$$\phi^{\uparrow} = \bar{\phi}^{\uparrow} \Leftrightarrow \phi^{\uparrow}(\gamma) = \phi^{\uparrow}(\bar{\gamma}), \quad \Lambda^{\sharp}(\phi^{\uparrow}) = \Lambda^{\sharp}(\bar{\phi}^{\uparrow}).$$

2. Poisson bracket

We introduce the Poisson bracket in our cosymplectic framework by an approach which is rather analogous to that of symplectic manifolds[34,37]

We define the *Poisson bracket* on $\mathrm{map}(J_1\boldsymbol{E}, \mathbb{R})$ by $\{f,g\} := i(df \wedge dg)\Lambda$, which has the coordinate expression $\{f,g\} = G_0^{ij}(\partial_i f \partial_j^0 g - \partial_i g \partial_j^0 f) - (\Gamma_{00}^{ij} - \Gamma_{00}^{ji})\partial_i^0 f \partial_j^0 g$.

For each $f, g \in \mathrm{map}(J_1\boldsymbol{E}, \mathbb{R})$, we have[37] $\gamma.\{f,g\} = \{\gamma.f, g\} + \{f, \gamma.g\}$. Hence, the subsheaf $\mathrm{cons}(J_1\boldsymbol{E}, \mathbb{R}) \subset \mathrm{map}(J_1\boldsymbol{E}, \mathbb{R})$ is closed with respect to the Poisson bracket.

3. Hamiltonian lift of phase functions

In our cosymplectic framework we can introduce the vertical Hamiltonian lift, which partially resembles the usual Hamiltonian lift of symplectic manifolds. Moreover, we can introduce a further affine Hamiltonian lift which depends on an arbitrary choice of a time scale. Furthermore, we obtain a distinguished affine Hamiltonian lift through the distinguished time scale exhibited by each phase function.[34,37]

For each $f \in \mathrm{map}(J_1\boldsymbol{E}, \mathbb{R})$, we define its *vertical Hamiltonian lift* to be the vertical vector field $\Lambda^{\sharp}(df) = (\Omega^{\flat}{}_0)^{-1}(df - \gamma.f) \in \sec(J_1\boldsymbol{E}, VJ_1\boldsymbol{E})$, with coordinate expression $\Lambda^{\sharp}(df) = -G_0^{ij}\partial_j^0 f \partial_i + (G_0^{ij}\partial_j f + (\Gamma_{00}^{ij} - \Gamma_{00}^{ji})\partial_j^0 f)\partial_i^0$.

For each $f, g \in \mathrm{map}(J_1\boldsymbol{E}, \mathbb{R})$, we have $[\Lambda^{\sharp}(df), \Lambda^{\sharp}(dg)] = \Lambda^{\sharp}(d\{f,g\})$. Hence, the map $\mathrm{map}(J_1\boldsymbol{E}, \mathbb{R}) \to \sec(J_1\boldsymbol{E}, TJ_1\boldsymbol{E}) : f \mapsto \Lambda^{\sharp}(df)$ turns out to be a morphism of Lie algebras.

For each $f \in \mathrm{map}(J_1\boldsymbol{E}, \mathbb{R})$, we define its *Hamiltonian lift*, with respect to the *time scale* $\tau \in \mathrm{map}(J_1\boldsymbol{E}, \bar{\mathbb{T}})$, to the vector field $X^{\uparrow}{}_{\mathrm{ham}}[\tau, f] := \gamma(\tau) + \Lambda^{\sharp}(df) \in \sec(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$, with coordinate expression

$$H^{\uparrow}{}_{\mathrm{ham}}[\tau, f] = \tau^0\partial_0 + (\tau^0 x_0^i - G_0^{ij}\partial_j^0 f)\partial_i + (\tau^0 \gamma_{00}^i + G_0^{ij}\partial_j f + (\Gamma_{00}^{ij} - \Gamma_{00}^{ji})\partial_j^0 f)\partial_i^0.$$

We stress that we need the choice of the time scale τ because γ is a scaled vector field. This fact is not a minor point of our theory; instead, it plays an essential role throughout the classical and quantum theories.

Actually, each $f \in \mathrm{map}(J_1\boldsymbol{E}, \mathbb{R})$ yields the time scale $f'' := \frac{1}{3}\langle \bar{G}, D^2 f \rangle$, where $D^2 f \in \mathrm{fib}(J_1\boldsymbol{E}, \mathbb{T}^2 \otimes (V^*\boldsymbol{E} \otimes V^*\boldsymbol{E}))$ is the second fiber derivation of f with respect to the affine fiber of the bundle $J_1\boldsymbol{E} \to \boldsymbol{E}$. Thus, we have the coordinate expression $f'' = f^0 u_0 = \frac{1}{3} G_0^{ij}\partial_i^0 \partial_j^0 f u_0$. The map f'' is called the *time component of* f.

We define the *Hamiltonian lift* of each $f \in \mathrm{map}(J_1, \boldsymbol{E}, \mathbb{R})$ to be the vector field

$$X^{\uparrow}{}_{\mathrm{ham}}[f] := X^{\uparrow}_{\mathrm{ham}}[f'', f] = \gamma(f'') + \Lambda^{\sharp}(df) \in \sec(j_1\boldsymbol{E}, TJ_1\boldsymbol{E}).$$

E. Special phase functions

In the following we collect some basic facts on special phase functions, their Lie bracket and their tangent, Hamiltonian and holonomic lifts.[34,37]

1. The sheaf of special phase functions

A *special phase function* is defined to be a function $f \in \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$, such that $D^2 f = \tau \otimes G$, with $\tau \in \mathrm{map}(\boldsymbol{E},\overline{\mathbb{T}})$. Clearly, if $f \in \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$ is a special phase function, then we obtain $\tau = f''$, hence $D^2 f = f'' \otimes G$, with $f'' \in \mathrm{map}(\boldsymbol{E},\overline{\mathbb{T}})$.

The coordinate expression of a special phase function is of the type

$$f = f^0 \tfrac{1}{2} G^0_{ij} x^i_0 x^j_0 + f^i G^0_{ij} x^j_0 + \breve{f} \quad \text{with} \quad f^0, f^i, \breve{f} \in \mathrm{map}(\boldsymbol{E},\mathbb{R}).$$

Given an observer o, a special phase function f can be written as

$$f = f'' \lrcorner \mathcal{K}[o] + f'[o] \lrcorner \mathcal{Q}[o] + f[o],$$

where, in adapted coordinates,

$$f'' = \tfrac{1}{3}\langle \bar{G}, D^2 f\rangle = f^0 u_0 \in \mathrm{map}(\boldsymbol{E},\overline{\mathbb{T}}),$$

$$f'[o] = G^\sharp(Df) \circ o = f^i \partial_i \in \mathrm{sec}(\boldsymbol{E}, \mathbb{T}^* \otimes V\boldsymbol{E}),$$

$$f[o] = f \circ o = \breve{f} \in \mathrm{map}(\boldsymbol{E},\mathbb{R}).$$

Given a horizontal potential $A^\uparrow$ and an observer o, a special phase function f can be written as $f = f'' \lrcorner \mathcal{H}[A^\uparrow, o] + f'[o] \lrcorner \mathcal{P}[A^\uparrow, o] + (f[o] + f^0 A_0 - f^i A_i)$.

The subsheaf of special phase functions is denoted by $\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$.

Moreover, we shall be involved with the distinguished subsheaves related to the affine structure of the bundle $J_1\boldsymbol{E} \to \boldsymbol{E}$. Thus, we define the following subsheaves:

- the sheaf $\mathrm{proj}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$ consisting of functions, called *projectable*, whose time component $f'' \in \mathrm{map}(\boldsymbol{T},\overline{\mathbb{T}})$ depends only on $\boldsymbol{T}$;
- the sheaf $\mathrm{fine}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{proj}(J_1\boldsymbol{E},\mathbb{R})$ consisting of projectable functions, called *fine*, whose time component $f'' \in \overline{\mathbb{T}}$ is constant;
- the sheaf $\mathrm{aff}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{fine}(J_1\boldsymbol{E},\mathbb{R})$ consisting of projectable functions, called *affine*, whose time component $f'' = 0$ vanishes, i.e., the subsheaf of affine functions with respect to the affine fibers of the bundle $J_1\boldsymbol{E} \to \boldsymbol{E}$;
- the sheaf $\mathrm{map}(\boldsymbol{E},\mathbb{R}) \subset \mathrm{aff}(J_1\boldsymbol{E},\mathbb{R})$ consisting of affine functions such that $Df = 0$, i.e., the subsheaf of affine functions which depend only on $\boldsymbol{E}$.

2. Lifts of special phase functions

Let us analyze three distinguished lifts of special phase functions into vector fields: the Hamiltonian lift, the tangent lift and the holonomic lift.

Let us start with the Hamiltonian lift. The special phase functions are characterized by the following property.

Theorem 2.5: *Let* $\tau \in \mathrm{map}(J_1\boldsymbol{E},\overline{\mathbb{T}})$ *and* $f \in \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$. *Then, the following conditions are equivalent*:

1) $X^\uparrow_{\mathrm{ham}}[\tau, f] \in \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ *is projectable on a vector field* $X[\tau, f] \in \mathrm{sec}(\boldsymbol{E}, T\boldsymbol{E})$,

2) $f \in \mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$ *and* $\tau = f''$.

If either of the above conditions is fulfilled, then we obtain

$$X^\uparrow_{\mathrm{ham}}[\tau, f] = X^\uparrow{}_{\mathrm{ham}}[f] := \gamma(f'') + \Lambda^\sharp(df).$$

QED

The *Hamiltonian lift* of special phase functions turns out to be the $\mathrm{map}(\boldsymbol{T},\mathbb{R})$-linear map $X^\uparrow{}_{\mathrm{ham}} : \mathrm{spec}(J_1\boldsymbol{E},\mathbb{R}) \to \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E}) : f \mapsto X^\uparrow{}_{\mathrm{ham}}[f] = X^\uparrow{}_{\mathrm{ham}}[f'', f]$, with coordinate expression $X^\uparrow{}_{\mathrm{ham}}[f] = f^0\partial_0 - f^i\partial_i + X^i_0\partial^0_i$, where

$$X_0^i = G_0^{ij}\Big(\tfrac{1}{2}\partial_j f^0 G_{hk}^0 x_0^h x_0^k + (\partial_j f_h^0 + f^k(\partial_k G_{jh}^0 - \partial_j G_{kh}^0) - f^0\partial_0 G_{jh}^0)x_0^h + \partial_j \breve{f} + f^h(\partial_h A_j - \partial_j A_h) - f^0(\partial_0 A_j - \partial_j A_0)\Big).$$

Hence, the kernel of $X^{\uparrow}{}_{\mathrm{ham}}$ is the subsheaf $\mathrm{map}(\boldsymbol{T},\mathbb{R}) \subset \mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$.

Then, let us analyze the tangent lift. We obtain the *tangent lift* of special phase functions defined as the map $X:\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R}) \to \mathrm{sec}(\boldsymbol{E},T\boldsymbol{E}):f \mapsto X[f] := X[f'',f]$, with coordinate expresssion $X[f]=f^0\partial_0 - f^i\partial_i$. As a consequence, X is surjective and its kernel is the subsheaf $\mathrm{map}(\boldsymbol{E},\mathbb{R}) \subset \mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$. We also obtain the map $\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})/\mathrm{map}(\boldsymbol{E},\mathbb{R}) \to \mathrm{sec}(\boldsymbol{E},T\boldsymbol{E}):[f] \mapsto X[f]$, whose inverse has Coordinate expression $X^0\partial_0 + X^i\partial_i \mapsto \big[X^0\frac{1}{2}G_{ij}^0 x_0^i x_0^j - G_{ij}^0 X^j x_0^i\big]$.

Eventually, let us introduce the holonomic lift.[61]

We define the *holonomic lift* of special phase functions to be the $\mathbb{R}$-linear map $X^{\uparrow}{}_{\mathrm{hol}}:\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R}) \to \mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E}):f \mapsto X^{\uparrow}{}_{\mathrm{hol}}[f] := (X[f])_{(1)}$, with coordinate expression $X^{\uparrow}{}_{\mathrm{hol}}[f] = f^0\partial_0 - f^i\partial_i - (\partial_0 f^i + \partial_j f^i x_0^j + \partial_0 f^0 x_0^i)\partial_i^0$.

The kernel of $X^{\uparrow}{}_{\mathrm{hol}}$ is the subsheaf $\mathrm{map}(\boldsymbol{E},\mathbb{R}) \subset \mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$.

3. Special Lie bracket

The special phase functions are not closed under the Poisson bracket. Also for this reason, one introduces a nonstandard Lie bracket.[34,37]

We define the *special bracket* on $\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$ by $[\![f,g]\!] := \{f,g\} + \gamma(f'')\cdot g - \gamma(g'')\cdot f$, with coordinate expression

$$[\![f,g]\!]^\lambda = f^0\partial_0 g^\lambda - g^0\partial_0 f^\lambda - f^h\partial_h g^\lambda + g^h\partial_h f^\lambda,$$

$$[\![f,\breve{g}]\!] = f^0\partial_0\breve{g} - g^0\partial_0\breve{f} - f^h\partial_h\breve{g} + g^h\partial_h\breve{f} - (f^0 g^h - g^0 f^h)\Phi_{0h} + f^h g^k \Phi_{hk}.$$

The sheaf $\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$ is an $\mathbb{R}$-Lie algebra with respect to the special bracket.

The subsheaves

$$\mathrm{aff}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{fine}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{proj}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{spec}(J_1\boldsymbol{E},\mathbb{R}) \subset \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$$

are subsheaves of $\mathbb{R}$-Lie subalgebras with respect to the special bracket. Moreover, the subsheaf $\mathrm{map}(\boldsymbol{E},\mathbb{R}) \subset \mathrm{aff}(J_1\boldsymbol{E},\mathbb{R})$ is a subsheaf of ideals.

At a first insight, the special bracket resembles the Jacobi bracket.[48] However, these brackets have essential differences.

In fact, in our context, the Jacobi bracket would be $[f,g] := \{f,g\} + f\gamma\cdot g - g\gamma\cdot f$ and not $[\![f,g]\!] := \{f,g\} + \gamma(f'')\cdot g - \gamma(g'')\cdot f$. Indeed, the special phase functions are not closed with respect to the Jacobi bracket; moreover, in our context, the Jacobi bracket is not well defined with respect to scale dimensions, as it is not invariant with respect to time scales. Except for this trouble, the Jacobi bracket could be defined for all phase functions, while the special bracket can be defined only for special phase functions, as it involves their "time components." We stress that the Jacobi bracket depends on the first jets of the functions, while the special bracket depends on the second jet, because the time component of the special phase functions depends on the second jet.

Furthermore, we observe that in our context we have $[\Lambda,\Lambda]=0$ and not $[\Lambda,\Lambda]=2\gamma\wedge\Lambda$, but, still, the special bracket fulfills the Jacobi property of Lie brackets. These facts do not conflict with the Lichnerowicz theorem concerning the classification of Lie algebras of functions (see, for instance, Ref. 48, p. 336), because the special phase functions are not closed with respect to the real multiplication.

4. Morphisms of Lie algebras

Let us analyze the relation between the special bracket of special phase functions and the Lie bracket of their prolongations.

The map $X^{\uparrow}_{\mathrm{ham}}:\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})\to\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$ is *not* a morphism of Lie algebras, with respect to the special bracket and the Lie bracket, respectively. On the other hand, we have the following result.

Proposition 2.6:[37] For each $f,g\in\mathrm{proj}(J_1\boldsymbol{E},\mathbb{R})$, we have

$$X^{\uparrow}_{\mathrm{ham}}[[\![f,g]\!]]=[X^{\uparrow}_{\mathrm{ham}}[f],X^{\uparrow}_{\mathrm{ham}}[g]].$$

Thus, the sheaf of Hamiltonian lifts of projectable special phase functions is closed with respect to the Lie bracket and the map $X^{\uparrow}_{\mathrm{ham}}:\mathrm{proj}(J_1\boldsymbol{E},\mathbb{R})\to\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$ is a morphism of Lie algebras. QED

Proposition 2.7:[34] For each $f,g\in\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$, we have

$$X[[\![f,g]\!]]=[X[f],X[g]].$$

Thus, the map $X:\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})\to\mathrm{sec}(\boldsymbol{E},T\boldsymbol{E})$ is a morphism of Lie algebras. QED

Proposition 2.8: For each $f,g\in\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$, we have

$$X^{\uparrow}_{\mathrm{hol}}[[\![f,g]\!]]=[X^{\uparrow}_{\mathrm{hol}}[f],X^{\uparrow}_{\mathrm{hol}}[g]].$$

Hence, the map $\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})\to\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E}):f\mapsto X^{\uparrow}_{\mathrm{hol}}[f]$ is a morphism of Lie algebras. Its kernel equals map $(\boldsymbol{E},\mathbb{R})$.

Proof: If $f,g\in\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$, then, by virtue of Proposition 2.7 and Proposition 2.2, we obtain

$$X^{\uparrow}_{\mathrm{hol}}[[\![f,g]\!]]:=(X[[\![f,g]\!]])_{(1)}=[X[f];X[g]]_{(1)}=[(X[f])_{(1)},(X[g])_{(1)}]:=[X^{\uparrow}_{\mathrm{hol}}[f],X^{\uparrow}_{\mathrm{hol}}[g]].$$

QED

III. CLASSICAL SYMMETRIES

The following deals with the main aim of the paper. It is devoted to the analysis of the distinguished subalgebras of the algebra of special phase functions and to the classification of classical infinitesimal symmetries.

A. Subalgebras of special phase functions

We have distinguished subsheaves of the sheaf of special phase functions, which are closed with respect to the special bracket. These subalgebras will play an important role with respect to the infinitesimal symmetries of the classical structure.

1. Subalgebra of conserved special phase functions

We define the sheaf $\mathrm{cons\,spec}(J_1\boldsymbol{E},\mathbb{R}):=\mathrm{cons}(J_1\boldsymbol{E},\mathbb{R})\cap\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$, and, analogously, the subsheaves $\mathrm{cons\,proj}(J_1\boldsymbol{E},\mathbb{R})$, $\mathrm{cons\,fine}(J_1\boldsymbol{E},\mathbb{R})$, $\mathrm{cons\,aff}(J_1\boldsymbol{E},\mathbb{R})$, and $\mathrm{cons\,map}(\boldsymbol{E},\mathbb{R})$.

We stress that the special bracket reduces to the Poisson bracket on the sheaf $\mathrm{cons}(J_1\boldsymbol{E},\mathbb{R})$, hence also on the above subsheaves.

Proposition 3.1: The sheaf $\mathrm{cons\,spec}(J_1\boldsymbol{E},\mathbb{R})$ is closed with respect to the special bracket.

Proof: If $f,g\in\mathrm{cons\,spec}(J_1\boldsymbol{E},\mathbb{R})$, then $\gamma\cdot[\![f,g]\!]=\gamma.\{f,g\}=\{\gamma.f,g\}+\{f,\gamma.g\}=0$. QED

Lemma 3.2: For each $\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$, we have the coordinate expression

$$\begin{aligned}\gamma_0.f\equiv\gamma(u_0).f=&\tfrac{1}{6}(\partial_i f^0G^0_{hk}+\partial_k f^0G^0_{ih}+\partial_h f^0G^0_{ki})x^i_0x^h_0x^k_0+\tfrac{1}{2}(\partial_0 f^0G^0_{hk}\\&-f^0\partial_0G^0_{hk}+f^i\partial_iG^0_{hk}+\partial_h f^iG^0_{ik}+\partial_k f^iG^0_{ih})x^h_0x^k_0\\&-(f^0(\partial_0A_h-\partial_hA_0)+f^i(\partial_hA_i-\partial_iA_h)-\partial_0f^iG^0_{ih}-\partial_h\breve{f})x^h_0+\partial_h\breve{f}-f^i(\partial_0A_i-\partial_iA_0).\end{aligned}$$

Proof: The proof follows from a long computation in coordinates by using the coordinate expressions

$$\gamma_{00}^{\ i} = -G_0^{ij}\Big(\big(\partial_h G^0_{jk} - \tfrac{1}{2}\partial_j G^0_{hk}\big)x_0^h x_0^k + (\partial_0 G^0_{hj} + (\partial_h A_j - \partial_j A_h))x_0^h + \partial_0 A_j - \partial_j A_0\Big),$$

$$f = f^0 \tfrac{1}{2} G^0_{hk} x_0^h x_0^k + f^h G^0_{hk} x_0^k + \breve{f}.$$

QED

Proposition 3.3: The sheaf cons spec$(J_1\boldsymbol{E}, \mathbb{R})$ is constituted by the special phase functions f such that

$$\partial_i f^0 G^0_{hk} + \partial_k f^0 G^0_{ih} + \partial_h f^0 G^0_{ki} = 0,$$

$$\partial_0 f^0 G^0_{hk} - f^0 \partial_0 G^0_{hk} + f^i \partial_i G^0_{hk} + \partial_h f^i G^0_{ik} + \partial_k f^i G^0_{ih} = 0,$$

$$f^0(\partial_0 A_h - \partial_h A_0) + f^i(\partial_h A_i - \partial_i A_h) - \partial_0 f^i G^0_{ih} - \partial_h \breve{f} = 0,$$

$$\partial_0 \breve{f} - f^i(\partial_0 A_i - \partial_i A_0) = 0.$$

QED

A general analysis of the above system is beyond the scope of the present paper. Here, we just discuss some equivalences and simple examples in the basic model of spacetime. A similar remark holds for the systems of differential equations, which will appear in the forthcoming sections.

Proposition 3.4: We have the useful identities $\gamma_0 . \mathcal{H}_0 = -\partial_0 \mathcal{L}_0$ and $\gamma_0 . \mathcal{P}_i = \partial_i \mathcal{L}_0$. Moreover, we have the following equivalences:

$$\gamma . x_0^i = 0 \Leftrightarrow K_\lambda{}^r{}_\mu = 0,$$

$$\gamma . \mathcal{K}_0 = 0 \Leftrightarrow \partial_0 G^0_{hk} = 0, \quad \partial_0 A_h - \partial_h A_0 = 0,$$

$$\gamma . \mathcal{H}_0 = 0 \Leftrightarrow \partial_0 G^0_{hk} = 0, \quad \partial_0 A_\lambda = 0,$$

$$\gamma . \mathcal{Q}_i = 0 \Leftrightarrow \partial_i G^0_{hk} = 0, \quad \partial_i A_\lambda - \partial_\lambda A_i = 0,$$

$$\gamma . \mathcal{P}_i = 0 \Leftrightarrow \partial_i G^0_{hk} = 0, \quad \partial_i A_\lambda = 0,$$

$$\gamma . \mathcal{L}_0 = 0 \Leftrightarrow \nabla_h A_k + \nabla_k A_h = \partial_0 G^0_{hk}, \quad \nabla_h A_0 = 0, \quad A_0^i(\partial_0 A_i - \partial_i A_0) = \partial_0 A_0.$$

QED

Example 3.5: In the special Newtonian spacetime, the sheaf cons spec$(J_1\boldsymbol{E}, \mathbb{R})$ is constituted by the special phase functions f such that

$$\partial_i f^0 = 0,$$

$$\partial_0 f^0 = -2\partial_1 f^1 = -2\partial_2 f^2 = -2\partial_3 f^3,$$

$$\partial_1 f^2 = -\partial_2 f^1, \quad \partial_1 f^3 = -\partial_3 f^1, \quad \partial_2 f^3 = -\partial_3 f^2,$$

$$\partial_0 f^i = -\partial_i \breve{f},$$

$$\partial_0 \check{f} = 0.$$

A solution of this system is given by

$$f^0 = -a_0(x^0)^2 + d^0, \quad f^i = (a_0 x^i + b_0^i)x^0, \quad \check{f} = -\left(\tfrac{1}{2}a_0 \sum_i (x^i)^2 + \sum_i b_0^i x^i + c\right),$$

where $a_0, b_0^i, c, d^0 \in \mathbb{R}$. In particular, we obtain cons spec$(J_1\boldsymbol{E}, \mathbb{R}) \subset$ proj$(J_1\boldsymbol{E}, \mathbb{R})$.

For instance, the components of the kinetic energy, of the momentum, and of the angular momentum with respect to an inertial observer are conserved special phase functions. QED

2. Subalgebra of holonomic functions

We can compare the holonomic and Hamiltonian lifts of a special phase function. The special phase functions whose holonomic and Hamiltonian lifts coincide constitute a subalgebra with respect to the special bracket.

We call $f \in$ spec $(J_1\boldsymbol{E}, \mathbb{R})$ *holonomic* if $X^{\uparrow}{}_{\text{hol}}[f] = X^{\uparrow}{}_{\text{ham}}[f]$.

We denote the subsheaf of holonomic functions by hol$(J_1\boldsymbol{E}, \mathbb{R}) \subset$ spec$(J_1\boldsymbol{E}, \mathbb{R})$.

Accordingly, we set

$$\text{hol fine}(J_1\boldsymbol{E}, \mathbb{R}) := \text{hol}(J_1\boldsymbol{E}, \mathbb{R}) \cap \text{fine}(J_1\boldsymbol{E}, \mathbb{R}),$$

$$\text{hol aff}(J_1\boldsymbol{E}, \mathbb{R}) := \text{hol}(J_1\boldsymbol{E}, \mathbb{R}) \cap \text{aff}(J_1\boldsymbol{E}, \mathbb{R}),$$

$$\text{hol map}(\boldsymbol{E}, \mathbb{R}) := \text{hol}(J_1\boldsymbol{E}, \mathbb{R}) \cap \text{map}(\boldsymbol{E}, \mathbb{R}).$$

Proposition 3.6: The sheaf hol $(J_1\boldsymbol{E}, \mathbb{R})$ is constituted by the special phase functions f such that

$$\partial_i f^0 = 0,$$

$$\partial_0 f^0 G_{ij}^0 - f^0 \partial_0 G_{ij}^0 + f^h \partial_h G_{ij}^0 + \partial_j f^h G_{ih}^0 + \partial_i f^h G_{jh}^0 = 0,$$

$$f^0(\partial_i A_0 - \partial_0 A_i) + \partial_0 f^h G_{ih}^0 + f^h(\partial_h A_i - \partial_i A_h) + \partial_i \check{f} = 0.$$

As a consequence, we obtain hol $(J_1\boldsymbol{E}, \mathbb{R}) \subset$ proj $(J_1\boldsymbol{E}, \mathbb{R})$.

Proof: By the coordinate expressions of the holonomic and Hamiltonian lifts of projectable special phase functions

$$X^{\uparrow}{}_{\text{hol}}[f] = f^0\partial_0 - f^i\partial_i - (\partial_0 f^i + \partial_j f^i x_0^j + \partial_0 f^0 x_0^i + \partial_j f^0 x_0^j x_0^i)\partial_i^0,$$

$$\begin{aligned} X^{\uparrow}{}_{\text{ham}}[f] = f^0\partial_0 - f^i\partial_i + G_0^{ij}\Big(\partial_j \check{f} + \partial_j f^0 \tfrac{1}{2} G_{hk}^0 x_0^h x_0^k + \partial_j f^h G_{hk}^0 x_0^k - f^0(\partial_0 G_{hj}^0 x_0^h \\ + (\partial_0 A_j - \partial_j A_0)) + f^h(\partial_h G_{jk}^0 x_0^k - (\partial_j A_h - \partial_h A_j))\partial_i^0, \end{aligned}$$

we obtain the following coordinate expression of the condition $X^{\uparrow}{}_{\text{hol}}[f] = X^{\uparrow}{}_{\text{ham}}[f]$:

$$\begin{aligned} -(\partial_0 f^i + \partial_j f^i x_0^j + \partial_0 f^0 x_0^i + \partial_j f^0 x_0^j x_0^i) = G_0^{ij}\Big(\partial_j \check{f} + \partial_j f^0 \tfrac{1}{2} G_{hk}^0 x_0^h x_0^k + \partial_j f^h G_{hk}^0 x_0^k - f^0(\partial_0 G_{hj}^0 x_0^h \\ + (\partial_0 A_j - \partial_j A_0)) + f^h(\partial_h G_{jk}^0 x_0^k - (\partial_j A_h - \partial_h A_j)). \end{aligned}$$

This is equivalent to the system

$$-\partial_h f^0 \delta_k^i = \partial_j f^0 \frac{1}{2} G_0^{ij} G_{hk}^0,$$

$$-(\partial_h f^i + \partial_0 f^0 \delta^i_h) = G_0^{ij}(\partial_j f^k G^0_{hk} - f^0 \partial_0 G^0_{hj} + f^k \partial_k G^0_{jh}),$$

$$-\partial_0 f^i = G_0^{ij}(\partial_j \breve{f} - f^0(\partial_0 A_j - \partial_j A_0) + f^h(\partial_h A_j - \partial_j A_h)).$$

By contracting the first equality with $G_0^{hk} G^0_{ir}$ and the second and third equalities with G^0_{ir}, we get

$$\partial_r f^0 = 0,$$

$$-(\partial_h f^i G^0_{ir} + \partial_0 f^0 G^0_{hr}) = \partial_r f^k G^0_{hk} - f^0 \partial_0 G^0_{hr} + f^k \partial_h G^0_{rk},$$

$$-\partial_0 f^i G^0_{ir} = \partial_r \breve{f} - f^0(\partial_0 A_r - \partial_r A_0) + f^h(\partial_h A_r - \partial_r A_h)$$

and thus

$$\partial_r f^0 = 0,$$

$$-(\partial_i f^h G^0_{hj} + \partial_0 f^0 G^0_{ij}) = \partial_j f^h G^0_{ih} - f^0 \partial_0 G^0_{ij} + f^h \partial_i G^0_{jh},$$

$$-\partial_0 f^h G^0_{hi} = \partial_i \breve{f} - f^0(\partial_0 A_i - \partial_i A_0) + f^h(\partial_h A_i - \partial_i A_h)$$

QED

Proposition 3.7: The sheaf hol $(J_1\boldsymbol{E}, \mathbb{R})$ is closed with respect to the special bracket.

Proof: If $f, g \in \mathrm{hol}(J_1\boldsymbol{E}, \mathbb{R})$, then, obtain

$$X^{\uparrow}{}_{\mathrm{ham}}[[\![f,g]\!]] = [X^{\uparrow}{}_{\mathrm{ham}}[f], X^{\uparrow}{}_{\mathrm{ham}}[g]] = [X^{\uparrow}{}_{\mathrm{hol}}[f], X^{\uparrow}{}_{\mathrm{hol}}[g]] = X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]].$$

QED

Example 3.8: In the special Newtonian spacetime, the sheaf $\mathrm{hol}(J_1\boldsymbol{E}, \mathbb{R})$ is constituted by the special phase functions f such that

$$\partial_i f^0 = 0,$$

$$\partial_0 f^0 = -2\partial_1 f^1 = -2\partial_2 f^2 = -2\partial_3 f^3,$$

$$\partial_1 f^2 = -\partial_2 f^1, \quad \partial_1 f^3 = -\partial_3 f^1, \quad \partial_2 f^3 = -\partial_3 f^2,$$

$$\partial_0 f^i = -\partial_i \breve{f}.$$

A solution of this system is given by

$$f^0 = -2\int a d^0, \quad f^i = a x^i + b^i, \quad \breve{f} = -\left(\frac{1}{2}\partial_0 a \sum_i (x^i)^2 + \sum_i \partial_0 b^i x^i + c\right),$$

where $a, b^i c \in \mathrm{map}(\boldsymbol{T}, \mathbb{R})$. QED

3. Subalgebra of self-holonomic functions

Here, we consider special phase functions such that their holonomic prolongation is related to their differential through the cosymplectic two-form. These special phase functions turn out to be conserved and holonomic.

We call $f \in \mathrm{spec}(J_1\boldsymbol{E}, \mathbb{R})$ *self-holonomic* if $i(X^{\uparrow}{}_{\mathrm{hol}}[f])\Omega = df$.

We denote the subsheaf of self-holonomic functions by $\mathrm{self}(J_1\boldsymbol{E},\mathbb{R})\subset\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$. Accordingly, we set

$$\mathrm{self\ fine}(J_1\boldsymbol{E},\mathbb{R}) := \mathrm{self}(J_1\boldsymbol{E},\mathbb{R})\cap\mathrm{fine}(J_1\boldsymbol{E},\mathbb{R}),$$

$$\mathrm{self\ aff}(J_1\boldsymbol{E},\mathbb{R}) := \mathrm{self}(J_1\boldsymbol{E},\mathbb{R})\cap\mathrm{aff}(J_1\boldsymbol{E},\mathbb{R}),$$

$$\mathrm{self\ map}(\boldsymbol{E},\mathbb{R}) := \mathrm{self}(J_1\boldsymbol{E},\mathbb{R})\cap\mathrm{map}(\boldsymbol{E},\mathbb{R}).$$

Lemma 3.9: If $f\in\mathrm{self}(J_1\boldsymbol{E},\mathbb{R})$, then $\gamma.f=0$, hence

$$\mathrm{self}(J_1\boldsymbol{E},\mathbb{R})\subset\mathrm{cons}(J_1\boldsymbol{E},\mathbb{R}).$$

Proof: We have $\gamma.f=i(\gamma)df=i(\gamma)i(X^{\uparrow}{}_{\mathrm{hol}}[f])\Omega=-i(X^{\uparrow}{}_{\mathrm{hol}}[f])i(\gamma)\Omega=0$. QED

Lemma 3.10: If $f\in\mathrm{self}(J_1\boldsymbol{E},\mathbb{R})$, then $X^{\uparrow}{}_{\mathrm{hol}}[f]=X^{\uparrow}{}_{\mathrm{ham}}[f]$, hence

$$\mathrm{self}(J_1\boldsymbol{E},\mathbb{R})\subset\mathrm{hol}(J_1\boldsymbol{E},\mathbb{R}).$$

Proof: The equality $i(X^{\uparrow}{}_{\mathrm{hol}}[f])\Omega=df$ yields

$$X^{\uparrow}{}_{\mathrm{ham}}[f] := \gamma(f'')+\Lambda^{\sharp}(df)=\gamma(f'')+\Lambda^{\sharp}(\Omega^{\flat}(X^{\uparrow}{}_{\mathrm{hol}}[f])).$$

Therefore, we have

$$X^{\uparrow}{}_{\mathrm{ham}}[f]=\gamma(f'')+X^{\uparrow}{}_{\mathrm{hol}}[f]-\gamma(X^{\uparrow}{}_{\mathrm{hol}}[f])=\gamma(f'')+X^{\uparrow}{}_{\mathrm{hol}}[f]-\gamma(X[f])$$

$$=\gamma(f'')+X^{\uparrow}{}_{\mathrm{hol}}[f]-\gamma(f'')=X^{\uparrow}{}_{\mathrm{hol}}[f].$$

QED

Proposition 3.11: For each $f,g\in\mathrm{self}(J_1\boldsymbol{E},\mathbb{R})$, we obtain

$$\Omega^{\flat}(X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]])=d[\![f,g]\!].$$

Hence, the subsheaf $\mathrm{self}(J_1\boldsymbol{E},\mathbb{R})\subset\mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$ is closed with respect to the special bracket.

Proof: It sufficies to prove that

$$\Lambda^{\sharp}(\Omega^{\flat}(X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]]))=\Lambda^{\sharp}(d[\![f,g]\!]),$$

$$i(\gamma)(\Omega^{\flat}(X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]]))=i(\gamma)(d[\![f,g]\!]).$$

In fact, we have

$$\Lambda^{\sharp}(\Omega^{\flat}(X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]]))=X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]]-\gamma(X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]])$$

$$=X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]]-\gamma(X[[\![f,g]\!]])$$

$$=X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]]-\gamma([\![f,g]\!]'').$$

By Lemma 2.10 we have

$$\Lambda^{\sharp}(\Omega^{\flat}(X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]]))=X^{\uparrow}{}_{\mathrm{ham}}[[\![f,g]\!]]-\gamma([\![f,g]\!]'')$$

$$=\Lambda^{\sharp}(d[\![f,g]\!]).$$

On the other hand, the identity $i(\gamma)\Omega=0$ yields $i(\gamma)\Omega^{\flat}(X^{\uparrow}{}_{\mathrm{hol}}[[\![f,g]\!]])=0$ and the definition of the special bracket and Lemma 3.9 yield

$$i(\gamma)d[\![f,g]\!] = i(\gamma)d(\{f,g\} + \gamma(f'') \,.\, g - \gamma(g'') \,.\, f)$$

$$= \{\gamma \,.\, f, g\} + \{f, \gamma \,.\, g\} + i(\gamma)d(\gamma(f'') \cdot g - \gamma(g'') \,.\, f) = 0.$$

Hence, $\Omega^\flat(X^\uparrow{}_{\mathrm{hol}}[[\![f,g]\!]]) = d[\![f,g]\!]$. QED

Now, we state the conditions aimed at classifying the self-holonomic functions.

Lemma 3.12: For each $f \in \mathrm{proj}(J_1\boldsymbol{E}, \mathbb{R})$, we obtain

$$\begin{aligned} i(X^\uparrow{}_{\mathrm{hol}}[f])\Omega = {} & G^0_{ij}(f^0 x^j_0 + f^j)d^i_0 + \Big(f^0\Big((\partial_0 A_j - \partial_j A_0) + \partial_0 G^0_{jh} x^h_0 + \tfrac{1}{2}\partial_j G^0_{hk} x^h_0 x^k_0\Big) \\ & - f^i((\partial_i A_j - \partial_j A_i) + (\partial_i G^0_{jh} - \partial_j G^0_{ih})x^h_0) - G^0_{ij}(\partial_0 f^i + \partial_h f^i x^h_0 + \partial_0 f^0 x^i_0)\Big)d^j \\ & + \Big(f^j\Big((\partial_0 A_j - \partial_j A_0) + \partial_0 G^0_{jh} x^h_0 + \tfrac{1}{2}\partial_j G^0_{hk} x^h_0 x^k_0\Big) + (\partial_0 f^i + \partial_k f^i x^k_0 + \partial_0 f^0 x^i_0) G^0_{ij} x^j_0\Big)d^0. \end{aligned}$$

Proof: The proof follows from a long computation in coordinates, by taking into account the coordinate expressions

$$X^\uparrow{}_{\mathrm{hol}}[f] = f^0\partial_0 - f^i\partial_i - (\partial_0 f^i + \partial_j f^i x^j_0 + \partial_0 f^0 x^i_0)\partial^0_i,$$

$$\begin{aligned} \Omega = {} & G^0_{ij} d^i_0 \wedge (d^j - x^j_0 d^0) + \Big((\partial_0 A_j - \partial_j A_0) + \partial_0 G^0_{jh} x^h_0 \\ & + \tfrac{1}{2}\partial_j G^0_{hk} x^h_0 x^k_0\Big)d^0 \wedge d^j + \tfrac{1}{2}((\partial_i A_j - \partial_j A_i) + (\partial_i G^0_{jh} - \partial_j G^0_{ih})x^h_0)d^i \wedge d^j. \end{aligned}$$

QED

Lemma 3.13: For each $f \in \mathrm{proj}(J_1\boldsymbol{E}, \mathbb{R})$, we obtain

$$\begin{aligned} df = {} & \Big(\partial_0 f^0 \tfrac{1}{2} G^0_{hk} x^h_0 x^k_0 + \partial_0 f^h G^0_{hk} x^k_0 + \partial_0 \breve{f} + f^0 \tfrac{1}{2}\partial_0 G^0_{hk} x^h_0 x^k_0 + f^h \partial_0 G^0_{hk} x^k_0\Big)d^0 \\ & + \Big(\partial_j f^h G^0_{hk} x^k_0 + \partial_j \breve{f} + f^0 \tfrac{1}{2}\partial_j G^0_{hk} x^h_0 x^k_0 + f^h \partial_j G^0_{hk} x^k_0\Big)d^j \\ & + (f^0 G^0_{ih} x^h_0 + f^h G^0_{ih})d^i_0. \end{aligned}$$

QED

Proposition 3.14: The sheaf $\mathrm{self}(J_1\boldsymbol{E}, \mathbb{R})$ is constituted by the special phase functions f such that

$$\partial_i f^0 = 0,$$

$$f^0\partial_0 G^0_{ij} - \partial_0 f^0 G^0_{ij} - f^h \partial_h G^0_{ij} - \partial_j f^h G^0_{ih} - \partial_i f^h G^0_{jh} = 0,$$

$$f^0(\partial_0 A_j - \partial_j A_0) - f^i(\partial_i A_j - \partial_j A_i) - G^0_{ij}\partial_0 f^i - \partial_j \breve{f} = 0,$$

$$f^i(\partial_i A_0 - \partial_0 A_i) + \partial_0 \breve{f} = 0.$$

Proof: By virtue of Lemmas 3.12 and 3.13, for each $f \in \mathrm{proj}(J_1\boldsymbol{E}, \mathbb{R})$, we have $i(X^\uparrow{}_{\mathrm{hol}}[f])\Omega = df$ if and only if

$$\begin{aligned} & f^j\Big((\partial_0 A_j - \partial_j A_0) + \partial_0 G^0_{jh} x^h_0 + \tfrac{1}{2}\partial_j G^0_{hk} x^h_0 x^k_0\Big) + (\partial_0 f^i + \partial_h f^i x^h_0 + \partial_0 f^0 x^i_0) G^0_{ik} x^k_0 \\ & = \partial_0 f^0 \tfrac{1}{2} G^0_{hk} x^h_0 x^k_0 + \partial_0 f^h G^0_{hk} x^k_0 + \partial_0 \breve{f} + f^0 \tfrac{1}{2}\partial_0 G^0_{hk} x^h_0 x^k_0 + f^h \partial_0 G^0_{hk} x^k_0, \end{aligned}$$

$$\begin{aligned} & f^0\Big((\partial_0 A_j - \partial_j A_0) + \partial_0 G^0_{jh} x^h_0 + \tfrac{1}{2}\partial_j G^0_{hk} x^h_0 x^k_0\Big) - f^i((\partial_i A_j - \partial_j A_i) + (\partial_i G^0_{jh} - \partial_j G^0_{ih})x^h_0) \\ & - G^0_{ij}(\partial_0 f^i + \partial_h f^i x^h_0 + \partial_0 f^0 x^i_0) = \partial_j f^h G^0_{hk} x^k_0 + \partial_j \breve{f} + f^0 \tfrac{1}{2}\partial_j G^0_{hk} x^h_0 x^k_0 + f^h \partial_j G^0_{hk} x^k_0. \end{aligned}$$

By comparing the coefficients of the two above polynomial equalities, we obtain the following equivalent system:

$$f^j(\partial_0 A_j - \partial_j A_0) - \partial_0 \breve{f} = 0,$$

$$f^0(\partial_0 A_j - \partial_j A_0) - f^i(\partial_i A_j - \partial_j A_i) - G^0_{ij}\partial_0 f^i - \partial_j \breve{f} = 0,$$

$$f^0 \partial_0 G^0_{jh} - \partial_0 f^0 G^0_{hj} - f^i \partial_i G^0_{jh} - \partial_h f^i G^0_{ij} - \partial_j f^i G^0_{ih} = 0.$$

QED

The system of the previous Proposition can be reexpressed in terms of an observer and the tangent lift of the projectable special phase function.

Proposition 3.15: Let us consider an observer o. Then, the sheaf $\mathrm{self}(J_1\boldsymbol{E},\mathbb{R})$ is constituted by the projectable special phase functions f such that

$$L[X[f]]G = df'' \lrcorner G,$$

$$X[f] \lrcorner \Phi[o] + \nu^*[o](G^\flat(L[o]X[f])) = d(f[o]).$$

Proof: We can write the system which characterizes self-holonomic functions (Proposition 3.14) as

$$\partial_\mu G^0_{hk} X[f]^\mu + G^0_{ih}\partial_k(X[f]^i) + G^0_{ik}\partial_h(X[f]^i) = \partial_0 f^0 G^0_{hk},$$

$$X[f]^\mu(\partial_\mu A_j - \partial_j A_\mu) + G^0_{ij}\partial_0(X[f]^i) - \partial_j \breve{f} = 0,$$

$$X[f]^i(\partial_i A_0 - \partial_0 A_i) - \partial_0 \breve{f} = 0.$$

On the other hand, we have the coordinate expressions

$$L[X[f]]G = (\partial_\mu G^0_{hk} X[f]^\mu + G^0_{ih}\partial_k(X[f]^i) + G^0_{ik}\partial_h(X[f]^i))u_0 \otimes \breve{d}^h \otimes \breve{d}^k,$$

$$df'' \lrcorner G = \partial_0 f^0 G^0_{hk} u_0 \otimes \breve{d}^h \otimes \breve{d}^k,$$

$$X[f] \lrcorner \Phi[o] + \nu^*[o](G^\flat(L[o]X[f])) = X[f]^\mu \Phi_{\mu\nu} d^\nu + G^0_{ij}\partial_0(X[f]^i)d^j,$$

$$d(f[o]) = \partial_\mu \breve{f}.$$

QED

We have the following further intrinsic characterizations of self-holonomic special phase functions, which will play an important role in the classification of classical symmetries.

Theorem 3.16: *Let* $f \in \mathrm{proj}(J_1\boldsymbol{E},\mathbb{R})$. *Then, the following conditions are equivalent:*

1) $i[X^\uparrow{}_{\mathrm{hol}}[f]]\Omega = df$,
2) $L[X^\uparrow{}_{\mathrm{hol}}[f]]\Omega = 0$, *with* $f \in \mathrm{cons}(J_1\boldsymbol{E},\mathbb{R})$,
3) $X^\uparrow{}_{\mathrm{hol}}[f] = X^\uparrow{}_{\mathrm{ham}}[f]$, *with* $f \in \mathrm{cons}(J_1\boldsymbol{E},\mathbb{R})$.

Proof: 1)$\Rightarrow$2). Let $i(X^\uparrow{}_{\mathrm{hol}}[f])\Omega = df$. Then $L(X^\uparrow{}_{\mathrm{hol}}[f])\Omega := di(X^\uparrow{}_{\mathrm{hol}}[f])\Omega = ddf = 0$.
On the other hand, the identity $i(\gamma)\Omega = 0$ yields $i(\gamma)df = 0$, i.e., $f \in \mathrm{cons}(J_1\boldsymbol{E},\mathbb{R})$.
2)$\Rightarrow$3). Let $L[X^\uparrow{}_{\mathrm{hol}}[f]]\Omega = 0$, i.e., $di(X^\uparrow{}_{\mathrm{hol}}[f])\Omega = 0$.
Then, we have locally the equality $i(X^\uparrow{}_{\mathrm{hol}}[f])\Omega = dg$, with $g \in \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$.
On the other hand, the identity $i(\gamma)\Omega = 0$ yields $i(\gamma)dg = 0$, i.e., $g \in \mathrm{cons}(J_1\boldsymbol{E},\mathbb{R})$.

As a consequence we obtain $(\Lambda^\sharp \circ \Omega^\flat)(X^\uparrow{}_{\mathrm{hol}}[f]) = \Lambda^\sharp(dg)$ and from this we can deduce that $X^\uparrow{}_{\mathrm{hol}}[f] - \gamma(X^\uparrow{}_{\mathrm{hol}}[f]) = X^\uparrow{}_{\mathrm{hol}}[f] - \gamma(f'') = \Lambda^\sharp(dg)$. Hence $X^\uparrow{}_{\mathrm{hol}}[f] = \gamma(f'') + \Lambda^\sharp(dg) := X^\uparrow{}_{\mathrm{ham}}[f'', g]$.

On the other hand, since $X^\uparrow{}_{\mathrm{hol}}[f]$ is projectable on $\boldsymbol{E}$, Theorem 2.5 implies $g \in \mathrm{spec}(J_1\boldsymbol{E}, \mathbb{R})$ and $g'' = f''$.

Hence, we obtain $X^\uparrow{}_{\mathrm{hol}}[f] = X^\uparrow{}_{\mathrm{ham}}[g]$, which yields $X[f] = X[g]$, hence $f = g + h$, with $h \in \mathrm{map}(\boldsymbol{E}, \mathbb{R})$.

On the other hand, $f, g \in \mathrm{cons}(J_1\boldsymbol{E}, \mathbb{R})$ implies $h \in \mathrm{cons\ map}(\boldsymbol{E}, \mathbb{R}) = \mathbb{R}$.

Therefore, we obtain $X^\uparrow{}_{\mathrm{hol}}[f] = X^\uparrow{}_{\mathrm{ham}}[f]$ in the domain of definition of g. But, if the above equality holds locally, then it holds in the domain of definition of f.

3) $\Rightarrow$ 1). Let $f \in \mathrm{cons}(J_1\boldsymbol{E}, \mathbb{R})$. Then, the identities concerning the linear musical isomorphisms and the identity $i(\gamma)\Omega = 0$ yield $i(X^\uparrow{}_{\mathrm{ham}}[f])\Omega := i(\gamma(f'') + \Lambda^\sharp(df))\Omega = (\Omega^\flat \circ \Lambda^\sharp)(df) = df - i(\gamma)df = df$.

Hence, $X^\uparrow{}_{\mathrm{hol}}[f] = X^\uparrow{}_{\mathrm{ham}}[f]$ implies $i(X^\uparrow{}_{\mathrm{hol}}[f])\Omega = df$ QED

Corollary 3.17: We have self $(J_1\boldsymbol{E}, \mathbb{R}) = \mathrm{cons}(J_1, \boldsymbol{E}\mathbb{R}) \cap \mathrm{hol}(J_1\boldsymbol{E}, \mathbb{R})$. QED

Indeed, an even stronger result holds.

Theorem 3.18: We have $\mathrm{self}(J_1\boldsymbol{E}, \mathbb{R}) = \mathrm{cons\ proj}(J_1\boldsymbol{E}, \mathbb{R})$.

Proof: The classifying systems of Proposition 3.14 and of Proposition 3.3 coincide.

Hence, $\mathrm{self}(J_1\boldsymbol{E}, \mathbb{R}) = \mathrm{cons\ proj}(J_1\boldsymbol{E}, \mathbb{R})$. QED

4. Subalgebra of unimodular functions

Next, we consider the subalgebras of the algebra of projectable special phase functions related to the divergence of the tangent lift.

A vector field $X \in \mathrm{proj}(\boldsymbol{E}, T\boldsymbol{E})$ is called *conformal unimodular, or unimodular*, if we have, respectively, $d(\mathrm{div}_\eta X) = 0$, or $\mathrm{div}_\eta X = 0$.

For each $X, \bar{X} \in \mathrm{proj}(\boldsymbol{E}, T\boldsymbol{E})$, we have $\mathrm{div}_\eta([X, \bar{X}]) = X.\mathrm{div}_\eta \bar{X} - \bar{X}.\mathrm{div}_\eta X$. Hence, the sheaves of conformal unimodular and unimodular vector fields of $T\boldsymbol{E}$ are closed with respect to the Lie bracket.

A function $f \in \mathrm{spec}(J_1\boldsymbol{E}, \mathbb{R})$ is said to be *unimodular*, or *conformal unimodular* if, respectively, $\mathrm{div}_\eta X[f] = 0$, or $d(\mathrm{div}_\eta X[f]) = 0$. The subsheaves of unimodular and conformal unimodular projectable special phase functions are denoted, respectively, by $\mathrm{unim}(J_1\boldsymbol{E}, \mathbb{R}) \subset \mathrm{proj}(J_1\boldsymbol{E}, \mathbb{R})$ and $\mathrm{c\text{-}unim}(J_1\boldsymbol{E}, \mathbb{R}) \subset \mathrm{proj}(J_1\boldsymbol{E}, \mathbb{R})$.

In the above definition, we need to consider projectable special phase functions, because $\mathrm{div}_\eta X$ is defined only for a projectable spacetime vector field X, due to the fact that η is a vertical form.

A vector field $X^\uparrow \in \mathrm{proj}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ is called *conformal unimodular*, or *unimodular*, if we have, respectively, $d(\mathrm{div}_\eta X^\uparrow) = 0$, or $\mathrm{div}_\eta X^\uparrow = 0$.

The sheaves of conformal unimodular and unimodular vector fields of $J_1\boldsymbol{E}$ are closed with respect to the Lie bracket.

Proposition 3.19: The sheaves of conformal unimodular and unimodular special phase functions are closed with respect to the special bracket.

Proof: If $f, g \in \mathrm{proj}(J_1\boldsymbol{E}, \mathbb{R})$, then we obtain

$$\mathrm{div}_\eta(X[[\![f, g]\!]]) = \mathrm{div}_\eta[X[f], X[g]] = X[g]\,.\,\mathrm{div}_\eta(X[f]) - X[f]\,.\,\mathrm{div}_\eta(X[g])\,.$$

QED

Proposition 3.20: If $f \in \mathrm{self\ fine}(J_1\boldsymbol{E}, \mathbb{R})$, then $\mathrm{div}_\eta(X[f]) = 0$, hence

$$\mathrm{self\ fine}(J_1\boldsymbol{E}, \mathbb{R}) = \mathrm{cons\ fine}(J_1\boldsymbol{E}, \mathbb{R}) \subset \mathrm{unim}(J_1\boldsymbol{E}, \mathbb{R})\,.$$

Proof: The equality $i(X^\uparrow{}_{\mathrm{hol}}[f])\Omega = df$ yields $L[X^\uparrow{}_{\mathrm{hol}}[f]]\Omega = 0$, hence, by virtue of Proposition 2.4, $\mathrm{div}_\eta(X[f]) = 0$. QED

5. Subalgebra of classic generators

Eventually, we consider the subalgebra of the algebra of special phase functions, which generates the infinitesimal symmetries of the full classical structure.

Each $f \in \text{cons fine}(J_1\boldsymbol{E},\mathbb{R})$ is called a *classical generator*. We denote the sheaf of classical generators by $\text{clas}(J_1\boldsymbol{E},\mathbb{R}) := \text{cons fine}(J_1\boldsymbol{E},\mathbb{R})$.

Theorem 3.21: We have $\text{clas}(J_1\boldsymbol{E},\mathbb{R}) = \text{self fine}(J_1\boldsymbol{E},\mathbb{R}) \subset \text{hol}(J_1\boldsymbol{E},\mathbb{R})$ and $\text{clas}(J_1\boldsymbol{E},\mathbb{R}) \subset \text{unim}(J_1\boldsymbol{E},\mathbb{R})$.

Proof: It follows immediately from Theorem 3.18, Lemma 3.10 and Proposition 3.20. QED

By reformulating a previous result, we have the following characterization of the classical generators.

Corollary 3.22: The sheaf $\text{clas}(J_1\boldsymbol{E},\mathbb{R})$ is constituted by the special phase functions f such that

$$\partial_\lambda f^0 = 0,$$

$$f^0\partial_0 G^0_{ij} - f^h\partial_h G^0_{ij} - \partial_j f^h G^0_{ih} - \partial_i f^h G^0_{jh} = 0,$$

$$f^0(\partial_0 A_j - \partial_j A_0) - f^i(\partial_i A_j - \partial_j A_i) - G^0_{ij}\partial_0 f^i - \partial_j \breve{f} = 0,$$

$$f^i(\partial_i A_0 - \partial_0 A_i) + \partial_0 \breve{f} = 0.$$

QED

Example 3.23: In the special Newtonian spacetime, the sheaf $\text{clas}(J_1\boldsymbol{E},\mathbb{R})$ is constituted by the special phase functions f such that

$$\partial_\lambda f^0 = 0,$$

$$\partial_1 f^1 = \partial_2 f^2 = \partial_3 f^3 = 0,$$

$$\partial_1 f^2 = -\partial_2 f^1, \quad \partial_1 f^3 = -\partial_3 f^1, \quad \partial_2 f^3 = -\partial_3 f^2,$$
$$\partial_0 f^i = -\partial_i \breve{f},$$
$$\partial_0 \breve{f} = 0.$$

For instance, a solution of this system is given by

$$f^0 = a^0,$$

$$f^i = b^i_j x^j + c^i_0 x^0 + d^i,$$

$$\breve{f} = -\sum_{1\le i\le 3} c^i_0 x^i + e,$$

where $a^0, b^i_j, c^i_0, d^i, e \in \mathbb{R}$ and $b^i_j = -b^j_i$. QED

B. Classical infinitesimal symmetries

We classify the vector fields of the phase space which are infinitesimal symmetries of spacetime and its structures.

1. Infinitesimal symmetries of geometric structures

We start by defining the infinitesimal symmetries of some typical geometric structures. All concepts below are defined in such a way that the corresponding local group of diffeomeorphisms act on the geometric structure and preserve it.

We introduce the following general concepts.

1. We define an *infinitesimal symmetry* of a fibered manifold $p:\boldsymbol{F}\to\boldsymbol{B}$ to be a projectable vector field X of $\boldsymbol{F}$.
2. We define an *infinitesimal symmetry* of a bundle $q:\boldsymbol{G}\to\boldsymbol{M}$, which is a natural prolongation of a manifold $\boldsymbol{M}$, to be the projectable vector field Y obtained by the corresponding natural lift of a vector field X of $\boldsymbol{M}$.
3. We define an *infinitesimal symmetry* of a bundle $q:\boldsymbol{G}\to\boldsymbol{F}$, which is a natural prolongation of a fibered manifold $p:\boldsymbol{F}\to\boldsymbol{B}$ to be the projectable vector field Y obtained by the corresponding natural lift of a vector field X of $\boldsymbol{F}$.
3. We define an *infinitesimal symmetry* of a tensor σ of a manifold $\boldsymbol{M}$ to be a vector field X of $\boldsymbol{M}$ such that $L[X]\sigma=0$.
4. We define an *infinitesimal symmetry* of a covariant vertical tensor σ of a fibered manifold $p:\boldsymbol{F}\to\boldsymbol{B}$ to be a projectable vector field X of $\boldsymbol{F}$ such that $L[X]\sigma=0$.
5. We define an *infinitesimal symmetry* of an affine space $\boldsymbol{A}$ to be a constant vector field of $\boldsymbol{A}$.

2. Infinitesimal symmetries of spacetime and phase space

According to the above guideline, we introduce the infinitesimal symmetries of time, of spacetime, and of the phase space as the vector fields which preserve the affine structure of time, the time fibering of spacetime, and the natural first jet functor.

An *infinitesimal symmetry of time* is defined to be an infinitesimal symmetry of the affine structure of $\boldsymbol{T}$, which can be regarded just as an element $\underline{X}\in\overline{\mathbb{T}}$ (i.e., a constant vector field of $\boldsymbol{T}$).

An *infinitesimal symmetry of spacetime* is defined to be an infinitesimal symmetry of the time fibering t yielding also an infinitesimal symmetry of the affine structure of $\boldsymbol{T}$, i.e., a vector field $X\in\mathrm{fine}(\boldsymbol{E},T\boldsymbol{E})$.

An *infinitesimal symmetry of the phase space* is defined to be the infinitesimal symmetry of the first jet prolongation of spacetime yielding also an infinitesimal symmetry of the time fibering t and an infinitesimal symmetry of the affine structure of $\boldsymbol{T}$, i.e., the holonomic prolongation of an infinitesimal symmetry of spacetime $X_{(1)}\in\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$, with $X\in\mathrm{fine}(\boldsymbol{E},T\boldsymbol{E})$.

We define, respectively, a spacetime *infinitesimal symmetry* of dt and a phase, *infinitesimal symmetry* of dt to be vector fields $X\in\mathrm{sec}(\boldsymbol{E},T\boldsymbol{E})$ and $X^{\uparrow}\in\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$, such that $L[X]dt=0$ and $L[X^{\uparrow}]dt=0$.

Proposition 3.24: The infinitesimal symmetries of dt are the vector fields of the type $X\in\mathrm{fine}(\boldsymbol{E},T\boldsymbol{E})$ and $X^{\uparrow}\in\mathrm{fine}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$.

Proof: In fact, we have $L[X]dt=di(X)dt$ and $L[X^{\uparrow}]dt=di(X^{\uparrow})dt$. QED

Corollary 3.25: A vector field $X\in\mathrm{sec}(\boldsymbol{E},T\boldsymbol{E})$ is an infinitesimal symmetry of spacetime if and only if it is an infinitesimal symmetry of dt. QED

3. Infinitesimal symmetries of the cosymplectic two-form

We define an *infinitesimal symmetry* of Ω to be a vector field $X^{\uparrow}\in\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$, such that $L[X^{\uparrow}]\Omega=0$.

Theorem 3.26: *The infinitesimal symmetries* $X^{\uparrow}\in\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$ *of* Ω *are of the local type* $X^{\uparrow}=X^{\uparrow}{}_{\mathrm{ham}}[\tau,f]$, *with* $\tau\in\mathrm{map}(J_1\boldsymbol{E},\overline{\mathbb{T}})$ *and* $f\in\mathrm{cons}(J_1\boldsymbol{E},\mathbb{R})$, *where* f *is determined up to a constant*.

Proof: Let us consider any $X^{\uparrow}\in\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$ and set $\tau:=dt(X^{\uparrow})\in\mathrm{map}(J_1\boldsymbol{E},\overline{\mathbb{T}})$.

Then, $X^{\uparrow}$ can be uniquely written as $X^{\uparrow}=\gamma(\tau)+\bar{X}^{\uparrow}$, with $\bar{X}^{\uparrow}\in\mathrm{sec}(J_1\boldsymbol{E},VJ_1\boldsymbol{E})$.

Moreover, by recalling the identity $i(\gamma)\Omega=0$, we obtain $L[\gamma(\tau)]\Omega=0$.

Furthermore, by recalling the identity $d\Omega=0$, we have $L[\bar{X}^{\uparrow}]\Omega=0$ if and only if $di(\bar{X}^{\uparrow})\Omega=0$, i.e., if and only if locally $i(\bar{X}^{\uparrow})\Omega=df$, with $\gamma.f=0$, i.e., by virtue of the results of Sec. II D 1, if and only if locally $\bar{X}^{\uparrow}=\Lambda^{\sharp}(df)$, with $\gamma.f=0$. QED

Corollary 3.27: The infinitesimal symmetries $X^{\uparrow}\in\mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$ of dt and Ω are of the local type $X^{\uparrow}=X^{\uparrow}{}_{\mathrm{ham}}[\tau,f]$, with $\tau\in\overline{\mathbb{T}}$ and $f\in\mathrm{cons}(J_1\boldsymbol{E},\mathbb{R})$, where f is defined up to a constant. QED

4. Infinitesimal symmetries of the classical structure

Next, we classify the infinitesimal symmetries of dt and Ω, which are projectable on $\boldsymbol{E}$. Indeed, the projectability condition yields an important consequence: namely, it implies that the vector field is generated by a special phase function.

Corollary 3.28: The infinitesimal symmetries $X^{\uparrow} \in \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ of Ω, which are projectable on $\boldsymbol{E}$, are of the local type $X^{\uparrow}=X^{\uparrow}{}_{\mathrm{ham}}[f]$, with $f \in \mathrm{cons\ spec}(J_1\boldsymbol{E}, \mathbb{R})$, where f is defined up to a constant.

Proof: It follows from Theorem 3.26 and Theorem 2.5. QED

Corollary 3.29: The infinitesimal symmetries $X^{\uparrow} \in \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ of dt and Ω, which are projectable on $\boldsymbol{E}$, are of the type $X^{\uparrow}=X^{\uparrow}{}_{\mathrm{ham}}[f]$, with $f \in \mathrm{cons\ fine}(J_1\boldsymbol{E}, \mathbb{R})$, where f is determined up to a constant.

Proof: It follows from the above Corollary 3.28 and Proposition 3.24. QED

Corollary 3.30: Let us consider a vector field $X \in \mathrm{sec}(\boldsymbol{E}, T\boldsymbol{E})$.

If its holonomic prolongation $X_{(1)} \in \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ is an infinitesimal symmetry of dt and Ω, then we obtain locally $X_{(1)}=X^{\uparrow}{}_{\mathrm{hol}}[f]=X^{\uparrow}{}_{\mathrm{ham}}[f]$, with $f \in \mathrm{cons\ fine}(J_1\boldsymbol{E}, \mathbb{R})$ and $X=X[f]$.

Proof: By virtue of Corollary 3.29, we obtain $X_{(1)}=X^{\uparrow}{}_{\mathrm{ham}}[f]$, with $f \in \mathrm{cons\ fine}(J_1\boldsymbol{E}, \mathbb{R})$.

On the other hand, by virtue of Proposition 2.2, $X_{(1)}$ projects on X and, by virtue of Theorem 2.5, $X^{\uparrow}{}_{\mathrm{ham}}[f]$ projects on $X[f]$. Hence, we obtain $X=X[f]$ and $X_{(1)}=X^{\uparrow}{}_{\mathrm{hol}}[f]$. QED

We can reformulate the above result in a slightly stronger way.

An *infinitesimal symmetry of the classical structure* is defined to be a vector field $X^{\uparrow} \in \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$, which is an infinitesimal symmetry of dt and Ω and which is projectable on $\boldsymbol{E}$.

Corollary 3.31: The infinitesimal symmetries $X^{\uparrow} \in \mathrm{sec}(J_1\boldsymbol{E}, TJ_1\boldsymbol{E})$ of the classical structure are of the local type $X^{\uparrow}=X^{\uparrow}{}_{\mathrm{hol}}[f]=X^{\uparrow}{}_{\mathrm{ham}}[f]$, with $f \in \mathrm{cons\ fine}(J_1\boldsymbol{E}, \mathbb{R})$.

Proof: By virtue of Corollary 3.29, we obtain $X^{\uparrow}=X^{\uparrow}{}_{\mathrm{ham}}[f]$, with $f \in \mathrm{cons\ fine}(J_1\boldsymbol{E}, \mathbb{R})$.

On the other hand, by virtue of Theorem 3.21, we have $\mathrm{cons\ fine}(J_1\boldsymbol{E}, \mathbb{R})=\mathrm{self\ fine}(J_1\boldsymbol{E}, \mathbb{R})$, hence $X^{\uparrow}{}_{\mathrm{hol}}[f]=X^{\uparrow}{}_{\mathrm{ham}}[f]$. QED

Proposition 3.32: The subsheaf of infinitesimal symmetries of the classical structure is a sheaf of Lie subalgebras.

Proof: It follows from the fact that the holonomic lift of special phase functions is a morphism of Lie algebras and that the holonomic lift of projectable special phase functions is a morphism of Lie algebras. QED

Of course, we can analogously prove that also the other subsheaves of infinitesimal symmetries considered above are subalgebras.

C. Classical currents

We devote the following to the analysis of distinguished functions that are generated by symmetries of our structure.

1. Functions generated by a horizontal potential

Each pair consisting of a spacetime vector field X and a horizontal potential $A^{\uparrow}$ of Ω yield a special phase function. This construction turns out to be an important source of special phase functions in our classical and quantum theories. Indeed, the above simple definition encodes deep aspects relating the horizontal potentials of Ω and the classical and quantum symmetries.

Let us consider a spacetime vector field $X \in \mathrm{sec}(\boldsymbol{E}, T\boldsymbol{E})$ and a horizontal potential $A^{\uparrow} \in \mathrm{fib}(J_1\boldsymbol{E}, T^*\boldsymbol{E})$ of Ω.

We define the *function generated* by X and $A^{\uparrow}$ as $-X \rfloor A^{\uparrow} \in \mathrm{map}(J_1\boldsymbol{E}, \mathbb{R})$.

Proposition 3.33: The function $-X \rfloor A^{\uparrow}$ is a special phase function.

Its coordinate expression is $-X \rfloor A^{\uparrow}=X^0\frac{1}{2}G^0_{ij}x^i_0x^j_0-X^iG^0_{ij}x^j_0-X^{\lambda}A_{\lambda}$ and, with reference to an observer o, we have $-X \rfloor A^{\uparrow}=X \rfloor \mathcal{K}[o]-\nu[o](X) \rfloor \mathcal{Q}[o]-X \rfloor A[o]$.

Proof: It follows from the coordinate expression of $A^{\uparrow}$. QED

Now, as a particular case, let us consider an $f \in \mathrm{spec}(J_1\boldsymbol{E}, \mathbb{R})$ and its tangent prolongation $X[f] \in \mathrm{sec}(\boldsymbol{E}, T\boldsymbol{E})$.

Corollary 3.34: We obtain the special phase function $-X[f]\lrcorner A^{\uparrow}\in \mathrm{spec}(J_1\boldsymbol{E},\mathbb{R})$, with observed expression $-X[f]\lrcorner A^{\uparrow}=f\circ o-X[f]\lrcorner A[o]$. In an adapted chart, we get

$$-X[f]\lrcorner A^{\uparrow}=f^0\left(\tfrac{1}{2}G^0_{ij}x^i_0x^j_0-A_0\right)+f^i(G^0_{ij}x^j_0+A_i)=f-(\check{f}+f^0A_0-f^iA_i).$$

Indeed, we obtain $X[-X[f]\lrcorner A^{\uparrow}]=X[f]$. QED

Corollary 3.35: For each observer o, the function

$$\bar{f}:=f\circ o+X[f]\lrcorner A[o]=f+X[f]\lrcorner A^{\uparrow}\in \mathrm{map}(\boldsymbol{E},\mathbb{R}),$$

does not depend on the choice of the observer o. Therefore, the coordinate expression $\bar{f}=\check{f}+f^0A_0-f^iA_i$ does not depend on the adapted chart.

proof: In fact, f and $X[f]\lrcorner A^{\uparrow}$ do not depend on the choice of any observer. QED

For instance, we have $-X[\mathcal{L}_0]\lrcorner A^{\uparrow}=\mathcal{L}_0-2A_0+G^{ij}_0A_iA_j$, $-X[\mathcal{H}_0]\lrcorner A^{\uparrow}=\mathcal{H}_0$, and $-X[\mathcal{P}_i]\lrcorner A^{\uparrow}=\mathcal{P}_i$.

2. Nöther's theorem

The previous results on infinitesimal symmetries can be applied to the Lagrangian formalism. Here, we call in mind some of results already presented in Ref. 62 and add new results as well.

Let us consider a horizontal potential $A^{\uparrow}\in \mathrm{fib}(J_1\boldsymbol{E},T^*\boldsymbol{E})$ of Ω and the associated Lagrangian $\mathcal{L}\in \mathrm{sec}(J_1\boldsymbol{E},H^*J_1\boldsymbol{E})$ and momentum $\mathcal{P}\in \mathrm{sec}(J_1\boldsymbol{E},T^*J_1\boldsymbol{E})$.

We define an *infinitesimal symmetry* of $A^{\uparrow}$ to be a vector field $X^{\uparrow}\in \mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$, such that $L[X^{\uparrow}]A^{\uparrow}=0$.

Lemma 3.36: Each infinitesimal symmetry of $A^{\uparrow}$ is an infinitesimal symmetry of Ω. QED

We can formulate the following (Nöther) theorem which relates holonomic infinitesimal symmetries of $A^{\uparrow}$ to conserved functions. For this, let us consider an $X\in \mathrm{sec}(\boldsymbol{E},T\boldsymbol{E})$.

We say that X is a *holonomic infinitesimal symmetry* of a tensor ϕ of the phase space if its holonomic prolongation $X_{(1)}\in \mathrm{sec}(J_1\boldsymbol{E},TJ_1\boldsymbol{E})$ is an infinitesimal symmetry of ϕ, i.e., if $L[X_{(1)}]\phi=0$.

Theorem 3.37: *If* $L[X_{(1)}]A^{\uparrow}=0$, *then the one-form* $i(X_{(1)})\Omega\in \mathrm{sec}(J_1\boldsymbol{E},T^*J_1\boldsymbol{E})$ *is exact and the function* $f:=-X\lrcorner A^{\uparrow}\in \mathrm{map}(J_1\boldsymbol{E},\mathbb{R})$ *turns out to be a potential of* $i(X_{(1)})\Omega$. *Moreover, we obtain* $f\in \mathrm{cons\ self}(J_1\boldsymbol{E},\mathbb{R})$ *and* $X_{(1)}=X^{\uparrow}{}_{\mathrm{hol}}[f]=X^{\uparrow}{}_{\mathrm{ham}}[f]$.

Proof: We have $i(X_{(1)})\Omega=i(X_{(1)})dA^{\uparrow}=L[X_{(1)}]A^{\uparrow}-di(X_{(1)})A^{\uparrow}=0-di(X)A^{\uparrow}=df$.

Hence, f is a potential $i(X_{(1)})\Omega$. Moreover, by virtue of Lemma 3.36 and Corollary 3.28, we obtain $f\in \mathrm{cons\ self}(J_1\boldsymbol{E},\mathbb{R})$ and $X_{(1)}=X^{\uparrow}{}_{\mathrm{hol}}[f]=X^{\uparrow}{}_{\mathrm{ham}}[f]$ in the whole domain of $A^{\uparrow}$. QED

Corollary 3.38: If X is an infinitesimal symmetry of dt and a holonomic infinitesimal symmetry of $A^{\uparrow}$, then the potential $f:=-X\lrcorner A^{\uparrow}=-(X\lrcorner\mathcal{P}+X\lrcorner\mathcal{L})$ of $i(X_{(1)})\Omega$ is a classical generator.

Proof: It follows from the above Theorem 3.37, Corollary 3.30, the definition of classical generators and Proposition 3.24. QED

Corollary 3.39: If an observer $o\in \mathrm{sec}(\boldsymbol{E},\mathbb{T}^*\otimes T\boldsymbol{E})$ is a (scaled) infinitesimal symmetry of $A^{\uparrow}$, then the associated (scaled) potential of $i(o_{(1)})\Omega$ is just the associated Hamiltonian $\mathcal{H}[A^{\uparrow},o]:=-o\lrcorner A^{\uparrow}\in \mathrm{map}(J_1\boldsymbol{E},\mathbb{T}^*\otimes\mathbb{R})$. In particular, $\mathcal{H}[A^{\uparrow},o]$ turns out to be a conserved (scaled) function. QED

Next, we prove that the holonomic infinitesimal symmetries of dt and of the horizontal potential are just the holonomic infinitesimal symmetries of dt and of the Lagrangian.

Lemma 3.40: For each $X\in \mathrm{fine}(\boldsymbol{E},T\boldsymbol{E})$, we have the coordinate expressions

$$L[X_{(1)}]\mathcal{L}=(X^{\mu}\partial_{\mu}\mathcal{L}_0+\partial_0X^j\partial^0_j\mathcal{L}_0+\partial_hX^jx^h_0\partial^0_j\mathcal{L}_0)d^0,$$

$$L[X_{(1)}]\mathcal{P}=\partial^0_i(X^{\mu}\partial_{\mu}\mathcal{L}_0+\partial_0X^j\partial^0_j\mathcal{L}_0+\partial_hX^jx^h_0\partial^0_j\mathcal{L}_0)d^i-\partial^0_i(X^{\mu}\partial_{\mu}\mathcal{L}_0+\partial_0X^j\partial^0_j\mathcal{L}_0+\partial_hX^jx^h_0\partial^0_j\mathcal{L}_0)x^i_0d^0.$$

Proof: We have

$$
\begin{aligned}
L[X_{(1)}]\mathcal{P} &= (X^\mu \partial_\mu \partial_i^0 \mathcal{L}_0 + \partial_0 X^j \partial_j^0 \partial_i^0 \mathcal{L}_0 + \partial_h X^j x_0^h \partial_j^0 \partial_i^0 \mathcal{L}_0 + \partial_i X^j \partial_j^0 \mathcal{L}_0) d^i \\
&\quad - ((X^\mu \partial_\mu \partial_i^0 \mathcal{L}_0 + \partial_0 X^j \partial_j^0 \partial_i^0 \mathcal{L}_0 + \partial_h X^j x_0^h \partial_j^0 \partial_i^0 \mathcal{L}_0) x_0^i + \partial_0 X^i \partial_i^0 \mathcal{L}_0 + \partial_h X^i x_0^h \partial_i^0 \mathcal{L}_0 - \partial_0 X^j \partial_j^0 \mathcal{L}_0) d^0 \\
&= (X^\mu \partial_\mu \partial_i^0 \mathcal{L}_0 + \partial_0 X^j \partial_j^0 \partial_i^0 \mathcal{L}_0 + \partial_h X^j x_0^h \partial_j^0 \partial_i^0 \mathcal{L}_0 + \partial_i X^j \partial_j^0 \mathcal{L}_0) d^i \\
&\quad - ((X^\mu \partial_\mu \partial_i^0 \mathcal{L}_0 + \partial_0 X^j \partial_j^0 \partial_i^0 \mathcal{L}_0 + \partial_h X^j x_0^h \partial_j^0 \partial_i^0 \mathcal{L}_0) x_0^i + \partial_h X^i x_0^h \partial_i^0 \mathcal{L}_0) d^0 \\
&= \partial_i^0 (X^\mu \partial_\mu \mathcal{L}_0 + \partial_0 X^j \partial_j^0 \mathcal{L}_0 + \partial_h X^j x_0^h \partial_j^0 \mathcal{L}_0 - \partial_i X^j \partial_j^0 \mathcal{L}_0 + \partial_i X^j \partial_j^0 \mathcal{L}_0) d^i \\
&\quad - (\partial_i^0 (X^\mu \partial_\mu \mathcal{L}_0 + \partial_0 X^j \partial_j^0 \mathcal{L}_0 + \partial_h X^j x_0^h \partial_j^0 \mathcal{L}_0) x_i^0 \\
&\quad - \partial_i X^j x_0^i \partial_j^0 \mathcal{L}_0 + \partial_h X^i x_0^h \partial_i^0 \mathcal{L}_0) d^0 \\
&= \partial_i^0 (X^\mu \partial_\mu \mathcal{L}_0 + \partial_0 X^j \partial_j^0 \mathcal{L}_0 + \partial_h X^j x_0^h \partial_j^0 \mathcal{L}_0) d^i \\
&\quad - \partial_i^0 (X^\mu \partial_\mu \mathcal{L}_0 + \partial_0 X^j \partial_j^0 \mathcal{L}_0 + \partial_h X^j x_0^h \partial_j^0 \mathcal{L}_0) x_0^i d^0 .
\end{aligned}
$$

QED

Proposition 3.41: For each $X \in \mathrm{fine}(\boldsymbol{E}, T\boldsymbol{E})$, we have the following implication

$$L[X_{(1)}]\mathcal{L} = 0 \Rightarrow L[X_{(1)}]\mathcal{P} = 0 .$$

QED

Theorem 3.42:[62] *For each* $X \in \mathrm{fine}(\boldsymbol{E}, T\boldsymbol{E})$, *the following equivalence holds*

$$L[X_{(1)}]A^\uparrow = 0 \Leftrightarrow L[X_{(1)}]\mathcal{L} = 0 .$$

Proof: If $L[X_{(1)}]A^\uparrow = 0$, then, by virtue of Lemma 2.3, we have

$$L[X_{(1)}]\mathcal{L} := L[X_{(1)}] i(\Delta) A^\uparrow = -i(\Delta) L[X_{(1)}]A^\uparrow + i([X_{(1)}, \Delta])A^\uparrow = 0 + 0 .$$

If $L[X_{(1)}]\mathcal{L} = 0$, then, by virtue of Sec. II C 2, and Proposition 3.41

$$L[X_{(1)}]A^\uparrow = L[X_{(1)}](\mathcal{L} + P) = 0 + 0 .$$

QED

Consider a fast nonrelativistic, positively charged particle (ion) traversing a crystal, assumed to be simple cubic and monatomic for simplicity. Let the Cartesian coordinates X_1, X_2, X_3 be parallel to the crystal axes, and η_i be the initial value of the component of the particle's momentum vector along X_i. If $|\eta_3|$ is sufficiently large compared to $|\eta_1|, |\eta_2|$, then (under mild technical assumptions) the ion's motion is well approximated for a long time by a solution of the equations of motion (EOM) of the axial-continuum Hamiltonian $\bar{H}$, obtained from the ion's nonrelativistic Hamiltonian H by replacing the potential $V(X_1, X_2, X_3)$, describing its interaction with the atoms of the crystal, by its average $\bar{V}(X_1, X_2)$ over X_3. Furthermore, if $|\eta_2|, |\eta_3|$ are sufficiently large compared with $|\eta_1|, |\eta_2|$, respectively, then to a good approximation its motion is given, again for a long time, by a solution of the EOM of the planar continuum Hamiltonian $\bar{\bar{H}}$, obtained from $\bar{H}$ by replacing $\bar{V}(X_1, X_2)$ by its average $\bar{\bar{V}}(X_1)$ over X_2. We define motions of the first (respectively, second) type as axial (respectively, planar) channeling. In this paper, the transition from the first to the second kind of motion, occurring when the crystal is suitably rotated, is discussed in a mathematically rigorous way by using an improved version of first-order single-phase averaging theory. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2209554]

I. INTRODUCTION

The transition from axial to planar channeling in crystals has been investigated by many authors, both experimentally and theoretically (see, e.g., Refs. 1–3 and the references cited therein). Previous theoretical studies differ from the present one in two main respects. First, they were carried out by using numerical or partially formal analytical procedures. Second, they deal with all stages of the transition. Here we study the phenomenon in a mathematically rigorous way in a simple cubic crystal model by using an improved version of the first-order single-phase averaging theory of nonlinear dynamical systems.[4] The transition from axial to planar channeling which we study occurs for sufficiently large values of the components of the initial momentum along the X_2, X_3 crystal axes, keeping fixed its component along the X_1 axis, and is induced by rotating the crystal while immersed in the incident particle beam. The present paper deals with a relatively late stage of the phenomenon, when the transition is almost complete.

Consider such a crystal traversed by a fast nonrelativistic, positively charged particle (ion) in a direction almost, but not exactly, parallel to the X_3 cubic axis. We assume that the particle's motion is "governed" by the nonrelativistic Hamiltonian $H: (\mathbf{R}^3 \backslash \mathbf{Z}^3) \times \mathbf{R}^3 \to (0, \infty)$ defined by

$$H(X,P) = \frac{1}{2}\sum_{i=1}^{3} P_i^2 + V(X) \tag{1.1a}$$

in suitable units. Here $X=(X_1, X_2, X_3) \in \mathbf{R}^3 \backslash \mathbf{Z}^3$and $P=(P_1, P_2, P_3) \in \mathbf{R}^3$denote the coordinate and momentum vectors of the particle, and

$$V(X) = \sum_{k \in \mathbf{Z}^3} v(X-k) \tag{1.1b}$$

denotes the potential acting on the particle at $X \in \mathbf{R}^3 \backslash \mathbf{Z}^3$, due to the combined effect of the repulsive, shielded Coulomb potentials of the individual atoms of a single species, idealized as pointwise, which are located at the sites of a cubic lattice $\mathbf{Z}^3$. The potential at $X \in \mathbf{R}^3 \backslash \mathbf{Z}^3$ due to the presence of an atom at $k \in \mathbf{Z}^3$ is given by $v(X-k)$. We assume that $v \in C^2(\mathbf{R}^3 \backslash \{0\})$ and is strictly positive, and that $v(Y) = O(\|Y\|^{-1}), \|Y\| \to 0$.[5] Additionally, we assume that the series (1.1b) converges uniformly on compacts in $\mathbf{R}^3 \backslash \mathbf{Z}^3$, thus defining a strictly positive potential $V(X)$ of this same class which tends to infinity as $X \to k \in \mathbf{Z}^3$ and is 1-periodic in each coordinate $X_i (i = 1,2,3)$ in terms of the present units.

We will say that the particle is axially channeled along the X_3 direction if its motion is well approximated by a solution of the equations of motion (EOM) of the axial-continuum Hamiltonian $\bar{H}: (\mathbf{R}^3 \backslash \mathbf{Z}^3) \times \mathbf{R}^3 \to (0, \infty)$ for a long time, where

$$\bar{H}(X,P) = \frac{1}{2} \sum_{i=1}^{3} P_i^2 + \bar{V}(X_1, X_2), \tag{1.2a}$$

with

$$\bar{V}(X_1, X_2) = \int_{(0,1)} V(X_1, X_2, X_3') \mathrm{d}X_3'. \tag{1.2b}$$

By our assumptions on V, the integral in (1.2b) exists as a Riemann integral and defines a strictly positive function $\bar{V}$ of class $C^2(\mathbf{R}^2 \backslash \mathbf{Z}^2)$, which is *unbounded* from above in a neighborhood of each point of $\mathbf{Z}^2$. To say that the particle is channeled parallel to the X_2, X_3 plane will mean that its motion is well approximated by the solution of the EOM of the planar continuum Hamiltonian $\bar{\bar{H}}: (\mathbf{R}^3 \backslash \mathbf{Z}^3) \times \mathbf{R}^3 \to (0, \infty)$, again for a long time, where

$$\bar{\bar{H}}(X,P) = \frac{1}{2} \sum_{i=1}^{3} P_i^2 + \bar{\bar{V}}(X_1). \tag{1.3a}$$

Here

$$\bar{\bar{V}}(X_1) = \int_{(0,1)^2} V(X_1, X_2', X_3') \mathrm{d}X_2' \, \mathrm{d}X_3', \tag{1.3b}$$

where the double integral exists in the above sense for $X_1 \in \mathbf{R} \backslash \mathbf{Z}$, and defines a strictly positive function $\bar{\bar{V}}$ of class $C^1(\mathbf{R} \backslash \mathbf{Z})$, which is *bounded* from above in a neighborhood of each point of $\mathbf{Z}$, again by our hypotheses on V. More precise definitions of axial and planar channeling for the cases of interest will be given in the respective Secs. II and III.

For simplicity, we will confine ourselves to discussing channeling along the said axis and planes. A generalization to channeling along arbitrary axes and planes in simple cubic or more complicated crystals involves no essentially new ideas.

Let the initial values of the position and momentum vectors $X = (X_1, X_2, X_3)$, $P = (P_1, P_2, P_3)$ be denoted by $\xi = (\xi_1, \xi_2, \xi_3)$, $\eta = (\eta_1, \eta_2, \eta_3)$, respectively. Under the present hypotheses on V, one can show that if η is almost, but not exactly, parallel to the X_3 axis and $\|\eta\|$ is sufficiently large, the particle remains axially channeled along X_3 over distances of order $\sqrt{2E}$, where E is the total particle energy in the present units [Eq. (2.4b)]. If in addition $|\eta_2| \gg |\eta_1|$ and $|\eta_1|$ is small enough, it becomes planarly channeled between two adjacent atomic planes parallel to the X_2, X_3 plane over distances of order $\sqrt{2E_\perp}, E_\perp$ being the transverse particle energy in these units [Eq. (3.1b)].

In the usual terminology, the variation from the first situation to the second constitutes a transition from axial to planar channeling. A more precise characterization of the transition is given in Sec. III.

The organization of this paper is as follows. In Sec. II, we discuss axial channeling in simple cubic crystals using an improved version of single-phase first-order averaging theory. The main results of the discussion are summarized in Theorems 2.1 and 2.2, the former being used in the proof of the latter. The existence of an axial-to-planar transition in these crystals is asserted by Theorem 3.3 of Sec. III. This result is established there with the aid of Theorems 2.2 and 3.2, the proof of the latter being based on Theorem 3.1. In Appendix A we state Propositions A.1 and A.2 concerning certain inequalities needed in Secs. II and III. Finally in Appendix B we establish Theorem B.1, a basic result of first-order single-phase averaging theory which we use to prove Theorems 2.1 and 3.1 in Secs. II and III, respectively.

II. AXIAL CHANNELING (Ref. 6)

Consider the equations of motion (EOM)

$$\frac{\mathrm{d}X_i}{\mathrm{d}t} = P_i \quad (i=1,2,3), \tag{2.1a}$$

$$\frac{\mathrm{d}P_i}{\mathrm{d}t} = -D_i V(X) \quad (i=1,2,3),$$

corresponding to the Hamiltonian (1.1a), D_i being the partial derivative with respect to the ith entry in $V(.,.,.)$. Since V is strictly positive and of class $C^2(\mathbf{R}^3\backslash\mathbf{Z}^3)$, there exists[7] for all $t\in\mathbf{R}$ and all $\omega:=(\xi,\eta)\in(\mathbf{R}^3\backslash\mathbf{Z}^3)\times\mathbf{R}^3$ a unique solution $X_i(t,\omega),P_i(t,\omega)(i=1,2,3)$ of Eqs. (2.1a) satisfying the initial conditions

$$X_i(0,\omega)=\xi_i, \quad P_i(0,\omega)=\eta_i \quad (i=1,2,3). \tag{2.1b}$$

Henceforth we assume that $\zeta=(\xi_1,\xi_2,\eta_1,\eta_2)$ is in the multiply connected open set

$$U(K)=\left\{((x_1,x_2),(x_3,x_4))\in(\mathbf{R}^2\setminus\mathbf{Z}^2)\times\mathbf{R}^2:\tfrac{1}{2}(x_3^2+x_4^2)+\bar{V}(x_1,x_2)<K\right\}, \tag{2.2}$$

where K is a positive constant such that $K>\inf_{y\in\mathbf{R}^2\backslash\mathbf{Z}^2}\bar{V}(y)$. Hence $U(K)$ is a nonempty set which is invariant under the transverse Hamiltonian $\bar{H}_\perp:(\mathbf{R}^2\backslash\mathbf{Z}^2)\times\mathbf{R}^2\to(0,\infty)$ defined by

$$\bar{H}_\perp(X_\perp,P_\perp)=\frac{1}{2}\sum_{j=1,2}P_j^2+\bar{V}(X_\perp), \tag{2.3}$$

where $X_\perp=(X_1,X_2)$ and $P_\perp=(P_1,P_2)$. Typically, $\bar{V}(x_1,x_2)$ consists of a set of sharp, infinitely high peaks surrounding the atomic rows parallel to the X_3 axis. For sufficiently large K, the projection $U_p(K)=\{(x_1,x_2)\in\mathbf{R}^2\backslash\mathbf{Z}^2:((x_1,x_2),(x_3,x_4))\in U(K)\}$ of $U(K)$ into the X_1,X_2 plane is a multiply connected set reminiscent of Swiss cheese, the holes being deformed circular disks surrounding these rows.

The total energy E of the solution $X_i(t,\omega),P_i(t,\omega)(i=1,2,3)$ is defined by

$$E:=H(X(t,\omega),P(t,\omega))=H(X(0,\omega),P(0,\omega))=\frac{1}{2}\sum_{j=1}^{3}\eta_j^2+V(\xi), \tag{2.4a}$$

where $X(t,\omega)=(X_1(t,\omega),X_2(t,\omega),X_3(t,\omega))$ and $P(t,\omega)=(P_1(t,\omega),P_2(t,\omega),P_3(t,\omega))$, and where we have used (2.1) and conservation of energy. We define the positive parameter

$$\varepsilon =: 1/\sqrt{2E} = \left\{ \sum_{j=1}^{3} \eta_j^2 + 2V(\xi) \right\}^{-1/2}, \tag{2.4b}$$

with the range of values $(0, 1/\sqrt{2V_0}]$, where $V_0 = \inf_{x \in \mathbf{R}^3 \setminus \mathbf{Z}^3} V(x) = \min_{x \in \mathbf{R}^3 \setminus \mathbf{Z}^3} V(x) \in (0, \infty)$. This parameter will play an important role in the sequel.

For convenience we suppose henceforth that

$$\xi_1 \in (0,1), \quad \xi_j = 0 \quad (j = 2,3), \quad \eta_k > 0 \quad (k = 1,2,3), \tag{2.5}$$

in the absence of an explicit statement to the contrary. Moreover, in the present section we fix $\xi_1, \eta_k (k=1,2)$, leaving η_3 as the only free parameter. Because of (2.4b) and (2.5), we will view ε in this section as a function of η_3 alone, with $\varepsilon \sim 1/\eta_3$ for $\eta_3 \to \infty$.

In order to formulate the relevant equations of motion in a manner suitable for the application of averaging theory, we will isoenergetically reduce the sixth-order autonomous system (2.1a) to a fourth order nonautonomous one.[8] This will be done by changing t to an independent variable u, given by

$$u = X_3(t,\omega) = \int_0^t P_3(s,\omega)\mathrm{d}s = (1/\varepsilon) \int_0^t \{1 - 2\varepsilon^2 [V(X(s,\omega)) + (1/2)P_\perp^2(s,\omega)]\}^{1/2}\, \mathrm{d}s, \tag{2.6}$$

where we have used (1.1a), (2.1), and (2.4b); assumed that $P_3(s,\omega)$ does not change sign for $s \in [0,t]$; and written $P_\perp^2(s,\omega) = \Sigma_{i=1}^2 P_i^2(s,\omega)$.

Let

$$x_i(u,\varepsilon) = X_i(t,\omega) \quad (i = 1,2),$$

$$x_{i+2}(u,\varepsilon) = P_i(t,\omega) \quad (i = 1,2), \tag{2.7}$$

where the dependence of $x_j(u,\varepsilon)$ on ω is not exhibited explicitly. By (2.1), (2.6), and (2.7), at least formally, $x(u,\varepsilon) = (x_1(u,\varepsilon), \ldots, x_4(u,\varepsilon))$ solves the IVP (initial-value problem)

$$\frac{\mathrm{d}x}{\mathrm{d}u} = \varepsilon f(x,u) + \varepsilon^2 r(x,u,\varepsilon), \tag{2.8a}$$

$$x(0,\varepsilon) = \zeta \in U(K), \tag{2.8b}$$

where we use x in (2.8a) as shorthand for $x(\mathrm{u},\varepsilon)$. An analogous shorthand notation will be used to define other IVPs occurring in the paper. However, in order to define the functions f and r in (2.8a), we will let x stand for any point $(x_1,x_2,x_3,x_4) \in \mathbf{R}^4$. No confusion should arise from this usage in this section or from the analogous usage in Sec. III. With x understood in the latter sense, we write

$$f(x,u) = (x_3, x_4, -D_1 V(x_1,x_2,u), -D_2 V(x_1,x_2,u)), \tag{2.9a}$$

$$r(x,u,\varepsilon) = \varepsilon^{-1}\{[k(x,u,\varepsilon)]^{-1} - 1\} f(x,u), \tag{2.9b}$$

$$k(x,u,\varepsilon) = \left\{1 - 2\varepsilon^2 \left[V(x_1,x_2,u) + \tfrac{1}{2}(x_3^2 + x_4^2) \right] \right\}^{1/2}. \tag{2.9c}$$

Since $V(x_1,x_2,u)$ is C^2 for $(x_1,x_2) \in \mathbf{R}^2 \setminus \mathbf{Z}^2, u \in \mathbf{R}$ and since it is 1-periodic in u, (2.9a) defines $f(.,.)$ as a C^1-mapping from $U(\mathbf{K}) \times \mathbf{R}$ into $\mathbf{R}^4$, which is 1-periodic in the second entry. Moreover, at each $\varepsilon \in (0, \varepsilon^{(0)}), r(.,.,\varepsilon)$, defined by (2.9a), (2.9b), and (2.9c), is a *bounded* C^1 mapping from $U(K) \times \mathbf{R}$ into $\mathbf{R}^4$. Here $\varepsilon^{(0)} = \varepsilon^{(0)}(K)$ is a positive constant defined in Proposition A.1 of Appendix A. The boundedness property of this mapping is expressed by the estimate

$$\sup_{(x,u,\varepsilon)\in U(K)\times\mathbf{R}\times(0,\varepsilon^{(0)})}\|r(x,u,\varepsilon)\|<\infty \tag{2.10}$$

asserted by that proposition, and its C^1 property is implied by elementary arguments.

In order to determine rigorously a set of values of u,t where relations (2.7) between the IVPs (initial-value problems) (2.1) and (2.8) hold, we proceed in a reverse manner to that by which (2.8) was obtained heuristically from (2.1). We first define the mapping $u\mapsto t$ by

$$t=\varepsilon\int_0^u\{1-2\varepsilon^2[V(x_1(r,\varepsilon),x_2(r,\varepsilon),r)+(1/2)[x_3^2(r,\varepsilon)+x_4^2(r,\varepsilon)]]\}^{-1/2}\,\mathrm{d}r \tag{2.6$'$}$$

for $u\in J(\varepsilon,T),0<\varepsilon<\varepsilon^{(1)}$. Here $J(\varepsilon,T)=(-\alpha(\varepsilon,T),T/\varepsilon+\alpha(\varepsilon,T))$, where $\alpha(\varepsilon,T)>0$ is considered below, the constant $T\in(0,\infty)$ is defined in the paragraph containing (2.13), and both T and $\varepsilon^{(1)}=\varepsilon^{(1)}(K,\zeta,T)$ appear in Theorem 2.1. (If $u<0,\int_0^u=-\int_{-u}^0$.) By this theorem, the solution $x(u,\varepsilon)=(x_1(u,\varepsilon),\ldots,x_4(u,\varepsilon))$ of the IVP (2.8) exists uniquely and remains in $U(K)$ for $0\le u\le T/\varepsilon,0<\varepsilon<\varepsilon^{(1)}<\varepsilon^{(0)}$. Since $U(K)$ is open, $x(u,\varepsilon)$ also has these properties if $u\in J(\varepsilon,T),0<\varepsilon<\varepsilon^{(1)}$, provided that $\alpha(\varepsilon,T)$ is small enough at each such ε,T, by virtue of elementary existence and uniqueness theorems of ODEs. Since $x(r,\varepsilon)\in U(K)$ for $0\le r\le u\in J(\varepsilon,T)$ at all the latter ε,T, the quantity in curly brackets in (2.6$'$) is positive at these r,ε values by (A4) in Appendix A, and hence the mapping $u\mapsto t$ exists at the latter ε values. Indeed, one can show that at each $\varepsilon\in(0,\varepsilon^{(1)}),T\in(0,\infty)$the relation (2.6$'$) defines a C^1 diffeomorphism $u\mapsto t$ from $J(\varepsilon,T)$ onto a finite open interval $J'(\varepsilon,T)$ containing the point $t=0$, whose inverse $t\mapsto u$ is given by (2.6). Second, for $t\in J'(\varepsilon,T),\ \varepsilon\in(0,\varepsilon^{(1)})$ we define $X_i(t,\omega),\ P_i(t,\omega)(i=1,2)$ by (2.7), and set $X_3(t,\omega)=u,\ P_3(t,\omega)=\mathrm{d}u/\mathrm{d}t$. This can be shown to imply that $X_i(t,\omega),\ P_i(t,\omega)(i=1,2,3)$ satisfies the IVP (2.1) at each of the latter t,ε. Hence, this solution of (2.1) coincides locally, and therefore globally, with the global solution $X_i(t,\omega),\ P_i(t,\omega)(i=1,2,3)$ mentioned in the first paragraph of this section. We have thus justified (2.7) for $u\in J(\varepsilon,T),\ T\in(0,\infty)$. Hence (2.7) holds for $t\in[0,T],\ \varepsilon\in(0,\varepsilon^{(1)})$, since at each such ε,T the latter interval is contained in the image of $0\le u\le T/\varepsilon$ under the diffeomorphism $u\mapsto t$.

Define

$$\bar{f}(x)=(x_3,x_4,-D_1\bar{V}(x_1,x_2),-D_2\bar{V}(x_1,x_2)) \tag{2.11}$$

for $x=(x_1,x_2,x_3,x_4)\in\mathbf{R}^4$. Then the "averaged" IVP

$$\frac{\mathrm{d}\bar{x}}{\mathrm{d}u}=\varepsilon\bar{f}(\bar{x}), \tag{2.12a}$$

$$\bar{x}(0,\varepsilon)=\zeta, \tag{2.12b}$$

has a unique solution $\bar{x}(u,\varepsilon)=(\bar{x}_i(u,\varepsilon))(i=1,\ldots,4)$ for $u\in\mathbf{R},\varepsilon>0$. This follows from the strict positivity of $\bar{V}\in C^2(\mathbf{R}^2\backslash\mathbf{Z}^2)$ by arguments of the same type as ones adduced earlier in a similar connection.[7]

At each $\varepsilon>0$ the IVP (2.12) is equivalent to the IVP

$$\frac{\mathrm{d}y}{\mathrm{d}\tau}=\bar{f}(y), \tag{2.13a}$$

$$y(0)=\zeta, \tag{2.13b}$$

which has a unique solution $y(\tau)$, where $\tau:=\varepsilon u$. We have

$$\bar{x}(u,\varepsilon) = y(\tau) = (y_1(\tau), y_2(\tau), y_3(\tau), y_4(\tau)), \tag{2.14}$$

where we omit the dependence of the $y_k(\tau)$ on ζ. Note that system (2.13a) constitutes the EOM of the transverse Hamiltonian $H_\perp(y_1,y_2,y_3,y_4)=\frac{1}{2}(y_3^2+y_4^2)+\bar{V}(y_1,y_2)$ in terms of the time τ, where y_3, y_4 are the momenta canonically conjugate to the respective coordinates y_1, y_2. Since $H_\perp$ conserves transverse energy, and (2.14) and $\zeta \in U(K)$ hold, the unique solution $\bar{x}(u,\varepsilon)$ of the IVP (2.12) remains confined to $U(K)$ for all $u \in \mathbf{R}, \varepsilon > 0$. Let $[0, T_1(\zeta))$ be the maximum forward interval of existence of the solution of the IVP (2.13), and T a positive number *less* than $T_1(\zeta)$. Obviously, $T_1(\zeta)=\infty$, and hence $T \in (0,\infty)$.

Theorem 2.1: Let $T \in (0,\infty)$ be given. Then there exist positive constants $c = c(K,\zeta,T)$, $\varepsilon^{(1)}=\varepsilon^{(1)}(K,\zeta,T)$, independent of ε and hence of η_3, with $\varepsilon^{(1)} < \varepsilon^{(0)} = \varepsilon^{(0)}(K)$ and such that the IVP (2.8) has a unique solution $x(u,\varepsilon)$ which remains in $U(K)$ and is uniformly approximated therein by $\bar{x}(u,\varepsilon)$ according to

$$\|x(u,\varepsilon) - \bar{x}(u,\varepsilon)\| < c\varepsilon \tag{2.15}$$

for $0 \le u \le T/\varepsilon$, $0 < \varepsilon < \varepsilon^{(1)}$.

Proof: This theorem is a special case of Theorem B.1 in Appendix B. To show this, we first note the following correspondences between key symbols used in the former and latter theorems: $U \in \mathbf{R}^n \to U(K) \in \mathbf{R}^4$, $\alpha \in \mathbf{R}^n \to \zeta \in \mathbf{R}^4$, $T \to T$, $\varepsilon_0 \to \varepsilon^{(0)}$, $\varepsilon_1 \to \varepsilon^{(1)}$, $x(u,\varepsilon) \to x(u,\varepsilon)$, $y(u,\varepsilon) \to \bar{x}(u,\varepsilon)$, $C_1 \to c$, where we remark that $U(K)$ is uniquely determined by K. Second, we note that the IVP (2.8) [respectively, (2.12)] has the same form as the IVP (B1) [respectively, (B3)]. Third, we observe that the functions f, r in (2.8a) satisfy special cases of the conditions (B2) imposed on their respective generalizations in (B1) [see the paragraph containing (2.10)]. Keeping in mind these remarks, one readily sees that Theorem B.1 implies the present theorem. □

The solution $\bar{X}_i(t,\omega), \bar{P}_i(t,\omega)(i=1,2,3)$ of the EOM

$$\frac{d\bar{X}i}{dt} = \bar{P}_i \ (i=1,2,3), \tag{2.16a}$$

$$\frac{d\bar{P}_i}{dt} = -D_i\bar{V}(\bar{X}_1,\bar{X}_2) \quad (i=1,2,3),$$

corresponding to the averaged Hamiltonian $\bar{H}$ and satisfying the same initial conditions

$$\bar{X}_i(0,\omega) = \xi_i, \quad \bar{P}_i(0,\omega) = \eta_i \quad (i=1,2,3) \tag{2.16b}$$

as that of the EOM (2.1a) exists and is unique for all $t \in \mathbf{R}$ for reasons similar to those ensuring that the solution of the IVP (2.13) has these same properties. By (2.16b) and (2.5), the projection of the particle's motion along the X_3 axis is uniform and given by

$$\bar{X}_3(t,\omega) = \eta_3 t, \quad \bar{P}_3(t,\omega) = \eta_3. \tag{2.17}$$

Note that

$$(\bar{X}_1(t,\omega),\bar{X}_2(t,\omega),\bar{P}_1(t,\omega),\bar{P}_2(t,\omega)) = (y_1(t),y_2(t),y_3(t),y_4(t)) \tag{2.18}$$

for $t \in \mathbf{R}$. Indeed, the 4-vector on the lhs of (2.18) satisfies an IVP of the form

$$\frac{dy}{dt} = \bar{f}(y), \tag{2.19a}$$

$$y(0) = \zeta \tag{2.19b}$$

at each $t \in \mathbf{R}$, as follows from (2.16), the fact that the initial conditions satisfied by the components of the latter 4-vector are of the form (2.12b), and the uniqueness of solution of the IVP (2.19). These properties immediately imply (2.18).

Set $Z(t,\omega)=(X(t,\omega),P(t,\omega)) \in \mathbf{R}^6$ and define $\bar{X}(t,\omega)$, $\bar{P}(t,\omega)$, $\bar{Z}(t,\omega)$ similarly to $X(t,\omega)$, $P(t,\omega)$, $Z(t,\omega)$ in terms of barred quantities. We now use Theorem 2.1 to prove the next theorem, which is its analogue in terms of $Z(t,\omega)$ and $\bar{Z}(t,\omega)$.

Theorem 2.2: Let $T \in [0,\infty)$ be given. Then there exist positive constants $C = C(K,\zeta,T), \varepsilon^{(2)} = \varepsilon^{(2)}(K,\zeta,T)$, independent of η_3, with $\varepsilon^{(2)} < \varepsilon^{(1)}$, and such that $Z(t,\omega)$ is uniformly approximated by $\bar{Z}(t,\omega)$ according to

$$\|Z(t,\omega) - \bar{Z}(t,\omega)\| < C\varepsilon \tag{2.20}$$

for $0 \le t \le T, 0 < \varepsilon < \varepsilon^{(2)}$.

This theorem suggests the following definition.

Definition 2.1: For any $\delta > 0$, we say that a particle with Hamiltonian H [see (1.1a), (1.1b)] is δ-axially channeled for given parameters K,ω if for each of the t,ε values mentioned in Theorem 2.2 the inequality (2.20) holds with its right-hand side (rhs) replaced by δ.

Proof of Theorem 2.2: Fixing $i=1,2$ for the moment, we have

$$\begin{aligned} |Z_i(t,\omega) - \bar{Z}_i(t,\omega)| &= |X_i(t,\omega) - \bar{X}_i(t,\omega)| = |x_i(u,\varepsilon) - y_i(t)| \le |x_i(u,\varepsilon) - \bar{x}_i(u,\varepsilon)| + |y_i(t) - y_i(\tau)| \\ &< \text{const}\,\varepsilon + |y_i(t) - y_i(\tau)| \end{aligned} \tag{2.21}$$

by (2.7), (2.14), (2.18), and Theorem 2.1, for $0 \le u \le T/\varepsilon$, $0 < \varepsilon < \varepsilon^{(1)}$, and for the corresponding values of t determined by the diffeomorphism $u \mapsto t$, which include all $t \in [0,T]$, as mentioned above. In (2.21) and henceforth, "const" denotes a constant dependent on K,ζ, but independent of η_3. Recalling that $\tau = \varepsilon u$, and using arguments analogous to ones adduced to establish (3.56) in the proof of Theorem 3 of Ref. 5, we see that

$$\begin{aligned} |y_i(t) - y_i(\tau)| &\le |\eta_i| \,.\, |t-\tau| + \left| \int_\tau^t \mathrm{d}s \int_0^s \mathrm{d}r\, D_i \bar{V}(y_1(r), y_2(r)) \right| \\ &\le |\eta_i| \,.\, |t-\tau| + \tfrac{1}{2}|t^2 - \tau^2| \sup_{r \in \mathbf{R}} |D_i \bar{V}(y_1(r), y_2(r))| \\ &\le |\eta_i| \,.\, |t-\tau| + \tfrac{1}{2}|t^2 - \tau^2| \sup_{(y_1,y_2) \in [U_p(K)]^{\mathrm{cl}} \cap [0,1]^2} |D_i \bar{V}(y_1,y_2)| < \text{const}\,\varepsilon^2, \end{aligned} \tag{2.22}$$

at all $t \in [0,T]$, $0 < \varepsilon < \varepsilon^{(2)}$, where $\varepsilon^{(2)}$ is a constant sufficiently smaller than $\varepsilon^{(1)}$. The third inequality (2.22) follows because $(y_1(t), y_2(t)) \in U_p(K)$ at all such t,ε by Theorem 2.1 and because $D_i \bar{V}(y_1,y_2)$ is 1-periodic in its arguments. The fourth inequality (2.22) is implied by the facts that at the t,ε in question $t+\tau < 2T$ and $|t-\tau| < \text{const}\,\varepsilon^2$, and that the last sup in (2.22) is finite. Its finiteness follows by $\bar{V} \in C^2(\mathbf{R}^2 \backslash \mathbf{Z}^2)$ and because the distance between the closure $[U_p(K)]^{\mathrm{cl}}$ of $U_p(K)$ and the set $\mathbf{Z}^2$ of singular points of $D_i \bar{V}$ is positive. Thus, $D_i \bar{V}(y_1,y_2)$ is continuous, and therefore bounded on the compact subset $[U_p(K)]^{\mathrm{cl}} \cap [0,1]^2 \subset \mathbf{R}^2$. Only the second inequality in the penultimate sentence calls for comment. At the latter t,ε, it is directly implied by the fact that

$$t - \tau < \tau\{[K + V_1(K) - V_2]\varepsilon^2 + O(\varepsilon^4)\}$$

for $\varepsilon \downarrow 0$, uniformly with respect to the relevant variables, as one easily sees using (2.6) and (A4).

By (2.21) and (2.22),

$$|Z_i(t,\omega) - \bar{Z}_i(t,\omega)| < \text{const}\,\varepsilon \tag{2.23}$$

for $i=1,2$ when t,ε are as stated in the theorem, making $\varepsilon^{(2)}$ even smaller than above if necessary. Similar considerations show that (2.23) holds for $i=3,4$ at each such t,ε in terms of constants of the indicated type. For $i=5,6$ one can easily prove that (2.23) holds at such t,ε by using, in particular, conservation of energy and (A4). Therefore, (2.20) obtains in the stated sense. □

III. TRANSITION TO PLANAR CHANNELING

We begin with a few definitions and, for the moment, regard the components of the vector ω as freely choosable real parameters.

The transverse particle energy $E_\perp$ is defined as the energy of the solution $(X_\perp(t,\omega), P_\perp(t,\omega))$ of the EOM of the transverse Hamiltonian (2.3) by

$$E_\perp := H_\perp(X_\perp(t,\omega),P_\perp(t,\omega)) = H_\perp(X_\perp(0,\omega),P_\perp(0,\omega)) = \tfrac{1}{2}\sum_{j=1,2}\eta_j^2 + \bar{V}(\xi_1,\xi_2), \tag{3.1a}$$

where we have used (2.3), (2.16b), and conservation of energy. Analogously to before, we define the positive parameter

$$\varepsilon_\perp := 1/\sqrt{2E_\perp} = \left\{\sum_{j=1,2}\eta_j^2 + 2\bar{V}(\xi_1,\xi_2)\right\}^{-1/2}, \tag{3.1b}$$

having the range of values $(0, 1/\sqrt{2\bar{V}_0}]$, where $\bar{V}_0 = \inf_{x\in\mathbf{R}^2\setminus\mathbf{Z}^2}\bar{V}(y) = \min_{x\in\mathbf{R}^2\setminus\mathbf{Z}^2}\bar{V}(y) \in (0,\infty)$. This parameter plays a role in this section comparable to that of ε in the previous one.

From now on in this section, we fix $\xi=(\xi_1,\xi_2,\xi_3)$, η_1, leaving η_2,η_3 as the only free parameters. Moreover, henceforth ξ_j, $\eta_k(j,k=1,2,3)$ will be assumed to satisfy the conditions (2.5). The transition from axial to planar channneling occurs when η_2,η_3 are both sufficiently large, as explained in detail near the end of the section.

We proceed to isoenergetically reduce the fourth-order subsystem (2.16a) for $i=1,2$ to second order. We do this by introducing a new "time" v as the independent variable,

$$v = \bar{X}_2(t,\omega) = \int_0^t \bar{P}_2(s,\omega)\mathrm{d}s = (1/\varepsilon_\perp)\int_0^t \{1 - 2\varepsilon_\perp^2[\bar{V}(\bar{X}_\perp(s,\omega)) + (1/2)\bar{P}_1^2(s,\omega)]\}^{1/2}\,\mathrm{d}s, \tag{3.2}$$

where we have used (2.3), (2.16a), (2.16b), and (3.1); assumed that $\bar{P}_2(s,\omega)$ does not change sign for $s\in[0,t]$; and defined $\bar{X}_\perp(t,\omega)=(\bar{X}_1(t,\omega),\bar{X}_2(t,\omega))$. No confusion would arise from the different meanings of v in (3.2) and (1.1b).

Define

$$z_1(v,\varepsilon_\perp) = \bar{X}_1(t,\omega), \quad z_2(v,\varepsilon_\perp) = \bar{P}_1(t,\omega). \tag{3.3}$$

By (3.2) and (3.3), at least formally, the fourth-order system (2.16a) for $i=1,2$ and the corresponding initial conditions (2.16b) can be expressed as

$$\frac{\mathrm{d}z}{\mathrm{d}v} = \varepsilon_\perp g(z,v) + \varepsilon_\perp^2\rho(z,v,\varepsilon_\perp), \tag{3.4a}$$

$$z(0,\varepsilon_\perp) = \bar{\zeta}. \tag{3.4b}$$

Here $z=(z_1,z_2)\in(\mathbf{R}\setminus\mathbf{Z})\times\mathbf{R}$, $\bar{\zeta}=(\xi_1,\eta_1)$, and

$$g(z,v) = (z_2, -D_1\bar{V}(z_1,v)), \tag{3.5a}$$

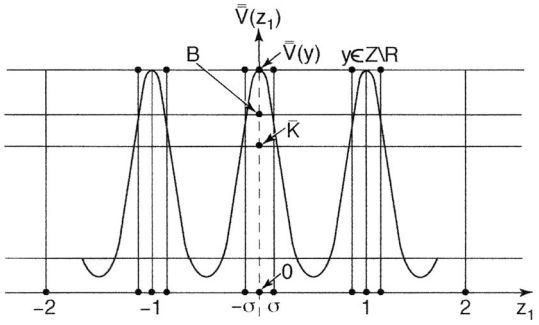

FIG. 1. Example of a function $\bar{\bar{V}}$ having the properties (1) and (2) stated in the paragraph containing (3.7).

$$\rho(z,v,\varepsilon_\perp)=\varepsilon_\perp^{-1}\{[\ell(z,v,\varepsilon_\perp)]^{-1}-1\}g(z,v), \tag{3.5b}$$

$$\ell(z,v,\varepsilon_\perp)=\{1-2\varepsilon_\perp^2[\bar{V}(z_1,v)+(1/2)z_2^2]\}^{1/2}. \tag{3.5c}$$

For the potential V defined in Sec. I, (3.5a) defines $g(.,.)$ as a C^1 mapping from $\bar{U}(\bar{K})\times\mathbf{R}$ into $\mathbf{R}^2$ which is 1-periodic in the second entry. Here $\bar{U}(\bar{K})$ is defined as the nonempty, multiply connected open set

$$\bar{U}(\bar{K})=\left\{(z_1,z_2)\in(\mathbf{R}\setminus\mathbf{Z})\times\mathbf{R}:\tfrac{1}{2}z_2^2+\bar{\bar{V}}(z_1)<\bar{K}\right\}, \tag{3.6}$$

where $\bar{K}$ is a positive constant such that $0<\inf_{y\in\mathbf{R}\backslash\mathbf{Z}}\bar{\bar{V}}(y)<\bar{K}<\sup_{y\in\mathbf{R}\backslash\mathbf{Z}}\bar{\bar{V}}(y)<\infty$. Moreover, if certain additional, physically reasonable conditions on $\bar{\bar{V}}$ and $\bar{K}$ stated below are satisfied, then Proposition A.2 in Appendix A guarantees that $\rho(.,.,\varepsilon_\perp)$, as defined by (3.5a), (3.5b), and (3.5c), is a bounded C^1 mapping from $\bar{U}(\bar{K})\times\mathbf{R}$ into $\mathbf{R}^2$ at each $\varepsilon_\perp\in(0,\varepsilon_\perp^{(0)})$. Here $\varepsilon_\perp^{(0)}=\varepsilon_\perp^{(0)}(\bar{K})$ is a positive constant defined by (A8), which is such that

$$\sup_{(z,v,\varepsilon_\perp)\in\bar{U}(\bar{K})\times\mathbf{R}\times(0,\varepsilon_\perp^{(0)})}\|\rho(z,v,\varepsilon_\perp)\|<\infty, \tag{3.7}$$

by virtue of that proposition. The latter holds if $\bar{\bar{V}}$ and $\bar{K}$ satisfy the following conditions: (1) there exist positive constants $\sigma<1/2$ and $B<\sup_{y\in\mathbf{R}\backslash\mathbf{Z}}\bar{\bar{V}}(y)$ such that $\bar{\bar{V}}(z_1)\geq B$ iff $z_1\in[n-\sigma,n+\sigma]$ $\forall n\in\mathbf{Z}$; and (2) $\bar{K}<B$ (see Fig. 1). To simplify the notation, we fix σ and B henceforth, which allows us to omit stating the dependence of the relevant quantities on them without fear of confusion. Defining $\bar{U}_p(\bar{K})=\{z_1\in\mathbf{R}\backslash\mathbf{Z}:(z_1,z_2)\in\bar{U}(\bar{K})\}$, it follows that $\operatorname{dist}\{\bar{U}_p(\bar{K}),\mathbf{Z}\}>0$ under the conditions stated in the penultimate sentence. The definition of the key constant $\varepsilon_\perp^{(0)}$ in (A8) makes sense because of the latter inequality. The boundedness of the mapping $\rho(.,.,\varepsilon_\perp)$ at each $\varepsilon_\perp\in(0,\varepsilon_\perp^{(0)})$ follows immediately from (3.7), and its asserted C^1 property is easily proved.

We now determine a set of v,t values for which (3.3) holds by arguments analogous to those adduced in the case of (2.7). Supposing that $0<\varepsilon_\perp<\varepsilon_\perp^{(1)}<\varepsilon_\perp^{(0)}$ and $T\in(0,\infty)$, we first define the mapping $v\mapsto t$ by

$$t=\varepsilon_\perp\int_0^v\{1-\varepsilon_\perp^2[\bar{V}(z_1(r,\varepsilon_\perp),r)+(1/2)z_2^2(r,\varepsilon_\perp)]\}^{-1/2}\,\mathrm{d}r \tag{3.2$'$}$$

for $v\in L(\varepsilon_\perp,T)$, a bounded open interval of the form $(-\beta(\varepsilon_\perp,T),T/\varepsilon_\perp+\beta(\varepsilon_\perp,T))$, where $\beta(\varepsilon_\perp,T)$ is a sufficiently small positive constant. Theorem 3.1, together with (A10), the openness of $\bar{U}(\bar{K})$, and elementary existence-uniqueness theorems of ODEs show that the quantity inside the curly brackets in (3.2$'$) exists and is positive for $0\leq r\leq v\in L(\varepsilon_\perp,T)$. It follows that for each $\varepsilon_\perp\in(0,\varepsilon_\perp^{(1)})$, $T\in(0,\infty)$ (3.2$'$) defines a C^1 diffeomorphism $v\mapsto t$ from $L(\varepsilon_\perp,T)$ onto a bounded

open interval $L'(\varepsilon_\perp,T)$ containing $t=0$, whose inverse $t\mapsto v$ is given by (3.2). In the second place, for $t\in L'(\varepsilon_\perp,T)$, $\varepsilon_\perp\in(0,\varepsilon_\perp^{(1)})$ we define $\bar{X}_1(t,\omega)$, $\bar{P}_1(t,\omega)$ by (3.7) and set $\bar{X}_2(t,\omega)=v$, $\bar{P}_2(t,\omega)=\mathrm{d}v/\mathrm{d}t$. Hence $\bar{X}_i(t,\omega)$, $\bar{P}_i(t,\omega)(i=1,2)$ satisfies the IVP (2.16) for $i=1,2$ if $t\in L'(\varepsilon_\perp,T)$, thus coinciding locally with the global solution with the same name defined earlier. This entails that (3.3) holds if $v\in L(\varepsilon_\perp,T)$, $\varepsilon_\perp\in(0,\varepsilon_\perp^{(1)})$, and hence if $t\in[0,T],\varepsilon_\perp\in(0,\varepsilon_\perp^{(1)})$.

