ for which $\Lambda_j^w=-1$ for some $j\in I$ cancel among themselves. It is then left to determine the remaining γ_{Λ^w} by the recurrence relation mentioned earlier.

We now show that for some arbitrary weight Λ which has Λ_i, $i \in I$ being non-negative integers that this is the unique weight among $\Lambda^{w'}$, $w' \in \mathcal{W}'$ having this property. Clearly under these assumptions $(\Lambda^{w_i})_i = (\alpha_i^\vee, \Lambda^{w_i}) = -\Lambda_i - 2$ is negative for $i \in I$. Since $\mathcal{W}'$ is generated by all w_i, $i \in I$, then we may consider all $w' = w_{i_1} \cdots w_{i_n}$, $i_j \in I$ such that $\ell(w') = n$. Denoting by Φ'_+ all those positive roots formed from linear combinations of the subset of simple roots α_i, $i \in I$, then we have the result that $\ell(w_i w') = \ell(w') + 1$ if and only if $w'^{-1}(\alpha_i) \in \Phi'_+$. (The argument for this is similar to one given in Ref. 22.) In this case we have that $(\Lambda^{w_i w'})_i = -(\alpha^\vee, \Lambda + \rho) - 1$ where $\alpha = w'^{-1}(\alpha_i) \in \Phi'_+$. Since $(\alpha^\vee, \Lambda + \rho) \geqslant 0$ then $(\Lambda^{w_j w'})_i$ must be negative. Hence all $\Lambda^{w'}$, $w' \in \mathcal{W}'$, $w' \neq 1$, have at least on of $\Lambda_i^{w'}$, $i \in I$ which is negative.

If some $\Lambda^{w'w} = \Lambda^{u'u}$ for some w', $u' \in \mathcal{W}'$ and with Λ_i^w, $\Lambda_i^u \geqslant 0$, $i \in I$, then clearly we may write $\Lambda^u = \Lambda^{u'^{-1}w'w}$ which contradicts the above unless $u = w$, $u' = w'$. Thus any two sets of such weights $\{\Lambda^{w'w}, w' \in \mathcal{W}'\}$ and $\{\Lambda^{w'u}, w' \in \mathcal{W}'\}$ for $w \neq u$ are disjoint.

If for some weight $\Lambda_j = -1$ for some $j \in I$ then $\Lambda^{w_j} = \Lambda$ since $(\alpha_j^\vee, \Lambda^w + \rho) = 0$. We claim that the only $\Lambda^{w'}$ for $w' \in \mathcal{W}'$ which equal Λ in this case are those for which w' is composed of the w_j. For simplicity we consider the case when $\Lambda_j = -1$ and otherwise Λ_i is non-negative for $i \in I$. In this case if $\Lambda^{w'} = \Lambda$ then clearly $\Lambda^{w_j w'} = \Lambda$ so that, for $\alpha = w^{-1}(\alpha_j)$, $(\Lambda^{w_j w'})_j = -(\alpha^\vee, \Lambda + \rho) - 1 = -1$ by assumption. Thus $(\alpha^\vee, \Lambda + \rho) = 0$ which is only the case if $\alpha \propto \alpha_j$. The only roots with this property are $\pm\alpha_i$ so that $w' = 1, w_j$. Also this implies that, for w', $u' \in \mathcal{W}'$, $\Lambda^{w'} = \Lambda^{u'}$ if and only if $u' = w'$ or $u' = w'w_j$. The generalization is clear.

APPENDIX B: WEYL CHARACTER FORMULAS FOR SO(*d*)

We now consider SO(d) character formulas. We define the variables $x_i = e^{e_i}(\mu) = e^{\mu_i}$ for some arbitrary SO(d) weight $\mu = \Sigma_{i=1}^r \mu_i e_i$.

For SO($2r$) the action of the Weyl group, $\mathcal{W}_{2r} = \mathcal{S}_r \ltimes \mathbb{Z}^{r-1}$, on weights in the orthonormal basis is given by $\mathcal{S}_r$ permutations on the labels followed by reflections involving an even number of sign flips in the labels. This means that for $\varrho = \rho_i \cdots \rho_j \in \mathbb{Z}^{r-1}$ where $\rho_i(\ell_1, \ldots, \ell_i, \ldots, r) = (\ell_1, \ldots, -\ell_i, \ldots \ell_r)$, $\rho_i^2 = 1$ then the number of ρ_i in the composition of ϱ is even and $\mathrm{sgn}(\varrho) = 1$. Using that

$$\sum_{\sigma \in \mathcal{S}_r} \mathrm{sgn}(\sigma) x_{\sigma(1)}^{\ell_1} \cdots x_{\sigma(r)}^{\ell_r} = \det[x_i^{\ell_j}], \tag{B1}$$

and the restriction mentioned on $\varrho \in \mathbb{Z}^{r-1}$ then[23]

$$\mathfrak{W}_{2r}\left(\prod_{i=1}^r x_i^{\ell_i}\right) = \frac{1}{2}\det[x_i^{\ell_j} + x_i^{-\ell_j}] + \frac{1}{2}\det[x_i^{\ell_j} - x_i^{-\ell_j}], \tag{B2}$$

for $\mathfrak{W}_{2r}$ denoting the SO($2r$) Weyl symmetry operator. For some highest weight $\ell = \Sigma_{i=1}^r \ell_i e_i$ corresponding Verma module character is given by

$$C_{\underline{\ell}}^{(2r)}(x) \equiv C_{\underline{\ell}}^{(2r)}(\mu) = \prod_{i=1}^r x_i^{\ell_i} \prod_{1 \leqslant j < k \leqslant r, \varepsilon = \pm} (1 - e^{(\alpha_{jk,\varepsilon}, \mu)})^{-1} = \prod_{i=1}^r x_i^{\ell_i + r - i} \Delta(x_1 + x_1^{-1}, \ldots, x_r + x_r^{-1})^{-1}, \tag{B3}$$

where $\alpha_{ij,\pm} = -e_i \pm e_j$, $1 \leqslant i < j \leqslant r$ are the negative roots and $\Delta(x)$ is the Vandermonde determinant (4.13). Using the fact that $\Delta(x_1 + x_1^{-1}, \ldots, x_r + x_r^{-1})$ is left alone by any $\varrho\sigma \in \mathcal{S}_r \ltimes \mathbb{Z}^{r-1}$ then we have quite simply that the Weyl character of the irreducible representation with dominant integral highest weight ℓ [given by $\chi_{\underline{\ell}}^{(2r)}(x) = \mathfrak{W}_{2r}(C_{\underline{\ell}}^{(2r)}(x))$] reduces to

$$\chi_{\underline{\ell}}^{(2r)}(x) = \tfrac{1}{2}(\det[x_i^{k_j} + x_i^{-k_j}] + \det[x_i^{k_j} - x_i^{-k_j}])\Delta(x_1 + x_1^{-1}, \ldots, x_r + x_r^{-1})^{-1}, \tag{B4}$$

for $k_i = \ell_i + r - i$. The dimension of the irreducible representation is given by

$$\dim(\mathcal{I}_{\underline{\ell}}^{(2r)}) = 2^{r-1}\prod_{i=1}^{r}\frac{1}{(2r-2i)!}\prod_{1\leqslant i<j\leqslant r}(\ell_i-\ell_j+j-i)(\ell_i+\ell_j+2r-i-j). \tag{B5}$$

For SO($2r+1$) the action of the Weyl group, $\mathcal{W}_{2r+1}=\mathcal{S}_r\ltimes\mathbb{Z}^r$, on weights in the orthonormal basis is given by $\mathcal{S}_r$ permutations on the labels followed by reflections involving any number of sign flips in the labels. Using (B1) we therefore have that[23]

$$\mathfrak{W}_{2r+1}\left(\prod_{i\neq 1}^{r}x_i^{\ell_i}\right) = \det[x_i^{\ell_j}-x_i^{-\ell_j}], \tag{B6}$$

for $\mathfrak{W}_{2r+1}$ denoting the SO($2r+1$) Weyl symmetry operator. This time for some highest weight $\ell=\Sigma_{i=1}^{r}\ell_i e_i$ the corresponding Verma module character is given by

$$\begin{aligned}C_{\underline{\ell}}^{(2r+1)}(x) \equiv C_{\underline{\ell}}^{(2r+1)}(\mu) &= \prod_{i=1}^{r}x_i^{\ell_i}\prod_{1\leqslant j<k\leqslant r,\varepsilon=\pm}(1-e^{(\alpha_{jk,\varepsilon},\mu)})^{-1}\prod_{1\leqslant l\leqslant r}(1-e^{(e_l,\mu)})^{-1}\\ &= \prod_{i=1}^{r}x_i^{\ell_i+(1/2)+r-i}\Delta(x_1+x_1^{-1},\ldots,x_r+x_r^{-1})^{-1}(x_1^{1/2}-x_1^{-1/2})^{-1}\cdots(x_r^{1/2}-x_r^{-1/2})^{-1},\end{aligned} \tag{B7}$$

since $-e_i$, $1\leqslant i\leqslant r$ are the weights of the extra negative roots in this case. Using that $\Delta(x_1+x_1^{-1},\ldots,x_r+x_r^{-1})^{-1}(x_1^{1/2}-x_1^{-1/2})^{-1}\cdots(x_r^{1/2}-x_r^{-1/2})^{-1}$ is left alone by any $\varrho\sigma\in\mathcal{S}_r\ltimes\mathbb{Z}^r$ then the Weyl character of the irreducible representation with dominant integral highest weight ℓ is given by, using (B6) and (B7),

$$\chi_{\underline{\ell}}^{(2r+1)}(x) = \det[x_i^{k_j}-x_i^{-k_j}]\Delta(x_1+x_1^{-1},\ldots,x_r+x_r^{-1})^{-1}(x_1^{1/2}-x_1^{(-1/2)})^{-1}\cdots(x_r^{1/2}-x_r^{-1/2})^{-1}, \tag{B8}$$

where $k_i=\ell_i+\frac{1}{2}+r-i$. The dimension of the irreducible representation is given by

$$\dim(\mathcal{I}_{\underline{\ell}}^{(2r+1)}) = \prod_{i=1}^{r}\frac{1}{(2r+1-2i)!}(2\ell_i+2r+1-2i)\prod_{1\leqslant i<j\leqslant r}(\ell_i-\ell_j+j-i)(\ell_i+\ell_j+2r+1-i-j). \tag{B9}$$

APPENDIX C: UNITARITY BOUNDS

Descendant states have bases, for $p=0,1,\ldots$,

$$\mathcal{B}^{(p)} = \left\{\prod_{\substack{v=i\varepsilon,0\\1\leqslant i\leqslant r,\varepsilon=\pm}}\mathcal{P}_v^{n_v}|\Delta;\underline{\ell}'\rangle, \sum_v n_v = p\right\}, \tag{C1}$$

for n_v being positive integers [with $n_0=0$ for SO($2r$)] and ℓ' being a weight in the weight system of the module of SO(d) with highest weight ℓ. For $p=0$ the norms of corresponding states are strictly positive for ℓ' being weights in the SO(d) irreducible representation with dominant integral highest weight ℓ and $\||\Delta;\ell'\rangle\|^2=\langle\Delta,\overline{\underline{\ell}'}\,|\,\Delta,\underline{\ell}'\rangle>0$.

Examining the simplest descendant states with basis $\mathcal{B}^{(1)}$ then these have SO(d) highest weight states

$$\mathcal{H}_d = \{|\Delta+1;\underline{\ell}+\underline{v}\rangle\}, \tag{C2}$$

where $v=\varepsilon e_i$, along with $v=0$ for $d=2r+1$, these of course occurring in the decomposition of the product between the vector representation and the representation with highest weight ℓ into irreducible representations, $e_1\otimes\ell=\oplus_v\ell\oplus v$. Remarkably, most of the restrictions necessary for the

states in $\mathcal{H}_d$ to have positive definite norm are sufficient for the unitarity constraints to be satisfied for all descendant states in $\mathcal{B}^{(p)}$—also conjectured in Ref. 18.

The simplest states in $\mathcal{H}_d$ may be constructed explicitly and are

$$|\Delta+1;\underline{\ell}+\underline{e}_1\rangle = \mathcal{P}_{1+}|\Delta;\underline{\ell}\rangle^{\mathrm{hw}},$$

$$|\Delta+1;\underline{\ell}+\underline{e}_2\rangle = (-2i(\ell_1-\ell_2)\mathcal{P}_{2+}+\mathcal{P}_{1+}E_{12}^{-+})|\Delta;\underline{\ell}\rangle^{\mathrm{hw}}, \tag{C3}$$

$$\begin{aligned}|\Delta+1;\underline{\ell}+\underline{e}_3\rangle = (&-4(\ell_1-\ell_3+1)(\ell_2-\ell_3)\mathcal{P}_{3+}-2i(\ell_1-\ell_3+1)\mathcal{P}_{2+}E_{23}^{-+}\\ &+(\ell_2-\ell_3+1)\mathcal{P}_{1+}E_{12}^{-+}E_{23}^{-+}-(\ell_2-\ell_3)\mathcal{P}_{1+}E_{23}^{-+}E_{12}^{-+})|\Delta;\underline{\ell}\rangle^{\mathrm{hw}},\end{aligned}$$

which are all annihilated by SO(d) raising operators. Using the conformal algebra and the unitarity conditions, the norms of these three states are given by

$$\|\|\Delta+1;\underline{\ell}+\underline{e}_1\rangle\|^2 = 4(\Delta+\ell_1)\|\|\Delta;\underline{\ell}\rangle\|^2,$$

$$\|\|\Delta+1;\underline{\ell}+\underline{e}_2\rangle\|^2 = 16(\Delta+\ell_2-1)(\ell_1-\ell_2)(\ell_1-\ell_2+1)\|\|\Delta;\underline{\ell}\rangle\|^2, \tag{C4}$$

$$\begin{aligned}\|\|\Delta+1;\underline{\ell}+\underline{e}_3\rangle\|^2 = &64(\Delta+\ell_3-2)(\ell_1-\ell_3+1)(\ell_1-\ell_3+2)\\ &\times(\ell_2-\ell_3)(\ell_2-\ell_3+1)\|\|\Delta;\underline{\ell}\rangle\|^2,\end{aligned}$$

and for these to be strictly positive this places obvious restrictions on Δ. Other examples which may be readily achieved are, for SO(3,2),

$$\begin{aligned}&|\Delta+1;\,\ell\,+1\rangle = \mathcal{P}_{1+}|\Delta;\,\ell\,\rangle^{\mathrm{hw}},\quad |\Delta+1;\,\ell\,\rangle = (-2i\,\ell\,\mathcal{P}_0+\mathcal{P}_{1+}E_1^-)|\Delta;\,\ell\,\rangle^{\mathrm{hw}},\\ &|\Delta+1;\,\ell-1\rangle = (2\,\ell\,(2\,\ell-1)\mathcal{P}_{1-}-2i(2\,\ell-1)\mathcal{P}_0E_1^-+\mathcal{P}_{1+}(E_1^-)^2)|\Delta;\,\ell\,\rangle^{\mathrm{hw}},\end{aligned} \tag{C5}$$

for which the norms are

$$\begin{aligned}&\|\|\Delta+1;\,\ell\,+1\rangle\|^2 = 4(\Delta+\,\ell\,)\|\|\Delta;\,\ell\,\rangle\|^2,\quad \|\|\Delta+1;\,\ell\,\rangle\|^2 = 8(\Delta-1)\,\ell\,(\ell+1)\|\|\Delta;\,\ell\,\rangle\|^2,\\ &\|\|\Delta+1;\,\ell-1\rangle\|^2 = 16(\Delta-\,\ell-1)\ell^2(4\ell^2-1)\|\|\Delta;\,\ell\,\rangle\|^2.\end{aligned} \tag{C6}$$

Another important example is for SO(4,2) whereby along with (C3), for $\underline{\ell}=(\ell_1,\ell_2)$, we also have

$$\begin{aligned}&|\Delta+1;\ell_1,\ell_2-1\rangle = (-2i(\ell_1+\ell_2)\mathcal{P}_{2-}+\mathcal{P}_{1+}E_{12}^{--})|\Delta;\underline{\ell}\rangle^{\mathrm{hw}},\\ &|\Delta+1;\ell_1-1,\ell_2\rangle = (-4(\ell_1^2-\ell_2^2)\mathcal{P}_{1-}-2i(\ell_1-\ell_2)\mathcal{P}_{2+}E_{12}^{--}-2_i(\ell_1+\ell_2)\mathcal{P}_{2-}E_{12}^{-+}+\mathcal{P}_{1+}E_{12}^{-+}E_{12}^{--})\\ &\qquad\times|\Delta;\underline{\ell}\rangle^{\mathrm{hw}},\end{aligned} \tag{C7}$$

for which the norms are

$$\begin{aligned}&\|\|\Delta+1;\ell_1,\ell_2-1\rangle\|^2 = 16(\Delta-\ell_2-1)(\ell_1+\ell_2)(\ell_1+\ell_2+1)\|\|\Delta;\underline{\ell}\rangle\|^2,\\ &\|\|\Delta+1;\ell_1-1,\ell_2\rangle\|^2 = 64(\Delta-\ell_1-2)(\ell_1^2-\ell_2^2)(\ell_1-\ell_1+1)(\ell_1+\ell_2+1)\|\|\Delta;\underline{\ell}\rangle\|^2.\end{aligned} \tag{C8}$$

Constructing other such elements of $\mathcal{H}_d$ is cumbersome. We here outline a simpler procedure for finding the unitarity constraints for $B^{(1)}$. The norms of the highest weight states in $\mathcal{H}_d$ are more generally given by

$$\|\|\Delta+1;\underline{\ell}+\underline{v}\rangle\|^2=(\Delta+g_{\underline{\ell}}^{(v)})f_{\ell}^{(v)}, \tag{C9}$$

where the functions $f_{\ell}^{(v)}$ are strictly positive for ℓ being strictly inside the dominant Weyl chamber, (3.1) or (3.2). We have that, assuming that ℓ is strictly inside the dominant Weyl chamber,

$$\mathcal{K}_{1-}|\Delta+1;\underline{\ell}+\underline{v}\rangle=0\Rightarrow\Delta+g_{\underline{\ell}}^{(v)}=0, \tag{C10}$$

which is in turn implied by the state $|\Delta+1;\underline{\ell}+\underline{v}\rangle$ being null. As an aid to solving (C10) we extend the definition of $\mathcal{B}^{(1)}$ in (C1) and consider $\ell'\in\mathcal{V}_{\ell}$ (the Verma module with dominant integral highest weight ℓ). Consider the following highest weight states with respect to SO(d), namely,

$$|\Delta+1;\underline{\ell}^{w_v}+\underline{e}_1\rangle=\mathcal{P}_{1+}|\Delta;\underline{\ell}^{w_v}\rangle,\quad \mathcal{K}_{1-}|\Delta+1;\underline{\ell}^{w_v}+\underline{e}_1\rangle=0\Rightarrow\Delta+\ell_1^{w_v}=0, \tag{C11}$$

where w_v are such members of the Weyl group $\mathcal{W}_r$ for which

$$\ell^{w_v}+e_1=(\ell+w_v^{-1}(e_1))^{w_v}=(\ell+v)^{w_v}, \tag{C12}$$

for some $v=\varepsilon e_j$ for $\varepsilon=\pm$. [Note that for SO($2r+1$) the vector $v=0$ is not on the Weyl orbit of e_1—we need a different approach to deal with this.] Thus the states (C11) are related to those in $\mathcal{H}_d$ by the action of SO(d) lowering operators on $|\Delta+1;\underline{\ell}+\underline{v}\rangle$. [For instance, we have that $|\Delta+1;\underline{\ell}^{\sigma_{12}}+\underline{e}_1\rangle=(E_{12}^{-+})^{\ell_1-\ell_2}|\Delta+1;\underline{\ell}+\underline{e}_2\rangle$ for $\sigma_{12}(\ell_1,\ell_2,\ldots)=(\underline{\ell}_2,\ell_1,\ldots)$ and with $|\Delta+1,\underline{\ell}+\underline{e}_2\rangle$ given in (C7).] Also, $\mathcal{K}_{1-}$ commutes with all such lowering operators so that the conditions (C10) and (C11) should be identical. Thus, using (3.14) [for $\varepsilon_1=\varepsilon,\sigma(1)=j$],

$$g_{\underline{\ell}}^{(\varepsilon e_j)}=\ell_1^{w_{\varepsilon e_j}}=\varepsilon\ell_j+(\varepsilon-1)\tfrac{1}{2}d-\varepsilon j+1, \tag{C13}$$

determining $g_{\ell}^{(v)}$, $v\neq0$ in (C9) for the states in $\mathcal{H}_d$.

To deal with the state $|\Delta+1;\ell\rangle\in\mathcal{H}_{2r+1}$ for SO($2r+1,2$) we first note an interesting observation. Consider the state $|\Delta+1;\underline{\ell}+\underline{e}_{r+1}\rangle\in\mathcal{H}_{2r+2}$ which is given by

$$|\Delta+1;\underline{\ell}+\underline{e}_{r+1}\rangle=\left(A_{\underline{\ell}}\mathcal{P}_{r+1+}+\sum_{1\leqslant i\leqslant r,\sigma}B_{\underline{\ell},i,\sigma}\mathcal{P}_{i+}E_{\sigma(ii+1)}^{-+}E_{\sigma(i+1i+2)}^{-+}\cdots E_{\sigma(rr+1)}^{-+}\right)|\Delta,\underline{\ell}\rangle^{\mathrm{hw}}, \tag{C14}$$

where σ permutes $(ii+1),\ldots,(rr+1)$ and $A_{\underline{\ell}}$, $B_{\underline{\ell},i,\sigma}$ are determined from the requirement that $E_{12}^{+-},\ldots,E_{rr+1}^{+-}$ annihilate the state (E_{rr+1}^{++} automatically annihilates it). Defining $\widetilde{A}_{(\ell_1,\ldots,\ell_r)}=A_{(\ell_1,\ldots,\ell_r,0)},\widetilde{B}_{(\ell_1,\ldots,\ell_r),i,\sigma}=B_{(\ell_1,\ldots,\ell_r,0),i,\sigma}$, then we claim that $|\Delta+1;\ell\rangle\in\mathcal{H}_{2r+1}$ is given by

$$|\Delta+1;\underline{\ell}\rangle=\left(\widetilde{A}_{\underline{\ell}}\mathcal{P}_0+\sum_{1\leqslant i\leqslant r,\sigma}\widetilde{B}_{\underline{\ell},i,\sigma}\mathcal{P}_i^{+}E_{\sigma(ii+1)}^{-+}E_{\sigma(i+1i+2)}^{-+}\cdots E_{\sigma(r)}^{-}\right)|\Delta,\underline{\ell}\rangle^{\mathrm{hw}}, \tag{C15}$$

where now σ permutes $(ii+1),\ldots,(r)$. This follows when we show that the conditions on $\widetilde{A}_{\ell},\widetilde{B}_{\underline{\ell},i,\sigma}$ arising from $E_{ii+1}^{+-},E_r^{+},1\leqslant i\leqslant r-1$ annihilating (C15) are exactly equivalent to those on $\bar{A}_{\underline{\ell}}B_{\underline{\ell},i,\sigma}$ arising from $E_{ii+1}^{+-},E_{rr+1}^{+-},1\leqslant i\leqslant r-1$ annihilating (C14) for $\ell_{r+1}=0$ if we identify $\mathcal{P}_0$ with $\mathcal{P}_{r+1}$ and $E_r^{-}$with E_{rr+1}^{-+}. We have that $[\mathcal{K}_{1-},\mathcal{P}_{r+1+}]=-2iE_{1r+1}^{-+}=(-2i)^{1-r}[E_{12}^{-+},\ldots,[E_{r-1r}^{-+},E_{rr+1}^{-+}]\cdots]$ and $[\mathcal{K}_{1-},\mathcal{P}_0]=-2iE_1^{-}=(-2i)^{1-r}[E_{12}^{-+},\ldots,[E_{r-1r}^{-+},E_r^{-}]\cdots]$. Due to this and as $\widetilde{A}_{(\ell_1,\ldots,\ell_r)}=A_{(\ell_1,\ldots,\ell_r,0)},\widetilde{B}_{(\ell_1,\ldots,\ell_r),i,\sigma}=B_{(\ell_1,\ldots,\ell_r,0),i,\sigma}$ then $\mathcal{K}_{1-}$ annihilating (C14) for $\ell_{r+1}=0$ results in the same equations for Δ as for $\mathcal{K}_{1-}$ annihilating (C15) if we identify E_{rr+1}^{-+} with E_r^{-}. Thus, from (C13) for $j=r+1,\varepsilon=+,\ell_{r+1}=0$,

$$\mathcal{K}_{1-}|\Delta+1,\underline{\ell}\rangle=0\Rightarrow g_{\underline{\ell}}^{(0)}=-r. \tag{C16}$$

Now that we have determined $g_{\ell}^{(v)}$ in (C9) to be given by (C13) and (C16), we may determine the unitarity bounds for states in $\mathcal{B}^{(\mathrm{T})}$, the simplest descendants. For $\mathcal{H}_d$ and $\ell_1=\cdots=\ell_p>|\ell_{p+1}|$,

$p \leqslant r-1$ then we have that $f^{(v)}_{\underline{\ell}}=0$ in (C9) for $v=-e_1, \varepsilon e_j, e_p$, $j=2,\ldots,p-1$ [here and in the following, this is because the corresponding states $|\Delta+1;\underline{\ell}+\underline{v}\rangle$ for ℓ being on the boundary of the dominant Weyl chamber are null as SO(d) representations] and that

$$\begin{aligned}\Delta &\geqslant \max\{-g^{(e_1)}_{\underline{\ell}}, -g^{(-e_p)}_{\underline{\ell}}, -g^{(e_j)}_{\underline{\ell}}, -g^{(-e_j)}_{\underline{\ell}}, p+1 \leqslant j \leqslant r\} \cup \{-g^{(0)}_{\underline{\ell}} \text{ for } d=2r+1\} \\ &= -g^{(-e_p)}_{\underline{\ell}} = \ell_1 + d - p - 1, \end{aligned} \tag{C17}$$

which matches the first requirement in (3.8). At the unitarity bound $\Delta=\ell_1+d-p-1$ then all the states $|\Delta+1;\underline{\ell}+\underline{v}\rangle$ for $v=-e_1, \varepsilon e_j, 2 \leqslant j \leqslant p$ in $\mathcal{H}_d$ are null.

In even dimensions, for $\ell_1=\cdots=\pm\ell_r$ for $\mathcal{H}_{2r}$ then we have that $f^{(v)}_{\underline{\ell}}=0$ in (C9) for $v=-e_1, \varepsilon e_j, \pm e_r$, $j=2,\ldots,r-1$,

$$\Delta \geqslant \max\{-g^{(e_1)}_{\underline{\ell}}, -g^{(\mp e_r)}_{\underline{\ell}}\} = \ell_1 + r - 1, \tag{C18}$$

with in addition the state $|\Delta+1;\underline{\ell} \mp \underline{e}_r\rangle$ being null at the unitarity bound.

In odd dimensions, for $\ell_1=\cdots=\ell_r>\frac{1}{2}$ for $\mathcal{H}_{2r+1}$ then $f^{(v)}_{\underline{\ell}}=0$ in (C9) for $v=-e_1, \varepsilon e_j, e_r$, $j=2,\ldots,r-1$ and

$$\Delta \geqslant \max\{-g^{(e_1)}_{\underline{\ell}}, -g^{(-e_r)}_{\underline{\ell}}, -g^{(0)}_{\underline{\ell}}\} = \ell_1 + r, \tag{C19}$$

with in addition the state $|\Delta+1, \underline{\ell}-\underline{e}_r\rangle$ being null at the unitarity bound. For $\ell_1=\cdots=\ell_r=\frac{1}{2}$ then $f^{(v)}_{\underline{\ell}}=0$ in (C9) for $v=-e_1, \varepsilon e_j$, $j=2,\ldots,r$ and

$$\Delta \geqslant \max\{-g^{(e_1)}_{\underline{\ell}}, -g^{(0)}_{\underline{\ell}}\} = r = \left[\tfrac{1}{2}d\right], \tag{C20}$$

with the state $|\Delta+1, \underline{\ell}\rangle$ being null at the unitarity bound.

APPENDIX D: EXPANSION AND PRODUCT FORMULAS

In this appendix various formulas from Sec. IV are proven. We make use of a simple property of the function $P^{(d)}(s,x)$ defined for $d=2r$ in (3.19) and $d=2r+1$ in (3.30). Under the action of the Weyl symmetry operator $\mathfrak{W}_d$ (defined in Appendixes A and B) it obeys

$$\mathfrak{W}_d(f(s,x)P^{(d)}(s,x)) = \mathfrak{W}_d(f(s,x))P^{(d)}(s,x), \tag{D1}$$

for any $f(s,x)$, as $P^{(d)}(s,x)$ is invariant under the action of any element of the SO(d) Weyl group, $\mathcal{W}_d$. Note also that $\mathcal{W}_d$ has no effect on the variable s.

We discuss the even dimensional cases of (4.11), (4.14), (4.15) first. For (4.14) we have that

$$\sum_{q=0}^{\infty} s^{\ell+r+q-1}\chi^{(2r)}_{(\ell+q,\ell,\ldots,\pm\ell)}(x) = s^{\ell+r-1}\mathfrak{W}_{2r}\left(\sum_{q=0}^{\infty}(sx_1)^q C^{(2r)}_{(\ell,\ldots,\pm\ell)}(x)\right) = s^{\ell+r-1}\mathfrak{W}_{2r}\left(\frac{1}{1-sx_1}C^{(2r)}_{(\ell,\ldots,\pm\ell)}(x)\right), \tag{D2}$$

which follows just by the definition of the character of the irreducible representation (B4) in terms of the Verma module character (B3). Using (D1) then (D2) may be rewritten as

$$\begin{aligned} &s^{\ell+r-1}P^{(2r)}(s,x)\mathfrak{W}_{2r}\left((1-sx_1^{-1})\prod_{i=2}^{r}(1-sx_i)(1-sx_i^{-1})C^{(2r)}_{(\ell,\ldots,\pm\ell)}(x)\right) \\ &\quad = s^{\ell+r-1}P^{(2r)}(s,x)\sum_{\substack{n_{i-},n_{j+}=0,1 \\ 0\leqslant n=\sum n_{i\varepsilon}\leqslant 2r-2}}(-s)^n\chi^{(2r)}_{(\ell-n_{1-},\ell+n_{2+}-n_{2-},\ldots,\pm\ell+n_{r+}-n_{r-})}(x). \end{aligned} \tag{D3}$$

For $n>0$ in (D3) we may use

$$\chi^{(d)}_{(\ell_1,\ldots,\ell_j,\ell-1,\ell+1,\ell_{j+3},\ldots,\ell_r)}(x) = -\chi^{(d)}_{(\ell_1,\ldots,\ell_j,\ell,\ell,\ell_{j+3},\ldots,\ell_r)}(x), \tag{D4}$$

to show that the contributions for given n reduce to a single one from

$$\begin{gathered}\chi^{(2r)}_{(\ell,\ldots,\ell,\ell-1,\ldots,\ell-1,\pm\ell\mp1)}(x),\\ \uparrow\\ n\text{th position}\end{gathered} \tag{D5}$$

with all contributions for $n>r$ vanishing. Hence we have that (D2) reduces to $\mathcal{D}^{(2r)}_{[\ell+r-1,\ell]_\pm}(s,x)$ defined in (3.26) thus proving (4.14). Notice that (4.11) is a special case of (4.14) when we take $\ell=0$ in the latter [whereby, as mentioned before, $\mathcal{D}^{(2r)}_{[\ell+r-1,\ell]_\pm}(s,x)\to s^{r-1}(1-s^2)P^{(2r)}(s,x)$].

We may prove (4.15) in a very similar way. The sum on the right-hand side of (4.15) may be reduced to

$$s^{\ell+r+j-1}\mathfrak{W}_{2r}\left((1-sx_1)^{-1}\prod_{i=r-j+1}^{r}(1-sx_i)^{-1}(1-sx_i^{-1})^{-1}C^{(2r)}_{(\ell,\ldots,\ell,\ell_1,\ldots,\ell_j)}(x)\right), \tag{D6}$$

in a similar fashion as (D2), when we perform the sums over $p_1,\ldots,p_j,q$. This may be rewritten using (D1) as

$$\begin{aligned}&s^{\ell+r+j-1}P^{(2r)}(s,x)\mathfrak{W}_{2r}\left((1-sx_1)\prod_{i=2}^{r-j}(1-sx_i)(1-sx_i^{-1})C^{(2r)}_{(\ell,\ldots,\ell,\ell_1,\ldots,\ell_j)}(x)\right)\\ &\quad= s^{\ell+r+j-1}P^{(2r)}(s,x)\sum_{\substack{n_{i-},n_{j+}=0,1\\ 0\leqslant n=\sum n_{i\varepsilon}\leqslant 2r-2j-2}}(-s)^n\chi^{(2r)}_{(\ell-n_{1-},\ell+n_{2+}-n_{2-},\ldots,\ell+n_{r-j+}-n_{r-j-},\ell_1,\ldots,\ell_r)}(x).\end{aligned} \tag{D7}$$

For similar reasons as before, for $n>0$ the contributions for given n reduce to a single one from

$$\begin{gathered}\chi^{(2r)}_{(\ell,\ldots,\ell,\ell-1,\ldots,\ell-1,\ell_1,\ldots,\ell_j)}(x),\\ \uparrow\\ n\text{th position}\end{gathered} \tag{D8}$$

so that (D7) equals $\mathcal{D}^{(2r)}_{[\ell+r+j-1,\ell,\ell_1,\ldots,\ell_j]}(s,x)$ in (3.25) for $p=r-j$.

Turning to the odd dimensional cases of (4.27), (4.29), (4.30), (4.31) these may be proven in a very similar way as for the even dimensional cases when we use (D1). Note that we may use the definition of the irreducible character (B8) in terms of the Verma module character (B7) and (3.30) to rewrite the sum on the right-hand side of (4.30) as

$$\begin{aligned}&s^rP^{(2r+1)}(s,x)(1-s)\mathfrak{W}_{2r+1}\left((1-sx_1^{-1})\prod_{i=2}^{r}(1-sx_i)(1-sx_i^{-1})C^{(2r+1)}_{(1/2,\ldots,1/2)}(x)\right)\\ &\quad= s^rP^{(2r+1)}(s,x)(1-s)\chi^{(2r+1)}_{(1/2,\ldots,1/2)}(x),\end{aligned} \tag{D9}$$

which matches (3.34). The free scalar case of (4.29) follows in a similar fashion. The identity (4.27) is in fact equivalent to (4.29). The sum on the right-hand side of (4.31) may be rewritten as

$$s^{\ell+r+j}\mathfrak{W}_{2r+1}\left((1-s)^{-1}(1-sx_1)^{-1}\prod_{i=r-j+1}^{r}(1-sx_i)^{-1}(1-sx_i^{-1})^{-1}C^{(2r+1)}_{(\ell,\ldots,\ell,\ell_1,\ldots,\ell_j)}(x)\right), \tag{D10}$$

when we perform the sums over p_i,q,t. This may be rewritten as

$$s^{\ell+r+j}P^{(2r+1)}(s,x)\mathfrak{W}_{2r+1}\left((1-sx_1)\prod_{i=2}^{r-j}(1-sx_i)(1-sx_i^{-1})C^{(2r+1)}_{(\ell,\ldots,\ell,\ell_1,\ldots,\ell_j)}(x)\right)$$
$$= s^{\ell+r+j}P^{(2r+1)}(s,x)\sum_{\substack{n_{i-},n_{j+}=0,1\\ 0\leqslant n=\sum n_{i\varepsilon}\leqslant 2r-2j-2}}(-s)^n\chi^{(2r+1)}_{(\ell-n_{1-},\ell+n_{2+}-n_{2-},\ldots,\ell+n_{r-j+}-n_{r-j-},\ell_1,\ldots,\ell_r)}(x). \tag{D11}$$

Using (D4), for $n>0$ the contributions for given n reduce to a single one from

$$\chi^{(2r+1)}_{(\ell,\ldots,\ell,\underset{\uparrow}{\ell-1},\ldots,\ell-1,\ell_1,\ldots,\ell_j)}(x), \qquad \begin{matrix}\\ n\text{th position}\end{matrix} \tag{D12}$$

so that (D11) equals $\mathcal{D}^{(2r+1)}_{[\ell+r+j,\ell,\ell_1,\ldots,\ell_j]}(s,x)$ in (3.32) for $p=r-j$.

To prove some product formulas we will use the expansions above and the following:

$$\mathfrak{W}_d(f(x)\chi^{(d)}_\ell(x))=\mathfrak{W}_d(f(x))\chi^{(d)}_\ell(x), \tag{D13}$$

for any $f(x)$.

For even dimensions we now prove (4.22) and (4.23) for $\ell'=\frac{1}{2}$. In this case we have that

$$\mathcal{D}^{(4m+2)}_{[(1/2)+2m;(1/2)]\pm}(s,x)=s^{(1/2)+2m}(\chi^{(4m+2)}_{(1/2,\ldots,1/2,\pm 1/2)}(x)-s\chi^{(4m+2)}_{(1/2,\ldots,1/2,\mp 1/2)}(x)), \tag{D14}$$

where we may determine from (B4) that

$$\chi^{(4m+2)}_{(1/2,\ldots,1/2)}(x)=\prod_{i=1}^{2m+1}x_i^{-1/2}\sum_{\substack{m\geqslant t\geqslant 0\\ 2m+1\geqslant j_1>\cdots>j_{2t+1}\geqslant 1}}x_{j_1}\cdots x_{j_{2t+1}},$$
$$\chi^{(4m+2)}_{(1/2,\ldots,-1/2)}(x)=\prod_{i=1}^{2m+1}x_i^{-1/2}\left(1+\sum_{\substack{m\geqslant t\geqslant 1\\ 2m+1\geqslant j_1>\cdots>j_{2t}\geqslant 1}}x_{j_1}\cdots x_{j_{2t}}\right). \tag{D15}$$

We use (D14) and (4.14) to expand $\mathcal{D}^{(4m+2)}_{[\ell+2m,\ell]\pm}(s,x)$ in (4.22) and then match powers of s on both sides. Clearly the O(1) terms on both sides of (4.22) agree. At O(s^q) for $q\geqslant 1$ we must show that

$$\chi^{(4m+2)}_{(\ell+q,\ell,\ldots,\ell)}(x)\chi^{(4m+2)}_{(1/2,\ldots,-1/2)}(x)-\chi^{(4m+2)}_{(\ell+q-1,\ell,\ldots,\ell)}(x)\chi^{(4m+2)}_{(1/2,\ldots,1/2)}(x)$$
$$=\sum_{\substack{t_i=\ell\pm(1/2)\\ t_i\geqslant t_{i+1}}}\chi^{(4m+2)}_{[\ell+(1/2)+q,\ell+(1/2),t_1,t_1,\ldots,t_{m-1},t_{m-1},\ell-(1/2)]}(x)-\chi^{(4m+2)}_{[\ell+(1/2)+q-2,\ell+(1/2),t_1,t_1,\ldots,t_{m-1},t_{m-1},\ell-(1/2)]}(x). \tag{D16}$$

Using (D13) and (D15) we may rewrite the left-hand side of (D16) as

$$\mathfrak{W}_{(4m+2)}(C^{(4m+2)}_{(\ell+q,\ell,\ldots,\ell)}(x)\chi^{(4m+2)}_{(1/2,\ldots,-1/2)}(x)-C^{(4m+2)}_{(\ell+q-1,\ell,\ldots,\ell)}(x)\chi^{(4m+2)}_{(1/2,\ldots,1/2)}(x))$$
$$=\mathfrak{W}_{4m+2}\left(C^{(4m+2)}_{[\ell+q-(3/2),\ell-(1/2),\ldots,\ell-(1/2)]}(x)(x_1^2-1)\sum_{\substack{m\geqslant t\geqslant 1\\ 2m+1\geqslant j_1>\cdots>j_{2t-1}\geqslant 2}}x_{j_1}\cdots x_{j_{2t-1}}\right). \tag{D17}$$

For $q\geqslant 1$ most of the terms in (D17) vanish under the action of the Weyl symmetry operator and it reduces to

$$\mathfrak{W}_{4m+2}\left(C^{(4m+2)}_{[\ell+q-(3/2),\ell-(1/2),\ldots,\ell-(1/2)]}(x)(x_1^2-1)\sum_{t=1}^{m}x_2x_3\cdots x_{2t}\right), \tag{D18}$$

and from here it is easy to show that this agrees with the right-hand side of (D16).

Similarly, using (D14) and (4.14) to expand $\mathcal{D}^{(4m+2)}_{[\ell+2m,\ell]_\pm}(s,x)$ in (4.23), then matching powers of s on both sides of the equation (4.23) we must show that for $q\geqslant 0$,

$$\begin{aligned}&\chi^{(4m+2)}_{(\ell+q,\ell,\ldots,\varepsilon\ell)}(x)\chi^{(4m+2)}_{[1/2,\ldots,\varepsilon(1/2)]}(x)-\chi^{(4m+2)}_{(\ell+q-1,\ell,\ldots,\varepsilon\ell)}(x)\chi^{(4m+2)}_{[1/2,\ldots,-\varepsilon(1/2)]}(x)\\&\quad=\sum_{\substack{t_i=\ell\pm(1/2)\\ t_i\geqslant t_i+1}}\chi^{(4m+2)}_{[\ell+(1/2)+q,t_1,t_1,\ldots,t_m,\varepsilon t_m]}(x)-\chi^{(4m+2)}_{[\ell+(1/2)+q-2,t_1,t_1,\ldots,t_m,\varepsilon t_m]}(x),\end{aligned} \tag{D19}$$

for $\varepsilon=\pm$. Using (D13) and (D15) we may rewrite the left-hand side of (D19) for $\varepsilon=+$ as

$$\begin{aligned}&\mathfrak{W}_{4m+2}(C^{(4m+2)}_{(\ell+q,\ell,\ldots,\ell)}(x)\chi^{(4m+2)}_{(1/2,\ldots,1/2)}(x)-C^{(4m+2)}_{(\ell+q-1,\ell,\ldots,\ell)}(x)\chi^{(4m+2)}_{(1/2,\ldots,-1/2)}(x))\\&\quad=\mathfrak{W}_{4m+2}\left(C^{(4m+2)}_{[\ell+q-(3/2),\ell-(1/2),\ldots,\ell-(1/2)]}(x)(x_1^2-1)\left(1+\sum_{\substack{m\geqslant t\geqslant 1\\ 2m+1\geqslant j_1>\ldots>j_{2t}\geqslant 2}}x_{j_1}\cdots x_{j_{2t}}\right)\right).\end{aligned} \tag{D20}$$

For $q\geqslant 0$ most of the terms in (D20) vanish under the action of the Weyl symmetry operator and it reduces to

$$\mathfrak{W}_{4m+2}\left(C^{(4m+2)}_{[\ell+q-(3/2)\ell-(1/2),\ldots,\ell-(1/2)]}(x)(x_1^2-1)\left(1+\sum_{t=1}^{m}x_2x_3\cdots x_{2t+1}\right)\right), \tag{D21}$$

and from here it is easy to show that this agrees with the right-hand side of (D19) for $\varepsilon=+$.

We also have that

$$\mathcal{D}^{(4m)}_{[(1/2)+2m-1;(1/2)]_\pm}(s,x)=s^{(1/2)+2m-1}\left(\chi^{(4m)}_{(1/2,\ldots,1/2,\pm 1/2)}(x)-s\chi^{(4m)}_{(1/2,\ldots,1/2,\mp 1/2)}(x)\right), \tag{D22}$$

where,

$$\begin{aligned}\chi^{(4m)}_{(1/2,\ldots,-1/2)}(x)&=\prod_{i=1}^{2m}x_i^{-1/2}\sum_{\substack{m-1\geqslant t\geqslant 0\\ 2m\geqslant j_1>\ldots>j_{2t+1}\geqslant 1}}x_{j_1}\cdots x_{j_{2t+1}},\\ \chi^{(4m)}_{(1/2,\ldots,1/2)}(x)&=\prod_{i=1}^{2m}x_i^{-1/2}\left(1+\sum_{\substack{m\geqslant t\geqslant 1\\ 2m\geqslant j_1>\ldots>j_{2t}\geqslant 1}}x_{j_1}\cdots x_{j_{2t}}\right),\end{aligned} \tag{D23}$$

and this allows similar product formulas in $d=4m$ dimensions to be derived straightforwardly in an analogous fashion as above.

We present an analysis of the behavior of the electromagnetic self-force for charged particles in a conformally static spacetime, interpreting the results with the help of optical geometry. Some conditions for the vanishing of the local terms in the self-force are derived and discussed. © *2006 American Institute of Physics.*

I. INTRODUCTION

The motion of a point particle with mass m, electric charge e, and four-velocity v^a is described by

$$ma_a = K_a + F_a, \tag{1.1}$$

where $a_a := v^b \nabla_b v_a$ is the particle four-acceleration, K_a is the sum of the external four-forces acting on the particle, and F_a accounts for the backreaction of the particle's own electromagnetic field on its motion. [We use latin indices a, b,… from the beginning of the alphabet as abstract indices,[1] while greek letters μ, ν,… denote components in some chart and run from 0 to 3. We work in units in which $G=c=1$, and choose the positive signature for the metric. We follow the conventions of Ref. 1 for the curvature tensors; the Ricci tensor R_{ab} has then the opposite sign than in Refs. 2 and 3.] In contrast to a well-established tradition, we shall avoid referring to F_a as the *radiation reaction*, because such terminology is somehow improper and can be misleading;[4,5] we shall use the term *self-force* instead. According to the classic analysis of DeWitt-Brehme-Hobbs,[2,3] F_a can be written as the sum of two contributions, $F_a = F_a^{(\mathrm{l})} + F_a^{(\mathrm{nl})}$, where

$$F_a^{(\mathrm{l})} = \tfrac{2}{3} e^2 k_a{}^b v^c \nabla_c a_b + \tfrac{1}{3} e^2 k_a{}^b R_{bc} v^c \tag{1.2}$$

and

$$F_a^{(\mathrm{nl})} = e^2 v^b \int_{-\infty}^{\tau} \mathrm{d}\tau' f_{aba'} v^{a'}. \tag{1.3}$$

[The equation of motion obtained putting together (1.1)–(1.3) contains third derivatives of the particle coordinates, and hence leads to unphysical conclusions such as preacceleration and runaway solutions, as it happens for the Lorentz-Dirac equation in flat spacetime.[4] These pathologies can be removed by a reduction-of-order technique.[6] Nevertheless, in the following we shall consider the standard expression (1.2) for $F_a^{(\mathrm{l})}$, that differs from the one so obtained only to higher orders, and is therefore equivalent to it as long as one limits oneself to the classical domain, in

[a)]Electronic mail: sebastiano.sonego@uniud.it
[b)]Electronic mail: marek@fy.chalmers.se

which the theory is defined.] Here v^a and τ are the four-velocity and proper time of the particle, $k_a{}^b=\delta_a{}^b+v_a v^b$ is the projector onto the three-space orthogonal to v^a, R_{ab} is the Ricci tensor, and $f_{aba'}$ is a bi-tensor associated with the presence of "tails" in the electromagnetic field.[2,7] The term $F_a^{(\mathrm{l})}$ is the relativistic generalization to a curved spacetime of the noncovariant expression $(2/3)e^2\ddot{\mathbf{v}}$ for the self-force,[4,5] and can be regarded as purely local, as it depends only on quantities evaluated at the actual position of the particle. On the contrary, the contribution $F_a^{(\mathrm{nl})}$ depends on the entire past history of the particle and on the property of spacetime of being able to backscatter electromagnetic waves,[2,7] encapsulated in the quantity $f_{aba'}$, and represents therefore an essentially nonlocal contribution. The two terms on the right-hand side of (1.2) are known as the von Laue[4,5] and the Hobbs[3] forces, respectively. We shall denote them as

$$F_a^{(\mathrm{vL})} := \tfrac{2}{3}e^2 k_a{}^b v^c \nabla_c a_b \tag{1.4}$$

and

$$F_a^{(\mathrm{H})} := \tfrac{1}{3}e^2 k_a{}^b R_{bc} v^c, \tag{1.5}$$

so (1.2) can be rewritten as $F_a^{(\mathrm{l})}=F_a^{(\mathrm{vL})}+F_a^{(\mathrm{H})}$. [Noteworthy, the von Laue force can also be written as $F_a^{(\mathrm{vL})}=\frac{2}{3}e^2\nabla_{(v)}^{(\mathrm{FW})}a_a$, where $\nabla_{(v)}^{(\mathrm{FW})}$ is the Fermi-Walker derivative along v^a, which for a generic field of one-forms u_a is[8] $\nabla_{(v)}^{(\mathrm{FW})}u_a := v^b\nabla_b u_a+(a_a v^b - v_a a^b)u_b$. Hence, the von Laue term $F_a^{(\mathrm{vL})}$ vanishes iff the acceleration a_a is Fermi-Walker transported along the particle worldline.] It should be clear from the outset that all this, as well as the treatment that follows, applies to classical point particles—an unrealistic model which presents pathologies, given that the size of a classical object cannot be smaller than its Compton wavelength. The extension to particles of a finite size has been discussed recently.[9]

In the last decade there has been a renewed interest in calculations of self-forces of different nature. The main motivation for such a revival is the possibility to go beyond the test particle approximation when studying motion in a gravitational field, which is important for investigations about the generation of gravitational waves. (For recent reviews, see Ref. 10, and references therein.) However, due to the complexity of the calculations in the gravitational case, several authors have considered simpler models involving the scalar and electromagnetic self-interactions, which are also interesting by themselves. In particular, much attention has been paid to the nonlocal contribution. In this article we shall instead focus on the behavior of the local term $F_a^{(\mathrm{l})}$ for the electromagnetic case, arguing that it can be understood more easily in terms of the so-called optical geometry, rather than of the usual geometry of spacetime. A similar analysis could be carried out for scalar and gravitational self-forces, but we shall not cover such cases here. Also, we leave for further investigation the issue of whether optical geometry could be successfully applied to the challenging problem of computing the nonlocal term (see, however, the end of Sec. V for a brief discussion of this point).

We begin by considering, in the next section, a situation in which the charge moves uniformly on a circular orbit in a static, spherically symmetric spacetime, comparing the results in the special cases of Einstein's universe and Schwarzschild spacetime. For the latter, we shall see that $F_a^{(\mathrm{l})}=0$ at the closed photon orbit $r=3M$. This property will be interpreted in Sec. III by introducing the notion of optical geometry, in which light paths on $t=$const hypersurfaces are geodesics. In Sec. IV we generalize the analysis to an arbitrary conformally static spacetime, showing that if a charge moves with constant speed along a possible light path, the self-force is the one associated with optical geometry (apart from an obvious conformal rescaling), and providing other conditions for the different parts of the self-force to vanish. Section V contains a brief summary of the results.

II. UNIFORM CIRCULAR MOTION IN STATIC SPHERICALLY SYMMETRIC SPACETIMES

Let us begin by discussing a rather special, but highly significant case. Consider a charge moving on a circular orbit $r=\text{const}$ in the plane $\theta=\pi/2$ of a static, spherically symmetric spacetime, with metric

$$g=-e^{2\Phi(r)}\mathrm{d}t^2+\alpha(r)\mathrm{d}r^2+r^2(\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\varphi^2), \tag{2.1}$$

where Φ and α are known functions, with α positive. The components of the four-velocity are

$$v^\mu=\Gamma(\delta^\mu_t+\Omega\delta^\mu_\varphi), \tag{2.2}$$

where Ω is a parameter and $\Gamma=(e^{2\Phi}-\Omega^2r^2)^{-1/2}$ is fixed by the normalization $v_\mu v^\mu=-1$. It is convenient to introduce the velocity $v=e^{-\Phi}\Omega r$ measured by static observers, and the corresponding Lorentz factor $\gamma:=(1-v^2)^{-1/2}=e^{\Phi}\Gamma$.

If the motion is uniform, i.e., $\Omega=\text{const}$, the only nonvanishing component of the acceleration is

$$a_r=\Gamma^2\left(e^{2\Phi}\frac{\mathrm{d}\Phi}{\mathrm{d}r}-\Omega^2r\right), \tag{2.3}$$

and the von Laue force is given by

$$F^{(\mathrm{vL})}_\mu=\frac{2}{3}e^2\gamma^5\Omega r\frac{e^{-\Phi}}{\alpha}\left(1-r\frac{\mathrm{d}\Phi}{\mathrm{d}r}\right)\left(e^{2\Phi}\frac{\mathrm{d}\Phi}{\mathrm{d}r}-\Omega^2r\right)(-\Omega\delta^t_\mu+\delta^\varphi_\mu). \tag{2.4}$$

The Hobbs term is

$$F^{(\mathrm{H})}_\mu=\tfrac{1}{3}e^2\gamma^3\Omega e^{-\Phi}(e^{-2\Phi}r^2R_{tt}+R_{\varphi\varphi})(-\Omega\delta^t_\mu+\delta^\varphi_\mu), \tag{2.5}$$

where

$$R_{tt}=\frac{e^{2\Phi}}{\alpha}\left(\frac{\mathrm{d}^2\Phi}{\mathrm{d}r^2}+\frac{2}{r}\frac{\mathrm{d}\Phi}{\mathrm{d}r}+\left(\frac{\mathrm{d}\Phi}{\mathrm{d}r}\right)^2-\frac{1}{2\alpha}\frac{\mathrm{d}\Phi}{\mathrm{d}r}\frac{\mathrm{d}\alpha}{\mathrm{d}r}\right) \tag{2.6}$$

and

$$R_{\varphi\varphi}=1-\frac{1}{\alpha}+\frac{r}{\alpha}\left(\frac{1}{2\alpha}\frac{\mathrm{d}\alpha}{\mathrm{d}r}-\frac{\mathrm{d}\Phi}{\mathrm{d}r}\right) \tag{2.7}$$

are the only relevant nonvanishing components of the Ricci tensor. [The component $R_{\varphi\varphi}$ in (2.7) is evaluated at $\theta=\pi/2$. The general expression for $R_{\varphi\varphi}$ contains an overall extra coefficient $\sin^2\theta$.] Because of the rather complicated dependence on Φ, α, and their derivatives, it is more instructive to focus on two particular cases.

A. Einstein's universe

The metric of Einstein's static universe corresponds to $\Phi=0$ and $\alpha(r)=(1-r^2/R^2)^{-1}$, where R is a positive parameter (the "radius" of the three-dimensional spherical space). The coordinate $r\in[0,R[$, however, does not cover the whole manifold, so it is convenient to introduce a new variable $\chi\in[0,\pi]$ defined through $r=R\sin\chi$. The metric then takes the form

$$g=-\mathrm{d}t^2+R^2\mathrm{d}\chi^2+R^2\sin^2\chi(\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\varphi^2), \tag{2.8}$$

showing that $R\chi$ measures the proper distance from the point $\chi=0$. The function α becomes $\alpha(\chi)=1/\cos^2\chi$, and the only nonvanishing component of the acceleration is

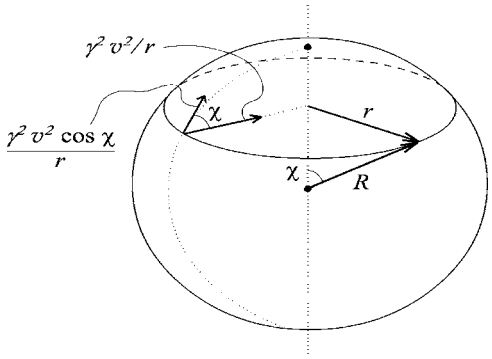

FIG. 1. Embedding diagram for the surface $t=$const, $\theta=\pi/2$ in Einstein's universe, showing the geometrical meaning of the quantities R, r, and χ. The centripetal acceleration of a particle moving at $r=$const is given by the tangential component of the acceleration in the fictitious three-dimensional Euclidean space. For $\chi<\pi/2$ the centripetal acceleration points in the direction of decreasing r, while for $\pi/2<\chi<\pi$ it points in the direction of increasing r.

$$a_\chi = \frac{\partial r}{\partial \chi} a_r = -\frac{\Omega^2 R^2 \sin\chi\cos\chi}{1-\Omega^2 R^2 \sin^2\chi}. \tag{2.9}$$

The magnitude (with sign) of the acceleration is $\gamma^2(v^2/r)\cos\chi$, so the acceleration differs from the special relativistic expression $\gamma^2 v^2/r$ only by the factor $\cos\chi$, whose origin can be easily understood by looking at Fig. 1. Note that the acceleration for orbits with $\chi\in\,]\pi/2,\pi[$ has the opposite sign than for those with $\chi\in\,]0,\pi/2[$, and vanishes when $\chi=\pi/2$.

The von Laue force is

$$F_\mu^{(\mathrm{vL})} = \tfrac{2}{3} e^2 \gamma^5 \Omega^3 R^2 \sin^2\chi\cos^2\chi(-\Omega\delta_\mu^t + \delta_\mu^\varphi). \tag{2.10}$$

It also vanishes for $\chi=\pi/2$, but does not exhibit any change in sign.

Finally, let us compute the Hobbs force. The components of the Ricci tensor can be evaluated directly from expressions (2.6) and (2.7), or simply remembering that the symmetries of Einstein's universe imply $R_{\mu\nu}=(2/R^2)h_{\mu\nu}$, where

$$h = (1-r^2/R^2)^{-1}\mathrm{d}r^2 + r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\varphi^2) = R^2\mathrm{d}\chi^2 + R^2\sin^2\chi(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\varphi^2) \tag{2.11}$$

is the metric tensor on the $t=$const hypersurfaces.[11] Thus, we have

$$F_\mu^{(\mathrm{H})} = \tfrac{2}{3} e^2 \gamma^3 \Omega \sin^2\chi(-\Omega\delta_\mu^t + \delta_\mu^\varphi). \tag{2.12}$$

This expression is nonvanishing for all nontrivial values of χ. Therefore, the local part of the self-force,

$$F_\mu^{(\mathrm{l})} = \tfrac{2}{3} e^2 \gamma^5 \Omega \sin^2\chi(1+\Omega^2 R^2\cos 2\chi)(-\Omega\delta_\mu^t + \delta_\mu^\varphi), \tag{2.13}$$

never vanishes, in spite of the fact that when the motion takes place on the spatial geodesic $\chi=\pi/2$, the von Laue force does.

B. Schwarzschild spacetime

In Schwarzschild spacetime,

$$\Phi = \frac{1}{2}\ln\left(1-\frac{2M}{r}\right) \tag{2.14}$$

and $\alpha=e^{-2\Phi}$. Then, from Eq. (2.3) we obtain

$$a_r = \Gamma^2\left(\frac{M}{r^2} - \Omega^2 r\right) = \frac{M - \Omega^2 r^3}{r(r - 2M - \Omega^2 r^3)} \tag{2.15}$$

and, from (2.4),

$$F_\mu^{(\mathrm{vL})} = \frac{2}{3}e^2\gamma^5\Omega r\left(1 - \frac{2M}{r}\right)^{-3/2}\left(1 - \frac{3M}{r}\right)\left(\frac{M}{r^2} - \Omega^2 r\right)(-\Omega\delta_\mu^t + \delta_\mu^\varphi). \tag{2.16}$$

Since $R_{ab}=0$, the Hobbs force vanishes identically, so $F_\mu^{(\mathrm{l})}=F_\mu^{(\mathrm{vL})}$.

Let us now study the behavior of a_r and $F_\mu^{(\mathrm{l})}$ for different values of r. When r/M is very large (Newtonian gravity), Eq. (2.15) can be approximated as

$$a_r \approx \gamma^2\left(\frac{M}{r^2} - \Omega^2 r\right). \tag{2.17}$$

Apart from the factor γ^2, which represents only special-relativistic corrections, the norm of a_a is just the difference between the gravitational and the centripetal accelerations in Newtonian mechanics. This agrees with the physical interpretation of a_a, which represents the thrust per unit mass that must be applied to the particle in order to keep it at the fixed value of r with angular velocity Ω. In particular, $a_a=0$ for a Keplerian motion, $\Omega^2=\Omega_K(r)^2 := M/r^3$ or $r=r_K(\Omega) := (M/\Omega^2)^{1/3}$. In the same approximation,

$$F_\mu^{(\mathrm{l})} \approx \frac{2}{3}e^2\Omega r\gamma^5\left(\frac{M}{r^2} - \Omega^2 r\right)(-\Omega\delta_\mu^t + \delta_\mu^\varphi). \tag{2.18}$$

The local part of the self-force behaves then in the following way: When the motion is Keplerian it vanishes, consistent with the fact that $a_a=0$; in the super-Keplerian regime $[\Omega^2>\Omega_K(r)^2$ or $r>r_K(\Omega)]$ it points backward with respect to the direction of motion; finally, in the sub-Keplerian regime $[\Omega^2<\Omega_K(r)^2$ or $r<r_K(\Omega)]$ it points forward with respect to the direction of motion. In the particular case of a static charge, $\Omega=0$ and $F_\mu^{(\mathrm{l})}=0$.

It is interesting to note that this behavior is peculiar to gravity and has no counterpart for motion in other central fields such as, e.g., a Coulomb one. This is easily seen by computing the self-force associated with circular motion in Minkowski spacetime,

$$F_\mu \equiv F_\mu^{(\mathrm{l})} = -\tfrac{2}{3}e^2\Omega^3 r^2\gamma^5(-\Omega\delta_\mu^t + \delta_\mu^\varphi), \tag{2.19}$$

where the second equality follows immediately from (2.16) with $M=0$ (see also Ref. 12, where this expression is derived explicitly for the case of synchrotron radiation). Now, the self-force always points backward with respect to the direction of motion, regardless of the magnitude of Ω. This is related to the fact that the right-hand side of Eq. (2.19) does not contain any indication about the central force responsible for keeping the charge on circular motion, contrary to what happens in the gravitational case, where a term M/r^2 appears together with $\Omega^2 r$. The combination $M/r^2-\Omega^2 r$ is the same that appears in a_r—see Eq. (2.15)—and is ultimately linked to the association between gravity and curvature. Thus, although for most purposes one can think of Newtonian gravity as a field on a flat background, the present analysis shows that this picture would lead to incorrect conclusions as far as the self-force is concerned. [Apparently, this point is not appreciated in the extant literature. See, e.g., Ref. 4, p. 183, for an explicit statement that the Newtonian and Coulomb problems are alike.]

Let us come back to the analysis of a_r and $F_\mu^{(\mathrm{l})}$. For $r>3M$ the qualitative behavior of these quantities at different values of r is like in the Newtonian limit examined above, even when r/M is not large. However, it is easily seen from Eqs. (2.15) and (2.16) that when $r=3M$, $a_r=(3M)^{-1}$ and $F_\mu^{(\mathrm{l})}=0$. Thus, the thrust needed in order to keep a particle on the closed photon orbit does not depend on the particle speed.[13] Furthermore, if the particle is charged, the local part of the self-force vanishes, in spite of the fact that motion takes place on a circle and is not geodesic. [This point is related to earlier results.[14]] Finally, for orbits with $2M<r<3M$, it follows from

(2.16) that the local part of the self-force always points backward with respect to the direction of motion. Since such orbits are necessarily sub-Keplerian, as follows from the inequality

$$(\Omega^2 - \Omega_K(r)^2)r^2 < 1 - 3M/r, \tag{2.20}$$

this behavior is the opposite than for $r > 3M$. [Proof of (2.20): Consider the condition $2M/r + \Omega^2 r^2 < 1$, which guarantees that Γ be real or, equivalently, that the particle worldline be timelike; subtract $\Omega_K(r)^2 r^2$ from both sides, and use the definition $\Omega_K(r)^2 := M/r^3$.]

III. OPTICAL GEOMETRY

The behavior of a_r can be understood in the following way. The component a_r of the acceleration, given by expression (2.15), is proportional to the thrust necessary to keep the particle on its orbit, and can be written as the difference between a gravitational part $a_r^{(g)}$, independent of Ω, and a centripetal part $a_r^{(c)}$:

$$a_r^{(g)} = \frac{M}{r^2(1 - 2M/r)}, \tag{3.1}$$

$$a_r^{(c)} = \Omega^2 r \, \frac{r - 3M}{(1 - 2M/r)(r - 2M - \Omega^2 r^3)}. \tag{3.2}$$

(Of course, $a_r^{(g)}$ and $a_r^{(c)}$ have signs opposite to those of the gravitational and centripetal forces. Alternatively, one can identify $a_r^{(c)}$ with the centrifugal field acting on the particle in the comoving frame.) It is then evident from (3.2) that the centripetal force vanishes at $r = 3M$, for which $a_r = a_r^{(g)} = (3M)^{-1}$. In addition, (3.2) predicts that $a_r^{(c)}$ has an opposite sign in the regions $r > 3M$ and $r < 3M$.

These properties admit a simple explanation if one imagines that the particle motion takes place in the so-called optical spacetime,[15] with a metric $\tilde{g} = (1 - 2M/r)^{-1} g$, under the action of a "gravitational potential" Φ given by (2.14), which produces a "gravitational field"[16]

$$\tilde{\mathrm{g}}_\mu = - k_\mu{}^\nu \nabla_\nu \Phi = - \left(1 - \frac{2M}{r}\right)^{-1} \frac{M}{r^2} \delta^r_\mu. \tag{3.3}$$

We have then $a_r^{(g)} = -\tilde{\mathrm{g}}_r$ and, in the optical spacetime, the magnitude of the gravitational field is given by the simple Newtonian expression $(\tilde{g}^{\mu\nu} \tilde{\mathrm{g}}_\mu \tilde{\mathrm{g}}_\nu)^{1/2} = M/r^2$. Also, defining $\tilde{v}^\mu := (1 - 2M/r)^{1/2} v^\mu$, so that $\tilde{g}_{\mu\nu} \tilde{v}^\mu \tilde{v}^\nu = -1$, one gets

$$\tilde{a}_\mu = \tilde{g}_{\mu\sigma} \tilde{v}^\nu \tilde{\nabla}_\nu \tilde{v}^\sigma = - \frac{\Gamma^2 \Omega^2 (r - 3M)}{1 - 2M/r} \delta^r_\mu, \tag{3.4}$$

and $a_r^{(c)} = \tilde{a}_r$. The magnitude of the acceleration in optical spacetime is

$$(\tilde{g}^{\mu\nu} \tilde{a}_\mu \tilde{a}_\nu)^{1/2} = \Gamma^2 \Omega^2 |r - 3M|. \tag{3.5}$$

The presence of the factor $(r - 3M)$ in $a_r^{(c)}$ can be understood intuitively[17] considering an embedding diagram[18] of the section $\theta = \pi/2$ of the optical space $(\mathcal{S}, \tilde{h}_{ab})$, where $\mathcal{S}$ is any $t = \text{const}$ hypersurface of the Schwarzschild spacetime, and the metric $\tilde{h}_{ab}$ has the coordinate representation[15]

$$\tilde{h} = \left(1 - \frac{2M}{r}\right)^{-2} \mathrm{d}r^2 + \left(1 - \frac{2M}{r}\right)^{-1} r^2 (\mathrm{d}\theta^2 + \sin^2 \theta \, \mathrm{d}\varphi^2) \tag{3.6}$$

(see Fig. 2 and the Appendix).

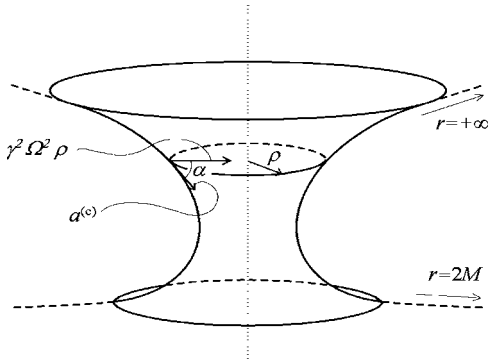

FIG. 2. Embedding diagram for part of the surface $t=\text{const}$, $\theta=\pi/2$ in Schwarzschild spacetime, with the optical geometry. The throat corresponds to $r=3M$. The centripetal acceleration of a particle moving at $r=\text{const}$ is given by the tangential component of the acceleration in the fictitious three-dimensional Euclidean space. Notice that for $r>3M$ the centripetal acceleration points in the direction of decreasing r, while for $2M<r<3M$ it points in the direction of increasing r.

Let us now consider the self-force. The von Laue term associated with the optical quantities has the components

$$\tilde{F}_\mu^{(\mathrm{vL})}=-\frac{2}{3}e^2\gamma^5\Omega^3r^2\left(1-\frac{2M}{r}\right)^{-2}\left(1-\frac{3M}{r}\right)^2(-\Omega\delta_\mu^t+\delta_\mu^\varphi), \tag{3.7}$$

so it always points backward with respect to the direction of motion, vanishes only at $r=3M$, and reduces to (2.19) in the region $r\gg M$. The Hobbs force in the optical space can be computed either directly, or by using the transformation formula (2.11) of Ref. 19. Its components are

$$\tilde{F}_\mu^{(\mathrm{H})}=\frac{2}{3}e^2\gamma^3\Omega\frac{M}{r}\left(1-\frac{2M}{r}\right)^{-1}\left(1-\frac{3M}{r}\right)(-\Omega\delta_\mu^t+\delta_\mu^\varphi). \tag{3.8}$$

For $r\gg M$, this becomes

$$\tilde{F}_\mu^{(\mathrm{H})}\approx\frac{2}{3}e^2\gamma^3\Omega\frac{M}{r}(-\Omega\delta_\mu^t+\delta_\mu^\varphi). \tag{3.9}$$

Note that the magnitude of the von Laue force is proportional to Ω^3r, like in Minkowski space, while the magnitude of the Hobbs force is proportional to $M\Omega/r^2$, which can be rewritten as M/r^3 times the speed Ωr. Thus, from the perspective offered by optical geometry, the coefficient

$$\frac{M}{r^2}-\Omega^2r$$

that appears in Eq. (2.18) should not be regarded as representing the difference between the gravitational and the centripetal forces, because the first term actually arises from the *curvature* of $(\mathcal{S},\tilde{h}_{ab})$. The same coefficient is present for uniform circular motion at $r=\text{const}$ on $(\mathcal{S},\tilde{h}_{ab})$, regardless of the nature (gravitational or other) of the "central" force. Therefore, when the local part of the self-force is analyzed in optical geometry, the puzzling peculiarity of gravity that was noticed in Sec. II B disappears.

It is worth pointing out that $F_\mu^{(\mathrm{l})}$, $\tilde{F}_\mu^{(\mathrm{vL})}$, and $\tilde{F}_\mu^{(\mathrm{H})}$ all vanish at $r=3M$, as it follows from Eqs. (2.16), (3.7), and (3.8). However, while the property $\tilde{F}_\mu^{(\mathrm{vL})}(3M)=0$ is natural from the point of view of optical geometry, because the circle $r=3M$ is a geodesic of $(\mathcal{S},\tilde{h}_{ab})$ and the charge motion is uniform, the fact that also $\tilde{F}_\mu^{(\mathrm{H})}(3M)=0$—hence $F_\mu^{(\mathrm{l})}(3M)=0$—is due to the algebraic properties

of the optical Ricci tensor at $r=3M$ rather than to the geodesic character in $(\mathcal{S},\tilde{h}_{ab})$ of the closed photon orbit (see Sec. IV B). Therefore, the change of sign of $F^{(\mathrm{l})}_{\mu}$ at $r=3M$ has a different origin than for other phenomena in which a similar "reversal" takes place.[20]

IV. GENERAL RESULTS

If $(\mathcal{M},g_{ab})$ and $(\mathcal{M},\tilde{g}_{ab})$ are two conformally related spacetimes, with

$$\tilde{g}_{ab}=e^{-2\Phi}g_{ab}, \tag{4.1}$$

the local and nonlocal parts of the corresponding self forces are related as $F^{(\mathrm{l})}_a=e^{-\Phi}\tilde{F}^{(\mathrm{l})}_a$ and $F^{(\mathrm{nl})}_a=e^{-\Phi}\tilde{F}^{(\mathrm{nl})}_a$.[19] Then, in order to compute $F^{(\mathrm{l})}_a$ or $F^{(\mathrm{nl})}_a$, one can work in a conformally related spacetime $(\mathcal{M},\tilde{g}_{ab})$ rather than in the physical one $(\mathcal{M},g_{ab})$. We now use this remark to put the results of Sec. II into a more general context extending the line of reasoning outlined in Sec. III, and to establish some extra necessary and/or sufficient conditions for the different parts of $F^{(\mathrm{l})}_a$ to vanish.

Let us consider a charge with four-velocity v^a in an arbitrary conformally static spacetime $(\mathcal{M},g_{ab})$. [This restriction is motivated mainly by simplicity. Optical geometry can be straightforwardly defined also for conformally stationary spacetimes,[21] and has been extended even to cases where no global time symmetry exists, as it happens in gravitational collapse.[22] For recent results concerning generalizations of optical geometry, see Ref. 23.] By definition, such a spacetime admits a hypersurface-orthogonal timelike conformal Killing vector field $\eta=\partial/\partial t$, corresponding to a conformal Killing time t. One can then define the scalar function

$$\Phi:=\tfrac{1}{2}\ln(-g_{ab}\eta^a\eta^b) \tag{4.2}$$

and consider the ultrastatic spacetime $(\mathcal{M},\tilde{g}_{ab})$ with $\tilde{g}_{ab}$ given by (4.1), in which η^a is a Killing vector field with unit norm, $\pounds_\eta\tilde{g}_{ab}=0$ and $\tilde{g}_{ab}\eta^a\eta^b=-1$.[24] It is not difficult to check that the projection, along the integral curves of η^a, of null geodesics of $(\mathcal{M},g_{ab})$ onto the spatial hypersurfaces $\mathcal{S}$ defined by the condition $t=$const, are geodesics of $(\mathcal{S},\tilde{h}_{ab})$, where $\tilde{h}_{ab}:=\tilde{g}_{ab}+\eta_a\eta_b$ and $\eta_a:=\tilde{g}_{ab}\eta^b$. Hence, generalizing what we have done in Sec. III, all quantities pertaining to the spacetime $(\mathcal{M},\tilde{g}_{ab})$ will be denoted as "optical." Instead of $F^{(\mathrm{l})}_a$, we can then consider $\tilde{F}^{(\mathrm{l})}_a$, computed in the optical spacetime $(\mathcal{M},\tilde{g}_{ab})$ starting from the rescaled four-velocity $\tilde{v}^a=e^{\Phi}v^a$.

At any point on the particle worldline, $\tilde{v}^a$ can be decomposed in a unique way as

$$\tilde{v}^a=\gamma(\eta^a+v\tilde{\tau}^a), \tag{4.3}$$

where $v\in\,]-1,1[$ is the speed of the particle according to an observer with four-velocity parallel to η^a, the coefficient $\gamma:=(1-v^2)^{-1/2}$ is the corresponding Lorentz factor, and $\tilde{\tau}^a$ is a spacelike vector orthogonal to η^a, such that $\tilde{g}_{ab}\tilde{\tau}^a\tilde{\tau}^b=1$. The four-acceleration $\tilde{a}_a:=\tilde{v}^b\tilde{\nabla}_b\tilde{v}_a$ of the particle in the optical spacetime $(\mathcal{M},\tilde{g}_{ab})$ is then

$$\tilde{a}_a=\gamma^2\tilde{T}_a\tilde{v}^b\tilde{\nabla}_b v+\gamma^2v^2\tilde{\tau}^b\tilde{\nabla}_b\tilde{\tau}_a+\gamma^2v\,\eta^b\tilde{\nabla}_b\tilde{\tau}_a, \tag{4.4}$$

where

$$\tilde{T}^a:=\frac{\tilde{k}^a{}_b\tilde{\tau}^b}{\sqrt{\tilde{k}_{cd}\tilde{\tau}^c\tilde{\tau}^d}}=\gamma(\tilde{\tau}^a+v\,\eta^a) \tag{4.5}$$

is a unit vector in $(\mathcal{M},\tilde{g}_{ab})$, orthogonal to $\tilde{v}^a$. Using now the orthogonality condition $\eta^a\tilde{\tau}_a=0$, and the property $\tilde{\nabla}_b\eta_a=0$ that follows from the fact that $(\mathcal{M},\tilde{g}_{ab})$ is ultrastatic, we have

$$\tilde{\nabla}_b\tilde{\tau}_a=\tilde{\mathrm{D}}_b\tilde{\tau}_a-\eta_b\eta^c\tilde{\nabla}_c\tilde{\tau}_a, \tag{4.6}$$

where $\tilde{\mathrm{D}}_b$ is the covariant derivative along directions orthogonal to η^a, hence on $(\mathcal{S},\tilde{h}_{ab})$. In order for both Eqs. (4.4) and (4.6) to make sense, one needs to know $\tilde{\tau}^a$ off the particle worldline. The

natural extension of $\tilde{\tau}^a$ is such that its integral curves (located on $t=$const hypersurfaces) coincide with the projection on $\mathcal{S}$ of the particle worldline along the integral curves of η^a. This is equivalent to requiring that $\pounds_\eta \tilde{\tau}^a = 0$, i.e., that $\eta^b \tilde{\nabla}_b \tilde{\tau}^a = \tilde{\tau}^b \tilde{\nabla}_b \eta^a$, and the latter quantity vanishes in an ultrastatic spacetime. Hence, $\eta^b \tilde{\nabla}_b \tilde{\tau}_a = 0$, and the particle acceleration in optical spacetime takes the very simple form

$$\tilde{a}_a = \gamma^2 \tilde{T}_a \tilde{v}^b \tilde{\nabla}_b v + \gamma^2 v^2 \tilde{\tau}^b \tilde{\mathrm{D}}_b \tilde{\tau}_a, \tag{4.7}$$

in which one can identify a tangential and an orthogonal (centripetal) component.[16]

The relationship[19]

$$\tilde{a}_a = a_a - k_a{}^b \nabla_b \Phi \tag{4.8}$$

generalizes the result, already obtained in Sec. III for the special case of Schwarzschild spacetime, according to which one can write the particle acceleration in optical spacetime, $\tilde{a}_a$, as the sum between the nongravitational thrust per unit mass, a_a, and a gravitational force per unit mass, $\tilde{\mathrm{g}}_a = -k_a{}^b \nabla_b \Phi$:

$$\tilde{a}_a = a_a + \tilde{\mathrm{g}}_a. \tag{4.9}$$

Equation (4.9) contains a precise formulation of the equivalence principle, because the quantity that is physically measurable at the particle location—the thrust, proportional to a_a—allows one only to determine the difference $\tilde{a}_a - \tilde{\mathrm{g}}_a$ between $\tilde{a}_a$ and $\tilde{\mathrm{g}}_a$, but not $\tilde{a}_a$ and $\tilde{\mathrm{g}}_a$ separately (unless one possesses extra knowledge, of a nonlocal nature, about the structure of the spacetime under consideration). [In particular, the two situations with $\tilde{a}_a = a_a$ and $\tilde{\mathrm{g}}_a = 0$, or with $\tilde{a}_a = 0$ and $\tilde{\mathrm{g}}_a = -a_a$, cannot be distinguished by a measurement of the thrust.] Inserting (4.7) into (4.9), and identifying $-\gamma^2 \tilde{T}_a \tilde{v}^b \tilde{\nabla}_b v$ and $-\gamma^2 v^2 \tilde{\tau}^b \tilde{\mathrm{D}}_b \tilde{\tau}_a$ with suitable inertial forces per unit mass,[16,25] one finds a general relativistic version of the statement, commonly expressed within the framework of Newtonian mechanics, that in a frame comoving with the particle there is perfect balance between the nongravitational thrust, the gravitational force, and the inertial forces acting on the particle.

On replacing (4.7) into the definition of $\tilde{F}_a^{(1)}$ one can find the local part of the self-force expressed in terms of v and $\tilde{\tau}^a$, that characterize the motion in optical spacetime $(\mathcal{M}, \tilde{g}_{ab})$. However, since the general expression is not particularly illuminating, let us focus instead on the most interesting particular cases.

A. Uniform motion along optical geodesics

It is obvious from Eq. (4.7) that a particle which moves uniformly (i.e., with $\tilde{v}^b \tilde{\nabla}_b v = 0$) along optical geodesics of space (so that $\tilde{\tau}^b \tilde{\mathrm{D}}_b \tilde{\tau}_a = 0$) has vanishing acceleration in $(\mathcal{M}, \tilde{g}_{ab})$, that is, $\tilde{a}_a = 0$. Then $\tilde{F}_a^{(1)}$ consists only of the Hobbs term and we can write

$$F_a = e^{-\Phi} \left(\frac{1}{3} e^2 k_a{}^b \tilde{R}_{bc} \tilde{v}^c + e^2 \tilde{v}^b \int_{-\infty}^{\tilde{\tau}} \mathrm{d}\tilde{\tau}' \tilde{f}_{aba'} \tilde{v}^{a'} \right). \tag{4.10}$$

Thus, the particle is indeed subjected to a self-force, but just to the one that is associated with the geometric properties of the optical space. In a sense, the charge "feels" the geometry of $(\mathcal{M}, \tilde{g}_{ab})$ rather than the one of the physical spacetime $(\mathcal{M}, g_{ab})$.

It may be interesting to note that, with the only exception of ultrastatic spacetimes, for which the ordinary and the optical geometries simply coincide, there are no lines in the ordinary space $(\mathcal{S}, h_{ab})$ such that the von Laue term vanishes identically for a charge that moves uniformly along them. On the contrary, in $(\mathcal{S}, \tilde{h}_{ab})$ the conditions that $v=$const and $\tilde{F}_a^{(\mathrm{vL})} = 0$ uniquely select optical geodesics.

B. Special metrics

If $k_a{}^b\widetilde{R}_{bc}\tilde{v}^c=0$, then expression (4.10) implies that $F_a=F_a^{(\mathrm{nl})}$, because $F_a^{(\mathrm{l})}$ and $F_a^{(\mathrm{nl})}$ do not mix under a conformal transformation.[19] [For a more general, nonuniform motion, one finds $\widetilde{F}_a^{(\mathrm{l})}=\widetilde{F}_a^{(\mathrm{vL})}$.] This can happen iff $\widetilde{R}_a{}^b\tilde{v}_b=\lambda\tilde{v}_a$ for some λ, and it is easy to see, by contracting this equation with η^a and noting that $\eta^a\widetilde{R}_a{}^b=0$ in an ultrastatic spacetime, that it must be $\lambda=0$. Using again the decomposition (4.3) and the property $\widetilde{R}_{ab}\eta^b=0$, one finally finds that the Hobbs term vanishes iff $v\widetilde{R}_a{}^b\tilde{\tau}_b=0$. Thus, excluding the trivial case $v=0$, there is no local self-force for uniform motion along optical geodesics whose directions are eigenvectors of $\widetilde{R}_a{}^b$ with zero eigenvalue. Such directions exist iff the determinant of the matrix made by the components $\widetilde{R}_i^j$ with $i,j=1,2,3$ is zero, i.e., iff such matrix is degenerate.

Let us reconsider the examples of Sec. II in the light of this conclusion. For the Einstein universe, $\widetilde{R}_i^j=R_i^j=(2/R^2)\delta_i^j$, which is always nondegenerate. For Schwarzschild spacetime,

$$\widetilde{R}_{\varphi i}=\frac{2M}{r}\left(1-\frac{2M}{r}\right)^{-1}\left(1-\frac{M}{r}(2+\sin^2\theta)\right)\delta_i^{\varphi} \tag{4.11}$$

and, for $\theta=\pi/2$, $\widetilde{R}_i^j$ becomes degenerate at $r=3M$. Hence, $F_a^{(\mathrm{l})}$ vanishes at $r=3M$ for uniform motion in an equatorial plane along *any* optical geodesic, not only for the circular orbit considered in Sec. II B. This result is far from trivial, but its derivation is rather straightforward working in the optical space.

C. Geodesic motion

For charges following a geodesic in $(\mathcal{M},g_{ab})$ the four-acceleration a_a vanishes, so the von Laue term $F_a^{(\mathrm{vL})}$ is identically zero. [We avoid referring to this situation as "free fall," because the latter would be appropriately identified by the vanishing of the external force in Eq. (1.1), $K_a=0$, whereas geodesic motion corresponds to $K_a+F_a=0$.] In optical geometry this result is not obvious, because it follows from a compensation between contributions coming from the "optical" von Laue and Hobbs terms. More precisely, applying (4.8) to this case one immediately finds $\tilde{a}_a=-k_a{}^b\nabla_b\Phi$. Then, the von Laue term $\widetilde{F}_a^{(\mathrm{vL})}$ in optical space contains first and second derivatives of Φ, that are canceled by identical contributions coming from the Hobbs term $\widetilde{F}_a^{(\mathrm{H})}$, because of the way the Ricci tensor changes under a conformal transformation.[19]

Thus, from the perspective of optical geometry, the fact that $F_a^{(\mathrm{vL})}=0$ just when $\tilde{a}_a=-k_a{}^b\nabla_b\Phi$ is somewhat surprising. For example, it is not evident that $\widetilde{F}_a^{(\mathrm{l})}=0$ for the Keplerian motions of Sec. II B because in optical geometry, where gravity is described by the physical field Φ, Keplerian motions have nothing qualitatively different from, say, orbits in a Coulomb field. In fact, it turns out that it is only thanks to a cancellation between the von Laue and the Hobbs terms in the optical geometry that $\widetilde{F}_a^{(\mathrm{l})}=0$. However, if one thinks that for a Keplerian motion in Schwarzschild spacetime $F_a^{(\mathrm{vL})}=F_a^{(\mathrm{H})}=0$, and that $\widetilde{F}_a^{(\mathrm{l})}=\mathrm{e}^{\Phi}F_a^{(\mathrm{l})}$, then such a compensation is only expected. Geodesics in $(\mathcal{M},g_{ab})$ are not geodesics in $(\mathcal{M},\tilde{g}_{ab})$, so $\widetilde{F}_a^{(\mathrm{vL})}$ does not vanish in general, and since $\widetilde{R}_{ab}\neq 0$, the Hobbs force $\widetilde{F}_a^{(\mathrm{H})}$ also does not vanish. Nevertheless, $\widetilde{F}_a^{(\mathrm{vL})}$ and $\widetilde{F}_a^{(\mathrm{H})}$ combine to form a vanishing local self-force, $\widetilde{F}_a^{(\mathrm{l})}=0$.

This remark should not be regarded as a drawback of the description based on optical geometry, though. Indeed, the fact that $F_a^{(\mathrm{vL})}$ does, or does not, vanish is not particularly important, because the physically interesting quantity is not $F_a^{(\mathrm{vL})}$, but $F_a^{(\mathrm{l})}$. And whether $F_a^{(\mathrm{l})}=0$ (or, equivalently, $\widetilde{F}_a^{(\mathrm{l})}=0$) cannot be established simply by looking at $F_a^{(\mathrm{vL})}$ (or $\widetilde{F}_a^{(\mathrm{vL})}$), unless one is in a situation for which $F_a^{(\mathrm{H})}=0$ (or $\widetilde{F}_a^{(\mathrm{H})}=0$). Thus, in the case of Schwarzschild spacetime the evaluation of $F_a^{(\mathrm{vL})}$ turns out to be convenient only because, since $R_{ab}=0$ there, the Hobbs force vanishes

identically, so $F_a^{(\mathrm{vL})}$ coincides with $F_a^{(\mathrm{l})}$. However, in a spacetime for which it is $\tilde{R}_{ab}$ that vanishes, one has $\tilde{F}_a^{(\mathrm{H})}=0$. Consequently, it is now $\tilde{F}_a^{(\mathrm{vL})}$ that one should inspect, in order to get information about the behavior of $F_a^{(\mathrm{l})}=0$.

D. Conformally static charge

In order to further illustrate the point made in the last paragraph of Sec. IV C, let us consider a conformally static charge, i.e., one with four-velocity $v^a=n^a$, where

$$n^a := e^{-\Phi}\eta^a = (-g_{bc}\eta^b\eta^c)^{-1/2}\eta^a \tag{4.12}$$

is the unit vector field parallel to η^a. This is obviously a subcase of the situations covered in Sec. IV A and since $\tilde{R}_{ab}\eta^b=0$, it is evident in optical geometry that $\tilde{F}_a^{(\mathrm{vL})}=\tilde{F}_a^{(\mathrm{H})}=0$, so also $\tilde{F}_a^{(\mathrm{l})}=0$ and $F_a^{(\mathrm{l})}=0$. On the other hand, this conclusion is not obvious at all if one works in the spacetime $(\mathcal{M},g_{ab})$, because in order to establish it, one must use highly nontrivial properties of the vector field n^a, that lead to cancelations between terms coming from $F_a^{(\mathrm{vL})}$ and $F_a^{(\mathrm{H})}$ (none of which, however, vanishes separately). Hence, in this case it is optical geometry that allows one to establish that $F_a^{(\mathrm{l})}=0$ in a simple way, by using the decomposition $\tilde{F}_a^{(\mathrm{l})}=\tilde{F}_a^{(\mathrm{vL})}+\tilde{F}_a^{(\mathrm{H})}$. The alternative split, $F_a^{(\mathrm{l})}=F_a^{(\mathrm{vL})}+F_a^{(\mathrm{H})}$, leads instead to rather cumbersome calculations.

V. CONCLUSIONS

Let us summarize the results of Secs. II–IV. We have seen that, for uniform motion along a spatial geodesic $\chi=\pi/2$ in Einstein's static universe, the von Laue force vanishes, whereas the Hobbs force does not (hence, the local part of the self-force also does not vanish). In Schwarzschild spacetime, for uniform motion along a circle at $r=3M$, the von Laue force vanishes; since the Hobbs force is identically zero (Schwarzschild spacetime is Ricci-flat), this implies that $F_a^{(\mathrm{l})}(3M)=0$. Similarly, in the optical Schwarzschild spacetime, $\tilde{F}_a^{(\mathrm{vL})}(3M)=\tilde{F}_a^{(\mathrm{H})}(3M)=\tilde{F}_a^{(\mathrm{l})}(3M)=0$. All these are instances of the following general results, valid in an arbitrary conformally static spacetime: (i) for geodesic motion in optical spacetime $(\mathcal{M},\tilde{g}_{ab})$—uniform motion along optical geodesics—, $\tilde{F}_a^{(\mathrm{vL})}=0$; (ii) for geodesic motion in the spacetime $(\mathcal{M},g_{ab})$, $F_a^{(\mathrm{vL})}=0$. Note that, however, the physically interesting result does not concern $F_a^{(\mathrm{vL})}$ or $\tilde{F}_a^{(\mathrm{vL})}$, but the entire local part of the self-force. Whether this vanishes in cases (i) and (ii) depends on the additional feature that the matrix $\tilde{R}_i^{\ j}$ or $R_\mu^{\ \nu}$, respectively, be degenerate. Also, note that the particular case of (i), that for a conformally static charge $F_a^{(\mathrm{l})}=\tilde{F}_a^{(\mathrm{l})}=0$, although nontrivial, is straightforward when regarded from the perspective offered by optical geometry. Hence, the latter appears to be a useful tool in calculations of self-force and related effects, as it happens already in several other circumstances.[15–17,20–22,25–28]. Indeed, although in this paper we deliberately avoided dealing with the nonlocal part of the self-force $F_a^{(\mathrm{nl})}$, there are good reasons to believe that working in the optical spacetime might also simplify its evaluation—a rather challenging task, in general. This is suggested by the fact that computing $F_a^{(\mathrm{nl})}$ amounts, basically, to finding the bi-tensor $f_{aba'}$ in Eq. (1.3). In turn, this amounts to the determination of a particular electromagnetic field in spacetime, and we know already from Ref. 28 that this is sometimes easier to do using optical geometry. We leave the development of this subject for future investigations.