The averaged IVP corresponding to (3.4) has the form

$$\frac{\mathrm{d}\bar{z}}{\mathrm{d}v}=\varepsilon_\perp\bar{g}(\bar{z})=\varepsilon_\perp(\bar{z}_2,-D_1\bar{\bar{V}}(\bar{z}_1)),\tag{3.8a}$$

$$\bar{z}(0,\varepsilon_\perp)=\bar{\zeta},\tag{3.8b}$$

where $\bar{z}=(\bar{z}_1,\bar{z}_2)\in(\mathbf{R}\backslash\mathbf{Z})\times\mathbf{R}$. In analogy with (2.14), we express the solution of the VIP (3.8) as

$$\bar{z}(v,\varepsilon_\perp)=w(\tau_\perp)=(w_1(\tau_\perp),w_2(\tau_\perp))\tag{3.9}$$

for $\varepsilon_\perp>0$. Here $\tau_\perp=\varepsilon_\perp v$, and $w(\tau_\perp)$, whose dependence and that of its components on $\bar{\zeta}$ has been omitted, is the unique solution of the IVP

$$\frac{\mathrm{d}w}{\mathrm{d}\tau_\perp}=\bar{g}(w),\tag{3.10a}$$

$$w(0)=\bar{\zeta},\tag{3.10b}$$

existing for all $\tau_\perp\in\mathbf{R}$.[7]

Analogously to the fact that (2.13a) are the EOM of the Hamiltonian $H_\perp(y_1,y_2,y_3,y_4)$ in terms of the time τ, (3.10a) are those of the Hamiltonian $h(w_1,w_2)=w_2^2/2+\bar{\bar{V}}(w_1)$ in terms of the time $\tau_\perp$, w_2 being the momentum canonically conjugate to the coordinate w_1. Note that $w(\tau_\perp)$ describes a particle bouncing periodically within the interval $(0,1)$ in the projection $\bar{U}_p(\bar{K})$ of $\bar{U}(\bar{K})$ into the X_1 axis. This follows from $0<\xi_1<1,\bar{\zeta}=(\xi_1,\eta_1)\in\bar{U}(\bar{K})$. Indeed, the last relation and our assumptions on $\bar{\bar{V}}$ and $\bar{K}$ entail that $(1/2)\eta_1^2+\bar{\bar{V}}(\xi_1)<\bar{K}<B<\sup_{y\in(0,1)}\bar{\bar{V}}(y)$. Hence the energy of the particle is too small for it to escape from the relevant potential well, and consequently it oscillates in (0,1) for all $\tau_\perp\in[0,\infty)$. In the next two theorems, T denotes a positive number less than $T_1(\bar{\zeta})$, where $[0,T_1(\bar{\zeta}))$ is the maximum forward interval of the solution of the IVP (3.10). Since $T_1(\bar{\zeta})=\infty$, T can be freely chosen in $(0,\infty)$.

Theorem 3.1: Let $T\in(0,\infty)$ be given. Then there exist positive constants $c_\perp=c_\perp(\bar{K},\bar{\zeta},T),\varepsilon_\perp^{(1)}=\varepsilon_\perp^{(1)}(\bar{K},\bar{\zeta},T)$, independent of η_2,η_3, with $\varepsilon_\perp^{(1)}<\varepsilon_\perp^{(0)}=\varepsilon_\perp^{(0)}(\bar{K})$, and such that the solution $\bar{z}(v,\varepsilon_\perp)$ remains in $\bar{U}(\bar{K})$ and uniformly approximates $z(v,\varepsilon_\perp)$ therein according to

$$\|z(v,\varepsilon_\perp)-\bar{z}(v,\varepsilon_\perp)\|<c_\perp\varepsilon_\perp\tag{3.11}$$

for $0\le v\le T/\varepsilon_\perp,0<\varepsilon_\perp<\varepsilon_\perp^{(1)}$.

Proof: By (3.4), (3.8), and the properties of $g(z,v),\rho(z,v,\varepsilon_\perp)$ in the paragraph containing (3.6), the theorem is directly implied by Theorem B.1, except for the assertion that $c_\perp,\varepsilon_\perp^{(1)}$ are independent of η_3. With this exception, the present theorem follows by reasoning analogous to that used to prove Theorem 2.1. The η_3-independence property is a trivial consequence of the fact that $\varepsilon_\perp$ does not depend on η_3. □

Let

$$(\bar{\bar{X}}_1(t,\omega),\bar{\bar{P}}_1(t,\omega))=(w_1(t),w_2(t)),\tag{3.12a}$$

$$\bar{\bar{X}}_i(t,\omega) = \eta_i t + \xi_i, \quad \bar{\bar{P}}_i(t,\omega) = \eta_i \quad (i=2,3), \tag{3.12b}$$

and define $\bar{\bar{X}}(t,\omega), \bar{\bar{P}}(t,\omega)$ analogously to the corresponding unbarred quantities. Arguments of the same type as those advanced above in a similar connection show that $\bar{\bar{Z}}(t,\omega)=(\bar{\bar{X}}(t,\omega), \bar{\bar{P}}(t,\omega)) \in \mathbf{R}^6$ is the solution of the EOM corresponding to the Hamiltonian $\bar{\bar{H}}$. By (3.12) and a previous remark, this solution describes a planarly channeled particle bouncing periodically in the X_1 direction between two adjacent atomic planes parallel to the X_2, X_3 plane which intersect the X_1 axis at $X_1=0,1$, and travelling at constant speed in the X_2 and X_3 directions.

The next theorem is analogous to Theorem 3.1 in terms of t.

Theorem 3.2: Let $T \in (0,\infty)$ be given. Then there exist positive constants $C_\perp = C_\perp(\bar{K},\bar{\zeta},T), \varepsilon_\perp^{(2)} = \varepsilon_\perp^{(2)}(\bar{K},\bar{\zeta},T)$, independent of η_2, η_3, with $\varepsilon_\perp^{(2)} < \varepsilon_\perp^{(1)}$, and such that $\bar{Z}(t,\omega)$ is uniformly approximated by $\bar{\bar{Z}}(t,\omega)$ according to

$$\|\bar{Z}(t,\omega) - \bar{\bar{Z}}(t,\omega)\| < C_\perp \varepsilon_\perp \tag{3.13}$$

for $0 \le t \le T, 0 < \varepsilon_\perp < \varepsilon_\perp^{(2)}$.

Proof: Follows by Theorem 3.1 and arguments similar to those invoked to prove Theorem 2.2. □

We will consider a single fixed $T \in (0,\infty)$ henceforth in this section. This is convenient in formulating the key estimate used to establish the existence of a transition from axial to planar channeling as well as for other purposes. This estimate, immediately implied by (2.20) and (3.13), is given by

$$\|Z(t,\omega) - \bar{\bar{Z}}(t,\omega)\| < C(K,\zeta)\varepsilon + C_\perp(\bar{K},\bar{\zeta})\varepsilon_\perp, \tag{3.14}$$

where $0 \le t \le T$, and where we have dropped the T symbols in the pertinent constants, as we will do from now on without fear of confusion. Intuitively, in order for the transition to occur, the rhs of (3.14) must be small, which entails that η_2, η_3 must be large.

Remark on nomenclature: Henceforth K, ω and its components, and ε will be modified by the addition of a superscript zero, e.g., $K^0, \omega^0 = (\xi_1^0, \xi_2^0, \xi_3^0, \eta_1^0, \eta_2^0, \eta_3^0)$ [with ξ_j^0, η_k^0 obeying (2.5) for $j,k=1,2,3$] when they refer to axial channeling, and $\varepsilon^{(2)}$ will be written as $\varepsilon^{(2)}(K^0,\zeta^0)$ when referring to this case. In the absence of such a superscript, the parameters mentioned below correspond to planar channeling. The words "particle P" will designate a particle where motion is "governed" by the Hamiltonian H in (1.1a).

Definition 3.1: For any $\delta > 0$, we say that particle P is δ-planarly channeled for given parameters $K, \bar{K}, \omega$ if the inequality

$$\|Z(t,\omega) - \bar{\bar{Z}}(t,\omega)\| < \delta \tag{3.15}$$

holds for all $t \in [0,T]$ for some $\varepsilon \in (0, \varepsilon^{(2)}(K,\zeta)), \varepsilon_\perp \in (0, \varepsilon_\perp^{(2)}(\bar{K},\bar{\zeta}))$.

Definition 3.2: For any $\delta^0, \delta > 0$, we say that particle P has made a (δ^0,δ) axial-to-planar transition [or simply a (δ^0,δ) transition] with initial parameters K^0, ω^0 and final parameters K, $\bar{K}, \omega$ if for all $t \in [0,T]$ the inequality

$$\|Z(t,\omega^0) - \bar{Z}(t,\omega^0)\| < \delta^0 \tag{3.16}$$

holds for some $\varepsilon^0 \in (0, \varepsilon^{(2)}(K^0,\zeta^0))$ and (3.15) holds for some $\varepsilon \in (0, \varepsilon^{(2)}(K,\zeta)), \varepsilon_\perp \in (0, \varepsilon_\perp^{(2)}(\bar{K},\bar{\zeta}))$.

Remarks: By Theorem 2.2, particle P is δ^0-axially channeled for fixed $\delta^0 > 0$, $\xi_j^0 (j=1,2,3), \eta_k^0 (k=1,2)$ at all $t \in [0,T]$ if η_3^0 is sufficiently large. Therefore, to prove that a (δ^0,δ) transition has occurred, it suffices to show that (3.15) holds at the stated $t, \varepsilon, \varepsilon_\perp$.This simple fact will be used in the proof of the next theorem.

Theorem 3.3 (Existence of the axial-to-planar transition): For arbitrary $\delta^0, \delta > 0$, particle P makes a (δ^0, δ) transition with initial parameters K^0, ω^0 and final parameters $K, \bar{K}, \omega$ as defined in the proof below.

Proof: It is important to keep in mind that $\varepsilon_\perp^{(2)}(\bar{K}, \bar{\zeta}), C_\perp(\bar{K}, \bar{\zeta})$ are independent of η_2, η_3, and that $\varepsilon^{(2)}(K, \zeta), C(K, \zeta)$ are independent of η_3. We remind the reader that $\bar{\zeta} = (\xi_1, \eta_1)$ is fixed, and we also fix $\delta > 0$. By the inequality $(1/2)(\eta_1^2 + \eta_2^2) + \bar{V}(\xi_1, \xi_2) < K$ and definition (3.1b), we may (and will) choose K and $\eta_2 > \eta_1 > 0$ so large that $K/2 < (1/2)(\eta_1^2 + \eta_2^2) + \bar{V}(\xi_1, \xi_2)$ and $1/\sqrt{K} < \varepsilon_\perp^{(2)}(\bar{K}, \bar{\zeta}, \xi_2)$, and hence so large that $\varepsilon_\perp$ satisfies

$$1/\sqrt{2K} < \varepsilon_\perp < 1/\sqrt{K} < \varepsilon_\perp^{(2)}(\bar{K}, \bar{\zeta}). \tag{3.17}$$

In addition, we may (and will) assume that K is so large that, because of the second inequality (3.17),

$$C_\perp(\bar{K}, \bar{\zeta})\varepsilon_\perp < \delta/2. \tag{3.18}$$

Recalling (2.4b), we next choose $\eta_3 > \eta_2$ so large that ε satisfies the inequalities

$$\varepsilon < \varepsilon^{(2)}(K, \zeta), \tag{3.19}$$

$$C(K, \zeta)\varepsilon < \delta/2. \tag{3.20}$$

By (3.17)–(3.20) and Theorems 2.2 and 3.2 it follows that (2.10) and (3.14) hold for all $t \in [0, T]$. Moreover, by (2.20), (3.14), (3.18), and (3.20) it follows that, for the chosen parameters, (3.15) holds at all such t, and we are done. □

The version of Theorem 3.3 stated next is important physically, and follows by arguments similar to those used to prove that theorem. Its importance stems from its assertion that if the total particle energy is large enough, then one can induce a transition from axial to planar channeling by appropriately rotating the crystal while keeping this energy fixed.

Theorem 3.4: For arbitrary $\delta_0 > 0$, let particle P be δ_0-axially channeled, with parameters K^0, ω^0, where η_3^0 is sufficiently large. Then for arbitrary $\delta > 0$ it makes a (δ_0, δ) transition from the initial parameters K^0, ω^0 to the final parameters $K, \bar{K}, \omega$ chosen as explained in the proof of Theorem 3.3, with $\xi_j = \xi_j^0 (j = 1, 2, 3)$ and $\eta = \mathbf{R}\eta^0$, where $\mathbf{R}$ denotes a (proper) rotation operator in $\mathbf{R}^3$. That is, $\|\eta\| = \|\eta^0\|$, and thus $\varepsilon = \varepsilon^0$.

ACKNOWLEDGMENT

The author thanks H.S. Dumas for useful comments.

APPENDIX A: AUXILIARY PROPOSITIONS

In this appendix we state Propositions A.1 and A.2, which play important roles in Secs. II and III. The notation used in this appendix is in accord with that in those two sections.

Recall that K is a positive constant such that $K > \inf_{y \in \mathbf{R}^2 \setminus \mathbf{Z}^2} \bar{V}(y)$. We fix the value of K in this appendix and set

$$V_1(K) = \sup_{((x_1, x_2), u) \in U_p(K) \times \mathbf{R}} V(x_1, x_2, u),$$

$$V_2 = \inf_{(x_1, x_2) \in \mathbf{R}^2 \setminus \mathbf{Z}^2} \bar{V}(x_1, x_2), \tag{A1}$$

where $U_p(K) \subset \mathbf{R}^2$ is defined in the paragraph containing (2.3).

Proposition A.1: Let $\varepsilon^{(0)} = \varepsilon^{(0)}(K)$ be a positive constant given by

$$\varepsilon^{(0)} = \kappa/\sqrt{2[K + V_1(K) - V_2]}, \tag{A2}$$

where $\kappa \in (0,1)$ is a fixed numerical constant as close to unity as desired. Then

$$\sup_{(x,u,\varepsilon) \in U(K)\times\mathbf{R}\times(0,\varepsilon^{(0)})} \|r(x,u,\varepsilon)\| < \infty, \tag{A3}$$

where $U(K)$ and $r(x,u,\varepsilon)$ are given by (2.2) and (2.9b), respectively.

Remarks: Before proving this proposition, we make the following remarks to show that it makes sense. As to (A2), note that under the assumptions on V in Sec. I it follows that $0 < V_1(K) < \infty$, $V_2 > 0$, $K + V_1(K) - V_2 > 0$. Indeed, if $V_1(K) = \infty$, there would exist a sequence in $U_p(K)$ tending to some point in $\mathbf{Z}^2$, along which $\bar{V}(x_1,x_2) < \infty$, since $\bar{V}(x_1,x_2) < \infty$ on $(\mathbf{R}\backslash\mathbf{Z})^2$ and $\bar{V}(x_1,x_2) \to \infty$ along such a sequence. But this is impossible, since $\bar{V}(x_1,x_2) < K$ on $U_p(K)$. So (A2) is well defined. As to (A3), recall that $\varepsilon \in (0, 1/\sqrt{2V_0}]$, where V_0 is defined in the paragraph containing (2.4b). By this and the easily proved fact that $\varepsilon^{(0)} \in (0, 1/\sqrt{2V_0}]$, (A3) makes sense.

Proof of Proposition A.1: By (A1), (A2), and (2.2),

$$1 - 2\varepsilon^2\{(1/2)(x_3^2 + x_4^2) + V(x_1,x_2,u)\} > 1 - 2\varepsilon^2[K + V_1(K) - V_2] = 1 - \kappa^2 > 0 \tag{A4}$$

for $(x,u,\varepsilon) \in U(K)\times\mathbf{R}\times(0,\varepsilon^{(0)})$. Hence,

$$\inf_{(x,u,\varepsilon) \in U(K)\times\mathbf{R}\times(0,\varepsilon^{(0)})} k(x,u,\varepsilon) > 0 \tag{A5}$$

by (A4) and (2.9c).

We claim that

$$[1 - k(x,u,\varepsilon)]/\varepsilon = \mathrm{O}(\varepsilon) \tag{A6}$$

for $\varepsilon \downarrow 0$, uniformly with respect to (x,u) in $U(K)\times\mathbf{R}$. The boundedness property (A3) follows directly from (2.9b), the property of $f(.,.)$ in the paragraph containing (2.10), (A5), and the fact that (A6) holds in this uniform sense. This fact is an easy consequence of (2.9c), (A4), and elementary arguments. □

Henceforth in this appendix we assume that $B, \bar{K}$ are positive constants such that $\bar{K} < B < \sup_{y\in\mathbf{R}} \bar{\bar{V}}(y) < \infty$ and that the properties (1) and (2) stated in the fifth sentence of the paragraph containing (3.6) hold (see Fig. 1). Define

$$\bar{V}_1(\bar{K}) = \sup_{(x_1,u)\in\bar{U}_p(\bar{K})\times\mathbf{R}} \bar{V}(x_1,u),$$

$$\bar{V}_2 = \inf_{x_1\in\mathbf{R}\backslash\mathbf{Z}} \bar{\bar{V}}(x_1), \tag{A7}$$

where $\bar{U}_p(\bar{K})$ is defined in the last mentioned paragraph.

Proposition A.2: Let $\varepsilon_\perp^{(0)} = \varepsilon_\perp^{(0)}(\bar{K})$ be a positive constant given by

$$\varepsilon_\perp^{(0)} = \kappa/\sqrt{2[\bar{K} + \bar{V}_1(\bar{K}) - \bar{V}_2]}. \tag{A8}$$

Then,

$$\sup_{(z,v,\varepsilon_\perp)\in\bar{U}(\bar{K})\times\mathbf{R}\times(0,\varepsilon_\perp^{(0)})} \|\rho(z,v,\varepsilon_\perp)\| < \infty, \tag{A9}$$

where $\rho(z,v,\varepsilon_\perp)$ is defined by (3.5b).

Remarks: Their purpose is to show that Proposition A.2 makes sense under the hypotheses on $\bar{V}, \bar{\bar{V}}, \bar{K}$ in Secs. I and III. As to (A8), note that under these hypotheses $0 < \bar{V}_1(\bar{K}) < \infty$, $\bar{V}_2(\bar{K}) > 0$,

$\bar{K}+\bar{V}_1(\bar{K})-\bar{V}_2>0$. Only the finitess of $\bar{V}_1(\bar{K})$ merits comment. Suppose that $\bar{V}_1(\bar{K})=\infty$. Then, since $\bar{V}(x_1,u)<\infty\ \forall\,(x_1,u)\in(\mathbf{R}\backslash\mathbf{Z})\times\mathbf{R}$ and $\bar{V}(x_1,u)$ is unbounded from above in a neighborhood of each point of $\mathbf{Z}$ at every such u, there exists a sequence in $\bar{U}_p(\bar{K})$ converging to a point in $\mathbf{Z}$. This contradicts the inequality dist $\{\bar{U}_p(\bar{K}),\mathbf{Z}\}>0$ proved in the paragraph containing (3.7). As to (A9), recall that $\varepsilon_\perp\in(0,1/\sqrt{2\bar{V}_0}]$, where $\bar{V}_0$ is defined in the paragraph containing (3.1b). By this and the readily proved fact that $\varepsilon_\perp^{(0)}\in(0,1/\sqrt{2\bar{V}_0}]$, (A9) makes sense.

Proof of Proposition A.2: By (A7), (A8), and (3.7), we have

$$1-2\varepsilon_\perp^2\{(1/2)z_2^2+\bar{V}(z_1,v)\}>1-2\varepsilon_\perp^2[\bar{K}+\bar{V}_1(\bar{K})-\bar{V}_2]>1-\kappa^2>0 \tag{A10}$$

for $(z,v,\varepsilon_\perp)\in\bar{U}(\bar{K})\times\mathbf{R}\times(0,\varepsilon_\perp^{(0)})$. Hence

$$\inf_{(z,v,\varepsilon_\perp)\in\bar{U}(\bar{K})\times\mathbf{R}\times(0,\varepsilon_\perp^{(0)})}\ell\,(z,v,\varepsilon_\perp)>0, \tag{A11}$$

where $\ell(z,v,\varepsilon_\perp)$ is given by (3.5c).

One arrives at (A9) by using (A11) and arguments analogous to those adduced to establish (A3) in the proof of Lemma A.1. □

APPENDIX B: FIRST-ORDER AVERAGING THEOREM FOR A CLASS OF PERIODIC SYSTEMS

The main purpose of this appendix is to state and prove Theorem B.1, which underpins our results in Secs. II and III in an essential way. This theorem is a version of a very general existence, uniqueness, and approximation theorem in Ref. 4.

Consider the IVP

$$\frac{\mathrm{d}x}{\mathrm{d}u}=\varepsilon f(x,u)+\varepsilon^2 r(x,u,\varepsilon), \tag{B1a}$$

$$x(0,\varepsilon)=\alpha\in U. \tag{B1b}$$

Here $x\in\mathbf{R}^n(n\geq 1)$, $U\subset\mathbf{R}^n$ is a connected open set, $u\in\mathbf{R}$, and $\varepsilon\in(0,\infty)$. The functions f,r are assumed to have the following properties:

$$f(.,.)\in C^1(U\times\mathbf{R})\quad\text{and}\quad f(x,u)=f(x,u+1)\ \text{for}\ x\in U,\quad u\in\mathbf{R}; \tag{B2a}$$

$$r(.,.,\varepsilon)\in C^1(U\times\mathbf{R})\ \text{for}\ \varepsilon\in(0,\varepsilon_0), \tag{B2b}$$

where $\varepsilon_0=\varepsilon_0(U)$ is a positive constant such that

$$\sup_{(x,u,\varepsilon)\in U\times\mathbf{R}\times(0,\varepsilon_0)}\|r(x,u,\varepsilon)\|<\infty. \tag{B2c}$$

Under these hypotheses, one can approximate the solution of the IVP (B1) over a u interval of length of order $1/\varepsilon$ for sufficiently small $\varepsilon>0$ by the solution $y(u,\varepsilon)$ of the "averaged" VIP

$$\frac{\mathrm{d}y}{\mathrm{d}u}=\varepsilon\bar{f}(y), \tag{B3a}$$

$$y(0,\varepsilon)=\alpha\in U, \tag{B3b}$$

as stated precisely by Theorem B.1 below. Here $\bar{f}:U\to\mathbf{R}^n$ is defined by

$$\bar{f}(y) = \int_0^1 f(y,s)\mathrm{d}s. \tag{B4}$$

Via $\tau=\varepsilon u$, the IVP (B3) is equivalent to the IVP,

$$\frac{\mathrm{d}y_0}{\mathrm{d}\tau} = \bar{f}(y_0), \tag{B5a}$$

$$y_0(0) = \alpha \tag{B5b}$$

for $\varepsilon>0$,where $y(u,\varepsilon)=y_0(\tau)$.

By (B2a)–(B2c) and standard existence and uniqueness theorems, there exists a maximal forward interval $0\le\tau<T_1=T_1(\alpha)$ in which the IVP (B5) has a unique solution $y_0(\tau)$, where T_1 may be a finite positive real or $+\infty$. Let T be a positive constant *less* than T_1. Then the VIP (B3) has a unique solution $y(u,\varepsilon)=y_0(\varepsilon u)$ in U for $0\le u\le T/\varepsilon$ at each $\varepsilon>0$, which lies in the compact orbit $S\subset U$ "swept out" by $y_0(\tau)$ in the interval $0\le\tau\le T$. Hence S is at a *positive* distance from the boundary of U. Let $d>0$ be *less* than this distance.

Theorem B.1: Let the functions f,r in the IVP (B1) have the properties (B2a)–(B2c), and let such a constant T be given. Then there exist positive, ε-independent constants $\varepsilon_1=\varepsilon_1(U,\alpha,T)$, $C_1=C_1(U,\alpha,T)$, with $\varepsilon_1<\varepsilon_0=\varepsilon_0(U)$ and having the property that the IVP (B1) has a unique solution $x(u,\varepsilon)$ which remains in U and is uniformly approximated therein by the unique solution $y(u,\varepsilon)$ of the IVP (B3) in accordance with

$$\|x(u,\varepsilon) - y(u,\varepsilon)\| < C_1\varepsilon \tag{B6}$$

for $0\le u\le T/\varepsilon$, $0<\varepsilon<\varepsilon_1$.

Proof: By (B2a)–(B2c), the IVP (B1) has a unique solution $x(u,\varepsilon)$ in U on a maximal forward interval $[0,\beta(\varepsilon))$ for $0<\varepsilon<\varepsilon_0$. A key element of the present proof is to show that $[0,T/\varepsilon]\subset[0,\beta(\varepsilon))$ for small enough $\varepsilon>0$.

In integral form, the IVP (B1) and its averaged version (B3) become

$$x(u,\varepsilon) = \alpha + \varepsilon\int_0^u f(x(s,\varepsilon)\mathrm{d}s + \varepsilon^2\int_0^u r(x(s,\varepsilon),s,\varepsilon)\mathrm{d}s \tag{B7}$$

for $u\in[0,\beta(\varepsilon))$, $0<\varepsilon<\varepsilon_0$, and

$$y(u,\varepsilon) = \alpha + \varepsilon\int_0^u f(y(s,\varepsilon)\mathrm{d}s - \varepsilon\int_0^u \tilde{f}(y(s,\varepsilon),s)\mathrm{d}s \tag{B8}$$

for $u\in[0,T/\varepsilon]$, $\varepsilon>0$, where

$$\tilde{f}(y,u) = f(y,u) - \bar{f}(y). \tag{B9}$$

Subtracting (B8) from (B7), we obtain

$$\|x(u,\varepsilon) - y(u,\varepsilon)\| \le \varepsilon\int_0^u \|f(x(s,\varepsilon),\varepsilon) - f(y(s,\varepsilon),\varepsilon)\|\mathrm{d}s + \varepsilon\int_0^u \|\tilde{f}(y(s,\varepsilon),\varepsilon)\|\mathrm{d}s$$
$$+ \varepsilon^2\int_0^u \|r(x(s,\varepsilon),s,\varepsilon)\|\mathrm{d}s \tag{B10}$$

for $u\in[0,J(\beta(\varepsilon))$, $0<\varepsilon<\varepsilon_0$. Here $J(\beta(\varepsilon)) := [0,\beta(\varepsilon))\cap[0,T/\varepsilon]$.

We now estimate the three integrals on the rhs of (B10) at the latter values of u,ε. By our assumption that $f(.,.)\in C^1(U\times\mathbf{R})$, the following inequality holds for the first integral:

$$\int_0^u \|f(x(s,\varepsilon),\varepsilon) - f(y(s,\varepsilon),\varepsilon)\| \mathrm{d}s < L \int_0^u \|x(s,\varepsilon) - y(s,\varepsilon)\| \mathrm{d}s, \tag{B11a}$$

where L is an x-Lipschitz constant of $f(x,\varepsilon)$ in a compact $d/2$-neighborhood U_d of the orbit S in U, and hence depending solely on U_d. By Lemma 5 of Ref. 4, the second integral obeys the inequality[9]

$$\left\| \int_0^u \tilde{f}(y(s,\varepsilon),\varepsilon) \mathrm{d}s \right\| < \Gamma(\varepsilon t + 1), \tag{B11b}$$

where Γ is a constant which depends on α, U, but not T or ε. Finally, the third integral in (B10) satisfies the inequality

$$\int_0^u \|r(x(s,\varepsilon),\varepsilon)\| \mathrm{d}s \leq \Gamma_1 u, \tag{B11c}$$

where Γ_1 denotes the sup in (B2c).

By (B10) and (B11a)–(B11c), we immediately infer that

$$\|x(u,\varepsilon) - y(u,\varepsilon)\| < \varepsilon L \int_0^u \|x(s,\varepsilon) - y(s,\varepsilon)\| \mathrm{d}s + \Gamma\varepsilon(\varepsilon t + 1) + \Gamma_1 \varepsilon^2 u \tag{B12}$$

for $u \in [0, J(\beta(\varepsilon))$, $0 < \varepsilon < \varepsilon_0$. Using (B12) and Gronwall's inequality,[10] we find after a simple computation:

$$\|x(u,\varepsilon) - y(u,\varepsilon)\| < M\varepsilon(1 + \varepsilon u)\exp(L\varepsilon u) \tag{B13}$$

at the last mentioned u, ε values, where M is a constant depending on α, U, but not T or ε. Let $\varepsilon_1 < \varepsilon_0$ be a positive constant so small that $M\varepsilon_1(1+T)\exp(LT) < d/2$, and suppose that the inequality $\beta(\varepsilon) \leq T/\varepsilon$ holds at *some* positive $\varepsilon < \varepsilon_1$. Then the unique solution $x(u,\varepsilon)$ of the IVP (B1) corresponding to this ε and to the values of α, T under consideration keeps away from the boundary of U for $u \in [0, \beta(\varepsilon))$, thus contradicting maximality. Therefore, $\beta(\varepsilon) > T/\varepsilon$ at *all* positive $\varepsilon < \varepsilon_1$. It follows that (B6) holds in terms of the ε-independent constants ε_1 and $C_1 = M(1 + T)\exp(LT)$ at the values of u, ε stated in the theorem. □

(Received 4 October 2005; accepted 1 May 2006; published online 15 June 2006)

We consider thermodynamic systems with finitely many degrees of freedom and subject to an external control action. We derive some basic results on the dependence of the relative entropy production rate on the controlling force. Applications to macromolecular cooling and to controlling the convergence to equilibrium rate are sketched. Analogous results are derived for closed and open n-level quantum systems. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2207716]

I. INTRODUCTION

Advances in nanotechnology permit nowadays to implement feedback control actions on nanodevices. For instance, in surface topography, the deflection of a cantilever is captured by a photodetector that records the angle of reflection from a laser beam focused on the mirrored surface on the back side of the cantilever. Position feedback control is used to maintain the probe at a constant force or distance from the object surface. Position can also be differentiated, allowing us to apply a velocity-dependent external force. A velocity-dependent feedback control (VFC) has been recently implemented to reduce thermal noise of a cantilever in atomic force microscopy (AFM)[23] and in dynamic force microscopy.[41] A contribution to a rigorous thermodynamical foundation of macromolecules under VFC operating in nonequilibrium steady state is provided in Ref. 18. The entropy production rate there is decomposed into a *positive entropy production rate* (PEPR) and an *entropy pumping rate* (EPuR). The latter indicates how much entropy is pumped out or into the macromolecule by the control force. It may render the overall entropy production negative. This is at the basis of a macromolecular cooling mechanism.[4,23,41]

In this paper, we study entropy production in the presence of an external force in a more general situation. Our approach is new and complementary to Ref. 18 in that we study the free energy change rather than the total entropy change of the heat bath and of the Brownian particles as done in Ref. 18. As "distance" between two probability densities associated to the unperturbed and perturbed evolution we employ the information *relative entropy* (in the quantum case, the von Neumann relative entropy for density operators). We show that it is possible to derive some basic formulas on the entropy production rate that extend those of Ref. 18 whenever the evolution of the physical system is in some suitable sense *Markovian*. We study nonequilibrium thermodynamical systems with finitely many degrees of freedom. Corresponding results are also sketched for n-level closed and open quantum systems. The perturbation of the Hamiltonian is interpreted as a *control function* which is designed by the controller in order to obtain a desired behavior of the system (reduction of thermal noise, transfer to another state, etc.).

Among potential applications, we mention molecular kinetics,[8] macromolecular cooling,[4,18,23,41] and quantum computation.[31] As it is well known, relative entropy plays a central

[a)]Electronic mail: pavon@math.unipd.it
[b)]Electronic address: ticozzi@dei.unipd.it

role in many areas of modern science besides physics such as mathematical statistics, information theory, probability, signal processing and quantum information processing; see, e.g., Refs. 3, 5–7, 11–13, 19, 20, 34, 35, and 37 , and Ref. 43 and references therein. Some of these results have been announced without proofs in our conference papers.[32,33]

The paper is outlined as follows. In the next section, we consider finite-dimensional, nonequilibrium thermodynamical systems. In Sec. III, we derive a basic formula on relative entropy evolution for probability densities satisfying a continuity-type equation. This result is then applied in the following section to controlled thermodynamic systems. Section V is devoted to the study of von Neumann entropy production for closed and open finite-dimensional quantum systems. In the Appendix, we show that the basic result may also be extended to *non-Markovian* finite-energy diffusions.

II. THERMODYNAMIC SYSTEMS

Consider an open thermodynamic system whose macroscopic evolution is modeled by an n-dimensional Markov diffusion process $\{x(t); t_0 \leq t\}$. The components of x form a *complete set*, i.e., all other variables have a much shorter relaxation time.[14] Let $\bar{\rho}(x)$ be the Maxwell-Boltzmann probability density corresponding to thermodynamical equilibrium

$$\bar{\rho}(x) = Z^{-1} \exp\left[-\frac{H(x)}{kT} \right]. \tag{1}$$

Here H is the (continuously differentiable) Hamiltonian function, and the (forward) Ito differential of x is

$$dx(t) = \left[-\frac{1}{2kT} \Sigma \Sigma^T \nabla H(x(t)) + u(x(t),t) \right] dt + \Sigma dW, \tag{2}$$

where W is a standard n-dimensional Wiener process. The probability density ρ_t of $x(t)$ satisfies the *Fokker-Planck equation*

$$\frac{\partial \rho}{\partial t} + \nabla \cdot \left[\left(-\frac{1}{2kT} \Sigma \Sigma^T \nabla H + u \right) \rho \right] = \frac{1}{2} \sum_{i,j=1}^{n} (\Sigma \Sigma^T)_{ij} \frac{\partial^2 \rho}{\partial x_i \, \partial x_j}. \tag{3}$$

In the uncontrolled case $u=0$, under reasonable assumptions, see, e.g., Ref. 22, as $t \to \infty$, the density ρ_t of $x(t)$ tends to $\bar{\rho}$ in *relative entropy* and, consequently, in total variation.[21] For the ergodic properties of this class of diffusions, see, e.g., Ref. 40, Sec. 7.5.

Example II.1: In polymer dynamics,[9] the *macromolecule* is described by a Hamiltonian

$$H(x,y) = \tfrac{1}{2} \langle y, My \rangle + \varphi(x),$$

where M stands for the direct sum

$$M = M_1 \oplus \cdots \oplus M_N, \quad M_k = m_k I_3, \quad k = 1, \ldots, N.$$

Here x and y are $3N$-dimensional vectors, with x_i, y_i three-dimensional position and momentum of the ith hard building block of the macromolecule. Moreover, $\varphi(x)$ is the *internal potential* of macromolecule (in AFM experiment,[23] $\varphi(x) = Kx^2/2$, where K is the spring constant of the cantilever). Random collisions between solvent water molecules and building blocks of the macromolecule are modeled by the formal derivative of a Wiener process, namely *Gaussian white noise*. The six-dimensional stochastic process $(q_{i,x}, q_{i,y}, q_{i,z}, p_{i,x}, p_{i,y}, p_{i,z})$ associated with the ith block obeys the equation

$$dq_{i\alpha} = \partial_{p_{i\alpha}} H(q,p) dt, \tag{4}$$

$$dp_{i\alpha} = [-\partial_{q_{i\alpha}} H(q,p) + f_{i\alpha} + u_{i\alpha}(q,p)]dt + \Gamma_{i\alpha}^{j\beta} dW_{j\beta}(t), \tag{5}$$

where Einstein's convention has been used. Here f is a frictional force and u is a *position-velocity dependent control*. In the AFM experiment, $f=-\gamma V$, $u=-\alpha V$, $\gamma>0$, $\alpha>0$, with V a velocity. The control here acts *like* a frictional force on the macromolecule. Since the frictional coefficient has been increased, one can introduce an *effective* temperature T_{eff} which is lower than the thermostat temperature T. As is well known, different uncontrolled ($u=0$) versions of this model[16] play an important role also in other applications such as nonlinear circuits with noisy resistors.[42]

To simplify the writing, we shall assume henceforth that in (2) $\Sigma\Sigma^T=\sigma^2 I_n$. The results of this paper, however, extend in a straightforward way to the case where the diffusion matrix $\Sigma\Sigma^T$ is any symmetric, nonnegative definite [possibly singular as in (4) and (5)] matrix. Let us first recall a few basic concepts concerning the uncontrolled, nonequilibrium system (2). Let us introduce the *fluxes* $J(x,t)$ and *forces* $\Phi(x,t)$ by

$$J(x,t) = -\frac{1}{2}\sigma^2 \nabla \rho_t(x) - \frac{1}{2kT}\sigma^2 \nabla H(x)\rho_t(x),$$

$$\Phi(x,t) = -\nabla\mu(x,t),$$

where $\mu=H+kT\log\rho_t$ is the *electrochemical potential*. Notice the following:

(1) The Fokker-Plank equation (3) may be rewritten (see e.g., Ref. 14) as a continuity equation

$$\frac{\partial\rho}{\partial t} + \nabla\cdot J = 0. \tag{6}$$

(2) Both fluxes and forces are zero in equilibrium. Moreover,

$$J(x,t) = \frac{\sigma^2}{2kT}\Phi(x,t)\rho_t(x), \tag{7}$$

which plays the role of *constitutive relations*.

(3) For ρ and σ non-negative measurable functions on $\mathbb{R}^n$, we define the information *relative entropy* (*divergence, Kullback-Leibler distance*) by

$$\mathbb{D}(\rho\|\sigma) = \int_{\mathbb{R}^n} \log\frac{\rho}{\sigma}\rho\, dx.$$

As it is well known,[19] when ρ and σ are integrable functions with

$$\int_{\mathbb{R}^n}\rho(x)\,dx = \int_{\mathbb{R}^n}\sigma(x)\,dx,$$

we have $\mathbb{D}(\rho||\sigma)\geq 0$. Moreover, $\mathbb{D}(\rho||\sigma)=0$ if and only if $\rho=\sigma$. Define the *free energy* functional

$$F(\rho_t) = kT\int_{\mathbb{R}^n}\log\frac{\rho_t}{\bar\rho}\rho_t\,dx = kT\mathbb{D}(\rho_t||\bar\rho).$$

The free energy decay may now be expressed as[14]

$$\frac{d}{dt}F(\rho_t) = -\frac{\sigma^2 kT}{2}\int_{\mathbb{R}^n}\left|\nabla \log\frac{\rho_t}{\bar{\rho}}\right|^2 \rho_t\, dx = -\int J(x,t)\Phi(x,t)\, dx. \tag{8}$$

Suppose now that, like in the AFM experiment, the thermodynamic system is subject to a feedback control action so that the macroscopic evolution is given by (2) with $u \neq 0$. The density ρ_t^u of the solution x_t^u satisfies the controlled Fokker-Planck equation (3). We are interested in the evolution of $\mathbb{D}(\rho_t^u||\rho_t^0)$, where $\{\rho_t^0, t \geq t_0\}$ is an uncontrolled evolution ($u \equiv 0$). We first need a simple but useful result.

III. A RELATIVE ENTROPY PRODUCTION FORMULA

Consider two families of non-negative functions on $\mathbb{R}^n$: $\{\rho_t; t_0 \leq t \leq t_1\}$ and $\{\tilde{\rho}_t; t_0 \leq t \leq t_1\}$. We are interested in how the relative entropy $\mathbb{D}(\tilde{\rho}_t||\rho_t)$ evolves in time.

Assumptions A1: There exist measurable functions $f(x,t)$ and $\tilde{f}(x,t)$ such that $\{\rho_t; t_0 \leq t \leq t_1\}$ and $\{\tilde{\rho}_t; t_0 \leq t \leq t_1\}$ are everywhere positive C^1 solutions of

$$\frac{\partial \rho_t}{\partial t} + \nabla \cdot (f\rho_t) = 0, \tag{9}$$

$$\frac{\partial \tilde{\rho}_t}{\partial t} + \nabla \cdot (\tilde{f}\tilde{\rho}_t) = 0. \tag{10}$$

Assumption A2: For every $t \in [t_0, t_1]$

$$\lim_{|x|\to\infty} f(x,t)\tilde{\rho}_t(x) = 0,$$

$$\lim_{|x|\to\infty} \tilde{f}(x,t)\tilde{\rho}_t(x) = 0,$$

$$\lim_{|x|\to\infty} \tilde{f}(x,t)\tilde{\rho}_t(x) \log\frac{\tilde{\rho}_t}{\rho_t}(x) = 0.$$

Theorem III.1: *Suppose* $\mathbb{D}(\tilde{\rho}_t||\rho_t) < \infty, \forall t \geq 0$. *Assume moreover Assumptions A*1 *and A*2 *above. Then*

$$\frac{d}{dt}\mathbb{D}\left(\tilde{\rho}_t||\rho_t\right) = \int_{\mathbb{R}^n}\left[\nabla \log\frac{\tilde{\rho}_t}{\rho_t} \cdot (\tilde{f} - f)\right]\tilde{\rho}_t\, dx.$$

Proof:

$$\begin{aligned}
\frac{d}{dt}\mathbb{D}(\tilde{\rho}_t\|\rho_t) &= \int_{\mathbb{R}^n}\frac{d}{dt}[(\log\tilde{\rho}_t - \log\rho_t)\tilde{\rho}_t]\, dx = \int_{\mathbb{R}^n}\left\{\left[\frac{1}{\tilde{\rho}_t}\frac{\partial\tilde{\rho}_t}{\partial t} - \frac{1}{\rho_t}\frac{\partial\rho_t}{\partial t}\right]\tilde{\rho}_t + \log\frac{\tilde{\rho}_t}{\rho_t}\frac{\partial\tilde{\rho}_t}{\partial t}\right\} dx \\
&= \int_{\mathbb{R}^n}\left[-\nabla\cdot(\tilde{f}\tilde{\rho}_t) + \frac{\tilde{\rho}_t}{\rho_t}\nabla\cdot(f\rho_t) - \log\frac{\tilde{\rho}_t}{\rho_t}\nabla\cdot(\tilde{f}\tilde{\rho}_t)\right] dx \\
&= \int_{\mathbb{R}^n}\left[\nabla\log\frac{\tilde{\rho}_t}{\rho_t}\cdot\tilde{f}\tilde{\rho}_t - \nabla\frac{\tilde{\rho}_t}{\rho_t}\cdot f\frac{\rho_t}{\tilde{\rho}_t}\tilde{\rho}_t\right] dx \\
&= \int_{\mathbb{R}^n}\left[\nabla\log\frac{\tilde{\rho}_t}{\rho_t}\cdot(\tilde{f}-f)\right]\tilde{\rho}_t\, dx,
\end{aligned}$$

where we have used (9) and (10) and integration by parts (the boundary terms are zero because of

Assumption 2). □

For $\rho_t(x) \equiv 1$, we have that $-\mathbb{D}(\tilde{\rho}_t||\rho_t) = S(\tilde{\rho}_t)$ is the entropy. Taking $f(x,t) \equiv 0$, we see that the first condition in Assumption A2 is verified. Theorem III.1 then gives (exchanging ρ_t with $\tilde{\rho}_t$) the following:

Corollary III.2: Suppose $\{\rho_t; t_0 \leq t \leq t_1\}$ *is of class* C^1 *and*

$$\lim_{|x|\to\infty} v(x,t)\rho_t(x) = 0, \lim_{|x|\to\infty} v(x,t)\rho_t(x) \log \rho_t(x) = 0.$$

Suppose $S(\rho_t) < \infty$, $\forall\, t \in [t_0, t_1]$. *Then*

$$\frac{d}{dt} S(\rho_t) = -\int_{\mathbb{R}^n} [\nabla \log \rho_t \cdot f] \rho_t \, dx. \tag{11}$$

IV. ENTROPY PRODUCTION FOR CONTROLLED EVOLUTION

Consider now again the controlled thermodynamic system of Sec. II (2). Let ρ_t^u denote the density of the controlled process satisfying (3). We are interested in the evolution of $\mathbb{D}(\rho_t^u||\rho_t^0)$, where $\{\rho_t^0, t \geq t_0\}$ is an uncontrolled evolution ($u \equiv 0$). First of all, recall that the Fokker-Planck equations of the uncontrolled and controlled system may be written as continuity equations as in (6). Thus, we can apply Theorem III.1 with

$$f = -\frac{\sigma^2}{2kT} \nabla H(x) - \frac{\sigma^2}{2} \nabla \log \rho_t^0(x), \quad \tilde{f} = -\frac{\sigma^2}{2kT} \nabla H(x) + u(x,t) - \frac{\sigma^2}{2} \nabla \log \rho_t^u(x).$$

We get

$$\frac{d}{dt} \mathbb{D}\left(\rho_t^u||\rho_t^0\right) = \int_{\mathbb{R}^n} \left(\nabla \log \frac{\rho_t^u}{\rho_t^0} \cdot \left(u - \frac{\sigma^2}{2} \nabla \log \frac{\rho_t^u}{\rho_t^0} \right) \right) \rho_t^u \, dx. \tag{12}$$

Suppose now $\rho_t^0 \equiv \bar{\rho}$, where $\bar{\rho}$ is the Maxwell-Boltzmann distribution (1). We obtain the following:

*Theorem IV.1: Under assumptions A*1 *and A*2,

$$\frac{d}{dt} \mathbb{D}(\rho_t^u||\bar{\rho}) = -\frac{\sigma^2}{2} \int_{\mathbb{R}^n} \|\nabla \log \frac{\rho_t^u}{\bar{\rho}}\|^2 \rho_t^u \, dx + \int_{\mathbb{R}^n} \nabla \log \frac{\rho_t^u}{\bar{\rho}} \cdot u \rho_t^u \, dx. \tag{13}$$

Remark IV 2: Formula (13) generalizes the decomposition of the entropy production exhibited in Ref. 18 for the controlled Langevin equations. In Ref. 18, the total entropy change of the heat bath and of the Brownian macromolecules is studied. The entropy production rate (EPR) is decomposed into the sum of two terms. The first, named PEPR (*positive entropy production rate*), is an always positive term expressed as the product of the thermodynamic force and the corresponding flux as in (8). The second, named EPuR (*entropy pumping rate*), describes the amount of entropy pumped out of or into the macromolecule by the external agent. We recognize that (13) implies that $-(d/dt)\mathbb{D}(\rho_t^u||\bar{\rho})$ is also decomposed into an always positive term and into a term depending explicitly on the control function.

One can try to employ (13) to analyze macromolecular cooling.[4,18,23,41] Another direction of application is the following. Suppose we are interested in modifying the rate at which the solution ρ_t of (3) tends to the invariant density (1). Let

$$\alpha(t) > -\frac{\sigma^2}{2},$$

and consider in (2) the feedback control

$$u(x,t) = -\alpha(t)\,\nabla\,\log\frac{\rho_t^u}{\bar{\rho}}(x). \tag{14}$$

Then, ρ_t^u satisfies the Fokker-Planck equation

$$\frac{\partial\rho^u}{\partial t} - \nabla\cdot\left(\left(\frac{\sigma^2}{2}+\alpha(t)\right)\frac{1}{kT}\nabla H\rho^u\right) = \left(\frac{\sigma^2}{2}+\alpha(t)\right)\Delta\rho^u. \tag{15}$$

A few observations are now in order.

(1) Although the feedback control law is *nonlinear* in ρ_t^u, Eq. (15) is *linear*.
(2) The initial value problem for Eq. (15) is well posed since $\sigma^2/2+\alpha(t)>0$.
(3) Equation (15) still has as invariant density the Maxwell-Boltzmann distribution (1).
(4) It is conceivable to solve (15) off-line, and consequently compute the feedback law (14) beforehand.
(5) The flow of one-dimensional probability densities $\{\rho_t^u; t\geq 0\}$ of $x^u(t)$ satisfying (2) with the control given by (14) is the same as for the uncontrolled stochastic process ξ with differential

$$d\xi = -\left(\frac{\sigma^2}{2}+\alpha(t)\right)\frac{1}{kT}\nabla H(\xi)dt + \sqrt{\sigma^2+2\alpha(t)}dW, \tag{16}$$

provided $\xi(0)$ is distributed according to ρ_0^u.
(6) The friction and diffusion coefficients in (16), although time varying, still satisfy the Einstein fluctuation-dissipation relation (see, e.g., Ref. 28).

We now employ (13) to compute the relative entropy derivative. We get

$$\frac{d}{dt}\mathbb{D}(\rho_t^u\|\bar{\rho}) = -\left(\frac{\sigma^2}{2}+\alpha(t)\right)\int_{\mathbb{R}^n}|\nabla\log\frac{\rho_t^u}{\bar{\rho}}|^2\rho_t^u\,dx. \tag{17}$$

Hence, the controlled diffusion still tends to the Maxwell-Boltzmann distribution but at a different, "modulated" rate. In the linear Gauss-Markov case (i.e., when H is quadratic), the results assume a very concrete form. In particular, Eq. (15) may be replaced by a linear matricial equation (see Ref. 33 for details).

The results of this section may be readily extended to non-Markovian, finite-energy diffusions employing the Nelson-Föllmer kinematics[10,29] (see the Appendix). Notice that this family plays a central role in several branches of mathematical physics (see, e.g., Refs. 11 and 30). The results also extend without too much difficulty to a large class of diffusions with constant but singular diffusion coefficient such as in the case of the Orstein-Uhlenbeck model of physical Brownian motion[28] or, more generally, in the case of model (4) and (5). They may also be established for a large class of Markovian diffusion processes with local diffusion coefficient given the results in Refs. 15 and 25–28.

V. *n*-LEVEL QUANTUM SYSTEMS

It is apparent that Theorem III.1 can be applied to statistical mixtures in classical mechanics [Ref. 32, Sec. IV]. Indeed, Liouville's equation, expressing conservation of density in phase space, is just a continuity equation for the Hamiltonian evolution. One then gets the idea that it might be possible to establish a similar result in the quantum case, replacing the Liouville equation with the Landau-von Neumann equation for the density operator. First of all, we need to recall the basic formalism of statistical quantum mechanics.

A. Closed quantum systems

As in standard quantum mechanics,[36] to every physical system S is associated a complex Hilbert space $\mathcal{H}_S$. In the standard formulation, the state of the system is described by a unit vector $\psi \in \mathcal{H}_S$. For the sake of simplicity, here we will consider only finite-dimensional Hilbert spaces, but results hold in the general case.

We consider situations in which uncertainty on the system state affects our model. The quantum analog of a classical probability density is a density operator ρ in $\mathcal{H}_S$: A density operator is a positive semi-definite, unit trace operator on $\mathcal{H}_S$. They form a convex set $\mathcal{D}(\mathcal{H}_S)$ and the extremals of $\mathcal{D}(\mathcal{H}_S)$ are the one-dimensional orthogonal projections. These are called *pure states* and are equivalent to unit vectors in $\mathcal{H}_S$ up to an overall phase factor, by setting $\rho = \langle \psi, \cdot \rangle \psi$. Physical observables are represented by Hermitian operators on $\mathcal{H}_S$.

Let A be an observable: The expected value of A for a system described by a density operator ρ is defined as

$$\langle a \rangle_\rho := \mathrm{trace}(\rho \mathrm{A}). \tag{18}$$

Hence, the variance for an observable A given ρ is naturally defined as

$$\mathrm{Var}(A)_\rho := \langle (A - \langle a \rangle_\rho)^2 \rangle_\rho. \tag{19}$$

It is easy to see that if ρ_p is a pure state, then there exists an observable A such that the variance $\mathrm{Var}(A)_{\rho_p} = 0$, clarifying the definition and the analogy with the classical case. The time evolution for the density operator of an isolated quantum system is determined by the Hamiltonian, i.e., the energy observable. The dynamical equation is the *Landau-von Neumann equation*:

$$i\hbar \frac{d}{dt} \rho_t = [H, \rho_t], \tag{20}$$

where $[\cdot, \cdot]$ denotes the commutator

$$[A, B] := AB - BA,$$

and $\hbar$ is Planck's constant divided by 2π.

Quantum analogs of entropic functionals have been considered since the very beginning of the mathematical foundation of quantum mechanics.[44] Recently renewed interest came from quantum information applications.[31] We are interested here in the quantum relative entropy, which is defined as

$$\mathbb{D}(\rho \| \tilde{\rho}) := \mathrm{trace}(\rho(\log \rho - \log \tilde{\rho})). \tag{21}$$

We define $0 \log 0 = 0$. As in the classical case, quantum relative entropy has the property of a pseudo-distance (see, e.g., Refs. 31 and 37). We now consider the effect of a perturbation ΔH on the evolution of a quantum system originally driven by a free Hamiltonian H (we denote by $\tilde{H} = H + \Delta H$ the perturbed Hamiltonian).

Proposition V.1: Let ρ_t and $\tilde{\rho}_t$ be the solution of (20) *corresponding to the unperturbed and the perturbed Hamiltonians, respectively. The relative entropy production for the perturbed evolution is given by*

$$\frac{d}{dt} \mathbb{D}(\rho \| \tilde{\rho}) = \frac{i}{\hbar} \langle [\Delta H, \log \tilde{\rho}] \rangle_\rho. \tag{22}$$

Proof: Observing that $[\rho, \log \rho] = 0$ and, consequently,

$$\frac{d}{dt} \mathrm{trace}(\rho \log \rho) = 0$$

(i.e., the *von Neumann entropy* is time invariant under Hamiltonian evolution), and using the cyclic property of trace, we have

$$\frac{d}{dt}\mathbb{D}(\rho\|\tilde{\rho}) = \frac{d}{dt}\mathrm{trace}(\rho\log\rho) + \frac{i}{\hbar}\mathrm{trace}([H,\rho]\log\tilde{\rho} + \rho[\tilde{H},\log\tilde{\rho}])$$

$$= \frac{i}{\hbar}\mathrm{trace}([H,\rho\log\tilde{\rho}] + \rho[\Delta H,\log\tilde{\rho}]) = \frac{i}{\hbar}\mathrm{trace}(\rho[\Delta H,\log\tilde{\rho}]). \tag{23}$$

Q.E.D.

We remark that the initial conditions for the perturbed and the unperturbed evolution can be different, and we can easily exchange the role of perturbed and unperturbed evolution adding a minus sign on the right-hand side. The analogy with the corresponding relative entropy evolution formula in classical mechanics[32] is apparent. As in the classical case, the perturbation can be interpreted as an additive control Hamiltonian.

B. Open quantum systems

When we consider a quantum system interacting with the environment in some uncontrollable way, namely an *open quantum system*,[1,31] the situation changes significantly. The complete dynamical description of the situation should be done considering the tensor product space of both the system and the environment space. Usually, the environment has too many degrees of freedom to be modeled. Moreover, only partial information about environment initial state interactions may be available. In these cases, we can still obtain a dynamical equation for the system state by averaging over the environment degrees of freedom.[1] If the system evolution is assumed to be Markovian, strongly continuous in time, and completely positive,[31] a general form for the generator of the system density operator dynamics is the following:[24]

$$\frac{d}{dt}\rho_t = -\frac{i}{\hbar}[H,\rho_t] + \mathcal{L}[\rho_t], \tag{24}$$

where H is the effective Hamiltonian, in general different from the free drift Hamiltonian, and the generator for the dissipative evolution $\mathcal{L}$ has the form

$$\mathcal{L}[\rho] = \frac{1}{2}\sum_k ([L_k\rho,L_k^\dagger] + [L_k,\rho L_k^\dagger]). \tag{25}$$

The operators L_k can be derived under different assumptions on the couplings with the environment or on a phenomenological basis (see, e.g., Ref. 1 and reference therein). This equation can be seen as a quantum analog of a Fokker-Planck equation, since it describes the time evolution of the density operator in the absence of conditioning measurements. Assume that (24) admits a stationary state commuting with the effective Hamiltonian, and denote it with $\bar{\rho}$. Noting that

$$\mathrm{trace}\left(\rho\frac{d}{dt}\log\rho\right) = \mathrm{trace}\left(\frac{d}{dt}\rho\right) = 0,$$

since the generator (24) has zero trace, we obtain for the relative entropy production (see also Ref. 39)

$$\frac{d}{dt}\mathbb{D}(\rho||\bar{\rho}) = \mathrm{trace}(\mathcal{L}[\rho](\log\rho - \log\bar{\rho})) \leq 0. \tag{26}$$

The fact that $\mathbb{D}(\rho||\bar{\rho})$ is nonincreasing for the dynamical semigroup generated by (24) was established by Lindblad (see, e.g., Ref. 1). To extend this result to the case of a perturbed Hamiltonian, we consider now $\bar{\rho}$ as a *fixed target state*, since the introduction of perturbations could in general change the stationary states. In this setting, we get

$$\frac{d}{dt}\mathbb{D}(\rho\|\bar{\rho}) = \mathrm{trace}\left(\frac{\mathrm{i}}{\hbar}[\tilde{\mathrm{H}},\rho]\log\bar{\rho} + \mathcal{L}[\rho](\log\rho - \log\bar{\rho})\right)$$

$$= -\frac{i}{\hbar}\langle[\Delta H,\log\bar{\rho}]\rangle_{\rho} + \mathrm{trace}(\mathcal{L}[\rho](\log\rho - \log\bar{\rho})), \tag{27}$$

where now ρ is undergoing a *perturbed evolution* $\tilde{H}=H+\Delta H$ and $[\bar{\rho},H]=0$ as before. In the quantum case, however, the effectiveness of a control Hamiltonian is severely limited. For instance, in the closed system case, the density operator eigenvalues cannot be modified by a control Hamiltonian, precluding convergence in relative entropy if the target state has a different spectrum from the initial condition. A detailed analysis of the dissipative case from a control theoretic viewpoint can be found, e.g., in Refs. 2 and 38. Whether these formulas could be of help in designing or analyzing control strategies will be a matter of further work (see also comments on this issue in Ref. 33, Sec. VII).

Further analogies with the classical thermodynamics setting can be unravelled if we restrict our attention to Eq. (24) when it is derived from, e.g., a *weak coupling* limit.[1] This is essentially a constructive derivation of equations of the form (24) from the joint (tensor) description of the system and the environment, which is consistent with classical thermodynamics. In fact, the Gibbs state

$$\rho_G = Z^{-1}e^{-\beta H},$$

where Z is the *partition function* and H is the system Hamiltonian, is a stationary state for the resulting equation. Since, as we already recalled, relative entropy with respect to the stationary state is nonincreasing, for this class of dissipative Markovian evolutions we have a full correspondence with the classical mechanical case.[32]

VI. CONCLUSION AND OUTLOOK

We have derived explicit dependence of the *relative entropy production rate* on the control action for various uncertain physical systems exhibiting a *Markovian evolution*. Further work is needed to find other significant applications of the results as well as possible extension to other, more complex, systems with Markovian evolution such as interacting particle systems.

APPENDIX: FINITE-ENERGY DIFFUSIONS

Let $\Omega := \mathcal{C}([t_0,t_1],\mathbb{R}^n)$ denote the family of n-dimensional continuous functions, and let P and $\tilde{P}$ be two probability distributions on Ω. The *relative entropy* $H(\tilde{P},P)$ of $\tilde{P}$ with respect to P is defined by

$$H(\tilde{P},P) = \begin{cases} E_{\tilde{P}}\left[\log\dfrac{d\tilde{P}}{dP}\right] & \text{if } \tilde{P} \ll P, \\ +\infty & \text{otherwise.} \end{cases}$$

Let W_x denote Wiener measure on Ω starting at $x\in\mathbb{R}^n$, and let

$$W := \int W_x\, dx$$

be stationary Wiener measure. Let $\sigma>0$, and denote by $\mathbb{D}$ the family of distributions P on Ω such that $H(P,\sigma W)<\infty$. Let $\mathcal{F}_t$ and $\mathcal{G}_t$ denote the σ algebras of events observable up to time t and from time t on, respectively. It then follows from the Girsanov's theory[10,17] that $P\in\mathbb{D}$ possesses both a forward drift β^P and a backward drift γ^P, namely under P, the increments of the canonical coordinate process $x(t,\omega)=\omega(t)$ admit the representations

$$x(t) - x(s) = \int_s^t \beta^P(\tau)d\tau + \sigma[w_+(t) - w_+(s)], \quad t_0 \le s < t \le t_1, \tag{A1}$$

$$x(t) - x(s) = \int_s^t \gamma^P(\tau)d\tau + \sigma[w_-(t) - w_-(s)], \quad t_0 \le s < t \le t_1. \tag{A2}$$

$\beta^P(t)$ is at each time t $\mathcal{F}_t$-measurable and $w_+(\cdot)$ is a standard, n-dimensional Wiener process. Symmetrically, $\gamma^P(t)$ is $\mathcal{G}_t$-measurable and w_- is another standard Wiener process. Moreover, β^P and γ^P satisfy the finite-energy condition

$$E\left\{\int_{t_0}^{t_1} \beta^P(t)\cdot\beta^P(t)dt\right\} < \infty, \quad E\left\{\int_{t_0}^{t_1} \gamma^P(t)\cdot\gamma^P(t)dt\right\} < \infty. \tag{A3}$$

It was shown in Ref. 13 that the one-time probability density $p_t(\cdot)$ of $x(t)$ (which exists for every t) is absolutely continuous on $\mathbb{R}^n$ and the following relation holds a.s. $\forall t > 0$

$$E\{\beta^P(t) - \gamma^P(t)|x(t)\} = \sigma^2 \nabla \log p_t(x(t)). \tag{A4}$$

Let us introduce the *current drift* and the *current drift field* of P

$$v^P(t) = \frac{\beta^P(t) + \gamma^P(t)}{2}, \quad v^P(x,t) = E\{v^P(t)|x(t) = x\}. \tag{A5}$$

Then, the one-time density p_t satisfies weakly[32] a continuity-type equation

$$\frac{\partial p_t}{\partial t} + \nabla\cdot(v^P p_t) = 0. \tag{A6}$$

Hence, Theorem III.1 holds true for finite energy diffusions provided we define the v fields according to (A5).

Global spectrum fluctuations for the β-Hermite and β-Laguerre ensembles via matrix models

Ioana Dumitriu[a] and Alan Edelman
University of California, Berkeley, Berkeley, California 94720

(Received 24 March 2006; accepted 30 March 2006; published online 30 June 2006)

We study the global spectrum fluctuations for β-Hermite and β-Laguerre ensembles via the tridiagonal matrix models introduced previously by the present authors [J. Math. Phys. **43**, 5830 (2002)], and prove that the fluctuations describe a Gaussian process on polynomials. We extend our results to slightly larger classes of random matrices. © *2006 American Institute of Physics.*

I. INTRODUCTION

A. The semicircle law, deviations and fluctuations, numerically

The most celebrated theorem of random matrix theory, the Wigner semicircle law,[44,45] may be illustrated as in Fig. 1 by histogramming the eigenvalues of a single random symmetric matrix using the simple MATLAB code (normalization omitted)

```
A = randn(n); S = (A + A')/sqrt(8 * n); a = hist(eig(S),[-1:delta:1]);
bar([-1:delta:1],a/(n * delta))
```

Every time we run this experiment, we obtain deviations from the semicircle. The difference from theory is readily explained computationally:

- we use a finite matrix size n, while the semicircle law is a theorem about the $n=\infty$ limit;
- histograms bin eigenvalues into boxes of finite width, while the semicircle density is a continuous function.

There can also be numerical error in the experiments due to finite precision computations and truncation error, but in practice this does not appear to be significant.

It is worth noting that the above-noted algorithm is inefficient in two ways: first, it uses the full matrix A, rather than the equivalent tridiagonal matrix $H_{\beta,n}$ of Table II (with $\beta=1$), and it calculates the eigenvalues to obtain the histogram. For more on how to obtain the histogram plot efficiently and without calculating the eigenvalues, see Sec. V.

To study the next order behavior in the law, for large n, we can subtract away the semicircle and multiply by n. The next order *average* behavior is what we call the deviation and it was first computed by Johansson[21] to be

$$DEVIATION = \frac{1}{4}\delta_{-1}(x) + \frac{1}{4}\delta_1(x) - \frac{1}{2\pi}\sqrt{1-x^2}. \tag{1}$$

This expression for the deviation is the $\beta=1$ (corresponding to real matrices) instance of the more general $\beta>0$ case (which was also computed by Johansson, and will be explained in the next sections). The $\beta>0$ deviation contains a $(2/\beta-1)$ multiplicative factor in front of the expression on the right of (1), which notably disappears for $\beta=2$.

[a]Electronic mail: dumitriu@math.berkeley.edu

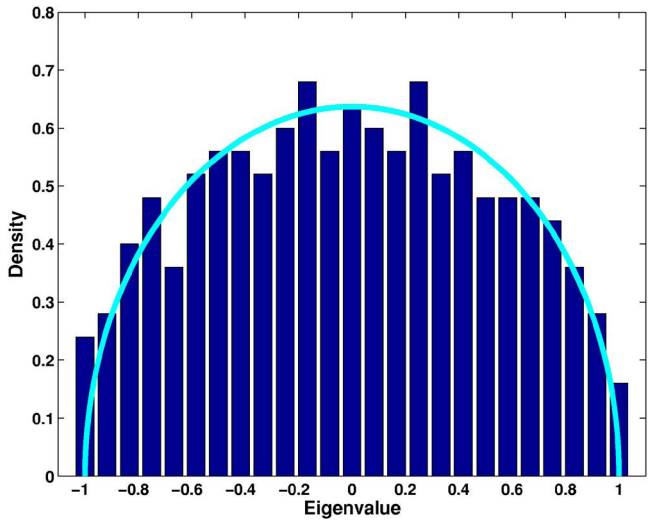

FIG. 1. (Color online) 25 bin-histogram of the eigenvalues of a 300×300 symmetric matrix from the real Gaussian distribution, vs the semicircle.

One can see this deviation result as stating that as $n\to\infty$ the eigenvalues are decremented in the interior at a rate that is fastest at the center, pulling the eigenvalues toward the endpoints.

Upon further examination of the next-order term, one can observe a phenomenon not appearing in the leading order term; there are fluctuations around the mean.

Each time we run a trial we can compute this fluctuation. For example, if we have 25 bins, the random fluctuation vector $v=(v_1,\ldots,v_{25})^T$ is the difference between the count in each bin and the number of eigenvalues predicted by the semicircle plus the deviation. The entries of v can vary quite wildly, but inner products with discretized smooth functions result in normal distributions in the continuous limit. Specifically, if f_k is the vector of size 25 consisting of the evaluations of $f(x)=x^k$ on the centers of the bins, then the dot products $f_k^T v$ are heading toward Gaussians with covariances $E[(f_{k_1}^T v)(f_{k_2}^T v)]$.

Precise statements require the size of the matrix to go to infinity and the histogram to melt into a smooth density function so that the v vector becomes a Gaussian process.

Denote by $FLUCTUATION(f(x))$ the random quantity representing the limit obtained of $f^T v$ where, as above, f is the vector of function values and v is the vector of histogram differences. For smooth functions, $FLUCTUATION(f(x))$ converges to a normal distribution; for example, in the limit as $n\to\infty$,

$$FLUCTUATION(x^k)\sim 2N(0,\sigma_k^2), \tag{2}$$

where

$$\sigma_k^2=\begin{cases}\dfrac{k}{2^{2k}}\left(\dfrac{k-1}{\frac{k-1}{2}}\right)^2 & \text{if } k=1 \bmod 2\\[2ex] \dfrac{k}{2^{2k+2}}\left(\dfrac{k}{\frac{k}{2}}\right)^2 & \text{if } k=0 \bmod 2.\end{cases}$$

For general β, the right side of (2) gains a multiplicative factor of $1/\beta$.

The limit of the entry (k_1,k_2) of the covariance matrix becomes the covariance between $FLUCTUATION(x^{k_1})$ and $FLUCTUATION(x^{k_2})$ (see Theorem 1.2 with $\beta=1$).

TABLE I. Random matrix ensembles with eigenvalue distribution proportional to $f(x_1,\ldots,x_n)\propto\Pi_{i<j}|x_i-x_j|^\beta\Pi_w(x_i)$ with w defined on an interval $I\subseteq\mathbb{R}$. MANOVA stands for Multivariate ANalysis Of Variance.

Name	Parameters	I	w	Historical name/constraints
Hermite	$\beta>0$	$\mathbb{R}$	$w(x)=e^{-x^2/2}$	Gaussian $\beta=1,2,4$
Laguerre	$\beta>0$ $a>(n-1)\beta/2$	$[0,\infty)$	$w(x)=x^p e^{-x/2}$ $p=a-(n-1)\beta/2-1$	Wishart $\beta=1,2$ $a=m\beta/2, m\in\mathbb{N}$
Jacobi	$\beta>0$ $a_1,a_2>(n-1)\beta/2$	$[0,1]$	$w(x)=x^{p_1}(1-x)^{p_2}$ $p_1=a_1-(n-1)\beta/2-1$ $p_2=a_2-(n-1)\beta/2-1$	MANOVA $\beta=1,2$ $a_1=m_1\beta/2, m_1\in\mathbb{N}$ $a_2=m_2\beta/2, m_2\in\mathbb{N}$

B. β-Hermite and β-Laguerre ensembles

This paper studies deviations and fluctuations in a wider context than real symmetric matrices with semicircular asymptotic density: We consider Hermite and Laguerre matrices with general parameter $\beta>0$. For a great reference for these ensembles, see Forrester's upcoming book.[16]

Classical finite random matrix theory considers the study of eigenvalue ensembles with joint density

$$f(x_1,\ldots,x_n)=c_{w,n}\prod_{i<j}|x_i-x_j|^\beta\prod_{i=1}^n w(x_i),$$

with w a scalar weight function on an interval I. This interval may be a subinterval of the real line, or the unit circle in the complex plane; other possibilities have been considered, too, and generalizations are easily conceived. A good reference for these formulas can be found in Lal Mehta's book.[27]

Some of the most studied eigenvalue ensembles have Hermite, Laguerre, and Jacobi weight functions on the real line, or uniform weight on the unit circle. In this paper we will be examining the ensembles with Hermite and Laguerre weights on the real line (respectively, half-line); see Table I.

For more references on Gaussian ensembles, see Ref. 27; for Wishart and MANOVA ensembles, see Ref. 30; for Hermite, Laguerre, and Jacobi ensembles, see Ref. 16.

For three particular values of β, namely 1, 2, and 4, these ensembles have been studied since the birth of the field, as the Gaussian real, complex, and quaternion ensembles (Hermite with $\beta=1,2,4$) of nuclear physics.[44,45,14,1] Similarly, the Wishart real and complex (Laguerre with $\beta=1,2$ and some restrictions on the Laguerre parameter) matrices emerged from the world of statistical multivariate analysis.[46,6,20,24]

The parameter β (making the connection to the Boltzmann factor of statistical physics) is seen by some communities (e.g., statistical mechanics) as an inverse temperature, or repulsion strength, of the ensemble of eigenvalues (the higher the β, the more separated the eigenvalues). It also has the advantage of the easy mnemonic of 1,2, and 4 corresponding to real, complex, and quaternion entries in the matrix models. However, some communities (like algebraic combinatorics) consider a different parameter, $\alpha=2/\beta$, which tends to simplify certain formulas.[28,36] In this paper we will use both notations, for convenience, and make sure that the reader is informed when changes take place.

The reason for the attractivity and success that the study of Gaussian orthogonal, unitary, and symplectic (Hermite with $\beta=1,2,4$), and the Wishart real and complex (Laguerre with $\beta=1,2$), ensembles have enjoyed lies in the existence of matrix models with real, complex, and quaternion

TABLE II. *Unscaled and scaled* tridiagonal matrix models for the β-Hermite and β-Laguerre ensembles with any $\beta>0$, $n\in\mathbb{N}$, $a\in\mathbb{R}$, and $a>(\beta/2)(n-1)$.

Hermite matrix, unscaled	$H_{\beta,n}\sim\frac{1}{\sqrt{2}}\begin{pmatrix} N(0,2) & \chi_{(n-1)\beta} & & & \\ \chi_{(n-1)\beta} & N(0,2) & \chi_{(n-2)\beta} & & \\ & \ddots & \ddots & \ddots & \\ & & \chi_{2\beta} & N(0,2) & \chi_{\beta} \\ & & & \chi_{\beta} & N(0,2) \end{pmatrix}$
Hermite matrix, scaled	$\tilde{H}_{\beta,n}=\frac{1}{\sqrt{2n\beta}}H_{\beta,n}$
Laguerre matrix, unscaled	$L^a_{\beta,n}=B^a_{\beta,n}(B^a_{\beta,n})^T$, where $B^a_{\beta,n}\sim\begin{pmatrix} \chi_{2a} & & & \\ \chi_{\beta(n-1)} & \chi_{2a-\beta} & & \\ & \ddots & \ddots & \\ & & \chi_{\beta} & \chi_{2a-\beta(n-1)} \end{pmatrix}$
Laguerre matrix, scaled	$\tilde{L}^a_{\beta,n}=\frac{\gamma}{n\beta}L^a_{\beta,n}$

entries (see Refs. 27 and 30). These models have not only originated the study, but have also allowed for a relatively thorough analysis of the finite and asymptotical eigenstatistics (statistical properties of the eigenvalues).

One of the developments in the study of arbitrary β-Hermite, -Laguerre, and -Jacobi ensembles is the introduction of general *real* matrix models (see Refs. 11, 25, and 38). For every β, there are simple *real tridiagonal matrices* which model the corresponding eigenvalue distributions given by Table I. For the β-Hermite and -Laguerre ensembles, we present these forms in Table II. These matrix forms allow for efficient Monte Carlo experiments and an alternative representation for the study of eigenstatistics in the general β case.

This paper contains one example of such analysis. With the help of these matrix models, we compute asymptotical global spectrum fluctuations for the β-Hermite and -Laguerre ensembles. For the latter, these results are new in the general β context; the global spectrum fluctuations of complex Wishart matrices (β-Laguerre with $\beta=2$) were studied by Speicher *et al.*,[26] and before by Cabanal-Duvillard.[5] Johansson's more extensive study[21] covers our results for the β-Hermite ensembles.

To prove our theorems, we use a very diverse set of methods and techniques from Jack polynomial theory, special functions, perturbation theory, and combinatorial pathcounting. Some of the techniques we used in studying the traces of powers of random matrices have been inspired by the work of Soshnikov and Sinai,[33,34] and by the study of traces of unitary random matrices by Diaconis and Shahshahani.[9]

C. Statements of results

Among the asymptotical eigenstatistics one may distinguish two classes of properties: local (like the scaled distributions and fluctuations of extremal eigenvalues, or like the level spacing distribution, i.e., the distance between neighboring eigenvalues) and global (like the limiting level density, i.e., the distribution of a random eigenvalue, and fluctuations thereof). The term global tends to refer to a property that involves all or a significant portion of the eigenvalues, while local tends to refer to a property that occurs near an individual or a constant number of eigenvalues. Among the more famous local properties we enumerate the level spacings for the Gaussian ensembles (see Refs. 27 and 39) and the extremal (largest, corresponding to "soft edge," smallest, to "hard edge") eigenvalue asymptotics (see Refs. 41, 40, 22, and 23). All these results relate to real, complex, or quaternion matrices; in the category of results relating to general β, we have to mention recent work by Desrosiers and Forrester,[8] where they analyze the asymptotical corrections to the eigenvalue density, and, for $\beta \in 2\mathbb{N}$, obtain the expected $O(n^{2/3})$ order in the fluctuation of the largest eigenvalue in the case of both β-Hermite and -Laguerre ensembles.

For n (the size of the ensembles) finite, the n eigenvalues may be considered as n fluctuating particles. Roughly speaking, the larger the β, the less fluctuation there is in the particles (hence β is seen as an inverse temperature). As $\beta \to \infty$ the particle positions behave like multivariate normals with variance $O(1/\beta)$ and means located at the roots of a Hermite (respectively, Laguerre) polynomial (see Ref. 12).

For a fixed β, as $n \to \infty$ and, in the case of Laguerre ensembles, $2a/(n\beta) \to \gamma$, the particles have an emerging (global) level density which obeys a simple law (Wigner's semicircle law[45] for the Hermite ensembles, respectively the Marčenko-Pastur laws[29] for the Laguerre ensembles). The roots of the Hermite, respectively Laguerre, polynomial have this same asymptotical density—the fluctuations do not change the asymptotics, as they are on a smaller scale.

In Ref. 10, we have proved convergence almost surely (as $n \to \infty$) of the asymptotical eigenvalue distribution of the β-Hermite ensemble to the semicircle distribution S with density $(2/\pi)\sqrt{1-x^2}$, and of the asymptotical eigenvalue distribution of the β, a-Laguerre ensemble (with $n\beta/(2a) \to \gamma \leqslant 1$) to the Marčenko-Pastur E_γ distribution with density $\frac{1}{2\pi\gamma}\frac{\sqrt{(x-(\sqrt{\gamma}-1)^2)((\sqrt{\gamma}+1)^2-x)}}{x}$. We recall that convergence almost surely is stronger (and implies) convergence in distribution, a.k.a. convergence of moments.

We examine here the distribution of the statistic $\Sigma_{i=1}^n f(\lambda_i)$, where f is a function of the *scaled* eigenvalues λ_i. The scaling is $\lambda \to \sqrt{2n\beta}\lambda$ for the β-Hermite ensembles and $\lambda \to n\beta/\gamma\lambda$ for the β-Laguerre ensembles (see Table II).

General β results for this kind of statistic can be found in Refs. 4 and 21; this or similar linear statistics have been considered also in Ref. 15 (for unitary matrices), Ref. 32 (for Wishart matrices), and, heuristically, in Ref. 31. Another path of interest is represented by asymptotical large deviations from the density (spectral measure); we mention the results of Refs. 5, 2, and 18 (which also covers global fluctuations for Wishart matrices), Refs. 19 and 7 (which covers moderate deviations).

For the linear statistic $\Sigma_{i=1}^n f(\lambda_i)$, the Wigner and Marčenko-Pastur laws for the β-Hermite and β-Laguerre ensembles state that for any "well-behaved" function f,

$$\frac{1}{n}\sum_{i=1}^{n} f(\lambda_i) \to \frac{2}{\pi}\int_{-1}^{1} f(t)\sqrt{1-t^2}\,dt, \quad \text{respectively,} \tag{3}$$

$$\frac{1}{n}\sum_{i=1}^{n} f(\lambda_i) \to \frac{1}{2\pi\gamma}\int_{(\sqrt{\gamma}-1)^2}^{(\sqrt{\gamma}+1)^2} f(t)\frac{\sqrt{(t-(\sqrt{\gamma}-1)^2)((\sqrt{\gamma}+1)^2-t)}}{t}\,dt, \tag{4}$$

where the convergence in the above is almost certain. (Such a result is sometimes given the name of "strong law of large numbers.")

Examining the fluctuations from these laws takes us one step further. For f a polynomial, we prove that once we subtract the expected average over the limiting level density [i.e., the right-hand sides of (3) and (4)], the rescaled resulting quantity tends asymptotically to a normal distribution with mean and variance depending on f. In other words, once the semicircle or Marčenko-Pastur distributions are subtracted, the fluctuations in the statistic $\Sigma_{i=1}^{n} f(\lambda_i)$ tend asymptotically to a Gaussian process on polynomials f.

How much more we can extend the class of functions that this process is well-defined on depends on the entries of the covariance matrix $C=\{C_{ij}\}$ (which can be expressed in any polynomial basis). One would be tempted to believe that a Gaussian process W defined on polynomials could, in principle, be extended to a class of continuous functions $h(x)$ with the property that, given a sequence of polynomials $p_n(x) \to h(x)$ in some norm, given $v_n = Var_W(p_n)$, $v_n \to \tilde{v} < \infty$, such that $\tilde{v} = Var_W(h)$.

Definition 1.1: Let $\gamma \in [0,1]$ be a real parameter, and let $a=(\sqrt{\gamma}-1)^2$, $b=(\sqrt{\gamma}+1)^2$. We define the following two measures:

$$\mu_H(x) := \begin{cases} \frac{1}{4}\delta_1(x) + \frac{1}{4}\delta_{-1}(x) - \frac{1}{2\pi}\frac{1}{\sqrt{1-x^2}} & \text{if } x \in [-1,1] \\ 0 & \text{otherwise}, \end{cases}$$

$$\mu_L^{\gamma}(x) := \begin{cases} \frac{1}{4}\delta_b(x) + \frac{1}{4}\delta_a(x) - \frac{1}{2\pi}\frac{1}{\sqrt{(x-a)(b-x)}} & \text{if } x \in [a,b] \\ 0 & \text{otherwise}. \end{cases}$$

Theorem 1.2: *Let $\tilde{H}_{\beta,n}$ be a scaled matrix from the β-Hermite ensemble of size n, with (scaled) eigenvalues $(\lambda_1, \ldots, \lambda_n)$, and let $k \geqslant 1$ be a positive integer. For all $i=1,\ldots,k$, let*

$$X_i = \operatorname{tr}((\tilde{H}_{\beta,n})^i) - n\frac{1}{4^{i/2}\left(\frac{i}{2}+1\right)}\binom{i}{\frac{i}{2}}\delta_{(i \bmod 2),0} - \left(\frac{2}{\beta}-1\right)\int_{-1}^{1} t^i \mu_H(t)\,\mathrm{d}t$$

$$\equiv \sum_{j=1}^{n} \lambda_j^i - n\frac{2}{\pi}\int_{-1}^{1} t^i\sqrt{1-t^2}\,\mathrm{d}t - \left(\frac{2}{\beta}-1\right)\int_{-1}^{1} t^i \mu_H(t)\,\mathrm{d}t.$$

Let $(Y_1, Y_2, \ldots, Y_k)$ be a centered multivariate Gaussian with covariance matrix

$$\operatorname{Cov}(Y_i, Y_j) = \begin{cases} \frac{1}{2^{i+j}}\frac{2ij}{i+j}\binom{i-1}{\frac{i-1}{2}}\binom{j-1}{\frac{j-1}{2}} & \text{if } i=j=1 \bmod 2 \\ \frac{1}{2^{i+j+2}}\frac{2ij}{i+j}\binom{i}{\frac{i}{2}}\binom{j}{\frac{j}{2}} & \text{if } i=j=0 \bmod 2 \\ 0 & \text{otherwise}. \end{cases} \tag{5}$$

Then, as $n \to \infty$,

$$(X_1, X_2, \ldots, X_k) \Rightarrow \sqrt{\frac{2}{\beta}}(Y_1, Y_2, \ldots, Y_k).$$

Remark 1.3: For any size k, if we add a first row and a first column of zeros to the covariance matrix (5), *the resulting* $(k+1)\times(k+1)$ *matrix* C_k *has a scaled Cholesky decomposition as* $C_k = T_k D_k T_k^T$, *where* D_k *is the diagonal matrix having on the diagonal the vector* $(0,1,2,3,\ldots,k)$, *and* T_k *has an interpretation as the change-of-base matrix in the space of univariate polynomials from monomials basis to the Chebyshev polynomials basis. One can also look at the infinite version* $C_\infty = T_\infty D_\infty T_\infty^T$.

Remark 1.4: This Gaussian process has been first described in a more general context (and extended to a larger class of continuous functions h) by Johansson in Ref. 21. *Johansson conjectured that the regularity conditions imposed on h were purely technical, and that in fact the correct condition should be that the function h admits a Fourier-like expansion in the Chebyshev basis. We restate this as follows: write h as an (infinite) vector* $\vec{h}$ *of coefficients in the Chebyshev basis; then* $V_C(h) := \vec{h}^T D_\infty \vec{h}$ *is the variance of h under the Gaussian process expressed in Chebyshev basis. Johansson's conjecture is equivalent to saying that the process could be extended to any class of functions h such that V(h) (or equivalently, the variance of h under the Gaussian process expressed in monomial basis,* $V_m(h) := (T_\infty \vec{h})^T C_\infty (T_\infty \vec{h})$ *is finite; note that* $T_\infty \vec{h}$ *is the vector of coefficients in monomial basis.*

Theorem 1.5: *Let* $\tilde{L}^a_{\beta,n}$ *be a scaled matrix from the* β*-Laguerre ensemble of parameter a and size n, with (scaled) eigenvalues* $(\lambda_1, \ldots, \lambda_n)$, *and let* $k \geqslant 1$ *be a positive integer. Assume that* $n\beta/(2a) \to \gamma \leqslant 1$, *and let* $\gamma_{min} = (\sqrt{\gamma}-1)^2$, $\gamma_{max} = (\sqrt{\gamma}+1)^2$. *For all* $i = 1, \ldots, k$, *let*

$$\begin{aligned} X_i &= \mathrm{tr}((\tilde{L}^a_{\beta,n})^i) - n\sum_{r=0}^{i-1} \frac{1}{r+1}\binom{k}{r}\binom{k-1}{r}\gamma^r - \left(\frac{2}{\beta}-1\right)\int_{\gamma_{\min}}^{\gamma_{\max}} t^i \mu_L^\gamma(t)\mathrm{d}t \\ &\equiv \sum_{j=1}^{n} \lambda_j^i - n\frac{1}{2\pi\gamma}\int_{\gamma_{\min}}^{\gamma_{\max}} t^i \sqrt{(t-\gamma_{\min})(\gamma_{\max}-t)}\mathrm{d}t - \left(\frac{2}{\beta}-1\right)\int_{\gamma_{\min}}^{\gamma_{\max}} t^i \mu_L^\gamma(t)\mathrm{d}t. \end{aligned}$$

Let $(Y_1, Y_2, \ldots, Y_k)$ *be a centered multivariate Gaussian with covariance matrix*

$$\mathrm{Cov}(Y_i, Y_j) = T_D(i,j) + T_S(i,j), \tag{6}$$

where

$$T_D(i,j) = \sum_{q=1}^{i+j-1} (-1)^{q+1}\gamma^{j+j-q}\frac{\binom{i+j}{q}}{i+j}\sum_{l=q+1}^{i+j}\frac{(-1)^l}{\binom{i+j-1}{l-1}}\sum_{\substack{r+s=l \\ 1\leqslant r\leqslant i \\ 1\leqslant s\leqslant j}} rs\binom{i}{r}^2\binom{j}{s}^2,$$

and

$$T_S(i,j) = \sum_{q=0}^{i+j-2} (-1)^q \gamma^{j+j-q}\frac{\binom{i+j}{q}}{i+j}\sum_{l=q}^{i+j-2}\frac{(-1)^l}{\binom{i+j-1}{l}}\sum_{\substack{r+s=1 \\ 0\leqslant r\leqslant i-1 \\ 0\leqslant s\leqslant j-1}} (i-r)(j-s)\binom{i}{r}^2\binom{j}{s}^2.$$

Then, as $n \to \infty$,

$$(X_1, X_2, \ldots, X_k) \Rightarrow \sqrt{\frac{2}{\beta}}(Y_1, Y_2, \ldots, Y_k).$$

Remark 1.6: For any size k, if we add a first row and a first column of zeros to the covariance matrix (6), the resulting matrix C should admit a scaled Cholesky decomposition of the form $C_k = T_k D_k T_k^T$, *with* D_k *being the diagonal matrix with diagonal entries* $\{j\gamma^{-j}\}_{0\leqslant j\leqslant k}$, *and* T_k *being the change-of-basis matrix in the space of polynomials from monomial basis to the shifted* Chebyshev *polynomials of the first kind (as defined by Cabanal-Duvillard*[5] *and used in Ref. 26). Note that the constant c in Ref. 26 is our* $1/\gamma$. *It may also be useful to look at* $C_\infty = T_\infty D_\infty T_\infty^T$.

Remark 1.7: It is worth noting that results like Theorems 1.2 and 1.5, where one averages over a set of quantities, then subtracts the mean and scales by the variance to obtain a limiting Gaussian, are sometimes called **central limit theorems** *(see, for example, Refs. 32 and 33). Free Probability uses this term as well, see, for example Ref. 35, in a different context, namely, to express the fact that averaging over random matrices creates an eigenvalue distribution that approaches the semicircular law. Both uses of the term "central limit theorem" draw different parallels to the classical case*.

Our approach to proving Theorems 1.2 and 1.5 consists of computing the first-order deviation from the mean (in Sec. II), showing that the centered process is Gaussian on monomials (by the method of moments), and computing the covariance matrices (in Sec. III).

Finally, in Sec. IV, we generalize our approach to two different classes of random matrices.

II. DEVIATION FROM THE SEMICIRCLE AND MARČENKO-PASTUR LAWS

A. Dependence on β: Symmetric functions and the "palindrome" effect

As stated in Sec. I, we are interested in computing the deviation to the semicircle and Marčenko-Pastur laws (denoted below by $LAW(\infty)$, as opposed to the $LAW(n)$, which is the level density for finite n). These deviations have the form

$$LAW(n) \sim LAW(\infty) + \frac{1}{n}\left(\frac{2}{\beta} - 1\right) DEVIATION + o\left(\frac{1}{n}\right),$$

as $n \to \infty$.

By integrating the above against x^k, we can write this in the moment form

$$moment_k(n) = moment_k(\infty) + \frac{1}{n}\left(\frac{2}{\beta} - 1\right) moment_k(DEVIATION) + o\left(\frac{1}{n}\right),$$

again as $n \to \infty$.

We mention two interesting points, the first of which we prove in this section:

1. The factor $2/\beta - 1$ in the first-order term in n and the fact that *DEVIATION* does not depend on β can be obtained from a symmetry principle alone. It is a direct consequence of Jack polynomial theory that the coefficient of $1/n^j$ in $moment_k(n)$ is a *palindromic* polynomial (we define "palindromic" below) in $-2/\beta$, and from the tridiagonal matrix models it follows that the degree of this polynomial is j; thus when $j=1$ this polynomial must be a multiple of $2/\beta - 1$. Mathematically, this is significant because in order to study the deviations, it is sufficient to then study the non-random case, $\beta = \infty$. In summary, the powerful Jack polynomial theory allows us to take a complicated random matrix problem and reduce it to an exercise on the properties of univariate Hermite and Laguerre polynomials.
2. With the Maple Library *MOPs*,[13] we can compute symbolically the exact values of $moment_k(n)$ for small values of k, *as a function of n and* β. In other words, while this paper concerns itself with the constant and $O(1/n)$ behavior, it is worth remembering that higher order terms are in principle available to us.

To make notation a bit clearer, we have used the $\alpha=2/\beta$ in the following; we also recall the scaled matrices $\widetilde{H}_{\beta,n}$ and $\widetilde{L}^{a}_{\beta,n}$, from Sec. I B. The following are the first three non-trivial moments for the traces of the scaled β-Hermite and β-Laguerre matrices with $a=n\beta/(2\gamma)=n/(\alpha\gamma)$. We omit the n and a in the notation for reasons of space,

$$\frac{1}{n}E[\mathrm{tr}(H_{2/\alpha}^2)]=\frac{1}{4}+\frac{\alpha-1}{4n},$$

$$\frac{1}{n}E[\mathrm{tr}(H_{2/\alpha}^4)]=\frac{2}{16}+\frac{5\alpha-5}{16n}+\frac{3\alpha^2-5\alpha+3}{16n^2},$$

$$\frac{1}{n}E[\mathrm{tr}(H_{2/\alpha}^6)]=\frac{5}{64}+\frac{11\alpha-11}{32n}+\frac{16\alpha^2-27\alpha+16}{32n^2}+\frac{15\alpha^3-32\alpha^2+32\alpha-15}{64n^3},$$

$$\frac{1}{n}E[\mathrm{tr}(L_{2/\alpha})]=1,$$

$$\frac{1}{n}E[\mathrm{tr}(L_{2/\alpha}^2)]=(1+\gamma)+\frac{\gamma(\alpha-1)}{n},$$

$$\frac{1}{n}E[\mathrm{tr}(L_{2/\alpha}^3)]=(1+3\gamma+\gamma^2)+\frac{3\gamma(\gamma+1)(\alpha-1)}{n}+\frac{\gamma^2(2\alpha^2-3\alpha+2)}{n^2}.$$

Note that the $O(1)$ terms in the above correspond to the second, fourth, and sixth moments of the semicircle, in the Hermite case, respectively, to the first, second, and third moments of the Marčenko-Pastur distributions in the Laguerre case; these are Catalan numbers (scaled down by powers of 4 because of the semicircle $[-1,1]$ normalization), respectively, Narayana polynomials in γ.

The $O(1/n)$ terms, the moments of the deviation, are always multiplied by $\alpha-1$, while the other coefficients of the negative powers of n in the above are "palindromic polynomials" of $(-\alpha)$; we recall the definition in the following.

Definition 2.1: A classical "palindromic polynomial" is defined by the fact that its list of coefficients is the same whether read from beginning to end or from end to beginning.

Remark 2.2: An odd-degree palindromic polynomial in x is a multiple of $(x+1)$.

To prove that the dependence of the first-order term in the deviation is indeed a multiple of $\alpha-1$, i.e., of $2/\beta-1$, we will use elements of Jack polynomial theory, and also a stronger form of a duality principle proved in Ref. 10.

We introduce in the following two notational conventions to be used throughout the rest of the paper.

Definition 2.3: We denote by $E_{\delta}^{H}[P(x_1,\ldots,x_s)]$, respectively, $E_{\delta,a}^{L}[P(x_1,\ldots,x_s)]$, the expectations of the polynomial P over the **scaled** *$2/\delta$-Hermite, respectively, $2/\delta$, a-Laguerre, ensembles of size s.*

We denote by $\mathcal{E}_{\delta}^{H}[P(x_1,\ldots,x_s)]$, respectively, *$\mathcal{E}_{\delta,a}^{L}[P(x_1,\ldots,x_s)]$, the expectations of the polynomial P over the unscaled $2/\delta$-Hermite, respectively, $2/\delta$, a-Laguerre, ensembles of size s.*

Let $\mathbb{R}[x_1,\ldots,x_n]$ be the space of symmetric polynomials in n variables (by symmetric we mean invariant under any permutation of the variables). A homogeneous basis for this vector space is a set of linearly independent, symmetric, and homogeneous polynomials which generate $\mathbb{R}[x_1,\ldots,x_n]$. One such basis is given by the power-sum functions, defined multiplicatively below. For reference, see Refs. 37 and 28.

Definition 2.4: Let $\lambda\equiv(\lambda_1,\lambda_2,\ldots,\lambda_n)$ denote an ordered partition $(\lambda_1\geqslant\lambda_2\geqslant\cdots\geqslant\lambda_n)$. We define the power sum functions by

$$p_{\lambda_i}=\sum_{j=1}^{n}x_j^{\lambda_i},\quad \textit{and}$$

$$p_\lambda = p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_n}.$$

The Jack polynomials J_λ^α constitute a parameter-dependent (the parameter being usually denoted by α) class of orthogonal multivariate polynomials; they are indexed by the powers of the highest-order term λ (in lexicographical ordering).

Throughout this section, we will think of the parameter α as a sort of inverse to β (recall that we have denoted $\alpha = 2/\beta$).

The Jack polynomials allow for several equivalent definition (up to certain normalization constraints). We will work here with definition 2.5, which arose in combinatorics. We follow Macdonald's book.[28]

Definition 2.5: The Jack polynomials J_λ^α are orthogonal with respect to the inner product defined in the following on power-sum functions

$$\langle p_\lambda, p_\mu \rangle_\alpha = \alpha^{l(\lambda)} z_\lambda \delta_{\lambda\mu},$$

where $z_\lambda = \Pi_{i=1}^{l(\lambda)} a_i! i^{a_i}$, a_i being the number of occurrences of i in λ. In addition, the coefficient of the lowest-order term in J_λ^α, which corresponds to the partition $[1^{|\lambda|}] \equiv (1,1,\ldots,1)$ (of length $|\lambda|$), is $|\lambda|!$.

From now on, we will use the notations I_n for the vector of n ones and we will refer to the quantity $J_\kappa^\alpha(x_1,\ldots,x_n)/J_\kappa^\alpha(I_n)$ as the *normalized* Jack polynomial.

To prove our results, we will need the two lemmas to follow, the first of which is a stronger variant of the duality principle proved in Ref. 10 as Theorem 8.5.3 (the proof is virtually the same as in Ref. 10 and we will not repeat it here). The second one is a rewrite of a particular case ($z_a = 0$ and formula (4.14a)) of formula (4.36b) in Ref. 3.

Lemma 2.6: Let κ' denote the conjugate partition to κ (obtained by transposing the rows and columns in the Young tableau). Then for any integers $m, n \geqslant 0$,

$$\mathcal{E}_\alpha^H \left[\frac{J_\kappa^\alpha(x_1,\ldots,x_n)}{J_\kappa^\alpha(I_n)} \right] = (-\alpha)^{-k/2} \mathcal{E}_{1/\alpha}^H \left[\frac{J_{\kappa'}^{1/\alpha}(y_1,\ldots,y_m)}{J_{\kappa'}^{1/\alpha}(I_m)} \right].$$

Lemma 2.7: The following identity is true:

$$\mathcal{E}_{\alpha,a}^L \left[\frac{J_\lambda^\alpha(x_1,\ldots,x_n)}{J_\kappa^\alpha(I_n)} \right] = 2^k \sum_{(x,y)\in\kappa} \left(a - \frac{x}{\alpha} + y \right).$$

In particular, for $a = n/(\alpha\gamma)$,

$$\mathcal{E}_{\alpha,n/\gamma\alpha}^L \left[\frac{J_\kappa^\alpha(x_1,\ldots,x_n)}{J_\kappa^\alpha(I_n)} \right] = 2^k \sum_{(x,y)\in\kappa} \left(\frac{n}{\alpha\gamma} - \frac{x}{\alpha} + y \right).$$

We can now prove the two main results of this section.

Theorem 2.8: *For k an even integer, let*

$$\mathcal{E}_\alpha^H [p_{[k]}(x_1,\ldots,x_n)] = \sum_{j=0}^{k/2} f(\alpha,j) n^{k/2+1-j},$$

with $p_{[k]}$ being the power-sum corresponding, to partition $[k]$. Then $f(\alpha,j)$ is an integer-coefficient polynomial in $1/\alpha$ of degree at most $k/2$ such that

$$f(\alpha,j) = (-\alpha)^{-k+j} f(1/\alpha, j).$$

Remark 2.9: When we scale the ensembles, we have to multiply the expectation by $(2n\beta)^{-k/2} = (\alpha/(4n))^{k/2}$, which means that

$$\frac{1}{n}E_{\alpha}^{H}[p_{[k]}(x_1,\ldots,x_n)]=\frac{1}{2^k}\sum_{j=0}^{k/2}\alpha^{k/2}f(\alpha,j)n^{-j}.$$

The corollary below follows.

Corollary 2.10: It follows that $g(\alpha,j):=\alpha^{k/2}f(\alpha,j)$ *is an integer-coefficient polynomial of* α *for which*

$$g(\alpha,j)=(-\alpha)^j g\left(\frac{1}{\alpha},j\right),$$

so the degree of $g(\alpha,j)$ *is at most* j*. This yields, in particular,* $g(\alpha,1)=c_k(\alpha-1)$*, with* c_k *a constant depending on* k*.*

Similarly, for the Laguerre ensembles, we have the following theorem.

Theorem 2.11: *Let* $a=n/\alpha\gamma$*, and*

$$\mathcal{E}_{\alpha,a}^{L}[p_{[k]}(x_1,\ldots,x_n)]=2^k\sum_{j=1}^{k+1}\sum_{r=0}^{j-1}f(\alpha,j,r)\frac{n^j}{\gamma^r},$$

with $p_{[k]}$ *being the power-sum corresponding to partition* $[k]$*. Then* $f(\alpha,j,r)$ *is a polynomial in* $1/\alpha$ *of degree at most* k *such that*

$$f(\alpha,j,r)=(-\alpha)^{-k-j+1}f(1/\alpha,j,r).$$

Remark 2.12: When we scale the ensembles, we have to multiply the expectation by $(\gamma/(n\beta))^k=(\gamma\alpha/(2n))^k$*, which means that*

$$\frac{1}{n}E_{\alpha,a}^{L}[p_{[k]}(x_1,\ldots,x_n)]=\sum_{j=1}^{k+1}\sum_{r=0}^{j-1}\alpha^k f(\alpha,j,r)n^{-k+j-1}\gamma^{k-r}.$$

The corollary below follows.

Corollary 2.13: It follows that $g(\alpha,j,r)=\alpha^k f(\alpha,j,r)$ *is an integer-coefficient polynomial of* α *for which*

$$g(\alpha,j,r)=(-\alpha)^{k-j+1}g(1/\alpha,j,r),$$

so that the degree of $g(\alpha,j,r)$ *is at most* $k-j+1$*. This yields, in particular,* $g(\alpha,k,r)=c_{k,r}(\alpha-1)$*.*

Proof of Theorem 2.8: Note that $1/\alpha=2/\beta$ and that $p_{[k]}(x_1,\ldots,x_n)=\mathrm{tr}(X^k)$, for any matrix X with eigenvalues $x_1,\ldots,x_n$. By using the unscaled matrix model $H_{\beta,n}$ for the β-Hermite ensembles found in Table II, one can obtain, as in Application 3 of Ref. 11 (more precisely, from Corollary 4.3), that $\mathcal{E}_{\alpha}^{H}[p_{[k]}(x_1,\ldots,x_n)]$ is an integer-coefficient polynomial in $1/\alpha$ of degree $k/2$, and a polynomial in n of degree $k/2+1$. Hence $f(\alpha,j)$ is an integer-coefficient polynomial in $1/\alpha$ of degree at most $k/2$.

Let us now express $p_{[k]}$ in Jack polynomial basis:

$$p_{[k]}=\sum_{\lambda\vdash k}c_{\lambda}(\alpha)J_{\lambda}^{\alpha}, \tag{7}$$

omitting the variables for simplicity.

Let $\mathbb{Q}(\alpha)$ be the field of all rational functions of α with rational coefficients.

Let $\Lambda\times\mathbb{Q}(\alpha)$ be the vector space of all symmetric polynomials of bounded degree with coefficients in $\mathbb{Q}(\alpha)$.

For every $0\neq\theta\in\mathbb{Q}(\alpha)$, define the $\mathbb{Q}(\alpha)$-algebra automorphism $\omega_\theta:\Lambda\times\mathbb{Q}(\alpha)\to\Lambda\times\mathbb{Q}(\alpha)$ by the condition $\omega_\theta(p_k)=(-1)^{k-1}\theta p_k$, for all $k\geqslant 1$. This family of automorphisms appears in [Ref. 28, Chap. 10], and similarly in Ref. 36. In particular, $\omega=\omega_1$ is known as the Macdonald involution (and can be found in [Ref. 28, Chap. 1]).

We will use the following formula due to Stanley,[36] which can also be found as formula (10.24) in Ref. 28:

$$\omega_\alpha J_\kappa^\alpha = \alpha^{|\kappa|} J_{\kappa'}^{1/\alpha}, \tag{8}$$

where κ' is the conjugate partition of κ (obtained from κ by transposing rows and columns in the Young tableau).

The first step of the proof is given by the following lemma.

Lemma 2.14: The coefficients in Eq. (7) satisfy

$$c_\lambda(\alpha) = (-\alpha)^{1-k} c_{\lambda'}(1/\alpha).$$

Proof: We apply ω_α to both sides of (7), and use (7) with parameters α and $1/\alpha$ to obtain

$$\omega_\alpha p_{[\kappa]} = (-1)^{k-1} \alpha p_{[k]} = (-1)^{k-1} \alpha \sum_{\lambda \vdash k} c_\lambda(1/\alpha) J_\lambda^{1/\alpha}.$$

On the other hand, since ω_α is linear, with the help of (8) we write

$$\omega_\alpha p_{[k]} = \sum_{\lambda \vdash k} c_\lambda(\alpha) \alpha^k J_{\lambda'}^{1/\alpha}.$$

Since there is a unique way of writing $\omega_\alpha p_{[k]}$ in Jack polynomial basis, it follows that

$$c_\lambda(\alpha) = (-\alpha)^{1-k} c_{\lambda'}(1/\alpha).$$

□

Remark 2.15: Note that Lemma 2.14 does not say anything about expectations.

We now write the expectation of $p_{[k]}$ over the unscaled Hermite ensemble using (7):

$$\mathcal{E}_\alpha^H[p_{[k]}(x_1, \ldots, x_n)] = \sum_{\lambda \vdash k} c_\lambda(\alpha) J_\lambda^\alpha(I_n) \mathcal{E}_\alpha^H \left[\frac{J_\lambda^\alpha(x_1, \ldots, x_n)}{J_\lambda^\alpha(I_n)} \right].$$

We know (for example, from Ref. 36, Theorem 5.4) that $J_\lambda^\alpha(I_n) = \Pi_{(x,y)\in\lambda}(n - x + \alpha y)$; hence

$$\mathcal{E}_\alpha^H[p_{[k]}(x_1, \ldots, x_n)] = \sum_{\lambda \vdash k} c_\lambda(\alpha) \mathcal{E}_\alpha^H \left[\frac{J_\lambda^\alpha(x_1, \ldots, x_n)}{J_\lambda^\alpha(I_n)} \right] \prod_{(x,y)\in\lambda} (n - x + \alpha y). \tag{9}$$

By Lemma 2.6,

$$\mathcal{E}_\alpha^H \left[\frac{J_\lambda^\alpha(x_1, \ldots, x_n)}{J_\lambda^\alpha(I_n)} \right]$$

does *not* depend on n. Write

$$\prod_{(x,y)\in\lambda} (n - x + \alpha y) = \sum_{j=0}^{|\lambda|} b_\lambda(j, \alpha) n^j,$$

we have

$$\prod_{(x,y)\in\lambda} (n - x + \alpha y) = \prod_{(y,x)\in\lambda'} \left(n + \alpha \left(y - \frac{x}{\alpha} \right) \right),$$

and consequently

$$b_\lambda(j, \alpha) = (-\alpha)^{k-j} b_{\lambda'}(j, 1/\alpha). \tag{10}$$

Using (9) and (10), Lemma 2.14, Lemma 2.6, and substituting $k/2+1-j$ for j (in the power index of n), we obtain the statement of Theorem 2.8. □

Proof of Theorem 2.11: The fact that $f(\alpha,j,r)$ is a polynomial in $1/\alpha$ of degree k follows similarly to Corollary 4.3 in Application 3 of Ref. 11.

We write

$$\mathcal{E}^L_{\alpha,a}[p_{[k]}(x_1,\ldots,x_n)] = \sum_{\lambda\vdash k} c_\lambda(\alpha)\mathcal{E}^L_{\alpha,a}\left[\frac{J^\alpha_\lambda(x_1,\ldots,x_n)}{J^\alpha_\lambda(I_n)}\right]\prod_{(x,y)\in\lambda}(n-x+\alpha y) \tag{11}$$

$$= 2^k\sum_{\lambda\vdash k} c_\lambda(\alpha)\prod_{(x,y)\in\lambda}\left(\frac{n}{\alpha\gamma}-\frac{x}{\alpha}+y\right)\prod_{(x,y)\in\lambda}(n-x+\alpha y). \tag{12}$$

If we write

$$\prod_{(x,y)\in\lambda}\left(\frac{n}{\alpha\gamma}-\frac{x}{\alpha}+y\right) = \sum_{j=0}^{|\lambda|}\tilde{b}_\lambda(j,\alpha)n^j\gamma^{-j},$$

it is not hard to see that

$$\tilde{b}_\lambda(j,\alpha) = (-\alpha)^{-k-j}\tilde{b}_{\lambda'}(j,1/\alpha). \tag{13}$$

Using (10) and (13), and Lemma 2.14, we obtain the statement of Theorem 2.11. □

B. Computing the β-independent part of the deviation

In this section we will examine the deviation at $\beta=\infty$ for the Hermite and Laguerre ensembles. In proving this we employ a simple differential equations trick that will allow us to compute the zero- and first-order terms in the mean of the eigenvalue distributions at $\beta=\infty$.

Given a function $y(x)$ which satisfies the second-order homogeneous differential equation

$$f(x)y''(x)+g(x)y'(x)+h(x)y(x)=0,$$

denote by $m(x)$ the function $m(x)=y'(x)/y(x)$ [with poles at the zeroes of $y(x)$].

Proposition 2.16: The function $m(x)$ satisfies the first-order differential algebraic equation

$$m^2(x)+\frac{g(x)}{f(x)}m(x)+\frac{h(x)}{f(x)}+m'(x)=0.$$

The proof is immediate.

Remark 2.17: If the function $y(x)$ is a polynomial with a finite number k of distinct roots, $m(x)$ is the generating function for the powers of y's roots.

Let $\tilde{H}_{\beta,n}$ and $\tilde{L}^a_{\beta,n}$ denote matrices from the β-Hermite, respectively, β-Laguerre ensembles. As in Ref. 10, to obtain the deviation, we once again will examine the averaged traces of powers of the matrices $\tilde{H}_{\beta,n}$ and $\tilde{L}^a_{\beta,n}$, this time looking at the first-order terms.

As a consequence of Corollaries 2.10 and 2.13, for k an even positive integer in the Hermite case, and k an arbitrary positive integer in the Laguerre case with parameter $a=(n\beta)/(2\gamma)$,

$$\frac{1}{n}E^H_\beta[p_{[k]}(x_1,\ldots,x_n)] = c_k + c^1_k\frac{\frac{2}{\beta}-1}{n}+O(n^{-2}),$$

while

$$\frac{1}{n}E_\beta^{L,a}[p_{[k]}(x_1,\ldots,x_n)] = c_k(\gamma) + c_k^1(\gamma)\frac{\frac{2}{\beta}-1}{n} + O(n^{-2}).$$

It follows that the deviation is given by the moments c_k^1, respectively, $c_k^1(\gamma)$, times the scaling factor $2/\beta-1$. Equivalently, if we examine the generating functions

$$m(n,\beta,x) = \frac{1}{n}E_\beta^H\left[\sum_{i=1}^{n}\frac{1}{x-\lambda_i}\right] = \frac{1}{n}\sum_{k=0}^{\infty}\frac{E_\beta^H[p_{[k]}(x_1,\ldots,x_n)]}{x^{k+1}} = \sum_{k=0}^{\infty}\left(\frac{c_k}{x^{k+1}} + \frac{1}{n}\left(\frac{2}{\beta}-1\right)\frac{c_k^1}{x^{k+1}} + \cdots\right)$$

and $(a=n/\alpha\gamma=n\beta/2\gamma)$

$$m(n,a,\beta,x) = \frac{1}{n}E_{\beta,a}^L\left[\sum_{i=1}^{n}\frac{1}{x-\lambda_i}\right] = \frac{1}{n}\sum_{k=0}^{\infty}\frac{E_{\beta,a}^L[p_{[k]}(x_1,\ldots,x_n)]}{x^{k+1}} = \sum_{k=0}^{\infty}\left(\frac{c_k}{x^{k+1}} + \frac{1}{n}\left(\frac{2}{\beta}-1\right)\frac{c_k^1(\gamma)}{x^{k+1}} + \cdots\right)$$

then in order to find the first-order asymptotics of $m(n,\beta,x)$ and $m(n,a,\beta,x)$, it is enough to compute $\Sigma_{k=0}^{\infty}(c_k^1/x^{k+1})$, respectively, $\Sigma_{k=0}^{\infty}[c_k^1(\gamma)/x^{k+1}]$.

We will do this by keeping n fixed, letting $\beta\to\infty$, and computing the zero- and first-order terms in $1/n$ in the generating function of the resulting matrix ensemble.

Remark 2.18: Knowing that the quantities $(1/n)E_\beta^H[p_{[k]}(x_1,\ldots,x_n)]$ *and* $(1/n)E_\beta^{L,a}[p_{[k]}(x_1,\ldots,x_n)]$ *are polynomial expressions in* $1/n$ *and* $2/\beta$ *(which follows immediately by recalling the results of Theorems 2.8 and 2.11) is the key factor in allowing us to let* $\beta\to\infty$ *while keeping in fixed.*

To aid us in our calculations, we will make use of a beautiful property of the χ_r distribution, which will allow us to replace our tridiagonal models with even simpler ones. We give this property as a Proposition.

Proposition 2.19: Let $\{X_n\}_{n\in\mathbb{N}}$ *be a set of random variables with distributions* χ_{r_n}, $n\in\mathbb{N}$, *such that* $r_n\to\infty$ *as* $n\to\infty$. *Then the sequence* $\{X_n-\sqrt{r_n}\}_{n\in\mathbb{N}}$ *converges in distributions to a centered normal of variance* $1/2$.

It follows then that, as we have already shown in Ref. 12, that given n and $\gamma\leqslant 1$ fixed, the entries of the scaled random matrices $\tilde{H}_{\beta,n}$ and $\tilde{L}_{\beta,n}^a=B_{\beta,n}^a(B_{\beta,n}^a)^T$ [with $a=(n\beta)/(2\gamma)$] converge as $\beta\to\infty$ to the following models:

$$\tilde{H}_{\beta,n}\to H = \frac{1}{2\sqrt{n}}\begin{pmatrix} 0 & \sqrt{n-1} & & & & \\ \sqrt{n-1} & 0 & \sqrt{n-2} & & & \\ & \sqrt{n-2} & 0 & & & \\ & & & \ddots & & \\ & & & & 0 & \sqrt{1} \\ & & & & \sqrt{1} & 0 \end{pmatrix}, \tag{14}$$

respectively, to

$$\tilde{L}^a_{\beta,n} \to L_\gamma = \frac{\gamma}{n}\begin{pmatrix} \frac{n}{\gamma} & \sqrt{\frac{n}{\gamma}}\sqrt{n-1} & & & & \\ \sqrt{\frac{n}{\gamma}}\sqrt{n-1} & \frac{n}{\gamma}+n-2 & \sqrt{\frac{n}{\gamma}-1}\sqrt{n-2} & & & \\ & \sqrt{\frac{n}{\gamma}-1}\sqrt{n-2} & \frac{n}{\gamma}+n-3 & & & \\ & & \ddots & & & \\ & & & \sqrt{\frac{n}{\gamma}-n+2}\sqrt{2} & & \\ & & \sqrt{\frac{n}{\gamma}-n+2}\sqrt{2} & \frac{n}{\gamma}-n+4 & \sqrt{\frac{n}{\gamma}-n+1}\sqrt{1} & \\ & & & \sqrt{\frac{n}{\gamma}-n+1}\sqrt{1} & \frac{n}{\gamma}-n+2 & \end{pmatrix}. \tag{15}$$

Note also that if we denote by $\tilde{B}^a_{\beta,n}$ the matrix such that $\tilde{L}^a_{\beta,n}=\tilde{B}^a_{\beta,n}(\tilde{B}^a_{\beta,n})^T$, then

$$\tilde{B}^a_{\beta,n} \to B_\gamma = \sqrt{\frac{\gamma}{n}}\begin{pmatrix} \sqrt{\frac{n}{\gamma}} & & & & \\ \sqrt{n-1} & \sqrt{\frac{n}{\gamma}-1} & & & \\ & \sqrt{n-2} & \sqrt{\frac{n}{\gamma}-2} & & \\ & & \ddots & & \\ & & \sqrt{2} & \sqrt{\frac{n}{\gamma}-n+2} & \\ & & & \sqrt{1} & \sqrt{\frac{n}{\gamma}-n+1} \end{pmatrix} \tag{16}$$

and that $L_\gamma=B_\gamma B_\gamma^T$.

Since H, L_γ, and b_γ are *non-random* matrices, all expectations are exact.

1. $\beta=\infty$, Hermite case

The matrix H (see (14)) has as eigenvalues $h_1/\sqrt{2n},\ldots,h_n/\sqrt{2n}$, where $h_1,\ldots,h_n$ are the roots of the nth Hermite polynomial $H_n(x)$ (this can be easily deduced from the three-term recurrence for the Hermite polynomials, see, for example, Ref. 42). For a more detailed description of the properties of this matrix, see Ref. 12.

It follows that the generating function we need to compute is

$$\tilde{m}(n,x) = \frac{1}{n}\sum_{i=1}^{n} \frac{1}{x - \frac{h_i}{\sqrt{2n}}}.$$

We use the well-known identity

$$\sum_{i=1}^{n} \frac{1}{x-x_i} = \frac{p'(x)}{p(x)}, \tag{17}$$

where x_i are distinct values, and $p(x)$ is the polynomial whose roots the x_i's are, to obtain that

$$\tilde{m}(n,x) = \sqrt{\frac{n}{2}}\frac{H_n'(x\sqrt{2n})}{H_n(x\sqrt{2n})},$$

and by applying Proposition 2.16 to the second-order differential equation satisfied by the Hermite polynomials (for a reference, see Ref. 42), we get that $\tilde{m}(n,x)$ satisfies the algebraic differential equation

$$(\tilde{m}(n,x))^2 - 4x\tilde{m}(n,x) + 4 + \frac{\tilde{m}'(n,x)}{n} = 0. \tag{18}$$

Writing $\tilde{m}(n,x) = m_0(x) - (1/n)m_1(x) + O(n^{-2})$, we obtain from (18) that

$$m_0(x) = 2(x - \sqrt{x^2-1}),$$

$$m_1(x) = \frac{(x - \sqrt{x^2-1})}{2(x^2-1)}.$$

Computing the inverse Cauchy transform for $m_0(x)$ and $m_1(x)$ yields the semicircle distribution and, respectively,

$$\mu_H(x) = \begin{cases} \frac{1}{4}(\delta_1(x) + \delta_{-1}(x)) - \frac{1}{2\pi}\frac{1}{\sqrt{1-x^2}} & \text{if } x \in [-1,1] \\ 0 & \text{otherwise.} \end{cases} \tag{19}$$

We have thus proved the following result.

Lemma 2.20: For any polynomial P,

$$E_\beta^H\left[\sum_{i=1}^n P(x_i)\right] - n\int_{-1}^1 P(x)s(x)\mathrm{d}x \to \left(\frac{2}{\beta} - 1\right)\int_{-1}^1 P(x)\mu_H(x)\mathrm{d}x,$$

as $n \to \infty$.

Remark 2.21: As a side note, in the computation above we have provided yet another way to obtain the semicircle law for all β.

2. $\beta = \infty$, Laguerre case

The matrix L_γ has as eigenvalues $\gamma l_1/n, \ldots, \gamma l_n/n$, where $l_1, \ldots, l_n$ are the roots of the nth Laguerre polynomial $L_n^{n(1/\gamma - 1)}(x)$ (see Ref. 43) (this can be easily deduced from one of the many recurrences for Laguerre polynomials, found for example as (26) in Ref. 43). To get a more detailed description of the properties of this matrix, refer to Ref. 12, substituting $n(1/\gamma) - 1$ for γ.

Since we need to rescale the eigenvalues by an additional n, it follows that the quantity of interest is

$$\tilde{m}(n,\gamma,x) = \frac{1}{n}\sum_{i=1}^n \frac{1}{x - \frac{\gamma l_i}{n}},$$

Once again we use identity 17 and obtain that

$$\tilde{m}(n,\gamma,x)=\frac{1}{n}\frac{(L_n^{n(1/\gamma-1)})'\left(\frac{xn}{\gamma}\right)}{L_n^{n(1/\gamma-1)}\left(\frac{xn}{\gamma}\right)},$$

and by applying Proposition 2.16 to the second-order differential equation satisfied by Laguerre polynomials (for a reference, see Ref. 43), we get that $\tilde{m}(n,\gamma,x)$ satisfies the algebraic differential equation

$$\gamma(\tilde{m}(n,\gamma,x))^2-\tilde{m}(n,\gamma,x)\left(1-\frac{1}{x}+\frac{\gamma}{x}\right)+\frac{1}{x}+\frac{\gamma\tilde{m}'(n,\gamma,x)+\frac{\gamma\tilde{m}(n,\gamma,x)}{x}}{n}=0. \tag{20}$$

Writing $\tilde{m}(n,\gamma,x)=m_0(x)-(1/n)m_1(x)+O(n^{-2})$, we obtain from (20) that

$$m_0(x)=\frac{x+\gamma-1-\sqrt{(x-(\sqrt{\gamma}-1)^2)(x-(\sqrt{\gamma}+1)^2)}}{2\gamma x},$$

$$m_1(x)=\frac{x-\gamma-1-\sqrt{(x-(\sqrt{\gamma}-1)^2)(x-(\sqrt{\gamma}+1)^2)}}{2(x-(\sqrt{\gamma}-1)^2)(x-(\sqrt{\gamma}+1)^2)}.$$

By calculating the inverse Cauchy transforms of $m_0(x)$ and $m_1(x)$, one obtains the Marčenko-Pastur distribution, respectively,

$$t_\gamma(x)=\begin{cases}\frac{1}{4}\delta_b(x)+\frac{1}{4}\delta_a(x)-\frac{1}{2\pi}\frac{1}{\sqrt{(x-a)(b-x)}} & \text{if } x\in[a,b]\\ 0 & \text{otherwise,}\end{cases} \tag{21}$$

with $a=(\sqrt{\gamma}-1)^2$, $b=(\sqrt{\gamma}+1)^2$.