APPENDIX: CENTRIPETAL ACCELERATION IN OPTICAL GEOMETRY

We present a derivation of Eq. (3.5) based on the embedding diagram of Fig. 2. In the fictitious three-dimensional Euclidean space, the centripetal acceleration of a particle that moves uniformly on the orbit $r=\text{const}$ is $a_E^{(c)}=\gamma^2\Omega^2\rho$, where $\rho=(1-2M/r)^{-1/2}r$ is the distance from the axis[18]—also called "radius of gyration"[26] because $v=(1-2M/r)^{-1/2}\Omega r=\Omega\rho$. The centripetal acceleration in the optical space is given by the tangential component of a_{E}, namely

$$a^{(c)}=\gamma^2\Omega^2\rho\cos\alpha, \tag{A1}$$

where α is the angle indicated in Fig. 2. Let $z=f(\rho)$ be the equation of the surface in Fig. 2. The surface is isometric to the section $\theta=\pi/2$ of the optical space if[18]

$$\left(1+\left(\frac{\mathrm{d}f}{\mathrm{d}\rho}\right)^2\right)\mathrm{d}\rho^2=\left(1-\frac{2M}{r}\right)^{-2}\mathrm{d}r^2. \tag{A2}$$

But we have also $\mathrm{d}f/\mathrm{d}\rho=\tan\alpha$, so

$$\cos\alpha=\left(1-\frac{2M}{r}\right)\left|\frac{\mathrm{d}\rho}{\mathrm{d}r}\right|=\left(1-\frac{2M}{r}\right)^{-1/2}\left|1-\frac{3M}{r}\right|. \tag{A3}$$

Substituting into (A1) we recover Eq. (3.5).

Without making use of the Ernst formalism we look directly for particular solutions of field equations describing stationary axisymmetric vacuum space–time using Weyl coordinates. The solutions that we obtain, by simple separation of variables, are parametrized in the general case by a III transcendent of Painlevé with two arbitrary constants. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2206689]

I. INTRODUCTION

Here we study the stationary axisymmetric vacuum metric presented by Lewis.[1] This metric depends on four potentials and we present it in Weyl coordinates. We know that the solutions can be expressed in three distinct classes for the cylindrical case[2] and for the general case.[3] We have shown[3] that the solutions of Lewis metric implies a functional relation between the three principal potentials.

To find new solutions of Lewis metric here we use the method of separation of variables ρ and z. Through this procedure the solutions are parametrized by the III transcendental of Painlevé with two arbitrary constants,[4–6] one structure constant a and one constant of integration C.

Wils presented a very interesting review[7] of solutions of Einstein's field equations producing transcendents of Painlevé. Persides and Xanthopoulos[8] and Calvert and Woodhouse,[9] in the axisymmetric case, found solutions parametrized by Painlevé transcendents III and V, using different methods.

Section II presents the field equations, Sec. III gives the transcendent solutions and the paper finishes with a short conclusion.

II. FIELD EQUATIONS

The general line element for a stationary axisymmetric space–time can be written in the Lewis form[1]

$$ds^2 = -f\,dt^2 + 2k\,dt\,d\phi + e^{\mu}(d\rho^2 + dz^2) + l\,d\phi^2, \tag{1}$$

where f, k, μ, and l are only functions of the Weyl coordinates ρ and z. For convenience[3] we assume

[a]Electronic mail: gariel@ccr.jussieu.fr
[b]Electronic mail: santos@ccr.jussieu.fr and n.o.santos@qmul.ac.uk

$$f = \rho\mathcal{F}(\rho,z), \quad k = \rho\mathcal{K}(\rho,z), \quad l = \rho\mathcal{L}(\rho,z). \tag{2}$$

Following the procedure of Ref. 3 with

$$\mathcal{F}\mathcal{L} + \mathcal{K}^2 = 1, \tag{3}$$

we obtain the vacuum field equations in the symmetric form

$$\mathcal{K}\Delta\mathcal{F} = \mathcal{F}\Delta\mathcal{K}, \tag{4}$$

$$\mathcal{L}\Delta\mathcal{K} = \mathcal{K}\Delta\mathcal{L}, \tag{5}$$

$$\mathcal{F}\Delta\mathcal{L} = \mathcal{L}\Delta\mathcal{F}, \tag{6}$$

where the Laplacian Δ is defined by

$$\Delta \equiv \partial_{\rho\rho} + \frac{1}{\rho}\partial_\rho + \partial_{zz}, \tag{7}$$

with the indexes standing for differentiation.

III. TRANSCENDENT SOLUTION

We look for solutions of the system (4)–(6) of the form

$$\mathcal{F} = F(\rho)H_1(z), \tag{8}$$

$$\mathcal{K} = K(\rho)H_2(z), \tag{9}$$

$$\mathcal{L} = L(\rho)H_3(z), \tag{10}$$

satisfying (3). Substituting (8)–(10) into (3) and differentiating twice with respect to ρ and z we obtain

$$H_1H_3 = 1, \quad H_2 = 1, \tag{11}$$

and with the field equations (4)–(6) we find

$$H_1 = e^{-az}, \quad H_2 = 1, \quad H_3 = e^{az}, \tag{12}$$

where $a \neq 0$ is an arbitrary constant. When $a=0$ we find again the cylindrically symmetric case.[2] Therefore the field equations (4)–(6) can be written

$$K\left(F_{\rho\rho} + \frac{1}{\rho}F_\rho + a^2F\right) = F\left(K_{\rho\rho} + \frac{1}{\rho}K_\rho\right), \tag{13}$$

$$L\left(K_{\rho\rho} + \frac{1}{\rho}K_\rho\right) = K\left(L_{\rho\rho} + \frac{1}{\rho}L_\rho + a^2L\right), \tag{14}$$

$$F\left(L_{\rho\rho} + \frac{1}{\rho}L_\rho\right) = L\left(F_{\rho\rho} + \frac{1}{\rho}F_\rho\right), \tag{15}$$

respectively, and we see that (13) is a consequence of (14) and (15). We can integrate (15) and obtain

$$\frac{F_\rho}{F} - \frac{L_\rho}{L} = \frac{C}{\rho FL}, \tag{16}$$

where C is an integration constant and from (3) and (11),

$$FL + K^2 = 1. \tag{17}$$

Finally we find

$$\frac{L_\rho}{L} = \frac{1}{K^2 - 1}\left(KK_\rho + \frac{C}{2\rho}\right). \tag{18}$$

We can rewrite (14) as

$$\frac{1}{K}\left(K_{\rho\rho} + \frac{1}{\rho}K_\rho\right) = \left(\frac{L_\rho}{L}\right)_\rho + \left(\frac{L_\rho}{L}\right)^2 + \frac{1}{\rho}\frac{L_\rho}{L} + a^2, \tag{19}$$

and with (18) it becomes a second-order differential equation for $K(\rho)$, or $\mathcal{K}$,

$$(1 - K^2)\left(K_{\rho\rho} + \frac{1}{\rho}K_\rho\right) + KK_\rho^2 - K\left(\frac{C^2}{4\rho^2} + a^2(1 - K^2)^2\right) = 0. \tag{20}$$

Considering the transformation

$$\rho = \sqrt{x}, \quad K = \left(\frac{R}{R-1}\right)^{1/2}, \tag{21}$$

where R is a function of ρ and ranging $R \in]-\infty, 0]$ and $R \in]1, \infty[$, then (20) becomes

$$R_{xx} + \frac{1}{x}R_x - \left(\frac{1}{2R} + \frac{1}{R-1}\right)R_x^2 - \frac{C^2R}{8x^2}(R-1)^2 - \frac{a^2R}{2x} = 0. \tag{22}$$

The second-order differential equation (22) is a canonical particular type of the V transcendent of Painlevé depending on two parameters.[4,6,10] We observe that (22) is the same that appears in Ref. 6 [see Eq. (2.16)] obtained from the field equation using the Ernst potential. Furthermore, (22) corresponds to the standard form of the V transcendent of Painlevé as proposed by Okamoto[11] with the parameter $\beta=0$, i.e., $v_1+v_2=0$ and $t=x$.

We can use a differential transformation between the III transcendent of Painlevé and the V transcendent (20).[12] Setting

$$r = 1 - K^2, \tag{23}$$

in (20), we obtain

$$r_{\rho\rho} - \frac{1}{2}\left(\frac{1}{r} + \frac{1}{r-1}\right)r_\rho^2 + \frac{1}{\rho}r_\rho - \frac{C^2}{2\rho}\left(1 - \frac{1}{r}\right) - 2a^2(r-1)r\rho = 0. \tag{24}$$

Now let us consider the system

$$y_\rho = 2y^2(2r-1) + \frac{C-1}{\rho}y - \frac{a^2}{2}, \tag{25}$$

$$r_\rho = \left(4yr + \frac{C}{\rho}\right)(1-r). \tag{26}$$

Eliminating y in this system we obtain (24), while eliminating r, we obtain a particular form of the III transcendent of Painlevé,

$$y_{\rho\rho} - \frac{1}{y}y_\rho^2 + \frac{1}{\rho}y_\rho - \frac{1}{\rho}(\alpha y^2 + \beta) - \gamma y^3 - \frac{\delta}{y} = 0, \tag{27}$$

with

$$\alpha = 2C, \quad \beta = \frac{a^2}{2}(C-2), \quad \gamma = 4, \quad \delta = -\frac{a^4}{4}, \tag{28}$$

where we can rescale, $\rho \to \rho/a$ and choose $a=1$. The link between r, of the V transcendent of Painlevé, and y, of the III transcendent, given by (25) and (26), is differential, and we observe that if in (20) we substitute

$$y = \frac{1}{2(K^2-1)}\left(\frac{K_\rho}{K} + \frac{C}{2\rho}\right), \tag{29}$$

with $K = \sqrt{1-r}$ we reobtain (26).

Finally, we find from (12), (17), (18), (21), and (22),

$$F = -(R-1)^{-1/2} \exp\left(\frac{C}{2}\int_{\rho_0}^{\rho} \frac{1-R}{\rho} \mathrm{d}\rho\right), \tag{30}$$

$$K = \left(\frac{R}{R-1}\right)^{1/2}, \tag{31}$$

$$L = (R-1)^{-1/2} \exp\left(\frac{C}{2}\int_{\rho_0}^{\rho} \frac{R-1}{\rho} \mathrm{d}\rho\right), \tag{32}$$

where $R(\rho^2)$ is a solution of (22), and from (2) and (8)–(10),

$$f = \rho e^{-az} F(\rho), \tag{33}$$

$$k = \rho K(\rho), \tag{34}$$

$$l = \rho e^{az} L(\rho). \tag{35}$$

Hence (33)–(35) are solutions of the potentials f, k, and l for an axisymmetric vacuum field (1) parametrized by a III transcendent of Painlevé with $C \neq 0$ in place of the usual harmonic functions like in the three classes of Lewis space–time.[3]

IV. CONCLUSION

Departing from a formulation of the stationary axisymmetric space–time given originally by Lewis, we consider a solution of the field equations where the potentials are parametrized in a particular reducible to a Painlevé III transcendent with two non-null constants, and not by a harmonic function which are known as Lewis solutions which suppose, not only the relation (17) but also a functional relation between the potentials.[3] This method presents a particular advantage since the calculations are straightforward and clear.

(Received 25 November 2005; accepted 11 May 2006; published online 20 June 2006)

The second order Killing and conformal tensors are analyzed in terms of their spectral decomposition, and some properties of the eigenvalues and the eigenspaces are shown. When the tensor is of type I with only two different eigenvalues, the condition to be a Killing or a conformal tensor is characterized in terms of its underlying almost-product structure. A canonical expression for the metrics admitting these kinds of symmetries is also presented. The space–time cases 1+3 and 2+2 are analyzed in more detail. Starting from this approach to Killing and conformal tensors a geometric interpretation of some results on quadratic first integrals of the geodesic equation in vacuum Petrov-Bel type D solutions is offered. A generalization of these results to a wider family of type D space–times is also obtained. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2207717]

I. INTRODUCTION

Killing tensors are associated with first integrals to the geodesic equation. In the second order case, they define quadratic first integrals and they play a central role in the theory of separability of the Hamilton-Jacobi equation. The relationship between separability and Killing tensors was shown by Eisenhart[1] and abundant literature exists regarding this property (for example, see Ref. 2 and references therein).

Within the relativistic framework the study of Killing tensors grew when Walker and Penrose[3] showed how the existence of a Killing tensor explains the Carter results[4] on the integrability by variable separation of the geodesic equation in the Kerr solution. Since then a lot of studies have been devoted to determining and classifying the space–times admitting Killing tensors and also to obtaining the Killing tensors of a given metric. A summary of known results on this subject can be found in Ref. 5.

The problem of finding the metrics admitting a quadratic integral of the geodesic equation was established by Eisenhart.[1] He wrote the *intrinsic Killing tensor equations*, i.e., the Killing equations in terms of the eigenvectors e_i and the eigenvalues ρ_i of a Killing tensor, and he pointed out that (see Ref. 1, p. 129): "the problem of finding all V_n admitting a quadratic integral consists in finding a tensor g and an orthogonal ennuple e_i that satisfy the conditions obtained by the elimination of the ρ's from the intrinsic Killing tensor equations. The general solution has not been obtained, but we shall consider two particular solutions of the problem." Later, he considered the

[b)]Electronic mail: joan.ferrando@uv.es
[c)]Electronic mail: juan.a.saez@uv.es

trivial case when all the ρ's are equal, and the case with different eigenvalues and normal principal congruences, a case which led to the Stäckel form of the metric.[6,1]

The general solution to the problem set by Eisenhart is far from being solved, although a number of results are known for some classes of Einstein-Maxwell solutions or algebraically special space–times, as well as those for flat metrics.[5] Nevertheless, the usual way in which this subject is tackled differs from the Eisenhart conception. Indeed, the common approach consists of studying the integrability conditions of the Killing tensor equations, whereas the Eisenhart method involves the following: (i) to write the intrinsic Killing tensor equations, (ii) to determine the equivalent equations involving exclusively the eigenspaces and the metric tensor (the eigenvalues having been removed), and (iii) to study the integrability conditions of the aforementioned equations. Both procedures, the usual one and Eisenhart's, may be suitable depending on the different situations. In this work we adopt the Eisenhart approach and we will show how useful it is by considering the case of Killing tensors with two complementary eigenspaces.

The conformal extension of the Killing tensor equation determines the conformal tensors which define first integrals to the null geodesic equation. Here we also analyze the Eisenhart problem for the class of conformal tensors with two complementary eigenspaces.

In the problem of finding the Riemannian spaces admitting a Killing or a conformal tensor two different aspects can be considered. On the one hand, we can look for a general canonical expression for the metric tensors with these kinds of first integrals. In this case, we must also obtain the expression of the Killing or conformal tensors in terms of the elements appearing in this canonical form. This approach may be useful in working in spaces with these symmetries, the adapted coordinates allowing calculations to be simplified and throwing light on the geometric interpretation of the expressions we can find.

On the other hand, we can give explicit and intrinsic conditions that characterize the metric tensors, and then we must offer the expression of the Killing or conformal tensors in terms of metric concomitants (namely, the Riemann tensor and its covariant derivatives). This approach is helpful in analyzing when a metric, which is known in an arbitrary coordinate system, has these kinds of symmetries. Moreover, we can obtain these tensorial symmetries without solving the Killing or conformal equations.

In this work we analyze both viewpoints. Regarding the first one, we can quote several results previously obtained in the relativistic framework. Thus, canonical forms for the four-dimensional space–time metrics admitting a Killing or a conformal tensor of type $2+2$ have been proposed in literature.[7,8] In this case the Killing or conformal tensor admits two complementary eigenplanes. Here we generalize these results by considering a general $p+q$ tensor (with two complementary eigenspaces of dimensions p and q, respectively) in a generic Riemannian space with arbitrary signature and dimension.

The second approach, the intrinsic characterization of the metrics admitting Killing and conformal tensors, has also been partially considered in relativity. Thus, it is known that every Petrov-Bel type D vacuum solution admits a conformal tensor of type $2+2$ which may be obtained form the Weyl tensor.[5] Here we extend this result by characterizing all the Petrov-Bel type D metrics with conformal tensors. Moreover we also identify the type D solutions admitting a Killing tensor, thus generalizing some results that are known for the vacuum case.[5]

It is worth remarking that the Eisenhart approach used here allows the intrinsic and explicit labeling of the metrics to be obtained easily. Indeed, in this approach we give conditions for the underlying $2+2$ structure of the Killing or conformal tensors. Moreover, for the Petrov-Bel type D metrics, this is the principal structure one of the Weyl tensor, and it is explicitly known in terms of the metric tensor.[9] The reason why it is of interest to obtain an explicit and intrinsic characterization of a space–time metric has been pointed out elsewhere[10] and the method used here has been useful in labeling the Schwarszchild[10] and Reissner-Nordström[11] solutions, the static Petrov type I space–times[9] and the Petrov type I space–times admitting isotropic radiation.[12]

Here we show that the eigenspaces of a Killing or a conformal tensor are umbilical planes. Moreover they are totally geodesic for a conformal metric. This geometric interpretation could be useful in clarifying the role played by the Killing tensor in the separability theory.

The paper is organized as follows. Some notation, definitions and properties related to regular Riemannian p planes are introduced in Sec. II. In Sec. III we study some properties of the eigenvectors and eigenvalues of a Killing or a conformal tensor. The type I case (when the tensor admits an orthonormal basis of eigenvectors) is analyzed in detail in Sec. IV and we write the Eisenhart intrinsic Killing tensor equations in a form that is more useful to our purposes. In Sec. V we use this new form for the Killing tensor equations to analyze the Eisenhart problem when the Killing or the conformal tensor has two complementary eigenspaces. A canonical form for the metrics admitting these kinds of first integrals is presented in Sec. VI. In Sec. VII we study the $1+(n-1)$ case and outline when these Killing or conformal tensors are not reducible. In the last two sections some results concerning the usual four-dimensional space–time are obtained. The $2+2$ space–time structures associated to a Killing or conformal tensor are analyzed in detail in Sec. VIII. Finally, Sec. IX is devoted to obtaining an intrinsic and explicit characterization of the Petrov-Bel type D metrics admitting Killing or conformal tensors attached to its principal structure, and we also present an algorithm to obtain these quadratic first integrals in a given type D space–time.

II. SOME NOTATION AND USEFUL CONCEPTS

On an n-dimensional Riemannian manifold (M,g) we shall refer to a (regular) p-dimensional distribution V as a p plane. Let v be the projector on V and $h=g-v$ the projector on the plane orthogonal to V. The generalized second fundamental form of V is defined as the (2,1)-tensor Q_v given by

$$Q_v(x,y) = h(\nabla_{v(x)}v(y)) \tag{1}$$

for every pair of vector fields x, y. We can consider the decomposition of Q_v into its antisymmetric part A_v and its symmetric part $S_v \equiv S_v^T + (1/p)v \otimes \mathrm{Tr}\, S_v$, where S_v^T is a traceless tensor:

$$Q_v = A_v + \frac{1}{p} v \otimes \mathrm{Tr}\, S_v + S_v^T. \tag{2}$$

The plane V is a foliation if, and only if, $A_v=0$. In this case $Q_v=S_v$ and it coincides with the second fundamental form of the integral manifolds of the foliation V.[13] Moreover V is minimal, umbilical or geodesic if, and only if, $\mathrm{Tr}\, S_v=0$, $S_v^T=0$ or $S_v=0$, respectively. Then one can generalize these geometric concepts for plane fields which are not necessarily a foliation.

Definition 1: A plane field V is said to be geodesic, umbilical or minimal if the symmetric part S_v of its (generalized) second fundamental form Q_v satisfies $S_v=0$, $S_v^T=0$ or $\mathrm{Tr}\, S_v=0$, respectively.

From these definitions, and defining $\{x,y\}=\nabla_x y+\nabla_y x$, a lemma easily follows.

Lemma 1: A plane field V is umbilical for the metric g if, and only if, a vector field $\boldsymbol{a}$ *exists such that $h(\{x,y\})=g(x,y)\,\boldsymbol{a}$ for every $x,y \in V$, h being the projector on the plane orthogonal to V.*

On a n-dimensional Riemannian manifold (M,g) an almost-product structure is defined by a p-plane field V and its orthogonal complement H. The almost-product structures can be classified taking into account the invariant decomposition of the covariant derivative of the *structure tensor* $\Pi=v-h$. Likewise, they can be classified according to the foliation, minimal, umbilical or geodesic character of each plane.[14,15] We will say that a structure (V,H) is integrable when both planes are foliations and we will say that it is minimal, umbilical or geodesic if both of the planes are so.

In an oriented four-dimensional space–time (V_4,g) of signature $(-\ +\ +\ +)$ a more accurate classification for the almost-product structures follows taking into account the causal character of the planes.[16] Elsewhere[11] we have classified the Petrov-Bel type D space–times in accordance with the class of the $2+2$ principal structure of the Weyl tensor.

III. SECOND ORDER KILLING AND CONFORMAL TENSORS

The quadratic first integrals of the geodesic equation are associated with second rank *Killing tensors*.[1] Indeed, if K is a solution to the generalized *Killing equation*

$$[K,g]=0 \quad ([K,g]_{abc}=\nabla_{(a}K_{bc)}), \tag{3}$$

then the scalar $K(v,v)$ is constant along an affine parametrized geodesic with tangent vector v.

It is known[5] that if K is a Killing tensor, its traceless part $P=K-(1/n)\mathrm{Tr}\,Kg$ is a *conformal tensor*, i.e., it satisfies the *conformal equation*

$$[P,g]=\mathcal{S}\{g\otimes t\}, \tag{4}$$

where t is, up to a factor, the divergence of P, $t=[2/(n+2)]\nabla\cdot P$, and $\mathcal{S}\{B\}$ denotes the total symmetrization of a tensor B. Then, the scalar $P(v,v)$ is constant along an affinely parametrized null geodesic with tangent vector v. Moreover, Killing equation (3) implies

$$2n\,\nabla\cdot P+(n+2)\mathrm{d}\,\mathrm{Tr}\,K=0. \tag{5}$$

Then, we have the following.

Lemma 2: If K is a second rank Killing tensor [solution to (3)] then its traceless part $P=K-(1/n)\mathrm{Tr}\,Kg$ *is a conformal tensor [solutions to (4)] and it satisfies*

$$\mathrm{d}\nabla\cdot P=0. \tag{6}$$

Conversely if a traceless conformal tensor P satisfies (6), a scalar π *exists such that* $\mathrm{d}\pi=\nabla\cdot P$. *Then,* $K=P-[2/(n+2)]\pi g$ *is a Killing tensor.*

In this work we analyze some properties of the eigenvalues and eigenspaces of Killing and conformal tensors and we present some of their properties. We proceed by studying both classes of tensors simultaneously and we will comment on the differences when they exist. So, if we consider a second rank tensor T solution to (4) the consequences on its eigenspaces and eigenvalues apply to both, Killing and conformal tensors. We particularize the conformal case by taking T as a traceless tensor. If we add condition (6), then T is the traceless part of a Killing tensor. But we can also recover the Killing tensor case by taking the vector t to be zero. It is worth pointing out that if P is a traceless conformal tensor, then $P+\Phi g$ is a conformal tensor, and both define the same first integrals of the null geodesic equation. Nevertheless, here we will always work with the traceless representative.

We denote E_ρ the eigenspace of T corresponding to the eigenvalue ρ. Then, if $x,y\in E_\rho$, a straightforward calculation leads to

$$[T,g](x,y,\cdot)=x(\rho)y+y(\rho)x+g(x,y)\mathrm{d}\rho-(T-\rho g)\{x,y\}. \tag{7}$$

On the other hand,

$$\mathcal{S}\{g\otimes t\}(x,y,\cdot)=g(x,y)t+g(t,x)y+g(t,y)x. \tag{8}$$

So, for two eigenvectors $x,y\in E_\rho$, the conformal condition (4) implies

$$(T-\rho g)\{x,y\}=g(x,y)s+g(s,x)y+g(s,y)x, \quad s\equiv\mathrm{d}\rho-t. \tag{9}$$

On the other hand, if we consider three eigenvectors x,y,z corresponding to three different eigenvalues, a similar calculation leads to

$$T(x,\{y,z\})+T(z,\{x,y\})+T(y,\{z,x\})=0. \tag{10}$$

Thus, we can state the following.

Lemma 3: Let T be a Killing (*respectively, conformal*) *tensor. Then we have the following.*

(i) *If* $x,y\in E_\rho$ *are eigenvectors associated with the eigenvalue* ρ, *Eq. (9) holds, where the*

vector t is zero (*respectively*, $t=[2/(n+2)]\nabla\cdot T$).

(ii) *If* x,y,z *are eigenvectors corresponding to three different eigenvalues, Eq. (10) holds.*

A consequence of Lemma 3 follows by taking $x=y$ in Eq. (9). Indeed, if one makes a new product with x one obtains

$$x^2 g(\mathrm{d}\rho - t, x) = 0 \tag{11}$$

and so, if x,y are non-null vectors, Eq. (9) becomes

$$(T-\rho g)\{x,y\} = g(x,y)(\mathrm{d}\rho - t). \tag{12}$$

If E_ρ is a regular eigenspace of T, then a basis of E_ρ formed with non-null eigenvectors exists and, consequently, (12) holds even for the null eigenvectors. Moreover, taking into account (11) we have the following.

Lemma 4: Let E_ρ *be a regular eigenspace of a Killing (respectively, conformal) tensor* T. *Then* (12) *with* $t=0$ (*respectively*, $t=[2/(n+2)]\nabla\cdot T$) *holds for every* $x,y\in E_\rho$.

Moreover, $\mathrm{d}\rho\in E_\rho^\perp$ *[respectively*, $2\nabla\cdot T-(n+2)\mathrm{d}\rho\in E_\rho^\perp$*]*.

IV. EIGENVALUES AND EIGENVECTORS OF SECOND ORDER KILLING AND CONFORMAL TENSORS OF TYPE I

Let us now go to type I Killing and conformal tensors, that is, those admitting an orthonormal basis of eigenvectors. In this case every eigenspace is regular and then the Killing (or conformal) equation implies (10) and (12). Moreover a basis of eigenvectors exists and, consequently, these restrictions are also sufficient conditions for T to be a Killing (or conformal) tensor. Thus, we have the following.

Proposition 1: Let T *be a symmetric 2-tensor of type I and let* E_i *be the eigenspaces corresponding to the eigenvalues* ρ_i. *Then,* T *is a Killing* (*respectively, conformal*) *tensor if, and only if*

(i) $(T-\rho_i g)\{x,y\}=g(x,y)(\mathrm{d}\rho_i - t)$, *for every* $x,y\in E_i$, *where the vector* t *is zero* (*respectively*, $t=[2/(n+2)]\nabla\cdot T$).

(ii) $T(x,\{y,z\})+T(z,\{x,y\})+T(y,\{z,x\})=0$, *for* x, y, z, *eigenvectors with different eigenvalue*.

Let K be a Killing tensor of type I and let $\{e_a\}$ and $\{\rho_a\}$ be an orthonormal basis of eigenvectors and the corresponding eigenvalues. A straightforward calculation allows us to write the two conditions in Proposition 1 in terms of $\{e_a\}$ and $\{\rho_a\}$ obtaining, in this way

$$\rho_a s_{bca} + \rho_b s_{cab} + \rho_c s_{abc} = 0, \quad a,b,c \neq , \tag{13}$$

$$e_a^2 e_b(\rho_a) - (\rho_b - \rho_a) s_{aab} = 0, \quad a \neq b, \tag{14}$$

$$e_b(\rho_b) = 0, \tag{15}$$

where s_{abc} are the symmetrized rotation coefficients, $s_{abc}=g(e_c,\{e_a,e_b\})$. If we set Eqs. (13)–(15) in terms of the rotation coefficients we easily recover the *intrinsic Killing tensor equations* obtained by Eisenhart.[1] In order to study the metrics which admit a second order Killing tensor, Eisenhart[1] started from these intrinsic equations and he looked for a set of equivalent conditions involving the eigenvectors exclusively. He considered the case when all the eigenvalues are equal and the case with different eigenvalues and normal principal congruences.[1] In this work we solve this Eisenhart problem for both the Killing and conformal tensors, when the second order tensor admits two complementary eigenspaces. We could also start from Eqs. (13)–(15) and similar conditions for the conformal case, but we will choose an alternative approach that makes the geometric properties of the eigenspaces of the Killing and conformal tensors more evident.

Let ρ_i and h_i be the eigenvalue and the projector associated with the eigenspace E_i, and let p_i be its dimension. Then

$$T = \sum \rho_i h_i, \quad g = \sum h_i, \quad \mathrm{Tr}\, h_i = p_i. \tag{16}$$

With this notation, the second statement of Lemma 4 becomes $h_i(\mathrm{d}\rho_i - t) = 0$ and, consequently,

$$t = \sum h_i(\mathrm{d}\rho_i). \tag{17}$$

On the other hand, by projecting condition (i) in Proposition 1 on every eigenspace E_j one obtains

$$(\rho_j - \rho_i) h_j(\{x,y\}) = g(x,y) h_j(\mathrm{d}\rho_i - t). \tag{18}$$

So, if v_i denotes the projection on the orthogonal space $E_i^{\perp}$, one has

$$v_i(\{x,y\}) = g(x,y) \sum_{j \neq i} \frac{1}{\rho_j - \rho_i} h_j(\mathrm{d}\rho_i - t) \tag{19}$$

for every $x, y \in E_i$. Then, according to Lemma 1 and taking into account that t is zero for a Killing tensor and it can be written as (17) for a conformal one, we arrive to the following:

Theorem 1: *Let T be a symmetric 2-tensor of type I and let h_i be the projector corresponding to the eigenvalue ρ_i. Then, T is a Killing or a conformal tensor if, and only if,*

(i) *The eigenspaces are umbilical subspaces, that is, their second fundamental form can be written as $S_i = \frac{1}{2} h_i \otimes \boldsymbol{a}_i$.*

(ii) *For every eigenspace the trace of its second fundamental form $\mathrm{Tr}\, S_i = (p_i/2)\boldsymbol{a}_i$ satisfies*

$$\boldsymbol{a}_i = \sum_{j \neq i} \frac{1}{\rho_j - \rho_i} h_j(\mathrm{d}\rho_i), \quad h_i(\mathrm{d}\rho_i) = 0, \quad \textit{for a Killing tensor}, \tag{20}$$

$$\boldsymbol{a}_i = -\sum_{j \neq i} h_j(\mathrm{d}\ln|\rho_i - \rho_j|), \quad \sum p_i \rho_i = 0, \quad \textit{for a conformal tensor}. \tag{21}$$

(iii) $T(x,\{y,z\}) + T(z,\{x,y\}) + T(y,\{z,x\}) = 0$, *for x, y, z, eigenvectors with different eigenvalues.*

The first condition of this theorem gives a geometric property involving the eigenvectors exclusively: every eigenspace is an umbilical subspace. Thus, it offers a decoupled equation that partially solves the Eisenhart problem. In the next section we will analyze the other two conditions in Theorem 1 for the case of two complementary eigenspaces. The last condition makes no sense in this case and we will see that the second one can be easily decoupled.

V. GEOMETRY OF KILLING AND CONFORMAL TENSORS OF TYPE $p+q$

A particular case of type I second order tensors are those having two complementary eigenspaces of dimensions p and $q = n - p$. So, a $p+q$ almost-product structure (V,H) is associated with these tensors, and we say that they are of type $p+q$. If v and h are the projectors onto the eigenspaces and α and β are the eigenvalues, such a tensor takes the form $T = \alpha v + \beta h$. In this case the previous theorem can be stated concisely in terms of the canonical elements $(v,h;\alpha,\beta)$ as

Proposition 2: A symmetric 2-tensor $K = \alpha v + \beta h$ of type $p+q$ is a Killing tensor if, and only if, the following conditions hold:

(i) *The eigenstructure (V,H) is umbilical, that is, the second fundamental forms can be written as*

$$S_v = \tfrac{1}{2} v \otimes \boldsymbol{a}, \quad S_h = \tfrac{1}{2} h \otimes \boldsymbol{b}. \tag{22}$$

(ii) *The traces of the second fundamental forms, $\mathrm{Tr}\, S_v = (p/2)\boldsymbol{a}$ and $\mathrm{Tr}\, S_h = (q/2)\boldsymbol{b}$, and the eigenvalues α, β are related by*

$$\boldsymbol{a} = \frac{1}{\beta - \alpha} \mathrm{d}\alpha, \quad \boldsymbol{b} = \frac{1}{\alpha - \beta} \mathrm{d}\beta. \tag{23}$$

A similar result takes place for conformal tensors as the following proposition says.

Proposition 3: A traceless symmetric 2-tensor $P=\alpha(qv-ph)$ of type $p+q$ is a conformal tensor if, and only if, the following conditions hold:

(i) *The eigenstructure (V,H) is umbilical, that is, the second fundamental forms can be written as*

$$S_v = \tfrac{1}{2} v \otimes \boldsymbol{a}, \quad S_h = \tfrac{1}{2} h \otimes \boldsymbol{b}. \tag{24}$$

(ii) *The traces of the second fundamental forms,* $\mathrm{Tr}\, S_v = (p/2)\boldsymbol{a}$ *and* $\mathrm{Tr}\, S_h = (q/2)\boldsymbol{b}$, *and the scalar α are related by*

$$\boldsymbol{a} + \boldsymbol{b} = -\,\mathrm{d}\ln|\alpha|. \tag{25}$$

It is worth remembering that, for the space-time 2+2 case, the umbilical nature of the structure is equivalent to the geodesic and shear-free character of its two null principal directions.[11] Consequently, the above propositions generalize some results for the space–time Killing and conformal tensors of type 2+2 (see Ref. 5, theorem 35.4) to an arbitrary dimension n and an arbitrary type $p+q$. Now we want to remark that the covariant formalism used here allows us to accomplish the second step in the Eisenhart method: the characterization of the Killing and conformal tensors in terms of their eigenspaces.

The characterization of a $p+q$ Killing or conformal tensor presented in the propositions above involves the structure tensor [conditions (i) and (ii)] and the eigenvalues [condition (ii)]. The next step consists of removing the eigenvalues in order to obtain the conditions that an almost product structure must satisfy in order to be the eigenstructure of a Killing or a conformal tensor. Condition (ii) of Proposition 2 can be written as

$$(\alpha - \beta)\boldsymbol{a} = -\,\mathrm{d}\alpha, \quad (\alpha - \beta)\boldsymbol{b} = \mathrm{d}\beta. \tag{26}$$

Then we have $(\beta-\alpha)(\boldsymbol{a}+\boldsymbol{b})=\mathrm{d}(\alpha-\beta)$. If we differentiate (26) and make the substitution of $\mathrm{d}(\alpha-\beta)$ we get

$$\mathrm{d}\boldsymbol{a} + \boldsymbol{a} \wedge \boldsymbol{b} = 0, \quad \mathrm{d}\boldsymbol{b} + \boldsymbol{b} \wedge \boldsymbol{a} = 0. \tag{27}$$

Conversely, if $\boldsymbol{a}$, $\boldsymbol{b}$ satisfy Eqs. (27), two functions x, y exist such that

$$\boldsymbol{a} + \boldsymbol{b} = \mathrm{d}x, \quad \boldsymbol{a} - \boldsymbol{b} = e^{x}\mathrm{d}y.$$

Then, taking $\alpha=e^{-x}-y$ and $\beta=-e^{-x}-y$, Eq. (26) is satisfied and $K=\alpha v+\beta h$ is a Killing tensor provided that (22) holds. The freedom in choosing x and y leads to the family of Killing tensors $CK+Dg$, C and D being arbitrary constants.

In the same way, condition (25) for a conformal tensor implies that $\mathrm{d}(\boldsymbol{a}+\boldsymbol{b})=0$. Conversely, if $\mathrm{d}(\boldsymbol{a}+\boldsymbol{b})=0$, a function x exists such that $\boldsymbol{a}+\boldsymbol{b}=\mathrm{d}x$. Then, the traceless tensor $P=e^{-x}(qv-ph)$ is a conformal Killing tensor provided that (24) holds. The freedom in choosing x leads to the family CP, C being an arbitrary constant. Thus, we have obtained the following.

Theorem 2: *The necessary and sufficient conditions for a $p+q$ almost-product structure (V,H) to be the eigenstructure of a Killing or a conformal tensor are the following.*

(i) *(V,H) is umbilical, that is, the second fundamental forms take the expression*

$$S_v = \tfrac{1}{2} v \otimes \boldsymbol{a}, \quad S_h = \tfrac{1}{2} h \otimes \boldsymbol{b}. \tag{28}$$

(ii) *The traces,* $\mathrm{Tr}\, S_v = (p/2)\boldsymbol{a}$ and $\mathrm{Tr}\, S_h = (q/2)\boldsymbol{b}$, *of the second fundamental forms satisfy*

$$\mathrm{d}\boldsymbol{a} + \boldsymbol{a} \wedge \boldsymbol{b} = 0, \quad \mathrm{d}\boldsymbol{b} + \boldsymbol{b} \wedge \boldsymbol{a} = 0 \quad \textit{for Killing tensors}, \tag{29}$$

$$\mathrm{d}(\boldsymbol{a}+\boldsymbol{b})=0 \quad \textit{for conformal tensors}. \tag{30}$$

If (28) *and* (29) *hold, two functions* x, y *exist such that* $\boldsymbol{a}+\boldsymbol{b}=\mathrm{d}x$, $\boldsymbol{a}-\boldsymbol{b}=e^{x}\,\mathrm{d}y$. *Then taking* $\alpha=e^{-x}-y$, $\beta=-e^{-x}-y$, $K=C(\alpha v+\beta h)+Dg$ *is a Killing tensor*, C *and* D *being two arbitrary constants*.

If (28) *and* (30) *hold, a function* x *exists such that* $\mathrm{d}x=\boldsymbol{a}+\boldsymbol{b}$. *Then*, $P=Ce^{-x}(qv-ph)$ *is a conformal Killing tensor*, C *being an arbitrary constant*.

This theorem offers the second step in solving the Eisenhart problem for Killing or conformal tensors with two complementary eigenspaces. In fact, once the eigenvalues have been removed, we have obtained necessary and sufficient conditions involving the sole eigenspaces. In Sec. VIII we will see that, for the space–time 2+2 case, these conditions can be written as tensorial conditions on the structure tensor (or on the canonical 2-form associated with the structure). This fact allows us to give an intrinsic and explicit characterization of the four-dimensional Petrov-Bel type D space–times admitting a Killing or a conformal tensor in Sec. IX.

VI. METRICS ADMITTING A KILLING OR A CONFORMAL TENSOR OF TYPE $p+q$

In this section we show that a metric admitting a Killing or a conformal tensor of type $p+q$ admits a canonical expression in terms of a particular conformal metric and a specific conformal factor. First we state a corollary which trivially follows on from Propositions 2 and 3.

Corollary 1: Let (V,H) *be a* $p+q$ *almost-product structure for the metric tensor* g. *The following statements are equivalent:*

(i) (V,H) *is a* $p+q$ *totally geodesic almost-product structure*.
(ii) $Cv+Dh$ *is a Killing tensor*, C *and* D *being arbitrary constants*.
(iii) $C(qv-ph)$ *is a conformal tensor*, C *being an arbitrary constant*.

This corollary states that the Riemannian spaces admitting a second order Killing tensor with constant eigenvalues are those admitting a $p+q$ totally geodesic structure (V,H). We will show now that these Riemannian spaces generate all the spaces admitting Killing or conformal tensors by using an adequate conformal transformation.

The umbilical property is known to be a conformal invariant.[15,11] Moreover, if we take into account the change of the second fundamental form through a conformal transformation,[11] condition (25) for a conformal tensor states that the eigenstructure (V,H) is minimal for the conformal metric $\tilde{g}=|\alpha|^{-1}g$. Consequently, the family of metrics that admit a $p+q$ conformal tensor are those that are conformal to a metric which admits a totally geodesic $p+q$ structure. More precisely, we have the following.

Proposition 4. The metrics g *that admit a* $p+q$ *conformal tensor are those that may be written as* $g=|\alpha|\tilde{g}$, *where* $\tilde{g}$ *is a metric admitting a totally geodesic* $p+q$ *structure* (V,H).

Then the conformal tensor for g *is* $P=C\alpha(qv-ph)$, C *being an arbitrary constant*.

This proposition and Corollary 1 generalize to an arbitrary dimension n and an arbitrary type $p+q$ a result by Hauser and Malhiot[8] concerning the 2+2 space–time case. Moreover we also recover another known result easily:[17] a (contravariant) conformal tensor for a metric is a conformal tensor for every conformally related metric.

A similar result holds for Killing tensors. In fact, the sum of expressions (29) says that $\mathrm{d}(a+b)=0$, which is exactly the condition necessary for (V,H) to be the eigenstructure of a conformal tensor, and so the metric is conformal to a metric admitting a $p+p$ totally geodesic structure. But now, the conformal factor is not arbitrary because it must satisfy the two equations in (29). A detailed analysis of these conditions leads to the following.

Proposition 5: The metrics g *that admit a* $p+q$ *Killing tensor are those that may be written as* $g=|\alpha-\beta|\tilde{g}$, *where* $\tilde{g}$ *is a metric admitting a totally geodesic* $p+q$ *structure* (V,H), *and* α *and* β *are functions such that* $v(\mathrm{d}\alpha)=0$, $h(\mathrm{d}\beta)=0$.

Moreover, the Killing tensor for g *is* $K=C(\alpha v+\beta h)+Dg$, C *and* D *being arbitrary constants*.

The two propositions above imply that the study of the Riemannian spaces admitting a Killing

or a conformal tensor reduces to the study of the metrics $\tilde{g}$ admitting a totally geodesic $p+q$ structure. As Proposition 4 states, for every metric $\tilde{g}$ of this type we obtain a metric g admitting a conformal tensor by using an arbitrary conformal factor, $g=\Omega^2\tilde{g}$.

Nevertheless, Proposition 5 states that the richness of metrics admitting a Killing tensor conformally related to a $\tilde{g}$ of this type depends on the quantity of normal directions aligned with one of the planes of the structure. This fact induces a classification of the metrics admitting a totally geodesic $p+q$ structure.

In the more regular metrics no aligned normal direction exists and only constant conformal factors can be considered, the Killing tensor then have constant eigenvalues.

The more degenerate class corresponds to the product metrics $\tilde{g}=\tilde{v}+\tilde{h}$, $\tilde{v}_{AB}(x^C)$ and $\tilde{h}_{ij}(x^k)$ being two arbitrary p and q dimensional metrics, respectively; then, the available conformal factors are $\Omega^2=|\alpha-\beta|$, $\alpha(x^k)$ and $\beta(x^C)$ being arbitrary functions depending on the product coordinates and they coincide with the Killing tensor eigenvalues.

An intermediate situation occurs when, for example, only one normal aligned direction exists on each plane. Then, through the adequate conformal transformation we can obtain a metric admitting a Killing tensor with nonconstant eigenvalues. In dealing with $2+2$ space–time Killing tensors this case leads to the Hauser and Malhiot[7,8] canonical form for the metric.

VII. KILLING AND CONFORMAL TENSORS OF TYPE $1+(n-1)$

Let us consider the case of a $1+(n-1)$ structure (V,H) defined by the unitary direction u ($u^2=\epsilon=\pm 1$) and its orthogonal complement. Then $g=v+h$ where $v=\epsilon u\otimes u$ and $h=g-\epsilon u\otimes u$. In terms of the usual kinematic coefficients of u ($\nabla u=\epsilon u\otimes\dot{u}+[1/(n-1)]\theta h+\sigma+\Omega$) the (generalized) second fundamental forms are

$$Q_v=u\otimes u\otimes\dot{u},\quad Q_h=-\epsilon\left(\frac{1}{n-1}\theta h+\sigma+\Omega\right)\otimes u. \tag{31}$$

The condition for (V,H) to be an umbilical structure just states $\sigma=0$, and then

$$S_v=u\otimes u\otimes\dot{u},\quad S_h=-\epsilon\frac{1}{n-1}\theta h\otimes u. \tag{32}$$

Thus taking into account Theorem 2, we find that the necessary and sufficient condition for u to define the eigenstructure of a conformal tensor is

$$\sigma=0,\quad \mathrm{d}\left(\dot{u}-\frac{\theta}{n-1}u\right)=0. \tag{33}$$

But these conditions state that u defines the direction of a conformal Killing vector.[18] Thus, we have the following.

Proposition 6: A $1+(n-1)$ *structure defined by the unitary direction u is the eigenstructure of a conformal Killing tensor if, and only if, u defines the direction of a conformal Killing vector, that is, it satisfies (33).*

This proposition implies that every traceless conformal tensor of type $1+(n-1)$ is the traceless part of $\xi\otimes\xi$, ξ being a Killing conformal vector. In other words, *every* $1+(n-1)$ *conformal tensor is reducible*

A similar procedure allows us to characterize the fact that u defines the eigenstructure of a $1+(n-1)$ Killing tensor. But in this case we find that it is not, necessarily, reducible. Indeed, taking into account (32) the condition (29) of Theorem 2 is equivalent to

$$\mathrm{d}\left(\dot{u}-\frac{\theta}{n-1}u\right)=0, \quad \theta\,\mathrm{d}u+\mathrm{d}\theta\wedge u+2\epsilon\theta u\wedge\dot{u}=0.$$

When $\theta=0$ these equations hold if $\mathrm{d}\dot{u}=0$, that is, if u defines the direction of a Killing vector. On the contrary, if $\theta\neq 0$, the second equation implies $\mathrm{d}u\wedge u=0$, and so $\mathrm{d}u=\epsilon u\wedge\dot{u}$. In this case, u defines the direction of a normal conformal Killing vector and the second equation can be written as

$$\mathrm{d}(\theta^{1/3}u)=0. \tag{34}$$

These results are summarized in the following.

Proposition 7: The $1+(n-1)$ *structure defined by the unitary direction u is the eigenstructure of a Killing tensor if, and only if, one of the following conditions hold*:

(i) *u defines the direction of a Killing vector, that is, it satisfies* $\sigma=0=\theta$, $\mathrm{d}\dot{u}=0$.
(ii) *u defines the direction of a normal conformal Killing vector with integrant factor* $\theta^{1/3}$, *that is, it satisfies equations (33) and (34).*

This proposition shows that we can distinguish two classes of Killing tensors of type $1+(n-1)$. On the one hand, we have the reducible ones, that is, those that can be written as $\xi\otimes\xi+Bg$, ξ being a Killing vector and B an arbitrary constant. On the other hand, a class of irreducible Killing tensors that can be obtained from normal conformal Killing vectors. This last class has been considered by Koutras[19] and Rani *et al.*[17]

The results in the preceding section allow us to give the canonical form for the metric tensors admitting irreducible Killing tensors of type $1+(n-1)$. Indeed, as the eigenstructure is integrable, the metric will be conformally related to a $1+(n-1)$ product metric. Moreover Proposition 5 gives the conformal factor. Finally, we can state the following

Proposition 8: The metrics admitting an irreducible Killing tensor of type $1+(n-1)$ *are those that may be written as*

$$g=|\alpha(x^i)-\beta(x^0)|[\epsilon\,\mathrm{d}x^0\otimes\mathrm{d}x^0+\gamma(x^i)], \tag{35}$$

where $\gamma(x^i)$ *is an arbitrary* $(n-1)$*-dimensional metric.*

The Killing tensor is then given by $C|\alpha-\beta|[\epsilon\alpha\,\mathrm{d}x^0\otimes\mathrm{d}x^0+\beta\gamma(x^i)]+Dg$, *C and D being arbitrary constants.*

VIII. SPACE–TIME KILLING AND CONFORMAL TENSORS OF TYPE [(11) (11)]

Let T be a Killing or a conformal tensor of type [(11) (11)] in an oriented four-dimensional space–time (V_4,g) of signature $(-+++)$. Then T has two eigenspaces: a timelike two-plane V and its spacelike orthogonal complement H. The almost-product eigenstructure (V,H) is determined by the *canonical* unitary 2-form U, volume element of the timelike plane V. Then, the respective projectors are $v=U^2$ and $h=-(*U)^2$, where $U^2=U\times U=\mathrm{Tr}_{23}\,U\otimes U$ and $*$ is the Hodge dual operator.

In order to study the geometric properties of a 2+2 structure it is useful to introduce the self-dual unitary 2-form $\mathcal{U}\equiv(1/\sqrt{2})(U-i*U)$ associated with U. The metric on the self-dual 2-forms space is $\mathcal{G}=\frac{1}{2}(G-i\eta)$, where η is the metric volume element of the space–time, $G=\frac{1}{2}g\wedge g$ is the metric on the 2-forms space, and $\wedge$ denotes the double-forms exterior product, $(A\wedge B)_{\alpha\beta\mu\nu}=A_{\alpha\mu}B_{\beta\nu}+A_{\beta\nu}B_{\alpha\mu}-A_{\alpha\nu}B_{\beta\mu}-A_{\beta\mu}B_{\alpha\nu}$. Then, we can consider some first order differential concomitants of U that determine the geometric properties of the structure. Indeed, if $i(\cdot)$ denotes the interior product and δ the exterior codifferential, $\delta=*d*$, we have the following lemma.[11]

Lemma 5: Let us consider the 2+2 *structure defined by* $\mathcal{U}=(1/\sqrt{2})(U-i*U)$. Then

(i) *The traces of the second fundamental forms take the expression*

$$\mathrm{Tr}\,Q_v=\boldsymbol{a}[U]\equiv-i(\delta*U)*U, \quad \mathrm{Tr}\,Q_h=\boldsymbol{b}[U]\equiv i(\delta U)U. \tag{36}$$

(ii) *The structure is umbilical, if, and only if,*

$$\Sigma[U] \equiv \nabla\mathcal{U} - i(\delta\mathcal{U})\mathcal{U}\otimes\mathcal{U} - i(\delta\mathcal{U})\mathcal{G} = 0. \tag{37}$$

With this notation, we can write the intrinsic equations in Propositions 2 and 3 for the case of Killing or conformal tensors of type [(11) (11)] by using the eigenvalues and the canonical 2-form U exclusively.

Proposition 9: The traceless symmetric tensor $P=\alpha[U^2+(*U)^2]$ *is a conformal tensor if, and only if, the canonical elements* $\{\alpha, U\}$ *satisfy (37) and*

$$-\mathrm{d}\ln|\alpha| = \Phi[U] \equiv i(\delta U)U - i(\delta * U) * U. \tag{38}$$

Proposition 10: The symmetric tensor $K=\alpha U^2+\beta(*U)^2$ *is a Killing tensor if, and only if, the canonical elements* $\{\alpha, \beta, U\}$ *satisfy (37) and (38) and*

$$\mathrm{d}\alpha = (\alpha-\beta)i(\delta * U) * U. \tag{39}$$

This last proposition is the tensorial version of the intrinsic equations for a Killing tensor that are known in Newmann-Penrose formalism (Ref. 5, Theorem 35.4). Now we can easily write the conditions in Theorem 2 in terms of the canonical 2-form U, that is, we obtain the characterization of the Killing and conformal tensor in the sole variable U.

Theorem 3: The 2+2 *structure defined by the unitary simple 2-form U is the eigenstructure of a conformal tensor if, and only if, U satisfies*

$$\Sigma[U] \equiv \nabla\mathcal{U} - i(\delta\mathcal{U})\mathcal{U}\otimes\mathcal{U} - i(\delta\mathcal{U})\mathcal{G} = 0, \tag{40}$$

$$\mathrm{d}\Phi[U] \equiv \mathrm{d}[i(\delta U)U - i(\delta * U) * U] = 0. \tag{41}$$

If these conditions hold, a function α *exists such that* $\Phi[U]=-\mathrm{d}\ln|\alpha|$. *Then, the conformal tensor is* $P=C\alpha[U^2+(*U)^2]$, C *being an arbitrary constant.*

Theorem 4: *The* 2+2 *structure defined by the unitary simple 2-form U is the eigenstructure of a Killing tensor if, and only if, U satisfies*

$$\Sigma[U] \equiv \nabla\mathcal{U} - i(\delta\mathcal{U})\mathcal{U}\otimes\mathcal{U} - i(\delta\mathcal{U})\mathcal{G} = 0, \tag{42}$$

$$\mathrm{d}\Phi[U] \equiv \mathrm{d}[i(\delta U)U - i(\delta * U) * U] = 0, \tag{43}$$

$$\mathrm{d}i(\delta U)U = i(\delta U)U \wedge i(\delta * U) * U. \tag{44}$$

If these conditions hold, two functions α *and* β *exist such that* $\Phi[U]=-\mathrm{d}\ln|\alpha-\beta|$ *and* $\mathrm{d}(\alpha+\beta)=2(\alpha-\beta)[i(\delta U)U+i(\delta * U) * U]$. *Then, the Killing tensor is* $K=C[\alpha U^2-\beta(*U)^2]+Dg$, C *and* D *being two arbitrary constants*

It is worth pointing out that the first order differential properties of a 2+2 structure admit a kinematical interpretation[16] and, in particular, the umbilical conditions (40) and (42) equivalently imply that the two principal null directions of the structure are geodesic and shear-free congruences.[11] Thus, we recover a known result obtained independently by Hauser and Malhiot[7] and by Collinson.[20]

On the other hand, condition (41) states that the structure is pre-Maxwellian.[21,22] Then, taking into account the study of these structures given in Ref. 22 we have the following.

Corollary 2: The 2+2 *traceless tensor* $P=\alpha(v-h)$ *is a conformal tensor if, and only if,* $T=\alpha^{-2}(v-h)$ *is a conservative Maxwell-Minkowski energy tensor and the principal directions of the associated electromagnetic field are geodesic and shear-free congruences.*

IX. PETROV-BEL TYPE D SPACE–TIMES ADMITTING KILLING OR CONFORMAL TENSORS

The results in the preceding sections help us to characterize intrinsically and explicitly some families of metrics. More precisely, in this section: (i) we obtain necessary and sufficient conditions on the metric concomitants for a four-dimensional space–time to be a Petrov-Bel type D solution admitting a 2+2 Killing or conformal tensor and, when they hold, (ii) we give an algorithm to determine these tensors.

In the preceding section we have characterized the 2+2 Killing and conformal tensors in terms of the volume element U of their timelike eigenplane. Moreover, for the case of Petrov-Bel type D metrics, this 2-plane determines the Weyl principal structure and, consequently, U can be obtained from the Weyl tensor. The intrinsic and explicit characterization of type D solutions and the covariant obtaining of the Weyl canonical bivector have been given in Ref. 9. Consequently we can state the following invariant characterizations.

Proposition 11: A Petrov-Bel type D metric admits a conformal tensor if, and only if, the Weyl principal null directions define geodesic shear-free congruences and the Weyl canonical 2-form satisfies (43).

A Petrov-Bel type D metric admits a Killing tensor if, and only if, the Weyl principal null directions define geodesic shear-free congruences and the Weyl canonical 2-form satisfies (43) and (44).

Finally, taking into account the algebraic results for Petrov-Bel type D metrics quoted above (see Ref. 9), we obtain from Theorems 3 and 4 the explicit expression of the conditions in Proposition 11 and the algorithm for obtaining the conformal or Killing tensors.

Theorem 5: Let $\mathcal{W}\equiv\mathcal{W}(g)=\frac{1}{2}(W(g)-\mathrm{i}*W(g))$ *and* $\mathcal{G}\equiv\mathcal{G}(g)=\frac{1}{2}\left(\frac{1}{2}g\wedge g-\mathrm{i}\,\eta(g)\right)$ *the self-dual Weyl tensor and self-dual metric associated with a space–time metric* g, *and let us take the metric concomitants*

$$\rho\equiv-\frac{\mathrm{Tr}\mathcal{W}^3}{\mathrm{Tr}\mathcal{W}^2},\quad \mathcal{S}\equiv\frac{1}{3\rho}(\mathcal{W}-\rho\mathcal{G}),\quad \mathcal{U}\equiv\frac{\mathcal{S}(\mathcal{X})}{\sqrt{\mathcal{S}(\mathcal{X},\mathcal{X})}},\tag{45}$$

$$\Sigma\equiv\nabla\mathcal{U}-i(\delta\mathcal{U})\mathcal{U}\otimes\mathcal{U}-i(\delta\mathcal{U})\mathcal{G},\tag{46}$$

$$U\equiv\sqrt{2}\,\mathrm{Re}\{\mathcal{U}\},\quad \boldsymbol{a}\equiv-i(\delta*U)*U,\quad \boldsymbol{b}\equiv i(\delta U)U,\tag{47}$$

where $\mathcal{X}$ *is an arbitrary self-dual bivector.*

The necessary and sufficient conditions for g *to be a Petrov-Bel type D solution admitting a* 2+2 *conformal tensor are*

$$\rho\neq0,\quad \mathcal{S}^2+\mathcal{S}=0,\quad \Sigma=0,\quad \mathrm{d}(\boldsymbol{a}+\boldsymbol{b})=0.\tag{48}$$

When (48) hold, a function α *exists such that* $-\mathrm{d}\ln|\alpha|=\boldsymbol{a}+\boldsymbol{b}$. *Then, the conformal tensor is* $P=C\alpha[U^2+(*U)^2]$, C *being an arbitrary constant.*

The necessary and sufficient conditions for g *to be a type D solution admitting a* 2+2 *Killing tensor are* 48 *and*

$$\mathrm{d}\boldsymbol{b}+\boldsymbol{b}\wedge\boldsymbol{a}=0.\tag{49}$$

When (48) and (49) hold, two functions α *and* β *exist such that* $-\mathrm{d}\ln|\alpha-\beta|=\boldsymbol{a}+\boldsymbol{b}$ *and* $\mathrm{d}(\alpha+\beta)=2(\alpha-\beta)[\boldsymbol{b}-\boldsymbol{a}]$. *Then, the Killing tensor is* $K=C[\alpha U^2-\beta(*U)^2]+Dg$, C *and* D *being two arbitrary constants.*

For Petrov-Bel type D solutions with a vanishing Cotton tensor (the Weyl tensor is divergence-free) the Bianchi identities take the expression[11]

$$\nabla\mathcal{U} = i(\mathcal{U})[\mathcal{U}\otimes\mathcal{U}+\mathcal{G}], \quad i(\mathcal{U})\mathcal{U} = \tfrac{1}{3}\mathrm{d}\ln\rho, \tag{50}$$

where $\mathcal{U}$ is the Weyl canonical bivector and ρ the double Weyl eigenvalue. The real part of the second equation in (50) states

$$\tfrac{2}{3}\mathrm{d}\ln|\rho| = \Phi[U] \equiv i(\delta U)U - i(\delta * U) * U. \tag{51}$$

Thus, the principal structure of a type D divergence-free Weyl tensor is umbilical and pre-Maxwellian and, as a consequence of Theorem 3, it is the structure of a conformal tensor. Moreover, in this case the eigenvalue of the conformal tensor can be obtained algebraically from the Weyl eigenvalues if we take into account Proposition 9. Thus, we have the following.

Theorem 6: *Every Petrov-Bel type D solution with vanishing Cotton tensor admits a conformal tensor. Let* ρ, $\mathcal{S}$, *and* $\mathcal{U}$ *be the Weyl concomitants given in* (45). *Then we have the following*.

(i) *These space–times are characterized by the conditions*

$$\rho \neq 0, \quad \mathcal{S}^2 + \mathcal{S} = 0, \quad \delta W = 0. \tag{52}$$

(ii) *The conformal tensor is given by*

$$P = C|\rho|^{-2/3}\mathcal{U}\times\tilde{\mathcal{U}}. \tag{53}$$

This theorem generalizes the result about the existence of conformal tensors in Petrov-Bel type D vacuum solutions (see Ref. 5, Theorem 35.2).

We finish with two comments. The characterization of the Killing or conformal tensors in terms of their underlying structure has allowed us to give an explicit and intrinsic labeling of the Petrov-Bel type D space–times admitting Killing or conformal tensors, as well as to generalize some known results on the existence of these symmetries. Furthermore, our Eisenhart-type approach to the Killing and conformal tensor may also be useful in analyzing and extending other properties. For example, it is known that all type D vacuum solutions that admit a Killing tensor, also admit a Killing-Yano tensor.[20,23] Our result here and those given in Ref. 22 allow us to generalize this property. This question and other related topics will be considered elsewhere.[24]

Our study of the geometry of the Killing and conformal tensors and the canonical expressions of the metric tensor in terms of this geometry can be applied, in particular, to n-dimensional Lorentzian metrics. We know that, for four-dimensional Petrov-Bel type D space–times, this underlying geometry is closely related with the Weyl tensor and, this fact allows us to determine the $2+2$ Killing and conformal tensors (see Theorems 5 and 6). The generalization of these results to higher dimensions is an open problem that could be fruitful in some classes of the Weyl tensor. But this study will require a further analysis of the Weyl classification in higher dimensions.[25,26]

We provide a coordinate-free version of the local classification, due to Walker [Q. J. Math. **1**, 69 (1950)], of null parallel distributions on pseudo-Riemannian manifolds. The underlying manifold is realized, locally, as the total space of a fiber bundle, each fiber of which is an affine principal bundle over a pseudo-Riemannian manifold. All structures just named are naturally determined by the distribution and the metric, in contrast with the noncanonical choice of coordinates in the usual formulation of Walker's theorem. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2209167]

I. INTRODUCTION

In 1950, Walker[1] described the local structure of all pseudo-Riemannian manifolds with null parallel distributions. The present paper provides a coordinate-free version of Walker's theorem.

Many authors, beginning with Walker himself,[2] have invoked Walker's 1950 result, often to generalize it or derive other theorems from it. In our bibliography, which is by no means complete, Refs. 3–16 all belong to this category. They invariably cite Walker's result in its original, local-coordinate form (reproduced in the Appendix).

Such an approach, perfectly suited for the applications just mentioned, tends nevertheless to obscure the geometric meaning of Walker's theorem. In fact, Walker coordinates are far from unique; choosing them results in making noncanonical objects a part of the structure.

To keep the picture canonical, some authors[3,5] replace a single Walker coordinate system by a whole maximal atlas of them. What we propose here, instead, is to use only ingredients such as fiber bundles, widely seen as more directly "geometric" than a coordinate atlas (even though one may ultimately need atlases to define them).

In our description, the coordinate-independent content of Walker's theorem amounts to realizing the underlying manifold, locally, as a fiber bundle whose fibers are also bundles, namely, affine principal bundles over pseudo-Riemannian manifolds. The bundle structures are all naturally associated with the original null parallel distribution; the distribution and the metric can in turn be reconstructed from them.

II. PRELIMINARIES

Throughout this paper, all manifolds, bundles, sections, subbundles, connections, and mappings, including bundle morphisms, are assumed to be of class C^∞. A bundle morphism may operate only between two bundles with the same base manifold, and acts by identity on the base.

A bundle always means a C^∞ locally trivial bundle and the same symbol, such as M, is used both for a given bundle and for its total space; the bundle projection $M \to \Sigma$ onto the base manifold

[a)]Electronic mail: andrzej@math.ohio-state.edu
[b)]Electronic mail: roter@im.pwr.wroc.pl

Σ is denoted by π (or, sometimes, p). We let M_y stand for the fiber $\pi^{-1}(y)$ over any $y \in \Sigma$, while $\mathrm{Ker}\, \mathrm{d}\pi$ is the vertical distribution treated as a vector bundle (namely, a subbundle of the tangent bundle TM).

For real vector bundles $\mathcal{X}, \mathcal{Y}$ over a manifold Σ and a real vector space V with $\dim V < \infty$, we denote by $\mathrm{Hom}(\mathcal{X}, \mathcal{Y})$ the vector bundle over Σ whose sections are vector-bundle morphisms $\mathcal{X} \to \mathcal{Y}$, and by $\Sigma \times V$ the product bundle with the fiber V, the sections of which are functions $\Sigma \to V$. Thus, $\mathcal{X}^* = \mathrm{Hom}(\mathcal{X}, \Sigma \times \mathbf{R})$ is the dual of $\mathcal{X}$.

We will say that a given fiberwise structure in a bundle M over a manifold Σ *depends C^∞-differentiably on $y \in \Sigma$*, or *varies C^∞-differentiably with y*, if suitable C^∞ local trivializations of M make the structure appear as constant (the same in each fiber).

The symbol ∇ will be used for various connections in vector bundles. Our sign convention about the curvature tensor $R = R^\nabla$ of a connection ∇ in a vector bundle $\mathcal{X}$ over a manifold Σ is

$$R(u,v)\psi = \nabla_v \nabla_u \psi - \nabla_u \nabla_v \psi + \nabla_{[u,v]} \psi, \tag{1}$$

for sections ψ of $\mathcal{X}$ and vector fields u, v tangent to Σ. By the Leibniz rule, when ∇ is the Levi-Civita connection of a pseudo-Riemannian metric g and u, v, w are tangent vector fields, $2\langle \nabla_w v, u \rangle$ equals[17]

$$d_w\langle v,u\rangle + d_v\langle w,u\rangle - d_u\langle w,v\rangle + \langle v,[u,w]\rangle + \langle u,[w,v]\rangle - \langle w,[v,u]\rangle, \tag{2}$$

where d_v is the directional derivative and $\langle , \rangle$ stands for $g(,)$.

Remark 2.1: Let $\pi: M \to \Sigma$ be a bundle projection. A vector field w on the total space M is π-projectable onto the base manifold Σ if and only if, for every vertical vector field u on M, the Lie bracket $[w,u]$ is also vertical. This well-known fact is easily verified in local coordinates for M which make π appear as a standard Euclidean projection.

III. AFFINE PRINCIPAL BUNDLES

All principal bundles discussed below have Abelian structure groups G, so one need not decide whether G acts from the left or right.

Let N be a G-principal bundle over a base manifold L, where G is an Abelian Lie group. By the *N-prolongation* of the tangent bundle TL we mean the vector bundle $\mathcal{F}$ over L whose fiber $\mathcal{F}_c$ over $c \in L$ is the space of all G-invariant vector fields tangent to N along N_c (and defined just on N_c), with N_c denoting, as usual, the fiber of N over c. A vector subbundle $\mathcal{G} \subset \mathcal{F}$ now can be defined by requiring $\mathcal{G}_c$, for any $c \in L$, to consist of all G-invariant vector fields defined just on N_c which are vertical (i.e., tangent to N_c). Since each $\mathcal{G}_c$ is canonically isomorphic to the Lie algebra $\mathfrak{g}$ of G, the vector bundle $\mathcal{G}$ is naturally trivialized, that is, identified with the product bundle $L \times \mathfrak{g}$. Therefore

$$L \times \mathfrak{g} = \mathcal{G} \subset \mathcal{F}. \tag{3}$$

The quotient bundle $\mathcal{F}/\mathcal{G}$ is in turn naturally isomorphic to TL, via the differential of the bundle projection $N \to L$.

An *affine space* is a set A with a simply transitive action on A of the additive group of a vector space V. One calls V the *vector space of translations* of the affine space A.

An *affine bundle M* over a manifold Σ is a bundle with fibres M_y, $y \in \Sigma$, carrying the structures of affine spaces whose vector spaces $\mathcal{X}_y$ of translations form a vector bundle $\mathcal{X}$ over Σ, called the *associated vector bundle* of M. We also require the affine-space structure of M_y to vary C^∞-differentiably with $y \in \Sigma$, in the sense of Sec. II.

If, in addition, $\mathcal{X} = \Sigma \times V$, that is, the associated vector bundle of M happens to be a product bundle, then M is also a V-principal bundle, with the obvious action of the additive group of the vector space V. Such *affine principal bundles* are distinguished from arbitrary affine bundles by having a structure group that, instead of general affine transformations of a model fiber, contains only translations.

IV. PARTIAL METRICS AND EXTENSIONS

Let $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ be real vector bundles over a manifold Q. By an $\mathcal{E}$-valued *pairing* of $\mathcal{C}$ and $\mathcal{D}$ we mean any vector-bundle morphism $\beta:\mathcal{C}\otimes\mathcal{D}\to\mathcal{E}$. This amounts to a C^∞ assignment of a bilinear mapping $\beta(z):\mathcal{C}_z\times\mathcal{D}_z\to\mathcal{E}_z$ to every $z\in Q$. An $\mathcal{E}$-valued *partial pairing* of $\mathcal{C}$ and $\mathcal{D}$ consists, by definition, of two vector subbundles $\mathcal{C}'\subset\mathcal{C}$ and $\mathcal{D}'\subset\mathcal{D}$, of some codimensions k and l, along with pairings $\gamma:\mathcal{C}\otimes\mathcal{D}'\to\mathcal{E}$ and $\gamma:\mathcal{C}'\otimes\mathcal{D}\to\mathcal{E}$ which coincide on the subbundle $\mathcal{C}'\otimes\mathcal{D}'$ (and so may be represented by the same symbol γ without risk of ambiguity). One can obviously restrict a given pairing $\beta:\mathcal{C}\otimes\mathcal{D}\to\mathcal{E}$ to $\mathcal{C}\otimes\mathcal{D}'$ and $\mathcal{C}'\otimes\mathcal{D}$, so that a partial pairing γ is obtained; we will then say that β is a *total-pairing extension* of γ.

Lemma 4.1: *For any fixed partial pairing* γ, *with* $\mathcal{C}$, $\mathcal{D}$, $\mathcal{E}$, $\mathcal{C}'$, $\mathcal{D}'$, k, l, *and* Q *as above*, *and with* m *denoting the fiber dimension of* $\mathcal{E}$, *the total-pairing extensions of* γ *coincide with sections of a specific affine bundle of fiber dimension klm over* Q, *whose associated vector bundle is* $\mathrm{Hom}(\mathcal{C}/\mathcal{C}'\otimes\mathcal{D}/\mathcal{D}',\mathcal{E})$.

Proof: Our γ is nothing else than a vector-bundle morphism $\mathcal{X}\to\mathcal{E}$, where $\mathcal{X}\subset\mathcal{C}\otimes\mathcal{D}$ is the subbundle spanned by $\mathcal{C}\otimes\mathcal{D}'$ and $\mathcal{C}'\otimes\mathcal{D}$. The affine bundle in question is the preimage of the section γ under the (surjective) restriction morphism $\mathrm{Hom}(\mathcal{C}\otimes\mathcal{D},\mathcal{E})\to\mathrm{Hom}(\mathcal{X},\mathcal{E})$. □

As usual,[5] by a *pseudo-Riemannian fiber metric* g in a vector bundle $\mathcal{T}$ over a manifold M we mean any family of nondegenerate symmetric bilinear forms $g(x)$ in the fibers $\mathcal{T}_x$ that constitutes a C^∞ section of the symmetric power $(\mathcal{T}^*)^{\odot 2}$. Equivalently, such g is a pairing of $\mathcal{T}$ and $\mathcal{T}$ valued in the product bundle $M\times\mathbf{R}$, symmetric and nondegenerate at every point of M.

Let $\mathcal{T}$ again be a vector bundle over a manifold M. We define a *partial fiber metric* in $\mathcal{T}$ to be a triple $(\mathcal{P},\mathcal{P}',\alpha)$ formed by vector subbundles $\mathcal{P}$ and $\mathcal{P}'$ of $\mathcal{T}$ along with a pairing $\alpha:\mathcal{P}'\otimes\mathcal{T}\to M\times\mathbf{R}$, valued in the product bundle $M\times\mathbf{R}$, such that

(i) $\mathcal{T},\mathcal{P}$, and $\mathcal{P}'$ are of fiber dimensions n,r and, respectively, $n-r$ for some n,r with $0\le r\le n/2$, while $\mathcal{P}\subset\mathcal{P}'$,
(ii) at every $x\in M$ the bilinear mapping $\alpha(x):\mathcal{P}'_x\times\mathcal{T}_x\to\mathbf{R}$ has the rank $n-r$, its restriction to $\mathcal{P}'_x\times\mathcal{P}'_x$ is symmetric, and its restriction to $\mathcal{P}'_x\times\mathcal{P}_x$ equals 0.

By a *total-metric extension* of $(\mathcal{P},\mathcal{P}',\alpha)$ we then mean any pseudo-Riemannian fiber metric in $\mathcal{T}$ whose restriction to $\mathcal{P}'\otimes\mathcal{T}$ is α.

Lemma 4.2: *The total-metric extensions* g *of any partial fiber metric* $(\mathcal{P},\mathcal{P}',\alpha)$, *with* r,M *as above*, *coincide with the sections of a specific affine bundle of fiber dimension* $r(r+1)/2$ *over* M. *For every such* g *the subbundle* $\mathcal{P}$ *is* g*-null and* $\mathcal{P}'$ *is its* g*-orthogonal complement*.

Proof: For any fixed point $x\in M$, let us choose a basis $e_1,\ldots,e_n$ of $\mathcal{T}_x$ such that $e_1,\ldots,e_r\in\mathcal{P}_x$ and $e_1,\ldots,e_{n-r}\in\mathcal{P}'_x$. The matrix of $g(x)$, for any total-metric extension g of our partial fiber metric, then is the matrix appearing in Walker's original theorem (see the Appendix), with $\det A\neq 0$, and with the two occurrences of I replaced by some nonsingular $r\times r$ matrix C and its transpose C'. The submatrices A,H,C (and H',C') are prescribed, while the freedom in choosing $g(x)$ is represented by an arbitrary symmetric $r\times r$ matrix B. □

V. WALKER'S THEOREM

Suppose that the following data are given:

(a) Integers n and r with $0\le r\le n/2$.
(b) An r-dimensional manifold Σ.
(c) A bundle over Σ with some total space M, whose every fiber M_y, $y\in\Sigma$, is a $T^*_y\Sigma$-principal bundle over a $(n-2r)$-dimensional manifold Q_y (cf. the last paragraph of Sec. III).
(d) A pseudo-Riemannian metric h_y on each $Q_y, y\in\Sigma$.

We assume that all y-dependent objects in (c) and (d), including the principal-bundle structure,

vary C^∞-differentiably with $y \in \Sigma$ (in the sense of Sec. II) and, in particular, the Q_y are the fibers of a bundle over Σ with a total space Q of dimension $n-r$. When $r=n/2$, each h_y is the "zero metric" on the discrete space Q_y, cf. Sec. VIII.

Let $\mathcal{F}$ be the vector bundle over Q whose restriction to Q_y, for each $y \in \Sigma$, is the M_y-prolongation of the tangent bundle TQ_y (see Sec. III) for the $T^*_y\Sigma$-principal bundle M_y over Q_y. Relation (3) now yields $\mathrm{p}^*(T^*\Sigma) \subset \mathcal{F}$, where $\mathrm{p}: Q \to \Sigma$ denotes the bundle projection. In other words, $\mathrm{p}^*(T^*\Sigma)$ may be treated as a vector subbundle of $\mathcal{F}$.

Furthermore, the quotient-bundle identification following formula (3) yields $\mathcal{F}/\mathrm{p}^*(T^*\Sigma) = \mathrm{Ker}\, \mathrm{dp}$ (the vertical subbundle of TQ, for the projection $\mathrm{p}: Q \to \Sigma$).

We define a partial pairing γ of $\mathcal{F}$ and TQ valued in the product bundle $Q \times \mathbf{R}$, as in Sec. IV, for our Q along with $\mathcal{C}=\mathcal{F}$, $\mathcal{D}=TQ$, $\mathcal{E}=Q\times\mathbf{R}$, $\mathcal{C}'=\mathrm{p}^*(T^*\Sigma)$ and $\mathcal{D}'=\mathrm{Ker}\, \mathrm{dp}$. Namely, given $z \in Q$, we set $\gamma(\xi,\zeta)=\xi(\mathrm{dp}_z\zeta)$ for $\xi \in T^*_y\Sigma=[\mathrm{p}^*(T^*\Sigma)]_z$ and $\zeta \in T_zQ$, with $y=\mathrm{p}(z) \in \Sigma$, as well as $\gamma(u,\psi)=h_y([u],\psi)$ for $u \in \mathcal{F}_z$ and $\psi \in \mathrm{Ker}\, \mathrm{dp}_z$, where $u \mapsto [u]$ denotes the surjective vector-bundle morphism $\mathcal{F} \to \mathrm{Ker}\, \mathrm{dp}$ with the kernel $\mathrm{p}^*(T^*\Sigma)$.

Our construction has two steps involving arbitrary choices.

Step 1: We choose $\beta: \mathcal{F} \otimes TQ \to Q \times \mathbf{R}$ to be any total-pairing extension of γ.

According to Lemma 4.1, such β is just an arbitrary section of an affine bundle of fiber dimension $(n-2r)r$ over Q. For the meaning of the above discussion in Walker's original language, see the Appendix.

The remainder of our construction proceeds as follows. Using β, we define a partial metric $(\mathcal{P},\mathcal{P}',\alpha)$ in the tangent bundle TM. Specifically, $\mathcal{T},\mathcal{P},\mathcal{P}'$ and n,r with the properties listed in (i) and (ii) of Sec. IV are chosen so that $\mathcal{T}=TM$, while n,r are the integers in (a) above, $\mathcal{P}$ is the subbundle of TM whose restriction to $M_y \subset M$, for each $y \in \Sigma$, is the vertical distribution on the $T^*_y\Sigma$-principal bundle M_y over Q_y, and $\mathcal{P}'=\mathrm{Ker}\, \mathrm{d}\pi$ is the vertical distribution of the bundle projection $\pi: M \to \Sigma$. We also set $\alpha(u',w)=\beta(u,\zeta)$ for any $x \in M$ and any vectors $w \in T_xM$, $u' \in \mathcal{P}'_x=T_xM_y$ with $y=\pi(x) \in \Sigma$, where u is the $T^*_y\Sigma$-invariant vector field tangent to M_y along the $T^*_y\Sigma$-orbit of x and having the value u' at x, while ζ is the image of w under the differential at x of the bundle projection $M \to Q$.

Step 2: We select an arbitrary total-metric extension g of $(\mathcal{P},\mathcal{P}',\alpha)$ restricted to U, where U is any fixed nonempty open subset of M.

The construction just described gives a null distribution $\mathcal{P}$ of dimension r on the n-dimensional pseudo-Riemannian manifold (U,g). This is clear from Lemma 4.2, which also implies that such metrics g are just arbitrary sections of some affine bundle over U.

The reader is again referred to the Appendix for a description of what the above steps correspond to in Walker's formulation.

We can now state a coordinate-free version of Walker's theorem.

Theorem 5.1: *If g and $\mathcal{P}$ are obtained as above from any prescribed data* (a)–(d), *then g is a pseudo-Riemannian metric on the n-dimensional manifold U, and $\mathcal{P}$ is a g-null, g-parallel distribution of dimension r on U.*

Conversely, up to an isometry, every null parallel distribution $\mathcal{P}$ on a pseudo-Riemannian manifold (M,g) is, locally, the result of applying the above construction to some data (a)–(d). *The data themselves are naturally associated with g and $\mathcal{P}$.*

A proof of Theorem 5.1 is given in the next two sections.

VI. PROOF OF THE FIRST PART OF THEOREM 5.1

By Lemma 4.2, $\mathcal{P}$ is g-null and $\mathcal{P}'$ is its g-orthogonal complement. That $\mathcal{P}$ is g-parallel will be clear if we establish the relation $\langle \nabla_w v, u\rangle = 0$, where ∇ is the Levi-Civita connection of g and $\langle,\rangle$ stands for $g(,)$, while v,u,w are any vector fields tangent to M such that v is a section of $\mathcal{P}$ and u is a section of $\mathcal{P}'$. We may further require w to be projectable under both bundle projections $M \to Q$ and $\pi: M \to \Sigma$. Finally, we may also assume that v restricted to each $T^*_y\Sigma$-principal bundle space M_y is an infinitesimal generator of the action of $T^*_y\Sigma$, while u restricted to each M_y is $T^*_y\Sigma$-invariant, (Locally, such w,v,u span the vector bundles $TM,\mathcal{P}$ and $\mathcal{P}'$.)

First, $[w,v]$ is a section of $\mathcal{P}$ and $[u,w]$ is a section of $\mathcal{P}'$ (from Remark 2.1 applied to both bundle projections), while $[v,u]=0$ by $T_y^*\Sigma$-invariance of u. The last three terms in (2) thus all equal zero.

Our claim will follow if we show that the first three terms in (2) vanish as well. To this end, note that $d_w\langle v,u\rangle=0$ since $\langle v,u\rangle=0$. Next, $d_v\langle w,u\rangle=0$. Namely, $\langle w,u\rangle=\alpha(u,w)=\beta(u,\zeta)$, for α,β,ζ described in Sec. V, is constant in the direction of v (and, in fact, constant along each leaf of $\mathcal{P}$): at a point $x\in M_y\subset M$ we obtain ζ as the projection image of $w(x)$, while u is $T_y^*\Sigma$-invariant, so that, due to projectability of w, both u and ζ depend only on the image of x under the bundle projection $M\to Q$, rather than x itself. Finally, $d_u\langle w,v\rangle=0$ as $\langle w,v\rangle=\xi(\tilde{w})$ is a function $\Sigma\to\mathbf{R}$, that is, a function $M\to\mathbf{R}$ constant along $\mathcal{P}'$. Here ξ is the section of $T^*\Sigma$ corresponding to v under the inclusion $\mathrm{p}^*(T^*\Sigma)\subset\mathcal{F}$ of Sec. V, while $\tilde{w}$ is the vector field on Σ onto which w projects; therefore, $\langle w,v\rangle=\xi(\tilde{w})$, since in Sec. V we set $\gamma(\xi,\zeta)=\xi(\mathrm{dp}_z\zeta)$.

VII. PROOF OF THE SECOND PART OF THEOREM 5.1

For any null parallel distribution $\mathcal{P}$ of dimension r on an $n-$dimensional pseudo-Riemannian manifold (M,g), the g-orthogonal complement $\mathcal{P}^\perp$ is a parallel distribution of dimension $n-r$. If the sign pattern of g has i_- minuses and i_+ pluses, it follows that

$$r\le\min(i_-,i_+), \tag{4a}$$

$$\mathcal{P}\subset\mathcal{P}^\perp, \tag{4b}$$

$$r\le n/2. \tag{4c}$$

In fact, $\mathcal{P}$ is null, which gives (4b) and $r\le n-r$, that is (4c), while (4a) follows since, in a pseudo-Euclidean space with the sign pattern as above, i_- (or, i_+) is the maximum dimension of a subspace on which the inner product is negative (or, positive) semidefinite.

Every null parallel distribution $\mathcal{P}$ satisfies the curvature relations

$$R(\mathcal{P},\mathcal{P}^\perp,-,-)=0, \tag{5a}$$

$$R(\mathcal{P},\mathcal{P},-,-)=0, \tag{5b}$$

$$R(\mathcal{P}^\perp,\mathcal{P}^\perp,\mathcal{P},-)=0, \tag{5c}$$

(5a) meaning that $R(v,u,w,w')=0$ whenever v,u,w,w' are vector fields, v is a section of $\mathcal{P}$, and u is a section of $\mathcal{P}^\perp$. [Similarly for (5b) and (5c).] In fact, for such v,u,w,w', (1) implies that $R(w,w')v$ is a section of $\mathcal{P}$, and so it is orthogonal to u. This proves (5a); (5a) and (4b) yield (5b), while (5a) and the first Bianchi identity give (5c).

We now show how a null parallel distribution $\mathcal{P}$ on a pseudo-Riemannian manifold (M,g) gives rise to objects (a)–(d) in Sec. V.

First, n and r are the dimensions of M and $\mathcal{P}$. By (4c), $r\le n/2$.

Being parallel, the distribution $\mathcal{P}^\perp$ is integrable. Since our discussion is local, we will assume, from now on, that M is the total space of a bundle over some r-dimensional base manifold Σ, whose fibers M_y, $y\in\Sigma$, are all contractible and coincide with the leaves of $\mathcal{P}^\perp$. As $\mathcal{P}$ is parallel, the Levi-Civita connection ∇ induces a connection in the vector bundle obtained by restricting $\mathcal{P}$ to any given submanifold N of M. In the case where $N=M_y$ is a leaf of $\mathcal{P}^\perp$, we have, for each $y\in\Sigma$, the following conclusion.

$$\begin{aligned}&T_y^*\Sigma \text{ is naturally isomorphic to the space } V_y \text{ of those sections of the restriction}\\&\text{of } \mathcal{P} \text{ to } M_y \text{ which are parallel (along } M_y).\end{aligned} \tag{6}$$

Instead of establishing (6) directly, we will show that *sections of $T^*\Sigma$ can be naturally identified with sections of $\mathcal{P}$ parallel along $\mathcal{P}^\perp$*, using an identification which is clearly valuewise, i.e., consists of operators $V_y \to T^*_y\Sigma, y \in \Sigma$. To this end, we denote by π the bundle projection $M \to \Sigma$. Every vector field on Σ is the π-image $(\mathrm{d}\pi)w$ of some π-projectable vector field w on M. Let v now be a section of the vector bundle $\mathcal{P}$ over M, parallel in the direction of $\mathcal{P}^\perp$. Our identification associates with v the cotangent vector field ξ on Σ that sends each vector field $(\mathrm{d}\pi)w$ to $g(v,w)$ treated as a function $\Sigma \to \mathbf{R}$. Note that ξ is well defined: two π-projectable vector fields w on M with the same π-image $(\mathrm{d}\pi)w$ differ by a section of $\mathcal{P}^\perp = \mathrm{Ker}\,\mathrm{d}\pi$, necessarily orthogonal to v, so that $g(v,w)$ is the same for both choices of w. Also, $g(v,w): M \to \mathbf{R}$ actually descends to a function $\Sigma \to \mathbf{R}$, i.e., is constant along the fibers M_y (leaves of $\mathcal{P}^\perp$). In fact, $d_u[g(v,w)]=0$ for any section u of $\mathcal{P}^\perp$, as $\nabla_u v = 0$ in view of the assumption about v, and $\nabla_u w = [u,w] + \nabla_w u$, while $[u,w]$ (or $\nabla_w u$) is a section of $\mathcal{P}^\perp$ by Remark 2.1 (or, since $\mathcal{P}^\perp$ is parallel).

Injectivity of the above assignment $v \mapsto \xi$ is obvious, since π-projectable vector fields w span TM. Surjectivity of the resulting operators $V_y \to T^*_y\Sigma$ now follows: both spaces have the same dimension, as the connections induced by ∇ in the restrictions of $\mathcal{P}$ to the leaves M_y are flat in view of (5c) [cf. (1)]. This proves (6).

Flatness of the induced connections also implies that the leaves of $\mathcal{P}$ contained in any given leaf M_y of $\mathcal{P}^\perp$ are the fibers of a V_y-principal bundle with the total space M_y over some base manifold Q_y. (Here M should be replaced with an open subset, if necessary.) Since each $T^*_y\Sigma$ is identified with V_y by (6), we thus obtain the data (c) of Sec. V.

Next, we define the metric h_y on each Q_y, required by (d) in Sec. V, so that it assigns the function $g(u,u')$ to two vector fields on Q_y which are images, under the $T^*_y\Sigma$-principal bundle projection $M_y \to Q_y$, of $T^*_y\Sigma$-invariant vector fields u, u' on M_y. Constancy of $g(u,u')$ along the $T^*_y\Sigma$-orbits, meaning that $d_v[g(u,u')]=0$ for any section v of $\mathcal{P}$ defined on M_y and parallel along $\mathcal{P}^\perp$, now follows: as v is $\mathcal{P}^\perp$-parallel and u is $T^*_y\Sigma$-invariant, we have $\nabla_u v = [v,u] = 0$, cf. (6), so that $\nabla_v u = 0$. For the same reason, $\nabla_v u' = 0$.

Finally, a suitable version of the construction in Sec. V, applied to the data (a)–(d) defined above, leads to the original g and $\mathcal{P}$, which is a consequence of how the identification (6) and the definition of h_y use g. The choices of the total-pairing and total-metric extensions, required in Sec. V, are provided by g as well. For instance, β in Step 1 is given by $\beta(u,\zeta) = g(u,w)$, where u is a section of $\mathcal{P}^\perp$ commuting with every section v of $\mathcal{P}$ that is parallel along $\mathcal{P}^\perp$, and ζ is a vector field on Q (the union of all Q_y), while w is any vector field on M projectable onto ζ under the bundle projection $M \to Q$. That $g(u,w)$ depends just on u and ζ (but not on w) is clear: two choices of w differ by a section of $\mathcal{P}$. Also, $g(u,w)$ is constant in the direction of $\mathcal{P}$ (and so it may be treated as a function $Q \to M$). Namely, $d_v[g(u,w)]=0$ for any section v of $\mathcal{P}$ parallel along $\mathcal{P}^\perp$, which follows as $\nabla_v u = \nabla_u v = 0$ (note that $[u,v]=0$), while $\nabla_v w = [v,w] + \nabla_w v$, and $[v,w]$ (or $\nabla_w v$) is a section of $\mathcal{P}$ by Remark 2.1 (or, respectively since $\mathcal{P}$ is parallel). This completes the proof of Theorem 5.1.

VIII. THE MID-DIMENSIONAL CASE

For an r-dimensional null parallel distribution $\mathcal{P}$ on a pseudo-Riemannian manifold (M,g) of dimension $n=2r$, the discussion in Sec. V amounts to nothing new: implicitly at least, it is already present in Sec. (6) of Walker's original paper.[1] See also Sec. 9 in Ref. 3. (A related global result is Theorem 5 in Ref. 5.) In this section we point out how the construction may be simplified when $n=2r$.

Let $\mathcal{P}$ and (M,g) be as above, with $n=2r\geq 2$. The relations $i_- + i_+ = n$ and (4a) imply that g has the *neutral* sign pattern: $i_- = i_+ = r = n/2$. In (c) and (d) of Sec. V, each Q_y is a 0-dimensional (discrete) manifold, and h_y is the "zero metric" on Q_y. Also, the choice of a total-pairing extension β in Step 1 of Sec. V is now unique: the affine bundle having β as a section is of fiber dimension 0. The construction in Sec. V can therefore be rephrased as follows. Given

(a) an even integer $n \geq 2$,
(b) a manifold Σ of dimension $r = n/2$,

(c) an affine bundle over Σ with some total space M, for which $T^*\Sigma$ is the associated vector bundle (Sec. III),

we define a partial metric $(\mathcal{P},\mathcal{P}',\alpha)$ in the tangent bundle TM by choosing $\mathcal{P}=\mathcal{P}'$ to be the vertical distribution $\operatorname{Ker} \mathrm{d}\pi$ for the bundle projection $\pi: M\to\Sigma$, and setting $\alpha(\xi,w)=\xi(\mathrm{d}\pi_x w)$ for any $x \in M, \xi\in\mathcal{P}_x=T^*_y\Sigma$, where $y=\pi(x)$, and $w\in T_xM$. Selecting any total-metric extension g of $(\mathcal{P},\mathcal{P}',\alpha)$ on a fixed nonempty open set $U\subset M$, we now obtain an n-dimensional pseudo-Riemannian manifold (U,g) on which $\mathcal{P}$ is a g-null, g-parallel distribution of dimension $r=n/2$.

Conversely, up to an isometry, every null parallel distribution $\mathcal{P}$ of dimension $r\geq 1$ on a pseudo-Riemannian manifold (M,g) with $\dim M=2r$ arises, locally, from the above construction applied to some data (a)–(c), themselves naturally determined by g and $\mathcal{P}$.

ACKNOWLEDGMENT

The authors wish to thank Zbigniew Olszak for helpful comments.

APPENDIX: WALKER'S ORIGINAL STATEMENT

Walker stated his classification result as follows.[1]

Theorem 1: *A canonical form for the general V_n of class C^∞ (or C^ω) admitting a parallel null r-plane is given by the fundamental tensor*

$$(g_{ij})=\begin{pmatrix} O & O & I \\ O & A & H \\ I & H' & B \end{pmatrix},$$

where I is the unit $r\times r$ matrix and A,B,H,H' are matrix functions of the coordinates, of the same class as V_n, satisfying the following conditions but otherwise arbitrary:

(i) *A and B are symmetric, A is of order $(n-2r)\times(n-2r)$ and nonsingular, B is of order $r\times r$, H is of order $(n-2r)\times r$, and H' is the transpose of H.*

(ii) *A and H (and therefore H') are independent of the coordinates $x^1,\ldots,x^r$.*

A basis for the parallel null r-plane is the set of vectors $\delta^i_1,\delta^i_2,\ldots,\delta^i_r$.

Here is how the coordinates and matrix functions appearing above correspond to the objects used for the construction in Sec. V. Walker's coordinates $x^i, i=1,\ldots,n$, serve as a coordinate system for the manifold M of Sec. V. Coordinates for other manifolds appearing in Sec. V are obtained from x^i by restricting the range of the index i, to $i>n-r$ (for Σ), $i>r$ (for Q), $i\leq n-r$ (for each M_y) and $r<i\leq n-r$ (for each Q_y). The center submatrix A in Walker's matrix corresponds to the family $h_y, y\in\Sigma$, of pseudo-Riemannian metrics [(d) in Sec. V] and, consequently, also to the formula for $\gamma(u,\psi)$, while the last two matrices $O\ I$ in the first row represent the definition of $\gamma(\xi,\zeta)$. The Walker-matrix counterpart of the extension β chosen in Step 1 is the $(n-r)\times(n-r)$ submatrix with the rows $O\ I$ and $A\ H$, so that the freedom in choosing β amounts to arbitrariness in the selection of H (and H is independent of the coordinates $x^i, i=1,\ldots,r$, which translates into the fact that β is a morphism of vector bundles over the manifold Q with the coordinates $x^i, i>r$). Once chosen, β is used in Sec. V to define $\mathcal{P},\mathcal{P}'$ and α. In terms of Walker's coordinates and matrix functions, $\mathcal{P}$ (or, $\mathcal{P}'$) is spanned by the x^i coordinate directions with $i\leq r$ (or, respectively, $i\leq n-r$), while the analog of α is the $(n-r)\times n$ submatrix with the rows $O\ O\ I$ and $O\ A\ H$. Finally, the extension in Step 2 is nothing else than augmenting this last submatrix by a third row, $I\ H'B$, in which B is completely arbitrary.