We have thus proved the following result.

Lemma 2.22: For any polynomial P,

$$E_{\beta,a}^L\left[\sum_{i=1}^n P(x_i)\right]-n\int_a^b P(x)e_\gamma(x)\mathrm{d}x\to\left(\frac{2}{\beta}-1\right)\int_a^b P(x)t_\gamma(x)\mathrm{d}x,$$

as $n\to\infty$.

III. FLUCTUATION OF THE SEMICIRCLE AND MARČENKO-PASTUR LAWS

In this section we compute the fluctuations terms for the β-Hermite and β-Laguerre ensembles; we show that the fluctuation of the trace of any given power of the matrix corresponding to the ensemble approaches in distribution a normal variable.

The essence of the argument is simple. We will think of the random matrix as the sum between the non-random matrix of means (which we can also think about *roughly* as the $\beta=\infty$ non-random matrix) and a random matrix of the centered entries, and do some obvious computations of traces of powers. Much of the work goes into the technical carefulness to provide a complete argument, but the readers should not let the details draw them away from the simplicity of the idea, which is based on the matrix formula

$$\mathrm{tr}(T^k)=\sum_{i_1,\ldots,i_k}t_{i_1i_2}t_{i_2i_3}\cdots t_{i_ki_1},$$

with the proviso that the above-noted sum is especially simple when the matrix $T=(t_{ij})_{i,j}$ is symmetric and tridiagonal.

We provide here a heuristic explanation for the Hermite case, just for the purpose of emphasizing that the main idea is simple.

One can think of the random matrix, for all practical purposes, as

$$T \approx T_{\beta=\infty} + \frac{1}{\sqrt{\beta n}} G,$$

where G is a symmetric tridiagonal matrix of $O(1)$-variance Gaussians (similar to the decomposition we used in Ref. 12), with entries which are mutually independent, up to the symmetry condition.

Then for any polynomial h,

$$\mathrm{tr}(h(T)) \approx \mathrm{tr}(h(T_{\beta=\infty})) + \frac{1}{\sqrt{\beta n}} \mathrm{tr}(h'(T_{\beta=\infty})G),$$

the second term is clearly normally distributed, and all we have to do is compute the variance and show it is finite (which we can achieve by examining the cases when h is a monomial).

It is worth noting that, in principle, one should be able to do this computation for continuously differentiable functions h with some additional conditions imposed by the fact that the variance needs to be finite.

The technicalities arise because $n \to \infty$ and the above-mentioned equalities are just approximations, but this should not detract from the main idea. Using the method of moments, we will show that we do *not* need G's entries to be Gaussian (or even *approximately* Gaussian) in order for the *fluctuation* to monomials h to be Gaussian.

A. The β-Hermite case

We write the scaled matrix $\widetilde{H}_{\beta,n}$ as

$$\widetilde{H}_{\beta,n} = A + \frac{1}{\sqrt{n\beta}} Y, \tag{22}$$

where $A = E^H_\beta[\widetilde{H}_{\beta,n}]$ is the symmetric tridiagonal matrix of mean entries $(A(i,i+1) = (1/(2\sqrt{n\beta}))E[\chi_{(n-i)\beta}]$; all other entries are 0), and Y is symmetric tridiagonal matrix of centered variables (with a diagonal of independent Gaussians of variance 1/2). Technically, A and Y depend both on n and on β; we drop these indices from notation for the sake of simplicity.

Remark 3.1: From Proposition 2.19, we know that if $A = (a_{ij})_{1 \leq i,j \leq n}$, *then for any* $\epsilon > 0$, *there exists* $i_\epsilon \in \mathbb{N}$ *such that*

$$(2\sqrt{n\beta}a_{i,i+1} - \sqrt{(n-i)\beta}) < \epsilon \text{ for any } i \leq (n - i_\epsilon),$$

and that $Y_{i,i+1} \to N(0, 1/8)$ *in distribution as* $i \to \infty$, *while* $Y_{i,i} \sim N(0, 1/2)$ *for all* i.

Remark 3.2: (bounded moments) Note that the entries of A are **bounded**, *both from below and from above; we will think of them as* $O(1)$. *Similarly, for any* k *and* l *finite, we know from the above that there exists an* M *such that*

$$E\left[\prod_{i=1}^{kl} Y_{j_i j'_i}^{c_i}\right] \leq M,$$

for all $0 \leq c_i \leq kl$, *and for all* $j_1, \ldots, j_{kl}$ *and* $j'_1, \ldots, j'_{kl}$ *such that* $|j_i - j'_i| \leq 1$.

Given integers k and n, consider the random variable

$$\omega_k(n) = \mathrm{tr}(\widetilde{H}^k_{\beta,n}) - E^H_\beta[\mathrm{tr}(\widetilde{H}^k_{\beta,n})].$$

Claim 3.2.1: For any fixed integers k *and* l,

$$\lim_{n\to\infty} E[(\omega_k(n))^l] = \begin{cases} \left(\frac{2}{\beta}\right)^{l/2} \frac{(l-1)!!}{2^{(k+1)l}} k^{l/2} \left(\begin{matrix} k \\ \frac{k}{2} \end{matrix}\right)^l & \text{if } k, l \text{ are even} \\ \left(\frac{2}{\beta}\right)^{l/2} \frac{(l-1)!!}{2^{kl}} k^{l/2} \left(\begin{matrix} k-1 \\ \frac{k-1}{2} \end{matrix}\right)^l & \text{if } k \text{ is odd and } l \text{ is even} \\ 0 & \text{if } l \text{ is odd.} \end{cases}$$

Claim 3.2.2: For any fixed integers k_1 and k_2,

$$\lim_{n\to\infty} \mathrm{Cov}(\omega_{k_1}(n), \omega_{k_2}(n)) = \begin{cases} \frac{2}{\beta} \frac{1}{2^{k_1+k_2}} \frac{2k_1k_2}{k_1+k_2} \left(\begin{matrix} k_1-1 \\ \frac{k_1-1}{2} \end{matrix}\right) \left(\begin{matrix} k_2 \\ \frac{k_2-1}{2} \end{matrix}\right) & \text{if } k_1, k_2 \text{ are odd} \\ \frac{2}{\beta} \frac{1}{2^{k_1+k_2+2}} \frac{2k_1k_2}{k_1+k_2} \left(\begin{matrix} k_1 \\ \frac{k_1}{2} \end{matrix}\right) \left(\begin{matrix} k_2 \\ \frac{k_2}{2} \end{matrix}\right) & \text{if } k_1, k_2 \text{ are even} \\ 0 & \text{otherwise.} \end{cases}$$

Remark 3.3: Claims 3.2.1 and 3.2.2 show that the centered fluctuation of the β-Hermite ensembles describes the Gaussian process on monomials defined in Theorem 1.2.

For the remainder of this section, we will prove Claims 3.2.1 and 3.2.2. To give the reader a rough idea of where the calculations will lead, we provide in the following an intuition of what we will be doing.

Intuitive explanation: The first step is to note that $\mathrm{tr}(T^k)$ is a sum of products of k entries of T; for a tridiagonal matrix $T=(t_{i,j})_{1\leq i,j\leq n}$ with $t_{i,j}=0$ if $|i-j|>1$,

$$\mathrm{tr}(T^k) = \sum_{1\leq i_1,\ldots,i_k\leq n} t_{i_1,i_2} t_{i_2,i_3} \ldots t_{i_k,i_1},$$

where the sum needs to be taken only over the sequences $i_1,\ldots,i_k$ such that $|i_j-i_{j+1}|\leq 1$, for all $j=1,\ldots,k-1$, and also $|i_k-i_1|\leq 1$.

We have a sliding "window" of size k down the diagonal of the matrix T in which we take products of powers of the elements. In particular, for the matrix A, this is easy to visualize, because with the exception of a finite bottom right corner, the entries of A in any finite window look roughly the same.

The second step is to identify the significant terms, i.e., the terms that have non-zero asymptotical contributions. Roughly speaking, these will be the terms which will contain *precisely* one element of Y, and all the others from A. Nothing surprising here, as Y is scaled by $1/\sqrt{n\beta}$ (see (22)).

Finally, we will compute the contribution from the significant terms and show it agrees with the result of Claim 3.2.1. Then we will note that the same reasoning yields the result of Claim 3.2.2.

We now proceed to make the above-noted intuitive description rigorous. We need to introduce some notation.

Definition 3.4: For given n and p, we denote by $\mathcal{S}_{n,p}\subset\{1,\ldots,n\}^p$ the set of sequences of integers $i_1,\ldots,i_p$ such that $(i_1,\ldots,i_p)\in\{1,\ldots,n\}^p$ and $|i_j-i_{j+1}|\leq 1$ for all $j=1,\ldots,p-1$, and also $|i_p-i_1|\leq 1$.

We denote by $\mathcal{I}$ an element of $\mathcal{S}_{n,p}$, and we denote by

$$(T)_{\mathcal{I}} := t_{i_1,i_2} t_{i_2,i_3} \cdots t_{i_p,i_1},$$

where $(i_1,i_2,\ldots,i_p)=:\mathcal{I}$.

For a given $\mathcal{I} \in \mathcal{S}_{n,p}$, note that we can break up the sequence $(i_1, \ldots, i_p)$ into concatenations of sequences

$$J = ((i_{p_0}, \ldots, i_{p_1}), (i_{p_2}, \ldots, i_{p_3}), (i_{p_4}, \ldots, i_{p_5}), \ldots, (i_{p_{2q}}, \ldots, i_{p_{2q+1}})),$$

and

$$R = ((i_{p_1}, \ldots, i_{p_2}), (i_{p_3}, \ldots, i_{p_4}), \ldots, (i_{p_{2q-1}}, \ldots, i_{p_{2q}})),$$

such that in each of the sequences $i_{p_{2k}}, i_{p_{2k}}+1, \ldots, i_{p_{2k+1}}$ (for $k=0, \ldots, q$) which form J, consecutive indices differ by exactly 1, and in addition to this

$$(i_1, \ldots, i_p) = (i_{p_0}, \ldots, i_{p_1}, i_{p_1+1}, \ldots, i_{p_2}, i_{p_2+1}, \ldots, i_{p_3}, \ldots, i_{p_{2q+1}}).$$

We allow for the possibility of having empty sequences $i_{p_0}, \ldots, i_{p_1}$ in the beginning and/or $i_{p_{2q}}, \ldots, i_{p_{2q+1}}$ in the end of J.

Remark 3.5: To give an intuition for these sequences, note that any term in $\mathrm{tr}((H_{\beta,n})^k)$ *can be thought of in terms of products of entries from A and entries from Y*; *the sequences J and R will be overlapping "runs" recording the former, respectively, the latter.*

Also note that, given a fixed $\mathcal{I}$, *each J satisfying the requirements above has exactly one* $R = R(J)$ *corresponding to it, and that to different R's correspond different J's. Furthermore, since k is finite, a given R may be associated only to a finite number of sequences* $\mathcal{I}$ (*since all indices must be within k of each other*).

Definition 3.6: We define the set $\mathcal{J} = \mathcal{J}(\mathcal{I})$ *as the set of pairs* (J,R) *that corresponds to a given* $\mathcal{I}$. *For a tridiagonal matrix T, we define*

$$(T)_J = t_{i_{p_0}, i_{p_0}+1} \cdots t_{i_{p_1}-1, i_{p_1}} t_{i_{p_2} i_{p_2}+1} \cdots t_{i_{p_3}-1, i_{p_3}} \cdots t_{i_{2q}, i_{2q}+1} \cdots t_{i_{2p+1}-1, i_{2q+1}},$$

similarly,

$$(T)_R = t_{i_{p_1}, i_{p_1}+1} \cdots t_{i_{p_2}-1, i_{p_2}} t_{i_{p_3} i_{p_3}+1} \cdots t_{i_{p_4}-1, i_{p_4}} \cdots t_{i_{2q-1}, i_{2q-1}+1} \cdots t_{i_{2q}-1, i_{2q}}.$$

For any sequence $\mathcal{I} \in \mathcal{S}_{n,p}$, we can write

$$(\tilde{H}_{\beta,n})_{\mathcal{I}} = \left(A + \frac{1}{\sqrt{n\beta}} Y \right)_{\mathcal{I}} = \sum_{(J,R) \in \mathcal{J}} \frac{1}{(n\beta)^{P/2}} (A)_J (Y)_R, \tag{23}$$

with P being the total length of the "runs" in the sequence R (i.e., $P = (p_2 - p_1 + 1) + (p_4 - p_3 + 1) + \cdots + (p_{2q} - p_{2q-1} + 1)$).

We have now enough information to start the proof of Claim 3.2.1.

Proof of Claim 3.2.1: First we examine

$$E[(\omega_k(n))^l] = E[(\mathrm{tr}(\tilde{H}^k_{\beta,n}) - E^H_\beta[\mathrm{tr}(\tilde{H}^k_{\beta,n})])^l],$$

note that

$$E[(\omega_k(n))^l] = E\left[\sum_{\mathcal{I}_1, \ldots, \mathcal{I}_l \in \mathcal{S}_{n,k}} \prod_{j=1}^{l} ((\tilde{H}_{\beta,n})_{\mathcal{I}_j} - E[(\tilde{H}_{\beta,n})_{\mathcal{I}_j}]) \right].$$

Using (23), we write

$$E[(\omega_k(n))^l] = E\left[\sum_{\substack{\mathcal{I}_j \in \mathcal{S}_{n,k} \\ 1 \leqslant j \leqslant l}} \sum_{(J_j, R_j) \in \mathcal{J}_j} \frac{1}{(n\beta)^{P_j/2}} \prod_{j=1}^{l} ((A)_{J_j} (Y)_{R_j} - E[(A)_{J_j} (Y)_{R_j}]) \right]. \tag{24}$$

Since A is a non-random matrix, it follows that we can rewrite (24) as

$$E[(\omega_k(n))^l] = \sum_{\substack{\mathcal{I}_j \in \mathcal{S}_{n,k} \\ 1 \leqslant j \leqslant l}} \sum_{(J_j,R_j) \in \mathcal{J}_j} \left(\prod_{j=1}^{l} \frac{1}{(n\beta)^{P_j/2}} (A)_{J_j} \right) E\left[\prod_{j=1}^{l} ((Y)_{R_j} - E[(Y)_{R_j}]) \right]. \tag{25}$$

Denoting by $q = q(\mathcal{I}_1, \ldots, \mathcal{I}_l) := \Sigma_{j=1}^{l} P_j/2$, we obtain that

$$E[(\omega_k(n))^l] = \sum_{\substack{\mathcal{I}_j \in \mathcal{S}_{n,k} \\ 1 \leqslant j \leqslant l}} \sum_{(J_j,R_j) \in \mathcal{J}_j} \frac{1}{(n\beta)^q} \left(\prod_{j=1}^{l} (A)_{J_j} \right) E\left[\prod_{j=1}^{l} ((Y)_{R_j} - E[(Y)_{R_j}]) \right]. \tag{26}$$

Lemma 3.7: The non-zero terms in (26) have $q \geqslant l/2$.

Proof: If any of the l terms in the product $\Pi_{j=1}^{l}((Y)_{R_j} - E[(Y)_{R_j}])$ involves only variables that are independent from all other variables appearing in the remaining $l-1$ terms of the product, the expected value of the product is 0. This includes the case when at least one of the R_j's is empty. Hence, in all of the terms that have non-zero contribution to the expectation, each R_j must be non-empty, and thus $2q = \Sigma_{j=1}^{l} P_j \geqslant l$. □

Remark 3.8: Note that in fact something stronger follows, namely, that for each $1 \leqslant j_1 \leqslant l$, *there exists an* $1 \leqslant j_2 \leqslant n$, $j_2 \neq j_1$, *such that the some variable appearing in* $(Y)_{R_{j_1}}$ *also appears in* $(Y)_{R_{j_2}}$.

Since the entries of A are $O(1)$, and k and l are fixed, the factors $\Pi_{j=1}^{l}(A)_{J_j}$ are all $O(1)$. By Remark 3.8 and Lemma 3.7, it follows that every term with non-zero contribution in the double sum (26) corresponds to an l-tuple $(R_1, \ldots, R_l)$ with the property described in Remark 3.8. Each such l-tuple comes with a weight proportional to $1/n^q$.

To compute the asymptotics of the sum, we will do the following thought experiment: select a non-zero contribution term and draw the "correlation" graph with R_j as vertices, and an edge between R_{j_1} and R_{j_2} if and only if $(Y)_{R_{j_1}}$ and $(Y)_{R_{j_2}}$ are correlated (i.e., share variables). The resulting graph will have s connected components, with $1 \leqslant s \leqslant \lfloor l/2 \rfloor$.

Call these connected components $C_1, \ldots, C_s$. Consider now the set of variables $V_1, \ldots, V_s$, such that $v \in V_i$ if and only if there is an R_j in C_i such that v appears in $(Y)_{R_j}$. Select from each V_i a single variable; these variables will be independent. A variable corresponds to a choice of one index and three possibilities (since it will be of the form $Y_{i,i+1}$, $Y_{i+1,i}$, or $Y_{i,i}$).

If we were to choose a set of s independent variables from Y, roughly, to how many such l-tuples $(R_1, \ldots, R_l)$ would this choice correspond, and in turn, to how many sequences $\mathcal{I}_1, \ldots, \mathcal{I}_l$ do these correspond? In other words, to how many non-zero contribution terms in the sum (26) can a choice of s independent variables correspond?

The answer is $O(1)$.

Indeed, by the way we defined $\mathcal{I}$ and R, it follows that, once we have chosen a variable $v \in V_i$, for all other variables in V_i we have a finite number of corresponding indices to choose from. This happens because the correlation of R_j's induces a "clustering" of variables (since all indices must be within $|V_i| \times (k+1) \leqslant l(k+1)$ of each other).

Hence, for each of the possible $O(n^s)$ choices of s "representative" variables, we have only $O(1)$ possible non-zero contribution terms in the sum (26).

Going backwards, it follows that for any s, there are $O(n^s)$ terms for which the correlation graph has s components. Since each of these terms has weight at most $1/n^q \leqslant 1/n^{l/2}$, we have proved the following lemma.

Lemma 3.9: The contribution to the expectation sum (26) from all terms with $s < l/2$ *or* $q > l/2$ *is asymptotically negligible*.

Thus, the only terms of asymptotical significance are those for which $s = q = l/2$. If l is odd, this immediately implies

Lemma 3.10: With the notations above, for k and l fixed, l odd,

$$\lim_{n \to \infty} E[\omega_k(n)^l] = 0.$$

Let us examine what happens when l is even and $s=q=l/2$. Such terms are easy to understand: they correspond precisely to l-tuples $(R_1,\ldots,R_l)$ for which $|R_j|=1$ for all j, and for each $1\leqslant j_1\leqslant l$ there exists a unique $1\leqslant j_2\leqslant l$ such that $(Y)_{R_{j_1}}=(Y)_{R_{j_2}}$.

We make the following simple observation.

Lemma 3.11: The number of diagonal terms $Y_{i,i}$ contained in each $(Y)_{R_j}$, counting multiplicities, has to have the same parity as k.

Proof: Indeed, by the definition of any R, all the diagonal terms found in $(\tilde{H}_{\beta,n})_{\mathcal{I}}$ must be found in $(Y)_R$. The parity of these terms, counting multiplicities, has to be the same as the parity of k. This is easy to see; if $\mathcal{I}=(i_1,i_2,\ldots,i_k)$, then by Definition 3.6

$$i_1-i_2+i_2-i_3+\cdots+i_{k-1}-i_k+i_k-i_1=0,$$

and since each difference i_j-i_{j+1} above is either 0, 1, or −1, it follows that the number of differences equal to 0 has the same parity as k. The number of differences equal to 0 is the number of diagonal terms. □

It then follows that, for all l-tuples of $(R_1,\ldots,R_l)$ for which $s=q=l/2$,

- if k is odd, all variables present in the $(Y)_{R_j}$'s are diagonal variables, and
- if k is even, all variables present in the $(Y)_{R_j}$'s are off-diagonal variables.

We summarize here what we now know about the terms we need to study when l is even.

Lemma 3.12: The only asymptotically relevant terms have the property that there exist $l/2$ distinct indices $i_1,\ldots,i_{l/2}$ such that for each i_j there exist precisely two values $j_1<j_2$ for which

1. *if k is odd, $R_{j_1}=R_{j_2}=\{(i_j,i_j)\}$,*
2. *if k is even, either one of these four possibilities:*
   - $R_{j_1}=R_{j_2}=\{(i_j,i_j+1)\}$, *or*
   - $R_{j_1}=R_{j_2}=\{(i_j+1,i_j)\}$, *or*
   - $R_{j_1}=\{(i_j,i_j+1)\}$ *and* $R_{j_2}=\{(i_j+1,i_j)\}$, *or*
   - $R_{j_1}=\{(i_j+1,i_j)\}$ *and* $R_{j_2}=\{(i_j,i_j+1)\}$.

Note that in this case, $(Y)_{R_{j_1}}=(Y)_{R_{j_2}}$, because the matrix is symmetric. We call all such terms **significant**.

We will now need a stronger result than Remark 3.2.

Lemma 3.13: For any given $\epsilon>0$ and $k,l\in\mathbb{N}$, with l even, there exists some $i_\epsilon\in\mathbb{N}$ such that for any significant term $(\Pi_{j=1}^{l}(A)_{j_i})E[\Pi_{j=1}^{l}((Y)_{R_i}-E[(Y)_{R_i}])]$ and the corresponding $l/2$-tuplet $(i_1,\ldots,i_{l/2})$, if $k\leqslant i_1,\ldots,i_{l/2}\leqslant n-i_\epsilon$, then

- *if k is odd,*

$$\left|\left(\prod_{j=1}^{l}(A)_{J_j}\right)E\left[\prod_{j=1}^{l}((Y)_{R_j}-E[(Y)_{R_j}])\right]-\frac{1}{2^{(k-1)l+l/2}}\prod_{m=1}^{l/2}\left(1-\frac{i_m}{n}\right)^{k-1}\right|<\epsilon;$$

- *if k is even,*

$$\left|\left(\prod_{j=1}^{l}(A)_{J_j}\right)E\left[\prod_{j=1}^{l}((Y)_{R_j}-E[(Y)_{R_j}])\right]-\frac{1}{2^{(k-1)l+3l/2}}\prod_{m=1}^{l/2}\left(1-\frac{i_m}{n}\right)^{k-1}\right|<\epsilon.$$

Proof: The lemma follows easily from Proposition 2.19 and Remark 3.1, together with the fact that if R_j contains the index i, then all indices present in J_j are within k of i. □

We prove now that it is enough to look at the significant terms for which $n-i_\epsilon\geqslant i_1,\ldots,i_{l/2}\geqslant k$ (i.e., those covered by Lemma 3.13).

Lemma 3.14: The contribution of significant terms for which some $i_j>n-i_\epsilon$ or $i_j<k$ is asymptotically negligible, i.e., $o(1)$.

Proof: Each contribution from a significant term

$$\left(\prod_{j=1}^{l}(A)_{J_j}\right)E\left[\prod_{j=1}^{l}((Y_{R_j}-E[(Y)_{R_j}])\right]$$

is bounded by some constant $\tilde{M}$, by Lemmas 3.2 and 3.1. Since restricting a choice of i_j to be greater than $n-i_\epsilon$ or less than k yields a finite number of choices for that particular i_j, and since $j<l$ is finite, it follows that there are only $O(n^{l/2-1})$ such restricted terms. But since the contribution of any such term is weighted by $1/n^{l/2}$, the statement of the lemma follows. □

So we have reduced the computation to examining the contribution from the terms for which $n-i_\epsilon \geqslant 1,\ldots,i_{l/2}\geqslant k$. Assume w.l.o.g $i_\epsilon > k$ (we can always choose a smaller ϵ).

Given an ordered $l/2$-tuplet of distinct indices $n-i_\epsilon\geqslant 1,\ldots,i_{l/2}\geqslant k$, how many terms can correspond to them? First, there are $(l-1)!!$ ways of pairing these indices to the R_j's in this order. Second, once the pairing is given,

- for k odd, the corresponding $\mathcal{I}_j$ sequence must be a sequence where all but one consecutive difference are ± 1 (the one difference that is 0 corresponds to the insertion of the diagonal term). There are $\left(k\binom{k-1}{(k-1)/2}\right)$ such choices for each $\mathcal{I}_j$, for a total of $\left(k\binom{k-1}{(k-1)/2}\right)^l$ choices.
- for k even, the corresponding $\mathcal{I}_j$ sequence must be a sequence where all consecutive difference are ± 1, and one of these differences corresponding to the "marked" term that belongs to R_j. Taking into account all four possible cases, we obtain a total number of $k^2\binom{k}{k/2}^2$ for each pair of matched $\mathcal{I}_j$'s, and thus a total number of $\left(k\binom{k}{k/2}\right)^{l/2}$ choices.

Note that in either one of the two above-mentioned cases, all choices of sequences are valid, because the indices in each sequence will stay between 1 and n (this is where we need that all $k\leqslant i_j\leqslant n-i_\epsilon$).

Thus, the total number of significant terms which correspond to a given ordered $l/2$-tuplet of distinct indices $n-i_\epsilon\geqslant 1,\ldots,i_{l/2}\geqslant k)$ is

- $(l-1)!!\left(k\binom{k-1}{(k-1)/2}\right)^l$ if k is odd, and
- $(l-1)!!\left(k\binom{k}{k/2}\right)^l$ if k is even.

From Lemmas 3.9, 3.12, 3.13, and 3.14, we obtain that for any given ϵ, if k is odd,

$$E[(\omega_k(n))^l]=\sum_{\substack{\text{all significant terms}\\ \text{with } k\leqslant i_j\leqslant n-i_\epsilon\forall j}}\frac{1}{(n\beta)^q}\left(\prod_{j=1}^{l}(A)_{J_j}\right)E\left[\prod_{j=1}^{l}((Y)_{R_j}-E[(Y)_{R_j}])\right]+o(1),$$

and so

$$\left|E[(\omega_k(n))^l]-(l-1)!!\left(k\binom{k-1}{\frac{k-1}{2}}\right)^l\frac{1}{2^{kl-l/2}}\sum_{\substack{\text{all significant terms}\\ \text{with } k\leqslant i_j\leqslant n-i_\epsilon\forall j}}\frac{1}{(n\beta)^{l/2}}\prod_{j=1}^{l/2}\left(1-\frac{i_j}{n}\right)^{k-1}\right|$$

$$\leqslant(l-1)!!\left(k\binom{k-1}{\frac{k-1}{2}}\right)^l\frac{1}{2^{kl-l/2}}\sum_{\substack{n-i_\epsilon\geqslant i_1,\ldots,i_{l/2}\geqslant k\\ \text{all } i_j \text{ distinct}}}\frac{1}{(n\beta)^{l/2}}\epsilon+o(1)$$

$$=(l-1)!!\left(k\binom{k-1}{\frac{k-1}{2}}\right)^l\frac{1}{2^{kl-l/2}}\epsilon(1+o(1))+o(1)=(l-1)!!\left(k\binom{k-1}{\frac{k-1}{2}}\right)^l\frac{1}{2^{kl-l/2}}\epsilon(1+o(1)).$$

Since ϵ was arbitrarily small, it follows that if we can compute

$$S = (l-1)!!\left(k\binom{k-1}{\frac{k-1}{2}}\right)^l \frac{1}{2^{kl-l/2}} \sum_{\substack{n-i_\epsilon \geqslant i_1,\ldots,i_{l/2}\geqslant k \\ \text{all } i_j \text{ distinct}}} \frac{1}{(n\beta)^{l/2}} \prod_{j=1}^{l/2} \left(1-\frac{i_j}{n}\right)^{k-1},$$

we are done. But, since l and k are fixed, the sum in S is asymptotically the same as the value of the integral $((1/\beta)\int_0^1 (1-x)^{k-1}\mathrm{d}x)^{l/2}$, hence

$$\sum_{\substack{n-i_\epsilon \geqslant i_1,\ldots,i_{l/2}\geqslant k \\ \text{all } i_j \text{ distinct}}} \frac{1}{(n\beta)^{l/2}} \prod_{j=1}^{l/2} \left(1-\frac{i_j}{n}\right)^{k-1} \sim \frac{1}{\beta^{l/2}} \frac{1}{k^{l/2}},$$

hence

$$E[(\omega_k(n))^l] - \left(\frac{2}{\beta}\right)^{l/2} \frac{(l-1)!!}{2^{kl}} k^{l/2} \binom{k-1}{\frac{k-1}{2}}^l = O(\epsilon),$$

for arbitrarily small ϵ.

Similarly, for k even, we obtain through the same sort of calculation that

$$E[(\omega_k(n))^l] - \left(\frac{2}{\beta}\right)^{l/2} \frac{(l-1)!!}{2^{(k+1)l}} k^{l/2} \binom{k}{\frac{k}{2}}^l = O(\epsilon),$$

for arbitrarily small ϵ.

Claim 3.2.1 is thus proved. □

Proof of Claim 3.2.2: The proof is based on the same idea as the proof of Claim 3.2.1; the same reasoning applies to yield the asymptotical covariance result. □

Remark 3.15: Note that we never actually used the full power of the fact that the entries of the tridiagonal symmetric matrix Y tend to independent centered **normal** *variables. We only used the following three properties:*

- $E[Y_{i,i}] = E[Y_{i+1,i}] = 0$;
- $\mathrm{Var}[Y_{i,i}] = \frac{1}{2}$, *while* $\lim_{n\to\infty} \mathrm{Var}[Y_{i+1,i}] = \frac{1}{8}$;
- *for any k, there exists a number* $M_k > 0$ *such that* $|E[(Y_{i,j})^k]| < M_k$, *for all* $1 \leqslant i, j \leqslant n$ (*boundedness of moments*).

B. The β-Laguerre case

Given an integer k, consider the random variable

$$\eta_{k,\gamma}(n) = \mathrm{tr}((\tilde{L}^a_{\beta,n})^k) - E^L_{\beta,a}[\mathrm{tr}((\tilde{L}^a_{\beta,n})^k)].$$

The main results of this section are given in the Claims to follow.

Claim 3.15.1: For any fixed integers k and l,

$$\lim_{n\to\infty} E[(\eta_{k,\gamma}(n))^l] = \begin{cases} \left(\frac{2}{\beta}\right)^{l/2} (\mathrm{Sum}_1(k,\gamma) + \mathrm{Sum}_2(k,\gamma))^{l/2} (l-1)!! & \text{if } l \text{ is even} \\ 0, & \text{if } l \text{ is odd}, \end{cases}$$

where

$$\mathrm{Sum}_1(k,\gamma)=\sum_{q=1}^{2k-1}(-1)^{q+1}\gamma^{2k-q}\frac{\binom{2k}{q}}{2k}\sum_{j=q+1}^{2k}\frac{(-1)^j}{\binom{2k-1}{j-1}}\sum_{\substack{s_1+s_2=j\\1\leqslant s_1,s_2\leqslant k}}s_1s_2\binom{k}{s_1}^2\binom{k}{s_2}^2,$$

$$\mathrm{Sum}_2(k,\gamma)=\sum_{q=0}^{2k-2}(-1)^{q}\gamma^{2k-q}\frac{\binom{2k}{q}}{2k}\sum_{j=q}^{2k-2}\frac{(-1)^j}{\binom{2k-1}{j}}\sum_{\substack{s_1+s_2=j\\0\leqslant s_1,s_2\leqslant k-1}}(k-s_1)(k-s_2)\binom{k}{s_1}^2\binom{k}{s_2}^2.$$

Claim 3.15.2: For any fixed integers k and l,

$$\lim_{n\to\infty}\mathrm{Cov}(n_{i,\gamma}(n),\eta_{j,\gamma}(n))=\frac{2}{\beta}(\mathrm{Sum}_1(i,j,\gamma)+\mathrm{Sum}_2(i,j,\gamma)),$$

where

$$\mathrm{Sum}_1(i,j,\gamma)=\sum_{q=1}^{i+j-1}(-1)^{q+1}\gamma^{j+j-q}\frac{\binom{i+j}{q}}{i+j}\sum_{j=q+1}^{i+j}\frac{(-1)^j}{\binom{i+j-1}{j-1}}\sum_{\substack{r+s=j\\1\leqslant r\leqslant i\\1\leqslant s\leqslant j}}rs\binom{i}{r}^2\binom{j}{s}^2,$$

$$\mathrm{Sum}_2(i,j,\gamma)=\sum_{q=0}^{i+j-2}(-1)^{q}\gamma^{j+j-q}\frac{\binom{i+j}{q}}{i+j}\sum_{j=q}^{i+j-2}\frac{(-1)^j}{\binom{i+j-1}{j}}\sum_{\substack{r+s=j\\0\leqslant r\leqslant i-1\\0\leqslant s\leqslant j-1}}(i-r)(j-s)\binom{i}{r}^2\binom{j}{s}^2.$$

The method we employ for proving these claims is basically the same as in Sec. III A; the only things that change are the details of the sequences we will deal with. In the following we will point out where definitions and calculations differ from before, but we will not go over the reduction arguments again, for the sake of brevity.

We write the scaled matrix $\tilde{B}^a_{\beta,n}$ as

$$\tilde{B}^a_{\beta,n}=D+\frac{1}{\sqrt{\beta n}}Z,$$

where $D=E^L_{\beta,a}[\tilde{B}^a_{\beta,n}]$ is the bidiagonal matrix of mean entries $D(i,i)=(\sqrt{\gamma}/\sqrt{n\beta})E[\chi_{2a-i\beta}]$ and $D(i+1,i)=(\sqrt{\gamma}/\sqrt{n\beta})E[\chi_{(n-i)\beta}]$, and Z is the lower bidiagonal matrix of centered variables; we drop the dependence of D and Z on β, a, and n, for simplicity.

Remark 3.16: From Proposition 2.19, if $D=(d_{ij})_{1\leqslant i,j\leqslant n}$, given any $\varepsilon>0$, there is an $i_\epsilon\in\mathbb{N}$ such that

$$|\sqrt{n\beta/\gamma}\,d_{i,i}-\sqrt{n\beta/\gamma-i\beta}|\leqslant\epsilon,\quad \textit{and}$$

$$|\sqrt{n\beta/\gamma}\,d_{i+1,i}-\sqrt{(n-i)\beta}|\leqslant\epsilon,$$

for any $i\leqslant n-i_\epsilon$.

Here we also used the fact that $2a/(n\beta)\sim 1/\gamma$.

Similarly, again from Proposition 2.19, we know that $Z_{i,i} \to N(0, \gamma/2)$ *and* $Z_{i+1,i} \to N(0, \gamma/2)$ *in distribution*.

As in Sec. III A we start from the expression for $\mathrm{tr}((BB^T)^k)$, for B a lower bidiagonal matrix:

$$\mathrm{tr}((BB^T)^k) = \sum_{1 \leqslant i_1, i_2, \ldots, i_{2k} \leqslant n} b_{i_1,i_2} b_{i_2,i_3} \cdots b_{i_{2k-1},i_{2k}} b_{i_{2k},i_1},$$

where the sum is taken over sequences $(i_1, \ldots, i_{2k})$ with the property that $i_{2j-1} - i_{2j} \in \{0, 1\}$, for all $1 \leqslant j \leqslant k$, and $i_{2j} - i_{2j+1} \in \{0, -1\}$, for all $1 \leqslant j \leqslant k-1$, and also $i_{2k} - i_1 \in \{0, -1\}$.

Just as before, we will introduce a few notations (we "recycle" some of the notations we used before; note that the quantities change).

Definition 3.17: We denote by $S_{n,k} \in \{1, \ldots, n\}^{2k}$ *the set of sequences of integers* $i_1, \ldots, i_{2k}$ *such that* $i_{2j-1} - i_{2j} \in \{0, 1\}$, *for all* $1 \leqslant j \leqslant k$, *and* $i_{2j} - i_{2j+1} \in \{0, -1\}$, *for all* $1 \leqslant j \leqslant k-1$, *and also* $i_{2k} - i_1 \in \{0, -1\}$. *We denote by* $\mathcal{I}$ *an element in* $S_{n,k}$.

For each such $\mathcal{I}$, we consider all the ways in which we can "break up" $\mathcal{I} := (i_1, \ldots, i_{2k})$ into overlapping "runs" J and R, i.e.,

$$J = ((i_{p_0}, \ldots, i_{p_1}), (i_{p_2}, \ldots, i_{p_3}), (i_{p_4}, \ldots, i_{p_5}), \ldots, (i_{p_{2q}}, \ldots, i_{p_{2q+1}})),$$

and

$$R = ((i_{p_1}, \ldots, i_{p_2}), (i_{p_3}, \ldots, i_{p_4}), \ldots, (i_{p_{2q-1}}, \ldots, i_{p_{2q}})),$$

with

$$(i_1, \ldots, i_{2k}) = (i_{p_0}, \ldots, i_{p_1}, i_{p_1+1}, \ldots, i_{p_2}, i_{p_2+1}, \ldots, i_{p_3}, \ldots, i_{p_{2q+1}}).$$

Note that this preserves the requirement that $i_j - i_{j+1} \in \{0, (-1)^{1+j \bmod 2}\}$ for all j.

We allow for the possibility of having empty sequences $i_{p_0}, \ldots, i_{p_1}$ in the beginning and/or $i_{p_{2q}}, \ldots, i_{p_{2q+1}}$ in the end of J.

Definition 3.18: For any $\mathcal{I}$, *we introduce the set* $\mathcal{J} = \mathcal{J}(\mathcal{I})$ *of pairs* (J, R) *corresponding to the sequence* $\mathcal{I}$. *For a bidiagonal matrix* B, *we define*

$$(BB^T)_{\mathcal{I}} = b_{i_1,i_2} b_{i_2,i_3} \cdots b_{i_{2k-1},i_{2k}} b_{i_{2k},i_1},$$

$$(BB^T)_J = b_{i_{p_0},i_{p_0}+1} \cdots b_{i_{p_1}-1,i_{p_1}} b_{i_{p_2}b_{p_2}+1} \cdots b_{i_{p_3}-1,i_{p_3}} \cdots b_{i_{2q},i_{2q}+1} \cdots b_{i_{2q+1}-1,i_{2q+1}},$$

$$(BB^T)_R = b_{i_{p_1},i_{p_1}+1} \cdots b_{i_{p_2}-1,i_{p_2}} b_{i_{p_3}i_{p_3}+1} \cdots b_{i_{p_4}-1,i_{p_4}} \cdots b_{i_{2q-1},i_{2q-1}+1} \cdots b_{i_{2q}-1,i_{2q}}.$$

Remark 3.19: Note that any term in $\mathrm{tr}((L^{\alpha}_{\beta,n})^k)$ *will consist of terms in* D *and terms in* Z, *with a sequence of runs* J *recording the former, and a sequence of runs* R *recording the latter*.

Proof of Claim 3.15.2: As before, we note that

$$(\widetilde{L}^{a}_{\beta,n})_{\mathcal{I}} = \left(\left(D + \frac{1}{\sqrt{n\beta}} Z \right) \left(D + \frac{1}{\sqrt{n\beta}} Z \right)^T \right)_{\mathcal{I}} = \sum_{(J,R) \in \mathcal{J}} \frac{1}{(n\beta)^{P/2}} (D)_J (Z)_R, \tag{27}$$

with $P = p_2 - p_1 + 1 + \cdots + p_{2q} - p_{2q-1} + 1$.

Similarly with (26), write

$$E[(\eta_{k,\gamma}(n))^l] = \sum_{\substack{\mathcal{I}_j \in \mathcal{S}_{n,k} \\ 1 \leqslant j \leqslant l}} \sum_{(J_j,R_j) \in \mathcal{J}_j} \frac{1}{(n\beta)^q} \left(\prod_{j=1}^{l} (D)_{J_j} \right) E\left[\prod_{j=1}^{l} ((Z)_{R_j} - E[(Z)_{R_j}]) \right], \tag{28}$$

with $q=q(\mathcal{I}_1,\ldots,\mathcal{I}_l):=\Sigma_j P_j/2$.

The rest of the argument follows in the footsteps of the proof of Claim 3.2.1. Just as before, it can be shown that the only terms with significant contribution are those for which, for each j, $(Z)_{R_j}$ consists of a single term, and, in addition to that, the set of R_j's can be split in pairs (R_{j_1},R_{j_2}) such that $(Z)_{R_{j_1}}=(Z)_{R_{j_2}}$. This yields

$$\lim_{n\to\infty} E[(\eta_{k,\gamma}(n))^{2p+1}]=0.$$

Also, if l is even, the argument that we can consider only the terms for which there is an $l/2$-tuple $(i_1,\ldots,i_{l/2})$ which "avoids" the upper and lower corners of the matrix (like in Lemmas 3.13 and 3.14) still applies.

The one way in which this computation differs from the one we made for the proof of Claim 3.2.1 lies in the fact that approximating $(D)_J$, given an index i_1 present in J, becomes a little trickier, since the diagonal and off-diagonal elements will approximate, respectively, to $\sqrt{\gamma}\sqrt{1/\gamma-i/n}$ and $\sqrt{\gamma}\sqrt{1-i/n}$.

Thus, one more parameter will become important, namely, the number of off-diagonal terms in each $(D)_{J_j}$. Note that in each sequence $\mathcal{I}$ we must have an *even* number $2s$ of off-diagonal terms (either from D or from Z), since $i_1-i_2+\cdots+i_{2k}-i_1=0$, and this also implies that we have an even number $2(k-s)$ of diagonal terms.

1. Suppose we fix the term in Z_{R_j} to be the diagonal term $z_{i,i}$; to how many sequences $\mathcal{I}$ with a fixed number $2s$ of off-diagonal terms can this correspond? The answer is $2(k-s)\ \binom{k}{s}^2$; we have $\binom{k}{s}$ ways of picking the off-diagonal terms (because of the alternating property), and once those are picked we have $2(k-s)$ choices for the location of $z_{i,i}$ among the diagonal terms remaining; this determines the sequence uniquely.

Each such sequence will have asymptotical weight

$$(D)_J\sim\gamma^{k-1/2}\left(\frac{1}{\gamma}-\frac{i}{n}\right)^{k-s-1/2}\left(1-\frac{i}{n}\right)^{s}.$$

2. Suppose we now fix the term in Z_{R_j} to be the off-diagonal term $z_{i+1,i}$; to how many sequences $\mathcal{I}$ with a fixed number $2s$ of off-diagonal terms can this correspond? The answer is $2s\ \binom{k}{s}^2$; we have $\binom{k}{s}$ ways of picking the off-diagonal terms (because of the alternating property), and once those are picked we have $2s$ choices for the location of $z_{i+1,i}$ among them.

Each such sequence will have asymptotical weight

$$(D)_J\sim\gamma^{k-1/2}\left(\frac{1}{\gamma}-\frac{i}{n}\right)^{k-s}\left(1-\frac{i}{n}\right)^{s-1/2}.$$

Finally, using the binomial formula

$$\left(\frac{1}{\gamma}-\frac{t}{n}\right)^{s-1}=\sum_{i=0}^{s-1}(-1)^i\binom{s-1}{i}\gamma^{-s+1-i}\left(\frac{t}{n}\right)^i,$$

and after some processing and use of the Riemann-sum and Beta-function formula

$$\lim_{n\to\infty}\frac{1}{n}\sum_{t=0}^{n}\left(1-\frac{t}{n}\right)^{2k-r-s}\left(\frac{t}{n}\right)^{r+s-1}=\int_0^1(1-x)^{2k-r-s}x^{r+s-1}\mathrm{d}x=\frac{(2k-r-s)!(r+s-1)!}{(2k)!},$$

combined with all the possible pairings of the R_j's (which yields the necessary $(l-1)!!$), we obtain the result of claim 3.15.1. □

Claim 3.15.2 has a similar proof.

Remark 3.20: As in Sec. III A, we never actually use the full power of the fact that the entries of the bidiagonal matrix Z tend to independent centered ***normal*** *variables. We only used the following three properties:*

- $E[Z_{i,i}]=E[Z_{i+1,i}]=0$;
- $\lim_{n\to\infty} Var[Z_{i+1,i}]=\lim_{n\to\infty} Var[Z_{i,i}]=\frac{\gamma}{2}$;
- *for any* k, *there exists a number* $M_k>0$ *such that* $|E[(Z_{i,j})^k]|<M_k$, *for all* $1\leqslant i,j\leqslant n$ (*boundedness of moments*).

IV. A MORE GENERAL SETTING

We present here a way to generalize the "non-random matrix+small random fluctuation" decompositions we have used in Sec. III in order to analyze the deviation and fluctuation from the asymptotical law for the eigenvalue density in the case of the Hermite and Laguerre β-ensembles.

A. Tridiagonals

Let f and g be two integrable functions $f,g:[0,1]\to\mathbb{R}$ such that the integrals $\int_0^1 f^a(x)g^b(x)\mathrm{d}x$ exist for all $a,b\in\mathbb{N}$, and such that the quantities

$$m_k := \sum_{r=0}^{\lfloor k/2\rfloor} \binom{k}{r,r,k-2r} \int_0^1 f^{k-2r}(x)g^{2r}(x)\mathrm{d}x \tag{29}$$

are the moments of a (uniquely determined) distribution ρ, defined on a compact $[a,b]$.

For any $n\in\mathbb{R}$, we then consider the $n\times n$ matrix F_T:

$$F_T=\begin{pmatrix} f\left(\frac{n}{n}\right) & g\left(\frac{n-1}{n}\right) & & & & & \\ g\left(\frac{n-1}{n}\right) & f\left(\frac{n-1}{n}\right) & g\left(\frac{n-2}{n}\right) & & & & \\ & g\left(\frac{n-2}{n}\right) & \ddots & \ddots & & & \\ & & & \ddots & \ddots & g\left(\frac{1}{n}\right) & \\ & & & & g\left(\frac{1}{n}\right) & f\left(\frac{1}{n}\right) & \end{pmatrix},$$

so the diagonal of F_T is an equidiscretization of f with step $1/n$ (with the exception of the endpoint at 0, which is missing), and the off-diagonal is an equidiscretization of g with step $1/n$ (missing both the endpoint at 1 and the one at 0).

We consider the tridiagonal symmetric matrix

$$R_T=\begin{pmatrix} x_n & y_{n-1} & & & & & \\ y_{n-1} & x_{n-1} & y_{n-2} & & & & \\ & y_{n-2} & \ddots & \ddots & & & \\ & & \ddots & \ddots & y_2 & & \\ & & & y_2 & x_2 & y_1 & \\ & & & & y_1 & x_1 & \end{pmatrix},$$

with the variables x_i and y_j being mutually independent and satisfying the following three properties:

- $E[x_i]=E[y_j]=0$, for all $1\leqslant i\leqslant n$, $1\leqslant j\leqslant n-1$,
- $\mathrm{Var}[x_i]=\sigma^2$, for all $1\leqslant i\leqslant n$, and $\mathrm{Var}[y_j]=\eta^2$, for all $1\leqslant j\leqslant n-1$,

- for all k there exists a $M_k > 0$ such that $|E[(x_i)^k]| < M_k$ and $|E[(y_j)^k]| < M_k$, for all $1 \leqslant i \leqslant n$, $1 \leqslant j \leqslant n-1$.

Note that F_T is non-random matrix, while R_T is a random one.

Now we consider the matrix model

$$M_T = F_T + \frac{1}{\sqrt{n}} R_T. \tag{30}$$

We will compute the asymptotical eigenvalue distribution, the first-order deviation from it, and the first-order fluctuation for the random matrix M_T.

We need two more definitions.

Definition 4.1: Let P be a path on the lattice $\mathbb{Z}^2$, *starting at* $(0,0)$ *and ending at* $(k,0)$, *with up* $((x,y) \to (x+1,y+1))$, *down* $((x,y) \to (x+1,y-1))$, *and level* $((x,y) \to (x+1,y))$ *steps. For each level* $j \in \mathbb{Z}$, *we define the quantities* $a_j(P)$ *and* $b_j(P)$, *as follows:*

$$a_j(P) := \#\ \textit{of level steps from } j \textit{ to } j;$$

$$b_j(P) := \#\ \textit{of down steps from } j \textit{ to } j-1.$$

Note that, since the path P ends at $(k,0)$, *the number of up steps it takes must always equal the number of down steps it takes.*

Also let

$$\mathcal{P}_{r,k} := \{\textit{paths from } (0,0) \textit{ to } (k,0) \textit{ with exactly } r \textit{ down steps}\},$$

$$\mathcal{P}_{r,k,i} := \{\textit{paths in } \mathcal{P}_{r,k} \textit{ which descend to, but not below, } y = -i\},$$

$$p_{r,k,i} := |\mathcal{P}_{r,k,i}|,$$

$$\mathcal{P}_k := \cup_{r=0}^{\lfloor k/2 \rfloor} \mathcal{P}_{r,k}.$$

Theorem 4.2: *Let* M_T *be a matrix from the ensemble defined by* (30), *of size n, with eigenvalues* $(\lambda_1, \ldots, \lambda_n)$, *and let* $k \geqslant 1$ *be a positive integer. For all* $i = 1, \ldots, k$, *let*

$$\begin{aligned}
\mu_i = \sum_{r=0}^{\lfloor i/2 \rfloor} \Bigg(& f(1)^{i-2r} g(1)^{2r} \left(\sum_{j=0}^{r-1} (r-j) p_{k,j,r} - \frac{1}{2} \binom{i}{r,r,i-2r} \right) + f(0)^{i-2r} g(0)^{2r} \left(\sum_{j=0}^{r-1} (r-j) p_{i,j,r} \right. \\
& \left. - \frac{3}{2} \binom{i}{r,r,i-2r} \right) \Bigg) - \sum_{P \in \mathcal{P}_{r,i}} \sum_{j \in \mathbb{Z}} j a_j(P) \int_0^1 f^{i-2r-1}(t) g^{2r}(t) f'(t) \mathrm{d}t \\
& - 2 \sum_{P \in \mathcal{P}_{r,i}} \sum_{j \in \mathbb{Z}} j b_j(P) \int_0^1 f^{i-2r}(t) g^{2r-1}(t) g'(t) \mathrm{d}t + \sigma^2 \left(\sum_{P \in \mathcal{P}_{r,i}} \sum_{j \in \mathbb{Z}} \binom{a_j(P)}{2} \right) \int_0^1 f^{i-2r-2}(t) g^{2r}(t) \mathrm{d}t \\
& + \eta^2 \left(\sum_{P \in \mathcal{P}_{r,i}} \sum_{j \in \mathbb{Z}} \binom{2b_j(P)}{2} \right) \int_0^1 f^{i-2r}(t) g^{2r-2}(t) \mathrm{d}t.
\end{aligned}$$

Also, for any $1 \leqslant i \leqslant k$, *let*

$$X_i = \mathrm{tr}((M_T)^i) - n \int_a^b x^i \rho(x) \mathrm{d}x - \mu_i,$$

$$\equiv \sum_{j=1}^{n} \lambda_j^i - n \int_a^b x^i \rho(x) \mathrm{d}x - \mu_i$$

Let $(Y_1, Y_2, \ldots, Y_k)$ *be a centered multivariate Gaussian with covariance matrix*

$$\mathrm{Cov}(Y_i,Y_j)=\sigma^2\sum_{\substack{0\leqslant r\leqslant \lfloor i/2\rfloor -1\\ 0\leqslant s\leqslant \lfloor j/2\rfloor -1}}(i-2r)(j-2s)\binom{i}{r,r,i-2r}\binom{j}{s,s,j-2s}\int_0^1 f^{A(r,s)}(x)g^{B(r,s)}(x)\mathrm{d}x$$
$$+\eta^2\sum_{\substack{1\leqslant r\leqslant \lfloor i/2\rfloor \\ 1\leqslant s\leqslant \lfloor j/2\rfloor}}4rs\binom{i}{r,r,i-2r}\binom{j}{s,s,j-2s}\int_0^1 f^{C(r,s)}(x)g^{D(r,s)}(x)\mathrm{d}x,$$

where $A(r,s)=i-2r+j-2s-2$, $B(r,s)=2r+2s$, $C(r,s)=2r+2s-2$, *and* $D(r,s)=i-2r+j-2s$.

Then, as $n\to\infty$,

$$(X_1,X_2,\ldots,X_k)\Rightarrow(Y_1,Y_2,\ldots,Y_k).$$

Proof: A technical but simple calculation in the spirit of the ones performed in Sec. III A shows that m_k are the moments of the asymptotic level density, via the expansion of $\mathrm{tr}(M_T^k)$ as a sum of products of the entries of M_T and separation of the zero-order term. Furthermore, examining the first-order terms in this expansion yields the covariance result, using the same counting techniques as in Sec. III A.

Computing the first-order deviation from the mean is slightly more complicated, as first-order terms in the expansion come from four sources; we only enumerate these sources here and indicate how they play a part in the total sum.

We begin with expressing

$$E[\mathrm{tr}(M_T^k)]=E\left[\mathrm{tr}\left(\left(F_T+\frac{1}{\sqrt{n}}R_T\right)^k\right)\right]=E\left[\sum_{\mathcal{I}\in S_{n,k}}(M_T)_{\mathcal{I}}\right]=E\left[\sum_{\mathcal{I}\in S_{n,k}}\sum_{(J,R)\in\mathcal{J}}\frac{1}{n^{P/2}}(F_T)_J(R_T)_R\right],$$

where we have used the notation of Sec. III A.

It is easy to prove, like we did in Sec. III A, that the zero-order terms are given by the pairs (J,R) where $R=\emptyset$, that the terms $(R_T)_R$ which contain a single variable (at first power) are annihilated by the expectation (since all variables in R_T are centered), and that the terms where $(R_T)_R$ contains three or more variables (counting multiplicities) do not contribute to the first-order deviation.

To each sequence $\mathcal{I}$ (recall that $\mathcal{I}=(i_1,\ldots,i_k)$ with $|i_j-i_{j+1}|\in\{0,1\}$ for $1\leqslant i\leqslant k-1$ and $|i_k-i_1|\in\{0,1\}$) we associate in a one-to-one fashion, a path from (0,0) to $(k,0)$ taking steps up, down, or level (depending on the nest term being larger, smaller, or equal to the current one). The zero-order terms sum asymptotically to m_k (with the integral being obtained from the Riemann sum and with $\binom{k}{r,r,k-2r}=|\mathcal{P}_k|$).

Three of the first-order term sources come from those terms that have $|R|=\emptyset$, while the fourth comes from the terms for which $(R_T)_R$ contains a single variable, at the second power. Note also that the terms for which $(R_T)_R$ contains two different variables will be annihilated by the expection.

Source 1. In the zero-order count, we ignore the fact that at the "edges," i.e., upper left corner, corresponding to $i_1\in\{1,\ldots,\lfloor k/2\rfloor\}$, and lower right corner, corresponding to $i_1\in\{n-\lfloor k/2\rfloor,\ldots,n\}$, not all paths in $\mathcal{P}_{k,r}$ can appear in the sum. This approximation yields a first-order term which is asymptotically equal to

$$S_1:=\sum_{r=0}^{\lfloor k/2\rfloor}\left((f(1)^{k-2r}g(1)^{2r}+f(0)^{k-2r}g(0)^{2r})\left(\sum_{i=0}^{r-1}(r-i)p_{k,i,r}-\binom{k}{r,r,k-2r}\right)\right).$$

Source 2. In the zero-order approximation, we approximate the value of the integral $\int_0^1 f^{k-2r}(x)g^{2r}(x)\mathrm{d}x$ by the Riemann sum $(1/n)\Sigma_{i=0}^n f(i/n)^{k-2r}\,g(i/n)^{2r}$. Using the Euler-Maclauren formula, this yields a first-order term asymptotically equal to

$$S_2 := \sum_{r=0}^{\lfloor k/2 \rfloor} \frac{1}{2} \binom{k}{r,r,k-2r} (f(1)^{k-2r} g(1)^{2r} - f(0)^{k-2r} g(0)^{2r}).$$

Source 3. Finally, in the zero-order approximation, we replace $f((i-j)/n)$ and $g((i-j)/n)$ by $f(i/n)$, respectively $g(i/n)$ for each $j \in \{-k, \ldots, k\}$. A Taylor series approximation and the counting of terms shows that this way we need to subtract off haveing a first-order term which is asymptotically

$$S_3 := \sum_{r=0}^{\lfloor k/2 \rfloor} \sum_{P \in \mathcal{P}_{r,k}} \sum_{j \in \mathbb{Z}} \left(j a_j(P) \int_0^1 f^{k-2r-1}(t) g^{2r}(t) f'(t) \mathrm{d}t - 2 j b_j(P) \int_0^1 f^{k-2r}(t) g^{2r-1}(t) g'(t) \mathrm{d}t \right).$$

Source 4. The last source of first-order terms comes from the terms in which $(R_T)_R$ contains a single variable at the second power, and its contribution is asymptotically equal to

$$S_4 := \sigma^2 \left(\sum_{P \in \mathcal{P}_{r,k}} \sum_{j \in \mathbb{Z}} \binom{a_j(P)}{2} \right) \int_0^1 f^{k-2r-2}(t) g^{2r}(t) \mathrm{d}t + \eta^2 \left(\sum_{P \in \mathcal{P}_{r,k}} \sum_{j \in \mathbb{Z}} \binom{2b_j(P)}{2} \right) \int_0^1 f^{k-2r}(t) g^{2r-2}(t) \mathrm{d}t.$$

Finally, adding S_1, S_2, S_3, and S_4 yields the statement of Theorem 4.2. □

Remark 4.3: Note that when $f(x)=\sqrt{x}/2$, $g(x)=0$ *for all* $x \in [0,1]$, $\sigma^2 = 1/(2\beta)$, *and* $\eta^2 = 1/(8\beta)$, *both the level density asymptotics* **and** *the covariance matrix for the fluctuations are the same as for the* β*-Hermite ensemble of Sec. III A.*

Crucially, the deviation is **different**. *The reason is that in the approximation*

$$E\left[\tfrac{1}{2}\chi_{(n-i)\beta}\right] \sim \tfrac{1}{2}\sqrt{(n-i)\beta},$$

the next order term is of order $1/\sqrt{(n-i)\beta}$, *which plays a part in computing the deviation.*

We remind the reader that we computed the deviation for the β*-Hermite ensembles by using the palindromic property of expectations of trace, thus reducing the problem to computing the deviation for the "*$\beta=\infty$*" case, for which we used Hermite polynomials properties. This allowed us to find the distribution behind the moments of the deviation.*

B. Bidiagonals

Let f and g be two integrable functions, $f, g, : [0,1] \to \mathbb{R}$, such that the integrals $\int_0^1 f^a(x) g^b(x) \mathrm{d}x$ exist for all $a, b \in \mathbb{N}$, and such that the quantities

$$\tilde{m}_k := \sum_{r=0}^{k} \binom{k}{r}^2 \int_0^1 f^{2r}(x) g^{2(k-r)}(x) \mathrm{d}x$$

are the moments of a (uniquely determined) distribution ν defined on $[a,b]$.

For any $n \in \mathbb{N}$, we consider the $n \times n$ matrix F_B, defined in the following:

$$F_B = \begin{pmatrix} f\left(\frac{n}{n}\right) & & & \\ g\left(\frac{n-1}{n}\right) & f\left(\frac{n-1}{n}\right) & & \\ & \ddots & \ddots & \\ & & g\left(\frac{1}{n}\right) & f\left(\frac{1}{n}\right) \end{pmatrix},$$

in other words the diagonal of F_B is an equidiscretization of f with step $1/n$ (with the exception of the endpoint at 0, which is missing), and the subdiagonal is an equidiscretization of g with step $1/n$ (missing both the endpoint at 0 and the one at 1).

We next consider the random bidiagonal matrix

$$R_B = \begin{pmatrix} x_n & & & \\ y_{n-1} & x_{n-1} & & \\ & \ddots & \ddots & \\ & & y_1 & x_1 \end{pmatrix},$$

where the variables x_i, y_j are mutually independent and satisfying the following properties:

- $E[x_i]=E[y_j]=0$ for all $1\leqslant i\leqslant n$, $1\leqslant j\leqslant n-1$,
- $\mathrm{Var}[x_i]=\sigma^2$ for all $1\leqslant i\leqslant n$ and $\mathrm{Var}[y_j]=\eta^2$, for all $1\leqslant j\leqslant n-1$,
- for all k there is a constant $M_k>0$ such that $|E[(x_i)^k]|<M_k$ and $|E[(y_j)^k]|<M_k$ for all $1\leqslant i\leqslant n$ and $1\leqslant j\leqslant n-1$.

Finally, consider the matrix

$$M_L = M_B M_B^T, \tag{31}$$

with

$$M_B = F_B + \frac{1}{\sqrt{n}} R_B.$$

Note that while F_B is a non-random matrix, R_B, M_B, and M_L are random.

We will compute the asymptotical level density and the first-order deviation and fluctuation for the random matrix M_L.

We need to define the following quantities.

Definition 4.4: Let Q be a path on the lattice $\mathbb{Z}^2$, starting at $(0,0)$ and ending at $(2k,0)$, with up $((x,y)\to(x+1,y+1))$, down $((x,y)\to(x+1,y-1))$, and level $((x,y)\to(x+1,y))$ steps. In addition, we require that the path is alternating, i.e., on each odd-numbered step (first, third, etc.) the path is only allowed to go down or stay at the same level, whereas on each even-numbered step (second, fourth, etc.), the path is allowed only to go up or stay at the same level.

For each level $j\in\mathbb{Z}$, we define the quantities $c_j(Q)$ and $d_j(Q)$, as follows:

$$c_j(Q) := \#\text{ of level steps from } j \text{ to } j,$$
$$d_j(Q) := \#\text{ of down steps from } j \text{ to } j-1.$$

Note that, since the path Q ends at $(2k,0)$, the number of up steps it takes must always equal the number of down steps it takes.

Also let

$$\mathcal{Q}_{r,k} := \{\text{alternating paths from } (0,0) \text{ to } (2k,0) \text{ with exactly } r \text{ down steps}\},$$
$$\mathcal{Q}_{r,k,i} := \{\text{alternating paths in } \mathcal{Q}_{r,k} \text{ which descends to, but not below, } y=-i\},$$
$$q_{r,k,i} := |\mathcal{Q}_{r,k,i}|,$$
$$\mathcal{Q}_k := \cup_{r=0}^{k}\mathcal{Q}_{r,k}.$$

Theorem 4.5: *Let M_L be the matrix from the ensembles defined by* (31)*, of size n, with eigenvalues $(\lambda_1,\ldots,\lambda_n)$, and let $k\geqslant 1$ be a positive integer. For all $1\leqslant i\leqslant k$, let*

$$\begin{aligned}\tilde{\mu}_i = &\sum_{r=0}^{i}\left(f(1)^{2i-2r}g(1)^{2r}\left(\sum_{j=0}^{r-1}(r-i)q_{i,j,r}-\frac{1}{2}\binom{i}{r}^2\right)+f(0)^{2i-2r}g(0)^{2r}\left(\sum_{j=0}^{r-1}(r-j)q_{i,j,r}-\frac{3}{2}\binom{i}{r,r}^2\right)\right)\\ &-\sum_{Q\in\mathcal{Q}_{r,i}}\sum_{j\in\mathbb{Z}}jc_j(Q)\int_0^1 f^{2i-2r-1}(t)g^{2r}(t)f'(t)\mathrm{d}t-2\sum_{Q\in\mathcal{Q}_{r,i}}\sum_{j\in\mathbb{Z}}jd_j(Q)\int_0^1 f^{2i-2r}(t)g^{2r-1}(t)g'(t)\mathrm{d}t\\ &+\sigma^2\left(\sum_{Q\in\mathcal{Q}_{r,i}}\sum_{j\in\mathbb{Z}}\binom{c_j(Q)}{2}\right)\int_0^1 f^{2i-2r-2}(t)g^{2r}(t)\mathrm{d}t\end{aligned}$$

$$+\eta^2\left(\sum_{Q\in\mathcal{Q}_{r,i}}\sum_{j\in\mathbb{Z}}\binom{2d_j(Q)}{2}\right)\int_0^1 f^{2i-2r}(t)g^{2r-2}(t)\mathrm{d}t.$$

Also, for for any $1\leqslant i\leqslant k$, *let*

$$X_i=\mathrm{tr}((M_l)^i)-n\int_a^b x^i\nu(x)\mathrm{d}x-\tilde{\mu}_i,$$

$$\equiv\sum_{j=1}^{i}\lambda_j^i-n\int_a^b x^i\nu(x)\mathrm{d}x-\tilde{\mu}_i.$$

Let $(Y_1,Y_2,\ldots,Y_k)$ *be a centered multivariate Gaussian with covariance matrix*

$$\mathrm{Cov}(x^i,x^j)=4\sigma^2\sum_{\substack{1\leqslant r\leqslant i\\1\leqslant s\leqslant j}}rs\binom{i}{r}^2\binom{j}{s}^2\int_0^1 f^{A(r,s)}(x)g^{B(r,s)}(x)\mathrm{d}x+4\eta^2\sum_{\substack{0\leqslant r\leqslant i-1\\0\leqslant s\leqslant j-1}}(i-r)(j-s)$$
$$\times\binom{i}{r}^2\binom{j}{s}^2\int_0^1 f^{A(r,s)+2}(x)g^{B(r,s)-2}(x)\mathrm{d}x,$$

with $A(r,s)=2(r+s-1)$ *and* $B(r,s)=2(i+j-r-s)$.

Then, as $n\to n$,

$$(X_1,X_2,\ldots,X_k)\Rightarrow(Y_1,Y_2,\ldots,Y_k).$$

Proof: The proof of Theorem 4.5 is based on the same calculations as Theorem 4.2. The covariance can be computed using the same general principles as in Sec. III B, and the examination of the zero-order and first-order terms in the mean can be done as in Sec. IV B. Moreover, the sources of the first-order terms are the same as in Sec. IV B; it is only the type of path we are counting that changes (from paths of length k to alternating paths of length $2k$). □

Remark 4.6: Note that when $f=\sqrt{1/\gamma-1+x}$, $g=\sqrt{x}$, $\sigma^2=\eta^2=\gamma/(2\beta)$, *both the level density asymptotics* and *the covariance matrix for the fluctuations are the same as for the* β*-Laguerre ensemble of Sec. III B.*

Once again, the deviation is ***different****, for the same reason as in Sec. IV B: in the approximation* $E\left[\frac{1}{2}\chi_{(n-i)\beta}\right]\sim\frac{1}{2}\sqrt{(n-i)\beta}$ *the next order term is of order* $1/\sqrt{(n-i)\beta}$, *which plays a part in computing the deviation.*

We computed the deviation for the β*-Laguerre ensembles by using the palindromic property of expectations of trace, thus reducing the problem to computing the deviation for the "*$\beta=\infty$*" case, for which we used Laguerre polynomials properties. This allowed us to find the distribution behind the moments of the deviation.*

V. HISTOGRAMMING EIGENVALUES EFFICIENTLY

We propose a very effective numerical trick for counting the number of eigenvalues in an interval numerically. This method does not require the computation of eigenvalues and requires a number of operations that is $O(n)$, rather than $O(n^2)$, which allows for counts for matrices of a very large size. The method is the standard Sturm sequence method for tridiagonal symmetric matrices. We take as input D, a vector of length n, which is the diagonal of the matrix, and E, a vector of length $n-1$, the squares of the elements on the super or subdiagonal. This avoids unnecessary square roots in the formation of the matrix which can slow down computation.

The algorithm is remarkably simple. For a given value σ, which is not an eigenvalue of the matrix, compute

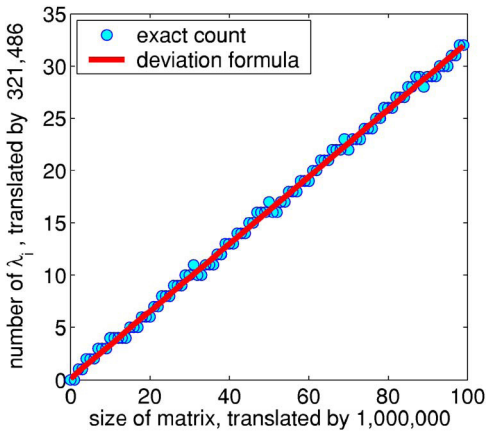

FIG. 2. (Color online) Calculating the deviation in the interval $I=[0.2,0.8]$ for the $\beta=\infty$ Hermite ensemble with sizes $10^6:1:(10^6+99)$; circles represent the eigenvalue count minus the area under the semicircle over I; the solid line is the theoretical deviation given in (33).

$$t_i := D_i - \sigma - E_{i-1}/t_{i-1}$$

for $t=1$ through n with $t_0=1$ and $E_0=0$.

From Sturm's theorem (see, for example Ref. 17, Theorem 13) we know that the number of eigenvalues of the tridiagonal matrix less than or equal to σ is the number of t_i's that are negative, with $1 \leqslant i \leqslant n$.

To histogram eigenvalues of β ensembles for n's into the millions or even the billions, one can simply compute E from a chi-square random number generator (implemented in MATLAB's Statistics Toolbox as `chi2rnd`), and D from a normal random number generator for the β-Hermite case (`randn`) or from another chi-square in the β-Laguerre case.

An interesting special case is the β-Hermite case with $\beta=\infty$, which computes the roots of the corresponding scaled Hermite polynomial. This may be performed by taking D to be the zero vector of length n and $E=(n-1,n-2,\ldots,2,1)/(4n)$.

When $\beta=\infty$, there is no fluctuation, but there are deviations for large n. The Sturm theorem roughly states that the number of eigenvalues in an interval I is linear of the form

$$(\#\ \text{eigenvalues}) = n(\text{area under the semicircle}) + DEVIATION, \tag{32}$$

where

$$DEVIATION = \frac{1}{2\pi}\arcsin(x)\Big|_I \tag{33}$$

and we subtract $1/4$ if I contains $+1$ and $1/4$ if I contains -1.

In one numerical experiment (see Fig. 2), we took $n=1\,000\,000+i$ for $i=0,1,\ldots,99$ and computed the deviation from the mean, i.e., the number of eigenvalues in the interval I minus the area

$$A = n\frac{1}{2\pi}\int_I \sqrt{1-x^2}\mathrm{d}x;$$

we did this arbitrarily for the interval $I=[0.2,0.8]$. Since this experiment is non-random it is repeatable without any reference to a random number generator. We found the experimental deviation of 0.1167 which is close to the theoretical deviation of 0.1155, given by (33).

Figure 2 plots the results of the experiment. The red line which contains the theoretical value of the intercept represents the best fit line to the data in the sense that the average vertical deviation is minimized.

VI. REMARKS AND OPEN PROBLEMS

There are many object-counting (combinatorial) approaches to the study of traces of powers of random matrices; they depend on the matrix model, and on the polynomial whose trace is being computed. For example, the counting approach of Ref. 34 uses full matrix models (all entries are non-zero variables), and traces of powers (thus using the monomial basis, like we have done here), and counts paths in the complete graph of size n. By contrast, in Ref. 26, the polynomials used are the shifted Chebyshev polynomials, and the objects counted are non-crossing annular partitions; the matrix models are still full. Here, we use tri/bidiagonal matrix models, consider the monomials, and count essentially paths with three types of steps (up, down, level) in the plane.

Though the objects we count here are simpler than in Ref. 26, our counting technique expresses the results in a less compact form than in Refs. 21 and 26. In the latter two papers, the covariance matrix is diagonalized by the choice of polynomial basis, whereas in our paper it is obtained as full because we work with the monomials. There seems to be a trade-off between the simplicity of the object to be counted and the simplicity of the form in which the covariance matrix is expressed.

We would like to conjecture that by using a hybrid way of counting, for example, using the tridiagonal matrices and some of the techniques of Ref. 26, both the counting process and the resulting format of the answer could be simplified. The development of such a technique would be of great interest.

ACKNOWLEDGMENTS

The authors would like to thank Alexei Borodin, Alexander Soshnikov, and Roland Speicher for many useful conversations on the subjects of global fluctuations, traces of powers of random matrices, and free probability. We also thank Inderjit Dhillon for providing Sturm sequence code, which we used for the histogramming of eigenvalues. This research study has been conducted while I.D. was a Miller Research Fellow, sponsored by the Miller Institute for Basic Research in Sciences at U.C. Berkeley. Finally, the authors would like to thank the National Science Foundation (DMS-0411962).

On the Birkhoff factorization problem for the Heisenberg magnet and nonlinear Schrödinger equations

Saša Krešić-Jurić
Department of Mathematics and Physics, Faculty of Electrical Engineering, Mechanical Engineering & Naval Architecture, Rudjera Boskovica b.b., Split, 21000 Croatia

(Received 24 October 2005; accepted 12 April 2006; published online 31 May 2006)

A geometrical description of the Heisenberg magnet (HM) equation with classical spins is given in terms of flows on the quotient space G/H_+, where G is an infinite dimensional Lie group and H_+ is a subgroup of G. It is shown that the HM flows are induced by an action of $\mathbb{R}^2$ on G/H_+, and that the HM equation can be integrated by solving a Birkhoff factorization problem for G. For the HM flows that are Laurent polynomials in the spectral variable, we derive an algebraic transformation between solutions of the nonlinear Schrödinger (NLS) and Heisenberg magnet equation. The Birkhoff factorization problem for G is treated in terms of the geometry of the Segal-Wilson Grassmannian $\mathrm{Gr}(H)$. The solution of the problem is given in terms of a pair of Baker functions for special subspaces in $\mathrm{Gr}(H)$. The Baker functions are constructed explicitly for subspaces that yield multisoliton solutions of NLS and HM equations. © *2006 American Institute of Physics.*

I. INTRODUCTION

From the work of Zakharov-Shabat[1] and Sato-Segal-Wilson,[2] it is known that completely integrable partial differential equations, such as the Korteweg-de Vries (KdV) or the nonlinear Schrödinger (NLS) equation, are related with loop groups and infinite dimensional Grassmannians. Our aim in this paper is to describe the Heisenberg magnet (HM) equation,

$$\frac{\partial \vec{S}}{\partial t} = \vec{S} \times \frac{\partial^2 \vec{S}}{\partial x^2}, \quad S_1^2 + S_2^2 + S_3^2 = 1, \tag{1}$$

in the context of loop groups, and to explore the construction of its solutions from the point of view that is close to that of Segal-Wilson's work on KdV. The HM equation is a completely integrable system for which integrability was proved in Ref. 3 and the inverse scattering transform was developed in Ref. 4. Equation (1) is the isotropic case of the Landau-Lifshitz (LL) equation, $\vec{S}_t = \vec{S} \times \vec{S}_{xx} + \vec{S} \times J\vec{S}$, when the interaction constants are given by $J = \mathrm{diag}(J_0, J_0, J_0)$. The LL model was studied by a number of authors. In Ref. 5, it was integrated by the Riemann factorization problem on a torus. Soliton solutions using the dressing procedure and real algebraic-geometric solutions using theta functions were found in Refs. 6 and 7. For a historical account of the HM and LL equations, see Ref. 8. For our consideration of particular interest is the work by Carrey *et al.*,[9] in which a spectral curve for the zero-curvature form of the LL hierarchy was introduced. The authors show that the LL flows are induced by a group action on an infinite dimensional homogeneous space, and that solutions of the LL hierarchy can be constructed by an analog of Birkhoff factorization for elliptic curves. However, the factorization problem is fairly difficult to solve explicitly which poses an obstacle in computing the flows. The motivation for the present work stems from the fact that the computation of the HM flows is reduced to solving a Birkhoff factorization for a subgroup of $\Lambda GL(2,\mathbb{C})$, $GL(2,\mathbb{C})$-valued loops defined on the unit circle. This has the consequence that the homogeneous space on which the HM flows are defined is closely

related to the Segal-Wilson Grassmannian. We study solutions of the HM equation in terms of the geometry of the Grassmannian, and explore its relation to solutions of the focusing NLS equation. We show that solutions of the NLS equation can be expressed in terms of the Baker functions for certain subspaces of the Grassmannian. By using the gauge transformation between the NLS and HM equations, one can associate these subspaces to solutions of the HM equation. We also exhibit subspaces that yield multisoliton solutions of NLS and find an algebraic transformation that maps these solutions to multisoliton solutions of HM.

The paper is organized as follows. In Sec. II we give a brief account of the group theoretic approach to integrable systems. We describe a general construction of partial differential equations that can be formulated as the zero-curvature condition on the Lie algebra of a Banach-Lie group G. The solutions of such equations are represented by flows induced by an action of $\mathbb{R}^n$ on an infinite dimensional homogeneous space. The flows can be integrated by solving a Birkhoff factorization problem for G. In Sec. III we discuss the HM equation within the framework of Sec. II. We define a loop group $G \subset \Lambda GL(2,\mathbb{C})$ and show that the HM flows are induced by an action of $\mathbb{R}^n$ on the homogeneous space G/H_+, where H_+ is a subgroup of "positive" loops in G. We also show that by choosing a different subgroup $G_+ \subset G$ the action induces the NLS flows on G/G_+ that are related with the HM flows by a gauge transformation. This transformation is interpreted as a map between the quotient spaces $\Gamma: G/G_+ \to G/H_+$. We show that if the NLS flows are Laurent polynomials in the spectral variable $z \in S^1$, then Γ is an algebraic transformation between the NLS and HM solutions. In Sec. IV we describe a method for solving the Birkhoff factorization problem for NLS by modeling the space G/G_+ as the Segal-Wilson Grassmannian $\mathrm{Gr}(H)$ of the Hilbert space $H=L^2(S^1,\mathbb{C}^2)$. We associate subspaces in $\mathrm{Gr}(H)$ to solutions of NLS and show that the NLS flows can be computed explicitly in terms of a pair of Baker functions for such subspaces. By modifying the ideas from Ref. 2 we construct subspaces that yield the multisoliton solutions of NLS. These solutions are then mapped to the multisoliton solutions of HM by the transformation Γ.

II. GROUP THEORETIC FORMULATION OF INTEGRABLE SYSTEMS

In this section we give a brief account of the group theoretic construction of integrable systems that admit the zero-curvature representation. A more detailed discussion of the subject can be found, for example, in Ref. 10.

Definition 1: Let G be a Banach Lie group. We say that G admits a Birkhoff factorization denoted (G,G_-,G_+) *if G contains closed subgroups* G_- *and* G_+ *such that* $G_- \cap G_+ = \{e\}$ *and the product* G_-G_+ *is open in G.*

Let $\mathfrak{g}$ be the Lie algebra of G with the Lie bracket $[\cdot,\cdot]$. The set G_-G_+ is open in G if and only if $\mathfrak{g}$ splits into a direct sum of subalgebras $\mathfrak{g}=\mathfrak{g}_- \oplus \mathfrak{g}_+$, where $\mathfrak{g}_\pm$ is the Lie algebra of $G_\pm$. The Birkhoff factorization is modeled to generalize the factorization of $GL(n,\mathbb{C})$ into upper and lower triangular matrices to infinite dimensions. Let $X_1, X_2, \ldots, X_n$ be pairwise commuting elements of $\mathfrak{g}_+$, $[X_i, X_j]=0$, and consider a differentiable action $\mathbb{R}^n \times G \to G$ defined by

$$\mathbf{t} * g = \exp\left(\sum_{i=1}^{n} t_i X_i\right) g, \tag{2}$$

where $\mathbf{t}=(t_1,t_2,\ldots,t_n)$. If $g \in G_-G_+$, then for $\mathbf{t}$ in a neighborhood of $0 \in \mathbb{R}^n$ we have $\mathbf{t}*g \in G_-G_+$ because G_-G_+ is open in G. Hence, $\mathbf{t}*g$ can be factored in a unique way as

$$\mathbf{t} * g = g_-(\mathbf{t}) g_+(\mathbf{t}), \tag{3}$$

where $g_\pm(\mathbf{t}) \in G_\pm$. We say that the action (2) induces the flow $g_\pm(\mathbf{t})$ on $G_\pm$. The element $X_i \in \mathfrak{g}_+$ is called the infinitesimal generator of the t_i flow. Note that the action (2) descends to an action on the quotient space G/G_+ by $\mathbf{t}*(gG_+)=(\mathbf{t}*g)G_+$, thus inducing the flow $g_-(\mathbf{t})G_+$ on G/G_+.

Next, we show that the flow $g_-(\mathbf{t})$ represents solutions to a hierarchy of partial differential equations (PDE) in zero-curvature form on the Lie algebra of $\mathfrak{g}_+$. Let $p_+:\mathfrak{g}\to\mathfrak{g}_+$ denote the orthogonal projection. Observe that Eqs. (2) and (3) imply

$$\mathrm{Ad}(g_-^{-1})X_i = g_-^{-1}\frac{\partial g_-}{\partial t_i} + \frac{\partial g_+}{\partial t_i}g_+^{-1}. \tag{4}$$

By projecting Eq. (4) onto $\mathfrak{g}_+$, we obtain the following system of differential equations:

$$\frac{\partial g_+}{\partial t_i} = M_i(\mathbf{t})g_+(\mathbf{t}), \quad \text{where } M_i(\mathbf{t}) = p_+(\mathrm{Ad}(g_-^{-1}(\mathbf{t}))X_i), \quad 1\le i\le n. \tag{5}$$

Since $[X_i,X_j]=0$, the t_i and t_j flows commute so the compatibility condition $\partial_i\partial_j g_+=\partial_j\partial_i g_+$ yields the zero-curvature equation[1]

$$\frac{\partial M_i}{\partial t_j} - \frac{\partial M_j}{\partial t_i} + [M_i,M_j] = 0, \quad i,j = 1,2,\ldots,n. \tag{6}$$

Equation (6) represents a hierarchy of partial differential equations for the vector fields $M_i(\mathbf{t})$. In concrete realizations of integrable systems, G is a Banach loop group, and Eq. (6) is equivalent with a system of differential equations for matrix elements $\{u(\mathbf{t})\}$ of M_i and M_j. The zero-curvature equation is an evolution equation for $u(x,t)$, where $x=t_1$ is the space variable and $t=t_k$, $k\ge 2$, is the time variable in the kth equation of the hierarchy. Since $u(\mathbf{t})$ can be calculated explicitly from $g_-(\mathbf{t})$, $u(\mathbf{t})$ is represented by the flow $g_-(\mathbf{t})G_+$ on the homogeneous space G/G_+. The group theoretic approach to integrable systems can be used to study explicit solutions, symmetries, and conservation laws in terms of these flows. Note that the map $g\mapsto g_-(\mathbf{t})$ is invariant under the right multiplication of g by an element of G_+. Hence, we may assume that $g=g_-(0)$, so g encodes initial data for Eq. (6). Clearly,

$$\exp\left(\sum_{i=1}^{n}\Delta t_i X_i\right)(g_-(\mathbf{t})G_+) = g_-(\mathbf{t}+\Delta\mathbf{t})G_+,$$

which means that the left multiplication of $g_-(\mathbf{t})G_+$ by $\exp(\Delta t_k X_k)$ pushes $u(\mathbf{t})$ in the t_k direction by the amount Δt_k. In this sense, the Birkhoff factorization linearizes the equation for $u(\mathbf{t})$; hence the map $g_-(\mathbf{t})\mapsto u(\mathbf{t})$ can be viewed as an abstract version of the inverse scattering transform for Eq. (6).

III. BIRKHOFF FACTORIZATION FOR THE HEINSENBERG MAGNET EQUATION

In this section we discuss the Heisenberg magnet equation from the geometrical viewpoint presented in Sec. II. We define a loop group G and show that the flows corresponding to the HM and NLS equations are induced by an action of $\mathbb{R}^n$ on the homogeneous spaces G/H_+ and G/G_+, where H_+ and G_+ are subgroups of "positive" loops in G. Furthermore, we show that the gauge transformation between the NLS and HM equations can be interpreted as a map between the quotient spaces on which the flows are defined. For loops that are Laurent polynomials in the spectral parameter $z\in S^1$ this leads to an algebraic transformation between solutions of the NLS and HM equations.

In order to provide G with a Banach structure we start by introducing the Wiener algebra (see Dorfmeister[11])

$$\mathcal{A} = \left\{ f:S^1\to\mathbb{C} \middle| f(z) = \sum_{n=-\infty}^{\infty} c_n z^n, \sum_{n=-\infty}^{\infty}|c_n| < \infty \right\}.$$

This is a Banach algebra relative to the norm $\|f\|_1=\Sigma_{n=-\infty}^{\infty}|c_n|$. The algebra $\mathcal{A}$ consists of continuous functions on S^1 that have an absolutely convergent Fourier series. Let $gl(n,\mathcal{A})$ denote the

Banach algebra of matrices with elements in $\mathcal{A}$ equipped with the commutator bracket and the norm $\|g\|=\Sigma_{i,j}\|g_{ij}\|_1$. In view of Wiener's lemma,[12] the matrix $g(z)$ is invertible if and only if $\det(g(z))\neq 0$ for all $z\in S^1$. Hence, the group of invertible elements $GL(n,\mathcal{A})=\{g \in gl(n,\mathcal{A})\,|\det(g(z))\neq 0\,\forall\, z\in S^1\}$ is a Banach-Lie group as an open submanifold of $gl(n,\mathcal{A})$. Let σ be a continuous automorphism of the algebra $gl(n,\mathcal{A})$and define the group

$$G=\{g \in GL(n,\mathcal{A})|\sigma(g)=g\}.$$

G is a closed submanifold of $gl(n,\mathcal{A})$, and hence a Banach-Lie group with Lie algebra,

$$\mathfrak{g}=\{g \in gl(n,\mathcal{A})|\sigma(g)=g\}.$$

We shall use the above construction of loop group G in order to derive the HM and NLS flows. We remark that in some cases it is more convenient to use an involution τ on $gl(n,\mathcal{A})$, $\tau^2=id$, and to consider the subgroup $\widetilde{G}=\{g\in GL(n,\mathcal{A})\,|\,\tau(g)g=I\}$. This construction includes twisted loop groups related to systems such as the modified KdV equation[13] and the Neumann oscillator.[14] For more examples of loop groups and integrable systems see Ref. 11.

In order to relate the HM equation with the loop group G define the automorphism $\sigma: gl(2,\mathcal{A})\to gl(2,\mathcal{A})$ by

$$\sigma(g(z))=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}\overline{g(\bar{z})}\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}.$$

Evaluating the condition $\sigma(g)=g$, we obtain

$$G=\left\{g \in GL(2,\mathcal{A})|g(z)=\begin{pmatrix}a(z) & b(z)\\ -\overline{b(\bar{z})} & \overline{a(\bar{z})}\end{pmatrix}\right\}. \tag{7}$$

Consider the subgroups

$$H_-=\left\{h \in G|h(z)=\sum_{n=0}^{\infty}A_n z^{-n}\right\} \quad \text{and} \quad H_+=\left\{h \in G|h(z)=I+\sum_{n=1}^{\infty}B_n z^{n}\right\}.$$

Clearly, H_- and H_+ are closed subgroups of G and $H_-\cap H_+=\{I\}$. Furthermore, the Lie algebras of H_- and H_+ decompose the Lie algebra of G into a direct sum $\mathfrak{g}=\mathfrak{h}_-\oplus\mathfrak{h}_+$, hence the set H_-H_+ is open in G. Thus (G,H_-,H_+) is a Birkhoff factorization for G. We will frequently use the Pauli spin matrices,

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \text{and}\quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}.$$

Now consider the pairwise commuting elements $X_k(z)=\sigma z^k\in\mathfrak{h}_+$ where $\sigma=i\sigma_3$, and define a differentiable action of $\mathbb{R}^n$ on G by

$$\mathbf{t}*h=\exp\left(\sum_{k=1}^{n}t_k\sigma z^k\right)h. \tag{8}$$

For any $h\in H_-H_+$ we have a unique factorization $\mathbf{t}*h=h_-(\mathbf{t})h_+(\mathbf{t})$ for $h\in H_-H_+$ when $\mathbf{t}$ is near $0\in\mathbb{R}^n$ because H_-H_+ is open in G. Let $p_+:\mathfrak{g}\to\mathfrak{h}_+$ denote the orthogonal projection onto strictly positive powers of z, and consider the matrices

$$M_k(\mathbf{t})=p_+(h_-^{-1}(\mathbf{t})\sigma z^k h_-(\mathbf{t})),\quad 1\le k\le n. \tag{9}$$

Observe that M_k is a matrix polynomial of order k in the parameter z. According to the general scheme outlined in Sec. II, the matrices (9) satisfy the zero-curvature condition (6). The system of equations obtained in this way will be called the HM hierarchy. The following result shows that

the first equation in the HM hierarchy is Eq. (1), and that solutions of Eq. (1) are obtained from the factorization $(x,t)*h=h_-(x,t)h_+(x,t)$ for some $h\in H_-H_+$.

Lemma 1: Consider the Birkhoff factorization $(x,t)*h=h_-(x,t)h_+(x,t)$ *for some initial data* $h\in H_-H_+$, *and let* $h_-(x,t)=\Sigma_{k=0}^{\infty}A_k(x,t)z^{-k}$. *Then* $S(x,t)=A_0^{-1}(x,t)\sigma_3A_0(x,t)$ *is the matrix representation of a solution of the HM equation* (1).

Proof: Substituting $h_-(x,t)=\Sigma_{k=0}^{\infty}A_k(x,t)z^{-k}$ into Eq. (9) we obtain the matrix polynomials,

$$M_1=(A_0^{-1}\sigma A_0)z,\quad M_2=(A_0^{-1}\sigma A_0)z^2+[A_0^{-1}\sigma A_0,A_0^{-1}A_1]z.$$

We show that

$$\frac{M_1}{\partial t}-\frac{M_2}{\partial x}+[M_1,M_2]=0 \tag{10}$$

is the zero-curvature representation of Eq. (1). Define the matrices $S=A_0^{-1}\sigma_3A_0$ and $P=A_0^{-1}A_1$. Since

$$A_0=\begin{pmatrix} a_0 & b_0 \\ -\overline{b_0} & \overline{a_0}\end{pmatrix},$$

S is a Hermitian matrix of the form

$$S=\begin{pmatrix} S_3 & S_1-iS_2 \\ S_1+iS_2 & -S_3\end{pmatrix}=\sum_{k=1}^{3}S_k\sigma_k,$$

for some real-valued functions $S_k(x,t)$. Moreover, we have $S^2=I$, which implies $S_1^2+S_2^2+S_3^2=1$. From this, it follows that Eq. (10) is equivalent with the system of equations for S and P,

$$i\frac{\partial S}{\partial x}+[S,[S,P]]=0, \tag{11}$$

$$\frac{\partial S}{\partial t}-\frac{\partial}{\partial x}[S,P]=0. \tag{12}$$

By substituting the identity $[S,[S,P]]=2S[P,S]$ into Eq. (11), we obtain $[S,P]=(i/2)SS_x$. Then Eq. (12) yields

$$\frac{\partial S}{\partial t}=\frac{i}{2}\left[\frac{\partial^2S}{\partial x^2}S+\left(\frac{\partial S}{\partial x}\right)^2\right]. \tag{13}$$

Finally, we note that $2(S_x)^2=-S_{xx}S-SS_{xx}$, thus Eq. (13) becomes

$$\frac{\partial S}{\partial t}=\frac{1}{4i}\left[S,\frac{\partial^2S}{\partial x^2}\right]. \tag{14}$$

After dilating the time variable $t\mapsto t/2$ we conclude that Eq. (14) is equivalent with Eq. (1). ■

Thus, solutions of the HM equation are represented by the flows $h_-(x,t)H_+$ on the homogeneous space G/H_+.

Next, we discuss the gauge transformation between the focusing NLS and HM equations in the context of Birkhoff factorization for G. Recall that the gauge transformation $\gamma_g:\mathfrak{g}\times\mathfrak{g}\to\mathfrak{g}\times\mathfrak{g}$ by an element $g(x,t)\in G$ is defined by

$$\gamma_g(U,V)=\left(\mathrm{Ad}(g)U+\frac{\partial g}{\partial x}g^{-1},\mathrm{Ad}(g)V+\frac{\partial g}{\partial t}g^{-1}\right).$$

This transformation preserves the zero-curvature condition, and two systems of equations are said to be gauge equivalent if their zero-curvature representations are related by a gauge transformation.

It is well known that Eq. (1) is gauge equivalent with the focusing NLS equation,

$$i\frac{\partial u}{\partial t}-\frac{1}{2}\frac{\partial^2 u}{\partial x^2}-4u|u|^2=0, \tag{15}$$

where $u(x,t)$ is a complex valued function.[3] We show that on the group level the gauge transformation $NLS\mapsto HM$ can be interpreted as a map between the quotient spaces $\Gamma: G/G_+\to G/H_+$, where (G,G_-,G_+) is the Birkhoff factorization for G defined by the subgroups

$$G_-=\left\{g\in G|g(z)=I+\sum_{n=1}^{\infty}A_n z^{-n}\right\},\quad G_+=\left\{g\in G|g(z)=\sum_{n=0}^{\infty}B_n z^n\right\}. \tag{16}$$

Clearly, $\mathfrak{g}=\mathfrak{g}_-\oplus\mathfrak{g}_+$ where $\mathfrak{g}_\pm$ is the Lie algebra of $G_\pm$. One can think of (G,H_-,H_+) and (G,G_-,G_+) as two factorizations that differ in the normalization conditions: $h_+(0)=I$ and $g_-(\infty)=I$.

The NLS equation can be written in zero-curvature form as follows. Suppose that the action of $\mathbb{R}^n$ on G is given by (8), and consider now the factorization $\mathbf{t}*g=g_-(\mathbf{t})g_+(\mathbf{t})$ for some $g\in G_-G_+$. Let $q_+:\mathfrak{g}\to\mathfrak{g}_+$ denote the orthogonal projection onto non-negative powers of z. Then the matrix polynomials defined by

$$\hat{M}_k(\mathbf{t})=q_+(g_-^{-1}(\mathbf{t})\sigma z^k g_-(\mathbf{t})),\quad k=1,2,\ldots,n, \tag{17}$$

satisfy the system of equations (6), which is called the NLS hierarchy. It is not difficult to see that Eq. (15) is the first equation in the hierarchy. Denoting $g_-(x,t)=I+\sum_{n=1}^{\infty}A_n(x,t)z^{-n}$ and evaluating Eq. (17), we obtain

$$\hat{M}_1=\sigma z+[\sigma,A_1],\quad \hat{M}_2=\sigma z^2+[\sigma,A_1]z+[\sigma,A_2]-A_1[\sigma,A_1].$$

Since

$$A_n=\begin{pmatrix}a_n & b_n\\ -\bar{b}_n & \bar{a}_n\end{pmatrix},$$

the matrices $\hat{M}_1$ and $\hat{M}_2$ have the form

$$\hat{M}_1=\sigma z+2\begin{pmatrix}0 & ib_1\\ -\overline{ib_1} & 0\end{pmatrix},\quad \hat{M}_2=\sigma z^2+2\begin{pmatrix}0 & ib_1\\ -\overline{ib_1} & 0\end{pmatrix}z+2\begin{pmatrix}-i|b_1|^2 & v\\ -\bar{v} & i|b_1|^2\end{pmatrix}, \tag{18}$$

where $v=i(b_2-a_1b_1)$. It is easily verified that the zero-curvature condition (6) for $\hat{M}_1$ and $\hat{M}_2$ is equivalent with Eq. (15) for $u=b_1$. The NLS equation can also be obtained by a reduction as a special case of the AKNS hierarchy.[15]

We have seen that the loop group G defined by Eq. (7) admits two factorizations: (G,G_-G_+) and (G,H_-H_+). In fact, the sets G_-G_+ and H_-H_+ are equal, so we may denote them by K. Since each $k\in K$ can be factored uniquely as $k=g_-g_+=h_-h_+$ we can define a map $\Gamma: K/G_+\to K/H_+$ by $\Gamma(g_-G_+)=h_-H_+$. The elements $h_\pm$ are related to $g_\pm$ simply by $h_-=g_-B_0$ and $h_+=B_0^{-1}g_+$, where B_0 is the zeroth-order Fourier coefficient of g_+. Note that if $k(x,t)=(x,t)*g$ is the flow in G based at $k(0,0)=g\in G_-$, then the cosets $k(x,t)G_+$ and $k(x,t)H_+$ represent the NLS and HM flows, respectively. Thus, on the group level Γ maps the NLS solutions to HM solutions. Moreover, since g_+

$=B_0 h_+$ and the vector fields (M_1, M_2) satisfy Eq. (5), we conclude that (M_1, M_2) and $(\hat{M}_1, \hat{M}_2)$ are related by $(M_1, M_2) = \gamma(\hat{M}_1, \hat{M}_2)$, where γ is the gauge transformation by B_0^{-1}.Thus, we have the following.

Lemma 2: Let $\tilde{K}$ be the set of flows $\{(x,t) * g \,|\, g \in G_-\}$. Then the diagram

$$\begin{array}{ccc} \mathfrak{g}_+ \times \mathfrak{g}_+ & \overset{\gamma}{\rightarrow} & \mathfrak{h}_+ \times \mathfrak{h}_+ \\ \hat{\pi} \uparrow & & \uparrow \pi \\ \tilde{K}/G_+ & \overset{\Gamma}{\rightarrow} & \tilde{K}/H_+ \end{array}$$

is commutative, where the maps $\hat{\pi}(g_- G_+) = (\hat{M}_1, \hat{M}_2)$ and $\pi(h_- H_+) = (M_1, M_2)$ are defined in terms of Eqs. (17) and (9), *respectively, and γ is the gauge transformation by B_0^{-1}.*

If $g_-(x,t)$ is a Laurent polynomial in the spectral parameter $z \in S^1$, then Γ leads to a simple algebraic transformation between the NLS and HM solutions. Suppose for the moment that $g_-(x,t)$ has a pole of order N at $z=0$, so that

$$(x,t) * g = \left(I + \sum_{k=1}^{N} A_k(x,t) z^{-k} \right) \left(\sum_{k=0}^{\infty} B_k(x,t) z^k \right), \tag{19}$$

where $g = I + \Sigma_{k=1}^{N} A_k(0,0) z^{-k}$. Comparing the coefficients with z^{-N} on both sides of Eq. (19), we conclude that $B_0(x,t) = A_N^{-1}(x,t) A_N(0,0)$. The solution of the HM equation is thus given by

$$S(x,t) = B_0^{-1}(x,t) \sigma_3 B_0(x,t)$$

$$= A_N^{-1}(0,0) A_N(x,t) \sigma_3 A_N^{-1}(x,t) A_N(0,0).$$

Denote

$$A_N(x,t) = \begin{pmatrix} a & b \\ -\bar{b} & \bar{a} \end{pmatrix}$$

and let $a(0,0) = a_0$, $b(0,0) = b_0$. A straightforward computation shows that the elements of S can be expressed as

$$S_3 = \frac{(|a|^2 - |b|^2)(|a_0|^2 - |b_0|^2) + 4\,\mathrm{Re}(ab\overline{a_0 b_0})}{(|a|^2 - |b|^2)(|a_0|^2 - |b_0|^2)},$$

$$S_1 + iS_2 = \frac{2[(|a|^2 - |b|^2) a_0 \bar{b}_0 + ab\bar{b}_0^2 - \overline{ab} a_0^2]}{(|a|^2 - |b|^2)(|a_0|^2 - |b_0|^2)}. \tag{20}$$

Hence, if $g_-(x,t)$ has a pole at $z=0$, then the transformation (20) completely determines the vector $\vec{S} = (S_1, S_2, S_3)$ from the lowest order Fourier coefficient of the NLS flow $g_-(x,t)$. We will show in the next section that factorization (19) leads to multisoliton solutions of NLS. In this case the transformation $\Gamma : \tilde{K}/G_+ \to \tilde{K}/H_+$ maps multisoliton solutions of NLS to multisoliton solutions of HM. Finally, we remark that the correct choice of the loop group is important for obtaining the desired classes of solutions. For example, the NLS equation can also be derived from the group $G \cap SL(2, \mathcal{A})$, but the subgroup $(G \cap SL(2, \mathcal{A}))_-$ no longer contains Laurent polynomials, and hence no soliton solutions.

As an example of transformation (20) consider the initial data

$$g(z) = I + \begin{pmatrix} 0 & -i\alpha \\ -i\alpha & 0 \end{pmatrix} z^{-1}.$$

The time evolution of $g(z)$ determined by Eq. (19) is given by

$$g_-(x,t) = I + \begin{pmatrix} -i\alpha \tanh(2\alpha x) & -i\alpha e^{-i\alpha^2 t} \operatorname{sech}(2\alpha x) \\ -i\alpha e^{i2\alpha^2 t} \operatorname{sech}(2\alpha x) & i\alpha \tanh(2\alpha x) \end{pmatrix} z^{-1}.$$

Then the transformation (20) yields

$$S_1(x,t) = 2\cos(2\alpha^2 t)\tanh(2\alpha x)\operatorname{sech}(2\alpha x),$$

$$S_2(x,t) = -2\sin(2\alpha^2 t)\tanh(2\alpha x)\operatorname{sech}(2\alpha x),$$

$$S_3(x,t) = 2\operatorname{sech}^2(2\alpha x) - 1.$$

This is a solution of the HM equation that represents the magnetization vector $\vec{S}$ of unit length that rotates about the z axis.

IV. EXPLICIT SOLUTION OF THE BIRKHOFF FACTORIZATION PROBLEM

In this section we describe a geometrical solution of the Birkhoff factorization problem for the focusing NLS equation in terms of an infinite dimensional Grassmannian $\mathrm{Gr}(H)$. Our approach is based on the ideas of Segal and Wilson[2] who obtained solutions of the KdV equation in terms of the Baker function for special subspaces in $\mathrm{Gr}(H)$. By a similar procedure we construct a pair of Baker functions that yield solutions of the NLS equation. The geometrical approach to the NLS equation has been studied by several authors. Guil and Mañas[15] have used the Grassmannian model in the study of self-similar solutions of the AKNS hierarchy. As a byproduct, they characterized points in the Segal-Wilson Grassmannian that correspond to Nakamura-Hirota rational solutions of the nonfocusing NLS equation.[16] In Ref. 17 Previato obtained solutions of the focusing and nonfocusing NLS in terms of theta functions for the corresponding hyperelliptic curve. Although the Grassmannian model for integrable systems has been well studied, the solution of the factorization problem for NLS given here does not seem to appear in the literature.

In the following we give a brief account of the Segal-Wilson Grassmannian of the Hilbert space $H=L^2(S^1,\mathbb{C}^2)$. More details can be found in Refs. 2 and 18. Let H be the Hilbert space of square integrable functions on S^1 with values in $\mathbb{C}^2$, $f(z)=\Sigma_{k\in\mathbb{Z}}a_k z^k$, $a_k\in\mathbb{C}^2$ and $|z|=1$. The space H has a natural decomposition $H=H_+\oplus H_-$ into closed subspaces $H_+=\{\Sigma_{k\geq 0}a_k z^k\}$ and $H_-=\{\Sigma_{k<0}a_k z^k\}$. The Grassmannian $\mathrm{Gr}(H)$ is the set of closed subspaces $W\subset H$ such that the orthogonal projection $p_+: W\to H_+$ is a Fredholm operator and $p_-: W\to H_-$ is a Hilbert-Schmidt operator. It is not difficult to see that $\mathrm{Gr}(H)$ is a Hilbert manifold modeled on the space of Hilbert-Schmidt operators $\mathcal{C}_2(H_+,H_-)$. A chart around $W\in\mathrm{Gr}(H)$ is the set $\mathcal{U}_W=\{G(T)\,|\,T\in\mathcal{C}_2(W,W^\perp)\}$, where $G(T)=\{x+Tx\,|\,x\in W\}$ is the graph of T, together with the map $\mathcal{U}_W\to\mathcal{C}_2(W,W^\perp)$ defined by $G(T)\mapsto T$. Since W and $W^\perp$ are both infinite dimensional, the Hilbert spaces $\mathcal{C}_2(W,W^\perp)$ and $\mathcal{C}_2(H_+,H_-)$ are isomorphic.

Recall that the index of a Fredholm operator T is defined by $\mathrm{ind}(T)=\dim(\ker(T))-\dim(\mathrm{coker}(T))$. If $W\in\mathrm{Gr}(H)$, then the index of $p_+: W\to H_+$ is called the virtual dimension of W, $v.\dim(W)$. The Grassmannian is not connected since the connected components are indexed by the integers $v.\dim(W)$. Only the component $\mathrm{Gr}_0(H)=\{W\in\mathrm{Gr}(H)\,|\,v.\dim(W)=0\}$ will play a role in applications to NLS. The set $\mathrm{Gr}_0(H)\cap\mathcal{U}_{H_+}$ is sometimes called the "big cell," and has the following important property.

Lemma 3: (i) $W\in\mathrm{Gr}_0(H)\cap\mathcal{U}_{H_+}$ *if and only if* $p_+: W\to H_+$ *is an isomorphism.* (ii) *If* $W\in\mathrm{Gr}_0(H)$, *then* $W\in\mathcal{U}_{H_+}$, *if and only if* $W\cap H_-=\{0\}$.

Proof: (i) Suppose that $W\in\mathrm{Gr}_0(H)\cap\mathcal{U}_{H_+}$. Then $p_+: W\to H_+$ has index zero and the subspace

W is of the form $W=\{x+Tx|x\in H_+\}$ for some Hilbert-Schmidt operator $T:H_+\to H_-$. If $p_+(x+Tx)=0$, then clearly $x=0$; hence p_+ is injective. Furthermore, $\mathrm{ind}(p_+)=0$ implies that $\dim(\mathrm{coker}(p_+))=0$. Thus, p_+ is both injective and surjective, and hence an isomorphism.

Now suppose that $p_+:W\to H_+$ is an isomorphism. Then clearly $\mathrm{ind}(p_+)=0$, and hence $W\in \mathrm{Gr}_0(H)$. Since the projection $p_-:W\to H_-$ is a Hilbert-Schmidt operator, so is the product $T=p_-p_+^{-1}:H_+\to H_-$. We note that $W=\{x+Tx|x\in H_+\}$, which proves that $W\in\mathcal{U}_{H_+}$. Thus, $W\in \mathrm{Gr}_0(H)\cap\mathcal{U}_{H_+}$. Part (ii) is proved in a similar fashion. ■

The full group $\mathrm{GL}(H)$ of bounded invertible operators with bounded inverse does not act on $\mathrm{Gr}(H)$, as it does not preserve the properties of the projections $p_\pm:W\to H_\pm$. However, the restricted general linear group $\mathrm{GL}_{\mathrm{res}}(H)$ acts on $\mathrm{Gr}(H)$. $\mathrm{GL}_{\mathrm{res}}(H)$ is the subgroup of $\mathrm{GL}(H)$ consisting of operators whose block form $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ with respect to the decomposition $H=H_+\oplus H_-$ has off-diagonal terms Hilbert-Schmidt: $b\in\mathcal{C}_2(H_-,H_+)$ and $c\in\mathcal{C}_2(H_+,H_-)$. The diagonal terms are then automatically Fredholm. The action of $\mathrm{GL}_{\mathrm{res}}(H)$ is transitive since the orbit through H_+ is $\mathrm{Gr}(H)$.

We shall be interested in the group Γ_+ of holomorphic maps on the unit disk $g:D_0\to GL(2,\mathbb{C})$, $D_0=\{|z|\le 1\}$. The elements of Γ_+ can be viewed as multiplication operators on H. A computation involving the expansion of $g(z)$ into the Taylor series around $z=0$ shows that if $g(z)$ is holomorphic, then the corresponding multiplication operator $M_g:H_+\oplus H_-\to H_+\oplus H_-$ has the block form $M_g=\begin{pmatrix} a & b \\ 0 & d \end{pmatrix}$, where a and d are invertible and b is Hilbert-Schmidt. Hence $M_g\in\mathrm{GL}_{\mathrm{res}}(H)$, and so Γ_+ acts on $\mathrm{Gr}(H)$. In fact, since a is invertible, Γ_+ acts on the connected component $\mathrm{Gr}_0(H)$. By a similar argument, it can be shown that the group Γ_- of based holomorphic maps $g:D_\infty\to GL(2,\mathbb{C})$, $D_\infty=\{|z|\ge 1\}$, where $g(\infty)=I$ also acts on $\mathrm{Gr}_0(H)$. Due to the analytical structure of the group G introduced in Sec. III, we have $G_\pm\subset\Gamma_\pm$ [see Eq. (16)]. In particular, the loop $\exp(\Sigma_{k=1}^n t_k\sigma z^k)\in\Gamma_+$ acts on $\mathrm{Gr}_0(H)$. For any $W\in\mathrm{Gr}_0(H)\cap\mathcal{U}_{H_+}$, define the subspace

$$W(\mathbf{t})=\exp\left(\sum_{k=1}^n t_k\sigma z^k\right)W.$$

Clearly, $W(\mathbf{t})\in Gr_0(H)\cap\mathcal{U}_{H_+}$ when $\mathbf{t}$ is near $0\in\mathbb{R}^n$ because $\mathcal{U}_{H_+}$ is open and Γ_+ acts on $\mathrm{Gr}_0(H)$. Hence, by Lemma 3(i) the orthogonal projection $p_+:W(\mathbf{t})\to H_+$ is an isomorphism.

Definition 2: Let $W\in\mathrm{Gr}_0(H)\cap\mathcal{U}_{H_+}$ and consider the isomorphism $p_+:W(\mathbf{t})\to H_+$. The Baker functions for the subspace W are the unique elements $\Psi_1(\mathbf{t},z)$, $\Psi_2(\mathbf{t},z)\in W$ such that

$$\exp\left(\sum_{k=1}^n t_k\sigma z^k\right)\Psi_1(\mathbf{t},z)=p_+^{-1}(e_1),\quad \exp\left(\sum_{k=1}^n t_k\sigma z^k\right)\Psi_2(\mathbf{t},z)=p_+^{-1}(e_2),\tag{21}$$

where $e_1=\begin{pmatrix}1\\0\end{pmatrix}$, $e_2=\begin{pmatrix}0\\1\end{pmatrix}$.

In the following we show that the flows of the NLS hierarchy can be expressed in terms of the Baker functions Ψ_1 and Ψ_2. For certain subspaces W this yields the multisoliton solutions of NLS. Let $g\in G_-$ and consider the subspace $gH_+\in\mathrm{Gr}(H)$. Suppose for the moment that gH_+ contains a subspace W such that $W\in\mathrm{Gr}_0(H)\cap\mathcal{U}_{H_+}$, and let Ψ_1, Ψ_2 be the Baker functions for W. The existence of such subspaces will be shown shortly. Since $W\subset gH_+$ we have $\Psi_1=gf_1$, $\Psi_2=gf_2$ for some $f_1,f_2\in H_+$, and

$$\exp\left(\sum_{k=1}^n t_k\sigma z^k\right)gf_1=p_+^{-1}(e_1),\quad \exp\left(\sum_{k=1}^n t_k\sigma z^k\right)gf_2=p_+^{-1}(e_2).$$

This can be combined into the matrix equation

$$\exp\left(\sum_{k=1}^{n} t_k \sigma z^k\right) g[f_1|f_2] = [p_+^{-1}(e_1)|p_+^{-1}(e_2)].$$

We note that the matrices involved here have the form

$$[f_1|f_2] = \sum_{k=0}^{\infty} B_k z^k, \quad [p_+^{-1}(e_1)|p_+^{-1}(e_2)] = I + \sum_{k=1}^{\infty} A_k z^{-k}.$$

If the matrix $[f_1|f_2]$ is invertible, then by uniqueness of the Birkhoff factorization (G, G_-, G_+), we have

$$\exp\left(\sum_{k=1}^{n} t_k \sigma z^k\right) g = g_-(\mathbf{t}) g_+(\mathbf{t}), \quad g_\pm \in G_\pm, \tag{22}$$

where $g_+(\mathbf{t}) = [f_1|f_2]^{-1}$ and $g_-(\mathbf{t}) = [p_+^{-1}(e_1)|p_+^{-1}(e_2)]$, which is precisely the factorization problem for NLS. The importance of the last relation is that in view of Eq. (21) the flow $g_-(\mathbf{t})$ can be expressed in terms of the Baker functions:

$$g_-(\mathbf{t}) = \exp\left(\sum_{k=1}^{n} t_k \sigma z^k\right) [\Psi_1|\Psi_2]. \tag{23}$$

This result can be formulated as the following theorem.

Theorem 1: *Let $g \in G_-$ and let W be a subspace of $gH_+ \in Gr(H)$ such that $W \in Gr_0(H) \cap \mathcal{U}_{H_+}$. Then the flow $g_-(\mathbf{t})$ given by Eq.* (23) *is the unique solution of the NLS factorization problem* (22), *where Ψ_1 and Ψ_2 are the Baker functions for W.*

Example 1 (one-soliton solution): Perhaps the simplest interesting example of a subspace in $\mathrm{Gr}_0(H) \cap \mathcal{U}_{H_+}$ is the one which yields the one-soliton solution of NLS. Its construction resembles the one-soliton space for the KdV equation given in Ref. 2. Consider the points in the unit disk $0 < |p_i| < 1$, $i = 1, 2$, and the parameters $\lambda, \mu \in \mathbb{C}^\times$, $\lambda \neq \mu$. Define W_1 to be the L^2 closure of the space of functions $f: S^1 \to \mathbb{C}^2$, $f = \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}$, where f_1 and f_2 are holomorphic in D_0, except possibly for a simple pole at $z = 0$; and that satisfy the condition

$$f_1(p_1) = \lambda f_2(p_1), \quad f_1(p_2) = \mu f_2(p_2). \tag{24}$$

It is straightforward to verify that $W_1 \in \mathrm{Gr}_0(H)$ and $W_1 \cap H_- = \{0\}$. It follows from Lemma 3(ii) that $W_1 \in \mathrm{Gr}_0(H) \cap \mathcal{U}_{H_+}$, so $p_+: W_1(\mathbf{t}) \to H_+$ is an isomorphism. In order to obtain the Baker functions for the NLS equation let us write $x = t_1$, $t = t_2$, and suppress t_k for $k \geq 3$. Denote

$$p_+^{-1}(e_1) = \begin{pmatrix} az^{-1} + 1 \\ cz^{-1} \end{pmatrix}, \quad p_+^{-1}(e_2) = \begin{pmatrix} bz^{-1} \\ dz^{-1} + 1 \end{pmatrix}.$$

Then the Baker functions for W_1 have the form

$$\Psi_1(x,t,z) = \exp(-x\sigma z - t\sigma z^2) p_+^{-1}(e_1) = \begin{pmatrix} (1 + az^{-1}) e^{-ixz - itz^2} \\ cz^{-1} e^{ixz + itz^2} \end{pmatrix},$$

$$\Psi_2(x,t,z) = \exp(-x\sigma z - t\sigma z^2) p_+^{-1}(e_2) = \begin{pmatrix} bz^{-1} e^{-ixz - itz^2} \\ (1 + dz^{-1}) e^{ixz + itz^2} \end{pmatrix}.$$

Since Ψ_1 and Ψ_2 satisfy the condition (24), the coefficients a, b, c, d are given by

$$a = \frac{p_1 \mu e^{i\theta_2} - p_2 \lambda e^{i\theta_1}}{\lambda e^{i\theta_1} - \mu e^{i\theta_2}}, \quad b = -\frac{\lambda\mu(p_1 - p_2)}{\lambda e^{-i\theta_2} - \mu e^{-i\theta_1}}, \tag{25}$$

$$c = \frac{p_1 - p_2}{\lambda e^{i\theta_1} - \mu e^{i\theta_2}}, \qquad d = -\frac{p_1 \lambda e^{-i\theta_2} - p_2 \mu e^{-i\theta_1}}{\lambda e^{-i\theta_2} - \mu e^{-i\theta_1}}, \tag{26}$$

where $\theta_k = 2(xp_k + tp_k^2)$, $k = 1, 2$. In view of the relation

$$g_-(x,t) = \exp(x\sigma z + t\sigma z^2)[\Psi_1 | \Psi_2] = I + \begin{pmatrix} a & b \\ c & d \end{pmatrix} z^{-1},$$

for the Baker functions to generate solutions of the NLS equation we must have $g_-(x,t) \in G_-$, i.e., the matrix coefficients must satisfy $c = -\bar{b}$ and $d = \bar{a}$. These conditions are satisfied, provided $p_1 = \bar{p}_2$ and $\lambda\bar{\mu} = -1$. Let us write $p_1 = \alpha + i\beta$ and $\lambda = e^{-2\beta x_0} e^{i2\varphi}$ for some $\varphi, x_0 \in \mathbb{R}$. Then it follows from Eq. (25) that a and b have the particularly simple form

$$a(x,t) = -\alpha + i\beta \tanh[2\beta(x + \alpha t + x_0)],$$

$$b(x,t) = i\beta \exp[i2(\alpha x + (\alpha^2 - \beta^2)t + \varphi)] \operatorname{sech}[2\beta(x + \alpha t + x_0)].$$

According to the discussion in Sec. III [see Eq. (18)] the coefficient $b(x,t)$ is a solution of Eq. (15), which is the well-known one-soliton solution of NLS.

Example 2 (n-soliton solution): The n-soliton solution is obtained by a simple generalization of the above construction. Consider n points in the unit disk $0 < |p_i| < 1$, $1 \le i \le n$, and n parameters $\lambda_1, \lambda_2, \ldots, \lambda_n \in \mathbb{C}^\times$. Let W_n the L^2 closure of the space of functions $f: S^1 \to \mathbb{C}^2$, where f_1 and f_2 are holomorphic in D_0 except possibly for a pole of order n at $z = 0$, and that satisfy the $2n$ conditions

$$f_1(p_j) = \lambda_j f_2(p_j), \quad f_1(\bar{p}_j) = \mu_j f_2(\bar{p}_j), \quad j = 1, 2, \ldots, n, \tag{27}$$

where $\lambda_j \bar{\mu}_j = -1$. The Baker functions for W_n are given by

$$\Psi_1(x,t,z) = \begin{pmatrix} (1 + \sum_{k=1}^n a_k z^{-k}) e^{-i(xz + tz^2)} \\ (\sum_{k=1}^n c_k z^{-k}) e^{i(xz + tz^2)} \end{pmatrix},$$

$$\Psi_2(x,t,z) = \begin{pmatrix} (\sum_{k=1}^n b_k z^{-k}) e^{-i(xz + tz^2)} \\ (1 + \sum_{k=1}^n d_k z^{-k}) e^{i(xz + tz^2)} \end{pmatrix}.$$

Conditions (27) yield the following system of equations for a_k, b_k, c_k, d_k:

$$\sum_{k=1}^n \left(\lambda_j e^{i\theta_j} \frac{1}{p_j^k} c_k - \frac{1}{p_j^k} a_k \right) = 1, \quad \sum_{k=1}^n \left(\mu_j e^{i\bar{\theta}_j} \frac{1}{\bar{p}_j^k} c_k - \frac{1}{\bar{p}_j^k} a_k \right) = 1, \tag{28}$$

$$\sum_{k=1}^n \left(\frac{1}{\lambda_j e^{i\theta_j}} \frac{1}{p_j^k} b_k - \frac{1}{p_j^k} d_k \right) = 1, \quad \sum_{k=1}^n \left(\frac{1}{\mu_j e^{i\bar{\theta}_j}} \frac{1}{\bar{p}_j^k} b_k - \frac{1}{\bar{p}_j^k} d_k \right) = 1, \tag{29}$$

where $\theta_j = 2(xp_j + tp_j^2)$, $1 \le j \le n$. The consistency condition $\lambda_j \bar{\mu}_j = -1$ ensures that $c_k = -\bar{b}_k$ and $d_k = \bar{a}_k$. The n-soliton solution of NLS is then given as the quotient of the determinants $b_1 = \Delta_1 / \Delta$, where

$$\Delta = \prod_{j=1}^{n} \frac{1}{\lambda_j \mu_j} \begin{vmatrix} q_1 e^{-i\theta_1} & q_1^2 e^{-i\theta_1} & \cdots & q_1^n e^{-i\theta_1} & -\lambda_1 q_1 & -\lambda_1 q_1^2 & \cdots & -\lambda_1 q_1^n \\ \vdots & & & & & & & \vdots \\ q_n e^{-i\theta_n} & q_n^2 e^{-i\theta_n} & \cdots & q_n^n e^{-i\theta_n} & -\lambda_n q_n & -\lambda_n q_n^2 & \cdots & -\lambda_n q_n^n \\ \bar{q}_1 e^{-i\bar{\theta}_1} & \bar{q}_1^2 e^{-i\bar{\theta}_1} & \cdots & \bar{q}_1^n e^{-i\bar{\theta}_1} & -\mu_1 \bar{q}_1 & -\mu_1 \bar{q}_1^2 & \cdots & -\mu_1 \bar{q}_1^n \\ \vdots & & & & & & & \vdots \\ \bar{q}_n e^{-i\bar{\theta}_n} & \bar{q}_n^2 e^{-i\bar{\theta}_n} & \cdots & \bar{q}_n^n e^{-i\bar{\theta}_n} & -\mu_n \bar{q}_n & -\mu \bar{q}_n^2 & \cdots & -\mu_n \bar{q}_n^n \end{vmatrix},$$

$q_j = 1/p_j$, and Δ_1 is obtained by replacing the first column of Δ by the vector $(\lambda_1 \ldots \lambda_n \mu_1 \ldots \mu_n)^T$. The explicit form of b_1 becomes fairly complicated as n increases. To conclude our discussion we remark that by solving system (28) and (29) for the lowest order coefficients a_n and b_n, and applying the transformation (20) to a_n and b_n we obtain the n-soliton solution of the HM equation. Hence, we can associate solutions of the HM equation to the subspaces $W_n \in \mathrm{Gr}(H)$ via the mappings $W_n \mapsto (a_n, b_n) \mapsto (S_1, S_2, S_3)$.