Two-component cosmological fluids with gravitational instabilities

R. M. Gailis[a] and N. E. Frankel[b]
School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia

(Received 7 September 2005; accepted 8 May 2006; published online 29 June 2006)

A survey of linearized cosmological fluid equations with a number of different matter components is made. To begin with, the one-component case is reconsidered to illustrate some important mathematical and physical points rarely discussed in the literature. The work of some previous studies of two-component systems are examined and reanalyzed to point out some deficiencies of solutions, and further solutions and physical interpretation are then presented. This leads into a general two-component model with variable velocity dispersion parameters and mass density fractions of each component. The equations, applicable to both hot dark matter (HDM) and cold dark matter (CDM) universes are solved in the long wavelength limit. This region is of interest, because some modes in this range of wave numbers are Jeans unstable. The mixture Jeans wave number of the two-component system is introduced and interpreted, and the solutions are discussed, particularly in comparison to analogous solutions previously derived for plasma modes. This work is applicable to that region in the early Universe ($20<z<140$), where large scale structure formation is thought to have occurred. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2209172]

I. INTRODUCTION

The theory of structure formation in the Universe has become one of the most popular and intensely studied topics in modern cosmology. Throughout the past century there has been an accumulating volume of work on the analytic investigation of the cosmological structure formation equations. The various approaches include both fluid and kinetic theory formulations. They principally consider the gravitational interaction of components of the cosmological medium, though sometimes other forms of interaction such as magnetic fields are also included (for some standard examples see, e.g., Refs. 1 and 2). The analysis of these equations has employed ever more diverse and complicated techniques and approximation schemes to model increasingly realistic physical situations. This has been comprehensively supported and now superseded by large *N*-body simulations. The algorithms which govern these large numerical studies have grown progressively more refined and subtle, and are now producing very accurate and realistic results, which can be directly compared with observations (e.g., Ref. 3).

Despite the current trends in modern cosmological structure formation theory, much can still be learned from relatively simple analytic models. We consider such models, in the face of modern computing power, to analyze at a fundamental level some of the basic physical processes which cause the clustering observed in the Universe. This helps to isolate physical mechanisms difficult to discern numerically. In this paper our interest will focus on the linearized cosmological fluid equations. These equations have been used to build up the components of the cosmological density perturbation power spectrum, and must be evolved through the various stages of cosmological

evolution, and over a large range of physical scales. There are several reasons for taking such an approach. The equations may be solved numerically to give detailed power spectra for the various cosmological models currently viable. The power spectra may then be used as initial data to evolve the large *N*-body simulations, which are ultimately compared to observations. The equations may also be used to build up a semiquantitative picture of the evolution of the power spectrum. This can show how the various sized perturbations scale with respect to the Friedmann expansion parameter a during different epochs of the Universe, and give a direct insight into some of the fundamental physical processes operating to produce structure in the Universe (see, e.g., Ref. 1).

The evolution of perturbation modes with wavelength greater than the Hubble radius may be studied through a relativistic formulation of the perturbation equations, whereas for modes with wavelengths smaller than this radius, a Newtonian formalism suffices. There is a range of physical parameters and variety of differential equations describing the evolution processes of density fluctuations in the early Universe. This involves such elements as equations of state for energy constituents, and specification of the expansion parameter a by the Friedmann cosmological equations. As a consequence, there is a large wealth of literature on this subject, and most of the currently important techniques and results have been collected in some well-known textbooks.[1,2,4] Some of the relatively complicated systems of equations have also been studied in the literature, and it is our goal to both review many of these studies, and to extend them in new directions, achieving some new unique results.

In this paper we will only study the Newtonian limit of the linearized cosmological perturbation equations, valid for density fluctuations on scales well within the Hubble radius. Our main concern is with some mathematically more complicated multicomponent models, which although not usually considered in standard power spectrum analysis, have realistic and interesting physical meaning. The primary concept of the Jeans gravitational instability[5] has been investigated in a static universe for multicomponent models, to reveal the more complicated structure of modes possible.[6,7] This provides some interesting qualitative ideas about the possible mechanisms for structure formation, but the lack of an expanding background space–time in the models leads to unrealistic solutions, exponential in form. The inclusion of cosmological expansion in the equations leads to the more realistic power law and logarithmic solutions, familiar from the standard power spectrum analysis. Previous work in this area has focused both on some particular models,[8] and on a more general classification of the equations and solutions for a range of parameter values (some of them only of mathematical interest) and physical contexts.[9–11] Analytic solutions for some of the most general cases of the equations considered above, which often have significant physical interest, have not been achieved. It is our aim here to rectify this situation and investigate a system of equations modeling a two-component fluid in the matter dominated post-recombination era of an Einstein-deSitter universe. One of these components consists of baryons, and the other some form of nonrelativistic dark matter particles. Through this work we will amend what appear to be some errors in the previous general studies of Haubold and Mathai.[11]

This paper makes a comprehensive study of the linear perturbation equations for cosmological fluids with gravitational instabilities with application to large scale structure formation. For a historical perspective we note that Lifshitz[12] concluded that gravitational instability could not be responsible for the formation of structure in the Universe. The correct conclusion, that gravitational instability suffices, was pointed out by Novikov.[13] As our work details the mathematical structure of the appropriate equations describing cosmological structure formation, we note the nice series of papers by Ratra and Peebles[14] directed to understanding the applications of special functions to the problem of gravitational instability in cosmological models. We further note the nice series by Buchert *et al.*[15] concerning analytic results and their relevance to observational cosmology.

We will also make a comparison with work done in cosmological plasma physics in an Einstein-deSitter background.[16–18] This is interesting due to the mathematically very similar form of fluid equations for both types of systems. This similarity is largely due to the similarity of the electromagnetic and gravitational forces. In this paper we will analyze the long wavelength region

of the solutions. This corresponds to the Jeans unstable region of parameter space, and requires use of Frobenius methods of expansion of the differential equations. In a follow-up paper[19] we will investigate the short wavelength region of the solutions, which will require a WKB approximation scheme to be developed.

In these papers we take explictly the temperature relationship $T \sim 1/a(t)^2$, where $a(t)$ is the radius of the Universe. We give here the explanation why this is so. Following standard textbook material in Padmanabhan[1] [as summarized in equation (3.118)] and Peebles (1993, p. 179) we find that the baryons follow this relationship when

$$1 + z = 142(\Omega_b h^2/0.024)^{2/5}.$$

Here Ω_b has been scaled to the WMAP best fit value. Thus for redshifts below $z \sim 140$ the baryon temperature drops as $1/a^2$ down to $z \sim 20$, where the Universe reionizes (probably in a patchy fashion) and the $1/a^2$ scaling no longer holds. This $20 < z < 140$ redshift region is important, as it is where early large scale structure formation is thought to have occurred.

The paper is to be organized as follows. In Sec. II we introduce the most general cosmological density perturbation equations in the Newtonian approximation. We review and classify previous work on these equations to put our current work into context, showing what has been achieved, what needs amendment, and where we will seek to expand current knowledge. In Sec. III we revert to the one-component equations, to illustrate some of the basic principles which will be important later in our analysis, and to reveal some apparently new results. This will enable us to begin to tackle the two-component problem in Sec. IV. In this section the CDM two-component model in an expanding universe will be investigated. This has ties with the previous work cited, and we will demonstrate the limitations of the existing formalism here. We present new results apparently overlooked in the work of Haubold and Mathai.[11] After this, we are ready to study the most general baryonic and dark matter equations in Sec. V, where we will consider the long wavelength approximation, applicable to either HDM or CDM. This is followed by our conclusions in Sec. VI.

II. A CLASSIFICATION OF COSMOLOGICAL DENSITY PERTURBATION EQUATIONS

As discussed in Sec. I, there are a vast spectrum of equations describing cosmological density perturbations in different physical regimes. We begin directly with the linearized Newtonian approach. The equations for an n-component system of nonrelativistic species is derived in all the standard texts. Given a density perturbation δ_i in the ith component of the mass density ρ_i,

$$\delta_i(\mathbf{r},t) = \frac{\delta\rho_i}{\rho_i}, \tag{2.1}$$

it may be decomposed into its Fourier plane wave modes with wave vector $\mathbf{k}$,

$$\delta_i(\mathbf{r},t) = \frac{1}{(2\pi)^3}\int \delta_{\mathbf{k}i}(t)\exp(-i\mathbf{k}\cdot\mathbf{r})d^3r. \tag{2.2}$$

Here $\mathbf{r}$ is the physical spatial coordinate, and t is cosmic time.

To be able to solve the equations, the implicit time dependence of the physical variables needs to be removed. We will adopt the convention that barred variables will denote comoving quantities, independent of time. Thus we define the comoving wave number $\bar{\mathbf{k}} = a\mathbf{k}$. Using the Eulerian equations of motion describing a perfect fluid, a set of coupled second order equations for the Fourier modes $\delta_i(t)$ (where we now drop the subscript $\mathbf{k}$) are achieved:

$$\frac{d^2\delta_i}{\mathrm{d}t^2} + 2\frac{\dot{a}}{a}\frac{\mathrm{d}\delta_i}{\mathrm{d}t} + \frac{v_i^2\bar{k}^2}{a^2}\delta_i = 4\pi G\sum_{i=1}^{n}\rho_i\delta_i, \quad i = 1,2,\ldots,n. \tag{2.3}$$

Overdots will denote derivatives with respect to t. The above equations contain the sound velocity

$$v_i^2 = \frac{\mathrm{d}p_i}{\mathrm{d}\rho_i} \propto \rho_i^{\gamma_i - 1}. \tag{2.4}$$

The sound velocity depends on the equation of state of the medium, and is in general dependent on time. We have introduced the specific heat ratio γ_i, and assumed an equation of state of the form $p_i \propto \rho_i^{\gamma_i}$.

The introduction of a sound velocity implicitly assumes that the fluids involved are collisional. This means that there are considerable interactions between the particles comprising each matter component. It is in fact generally assumed that dark matter is *collisionless*, in which case a fluid equation is not strictly correct. The dark matter component would better be modeled by a distribution function satisfying the Vlasov equation. "Fluid-like" equations can still be derived in this case by taking velocity moments of the Vlasov equation, and identifying the velocity dispersion with the above parameter v_i. Thus although in the present paper we will refer to "sound velocities," this should be taken as a generic expression for a velocity dispersion parameter. Such an approach should work fine for CDM, but may neglect an important damping term found in HDM models. The complete analogous equation to (2.3) for HDM gives a fluid equation perspective on free-streaming, the phenomenon found in HDM models of neutrinolike matter. An approximate equation has been derived for a hot neutrinolike component by Setayeshgar,[20] which tends to wipe out perturbations below a certain scale (see also the lecture notes by Bertschinger[21]). In this work the exact Vlasov equation kinetic treatment was considered, and the usual Fermi-Dirac distribution function was replaced by a carefully chosen approximate form, allowing the conversion of the integro-differential equation into the following pure differential equation:

$$\ddot{\delta}_\nu + \left(\frac{2\dot{a}}{a} + \frac{2\bar{k}v_\nu}{a^2} \right) \dot{\delta}_\nu + \frac{v_\nu^2 \bar{k}^2}{a^2} \delta_\nu = 4\pi G \sum_{i=1}^{n} \rho_i \delta_i. \tag{2.5}$$

Here the damping term $2\bar{k}v_\nu$ gives rise to nonoscillating solutions heavily damped at short wavelengths. Thus an equation of the form (2.3) is not correct for HDM of a neutrinolike nature. We examine the general equations for both CDM and HDM, without specifying too carefully the exact nature of the dark component involved. This allows comparison of the results in this paper with previous work in the literature, which has also neglected this point. If some aspects of HDM models are poorly described by (2.3), the equations are still applicable to other two-component cosmological systems such as a hydrogen-helium gas not in equilibrium, where the lighter hydrogen component has a greater sound speed.

At present (2.3) has been displayed in a quite general form, with an unspecified scale factor a, given by the Friedmann cosmological equation

$$\frac{\dot{a}^2}{a^2} = \frac{8\pi G}{3}\rho + \frac{\Lambda}{3} - \frac{k_c}{a^2}. \tag{2.6}$$

General parameters describing the nature of the Universe in this equation are $k_c = 0, \pm 1$, the spatial curvature, and Λ, the cosmological constant. It is difficult to make much progress without first becoming more specific about the energy content of the Universe. All the studies cited previously[8–11] have only examined the Einstein-deSitter, matter dominated case, with various physical components and equations of state possible. The studies,[10,11] all of which are equivalent, make the pretense to study the radiation dominated era as well, but this is incorrect for the equations presented. It was explicitly assumed that $a \propto t^{2/3}$ in the scaling of the energy densities $\rho_i = \Omega_i/(6\pi G t^2)$ and the velocity parameters, yet an allowance was made for a general Hubble expansion $H = \eta t^{-1}$. The general parameter η can only be equal to $\frac{2}{3}$ for the equations presented to be physically correct. The fluid equations were formulated to allow for general equations of state, by writing the sound velocities such that both their magnitudes and time dependences were freely parametrized. A range of solutions were obtained for different cases of the parameters, and were generally classified by Meijer G functions.[22,23] We will show that the solutions found for a CDM

and baryon model have been evaluated incorrectly, and will proceed to find their general exact representation. We will also proceed to investigate a more general dark matter and baryon problem than considered in any of the above. In Ref. 9, several subcases of the above-mentioned studies were considered in some detail, and given a range of physical interpretations. The solutions were of a mathematically simpler nature, involving either Bessel functions or simple power law behavior. The investigations in Ref. 8 concentrated on a three-component medium, involving baryons, CDM and photons. They incorrectly used the nonrelativistic Newtonian cosmological equations to model the photon component, so that the solutions, expressed in terms of Meijer G functions, cannot be considered as physically relevant.

Let us now make the choice of the matter dominated era of cosmological evolution in which to set (2.3), and in particular the post-recombination era, where baryons had decoupled from photons. This allows us to determine how the energy density and sound velocity scale with respect to a, and consequently exhibit all explicit time dependences in the equations. We therefore introduce the comoving total background density $\bar{\rho}_0 \equiv a^3 \rho_0$, and the constant $\epsilon_i \equiv \rho_i / \rho_0$, the fraction of the total mass density contributed by species i. This is distinct from the in general time-dependent quantity $\Omega_i(t) \equiv \rho_i / \rho_c$, where ρ_c is the critical density of the Universe

$$\rho_c = \frac{3H^2}{8\pi G}. \tag{2.7}$$

We will consider a two-component fluid comprised of baryons (subscripted by B) and dark matter (subscripted by D). In the post-recombination era, the adiabatic speed of sound of species i assumes the following behavior:

$$v_i^2 \propto T_i \propto a^{-2}, \tag{2.8}$$

where T_i is the temperature of the component. This prompts us to define the time-independent quantity $\bar{v}_i^2 \equiv a^2 v_i^2$. With these definitions, the linearized cosmological perturbation equations may be written as

$$\frac{d^2\delta_B}{\mathrm{d}t^2} + 2\frac{\dot{a}}{a}\frac{\mathrm{d}\delta_B}{dt} + \frac{\bar{v}_B^2 \bar{k}^2}{a^4}\delta_B = \frac{4\pi G\bar{\rho}_0}{a^3}(\epsilon_B\delta_B + \epsilon_D\delta_D), \tag{2.9}$$

$$\frac{d^2\delta_D}{\mathrm{d}t^2} + 2\frac{\dot{a}}{a}\frac{\mathrm{d}\delta_D}{\mathrm{d}t} + \frac{\bar{v}_D^2 \bar{k}^2}{a^4}\delta_D = \frac{4\pi G\bar{\rho}_0}{a^3}(\epsilon_B\delta_B + \epsilon_D\delta_D). \tag{2.10}$$

The equations currently still represent a fairly general cosmological setting. The curvature parameter k_c and cosmological constant Λ have not been specified, and control the behavior of a through the Friedmann equation (2.6). To see how these influence the evolution of the density perturbations, we transform the dependent variable from t to a. We also use (2.6) and another cosmological dynamics equation for the acceleration of a:

$$\ddot{a} = \frac{4}{3}\pi G\frac{\bar{\rho}_0}{a^2} + \frac{\Lambda}{3}a. \tag{2.11}$$

This equation is derived in conjunction with the Friedmann equation by taking the spatial components of the Einstein equation. The cosmological perturbation equations are now able to be written in a form purely dependent on a, and parametrized explicitly by the cosmological dynamical constants:

$$\left(\frac{8}{3}\pi G\bar{\rho}_0 + \frac{\Lambda}{3}a^3 - k_c a\right)\delta_B'' + a^{-1}(4\pi G\bar{\rho}_0 + \Lambda a^3 - 2k_c a)\delta_B' + \frac{\bar{v}_B^2\bar{k}^2}{a^3}\delta_B - \frac{4\pi G\bar{\rho}_0}{a^2}(\epsilon_B\delta_B + \epsilon_D\delta_D) = 0, \tag{2.12}$$

$$\left(\frac{8}{3}\pi G\bar{\rho}_0+\frac{\Lambda}{3}a^3-k_c a\right)\delta_D''+a^{-1}(4\pi G\bar{\rho}_0+\Lambda a^3-2k_c a)\delta_D'+\frac{\bar{v}_D^2\bar{k}^2}{a^3}\delta_D-\frac{4\pi G\bar{\rho}_0}{a^2}(\epsilon_B\delta_B+\epsilon_D\delta_D)=0. \tag{2.13}$$

In the above, a prime denotes differentiation with respect to a.

A general analysis of (2.12) and (2.13) has not been attempted previously. To begin with, we can test for exactness of the equations (see Ref. 24, pp. 92, 93), to determine whether a first integral exists. In general, a second order ordinary differential equation of the form

$$A_0(x)y''+A_1(x)y'+A_2(x)y=0 \tag{2.14}$$

[arbitrary functions $A_i(x)$] is exact if

$$A_0''-A_1'+A_2=0. \tag{2.15}$$

Let us first consider the one-component example. This is the uncoupled case of (2.12) ($\epsilon_D=0$, $\epsilon_B=1$), which gives

$$A_0''-A_1'+A_2=\frac{\bar{v}_B^2\bar{k}^2}{a^3}. \tag{2.16}$$

Thus the one-component equation is only exact for a pressureless gas $\bar{v}_B=0$. This means that no closed form solution is possible, and approximations need to be made. We note that the pressureless one-component case has been studied extensively (e.g., Ref. 2) for various values of the parameters.

To make progress with the perturbation equations, and also to make contact with previous work in the literature, we need to make some assumptions about k_c and Λ. The $k_c\neq 0$ cases tend to be more complicated mathematically, as generally only parametric solutions can be found, where a is represented by hyperbolic functions ($k_c=-1$ open universe) or trigonometric functions ($k_c=1$ closed universe). Current observations, and the weight of theoretical tendencies in cosmology (e.g., $\Omega=1$ as demanded by inflation) make the choice of flat universe $k_c=0$ seem the most favorable. Ω contains a contribution from Λ as well as matter components. The large amount of observational data now being analyzed, increasingly points to the existence of a cosmological constant comprising a major fraction of the energy density (see, e.g., Ref. 25–27), with a value of $\Omega_\Lambda\simeq 0.7$. The Einstein-deSitter ($\Lambda=0$, $\Omega=1$) model is generally not the model of choice anymore for detailed numerical studies in cosmology, however we do not make a claim that the solutions presented here are of an exact quantitative nature. Many other factors must also be taken into account when attempting to build up an exact, numerical model of structure formation. We wish to correct and extend some previous results, as well as perform some semiquantitative analysis. Our intent is to keep work analytically tractable at this stage.

We set $k_c=\Lambda=0$ in (2.12) and (2.13). In the Einstein-deSitter model, the critical density can be written explicitly as

$$\rho_c=\frac{\bar{\rho}_0}{a^3}=\frac{1}{6\pi G t^2}, \tag{2.17}$$

and the relation $\epsilon_B+\epsilon_D=1$ holds. We also introduce quantities resembling the comoving Jeans wave numbers for each component taken separately,

$$\bar{k}_B^2=\frac{4\pi G\bar{\rho}_0}{\bar{v}_B^2},\quad \bar{k}_D^2=\frac{4\pi G\bar{\rho}_0}{\bar{v}_D^2}. \tag{2.18}$$

The difference with the true comoving Jeans wave number for a one-component fluid is the inclusion of the total mass density $\bar{\rho}_0$, rather than just the mass density of the component in question $\bar{\rho}_i$. Equations (2.12) and (2.13) now become

$$\delta_B'' + \frac{3}{2a}\delta_B' + \frac{3}{2a^3}\left(\frac{\bar{k}}{\bar{k}_B}\right)^2 \delta_B = \frac{3}{2a^2}(\epsilon_B\delta_B + \epsilon_D\delta_D), \tag{2.19}$$

$$\delta_D'' + \frac{3}{2a}\delta_D' + \frac{3}{2a^3}\left(\frac{\bar{k}}{\bar{k}_D}\right)^2 \delta_D = \frac{3}{2a^2}(\epsilon_B\delta_B + \epsilon_D\delta_D). \tag{2.20}$$

The effects of the various physical processes are now clearly evident. The expansion of the Universe produces a damping term $3\delta_i'/(2a)$, causing the solutions to be in power law form rather than exponential. The relation of the mode wave number to the Jeans wave number is expressed as a ratio, transparently showing in which region of physical scales the mode lies. This ratio can be compared to the fractions ϵ_B and ϵ_D to decide whether gravity or pressure dominates the dynamics. The true Jeans instability scale for a two-component medium is not given by either $\bar{k}_B$ or $\bar{k}_D$, but by a combination of the two, as demonstrated in Refs. 6 and 7. This scale will be introduced in due course.

We finally perform a couple more manipulations, to cast the equations in their simplest form. We define the dimensionless parameters

$$K_B = \frac{\bar{k}}{\bar{k}_B}, \quad K_D = \frac{\bar{k}}{\bar{k}_D}. \tag{2.21}$$

Then $K_i < 1$ corresponds to the Jeans unstable region in the one-component analog of the equations, and $K_i > 1$ to the acoustic region. We also make the variable transformation $\chi = a^{-1/2}$. This gives the final form of the system of differential equations to be studied in the ensuing sections,

$$\delta_B'' + 6\left(K_B^2 - \frac{\epsilon_B}{\chi^2}\right)\delta_B - \frac{6\epsilon_D}{\chi^2}\delta_D = 0, \tag{2.22}$$

$$\delta_D'' + 6\left(K_D^2 - \frac{\epsilon_D}{\chi^2}\right)\delta_D - \frac{6\epsilon_B}{\chi^2}\delta_B = 0. \tag{2.23}$$

A prime now denotes differentiation with respect to χ. These equations bear a strong resemblance to the equations of an electron-proton cosmological plasma studied in Ref. 18 [Eqs. (4.8) and (4.9) of that paper]. As is well known from the analogy between the simple Jeans instability and Langmuir modes, this resemblance is not surprising when the mathematical similarity between the electromagnetic and gravitational forces is considered. The techniques employed in Ref. 18 will be useful in our current analysis. In this paper we will employ the Frobenius method in obtaining long wavelength solutions. In a related paper,[19] some general WKB techniques are developed further than previously. Apart from facilitating some short wavelength solutions to the current problem, these techniques will also indicate further results possible in cosmological plasma physics.

Before we proceed to a general analysis of (2.22) and (2.23), we wish to digress to the simpler case of a one-component system. Surprisingly, we will derive some apparently new results, which provide a conceptually useful introduction to the ensuing analysis.

III. THE ONE-COMPONENT EQUATION REVISITED

The Einstein-deSitter one-component equation for a baryonic or dark matter fluid in the post-recombination era is a canonical example studied in all textbooks for linearized cosmological perturbation theory. It gives the familiar Jeans unstable power law solutions $\delta \propto t^{2/3}$, t^{-1} in the limit of large scales, and acoustic oscillations in the limit of small scales. Despite this, we have not found the full exact solutions completely displayed and analyzed in any textbooks or review articles in the current literature. Although a full analysis will not bring any startling new physical

revelations, the mathematical techniques required are of some interest in their relation to the physics, and as an introduction to the more complicated analysis we will require later. This section may be seen as a useful orientation to the further work carried out in the bulk of this paper.

We begin with the one-component version of (2.19), i.e., with $\epsilon_B=1$ and $\epsilon_D=0$ [or vice versa for (2.20)]. Analogous to the definitions of K_B and K_D, we define the one-component comoving Jeans ratio for the fluid, which has comoving Jeans wave number $\bar{k}_J$, as $K_J=\bar{k}/\bar{k}_J$. The one-component density perturbation equation then becomes

$$\delta'' + \frac{3}{2a}\delta' + \left(\frac{3}{2a^3}K_J^2 - \frac{3}{2a^2}\right)\delta = 0. \tag{3.1}$$

The solution of this equation is a Bessel function of order 5/2. A Bessel function of half odd-integer order can be recast in terms of a spherical Bessel function. To begin with, we will choose the spherical Bessel functions of the first and second kind, j_ν and y_ν, respectively. The solution may be rewritten as

$$\delta(a) = c_1 a^{-1/2} j_2\left(\sqrt{\frac{6}{a}}K_J\right) + c_2 a^{-1/2} y_2\left(\sqrt{\frac{6}{a}}K_J\right), \tag{3.2}$$

with arbitrary constants of integration c_1 and c_2. For this case the fortuitous circumstance arises that the solutions may be represented in terms of elementary trigonometric functions (see, e.g., Ref. 28). The solutions as shown are exact mathematical representations, containing all the information of the modes over all scales. As is usually the case with such solutions, a simple inspection does not reveal all the physical properties of the modes in an obvious manner. For example, it is a little difficult to interpret the time dependence of the modes through the argument of the Bessel functions $\sqrt{6/a}K_J$. We will require various approximations and numerical plotting to extract more physical meaning out of the solutions.

To begin with, we seek to place the solutions into a canonical form, for easy comparison with other examples. The most useful such form comprises, to leading order, a product of a power law time factor and complex exponential factor. This approach was adopted in the studies of cosmological plasmas[16–18] for one- and two-component systems. As mentioned previously, due to the similarity between the gravitational and electromagnetic forces, the corresponding modes display many similarities.

The most useful Bessel function solutions for our purposes are the Hankel functions, due to the fact that their leading order terms contain complex exponentials. We use the spherical Hankel functions $h_2^{(1)}$ and $h_2^{(2)}$, given by the expressions

$$h_2^{(1)}(z) = \frac{1}{z}\exp\left[i\left(z - \frac{3\pi}{2}\right)\right]\left(1 - \frac{3}{z^2} - \frac{3}{iz}\right), \tag{3.3}$$

$$h_2^{(2)}(z) = \frac{1}{z}\exp\left[-i\left(z - \frac{3\pi}{2}\right)\right]\left(1 - \frac{3}{z^2} + \frac{3}{iz}\right). \tag{3.4}$$

We may make the comparison here to plasma results, where analogous series were obtained for large z. Contrary to this paper, where the series has a finite number of terms, the series for plasma modes were only asymptotic.

We write the explicit one-component solution via Hankel functions as

$$\delta(a) = \left(1 + \frac{a}{2K_j^2} + \frac{a^2}{4K_J^4}\right)^{1/2} \exp\left\{\pm i\left[\frac{\sqrt{6}K_J}{a^{1/2}} + \arctan\left(\frac{\sqrt{6}K_J a^{-1/2}}{2K_J^2 a^{-1} - 1}\right)\right]\right\}. \tag{3.5}$$

It must be stressed that unlike the plasma solutions, this is an exact result. The modulus of the solution grows with respect to time to leading order as $\delta \propto a$ if $K_J \ll 1$, or else if $K_J \gg 1$ the modulus is approximately constant, with a first order time correction proportional to a. There is also a

complex exponential portion to the solution, which usually gives a dispersion relation. The dispersion relation may be extracted by differentiating the phase with respect to t. This follows from the general fact that given an observed frequency ω, a solution of the form

$$\delta \propto \exp\left[\pm i \int^t \omega(t)\mathrm{d}t\right] \tag{3.6}$$

is expected. This is assuming, of course, that the solution oscillates—if not, some other form of real valued solution must be available. Using the matter dominated time dependence of a, namely

$$a = \left(\frac{t}{t_i}\right)^{2/3}, \tag{3.7}$$

where t_i is an arbitrary constant, we find the frequency to be

$$\omega = \frac{\bar{v}_s \bar{k} a^{-2}}{1 + \frac{1}{2}K_J^{-2}a + \frac{1}{4}K_J^{-4}a^2} \approx \frac{\bar{v}_s \bar{k}}{a^2}\left(1 - \frac{1}{2}\frac{a}{K_J^2} + \frac{1}{8}\frac{a^3}{K_J^6} - \frac{1}{16}\frac{a^4}{K_J^8} + \cdots\right), \quad K_J > 1. \tag{3.8}$$

The result has been expanded for $K_J > 1$, as we may suspect that due to the Jeans instability, acoustic waves only exist in this region, and thus we can only attach physical meaning to ω for $K_J > 1$. This assertion will be derived rigorously in what ensues.

The result of (3.8) may come as a surprise. How does it relate to the well-known Jeans dispersion relation derived for a static space–time

$$\omega^2 = v_s^2 k^2 - 4\pi G\rho_0 \ ? \tag{3.9}$$

In a cosmological setting, we may expect the dispersion relation to follow a similar form, with appropriate time factors included. For plasma modes, it was demonstrated in Ref. 18 that the dispersion relations could be written down to leading order in exactly the same form as their static space–time counterparts in terms of physical (nonbarred) variables, and then converted to comoving variables by inserting the correct time factors. Thus we may expect

$$\omega \approx \frac{\bar{v}_s \bar{k}}{a^2}\left(1 - \frac{a}{K_J^2}\right)^{1/2} \tag{3.10}$$

at least in the form of a binomial expansion, namely

$$\omega \sim \frac{\bar{v}_s \bar{k}}{a^2}\left(1 - \frac{1}{2}\frac{a}{K_J^2} - \frac{1}{8}\frac{a^2}{K_J^4} - \frac{1}{16}\frac{a^3}{K_J^6} + \cdots\right). \tag{3.11}$$

This form for ω may also be expected to contain some other time dependent terms, as was demonstrated for a number of plasma modes. Comparing the expansions in (3.8) and (3.11), we see in fact that they only agree to first order. This still indicates some form of Jeans instability, but the dispersion relations are quite different. This difference in behavior between the linearized gravitational modes and plasma modes may be attributed to the special role the density plays in the gravitational perturbation equations. Equation (3.1) contains only one free parameter, the Jeans ratio K_J, whereas the plasma equations contain both the sound velocity and plasma frequency, which cannot be reduced to one parameter. This implies that the relation between the gravitational source and the Friedmann equation, which fixes the background space–time, means that the same form for the dispersion relation as found in static space–time need not necessarily be expected in the expanding Einstein-deSitter model.

We have a general solution in terms of a modulus and complex exponential, which is exact and thus contains all the information of the problem. How do we infer the usual Jeans instability behavior from this? Let us examine plots of the solutions to gain a pictorial idea of what is

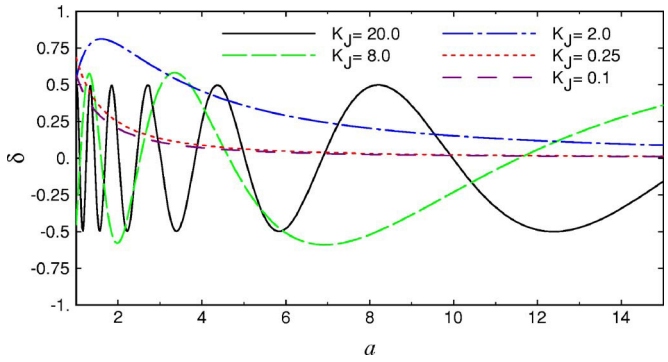

FIG. 1. (Color online) The transition of the decaying one-component modes as K_J varies through the Jeans instability.

happening. In Figs. 1 and 2 we see the transition from acoustic oscillations to growing and decaying modes as K_J is decreased—we are examining ever larger scales, and passing through the instability. To all fit on the same set of axes, the plots have been approximately normalized. The dependent variable a is rather arbitrary [as can be deduced from (3.7)]. An appropriate starting time t_i may be chosen to normalize a to 1 at the beginning of the chosen epoch of evolution, and the solutions may then be propagated forward in time. The tendency for the period of the acoustic oscillations to grow longer in time is evident from the plots, and the approximate constancy of the amplitude predicted previously from (3.5) is evident. In the extreme case, the oscillation period becomes so long that a perturbation cannot complete one full oscillation, and then the instability arises. This behavior can clearly be seen in Figs. 1 and 2 for the K_J=2.0, 8.0 plots.

We now perform some approximations to make contact with some better known results of the one-component problem. Let us begin with a small K_J^2/a expansion. For the spherical Hankel solutions (3.5), we find

$$\delta \sim \frac{a}{2K_J^2}\left[1+\frac{K_J^2}{a}+O\left(\frac{K_J^4}{a^2}\right)\right]\exp\left\{\mp i\sqrt{6}\frac{K_J}{a^{1/2}}\left[1-\frac{4}{5}\frac{K_J^4}{a^2}+O\left(\frac{K_J^6}{a^3}\right)\right]\right\}. \tag{3.12}$$

The above expansion explains what happens to acoustic oscillations when $K_J \lesssim 1$. In this region, the leading order factor $K_J a^{-1/2}$ in the exponential must always lie between 1 and 0 numerically, and decreases with increasing time. This is because $a \geqslant 1$ and increases monotonically for all time. Thus the solution lies within one period of oscillation for all time, and only the growing or decaying modes may be observed. When K_J becomes larger than 1, more than one period of oscillation may be spanned by the $K_J a^{-1/2}$ factor, and the solution will begin to develop acoustic waves. The expansion (3.12) shows $\delta \propto a$, which only gives the familiar growing mode, discussed in all texts. The decaying mode has not been found in the current analysis, because spherical

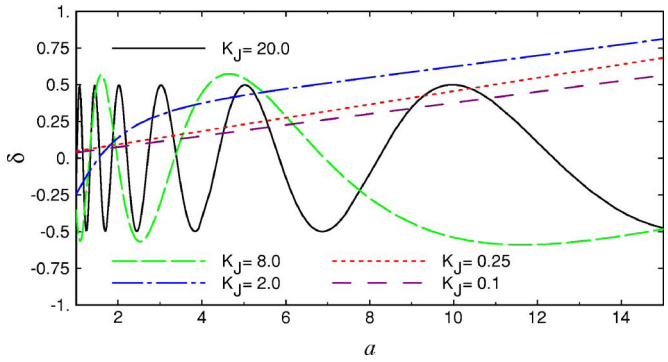

FIG. 2. (Color online) The transition of the growing one-component modes as K_J varies through the Jeans instability.

Hankel functions have been chosen to represent the Bessel function solutions. The spherical Hankel functions are linear combinations of the original j_2 and y_2 solutions, which contain both modes. The decaying mode has been "asymptotically swamped" by the growing mode in this linear combination. The decaying mode may be liberated by a direct small variable expansion of (3.2) for each spherical Bessel function. We find the j_2 component gives the decaying mode

$$\delta \sim a^{-3/2}\left[1 - \frac{3}{7}\frac{K_J^2}{a} + O\left(\frac{K_J^4}{a^2}\right)\right], \tag{3.13}$$

and the y_2 component gives the same growing mode as (3.12) in the slightly different form

$$\delta \sim a\left[1 + \frac{K_J^2}{a} + O\left(\frac{K_J^4}{a^2}\right)\right] \tag{3.14}$$

without the exponential phase factor. These solutions clearly correspond to the usual textbook modes found when pressure is ignored. They have included the pressure corrections, given as a series in the Jeans ratio, with matching time factors to all orders in the expansion.

We now turn to the large parameter expansion, from which we expect to liberate the acoustic oscillations. Equation (3.5) is in fact already in the form of a large parameter expansion, only that it has a finite number of terms, and is consequently exact. The phase of the exponential does not seem to show the structure of the familiar Jeans dispersion relation. This was discussed above, where it was indicated that this is not necessarily to be expected. It is possible to see why this is so in a lucid fashion by applying the WKB method to the original equation (3.1). Through this method we will derive a dispersion relation displaying very similar characteristics to the familiar textbook one, that shows the presence of the Jeans instability. A more complicated WKB approximation scheme was developed in Ref. 18 to deal with plasma modes of a more intricate form, involving larger numbers of coupled equations. This method is used in Ref. 19 to handle the two-component cosmological density perturbation equations in the short wavelength approximation. For the present simple second order equation, the standard textbook approach suffices (for a good explanation of WKB methods, see Ref. 29).

To see the physics most clearly, we transform (3.1) to depend on t. Using the variable transformation given by (3.7), the equation

$$\ddot{\delta} + \frac{4}{3t}\dot{\delta} + \left(\frac{2}{3}K_J^2\frac{t_i^{2/3}}{t^{8/3}} - \frac{2}{3t^2}\right)\delta = 0 \tag{3.15}$$

results. The usual Jeans dispersion relation can be directly seen in this equation. Consider the factor $2/(3t^2)$, arising from the gravitational source term. This term may be transformed to explicitly see the source parameters emerge. We consider the physical (time-dependent) value of the total energy density

$$4\pi G\rho_0 = 4\pi G\rho_c = \frac{4\pi G}{6\pi G t^2} = \frac{2}{3t^2}, \tag{3.16}$$

and the relation

$$K_J^2 = \tfrac{3}{2}\bar{v}_s^2\bar{k}^2 t_i^2. \tag{3.17}$$

Then the Jeans dispersion relation can be directly seen in (3.15),

$$\bar{v}_s^2\bar{k}^2\left(\frac{t_i}{t}\right)^{8/3} - \frac{2}{3t^2} = v_s^2k^2 - 4\pi G\rho_0. \tag{3.18}$$

In the static space–time case the physical variables would of course not depend on time, and the first derivative term $4\dot{\delta}/(3t)$ in (3.15) would not exist. This leads to the exact exponential solutions

and the familiar dispersion relation given by (3.18), as originally found by Jeans.

The most straightforward way to effect a WKB approximation in the present situation is to remove the first derivative from the equation. One way to do this is by the variable change $\chi = a^{-1/2}$. We then find the equation

$$\frac{d^2\delta}{d\chi^2} + \left(6K_J^2 - \frac{6}{\chi^2}\right)\delta = 0. \tag{3.19}$$

Now we suggestively define

$$\tilde{\omega}(\chi) = \left(6K_J^2 - \frac{6}{\chi^2}\right)^{1/2}. \tag{3.20}$$

Applying the WKB approximation to (3.19) gives the leading order solution

$$\delta(\chi) \sim \tilde{\omega}^{-1/2} \exp\left[\pm i \int \tilde{\omega}(\chi) d\chi\right]. \tag{3.21}$$

A dispersion relation has indeed been derived, and is given by $\tilde{\omega}$ as defined in (3.20). If we consider

$$\int \tilde{\omega}(\chi) d\chi = -\int \left(\frac{2}{3}K_J^2 \frac{t^{2/3}}{t_i^{8/3}} - \frac{2}{3t^2}\right)^{1/2} dt = -\int \left(\frac{t}{t_i}\right)^{-4/3}\left[\bar{v}_s^2\bar{k}^2 - \frac{2}{3t_i^2}\left(\frac{t}{t_i}\right)^{2/3}\right]^{1/2} dt, \tag{3.22}$$

then a physical frequency $\omega(t)$ can be identified by use of (3.18) and the relation $t_i^2 = 1/(6\pi G\bar{\rho}_0)$. Thus

$$\int \tilde{\omega}(\chi) d\chi = \int \omega(t) dt = \int (v_s^2 k^2 - 4\pi G\rho_0)^{1/2}\, dt, \tag{3.23}$$

and the physical connection has been made. Another point to note is that the amplitude $\tilde{\omega}(\chi)^{-1/2}$ is time independent to leading order (because $K_J \gg 1$). Thus the amplitude is approximately constant, as noted previously.

To make a direct comparison of (3.21) and (3.5), we now evaluate the integral in the phase of the WKB solutions. A change of integration variable from χ back to a sets the integral into a form which has been tabulated,[30] and we find

$$\int \tilde{\omega}(\chi) d\chi = \left(\frac{6K_J^2}{a} - 6\right)^{1/2} - \frac{\sqrt{6}}{2}\arcsin\left(1 - \frac{2a}{K_J^2}\right). \tag{3.24}$$

The solution generated by the WKB method may be compared to the exact one given by (3.5). The amplitudes and phases need to be expanded for large K_J,

$$\text{WKB phase,} \quad \left(\frac{6K_J^2}{a} - 6\right)^{1/2} - \frac{\sqrt{6}}{2}\arcsin\left(1 - \frac{2a}{K_J^2}\right) = \sqrt{6}\frac{K_J}{a^{1/2}}\left[1 - \frac{\pi}{4}\frac{a^{1/2}}{K_J} + O\left(\frac{a}{K_J^2}\right)\right], \tag{3.25}$$

$$\text{exact phase,} \quad \frac{\sqrt{6}K_J}{a^{1/2}} + \arctan\left(\frac{\sqrt{6}K_J a^{-1/2}}{2K_J^2 a^{-1} - 1}\right) = \sqrt{6}\frac{K_J}{a^{1/2}}\left[1 + \frac{a}{2K_J^2} + O\left(\frac{a}{K_J^2}\right)\right], \tag{3.26}$$

$$\text{WKB amplitude,} \quad (6K_J^2 - 6a)^{-1/4}\frac{1}{6^{1/4}K_J^{1/2}}\left[1 + \frac{a}{4K_J^2} + O\left(\frac{a^2}{K_J^4}\right)\right], \tag{3.27}$$

$$\text{exact amplitude,} \quad \left(1+\frac{a}{2K_J^2}+\frac{a^2}{4K_J^4}\right)^{1/2}\left[1+\frac{a}{4K_J^2}+O\left(\frac{a^2}{K_J^4}\right)\right]. \tag{3.28}$$

It can be seen that the two solutions only agree to leading order (modulo time independent constant factors). Given that the WKB method only gives a leading order solution to the problem, no more can be expected. This discussion has highlighted the difference between the expected dispersion relations of static space–time to those derived in an expanding universe context. WKB can reproduce the same form as the static space–time dispersion relations, but this may only agree to leading order to the true dispersion relation found in an expanding universe scenario.

IV. IMPROVEMENTS ON PREVIOUS CDM PERTURBATION RESULTS

We now return to the two-component equations and consider the case of CDM perturbations characterized by strictly zero temperature. If the velocity dispersion is considered to be an adiabatic sound velocity as given by (2.8), then $T_i=0$ corresponds to $K_D=0$ in (2.23). Such an approximation facilitates an exact analytic solution to the problem, which is otherwise impossible. The resulting system of equations was one of the main cases investigated in the general analysis of Ref. 11. In this section we will point out what appears to be an error in the analysis of that paper, which leads to some markedly different solutions, derived in what ensues.

Before we proceed with this, it is pertinent to point out a general problem with taking $K_D=0$ in Eqs. (2.22) and (2.23). For simplicity, it is possible to neglect space–time expansion, as the qualitative behavior will be the same. Thus the static space–time cosmological equations studied in Ref. 7 are sufficient for this discussion. These equations are also examined in Ref. 19, and using the notation employed there we have

$$\ddot{\delta}_D+(v_D^2k^2-W_D)\delta_D-W_B\delta_B=0, \tag{4.1}$$

$$\ddot{\delta}_B+(v_B^2k^2-W_B)\delta_B-W_D\delta_D=0, \tag{4.2}$$

with $W_i=4\pi G\rho_i$. This system of equations can be reduced to a first order linear autonomous dynamical system describing a state vector

$$\mathbf{x}=(x_1,x_2,x_3,x_4)^T\equiv(\dot{\delta}_D,\delta_D,\dot{\delta}_B,\delta_B)^T, \tag{4.3}$$

where T denotes the transpose of a vector. The dynamical system has a k-dependent critical point found by solving the equation $\dot{\mathbf{x}}=0$. This critical point happens to give the Jeans wave number of the mixture, and is given by

$$k^2=k_M^2\equiv k_B^2+k_D^2=\frac{W_B}{v_B^2}+\frac{W_D}{v_D^2}. \tag{4.4}$$

Note the slight difference in this definition of k_i in comparison to $\bar{k}_i$ defined in (2.18). It is already evident that a problem arises if we take $v_D\to 0$ in (4.4), and this will be physically elucidated by studying the four independent modes of the system, given by the eigenvalues of the dynamical system.

The eigenvalues give the structure of the modes (see Ref. 7 or Ref. 19 for the details). They are found to be of the general form

$$\lambda_1=-\lambda_2=\frac{1}{\sqrt{2}}\sqrt{f+\sqrt{f^2+4g}}, \tag{4.5}$$

$$\lambda_3 = -\lambda_4 = \frac{1}{\sqrt{2}}\sqrt{f - \sqrt{f^2 + 4g}}.$$

For the case of CDM currently under consideration, where $v_D = 0$, the k-dependent functions f and g are given by

$$f(k) = W_B + W_D - k^2 v_B^2, \tag{4.6}$$

$$g(k) = k^2 W_D^2 v_B^2. \tag{4.7}$$

It was previously found that the eigenvalues λ_1 and λ_2 described the Jeans unstable modes, whereas λ_3 and λ_4 described acoustic oscillations at all wave numbers. An examination of λ_1 in the current context will show this not to be the case for CDM. If we define (analogously to the one-component scenario)

$$K_J = \frac{v_B^2 k^2}{W_B + W_D}, \tag{4.8}$$

λ_1 may be written as follows:

$$\lambda_1 = \frac{1}{\sqrt{2}}(W_B + W_D)^{1/2}\{1 - K_J^2 + [(1 - K_J^2)^2 + 4\epsilon_D K_J^2]^{1/2}\}^{1/2}. \tag{4.9}$$

This does not equal zero for $K_J = 1$, and it is straightforward to show that it has no zeros for all $k \neq 0$. Thus a CDM perturbation would collapse for *all* scales, clearly a physical impossibility.

If we examine Eqs. (4.1) and (4.2), it can be seen that with the removal of the pressure term $v_D k^2$, there is no mechanism to counter the remaining gravitational source terms $-W_D \delta_D$ and $-W_B \delta_B$, whose sign indicate an attractive forcing, initiating gravitational collapse. This is the case no matter how small the fraction of dark matter compared to baryons, thus no amount of baryonic pressure support can prevent a collapse at any scale. This physically absurd situation is the root of the problem of taking $v_D \to 0$ in the fluid models. A physically correct equation must include some sort of velocity dispersion term, even if the matter is totally collisionless and an adiabatic speed of sound cannot be defined.

With these thoughts in mind, we must view the current section as more of a mathematical digression, than a physically realistic model. It nevertheless serves a purpose. We can make contact with the work of Ref. 11, and uncover some interesting mathematical properties associated with these cosmological perturbation equations in general. We find mathematical subtleties overlooked in Ref. 11, which also indicate the nature of the general solutions to follow in the next section. They allow an interesting comparison with cosmological plasma modes discussed in Ref. 18, where the limit $T_D \to 0$ is valid. The special nature of gravity, and the extra complications it entails are revealed by this comparison.

We now proceed to obtain a solution of Eqs. (2.22) and (2.23) (with $K_D = 0$) in the long wavelength (small k) limit. A short wavelength solution is trivially obtained by setting $K_D = 0$ everywhere in the results presented in Ref. 19. To align ourselves with earlier notation, and to stress the fact that there is only one Jeans related scale now occurring, we will rename K_B to K_J. Rather than directly reducing Eqs. (2.22) and (2.23) into a single equation, we attempt a solution by the Frobenius method. This is useful as a precursor to the general solution derived in the following section in a similar manner.

To begin with, we assume an arbitrary expansion of the solutions in the form

$$\delta_B(\rho, \chi) = \chi^\rho \sum_{n=0}^{\infty} a_n \chi^n, \tag{4.10}$$

$$\delta_D(\rho,\chi) = \chi^\rho \sum_{n=0}^{\infty} b_n \chi^n. \tag{4.11}$$

Here ρ is an arbitrary exponent to be determined, and a_n and b_n are series coefficients also to be determined by the Frobenius method. We substitute these series into (2.22) and (2.23) to obtain a set of algebraic relations between the undetermined coefficients. Then all coefficients of like power of χ are collected and equated to zero.

Arising out of this procedure are a pair of indicial equations for ρ, with one of a_0 or b_0 remaining an arbitrary constant,

$$\rho(\rho-1)a_0 - 6\epsilon_B a_0 - 6\epsilon_D b_0 = 0, \tag{4.12}$$

$$\rho(\rho-1)b_0 - 6\epsilon_D b_0 - 6\epsilon_B a_0 = 0. \tag{4.13}$$

A set of recursion relations also arise for all higher order coefficients:

$$6K_J^2 a_n + [(\rho+n+2)(\rho+n+1) - 6\epsilon_B]a_{n+2} - 6\epsilon_D b_{n+2} = 0, \tag{4.14}$$

$$[(\rho+n+2)(\rho+n+1) - 6\epsilon_D]b_{n+2} - 6\epsilon_B a_{n+2} = 0. \tag{4.15}$$

In retaining the arbitrary constant a_0 or b_0, it is assumed that all odd indexed terms vanish from propagation of the initial values $a_1 = b_1 = 0$ through the recursion relations.

If we solve (4.12) and (4.13) for ρ, we find four possible values,

$$\rho = 0, 1, 3, -2. \tag{4.16}$$

A comparison with the analogous case for cosmological plasma modes[18] immediately shows a difference in the nature of the exponents. In the preceding case the exponents are exactly determined integers, whereas for plasmas the exponents depended on the plasma frequency. When the one-component solutions were discussed in the preceding section, an analogous difference was observed between the spherical Bessel function solutions of the gravitational perturbation modes, and the general order Bessel function solutions of the plasma modes. Whereas in the one-component study the solutions were simplified by this property of gravity, in the present case they are in fact complicated. The plasma solutions were representable in terms of ${}_2F_3$ generalized hypergeometric functions, but a similar representation is not well-defined here. This is because the exponents differ by integers—a fact which necessitates a modification of the basic Frobenius method. This modification is borne out in the solutions by the fact that parameters appearing in the denominator of generalized hypergeometric function expansions cannot differ by integers. In such situations the generalized hypergeometric functions are not definable, and one must resort to classifying solutions of the equation by Meijer G-functions.

To apply the Frobenius method to indices differing by integers, the recursion relations must first be solved for general ρ. This is achieved by employing (4.12) and (4.13), and writing the system of differential equations as

$$\mathbf{L}\begin{bmatrix} \delta_B(\rho,\chi) \\ \delta_D(\rho,\chi) \end{bmatrix} = \begin{bmatrix} \rho(\rho-1)a_0 - 6\epsilon_B a_0 - 6\epsilon_D b_0 \\ \rho(\rho-1)b_0 - 6\epsilon_D b_0 - 6\epsilon_B a_0 \end{bmatrix} \chi^{\rho-2}, \tag{4.17}$$

where the operator $\mathbf{L}$ is defined by

$$\mathbf{L} = \begin{bmatrix} \frac{\partial^2}{\partial\chi^2} + 6\left(K_J^2 - \frac{\epsilon_B}{\chi^2}\right) & -\frac{6\epsilon_D}{\chi^2} \\ -\frac{6\epsilon_B}{\chi^2} & \frac{\partial^2}{\partial\chi^2} - \frac{6\epsilon_D}{\chi^2} \end{bmatrix}. \tag{4.18}$$

At present there is no relation between a_0 and b_0, but the recursion relations will provide one. A lengthy algebraic exercise is needed to solve the recursion relations. The result is

$$a_{2n} = a_0 \frac{\left(\frac{1}{2}\rho - \frac{1}{2}\nu_D + \frac{3}{4}\right)_n \left(\frac{1}{2}\rho + \frac{1}{2}\nu_D + \frac{3}{4}\right)_n}{\left(\frac{1}{2}\rho - \frac{1}{2}\right)_n \left(\frac{1}{2}\rho + \frac{1}{2}\right)_n \left(\frac{1}{2}\rho + 1\right)_n \left(\frac{1}{2}\rho + 2\right)_n} \left(-\frac{3}{2}K_J^2\right)^n, \tag{4.19}$$

$$b_{2n} = \frac{6a_0\epsilon_B}{\rho(\rho-1) - 6\epsilon_D} \frac{\left(\frac{1}{2}\rho - \frac{1}{2}\nu_D - \frac{1}{4}\right)_n \left(\frac{1}{2}\rho + \frac{1}{2}\nu_D - \frac{1}{4}\right)_n}{\left(\frac{1}{2}\rho - \frac{1}{2}\right)_n \left(\frac{1}{2}\rho + \frac{1}{2}\right)_n \left(\frac{1}{2}\rho + 1\right)_n \left(\frac{1}{2}\rho + 2\right)_n} \left(-\frac{3}{2}K_J^2\right)^n. \tag{4.20}$$

In the above, the parameter ν_D has been introduced as a shorthand,

$$\nu_D \equiv \sqrt{\tfrac{1}{4} + 6\epsilon_D}, \tag{4.21}$$

and the notation $(\,)_n$ is the Pochhammer symbol. It is clear that the coefficients as derived will not exist for $\rho = 1, -2$. This is the basis for requiring a modification to the straightforward method of substituting in the four calculated values of ρ (4.16) into (4.19) and (4.20) to generate four independent solutions.

To proceed, we extract from (4.19) and (4.20) the relation

$$b_0 = \frac{6a_0\epsilon_B}{\rho(\rho-1) - 6\epsilon_D}, \tag{4.22}$$

which allows (4.17) to be rewritten as

$$\mathbf{L}\begin{bmatrix} \delta_B(\rho,\chi) \\ \delta_D(\rho,\chi) \end{bmatrix} = a_0 \begin{bmatrix} \frac{1}{\epsilon_B} \frac{\rho(\rho-1)(\rho+2)(\rho-3)}{\rho(\rho-1) - 6\epsilon_D} \\ 0 \end{bmatrix} \chi^{\rho-2}. \tag{4.23}$$

For $\rho = 0, 3$, direct substitution is permissible to obtain two independent solutions, which turn out to be generalized hypergeometric ${}_2F_3$ functions, analogously to the plasma results. For $\rho = 1, -2$, we take advantage of the fact that a_0 is arbitrary, and set it, respectively, equal to $\rho - 1$ and $\rho + 2$. After differentiation with respect to ρ and evaluation at the respective points $\rho = 1$ and $\rho = -2$, we obtain the result

$$\mathbf{L} \begin{bmatrix} \frac{\partial}{\partial\rho}\delta_B(\rho,\chi) \\ \frac{\partial}{\partial\rho}\delta_D(\rho,\chi) \end{bmatrix} \Bigg|_{\rho=1,-2} = 0. \tag{4.24}$$

This gives two more solutions.

The above discussion has defined an algorithm for finding small k expansions of the solutions of the cosmological density perturbation equations. This algorithm is readily implemented into a symbolic manipulation computer code. We will write such a code to find the solutions to the general equations in the next section. The solutions for the CDM case under consideration may

now be written down. The need to differentiate with respect to ρ for the $\rho=1,-2$ cases result in solutions involving digamma functions ψ and logarithmic terms—quite a complication to the ${}_2F_3$ functions derived for the plasma perturbations in Ref. 18. To display the modes in their simplest form, linear combinations of the modes derived directly by the above algorithm need to be taken, and the use of various mathematical identities involving digamma functions employed. The final set of four CDM modes are given as follows:

$$\delta_{B1}(\chi)=\frac{c_1}{\epsilon_B}\sum_{n=0}^{\infty}\frac{\left(\frac{3}{4}-\frac{1}{2}\nu_D\right)_n\left(\frac{3}{4}+\frac{1}{2}\nu_D\right)_n}{\left(-\frac{1}{2}\right)_n\left(\frac{1}{2}\right)_n(2)_n n!}\left(-\frac{3}{2}K_J^2\chi^2\right)^n$$
$$=\frac{c_1}{\epsilon_B}{}_2F_3\left(\frac{3}{4}-\frac{1}{2}\nu_D,\frac{3}{4}+\frac{1}{2}\nu_D;-\frac{1}{2},\frac{1}{2},2;-\frac{3}{2}K_J^2\chi^2\right), \tag{4.25}$$

$$\delta_{D1}(\chi)=\frac{c_1}{\epsilon_D}\sum_{n=0}^{\infty}\frac{\left(-\frac{1}{4}-\frac{1}{2}\nu_D\right)_n\left(-\frac{1}{4}+\frac{1}{2}\nu_D\right)_n}{\left(-\frac{1}{2}\right)_n\left(\frac{1}{2}\right)_n(2)_n n!}\left(-\frac{3}{2}K_J^2\chi^2\right)^n$$
$$=\frac{c_1}{\epsilon_D}{}_2F_3\left(-\frac{1}{4}-\frac{1}{2}\nu_D,-\frac{1}{4}+\frac{1}{2}\nu_D;-\frac{1}{2},\frac{1}{2},2;-\frac{3}{2}K_J^2\chi^2\right), \tag{4.26}$$

$$\delta_{B2}(\chi)=c_2\frac{\chi}{\epsilon_B}+c_2\frac{\chi}{\epsilon_B}\sum_{n=1}^{\infty}\frac{\left(\frac{5}{4}-\frac{1}{2}\nu_D\right)_n\left(\frac{5}{4}+\frac{1}{2}\nu_D\right)_n}{\left(\frac{3}{2}\right)_n\left(\frac{5}{2}\right)_n(n-1)!n!}\left(-\frac{3}{2}K_J^2\chi^2\right)^n\left[\psi\left(\frac{5}{4}-\frac{1}{2}\nu_D+n\right)\right.$$
$$\left.+\psi\left(\frac{5}{4}+\frac{1}{2}\nu_D+n\right)-\psi(n)-\psi(n+1)-\psi\left(n+\frac{3}{2}\right)-\psi\left(n+\frac{5}{2}\right)+\log\chi^2\right], \tag{4.27}$$

$$\delta_{D2}(\chi)=-c_2\frac{\chi}{\epsilon_D}-c_2\frac{\chi}{\epsilon_D}\sum_{n=1}^{\infty}\frac{\left(\frac{1}{4}-\frac{1}{2}\nu_D\right)_n\left(\frac{1}{4}+\frac{1}{2}\nu_D\right)_n}{\left(\frac{3}{2}\right)_n\left(\frac{5}{2}\right)_n(n-1)!n!}\left(-\frac{3}{2}K_J^2\chi^2\right)^n\left[\psi\left(\frac{1}{4}-\frac{1}{2}\nu_D+n\right)\right.$$
$$\left.+\psi\left(\frac{1}{4}+\frac{1}{2}\nu_D+n\right)-\psi(n)-\psi(n+1)-\psi\left(n+\frac{3}{2}\right)-\psi\left(n+\frac{5}{2}\right)+\log\chi^2\right], \tag{4.28}$$

$$\delta_{B3}(\chi)=c_3\chi^3{}_2F_3\left(\frac{9}{4}-\frac{1}{2}\nu_D,\frac{9}{4}+\frac{1}{2}\nu_D;\frac{5}{2},\frac{7}{2},2;-\frac{3}{2}K_J^2\chi^2\right), \tag{4.29}$$

$$\delta_{D3}(\chi)=c_3\chi^3{}_2F_3\left(\frac{5}{4}-\frac{1}{2}\nu_D,\frac{5}{4}+\frac{1}{2}\nu_D;\frac{5}{2},\frac{7}{2},2;-\frac{3}{2}K_J^2\chi^2\right), \tag{4.30}$$

$$\delta_{B4}(\chi) = c_4\left(\frac{3}{2}K_J^2\chi^2\right)^{-1} + 2c_4\epsilon_D\sum_{n=1}^{\infty}\frac{\left(\frac{3}{4}-\frac{1}{2}\nu_D\right)_n\left(\frac{3}{4}+\frac{1}{2}\nu_D\right)_n}{\left(-\frac{1}{2}\right)_n\left(\frac{1}{2}\right)_n(2)_n n!}\left(-\frac{3}{2}K_J^2\chi^2\right)^n\left[\psi\left(\frac{3}{4}-\frac{1}{2}\nu_D+n\right)\right.$$
$$\left.+\psi\left(\frac{3}{4}+\frac{1}{2}\nu_D+n\right)-\psi(n+2)-\psi(n+1)-\psi\left(n-\frac{1}{2}\right)-\psi\left(n+\frac{1}{2}\right)+\log\chi^2\right], \quad (4.31)$$

$$\delta_{D4}(\chi) = c_4\left(\frac{3}{2}K_J^2\chi^2\right)^{-1} - 2c_4\epsilon_B\sum_{n=1}^{\infty}\frac{\left(-\frac{1}{4}-\frac{1}{2}\nu_D\right)_n\left(-\frac{1}{4}+\frac{1}{2}\nu_D\right)_n}{\left(-\frac{1}{2}\right)_n\left(\frac{1}{2}\right)_n(2)_n n!}\left(-\frac{3}{2}K_J^2\chi^2\right)^n\left[\psi\left(-\frac{1}{4}-\frac{1}{2}\nu_D+n\right)\right.$$
$$\left.+\psi\left(-\frac{1}{4}+\frac{1}{2}\nu_D+n\right)-\psi(n+2)-\psi(n+1)-\psi\left(n-\frac{1}{2}\right)-\psi\left(n+\frac{1}{2}\right)+\log\chi^2\right]. \quad (4.32)$$

The same solutions may be obtained by considering Meijer *G*-function solutions to the original differential equations. The procedure for determining solutions to generalized hypergeometriclike equations which contain parameters differing by integers is discussed in detail by Luke,[23] pp.138–143. The study outlined a method for developing Meijer *G*-function solutions from the equations, which involved the differentiation of generalized hypergeometric functions with respect to their parameters—a procedure analogous to the differentiation of ρ indices in the above. The analysis involved is lengthy and tedious, but leads to the solutions obtained above. We refrain from a physical interpretation of the above gravitational modes for now, and take that up in the next section when we discuss the more general solutions. The one obvious difference will be the fact that no Jeans instability is apparent for any of the above modes, with two modes always collapsing and two modes always acoustic, whereas for the general modes a Jeans instability will be apparent.

We now compare the solutions obtained to those of Refs. 10 and 11. In these studies general solutions were written as

$$\phi_1 \equiv t^{-\alpha}\delta_B = c_1G_1 + c_2G_2 + c_3G_3 + c_4G_4. \quad (4.33)$$

Here c_i are constants, and the functions G_i denote Meijer *G* functions,

$$G_h = G_{2,4}^{m,n}\left(x\Big|\begin{matrix}a_1^*+1, a_2^*+1\\ b_h^*, b_1^*\cdots\#\cdots b_4^*\end{matrix}\right), \quad h=1,2,3,4. \quad (4.34)$$

The notation # signifies that b_h is to be omitted in its usual place. The *G* function is defined so that $0\leqslant m\leqslant 4$ and $0\leqslant n\leqslant 2$. The parameters a_i^*, b_j^* depend on ϵ_B, ϵ_D, the adiabatic index γ_B, and the exponent η of t in the Hubble expansion parameter (which we pointed out earlier *must* be equal to $\frac{2}{3}$ for the equations as formulated to be physically correct—even though Refs. 10 and 11 used a greater range of values). The time parameter $x=\frac{3}{2}K_J^2\chi^2$ in our notation. A particular set of solutions is given by m and n being given specific values. In general, $m=1$, $n=2$ will give such a set of solutions for small x in the above example. The *G* functions can then normally be expressed in terms of ${}_2F_3$ functions (for example, the plasma solutions), but in the particular case under discussion, since some of the b_j^* differ by integers, this is not possible. It is this point that Haubold and Mathai missed in Ref. 11.

Let us give specifics to illustrate the point. Under the general classification scheme, the CDM case under consideration corresponds to $\eta=\frac{2}{3}$, $\gamma_i=\frac{5}{3}$, in the notation of Ref. 11. This implies that the parameters take the following values:

$$a_1^*, a_2^* = -1 \pm \tfrac{1}{2}\nu_D,$$

$$b_1^*, b_2^* = \pm \tfrac{1}{4}, \quad b_3^*, b_4^* = \pm \tfrac{5}{4}.$$

To evaluate the G functions in this special case, where some parameters differ by integers, the integral representation of the G functions was considered in Ref. 11:

$$G_1 = \frac{1}{2\pi i}\int_L \frac{\Gamma\left(\frac{1}{4}+s\right)\Gamma(-a_1^*-s)\Gamma(-a_2^*-s)}{\Gamma\left(\frac{5}{4}-s\right)\Gamma\left(-\frac{1}{4}-s\right)\Gamma\left(\frac{9}{4}-s\right)} x^{-s}\,\mathrm{d}s. \tag{4.35}$$

Using the fact that

$$\frac{\Gamma\left(\frac{1}{4}+s\right)}{\Gamma\left(-\frac{1}{4}-s\right)} - \frac{\Gamma\left(\frac{5}{4}+s\right)}{\Gamma\left(\frac{3}{4}-s\right)}, \tag{4.36}$$

it was found that

$$G_1 = -x^{5/4}\frac{\Gamma\left(-a_1^*+\frac{5}{4}\right)\Gamma\left(-a_2^*+\frac{5}{4}\right)}{\Gamma\left(\frac{5}{2}\right)\Gamma(2)\Gamma\left(\frac{7}{2}\right)}\,{}_2F_3\left(-a_1^*+\frac{5}{4},-a_2^*+\frac{5}{4};\frac{5}{2},2,\frac{7}{2};-x\right), \tag{4.37}$$

which agrees with δ_{B3} in (4.29). Performing the same analysis as above for G_3 however, it is found that G_1 and G_3 are exactly the same function. It appears as though this was never checked in Ref. 11. The same applies to G_2 and G_4,

$$G_2 = G_4 = -x^{-1/4}\frac{\Gamma\left(-a_1^*-\frac{1}{4}\right)\Gamma\left(-a_2^*-\frac{1}{4}\right)}{\Gamma\left(\frac{1}{2}\right)\Gamma(2)\Gamma\left(-\frac{1}{2}\right)}\,{}_2F_3\left(-a_1^*-\frac{1}{4},-a_2^*-\frac{1}{4};\frac{1}{2},2,-\frac{1}{2};-x\right), \tag{4.38}$$

which agrees with δ_{B1} in (4.25). Thus the solutions degenerate by employing this method, and two of the solutions, namely δ_{B2} and δ_{B4} which contain logarithmic terms, are totally missed. The correct way to evaluate the G functions when some parameters differ by integers is given by Luke,[23] pp. 143–147. A careful study of this rather complicated procedure will show that the logarithmic solutions δ_{B2} and δ_{B4} are found in this way.

It is interesting to note that a linear combination of the solutions δ_{B2} and δ_{B4} are in fact found in Ref. 11 in the large x limit. In this case the function $G_{2,4}^{4,1}$ was evaluated from the contour integral representation to achieve some analogous series to (4.27) and (4.31). Although the solutions (4.25)–(4.32) are valid for all x, such a representation does not seem very useful for x large, as the solutions are comprised of an infinite ascending series in x. Thus very many terms would be required to represent the solutions accurately in this limit through δ_{B2} and δ_{B4}. In Ref. 19 we develop a much better method for evaluating the solutions for large x using a WKB approximation scheme.

We have now thoroughly investigated the CDM two-component model using the $K_D=0$ limit, and tidied up previous work in this area. As discussed earlier, although this work is of dubious physical relevance, it has been an interesting mathematical investigation, and has allowed comparisons with the previous work in cosmological perturbation theory and cosmological plasma physics. We now turn to the more general two-component model, which has a firmer physical basis.

V. THE GENERAL TWO-COMPONENT SOLUTIONS

We finally investigate the most general set of equations, those with both K_B and K_D nonzero. The equations thus posed can model both CDM and HDM, though the discussion initiated earlier about the lack of a free streaming damping term for neutrinolike HDM should be heeded.

The algorithm needed to solve the equations was developed in the preceding section for $K_D=0$, and can be used here. Thus if (4.10) and (4.11) are substituted into (2.22) and (2.23), we obtain the same indicial equations (4.12) and (4.13) as previously, and the following set of coupled recursion relations:

$$(\rho+n+2)(\rho+n+1)(\rho+n+4)(\rho+n-1)a_{n+2}+6K_B^2\left(\rho+n+\tfrac{3}{2}-\nu_D\right)\left(\rho+n+\tfrac{3}{2}+\nu_D\right)a_n + 36\epsilon_D K_D^2 b_n=0, \tag{5.1}$$

$$(\rho+n+2)(\rho+n+1)(\rho+n+4)(\rho+n-1)b_{n+2}+6K_D^2\left(\rho+n+\tfrac{3}{2}-\nu_B\right)\left(\rho+n+\tfrac{3}{2}+\nu_B\right)b_n + 36\epsilon_B K_B^2 a_n=0. \tag{5.2}$$

Here $\nu_B^2=\frac{1}{4}+6\epsilon_B$ in analogy with the previous definition of ν_D. A closed solution for this set of recursion relations cannot be obtained for all n, so that solutions to (2.22) and (2.23) can only be generated iteratively, to whatever order desired. Lacking the ability to generate an infinite series representation for the solutions means that they cannot be classified by known analytic functions. To handle the complicated algebra involved in finding successive terms iteratively, we have developed a symbolic computation code using the functional programming language Mathematica. The algorithm described in the preceding section can be used to generate a solution up to a certain power in χ.

The coefficients increase in complexity very quickly for increasing n. Although the code can generate solutions up to arbitrary order, we find it sufficient to present only the first two orders for each solution here. We express the results in terms of the original parameters K_B and K_D, rather than in terms of ν_B and ν_D, as no simplification is gained in using the latter. The solutions, corresponding to $\rho=0,1,3,-2$, respectively, are

$$\delta_{B1}(\chi)=1+\tfrac{3}{2}(K_B^2-3\epsilon_D K_B^2-3\epsilon_B K_D^2)\chi^2+O(\chi^4), \tag{5.3}$$

$$\delta_{D1}(\chi)=-\frac{\epsilon_B}{\epsilon_D}\left[1+\frac{3}{2}(K_D^2-3\epsilon_D K_B^2-3\epsilon_B K_D^2)\chi^2+O(\chi^4)\right], \tag{5.4}$$

$$\delta_{B2}(\chi)=\chi+\frac{1}{25}\left(6K_B^2-31\epsilon_D K_B^2-31\epsilon_B K_D^2+5\frac{\epsilon_B}{\epsilon_D}K_D^2\right)\chi^3+\frac{6}{5}\epsilon_B(K_D^2-K_B^2)\chi^3\log\chi+O(\chi^5), \tag{5.5}$$

$$\delta_{D2}(\chi)=-\frac{\epsilon_B}{\epsilon_D}\left[\chi-\frac{1}{25}(31\epsilon_D K_B^2+31\epsilon_B K_D^2-K_D^2)\chi^3-\frac{6}{5}\epsilon_D(K_D^2-K_B^2)\chi^3\log\chi+O(\chi^5)\right], \tag{5.6}$$

$$\delta_{B3}(\chi)=\chi^3+\tfrac{3}{70}(3\epsilon_D K_B^2-3\epsilon_D K_D^2-10K_B^2)\chi^5+O(\chi^7), \tag{5.7}$$

$$\delta_{D3}(\chi)=\chi^3+\tfrac{3}{70}(3\epsilon_B K_D^2-3\epsilon_B K_B^2-10K_D^2)\chi^5+O(\chi^7), \tag{5.8}$$

$$\delta_{B4}(\chi)=\chi^{-2}+\left(K_B^2-5\frac{\epsilon_B}{\epsilon_D}K_D^2+5\epsilon_D K_B^2-5\epsilon_D K_D^2\right)+6\epsilon_D(K_B^2-K_D^2)\log\chi+O(\chi^2), \tag{5.9}$$

TABLE I. A comparison of gravitational and plasma linear perturbation modes

Gravitational modes	Plasma modes
$\delta_1 \sim \chi^0 \sim t^0$	$y_1 \sim \eta^0 \sim t^0$
$\frac{\delta_B}{\delta_D} \sim -\frac{\epsilon_D}{\epsilon_B}$	$\frac{n_e}{n_i} \sim 1$
Lower ${}_2F_3$ parameters: $-\frac{1}{2}, \frac{1}{2}, 2$	$\frac{1}{2}, \frac{3}{4}-\frac{1}{2}\nu, \frac{3}{4}+\frac{1}{2}\nu$
Acoustic mode	Ion-sound mode
$\delta_2 \sim \chi \sim a^{-1/2} \sim t^{-1/3}$	$y_2 \sim \eta^{-1} \sim a^{-1/2} \sim t^{-1/3}$
$\frac{\delta_B}{\delta_D} \sim -\frac{\epsilon_D}{\epsilon_B}$	$\frac{n_e}{n_i} \sim 1$
Logarithmic solutions	Parameters do not correspond
Acoustic mode	Ion-sound mode
$\delta_3 \sim \chi^3 \sim a^{-3/2} \sim t^{-1}$	$y_3 \sim \eta^{-1/2-\nu} \sim a^{-1/4-(1/2)\nu} \sim t^{-1/6-(1/3)\nu}$
$\frac{\delta_B}{\delta_D} \sim 1$	$\frac{n_e}{n_i} \sim -\frac{P_e^2}{P_i^2}$
Lower ${}_2F_3$ parameters: $-\frac{5}{2}, \frac{7}{2}$ 2	$1+\nu, \frac{3}{4}+\frac{1}{2}\nu,, \frac{5}{4}+\frac{1}{2}\nu$
Collapsing mode	Langmuir mode
$\delta_4 \sim \chi^{-2} \sim a \sim t^{2/3}$	$y_4 \sim \eta^{-1/2+\nu} \sim a^{-1/4+(1/2)\nu} \sim t^{-1/3+(1/3)\nu}$

$$\delta_{D4}(\chi) = \chi^{-2} + (6K_D^2 - 5\epsilon_B K_B^2 + 5\epsilon_B K_D^2) + 6\epsilon_D(K_D^2 - K_B^2)\log\chi + O(\chi^2). \tag{5.10}$$

It remains now to make a physical interpretation of these solutions. This is most usefully achieved by constructing a table comparing different properties of the modes, and comparing the solutions to the corresponding cosmological plasma modes. The results are summarized in Table I, which uses notation defined in Ref. 18. Both the $K_D=0$ modes of the preceding section and the modes of this current section are included in each category under the table. The plasma modes $y_1, \ldots, y_4$ of Ref. 18, Eq. (4.16) correspond to the $K_D=0$ modes (4.25)–(4.32). The current gravitational modes (5.3)–(5.10) (that is $\delta_1, \ldots, \delta_4$) correspond to the more general expansions Eqs. (4.20), (4.21), (4.29)–(4.32) of Ref. 18.

In Table I, the power of χ gives the corresponding exponent ρ. The parameter $\nu \equiv \sqrt{\frac{1}{4} - P_i^2 - P_e^2}$ found in the plasma modes depends on the plasma frequencies of the electron and ion components. For the gravitational modes, the signs of P_i and P_e must be reversed since (as opposed to the electromagnetic force) gravity is always attractive. In addition $P_i^2 + P_e^2$ corresponds to $\epsilon_B + \epsilon_D = 1$ (once again the special nature of gravity in cosmology is apparent). This implies that the general parameter ν in the plasma modes should be replaced with $\frac{5}{2}$ for the gravitational modes—the reason why many of the parameters in the ${}_2F_3$ and Meijer G functions were pure rational numbers not depending on physical constants. Notice that the ratio of the amplitudes of baryonic/dark matter modes and electron/ion modes differ. This is because the couplings in the differential equations are different. For the gravitational modes the couplings involve terms such as $\epsilon_D\delta_D$ and $\epsilon_B\delta_B$, whereas for the plasma modes the couplings involve terms such as $P_i^2\bar{n}_{e1}$ and $P_e^2\bar{n}_{i1}$.

We have indicated the corresponding collapsing and acoustic modes for the gravitational density perturbations. It is difficult to show this rigorously for the series solutions as presented. We

can make comparisons to the one-component results, and identify the leading order powers of the expansion parameter a. This yields the classification as stated. We can also make an analogy to the ion-sound modes of plasma physics, which are of a similar nature to acoustic oscillations. They show a collective behavior of both components oscillating approximately in phase.

We are finally left with the question of how the Jeans scale enters into the solutions. In Sec. IV the mixture wave number k_M, Eq. (4.4) was briefly introduced as being the only physically meaningful scale for instabilities in a two-component fluid. To make this quantity dimensionless, it would be appropriate to make the definition

$$K_M^2 = \frac{k^2}{W_B/v_B^2 + W_D/v_D^2}. \tag{5.11}$$

This quantity is only of relevance to a static spacetime scenario. To place it in the context of the expanding Universe, the substitutions

$$W_B \to \frac{6\epsilon_B}{\chi^2}, \quad v_B^2 k^2 \to 6K_B^2,$$

$$W_D \to \frac{6\epsilon_D}{\chi^2}, \quad v_D^2 k^2 \to 6K_D^2$$

are required. Then K_M takes on the revised definition

$$K_M^2 = \frac{\chi^2}{\epsilon_B/K_B^2 + \epsilon_D/K_D^2} = \frac{\chi^2}{\chi_c^2}. \tag{5.12}$$

We have introduced the quantity $\chi_c(k)$, which can be thought of as a critical time. For $\chi > \chi_c$, $K_M > 1$ and acoustic oscillations would only be expected to exist for all modes. For $\chi < \chi_c$, $K_M < 1$ and two of the modes become unstable and undergo gravitational collapse. Since the precise magnitude of the scale factor a is not determined by cosmology [see Eq. (3.7), which contains an arbitrary initial time t_i], we may arbitrarily assign an initial time $a_0 = 1$, so that $\chi_0 = 1$ and decreases with increasing time. Then we may interpret the Jeans instability in two ways by considering the critical time χ_c. Initially we may study all k-dependent modes at a particular time χ, where a subset will be unstable for values of k for which $\chi_c(k) > \chi$ (we stress that χ_c is a function of k). We may then consider what occurs as the modes evolve through time from this particular instant. The critical time χ_c is fixed for any particular mode, so that a subset of modes that were originally acoustic will become unstable as $\chi \to \chi_c^+$ (those modes corresponding to the solutions δ_3 and δ_4 in Table I). Consequently more and more modes pass through the instability as the Universe evolves. The physical wave number k is of course dependent on time, thus the dependence of the instability on a time χ_c shows the inextricable link between the wave number and time.

It is illuminating at this stage to refer back to the one-component modes discussed in Sec. III. For the one-component case, solutions were found in terms of the combination $K_J a^{-1/2}$. With the identification $\chi = a^{-1/2}$, the quantity χ_c is seen to be the two-component analog of K_J.

It would be useful to convert the expansions (5.3)–(5.10) to depend on K_M or χ_c, to see how the Jeans scale enters. This is achieved by the following relations:

$$K_B^2 = \frac{1}{\chi_c^2}(\epsilon_B + \epsilon_D V^2), \quad K_D^2 = \frac{1}{\chi_c^2}\left(\epsilon_D + \frac{\epsilon_B}{V^2}\right). \tag{5.13}$$

Here $V = v_B/v_D$ is the ratio of sound velocities. We then find that the expansions are all in terms of increasing powers of χ/χ_c, with coefficients in terms of ϵ_B, ϵ_D, and V:

$$\delta_{B1}(\chi) = 1 + \frac{3}{2}\left(\epsilon_B + \epsilon_D V^2 - 6\epsilon_B\epsilon_D - 3\epsilon_D^2 V^2 - \frac{3\epsilon_B^2}{V^2}\right)\frac{\chi^2}{\chi_c^2} + O\left(\frac{\chi^4}{\chi_c^4}\right), \tag{5.14}$$

$$\delta_{D1}(\chi) = -\frac{\epsilon_B}{\epsilon_D}\left[1 + \frac{3}{2}\left(\epsilon_D + \frac{\epsilon_B}{V^2} - 6\epsilon_B\epsilon_D - 3\epsilon_D^2V^2 - \frac{3\epsilon_B^2}{V^2}\right)\frac{\chi^2}{\chi_c^2} + O\left(\frac{\chi^4}{\chi_c^4}\right)\right], \tag{5.15}$$

$$\delta_{B2}(\chi) = \chi\left\{1 + \frac{1}{25}\left[5 + \epsilon_D + \frac{6\epsilon_B}{V^2} + \frac{5\epsilon_B^2}{\epsilon_D V^2} - 31\left(\epsilon_D V + \frac{\epsilon_B}{V}\right)^2\right]\frac{\chi^2}{\chi_c^2} + \frac{6}{5}\epsilon_B\left(\epsilon_D - \epsilon_B - \epsilon_D V^2 + \frac{\epsilon_B}{V^2}\right)\frac{\chi^2}{\chi_c^2}\log\chi + O\left(\frac{\chi^4}{\chi_c^4}\right)\right\}, \tag{5.16}$$

$$\delta_{D2}(\chi) = -\frac{\epsilon_B}{\epsilon_D}\chi\left\{1 - \frac{1}{25}\left[\epsilon_D - \frac{\epsilon_B}{V^2} + 31\left(\epsilon_D V + \frac{\epsilon_B}{V}\right)^2\right]\frac{\chi^2}{\chi_c^2} - \frac{6}{5}\epsilon_D\left(\epsilon_D - \epsilon_B - \epsilon_D V^2 + \frac{\epsilon_B}{V^2}\right)\frac{\chi^2}{\chi_c^2}\log\chi + O\left(\frac{\chi^4}{\chi_c^4}\right)\right\}, \tag{5.17}$$

$$\delta_{B3}(\chi) = \chi^3\left\{1 + \frac{3}{70}\left[3\epsilon_D\left(\epsilon_B - \epsilon_D + \epsilon_D V^2 - \frac{\epsilon_B}{V^2}\right) - 10(\epsilon_B + \epsilon_D V^2)\right]\frac{\chi^2}{\chi_c^2} + O\left(\frac{\chi^4}{\chi_c^4}\right)\right\}, \tag{5.18}$$

$$\delta_{D3}(\chi) = \chi^3\left\{1 + \frac{3}{70}\left[3\epsilon_B\left(\epsilon_D - \epsilon_B - \epsilon_D V^2 + \frac{\epsilon_B}{V^2}\right) - 10\left(\epsilon_D + \frac{\epsilon_B}{V^2}\right)\right]\frac{\chi^2}{\chi_c^2} + O\left(\frac{\chi^4}{\chi_c^4}\right)\right\}, \tag{5.19}$$

$$\delta_{B4}(\chi) = \chi^{-2}\left\{1 + \left[-4\epsilon_B + \epsilon_D V^2 + 5\epsilon_B\epsilon_D + 5\epsilon_D^2(V^2 - 1) - 5\left(\frac{\epsilon_B}{\epsilon_D} + \epsilon_D\right)\frac{\epsilon_B}{V^2}\right]\frac{\chi^2}{\chi_c^2} + 6\epsilon_D\left(\epsilon_B - \epsilon_D + \epsilon_D V^2 - \frac{\epsilon_B}{V^2}\right)\frac{\chi^2}{\chi_c^2}\log\chi + O\left(\frac{\chi^4}{\chi_c^4}\right)\right\}, \tag{5.20}$$

$$\delta_{D4}(\chi) = \chi^{-2}\left\{1 + \left[6\epsilon_D - 5\epsilon_B^2 + 5\epsilon_B\epsilon_D(1 - V^2) + \frac{5\epsilon_B^2}{V^2}\right]\frac{\chi^2}{\chi_c^2} - 6\epsilon_B\left(\epsilon_B - \epsilon_D + \epsilon_D V^2 - \frac{\epsilon_B}{V^2}\right)\frac{\chi^2}{\chi_c^2}\log\chi + O\left(\frac{\chi^4}{\chi_c^4}\right)\right\}. \tag{5.21}$$

This is a convenient parametrization of the solutions. The scale of the modes are chosen by χ_c, the nature of the matter involved is determined by V, and the proportions are determined by ϵ_B and ϵ_D. A complete solution to the problem has thus been achieved up to whatever order desired.

VI. CONCLUSIONS AND FURTHER WORK

A method for determining the small k solutions of a general two-component cosmological density perturbation model has been expounded in this paper. We have only displayed the solutions to first order, but it is possible to derive them up to any order by the method in principle. We have explored the mathematical properties and peculiarities of density perturbations influenced by gravitational interaction, particularly contrasting them to plasma modes, and correcting a number of previous misconceptions in the literature. The expanding Universe introduces new features not predictable from simple static space–time considerations. In particular, totally new structures to the dispersion relations are found, even in the one-component example. We have shown how the mixture Jeans wave number enters the solutions, and clarified its role in an expanding universe context.

More work is required to investigate the solutions around the critical scale defined by k_M. Although the expansions as derived in this paper are applicable to this region, they are not

particularly useful, as many terms in the equations need to be retained when the expansion parameter χ/χ_c is of $O(1)$. It is unclear how an analytical investigation of this region could proceed at present. We have performed some preliminary studies which involved producing a large number of terms in the expansions (5.3)–(5.10) using the Mathematica program described, and then substituting in numerical values for the various physical parameters to obtain numerical coefficients with an ascending series in χ. At present the plots of these expansions over a range of values of χ do not yield reliable results—it is possible that many more terms than are practically calculable will be required, and a very high order of numerical precision will have to be maintained. Other methods of analyzing the modes in this interesting region probably need to be investigated.

Of ultimate interest is exploring how these type of modes contribute to the power spectrum. More physical effects may need to be introduced, such as a cosmological constant, or the addition of more matter components. To determine the actual density contrast at a given scale $1/k$, the Fourier modes of the density contrast as derived in this paper would also need to be integrated over the whole range $0<k<1/k$. It would be of considerable interest to compare the power spectra calculated by such a method with the well-known power spectra of the various cosmological models in existence today.

In concluding, we remark that a similar analysis could be carried out in the postrecombination region $140<z<1150$, where now the baryons follow the $T\sim 1/a$ relationship. The differential equations in Sec. II will now be different, as will be their solutions; but we expect that the ensuing analysis would yield qualitatively similar results but quantitatively different scaling. This would be a useful future study.

Short wavelength analysis of the evolution of perturbations in a two-component cosmological fluid

R. M. Gailis[a] and N. E. Frankel[b]
School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia

(Received 7 September 2005; accepted 8 May 2006; published online 29 June 2006)

The equations describing a two-component cosmological fluid with linearized density perturbations are investigated in the small wavelength or large k limit. The equations are formulated to include a baryonic component, as well as either a hot dark matter (HDM) or cold dark matter (CDM) component. Previous work done on such a system in static space–time is extended to reveal some interesting physical properties, such as the Jeans wave number of the mixture, and resonant mode amplitudes. A WKB technique is then developed to study the expanding universe equations in detail, and to see whether such physical properties are also of relevance in this more realistic scenario. The Jeans wave number of the mixture is reinterpreted for the case of an expanding background space–time. The various modes are obtained to leading order, and the amplitudes of the modes are examined in detail to compare to the resonances observed in the static space–time results. It is found that some conclusions made in the literature about static space–time results cannot be carried over to an expanding cosmology. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2209551]

I. INTRODUCTION

The analysis of cosmological perturbations in the Newtonian limit is a well studied problem in theories of structure formation, and it may be supposed that there is little left to learn from this theory. Most of the effort has gone into the study of the one-component cosmological fluid equations, and the results have been well expounded in many standard texts.[1–5] There is, however, still a wealth of problems remaining in the detailed analysis of two-component cosmological fluids and their linearized gravitational perturbation modes. In particular, if pressure effects are included so that the Jeans instability becomes an issue, the equations present a considerable analytic challenge, and a range of new physical effects become apparent. Some of these effects have been studied in the contrived case of a static space–time background.[6,7] In this scenario there is no expansion, so that the mathematics is considerably simplified, and solutions can easily be found. This is useful to gain some qualitative idea about physical phenomena observable, but to gain a true picture in a cosmological context, the expanding background space–time given by the Friedmann-Robertson-Walker cosmologies is required.

There have been a variety of studies of the multicomponent cosmological fluid equations, ranging from some relatively specific applications under certain cosmological scenarios,[8,9] to a broad mathematical study and classification.[10] A discussion of the application and validity of some of the equations mentioned in these previous studies, together with the solution of an unsolved set of two-component post-recombination equations, has recently been undertaken by the authors.[11] The system of equations described the interaction between a dark matter and baryonic component in the Newtonian regime (density fluctuations on scales well within the Hubble radius). A series

expansion of the solutions for small wave number k (large scales) was presented. This allowed comparison with some of the previous work, in particular with the Meijer G-function classifications given by Ref. 10. This region of k-space is also interesting because it is the region in which the Jeans instability is known to occur.

In this paper we wish to complete this study by examining the large k asymptotic region of the solutions. Such a study is worthwhile, in order to make contact with the static space–time results of Ref. 7. Although not realistic as cosmological solutions, these results displayed a number of little known physical phenomena associated with the linearized modes, which we wish to expand on here. The techniques required to analyze the expanding universe solutions are also of interest in their own right mathematically, where a generalized WKB method will be expounded. It is possible to make a comparison with the work done in cosmological plasma physics in an Einstein-deSitter background.[12–14] This is interesting because of the mathematically very similar form of fluid equations for both type of systems, which is due to the similarity of the electromagnetic and gravitational forces. Thus mathematical techniques employed in the analysis of plasma equations will be useful in this paper, and give clues as to how to proceed with some challenging mathematical analysis of gravitational density perturbation modes.

The paper is to be organized as follows. The relevant equations will be introduced in Sec. II. The discussion will then be focused in Sec. III, by reconsidering the two-component modes in a static space–time. This investigation is by necessity of a qualitative nature, but gives a useful introduction to the concepts and interesting physical effects not found in the standard one-component analysis. The work of Ref. 7 will also be extended. The expanding universe baryonic and dark matter equations will then be considered in Sec. IV. The short wavelength (WKB) approximation will be utilized to complete the study of these equations initiated in Ref. 11. The relevance of the previous work on static space–time systems is revealed through this analysis. This will allow meaningful conclusions to be drawn about this whole area of study, and point to where promising future work may lie. These aspects are discussed in Sec. V.

II. THE GOVERNING EQUATIONS

A broad survey of the Newtonian cosmological perturbation equations under various cosmological scenarios was given in Ref. 11. This paper also gave a detailed derivation of the equations of interest for present analysis. We will not repeat such a detailed discussion here, but directly introduce the relevant equations.

The starting point is the equations for an n-component system of nonrelativistic species, as derived in all the standard texts. Given a density perturbation δ_i of the ith component of the mass density ρ_i,

$$\delta_i(\mathbf{r},t) = \frac{\delta\rho_i}{\rho_i}, \tag{2.1}$$

it may be decomposed into its Fourier plane wave modes with wave vector $\mathbf{k}$,

$$\delta_i(\mathbf{r},t) = \frac{1}{(2\pi)^3}\int \delta_{\mathbf{k}i}(t)\exp(-i\mathbf{k}\cdot\mathbf{r})d^3r. \tag{2.2}$$

Here $\mathbf{r}$ is the physical spatial coordinate, and t is cosmic time. Using the Eulerian equations of motion describing a perfect fluid, a set of coupled second order equations for the Fourier modes $\delta_i(t)$ (where we now drop the subscript $\mathbf{k}$) are achieved,

$$\frac{d^2\delta_i}{\mathrm{d}t^2} + 2\frac{\dot{a}}{a}\frac{\mathrm{d}\delta_i}{\mathrm{d}t} + v_i^2k^2\delta_i = 4\pi G\sum_{i=1}^{n}\rho_i\delta_i, \quad i = 1,2,\ldots,n. \tag{2.3}$$

Overdots will denote derivatives with respect to t.

The above equations contain the universe expansion factor a and sound velocities v_i. We use the expression "sound velocity" fairly loosely. The parameters v_i could also denote a general

velocity dispersion for a collisionless fluid. To be able to solve the equations, the time dependence of the physical variables needs to be made explicit. We will adopt the convention that barred variables will denote comoving quantities, independent of time. Thus the definition of comoving wave number $\bar{\mathbf{k}}=a\mathbf{k}$ arises naturally. An assumption must also be made about the scaling of the sound velocities v_i. In the post-recombination era, the adiabatic speed of sound follows the behavior $v \propto a^{-1}$, so we will introduce the time independent quantities $\bar{v}_i \equiv a v_i$. The total background energy density ρ_0 can also be made independent of time by the definition $\bar{\rho}_0 \equiv a^3 \rho_0$. This enables us to introduce the useful parameter $\epsilon_i = \rho_i / \rho_0$, the fraction of mass density contributed by species i.

We will not go into detail on how the equations are transformed into their simplest form here (instead see Ref. 11), but briefly describe the important points. The equations are first transformed so that a is the only explicit temporal variable. This allows parameters specifying particular large scale cosmological dynamics to enter the equations, namely the cosmological constant Λ and spatial curvature k_c. In this paper, a background Einstein-deSitter cosmology will be employed ($k_c=0$, $\Lambda=0$). Although this model has been ruled out with high confidence by current observations, it is sufficient for our purposes. We wish to study some important physical process without additional complications.

It is found that the following important parameters arise:

$$\bar{k}_B^2 = \frac{4\pi G \bar{\rho}_0}{\bar{v}_B^2}, \quad \bar{k}_D^2 = \frac{4\pi G \bar{\rho}_0}{\bar{v}_D^2}. \tag{2.4}$$

They resemble the comoving Jeans wave numbers for each component taken separately. The strict Jeans one-component wave numbers are given by replacing ρ_0 with ρ_i in (2.4) (see next section). The wavelength parameters defined above indicate whether gravity $\bar{k}_i > \bar{k}$ or pressure support $\bar{k}_i < \bar{k}$ dominate the dynamics, and thus whether the region of k-space under consideration is Jeans unstable. It may also be noted that the relation $\epsilon_B + \epsilon_D = 1$ holds.

It is useful to define the parameters

$$K_B = \frac{\bar{k}}{\bar{k}_B}, \quad K_D = \frac{\bar{k}}{\bar{k}_D}, \tag{2.5}$$

for a clear dimensionless partitioning of parameter space. $K_i < 1$ corresponds to the Jeans unstable region in the single component analog of the equations, and $K_i > 1$ to the acoustic region. The cosmological fluid equations are finally written in terms of the variable $\chi = a^{-1/2}$, to give the canonical form of the system of differential equations to be studied in this paper,

$$\delta_B'' + 6\left(K_B^2 - \frac{\epsilon_B}{\chi^2}\right)\delta_B - \frac{6\epsilon_D}{\chi^2}\delta_D = 0, \tag{2.6}$$

$$\delta_D'' + 6\left(K_D^2 - \frac{\epsilon_D}{\chi^2}\right)\delta_D - \frac{6\epsilon_B}{\chi^2}\delta_B = 0. \tag{2.7}$$

The prime denotes differentiation with respect to χ.

These equations bear a strong resemblance to the equations of an electron-proton cosmological plasma studied in Ref. 14 [Eqs. (4.8) and (4.9) of that paper]. Considering the mathematical similarity between the electromagnetic and gravitational forces, this was to be expected. A manifestation of this fact is the close resemblance between the dispersion relation for the simple one-component Jeans instability and Langmuir modes. The techniques employed in Ref. 14 will be adopted and developed further to the current problem. In particular, some general WKB techniques will be extended. This will also indicate further results obtainable in cosmological plasma physics.

We now digress to an analysis of the static space–time perturbation equations to introduce some new physical phenomena, which are to be scrutinized for their applicability in an expanding universe.

III. THE STATIC TWO-COMPONENT PROBLEM

A. Eigenvalues and eigenvectors

The static space–time results for a two-component fluid are well understood, though receive little attention in standard linearized structure formation theory, which aims to produce the power spectrum of density perturbations. We will extend the current results to facilitate understanding the general expanding universe scenario later. This section aims to develop some concepts in a relatively simple setting. Previous work on the static problem has been done in Refs. 6 and 7. We will in particular rely quite heavily on the notation and results of Ref. 7 in this section. Although the solutions are unrealistic as an application to cosmology, they display some similar qualitative features, and allow an exposition of the basic physical ideas without the complication of space–time expansion being introduced. The static nature of the space–time simplifies the mathematics greatly, and is thus useful in understanding the general problem.

In this section, there is no need to refer to barred (comoving) physical quantities, and all physical variables may be assumed to be constant in time, unless otherwise specified. With the expansion parameter a set equal to unity, the general fluid equations (2.3) may be written as

$$\ddot{\delta}_D + (v_D^2 k^2 - W_D)\delta_D - W_B\delta_B = 0, \tag{3.1}$$

$$\ddot{\delta}_B + (v_B^2 k^2 - W_B)\delta_B - W_D\delta_D = 0, \tag{3.2}$$

with an overdot denoting differentiation with respect to t, and $W_i = 4\pi G\rho_i$. A study of the behavior of the solutions to these equations is most readily undertaken by reducing the system to a first order autonomous dynamical system, undertaken in Ref. 7. To analyze the dynamical system, a solution needs to be found for the state vector

$$\mathbf{x} = (x_1, x_2, x_3, x_4)^T \equiv (\dot{\delta}_D, \delta_D, \dot{\delta}_B, \delta_B)^T. \tag{3.3}$$

We just state the results here.

The most important feature discovered in Ref. 7 was the existence of a parameter dependent critical point of the dynamical system given by

$$k^2 = k_M^2 \equiv k_B^2 + k_D^2 = \frac{W_B}{v_B^2} + \frac{W_D}{v_D^2}, \tag{3.4}$$

where k_B and k_D have been defined in terms of the density and velocity parameters of each matter component, and are slightly different from $\bar{k}_B$ and $\bar{k}_D$ defined in (2.4). The special value of the wave number k_M, may be thought of as the Jeans wave number of a two-component fluid (the mixture wave number). It comprises the Jeans wave numbers of each fluid taken separately, but it is possible to show that $k=k_M$ is the only physical quantity which indicates an instability—both $k=k_D$ and $k=k_B$ have no such interpretation for the coupled two-component case.

With solutions of the form

$$\mathbf{x}(t) = \sum_{i=1}^{4} \alpha_i \exp(\lambda_i t)\boldsymbol{\xi}_i, \tag{3.5}$$

where the α_i are amplitude functions dependent on k and determined by initial conditions, the solutions for the eigenvalues λ_i and eigenvectors $\boldsymbol{\xi}_i$ of the dynamical system are, respectively,

$$\lambda_1 = -\lambda_2 = \tfrac{1}{\sqrt{2}}\sqrt{f + \sqrt{f^2 + 4g}},$$

$$\lambda_3 = -\lambda_4 = \tfrac{1}{\sqrt{2}}\sqrt{f - \sqrt{f^2 + 4g}}, \tag{3.6}$$

with

$$f(k) = W_B + W_D - k^2(v_B^2 + v_D^2), \tag{3.7}$$

$$g(k) = k^2(W_B v_D^2 + W_D v_B^2) - k^2 v_B^2 v_D^2, \tag{3.8}$$

and

$$\boldsymbol{\xi}_i = (\beta_i \lambda_i, \beta_i, \lambda_i, 1)^T, \quad i = 1,2,3,4, \tag{3.9}$$

with

$$\beta_1 = \beta_2 = \tfrac{1}{2W_D}(h + \sqrt{h^2 + 4W_B W_D}),$$

$$\beta_3 = \beta_4 = \tfrac{1}{2W_D}(h - \sqrt{h^2 + 4W_B W_D}), \tag{3.10}$$

and

$$h(k) = W_D - W_B + k^2(v_B^2 - v_D^2). \tag{3.11}$$

For calculational purposes, we note that

$$h^2 + 4W_B W_D = f^2 + 4g. \tag{3.12}$$

An examination of the real and imaginary parts of the λ_i will show that the λ_1 and λ_2 modes represent acoustic oscillations for $k > k_M$ and growing and decaying modes for $k < k_M$. The λ_3 and λ_4 modes however always represent acoustic oscillations. The exponential nature of the solutions indicate that the growing and decaying modes do not have the typical power law behavior exhibited by expanding universe solutions, however the solutions exhibit the correct qualitative behavior in the regions below and above the critical point given by $k = k_M$.

To gain a feel for the properties of the above eigenvalues and eigenvectors, which allows us to make direct contact with the physics of the solutions, we study the quantities in various asymptotic regimes, and examine some plots. This will be effectively facilitated if the quantities are reparametrized in terms of some dimensionless variables. We need only consider the eigenvalues λ_1 and λ_3. To indicate the nature of the dark matter, the sound velocities may be coalesced into the single variable

$$V^2 = \frac{v_B^2}{v_D^2}. \tag{3.13}$$

Then $V \ll 1$ corresponds to HDM while $V \gg 1$ corresponds to CDM. We also introduce the quantities ϵ_D and ϵ_B as used elsewhere in the paper. In this context, they may be defined as

$$\epsilon_D = \frac{W_D}{W_B + W_D}, \quad \epsilon_B = \frac{W_B}{W_B + W_D}. \tag{3.14}$$

We also parametrize the wave-number dependence in units of the mixed Jeans wave number; thus we define

$$K_M = \frac{k}{k_M}. \tag{3.15}$$

It then follows that the eigenvalues may be written as

$$\lambda_{1,3} = \frac{1}{\sqrt{2}}(W_B + W_D)^{1/2}\left\{1 - K_M^2 - \left(\epsilon_D V^2 + \frac{\epsilon_B}{V^2}\right)K_M^2 \pm \left[\left(1 - K_M^2 - \left(\epsilon_D V^2 + \frac{\epsilon_B}{V^2}\right)K_M^2\right)^2 + 4\left(\frac{\epsilon_B}{V} + \epsilon_D V\right)^2 K_M^2(1 - K_M^2)\right]^{1/2}\right\}^{1/2}. \tag{3.16}$$

These expressions may be expanded for small and large K_M. The results are

$$\lambda_1 \sim (W_B + W_D)^{1/2}\left[1 + \frac{1}{2V^2}(-\epsilon_B + \epsilon_B^2 - V^2 + 2\epsilon_B\epsilon_D V^2 - \epsilon_D V^4 + \epsilon_D^2 V^4)K_M^2 + \cdots\right], \quad K_M \ll 1, \tag{3.17}$$

$$\lambda_1 \sim iK_M\frac{1}{\sqrt{2}}(W_B + W_D)^{1/2}\{1 + \epsilon_B/V^2 + \epsilon_D V^2 - [(1 + \epsilon_B/V^2 + \epsilon_D V^2)^2 - 4(\epsilon_B/V + \epsilon_D V)^2]^{1/2}\}^{1/2}, \quad K_M \gg 1, \tag{3.18}$$

$$\lambda_3 \sim iK_M(W_B + W_D)^{1/2}(\epsilon_B/V^2 + \epsilon_D V^2), \quad K_M \ll 1, \tag{3.19}$$

$$\lambda_3 \sim iK_M\frac{1}{\sqrt{2}}(W_B + W_D)^{1/2}\{1 + \epsilon_B/V^2 + \epsilon_D V^2 + [(1 + \epsilon_B/V^2 + \epsilon_D V^2)^2 - 4(\epsilon_B/V + \epsilon_D V)^2]^{1/2}\}^{1/2}, \quad K_M \gg 1. \tag{3.20}$$

These expansions confirm the earlier statement, whereby the λ_3 (and equivalently λ_4) modes display acoustic oscillations at all wavelengths, whereas the λ_1 (and equivalently λ_2) modes undergo a Jeans instability to growing (decaying) modes for $K_M < 1$. It is also evident that at very large wave numbers (small scales) the acoustic oscillations have a very large frequency, growing in proportion to the wave number, whereas for very low wave numbers the λ_3 modes behave in a very slowly varying oscillatory manner, the frequency again being proportional to the wave number. In this regime the λ_1 and λ_2 modes comprise exponentially growing or decaying perturbations over an almost wave number independent timescale, approximately equal to $(W_B + W_D)^{1/2}$. These properties are illustrated in Fig. 1, where the absolute values of the eigenvalues are plotted as a function of K_M for a variety of H/CDM scenarios. The values $\epsilon_B = 0.1$ and $\epsilon_D = 0.9$ have been used in the plots, which is a fairly typical proportion of baryonic and dark matter mass density expected in the Universe.

B. Interesting scales

It is evident that at certain scales the eigenvalues undergo some qualitatively interesting changes, which have been marked on the plots by some arrows. For wave numbers around $K_M = 1$, the λ_1 eigenvalue drops very quickly to zero, indicating the Jeans instability, but the λ_3 eigenvalue displays uniform behavior in this region. There is another interesting scale in the $K_M < 1$ region for small V. The physical motivation for this scale was discussed in Ref. 7. It corresponds to a critical wave number k_C, defined to be when the frequencies of each component taken separately coincide, i.e., when

$$v_B^2 k^2 - W_B = v_D^2 k^2 - W_D. \tag{3.21}$$

The wave number $k = k_C$ is consequently given by

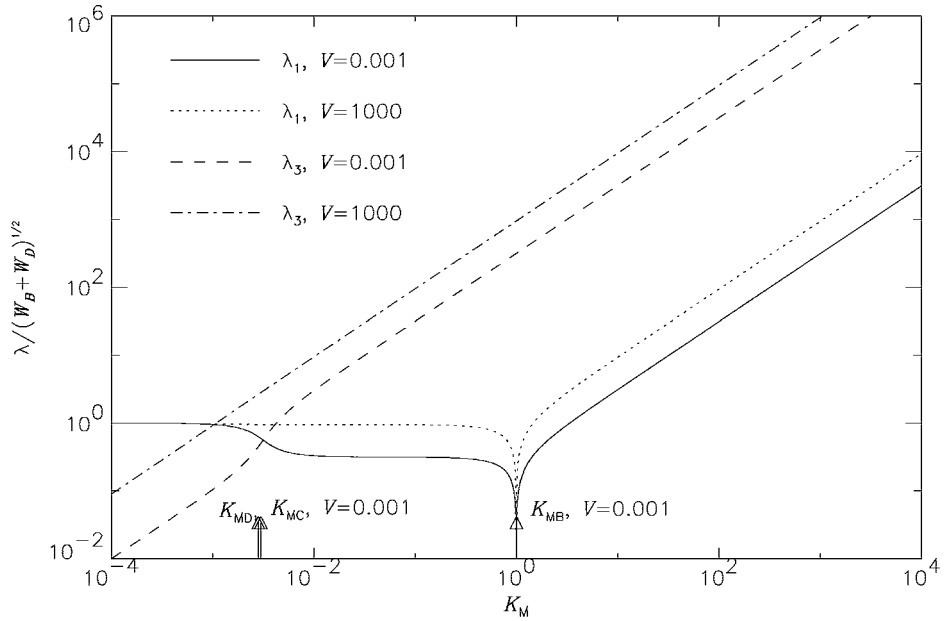

FIG. 1. The eigenvalues for HDM and CDM in the static universe scenario with ϵ_B=0.1, ϵ_D=0.9.

$$k_C = \left(\frac{W_D - W_B}{v_D^2 - v_B^2} \right)^{1/2}. \tag{3.22}$$

It is interesting that the importance of this scale is only apparent for small V, where a sudden increase in the magnitude of λ_3 and decrease in the magnitude of λ_1 is apparent. For all $V \gtrsim 1$, the plots would be almost identical to the displayed plots of $V=1000$ in Fig. 1.

To gain a better understanding of this behavior, it is useful to convert k_C into units of k_M, which are the plotting units of all the figures. Thus

$$K_{MC} \equiv \frac{k_C}{k_M} = \left(\frac{\epsilon_D - \epsilon_B}{\epsilon_D - \epsilon_B - \epsilon_D V^2 + \epsilon_B / V^2} \right)^{1/2}. \tag{3.23}$$

It is interesting to compare this quantity to the individual Jeans instability scales for each fluid taken separately,

$$K_{MD} \equiv \frac{k_D}{k_M} = \left(\frac{\epsilon_D}{\epsilon_B / V^2 + \epsilon_D} \right)^{1/2}, \tag{3.24}$$

$$K_{MB} \equiv \frac{k_D}{k_M} = \left(\frac{\epsilon_B}{\epsilon_B + \epsilon_D V^2} \right)^{1/2}. \tag{3.25}$$

A better qualitative feel for these scales is facilitated by considering their expansions in the HDM and CDM regimes. For HDM, with $V \ll 1$ we find

$$K_{MC}^2 = V^2 \left(\frac{\epsilon_D}{\epsilon_B} - 1 \right) \left[1 - \left(\frac{\epsilon_D}{\epsilon_B} - 1 \right) V^2 + O(V^4) \right], \tag{3.26}$$

$$K_{MD}^2 = V^2 \frac{\epsilon_D}{\epsilon_B} \left[1 - \frac{\epsilon_D}{\epsilon_B} V^2 + O(V^4) \right], \tag{3.27}$$

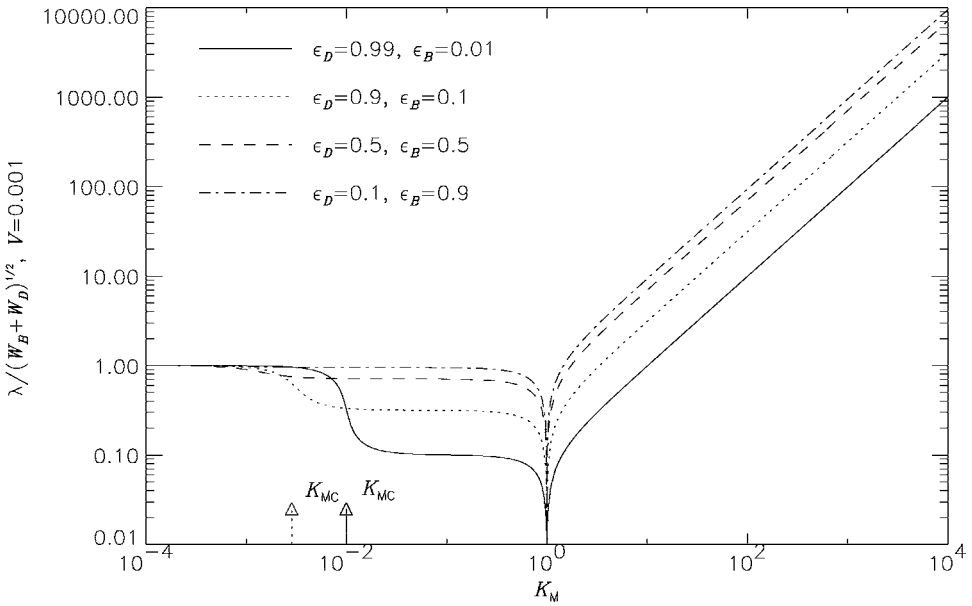

FIG. 2. The eigenvalue λ_1 for a range of ϵ_D and ϵ_B, with $V=0.001$ in the static universe scenario.

$$K_{MB}^2 = 1 - \frac{\epsilon_D}{\epsilon_B} V^2 + O(V^4). \tag{3.28}$$

From this it may be concluded that if

(1) $\epsilon_D \gg \epsilon_B$, then $K_{MC} \sim K_{MD}$,
(2) $\epsilon_D \gtrsim \epsilon_B$, then $K_{MC} \ll 1$,
(3) $\epsilon_B > \epsilon_D$, then K_{MC} is imaginary (no physical significance).

This last point is also borne out by the original definition (3.22), where it is seen that for k_C to be real, the dominant component must also be the hotter component. For CDM, with $V \gg 1$ the corresponding relations are given by

$$K_{MC}^2 = V^{-2}\left(\frac{\epsilon_B}{\epsilon_D} - 1\right)\left[1 - \left(\frac{\epsilon_B}{\epsilon_D} - 1\right)V^{-2} + O(V^{-4})\right], \tag{3.29}$$

$$K_{MD}^2 = 1 - \frac{\epsilon_B}{\epsilon_D} V^{-2} + O(V^{-4}), \tag{3.30}$$

$$K_{MB}^2 = V^{-2}\frac{\epsilon_B}{\epsilon_D}\left[1 - \frac{\epsilon_B}{\epsilon_D} V^{-2} + O(V^{-4})\right]. \tag{3.31}$$

This shows that if

(1) $\epsilon_B \gg \epsilon_D$, then $K_{MC} \sim K_{MB}$,
(2) $\epsilon_B \gtrsim \epsilon_D$, then $K_{MC} \ll 1$,
(3) $\epsilon_D > \epsilon_B$, then K_{MC} is imaginary (no physical significance).

The position of the arrows in Fig. 1 bear out the above relations, as do the arrows in Fig. 2 and 3 to be discussed more below.

In conclusion, the fact that all eigenvalues have been plotted for the values $\epsilon_B=0.1$ and $\epsilon_D=0.9$ means that the scale k_C is only physically relevant for HDM. This is why all plots for $V \gtrsim 1$ (CDM) are so similar. Given that the real Universe is now considered almost certainly CDM

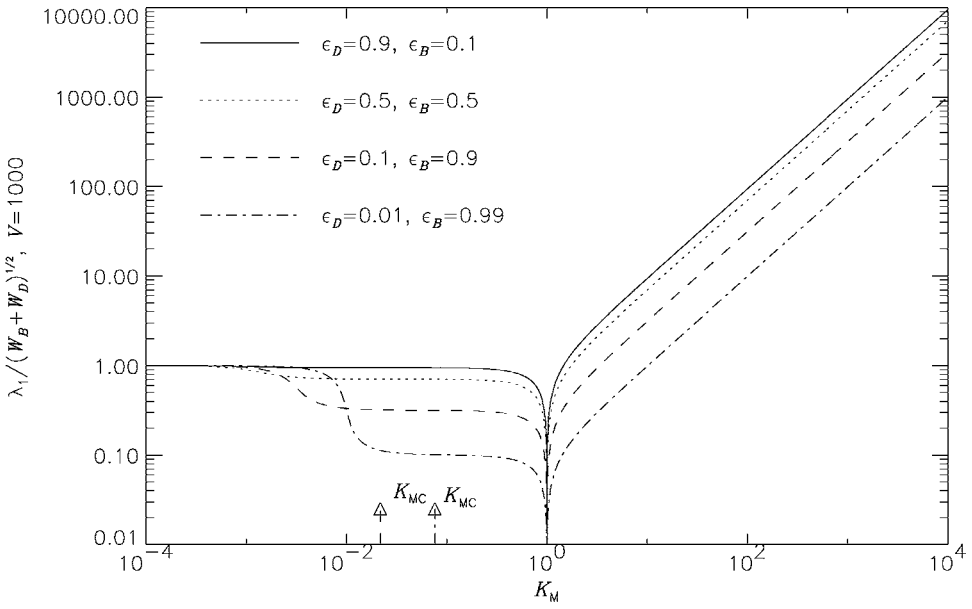

FIG. 3. The eigenvalue λ_1 for a range of ϵ_D and ϵ_B, with $V=1000$ in the static universe scenario.

dominated, it is doubtful as to whether this potentially interesting physical effect given by the equations has any discernible effect on structure formation scenarios in pure CDM models. A H +CDM model may give similar interesting results as discussed here. This however is a three-component problem beyond the scope of this paper, but may be considered a worthwhile topic of research for future work in this area.

C. Other qualitative behavior

We briefly consider some other features of the solutions, to help better understand the mathematical properties. The qualitative features we wish to explore are the same for both the λ_1 and λ_3 modes, so we will concentrate only on the λ_1 modes here. The eigenvalue λ_1 is plotted for different values of ϵ_B and ϵ_D in Fig. 2 and 3. An interesting feature of these figures is that there is a one-to-one correspondence between each of the four plots in one figure to a particular plot in the other figure, yet each plot corresponds to different physical parameters in each figure. This property highlights the symmetry of the eigenvalues. If the original analytic expression (3.16) for λ_1 is examined, it is clear that the expression retains an identical form if ϵ_D and ϵ_B are interchanged together with V and $1/V$. Real values of K_{MC} have also been marked in. They indicate when the critical scale k_C is physically relevant. Related to this property is the fact that in Fig. 2 all plots for $\epsilon_D \lesssim 0.1$ and $\epsilon_B \gtrsim 0.9$ are almost identical to the values of $\epsilon_D=0.1$ and $\epsilon_B=0.9$. Analogously, in Fig. 3 the same may be said for all plots $\epsilon_D \gtrsim 0.9$ and $\epsilon_B \lesssim 0.1$.

We now turn to study the behavior of β_1 and β_3, which give an indication of the relative proportion of baryonic and dark matter in each of the modes [see, for example, the x_2 and x_4 components of the eigenvectors in Eq. (3.9)]. In dimensionless variables, β_1 and β_3 may be written as

$$\beta_{1,3}=\frac{1}{2}\left\{1-\frac{\epsilon_B}{\epsilon_D}+\left(\frac{\epsilon_B}{\epsilon_D}-\frac{\epsilon_B}{\epsilon_D V^2}+V^2-1\right)K_M^2 \pm\left[\frac{1}{\epsilon_D^2}+2\left(1-\frac{\epsilon_B}{\epsilon_D}\right)\left(\frac{\epsilon_B}{\epsilon_D}-\frac{\epsilon_B}{\epsilon_D V^2}+V^2-1\right)K_M^2\right.\right.$$
$$\left.\left.+\left(\frac{\epsilon_B}{\epsilon_D}-\frac{\epsilon_B}{\epsilon_D V^2}+V^2-1\right)^2 K_M^4\right]^{1/2}\right\}. \tag{3.32}$$

It is obvious from inspection that for all wave numbers β_1 and β_3 are real valued and $\beta_1>0$,

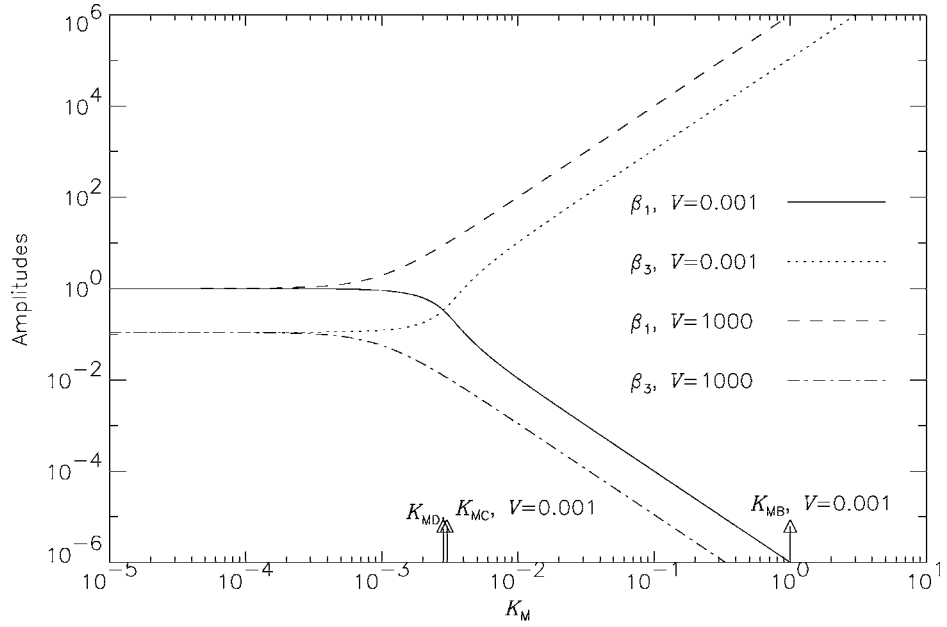

FIG. 4. The eigenvector amplitude functions β_1 and β_3 for HDM and CDM in the static universe scenario.

$\beta_3 < 0$. The almost symmetrical nature of the quantities are well illustrated in Fig. 4 for the opposing cases of H/CDM. Of interest here again is the scale K_{MC}, around which all the β_i undergo an abrupt change. Figure 4 shows that either β_1 or β_3 will dominate very rapidly for increasing wave number, depending on the value of V. Stated more specifically, for the HDM scenario ($V \ll 1$), baryons will dominate the λ_1 modes and dark matter will dominate the λ_3 modes, and vice versa for the CDM scenario ($V \gg 1$). We refrain from examining the asymptotics of β_1 and β_3 now, and leave that task to when we derive analogous expressions in the expanding universe scenario. The asymptotics will confirm the present qualitative discussion.

D. Initial conditions and amplitudes

Having completed a study of the behavior of the general solutions, we now turn to consider the effect of initial conditions. The study of the amplitudes of the various modes was studied with particular interest in Ref. 7, where the presence of a resonance was discovered at the scale k_C. We extend that work here to consider the amplitude functions at a wider range of scales, and for CDM as well. This will be of relevance when the expanding universe scenario is analyzed in the next section, where the $K_M > 1$ range of scales needs to be considered. It is also of course of relevance from the fact that the Universe is believed to be CDM dominated.

The amplitudes are k-dependent functions, which also depend on the various constants in the problem. Consider the initial conditions at some time t_0 given by the constants $x_i(t_0) = x_{i0}$. Here and henceforth, any variable subscripted with a 0 (possibly together with other subscripts) denotes that quantity evaluated at $t = t_0$. As a reasonable simplifying assumption, the perturbations are assumed to start from rest, so that $x_{10} = x_{30} = 0$. The matter density perturbations may then be written in the form

$$\delta_D(\tau) = x_{20}[\zeta_1(e^{\lambda_1 \tau} + e^{-\lambda_1 \tau}) + \zeta_2 \cos(i\lambda_3 \tau)], \tag{3.33}$$

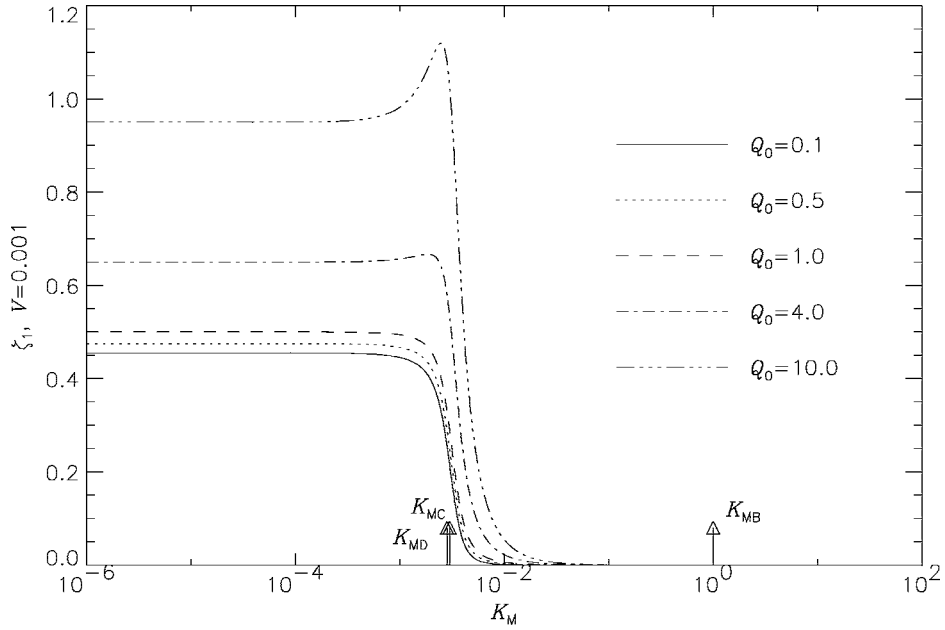

FIG. 5. The k-dependent amplitudes of the λ_1 dark matter modes in a HDM universe for a range of initial conditions $Q_0=x_{40}/x_{20}$.

$$\delta_B(\tau) = x_{40}[\zeta_3(e^{\lambda_1\tau} + e^{-\lambda_1\tau}) + \zeta_4 \cos(i\lambda_3\tau)], \tag{3.34}$$

where the time origin has been shifted by the definition $\tau=t-t_0$. The amplitude functions ζ_i are constructed out of the mode eigenvector functions β_i, as well as the ratio of initial densities $Q_0 = x_{40}/x_{20}$. They are

$$\zeta_1 = \frac{\beta_1}{2}\frac{1-Q_0\beta_3}{\beta_1-\beta_3}, \quad \zeta_2 = \beta_3\frac{Q_0\beta_1-1}{\beta_1-\beta_3}, \tag{3.35}$$

$$\zeta_3 = \frac{1}{2}\frac{Q_0^{-1}-\beta_3}{\beta_1-\beta_3}, \quad \zeta_4 = \frac{\beta_1-Q_0^{-1}}{\beta_1-\beta_3}. \tag{3.36}$$

Of particular interest is the fact that some of the ζ_i display a resonance around the scale k_C. This scale has of course previously shown its significance in the behavior of the eigenvalues and the β_i. The fact that k_C defines the scale at which the collapse times of the components taken separately coincide indicates that a resonance may well be expected to occur at this scale. The behavior of the various amplitudes over a wide range of scales, and in both the HDM and CDM scenarios are illustrated in Figs. 5–12. The distinguishing feature of all the plots of HDM amplitudes is the rapid change of the functions around the scale k_C.

The analytic properties of ζ_1 and in particular ζ_3 are discussed at some length in Ref. 7. Under some restrictive conditions (only HDM and certain initial values of Q_0) it was shown that ζ_1 would not obtain a resonance, whereas ζ_3 would for

$$Q_0 < \frac{1}{2}\left(\frac{v_D^2}{v_B^2} - \frac{W_D}{W_B}\frac{v_B^2}{v_D^2}\right). \tag{3.37}$$

In contrast no resonances are observed in the CDM scenario, but the amplitudes still undergo a rapid change around the scale K_{MB}. Both $K_M=K_{MB}$ and $K_M=K_{MD}$ are always less than $K_M=1$, so that no significant behavior occurs in the long wavelength limit, a fact of some importance in later work.

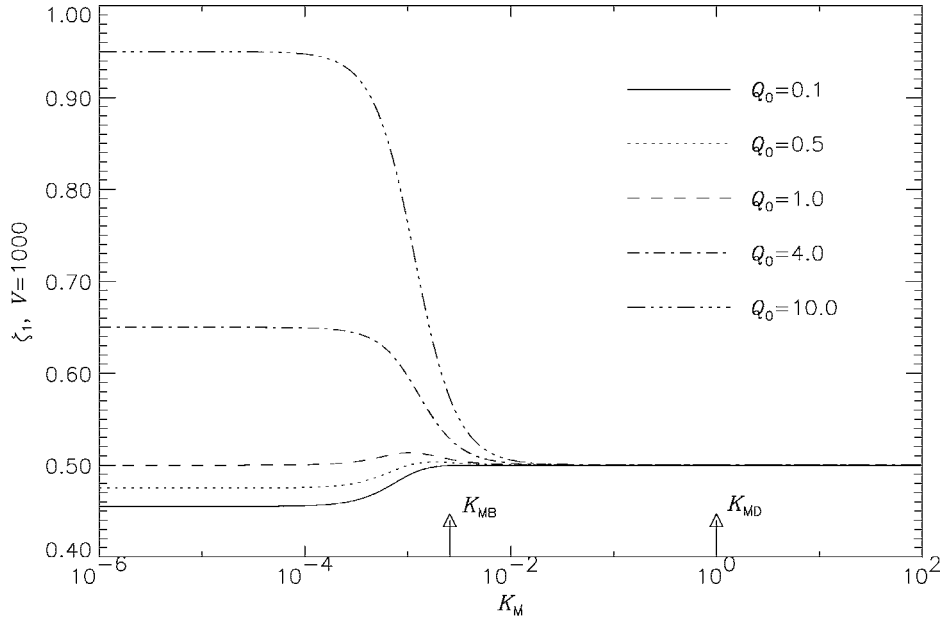

FIG. 6. The k-dependent amplitudes of the λ_1 dark matter modes in a CDM universe for a range of initial conditions $Q_0=x_{40}/x_{20}$.

IV. THE SHORT WAVELENGTH APPROXIMATION IN THE EXPANDING UNIVERSE

A. Matrix formulation

We are now prepared to tackle the most general equations formulated for the current problem, given by (2.6) and (2.7). The solution to this system of equations cannot be classified by known analytic functions, so approximation schemes need to be implemented. This paper investigates a short wavelength approximation, which would be expected to probe the acoustic regime of the

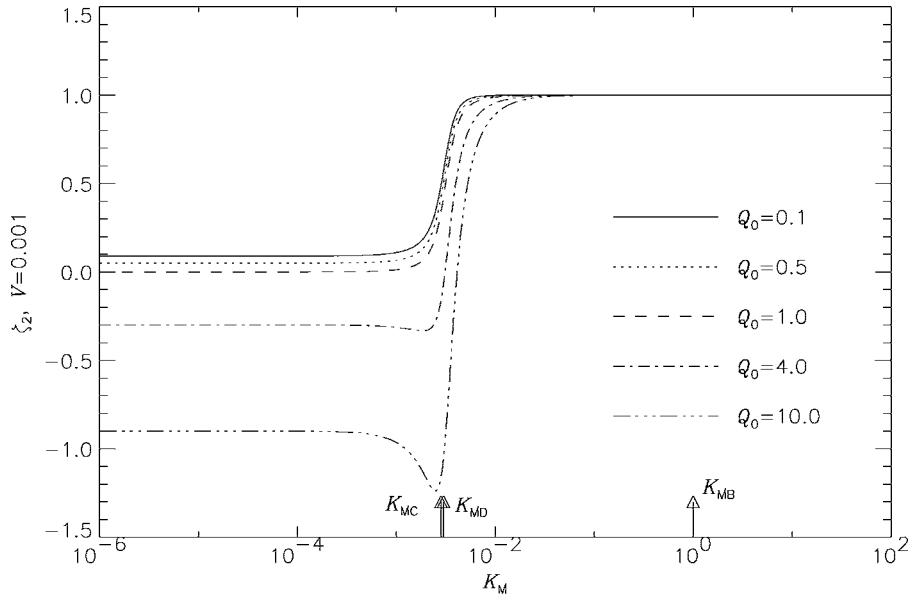

FIG. 7. The k-dependent amplitudes of the λ_3 dark matter modes in a HDM universe for a range of initial conditions $Q_0=x_{40}/x_{20}$.

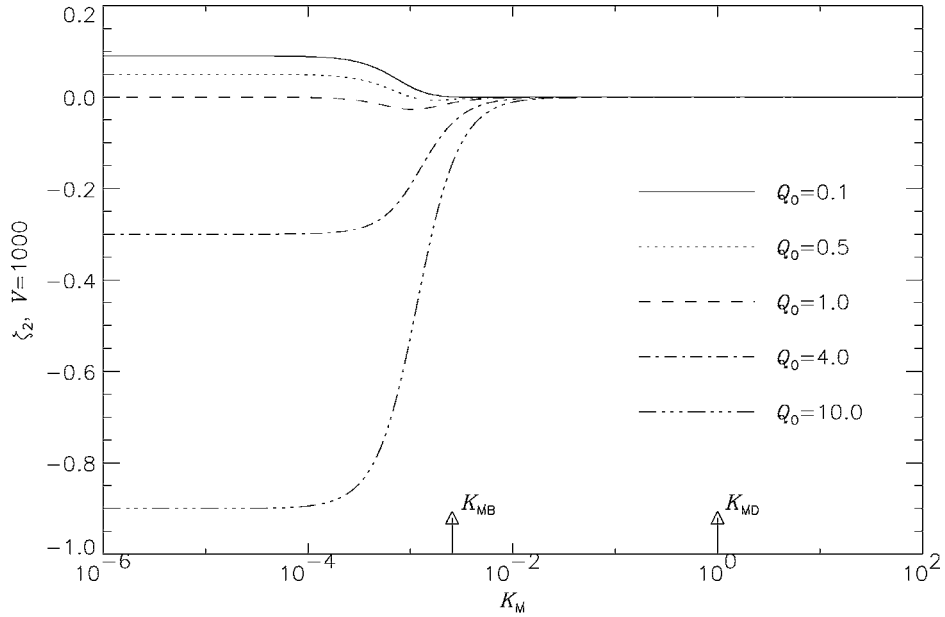

FIG. 8. The k-dependent amplitudes of the λ_3 dark matter modes in a CDM universe for a range of initial conditions $Q_0=x_{40}/x_{20}$.

modes. A WKB-type method may be employed for this. This is interesting, because through the derivation the explicit physical approximations required and type of solutions obtainable will naturally arise as a consequence of the method. A WKB method for coupled systems of equations in a cosmological plasma setting was expounded in Ref. 14. We will further develop that method here for the current system, which is more complicated than anything considered previously.

To begin with, the equations must be reduced to a first order system. Thus as in the static case (3.3), we define

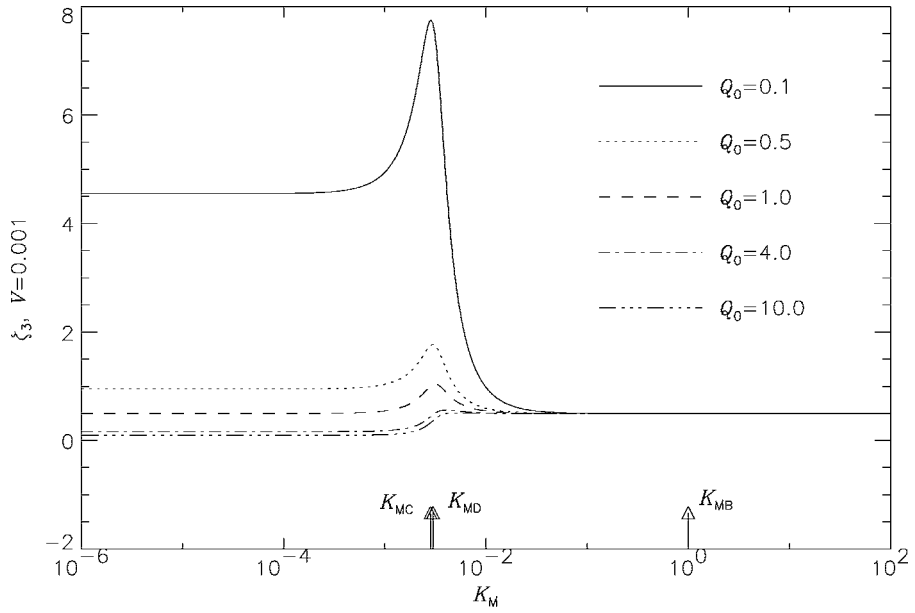

FIG. 9. The k-dependent amplitudes of the λ_1 baryonic modes in a HDM universe for a range of initial conditions $Q_0=x_{40}/x_{20}$.

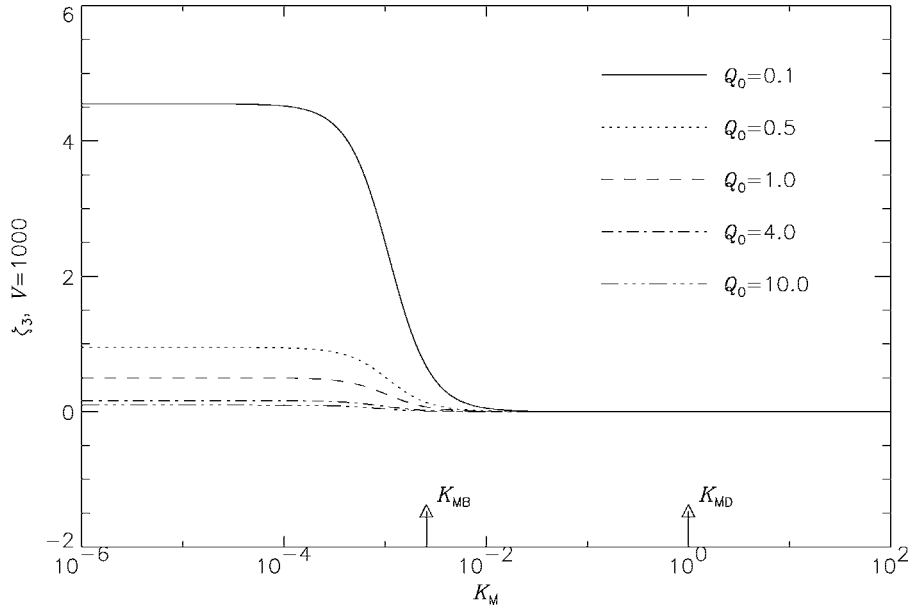

FIG. 10. The k-dependent amplitudes of the λ_1 baryonic modes in a CDM universe for a range of initial conditions $Q_0 = x_{40}/x_{20}$.

$$\mathbf{x} = (x_1, x_2, x_3, x_4)^T \equiv (\delta_D', \delta_D, \delta_B', \delta_B)^T. \tag{4.1}$$

The system may be written in matrix form

$$\mathbf{x}' = \mathbf{T}\mathbf{x}, \tag{4.2}$$

with the definition

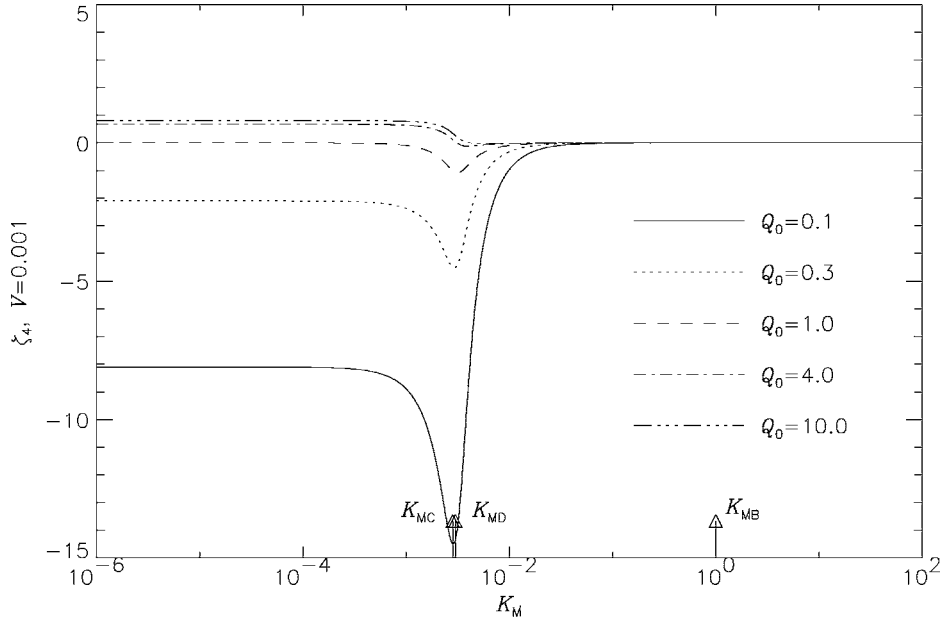

FIG. 11. The k-dependent amplitudes of the λ_3 baryonic modes in a HDM universe for a range of initial conditions $Q_0 = x_{40}/x_{20}$.

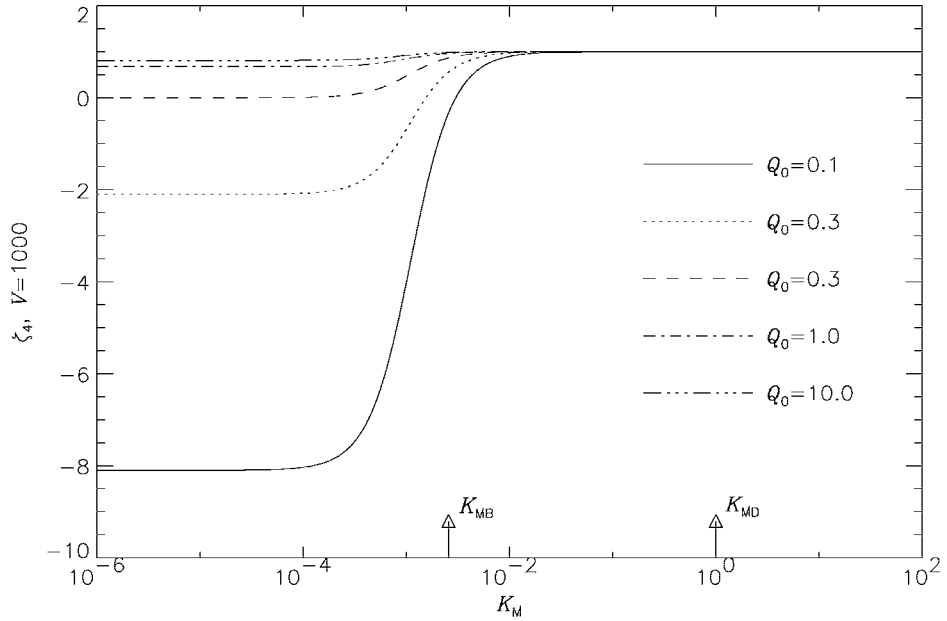

FIG. 12. The k-dependent amplitudes of the λ_3 baryonic modes in a CDM universe for a range of initial conditions $Q_0 = x_{40}/x_{20}$.

$$\mathbf{T} = \begin{bmatrix} 0 & -6K_D^2 + \dfrac{6\epsilon_D}{\chi^2} & 0 & \dfrac{6\epsilon_B}{\chi^2} \\ 1 & 0 & 0 & 0 \\ 0 & \dfrac{6\epsilon_D}{\chi^2} & 0 & -6K_B^2 + \dfrac{6\epsilon_B}{\chi^2} \\ 0 & 0 & 1 & 0 \end{bmatrix}. \tag{4.3}$$

The idea behind the method is to attempt to remove the coupling between equations as much as possible, hopefully relegating it to some lower order, which can then be dealt with by a suitable approximation. To this end we define the matrices **A** and **f** such that

$$\mathbf{x} = \mathbf{A}\mathbf{f}. \tag{4.4}$$

A is chosen appropriately in order to diagonalize **T**. Then (4.2) may formally be written as

$$\mathbf{f}' = \mathbf{A}^{-1}\mathbf{T}\mathbf{A}\mathbf{f} - \mathbf{A}^{-1}\mathbf{A}'\mathbf{f}, \quad \det \mathbf{A} \neq 0. \tag{4.5}$$

To diagonalize **T**, we must first find its eigenvalues and eigenvectors. The structure of **T** is very similar to its static space–time counterpart, so the four eigenvalues also have the form given by (3.6). In the present case however, f and g are functions of χ and $\bar{k}$, defined as

$$f(\chi,\bar{k}) = \frac{6}{\chi^2} - 6(K_B^2 + K_D^2), \tag{4.6}$$

$$g(\chi,\bar{k}) = \frac{36}{\chi^2}(K_D^2\epsilon_B + K_B^2\epsilon_D) - 36K_B^2K_D^2. \tag{4.7}$$

Note that unlike the static space–time results, where f contained an expression of the form $W_B + W_D$, no analogous expression exists here due to the physical constraint of the Einstein-deSitter universe, $\epsilon_B + \epsilon_D = 1$. The eigenvectors $\boldsymbol{\xi}_i$ corresponding the eigenvalues λ_i are also identical in

structure to their static space–time counterparts (3.9). In this case the functions β_i are given by

$$\beta_1 = \beta_2 = \frac{1}{2}\frac{\chi^2}{6\epsilon_D}\left(h + \sqrt{h^2 + 4\frac{36\epsilon_B\epsilon_D}{\chi^4}}\right), \tag{4.8}$$

$$\beta_3 = \beta_4 = \frac{1}{2}\frac{\chi^2}{6\epsilon_D}\left(h - \sqrt{h^2 + 4\frac{36\epsilon_B\epsilon_D}{\chi^4}}\right), \tag{4.9}$$

with

$$h(\chi,\bar{k}) = \frac{6}{\chi^2}(\epsilon_D - \epsilon_B) + 6(K_B^2 - K_D^2). \tag{4.10}$$

It is worthwhile to point out here for the sake of calculations that

$$S \equiv \sqrt{h^2 + 4\frac{36\epsilon_B\epsilon_D}{\chi^4}} = \sqrt{f^2 + 4g}. \tag{4.11}$$

The eigenvectors may be used to form the diagonalizing matrix

$$\mathbf{A} = (\boldsymbol{\xi}_1, \boldsymbol{\xi}_2, \boldsymbol{\xi}_3, \boldsymbol{\xi}_4), \tag{4.12}$$

whose inverse exists. This enables the formal equation (4.5) to be written explicitly

$$\begin{bmatrix} f_1' \\ f_2' \\ f_3' \\ f_4' \end{bmatrix} \begin{bmatrix} \lambda_1 & 0 & 0 & 0 \\ 0 & -\lambda_1 & 0 & 0 \\ 0 & 0 & \lambda_3 & 0 \\ 0 & 0 & 0 & -\lambda_3 \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \\ f_3 \\ f_4 \end{bmatrix} - \begin{bmatrix} \epsilon_1 & \epsilon_2 & \epsilon_3 & \epsilon_4 \\ \epsilon_2 & \epsilon_1 & \epsilon_4 & \epsilon_3 \\ \epsilon_5 & \epsilon_6 & \epsilon_7 & \epsilon_8 \\ \epsilon_6 & \epsilon_5 & \epsilon_8 & \epsilon_7 \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \\ f_3 \\ f_4 \end{bmatrix}. \tag{4.13}$$

We have introduced eight new parameters here, all of which can be written in terms of λ_1, λ_3, β_1, and β_3. In what follows, let us use the shorthand

$$\beta_{13} \equiv \beta_1 - \beta_3 = \frac{\chi^2}{6\epsilon_D}S = \frac{1}{\epsilon_D}\sqrt{1 + 2\chi^2(\epsilon_D - \epsilon_B)(K_B^2 - K_D^2) + \chi^4(K_B^2 - K_D^2)^2}. \tag{4.14}$$

The parameters are defined by

$$\epsilon_1 = \frac{\beta_1'}{\beta_{13}} + \frac{\lambda_1'}{2\lambda_1}, \tag{4.15}$$

$$\epsilon_2 = -\frac{\lambda_1'}{2\lambda_1}, \tag{4.16}$$

$$\epsilon_3 = \frac{\beta_3'}{2\beta_{13}}\left(1 + \frac{\lambda_3}{\lambda_1}\right), \tag{4.17}$$

$$\epsilon_4 = \frac{\beta_3'}{2\beta_{13}}\left(1 - \frac{\lambda_3}{\lambda_1}\right), \tag{4.18}$$

$$\epsilon_5 = -\frac{\beta_1'}{2\beta_{13}}\left(1 + \frac{\lambda_1}{\lambda_3}\right), \tag{4.19}$$

$$\epsilon_6 = -\frac{\beta_1'}{2\beta_{13}}\left(1 - \frac{\lambda_1}{\lambda_3}\right), \tag{4.20}$$

$$\epsilon_7 = -\frac{\beta_3'}{\beta_{13}} + \frac{\lambda_3'}{2\lambda_3}, \tag{4.21}$$

$$\epsilon_8 = -\frac{\lambda_3'}{2\lambda_3}. \tag{4.22}$$

Let us consider the meaning of (4.13) more closely. Using the terminology of WKB theory, the first matrix on the right-hand side will give us the leading order "control factor"—the fastest varying part of the solution, typically an exponential factor. This factor may indicate rapid oscillations for imaginary λ_i, or rapid growth or decay for real λ_i. The second matrix contains a collection of parameters, which determine further slowly varying behavior. For this to be true, the condition $\epsilon_i \ll \lambda_j$, $\forall i, j$ must hold. It is then possible to show that the four equations all decouple to leading order, and WKB solutions may be written down. The proof of this is quite involved, but it is worthwhile to pursue. A bonus of the proof is that through a careful consideration of the approximations required, some instructive physics is learned along the way.

B. The WKB approximation criteria

In an attempt to decouple the equations, we need to consider more carefully the various criteria which constitute the condition $\epsilon_i \ll \lambda_j$, $\forall i, j$, which allow the WKB method to work. To begin with, we will assume the λ_i's are of about the same order. Although their magnitude varies greatly over various scales, an examination of Fig. 1 shows this assumption to hold fairly well in general. When we find, through the reasoning which follows, the precise scales of interest for a WKB approximation, we will see that this assumption is justified *post facto*. The essence of the WKB approximation is to assume

$$\left|\frac{\lambda_i'}{\lambda_i}\right| \ll |\lambda_i|, \tag{4.23}$$

that is, the eigenvalues vary slowly over the time scale which they define. In the current context, this corresponds physically to many oscillations in a universe expansion time for the acoustic region of k-space, or a far shorter collapse time than a universe expansion time for perturbations in the region where modes are Jeans unstable. In what follows, exactly which type of modes (acoustic or collapse) do fall into the category defined by (4.23) will become apparent.

From the results of static space–time, we suspect that a Jeans instability must exist, and in such a region, it should follow that one of the λ_i be zero, rendering (4.23) false. Consequently, we need to find the critical points of the λ_i, dependent on the wave number k. A consideration of the equation $\lambda_1^2(\chi)=0$ gives a solution for a "critical time" $\chi=\chi_c$,

$$\chi_c^2 \equiv \frac{\epsilon_B}{K_B^2} + \frac{\epsilon_D}{K_D^2}. \tag{4.24}$$

It turns out that λ_3 however has no such time.

Let us examine the behavior of $\lambda_1(\chi)$ around $\chi \sim \chi_c$ more closely. We set $\chi^2=\chi_c^2(1+\epsilon)$ for a small parameter ϵ, and expand λ_1 in powers of ϵ. It turns out that

$$f + \sqrt{f^2 + 4g} = -12\epsilon K_B^2 K_D^2 \frac{K_D^2\epsilon_B + K_B^2\epsilon_D}{K_D^4\epsilon_B + K_B^4\epsilon_D} + O(\epsilon^2), \tag{4.25}$$

so that $\lambda_1 \propto \sqrt{-\epsilon}$ for $\chi \sim \chi_c$. This dependence of λ_1 on ϵ gives a clear picture of how λ_1 changes around the critical point. For $\chi > \chi_c$, $\epsilon > 0$ and λ_1 is imaginary. This corresponds to acoustic

oscillations, in the stable part of k-space. For $\chi<\chi_c$, $\epsilon<0$ and λ_1 is real. This corresponds to an unstable part of k-space, so that χ_c is an indication of the transition through the Jeans instability. The time parameters may be defined so that initial time corresponds to $a_0=1$. This is because the explicit magnitude of a_0 is not determined by cosmology. By the definition $\chi=a^{-1/2}$, it is clear that χ begins at 1 and decreases with increasing time. This gives us two ways of looking at the Jeans instability. One way is to consider the instability at a particular instant in time. For a particular time χ, a subset of modes will be unstable for values of k for which $\chi_c(k)>\chi$ (we stress that χ_c is a function of k). We may then consider what occurs as these modes evolve through time from this particular instant. The critical time χ_c is fixed for any one mode, so that the modes which were originally acoustic will become unstable as $\chi\to\chi_c^+$. Consequently more and more modes pass through the instability as the Universe evolves. The physical wave number k is of course dependent on time, thus the dependence of the instability on a time χ_c shows the inextricable link between the wave number and time.

We wish to relate these concepts back to the result discussed for static space–time, and so must ask how the critical time χ_c is related to the critical wave number k_M of the mixture of components. In static space–time we defined

$$K_M^2=\frac{k^2}{W_B/v_B^2+W_D/v_D^2} \tag{4.26}$$

as the dimensionless parameter, indicating the relation of a mode to the instability at $K_M=1$. To place this quantity in an expanding universe context, the substitutions

$$W_B\to\frac{6\epsilon_B}{\chi^2},\quad v_B^2k^2\to 6K_B^2,$$

$$W_D\to\frac{6\epsilon_D}{\chi^2},\quad v_D^2k^2\to 6K_D^2$$

are required. This gives K_M the following form:

$$K_M^2=\frac{\chi^2}{\epsilon_B/K_B^2+\epsilon_D/K_D^2}=\frac{\chi^2}{\chi_c^2}. \tag{4.27}$$

It is explicitly seen here that the scale of instability changes with time, as was explained above. The analogy with the one-component case discussed in Ref. 11 may be made here, where solutions were found in terms of the one-component Jeans wave number $K_Ja^{-1/2}$. With $\chi=a^{-1/2}$, we see that the quantity χ_c^{-1} in the two-component case is the exact analogy of K_J for the one-component case.

Now that we have determined that λ_1 approaches zero in a particular region, it becomes clear that the WKB approximation will not be valid in this region $\chi\sim\chi_c$, from the condition (4.23). Let us examine λ_1'/λ_1^2 in more detail, to determine its behavior over the whole of k-space. An explicit evaluation using the definitions of f and g from (4.6) and (4.7) gives

$$\frac{\lambda_1'}{\lambda_1^2}=-\frac{3}{(\lambda_1\chi)^3}(1+F), \tag{4.28}$$

where

$$F=\frac{1+(\epsilon_D-\epsilon_B)(K_B^2-K_D^2)\chi^2}{\epsilon_D\beta_{13}}. \tag{4.29}$$

In the ensuing discussion we use the quantity $\bar{k}$ to describe the comoving wave-number dependence of the quantities involved. If we denote the numerator of (4.29) by N, it is simple to see that $N^2<\epsilon_D^2\beta_{13}^2$ for all $\bar{k}$ [see (4.14)], so that $|F|\leq 1$. We also consider the limits of F for large and

small $\bar{k}$. For $\bar{k}\to 0$, $F\to 1$ and for $\bar{k}\to\infty$, $F\to\epsilon_D-\epsilon_B$ if $K_B>K_D$, and $F\to\epsilon_B-\epsilon_D$ if $K_D>K_B$. This means that asymptotically F is independent of $\bar{k}$, and since $|F|\leq 1$ for all $\bar{k}$, λ_1'/λ_1^2 does not change sign. It now becomes clear that the magnitude of λ_1'/λ_1^2 is mainly dependent on the factor $(\lambda_1\chi)^{-3}$. We already know that as $\bar{k}\to\bar{k}_M$, $\lambda_1\to 0$ so that in this region it has been confirmed that $\lambda_1'/\lambda_1^2\gg 1$. Suitable regions where WKB might be valid must be sought far from the neighborhood $\bar{k}\sim\bar{k}_M$. The dependence of λ_1'/λ_1^2 on $\lambda_1\chi$ leads us to suggest the WKB criterion in the amended form $\lambda_1\chi\gg 1$. This makes good physical sense, because if λ_1 is considered a frequency/inverse of a dynamical collapse time, the WKB criteria requires that a large number of oscillations/significant change in δ_i occurs during an expansion time.

A similar analysis needs to be performed for λ_3. We find

$$\frac{\lambda_3'}{\lambda_3^2}=-\frac{3}{(\lambda_3\chi)^3}(1-F). \tag{4.30}$$

This too demands the criterion $\lambda_3\chi\gg 1$. To find how λ_3 behaves, consider first the $\bar{k}\to 0$ limit. This limit gives $\lambda_3\to 0$, so this region of k-space is clearly inappropriate for WKB analysis. We note, however, that since $\lambda_3\neq 0$ at $\bar{k}=\bar{k}_M$, this region should be checked more closely. After a careful examination of λ_3,

$$\lambda_3\chi=\sqrt{3}\sqrt{1-(K_B^2+K_D^2)\chi^2-\epsilon_D\beta_{13}}, \tag{4.31}$$

it becomes apparent that $\lambda_3\chi\gg 1$ only when both $K_B\gg 1$ and $K_D\gg 1$. This corresponds to the region $\bar{k}\gg\bar{k}_M$, and so the region $\bar{k}\sim\bar{k}_M$ must be excluded from consideration as well. For λ_3, we are only left with the region $\bar{k}\gg\bar{k}_M$ as fulfilling the WKB criterion. For completeness, the same reasoning should also be applied to λ_1. The $\bar{k}\to 0$ limit applied to λ_1 gives

$$\frac{3}{(\lambda_1\chi)^3}\to\frac{1}{2\sqrt{6}}, \tag{4.32}$$

which is not much less than 1, as is required to define it as a region amenable to WKB analysis. Thus the $\bar{k}\ll\bar{k}_M$ region is inappropriate for λ_1 as well.

In conclusion, $\bar{k}\gg\bar{k}_M$ is the *only* region for which the WKB approximation holds. We may summarize the methods available to analyze the two-component problem in various regions of k-space by the following classification.

$\bar{k}\gg\bar{k}_M$: The WKB method will give acoustic oscillations for all modes, with the rapidly varying part of the solution taking the form $\exp(\pm i|\lambda_i|\chi)$.

$\bar{k}\ll\bar{k}_M$: A Frobenius expansion (small parameter expansion) of the solutions needs to be developed. Some growing and decaying modes following a power law behavior may be expected for solutions corresponding to λ_1, while some low frequency acoustic oscillations may be expected for solutions corresponding to λ_3.

$\bar{k}\sim\bar{k}_M$: This region of parameter space is not accessible to analytic solution. Some numerics will be required to investigate this interesting region.

We will continue with the WKB analysis in this paper, and show how the equations (4.13) decouple. An investigation of the other regions of k-space are taken up in Ref. 11.

We still need to check how β_1 and β_3 vary, to ensure that all the ϵ_i are small. In particular, we need to consider whether relations of the form

$$\frac{\beta_i'}{\beta_{13}}\ll\lambda_j,\quad i,j=1,3 \tag{4.33}$$

are true. The analysis proceeds very similarly to that described above for the derivatives of λ_1 and λ_3, and a full description will not be given here. As a brief example, it can be shown that

$$\frac{\beta_1'}{\beta_{13}\lambda_1} \sim \frac{1}{\lambda_1 \chi} \tag{4.34}$$

for $\bar{k} \gg \bar{k}_M$, once again fulfilling the criterion $\lambda_1 \chi \gg 1$. Other cases follow similarly. Given that the relations (4.33) do hold, we can finally make the important statement that $\epsilon_i \ll \lambda_j$, $\forall i, j$ if $\bar{k} \gg \bar{k}_M$.

C. The solutions

Now that we have worked out the region of k-space in which the WKB method produces valid leading order solutions, we proceed to derive these solutions by decoupling the equations. To illustrate how the equations (4.13) decouple, we begin with an example. Taking the top row of the matrix equation, the following suggestive equation for f_1 may be written

$$f_1' - (\lambda_1 - \epsilon_1) f_1 = -\epsilon_2 f_2 - \epsilon_3 f_3 - \epsilon_4 f_4. \tag{4.35}$$

This may be treated as a first order inhomogeneous ordinary differential equation (ODE) for f_1. The homogeneous portion has a simple solution

$$f_1 \sim c_1 \exp\left[\int_{\chi_0}^{\chi} (\lambda_1 - \epsilon_1) \mathrm{d}\chi \right], \tag{4.36}$$

with a constant of integration c_1. This may be considered to be a first approximation to the solution, though it remains to be shown that it is the full leading order result. To evaluate the inhomogeneous portion of the solution of (4.35), we require the first approximations for the other f_i as well. A corresponding analysis to that illustrated for f_1 yields

$$f_2 \sim c_2 \exp\left[-\int_{\chi_0}^{\chi} (\lambda_1 + \epsilon_1) \mathrm{d}\chi \right], \tag{4.37}$$

$$f_3 \sim c_3 \exp\left[\int_{\chi_0}^{\chi} (\lambda_3 - \epsilon_7) \mathrm{d}\chi \right], \tag{4.38}$$

$$f_4 \sim c_4 \exp\left[-\int_{\chi_0}^{\chi} (\lambda_3 + \epsilon_7) \mathrm{d}\chi \right]. \tag{4.39}$$

When these are substituted into (4.35), we achieve the rather complicated result

$$\begin{aligned} f_1 \sim \exp\left[\int_{\chi_0}^{\chi} (\lambda_1 - \epsilon_1) \mathrm{d}\chi \right] \Bigg\{ & c_{11} + c_{12} \int_{\chi_0}^{\chi} \mathrm{d}\chi \epsilon_2 \exp\left[-2 \int_{\chi_0}^{\chi} \lambda_1 \mathrm{d}\chi \right] \\ & + c_{13} \int_{\chi_0}^{\chi} \mathrm{d}\chi\, \epsilon_3 \exp\left[\int_{\chi_0}^{\chi} (-\lambda_1 + \lambda_3 + \epsilon_1 - \epsilon_7) \mathrm{d}\chi \right] \\ & + c_{14} \int_{\chi_0}^{\chi} \mathrm{d}\chi\, \epsilon_4 \exp\left[\int_{\chi_0}^{\chi} (-\lambda_1 - \lambda_3 + \epsilon_1 - \epsilon_7) \mathrm{d}\chi \right] \Bigg\}. \end{aligned} \tag{4.40}$$

There are a number of integrals present here which need to be estimated to determine how the approximation is to proceed.

As an example of a generic type of integral to evaluate, consider

$$I = \int_{\chi_0}^{\chi} \mathrm{d}\chi\, \epsilon_2 \exp\left[-2\int_{\chi_0}^{\chi} \lambda_1\, \mathrm{d}\chi \right]. \tag{4.41}$$

Since the region of interest is $\bar{k} \gg \bar{k}_M$, λ_1 is imaginary, and consequently the definition of the real function $\psi(\chi) \equiv -i\lambda(\chi)$ is useful. We integrate I by parts to obtain

$$I = \left. \frac{\lambda_1'}{4\lambda_1^2} \exp\left[-2i\int_{\chi_0}^{\chi} \psi(\chi)\mathrm{d}\chi \right] \right|_{\chi_0}^{\chi} - \frac{1}{4}\int_{\chi_0}^{\chi} \mathrm{d}\chi \left(\frac{d}{\mathrm{d}\chi}\frac{\lambda_1'}{\lambda_1^2} \right) \exp\left[-2i\int_{\chi_0}^{\chi} \psi(\chi)\mathrm{d}\chi \right]. \tag{4.42}$$

It is our aim to show that all corrections to the leading order results (4.36)–(4.39) are of $O(\epsilon)$, where ϵ generically denotes any of the small quantities ϵ_i, $i=1,2,\ldots,8$. It is already obvious that the first term in (4.42) is of $O(\epsilon)$, because it consists of a λ_1'/λ_1^2 term multiplied by a phase factor. We may constrain the second term by

$$\left| \int_{\chi_0}^{\chi} \mathrm{d}\chi \left(\frac{d}{\mathrm{d}\chi}\frac{\lambda_1'}{\lambda_1^2} \right) \exp\left[-2i\int_{\chi_0}^{\chi} \psi(\chi)\mathrm{d}\chi \right] \right| \leq \int_{\chi_0}^{\chi} \mathrm{d}\chi \left| \left(\frac{d}{d\chi}\frac{\lambda_1'}{\lambda_1^2} \right) \right| \left| \left. \frac{\lambda_1'}{\lambda_1^2} \right|_{\chi_0}^{\chi} \right|. \tag{4.43}$$

This shows that indeed $I \sim O(\epsilon)$.

The same type of analysis may be performed for the other more complicated integrals. In general, integration by parts is involved, and the terms may be shown to be bounded by some expressions of the form λ_i'/λ_j^2, or $\beta_i'/(\beta_{13}\lambda_j)$. It is found that in the WKB approximation, (4.36) is the correct leading order term, and the integrals arising from considering the inhomogeneous portion of the ODE (4.35) are all of $O(\epsilon)$ below this leading order term. Similar correction integrals to those found in (4.40) may be written down for f_2, f_3, and f_4, all of which take the same generic form as those evaluated in the f_1 case. A lengthy analysis will show that all the corrections are of $O(\epsilon)$, so we have shown that to leading order we may effectively neglect the off-diagonal ϵ_i in (4.13). In conclusion, the full leading order WKB solution to $\mathbf{f}$ is given by (4.36)–(4.39).

These solutions contain two important terms in the integrals. The λ_1 and λ_3 terms represent the rapidly varying oscillatory portion of the solutions, i.e., the control factor mentioned earlier. To obtain the true frequencies, these integrals need to be converted to integrals over t. We expect the ϵ_1 and ϵ_7 terms to represent some slowly varying time-dependent amplitude. To reveal the time-dependent structure of the solutions more explicitly, the integrals of ϵ_1 and ϵ_7 need to be evaluated. This is facilitated greatly by the relation

$$\beta_1\beta_3 = -\frac{\epsilon_B}{\epsilon_D}. \tag{4.44}$$

For ϵ_1 consider the integral

$$\int_{\chi_0}^{\chi} \frac{\beta_1'}{\beta_1 - \beta_3}\mathrm{d}\chi = \int_{\chi_0}^{\chi} \frac{\beta_1\beta_1'}{\beta_1^2 + \epsilon_B/\epsilon_D}\mathrm{d}\chi = \left. \frac{1}{2}\log\left(\beta_1^2 + \frac{\epsilon_B}{\epsilon_D} \right) \right|_{\chi_0}^{\chi}. \tag{4.45}$$

Using (4.44) once more we find

$$\int_{\chi_0}^{\chi} \frac{\beta_1'}{\beta_1 - \beta_3} d\chi = \frac{1}{2}\log\left[\frac{\beta_1(\chi)}{\beta_1(\chi) - \beta_3(\chi)} \right] - \frac{1}{2}\log\left[\frac{\beta_1(\chi_0)}{\beta_1(\chi_0) - \beta_3(\chi_0)} \right]. \tag{4.46}$$

For notational expedience, we define the tilde quantities

$$\tilde{\beta}_i(\chi) = \frac{\beta_i(\chi)}{\beta_i(\chi_0)}, \quad i = 1,3, \tag{4.47}$$

$$\tilde{\beta}_{13}(\chi) = \frac{\beta_1(\chi) - \beta_3(\chi)}{\beta_1(\chi_0) - \beta_3(\chi_0)}, \tag{4.48}$$

$$\tilde{\lambda}_i(\chi) = \frac{\lambda_i(\chi)}{\lambda_i(\chi_0)}, \quad i = 1,3, \tag{4.49}$$

with the obvious property that $\tilde{f}(\chi_0)=1$, for any quantity $f(\chi)$. This allows us to write the integrals as follows:

$$-\int_{\chi_0}^{\chi} \epsilon_1 \, \mathrm{d}\chi = \frac{1}{2} \log\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_1 \tilde{\lambda}_1} \right), \tag{4.50}$$

$$-\int_{\chi_0}^{\chi} \epsilon_7 \, \mathrm{d}\chi = \frac{1}{2} \log\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_3 \tilde{\lambda}_3} \right). \tag{4.51}$$

Here the integral involving ϵ_7 was calculated using identical techniques as just illustrated for ϵ_1.

At last the final form of leading order solution for **f** may be written down, with the explicit time-dependent amplitude and rapidly varying oscillatory part,

$$f_{1,2} \sim c_{1,2} \left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_1 \tilde{\lambda}_1} \right)^{1/2} \exp\left(\pm \int_{\chi_0}^{\chi} \lambda_1 \, \mathrm{d}\chi \right), \tag{4.52}$$

$$f_{3,4} \sim c_{3,4} \left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_3 \tilde{\lambda}_3} \right)^{1/2} \exp\left(\pm \int_{\chi_0}^{\chi} \lambda_3 \, \mathrm{d}\chi \right). \tag{4.53}$$

We are now in a position to recover the original physical state vector **x** by multiplying these auxiliary functions by the matrix **A**, as given in the original definition (4.4). The matrix **A** contains λ's and β's, which are *not* tilde quantities. The full general solution to (2.6) and (2.7) is finally given by

$$\begin{bmatrix} \delta_D' \\ \delta_D \\ \delta_B' \\ \delta_B \end{bmatrix} \sim c_1 \left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_1 \tilde{\lambda}_1} \right)^{1/2} \boldsymbol{\xi}_1 \exp\left(i \int_{\chi_0}^{\chi} |\lambda_1| \mathrm{d}\chi \right) + c_2 \left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_1 \tilde{\lambda}_1} \right)^{1/2} \boldsymbol{\xi}_2 \exp\left(-i \int_{\chi_0}^{\chi} |\lambda_1| \mathrm{d}\chi \right)$$
$$+ c_3 \left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_3 \tilde{\lambda}_3} \right)^{1/2} \boldsymbol{\xi}_3 \exp\left(i \int_{\chi_0}^{\chi} |\lambda_3| \mathrm{d}\chi \right) + c_4 \left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_3 \tilde{\lambda}_3} \right)^{1/2} \boldsymbol{\xi}_4 \exp\left(-i \int_{\chi_0}^{\chi} |\lambda_3| \mathrm{d}\chi \right). \tag{4.54}$$

Here the $\boldsymbol{\xi}_i$ are the eigenvectors defined by (3.9). In summary, this leading order solution represents acoustic oscillations in the short wavelength limit, defined as

$$k^2 \gg k_M^2 = \frac{4\pi G \rho_B}{v_B^2} + \frac{4\pi G \rho_D}{v_D^2}, \tag{4.55}$$

which is a time-dependent quantity. Equivalently, we may view the limit as given by

$$\frac{\epsilon_B}{K_B^2} + \frac{\epsilon_D}{K_D^2} \gg \chi^2. \tag{4.56}$$

A Jeans instability will not be evident for the solutions in this region of k-space, but the time dependence will mean that the period of oscillation becomes longer until a point is reached at which the WKB approximation is no longer accurate, and the solutions as displayed are not realistic representations of the underlying physics. Then different approximations need to be considered. The methods involved are discussed in detail in Ref. 11.

D. Relative amplitudes of the solutions

The slowly varying time-dependent amplitudes of the solutions (4.54) show how either dark matter or baryons dominate various modes, depending on whether HDM or CDM is being considered. This feature was noticed in the static case, and we now demonstrate it more fully through asymptotic analysis in the expanding universe scenario. The information is contained in the eigenvectors $\boldsymbol{\xi}_i$, which give the relative amplitudes. It can be seen directly from (3.9) that

$$\frac{\delta_B}{\delta_D} \propto \frac{1}{\beta_1} = -\frac{\epsilon_D}{\epsilon_B}\beta_3 \tag{4.57}$$

for the λ_1 modes, and

$$\frac{\delta_B}{\delta_D} \propto \frac{1}{\beta_3} = -\frac{\epsilon_D}{\epsilon_B}\beta_1 \tag{4.58}$$

for the λ_3 modes. At first glance this may appear a little surprising, as there seems to be an asymmetry in the solutions. If the indices are interchanged $D \leftrightarrow B$, the amplitudes do not appear to be the same, yet all such an interchange is doing is swapping the order the equations are written down in.

As an illustration for the λ_1 modes

$$\begin{bmatrix} \delta_D \\ \delta_B \end{bmatrix} \propto \begin{bmatrix} \beta_1 \\ 1 \end{bmatrix}, \quad \text{with } \beta_1 = \frac{\chi^2}{12\epsilon_D}(h+S), \tag{4.59}$$

whereas after the interchange $D \leftrightarrow B$,

$$\begin{bmatrix} \delta_B \\ \delta_D \end{bmatrix} \propto \begin{bmatrix} \beta_1^* \\ 1 \end{bmatrix}, \quad \text{with } \beta_1^* = \frac{\chi^2}{12\epsilon_B}(-h+S). \tag{4.60}$$

The quantity β_1^* is defined as being the form of β_1 after the interchange has been made. The square root term S, defined in (4.11) is invariant under the interchange, whereas an examination of (4.10) shows that under the interchange $h \to -h$. It is however simple to show that $\beta_1\beta_1^* = 1$, which is to be expected from the symmetry of the differential equations. The same result holds for the λ_3 mode, where it can be shown that $\beta_3\beta_3^* = 1$ for the quantities

$$\beta_3 = \frac{\chi^2}{12\epsilon_D}(h-S), \quad \beta_3^* = \frac{\chi^2}{12\epsilon_B}(-h-S)\,. \tag{4.61}$$

We now examine the behavior of the amplitudes more carefully, to find the dominant components of matter. A useful large expansion parameter in the analysis will be the quantity $y \equiv |K_B^2 - K_D^2|\chi^2$. Let us also introduce the notation $\sigma = \text{sign}(K_B^2 - K_D^2) = \pm 1$, and expand the eigenvalues in y. For the λ_1 modes we may write

$$\beta_1 = \frac{y}{2\epsilon_D}\left[\sigma + \frac{\epsilon_D - \epsilon_B}{y} + \sqrt{1 + 2\sigma(\epsilon_D - \epsilon_B)y^{-1} + y^{-2}}\right], \tag{4.62}$$

from which the following results may be deduced:

$$\beta_1 = \begin{cases} \dfrac{y}{\epsilon_D}\left[1 + \dfrac{\epsilon_D - \epsilon_B}{y} + O(y^{-2})\right], & K_B > K_D, \quad (\sigma = 1), \\ \dfrac{1 - (\epsilon_D - \epsilon_B)^2}{4\epsilon_D y}\left[1 + \dfrac{\epsilon_D - \epsilon_B}{y} + O(y^{-2})\right], & K_D > K_B, \quad (\sigma = -1). \end{cases} \tag{4.63}$$

This indicates that for CDM ($K_B > K_D$)

$$\beta_1 \propto (K_B^2 - K_D^2)\chi^2,$$

and the dark matter oscillations are dominant in the λ_1 modes, although as time increases they become less so. On the other hand, for HDM ($K_D > K_B$)

$$\beta_1 \propto \frac{1}{(K_D^2 - K_B^2)\chi^2},$$

and the baryon oscillations dominate, and their dominance increases with time. The λ_3 modes display complementary behavior,

$$\beta_3 = \begin{cases} \dfrac{-1 + (\epsilon_D - \epsilon_B)^2}{4\epsilon_D y}\left[1 + \dfrac{\epsilon_B - \epsilon_D}{y} + O(y^{-2})\right], & K_B > K_D, \quad (\sigma = 1), \\ -\dfrac{y}{\epsilon_D}\left[1 - \dfrac{\epsilon_B - \epsilon_D}{y} + O(y^{-2})\right], & K_D > K_B, \quad (\sigma = -1). \end{cases} \tag{4.64}$$

In this case for CDM,

$$\beta_3 \propto -\frac{1}{(K_B^2 - K_D^2)\chi^2},$$

so that the baryon oscillations dominate, and the dominance increases with time, while for HDM,

$$\beta_3 \propto -(K_D^2 - K_B^2)\chi^2,$$

which shows that dark matter oscillations dominate, but the dominance decreases with time. In summary, in a CDM scenario ($K_D > K_B$) baryons dominate the λ_3 mode and dark matter dominates the λ_1 mode, whereas the situation is opposite for HDM.

The apparent asymmetry of these results with respect to interchange of subscripts $B \leftrightarrow D$ can be easily explained by taking into account the relations (4.59)–(4.61). It was shown that after an interchange $B \leftrightarrow D$, the β's are given by

$$\beta_1^* = -\beta_3 \quad \text{and} \quad \beta_3^* = -\beta_1. \tag{4.65}$$

This is the correct way to view the asymptotic forms for the β's after an interchange, rather than by a direct swapping of subscripts. By deriving the asymptotic results, information has been lost and direct swapping is no longer valid. As an example, for $K_B > K_D$,

$$\beta_1 \sim (K_B^2 - K_D^2)\chi^2 \rightarrow \beta_1^* = -\beta_3 \sim \frac{1}{(K_B^2 - K_D^2)\chi^2}, \tag{4.66}$$

and the expected result $\beta_1\beta_1^* = 1$ holds.

Now that we have gained some insight into the behavior of the modes in a generic sense, let us be a little more specific and investigate the full leading order solutions under some tighter physical constraints to see some more physical effects emerge.

E. Initial conditions and resonances

We attempt to reproduce the resonances described in the static space–time case by imposing some initial conditions on our solutions, and eliminating the arbitrary constants of integration c_i, $i=1,\ldots,4$, using a similar procedure to that employed previously. In the static space–time scenario we just stated the results, but here we explicitly go through the derivation. The general solution may be expediently written in the form

$$x_i(\chi)=\sum_{j=1}^{4} c_j v_{(j)i}(\chi)\exp\left(\int_{\chi_0}^{\chi}\lambda_j\,\mathrm{d}\chi\right). \tag{4.67}$$

The amplitudes are given by the vectors

$$\mathbf{v}_{(1),(2)}=\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_1\tilde{\lambda}_1}\right)^{1/2}\boldsymbol{\xi}_{1,2},\quad \mathbf{v}_{(3),(4)}=\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_3\tilde{\lambda}_3}\right)^{1/2}\boldsymbol{\xi}_{3,4}. \tag{4.68}$$

At $\chi=\chi_0$, $v_{(j)}(\chi_0)=\boldsymbol{\xi}_j(\chi_0)$, and an equation for the initial conditions x_{i0} is obtained,

$$x_{i0}=\sum_{j=1}^{4} c_j\xi_{(j)i}(\chi_0). \tag{4.69}$$

Note that henceforth any variable subscripted with a 0 (possibly together with other subscripts) denotes that quantity evaluated at $\chi=\chi_0$. As a reasonable simplifying assumption, we once again take $x_{10}=x_{30}=0$, i.e., the perturbations start from rest. This gives a simple algebraic system for the c_i, with the solution

$$\begin{bmatrix} c_1\\ c_2\\ c_3\\ c_4\end{bmatrix}=\frac{x_{20}}{2\beta_{130}}\begin{bmatrix} 1-Q_0\beta_{30}\\ 1-Q_0\beta_{30}\\ Q_0\beta_{10}-1\\ Q_0\beta_{10}-1\end{bmatrix}, \tag{4.70}$$

where the ratio of initial conditions $Q_0=x_{40}/x_{20}$ is used once more.

When the above expressions for the c_i are substituted back into the general solution (4.54), a simplified result follows:

$$\begin{bmatrix}\delta_D'\\ \delta_D\\ \delta_B'\\ \delta_B\end{bmatrix}\sim\frac{x_{20}}{\beta_{130}}(1-Q_0\beta_{30})\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_1\tilde{\lambda}_1}\right)^{1/2}\begin{bmatrix} i\beta_1\lambda_1\sin\\ \beta_1\cos\\ i\lambda_1\sin\\ \cos\end{bmatrix}\left(\int_{\chi_0}^{\chi}|\lambda_1|\mathrm{d}\chi\right)+\frac{x_{20}}{\beta_{130}}(Q_0\beta_{10}-1)$$
$$\times\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_3\tilde{\lambda}_3}\right)^{1/2}\begin{bmatrix} i\beta_3\lambda_3\sin\\ \beta_3\cos\\ i\lambda_3\sin\\ \cos\end{bmatrix}\left(\int_{\chi_0}^{\chi}|\lambda_3|\mathrm{d}\chi\right). \tag{4.71}$$

Let us concentrate in particular on the x_2 and x_4 components, which describe the actual matter content of the Universe, and may have some interesting implications for structure formation results. We may write the solutions in a form analogous to the static space–time results,

$$\delta_D(\chi) = x_{20}\left[\zeta_1 \cos\left(\int_{\chi_0}^{\chi} |\lambda_1| d\chi\right) + \zeta_2 \cos\left(\int_{\chi_0}^{\chi} |\lambda_3| d\chi\right)\right], \tag{4.72}$$

$$\delta_B(\chi) = x_{40}\left[\zeta_3 \cos\left(\int_{\chi_0}^{\chi} |\lambda_1| d\chi\right) + \zeta_4 \cos\left(\int_{\chi_0}^{\chi} |\lambda_3| d\chi\right)\right]. \tag{4.73}$$

The amplitudes are given by the expressions

$$\zeta_1 = \beta_1 \frac{1 - Q_0\beta_{30}}{\beta_{130}}\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_1\tilde{\lambda}_1}\right)^{1/2}, \tag{4.74}$$

$$\zeta_2 = \beta_3 \frac{Q_0\beta_{10} - 1}{\beta_{130}}\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_3\tilde{\lambda}_3}\right)^{1/2}, \tag{4.75}$$

$$\zeta_3 = \frac{Q_0^{-1} - \beta_{30}}{\beta_{130}}\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_1\tilde{\lambda}_1}\right)^{1/2}, \tag{4.76}$$

$$\zeta_4 = \frac{\beta_{10} - Q_0^{-1}}{\beta_{130}}\left(\frac{\tilde{\beta}_{13}}{\tilde{\beta}_3\tilde{\lambda}_3}\right)^{1/2}. \tag{4.77}$$

The immediate obvious differences for these amplitudes with the static space–time results are the following.

(1) Missing factors of $\frac{1}{2}$ for ζ_1 and ζ_3, because the solutions are now all of a cosine form, rather than real exponentials (which is due to the fact that we are considering the $\bar{k} \gg \bar{k}_M$ region).
(2) The amplitudes are all time varying.
(3) The amplitudes contain extra tilde factors which equal one at the initial time, but in general contain other time-dependent terms not present even as constant factors in the static space–time amplitudes.

For $\chi = \chi_0$ the amplitudes correspond exactly to those of the static space–time amplitudes, and Figs. 5–12 are accurate representations of the amplitudes over a wide range of k. As time increases, the amplitudes tend to grow, but retain the same qualitative shape with the most marked features still occurring around the scale $K_M = K_{MC}$. Since the WKB solutions are only valid for $k \gg k_M$, this interesting region of k-space does not apply, and the ζ_i as presently defined should not be extrapolated to have any meaning around $K_M = K_{MC}$. In the $K_M \gg 1$ region the ζ_i show no significant behavior, just tending to constant values close to zero or one. In particular no resonances are apparent. Thus the potentially interesting resonant features discovered by de Carvalho and Macedo[7] do not apply in the physically more realistic expanding universe scenario. Any significant effects would have to be sought from the small k solutions presented in Ref. 11.

In addition to these statements, it must be added that the λ_i eigenvalues characterizing the modes in the large k region do not have any physical significance in the small k region either. This was already apparent in the small k expansions for the one-component solutions discussed in Ref. 11. The characteristic Jeans dispersion relation

$$\omega = \sqrt{v_s^2 k^2 - 4\pi G\rho_0} \tag{4.78}$$

is not apparent in the small K_J expansions presented in Ref. 11, and likewise, the λ_i found in the present paper are not apparent in the general solutions given by Eqs. (5.3)–(5.10) of Ref. 11. With

these facts in mind, the discussion of the physical information we are able to extract from the WKB solutions at present is complete.

V. CONCLUSIONS AND FURTHER WORK

The structure and behavior of the eigenvalues and eigenvectors of two-component cosmological density perturbations have been studied in great detail in this paper. We have reviewed the previous work done in a static space–time background, and produced further results in this simple context. This has enabled the far more difficult expanding universe problem to be tackled.

The WKB method employed has produced the full leading order behavior of all the modes in the Einstein-deSitter expanding universe scenario. These solutions represent acoustic oscillations for wavelengths much smaller than the Jeans scale. The Jeans scale of the mixture has arisen in a natural way out of the analysis of the eigenvalues obtained through the WKB method, with some interesting interpretation. It is now a straightforward task to adapt the methods developed here to study a variety of further cosmological plasma modes. The ion-sound and two-component Langmuir oscillations would follow directly from the results presented here, and more complicated modes involving magnetic fields could also be obtained by similar procedures.

We have also obtained the time- and k-dependent amplitudes of the modes in a fairly general setting (the one restriction being initial perturbations beginning from rest). These results have shown that the amplitudes are very constant in the region of interest. The existence of resonances in the amplitudes found for static space–time results do not apply here, as all resonances occurred for wave numbers far smaller than k_M. Thus a resonant amplitude cannot be viewed as a mechanism for producing structures of a preferred scale in a two-component model. The eigenvalues derived in this paper also do not have any direct physical interpretation around the Jeans scale, or for small k expansions of the solutions of Eqs. (2.6) and (2.7). Thus the results obtained in this paper must be considered to be restricted to the parameter regions considered here.

It may be interesting to investigate different models such as a three-component HDM +CDM+baryon fluid, or models involving a cosmological constant (especially given the weight of current observations[15–17]). The analytics would become considerably more complicated, but some other interesting resonant scales may be found with a direct implication for structure formation.