Block-diagonalizability problem for hydrodynamic type systems

Oleg I. Bogoyavlenskij
Department of Mathematics, Queen's University, Kingston, Canada K7L 3N6

(Received 8 January 2006; accepted 26 April 2006; published online 9 June 2006)

The necessary and sufficient conditions are derived for the reducibility of a hydrodynamic type system into a block-diagonal form with k mutually interacting blocks. Applications to the perturbations of the Benney system and to the Hamiltonian systems of partial differential equations are presented. The algebraic identities connecting the Nijenhuis tensors $N_{B(A)}(u,v)$ and $N_A(u,v)$ and Haantjes tensors $H_{B(A)}(u,v)$ and $H_A(u,v)$ are discovered. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2206692]

I. INTRODUCTION

As is known, the block diagonalizability of a hydrodynamic type system

$$\frac{\partial u^\ell}{\partial t}=\sum_{j=1}^{n} A_m^\ell(u^1,\ldots,u^n)\frac{\partial u^m}{\partial x} \tag{1.1}$$

drastically effects its properties and the computer time required for its numerical investigation. Until now no necessary and sufficient conditions for the block diagonalizability were known. The Courant problem on the block diagonalizability[1] is formulated as follows.

When a given system (1.1) can be transformed in some coordinates $v^1(u),\ldots,v^n(u)$ *into block-diagonal form*

$$\frac{\partial v^{m_j+i}}{\partial t}=\sum_{\ell=1}^{n_j}\tilde{A}_{m_j+\ell}^{m_j+i}(v^1,\ldots,v^n)\frac{\partial v^{m_j+\ell}}{\partial x} \tag{1.2}$$

with $n_j\times n_j$ *mutually interacting blocks where* $n_1+\cdots+n_k=n$*?* Here $j=1,\ldots,k$, $i=1,\ldots,n_j$ and $m_j=n_1+\cdots+n_{j-1}$; $u^1,\ldots,u^n$ and $v^1(u),\ldots,v^n(u)$ form systems of local coordinates in the Euclidean space R^n. The first result concerning the block-diagonalizability problem follows from the Haantjes theorem[2] on the X_m-forming sets of eigenvalues of a (1,1)-tensors $A_j^i(u^1,\ldots,u^n)$. The theorem is proved in Ref. 2 and is equivalent to the following statement.

The necessary and sufficient condition for the complete diagonalizability of the system (1.1) with real and distinct eigenvalues of $A_j^i(u)$ *is the vanishing of the corresponding Haantjes (1,2)-tensor*[2]

$$H_{Ajk}^i=A_\alpha^i A_\beta^\alpha N_{jk}^\beta+N_{\alpha\beta}^i A_j^\alpha A_k^\beta-A_\alpha^i N_{\beta k}^\alpha A_j^\beta-A_\alpha^i N_{j\beta}^\alpha A_k^\beta \tag{1.3}$$

that is defined in terms of the Nijenhuis tensor[3]

$$N_{Aik}^j=A_i^\alpha\frac{\partial A_k^j}{\partial u^\alpha}-A_k^\alpha\frac{\partial A_i^j}{\partial u^\alpha}+A_\alpha^j\frac{\partial A_i^\alpha}{\partial u^k}-A_\alpha^j\frac{\partial A_k^\alpha}{\partial u^i}. \tag{1.4}$$

The more general case of complex eigenvalues of $A_j^i(u)$ was not studied in Refs. 2 and 3. It is evident however that for a generic system of pde's (1.1) some of the eigenvalues of $A_j^i(u)$ are complex.

In this paper we prove Theorem 1 that gives the necessary and sufficient conditions for the block diagonalizability of systems (1.1). The proof of Theorem 1 presented in Sec. III is based on a new algebraic identity that connects the Nijenhuis tensor $N_{B(A)}(u,v)$ with the $N_A(u,v)$ where $B(A)$ is an arbitrary polynomial in A. The identity and its analog for the Haantjes tensor are proved in Sec. II. In Sec. IV we demonstrate applications to the perturbations of the Benney system[4] and to the Hamiltonian systems of partial differential equations in R^3.

The Nijenhuis tensor appears in many problems of mathematical physics and differential geometry, mostly as the vanishing condition $N_A(u,v)=0$: The Gelfand-Dorfman-Magri-Morosi theorem[5,6] states that the two Poisson structures P_1 and P_2 are compatible in Magri's sense[7] if and only if $N_A(u,v)=0$ where $A=P_1P_2^{-1}$. The Newlander-Nirenberg theorem[8] states that a quasicomplex structure $A(x)$, $A^2(x)=-1$, is complex if and only if the Nijenhuis tensor $N_A(u,v)$ vanishes. The condition $N_A(u,v)=0$ is used in Refs. 6, 9, and 10 as the definition of the Poisson-Nijenhuis structures and in Ref. 11 as the definition of the Nijenhuis G-manifolds with applications to the KP systems. The condition $N_A(u,v)=0$ is used in Refs. 12 and 13 as a sufficient condition for the existence of conservation laws for systems of pde's (1.1).

In Refs. 14 and 15 we applied the nonzero Nijenhuis and Haantjes tensors to study the necessary criteria for the existence of the Hamiltonian and bi-Hamiltonian structures for systems (1.1).

II. ALGEBRAIC IDENTITIES FOR THE NIJENHUIS AND HAANTJES TENSORS

(i) The Nijenhuis tensor is defined by the formula[3]

$$N_A(u,v)=A^2[\tilde{u},\tilde{v}]+[A\tilde{u},A\tilde{v}]-A[A\tilde{u},\tilde{v}]-A[\tilde{u},A\tilde{v}], \tag{2.1}$$

where u and v are tangent vectors at a point $x\in R^n$, $\tilde{u}$ and $\tilde{v}$ are arbitrary vector fields extending the vectors u and v, and $[\tilde{u},\tilde{v}]$ is the commutator of the vector fields. The expression (2.1) is independent of the extensions $\tilde{u}$ and $\tilde{v}$.

The Haantjes (1,2)-tensor $H_A(u,v)$ (Ref. 2) is defined in terms of the Nijenhuis tensor $N_A(u,v)$ (2.1),

$$H_A(u,v)=A^2N(u,v)+N(Au,Av)-AN(Au,v)-AN(u,Av) \tag{2.2}$$

and has components (1.3).

Let $B(A)$ be any polynomial in A with the variable coefficients

$$B(A)=\sum_{m=0}^{k} b_m(x)A^m(x). \tag{2.3}$$

In this section we derive the formulas that connect the Nijenhuis tensors $N_{B(A)}(u,v)$ and $N_A(u,v)$ and the Haantjes tensors $H_{B(A)}(u,v)$ and $H_A(u,v)$. The formulas give a complete solution to the problem on the interconnections between the tensors $N_{B(A)}(u,v)$ and $N_A(u,v)$ raised by Nijenhuis in Ref. 3.

(ii) *The (1,2)-tensors representation of the ring of polynomials* $P[z,\lambda,\mu]$. Let us consider the commutative ring $P_3=P[z,\lambda,\mu]$ of polynomials in three independent variables z,λ,μ with coefficients depending on a point x of a manifold M^n. Elements of the ring P_3 are polynomials

$$S(z,\lambda,\mu)=\sum_{i,j,k}^{N} a_{ijk}(x)z^i\lambda^j\mu^k, \quad x\in M^n, \tag{2.4}$$

where coefficients $a_{ijk}(x)$ are arbitrary smooth functions on M^n.

We introduce a representation T of the ring P_3 in the linear space of (1,2)-tensors $V(u,v)$ on M^n. The representation depends on an arbitrary (1,1)-tensor $A(x)$ on M^n and is defined for an arbitrary polynomial $S(z,\lambda,\mu)$ (2.4) by the formula

$$(T_S V)(u,v) = \sum_{i,j,k}^{N} a_{ijk}(x) A^i V(A^j u, A^k v). \tag{2.5}$$

Here the action of λ and μ is associated, respectively, with the first and the second entries of $V(u,v)$; the action of z is associated with the value of V. The representation (2.5) possesses the standard properties

$$T_{S_1+S_2} = T_{S_1} + T_{S_2}, \quad T_{S_1 \cdot S_2} = T_{S_2 \cdot S_1} = T_{S_1} \cdot T_{S_2}. \tag{2.6}$$

The first identity (2.6) is obvious; the second one is evidently true for any monomials $S_1 = a(x) z^i \lambda^j \mu^k$ and $S_2 = b(x) z^p \lambda^q \mu^r$; hence the general case follows by the bilinearity.

(iii) In terms of the representation T_S (2.5), formula (2.2) takes the form

$$H_A(u,v) = T_D N_A(u,v), \tag{2.7}$$

where D is the polynomial $D(z,\lambda,\mu) = (z-\lambda)(z-\mu)$. It is evident that any (1,2)-tensor $W(u,v)$ of the form

$$W(u,v) = \sum_{m=0}^{N} [u(g_m(x)) A^m v + v(h_m(x)) A^m u]$$

is annihilated by the operator T_D,

$$T_D W(u,v) = 0. \tag{2.8}$$

Let $B(z)$ be a polynomial, $B(z) = \sum_{m=0}^{k} b_m(x) z^m$. We will use the well-known Bezout identity

$$B(z) - B(\lambda) = (z-\lambda) Q_B(z,\lambda), \tag{2.9}$$

where $Q_B(z,\lambda)$ is the symmetric polynomial

$$Q_B(z,\lambda) = \sum_{m=1}^{k} b_m(x) \sum_{p+q=m-1} z^p \lambda^q. \tag{2.10}$$

Remark 1: All tensors $U(A)$ considered in this paper have the form

$$U\left(A^i_j, \frac{\partial^k A^i_j(x)}{\partial x_{\alpha_1} \cdots \partial x_{\alpha_k}} \right)$$

and are polynomials with respect to their arguments. Therefore the tensors $U(A)$ can be continued onto the complexifications of the tangent bundle $T(M^n)$ and the cotangent bundle $T^*(M^n)$. We will mean this continuation when the (1,1)-tensor $A^i_j(x)$ has complex eigenvalues and eigenvectors.

Remark 2: Let a (k,l)-tensor $U(A)$ analytically depend on the entries of the (1,1)-tensor $A^i_j(x)$ and their partial derivatives up to a finite order N. If tensor $U(A)$ is equal to zero for all (1,1) tensors $A^i_j(x)$ with distinct (complex) eigenvalues then $U(A) \equiv 0$ for any (1,1)-tensor $A^i_j(x)$. This evidently follows by continuation from the nondegenerate case $A^i_j(x)$ with distinct eigenvalues.

Let $\lambda_1(x), \ldots, \lambda_k(x)$ be the eigenvalues of an operator $A(x)$, corresponding to the eigenvectors $e_1(x), \ldots, e_k(x)$, $k \leqslant n$. The operator $B(A(x))$ (2.3) has the same eigenvectors $e_i(x)$ with the eigenvalues $B(\lambda_i(x))$.

For the Nijenhuis (1,2)-tensor $N_{B(A)}(u,v)$ (2.1), the formula holds

$$N_{B(A)}(e_i,e_j) = (B(A) - B(\lambda_i))(B(A) - B(\lambda_j))[e_i,e_j] + (B(\lambda_i) - B(\lambda_j))(e_i(B(\lambda_j))e_j + e_j(B(\lambda_i))e_i). \tag{2.11}$$

Indeed, formula (2.11) follows from the Nijenhuis formula[3]

$$N_A(e_i,e_j)=(A-\lambda_i)(A-\lambda_j)[e_i,e_j]+(\lambda_i-\lambda_j)(e_i(\lambda_j)e_j+e_j(\lambda_i)e_i). \tag{2.12}$$

Lemma 1: For any polynomial $B(A)$ (2.3), *the Nijenhuis tensor* $N_B(u,v)$ *is connected with* $N_A(u,v)$ *by the formula*

$$\begin{aligned} N_B(u,v)=&\sum_{m,l=1}^{k} b_m b_l \sum_{p<m,q<l} A^{m+l-p-q-2}N_A(A^p u,A^q v)\\ &+\sum_{m=0}^{k}[B(A)u(b_m)A^m v-B(A)v(b_m)A^m u-u(b_m)B(A)A^m v+v(b_m)B(A)A^m u]. \end{aligned} \tag{2.13}$$

Proof: We first assume that the operator $A(x)$ has distinct eigenvalues $\lambda_1(x),\dots,\lambda_n(x)$. Using the Bezout identity (2.9), we find

$$\begin{gathered} Q_B(\lambda,\lambda)=\frac{\partial B(\lambda)}{\partial\lambda},\\ e(B(\lambda))=\sum_{m=0}^{k}(b_m e(\lambda^m)+e(b_m)\lambda^m)=Q_B(\lambda,\lambda)e(\lambda)+\sum_{m=0}^{k}e(b_m)\lambda^m, \end{gathered} \tag{2.14}$$

where e is an arbitrary tangent vector, $e\in T_x(M^n)$. In view of the identities (2.9) and (2.14), formula (2.11) takes the form

$$\begin{aligned} N_B(e_i,e_j)=&Q_B(A,\lambda_i)Q_B(A,\lambda_j)(A-\lambda_i)(A-\lambda_j)[e_i,e_j]\\ &+Q_B(\lambda_i,\lambda_j)(\lambda_i-\lambda_j)[Q_B(\lambda_j,\lambda_j)e_i(\lambda_j)e_j+Q_B(\lambda_i,\lambda_i)e_j(\lambda_i)e_i]\\ &+\sum_{m=0}^{k}(B(\lambda_i)-B(\lambda_j))[e_i(b_m)\lambda_j^m e_j+e_j(b_m)\lambda_i^m e_i]. \end{aligned}$$

Applying the Nijenhuis formula (2.12), we obtain

$$\begin{aligned} N_B(e_i,e_j)=&Q_B(A,\lambda_i)Q_B(A,\lambda_j)N_A(e_i,e_j)+\sum_{m=0}^{k}[B(A)e_i(b_m)A^m e_j-B(A)e_j(b_m)A^m e_i-e_i(b_m)B(A)A^m e_j\\ &+e_j(b_m)B(A)A^m e_i]. \end{aligned} \tag{2.15}$$

In view of (2.5), the first term in (2.15) has the form

$$Q_B(A,\lambda_i)Q_B(A,\lambda_j)N_A(e_i,e_j)=T_{Q_B(z,\lambda)Q_B(z,\mu)}N_A(e_i,e_j).$$

Thus we get

$$\begin{aligned} N_B(u,v)=&T_{Q_B(z,\lambda)Q_B(z,\mu)}N_A(u,v)\\ &+\sum_{m=0}^{k}[B(A)u(b_m)A^m v-B(A)v(b_m)A^m u-u(b_m)B(A)A^m v+v(b_m)B(A)A^m u], \end{aligned} \tag{2.16}$$

where $u=e_i$ and $v=e_j$. Hence formula (2.16) follows by the bilinearity for arbitrary vectors u and v, for the case of distinct eigenvalues of $A(x)$. The formula (2.13) coincides with (2.16) in view of the definitions (2.5) and (2.10). Thus formula (2.13) is proven for any (1,1)-tensor $A^i_j(x)$ having distinct eigenvalues. Applying Remark 2, we obtain that formula (2.13) holds for an arbitrary (1,1)-tensor $A^i_j(x)$. □

Lemma 2: For any polynomial $B(A,x)$ with variable coefficients, the Haantjes tensor $H_B(u,v)$ is connected with $H_A(u,v)$ by the formula

$$H_B(u,v) = T_{Q_B^2(z,\lambda)Q_B^2(z,\mu)} H_A(u,v). \tag{2.17}$$

Proof: The Haantjes tensor $H_{B(A)}(u,v)$ is connected with the Nijenhuis tensor $N_{B(A)}(u,v)$ by the relation

$$H_B(u,v) = B^2 N_B(u,v) + N_B(Bu,Bv) - BN_B(Bu,v) - BN_B(u,Bv),$$

that is equivalent to the expression

$$H_{B(A)}(u,v) = T_{(B(z)-B(\lambda))(B(z)-B(\mu))} N_{B(A)}(u,v).$$

Using the Bezout identity (2.9), we obtain

$$H_{B(A)}(u,v) = T_{Q_B(z,\lambda)Q_B(z,\mu)} T_D N_{B(A)}(u,v),$$

where $D=(z-\lambda)(z-\mu)$. Substituting here formula (2.16) and using Eqs. (2.7) and (2.8), we obtain the identity (2.17). □

Proposition 1: The Nuijenhuis tensors $N_A(u,v)$ and $N_{B(A)}(u,v)$ are connected by the identity

$$\begin{aligned} &A^2 N_B(u,v) + N_B(Au,Av) - AN_B(Au,v) - AN_B(u,Av) \\ &\quad = B^2 N_A(u,v) + N_A(Bu,Bv) - BN_A(Bu,v) - BN_B(u,Bv). \end{aligned} \tag{2.18}$$

Indeed, applying operator T_D, $D=(z-\lambda)(z-\mu)$, to the identity (2.16) and using Bezout formula (2.9) and Eq. (2.8), we arrive at the identity (2.18). □

III. THE BLOCK-DIAGONALIZABILITY PROBLEM

For a generic hydrodynamic type system in the block-diagonal form (1.2), the eigenvalues corresponding to any two different blocks $\widetilde{A}^{m_j+i}_{m_j+\ell}(v^1,\dots,v^n)$ do not coincide with each other almost everywhere for $x \in R^n$ (while inside a given block some eigenvalues can coincide, for example, if its Jordan normal form is not diagonal).

Theorem 1: *For a system of hydrodynamic type (1.1) to be reducible to a block-diagonal form with k blocks of dimensions $n_j \times n_j$ with $n_1+\cdots+n_k=n$ it is necessary and sufficient that in the tangent spaces $T_x(R^n)$ there exist k smooth distributions $L_{1x},\dots,L_{kx}$ of dimensions $n_1,\dots,n_k$ such that $L_{1x}\oplus\cdots\oplus L_{kx}=T_x(R^n)$ and the conditions*

$$A(L_{ix}) \subset L_{ix}, \quad H_A(L_{ix},L_{ix}) \subset L_{ix}, \quad H_A(L_{ix},L_{jx}) \subset L_{ix}+L_{jx} \tag{3.1}$$

hold provided that the eigenvalues of the operator $A(x)$ in any two different subspaces L_{ix} and L_{jx} are different almost everywhere for $x \in R^n$. Here $i \neq j$; $i,j \in \{1,\dots,k\}$.

Proof: (i) The necessary condition. Suppose that in some coordinates $v^1,\dots,v^n$ system (1.1) has block-diagonal form (1.2) with the diagonal blocks in the subspaces $v^1,\dots,v^{n_1} \in L_1$, $v^{n_1+1},\dots,v^{n_1+n_2} \in L_2,\dots,v^{n-n_k+1},\dots,v^n \in L_k$ that form the distributions L_j, $L_1\oplus\cdots\oplus L_k=T(R^n)$. Then the (1,1)-tensor $\widetilde{A}^{\alpha}_{\beta}(v^1,\dots,v^n)$ has invariant subspaces L_i and L_i+L_j and the definition (2.1) yields $N(L_{ix},L_{ix}) \subset L_{ix}$ and $N(L_{ix},L_{jx}) \subset L_{ix}+L_{jx}$. Hence using Eq. (2.2) and $A(L_{ix}) \subset L_{ix}$ we get the necessary conditions (3.1).

(ii) The sufficient condition. Let $P(\lambda)=\det(A-\lambda)$ be the characteristic polynomial of the (1,1)-tensor A^{α}_{β}, all depend on a point $x \in R^n$. Let $A_i(x)$ be the restriction of the operator $A(x)$ onto the invariant subspace L_{ix} and $P_i(\lambda)=\det(A_i(x)-\lambda)$ be the corresponding characteristic polynomial. Since $L_{1x}\oplus\cdots\oplus L_{kx}=T_x(R^n)$, we obtain $P(\lambda)=P_1(\lambda)\cdots P_k(\lambda)$. Let us define the polynomials

$$B_j(\lambda) = P_1(\lambda)\cdots P_{j-1}(\lambda)P_{j+1}(\lambda)\cdots P_k(\lambda) = P(\lambda)/P_j(\lambda). \tag{3.2}$$

By the Cayley-Hamilton theorem we have $P_\ell(A_\ell)=0$. Hence we get $B_j(A_\ell)=0$ for $j\neq\ell$; $j,\ell \in \{1,\ldots,k\}$. The operator $B_j(A_j)$ is nondegenerate almost everywhere because the operators A_{jx} and $A_{\ell x}$ do not have coinciding eigenvalues for $j\neq\ell$ almost everywhere for $x\in R^n$. Hence the restriction of the operator $B_j(A)$ onto the invariant subspace $L_{jx}\subset T_x(R^n)$ is nondegenerate and is zero on all other subspaces $L_{\ell x}\subset T_x(R^n)$.

The polynomial $B_j(\lambda)$ has some form

$$B_j(\lambda) = \sum_{m=0}^{n-n_j} b_{jm}(x)\lambda^m, \tag{3.3}$$

where coefficients $b_{jm}(x)$ depend on point $x\in R^n$. Let $H_{B_j}(u,v)$ be the Haantjes (1,2)-tensor defined by the (1,1)-tensor

$$B_j(A) = \sum_{m=0}^{n-n_j} b_{jm}(x)A^m. \tag{3.4}$$

Applying Lemma 2, we obtain the formula

$$H_{B_j}(u,v) = T_{Q^2_{B_j}(z,\lambda)Q^2_{B_j}(z,\mu)}H_A(u,v).$$

Hence equations (3.1) yield

$$H_{B_j}(L_{ix},L_{mx}) \subset L_{ix}+L_{mx}, \quad i\neq m; \quad i,m\in\{1,\ldots,k\}. \tag{3.5}$$

Let us consider the $(n-n_j)$-dimensional distribution

$$M_{jx} = L_{1x}+\cdots+L_{(j-1)x}+L_{(j+1)x}+\cdots+L_{kx}. \tag{3.6}$$

Equations (3.5) and (3.6) yield

$$H_{B_j}(M_{jx},M_{jx}) \subset M_{jx}. \tag{3.7}$$

For any eigenvector fields $e_p(x)$, $e_q(x)$ corresponding to the eigenvalues $\lambda_p(x)$, $\lambda_q(x)$ of a (1,1)-tensor C, the formula[14]

$$H_C(e_p,e_q) = (C-\lambda_p)^2(C-\lambda_q)^2[e_p,e_q] \tag{3.8}$$

holds, where $[e_p,e_q]$ is the commutator of the vector fields. By the definition of the (1,1)-tensor $B_j(A)$, all vector fields $v(x)\in M_{jx}$ are zero eigenvector fields of the (1,1)-tensor $B_j(A)$, $B_j(A)v=0$, because the (1,1)-tensor $B_j(A)$ annihilates the distribution M_j. Applying formula (3.8) to the arbitrary vector fields $v,w\in M_j$, we obtain

$$H_{B_j}(v,w) = (B_j(A))^4[v,w]. \tag{3.9}$$

Since $L_{jx}\oplus M_{jx}=T_x(R^n)$ and the restriction of the operator $B_j(A)$ onto the invariant subspace L_{jx} is nondegenerate, the generalized zero eigenspace of the operator $B_j(A(x))$ is exactly the subspace M_{jx} (3.6). Hence Eqs. (3.7) and (3.9) yield $[v,w](x)\in M_{jx}$ for any vector fields $v(x),w(x)\in M_{jx}$ and almost everywhere for $x\in R^n$. Hence by the continuity $[v,w](x)\in M_{jx}$ everywhere and the distribution M_j is involutive. Equation (3.9) implies $H_{B_j}(M_{jx},M_{jx})=0$; Eq. (2.1) yields $N_{B_j}(M_{jx},M_{jx})=0$. Applying Frobenius theorem,[16] we obtain that each point $x\in R^n$ belongs to an $(n-n_j)$-dimensional integral submanifold that is tangent to the linear subspaces M_{jx}. Hence there exist n_j functionally independent functions $f_{j1}(x),\ldots,f_{jn_j}(x)$ such that

$$\mathrm{d}f_{jm}(L_i)=0, \quad i\neq j, \quad m=1,\ldots,n_j,$$

and differentials $\mathrm{d}f_{jm}$ form a basis of the dual space L_j^*. Hence all differentials $\mathrm{d}f_{jm}$ for $j=1,\ldots,k$ and $m=1,\ldots,n_j$ form a basis of the dual space $T^*(R^n)=L_1^*\oplus\cdots\oplus L_k^*$. Therefore the n functions $v_\ell=f_{im}(x)$, $\ell=1,\ldots,n$, form a system of local coordinates on the manifold R^n.

The integrability of the distributions M_j implies the integrability of each distribution L_j because L_j is the intersection of all distributions M_ℓ for $\ell\neq j$. The distribution L_j is defined by the equations

$$\mathrm{d}f_{im}(L_j)=0, \quad i\neq j; \quad i,j\in\{1,\ldots,k\}, \quad m=1,\ldots,n_i.$$

Hence in the coordinates $v_\ell=f_{im}(x)$ the integral submanifolds of the distribution L_j are n_j-dimensional planes defined by the equations

$$f_{im}(x)=c_{im}=\mathrm{const}, \quad i\neq j; \quad i,j\in\{1,\ldots,k\}, \quad m=1,\ldots,n_i.$$

Coordinates f_{jm}, $m=1,\ldots,n_j$, are arbitrary on L_j. Since the subspaces L_{jx} are A invariant, the (1,1)-tensor A_β^α has the block-diagonal form in the local coordinates $f_{im}(x)$ with $(n_j\times n_j)$-dimensional blocks. This gives the block diagonalization of the system (1.1) in the local coordinates $v_\ell=f_{im}$, $\ell=1,\ldots,n$. □

IV. CONCRETE APPLICATIONS

(i) Theorem 1 has the following equivalent form in terms of the Nijenhuis tensor (notations are the same).

Theorem 2: *The necessary and sufficient conditions for the block diagonalizability of system (1.1) are*

$$A(L_{ix})\subset L_{ix}, \quad N_A(L_{ix},L_{ix})\subset L_{ix}, \quad N_A(L_{ix},L_{jx})\subset L_{ix}+L_{jx}, \tag{4.1}$$

provided that the eigenvalues of the operator $A(x)$ in any two different subspaces L_{ix} and L_{jx} are different almost everywhere for $x\in R^n$. Here $i\neq j$; $i,j\in\{1,\ldots,k\}$.

Indeed, the necessity of conditions (4.1) is proved in Theorem 1. Their sufficiency follows from Theorem 1 because Eqs. (2.2) and (4.1) imply Eqs. (3.1). □

For the case of block diagonalization with only two diagonal blocks and $L_{1x}\oplus L_{2x}=T_x(R^n)$, the necessary and sufficient conditions (4.1) have the simple form $A(L_{ix})\subset L_{ix}$, $N_A(L_{ix},L_{ix})\subset L_{ix}$, $i=1,2$.

(ii) *Example 1:* Let us consider the hydrodynamic type system

$$u_{it}=-u_iu_{ix}-\sum_{j=1}^{k}f_j(\eta_j)\eta_{jx}, \quad \eta_{it}=-\eta_iu_{ix}-u_i\eta_{ix}, \tag{4.2}$$

where $i=1,\ldots,k$. The systems (4.2) with arbitrary functions $f_j(\eta_j)$ form perturbations of the Benney system[4] that corresponds to $f_j(\eta_j)=1$. Let $e_i=\partial/\partial u_i$, $h_i=\partial/\partial\eta_i$ be the basis tangent vectors. For system (4.2), the (1,1)-tensor A_j^i has the form

$$A(e_i)=-u_ie_i-\eta_ih_i, \quad A(h_i)=-f_iE-u_ih_i, \quad E=e_1+\cdots+e_k. \tag{4.3}$$

The corresponding Nijenhuis tensor is defined by the formulas

$$N(e_i,e_j)=0, \quad N(h_i,h_j)=f_ih_j-f_jh_i, \quad N(e_i,h_j)=-f_ie_i+\eta_if_j'\delta_j^iE, \tag{4.4}$$

where $f_j'=\mathrm{d}f_j/\mathrm{d}\eta_j$. Let v be a tangent vector $v=\Sigma_i(x_ie_i+y_ih_i)$. We define a 1-form $\psi(v)=f_1y_1+\cdots+f_ky_k$. For any tangent vector $w=\Sigma_i(\alpha_ie_i+\beta_ih_i)$, formulas (4.4) yield

$$N(v,w)=\psi(v)w-\psi(w)v+\varphi(v,w)E, \tag{4.5}$$

where $\varphi(v,w)$ is the 2-form,

$$\varphi(v,w)=\sum_{i=1}^{k}(x_i\beta_i-y_i\alpha_i)\,\eta_i f_i'(\eta_i). \tag{4.6}$$

For the Haantjes tensor (2.2) we find

$$H(v,w)=\varphi(v,w)A^2E+\varphi(Av,Aw)E-[\varphi(Av,w)+\varphi(v,Aw)]AE. \tag{4.7}$$

For the Benney system one has $f_j(\eta_j)=1$ and hence $\varphi(v,w)=0$. Hence the Benney system that is a hyperbolic one[4] can be transformed to a diagonal form because its Haantjes tensor (4.7) vanishes.

A generic perturbation (4.2) of the Benney system for $f_j'(\eta_j)\neq 0$ cannot be transformed into a block-diagonal form with three or more diagonal blocks. Indeed, for $f_j'(\eta_j)\neq 0$ the 2-form (4.6) is nondegenerate so its Lagrangian planes $\varphi(v,w)=0$ have dimension k. If a representation with three or more diagonal blocks existed then $T_x(R^n)=L_1\oplus L_2\oplus L_3$ where L_i are invariant subspaces satisfying (4.1). One subspace, say L_1, has dimension $m<k$. Let $L=L_2\oplus L_3$, then $k<\dim L=2k-m<2k$. Hence L is not a Lagrangian plane for the form $\varphi(v,w)$ (4.6) and there exist vectors v, $w\in L$ such that $\varphi(v,w)\neq 0$. Hence Eqs. (4.1) and (4.5) yield that vector $E\in L$. Vector E is a cyclic vector for the operator A_j^i (4.3): the vectors $E,AE,A^2E,\ldots,A^{2k-1}E$ form a basis. All these vectors in view of (4.1) belong to the subspace L. Hence $\dim L=2k$. The contradiction proves that the block-diagonalization with three or more blocks is impossible. □

(iii) The Haantjes theorem[2] on the X_m-forming sets of eigenvalues of a (1,1)-tensors $A_j^i(u)$ implies that for the complete diagonalizability of a system (1.1) with real and distinct eigenvalues of $A_j^i(u)$ it is necessary and sufficient that the Haantjes tensor (1.3) vanishes.

Proposition 2: If a (1,1)-tensor $A_j^i(u)$ (1.1) has complex and real distinct eigenvalues and its Haantjes tensor is zero then it has a block-diagonal representation with 2×2 and 1×1 blocks.

Proof: Since all eigenvalues of $A_j^i(u)$ are distinct, to each pair of complex conjugate eigenvalues it corresponds a two-dimensional invariant distribution L_j and to each real eigenvector it corresponds an invariant vector field L_k. Since $H_A(v,w)=0$, the conditions (3.1) of Theorem 1 are satisfied and we obtain the existence of the required block-diagonal form. □

Remark 3: Proposition 2 proves that condition $H_A(v,w)=0$ is sufficient for the 2×2 and 1×1 block diagonalization. However it is not necessary as the following example shows. Let us consider the simplest block-diagonal (1,1)-tensor

$$A_j^i=\begin{pmatrix}\alpha & -\beta & 0\\ \beta & \alpha & 0\\ 0 & 0 & \gamma\end{pmatrix}, \tag{4.8}$$

where α,β,γ are arbitrary smooth functions of x^1,x^2,x^3. Matrix (4.8) has eigenvalues $\lambda_{1,2}=\alpha\pm i\beta$, $\lambda_3=\gamma$. The corresponding Haantjes tensor (1.3) is nonzero:

$$H_{23}^1=2\beta^2\left((\alpha-\gamma)\frac{\partial\beta}{\partial x^3}-\beta\frac{\partial\alpha}{\partial x^3}\right).$$

(iv) A Hamiltonian system of n pde's (1.1) is called nondegenerate if the corresponding (2,0)-tensor $g^{ij}(u)$ is nondegenerate.

Proposition 3: A nondegenerate Hamiltonian system (1.1) in R^3 with $H_A(v,w)\neq 0$ does not have any block-diagonal representations.

Proof: For the three-dimensional case, the Haantjes tensor $H_A(v,w)$ defines a Lie algebra structure $\mathcal{G}_x$ in each tangent space $T_x(M^3)$.[14] For any nondegenerate Hamiltonian system (1.1) with $H_A(v,w)\neq 0$, the Lie algebras $\mathcal{G}_x$ are simple,[14] so the derivative Lie subalgebras $\mathcal{G}_x'=\mathcal{G}_x$. Suppose that in some coordinates u^1,u^2,u^3 the system has a block-diagonal form

$$A_j^i = \begin{pmatrix} a_{11} & a_{12} & 0 \\ a_{21} & a_{22} & 0 \\ 0 & 0 & a_{33} \end{pmatrix}. \tag{4.9}$$

Then for the coordinate basis vectors e_1, e_2, e_3, the formulas (4.9), (2.1), and (2.2) imply $H_A(e_1, e_2)=0$. Hence the derivative Lie subalgebras $\mathcal{G}'_x$ are generated by two vectors $H_A(e_1, e_3)$ and $H_A(e_2, e_3)$ and $\mathcal{G}'_x \neq \mathcal{G}_x$. The contradiction proves that the block-diagonal representation (4.9) is impossible. □

Proposition 4: The following identities hold: for the Haantjes tensor

$$H_{f(x)A+g(x)I}(u,v) = f^4(x) H_A(u,v), \tag{4.10}$$

where I is the unit (1,1) tensor, $I_j^k = \delta_j^k$, $f(x)$ *and* $g(x)$ *are smooth functions; and for the Nijenhuis tensor*

$$N_{f(x)A+g(x)I}(u,v) = f^2(x) N_A(u,v) + f[(Au(f) - u(g))Av - (Av(f) - v(g))Au - u(f)A^2v + v(f)A^2u + Au(g)v - Av(g)u]. \tag{4.11}$$

Indeed, for the operator

$$B(A,x) = f(x)A(x) + g(x)I, \tag{4.12}$$

we have

$$b_1(x) = f(x), \quad b_0(x) = g(x), \quad Q_B(z,\lambda) = f(x). \tag{4.13}$$

Since $Q_B(z,\lambda)Q_B(z,\mu)=f^2(x)$, formula (2.17) implies identity (4.10). The identity (4.11) follows from formula (2.16) after substituting expressions (4.12) and (4.13). □

Remark 4: Formula (4.10) means that the Haantjes tensor $H_A(u,v)$ is invariant with respect to the gauge transformations (4.12). The gauge invariance of the Haantjes (1,2)-tensor was first discovered in Ref. 14. Formula (4.11) shows that the Nijenhuis tensor $N_A(u,v)$ is not gauge invariant.

Remark 5: In Ref. 17 we prove that the necessary and sufficient conditions for the reducibility of a system (1.1) into k noninteracting subsystems[1] have the form

$$A(L_{ix}) \subset L_{ix}, \quad N_A(L_{ix}, L_{ix}) \subset L_{ix}, \quad N_A(L_{ix}, L_{jx}) = 0,$$

where notations are the same as in Theorem 1.

This paper discusses a class of nonlinear Schrödinger equation with harmonic potential. By constructing a cross-constrained variational problem and so-called invariant manifolds of the evolution flow, we derive a sharp criterion for blow-up and global existence of the solutions. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2209168]

I. INTRODUCTION

In this paper, we study the Cauchy problem for the nonlinear Schrödinger equation with harmonic potential

$$i\varphi_t = -\Delta\varphi + |x|^2\varphi - |\varphi|^{p-1}\varphi, \quad t > 0,\ x \in R^N,$$

$$\varphi(0,x) = \varphi_0(x), \tag{1}$$

where $\varphi=\varphi(t,x)$ denotes the complex-value wave function, $i=\sqrt{-1}$, Δ is the Laplace operator on R^N, $1<p<(N+2)/(N-2)^+$ [we use the convention $(N+2)/(N-2)^+=N-2$ when $N\geq 3$ and $(N+2)/(N-2)^+=\infty$ when $N=1,2$]. When $p=3$, (1) describes attractive Bose-Einstein condensation.[1–3]

For nonlinear Schrödinger equation without potential

$$i\varphi_t + \Delta\varphi + |\varphi|^{p-1}\varphi = 0, \quad t > 0,\ x \in R^N, \quad \varphi(0,x) = \varphi_0(x), \tag{2}$$

many results[4–7] have been achieved. In particular, Zhang[8,9] obtained a sharp criterion for blow-up and global existence of solutions by variational methods.

For (1), Cazenave[10] and Oh[11] established the local existence in corresponding energy space. Zhang[12,13] obtained blow-up and global existence of solutions, the stability of standing waves.

In this paper, we further exploit the sharp conditions of global existence which is attributed to Zhang.[9,14] By establishing a cross-constrained variational problem and the invariant sets under the flow generated by the Cauchy problem (1), we can derive some new blowup theorems and establish the sharp criterion for global existence and blowup of the solutions of (1). From viewpoint of physics, the sharp criterion is just a sharp stability threshold of attractive Bose-Einstein condensation.[1,12] These arguments originate in Pagne and Scattinger,[15] Levine,[16] Berestycki and Cazenave,[17] Weinstein.[18]

[b)]Electronic mail: jianzhan@mail.sc.cninfo.net

This paper is organized as follows. In the second section, we give some preliminaries. In the third section, we construct two constrained variational problems. In the fourth section, we give some new theorems of blow-up and sharp sufficient conditions of global existence.

II. PRELIMINARIES

For (1), we define the energy space in the course of nature by

$$H := \{\psi \in H^1(\mathbb{R}^N), \int |x|^2|\psi|^2 \, dx < \infty\}. \tag{3}$$

Here and hereafter, for simplicity, we denote $\int_{\mathbb{R}^N} dx$ by $\int dx$, H becomes a Hilbert space, continuously embedded in $H^1(\mathbb{R}^N)$, when endowed with the inner product as follows:

$$\langle \psi, \phi \rangle_H := \int \nabla\psi \nabla \bar{\phi} + \psi\bar{\phi} + |x|^2\psi\bar{\phi} \, dx, \tag{4}$$

whose associated norm we denote by $\|\cdot\|_H$.

From Cazenave[10] and Oh,[11] we can get the local well-posedness for the Cauchy problem (1) in energy space H.

Proposition 2.1: Let $\varphi_0 \in H$. Then there exists a unique solution φ of the Cauchy problem (1) *in $C([0,T];H)$ for some $T \in (0,\infty]$ (maximal existence time), and either $T=\infty$ (global existence) or else $T<\infty$ and*

$$\lim_{t\to T} \|\varphi\|_H = \infty \text{ (blow-up)}.$$

First we have the following lemmas.[7,10,19]

Lemma 2.2: Let $\varphi_0 \in H$ and φ be a solution of the Cauchy problem (1) *in $C([0,T];H)$. Set the energy functional*

$$E(\varphi) = \frac{1}{2}\int \left(|\nabla\varphi|^2 + |x|^2|\varphi|^2 - \frac{2}{p+1}|\varphi|^{p+1} \right) dx.$$

Then one has

$$\int |\varphi|^2 \, dx = \int |\varphi_0|^2 \, dx, \tag{5}$$

$$E(\varphi) \equiv E(\varphi_0). \tag{6}$$

Lemma 2.3: Let $\varphi_0 \in H$ and $1<p<1+(4/N)$. Then the solution φ of the Cauchy problem (1) *exists globally.*

Lemma 2.4: Let $\varphi_0 \in H$ and $1+(4/N) \le p < (N+2)/(N-2)^+$. If $E(\varphi_0)<0$. Then the solution φ of the Cauchy problem (1) *blows up in a finite time.*

Remark 2.5: From the above two lemmas we see that $p=1+\frac{4}{N}$ is critical nonlinearity index for blow-up and global existence. In the following we call $p<1+(4/N), p=1+(4/N), p>1+(4/N)$ subcritical, critical, supercritical cases, respectively.

Lemma 2.6: Let $\varphi_0 \in H$ and φ be the solution of the Cauchy problem (1) *in $C([0,T];H)$, $|x|\varphi_0 \in L^2(R^N)$. Set $J(t)=\int |x|^2|\varphi|^2 \, dx$. Then one has*

$$J''(t) = 8\int \left(|\nabla\varphi|^2 - |x|^2|\varphi|^2 - \frac{N(p-1)}{2(p+1)}|\varphi|^{p+1} \right) \mathrm{d}x. \tag{7}$$

III. THE CROSS-CONSTRAINED VARIATIONAL PROBLEM

For $u \in H$ and $1 < p < (N+2)/(N-2)^+$, we define the following functionals:

$$I(u) = \frac{1}{2}\int \left(|\nabla u|^2 + |u|^2 + |x|^2|u|^2 - \frac{2}{p+1}|u|^{p+1} \right) \mathrm{d}x, \tag{8}$$

$$S(u) = \int \left(|\nabla u|^2 + |u|^2 - \frac{N(p-1)}{2(p+1)}|u|^{p+1} \right) \mathrm{d}x, \tag{9}$$

$$Q(u) = \int \left(|\nabla u|^2 + |x|^2|u|^2 - \frac{N(p-1)}{2(p+1)}|u|^{p+1} \right) \mathrm{d}x, \tag{10}$$

and define the manifold

$$M := \{u \in H \setminus \{0\}, S(u) < 0, Q(u) = 0\}.$$

Now we consider two constrained variational problems,

$$d_\omega = \inf_{\{u \in H\setminus\{0\}, S(u)=0\}} I(u), \tag{11}$$

$$d_M = \inf_{u \in M} I(u). \tag{12}$$

First we have the following.

Lemma 3.1: $d_\omega > 0$ *provided* $1 + (4/N) < p < (N+2)/(N-2)^+$.

Proof: From $S(u) = 0$, we have

$$I(u) = \int \left(\frac{1}{2} - \frac{2}{N(p-1)} \right) |\nabla u|^2 + \left(\frac{1}{2} - \frac{2}{N(p-1)} \right) |u|^2 + \frac{1}{2}|x|^2|u|^2 \, \mathrm{d}x. \tag{13}$$

Since $1 + (4/N) < p < (N+2)/(N-2)^+$, (13) and $u \neq 0$ implies that $I(u) > 0$. Thus from (11), we get $d_\omega \geq 0$. In the following we use the Sobolev embedding inequality:

$$\int |u|^{p+1} \, \mathrm{d}x \leq c\left(\int |\nabla u|^2 + |u|^2 \, \mathrm{d}x \right)^{(p+1)/2}. \tag{14}$$

Here and hereafter c denotes various positive constants. From $S(u) = 0$ it follows that

$$\int |\nabla u|^2 + |u|^2 \, \mathrm{d}x = \frac{N(p-1)}{2(p+1)} \int |u|^{p+1} \, \mathrm{d}x \leq c\left(\int |\nabla u|^2 + |u|^2 \, \mathrm{d}x \right)^{(p+1)/2}.$$

From $p > 1$ it follows that

$$\int |\nabla u|^2 + |u|^2 + |x|^2|u|^2 \, \mathrm{d}x > \int |\nabla u|^2 + |u|^2 \, \mathrm{d}x \geq c > 0. \tag{15}$$

Since $p > 1 + (4/N)$, (13) and (15) yields that

$$I(u) \geq c > 0, \quad \textit{for all } u \in M.$$

Thus (11) implies that $d_\omega > 0$ for $1 + (4/N) < p < (N+2)/(N-2)^+$. □

Next from (12) we have the following.

Lemma 3.2: $d_M>0$ *provided* $1+(4/N)<p<(N+2)/(N-2)^+$.

Proof: Let $u\in M$. From $S(u)<0$, we have $u\neq 0$. From $Q(u)=0$, we have

$$I(u)=\int\left(\frac{1}{2}-\frac{2}{N(p-1)}\right)|\nabla u|^2+\frac{1}{2}|u|^2+\left(\frac{1}{2}-\frac{2}{N(p-1)}\right)|x|^2|u|^2\,\mathrm{d}x. \tag{16}$$

Since $1+(4/N)<p<(N+2)/(N-2)^+$, (16) and $u\neq 0$ implies that $I(u)>0$ for all $u\in M$. Thus from (12), we get $d_M\geq 0$. Now we use the Sobolev embedding inequality

$$\int|u|^{p+1}\,\mathrm{d}x\leq c\left(\int|\nabla u|^2+|u|^2\,\mathrm{d}x\right)^{(p+1)/2}. \tag{17}$$

Here and hereafter c denotes various positive constants. From $S(u)<0$ it follows that

$$\int|\nabla u|^2+|u|^2\,\mathrm{d}x<\frac{N(p-1)}{2(p+1)}\int|u|^{p+1}\,\mathrm{d}x\leq c\left(\int|\nabla u|^2+|u|^2\,\mathrm{d}x\right)^{(p+1)/2}.$$

From $p>1$ it follows that

$$\int|\nabla u|^2+|u|^2+|x|^2|u|^2\,\mathrm{d}x>\int|\nabla u|^2+|u|^2\,\mathrm{d}x\geq c>0. \tag{18}$$

Since $p>1+(4/N)$, (16) and (18) yields that

$$I(u)\geq c>0,\quad \textit{for all } u\in M.$$

Thus (12) implies that $d_M>0$ for $1+(4/N)<p<(N+2)/(N-2)^+$. □

Now we define

$$d:=\min\{d_\omega,d_M\}. \tag{19}$$

Then from Lemma 3.1 and Lemma 3.2 it implies the following.

Theorem 3.3: $d>0$ *when* $1+(4/N)<p<(N+2)/(N-2)^+$.

Remark 3.4: We call the variational problem (12) *cross-constrained variational problem since there are two constrained conditions in* (12). *The following corresponding invariant manifold will be called cross-invariant manifold.*

Theorem 3.5: *Define*

$$K:=\{\phi\in H,I(\phi)<d,Q(\phi)<0,S(\phi)<0\}. \tag{20}$$

If $1+(4/N)<p<(N+2)/(N-2)^+$, *then K is an invariant manifold of* (1), *that is, if* $\varphi_0\in K$, *then the solution* $\varphi(t,x)$ *of the Cauchy problem* (1) *also satisfies* $\varphi(t,x)\in K$ *for any* $t\in[0,T)$.

Proof: Let $\varphi_0\in K$. By Proposition 2.1, there exists a unique $\varphi(t,x)\in C([0,T);H)$ with $T\leq\infty$ such that $\varphi(t,x)$ is a solution of the Cauchy problem (1). From (5), (6), we have

$$I(\varphi)=I(\varphi_0),\quad t\in[0,T). \tag{21}$$

Thus $I(\varphi_0)<d$ implies that $I(\varphi)<d$ for any $t\in[0,T)$.

Now we show $S(\varphi)<0$ for $t\in[0,T)$. If otherwise, from the continuity, there were a $t_0\in[0,T)$ such that $S(\varphi(t_0,.))=0$. By (21), $I(\varphi(t_0,.))=\int\left[\frac{1}{2}-[2/N(p-1)]\right]|\nabla\varphi(t_0,.)|^2+\frac{1}{2}|\varphi(t_0,.)|^2+\left[\frac{1}{2}-[2/N(p-1)]\right]|x|^2|\varphi(t_0,.)|^2\,\mathrm{d}x=I(\varphi_0)>0$, note that $1+(4/N)<p<(N+2)/(N-2)^+$, thus $\varphi(t_0,x)\neq 0$. From (11) and (19) it follows that $I(\varphi(t_0,.))\geq d$. This is contradictory with $I(\varphi(t,.))<d$ for $t\in[0,T)$. Therefore $S(\varphi(t,.))<0$ for all $t\in[0,T)$.

At last we show $Q(\varphi(t,.))<0$ for $t\in[0,T)$. If otherwise, from the continuity, there were a $t_1\in[0,T)$ such that $Q(\varphi(t_1,.))=0$. Because we have showed $S(\varphi(t_1,.))<0$, it follows that $\varphi(t_1,.)\in M$. Thus (12) and (19) implies $I(\varphi(t_1,.))\geq d_M\geq d$. This is contradictory with $I(\varphi(t,.))<d$ for $t\in[0,T)$. Therefore $Q(\varphi(t,.))<0$ for all $t\in[0,T)$.

From the above we proved $\varphi(t,x)\in K$ for any $t\in[0,T)$.

This completes the proof of this theorem. □

By the same argument as Theorem 3.5, we can get the following results.

Theorem 3.6: *Define*

$$K_+ := \{\phi\in H, I(\phi)<d, Q(\phi)>0, S(\phi)<0\},$$

$$R_- := \{\phi\in H, I(\phi)<d, S(\phi)<0\},$$

$$R_+ := \{\phi)\in H, I(\phi)<d, S(\phi)>0\}.$$

If $1+(4/N)<p<(N+2)/(N-2)^+$, *then* K_+, R_-, R_+ *are all invariant manifolds of* (1).

IV. SHARP CONDITIONS FOR GLOBAL EXISTENCE

Theorem 4.1: *Let* $1+(4/N)<p<(N+2)/(N-2)^+$. *If* $\varphi_0\in K_+\cup R_+$, *then the solution* φ *of the Cauchy problem* (1) *globally exists on* $t\in[0,\infty)$.

Proof: First we let $\varphi_0\in K_+$. Thus Theorem 3.6 implies that the solution φ of the Cauchy problem (1) satisfies that $\varphi(t,.)\in K_+$ for $t\in[0,T)$. For fixed $t\in[0,T)$, denote $\varphi(t,.)=\varphi$. Thus we have $I(\varphi)<d$, $Q(\varphi)>0$. It follows that from (8) and (10),

$$\int\left(\frac{1}{2}-\frac{2}{N(p-1)}\right)|\nabla\varphi|^2+\frac{1}{2}\omega|\varphi|^2\,dx+\left(\frac{1}{2}-\frac{2}{N(p-1)}\right)|x|^2|\varphi|^2\,dx<d. \tag{22}$$

For $1+(4/N)<p<(N+2)/(N-2)^+$, from (22), we always have

$$\int|\nabla\varphi|^2+|x|^2|\varphi|^2\,dx<c. \tag{23}$$

Therefore Proposition 2.1 implies that φ globally exists on $t\in[0,\infty)$.

Thus for $\varphi_0\in K_+$ we proved the solution φ of the Cauchy problem (1) globally exists on $t\in[0,\infty)$.

Now let $\varphi_0\in R_+$. Thus Theorem 3.6 implies that the solution φ of the Cauchy problem (1) satisfies that $(\varphi(t,.))\in R_+$ for $t\in[0,T)$. Thus we have $I(\varphi)<d$, $S(\varphi)>0$. It follows that

$$\left(\frac{1}{2}-\frac{2}{N(p-1)}\right)\int|\nabla\varphi|^2+\omega|\varphi|^2\,dx+\int\frac{1}{2}|x|^2|\varphi|^2\,dx<d. \tag{24}$$

Thus Proposition 2.1 implies that φ globally exists on $t\in[0,\infty)$.

This completes the proof of this theorem. □

Theorem 4.2: *Let* $1+(4/N)<p<(N+2)/(N-2)^+$. *If* $\varphi_0\in K$ *and* $|\cdot|\varphi_0\in L^2(R^N)$, *then the solution* φ *of the Cauchy problem* (1) *blows up in a finite time.*

Proof: From $\varphi_0\in K$, Theorem 3.5 implies that the solution φ of the Cauchy problem (1) satisfies that $\varphi(t,.)\in K$ for $t\in[0,T)$. For $J(t)=\int|x|^2|\varphi|^2\,dx$, (7) and (10) imply that

$$J''(t)<8Q(\varphi(t,.)),\quad t\in[0,T). \tag{25}$$

Fix $t\in[0,T)$, and denote $\varphi(t,.)=\varphi$. Since $\varphi\in K$, it follows that

$$J''(t) < 8Q(\varphi) < 0. \tag{26}$$

Obviously $J(t)$ cannot verify (26) for all time t.[19] Therefore from Proposition 2.1, it must be the case that $T<\infty$, which implies

$$\lim_{t\to T}\|\varphi\|_H = \infty .$$

This completes the proof of this theorem. □

Remark 4.3: It is clear that

$$\{\phi \in H, I(\phi) < d\} = R_+ \cup K_+ \cup K.$$

Thus Theorem 4.2 shows that Theorem 4.1 is sharp.

By the above remark, we immediately have the following.

Corollary 4.4: Let $1+(4/N)<p<(N+2)/(N-2)^+$ *and* φ_0 *satisfy* $I(\varphi)<d$, *then the solution* φ *of the Cauchy problem* (1) *blows up in a finite time if and only if* $\varphi_0 \in K$.

By Theorem 4.1 we also get another condition for global existence of the solution of (1).

Corollary 4.5: If $\varphi_0 \in H$ *and satisfy* $\|\varphi_0\|_H^2 < 2d$, *then the solution* φ *of the Cauchy problem* (1) *globally exists on* $t \in [0,\infty)$.

Proof: From $\|\varphi_0\|_H^2 < 2d$, we have $I(\varphi_0) < d$. Moreover we claim that $S(\varphi_0) > 0$. If otherwise, there were a $0<\lambda\leq 1$ such that $S(\lambda\varphi_0)=0$. Thus $I(\lambda\varphi_0)\geq d$. On the other hand,

$$\|\lambda\varphi_0\|_H^2 = \lambda^2\|\varphi_0\|_H^2 < 2\lambda^2 d < 2d.$$

It follows that $I(\lambda\varphi_0)<d$. This is a contradiction. Therefore we have $\varphi_0 \in R_+$. Thus Theorem 4.1 implies this corollary. □

Remark 4.6: It is clear that d_ω *and* d_M *in this paper is different from in Ref.* 14.

Scale invariance in the spectral action

(Received 19 January 2006; accepted 15 March 2006; published online 16 June 2006)

The arbitrary mass scale in the spectral action for the Dirac operator is made dynamical by introducing a dilaton field. We evaluate all the low-energy terms in the spectral action and determine the dilaton couplings. These results are applied to the spectral action of the noncommutative space defined by the standard model. We show that the effective action for all matter couplings is scale invariant, except for the dilaton kinetic term and Einstein-Hilbert term. The resulting action is almost identical to the one proposed for making the standard model scale invariant as well as the model for extended inflation and has the same low-energy limit as the Randall-Sundrum model. Remarkably, all desirable features with correct signs for the relevant terms are obtained uniquely and without any fine tuning. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2196748]

I. INTRODUCTION

It is known that the standard model of strong and electroweak interactions is classically almost scale invariant, and that the only terms that break the dilatation symmetry are the mass terms in the Higgs sector. Scale invariance of the classical Lagrangian can be achieved by introducing a compensating dilaton field.[1–3] Breaking of scale invariance occurs after the electroweak symmetry is broken spontaneously through the generation of radiative corrections to the scalar potential. The dilaton mass scale is much larger than the weak scale and could be as large as the GUT scale or Planck scale. This leads naturally to consider the coupling of the dilaton to gravity. The dilaton is always part of the low energy spectrum in string theory. Historically it first appeared in the Jordan-Brans-Dicke theory of gravity which corresponds to one particular coupling of the dilaton to the metric.[2] The dilaton plays a fundamental role in models of inflation.[4] It also appears in the gravitational couplings of the noncommutative Connes-Lott formulation of the standard model,[5–8] where the dilaton is the scalar field that couples the two sheets of space time. The resulting matter interactions in this case are also scale invariant, and the gravitational couplings are different than the Jordan-Brans-Dicke theory. More recently, a scalar field, the radion field, appeared in the Randall-Sundrum (RS) scenario of compactification[9] which is related to the question of masses and scales in physics. The RS scenario was shown to be equivalent to the results derived from noncommutative geometry,[10] which is not too surprising, because both the Connes-Lott model and the RS model, describe a system with two branes.

At present, and within the noncommutative geometric picture, the spectral action gives the most elegant formulation of the standard model.[11,12] All details of the standard model as well as its unification with gravity are achieved by postulating the action

$$\text{Trace } F(D^2/m^2) + \langle \Psi | D | \Psi \rangle,$$

where D is the Dirac operator of a certain noncommutative space and Ψ is a spinor in the Hilbert space of the observed quarks and leptons. However, the dilaton field does not appear in the spectral action, which is to be contrasted with the Connes-Lott formulation of the noncommutative action where the dilaton field is part of the gravitational interactions. This suggests that the Dirac

operator used in the construction of the spectral action should be modified in order to take into account the presence of the dilaton.

The appearance of the dilaton field in physical models is related to the question of mass and scales. It is therefore natural to consider replacing the mass parameter in the ratio D^2/m^2 by a function of the dilaton, thus introducing a sliding scale, as the Dirac operator have the dimension of mass. This is also relevant when dealing with noncompact manifolds where D no longer has discrete spectrum and the counting of eigenvalues requires a localization. Let the dynamical scale factor ρ be written in the form

$$\rho = me^{\phi},$$

where we assume that ϕ is dimensionless. The dilaton can be related to a scalar field σ of dimension one by writing

$$\phi = \frac{1}{f}\sigma,$$

where f is the dilaton decay constant. The mass scale m can be absorbed by the redefinition

$$\phi \to \phi - \ln m,$$

and therefore we can assume, without any loss in generality, that $\rho = e^{\phi}$. One can always recover the scale m by performing the opposite transformation $\phi \to \phi + \ln m$. Now using ρ instead of the scalar m in the counting of eigenvalues:

$$N(m) = \mathrm{Dim}\{D^2 \leqslant m^2\} \to N(\rho) = \mathrm{Dim}\{D^2 \leqslant \rho^2\}$$

is equivalent to replacing the operator D^2/m^2 in Ref. 11 by

$$P = e^{-\phi} D^2 e^{-\phi}.$$

If we insist that the metric $g_{\mu\nu}$ be dimensionless to insure that its flat limit be the Minkowski metric, then the scale m will explicitly appear in the action after rescaling $e^{\phi} \to me^{\phi}$. Otherwise we can absorb this mass scale by assuming that the metric has the dimension of mass.

The aim of this article is to determine the interactions of the dilaton field ϕ with all other fields present in the spectral action formulation of the standard model. Because of the spectral character of the action, it is completely determined from the form of P and there is no room for fine tuning the results. It is then very reassuring to find that the resulting interactions are identical to those constructed in the literature by postulating a hidden scale invariance of the matter interactions.[3] These are also equivalent to the interactions of the radion field in the RS model.[9] All of these results now support the conclusion that space time at high energies reveals its discrete structure, and is governed by noncommutative geometry. The plan of this article is as follows. In Sec. II we briefly review the derivation of the spectral action and comment on the modifications needed to include the dilaton. In Sec. III we derive the Seeley-de Witt coefficients of the spectral action in presence of the dilaton. In Sec. IV we give the full low-energy spectral action including dilaton interactions specialized to the noncommutative space of the standard model. In Sec. V we compare our results with those obtained by imposing scale invariance on the standard model interactions, to the RS model and the model of extended inflation. Section six is the conclusion. The appendices contain detailed proofs of some identities used.

II. A SUMMARY OF SPECTRAL ACTION

We begin by summarizing the results of Ref. 11. The square of the Dirac operator appearing in the spectral triple of a noncommutative space is written in the following form suitable to apply the standard local formulas for the heat expansion (see Ref. 13 Sec. 4.8).

$$D^2 = -(g^{\mu\nu} I \partial_\mu \partial_\nu + A^\mu \partial_\mu + B), \tag{1}$$

where $g^{\mu\nu}$ plays the role of the inverse metric, I is the unit matrix, and A^μ and B are matrix functions computed from the Dirac operator. The bosonic part of the spectral action can be expanded in a power series as a function of the inverse scale m, and is given in dimension 4 by

$$\mathrm{Trace}(F(D^2/m^2)) \simeq \sum_{n \geqslant 0} f_n a_n(D^2/m^2),$$

where F is a positive function and

$$f_0 = \int_0^\infty F(u) u \, \mathrm{d}u, \quad f_2 = \int_0^\infty F(u) \mathrm{d}u, \quad f_{2n+4} = (-1)^n F^{(n)}(0), \quad n \geqslant 0. \tag{2}$$

The positivity of the function F will insure that the actions for gravity, Yang-Mills, Higgs couplings are all positive and the Higgs mass term is negative. We will comment on the positive sign of the cosmological constant at the end of the article.

The first few Seeley-deWitt coefficients $a_n(D^2/m^2)$ are given (see Ref. 13, Theorem 4.8) by [according to our notations the scalar curvature R is negative for spheres (see Ref. 13 Sec. 2.3) and the space is Euclidean]

$$a_0(D^2/m^2) = \frac{m^4}{16\pi^2} \int_M \mathrm{d}^4x \sqrt{g} \, \mathrm{Tr}(1), \tag{3}$$

$$a_2(D^2/m^2) = \frac{m^2}{16\pi^2} \int_M \mathrm{d}^4x \sqrt{g} \, \mathrm{Tr}\left(-\frac{R}{6} + E\right), \tag{4}$$

$$a_4(D^2/m^2) = \frac{1}{16\pi^2} \frac{1}{360} \int_M \mathrm{d}^4x \sqrt{g} \, \mathrm{Tr}(-12R^\mu_{;\mu} + 5R^2 - 2R_{\mu\nu}R^{\mu\nu} + 2R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} - 60RE + 180E^2 + 60E^\mu_{;\mu} + 30\Omega_{\mu\nu}\Omega^{\mu\nu}), \tag{5}$$

whereas the odd ones all vanish

$$a_{2n+1}(D^2/m^2) = 0.$$

The notations are as follows, one lets $\Gamma^\rho_{\mu\nu}(g)$ be the Christoffel symbols of the Levi-Civita connection of the metric g and lets

$$\Gamma^\rho(g) = g^{\mu\nu}\Gamma^\rho_{\mu\nu}(g).$$

The connection form $\overline{\omega}$, its curvature Ω, and the endomorphism E are then defined by (see Ref. 13 Sec. 4.8)

$$\overline{\omega}_\mu = \tfrac{1}{2} g_{\mu\nu}(A^\nu + \Gamma^\nu(g) I), \tag{6}$$

$$\Omega_{\mu\nu} = \partial_\mu \overline{\omega}_\nu - \partial_\nu \overline{\omega}_\mu + [\overline{\omega}_\mu, \overline{\omega}_\nu], \tag{7}$$

$$E = B - g^{\mu\nu}(\partial_\mu \overline{\omega}_\nu + \overline{\omega}_\mu \overline{\omega}_\nu - \Gamma^\rho_{\mu\nu}(g)\overline{\omega}_\rho). \tag{8}$$

To understand algebraically the dependence in the operator D it is convenient to express the previous coefficients as residues and this is done as follows in the generality that we need. One lets P be a second order elliptic operator with positive scalar principal symbol and defines a zeta function as

$$\zeta_P(s) = \mathrm{Trace}(P^{-s/2}).$$

One then gets in the required generality for our purpose the equality

$$\mathrm{Trace}(F(P/m^2)) \sim \frac{m^4}{2}\mathrm{Res}_{s=4}\zeta_P(s)f_0 + \frac{m^2}{2}\mathrm{Res}_{s=2}\zeta_P(s)f_2 + \zeta_P(0)f_4 + \cdots,$$

which, using the Wodzicki residue which is given independently of D by

$$⨍ T = \mathrm{Res}_{s=0}\,\mathrm{Trace}\,(T(D^2)^{-s/2}), \tag{9}$$

can be written as

$$\mathrm{Trace}\,(F(P/m^2)) \sim \frac{m^4}{2}f_0⨍ P^{-2} + \frac{m^2}{2}f_2⨍ P^{-1} + f_4\zeta_P(0) + \cdots. \tag{10}$$

We want to compute the spectral action associated with the operator $P=e^{-\phi}D^2e^{-\phi}$, i.e., to determine the dependence of the spectral action on the dilaton field ϕ. The first term $⨍P^{-2}$ is a Dixmier trace and one can permute the functions with the operators without altering the result since the Dixmier trace vanishes on operators of order <-4. One thus gets, for any test function h,

$$⨍ hP^{-2} = ⨍ he^{4\phi}D^{-4}$$

which shows that we get an overall factor of $e^{4\phi}$ multiplying $a_0(x,D^2)$. For the second term $⨍P^{-1}$ we have

$$⨍ hP^{-1} = ⨍ he^{\phi}D^{-2}e^{\phi} = ⨍ he^{2\phi}D^{-2}$$

using the trace property of the residue and again we get an overall factor of $e^{2\phi}$ multiplying $a_2(x,D^2)$. Note that the result remains valid when the test function h is taken with values in endomorphisms of the vector bundle on which P is acting. This suggests that the invariance of the a_2 term (up to the $e^{2\phi}$ scale factor) takes place before taking the fiberwise trace. The direct computation as follows in Eq. (18) will confirm this point.

The term $f_4\zeta_P(0)$ is more tricky to analyze and we shall only give now a heuristic argument explaining why it should be independent of ϕ. We shall then check it by a direct calculation. The formal argument proceeds as follows. First one lets

$$P(t) = e^{-t\phi}D^2e^{-t\phi}$$

so that $P(0)=D^2$ and $P(1)=P$ with the previous notations. Let then

$$Y(t) = \log P(t) - \log P(0).$$

Using the equality $(a>0)$

$$\log a = \int_0^\infty \left(\frac{1}{\lambda+1} - \frac{1}{\lambda+a}\right)\mathrm{d}\lambda,$$

applied to $P(t)$ one obtains the relation

$$\frac{\mathrm{d}}{\mathrm{d}t}Y(t) = -\int_0^\infty (P(t)+\lambda)^{-1}(\phi P(t) + P(t)\phi)(P(t)+\lambda)^{-1}\mathrm{d}\lambda. \tag{11}$$

One then shows that

$$\frac{\mathrm{d}}{\mathrm{d}t}Y(t) = -2\phi + [P(t), C(t)], \tag{12}$$

where $C(t)$ is a pseudodifferential operator (see Appendix A). Thus one gets a similar expression

$$Y = Y(1) = -2\phi + \int_0^1 [P(t), C(t)]\mathrm{d}t. \tag{13}$$

Next one uses the expansional formula

$$e^{A+B}e^{-A} = \sum_0^\infty \int_{0\leqslant t_1\leqslant\cdots\leqslant t_n\leqslant 1} B(t_1)B(t_2)\ldots B(t_n)\prod \mathrm{d}t_i,$$

where

$$B(t) = e^{tA}Be^{-tA}.$$

One lets $A=-s\log P(0)$ and $B=-sY$. This gives an equality of the form

$$P^{-s} = D^{-2s} - s\int_0^1 \sigma_{-st}(Y)\mathrm{d}t D^{-2s}$$
$$+ \sum_2^\infty (-s)^n \int_{0\leqslant t_1\leqslant\cdots\leqslant t_n\leqslant 1} \sigma_{-st_1}(Y)\sigma_{-st_2}(Y)\cdots\sigma_{-st_n}(Y)\prod \mathrm{d}t_i D^{-2s},$$

where

$$\sigma_u(T) = (D^2)^u T (D^2)^{-u}.$$

One infers from this equality and the absence of poles of order >1 in the zeta functions of the form $\mathrm{Tr}(QD^{-2s})$ that the terms of order $n>1$ in s will not contribute to the value at $s=0$. Thus the following should hold:

$$\zeta_P(0) - \zeta_{D^2}(0) = -\frac{1}{2}\fint Y$$

and using (13) one gets

$$\zeta_P(0) - \zeta_{D^2}(0) = \fint \phi = 0,$$

as the residue vanishes on differential operators. It would take a lot more care to really justify the previous manipulations. Instead, in the next section, we shall show by a brute force calculation that a_4 is independent of ϕ so that the above-mentioned identity is valid.

We thus see that in the first few terms of the spectral action, the only modification we expect when the operator D^2 is replaced by P is to get an overall factor of $e^{(4-n)\phi}$ multiplying $a_n(x, D^2)$:

$$\mathrm{Trace}(F(P)) \simeq \sum_{n=0}^6 f_n \int \mathrm{d}^4x\sqrt{g}e^{(4-n)\phi}a_n(x, D^2) + \cdots.$$

Also as will be shown in Appendix B, we have the identity

$$a_n(x, e^{-\phi}D^2e^{-\phi}) = a_n(x, D^2e^{-2\phi}) = a_n(x, e^{-2\phi}D^2).$$

It is easy to check that by applying the inverse transformation $\phi\to\phi+\ln m$ one recovers all the m scaling factors obtained in Ref. 11. In the next section, we shall confirm this result by directly evaluating the spectral action associated with the operator P and in particular the low-energy terms

a_0, a_2, and a_4. We will not attempt to evaluate higher order terms as these are not needed in our analysis.

III. DILATON AND SEELEY-deWITT COEFFICIENTS

We compare quite generally the Seeley-deWitt coefficients of an operator $P_0=D^2$ given by (1) and those of the rescaled operator $P=e^{-\phi}D^2e^{-\phi}$. We use the rescaled metric G in the Einstein frame, where the dilaton factor is absorbed in the metric. First we write

$$P = e^{-\phi}D^2e^{-\phi} = -(G^{\mu\nu}\partial_\mu\partial_\nu + \mathcal{A}^\mu\partial_\mu + \mathcal{B}), \tag{14}$$

where

$$G^{\mu\nu} = e^{-2\phi}g^{\mu\nu},$$

$$\mathcal{A}^\mu = e^{-2\phi}A^\mu - 2G^{\mu\nu}\partial_\nu\phi,$$

$$\mathcal{B} = e^{-2\phi}B + G^{\mu\nu}(\partial_\mu\phi\partial_\nu\phi - \partial_\mu\partial_\nu\phi) - e^{-2\phi}A^\mu\partial_\mu\phi.$$

The Seeley-deWitt coefficients for $a_n(P)$ are expressed in terms of $\mathcal{E}$ and $\mathbf{\Omega}_{\mu\nu}$ defined by (6) so that,

$$\mathcal{E} = \mathcal{B} - G^{\mu\nu}(\partial_\mu\overline{\omega'}_\nu + \overline{\omega'}_\mu\overline{\omega'}_\nu - \Gamma^\rho_{\mu\nu}(G)\overline{\omega'}_\rho),$$

$$\overline{\omega'}_\mu = \tfrac{1}{2}G_{\mu\nu}(\mathcal{A}^\nu + \Gamma^\nu(G)),$$

$$\mathbf{\Omega}_{\mu\nu} = \partial_\mu\overline{\omega'}_\nu - \partial_\nu\overline{\omega'}_\mu + [\overline{\omega'}_\mu, \overline{\omega'}_\nu].$$

These relations imply that

$$\overline{\omega'}_\mu = \tfrac{1}{2}g_{\mu\nu}A^\nu - \partial_\mu\phi + \tfrac{1}{2}G_{\mu\nu}\Gamma^\nu(G).$$

The conformal transformations of the Christoffel connection give

$$\Gamma^\mu_{\nu\rho}(G) = \Gamma^\mu_{\nu\rho}(g) + (\delta^\mu_\nu\partial_\rho\phi + \delta^\mu_\rho\partial_\nu\phi - g_{\nu\rho}g^{\mu\sigma}\partial_\sigma\phi),$$

$$\Gamma^\mu(G) = e^{-2\phi}\Gamma^\mu(g) - 2e^{-2\phi}g^{\mu\nu}\partial_\nu\phi.$$

Using these relations we finally get

$$\overline{\omega'}_\mu = \overline{\omega}_\mu - 2\partial_\mu\phi, \tag{15}$$

$$\mathcal{E} = e^{-2\phi}(E + g^{\mu\nu}(\nabla^g_\mu\nabla^g_\nu\phi + \partial_\mu\phi\partial_\nu\phi)), \tag{16}$$

where the covariant derivative ∇^g_μ is taken with respect to the metric g. It is quite striking that the perturbation is only a scalar multiple of the identity matrix and does not involve the endomorphisms A^μ at all.

The term a_0 only involves $\sqrt{G}\,\mathrm{Tr}(1)$ which, when expressed in terms of the metric g gives $\sqrt{g}e^{4\phi}\mathrm{Tr}(1)$.

The a_2 term is proportional to

$$\int \mathrm{d}^4x\sqrt{G}\,\mathrm{Tr}\left(\mathcal{E}-\frac{1}{6}R(G)\right),$$

where the curvature scalar is constructed as function of the metric G. We now use (16) and the relation

$$R(G)=e^{-2\phi}(R(g)+6g^{\mu\nu}(\nabla^g_\mu\nabla^g_\nu\phi+\partial_\mu\phi\partial_\nu\phi)) \tag{17}$$

to obtain at the level of endomorphisms (before taking the fiberwise trace)

$$\mathcal{E}-\tfrac{1}{6}R(G)=e^{-2\phi}\left(E-\tfrac{1}{6}R(g)\right). \tag{18}$$

This of course implies the required rescaling of the a_2 term in the required generality, but it is more precise since it holds before taking the trace. We shall use this more precise form in the proof of the invariance of the a_4 term.

The term $a_4(P)$ is given by

$$\frac{1}{16\pi^2}\frac{1}{360}\int d^4x\sqrt{G}\,\mathrm{Tr}\,[(5R^2(G)-2R_{\mu\nu}(G)R^{\mu\nu}(G)+2R_{\mu\nu\rho\sigma}(G)R^{\mu\nu\rho\sigma}(G))$$

$$-60R(G)\mathcal{E}+180\mathcal{E}^2+30\mathbf{\Omega}_{\mu\nu}\mathbf{\Omega}_{\rho\sigma}G^{\mu\rho}G^{\nu\sigma}\,],$$

where we have omitted the total derivative terms $12(-R(G)+5\mathcal{E})^{\mu}_{;\mu}$. As the modification from $\overline{\omega}_\mu$ to $\overline{\omega'}_\mu$ is Abelian (15) we get

$$\mathbf{\Omega}_{\mu\nu}=\Omega_{\mu\nu}$$

and

$$\mathbf{\Omega}_{\mu\nu}\mathbf{\Omega}_{\rho\sigma}G^{\mu\rho}G^{\nu\sigma}=e^{-4\phi}\Omega_{\mu\nu}\Omega_{\rho\sigma}g^{\mu\rho}g^{\nu\sigma}.$$

Next we group the terms

$$180\mathcal{E}^2-60\mathcal{E}R(G)+5R^2(G)=180\left(\mathcal{E}-\tfrac{1}{6}R(G)\right)^2,$$

which yields upon using Eq. (18)

$$180e^{-4\phi}\left(E-\tfrac{1}{6}R(g)\right)^2.$$

We are left with the terms

$$30\mathbf{\Omega}_{\mu\nu}\mathbf{\Omega}_{\rho\sigma}G^{\mu\rho}G^{\nu\sigma}-2R_{\mu\nu}(G)R^{\mu\nu}(G)+2R_{\mu\nu\rho\sigma}(G)R^{\mu\nu\rho\sigma}(G).$$

We now use

$$30\,\mathrm{Tr}(\mathbf{\Omega}_{\mu\nu}\mathbf{\Omega}_{\rho\sigma}G^{\mu\rho}G^{\nu\sigma})=30e^{-4\phi}\mathrm{Tr}(\Omega_{\mu\nu}\Omega_{\rho\sigma}g^{\mu\rho}g^{\nu\sigma}).$$

$$-2R_{\mu\nu}(G)R^{\mu\nu}(G)+2R_{\mu\nu\rho\sigma}(G)R^{\mu\nu\rho\sigma}(G)=-R(G)^*R^*(G)+3C_{\mu\nu\rho\sigma}(G)C^{\mu\nu\rho\sigma}(G).$$

In deriving the last relation we made use of the two identities

$$R^*R^*-R^2=R^2_{\mu\nu\rho\sigma}-4R^2_{\mu\nu},$$

$$C^2_{\mu\nu\rho\sigma}-\tfrac{1}{3}R^2=R^2_{\mu\nu\rho\sigma}-2R^2_{\mu\nu},$$

where $C_{\mu\nu\rho\sigma}$ is the conformal tensor and

$$R^*R^* = \frac{1}{4\sqrt{g}}\epsilon^{\mu\nu\rho\sigma}\epsilon_{\alpha\beta\gamma\delta}R^{\alpha\beta}_{\mu\nu}R^{\gamma\delta}_{\rho\sigma}.$$

These imply

$$R^2_{\mu\nu\rho\sigma} = 2C^2_{\mu\nu\rho\sigma} - R^*R^* + \tfrac{1}{3}R^2,$$

$$R^2_{\mu\nu} = \frac{1}{2}C^2_{\mu\nu\rho\sigma} - \frac{1}{2}R^*R^* + \tfrac{1}{3}R^2.$$

The square of the conformal tensor is known to be conformal invariant

$$\int d^4x\sqrt{G}C_{\mu\nu\rho\sigma}(G)C^{\mu\nu\rho\sigma}(G) = \int \mathrm{d}^4x\sqrt{g}C_{\mu\nu\rho\sigma}(g)C^{\mu\nu\rho\sigma}(g).$$

The topological Gauss-Bonnet term is metric independent and therefore conformal invariant

$$\int \mathrm{d}^4x\sqrt{G}R(G)^*R^*(G) = \int \mathrm{d}^4x\sqrt{g}R(g)^*R^*(g),$$

and this can be rewritten as

$$\frac{1}{4}\int \mathrm{d}^4x\frac{1}{\sqrt{g}}\epsilon^{\mu\nu\rho\sigma}\epsilon_{\alpha\beta\gamma\delta}R^{\alpha\beta}_{\mu\nu}R^{\gamma\delta}_{\rho\sigma}.$$

This shows that the a_4 term has the expected invariance under the rescaling of the operator $P_0 \to P = e^{-\phi}P_0e^{-\phi}$.

IV. SPECTRAL ACTION WITH DILATON

We now use the result of the previous section to compute the spectral action with dilaton as a function of the rescaled metric G in the Einstein frame, where the dilaton factor is absorbed in the metric.

The lowest term in the spectral action is given by

$$\frac{45}{4\pi^2}f_0\int \mathrm{d}^4x\sqrt{g}e^{4\phi} = \frac{45}{4\pi^2}f_0\int \mathrm{d}^4x\sqrt{G}.$$

(Note that the dimension of the bundle on which the operator is acting is $4\times3\times15$ where the 4 is the dimension of spinors, 3 the number of generations, and $15=4\times3+3$ is the content of each generation).

The next term in the spectral action with dilaton of the standard model is, in terms of the original metric g:

$$\frac{3}{4\pi^2}f_2\int \mathrm{d}^4x\sqrt{g}e^{2\phi}\left(\frac{5}{4}R(g) - 2y^2H^*H\right). \tag{19}$$

We can transform this back to the Einstein frame with metric $G_{\mu\nu}$ so that the curvature scalar term has no scale factors in front of it. Using Eq. (17) with $g\to G$ and $\phi\to-\phi$ the curvature $R(g)$ is

$$R(g) = e^{2\phi}(R(G) + 6G^{\mu\nu}(-\nabla^G_\mu\nabla^G_\nu\phi + \partial_\mu\phi\partial_\nu\phi)),$$

and we obtain

$$\int \mathrm{d}^4x\sqrt{g}e^{2\phi}R(g) = \int \mathrm{d}^4x\sqrt{G}(R(G) + 6G^{\mu\nu}(-\nabla^G_\mu\nabla^G_\nu\phi + \partial_\mu\phi\partial_\nu\phi))$$

$$= \int \mathrm{d}^4x\sqrt{G}(R(G) + 6G^{\mu\nu}\partial_\mu\phi\partial_\nu\phi)$$

after integrating by parts. The a_2 term (19) thus becomes

$$\frac{3}{4\pi^2}f_2\int \mathrm{d}^4x\sqrt{G}\left(\frac{5}{4}R(G) + \frac{15}{2}G^{\mu\nu}\partial_\mu\phi\partial_\nu\phi - 2y^2H'^*H'\right), \tag{20}$$

where we have defined

$$H = e^\phi H',$$

so that the only appearance of the dilaton ϕ is through its kinetic energy.

Let us pause a bit and discuss signs at this point. For a positive test function F the coefficients f_0, f_2, f_4 are all positive. It is important that the Einstein term $\int \mathrm{d}^4x\sqrt{G}R(G)$ appears in (20) with the correct sign for the Euclidean functional integral, and that the kinetic term for ϕ namely $\int \mathrm{d}^4x\sqrt{G}G^{\mu\nu}\partial_\mu\phi\partial_\nu\phi$ appears with a positive coefficient in (20).

The next term coming from $a_4(x,P)$ is unchanged for the spectral action with dilaton, and thus given independently of ϕ by Ref. 11,

$$\frac{f_4}{4\pi^2}\int \mathrm{d}^4x\sqrt{g}\left(\frac{1}{32}(11R(g)^*R^*(g) - 18C_{\mu\nu\rho\sigma}(g)C_{\alpha\beta\gamma\delta}(g)g^{\mu\alpha}g^{\nu\beta}g^{\rho\gamma}g^{\sigma\delta})\right.$$
$$+ 3y^2\left(D_\mu H^*D_\nu H g^{\mu\nu} - \frac{1}{6}R(g)H^*H\right)$$
$$\left. + \left(g_3^2G^i_{\mu\nu}G^i_{\rho\sigma} + g_2^2F^\alpha_{\mu\nu}F^\alpha_{\rho\sigma} + \frac{5}{3}g_1^2B_{\mu\nu}B_{\rho\sigma}\right)g^{\mu\rho}g^{\nu\sigma} + 3z^2(H^*H)^2\right),$$

where we have omitted total derivatives as they only contribute to boundary terms. Let us show that we can rewrite this term in the following way as a function of the metric $G_{\mu\nu}$ by making use of the conformal invariance of a_4:

$$\frac{f_4}{4\pi^2}\int \mathrm{d}^4x\sqrt{G}\left(\frac{1}{32}(11R(G)^*R^*(G) - 18C_{\mu\nu\rho\sigma}(G)C_{\alpha\beta\gamma\delta}(G)G^{\mu\alpha}G^{\nu\beta}G^{\rho\gamma}G^{\sigma\delta})\right.$$
$$+ 3y^2\left(D_\mu H'^*D_\nu H' G^{\mu\nu} - \frac{1}{6}R(G)H'^*H'\right)$$
$$\left. + \left(g_3^2G^i_{\mu\nu}G^i_{\rho\sigma} + g_2^2F^\alpha_{\mu\nu}F^\alpha_{\rho\sigma} + \frac{5}{3}g_1^2B_{\mu\nu}B_{\rho\sigma}\right)G^{\mu\rho}G^{\nu\sigma} + 3z^2(H'^*H')^2\right).$$

The terms which only involve the metric are conformal by construction. The same holds for the terms which involve the gauge fields since the Yang-Mills action is conformal. Thus we need only to take care of the terms that involve the Higgs fields. We have to show that the following expression is unchanged by $g\to G$ and $H\to H'$;

$$\frac{3f_4y^2}{4\pi^2}\int \mathrm{d}^4x\sqrt{g}\left(g^{\mu\nu}D_\mu H^*D_\nu H - \frac{1}{6}R(g)H^*H\right).$$

To see this we first rescale the kinetic energy of the Higgs field

$$\sqrt{g}g^{\mu\nu}D_\mu H^* D_\nu H = \sqrt{G}G^{\mu\nu}e^{-2\phi}D_\mu(e^\phi H'^*)D_\nu(e^\phi H')$$
$$= \sqrt{G}G^{\mu\nu}(D_\mu H'^* D_\nu H' + \partial_\mu\phi H'^* D_\nu H'$$
$$+ D_\mu H'^* H'\partial_\nu\phi + H'^* H'\partial_\mu\phi\partial_\nu\phi).$$

The conformal coupling of the Higgs field to the scalar curvature transforms as

$$-\frac{1}{6}\sqrt{g}R(g)H^*H = -\frac{1}{6}\sqrt{G}H'^* H'(R(G) - 6G^{\mu\nu}((\nabla_\mu\nabla_\nu)^G\phi - \partial_\mu\phi\partial_\nu\phi)).$$

After integrating by parts the term

$$\int d^4x\sqrt{G}H'^* H'(\nabla_\mu\nabla_\nu)^G\phi G^{\mu\nu},$$

we find that all cross terms cancel, thus obtaining

$$\int d^4x\sqrt{g}\left(g^{\mu\nu}D_\mu H^* D_\nu H - \frac{1}{6}R(g)H^*H\right) = \int d^4x\sqrt{G}\left(G^{\mu\nu}D_\mu H'^* D_\nu H' - \frac{1}{6}R(G)H'^* H'\right).$$

The quartic Higgs interactions are evidently scale invariant

$$\int d^4x\sqrt{g}(H^*H)^2 = \int d^4x\sqrt{G}(H'^* H')^2.$$

Collecting all terms, the low-energy bosonic part of the spectral action with dilaton is given by

$$I_b = \frac{45}{4\pi^2}f_0\int d^4x\sqrt{G} + \frac{3}{4\pi^2}f_2\int d^4x\sqrt{G}\left(\frac{5}{4}R(G) + \frac{15}{2}G^{\mu\nu}\partial_\mu\phi\partial_\nu\phi - 2y^2H'^* H'\right)$$
$$+ \frac{f_4}{4\pi^2}\int d^4x\sqrt{G}\left(\frac{1}{32}(11R(G)^*R^*(G) - 18C_{\mu\nu\rho\sigma}(G)C^{\mu\nu\rho\sigma}(G)) + 3y^2\left(D_\mu H'^* D_\nu H' G^{\mu\nu}\right.\right.$$
$$\left.\left. - \frac{1}{6}R(G)H'^* H'\right) + \left(g_3^2 G^i_{\mu\nu}G^i_{\rho\sigma} + g_2^2 F^\alpha_{\mu\nu}F^\alpha_{\rho\sigma} + \frac{5}{3}g_1^2 B_{\mu\nu}B_{\rho\sigma}\right)G^{\mu\rho}G^{\nu\sigma} + 3z^2(H'^* H')^2\right). \tag{21}$$

For higher order terms one expects a scaling factor of the form $e^{(4-n)\phi}$ to be present, but derivatives of the dilaton field ϕ may also occur. Therefore in the Einstein frame, one does not expect the dilaton field ϕ to acquire a potential. As will be discussed later, this will change when quantum corrections are taken into account and the dilaton acquires a potential of the Coleman-Weinberg type.[14]

Fermionic interactions take the simple form

$$\langle\Psi|D|\Psi\rangle = \int d^4x\sqrt{g}\overline{\Psi}D\Psi,$$

where the metric $g_{\mu\nu}$ is used to insure hermiticity of D. We will now show that the fermions will not feel the dilaton. To see this we first redefine the spinors by

$$\Psi = e^{(3/2)\phi}\Psi',$$

then we have, for the parts not involving the Higgs or gauge fields,

$$\langle\Psi|D|\Psi\rangle = \int d^4x\sqrt{G}e^{-4\phi}e^{(3/2)\phi}\bar{\Psi}'\gamma^c e^{\phi}E_c^{\mu}\left(\partial_\mu + \frac{1}{4}\omega_\mu^{ab}(e)\gamma_{ab}\right)(e^{(3/2)\phi}\Psi'),$$

where the rescaled vierbein is $E_\mu^a = e^{\phi}e_\mu^a$. We have to express the spin connection $\omega_\mu^{ab}(e)$ in terms of the spin connection of the rescaled vierbein $\Omega_\mu^{ab}(E)$. To do this we use the equations

$$\partial_\mu e_\nu^a - \partial_\nu e_\mu^a - \omega_\mu^{ab}(e)e_{\nu b} + \omega_\nu^{ab}(e)e_{\mu b} = 0,$$

$$\partial_\mu E_\nu^a - \partial_\nu E_\mu^a - \Omega_\mu^{ab}(E)E_{\nu b} + \Omega_\nu^{ab}(E)E_{\mu b} = 0,$$

and these imply that

$$\omega_\mu^{ab}(e) = \Omega_\mu^{ab}(E) + (e_\mu^a e^{\nu b} - e_\mu^a e^{\nu b})\partial_\nu\phi.$$

Therefore

$$\gamma^c e_c^{\mu}\left(\tfrac{3}{2}\partial_\mu\phi + \tfrac{1}{4}\omega_\mu^{ab}(e)\gamma_{ab}\right) = \gamma^c e^{\phi}E_c^{\mu}\left(\tfrac{1}{4}\Omega_\mu^{ab}(E)\gamma_{ab}\right),$$

and the fermionic action reduces to the nice form

$$\int \mathrm{d}^4x\sqrt{G}\,\overline{\Psi'}\gamma^c E_c^{\mu}\left(\partial_\mu + \frac{1}{4}\Omega_\mu^{ab}(E)\gamma_{ab}\right)\Psi',$$

which is independent of the dilaton. Finally the parts involving interactions between the fermions and the Higgs or gauge fields could be written in the forms

$$\int \mathrm{d}^4x\sqrt{g}\overline{\Psi}\gamma_5 H\Psi = \int d^4x\sqrt{G}\,\overline{\Psi'}\gamma_5 H'\Psi',$$

$$\int \mathrm{d}^4x\sqrt{g}\overline{\Psi}\gamma^\rho e_a^{\mu}A_\mu\Psi = \int \mathrm{d}^4x\sqrt{G}\,\overline{\Psi'}\gamma^\rho E_a^{\mu}A_\mu\Psi'.$$

The fermionic interactions are

$$I_f = \langle Q|D_q|Q\rangle + \langle L|D_l|L\rangle,$$

where

$$Q = \begin{pmatrix} u_L \\ d_L \\ d_R \\ u_R \end{pmatrix}, \quad \begin{pmatrix} \nu_L \\ e_L \\ e_R \end{pmatrix}$$

and these take exactly the same form as those without dilaton when expressed in terms of the metric $G_{\mu\nu}$. Rewriting this in terms of the fermionic fields

$$Q' = e^{-(3/2)\phi}Q, \quad L' = e^{-(3/2)\phi}L,$$

and the Higgs field H' we obtain

$$I_f = \int \mathrm{d}^4x\sqrt{G}(\overline{L'}D_l'L' + \overline{Q'}D_q'Q'),$$

where[11]

$$D_l' = \begin{pmatrix} \gamma^\mu \otimes \left(D_\mu \otimes 1_2 - \frac{i}{2} g_2 A_\mu^\alpha \sigma^\alpha + \frac{i}{2} g_1 B_\mu \otimes 1_2\right) \otimes 1_3 & \gamma_5 \otimes k^e \otimes H' \\ \gamma_5 \otimes k^{*e} \otimes H^{*\prime} & \gamma^\mu \otimes (D_\mu + i g_1 B_\mu) \otimes 1_3 \end{pmatrix}$$

$$D_q' = \begin{pmatrix} \gamma^\mu \otimes \nabla_\mu^{(1,2)} \otimes 1_3 & \gamma_5 \otimes k^d \otimes H' & \gamma_5 \otimes k^u \otimes \widetilde{H'} \\ \gamma_5 \otimes k^{*d} \otimes H^{*\prime} & \gamma^\mu \otimes \left(D_\mu + \frac{i}{3} g_1 B_\mu\right) \otimes 1_3 & 0 \\ \gamma_5 \otimes k^{*u} \otimes \widetilde{H}'^* & 0 & \gamma^\mu \otimes \left(D_\mu - \frac{2i}{3} g_1 B_\mu\right) \otimes 1_3 \end{pmatrix}$$
$$+ \gamma^\mu \otimes 1_4 \otimes 1_3 \otimes \left(-\frac{i}{2} g_3 V_\mu^i \lambda^i\right),$$

and

$$\gamma^\mu = \gamma^a E_a^\mu,$$

$$D_\mu = \partial_\mu + \tfrac{1}{4} \Omega_\mu^{ab}(E) \gamma_{ab},$$

$$\nabla_\mu^{(1,2)} = D_\mu \otimes 1_2 - \frac{i}{2} g_2 A_\mu^\alpha \sigma^\alpha - \frac{i}{6} g_1 B_\mu \otimes 1_2.$$

From the previous considerations we deduce that the only effect of the dilaton on the low-energy terms of the spectral action is that the dilaton gets a kinetic term with no other interactions. This confirms that all matter interactions in the above-mentioned Lagrangian are scale invariant when expressed in the rescaled fields $G_{\mu\nu}$, H', and Ψ'. Only the Einstein term and the dilaton kinetic energy are not scale invariant.

Note that the invariance of the action for the Fermions, that is the equality

$$\langle \Psi | D | \Psi \rangle = \langle \Psi' | D' | \Psi' \rangle', \tag{22}$$

where D' corresponds to the metric G and the fields H', does not mean that the operators D and D' are the same. Indeed the transformation $\Psi \to \Psi'$ is not unitary and one has

$$\langle \Psi' | \Psi' \rangle' = \langle \Psi | e^\phi | \Psi \rangle, \tag{23}$$

which gives the unitary equivalence

$$D' \sim e^{-\phi/2} D e^{-\phi/2}. \tag{24}$$

One might then be tempted to conclude that the square of $e^{-\phi/2} D e^{-\phi/2}$ should be unitarily equivalent to $P = e^{-\phi} D^2 e^{-\phi}$ but this does not hold precisely because of the additional kinetic term in the spectral action with dilaton. Indeed one can prove (Appendix C) in the general framework of spectral triples, with a minimum amount of hypothesis, the identity

$$\int e^{2\phi} D^{-2} = \int (e^{-\phi/2} D e^{-\phi/2})^{-2} + \frac{1}{2} \int [D, e^\phi][D, e^\phi]^* D^{-4} \tag{25}$$

with $D' = e^{-\phi/2} D e^{-\phi/2}$ the last term gives the canonical kinetic energy of the dilaton

$$\frac{1}{2} \int [D' \phi][D', \phi]^* D'^{-4}$$

with the correct sign.

V. APPLICATIONS

We have shown that the dilaton interactions of the spectral action are almost the same as the ones proposed in the literature,[2,3] the difference lies in the derivative couplings of the dilaton field. These were obtained by requiring the standard model matter sector to be scale invariant by introducing a compensating dilaton field. The origin of the dilatational symmetry breaking are the mass terms of the Higgs potential, and these are scaled with the dilaton field to make them scale invariant. In a curved space time all fields couple to gravity, and the dilaton. The proposed action for the gravity-dilaton-Higgs sectors, in our notation, was derived to be (this expression is in the conventions of Ref. 4 and is in Minkowski space)[3,4]

$$I=\int \mathrm{d}^4x\sqrt{G}\left(-\frac{1}{2\kappa^2}R+\frac{1}{2}\left(1+\frac{6}{\kappa^2 f^2}\right)G^{\mu\nu}\partial_\mu\phi\partial_\nu\phi+G^{\mu\nu}D_\mu H'^{*}D_\nu H'-V_0(H'^{*}H')\right).$$

There it was shown that in curved space-time this corresponds to the Jordan-Brans-Dicke theory of gravity. The only difference between this action and the spectral action is that the latter has the conformal coupling

$$\tfrac{1}{6}R(G)(H'^{*}H')^2,$$

which is necessary to make the matter couplings scale invariant. A slight modification was also proposed in the study of models of extended inflation, by also considering the possibility of modifying the Higgs sector by taking[4]

$$e^{(2/f)\phi}G^{\mu\nu}D_\mu H^{*}D_\nu H-e^{(4/f)\phi}V_0(H^{*}H).$$

This differs from the spectral action by the appearance of derivative couplings of the form

$$G^{\mu\nu}D_\mu H'^{*}H'\partial_\nu\phi.$$

It is amusing to note that this alternative proposed action is exactly the same action as the one derived for the Connes-Lott gravitational interactions.[6,10] Therefore the two models proposed in the literature for making the Higgs sector scale invariant are the same as the interactions obtained for the noncommutative standard model, either for the spectral action formulation, or the Connes-Lott formulation. We also note that scale invariance of the action is broken by the Einstein term and by the kinetic term for the dilaton. This is remarkable because it was shown that if the full action is scale invariant, then the couplings will not lead to a model with extended inflation. Quantum corrections and renormalization conditions break scale invariance in the matter sector of the standard model and lead to an exponentially large hierarchy between the mass scale f where $\phi=(1/f)\sigma$ and the electroweak scale without fine tuning. The scale f is normally of the order of the Planck scale. The dilaton mass obtained depends on the Higgs mass, but should be constrained to be smaller than 10^{-6} eV.

The noncommutative space of the standard model is obtained by taking the product of a four-dimensional Riemannian manifold times a discrete space dictated by the symmetries of the Hilbert space spanned by the quarks and leptons. The presence of left- and right-handed fermions provides the intuitive picture where these fermions are placed on different sheets. The gauge fields in the discrete dimensions are the Higgs fields, with the inverse of the distance between the sheets interpreted as the electroweak energy scale. This picture is similar to the RS scenario where the four-dimensional space is embedded into a five-dimensional space as a three-brane positioned at the points $x_5=0$ and $x_5=\pi r_c$, where r_c is the compactification radius. The action for the Higgs sector in the RS model[9] was obtained to be

$$\int d^4x\sqrt{g}(g^{\mu\nu}D_\mu H^* D_\nu H - \lambda(|H|^2 - v_0^2))$$

$$= \int d^4x\sqrt{\bar{g}}(\bar{g}^{\mu\nu}D_\mu H'^* D_\nu H' - \lambda(|H'|^2 - e^{-2kr_c\pi}v_0^2)),$$

where

$$g^{\mu\nu} = e^{-2kr_c\pi}\bar{g}^{\mu\nu},$$

$$H' = e^{2kr_c\phi}H,$$

in the visible sector located at $x_5 = \pi r_c$. The physical mass scales are set by the symmetry breaking scale $v = e^{-kr_c\pi}v_0$ so that $m = m_0 e^{-kr_c\pi}$. The bare symmetry breaking scale v_0 is taken to be of the order of the Planck scale at 10^{19} GeV and the scaling factor $e^{kr_c\pi}$ tuned to be of the order of 10^{15} so that the low-energy masses are of the order of TeV. The hierarchy problem is only partially solved in a technical sense because the tuning could not be maintained at the quantum level. A choice of $kr_c = 10$ can generate the large scale 10^{15} GeV. Comparing the Higgs sectors in the RS action with that in the spectral action we immediately see that they are identical provided we identify the expectation value of the dilaton field $\langle\phi\rangle$ with $kr_c\pi$.

VI. CONCLUSIONS

The Dirac operator being a differential operator has the dimensions of mass. The spectral action in noncommutative geometry is defined as a function of a dimensionless operator which is taken to be the Dirac operator divided by some arbitrary large mass scale. The arbitrariness of the mass scale naturally suggests to make this scale dynamical by introducing a dilaton field in the Dirac operator of the noncommutative space defined by the standard model. To understand the appearance of the mass scales of the spectral action, we evaluated all interactions of the dilaton with the matter sector in the standard model. We found the remarkable result that the low-energy action, when evaluated in the Einstein frame, is scale invariant except for the Einstein-Hilbert term and the dilaton kinetic term. The resulting model is almost identical to the one proposed in the literature.[2–4] The main motivation in these works is the observation that the standard model is classically almost scale invariant, with the symmetry only broken by the mass term in the Higgs potential. The symmetry is restored by the use of a dilaton field. When coupled to gravity, neither the dilaton kinetic energy nor the scalar curvature are scale invariant, leading to a Jordan-Brans-Dicke theory of gravity. The vacuum expectation value of the Higgs field is then dependent on the dilaton and is classically undetermined. Quantum corrections break the scale invariance of the scalar potential and change the vacuum expectation value of the Higgs field. The dilaton acquires a large negative expectation value given by $-m$ and a small mass. The hierarchy in mass scales is due to the large Yukawa coupling of the top quark. The dilaton expectation value can range between the GUT scale of 10^{15} GeV to the Planck scale of 2.4×10^{18} GeV. The hierarchy in mass scales is not possible if the dilaton kinetic energy and the gravitational action were scale invariant. It is remarkable that all the essential features of building a scale invariant standard model interactions to generate a mass hierarchy and predict the Higgs mass are naturally included in the spectral action without any fine tuning. It is worth mentioning that the scalar potential of exactly the same model considered here was shown to admit extended inflation and a metastable ground state. It also evades the problems of the original version of extended inflation.

The vacuum expectation value of the dilaton field is determined by getting contributions from classical and radiative corrections to the vacuum energy density. One does not obtain naturally a vanishing cosmological constant. There are two possibilities to cure this problem. The first is to determine the low-energy value of the cosmological constant as determined by the renormalization group equations and then fine tune this value to cancel the contributions of the Coleman-Weinberg

potential. The second possibility to cure this problem is to fix the total invariant volume. This restricts general relativity to the form considered in Ref. 15, where the volume form is held fixed. There it was shown that this picture is consistent both at the classical and quantum levels.[16–18] This fixes the total invariant volume and eliminates the scalar mode of the metric tensor $g_{\mu\nu}$. This is done at the expense of introducing the dilaton mode ϕ.[3] In noncommutative geometry the volume is fixed by a Hochschild cycle c whose compatibility with the Dirac operator D is a basic constraint on the Hilbert space representation giving the metric.[19] One applies the representation to monomials

$$\pi(f_0,f_1,f_2,f_3,f_4) = f_0[D,f_1][D,f_2][D,f_3][D,f_4],$$

and requires that when applied to the Hochschild cycle c it gives

$$\pi(c) = \gamma_5.$$

The cosmological constant becomes determined by the initial conditions of the theory.

To summarize, we have shown that the spectral action includes naturally a dilaton field which guarantees the scale invariance of the standard model interactions, and provides a mechanism to generate mass hierarchies. This is in addition to the advantages obtained previously in Ref. 11 which are now well known.[12] There it was shown that all the correct features of the standard model are obtained without any fine tuning, such as unification with gravity, unification of the three gauge coupling constants and relating the Higgs to the gauge couplings. These results should be taken to support the idea that all the geometric information about the physical space is captured by the knowledge of the Dirac operator of an appropriate noncommutative space.

APPENDIX A

In this appendix we shall prove formula (12). Given an elliptic positive invertible second order operator Q and a differential operator T we use the notation $\nabla(T)=[Q,T]$ and the following identity (for $n\geqslant 0$):

$$Q^{-1}T = \sum_0^n (-1)^k \nabla^k(T) Q^{-k-1} + (-1)^{n+1} Q^{-1} \nabla^{n+1}(T) Q^{-n-1}. \tag{A1}$$

We apply this to $Q=P(t)+\lambda$, $T=\phi P(t)+P(t)\phi$. The operator $\nabla^k(T)$ is independent of λ and is a differential operator of order $\leqslant 2+k$ since $\nabla^k(\phi)$ is at most of order k. Thus the operator $\nabla^k(T)Q^{-k-1}$ is pseudodifferential of order at most $2+k-2(k+1)=-k$ and the remainder in (A1) is of order at most $-n-1$. This shows that when working modulo operators of order less than $-n$ we have

$$(P(t)+\lambda)^{-1}T \sim T(P(t)+\lambda)^{-1} + \sum_1^n (-1)^k \nabla^k(T)(P(t)+\lambda)^{-k-1}$$

so that

$$(P(t)+\lambda)^{-1}T(P(t)+\lambda)^{-1} \sim T(P(t)+\lambda)^{-2} + \sum_1^n (-1)^k \nabla^k(T)(P(t)+\lambda)^{-k-2}.$$

But one has

$$\sum_{1}^{n}(-1)^k\nabla^k(T)(P(t)+\lambda)^{-k-2}=[P(t),A(t,\lambda)],$$

where

$$A(t,\lambda)=\sum_{1}^{n}(-1)^k\nabla^{k-1}(T)(P(t)+\lambda)^{-k-2}.$$

Thus integrating from $\lambda=0$ to ∞ and using (11) we get that, modulo operators of order less than $-n$,

$$\frac{\mathrm{d}}{\mathrm{d}t}Y(t)\sim-\int_0^\infty(\phi P(t)+P(t)\phi)(P(t)+\lambda)^{-2}\mathrm{d}\lambda+[P(t),A(t)]$$

where

$$A(t)=-\int_0^\infty A(t,\lambda)\mathrm{d}\lambda.$$

This thus gives

$$\frac{\mathrm{d}}{\mathrm{d}t}Y(t)\sim-(\phi P(t)+P(t)\phi)P(t)^{-1}+[P(t),A(t)]=-2\phi+[P(t),C(t)],\quad C(t)=A(t)-\phi P(t)^{-1}.$$

It is important to note that all of the previous manipulations hold in the general context of spectral triples with simple dimension spectrum. Moreover one can prove fairly strong properties of the spectral action in this general context.

APPENDIX B

In this appendix we shall prove the identity

$$a_n(x,P)=a_n(x,P_1)=a_n(x,P_2),$$

where $P=e^{-\phi}D^2e^{-\phi}$ and $P_1=D^2e^{-2\phi}$, $P_2=e^{-2\phi}D^2$. It can then be used to simplify some of the computations of Sec. III.

One simply writes

$$P=e^{-\phi}P_1e^{\phi}$$

so that

$$\mathrm{Trace}\,(P^{-s})=\mathrm{Trace}\,(P_1^{-s}).$$

From this the identity $a_n(x,P)=a_n(x,P_1)$ immediately follows.

One can also do a direct check as follows, one first writes

$$P=-(G^{\mu\nu}I\partial_\mu\partial_\nu+\mathcal{A}^\mu\partial_\mu+\mathcal{B}),$$

$$P_1=-(G^{\mu\nu}I\,\partial_\mu\partial_\nu+\mathcal{A}_1^\mu\partial_\mu+\mathcal{B}_1),$$

where

$$G^{\mu\nu} = e^{-2\phi} g^{\mu\nu},$$

$$\mathcal{B} = e^{-2\phi} B + G^{\mu\nu}(\partial_\mu \phi \partial_\nu \phi - \partial_\mu \partial_\nu \phi) - e^{-2\phi} A^\mu \partial_\mu \phi,$$

$$\mathcal{A}^\mu = e^{-2\phi} A^\mu - 2G^{\mu\nu}\partial_\nu \phi,$$

$$\mathcal{A}_1^\mu = e^{-2\phi} A^\mu - 4G^{\mu\nu}\partial_\nu \phi,$$

$$\mathcal{B}_1 = e^{-2\phi} B + 2G^{\mu\nu}(2\partial_\mu \phi \partial_\nu \phi - \partial_\mu \partial_\nu \phi) - 2e^{-2\phi} A^\mu \partial_\mu \phi.$$

These relations imply

$$\mathcal{A}_1^\mu = \mathcal{A}^\mu - 2G^{\mu\nu}\partial_\nu \phi,$$

$$\mathcal{B}_1 = \mathcal{B} + G^{\mu\nu}(\partial_\mu \phi \partial_\nu \phi - \partial_\mu \partial_\nu \phi) - \mathcal{A}^\mu \partial_\mu \phi.$$

We also have

$$\begin{aligned} \overline{\omega'}_{1\mu} &= \tfrac{1}{2} G_{\mu\nu}(\mathcal{A}_1^\nu + \Gamma^\nu(G)) \\ &= \overline{\omega'}_\mu - \partial_\mu \phi, \end{aligned}$$

so that

$$\mathcal{E}_1 = \mathcal{B}_1 - G^{\mu\nu}(\partial_\mu \overline{\omega'}_{1\nu} + \overline{\omega'}_{1\mu}\overline{\omega'}_{1\nu} - \Gamma^\rho_{\mu\nu}(G)\overline{\omega'}_{1\rho}) = \mathcal{E}.$$

Similarly

$$\mathbf{\Omega}_{1\mu\nu} = \mathbf{\Omega}_{\mu\nu}$$

and the equality of the Seely-de Witt coefficients follow from the fact that these depend only on $\mathcal{E}$, $\mathbf{\Omega}_{\mu\nu}$ and the curvature tensors are functions of the same metric $G_{\mu\nu}$.

APPENDIX C

In this appendix we shall show (25) and the appearance of the kinetic term in the general framework of spectral triples using the following manipulations. One has

$$\fint (e^{-\phi/2} D e^{-\phi/2})^{-2} = \fint e^\phi D^{-1} e^\phi D^{-1}. \tag{C1}$$

Also

$$D^{-1} e^\phi = e^\phi D^{-1} - D^{-1}[D, e^\phi] D^{-1}, \tag{C2}$$

which allows to write (C1) as

$$\fint (e^{-\phi/2} D e^{-\phi/2})^{-2} = \fint e^{2\phi} D^{-2} - \fint e^\phi D^{-1}[D, e^\phi] D^{-2}, \tag{C3}$$

and using (C2) again,

$$-\fint e^\phi D^{-1}[D, e^\phi] D^{-2} = -\fint e^\phi [D, e^\phi] D^{-3} - \fint D^{-1}[D, e^\phi] D^{-1}[D, e^\phi] D^{-2}.$$

The first of the two terms vanishes since the residue is a trace. The second is given by

$$-\int D^{-1}[D,e^{\phi}]D^{-1}[D,e^{\phi}]D^{-2}=\int [D,e^{\phi}]^2D^{-4}+R, \tag{C4}$$

where R is the remainder

$$R=-\int D^{-2}[D^2,e^{\phi}]D^{-1}[D,e^{\phi}]D^{-2}.$$

Let us show that

$$R=-\frac{1}{2}\int [D^2,e^{\phi}]^2D^{-6}. \tag{C5}$$

To see this write

$$R=-\int D^{-2}[D^2,e^{\phi}]DD^{-2}[D,e^{\phi}]D^{-2}, \tag{C6}$$

and note that the commutator of D with $[D^2,e^{\phi}]$ is equal to $[D^2,[D,e^{\phi}]]$ and has order 1 so that

$$\int D^{-2}[D,[D^2,e^{\phi}]]D^{-2}[D,e^{\phi}]D^{-2}=0.$$

Thus moving D to the left and using the trace property of the residue one gets

$$R=-\frac{1}{2}\int [D^2,e^{\phi}]D^{-2}(D[D,e^{\phi}]+[D,e^{\phi}]D)D^{-4},$$

and one obtains (C5). Summarizing, we have shown the equality

$$\int (e^{-\phi/2}De^{-\phi/2})^{-2}=\int e^{2\phi}D^{-2}+\int [D,e^{\phi}]^2D^{-4}-\frac{1}{2}\int [D^2,e^{\phi}]^2D^{-6}.$$

Thus to obtain (C1) one just needs to prove the equality

$$\int [D,a]^2D^{-4}=\int [D^2,a]^2D^{-6}, \tag{C7}$$

and apply it to $a=e^{\phi}$. One can check (C7) directly in the Riemannian case by computing the residue as the integral of the principal symbols on the unit sphere bundle. The factor 2^2 from the Poisson brackets $[D^2,a]$ is compensated by the integral of ξ_{μ}^2 on the sphere which gives $\frac{1}{4}$. In the general framework of spectral triples one gets (C7) from the general hypothesis

$$\int a[D,b]D^{-3}=0, \quad \forall\, a,b\in\mathcal{A}.$$

Note that the commutator $[D,e^{\phi}]$ is skew adjoint and in particular $[D,e^{\phi}]^*=-[D,e^{\phi}]$. Thus we get the correct sign in

$$\int e^{2\phi}D^{-2}=\int (e^{-\phi/2}De^{-\phi/2})^{-2}+\frac{1}{2}\int [D,e^{\phi}][D,e^{\phi}]^*D^{-4}. \tag{C8}$$

(Received 15 March 2006; accepted 1 May 2006; published online 19 June 2006)

The group chain U(8)⊃O(8)⊃SU(3) plays an important role in many particle systems whenever the fundamental particles have eight degrees of freedom. As a particular example, the systems of many gluons and pairs of quark-antiquark are discussed, which can be coupled to a flavor octet. In order to determine the explicit structure of states and decay probabilities, the calculation of the Clebsch-Gordan coefficients (CGC) of this group chain is indispensable. In this contribution, the polynomial states of the U(8) chain are constructed and also the isoscalar factors of the CGC's. Tables of isoscalar factors are presented. The method shown serves as an example for higher rank groups. © *2006 American Institute of Physics.*

I. INTRODUCTION

Clebsch-Gordan coefficients (CGC) play an important role in physics. The group structure related to it depends on the particular problem to consider. For example, in the case of angular momentum, spin or total spin of a many particle system, the underlying structure is the group SU(2). Knowing the CGC serves to calculate matrix elements of tensors of SU(2), which are, for example, related to interactions in a Hamiltonian and/or to transition operators. The fundamental group involved [here the SU(2)] depends on the basic degrees of freedom of the lowest nontrivial irreducible spin representation (irrep), which is spin $\frac{1}{2}$. There are other types of CGC, which are related to different basic degrees of freedom. As a further example we mention the SU(3) group. It appears in nuclear physics as the symmetry group of the harmonic oscillator in three dimensions and it defines the fundamental structure of the shell model.[1] Much effort has been involved to obtain these CGC's. The culmination is the work presented in Refs. 2–4 where up to recoupling coefficients are given, equivalent to the 6-j and 9-j symbols of SU(2).[5] The SU(3) CGC's are also used in particle physics, where the meaning of SU(3) is different and rather related to flavor or color.

In order to obtain the CGC's, in the example of SU(2) and SU(3) the recursion relations, obtained from the algebraic properties of the Lie algebra, were exploited. The number of these recursion relations is given by the number of generators minus the rank of the group. For SU(2) it is 2 while for SU(3) it is 6, still a manageable number. However, for groups like U(8), of interest here, this number of recursion relations raises to 56. Thus, alternative procedures are called for.

Now, why to use an U(8) group? The group U(8) appears whenever eight degrees of freedom are involved. Of course, the main motivation is the current need of this group in a particular, though very important, area in physics, namely particle physics. The description of many particle state becomes more important since the recognition that a hadron state is not just a three-quark state (for baryons), a quark-antiquark state (for mesons) or a two gluon state (for low-lying glueballs), i.e., there is an additional background of pairs of quark-antiquark and gluons. The spin problem of the nucleon[6] is one hint in this direction. It implies the urgent need to obtain the CGC's in higher rank groups. Simple SU(3) coupling coefficients, related, for example, to color and/or flavor, will not suffice. The SU(3) CGC is expressed in terms of a product of an SU(2) CGC and an *isoscalar factor*. This will be similar for U(8)⊃O(8)⊃SU(3), i.e., the CGC will be expressed in terms of already known SU(3) CGC's and isoscalar factors. The U(8) group also appears in

many gluon systems. Gluons have eight color degrees of freedom[7] and thus the color part can be described by a U(8) group. Because the gluon has spin one it has three mathematical spin degrees of freedom (to distinguish them from the physical ones which only involve the transverse modes), i.e., a many gluon system can be described by $U(24) \supset U(8) \otimes U(3)$,[8] where the U(3) refers to the spin part and a many gluon state must be in the complete symmetric irreducible representation $[N]$ of U(24). Because $[N]$ is symmetric, the color and spin part are intimately connected due to complementarity.[9] The U(8) group can be reduced to the color SU(3) group and further the U(3) to the spin SO(3) group, with integer spins only. The group reduction is well known and given in Refs. 8 and 10. The construction of states is less known. For symmetric irreps, the first attempts are presented in Refs. 11 and 12, though, the SU(3) subgroup considered in Ref. 12 is not the color group.

The symmetric irreps play a particular important role in a system of many quark-antiquark pairs, as in the model presented in Refs. 13–15, where an effective model of QCD is proposed considering many quark and antiquark states. A general classification for many quark and antiquark states in the *s*-orbital level was given. In order to simplify calculations, pairs of quark-antiquark were mapped to bosons.[16] There are four different types of bosons corresponding to quark-antiquark pairs with flavor (λ,λ) $(\lambda=0,1)$ and spin S $(S=0,1)$ denoted by $[\lambda,S]$. The cases $[0,0]$ and $[0,1]$ correspond to a one- and three-dimension harmonic oscillator, known from textbooks. The case $[1,0]$ corresponds to the eight-dimensional harmonic oscillator, i.e., to the U(8) group with just a symmetric irrep. The last case $[1,1]$ is mathematically identical to the many gluon problem and allows up to three rows in the Young diagram of U(8). The same structure appears in any model whose basic ingredients are quark-antiquark and/or gluon pairs.

Restricting to symmetric irreps, coupling coefficients are still important in obtaining information on decay properties and for the coupling of two systems. Though, so far we mainly mentioned bosonic systems, the isoscalar factors, calculated in this contribution, also serve for the equivalent *fermion pairs*.

Another motivation is to decide whether the pentaquark[17–21] exists in the model or not. A first estimate within the schematic model, where we have information about the distribution of quark-antiquark pairs in the pentaquark and in the residual particles, indicates that the pentaquark is just the sum of a nucleon and a kaon or at most a molecule in these particles, i.e., the width of the state should be very large and a peak should not be seen, confirmed in part by other experiments and also criticized in Ref. 22 (and references therein). If this is the case, it can only be decided through an explicit calculation, using U(8) CGC's.

Of course, the immediate application to topics in particle physics is only one possible application, used here as an example.

Does one also need the explicit form of the states defined by the U(8) group? The answer is that they are necessary for the calculation of CGC's. In the calculation of CGC's one usually exploits the algebraic properties of a group obtaining recursion relations, as illustrated in Ref. 5 for the SU(2) group and in Refs. 2–4 for the SU(3) group. However, for higher rank groups these methods get more involved and unpractical. In Refs. 23 and 24 a more practical procedure was proposed for the $U(5) \supset SO(5) \supset SO(3)$, playing an important role in the geometric model of the nucleus.[1] There, the polynomial expressions of the U(5) states were constructed explicitly using elementary tensors in terms of boson creation operators. The Clebsch-Gordan coefficients were obtained by direct calculation of the integrals involving the polynomial states, with the help of algebraic routines. The basic idea for the construction of the polynomials were borrowed from Refs. 25 and 26. In conclusion, the explicit knowledge of the polynomial states is of great use.

Thus, a first and important step forward towards the construction of many particle states is the explicit construction of these states in the symmetric irrep of U(8). The CGC's are obtained as integrals over a product of three polynomials. The first steps of the procedure were presented in Ref. 27 where the basic ingredients are illustrated for the case of the well investigated group chain $SU(3) \supset SO(3)$.

In this contribution, explicit expressions of the polynomial states up to eight particles and tables of U(8) isoscalar factors are presented, which are useful for models treating, for example,

TABLE I. Content of SU(3) irreps for a given seniority. When a SU(3) irrep appears more than once (multiplicity larger than 1) it is indicated by an upper index.

ν	(λ,μ)
0	$(0,0)$
1	$(1,1)$
2	$(1,1)+(2,2)$
3	$(0,0)+(3,0)+(0,3)+(2,2)+(3,3)$
4	$(1,1)+(2,2)+(4,1)+(1,4)+(3,3)+(4,4)$
5	$(1,1)+(2,2)+(4,1)+(1,4)+(3,3)+(5,2)+(2,5)+(4,4)$ $+(5,5)$
6	$(0,0)+(3,0)+(0,3)+(2,2)+(3,3)^2+(6,0)+(0,6)+(5,2)$ $+(2,5)+(4,4)+$ $(6,3)+(3,6)+(5,5)+(6,6)$
7	$(1,1)+(2,2)+(4,1)+(1,4)+(3,3)+(5,2)+(2,5)+(4,4)^2$ $+(7,1)+(1,7)+$ $(6,3)+(3,6)+(5,5)+(7,4)+(4,7)+(6,6)+(7,7)$
8	$(1,1)+(2,2)+(4,1)+(1,4)+(3,3)+(5,2)+(2,5)+(4,4)^2$ $+(7,1)+(1,7)+$ $(6,3)+(3,6)+(5,5)^2+(8,2)+(2,8)+(7,4)+(4,7)+(6,6)$ $+(8,5)+(5,8)+$ $(7,7)+(8,8)$

many gluon and fermion pair systems, as outlined above. These tables are of great use in determining the structure and the decay properties of a many particle state, like hadrons or a system of many quarks, antiquarks and gluons, and the quark-gluon plasma.