(Received 12 December 2005; accepted 17 April 2006; published online 1 June 2006)

We study a pair of neutrally stable eigenvalues of zero energy in the linearized NLS equation. We prove that the pair of isolated eigenvalues, where each eigenvalue has geometric multiplicity one and algebraic multiplicity N, is associated with $2P$ negative eigenvalues of the energy operator, where $P=N/2$ if N is even and $P=(N-1)/2$ or $P=(N+1)/2$ if N is odd. When the potential of the linearized NLS problem is perturbed due to parameter continuations, we compute the exact number of unstable eigenvalues that bifurcate from the neutrally stable eigenvalues of zero energy. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2203233]

I. INTRODUCTION

Spectral stability of solitary waves is defined by the number of unstable eigenvalues in a linearized problem associated with the underlying nonlinear equation. Unstable eigenvalues for solitary waves of the nonlinear Schrödinger (NLS) equation have been recently studied within the inertia law,[1] the constrained variational problems and wave operators,[2] and the Grillakis projection method.[3]

The count of unstable eigenvalues is simplified in Refs. 1 and 2, with the technical assumption that the unstable and potentially unstable eigenvalues are structurally stable to parameter continuations. In particular, the count of eigenvalues is modified if the linearized problem admits an isolated eigenvalue of zero Krein signature (see Ref. 3 for definitions), which we refer to here as *an eigenvalue of zero energy*. The simplest instability bifurcation, called *the Hamiltonian-Hopf bifurcation*, occurs when the eigenvalue of zero Krein signature arises due to coalescence of two simple eigenvalues with positive and negative Krein signatures.[4,5]

In our present paper, we focus on a general Hamiltonian-Hopf bifurcation within the framework of a scalar NLS equation. We study properties of this general bifurcation and the number of unstable eigenvalues that are generated due to parameter continuations. Specifically, we use the notations from Ref. 2 and consider the linearized operator $\sigma_3\mathcal{H}$, where $\mathcal{H}$ is the energy operator,

$$\mathcal{H}=\begin{pmatrix} -\Delta+\omega+f(x) & g(x) \\ g(x) & -\Delta+\omega+f(x) \end{pmatrix}, \tag{1.1}$$

the standard Pauli matrices are used,

$$\sigma_1=\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_3=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{1.2}$$

$x\in\mathbb{R}^n$, $n\geq 1$, $\omega>0$, and $f,g:\mathbb{R}^n\to\mathbb{R}$ are exponentially decaying C^∞ functions. The spectral problem for the operator $\sigma_3\mathcal{H}$ is considered on $L^2(\mathbb{R}^n,\mathbb{C}^2)$:

a)Electronic mail: vvougalt@fields.utoronto.ca
b)Electronic mail: dmpeli@math.mcmaster.ca

$$\sigma_3 \mathcal{H} \boldsymbol{\psi} = z \boldsymbol{\psi}, \tag{1.3}$$

where $\boldsymbol{\psi}=(\psi_1,\psi_2)^T$. Eigenvalues z of the spectral problem (1.3) are called *unstable* if $\mathrm{Im}(z)>0$, *neutrally stable* if $\mathrm{Im}(z)=0$ and *stable* if $\mathrm{Im}(z)<0$ (see Ref. 2). The following notations are used for inner products: $\langle \mathbf{c},\mathbf{d}\rangle_{\mathbb{C}^N}$ for $\mathbf{c},\mathbf{d}\in\mathbb{C}^N$, $\langle \mathbf{f},\mathbf{g}\rangle$ for $\mathbf{f},\mathbf{g}\in L^2(\mathbb{R}^n,\mathbb{C}^2)$ and (f,g) for $f,g\in L^2(\mathbb{R}^n)$.

It is shown in the previous paper[2] that the spectrum of the linearized operator $\sigma_3\mathcal{H}$ is defined in part by the sign of the energy quadratic form in $H^1(\mathbb{R}^3,\mathbb{C}^2)$:

$$h = \langle \boldsymbol{\psi}, \mathcal{H}\boldsymbol{\psi}\rangle. \tag{1.4}$$

In particular, the number of unstable eigenvalues in the point spectrum of $\sigma_3\mathcal{H}$ in the upper half-plane is bounded by the number of negative eigenvalues of $\mathcal{H}$, while the energy quadratic form (1.4) is positive definite on the nonsingular part of the essential spectrum of $\sigma_3\mathcal{H}$. The singular part of the essential spectrum of $\sigma_3\mathcal{H}$ (which only includes the embedded eigenvalues but not the embedded resonances) is studied with the Fermi Golden rule, from which it follows that the embedded eigenvalue z of positive energy $h>0$ disappears under generic perturbation, while that of negative energy $h<0$ bifurcates into isolated complex eigenvalues of the point spectrum of $\sigma_3\mathcal{H}$.[2,5]

One of the technical assumptions in Ref. 2 postulates that the real eigenvalues z of the point spectrum of $\sigma_3\mathcal{H}$ have nonzero energy $h\neq 0$. In the present work we remove this assumption and study the case when there exists a pair of isolated eigenvalues $z=\pm z_0$, where $0<z_0<\omega$, which corresponds to the zero energy $h=0$. We show that a pair of isolated eigenvalues of zero energy has a higher algebraic multiplicity in the spectrum of $\sigma_3\mathcal{H}$. Our precise result is formulated as follows.

Theorem 1: *Let $z=\pm z_0$ be a pair of isolated eigenvalues of $\sigma_3\mathcal{H}$, where each eigenvalue has geometric multiplicity one and algebraic multiplicity N. Let $\mathcal{X}_g$ be a subspace spanned by a set of generalized eigenvectors $\{\boldsymbol{\psi}_j,\sigma_1\boldsymbol{\psi}_j\}_{j=0}^{N-1}$, such that $s_0=\frac{1}{2}\langle\sigma_3\boldsymbol{\psi}_{N-1},\boldsymbol{\psi}_0\rangle\neq 0$. Then,*

$$n(\mathcal{H})\big|_{\mathcal{X}_g} = 2P,$$

where $P=N/2$, when N is even, $P=(N-1)/2$, when N is odd, and $s_0>0$, and $P=(N+1)/2$, when N is odd, and $s_0<0$. Therefore, $n(\mathcal{H})\geq 2P$.

When the potentials of the linearized operator $\sigma_3\mathcal{H}$ are perturbed by a continuous deformation, we compute the exact number of unstable eigenvalues with $\mathrm{Im}(z)>0$ that bifurcate from the eigenvalue z_0 of zero energy $h=0$. In particular, we study the perturbed spectral problem:

$$\sigma_3(\mathcal{H}+\varepsilon\mathcal{V}_p(x))\boldsymbol{\psi} = z\boldsymbol{\psi}, \tag{1.5}$$

where the perturbation matrix $\mathcal{V}_p(x)$ is C^∞, real-valued and bounded, such that $\mathcal{V}_p\in L^\infty(\mathbb{R}^n)$. We assume that the perturbation matrix $\mathcal{V}_p$ is *generic* in the sense that $\langle\boldsymbol{\psi}_0,\mathcal{V}_p\boldsymbol{\psi}_0\rangle\neq 0$, where $\boldsymbol{\psi}_0$ is the eigenvector of $\sigma_3\mathcal{H}$ for the eigenvalue $z=z_0$. Our precise result is formulated as follows.

Theorem 2: *Let z_0 be an isolated eigenvalue of $\sigma_3\mathcal{H}$ with geometric multiplicity one and algebraic multiplicity N. Let $\boldsymbol{\psi}_0$ be the corresponding eigenvector of $\sigma_3\mathcal{H}$, such that $s_0=\frac{1}{2}\langle\sigma_3\boldsymbol{\psi}_{N-1},\boldsymbol{\psi}_0\rangle\neq 0$. Then, there exists a small $\varepsilon_0>0$, such that the problem (1.5) with $0<|\varepsilon|<\varepsilon_0$ has N simple eigenvalues near $z=z_0$, which are approximated to the leading order by roots of*

$$(z_k-z_0)^N = \frac{\varepsilon}{2s_0}\langle\boldsymbol{\psi}_0,\mathcal{V}_p\boldsymbol{\psi}_0\rangle + O(\varepsilon^{(N+1)/N}), \quad k=1,\ldots,N. \tag{1.6}$$

We note that results of Theorems 1 and 2 are no longer restricted to the case $n=3$, unlike the previous work.[2] Theorem 1 is proved in Sec. II, while Theorem 2 is proved in Sec. III.

A typical example of the spectral problem (1.3) with operators (1.1)–(1.2) arises in the linearization of the nonlinear Schrödinger (NLS) equation,

$$i\psi_t = -\Delta\psi + U(x)\psi + F(|\psi|^2)\psi, \tag{1.7}$$

where $F(0)=0$ and $U(x)$ decays to zero, at the solitary wave solution $\psi=\phi(x)e^{i\omega t}$, where $\phi(x)$ is a real-valued function and $\omega>0$ is a parameter. Linearization of the NLS equation (1.7) with the ansatz,

$$\psi = (\phi(x) + \varphi(x)e^{-izt} + \bar{\theta}(x)e^{i\bar{z}t})e^{i\omega t}, \tag{1.8}$$

leads to the spectral problem (1.3) with $\boldsymbol{\psi}=(\varphi,\theta)^T$, $f(x)=U(x)+F(\phi^2)+F'(\phi^2)\phi^2$, and $g(x)=F'(\phi^2)\phi^2$. When $F(\phi^2)$ is C^∞ and $U(x)$ and $\phi(x)$ are exponentially decaying C^∞ functions, then the assumptions on $f(x)$, $g(x)$ are satisfied.

The Hamiltonian-Hopf bifurcation is typical with $N=2$ when the real isolated eigenvalue $z=z_0$ has a geometric multiplicity *one* and an algebraic multiplicity *two*.[3,4] If (ω,ϕ) is a pair for the solitary wave solution that corresponds to the bifurcation case and $\varepsilon=\delta\omega$ is a variation of parameter ω while $\varepsilon\ \delta\phi$ is a variation of the solution $\phi(x)$ along the solution family, then the perturbation matrix $\mathcal{V}_p(x)$ takes the form:

$$\mathcal{V}_p = \begin{pmatrix} 1+\delta f(x) & \delta g(x) \\ \delta g(x) & 1+\delta f(x) \end{pmatrix},$$

where

$$\varepsilon\ \delta f(x) \equiv F((\phi+\varepsilon\delta\phi)^2) - F(\phi^2) + F'((\phi+\varepsilon\delta\phi)^2)(\phi+\varepsilon\delta\phi)^2 - F'(\phi^2)\phi^2,$$

$$\varepsilon\ \delta g(x) \equiv F'((\phi+\varepsilon\delta\phi)^2)(\phi+\varepsilon\delta\phi)^2 - F'(\phi^2)\phi^2,$$

are variations of the potentials $f(x)$ and $g(x)$ along the solution family. The particular perturbation matrix $\mathcal{V}_p(x)$ satisfies the assumption that $\mathcal{V}_p(x)$ is C^∞ bounded matrix-valued function. An analysis of a general Hamiltonian–Hopf bifurcation is described in Sec. IV.

II. PROPERTIES OF AN EIGENVALUE OF ZERO ENERGY

We rewrite the system (1.3) in new variables $\boldsymbol{\psi}=(u+w,u-w)^T$:

$$\sigma_1 \mathrm{H}\mathbf{u} = z\mathbf{u}, \tag{2.1}$$

where $\mathbf{u}=(u,w)^T$ and H is the new energy operator:

$$H = \begin{pmatrix} L_+ & 0 \\ 0 & L_- \end{pmatrix}, \tag{2.2}$$

with $L_\pm=-\Delta+\omega+f(x)\pm g(x)$. Let $n(H)$ denote the negative index of the energy operator H, which is the number of negative eigenvalues of H in $L^2(\mathbb{R}^n,\mathbb{C}^2)$ counting their multiplicity. Let $n(H)|_X$ be the negative index of H restricted to some subspace $X\subset L^2(\mathbb{R}^n,\mathbb{C}^2)$. We assume that there exists an isolated eigenvalue $0<z_0<\omega$ and eigenvector $\mathbf{u}_0=(u_0,w_0)^T$ of the spectral problem (2.1), such that

$$\sigma_1 \mathrm{H}\mathbf{u}_0 = z_0\mathbf{u}_0. \tag{2.3}$$

The adjoint problem has then the same eigenvalue z_0 with the eigenvector $\mathbf{u}_{0,\mathbf{a}}$, such that

$$\mathrm{H}\sigma_1\mathbf{u}_{0,a} = z_0\mathbf{u}_{0,a}, \quad \mathbf{u}_{0,a} = \sigma_1\mathbf{u}_0. \tag{2.4}$$

We assume that the eigenvalue z_0 has zero energy $h=\langle\mathbf{u}_0,H\mathbf{u}_0\rangle=0$, such that the algebraic multiplicity of the eigenvalue z_0 exceeds its geometric multiplicity. We consider the situation when the geometric multiplicity of the eigenvalue z_0 is one, while its algebraic multiplicity is N, such that $\ker(\sigma_1 H-z_0)=\{\mathbf{u}_0\}$ and $N_g(\sigma_1 H-z_0)=\{\mathbf{u}_0,\mathbf{u}_1,\ldots,\mathbf{u}_{N-1}\}$. The generalized eigenvectors $\mathbf{u}_j=(u_j,w_j)^T$, $1\le j\le N-1$ are defined from the Jordan chain equations:

$$\sigma_1 H \mathbf{u}_j = z_0 \mathbf{u}_j + \mathbf{u}_{j-1}. \tag{2.5}$$

The adjoint problem has $N-1$ generalized eigenvectors $\mathbf{u}_{j,a}=\sigma_1\mathbf{u}_j$, $1\leq j\leq N-1$ that solve the inhomogeneous equations:

$$H\sigma_1 \mathbf{u}_{j,a} = z_0 \mathbf{u}_{j,a} + \mathbf{u}_{j-1,a}. \tag{2.6}$$

If z_0 is an eigenvalue of $\sigma_1 H$, then $-z_0$ is also an eigenvalue of both $\sigma_1 H$ and its adjoint $H\sigma_1$, such that $\dim(N_g(\sigma_1 \mathrm{H}+z_0))=\dim(N_g(\mathrm{H}\sigma_1+z_0))=N$. Explicitly, we have

$$\sigma_1 H \mathbf{u}_0^- = -z_0 \mathbf{u}_0^-, \tag{2.7}$$

$$\sigma_1 H \mathbf{u}_j^- = -z_0 \mathbf{u}_j^- + \mathbf{u}_{j-1}^-, \tag{2.8}$$

where $\mathbf{u}_0^-=\sigma_3\mathbf{u}_0$ and $\mathbf{u}_j^-=(-1)^j\sigma_3\mathbf{u}_j$ and similarly

$$\mathrm{H}\sigma_1 \mathbf{u}_{0,a}^- = -z_0 \mathbf{u}_{0,a}^-, \tag{2.9}$$

$$\mathrm{H}\sigma_1 \mathbf{u}_{j,a}^- = -z_0 \mathbf{u}_{j,a}^- + \mathbf{u}_{j-1,a}^-, \tag{2.10}$$

where $\mathbf{u}_{0,a}^-=\sigma_1\mathbf{u}_0^-$ and $\mathbf{u}_{j,a}^-=\sigma_1\mathbf{u}_j^-$. Let $X_g=N_g(\sigma_1 H-z_0)\oplus N_g(\sigma_1 H+z_0)$ be the subspace spanned by the generalized eigenvectors $\{\mathbf{u}_j,\sigma_3\mathbf{u}_j\}_{j=0}^{N-1}$. Let L_+ and L_- be diagonal compositions of $(L_+,0)$ and $(0,L_-)$. The exact number of negative eigenvalues of H restricted to the subspace X_g is given by Theorem 1 in notations of the equivalent system (1.3). In order to prove Theorem 1, we establish some useful relations between eigenvectors of the generalized subspace X_g.

Lemma 2.1: Let $2N=\dim(X_g)$, *where* $2\leq N<\infty$. *Then, it is true that*

$$\langle \sigma_1\mathbf{u}_0, \mathbf{u}_j\rangle = 0, \quad 0\leq j\leq N-2, \quad \langle \sigma_1\mathbf{u}_0, \mathbf{u}_{N-1}\rangle \neq 0. \tag{2.11}$$

Proof: By the Fredholm Alternative Theorem, it follows from (2.4) and (2.5) that $\langle \mathbf{u}_{j-1},\mathbf{u}_{0,a}\rangle=0$, $1\leq j\leq N-1$ and $\langle \mathbf{u}_{N-1},\mathbf{u}_{0,a}\rangle\neq 0$. Since $\mathbf{u}_{0,a}=\sigma_1\mathbf{u}_0$, these conditions are equivalent to the statement (2.11). ■

Let U be an auxiliary matrix with the elements:

$$U_{i,j} = \langle \sigma_1\mathbf{u}_{i-1}, \mathbf{u}_{j-1}\rangle, \quad 1\leq i, j\leq N. \tag{2.12}$$

We study the structure of the matrix U.

Definition 2.2: *Suppose* M *is a square matrix of size* N. *The subset of its elements* $M_{i,j}$, $1\leq i,j\leq N$, *such that* $i+j=k+1$ *is said to be the* k*th antidiagonal of the matrix* M, *where* $1\leq k\leq 2N-1$. *The* k*th antidiagonal of* M *is said to be constant if all its elements are equal.*

Lemma 2.3: *Each* k*th antidiagonal of* U *is constant. There exists a basis* $\{\hat{\mathbf{u}}_j,\sigma_3\hat{\mathbf{u}}_j\}_{j=0}^{N-1}$ *in the subspace* X_g, *such that*

$$U = s_0 \begin{pmatrix} 0 & 0 & \dots & 0 & 1 \\ 0 & 0 & \dots & 1 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 0 & \dots & \dots & 0 \end{pmatrix}, \tag{2.13}$$

where $s_0=\langle \sigma_1\hat{\mathbf{u}}_{N-1},\hat{\mathbf{u}}_0\rangle$. *Moreover,*

$$\langle \sigma_1\sigma_3\hat{\mathbf{u}}_i, \hat{\mathbf{u}}_j\rangle = 0, \quad 0\leq i, j\leq N-1. \tag{2.14}$$

Proof: By Lemma 2.1, the first antidiagonal of U is zero. It follows from (2.5) and (2.6) that

$$\langle \mathbf{u}_{i-1,a}, \mathbf{u}_j \rangle = \langle \mathbf{u}_{i,a}, \mathbf{u}_{j-1} \rangle, \quad 1 \le i, j \le N-1. \tag{2.15}$$

Therefore, the relation $\langle \sigma_1 \mathbf{u}_i, \mathbf{u}_{j-1} \rangle = \langle \sigma_1 \mathbf{u}_{i-1}, \mathbf{u}_j \rangle$ holds for $2 \le i+j \le 2N-2$. Since $\langle \sigma_1 \mathbf{u}_0, \mathbf{u}_j \rangle = 0$ by Lemma 2.1 for any $0 \le j \le N-2$, then all antidiagonals of U are zero for $1 \le k \le N-1$, such that $\langle \sigma_1 \mathbf{u}_i, \mathbf{u}_j \rangle = 0$ for $0 \le i+j \le N-2$. We show that by a proper choice of the generalized eigenvectors all but the main antidiagonals of U are zero for $N \le k \le 2N-1$. We introduce a sequence of transformations for $1 \le j \le N-1$:

$$\hat{\mathbf{u}}_k = \mathbf{u}_k, \quad 0 \le k \le j-1,$$

$$\hat{\mathbf{u}}_k = \mathbf{u}_k - \alpha_j \mathbf{u}_{k-j}, \quad j \le k \le N-1, \tag{2.16}$$

where the constants α_j are chosen from the condition that

$$\langle \sigma_1 \hat{\mathbf{u}}_j, \hat{\mathbf{u}}_{N-1} \rangle = 0, \quad 1 \le j \le N-1. \tag{2.17}$$

It is clear from (2.5) that the modified generalized eigenvectors $\{\hat{\mathbf{u}}_k\}_{k=0}^{N-1}$ satisfy the same inhomogeneous problems for any $1 \le j \le N-1$. By using recurrently the relations (2.16), we find that

$$\langle \sigma_1 \hat{\mathbf{u}}_j, \hat{\mathbf{u}}_{N-1} \rangle = \langle \sigma_1 \mathbf{u}_j, \mathbf{u}_{N-1} \rangle - 2\alpha_j \langle \sigma_1 \mathbf{u}_0, \mathbf{u}_{N-1} \rangle,$$

such that

$$\alpha_j = \frac{\langle \sigma_1 \mathbf{u}_j, \mathbf{u}_{N-1} \rangle}{2\langle \sigma_1 \mathbf{u}_0, \mathbf{u}_{N-1} \rangle}.$$

Since all antidiagonals of U are constants, the previous orthogonalization implies that $\langle \sigma_1 \hat{\mathbf{u}}_i, \hat{\mathbf{u}}_j \rangle = 0$, $N \le i+j \le 2N-2$. Furthermore, we have the normalization $\langle \sigma_1 \hat{\mathbf{u}}_{N-1}, \hat{\mathbf{u}}_0 \rangle = s_0$ on the main antidiagonal. It follows from (2.5) and (2.10) that

$$2z_0 \langle \mathbf{u}_{i,a}^-, \mathbf{u}_j \rangle + \langle \mathbf{u}_{i,a}^-, \mathbf{u}_{j-1} \rangle - \langle \mathbf{u}_{i-1,a}^-, \mathbf{u}_j \rangle = 0, \quad 1 \le i, j \le N-1. \tag{2.18}$$

Using the relation (2.18), we prove (2.14) by induction. ■

Corollary 2.4: *There exists a basis of generalized eigenvectors* $\{\hat{\mathbf{u}}_j, \sigma_3 \hat{\mathbf{u}}_j\}_{j=0}^{N-1}$ *in the subspace* X_g, *such that it satisfies the skew-orthogonality relations*,

$$\langle \sigma_1 \hat{\mathbf{u}}_i, \hat{\mathbf{u}}_j \rangle = s_0 \delta_{i,N-1-j}, \quad 0 \le i, j \le N-1, \tag{2.19}$$

and any $\mathbf{f} \in L^2(\mathbb{R}^n, \mathbb{C}^2)$ *can be decomposed as follows:*

$$\mathbf{f} = \sum_{j=0}^{N-1} (c_j \hat{\mathbf{u}}_j + d_j \sigma_3 \hat{\mathbf{u}}_j) + \mathbf{f}_c, \tag{2.20}$$

where

$$c_j = \frac{1}{s_0} \langle \sigma_1 \hat{\mathbf{u}}_{N-1-j}, \mathbf{f} \rangle, \quad d_j = -\frac{1}{s_0} \langle \sigma_1 \sigma_3 \hat{\mathbf{u}}_{N-1-j}, \mathbf{f} \rangle, \quad 0 \le j \le N-1$$

and

$$\langle \sigma_1 \hat{\mathbf{u}}_j, \mathbf{f}_c \rangle = \langle \sigma_1 \sigma_3 \hat{\mathbf{u}}_j, \mathbf{f}_c \rangle = 0, \quad 0 \le j \le N-1.$$

Remark 2.5: Let P_g be the skew-orthogonal projection operator to the subspace X_g. We have $P_g^2 = P_g$ and $(I-P_g)^2 = I-P_g$ on $L^2(\mathbb{R}^n, \mathbb{C}^2)$. Operators P_g and $(I-P_g)$ are bounded, such that

$$\|P_g\| \leq \frac{2}{|s_0|} \sum_{k=0}^{N-1} \|\hat{\mathbf{u}}_{N-1-k}\|_{L^2} \|\hat{\mathbf{u}}_k\|_{L^2}, \quad \|I - P_g\| \leq 1 + \|P_g\|,$$

where the operator norm $\|\cdot\|_{L^2 \to L^2}$ is denoted as $\|\cdot\|$.

Remark 2.6: In what follows, the hats over the basis elements of the subspace X_g will be omitted for the simplicity of notations. Let $H|_{X_g} = P_g^* H P_g$ be the restriction of the energy operator to the generalized subspace X_g. The restriction of the energy operator is defined in terms of the matrices M_+ and M_-, where

$$(M_+)_{i,j} = (L_+ u_{i-1}, u_{j-1}), \quad 1 \leq i, j \leq N,$$

$$(M_-)_{i,j} = (L_- w_{i-1}, w_{j-1}), \quad 1 \leq i, j \leq N. \tag{2.21}$$

The structure of the matrices M_+ and M_- follows from that of the matrix U.

Lemma 2.7: *The matrices M_+ and M_- are equal and have the structure*:

$$M_+ = M_- = \frac{s_0}{2} \begin{pmatrix} 0 & 0 & \dots & 0 & z_0 \\ 0 & 0 & \dots & z_0 & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ z_0 & 1 & \dots & \dots & 0 \end{pmatrix}. \tag{2.22}$$

Proof: Using the definitions (2.12) and (2.21), the systems (2.3) and (2.5), and the identity (2.14), we derive the relations

$$2(M_+)_{1,j} = z_0 U_{j,1}, \quad 2(M_-)_{1,j} = z_0 U_{1,j}, \quad 1 \leq j \leq N,$$

and

$$2(M_+)_{i,j} = z_0 U_{j,i} + U_{j,i-1}, \quad 2(M_-)_{i,j} = z_0 U_{i,j} + U_{i-1,j}, \quad 2 \leq i \leq N, \quad 1 \leq j \leq N.$$

By Lemma 2.3, these formulas imply the representation (2.22). ■

Remark 2.8: The structure of matrices U and $M_\pm$ enables us to estimate the number of their positive and negative eigenvalues. Since $s_0 \neq 0$ and $z_0 \neq 0$, the main anti-diagonal of the matrices is nonzero, such that their determinant is nonzero and no zero eigenvalue exists. We denote the number of positive and negative eigenvalues of an abstract symmetric non-singular matrix M by $p(M)$ and $n(M)$ respectively, such that $p(M)+n(M)=N$.

Lemma 2.9: *Let M be a symmetric N-by-N matrix, such that each kth antidiagonal of M is zero for $1 \leq k \leq N-1$ and the Nth antidiagonal of M is $a \neq 0$. If N is even, then $n(M)=p(M)=N/2$. If N is odd, then $n(M)=(N-1)/2$ and $p(M)=(N+1)/2$ for $a>0$ and $n(M)=(N+1)/2$ and $p(M)=(N-1)/2$ for $a<0$.*

Proof: Let $\{\lambda_k\}_{k=0}^{N-1}$ be eigenvalues of M ordered by $\lambda_0 \leq \lambda_1 \leq \dots \leq \lambda_{N-1}$. It follows from the structure of M that $\det M = (-1)^{N(N-1)/2} a^N$. We introduce the auxiliary subspace $V_d \subset \mathbb{R}^N$ spanned by the unit vectors $\{\mathbf{e}_k\}_{k=1}^d$ in $\mathbb{R}^N$, where $d=N/2$ when N is even and $d=(N-1)/2$ when N is odd. Let P_d be the orthogonal projection from $\mathbb{R}^N$ onto V_d, such that P_d has the matrix elements:

$$(P_d)_{i,j} = \begin{cases} 1, & 1 \leq i = j \leq d, \\ 0, & d+1 \leq i = j \leq N, \\ 0, & i \neq j. \end{cases} \tag{2.23}$$

A trivial computation gives that the elements of $M|_{V_d}$ are

$$(P_d M P_d)_{i,j} = (P_d)_{i,i} M_{i,j} (P_d)_{j,j}, \quad 1 \leq i,j \leq N,$$

which are nonzero only if $i,j \leq d$ and $i+j \geq N+1$. However, the intersection of these two sets is empty due to the definition of d. Therefore, the matrix $P_d M P_d = 0$ and all d eigenvalues of $M|_{V_d}$ are

zero. By the Rayleigh-Ritz theorem (see Theorem XIII.3 in Ref. 6), d eigenvalues of M are nonpositive due to the upper bound by the eigenvalues of $M|_{V_d}$. Therefore, $n(M) \geq d$. The same argument for $-M$ shows that $p(M) \geq d$. This proves that $n(M)=p(M)=N/2$ if N is even. If N is odd, there are two possibilities: either $n(M)=(N-1)/2$ and $p(M)=(N+1)/2$ or $n(M)=(N+1)/2$ and $p(M)=(N-1)/2$. Since

$$\text{sign}(\det(M)) = (-1)^{N(N-1)/2}(\text{sign}(a))^N = (-1)^{n(M)},$$

we find that the first case occurs for $a>0$ and the second case occurs for $a<0$. ■

Proof of Theorem 1: We recall that $\mathrm{H}|_{X_g} = P_g^* H P_g$ denotes the restriction of the energy operator to the generalized subspace X_g. By Lemma 2.7, a trivial calculation shows that the quadratic form of $H|_{X_g}$ can be rewritten as

$$\left\langle H\big|_{X_g}\mathbf{u},\mathbf{u}\right\rangle = 2\langle M_+\mathbf{c},\mathbf{c}\rangle_{\mathbb{C}^N} + 2\langle M_+\mathbf{d},\mathbf{d}\rangle_{\mathbb{C}^N}, \tag{2.24}$$

where $\mathbf{c}=(c_0,c_1,\ldots,c_{N-1})^T \in \mathbb{C}^N$, $\mathbf{d}=(d_0,d_1,\ldots,d_{N-1})^T \in \mathbb{C}^N$, and the matrices $M_\pm$ are defined by (2.21). Let $\{\mathbf{v}_s\}_{s=1}^{n(M_+)}$ be an orthonormal set of eigenvectors corresponding to negative eigenvalues of the matrix M_+. Then we can construct a subspace of X_g, spanned by the vectors $\tilde{\mathbf{u}}_s = \Sigma_{k=0}^{N-1}(\mathbf{v}_s)_k \mathbf{u}_\mathbf{k}$ and $\sigma_3\tilde{\mathbf{u}}_s$ for $1 \leq s \leq n(M_+)$. It follows from (2.24) that the operator $H|_{X_g}$ is negative definite on this subspace, i.e., via the Rayleigh-Ritz theorem $n(H)|_{X_g} \geq 2n(M_+)$. Let $\mathcal{M}_+ = M_+ \otimes M_+$ be the block matrix on $\mathbb{C}^{2N}$. To obtain the inequality reverse to the one above we consider the orthonormal set of eigenvectors $\{\mathbf{w}_s\}_{s=1}^{n(H)|_{X_g}}$, which spans the negative subspace of $H|_{X_g}$. Applying the projection operator, we have $P_g\mathbf{w}_\mathbf{s} = \Sigma_{k=0}^{N-1}(\boldsymbol{\alpha}_s)_k\mathbf{u}_k + \Sigma_{k=0}^{N-1}(\boldsymbol{\beta}_s)_k\sigma_3\mathbf{u}_\mathbf{k}$. Therefore, there is a subspace of $\mathbb{C}^{2N}$ spanned by the vectors $(\boldsymbol{\alpha}_s,\boldsymbol{\beta}_s)^T$, $1 \leq s \leq n(H)|_{X_g}$. It follows from (2.24) that the matrix $\mathcal{M}_+$ is negative definite on this subspace, which yields $n(\mathcal{M}_+)=2n(M_+) \geq n(H)|_{X_g}$. We have $a=\frac{1}{2}z_0 s_0$ and $z_0>0$, such that it follows by Lemmas 2.7 and 2.9 that $n(H)|_{X_g}=2n(M_+)=2P$. By the Rayleigh–Ritz Theorem,[6] we then have $n(H) \geq n(H)|_{X_g}$. ■

III. SPLITTING OF AN EIGENVALUE OF ZERO ENERGY

When the perturbation is applied to the spectral problem (2.1), one can expect that the multiple isolated eigenvalue $z=z_0$ is destroyed and N simple eigenvalues bifurcate in the neighborhood of $z=z_0$. This splitting of the multiple eigenvalue $z=z_0$ may result in the instability bifurcations if $\text{Im}(z)>0$ for some of the simple eigenvalues. The location of N simple eigenvalues in the neighborhood of $z=z_0$ for small nonzero ε is given by Theorem 2 in notations of the perturbed spectral problem (1.5). For convenience, we rewrite (1.5) in the equivalent form

$$\sigma_1(H+\varepsilon V_p)\mathbf{u} = z\mathbf{u}, \tag{3.1}$$

where $V_p(x)$ is C^∞, real-valued, and a bounded perturbation matrix given by $V_p = U^{-1}\mathcal{V}_p U$, with

$$U = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = U^{-1}.$$

In order to prove Theorem 2, we use the resolvent $R(z)=(\sigma_1\mathrm{H}-z)^{-1}$ defined for the values of z away from the spectrum of $\sigma_1 H$. The perturbed problem (3.1) is rewritten in the resolvent form

$$(I+\varepsilon R(z)\sigma_1 V_p)\mathbf{u} = 0. \tag{3.2}$$

We shall consider the subspace $X_g^+ = N_g(\sigma_1\mathrm{H}-z_0)$ with the projection operator P_g^+ onto this subspace. In what follows, the superscript for the subspace X_g^+ and the projection operator P_g^+ will be omitted for the simplicity of notations. Our plan is to use the projection operator P_g and to reduce the perturbed problem (3.1) to the finite-dimensional equations on the subspace X_g, where a regular perturbation theory can be applied.[7] For this purpose, we study properties of the resolvent $R(z)$ and the related projection operator onto X_g.

Lemma 3.1: Let the subspace X_g be spanned by the set $\{\mathbf{u}_j\}_{j=0}^{N-1}$. Then,

$$R(z)\mathbf{u}_j = \sum_{k=0}^{j} \frac{(-1)}{(z-z_0)^{j-k+1}}\mathbf{u}_k, \tag{3.3}$$

for $z \neq z_0$ and $0 \leq j \leq N-1$.

Proof: The formula (3.3) with $j=0$ follows from the problem (2.3). We use the induction method and assume that the formula (3.3) holds for some $j=s$ for $0 \leq s \leq N-2$. It follows from (2.5) that

$$R(z)\mathbf{u}_{s+1} = \frac{1}{z-z_0}R(z)\mathbf{u}_s - \frac{1}{z-z_0}\mathbf{u}_{s+1},$$

such that

$$R(z)\mathbf{u}_{s+1} = \sum_{k=0}^{s+1} \frac{(-1)}{(z-z_0)^{s-k+2}}\mathbf{u}_k,$$

and the formula (3.3) remains true for $j=s+1$. ■

Corollary 3.2: Let z be not in the spectrum of $\sigma_1 H$. Then,

$$(I-P_g)R(z)P_g = 0, \quad P_g R(z)(I-P_g) = 0.$$

Proof: Let $\mathbf{f}$ be an arbitrary function in $L^2(\mathbb{R}^n, \mathbb{C}^2)$. By Lemma 3.1, we have $R(z)P_g\mathbf{f} \in X_g$ for $z \neq z_0$, and therefore $(I-P_g)R(z)P_g\mathbf{f}=0$. On the other hand, for any $k=0, \ldots, N-1$ we have

$$\langle R(z)(I-P_g)\mathbf{f}, \sigma_1\mathbf{u}_k\rangle = \langle (I-P_g)\mathbf{f}, (H\sigma_1 - \bar{z})^{-1}\sigma_1\mathbf{u}_k\rangle = \langle (I-P_g)\mathbf{f}, \sigma_1 R(\bar{z})\mathbf{u}_k\rangle = 0$$

such that $P_g R(z)(I-P_g)\mathbf{f}=0$. ■

Remark 3.3: Let $\bar{D}(z_0,\delta)=\{z \in \mathbb{C}: |z-z_0| \leq \delta\}$ be a closed disk that contains no eigenvalues of the operator $\sigma_1 H$ other than $z=z_0$. The resolvent $R(z)$ has the only singularity in $\bar{D}(z_0,\delta)$ at $z=z_0$.

Lemma 3.4: Let $T(z)=(I-P_g)R(z)(I-P_g)\sigma_1 V_p$. The operator $T(z)$ is uniformly bounded in $\bar{D}(z_0,r) \subseteq \bar{D}(z_0,\delta)$, such that

$$\|T(z)\| \leq C < \infty, \tag{3.4}$$

where $r>0$ and $C>0$.

Proof: The proof is a standard argument, which uses the analyticity of the resolvent outside the spectrum, the Corollary 3.3, the boundedness of the operator $I-P_g$, and the fact that $V_p \in L^\infty$. ■

Lemma 3.5: The problem (3.2) *projected onto the subspace X_g is equivalent to the problem:*

$$[I + \varepsilon R(z)P_g\sigma_1 V_p(I+S(\varepsilon,z))]P_g\mathbf{u} = 0, \tag{3.5}$$

where the operator $S(\varepsilon,z)$ is analytic in ε and $\|S(\varepsilon,z)\| \leq 2C|\varepsilon|$, while C is defined in (3.4), *$z \in \bar{D}(z_0,r)$, and $\varepsilon \neq 0$ is small, such that $|\varepsilon| \leq 1/2C$.*

Proof: Applying P_g and $(I-P_g)$ to the problem (3.2), we obtain

$$P_g\mathbf{u} + \varepsilon P_g R(z)\sigma_1 V_p P_g\mathbf{u} + \varepsilon P_g R(z)\sigma_1 V_p(I-P_g)\mathbf{u} = 0$$

and

$$[I + \varepsilon(I-P_g)R(z)\sigma_1 V_p](I-P_g)\mathbf{u} = -\varepsilon(I-P_g)R(z)\sigma_1 V_p P_g\mathbf{u}.$$

By Corollary 3.2, we have

$$[I+\varepsilon P_g R(z) P_g \sigma_1 V_p] P_g \mathbf{u} + \varepsilon P_g R(z) P_g \sigma_1 V_p (I-P_g)\mathbf{u} = 0 \tag{3.6}$$

and

$$[I+\varepsilon T(z)](I-P_g)\mathbf{u} = -\varepsilon T(z) P_g \mathbf{u}. \tag{3.7}$$

By Lemma 3.1, we have $P_g R(z) P_g = R(z) P_g$ for $z \neq z_0$, such that we need to derive the equation expressing $(I-P_g)\mathbf{u}$ via $P_g\mathbf{u}$. It follows from (3.7) that

$$(I-P_g)\mathbf{u} = [(I+\varepsilon T(z))^{-1} - I] P_g \mathbf{u}, \tag{3.8}$$

such that the equation (3.6) yields

$$[I+\varepsilon R(z) P_g \sigma_1 V_p [I+\varepsilon T(z)]^{-1}] P_g \mathbf{u} = 0.$$

The operator $[I+\varepsilon T(z)]^{-1}$ can be written as $I+S(\varepsilon,z)$, where

$$S(\varepsilon,z) = \sum_{k=1}^{\infty} [-\varepsilon T(z)]^k. \tag{3.9}$$

By Lemma 3.4 and a comparison with the geometric series, the series (3.9) converges absolutely in the $\|.\|$ norm for $z \in \bar{D}(z_0,r)$. When $|\varepsilon| \leq 1/2C$, we have $\|S(\varepsilon,z)\| \leq 2C|\varepsilon|$. ■

Remark 3.6: By Lemma 3.5, the finite-rank operator on the left-hand side of the projection equations (3.5) is analytic in ε for small ε. The determinant of the left-hand side is the Weinstein–Aronszajn determinant, properties of which and its relation to the spectrum of the perturbed operator are rigorously derived in Ref. 7, pp. 244–250. We truncate the projection equations (3.5) by linear terms in ε and obtain the finite rank operator $W(\varepsilon,z) = I + \varepsilon R(z) P_g \sigma_1 V_p$ on the subspace X_g. The matrix elements of $W(\varepsilon,z)$ are expressed in terms of the elements $\{\mathbf{u}_j\}_{j=0}^{N-1}$ of the subspace X_g.

Lemma 3.7: For all $i,j=1,\ldots,N$, we have

$$W_{i,j}(\varepsilon,z) = \delta_{i,j} - \frac{\varepsilon}{s_0} \sum_{s=i-1}^{N-1} \frac{\langle \mathbf{u}_{N-1-s}, V_p \mathbf{u}_{j-1} \rangle}{(z-z_0)^{s-i+2}}. \tag{3.10}$$

Proof: Due to the orthogonality relations (2.19), the matrix elements of the finite rank operator W are equal to

$$W_{i,j}(\varepsilon,z) = \frac{1}{s_0} \langle \sigma_1 \mathbf{u}_{N-i}, W \mathbf{u}_{j-1} \rangle, \quad 1 \leq i,j \leq N. \tag{3.11}$$

Corollary 2.4 and Lemma 3.1 yield

$$\varepsilon R(z) P_g \sigma_1 V_p \mathbf{u}_j = -\frac{\varepsilon}{s_0} \sum_{s=0}^{N-1} \sum_{q=0}^{s} \frac{\langle \mathbf{u}_{N-1-s}, V_p \mathbf{u}_j \rangle}{(z-z_0)^{s-q+1}} \mathbf{u}_q.$$

Substituting this relation into the representation (3.11) and using the orthogonality conditions (2.19) we derive the identity (3.10). ■

Proof of Theorem 2: According to Ref. 7, the Weinstein-Aronszajn determinant is a meromorphic function, which has the pole of the Nth order at $z=z_0$. The eigenvalues of the perturbed problem (3.1) are given by the zeros $z=z_k$ of the Weinstein–Aronszajn determinant. We define the operator $F(\varepsilon,z) = (z-z_0)W(\varepsilon,z)$, such that $\det F(\varepsilon,z)$ is a polynomial in $z-z_0$ and ε. By Lemma 3.7, the matrix elements of $F(\varepsilon,z)$ are equal to

$$F_{i,j}(\varepsilon,z)=(z-z_0)\,\delta_{i,j}-\frac{\varepsilon}{s_0}\sum_{s=i-1}^{N-1}\frac{\langle \mathbf{u}_{N-1-s},V_p\mathbf{u}_{j-1}\rangle}{(z-z_0)^{s-i+1}},\quad i,j=1,\ldots,N.$$

Since $\det F(\varepsilon,z)$ is a polynomial in ε, we have the expansion:

$$\det F(\varepsilon,z)=\det F(0,z)+\varepsilon\frac{\partial}{\partial\varepsilon}\det F(0,z)+O(\varepsilon^2,z-z_0),\tag{3.12}$$

where $O(\varepsilon^2,z-z_0)$ is a polynomial in ε and $z-z_0$. The expansion (3.12) allows us to obtain the estimate on the zeros $z=z_k$ of the Weinstein–Aronszajn determinant. We find that

$$\det F(0,z)=(z-z_0)^N$$

and

$$\frac{\partial}{\partial\varepsilon}\det F(0,z)=\sum_{i=1}^{N}\det D^i(z),$$

where

$$D^i_{q,j}(z)=\begin{cases}(z-z_0)\,\delta_{q,j}, & q\neq i,\\ D^i_{i,j}(z), & q=i,\end{cases}$$

such that

$$D^i_{i,j}(z)=-\frac{1}{s_0}\sum_{s=i-1}^{N-1}\frac{\langle \mathbf{u}_{N-1-s},V_p\mathbf{u}_{j-1}\rangle}{(z-z_0)^{s-i+1}},$$

or explicitly

$$D^i(z)=\begin{pmatrix} z-z_0 & 0 & 0 & \ldots & 0 & 0 & 0\\ \vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots\\ 0 & \ldots & z-z_0 & 0 & 0 & \ldots & 0\\ D^i_{i,1}(z) & D^i_{i,2}(z) & \ldots & D^i_{i,i}(z) & \ldots & \ldots & D^i_{i,N}(z)\\ 0 & \ldots & 0 & 0 & z-z_0 & \ldots & 0\\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & 0 & 0 & \ldots & 0 & z-z_0 \end{pmatrix}.$$

A straightforward computation shows that

$$\det D^i(z)=(z-z_0)^{N-1}D^i_{i,i}(z)=-\frac{1}{s_0}\sum_{s=i-1}^{N-1}(z-z_0)^{N-2-(s-i)}\langle \mathbf{u}_{N-1-s},V_p\mathbf{u}_{i-1}\rangle.$$

The expansion (3.12) implies that the zeros of the Weinstein–Aronszajn determinant are given by the algebraic equation

$$(z-z_0)^N-\frac{\varepsilon}{s_0}\sum_{i=1}^{N}\sum_{s=i-1}^{N-1}(z-z_0)^{N-2-(s-i)}\langle \mathbf{u}_{N-1-s},V_p\mathbf{u}_{i-1}\rangle+\varepsilon^2F_2(z-z_0,\varepsilon)=0,\tag{3.13}$$

where $\lim_{\varepsilon\to0}F_2(z-z_0,\varepsilon)$ exists. By the Implicit Function Theorem, roots of the algebraic equation (3.13) exist and satisfy the estimate $z-z_0=O(\varepsilon^{1/N})$. Therefore, the zero energy eigenvalue of the unperturbed problem splits into N simple eigenvalues, which are given asymptotically by roots of

$$(z_k - z_0)^N = \frac{\varepsilon}{s_0}\langle \mathbf{u}_0, V_p \mathbf{u}_0\rangle + O(\varepsilon^{(N+1)/N}), \quad k = 1, \ldots, N. \tag{3.14}$$

Equation (3.14) coincides with (1.6) in notations of (1.5). ■

IV. A GENERAL HAMILTONIAN–HOPF INSTABILITY BIFURCATION

The pair of eigenvalues of zero energy $z = \pm z_0$ is neutrally stable in the linearized spectral problem (2.1), since $\mathrm{Im}(z_0) = 0$. If there are no other isolated eigenvalues with $\mathrm{Im}(z) > 0$, it would imply that the spectral problem (2.1) is weakly spectrally stable. However, the multiple eigenvalue of zero energy is structurally unstable and splits into simple eigenvalues, when the spectral problem (2.1) is perturbed with a bounded potential V_p in the form (3.1). When simple eigenvalues from the roots of (3.14) satisfy $\mathrm{Im}(z_k) > 0$ for some k, the spectral problem (3.1) undertakes an instability bifurcation, referred to as the *general Hamiltonian–Hopf bifurcation*. We show that there is only one bifurcation that gives a transition to instability, such that neutrally stable eigenvalues for one sign of ε split into stable and unstable eigenvalues for the other sign of ε. This bifurcation occurs for $N = 2$. Other bifurcations with $N \geq 3$ lead to unstable eigenvalues for either sign of $\varepsilon \neq 0$. We compute the exact number of unstable eigenvalues for each N, considering separately the cases $N = 2$ and $N \geq 3$.

Proposition 4.1: Let $\langle \mathbf{u}_0, V_p \mathbf{u}_0\rangle \neq 0$ *and* $0 < |\varepsilon| < \varepsilon_0$. *When* $N = 2$, *there exist two neutrally stable eigenvalues of the spectral problem* (3.1) *in a local neighborhood of* $z = z_0$ *for* $\mathrm{sign}(\varepsilon s_0 \langle \mathbf{u}_0, V_p \mathbf{u}_0\rangle) = 1$, *one of positive and the other one of negative energy*, *and two (stable and unstable) eigenvalues for* $\mathrm{sign}(\varepsilon s_0 \langle \mathbf{u}_0, V_p \mathbf{u}_0\rangle) = -1$.

Proof: It follows from (3.14) with $N = 2$ that

$$z_{1,2}^+ = z_0 \pm \sqrt{\frac{\varepsilon}{s_0}\langle \mathbf{u}_0, V_p \mathbf{u}_0\rangle} + O(\varepsilon), \tag{4.1}$$

when $\mathrm{sign}(\varepsilon s_0 \langle \mathbf{u}_0, V_p \mathbf{u}_0\rangle) = 1$ and

$$z_{1,2}^- = z_0 \pm i\sqrt{\left|\frac{\varepsilon}{s_0}\langle \mathbf{u}_0, V_p \mathbf{u}_0\rangle\right|} + O(\varepsilon),$$

when $\mathrm{sign}(\varepsilon s_0 \langle \mathbf{u}_0, V_p \mathbf{u}_0\rangle) = -1$. Since the total multiplicity of eigenvalues near $z = z_0$ is continuous in ε and complex eigenvalues occur in pairs, the eigenvalues $z_{1,2}^+$ are real and neutrally stable. The eigenvalues $z_{1,2}^-$ are complex, such that z_1^+ is stable and z_1^- is unstable. Let $\mathbf{v}_{1,2}^+$ be the eigenvectors of the problem (3.1) that correspond to $z_{1,2}^+$. We need to show that the energy operator is positive on one of the eigenvectors and negative on the other eigenvector. It follows from (3.1) that

$$\langle (H + \varepsilon V_p)\mathbf{v}_j^+, \mathbf{v}_j^+\rangle = z_j^+ \langle \sigma_1 \mathbf{v}_j^+, \mathbf{v}_j^+\rangle, \quad j = 1, 2. \tag{4.2}$$

Using the projection onto the subspace X_g, we rewrite (4.2) as follows:

$$\langle \sigma_1 \mathbf{v}_j^+, \mathbf{v}_j^+\rangle = \langle \sigma_1 P_g \mathbf{v}_j^+, P_g \mathbf{v}_j^+\rangle + \langle \sigma_1 (I - P_g)\mathbf{v}_j^+, (I - P_g)\mathbf{v}_j^+\rangle + 2\langle \sigma_1 P_g \mathbf{v}_j^+, (I - P_g)\mathbf{v}_j^+\rangle. \tag{4.3}$$

Let us estimate each of these three terms and show that only the first one plays the leading role. We have

$$P_g \mathbf{v}_j^+ = c_0^+ \mathbf{u}_0 + c_1^+ \mathbf{u}_1, \tag{4.4}$$

where the constants c_0^+ and c_1^+ satisfy

$$W_{2,1}(\varepsilon, z_j^+)c_0^+ + W_{2,2}(\varepsilon, z_j^+)c_1^+ + O(\varepsilon^2) = 0. \tag{4.5}$$

Using the explicit expression (3.10), we have

$$W_{2,1}(\varepsilon,z_j^+)=-\frac{\varepsilon}{s_0}\frac{\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle}{z_j^+-z_0},\quad W_{2,2}(\varepsilon,z_j^+)=1-\frac{\varepsilon}{s_0}\frac{\langle \mathbf{u}_0,V_p\mathbf{u}_1\rangle}{z_j^+-z_0}. \tag{4.6}$$

This expression can be rewritten by using (4.1), or, explicitly,

$$\frac{|\varepsilon|}{z_j^+-z_0}=(-1)^{j+1}\sqrt{\frac{s_0\varepsilon}{\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle}}+O(\varepsilon),$$

such that

$$W_{2,1}(\varepsilon,z_j^+)=(-1)^j\sqrt{\frac{\varepsilon}{s_0}\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle}+O(\varepsilon)$$

and

$$W_{2,2}(\varepsilon,z_j^+)=1+(-1)^j\,\mathrm{sign}(\varepsilon s_0)\sqrt{\frac{\varepsilon}{s_0\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle}}\langle \mathbf{u}_0,V_p\mathbf{u}_1\rangle+O(\varepsilon).$$

We let $c_0^+=1$ by scaling and obtain from (4.5) that

$$c_1^+=(-1)^{j+1}\sqrt{\frac{\varepsilon}{s_0}\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle}+O(\varepsilon).$$

By the triangle inequality applied to (4.4), we have the norm estimate

$$\|P_g\mathbf{v}_j^+\|_{L^2}\le\|\mathbf{u}_0\|_{L^2}+O(\sqrt{\varepsilon})\|\mathbf{u}_1\|_{L^2}. \tag{4.7}$$

For the first term on the right side of (4.3) using (4.4), we derive

$$\langle\sigma_1P_g\mathbf{v}_j^+,P_g\mathbf{v}_j^+\rangle=2(-1)^{j+1}\,\mathrm{sign}(s_0)\sqrt{\varepsilon s_0\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle}+O(\varepsilon). \tag{4.8}$$

For the second and the third terms on the right side of (4.3), we get bounds via the identity (3.8), the Schwarz inequality, the estimate on the norm of the operator $S(\varepsilon,z)$ given in Lemma 3.5, and the bound (4.7). Thus

$$|\langle\sigma_1(I-P_g)\mathbf{v}_j^+,(I-P_g)\mathbf{v}_j^+\rangle|\le\|S(\varepsilon,z_j^+)P_g\mathbf{v}_j^+\|_{L^2}^2\le\widetilde{C}^2\varepsilon^2(\|\mathbf{u}_0\|_{L^2}+O(\sqrt{\varepsilon})\|\mathbf{u}_1\|_{L^2})^2$$

and

$$|2\langle\sigma_1P_g\mathbf{v}_j^+,(I-P_g)\mathbf{v}_j^+\rangle|\le2\|P_g\mathbf{v}_j^+\|_{L^2}\|S(\varepsilon,z_j^+)P_g\mathbf{v}_j^+\|_{L^2}\le2\widetilde{C}|\varepsilon|(\|\mathbf{u}_0\|_{L^2}+O(\sqrt{\varepsilon})\|\mathbf{u}_1\|_{L^2})^2.$$

Using the inequalities above along with (4.8) in the identity (4.3) and substituting into (4.2), we arrive at

$$\langle(H+\varepsilon V_p)\mathbf{v}_1^+,\mathbf{v}_1^+\rangle=2z_0\,\mathrm{sign}(s_0)\sqrt{\varepsilon s_0\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle}+O(\varepsilon), \tag{4.9}$$

$$\langle(H+\varepsilon V_p)\mathbf{v}_2^+,\mathbf{v}_2^+\rangle=-2z_0\,\mathrm{sign}(s_0)\sqrt{\varepsilon s_0\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle}+O(\varepsilon), \tag{4.10}$$

for ε sufficiently small and $\mathrm{sign}(\varepsilon s_0\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle)=1$. Thus, the quadratic forms (4.9) and (4.10) have opposite signs. ■

Proposition 4.2: Let $\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle\neq0$ *and* $0<|\varepsilon|<\varepsilon_0$. *When* $N\ge3$, *there exist unstable eigenvalues of the spectral problem* (3.1) *in a local neighborhood of* $z=z_0$ *for either sign of* $\varepsilon\neq0$. *When N is odd, there are* $(N-1)/2$ *unstable eigenvalues. When N is even, there are* $N/2-1$ *unstable eigenvalues for* $\mathrm{sign}(\varepsilon s_0\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle)=1$ *and* $N/2$ *unstable eigenvalues for* $\mathrm{sign}(\varepsilon s_0\langle \mathbf{u}_0,V_p\mathbf{u}_0\rangle)=-1$.

Proof: We have

$$z_k^+ = z_0 + \sqrt[N]{\frac{\varepsilon}{s_0}\langle \mathbf{u}_0, V_p \mathbf{u}_0 \rangle} e^{i[2\pi(k-1)/N]} + O(\varepsilon^{2/N}), \quad k = 1, \ldots, N, \tag{4.11}$$

for $\text{sign}(\varepsilon s_0 \langle \mathbf{u}_0, V_p \mathbf{u}_0 \rangle) = 1$ and

$$z_k^- = z_0 + \sqrt[N]{\left|\frac{\varepsilon}{s_0}\langle \mathbf{u}_0, V_p \mathbf{u}_0 \rangle\right|} e^{i[(-\pi+2\pi k)/N]} + O(\varepsilon^{2/N}), \quad k = 1, \ldots, N, \tag{4.12}$$

for $\text{sign}(\varepsilon s_0 \langle \mathbf{u}_0, V_p \mathbf{u}_0 \rangle) = -1$. Unstable eigenvalues with $\text{Im}(z_k) > 0$ exist among both $\{z_k^+\}_{k=1}^N$ and $\{z_k^-\}_{k=1}^N$, e.g., $\text{Im}(z_2^+) > 0$ and $\text{Im}(z_1^-) > 0$. The count of unstable eigenvalues follows from the explicit expressions (4.11) and (4.12). ■

Remark 4.3: In practical situations, the NLS equation (1.7) has limits when the eigenvalues of the spectral problem (1.3) are all neutrally stable. When the NLS equation (1.7) deviates from the stable limit due to parameter continuations, real eigenvalues z start to move, which may lead to coalescence. The practical outcome of the above analysis shows that the coalescence of N neutrally stable eigenvalues with $N \geq 3$ cannot lead to a multiple eigenvalue $z = z_0$ of geometric multiplicity one and algebraic multiplicity N. If the resulting eigenvalue $z = z_0$ has zero energy, then it corresponds to several Jordan blocks, where each block splits according to our analysis in Propositions 4.1 and 4.2.

Dynamics of planar domains with moving boundaries driven by the gradient of a scalar field that satisfies an elliptic PDE is studied. We consider the question: For which kind of PDEs are the domains algebraic, provided the field has singularities at a fixed point inside the domain? The construction reveals a direct connection with the theory of the Calogero-Moser systems related to finite reflection groups and their integrable deformations. © *2006 American Institute of Physics.*

I. NONHOMOGENEOUS POROUS MEDIUM FLOWS

Laplacian growth is a process that governs the dynamics of the boundary $\partial\Omega=\partial\Omega(t)$ in the plane separating two disjoint, open regions (Ω and $\mathbb{C}\backslash\bar{\Omega}$) in which harmonic (scalar) fields are defined. These may be interpreted as the pressure fields for incompressible fluids (porous-medium flows, Hele-Shaw flows, etc. See, e.g., Ref. 14, and references therein). In the recent literature there have appeared several new formulations of the Laplacian growth related with the theory of integrable systems and random matrices, quantum Hall effect, and Dirichlet boundary problem in two dimensions (see, e.g., Refs. 8, 9, and 15, and references therein).

In the present paper, we consider a new connection with the theory of quantum integrable systems. To be more precise, we study an integrable generalization of the Laplacian growth, when the boundary is driven by a field satisfying an elliptic PDE, that is not generally reduced to a Beltrami-Laplace equation ("non-Laplacian" growth). To be specific, we use the porous medium fluid dynamics interpretation.

We find variable-coefficient elliptic PDEs for which the boundary dynamics can be described explicitly and the moving fluid occupies evolving algebraic domains (see the following). These, turn out to be PDEs of the Calogero-Moser type, related to finite reflection (Coxeter) groups as well as their integrable deformations (see Secs. VII–IX), that possibly complete the list of all second-order PDEs connected with the algebraic domains (our main conjecture).

In this section we set the problem in terms of the porous medium fluid dynamics. Formulation of the problem in terms of quadrature domains is given in the next section.

Consider a flow of an incompressible liquid in a thin nonplanar layer of nonhomogeneous porous medium. The layer can be viewed as a two-dimensional surface embedded in the three-dimensional Euclidean space. We let the layer curvature, permeability, porosity, and thickness depend on the surface spatial coordinates x,y. We can choose x,y such that locally

[a)]Electronic mail: loutsenk@maths.ox.ac.uk
[b)]Electronic mail: yermola@sissa.it

$$dl^2 = G(x,y)(dx^2 + dy^2),$$

where dl is the surface length element. The surface area element is $d\Sigma = G dx dy$, and the volume of the liquid that can be absorbed in the range $x+dx, y+dy$ equals

$$dV = \eta h d\Sigma = \eta h G dx dy,$$

where $\eta = \eta(x,y), h = h(x,y)$ are the medium porosity and the layer thickness, respectively.

In the porous medium, the flow velocity $v = (dx/dt, dy/dt)$ is proportional to the gradient $\nabla = (\partial/\partial x, \partial/\partial y)$ of the pressure P,

$$v = -\frac{\kappa}{\sqrt{G}} \nabla P,$$

where $\kappa = \kappa(x,y)$ is the medium permeability.

It is seen from the above that only the two combinations of variable coefficients, namely

$$\eta h G, \quad \frac{\kappa}{\sqrt{G}}$$

enter the flow equation of motion, and it is convenient to absorb h and G into definitions of the other coefficients. Therefore, without loss of generality, we can consider the flow in the plane parametrized by the complex coordinates $z = x+iy, \bar{z} = x-iy$, choosing η and κ to depend on $z, \bar{z}$ and setting remaining coefficients to unity. The liquid volume conservation leads to the continuity equation

$$(\nabla \cdot \eta v) = 0, \tag{1}$$

while the dynamical law of motion rewrites as

$$v = -\kappa \nabla P. \tag{2}$$

We consider a situation where the liquid occupies bounded, simply connected open region Ω of the plane, whose time evolution $\Omega = \Omega(t)$ is induced by the flow.

At fixed time t, the pressure is constant along the boundary

$$P(\partial\Omega(t)) = P_0(t). \tag{3}$$

Note that dynamics of simply connected domains is independent of $P_0(t)$, and the latter is often set to zero.

The normal velocity of the boundary v_n and that of the flow coincide at $\partial\Omega$,

$$v_n = n \cdot v \quad \text{if } z \in \partial\Omega. \tag{4}$$

The flow is singularity driven. For instance

$$P \to \frac{-q(t)}{2\kappa(z_1,\bar{z}_1)\eta(z_1,\bar{z}_1)} \log|z - z_1| + \sum_{j=1}^{k} \left(\frac{\mu_j(t)}{(z-z_1)^j} + \frac{\bar{\mu}_j(t)}{(\bar{z}-\bar{z}_1)^j} \right) \quad \text{as } z \to z_1, \tag{5}$$

when a multipole source of order $k+1$ is located at $z = z_1$. Equations (1)–(5) constitute the free boundary problem where the evolution of the boundary $\partial\Omega(t)$ is completely determined by the initial condition $\partial\Omega(0)$ and strengths $q(t) = \bar{q}(t), \mu_j(t), \bar{\mu}_j(t), j = 1, \ldots, k$ as well as position z_1 of the sources.

II. CONSERVATION LAWS AND QUADRATURE DOMAINS

From (1), (2), (5) it follows that the pressure satisfies the elliptic PDE

$$\nabla \kappa \eta \nabla P = -\pi \hat{q}[\delta(x-x_1)\delta(y-y_1)], \tag{6}$$

where $\hat{q}=\hat{q}(t)$ is the differential operator of order k,

$$\hat{q} = q(t) + \sum_{j=1}^{k} (-1)^j \left(q_j(t) \frac{\partial^j}{\partial z^j} + \bar{q}_j(t) \frac{\partial^j}{\partial \bar{z}^j} \right), \quad \bar{q} = q. \tag{7}$$

Let $\phi(z,\bar{z})$ be a time-independent function satisfying

$$\nabla \kappa \eta \nabla \phi = 0, \quad z \in \Omega \tag{8}$$

in the whole region Ω, including point $z=z_1$.

Let us now estimate the time derivatives of the following quantities:

$$M[\phi] = \int_{\Omega(t)} \eta \phi \mathrm{d}x\mathrm{d}y.$$

Considering an infinitesimal variation of the fluid domain $\Omega(t) \to \Omega(t+dt)$, we get

$$\frac{\mathrm{d}M[\phi]}{\mathrm{d}t} = \oint_{\partial\Omega(t)} v_n \eta \phi \mathrm{d}l,$$

where $\mathrm{d}l$ is the boundary arclength. From (2), (2), (4) it follows

$$\frac{\mathrm{d}M[\phi]}{\mathrm{d}t} = \oint_{\partial\Omega(t)} (P\kappa\eta\nabla\phi - \phi\kappa\eta\nabla P)\cdot n dl.$$

Applying the Stokes theorem and remembering that P and ϕ satisfy (6), (8), we obtain

$$\frac{\mathrm{d}M[\phi]}{dt} = \pi \hat{q}^*[\phi](z_1,\bar{z}_1), \quad \hat{q}^* = q(t) + \sum_{j=1}^{k} \left(q_j(t) \frac{\partial^j}{\partial z^j} + \bar{q}_j(t) \frac{\partial^j}{\partial \bar{z}^j} \right). \tag{9}$$

Note that mixed derivatives are absent in $\hat{q}$ [cf. (7)], for by (8), $\partial^2\phi/\partial z\,\partial\bar{z}$ is expressed through first derivatives of ϕ. $\bar{q}_j$ is the complex conjugate of q_j, since both $\phi(z,\bar{z})$ and $\bar{\phi}(\bar{z},z)$ satisfy (8).

It follows that $M[\phi]$ is conserved for any solution of (8), such that $\hat{q}^*[\phi](z_1,\bar{z}_1)=0$.

The conservation laws have been first obtained for the homogeneous medium flows in Ref. 12, the variable-coefficient generalization seems to have been first presented in Ref. 7. A wider class of conservation laws was considered in Ref. 10.

The flow in the homogeneous medium

$$\kappa = 1, \quad \eta = 1 \tag{10}$$

is the simplest example, where the conservation laws can be written down explicitly.[12] In this example, any (anti)analytic in Ω function satisfies (8),

$$\phi(z,\bar{z}) = f(z) + g(\bar{z}), \quad \text{for } \kappa = 1, \quad \eta = 1, \tag{11}$$

where f,g are univalent in Ω and the quantities

$$\int_{\Omega(t)} (f(z)(z-z_1)^k + g(\bar{z})(\bar{z}-\bar{z}_1)^k)\mathrm{d}x\mathrm{d}y$$

are integrals of motion for the free-boundary flows driven by a multipole source of order $k+1$ located at $z=z_1$ in homogeneous medium.

Returning to the general case, we integrate (9)

$$M[\phi](t) = M[\phi](0) + \pi\hat{Q}[\phi](z_1,\bar{z}_1),$$

where

$$\hat{Q} = \int_0^t \hat{q}^*(t')\mathrm{d}t' = Q + \sum_{j=1}^{k}\left(Q_j\frac{\partial^j}{\partial z^j} + \bar{Q}_j\frac{\partial^j}{\partial \bar{z}^j}\right). \tag{12}$$

Therefore, $M[\phi](t)$ and, consequently, form of the domain, does not depend on the history of the sources and is a function of "multipole fluxes"

$$Q = \int_0^t q(t')\mathrm{d}t', \quad Q_j = \int_0^t q_j(t')\mathrm{d}t', \quad \bar{Q}_j = \int_0^t \bar{q}_j(t')\mathrm{d}t', \; j = 1, \ldots, k$$

injected by time t.

Now consider the special case when $M[\phi](0)=0$ that describes the injection of the fluid to an initially empty medium. In such a case

$$\int_\Omega \eta(z,\bar{z})\phi(z,\bar{z})\mathrm{d}x\mathrm{d}y = \pi\hat{Q}[\phi](z_1,\bar{z}_1). \tag{13}$$

Equation (13) is a generalization of quadrature identities (those expressing integrals over Ω through evaluation of integrands and a finite number of their derivatives at a finite number of points inside Ω) appearing in the theory of harmonic functions[13] to the case of elliptic equations with variable coefficients. Special domains for which the quadrature identities hold are called quadrature domains in the theory of harmonic functions. We extend this definition to solutions of any elliptic PDE with regular in Ω coefficients.

To construct quadrature domains (or equivalently domains resulted from injection of fluid into an initially empty medium), one needs an explicit form of a general solution of (8). Such explicit solutions are available for a class of the second-order differential equations that are related to the Schrödinger operators of integrable systems on the plane. We, however, postpone construction of these solution to Sec. IV and present our main result in the next section.

III. THE MAIN RESULT

Let us start with the simplest possible example, where the liquid is injected into initially empty homogeneous porous medium through the single monopole source at $z=z_1=x_1+iy_1$. By symmetry, the solution is a circular disc of the radius $r(t)$, centered at $z=z_1$,

$$|z-z_1| < r(t). \tag{14}$$

The pressure satisfies

$$\Delta P = -\pi\tilde{q}(t)\delta(x-x_1)\delta(y-y_1),$$

where the source strength and the total flux are

$$\tilde{q}(t) = \frac{\mathrm{d}r(t)^2}{\mathrm{d}t}, \quad \tilde{Q} = r^2,$$

respectively.

The remarkable fact is that the variable-coefficient problem for a medium with constant porosity and permeability that varies as an inverse square of one Cartesian coordinate

$$\kappa = \frac{1}{x^2}, \quad \eta = 1 \tag{15}$$

admits the same circular solution (14) if the flow is driven by a combination of the same monopole source of strength $q=\tilde{q}(t)$ and a dipole source of strength $q_1=-\tilde{q}\tilde{Q}/2x_1$, both located at the point $z=z_1$,

$$\nabla \frac{1}{x^2} \nabla P = -\pi \hat{q}[\delta(x-x_1)\delta(y-y_1)], \quad \hat{q} = \frac{\mathrm{d}r^2}{\mathrm{d}t}\left(1 - \frac{r^2}{2x_1}\frac{\partial}{\partial x}\right). \tag{16}$$

Indeed, it is not difficult to check that

$$P = r\frac{\mathrm{d}r}{\mathrm{d}t}\left((2x_1x + \rho^2 + r^2)\log\rho - \frac{r^2x(x-x_1)}{\rho^2} - \rho^2 + x(x-x_1) - (2x_1x+\rho^2)\log(r)\right), \tag{17}$$

where $\rho=|z-z_1|$, satisfies (16), and the boundary conditions (2), (15),

$$\frac{\mathrm{d}r}{\mathrm{d}t} = -\frac{1}{x^2}\left(\frac{\partial P}{\partial n}\right)_{\rho=r},$$

as well as (6) holds at the disc boundary.

Also the following quadrature identity holds:

$$\int_{|z-z_1|<r} \phi \mathrm{d}x\mathrm{d}y = \pi r^2 \phi(z_1,\bar{z}_1) + \frac{\pi r^4}{4x_1}\left(\frac{\partial \phi}{\partial x}\right)_{z=z_1},$$

which is a simplest nontrivial generalization of the mean value theorem for harmonic functions to the case of regular in (14) solutions of the elliptic PDE

$$\nabla \frac{1}{x^2} \nabla \phi = 0.$$

The above example is a special case of the main result presented in the following.

Let $\Omega(t)$ be a domain, resulted from the injection of the fluxes $\tilde{Q},\tilde{Q}_j, j=1,\ldots,\tilde{k}$ into a homogeneous medium through a multipole source of order $\tilde{k}+1$ located at $z=z_1$. Then the same domain can be formed by an injection of a special combination of fluxes $Q,Q_j, j=1,\ldots,k$ through a multipole source of order $k+1$, where $k=(\tilde{k}+1)(s(n+l)+1)-1$ located at $z=z_1$ into an initially empty nonhomogeneous medium with permeability

$$\kappa = \frac{1}{(z^s+\bar{z}^s)^{2n}(z^s-\bar{z}^s)^{2l}}, \quad n > l \geqslant 0, \quad s > 0, \quad \eta = 1 \tag{18}$$

and constant porosity, where s,n,l are integers.

In more details, the multipole fluxes of nonhomogeneous medium problem must be fixed functions of fluxes of its homogeneous medium counterpart

$$Q=\tilde{Q},\quad Q_j=Q_j(\tilde{Q},\tilde{Q}_1,\ldots,\tilde{Q}_{\tilde{k}},\bar{\tilde{Q}}_1,\ldots,\bar{\tilde{Q}}_{\tilde{k}},z_1,\bar{z}_1),\quad j=1\ldots(\tilde{k}+1)(s(n+l)+1)-1.$$

For instance, in the above example of circular $\tilde{k}=0$ solution in a medium with permeability (15) [that is the special case $n=1,l=0,s=1$ of (18)]

$$k=(0+1)(1(1+0)+1)-1=1,\quad Q=\tilde{Q},\quad Q_1=\frac{\tilde{Q}^2}{4x_1}.$$

Note that (18) can be rewritten in the form

$$\kappa=\frac{1}{\zeta(x,y)^2},\quad \zeta(x,y)=\prod_{\alpha\in\mathcal{R}_+}(\alpha\cdot z)^{m_\alpha},\quad (a\cdot b):=\mathrm{Re}(\bar{a}b),$$

where $\mathcal{R}=\{\alpha\}$ is a set of root vectors of a finite reflection (Coxeter) group on the plane (Dihedral group). $\mathcal{R}$ is invariant under reflections

$$z\to z-2\frac{(\alpha\cdot z)}{(\alpha\cdot\alpha)}\alpha$$

in a mirror (line), normal to any root vector $\alpha\in\mathcal{R}$, and $\mathcal{R}_+$ denotes "positive" subset of $\mathcal{R}$, containing a half of all root vectors [i.e., $\mathcal{R}=(-\mathcal{R}_+)\cup\mathcal{R}_+$]. The multiplicities m_α must be non-negative integers that are functions on the group orbits. If $l=0$, the reflection group has one orbit and $m_\alpha=n$. Otherwise, the group has two orbits and multiplicities m_α take values n and l on each orbit respectively. The permeability (18) is therefore an invariant of the group of symmetries of a regular $4s$-polygon ($2s$-polygon if $l=0$) and its singular locus [i.e., union of all points z, such that $1/\kappa(z,\bar{z})=0$] coincides with the union of mirrors.

The pressure satisfies the elliptic PDE

$$\nabla\zeta(x,y)^{-2}\nabla P=\zeta(x,y)^{-1}H\zeta(x,y)^{-1}P=-\pi\hat{q}[\delta(x-x_k)\delta(y-y_k)]$$

$$\mathrm{order}(\hat{q})=(\tilde{k}+1)(\deg(\zeta(x,y))+1)-1=(\tilde{k}+1)\left(1+\sum_{\alpha\in\mathcal{R}_+}m_\alpha\right)-1,$$

where H is the Schrödinger operator of the Calogero-Moser system related to the dihedral group[3,6,11]

$$H=\Delta-\sum_{\alpha\in\mathcal{R}_+}(\alpha\cdot\alpha)\frac{m_\alpha(m_\alpha+1)}{(\alpha\cdot z)^2}.$$

Also, regular in Ω solutions $\phi(z,\bar{z})$ of the elliptic PDEs $\nabla\zeta(x,y)^{-2}\nabla\phi=0$ satisfy the quadrature identities

$$\int_\Omega\phi dxdy=\hat{Q}[\phi](z_1,\bar{z}_1),\quad \mathrm{order}(\hat{Q})=(\tilde{k}+1)(\deg(\zeta(x,y))+1)-1$$

that are generalization of the mean value theorem for harmonic functions to the case of solutions of the variable-coefficient elliptic PDEs in (generally) non-circular domains.

Before proving the main result we need to construct a complete set of solutions to (8) for the medium with κ,η given by (18).

IV. NONHOMOGENEOUS POROUS MEDIUM FLOWS AND INTEGRABLE SYSTEMS RELATED TO THE FINITE REFLECTION GROUPS

In this section we show how to obtain a general solution $\phi(z,\bar{z})$ to (8), (18). It is instructive to consider the special case $s=1,l=0$ of (18)

$$\kappa = \frac{1}{x^{2n}}, \quad \eta = 1, \tag{19}$$

when permeability depends on one Cartesian coordinate only. Construction of solutions in the general case (18) is conceptually similar.

Consider the simplest nontrivial example $n=1$ in (19) and start with factorizing the differential operator ∂_x^2 as

$$\frac{\partial^2}{\partial x^2} = \left(\frac{1}{x}\frac{\partial}{\partial x}\right)\left(x\frac{\partial}{\partial x} - 1\right).$$

By associativity of differential operators

$$\left(x\frac{\partial}{\partial x} - 1\right)\underbrace{\left(\frac{1}{x}\frac{\partial}{\partial x}\right)\left(x\frac{\partial}{\partial x} - 1\right)}_{\partial_x^2} = \underbrace{\left(x\frac{\partial}{\partial x} - 1\right)\left(\frac{1}{x}\frac{\partial}{\partial x}\right)}_{x^2\partial_x\frac{1}{x^2}\partial_x}\left(x\frac{\partial}{\partial x} - 1\right).$$

Therefore,

$$T_1\Delta = L_1T_1, \quad T_1 = x\frac{\partial}{\partial x} - 1, \quad L_1 = x^2\,\nabla\,\frac{1}{x^2}\nabla \tag{20}$$

and the elliptic equation (8) is nontrivially related to the Laplace equation when $\kappa\eta = 1/x^2$. In general, the identity

$$T\Delta = LT$$

that relates two differential operators (e.g., Δ and L above) through a differential operator T is called an intertwining identity and T is an intertwining operator.

A differential operator that is related to Δ through the intertwining identity equals, modulo a gauge transformation, a Schrödinger operators of an integrable system. Indeed,

$$T(\Delta - \lambda) = (L - \lambda)T$$

and when ν is an eigenfunction of Δ with the eigenvalue λ, $T[\nu]$ is an eigenfunction of L with the same eigenvalue or zero.

The factorization approach leading to the simplest nontrivial intertwining identity (20) can be now applied to L_1, etc. By induction we get the intertwining identity for an arbitrary nonnegative integer n in (19),

$$T_n\Delta = L_nT_n, \quad L_n = x^{2n}\,\nabla\,\frac{1}{x^{2n}}\,\nabla\,, \tag{21}$$

where

$$T_n = x^n\left(\frac{\partial}{\partial x} - \frac{n}{x}\right)\left(\frac{\partial}{\partial x} - \frac{n-1}{x}\right)\cdots\left(\frac{\partial}{\partial x} - \frac{1}{x}\right) = \sum_{i=0}^{n} a_{i;n}x^i\frac{\partial^i}{\partial x^i}. \tag{22}$$

Any solution ϕ to (8), (19) in Ω can be represented in the form

$$\phi = T_n[f], \quad \Delta f = 0, \quad z \in \Omega. \tag{23}$$

Let us show this for $n=1$, where T_1 is given by (20). Introduce f satisfying

$$x\frac{\partial f}{\partial x} - f = \phi,$$

where $L_1[\phi]=0$ in Ω and $\phi=0$ for $z \notin \Omega$. It is not difficult to see that

$$f(z,\bar{z}) = x\int_{-\infty}^{x} \frac{\phi(x'+iy,x'-iy)}{(x')^2}\mathrm{d}x' + xF(y),$$

where $F(y)$ is an arbitrary regular function of y. Therefore, for any ϕ regular in Ω (which is the case) there exists a regular in Ω function f, such that $T_1[f]=\phi$. From the intertwining identity (20) it follows that $T_1\Delta f=0$ and $\Delta f \in \mathrm{Ker}(T_1)$, if $z \in \Omega$, i.e.,

$$\Delta[f] = xC(y), \quad z = x+iy \in \Omega,$$

where $C(y)$ is an arbitrary function of y. It follows that

$$\Delta[f+xF(y)] = 0, \quad \frac{\mathrm{d}^2F(y)}{\mathrm{d}y^2} = C(y).$$

Since f is defined modulo $xF(y)$, we can set $F=0$ and any solution of $L_1[\phi]=0$ can be represented as $\phi=T_1[f]$, where $\Delta[f]=0$. Similar proof applies to the arbitrary n case (23).

In the general case (18)

$$T_{n,l;s}\Delta = L_{n,l;s}T_{n,l;s}, \quad L_{n,l;s} = (z^s+\bar{z}^s)^{2n}(z^s-\bar{z}^s)^{2l}\,\nabla\,\frac{1}{(z^s+\bar{z}^s)^{2n}(z^s-\bar{z}^s)^{2l}}\,\nabla\,,$$

where the intertwining operator can be expressed in the form of a Wronskian[3]

$$T_{n,l;s}[f] = \rho^{s(n+l)}\frac{W[\sin(\theta_1),\sin(\theta_2),\ldots,\sin(\theta_n),f]}{\cos(s\theta)^{n(n-1)/2}\sin(s\theta)^{l(l-1)/2}}, \quad W[f_1,\ldots,f_k] := \det\left[\frac{\partial^{j-1}f_i}{\partial\theta^{j-1}}\right]_{1\leqslant i,j\leqslant k} \tag{24}$$

with

$$z=\rho e^{i\theta}, \quad \theta_k = \begin{cases} k\left(s\theta+\dfrac{\pi}{2}\right), & k=1,2,\ldots n-l \\ (2k+l-n)\left(s\theta+\dfrac{\pi}{2}\right), & n-l<k\leqslant n \end{cases}.$$

It is important that the intertwining operator $T_{n,l;s}$ is a homogeneous differential polynomial in $z,\bar{z},\partial_z,\partial_{\bar{z}}$. This fact allows one to construct the quadrature domains for solutions ϕ of $L_{n,l;s}[\phi]=0$.

Note that, in general, there exist several independent operators intertwining Δ and another second-order differential operator (forming a linear space of intertwining operators). For instance, T_n in (21) that intertwines Δ with $L_n=L_{n,0;1}$ is not the special case $T_{n,0;1}$ of (24). However, any nonzero linear combination of them can be used to obtain solutions to the corresponding elliptic equations $L_{n,0;1}[\phi]=0$.

V. PROOF OF THE MAIN RESULT

The zero-initial condition solution of the homogeneous-porous medium flow that is driven by a multipole source of order $\tilde{k}+1$ is described by the polynomial conformal map of degree $\tilde{k}+1$ from the unit disc in the parametric $|w|$-plane into the fluid region Ω,

$$z(w) = z_1 + rw + \sum_{i=1}^{\tilde{k}} u_i w^{i+1}, \quad |w| < 1. \tag{25}$$

The map is analytic in $|w|<1$, and the unit circle $|w|=1$ is mapped to the boundary $\partial\Omega$. As shown above such regions are also quadrature domains. They are special (polynomial) cases of (rational) algebraic domains.[14] The map coefficients $r, u_i, i=1,\ldots,\tilde{k}$ are functions of $\tilde{Q}, \tilde{Q}_i, \bar{\tilde{Q}}_i, i=1,\ldots,\tilde{k}$. The "conformal radius" r can be chosen to be real.

The main idea of the proof is to show that the quadrature identity (13) for solutions of (8), (18) holds in domains defined by (25).

Consider illustrative examples of the problem (19) with permeability changing in one direction. As shown in the previous section any solution of the elliptic equation $L_n[\phi]=0$ can be represented as

$$T_n[f(z) + g(\bar{z})], \tag{26}$$

where $f(z), g(\bar{z})$ are holomorphic and anti-holomorphic, respectively.

According to (13) we have to show that

$$\int_\Omega T_n[f(z)]\mathrm{d}x\mathrm{d}y = \pi\hat{Q}T_n[f(z)]_{z=z_1}$$

holds for any analytic in Ω function $f(z)$ when Ω is defined by the conformal map (25). Using the Green theorem and taking (22) into account we rewrite the last equation as

$$\sum_{j=0}^{n} \frac{a_{j;n}}{2^j(j+1)} \frac{1}{2\pi i} \oint_{\partial\Omega} (z+\bar{z})^{j+1} \frac{\partial^j f(z)}{\partial z^j} \mathrm{d}z = \hat{Q}T_n[f(z)]_{z=z_1}. \tag{27}$$

Since $\bar{w}=1/w$ if $|w|=1$, $\bar{z}(\bar{w})=\bar{z}(1/w)$ along the boundary, we can rewrite the left-hand side of the last equation as

$$\sum_{j=0}^{n} \frac{a_{j;n}}{2^j(j+1)} \frac{1}{2\pi i} \oint_{|w|=1} \left((z(w)+\bar{z}(1/w))^{j+1} \left(\frac{1}{\frac{\partial z(w)}{\partial w}} \frac{\partial}{\partial w} \right)^j [f(z(w))] \right) \frac{\partial z(w)}{\partial w} \mathrm{d}w.$$

Since $z(w)$ is analytic in $|w|<1$, $\bar{z}(1/w)$ has poles only at $w=0$, and the above integral is a pure sum of residues

$$\sum_{j=0}^{(\tilde{k}+2)(n+1)-2} V_j \left(\frac{\partial^j f(z)}{\partial z^j} \right)_{z=z_1}, \tag{28}$$

where $V_j, j=0\ldots(\tilde{k}+2)(n+1)-2$ are functions of the parameters $z_1, \bar{z}_1, r, u_j, \bar{u}_j, j=1\ldots\tilde{k}$ of the conformal map (25). Equating it with the right-hand side of (27), we see that $\hat{Q}_k$ must be (differential operators) of order $(\tilde{k}+1)(n+1)-1$ and

$$\hat{Q}T_n[f(z)]_{z=z_1} = \sum_{j=0}^{(\tilde{k}+2)(n+1)-2} U_j \left(\frac{\partial^j f(z)}{\partial z^j} \right)_{z=z_1}, \tag{29}$$

where $U_j, j=0\ldots(\tilde{k}+2)(n+1)-2$ are linear functions of $Q, Q_j, \bar{Q}_j, j=1\ldots(\tilde{k}+1)(n+1)-1$. Therefore, the quadrature identity (27) is satisfied if the following system of $2(\tilde{k}+2)(n+1)-1$ linear equations

$$V_j - U_j = 0, \quad \bar{V}_j - \bar{U}_j = 0, \quad j = 0 \ldots (\tilde{k}+2)(n+1) - 2 \tag{30}$$

for $2(\tilde{k}+1)(n+1)$ unknowns

$$Q, \bar{Q}, Q_j, \bar{Q}_j, \quad j = 1 \ldots (\tilde{k}+1)(n+1) - 1 \tag{31}$$

has solutions.

Note that the condition $\bar{Q}=Q$ is satisfied automatically, since, as is easily seen from (27), (25), (12), the $j=0$ subset of (30)

$$V_0 - U_0 = 0, \quad \bar{V}_0 - \bar{U}_0 = 0$$

are equations for $Q, \bar{Q}$ that have the same form for any $n \geqslant 0$ in (22). They have real solution

$$Q = \tilde{Q} = r^2 + \sum_{i=1}^{\tilde{k}} (i+1) u_i \bar{u}_i.$$

The number of equations in (30) exceeds the number of unknowns (31) by $2n$ and the system of equations (30) is overdermined for the nonhomogeneous medium problem $n > 0$.

For instance, for the circular domain $\tilde{k}=0$,

$$z(w) = z_1 + rw$$

in a medium with permeability $1/x^2$, that has been considered in Sec. III, the system of equations (30) consists of six equations

$$\begin{aligned}
&Q - r^2 = 0, \quad \bar{Q} - r^2 = 0, \\
&2Qx_1 - Q_1 + \bar{Q}_1 - 2x_1 r^2 = 0, \quad 2\bar{Q}x_1 - \bar{Q}_1 + Q_1 - 2x_1 r^2 = 0, \\
&4Q_1 x_1 - r^4 = 0, \quad 4\bar{Q}_1 x_1 - r^4 = 0
\end{aligned}$$

for four unknowns $Q, \bar{Q}, Q_1, \bar{Q}_1$. It has the following solution:

$$Q = \bar{Q} = r^2, \quad Q_1 = \bar{Q}_1 = r^4/4x_1.$$

Returning to the general case, we are going to show that not all equations in (30) are independent, the system is compatible and has a unique solution, which proves our main result.

To prove the compatibility, we introduce the basis

$$\phi_j(z,\bar{z}) = c_j T_n[(z-z_1)^{j+n}], \quad \bar{\phi}_j(\bar{z},z) = c_j T_n[(\bar{z}-\bar{z}_1)^{j+n}], \quad j = 0,1,2, \ldots, \tag{32}$$

where $c_j = j!/(j+n)!\, x_1^n$, in the space of solutions $\phi(z,\bar{z})$ of $L_n[\phi]=0$ that are regular in neighborhood of $z=z_1$, and then show that the quadrature identity (13) holds for any element of this basis.

Indeed, according to (22), (32) is a set of solutions of $L_n[\phi]=0$ that continuously tends to the basis of functions analytic in a neighborhood of $z=z_1$,

$$\phi_j(z,\bar{z}) \to (z-z_1)^j, \quad j = 0,1,2, \ldots, \quad x_1 \to \infty$$

as the position of the source $z_1 = x_1 + iy_1$ goes to infinity. On the other hand, $L_n[\phi(z,\bar{z})]=0, z \in \Omega$ continuously tends to the Laplace equation when region Ω is moved to infinity. Therefore, set (32) is homotopically equivalent to $(z-z_1)^j, (\bar{z}-\bar{z}_1)^j, j=0,1,2,\ldots$ under a continuous deformation of the Laplace operator and thus contains a basis of solutions of $L_n[\phi]=0$ that is regular in a neighborhood of $z=z_1$.

It then follows from (28) and (29) that the quadrature identity holds if

$$(V_j - U_j)\left(\frac{d^j f(z)}{dz^j}\right)_{z=z_1} = 0, \quad (\bar{V}_j - \bar{U}_j)\left(\frac{d^j f(\bar{z})}{d\bar{z}^j}\right)_{z=z_1} = 0, \quad j = 0 \ldots (\tilde{k}+2)(n+1) - 2 \tag{33}$$

for

$$f(z) \in \{(z - z_1)^j, j \geqslant n\}.$$

Since $j \geqslant n$, the left-hand sides of the first n equations in (33) vanish, and there remains $2(\tilde{k}+1) \times (n+1)$ independent equations and the equal number of unknowns (31).

We now have to prove the compatibility of remaining equations. (30) is a nonhomogeneous system of linear equations for unknowns $Q, \bar{Q}, Q_j, \bar{Q}_j, j = 1 \ldots (\tilde{k}+1)(n+1) - 1$, that fixes dependence of these unknowns on parameters $z_1, \bar{z}_1, r, u_1, \ldots, u_{\tilde{k}}, \bar{u}_1, \ldots, \bar{u}_{\tilde{k}}$. The system is compatible if its homogeneous part does not have nontrivial solutions. Let us suppose that it does. Recall that the homogeneous part of the system has been obtained by action of the operator $\hat{Q}$ to an arbitrary solution of $L_n[\phi] = 0$ at point $z = z_1$. So, if the homogeneous part of the system had nontrivial solutions, then operator $\hat{Q}$ would annihilate any solution ϕ of $L_n[\phi] = 0$ at $z = z_1$, i.e.,

$$\hat{Q} T_n[f(z)] = 0 \quad \text{at } z = z_1, \tag{34}$$

where $f(z)$ is any analytic in Ω function. If the above were true, then changing continuously the position $z = z_1$ of the source, we could construct such operator $\hat{Q}$, with coefficients depending on z, that $\hat{Q} T_n[f(z)] = 0$ in some region of the plane for an arbitrary $f(z)$. But this is evidently impossible, since the highest symbols of $\hat{Q}$ and T_n contain pure derivatives in z, so does their composition.

Therefore, (30) has a unique solution and quadrature identity holds in the polynomial algebraic domains, that leads to our main result (see Sec. III).

Similar result can be analogously proved for the general system with permeability given by (18).

VI. GENERALIZATION TO HIGHER DIMENSIONS

Our study can be extended to PDEs in more than two dimensions, since the derivation of the conservation laws in Sec. II is not restricted to the two-dimensional flows.

For instance, if we take solution $\phi(\xi)$ of $\nabla \xi_1^{-2} \nabla \phi = 0$, where $\xi := (\xi_1, \ldots, \xi_d)$ and $\nabla := (\partial/\partial\xi_1, \ldots, \partial/\partial\xi_d)$, then the following quadrature identity holds:

$$\int_{|\xi - \xi'| < r} \phi(\xi) \mathrm{d}\xi_1 \ldots \mathrm{d}\xi_d = v_d \left(\phi(\xi) + \frac{r^2}{(d+2)\xi_1} \frac{\partial \phi(\xi)}{\partial \xi_1} \right)_{\xi = \xi'} \tag{35}$$

in the d-dimensional ball of radius r with center at $\xi = \xi'$, where $v_d = \int_{|\xi - \xi'| < r} \mathrm{d}\xi_1 \ldots \mathrm{d}\xi_d$ is the volume of the ball. Since the Hadamard expansion of the fundamental solution of the Calogero-Moser type operators truncates (see, e.g., Refs. 4 and 6), the pressure distribution in the corresponding free-boundary flow can be written down explicitly for any d [e.g., we have used the technique of Ref. 4 for derivation of (17)].

VII. GENERALIZATIONS TO NON-COXETER ARRANGEMENTS

According to works on algebraic integrability,[6] it is likely that the second-order elliptic operators related to the Coxeter root systems as well as their special deformations exhaust all possible operators that can be related to the Laplace operators through intertwining operators with rational coefficients. These are elliptic operators for which a rational Baker-Akhieser function exists. We call all such operators the algebraic Calogero-Moser operators. For instance, the algebraic Calogero-Moser equations[6] related to the porous medium problems (8) with the permeability

$$\kappa = x^{-2m}((2m+1)y^2 - x^2)^{-2}, \quad \eta = 1, \tag{36}$$

where $m=2,3,4,\ldots$, are the simplest examples that extend the main result of the present paper to non-Coxeter arrangements of mirrors.

A more general class of such algebraic Calogero-Moser systems was found in Ref. 3, and it was shown in Ref. 2 that they exhaust all algebraically integrable systems with linear arrangements of mirrors in two dimensions. Such systems are labeled by a sequence of integer positive numbers $0 \leqslant k_1 < k_2 < \ldots < k_n$ and a sequence $\omega_1, \ldots, \omega_n$ of complex parameters ("phases"). The corresponding algebraically integrable elliptic operator is

$$L = \zeta^2 \nabla \zeta^{-2} \nabla \tag{37}$$

where rational function $\zeta = \zeta(x,y)$ is the ratio of Wronskians

$$\zeta(x,y) = \rho^{k_n} \frac{W[\sin(\theta_1), \ldots \sin(\theta_{n-1}), \sin(\theta_n)]}{W[\sin(\theta_1), \ldots \sin(\theta_{n-1})]}, \quad \theta_j = k_j\theta + \omega_j, \quad z = \rho e^{i\theta}. \tag{38}$$

The corresponding intertwining operator is of the order n and can be rewritten in the form of a Wronskian

$$T[f] = \rho^{k_n} \frac{W[\sin(\theta_1), \ldots \sin(\theta_n), f]}{W[\sin(\theta_1), \ldots \sin(\theta_{n-1})]}$$

with (24) being a special case. The results of the present paper, e.g., algebraicity of quadrature domains, etc., also hold for systems with

$$\kappa = 1/\zeta(x,y)^2, \quad \eta = 1$$

where ζ is given by (38), with such $k_1, \ldots k_n$ and $\omega_1, \ldots \omega_n$ that the Wronskian in the denominator of (38) divides that in the numerator and ζ is a polynomial in x, y [these include systems with Coxeter arrangements of mirrors, deformed systems of type (36), and many others]. For these kinds of systems, the intertwining operator has polynomial coefficients and the corresponding Baker-Akhieser function is polynomial in the spectral parameter.