The paper is structured as follows: In the second section we give the classification and the explicit expressions of the states up to eight particles in the symmetric representation of $U(8)\supset O(8)\supset SU(3)\supset SU(2)\otimes U(1)$ in terms of the polynomials in boson creation and annihilation operators. We show how to obtain states with good seniority. In Sec. III the isoscalar factors are calculated. In Sec. IV conclusions are drawn.

II. THE HIGHEST WEIGHT STATES IN SU(3) OF $U(8)\supset O(8)\supset SU(3)\supset SU(2)\otimes U(1)$

The particles under consideration have eight degrees of freedom and belong to the SU(3) irrep $(1,1)$.

For symmetric irreps, the relevant group chain is

$$\begin{array}{ccccccc} U(8) & \supset & O(8) & \supset & SU(3) & \supset & U(1)\otimes SU(2) \\ [N] & & (\nu 000) & & (\lambda,\mu) & & Y \quad T,\ T_z, \end{array} \tag{1}$$

where Y is the hypercharge, T the isospin, and T_z its third component. The N is the total number of bosons, ν the seniority [number of bosons *not coupled* in pairs with flavor $(0,0)$]. The CGC's of the chain $SU(3)\supset U(1)\otimes SU(2)$ are well known and available.[28,29]

The classification of the states, described by the group chain $U(8)\supset SU(3)$, is immediately obtained, using Ref. 10. The reduction of U(8) to O(8) is obtained recursively: For a given N the possible values of the seniority are $\nu=N,N-2,\ldots,0$ or 1. When the content up to a given seniority $\nu=N$ is known, the one for $\nu=(N+2)$ is obtained, determining the content of the irrep $[N+2]$ of U(8) and subtracting the SU(3) content of all seniorities up to $\nu=N$. The SU(3) content of O(8) for $\nu=0$ is (0,0) and for $\nu=1$ it is (1,1), which can be used as initial conditions. In Table I we give the list up to seniority eight.

The generators of U(8) are given by

TABLE II. Linearization of the index (YTT_z) to ξ.

ξ	Y	T	T_z
1	0	1	1
2	1	$\frac{1}{2}$	$\frac{1}{2}$
3	−1	$\frac{1}{2}$	$\frac{1}{2}$
4	0	1	0
5	0	0	0
6	1	$\frac{1}{2}$	$-\frac{1}{2}$
7	−1	$\frac{1}{2}$	$-\frac{1}{2}$
8	0	1	−1

$$\boldsymbol{C}^{\rho\Gamma}_{YTT_3} = [\boldsymbol{b}^\dagger \otimes \boldsymbol{b}]^{\rho\Gamma}_{YTT_z}, \tag{2}$$

where Γ is a short-hand notation for (λ,μ) and ρ is a multiplicity label which is 1 except for the irrep $\Gamma=(1,1)$ where it obtains values 1 and 2. For this case, the value $\rho=1$ refers to the antisymmetric coupling and $\rho=2$ to the symmetric coupling.[30] The possible values of Γ are (0,0), (2,2), and $(1,1)_2$ for the symmetric and (3,0), (0,3), and $(1,1)_1$ for the antisymmetric coupling. The index (YTT_z) can be linearized to ξ as defined in Table II, which is of use in the further discussion.

The generators of O(8) are given by the coupling to the antisymmetric irreps Γ, implying 28 generators for the algebra of O(8). The generators of the SU(3) subgroup are obtained, restricting the Γ to $(1,1)_1$.

The Lie algebra for the generators (2) is given by

$$\begin{aligned}[\boldsymbol{C}^{\rho\Gamma'}_{\xi'}, \boldsymbol{C}^{\rho\Gamma}_{\xi}] = {} & (-1)^{\mathrm{sign}(\lambda_0,\mu_0)+\mathrm{sign}(\lambda,\mu)+\rho^{(\lambda,\mu)}_{\max}+\lambda+\mu-\rho}\left(1-(-1)^{\mathrm{sign}(\lambda,\mu)+\mathrm{sign}(\lambda',\mu')+\mathrm{sign}(\lambda_0,\mu_0)}\right) \\ & \times \sum_{\rho_{\max}}^{\rho^{(\lambda_0,\mu_0)}_{\max}} \sum_{(\lambda_0,\mu_0)\xi_0} (-1)^{\rho^{(\lambda_0,\mu_0)}_{\max}-\rho_0} \sum_{\rho''=1}^{\rho_{\max}} (-1)^{\rho_{\max}-\rho''} \sqrt{\frac{\dim(\lambda,\mu)}{8}} \\ & \times \langle(\lambda,\mu)\xi,(\lambda',\mu')\xi'|(\lambda_0,\mu_0)\xi_0\rangle_{\rho''} \\ & \times U[(\mu_0,\lambda_0)(1,1)(\mu,\lambda)(1,1);(1,1)\rho_0\rho(\lambda',\mu')\rho'\rho''][\boldsymbol{b}^\dagger \otimes \boldsymbol{b}]^{\rho_0(\lambda_0,\mu_0)}_{\xi_0}. \end{aligned} \tag{3}$$

The $\rho^{(\lambda_0,\mu_0)}_{\max}$ refers to the multiplicity in the coupling $(1,1)\otimes(1,1)\to(\lambda_0,\mu_0)$, the $\rho^{(\lambda,\mu)}_{\max}$ to the multiplicity in the coupling $(1,1)\otimes(1,1)\to(\lambda,\mu)$, $\rho_{\max}$ to $(\lambda,\mu)\otimes(\lambda',\mu')\to(\lambda_0,\mu_0)$, $\mathrm{sign}(\lambda,\mu)$ to the symmetry property of the $(1,1)\otimes(1,1)\to(\lambda,\mu)$ under exchange of the first two irreps in the GCG (symmetric or antisymmetric) and $U[\cdots]$ is the U-coefficient, whose definition can be found in Ref. 30.

As a particular case, the algebra for the subgroup SU(3), which is a subgroup of O(8), is given by

$$[\boldsymbol{C}^{1(1,1)}_{\xi'}, \boldsymbol{C}^{1(1,1)}_{\xi}] = \sum_{\xi_0} \langle(1,1)\xi',(1,1)\xi|(1,1)\xi_0\rangle_1 [\boldsymbol{b}^\dagger \otimes \boldsymbol{b}]^{(1,1)_1}_{\xi_0}. \tag{4}$$

In terms of the standard notation of the SU(3) generators,[31] the relation to the $\boldsymbol{C}^{1(1,1)}_{\mu}$ of Eq. (2) is $(\boldsymbol{T}_0=\boldsymbol{T}_z)$

$$\begin{aligned} \boldsymbol{T}_\pm &= \pm\sqrt{6}[\boldsymbol{b}^\dagger \otimes \boldsymbol{b}]^{1(1,1)}_{01\pm1}, \quad \boldsymbol{T}_0 = -\sqrt{3}[\boldsymbol{b}^\dagger \otimes \boldsymbol{b}]^{1(1,1)}_{010}, \\ \boldsymbol{V}_\pm &= \pm\sqrt{6}[\boldsymbol{b}^\dagger \otimes \boldsymbol{b}]^{1(1,1)}_{\pm1(1/2)\pm(1/2)}, \\ \boldsymbol{U}_\pm &= \sqrt{6}[\boldsymbol{b}^\dagger \otimes \boldsymbol{b}]^{1(1,1)}_{\pm1(1/2)\mp(1/2)}, \end{aligned} \tag{5}$$

$$\boldsymbol{Y} = -2[\boldsymbol{b}^\dagger \otimes \boldsymbol{b}]^{1(1,1)}_{000}.$$

In the next step we express an arbitrary tensor of U(8) in terms of a product of powers of "elementary" tensors, which are called *elementary couplings* (epd's)[25,26] (sometimes also called *integrity basis*). The origin of this name is that any tensor of a given order can be expressed in terms of products of powers in these epd's. The epd's are basic tensors each coupled to the maximum weight in SU(3). Because these elementary tensors are of maximum weight in SU(3), any product of two or more of these tensors result again in a tensor of maximum weight in SU(3), in the same way two tensors with spin j_1 and j_2 with maximal projection, i.e., $m_1=j_1$ and $m_2=j_2$, result in a new tensor with spin $j=j_1+j_2$ and projection $m=j$. Products of powers in these epd's generate U(8) states with quantum numbers N and (λ,μ) in the maximum weight state of SU(3). One must take care that the list of epd's is complete, checking if all irreps of U(8) can be written in terms of them. If one state is missing, a further epd must be added.

In Ref. 11 a procedure is developed how to obtain these epd's using *generating functions*. Please consult this reference for more details and further references. This method was applied successfully to various areas of physics, like the geometric collective model[1,25,26] and in Ref. 11 more possible applications are given, like the problem we are interested in this contribution. In Ref. 11 the following epd's (sometimes denoted as *integrity basis*) where obtained using the method of generating functions [see Eq. (16) of Ref. 11]. The epd's are given by

$$\begin{aligned}
\boldsymbol{A} &= \boldsymbol{b}^\dagger_{011},\\
\boldsymbol{B} &= [\boldsymbol{b}^\dagger \otimes \boldsymbol{b}^\dagger]^{(0,0)}_{000},\\
\boldsymbol{C} &= [\boldsymbol{b}^\dagger \otimes \boldsymbol{b}^\dagger]^{(1,1)}_{011},\\
\boldsymbol{D} &= [\boldsymbol{b}^\dagger \otimes [\boldsymbol{b}^\dagger \otimes \boldsymbol{b}^\dagger]^{(1,1)}]^{(0,0)}_{000},\\
\boldsymbol{E} &= [\boldsymbol{b}^\dagger \otimes [\boldsymbol{b}^\dagger \otimes \boldsymbol{b}^\dagger]^{(1,1)}]^{(3,0)}_{1(3/2)(3/2)},\\
\boldsymbol{F} &= [\boldsymbol{b}^\dagger \otimes [\boldsymbol{b}^\dagger \otimes \boldsymbol{b}^\dagger]^{(1,1)}]^{(0,3)}_{-1(3/2)(3/2)},
\end{aligned} \tag{6}$$

where the coupling of two boson creation operators must be always symmetric, otherwise it would give zero due to the symmetry properties of the CGC. These are expressions obtained by coupling the definite SU(3) tensors $\boldsymbol{b}^\dagger_\xi$ to new tensors using the SU(3) CGC's.

A *pedestrian way* to look at it, is to ask: How many basic tensors one needs to construct all possible state polynomials which are in the maximum weight in SU(3)? Table I is here for assistance: For a given number of bosons N the SU(3) content is obtained by summing the seniority content for $\nu=N,N-2,\ldots,0$ or 1. For $N=1$ we need a tensor with the SU(3) structure (1,1), which is just $\boldsymbol{A}$. However, powers of the type $\boldsymbol{A}^{n_1}$ gives only polynomials with the SU(3) irrep labels (n_1,n_1). Inspecting Table I we see that for $N=2$ the SU(3) content is $(0,0)+(1,1)+(2,2)$, implying that we also need tensors with the SU(3) labels (0,0) and (1,1), which gives us the tensors $\boldsymbol{B}$ and $\boldsymbol{C}$. The irrep (2,2) is presented by $\boldsymbol{A}^2$. Powers and products of$\mathbf{A}$, $\boldsymbol{B}$, and $\boldsymbol{C}$ are still not sufficient: For $N=3$ the SU(3) content is given by $(0,0)+(3,0)+(0,3)+(1,1)+(2,2)+(3,3)$. The states with (3,3), (2,2), and (1,1) are, respectively, presented by $\boldsymbol{A}^3$, $\boldsymbol{AC}$, and $\boldsymbol{AB}$. We note the need of tensors with SU(3) labels (0,0), (3,0), and (0,3), which are just the $\boldsymbol{D}$, $\boldsymbol{E}$, and $\boldsymbol{F}$ tensors. Continuing to larger N one notes that all other polynomial states are obtained by the product of powers in these basic tensors. An ambiguity, however, arises when the product of the tensors $\boldsymbol{E}$ with $\boldsymbol{F}$ or powers of $\boldsymbol{C}^3$ are considered. For example, for $N=6$ and the SU(3) irrep (6,3) there are the following possible representations, namely $\boldsymbol{FA}^3$ and $\boldsymbol{EA}^3$, though, (6,3) appears only once. This will be discussed in what follows.

A maximum weight state [in SU(3)] is a monomial in these epd's, where according to Ref. 11 the epd $\boldsymbol{C}$ appears only in powers of 0, 1 or 2, i.e., the $\boldsymbol{C}^3$ can be expressed as a linear combination in the other epd's. Instead of choosing $\boldsymbol{C}^3$ as dependent, the $\boldsymbol{E}$ and $\boldsymbol{F}$ can be used as dependent epd's. These two epd's satisfy a relation which permits the appearance of powers in $\boldsymbol{E}$ or $\boldsymbol{F}$ only. The relation of the product $\boldsymbol{EF}$ to the other epd's is given by

$$\boldsymbol{EF} = -\frac{1}{6}\sqrt{\frac{15}{2}}\boldsymbol{C}^3 + \sqrt{\frac{3}{5}}\boldsymbol{A}^2\boldsymbol{BC} - \frac{2}{\sqrt{15}}\boldsymbol{A}^3\boldsymbol{D}, \tag{7}$$

i.e., any product of $\boldsymbol{EF}$ can be expressed in terms of the other epd's, implying that either only powers in $\boldsymbol{E}$ or $\boldsymbol{F}$ may appear. This relation can also be used to express third powers of $\boldsymbol{C}$ in terms of the other epd's, as is suggested in Ref. 11. We take the choice (7) as also was done in Ref. 12.

Choosing $\boldsymbol{E}$ and $\boldsymbol{F}$ as dependent epd's, there are two types of polynomials, one with $(\lambda+3k,\lambda)$ and the other with $(\lambda,\lambda+3k)$, respectively, i.e.,

$$\boldsymbol{E}^{n_5}\boldsymbol{D}^{n_4}\boldsymbol{C}^{n_3}\boldsymbol{B}^{n_2}\boldsymbol{A}^{n_1}|0\rangle, \quad \boldsymbol{F}^{n_5}\boldsymbol{D}^{n_4}\boldsymbol{C}^{n_3}\boldsymbol{B}^{n_2}\boldsymbol{A}^{n_1}|0\rangle, \tag{8}$$

which now covers all possible irreps of U(8), as proven in Ref. 11. Fixing the total number of quanta N, the λ and μ for the first case (only powers of $\boldsymbol{E}$ appear), we obtain the following relation between the powers of the monomial:

$$\begin{aligned} N &= n_1 + 2n_2 + 2n_3 + 3n_4 + 3n_5, \\ \lambda &= n_1 + n_3 + 3n_5, \\ \mu &= n_1 + n_3. \end{aligned} \tag{9}$$

These relations are obtained, applying the number operator to the polynomial state, taking into account the order of the tensors in the creation operators and by noting that the tensors $\boldsymbol{A}$, $\boldsymbol{C}$ are in the maximum weight and transform as $(1,1)$, while $\boldsymbol{E}$ transforms as $(3,0)$, which is also in the maximum SU(3) weight.

Similar relations hold when only powers of $\boldsymbol{F}$ appear

$$\begin{aligned} N &= n_1 + 2n_2 + 2n_3 + 3n_4 + 3n_5, \\ \lambda &= n_1 + n_3, \\ \mu &= n_1 + n_3 + 3n_5. \end{aligned} \tag{10}$$

Up to now, the polynomials have no definite seniority ν, the quantum number of the O(8) group. This is achieved requiring that the application of

$$\overline{\boldsymbol{B}} = [\boldsymbol{b}\otimes\boldsymbol{b}]^{(0,0)}_{000} \tag{11}$$

on a polynomial in terms of the monomials of Eq. (8), gives zero (no pairs are contained, see, e.g., Refs. 25 and 26). This leads to the polynomials which have a seniority $\nu=N$. Explicitly, the condition reads

$$\overline{\boldsymbol{B}}P_{N=\nu(\lambda,\mu)}(\boldsymbol{A},\boldsymbol{B},\boldsymbol{C},\boldsymbol{D},\boldsymbol{E}(\boldsymbol{F}))|0\rangle = 0, \tag{12}$$

where the polynomial has the following structure for the case when only powers of $\boldsymbol{E}$ appear

$$\boldsymbol{P}_1 = \boldsymbol{E}^{(\lambda-\mu)/3}\sum_{n_1 n_2} c_{n_1 n_2}\boldsymbol{A}^{n_1}\boldsymbol{B}^{n_2}\boldsymbol{C}^{\mu-n_1}\boldsymbol{D}^{(N-\lambda-\mu+n_1-2n_2)/3}, \tag{13}$$

and similar when only powers of $\boldsymbol{F}$ appear

TABLE III. List of the polynomial coefficients with definite seniority for $\nu=0$ until $\nu=4$. For the coefficients only numerical values are given. They can be expressed in terms of square roots of rational numbers. However, for larger N there are cases where this cannot be done (see comments in text), which is the reason for this presentation. The powers of all epd's can be deduced using Eqs. (13) and (14), the value of the SU(3) irrep and the numbers of n_1, n_2 listed.

ν	(λ,μ)	n_1	n_2	State No. k	$c_{n_1n_2}$
0	(0,0)	0	0	1	1

4	(2,2)	2	1	1	−0.019 287 92
4	(1,1)	0	1	1	0.031 497 04
4	(1,1)	1	0	1	−0.195 180 02

$$\boldsymbol{P}_2 = \boldsymbol{F}^{(\mu-\lambda)/3} \sum_{n_1 n_2} c_{n_1 n_2} \boldsymbol{A}^{n_1} \boldsymbol{B}^{n_2} \boldsymbol{C}^{\lambda-n_1} \boldsymbol{D}^{(N-\mu-\lambda+n_1-2n_2)/3}. \tag{14}$$

Each of these polynomials we will abbreviate by

$$\boldsymbol{P} = \sum_{n_1 n_2} c_{n_1 n_2} |n_1 n_2\rangle, \tag{15}$$

where we omitted the labels (λ,μ) and applied the operators on the vacuum, resulting in a ket-state. Applying from the left $\langle n_1' n_2' | \overline{\boldsymbol{B}}$, with $n_1'+n_2'+1=n_1+n_2$ and the same (λ,μ) on both sides, we arrive at the defining equation for the coefficients $c_{n_1n_2}$,

$$\sum_{n_1 n_2} c_{n_1 n_2} \langle n_1' n_2' + 1 | n_1 n_2 \rangle = 0. \tag{16}$$

The overlaps $\langle n_1' n_2' + 1 \,|\, n_1 n_2 \rangle$ in the sum are calculated. How to determine the overlaps is described in more detail in Sec. III. Having obtained the overlaps, the above equation is solved numerically, leading in this way to maximal weight states in SU(3) with good seniority and $N=\nu$. The state with $N>\nu$ is depicted below in Eq. (32).

In Tables III–VIII we give a list of all polynomials up to eight bosons, with the additional restriction of $N=\nu$. In case there is more than one state, an additional multiplicity index is assigned, called k. Only numerical values are given, though, most of the numbers listed in the tables can be expressed as square roots of rational numbers. However, when more than one state for a given seniority and SU(3) irrep (λ,μ) appears, a Schmidt orthogonalization procedure is applied, yielding only simple numbers for the first state but in general real numbers for states with a higher index in k. In calculations within the models of Refs. 8, 13, and 14 no more than six bosons are needed.

Up to now, only highest weight states in SU(3) were considered. In the highest weight of the irrep (λ,μ) the value of the hypercharge and the third component of the isospin is given by

TABLE IV. The same as in Table III, but now for $\nu = 5$.

ν	(λ,μ)	n_1	n_2	State No.	$c_{n_1 n_2}$
5	(5,5)	5	0	1	0.091 287 09
5	(4,4)	3	0	1	0.194 624 74

5	(1,1)	1	2	1	−0.003 521 48

$(\lambda-\mu)/3$ and $(\lambda+\mu)/2$,[31] respectively. A state with a lower weight can be reached via the application of $\boldsymbol{T}_-^{\alpha}\boldsymbol{U}_+^{\beta}\boldsymbol{V}_-^{\gamma}$. When the weight of a state is given by (Y,T) and the difference to the highest weight is $-\Delta T_z$, for the third component of the isospin, and $+\Delta Y$ for the hypercharge, the exponents α, β, and γ fulfill the relations

$$\Delta T_z = \alpha + \tfrac{1}{2}(\beta+\gamma), \quad \Delta Y = \beta - \gamma. \tag{17}$$

As can be seen, there is in general more than one possibility. The final state reached has only a definite isospin when β or γ is zero. In general, the construction of the states with definite isospins, for a fixed weight Y and T_z must still be performed.

For the construction of states with a definite isospin, the overlap of the states

States with definite isospin are obtained by diagonalizing the operator $\boldsymbol{T}^2 = \boldsymbol{T}_+\boldsymbol{T}_- + \boldsymbol{T}_z(\boldsymbol{T}_z - 1)$ within the states given above. Note, however, that $|\alpha\beta\gamma>$ are not orthogonal with respect to different values of α, β, and γ. The overlap is given in (19). The most practical method is to solve numerically the equation

$$\sum_{\alpha'\beta'\gamma'} \frac{\langle \alpha'\beta'\gamma'|\boldsymbol{T}^2|\alpha\beta\gamma\rangle}{\sqrt{\langle \alpha'\beta'\gamma'|\alpha'\beta'\gamma'\rangle\langle\alpha\beta\gamma|\alpha\beta\gamma\rangle}} a_{\alpha'\beta'\gamma'} = T(T+1) \sum_{\alpha'\beta'\gamma'} \frac{\langle \alpha'\beta'\gamma'|\alpha\beta\gamma\rangle}{\sqrt{\langle \alpha'\beta'\gamma'|\alpha'\beta'\gamma'\rangle\langle\alpha\beta\gamma|\alpha\beta\gamma\rangle}} a_{\alpha'\beta'\gamma'}, \tag{20}$$

where the coefficients $a_{\alpha\beta\gamma}$ are the expansion coefficients in the basis $|\alpha\beta\gamma>$. The matrix elements of $\boldsymbol{T}_+\boldsymbol{T}_-$ are obtained through the overlaps

$$\frac{\langle \alpha'+1\beta'\gamma'|\alpha+1\beta\gamma\rangle}{\sqrt{\langle \alpha'\beta'\gamma'|\alpha'\beta'\gamma'\rangle\langle\alpha\beta\gamma|\alpha\beta\gamma\rangle}}, \tag{21}$$

while T_z is diagonal.

The state with definite isospin is then given by

$$|N\nu(\lambda,\mu)YTT_z\rangle = \sum_{\alpha\beta\gamma} a^{YTT_z}_{\alpha\beta\gamma} |N\nu(\lambda,\mu)\alpha\beta\gamma\rangle / \sqrt{\langle\alpha\beta\gamma|\alpha\beta\gamma\rangle}, \tag{22}$$

with the constriction on α, β, and γ given by $Y = [(\lambda+\mu)/3] + (\beta-\gamma)$ and $T_z = [(\lambda-\mu)/2] - \alpha - \frac{1}{2}(\beta+\gamma)$.

Care must still be taken with respect to the phase. The lower weight states are obtained via the application of $\boldsymbol{T}_-$, $\boldsymbol{U}_+$, and $\boldsymbol{V}_-$. For example, when only a power of the $\boldsymbol{T}_-$ operator is applied to the maximal weight state, we arrive at $|\alpha 00\rangle$ *with a positive sign in front* and the same isospin as in the maximum weight state. Similar, parting from the highest weight state, the application of only U_+ or only V_- leads to a state with definite isospin $(\lambda+\mu-\beta)/2$ (for $\gamma=0$) or $(\lambda+\mu-\gamma)/2$ (for $\beta=0$). Posterior application of T_- leads to states with the same isospin. Therefore, we require that the component $|\alpha\beta\gamma\rangle$ with either β or γ equal to zero, within a state of definite isospin, has also a positive sign in front of $|\alpha\beta 0\rangle$ (for $\gamma=0$) or $|\alpha 0\gamma\rangle$ (for $\beta=0$). In case the numerical program produced states with an opposite sign, we corrected for it by multiplying all coefficients by (-1).

III. THE ISOSCALAR FACTORS AND CLEBSCH-GORDAN COEFFICIENTS

Once the states are obtained, we can proceed in the calculation of the CGC's. Before that, a general remark on the Wigner-Eckart theorem for a given group chain $G \supset H$ is due: When Γ represents the label of the group G and μ of its subgroup H and $\boldsymbol{T}^{\Gamma}_{\mu}$ is a tensor, then the matrix elements can be expressed as[9]

$$\langle \Gamma'\mu'|\boldsymbol{T}^{\Gamma_0}_{\mu_0}|\Gamma\mu\rangle = \sum_{\rho} \langle \Gamma\mu,\Gamma_0\mu_0|\Gamma'\mu'\rangle_{\rho}\langle \Gamma'\|T^{\Gamma_0}\|\Gamma\rangle_{\rho}, \tag{23}$$

where ρ is a multiplicity index in the coupling $\Gamma\otimes\Gamma_0\rightarrow\Gamma'$, the first factor in the sum over ρ is the CGC and the last one the reduced matrix element. In order to distinguish the reduced matrix element of a group G different from SU(2), often the notation of "multiple reduced" matrix element is used. Like in SU(3) (Ref. 30) where the reduced matrix element of SU(3) is called *triple reduced* matrix element. Here we will continue to use this notation for SU(3) and for the reduced matrix element of $U(8)\supset O(8)\supset SU(3)$ the name of *quadruple reduced matrix element* is

proposed. The sum over the multiplicity index is only applied when the multiplicity is larger than one.

Now we will return to the determination of the $U(8) \supset O(8) \supset SU(3)$ CGC's and its isoscalar factors.

In a first step we determine the triple reduced matrix elements with respect to the SU(3) group.[30] The equation to solve is

$$\begin{aligned}
&\langle N_3 \nu_3 k_3(\lambda_3,\mu_3) Y_3 T_3 T_{3z} | P_{N_1 \nu_1 k_1(\lambda_1,\mu_1) Y_1 T_1 T_{1z}}(\boldsymbol{b}^\dagger) | N_2 \nu_2 k_2(\lambda_2,\mu_2) Y_2 T_2 T_{2z} \rangle \\
&\quad = \sum_\rho \langle (\lambda_2,\mu_2) Y_2 T_2 T_{2z}; (\lambda_1,\mu_1) Y_1 T_1 T_{1z} | (\lambda_3,\mu_3) Y_3 T_3 T_{3z} \rangle_\rho \\
&\qquad \times \langle N_3 \nu_3 k_3(\lambda_3,\mu_3) ||| P_{N_1 \nu_1 k_1(\lambda_1,\mu_1)}(\boldsymbol{b}^\dagger) ||| N_2 \nu_2 k_2(\lambda_2,\mu_2) \rangle .
\end{aligned} \tag{24}$$

Let us suppose that we have the result concerning the first line in Eq. (24). How to obtain it will be explained further below. The SU(3) Clebsch-Gordan coefficients are well known[29] and, thus, (24) represents an equation to determine the triple reduced matrix elements. It suffices to use maximal weight states for the polynomial 1 and 3, while the weight of the second polynomial is given by the difference of the weight of the third with the first polynomial.

In the next step, the Wigner-Eckart theorem for the $U(8) \supset O(8) \supset SU(3)$ group chain is used, i.e.,

$$\begin{aligned}
&\langle N_3 \nu_3 k_3(\lambda_3,\mu_3) Y_3 T_3 T_{3z} | P_{N_1 \nu_1 k_1(\lambda_1,\mu_1) Y_1 T_1 T_{1z}}(\boldsymbol{b}^\dagger) | N_2 \nu_2 k_2(\lambda_2,\mu_2) Y_2 T_2 T_{2z} \rangle \\
&\quad = (N_2 \nu_2 k_2(\lambda_2,\mu_2) Y_2 T_2 T_{2z}; N_1 \nu_1 k_1(\lambda_1,\mu_1) Y_1 T_1 T_{1z} | N_3 \nu_3 k_3(\lambda_3,\mu_3) Y_3 T_3 T_{3z}) \langle N_3 |||| P_{N_1}(\boldsymbol{b}^\dagger) |||| N_2 \rangle .
\end{aligned} \tag{25}$$

There is no sum over a multiplicity index because the labels of the U(8) irrep is the number $[N]$, given here in the notation of a Young diagram, and the multiplication of two symmetric irreps is always free of multiplicities.

Comparing Eq. (25) with Eq. (24) we arrive at

$$\begin{aligned}
&(N_2 \nu_2 k_2(\lambda_2,\mu_2) Y_2 T_2 T_{2z}; N_1 \nu_1 k_1(\lambda_1,\mu_1) Y_1 T_1 T_{1z} | N_3 \nu_3 k_3(\lambda_3,\mu_3) Y_3 T_3 T_{3z}) \\
&\quad = \sum_\rho \langle (\lambda_2,\mu_2) Y_2 T_2 T_{2z}; (\lambda_1,\mu_1) Y_1 T_1 T_{1z} | (\lambda_3,\mu_3) Y_3 T_3 T_{3z} \rangle_\rho \\
&\qquad \times \frac{\langle N_3 \nu_3 k_3(\lambda_3,\mu_3) ||| P_{N_1 \nu_1 k_1(\lambda_1,\mu_1)}(\boldsymbol{b}^\dagger) ||| N_2 \nu_2 k_2(\lambda_2,\mu_2) \rangle_\rho}{\langle N_3 |||| P_{N_1}(\boldsymbol{b}^\dagger) |||| N_2 \rangle} .
\end{aligned} \tag{26}$$

The CGC of the SU(3) group are known, thus, it suffices to determine

$$\begin{aligned}
&\langle N_2 \nu_2 k_2(\lambda_2,\mu_2), N_1 \nu_1 k_1(\lambda_1,\mu_1) \| N_3 \nu_3 k_3(\lambda_3,\mu_3) \rangle_\rho \\
&\qquad = \frac{\langle N_3 \nu_3 k_3(\lambda_3,\mu_3) ||| P_{N_1 \nu_1 k_1(\lambda_1,\mu_1)}(\boldsymbol{b}^\dagger) ||| N_2 \nu_2 k_2(\lambda_2,\mu_2) \rangle_\rho}{\langle N_3 |||| P_{N_1}(\boldsymbol{b}^\dagger) |||| N_2 \rangle} ,
\end{aligned} \tag{27}$$

which we will denote as *isoscalar factors* of the group chain $U(8) \supset O(8) \supset SU(3)$.

Equation (27) implies that the triple reduced matrix element with respect to the group chain $SU(3) \supset SU(2) \otimes U(1)$ and the quadruple reduced matrix element of $U(8) \supset O(8)$ must be determined. The last is the simplest one. For that, the U(8) CGC's are calculated, assuming the seniority ν_k in all polynomials *equal to* N_k (then, the CGC is just 1). The polynomials have the form

$$P_k = \frac{1}{\sqrt{N_k!}} \boldsymbol{A}^{N_k} |0\rangle , \tag{28}$$

with $k=1,2,3$. The result is

$$\langle N_3 || || P^{[N_1]} || || N_2 \rangle = \left[\frac{N_3!}{N_1!\, N_2!} \right]^{1/2} . \tag{29}$$

The triple reduced matrix elements of the group chain $\mathrm{SU}(3) \supset \mathrm{SU}(2) \otimes \mathrm{U}(1)$ are obtained through the use of Eq. (24), as already explained.

The important part is the calculation of the left-hand side of Eq. (24). In a first step the overlaps $\langle n_1' n_2' | n_1 n_1 \rangle$, as defined in Eqs. (15) and (16), are determined. For that, we write the explicit form of the epd's in terms of the boson creation operators. To simplify notations, we rename a boson creation operator $\boldsymbol{b}_\xi^\dagger$ by a coordinate x_ξ and the corresponding annihilation operator $\boldsymbol{b}^\xi$ by a derivative $\partial/\partial x_\xi$. Both satisfy the same commutation relations (with this, it is easier to translate it to an algebraic routine, like MATEMATICA,[32] which assists in the evaluation of the overlaps). In terms of this new notation and using the association of the linear index ξ to (YTT_z) (see Table II), the epd's of U(8) have the following structure:

$$\begin{aligned}
\boldsymbol{A} &= x_1, \\
\boldsymbol{B} &= \frac{1}{\sqrt{8}}(x_4^2 - 2x_1x_8 + x_5^2 - 2x_2x_7 + 2x_3x_6), \\
\boldsymbol{C} &= 2\sqrt{\frac{3}{10}} x_3x_2 - \frac{2}{\sqrt{5}} x_1x_5, \\
\boldsymbol{D} &= \sqrt{\frac{3}{10}} \left(-\frac{3}{2}\sqrt{2} x_1x_6x_7 + \sqrt{3} x_1x_5x_8 + \frac{\sqrt{3}}{2} x_3x_5x_6 - \frac{\sqrt{3}}{2} x_2x_5x_7 \right. \\
&\quad \left. + \frac{3}{2} x_2x_4x_7 - \frac{3}{2}\sqrt{2} x_2x_3x_8 + \frac{3}{2} x_3x_4x_6 - \frac{\sqrt{3}}{2} x_4^2x_5 + \frac{1}{2\sqrt{3}} x_5^3 \right), \\
\boldsymbol{E} &= \sqrt{\frac{3}{5}} x_2^2x_3 - \frac{3}{\sqrt{10}} x_1x_2x_5 - \sqrt{\frac{3}{5}} x_1^2x_6 + \sqrt{\frac{3}{10}} x_1x_2x_4, \\
\boldsymbol{F} &= -\sqrt{\frac{3}{5}} x_1^2x_7 + \sqrt{\frac{3}{10}} x_1x_3x_4 - \sqrt{\frac{3}{5}} x_3^2x_2 + \frac{3}{\sqrt{10}} x_1x_3x_5 .
\end{aligned} \tag{30}$$

These expressions are obtained using the explicit values of the SU(3) CGS's, as obtained in Refs. 2–4. One can easily verify that they are in the maximum weight of the corresponding SU(3) label [see Eq. (6)]. The Hermitian conjugate expressions are obtained by changing x_ξ to $\partial/\partial x_\xi$.

What we also need is the explicit form of the lowering operators T_-, U_+, and V_-, in order to obtain a lower weight state in what we call the second polynomial. Starting from Eq. (5) and using the explicit form of the SU(3) CGC's, we obtain

$$\boldsymbol{T}_- = \sqrt{2} x_8 \frac{\partial}{\partial x_4} + \sqrt{2} x_4 \frac{\partial}{\partial x_1} + x_6 \frac{\partial}{\partial x_2} + x_7 \frac{\partial}{\partial x_3},$$

$$\boldsymbol{U}_+ = -\sqrt{\frac{3}{2}}x_5\frac{\partial}{\partial x_3} + \frac{1}{\sqrt{2}}x_4\frac{\partial}{\partial x_3} + x_8\frac{\partial}{\partial x_7} - \frac{1}{\sqrt{2}}x_6\frac{\partial}{\partial x_4} + \sqrt{\frac{3}{2}}x_6\frac{\partial}{\partial x_5} - x_2\frac{\partial}{\partial x_1}, \tag{31}$$

$$\boldsymbol{V}_- = \frac{1}{\sqrt{2}}x_4\frac{\partial}{\partial x_2} + \sqrt{\frac{3}{2}}x_5\frac{\partial}{\partial x_2} + x_8\frac{\partial}{\partial x_6} + x_3\frac{\partial}{\partial x_1} + \sqrt{\frac{3}{2}}x_7\frac{\partial}{\partial x_5} + \frac{1}{\sqrt{2}}x_7\frac{\partial}{\partial x_4}.$$

For the overlaps, we must apply these lowering operators to a highest weight state in SU(3) of what we called the second polynomial, as given in Eq. (18), using the norm depicted in Eq. (19) and multiply it with what we called the first polynomial in the highest weight state. That is, we must construct $P_{N_1\nu_1k_1(\lambda_1,\mu_1)Y_1^{\max}T_1^{\max}T_1^{\max}}(x)\ P_{N_2\nu_2k_2(\lambda_2,\mu_2)Y_2T_2T_{2z}}(x)$. This gives us an expression which depends on the x_ξ only. On that we must apply the conjugate expression of what we call the third polynomial, which is a pure function of derivatives, i.e. $P_{N_3\nu_3k_3(\lambda_3,\mu_3)Y_3^{\max}T_3^{\max}T_3^{\max}}(\partial/\partial x)$. In principle, this quite involved calculation can be done by hand. It is advisable to take the assistance of an algebraic routine like MATEMATICA,[32] considering that the number of overlaps to calculate is in the thousands. With this help, we finally obtain the overlap on the left-hand side of Eq. (24).

Not all possible matrix elements were calculated but only those with $N_1=\nu_1$, $N_2=\nu_2$ and, thus, $N_3=\nu_1+\nu_2$ and $N_3\geq\nu_3$. The corresponding isoscalar factors of Eq. (27) were determined. In order to obtain all other possible isoscalar factors, with $N_k>\nu_k$ $(k=1,2)$ and $N_3=N_1+N_2$, we note that the corresponding state can be written as

$$|N_k\nu_k\xi_k\rangle = \left[\frac{(\nu_k+3)!}{4^{(N_k-\nu_k)/2}\left(\frac{N_k-\nu_k}{2}\right)!\left(\frac{N_k+\nu_k+6}{2}\right)!}\right]^{1/2}(\boldsymbol{b}^\dagger\cdot\boldsymbol{b}^\dagger)^{(N_k-\nu_k)/2}|\nu_k\xi_k\rangle, \tag{32}$$

where now ξ_k denote all other quantum numbers $(\lambda_k,\mu_k)\ Y_kT_kT_{kz}$, $|\nu_k\xi_k\rangle$ is the state with $N_k=\nu_k$ and $(\boldsymbol{b}^\dagger\cdot\boldsymbol{b}^\dagger)$ is the scalar product between the boson creation operators.

Introducing this on the left-hand side of Eq. (25) leads to

$$\begin{aligned}&\langle N_3\nu_3\xi_3|P_{N_1\nu_1\xi_1}(\boldsymbol{b}^\dagger)|N_2\nu_2\xi_2\rangle\\ &=\left[\frac{(\nu_1+3)!\,(\nu_2+3)!\left(\frac{N_3-\nu_3}{2}\right)!\left(\frac{N_3+\nu_3+6}{2}\right)!}{\left(\frac{N_1-\nu_1}{2}\right)!\left(\frac{N_2-\nu_2}{2}\right)!\left(\frac{N_1+\nu_1+6}{2}\right)!\left(\frac{N_2+\nu_2+6}{2}\right)!\left(\frac{\nu_1+\nu_2-\nu_3}{2}\right)!\left(\frac{\nu_1+\nu_2+\nu_3+6}{2}\right)!}\right]^{1/2}\\ &\times\langle N_3=\nu_1+\nu_2,\nu_3\xi_3|P_{N_1=\nu_1\nu_1\xi_1}(\boldsymbol{b}^\dagger)|N_2=\nu_2,\nu_2\xi_2\rangle.\end{aligned} \tag{33}$$

Using (25), we arrive at the following relations of CGC's:

$$\begin{aligned}&\langle N_2\nu_2\xi_2,N_1\nu_1\xi_1|N_3\nu_3\xi_3\rangle\\ &=\left[\frac{(\nu_1+3)!\,N_1!}{\left(\frac{N_1-\nu_1}{2}\right)!\,\nu_1!\left(\frac{N_1+\nu_1+6}{2}\right)!}\frac{(\nu_2+3)!\,N_2!}{\left(\frac{N_2-\nu_2}{2}\right)!\,\nu_2!\left(\frac{N_2+\nu_2+6}{2}\right)!}\frac{\left(\frac{N_3-\nu_3}{2}\right)!\left(\frac{N_3+\nu_3+6}{2}\right)!}{N_3!}\right.\\ &\left.\times\frac{(\nu_1+\nu_2)!}{\left(\frac{\nu_1+\nu_2-\nu_3}{2}\right)!\left(\frac{\nu_1+\nu_2+\nu_3+6}{2}\right)!}\right]^{1/2}\\ &\times\langle N_2=\nu_2,\nu_2\xi_2,N_1=\nu_1,\nu_1\xi_1|N_3=(\nu_1+\nu_2),\nu_3\xi_3\rangle.\end{aligned} \tag{34}$$

The same holds for the isoscalar factors, which can be verified using Eq. (26).

Programs for all the steps mentioned are available and can be handed over on request.

In Table IX a partial list of the isoscalar factors for up to eight bosons is given, involving only the SU(3) irreps (0,0), (1,1), (3,0), (0,3) and restricting to $\nu_1\geq\nu_2$ (for $\nu_1<\nu_2$ we use the symmetric property of the isoscalar factors under permutation of the first two irreps). Irreps with a higher value were calculated, too, but are not tabulated. In total there are about 15 000 isoscalar factors calculated involving states up to eight particles. Here, we only give a partial list containing, as we think, the isoscalar factors of most interest. These involve the SU(3) irreps (0,0), (1,1), (3,0),

TABLE IX. Partial list of isoscalar factors (denoted by IF) for the group chain $U(8) \supset O(8) \supset SU(3)$. Only those are listed with $\nu_k = N_k$ $(k=1,2)$ and $\nu_1 > \nu_2$, thus, the $N_3 = \nu_1 + \nu_2$. For this reason, the value of N_3 is not listed. Equation (34) must be applied in order to obtain the isoscalar factors for $N_1 > \nu_1$, $N_2 > \nu_2$ and $N_3 = N_1 + N_2$.

and (0,3). For example, when a many quark-antiquark state with one additional gluon is considered, the quark state must be in a color (1,1) irrep as the gluon. Likewise, when one quark-antiquark pair is coupled to a color (or flavor) octet, the other pair must be in the same state (not necessarily for the flavor case). More complicated isoscalar factors are available on request.

Next we explain the tests performed in order to assure that the results are of confidence. First of all, we calculated by hand many of the overlap matrix elements of the polynomial No. 3 with the product of the polynomials with Nos. 2 and 1 and compared them to the values obtained via the MATEMATICA code. This we did up to eight bosons choosing arbitrarily the states. Then we checked if the isoscalar factors obtained satisfy the orthogonality condition. We use the orthogonality relation of the U(8) CGC's, i.e.,

$$\sum_{\nu_i k_i \xi_i} \langle N_2 \nu_2 k_2 \xi_2, N_1 \nu_2 k_1 \xi_1 | N_3 \nu_3 k_3 \xi_3 \rangle \langle N_2 \nu_2 k_2 \xi_2, N_1 \nu_2 k_1 \xi_1 | N_3' \nu_3' k_3' \xi_3' \rangle = \delta_{N_3, N_3'} \delta_{\nu_3, \nu_3'} \delta_{\xi_3, \xi_3'}, \quad (35)$$

where the index i is 1 or 2.

We arrive at the following condition for the isoscalar factors, given in (27),

$$\sum_{\nu_i k_i (\lambda_i, \mu_i) \rho} \langle N_2 \nu_2 k_2 (\lambda_2, \mu_2), N_1 \nu_1 k_1 (\lambda_1, \mu_1) \| N_3 \nu_3 k_3 (\lambda_3, \mu_3) \rangle_\rho \times \langle N_2 \nu_2 k_2 (\lambda_2, \mu_2), N_1 \nu_1 k_1 (\lambda_1, \mu_1) \| N_3' \nu_3' k_3' (\lambda_3, \mu_3) \rangle_\rho = \delta_{N_3 N_3'} \delta_{\nu_3 \nu_3'} \delta_{k_3 k_3'}. \quad (36)$$

This orthogonality relation we have checked throughout the range from zero to eight bosons. In total about 350 orthogonality relations, involving several thousand isoscalar factors, were checked.

IV. CONCLUSIONS

In this contribution we have constructed the isoscalar factors for the group chain $U(8) \supset O(8) \supset SU(3)$. Only the totally symmetric irreps $[N]$ of $U(8)$ were taken into account. This is of use in any model/theory which deals with quark-antiquark and/or gluon pairs, as in the model published in Refs. 13–15. The CGC's will be used to calculate transition probabilities and can be used in any other model involving quark-antiquark and/or gluon pairs, like the background in hadron states. The coefficients are also of importance for many gluon systems, restricting to the completely symmetric irreps of $U(8)$, which lie at lower energies.

The method presented is very practical for high rank groups when only few particular irreps are of interest and thus serves as an example. It is more powerful than traditional methods, which use the whole algebraic structure of the group and all recursion relations possible.

For many gluon systems, up to three rows in the Young diagrams are needed, i.e., $[h_1, h_2, h_3]$. Therefore, the next step is to consider two rowed Young diagrams. Steps in this direction are already taken by the authors.

We presented the procedure on how to obtain the Clebsch-Gordan coefficients of the chain $U(8) \supset O(8) \supset SU(3) \supset U(1) \otimes SU(2)$ for symmetric irreducible representations in $U(8)$, through the use of isoscalar factors.

The importance of the Clebsch-Gordan coefficients of the chain starting with $U(8)$ lies not only in the possibility to obtain, via their use, branching ratios of hadron decays involving gluons and quark-antiquark pairs, but it can also be used in any other problem related to a $U(8)$ group, i.e., eight degrees of freedom, not necessarily in particle physics, though this was the main motivation. Another area where the $U(8)$ group could play a role, though probably still far in the future, is in *quantum computing*,[33] related to cyclic networks of quantum gates with three-qubits as elementary structure. Trying to describe a system of many three-qubits will require $U(8)$ CGS's, though, one must still understand the basic three-qubit structure alone.

(Received 26 January 2006; accepted 13 April 2006; published online 28 June 2006)

The closed representation of the generalized (known also as reduced or modified) Green's function for the Helmholtz partial differential operator on the surface of the two-dimensional unit sphere is derived. In its compact form, the derived formula contains a Legendre polynomial and a derivative of the Legendre function of the first kind with respect to its index. An explicit expression for that derivative is found and used to obtain an expanded (and potentially more suitable in applications) form of the generalized Green's function for the operator in question. The related problem of constructing the closed form of the generalized Green's function for the Legendre ordinary differential operator on the segment $-1<x<1$, with the boundary conditions of finiteness at $x=\pm 1$, is also solved. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2203430]

I. INTRODUCTION

Let $\mathbb{S}^2$ be the surface of the unit sphere in $\mathbb{R}^3$, parametrized by the unit radius vector $\mathbf{n}$. The spatial orientation of the vector $\mathbf{n}$ (hence, also the location of a point on $\mathbb{S}^2$ for which $\mathbf{n}$ is the radius vector) is uniquely determined by fixing the polar angle $0\leqslant\theta\leqslant\pi$ and the azimuthal angle $0\leqslant\varphi<2\pi$ in some spherical system of coordinates, with the origin of the latter located at the center of $\mathbb{S}^2$.

Some models of propagation of time-harmonic waves on spherical surfaces used in mathematical geophysics (cf., e.g., the recent work of Yoshizawa and Kennett[29]) lead to the inhomogeneous scalar Helmholtz equation on $\mathbb{S}^2$:

$$[\boldsymbol{\nabla}_{\mathbf{n}}^2+\lambda(\lambda+1)]\Psi(\lambda;\mathbf{n})=\Phi(\mathbf{n}). \tag{1.1}$$

In this equation

$$\boldsymbol{\nabla}_{\mathbf{n}}^2=\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\sin\theta\frac{\partial}{\partial\theta}+\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\varphi^2} \tag{1.2}$$

is the angular part of the Laplace operator (the spherical Laplacian) and $\Phi(\mathbf{n})$ is a source term. For the sake of later convenience, the square of the (in general complex) propagation constant has been written in the form $\lambda(\lambda+1)$, where $\lambda\in\mathbb{C}$. Equation (1.1) is to be solved subject to some boundary and/or regularity conditions imposed on $\Psi(\lambda;\mathbf{n})$. If the wave described by Eq. (1.1) propagates over the entire spherical surface, which will be implicit throughout the rest of this paper, these conditions are the single valuedness and finiteness of $\Psi(\lambda;\mathbf{n})$.

With present-day computers and software (see, e.g., the paper by Adams and Swarztrauber[1]), Eq. (1.1), with the aforementioned regularity conditions, may be solved numerically on $\mathbb{S}^2$ for a

a)Electronic mail: radek@mif.pg.gda.pl

practically arbitrary form of the source function $\Phi(\mathbf{n})$. On the other hand, it appears that the formal analytical solution to Eq. (1.1) is also available; except for the case when $\lambda(\lambda+1)$ is an eigenvalue of $-\boldsymbol{\nabla}_{\mathbf{n}}^2$ on $\mathbb{S}^2$, it is given by

$$\Psi(\lambda;\mathbf{n}) = \oint_{\mathbb{S}^2} \mathrm{d}^2\mathbf{n}'\, G(\lambda;\mathbf{n},\mathbf{n}')\Phi(\mathbf{n}'), \tag{1.3}$$

where $G(\lambda;\mathbf{n},\mathbf{n}')$ is the Green's function for the Helmholtz operator

$$\mathcal{H}(\lambda;\mathbf{n}) = \boldsymbol{\nabla}_{\mathbf{n}}^2 + \lambda(\lambda+1) \tag{1.4}$$

on $\mathbb{S}^2$. Following the general theory,[8,12,13,15,17,20,23,25,27,28] $G(\lambda;\mathbf{n},\mathbf{n}')$ is defined as a solution to the inhomogeneous partial differential equation (with $\mathbf{n}'$ fixed)

$$[\boldsymbol{\nabla}_{\mathbf{n}}^2 + \lambda(\lambda+1)]G(\lambda;\mathbf{n},\mathbf{n}') = \delta^{(2)}(\mathbf{n}-\mathbf{n}'), \tag{1.5}$$

subject to the constraints of single-valuedness and finiteness (with the latter relaxed at the point $\mathbf{n}=\mathbf{n}'$). In Eq. (1.5) the inhomogeneity $\delta^{(2)}(\mathbf{n}-\mathbf{n}')$ is the Dirac delta function on $\mathbb{S}^2$. The closed form of the Green's function $G(\lambda;\mathbf{n},\mathbf{n}')$ is known[2–7,9,10,24,26] to be

$$G(\lambda;\mathbf{n},\mathbf{n}') = \frac{1}{4\sin(\pi\lambda)} P_\lambda(-\mathbf{n}\cdot\mathbf{n}') \quad (\lambda \notin \mathbb{Z}), \tag{1.6}$$

where

$$P_\lambda(x) = {}_2F_1\left(-\lambda,\lambda+1;1;\frac{1-x}{2}\right) = \sum_{n=0}^{\infty} \frac{(-\lambda)_n(\lambda+1)_n}{(n!)^2}\left(\frac{1-x}{2}\right)^n \quad (-1 \leqslant x \leqslant 1) \tag{1.7}$$

is the Legendre function of the first kind,[16,22] with

$$(\zeta)_n = \frac{\Gamma(\zeta+n)}{\Gamma(\zeta)} \quad (n \in \mathbb{N}) \tag{1.8}$$

denoting the Pochhammer symbol.[22]

Equation (1.3) fails to represent a solution of Eq. (1.1) on $\mathbb{S}^2$ when $\lambda \in \mathbb{Z}$, i.e., if it holds that

$$\lambda(\lambda+1) = L(L+1) \quad (L \in \mathbb{N}). \tag{1.9}$$

This corresponds to the situation when the operator (1.4) has a null eigenvalue in its spectrum. It is known from the general theory of linear inhomogeneous equations[20] that in such a case a solution to Eq. (1.1) exists only if the source term is orthogonal to the null space of the operator $\mathcal{H}(L;\mathbf{n})$, spanned by $2L+1$ complex spherical harmonics

$$Y_{LM}(\mathbf{n}) = \frac{(-)^{L+M}}{2^L L!}\sqrt{\frac{2L+1}{4\pi}\frac{(L-M)!}{(L+M)!}}\sin^M\theta\frac{\mathrm{d}^{L+M}\sin^{2L}\theta}{\mathrm{d}\cos^{L+M}\theta}e^{iM\varphi}, \tag{1.10}$$

with $M \in \{0,\pm1,\ldots,\pm L\}$ [the phase choice in Eq. (1.10) conforms to the widely accepted Condon and Shortley[11] convention], i.e., when

$$\oint_{\mathbb{S}^2} \mathrm{d}^2\mathbf{n} Y_{LM}^*(\mathbf{n})\Phi(\mathbf{n}) = 0 \quad (M \in \{0,\pm1,\ldots,\pm L\}). \tag{1.11}$$

If the constraints (1.9) and (1.11) hold simultaneously, a (nonunique) solution to the spherical Helmholtz equation (1.1) is formally given by

$$\Psi_L(\mathbf{n}) = \sum_{M=-L}^{L} a_{LM} Y_{LM}(\mathbf{n}) + \oint_{\mathbb{S}^2} \mathrm{d}^2\mathbf{n}' \overline{G_L}(\mathbf{n},\mathbf{n}')\Phi(\mathbf{n}'), \tag{1.12}$$

where $\{a_{LM}\}$, $(M \in \{0, \pm 1, \ldots, \pm L\})$, are arbitrary constants, while $\overline{G_L}(\mathbf{n},\mathbf{n}')$ is a generalized (known also as reduced or modified) Green's function for the Helmholtz operator $\mathcal{H}(L;\mathbf{n})$. This function is defined as this particular solution to the inhomogeneous partial differential equation

$$[\boldsymbol{\nabla}_{\mathbf{n}}^2 + L(L+1)]\overline{G_L}(\mathbf{n},\mathbf{n}') = \delta^{(2)}(\mathbf{n}-\mathbf{n}') - \sum_{M=-L}^{L} Y_{LM}(\mathbf{n}) Y_{LM}^*(\mathbf{n}') \quad (L \in \mathbb{N}), \tag{1.13}$$

which is single-valued and finite on $\mathbb{S}^2$ (except at the point $\mathbf{n}=\mathbf{n}'$), being, in addition, orthogonal to the null space of the operator $\mathcal{H}(L;\mathbf{n})$:

$$\oint_{\mathbb{S}^2} \mathrm{d}^2\mathbf{n} Y_{LM}^*(\mathbf{n}) \overline{G_L}(\mathbf{n},\mathbf{n}') = 0 \quad (M \in \{0, \pm 1, \ldots, \pm L\}). \tag{1.14}$$

In contrary to the case of $G(\lambda;\mathbf{n},\mathbf{n}')$, despite performing the extensive search through the mathematical and physical literature, we have found no studies on the *closed* form of $\overline{G_L}(\mathbf{n},\mathbf{n}')$, except for the particular case $L=0$ (cf. Refs. 12, 14, 18, and 19). It is therefore the purpose of this work to fill in this gap by presenting the construction of the closed representation of the generalized Green's function for the Helmholtz operator (1.4), constrained by Eq. (1.9), on the unit sphere $\mathbb{S}^2$.

The structure of the paper is as follows. First, in Sec. II we show that $\overline{G_L}(\mathbf{n},\mathbf{n}')$ may be expressed compactly in terms of the derivative $[\partial P_\lambda(-\mathbf{n}\cdot\mathbf{n}')/\partial\lambda]_{\lambda=L}$. Then, in Sec. III we find the explicit representation of $[\partial P_\lambda(x)/\partial\lambda]_{\lambda=L}$, the result which, apart from being important in the context of the present work, seems to be also of interest for itself. Finally, in Sec. IV we combine the findings of Secs. II and III, arriving at the sought explicit closed form of $\overline{G_L}(\mathbf{n},\mathbf{n}')$. We also show that in the particular case $L=0$ the known result for the spherical Laplacian[14,19] is recovered. In addition, we provide the inhomogeneous three-term recurrence relation satisfied by $\overline{G_L}(\mathbf{n},\mathbf{n}')$. The intermediate result obtained in Sec. III is of wider applicability than the subject of this work might suggest. We illustrate this in the Appendix, where the closed form of the generalized Green's function for the one-dimensional Legendre operator

$$\mathcal{L}(L;x) = \frac{\mathrm{d}}{\mathrm{d}x}(1-x^2)\frac{\mathrm{d}}{\mathrm{d}x} + L(L+1) \quad (L \in \mathbb{N}) \tag{1.15}$$

on the interval $-1<x<1$, with the boundary conditions of finiteness at $x=\pm 1$, is constructed.

II. COMPACT CLOSED FORM OF THE GENERALIZED GREEN'S FUNCTION FOR THE HELMHOLTZ OPERATOR ON $\mathbb{S}^2$

From the general theory of Green's functions (cf. the relevant references cited in Sec. I) it follows that one may construct the generalized spherical Helmholtz Green's function $\overline{G_L}(\mathbf{n},\mathbf{n}')$ in the form of the so-called spectral series

$$\overline{G_L}(\mathbf{n},\mathbf{n}') = \sum_{\substack{l=0 \\ (l\neq L)}}^{\infty} \sum_{m=-l}^{l} \frac{Y_{lm}(\mathbf{n}) Y_{lm}^*(\mathbf{n}')}{L(L+1) - l(l+1)}. \tag{2.1}$$

Comparing this with the spectral series representation of the Green's function $G(\lambda;\mathbf{n},\mathbf{n}')$, known to be

$$G(\lambda;\mathbf{n},\mathbf{n}') = \sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{Y_{lm}(\mathbf{n})Y_{lm}^*(\mathbf{n}')}{\lambda(\lambda+1)-l(l+1)}, \tag{2.2}$$

it may be inferred that the functions $\overline{G}_L(\mathbf{n},\mathbf{n}')$ and $G(\lambda;\mathbf{n},\mathbf{n}')$ are related through

$$\overline{G}_L(\mathbf{n},\mathbf{n}') = \lim_{\lambda(\lambda+1)\to L(L+1)}\frac{\partial}{\partial[\lambda(\lambda+1)]}\{[\lambda(\lambda+1)-L(L+1)]G(\lambda;\mathbf{n},\mathbf{n}')\}. \tag{2.3}$$

This, after exploiting the result (1.6), may be rewritten as

$$\overline{G}_L(\mathbf{n},\mathbf{n}') = \frac{1}{4(2L+1)}\lim_{\lambda\to L}\frac{\partial}{\partial\lambda}\frac{(\lambda-L)(\lambda+L+1)}{\sin(\pi\lambda)}P_\lambda(-\mathbf{n}\cdot\mathbf{n}'). \tag{2.4}$$

The limit on the right-hand side of the above equation may be evaluated by using the l'Hospital rule. After exploiting the fact that for a non-negative integer index the Legendre function (1.7) degenerates to the Legendre polynomial

$$P_L(x) = \frac{1}{2^L L!}\frac{\mathrm{d}^L(x^2-1)^L}{\mathrm{d}x^L} \quad (L\in\mathbb{N}), \tag{2.5}$$

and making use of the following reflection property of the Legendre polynomials:

$$P_L(-x) = (-)^L P_L(x) \quad (L\in\mathbb{N}), \tag{2.6}$$

one eventually finds that the closed form of $\overline{G}_L(\mathbf{n},\mathbf{n}')$ is

$$\overline{G}_L(\mathbf{n},\mathbf{n}') = \frac{(-)^L}{4\pi}\frac{\partial P_\lambda(-\mathbf{n}\cdot\mathbf{n}')}{\partial\lambda}\bigg|_{\lambda=L} + \frac{1}{4\pi}\frac{P_L(\mathbf{n}\cdot\mathbf{n}')}{2L+1}. \tag{2.7}$$

From the purely theoretical point of view, arriving at Eq. (2.7) completes the task of determining the closed form of $\overline{G}_L(\mathbf{n},\mathbf{n}')$. However, in most of the actual applications formula (2.7) will be unhandy, if not useless. To find a representation of $\overline{G}_L(\mathbf{n},\mathbf{n}')$ which is suitable for practical purposes, the derivative $[\partial P_\lambda(x)/\partial\lambda]_{\lambda=L}$ must be evaluated explicitly. We shall be concerned with the latter problem in the following section.

III. EVALUATION OF $[\partial P_\lambda(x)/\partial\lambda]_{\lambda=L}$

Throughout the whole section, it will be implicit that L is an arbitrary non-negative integer and that $-1\leqslant x\leqslant 1$.

Consider the definition (1.7). Differentiating it with respect to λ, after making use of the following differential property of the Pochhammer symbol:

$$\frac{\mathrm{d}(\zeta)_n}{\mathrm{d}\zeta} = [\psi(\zeta+n)-\psi(\zeta)](\zeta)_n, \tag{3.1}$$

where

$$\psi(\zeta) = \frac{1}{\Gamma(\zeta)}\frac{\mathrm{d}\Gamma(\zeta)}{\mathrm{d}\zeta} \tag{3.2}$$

is the digamma function,[16,22] one obtains

$$\frac{\partial P_\lambda(x)}{\partial \lambda} = \sum_{n=1}^{\infty} \frac{(-\lambda)_n(\lambda+1)_n}{(n!)^2}[\psi(\lambda+1+n) - \psi(\lambda+1) + \psi(-\lambda) - \psi(-\lambda+n)]\left(\frac{1-x}{2}\right)^n. \tag{3.3}$$

It is evident from Eq. (3.3) that the function $\partial P_\lambda(x)/\partial\lambda$ obeys

$$\left.\frac{\partial P_{\lambda'}(x)}{\partial \lambda'}\right|_{\lambda'=-\lambda-1} = -\left.\frac{\partial P_{\lambda'}(x)}{\partial \lambda'}\right|_{\lambda'=\lambda}. \tag{3.4}$$

The right-hand side of Eq. (3.3) may be simplified. On exploiting the known relation[16,22]

$$\psi(\zeta) = \psi(1-\zeta) - \pi\cot(\pi\zeta) \tag{3.5}$$

one finds

$$-\psi(\lambda+1) + \psi(-\lambda) - \psi(-\lambda+n) = -\psi(\lambda+1-n). \tag{3.6}$$

Hence, it follows that

$$\frac{\partial P_\lambda(x)}{\partial \lambda} = \sum_{n=1}^{\infty} \frac{(-\lambda)_n(\lambda+1)_n}{(n!)^2}[\psi(\lambda+1+n) - \psi(\lambda+1-n)]\left(\frac{1-x}{2}\right)^n. \tag{3.7}$$

Equation (3.7) does not look simple. However, at this stage we may take advantage of the fact that for the purposes of the present work the derivative $\partial P_\lambda(x)/\partial\lambda$ is to be evaluated for $\lambda = L \in \mathbb{N}$ only.

At first, consider what happens if $\lambda = 0$. Since

$$\lim_{\lambda\to 0} \frac{\psi(\lambda+1+n)}{\Gamma(-\lambda)} = 0 \quad (n \in \mathbb{N}) \tag{3.8}$$

and

$$\lim_{\lambda\to 0} \frac{\psi(\lambda+1-n)}{\Gamma(-\lambda)} = 1 \quad (n \in \mathbb{N}\setminus\{0\}), \tag{3.9}$$

in this particular case we arrive at the known result[16,22]

$$\left.\frac{\partial P_\lambda(x)}{\partial \lambda}\right|_{\lambda=0} = -\sum_{n=1}^{\infty} \frac{1}{n}\left(\frac{1-x}{2}\right)^n = \ln\frac{1+x}{2}. \tag{3.10}$$

Next, the Legendre function (1.7) is known[16,22] to satisfy the three-term homogeneous recurrence relation

$$(\lambda+1)P_{\lambda+1}(x) - (2\lambda+1)xP_\lambda(x) + \lambda P_{\lambda-1}(x) = 0. \tag{3.11}$$

Differentiating this relation with respect to λ yields the three-term inhomogeneous recurrence relation for the function (3.7)

$$(\lambda+1)\frac{\partial P_{\lambda+1}(x)}{\partial\lambda} - (2\lambda+1)x\frac{\partial P_\lambda(x)}{\partial\lambda} + \lambda\frac{\partial P_{\lambda-1}(x)}{\partial\lambda} = -P_{\lambda+1}(x) + 2xP_\lambda(x) - P_{\lambda-1}(x), \tag{3.12}$$

which, upon exploiting again Eq. (3.11), may be rewritten in the form

$$(\lambda+1)\frac{\partial P_{\lambda+1}(x)}{\partial\lambda}-(2\lambda+1)x\frac{\partial P_\lambda(x)}{\partial\lambda}+\lambda\frac{\partial P_{\lambda-1}(x)}{\partial\lambda}=\frac{1}{2\lambda+1}[P_{\lambda+1}(x)-P_{\lambda-1}(x)]. \tag{3.13}$$

If $\lambda=L\in\mathbb{N}$, the recurrence (3.13) becomes

$$(L+1)\left.\frac{\partial P_\lambda(x)}{\partial\lambda}\right|_{\lambda=L+1}-(2L+1)x\left.\frac{\partial P_\lambda(x)}{\partial\lambda}\right|_{\lambda=L}+L\left.\frac{\partial P_\lambda(x)}{\partial\lambda}\right|_{\lambda=L-1}=\frac{1}{2L+1}[P_{L+1}(x)-P_{L-1}(x)]. \tag{3.14}$$

Equation (3.14) is to be solved with formula (3.10) taken as an initial condition. Now, it is known from the general theory of linear difference equations[21] that the solution to the problem (3.14) and (3.10) may be sought in the form

$$\left.\frac{\partial P_\lambda(x)}{\partial\lambda}\right|_{\lambda=L}=F_L(x)+W_L(x), \tag{3.15}$$

where $F_L(x)$ solves

$$(L+1)F_{L+1}(x)-(2L+1)xF_L(x)+LF_{L-1}(x)=0 \tag{3.16}$$

subject to the inhomogeneous initial condition

$$F_0(x)=\ln\frac{1+x}{2}, \tag{3.17}$$

while $W_L(x)$ satisfies

$$(L+1)W_{L+1}(x)-(2L+1)xW_L(x)+LW_{L-1}(x)=\frac{1}{2L+1}[P_{L+1}(x)-P_{L-1}(x)] \tag{3.18}$$

subject to the homogeneous initial condition

$$W_0(x)=0. \tag{3.19}$$

Equations (3.18) and (3.19) imply that $W_L(x)$ is a polynomial in x, of degree L, such that

$$W_L(1)=0. \tag{3.20}$$

We shall make use of this observation shortly.

The solution to the problem constituted by Eqs. (3.16) and (3.17) is immediately found to be

$$F_L(x)=P_L(x)\ln\frac{1+x}{2}. \tag{3.21}$$

To find $W_L(x)$, we observe that the derivative $\partial P_\lambda(x)/\partial\lambda$ satisfies the inhomogeneous differential equation

$$\left[\frac{\mathrm{d}}{\mathrm{d}x}(1-x^2)\frac{\mathrm{d}}{\mathrm{d}x}+\lambda(\lambda+1)\right]\frac{\partial P_\lambda(x)}{\partial\lambda}=-(2\lambda+1)P_\lambda(x), \tag{3.22}$$

obtainable from the Legendre identity

$$\left[\frac{\mathrm{d}}{\mathrm{d}x}(1-x^2)\frac{\mathrm{d}}{\mathrm{d}x}+\lambda(\lambda+1)\right]P_\lambda(x)=0 \tag{3.23}$$

by its differentiation with respect to λ. On combining Eqs. (3.22), (3.15), and (3.21), and after making use of the known relationship[22]

$$x\frac{\mathrm{d}P_L(x)}{\mathrm{d}x} - LP_L(x) = \frac{\mathrm{d}P_{L-1}(x)}{\mathrm{d}x}, \tag{3.24}$$

one deduces that $W_L(x)$ satisfies the inhomogeneous differential equation

$$\left[\frac{\mathrm{d}}{\mathrm{d}x}(1-x^2)\frac{\mathrm{d}}{\mathrm{d}x} + L(L+1)\right]W_L(x) = 2\frac{\mathrm{d}P_{L-1}(x)}{\mathrm{d}x} - 2\frac{\mathrm{d}P_L(x)}{\mathrm{d}x}. \tag{3.25}$$

Since $W_L(x)$ is the polynomial, the pertinent boundary conditions supplementing Eq. (3.25) are

$$W_L(x) \text{ bounded for } x \to \pm 1. \tag{3.26}$$

It is evident that by solving the boundary value problem constituted by Eqs. (3.25) and (3.26) one is able to determine $W_L(x)$ only up to a multiple of the Legendre polynomial $P_L(x)$, since the latter solves the associated homogeneous boundary value problem. With this fact in mind, on applying the machinery of Green's functions, $W_L(x)$ is found to have the form

$$W_L(x) = c_L P_L(x) + 2\int_{-1}^{1} \mathrm{d}x'\, \overline{g_L}(x,x')\left[\frac{\mathrm{d}P_{L-1}(x')}{\mathrm{d}x'} - \frac{\mathrm{d}P_L(x')}{\mathrm{d}x'}\right], \tag{3.27}$$

where

$$\overline{g_L}(x,x') = \frac{1}{2}\sum_{\substack{l=0 \\ (l\neq L)}}^{\infty} \frac{2l+1}{(L-l)(L+l+1)}P_l(x)P_l(x') \tag{3.28}$$

is the generalized Green's function (in its spectral form, cf. the Appendix) for the Legendre operator (1.15), while c_L is a coefficient which remains to be determined. The integral on the right-hand side of Eq. (3.27) may be evaluated if one makes use of the known relationship[16]

$$\frac{\mathrm{d}P_L(x)}{\mathrm{d}x} = \sum_{l=0}^{\mathrm{int}[(L-1)/2]} (2L-4l-1)P_{L-2l-1}(x) \tag{3.29}$$

[in Eq. (3.29), and hereafter, it is implicit that if the upper limit of the summation is smaller than the lower one, than the sum is identically zero], which implies that it holds that

$$\frac{\mathrm{d}P_{L-1}(x)}{\mathrm{d}x} - \frac{\mathrm{d}P_L(x)}{\mathrm{d}x} = \sum_{l=0}^{L-1} (-)^{L+l}(2l+1)P_l(x). \tag{3.30}$$

On inserting Eqs. (3.28) and (3.30) into Eq. (3.27), after exploiting the orthogonality property[16,22]

$$\int_{-1}^{1} \mathrm{d}x\, P_L(x)P_{L'}(x) = \frac{2}{2L+1}\delta_{LL'}, \tag{3.31}$$

one obtains $W_L(x)$ in the form

$$W_L(x) = c_L P_L(x) + 2\sum_{l=0}^{L-1} (-)^{L+l}\frac{2l+1}{(L-l)(L+l+1)}P_l(x). \tag{3.32}$$

It remains to determine the coefficient c_L. To this end, in Eq. (3.32) one sets $x=1$ and then exploits the property

$$P_\lambda(1) = 1, \tag{3.33}$$

and also Eq. (3.20), obtaining

$$c_L = -2\sum_{l=0}^{L-1}(-)^{L+l}\frac{2l+1}{(L-l)(L+l+1)}. \tag{3.34}$$

This leads to the following representation of the polynomial $W_L(x)$:

$$W_L(x) = 2\sum_{l=0}^{L-1}(-)^{L+l}\frac{2l+1}{(L-l)(L+l+1)}[P_l(x)-P_L(x)]. \tag{3.35}$$

[Observe that, according to the convention introduced below Eq. (3.29), from Eq. (3.35) it follows that $W_0(x)=0$, which is in agreement with Eq. (3.19).]

The results obtained above may be summarized in the following formula for the sought derivative $[\partial P_\lambda(x)/\partial\lambda]_{\lambda=L}$:

$$\left.\frac{\partial P_\lambda(x)}{\partial\lambda}\right|_{\lambda=L} = P_L(x)\ln\frac{1+x}{2} + 2\sum_{l=0}^{L-1}(-)^{L+l}\frac{2l+1}{(L-l)(L+l+1)}[P_l(x)-P_L(x)]. \tag{3.36}$$

In particular, from Eq. (3.36) it follows that

$$\left.\frac{\partial P_\lambda(x)}{\partial\lambda}\right|_{\lambda=1} = x\ln\frac{1+x}{2} + (x-1), \tag{3.37}$$

$$\left.\frac{\partial P_\lambda(x)}{\partial\lambda}\right|_{\lambda=2} = \frac{1}{2}(3x^2-1)\ln\frac{1+x}{2} + \left(\frac{7}{4}x^2 - \frac{3}{2}x - \frac{1}{4}\right), \tag{3.38}$$

$$\left.\frac{\partial P_\lambda(x)}{\partial\lambda}\right|_{\lambda=3} = \frac{1}{2}(5x^3-3x)\ln\frac{1+x}{2} + \left(\frac{37}{12}x^3 - \frac{5}{2}x^2 - \frac{5}{4}x + \frac{2}{3}\right). \tag{3.39}$$

We parenthetically observe also that, if needed, the derivatives $[\partial P_\lambda(x)/\partial\lambda]_{\lambda=-L-1}$ may be deduced from Eqs. (3.4) and (3.36).

IV. DISCUSSION

From Eqs. (2.7), (3.36), and (2.6) one deduces that the explicit form of the generalized Green's function for the Helmholtz operator (1.4), with the constraint (1.9), is

$$\overline{G}_L(\mathbf{n},\mathbf{n}') = \frac{1}{4\pi}P_L(\mathbf{n}\cdot\mathbf{n}')\left[\ln\frac{1-\mathbf{n}\cdot\mathbf{n}'}{2} - 2\sum_{l=0}^{L-1}(-)^{L+l}\frac{2l+1}{(L-l)(L+l+1)} + \frac{1}{2L+1}\right] + \frac{1}{2\pi}\sum_{l=0}^{L-1}\frac{2l+1}{(L-l)(L+l+1)}P_l(\mathbf{n}\cdot\mathbf{n}'). \tag{4.1}$$

In the particular case $L=0$, when the spherical Helmholtz operator (1.4) reduces to the spherical Laplacian, Eq. (4.1) yields

$$\overline{G}_0(\mathbf{n},\mathbf{n}') = \frac{1}{4\pi}\left(\ln\frac{1-\mathbf{n}\cdot\mathbf{n}'}{2} + 1\right). \tag{4.2}$$

This result agrees with that of Kneser[19](see also the paper by Freeden[14]), after rescaling his formula to achieve the consistency with our defining Eq. (1.13), but at the first sight seems to contradict the finding of Courant and Hilbert,[12] whose result, again after due rescaling, in our notation is

$$\overline{G_0^{(\mathrm{CH})}}(\mathbf{n},\mathbf{n}') = \frac{1}{4\pi}\left(\ln\frac{1-\mathbf{n}\cdot\mathbf{n}'}{2} + 2\ln 2\right). \tag{4.3}$$

The reason for this discrepancy is that the latter authors did not impose the orthogonality constraint (1.14) on the solution to the inhomogeneous equation (1.13), specialized to the case $L=0$. Consequently, in their approach the generalized Green's function for the spherical Laplace operator is determined only up to a multiple of $Y_{00}(\mathbf{n})Y_{00}^{*}(\mathbf{n}')$, i.e., up to an additive constant. If this constant is added to $\overline{G_0^{(\mathrm{CH})}}(\mathbf{n},\mathbf{n}')$, and then chosen so that the result satisfies the constraint (1.14), our finding (4.2) is recovered.

Finally, we find it noteworthy that Eqs. (2.7), (3.11), and (3.14) imply that the function $\overline{G_L}(\mathbf{n},\mathbf{n}')$ satisfies the three-term inhomogeneous recurrence relation

$$\begin{aligned}(L+1)\overline{G_{L+1}}(\mathbf{n},\mathbf{n}') - (2L+1)\mathbf{n}\cdot\mathbf{n}'\overline{G_L}(\mathbf{n},\mathbf{n}') + L\overline{G_{L-1}}(\mathbf{n},\mathbf{n}') \\ = \frac{1}{4\pi}\left[\frac{P_{L+1}(\mathbf{n}\cdot\mathbf{n}')}{(2L+1)(2L+3)} + \frac{P_{L-1}(\mathbf{n}\cdot\mathbf{n}')}{|2L-1|(2L+1)}\right],\end{aligned} \tag{4.4}$$

subject to the initial condition constituted by Eq. (4.2).

APPENDIX: CLOSED FORM OF THE GENERALIZED GREEN'S FUNCTION FOR THE LEGENDRE OPERATOR (1.15)

The Legendre Green's function $g(\lambda;x,x')$ is defined as the solution to the inhomogeneous differential equation (with x' fixed)

$$\left[\frac{\mathrm{d}}{\mathrm{d}x}(1-x^2)\frac{\mathrm{d}}{\mathrm{d}x} + \lambda(\lambda+1)\right]g(\lambda;x,x') = \delta(x-x') \quad (-1 < x,x' < 1) \tag{A1}$$

satisfying the boundary conditions

$$g(\lambda;x,x') \text{ bounded for } x \to \pm 1. \tag{A2}$$

In Eq. (A1), and hereafter, $\delta(x-x')$ is the one-dimensional Dirac delta distribution. The function $g(\lambda;x,x')$ has the spectral series representation

$$g(\lambda;x,x') = \frac{1}{2}\sum_{l=0}^{\infty}\frac{2l+1}{\lambda(\lambda+1)-l(l+1)}P_l(x)P_l(x') \quad (\lambda \notin \mathbb{Z}), \tag{A3}$$

while its closed form may be shown to be

$$g(\lambda;x,x') = \frac{\pi}{2\sin(\pi\lambda)}P_\lambda(-x_<)P_\lambda(x_>) \quad (\lambda \notin \mathbb{Z}), \tag{A4}$$

with

$$x_< = \min(x,x'), \quad x_> = \max(x,x'). \tag{A5}$$

Evidently, $g(\lambda;x,x')$ fails to exist if $\lambda \in \mathbb{Z}$, i.e., if the condition (1.9) is satisfied. In this appendix, with the help of the results of Sec. III, we shall find the closed form of the generalized Legendre Green's function $\overline{g_L}(x,x')$ for this case.

The function $\overline{g_L}(x,x')$ is defined as this particular solution to the inhomogeneous equation (with x' fixed)

$$\left[\frac{\mathrm{d}}{\mathrm{d}x}(1-x^2)\frac{\mathrm{d}}{\mathrm{d}x}+L(L+1)\right]\overline{g}_L(x,x')=\delta(x-x')-\frac{2L+1}{2}P_L(x)P_L(x')\quad(-1<x,x'<1),\tag{A6}$$

which satisfies the boundary conditions

$$\overline{g}_L(x,x')\text{ bounded for }x\to\pm 1\tag{A7}$$

and the orthogonality constraint

$$\int_{-1}^{1}\mathrm{d}x\,P_L(x)\overline{g}_L(x,x')=0.\tag{A8}$$

The spectral series representation of $\overline{g}_L(x,x')$ is

$$\overline{g}_L(x,x')=\frac{1}{2}\sum_{\substack{l=0\\(l\neq L)}}^{\infty}\frac{2l+1}{L(L+1)-l(l+1)}P_l(x)P_l(x')\tag{A9}$$

and this particular form of $\overline{g}_L(x,x')$ has been helpful in deriving Eq. (3.32).

To find the closed form of $\overline{g}_L(x,x')$, we observe that, as it follows from Eqs. (A3) and (A9), it is related to the Green's function $g(\lambda;x,x')$ through

$$\overline{g}_L(x,x')=\lim_{\lambda(\lambda+1)\to L(L+1)}\frac{\partial}{\partial[\lambda(\lambda+1)]}\{[\lambda(\lambda+1)-L(L+1)]g(\lambda;x,x')\}.\tag{A10}$$

In virtue of Eq. (A4), this relation may be rewritten as

$$\overline{g}_L(x,x')=\frac{\pi}{2}\frac{1}{2L+1}\lim_{\lambda\to L}\frac{\partial}{\partial\lambda}\frac{(\lambda-L)(\lambda+L+1)}{\sin(\pi\lambda)}P_\lambda(-x_<)P_\lambda(x_>).\tag{A11}$$

Performing the limiting passage with the aid of the l'Hospital rule gives

$$\overline{g}_L(x,x')=\frac{(-)^L}{2}\frac{\partial P_\lambda(-x_<)}{\partial\lambda}\bigg|_{\lambda=L}P_L(x_>)+\frac{(-)^L}{2}P_L(-x_<)\frac{\partial P_\lambda(x_>)}{\partial\lambda}\bigg|_{\lambda=L}+\frac{1}{2}\frac{P_L(x_<)P_L(x_>)}{2L+1},\tag{A12}$$

and transforming further Eq. (A12) with the help of Eqs. (3.15), (3.21), and (2.6) leads to the final result

$$\overline{g}_L(x,x')=\frac{1}{2}P_L(x_<)P_L(x_>)\ln\frac{(1-x_<)(1+x_>)}{4}+\frac{1}{2}W_L(-x_<)P_L(-x_>)+\frac{1}{2}P_L(x_<)W_L(x_>)+\frac{1}{2}\frac{P_L(x_<)P_L(x_>)}{2L+1},\tag{A13}$$

with $W_L(x)$ given explicitly by Eq. (3.35). In the particular case $L=0$, Eq. (A13) simplifies to the well-known formula[12,20]

$$\overline{g}_0(x,x')=\frac{1}{2}\ln\frac{(1-x_<)(1+x_>)}{4}+\frac{1}{2}.\tag{A14}$$

Jacobi ϑ-functions and discrete Fourier transforms

M. Ruzzi[a)]
Instituto de Física Teórica, São Paulo State University 01405-900 Rua Pamplona, 145 São Paulo, SP, Brazil

(Received 18 April 2006; accepted 11 May 2006; published online 28 June 2006)

Properties of the Jacobi ϑ_3-function and its derivatives under discrete Fourier transforms are investigated, and several interesting results are obtained. The role of modulo N equivalence classes in the theory of ϑ-functions is stressed. An important conjecture is studied. © *2006 American Institute of Physics.*

I. INTRODUCTION

Methods in mathematical physics usually provide an interface between quite different areas of physics, and it is not unusual that such areas advance in parallel, mostly ignoring each other's steps. This is the case with finite dimensional inner product spaces (hereafter mentioned as the "discrete"), with its leading role in quantum mechanics (hence quantum information theory) and in finite signal analysis. References 1–3 provide some links between those theories.

Both quantum mechanics of finite dimensional Hilbert spaces and finite signal analysis rely heavily on the discrete Fourier transform (DFT, sometimes mentioned finite or fractional Fourier transform), and, regarding quantum mechanics, after the seminal work of Weyl on finite dimensional systems,[4] it was Schwinger who observed and explored the fact that two physical observables whose families of eigenstates are connected *via* DFT share a maximum degree of incompatibility.[5]

Although, at first glance, a finite system might look much simpler than anything defined on a nonenumerable infinite dimensional Hilbert space (hereafter referred to as the "continuum"), there is much more knowledge about the latter than the former. In one phrase, in the continuum we have one, and only one, harmonic oscillator, while in the discrete there are a lot of candidates for that role, each one surely with its virtues, but surely no undisputed champion.

The eigenstates associated to the harmonic oscillator, the Gaussian function and the Hermite polynomials, have a very distinguishable behavior under the action of the (usual) Fourier transform, so widely known that any comment on this regard is completely superfluous. Over such properties rests a huge amount of physical knowledge. On the other hand, however, although the discrete Fourier transform (DFT) is a well known tool, there is nothing on this context which could claim for itself a role analogous to that of the Gaussian function/Fourier transform "duo."

A decisive step in an attempt to "regain," in the discrete, all interpretative power derived from the qualitative behavior of the harmonic oscillator eigenfunctions, lost when one leaves the continuum realm, was given in Ref. 6, where the eigenstates of the DFT are obtained. The purpose of this paper is to further explore this path, showing results which closely parallel those of the continuum. Those results are obtained in a strikingly simple fashion, exploring the technique of breaking infinite sums in modulo N equivalence classes. Pertinent research on the eigenstates of the DFT can also be found in Ref. 7.

A remark must be made about the orthogonality of the DFT's eigenstates. Mehta has conjectured that those states are indeed orthogonal, what seems to be most reasonable. One may be led to believe that, just as in the continuum, the eigenstates of the DFT may be also (nondegenerate)

[a)]Email address: mruzzi@ift.unesp.br

eigenstates of some other (unitary or self-adjoint) operator, and thus orthogonal. Further evidence supporting such conjecture is that the continuous limit of the DFT eigenstates recovers, as expected, the Gaussian times the Hermite polynomials. However, as it will be shown, quite surprisingly, the conjecture *does not* hold, giving another fine example of the peculiarities of the finite dimensional context.

The eigenstates of the DFT are seen to be the Jacobi ϑ_3-function and its derivatives.[8] Interest in Jacobi ϑ-functions, by their own turn, may come from a variety of directions. First, its mathematical interest goes without saying (see, for example, Ref. 9 and references therein). To cite relatively recent examples in physics, in quantum physics it is deeply related to coherent states associated to both circle[10] and finite lattice topology.[11] Its modular properties have proven to be of fundamental importance in superstring theory, as it is shown by standard literature in this field.[12]

The basic notation adopted in this paper and some preliminary results are presented in the next section. Following, orthogonality of the DFT's eigenstates is discussed. Section IV contains the main results, for which a two variable generalization is verified in the subsequent section. Further relations among ϑ_3-functions are obtained in Sec. VI, which precedes the concluding section.

II. PRELIMINARY RESULTS

In Ref. 6 it is shown that there is a set of functions with the following remarkable property

$$f_n(j) = \frac{i^n}{\sqrt{N}} \sum_{k=0}^{N-1} f_n(k) \exp\left[\frac{2\pi i}{N} kj\right], \tag{1}$$

where N is a natural number. The functions

$$f_n(j) = \sum_{\alpha=-\infty}^{\infty} \exp\left[-\frac{\pi}{N}(\alpha N + j)^2\right] H_n\big(\epsilon(\alpha N + j)\big), \quad \epsilon = \sqrt{\frac{2\pi}{N}} \tag{2}$$

are defined making use of the Hermite polynomial H_n. Writing $H_n(x)$ in terms of its generating function, $H_n(x) = \frac{\partial^n}{\partial t^n} \exp[2xt - t^2]|_{t=0}$, it is possible to write this state (to use a quantum mechanical terminology) as[8]

$$f_n(j) = \frac{1}{\sqrt{N}} \frac{\partial^n}{\partial t^n} \vartheta_3\left(\frac{j}{N} - \frac{\epsilon}{\pi} t, \frac{i}{N}\right) \exp[t^2]\Big|_{t=0}, \tag{3}$$

where

$$\vartheta_3(z,\tau) = \sum_{\alpha=-\infty}^{\infty} \exp[i\pi\tau\alpha^2] \exp[2\pi i \alpha z], \quad \mathrm{Im}(\tau) > 0, \tag{4}$$

is the Jacobi ϑ_3-function, following Vilenkin's notation.[13] In this notation the basic properties of this even function read as

$$\vartheta_3(z + m + n\tau, \tau) = \exp[-i\pi\tau m^2] \exp[-2\pi i n z] \vartheta_3(z,\tau), \tag{5}$$

$$\vartheta_3(z, i\tau) = \tau^{-1/2} \exp\left[-\frac{\pi z^2}{\tau}\right] \vartheta_3\left(\frac{z}{i\tau}, \frac{i}{\tau}\right), \tag{6}$$

emphasizing its period 1 and quasiperiod τ. A beautiful consequence of (6) is that this function can be written as a sum of Gaussians,

$$\vartheta_3\left(\frac{z}{L},\frac{i}{\sigma^2}\right)=\sigma\sum_{\alpha=-\infty}^{\infty}\exp\left[-\pi\left(\frac{\sigma}{L}\right)^2(\alpha L+z)^2\right], \tag{7}$$

a form in which the width L/σ becomes apparent. Property (6) also provides an easy way to obtain the additional identity (also given by Ref. 6)

$$f_n(j)=\epsilon(-i)^n\sum_{\alpha=-\infty}^{\infty}\exp\left[-\frac{\pi}{N}\alpha^2+\frac{2\pi i}{N}j\alpha\right]H_n(\epsilon\alpha), \tag{8}$$

which is in fact a generalization of Eq. (7) (if one compares it to Eq. (2)).

III. ORTHOGONALITY OF THE f_n'S

According to Eq. (1), the functions $\{f_n(j)\}$ are eigenstates of the DFT with associated eigenvalue i^n. Mehta has conjectured that $\{f_n(j)\}_{n=0}^{N-1}$ is an orthogonal set, and thus complete, over a finite set of N points (for odd N. For even N one must replace $f_{N-1}(j)$ by $f_N(j)$). This reasonable conjecture, quite surprisingly indeed, does not hold for arbitrary N (it holds for large N). As, in the following, evidence will be collected *against* the original conjecture, details shall be kept to a level higher than usual.

Let (f_n,f_m) denote the inner product

$$(f_n,f_m)=\sum_{j=0}^{N-1}f_n^*(j)f_m(j)=\epsilon^2(-i)^{n+m}\sum_{j=0}^{N-1}\sum_{\alpha,\beta=-\infty}^{\infty}\exp\left[-\frac{\pi}{N}(\alpha^2+\beta^2)+\frac{2\pi i}{N}j(\alpha-\beta)\right]H_n(\epsilon\alpha)H_m(\epsilon\beta).$$

The sum over $\{j\}$ is a realization of the modulo N Kroenecker delta,

$$\delta_{\alpha,\beta}^{[N]}=\begin{cases}1 & \alpha=\beta\ (\mathrm{mod}\ N),\\ 0 & \alpha\neq\beta\ (\mathrm{mod}\ N),\end{cases}$$

thus

$$(f_n,f_m)=2\pi(-i)^{n+m}\sum_{\alpha,\beta=-\infty}^{\infty}\delta_{\alpha,\beta}^{[N]}\exp\left[-\frac{\pi}{N}(\alpha^2+\beta^2)\right]H_n(\epsilon\alpha)H_m(\epsilon\beta). \tag{9}$$

The well-known identity,

$$\exp\left[-\frac{1}{2}x^2\right]H_k(x)=\frac{i^k}{\sqrt{2\pi}}\int_{-\infty}^{\infty}dy\exp\left[-\frac{1}{2}y^2+ixy\right]H_k(y),$$

together with the sum over $\{\beta\}$ leads to

$$(f_n,f_m)=\sum_{\alpha,\gamma=-\infty}^{\infty}\int_{-\infty}^{\infty}dy\,dz\exp\left[-\frac{1}{2}(y^2+z^2)+iy\epsilon\alpha+iz\epsilon(\alpha+\gamma N)\right]H_n(y)H_m(z),$$

where the infinite sum on $\{\gamma\}$ covers the equivalence class present in $\delta_{\alpha,\beta}^{[N]}$. Now, the sum over $\{\alpha\}$ by its turn is a realization of a modulo 2π Dirac delta, thus, with the integration over $\{z\}$ and convenient changes of variables,

$$(f_n,f_m)=2\pi\sum_{\gamma,\upsilon=-\infty}^{\infty}\int_{-\infty}^{\infty}dy\exp\left[-y^2-\frac{\pi^2\upsilon^2}{\epsilon^2}+i(y\epsilon N-\upsilon\pi N)\gamma\right]H_n\left(y-\frac{\pi\upsilon}{\epsilon}\right)H_m\left(y+\frac{\pi\upsilon}{\epsilon}\right),$$

where again an infinite sum is introduced due to the modulo 2π delta.

The above expression is rather elucidative. It is not hard to realize that the infinite sums over $\{\gamma,\upsilon\}$ are a direct consequence of the equivalence classes brought in by the modulo N Kroenecker

delta present in Eq. (9). For large N, the term corresponding to $\gamma=\upsilon=0$ becomes increasingly important, and a simple check shows that this term is exactly $\delta_{n,m}$. Thus, as expected, the limit $N\to\infty$ recovers the usual harmonic oscillator results. For finite (and small) N, however, all terms in the above summation must be taken into account.

Following then, the sum on γ is seen to be a realization of the modulo 2π Dirac delta, $\delta^{[2\pi]}(y\epsilon N-\upsilon\pi N)$, and after a change of variables one has

$$(f_n,f_m)=2\pi\epsilon\sum_{\mu,\upsilon=-\infty}^{\infty}\exp\left[-\frac{2\pi}{N}\left(\mu+\frac{N\upsilon}{2}\right)^2-\frac{N\pi\upsilon^2}{2}\right]H_n(\epsilon\mu)H_m\left(\frac{2\pi\upsilon}{\epsilon}+\epsilon\mu\right).$$

Again, summation over $\{\mu\}$ must be included to account for the 2π periodicity of the Dirac delta. Splitting the sum on ν in two sums, over the odd and even integers and shifting the sum on μ by νN results in

$$\begin{aligned}(f_n,f_m)=&\,2\pi\epsilon\sum_{\mu,\upsilon=-\infty}^{\infty}\exp\left[-\frac{2\pi}{N}\mu^2-2\pi N\upsilon^2\right]H_n(\epsilon\mu-\epsilon N\upsilon)H_m(\epsilon\mu+\epsilon N\upsilon)\\&+2\pi\epsilon\sum_{\mu,\upsilon=-\infty}^{\infty}\exp\left[-\frac{2\pi}{N}\left(\mu+\frac{N}{2}\right)^2-2\pi N(\upsilon+1/2)^2\right]H_n(\epsilon\mu-\epsilon N\upsilon)H_m(\epsilon(\mu+\upsilon N+N)).\end{aligned}$$

Denoting the second term above by $(f_n,f_m)_{\text{odd}}$, if $N=2h+k$, where the binary variable k controls the parity of N, then

$$(f_n,f_m)_{\text{odd}}=2\pi\epsilon\sum_{\mu,\upsilon=-\infty}^{\infty}\exp\left[-\frac{2\pi}{N}(\mu+h+k/2)^2-2\pi N(\upsilon+1/2)^2\right]H_n(\epsilon\mu-\epsilon N\upsilon)H_m(\epsilon(\mu+\upsilon N+N))$$

and yet again shifting the sum on μ by $h+k/2$ and the one on ν by $1/2$,

$$(f_n,f_m)_{\text{odd}}=2\pi\epsilon\sum_{\mu=-\infty}^{\infty}(k)\sum_{\upsilon=-\infty}^{\infty}(1)\exp\left[-\frac{2\pi}{N}\mu^2-2\pi N\upsilon^2\right]H_n(\epsilon(\mu-N\upsilon))H_m(\epsilon(\mu+\upsilon N)),$$

where now $\Sigma_{\mu=-\infty}^{\infty}(k)$ denotes a sum over the integers (half-integers) if $k=0$ ($k=1$), so that back to the general expression,

$$\begin{aligned}(f_n,f_m)=&\,2\pi\epsilon\sum_{\mu,\upsilon=-\infty}^{\infty}\exp\left[-\frac{2\pi}{N}\mu^2-2\pi N\upsilon^2\right]H_n(\epsilon(\mu-N\upsilon))H_m(\epsilon(\mu+\upsilon N))\\&+2\pi\epsilon\sum_{\mu=-\infty}^{\infty}(k)\sum_{\upsilon=-\infty}^{\infty}(1)\exp\left[-\frac{2\pi}{N}\mu^2-2\pi N\upsilon^2\right]H_n(\epsilon(\mu-N\upsilon))H_m(\epsilon(\mu+\upsilon N)).\end{aligned}$$

Now, recourse to the Hermite polynomial's generating function gives

$$\begin{aligned}(f_n,f_m)=2\pi\epsilon\frac{\partial^n}{\partial t^n}\frac{\partial^m}{\partial s^m}\Bigg\{&\sum_{\mu,\upsilon=-\infty}^{\infty}\exp\left[-\frac{2\pi}{N}\mu^2+2\mu\epsilon(t+s)-2\epsilon\nu N(t-s)-t^2-s^2\right]\\&+\sum_{\mu=-\infty}^{\infty}(k)\sum_{\upsilon=-\infty}^{\infty}(1)\exp\left[-\frac{2\pi}{N}\mu^2+2\mu\epsilon(t+s)-2\epsilon\nu N(t-s)-t^2-s^2\right]\Bigg\}_{t=s=0}.\end{aligned}$$

The sum on $\{\mu\}$ results in a ϑ_3-function in the first term, and a ϑ_3 for $k=0$ or a ϑ_2 for $k=1$ in the second. The sum on $\{\nu\}$, by its turn, gives ϑ_3-function in the first term, and a ϑ_2 in the second, as

$$(f_n,f_m)=2\pi\epsilon\frac{\partial^n}{\partial t^n}\frac{\partial^m}{\partial s^m}\left\{\left[\vartheta_3\left(\frac{i\epsilon(t+s)}{\pi},\frac{2i}{N}\right)\vartheta_3\left(\frac{i\epsilon N(t-s)}{\pi},2Ni\right)+\vartheta_{3-k}\left(\frac{i\epsilon(t+s)}{\pi},\frac{2i}{N}\right)\vartheta_2\left(\frac{i\epsilon N(t-s)}{\pi},2Ni\right)\right]\exp[-t^2-s^2]\right\}\Bigg|_{t=s=0}.$$

Using the basic properties,

$$\vartheta_3(z,i\tau)=\tau^{-1/2}\exp\left[-\frac{\pi z^2}{\tau}\right]\vartheta_3\left(\frac{z}{i\tau},\frac{i}{\tau}\right),$$

$$\theta_2(z,i\tau)=\tau^{-1/2}\exp\left[-\frac{\pi z^2}{\tau}\right]\vartheta_4\left(\frac{z}{i\tau},\frac{i}{\tau}\right),$$

one gets

$$(f_n,f_m)=\frac{2\pi^{3/2}}{N}\frac{\partial^n}{\partial t^n}\frac{\partial^m}{\partial s^m}\left\{\left[\vartheta_3\left(\frac{i\epsilon(t+s)}{\pi},\frac{2i}{N}\right)\vartheta_3\left(\frac{\epsilon(t-s)}{2\pi},\frac{i}{2N}\right)+\vartheta_{3-k}\left(\frac{i\epsilon(t+s)}{\pi},\frac{2i}{N}\right)\vartheta_4\left(\frac{\epsilon(t-s)}{2\pi},\frac{i}{2N}\right)\right]\exp[-2ts]\right\}_{t=s=0}.$$

Finally, compact expressions can be achieved with

$$\theta_3(z,\tau)=\frac{1}{2}\left[\theta_3\left(\frac{z}{2},\frac{\tau}{4}\right)+\theta_4\left(\frac{z}{2},\frac{\tau}{4}\right)\right],$$

$$\theta_2(z,\tau)=\frac{1}{2}\left[\theta_3\left(\frac{z}{2},\frac{\tau}{4}\right)-\theta_4\left(\frac{z}{2},\frac{\tau}{4}\right)\right],$$

thus for $k=0$

$$(f_n,f_m)=\frac{\pi^{3/2}}{N}\frac{\partial^n}{\partial t^n}\frac{\partial^m}{\partial s^m}\ \vartheta_3\left(\frac{i\epsilon(t+s)}{\pi},\frac{2i}{N}\right)\vartheta_3\left(\frac{\epsilon(t-s)}{\pi},\frac{2i}{N}\right)\exp[-2ts]\Bigg|_{t=s=0}$$

and for $k=1$

$$(f_n,f_m)=\frac{\pi^{3/2}}{N}\frac{\partial^n}{\partial t^n}\frac{\partial^m}{\partial s^m}\left\{\vartheta_3\left(\frac{i\epsilon(t+s)}{\pi},\frac{2i}{N}\right)\vartheta_3\left(\frac{\epsilon(t-s)}{\pi},\frac{2i}{N}\right)-2\vartheta_4\left(\frac{i\epsilon(t+s)}{2\pi},\frac{i}{2N}\right)\vartheta_4\left(\frac{\epsilon(t-s)}{2\pi},\frac{i}{2N}\right)\exp[-2ts]\right\}_{t=s=0}.$$

Again, the limit $N\to\infty$ easily recovers the usual results, as the i factor inside the ϑ-functions guarantees that, in this limit, only a term proportional to $(\partial^n/\partial t^n)(\partial^m/\partial s^m)\exp[-4ts]|_{t=s=0}$ survives. Anyhow, with the above expressions any term (f_n,f_m) can be calculated as a sum of ϑ-function derivatives evaluated at zero. The particular situation $m=0$, for example, for N even, is quite instructive. In this case

$$(f_n,f_0)=\frac{\pi^{3/2}}{N}\frac{\partial^n}{\partial t^n}\vartheta_3\left(\frac{i\epsilon t}{\pi},\frac{2i}{N}\right)\vartheta_3\left(\frac{\epsilon t}{\pi},\frac{2i}{N}\right)_{t=0},$$

$$(f_n,f_0)= \frac{\pi^{3/2}}{N}\sum_{j=0}^{n}\binom{n}{j}i^j\frac{\partial^j}{\partial t^j}\vartheta_3\left(\frac{\epsilon t}{\pi},\frac{2i}{N}\right)\Bigg|_{t=0}\left(\frac{\partial^{n-j}}{\partial t^{n-j}}\vartheta_3\left(\frac{\epsilon t}{\pi},\frac{2i}{N}\right)\Bigg|_{t=0}\right),$$

and it is immediate to see that all n=odd terms are zero. For $n=2$ (and for all even numbers not multipliers of 4), the symmetry of the binomial term and the multiplicity of the powers of i lead to a pairwise cancellation of all non-zero terms. For $n=4$ (and its multipliers), the situation is different. The simplest case is $n=4$,

$$(f_4,f_0)= \frac{\pi^{3/2}}{N}\sum_{j=0}^{4}\binom{4}{j}i^j\frac{\partial^j}{\partial t^j}\vartheta_3\left(\frac{\epsilon t}{\pi},\frac{2i}{N}\right)\Bigg|_{t=0}\left[\frac{\partial^{4-j}}{\partial t^{4-j}}\vartheta_3\left(\frac{\epsilon t}{\pi},\frac{2i}{N}\right)\Bigg|_{t=0}\right]$$

$$(f_4,f_0)=\frac{\pi^{3/2}}{N}\left\{2\vartheta_3\left(0,\frac{2i}{N}\right)\vartheta_3'''\left(0,\frac{2i}{N}\right)-6\left[\vartheta_3''\left(0,\frac{2i}{N}\right)\right]^2\right\}.$$

This term (with proper normalization) goes to zero quite fast with increasing N. In fact, for $N=10$ it is already of order of 10^{-6}. On the other hand, it is immaterial to discuss the case $N=4$ (or smaller), as in this situation the distinct eigenvalues of the Fourier operator are enough to guarantee orthogonality of the whole set. Considering all this, it comes down to, literally, one-half a dozen different values of the dimensionality N (the range $[5,10]$) for which a significant deviation from the "expected" results (that is, orthogonality) can be observed.

IV. DFT AND WIDTH INVERSION

Starting from the own definition of the ϑ_3-function, Eq. (4), with $\xi\in\mathbf{R}$, a fractional shift of the ϑ_3 function can be calculated,

$$\vartheta_3\left(z+\frac{k}{N},\frac{i\xi^2}{N}\right)=\sum_{\alpha=-\infty}^{\infty}\exp\left[-\frac{\pi}{N}\xi^2\alpha^2\right]\exp\left[2\pi i\alpha\left(z+\frac{k}{N}\right)\right],$$

where k is an integer. The sum over $\{\alpha\}$ can be broken into modulo N equivalence classes as

$$\vartheta_3\left(z+\frac{k}{N},\frac{i\xi^2}{N}\right)=\sum_{j=0}^{N-1}\sum_{\beta=-\infty}^{\infty}\exp\left[-\frac{\pi}{N}\xi^2(j+\beta N)^2\right]\exp\left[2\pi i(j+\beta N)\left(z+\frac{k}{N}\right)\right].$$

Conveniently regrouping the terms one gets

$$\vartheta_3\left(z+\frac{k}{N},\frac{i\xi^2}{N}\right)=\sum_{j=0}^{N-1}\left(\sum_{\beta=-\infty}^{\infty}\exp\left[-\pi N\xi^2\beta^2\right]\exp\left[2\pi i\beta(i\xi^2 j+Nz)\right]\right)\times\exp\left[-\frac{\pi}{N}\xi^2 j^2+2\pi ijz+\frac{2\pi i}{N}jk\right],$$

where the term inside the brackets can be identified as ϑ_3-function,

$$\vartheta_3\left(z+\frac{k}{N},\frac{i\xi^2}{N}\right)=\sum_{j=0}^{N-1}\vartheta_3(i\xi^2 j+Nz,iN\xi^2)\exp\left[-\frac{\pi}{N}\xi^2 j^2+2\pi ijz+\frac{2\pi i}{N}jk\right].$$

Use of property (6) leads to

$$\vartheta_3\left(z+\frac{k}{N},\frac{i\xi^2}{N}\right)=\frac{1}{\sqrt{N\xi^2}}\sum_{j=0}^{N-1}\vartheta_3\left(\frac{iz}{\xi^2}-\frac{j}{N},\frac{i}{N\xi^2}\right)\exp\left[-\frac{\pi N}{\xi^2}z^2+\frac{2\pi i}{N}jk\right] \tag{10}$$

and taking advantage of the Fourier coefficients $\exp\left[\frac{2\pi i}{N}jk\right]$ it is easy to obtain the inverse relation

$$\vartheta_3\left(\frac{iz}{\xi^2}-\frac{k}{N},\frac{i}{N\xi^2}\right)=\sqrt{\frac{N}{\xi^2}}\sum_{j=0}^{N-1}\vartheta_3\left(z+\frac{j}{N},\frac{i\xi^2}{N}\right)\exp\left[\frac{\pi N}{\xi^2}z^2-\frac{2\pi i}{N}jk\right]. \tag{11}$$

Particular cases of these equations are most interesting, and a lot of peculiar relations can be obtained with the different possible choices of z,k and ξ. Two straightforward examples are: First, setting $z=0$ in (10),

$$\vartheta_3\left(\frac{k}{N},\frac{i\xi^2}{N}\right)=\frac{1}{\sqrt{N}}\sum_{j=0}^{N-1}\vartheta_3\left(\frac{j}{N},\frac{i}{N\xi^2}\right)\exp\left[\frac{2\pi i}{N}jk\right], \tag{12}$$

and, according to Eq. (7), the ϑ_3-function on the left-hand side has width ξ, while the one under the action of the DFT has width ξ^{-1}. This property is the obvious discrete counterpart of the well-known behavior of the Gaussian function under the usual Fourier transform.

The case $k=0$, by its turn, after some manipulation gives

$$\vartheta_3(Nz,iN\xi^2)=\sqrt{\frac{N}{\xi^2}}\sum_{j=0}^{N-1}\vartheta_3\left(z+\frac{j}{N},\frac{i\xi^2}{N}\right).$$

A. Application

With the above results it is possible to generalize the result of Ref. 6 in a straightforward way. Introducing

$$f_n(j,\xi)=\sqrt{\frac{N}{\xi}}\ \frac{\partial^n}{\partial t^n}\vartheta_3\left(\frac{j}{N}-\frac{\epsilon}{\pi}\xi t,\frac{i\xi^2}{N}\right)\exp[t^2]\Big|_{t=0},$$

its DFT can be directly calculated,

$$\overline{f_n}(k,\xi)=\frac{1}{\sqrt{N}}\sum_{j=0}^{N-1}\exp\left[\frac{2\pi i}{N}jk\right]f_n(j,\xi),$$

$$\overline{f_n}(k,\xi)=\frac{1}{\sqrt{\xi}}\frac{\partial^n}{\partial t^n}\sum_{j=0}^{N-1}\exp\left[\frac{2\pi i}{N}jk\right]\ \vartheta_3\left(\frac{j}{N}-\frac{\epsilon}{\pi}\xi t,\frac{i\xi^2}{N}\right)\exp[t^2]\Big|_{t=0},$$

and use of Eq. (11) together with change of variables from t to it leads to

$$\overline{f_n}(k,\xi)=\sqrt{N\xi}i^n\frac{\partial^n}{\partial t^n}\ \vartheta_3\left(\frac{k}{N}-\frac{\epsilon t}{\pi\xi},\frac{i}{N\xi^2}\right)\exp[t^2]\Big|_{t=0},$$

thus

$$f_n(k,\xi^{-1})=i^n\sum_{j=0}^{N-1}\exp\left[\frac{2\pi i}{N}jk\right]f_n(j,\xi), \tag{13}$$

which reproduces Eq. (1) for $\xi=1$. From this relation, most identities obtained in Ref. 6 may also be generalized.

V. TWO VARIABLE'S DFT

Yet another generalization of the main result of Ref. 6 regards a two variable DFT, which, for the sake of briefness, here it will be merely verified. Apart from the obvious product solution $f_m(j)f_n(l)$, if one considers the quantity

$$F_{m,n}(j,l)=\sum_{k=0}^{N-1} f_m(k)f_n(k-l)\exp\left[\frac{2\pi i}{N}jk\right],$$

which obeys

$$(F_{m,n}(j,l))^*=F_{m,n}(j,l)\exp\left[\frac{2\pi i}{N}jl\right],$$

use of Eq. (1), and some simple manipulations lead to the nontrivial result

$$|F_{m,n}(j,l)|^2=\frac{(-i)^{m+n}}{N}\sum_{a,b=0}^{N-1}|F_{m,n}(a,b)|^2\exp\left[\frac{2\pi i}{N}(ma+nb)\right].$$

As in the one variable case, these states obey

$$\sum_{j,l=0}^{N-1}|F_{m,n}(j,l)|^2|F_{m',n'}(j,l)|^2=\delta_{m,m'}\delta_{n,n'},\quad m+n\neq m'+n'(\mathrm{mod}\,4),$$

which imply a multitude of relations involving derivatives of the ϑ_3-functions (or the Hermite polynomials). Motivated by the preceding section, it should be investigated whether this relation holds for $m+n=m'+n'(\mathrm{mod}\,4)$.

VI. FURTHER RELATIONS INVOLVING THE WIDTH

So far it has been seen that to break up the infinite sum present in the definition of the Jacobi ϑ_3-function leads to interesting properties of this very function. In order to further explore this technique, from Eq. (7) it is straightforward to write

$$\vartheta_3\left(\frac{z}{L},\frac{i\xi^2}{L}\right)=\frac{\sqrt{L}}{\xi}\sum_{\alpha=-\infty}^{\infty}\exp\left[-L\pi\left(\frac{z}{\xi L}+\frac{\alpha}{\xi}\right)^2\right],\tag{14}$$

with L a positive real number. Choosing ξ integer, it is possible to break the sum over $\{\alpha\}$ into modulo ξ equivalence classes

$$\vartheta_3\left(\frac{z}{L},\frac{i\xi^2}{L}\right)=\frac{\sqrt{L}}{\xi}\sum_{j=0}^{\xi-1}\sum_{\mu=-\infty}^{\infty}\exp\left[-L\pi\left(\frac{z}{\xi L}+\frac{j+\mu\xi}{\xi}\right)^2\right],$$

$$\vartheta_3\left(\frac{z}{L},\frac{i\xi^2}{L}\right)=\frac{\sqrt{L}}{\xi}\sum_{j=0}^{\xi-1}\sum_{\mu=-\infty}^{\infty}\exp\left[-L\pi\left(\frac{z+jL}{\xi L}+\mu\right)^2\right],$$

and the infinite sum can be identified as a ϑ_3,

$$\vartheta_3\left(\frac{z}{L},\frac{i\xi^2}{L}\right)=\frac{1}{\xi}\sum_{j=0}^{\xi-1}\vartheta_3\left(\frac{z+jL}{\xi L},\frac{i}{L}\right).\tag{15}$$

It is quite interesting to set $z=z\xi$ above and observe that

$$\vartheta_3\left(\frac{z\xi}{L},\frac{i\xi^2}{L}\right)=\frac{1}{\xi}\sum_{j=0}^{\xi-1}\vartheta_3\left(\frac{z}{L}+\frac{j}{\xi},\frac{i}{L}\right),$$

which, for the particular case $\xi=2$ gives the well-known result

$$\vartheta_3\left(\frac{2z}{L},\frac{4i}{L}\right)=\frac{1}{2}\left[\vartheta_3\left(\frac{z}{L},\frac{i}{L}\right)+\vartheta_3\left(\frac{z}{L}+\frac{1}{2},\frac{i}{L}\right)\right],$$

$$\vartheta_3\left(\frac{2z}{L},\frac{4i}{L}\right)=\frac{1}{2}\left[\vartheta_3\left(\frac{z}{L},\frac{i}{L}\right)+\vartheta_4\left(\frac{z}{L},\frac{i}{L}\right)\right].$$

Similar reasoning would lead to the complementary relation

$$\vartheta_3\left(\frac{z}{L},\frac{i}{L}\right)=\frac{1}{\xi}\sum_{j=0}^{\xi-1}\vartheta_3\left(\frac{z}{\xi L}+\frac{j}{\xi},\frac{i}{L\xi^2}\right). \tag{16}$$

And again, the particular case $\xi=2$ gives

$$\vartheta_3\left(\frac{z}{L},\frac{i}{L}\right)=\frac{1}{2}\left[\vartheta_3\left(\frac{z}{2L},\frac{i}{4L}\right)+\vartheta_4\left(\frac{z}{2L},\frac{i}{4L}\right)\right].$$

Equations (15) and (16) can be combined to provide an alternative width inversion relation

$$\vartheta_3\left(\frac{z\xi}{L},\frac{i\xi^2}{L}\right)=\frac{1}{\xi^2}\sum_{j,j'=0}^{\xi-1}\vartheta_3\left(\frac{z}{\xi L}+\frac{j'}{\xi}+\frac{j}{\xi^2},\frac{i}{L\xi^2}\right).$$

VII. CONCLUSIONS

The results here presented seem to argue in favor of one basic point: The Jacobi ϑ_3-function, together with the DFT, plays, in finite dimensional spaces, the same role played by the Gaussian function in conjunction with the usual Fourier transform. Concerning quantum mechanics, Schwinger has already noted that, if the families of eigenstates of two different observables are connected *via* DFT, then those observables share a maximum degree of incompatibility.[5] In this connection, the width inversion relation obeyed by the $f_n(j,\xi)$ functions strongly suggests that one may be able to construct, for finite dimensional spaces, states which behavior resembles that of the continuous minimum uncertainty states.

However, such a reasoning meets an important hindrance if one considers that the orthogonality of the DFT's eigenstates ultimately fails. It is a fact, however, that with increasing N it becomes, in a numerical sense, true, and in this case the $N\to\infty$ limit is reached, as witty as it may sound, somewhere near one dozen. This fact may illustrate a true finite dimensional idiosyncrasy, or it might lead one to look for the possibility of finding different sets of DFT's eigenstates, an issue which is a matter of current research.

(Received 19 January 2006; accepted 4 May 2006; published online 29 June 2006)

The inverse scattering transform for the vector defocusing nonlinear Schrödinger (NLS) equation with nonvanishing boundary values at infinity is constructed. The direct scattering problem is formulated on a two-sheeted covering of the complex plane. Two out of the six Jost eigenfunctions, however, do not admit an analytic extension on either sheet of the Riemann surface. Therefore, a suitable modification of both the direct and the inverse problem formulations is necessary. On the direct side, this is accomplished by constructing two additional analytic eigenfunctions which are expressed in terms of the adjoint eigenfunctions. The discrete spectrum, bound states and symmetries of the direct problem are then discussed. In the most general situation, a discrete eigenvalue corresponds to a quartet of zeros (poles) of certain scattering data. The inverse scattering problem is formulated in terms of a generalized Riemann-Hilbert (RH) problem in the upper/lower half planes of a suitable uniformization variable. Special soliton solutions are constructed from the poles in the RH problem, and include dark-dark soliton solutions, which have dark solitonic behavior in both components, as well as dark-bright soliton solutions, which have one dark and one bright component. The linear limit is obtained from the RH problem and is shown to correspond to the Fourier transform solution obtained from the linearized vector NLS system. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2209169]

I. INTRODUCTION

The inverse scattering transform (IST) for the scalar nonlinear Schrödinger (NLS) equation

$$iq_t = q_{xx} - 2\sigma|q|^2 q \tag{1.1}$$

(subscripts x and t denote partial differentiation throughout) has been extensively studied in the literature, both in the focusing ($\sigma=-1$) and in the defocusing ($\sigma=1$) cases.[1–3] In particular, the defocusing case with nonvanishing boundary conditions was first studied in 1973;[4] the problem was subsequently clarified and generalized in various works,[5–10] and a detailed study can be found in the monograph.[11] Equation (1.1) with $\sigma=1$ admits soliton solutions with nontrivial boundary conditions, the so-called dark/gray solitons, which have the form

$$q(x,t) = q_0 e^{2iq_0^2 t}[\cos\alpha + i\sin\alpha\tanh[\sin\alpha q_0(x - 2q_0\cos\alpha t - x_0)]] \tag{1.2}$$

with q_0, α and x_0 arbitrary real parameters. Such solutions satisfy the boundary conditions

$$q(x,t) \to q_{\pm}(t) = q_0 e^{2iq_0^2 t \pm i\alpha} \quad \text{as } x \to \pm\infty$$

and appear as localized dips of intensity $q_0^2 \sin^2 \alpha$ on the background field q_0.

While the IST for the scalar NLS equation was developed many years ago, both with vanishing and nonvanishing boundary conditions, the basic formulation of IST has not been fully developed for the vector nonlinear Schrödinger (VNLS) equation

$$i\mathbf{q}_t = \mathbf{q}_{xx} - 2\sigma\|\mathbf{q}\|^2\mathbf{q}, \tag{1.3}$$

where $\mathbf{q}=\mathbf{q}(x,t)$ is, in general, an M-component vector and $\|\cdot\|$ is the standard Euclidean norm. The focusing case ($\sigma=-1$) with vanishing boundary conditions in two components was developed by Manakov in 1974.[12] However, the IST for the VNLS with nonzero boundary conditions has been open for over 30 years (partial results can be found in Ref. 13). It is worth noting that Ref. 14 provides an elegant direct and inverse scattering theory for decaying potentials on the real line. The extension to nondecaying potentials, however, is not straightforward and therefore here we employ a different approach. We should also remark that direct methods have been applied to VNLS as a way to derive explicit bright and dark soliton solutions, see for instance Refs. 17–20 and the review article Ref. 21.

In this work we present the IST for the two-component defocusing VNLS equation [namely, Eq. (1.3) with $\sigma=1$ and $M=2$] with nonvanishing boundary conditions as $x\to\pm\infty$. In Sec. II we discuss the direct scattering problem. Section II A is devoted to the study of the analyticity of the scattering eigenfunctions. Similar to the scalar equation, the spectral parameter of the associated block-matrix scattering problem for the VNLS is an element of a two-sheeted Riemann surface. The vector problem however presents additional difficulties due, in part, to the fact that two out of the six scattering eigenfunctions, defined via their asymptotics at infinity, do not admit an analytic extension on either sheet of the surface. Therefore a suitable modification both of the direct and of the inverse problem is necessary. On the direct side, this is achieved by defining in Sec. II B an "adjoint" scattering problem, which provides two additional analytic solutions of the original scattering problem. In Sec. II C we study the symmetries, and in Sec. II D we introduce a uniformization variable. In Sec. II E we study the asymptotic behavior of the eigenfunctions for large values of the scattering parameter, and in Sec. II F we discuss the discrete spectrum. The inverse problem is formulated in Sec. III as a Riemann-Hilbert (RH) problem associated with analytic eigenfunctions. The RH problem is then transformed into a closed linear system of algebraic-integral equations. The time evolution of the scattering data and the conserved quantities are discussed in Sec. IV. Explicit solutions are obtained in Sec. V; they include vector generalization of the dark and gray soliton solutions of the scalar case as well as more exotic dark-bright soliton solutions. Finally, in Sec. VI the linearized solution of the VNLS equation is obtained and found to be consistent with that of the RH formulation, and in the Appendix we discuss the WKB expansion of the eigenfunctions at large values of the scattering parameter.