More generally, one can consider a situation where the porosity $\eta(x,y)$ is not constant, and is such that the quadrature identities (13) hold in domains determined by the conformal maps (25) not only when $\zeta(x,y)$ is a polynomial, but also when it is a rational function (38) of x,y. We consider related examples in the next section.

VIII. SYSTEMS WITH AFFINE SINGULAR LOCI

We considered systems with mirrors arranged linearly, i.e., all mirrors passing through the same point (origin). There, however, exist generalizations of the above construction with affine arrangement of mirrors. In the present section we give examples of such systems that are nonhomogeneous in one direction. These are related to rational solutions of the Korteveg-de-Vries equation. The permeability and porosity are expressed in terms of the Adler-Moser[1] polynomials $p_n(x)$ (first introduced by Burcnhall and Chaundy in Ref. 5) as follows:

$$\kappa\eta = \zeta(x)^{-2}, \quad \zeta(x) = \frac{p_n(x)}{p_{n-1}(x)}, \quad \eta = p_{n-1}(x)S(x) \tag{39}$$

where $S(x)$ is an arbitrary polynomial of x. The Adler-Moser polynomial p_n can be represented as the Wronskian

$$p_0 = 1, \quad p_n(x;t_3, \ldots, t_n) = W[\psi_1(x), \psi_2(x), \ldots, \psi_n(x)], \quad \psi_1 = x, \quad \partial_x^2 \psi_n = \psi_{n-1}.$$

The nth Adler-Moser polynomial depends on $n-1$ parameters $t_3, \ldots t_{2n-1}$ [that can be viewed as integration constants for $\psi_k(x), k=2\ldots n$) and is of degree $n(n+1)/2$ in x. $t_3, t_5, \ldots$ are the KdV

hierarchy flow parameters ("times"), while $p_n, n=0,1,2,\ldots$ are τ-functions of the hierarchy. Examples of several first Adler-Moser polynomials are

$$p_0 = 1, \quad p_1 = x, \quad p_2 = x^3 + t_3, \ldots .$$

Elliptic operator (37) is related to the Laplace operator by the intertwining operator that can be written in terms of the Wronskians

$$T[f] = \frac{W[\psi_1, \ldots, \psi_n, f]}{W[\psi_1, \ldots \psi_{n-1}]}.$$

It is a differential operator of order n with rational coefficients.

Note that expression (39) for κ, η is given for generic values of $t_3, t_5, \ldots$, when the greatest common divisor of p_n and p_{n-1} is a constant. For instance, (19), (21) correspond to a special case of Adler-Moser polynomials, when all times $t_{2i-1}, i>1$ are set to zero and $p_n = x^{n(n+1)/2}$ is divisible by $p_{n-1} = x^{n(n-1)/2}$. In this case the intertwining operator has polynomial coefficients and one can choose η to be a constant, rather than a polynomial of nonzero degree in x [cf. (37)].

The quadrature identities (13) hold in algebraic domains determined by (25). In generic case, the order of $\hat{Q}$ in the right-hand side of (13) is

$$\operatorname{order}(\hat{Q}) = \left(\deg(S(x)) + \frac{n(n+1)}{2} + 1 \right) \deg(z(w)) - 1 .$$

For example, in circular domain (14) with $S(x)=1$ and $n=2$ in (39)

$$\int_{|z-z_1|<r} x\phi \mathrm{d}x\mathrm{d}y = \pi \sum_{i=0}^{3} Q_i \left(\frac{\partial^i \phi}{\partial x^i} \right)_{z=z_1}, \tag{40}$$

where ϕ is any solution of

$$\nabla \frac{x^2}{(x^3 + t_3)^2} \nabla \phi = 0$$

regular in (14), and

$$Q_0 = x_1 r^2, \quad Q_1 = \frac{x_1 r^4 (6x_1^2 + r^2)}{8(x_1^3 + t_3)}, \quad Q_2 = \frac{r^6 (16x_1^5 + 16x_1^2 t_3 + r^2 t_3)}{128(x_1^3 + t_3)^2}, \quad Q_3 = \frac{x_1 r^8}{192(t_3 + x_1^3)}.$$

IX. CONCLUSION, MAIN CONJECTURE

In this article we have found examples of nonhomogeneous porous medium flows, driven by multipole source located at a fixed point, whose boundaries obey the same dynamics as those of the homogeneous-medium flows also driven by a multipole source located at the same point. Namely, in the main set of examples, the medium permeability is a homogeneous rational function of x, y, and an invariant of the dihedral group. We also considered examples with permeability that is a homogeneous rational function of x, y, which is not generally dihedral-invariant, as well as examples with affine arrangements of singular loci. For the latter examples, the medium permeability as well as its porosity are nonhomogeneous rational functions of x, y. The multipole fluxes of the nonhomogeneous medium problem must be fixed functions of those of its homogeneous medium counterpart. Related variable-coefficient elliptic PDEs for the pressure distribution are of the algebraic Calogero-Moser type[6] and the quadrature identities for solutions of such equations hold in algebraic domains determined by polynomial conformal maps of unit disc.

In conclusion, one may pose the classification problem: *Find the complete list of all PDEs whose solutions satisfy quadrature identities in polynomial algebraic domains*. In view of the above it is reasonable to expect that it has the following solution:

Conjecture: The algebraic Calogero-Moser equations exhaust, up to a gauge equivalence, all possible second-order elliptic PDEs whose solutions satisfy quadrature identities in polynomial algebraic domains.

As mentioned in Sec. VI, our study can be extended to PDEs in more than two dimensions. Although we cannot use conformal maps to parametrize algebraic domains in higher dimensions, we can still pose the classification problem for domains with spherical boundaries, looking for a complete list of elliptic equations for which generalized mean value theorem holds. More precisely, one can look for equations in d-dimensions whose solutions possess the following property: *There exists such d-dimensional measure that the integral of an arbitrary solution taken over an arbitrary d-dimensional ball equals a linear combination of the value of the solution and those of a finite number of its derivatives at the ball center. Coefficients of the linear combination may depend on the ball position and radius, while the measure is determined by coefficients of the elliptic PDE only*. Typical examples of this property are (35) (where the measure is simply $d\xi_1 \ldots d\xi_d$) and (40) (with measure $x\mathrm{d}x\mathrm{d}y$).

Extending our conjecture to higher dimensions we may expect that algebraic Calogero-Moser equations complete the above list. Note, that our classification problem seems to be equivalent to classical Hadamard's problem of classification of Huygens' operators. As in our case, all known examples of such Huygens' operators are related to algebraic Calogero-Moser systems.[6]

Dynamical systems on $\mathbb{R}^n$ presenting geometric chaos, i.e., open domains where bounded and unbounded orbits are intermingled, have been constructed. The opposite situation (open scattering) has been studied for integrable Hamiltonian and non-Hamiltonian vector fields and for equations of type $\ddot{\mathbf{x}}=-\nabla V(\mathbf{x})$ when the potential has the form $V=a(r)+b(r)F(\theta)$ in spherical coordinates. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2206880]

I. INTRODUCTION

Let $\mathbf{X}$ be a smooth dynamical system on $\mathbb{R}^n$. The solution $\mathbf{x}(\mathbf{x}_0;t)$ through $\mathbf{x}_0$ is called a *scattering orbit* if

$$\lim_{t\to\omega,\omega'} \|\mathbf{x}(\mathbf{x}_0;t)\| = +\infty,$$

$$\omega \in \mathbb{R}^+ \cup \{+\infty\}, \quad \omega' \in \mathbb{R}^- \cup \{-\infty\}, \tag{1}$$

(ω',ω) being the maximal interval around $t_0=0$ on which $\mathbf{x}(\mathbf{x}_0;t)$ is defined.

Orbits of this kind often appear in Mechanics concerning the vector field (vf)

$$\mathbf{X} = (\dot{\mathbf{x}}, -\nabla V(\mathbf{x})),$$

$$\mathbf{x} \in \mathbb{R}^m \tag{2}$$

associated with the Newtonian equation

$$\ddot{\mathbf{x}} = -\nabla V(\mathbf{x}) \tag{3}$$

ruling the motion of a particle in the potential $V(\mathbf{x})$, cf. Ref. 1.

In this paper we study the robustness of scattering trajectories, i.e., if we consider orbits through initial conditions close to $\mathbf{x}_0$, are all these orbits also of scattering type? A negative answer could yield a nonuniform behavior which would make predictability impossible due to the practical small uncertainties in initial conditions. The nonuniformity would be reflected by the existence of bounded solutions arbitrarily near scattering ones.

It is important to note that in this work we are interested in analyzing whether the orbits near a given scattering trajectory are bounded or not. In this sense our approach is closer to the concept of uniform behavior of a dynamical system[2] than to the well-known concept of chaotic scattering.

Recall that, via numerical experiments, it has been suggested that chaotic scattering can appear in vf of type (2) when there exist multiple exit modes for the solutions. Chaotic scattering

[a)]Electronic mail: adiaz@mat.ucm.es

usually refers to the fractality of the boundaries separating the basins of different exits, the appearance of the Wada phenomenon being the most typical situation. There is a vast literature on chaotic scattering, the interested reader can consult, e.g., Refs. 3–8 although we will not focus on this phenomenon.

Although chaotic scattering usually gives rise to complex phase portraits we are not interested in complexity arising from the existence of multiple exit modes but in unpredictability associated with the concept of geometric chaos.[9] We say that there exists *geometric chaos* in $\mathcal{R}$ when the set $\mathcal{K}\subset\mathcal{R}$, $\mathcal{R}$ standing for an open set of $\mathbb{R}^n$, formed by the initial conditions $\mathbf{x}_0$ supporting a scattering solution $\mathbf{x}(\mathbf{x}_0,t)$, and its complement $\mathcal{K}^c$ in $\mathcal{R}$, formed by nonscattering trajectories, are both dense in $\mathcal{R}$. Rigorous mathematical examples of chaotic scattering are given in Sec. II for vf in $\mathbb{R}^n$ with first integrals. As far as we know these are the first examples in the literature of integrable vf presenting geometric chaos.

Conditions in order that geometric chaos does not arise are also given in Sec. II.

We warn the reader that a similar phenomenon (that is, Arnold's diffusion[10]) appears when a completely integrable Hamiltonian system with m $(m>2)$ degrees of freedom is perturbed in the form

$$\mathbf{X}_H \to \mathbf{X}_H + \epsilon \mathbf{X}_{H_1},$$

$$\epsilon \in \mathbb{R};\ \epsilon \neq 0 \text{ and small}. \tag{4}$$

The only difference being that geometric chaos appears without needing to perturb another vf. On the other hand, geometric chaos can appear for $\mathbb{R}^n$ vf for any value of n $(n\geqslant 3)$ while Arnold's diffusion only appears when $n\geqslant 4$ $(n=2m)$. Note also that Arnold's diffusion has been observed, cf. Refs. 11 and 12, in many physical systems: motion of a charge in the focusing magnetic field of an accelerator, motion of electrons in a magnetic bottle, interactions of colliding electron-positrons beams, etc.

The opposite situation to geometric chaos is *open scattering*, in which there exists a neighborhood $\mathcal{N}(\gamma)$ of a scattering trajectory γ such that all the orbits of $\mathbf{X}$ with initial conditions in $\mathcal{N}(\gamma)$ are scattering trajectories. This situation is studied in Sec. III for Liouville integrable systems and for Newtonian vector fields verifying certain assumptions.

It becomes evident that open scattering gives rise to uniformity in the sense that all trajectories near certain scattering trajectory are of scattering type, although the behavior of the system could be nonuniform in the sense of chaotic scattering (but we will not focus here on this issue). Open scattering is desirable from the physical viewpoint because the presence of geometric chaos makes it impossible to predict whether the evolution of an initial condition will remain in some compact set or on the contrary it will tend to infinity. One of the most relevant results that we obtain is that, even when $2n-2$ conserved quantities exist (n is the number of degrees of freedom), geometric chaos may arise, thus extending the results of nonuniformity obtained in Ref. 2. This phenomenon is not as well known as chaotic scattering and hence it complements the literature on chaos in Hamiltonian systems. Furthermore we provide criteria in order to avoid geometric chaos in physically relevant Newtonian systems, thus justifying the interest of our study both in Physics and Applied Mathematics.

II. GEOMETRIC CHAOS

Smooth $\mathbb{R}^3$ vf with a first integral whose level sets are tori are constructed, see Sec. II A, exhibiting geometric chaos over an open domain $\mathcal{R}\subset\mathbb{R}^3$. The set $\mathcal{K}^c$, which is the complement of the set $\mathcal{K}=\cup$ (scattering orbits), is formed by S^1 orbits of $\mathbf{X}$. This construction is generalized to $\mathbb{R}^n$ vf with r $(1\leqslant r\leqslant n-2)$ first integrals whose level sets are diffeomorphic to $(S^1)^{n-r}$. When $\mathbf{X}$ has $n-1$ first integrals it is proved that geometric chaos is not possible.

Examples are also given of $\mathbb{R}^3$ vf with a first integral whose level sets are cylinders, see Sec.

II B, for which geometric chaos is impossible. For $\mathbb{R}^3$ vf with a first integral whose level sets are different from tori or cylinders the discussion of geometric chaos is given at the end of Secs. II A and II B.

A. Geometric chaos in integrable systems

Let $\mathbf{X}$ be any C^∞ vf in $\mathbb{R}^3$ with a differentiable first integral $I(\mathbf{x})$ such that:

$$\begin{aligned} &\text{(a) } I(\mathbf{x}) = I(\mathbf{x}_0) = I_0 \text{ are tori if } \mathbf{x}_0 \notin z-\text{axis}.\\ &\text{(b) The orbits of the vf } \mathbf{X}|_{I=I_0} \text{ are either dense in } I_0 \text{ (irrational orbits) or are,}\\ &\quad \text{all of them, topological circles.}\\ &\text{(c) Both } S^1 \text{ tori (i.e., rational tori) and irrational tori are dense in an open domain.} \end{aligned} \tag{5}$$

A physical example for which these conditions are fulfilled is

$$\mathbf{X} = \mathbf{B} + \partial_\phi, \tag{6}$$

$\mathbf{B}$ standing for the magnetic vf created by a circular wire of center (0, 0, 0) lying on the (x,y) plane,[13] and ∂_ϕ being the vf $-y\partial_x + x\partial_y$ representing rotations around the z axis. It can be proved[13] that the magnetic field has the form $\mathbf{B}=A_1(r,z)\partial_r + A_2(r,z)\partial_z$ in cylindrical coordinates (r,ϕ,z). The orbits of $\mathbf{B}$ on the (r,z) planes consist of the z axis and topological circles around the point of intersection between the wire and these planes. This gives rise to a global first integral $I(r,z)$ on $\mathbb{R}^3$ whose level sets are tori around the circular wire. The frequency of $\mathbf{B}$ on these tori is a nonconstant function $\omega(I)$, and hence the tori on which $\omega(I)/2\pi \in \mathbb{Q}$ are filled by periodic orbits of $\mathbf{X}$, otherwise we have irrational tori. $\mathbf{X}$ becomes globally smooth after multiplication of any function which goes to zero fast enough on the wire.

Note that assumption (4)-(5b) is automatically fulfilled when $\mathbf{X}$ is divergence-free and has no zeros on $\mathcal{R}$.[1]

Consider now the set

$$\mathbb{R}^3 \setminus \mathfrak{s}, \tag{7}$$

$\mathfrak{s}$ being any C^1, properly embedded, unbounded curve starting at (1, 1, 1) and transversal to the level sets of I lying on the domain $\mathcal{R}$ ($\mathcal{R}$ being the complement in $\mathbb{R}^3\setminus$ (z axis) of the domain bounded by the torus $I=I(1,1,1)$). Assume that $\mathfrak{s}$ intersects each level set of I in $\mathcal{R}$ only once.

It can be seen that $\mathbb{R}^3\setminus\mathfrak{s}$ is diffeomorphic to $\mathbb{R}^3$ via a smooth diffeomorphism D. Indeed, consider that $\mathfrak{s}$ is a half straight-line starting at (1, 1, 1) and take a foliation of $\mathbb{R}^3\setminus(1,1,1)$ by spheres S_r of centers (1, 1, 1) and radii $r>0$, becoming topological planes after removing in S_r the point $S_r \cap \mathfrak{s}$.

Now, any torus T ($T \subset \mathcal{R}$) becomes a horned torus after deletion of the point $T \cap \mathfrak{s}$ and the vf $\mathbf{X^D}$ transformed of $\mathbf{X}|_{\mathbb{R}^3\setminus\mathfrak{s}}$ under D is again an $\mathbb{R}^3$ smooth vector field. $\mathbf{X^D}$ exhibits geometric chaos because the horns of $T\setminus(T\cap\mathfrak{s})$ blow-up to infinity under the action of D, while the S^1 orbits on the tori are preserved (except for the S^1 orbits passing through $T\cap\mathfrak{s}$, which are transformed in unbounded orbits of $\mathbf{X^D}$). Dense orbits in tori become scattering dense orbits in the horned tori $D(T\setminus(T\cap\mathfrak{s}))$.

The above conclusion holds for $\mathbb{R}^n$ vf $\mathbf{X}$ ($n>3$) when r C^1 first integrals of $\mathbf{X}$ are given, the (regular) level sets of them are codimension r tori $(S^1)^{n-r}$ and (5b), (5c) hold. The only modification is that (7) becomes

$$\mathbb{R}^n \setminus L_r, \tag{8}$$

L_r being a half-linear space of dimension r ($L_1=\mathfrak{s}$, $L_2=$a half plane,…) transversal to the tori $(S^1)^{n-r}$, which guarantees a unique intersection among each of these tori and L_r. Note that $\mathbb{R}^n\setminus L_r$

is smooth diffeomorphic to $\mathbb{R}^n$ (this follows from a well-known theorem by Stallings[14]). In fact, this diffeomorphism can be taken as a symplectomorphism, ensuring that $\mathbf{X_D}$ remains Hamiltonian if $\mathbf{X}$ is ($n=2m$, the symplectic structure in $\mathbb{R}^{2m}$ possibly being nonglobally equivalent to the standard one[15,16]).

For example, when $n=4$ and $r=2$ (consider an $\mathbb{R}^2$ foliation similar to the one introduced for $n=3$, $r=1$), take $\mathbf{X}$ as the vf associated with the uncoupled differential equations

$$\ddot{x} = -x,$$

$$\ddot{y} = -y^3. \tag{9}$$

The explicit expression of the vf $\mathbf{X^D}$ associated with Eq. (9) can be immediately obtained from the expression of the diffeomorphism D, which in this case is given by

$$D = D_1 \times D_2,$$

$$R^4 \setminus L_2 = (R^2 \setminus L_1)^1 \times (R^2 \setminus L_1)^2,$$

$$D_i = \Psi_i \circ \Phi_i,$$

$$(R^2 \setminus L_1)^i = R^2 \setminus \{x_i \leqslant 0, y_i = 0\},$$

$$i = 1,2, \tag{10}$$

Ψ_i and Φ_i being defined by

$$(r_i, \Theta_i) \in (R^2 \setminus L_1)^i \xrightarrow{\Phi_i} (r_i, \Theta_i/2) \xrightarrow{\Psi_i} (\log x_i, y_i),$$

$$r_i > 0, \quad -\pi < \Theta_i < \pi \tag{11}$$

(r_i, Θ_i) being polar coordinates in the splitted planes $(R^2 \setminus L_1)^i$, around (0, 0) with $(L_1)=\{\Theta_i = \pi\}$.

Note that the effect of Φ_i is that of transforming $(R^2 \setminus L_1)^i$ in the half-plane $x_i > 0$, and the effect of Ψ_i that of transforming this half-plane into $\mathbb{R}^2$.

Once D has been defined, $\mathbf{X^D}$ is obtained by just transforming the $\mathbb{R}^4$ vf $\mathbf{X}$ associated with Eq. (9):

$$\mathbf{X} = (\dot{\mathbf{x}}, -\mathbf{x}, \dot{\mathbf{y}}, -\mathbf{y}^3), \tag{12}$$

under D. This gives rise to a very involved expression for $\mathbf{X^D}$ which for brevity is omitted.

The tori foliating open sets of $\mathbb{R}^4$ are given by

$$(\dot{x}^2/2 + x^2/2 = c_1) \times (\dot{y}^2/2 + y^4/4 = c_2), \tag{13}$$

and $L_r = L_2$ (a half plane in phase-space). Assumptions (5b) and (5c) are satisfied since the ratio of the frequencies of the orbits in the uncoupled equations is a C^ω nonconstant function.

Let us now prove that when $r=n-1$ (i.e., the vector field $\mathbf{X}$ is completely integrable) and the first integrals are independent of ϑ (a periodic orbit of $\mathbf{X}$) then geometric chaos cannot arise. Let $(I_1, \ldots, I_{n-1})$ be the first integrals of $\mathbf{X}$. Indeed let us construct $n-1$ vector fields $\mathbf{S_i}$ in a neighborhood $N(\vartheta)$ of ϑ as

$$\mathbf{S_i} = \sum_{j=1}^{n-1} a_{ij} \nabla I_j \tag{14}$$

such that

$$\mathbf{S_i}(I_j) = \delta_{ij}, \tag{15}$$

δ_{ij} standing for the Kronecker delta. Note that in Eq. (15) $\mathbf{S_i}(I_j)$ denotes the Lie derivative of the function I_j along the streamlines of $\mathbf{S_i}$. Therefore, $\mathbf{S_i}(I_j)=\mathbf{S_i}\cdot\nabla I_j$, the dot standing for the standard Euclidean scalar product in $\mathbb{R}^3$.

The Lie derivative of I_j is, of course, defined by,

$$\mathbf{S_i}(I_j) = \left.\frac{dI_j(\alpha_i(t;\mathbf{x}))}{dt}\right|_{t=0}, \tag{16}$$

$\alpha_i(t;\mathbf{x})$ begin the flow induced by $\mathbf{S_i}$.

It is straightforward to see that the coefficients a_{ij} in (14) are smooth functions and are uniquely defined by Eq. (15) in $N(\vartheta)$. $\mathbf{S_i}$ are obviously [by (15)] $n-1$ independent symmetries of $\mathbf{X}$, thus implying, on account of the compactness of ϑ, that $N(\vartheta)$ is covered by periodic orbits of $\mathbf{X}$. This rules out the existence of geometric chaos. The reader can have a look at Ref. 9 where some criteria for the existence of open scattering in completely integrable vector fields are given.

The generalization of the results of this section to $r<n-1$ first integrals foliating an open subset of $\mathbb{R}^n$ with fiber F ($\dim F=n-r$), $F\neq(S^1)^{n-r}$ is problematic since, except for tori, we are not aware of foliations of open domains of $\mathbb{R}^n$ satisfying assumptions (5b) and (5c).

B. A topological obstruction to the existence of geometric chaos

We now give examples of $\mathbb{R}^3$ analytic vf with a first integral I whose (regular) level sets are cylinders for which geometric chaos is impossible. The analyticity of I is a key property in the construction.

Consider the vf $\mathbf{X}$ defied by

$$\mathbf{X} = \mathbf{X}_2(x,y) + a(x,y,z)\partial_z, \tag{17}$$

$\mathbf{X}_2, a \in C^\omega$, satisfying

$$I = I(x,y), \quad \mathbf{X}(I) = 0,$$

$$I(x,y) = c \text{ are circular cylinders (in } \mathbb{R}^3),$$

$$\text{rank } (\nabla I)|_{(x,y)\neq(0,0)} = 1,$$

$$\text{periods } T(c) \text{ of } \mathbf{X}_2 \text{ on } I=c \text{ cover (as } c \text{ varies in } \mathbb{R}) \text{ an open interval of } \mathbb{R},$$

where $\mathbf{X}(\mathbf{I})$ denotes the Lie derivative of I along the streamlines of $\mathbf{X}$. Calling $(x(t),y(t))$ the periodic solution of $\dot{\mathbf{x}}=\mathbf{X}_2(\mathbf{x})$ with initial condition $(x_0,y_0)\in\mathbb{R}^2$, its period T_0 is an analytic function of $c_0=I(x_0,y_0)$.

We get $z(t)$ along this solution via

$$\frac{\mathrm{d}z}{\mathrm{d}t} = a(x,y,z)|_{(x(t),y(t))} = F_0(t;z), \tag{18}$$

F_0 being C^ω and periodic in t (of period T_0).

Any periodic solution $\mathbf{p}$ of $\mathbf{X}$ lying on the cylinder $I(x,y)=c_0$ satisfies, see Ref. 17,

$$\Pi^n(z;T_0) = z,$$

$$z \in \mathbf{p}; n(z,T_0) \in \mathbb{N}, \tag{19}$$

Π being the Poincaré map

$$\Pi(z;T_0) = \phi(t = T_0; z_0 = z) \tag{20}$$

associated with Eq. (18) and $\phi(t;z_0)$ the general solution of Eq. (18). Remember[17] that Π is an analytic function of z and T_0 (since $\mathbf{X}$ is analytic).

Let $\mathcal{R}$ be an open $\mathbb{R}^3$-domain and assume the existence of a periodic orbit $\Theta(P)$ through a point $P \in \mathcal{R}$ (on the cylinder $I=c_0$). The analyticity of the Poincaré map Π of $\mathbf{X}|_{I=c_0}$ near $\Theta(P)$ implies[17] that in a neighborhood $N(\Theta(P))$ either all the orbits of $\mathbf{X}|_{I=I_0}$ are of type S^1 or none, but $\Theta(P)$, is of type S^1 (limit cycle). In the second case the cylinders $I=c$ (for c running on an interval of $\mathbb{R}$ centered at c_0) would hold a one-parameter family of S^1 orbits of $\mathbf{X}$ (possibly with only one element), whose closure can never be an open subset of $\mathbb{R}^3$.

In the first case (taking into account the topology of $I=c_0$) it follows that the period $n(z,T_0)$ of Π is independent of z and T_0, and is in fact equal to 1. Therefore we get [see Eq. (19)]

$$\Pi(z;T_0) = z,$$

$$\forall T_0 \text{s.t.} N(\Theta(P)) \cap (I = c_0) \text{ is foliated by } S^1 \text{ orbits}. \tag{21}$$

Summarizing, any cylinder $I=c$ on which a S^1 orbit lies is either foliated with S^1 orbits or contains a countable number $m(c)$ of isolated S^1 orbits ($m(c)=0$ not being excluded).

When geometric chaos is present, the closure of the values of T_0 for which Eq. (21) holds must contain an interval J of $\mathbb{R}$. Since $\Pi(z;T_0)-z$ is C^ω, its zeros z_i on J are either a finite set or otherwise $\Pi(z;T_0)-z \equiv 0$ on J, and hence we can write

$$\Pi(z;T_0) \equiv z,$$

$$\forall T_0 \in J, \tag{22}$$

thus implying that the cylinders through $\mathcal{R}$ are foliated by S^1 orbits. Therefore geometric chaos is also impossible. Note that the key points in the proof are the analyticity of $\mathbf{X}$ and that the topology of $I=I_0$ is $S^1 \times \mathbb{R}$, which implies that the period n in Eq. (19) is constant ($n=1$). For example, if $I=I_0$ were a torus $S^1 \times S^1$ the period would not be constant in general and the proof would fail (rational and irrational tori are generally intermingled).

In ending this section let us observe that when the level sets of the first integral of $\mathbf{X}$ are neither tori nor cylinders the problem of knowing whether or not an S^1 orbit of $\mathbf{X}$ belongs to a chaotic region $\mathcal{R}$ is a global one and therefore it cannot generally be solved by using local techniques, like considerations concerning the local Poincaré map.

III. OPEN SCATTERING

Section III A deals with open-scattering for $\mathbb{R}^{2n}$ Hamiltonian vf $\mathbf{X}_H$ with n first integrals in involution (Liouville-integrability). In Sec. III B open-scattering in the presence of ignorable coordinates is studied. Finally, in Sec. III C, some analytical conditions based on inequalities are given ensuring open-scattering for positive values of the energy.

Let us first show some examples of vf with and without *open scattering orbits*. Recall that a scattering solution of a vf $\mathbf{X}$ [see Eq. (1)] is called open if Eq. (1) is satisfied not only at the point $\mathbf{x}_0$, but for every $\mathbf{y}_0$ in an open neighborhood $N(\mathbf{x}_0)$ of $\mathbf{x}_0$.

It is well known that the $\mathbb{R}^4$ vf associated with the Newton equations

$$\ddot{\mathbf{x}} = -\nabla V(r),$$

$$\mathbf{x} \in \mathbb{R}^2,$$

$$\lim_{r\to\infty} V(r) = 0, \tag{23}$$

where $r=\|\mathbf{x}\|$, do certainly possess open scattering orbits (see, e.g., Arnold in Ref. 1).

An example of $\mathbb{R}^2$ Hamiltonian vf without open scattering orbits (because its only unbounded orbit is isolated) is

$$\mathbf{X_H} = \left(\frac{\partial H}{\partial y}, -\frac{\partial H}{\partial x}\right), \tag{24}$$

$H(x,y)$ being the Newtonian potential created by the charge dipole $(-q,q)$ lying on $((-1,0),(1,0))$, that is

$$H = -\frac{q}{\sqrt{(x+1)^2+y^2}} + \frac{q}{\sqrt{(x-1)^2+y^2}}. \tag{25}$$

The vf $\mathbf{X_H}$ defined by (24) and (25) has the y axis as a scattering orbit which is surrounded by S^1 orbits of $\mathbf{X_H}$ centered at $(-1,0)$ and $(1,0)$ (i.e., the level sets $H(x,y)=c$ of H, $c\neq 0$).

Note that this vf can be globalized either by multiplication by a suitable smooth function $\lambda(x,y)$ vanishing at $(-1,0)$ and $(1,0)$ or by constructing a vf $\mathbf{Y}_{\tilde{\mathbf{H}}}$, with $\tilde{H}$ an adequate function of H.

Can a similar example (of isolated scattering orbit) be found for vf of type $(\dot{\mathbf{x}}, -\nabla V(\mathbf{x}))$, $\mathbf{x}\in\mathbb{R}^n$?

A. Open scattering and Liouville integrability

For the sake of simplicity let us assume that $n=2$ (the case $n>2$ can be treated in a similar way). Consider that the Hamiltonian vf $\mathbf{X_H}$ in $\mathbb{R}^4$ is Liouville integrable;[1] that is, in addition to the Hamiltonian H, a second first integral I is known such that

1. rank $(\nabla I, \nabla H)=2$ either globally or at least in the open domain $\mathcal{D}$ where we are working.
2. (H,I) Poisson-commute.
3. $\mathbf{X_H}$ and $\mathbf{X_I}$ are complete vf globally or at least in $\mathcal{D}$.
4. The topology of the level sets $(H=C_1, I=C_2)$ near the level set $L_0=(H=C_{10}, I=C_{20})$ does not vary with (C_1,C_2). Assume that $\mathcal{D}$ contains L_0 and it is saturated by level sets of (H,I).

We are now given a scattering orbit S lying on the level set L_0. Call L any level set $(H=C_1, I=C_2)$ near L_0. Note that L_0 must be diffeomorphic to $\mathbb{R}^2$ or $S^1\times\mathbb{R}$ (tori being excluded by the presence of S, which is unbounded), by the well-known Arnold-Liouville's theorem.[1] In what follows $\mathcal{D}$ will be an open neighborhood of L_0.

Open scattering does certainly appear when $L_0\cong\mathbb{R}^2$. Indeed, since $\nabla H\neq 0$ on L then $\mathbf{X_H}|_L \neq 0$ and hence (by Poincaré-Bendixon theorem[17]) the orbits of $\mathbf{X_H}|_L$ must be of type $\mathbb{R}$.

When $L_0\cong S^1\times\mathbb{R}$ the action of $\mathbf{X_I}$ on S (remember that $\mathbf{X_I}$ is complete on $\mathcal{D}$) defines a foliation on L_0 whose leaves are diffeomorphic to $\mathbb{R}$. In fact $\mathbf{X_H}|_{L_0}$ is conjugate to a helicoidal vector field, i.e., there exists coordinates $(\phi,z)\in S^1\times\mathbb{R}$ on L_0 such that[10]

$$\mathbf{X_H}|_{L_0} = a\partial_\phi + b\partial_z, \tag{26}$$

$a,b\in\mathbb{R}$ and $b\neq 0$ because of the presence of S in L_0.

Equation (26) implies that all the orbits of $\mathbf{X_H}|_{L_0}$ go from one end of L_0 to the other, thus proving that $\mathbf{X_H}|_{L_0}$ is structurally stable.[18] Therefore L is foliated by $\mathbb{R}$ orbits and hence there is open scattering in $\mathcal{D}$.

When the level sets L near L_0 do not keep a fixed topological type, e.g., there are bifurcations from $\mathbb{R}^2$ to $S^1\times\mathbb{R}$ or from $S^1\times\mathbb{R}$ to $S^1\times S^1$ we cannot conclude anything on open scattering. An illustrative example is the Kepler problem when L_0 is the level set $(H=C_{10}, I=C_{20}\neq 0)$ of the first integrals

$$H = \frac{\dot{x}^2 + \dot{y}^2}{2} - \frac{1}{\sqrt{x^2 + y^2}}, \quad I = x\dot{y} - y\dot{x}.$$

Assumptions (1)–(4) are fulfilled if $C_{10} > 0$, thus implying open scattering. If $C_{10} = 0$ then only assumptions (1)–(3) hold because the level sets ($H < 0$, $I = C_{20}$) are tori. In this case open scattering does not occur.

B. Open scattering and ignorable coordinates

We now study the effect on open scattering of the existence of $n-1$ ignorable coordinates (call them $y_2, \ldots, y_n$) in the n first integrals ($I_1, \ldots, I_n$) of the second order differential equation (not necessarily Hamiltonian)

$$\ddot{\mathbf{y}} = C(\mathbf{y}, \dot{\mathbf{y}}),$$

$$\mathbf{y} = (y_1, \ldots, y_n) \in \mathbb{R}^n. \tag{27}$$

System (27) is assumed to have the n first integrals:

$$I_1(y_1, \dot{y}_1, \ldots, \dot{y}_n),$$

$$\vdots$$

$$I_n(y_1, \dot{y}_1, \ldots, \dot{y}_n). \tag{28}$$

Assume that $\dot{y}_2, \ldots, \dot{y}_n$ can be globally eliminated in

$$I_1(y_1, \dot{y}_1, \ldots, \dot{y}_n) = C_1,$$

$$\vdots$$

$$I_n(y_1, \dot{y}_1, \ldots, \dot{y}_n) = C_n. \tag{29}$$

We get in this way

$$\Lambda(y_1, \dot{y}_1; C_1, \ldots, C_n) = 0, \tag{30}$$

Λ being called the eliminant (sometimes also called resultant, particularly when $I_1, \ldots, I_n$ are polynomials in $\dot{y}_2, \ldots, \dot{y}_n$).

If $y_1 \in \mathbb{R}$ ($y_2, \ldots, y_n$ can vary either on $\mathbb{R}$ or S^1) and Eq. (27) possesses a scattering solution S on the level set $(C_{10}, \ldots, C_{n0})$, $y_1(t)$ being unbounded, then the curve ϑ_0 on the $(y_1, \dot{y}_1)$ plane defined by $\Lambda(y_1, \dot{y}_1; C_{10}, \ldots, C_{n0}) = 0$ has some connected component which is also unbounded. If the values $(C_1, \ldots, C_n)$ of the first integrals are close to $(C_{10}, \ldots, C_{n0})$, does the curve ϑ defined by $\Lambda(y_1, \dot{y}_1; C_1, \ldots, C_n) = 0$ remain unbounded? In the next paragraph we give a sufficient condition ensuring that if $(C_1, \ldots, C_n)$ are near $(C_{10}, \ldots, C_{n0})$ then ϑ is close to ϑ_0, thus proving that open scattering around S occurs.

If $\|\nabla\Lambda\,(y_1, \dot{y}_1; C_{10}, \ldots, C_{n0})|_{\vartheta_0}\| \geqslant c > 0$ then the curves ϑ for $(C_1, \ldots, C_n)$ close enough to $(C_{10}, \ldots, C_{n0})$ are diffeomorphic to ϑ_0. Indeed, this assumption on $\nabla\Lambda$ is a particular case of Malgrange condition and hence it implies the nonexistence of asymptotic critical values.[19] Although ϑ_0 is noncompact the fact that $\|\nabla\Lambda\|$ is bounded below implies that Thom's isotopy theorem[20] holds, thus showing that a small perturbation of Λ gives rise to a curve ϑ which is diffeomorphic (via a smooth diffeotopy arbitrarily close to the identity) to ϑ_0. If $(C_1, \ldots, C_n)$ are near $(C_{10}, \ldots, C_{n0})$ then, on account of the continuous dependence, $\Lambda(y_1, \dot{y}_1; C_1, \ldots, C_n)$ is a small perturbation of $\Lambda(y_1, \dot{y}_1; C_{10}, \ldots, C_{n0})$, and the result follows.

Newton equations for central potentials satisfy Eq. (28) in the polar chart $(y_1=r, y_2=\theta)$. In this case the first integrals take the form $I_1=\frac{1}{2}\dot{y}_1^2+\frac{1}{2}y_1^2\dot{y}_2^2+V(y_1)$, $I_2=y_1^2\dot{y}_2$.

Let us illustrate the main result of this section with a classical example: the Kepler problem. In this case it is easy to check that the eliminant is given by

$$\Lambda(y_1,\dot{y}_1;C_1,C_2)=\frac{1}{2}\dot{y}_1^2+\frac{C_2^2}{2y_1^2}-\frac{1}{y_1}-C_1=0. \tag{31}$$

The critical points of Λ are $p_1(y_1=C_2^2,\dot{y}_1=0)$ and $p_2(y_1\to\infty,\dot{y}_1=0)$. Since

$$\Lambda(p_1)=-\frac{1}{C_2^2}-C_1 \text{ and } \Lambda(p_2)=-C_1$$

it follows, on account of the previous discussion, that when $C_1=C_{10}>0$ and $C_2=C_{20}\neq 0$ there exists open scattering (hyperbolic orbits). If $C_1=C_{10}=0$ (parabolic orbits) then the curve ϑ_0 has an asymptotic critical value and the criterion does not work, in fact in this case there is no open scattering because the orbits with $C_1<0$ are periodic.

A particularly relevant situation in which equations of type (30) arise is for Stackel's separable systems.[21] In this case it is not difficult to reach the following expression

$$\Lambda_i(y_i,\dot{y}_i;C_1,\ldots,C_n)=\tfrac{1}{2}\dot{y}_i^2+\phi_i(y_i;C_1,\ldots,C_n)=0 \tag{32}$$

for each $i=1,\ldots,n$. If the (type $\mathbb{R}$) coordinate y_k is unbounded for the scattering orbit S then our criterion applied to Λ_k implies open scattering.

C. Potentials with open scattering for positive energy

In the Kepler problem all the trajectories with energy $E>0$ (and nonvanishing angular momentum) are scattering orbits, thus exhibiting the open scattering phenomenon when $E>0$. We now give a procedure in order to get open scattering in Newtonian systems $\ddot{\mathbf{x}}=-\nabla V(\mathbf{x})$, $\mathbf{x}\in\mathbb{R}^n$, when $V(\mathbf{x})$ is of type $a(r)+b(r)F(\theta)$, $(r,\theta)\in\mathbb{R}^+\times S^{n-1}$ being spherical coordinates in $\mathbb{R}^n$, and the energy $E>0$.

The method is based on the inequalities

$$\ddot{r}\geqslant -a'(r)-b'(r)F(\theta),$$

$$a(r)+b(r)F(\theta)\leqslant E \tag{33}$$

obtained from the equation $\ddot{\mathbf{x}}=-\nabla V(\mathbf{x})$ written in spherical coordinates and the energy conservation law

$$\frac{\dot{\mathbf{x}}^2}{2}+V(\mathbf{x})=E. \tag{34}$$

Assume that $b(r)<0, b'(r)<0$ or $b(r)>0, b'(r)>0$ (if r is large enough), in these cases, by eliminating $F(\theta)$ in Eq. (33), we get the following inequality:

$$\ddot{r}\geqslant\frac{\mathrm{d}W(r)}{\mathrm{d}r}, \tag{35}$$

where $W(r)=a(r)+E\ln|b(r)|-\int b'(r)a(r)/b(r)\mathrm{d}r$.

Inequalities of type (35) have been studied in Refs. 22 and 23 in order to prove the existence of scattering solutions. The arguments developed in these works yield that open scattering occurs when $W(r)<c$ $(c\in\mathbb{R})$ and $W''(r)<0$ for large values of r.

For example, if $a(r)=-1/r^k$ $(k>1)$ and $b(r)$ satisfies $0<b(r)<k$, $b'(r)>0$, $b''(r)<0$ if $r>R$ then open scattering exists for positive energy. Indeed $W(r)$ is given by

$$W = -\frac{1}{r^k} + E \ln b(r) + \int \frac{b'(r)}{r^k b(r)} \mathrm{d}r. \tag{36}$$

It is not difficult to check that $W(r)$ is bounded above when $r > R$ and furthermore

$$W''(r) = -\frac{k(1+k)}{r^{k+2}} + \left(E + \frac{1}{r^k}\right) \frac{b''(r)b(r) - b'(r)^2}{b(r)^2} - \frac{b'(r)}{r^{k+1}b(r)}. \tag{37}$$

Equation (37) implies that $W''(r) < 0$ (r large) when $E > 0$ and therefore open scattering is guaranteed for positive energy.

The criterion of this section is analytical and very easy to check in specific examples. Other potentials that can be studied with this technique are of type $V(r) = a(r)G(\theta) + b(r)F(\theta)$, $G(\theta) \geqslant c > 0$.

IV. CONCLUSION

In this paper we have studied the robustness of scattering type trajectories when the initial condition is perturbed. We have shown that geometric chaos is possible even for integrable vector fields, thus obtaining a new chaotic phenomenon different from the well-known chaotic scattering. In the phenomenon that we have reported the complexity and nonuniformity of the trajectories is manifested in the (practical) impossibility of determining whether a given solution is bounded or not because scattering and nonscattering orbits are intermingled. We have also found some topological obstructions to the presence of geometric chaos.

The opposite situation to geometric chaos is open scattering. In this case all the orbits through some open set are of scattering type. This situation is desirable from the physical viewpoint because it guarantees that all the orbits will escape to infinity, i.e., there is no uncertainty in the boundedness of the trajectories. We have provided criteria for ensuring open scattering in some particularly relevant situations, like Liouville integrable systems, Stackel separable systems and potential systems with positive energy.

It remains open to ascertain how often is the presence of geometric chaos in Hamiltonian systems (e.g., is geometric chaos robust under small perturbations of the vector field?), and to provide more criteria guaranteeing open scattering.

A one-dimensional system made up of a compressible fluid and several mechanical oscillators, coupled to the acoustic field in the fluid, is analyzed for different settings of the oscillator array. The dynamical models are formulated in terms of singular perturbations of the decoupled dynamics of the acoustic field and the mechanical oscillators. Detailed spectral properties of the generators of the dynamics are given for each model we consider. In the case of a periodic array of mechanical oscillators it is shown that the energy spectrum presents a band structure. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2209553]

INTRODUCTION

In this paper we study the dynamics of a system consisting of one or more mechanical oscillators (the sources) coupled with the acoustic field they produce in the compressible fluid surrounding them.

Classical electromagnetism is perhaps the most well-known case in theoretical physics where all attempts to construct a complete, covariant, causal, divergence-free theory for the evolution of the fields together with their sources were unsuccessful up to now (in fact, it is hard to say that there is a single case in classical or in quantum physics in which this problem was completely solved).

Whereas theories with extended rigid charges are quite well understood both at the classical and the quantum level [see, e.g., a recent book (Spohn, 2004) for a systematic introduction to the subject and for a long list of references], there is no mathematically consistent theory of point charges interacting with their own electromagnetic field. Indeed, Newton equations with a Lorentz force require the fields to be evaluated at the particle positions, and this produces infinities due to the presence of the pointlike sources. These difficulties directly lead to the need of mass renormalization. In his seminal paper, Dirac (1938) [see also Infeld and Wallace (1940), Kijowski (1994), and Marino (2002)], without using a Lorentz force but exploiting the conservation of energy and momentum and considering their flow through a thin tube of radius r, derived an equation for the motion of a charged point particle (the Lorentz-Dirac equation). As Dirac himself pointed out, the equation obtained in the limit $r \downarrow 0$, together with the mass renormalization, leads to the presence of runaway solutions, i.e., solutions for which the acceleration increases beyond any bound even in the absence of external fields.

An approach based on the theory of singular perturbations of the free dynamics was initiated in Noja and Posilicano (1998, 1999) for the case of classical electrodynamics of a point particle in the dipole (or linearized) case. Here the generator of the limit dynamics of both the field and the particle appears to be a singular perturbation of the generator of the free dynamics. The phenom-

[b]Electronic mail: figari@na.infn.it
[c]Electronic mail: andrea.posilicano@uninsubria.it

enological mass plays the role of the parameter describing a suitable family of self-adjoint extensions and the boundary condition naturally appearing in the domain of the generator results to be nothing else that a regularized (and linearized) version of the usual velocity-momentum relation in the presence of an electromagnetic field. In this framework runaway solutions are unavoidable because a negative eigenvalue appears in the spectrum of the generator after mass renormalization.

Our interest in a similar problem in acoustics was prompted by the appearance in 1999 of a paper by Templin (1999). In that paper the author analyzed the dynamics of a simple model of a spherical oscillator interacting with the acoustic field it generates. The existence of a spherically symmetric radiation field (the *acoustic monopole*) makes the acoustic case significantly different from the electromagnetic one. Moreover, the pressure field at the surface of the sphere completely characterizes the contact forces responsible for the interaction between the source and field in the acoustic case.

Templin performed a detailed analysis of the field emitted by the acoustic monopole, explicitly computing both its radiation and near-field components. He noticed that a deduction of the *reaction field* obtained from the emitted radiation power, therefore neglecting the near field component, brings to an equation for the radius of the oscillating sphere showing *runaway solutions*.

In analogy with what was done for the electromagnetic case in Noja and Posilicano (1998), we want to provide a formalization of the problem of a finite or infinite number of oscillators coupled with their acoustic field in terms of singular perturbations of the generator of the free dynamics.

In this paper we will consider only the one-dimensional case. In the abstract setting we will work in the physical model of interaction between the sources and the field will appear as the only possible extension of the free dynamics. The generalization to three dimensions is not straightforward. On the one hand, a model of a physically relevant, symmetric, mechanical oscillator with finite degrees of freedom is lacking. On the other hand, point perturbations of the free dynamics are much more singular in higher dimensions. We plan to discuss the three-dimensional case in future work.

We want to stress an aspect of the dynamical system we analyze here that was extensively studied in different contexts. As an immediate consequence of the third Newton's law and of the assumption of persistent contact between the fluid and the surface of the oscillators, the total energy, sum of the (positive) energy of the acoustic field E_{ac} and the (positive) energy of the oscillators E_{osc}, is a constant of motion. As an immediate consequence, one can exclude the existence of runaway solutions in this case. Moreover, lacking a mechanism of reflection of the acoustic waves at some exterior boundary, the motion of the oscillators should be damped and the energy should finally diffuse over the field degrees of freedom for almost every initial condition. The situation is reminiscent of the one investigated in Soffer and Weinstein (1998a, 1998b, 1999) that concerned the diffusion of energy from bound states to continuous states triggered by time-dependent perturbations in quantum and classical systems. In our system there is no external potential, the interaction being given by internal forces.

This paper is organized as follows. In Sec. I we introduce a list of notations and we briefly recall the equations for the acoustic field. Afterwards we exemplify the problem of the interaction between the field and a source in the completely solvable case of a single wall attracted toward the origin by a linear restoring force.

In Sec. II we analyze the case of a finite number of sources in the framework of the possible extensions of the free dynamics outside the points where the sources are placed. In Sec. III we generalize the construction to the case of infinitely many sources and study the case of sources periodically placed on the real line. We give detailed results on the characteristic band structure of the spectrum of the generator of the dynamics.

To the best of our knowledge, these kinds of systems of oscillators coupled with the acoustic field was never proposed and solved. A remark on the band structure of a similar model is in Griffiths and Steinke (2001).

I. THE ACOUSTIC MONOPOLE IN ONE DIMENSION

We give a detailed description of our model in the simplest case of one oscillator coupled with the acoustic field.

Consider an infinite pipe filled with a nonviscous, compressible fluid. We suppose that there is no friction between the fluid and the pipe, and we choose a coordinate system with the x axis parallel to the axis of the pipe. The mechanical oscillator is made up of a very thin wall of mass M positioned in the pipe perpendicularly to the axis in $x=0$. The thin wall is connected to a spring of elastic constant K. We analyze only one-dimensional cases, hence the acoustic field is described by the pressure field $p(x,t)$ and the velocity field $v(x,t)$. The motion of the mechanical oscillator is described through the position and the velocity of the thin wall.

The field $p(x,t)$ represents deviations of the pressure in point x at time t with respect to an equilibrium pressure P_0. In the linearized acoustics regime the continuity equation, the Newton's second law, and the adiabatic equation of state read

$$\frac{\partial \rho}{\partial t} + \rho_0 \frac{\partial v}{\partial x} = 0, \quad \rho_0 \frac{\partial v}{\partial t} = -\frac{\partial p}{\partial x}, \quad p = a^2 \rho, \tag{1.1}$$

where $\rho(x,t)$ is the deviation of the density in point x at time t with respect to the equilibrium density ρ_0 and a is the velocity of sound in the fluid.

Then we have for $p(x,t)$ and $v(x,t)$ the following coupled differential equations:

$$\frac{\partial p}{\partial t} = -a^2 \rho_0 \frac{\partial v}{\partial x}, \quad \frac{\partial v}{\partial t} = -\frac{1}{\rho_0} \frac{\partial p}{\partial x}. \tag{1.2}$$

We consider only small oscillations of the thin wall around its equilibrium position $x=0$, we indicate with $y(t)$ the displacement of the wall from its equilibrium position at time t, and we suppose that the wall always remains in contact with the fluid:

$$v(y(t),t) = \frac{dy(t)}{dt} \quad \forall\, t \geqslant 0. \tag{1.3}$$

Notice that we consider a wall of zero thickness. We make the approximation $v(y(t),t) \simeq v(0,t)$ and condition (1.3) becomes

$$v(0,t) = \frac{dy(t)}{dt} \quad \forall\, t \geqslant 0. \tag{1.4}$$

The equation of motion for the position of the thin wall $y(t)$ is

$$M\ddot{y}(t) = -Ky(t) - S(p(0^+,t) - p(0^-,t)), \tag{1.5}$$

where S is the area of the transverse section of the pipe and we made the approximation $p(y^{\pm}(t),t) \simeq p(0^{\pm},t)$.

The total energy of the system is given by

$$E_{\text{tot}} = E_{\text{ac}} + E_{\text{osc}}, \tag{1.6}$$

with

$$E_{\text{ac}} = \frac{S}{2a^2\rho_0} \int_{-\infty}^{\infty} p(x)^2 dx + \frac{S\rho_0}{2} \int_{-\infty}^{\infty} v(x)^2 dx, \tag{1.7}$$

$$E_{\text{osc}} = \frac{K}{2} y^2 + \frac{M}{2} \dot{y}^2. \tag{1.8}$$

E_{ac} is the energy stored in the acoustic field while E_{osc} is the energy of the mechanical oscillator.

As the system is isolated, the energy is constant. The motion of the wall produces acoustic waves, thus transferring continuously energy from the oscillator to the acoustic field. One then expects that $y(t)$ decreases to zero when $t\to\infty$.

In spite of being a simple exercise, the exact computation of the solution of problems (1.2), (1.4), and (1.5) and, in turn, of the damping rate of the oscillations rarely appears in textbooks.

In the following we give the solution of the Cauchy problem of coupled ordinary and partial differential equations with time-dependent boundary conditions

$$\begin{aligned}
&\frac{\partial p}{\partial t} = -a^2\rho_0\frac{\partial v}{\partial x} \quad \forall\, t\geqslant 0 \ \ \forall\, x\in\mathbb{R}\setminus\{0\},\\
&\frac{\partial v}{\partial t} = -\frac{1}{\rho_0}\frac{\partial p}{\partial x} \quad \forall\, t\geqslant 0 \ \ \forall\, x\in\mathbb{R}\setminus\{0\},\\
&\ddot{y}(t) = -\omega_0^2 y(t) - \frac{S}{M}(p(0^+,t)-p(0^-,t)) \quad \forall\, t\geqslant 0,\\
&p(x,0) = f(x) \quad \forall\, x\in\mathbb{R}\setminus\{0\},\\
&v(x,0) = g(x) \quad \forall\, x\in\mathbb{R}\setminus\{0\},\\
&y(0) = y_0,\\
&\dot{y}(0) = \dot{y}_0,\\
&v(0,t) = \dot{y}(t) \quad \forall\, t\geqslant 0,
\end{aligned} \tag{1.9}$$

where $f(x)$ and $g(x)$ are two real functions and $\omega_0^2 = K/M$.

Suppose that

$$f(x)\in C_0^2(\mathbb{R}); \quad g(x)\in C_0^2(\mathbb{R}) \quad \text{and} \quad y_0 = \frac{1}{\omega_0^2\rho_0}f'(0); \quad \dot{y}_0 = g(0), \tag{1.10}$$

then the solution of problem (1.9) reads

$$p(x,t) = p_f(x,t) + a\rho_0\,\mathrm{sgn}(x)\,Y\left(t-\frac{|x|}{a}\right), \tag{1.11}$$

$$v(x,t) = v_f(x,t) + Y\left(t-\frac{|x|}{a}\right), \tag{1.12}$$

$$y(t) = -\frac{\dot{v}_f(0,t)}{\omega_0^2} + \frac{\displaystyle\int_0^t \frac{F(t')}{\beta_+}e^{\beta_+(t-t')}dt' - \int_0^t \frac{F(t')}{\beta_-}e^{\beta_-(t-t')}dt'}{\beta_+-\beta_-}, \tag{1.13}$$

where $p_f(x,t)$ and $v_f(x,t)$ are solution of the wave equation in $(-\infty,+\infty)$ with initial conditions $f(x)$ and $g(x)$:

$$p_f(x,t) = \frac{f(x-at)+f(x+at)}{2} + \frac{a\rho_0}{2}(g(x-at)-g(x+at)), \tag{1.14}$$

$$v_f(x,t) = \frac{g(x-at)+g(x+at)}{2} + \frac{1}{2a\rho_0}(f(x-at)-f(x+at)),$$
$$F(t) = -\ddot{v}_f(0,t) - \omega_0^2 v_f(0,t), \tag{1.15}$$

and

$$Y(t) = \frac{\int_0^t F(t')e^{\beta_+(t-t')}dt' - \int_0^t F(t')e^{\beta_-(t-t')}dt'}{\beta_+ - \beta_-}, \tag{1.16}$$

with $\beta_\pm = (-\gamma \pm \sqrt{\gamma^2 - 4\omega_0^2})/2$ with $\gamma = 2a\rho_0 S/M$.

With conditions (1.10) one can easily obtain that $y(t)$ and $\dot{y}(t)$ are both continuous and decrease exponentially to zero with a decay constant $\tau = \gamma/2$.

II. SINGULAR PERTURBATIONS OF THE FREE DYNAMICS

In this section we present a generalization of problem (1.9) formulated in terms of a unitary flow on a space of finite energy.

Let us consider a system of n thin walls positioned in a pipe, perpendicular to its axis. Let $\mathcal{S} = \{s_1, \ldots, s_n\} \subset \mathbb{R}$ be the set of equilibrium positions of the thin walls. The ith thin wall, placed in s_i has mass M_i and is connected to a spring of elastic constant K_i. The acoustic field is described by the pressure field p and the velocity field v. The motion of the walls is described by the displacements y_j from their equilibrium positions and by the corresponding velocities z_j.

The generator of the dynamics, $\hat{A}$, will be defined as a singular perturbation of the skew-adjoint operator A generating the uncoupled evolution of the acoustic field and of the oscillators.

The system of first-order differential equations,

$$\frac{\partial p}{\partial t} = -a^2\rho_0 \frac{\partial v}{\partial x} \quad \forall\, x \in \mathbb{R}, \tag{2.1}$$

$$\frac{\partial v}{\partial t} = -\frac{1}{\rho_0}\frac{\partial p}{\partial x} \quad \forall\, x \in \mathbb{R}, \tag{2.2}$$

$$\frac{dy_j}{dt} = z_j \quad 1 \leqslant j \leqslant n, \tag{2.3}$$

$$\frac{dz_j}{dt} = -\frac{K_j}{M_j} y_j \quad 1 \leqslant j \leqslant n, \tag{2.4}$$

describes, in the linear approximation, the independent evolution of n mechanical oscillators and of the acoustic field.

We want to show first how Eqs. (2.1)–(2.4) define an unitary flow in a complex Hilbert space. To this aim let us consider Eqs. (2.1)–(2.4) for complex functions v, p, y_j, z_j of position and time.

The set of all the displacements and velocities will be represented respectively by the vectors in $\mathbb{C}^n$:

$$\underline{y} = y_1\underline{e}_1 + \cdots + y_n\underline{e}_n, \quad \underline{z} = z_1\underline{e}_1 + \cdots + z_n\underline{e}_n, \tag{2.5}$$

where $\underline{e}_1, \cdots, \underline{e}_n$ is the canonical orthonormal basis in $\mathbb{C}^n$.

Let us denote by $L^2(\mathbb{R})$ the space of square-integrable functions on the real line. $\bar{H}^1(\mathbb{R})$ indicates the homogeneous Sobolev space of locally square-integrable functions with a square-integrable (distributional) derivative, and $H^1(\mathbb{R})$ is the usual Sobolev space $H^1(\mathbb{R}) := \bar{H}^1(\mathbb{R}) \cap L^2(\mathbb{R})$.

Therefore the linear operator A in $L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n$ generating the dynamics (2.1)–(2.4) is defined by

$$A: H^1(\mathbb{R}) \oplus H^1(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n \to L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n, \tag{2.6}$$

$$A(p,v,\underline{y},\underline{z}) := \left(-a^2\rho_0 \frac{dv}{dx}, -\frac{1}{\rho_0}\frac{dp}{dx}, \underline{z}, -\sum_{1\leqslant j\leqslant n} \frac{K_j}{M_j} y_j \underline{e}_j \right), \tag{2.7}$$

where a, ρ_0, K_j, M_j, $1 \leqslant j \leqslant n$, are the positive real constants representing the physical parameters.

In the following, a capital Greek letter will indicate a generic vector $(p,v,\underline{y},\underline{z})$ in $L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n$.

A is a real operator, i.e., it preserves the (physical) linear subspace of real elements

$$\{(p,v,\underline{y},\underline{z}): p(x) \in \mathbb{R}, v(x) \in \mathbb{R}, \underline{y} \in \mathbb{R}^n, \underline{z} \in \mathbb{R}^n\}. \tag{2.8}$$

A is skew-symmetric with respect to the scalar product

$$\langle\langle \Psi_1, \Psi_2 \rangle\rangle \equiv \frac{1}{a^2\rho_0}\langle p_1, p_2\rangle + \rho_0 \langle v_1, v_2\rangle + \frac{1}{S}\sum_{1\leqslant j\leqslant n} K_j \bar{y}_{1j} y_{2j} + M_j \bar{z}_{1j} z_{2j}, \tag{2.9}$$

where $\langle\cdot,\cdot\rangle$ indicates the standard scalar product in $L^2(\mathbb{R})$, $\mathcal{S}$ is the area of the transverse section of the pipe, and denotes complex conjugation. $L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n$ is a Hilbert space with the scalar product (2.9).

The square norm of a vector Ψ, $\|\Psi\|^2 = \langle\langle \Psi, \Psi\rangle\rangle$, defines the total energy of the system in the state Ψ,

$$E_{\text{tot}} = \frac{S}{2}\|\Psi\|^2 = E_{\text{ac}} + E_{\text{osc}}, \tag{2.10}$$

where E_{ac} is the energy stored in the acoustic field while E_{osc} is the energy of the oscillators:

$$E_{\text{ac}} = \frac{\mathcal{S}}{2a^2\rho_0}\langle p,p\rangle + \frac{\rho_0 \mathcal{S}}{2}\langle v,v\rangle; \quad E_{\text{osc}} = \frac{1}{2}\sum_{1\leqslant j\leqslant n} (K_j |y_j|^2 + M_j |z_j|^2). \tag{2.11}$$

For any $\zeta \in \mathbb{C}\backslash i\mathbb{R}$ the resolvent of A is

$$(-A+\zeta)^{-1}(p,v,\underline{y},\underline{z}) = \left(\rho_0 \left(-\frac{d^2}{dx^2} + \frac{\zeta^2}{a^2} \right)^{-1} \left(-\frac{dv}{dx} + \frac{\zeta}{a^2\rho_0} p \right), \right.$$

$$\frac{1}{a^2\rho_0}\left(-\frac{d^2}{dx^2} + \frac{\zeta^2}{a^2} \right)^{-1} \left(-\frac{dp}{dx} + \zeta\rho_0 v \right), \quad \sum_{1\leqslant j\leqslant n} \frac{M_j z_j + \zeta M_j y_j}{K_j + \zeta^2 M_j} \underline{e}_j, \tag{2.12}$$

$$\left. \sum_{1\leqslant j\leqslant n} \frac{-K_j y_j + \zeta M_j z_j}{K_j + \zeta^2 M_j} \underline{e}_j \right).$$

Since

$$\text{Ran}(-A \pm 1) = L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n, \tag{2.13}$$

A is skew-adjoint. Moreover, the essential spectrum of A is purely absolutely continuous and

$$\sigma_{\mathrm{ess}}(A)=\sigma_{\mathrm{ac}}(A)=i\mathbb{R},\quad \sigma_{\mathrm{pp}}(A)=\left\{\pm i\sqrt{\frac{K_j}{M_j}},1\leqslant j\leqslant n\right\}. \tag{2.14}$$

Being skew-adjoint, the operator A describes, by the Stone theorem, the uncoupled evolution of the acoustic field and of the oscillators through the unitary flow $\exp tA$ corresponding to the Cauchy problem for the first-order differential equation

$$\frac{d}{dt}\Psi(t)=A\Psi(t), \tag{2.15}$$

which is equivalent to the system written at the beginning of the section.

Now we consider the linear operator A_0 obtained by restricting A on the set of vectors in its domain satisfying

$$\{v(s_j)=z_j,\ 1\leqslant j\leqslant n\}, \tag{2.16}$$

which represents the kinematic constraint (1.4) at each thin wall. A_0 is a closed, densely defined, skew-symmetric linear operator with defect indices (n,n). We want to characterize the skew-adjoint extensions of A_0. The family of extensions of A_0 can be parameterized by relations $K\subset\mathbb{C}^n\oplus\mathbb{C}^n$, which are skew-symmetric, i.e., such that $K=(IK)^{\perp}$, where $I(\underline{z}_1,\underline{z}_2):=(\underline{z}_2,\underline{z}_1)$ [see, e.g., Gorbachuk and Gorbachuk (1991), Theorem 1.6, Chap. 3, for the analogous self-adjoint case]. A skew-symmetric relation in $\mathbb{C}^n\oplus\mathbb{C}^n$ extends the notion of the graph of a skew-symmetric operator $\Theta:\mathbb{C}^n\to\mathbb{C}^n$ through the relation $K=\{(\underline{z},\Theta\underline{z}),\underline{z}\in\mathbb{C}^n\}$. In order to be a candidate to describe the interacting dynamics of the system under analysis, a skew-adjoint extension of A_0 must be local and real, i.e., it must generate a coupling between the fields evaluated in s_j and the jth oscillator, $1\leqslant j\leqslant n$, and it must preserve the linear space of physical data defined in (2.8). The only admissible extension different from A itself will be the one corresponding to the graph of the zero operator, $\Theta=0$. The next theorem completely characterizes such an extension.

Theorem 2.1: *The only local, real, and skew-adjoint extension of A_0 is given by*

$$\hat{A}:D(\hat{A})\subset L^2(\mathbb{R})\oplus L^2(\mathbb{R})\oplus\mathbb{C}^n\oplus\mathbb{C}^n\to L^2(\mathbb{R})\oplus L^2(\mathbb{R})\oplus\mathbb{C}^n\oplus\mathbb{C}^n, \tag{2.17}$$

$$D(\hat{A})=\{\Psi\equiv(p,v,\underline{y},\underline{z}):p\in L^2(\mathbb{R})\cap H^1(\mathbb{R}\setminus\mathcal{S}),v\in H^1(\mathbb{R}),\underline{y}\in\mathbb{C}^n,\underline{z}\in\mathbb{C}^n,p(s_i^+)-p(s_i^-)=\sigma_i,v(s_j)=z_j,\underline{\sigma}\in\mathbb{C}^n\}, \tag{2.18}$$

$$\hat{A}(p,v,\underline{y},\underline{z}):=\left(-a^2\rho_0\frac{dv}{dx},-\frac{1}{\rho_0}\frac{dp_0}{dx},\underline{z},-\sum_{1\leqslant j\leqslant n}\left(\frac{K_j}{M_j}y_j+\frac{S}{M_j}\sigma_j\right)\underline{e}_j\right). \tag{2.19}$$

Here $p_0\in\bar{H}^1(\mathbb{R})$,

$$p_0(x):=p(x)-\frac{1}{2}\sum_{1\leqslant j\leqslant n}\sigma_j\,\mathrm{sgn}(x-s_j), \tag{2.20}$$

denotes the regular part of p. The resolvent of $\hat{A}$ is given by

$$(-\hat{A}+\zeta)^{-1}=(-A+\zeta)^{-1}+\sum_{1\leqslant i,j\leqslant n}(\Gamma(\zeta)^{-1})_{ij}G^i_\zeta\otimes\breve{G}^j_{\bar{\zeta}},\quad \zeta\in\mathbb{C}\setminus i\mathbb{R}, \tag{2.21}$$

where

$$\Gamma(\zeta)_{ij}:=-\zeta\left(\pm\frac{e^{\mp\zeta|s_i-s_j|/a}}{2a\rho_0\zeta}+\frac{S\delta_{ij}}{K_j+\zeta^2M_j}\right),\quad \pm\,\mathrm{Re}\,\zeta>0 \tag{2.22}$$

and

$$\breve{G}^j_\zeta(x) = \left(\mathcal{G}'_\zeta(x-s_j), \frac{\zeta}{a^2\rho_0}\mathcal{G}_\zeta(x-s_j), \frac{S}{K_j+\zeta^2 M_j}\underline{e}_j, \frac{-\zeta S}{K_j+\zeta^2 M_j}\underline{e}_j \right), \tag{2.23}$$

$$G^j_\zeta(x) = \left(-\mathcal{G}'_\zeta(x-s_j), \frac{\zeta}{a^2\rho_0}\mathcal{G}_\zeta(x-s_j), \frac{-S}{K_j+\zeta^2 M_j}\underline{e}_j, \frac{-\zeta S}{K_j+\zeta^2 M_j}\underline{e}_j \right), \tag{2.24}$$

$$\mathcal{G}_\zeta(x) = \pm\frac{a}{2\zeta}e^{\mp\zeta|x|/a}, \quad \mathcal{G}'_\zeta(x) = -\frac{1}{2}\,\mathrm{sgn}(x)e^{\mp\zeta|x|/a}, \quad \pm\,\mathrm{Re}\,\zeta > 0. \tag{2.25}$$

Proof: Since iA_0 is a closed, densely defined, symmetric operator with defect indices (n,n), all its self-adjoint extensions can be obtained by the famed von Neumann theory on self-adjoint extensions [see, e.g., Theorem X.2 in Reed and Simon (1975)]. However, since A_0 is obtained by restricting the skew-adjoint operator A to the kernel of the continuous, surjective linear operator

$$\tau: H^1(\mathbb{R}) \oplus H^1(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n \to \mathbb{C}^n, \tag{2.26}$$

$$\tau(p,v,\underline{y},\underline{z}) := \sum_{1\leqslant j\leqslant n} (v(s_j)-z_j)\underline{e}_j, \tag{2.27}$$

it is easier to make use of the (equivalent) procedure developed in Posilicano (2001) [also see the Appendix in Posilicano (in press) for a compact review]. Here below we provide the (almost) self-contained construction of the skew-adjoint extensions of A_0 by using such a procedure.

Given the map τ we can define the bounded linear operator

$$\breve{G}(\zeta) := \tau(-A+\zeta)^{-1}: L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n \to \mathbb{C}^n. \tag{2.28}$$

By the relation

$$\breve{G}(\zeta)(p,v,\underline{y},\underline{z}) = \sum_{1\leqslant j\leqslant n} \langle\langle \breve{G}^j_{\overline{\zeta}}, (p,v,\underline{y},\underline{z})\rangle\rangle \underline{e}_j, \quad 1\leqslant j\leqslant n, \tag{2.29}$$

$\breve{G}(\zeta)$ is represented by the vector $\breve{G}^j_\zeta$. By $\breve{G}(\zeta)$ we define the bounded linear operator

$$G(\zeta) := -\breve{G}(-\overline{\zeta})^*: \mathbb{C}^n \to L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n, \tag{2.30}$$

where $\breve{G}(\zeta)^*$ indicates the adjoint of $\breve{G}(\zeta)$. The action of $G(\zeta)$ on $\mathbb{C}^n$ is given by

$$G(\zeta)\underline{e}_j = G^j_\zeta, \quad 1\leqslant j\leqslant n. \tag{2.31}$$

Let us notice that

$$\mathrm{Ran}(G(\zeta)) \cap H^1(\mathbb{R}) \oplus H^1(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n = \{0\}. \tag{2.32}$$

Now we consider the linear operator $\Gamma_\Theta(\zeta): \mathbb{C}^n \to \mathbb{C}^n$ represented by the matrix $\Theta_{ij} + \Gamma(\zeta)_{ij}$, where $\Theta: \mathbb{C}^n \to \mathbb{C}^n$ is skew-Hermitian. By noticing that

$$\Gamma_\Theta(\zeta) - \Gamma_\Theta(\xi) = \tau(G(\xi) - G(\zeta)) \tag{2.33}$$

and that, by the definition of $G(\zeta)$ and by the first resolvent identity,

$$(\zeta-\xi)(-A+\xi)^{-1}G(\zeta) = G(\xi) - G(\zeta), \tag{2.34}$$

one has that $\Gamma_\Theta(\zeta)$ satisfies the identity

$$\Gamma_\Theta(\zeta) - \Gamma_\Theta(\xi) = (\zeta - \xi)\breve{G}(\xi)G(\zeta). \tag{2.35}$$

By the definitions of $\breve{G}(\zeta)$ and $G(\zeta)$, by (2.35) and by $\Gamma_\Theta(\bar{\zeta})^* = -\Gamma_\Theta(-\zeta)$, it follows that $\det \Gamma_\Theta(\zeta) \neq 0$ for any $\zeta \in \mathbb{C}\backslash i\mathbb{R}$ and that

$$\hat{R}(\zeta) := (-A + \zeta)^{-1} + G(\zeta)\Gamma_\Theta(\zeta)^{-1}\breve{G}(\zeta) \tag{2.36}$$

satisfies the first resolvent identity

$$(\zeta - \xi)\hat{R}(\xi)\hat{R}(\zeta) = \hat{R}(\xi) - \hat{R}(\zeta) \tag{2.37}$$

and

$$\hat{R}(\bar{\zeta})^* = -\hat{R}(-\zeta) \tag{2.38}$$

[for details see Posilicano (2001)]. Moreover, $\hat{R}(\zeta)$ is injective by (2.32). Therefore

$$\hat{A} := -\hat{R}(\zeta)^{-1} + \zeta \tag{2.39}$$

is well defined on

$$D(\hat{A}) := \mathrm{Ran}(\hat{R}(\zeta)). \tag{2.40}$$

By (2.37) such a definition of $\hat{A}$ is ζ independent. $\hat{A}$ is skew-symmetric by (2.38) and is skew-adjoint since

$$\mathrm{Ran}(-\hat{A} \pm 1) = L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n \tag{2.41}$$

by construction.

Since we require $\hat{A}$ to be real, i.e., to preserve the linear space (2.8), we have to restrict the choice of Θ to real, skew-symmetric matrices. Off-diagonal elements in the matrix Θ would correspond to nonlocal couplings between the pressure field and the oscillators. Since we are looking for local interactions the only admissible choice for the skew-symmetric matrix Θ is $\Theta = 0$.

By (2.40) $(p, v, \underline{y}, \underline{z}) \in D(\hat{A})$ if and only if

$$p(x) = p_\zeta(x) - \sum_{1 \leq i,j \leq n} (\Gamma(\zeta)^{-1})_{ij}(v_\zeta(s_j) - z_{\zeta j})\mathcal{G}'_\zeta(x - s_i), \tag{2.42}$$

$$v(x) = v_\zeta(x) + \frac{\zeta}{a^2\rho_0} \sum_{1 \leq i,j \leq n} (\Gamma(\zeta)^{-1})_{ij}(v_\zeta(s_j) - z_{\zeta j})\mathcal{G}'_\zeta(x - s_i), \tag{2.43}$$

$$\underline{y} = \underline{y}_\zeta - S \sum_{1 \leq i,j \leq n} (\Gamma(\zeta)^{-1})_{ij} \frac{v_\zeta(s_j) - z_{\zeta j}}{K_i + \zeta^2 M_i} \underline{e}_i, \tag{2.44}$$

$$\underline{z} = \underline{z}_\zeta - \zeta S \sum_{1 \leq i,j \leq n} (\Gamma(\zeta)^{-1})_{ij} \frac{v_\zeta(s_j) - z_{\zeta j}}{K_i + \zeta^2 M_i} \underline{e}_i, \tag{2.45}$$

with $(p_\zeta(x), v_\zeta(x), \underline{y}_\zeta, \underline{z}_\zeta) \in D(A)$. Posing

$$\hat{A}(p, v, \underline{y}, \underline{z}) \equiv (\hat{A}_1(p, v, \underline{y}, \underline{z}), \hat{A}_2(p, v, \underline{y}, \underline{z}), \hat{A}_3(p, v, \underline{y}, \underline{z}), \hat{A}_4(p, v, \underline{y}, \underline{z})), \tag{2.46}$$

the action of $\hat{A}$ on $(p, v, \underline{y}, \underline{z})$ is given by

$$[\hat{A}_1(p,v,\underline{y},\underline{z})](x) = -a^2\rho_0\frac{dv_\zeta}{dx}(x) - \zeta\sum_{1\leqslant i,j\leqslant n}(\Gamma(\zeta)^{-1})_{ij}(v_\zeta(s_j)-z_{\zeta j})\mathcal{G}'_\zeta(x-s_i), \tag{2.47}$$

$$[\hat{A}_2(p,v,\underline{y},\underline{z})](x) = -\frac{1}{\rho_0}\frac{dp_\zeta}{dx}(x) + \frac{\zeta^2}{a^2\rho_0}\sum_{1\leqslant i,j\leqslant n}(\Gamma(\zeta)^{-1})_{ij}(v_\zeta(s_j)-z_{\zeta j})\mathcal{G}'_\zeta(x-s_i), \tag{2.48}$$

$$\hat{A}_3(p,v,\underline{y},\underline{z}) = \underline{z}_\zeta - \zeta S\sum_{1\leqslant i,j\leqslant n}(\Gamma(\zeta)^{-1})_{ij}\frac{v_\zeta(s_j)-z_{\zeta j}}{K_i+\zeta^2 M_i}\underline{e}_i, \tag{2.49}$$

$$\hat{A}_4(p,v,\underline{y},\underline{z}) = -\sum_{1\leqslant j\leqslant n}\frac{K_j}{M_j}y_{\zeta j}\underline{e}_j - \zeta^2 S\sum_{1\leqslant i,j\leqslant n}(\Gamma(\zeta)^{-1})_{ij}\frac{v_\zeta(s_j)-z_{\zeta j}}{K_i+\zeta^2 M_i}\underline{e}_i. \tag{2.50}$$

By the definitions of $D(\hat{A})$ and $\Gamma(\zeta)$ one has

$$\hat{A}_1(p,v,\underline{y},\underline{z}) = -a^2\rho_0\frac{dv}{dx}, \tag{2.51}$$

$$\hat{A}_3(p,v,\underline{y},\underline{z}) = \underline{z}, \tag{2.52}$$

and, defining

$$\sigma_i := p(s_i^+) - p(s_i^-) = \sum_{1\leqslant j\leqslant n}(\Gamma(\zeta)^{-1})_{ij}(v_\zeta(s_j)-z_{\zeta j}), \tag{2.53}$$

formula (2.50) becomes

$$\hat{A}_4(p,v,\underline{y},\underline{z}) = -\sum_{1\leqslant j\leqslant n}\frac{K_j}{M_j}y_{\zeta j}\underline{e}_j - \zeta^2 S\sum_{1\leqslant i\leqslant n}\frac{\sigma_i}{K_i+\zeta^2 M_i}\underline{e}_i \tag{2.54}$$

$$= -\sum_{1\leqslant j\leqslant n}\left(\frac{K_j}{M_j}y_j + \frac{S}{M_j}\sigma_j\right)\underline{e}_j. \tag{2.55}$$

Then, posing

$$p(x) = p_\zeta(x) - \sum_{1\leqslant j\leqslant n}\sigma_j\mathcal{G}'_\zeta(x-s_j) = p_0(x) + \frac{1}{2}\sum_{1\leqslant j\leqslant n}\sigma_j\,\mathrm{sgn}(x-s_j), \tag{2.56}$$

one obtains

$$[\hat{A}_2(p,v,\underline{y},\underline{z})](x) = -\frac{1}{\rho_0}\frac{dp_0}{dx}(x) - \sum_{1\leqslant j\leqslant n}\frac{\sigma_j}{\rho_0}\left(\frac{d}{dx}\frac{|x-s_j|}{2(x-s_j)} - \left(-\frac{d^2}{dx^2}+\frac{\zeta^2}{a^2}\right)\mathcal{G}_\zeta(x-y_j)\right) \tag{2.57}$$

$$= -\frac{1}{\rho_0}\frac{dp_0}{dx}. \tag{2.58}$$

Finally

$$v(s_k) = v_\zeta(s_k) + \frac{\zeta}{a^2\rho_0} \sum_{1\leqslant i,j\leqslant n} (\Gamma(\zeta)^{-1})_{ij}(v_\zeta(s_j) - z_{\zeta j}) \frac{a}{\pm 2\zeta} e^{\mp\zeta|s_k - s_i|/a} \tag{2.59}$$

$$= v_\zeta(s_k) - \sum_{1\leqslant i,j\leqslant n} (\Gamma(\zeta)^{-1})_{ij}(v_\zeta(s_j) - z_{\zeta j}) \left((\Gamma(\zeta))_{ki} + \frac{\zeta S \delta_{ki}}{K_i + \zeta^2 M_i} \right) \tag{2.60}$$

$$= z_{\zeta k} - \zeta S \sum_{1\leqslant j\leqslant n} (\Gamma(\zeta)^{-1})_{kj} \frac{v_\zeta(s_k) - z_{\zeta k}}{K_k + \zeta^2 M_k} = z_k. \tag{2.61}$$

□

By the previous theorem the differential equation

$$\frac{d}{dt}\Psi(t) = \hat{A}\Psi(t) \tag{2.62}$$

is equivalent to the system of equations

$$\frac{\partial p}{\partial t} = -a^2\rho_0 \frac{\partial v}{\partial x}, \tag{2.63}$$

$$\frac{\partial v}{\partial t} = -\frac{1}{\rho_0}\frac{\partial p_0}{\partial x} \equiv -\frac{1}{\rho_0}\left(\frac{\partial p}{\partial x} - \sum_{1\leqslant j\leqslant n} \sigma_j \delta_{s_j} \right), \tag{2.64}$$

$$\frac{d\underline{y}}{dt} = \underline{z}, \tag{2.65}$$

$$\frac{d\underline{z}}{dt} = -\sum_{1\leqslant j\leqslant n} \left(\frac{K_j}{M_j} y_j + \frac{S}{M_j}\sigma_j \right) \underline{e}_j, \tag{2.66}$$

and the corresponding Cauchy problem generates the strongly continuous unitary group of evolution $\exp t\hat{A}$ on $L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \mathbb{C}^n \oplus \mathbb{C}^n$, which preserves $D(\hat{A})$. Here δ_{s_j} denotes the Dirac mass at the point s_j and σ_j [see (2.18)] is the pressure jump at s_j.

It is worth noting that the only real, skew-adjoint extension of the free operator A restricted to the space of the vectors $(p, v, \underline{y}, \underline{z})$ such that $v(s_i, t) = z_i$ corresponds to the relevant physical coupling between the pressure field and the oscillators.

The next result will be useful in the spectral analysis of $\hat{A}$.

Lemma 2.2: The matrix

$$\Gamma_\pm(\lambda)^{-1} := \lim_{\varepsilon \downarrow 0} \Gamma(\lambda \pm \varepsilon)^{-1} \tag{2.67}$$

is well defined for any $\lambda \in i\mathbb{R}\backslash\{0\}$.

Proof: We give the proof only for the matrix $\Gamma_+(\lambda)$. The proof for $\Gamma_-(\lambda)$ is analogous.

Let the matrix $\Gamma_+(\zeta)$ be the analytic continuation to $\mathbb{C}\backslash\cup_{j=1}^n\{\pm i\sqrt{K_j/M_j}\}$ of $\Gamma(\zeta)$ defined for $\mathrm{Re}\,\zeta > 0$ in (2.22). Suppose that $s_i > s_j$ if $i > j$, then

$$\Gamma_+(\zeta) = -\Pi(\zeta) - T(\zeta), \tag{2.68}$$

where Π is the operator

$$\Pi = (\underline{\phi}^-(\zeta) \otimes \underline{\phi}^+(\bar{\zeta})) \tag{2.69}$$

with $\underline{\phi}^{\pm}(\zeta) = \Sigma_i e^{\pm \zeta s_i/a}/\sqrt{2a\rho_0}\underline{e}_i$. While $T(\zeta)$ is the upper triangular matrix

$$T(\zeta)_{ij} = \begin{cases} \dfrac{\zeta S \delta_{ij}}{K_i + \zeta^2 M_i} + \dfrac{\sinh \zeta(s_i - s_j)}{a\rho_0} & i \leqslant j \\ 0 & i > j, \end{cases} \tag{2.70}$$

we use the formula

$$\Gamma_+(\zeta)^{-1} = -\frac{1}{\Pi(\zeta) + T(\zeta)} = -\frac{1}{T(\zeta)} + \frac{1}{T(\zeta)}\Pi(\zeta)\frac{1}{\Pi(\zeta) + T(\zeta)} \tag{2.71}$$

$$= -\sum_{n=0}^{\infty} \frac{(-1)^n}{T(\zeta)}\left(\Pi(\zeta)\frac{1}{T(\zeta)}\right)^n, \tag{2.72}$$

valid for all ζ for which the series converges.

Matrix $T(\zeta)$ is invertible and its inverse $T(\zeta)^{-1}$ is a lower triangular matrix with $(T(\zeta)^{-1})_{ii} = 1/(T(\zeta))_{ii}$. The eigenvalues of $T(\zeta)^{-1}$ are $1/(T(\zeta))_{ii}$ and we can write

$$T(\zeta)^{-1} = D(\zeta)\tilde{T}(\zeta)^{-1}D(\zeta)^{-1}, \tag{2.73}$$

where $D(\zeta)$ is a unitary matrix, analytic for $\zeta \in \mathbb{C}\backslash\{0\}$, and

$$(\tilde{T}(\zeta)^{-1})_{ij} = \frac{1}{(T(\zeta))_{ii}}\delta_{ij} = \frac{K_i + \zeta^2 M_i}{\zeta S}\delta_{ij}. \tag{2.74}$$

We obtain for $\Gamma_+(\zeta)^{-1}$ the expression

$$\Gamma_+(\zeta)^{-1} = -D(\zeta)\sum_{n=0}^{\infty}(-1)^n(\underline{\psi}(\zeta) \otimes \underline{\chi}(\zeta))^n\tilde{T}(\zeta)^{-1}D(\zeta)^{-1}, \tag{2.75}$$

with

$$(\underline{\psi}(\zeta))_i = \frac{K_i + \zeta^2 M_i}{\zeta S}(D(\zeta)^{-1}\underline{\phi}^-(\zeta))_i, \tag{2.76}$$

$$(\underline{\chi}(\zeta))_i = (D(\zeta)^{-1}\underline{\phi}^+(\bar{\zeta}))_i. \tag{2.77}$$

Then

$$\Gamma_+(\zeta)^{-1} = -\frac{1}{T(\zeta)} + \sum_{n=0}^{\infty}(-1)^n(\langle\underline{\chi}(\zeta), \underline{\psi}(\zeta)\rangle_{\mathbb{C}^n})^n D(\zeta)\underline{\psi}(\zeta) \otimes \underline{\chi}(\zeta)\tilde{T}(\zeta)^{-1}D(\zeta)^{-1}. \tag{2.78}$$

For all ζ for which the series converges, one has

$$\Gamma_+(\zeta)^{-1} = -\frac{1}{T(\zeta)} + \frac{D(\zeta)\underline{\psi}(\zeta) \otimes \underline{\chi}(\zeta)\tilde{T}(\zeta)^{-1}D(\zeta)^{-1}}{1 + \langle\underline{\chi}(\zeta), \underline{\psi}(\zeta)\rangle_{\mathbb{C}^n}}. \tag{2.79}$$

Consider the scalar product in $\mathbb{C}^n$:

$$\langle \underline{\chi}(\zeta), \underline{\psi}(\zeta)\rangle_{\mathbb{C}^n} = \sum_{i=1}^{n} \overline{(D(\zeta)^{-1}\underline{\phi}^{+}(\bar{\zeta}))_i} \frac{K_i + \zeta^2 M_i}{\zeta S} (D(\zeta)^{-1}\underline{\phi}^{-}(\zeta))_i. \tag{2.80}$$

Notice that, for $\lambda \in i\mathbb{R}\backslash\{0\}$, $\langle \underline{\chi}(\lambda), \underline{\psi}(\lambda)\rangle_{\mathbb{C}^n} \in i\mathbb{R}$ and

$$-i\langle \underline{\chi}(\lambda), \underline{\psi}(\lambda)\rangle_{\mathbb{C}^n} \to +\infty \quad \text{for } \lambda \to +i\infty, \tag{2.81}$$

$$-i\langle \underline{\chi}(\lambda), \underline{\psi}(\lambda)\rangle_{\mathbb{C}^n} \to -\infty \quad \text{for } \lambda \to i0^{+}. \tag{2.82}$$

Then there exists at least one point $\lambda \in i\mathbb{R}$ in which $\langle \underline{\chi}(\lambda), \underline{\psi}(\lambda)\rangle_{\mathbb{C}^n} = 0$. In a neighborhood of this point the series converges and defines an analytic function. By (2.79) and (2.80) it is clear that $\Gamma_+(\zeta)^{-1}$ exists for any $\zeta \in \mathbb{C}\backslash\{0\}$. The same relations show that one can put $\Gamma_+(\zeta)^{-1} := 0$ if $\zeta = i\sqrt{K_j/M_j}$, $j = 1, \ldots, n$. □

The following theorem completely characterizes the spectrum of $\hat{A}$.

Theorem 2.3: *The essential spectrum of $\hat{A}$ is purely absolutely continuous and*

$$\sigma_{\mathrm{ess}}(\hat{A}) = \sigma_{\mathrm{ac}}(\hat{A}) = i\mathbb{R}, \quad \sigma_{pp}(\hat{A}) = \{0\}. \tag{2.83}$$

Any vector of the kind

$$\left(\frac{1}{2}\sum_{1\le j\le n} \sigma_j \operatorname{sgn}(x - s_j), 0, -\sum_{1\le j\le n} \frac{S}{K_j}\sigma_j \underline{e}_j, \underline{0}\right), \tag{2.84}$$

with

$$\sum_{1\le j\le n} \sigma_j = 0, \tag{2.85}$$

is an eigenvector corresponding to the $(n-1)$-fold degenerate eigenvalue $\lambda = 0$.

The generalized eigenfunctions $\hat{\Phi}^{\pm}(\lambda)$ corresponding to the point of the absolutely continuous spectrum relative to right $(+)$ and left $(-)$ incidence are given by

$$\hat{\Phi}^{\pm}(\lambda, x) = (\hat{\phi}_p^{\pm}(\lambda, x), \hat{\phi}_v^{\pm}(\lambda, x), \hat{\underline{\phi}}_{\underline{y}}^{\pm}(\lambda), \hat{\underline{\phi}}_{\underline{z}}^{\pm}(\lambda)), \quad \lambda \in i\mathbb{R}, \tag{2.86}$$

$$\hat{\phi}_p^{\pm}(\lambda, x) = Ce^{\pm\lambda x/a} \mp \frac{C}{2a\rho_0} \sum_{1\le i,j\le n} (\Gamma_+(\lambda)^{-1})_{ij} e^{\pm\lambda s_j/a} \operatorname{sgn}(x - s_i) e^{-\lambda|x - s_i|/a}, \tag{2.87}$$

$$\hat{\phi}_v^{\pm}(\lambda, x) = \mp C\frac{e^{\pm\lambda x/a}}{a\rho_0} \mp \frac{C}{2a^2\rho_0^2} \sum_{1\le i,j\le n} (\Gamma_+(\lambda)^{-1})_{ij} e^{\pm\lambda s_j/a} e^{-\lambda|x - s_i|/a}, \tag{2.88}$$

$$\hat{\underline{\phi}}_{\underline{y}}^{\pm}(\lambda) = \pm\frac{SC}{a\rho_0} \sum_{1\le i,j\le n} (\Gamma_+(\lambda)^{-1})_{ij} \frac{e^{\pm\lambda s_j/a}}{K_i + \lambda^2 M_i} \underline{e}_i, \tag{2.89}$$

$$\hat{\underline{\phi}}_{\underline{z}}^{\pm}(\lambda) = \pm\frac{\lambda SC}{a\rho_0} \sum_{1\le i,j\le n} (\Gamma_+(\lambda)^{-1})_{ij} \frac{e^{\pm\lambda s_j/a}}{K_i + \lambda^2 M_i} \underline{e}_i, \tag{2.90}$$

with $C = \sqrt{a\rho_0/(4\pi)}$.

Proof: For $\zeta \in \rho(A) \cap \rho(\hat{A})$, $(-\hat{A} + \zeta)^{-1} - (-A + \zeta)^{-1}$ is of finite rank; then from Weyl's criterion [see, e.g., Reed and Simon (1978) Theorem XIII.14] one has $\sigma_{\mathrm{ess}}(\hat{A}) = \sigma_{\mathrm{ess}}(A) = i\mathbb{R}$. Moreover, by the Birman-Kato invariance principle, the wave operators $\Omega_{\pm}(\hat{A}, A)$ exist and are complete [see,

e.g., Reed and Simon (1979), Corollary 2 to Theorem XI.11]. Thus $\sigma_{\mathrm{ac}}(\hat{A})=\sigma_{\mathrm{ac}}(A)$.

Let $\hat{\mu}_{\Psi}^{sc}$ be the singular continuous part of the spectral measure on $i\mathbb{R}$ corresponding to $\hat{A}$ and Ψ. Since $\|\breve{G}(\zeta)\Psi\|<\infty$ for all $\zeta\in\mathbb{C}\backslash\sigma_{pp}(A)$ and for all $\Psi\in D$,

$$D:=\{\Psi\equiv(p,v,\underline{y},\underline{z}):p\in L^1(\mathbb{R})\cap L^2(\mathbb{R}),\ v\in L^1(\mathbb{R})\cap L^2(\mathbb{R})\},\tag{2.91}$$

by Lemma 2 and Reed and Simon (1978), Theorem XIII.19, one has supp $\hat{\mu}_{\Psi}^{sc}\subseteq\{0\}\cup\sigma_{pp}(A)$, i.e., supp $\hat{\mu}_{\Psi}^{sc}=\emptyset$, since $\hat{\mu}_{\Psi}^{sc}$ has no atoms by its definition. Since D is dense this gives $\sigma_{sc}(\hat{A})=\emptyset$.

One can check that any vector Ψ of the kind (2.84) is in the domain of $\hat{A}$ and solves the equation $\hat{A}\Psi=0$. The degeneration of eigenvalue $\{0\}$ follows from condition (101).