II. DIRECT PROBLEM

It is well-known[12] that the two-component defocusing VNLS equation (1.3) with $\sigma=1$ and $M=2$ is associated to the Lax pair

$$v_x = (ik\mathbf{J} + \mathbf{Q})v, \tag{2.1a}$$

$$v_t = \begin{pmatrix} 2ik^2 + i\mathbf{q}^T\mathbf{r} & -2k\mathbf{q}^T - i\mathbf{q}_x^T \\ -2k\mathbf{r} + i\mathbf{r}_x & -2ik^2\mathbf{I}_2 - i\mathbf{r}\mathbf{q}^T \end{pmatrix} v, \tag{2.1b}$$

where $v(x,t,k)=(v^{(1)}(x,t,k),v^{(2)}(x,t,k),v^{(3)}(x,t,k))^T$ is the scattering eigenfunction, k is the scattering parameter, $\mathbf{q}(x,t)=(q^{(1)}(x,t),q^{(2)}(x,t))^T$ and $\mathbf{r}(x,t)=(r^{(1)}(x,t),r^{(2)}(x,t))^T=\mathbf{q}^*(x,t)$ are the scattering potentials, $\mathbf{I}_N$ is the $N\times N$ identity matrix, the superscript T denotes matrix transpose, and where

$$\mathbf{J} = \mathrm{diag}(-1,1,1), \quad \mathbf{Q}(x,t) = \begin{pmatrix} 0 & \mathbf{q}^T \\ \mathbf{r} & 0_{2\times 2} \end{pmatrix}. \tag{2.2}$$

Explicitly, the compatibility of the system of equations (2.1) (i.e., the equality of the mixed derivatives of the 3-component vector v with respect to x and t), together with the constraint $\mathbf{r}=\mathbf{q}^*$, is equivalent to the requirement that $\mathbf{q}(x,t)$ satisfy Eq. (1.3) with $\sigma=1$. Throughout this work, we consider potentials with the same time-independent amplitudes at both space infinities, which we can write without loss of generality as

$$\mathbf{q}(x,t) \sim \mathbf{q}_\pm(t) = e^{i\Theta_\pm(t)}\mathbf{q}_0, \quad \mathbf{r}(x,t) \sim \mathbf{r}_\pm(t) = e^{-i\Theta_\pm(t)}\mathbf{q}_0, \quad x \to \pm\infty, \tag{2.3}$$

where $\Theta_\pm(t)=\mathrm{diag}(\theta_\pm^{(1)},\theta_\pm^{(2)})$ and $\mathbf{q}_0=(q_0^{(1)},q_0^{(2)})^T \in \mathbb{R}^+\times\mathbb{R}^+$, and where $\|\mathbf{q}_0\|=\sqrt{(q_0^{(1)})^2+(q_0^{(2)})^2}$ is assumed to be non-zero. For brevity, in the following we will use $q_0=\|\mathbf{q}_0\|$.

A. Eigenfunctions, integral equations and analyticity

The eigenfunctions for the scattering problem (2.1a) with boundary conditions (2.3) are introduced by fixing the large-x asymptotics for $k\in\mathbb{R}$ with $|k|\geqslant q_0$,

$$\phi_1(x,k) \sim w_1^-(k)e^{-i\lambda x}, \quad \phi_2(x,k) \sim w_2^-(k)e^{ikx}, \quad \phi_3(x,k) \sim w_3^-(k)e^{i\lambda x}, \quad x\to-\infty, \tag{2.4a}$$

$$\psi_1(x,k) \sim w_1^+(k)e^{-i\lambda x}, \quad \psi_2(x,k) \sim w_2^+(k)e^{ikx}, \quad \psi_3(x,k) \sim w_3^+(k)e^{i\lambda x}, \quad x\to+\infty, \tag{2.4b}$$

where $\lambda(k)=\sqrt{k^2-q_0^2}$, the eigenvectors $w_1^\pm(k), w_2^\pm(k), w_3^\pm(k)$ are given by

$$w_1^-(k) = \begin{pmatrix} \lambda+k \\ i\mathbf{r}_- \end{pmatrix}, \quad w_2^-(k) = \begin{pmatrix} 0 \\ -i\mathbf{q}_-^\perp \end{pmatrix}, \quad w_3^-(k) = \begin{pmatrix} \lambda-k \\ -i\mathbf{r}_- \end{pmatrix}, \tag{2.5a}$$

$$w_1^+(k) = \begin{pmatrix} \lambda+k \\ i\mathbf{r}_+ \end{pmatrix}, \quad w_2^+(k) = \begin{pmatrix} 0 \\ -i\mathbf{q}_+^\perp \end{pmatrix}, \quad w_3^+(k) = \begin{pmatrix} \lambda-k \\ -i\mathbf{r}_+ \end{pmatrix}, \tag{2.5b}$$

and where we introduced a notation which we will use throughout this work: for any two-component vector $\mathbf{p}=(p^{(1)},p^{(2)})^T$ we write $\mathbf{p}^\perp=(p^{(2)},-p^{(1)})^T$. Note that for brevity we will omit the time dependence of the potentials and eigenfunctions throughout the discussion of the direct problem.

The Wronskian of a set $\{v_1,v_2,v_3\}$ of solutions of the scattering problem (2.1a) is defined in the usual way as

$$\mathrm{Wr}(v_1,v_2,v_3) = \det(v_1,v_2,v_3),$$

and satisfies the equation $d[\mathrm{Wr}(v_1,v_2,v_3)]/dx = ik\,\mathrm{Wr}(v_1,v_2,v_3)$. Taking into account the asymptotic behavior of the solutions in Eq. (2.4) we then have

$$\mathrm{Wr}(\phi_1,\phi_2,\phi_3) = \mathrm{Wr}(\psi_1,\psi_2,\psi_3) = -2\lambda q_0^2 e^{ikx}. \tag{2.6}$$

Hence, for any nondecaying potential $\mathbf{q}(x,t)$, the two Wronskians in Eq. (2.6) are nonzero for all $x\in\mathbb{R}$ and all k such that $\lambda(k)\neq 0$ (i.e., everywhere except at the branch points of λ). We also introduce the solutions with fixed (with respect to x) boundary conditions

$$M_1(x,k) = e^{i\lambda x}\phi_1(x,k), \quad M_2(x,k) = e^{-ikx}\phi_2(x,k), \quad M_3(x,k) = e^{-i\lambda x}\phi_3(x,k), \tag{2.7a}$$

$$N_1(x,k) = e^{i\lambda x}\psi_1(x,k), \quad N_2(x,k) = e^{-ikx}\psi_2(x,k), \quad N_3(x,k) = e^{-i\lambda x}\psi_3(x,k), \tag{2.7b}$$

which can be represented in terms of the integral equations

$$M_j(x,k) = w_j^-(k) + \int_{-\infty}^{\infty} \mathbf{G}_j^-(x-x',k)(\mathbf{Q}(x') - \mathbf{Q}_-)M_j(x',k)\mathrm{d}x', \tag{2.8a}$$

$$N_j(x,k) = w_j^+(k) + \int_{-\infty}^{\infty} \mathbf{G}_j^+(x-x',k)(\mathbf{Q}(x') - \mathbf{Q}_+)N_j(x',k)\mathrm{d}x' \tag{2.8b}$$

for $j=1,2,3$, where

$$\mathbf{Q}_\pm = \begin{pmatrix} 0 & \mathbf{q}_\pm^T \\ \mathbf{r}_\pm & 0_{2\times 2} \end{pmatrix}, \tag{2.9}$$

and where the matrix Green's functions $\mathbf{G}_j^\pm(x,k)$ are defined below. The choice of Green's functions, together with the choice of the inhomogeneous terms in Eqs. (2.8), determine the analytic properties of the corresponding eigenfunctions. The superscripts $\pm$ in the Green's functions, like in the inhomogeneous terms, refer to the corresponding eigenfunctions being defined in terms of their asymptotics as $x \to \pm\infty$.

Using the Fourier transform technique, one can show that

$$\begin{aligned}\mathbf{G}_1^\mp(x,k) = \pm\,\theta(\pm x)\Bigg\{ & \frac{1}{2\lambda(\lambda+k)}[(\lambda+k)(\lambda\mathbf{I}_3 - k\mathbf{J}) + i(\lambda+k)\mathbf{Q}_\mp + \widetilde{\mathbf{Q}}_\mp] + \frac{e^{2i\lambda x}}{2\lambda(\lambda-k)}[(\lambda-k)(\lambda\mathbf{I}_3 \\ & + k\mathbf{J}) - i(\lambda-k)\mathbf{Q}_\mp + \widetilde{\mathbf{Q}}_\mp] + \frac{e^{i(\lambda+k)x}}{q_0^2}\widetilde{\mathbf{Q}}_\mp\Bigg\},\end{aligned} \tag{2.10a}$$

$$\begin{aligned}\mathbf{G}_3^\mp(x,k) = \pm\,\theta(\pm x)\Bigg\{ & \frac{1}{2\lambda(\lambda-k)}[(\lambda-k)(\lambda\mathbf{I}_3 + k\mathbf{J}) - i(\lambda-k)\mathbf{Q}_\mp + \widetilde{\mathbf{Q}}_\mp] + \frac{e^{-2i\lambda x}}{2\lambda(\lambda+k)}[(\lambda+k)(\lambda\mathbf{I}_3 \\ & - k\mathbf{J}) + i(\lambda+k)\mathbf{Q}_\mp + \widetilde{\mathbf{Q}}_\mp] + \frac{e^{-i(\lambda-k)x}}{q_0^2}\widetilde{\mathbf{Q}}_\mp\Bigg\},\end{aligned} \tag{2.10b}$$

$$\begin{aligned}\mathbf{G}_2^\mp(x,k) = \pm\,\theta(\pm x)\Bigg\{ & \frac{e^{-i(\lambda+k)x}}{2\lambda(\lambda+k)}[(\lambda+k)(\lambda\mathbf{I}_3 - k\mathbf{J}) + i(\lambda+k)\mathbf{Q}_\mp + \widetilde{\mathbf{Q}}_\mp] + \frac{e^{i(\lambda-k)x}}{2\lambda(\lambda-k)}[(\lambda-k)(\lambda\mathbf{I}_3 \\ & + k\mathbf{J}) - i(\lambda-k)\mathbf{Q}_\mp + \widetilde{\mathbf{Q}}_\mp] + \frac{1}{q_0^2}\widetilde{\mathbf{Q}}_\mp\Bigg\},\end{aligned} \tag{2.10c}$$

where

$$\widetilde{\mathbf{Q}}_\pm = \begin{pmatrix} 0 & \mathbf{0}_{1\times 2} \\ \mathbf{0}_{2\times 1} & \mathbf{q}_\pm^\perp(\mathbf{r}_\pm^\perp)^T \end{pmatrix} \equiv \begin{pmatrix} 0 & 0 & 0 \\ 0 & q_\pm^{(2)} r_\pm^{(2)} & -r_\pm^{(1)} q_\pm^{(2)} \\ 0 & -r_\pm^{(2)} q_\pm^{(1)} & r_\pm^{(1)} q_\pm^{(1)} \end{pmatrix}. \tag{2.11}$$

Note that Eqs. (2.10) are significantly more complicated than the case of the vector system with zero boundary conditions (e.g., see Ref. 22).

So far, the integral equations and Green's functions are only defined for real k and λ. In order to extend the eigenfunctions to complex values of k, we note that, for instance, the Green's function $\mathbf{G}_1^-(x,k)$ does not grow exponentially as $|k| \to \infty$ if and only if

$$\mathrm{Im}\,\lambda \geqslant 0 \quad \text{and } \mathrm{Im}(\lambda+k) \geqslant 0. \tag{2.12a}$$

Similarly, $\mathbf{G}_1^+(x,k)$ does not grow exponentially as $|k| \to \infty$ if and only if

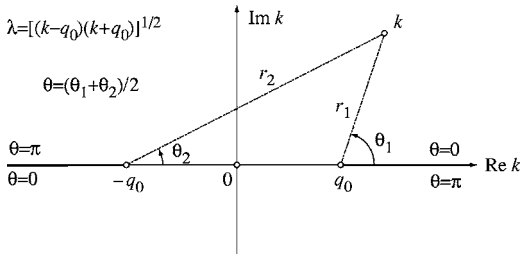

FIG. 1. The choice of branch cut for $\lambda=(k^2-q_0^2)^{1/2}$ in the complex k-plane. Here $\theta=(\theta_1+\theta_2)/2$.

$$\mathrm{Im}\,\lambda \leqslant 0 \quad \text{and } \mathrm{Im}(\lambda + k) \leqslant 0. \tag{2.12b}$$

It is therefore natural to introduce the Riemann surface of equation $\lambda^2=k^2-q_0^2$ obtained by gluing together two copies of the extended complex k-plane, which we will call $\mathbb{C}_1$ and $\mathbb{C}_2$, cut along the semilines $(-\infty,-q_0)$ and (q_0,∞).

On $\mathbb{C}_1$ one can introduce the local polar coordinates

$$k-q_0=r_1e^{i\theta_1}, \quad 0 \leqslant \theta_1 < 2\pi,$$

$$k+q_0=r_2e^{i\theta_2}, \quad -\pi \leqslant \theta_2 < \pi$$

with the magnitudes r_1 and r_2 uniquely fixed by the location of the point k: $r_1=|k-q_0|$ and $r_2=|k+q_0|$ (cf. Fig. 1). Then one can define

$$\lambda(k)=(r_1r_2)^{1/2}e^{i(\theta_1+\theta_2)/2}. \tag{2.13}$$

If $\theta=(\theta_1+\theta_2)/2$, then θ varies continuously between 0 and π both in the upper and in the lower k-planes, with a cut in the region $(-\infty,-q_0)\cup(q_0,\infty)$, and one has $\mathrm{Im}\,\lambda \geqslant 0$ and $\mathrm{Im}(\lambda \pm k) \geqslant 0$ for all $k \in \mathbb{C}_1$. Conversely, on $\mathbb{C}_2$ one defines

$$\lambda(k)=-(r_1r_2)^{1/2}e^{i(\theta_1+\theta_2)/2}, \tag{2.14}$$

which will give $\mathrm{Im}\,\lambda \leqslant 0$ and also $\mathrm{Im}(\lambda \pm k) \leqslant 0$, again with a cut in the region $(-\infty, -q_0)\cup(q_0,\infty)$. The upper branches of the cuts on sheet $\mathbb{C}_1$ are then glued with the lower branches on sheet $\mathbb{C}_2$ and vice versa as shown in Fig. 2(a).

With the above definitions, both conditions (2.12a) are satisfied if and only if k is on the upper sheet of the Riemann surface, and both conditions (2.12b) if and only if k is on the lower sheet. For potentials that rapidly approach $\mathbf{Q}_\pm$ as $x \to \pm\infty$, the Green's function $\mathbf{G}_1^-(x,k)$ then defines via Eq. (2.8a) an eigenfunction $M_1(x,k)$ which admits analytic extension on the entire upper sheet of the Riemann surface. Similarly, for suitable potentials the eigenfunction $N_1(x,k)$ defined by $\mathbf{G}_1^+(x,k)$ via Eq. (2.8b) admits analytic extension on the entire lower sheet. In a similar way one can investigate the properties of the remaining Green's functions. Overall we conclude that the eigenfunctions $M_1(x,k)=\phi_1(x,k)e^{i\lambda x}$ and $N_3(x,k)=\psi_3(x,k)e^{-i\lambda x}$ *are analytic on the upper sheet*, and $M_3(x,k)=\phi_3(x,k)e^{-i\lambda x}$ and $N_1(x,k)=\psi_1(x,k)e^{i\lambda x}$ *are analytic on the lower sheet*. Unlike the case of vanishing boundaries, however, the remaining two eigenfunctions, namely $M_2(x,k)$ and $N_2(x,k)$, in general are analytic neither on the upper nor on the lower sheet.

Equation (2.6) shows that for all real $k \neq \pm q_0$, the two matrices $\Phi(x,k)=(\phi_1,\phi_2,\phi_3)$ and $\Psi(x,k)=(\psi_1,\psi_2,\psi_3)$ each contain a set of three linearly independent solutions of the third-order scattering problem (2.4a). Thus it must be possible to express one set of solutions as a linear combination of the other, where the coefficients depend on k but are independent of x:

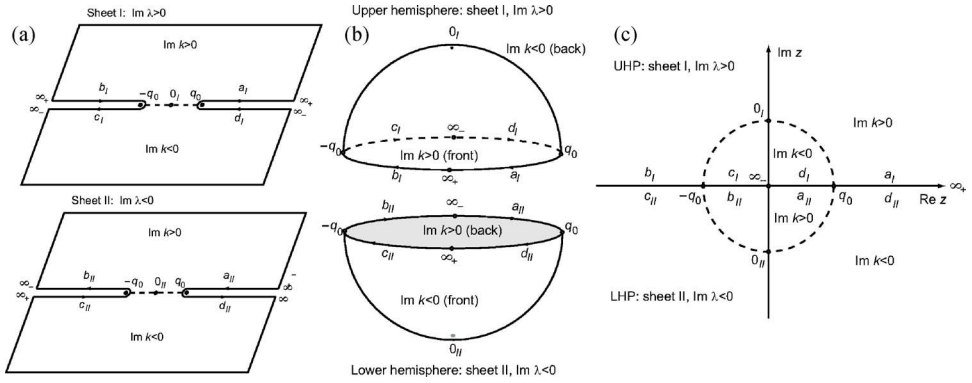

FIG. 2. (a) The two-sheeted covering of the complex plane defined by the scattering parameters (k,λ). (b) The topologically equivalent genus-0 Riemann sphere. (c) The corresponding complex plane for the uniformization variable $z=k+\lambda$ (which will be introduced in Sec. II D).

$$\Phi(x,k) = \Psi(x,k)\mathbf{A}^T(k), \tag{2.15a}$$

where $\mathbf{A}(k)=(a_{ij})$ is the 3×3 matrix of scattering coefficients. That is, $\phi_1(x,k)=a_{11}(k)\psi_1(x,k)+a_{12}(k)\psi_2(x,k)+a_{13}(k)\psi_3(x,k)$, with similar expressions for $\phi_2(x,k)$ and $\phi_3(x,k)$. Note that Eqs. (2.6) imply $\det(\mathbf{A})=1$. We can also express the "right" eigenfunctions in terms of the "left" ones,

$$\Psi(x,k) = \Phi(x,k)\mathbf{B}^T(k), \tag{2.15b}$$

where $\mathbf{B}(k)=(b_{ij})=\mathbf{A}^{-1}(k)$. Note that the scattering coefficients $a_{ij}(k)$ and $b_{ij}(k)$ are in general only defined where all of the eigenfunctions are, i.e., for $k\in\mathbb{R}$ and $|k|>q_0$, or, more precisely, on the oriented half-lines defined in Fig. 2, namely on $a_{\mathrm{I}}\equiv d_{\mathrm{II}}$, $b_{\mathrm{I}}\equiv c_{\mathrm{II}}$, $c_{\mathrm{I}}\equiv b_{\mathrm{II}}$, and $d_{\mathrm{I}}\equiv a_{\mathrm{II}}$. Note also that upper and lower banks of the cut are not equivalent, because both $\lambda(k)$ and the scattering eigenfunctions are discontinuous along the cut. These semilines define the contour $\mathcal{L}=a_{\mathrm{I}}\cup b_{\mathrm{I}}\cup c_{\mathrm{I}}\cup d_{\mathrm{I}}\equiv d_{\mathrm{II}}\cup c_{\mathrm{II}}\cup b_{\mathrm{II}}\cup a_{\mathrm{II}}$ namely $\mathcal{L}=(q_0+i0,\infty+i0)\cup(-\infty+i0,-q_0+i0)\cup-(-q_0-i0,-\infty-i0)\cup-(\infty-i0,q_0-i0)$ on the upper sheet.

Some of the scattering coefficients can be analytically extended off the real axis. From Eqs. (2.15) one can derive Wronskian representations for the scattering coefficients. Unlike the scalar case, however, such representations are not definitive in order to establish analyticity, since they all involve either $\phi_2(x,k)$ and/or $\psi_2(x,k)$, which do not admit analytic continuation. However, one can derive alternative representations for the scattering coefficients that provide the analytic extension sought for. For instance, using the first column of Eq. (2.15a) and the asymptotics (2.4b), one can check that

$$a_{11}(k) = \frac{1}{2\lambda(\lambda+k)} \lim_{x\to+\infty} e^{i\lambda x}[(\lambda+k)\phi_1^{(1)}(x,k) + iq_+^{(1)}\phi_1^{(2)}(x,k) + iq_+^{(2)}\phi_1^{(3)}(x,k)], \tag{2.16}$$

and since this expression for $a_{11}(k)$ only depends on the components of the vector $e^{i\lambda x}\phi_1(x,k)$, it indicates that for suitable potentials $a_{11}(k)$ can be analytically extended on the upper sheet of the Riemann surface. Similarly one finds that $a_{33}(k)$ and $b_{11}(k)$ can be analytically extended on the lower sheet of the Riemann surface, and $b_{33}(k)$ can be extended on the upper sheet of the Riemann surface. In general, however, the remaining scattering coefficients do not have any special analyticity properties.

The problem of determining the class of potentials for which a limit like (2.16) (with respect to a parameter, here x) of an analytic function of k is still an analytic function of k, is beyond the scope of this paper. We point out that this result is true for all the special solutions considered in this work.

B. Adjoint problem and auxiliary eigenfunctions

In order to formulate and solve the inverse scattering problem, one needs two independent sets of analytic eigenfunctions. The main issue at this stage is eliminating the nonanalytic eigenfunctions ϕ_2 and ψ_2. The approach introduced by Kaup in Ref. 15 for investigating the three-wave interaction is generalized here in order to obtain a representation of the nonanalytic eigenfunctions in terms of analytic eigenfunctions and scattering data. The key idea is to consider the "adjoint" eigenvalue problem

$$v_x^{\mathrm{ad}} = (-ik\mathbf{J} + \mathbf{Q}^T)v^{\mathrm{ad}} \tag{2.17}$$

where $\mathbf{Q}$ and $\mathbf{J}$ are defined in Eq. (2.2). One then recalls the well-known fact (see, for instance Ref. 16) that if $u^{\mathrm{ad}}(x,k)$ and $w^{\mathrm{ad}}(x,k)$ are two arbitrary solutions of the adjoint problem (2.17), then

$$v(x,k) = -\mathbf{J}(u^{\mathrm{ad}}(x,k) \wedge w^{\mathrm{ad}}(x,k))e^{ikx}, \tag{2.18}$$

where $\wedge$ denotes the vector product, is a solution of the original scattering problem (2.1a). As before, one defines two sets of solutions of Eq. (2.17), i.e., as $x \to -\infty$

$$\phi_1^{\mathrm{ad}}(x,k) \sim \begin{pmatrix} \lambda + k \\ -i\mathbf{q}_- \end{pmatrix} e^{i\lambda x}, \quad \phi_2^{\mathrm{ad}}(x,k) \sim \begin{pmatrix} 0 \\ i\mathbf{r}_-^{\perp} \end{pmatrix} e^{-ikx}, \quad \phi_3^{\mathrm{ad}}(x,k) \sim \begin{pmatrix} \lambda - k \\ i\mathbf{q}_- \end{pmatrix} e^{-i\lambda x} \tag{2.19a}$$

and as $x \to +\infty$

$$\psi_1^{\mathrm{ad}}(x,k) \sim \begin{pmatrix} \lambda + k \\ -i\mathbf{q}_+ \end{pmatrix} e^{i\lambda x}, \quad \psi_2^{\mathrm{ad}}(x,k) \sim \begin{pmatrix} 0 \\ i\mathbf{r}_+^{\perp} \end{pmatrix} e^{-ikx}, \quad \psi_3^{\mathrm{ad}}(x,k) \sim \begin{pmatrix} \lambda - k \\ i\mathbf{q}_+ \end{pmatrix} e^{-i\lambda x}. \tag{2.19b}$$

With techniques identical to those used to derive the integral equations and the Green's functions associated to the eigenfunctions of the scattering problem (2.1a), one can then show that $e^{i\lambda x}\phi_3^{\mathrm{ad}}(x,k)$ and $e^{-i\lambda x}\psi_1^{\mathrm{ad}}(x,k)$ are analytic in the upper sheet of the Riemann surface, $e^{-i\lambda x}\phi_1^{\mathrm{ad}}(x,k)$ and $e^{i\lambda x}\psi_3^{\mathrm{ad}}(x,k)$ are analytic on the lower sheet and $e^{ikx}\phi_2^{\mathrm{ad}}(x,k)$ and $e^{ikx}\psi_2^{\mathrm{ad}}(x,k)$ on neither sheet. Analogues of Eqs. (2.15) also exist,

$$\Phi^{\mathrm{ad}}(x,k) = \Psi^{\mathrm{ad}}(x,k)\tilde{\mathbf{B}}^T(k), \quad \Psi^{\mathrm{ad}}(x,k) = \Phi^{\mathrm{ad}}(x,k)\tilde{\mathbf{A}}^T(k), \tag{2.20}$$

where $\Phi^{\mathrm{ad}}(x,k) = (\phi_1^{\mathrm{ad}}, \phi_2^{\mathrm{ad}}, \phi_3^{\mathrm{ad}})$ and $\Psi^{\mathrm{ad}}(x,k) = (\psi_1^{\mathrm{ad}}, \psi_2^{\mathrm{ad}}, \psi_3^{\mathrm{ad}})$, and where $\tilde{\mathbf{A}}(k) = (\tilde{a}_{ij})$ and $\tilde{\mathbf{B}}(k) = (\tilde{b}_{ij}) = \tilde{\mathbf{A}}^{-1}(k)$ are the adjoint scattering matrices.

From these adjoint states, we can now use Eqs. (2.19) to define via (2.18) two new solutions of the original scattering problem (2.1a), namely,

$$\bar{\chi}(x,k) = -e^{ikx}\mathbf{J}(\phi_1^{\mathrm{ad}}(x,k) \wedge \psi_3^{\mathrm{ad}}(x,k)), \tag{2.21a}$$

$$\chi(x,k) = -e^{ikx}\mathbf{J}(\phi_3^{\mathrm{ad}}(x,k) \wedge \psi_1^{\mathrm{ad}}(x,k)). \tag{2.21b}$$

By construction, $\bar{\chi}(x,k)e^{-ikx}$ is analytic in the lower sheet [where $\phi_1^{\mathrm{ad}}(x,k)e^{-i\lambda x}$ and $\psi_3^{\mathrm{ad}}(x,k)e^{i\lambda x}$ are], and $\chi(x,k)e^{-ikx}$ is analytic in the upper sheet [where $\phi_3^{\mathrm{ad}}(x,k)e^{i\lambda x}$ and $\psi_1^{\mathrm{ad}}(x,k)e^{-i\lambda x}$ are]. Moreover, by comparing the asymptotic behavior as $x \to \pm\infty$ of eigenfunctions and adjoint eigenfunctions, one can check that, for all cyclic indices j,l,m,

$$\phi_j(x,k) = -e^{ikx}\mathbf{J}(\phi_l^{\mathrm{ad}}(x,k) \wedge \phi_m^{\mathrm{ad}}(x,k))/\Gamma_j(k), \tag{2.22a}$$

$$\psi_j(x,k) = -e^{ikx}\mathbf{J}(\psi_l^{\mathrm{ad}}(x,k) \wedge \psi_m^{\mathrm{ad}}(x,k))/\Gamma_j(k), \tag{2.22b}$$

and reciprocally

$$\phi_j^{\mathrm{ad}}(x,k) = -e^{-ikx}\mathbf{J}(\phi_l(x,k) \wedge \phi_m(x,k))/\Gamma_j(k), \tag{2.22c}$$

$$\psi_j^{\mathrm{ad}}(x,k) = -e^{-ikx}\mathbf{J}(\psi_l(x,k)\wedge\psi_m(x,k))/\Gamma_j(k), \tag{2.22d}$$

where

$$\Gamma_1(k)=\lambda-k, \quad \Gamma_2(k)=2\lambda, \quad \Gamma_3(k)=\lambda+k. \tag{2.23}$$

From Eqs. (2.22) and (2.15), (2.20) it then follows that

$$\widetilde{\mathbf{A}}^T(k)=\Gamma(k)\mathbf{A}(k)\Gamma^{-1}(k), \quad \widetilde{\mathbf{B}}^T(k)=\Gamma(k)\mathbf{B}(k)\Gamma^{-1}(k), \tag{2.24}$$

where $\Gamma(k)=\mathrm{diag}(\Gamma_1(k),\Gamma_2(k),\Gamma_3(k))$. Substituting the first of Eq. (2.20) into Eq. (2.21) and using (2.22b) yields

$$\chi(x,k)=2\lambda[b_{33}(k)\psi_2(x,k)-b_{23}(k)\psi_3(x,k)], \tag{2.25a}$$

$$\bar{\chi}(x,k)=2\lambda[b_{21}(k)\psi_1(x,k)-b_{11}(k)\psi_2(x,k)]. \tag{2.25b}$$

Each of these two relations provides a decomposition of the nonanalytic eigenfunction $\psi_2(x,k)$,

$$\psi_2(x,k)=\frac{b_{21}(k)}{b_{11}(k)}\psi_1(x,k)-\frac{1}{2\lambda}\frac{\bar{\chi}(x,k)}{b_{11}(k)}=\frac{b_{23}(k)}{b_{33}(k)}\psi_3(x,k)+\frac{1}{2\lambda}\frac{\chi(x,k)}{b_{33}(k)}. \tag{2.26}$$

Similar relations hold for the eigenfunction $\phi_2(x,k)$, where now the scattering coefficients $a_{ij}(k)$ are involved. Precisely, one finds

$$\bar{\chi}(x,k)=2\lambda[a_{23}(k)\phi_3(x,k)-a_{33}(k)\phi_2(x,k)], \tag{2.27a}$$

$$\chi(x,k)=2\lambda[a_{11}(k)\phi_2(x,k)-a_{21}(k)\phi_1(x,k)] \tag{2.27b}$$

and consequently one obtains similar representations for $\phi_2(x,k)$:

$$\phi_2(x,k)=\frac{a_{23}(k)}{a_{33}(k)}\phi_3(x,k)-\frac{1}{2\lambda}\frac{\bar{\chi}(x,k)}{a_{33}(k)}=\frac{a_{21}(k)}{a_{11}(k)}\phi_1(x,k)+\frac{1}{2\lambda}\frac{\chi(x,k)}{a_{11}(k)}. \tag{2.28}$$

These expressions will be key to define the inverse scattering problem in Sec. III.

C. Symmetries

Importantly, the scattering problem admits two symmetries, which relate the value of the eigenfunctions on different sheets of the Riemann surface. These symmetries translate into compatibility conditions (constraints) on the scattering data, and will play a fundamental role in the formulation of the inverse problem.

First symmetry $(k,\lambda)\to(k^*,\lambda^*)$*:* When the potential satisfies the symmetry condition $\mathbf{r}=\mathbf{q}^*$, one has $\mathbf{Q}^H=\mathbf{Q}$, and therefore from Eq. (2.17) it follows that

$$\frac{\partial}{\partial x}[v^{\mathrm{ad}}(k^*)]^*=(ik\mathbf{J}+\mathbf{Q}^H)(v^{\mathrm{ad}}(k^*))^*=(ik\mathbf{J}+\mathbf{Q})(v^{\mathrm{ad}}(k^*))^*.$$

Hence, taking into account the boundary conditions (2.4) and (2.19), we have

$$\phi_j^{\mathrm{ad}}(k,\lambda)=(\phi_j(k^*,\lambda^*))^*, \quad \psi_j^{\mathrm{ad}}(k,\lambda)=(\psi_j(k^*,\lambda^*))^*, \quad j=1,2,3 \tag{2.29}$$

and, as a consequence of Eqs. (2.24), (2.15), and (2.20)

$$\Gamma(k,\lambda)\mathbf{B}(k,\lambda)\Gamma^{-1}(k,\lambda)=\mathbf{A}^H(k^*,\lambda^*), \tag{2.30}$$

where $\Gamma(k,\lambda)=\mathrm{diag}(\Gamma_1,\Gamma_2,\Gamma_3)$ as before. In particular, Eqs. (2.30) give

$$b_{11}(k,\lambda) = a_{11}^{*}(k^{*},\lambda^{*}), \quad b_{33}(k,\lambda) = a_{33}^{*}(k^{*},\lambda^{*}) \tag{2.31}$$

showing that $a_{11}(k,\lambda)$ [respectively, $b_{33}(k,\lambda)$] has a zero on the upper sheet of the Riemann surface at a point $(k_n,\lambda(k_n))$ if and only if $b_{11}(k,\lambda)$ [respectively, $a_{33}(k,\lambda)$] has a zero at the conjugate point $(k_n^{*},\lambda^{*}(k_n^{*}))$ on the lower sheet.

Second symmetry $(k,\lambda)\to(k,-\lambda)$*:* This involution relates the values of the eigenfunctions on the two sheets, and in particular across the cuts, for arbitrary fixed k on either sheet and $\lambda\to-\lambda$. Indeed, the scattering problem is clearly invariant with respect to the exchange $(k,\lambda)\to(k,-\lambda)$, and by looking at the boundary conditions (2.4) and (2.5) one can check that

$$\psi_1(x,k,-\lambda) = -\psi_3(x,k,\lambda), \quad \phi_1(x,k,-\lambda) = -\phi_3(x,k,\lambda) \tag{2.32a}$$

while ψ_2 and ϕ_2 are invariant with the respect to the symmetry $\lambda\leftrightarrow-\lambda$, i.e.,

$$\psi_2(x,k,-\lambda) = \psi_2(x,k,\lambda), \quad \phi_2(x,k,-\lambda) = \phi_2(x,k,\lambda). \tag{2.32b}$$

Therefore, from the equations (2.15a) defining the scattering coefficients one has

$$a_{11}(k,-\lambda) = a_{33}(k,\lambda), \quad a_{22}(k,-\lambda) = a_{22}(k,\lambda), \tag{2.33a}$$

$$a_{12}(k,-\lambda) = -a_{32}(k,\lambda), \quad a_{13}(k,-\lambda) = a_{31}(k,\lambda), \quad a_{21}(k,-\lambda) = -a_{23}(k,\lambda). \tag{2.33b}$$

The same symmetry relations hold for the coefficients $b_{ij}(k)$, i.e.,

$$b_{11}(k,-\lambda) = b_{33}(k,\lambda), \quad b_{12}(k,-\lambda) = -b_{32}(k,\lambda), \quad b_{13}(k,-\lambda) = b_{31}(k,\lambda) \tag{2.34a}$$

$$b_{22}(k,-\lambda) = b_{22}(k,\lambda), \quad b_{21}(k,-\lambda) = -b_{23}(k,\lambda). \tag{2.34b}$$

Note that Eq. (2.33a) implies that $(k_n,\lambda(k_n))$ is a zero of $a_{11}(k,\lambda)$ in the upper sheet if and only if $(k_n,-\lambda(k_n))$ is a zero for $a_{33}(k,\lambda)$ in the lower sheet, and the same for $b_{11}(k,\lambda)$ and $b_{33}(k,\lambda)$. Finally, note that, taking into account Eqs. (2.32) and (2.34), comparing Eqs. (2.25a) and (2.25b) yields

$$\chi(x,k,\lambda) = \bar{\chi}(x,k,-\lambda). \tag{2.35}$$

D. Uniformization coordinate

In a similar way as for the scalar problem (e.g., see Ref. 11), we can introduce a uniformization variable z (global uniformizing parameter) defined by the conformal mapping

$$z = k + \lambda(k). \tag{2.36a}$$

The inverse mapping is given by

$$k = \tfrac{1}{2}(z + \hat{z}^{*}), \quad \lambda = z - k = \tfrac{1}{2}(z - \hat{z}^{*}), \tag{2.36b}$$

where we have introduced the shorthand notation

$$\hat{z} = q_0^2/z^{*}, \tag{2.36c}$$

which we will use throughout the rest of this work. (Note $\lambda-k=-\hat{z}^{*}$, which will also be useful later on.) With regard to the mapping $(k,\lambda)\to z$, it should be observed that (cf. Fig. 2(a),(c)):

(i) The branch cuts on the two sheets of the Riemann surface are mapped onto the real z-axis.
(ii) The two sheets $\mathbb{C}_1$ and $\mathbb{C}_2$ of the Riemann surface are, respectively, mapped onto the upper and lower half-planes of the complex z-plane.
(iii) A neighborhood of $k=\infty$ on either sheet is mapped onto a neighborhood of $z=\infty$ or $z=0$ depending on the sign of k_{im} (cf. Sec. II E).

(iv) The symmetry $k-i0\to k+i0$ on the contours (giving the discontinuity of eigenfunctions and scattering data on the banks of the cut) transforms into $z\to\hat{z}^*=q_0^2/z$ on the real z-axis.

According to the discussion in Secs. I A and I B, the eigenfunctions $\phi_1(x,z)e^{i\lambda(z)x}$, $\psi_3(x,z)e^{-i\lambda(z)x}$ and $\chi(x,z)e^{-ik(z)x}$ are analytic in the upper half-plane of z, while $\phi_3(x,z)e^{-i\lambda(z)x}$, $\psi_1(x,z)e^{i\lambda(z)x}$ and $\bar{\chi}(x,z)e^{-ik(z)x}$ are analytic in the lower half-plane. Similarly, the scattering coefficients $a_{11}(z)$ and $b_{33}(z)$ are analytic in the upper half-plane of z, while $a_{33}(z)$ and $b_{11}(z)$ are analytic in the lower half-plane.

It should be noted that although the uniformization coordinate will be important in the inverse problem, it is not essential in our formulation of the direct problem. We introduce it here because it turns out to be convenient when discussing the location of the discrete eigenvalues, which is done in Sec. II F.

In terms of the global parameter z, the first symmetry becomes $z\to z^*$. Under this transformation, the symmetry relations (2.29) and (2.30) are then, respectively, written as

$$\phi_j^{\mathrm{ad}}(x,z)=(\phi_j(x,z^*))^*,\quad \psi_j^{\mathrm{ad}}(x,z)=(\psi_j(x,z^*))^*,\quad j=1,2,3, \tag{2.37}$$

$$b_{\ell j}^*(z^*)=\Gamma_j(z)a_{j\ell}(z)\Gamma_\ell^{-1}(z),\quad \ell,j=1,2,3, \tag{2.38}$$

where

$$\Gamma_1(z)=-\hat{z}^*,\quad \Gamma_2(z)=2\lambda(z),\quad \Gamma_3(z)=z. \tag{2.39}$$

Equation (2.38) can also be written compactly as

$$\Gamma(z)\mathbf{B}(z)\Gamma^{-1}(z)=\mathbf{A}^H(z^*), \tag{2.40}$$

where $\Gamma(z)=\mathrm{diag}(\Gamma_1,\Gamma_2,\Gamma_3)$ as before. Taking into account Eq. (2.22), the symmetries (2.37) can be written in terms of eigenfunctions as follows:

$$\phi_j^*(x,z^*)=-e^{-ik(z)x}\mathbf{J}(\phi_l(x,z)\wedge\phi_m(x,z))/\Gamma_j(z) \tag{2.41a}$$

and

$$\psi_j^*(x,z^*)=-e^{-ik(z)x}\mathbf{J}(\psi_l(x,z)\wedge\psi_m(x,z))/\Gamma_j(z) \tag{2.41b}$$

where j,l,m are cyclic indices.

The second symmetry relates values of eigenfunctions and scattering coefficients at points (k,λ) and $(k,-\lambda)$ on the two sheets or at the cuts. In terms of the uniformization variable z, the transformation then becomes $z\to\hat{z}^*=q_0^2/z$. Hence the symmetry relations (2.33) can be written as

$$a_{11}(\hat{z}^*)=a_{33}(z),\quad a_{12}(\hat{z}^*)=-a_{32}(z), \tag{2.42a}$$

$$a_{13}(\hat{z}^*)=a_{31}(z),\quad a_{21}(\hat{z}^*)=-a_{23}(z), \tag{2.42b}$$

and the same relations hold for the coefficients $b_{ij}(z)$. Also note that the symmetry relations (2.32) between the auxiliary eigenfunctions can be written as

$$\phi_1(x,z)=-\phi_3(x,\hat{z}^*),\quad \psi_1(x,z)=-\psi_3(x,\hat{z}^*), \tag{2.43a}$$

$$\chi(x,z)=\bar{\chi}(x,\hat{z}^*). \tag{2.43b}$$

Taking into account Eq. (2.30) and recalling that $\mathbf{B}(z)=\mathbf{A}^{-1}(z)$ and that both matrices have unit determinant, on either side of the real z-axis we find

$$|a_{11}(z)|^2 + |a_{12}(z)|^2 \frac{\Gamma_1(z)}{\Gamma_2(z)} + |a_{13}(z)|^2 \frac{\Gamma_1(z)}{\Gamma_3(z)} = 1,$$

where $z \in \mathbb{R}$. Combining this with Eq. (2.39) we then obtain

$$|a_{11}(z)|^2 = 1 + \frac{q_0^2}{z^2}|a_{13}(z)|^2 + \frac{q_0^2}{z^2 - q_0^2}|a_{12}(z)|^2 \quad \forall\, z \in \mathbb{R}. \tag{2.44}$$

The second term on the right-hand side is non-negative; the last term, however, can be either positive or negative and therefore one cannot *a priori* exclude real zeros of $a_{11}(z)$ if $z \in (-q_0, q_0)$. Similar results follow for zeros of $a_{33}(z)$, $b_{11}(z)$, and $b_{33}(z)$, taking into account the symmetry relations (2.38) and (2.42).

Note that both symmetry transformations relate values in the upper half z-plane to values in the lower half z-plane, since both z^* and $\hat{z}^*$ are in the opposite half-plane as z. In the following we will assume that the scattering coefficients $a_{11}(z)$, etc., have no zeros on the real z-axis.

E. Asymptotic behavior of eigenfunctions and scattering data

In order to determine the asymptotic behavior of the eigenfunctions for large values of the scattering parameter k, we first note the following: in the upper sheet of the Riemann surface (i.e., when $\lambda_{\text{im}} \geqslant 0$), one has, above the cut (i.e., when $k_{\text{im}} > 0$)

$$\lambda + k \sim 2k + O(1), \quad \lambda - k \sim -\frac{q_0^2}{2k} + o(1/k) \quad \text{as } |k| \to \infty, \tag{2.45a}$$

and below the cut (i.e., when $k_{\text{im}} < 0$)

$$\lambda + k \sim \frac{q_0^2}{2k} + o(1/k), \quad \lambda - k \sim -2k + O(1) \quad \text{as } |k| \to \infty. \tag{2.45b}$$

Similar relations hold in the lower sheet of the Riemann surface (i.e., when $\lambda_{\text{im}} \leqslant 0$). Using these relations we can obtain the large-k expansion of the eigenfunctions on each sheet. It is more convenient however to express this behavior in terms of the uniformization variable z, which will be used in the inverse problem. To this aim, we note that (cf. Fig. 2)

(i) $|k| \to \infty$ in the upper-half-plane of sheet I corresponds to $z \to \infty$ in the upper-half z-plane,
(ii) $|k| \to \infty$ in the lower-half-plane of sheet II corresponds to $z \to \infty$ in the lower-half z-plane,
(iii) $|k| \to \infty$ in the lower-half-plane of sheet I corresponds to $z \to 0$ in the upper-half z-plane,
(iv) $|k| \to \infty$ in the upper-half-plane of sheet II corresponds to $z \to 0$ in the lower-half z-plane.

It should be noted here that there is no conceptual distinction between the points $z=0$ and $z=\infty$ in the z-plane, and one can change one into the other by simply defining $z=k-\lambda$ instead of $z=k+\lambda$.

Taking Eqs. (2.45) into account and using both the integral equations (2.8) and the WKB expansions of the eigenfunctions (see the Appendix) we obtain that as $z \to \infty$ in the upper-half z-plane one has

$$\phi_1(x,z)e^{i\lambda x} \sim \begin{pmatrix} z \\ i\mathbf{r}(x) \end{pmatrix}, \quad \psi_3(x,z)e^{-i\lambda x} \sim -\begin{pmatrix} \mathbf{q}^T(x)\mathbf{r}_+/z \\ i\mathbf{r}_+ \end{pmatrix}, \tag{2.46a}$$

while as $z \to 0$ in the upper-half z-plane one has

$$\phi_1(x,z)e^{i\lambda x} \sim \begin{pmatrix} \mathbf{q}^T(x)\mathbf{r}_-/\hat{z}^* \\ i\mathbf{r}_- \end{pmatrix}, \quad \psi_3(x,z)e^{-i\lambda x} \sim -\begin{pmatrix} \hat{z}^* \\ i\mathbf{r}(x) \end{pmatrix}. \tag{2.46b}$$

Similarly, as $z \to 0$ in the lower-half z-plane one has

$$\phi_3(x,z)e^{-i\lambda x} \sim -\begin{pmatrix} \hat{z}^* \\ i\mathbf{r}(x) \end{pmatrix}, \quad \psi_1(x,z)e^{i\lambda x} \sim \begin{pmatrix} \mathbf{q}^T(x)\mathbf{r}_+/\hat{z}^* \\ i\mathbf{r}_+ \end{pmatrix}, \tag{2.46c}$$

while as $z \to \infty$ in the lower-half z-plane one has

$$\phi_3(x,z)e^{-i\lambda x} \sim -\begin{pmatrix} \mathbf{q}^T(x)\mathbf{r}_-/z \\ i\mathbf{r}_- \end{pmatrix}, \quad \psi_1(x,z)e^{i\lambda x} \sim \begin{pmatrix} z \\ i\mathbf{r}(x) \end{pmatrix}. \tag{2.46d}$$

Asymptotic expansions for the adjoint eigenfunctions can also be obtained. Then, using the asymptotics of $\phi_j^{\mathrm{ad}}(x,z)$ and $\psi_j^{\mathrm{ad}}(x,z)$ as well as Eqs. (2.21), one can obtain the asymptotic expansions for the auxiliary eigenfunctions $\bar{\chi}(x,z)$ and $\chi(x,z)$. Explicitly, in the upper-half z-plane one has

$$\chi(x,z)e^{-ikx} \sim -\begin{pmatrix} \mathbf{q}^T(x)\mathbf{q}_-^\perp \\ i\mathbf{q}_-^\perp z \end{pmatrix} \quad \text{as } z \to \infty, \tag{2.47a}$$

$$\chi(x,z)e^{-ikx} \sim \begin{pmatrix} \mathbf{q}^T(x)\mathbf{q}_+^\perp \\ i\mathbf{q}_+^\perp \hat{z}^* \end{pmatrix} \quad \text{as } z \to 0, \tag{2.47b}$$

whereas in the lower-half z-plane

$$\bar{\chi}(x,z)e^{-ikx} \sim -\begin{pmatrix} \mathbf{q}^T(x)\mathbf{q}_- \\ i\mathbf{q}_-^\perp \hat{z}^* \end{pmatrix} \quad \text{as } z \to 0, \tag{2.47c}$$

$$\bar{\chi}(x,z)e^{-ikx} \sim \begin{pmatrix} \mathbf{q}^T(x)\mathbf{q}_+^\perp \\ i\mathbf{q}_+^\perp z \end{pmatrix} \quad \text{as } z \to \infty. \tag{2.47d}$$

Equations (2.16) and (2.46) also allow us to obtain the asymptotic behavior of the scattering coefficients. For example, in the upper-half z-plane, as $z \to \infty$ one has

$$a_{11}(z) \sim 1, \quad b_{33}(z) \sim \mathbf{q}_-^T\mathbf{r}_+/q_0^2, \tag{2.48a}$$

while as $z \to 0$ one has

$$a_{11}(z) \sim \mathbf{q}_+^T\mathbf{r}_-/q_0^2, \quad b_{33}(z) \sim 1. \tag{2.48b}$$

Similar expressions hold for $b_{11}(z)$ and $a_{33}(z)$ in the lower-half z-plane: namely, as $z \to 0$ one has

$$a_{33}(z) \sim 1, \quad b_{11}(z) \sim \mathbf{q}_-^T\mathbf{r}_+/q_0^2 \tag{2.48c}$$

while as $z \to \infty$ one has

$$a_{33}(z) \sim \mathbf{q}_+^T\mathbf{r}_-/q_0^2, \quad b_{11}(z) \sim 1. \tag{2.48d}$$

Note that $\mathbf{q}_+^T\mathbf{r}_- = (\mathbf{q}_-^T\mathbf{r}_+)^* = e^{i\Delta\theta^{(1)}}|q_0^{(1)}|^2 + e^{i\Delta\theta^{(2)}}|q_0^{(2)}|^2$, where we have introduced the asymptotic phase differences for the potentials, $\Delta\theta^{(1)} = \theta_+^{(1)} - \theta_-^{(1)}$ and $\Delta\theta^{(2)} = \theta_+^{(2)} - \theta_-^{(2)}$ (cf. Eq. (2.3)). Hereafter, we will assume that these asymptotic phase differences are the same in both components, namely

$$\Delta\theta^{(1)} = \Delta\theta^{(2)} =: \Delta\theta. \tag{2.49}$$

If Eqs. (2.49) are satisfied, then

$$\mathbf{q}_+^T\mathbf{r}_- = (\mathbf{q}_-^T\mathbf{q}_+)^* = e^{i\Delta\theta}q_0^2, \tag{2.50}$$

and the asymptotic behaviors of the scattering coefficients in Eqs. (2.48) simplify correspondingly.

F. Discrete eigenvalues and bound states

Recall that in the 2×2 scattering problem for the nondecaying scalar NLS equation there is a one-to-one correspondence between poles of the transmission coefficients [here, zeros of $a_{11}(z)$ etc] and eigenvalues, which, in turn, are related to bound states. Hence, the unitarity relation [i.e., the analog of Eq. (2.44)], together with the self-adjointness of the scattering problem, ensure that the transmission coefficients can only have poles at $k=k_n\in(-q_0,q_0)$, i.e., for $z=z_n$ on the circle C_0 of radius q_0 centered at the origin (e.g., see Ref. 11). As we will see in the following, in the case of vector NLS equation with nondecaying boundary conditions, the decay properties of the eigenfunctions at a pole of the transmission coefficients are not sufficient to give a bound state.

Importantly, when $\mathbf{r}=\mathbf{q}^*$ any solution $v(x,k)$ of the scattering problem (2.1a) satisfies the relation

$$-i(k-k^*)\|v(x,k)\|^2=\frac{\partial}{\partial x}[|v^{(1)}(x,k)|^2-|v^{(2)}(x,k)|^2-|v^{(3)}(x,k)|^2]. \tag{2.51}$$

Equation (2.51) shows that in order for $k=k_n$ to be an eigenvalue corresponding to a square integrable eigenfunction, k_n must be real (i.e., $k_n=k_n^*$). For $k_n\in\mathbb{R}$ with $|k_n|<q_0$ (i.e., for $z\in C_0$) one has $\lambda(k_n)=\pm i\sqrt{q_0^2-k_n^2}$ (with the upper/lower sign on sheet I/II of the Riemann surface, respectively). Correspondingly, $\phi_1(x,k_n,\lambda(k_n))$ and $\phi_3(x,k_n,\lambda(k_n))$ are exponentially decaying as $x\to-\infty$ while $\psi_1(x,k_n,\lambda(k_n))$ and $\psi_3(x,k_n,\lambda(k_n))$ are exponentially decaying as $x\to+\infty$. As we will see in Sec. II F 1, poles of the transmission coefficient at these points then give rise to bound states. It should be noted that, unlike the scalar case, the unitarity conditions [e.g., see Eq. (2.44)] are not enough to exclude poles of the transmission coefficients for $k\in\mathbb{R}$ with $|k|>q_0$ (i.e., for real values of z). In these cases, however, all eigenfunctions are oscillating as $x\to\pm\infty$. Hence, the only eigenvalues $k=k_n$ corresponding to square integrable eigenfunctions lie in the segment $(-q_0,q_0)$. In terms of the uniformization variable z, this means that *any* eigenfunctions belonging to $L_2(\mathbb{R})$ correspond to discrete eigenvalues on the circle C_0 of radius q_0. Therefore, if the scattering coefficients $a_{11}(z)$, etc., have a zero off the circle C_0, then the corresponding eigenfunctions cannot form a bound state, that is, either they are not decaying rapidly enough at both space infinities, or they are singular, which prevents the eigenfunction from being $L_2(\mathbb{R})$. We will see that both situations can in principle occur, the first case corresponding to zeros z_n of $a_{11}(z)$ inside the circle, while the second case to zeros outside the circle.

In order to locate discrete eigenvalues as it will apply to the inverse problem, it is convenient to introduce the 3×3 matrices

$$E_+(x,z)=(\phi_1,\chi,\psi_3),\quad E_-(x,z)=(\psi_1,\bar{\chi},\phi_3).$$

With this notation, $E_+(x,z)$ collects three eigenfunctions which are analytic in the upper-half z-plane, and $E_-(x,z)$ three eigenfunctions analytic in the lower-half-plane. Then we note that Eqs. (2.6), (2.25), and (2.27) together imply

$$\det(E_+(x,z))=\mathrm{Wr}(\phi_1(x,z),\chi(x,z),\psi_3(x,z))=-4q_0^2\lambda^2(z)a_{11}(z)b_{33}(z)e^{ik(z)x}, \tag{2.52a}$$

$$\det(E_-(x,z))=\mathrm{Wr}(\psi_1(x,z),\bar{\chi}(x,z),\phi_3(x,z))=4q_0^2\lambda^2(z)a_{33}(z)b_{11}(z)e^{ik(z)x}. \tag{2.52b}$$

Equation (2.52a) shows that the Wronskian vanishes (i.e., the three solutions which comprise E_+ become linearly dependent) at the zeros of $a_{11}(z)$ and $b_{33}(z)$. Due to the symmetries (2.38) and (2.42) among the scattering coefficients, however, we have

$$a_{11}(z_n)=0\Leftrightarrow b_{11}(z_n^*)=0\Leftrightarrow b_{33}(\hat{z}_n)=0\Leftrightarrow a_{33}(\hat{z}_n^*)=0 \tag{2.53}$$

[where as before we used the notation (2.36c), i.e., $\hat{z}=q_0^2/z^*$]. If the zero z_n of $a_{11}(z)$ is on the circle C_0 of radius q_0, then $\hat{z}_n\equiv z_n$, and therefore $a_{11}(z)$ and $b_{33}(z)$ vanish at the same point. Hence, the Wronskian (2.52a) will have a double zero at $z=z_n$ in this case. However, if $a_{11}(z)$ admits a simple zero at a point $z=z_n$ off the circle C_0 (i.e., $|z_n|\neq q_0$ and $\mathrm{Im}\,z_n>0$), then such zeros appear in

quartets (cf. Fig. 3), and the Wronskian (2.52a) will have a simple zero both at z_n and at $\hat{z}_n = q_0^2/z_n^*$ in the upper-half-plane. Similarly, with regard to Eq. (2.52b), $a_{33}(z)$ and $b_{11}(z)$ can either both vanish at the conjugate points $z_n^* \equiv \hat{z}_n^*$, on the lower-half circle, or vanish individually at two different points in the lower-half-plane ($\hat{z}_n^*$ and $z_n^* = q_0^2/z_n$, respectively). Hereafter we will use ζ_n to denote zeros of $a_{11}(z)$ *on the circle* C_0, and we will reserve the notation z_n for the zeros of $a_{11}(z)$ *off the circle* C_0.

1. Zeros on the circle

Let us first consider the case of zeros on the circle of radius q_0 and assume that $a_{11}(z)$ and $b_{33}(z)$ both have a simple zero at the point $z=\zeta_n=k_n+i\nu_n$, with $|k_n|<q_0$ and $\nu_n=\sqrt{q_0^2-k_n^2}>0$. As we noted earlier, in this case the Wronskians (2.52a) and (2.52b) each have a double zero, respectively, at $z=\zeta_n$ and at $z=\zeta_n^*$. In principle there are two possibilities: either $\chi(x,\zeta_n)=0$ or $\chi(x,\zeta_n)\neq 0$. If $\chi(x,\zeta_n)=0$, then also $\bar{\chi}(x,\zeta_n^*)=0$, due to the symmetry (2.43b) (since in this case $\zeta_n^* = q_0^2/\zeta_n$). If $\chi(x,\zeta_n)\neq 0$ instead, one also has $\bar{\chi}(x,\zeta_n^*)\neq 0$. In the following we show that in fact it is always the case that $\chi(x,\zeta_n)=\chi(x,\zeta_n^*)=0$.

Indeed, let ζ_n be a zero of $a_{11}(z)$ and $b_{33}(z)$ on the circle of radius q_0. Then, according to Eq. (2.21b), $\chi(x,\zeta_n)=0$ if and only if $\phi_3^{\mathrm{ad}}(x,\zeta_n)\wedge\psi_1^{\mathrm{ad}}(x,\zeta_n)=0$. Since $\phi_3^{\mathrm{ad}}(x,z)$ and $\psi_1^{\mathrm{ad}}(x,z)$ are eigenfunctions whose asymptotic behavior is fixed, they cannot vanish identically for all x. Hence for $\chi(x,\zeta_n)$ to be zero $\phi_3^{\mathrm{ad}}(x,\zeta_n)$ and $\psi_1^{\mathrm{ad}}(x,\zeta_n)$ must be proportional to each other. Then, due to the symmetry (2.29), it follows that $\phi_3(x,\zeta_n^*)\propto\psi_1(x,\zeta_n^*)$. Moreover, Eq. (2.43b) implies that $\chi(x,\zeta_n)=\bar{\chi}(x,\zeta_n^*)$, and therefore [recalling the definition (2.21a)] we conclude that

$$\chi(x,\zeta_n)=\bar{\chi}(x,\zeta_n^*)=0 \quad \text{iff } \phi_3(x,\zeta_n^*)\propto\psi_1(x,\zeta_n^*) \text{ and } \phi_1(x,\zeta_n)\propto\psi_3(x,\zeta_n). \tag{2.54}$$

Suppose now that $\chi(x,\zeta_n)\neq 0$ [and hence also $\bar{\chi}(x,\zeta_n^*)\neq 0$]. If Eqs. (2.25a) and (2.27b) can be continued off the real z-axis, then it follows that

$$\chi(x,\zeta_n)\propto\psi_3(x,\zeta_n), \quad \chi(x,\zeta_n)\propto\phi_1(x,\zeta_n)$$

[with nonzero proportionality coefficients because by assumption $\chi(x,\zeta_n)\neq 0$]. If this is the case, then $\phi_1(x,\zeta_n)\propto\psi_3(x,\zeta_n)$, and [due to the symmetry (2.29)] one also has $\phi_1^{\mathrm{ad}}(x,\zeta_n^*)\propto\psi_3^{\mathrm{ad}}(x,\zeta_n^*)$. But then it follows that $\bar{\chi}(x,\zeta_n^*)=0$, which contradicts the hypothesis. In conclusion, if ζ_n and ζ_n^* are a pair of zeros on the circle, then $\chi(x,\zeta_n)=\bar{\chi}(x,\zeta_n^*)=0$, Eq. (2.54) holds and one can write

$$\phi_1(x,\zeta_n)=b_n^{(1)}\psi_3(x,\zeta_n), \tag{2.55a}$$

$$\phi_3(x,\zeta_n^*)=\bar{b}_n^{(1)}\psi_1(x,\zeta_n^*), \tag{2.55b}$$

corresponding to a bound state. Note that due to the symmetry (2.32a) between the eigenfunctions, from Eqs. (2.55) it follows that

$$\bar{b}_n^{(1)}=b_n^{(1)}. \tag{2.56}$$

Since $\chi(x,\zeta_n)=\bar{\chi}(x,\zeta_n^*)=0$ for all zeros ζ_n of $a_{11}(z)$ and ζ_n^* of $a_{33}(z)$ on the circle of radius q_0, it is then natural in this case to rescale the Wronskians in Eq. (2.52a) as

$$\mathrm{Wr}\left(\phi_1(x,z),\frac{\chi(x,z)}{2\lambda(z)b_{33}(z)},\psi_3(x,z)\right)=-2q_0^2\lambda(z)a_{11}(z)e^{ik(z)x}, \tag{2.57a}$$

$$\mathrm{Wr}\left(\psi_1(x,z),\frac{\bar{\chi}(x,z)}{2\lambda(z)b_{11}(z)},\phi_3(x,z)\right)=2q_0^2\lambda(z)a_{33}(z)e^{ik(z)x}. \tag{2.57b}$$

The rescaled Wronskians will then have simple zeros at ζ_n and ζ_n^*.

2. Zeros off the circle

Suppose that $a_{11}(z)$, which is analytic in the upper-half z-plane, has a simple zero at a point $z=z_n=k_n+i\nu_n$, with $\nu_n>0$ and $|z_n|\neq q_0$. First of all, note that, according to (2.36b),

$$k(z_n)=\tfrac{1}{2}[k_n(1+|\hat{z}_n|^2/q_0^2)+i\nu_n(1-|\hat{z}_n|^2/q_0^2)],$$

$$\lambda(z_n)=\tfrac{1}{2}[k_n(1-|\hat{z}_n|^2/q_0^2)+i\nu_n(1+|\hat{z}_n|^2/q_0^2)].$$

Thus, the behavior of $e^{ik(z_n)x}$ at large x depends on whether $|z_n|\lessgtr q_0$ (recall that $\hat{z}=q_0^2/z^*$; hence, one has $|\hat{z}_n|\lessgtr q_0$ for $|z_n|\gtrless q_0$), and it will be exponentially decaying at one space infinity and exponentially growing at the other one. On the other hand, $\phi_1(x,z_n)\sim e^{-i\lambda(z_n)x}$ will be decaying as $x\to-\infty$ and $\psi_3(x,z_n)\sim e^{i\lambda(z_n)x}$ will be decaying as $x\to+\infty$ irrespective of whether z_n is inside or outside the circle.

If the zero z_n of $a_{11}(z)$ is off the circle C_0, then $b_{33}(z)$ will have a zero at point $\hat{z}_n=q_0^2/z_n^*\neq z_n$, but $b_{33}(z_n)\neq 0$ *in general*. Then from Eq. (2.52a) it follows that z_n is a simple zero of the Wronskian. In this case we assume that $\chi(x,z_n)$ does not vanish. Then from Eq. (2.25a) we deduce that

$$\chi(x,z_n)\sim -2i\lambda(z_n)b_{33}(z_n)\begin{pmatrix}0\\ \mathbf{q}_+^{\perp}\end{pmatrix}\exp\{\tfrac{1}{2}[ik_n(1+|z_n|^2/q_0^2)+\nu_n(1-|z_n|^2/q_0^2)]x\},\quad x\to+\infty, \tag{2.58}$$

where we note that the other contribution formally obtained from $b_{23}(z)\psi_3(x,z)$ in Eq. (2.25a) is exponentially small (and in any case, smaller than the contribution of the remaining term). On the other hand, from Eq. (2.27b) it follows that, at a zero z_n of $a_{11}(z)$, the eigenfunction $\chi(x,z_n)$ is proportional to $\phi_1(x,z_n)$:

$$\phi_1(x,z_n)=b_n^{(2)}\chi(x,z_n). \tag{2.59}$$

If $|z_n|>q_0$ (i.e., if the zero is *outside* the circle C_0), we would obtain a bound state, since the eigenfunctions $\chi(x,z_n)$ and $\phi_1(x,z_n)$ would be decaying at both space infinities. Therefore zeros of $a_{11}(z)$ outside the circle C_0 cannot occur for a smooth eigenfunction, since this would violate the eigenvalue relation (2.51). On the other hand, if $|z_n|<q_0$ (i.e., if the zero is *inside* C_0), the relation (2.59) still holds, but the eigenfunctions $\chi(x,z_n)$ and $\phi_1(x,z_n)$ will be exponentially growing as $x\to+\infty$, according to Eq. (2.58), and this does not contradict Eq. (2.51). Hence zeros z_n inside the circle C_0 are not forbidden.

Similarly, the Wronskian (2.52a) vanishes at the zero of $b_{33}(z)$ corresponding to z_n, that is [according to Eq. (2.53)], at the point $\hat{z}_n=q_0^2/z_n^*$. If z_n is inside the circle C_0 of radius q_0, then $\hat{z}_n$ will be outside the same circle, and *vice versa*. Also, in general $a_{11}(\hat{z}_n)\neq 0$, and consequently from Eq. (2.27b) it follows

$$\chi(x,\hat{z}_n)\sim -2i\lambda(\hat{z}_n)a_{11}(\hat{z}_n)\begin{pmatrix}0\\ \mathbf{q}_-^{\perp}\end{pmatrix}\exp\{\tfrac{1}{2}[ik_n(1+|z_n|^2/q_0^2)-\nu_n(1-|z_n|^2/q_0^2)]x\},\quad x\to-\infty. \tag{2.60}$$

From Eq. (2.25a), however, one deduces that $\chi(x,\hat{z}_n)$ is proportional to $\psi_3(x,\hat{z}_n)$,

$$\chi(x,\hat{z}_n)=\hat{b}_n^{(2)}\psi_3(x,\hat{z}_n). \tag{2.61}$$

Therefore, if $|z_n|>q_0$ (i.e., if $\hat{z}_n$ is *inside* C_0), this would be a bound state, since $\psi_3(x,\hat{z}_n)$ decays as $x\to+\infty$ and $\chi(x,\hat{z}_n)$ as $x\to-\infty$, according to Eq. (2.60). Hence, as before, this situation cannot occur for a smooth eigenfunction, in accordance with Eq. (2.51). On the other hand, if $|z_n|<q_0$ (i.e., if $\hat{z}_n$ is *outside* C_0), the eigenfunctions $\chi(x,z_n)$ and $\psi_3(x,z_n)$ are exponentially growing as $x\to+\infty$. Hence such situations do not contradict Eq. (2.51).

Finally, one has analogous results for the eigenfunctions in the lower-half-plane in correspondence to the points $z_n^*=k_n-i\nu_n$ [zeros of $b_{11}(z)$ off the circle C_0] and $\hat{z}_n^*=q_0^2/z_n$ [zeros of $a_{33}(z)$ off the circle C_0]. Specifically, at points z_n^*, where $b_{11}(z_n^*)=0$, one has

$$\bar{\chi}(x,z_n^*)=\bar{b}_n^{(2)}\psi_1(x,z_n^*). \tag{2.62}$$

Again, if $|z_n|>q_0$, this would correspond to a bound state. On the other hand, if $|z_n|<q_0$ the eigenfunctions in (2.62) will be growing as $x\to-\infty$. Also, at points $q_0^2/z_n\equiv\hat{z}_n^*$, where $a_{33}(\hat{z}_n^*)=0$, one has $\bar{\chi}(x,\hat{z}_n^*)$ proportional to $\phi_3(x,\hat{z}_n^*)$,

$$\phi_3(x,\hat{z}_n^*)=\check{b}_n^{(2)}\bar{\chi}(x,\hat{z}_n^*). \tag{2.63}$$

Summarizing, in the case of a pair of zeros z_n and $\hat{z}_n$ in the upper-half-plane such that $a_{11}(z_n)=0$ and $b_{33}(\hat{z}_n)=0$ (with z_n inside the circle C_0 of radius q_0 and $\hat{z}_n=q_0^2/z_n^*$ outside C_0), the eigenfunctions are related to each other as

$$\chi(x,\hat{z}_n)=\hat{b}_n^{(2)}\psi_3(x,\hat{z}_n), \tag{2.64a}$$

$$\phi_1(x,z_n)=b_n^{(2)}\chi(x,z_n)\equiv b_n^{(2)}\bar{\chi}(x,\hat{z}_n^*) \tag{2.64b}$$

[cf. Eqs. (2.61) and (2.59)], but neither $\chi(x,\hat{z}_n)$ nor $\phi_1(x,z_n)$ are bound states. In Eq. (2.64b) we used the symmetry (2.43b) to express $\chi(x,z)$ in terms of $\bar{\chi}(x,z)$. At the corresponding pair of zeros in the conjugate points in the lower half plane it is $a_{33}(\hat{z}_n^*)=0$ and $b_{11}(z_n^*)=0$, and one has the following relations:

$$\phi_3(x,\hat{z}_n^*)=\check{b}_n^{(2)}\bar{\chi}(x,\hat{z}_n^*)\equiv-b_n^{(2)}\bar{\chi}(x,\hat{z}_n^*), \tag{2.64c}$$

$$\bar{\chi}(x,z_n^*)=\bar{b}_n^{(2)}\psi_1(x,\hat{z}_n^*)\equiv-\hat{b}_n^{(2)}\psi_1(x,z_n^*) \tag{2.64d}$$

[cf. Eqs. (2.63) and (2.62)], where we have used the symmetries (2.43) for the eigenfunctions in order to express the proportionality constants in terms those appearing in Eqs. (2.64).

Finally, it should be noted that there is no conceptual difference between the interior and the exterior of the circle C_0. The reason why the z_n are only allowed to be inside C_0 is because they are defined as the zeros of $a_{11}(z)$. One could equivalently define z_n as the zeros of $b_{33}(z)$ (which amounts to switching $z_n\leftrightarrow\hat{z}_n$), in which case one would obtain that z_n are only allowed to be outside C_0.

G. Symmetries in the norming constants

Eigenvalues on the circle: We first consider a pair of zeros $\{\zeta_n,\zeta_n^*\}$ on the circle C_0 of radius q_0. At these points, Eqs. (2.55) hold, with $\bar{b}_n^{(1)}=b_n^{(1)}$, according to Eq. (2.56). Moreover, from symmetries Eqs. (2.41a) and (2.55) if follows

$$\psi_3^*(x,\zeta_n)=(1/b_n^{(1)})^*\phi_1^*(x,\zeta_n)=-(1/b_n^{(1)})^*e^{-ik(\zeta_n^*)x}\mathbf{J}(\phi_2(x,\zeta_n^*)\wedge\phi_3(x,\zeta_n^*))/\Gamma_1(\zeta_n^*)$$

and, on the other hand, Eq. (2.41b) implies

$$\psi_3^*(x,\zeta_n)=-e^{-ik(\zeta_n^*)x}\mathbf{J}(\psi_1(x,\zeta_n^*)\wedge\psi_2(x,\zeta_n^*))/\Gamma_3(\zeta_n^*).$$

Then observe that from Eqs. (2.26) and (2.28) it follows

$$\psi_1(x,\zeta_n^*)\wedge\psi_2(x,\zeta_n^*)=-\frac{1}{2\lambda(\zeta_n^*)}\psi_1(x,\zeta_n^*)\wedge\frac{\bar{\chi}(x,\zeta_n^*)}{b_{11}(\zeta_n^*)}, \tag{2.65a}$$

$$\phi_2(x,\zeta_n^*)\wedge\phi_3(x,\zeta_n^*)=-\frac{1}{2\lambda(\zeta_n^*)}\frac{\bar{\chi}(x,\zeta_n^*)}{a_{33}(\zeta_n^*)}\wedge\phi_3(x,\zeta_n^*), \tag{2.65b}$$

and from the discussion in Sec. II F 1 we have $\bar{\chi}(x,\zeta_n^*)/a_{33}(\zeta_n^*)\neq 0$. Back-substituting, we finally obtain

$$(b_n^{(1)})^*=-\frac{\Gamma_3(\zeta_n^*)}{\Gamma_1(\zeta_n^*)}\frac{b_{11}(\zeta_n^*)}{a_{33}(\zeta_n^*)}\bar{b}_n^{(1)}.$$

In order to simplify the above relation, first note that from Eq. (2.39) it follows $-\Gamma_1(\zeta_n^*)/\Gamma_3(\zeta_n^*)=\zeta_n/\zeta_n^*$. For the special case of reflectionless potential, with only one pair of eigenvalues (zeros) $\{\zeta_n,\zeta_n^*\}$ on the circle C_0 of radius q_0, one has

$$a_{11}(z)=\frac{z-\zeta_n}{z-\zeta_n^*},\quad a_{33}(z)=a_{11}(\hat{z}^*)=\frac{\zeta_n}{\zeta_n^*}\cdot\frac{z-\zeta_n^*}{z-\zeta_n},\quad b_{11}(z)=a_{11}^*(z^*)=\frac{z-\zeta_n^*}{z-\zeta_n}$$

so that $b_{11}(z)/a_{33}(z)\equiv\zeta_n^*/\zeta_n$. In conclusion, one has

$$(b_n^{(1)})^*=\left(\frac{\zeta_n^*}{\zeta_n}\right)^2\bar{b}_n^{(1)}\equiv\left(\frac{\zeta_n^*}{\zeta_n}\right)^2 b_n^{(1)} \tag{2.66}$$

which, in particular, implies that

$$\frac{\zeta_n^*}{\zeta_n}b_n^{(1)}\in\mathbb{R}.$$

Eigenvalues off the circle: We now consider the case of zeros off the circle C_0, and establish a relation between the norming constants $b_n^{(2)}$ and $\hat{b}_n^{(2)}$ in Eq. (2.64). Recall that

$$\chi(x,\hat{z}_n)=\hat{b}_n^{(2)}\psi_3(x,\hat{z}_n),\quad \phi_1(x,z_n)=b_n^{(2)}\chi(x,z_n)$$

and, instead of the second relation, we could as well make use of the symmetry relations (2.43) and consider

$$\phi_3(x,\hat{z}_n^*)=-b_n^{(2)}\bar{\chi}(x,\hat{z}_n^*). \tag{2.67}$$

Then we can write

$$\chi^*(x,\hat{z}_n)=(\hat{b}_n^{(2)})^*\psi_3^*(x,\hat{z}_n)=-\frac{1}{2\lambda(\hat{z}_n^*)\Gamma_3(\hat{z}_n^*)b_{11}(\hat{z}_n^*)}\frac{(\hat{b}_n^{(2)})^*}{b_n^{(2)}}\chi^*(x,\hat{z}_n)$$

[where Eqs. (2.41b), the first of Eqs. (2.26) and Eqs. (2.67), (2.37), and (2.21b) were used in turn]. As a result we obtain

$$(\hat{b}_n^{(2)})^*=-2\lambda(\hat{z}_n^*)\Gamma_3(\hat{z}_n^*)b_{11}(\hat{z}_n^*)b_n^{(2)}. \tag{2.68}$$

The previous relation can be simplified by taking into account that $-2\lambda(\hat{z}_n^*)=(z_n^2-q_0^2)/z_n$ and $\Gamma_3(\hat{z}_n^*)=q_0^2/z_n$, and that in the reflectionless case, with only one quartet of eigenvalues $\{z_n,z_n^*,\hat{z}_n,\hat{z}_n^*\}$ (cf. Fig. 3), one has

$$b_{11}(z)=\frac{z-z_n^*}{z-z_n},\quad b_{11}(\hat{z}_n^*)=\frac{q_0^2-|z_n|^2}{q_0^2-z_n^2}$$

(again recall $\hat{z}=q_0^2/z^*$), so that

$$(\hat{b}_n^{(2)})^* = \frac{q_0^2}{z_n^2}(|z_n|^2 - q_0^2) b_n^{(2)}. \tag{2.69}$$

III. INVERSE PROBLEM

In order to formulate the inverse scattering in terms of a Riemann-Hilbert (RH) problem, one needs a representation of eigenfunctions that are meromorphic in the upper-half z-plane in terms of a combination of eigenfunctions that are meromorphic in the lower-half-plane via suitably defined jump conditions. In this case one employs the two sets of analytic eigenfunctions $E_+(x,z) = (\phi_1, \chi, \psi_3)$ and $E_-(x,z) = (\psi_1, \bar{\chi}, \phi_3)$, which have already been used in Sec. II F. One then uses Eqs. (2.15a), which define the scattering coefficients, together with Eq. (2.25a) [which gives $\chi(x,z)$ in terms of $\psi_2(x,z)$ and $\psi_3(x,z)$] and Eqs. (2.26) [which give $\psi_2(x,z)$ in terms of $\psi_1(x,z)$ and $\bar{\chi}(x,z)$], to obtain for all $z \in \mathbb{R}$,

$$\frac{\phi_3(x,z)}{a_{33}(z)} e^{-i\lambda(z)x} = \psi_3(x,z) e^{-i\lambda(z)x} - \left[\frac{b_{31}(z)}{b_{11}(z)} \psi_1(x,z) + \frac{a_{32}(z)}{a_{33}(z)} \frac{\bar{\chi}(x,z)}{2\lambda(z) b_{11}(z)} \right] e^{-i\lambda(z)x}, \tag{3.1a}$$

$$\frac{\phi_1(x,z)}{a_{11}(z)} e^{i\lambda(z)x} = \psi_1(x,z) e^{i\lambda(z)x} + \left[\frac{a_{12}(z)}{a_{11}(z)} \frac{\chi(x,z)}{2\lambda(z) b_{33}(z)} - \frac{b_{13}(z)}{b_{33}(z)} \psi_3(x,z) \right] e^{i\lambda(z)x}, \tag{3.1b}$$

$$\frac{\chi(x,z)}{2\lambda(z) b_{33}(z)} e^{-ik(z)x} = -\frac{\bar{\chi}(x,z)}{2\lambda(z) b_{11}(z)} e^{-ik(z)x} + \left[\frac{b_{21}(z)}{b_{11}(z)} \psi_1(x,z) - \frac{b_{23}(z)}{b_{33}(z)} \psi_3(x,z) \right] e^{-ik(z)x}. \tag{3.1c}$$

Note that in the equations above we have used the relation $\mathbf{A}(z) = \mathbf{B}(z)^{-1}$ among the scattering coefficients. Recalling the symmetries (2.42) and (2.43b), the system of Eqs. (3.1) can be written as

$$\frac{\phi_3(x,z)}{a_{33}(z)} e^{-i\lambda(z)x} = \psi_3(x,z) e^{-i\lambda(z)x} - \left[\rho_1(z) \psi_1(x,z) - \rho_2(\hat{z}^*) \frac{\bar{\chi}(x,z)}{2\lambda(z) b_{11}(z)} \right] e^{-i\lambda(z)x}, \tag{3.2a}$$

$$\frac{\phi_1(x,z)}{a_{11}(z)} e^{i\lambda(z)x} = \psi_1(x,z) e^{i\lambda(z)x} - \left[\rho_1(\hat{z}^*) \psi_3(x,z) - \rho_2(z) \frac{\bar{\chi}(x,\hat{z}^*)}{2\lambda(z) b_{11}(\hat{z}^*)} \right] e^{i\lambda(z)x}, \tag{3.2b}$$

$$\frac{\chi(x,z)}{2\lambda(z) b_{33}(z)} e^{-ik(z)x} = -\frac{\bar{\chi}(x,z)}{2\lambda(z) b_{11}(z)} e^{-ik(z)x} + [\bar{\rho}_2(z) \psi_1(x,z) + \bar{\rho}_2(\hat{z}^*) \psi_3(x,z)] e^{-ik(z)x}, \tag{3.2c}$$

where again $\hat{z} = q_0^2/z^*$, and where we have introduced the analogs of reflection coefficients

$$\rho_1(z) = \frac{b_{31}(z)}{b_{11}(z)}, \quad \rho_2(z) = \frac{a_{12}(z)}{a_{11}(z)}, \quad \bar{\rho}_2(z) = \frac{b_{21}(z)}{b_{11}(z)}. \tag{3.3}$$

Note that only two of the above three coefficients are independent, since according to Eq. (2.40) one has

$$\bar{\rho}_2^*(z^*) = \frac{q_0^2}{q_0^2 - z^2} \rho_2(z). \tag{3.4}$$

A. Riemann-Hilbert problem

The system of Eqs. (3.2) can be considered as a generalized matrix Riemann-Hilbert problem on the real z-axis in the variables z, $\hat{z}^* \equiv q_0^2/z$, with poles in correspondence with the zeros of $a_{11}(z)$ and $b_{33}(z)$ in the upper-half-plane, as well as the zeros of $b_{11}(z)$ and $a_{33}(z)$ in the lower-half-plane. The next task is to solve the above RH problem by expressing the solutions in terms of a linear system of algebraic-integral equations.

Let us consider the first equation, namely Eq. (3.2a). From the asymptotic expansions (2.46) it follows

$$\frac{\phi_3(x,z)}{a_{33}(z)}e^{-i\lambda(z)x} \sim \psi_3(x,z)e^{-i\lambda(z)x} \sim \begin{pmatrix} 0 \\ -i\mathbf{r}_+ \end{pmatrix}, \quad z \to \infty, \tag{3.5a}$$

$$\frac{\phi_3(x,z)}{a_{33}(z)}e^{-i\lambda(z)x} \sim \psi_3(x,z)e^{-i\lambda(z)x} \sim \begin{pmatrix} -\hat{z}^* \\ -i\mathbf{r}(x) \end{pmatrix}, \quad z \to 0. \tag{3.5b}$$

Therefore, in Eq. (3.2a) we subtract from both sides the behavior at infinity and the pole at zero (which are the same for the left-hand side and the first term on the right-hand side). Also, note that the left-hand side is meromorphic in the lower-half-plane, with (simple) poles at the zeros of $a_{33}(z)$ (which we have denoted by $\zeta_n^*, \hat{z}_n^*$), while the first term on the right-hand side is analytic in the upper-half-plane. Hence, we also subtract from both sides of the equation the residues at the poles. We then introduce the Cauchy projectors,

$$P_\pm(f)(z) = \frac{1}{2\pi i}\int_{-\infty}^{\infty} \frac{f(\zeta)}{\zeta - (z \pm i0)}\mathrm{d}\zeta, \tag{3.6}$$

which are well defined for any function $f(\zeta)$ that is integrable on the real line (e.g., see Ref. 23). Applying P_+ to Eq. (3.2a) after the above-mentioned subtractions, we then get

$$\begin{aligned}\psi_3(x,z)e^{-i\lambda(z)x} = &-\begin{pmatrix} \hat{z}^* \\ i\mathbf{r}_+ \end{pmatrix} + \sum_{\substack{n=1 \\ |\zeta_n|=q_0}}^{N_1} \frac{\phi_3(x,\zeta_n^*)e^{-i\lambda(\zeta_n^*)x}}{a_{33}'(\zeta_n^*)(z-\zeta_n^*)} + \sum_{\substack{n=1 \\ |z_n|<q_0}}^{N_2} \frac{\phi_3(x,\hat{z}_n^*)e^{-i\lambda(\hat{z}_n^*)x}}{a_{33}'(\hat{z}_n^*)(z-\hat{z}_n^*)} \\ &+ \frac{1}{2\pi i}\int_{-\infty}^{\infty} \frac{\mathrm{d}\zeta}{\zeta - (z+i0)}\left[\rho_1(\zeta)\psi_1(x,\zeta) - \rho_2(\hat{\zeta}^*)\frac{\bar{\chi}(x,\zeta)}{2\lambda(\zeta)b_{11}(\zeta)}\right]e^{-i\lambda(\zeta)x},\end{aligned} \tag{3.7}$$

where N_1 and N_2 are, respectively, the number of zeros ζ_n of $a_{11}(z)$ on the circle C_0 of radius q_0 and of zeros z_n inside the circle C_0 (cf. section II F 2). Regarding the contribution of the discrete spectrum we now take into account that for any zero ζ_n on the circle C_0, according to Eq. (2.55b) we can write $\phi_3(x,\zeta_n^*) = \bar{b}_n^{(1)}\psi_1(x,\zeta_n^*)$, while for any zero z_n off the circle C_0, Eq. (2.64c) gives $\phi_3(x,\hat{z}_n^*) = -b_n^{(2)}\bar{\chi}(x,\hat{z}_n^*)$. Therefore, from Eq. (3.7) we obtain

$$\begin{aligned}\psi_3(x,z)e^{-i\lambda(z)x} = &-\begin{pmatrix} \hat{z}^* \\ i\mathbf{r}_+ \end{pmatrix} + \sum_{\substack{n=1 \\ |\zeta_n|=q_0}}^{N_1} \bar{C}_n^{(1)}\frac{\psi_1(x,\zeta_n^*)e^{-i\lambda(\zeta_n^*)x}}{z-\zeta_n^*} + \sum_{\substack{n=1 \\ |\zeta_n|<q_0}}^{N_2} C_n^{(2)}\frac{\bar{\chi}(x,\hat{z}_n^*)e^{-i\lambda(\hat{z}_n^*)x}}{\hat{z}_n^*(z-\hat{z}_n^*)} \\ &+ \frac{1}{2\pi i}\int_{-\infty}^{\infty} \frac{\mathrm{d}\zeta}{\zeta - (z+i0)}\left[\rho_1(\zeta)\psi_1(x,\zeta) - \rho_2(\hat{\zeta}^*)\frac{\bar{\chi}(x,\zeta)}{2\lambda(\zeta)b_{11}(\zeta)}\right]e^{-i\lambda(\zeta)x}.\end{aligned} \tag{3.8a}$$

In a similar way one can treat Eqs. (3.2b) and (3.2c). Applying a projector P_- and using (2.55a), (2.64b), and (2.64d) yields in these cases

$$\psi_1(x,z)e^{i\lambda(z)x} = \begin{pmatrix} z \\ i\mathbf{r}_+ \end{pmatrix} + \sum_{\substack{n=1 \\ |\zeta_n|=q_0}}^{N_1} \frac{z}{z-\zeta_n} C_n^{(1)} \psi_3(x,\zeta_n) e^{i\lambda(\zeta_n)x} + \sum_{\substack{n=1 \\ |\zeta_n|<q_0}}^{N_2} \frac{z}{z-z_n} C_n^{(2)} \bar{\chi}(x,\hat{z}_n^*) e^{i\lambda(z_n)x}$$
$$- \frac{z}{2\pi i} \int_{-\infty}^{\infty} \frac{d\zeta}{\zeta - (z-i0)} \left[\rho_1(\hat{\zeta}^*)\psi_3(x,\zeta) - \rho_2(\zeta) \frac{\bar{\chi}(x,\hat{\zeta}^*)}{2\lambda(\zeta) b_{11}(\hat{\zeta}^*)} \right] \frac{e^{i\lambda(\zeta)x}}{\zeta}, \tag{3.8b}$$

$$\frac{\bar{\chi}(x,z)e^{-ik(z)x}}{2\lambda(z)b_{11}(z)} = \begin{pmatrix} 0 \\ i\mathbf{q}_+^{\perp} \end{pmatrix} - \sum_{\substack{n=1 \\ |z_n|<q_0}}^{N_2} \bar{C}_n^{(2)} \psi_1(x,z_n^*) e^{-ik(z_n^*)x} \frac{z}{(z-\hat{z}_n)(z-z_n^*)}$$
$$- \frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{d\zeta}{\zeta - (z-i0)} [\bar{\rho}_2(\zeta)\psi_1(x,\zeta) + \bar{\rho}_2(\hat{\zeta}^*)\psi_3(x,\zeta)] e^{-ik(\zeta)x}. \tag{3.8c}$$

Note that in Eqs. (3.8) we have introduced the norming constants

$$\bar{C}_n^{(1)} = \frac{\bar{b}_n^{(1)}}{a_{33}'(\zeta_n^*)}, \quad C_n^{(1)} = \frac{b_n^{(1)}}{\zeta_n a_{11}'(\zeta_n)}, \quad C_n^{(2)} = \frac{b_n^{(2)}}{z_n a_{11}'(z_n)}, \quad \bar{C}_n^{(2)} = -\frac{\bar{b}_n^{(2)}}{z_n^* b_{11}'(z_n^*)} \equiv \frac{\hat{b}_n^{(2)}}{z_n^* b_{11}'(z_n^*)}. \tag{3.9}$$

From the symmetry (2.42), whenever $|\zeta_n|=q_0$, it follows

$$a_{11}'(\zeta_n) = -\frac{q_0^2}{\zeta_n^2} a_{33}'(\zeta_n^*) = -\frac{\zeta_n^*}{\zeta_n} a_{33}'(\zeta_n^*). \tag{3.10}$$

Hence, recalling Eq. (3.9) and (2.56), one has

$$\bar{C}_n^{(1)} = \frac{\bar{b}_n^{(1)}}{a_{33}'(\zeta_n^*)} = -\frac{b_n^{(1)}\zeta_n^*}{\zeta_n a_{11}'(\zeta_n)} \equiv -\zeta_n^* C_n^{(1)}. \tag{3.11a}$$

Also, symmetry (2.38) implies $(b_{11}'(z_n^*))^* = a_{11}'(z_n)$ and therefore

$$(\bar{C}_n^{(2)})^* = \frac{q_0^2}{z_n^2}(|z_n|^2 - q_0^2) C_n^{(2)}. \tag{3.11b}$$

Equations (3.8) are the fundamental equations for the inverse scattering problem. They contain the N_1+N_2 independent (complex) norming constants $C_n^{(1)}$ and $C_n^{(2)}$. In the absence of discrete eigenvalues (that is, when $N_1=N_2=0$), Eqs. (3.8) are a linear system of three vector integral equations for the three eigenfunctions $\psi_1(x,z)$, $\psi_3(x,z)$, and $\bar{\chi}(x,z)$. In general (that is, when $N_1 \neq 0$ or $N_2 \neq 0$), the system is consistently closed by evaluating the first equation at $z=\zeta_n$, for $n=1,\ldots,N_1$, the second at $z=\zeta_n^*$ for $n=1,\ldots,N_1$ and $z=z_n^*$ for $n=1,\ldots,N_2$ and the last one at $z=\hat{z}_n^*$, $n=1,\ldots,N_2$.

It should be noted that, using the WKB expansions for the eigenfunctions (see the Appendix) and the Wronskian relations for the scattering coefficients, one can show that the reflection coefficients (3.3) decay as appropriate powers of z both as $z\to 0$ and as $z\to\infty$ so as to make the integrals in Eqs. (3.8) convergent.

B. Trace formula

From the definition of the reflection coefficients (3.3) and the symmetries (2.38), we can write Eq. (2.44) as

$$|a_{11}(z)|^{-2} = 1 - \frac{z^2}{q_0^2}|\rho_1(z)|^2 - \frac{q_0^2}{z^2 - q_0^2}|\rho_2(z)|^2. \tag{3.12}$$

Recall that $a_{11}(z)$ is analytic in the upper-half z-plane, with $a_{11}(z) \sim 1$ as $|z| \to \infty$, and that it has (simple) zeros at the points $\{\zeta_n\}_{n=1}^{N_1}$ on the circle C_0 of radius q_0, and $\{z_n\}_{n=1}^{N_2}$ off the circle C_0. Therefore, assuming that it does not vanish for any $z \in \mathbb{R}$, one can explicitly write

$$a_{11}(z) = \prod_{n=1}^{N_1} \frac{z - \zeta_n}{z - \zeta_n^*} \prod_{n=1}^{N_2} \frac{z - z_n}{z - z_n^*} \exp\left\{ - \frac{1}{2\pi i} \int_{-\infty}^{+\infty} \frac{\log[1 - \zeta^2 |\rho_1(\zeta)|^2/q_0^2 - q_0^2|\rho_2(\zeta)|^2/(\zeta^2 - q_0^2)]}{\zeta - z} \mathrm{d}\zeta \right\}. \tag{3.13}$$

The scattering coefficients $a_{33}(z)$, $b_{11}(z)$, and $b_{33}(z)$ can obviously be obtained from $a_{11}(z)$ by symmetry [cf. Eqs. (2.38) and (2.42)]. In fact, it is worth noting that all other entries in the scattering matrix $\mathbf{A}(z) = (a_{ij}(z))$ and its inverse $\mathbf{B}(z) = (b_{ij}(z))$ can be reconstructed in terms of the reflection coefficients (3.3) and of the elements of the discrete spectrum, once the symmetries (2.38) and (2.42) are taken into account. In this sense, the reflection coefficients (3.3), together with the discrete eigenvalues and relative norming constants, constitute a minimal set of scattering data.

We also mention that from the asymptotic behavior (2.48b) of $a_{11}(z)$ as $z \to 0$, the following relation between the scattering data and the asymptotic phase differences $\Delta\theta = \theta_+^{(j)} - \theta_-^{(j)}$ in the potentials can be obtained:

$$e^{i\Delta\theta} = \prod_{n=1}^{N_1} \frac{\zeta_n}{\zeta_n^*} \prod_{n=1}^{N_2} \frac{z_n}{z_n^*} \exp\left\{ - \frac{1}{2\pi i} \int_{-\infty}^{+\infty} \frac{\log[1 - \zeta^2 |\rho_1(\zeta)|^2/q_0^2 - q_0^2|\rho_2(\zeta)|^2/(\zeta^2 - q_0^2)]}{\zeta} \mathrm{d}\zeta \right\}. \tag{3.14}$$

Equation (3.14) is the analog of the Θ-condition that was obtained in Ref. 11 for the scalar NLS equation.

IV. TIME EVOLUTION

Equation (2.1b) fixes the time evolution of eigenfunctions and scattering data, as well as the asymptotic phases of the potential. Thus, asymptotically, the time dependence of the eigenfunctions is given by

$$\frac{\partial v}{\partial t} \sim \begin{pmatrix} 2ik^2 + iq_0^2 & -2k\mathbf{q}_\pm^T \\ -2k\mathbf{r}_\pm & -2ik^2\mathbf{I}_2 - i\mathbf{r}_\pm\mathbf{q}_\pm^T \end{pmatrix} v \quad \text{as } x \to \pm\infty. \tag{4.1}$$

The eigenfunctions $\phi_j(x,t,k)$ and $\psi_j(x,t,k)$ however are defined at all times t by the asymptotic behavior in Eqs. (2.4) as $x \to \pm\infty$. Those boundary conditions are not compatible with the time evolution prescribed by Eq. (2.1b). To determine the time evolution of $\phi_j(x,t,k)$ and $\psi_j(x,t,k)$, one can introduce modified eigenfunctions which are simultaneously solutions of the x and t part of the Lax pair. For instance, let $\tilde{\phi}_1(x,t,k) = e^{i\omega_\infty^{(1)} t}\phi_1(x,t,k)$, so that

$$\frac{\partial \widetilde{\phi}_1}{\partial t} = i\omega_\infty^{(1)} \widetilde{\phi}_1 + e^{i\omega_\infty^{(1)} t} \frac{\partial \phi_1}{\partial t}. \tag{4.2}$$

Requiring that $\widetilde{\phi}_1(x,t,k)$ be a solution of the time-differential Eq. (2.1b) [and hence, asymptotically as $x \to -\infty$, of Eq. (4.1) with the lower sign], and recalling that $r_-^{(j)}(t)$ depends on t via the phase $\theta_-^{(j)}(t)$ [cf. (2.3)], one then obtains from (2.4) and (2.5),

$$\phi_1 \sim \begin{pmatrix} \lambda + k \\ i\mathbf{r}_-(t) \end{pmatrix} e^{-i\lambda x}, \quad \frac{\partial \phi_1}{\partial t} \sim \begin{pmatrix} 0 \\ \dot{\Theta}_-(t) i\mathbf{r}_-(t) \end{pmatrix} e^{-i\lambda x}, \quad \frac{\partial \phi_1}{\partial x} \sim -i\lambda \begin{pmatrix} \lambda + k \\ i\mathbf{r}_-(t) \end{pmatrix} e^{-i\lambda x},$$

where $\dot{\Theta}_\pm(t) = \mathrm{diag}(\dot{\theta}_\pm^{(1)}(t), \dot{\theta}_\pm^{(2)}(t))$ and the dot denotes differentiation with respect to time. Substituting these into Eq. (4.1) and looking at each of the three components of $\widetilde{\phi}_1(x,t,k)$ we then obtain, respectively, from each component,

$$\omega_\infty^{(1)} = 2k\lambda + q_0^2 = \dot{\theta}_-^{(1)} - q_0^2 + 2k\lambda = \dot{\theta}_-^{(2)} - q_0^2 + 2k\lambda.$$

In order for these three expressions to be compatible, it is necessary that $\dot{\theta}_-^{(1)}(t) = \dot{\theta}_-^{(2)}(t) = 2q_0^2$, that is,

$$\theta_-^{(j)}(t) = \theta_-^{(j)} + 2q_0^2 t, \quad j = 1,2, \tag{4.3}$$

which completely fixes the time evolution of the asymptotic phases $\theta_-^{(j)}$ for the potential. In a similar way one can obtain the evolution of the asymptotic phases as $x \to +\infty$ to show that

$$\theta_+^{(j)}(t) = \theta_+^{(j)}(0) + 2q_0^2 t, \quad j = 1,2. \tag{4.4}$$

[Note that Eq. (4.4) can also be obtained directly from the asymptotics of the VNLS Eq. (1.3) as $x \to \pm\infty$.] Moreover, one finds that all of the eigenfunctions $\phi_j(x,t,k)$ and $\psi_j(x,t,k)$ satisfy a modified version of Eq. (2.1b),

$$\frac{\partial v_j}{\partial t} = \begin{pmatrix} 2ik^2 + i\mathbf{q}^T\mathbf{r} & -2k\mathbf{q}^T - i\mathbf{q}_x^T \\ -2k\mathbf{r} + i\mathbf{r}_x & -2ik^2\mathbf{I}_2 - i\mathbf{r}\mathbf{q}^T \end{pmatrix} v_j - i\omega_\infty^{(j)} v_j, \tag{4.5}$$

where $\omega_\infty = \mathrm{diag}(\omega_\infty^{(1)}, \omega_\infty^{(2)}, \omega_\infty^{(3)})$, and

$$(\omega_\infty^{(1)}, \omega_\infty^{(2)}, \omega_\infty^{(3)}) = (2k\lambda + q_0^2, -2k^2 - 2q_0^2, q_0^2 - 2k\lambda).$$

Differentiating the scattering equations (2.15a) with respect to t and taking into account Eq. (4.5), one then obtains the time evolution of the elements of the scattering matrix $\mathbf{A}$,

$$\frac{\partial a_{j\ell}}{\partial t} = i(\omega_\infty^{(\ell)} - \omega_\infty^{(j)}) a_{j\ell}, \quad j,\ell = 1,2,3. \tag{4.6}$$

From Eq. (4.6) it follows immediately that all the diagonal elements $a_{\ell\ell}(k)$ of the scattering matrix are time independent. Since $a_{11}(k)$ and $a_{33}(k)$ [as well as $b_{11}(k)$ and $b_{33}(k)$, which are related to the previous ones by symmetries (2.31)] are constants of the motion, the eigenvalues k_n, being the zeros of $a_{11}(k)$, are also time independent. The same holds for the zeros of $a_{33}(k)$. It is convenient to write explicitly the time dependence of the off-diagonal scattering coefficients

$$a_{13}(k,t) = e^{-4ik\lambda t} a_{13}(k,0), \quad a_{31}(k,t) = e^{4ik\lambda t} a_{31}(k,0), \tag{4.7a}$$

$$a_{23}(k,t) = e^{2i(k^2 - k\lambda + q_0^2)t + iq_0^2 t} a_{23}(k,0), \quad a_{32}(k,t) = e^{-2i(k^2 - k\lambda + q_0^2)t - iq_0^2 t} a_{32}(k,0), \tag{4.7b}$$

$$a_{12}(k,t) = e^{-2i(k^2+k\lambda+q_0^2)t-iq_0^2t}a_{12}(k,0), \quad a_{21}(k,t) = e^{2i(k^2+k\lambda+q_0^2)t+iq_0^2t}a_{21}(k,0). \tag{4.7c}$$

The evolution of the coefficient $b_{j\ell}(k,t)$ is the same as that of the $a_{j\ell}(k,t)$.

In a similar way one can determine the time dependence of the norming constants. Indeed, differentiating (2.55a) and (2.55b) and taking into account Eq. (4.5) we get for an eigenvalue $\zeta_n = k_n + i\nu_n$ with $|\zeta_n| = q_0$,

$$b_n^{(1)}(t) = b_n^{(1)}(0)e^{4k_n\nu_n t}, \quad \bar{b}_n^{(1)}(t) = \bar{b}_n^{(1)}(0)e^{4k_n\nu_n t}. \tag{4.8}$$

Therefore, according to the definitions (3.9)

$$\bar{C}_n^{(1)}(t) = \bar{C}_n^{(1)}(0)e^{4k_n\nu_n t}, \quad C_n^{(1)}(t) = C_n^{(1)}(0)e^{4k_n\nu_n t}, \quad n = 1, \ldots, N_1. \tag{4.9}$$

Similarly, for eigenvalues z_n and $\hat{z}_n$ off the circle (cf. Fig. 3), Eqs. (2.61) and (2.59) yield

$$b_n^{(2)}(t) = b_n^{(2)}(0)\exp[-i(z_n^2 + 4q_0^2)t], \quad \hat{b}_n^{(2)}(t) = \hat{b}_n^{(2)}(0)\exp[i((z_n^*)^2 + 4q_0^2)t], \quad n = 1, \ldots, N_2. \tag{4.10}$$

A. Conserved quantities

According to Eq. (4.6), the scattering coefficient $a_{11}(z)$ is time independent. Since $a_{11}(z)$ is analytic in the upper-half z-plane and $a_{11}(z) \to 1$ as $z \to \infty$, it admits an asymptotic Laurent series expansion whose coefficients are constants of motion. Similarly, the coefficients of the Taylor series expansion of $a_{11}(z)$ about $z=0$ are constant of the motion as well. Moreover, one can write the following expansions of the modified eigenfunction $M_1(x,z)$:

$$M_1^{(j)}(x,z) = zM_{1,\infty}^{(j,-1)}(x) + M_{1,\infty}^{(j,0)}(x) + \frac{1}{z}M_{1,\infty}^{(j,1)}(x) + \frac{1}{z^2}M_{1,\infty}^{(j,2)}(x) + \cdots, \quad j = 1,2,3 \tag{4.11}$$

as $z \to \infty$, and

$$M_1^{(j)}(x,z) = M_{1,0}^{(j,0)}(x) + zM_{1,0}^{(j,1)}(x) + z^2M_{1,0}^{(j,2)}(x) + \cdots, \quad j = 1,2,3 \tag{4.12}$$

as $z \to 0$. Substituting Eqs. (4.11) and (4.12) in Eq. (2.16), we can then obtain two infinite sets of conserved quantities:

$$I_m = M_{1,\infty}^{(1,m)}(+\infty) + iq_+^{(1)}M_{1,\infty}^{(2,m-1)}(+\infty) + iq_+^{(2)}M_{1,\infty}^{(3,m-1)}(+\infty), \quad m = 0,1,2,\ldots, \tag{4.13a}$$

$$K_m = M_{1,0}^{(1,m-2)}(+\infty) + iq_+^{(1)}M_{1,0}^{(2,m)}(+\infty) + iq_+^{(2)}M_{1,0}^{(3,m)}(+\infty), \quad m = 1,2,\ldots, \tag{4.13b}$$

where

$$M_{1,\infty}^{(j,m)}(+\infty) = \lim_{x\to+\infty} M_{1,\infty}^{(j,m)}(x), \quad M_{1,0}^{(j,m)}(+\infty) = \lim_{x\to+\infty} M_{1,0}^{(j,m)}(x), \quad j = 1,2,3$$

and where $M_{1,\infty}^{(2,-1)}(+\infty)$, $M_{1,\infty}^{(3,-1)}(+\infty)$ and $M_{1,0}^{(1,-1)}(+\infty)$, $M_{1,0}^{(1,-2)}(+\infty)$ are all assumed to be identically zero.

The first few coefficients of the asymptotic expansions (4.11) and (4.12) are computed in the Appendix, by means of a WKB expansion. Taking into account (1.2) and (1.3) and (1.10), (1.11), we can write explicitly the first few conserved quantities in (4.13). From Eq. (4.13a) we have

$$I_0 = \int_{-\infty}^{\infty} (\|\mathbf{q}(x,t)\|^2 - q_0^2)\mathrm{d}x, \quad I_1 = \int_{-\infty}^{\infty} \mathbf{q}^T(x,t)\mathbf{r}_x(x,t)\mathrm{d}x, \tag{4.14a}$$

$$I_2 = \int_{-\infty}^{\infty} [\mathbf{q}^T(x,t)\mathbf{r}_{xx}(x,t) - \|\mathbf{q}(x)\|^2(\|\mathbf{q}(x,t)\|^2 - q_0^2)]\mathrm{d}x, \tag{4.14b}$$

or equivalently

$$I_2 = -\int_{-\infty}^{\infty} [\|\mathbf{q}_x(x,t)\|^2 + (\|\mathbf{q}(x,t)\|^4 - q_0^4)]\mathrm{d}x,$$

etc. Note that I_2 is the Hamiltonian of the VNLS equation (1.3). Similarly, from Eq. (4.13b) one obtains

$$K_1 = \mathbf{q}_+^T\mathbf{r}_-, \quad K_2 = \int_{-\infty}^{\infty} \mathbf{q}_+^T(\mathbf{r}(x,t)\mathbf{q}^T(x,t)\mathbf{r}_- - q_0^2\mathbf{r}_-)\mathrm{d}x, \tag{4.15a}$$

and so on and so forth. Note that assuming the asymptotic phase differences are the same in both components [cf. Eq. (2.49)], Eq. (4.15a) becomes

$$K_1 = e^{i\Delta\theta}q_0^2, \quad K_2 = e^{i\Delta\theta}q_0^2 I_0,$$

etc., which show that the asymptotic phase difference is constant, in agreement with Eq. (4.4).

Finally, note that motion constants are also given in terms of the scattering data by the trace formula (3.13). In fact, recalling that $a_{11}(z)$, as well as its zeros z_n, ζ_n (discrete eigenvalues) are time independent, the coefficients of the expansions of $a_{11}(z)$ both as $z \to 0$ and as $z \to \infty$ in the upper-half-plane of z, i.e.,

$$J_n = \int_{-\infty}^{+\infty} \zeta^n \log[1 - \zeta^2|\rho_1(\zeta)|^2/q_0^2 - q_0^2|\rho_2(\zeta)|^2/(\zeta^2 - q_0^2)]\mathrm{d}\zeta, \quad n \in \mathbb{Z} \tag{4.16}$$

provide an infinite set of conserved quantities, assuming all of these integrals are convergent.

V. EXPLICIT SOLUTIONS

Let us discuss the special solutions obtained in the case where there is no continuum spectrum, that is, for reflectionless potentials, $\rho_j(z) = \bar{\rho}_j(z) \equiv 0$ for $j = 1, 2$ and all $z \in \mathbb{R}$.

A. Dark-dark soliton solutions

We first consider the case of a reflectionless potential with one single eigenvalue on the circle C_0 of radius q_0 (i.e., $N_1 = 1$ and $N_2 = 0$), and let $\zeta_1 = k_1 + i\nu_1$ with $-q_0 < k_1 < q_0$ and $\nu_1 = \sqrt{q_0^2 - k_1^2}$. In this case the first two equations of the inverse problem [namely Eqs. (3.8a) and (3.8b)] reduce to the closed system

$$\psi_3(x,z)e^{-i\lambda(z)x} = -\begin{pmatrix} \hat{z}^* \\ i\mathbf{r}_+ \end{pmatrix} + \bar{C}_1^{(1)} \frac{\psi_1(x,\zeta_1^*)e^{-\nu_1 x}}{z - \zeta_1^*}, \tag{5.1a}$$

$$\psi_1(x,z)e^{i\lambda(z)x} = \begin{pmatrix} z \\ i\mathbf{r}_+ \end{pmatrix} + \frac{z}{z - \zeta_1} C_1^{(1)} \psi_3(x,\zeta_1)e^{-\nu_1 x}. \tag{5.1b}$$

Evaluating Eq. (5.1a) at $z = \zeta_1$ and Eq. (5.1b) at $z = \zeta_1^*$, we get a linear system whose solution is given by

$$\psi_3(x,\zeta_1) = -\begin{pmatrix} \zeta_1^* \\ i\mathbf{r}_+ \end{pmatrix} e^{-\nu_1 x} \frac{1 + \dfrac{i\bar{C}_1^{(1)}}{2\nu_1} e^{-2\nu_1 x}}{1 - \dfrac{C_1^{(1)}\bar{C}_1^{(1)}}{(2\nu_1)^2}\zeta_1^* e^{-4\nu_1 x}}, \tag{5.2a}$$

$$\psi_1(x,\zeta_1^*) = \begin{pmatrix} \zeta_1^* \\ i\mathbf{r}_+ \end{pmatrix} e^{-\nu_1 x} \frac{1 - \dfrac{i\zeta_1^*\bar{C}_1^{(1)}}{2\nu_1} e^{-2\nu_1 x}}{1 - \dfrac{C_1^{(1)}\bar{C}_1^{(1)}}{(2\nu_1)^2}\zeta_1^* e^{-4\nu_1 x}}, \tag{5.2b}$$

where we used the fact that $|\zeta_1|^2 = q_0^2$. We write the common denominator of Eqs. (5.2) as

$$1 - \frac{C_1^{(1)}\bar{C}_1^{(1)}}{(2\nu_1)^2}\zeta_1^* e^{-4\nu_1 x} \equiv (1 + \gamma e^{-2\nu_1 x})(1 - \gamma e^{-2\nu_1 x})$$

with $(2\nu_1\gamma)^2 = C_1^{(1)}\bar{C}_1^{(1)}\zeta_1^*$. Then from (3.11a) it follows

$$\bar{C}_1^{(1)} = -\zeta_1^* C_1^{(1)} \tag{5.3}$$

and therefore

$$\frac{i\bar{C}_1^{(1)}}{2\nu_1} = \mp \frac{\sqrt{C_1^{(1)}\bar{C}_1^{(1)}\zeta_1^*}}{2\nu_1} \equiv \mp\,\gamma \tag{5.4}$$

so that the eigenfunctions (5.2a) and (5.2b) can be written as

$$\psi_1(x,\zeta_1^*) = -\psi_3(x,\zeta_1) = \begin{pmatrix} \zeta_1^* \\ i\mathbf{r}_+ \end{pmatrix} e^{-i\nu_1 x} \frac{1}{1 \pm \gamma e^{-2\nu_1 x}}. \tag{5.5}$$

Recalling the definitions (3.9) and the symmetry relation (3.10), we get

$$C_1^{(1)}\bar{C}_1^{(1)}\zeta_1^* = -\bar{b}_1^{(1)} b_1^{(1)} / (a_{33}'(\zeta_1^*))^2.$$

Furthermore, in the pure one-soliton case, one has $\zeta_1^* a_{33}'(\zeta_1^*) = \zeta_1/(\zeta_1^* - \zeta_1)$ and hence the previous relation becomes $C_1^{(1)}\bar{C}_1^{(1)}\zeta_1^* = (2\nu_1)^2 \bar{b}_1^{(1)} b_1^{(1)} (\zeta_1^*/\zeta_1)^2$ so that $\gamma^2 = \bar{b}_1^{(1)} b_1^{(1)} (\zeta_1^*/\zeta_1)^2$. Finally, using the symmetry (2.66) we have

$$\gamma^2 = |b_1^{(1)}|^2,$$

that is $\gamma = |b_1^{(1)}|$ assuming without loss of generality that $\gamma > 0$. Then, from Eq. (5.4) it follows that $\bar{C}_1^{(1)} = \pm i(2\nu_1\gamma)$ that is, $\bar{C}_1^{(1)}$ is purely imaginary. In the following, in order to exclude singular solutions from the IST procedure, we assume the imaginary part of $\bar{C}_1^{(1)}$ is positive, i.e., corresponding to the upper sign. Then from (5.1a) we obtain

$$\psi_3(x,z)e^{-i\lambda(z)x} = -\begin{pmatrix} \hat{z}^* \\ i\mathbf{r}_+ \end{pmatrix} + \frac{2i\nu_1\gamma}{z - \zeta_1^*}\begin{pmatrix} \zeta_1^* \\ i\mathbf{r}_+ \end{pmatrix} \frac{e^{-2\nu_1 x}}{1 + \gamma e^{-2\nu_1 x}}. \tag{5.6}$$

According to (2.46b), from the last two components of (5.6) in the limit $z \to 0$ it follows

$$\mathbf{r}(x) = \mathbf{r}_+ \left[1 + \frac{2i\nu_1\gamma}{\zeta_1^*} \frac{e^{-2\nu_1 x}}{1+\gamma e^{-2\nu_1 x}} \right]. \tag{5.7}$$

Taking into account the time dependence of the norming constant as given in Eq. (4.9) and then taking the complex conjugate to get $\mathbf{q}(x,t)$ one obtains a solution of the VNLS equation

$$\mathbf{q}(x,t) = \mathbf{q}_+(0) e^{2iq_0^2 t} \left[1 + (e^{2i\alpha} - 1) \frac{e^{2q_0 (\sin\alpha)(x - 2q_0 (\cos\alpha)t - x_0)}}{1 + e^{2q_0 (\sin\alpha)(x - 2q_0 (\cos\alpha)t - x_0)}} \right], \tag{5.8a}$$

$$\zeta_1 = k_1 + i\nu_1 = q_0 e^{-i\alpha}, \quad e^{2\nu_1 x_0} = \gamma(0) \equiv |b_1^{(1)}(0)| \tag{5.8b}$$

which is of the same type as Eq. (1.2) in both components, multiplied by the constant polarization (i.e., unit magnitude) vector $\mathbf{p}_+ = \mathbf{q}_+(0)/q_0$. Let us also mention that from Eq. (5.7) it follows that $\mathbf{r}(x) \to \mathbf{r}_+$ as $x \to +\infty$. Also, as $x \to -\infty$ one has

$$\mathbf{r}(x) \sim \left(1 + \frac{2i\nu_1}{\zeta_1^*} \right) \mathbf{r}_+ = \frac{\zeta_1}{\zeta_1^*} \mathbf{r}_+$$

therefore the asymptotic behavior satisfies the analog of the Θ-condition for the scalar NLS equation (cf. Ref. 11), that is,

$$\frac{r_-^{(j)}}{r_+^{(j)}} = \frac{\zeta_1}{\zeta_1^*}, \quad j = 1,2 \tag{5.9}$$

in agreement with Eq. (3.14) with $\rho_j = 0$, $N_1 = 1$ and $N_2 = 0$. Note that the right-hand side of Eq. (5.9) is independent of j, which is consistent with the assumption that the asymptotic phase difference is the same in both components.

B. Dark-bright soliton solutions

We now consider one quarter of eigenvalues off the circle C_0 of radius q_0 (cf. Fig. 3) and no continuous spectrum (i.e., $N_1 = 0$ and $N_2 = 1$). The system of equation (3.8) for the inverse problem then reduces to

$$\psi_3(x,z) e^{-i\lambda(z)x} = -\begin{pmatrix} \hat{z}^* \\ i\mathbf{r}_+ \end{pmatrix} + \frac{C_1^{(2)}}{\hat{z}_1^*} \frac{\bar{\chi}(x,\hat{z}_1^*) e^{-i\lambda(\hat{z}_1^*)x}}{z - \hat{z}_1^*}, \tag{5.10a}$$

$$\psi_1(x,z) e^{i\lambda(z)x} = \begin{pmatrix} z \\ i\mathbf{r}_+ \end{pmatrix} + \frac{z}{z - z_1} C_1^{(2)} \bar{\chi}(x,\hat{z}_1^*) e^{i\lambda(z_1)x}, \tag{5.10b}$$

$$\frac{\bar{\chi}(x,z) e^{-ik(z)x}}{2\lambda(z) b_{11}(z)} = \begin{pmatrix} 0 \\ i\mathbf{q}_+^\perp \end{pmatrix} - \bar{C}_1^{(2)} \frac{z}{(z - \hat{z}_1)(z - z_1^*)} \psi_1(x, z_1^*) e^{-ik(z_1^*)x}, \tag{5.10c}$$

where $\bar{C}_1^{(2)}$ and $C_1^{(2)}$ are given by Eqs. (3.9). To obtain a closed system, we evaluate the second equation at point $z = z_1^*$ and the third equation at $z = \hat{z}_1^*$, which gives a system of two equations for two unknowns, $\psi_1(x, z_1^*)$ and $\bar{\chi}(x, \hat{z}_1^*)$. Then, back-substituting, we obtain the expression of all the (z-dependent) eigenfunctions. Indeed, from Eqs. (5.10b) and (5.10c) one obtains

$$\bar{\chi}(x,\hat{z}_1^*) = \frac{e^{ik(\hat{z}_1^*)x}}{1 + \beta_1\gamma_1 e^{-2\nu_1 x}} \left[\alpha_1 \begin{pmatrix} 0 \\ i\mathbf{q}_+^\perp \end{pmatrix} - \beta_1 \begin{pmatrix} z_1^* \\ i\mathbf{r}_+ \end{pmatrix} e^{-i(k(z_1^*) + \lambda(z_1^*))x} \right],$$

where

$$\alpha_1 = 2\lambda(\hat{z}_1^*)b_{11}(\hat{z}_1^*), \quad \beta_1 = \alpha_1 \bar{C}_1^{(2)} \frac{\hat{z}_1^*}{(\hat{z}_1^* - \hat{z}_1)(\hat{z}_1^* - z_1^*)}, \quad \gamma_1 = C_1^{(2)} \frac{z_1^*}{z_1^* - z_1} \tag{5.11}$$

and, substituting into Eq. (5.10b),

$$\psi_1(x,z)e^{i\lambda(z)x} = \begin{pmatrix} z \\ i\mathbf{r}_+ \end{pmatrix} + \frac{z}{z - z_1} C_1^{(2)} \frac{e^{iz_1 x}}{1 + \beta_1 \gamma_1 e^{-2\nu_1 x}} \left[\alpha_1 \begin{pmatrix} 0 \\ i\mathbf{q}_+^{\perp} \end{pmatrix} - \beta_1 \begin{pmatrix} z_1^* \\ i\mathbf{r}_+ \end{pmatrix} e^{-iz_1^* x} \right].$$

To find a dark-bright soliton solution, we take $r_+^{(1)}=0$ (and consequently $q_+^{(1)}=0$) with $r_+^{(2)} = (q_+^{(2)})^* \neq 0$, and we look at the second and third components of $\psi_1(x,t)e^{i\lambda x}$, which, according to (2.46d), in the limit $z \to \infty$ reconstruct the potential $\mathbf{r}(x)$. Explicitly, we get

$$r^{(1)}(x) = \alpha_1 q_+^{(2)} C_1^{(2)} e^{ik_1 x} \frac{e^{-\nu_1 x}}{1 + \beta_1 \gamma_1 e^{-2\nu_1 x}}, \tag{5.12a}$$

$$r^{(2)}(x) = r_+^{(2)} \left[1 - C_1^{(2)} \beta_1 \frac{e^{-2\nu_1 x}}{1 + \beta_1 \gamma_1 e^{-2\nu_1 x}} \right]. \tag{5.12b}$$

In the pure one-soliton case, using the analyticity properties we can write explicitly the scattering coefficients $b_{11}(z)$ and $a_{11}(z)$ and their derivatives. Recalling that $a_{11}(z)$ is analytic in the upper-half-plane, that it goes to 1 as $z \to \infty$, and assuming that it has a single, simple zero at $z=z_1$ [cf. Eq. (2.53)], we get

$$a_{11}(z) = \frac{z - z_1}{z - z_1^*}, \quad a_{11}'(z_1) = \frac{1}{z_1 - z_1^*}.$$

Thus, recalling that $b_{11}(z)=a_{11}^*(z^*)$ and substituting into Eq. (5.11), we obtain

$$\alpha_1 = \frac{q_0^2 - |z_1|^2}{z_1}, \quad \beta_1 = \bar{C}_1^{(2)} \frac{z_1^*}{z_1^* - z_1}, \quad \gamma_1 = C_1^{(2)} \frac{z_1^*}{z_1^* - z_1}. \tag{5.13}$$

Note that α_1 vanishes if $|z_1|=q_0$ so that for zeros on the circle C_0 the bright component becomes trivial. Note also that from Eq. (3.11b) it follows that

$$\beta_1 \gamma_1 \equiv \frac{q_0^2}{4\nu_1^2}(q_0^2 - |z_1|^2)|C_1^{(2)}|^2$$

which is real and positive for any eigenvalue z_1 inside the circle C_0 of radius q_0. Note that having $|z_1| > q_0$ (i.e., an eigenvalue outside C_0) would produce a singular potential.

Inserting the time dependence (4.10) into the expressions for the potential (5.12), we finally obtain the dark-bright soliton solution of the VNLS equation (1.3),

$$r^{(1)}(x,t) = \nu_1 (q_0^2/|z_1|^2 - 1)^{1/2} e^{i\varphi_1 - 2iq_0^2 t + ik_1 x - i(k_1^2 - \nu_1^2)t} \operatorname{sech}[\nu_1(x - 2k_1 t) + x_0], \tag{5.14a}$$

$$r^{(2)}(x,t) = q_0 e^{i\varphi_2 - 2iq_0^2 t} \left[1 + \frac{2i\nu_1}{z_1^*} \frac{\exp[-2\nu_1 x + 4k_1\nu_1 t + 2x_0]}{1 + \exp[-2\nu_1 x + 4k_1\nu_1 t + 2x_0]} \right], \tag{5.14b}$$

where

$$e^{2x_0} = \frac{q_0^2}{4\nu_1^2}(q_0^2 - |z_1|^2)|C_1^{(2)}(0)|^2, \quad \varphi_1 = \arg C_1^{(2)}(0) + \theta_+^{(2)}(0), \quad \varphi_2 = -\theta_+^{(2)}(0). \tag{5.15}$$

As usual, the solution $\mathbf{q}(x,t)$ of Eq. (1.3) is obtained taking the complex conjugate of Eq. (5.14). The dark-bright solution (5.14) can be written in the more compact form

$$q^{(1)}(x,t) = -\nu_1 \sin\alpha \sqrt{q_0^2 - |z_1|^2}\, \mathrm{sech}[\nu_1(x-2k_1t)+x_0] e^{-ik_1x + i[2q_0^2 + (k_1^2 - \nu_1^2)]t - i\varphi_1}, \tag{5.16a}$$

$$q^{(2)}(x,t) = q_0\{\cos\alpha + i\sin\alpha \tanh[\nu_1(x-2k_1t)+x_0]\} e^{2iq_0^2 t - i\varphi_2}, \tag{5.16b}$$

where

$$k_1 = |z_1|\cos\alpha, \quad \nu_1 = -|z_1|\sin\alpha. \tag{5.17}$$

Again, note that the condition $k_1^2+\nu_1^2 \equiv |z_1|^2 < q_0^2$ (i.e., the requirement that the discrete eigenvalue z_1 is inside the circle C_0 of radius q_0) is necessary and sufficient to ensure the regularity of the solution at all times.

Equation (5.16) describes a two-component solution in which the second component $q^{(2)}(x,t)$ represents a dark soliton similar to that in Eq. (1.2) (but with a different relation between amplitude and velocity), while the first component $q^{(1)}(x,t)$ describes a bright soliton similar to that of the scalar focusing NLS (but with a different relation between amplitude and phase). The two components travel together at the same speed $2k_1$. Note that the amplitude of the bright soliton component and that of the intensity dip in the dark soliton component are related by the condition $k_1^2+\nu_1^2 < q_0^2$, and the amplitude of the bright component goes to zero as the eigenvalue approaches the circle (i.e., in the limit $|z_1| \to q_0$). With proper identification of the parameters, Eqs. (5.16) also coincide with the dark-bright soliton solution given in Ref. 19 in the case of x-independent asymptotic boundaries and with $x_0=0$.

VI. SMALL AMPLITUDE LIMIT

It is useful to consider the limit in which the solution $\mathbf{q}(x,t)$ of Eq. (1.3) is a small perturbation of the background field.

A. Linearization

Recall that $\mathbf{q}(x,t) \to \mathbf{q}_\pm(t) = e^{i\Theta_\pm(t)}\mathbf{q}_0$ as $x \to \pm\infty$, with $\Theta_\pm(t) = \mathrm{diag}(\theta_\pm^{(1)}, \theta_\pm^{(2)})$, and $\theta_\pm^{(j)}(t) = \theta_\pm^{(j)}(0) + 2iq_0^2 t$, and with $q_0 = \|\mathbf{q}_0\|$ as usual. We then consider the "normalized" vector NLS equation

$$i\tilde{\mathbf{q}}_t = \tilde{\mathbf{q}}_{xx} + 2(q_0^2 - \|\tilde{\mathbf{q}}\|^2)\tilde{\mathbf{q}}, \tag{6.1}$$

for the rescaled field $\tilde{\mathbf{q}}(x,t) = \mathbf{q}(x,t)e^{-2iq_0^2 t}$, and we define

$$\tilde{\mathbf{q}}(x,t) = e^{i\Theta_+(0)}(\mathbf{q}_0 + \mathbf{u}(x,t)), \tag{6.2}$$

with $\|\mathbf{u}(x,t)\| \ll q_0$, so that $\mathbf{u}(x,t)$ represents a small perturbation of the background field $\mathbf{q}_+(t)$. Inserting Eq. (6.2) into the rescaled VNLS equation (6.1) and neglecting higher powers of $\mathbf{u}$ we then obtain a linearization of the VNLS equation around the background solution,

$$i\mathbf{u}_t = \mathbf{u}_{xx} - 2\mathbf{q}_0\mathbf{q}_0^T(\mathbf{u} + \mathbf{u}^*). \tag{6.3}$$

We now look for solutions of Eq. (6.3) employing standard Fourier transforms, where for convenience we write the transform pair as follows:

$$\mathbf{u}(x,t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \hat{\mathbf{u}}(k,t)e^{2ikx}\,dk, \quad \hat{\mathbf{u}}(k,t) = 2\int_{-\infty}^{\infty} \mathbf{u}(x,t)e^{-2ikx}\,dx. \tag{6.4}$$

Inserting the first of Eqs. (6.4) into Eq. (6.3) with (6.2), one finds a system of four first-order differential equations in time for the functions $\hat{\mathbf{u}}(k,t) \equiv (\hat{u}_1(k,t), \hat{u}_2(k,t))$ and $\hat{\mathbf{u}}^*(-k,t)^T \equiv (\hat{u}_1^*(-k,t), \hat{u}_2^*(-k,t))^T$, which can then be solved to obtain

$$\hat{\mathbf{u}}(k,t) = A_1(k)e^{4ik^2t}\mathbf{q}_0^{\perp} + (k - \sqrt{k^2+q_0^2})A_2(k)e^{-4ik\sqrt{k^2+q_0^2}t}\mathbf{q}_0 + (k + \sqrt{k^2+q_0^2})A_3(k)e^{4ik\sqrt{k^2+q_0^2}t}\mathbf{q}_0, \tag{6.5}$$

where $\mathbf{q}_0^{\perp} = (q_0^{(2)}, -q_0^{(1)})^T \in \mathbb{R}^2$. The functions $A_1(k), A_2(k), A_3(k)$ satisfy the symmetry conditions

$$A_2^*(-k) = -A_2(k), \quad A_3^*(-k) = -A_3(k), \tag{6.6}$$

and can be written in terms of the Cauchy data as follows:

$$A_1(k) = \frac{\hat{\mathbf{u}}_0^T(k)\mathbf{q}_0^{\perp}}{q_0^2}, \tag{6.7a}$$

$$A_2(k) = \frac{1}{4kq_0^2\sqrt{k^2+q_0^2}}[(-k + \sqrt{k^2+q_0^2})\mathbf{q}_0^T\hat{\mathbf{u}}_0(k) + (k + \sqrt{k^2+q_0^2})\mathbf{q}_0^T\hat{\mathbf{u}}_0^*(-k)], \tag{6.7b}$$

$$A_3(k) = \frac{1}{4kq_0^2\sqrt{k^2+q_0^2}}[(-k + \sqrt{k^2+q_0^2})\mathbf{q}_0^T\hat{\mathbf{u}}_0^*(-k) + (k + \sqrt{k^2+q_0^2})\mathbf{q}_0^T\hat{\mathbf{u}}_0(k)], \tag{6.7c}$$

where $\hat{\mathbf{u}}_0(k) = \hat{\mathbf{u}}(k,0)$. Together, Eqs. (6.5) and (6.7) yield the solution of the linearized VNLS Eq. (6.3) in terms of given Cauchy data, which in turn provides an approximation of the solution $\mathbf{q}(x,t)$ of the VNLS equation (1.3) in the small amplitude limit.

B. Small amplitude limit from the inverse problem

If we consider the equations of the inverse problem (3.8a), (3.8b), and (3.8c) with no solitons, in the small amplitude limit we can approximate each term on the left-hand side with a series in powers of $\rho_j(z,t)$. Keeping only linear terms in $\rho_j(z,t)$, according to Eq. (2.46b), the expansion as $z \to 0$ of the last two components of $\psi_3(x,z)e^{-i\lambda(z)x}$ yields

$$\mathbf{q}(x,t) = \mathbf{q}_+(t)\left[1 + \frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{d\zeta}{\zeta}\rho_1^*(\zeta,t)e^{2i\lambda(\zeta)x}\right] - \mathbf{r}_+^{\perp}(t)\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{d\zeta}{\zeta}\rho_2^*(\hat{\zeta}^*,t)e^{-i(k(\zeta)-\lambda(\zeta))x} \tag{6.8}$$

(with $\hat{\zeta} = q_0^2/\zeta^*$ as usual). In order to compare with the Fourier transform solutions obtained in the preceding sections, we recall that $\mathbf{q}_{\pm}(t) = e^{i\Theta_{\pm}(t)}\mathbf{q}_0$ and $\mathbf{r}_{\pm}(t) = \exp[-i\Theta_{\pm}(t)]\ \mathbf{q}_0$, and we consider again the normalization $\tilde{\mathbf{q}}(x,t) = \mathbf{q}(x,t)e^{-2iq_0^2t}$. Then, taking into account the time dependence of the scattering coefficients [cf. Eqs. (4.7)], from Eqs. (6.8) we get

$$\tilde{\mathbf{q}}(x,t) = \mathbf{q}_+\left[1 + \frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{d\zeta}{\zeta}\rho_1^*(\zeta,0)e^{2i\lambda(\zeta)x - 4ik(\zeta)\lambda(\zeta)t}\right] - \mathbf{r}_+^{\perp}\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{d\zeta}{\zeta}\rho_2^*(\hat{\zeta}^*,0)e^{-i(q_0^2/\zeta)x + i(q_0^2/\zeta)^2t}, \tag{6.9}$$

where now $\mathbf{q}_+ \equiv \mathbf{q}_+(0)$ and $\mathbf{r}_+ \equiv \mathbf{r}_+(0)$. In order to compare with the results in the preceding section, we then perform appropriate changes of variables. Consider the term in square brackets in Eq. (6.9). First, we revert from ζ to the original coordinates $k, \lambda(k)$, so that k runs over the contour $\mathcal{L}$ given by the branch cuts in Fig. 1 and defined in Sec. II A. Then we introduce the variable

$$\xi = \sqrt{k^2 - q_0^2},$$

so that $\xi\, d\xi = k\, dk$, obtaining

$$\int_{-\infty}^{\infty}\frac{\mathrm{d}\zeta}{\zeta}\rho_1^*(\zeta,0)e^{2i\lambda(\zeta)x}e^{-4ik(\zeta)\lambda(\zeta)t}=\int_{\mathcal{L}}\frac{\mathrm{d}k}{\lambda(k)}\rho_1^*(k,\lambda(k),0)e^{2i\lambda(k)x}e^{-4ik\lambda(k)t}$$
$$=\int_{-\infty}^{\infty}\frac{\mathrm{d}\xi}{\sqrt{\xi^2+q_0^2}}e^{2i\xi x}\big[\rho_1^*(\sqrt{\xi^2+q_0^2},\xi,0)e^{-4i\xi\sqrt{\xi^2+q_0^2}t}$$
$$-\rho_1^*(-\sqrt{\xi^2+q_0^2},\xi,0)e^{4i\xi\sqrt{\xi^2+q_0^2}t}\big]. \tag{6.10}$$

On the other hand, the second term in Eq. (6.9) can be written as an ordinary Fourier transform by simply performing the change of variable $2\xi=-q_0^2/\zeta$. By comparison, one can then show that Eq. (6.9), obtained solving the inverse problem in the limit of small amplitude, indeed coincides with the solution obtained via linearization, i.e., Eq. (6.2) with $\mathbf{u}(x,t)$ given by Eq. (6.4) and $\hat{\mathbf{u}}(k,t)$ by Eq. (6.5). More precisely, one has

$$A_1(\xi)=-\frac{1}{2k}e^{-i(\theta_+^{(1)}+\theta_+^{(2)})}\rho_2^*(-2\xi,\lambda(-2\xi),0), \tag{6.11a}$$

$$A_2(\xi)=\frac{i}{\sqrt{\xi^2+q_0^2}(\sqrt{\xi^2+q_0^2}-\xi)}\rho_1^*(\sqrt{\xi^2+q_0^2},\xi,0), \tag{6.11b}$$

$$A_3(\xi)=\frac{i}{\sqrt{\xi^2+q_0^2}(\sqrt{\xi^2+q_0^2}+\xi)}\rho_1^*(-\sqrt{\xi^2+q_0^2},\xi,0). \tag{6.11c}$$

Then, as a consequence of the symmetry conditions (6.6), it follows that

$$\rho_1(\sqrt{\xi^2+q_0^2},-\xi,0)=\frac{\sqrt{\xi^2+q_0^2}+\xi}{\sqrt{\xi^2+q_0^2}-\xi}\rho_1^*(\sqrt{\xi^2+q_0^2},\xi,0),$$

that is, in terms of the uniformization variable z,

$$\rho_1(\hat{z}^*)=\frac{z^2}{q_0^2}\rho_1^*(z),\quad z\in\mathbb{R}. \tag{6.12}$$

Note that Eq. (6.12) arises from the scattering data relations as well. Indeed, from the definitions (3.3) and symmetry (2.38) it follows

$$\rho_1^*(z)=\frac{b_{31}^*(z)}{b_{11}^*(z)}=\Gamma_1(z)\frac{a_{13}(z)}{a_{11}(z)}\Gamma_3^{-1}(z)\equiv-\frac{q_0^2}{z^2}\frac{a_{13}(z)}{a_{11}(z)} \tag{6.13a}$$

and the analog of symmetries (2.42) for the coefficients $b_{ij}(z)$ yields

$$\rho_1(z)=\frac{b_{31}(z)}{b_{11}(z)}=\frac{b_{13}(\hat{z}^*)}{b_{33}(\hat{z}^*)}. \tag{6.13b}$$

Recalling that $\mathbf{B}(z)=(b_{ij}(z))$ is the inverse matrix of $\mathbf{A}(z)=(a_{ij}(z))$, one can write

$$b_{13}(z)=a_{12}(z)a_{23}(z)-a_{13}(z)a_{22}(z),\quad b_{33}(z)=a_{11}(z)a_{22}(z)-a_{12}(z)a_{21}(z). \tag{6.14}$$

Then, since in the small amplitude limit terms $a_{ij}(z)$ with $i\neq j$ are $o(1)$ while $a_{jj}(z)=O(1)$, one has

$$\rho_1(z)=\frac{b_{13}(\hat{z}^*)}{b_{33}(\hat{z}^*)}\sim-\frac{a_{13}(\hat{z}^*)a_{22}(\hat{z}^*)}{a_{11}(\hat{z}^*)a_{22}(\hat{z}^*)},$$

and consequently Eq. (6.12) follows from Eq. (6.13).

VII. CONCLUSION

We have presented the inverse scattering transform (IST) for the defocusing VNLS equation (1.3) with nonvanishing boundary conditions as $|x|\to\infty$. The direct problem is constructed in terms of scattering eigenfunctions and adjoint eigenfunctions. The six scattering eigenfunctions provide four analytic functions, and the adjoint problem is used to construct two additional analytic functions. A global uniformizing parameter, z, is introduced in order to simplify and elucidate the analysis. The discrete eigenvalues are studied and it is found that one can have pairs of eigenvalues on a circle and/or quartets of eigenvalues symmetrically located inside and outside the circle. The inverse problem is formulated as a generalized Riemann-Hilbert (RH) problem for meromorphic functions in the complex plane of the uniformizing parameter z. The RH problem is transformed into a closed linear system of algebraic-integral equations. The trace formula, conservation laws, and explicit solutions (dark-dark and dark-bright solitons) are obtained. The solution in the small amplitude limit is studied by direct Fourier transform methods and it is shown to agree with the linearized reduction of the inverse problem.

APPENDIX: WKB EXPANSION OF THE EIGENFUNCTIONS

Consider the following ansatz for the expansion of the eigenfunction $M_1(x,z)$ as $z\to\infty$:

$$M_1^{(1)}(x,z) = zM_{1,\infty}^{(1,-1)}(x) + M_{1,\infty}^{(1,0)}(x) + z^{-1}M_{1,\infty}^{(1,1)}(x) + z^{-2}M_{1,\infty}^{(1,2)}(x) + \cdots , \tag{A1a}$$

$$M_1^{(2)}(x,z) = M_{1,\infty}^{(2,0)}(x) + z^{-1}M_{1,\infty}^{(2,1)}(x) + z^{-2}M_{1,\infty}^{(2,2)}(x) + \cdots , \tag{A1b}$$

$$M_1^{(3)}(x,z) = M_{1,\infty}^{(3,0)}(x) + z^{-1}M_{1,\infty}^{(3,1)}(x) + z^{-2}M_{1,\infty}^{(3,2)}(x) + \cdots . \tag{A1c}$$

Substituting these expressions into the scattering problem (2.1) with $k=(z+q_0^2/z)/2$ and matching the terms with the same order in z^{-n} for $n=-1,0,1,2,\ldots$ yields $M_{1,\infty}^{(1,-1)}(x)=\text{const}$, and the integral equation (2.8a) allows one to fix this constant value to

$$M_{1,\infty}^{(1,-1)}(x) = 1. \tag{A2a}$$

Proceeding further gives

$$M_{1,\infty}^{(2,0)}(x) = ir^{(1)}(x), \quad M_{1,\infty}^{(3,0)}(x) = ir^{(2)}(x), \quad \partial_x M_{1,\infty}^{(1,0)}(x) = i(\|\mathbf{q}(x)\|^2 - q_0^2), \tag{A2b}$$

that is,

$$M_{1,\infty}^{(1,0)}(x) = i\int_{-\infty}^{x} (\|\mathbf{q}(x')\|^2 - q_0^2)\mathrm{d}x' . \tag{A2c}$$

Similarly, at higher orders one has

$$M_{1,\infty}^{(j,m+1)}(x) = ir^{(j-1)}(x)M_{1,\infty}^{(1,m)}(x) - i\partial_x M_{1,\infty}^{(j,m)}(x), \quad m=0,1,2,\ldots \tag{A3a}$$

for $j=2,3$, as well as

$$\partial_x M_{1,\infty}^{(1,m)}(x) = -iq_0^2 M_{1,\infty}^{(1,m-1)}(x) + q^{(1)}(x)M_{1,\infty}^{(2,m)}(x) + q^{(2)}(x)M_{1,\infty}^{(3,m)}(x), \quad m=1,2,\ldots \tag{A3b}$$

which allow one to calculate iteratively all coefficients of the asymptotic expansion, with the recurrence relations in Eqs. (A3) anchored by Eqs. (A2). For instance, from Eq. (A3a) with $m=0$ we obtain

$$M_{1,\infty}^{(1,1)}(x) = I_1(x) - \tfrac{1}{2}(I_0(x))^2, \tag{A4a}$$

$$M_{1,\infty}^{(2,1)}(x) = r_x^{(1)}(x) - r^{(1)}(x)I_0(x), \quad M_{1,\infty}^{(3,1)}(x) = r_x^{(2)}(x) - r^{(2)}(x)I_0(x), \tag{A4b}$$

where

$$I_0(x) = \int_{-\infty}^{x} (\|\mathbf{q}(x')\|^2 - q_0^2)\mathrm{d}x', \quad I_1(x) = \int_{-\infty}^{x} \mathbf{q}^T(x')\mathbf{r}_{x'}(x')\mathrm{d}x'. \tag{A4c}$$

Furthermore, from Eq. (A3a) with $m=1$ it follows that

$$M_{1,\infty}^{(2,2)}(x) = ir^{(1)}(x)\left[I_1(x) - \tfrac{1}{2}(I_0(x))^2\right] - ir_{xx}^{(1)}(x) + i(r^{(1)}(x)I_0(x))_x, \tag{A5}$$

$$M_{1,\infty}^{(3,2)}(x) = ir^{(2)}(x)\left[I_1(x) - \tfrac{1}{2}(I_0(x))^2\right] - ir_{xx}^{(2)}(x) + i(r^{(2)}(x)I_0(x))_x \tag{A6}$$

which can be substituted into Eq. (A3b) for $m=2$ to get

$$M_{1,\infty}^{(1,2)}(x) = iI_0(x)I_1(x) - \frac{i}{6}(I_0(x))^3 - iI_2(x), \tag{A7}$$

where

$$I_2(x) = \int_{-\infty}^{x} [\mathbf{q}^T(x')\partial_{x'}^2\mathbf{r}(x') - \|\mathbf{q}(x')\|^2(\|\mathbf{q}(x')\|^2 - q_0^2)]\mathrm{d}x' \tag{A8}$$

and so on and so forth.

Similarly, one can write a Taylor series expansion of the eigenfunction $M_1(x,z)$ as $z\to 0$ in the form

$$M_1^{(1)}(x,z) = zM_{1,0}^{(1,1)}(x) + z^2M_{1,0}^{(1,2)}(x) + z^3M_{1,0}^{(1,3)}(x) + \cdots, \tag{A9a}$$

$$M_1^{(2)}(x,z) = M_{1,0}^{(2,0)}(x) + zM_{1,0}^{(2,1)}(x) + z^2M_{1,0}^{(2,2)}(x) + \cdots, \tag{A9b}$$

$$M_1^{(3)}(x,z) = M_{1,0}^{(3,0)}(x) + zM_{1,0}^{(3,1)}(x) + z^2M_{1,0}^{(3,2)}(x) + \cdots. \tag{A9c}$$

Substituting this into Eq. (2.1) and matching terms with the same powers of z^n yields $M_{1,0}^{(2,0)}(x)$ $=$const and $M_{1,0}^{(3,0)}(x)=$const. As before, the value of such constants is fixed by the integral equation (2.8a) to give

$$M_{1,0}^{(2,0)}(x) = ir_-^{(1)}, \quad M_{1,0}^{(3,0)}(x) = ir_-^{(3)}. \tag{A10a}$$

In turn, these allow one to get

$$q_0^2M_{1,0}^{(1,1)}(x) = \mathbf{q}^T(x)\mathbf{r}_-. \tag{A10b}$$

Proceeding to higher orders, one obtains the recurrence relations

$$\partial_x M_{1,0}^{(j,m)}(x) = iM_{1,0}^{(j,m-1)}(x) + r^{(j-1)}(x)M_{1,0}^{(1,m)}(x), \quad m = 1,2,\ldots \tag{A11a}$$

for $j=2,3$, as well as

$$q_0^2M_{1,0}^{(1,m+1)}(x) = i\partial_x M_{1,0}^{(1,m)}(x) - iq^{(1)}(x)M_{1,0}^{(2,m)}(x) - iq^{(2)}(x)M_{1,0}^{(3,m)}(x), \quad m = 0,1,\ldots. \tag{A11b}$$

For instance, the first terms are

$$q_0^2 M_{1,0}^{(2,1)}(x) = \int_{-\infty}^{x} [r^{(1)}(x')\mathbf{q}^T(x')\mathbf{r}_- - q_0^2 r_-^{(1)}]\mathrm{d}x',$$

$$q_0^2 M_{1,0}^{(3,1)}(x) = \int_{-\infty}^{x} [r^{(2)}(x')\mathbf{q}^T(x')\mathbf{r}_- - q_0^2 r_-^{(2)}]\mathrm{d}x',$$

which in turn give

$$q_0^4 M_{1,0}^{(1,2)}(x) = i\mathbf{r}_-^T\mathbf{q}_x(x) - i\mathbf{q}^T(x)\int_{-\infty}^{x} [\mathbf{r}(x')\mathbf{q}^T(x')\mathbf{r}_- - q_0^2\mathbf{r}_-]\mathrm{d}x'$$

and so on and so forth.

In a similar way one can obtain the asymptotic expansions for the remaining analytic eigenfunctions and adjoint eigenfunctions.

Modified non-Abelian Toda field equations and twisted quasigraded Lie algebras

T. Skrypnyk[a)]
Bogoliubov Institute for Theoretical Physics of NASU, Institute of Mathematics of NASU, Kiev, Ukraine

(Received 24 February 2006; accepted 1 May 2006; published online 30 June 2006)

We construct a new family of quasigraded Lie algebras that admit the Kostant-Adler scheme. They coincide with special quasigraded deformations of twisted subalgebras of the loop algebras. Using them we obtain new hierarchies of integrable equations in partial derivatives which we call "modified" non-Abelian Toda field hierarchies. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2207719]

I. INTRODUCTION

Integrability of equations of 1+1 field theory and condensed matter physics is based on the possibility to represent them in the form of the so-called zero-curvature equations,[28,27]

$$\frac{\partial U(x,t,\lambda)}{\partial t} - \frac{\partial V(x,t,\lambda)}{\partial x} + [U(x,t,\lambda), V(x,t,\lambda)] = 0, \tag{1}$$

where $U(x,t,\lambda)$, $V(x,t,\lambda)$ are auxiliary matrices depending on dynamical variables (fields), their derivatives, and an additional complex parameter λ usually called "spectral."

The most productive interpretation of the zero-curvature equations is achieved (see Refs. 5, 7, and 15) if one treats them as a consistency condition for a set of commuting Hamiltonian flows on a dual space to some infinite-dimensional Lie algebra $\tilde{\mathfrak{g}}$ of matrix-valued function of λ written in the Euler-Arnold (generalized Lax) form. In this case the corresponding U-V pairs coincide with the matrix gradients of mutually commuting Hamiltonians with respect to the natural Lie-Poisson bracket on $\tilde{\mathfrak{g}}^*$. The method that provides the needed set of the commuting Hamiltonian flows is the famous Kostant-Adler scheme.[18,15] The main ingredient of this scheme is an existence of the decomposition of the algebra $\tilde{\mathfrak{g}}$ into the sum of two subalgebras, $\tilde{\mathfrak{g}}=\tilde{\mathfrak{g}}_+ + \tilde{\mathfrak{g}}_-$. Although this approach was originally based on the graded loop algebras $L(\mathfrak{g})=\mathfrak{g}\otimes P(\lambda,\lambda^{-1})$ (Refs. 7 and 15) that possess decompositions into sums of two subalgebras, in Refs. 8 and 9 it was shown that a special Lie algebra $\mathfrak{g}_{\mathcal{E}}$, living on an elliptic curve $\mathcal{E}$, also possess the decomposition $\mathfrak{g}_{\mathcal{E}}=\mathfrak{g}^+_{\mathcal{E}}+\mathfrak{g}^-_{\mathcal{E}}$. In our papers (Refs. 10, 20, and 21) we have generalized results of Refs. 8 and 9 onto the case of special guasigraded Lie algebras $\mathfrak{g}_{\mathcal{H}}$ living on an algebraic curve $\mathcal{H}$. In papers Refs. 22 and 23 we gave a Lie algebraic explanation of this construction. We have constructed a family of quasigraded Lie algebras $\tilde{\mathfrak{g}}_A$ possessing the decomposition $\tilde{\mathfrak{g}}_A=\tilde{\mathfrak{g}}^+_A+\tilde{\mathfrak{g}}^-_A$ parametrized by some numerical matrices A, that may be viewed as a quasigraded deformations of loop algebras, such that loop algebras themselves correspond to the case $A\equiv 0$ and quasigraded Lie algebras $\mathfrak{g}_{\mathcal{H}}$ correspond to the case $A\in \mathrm{Diag}(n)$.

In our previous papers (Refs. 24 and 25), using the constructed quasigraded Lie algebras $\tilde{\mathfrak{g}}_A$ we have obtained new hierarchies of integrable equations that coincide with the various generalizations of Landau-Lifshitz and anisotropic chiral field hierarchies.

In the present paper we develop our approach to the hierarchies of the integrable equations based on the quasigraded Lie algebras. We combine our previous results,[22–25] ideas of Refs. 14, 4,

[a)]Electronic mail: tskrypnyk@imath.kiev.ua

and 3, and define new types of the quasigraded Lie algebras admitting Kostant-Adler scheme. They coincide with the "twisted" subalgebras of the Lie algebras $\tilde{\mathfrak{g}}_A$ defined with the help of a Z_p grading of a finite-dimensional Lie algebra $\mathfrak{g}: \mathfrak{g}=\sum_{k=0}^{p-1}\mathfrak{g}_{\bar{k}}$ or, equivalently, with some its automorphism σ of the order p. It turned out, that for a special choice of the matrices A (that depends on the chosen Z_p grading of $\mathfrak{g}$) it is possible to define twisted subalgebras $\tilde{\mathfrak{g}}_A^{\sigma}\subset\tilde{\mathfrak{g}}_A$ in the analogous way as for the case of ordinary loop algebras $L(\mathfrak{g})$.[11,3]

Using the technique of Refs. 5, 15, and 7 we develop a general scheme of obtaining nonlinear partial differential equations admitting the zero-curvature representation starting from the Lie algebras $\tilde{\mathfrak{g}}_A^{\sigma}$. For this purpose we explicitly construct the dual space, coadjoint action, its invariants and Lie-Poisson brackets for the case of the Lie algebra $\tilde{\mathfrak{g}}_A^{\sigma}$. In the result we obtain integrable hierarchies satisfying zero-curvature conditions associated with the Lie algebras $\tilde{\mathfrak{g}}_A^{\sigma}$.

We explicitly obtain the simplest equations of these hierarchies which we call "modified" non-Abelian Toda field equations. These are the system of the two sets of equations of the hyperbolic type that could be rewritten in the form of the one set of nonlinear equations in partial derivatives of the following form (compare with a standard non-Abelian Toda field equation[17,16]):

$$\frac{\partial}{\partial x_+}\left(g_0^{-1}\frac{\partial}{\partial x_-}g_0\right)=\left[g_0^{-1}\frac{\partial}{\partial x_-}g_0, g_0^{-1}C^{(-1)}g_0\right]_A, \tag{2}$$

where $g_0\in G_0$, G_0 is a group of the Lie subalgebra $\mathfrak{g}_{\bar{0}}$ stable under the action of the automorphism σ, $C^{(-1)}\in\mathfrak{g}_{-\bar{1}}$ is a constant element, $[X,Y]_A\equiv XAY-YAX$ is the so-called A-bracket.

In the case of the trivial automorphism σ the corresponding equations are equivalent to the chiral field type equations independently discovered in Refs. 6 and 23. In the case of the second-order automorphism and Lie algebra so(4) the equations (2) are equivalent to one more type of the so(3) anisotropic chiral field equations. In the case of the Coxeter automorphism (principal grading) equations (2) coincide with the Abelian modified Toda field equations introduced for the case of $\mathfrak{g}=\mathrm{gl}(n)$ in Ref. 19 and for the case of a general $\mathfrak{g}$ in Ref. 26. In the case of the general automorphism σ equations (2) are new.

The structure of the present paper is the following: in the second section we define the quasigraded Lie algebras $\tilde{\mathfrak{g}}_A$, their "twisted" subalgebras $\tilde{\mathfrak{g}}_A^{\sigma}$ and consider in details the case of "principal" twisted subalgebras. In the third section we define dual spaces, Lie-Poisson brackets, and Casimir functions on $\tilde{\mathfrak{g}}_A^{\sigma}$. In the fourth section we obtain the zero-curvature equations with the values in the twisted subalgebras $\tilde{\mathfrak{g}}_A^{\sigma}$ and consider the case of modified non-Abelian Toda field equations as the simplest equations they yield. We also consider several examples of the obtained equations, in particular, the case of the trivial automorphism σ, Coxeter automorphism and automorphism of the second order.

II. *K-A* ADMISSIBLE QUASIGRADED LIE ALGEBRAS

A. "Homogeneous" quasigraded Lie algebras $\tilde{\mathfrak{g}}_A$

Definition 2.1: The infinite-dimensional Lie algebra $\tilde{\mathfrak{g}}$ *is called* $\mathbb{Z}$*-quasigraded of type* (p,q) (*Ref.* 13) *if it admits the decomposition*

$$\tilde{\mathfrak{g}}=\sum_{j\in\mathbb{Z}}\mathfrak{g}_j, \quad \textit{such that } [\mathfrak{g}_i,\mathfrak{g}_j]\subset\sum_{k=-p}^{q}\mathfrak{g}_{i+j+k}.$$

The following proposition holds true.[22]

Proposition 2.1: Let $\tilde{\mathfrak{g}}$ *be* $\mathbb{Z}$*-quasi-graded of type* $(0,1)$, *or* $(1,0)$. *Then* $\tilde{\mathfrak{g}}$ *admits the decomposition into the sum of its two subalgebras* $\tilde{\mathfrak{g}}=\tilde{\mathfrak{g}}_+ + \tilde{\mathfrak{g}}_-$.

In order to construct $\mathbb{Z}$-quasigraded algebras of type $(0,1)$ we will deform the Lie algebraic structure in loop algebras. We will introduce the new Lie bracket into $L(\mathfrak{g})=\mathfrak{g}\otimes Pol(\lambda,\lambda^{-1})$:

$$[X \otimes p(\lambda), Y \otimes q(\lambda)]_F = [X,Y] \otimes p(\lambda)q(\lambda) - F(X,Y) \otimes \lambda p(\lambda)q(\lambda), \tag{3}$$

where $X, Y \in \mathfrak{g}$, $p(\lambda), q(\lambda) \in Pol(\lambda, \lambda^{-1})$, $[\ ,\ ]$ on the right-hand side of this identity denotes an ordinary Lie bracket in $\mathfrak{g}$ and the map $F: \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}$ is skew. It is evident by the very construction that the Lie algebras with so defined bracket are $\mathbb{Z}$-quasi graded algebras of type $(0,1)$ with the quasigrading being defined in the standard way by degrees of the spectral parameter λ.

The next Propositions hold true.

Proposition 2.2: Let the cochain F satisfy the following two requirements:

$$(J1) \quad \sum_{c.p.\{i,j,k\}} (F([X_i,X_j],X_k) + [F(X_i,X_j),X_k]) = 0,$$

$$(J2) \quad \sum_{c.p.\{i,j,k\}} F(F(X_i,X_j),X_k) = 0.$$

Then bracket (3) *satisfies the Jacobi identity.*

In the case of classical matrix Lie algebras it is possible to give an explicit construction of a large (multiparametric) family of cochains F, that satisfy conditions (J1) and (J2).

Let $\mathfrak{g}$ be a classical matrix Lie algebra of the type $\mathrm{gl}(n)$, $\mathrm{so}(n)$, and $\mathrm{sp}(n)$ over the field of the complex or real numbers. We will realize algebra $\mathrm{so}(n)$ as follows: $\mathrm{so}(n) = \{X \in \mathrm{gl}(n) \,|\, X = -sX^{\mathrm{T}}s\}$, where s is the symmetric matrix and $s^2 = 1$, algebra $\mathrm{sp}(n)$ as the following matrix algebra: $\mathrm{sp}(n) = \{X \in \mathrm{gl}(n) \,|\, X = wX^{\mathrm{T}}w\}$, where n is an even number, $w \in \mathrm{so}(n)$ and $w^2 = -1$.

As it follows from the results of Ref. 2 (see also Ref. 1) the following Proposition holds true.

Proposition 2.3: Let $\mathfrak{g}$ *be a classical matrix Lie algebra over the field* $\mathbb{K}$ *of complex or real numbers. Let us define the numerical* ($\mathbb{K}$*-valued*) $n \times n$ *matrix A of the following type:*

(1) *A is arbitrary for* $\mathfrak{g} = \mathrm{gl}(n)$,
(2) $A = sA^{\mathrm{T}}s$ *for* $\mathfrak{g} = \mathrm{so}(n)$,
(3) $A = -wA^{\mathrm{T}}w$ *for* $\mathfrak{g} = \mathrm{sp}(n)$.

Then maps $F_A: \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}$ *of the form* $F_A(X,Y) = [X,Y]_A = XAY - YAX$ *are correctly defined skew symmetric maps that satisfy conditions (J1) and (J2).*

We will denote the infinite-dimensional Lie algebra with the Lie bracket, given by (3), by $\tilde{\mathfrak{g}}_A$ and the finite-dimensional vector space $\mathfrak{g}$ with the bracket $[\ ,\ ]_A$ by $\mathfrak{g}_A$.

Remark 1: The algebra $\tilde{\mathfrak{g}}_A$ could be realized also in the space of special matrix valued functions of λ with an ordinary Lie bracket $[\ ,\ ]$ (see Refs. 20–23). Nevertheless we consider realization in the space $\mathfrak{g} \otimes \mathrm{Pol}(\lambda, \lambda^{-1})$ with the "deformed" bracket to be more convenient.

B. "Twisted" quasigraded Lie algebras $\tilde{\mathfrak{g}}_A^{\sigma}$

In this section we will define another class of the quasigraded Lie algebras of the type $(0,1)$. They will coincide with the "twisted" subalgebras of the algebras $\tilde{\mathfrak{g}}_F$.

Let $\mathfrak{g} = \Sigma_{k=0}^{p-1} \mathfrak{g}_{\bar{k}}$ (where $\bar{j}$ denotes a class of equivalence of the elements $j \in \mathbb{Z} \bmod p\mathbb{Z}$) be a $\mathbb{Z}/p\mathbb{Z}$ grading of $\mathfrak{g}$. Let $X_{\alpha}^{\bar{j}}$ be a basic element of the subspace $\mathfrak{g}_{\bar{j}}$.

Let us consider the following subspace in $\tilde{\mathfrak{g}}_F$:

$$\tilde{\mathfrak{g}}_F^{\sigma} = \bigoplus_{j \in \mathbb{Z}} \mathfrak{g}_{\bar{j}} \otimes \lambda^j, \tag{4}$$

The next proposition holds true

Proposition 2.4: The subspace $\tilde{\mathfrak{g}}_F^{\sigma}$ *is the closed Lie subalgebra in* $\tilde{\mathfrak{g}}_F$ *if and only if:*

$$F(\mathfrak{g}_{\bar{i}}, \mathfrak{g}_{\bar{j}}) \subset \mathfrak{g}_{\overline{i+j+1}}. \tag{5}$$

Remark 2: It is known, that the $\mathbb{Z}/p\mathbb{Z}$ grading of $\mathfrak{g}$ may be defined with the help of some automorphism σ of the order p. If we extend the automorphism σ to the map $\hat{\sigma}$ of the whole

algebra $\tilde{\mathfrak{g}}_F$, defining its action on the space $\mathfrak{g}\otimes \mathrm{Pol}(\lambda,\lambda^{-1})$ in the standard way:[11] $\hat{\sigma}(X\otimes\lambda^k)=\sigma(X)\otimes e^{-2\pi ik/p}\lambda^k$, then subalgebra $\tilde{\mathfrak{g}}_F^{\sigma}$ can be defined as follows

$$\tilde{\mathfrak{g}}_F^{\sigma}=\{X\otimes p(\lambda)\in\tilde{\mathfrak{g}}_F|\sigma(X\otimes p(\lambda))=X\otimes p(\lambda)\,.\}.$$

Remark 3: From the very definition of $\tilde{\mathfrak{g}}_F^{\sigma}$ and the commutation relation in $\tilde{\mathfrak{g}}_F$ it follows that the algebra $\tilde{\mathfrak{g}}_F^{\sigma}$ is Z-quasigraded of type $(0,1)$.

From the above proposition it follows in particular, that the algebra $\tilde{\mathfrak{g}}_F^{\sigma}$ admits the direct sum decomposition $\tilde{\mathfrak{g}}_F^{\sigma}=\tilde{\mathfrak{g}}_F^{\sigma+}+\tilde{\mathfrak{g}}_F^{\sigma-}$, where

$$\tilde{\mathfrak{g}}_F^{\sigma+}=\bigoplus_{j\geq 0}\mathfrak{g}_{\bar{j}}\otimes\lambda^j,\quad \tilde{\mathfrak{g}}_F^{\sigma-}=\bigoplus_{j<0}\mathfrak{g}_{\bar{j}}\otimes\lambda^j \tag{6}$$

Now let us pass to the case of the matrix Lie algebras and the cochains F_A given by the proposition (2.3). In this case, condition (5) can be specialized.

The following Proposition holds true.

Proposition 2.5: Let us define the map $\mathcal{A}:\mathfrak{g}\to\mathfrak{g}$ *by the following formula:*

$$\mathcal{A}(X)=1/2(AX+XA).$$

Then condition (5) *is satisfied if and only if*

$$\mathcal{A}(\mathfrak{g}_{\bar{i}})\subset\mathfrak{g}_{\overline{i+1}}. \tag{7}$$

Proof: It is easy to show, that the cochain F_A can be rewritten in the following form:

$$F_A(X,Y)=[\mathcal{A}(X),Y]+[X,\mathcal{A}(Y)]-\mathcal{A}([X,Y]).$$

From this it immediately follows that condition (5) is satisfied if and only if $\mathcal{A}(\mathfrak{g}_{\bar{i}})\subset\mathfrak{g}_{\overline{i+1}}$.

That proves the proposition.

We will denote the Lie algebra $\tilde{\mathfrak{g}}_F^{\sigma}$ defined with the help of cocycle F_A by $\tilde{\mathfrak{g}}_A^{\sigma}$.

C. Example: "Principal" quasigraded Lie algebra

Let an algebra $\mathfrak{g}$ with the bracket $[\ ,\ ]$ be semisimple (reductive) classical Lie algebra of the rank r. Let $\mathfrak{h}\subset\mathfrak{g}$ be its Cartan subalgebra, $\Delta_{\pm}$ be its set of positive (negative) roots, Π—the set of simple roots, $H_i\in\mathfrak{h}$ basis of Cartan subalgebra E_{α}, $\alpha\in\Delta$ the corresponding root vectors.

Let us define the so-called "principal" grading of $\mathfrak{g}$,[11] setting

$$\deg H_i=0,\quad \deg E_{\alpha_i}=1,\quad \deg E_{-\alpha_i}=-1.$$

It is evident that in such a way we obtain the grading of $\mathfrak{g}$: $\mathfrak{g}=\Sigma_{k=0}^{h-1}\mathfrak{g}_{\bar{k}}$ with the graded subspaces $\mathfrak{g}_{\bar{k}}$ be defined as follows: $\mathfrak{g}_{\bar{k}}=\mathrm{Span}_C\{E_{\alpha}\}$, where α is the root of the length k, i.e., $\alpha=\Sigma_{i=1}^{r}k_iE_{\alpha_i}$ if $\alpha\in\Delta_+$, $\alpha=\Sigma_{i=1}^{r}k_iE_{-\alpha_i}$ if $\alpha\in\Delta_-$ and $k=\Sigma_{i=1}^{r}k_i$, h is a Coxeter number of $\mathfrak{g}$. In particular $\mathfrak{g}_{\bar{0}}=\mathfrak{h}$, $\mathfrak{g}_{\bar{1}}=\mathrm{Span}_C\{E_{\alpha_i},E_{-\theta}|a_i\in\Pi\}$, $\mathfrak{g}_{\overline{-1}}=\mathrm{Span}_C\{E_{-\alpha_i},E_{\theta}|a_i\in\Pi\}$ and θ is the longest root of the length $h-1$.

If the matrix A satisfies condition (7) we may define the corresponding "principal" quasigraded Lie algebra $\tilde{\mathfrak{g}}_A^{\sigma}$ in the following way:

$$\tilde{\mathfrak{g}}_A^{\sigma}=\sum_{m\in\mathbb{Z}}\sum_{j\in 0}^{h-1}\mathfrak{g}_{\bar{j}}^{(m)}\otimes\lambda^{j+mh},\quad \text{where } \mathfrak{g}_{\bar{j}}^{(m)}\simeq\mathfrak{g}_{\bar{j}}. \tag{8}$$

Remark 4: For all the classical Lie algebras $\mathfrak{g}$ and matrices A satisfying condition (7) it is possible to introduce (see Ref. 26) the following "pseudoroots" β_i^A ($\beta_i^A:\mathfrak{g}_{\overline{-1}}\to\mathbb{K}$):

$$[X,H_i]_A=\beta_i^A(X)H_i, \tag{9}$$

where $X\in\mathfrak{g}_{\overline{-1}}$ and H_i are basic elements in Cartan subalgebra.

III. DUAL SPACE, POISSON BRACKET AND ALGEBRA OF INTEGRALS

In order to describe an application of the Lie algebras $\tilde{\mathfrak{g}}_A^\sigma$ to the theory of finite-dimensional integrable Hamiltonian systems it is necessary to define a corresponding Lie-Poisson bracket on $(\tilde{\mathfrak{g}}_A^\sigma)^*$ and its central functions (Casimir functions) which will be used in order to produce the needed set of mutually commuting Hamiltonians on $(\tilde{\mathfrak{g}}_A^\sigma)^*$.

A. Coadjoint representation and Casimir functions of $\tilde{\mathfrak{g}}_A^\sigma$

In this section we will construct a dual space, a coadjoint representation and its invariants for the case of the twisted algebras $\tilde{\mathfrak{g}}_A^\sigma$. Due to the fact, that $\tilde{\mathfrak{g}}_A^\sigma$ is a subalgebra of $\tilde{\mathfrak{g}}_A$ we may consider $(\tilde{\mathfrak{g}}_A^\sigma)^*$ as a subspace of an σ-invariants in $\tilde{\mathfrak{g}}_A^*$. If p is the order of σ then from the properties of an invariant form on simple Lie algebras it follows[11] that $(\mathfrak{g}_i^-, \mathfrak{g}_{\bar{j}}^-)=0$ if $i+j\neq 0 \bmod p$. Hence defining a pairing between $\tilde{\mathfrak{g}}_A^\sigma$and $(\tilde{\mathfrak{g}}_A^\sigma)^*$ in the standard way,

$$\langle X,L\rangle = \mathrm{res}_{\lambda=0}\lambda^{-1}\,\mathrm{Tr}(X(\lambda)L(\lambda)). \tag{10}$$

we obtain that the generic element $L(\lambda)\in(\tilde{\mathfrak{g}}_A^\sigma)^*$ has the following form:

$$L(\lambda)=\sum_{j\in Z}\sum_{\alpha=1}^{\dim \mathfrak{g}_{\bar{j}}^-} l_\alpha^{(j)} X_\alpha^{\overline{-j}}\lambda^{-j},$$

where $X_\alpha^{\overline{-j}}$ is a basic element of subspace $\mathfrak{g}_{\overline{-j}}$.

The following proposition holds true.

Proposition 3.1: Let the functions $I^m(L)$ be the invariants of a coadjoint representation of $\mathfrak{g}$, $L(\lambda)\in(\tilde{\mathfrak{g}}_A^\sigma)^*$ *be defined as above*. Let $A(\lambda)=1-A\lambda$. *Then the functions*

$$I_k^m(L(\lambda))=\mathrm{res}_{\lambda=0}\lambda^{-k-1}I^m(L(\lambda)A(\lambda)^{-1}), \tag{11}$$

are the invariants of the coadjoint representation of the Lie algebra $\tilde{\mathfrak{g}}_A^\sigma$.

A proof of this proposition follows from the explicit form of the coadjoint action which, as it is easy to show, has the following form:

$$ad^*_{X(\lambda)}\circ L(\lambda)=A(\lambda)X(\lambda)L(\lambda)-L(\lambda)X(\lambda)A(\lambda), \tag{12}$$

where $X(\lambda), Y(\lambda)\in\tilde{\mathfrak{g}}_A^\sigma$, $L(\lambda)\in(\tilde{\mathfrak{g}}_A^\sigma)^*$.

Remark 5: The matrix $A(\lambda)^{-1}$ must be understood as a power series in λ in the neighborhood of 0 or ∞: $A(\lambda)^{-1}=(1+A\lambda+A^2\lambda^2+\cdots)$ or $A(\lambda)^{-1}=-(A^{-1}\lambda^{-1}+A^{-2}\lambda^{-2}+\cdots)$.

B. Lie-Poisson bracket

Let us define the Poisson structure in the space $(\tilde{\mathfrak{g}}_A^\sigma)^*$. Using pairing (10) described in the preceding section we can define the Lie-Poisson bracket on $P((\tilde{\mathfrak{g}}_A^\sigma)^*)$ in the standard way:

$$\{F_1(L(\lambda)),F_2(L(\lambda))\}=\langle L(\lambda),[\nabla F_1(L(\lambda)),\nabla F_2(L(\lambda))]_{A(\lambda)}\rangle, \tag{13}$$

here

$$\nabla F_i(L(\lambda))=\sum_{j\in Z}\sum_{\alpha=1}^{\dim \mathfrak{g}_{\bar{j}}^-}\frac{\partial F_i}{\partial l_\alpha^{(j)}}X_\alpha^{\bar{j}}\lambda^j$$

and

$$[\nabla F_1(L(\lambda)),\nabla F_2(L(\lambda))]_{A(\lambda)}=\nabla F_1(L(\lambda))A(\lambda)\,\nabla F_2(L(\lambda))-\nabla F_2(L(\lambda))A(\lambda)\,\nabla F_1(L(\lambda))$$

and $X_\alpha^{\bar{j}}$ is a basic element of the subspace $\mathfrak{g}_{\bar{j}}^-$.

Let us explicitly calculate Poisson bracket (13). It is easy to show, that for the coordinate functions $l_\alpha^{(i)}$, $l_\beta^{(j)}$, where $l_\alpha^{(i)} \in (\mathfrak{g}_{\bar{i}})^*$, $l_\beta^{(j)} \in (\mathfrak{g}_{\bar{j}})^*$, this bracket will have the following form:

$$\{l_\alpha^{(i)}, l_\beta^{(j)}\} = \sum_\gamma C_{\alpha,\beta}^\gamma l_\gamma^{(i+j)} - \sum_\delta C_{\alpha,\beta}^\delta(A) l_\delta^{(i+j+1)}, \tag{14}$$

where l_γ and l_δ are coordinate functions on $(\mathfrak{g}_{\overline{i+j}})^*$ and $(\mathfrak{g}_{\overline{i+j+1}})^*$.

This bracket determines in the space of linear functions $\{l_\alpha^{(i)}\}$ the Lie algebra structure isomorphic to $\tilde{\mathfrak{g}}_A^\sigma$ and, hence, the subspaces $((\tilde{\mathfrak{g}}_A^\sigma)^\pm)^*$ are Poisson.

C. Infinite-component Hamiltonian systems via $\tilde{\mathfrak{g}}_A^\sigma$

In this section we construct Hamiltonian systems on the infinite-dimensional space $(\tilde{\mathfrak{g}}_A^\sigma)^*$ possessing infinite number of independent, mutually commuting integrals of motion. Let

$$L^\mp(\lambda) = \sum_{j \in \mathbb{Z}_\pm} \sum_{\alpha=1}^{\dim \mathfrak{g}_j^-} l_\alpha^{(j)} \lambda^{-j} X_\alpha^{\overline{-j}}$$

be the generic elements of the spaces $(\tilde{\mathfrak{g}}_A^{\sigma\pm})^*$. Let us consider the polynomial functions on $(\tilde{\mathfrak{g}}_A^\sigma)^*$ of the form

$$I_k^{m\mp}(L(\lambda)) \equiv I_k^m(L^\mp(\lambda)), \tag{15}$$

where $\{I_k^m(L(\lambda))\}$ are the Casimir functions of $\tilde{\mathfrak{g}}_A^\sigma$. The Hmiltonian flows corresponding to the Hamiltonians $I_k^{m\mp}(L(\lambda))$ are written in a standard way,

$$\frac{\partial l_\alpha^{(j)}}{\partial t_k^{m\mp}} = \{l_\alpha^{(j)}, I_k^{m\mp}(L(\lambda))\}. \tag{16}$$

The following theorem is true.

Theorem 3.1: *(i) The time flows defined by the equations (16) mutually commute. (ii) Euler-Arnold equations* (16) *could be written in the deformed Lax form*

$$\frac{\partial L(\lambda)}{\partial t_k^{m\mp}} = A(\lambda) M_k^{m\pm}(\lambda) L(\lambda) - L(\lambda) M_k^{m\pm}(\lambda) A(\lambda). \tag{17}$$

where

$$M_k^{m\pm}(\lambda) = \nabla I_k^m(L^\mp(\lambda)) = \sum_{j \in \mathbb{Z}_\pm} \sum_{\alpha=1}^{\dim \mathfrak{g}_j^-} \frac{\partial I_k^m}{\partial l_\alpha^{(j)}} X_a^{\bar{j}} \lambda^j.$$

(iii) The functions $I_q^p(L^\pm)$ are constant along all times $t_k^{m\pm}$ and $t_l^{n\mp}$.

The proof of this theorem repeats the proof of the analogous theorem for the case of ordinary loop algebras (see Ref. 15 and references therein).]

IV. "MODIFIED" TODA FIELD EQUATIONS

A. Zero-curvature condition with the values in $\tilde{\mathfrak{g}}_A^\sigma$

In this section we will obtain zero-curvature-ype equations with the values in the Lie algebras $\tilde{\mathfrak{g}}_A^\sigma$.

The following theorem holds true.

Theorem 4.1: *Let the infinite-dimensional Lie algebras $\tilde{\mathfrak{g}}_A^\sigma$, $\tilde{\mathfrak{g}}_A^{\sigma\pm}$, their dual spaces and polynomial Hamiltonians $I_k^m(L^\pm(\lambda))$, $I_s^n(L^\pm(\lambda))$ on them be defined as in preceding sections. Then the algebra-valued gradients of these functions satisfy the "deformed" zero-curvature equations*

$$\frac{\partial \nabla I_k^m(L^{\pm}(\lambda))}{\partial t_l^{n\pm}} - \frac{\partial \nabla I_s^n(L^{\pm}(\lambda))}{\partial t_k^{m\pm}} + [\nabla I_k^m(L^{\pm}(\lambda)), \nabla I_s^n(L^{\pm}(\lambda))]_{A(\lambda)} = 0, \tag{18}$$

$$\frac{\partial \nabla I_k^m(L^{\pm}(\lambda))}{\partial t_l^{n\mp}} - \frac{\partial \nabla I_s^n(L^{\mp}(\lambda))}{\partial t_k^{m\pm}} + [\nabla I_k^m(L^{\pm}(\lambda)), \nabla I_s^n(L^{\mp}(\lambda))]_{A(\lambda)} = 0. \tag{19}$$

Idea of the Proof: The statement of the theorem, i.e., validity of the equations (18) and (19), follows from the commutativity of the "deformed" Lax flows (17) constructed in the preceding section.

Remark 6: Using the above-mentioned realizations of $\tilde{\mathfrak{g}}_A^{\sigma}$ the deformed zero-curvature equations can be rewritten in the form of the standard zero-curvature equations, but in this case the corresponding *U-V* pairs will be more complicated and we will work with the zero-curvature equations in the "deformed" form (18) and (19).

Theorem 4.1 provides us with an infinite number of $\tilde{\mathfrak{g}}_A^{\sigma}$-valued *U-V* pairs that satisfy zero-curvature-type equations. The latter are nonlinear equations in partial derivatives in the dynamical variables—matrix elements of the matrix $L(\lambda)$. In the terminology of Ref. 27 equations generated by the infinite set of *U-V* pairs are called "integrable in the kinematic sense." In the next sections we will consider the simplest examples of such integrable equations and their hierarchies.

B. Modified non-Abelian Toda-field equations

In this section we obtain concrete examples of integrable equations satisfying the "deformed" zero-curvature representations constructed in the preceding section. The most interesting of them will be "modified" non-Abelian Toda field equations.

Let us at first consider a general situation. Let the Lie algebra $\tilde{\mathfrak{g}}_A^{\sigma}$ and its decomposition $\tilde{\mathfrak{g}}_A^{\sigma} = \tilde{\mathfrak{g}}_A^{\sigma+} + \tilde{\mathfrak{g}}_A^{\sigma-}$ be defined as in Sec. II C. Generic elements $L^{\pm}(\lambda) \in (\tilde{\mathfrak{g}}_A^{\sigma\mp})^*$ of the dual spaces have the following form:

$$L^{+}(\lambda) = \lambda L^{(-1)} + \lambda^2 L^{(-2)} + \cdots, \quad L^{-}(\lambda) = L^{(0)} + \lambda^{-1} L^{(1)} + \lambda^{-2} L^{(2)} + \cdots,$$

where $L^{(k)} \in \mathfrak{g}_{\overline{-k}}$. Now we can formulate the following theorem.

Theorem 4.2: *Let* $\mathfrak{g}$ *be one of the classical matrix Lie algebras* $gl(n)$, $so(n)$, $sp(n)$. *Let* $\mathfrak{g} = \sum_{j=0}^{p-1} \mathfrak{g}_k$ *be* Z_p *grading of* $\mathfrak{g}$ *corresponding to some automorphism* σ *of order p. Let the "deformation" matrix A satisfy conditions* (7). *Then*

(i) *among the corresponding equations* (19) *there is the equation equivalent to the system of the following differential equations:*

$$\frac{\partial U^{(0)}}{\partial x_+} = [U^{(0)}, V^{(-1)}]_A, \tag{20a}$$

$$\frac{\partial V^{(-1)}}{\partial x_-} = -[V^{(-1)}, U^{(0)}]. \tag{20b}$$

The corresponding U-V pair for the "deformed" zero-curvature conditions is

$$U = U^{(0)} = \sum_{\alpha=1}^{\dim \mathfrak{g}_0} u_{\alpha}^{(0)} X_{\alpha}^{\bar{0}} \in \mathfrak{g}_{\bar{0}}, \quad V = \lambda^{-1} V^{(-1)} = \lambda^{-1} \sum_{\alpha=1}^{\dim \mathfrak{g}_0} v_{\alpha}^{(-1)} X_{\alpha}^{\overline{-1}} \in \mathfrak{g}_{\overline{-1}} \lambda^{-1}. \tag{21}$$

(ii) *System of equations* (20a) and (20b) *is written in the form of the "modified" non-Abelian Toda field equations*,

$$\frac{\partial}{\partial x_+}\left(g_0^{-1} \frac{\partial}{\partial x_-} g_0\right) = \left[g_0^{-1} \frac{\partial}{\partial x_-} g_0, g_0^{-1} C^{(-1)} g_0\right]_A, \tag{22}$$

where g_0 is an element of the subgroup G_0 and $C^{(-1)}$ is a fixed element of the subspace $\mathfrak{g}_{-1}$.

Proof: To prove item (i) of the theorem we will show, that among the integrals I_k^m, I_l^n there are such integrals $I_{k_0}^{m_0}, I_{l_0}^{n_0}$ that

$$I_{k_0}^{m_0}(L^+(\lambda)) \equiv I_{k_0}^{m_0}(L^{(-1)}), \quad I_{l_0}^{n_0}(L^-(\lambda)) \equiv I_{l_0}^{n_0}(L^{(0)}).$$

Indeed, let us consider the generating series $I_{k_0}^{m_0}(L^+(\lambda))$,

$$I_{k_0}^{m_0}(L^+(\lambda)) = I^{m_0}(A^{-1}(\lambda)L^+(\lambda)) = I^{m_0}((1 + A\lambda + A^2\lambda^2 + \dots)(\lambda L^{(-1)} + \lambda^2 L^{(-2)} + \dots)).$$

Taking into account that I^{m_0} is a homogeneous polynomial on $\mathfrak{g}^*$ we easily obtain that $I_{m_0}^{m_0}(L^+(\lambda)) = I_{m_0}^{m_0}(L^{(-1)})$. Now, for the role of I^{m_0} we must take any Casimir function on $\mathfrak{g}$ that has a nontrivial restriction onto $\mathfrak{g}_{\overline{1}}$. Such the Casimir function always exists because the generic element of the space $\mathfrak{g}_{\overline{1}}$ is never nilpotent.

Let us now consider the generating series $I^{n_0}(L^-(\lambda))$. It is evident that if we choose the generating Casimir function as follows: $I^{n_0}(L^-(\lambda)) = \det A(\lambda)\mathrm{Det}(L^-(\lambda)A(\lambda)^{-1})$, we obtain

$$I^{n_0}(L^-(\lambda)) = \mathrm{Det}(L^-(\lambda)), \quad D_0^{n_0}(L^-(\lambda)) = \mathrm{Det}(L^{(0)}).$$

Matrix gradients of these functions have the following form:

$$\nabla I_{m_0}^{m_0}(L^+(\lambda)) \equiv V = \lambda^{-1} \sum_{\beta=1}^{\dim \mathfrak{g}_0} v_\beta^{(-1)} X_\beta^{\overline{-1}}, \nabla I_0^{n_0}(L^-(\lambda)) \equiv U = \sum_{\alpha=1}^{\dim \mathfrak{g}_0} u_\alpha^{(0)} X_\alpha^{\overline{0}},$$

where $u_\alpha \equiv \partial I_0^{n_0} / \partial l_\alpha^{(0)}$, $v_\beta \equiv \partial I_{m_0}^{m_0} / \partial l_\beta^{(-1)}$. Substituting this into zero-curvature condition

$$\frac{\partial U}{\partial x_+} - \frac{\partial V}{\partial x_-} + [U, V]_{A(\lambda)} = 0$$

we obtain item (i) of the theorem.

It is easy to verify, that by the substitution of variables $U^{(0)} = -g_0^{-1}(\partial/\partial x_-)g_0$, $V^{(-1)} = g_0^{-1}C^{(-1)}g_0$, where g_0 is an element of the subgroup $G_0 \subset G$ corresponding to the subalgebra $\mathfrak{g}_{\overline{0}}$ and $C^{(-1)}$ is a fixed element of the subspace $\mathfrak{g}_{\overline{-1}}$, we solve Eq. (20b) and obtain Eq. (22). That proves item (ii).

Theorem is proved.

Remark 7: In general, having the cocycle F satisfying conditions (J1) and (J2) and (5) on an *arbitrary* semisimple or reductive Lie algebra $\mathfrak{g}$ it is possible to write more general form of the system: (20a) and (20b), namely,

$$\frac{\partial U^{(0)}}{\partial x_+} = F(U^{(0)}, V^{(-1)}), \quad \frac{\partial V^{(-1)}}{\partial x_-} = -[V^{(-1)}, U^{(0)}]. \tag{23}$$

The corresponding generalized "modified" non-Abelian Toda field equation has the form

$$\frac{\partial}{\partial x_+}\left(g_0^{-1}\frac{\partial}{\partial x_-}g_0\right) = F\left(g_0^{-1}\frac{\partial}{\partial x_-}g_0, g_0^{-1}C^{(-1)}g_0\right), \tag{24}$$

where g_0 is an element of the group G_0 and $C^{(-1)}$ is a fixed element of the subspace $\mathfrak{g}_{-1}$. Of course these equations coincide with the Eqs. (20a), (20b), and (22) if $F \equiv F_A$. But in the case of the general F it is not possible to write coadjoint invariants of $\widetilde{\mathfrak{g}}_F^\sigma$ without the detailization of the form of F. That is why in the general case it is difficult to give to equations (23) interpretation of the consistency condition of two Hmiltonian flows without such detailization, and we have considered the case $F \equiv F_A$ as our basic example.

C. Example: anisotropic chiral field-type equation

In this section we consider the case $\sigma=\mathrm{id}$ that corresponds to the homogeneous grading of $\mathfrak{g}$. We will show that anisotropic "chiral field-type" equations independently discovered in Refs. 6 and 22 is a particular case of the non-Abelian modified Toda field equations. In this case $p=1$ and $\mathfrak{g}_i^- \simeq \mathfrak{g}_{\overline{i+1}}$ and we may put $\mathfrak{g}_{\bar{0}}=\mathfrak{g}_{\overline{-1}}=\mathfrak{g}$. Taking into account that no requirements (5) and (7) are imposed in this case onto the cochain F_A and matrix A we may formulate the following corollary of the Theorem 4.2.

Corollary 4.1: Let $\sigma=\mathrm{id}$. *In this case equations* (20a) and (20b) *coincide with the anisotropic chiral field-type equations*

$$\frac{\partial U}{\partial x_+}=[U,V]_A, \quad \frac{\partial V}{\partial x_-}=-[V,U]. \tag{25}$$

The corresponding U-V pair for the "deformed" zero-curvature conditions is

$$U(\lambda)=U, \quad V(\lambda)=\lambda^{-1}V, \quad U,V\in\mathfrak{g}.$$

Let us consider the most interesting small rank example of equations (25).

Example 1: Let $\mathfrak{g}=\mathrm{so}(3)$, $A=\mathrm{diag}(a_1,a_2,a_3)$. In this case we can consider elements of $U,V \in \mathfrak{g}^* \simeq \mathrm{so}(3)$ as vectors $\vec{u},\vec{v}\in\mathbb{R}^3$ and rewrite equations (25) in the following form:

$$\frac{\partial \vec{u}}{\partial x_+}=A([\vec{u}\times\vec{v}]), \quad \frac{\partial \vec{v}}{\partial x_-}=[\vec{u}\times\vec{v}], \tag{26}$$

where matrix A acts on $\vec{u}=\Sigma_{i=1,3}u_kX_k$ as on a vector in $\mathbb{R}^3$: $A(\vec{u})=\Sigma_{i=1,3}a_ku_kX_k$. In this case it is possible to introduce the vector-potential $\vec{\phi}$ such that $\vec{u}=A(\partial\vec{\phi}/\partial x_-)$, $\vec{v}=\partial\vec{\phi}/\partial x_+$ and rewrite two equations (26) in the form of one equation in partial derivatives,

$$\frac{\partial^2\vec{\phi}}{\partial x_+\,\partial x_-}=-\left[\frac{\partial\vec{\phi}}{\partial x_+}\times A\left(\frac{\partial\vec{\phi}}{\partial x_-}\right)\right]. \tag{27}$$

Anisotropic chiral field-type equations (25) are in a certain sense maximally "non-Abelian" among all of the non-Abelian modified Toda-field equations and contain a maximal number of independent variables. All other non-Abelian (and Abelian) modified Toda-field equations may be viewed as their reductions with the help of some automorphism of the order p. Of course, each of these reductions is possible only in the case when matrix A satisfy additionally condition (7). In the next section we will consider such conditions and the corresponding reductions in the case $\sigma^2=\mathrm{id}$.

D. Example: "intermediate" modified Toda equation

In this section we consider "intermediate" modified Toda equation that corresponds to the involutive automorphism: $\sigma^2=\mathrm{id}$. In this case $p=2$, $\mathfrak{g}=\mathfrak{g}_{\bar{0}}+\mathfrak{g}_{\bar{1}}$ and we set $\mathfrak{g}_0\equiv\mathfrak{g}_+$, $\mathfrak{g}_1\equiv\mathfrak{g}_-$. Besides it is possible to simplify condition (7). The following Proposition holds.

Proposition 4.1: Let an involutive automorphism σ *of* $\mathfrak{g}\subset gl(n)$ *be lifted to the automorphism (minus antiautomorphism) of the algebra* $gl(n)$ *as an associative algebra. Then condition* (7) *is satisfied if and only if*

$$\sigma(A)=-A \quad [\sigma(A)=A]. \tag{28}$$

Now we can formulate the corollary of the Theorem 4.2 in the following way.

Corollary 4.2: Let $\sigma^2=id$ *and matrix A satisfies condition* (28). *In this case equations* (20a) and (20b) *acquire the following form:*

$$\frac{\partial U_+}{\partial x_+}=[U_+,V_-]_A, \quad \frac{\partial V_-}{\partial x_-}=-[V_-,U_+]. \tag{29}$$

The corresponding U-V pair for the "deformed" zero-curvature conditions is

$$U = U_+, \quad V = \lambda^{-1} V_-, \quad V_- \in \mathfrak{g}_-, \quad U_+ \in \mathfrak{g}_+. \tag{30}$$

Equations (29) may be viewed as a reduction of the equations (25). Let us consider the following low rank example.

Example 2: Let $\mathfrak{g}=\mathrm{so}(4)$. We introduce the following standard basis of so(4): $X_k \equiv \epsilon_{ijk} X_{ij}$, $Y_k \equiv X_{k4}$, $i,j,k \in 1,3$, $X_{ij}=-X_{ji}$ and consider Z_2 grading of so(n): $\mathrm{so}(4)=\mathrm{so}(4)_0+\mathrm{so}(4)_1 \equiv \mathrm{so}(3)+\mathbb{R}^3$, where $\mathrm{so}(3)=\mathrm{Span}_C\{X_i\}$, $\mathbb{R}^3=\mathrm{Span}_C\{Y_i\}$. In this case the corresponding automorphism σ has the form $\sigma(X)=wXw^{-1}$, where $w=\mathrm{diag}(1,1,1,-1)$, and, evidently is lifted to the (inner) automorphism of gl(4). Hence, according to the condition (28) the matrix A should belong to $\mathrm{gl}(4)_1$ and be symmetric in order to provide that bracket $[\ ,\ ]_A$ be closed on so(4).

U-V pair and matrix A has in this case the following form:

$$U_+ = \sum_{1\le k\le 3} u_k X_k, \quad V_- = \sum_{1\le k\le 3} v_k Y_k, \quad A = \sum_{1\le k\le 3} a_k Y_k^+,$$

where $Y_k^+ = E_{k4} + E_{4k}$ and E_{kl} is the standard matrix basis in gl(n), $(E_{kl})_{\alpha\beta} = \delta_{k\alpha}\delta_{l\beta}$. Introducing in the evident manner three-component vectors $\vec{u}$, $\vec{v}$, $\vec{a}$ and the following notation, $J_a(\vec{u}) \equiv [\vec{a}\times\vec{u}]$, we may rewrite corresponding equations (31) as follows:

$$\frac{\partial \vec{u}}{\partial x_+} = [\vec{v} \times J_a(\vec{u})], \quad \frac{\partial \vec{v}}{\partial x_-} = [\vec{u} \times \vec{v}]. \tag{31}$$

These equations are also *the anisotropic chiral field-type equations*, possessing very special "anisotropy tensor" J_a. Equations (31) seems to be new. Their possible generalization are equations

$$\frac{\partial \vec{u}}{\partial x_+} = F(\vec{u},\vec{v}), \quad \frac{\partial \vec{v}}{\partial x_-} = [\vec{u} \times \vec{v}], \tag{32}$$

where F is any other Lie bracket on so(4) compatible with the standard one and satisfying condition (5) for the described above Z_2 gradation of so(4).

E. Example: "Abelian" modified Toda-field equation

Let us consider the equations (20a) and (20b) in the case of the "principal" quasigrading that was described in Sec. II C. In this case G_0 coincides with the Cartan subgroup, $\mathfrak{g}_0$ is the Cartan subalgebra and the corresponding modified Toda system is Abelian.

By the direct verification one can prove the following corollary of the Theorem 4.2.

Corollary 4.3: (i) Let σ be Coxeter automorphism and the matrix A satisfies condition (7). *In this case equations* (20a) and (20b) *coincide with the following "Volterra coupled system:"*

$$\partial_t u_i = u_i \beta_i^A(v), \quad \partial_x v_i = v_i \alpha_i(u), \tag{33}$$

where β_i^A are the "pseudoroots" on $\mathfrak{g}_{\overline{-1}}$ defined by (9) *and depending on the "deformation" matrix A and the Lie algebra $\mathfrak{g}$, $\alpha_i \in \Pi \cup \{-\Theta\}$ are linear forms (roots) on $\mathfrak{h}$, H_i is the basis in $\mathfrak{h}$, $E_{-\alpha_i}, E_\Theta$ is the basis in $\mathfrak{g}_{\overline{-1}}$, and*

$$U = u = \sum_{i=1}^{\dim \mathfrak{h}} u_i H_i, \quad V = \lambda^{-1} v = \lambda^{-1}\left(\sum_{\alpha_i \in \Pi \cup -\Theta} v_i E_{-\alpha_i}\right) \tag{34}$$

is the corresponding U-V pair.

(ii) The Volterra coupled system (33) *is written in the form of the abelian "modified" Toda-field equations.*

$$\partial_{xt}^2\psi_i = \partial_x\psi_i\left(\sum_{\alpha_j\in\Pi\cup\{-\Theta\}}\beta_{i,j}^A e^{\alpha_j(\psi)}\right), \tag{35}$$

where $\psi=\Sigma_{i=1}^n\psi_i H_i$, $\beta_{i,j}^A=\beta_i^A(E_{-\alpha_j})$, *and* $u_i=\partial_x\psi_i$.

Remark 8: In the cases of all classical matrix Lie algebra equation (35) could be written explicitly. They are obtained and analyzed in Ref. 26. In the particular case $\mathfrak{g}=\mathrm{gl}(n)$ and special choice of the matrix A, $A=\Sigma_{i=1}^{n-1}X_{ii+1}+X_{n1}$, equation (35) has the form

$$\partial_{xt}^2\psi_i = \partial_x\psi_i(e^{\psi_{i+1}-\psi_i}-e^{\psi_i-\psi_{i-1}}), \quad \text{where } i=1,n,n+1\equiv 1.$$

They coincide with the periodic closure of the infinite "modified Toda chain" obtained by other methods in Ref. 19.

V. CONCLUSION AND DISCUSSION

In the present paper using special quasigraded Lie algebras "twisted" with the help of an automorphism σ of finite order we have obtained new hierarchies of integrable equations in partial derivatives. We considered the simplest equations of these hierarchies. We called them "modified" non-Abelian Toda-field equations. In the case of the automorphisms of the maximal order they coincide with the Abelian "modified" Toda-field equations obtained for the case $\mathfrak{g}=\mathrm{gl}(n)$ (Ref. 19) and generalized for the case of general $\mathfrak{g}$ in Ref. 26.

The interesting open problem is to find soliton solutions of the discovered integrable equations. It would be also very interesting to construct τ-functions for the obtained integrable hierarchies using the representation theory methods.[12]

We would like to correct some inexactitudes in the statement of the last paragraph in page 013503–3 in our above cited paper and we apologize to the reader for this inconvenience.

The last paragraph in page 013503–3 and the first line in page 013503–4 in the above cited paper should be replaced by:

We next consider the Cauchy problem for Eq. (1.7) with the initial data

$$\phi(0,x) = f(x), \quad \phi_t(0,x) = g(x), \tag{1.13}$$

where f is a given C^2 vector-valued function, g is a given C^1 vector-valued function, and they satisfy

$$\Delta(f'(x), g(x)) > 0, \quad \forall\, x \in \mathbb{R}, \tag{1.13a}$$

here and hereafter the function $\Delta = \Delta(\cdot,\cdot)$ is defined by (1.11). Define

$$\Lambda_{\pm}(x) = \frac{1}{1+|f'(x)|^2}\left[-\langle f'(x), g(x)\rangle \pm \sqrt{\Delta(f'(x), g(x))}\,\right]. \tag{1.14}$$

We assume that, for every fixed $y \in \mathbb{R}$,

$$\Lambda_+(y) > \Lambda_-(x), \quad \forall\, x \in (-\infty, y). \tag{1.15}$$

Taking this opportunity, we also correct another inexactitude:
$\mathbb{R}^{2+n}$ in the title should be replaced by $\mathbb{R}^{1+(1+n)}$.

A Finslerian version of 't Hooft deterministic quantum models

Ricardo Gallego Torrome
Windhukstrasse 14, Hamburg, Germany

(Received 20 April 2005; accepted 16 May 2005; published online 5 July 2006)

Using the Finsler structure living in the phase space associated to the tangent bundle of the configuration manifold, deterministic models at the Planck scale are obtained. The Hamiltonian functions are constructed directly from the geometric data and some assumptions concerning time inversion symmetry. The existence of a maximal acceleration and speed is proved for Finslerian deterministic models. We investigate the spontaneous symmetry breaking of the orthogonal symmetry $SO(6N)$ of the Hamiltonian of a deterministic system. This symmetry break implies the nonvalidity of the argument used to obtain Bell's inequalities for spin states. It is introduced and motivated in the context of Randers spaces, an example of a simple 't Hooft model with interactions. © *2006 American Institute of Physics.*

I. INTRODUCTION

The possibility to use deterministic models at the Planck scale has been presented, for instance, in Refs. 1 and 2. Following these ideas, Hilbert space techniques are useful tools to deal with probabilistic predictions at atomic, nuclear, or standard model scale physics. Quantum mechanics is considered to be a powerful formalism to deal with the chaotic evolution of these systems. However, the behavior of physical systems at the Planck scale can be very different. Therefore deterministic models can be useful to describe the physical systems at this more fundamental level.

Particular motivations to investigate deterministic models at the Planck scale have been explained in Ref. 1. We recall briefly some of these reasons:

1. There is the feeling that fundamental concepts like locality, space, and time are becoming more and more obscure in contemporary physics and that this tendency will gradually grow in modern quantum theories. It seems that it is not a nice consequence of modern physics.
2. There are conceptual problems related with quantum cosmology. Let us suppose that the physical system being described is the entire universe through a master quantum wave function. The meaning of this wave function of the universe is problematic because we cannot make any experiment to test the correctness of it: we live in one universe only and we do not have an ensemble of identical universes to check the probabilistic predictions of the theory. It seems it is not possible to contrast a quantum model of the whole universe.
3. Black hole physics is problematic from the point of view of quantum mechanics. The research in this area has produced, among other results, the discovery of a fundamental principle as the holographic principle.[3] The interpretation of this principle is not intuitive from a field theory point of view; let us consider the fundamental area

$$A_p = 4 \ln 2 L_p^2,$$

where L_p is the Planck length. This principle can be stated in the following way:
The quantum degree of freedom of a quantum black hole are such that the total information

is distributed on a surface in such a way that a bit of information is contained in an area A_p. In a local quantum field theory the density of states is proportional to the volume of the system. Therefore, an interpretation of the holographic principle in the framework of a local quantum field theory becomes difficult.

4. Finally, physicists have found strong difficulties in their attempts to unify quantum mechanics with a theory of gravity. This unified theory should be important at short distances, where gravity become strong and comparable to other interactions. Usually the strategy consist of searching for the right laws of gravity at short distances, maintaining quantum mechanics as a complete theory. This persistent problem is a reason to reconsider the status of quantum mechanics as a fundamental theory at the scale where is gravity as strong as it is in other interactions.

The approach advocated in Ref. 1 is to investigate deterministic systems at the Planck scale as an alternative way to solve these problems. Due to a dissipative dynamics, after a long term evolution, different states evolve into the same one, reducing the dimensionality of the Hilbert space. All the ontological states evolving into the same state define an equivalence class. The equivalence classes can be nonlocally defined, and it is speculated that they are the states described by rays of a Hilbert space, as they are represented in quantum mechanics. In addition, it was shown that the use of Hilbert space theory in the description of these deterministic models is useful to find the connection with ordinary quantum mechanics.

The Hilbert space approach to deterministic systems has some problems. The main one is that the Hamiltonian of a deterministic system is linear in the momentum variables and therefore is not bounded from below. This implies the instability of the system. In addition, only few examples are known with a mechanism generating a Hamiltonian bounded from below, but these models do not involve interactions. Moreover, any deterministic description of quantum mechanics seems to be plagued by Bell's inequalities. It was conjectured in Ref. 1 that at the Planck scale physical systems do not meet the required symmetries used in the proof of Bell's inequalities for spin states. The reason is that at this level the system can be so complex that usual rotation symmetries do not hold.

The geometric nature or interpretation of important physical models are known. For instance, the point particle action is the length of a curve, the string action is a generalized area, and Yang-Mills actions are a function of connections on bundles. General relativity also has an interpretation in terms of the semi-Riemannian geometry. The objective nature of the geometric entities (that is, covariance respects a transformation group) implies the relevance of the geometric actions, making apparent the independence of the physical phenomenon from the particular way a description is adopted. We can say that the actions of important physical models are related to Riemannian or semi-Riemannian structures and generalized notions of distance metrics.

Finsler structures are actually natural and constitutes a branch from differential geometry and theoretical physics with a huge recent development (some general references for Finsler geometry and some of its applications are Refs. 3–9). Finsler structures are as natural as Riemannian structures but have less restrictions than Riemannian ones, and it sometimes seems strange why they have not appeared recently in field theory in a natural way. Nevertheless, recently considerable work has be done in some applications in string theory and general relativity (for instance in Ref. 6) and in the thermodynamics theory in curved spaces (Ref. 6 and references therein). Previous applications of Finsler geometry to physics were performed by the school of Miron at Rumania.[7–9]

However, our application of Finsler geometry to obtain deterministic models is completely different. It is based on the following general ideas:

1. In the construction of physical models, geometric structures are of extreme importance. Indeed, more of the main theories such as string and general relativity are formulated using metric theories, in particular structures existing in a pseudo-Riemannian manifold. Metric structures are usually required and natural.

2. If we are looking for a formalism that could be also applicable to the whole universe, it should contain an irreversible element. We live in one universe and the notion of reversible law is maybe not completely valid because it is not completely under experimental control when it is applied to a large portion of the universe or to the whole universe.

Finsler geometry has enough ingredients to address both points. It probably is not the only possibility, but we were able to use this sophisticated geometry to find some results that maybe can be useful for future research in this area. Finslerian distance (usually associated with the length of a curve using the Finsler metric) can be nonsymmetric, that is, the distance between point a and point b is not the same as the distance from b to a. We consider that nonsymmetric Finsler metrics (which means when the above asymmetry is possible) are useful to describe the behavior of irreversible evolutions at the fundamental scale. For example, the action of a particle moving in a Finsler space is not invariant under the inversion of the parameter of the curve. This asymmetry in the metric implies the possibility to describe an irreversible evolution from a geometric point of view. This is the main reason to use models in physics based on Finsler geometry (another idea of how to describe thermodynamics using Finsler structures can be found in Ref. 5. However, our application mainly differs from this one because we are concerned with the most basic level in the description of phenomena).

The aim of the present work is as follows. First, we investigate some general consequences of the 't Hooft theory. Second, in order to give a geometric basis for the theory, we explain the relation of 't Hooft's models with the Finsler structure of the cotangent bundle of the tangent bundle of the configuration manifold $\mathbf{M}$, $\mathbf{T}^*\mathbf{TM}$. Finslerian models are free of some problems of the initial 't Hooft's theory. In particular, they provide a geometric argument to obtain a lower bound for a Hamiltonian coming from a deterministic system.

The structure of this work is as follows. In Sec. II the basic notions and results of the 't Hooft theory are presented. Also, the main problems of this approach are explained.

In Sec. III the use of Finsler geometry to find deterministic models is presented. In addition, we develop some consequences of the Finslerian approach as the existence of a higher limit for generalized physical acceleration and speed. We describe the spontaneous symmetric breaking that can occur in the Finslerian deterministic model. The possible absence of Bell's inequalities for spin at the Planck scale is also argued, but the argument can be changed to a more general framework than Finslerian models, provided a geometric argument is possible.

In Sec. IV we to discuss our results in the context of the geometry of spaces of smooth Finsler structures. We describe a simple deterministic model where interactions are present. This model is based on some geometric construction and some additional physical requirements.

Finally, in the Appendix , the basic definitions and results of the Finsler geometry and other geometric objects mentioned in this work are given.

II. THE 't HOOFT THEORY

't Hooft has investigated the possibility to use deterministic models in order to describe physical systems at the Planck scale through a Hilbert space formulation[1,2] of these models. The physical system is described by an eigenstate $|x\rangle|$ of a set of commuting operators $\{\hat{X}_i(t)\}$,

$$[\hat{X}_i(t),\hat{X}_j(\tilde{t})]=0,\ \forall\ i,j,\quad \hat{X}_i(t)|x\rangle = x_i(t)|x\rangle\ ,$$

such that the eigenvalues $\{x_i(t)\}$ completely describe the state of the system. These states are called ontological. The parameter t is associated with a macroscopic phenomenon or device and used as the time parameter by an macroscopic observer, although we consider microscopic processes, which are at the level of the deterministic description. At each instant t, the physical system is in correspondence with a particular vector defined by the set of eigenvalues $\{x_i(t)\}$. This set of functions defines the real configuration of the system at any instant t. The Hilbert space is generated by the vectors representing the configurations of the physical system. A linear combination of elements of a basis of the Hilbert space produces a vector such that the square of the module of

each component is the probability of the system to be in this particular state.

The Hamiltonian of a deterministic system with $6N$ degrees of freedom in the phase space is

$$\mathbf{H} = \sum_{i=1}^{6N} p_i f^i(x) + g(x). \tag{2.1}$$

(x,p) are canonical variables, $\{x_i, p_j\} = \delta_{ij}$. After canonical quantization this Hamiltonian reproduces the evolution differential equations, which are the Heisenberg equations for the operators $\{X^i, i=1,\ldots,6N\}$,

$$\frac{d\hat{X}^i}{dt} = f^i(\hat{X}), \quad i = 1, \ldots, 6N. \tag{2.2}$$

When we take the average value of the Eq. (2.2) we obtain

$$|\tilde{x}\rangle\left(\frac{d\hat{X}^i}{dt} - f^i(\hat{X})\right)|x\rangle = 0, \quad i = 1, \ldots, 6N.$$

This implies the classical ordinary differential equations

$$\frac{dx^i}{dt} = f^i(x), \quad i = 1, \ldots, 6N \tag{2.3}$$

because the scalar product of the Hilbert space is positively defined. Any system whose evolution is given by Eqs. (2.3) and has a complete and defined set of initial conditions is called deterministic.

Let us consider the quantization of the Hamiltonian (2.1). It does not have a minimal eigenvalue because it is linear in momentum. However, the existence of a ground state is essential for the stability of the physical system. This parameter is a fundamental difficulty in the Hilbert space formulation of deterministic systems.

For this problem let us consider that a dissipative dynamics, a system with a rather turbulent or chaotic behavior at the beginning, can reach stability in a finite time. This kind of dissipation implies the possibility to define the physical states as equivalence classes at equilibrium. An equivalence class is defined by the set of ontological states that, after a long term in the parameter t, evolve to the same final state.

't Hooft has proposed the following solution to the problem of the missing of the lower bound of the Hamiltonian: *If dissipation of information it is possible*, *the final Hamiltonian could be bounded from below*. It was suggested in Refs. 1 and 2 that the actual quantum mechanics describes not the basic degrees of freedom of our universe, but the dynamics of equivalence classes reached by these basic states after a long term evolution with a dissipation of information: various states can evolve into the same equilibrium state. The ontological states follow a deterministic dynamics that is described by the set of first order, ordinary differential equations of type (2.3) (in addition with a complete set of initial conditions). These states are locally well defined. By contrast, the equivalence classes of states could not be locally well defined and their evolution is quantum mechanical.

This evolution onto equivalence classes can solve the problem of the ground state because their number is smaller than the number of ontological states. It could be that even with an infinite number of ontological states, we have a finite number of equivalence classes, a finite Hilbert space, and as a consequence the Hamiltonian has a defined ground state.[1] Several examples has been found by 't Hooft where there is a mechanism producing a Hamiltonian with a lower bound: the free bosonic system, the free Maxwell field, and the free massless neutrino system are deterministic systems. These examples at least prove the existence of deterministic models with a Hamiltonian bounded from below.

In this work we denote by a 't Hooft model a deterministic system with a mechanism producing a lower bound for the final Hamiltonian at equilibrium. By dissipative mechanism we mean an information loss mechanism.

III. FINSLERIAN DETERMINISTIC QUANTUM MODELS AT THE PLANCK SCALE

Let us denote by **M** the configuration manifold of all the degrees of freedom at the Planck scale. By configuration manifold we mean a submanifold **M** of a $2n$-manifold **N** such that $\mathbf{TM}=\mathbf{N}$. With this definition we adopt the formalism of Lagrange spaces[7] (indeed dual Lagrange spaces), instead of considering the formalism of higher order Lagrange spaces.[8]

The relation between Finsler structures and deterministic systems is based on the following points:

1. The ontological states at the Planck scale are described by points of the phase space $\mathbf{T}^*\mathbf{TM}$ and the tangent bundle **TM** is equipped with a dual Randers metric F^*.
2. The reduction of the ontological Hilbert space to the quantum mechanical Hilbert space is in correspondence with the reduction of the Randers structure $(\mathbf{TM},F^*)$ to the Riemannian structure $(\mathbf{TM},h)$. We postulate that this reduction corresponds to the average operation investigated in Ref. 10.
3. We assume that for each particle with a generalized velocity $y=dx^i/dt$ there is another particle associated such that it is evolving backwards in time t with velocity $-y$ and the separation between them is zero.

For the definition of a Finsler structure and Randers structures, basic notions in the present work, we refer to the Appendix or to Ref. 4. The term dual makes reference to the manifold $\mathbf{T}^*\mathbf{TM}$ where F^* lives in our formalism. These spaces are treated in the literature (see Ref. 6 and references therein) and are called Cartan spaces. Points 1 and 2 are the main link between geometry and physics in our proposal. Point 1 is a nominative axiom, relating notions from geometry and physics. Point 2 refers to the link between the geometric theory of Finsler geometry described in Ref. 10 with a reduction of the associated Hilbert space. This point is especially important to keep in mind when finding the link between quantum mechanics and deterministic models at the Planck scale. It is only explanatory; while point 1 is completely arbitrary, point 2 is just a consequence of point 1 and the theory developed in Ref. 10. Point 3 is a generalization of the particle-antiparticle creation in the context of a nonsymmetric geometry background. Due to this asymmetry, a nontrivial system arises with a defined fundamental time arrow.

In addition to the above statements, we note two other implicit facts in our construction:

1. There is a microscopic time arrow associated with the mechanism that produces the evolution from the Randers structure $(\mathbf{TM},F^*)$ to the actual Riemannian structure $(\mathbf{TM},h)$.
2. There is a Hamiltonian function obtained directly from the geometric data contained in the Randers structure $(\mathbf{TM},F^*)$.

Consider a Randers function F^* with the following form (see the Appendix for the definition of Randers space),

$$F^*(x,p)=\alpha(x,p)+\beta(x,p).$$

Then we perform the following identification between the Hamiltonian function and the nonsymmetric part of the Randers function,

$$\mathbf{H}=\sum_{i=1}^{n} p_i f^i(x) \rightarrow 2\sum_{i=1}^{n} \beta^i(x)p_i, \tag{3.1}$$

and if we identify component by component,

$$2\beta^i = f^i, \quad i = 1, \ldots, 6N. \tag{3.2}$$

The ordinary differential equations (2.3) are then

$$f^i = \beta^i = \frac{dx^i}{dt}, \quad i = 1, \ldots, 6N. \tag{3.3}$$

In order to quantize the model we use the canonical quantization through the prescription

$$x^i \to \hat{X}^i, \quad \beta^i(x) \to \beta^i(\hat{X}), \quad p_i \to -i\frac{\partial}{\partial x^i} = \hat{P}_i. \tag{3.4}$$

This representation holds the canonical quantization relation:

$$[\hat{X}_i, \hat{P}_j] = \delta_{ij}.$$

The reason why we choose the above Hamiltonian function (3.1) is as follows: the first term corresponds to a particle moving forward in time while the second term corresponds to a particle moving backward in time, both at the same position; there is a democracy in the choice of the macroscopic time arrow.

We would like to justify the Hamiltonian function (3.1) in more detail. Since we use phase space variables, we translate the above assumption from velocities to momentum variables. An example of a dual Finsler structure with Finsler function F^* living in the cotangent bundle $\mathbf{T}^*(\mathbf{TM})$ is defined using the following procedure: if $(\mathbf{TF}, F)$ is a Finsler structure, let us consider the dual Finsler structure defined by

$$F^*(x,p) := F(x,y_p) \text{ such that } y_p(\tilde{p}) := g_{y_p}(p,\tilde{p}),$$

$\vec{p} = p^i(\partial/\partial x^i) \in \mathbf{T}^*_u\mathbf{T}_x\mathbf{M}; y \in \mathbf{T}_u\mathbf{T}_x\mathbf{M}$. y_p is the dual vector of the 1-form p defined by the second relation. g_{y_p} is the fundamental tensor of the structure $(\mathbf{TM}, F)$ evaluated at the point y_p (for the definition, see the Appendix).

The classical Hamiltonian function (3.2) coincides with

$$\mathbf{H} = F^*(x,p) - F^*(\tau(x), \tau(p)) = 2\beta^i p_i. \tag{3.5}$$

The transformation τ is the time inversion operator with respect to the microscopic time t. The action of the time inversion operator in the canonical variables is defined such that the canonical relation $\{x_i, p_j\} = \delta_{ij}$ remains invariant.

The quantization of the above models is equivalent to the quantum mechanical description of a deterministic system. The quantized Hamiltonian is defined by

$$\hat{\mathbf{H}} = F^*(\hat{X}, \hat{P}) - F^*(\hat{T}\hat{X}\hat{T}^{-1}, \hat{T}\hat{P}\hat{T}^{-1}).$$

$\hat{T}$ is the time inversion operator. The Hamiltonian is

$$\hat{\mathbf{H}} = 2\beta^i(\hat{X})\hat{P}_i. \tag{3.6}$$

A simple calculation shows that for this Hamiltonian the relation $\hat{T}\hat{\mathbf{H}}\hat{T}^{-1} = -\hat{\mathbf{H}}$ holds and that the elementary evolution operator

$$\hat{\mathbf{U}}(t, t+\delta t) = \hat{I} - i\,\delta t\hat{\mathbf{H}}$$

is invariant under time inversion $\hat{T}$, producing a geometric time arrow (note that states are invariant by the time inversion operation).

Hamiltonian (3.6) is not bounded from below. In order to solve this problem we propose the following mechanism: Let us define the average classical Hamiltonian defined by

$$\langle \mathbf{H} \rangle := \int_{\mathbf{I}_x^*} \mathbf{H}(x,p) |\psi(x,p)|^2 d^{6N-1}p.$$

The manifold $\mathbf{I}_x^* \subset \mathbf{T}_\mathbf{x}^*(\mathbf{TM})$ is defined by $\mathbf{I}_x^* := \{p \in \mathbf{T}_\mathbf{x}^*(\mathbf{TM}) \,|\, F^*(x,p)=1\}$. $|\psi(x,p)|^2$ is a weight function on the indicatrix $\mathbf{I}_x^*$ and it is determined by the geometric data $(\mathbf{TM}, F^*)$.

The justification of this construction is as follows. In Ref. 10 the existence of a map from the Finsler category to the Riemannian category relating the most important geometric notions was proved. This map was basically interpreted as an "average" of the Finslerian objects (although in Ref. 10 we formulated our mathematical construction mainly related with the so-named Chern's connection. However, it was noted that a similar average operation is also applicable to other connection as the Cartan connection or in general to any linear connection in $\pi^*\mathbf{TM}$. We also think that the construction is also extendable to the nonlinear connection, a very important notion in Finsler geometry). Here we remark that this average operation is also applicable to the Hamiltonian operator after canonical quantization of the classical Hamiltonian because it is constructed using the Finsler function. This average is interpreted as a long term evolution of the initial Hamiltonian. Another more physical reason to integrate only over $\mathbf{I}_x^*$ is the "holographic principle in phase space": all the quantum information is contained in a submanifold of dimension $n-1$, in this case the indicatrix $\mathbf{I}_x^*$. This holographic principle is formulated in the phase space instead of the normal formulation in the configuration space and appears as a reinterpretation of the positive homogeneity requirement. It seems to be possible to translate this construction to the configuration space just through a generalized Fourier transformation.

The above average Hamiltonian function has an associated quantum operator (better a density operator) $\langle \hat{\mathbf{H}} \rangle$. This operator is defined by the action on an arbitrary element of the Hilbert space of the states of defined generalized coordinates:

$$\langle \mathbf{H} \rangle_x(\hat{X},\hat{P})|p\rangle := \int_{\mathbf{I}_x^*} \hat{\mathbf{H}}(\hat{X},\hat{P})|\psi(x,p)|^2|p\rangle d^{6N-1}p = \int_{\mathbf{I}_x^*} (\mathbf{H}(x,p)|\psi(x,p)|^2)|p+G(x)\rangle d^{6N-1}p,$$
$$\forall\, |p\rangle \in \mathcal{H}. \tag{3.7}$$

The average quantum Hamiltonian density operator $\langle \hat{\mathbf{H}} \rangle(\hat{X},\hat{P})$ is linear. $\{|p\rangle\}$ is the set of vectors such that the Finsler norm is 1: $\hat{P}^i|p\rangle = p^i|p\rangle$ with $F^*(x,p)=1$. The function $G(x)$ is the translation produced by the operators $\hat{X}^i$ on the momentum state $|p\rangle$, computable from the canonical conditions and the form of the operators $\beta^i(\hat{X})$.

The first property of the above Hamiltonian (3.7) comes from the definition of Randers space. All the terms are bounded and positively defined because the functions $\{\beta^i\}$ are bounded and also because we are integrating only over the indicatrix $\mathbf{I}_x^*$. Therefore we obtain the following result.

Theorem 1: *Let* $(\mathbf{TM}, F^*)$ *be a Randers space. Then there is a deterministic system with the average Hamiltonian density defined by relation (3.7) and with* $\hat{\mathbf{H}}$ *defined by Eq. (3.6). Then the average Hamiltonian* $\langle \mathbf{H} \rangle_x$ *is bounded.*

The local converse of this result also holds, proving the generality of the connection between deterministic systems and Randers geometry,

Theorem 2: *Let* $\hat{\mathbf{H}} = 2\beta^i(\hat{X})\hat{P}_i$ *be a quantum Hamiltonian operator describing a deterministic system. Suppose that the average Hamiltonian is bounded. Then there is a Randers structure that reproduces the above Hamiltonian, and the Randers function is defined locally at one point by the expression*

$$F(x,p) = \sqrt{\delta_{ij}p^i p^j} + f_i p^i.$$

Proof: We read from the Riemannian metric and the 1-form that characterizes the Randers structure from the Hamiltonian; the Hamiltonian of a deterministic system is of the form $\mathbf{H} = f^i(x)p$. We associated the following structure locally such that at the point x it is given by

$$a_{ij} = \delta_{ij}, \quad 2\beta^i(x) = f^i(x),$$

where the functions $f^i(x)$ characterize the deterministic system. That the final Hamiltonian is bounded implies that the functions $\beta^i(x)$ are also bounded, which is a fundamental requirement to obtain a Randers function.

It is important to note that the Randers structure of the thesis of Theorem 3.2 and the Randers structure of the hypothesis of Theorem 3.1 are not the same. The reason is because they describe different deterministic systems. In addition, let us note that the Riemannian structure $a_{ij}=\delta_{ij}$ is arbitrary: our choice was the simplest one, but it can be constrained because of the topology of the manifold **TM** (although locally the Finsler structure resembles the one in Theorem 3.2) and of the physical consistency, as we will see (β should be bounded by a_{ij}). When the metric a is given globally we can extend *beta*, defining a Randers space in the whole manifold **TM**, assuming that it is simply connected.

Another consequence of the geometric origin of the Hamiltonian is that because the requirements that F^* is a Randers function, the functions $\{\beta^i\}$ are bounded. This implies that generalized velocities and accelerations of the particles are bounded,

Corollary 3: *Consider a deterministic system associated with a Randers space. Then the generalized speed and acceleration of any physical subsystem are bounded.*

This consequence is interesting because it means the following for our model. From the geometric point of view, bounded means to respect the metric structure a_{ij} of the given Randers structure (α, β). Because both accelerations and velocities can become observables in some models, this also happens with the metric a_{ij}, which becomes not arbitrary and dynamical. The problem of finding the correct structure such that the 1-form β is bounded with the Riemannian metric a_{ij} implies some additional hypothesis concerning the dynamical behavior of both.

As consequence of the existence of a maximal physical acceleration, there is a limit for the strength of the gravitational field, if the strong equivalence principle holds. Therefore we are dealing with a theory that contains a finite gravitational interaction.

A simple mechanical model can give an estimation of the value of the maximal acceleration. Suppose that the universe has a limited energy content, there is a minimal distance L_p, the maximal speed is c, and the ontological degrees of freedom of the model describe the molecules of a classical gas. We can write the elementary work that the rest of the universe can make on a defined subsystem. Since this maximal work is equivalent to the energy of the particles involved, we obtain the relation

$$L_p m a_p \sim \delta m c^2.$$

The maximal exchange of energy is bounded by $\sim M_U c^2$, where M_U is the equivalent mass of the total energy of the universe, excluding the subsystem considered. The mass m appearing in the left side is just the mass of the particle, and if this mass is the Planck mass M_p, then

$$a_p \sim \frac{M_U}{M_p}\frac{c^2}{L_p}.$$

This acceleration is very huge when L_P is the Planck scale,

$$a_p \sim \frac{M_u}{M_p} 10^{52}\ \mathrm{m/s^2}.$$

If the change in the state of the subsystem is only produced by the neighborhood of the elementary particle, then instead of M_U there is a mass comparable to m. Therefore the maximal acceleration is

$$a_p \sim 10^{52}\ \mathrm{m/s^2}.$$

Note that this acceleration is independent of the mass of the particles. This implies that the equivalence principle for the maximal acceleration holds in this limit. In addition, this example

shows the equivalence between the maximal acceleration and a minimal length L_p, when there is a maximal speed c.

As another example of application of our geometric formalism, let us consider the Hamiltonian describing a deterministic system with 12 degrees of freedom associated with two pairs of particles living in a space **M** of dimension three. The symmetry group of the Hamiltonian is contained in the group $O(12)$ because it is the Euclidean product of two vectors of a 12-dimensional space (by associated particles we mean a pair of identical particles such that they are at the same position but one is moving forward and the other backward on the external time t). Let us consider a particular configuration describing a system of two correlated pairs of associated particles and their environment. The symmetry group for this special configuration contains the group $O(6)\times O(6)\times G$, where the first two terms $O(6)$ describe the symmetry related with the two separated pair of particles and G determines the symmetry of any other subsystem. This configuration implies a spontaneous symmetry break of the group $O(6N)$,

$$O(6N) \to O(6) \times O(6) \times G.$$

This symmetry break produces Goldstone's bosons that we consider part of the environment.

Consider the subsystem composed of two correlated pairs. The symmetry of this Hamiltonian is $O(6)\times O(6)$. The existence of an internal time t implies the existence of the time inversion transformation $\hat{T}$ defined by the action on the generalized canonical coordinates (let us recall that the velocity y is also considered as a coordinate in the Hilbert space approach to deterministic systems),

$$(x,y) \to (x,-y).$$

Invariance of the canonical quantization implies the transformation

$$(\hat{P}_x,\hat{P}_y) \to (-\hat{P}_x,\hat{P}_y),$$

because the time inversion is an antiunitary transformation on the Hilbert space.[11] A similar transformation for the classical momentum holds.

We remark that the consistency of this splitting of the cotangent space $\mathbf{T}^*\mathbf{TM}$ is based on the existence of an additional geometric structure associated with the time inversion $\hat{T}$. This additional structure again breaks the symmetry of the Hamiltonian,

$$O(6) \times O(6) \to O^2(3) \times O^2(3).$$

Because the physical system is deterministic and has a well defined momentum and generalized position values, it is in a particular defined state. The evolution of these states is in a one-to-one correspondence with the 1-form $(\beta^1_-(1),\beta^2_-(1),\beta^3_-(1),\beta^1_+(1),\beta^2_+(1),\beta^3_+(1))$ describing the evolution of the first pair and $(\beta^1_-(2),\beta^2_-(2),\beta^3_-(2),\beta^1_+(2),\beta^2_+(2),\beta^3_+(2))$ for the second (the notation $\pm$ corresponds to the splitting induced by time inversion in $\mathbf{T}_x\mathbf{M}$). But when the system follows the evolution guided by a particular value of the above forms, the symmetry is again broken,

$$O^2(3) \times O^2(3) \to O^2(2) \times O^2(2).$$

The final group $O^2(2)\times O^2(2)$ because it is the biggest group preserving a particular deterministic evolution.

Therefore it is not possible that the system could hold a nontrivial irreducible representation of the rotation group $SO(3)$ consistent with a deterministic evolution: the symmetry group for a defined system of two correlated pair of particles at the Planck scale is $O^2(2)\times O^2(2)$. This group is not enough to contain the rotation group $SO(3)$.

Theorem 4: *For a deterministic system composed by two correlated, identical pairs of associated particles with energies at the Planck scale, there is not a nontrivial irreducible representation of the rotation group leaving invariant the deterministic evolution defined by particular values of the beta function.*

One consequence of this fact is that the ordinary proof of Bell's inequalities for spin does not hold at the Planck scale for this system. The reason is that the proof uses the rotation symmetry and it does not hold for deterministic systems at this scale. Even the notion of spin is not truly defined in this context. Therefore the claim is that Bell's inequalities for spin does not hold for deterministic Finslerian models.

At ordinary energies the breaking $O^2(3)\times O^2(3)\rightarrow O^2(2)\times O^2(2)$ is not given. Only at high energies of order of the Planck scale can we expect this break because it means that the system cannot decouple from the ambient in a way that rotation transformations of the system make sense. However, at ordinary scales this decoupling indeed does make sense and the above symmetry break does not hold.

This possible absence was anticipated by 't Hooft and is independent of the nature of the model, Finslerian or not. Here we remark the geometric character of this phenomenon in the case of Finslerian deterministic models.

IV. DISCUSSION

The relations between the Finsler structure $(\mathbf{TM},F^*)$ and the Riemannian structure $(\mathbf{TM},h)$ are described in Ref. 10 (indeed the case of a general, smooth manifold $\mathbf{M}$ was considered). In addition, the existence of a map from the category of Finsler spaces to the category of Riemannian spaces mapping the Chern connection of F (generally, any linear connection living in $\pi^*\mathbf{M}$) to a linear connection on $\pi^*\mathbf{TM}$ and the hh curvature to the curvature of this linear connection was shown. These transformations can be interpreted as "average" operations of the Finsler structures and objects. The physical interpretation of these averages is that the Finsler structure living in the phase space manifold $\mathbf{T}^*\mathbf{TM}$ evolves after a long term to the equilibrium described by the Riemannian structure $(\mathbf{TM},h)$. This Riemannian structure describes the geometry of the phase space when the systems of all ontological states reach the equilibrium. However, the Hamiltonian describing the evolution of the averaged system when the system has evolved after a long term is not the Hamiltonian coming from the "average" Finsler structure $(\mathbf{TM},h)$ (that is indeed Riemannian). The reason is because these averaged physical systems are not systems of fundamental particles at the Planck scale, but could be composite objects like strings. Since they do not have times as small as the Planck time L_p/c, the Hamiltonian guiding their dynamics is the average Hamiltonian $\langle\hat{H}\rangle$, not the deterministic Hamiltonian based on the geometric structure, Finslerian or Riemannian.

When the system arrives into the equilibrium, the Finsler structure is just the Riemannian structure $(\mathbf{TM},h)$. From the definition of the fundamental or ontological Hamiltonian (3.6), we obtain in the equilibrium the condition

$$\hat{\mathbf{H}}=0.$$

The existence of macroscopic matter structures and gravity can be associated with the following decomposition:

$$\hat{\mathbf{H}}=\langle\hat{\mathbf{H}}\rangle+\delta\hat{\mathbf{H}}=\hat{\mathbf{H}}_{\text{matter}}+\delta\hat{\mathbf{H}}.$$

If we take the average of each member of this relation, one obtains at equilibrium

$$\langle\hat{\mathbf{H}}\rangle=\langle\langle\hat{\mathbf{H}}_U\rangle\rangle+\langle\delta\hat{\mathbf{H}}\rangle=\hat{\mathbf{H}}_{\text{matter}}+\langle\delta\hat{\mathbf{H}}\rangle=0.$$

We associate $\langle\hat{\mathbf{H}}_U\rangle=\hat{\mathbf{H}}_{\text{matter}}$, $\langle\delta\hat{H}\rangle=\hat{\mathbf{H}}_{\text{gravity}}$. Therefore in this model the distinction between matter and gravity appears as result of a long term evolution of the ontological states. Also it appears remarkable that while in equilibrium gravity appears to compensate matter, at nonequilibrium (that is when the structure is Finslerian) there is some kind of pregravity interaction, described by the Hamiltonian $\delta\hat{\mathbf{H}}$. The qualitative characteristic of this interaction should be study further. Matter seems identical (the particle content seems complete identical because the Hamiltonian for matter,

before and after average is the same $\langle \hat{\mathbf{H}} \rangle$. This fact implies the universality of our formalism in order to get any quantum system from a deterministic model.

Connecting with the 't Hooft theory, we describe in a geometric way the projection from an ontological state to an equivalence class as follows:

The projection after a long term evolution of a deterministic system to the equilibrium equivalence class is described by the transformation that averages the dual Finsler structures living in the manifold $\mathbf{T}^*\mathbf{TM}$.

It is a remarkable consequence of the Finslerian 't Hooft models that we obtain the prediction of the value of a maximal acceleration and speed for physical systems. This can be interpreted as the requirement of the existence of two natural constants by geometric consistency. In addition, the possible absence of Bell's inequalities for spin is a remarkable prediction for the general 't Hooft models: these inequalities are the main obstructions for the construction of hidden variables theories. In the present paper we have shown that the absence of Bell's inequalities is possible at the Planck scale, where not decoupling of the system with the ambient is taken and even the notion of three-dimensional rotations become unclear. This explanation is simultaneous with the prediction of the existence of pregravity interaction in a natural way. Therefore it is possible to construct the hidden variables theories at this energy without the introduction of nonlocal actions, and the mechanisms could be promoted by a pregravity interaction.

That all of the 't Hooft models have a local geometric interpretation in terms of Finsler geometry and the geometric origin of a microscopic time arrow obtained from the geometric data are the mayor goals of these models. In addition, we can motivate a deterministic model based in some construction of a Randers space containing interactions. Unfortunately, the model is not completely defined by the geometry and physical hypothesis should be introduced.

We start reviewing the treatment of 't Hooft of a deterministic system with a dissipative dynamics.[1] The quantum Hamiltonian i:

$$\hat{\mathbf{H}} = \vec{p} \cdot \vec{f}(\vec{g}).$$

Consider a scalar operator $\rho(\vec{q})$ such that $[\rho(\vec{q}), \hat{\mathbf{H}}]=0$. Then we can perform the following decomposition:

$$\hat{\mathbf{H}} = \hat{\mathbf{H}}_1 - \hat{\mathbf{H}}_2, \tag{4.1}$$

with

$$\hat{\mathbf{H}}_1 = \frac{1}{4\rho}(\rho^2 + \hat{\mathbf{H}})^2, \quad \hat{\mathbf{H}}_2 = \frac{1}{4\rho}(\rho^2 - \hat{\mathbf{H}})^2.$$

Both Hamiltonians commute, $[\hat{\mathbf{H}}_1, \hat{\mathbf{H}}_2]=0$.

In order to bound from below the complete Hamiltonian, one can introduce the constraint than on physical states the following condition holds:

$$\hat{\mathbf{H}}|\psi\rangle \to 0. \tag{4.2}$$

That should be understood as a long term evolution statement: the physical system evolves to states obeying condition (4.2). This constraint immediately implies the bound of the Hamiltonian:

$$\hat{\mathbf{H}} \to \hat{\mathbf{H}}_1 \to \rho^2 \geq 0.$$

These constraints can be motivated first if we mimic the system in terms of a nondissipative model and where the system corresponds to a quantum oscillator, where all the "orbits" are stable such that $\hat{\mathbf{H}}=\vec{p}\cdot\vec{f}(\vec{g})$ holds and such that $[H_s, \rho^2]=0$.

The stable orbits are restricted by the condition

$$e^{-\hat{\mathbf{H}}T}|\psi\rangle = |\psi\rangle, \tag{4.3}$$

where T is the period of the orbit $\rho=1$. This condition, equivalent to constraint (4.2), implies the limitation of trajectories to stable orbits at equilibrium.

Let us compare this construction with a parallel construction using Finslerian models. One starts directly with a classical Hamiltonian of the form

$$H = F(\vec{q},\vec{p}) - F(\vec{q},-\vec{p}).$$

After canonical quantization, we identify $\hat{\mathbf{H}}_1 = F(\vec{q},\vec{p}) = \alpha+\beta$, $\hat{\mathbf{H}}_2 = F(\vec{q},\vec{p}) = \alpha-\beta$.

We propose the constraint $\rho=1$ on physical states. It is equivalent to an average operation defined in the following way:

$$h_{ij} = \int_{\mathrm{S}} g_{ij}(x,y), \tag{4.4}$$

where the integration is done on the sphere $\mathbf{S}^{6\mathbf{N}-1} \subset \mathbf{T}_u^*\mathbf{T}_x\mathbf{M}$.

Taking this average in the underlying geometric structure corresponds to constrain the values of the quantum states: after a long term evolution, the physical states arrive to the submanifold $\mathbf{S}^{6\mathbf{N}-1}$.

Suppose now the system is composed of two identical elementary systems, with their dynamics described by a deterministic Hamiltonian of the form (4.1). Let us suppose they are modeled on Randers spaces, so their Hamiltonians are determined by (α_1,β_1) and (α_2,β_2). The 1-forms $\beta_i, i=1,2.$ have a norm of less than 1 by the corresponding Riemannian norms $\alpha_i, i=1,2$. There are at least two ways to produce a bigger Randers space using just the above geometric data:

1. The first way is valid for complete general structures

$$\alpha = \alpha_1 \oplus \alpha_2, \quad \beta = \beta_1 \oplus \beta_2.$$

   This construction does not produce interaction terms in the total Hamiltonian. There is *a priori* no relation $\alpha_1\alpha_2$.
2. The second form recovers the impossibility for an external observer to differentiate between identical particles:

$$\vec{p} = \vec{p}_1 \times \vec{0} + \vec{0} \times \vec{p}_2, \quad \vec{\beta} = \vec{\beta}_1 \times \vec{0} + \vec{0} \times \vec{\beta}_2,$$

$$\alpha = \alpha_1 \oplus \alpha_2, \quad \alpha_1 = \alpha_2.$$

   The quantum total Hamiltonian is given by

$$\vec{\beta}(\vec{p}) = \left(\frac{1}{2}\vec{\beta}_1(\vec{p}_1) + \vec{\beta}_1(\vec{p}_2) + \vec{\beta}_2(\vec{p}_1) + \vec{\beta}_2(\vec{p}_2)\right).$$

   The mixed terms produce the interaction. The condition $\alpha_1=\alpha_2$ ensures that the above construction is a Randers space.

In order to conclude the discussion we would like to discuss our idea with some recent applications of Finsler geometry in physics (see Ref. 6 and references therein). Our application of Finsler geometry and in particular, of Randers spaces, seems new even if it contains elements that have been already used in other contests. Considerable work was performed on higher order mechanics and generalized Finsler spaces (see Refs. 7–9 and also Ref. 6), but the bird of deterministic models at the Planck scale is very recent and the application of Finsler geometry presented in this paper is also new. In addition, we remark that we are not concerned at this stage with a field theory for these deterministic systems, but with the general formalism that we could use to describe them. Finsler geometry is rather intrincately complex with so many natural connections,

for instance, like Chern's or Cartan's connections. Also the notion of nonlinear connection is of fundamental importance. But we are not concern with these important topics in this paper because the construction proposed involves only notions at the metric level: our average is a universal procedure, valid for any linear connection $\pi^*\mathbf{TM}$. Further research can provide a mechanism to select a right d connection for a field theory of deterministic degrees of freedom. In addition, some additional research is needed to understand the extension of the average operation applied to the nonlinear connection.

APPENDIX: BASIC RESULTS ON FINSLER GEOMETRY FOR DETERMINISTIC SYSTEMS

In this Appendix we recall the basic notions of Finsler geometry used in the present work. The main reference for this Appendix is Ref. 4. We present the notions for an arbitrary smooth manifold $\mathbf{M}$.

Let $(x,\mathbf{U})$ be a local coordinate system over a point $x \in \mathbf{M}$, where $x \in \mathbf{U}$ have local coordinates $(x^1,\ldots,x^n)$, $\mathbf{U} \subset \mathbf{M}$ is an open set, and $\mathbf{TM}$ is the tangent bundle. We use Einstein's convention for up and down equal indices in this work.

A tangent vector at the point $x \in \mathbf{M}$ is denoted by $y^i(\partial/\partial x^i) \in \mathbf{T}_x\mathbf{M}$, $y^i \in \mathbf{R}$. We also denote by $\mathbf{TM}$ the set of sections of the tangent bundle. We can identify point x with its coordinates $(x^1,\cdots,x^n)$ and the tangent vector $y \in \mathbf{T}_x\mathbf{M}$ at x with its components $y=(y^1,\cdots,y^n)$. Then each local coordinate system $(x,\mathbf{U})$ induces a local coordinate system in $\mathbf{TM}$ denoted by $(x,y,\mathbf{U})$ such that $y=y^i(\partial/\partial x^i) \in \mathbf{T}_x\mathbf{M}$ has local natural coordinates $(x^1,\cdots,x^n, y^1,\cdots,y^n)$.

Let us denote by $\mathbf{N}=\mathbf{TM}\backslash\{0\}$. The notion of a Finsler structure is given through the following definition.

Definition 1: A Finsler structure F on the manifold $\mathbf{M}$ is a non-negative, real function $F:\mathbf{TM}\to[0,\infty[$ such that

1. *It is smooth in the split tangent bundle $\mathbf{N}$.*
2. *Positive homogeneity holds: $F(x,\lambda y)=\lambda F(x,y)$ for every $\lambda>0$.*
3. *Strong convexity holds: the Hessian matrix*

$$g_{ij}(x,y) := \frac{1}{2}\frac{\partial^2 F^2(x,y)}{\partial y^i\,\partial y^j} \tag{A1}$$

is positively definite in $\mathbf{N}$.

We also denote by a Finsler structure in $\mathbf{M}$ the pair $(\mathbf{M},F)$.

The minimal smoothness requirement for the Finsler structure is $\mathcal{C}^5$ in $\mathbf{N}$ when second Bianchi identities are used; more generally only, a $\mathcal{C}^4$ differentiable structure is required. The matrix $g_{ij}(x,y)$ is the matrix components of the fundamental tensor g. The homogeneity condition can be stronger: $F(x,\lambda y)=|\lambda|F(x,y)$. Then $(\mathbf{M},F)$ is called the absolutely homogeneous Finsler structure.

Example 2: A Randers space is characterized by a Finsler function of the form

$$F(x,y) = \alpha(x,y) + \beta(x,y), \tag{A2}$$

where $\alpha(x,y)=a_{ij}(x)y^iy^j$ is a Riemannian metric and $\beta(x,y)=\beta_i(x)y^i$. The requirement of being g_{ij} positively definite implies that the 1-form $(\beta_1,\cdots,\beta_n)$ is bounded, using the above Riemannian metric α. Examples of Randers spaces can be found, for instance, in Refs. 4 and 5.

Definition 3: (Ref. 4) *Let $(\mathbf{M},F)$ be a Finsler structure and $(x,y,\mathbf{U})$ a local coordinate system induced on $\mathbf{TM}$ from the coordinate system $(x,\mathbf{U})$ of $\mathbf{M}$. The Cartan tensor components are defined by the set of functions*

$$A_{ijk} = \frac{F}{2}\frac{\partial g_{ij}}{\partial y^k}, \quad i,j,k = 1,\ldots,n. \tag{A3}$$

These coefficients are homogeneous of degree zero in $(y^1,\ldots,y^n)$. In the Riemannian case A_{ijk} are zero and this fact characterizes Riemannian geometry from other types of Finsler geometries (Deicke's theorem).

Since the components of the fundamental and Cartan's tensors have a dependence on the tangent vector y, it is natural to use a manifold other than $\mathbf{M}$ to study Finsler geometry. One possible construction is the following: consider $\pi^*\mathbf{TM}$, the pullback bundle of $\mathbf{TM}$ by the projection

$$\pi:\mathbf{N}\to\mathbf{M}. \tag{A4}$$

The vector bundle $\pi^*\mathbf{TM}$ has as a base manifold $\mathbf{N}$, the fiber over the point $u=(x,y)\in\mathbf{N}$ is diffeomorphic to $\mathbf{T}_x\mathbf{M}$ for every point $u\in\mathbf{N}$ with $\pi(u)=x$, and the structure group is diffeomorphic to $\mathbf{GL}(n,\mathbf{R})$.

The vector bundle $\pi^*\mathbf{TM}\subset\mathbf{TM}\times\mathbf{N}$ and the projection on the first and second factors are given by

$$\pi_1:\pi^*\mathbf{TM}\to\mathbf{N}, \tag{A5}$$

$$\pi_2:\pi^*\mathbf{TM}\to\mathbf{TM}. \tag{A6}$$

$\pi^*\mathbf{TM}$ is completely determined as a subset of $\mathbf{TM}\times\mathbf{N}$ by the following relation; for every $u\in\mathbf{N}$ and $\xi\in\pi_1^{-1}(u)$,

$$(u,\xi)\in\pi^*\mathbf{TM}\quad\text{iff}\quad\pi\circ\pi_2(u,\xi)=\pi(u). \tag{A7}$$

A similar construction $\pi^*\mathbf{TM}$ can be performed over $\mathbf{SM}$, the sphere bundle over $\mathbf{N}$.