Suppose now $\lambda\in i\mathbb{R}\backslash\{0\}$ and consider the equation $\hat{A}\Psi=\lambda\Psi$. This produces, if $\Psi\equiv(p,v,\underline{y},\underline{z})$, the equation

$$v''-\frac{\lambda^2}{a^2}v=-\frac{\lambda}{a^2\rho_0}\sum_{1\leqslant j\leqslant n}\sigma_j\delta_{s_j},\tag{2.92}$$

with $\sigma_i\in\mathbb{C}$, $i=1,\ldots,n$, which has no square integrable solution.

The expression for the generalized eigenfunctions is a consequence of the Stone's formula [see, e.g., Reed and Simon (1972), Theorem VII.13], which gives the generalized expansion formula

$$\Psi=\mathrm{s}-\lim_{a\downarrow-\infty,b\uparrow\infty}\mathrm{s}-\lim_{\varepsilon\downarrow0}\frac{1}{2\pi}\int_a^b[\hat{R}(\lambda+\varepsilon)-\hat{R}(\lambda-\varepsilon)]\Psi d\lambda.\tag{2.93}$$

□

In the following lemma the asymptotic behavior of the oscillations of the thin walls is characterized. It is proved that the oscillators relax (as $|t|\to\infty$) toward their equilibrium positions for any initial data orthogonal to the eigenspace relative to eigenvalue zero. For example, this is true for any initial datum of the kind $\Psi_0\equiv(p,v,\underline{0},\underline{z})$, where the support of p is outside the interval containing the points $s_1,\cdots,s_n$ which denote the equilibrium position of the walls.

Lemma 2.4: Given Ψ_0 orthogonal to the eigenspace relative to eigenvalue zero, let us denote by $(\underline{y}(t),\underline{z}(t))$ the projection onto $\mathbb{C}^n\oplus\mathbb{C}^n$ of $e^{t\hat{A}}\Psi_0$. Then

$$\lim_{|t|\to\infty}\|\underline{y}(t)\|_{\mathbb{C}^n}=0\quad\text{and}\quad\lim_{|t|\to\infty}\|\underline{z}(t)\|_{\mathbb{C}^n}=0.$$

Proof: Let $\hat{P}(dk)$ be the projection-valued measure corresponding to the self-adjoint operator $-i\hat{A}$. Since Ψ_0 is in the absolutely continuous subspace, for any Ψ the bounded complex measure $\langle\langle\Psi,\hat{P}(dk)\Psi_0\rangle\rangle$ is absolutely continuous with respect to the Lebesgue measure and hence its density belongs to $L^1(\mathbb{R})$. Thus by the spectral theorem and Riemann-Lebesgue lemma,

$$\lim_{|t|\to\infty}\langle\langle\Psi,e^{t\hat{A}}\Psi_0\rangle\rangle=\lim_{|t|\to\infty}\int_{\mathbb{R}}e^{-itk}\langle\langle\Psi,\hat{P}(dk)\Psi_0\rangle\rangle=0.\tag{2.94}$$

By taking $\Psi=(0,0,\underline{e}_i,\underline{0})$ and $\Psi=(0,0,\underline{0},\underline{e}_i)$, $i=1,\ldots,n$, one then obtains

$$\lim_{|t|\to\infty}y_i(t)=0\quad\text{and}\quad\lim_{|t|\to\infty}z_i(t)=0.\tag{2.95}$$

□

In order to obtain a more precise estimate on the asymptotic behavior of solutions of Eq. (2.62), for particular initial conditions, a detailed analysis of $\Gamma(\lambda)^{-1}$ is required. For example, in specific cases one can prove the existence of frequencies that are totally transmitted by the array of oscillators.

III. KRONIG-PENNEY MODEL IN ACOUSTICS

It is possible to extend the previous construction to the case of an array of infinitely many oscillators. We prove that in the case of a periodic array of identical oscillators the energy spectrum shows a band structure.

As a first step we define the operator $\hat{A}$ introduced in Sec. II when $\mathcal{S}=\{s_1,s_2,\ldots\}$ is a denumerable set such that

$$d := \inf_{i\neq j}|s_i - s_j| > 0 \quad i,j \in \mathbb{N}. \tag{3.1}$$

Defining the linear map

$$\tau(p,v,\underline{y},\underline{z}) := \sum_{j=1}^{\infty} (v(s_j) - z_j)\underline{e}_j, \tag{3.2}$$

where $\{\underline{e}_j\}_1^\infty$ is the usual complete orthonormal system for ℓ^2, one has the following.

Lemma 3.1: τ is bounded as a map on $H^1(\mathbb{R})\oplus H^1(\mathbb{R})\oplus \ell^2\oplus\ell^2$ to ℓ^2.

Proof: We will follow closely Albeverio *et al.* (2005). Let $\{I_j\}_1^\infty$ be a partition of $\mathbb{R}$ and let $K(x-y)$ be the kernel of $(-\Delta+1)^{-1/2}$. Since

$$v(x) = \sum_{j=1}^{\infty} \int_{I_j} K(x-y)[(-\Delta+1)^{1/2}v](y)dy, \tag{3.3}$$

to prove the lemma amounts to show that the infinite matrix

$$M_{ij} := \left(\int_{I_j} K(x-s_i)^2 dx\right)^{1/2} \tag{3.4}$$

corresponds to a bounded linear operator M on ℓ^2. By Lemma C.3 in Albeverio *et al.* (2005), one has

$$\|M\|^2_{\ell^2,\ell^2} \leqslant \sup_i \sum_{j=1}^{\infty} \left(\int_{I_j} K(x-s_i)^2 dx\right)^{1/2} \sup_j \sum_{i=1}^{\infty} \left(\int_{I_j} K(x-s_i)^2 dx\right)^{1/2}. \tag{3.5}$$

Since

$$\frac{1}{\sqrt{x}} = \frac{2}{\pi}\int_0^\infty \frac{d\mu}{x+\mu^2}, \quad x>0,$$

by functional calculus one has

$$K(x-y) = \frac{1}{\pi}\int_0^\infty \frac{e^{-\sqrt{1+\mu^2}|x-y}}{\sqrt{1+\mu^2}} d\mu. \tag{3.6}$$

By taking $I_j=[s_j-\varepsilon_j, s_j+\delta_j)$, where ε_j is one half the distance between s_j and the preceding point and δ_j is one half the distance between s_j and the successive point, a straightforward calculation leads to

$$\int_{I_j} K(x-s_i)^2 dx \leqslant \frac{2}{d^2\pi^2} e^{-|s_i-s_j|/\sqrt{2}}, \tag{3.7}$$

from where the estimate $\|M\|_{\ell^2,\ell^2}<+\infty$ follows immediately.

The construction proceeds now along the same lines as in the case of a finite set of points. We state the final result:

Theorem 3.2: *Let* $\{K_j\}_1^\infty$ $\{M_j\}_1^\infty$, $K_j>0$, $M_j>0$ *be in* ℓ^∞ *and suppose that* $\{K_j/M_j\}_1^\infty$ *and* $\{1/M_j\}_1^\infty$ *are in* ℓ^∞ *too. The linear operator*

$$\hat{A}:D(\hat{A}) \subset L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \ell^2 \oplus \ell^2 \to L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus \ell^2 \oplus \ell^2, \tag{3.8}$$

$$\begin{aligned} D(\hat{A}) = \{(p,v,\underline{y},\underline{z}):& p \in L^2(\mathbb{R}) \cap H^1(\mathbb{R}\setminus\mathcal{S}), v \in H^1(\mathbb{R}), \underline{y} \in \ell^2, \underline{z} \in \ell^2, p(s_i^+) - p(s_i^-) = \sigma_i, v(s_j) \\ &= z_j, \underline{\sigma} \in \ell^2\}, \end{aligned} \tag{3.9}$$

$$\hat{A}(p,v,\underline{y},\underline{z}) := \left(-a^2\rho_0 \frac{dv}{dx}, -\frac{1}{\rho_0}\frac{dp_0}{dx}, \underline{z}, -\sum_{j=1}^{\infty}\left(\frac{K_j}{M_j}y_j + \frac{S}{M_j}\sigma_j\right)\underline{e}_j \right) \tag{3.10}$$

is real and skew-adjoint. Here $p_0 \in \bar{H}^1(\mathbb{R})$,

$$p_0(x) := p(x) - \frac{1}{2}\sum_{j=1}^{\infty}\sigma_j \operatorname{sgn}(x-s_j), \tag{3.11}$$

denotes the regular part of p. The resolvent of $\hat{A}$ *is given by*

$$(-\hat{A}+\zeta)^{-1} = (-A+\zeta)^{-1} + \sum_{i,j=1}^{\infty}(\Gamma(\zeta)^{-1})_{ij} G_\zeta^i \otimes \breve{G}_{\bar{\zeta}}^j, \quad \zeta \in C\setminus i\mathbb{R}. \tag{3.12}$$

Now we can proceed to the study of a periodic system. We use the same notation of Albeverio *et al.* (2005).

In this case $\mathcal{S}$ will be the "Bravais" lattice,

$$\mathcal{S} = \{nL : n \in \mathbb{Z}\}, \quad L>0, \tag{3.13}$$

and $\hat{\mathcal{S}}$ the "Brillouin" zone,

$$\hat{\mathcal{S}} = \left[-\frac{b}{2},\frac{b}{2}\right), \quad b = \frac{2\pi}{L}. \tag{3.14}$$

We consider a Hilbert space $\mathcal{H}$ on $L^2\oplus L^2\oplus\ell^2\oplus\ell^2$ in which the scalar product is defined by

$$\frac{1}{a^2\rho_0}\langle p_1,p_2\rangle + \rho_0\langle v_1,v_2\rangle + \frac{K}{S}\langle \underline{y}_1,\underline{y}_2\rangle + \frac{M}{S}\langle \underline{z}_1,\underline{z}_2\rangle \tag{3.15}$$

where $\langle\cdot,\cdot\rangle$ represents either the usual scalar product in L^2, when concerning pressure and velocity fields, or the usual scalar product in ℓ^2, for $\underline{y}$ and $\underline{z}$.

M, K, and S are positive constants representing the mass of oscillating walls, the elastic constant of the springs, and the area of the transverse section of the pipe.

The Hilbert space $\mathcal{H}$ can be decomposed as

$$\mathcal{H} = \tilde{W}^{-1}\hat{\mathcal{H}}(\hat{\mathcal{S}},b^{-1}d\theta;L^2([-L/2,L/2)) \oplus L^2([-L/2,L/2)) \oplus \mathbb{C}\oplus\mathbb{C}) \tag{3.16}$$

$$= \tilde{W}^{-1}\int_{[-b/2,b/2)}^{\oplus}\frac{d\theta}{b}(L^2([-L/2,L/2)) \oplus L^2([-L/2,L/2)) \oplus \mathbb{C}\oplus\mathbb{C}), \tag{3.17}$$

where

$$\tilde{W}:\mathcal{H} \to \hat{\mathcal{H}}(\hat{\mathcal{S}},b^{-1}d\theta;L^2([-L/2,L/2)) \oplus L^2([-L/2,L/2)) \oplus \mathbb{C}\oplus\mathbb{C}), \tag{3.18}$$

$$\tilde{W}(p,v,\underline{y},\underline{z}) \equiv ((\tilde{W}p)(\theta,\nu),(\tilde{W}v)(\theta,\nu),(\tilde{W}\underline{y})(\theta),(\tilde{W}\underline{z})(\theta)), \tag{3.19}$$

$$(\tilde{W}p)(\theta,\nu) \equiv \tilde{p}(\theta,\nu) = \sum_{n\in Z} e^{in\theta L} p(\nu+nL), \tag{3.20}$$

$$(\tilde{W}v)(\theta,\nu) \equiv \tilde{v}(\theta,\nu) = \sum_{n\in Z} e^{in\theta L} v(\nu+nL), \tag{3.21}$$

$$(\tilde{W}\underline{y})(\theta) \equiv \tilde{y}(\theta) = \sum_{n\in Z} e^{in\theta L} y_n, \tag{3.22}$$

$$(\tilde{W}\underline{z})(\theta) \equiv \tilde{z}(\theta) = \sum_{n\in Z} e^{in\theta L} z_n \quad \nu \in [-L/2,L/2), \quad \theta \in [-b/2,b/2), \tag{3.23}$$

and

$$\tilde{W}^{-1}:\hat{\mathcal{H}}(\hat{\mathcal{S}},b^{-1}d\theta;L^2([-L/2,L/2)) \oplus L^2([-L/2,L/2)) \oplus \mathbb{C} \oplus \mathbb{C}) \to \mathcal{H}, \tag{3.24}$$

$$\tilde{W}^{-1}(\tilde{p},\tilde{v},\underline{y},\underline{z}) \equiv ((\tilde{W}^{-1}\tilde{p})(\nu+nL),(\tilde{W}^{-1}\tilde{v})(\nu+nL),\{(\tilde{W}^{-1}\tilde{y})_n\},\{(\tilde{W}^{-1}\tilde{z})_n\}), \tag{3.25}$$

$$(\tilde{W}^{-1}\tilde{p})(\nu+nL) = b^{-1}\int_{-b/2}^{b/2} d\theta e^{-in\theta L}\tilde{p}(\theta,\nu), \tag{3.26}$$

$$(\tilde{W}^{-1}\tilde{v})(\nu+nL) = b^{-1}\int_{-b/2}^{b/2} d\theta e^{-in\theta L}\tilde{v}(\theta,\nu), \tag{3.27}$$

$$(\tilde{W}^{-1}\tilde{y})_n = b^{-1}\int_{-b/2}^{b/2} d\theta e^{-in\theta L}\tilde{y}(\theta), \tag{3.28}$$

$$(\tilde{W}^{-1}\tilde{z})_n = b^{-1}\int_{-b/2}^{b/2} d\theta e^{-in\theta L}\tilde{z}(\theta) \quad \nu \in [-L/2, \quad L/2), \quad n \in \mathbb{Z}. \tag{3.29}$$

The scalar product in $L^2([-L/2,L/2)) \oplus L^2([-L/2,L/2)) \oplus \mathbb{C} \oplus \mathbb{C}$ is defined by

$$\frac{1}{a^2\rho_0}\langle\tilde{p}_1,\tilde{p}_2\rangle_{L/2} + \rho_0\langle\tilde{v}_1,\tilde{v}_2\rangle_{L/2} + \frac{K}{S}\bar{\tilde{y}}_1\tilde{y}_2 + \frac{M}{S}\bar{\tilde{z}}_1\tilde{z}_2, \tag{3.30}$$

where $\langle\cdot,\cdot\rangle_{L/2}$ indicates the usual scalar product in $L^2([-L/2,L/2))$.

From Theorem 3.2 we obtain the following.

Corollary 3.3: The linear operator

$$\hat{A}:D(\hat{A}) \subset \mathcal{H} \to \mathcal{H}, \tag{3.31}$$

$$D(\hat{A}) = \{(p,v,\underline{y},\underline{z}):p \in L^2(\mathbb{R}) \cap H^1(\mathbb{R}\setminus\mathcal{S}), v \in H^1(\mathbb{R}), \underline{y} \in \ell^2, \underline{z} \in \ell^2, p(nL^+) - p(nL^-) = \sigma_n, v(nL) = z_n \ \forall\, n \in \mathbb{Z}, \underline{\sigma} \in \ell^2\}, \tag{3.32}$$

$$\hat{A}(p,v,\underline{y},\underline{z}) := \left(-a^2\rho_0\frac{dv}{dx},-\frac{1}{\rho_0}\frac{dp_0}{dx},\underline{z},-\frac{K}{M}\underline{y}-\frac{S}{M}\underline{\sigma}\right), \tag{3.33}$$

where the regular part of $p(x)$, *denoted with* $p_0 \in \bar{H}^1(\mathbb{R})$, is

$$p_0(x) = p(x) - \frac{1}{2}\sum_{n\in Z}\sigma_n \operatorname{sgn}(x-nL), \tag{3.34}$$

is real and skew-adjoint.

We want to study the spectral structure of $\hat{A}$. To this aim we introduce the family of operators $\hat{A}(\theta)$:

$$\hat{A}(\theta):D(\hat{A}(\theta)) \subset L^2((-L/2,L/2)) \oplus L^2((-L/2,L/2)) \oplus \mathbb{C} \oplus \mathbb{C} \to L^2((-L/2,L/2)) \oplus L^2((-L/2,L/2)) \oplus \mathbb{C} \oplus \mathbb{C}, \tag{3.35}$$

$$\begin{aligned} D(\hat{A}(\theta)) = \Bigg\{ & (\tilde{p}(\theta),\tilde{v}(\theta),\tilde{y}(\theta),\tilde{z}(\theta)):\tilde{p}(\theta) \in H^1((-L/2,L/2)\setminus\{0\}),\tilde{v}(\theta) \in H^1((-L/2,L/2)),\tilde{y}(\theta) \\ & \in \mathbb{C},\tilde{z}(\theta) \in \mathbb{C}\tilde{p}(\theta,0^+) - \tilde{p}(\theta,0^-) = \tilde{\sigma}(\theta),\tilde{v}(\theta,0) = \tilde{z}(\theta),\tilde{\sigma}(\theta) \in \mathbb{C},\tilde{p}\left(\theta,-\frac{L}{2}^+\right) \\ & = e^{i\theta L}\tilde{p}\left(\theta,\frac{L}{2}^-\right),\tilde{v}\left(\theta,-\frac{L}{2}^+\right) = e^{i\theta L}\tilde{v}\left(\theta,\frac{L}{2}^-\right)\Bigg\}; \quad \forall\ \theta \in \left[-\frac{b}{2},\frac{b}{2}\right) \end{aligned} \tag{3.36}$$

$$\hat{A}(\theta)(\tilde{p}(\theta),\tilde{v}(\theta),\tilde{y}(\theta),\tilde{z}(\theta)) := \left(-a^2\rho_0\frac{d\tilde{v}(\theta)}{d\nu},-\frac{1}{\rho_0}\frac{d\tilde{p}_0(\theta)}{d\nu},\tilde{z}(\theta),-\frac{K}{M}\tilde{y}(\theta)-\frac{S}{M}\tilde{\sigma}(\theta)\right), \tag{3.37}$$

where $\tilde{p}_0(\theta) \in H^1(\mathbb{R})$ is the regular part of $\tilde{p}(\theta)$,

$$\tilde{p}_0(\theta,\nu) = \tilde{p}(\theta,\nu) - \frac{1}{2}\tilde{\sigma}(\theta)\operatorname{sgn}(\nu). \tag{3.38}$$

Boundary conditions for $\tilde{p}(\theta,\nu)$ and $\tilde{v}(\theta,\nu)$ in $\nu=0$ and $\nu=\pm L/2$ are such that all operators in this family are skew-adjoint with respect to the scalar product (3.30).

The operator $\hat{A}$ is related to $\hat{A}(\theta)$ by the relation (see Albeverio *et al.* (2005))

$$\tilde{W}\hat{A}\tilde{W}^{-1} = \int_{[-b/2,b/2)}^{\oplus}\frac{d\theta}{b}\hat{A}(\theta). \tag{3.39}$$

The spectrum of $\hat{A}(\theta)$ is described by the following

Theorem 3.4: *Let* $\theta \in [-b/2,b/2)$, *then the spectrum of* $\hat{A}(\theta)$ *is purely discrete, in particular its eigenvalues* $E_n(\theta)$ are given by

$$E_n(\theta) = \lambda_n(\theta) = 2i\xi_n(\theta)\frac{a}{L}; \quad n \in \mathbb{Z}, \quad \xi_n(\theta) \in \mathbb{R}, \tag{3.40}$$

where $\xi_n(\theta)$ are the real solutions of

$$\sin\xi[\sin\xi - F(\xi)\cos\xi]\cos^2\frac{\theta L}{2} = \cos\xi[\cos\xi + F(\xi)\sin\xi]\sin^2\frac{\theta L}{2}, \tag{3.41}$$

$$F(\xi)=\frac{M}{M_g}\left(\pi^2\frac{\omega_o^2}{\omega_g^2}\frac{1}{\xi}-\xi\right);\quad M_g=\rho_0 SL,\quad \omega_o^2=\frac{K}{M},\quad \omega_g=2\pi\frac{a}{L}. \tag{3.42}$$

The corresponding eigenfunctions are

$$\Phi_n(\theta,x)=(\tilde{p}_n(\theta,\nu),\tilde{v}_n(\theta,\nu),\tilde{y}_n(\theta),\tilde{z}_n(\theta));\quad n\in\mathbb{Z},\quad \theta\in[-b/2,b/2), \tag{3.43}$$

$$\begin{aligned}\tilde{p}_n(\theta,\nu)=C_n\Bigg[&\left(\sin\left(\xi_n-\frac{\theta L}{2}\right)-F(\xi_n)\cos\left(\xi_n-\frac{\theta L}{2}\right)\right)\cos\frac{2\xi_n}{L}\nu+\\&-i\sin\left(\xi_n-\frac{\theta L}{2}\right)\left(\sin\frac{2\xi_n}{L}\nu-F(\xi_n)\frac{|\nu|}{\nu}\cos\frac{2\xi_n}{L}\nu\right)\Bigg],\end{aligned} \tag{3.44}$$

$$\begin{aligned}\tilde{v}_n(\theta,\nu)=-\frac{iC_n}{a\rho_0}\Bigg[&\left(\sin\left(\xi_n-\frac{\theta L}{2}\right)-F(\xi_n)\cos\left(\xi_n-\frac{\theta L}{2}\right)\right)\sin\frac{2\xi_n}{L}\nu\\&+i\sin\left(\xi_n-\frac{\theta L}{2}\right)\left(\cos\frac{2\xi_n}{L}\nu+F(\xi_n)\sin\frac{2\xi_n}{L}|\nu|\right)\Bigg],\end{aligned} \tag{3.45}$$

$$\tilde{y}_n(\theta)=-i\frac{C_nL}{a^2\rho_0\xi_n}\sin\left(\xi_n-\frac{\theta L}{2}\right), \tag{3.46}$$

$$\tilde{z}_n(\theta)=\frac{C_n}{a\rho_0}\sin\left(\xi_n-\frac{\theta L}{2}\right). \tag{3.47}$$

For $\theta\in[-b/2,b/2)$ *zero is an eigenvalue with eigenfunction*

$$\Psi_0=\left(C_0\left(\cos\frac{\theta L}{2}-i\sin\frac{\theta L}{2}\,\mathrm{sgn}(\nu)\right),0,2iC_0\frac{S}{K}\sin\frac{\theta L}{2},0\right). \tag{3.48}$$

Moreover, the following chain of inequalities holds:

$$\begin{aligned}&0<E_1(0)<E_1(-b/2)\leqslant E_2(-b/2)<E_2(0)\leqslant E_3(0)<E_3(-b/2)\leqslant E_4(-b/2)<E_4(0)\leqslant E_5(0)\\&<E_4(-b/2)\leqslant E_5(-b/2)<\cdots.\end{aligned} \tag{3.49}$$

In general, the eigenvalues $E_n(\theta)$ *are all distinct and nondegenerate. If* $\omega_o/\omega_g=n/2$ *with* $n\in\mathbb{N}$, *there is just one twofold degenerate eigenvalue equal to* $n\pi/2$; *such an eigenvalue corresponds to* $\theta=0$ *for n even and to* $|\theta|=b/2$ *for n odd.*

If $E(\theta)$ *is an eigenvalue then* $-E(\theta)$ *is an eigenvalue.*

Given $\theta\in[-b/2,b/2)$ *the following relation holds*:

$$E_n(-\theta)=E_n(\theta). \tag{3.50}$$

Proof: Eigenvalues and eigenfunctions (3.40)–(3.48) are given by direct computation. We solve the system of equations

$$\hat{A}(\theta)(\tilde{p}(\theta),\tilde{v}(\theta),\tilde{y}(\theta),\tilde{z}(\theta))=\lambda(\tilde{p}(\theta),\tilde{v}(\theta),\tilde{y}(\theta),\tilde{z}(\theta))\quad \lambda\in i\mathbb{R}; \tag{3.51}$$

with the condition $\tilde{v}(\theta,0)=\tilde{z}(\theta)$, the solution reads

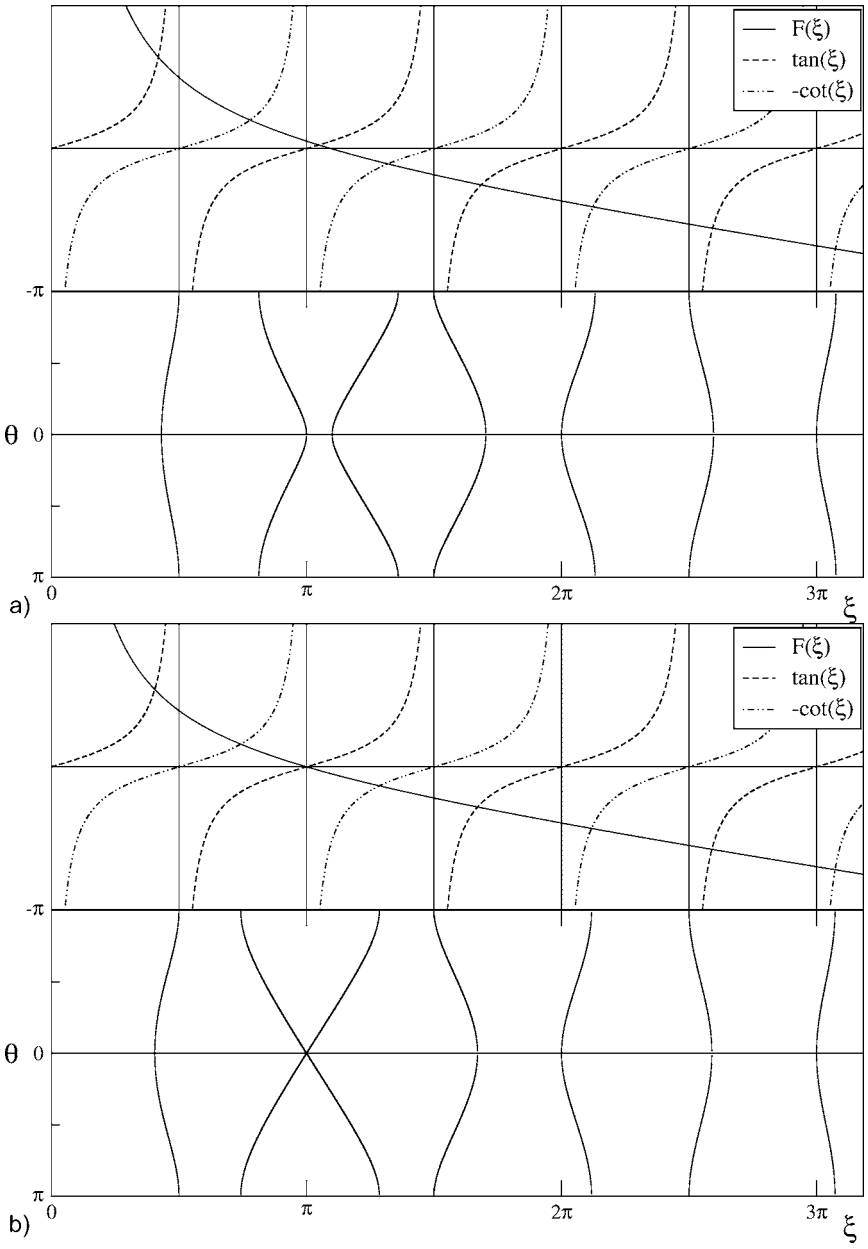

FIG. 1. Graphical solution of Eqs. (3.55) and (3.56). (b) and corresponding band structure for (a) a non-degenerate case (b) a degenerate case.

$$\tilde{p}(\theta,\nu) = C(\xi)\cos\frac{2\xi\nu}{L} + D(\xi)\left[\sin\frac{2\xi\nu}{L} - F(\xi)\mathrm{sgn}(\nu)\cos\frac{2\xi\nu}{L}\right], \tag{3.52}$$

$$\tilde{v}(\theta,\nu) = \frac{C(\xi)}{ia\rho_0}\sin\frac{2\xi\nu}{L} - \frac{D(\xi)}{ia\rho_0}\left[\cos\frac{2\xi\nu}{L} + F(\xi)\sin\frac{2\xi|\nu|}{L}\right], \tag{3.53}$$

where $\xi = -iL\lambda/(2a) \in \mathbb{R}$, and $C(\xi)$ and $D(\xi)$ are two unknown functions of ξ. To determine $C(\xi)$ and $D(\xi)$ we have to take into account the boundary conditions

$$\tilde{p}\left(\theta,-\frac{L}{2}^{+}\right)=e^{i\theta L}\tilde{p}\left(\theta,\frac{L}{2}^{-}\right),$$
$$\tilde{v}\left(\theta,-\frac{L}{2}^{+}\right)=e^{i\theta L}\tilde{v}\left(\theta,\frac{L}{2}^{-}\right). \tag{3.54}$$

This system has only the trivial solution $C(\xi)=0$ and $D(\xi)=0$ for the values of ξ for which the determinant of the matrix of the coefficients of the system is zero. The condition that the determinant is zero implies Eq. (3.41) for the eigenvalues. For ξ satisfying condition (3.41) the solutions of the system of dependent equations (3.54) give the eigenfunctions.

For $\theta=0$ and $\theta=-b/2$ relation (3.41) becomes

$$\tan\xi=0 \quad \text{or} \quad \tan\xi=F(\xi)=\frac{M}{M_g}\left(\pi^2\frac{\omega_o^2}{\omega_g^2}\frac{1}{\xi}-\xi\right); \quad \theta=0, \tag{3.55}$$

$$\cot\xi=0 \quad \text{or} \quad -\cot\xi=F(\xi)=\frac{M}{M_g}\left(\pi^2\frac{\omega_o^2}{\omega_g^2}\frac{1}{\xi}-\xi\right); \quad \theta=-b/2. \tag{3.56}$$

Graphic solutions of the transcendental equations (3.55) and (3.56) are given in the upper part of Figs. 1(a) and 1(b). The chain of inequalities (3.49) follows by the monotone behavior of $F(\xi)$.

Degeneration of eigenvalues for $\omega_o/\omega_g=n/2$, the fact that $-E(\theta)$ is an eigenvalue if $E(\theta)$ is an eigenvalue and relation (3.50) follow directly by Eq. (3.41) and by $F(\xi)=-F(-\xi)$. □

One can show that there is a band structure writing equation (3.41) as

$$\tan^2\frac{\theta L}{2}=\tan\xi\left[\frac{\tan\xi-F(\xi)}{1+F(\xi)\tan\xi}\right]. \tag{3.57}$$

It is possible to find solutions of Eq. (3.57) only for values of ξ such that the right-hand side is positive. In the lower part of Figs. 1(a) and 1(b) the resulting band structure is shown. The figures clearly show that the width of the gaps is connected to the structure of the spectrum. In particular, Fig. 1(b) shows that when there is a degenerate eigenvalue, $\omega_o/\omega_g=n\pi/2$ with $n\in\mathbb{N}$, a gap disappears because of the overlapping of two bands.

The bandwidth increases when the ratio M/M_g decreases.

Consider the Newton equation in the relativistic case (that is the Newton-Einstein equation) $\dot{p}=F(x)$, $F(x)=-\nabla V(x)$, $p=\dot{x}/\sqrt{1-(|\dot{x}|^2/c^2)}$, $p=\mathrm{d}p/\mathrm{d}t$, $\dot{x}=\mathrm{d}x/\mathrm{d}t$, $x \in C^1(\mathbb{R},\mathbb{R}^d)$, where $V \in C^2(\mathbb{R}^d,\mathbb{R})$, $|\partial_x^j V(x)| \leqslant \beta_{|j|}(1+|x|)^{-(\alpha+|j|)}$ for $|j| \leqslant 2$ and some $\alpha>1$. We give estimates and asymptotics for scattering solutions and scattering data for the equation for the case of small angle scattering. We show that at high energies the velocity valued component of the scattering operator uniquely determines the x-ray transform PF. Applying results on inversion of the x-ray transform P we obtain that for $d \geqslant 2$ the velocity valued component of the scattering operator at high energies uniquely determines F. In addition we show that our high energy asymptotics found for the configuration valued component of the scattering operator does not uniquely determine F. The results of the present work were obtained in the process of generalizing some results of Novikov to the relativistic case. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2206690]

I. INTRODUCTION

Consider the Newton equation in the relativistic case (that is the Newton-Einstein equation)

$$\dot{p} = F(x), \quad F(x) = -\nabla V(x),$$

$$p = \frac{\dot{x}}{\sqrt{1-\dfrac{|\dot{x}|^2}{c^2}}}, \quad \dot{p} = \frac{dp}{dt}, \quad \dot{x} = \frac{dx}{dt}, \quad x \in C^1(\mathbb{R},\mathbb{R}^d), \tag{1.1}$$

where

$$V \in C^2(\mathbb{R}^d,\mathbb{R}), \quad |\partial_x^j V(x)| \leqslant \beta_{|j|}(1+|x|)^{-(\alpha+|j|)} \tag{1.2}$$

for $|j| \leqslant 2$ and some $\alpha>1$ [here j is the multi-index $j \in (\mathbb{N} \cup \{0\})^d$, $|j|=\Sigma_{n=1}^d j_n$ and $\beta_{|j|}$ are positive real constants]. The equation (1.1) is an equation for $x=x(t)$ and is the equation of motion in $\mathbb{R}^d$ of a relativistic particle of mass $m=1$ and charge $e=1$ in an external electric field described by the scalar potential V (see Ref. 1 and, for example, Sec. 17 of Ref. 5). In this equation x is the position of the particle, p is its impulse, F is the force acting on the particle, t is the time and c is the speed of light.

For the equation (1.1) the energy

[a)]Electronic mail: jollivet@math.univ-nantes.fr

$$E = c^2\sqrt{1+\frac{|p(t)|^2}{c^2}} + V(x(t))$$

is an integral of motion. We denote by B_c the Euclidean open ball whose radius is c and whose center is 0.

Yajima[10] studied in dimension 3 (without loss of generality for the case of dimension $d \geqslant 2$) the direct scattering of relativistic particle in an external electromagnetic field described by four vector $(V(x),\mathbf{A}(x))$ where the scalar potential V and the vector potential $\mathbf{A}$ are both rapidly decreasing. We recall the results of Yajima[10] in our case.

Under the conditions (1.2), the following is valid (see Ref. 10): for any $(v_-,x_-) \in B_c \times \mathbb{R}^d$, $v_- \neq 0$, the equation (1.1) has a unique solution $x \in C^2(\mathbb{R},\mathbb{R}^d)$ such that

$$x(t) = v_- t + x_- + y_-(t), \tag{1.3}$$

where $\dot{y}_-(t) \to 0$, $y_-(t) \to 0$, as $t \to -\infty$; in addition for almost any $(v_-,x_-) \in B_c \times \mathbb{R}^d$, $v_- \neq 0$,

$$x(t) = v_+ t + x_+ + y_+(t), \tag{1.4}$$

where $v_+ \neq 0$, $|v_+| < c$, $v_+ = a(v_-,x_-)$, $x_+ = b(v_-,x_-)$, $\dot{y}_+(t) \to 0$, $y_+(t) \to 0$, as $t \to +\infty$.

The map $S: B_c \times \mathbb{R}^d \to B_c \times \mathbb{R}^d$ given by the formulas

$$v_+ = a(v_-,x_-), \quad x_+ = b(v_-,x_-) \tag{1.5}$$

is called the scattering map for the equation (1.1); in addition, $a(v_-,x_-)$, $b(v_-,x_-)$ are called the scattering data for the equation (1.1).

By $\mathcal{D}(S)$ we denote the domain of definition of S; by $\mathcal{R}(S)$ we denote the range of S [by definition, if $(v_-,x_-) \in \mathcal{D}(S)$, then $v_- \neq 0$ and $a(v_-,x_-) \neq 0$].

Under the conditions (1.2), the map S has the following simple properties (see Ref. 10): for any $(v,x) \in B_c \times \mathbb{R}^d$, $(v,x) \in \mathcal{D}(S)$ if and only if $(-v,x) \in \mathcal{R}(S)$; $\mathcal{D}(S)$ is an open set of $B_c \times \mathbb{R}^d$ and $\mathrm{Mes}((B_c \times \mathbb{R}^d) \setminus \mathcal{D}(S)) = 0$ for the Lebesgue measure on $B_c \times \mathbb{R}^d$ induced by the Lebesgue measure on $\mathbb{R}^d \times \mathbb{R}^d$; the map $S: \mathcal{D}(S) \to \mathcal{R}(S)$ is continuous and preserves the element of volume, $a(v_-,x_-)^2 = v_-^2$.

If $V(x) \equiv 0$, then $a(v_-,x_-) = v_-$, $b(v_-,x_-) = x_-$, $(v_-,x_-) \in B_c \times \mathbb{R}^d$, $v_- \neq 0$. Therefore for $a(v_-,x_-)$, $b(v_-,x_-)$ we will use the following representation:

$$\begin{aligned} a(v_-,x_-) &= v_- + a_{sc}(v_-,x_-) \\ b(v_-,x_-) &= x_- + b_{sc}(v_-,x_-) \end{aligned} \quad (v_-,x_-) \in \mathcal{D}(S). \tag{1.6}$$

We will use the fact that, under the conditions (1.2), the map S is uniquely determined by its restriction to $\mathcal{M}(S) = \mathcal{D}(S) \cap \mathcal{M}$, where

$$\mathcal{M} = \{(v_-,x_-) \in B_c \times \mathbb{R}^d | v_- \neq 0, v_- x_- = 0\}.$$

Consider

$$T\mathbb{S}^{d-1} = \{(\theta,x) | \theta \in \mathbb{S}^{d-1}, \quad x \in \mathbb{R}^d, \theta x = 0\},$$

where $\mathbb{S}^{d-1}$ is the unit sphere in $\mathbb{R}^d$.

Consider the x-ray transform P which maps each function f with the properties

$$f \in C(\mathbb{R}^d,\mathbb{R}^m), \quad |f(x)| = O(|x|^{-\beta}), \quad \text{as } |x| \to \infty, \quad \text{for some } \beta > 1$$

into a function $Pf \in C(T\mathbb{S}^{d-1},\mathbb{R}^m)$, where Pf is defined by

$$Pf(\theta,x) = \int_{-\infty}^{+\infty} f(t\theta + x)\mathrm{d}t, \quad (\theta,x) \in T\mathbb{S}^{d-1}.$$

Concerning the theory of the x-ray transform, the reader is referred to Refs. 8, 2, 6, and 7.

Let

$$\mu(c,d,\tilde{\beta},\alpha,r_v,r_x,r)=\frac{1}{\sqrt{1+\dfrac{r_v^2}{4(c^2-r_v^2)}}}\frac{2^{2\alpha+6}(1+3\tilde{\beta}/c)d^2\sqrt{d}\tilde{\beta}(r_v/\sqrt{2}+1-r)^3}{r(\alpha-1)(r_v/\sqrt{2}-r)^4(1+r_x/\sqrt{2})^{\alpha-1}} \tag{1.7a}$$

and let $z=z(c,d,\tilde{\beta},\alpha,r_x,r)$, $z_1=z_1(c,d,\beta_1,\alpha,r_x,r)$, and $z_2=z_2(c,d,\beta_1,\alpha,r_x)$ be defined as the roots of the following equations:

$$\mu(c,d,\tilde{\beta},\alpha,z,r_x,r)=1, \quad z\in\,]\sqrt{2}r,c[, \tag{1.7b}$$

$$\frac{z_1}{\sqrt{1-\dfrac{z_1^2}{c^2}}}-\frac{2^{\alpha+4}\beta_1\sqrt{d}}{\alpha(z_1/\sqrt{2}-r)(r_x/\sqrt{2}+1)^{\alpha}}=0, \quad z_1\in\,]\sqrt{2}r,c[, \tag{1.7c}$$

$$\frac{z_2}{\sqrt{1-\dfrac{z_2^2}{c^2}}}-\frac{8\beta_1\sqrt{d}}{\alpha(z_2/\sqrt{2})(1+r_x/\sqrt{2})^{\alpha}}=0, \quad z_2\in\,]0,c[, \tag{1.7d}$$

where r_v, r_x, and r are some non-negative numbers such that $0<r\leqslant 1$, $r<c/\sqrt{2}$, $\sqrt{2}r<r_v<c$, and where $\tilde{\beta}=\max(\beta_1,\beta_2)$.

The main results of the present work consist in the small angle scattering asymptotics and estimates for the scattering data a_{sc} and b_{sc} (and scattering solutions) for the equation (1.1) and in application of these asymptotics and estimates to inverse scattering for the equation (1.1) at high energies. Our main results include, in particular, Theorem 1.1 and Proposition 1.1 given below.

Theorem 1.1: *Let the conditions* (1.2) *be valid*, $\tilde{\beta}=\max(\beta_1,\beta_2)$, $(\theta,x)\in T\mathbb{S}^{d-1}$, *and let r be a positive constant such that* $0<r\leqslant 1$, $r<c/\sqrt{2}$. *Then*

$$PF(\theta,x)=\lim_{\substack{s\to c\\ s<c}}\frac{s}{\sqrt{1-\dfrac{s^2}{c^2}}}a_{sc}(s\theta,x), \tag{1.8a}$$

and, in addition,

$$\left|PF(\theta,x)-\frac{s}{\sqrt{1-\dfrac{s^2}{c^2}}}a_{sc}(s\theta,x)\right|\leqslant\frac{d^2\tilde{\beta}^2 2^{2\alpha+5}s(s/\sqrt{2}+1-r)^2}{\sqrt{1+\dfrac{s^2}{4(c^2-s^2)}}\alpha(\alpha-1)(s/\sqrt{2}-r)^4(1+|x|/\sqrt{2})^{2\alpha-1}} \tag{1.8b}$$

for $s<c$, $s>z(c,d,\tilde{\beta},\alpha,|x|,r)$, $s\geqslant z_1(c,d,\beta_1,\alpha,|x|,r)$;

$$\int_{-\infty}^{0}\int_{-\infty}^{\tau}F(s\theta+x)\mathrm{d}s\,\mathrm{d}\tau-\int_{0}^{+\infty}\int_{\tau}^{+\infty}F(s\theta+x)\mathrm{d}s\,\mathrm{d}\tau+PV(\theta,x)\theta=\lim_{\substack{s\to c\\ s<c}}\frac{s^2}{\sqrt{1-\dfrac{s^2}{c^2}}}b_{sc}(s\theta,x) \tag{1.9a}$$

and, in addition,

$$\left|\frac{b_{sc}(s\theta,x)}{\sqrt{1-\frac{s^2}{c^2}}}-\frac{1}{c^2}PV(\theta,x)\theta+\frac{1}{s^2}\int_0^{+\infty}\int_\tau^{+\infty}F(u\theta+x)\mathrm{d}u\,\mathrm{d}\tau-\frac{1}{s^2}\int_{-\infty}^{0}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\,\mathrm{d}\tau\right|$$
$$\leqslant\sqrt{1-\frac{s^2}{c^2}}\left[C+\frac{d^3\sqrt{d}\left(\beta_2+3\frac{\beta_1\beta_2}{c}\right)\beta_1 2^{3\alpha+8}\left(\frac{s}{\sqrt{2}}+1-r\right)^3}{\left(1-\frac{3}{4}\frac{s^2}{c^2}\right)\alpha(\alpha-1)^2\left(\frac{s}{\sqrt{2}}-r\right)^6\left(1+\frac{|x|}{\sqrt{2}}\right)^{2\alpha-2}}\right] \tag{1.9b}$$

for $s<c$, $s>z(c,d,\tilde{\beta},\alpha,|x|,r)$, $s\geqslant\max(z_1(c,d,\beta_1,\alpha,|x|,r),z_2(c,d,\beta_1,\alpha,|x|))$ *and some constant* $C=C(c,d,\beta_0,\beta_1,\alpha,|x|)$ *which can be given explicitly.*

Consider the vector function w of (θ,x) arising on the left-hand side of (1.9a),

$$w(V,\theta,x)=\int_{-\infty}^{0}\int_{-\infty}^{\tau}F(s\theta+x)\mathrm{d}s\,\mathrm{d}\tau-\int_0^{+\infty}\int_\tau^{+\infty}F(s\theta+x)\mathrm{d}s\,\mathrm{d}\tau+PV(\theta,x)\theta,\quad(\theta,x)\in T\mathbb{S}^{d-1}.$$

Proposition 1.1: The vector w as a function of potential V satisfying the conditions (1.2) *and of* $(\theta,x)\in T\mathbb{S}^{d-1}$ *has the following simple properties:*

(1) *under the conditions* (1.2), *for any potential V the vector* $w(V,\theta,x)$ *is orthogonal to* θ,
(2) *there exists a potential V which satisfies the conditions* (1.2) *and for which* $w(V,\theta,x)$ *is not null for all* $(\theta,x)\in T\mathbb{S}^{d-1}$,
(3) *for any spherical symmetric potential V satisfying the conditions* (1.2) *we have* $w(V,\theta,x)=0$ *for all* $(\theta,x)\in T\mathbb{S}^{d-1}$.

From (1.8a) and inversion formulas for the x-ray transform for $d\geqslant 2$ (see Refs. 8, 2, 6, and 7) it follows that a_{sc} determines uniquely F at high energies. Moreover for $d\geqslant 2$ methods of reconstruction of f from Pf (see Refs. 8, 2, 6, and 7) permit to reconstruct F from the velocity valued component a of the scattering map at high energies. The formula (1.9a) and the item (3) of Proposition 1.1 show that the first term of the asymptotics of b_{sc} does not uniquely determine the potential V or the force F. The item (2) of Proposition 1.1 ensures us that the asymptotics which was found for b_{sc} is nontrivial. Note that Nicoleau paid our attention to the fact that, in addition of the item (3) of Proposition 1.1, $w(V,\theta,x)$, $(\theta,x)\in T\mathbb{S}^{d-1}$, uniquely determines V satisfying (1.2) modulo spherical symmetric potentials.

Inverse scattering for the classical multidimensional Newton equation was first studied by Novikov[7] (the existence of the scattering states, asymptotic completeness and scattering map for the classical Newton equation was studied by Simon[9]). Novikov proved two formulas which link scattering data at high energies to the x-ray transform of F and V. These formulas are generalized to the relativistic case by the formulas (1.8a) and (1.9a) of Theorem 1.1. Then applying results on inversion of the x-ray transform, Novikov obtains that at high energies the velocity valued component of the scattering data determines uniquely the x-ray transform of F whereas the configuration valued component of the scattering operator determines uniquely the x-ray transform of V. Note that in the relativistic case [due to the formula (1.9a) and Proposition 1.1] the asymptotics of b_{sc} does not determine uniquely F. We follow Novikov's framework[7] to obtain our results. Note also that for the classical multidimensional Newton equation in a bounded open strictly convex domain an inverse boundary value problem at high energies was first studied in Ref. 3.

Further our paper is organized as follows. In Sec. II we transform the differential equation (1.1) with initial conditions (1.3) in an integral equation which takes the form $y_-=A_{v_-,x_-}(y_-)$. Then we study A_{v_-,x_-} on a suitable space and we give estimates and contraction estimates about A_{v_-,x_-} (Lemmas 2.1, 2.2, 2.3). In Sec. III we give estimates and asymptotics for the deflection $y_-(t)$ from (1.3) and for scattering data $a_{sc}(v_-,x_-)$, $b_{sc}(v_-,x_-)$ from (1.6) (Theorem 3.1 and Theorem 3.2). From these estimates and asymptotics the formulas (1.8a) and (1.9a) will follow when the parameters c, β_m, α, d, $\hat{v}_-$, x_- are fixed and $|v_-|$ increases [where $\beta_{|j|}$, α, d are constants from (1.2),

$\beta_m=\max(\beta_0,\beta_1,\beta_2)$; $\hat{v}_-=v_-/|v_-|$]. In these cases $\sup_{t\in\mathbb{R}}|\theta(t)|$ decreases, where $\theta(t)$ denotes the angle between the vectors $\dot{x}(t)=v_-+\dot{y}_-(t)$ and v_-, and we deal with small angle scattering. Note that, under the conditions of Theorem 3.1, without additional assumptions, there is the estimate $\sup_{t\in\mathbb{R}}|\theta(t)|<\frac{1}{4}\pi$ and we deal with rather small angle scattering (concerning the term "small angle scattering" see Ref. 7 and Sec. 20 of Ref. 4). Theorem 1.1 follows from Theorem 3.1 and Theorem 3.2. Section IV, Sec. V, and Sec. VI are devoted to Proofs of our Theorems and Lemmas.

II. A CONTRACTION MAP

Let us transform the differential equation (1.1) in an integral equation. Consider the function $g:\mathbb{R}^d\to B_c$ defined by

$$g(x)=\frac{x}{\sqrt{1+\frac{|x|^2}{c^2}}},$$

where $x\in\mathbb{R}^d$. One can see that g has, in particular, the following simple properties:

$$|g(x)-g(y)|\leqslant\sqrt{d}|x-y| \quad \text{for } x,y\in\mathbb{R}^d, \tag{2.1}$$

g is an infinitely smooth diffeomorphism between $\mathbb{R}^d$ and B_c, and its inverse is given by

$$\gamma(x)=\frac{x}{\sqrt{1-\frac{|x|^2}{c^2}}}, \quad x\in B_c.$$

Now, if x satisfies the differential equation (1.1) and the initial conditions (1.3), then x satisfies the integral equation

$$x(t)=v_-t+x_-+\int_{-\infty}^{t}\left[g\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(x(s))\mathrm{d}s\right)-v_-\right]\mathrm{d}\tau, \tag{2.2}$$

where $F(x)=-\nabla V(x)$, $v_-\in B_c\backslash\{0\}$.

For $y_-(t)$ this equation takes the form

$$y_-(t)=A_{v_-,x_-}(y_-)(t), \tag{2.3}$$

where

$$A_{v_-,x_-}(f)(t)=\int_{-\infty}^{t}\left[g\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f(s))\mathrm{d}s\right)-v_-\right]\mathrm{d}\tau, \quad v_-\in B_c\backslash\{0\}.$$

From (2.2), (1.2), and (2.1) [applied on "x"$=\gamma(v_-)+\int_{-\infty}^{\tau}F(x(s))\mathrm{d}s$ and "y"$=\gamma(v_-)$], and $y_-(t)\in C(\mathbb{R},\mathbb{R}^d)$, $y_-(t)\to 0$, as $t\to-\infty$, it follows, in particular, that

$$y_-(t)\in C^1(\mathbb{R},\mathbb{R}^d) \quad \text{and } |\dot{y}_-(t)|=O(|t|^{-\alpha}), \quad |y_-(t)|=O(|t|^{-\alpha+1}), \quad \text{as } t\to-\infty, \tag{2.4}$$

where $v_-\in B_c\backslash\{0\}$ and x_- are fixed.

Consider the complete metric space

$$M_{T,r}=\{f\in C^1(]-\infty,T],\mathbb{R}^d)|\ \|f\|_T\leqslant r\},$$

where

$$\|f\|_T = \max\left(\sup_{t\in]-\infty,T]} |\dot{f}(t)|, \sup_{t\in]-\infty,T]} |f(t) - t\dot{f}(t)| \right) \tag{2.5}$$

(where for $T=+\infty$ we understand $]-\infty,T]$ as $]-\infty,+\infty[$). From (2.4) it follows that, at fixed $T<+\infty$,

$$y_-(t) \in M_{T,r} \text{ for some } r \text{ depending on } y_-(t) \text{ and } T. \tag{2.6}$$

Lemma 2.1: Under the conditions (1.2), *the following is valid: if* $f\in M_{T,r}$, $0<r\leqslant 1$, $r<c/\sqrt{2}$, $|v_-|<c$, $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $v_-x_-=0$, *then*

$$\|A_{v_-,x_-}(f)\|_T \leqslant \rho_T(c,d,\beta_1,\alpha,|v_-|,|x_-|,r)$$
$$= \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}} \frac{2^{\alpha+1} d\beta_1 (|v_-|/\sqrt{2}+1-r)}{(\alpha-1)(|v_-|/\sqrt{2}-r)^2(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)T)^{\alpha-1}} \tag{2.7a}$$

for $T\leqslant 0$,

$$\|A_{v_-,x_-}(f)\|_T \leqslant \rho(c,d,\beta_1,\alpha,|v_-|,|x_-|,r)$$
$$= \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}} \frac{2^{\alpha+2} d\beta_1 (|v_-|/\sqrt{2}+1-r)}{(\alpha-1)(|v_-|\sqrt{2}-r)^2(1+|x_-|/\sqrt{2})^{\alpha-1}} \tag{2.7b}$$

for $T\leqslant +\infty$; *if* $f_1, f_2 \in M_{T,r}$, $0<r\leqslant 1$, $r<c/\sqrt{2}$, $|v_-|<c$, $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $v_-x_-=0$, *then*

$$\|A_{v_-,x_-}(f_2) - A_{v_-,x_-}(f_1)\|_T \leqslant \lambda_T(c,d,\beta_2,\alpha,|v_-|,|x_-|,r)\|f_2-f_1\|_T,$$

$$\lambda_T(c,d,\beta_2,\alpha,|v_-|,|x_-|,r) = \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}(\alpha-1)}$$
$$\times \frac{2^{\alpha+2} d\sqrt{d}\beta_2 (|v_-|/\sqrt{2}+1-r)^2}{(|v_-|/\sqrt{2}-r)^3(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)T)^{\alpha-1}} \tag{2.8a}$$

for $T\leqslant 0$,

$$\|A_{v_-,x_-}(f_2) - A_{v_-,x_-}(f_1)\|_T \leqslant \lambda(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r)\|f_2-f_1\|_T,$$

$$\lambda(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r) = \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}} \frac{2^{2\alpha+6}(\beta_2+3\beta_1\beta_2/c) d^2\sqrt{d}(|v_-|/\sqrt{2}+1-r)^3}{(\alpha-1)(|v_-|/\sqrt{2}-r)^4(1+|x_-|/\sqrt{2})^{\alpha-1}} \tag{2.8b}$$

for $T\leqslant +\infty$.

Note that

$$\max\left(\frac{\rho_T(c,d,\beta_1,\alpha,|v_-|,|x_-|,r)}{r}, \lambda_T(c,d,\beta_2,\alpha,|v_-|,|x_-|,r) \right) \leqslant \mu_T(c,d,\tilde{\beta},\alpha,|v_-|,|x_-|,r)$$
$$= \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}} \frac{2^{\alpha+2} d\sqrt{d}\tilde{\beta}(|v_-|/\sqrt{2}+1-r)^2}{r(\alpha-1)(|v_-|/\sqrt{2}-r)^3(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)T)^{\alpha-1}} \tag{2.9a}$$

for $T\leqslant 0$,

$$\max\left(\frac{\rho(c,d,\beta_1,\alpha,|v_-|,|x_-|,r)}{r},\ \lambda(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r)\right)$$

$$\leqslant \mu(c,d,\tilde{\beta},\alpha,|v_-|,|x_-|,r) = \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}}$$

$$\times \frac{2^{2\alpha+6}(1+3\tilde{\beta}/c)d^2\sqrt{d}\tilde{\beta}(|v_-|/\sqrt{2}+1-r)^3}{r(\alpha-1)(|v_-|/\sqrt{2}-r)^4(1+|x_-|/\sqrt{2})^{\alpha-1}} \tag{2.9b}$$

for $T\leqslant+\infty$, where $\tilde{\beta}=\max(\beta_1,\beta_2)$, $0<r\leqslant 1$, $r<c/\sqrt{2}$, $|v_-|<c$, $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $v_-x_-=0$.

From Lemma 2.1 and the estimates (2.9) we obtain the following result.

Corollary 2.1: Under the conditions (1.2), $0<r\leqslant 1$, $r<c/\sqrt{2}$, $|v_-|<c$, $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $v_-x_-=0$, *the following result is valid:*

if $\mu_T(c,d,\tilde{\beta},\alpha,|v_-|,|x_-|,r)<1$, *then* $A_{v_-x_-}$ *is a contraction map in* $M_{T,r}$ *for* $T\leqslant 0$;

if $\mu(c,d,\tilde{\beta},\alpha,|v_-|,|x_-|,r)<1$, *then* $A_{v_-x_-}$ *is a contraction map in* $M_{T,r}$ *for* $T\leqslant+\infty$.

Taking into account (2.6) and using Lemma 2.1, Corollary 2.1 and the lemma about the contraction maps we will study the solution $y_-(t)$ of the equation (2.3) in $M_{T,r}$.

We will use also the following results.

Lemma 2.2: Under the conditions (1.2), $f\in M_{T,r}$, $0<r\leqslant 1$, $r<c/\sqrt{2}$, $|v_-|<c$, $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $v_-x_-=0$, *the following is valid:*

$$|\dot{A}_{v_-x_-}(f)(t)| \leqslant \zeta_-(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,t) = \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}}$$

$$\times \frac{d\beta_1 2^{\alpha+1}}{\alpha(|v_-|/\sqrt{2}-r)(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)t)^{\alpha}}, \tag{2.10}$$

$$|A_{v_-x_-}(f)(t)| \leqslant \xi_-(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,t) = \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}}$$

$$\times \frac{d\beta_1 2^{\alpha+1}}{(\alpha-1)\alpha(|v_-|/\sqrt{2}-r)^2(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)t)^{\alpha-1}}, \tag{2.11}$$

for $t\leqslant T$, $T\leqslant 0$;

$$A_{v_-x_-}(f)(t) = k_{v_-x_-}(f)t + l_{v_-x_-}(f) + H_{v_-x_-}(f)(t), \tag{2.12}$$

where

$$k_{v_-x_-}(f) = g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s+x_-+f(s))\mathrm{d}s\right) - v_-, \tag{2.13a}$$

$$l_{v_-,x_-}(f) = \int_{-\infty}^{0} \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_- s + x_- + f(s))\mathrm{d}s \right) - v_- \right] \mathrm{d}\tau + \int_{0}^{+\infty} \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_- s + x_- + f(s))\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_- s + x_- + f(s))\mathrm{d}s \right) \right] \mathrm{d}\tau, \tag{2.13b}$$

$$|k_{v_-,x_-}(f)| \leqslant 2\zeta_-(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,0), \tag{2.14a}$$

$$|l_{v_-,x_-}(f)| \leqslant 2\xi_-(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,0), \tag{2.14b}$$

$$|\dot{H}_{v_-,x_-}(f)(t)| \leqslant \zeta_+(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,t) = \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}\alpha(|v_-|/\sqrt{2}-r)} \times \frac{d\beta_1 2^{\alpha+1}}{(1+|x_-|/\sqrt{2}+(|v_-|/\sqrt{2}-r)t)^{\alpha}}, \tag{2.15}$$

$$|H_{v_-,x_-}(f)(t)| \leqslant \xi_+(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,t) = \frac{1}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}\alpha(\alpha-1)(|v_-|/\sqrt{2}-r)^2} \times \frac{d\beta_1 2^{\alpha+1}}{(1+|x_-|/\sqrt{2}+(|v_-|/\sqrt{2}-r)t)^{\alpha-1}}, \tag{2.16}$$

for $T=+\infty$, $t\geqslant 0$.

Lemma 2.3: Let the conditions (1.2) *be valid,* $y_-(t)\in M_{T,r}$ *be a solution of* (2.3), $T=+\infty$, $0<r\leqslant 1$, $r<c/\sqrt{2}$, $|v_-|<c$, $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $v_-x_-=0$, *then*

$$|k_{v_-,x_-}(y_-) - k_{v_-,x_-}(0)| \leqslant \varepsilon'_a(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r) = \frac{d\sqrt{d}\beta_2 2^{\alpha+3}(|v_-|/\sqrt{2}+1-r)}{\alpha(|v_-|/\sqrt{2}-r)^2(1+|x_-|/\sqrt{2})^{\alpha}} \times \frac{\rho(c,d,\beta_1,\alpha,|v_-|,|x_-|,r)}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}}, \tag{2.17a}$$

$$\left| \frac{k_{v_-,x_-}(y_-)}{\sqrt{1-\dfrac{|v_-|^2}{c^2}}} - \int_{-\infty}^{+\infty} F(x_- + v_- s)\mathrm{d}s \right| \leqslant \varepsilon_a(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r) = \frac{d\beta_2 2^{\alpha+3}(1+|v_-|/\sqrt{2}-r)\rho(c,d,\beta_1,\alpha,|v_-|,|x_-|,r)}{\alpha(|v_-|/\sqrt{2}-r)^2(1+|x_-|/\sqrt{2})^{\alpha}}, \tag{2.17b}$$

$$|l_{v_-,x_-}(y_-) - l_{v_-,x_-}(0)| \leqslant \varepsilon_b(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r) = \frac{d^2\sqrt{d}(\beta_2+3\beta_1\beta_2/c)2^{2\alpha+6}(|v_-|/\sqrt{2}+1-r)^2}{\alpha(\alpha-1)(|v_-|/\sqrt{2}-r)^4(1+|x_-|/\sqrt{2})^{\alpha-1}} \times \frac{\rho(c,d,\beta_1,\alpha,|v_-|,|x_-|,r)}{\sqrt{1+|v_-|^2/(4(c^2-|v_-|^2))}}. \tag{2.17c}$$

Proofs of Lemmas 2.1, 2.2, 2.3 are given in Sec. V.

III. SMALL ANGLE SCATTERING

Under the conditions (1.2), for any $(v_-,x_-)\in B_c\times\mathbb{R}^d$, $v_-\neq 0$, the equation (1.1) has a unique solution $x\in C^2(\mathbb{R},\mathbb{R}^d)$ with the initial conditions (1.3). Consider the function $y_-(t)$ from (1.3). This function describes deflection from free motion.

Using Corollary 2.1 the lemma about contraction maps, and Lemmas 2.2 and 2.3 we obtain the following result.

Theorem 3.1: *Let the conditions (1.2) be valid,* $\mu(c,d,\widetilde{\beta},\alpha,|v_-|,|x_-|,r)<1$, $\widetilde{\beta}=\max(\beta_1,\beta_2)$, $0<r\leqslant 1$, $r<c/\sqrt{2}$, $|v_-|<c$, $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $v_-x_-=0$. *Then the deflection* $y_-(t)$ *has the following properties:*

$$y_-\in M_{T,r},\quad T=+\infty, \tag{3.1}$$

$$|\dot{y}_-(t)|\leqslant \zeta_-(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,t), \tag{3.2}$$

$$|y_-(t)|\leqslant \xi_-(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,t)\quad \textit{for } t\leqslant 0, \tag{3.3}$$

$$y_-(t)=a_{sc}(v_-,x_-)t+b_{sc}(v_-,x_-)+h(v_-,x_-,t), \tag{3.4}$$

where

$$\left|a_{sc}(v_-,x_-)-\left[\frac{\gamma(v_-)+\int_{-\infty}^{+\infty}F(v_-s+x_-)\mathrm{d}s}{\sqrt{1+\dfrac{|\gamma(v_-)+\int_{-\infty}^{+\infty}F(v_-s+x_-)\mathrm{d}s|^2}{c^2}}}-v_-\right]\right|\leqslant \varepsilon'_a(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r), \tag{3.5a}$$

$$\left|\frac{a_{sc}(v_-,x_-)}{\sqrt{1-\dfrac{|v_-|^2}{c^2}}}-\int_{-\infty}^{+\infty}F(v_-s+x_-)\mathrm{d}s\right|\leqslant \varepsilon_a(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r), \tag{3.5b}$$

$$|b_{sc}(v_-,x_-)-l_{v_-,x_-}(0)|\leqslant \varepsilon_b(c,d,\beta_1,\beta_2,\alpha,|v_-|,|x_-|,r), \tag{3.5c}$$

$$|a_{sc}(v_-,x_-)|\leqslant 2\zeta_-(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,0), \tag{3.6a}$$

$$|b_{sc}(v_-,x_-)|\leqslant 2\xi_-(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,0), \tag{3.6b}$$

$$|\dot{h}(v_-,x_-,t)|\leqslant \zeta_+(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,t), \tag{3.7}$$

$$|h(v_-,x_-,t)|\leqslant \xi_+(c,d,\beta_1,\alpha,|v_-|,|x_-|,r,t) \tag{3.8}$$

for $t\geqslant 0$, *where* $l_{v_-,x_-}(0)$ (*respectively*, ε'_a, ε_a, ε_b, ζ_-, ζ_+, ξ_- *and* ξ_+) *is defined in* (2.13b) [*respectively*, (2.17a), (2.17b), (2.17c), (2.10), (2.15), (2.11), *and* (2.16)].

We will use the following observations.

(I) Let $0<r\leqslant 1$, $r<c/\sqrt{2}$, $0\leqslant u$,

$$\frac{s_1}{\sqrt{1-\frac{s_1^2}{c^2}}}-\frac{2^{\alpha+4}\beta_1\sqrt{d}}{\alpha(s_1/\sqrt{2}-r)(u/\sqrt{2}+1)^{\alpha}}>\frac{s_2}{\sqrt{1-\frac{s_2^2}{c^2}}}-\frac{2^{\alpha+4}\beta_1\sqrt{d}}{\alpha(s_2/\sqrt{2}-r)(u/\sqrt{2}+1)^{\alpha}}$$

for $\sqrt{2}r<s_2<s_1<c$.

(II) Let $0<r\leqslant 1$, $r<c/\sqrt{2}$, $u\in\,]\sqrt{2}r,c[$,

$$\frac{u}{\sqrt{1-\frac{u^2}{c^2}}}-\frac{2^{\alpha+4}\beta_1\sqrt{d}}{\alpha(u/\sqrt{2}-r)(s_1/\sqrt{2}+1)^{\alpha}}>\frac{u}{\sqrt{1-\frac{u^2}{c^2}}}-\frac{2^{\alpha+4}\beta_1\sqrt{d}}{\alpha(u/\sqrt{2}-r)(s_2/\sqrt{2}+1)^{\alpha}}$$

for $0\leqslant s_2<s_1$.

(III) Let $0<r\leqslant 1$, $r<c/\sqrt{2}$, x some real non-negative number, $\tilde{\beta}=\max(\beta_1,\beta_2)$ and $\sqrt{2}r<s<c$ then

$$\mu(c,d,\tilde{\beta},\alpha,s,|x|,r)<1\Leftrightarrow s>z(c,d,\tilde{\beta},\alpha,|x|,r).$$

Observations (I) and (II) imply that $z_1(c,d,\beta_1,\alpha,s_2,r)>z_1(c,d,\beta_1,\alpha,s_1,r)$ for $\sqrt{2}r<s_2<s_1<c$ when c, β_1, α, d, r are fixed.

Theorem 3.1 gives, in particular, estimates for the scattering process and asymptotics for the velocity valued component of the scattering map when c, β_1, β_2, α, d, $\hat{v}_-$, x_- are fixed (where $\hat{v}_-=v_-/|v_-|$) and $|v_-|$ increases or, e.g., c, β_1, β_2, α, d, v_-, $\hat{x}_-$ are fixed and $|x_-|$ increases. In these cases $\sup_{t\in\mathbb{R}}|\theta(t)|$ decreases, where $\theta(t)$ denotes the angle between the vectors $\dot{x}(t)=v_-+\dot{y}_-(t)$ and v_-, and we deal with small angle scattering. Note that already under the conditions of Theorem 3.1, without additional assumptions, there is the estimate $\sup_{t\in\mathbb{R}}|\theta(t)|<\frac{1}{4}\pi$ and we deal with a rather small angle scattering. Theorem 3.1 with (3.5c) will give the asymptotics of the configuration valued component $b(v_-,x_-)$ of the scattering map if we can study the asymptotics of $l_{v_-,x_-}(0)$. This is the subject of Theorem 3.2.

Theorem 3.2: *Let c, d, β_0, β_1, α, $|x|$ be fixed. Then there exists a constant $C_{c,d,\beta_0,\beta_1,\alpha,|x|}$ such that*

$$\left|\frac{l_{v,x}(0)}{\sqrt{1-\frac{|v|^2}{c^2}}}-\frac{1}{c^2}PV(\hat{v},x)\hat{v}+\frac{1}{|v|^2}\int_0^{+\infty}\int_{\tau}^{+\infty}F(u\hat{v}+x)\mathrm{d}u\,\mathrm{d}\tau-\frac{1}{|v|^2}\int_{-\infty}^{0}\int_{-\infty}^{\tau}F(u\hat{v}+x)\mathrm{d}u\,\mathrm{d}\tau\right|$$
$$\leqslant C_{c,d,\beta_0,\beta_1,\alpha,|x|}\sqrt{1-\frac{|v|^2}{c^2}} \tag{3.9}$$

for any $v\in B_c$, $|v|\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, $vx=0$, and where $\hat{v}=v/|v|$.

The proof of Theorem 3.2 is given in Sec. VI. Using this proof one can compute $C_{c,d,\beta_0,\beta_1,\alpha,|x|}$ explicitly.

IV. PRELIMINARIES FOR THE MAIN PROOFS

A. Inequalities for *F*

Lemma 4.1: Under the conditions (1.2), *the following estimates are valid:*

$$|F(x)|=\left(\sum_{j=1}^{d}\left|\frac{\partial}{\partial x_j}V(x)\right|^2\right)^{1/2}\leqslant\beta_1\sqrt{d}(1+|x|)^{-(\alpha+1)}\quad \textit{for } x\in\mathbb{R}^d, \tag{4.1}$$

$$|F(x)-F(y)|\leqslant\beta_2 d\sup_{\varepsilon\in[0,1]}(1+|\varepsilon x+(1-\varepsilon)y|)^{-(\alpha+2)}|x-y|,\quad \textit{for } x,y\in\mathbb{R}^d. \tag{4.2}$$

Lemma 4.1 follows directly from the formula $F(x)=-\nabla V(x)$ and the conditions (1.2).

B. Infinitely smooth function $g:\mathbb{R}^d \to B_c$

Lemma 4.2: The following estimates hold:

$$|\nabla g_i(x)|^2 \leqslant \frac{1}{1+\dfrac{|x|^2}{c^2}} \quad \text{for } x \in \mathbb{R}^d, \quad i=1,\ldots,d, \tag{4.3}$$

$$|g(x)-g(y)| \leqslant \sqrt{d} \sup_{\varepsilon\in[0,1]} \frac{1}{\sqrt{1+\dfrac{|\varepsilon x+(1-\varepsilon)y|^2}{c^2}}} |x-y| \quad \text{for } x, \quad y \in \mathbb{R}^d, \tag{4.4}$$

$$|\nabla g_i(x)-\nabla g_i(y)| \leqslant \frac{3\sqrt{d}}{c} \sup_{\varepsilon\in[0,1]} \frac{1}{1+\dfrac{|\varepsilon x+(1-\varepsilon)y|^2}{c^2}} |x-y| \quad \text{for } x, \quad y \in \mathbb{R}^d, \tag{4.5}$$

where $g=(g_1,\ldots,g_d)$.

Lemma 4.2 follows from straightforward calculations.

Remark 4.1: Using the growth properties of $g(p)$ with respect to $|p|$ and following Novikov's framework,[7] we will easily generalize some of the results of Ref. 7 to the relativistic case. Note that $1/(1+|p|^2/c^2)\to 0$ when $p\in\mathbb{R}^d$, $|p|\to+\infty$.

C. Some estimates of integrals

We will use the following estimates. For $a>0$, $b>0$, $\beta>1$,

$$\int_{-\infty}^{t} (a+b|s|)^{-\beta}\,\mathrm{d}s = \frac{1}{(\beta-1)b(a-bt)^{\beta-1}} \quad \text{for } t\leqslant 0, \tag{4.6}$$

$$\int_{-\infty}^{t} (a+b|s|)^{-\beta}\,\mathrm{d}s \leqslant \frac{2}{(\beta-1)ba^{\beta-1}} \quad \text{for } t\geqslant 0. \tag{4.7}$$

For $a>0$, $b>0$, $\beta>2$,

$$\int_{-\infty}^{t}\int_{-\infty}^{\tau} (a+b|s|)^{-\beta}\,\mathrm{d}s\,\mathrm{d}\tau = \frac{1}{(\beta-2)(\beta-1)b^2(a-bt)^{\beta-2}} \quad \text{for } t\leqslant 0, \tag{4.8}$$

$$\int_{0}^{t}\int_{\tau}^{t} (a+bs)^{-\beta}\,\mathrm{d}s\,\mathrm{d}\tau \leqslant \frac{1}{(\beta-2)(\beta-1)b^2a^{\beta-2}} \quad \text{for } t\geqslant 0. \tag{4.9}$$

For $a\geqslant 1$, $b>0$, $\beta>2$,

$$\int_{-\infty}^{t} (a+b|s|)^{-\beta}(1+|s|)\mathrm{d}s \leqslant \frac{b+1}{(\beta-2)b^2(a-bt)^{\beta-2}} \quad \text{for } t\leqslant 0, \tag{4.10}$$

$$\int_{-\infty}^{t} (a+b|s|)^{-\beta}(1+|s|)\mathrm{d}s \leqslant 2\frac{b+1}{(\beta-2)b^2a^{\beta-2}} \quad \text{for } t\geqslant 0. \tag{4.11}$$

For $a\geqslant 1$, $b>0$, $\beta>3$,

$$\int_0^t \int_\tau^t (a+bs)^{-\beta}(1+s)\mathrm{d}s\,\mathrm{d}\tau \leqslant \frac{b+1}{(\beta-3)(\beta-2)b^3a^{\beta-3}} \quad \text{for } t \geqslant 0. \tag{4.12}$$

For the proof of (4.6)–(4.12), see Ref. 7.

D. About $z_1(c,d,\beta_1,\alpha,|x_-|,r)$

Let c, d, β_1, α, $|x_-|$, $0<r\leqslant 1$, $r<c/\sqrt{2}$, be fixed. We consider the one-dimensional infinitely smooth function $\sigma:]\sqrt{2}r,c[\to\mathbb{R}$ defined by

$$\sigma(s) = \frac{s}{\sqrt{1-\frac{s^2}{c^2}}} - \frac{2^{\alpha+4}\beta_1\sqrt{d}}{\alpha(s/\sqrt{2}-r)(|x_-|/\sqrt{2}+1)^\alpha}.$$

σ is an increasing function (its derivative is a positive function) and as a consequence $z_1(c,d,\beta_1,\alpha,|x_-|,r)$ is well defined in the Introduction and the observation (I) of Sec. III holds.

E. About $M_{T,r}$, $0<r\leqslant 1$, $r<c/\sqrt{2}$

Lemma 4.3: Let $f,f_1,f_2\in M_{T,r}$, $v_-\in B_c\backslash\{0\}$, $v_-x_-=0$, $|v_-|>\sqrt{2}r$, then

$$\varepsilon f_1 + (1-\varepsilon)f_2 \in M_{T,r} \quad \textit{for } 0\leqslant\varepsilon\leqslant 1, \tag{4.13}$$

$$2(1+|x_- + v_-s + f(s)|) \geqslant (1+|x_-|/\sqrt{2}+(|v_-|/\sqrt{2}-r)|s|) \quad \textit{for } s\leqslant T, \tag{4.14}$$

$$\left|\int_{-\infty}^t F(v_-s+x_-+f(s))\mathrm{d}s\right| \leqslant \frac{\beta_1\sqrt{d}2^{\alpha+2}}{\alpha(|v_-|/\sqrt{2}-r)(|x_-|/\sqrt{2}+1)^\alpha} \quad \textit{for } t\in\,]-\infty,+\infty], \tag{4.15}$$

$$\left(1+\frac{1}{c^2}\left|\gamma(v_-)+\varepsilon_1\int_{-\infty}^t F(v_-s+x_-+f_1(s))\mathrm{d}s+\varepsilon_2\int_w^u F(v_-s+x_-+f_2(s))\mathrm{d}s\right|^2\right)^{-\beta}$$
$$\leqslant \left(1+\frac{|v_-|^2}{4(c^2-|v_-|^2)}\right)^{-\beta}, \tag{4.16}$$

for u, $t\in\,]-\infty,T]$, $w\in[-\infty,u]$, $\beta>0$, $-1\leqslant\varepsilon_1$, $\varepsilon_2\leqslant 1$, f_1, $f_2\in M_{T,r}$ and if $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $|v_-|<c$, where γ is defined by

$$\gamma(v) = \frac{v}{\sqrt{1-|v|^2/c^2}},$$

for $v\in B_c$.

Proof of Lemma 4.3: For the proof of (4.14) see Ref. 7. Inequality (4.1) with (4.14) and (4.7) proves (4.15). (4.13) follows from the definition of $M_{T,r}$. Inequality (4.15) gives in particular for u, $t\in\,]-\infty,T]$, $w\in[-\infty,u]$, $\beta>0$, $-1\leqslant\varepsilon_1$, $\varepsilon_2\leqslant 1$, f_1, $f_2\in M_{T,r}$,

$$\left|\gamma(v_-)+\varepsilon_1\int_{-\infty}^t F(v_-s+x_-+f_1(s))\mathrm{d}s+\varepsilon_2\int_w^u F(v_-s+x_-+f_2(s))\mathrm{d}s\right|$$
$$\geqslant |\gamma(v_-)| - \frac{\beta_1\sqrt{d}2^{\alpha+3}}{\alpha(|v_-|/\sqrt{2}-r)(|x_-|/\sqrt{2}+1)^\alpha}$$

$$= \frac{|v_-|}{\sqrt{1-|v_-|^2/c^2}} - \frac{\beta_1\sqrt{d}2^{\alpha+3}}{\alpha(|v_-|/\sqrt{2}-r)(|x_-|/\sqrt{2}+1)^\alpha}$$

$$\geqslant \frac{c|v_-|}{2\sqrt{c^2-|v_-|^2}} \quad \text{if } |v_-| \geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r), \quad |v_-|<c,$$

which implies (4.16).

V. PROOFS OF LEMMAS 2.1, 2.2, 2.3

Proof of Lemma 2.1: The property

$$A_{v_-x_-}(f) \in C^1(]-\infty,T],\mathbb{R}^d) \quad \text{for } f \in M_{T,r} \quad (0<r\leqslant 1,\ r<|v_-|/\sqrt{2}) \tag{5.1}$$

follows from (1.2) and (2.1) [applied on "x" $=\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f(s))\mathrm{d}s$ and "y" $=\gamma(v_-)$] and the definition of $A_{v_-x_-}(f)$.

Now we always suppose that $0<r\leqslant 1$, $r<c/\sqrt{2}$, $|v_-|\geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)$, $|v_-|<c$, $v_-x_-=0$. Consider

$$\begin{aligned} A_{v_-x_-}(f)(t) &= \int_{-\infty}^{t}\left[g\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f(s))\mathrm{d}s\right)-v_-\right]\mathrm{d}\tau \\ \frac{\mathrm{d}}{\mathrm{d}t}A_{v_-x_-}(f)(t) &= g\left(\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f(s))\mathrm{d}s\right)-v_-. \end{aligned} \quad \text{for } f\in M_{T,r}, \tag{5.2}$$

First we shall prove some estimates about $(\mathrm{d}/\mathrm{d}t)A_{v_-x_-}(f)$.

Note that $g(\gamma(v_-))=v_-$. From (5.2) and (4.4) [applied on "x" $=\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f(s))\mathrm{d}s$ and "y" $=\gamma(v_-)$], (4.1), (4.14), and (4.16) it follows that

$$\left|\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-x_-}(f)(t)\right| \leqslant \frac{d\beta_1 2^{\alpha+1}}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}}\int_{-\infty}^{t}(1+|x_-|/\sqrt{2}+(|v_-|/\sqrt{2}-r)|s|))^{-(\alpha+1)}\,\mathrm{d}s. \tag{5.3}$$

Our next purpose is to prove estimates (5.5) and (5.9) given below.

From (5.3), (4.8), and (4.6) it follows that

$$|A_{v_-x_-}(f)(t)| \leqslant \frac{d\beta_1\,2^{\alpha+1}}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}\alpha(\alpha-1)\left(\dfrac{|v_-|}{\sqrt{2}}-r\right)^2\left(1+\dfrac{|x_-|}{\sqrt{2}}-\left(\dfrac{|v_-|}{\sqrt{2}}-r\right)t\right)^{\alpha-1}}, \tag{5.4a}$$

$$\left|t\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-x_-}(f)(t)\right| \leqslant \frac{d\beta_1\,2^{\alpha+1}}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}\alpha\left(\dfrac{|v_-|}{\sqrt{2}}-r\right)^2\left(1+\dfrac{|x_-|}{\sqrt{2}}-\left(\dfrac{|v_-|}{\sqrt{2}}-r\right)t\right)^{\alpha-1}}, \tag{5.4b}$$

for $t\leqslant T$, $t\leqslant 0$. From (5.4) it follows that

$$\left| A_{v_-,x_-}(f)(t) - t\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f)(t) \right| \leqslant \frac{d\beta_1 2^{\alpha+1}}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}(\alpha-1)(|v_-|/\sqrt{2}-r)^2(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)t)^{\alpha-1}}, \tag{5.5}$$

for $t \leqslant T$, $t \leqslant 0$.

For $t \leqslant T$, $t \geqslant 0$, note that

$$A_{v_-,x_-}(f)(t) - t\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f)(t) = A_{v_-,x_-}(f)(0) + \int_0^t \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_- + f(s))\mathrm{d}s \right) \right] \mathrm{d}\tau. \tag{5.6}$$

For $A_{v_-,x_-}(f)(0)$ we use the estimate (5.4a), i.e.,

$$|A_{v_-,x_-}(f)(0)| \leqslant \frac{d\beta_1 2^{\alpha+1}}{\sqrt{1+(|v_-|^2/(4(c^2-|v_-|^2)))}\alpha(\alpha-1)(|v_-|/\sqrt{2}-r)^2(1+|x_-|/\sqrt{2})^{\alpha-1}}. \tag{5.7}$$

We estimate the second term on the right-hand side of (5.6) in the following way: from (4.4), (4.16), (4.1), (4.14), and (4.9), it follows that

$$\begin{aligned} &\left| \int_0^t \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_- + f(s))\mathrm{d}s \right) \right] \mathrm{d}\tau \right| \\ &\leqslant \frac{\sqrt{d}}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}} \int_0^t \left| \int_t^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s \right| \mathrm{d}\tau \\ &\leqslant \frac{d\beta_1 2^{\alpha+1}}{\sqrt{1+(|v_-|^2/(4(c^2-|v_-|^2)))}\alpha(\alpha-1)(|v_-|/\sqrt{2}-r)^2(1+|x_-|/\sqrt{2})^{\alpha-1}}, \end{aligned} \tag{5.8}$$

for $0 \leqslant t \leqslant T$. From (5.6)–(5.8) it follows that

$$\left| A_{v_-,x_-}(f)(t) - t\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f)(t) \right| \leqslant \frac{d\beta_1 2^{\alpha+2}}{\sqrt{1+\dfrac{|v_-|^2}{(4(c^2-|v_-|^2))}}\alpha(\alpha-1)(|v_-|/\sqrt{2}-r)^2(1+|x_-|/\sqrt{2})^{\alpha-1}} \tag{5.9}$$

for $0 \leqslant t \leqslant T$. Using (5.3) and (4.6) and using (5.5) we obtain (2.7a). Using (5.3) and (4.7) and using (5.9) we obtain (2.7b).

Our next purpose is to prove estimate (5.14) given below. Consider $(\mathrm{d}/\mathrm{d}t)(A_{v_-,x_-}(f_2)(t) - A_{v_-,x_-}(f_1)(t))$ for $f_1, f_2 \in M_{T,r}$ $[0 < r \leqslant 1,\ r < c/\sqrt{2},\ |v_-| < c,\ v_-x_- = 0,\ |v_-| \geqslant z_1(c,d,\beta_1,\alpha,|x_-|,r)]$. First

$$\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_2)(t) - \frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_1)(t) = g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_- + f_2(s))\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_- + f_1(s))\mathrm{d}s \right) \tag{5.10}$$

for $t \leqslant T$. From (5.10), (4.4), and (4.16) it follows that

$$\left|\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_2)(t)-\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_1)(t)\right| \leqslant \frac{\sqrt{d}}{\sqrt{1+(|v_-|^2/(4(c^2-|v_-|^2)))}}\int_{-\infty}^{t}|F(v_-s+x_-+f_2(s)) - F(v_-s+x_-+f_1(s))|\mathrm{d}s, \tag{5.11}$$

for $t\leqslant T$. From (4.13), (4.14), and (4.2), it follows that

$$|F(v_-s+x_-+f_2(s))-F(v_-s+x_-+f_1(s))| \leqslant d\beta_2 2^{\alpha+2}(1+|x_-|/\sqrt{2}+(|v_-|/\sqrt{2}-r)|s|)^{-(\alpha+2)}|f_2(s) - f_1(s)| \quad \text{for } s\leqslant T. \tag{5.12}$$

Moreover

$$|f_2(s)-f_1(s)| \leqslant (1+|s|)\|f_2-f_1\|_T \quad \text{for } s\leqslant T. \tag{5.13}$$

Thus, from (5.11)–(5.13) it follows that

$$\left|\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_2)(t)-\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_1)(t)\right| \leqslant \frac{d\sqrt{d}\beta_2 2^{\alpha+2}\|f_2-f_1\|_T}{\sqrt{1+(|v_-|^2/(4(c^2-|v_-|^2)))}}\int_{-\infty}^{t}(1+|x_-|/\sqrt{2}+(|v_-|/\sqrt{2}-r) \times|s|)^{-(\alpha+2)}(1+|s|)\mathrm{d}s. \tag{5.14}$$

Our next purpose is to prove estimates (5.17) and (5.31) given below. From (5.14), (4.10), and (4.6) it follows that

$$|A_{v_-,x_-}(f_2)(t)-A_{v_-,x_-}(f_1)(t)| \leqslant \frac{d\sqrt{d}\beta_2 2^{\alpha+2}(|v_-|/\sqrt{2}+1-r)\|f_2-f_1\|_T}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}\alpha(\alpha-1)(|v_-|/\sqrt{2}-r)^3(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)t)^{\alpha-1}} \tag{5.15}$$

for $t\leqslant T$, $t\leqslant 0$. From (5.14) and (4.10) it also follows that

$$|t|\left|\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_2)(t)-\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_1)(t)\right| \leqslant \frac{d\sqrt{d}\beta_2 2^{\alpha+2}(|v_-|/\sqrt{2}+1-r)\|f_2-f_1\|_T}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}\alpha(|v_-|/\sqrt{2}-r)^3(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)t)^{\alpha-1}} \tag{5.16}$$

for $t\leqslant T$, $t\leqslant 0$. Hence from (5.15) and (5.16) it follows that

$$\left|A_{v_-,x_-}(f_2)(t)-A_{v_-,x_-}(f_1)(t)-t\frac{\mathrm{d}}{\mathrm{d}t}(A_{v_-,x_-}(f_2)(t)-A_{v_-,x_-}(f_1)(t))\right| \leqslant \frac{d\sqrt{d}\beta_2 2^{\alpha+2}(|v_-|/\sqrt{2}+1-r)\|f_2-f_1\|_T}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}(\alpha-1)(|v_-|/\sqrt{2}-r)^3(1+|x_-|/\sqrt{2}-(|v_-|/\sqrt{2}-r)t)^{\alpha-1}} \tag{5.17}$$

for $t\leqslant T$, $t\leqslant 0$.

For $0\leqslant t\leqslant T$, using (5.6) we obtain

$$\left|A_{v_-,x_-}(f_2)(t)-A_{v_-,x_-}(f_1)(t)-t\left(\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_2)(t)-\frac{\mathrm{d}}{\mathrm{d}t}A_{v_-,x_-}(f_1)(t)\right)\right| \leqslant |A_{v_-,x_-}(f_2)(0)-A_{v_-,x_-}(f_1)(0)|$$
$$+\left|\int_0^t\left[g\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f_2(s))\mathrm{d}s\right)-g\left(\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f_2(s))\mathrm{d}s\right)\right.\right.$$
$$\left.\left.-g\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f_1(s))\mathrm{d}s\right)+g\left(\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f_1(s))\mathrm{d}s\right)\right]\mathrm{d}\tau\right|. \tag{5.18}$$

From (5.15) it follows that

$$|A_{v_-,x_-}(f_2)(0)-A_{v_-,x_-}(f_1)(0)| \leqslant \frac{d\sqrt{d}\beta_2 2^{\alpha+2}(|v_-|/\sqrt{2}+1-r)\|f_2-f_1\|_T}{\sqrt{1+\dfrac{|v_-|^2}{4(c^2-|v_-|^2)}}\alpha(\alpha-1)\left(\dfrac{|v_-|}{\sqrt{2}}-r\right)^3\left(1+\dfrac{|x_-|}{\sqrt{2}}\right)^{\alpha-1}}. \tag{5.19}$$

In order to estimate the second term of the right-hand side of (5.18), we will estimate

$$\int_0^t\left[g_j\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f_2(s))\mathrm{d}s\right)-g_j\left(\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f_2(s))\mathrm{d}s\right)\right.$$
$$\left.-g_j\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f_1(s))\mathrm{d}s\right)+g_j\left(\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f_1(s))\mathrm{d}s\right)\right]\mathrm{d}\tau \tag{5.20}$$

for $1\leqslant j\leqslant d$ and $0\leqslant t\leqslant T$.

Let $1\leqslant j\leqslant d$ and $0\leqslant t\leqslant T$, $0\leqslant\tau\leqslant t$. Note that

$$g_j\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f_2(s))\mathrm{d}s\right)-g_j\left(\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f_2(s))\mathrm{d}s\right)$$
$$-\left(g_j\left(\gamma(v_-)+\int_{-\infty}^{\tau}F(v_-s+x_-+f_1(s))\mathrm{d}s\right)-g_j\left(\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f_1(s))\mathrm{d}s\right)\right)$$
$$=\Delta^1_{j,t}(\tau)+\Delta^2_{j,t}(\tau), \tag{5.21}$$

where

$$\Delta^1_{j,t}(\tau)=\int_t^{\tau}(F(v_-s+x_-+f_2(s))-F(v_-s+x_-+f_1(s)))ds$$
$$\bigstar\int_0^1\nabla g_j\left(\gamma(v_-)+\int_{-\infty}^{t}F(v_-s+x_-+f_2(s))\mathrm{d}s+\varepsilon\int_t^{\tau}F(v_-s+x_-+f_2(s))\mathrm{d}s\right)\mathrm{d}\varepsilon, \tag{5.22a}$$

$$\Delta_{j,t}^2(\tau) = \int_t^\tau F(v_-s + x_- + f_1(s))\mathrm{d}s$$
$$\star \int_0^1 \left[\nabla g_j\left(\gamma(v_-) + \int_{-\infty}^t F(v_-s + x_- + f_2(s))\mathrm{d}s + \varepsilon \int_t^\tau F(v_-s + x_- + f_2(s))\mathrm{d}s \right) \right.$$
$$\left. - \nabla g_j\left(\gamma(v_-) + \int_{-\infty}^t F(v_-s + x_- + f_1(s))\mathrm{d}s + \varepsilon \int_t^\tau F(v_-s + x_- + f_1(s))\mathrm{d}s \right) \right] \mathrm{d}\varepsilon, \tag{5.22b}$$

where ★ denotes the usual scalar product on $\mathbb{R}^d$.

Using (5.22a), (4.3), (4.2), (4.16), (4.14), and (5.13), we obtain

$$|\Delta_{j,t}^1(\tau)| \leqslant \frac{d\beta_2\, 2^{\alpha+2}}{\sqrt{1 + \dfrac{|v_-|^2}{4(c^2 - |v_-|^2)}}} \int_\tau^t (1 + |x_-|/\sqrt{2} + (|v_-|/\sqrt{2} - r)s)^{-(\alpha+2)}(1+s)\mathrm{d}s \|f_2 - f_1\|_T. \tag{5.23}$$

Thus from (4.12) it follows that

$$\int_0^t |\Delta_{j,t}^1(\tau)|\mathrm{d}\tau \leqslant \frac{d\beta_2\, 2^{\alpha+2}(|v_-|/\sqrt{2} + 1 - r)}{\sqrt{1 + \dfrac{|v_-|^2}{4(c^2 - |v_-|^2)}}\, \alpha(\alpha-1)(|v_-|/\sqrt{2} - r)^3(1 + |x_-|/\sqrt{2})^{\alpha-1}} \|f_2 - f_1\|_T. \tag{5.24}$$

Using (5.22b), (4.5), and (4.16), we obtain

$$|\Delta_{j,t}^2(\tau)| \leqslant \int_\tau^t |F(v_-s + x_- + f_1(s))|\mathrm{d}s \left[\frac{3\sqrt{d}}{c(1 + (|v_-|^2/(4(c^2 - |v_-|^2))))} \right.$$
$$\times \int_0^1 \left| \int_{-\infty}^t (F(v_-s + x_- + f_2(s)) - F(v_-s + x_- + f_1(s)))\mathrm{d}s \right.$$
$$\left. \left. + \varepsilon \int_t^\tau (F(v_-s + x_- + f_2(s)) - F(v_-s + x_- + f_1(s)))\mathrm{d}s \right| \mathrm{d}\varepsilon \right]. \tag{5.25}$$

We shall use

$$\left| \int_{-\infty}^t (F(v_-s + x_- + f_2(s)) - F(v_-s + x_- + f_1(s)))\mathrm{d}s \right.$$
$$\left. + \varepsilon \int_t^\tau (F(v_-s + x_- + f_2(s)) - F(v_-s + x_- + f_1(s)))\mathrm{d}s \right|$$
$$\leqslant 2 \int_{-\infty}^t |(F(v_-s + x_- + f_2(s)) - F(v_-s + x_- + f_1(s)))|\mathrm{d}s, \tag{5.26}$$

for all $0 \leqslant \varepsilon \leqslant 1$ (we remind that $\tau \leqslant t$).

From (5.25) and (5.26) it follows that

$$|\Delta_{j,t}^2(\tau)| \leqslant \int_\tau^t |F(v_- s + x_- + f_1(s))| \mathrm{d}s \times \frac{6\sqrt{d}}{c\left(1 + \dfrac{|v_-|^2}{4(c^2 - |v_-|^2)}\right)} \int_{-\infty}^t |(F(v_- s + x_- + f_2(s)) - F(v_- s + x_- + f_1(s)))| \mathrm{d}s. \tag{5.27}$$

Using (4.2), (4.14), (5.13), and (4.11) we obtain

$$\int_{-\infty}^t |F(v_- s + x_- + f_2(s)) - F(v_- s + x_- + f_1(s))| \mathrm{d}s \leqslant \frac{d\beta_2\, 2^{\alpha+3}(|v_-|/\sqrt{2} + 1 - r)}{\alpha(|v_-|/\sqrt{2} - r)^2(1 + |x_-|/\sqrt{2})^\alpha} \|f_2 - f_1\|_T. \tag{5.28}$$

Using (4.1), (4.14), and (4.9) we obtain

$$\int_0^t \int_\tau^t |F(v_- s + x_- + f_1(s))| \mathrm{d}s\, \mathrm{d}\tau \leqslant \frac{\sqrt{d}\beta_1 2^{\alpha+1}}{\alpha(\alpha-1)(|v_-|/\sqrt{2} - r)^2(1 + |x_-|/\sqrt{2})^{\alpha-1}}. \tag{5.29}$$

From (5.27)–(5.29) it follows that

$$\int_0^t |\Delta_{j,t}^2(\tau)| \mathrm{d}\tau \leqslant \frac{3}{c(1 + (|v_-|^2/(4(c^2 - |v_-|^2))))} \frac{d^2\beta_1\beta_2 2^{2\alpha+5}(|v_-|/\sqrt{2} + 1 - r)}{\alpha^2(\alpha-1)(|v_-|/\sqrt{2} - r)^4(1 + |x_-|/\sqrt{2})^{2\alpha-1}} \|f_2 - f_1\|_T. \tag{5.30}$$

From (5.18), (5.19), (5.21), (5.24), and (5.30), it follows that

$$\begin{aligned} &\left| A_{v_-,x_-}(f_2)(t) - A_{v_-,x_-}(f_1)(t) - t\left(\frac{\mathrm{d}}{\mathrm{d}t} A_{v_-,x_-}(f_2)(t) - \frac{\mathrm{d}}{\mathrm{d}t} A_{v_-,x_-}(f_1)(t)\right)\right| \\ &\quad \leqslant \frac{d\sqrt{d}\beta_2 2^{\alpha+2}(|v_-|/\sqrt{2} + 1 - r)}{\sqrt{1 + (|v_-|^2/(4(c^2 - |v_-|^2)))}\,\alpha(\alpha-1)(|v_-|/\sqrt{2} - r)^3(1 + |x_-|/\sqrt{2})^{\alpha-1}} \\ &\qquad \times \left[2 + \frac{3}{c\sqrt{(1 + (|v_-|^2/(4(c^2 - |v_-|^2))))}} \frac{d\beta_1\, 2^{\alpha+3}}{\alpha(|v_-|/\sqrt{2} - r)(1 + |x_-|/\sqrt{2})^\alpha}\right] \\ &\qquad \times \|f_1 - f_2\|_T. \end{aligned} \tag{5.31}$$

Using (5.14), (4.10), and (5.17) we obtain (2.8a). Using (5.14), (4.11), and (5.31) we obtain (2.8b). Lemma 2.1 is proved.

Proof of Lemma 2.2: The estimates (2.10) and (2.11) follow immediately from (5.3), (4.6), and (5.4a). From (4.1), (4.14), and (4.7) it follows that

$$\int_{-\infty}^{+\infty} F(v_- s + x_- + f(s)) \mathrm{d}s$$

converges absolutely for any $f \in M_{T,r}$. Moreover, using (4.4) and (4.16) and then (4.1), (4.14), and (4.8) we obtain for $u > 0$,

$$\int_u^{+\infty} \left| g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s\right) - g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + f(s))\mathrm{d}s\right)\right| \mathrm{d}\tau$$
$$\leqslant \frac{d\beta_1\, 2^{\alpha+1}}{\sqrt{1 + \dfrac{|v_-|^2}{4(c^2 - |v_-|^2)}}} \int_u^{+\infty} \int_{\tau}^{+\infty} (1 + |x_-|/\sqrt{2} + (|v_-|/\sqrt{2} - r)s)^{-(\alpha+1)}\, \mathrm{d}s\, \mathrm{d}\tau$$
$$\leqslant \frac{d\beta_1\, 2^{\alpha+1}(1 + |x_-|/\sqrt{2} + (|v_-|/\sqrt{2} - r)u)^{-(\alpha-1)}}{\sqrt{1 + \dfrac{|v_-|^2}{4(c^2 - |v_-|^2)}}\, \alpha(\alpha-1)(|v_-|/\sqrt{2} - r)^2} \tag{5.32}$$

As a consequence we can write

$$A_{v_-,x_-}(f)(t) = t\left[g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + f(s))\mathrm{d}s\right) - v_-\right] + \int_{-\infty}^{0} \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s\right) - v_-\right]\mathrm{d}\tau + \int_0^{+\infty} \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s\right) - g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + f(s))\mathrm{d}s\right)\right]\mathrm{d}\tau - \int_t^{+\infty} \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s\right) - g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + f(s))\mathrm{d}s\right)\right]\mathrm{d}\tau \tag{5.33}$$

and (2.12) and (2.13) follow, where

$$H_{v_-,x_-}(f)(t) = \int_t^{+\infty} \left[g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + f(s))\mathrm{d}s\right) - g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s\right)\right]\mathrm{d}\tau. \tag{5.34}$$

The formulas (5.34) and (5.32) prove (2.16). Using (5.34), (4.4), (4.16), (4.1), (4.14), and (4.6), we obtain (2.15).

Using (2.13a), (4.4), (4.16), (4.1), (4.14), and (4.7) we obtain (2.14a).

We write

$$l_{v_-,x_-}(f) = A_{v_-,x_-}(f)(0) + \int_0^{+\infty} \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + f(s))\mathrm{d}s\right) - g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + f(s))\mathrm{d}s\right)\right]\mathrm{d}\tau. \tag{5.35}$$

Using (5.35), (5.7), and (5.32), we obtain (2.14b).

Thus Lemma 2.2 is proved.

Proof of Lemma 2.3: Using (2.3) and (2.7b) we obtain

$$\|y_- - 0\|_T = \|y_-\|_T \leqslant \rho(c, d, \beta_1, \alpha, |v_-|, |x_-|, r), \quad T = +\infty.$$

Using (2.13a) and (5.10) with (5.14) and (4.11) ($T = +\infty$ and $t \to +\infty$), we obtain (2.17a).

From (5.35) it follows that

$$
\begin{aligned}
&|l_{v_-,x_-}(y_-) - l_{v_-,x_-}(0)| \\
&\quad \leqslant |A_{v_-,x_-}(y_-)(0) - A_{v_-,x_-}(0)(0)| \\
&\quad + \left| \lim_{t\to+\infty} \left\{ \int_0^t \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + y_-(s))\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_- + y_-(s))\mathrm{d}s \right) \right.\right. \\
&\quad - g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_-)\mathrm{d}s \right) + g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_-)\mathrm{d}s \right) \\
&\quad - \left(g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + y_-(s))\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_- + y_-(s))\mathrm{d}s \right) \right) \\
&\quad \left.\left. + \left(g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_-)\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_-)\mathrm{d}s \right) \right) \right] \mathrm{d}\tau \right\} \right|. \qquad (5.36)
\end{aligned}
$$

Using (4.4), (4.16), (4.1), (4.14), and (4.6) we obtain

$$
t \left| g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + f(s))\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_- + f(s))\mathrm{d}s \right) \right| \to 0 \text{ as } t \to +\infty \qquad (5.37)
$$

for $f \in M_{T,r}$.

From (5.36) and (5.37) it follows that

$$
\begin{aligned}
&|l_{v_-,x_-}(y_-) - l_{v_-,x_-}(0)| \\
&\quad \leqslant |A_{v_-,x_-}(y_-)(0) - A_{v_-,x_-}(0)(0)| \\
&\quad + \left| \lim_{t\to+\infty} \left\{ \int_0^t \left[g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_- + y_-(s))\mathrm{d}s \right) - g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_- + y_-(s))\mathrm{d}s \right) \right.\right. \\
&\quad \left.\left. - g\left(\gamma(v_-) + \int_{-\infty}^{\tau} F(v_-s + x_-)\mathrm{d}s \right) + g\left(\gamma(v_-) + \int_{-\infty}^{t} F(v_-s + x_-)\mathrm{d}s \right) \right] \mathrm{d}\tau \right\} \right|. \qquad (5.38)
\end{aligned}
$$

Using (5.19)–(5.21), (5.24), and (5.30), $\|y_-\|_T \leqslant \rho(c, d, \beta_1, \alpha, |v_-|, |x_-|, r)$, $T = +\infty$, and (5.38) we obtain (2.17c).

We shall prove (2.17b). First

$$
v_- + k_{v_-,x_-}(y_-) = g\left(\gamma(v_-) + \int_{-\infty}^{+\infty} F(v_-s + x_- + y_-(s))\mathrm{d}s \right). \qquad (5.39)
$$

Using the integral of motion E, we have $|v_-| = |v_- + k_{v_-,x_-}(y_-)|$ and applying γ to (5.39) we obtain

$$
\frac{k_{v_-,x_-}(y_-)}{\sqrt{1 - |v_-|^2/c^2}} = \int_{-\infty}^{+\infty} F(v_-s + x_- + y_-(s))\mathrm{d}s. \qquad (5.40)
$$

From (5.40), (5.12), (5.13), and (4.11) and $\|y_-\|_T \leqslant \rho(c, d, \beta_1, \alpha, |v_-|, |x_-|, r)$, $T = +\infty$, we obtain (2.17b).

Lemma 2.3 is proved.

VI. PROOFS OF THEOREM 3.2 AND PROPOSITION 1.1

Let $(\theta,x)\in T\mathbb{S}^{d-1}$, α, d, c, β_1, β_2 be fixed.

We shall use

$$\left|\frac{1}{s}\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|\leqslant\frac{\beta_1\sqrt{d}}{\alpha(s/\sqrt{2})(1+|x|/\sqrt{2})^{\alpha}} \tag{6.1a}$$

for $s\in]0,c[$ and $u\in]-\infty,0]$; replacing θ by $-\theta$ in (6.1a), we obtain

$$\left|\frac{1}{s}\int_{u}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|\leqslant\frac{\beta_1\sqrt{d}}{\alpha(s/\sqrt{2})(1+|x|/\sqrt{2})^{\alpha}} \tag{6.1b}$$

for $s\in]0,c[$ and $u\in[0,+\infty[$.

We prove (6.1a). As $\theta x=0$, the following formula is valid:

$$|x+w\theta|\geqslant|x|/\sqrt{2}+|w|/\sqrt{2}, \tag{6.2}$$

for any $w\in\mathbb{R}$. Then estimate (6.1a) follows from (4.1), (6.2), and (4.6).

Before proving Theorem 3.2, we need to introduce three lemmas and prove them.

Lemma 6.1: There exists integrable $\tilde{g}_{c,d,\beta_0,\beta_1,\alpha,|x|}:]-\infty,0]\to[0,+\infty[$ *such that*

$$\left|(1+\delta_1(c,\theta,x,s,u))^{-1/2}-1-\frac{V(x+u\theta)\sqrt{1-\frac{s^2}{c^2}}}{c^2}\right|\leqslant\tilde{g}_{c,d,\beta_0,\beta_1,\alpha,|x|}(u)(1-s^2/c^2), \tag{6.3}$$

for $u\in]-\infty,0]$ *and* $s<c$, $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, *and where*

$$\delta_1(c,\theta,x,s,u)=\frac{-2V(x+u\theta)\sqrt{1-\frac{s^2}{c^2}}+\left(\frac{1}{s^2}-\frac{1}{c^2}\right)\left|\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|^2}{c^2}\geqslant-\frac{3}{4}, \tag{6.4}$$

for $u\in]-\infty,0]$ *and* $s<c$, $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$.

Proof of Lemma 6.1.

Let $s\in]0,c[$, $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$ and $u\in]-\infty,0]$.

From (6.1a) and the definition of $z_2(c,d,\beta_1,\alpha,|x|)$ [see (1.7d)] it follows that

$$\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|\geqslant\frac{s}{2\sqrt{1-s^2/c^2}}. \tag{6.5}$$

Expanding the square of the norm we obtain

$$\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|^2=\frac{s^2}{1-s^2/c^2}-\frac{2V(x+u\theta)}{\sqrt{1-s^2/c^2}}+\left|\frac{1}{s}\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|^2. \tag{6.6}$$

Using (6.5) and (6.6), we obtain

$$\delta_1(c,\theta,x,s,u)=\frac{1+\frac{1}{c^2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|^2}{1+\frac{s^2}{c^2-s^2}}-1\geqslant\frac{1+\frac{s^2}{4(c^2-s^2)}}{1+\frac{s^2}{c^2-s^2}}-1\geqslant-3/4. \tag{6.7}$$

Moreover, from the definition of $\delta_1(c,\theta,x,s,u)$, (1.2) and (6.1a) and the hypothesis $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, $s<c$, it follows that

$$|\delta_1(c,\theta,x,s,u)|\leqslant\sqrt{1-s^2/c^2}\left[\frac{\beta_0 2(1+|x|/\sqrt{2}-u/\sqrt{2})^{-\alpha}}{c^2}+\frac{\sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}\beta_1^2 d2(1+|x|/\sqrt{2}-u/\sqrt{2})^{-2\alpha}}{z_2(c,d,\beta_1,\alpha,|x|)^2c^2\alpha^2}\right]. \tag{6.8}$$

Using Taylor expansion of the map $]-1,+\infty[\to\mathbb{R}$, $\delta\mapsto(1+\delta)^{-1/2}$ at $\delta=0$, we obtain that

$$(1+\delta_1(c,\theta,x,s,u))^{-1/2}-1-\frac{V(x+u\theta)\sqrt{1-\frac{s^2}{c^2}}}{c^2}=-\frac{1-s^2/c^2}{2s^2c^2}\left|\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|^2+\frac{3}{4}\int_0^1(1-w)\times(1+w\delta_1(c,\theta,x,s,u))^{-5/2}\,\mathrm{d}w\;\delta_1(c,\theta,x,s,u)^2. \tag{6.9}$$

We estimate the first term on the right-hand side of (6.9) with the help of (6.1a). We estimate the second term on the right-hand side of (6.9) with the help of (6.7) and (6.8). Using also the inequality $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, we finally obtain

$$\left|(1+\delta_1(c,\theta,x,s,u))^{-1/2}-1-\frac{V(x+u\theta)\sqrt{1-\frac{s^2}{c^2}}}{c^2}\right|\leqslant\widetilde{g}_{c,d,\beta_0,\beta_1,\alpha,|x|}(u),$$

where

$$\widetilde{g}_{c,d,\beta_0,\beta_1,\alpha,|x|}(u)=\frac{d\beta_1^2}{c^2z_2(c,d,\beta_1,\alpha,|x|)^2\alpha^2(1+|x|/\sqrt{2}-u/\sqrt{2})^{2\alpha}}+4^{5/2}\frac{3}{2c^4}\left[\beta_0(1+|x|/\sqrt{2}-u/\sqrt{2})^{-\alpha}+\frac{\sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}\beta_1^2 d(1+|x|/\sqrt{2}-u/\sqrt{2})^{-2\alpha}}{z_2(c,d,\beta_1,\alpha,|x|)^2\alpha^2}\right]^2.$$

Lemma 6.1 is proved.

Lemma 6.2: Let $\beta>0$, $s\in]0,c[$, $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$. *Then there exists a positive real number* $k_{\beta,c,d,\beta_1,\alpha,|x|}$ *such that*

$$\left|\left(1+\frac{1-s^2/c^2}{s^2c^2}\left|\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|^2\right)^{-\beta}-1\right|\leqslant(1-s^2/c^2)k_{\beta,c,d,\beta_1,\alpha,|x|}.$$

Proof of Lemma 6.2: We define

$$\delta_2(c,\theta,x,s)=\frac{1-s^2/c^2}{s^2c^2}\left|\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|^2\geqslant 0. \tag{6.10}$$

Using (6.1) and $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, we obtain

$$\delta_2(c,\theta,x,s) \leqslant (1-s^2/c^2)\frac{d\beta_1^2 8}{c^2 z_2(c,d,\beta_1,\alpha,|x|)^2\alpha^2(1+|x|/\sqrt{2})^{2\alpha}}. \tag{6.11}$$

Using the Taylor expansion of the map $]-1,+\infty[\to\mathbb{R}$, $\delta\mapsto(1+\delta)^{-\beta}$ at $\delta=0$ and using (6.10), we obtain

$$(1+\delta_2(c,\theta,x,s))^{-\beta}-1=-\beta\delta_2(c,\theta,x,s)\int_0^1(1+w\delta_2(c,\theta,x,s))^{-(\beta+1)}\,\mathrm{d}w. \tag{6.12}$$

From (6.10)–(6.12) it follows that

$$\left|(1+\delta_2(c,\theta,x,s))^{-\beta}-1\right| \leqslant \beta\delta_2(c,\theta,x,s) \leqslant (1-s^2/c^2)k_{\beta,c,d,\beta_1,\alpha,|x|},$$

where

$$k_{\beta,c,d,\beta_1,\alpha,|x|}=\frac{\beta\, d\beta_1^2\, 8}{c^2 z_2(c,d,\beta_1,\alpha,|x|)^2\alpha^2(1+|x|/\sqrt{2})^{2\alpha}}.$$

Lemma 6.2 is proved.

We always suppose that $(\theta,x)\in T\mathbb{S}^{d-1}$, α, d, c, β_1, β_2 are fixed. Let $s\in]0,c[$, $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, $u\in[0,+\infty[$, we define

$$A(c,\theta,x,s,u)=(1+t(c,\theta,x,s,u))^{-1/2}, \tag{6.13}$$

where

$$t(c,\theta,x,s,u)=\frac{1+\frac{1}{c^2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|^2}{1+\frac{1}{c^2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|^2}-1. \tag{6.14}$$

Expanding the square of the norms in the numerator and denominator of the fraction of the right-hand side of (6.14), we obtain that

$$\begin{aligned}t(c,\theta,x,s,u)=&\frac{-2V(x+u\theta)\sqrt{1-s^2/c^2}+\frac{1-s^2/c^2}{s^2}\left|\int_u^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|^2}{\left(1+\frac{(1-s^2/c^2)}{s^2c^2}\left|\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|^2\right)c^2}\\&-\frac{\frac{2(1-s^2/c^2)}{s^2}\int_u^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\,.\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau}{\left(1+\frac{(1-s^2/c^2)}{s^2c^2}\left|\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|^2\right)c^2}.\end{aligned} \tag{6.15}$$

Lemma 6.3: There exists $h_{c,d,\beta_0,\beta_1,\alpha,|x|}:[0,+\infty[\to[0,+\infty[$ *an integrable function such that for* $s\in]0,c[$, $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, $u\in[0,+\infty[$,

$$\left|A(c,\theta,x,s,u)-1-V(x+u\theta)\frac{\sqrt{1-s^2/c^2}}{c^2}\right| \leqslant (1-s^2/c^2)h_{c,d,\beta_0,\beta_1,\alpha,|x|}(u).$$

Proof of Lemma 6.3: We first look for a lower bound for $t(c,\theta,x,s,u)$. The following estimate is valid

$$\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|\geqslant\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|-\left|\frac{1}{s}\int_{u}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|. \tag{6.16}$$

From (6.1) it follows that

$$\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|\geqslant\frac{s}{\sqrt{1-s^2/c^2}}-\frac{2\beta_1\sqrt{d}}{\alpha(s/\sqrt{2})(1+|x|/\sqrt{2})^{\alpha}}. \tag{6.17}$$

Using first (6.1b) and then $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$ and (6.17) we obtain

$$\begin{aligned}\left|\frac{1}{s}\int_{u}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|&\leqslant\frac{\beta_1\sqrt{d}}{(s/\sqrt{2})\alpha(1+|x|/\sqrt{2})^{\alpha}}\leqslant\frac{1}{6}\left(\frac{s}{\sqrt{1-s^2/c^2}}-\frac{2\beta_1\sqrt{d}}{\alpha(s/\sqrt{2})(1+|x|/\sqrt{2})^{\alpha}}\right)\\&\leqslant\frac{1}{6}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|.\end{aligned} \tag{6.18}$$

From (6.16) and (6.18) it follows that

$$\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{u}F(x+\tau\theta)\mathrm{d}\tau\right|\geqslant\frac{5}{6}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|. \tag{6.19}$$

Using (6.14) and (6.19) we obtain

$$t(c,\theta,x,s,u)\geqslant\tfrac{25}{36}-1=-\tfrac{11}{36}. \tag{6.20}$$

Now we look for an upper bound for $t(c,\theta,x,s,u)$. The right-hand side of (6.15) consists of a subtraction of two fractions whose denominator is greater than c^2 and this implies

$$\begin{aligned}|t(c,\theta,x,s,u)|\leqslant c^{-2}\Bigg|&-2V(x+u\theta)\sqrt{1-s^2/c^2}+\frac{1-s^2/c^2}{s^2}\left|\int_{u}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\right|^2\\&-\frac{2(1-s^2/c^2)}{s^2}\int_{u}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\bigstar\int_{-\infty}^{+\infty}F(x+\tau\theta)\mathrm{d}\tau\Bigg|,\end{aligned} \tag{6.21}$$

where $\bigstar$ denotes the usual scalar product on $\mathbb{R}^d$. Thus, using (1.2), (6.1), (4.7) and the fact that $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, we obtain

$$\begin{aligned}|t(c,\theta,x,s,u)|\leqslant c^{-2}\sqrt{1-s^2/c^2}\Bigg[&2\beta_0(1+|x|/\sqrt{2}+u/\sqrt{2})^{-\alpha}\\&+\frac{\sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}}{z_2(c,d,\beta_1,\alpha,|x|)^2}\frac{d\beta_1^2 2}{\alpha^2(1+|x|/\sqrt{2}+u/\sqrt{2})^{2\alpha}}\\&+\frac{\sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}}{z_2(c,d,\beta_1,\alpha,|x|)^2}\frac{d\beta_1^2 8}{\alpha^2(1+|x|/\sqrt{2}+u/\sqrt{2})^{\alpha}(1+|x|/\sqrt{2})^{\alpha}}\Bigg].\end{aligned} \tag{6.22}$$

Using (6.13) and (6.20), the Taylor expansion of the map $]-1,+\infty[\mapsto\mathbb{R}$, $\delta\mapsto(1+\delta)^{-1/2}$ at $\delta=0$ and (6.15), we obtain

$$
\begin{aligned}
&\left| A(c,\theta,x,s,u) - 1 - \frac{V(x+u\theta)\sqrt{1-s^2/c^2}}{c^2} \right| \\
&= \left| \frac{1}{2} t(c,\theta,x,s,u) + \frac{3}{4}\int_0^1 (1-w)(1+wt(c,\theta,x,s,u))^{-5/2}\,\mathrm{d}w\; t(c,\theta,x,s,u)^2 \right. \\
&\quad \left. - \frac{V(x+u\theta)\sqrt{1-s^2/c^2}}{c^2} \right| \\
&\leqslant \left| \frac{V(x+u\theta)\sqrt{1-s^2/c^2}}{c^2} \left[1 - \left(1 + \frac{1-s^2/c^2}{c^2 s^2} \left| \int_{-\infty}^{+\infty} F(x+\tau\theta)\mathrm{d}\tau \right|^2 \right)^{-1} \right] \right| \\
&\quad + \frac{1}{2} \frac{\dfrac{1-s^2/c^2}{s^2} \left| \displaystyle\int_u^{+\infty} F(x+\tau\theta)\mathrm{d}\tau \right|^2 + \dfrac{2(1-s^2/c^2)}{s^2} \displaystyle\int_u^{+\infty} |F(x+\tau\theta)|\mathrm{d}\tau \int_{-\infty}^{+\infty} |F(x+\tau\theta)|\mathrm{d}\tau}{\left(1 + \dfrac{(1-s^2/c^2)}{s^2 c^2} \left| \displaystyle\int_{-\infty}^{+\infty} F(x+\tau\theta)\mathrm{d}\tau \right|^2 \right) c^2} \\
&\quad + \frac{3}{8}\left(\frac{25}{36}\right)^{-5/2} t(c,\theta,x,s,u)^2. \qquad (6.23)
\end{aligned}
$$

We use Lemma 6.2, conditions (1.2) and the fact that $s \geqslant z_2(c,d,\beta_1,\alpha,|x|)$ to estimate the first term on the right-hand side of the inequality (6.23). In order to estimate the second term on the right-hand side of the inequality (6.23), we use the fact that the denominator is greater than c^2, and we also use (6.1), (4.7), the fact that $s \geqslant z_2(c,d,\beta_1,\alpha,|x|)$. We estimate the third term on the right-hand side of the inequality with (6.22). Thus we obtain

$$
\left| A(c,\theta,x,s,u) - 1 - \frac{V(x+u\theta)\sqrt{1-s^2/c^2}}{c^2} \right| \leqslant (1-s^2/c^2) h_{c,d,\beta_0,\beta_1,\alpha,|x|}(u),
$$

where

$$
\begin{aligned}
h_{c,d,\beta_0,\beta_1,\alpha,|x|}(u) = \frac{1}{c^2}(1+|x|/\sqrt{2}+u/\sqrt{2})^{-\alpha} \Bigg\{ & \beta_0 k_{1,c,d,\beta_1,\alpha,|x|} \sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2} \\
& + \frac{\beta_1^2 d}{\alpha^2 z_2(c,d,\beta_1,\alpha,|x|)^2} ((1+|x|/\sqrt{2}+u/\sqrt{2})^{-\alpha} + 4(1+|x|/\sqrt{2})^{-\alpha}) \\
& + \frac{3}{2c^2}\left(\frac{25}{36}\right)^{-5/2} \Bigg[\beta_0 (1+|x|/\sqrt{2}+u/\sqrt{2})^{-\alpha/2} \\
& + \frac{d\beta_1^2 \sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}}{z_2(c,d,\beta_1,\alpha,|x|)^2 \alpha^2 (1+|x|/\sqrt{2}+u/\sqrt{2})^{\alpha/2}} \\
& \times ((1+|x|/\sqrt{2}+u/\sqrt{2})^{-\alpha} + 4(1+|x|/\sqrt{2})^{-\alpha}) \Bigg]^2 \Bigg\}.
\end{aligned}
$$

Lemma 6.3 is proved.

Proof of Theorem 3.2: Let $(\theta,x) \in T\mathbb{S}^{d-1}$, α, d, c, β_1, β_2, $s \in]0,c[$, $s \geqslant z_2(c,d,\beta_1,\alpha,|x|)$ be fixed. We shall study the asymptotics of $l_{s\theta,x}(0)$ which is defined by formula (2.13b).

First we look for the asymptotics of

$$\int_{-\infty}^{0}\left[g\left(\gamma(s\theta)+\int_{-\infty}^{\tau}F(us\theta+x)\mathrm{d}u\right)-s\theta\right]\mathrm{d}\tau.$$

By changes of variables, we obtain

$$\begin{aligned}&\int_{-\infty}^{0}\left[g\left(\gamma(s\theta)+\int_{-\infty}^{\tau}F(us\theta+x)\mathrm{d}u\right)-s\theta\right]\mathrm{d}\tau\\&=\int_{-\infty}^{0}\left[\frac{\dfrac{\theta}{\sqrt{1-s^2/c^2}}+\dfrac{1}{s^2}\displaystyle\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u}{\sqrt{1+c^{-2}\left|\dfrac{s\theta}{\sqrt{1-s^2/c^2}}+\dfrac{1}{s}\displaystyle\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right|^2}}-\theta\right]\mathrm{d}\tau.\end{aligned}\tag{6.24}$$

Expanding the square of the norm in the denominator of the fraction under the integral in (6.24), the denominator becomes

$$\left(1+c^{-2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2}=(1+\delta_1(c,\theta,x,s,\tau))^{-1/2}(1-s^2/c^2)^{1/2},\tag{6.25}$$

where δ_1 is defined by formula (6.4). We define

$$\begin{aligned}\Lambda_1(\theta,x,s)=\Bigg|&(1-s^2/c^2)^{-1/2}\int_{-\infty}^{0}\left[g\left(\gamma(s\theta)+\int_{-\infty}^{\tau}F(us\theta+x)\mathrm{d}u\right)-s\theta\right]\mathrm{d}\tau-c^{-2}\int_{-\infty}^{0}V(\tau\theta+x)\mathrm{d}\tau\,\theta\\&-s^{-2}\int_{-\infty}^{0}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\,\mathrm{d}\tau\Bigg|.\end{aligned}\tag{6.26}$$

From (6.26), (6.24), and (6.25), it follows that

$$\begin{aligned}\Lambda_1(\theta,x,s)\leqslant&\int_{-\infty}^{0}|(1+\delta_1(c,\theta,x,s,\tau))^{-1/2}-1-c^{-2}V(\tau\theta+x)\sqrt{1-s^2/c^2}|\\&\times\left(\frac{1}{\sqrt{1-s^2/c^2}}+s^{-2}\int_{-\infty}^{\tau}|F(u\theta+x)|\mathrm{d}u\right)\mathrm{d}\tau\\&+\int_{-\infty}^{0}\left|(1+c^{-2}V(\tau\theta+x)\sqrt{1-s^2/c^2})\left(\frac{\theta}{\sqrt{1-s^2/c^2}}+s^{-2}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right)\right.\\&\left.-\frac{\theta}{\sqrt{1-s^2/c^2}}-c^{-2}V(\tau\theta+x)\theta-s^{-2}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right|\mathrm{d}\tau.\end{aligned}\tag{6.27}$$

We estimate the first integral on the right-hand side of (6.27) by the use of Lemma 6.1. Therefore expanding the first product under the second integral of the form $\int_{-\infty}^{0}$ on the right-hand side of (6.27), we obtain

$$\begin{aligned}\Lambda_1(\theta,x,s)\leqslant&\sqrt{1-s^2/c^2}\int_{-\infty}^{0}\left[\widetilde{g}_{c,d,\beta_0,\beta_1,\alpha,|x|}(\tau)\left(1+s^{-2}\sqrt{1-s^2/c^2}\int_{-\infty}^{\tau}|F(u\theta+x)|\mathrm{d}u\right)\right.\\&\left.+\left|\frac{V(\tau\theta+x)}{s^2c^2}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right|\right]\mathrm{d}\tau.\end{aligned}\tag{6.28}$$

We define $|V|_\infty=\sup_{y\in\mathbb{R}^d}|V(y)|$. Using (6.28), (1.2), (6.1a), and (4.8) and the fact that $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, we obtain

$$\Lambda_1(\theta,x,s) \leqslant \sqrt{1-s^2/c^2}\left[\left(1+\frac{\sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}}{z_2(c,d,\beta_1,\alpha,|x|)^2}\frac{\beta_1\sqrt{d}\sqrt{2}}{\alpha(1+|x|/\sqrt{2})^{\alpha}}\right)\int_{-\infty}^{0}\tilde{g}_{c,d,\beta_0,\beta_1,\alpha,|x|}(\tau)\mathrm{d}\tau + \frac{\beta_1\sqrt{d}2|V|_{\infty}}{z_2(c,d,\beta_1,\alpha,|x|)^2c^2\alpha(\alpha-1)(1+|x|/\sqrt{2})^{\alpha-1}}\right]. \tag{6.29}$$

Now we look for the asymptotics of

$$\int_0^{+\infty}\left[g\left(\gamma(s\theta)+\int_{-\infty}^{\tau}F(us\theta+x)\mathrm{d}u\right)-g\left(\gamma(s\theta)+\int_{-\infty}^{+\infty}F(us\theta+x)\mathrm{d}u\right)\right]\mathrm{d}\tau.$$

By changes of variables, we obtain

$$\begin{aligned}&\int_0^{+\infty}\left[g\left(\gamma(s\theta)+\int_{-\infty}^{\tau}F(us\theta+x)\mathrm{d}u\right)-g\left(\gamma(s\theta)+\int_{-\infty}^{+\infty}F(us\theta+x)\mathrm{d}u\right)\right]\mathrm{d}\tau\\ &=\int_0^{+\infty}\left[\frac{\frac{\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s^2}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u}{\sqrt{1+c^{-2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right|^2}}\right.\\ &\left.-\frac{\frac{\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s^2}\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u}{\sqrt{1+c^{-2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u\right|^2}}\right]\mathrm{d}\tau.\end{aligned} \tag{6.30}$$

First we study the denominator of the first fraction under the integral of (6.30). From (6.14) and (6.13) it follows that

$$\begin{aligned}&\left(1+c^{-2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2}\\ &\quad=\left(1+c^{-2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2}A(c,\theta,x,s,\tau).\end{aligned} \tag{6.31}$$

We define

$$\begin{aligned}\Lambda_2(c,\theta,x,s)=\Bigg|&(1-s^2/c^2)^{-1/2}\int_0^{+\infty}\left[g\left(\gamma(s\theta)+\int_{\tau}^{+\infty}F(us\theta+x)\mathrm{d}u\right)\right.\\ &\left.-g\left(\gamma(s\theta)+\int_{-\infty}^{+\infty}F(us\theta+x)\mathrm{d}u\right)\right]\mathrm{d}\tau-c^{-2}\int_0^{+\infty}V(\tau\theta+x)\mathrm{d}\tau\,\theta\\ &+s^{-2}\int_0^{+\infty}\int_{\tau}^{+\infty}F(u\theta+x)\mathrm{d}u\,\mathrm{d}\tau\Bigg|.\end{aligned} \tag{6.32}$$

From (6.30)–(6.32) it follows that

$$\Lambda_2(c,\theta,x,s)\leqslant\Lambda_{2,1}(c,\theta,x,s)+\Lambda_{2,2}(c,\theta,x,s), \tag{6.33}$$

where

$$\Lambda_{2,1}(c,\theta,x,s)=\int_0^{+\infty}\left|(1-s^2/c^2)^{-1/2}\left(1+\frac{1}{c^2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2}\right.$$
$$\left.\times\left(A(c,\theta,x,s,\tau)-1-V(\tau\theta+x)\frac{\sqrt{1-\frac{s^2}{c^2}}}{c^2}\right)\left(\frac{\theta}{\sqrt{1-\frac{s^2}{c^2}}}+\frac{1}{s^2}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right)\right|\mathrm{d}\tau, \tag{6.34a}$$

$$\begin{aligned}\Lambda_{2,2}(c,\theta,x,s)=&\int_0^{+\infty}\left|(1-s^2/c^2)^{-1/2}\left(1+\frac{1}{c^2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2}\right.\\&\times\left[\left(1+V(\tau\theta+x)\frac{\sqrt{1-s^2/c^2}}{c^2}\right)\left(\frac{\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s^2}\int_{-\infty}^{\tau}F(u\theta+x)\mathrm{d}u\right)\right.\\&\left.\left.-\left(\frac{\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s^2}\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u\right)\right]\right.\\&\left.-\frac{V(\tau\theta+x)}{c^2}\theta+\frac{1}{s^2}\int_{\tau}^{+\infty}F(u\theta+x)\mathrm{d}u\right|\mathrm{d}\tau.\end{aligned} \tag{6.34b}$$

Let us estimate $\Lambda_{2,1}(c,\theta,x,s)$.

From Lemma 6.3 and (6.34a) it follows that

$$\begin{aligned}\Lambda_{2,1}(c,\theta,x,s)\leqslant&\sqrt{1-s^2/c^2}\left(1+\frac{1}{c^2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2}\\&\times\left(\frac{1}{\sqrt{1-s^2/c^2}}+\frac{1}{s^2}\int_{-\infty}^{+\infty}|F(u\theta+x)|\mathrm{d}u\right)\int_0^{+\infty}h_{c,d,\beta_0,\beta_1,\alpha,|x|}(\tau)\mathrm{d}\tau.\end{aligned} \tag{6.35}$$

In addition, expanding the square of the norm, we obtain

$$\begin{aligned}&\left(1+\frac{1}{c^2}\left|\frac{s\theta}{\sqrt{1-s^2/c^2}}+\frac{1}{s}\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2}\\&\quad=\sqrt{1-s^2/c^2}\left(1+\frac{1-s^2/c^2}{s^2c^2}\left|\int_{-\infty}^{+\infty}F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2}\end{aligned} \tag{6.36a}$$

$$\leqslant\sqrt{1-s^2/c^2}. \tag{6.36b}$$

Using (6.35), (6.36), (4.1), (6.2), and (4.7) and the fact that $s\geqslant z_2(c,d,\beta_1,\alpha,|x|)$, we obtain

$$\Lambda_{2,1}(c,\theta,x,s)\leqslant\sqrt{1-s^2/c^2}\left(1+\frac{\beta_1\sqrt{d}\sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}2\sqrt{2}}{z_2(c,d,\beta_1,\alpha,|x|)^2\alpha(1+|x|/\sqrt{2})^{\alpha}}\right)\int_0^{+\infty}h_{c,d,\beta_0,\beta_1,\alpha,|x|}(\tau)\mathrm{d}\tau. \tag{6.37}$$

Let us estimate $\Lambda_{2,2}(c,\theta,x,s)$.

From (6.34b) and (6.36a) it follows that

$$\Lambda_{2,2}(c,\theta,x,s) \leqslant \int_0^{+\infty} \left| \left(1+\frac{1-s^2/c^2}{s^2c^2}\left|\int_{-\infty}^{+\infty} F(u\theta+x)\mathrm{d}u\right|^2\right)^{-1/2} - 1 \right|$$
$$\times \left| -\frac{1}{s^2}\int_\tau^{+\infty} F(u\theta+x)\mathrm{d}u + \frac{V(\tau\theta+x)}{c^2}\theta + \frac{\sqrt{1-s^2/c^2}}{s^2c^2}V(\tau\theta+x) \right.$$
$$\left. \times \int_{-\infty}^{\tau} F(u\theta+x)\mathrm{d}u \right| \mathrm{d}\tau + \int_0^{+\infty} \left| \frac{\sqrt{1-s^2/c^2}}{s^2c^2}V(\tau\theta+x)\int_{-\infty}^{\tau} F(u\theta+x)\mathrm{d}u \right| \mathrm{d}\tau. \tag{6.38}$$

Thus using Lemma 6.2, conditions (1.2), (4.1), (6.2), (4.6), and (4.7) and the fact that $s \geqslant z_2(c,d,\beta_1,\alpha,|x|)$, it follows that

$$\Lambda_{2,2}(c,\theta,x,s) \leqslant \sqrt{1-s^2/c^2}\left[\frac{k_{1/2,c,d,\beta_1,\alpha,|x|}\sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}}{(\alpha-1)(1+|x|/\sqrt{2})^{\alpha-1}} \right.$$
$$\times \left(\frac{\sqrt{d}\beta_1 2}{z_2(c,d,\beta_1,\alpha,|x|)^2\alpha} + \frac{\beta_0\sqrt{2}}{c^2} + \frac{\sqrt{d}\beta_0\beta_1 4\sqrt{1-z_2(c,d,\beta_1,\alpha,|x|)^2/c^2}}{z_2(c,d,\beta_1,\alpha,|x|)^2c^2\alpha(1+|x|/\sqrt{2})^{\alpha}} \right)$$
$$\left. + \frac{\sqrt{d}\beta_0\beta_1 4}{z_2(c,d,\beta_1,\alpha,|x|)^2c^2\alpha(\alpha-1)(1+|x|/\sqrt{2})^{2\alpha-1}} \right]. \tag{6.39}$$

From (2.13b), (6.26), (6.29), (6.32), (6.34), (6.35), and (6.39) it follows that there exists $C_{c,d,\beta_0,\beta_1,\alpha,|x|}$ such that

$$\left| \frac{l_{s\theta,x}(0)}{\sqrt{1-s^2/c^2}} - \frac{1}{c^2}PV(\theta,x)\theta + \frac{1}{s^2}\int_0^{+\infty}\int_\tau^{+\infty} F(x+u\theta)\mathrm{d}u\,\mathrm{d}\tau - \frac{1}{s^2}\int_{-\infty}^{0}\int_{-\infty}^{\tau} F(x+u\theta)\mathrm{d}u\,\mathrm{d}\tau \right|$$
$$\leqslant \Lambda_1(c,\theta,x,s) + \Lambda_2(c,\theta,x,s) \leqslant C_{c,d,\beta_0,\beta_1,\alpha,|x|}\sqrt{1-s^2/c^2}. \tag{6.40}$$

The estimate (3.9) follows from (6.40).

Theorem 3.2 is proved.

Proof of Proposition 1.1: The item (1) follows immediately from

$$\frac{\mathrm{d}}{\mathrm{d}t}V(t\theta+x) = \nabla V(t\theta+x)\theta \quad \text{for all } (\theta,x) \in T\mathbb{S}^{d-1}, \quad t \in \mathbb{R}.$$

Proof of item (2). Take

$$V(x) = \frac{x_1}{(1+|x|^2)^\beta} \quad \text{for } x=(x_1,\ldots,x_d) \in \mathbb{R}^d, \beta > 1.$$

and take $(\theta,x) \in T\mathbb{S}^{d-1}$. By a straightforward calculation and using $\theta x = 0$, we obtain

$$\left(\int_{-\infty}^{0}\int_{-\infty}^{\tau} F(s\theta+x)\mathrm{d}s\,\mathrm{d}\tau - \int_0^{+\infty}\int_\tau^{+\infty} F(s\theta+x)\mathrm{d}s\,\mathrm{d}\tau + PV(\theta,x)\theta \right) \star x$$
$$= -4\beta\theta_1|x|^2\int_0^{+\infty}\int_\tau^{+\infty} \frac{s}{(1+s^2+|x|^2)^{\beta+1}}\mathrm{d}s\,\mathrm{d}\tau \neq 0 \text{ if and only if } x \neq 0 \text{ and } \theta_1 \neq 0,$$

where $\star$ denotes the scalar product.

Proof of item (3): Let V be a spherical symmetric potential [i.e., V takes the form $m(|x|)$] that satisfies the conditions (1.2) [e.g., $V(x)=(1+|x|^2)^{-\beta}$ where $\beta > \frac{1}{2}$]. Then $m \in C^1(]0,+\infty[,\mathbb{R})$ and

$\nabla V(x)=m'(|x|)(x/|x|)$. Let $(\theta,x)\in T\mathbb{S}^{d-1}$ and let $\theta^{\perp}$ be an orthogonal vector to θ. A straighforward calculation gives

$$F(s\theta+x)\theta^{\perp}=m'(\sqrt{s^2+|x|^2})\frac{x\star\theta^{\perp}}{\sqrt{s^2+|x|^2}}$$

for any $s\in\mathbb{R}$. Hence

$$\left(\int_{-\infty}^{0}\int_{-\infty}^{\tau}F(s\theta+x)\mathrm{d}s\,\mathrm{d}\tau-\int_{0}^{+\infty}\int_{\tau}^{+\infty}F(s\theta+x)\mathrm{d}s\,\mathrm{d}\tau+PV(\theta,x)\theta\right)\star\theta^{\perp}=0. \tag{6.41}$$

Item (3) follows from item (1) and formula (6.41).

Proposition 1.1 is proved.

In the framework of general relativistic classical mechanics on a spacetime with absolute time, we classify the infinitesimal symmetries of the classical structure by means of distinguished Lie subalgebras of the Lie algebra of "special phase function." These subalgebras are crucial also for the classification of infinitesimal quantum symmetries, which will be analyzed in a forthcoming paper. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2199068]

I. INTRODUCTION

This paper is the first part of a sequence of two papers. They are aimed at classifying systematically the symmetries of classical and quantum mechanics within the geometric framework of "covariant classical and quantum mechanics."

This framework is a geometric formulation of classical and quantum mechanics on a curved spacetime with absolute time and spacelike Riemannian metric, expressed in a manifestly coordinate free and observer independent way. We assume minimal axioms describing just the fundamental classical interactions, namely the gravitational and electromagnetic fields. The goal of this theory is to combine the standard quantum mechanics with those ideas and methods of Einstein's general relativity that are not related to the Lorentz metric and the speed of light, in order to understand quantum mechanics in a general relativistic observer independent way, as far as possible.

This approach requires methods based on fibered manifolds, jets, connections, and the Lie algebra of special phase functions. On the other hand, in the flat case the theory yields just the standard Schrödinger equation and the quantum operators for all usual examples. This approach has some analogies with other well-known geometric formulations of quantum mechanics, in particular, with geometric quantization (see, for instance, Refs. 1, 29, and 68). But, it presents several methodological novelties and results as well, by overcoming several typical difficulties in the theory of geometric quantization.

This approach was proposed in Refs. 33 and 34 and further developed by several authors (see, for instance, Refs. 38, 36, 61, and 62, and references therein). On the other hand, several authors have been involved with a formulation of classical and quantum mechanics in the framework of a curved Galileian background (see, for instance, Refs. 11, 18–24, 32, 40–44, 46, 54, and 65–67). One of the typical features of covariant classical mechanics is the role played by a cosymplectic

[a)]Electronic mail: marco.modugno@unifi.it
[b)]Electronic mail: saller@ba-mannheim.de
[c)]Electronic mail: tolksdor@mis.mpg.de

two-form. This is a concept more general than that of contact two-form and appropriate to account for the covariance of the theory. Actually, the literature on symplectic geometry is much wider and better known than that on cosymplectic geometry; however, several authors have analyzed the second one (see, for instance, Refs. 2, 8, 14, 17, 35, and 48, and references therein).

In the present paper, we start by introducing the basic objects of the theory, namely the spacetime fibered over absolute time, the spacelike Riemannian metric, the spacetime gravitational connection, and the electromagnetic field.

Then, we introduce the classical phase space and the main geometric objects induced by the spacetime structure, namely the contact maps, the phase connection, the second-order phase connection, the phase two-form and the phase two-vector. An important role is played by the phase two-form, which encodes all other objects and turns out to be cosymplectic. This set up allows us to introduce in a natural way the distinguished Lie algebra of special phase functions and their various lifts. The special Lie bracket is linked to the Poisson bracket and allows us to deal with spacetime functions, momentum, and energy on the same footing. An essential feature of special phase functions is that they admit a lift to the tangent space of spacetime.

Eventually, we classify systematically the infinitesimal symmetries of the above classical objects and show, step by step, that they are generated by distinguished subalgebras of the Lie algebra of special phase functions.

We observe that the classical Lagrangian formalism, Nöther's theorem, and the momentum map[1,10,15,16,27,28,30,45,58,57,60,64] arise naturally in the present scheme ruled by a cosymplectic two-form and by the Lie algebra of special phase functions. The literature dealing with Lie algebras associated with geometric structures of analytical mechanics from different perspectives is very wide (see, for instance, Refs. 3–7, 9, 12, 13, 25, 26, 31, 47, 49–51, 53, 52, and 56). On the other hand, the present paper is devoted to the specific setting of covariant classical mechanics of a particle effected by the fundamental classical fields.

This paper extends considerably the results obtained in Refs. 62 and 38, mainly by classifying the distinguished subalgebras of the Lie algebra of special phase functions and its relation to infinitesimal symmetries.

The above results will play an essential role in the subsequent paper devoted to infinitesimal quantum symmetries, where we achieve analogous results by a similar approach. In particular, we will prove in this forthcoming paper that the Lie algebra of special phase functions yields a Lie algebra of quantum currents; the conserved probability current is just a particular case of this construction.

Thus, throughout the two papers, a crucial role is played by the Lie algebra of special phase functions, which turn out to be the generators of the infinitesimal symmetries both of the classical and quantum theories. The special phase functions are the functions of the phase space whose second order vertical differential (with respect to the fibering of the phase space over spacetime) is proportional to the metric.

For each manifold $\boldsymbol{M}$, $\boldsymbol{N}$ and each fibered manifolds $\boldsymbol{F}\to\boldsymbol{B},\boldsymbol{G}\to\boldsymbol{B}$, we denote the sheaf of local maps $f:\boldsymbol{M}\to\boldsymbol{N}$ by map $(\boldsymbol{M},\boldsymbol{N})$, the sheaf of local sections $s:\boldsymbol{B}\to\boldsymbol{F}$ by $\mathrm{sec}(\boldsymbol{B},\boldsymbol{F})$ and the sheaf of local fibered morphisms $f:\boldsymbol{F}\to\mathbf{G}$ over $\boldsymbol{B}$ by $\mathrm{fib}(\boldsymbol{F},\boldsymbol{G})$.

II. COVARIANT CLASSICAL MECHANICS

A. Spacetime and its structure

1. Scale spaces

In the covariant formulation of physical theories the independence from the choice of coordinates and of units of measurements appear on the same footing. Thus, a rigorous treatment of units of measurement is necessary.

We introduce the fundamental *scale spaces* $\mathbb{U}$ as "positive 1-dimensional semi-vector spaces" over $\mathbb{R}^+$. A detailed account for this notion can be found in Refs. 34 and 37. Roughly speaking, they have the same algebraic structure as $\mathbb{R}^+$, but no distinguished generator over $\mathbb{R}^+$. We can naturally define the tensor product between scale spaces and ordinary vector spaces. Moreover, we

can naturally define the rational powers $\mathbb{U}^{p/q}$ of a scale space $\mathbb{U}$. Rules analogous to those of real numbers hold for scale spaces; accordingly, we adopt analogous notation. In particular, we shall write $\mathbb{U}^0 := \mathbb{U}, \mathbb{U}^{-1} := \mathbb{U}^*, \mathbb{U}^p := \otimes^p \mathbb{U}$.

These spaces will appear in the theory tensorialized with spacetime tensors. The scale spaces appearing in tensor products are not effected by differential operators, hence their elements can be treated as constants.

We introduce the space $\mathbb{T}$ of *future oriented time intervals*, the space $\mathbb{L}$ of *lengths*, and the space $\mathbb{M}$ of *masses*.

We shall refer to particles of mass $m \in \mathbb{M}$ and charge $q \in \mathbb{T}^{-1} \otimes \mathbb{L}^{3/2} \otimes \mathbb{M}^{1/2}$.

Moreover, we will consider time units $u_0 \in \mathbb{T}$, or their duals $u^0 \in \mathbb{T}^*$.

In order to unscale some objects of the theory, we will need a scale with scale dimensions of the *Planck constant* $\hbar : \mathbb{T}^{-1} \otimes \mathbb{L}^2 \otimes \mathbb{M}$. Actually, in the classical theory any such scale would do; on the other hand, in the quantum theory, we have to assume just the actual value of this scale.

2. Spacetime

Our basic framework is spacetime with its fibering over absolute time.[34,37]

We assume *time* to be an affine space $\boldsymbol{T}$ associated with the vector space $\overline{\mathbb{T}} := \mathbb{T} \otimes \mathbb{R}$ and *spacetime* to be an oriented four-dimensional manifold $\boldsymbol{E}$ fibered over time by the *absolute time map* $t : \boldsymbol{E} \to \boldsymbol{T}$.

We shall refer to *spacetime charts* $(x^\lambda) = (x^0, x^i)$ adapted to the time fibering, to the affine structure of time, to a time unit of measurement $u_0 \in \overline{\mathbb{T}}$ and to the orientation of spacetime.

We shall be concerned with the *tangent space* $T\boldsymbol{E}$ of spacetime and its *vertical tangent* subspace $J : V\boldsymbol{E} \subset T\boldsymbol{E}$, consisting of the vectors tangent to the fibers, which are called *spacelike*. Moreover, we shall be concerned with the *cotangent space* $T^*\boldsymbol{E}$ of spacetime and its *horizontal subspace* $H^*\boldsymbol{E} := \boldsymbol{E} \times \overline{\mathbb{T}}^* \subset T^*\boldsymbol{E}$, consisting of forms vanishing on vertical vectors, which are called *timelike*. Furthermore, we shall be concerned with the *horizontal space* $H\boldsymbol{E} := \boldsymbol{E} \times \overline{\mathbb{T}}$ and the *cotangent vertical* space $V^*\boldsymbol{E}$. The local coordinate bases of $T\boldsymbol{E}$, $V\boldsymbol{E}$, $T^*\boldsymbol{E}$, $H\boldsymbol{E}$, and $V^*\boldsymbol{E}$ are denoted by

$$\partial_\lambda \in \mathrm{sec}(\boldsymbol{E}, T\boldsymbol{E}), \quad \partial_i \in \mathrm{sec}(\boldsymbol{E}, V\boldsymbol{E}), \quad d^\lambda \in \mathrm{sec}(\boldsymbol{E}, T^*\boldsymbol{E}), \quad d^0 \in \mathrm{sec}(\boldsymbol{E}, H^*\boldsymbol{E})$$

$$u_0 \in \mathrm{sec}(\boldsymbol{E}, H\boldsymbol{E}), \quad \check{d}^i \in \mathrm{sec}(\boldsymbol{E}, V^*\boldsymbol{E}).$$

We have the distinguished scaled *time form* $dt : \boldsymbol{E} \to \mathbb{T} \otimes T^*\boldsymbol{E}$, with coordinate expression $dt = u_0 \otimes d^0$. It generates the horizontal subbundle $H^*\boldsymbol{E} \subset T^*\boldsymbol{E}$. We shall often make the natural identification $u^0 \simeq d^0$ via pullback.

We have the natural *timelike projection* and *spacelike projection*

$$dt : T\boldsymbol{E} \to H\boldsymbol{E} : X \mapsto dt(X) \quad \text{and} \quad J^* : T^*\boldsymbol{E} \to V^*\boldsymbol{E} : \alpha \mapsto \check{\alpha} := \alpha \circ J,$$

with coordinate expressions $dt(X) = X^0 u_0$ and $\check{\alpha} = \alpha_i \check{d}^i$.

In general, the inverted caret "$\check{}$" will denote the vertical restriction of spacetime forms. We stress that we *do not* have natural inclusions and projections of the following type

$$V^*\boldsymbol{E} \subset T^*\boldsymbol{E}, \quad H\boldsymbol{E} \subset T\boldsymbol{E} \quad \text{and} \quad T\boldsymbol{E} \to V\boldsymbol{E}, \quad T^*\boldsymbol{E} \to H^*\boldsymbol{E}.$$

This is an important feature of our relativistic model; indeed, we need the choice of an "observer" in order to achieve such inclusions and projections.

We shall be involved with the Lie subalgebras

$$\mathrm{proj}(\boldsymbol{E}, T\boldsymbol{E}) \subset \mathrm{sec}(\boldsymbol{E}, T\boldsymbol{E}) \quad \text{and} \quad \mathrm{fine}(\boldsymbol{E}, T\boldsymbol{E}) \subset \mathrm{proj}(\boldsymbol{E}, T\boldsymbol{E})$$

of spacetime vector fields which are projectable on $\boldsymbol{T}$ and whose time component is constant, respectively. Their coordinate expressions are of the type

$$X = X^0\partial_0 + X^i\partial_i \in \mathrm{proj}(\boldsymbol{E}, T\boldsymbol{E}) \quad \text{with} \quad X^0 \in \mathrm{map}(\boldsymbol{T}, \mathbb{R}), X^i \in \mathrm{map}(\boldsymbol{E}, \mathbb{R}),$$

$$X = X^0\partial_0 + X^i\partial_i \in \mathrm{fine}(\boldsymbol{E}, T\boldsymbol{E}) \quad \text{with} \quad X^0 \in \mathbb{R} \quad X^i \in \mathrm{map}(\boldsymbol{E}, \mathbb{R}).$$

3. Observers

Observers are essential tools for performing physical measurements. In the standard literature, the measurements are usually described by coordinates. But what is essentially necessary is the observer underlying a system of coordinates.

Our relativistic model does not exhibit any distinguished observer.

The choice of an observer yields the observed inclusions and projections which are not provided by the time fibering.

An *observer* is defined to be a (local) section $o:\boldsymbol{E}\to\mathbb{T}^*\otimes T\boldsymbol{E}$, which projects on $\mathbf{1}\in\mathbb{T}^*\otimes\mathbb{T}$, i.e., a (local) section $o:\boldsymbol{E}\to J_1\boldsymbol{E}$, where $J_1\boldsymbol{E}$ denotes the first jet space of spacetime. Thus, an observer is just a connection of the spacetime fibering.

The coordinate expression of an observer o is of the type $o=u^0\otimes(\partial_0+o_0^i\partial_i)$, where $o_0^i \in \mathrm{map}(\boldsymbol{E},\mathbb{R})$. The charts (x^λ) for which $o_0^i=0$ are said to be *adapted* to o. Conversely, each chart (x^λ) is adapted to a unique observer, whose coordinate expression turns out to be $o:=u^0\otimes\partial_0$.

Each observer o yields the *observed spacelike projection* $\nu[o]:T\boldsymbol{E}\to V\boldsymbol{E}:X\mapsto X-o(dt(X))$ and the *observed timelike projection* $o^*:T^*\boldsymbol{E}\to H^*\boldsymbol{E}:\alpha\circ o\simeq o\rfloor\alpha$, whose coordinate expressions are $\nu[o]=(d^i-o_0^id^0)\otimes\partial_i$ and $o^*=d^0\otimes(\partial_0+o_0^i\partial_i)$.

Moreover, an observer o yields the *observed spacelike inclusion* $\nu^*[o]:V^*\boldsymbol{E}\hookrightarrow T^*\boldsymbol{E}:\alpha\mapsto\alpha\circ\nu[o]$ and the *observed timelike inclusion* $o:H\boldsymbol{E}\hookrightarrow T\boldsymbol{E}:X\mapsto o(X)$, whose coordinate expressions are $\nu^*[o](\alpha)=\alpha_i(d^i-o_0^id^0)$ and $o(X)=X^0(\partial_0+o_0^i\partial_i)$.

Thus, an observer o yields the *observed splittings* of the tangent and cotangent spaces of spacetime into the direct sum of their timelike and spacelike components

$$T\boldsymbol{E}=H\boldsymbol{E}\oplus V\boldsymbol{E}:X\mapsto dt(X)+\nu[o](X),\quad T^*\boldsymbol{E}=H^*\boldsymbol{E}\oplus V^*\boldsymbol{E}:\alpha\mapsto o^*(\alpha)+\jmath^*(\alpha).$$

4. Metric field

The fibers of spacetime are equipped with a given Riemannian metric.[34,37]

We assume spacetime to be equipped with a scaled Riemannian metric of the fibers $g:\boldsymbol{E}\to\mathbb{L}^2\otimes(V^*\boldsymbol{E}\otimes V^*\boldsymbol{E})$.

With reference to a particle of mass m, it is useful to define the *rescaled spacelike metric* $G:=(m/\hbar)g:\boldsymbol{E}\to\mathbb{T}\otimes(V^*\boldsymbol{E}\otimes V^*\boldsymbol{E})$.

We denote the contravariant spacelike metric and the contravariant rescaled spacelike metric by $\bar g:\boldsymbol{E}\to\mathbb{L}^{*2}\otimes(V\boldsymbol{E}\otimes V\boldsymbol{E})$ and $\bar G:=(\hbar/m)\bar g:\boldsymbol{E}\to\mathbb{T}^*\otimes(V\boldsymbol{E}\otimes V\boldsymbol{E})$.

The spacelike metric g and the spacetime orientation naturally yield the scaled *spacelike volume form* $\eta:\boldsymbol{E}\to\mathbb{L}^3\otimes\Lambda^3V^*\boldsymbol{E}$, with coordinate expression $\eta=\sqrt{|g|}\check d^1\wedge\check d^2\wedge\check d^3$.

Moreover, the time form and the spacelike volume form yield the scaled *spacetime volume form* $v:=dt\wedge\eta:\boldsymbol{E}\to(\mathbb{T}\otimes\mathbb{L}^3)\otimes\wedge^4T^*\boldsymbol{E}$, with coordinate expression $v=\sqrt{|g|}u_0\otimes d^0\wedge d^1\wedge d^2\wedge d^3$.

For each $X\in\mathrm{sec}(\boldsymbol{E},T\boldsymbol{E})$, the Lie derivative $L[X]\bar G\in\mathrm{sec}(\boldsymbol{E},\mathbb{T}^*\otimes(V\boldsymbol{E}\otimes V\boldsymbol{E}))$ has the coordinate expression $L[X]\bar G=(X^\lambda\partial_\lambda G_0^{ij}-G_0^{hj}\partial_hX^i-G_0^{ih}\partial_hX^j)u^0\otimes\partial_i\otimes\partial_j$.

For each $X\in\mathrm{proj}(\boldsymbol{E},T\boldsymbol{E})$, the Lie derivative $L[X]G\in\mathrm{sec}(\boldsymbol{E},\mathbb{T}\otimes(V^*\boldsymbol{E}\otimes V^*\boldsymbol{E}))$, has the coordinate expression $L[X]G=(X^\lambda\partial_\lambda G_{ij}^0+G_{hj}^0\partial_iX^h+G_{ih}^0\partial_jX^h)u_0\otimes\check d^i\otimes\check d^j$.

For each $X\in\mathrm{sec}(\boldsymbol{E},T\boldsymbol{E})$, the *spacetime divergence* $\mathrm{div}_vX\in\mathrm{map}(\boldsymbol{E},\mathbb{R})$ is well defined by the equality $L[X]v=(\mathrm{div}_vX)v$.

For each $X\in\mathrm{proj}(\boldsymbol{E},T\boldsymbol{E})$, the *spacelike divergence* $\mathrm{div}_\eta X\in\mathrm{map}(\boldsymbol{E},\mathbb{R})$ and the *timelike divergence* $\mathrm{div}_{dt}X\in\mathrm{map}(\boldsymbol{E},\mathbb{R})$ are well defined, respectively, by the equalities $L[X]\eta=(\mathrm{div}_\eta,X)\eta$ and $L[X]dt=(\mathrm{div}_{dt}X)dt$.

We have the coordinate expressions

$$\mathrm{div}_v X = \frac{\partial_\lambda(X^\lambda\sqrt{|g|})}{\sqrt{|g|}}, \quad \mathrm{div}_\eta X = X^0\frac{\partial_0\sqrt{|g|}}{\sqrt{|g|}} + \frac{\partial_j(X^j\sqrt{|g|})}{\sqrt{|g|}}, \quad \mathrm{div}_{dt} X = \partial_0 X^0.$$

Hence, for each $X \in \mathrm{proj}(\boldsymbol{E}, T\boldsymbol{E})$, we obtain $\mathrm{div}_v X = \mathrm{div}_{dt} X + \mathrm{div}_\eta X$ and, for each $X \in \mathrm{fine}(\boldsymbol{E}, T\boldsymbol{E})$, we obtain $\mathrm{div}_v X = \mathrm{div}_\eta X$.

Moreover, for each $X \in \mathrm{proj}(\boldsymbol{E}, T\boldsymbol{E})$, we obtain $\mathrm{div}_\eta X = \frac{1}{2}\langle \bar{G}, L[X]G\rangle$.

5. Gravitational and electromagnetic fields

Spacetime is equipped with given gravitational and electromagnetic fields.[34]

We assume spacetime to be equipped with a *gravitational field*, i.e., with a linear connection $K^\natural : T\boldsymbol{E} \to T^*\boldsymbol{E} \otimes TT\boldsymbol{E}$, such that $\nabla^\natural dt = 0$ and $\nabla^\natural g = 0$, and such that its curvature tensor $R[K^\natural]$ fulfills the symmetry condition $R^\natural{}_{i\lambda j\mu} = R^\natural{}_{.j\mu i\lambda}$.

Proposition 2.1: The coordinate expression of the gravitational field is of the type

$$K^\natural{}_\lambda{}^0{}_\mu = 0,$$

$$K^\natural{}_0{}^i{}_0 = -G_0^{ij} 2\Phi_{0j},$$

$$K^\natural{}_0{}^i{}_h = K^\natural{}_h{}^i{}_0 = -\tfrac{1}{2} G_0^{ij}(\partial_0 G^0_{jh} + 2\Phi_{hj}),$$

$$K^\natural{}_k{}^i{}_h = K^\natural{}_h{}^i{}_k = -\tfrac{1}{2} G_0^{ij}(\partial_h G^0_{jk} - \partial_j G^0_{hk} + \partial_k G^0_{jh}),$$

where $\Phi^\natural[o] = \Phi^\natural{}_{\lambda\mu} d^\lambda \wedge d^\mu \in \mathrm{sec}(\boldsymbol{E}, \Lambda^2 T^*\boldsymbol{E})$ is a closed two-form, which depends on the chosen chart only through the associated observer o. QED

We shall denote by $A^\natural[o]$ the local potentials of $\Phi^\natural[o]$, according to $2dA^\natural[o] = \Phi^\natural[o]$.

We assume spacetime to be equipped with an *electromagnetic field*, i.e., with a closed scaled two-form $F : \boldsymbol{E} \to (\mathbb{L}^{1/2} \otimes \mathbb{M}^{1/2}) \otimes \Lambda^2 T^*\boldsymbol{E}$ (see also Ref. 46).

Given a particle with mass $m \in \mathbb{M}$ and charge $q \in \mathbb{T}^{-1} \otimes \mathbb{L}^{3/2} \otimes \mathbb{M}^{1/2}$, it is convenient to consider, respectively, the unscaled field and the rescaled field

$$\tfrac{q}{\hbar} F : \boldsymbol{E} \to \Lambda^2 T^*\boldsymbol{E} \quad \text{and} \quad \tfrac{q}{m}\hat{F} : \boldsymbol{E} \to \mathbb{T}^{-1} \otimes (V\boldsymbol{E} \otimes T^*\boldsymbol{E}),$$

where $\hat{F} = g^{\sharp 2}(F) = g^{ih} F_{\lambda h} \partial_i \otimes d^\lambda$.

The electromagnetic field F can be "joined," in a covariant way, to the gravitational field yielding the *"joined" spacetime connection* $K = K^\natural - dt \otimes (q/2m)\hat{F} - (q/2m)\hat{F} \otimes dt$.

The joined K still fulfills the properties that we have assumed for $K^\natural$. Moreover, all objects derived from the joined connection split into components related to the gravitational and the electromagnetic fields.

In particular, the observed potential $A[o]$ of the joined connection splits into the sum of the gravitational and electromagnetic potentials as $A[o] = A^\natural[o] + (q/\hbar)A^e$, where $A^e \in \mathrm{sec}(\boldsymbol{E}, (\mathbb{L}^{1/2} \otimes \mathbb{M}^{1/2}) \otimes T^*\boldsymbol{E})$ is a local (observer independent) potential of F, according to $2dA^e = F$.

Thus, from now on, with reference to a particle of mass m and charge q, we shall refer to the spacetime structure constituted by the 4-plet $(\boldsymbol{E}, t, G, K)$, whose elements fulfill the properties mentioned above.

6. Basic model of spacetime

The present paper deals with a curved spacetime. However, this model includes flat or partially flat spacetimes, as well.[34] Thus, the standard mechanics can be recovered as a particular case of our theory.

The simplest model of spacetime is given by the following construction.

We consider an oriented affine space $\boldsymbol{E}$ that is associated with the vector space $\bar{\boldsymbol{E}}$ and equipped with an affine map $t:\boldsymbol{E}\to\boldsymbol{T}$ of rank 1.

Let us consider the vector subspace $\boldsymbol{S}:=\ker Dt\subset\bar{\boldsymbol{E}}$. We can easily see that all fibers of the fibering $t:\boldsymbol{E}\to\boldsymbol{T}$ are affine subspaces of $\boldsymbol{E}$ associated with the same vector space $\boldsymbol{S}$. Hence, the spacetime fibered space turns out to be an Abelian principal bundle with structural group $\boldsymbol{S}$.

We assume as spacelike metric a constant Euclidean metric on $\boldsymbol{S}$.

Moreover, we assume as gravitational connection the connection induced by the affine structure of spacetime. Eventually, we assume a vanishing electromagnetic field.

Clearly, the above objects fulfill our axioms. We call such a spacetime a *special Newtonian spacetime*. In this model we can easily define the standard inertial motions and inertial observers.

We could consider also a little more complex model, which assumes the previous structure for background and adds a gravitational connection which is Ricci flat. This model accounts for the standard notions of classical mechanics, including Newton's law of gravitation.

The rigid body provides a further nontrivial example of our model.[59]

B. Phase space and the induced structure

1. Classical phase space

We assume as phase space of a classical particle the first jet space of sections of spacetime.[34,37]

The first jet space (Refs. 39 and 63) $J_1\boldsymbol{E}$ of $t:\boldsymbol{E}\to\boldsymbol{T}$ is a fibered manifold $t^1:J_1\boldsymbol{E}\to\boldsymbol{T}$ over $\boldsymbol{T}$ and an affine bundle $t^1_0:J_1\boldsymbol{E}\to\boldsymbol{E}$ over $\boldsymbol{E}$, associated with the vector bundle $\mathbb{T}^*\otimes V\boldsymbol{E}$. Hence, the vertical space of $J_1\boldsymbol{E}$ with respect to $\boldsymbol{E}$ turns out to be $V_0J_1\boldsymbol{E}=\mathbb{T}^*\otimes V\boldsymbol{E}$.

We denote the fibered charts of the phase space by (x^0,x^i,x^i_0).

The above affine structure yields the natural tensor $\nu:J_1\boldsymbol{E}\to\mathbb{T}\otimes(V^*\boldsymbol{E}\otimes VJ_1\boldsymbol{E})$, with $\nu=u_0\otimes\check{d}^i\otimes\partial^0_i$.

We recall the natural *contact maps* $\mathit{\Pi}:J_1\boldsymbol{E}\to\mathbb{T}^*\boldsymbol{E}\otimes T\boldsymbol{E}$ and $\theta:J_1\boldsymbol{E}\to\mathbb{T}^*\otimes V\boldsymbol{E}$, with $\mathit{\Pi}=u^0\otimes(\partial_0+x^i_0\partial_i)$ and $\theta=\partial_i\otimes(d^i-x^i_0d^0)$. From now on, $J_1\boldsymbol{E}$ is considered as a subspace of $\mathbb{T}^*\otimes T\boldsymbol{E}$, according to the natural embedding $\mathit{\Pi}$.

We shall be involved with the Lie subalgebras

$$\mathrm{proj}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})\subset\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})\quad\text{and}\quad\mathrm{fine}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})\subset\mathrm{proj}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$$

of vector fields of $J_1\boldsymbol{E}$, which are projectable on $\boldsymbol{E}$ and $\boldsymbol{T}$, and additionally whose time components are constant, respectively.

2. Holonomic prolongation of spacetime vector fields

We have a natural prolongation of spacetime vector fields to phase vector fields.

Proposition 2.2:[37,55] There is a natural fibered morphism $r_1:J_1T\boldsymbol{E}\to TJ_1\boldsymbol{E}$ over $J_1\boldsymbol{E}\underset{\boldsymbol{T}}{\times}J_1T\boldsymbol{T}$, with $(x^0,x^i,x^i_0;\dot{x}^0\dot{x}^i,\dot{x}^i_0)\circ r_1=(x^0,x^i,x^i_0;\dot{x}^0,\dot{x}^i,\dot{x}^i_0-\dot{x}^i_0\dot{x}^0_0)$.

Then, for each $X\in\mathrm{sec}(\boldsymbol{E},T\boldsymbol{E})$, we obtain the vector field, called *first holonomic prolongation* of X, $X_{(1)}:=r_1\circ J_1X\in\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$, which projects on X. Its coordinate expression is $X_{(1)}=X^0\partial_0+X^i\partial_i+(\partial_0X^i+\partial_jX^ix^j_0-\partial_0X^0x^i_0-\partial_jX^0x^j_0x^i_0)\partial^0_i$.

The map $r_1\circ J_1:\mathrm{sec}(\boldsymbol{E},T\boldsymbol{E})\to\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E}):X\mapsto X_{(1)}$ turns out to be an injective $\mathbb{R}$-linear morphism of Lie algebras. QED

In the particular case when the vector field X is projectable on $\boldsymbol{T}$, we recover the standard holonomic prolongation obtained through the first jet prolongation of the fibered flow of X. In fact, the above map restricts to the injective $\mathbb{R}$-linear map

$$\mathrm{proj}(\boldsymbol{E},T\boldsymbol{E})\to\mathrm{proj}(J_1\boldsymbol{E},TJ_1\boldsymbol{E}):X\mapsto X_{(1)},$$

with coordinate expression $X_{(1)}=X^0\partial_0+=X^i\partial_i+(\partial_0X^i+\partial_jX^ix^j_0-\partial_0X^0x^i_0)\partial^0_i$.

Later, we shall use the following technical results.

Lemma 2.3:[37] For each $X \in \sec(\boldsymbol{E}, T\boldsymbol{E})$, we have the equalities

$$L[X_{(1)}]\theta = (\text{Д} \,.\, (dt(X)))\,\theta \quad \text{and} \quad L[X_{(1)}]\,\text{Д} = -\,(\text{Д} \,.\, (dt(X)))\,\text{Д}\,,$$

with coordinate expressions

$$L[X_{(1)}]\theta = (\partial_0 X^0 + \partial_j X^0 x_0^j)(d^i - x_0^i d^0) \otimes \partial_i^0\,,$$

$$L[X_{(1)}]\,\text{Д} = -\,(\partial_0 X^0 + x_0^j \partial_j X^0)(\partial_0 + x_0^i \partial_i)\,.$$

QED

For each $X^{\uparrow} \in \text{proj}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ which projects on $X \in \text{proj}(\boldsymbol{E}, T\boldsymbol{E})$, the *spacelike divergence* $\text{div}_{\eta} X^{\uparrow} \in \text{map}(J_1\boldsymbol{E}, \mathbb{R})$ is well defined by the equality $L[X^{\uparrow}]\eta = (\text{div}_{\eta} X^{\uparrow})\,\eta$ and we obtain $\text{div}_{\eta} X^{\uparrow} = \text{div}_{\eta} X$.

3. Distinguished phase fields

The spacetime connection and the rescaled metric yield in a covariant way further objects on the phase space.[34,37]

The spacetime connection K yields a torsion free affine connection of the affine bundle $J_1\boldsymbol{E} \to \boldsymbol{E}$, called *phase connection*, $\Gamma[K]: J_1\boldsymbol{E} \to T^*\boldsymbol{E} \otimes TJ_1\boldsymbol{E}$, with coordinate expression $\Gamma_{\lambda 0}^{\ i} := \Gamma_{\lambda 0 j}^{\ i 0} x_0^j + \Gamma_{\lambda 00}^{\ i 0}$, where $\Gamma_{\lambda 0 \mu}^{\ i 0} = K_{\lambda}^{\ i}{}_{\mu}$ Conversely, Γ characterizes K.

The phase connection Γ splits into the gravitational and electromagnetic components as $\Gamma = \Gamma^{\natural} + \Gamma^e$ where $\Gamma^e = -(g/2m)(\hat{F} + \text{Д} \lrcorner \hat{F}) \in \sec(J_1\boldsymbol{E}, \mathbb{T}^* \otimes (T^*\boldsymbol{E} \otimes V\boldsymbol{E}))$.

We have $\Gamma_{00}^{i\,j} - \Gamma_{00}^{j\,i} = -G_0^{ih} G_0^{jk}((\partial_h G_{kl}^0 - \partial_k G_{hl}^0) x_0^l + \partial_h A_k - \partial_k A_h)$, with $\Gamma_{00}^{hk} := G_0^{hl} \Gamma_{l0}^k$.

Then, Γ yields the *second-order connection* $\gamma[\Gamma] := \text{Д} \lrcorner \Gamma : J_1\boldsymbol{E} \to J_2\boldsymbol{E} \subset \mathbb{T}^* \otimes TJ_1\boldsymbol{E}$, with $\gamma = u^0 \otimes (\partial_0 + x_0^i \partial_i + \gamma_{00}^{\ i} \partial_i^0)$, where

$$\begin{aligned}\gamma_{00}^{\ i} &= K_h^{\ i}{}_k x_0^h x_0^k + 2K_h^{\ i}{}_0 x_0^h + K_0^{\ i}{}_0 \\ &= -\,G_0^{ij}\Big(\Big(\partial_h G_{jk}^0 - \tfrac{1}{2}\partial_j G_{hk}^0\Big) x_0^h x_0^k + (\partial_0 G_{hj}^0 + \partial_h A_j - \partial_j A_h) x_0^h + \partial_0 A_j - \partial_j A_0\Big).\end{aligned}$$

Conversely, γ characterizes Γ.

The second-order connection γ splits into the gravitational and electromagnetic components as $\gamma^{\natural} + \gamma^e$, where $\gamma^e = -(q/m)\,\text{Д} \lrcorner \hat{F} : J_1\boldsymbol{E} \to (\mathbb{T}^* \otimes \mathbb{T}^*) \otimes V\boldsymbol{E}$ equals the Lorentz force.

Then, Γ and G yield the *phase two-form* $\Omega[G, \Gamma] := G \lrcorner (\nu[\Gamma] \wedge \theta) : J_1\boldsymbol{E} \to \Lambda^2 J_1 T\boldsymbol{E}$, with $\Omega = G_{ij}^0 (d_0^i - \gamma_{00}^{\ i} d^0 - \Gamma_{h0}^{\ i} \theta^h) \wedge \theta^j$, and where $\nu[\Gamma]$ is the vertical valued form associated with Γ. Conversely, Ω characterizes Γ and G.[62]

The two-form Ω splits into the gravitational and electromagnetic components as $\Omega = \Omega^{\natural} + \Omega^e$, where $\Omega^e = (q/2\hbar)F$.

Then, Γ and G yield the two-vector $\Lambda[G, \Gamma] := \bar{G} \lrcorner (\check{\Gamma} \wedge \nu) : J_1\boldsymbol{E} \to \Lambda^2 V J_1\boldsymbol{E}$, with $\Lambda = G_0^{ij}(\partial_i + \Gamma_{i0}^{\ h}) \wedge \partial_j^0$, where $\check{\Gamma} : J_1\boldsymbol{E} \to V^*\boldsymbol{E} \otimes V J_1\boldsymbol{E}$ is the vertical restriction of Γ.

The two-vector Λ splits into the gravitational and electromagnetic components as $\Lambda = \Lambda^{\natural} + \Lambda^e$, where $\Lambda^e = (q/2\hbar) G^{\sharp}(F) : J_1\boldsymbol{E} \to \Lambda^2 V J_1\boldsymbol{E}$.

We have the identities $i(\gamma)dt = 1$, $i(\gamma)\Omega = 0$, $L[\gamma]\Lambda = 0$, $[\Lambda, \Lambda] = 0$.

Therefore, $(J_1\boldsymbol{E}, dt, \Omega)$ turns out to be a scaled cosymplectic manifold, where γ is the associated scaled Reeb vector field and Λ is the associated two-vector.

We have the following results which will be used later.

Proposition 2.4:[62] For each $X \in \text{proj}(\boldsymbol{E}, T\boldsymbol{E})$, the following implications hold:

$$L[X_{(1)}]\Omega = 0 \Leftrightarrow L[X_{(1)}]\Gamma = 0, \quad L[X]G = 0\,,$$

$$L[X_{(1)}]\Omega = 0 \Rightarrow \text{div}_{\eta} X = 0\,.$$

QED

C. Classical mechanics

The spacetime structure and the joined connection allow us to formulate the dynamics of a classical particle under the action of the gravitational and electromagnetic fields.[34,37]

1. Classical kinematics

A *motion* is defined to be a section $s \in \mathrm{sec}(\boldsymbol{T},\boldsymbol{E})$ and its *absolute velocity* is defined to be the first jet prolongation $j_1 s \in \mathrm{sec}(\boldsymbol{T},J_1\boldsymbol{E})$.

An observer o yields the following objects:

- the affine fibered morphism $\nabla[o] := \mathbf{id} - (o \circ t_0^1) \in \mathrm{fib}(J_1\boldsymbol{E},\mathbb{T}^*\otimes V\boldsymbol{E})$ over $\boldsymbol{E}$,
- the observed *kinetic momentum* $\mathcal{Q}[o] := G^\flat \circ \nabla[o] : J_1\boldsymbol{E} \to V^*\boldsymbol{E}$ and the observed *kinetic energy* $\mathcal{K}[o] := \frac{1}{2} G \lrcorner (\nabla[o] \otimes \nabla[o]) : J_1\boldsymbol{E} \to \mathbb{T}^* \otimes \mathbb{R}$,
- for each motion s, the *observed velocity* $\nabla[o]s := j_1 s - o \circ s \in \mathrm{sec}(\boldsymbol{T},\mathbb{T}^*\otimes V\boldsymbol{E})$,

Their expressions, in adapted coordinates, are

$$\nabla[o] = x_0^i u^0 \otimes \partial_i, \quad \mathcal{Q}[o] = G^0_{ij} x_0^j \check{d}^i, \quad \mathcal{K}[o] = \tfrac{1}{2} G^0_{ij} x_0^i x_0^j u^0, \quad \nabla[o]s = \partial_0 s^i u^0 \otimes \partial_i.$$

In the special Newtonian spacetime, we can also define the usual *observed angular momentum* $\mathcal{M}[o,c] := r[c] \times \mathcal{Q}[o]$ with respect to an inertial motion c as reference center.

For each motion s, the absolute gravitational *acceleration* is defined to be the section $\nabla[\gamma^\natural] j_1 s := j_2 s - (\gamma^\natural \circ j_1 s) \in \mathrm{sec}(\boldsymbol{T},\mathbb{T}^*\otimes\mathbb{T}^*\otimes V\boldsymbol{E})$ and the absolute joined *acceleration* is defined to be the section $\nabla[\gamma] j_1 s := j_2 s - (\gamma \circ j_1 s) \in \mathrm{sec}(\boldsymbol{T},\mathbb{T}^*\otimes\mathbb{T}^*\otimes V\boldsymbol{E})$. Clearly, we have $\nabla[\gamma] j_1 s = \nabla[\gamma^\natural] j_1 s - \gamma^\mathscr{C} \circ j_1 s$. We have the coordinate expression

$$\nabla[\gamma] j_1 s = (\partial_{00} s^i - (K_h{}^i{}_k \circ s)\partial_0 s^h \partial_0 s^k - 2(K_0{}^i{}_h \circ s)\partial_0 s^h - (K_0{}^i{}_0 \circ s)) u^0 \otimes u^0 \otimes \partial_i.$$

2. Classical dynamics

We assume the *generalized Newton's law* as equation of motion for classical dynamics $\nabla[\gamma] j_1 s := j_2 s - \gamma \circ j_1 s = 0$.

A function $f \in \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$ such that $\gamma \cdot f = 0$ is said to be *conserved*. We denote the subsheaf of conserved functions by $\mathrm{cons}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$.

We can also obtain the classical dynamics by a Lagrangian formalism according to a cohomological procedure in the following way.

The phase two-form Ω admits locally *horizontal potentials* $A^\uparrow \in \mathrm{sec}(J_1\boldsymbol{E},T^*\boldsymbol{E})$, which are defined up to a closed spacetime form $\alpha \in \mathrm{sec}(\boldsymbol{E},T^*\boldsymbol{E})$. Each horizontal potential $A^\uparrow$ splits, in a covariant way, as $A^\uparrow = \mathcal{L}[A^\uparrow] + \mathcal{P}[A^\uparrow]$, through the horizontal component $\mathcal{L}[A^\uparrow] := \Pi \lrcorner A^\uparrow$, called *Lagrangian*, and the Π-vertical component $\mathcal{P}[A^\uparrow] := \theta \lrcorner A^\uparrow$, called *momentum*. Moreover, we obtain $D\mathcal{L}[A^\uparrow] = \check{\mathcal{P}}[A^\uparrow]$. Hence, each horizontal potential $A^\uparrow$ turns out to be just the *Poincaré-Cartan form* Θ of the associated Lagrangian $\mathcal{L}[A^\uparrow]$.

Moreover, the horizontal component of Ω turns out to be the fibered morphism $\mathcal{E} = G^\flat(\nabla[\gamma]) : J_2\boldsymbol{E} \to \mathbb{T}^* \otimes V^*\boldsymbol{E}$. Indeed, $\mathcal{E}$ turns out to be just the Euler-Lagrange operator associated with the Lagrangian $\mathcal{L}(A^\uparrow)$, for each horizontal potential $A^\uparrow$.

Next, let us choose a horizontal potential $A^\uparrow$ and an observer o.

Then, we define the *observed potential* to be the spacetime one-form $A[o] := o^* A^\uparrow \in \mathrm{sec}(\boldsymbol{E},T^*\boldsymbol{E})$. This form turns out to be just an observed potential of the joined connection K. Moreover, we define the observed *Hamiltonian* to be the function $\mathcal{H}[o] := -o \lrcorner A^\uparrow$ and the observed *momentum* to be the form $\mathcal{P}[o] := \nu[o] \lrcorner A^\uparrow$.

We have the following expressions, in adapted coordinates,

$$A^{\uparrow} = -\tfrac{1}{2}G^0_{ij}x^i_0x^j_0d^0 + G^0_{ij}x^j_0d^i + A_\lambda d^\lambda,$$

$$\mathcal{L} = \mathcal{L}_0d^0 = \left(\tfrac{1}{2}G^0_{ij}x^i_0x^j_0 + A_ix^i_0 + A_0\right)d^0, \quad \mathcal{P} = (G^0_{ij}x^j_0 + A_i)(d^i - x^i_0d^0),$$

$$A[o] = A_\lambda d^\lambda, \quad \mathcal{H}[o] = \mathcal{H}_0d^0 = \left(\tfrac{1}{2}G^0_{ij}x^i_0x^j_0 - A_0\right)d^0, \quad \mathcal{P}[o] = (G^0_{ij}x^j_0 + A_i)d^i.$$

D. Hamiltonian methods

We devote the following to the basic recalls concerning the splitting of the tangent space of the phase space, the Hamiltonian lift of phase functions, and the Poisson bracket of phase functions.[34,37]

1. Hamiltonian splitting

The time fibering and the second-order connection yield in a covariant way a splitting of the tangent and cotangent spaces of the phase space.

We have the natural dual splittings over $J_1\boldsymbol{E}$,

$$TJ_1\boldsymbol{E} = H_\gamma J_1\boldsymbol{E} \oplus VJ_1\boldsymbol{E} \quad \text{and} \quad T^*J_1\boldsymbol{E} = H^*J_1\boldsymbol{E} \oplus V^*_\gamma J_1\boldsymbol{E},$$

given by $X^{\uparrow} = dt(X^{\uparrow})\gamma + (X^{\uparrow} - dt(X^{\uparrow})\gamma)$ and $\phi^{\uparrow} = \phi^{\uparrow}(\gamma)dt + (\phi^{\uparrow} - \phi^{\uparrow}(\gamma)dt)$, where

- $VJ_1\boldsymbol{E} \subset TJ_1\boldsymbol{E}$ is the vertical subbundle with respect to dt,
- $H^*J_1\boldsymbol{E} \subset T^*J_1\boldsymbol{E}$ is the horizontal subbundle generated by dt,
- $H_\gamma J_1\boldsymbol{E} \subset TJ_1\boldsymbol{E}$ is the horizontal subbundle generated by γ,
- $V^*_\gamma J_1\boldsymbol{E} \subset T^*J_1\boldsymbol{E}$ is the vertical subbundle of forms which annihilate γ.

We define the *musical morphisms* to be the linear maps

$$\Omega^\flat : \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E}) \to \mathrm{sec}(J_1\boldsymbol{E}, V^*_\gamma J_1\boldsymbol{E}) : X^{\uparrow} \mapsto i(X^{\uparrow})\Omega,$$

$$\Lambda^\sharp : \mathrm{sec}(J_1\boldsymbol{E}, T^*J_1\boldsymbol{E}) \to \mathrm{sec}(J_1\boldsymbol{E}, VJ_1\boldsymbol{E}) : \phi^{\uparrow} \mapsto i(\phi^{\uparrow})\Lambda.$$

The musical morphisms restrict to the mutually inverse linear maps

$$\Omega^\flat_0 : \mathrm{sec}(J_1\boldsymbol{E}, VJ_1\boldsymbol{E}) \to \mathrm{sec}(J_1\boldsymbol{E}, V^*_\gamma J_1\boldsymbol{E})$$

$$\Lambda^\sharp_0 : \mathrm{sec}(J_1\boldsymbol{E}, V^*_\gamma J_1\boldsymbol{E}) \to \mathrm{sec}(J_1\boldsymbol{E}, VJ_1\boldsymbol{E}).$$

For each $X^{\uparrow} \in \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ and $\phi^{\uparrow} \in \mathrm{sec}(J_1\boldsymbol{E}, T^*J_1\boldsymbol{E})$, we obtain the equalities

$$(\Lambda^\sharp \circ \Omega^\flat)(X^{\uparrow}) = X^{\uparrow} - dt(X^{\uparrow})\gamma, \quad \Omega^\flat(X^{\uparrow}) = (\Lambda^\sharp{}_0)^{-1}(X^{\uparrow} - dt(X^{\uparrow})\gamma),$$

$$(\Omega^\flat \circ \Lambda^\sharp)(\phi^{\uparrow}) = \phi^{\uparrow} - \phi^{\uparrow}(\gamma)dt, \quad \Lambda^\sharp(\phi^{\uparrow}) = (\Omega^\flat{}_0)^{-1}(\phi^{\uparrow} - \phi^{\uparrow}(\gamma)dt).$$

Hence, we can write $X^{\uparrow} = dt(X^{\uparrow})\gamma + (\Lambda^\sharp \circ \Omega^\flat)(X^{\uparrow})$ and $\phi^{\uparrow} = \phi^{\uparrow}(\gamma)dt + (\Omega^\flat \circ \Lambda^\sharp)(\phi^{\uparrow})$.

Given a *time scale* $\tau \in \mathrm{map}(J_1\boldsymbol{E}, \overline{\mathbb{T}})$, we define the τ-horizontal subbundle $H_\tau J_1\boldsymbol{E} \subset TJ_1\boldsymbol{E}$ consisting of vectors whose time components are given by τ. Then, we obtain the mutually inverse affine maps

$$\Omega^\flat{}_\tau : \mathrm{sec}(J_1\boldsymbol{E}, H_\tau J_1\boldsymbol{E}) \to \mathrm{sec}(J_1\boldsymbol{E}, V^*_\gamma J_1\boldsymbol{E}) : X^{\uparrow} \mapsto i(X^{\uparrow})\Omega,$$

$$\Lambda^\sharp{}_\tau : \mathrm{sec}(J_1\boldsymbol{E}, V^*_\gamma J_1\boldsymbol{E}) \to \mathrm{sec}(J_1\boldsymbol{E}, H_\tau J_1\boldsymbol{E}) : \phi^{\uparrow} \mapsto \gamma(\tau) + i(\phi^{\uparrow})\Lambda.$$

For each $X^{\uparrow}, \bar{X}^{\uparrow} \in \sec(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ and $\phi^{\uparrow}, \bar{\phi}^{\uparrow} \in \sec(J_1\boldsymbol{E}, T^*J_1\boldsymbol{E})$, we have the following equivalences:

$$X^{\uparrow} = \bar{X}^{\uparrow} \Leftrightarrow dt(X^{\uparrow}) = dt(\bar{X}^{\uparrow}), \quad \Omega^{\flat}(X^{\uparrow}) = \Omega^{\flat}(\bar{X}^{\uparrow})$$