One essential notion in Finsler geometry is the nonlinear connection. We introduce the nonlinear connection coefficients, defined by the formula

$$\frac{N_j^i}{F}=\gamma_{jk}^i\frac{y^k}{F}-A_{jk}^i\gamma_{rs}^k\frac{y^r}{F}\frac{y^s}{F},\quad i,j,k,r,s=1,\ldots,n$$

where the *formal second kind Christoffel's symbols* γ_{jk}^i are defined in local coordinates by the formulas

$$\gamma_{jk}^i=\frac{1}{2}g^{is}\left(\frac{\partial g_{sj}}{\partial x^k}-\frac{\partial g_{jk}}{\partial x^s}+\frac{\partial g_{sk}}{\partial x^j}\right),\quad i,j,k=1,\ldots,n;$$

$A_{jk}^i=g^{il}A_{ljk}$, and $g^{il}g_{lj}=\delta_j^i$. Note that the coefficients N_j^i/F are invariant under the scaling $y\to\lambda y$, $\lambda\in\mathbf{R}^+$, $y\in\mathbf{T}_x\mathbf{M}$.

Let us consider the local coordinate system $(x,y,\mathbf{U})$ of the manifold $\mathbf{TM}$. A tangent basis for $\mathbf{T}_u\mathbf{N},u\in\mathbf{N}$ is defined by the distributions[4]

$$\left\{\left.\frac{\delta}{\delta x^1}\right|_u,\cdots\left.\frac{\delta}{\delta x^n}\right|_u,F\left.\frac{\partial}{\partial y^1}\right|_u,\ldots,F\left.\frac{\partial}{\partial y^n}\right|_u\right\},$$

$$\left.\frac{\delta}{\delta x^j}\right|_u=\frac{\delta}{\delta x^j}{}_u-\left.N_j^i\frac{\delta}{\delta y^i}\right|_u,\quad i,j=1,\ldots,n.$$

The set of local sections

$$\left\{\left.\frac{\delta}{\delta x^1}\right|_u,\ldots,\left.\frac{\delta}{\delta x^n}\right|_u,u\in\pi^{-1}(x),x\in\mathbf{U}\right\}$$

generates the local horizontal distribution $\mathcal{H}_U$ while

$$\left\{ \left.\frac{\partial}{\partial y^1}\right|_u, \ldots, \left.\frac{\partial}{\partial y^n}\right|_u, u \in \pi^{-1}(x), x \in \mathbf{U} \right\}$$

the vertical distribution $\mathcal{V}_U$. The subspaces $\mathcal{V}_u$ and $\mathcal{H}_u$ are such that the following splitting of $\mathbf{T}_u\mathbf{N}$ holds:

$$\mathbf{T}_u\mathbf{N} = \mathcal{V}_u \oplus \mathcal{H}_u, \quad \forall\, u \in \mathbf{N}.$$

This decomposition is invariant by the action of $\mathbf{GL}(n,\mathbf{R})$ and it defines a nonlinear connection (a connection in the sense of Ehresmann) on the principal fiber bundle $\mathbf{N}(\mathbf{M},\mathbf{GL}(n,\mathbf{R}))$.

Theorem 4: (*Chern's connection*, Ref. 4) *Let* $(\mathbf{M},F)$ *be a Finsler structure. The vector bundle* $\pi^*\mathbf{TM}$ *admits a unique linear connection characterized by the connection 1-forms* $\{\omega^i_j, i,j = 1,\ldots,n\}$ *such that the following structure equations hold:*

1. "*Torsion- free*" *condition*,

$$d(dx^i) - dx^j \wedge w^i_j = 0, \quad i,j = 1,\ldots,n. \tag{A8}$$

2. *Almost g-compatibility condition*,

$$dg_{ij} - g_{kj}w^k_i - g_{ik}w^k_j = 2A_{ijk}\frac{\delta y^k}{F}, \quad i,j,k = 1,\ldots,n. \tag{A9}$$

Chern's connection is nonmetric compatible but has null torsion. Cartan's connection is completely metric compatible, but has torsion. The relation between the Cartan connection 1-forms $(\omega_c)^k_i$ in relation with the Chern connection ω^k_i 1-forms are given by[4]

$$(\omega_c)^k_i = \omega^k_i + A^k_{ij}\frac{\delta y^j}{F}.$$

At this point we should stress the importance of the Cartan connection on physical applications and in general of the metric connections in field theory.[6] Chern's connection is not metric compatible, which is a bit problematic for physical applications; it is preferable to use Cartan's connection or d-connection, which is metric compatible.

The manifold $\mathbf{I}_x$ is called the indicatrix and is defined by

$$\mathbf{I}_x := \{y \in \mathbf{T}_x\mathbf{M} | F(x,y) = 1\}.$$

Let us denote by $\mathcal{F}(\mathbf{I}_x)$ the set of real, smooth functions on the indicatrix $\mathbf{I}_x$. Then the average operation is defined as follows.

Definition 5: Let $(\mathbf{M},F)$ *be a Finsler structure. Let* $f \in \mathcal{F}(\mathbf{I}_x)$ *be a real, smooth function defined on the indicatrix* $\mathbf{I}_x$ *and* $(\psi,\mathbf{I}_x)$ *the invariant measure. We define the map*

$$\begin{gathered} \langle\cdot\rangle_\psi : \mathcal{F}(\mathbf{I}_x) \to \mathbf{R} \\ f(x,y) \to \frac{1}{\mathrm{vol}(\mathbf{I}_x)} \int_{\mathbf{I}_x} d\,\mathrm{vol}\ \psi(x,y) f(x,y). \end{gathered} \tag{A10}$$

In the case of smooth Finsler structures the coefficients $\{h_{ij}, i,j = 1,\ldots,n\}$ are smooth in $\mathbf{M}$. They are the components of a Riemannian metric in $\mathbf{M}$.

Proposition 6: Let $(\mathbf{M},F)$ *be a Finsler structure. Then the functions*

$$h_{ij}(x) := \langle g_{ij}(x,y)\rangle, \quad \forall\, x \in \mathbf{M} \tag{A11}$$

are the components of a Riemannian metric in $\mathbf{M}$ *such that in a local basis* $(x,\mathbf{U})$ *is*

$$h(x) = h_{ij}dx^i \otimes dx^j. \tag{A12}$$

We should mention that the restriction on the indicatrix $\mathbf{I}_x$ in the integration is not necessary: we can perform similar averages procedures on any compact submanifold of codimension 1 and also of codimension 0 (see Ref. 10, Propositions 3.13 and 3.14). Indeed, Proposition 3.14 of Ref. 10 implies that we can take the limit of the whole tangent bundle, provided a convenient normalization is used.

The average operation can be extended to obtain average connections and average curvatures.[10] This fact can be used to introduce a field theory based on connections as fundamental variables for deterministic theories at the Planck scale.

We consider the dynamics on a quantum graph as the limit of the dynamics generated by a one-particle Hamiltonian in $\mathbb{R}^2$ with a potential having a deep strict minimum on the graph, when the width of the well shrinks to zero. For a generic graph we prove convergence outside the vertices to the free dynamics on the edges. For a simple model of a graph with two edges and one vertex, we prove convergence of the dynamics to the one generated by the Laplacian with Dirichlet boundary conditions in the vertex. © *2006 American Institute of Physics.*

I. INTRODUCTION

Several physical systems, like electronic nanostructures or periodic solids made up of aromatic molecules, display the common feature that the motion of the electrons can be thought of as being confined in one or more directions by a strong potential barrier, which prevents the particles from escaping from the structure and allows propagation in the remaining (free) directions.

In solid state physics, a concrete example of this phenomenon is given by quantum wires and carbon nanotubes, where the high purity achieved in fabrication techniques and the weakness of electron-phonon interaction give rise to ballistic transport. Therefore, using the strong-coupling method, one can in first approximation model the interaction of electrons with the crystal assuming that they move freely with an effective mass m [a more detailed discussion of the physical hypotheses on which this approximation is based can be found in Duclos and Exner (1995), Londergan *et al.* (1999)].

Taking into account the strong potential barrier which keeps them confined, their dynamics are then given by the one-particle Hamiltonian

$$\hat{H}_\varepsilon := -\frac{1}{2}\Delta + \frac{1}{2\varepsilon^2}W(q), \tag{1}$$

where we have chosen suitable units so that $\hbar$ and the effective mass are equal to 1.

The parameter ε is the natural small parameter of the problem and is linked to the ratio l/L, where L is the characteristic length of the wire along the free direction where the electrons can propagate and l is the analogous length in the confined directions.

In general, the function W is assumed to be zero on the quantum wire and strictly positive outside, so that when ε becomes small one expects the electron to be better and better confined to the wire. For this reason, W is called the *constraining potential*.

Our aim in this paper is to analyze the dynamics generated by (1) in the limit $\varepsilon \to 0$ for two-dimensional systems constrained to a singular one-dimensional manifold given by a graph Γ.

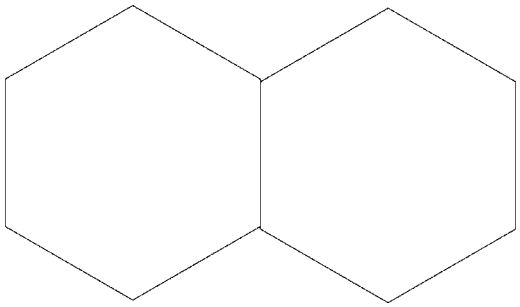

FIG. 1. Skeleton of naphthalene molecule.

We consider an explicit form of the constraining potential, i.e., the square of the distance of a point from the graph. This potential is obviously continuous, but does not belong to $C^1(\mathbb{R}^2)$, because of the vertices. Outside the vertices, the potential is a quadratic function of the coordinates, so it can be regarded as the first nonzero term of the Taylor expansion of more general functions which are zero on the graph, and whose gradient is zero on the edges. This is the natural class of constraining potentials considered in the literature to model holonomic constraints in classical and quantum mechanics [Bornemann (1998), Froese and Herbst (2001), and references therein]. We will argue that the results we find can be generalized to a wider class of potentials, whose Taylor expansion near the graph contains higher order terms.

As it is clear from the brief remarks given above, this case is relevant for solid state physics in order to determine the leading order behavior for the dynamics of electrons moving in a *branched* nanostructure, made up of several wires which meet in a crossing region represented by the vertices of the graph in the limit $\varepsilon \to 0$.

Another important field where Equation (1) can be applied is given by theoretical chemistry, in the so-called quantum network model (QNM) [for a recent review which contains also some comparison with experimental data see Amovilli *et al.* (2004) and references therein]. This model is used to study the motion of valence electrons (also called π-electrons) in aromatic molecules or periodic solids like graphene. In first approximation, they are thought to move freely through the skeleton of the molecule determined by σ-electrons, which create a potential keeping π-electrons confined to the molecular structure. The most famous example, described in Fig. 1, is probably naphthalene molecule, first studied by Ruedenberg and Scherr (1953).

The characteristic feature shared by the examples presented is that we always expect the limiting dynamics to take place on a graph, on which we must define a suitable Hamiltonian. The couple made up of the graph and a differential or pseudodifferential self-adjoint operator defined on it is usually called quantum graph [a detailed review on this topic is given in Kuchment (2002, 2004, 2005)].

The main problem one runs into if one wants to describe the physical systems mentioned above by a quantum graph is that there are a host of self-adjoint Hamiltonians which can be defined on it.

If, for example, one assumes that the dynamics outside the vertices is free, i.e., that the Hamiltonian is the Laplacian $-d^2/\mathrm{d}x^2$, where x is the natural arc length coordinate on the edges of the graph, and that the graph has one vertex and n edges, then the possible self-adjoint extensions are determined by n^2 parameters [Kostrykin and Schrader (1999)].

To eliminate this ambiguity, a natural procedure is to consider the quantum graph as a limit of a more realistic model. We call the method employing a strong constraining potential a *soft approximation* of the graph. As we have pointed out above, this is a physically reasonable approximation, which, for a smooth constraint, has been investigated, e.g., in Belov *et al.* (2004), Dell'Antonio and Tenuta (2004), Froese and Herbst (2001). As far as the authors' knowledge is concerned, the remark by Kuchment (2002) that "the graph case (i.e., in the presence of vertices) has not been explored" is still largely true.

Another appropriate choice, which we call *rigid approximation* of quantum graphs, is to consider a "thickened graph," composed in the simplest cases of thin tubes of radius ε, which has the same topology as the original graph and reduces to it when ε goes to zero. It is reasonable to suppose that the motion of the electron in this thickened structure is free, but one needs to specify boundary conditions to get a well-defined Laplacian. The most natural choice is to use Dirichlet boundary conditions, which correspond to an infinite constraining potential barrier. Some light on this case has been shed in two recent papers by Molchanov and Vainberg (unpublished) and Post (2005).

Post considers thickened graphs which near the vertices are strictly *smaller* than the ones defined by the distance function,

$$V_{\varepsilon,\Gamma} := \{(x,y) \in \mathbb{R}^2 : d_\Gamma(x,y) \leqslant \varepsilon\}, \tag{2}$$

and shows convergence to the Laplacian with Dirichlet boundary conditions at the vertices of the graph. This limitation on the size of the neighborhoods gives another reason why the study of a constraining potential equal to the square of the distance is interesting.

Molchanov and Vainberg analyze a somewhat less realistic model, where separation of variables is possible, and are interested in the asymptotic expansion of the solutions to the scattering problem on the thickened graph to the solutions of a problem on the quantum graph. Even though they are in a stationary setting, they conclude that, near the threshold of the absolutely continuous spectrum, one gets generically again Dirichlet boundary conditions at the vertices.

For technical reasons, however, much more attention has been devoted to the case of Neumann boundary conditions, which is by now well understood [Exner and Post (2005), Kuchment and Zeng (2001, 2003), Rubinstein and Schatzman (2001), Post (unpublished)].

We stress that, apart from Post (unpublished) and Molchanov and Vainberg (2006), all the papers we have quoted deal with the *convergence of the spectrum* of the Laplacian, defined on a thickened graph, to the spectrum of a self-adjoint operator, defined on a graph whose edges have finite length, while we are primarily interested in the convergence of the dynamics and eventually in scattering theory.

The dynamical problem for parabolic equations (diffusion processes) was studied by Freidlin (1996) and Freidlin and Wentzell (1993), who examined it in the context of the Neumann rigid approximation.

In the same setting, a weak form of resolvent convergence for the Laplacian was studied by Saitō [Saitō (2000, 2001)], but his results do not allow to infer the structure of time evolution.

In Post (unpublished) these results are improved, and norm resolvent convergence is established, under the hypotheses that the vertex neighborhoods are "small" (for the precise meaning of the term we refer to the original paper) and, for graphs embedded in $\mathbb{R}^2$, that the angle between two different edges has a global lower bound.

Another important difference in our paper is related to the class of initial conditions we consider. From a physical point of view, one expects that, when $\varepsilon \to 0$, the Hamiltonian (1) gives rise to fast oscillations of the electron in the directions orthogonal to the edges of the graph. To prove the results mentioned above, one projects, roughly speaking, on the ground state of this transverse oscillation. Nonetheless, in the spirit of adiabatic perturbation theory [Teufel (2003)] we expect to be able to get an effective dynamics inside every transverse subspace, because they become broadly separated in energy when ε goes to zero. For this reason, we consider initial wave functions which are localized inside one edge, and belong to an eigenspace of the transverse Hamiltonian (which will be defined more precisely in Sec. II).

We consider longitudinal initial conditions which are independent of ε. This corresponds to study longitudinal states which vary over a wavelength which is much bigger than the transverse one. As it has been stressed in Belov *et al.* (2004) however, longitudinal states are not homogeneous, and it would be interesting to consider also wave functions which vary on a scale of order $\varepsilon^{1/2}$, for example, analyzing in this way a semiclassical limit.

One should also remark that, in the Neumann case, the energy of the transverse ground state is independent of ε, because the Neumann Laplacian has always the eigenvalue zero correspond-

ing to the constant function, while in the Dirichlet and soft approximation cases, the energy of every transverse mode tends to infinity when $\varepsilon \to 0$. This makes it necessary to subtract a divergent phase to get a finite result.

We will now describe briefly the structure of this paper.

In Sec. II we study the convergence of the unitary group generated by (1) for an arbitrary graph (i.e., with an arbitrary number of vertices and edges). As we have already mentioned, we consider initial conditions which belong to a transverse eigenspace and are localized inside one edge of the graph and we choose a constraining potential given by the square of the distance of a point from the graph. Using weak convergence methods we study the limit flow on the graph outside the vertices. To describe completely the limit flow, we must study its structure in a neighborhood of the vertices.

This may be a difficult task; this can be seen from the exact treatment we give in Sec. III of a simpler system, in which the graph is a continuous curve in the plane.

In this example, the graph has one vertex and two straight edges at an angle $0 < \vartheta < \pi$. In this case we approximate the graph by a sequence of smooth curves converging to the graph when $\varepsilon \to 0$. We prove that generically (in particular if the curvature of the approximating curves is everywhere non-negative) the limit dynamics along the graph correspond to Dirichlet boundary conditions at the vertex.

The proof is achieved by reducing the problem to the study of the dynamics with Dirichlet boundary conditions on the boundary of narrow tubes containing the graph, using a refined version of a theorem due to Froese and Herbst (2001). This however is not possible for every smooth curve approximating the graph, and a condition on the curvature comes in. From this result, it seems that the constraining potential and Dirichlet boundary conditions are not always interchangeable, as one could naively think.

Even though the geometry of the graph is very simple, this model demonstrates a mechanism through which adiabatic decoupling among different transverse modes takes place. In particular, it shows that the bound states localized near the vertices that can arise [and indeed do arise if instead of the constraining potential one considers a narrow tube with Dirichlet boundary conditions, see Carini *et al.*(1992, 1993), Goldstone and Jaffe (1992)] do not interfere with the propagation of product states localized inside one of the edges *at the leading order*, because their spectral distance becomes infinite in the limit.

II. CONVERGENCE OUTSIDE THE VERTICES

In this section we consider a finite metric graph, denoted by Γ, whose edges can have infinite length. We assume that it is embedded in $\mathbb{R}^2$ and, for the sake of simplicity, that all the edges are straight lines.

We denote by $V=\{v_i\}_{i\in I}$ the (finite) set of vertices and by $E=\{e_j\}_{j\in J}$ the (finite) set of edges connecting them. We assume that there are no isolated vertices.

A graph is said to be a metric graph if to each edge e is assigned a length $l_e \in (0, +\infty]$. Edges of infinite length arise naturally if one considers scattering theory on graphs [see, e.g., Melnikov and Pavlov (1995) and references therein].

We can now identify each edge with a finite or infinite interval $[0, l_e]$, with the natural coordinate x_e along it. One can also define function spaces (e.g., L^p spaces, Sobolev spaces); in the case of Sobolev spaces, one must have some care at the vertices [see Kuchment (2004)].

As mentioned in the introduction, we approximate the dynamics on the graph using an Hamiltonian, acting on $L^2(\mathbb{R}^2)$, with a constraining potential given by the square of the distance from Γ,

$$\hat{H}(\varepsilon) = -\frac{1}{2}\Delta + \frac{1}{2\varepsilon^2} d_\Gamma^2,$$

$$d_\Gamma(q) := \inf_{\tilde{q}\in\Gamma}|q-\tilde{q}|, \quad q,\tilde{q}\in\mathbb{R}^2. \tag{3}$$

One could use a different potential, whose Taylor expansion away from the vertices contains higher order terms, but we make the important assumption that the Hessian is constant along the edges with the same value on all edges. This condition is reasonable in view of the analysis in Dell'Antonio and Tenuta (2004) and Froese and Herbst (2001) when the system is constrained to smooth submanifolds.

In this case, the energy of the transverse oscillation appears as a potential energy in the longitudinal motion, in the form $\omega(x)/\varepsilon$, where ω is the frequency of the oscillation. If ω does not depend on x, the resulting phase factor in the dynamics can be discarded. Otherwise, it originates a constraining potential along the edge, so that in the limit $\varepsilon\to 0$ we expect that the wave function concentrates along the minima of ω.

We denote by $\hat{U}_t(\varepsilon)$ the unitary evolution associated to Hamiltonian (3),

$$\hat{U}_t(\varepsilon) := \exp(-it\hat{H}(\varepsilon)), \tag{4}$$

and we take as initial a state which "lies in a subband," i.e., is in a fixed transverse mode and localized within one edge (see Fig. 2). These are the states which are thought to describe the propagation of particles in semiconductor structures.

We have then

$$\psi_0(x_{e_{j_0}}, y_{e_{j_0}}) = f(x_{e_{j_0}})\Phi_n^\varepsilon(y_{e_{j_0}}), \tag{5}$$

where $f\in C_0^\infty(0, l_{e_{j_0}})$ and Φ_n^ε is an eigenstate of the harmonic oscillator,

$$\left(-\frac{1}{2}\frac{\partial^2}{\partial y^2}+\frac{1}{2\varepsilon^2}y^2\right)\Phi_n^\varepsilon(y) = \frac{E_n}{\varepsilon}\Phi_n^\varepsilon(y),$$

$$E_n = n+\frac{1}{2}. \tag{6}$$

$x_{e_{j_0}}$ is the natural coordinate along the edge e_{j_0} and $y_{e_{j_0}}$ is the corresponding coordinate in the orthogonal direction. $x_{e_{j_0}}$ varies in the interval $[0, l_{e_{j_0}}]$ (or $[0,+\infty)$ if the edge has infinite length) and, since the edges are straight lines, $y_{e_{j_0}}$ is well defined and assumes values between $-\infty$ and $+\infty$ (to simplify the notation, from now we denote these coordinates just by x_j and y_j).

Applying $\hat{U}_t(\varepsilon)$ to ψ_0 we expect the appearance of a strongly oscillating factor, given by $\exp(-iE_nt/\varepsilon)$. To avoid this (irrelevant) phase, we consider the modified unitary group,

$$\tilde{H}(\varepsilon) := \hat{H}(\varepsilon) - \frac{E_n}{\varepsilon},$$

$$\psi_t^\varepsilon := \tilde{U}(\varepsilon)\psi_0 := \exp(-it\tilde{H}(\varepsilon))\psi_0. \tag{7}$$

To analyze the adiabatic decoupling, we split ψ_t^ε according to the different transverse components in each edge,

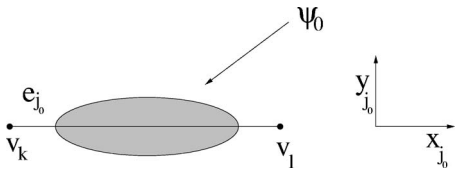

FIG. 2. Schematic representation of the initial state.

$$s_j^m(t,x_j;\varepsilon) := \int \mathrm{d}y_j\, \Phi_m^\varepsilon(y_j)^*\, \psi_t^\varepsilon(x_j,y_j),^1 \tag{8}$$

where x_j is the natural coordinate along e_j and y_j is orthogonal to it. (See Fig. 2)

Proposition 1: Let P_j^m be the operator from $\mathcal{S}(\mathbb{R}^2)$ to $H^k(\mathbb{R})$ defined by

$$P_j^m \psi(x_j) := \int_{\mathbb{R}} \mathrm{d}y_j\, \Phi_m^\varepsilon(y_j)^*\, \psi(x_j,y_j), \tag{9}$$

then P_j^m extends to a unique operator (of norm 1) from $H^k(\mathbb{R}^2)$ to $H^k(\mathbb{R})$, for every $k \in \mathbb{N}$, $k \geqslant 0$.

Proof. Given $\psi \in \mathcal{S}(\mathbb{R}^2)$ it is clear that

$$\begin{aligned}
\partial_x^l (P_j^m \psi)(x) &= \int_{\mathbb{R}} \mathrm{d}y \Phi_m(y)^* \partial_x^l \psi(x,y) = \langle \Phi_m, \partial_x^l \psi \rangle_{L^2(\mathbb{R}_y)} \Rightarrow |\partial_x^l (P_j^m \psi)(x)|^2 \\
&\leqslant \|\Phi_m\|^2_{L^2(\mathbb{R})} \cdot \int \mathrm{d}y |\partial_x^l \psi(x,y)|^2 \Rightarrow \int \mathrm{d}x |\partial_x^l (P_j^m \psi)(x)|^2 \\
&\leqslant \|\Phi_m\|^2_{L^2(\mathbb{R})} \cdot \|\partial_x^l \psi\|^2_{L^2(\mathbb{R}^2)} \Rightarrow \|P_j^m \psi\|^2_{H^k(\mathbb{R})} = \sum_{l=0}^{k} \|\partial_x^l P_j^m \psi\|^2_{L^2(\mathbb{R})} \leqslant \|\Phi_m\|^2 \sum_{l=0}^{k} \|\partial_x^l \psi(x,y)\|^2_{L^2(\mathbb{R}^2)}.
\end{aligned} \tag{10}$$

□

Corollary 1: The components $s_j^m(t,x_j;\varepsilon)$ are well defined, belong to $H^1(\mathbb{R})$ in the variable x_j and satisfy

$$\sup_{t\in[0,T]} \|s_j^m(t,\cdot\,;\varepsilon)\|_{L^2(\mathbb{R})} \leqslant \text{const.} \tag{11}$$

Proof: The domain of the quadratic form associated to $\widetilde{H}(\varepsilon)$ is given by

$$Q(\widetilde{H}(\varepsilon)) := H^1(\mathbb{R}^2) \cap Q(d^2), \tag{12}$$

where $Q(d^2) := \{\psi \in L^2(\mathbb{R}^2) : d_\Gamma(x,y)\psi \in L^2(\mathbb{R}^2)\}$. ψ_0 belongs to $Q(\widetilde{H}(\varepsilon))$, so ψ_t^ε is in $H^1(\mathbb{R}^2)$. □

Lemma 1:

$$\|\widetilde{H}(\varepsilon)\psi_0\| \leqslant C \quad \text{(independent of } \varepsilon\text{)}. \tag{13}$$

Proof: Since the Laplacian is invariant by rotations and translations, we have (for simplicity we drop the index j_0 in x and y)

[1]With an abuse of notation, we denote by $\psi_t^\varepsilon(x_j,y_j)$ the function ψ_t^ε written in coordinates (x_j,y_j). Since the different systems of coordinates associated to each edge are linked to one another by a rigid motion of the plane, this does not modify the differentiablity or integrability properties of ψ_t^ε. Note, instead, that $\Phi_m^\varepsilon(y_j)$ is an eigenfunction of the harmonic oscillator in the variable y_j.

$$\widetilde{H}(\varepsilon)\psi_0 = -\frac{1}{2}\partial_x^2 f\cdot\Phi_n - \frac{1}{2}f\cdot\partial_y^2\Phi_n + \frac{1}{2\varepsilon^2}d_\Gamma^2 f\cdot\Phi_n - \frac{E_n}{\varepsilon}f\cdot\Phi_n = -\frac{1}{2}\partial_x^2 f\cdot\Phi_n + \frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)f\cdot\Phi_n$$
$$-\frac{1}{2}f\cdot\partial_y^2\Phi_n + f\frac{1}{2\varepsilon^2}y^2\cdot\Phi_n - \frac{E_n}{\varepsilon}f\cdot\Phi_n = -\frac{1}{2}\partial_x^2 f\cdot\Phi_n + \frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)f\cdot\Phi_n.$$

Let a be the infimum of the support of f, and $b>a$ the supremum. Since f is supported inside the edge e_{j_0} and near each edge the distance from the graph is equal to $|y_j|$, the function $(1/2\varepsilon^2)(d_\Gamma^2-y^2)f\cdot\Phi_n$ will be zero when $|y|<D$, where D, depending on the support of f, can be small, but it is strictly positive. Therefore we have

$$\left\|\frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)f\cdot\Phi_n\right\|^2 = \int_a^b \mathrm{d}x\int_{|y|>D}\mathrm{d}y\frac{1}{4\varepsilon^4}(d_\Gamma^2 - y^2)^2|f(x)\Phi_n^\varepsilon(y)|^2. \tag{14}$$

Now we use the following two properties:

(i) d_Γ^2 is equal to a polynomial of second order in the variables (x,y);
(ii) Φ_n^ε is equal to a polynomial in $y/\varepsilon^{1/2}$ times $\exp(-y^2/2\varepsilon)$.

The norm (14) contains then terms of the form (P and Q are polynomials)

$$\int_a^b \mathrm{d}x|f(x)|^2\int_{|y|>D}\mathrm{d}y\,P(x,y)Q(x,y/\varepsilon^{1/2})\exp\left(-\frac{y^2}{\varepsilon}\right)$$
$$= \int_a^b \mathrm{d}x|f(x)|^2\int_{|y|>D}\mathrm{d}y\,P(x,y)Q(x,y/\varepsilon^{1/2})\exp\left[-\left(\frac{1}{\varepsilon}-M\right)y^2\right]\exp(-My^2)$$
$$\leqslant \exp\left[-\left(\frac{1}{\varepsilon}-M\right)D^2\right]\int_a^b \mathrm{d}x|f(x)|^2\int_{|y|>D}\mathrm{d}y\,P(x,y)Q(x,y/\varepsilon^{1/2})\exp(-My^2) = O(e^{-c/\varepsilon}).$$

This implies that

$$\left\|\frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)f\cdot\Phi_n\right\|^2 = O(e^{-c/\varepsilon}), \tag{15}$$

and therefore the thesis is proved. □

Corollary 2: For every system of coordinates (x_j,y_j) associated to an edge e_j we have

$$\frac{1}{2}\|\partial_{x_j}\psi_t^\varepsilon\|^2 + \frac{1}{2}\|\partial_{y_j}\psi_t^\varepsilon\|^2 + \frac{1}{2\varepsilon^2}\|d_\Gamma\psi_t^\varepsilon\|^2 \leqslant \frac{C}{\varepsilon}. \tag{16}$$

Corollary 3: Let $F_{d_\Gamma\geqslant\delta}$ be the characteristic function of the set $\{(x,y): d_\Gamma(x,y)\geqslant\delta\}$, where δ is any positive number, then

$$\sup_{t\in[0,T]}\|F_{d_\Gamma\geqslant\delta}\psi_t^\varepsilon\|_{L^2(\mathbb{R}^2)} = O(\varepsilon^{1/2}). \tag{17}$$

Proof: Last term in (16) gives

$$\tfrac{1}{2}\|d_\Gamma\psi_t^\varepsilon\|^2 \leqslant C\varepsilon.$$

Therefore we get

$$\delta^2\cdot\langle\psi_t^\varepsilon, F_{d_\Gamma\geqslant\delta}\psi_t^\varepsilon\rangle \leqslant \langle d_\Gamma\psi_t^\varepsilon, F_{d_\Gamma\geqslant\delta}d_\Gamma\psi_t^\varepsilon\rangle \leqslant 2C\varepsilon.$$

□

We are now ready to prove the following.

Theorem 1: *For $m\neq n$ and $j\in J$*

$$s_j^m(t,x_j;\varepsilon) \overset{*}{\rightharpoonup} 0, \quad \varepsilon \to 0, \tag{18}$$

where the convergence is in the weak topology of* $L^\infty((0,T),L^2(\mathbb{R}))$.

Proof: For convenience of the reader, we recall that a *bounded* sequence f_ε of functions in $L^\infty((0,T),L^2(\mathbb{R}))$ converges to a limit $f_0 \in L^\infty((0,T),L^2(\mathbb{R}))$ in the weak* topology if and only if

$$\int_0^T \mathrm{d}t\ \varphi(t)\langle \chi(\cdot), f_\varepsilon(t,\cdot)\rangle_{L^2(\mathbb{R})} \to \int_0^T \mathrm{d}t\ \varphi(t)\langle \chi(\cdot), f_0(t,\cdot)\rangle_{L^2(\mathbb{R})}$$

for every function $\varphi \in L^1(0,T)$ and every function $\chi \in L^2(\mathbb{R})$.

It is a standard fact about weak* topology that it is enough to consider only φ and χ in dense subsets of $L^1((0,T))$ and $L^2(\mathbb{R})$, respectively [see, e.g., Bornemann (1998), Appendix B or Rudin (1973), Theorems 3.15 and 3.16].

Let us then show first that

$$\sup_{t\in[0,T]} |\langle \chi(\cdot), s_j^m(t,\cdot;\varepsilon)\rangle_{L^2(\mathbb{R})}| \to 0, \quad \varepsilon \to 0, \tag{19}$$

for every function $\chi \in C_0^\infty(\mathbb{R}\backslash\{0,l_{e_j}\})$ if the edge e_j has finite length and for every $\chi \in C_0^\infty(\mathbb{R}\backslash\{0\})$ if e_j has infinite length. We consider explicitly only the latter case, the former being analogous.

If the support of χ is contained in $(-\infty,0)$ then

$$|\langle \chi, s_j^m\rangle_{L^2(\mathbb{R})}| = |\langle \chi\cdot\Phi_m^\varepsilon, \psi_t^\varepsilon\rangle_{L^2(\mathbb{R}^2)}| = |\langle \chi\cdot\Phi_m^\varepsilon, F_\chi\psi_t^\varepsilon\rangle| \leqslant \|\chi\cdot\Phi_m^\varepsilon\|\cdot\|F_\chi\psi_t^\varepsilon\| = O(\varepsilon^{1/2}),$$

where F_χ is the characteristic function of the support of χ and we have used Corollary 3.

If the support of χ in contained in $(0,+\infty)$, then, following the proof of Lemma 1 we can show that

$$\widetilde{H}(\varepsilon)[\chi(x_j)\Phi_m^\varepsilon(y_j)] = (\text{we drop the index } j) - \frac{1}{2}\partial_x^2\chi\cdot\Phi_m^\varepsilon + \frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)\chi\cdot\Phi_m^\varepsilon + \frac{E_m - E_n}{\varepsilon}\chi\cdot\Phi_m^\varepsilon.$$

Since χ is supported away from the vertex (located at x_j=0), an equation similar to (15) holds,

$$\left\| \frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)\chi\cdot\Phi_m^\varepsilon \right\|^2 = O(e^{-c/\varepsilon}).$$

Since $m \neq n$, we have then

$$\chi\Phi_m^\varepsilon = \frac{\varepsilon}{m-n}\left\{ \widetilde{H}(\varepsilon)[\chi(x_j)\Phi_m^\varepsilon(y_j)] + \frac{1}{2}\partial_x^2\chi\cdot\Phi_m^\varepsilon \right\} + O(e^{-c/\varepsilon}).$$

This implies

$$\begin{aligned}\langle \chi(\cdot), s_j^m(t,\cdot;\varepsilon)\rangle &= \langle \chi(\cdot)\Phi_m^\varepsilon, \psi_t^\varepsilon\rangle = \frac{\varepsilon}{m-n}\langle \chi(\cdot)\Phi_m^\varepsilon, \widetilde{H}(\varepsilon)\psi_t^\varepsilon\rangle + \frac{\varepsilon}{m-n}\left\langle \frac{1}{2}\partial_x^2\chi\cdot\Phi_m^\varepsilon, \psi_t^\varepsilon \right\rangle + O(e^{-c/\varepsilon}) \\ &= (\text{Lemma 1})O(\varepsilon).\end{aligned}$$

Now, if $\varphi \in L^1((0,T))$, we get

$$\left| \int_0^T \mathrm{d}t\ \varphi(t)\langle \chi(\cdot), s_j^m(t,\cdot;\varepsilon)\rangle_{L^2(\mathbb{R})} \right| \leqslant \|\varphi\|_{L^1}\cdot \sup_{t\in[0,T]} |\langle \chi(\cdot), s_j^m(t,\cdot;\varepsilon)\rangle|,$$

but we have just shown that the right-hand side goes to zero for $\chi \in C_0^\infty(\mathbb{R}\backslash\{0\})$ [or $C_0^\infty(\mathbb{R}\backslash\{0,l_{e_j}\})$ for an edge of finite length] which is dense in $L^2(\mathbb{R})$. □

Theorem 1 shows that, although in a weak sense, there is indeed adiabatic separation between the different transverse states even in the presence of vertices, if the initial state is localized in two

senses: first, it must be localized inside one edge to avoid mixing between the different transverse states associated to each edge and second, it must be in one (or a finite number of) transverse band(s).

Since the limit of s_j^m for $m \neq n$ is zero, to analyze in a complete way the (limit) evolution of ψ_0 we must determine the behavior of s_j^n, $j \in J$ as a function of time.

Theorem 2: *There exists a weak* convergent subsequence of* $s_j^n(t,x_j;\varepsilon)$ *in* $L^\infty((0,T),L^2(\mathbb{R}))$ *(denoted again by the same symbol), whose limit* $s_j^n(t,x_j;0) \in L^\infty((0,T),L^2(\mathbb{R}))$ *satisfies*

$$i\partial_t s_j^n(t,x_j;0) = -\frac{1}{2}\partial_x^2 s_j^n(t,x_j;0) \quad \text{in } \mathcal{D}'((0,T)\times(0,l_{e_j})). \tag{20}$$

Remark 1: By Corollary 1, $s_j^n(t,x_j;\varepsilon)$ is a bounded sequence in $L^\infty((0,T),L^2(\mathbb{R}))$. Since the balls in $L^\infty((0,T),L^2(\mathbb{R}))$ are compact metric spaces with respect to the weak* topology (see the theorems in the book of Rudin quoted above), a weak* convergent subsequence certainly exists.

Moreover, if one shows that all the weak* convergent subsequences converge to the same limit, then this implies that the sequence itself converges.

The equation satisfied by the limit in Theorem 2 is clearly independent of the subsequence, but it does not determine the behavior of the limit in the vertices, so we cannot conclude convergence of the sequence.

For this it would be necessary to control the behavior of the sequence in a neighborhood of the vertices. This difficulty [which is not present for smooth submanifolds, where the same strategy has been successfully applied by Bornemann (1998) in the classical case] is linked with the fact that the operator $-d^2/\mathrm{d}x^2$ defined for functions which vanish in a neighborhood of the origin has many self-adjoint extensions which define different dynamics.

We split the proof of the theorem into a number of lemmas.

Lemma 2: $s_j^n(t,x_j;\varepsilon)$ *belongs to* $C^1([0,T],L^2(\mathbb{R}))$ *and moreover it is an equicontinuous sequence of function from* $[0,T]$ *to* $L^2(\mathbb{R})$.

Proof: Let us denote by $\tilde{s}_j^n(t,x_j;\varepsilon) \in C^0([0,T],L^2(\mathbb{R}))$ the function

$$P_j^n[-i\tilde{H}(\varepsilon)\psi_t^\varepsilon].$$

Using Proposition 1 we have that

$$\left\| \frac{s_j^n(t+h,\cdot\,;\varepsilon)-s_j^n(t,\cdot\,;\varepsilon)}{h} - \tilde{s}_j^n(t,\cdot\,;\varepsilon) \right\|_{L^2(\mathbb{R})} = \left\| P_j^n\left[\frac{\tilde{U}_{t+h}(\varepsilon)-\tilde{U}_t(\varepsilon)}{h} + i\tilde{U}_t(\varepsilon)\tilde{H}(\varepsilon) \right]\psi_0 \right\|$$
$$\leqslant \left\| \left[\frac{\tilde{U}_{t+h}(\varepsilon)-\tilde{U}_t(\varepsilon)}{h} + i\tilde{U}_t(\varepsilon)\tilde{H}(\varepsilon) \right]\psi_0 \right\| \to 0.$$

This proves that

$$i\partial_t s_j^n(t,x_j;\varepsilon) = \tilde{s}_j^n(t,x_j;\varepsilon) = P_j^m[-i\tilde{U}_t(\varepsilon)\tilde{H}(\varepsilon)\psi_0]. \tag{21}$$

Since $\|\tilde{H}(\varepsilon)\psi_0\|$ is bounded (Lemma 1), $\|\tilde{s}_j^m(t,x_j;\varepsilon)\|$ is bounded, therefore

$$\|s_j^m(t,\cdot\,;\varepsilon)-s_j^m(t',\cdot\,;\varepsilon)\|_{L^2(\mathbb{R})} = \left\| \int_t^{t'} \mathrm{d}\tau\, \partial_\tau s_j^m(\tau,\cdot\,;\varepsilon) \right\| \leqslant \int_t^{t'} \mathrm{d}\tau \|\partial_\tau s_j^m(\tau,\cdot\,;\varepsilon)\| \leqslant C|t-t'|,$$

showing that $s_j^m(t,x_j;\varepsilon)$ is an equicontinuous sequence. □

Corollary 4: There exists a subsequence $s_j^m(t,x_j;\varepsilon)$ *which satisfies*

(1) $s_j^m(t,x_j;\varepsilon)$ *converges, in the weak topology of* $L^2(\mathbb{R})$, *uniformly in* t, *to a limit* $s_j^m(t,x_j;0) \in L^2(\mathbb{R})$. *Moreover, the limit is continuous in* t *in the weak topology of* L^2.

(2) $\partial_t s_j^m(t,x_j;\varepsilon) \overset{*}{\rightharpoonup} \partial_t s_j^m(t,x_j;0)$ *in* $L^\infty((0,T),L^2(\mathbb{R}))$, *where the derivative* $\partial_t s_j^m(t,x_j;0)$ *is to be interpreted as derivative in* $\mathcal{D}'((0,T)\times\mathbb{R}_x)$.

Proof: The sequence $s_j^m(t,x_j;\varepsilon)$ is contained in a ball in $L^2(\mathbb{R})$. This ball is a compact metric space with respect to the weak topology. Since the sequence is equicontinuous with respect to the strong topology, it will be equicontinuous with respect to the weak topology too. Therefore, the theorem of Ascoli-Arzelà [see, e.g., Royden (1988), Theorem 10.40] proves the first point.

Equation (21) implies that $\partial_t s_j^m(t,x_j;\varepsilon)$ is a bounded sequence in $L^\infty((0,T),L^2(\mathbb{R}))$, so, extracting possibly another subsequence, we have that there exists $g_j^m \in L^\infty((0,T),L^2(\mathbb{R}))$ such that (again, we denote the subsequence with the same symbol as the sequence itself)

$$\partial_t s_j^m(t,x_j;\varepsilon) \overset{*}{\rightharpoonup} g_j^m,$$

but this implies that $\forall\varphi\in C_0^\infty((0,T))$, $\forall\chi\in C_0^\infty(\mathbb{R})$,

$$\begin{aligned}\int_0^T \mathrm{d}t \int_{\mathbb{R}} \mathrm{d}x\, g_j^m(t,x)\varphi(t)\chi(x) &= \int_0^T \mathrm{d}t\, \varphi(t)\langle\chi(\cdot), g_j^m(t,\cdot)\rangle_{L^2(\mathbb{R})} \leftarrow \int_0^T \mathrm{d}t\, \varphi(t)\langle\chi, \partial_t s_j^m(t,\cdot\,;\varepsilon)\rangle \\ &= \int_0^T \mathrm{d}t\, \varphi(t)\partial_t\langle\chi, s_j^m(t,\cdot\,;\varepsilon)\rangle = -\int_0^T \mathrm{d}t\, \partial_t\varphi\langle\chi, s_j^m(t,\cdot\,;\varepsilon)\rangle \\ &\to -\int_0^T \mathrm{d}t\, \partial_t\varphi\langle\chi, s_j^m(t,\cdot\,;0)\rangle = \int_0^T \mathrm{d}t \int_{\mathbb{R}} \mathrm{d}x\, s_j^m(t,x;0)\partial_t\varphi(t)\chi(x), \\ &\Rightarrow g_j^m = \partial_t s_j^m(t,x_j;0) \quad \text{in } \mathcal{D}'((0,T)\times\mathbb{R}_x).\end{aligned}$$

□

We can now prove Theorem 2.

Proof: We suppose that edge e_j has infinite length. The proof for an edge of finite length is analogous.

Corollary 3, together with the proof of the first part of the proof of theorem 1 implies that

$$\sup_{t\in[0,T]} |\langle\chi, s_j^m(t,\cdot\,;\varepsilon)\rangle| = O(\varepsilon^{1/2}),$$

for all $j\in J$ and for all $\chi\in C_0^\infty(-\infty,0)$, but the first point of Corollary 4 gives

$$\langle\chi, s_j^m(t,\cdot\,;0)\rangle_{L^2(\mathbb{R})} = \lim_{\varepsilon\to 0}\langle\chi, s_j^m(t,\cdot\,;\varepsilon)\rangle = 0.$$

Equation (21) allows us to write, for all $\chi\in C_0^\infty(0,+\infty)$,

$$\begin{aligned}\langle\chi, i\partial_t s_j^m(t,\cdot\,;\varepsilon)\rangle_{L^2(\mathbb{R})} &= \langle\chi\cdot\Phi_n^\varepsilon, \widetilde{H}(\varepsilon)\psi_t^\varepsilon\rangle_{L^2(\mathbb{R}^2)} = \langle\widetilde{H}(\varepsilon)\chi\cdot\Phi_n^\varepsilon, \psi_t^\varepsilon\rangle \\ &= \left\langle -\frac{1}{2}\partial_x^2\chi\cdot\Phi_n^\varepsilon, \psi_t^\varepsilon\right\rangle + \left\langle \frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)\chi\cdot\Phi_n^\varepsilon, \psi_t^\varepsilon\right\rangle \\ &= \left\langle -\frac{1}{2}\partial_x^2\chi, s_j^m(t,\cdot\,;\varepsilon)\right\rangle_{L^2(\mathbb{R})} + \left\langle \frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)\chi\cdot\Phi_n^\varepsilon, \psi_t^\varepsilon\right\rangle.\end{aligned}$$

Since χ is supported in $(0,+\infty)$, Eq. (15) holds also in this case, therefore

$$\left\| \frac{1}{2\varepsilon^2}(d_\Gamma^2 - y^2)\chi\cdot\Phi_n^\varepsilon \right\|^2 = O(e^{-c/\varepsilon}).$$

We have then, for all $\varphi \in C_0^\infty(0,T)$, and for all $\chi \in C_0^\infty(0,+\infty)$,

$$\int_0^T \mathrm{d}t\ \varphi(t)\langle \chi, i\partial_t s_j^n\ (t,\cdot\,;0))\rangle_{L^2(\mathbb{R})} \leftarrow \int_0^T \mathrm{d}t\ \varphi(t)\langle \chi, i\partial_t s_j^n(t,\cdot\,;\varepsilon)\rangle_{L^2(\mathbb{R})} = \int_0^T \mathrm{d}t\ \varphi(t)$$
$$\times \left\langle -\frac{1}{2}\partial_x^2\chi, s_j^n(t,\cdot\,;\varepsilon)\right\rangle_{L^2(\mathbb{R})} + O(e^{-c/\varepsilon})\|\varphi\|_{L^1(0,T)} \to \int_0^T \mathrm{d}t\ \varphi(t)$$
$$\times \left\langle -\frac{1}{2}\partial_x^2\chi, s_j^n(t,\cdot\,;0)\right\rangle_{L^2(\mathbb{R})},$$

$$\Rightarrow i\partial_t s_j^n(t,x_j;0) = -\tfrac{1}{2}\partial_x^2 s_j^n(t,x_j;0) \quad \text{in } \mathcal{D}'((0,T)\times(0,+\infty)). \tag{22}$$

□

III. A GRAPH WITH TWO EDGES

In this section, we are going to put forward a different kind of soft approximation for a graph with one vertex and two infinite edges. We denote it by Γ_ϑ, where ϑ is the angle made by the two edges, $0<\vartheta<\pi$.

As we have already said in the introduction, we do not consider directly Γ_ϑ, but we approximate it by smooth curves, $\Gamma_{\vartheta,\delta}$, whose curvature becomes bigger and bigger in a region whose width, given by δ, goes to zero and we consider a potential constraining to this family of curves.

More precisely, to specify the approximating curves we need only to specify their curvature, k_δ, because, as it is well known, this determines the curve up to rigid motions of the plane. Naturally, we want that, when δ goes to zero, the curves tend to the graph. This in particular implies that the turning angle must become equal to ϑ when $\delta\to 0$.

A simple choice which satisfies these requests is (s is the arc length parameter)

$$k_\delta(s) := \frac{\vartheta}{\delta}k\left(\frac{s}{\delta}\right), \quad \int_{\mathbb{R}} \mathrm{d}s\ k(s) = 1,$$

$$k \in C_0^\infty(-1,1), \quad \begin{matrix} k=1, & |s|<1/2 \\ k=0, & |s|>3/4, \end{matrix} \tag{23}$$

which amounts to deformate the graph in a neighborhood of the vertex replacing it with an arc of a circle. Note that the δ scaling is fixed by the request that the turning angle of the approximating curves be ϑ,

$$\int_{\mathbb{R}} \mathrm{d}s \frac{\vartheta}{\delta}k\left(\frac{s}{\delta}\right) = \vartheta.$$

Actually, our result does not depend on this specific choice we have made, because, from the proof, one can see that the only essential ingredient is the singularity $1/\delta$, which is forced by the requirement that the turning angle is ϑ.

We consider the Hamiltonian

$$\hat{H}(\varepsilon,\delta(\varepsilon)) = -\frac{1}{2}\Delta + \frac{1}{\varepsilon^2}W_{\delta(\varepsilon)}, \quad \delta(\varepsilon)\to 0 \text{ when } \varepsilon\to 0,$$

where, for simplicity, we suppose that

$$W_{\delta(\varepsilon)}(x,y) = \frac{1}{2}d^2_{\delta(\varepsilon)}(x,y) = \frac{1}{2}\mathrm{dist}[(x,y),\Gamma_{\vartheta,\delta(\varepsilon)}]^2.$$

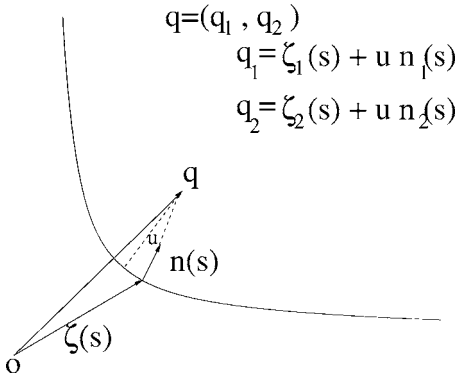
The remark we made above about the possibility to generalize the analysis to potentials with constant Hessian, applies here too. As in the preceding section, we are interested in the time evolution of a product state which is initially localized away from the vertex.

We expect that the particle oscillates very fast along the direction normal to the curve, so to analyze the motion we should use a suitable system of coordinates, adapted to the curve. A natural choice is given by *tubular coordinates*, which are a set of local coordinates suited to study tubular neighborhoods of embedded submanifolds [see, e.g., Lang (1995)]. If the submanifold one considers has codimension (and dimension) bigger than one, then the metric in tubular coordinates is in general not diagonal, and the Laplacian in these coordinates contains a gauge term which couples the longitudinal and the transverse motion [Mitchell (2001) and references therein].

In our case, since both the dimension and the codimension are equal to one, these problems do not appear.

Given a smooth curve C, with parametric equation $\zeta:\Omega\to\mathbb{R}^2$ such that $|\partial_s\zeta(s)|=1$, we can describe the position of points in a tubular neighborhood N of C via the curvilinear coordinates (s,u) defined by

$$q(s,u)=\zeta(s)+u\mathbf{n}(s), \tag{24}$$



where q is an arbitrary point of N, $\mathbf{n}(s)$ is the normal unit vector to the curve, and u is assumed to be smaller than the radius of curvature.

In the case we are dealing with, this means that curvilinear coordinates are defined only in the region

$$\{(x,y)\in\mathbb{R}^2: d_\delta(x,y)<\varrho\}, \tag{25}$$

where ϱ is the radius of curvature of $\Gamma_{\vartheta,\delta}$. When k_δ is different from zero, this quantity is proportional to δ itself, so, by hypothesis, it goes to zero when $\varepsilon\to 0$.

To get rid of the region $\{(x,y): d_\delta(x,y)>\delta\}$ we will use a theorem, proved first by Froese and Herbst in the more general context of a potential constraining to a submanifold [proposition 8.1 in Froese and Herbst (2001)], which basically says that if one starts from an initial state more and more localized near the constraint, then all that matters for the time evolution is a small region near the constraint itself. We repeat the proof of Froese and Herbst because we need to keep track of the dependence of all the constants in the estimates on δ, to apply them to the region $\{(x,y)\in\mathbb{R}^2: d_\delta(x,y)<\delta(\varepsilon)\}$.

Theorem 3: *Let* $\psi\in L^2(\mathbb{R}^2)$, $\|\psi\|=1$ *and* $\|\hat{H}(\varepsilon,\delta)\psi\|\leqslant C_1/\varepsilon$ (C_1 *independent of* δ). *Then*,

$$\|F_{d_\delta\geqslant\delta}e^{-it\hat{H}(\varepsilon,\delta)}\psi\|\leqslant(2C_1)^{1/2}\frac{\varepsilon^{1/2}}{\delta}. \tag{26}$$

F indicates the characteristic function of the region indicated.

Moreover, let $\hat{H}_D(\varepsilon,\delta)$ *be the Hamiltonian* $\hat{H}(\varepsilon,\delta)$ *with Dirichlet boundary conditions on the set* $\{(x,y)\in\mathbb{R}^2: d_\delta(x,y)=\delta\}$.

Let us suppose that $\delta=\delta(\varepsilon)$, $\lim_{\varepsilon\to 0}\delta(\varepsilon)=0$. *Taking into account* (26), *let us also assume that*

$$\lim_{\varepsilon\to 0}\frac{\varepsilon^{1/2}}{\delta(\varepsilon)}=0. \tag{27}$$

Then, for all $t\in[0,T]$, *we have*

$$\|F_{d_\delta<\delta}e^{-it\hat{H}(\varepsilon,\delta)}\psi-e^{-it\hat{H}_D(\varepsilon,\delta)}F_{d_\delta<\delta}\psi\|\leqslant C_2(C_1,T)\left(\frac{\varepsilon^{1/4}}{\delta^{5/2}}+\frac{\varepsilon^{1/2}}{\delta^3}\right). \tag{28}$$

Remark 2: The theorem implies that if we choose a $\delta(\varepsilon)$ such that

$$\lim_{\varepsilon\to 0}\frac{\varepsilon^{1/10}}{\delta(\varepsilon)}=0 \tag{29}$$

then we can restrict ourselves to analyze the Dirichlet Hamiltonian $\hat{H}_D(\varepsilon,\delta(\varepsilon))$, which is localized inside the region where tubular coordinates are defined. This, however, means that we must consider a "tube" encircling the graph whose diameter is much bigger than the localization of the transverse states, which for an harmonic oscillator is $\varepsilon^{1/2}$.

Remark 3: As already observed in Froese and Herbst (2001), the estimate (28) is not optimal.

Proof: Let us first prove (26).

Since $\|\hat{H}(\varepsilon,\delta)\psi\|\leqslant C_1/\varepsilon$, we have from Schwarz inequality

$$\langle\psi,\hat{H}(\varepsilon,\delta)\psi\rangle\leqslant\frac{C_1}{\varepsilon}.$$

This implies immediately that

$$\frac{C_1}{\varepsilon}\geqslant\langle\hat{H}^{1/2}\psi,\hat{H}^{1/2}\psi\rangle=\frac{1}{2}\|\nabla\psi\|^2+\frac{1}{2\varepsilon^2}\|d_\delta\psi\|^2\Rightarrow\|d_\delta\psi\|^2\leqslant 2C_1\varepsilon. \tag{30}$$

It follows then

$$\delta^2\langle F_{d_\delta\geqslant\delta}\psi,F_{d_\delta\geqslant\delta}\psi\rangle\leqslant\langle d_\delta F_{d_\delta\geqslant\delta}\psi,d_\delta F_{d_\delta\geqslant\delta}\psi\rangle\leqslant\|d_\delta\psi\|^2\leqslant 2C_1\varepsilon. \tag{31}$$

The same argument can be applied also to $e^{-it\hat{H}(\varepsilon,\delta)}\psi$, so (26) is proved.

We need now to prove an estimate on the behavior of the gradient of ψ away from the graph.

Let $\tilde{\chi}\in C_0^\infty(\mathbb{R})$ be 1 when $1/4<|x|<3/4$ and 0 when $|x|\leqslant 1/8$ or $|x|\geqslant 7/8$, then the function

$$\chi(u):=\tilde{\chi}\left(\frac{1}{2(\alpha-\lambda_1)}|u|+\frac{1}{4}-\frac{\lambda_1}{2(\alpha-\lambda_1)}\right)$$

will be when $\lambda_1<|u|<\alpha$ and 0 for $|u|$ near zero. If we choose λ_1 and α such that $0<\lambda_1<\alpha<\delta$, then χ is well defined [and $\in C_0^\infty(\mathbb{R})$] when u is the coordinate along the direction normal to the curve $\Gamma_{\vartheta,\delta}$.

We have then

$$\|F_{\lambda_1<d_\delta<\alpha}\nabla\psi\|=\|F_{\lambda_1<d_a<\alpha}\nabla(\chi\psi)\|\leqslant\|\nabla(\chi\psi)\|.$$

Using again the Schwarz inequality and the fact that $\chi\psi\in\mathcal{D}(\Delta)$ (the potential is bounded on the support of χ) we get

$$\|\nabla(\chi\psi)\| \leqslant \|\Delta(\chi\psi)\|^{1/2}\|\chi\psi\|^{1/2},$$

so, to estimate $\|F_{\lambda_1<d_\delta<\alpha}\nabla\psi\|$ we need to get an estimate on $\|\Delta(\chi\psi)\|$. To obtain it, we use an energy estimate of second order, i.e., we calculate the quadratic form associated to $\hat{H}(\varepsilon,\delta)^2$.

$$\hat{H}(\varepsilon,\delta)^2 = \frac{1}{4}|p|^4 + \left(\frac{1}{2\varepsilon^2}d_\delta^2\right)^2 + \sum_j p_j \frac{1}{2\varepsilon^2}d_\delta^2 p_j - \frac{1}{2\varepsilon^2}\Delta d_\delta^2, \tag{32}$$

where $p=-i\nabla$. The first three terms are positive operators, while if we take the mean value of the last one with respect to the state $\chi\psi$ we get

$$\begin{aligned}\langle\chi\psi,\Delta d_\delta^2\chi\psi\rangle &= \int_{d_\delta<\delta} \mathrm{d}x\,\mathrm{d}y|\chi\psi|^2\Delta d_\delta^2 = \int_{|u|<\delta}\mathrm{d}s\,\mathrm{d}u[1+uk_\delta(s)]|\chi\psi|^2[1+uk_\delta(s)]^{-1}\\ &\times\partial_u\{[1+uk_\delta(s)]2u\} = \int_{|u|<\delta}\mathrm{d}s\,\mathrm{d}u[1+uk_\delta(s)]|\chi\psi|^2\cdot 2\\ &+\int_{|u|<\delta}\mathrm{d}s\,\mathrm{d}u|\chi\psi|^2 2uk_\delta(s) \leqslant C\|\chi\psi\|^2,\end{aligned}$$

where the Jacobian of the change to curvilinear coordinates is given by

$$\frac{\partial(q_1,q_2)}{\partial(s,u)} = 1 + k_\delta(s)u \tag{33}$$

and in the last step we have used the fact that

$$\sup_{|u|<\delta}|uk_\delta(s)| \leqslant \delta k_\delta(s) = \vartheta k\left(\frac{s}{\delta}\right) \leqslant \text{const (independent of } \delta).$$

Taking the mean value of (32) with respect to $\chi\psi$ we obtain then

$$\left\|\frac{1}{2}\Delta(\chi\psi)\right\|^2 \leqslant \|\hat{H}(\varepsilon,\delta)(\chi\psi)\|^2 + \frac{C}{\varepsilon^2},$$

which can be written equivalently as

$$\frac{1}{2}\|\Delta(\chi\psi)\| \leqslant \frac{C^{1/2}}{\varepsilon} + \|\hat{H}(\varepsilon,\delta)\psi\| + \frac{1}{2}\|[\Delta,\chi]\psi\|.$$

The last term is equal to

$$[\Delta,\chi]\psi = (\Delta\chi)\psi + \nabla\chi\cdot\nabla\psi,$$

and we can estimate its norm changing to curvilinear coordinates,

$$\nabla\chi = \partial_x\tilde{\chi}(x(u))\frac{1}{2(\alpha-\lambda_1)}\frac{u}{|u|}\boldsymbol{n}(s),$$

$$\begin{aligned}\Delta\chi &= (1+k_\delta u)^{-1}\partial_u[(1+k_\delta u)\partial_u\chi] = \partial_u^2\chi + (1+k_\delta u)^{-1}k_\delta\partial_u\chi = \partial_x^2\tilde{\chi}(x(u))\frac{1}{2(\alpha-\lambda_1)^2}\\ &+\partial_x\tilde{\chi}(x(u))\frac{1}{2(\alpha-\lambda_1)}\frac{u}{|u|}\frac{k_\delta}{1+k_\delta u}.\end{aligned}$$

Using (30) to estimate $\|\nabla\psi\|$, we have then

$$\|[\Delta,\chi]\psi\| \leqslant \frac{C}{\varepsilon^{1/2}(\alpha-\lambda_1)} + \frac{C}{(\alpha-\lambda_1)^2} + \frac{C}{\delta(\alpha-\lambda_1)}. \tag{34}$$

In what follows, we will need to choose α and λ_1 proportional to δ. Assumption (27) implies then that all terms in (34) are *at most* of order ε^{-1}.

To sum up, we have

$$\|\Delta(\chi\psi)\| \leqslant \frac{C}{\varepsilon}, \tag{35}$$

from which it follows that [assuming that α and λ_1 are proportional to δ and that $\delta(\varepsilon)$ satisfies (27)]

$$\|F_{\lambda_1<d_\delta<\alpha}\nabla\psi\| \leqslant C\varepsilon^{-1/2}\frac{\varepsilon^{1/4}}{\delta^{1/2}} = \frac{C}{\varepsilon^{1/4}\delta^{1/2}}. \tag{36}$$

Let now $\tilde{\xi}$ be a function in $C_0^\infty(\mathbb{R})$ such that $\tilde{\xi}(x)=1$ when $|x|<1/4$ and $\tilde{\xi}(x)=0$ when $|x|>1/2$. We define the function ξ by the equation $\xi(u):=\tilde{\xi}(u/\delta)$, where u is the curvilinear coordinate normal to the curve.

Because of (26), to prove (28) is enough to show that

$$\|e^{it\hat{H}_D(\varepsilon,\delta)}\xi e^{-it\hat{H}(\varepsilon,\delta)}\psi - \xi\psi\| \leqslant C_2(C_1,T)\left(\frac{\varepsilon^{1/4}}{\delta^{5/2}} + \frac{\varepsilon^{1/2}}{\delta^3}\right)$$

for $t\in[0,T]$. Let

$$\phi_{t,\varepsilon,\delta} := e^{it\hat{H}_D(\varepsilon,\delta)}\xi e^{-it\hat{H}(\varepsilon,\delta)}\psi - \xi\psi.$$

Integrating the derivative we have

$$\begin{aligned}\phi_{t,\varepsilon,\delta} &= i\int_0^t \mathrm{d}s\, e^{is\hat{H}_D(\varepsilon,\delta)}[\hat{H}_D(\varepsilon,\delta)\xi - \xi\hat{H}(\varepsilon,\delta)]e^{-is\hat{H}(\varepsilon,\delta)}\psi \\ &= \int_0^t \mathrm{d}s\, e^{is\hat{H}_D(\varepsilon,\delta)}[\nabla\xi\cdot p - (i/2)\Delta\xi]e^{-is\hat{H}(\varepsilon,\delta)}\psi,\end{aligned}$$

therefore

$$\|\phi_{t,\varepsilon,\delta}\|^2 = \int_0^t \mathrm{d}s\langle e^{-is\hat{H}_D(\varepsilon,\delta)}\phi_{t,\varepsilon,\delta}, [\nabla\xi\cdot p - (i/2)\Delta\xi]e^{-is\hat{H}(\varepsilon,\delta)}\psi\rangle.$$

Let now $\tilde{\zeta}$ be a $C_0^\infty(\mathbb{R})$ function which is 1 on the support of $\partial_x\tilde{\xi}$ and 0 when $|x|$ is near zero. As above, we denote by $\zeta(u):=\tilde{\zeta}(u/\delta)$. We can then write

$$\begin{aligned}\|\phi_{t,\varepsilon,\delta}\|^2 &\leqslant \int_0^t \mathrm{d}s\|\zeta e^{-is\hat{H}_D(\varepsilon,\delta)}\phi_{t,\varepsilon,\delta}\|(\|\nabla\xi\cdot p e^{-is\hat{H}(\varepsilon,\delta)}\psi\| + \|(1/2)\Delta\xi e^{-is\hat{H}(\varepsilon,\delta)}\psi) \\ &\leqslant C\left(\frac{1}{\delta^{3/2}\varepsilon^{1/4}} + \frac{1}{\delta^2}\right)\int_0^t \mathrm{d}s\|\zeta e^{-is\hat{H}_D(\varepsilon,\delta)}\phi_{t,\varepsilon,\delta}\|,\end{aligned} \tag{37}$$

where we have used (36) and the definition of ξ.

Now

$$\begin{aligned}\langle \phi_{t,\varepsilon,\delta}, \hat{H}_D(\varepsilon,\delta)\phi_{t,\varepsilon,\delta}\rangle &\leqslant 2\langle \xi e^{-it\hat{H}(\varepsilon,\delta)}\psi, \hat{H}_D(\varepsilon,\delta)\xi e^{-it\hat{H}(\varepsilon,\delta)}\psi\rangle + 2\langle \xi\psi, \hat{H}_D(\varepsilon,\delta)\xi\psi\rangle \\ &= 2\left\langle \xi e^{-it\hat{H}(\varepsilon,\delta)}\psi, \left[-\tfrac{1}{2}\Delta\xi - i\nabla\xi\cdot p + \xi\hat{H}_D(\varepsilon,\delta)\right]e^{-it\hat{H}(\varepsilon,\delta)}\psi\right\rangle \\ &\quad + 2\left\langle \xi\psi, \left[-\tfrac{1}{2}\Delta\xi - i\nabla\xi\cdot p + \xi\hat{H}_D(\varepsilon,\delta)\right]\psi\right\rangle.\end{aligned}$$

Using again Equation (36) and the definition of ξ, we get

$$\left|\left\langle \xi\psi, -\frac{1}{2}\Delta\xi\psi\right\rangle\right| \leqslant \frac{C}{\delta^2},$$

$$|\langle \xi\psi, -i\nabla\xi\cdot p\psi\rangle| \leqslant \frac{C}{\varepsilon^{1/4}\delta^{3/2}},$$

$$|\langle \xi\psi, \xi\hat{H}_D(\varepsilon,\delta)\psi\rangle| \leqslant \frac{C}{\varepsilon},$$

and corresponding equations with $e^{-it\hat{H}(\varepsilon,\delta)}\psi$ instead of ψ. If we suppose that the sequence $\delta(\varepsilon)$ satisfies (27), then all the terms grow at most as ε^{-1}, so we obtain in the end

$$\langle \phi_{t,\varepsilon,\delta}, \hat{H}_D(\varepsilon,\delta)\phi_{t,\varepsilon,\delta}\rangle \leqslant \frac{C}{\varepsilon}.$$

Repeating the proof of (26), we can then show that

$$\|\zeta e^{-is\hat{H}_D(\varepsilon,\delta)}\phi_{t,\varepsilon,\delta}\| \leqslant \frac{C\varepsilon^{1/2}}{\delta},$$

and substituting this back in (37) we get

$$\|\phi_{t,\varepsilon,\delta}\|^2 \leqslant C\left(\frac{1}{\delta^{3/2}\varepsilon^{1/4}} + \frac{1}{\delta^2}\right)\frac{\varepsilon^{1/2}}{\delta} = C\left(\frac{\varepsilon^{1/4}}{\delta^{5/2}} + \frac{\varepsilon^{1/2}}{\delta^3}\right). \tag{38}$$

□

Now, let us fix a sequence $\delta(\varepsilon)$ satisfying (29). As in the preceding section, we consider the time evolution of a product state localized inside one of the two edges, away from the vertex,

$$\psi_t^\varepsilon = e^{-it\hat{H}(\varepsilon,\delta(\varepsilon))}\psi_0,$$

$$\psi_0(x,y) = f(x)\Phi_n^\varepsilon(y), \tag{39}$$

where (x,y) is the system of coordinates associated to one of the edges, $f \in C_0^\infty(\mathbb{R})$ and Φ_n^ε has been defined in (6). If we choose ε sufficiently small, the tubular coordinates associated to the curve $\Gamma_{\vartheta,\delta}$, (s_δ, u_δ), coincide with (x,y) apart from a small neighborhood of the vertex. The state ψ_0 is then well defined and independent of δ. The limit $\varepsilon \to 0$ gives us therefore the leading behavior of an initial state which propagates through a tube which curves slowly with respect to the transverse wavelength.

Equation (26) allows us to discard $F_{d_{\delta(\varepsilon)}>\delta(\varepsilon)}\psi_t^\varepsilon$, while (28) allows us to approximate $F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}\psi_t^\varepsilon$ with $e^{-it\hat{H}_D(\varepsilon,\delta(\varepsilon))}F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}\psi_0$.

We can now prove the following.

Proposition 2: Let ψ_t^ε *be given by* (39), *then, for* $t \in [0,T]$,

$$\|\exp[-it\hat{H}_D(\varepsilon,\delta(\varepsilon))]F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}\psi_0 - \exp[-it\hat{K}(\delta(\varepsilon)) - itE_n/\varepsilon](f)\cdot F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}\Phi_n^{\varepsilon}(u_{\delta(\varepsilon)})\| \to 0,$$
$$\varepsilon \to 0, \tag{40}$$

where

$$\hat{K}(\delta(\varepsilon)) = -\frac{1}{2}\partial_s^2 - \frac{k_\delta(s)^2}{8}. \tag{41}$$

Proof: The proof is an application of the fundamental theorem of calculus (also called, in this context, Duhamel formula),

$$\begin{aligned}
&\|\exp[-it\hat{H}_D(\varepsilon,\delta(\varepsilon))]F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}\psi_0 - \exp[-it\hat{K}(\delta(\varepsilon)) - itE_n/\varepsilon](f)\cdot F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}\Phi_n^{\varepsilon}(u_{\delta(\varepsilon)})\| \\
&= \|\{\exp[it\hat{H}_D(\varepsilon,\delta(\varepsilon))]\exp[-it\hat{K}(\delta(\varepsilon)) - itE_n/\varepsilon] - \mathbb{I}\}F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f\cdot\Phi_n^{\varepsilon}(u_{\delta(\varepsilon)}) \\
&\quad + F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f(x)\Phi_n^{\varepsilon}(u_\delta) - F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f(x)\Phi_n^{\varepsilon}(y)\| \leqslant \|\{\exp[it\hat{H}_D(\varepsilon,\delta(\varepsilon))]\exp[-it\hat{K}(\delta(\varepsilon)) \\
&\quad - itE_n/\varepsilon] - \mathbb{I}\}F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f\cdot\Phi_n^{\varepsilon}(u_\delta)\| + \|F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f(x)\Phi_n^{\varepsilon}(u_\delta) - F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f(x)\Phi_n^{\varepsilon}(y)\| \\
&= \|\{\exp[it\hat{H}_D(\varepsilon,\delta(\varepsilon))]\exp[-it\hat{K}(\delta(\varepsilon)) - itE_n/\varepsilon] - \mathbb{I}\}F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f\cdot\Phi_n^{\varepsilon}(u_\delta)\|,
\end{aligned}$$

because the second term is zero if ε (and therefore δ) is sufficiently small.

Applying now Duhamel formula,[2] we have that

$$\|\{\exp[it\hat{H}_D(\varepsilon,\delta(\varepsilon))]\exp[-it\hat{K}(\delta(\varepsilon)) - itE_n/\varepsilon] - \mathbb{I}\}F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f\cdot\Phi_n^{\varepsilon}(u_\delta)\| \leqslant \int_0^t \mathrm{d}s\|[\hat{H}_D(\varepsilon,\delta(\varepsilon))$$
$$-\hat{K}(\delta(\varepsilon)) - E_n/\varepsilon]\times\exp[-is\hat{K}(\delta(\varepsilon)) - isE_n/\varepsilon]F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f\cdot\Phi_n^{\varepsilon}(u_\delta)\|. \tag{42}$$

The Hamiltonian $\hat{H}_D(\varepsilon,\delta(\varepsilon))$ in curvilinear coordinates, acting on $L^2(\mathbb{R}\times[0,\delta],\mathrm{d}s\,\mathrm{d}u)$, is given by

$$\hat{H}_D(\varepsilon,\delta(\varepsilon)) = -\frac{1}{2}\frac{1}{[1+uk_\delta(s)]^2}\frac{\partial^2}{\partial s^2} + \frac{1}{[1+uk_\delta(s)]^3}uk'_\delta(s)\frac{\partial}{\partial s} + V(s,u) - \frac{1}{2}\frac{\partial^2}{\partial u^2} + \frac{1}{2\varepsilon^2}u^2,$$

where V is the geometric potential,

$$V(s,u) = \frac{1}{2}\left\{-\frac{k_\delta^2}{4[1+uk_\delta]^2} + \frac{uk''_\delta}{2[1+uk_\delta]^2} - \frac{5}{4}\frac{u^2(k'_\delta)^2}{[1+uk_\delta]^2}\right\}. \tag{43}$$

Making a unitary dilation by the factor $\varepsilon^{1/2}$ along u, we get an operator acting on $L^2(\mathbb{R}\times[0,\delta(\varepsilon)/\varepsilon^{1/2}],\mathrm{d}s\,\mathrm{d}u)$, given by

$$\begin{aligned}
D_{\varepsilon^{1/2}}\hat{H}_D(\varepsilon,\delta(\varepsilon))D^{\dagger}_{\varepsilon^{1/2}} &= -\frac{1}{2}\frac{1}{[1+\varepsilon^{1/2}uk_\delta(s)]^2}\frac{\partial^2}{\partial s^2} + \frac{1}{[1+\varepsilon^{1/2}uk_\delta(s)]^3}\varepsilon^{1/2}uk'_\delta(s)\frac{\partial}{\partial s} + V(s,\varepsilon^{1/2}u) \\
&\quad - \frac{1}{2\varepsilon}\frac{\partial^2}{\partial u^2} + \frac{1}{2\varepsilon}u^2,
\end{aligned} \tag{44}$$

where

$$D_{\varepsilon^{1/2}}\psi(u) = \varepsilon^{1/4}\psi(\varepsilon^{1/2}u).$$

[2]For every fixed δ, the domain of $\hat{K}(\delta)$ is $H^2(\mathbb{R})$, so $\exp[-it\hat{K}(\delta)](f)\cdot F_{d_\delta<\delta}\Phi(u_\delta)$ is in the domain of $\hat{H}_D(\varepsilon,\delta)$.

Therefore, Eq. (42) becomes

$$\begin{aligned}&\|\{\exp[it\hat{H}_D(\varepsilon,\delta(\varepsilon))]\exp[-it\hat{K}(\delta(\varepsilon))-itE_n/\varepsilon]-\mathbb{I}\}F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)}f\cdot\Phi_n^{\varepsilon}(u_\delta)\|\\&\leqslant\int_0^t \mathrm{d}s\|[D_{\varepsilon^{1/2}}\hat{H}_D(\varepsilon,\delta(\varepsilon))D^{\dagger}_{\varepsilon^{1/2}}-\hat{K}(\delta(\varepsilon))-E_n/\varepsilon]\\&\quad\times\exp[-is\hat{K}(\delta(\varepsilon))-isE_n/\varepsilon]f\cdot F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)/\varepsilon^{1/2}}\cdot\Phi_n^{\varepsilon=1}(u_\delta)\|.\end{aligned}$$

Therefore, it is clear from previous equations that

$$\|[V(s,\varepsilon^{1/2}u)+k_\delta^2/8]\exp[-is\hat{K}(\delta(\varepsilon))-isE_n/\varepsilon]f\cdot F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)/\varepsilon^{1/2}}\cdot\Phi_n^{\varepsilon=1}(u_\delta)\|=O(\varepsilon^{1/2}/\delta^3)\to 0,\quad \varepsilon\to 0,$$

$$\left\|\left(-\frac{1}{2\varepsilon}\frac{\partial^2}{\partial u^2}+\frac{1}{2\varepsilon}u^2-\frac{E_n}{\varepsilon}\right)\exp[-is\hat{K}(\delta(\varepsilon))-isE_n/\varepsilon]f\times F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)/\varepsilon^{1/2}}\cdot\Phi_n^{\varepsilon=1}(u_\delta)\right\|\to 0,\quad \varepsilon\to 0,$$

so we need to control only the terms containing the derivative with respect to s in (44).

Using Lemma 3, proved below, we have that

$$\begin{aligned}&\left\|\frac{1}{[1+\varepsilon^{1/2}uk_\delta(s)]^3}\varepsilon^{1/2}uk'_\delta(s)\frac{\partial}{\partial s}\exp[-it\hat{K}(\delta(\varepsilon))-itE_n/\varepsilon]f(s)\times F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)/\varepsilon^{1/2}}\cdot\Phi_n^{\varepsilon=1}(u_\delta)\right\|\\&\leqslant(\varepsilon^{1/2}\|k'_\delta\|_{L^\infty}\cdot\|\partial_s f\|_{L^2}+|t|\cdot\varepsilon^{1/2}\|k_\delta\|_{L^\infty}\|k'_\delta\|^2_{L^\infty}\|f\|_{L^2})\times\|u\Phi_n^{\varepsilon=1}(u)\|=O(\varepsilon^{1/2}/\delta^5)\to 0,\quad \varepsilon\to 0.\end{aligned}$$

In the same way we also have

$$\begin{aligned}&\left\|-\frac{1}{2}\left\{\frac{1}{[1+\varepsilon^{1/2}uk_\delta(s)]^2}-1\right\}\frac{\partial^2}{\partial s^2}\exp[-it\hat{K}(\delta(\varepsilon))-itE_n/\varepsilon]f(s)\times F_{d_{\delta(\varepsilon)}<\delta(\varepsilon)/\varepsilon^{1/2}}\cdot\Phi_n^{\varepsilon=1}(u_\delta)\right\|\\&\leqslant C\varepsilon^{1/2}\|k_\delta\|_\infty[\|\partial_s^2 f\|+|t|\times(2\|k_\delta\|_\infty\cdot\|k'_\delta\|_\infty\|\partial_s f\|+\|k'_\delta\|^2_\infty\|f\|+\|k_\delta\|_\infty\|k''_\delta\|_\infty\|f\|)]=O(\varepsilon^{1/2}/\delta^5)\to 0,\\&\quad\varepsilon\to 0.\end{aligned}$$

□

Remark 4: As stressed above, in this model the dynamics under a strong constraining potential are well approximated by Dirichlet boundary conditions on a "large" tube surrounding the smooth curve. Proposition 2 says that this choice gives the same result as the procedure of constraining first the particle to the motion to the curve, and then taking the limit when the curve approaches the graph.

Lemma 3: Let $\hat{H}$ be the one-dimensional Hamiltonian $\hat{H}=-\frac{1}{2}\partial_x^2+V$, where V is a potential bounded together with its first two derivatives, then, given $\psi\in H^1(\mathbb{R})$, we have

$$\|\partial_x\exp(-it\hat{H})\psi\|_{L^2(\mathbb{R})}\leqslant\|\partial_x\psi\|_{L^2(\mathbb{R})}+|t|\cdot\|\partial_x V\|_{L^\infty}\cdot\|\psi\|_{L^2(\mathbb{R})},\tag{45}$$

and, given $\varphi\in H^2(\mathbb{R})$,

$$\|\partial_x^2\exp(-it\hat{H})\varphi\|_{L^2(\mathbb{R})}\leqslant\|\partial_x^2\varphi\|_{L^2(\mathbb{R})}+|t|(2\|\partial_x V\|_{L^\infty}\cdot\|\partial_x\varphi\|_{L^2(\mathbb{R})}+\|\partial_x^2 V\|_{L^\infty}\cdot\|\varphi\|_{L^2(\mathbb{R})}).\tag{46}$$

Proof: Since V is bounded, the domain of the quadratic form associated to $\hat{H}$ is $H^1(\mathbb{R})$, and the time evolution sends it into itself. It makes therefore sense to write, for $\psi\in H^1(\mathbb{R})$,

$$[-i\partial_x, e^{-it\hat{H}}]\psi = e^{-it\hat{H}}\int_0^t \mathrm{d}s\ \partial_s e^{is\hat{H}}(-i\partial_x)e^{-is\hat{H}}\psi = ie^{-it\hat{H}}\int_0^t \mathrm{d}s\ e^{is\hat{H}}[\hat{H}, -i\partial_x]e^{-is\hat{H}}\psi$$

$$= e^{-it\hat{H}}\int_0^t \mathrm{d}s\ e^{is\hat{H}}\partial_x V e^{-is\hat{H}}\psi,$$

but this implies immediately

$$-i\partial_x e^{-it\hat{H}}\psi = e^{-it\hat{H}}(-i\partial_x)\psi + [-i\partial_x, e^{-it\hat{H}}]\psi \Rightarrow \|-i\partial_x e^{-it\hat{H}}\psi\| \leqslant \|-i\partial_x\psi\| + \int_0^t \mathrm{d}s\|\partial_x V e^{-is\hat{H}}\psi\|,$$

which gives (45).

Following the same path and noticing that

$$[\hat{H}, -\partial_x^2] = -\partial_x^2 V - 2\partial_x V\cdot\partial_x \tag{47}$$

we get (46). □

To complete the analysis of this case we need to study the limit of the dynamics $\exp[-it\hat{K}(\delta(\varepsilon))]$ when $\varepsilon\to 0$.

The limit of one-dimensional Hamiltonians containing rescaled potentials has been studied in detail in the context of the approximation of singular interactions, like the delta coupling, by short range smooth potentials (Albeverio *et al.* (2005) and references therein). The scaling used by us in (41) however, is not covered in the results presented in Albeverio *et al.*, but it can be analyzed using exactly the same techniques.

The idea is to show convergence in norm of the resolvent of $\hat{K}(\delta(\varepsilon))$ to the resolvent of the Hamiltonian with Dirichlet boundary conditions in $s=0$. As it is well known [Reed and Simon (1972), Theorem VIII.21] this implies strong convergence of the corresponding unitary group.

One could expect convergence to Dirichlet boundary conditions because the potential $-k_\delta^2/8$ is a strongly attractive well, which becomes deeper and deeper, but whose range is shorter and shorter. As explained in Englisch and Šeba (1986) in a different context, we expect this to give rise to Dirichlet boundary conditions. This in particular says that the strong convergence of the unitary group (or the norm resolvent convergence) does not capture the behavior of the eigenvalues which go to $-\infty$ when $\delta\to 0$, because, even though the ground state of $\hat{K}(\delta(\varepsilon))$ tends to $-\infty$, its resolvent converges to that of a semibounded operator. This phenomenon has already been illustrated in Gesztesy (1980).

We can now prove the following.

Theorem 4: *Let* $[\hat{K}(\delta(\varepsilon))-z^2]^{-1}$ *be the resolvent of* $\hat{K}(\delta(\varepsilon))$, *where* $\Im z>0$, *then*

$$[\hat{K}(\delta(\varepsilon)) - z^2]^{-1} \to [\hat{K}_D - z^2]^{-1}, \quad \varepsilon\to 0, \tag{48}$$

in the norm of bounded operators on $L^2(\mathbb{R})$, *where* K_D *is the free Laplacian on* $L^2(\mathbb{R})$ *with Dirichlet boundary conditions in* $s=0$.

Proof: The potential $Q(s) := -k^2/8$ is in $L^1(\mathbb{R})\cap L^\infty(\mathbb{R})$, so we can apply the dilation technique described in Albeverio *et al.* (1984) [see also Albeverio *et al.* (2005)]. Applying lemma A.1 of Albeverio *et al.* (1984) we get

$$[\hat{K}(\delta(\varepsilon)) - z^2]^{-1} = G_z - A_\delta(z)[\delta + B_\delta(z)]^{-1}C_\delta(z), \quad \Im z>0, \tag{49}$$

where G_z is the free resolvent, with kernel $g_z(w)$,

$$G_z := (\hat{H}_0 - z^2)^{-1}, \quad g_z(w) := \frac{i}{2z}e^{iz|w|},$$

$$\hat{H}_0 := -\frac{\partial^2}{\partial s^2}, \quad D(\hat{H}_0) = H^2(\mathbb{R}), \tag{50}$$

while $A_\delta(z)$, $B_\delta(z)$, and $C_\delta(z)$ are Hilbert-Schmidt operators with kernels

$$A_\delta(z,s,r) = g_z(s-\delta r)|Q(r)|^{1/2},$$

$$B_\delta(z,s,r) = -|Q(s)|^{1/2} g_z[\delta(s-r)]|Q(r)|^{1/2},$$

$$C_\delta(z,s,r) = -|Q(s)|^{1/2} g_z(\delta s - r). \tag{51}$$

It is not difficult to see [Lemma 2.3, Albeverio *et al.* (1984)] that

$$A_\delta \to A_0,$$

$$B_\delta \to B_0,$$

$$C_\delta \to C_0, \tag{52}$$

in Hilbert-Schmidt norm, where A_0, B_0, and C_0 have kernels

$$A_0(z,s,r) = g_z(s)|Q(r)|^{1/2},$$

$$B_0(z,s,r) = -g_z(0)|Q(s)|^{1/2}|Q(r)|^{1/2},$$

$$C_0(z,s,r) = -|Q(s)|^{1/2} g_z(-r). \tag{53}$$

The operator B_0 is not invertible on the whole Hilbert space, but it is clear from the expression of the kernel that it actually acts on the one-dimensional subspace, denoted by $\mathcal{H}_Q$, generated by the vector φ_Q given by

$$\varphi_Q(s) := \frac{|Q(s)|^{1/2}}{\||Q(s)|^{1/2}\|_{L^2(\mathbb{R})}} = \frac{|Q(s)|^{1/2}}{\|Q(s)\|^{1/2}_{L^1(\mathbb{R})}}. \tag{54}$$

So we can write

$$B_0 = -g_z(0)\|Q(s)\|_{L^1(\mathbb{R})} \varphi_Q \langle \varphi_Q, \cdot \rangle. \tag{55}$$

On $\mathcal{H}_Q$, B_0 is invertible and the inverse is given by

$$B_0^{-1} = -\frac{1}{g_z(0)\|Q(s)\|_{L^1(\mathbb{R})}} \varphi_Q \langle \varphi_Q, \cdot \rangle. \tag{56}$$

Since the operator C_0 has range equal to $\mathcal{H}_Q$ and A_0 acts nontrivially only on $\mathcal{H}_Q$, we get that

$$[\hat{K}(\delta(\varepsilon)) - z^2]^{-1} \to G_z - A_0 B_0^{-1} C_0,$$

which has a kernel given by

$$g_z(s-r) - \frac{g_z(s) g_z(-r)}{g_z(0)}, \tag{57}$$

which is the kernel of the resolvent of the Dirichlet Hamiltonian. □

Differential realization of pseudo-Hermiticity: A quantum mechanical analog of Einstein's field equation

Ali Mostafazadeh[a)]
Department of Mathematics, Koç University, 34450 Sariyer, Istanbul, Turkey

(Received 10 February 2006; accepted 16 May 2006; published online 7 July 2006)

For a given pseudo-Hermitian Hamiltonian of the standard form: $H=p^2/2m+v(x)$, we reduce the problem of finding the most general (pseudo-)metric operator η satisfying $H^\dagger=\eta H \eta^{-1}$ to the solution of a differential equation. If the configuration space is $\mathbb{R}$, this is a Klein-Gordon equation with a nonconstant mass term. We obtain a general series solution of this equation that involves a pair of arbitrary functions. These characterize the arbitrariness in the choice of η. We apply our general results to calculate η for the $\mathcal{PT}$-symmetric square well, an imaginary scattering potential, and a class of imaginary delta-function potentials. For the first two systems, our method reproduces the known results in a straightforward and extremely efficient manner. For all these systems we obtain the most general η up to second-order terms in the coupling constants. © *2006 American Institute of Physics.*

I. INTRODUCTION

The key aspect of the general theory of relativity (GR) that distinguishes it from other well-established physical theories is that in GR the very geometry of the spacetime, which is the arena of physical reality in classical physics, is itself a dynamical quantity. In contrast, in quantum mechanics (QM), the geometry of the Hilbert space, which plays a similar role as the spacetime does in classical physics, is an absolute entity. This is to some extent dictated by the well-known mathematical fact that all separable Hilbert spaces are unitary equivalent. For the past 75 years or so, this equivalence has been used to justify the absolutism associated with the convention of fixing the (inner product of the) Hilbert space from the outset. This is actually quite surprising, for the existence of an equivalence relation in a theory is clearly an evidence of the presence of a freedom in its formulation. In the case of QM, this is the freedom to choose the inner product of the Hilbert space, a freedom that has been left unused until recently.[1,2]

In Ref. 2, we have investigated the consequences of promoting the inner product of the Hilbert space into a degree of freedom. This revealed certain similarities between QM and GR and led to some interesting observations such as a direct link between geometric phases and the geometry of the Hilbert space and a new root to a certain nonlinear generalization of QM. In the present paper, we derive and examine a differential equation that includes among its solutions all possible choices of the inner product for a given physical system. This is the quantum mechanical analog of Einstein's field equation. (The same way Einstein's equation does not generally restrict the metric tensor to have a particular signature, the above-mentioned equation does not restrict its solutions to correspond to positive-definite metric operators.) For a system having $\mathbb{R}$ as its configuration space we obtain a series solution of this equation that involves two functional degrees of freedom. These signify the arbitrariness in the choice of the (pseudo-)metric operator. Our approach allows a more direct way of addressing some of the basic practical problems arising in

a)Electronic mail: amostafazadeh@ku.edu.tr

the application of quasi- and pseudo-Hermitian quantum mechanics.[1,3–13] In particular it provides an extremely powerful technical tool for the perturbative calculation of the (pseudo-)metric operators for various toy models.

II. DIFFERENTIAL REPRESENTATION OF PSEUDO-HERMITICITY

Consider a physical system described by a separable Hilbert space $\mathcal{H}$ and a pseudo-Hermitian Hamiltonian operator $H:\mathcal{H}\to\mathcal{H}$. Let $\mathcal{M}$ denote the set of all linear invertible Hermitian operators $\eta:\mathcal{H}\to\mathcal{H}$, then by definition[14] the pseudo-Hermiticity of H means that $\mathcal{M}_H:=\{\eta\in\mathcal{M}\,|\,H^\dagger=\eta H\eta^{-1}\}$ is a nonempty subset of $\mathcal{M}$. The elements of $\mathcal{M}$ are called pseudo-metric operators, for they may be used to define a pseudo-inner product (a nondegenerate sesquilinear form[15]) $\langle\cdot|\cdot\rangle_\eta:=\langle\cdot|\,\eta\cdot\rangle$ on $\mathcal{H}$, where $\langle\cdot|\cdot\rangle$ denotes the defining inner product of $\mathcal{H}$. (Strictly speaking, $\langle\cdot|\cdot\rangle_\eta$ is a nondegenerate sesquilinear form defined on the domain of η).

The Hamiltonian H is Hermitian with respect to $\langle\cdot|\cdot\rangle_\eta$ for all $\eta\in\mathcal{M}_H$.[14,16] If $\mathcal{M}_H$ includes a positive-definite element, i.e., a *metric operator*, η_+, then H is Hermitian with respect to the positive-definite inner product $\langle\cdot|\cdot\rangle_{\eta_+}$. This implies that H is diagonalizable and has a real spectrum. The converse of this statement holds true at least for the case that the spectrum of H is discrete, i.e., if H is diagonalizable and has a real spectrum then $\mathcal{M}_H$ includes a positive-definite element and equivalently H is Hermitian with respect to a positive-definite inner product.[17,18] Furthermore, in this case one can show that H is necessarily quasi-Hermitian, i.e., it may be mapped to a Hermitian Hamiltonian $h:\mathcal{H}\to\mathcal{H}$ via a similarity transformation, $H=\rho^{-1}h\rho$.[17,18] This and only this class of Hamiltonians are capable of supporting a unitary time evolution in an associated *physical Hilbert space*. The latter is defined by endowing $\mathcal{H}$ with the inner product $\langle\cdot|\cdot\rangle_{\eta_+}$ and will be denoted by $\mathcal{H}_{\eta_+}$.[4,5,7,9,19]

An important fact about this construction is that η_+ is not unique. Different choices for η_+ yield kinematically distinct quantum systems that nevertheless share the same dynamical structure. The quantum mechanical analog of the principle of general covariance of GR is the physical (unitary) equivalence of quantum systems $(\mathcal{H}_{\eta_+},H)$.[2] The metric operators η_+ and more generally pseudo-metric operators η are linked to and consequently determined by the Hamiltonian H via the pseudo-Hermiticity condition

$$H^\dagger=\eta H\eta^{-1}. \tag{1}$$

The same way Einstein's field equation links the metric tensor to the energy-momentum tensor, (1) links the pseudo-metric operator to the Hamiltonian. The resemblance may be made more pronounced for a Hamiltonian of the standard form,

$$H=\frac{\vec{p}^{\,2}}{2m}+v(\vec{x}), \tag{2}$$

that acts in $L^2(\mathbb{R}^n)$. Applying both sides of (1) on η, substituting (2), and representing the resulting equation in the $\vec{x}$-basis, we find

$$\left(-\nabla_x^2+\nabla_y^2+\frac{2m}{\hbar^2}[v(\vec{x})^*-v(\vec{y})]\right)\eta(\vec{x},\vec{y})=0, \tag{3}$$

where $\nabla_u^2:=\Sigma_{j=1}^n\partial^2/\partial u_j^2$ for $u=x,y$ and $\eta(\vec{x},\vec{y}):=\langle\vec{x}|\,\eta\,|\vec{y}\rangle$. For $n=1$, this is a Klein-Gordon equation with a variable mass term,

$$[-\partial_x^2+\partial_y^2+\mu^2(x,y)]\eta(x,y)=0,\quad \mu^2(x,y):=\frac{2m}{\hbar^2}[v(x)^*-v(y)]. \tag{4}$$

According to (3) if $\eta(\vec{x},\vec{y})$ is a solution, then so is $\eta(\vec{y},\vec{x})^*$. The pseudo-metric operators $\eta\in\mathcal{M}_H$ correspond to solutions that satisfy

$$\eta(\vec{x},\vec{y})^* = \eta(\vec{y},\vec{x}). \tag{5}$$

Note that even for non-pseudo-Hermitian Hamiltonians of the form (2), Eq. (3) admit solutions. However, these solutions fail to satisfy either the Hermiticity requirement (5) or the invertibility condition:

$$\int_{\mathbb{R}^n} \mathrm{d}^n\vec{y}\,\eta(\vec{x},\vec{y})\psi(\vec{y}) = 0 \text{ implies } \psi = 0. \tag{6}$$

If $\mathcal{M}_H$ happens to include positive-definite elements η_+, then these elements correspond to the solutions $\eta_+(\vec{x},\vec{y})$ of (3) that in addition to (5) satisfy

$$\int_{\mathbb{R}^n} \mathrm{d}^n\vec{x} \int_{\mathbb{R}^n} \mathrm{d}^n\vec{y}\,\psi(\vec{x})^* \eta_+(\vec{x},\vec{y})\psi(\vec{y}) > 0 \text{ for } \psi \neq 0. \tag{7}$$

The fact that for a diagonalizable Hamiltonian with a real and discrete spectrum such solutions exist is a consequence of the spectral theorems given in Refs. 17 and 18. Indeed if $\{\psi_n, \phi_n\}$ is a biorthonormal system associated with H, i.e., $H\psi_n = E_n\psi_n$, $H^\dagger\phi_n = E_n\phi_n$, $\langle\psi_n|\,\phi_m\rangle = \delta_{mn}$, then

$$\eta_+(\vec{x},\vec{y}) = \sum_n \phi_n(\vec{x})\phi_n(\vec{y})^* \tag{8}$$

is a solution of (3) that satisfies both (5) and (7). As shown in Refs. 20 and 21, in this case the most general (positive-definite) metric operator has the form $A^\dagger\eta_+A$, where A is invertible and commutes with H. The latter corresponds to a solution of (3) that is of the form

$$\eta'_+(\vec{x},\vec{y}) = \sum_n \int_{\mathbb{R}^n} \mathrm{d}^n\vec{u} \int_{\mathbb{R}^n} \mathrm{d}^n\vec{v} A(\vec{u},\vec{x})^* \phi_n(\vec{u})\phi_n(\vec{v})^* A(\vec{v},\vec{y}), \tag{9}$$

where $A(\vec{x},\vec{y})$ satisfies

$$\left(-\nabla_x^2 + \nabla_y^2 + \frac{2m}{\hbar^2}[v(\vec{x}) - v(\vec{y})]\right) A(\vec{x},\vec{y}) = 0, \tag{10}$$

and

$$\int_{\mathbb{R}^n} \mathrm{d}^n\vec{y} A(\vec{x},\vec{y})\psi(\vec{y}) = 0 \text{ implies } \psi = 0. \tag{11}$$

For a real-valued potential v, $\delta(\vec{x}-\vec{y})$ is a solution of (3). It corresponds to the choice $\eta = I$, where I is the identity operator acting in $\mathcal{H} = L^2(\mathbb{R})$. This is consistent with the Hermiticity of H. For a $\mathcal{PT}$-symmetric potential v that satisfies $v(-\vec{x}) = v(\vec{x})^*$, $\delta(\vec{x}+\vec{y})$ is a solution of (3). This is a manifestation of $\mathcal{P}$-pseudo-Hermiticity of the Hamiltonian,[14] for $\langle\vec{x}|\,\mathcal{P}\,|\vec{y}\rangle = \delta(\vec{x}+\vec{y})$.

For $n > 1$, (3) is an ultrahyperbolic equation with quite peculiar properties.[22] We will therefore focus our attention on the case $n = 1$. Our main purpose is to obtain the general solution of (3) without having to resort to its spectral decomposition (8). This is mainly because of the difficulties with summing the series in (8) or evaluating the integrals that replace the latter whenever the spectrum becomes continuous.[7]

In Ref. 9, we have pursued a similar approach to construct the most general η_+ for the imaginary cubic potential $v = i\varepsilon x^3$ in some low orders of perturbation theory. The approach of Ref. 9 applies to any (preferably imaginary) potential with a real spectrum. It yields an infinite system of iteratively decoupled partial differential equations whose solution provides the contributions to η_+ in various orders of the perturbation theory. Although these equations have the same structure, at each order one must compute their nonhomogeneous term and solve them separately. In contrast, in the present paper, we obtain a single differential equation satisfied by η, namely (4),

that applies for an arbitrary potential $v(x)$ rendering the Hamiltonian pseudo-Hermitian. An important advantage of the approach of the present paper over that of Ref. 9 is that in view of the simple structure of (4), we are able to offer (as discussed in Sec. III) a general scheme for constructing a series solution of this equation. This solution involves two arbitrary functions that provide an explicit characterization of the arbitrariness in the choice of η.

Another recent application of the powerful machinery of differential equations to compute (pseudo-)metric operators is due to Scholtz and Geyer.[10] These authors obtain a phase-space representation of the (pseudo-)metric operators η. They use the Moyal product techniques to deal with the difficult factor-ordering problems that arise in this representation. The following are the main differences between the method of Ref. 10 and the one presented in the present paper.

- The method of Ref. 10 leads to an equation for η that is a differential equation[11] provided that $v(x)$ is a polynomial potential. Even for a polynomial potential the general character and in particular the order of this differential equation depends on the structure of $v(x)$ and its degree. In contrast, in the present paper we offer a universal differential equation, namely (4), that applies for polynomial as well as nonpolynomial potentials, and has the same simple structure for all potentials. It is this appealing property that allows us to treat the well-known toy models of Sec. IV. The application of the method of Ref. 10 to these models yields pseudo-differential equations (differential equations of infinite order) whose solution is extremely difficult if not impossible.
- Suppose v is a polynomial potential, so that the method of Ref. 10 yields a differential equation, and suppose that one is able to solve this equation. Then one obtains an explicit expression for η in terms of the operators x and p that involves a number of arbitrary functions. The condition that η be Hermitian must be imposed to fix some of these functions. This is done by adopting a set of appropriate boundary conditions.[10](The author is unaware of a systematic method of selecting the boundary conditions that achieve this purpose.) In contrast, our method yields an expression for $\eta(x,y)$ that satisfies the Hermiticity condition $\eta(x,y)^*=\eta(y,x)$ manifestly and specifies a unique Hermitian η according to

$$(\eta\psi)(x)=\int_{\mathrm{R}} \mathrm{d}y\, \eta(x,y)\psi(y).$$

- It achieves this without making use of the Moyal product or having to select certain boundary conditions that ensures the Hermiticity of η. Its successful application, however, does not yield an explicit expression for η in terms of x and p. As explained in Ref. 9, the latter may be obtained by Fourier transforming $\eta(x,y)=\langle x|\eta|y\rangle$ over y to obtain $\langle x|\eta|p\rangle$ and arranging the terms in the expression for $\sqrt{2\pi\hbar}e^{-ixp/\hbar}\langle x|\eta|p\rangle$ in such a way that x's are placed to the left of p's. This is how the issue of ordering of factors is addressed in this construction.

A common feature of both methods is that solving the associated differential equations yields generally non-positive-definite pseudo-metric operators. The (positive-definite) metric operators η_+, if they exist, correspond to certain special solutions that are to be identified using different means. [The construction of η given here may be supplemented with the procedure proposed in Ref. 10 for selecting the positive-definite metric operators η_+ among η's. This is expected to be a difficult task in practice, and we will not pursue it here. We suffice to point out that given $\eta(x,y)$ we can obtain an expression for η in terms of x and p as outlined in Ref. 9. This allows for making direct contact with the approaches of Refs. 10 and 11].

III. SERIES EXPANSION FOR $\eta(x,y)$

We begin our analysis by expressing (4) in the form

$$(-\partial_x^2+\partial_y^2)\,\eta(x,y)=f(x,y)-f(y,x)^*, \tag{12}$$

where

$$f(x,y) := \frac{2m}{\hbar^2} v(y)\,\eta(x,y). \tag{13}$$

We note that for a Hermitian η, (12) is equivalent to

$$\eta(x,y) = \chi(x,y) + \chi(y,x)^*, \tag{14}$$

$$(-\partial_x^2 + \partial_y^2)\chi(x,y) = f(x,y). \tag{15}$$

Next, we recall that the general solution of the wave equation $(-\partial_x^2+\partial_y^2)u(x,y)=0$ is given by

$$u(x,y) = u_+(x-y) + u_-(x+y), \tag{16}$$

where $u_\pm:\mathbb{R}\to\mathbb{C}$ are a pair of arbitrary twice-differentiable functions (or distributions). Consequently, the general solution of (12) has the form

$$\eta(x,y) = u_+(x-y) + u_-(x+y) + \chi_p(x,y) + \chi_p(y,x)^*, \tag{17}$$

where $u_\pm$ satisfy $u_\pm(x)^* = u_\pm(\mp x)$ and $\chi_p(x,y)$ is a particular solution of (15). The latter is a nonhomogeneous wave equation in $1+1$ dimensions. It admits a particular solution that in view of (13) takes the form

$$\chi_p(x,y) = \frac{m}{\hbar^2}\int^y \mathrm{d}r \int_{x-y+r}^{x+y-r} \mathrm{d}s\; v(r)\,\eta(s,r). \tag{18}$$

Combining (16)–(18), we find

$$\eta(x,y) = u(x,y) + \mathcal{K}\eta(x,y), \tag{19}$$

where $\mathcal{K}$ is the integral operator defined by

$$\begin{aligned}\mathcal{K}\eta(x,y) &:= \frac{m}{\hbar^2}\left[\int^y \mathrm{d}r \int_{x-y+r}^{x+y-r} \mathrm{d}s\; v(r)\,\eta(s,r) + \int^x \mathrm{d}r \int_{-x+y+r}^{x+y-r} \mathrm{d}s\; v^*(r)\,\eta(s,r)^*\right]\\ &= \frac{m}{\hbar^2}\left[\int^y \mathrm{d}r \int_{x-y+r}^{x+y-r} \mathrm{d}s\; v(r)\,\eta(s,r) + \int^x \mathrm{d}s \int_{-x+y+s}^{x+y-s} \mathrm{d}r\; v(s)^*\,\eta(s,r)\right].\end{aligned} \tag{20}$$

In view of the analogy with the derivation of the Lippmann-Schwinger equation,[23] it is not difficult to see that (19) admits the following general series solution:

$$\eta(x,y) = [I-\mathcal{K}]^{-1}u(x,y) = \sum_{\ell=0}^{\infty} \mathcal{K}^\ell u(x,y). \tag{21}$$

Clearly, η is determined in terms of the arbitrary functions $u_\pm$.

For $v=0$, i.e., a free particle, $\eta(x,y)=u(x,y)$. As shown in Ref. 9, this is equivalent to

$$\eta = L(p) + K(p)\mathcal{P}, \tag{22}$$

where $L(p)^\dagger = L(p)$ and $K(p)^\dagger = \mathcal{P}K(p)\mathcal{P}$, equivalently L and K are respectively real-valued and $\mathcal{PT}$-invariant [this means $K(r)^* = K(-r)$ for all $r\in\mathbb{R}$] functions. (They may be further restricted to constants if one postulates the nonexistence of a hidden length scale for the problem. See Ref. 9 for details.) They are related to the Fourier transform [in our convention, the Fourier transform of a function φ is given by $\widetilde{\varphi}(k) := (2\pi)^{-1/2}\int_{-\infty}^{\infty}\mathrm{d}x e^{-ikx}\varphi(x)$] $\widetilde{u}_\pm$ of $u_\pm$ according to

$$L(p)=\sqrt{2\pi}\tilde{u}_+\left(\frac{p}{\hbar}\right),\quad K(p)=\sqrt{2\pi}\tilde{u}_-\left(-\frac{p}{\hbar}\right). \tag{23}$$

For a real-valued potential the ordinary choice for the metric operator that yields the L^2-inner product, i.e., $\eta=I$, corresponds to setting

$$u(x,y)=\delta(x-y)-\frac{m}{\hbar^2}\int^{x+y/2}\mathrm{d}r\, v(r). \tag{24}$$

To see this, we first calculate $K\delta(x-y)$ for an arbitrary (possibly complex-valued) potential v. Using the well-known properties of the step function

$$\theta(x):=\begin{cases}0 & \text{for } x<0\\ \frac{1}{2} & \text{for } x=0\\ 1 & \text{for } x>0,\end{cases} \tag{25}$$

we then find

$$\mathcal{K}\delta(x-y)=\frac{m}{\hbar^2}\left(\int^{x+y/2}\mathrm{d}r\Re[v(r)]+i\,\mathrm{sign}(y-x)\int^{x+y/2}\mathrm{d}r\Im[v(r)]\right), \tag{26}$$

where $\Re[v]$ and $\Im[v]$ respectively stand for the real and imaginary parts of v, and

$$\mathrm{sign}(x):=\theta(x)-\theta(-x)=\begin{cases}-1 & \text{for } x<0\\ 0 & \text{for } x=0\\ 1 & \text{for } x>0.\end{cases}$$

If v is a real potential, $\Re[v]=v$ and $\Im[v]=0$. In this case (26) together with (19) and $\eta(x-y)=\delta(x-y)$ yield (24).

For a purely imaginary potential, $\Re[v]=0$, $v=i\Im[v]$, and (26) takes the following form:

$$\mathcal{K}\delta(x-y)=\frac{m}{\hbar^2}\mathrm{sign}(y-x)\int^{x+y/2}\mathrm{d}r\, v(r). \tag{27}$$

IV. APPLICATIONS

A. $\mathcal{PT}$-symmetric square well

The $\mathcal{PT}$-symmetric square well potential,

$$v(x):=\begin{cases}-i\zeta\,\mathrm{sign}(x) & \text{for } |x|<\frac{L}{2}\\ \infty & \text{for } |x|>\frac{L}{2},\end{cases} \tag{28}$$

with $\zeta\in\mathbb{R}$ and $L\in\mathbb{R}^+$, defines one of the best-known exactly solvable toy models that captures the generic properties of pseudo-Hermitian quantum systems.[24,25] A thorough investigation of the physical content of this model is conducted in Ref. 4, where a particular perturbative calculation of a metric operator and the corresponding physical observables, localized states, probability density, and the underlying classical Hamiltonian is performed. This calculation makes use of the fact that the non-Hermiticity effects in this model diminish for energy states with larger spectral label N. More specifically, it is ζ/N^2 that plays the role of the perturbation parameter.

More recently, Bender and Tan[12] performed a more conventional perturbative calculation of a metric operator taking ζ as the perturbation parameter. This is the metric operator η_+ that is

associated with the $\mathcal{CPT}$-inner product $(\cdot,\cdot)_{\mathcal{CPT}}$,[26] that is $(\cdot,\cdot)_{\mathcal{CPT}}=\langle\cdot|\eta_+\cdot\rangle$.[21] Expressing η_+ in its exponential form, $\eta_+=e^{-Q}$, and noting that Bender and Tan set $\hbar=2m=L/\pi=1$, take $\epsilon=-\zeta$ for the coupling constant, and use "$\varepsilon(x)$" for "sign (x)," we can summarize their principal result [Eq. (11) of Ref. 12] as

$$\langle x|Q|y\rangle =: Q(x,y) = -\frac{i\zeta}{4}[x-y+\mathrm{sign}(x-y)(|x+y|-\pi)]+\mathcal{O}(\zeta^3), \tag{29}$$

where $\mathcal{O}(\zeta^n)$ stands for terms of order n and higher in powers of ζ. In particular, in view of the identity $x-y=|x-y|\mathrm{sign}(x-y)$, we have the following expression for the $\mathcal{CPT}$-metric operator η_+:

$$\eta_+(x,y)=\delta(x-y)+\frac{i\zeta}{4}(|x-y|+|x+y|-\pi)\mathrm{sign}(x-y)+\mathcal{O}(\zeta^2). \tag{30}$$

The perturbative calculation of the metric operator using the method developed in the preceding section is quite straightforward. Inserting (28) in (27) and performing the trivial integral in the resulting equation, we find

$$\mathcal{K}\delta(x-y)=\frac{im\zeta}{2\hbar^2}|x+y|\mathrm{sign}(x-y). \tag{31}$$

The most general metric operator η that reduces to the identity operator in the Hermitian limit $\zeta\to 0$ is obtained by setting

$$u(x,y)=\delta(x-y)+\zeta[w_+(x-y)+w_-(x+y)]+\mathcal{O}(\zeta^2) \tag{32}$$

in (21), where $w_\pm:[-L/2,L/2]\to\mathbb{C}$ are arbitrary functions satisfying $w_\pm(x)^*=w_\pm(\mp x)$ and $w_\pm(\pm L)=0$. [These conditions arise from the Hermiticity requirement on the metric operator and its spectral resolution (8).] This together with (31) yields

$$\eta(x,y)=\delta(x-y)+\zeta\left[w_+(x-y)+w_-(x+y)+\frac{im}{2\hbar^2}|x+y|\mathrm{sign}(x-y)\right]+\mathcal{O}(\zeta^2). \tag{33}$$

Setting $\hbar=2m=L/\pi=1$ in this equation, we find that the $\mathcal{CPT}$-metric operator (30) obtained by Bender and Tan[12] is a particular example of the metric operators (33). It corresponds to the choice $w_+(x)=(i/4)(|x|-\pi)\mathrm{sign}(x)$ and $w_-(x)=0$.

We can calculate higher-order terms in the expression for the metric operator using our iterative method. Each additional order will involve an arbitrary pair of functions that enter the expression for u in (21). This calculation is not only completely general (as it yields the most general metric operator), but it is also much simpler to perform. This is mainly because unlike its alternatives[4,12] it avoids approximating or summing complicated series.

B. An imaginary scattering potential

Consider the following variant of the $\mathcal{PT}$-symmetric square well potential:[27]

$$v(x) := \frac{i\zeta}{2}\left[\mathrm{sign}\left(x+\frac{L}{2}\right)+\mathrm{sign}\left(x-\frac{L}{2}\right)-2\,\mathrm{sign}(x)\right]=\begin{cases}-i\zeta\,\mathrm{sign}(x) & \text{for } |x|<\dfrac{L}{2}\\ 0 & \text{for } |x|>\dfrac{L}{2},\end{cases} \tag{34}$$

where $\zeta\in\mathbb{R}$ is a coupling constant and $L\in\mathbb{R}^+$ is a length scale.

In Ref. 7 we established the reality of the spectrum of this potential and used the spectral method of Refs. 14, 17, and 18 to obtain a perturbative expression for an associated metric operator η_+. This involved constructing an appropriate biorthonormal system for the model and performing a highly tedious calculation of the integrals appearing in the spectral resolution of η_+.

Indeed, this calculation could only be done after expanding all the relevant quantities in powers of ζ and restricting to the first-order terms. Although the results reported in Ref. 7 required performing extremely lengthy calculations partly done using Mathematica, the expression obtained for $\eta_+(x,y) := \langle x|\eta_+|y\rangle$ took a surprising simple form, namely

$$\eta_+(x,y) = \delta(x-y) + \frac{im\zeta}{4\hbar^2}(2L + 2|x+y| - |x+y+L| - |x+y-L|)\mathrm{sign}(x-y) + \mathcal{O}(\zeta^2). \quad (35)$$

Here we wish to use the scheme developed in the preceding section to construct the most general metric operator η that reduces to the identity operator in the Hermitian limit $\zeta \to 0$. In order to do this first we insert (34) in (27) and perform the trivial integral in the resulting equation to obtain

$$\mathcal{K}\delta(x-y) = \frac{im\zeta}{4\hbar^2}(|x+y+L| + |x+y-L| - 2|x+y|)\mathrm{sign}(y-x). \quad (36)$$

Substituting (32) in (21) and using (36), we then find

$$\eta(x,y) = \delta(x-y) + \zeta\left[w_+(x-y) + w_-(x+y) + \frac{im}{4\hbar^2}(2|x+y| - |x+y+L| - |x+y-L|)\mathrm{sign}(x-y)\right] + \mathcal{O}(\zeta^2), \quad (37)$$

where $w_\pm : \mathbb{R} \to \mathbb{C}$ are arbitrary functions satisfying $w_\pm^*(x) = w_\pm(\pm x)$. Clearly, the positive-definite inner product (35) constructed in Ref. 7 corresponds to setting $w_+(x) = imL/2\hbar^2\,\mathrm{sign}(x)$ and $w_-(x) = 0$.

C. Imaginary δ-function potentials

Consider the potential

$$v(x) = i\zeta\delta(x-a), \quad (38)$$

where $\zeta, a \in \mathbb{R}$. (Clearly, we can choose the origin of the x-axis so that $a=0$. We retain a for future use where we consider the multi-delta-function potentials.) It is not difficult to solve the time-independent Schrödinger equation for this potential and show that $H = (p^2/2m) + v(x)$ has a real continuous spectrum. [H is not $\mathcal{PT}$-symmetric. But one may attempt to use the results of Ref. 21 to construct a generalized $\mathcal{PT}$-operator (an antilinear involution) that commutes with H.] This in turn suggests that one can construct an associated pseudo-metric operator using the spectral method of Refs. 17 and 18. This construction is similar to the one offered in Ref. 7 for the potential (34). An explicit calculation of η using this method is however quite involved. A much simpler construction that we will describe in the following is based on the method of Sec. III.

First, we substitute (38) in (20) to establish

$$\mathcal{K}F(x,y) = \mathcal{F}(x,y) + \mathcal{F}(y,x)^*, \quad \mathcal{F}(x,y) := \frac{iz}{2}\theta(y-a)\int_{x-y+a}^{x+y-a} \mathrm{d}s F(s,a), \quad (39)$$

where $z := 2m\zeta/\hbar^2$ and $F(x,y)$ is a test function. If we choose a z-independent u, the series expansion (21) becomes a power series in the coupling constant z. For definiteness we shall first choose $u(x,y) = \delta(x-y)$. Setting $F(x,y) = \delta(x-y)$ in (39) and using the properties of the step function (25), we then find

$$\mathcal{K}u(x,y) = \frac{iz}{2}\theta(x+y-2a)\mathrm{sign}(y-x) =: u_1(x,y). \quad (40)$$

Alternatively, we could directly use (27) to obtain (40).

Next, we compute $\mathcal{K}^2 u(x,y)$ by substituting u_1 for F in (39). This yields

$$\mathcal{K}^2u(x,y)=\frac{z^2}{4}[\theta(x-a)+\theta(y-a)][(x+y-2a)\,\theta(x+y-2a)-|x-y|]. \tag{41}$$

The higher-order terms in (21) can be similarly calculated. Moreover, because of the simple form of (39) and (40), we can actually obtain an upper bound on $|\mathcal{K}^\ell u(x,y)|$ and use it to find a lower bound on the radius of the convergence of the series (21).

First, we recall[28] that if a function $g:\mathbb{R}\to\mathbb{C}$ is bounded on an interval $[\alpha,\beta]$ by some $M\in\mathbb{R}^+$, i.e., $|g(r)|<M$ for all $r\in[\alpha,\beta]$, then $|\int_\alpha^\beta dr\, g(r)|\leqslant M(\beta-\alpha)$. Now, let $F(x,y)$ be a function such that $|F(s,a)|$ has an upper bound M_F as s takes values between $|x-y|+a$ and $x+y-a$. Then, according to (39),

$$|\mathcal{K}F(x,y)|\leqslant|z|(|x-a|+|y-a|)M_F. \tag{42}$$

In view of (40), for all $x,y\in\mathbb{R}$, $|\mathcal{K}u(x,y)|\leqslant|z|/2$. To obtain an upper bound on $|\mathcal{K}^2u(x,y)|$ we set $F(x,y)=\mathcal{K}u(x,y)$ in (42), which allows us to identify M_F with $|z|/2$ and yields for all $x,y\in\mathbb{R}$:

$$|\mathcal{K}^2u(x,y)|\leqslant\frac{z^2}{2}(|x-a|+|y-a|). \tag{43}$$

We can directly verify this relation using (41). Repeating the procedure that leads to (43), we find for all $\ell\geqslant1$ and all $x,y\in\mathbb{R}$: $|\mathcal{K}^\ell u(x,y)|\leqslant|z|^\ell(|x-a|+|y-a|)^{\ell-1}/2$. This in turn implies, in view of the elementary comparison tests, that the series (21) converges (absolutely) for $|z|(|x-a|+|y-a|)<1$. Hence, it converges in an open disc in the x-y plane that is centered at $(x=a,\ y=a)$ and has a radius $\varrho>(\sqrt{2}|z|)^{-1}$.

In summary, for every given value of z, truncation of the series (21) yields a reliable approximation for η provided that we keep a sufficiently large number of terms in the series and deal with wave functions $\psi(x)$ that decay sufficiently rapidly as $|x|\to\infty$. (Our analysis only yields a lower bound on ϱ. It does not imply that ϱ is finite.)

We can extend our treatment to a potential consisting of more than one delta function:

$$v(x)=i\sum_{n=1}^{N}\zeta_n\delta(x-a_n), \tag{44}$$

where $N\in\mathbb{Z}^+$ and $\zeta_n,a_n\in\mathbb{R}$. An example is the $\mathcal{PT}$-symmetric potentials[29–31] corresponding to the cases that N is even and $\zeta_{N/2+k}=-\zeta_k$, $a_{(N/2)+k}=-a_k$ for all $k=1,2,\cdots N/2$. [Here we assume that (ζ_n,a_n) are such that the Hamiltonian is pseudo-Hermitian. This is the generic case, for the values of (ζ_n,a_n) that render the spectrum of the Hamiltonian nonreal form a measure-zero subset of the set $\mathbb{R}^{2N}$ of all possible values of (ζ_n,a_n).]

For these multi-delta-function potentials the calculation of the first-order term in $z_n:=2m\zeta_n/\hbar^2$ in the series expansion (21) reduces to the case $N=1$ that we considered above. In view of (40),

$$\mathcal{K}\delta(x,y)=\frac{i}{2}\sum_{n=1}^{N}z_n\theta(x+y-2a_n)\mathrm{sign}(y-x). \tag{45}$$

The most general η that reduces to $\eta=I$ in the Hermitian limit $z_n\to0$ is obtained up to second-order terms in z_n by setting $u(x,y)=\delta(x-y)+\sum_{n=1}^{N}z_n[w_{n+}(x-y)+w_{n-}(x+y)]+\mathcal{O}(z_n^2)$, where $w_{n\pm}:\mathbb{R}\to\mathbb{C}$ are arbitrary functions satisfying $w_{n\pm}(x)^*=w_{n\pm}(\mp x)$. This together with (45) and (21) yields

$$\eta(x,y) = \delta(x-y) + \sum_{n=1}^{N} z_n \left[w_{n+}(x-y) + w_{n-}(x+y) + \frac{i}{2}\theta(x+y-2a_n)\mathrm{sign}(y-x) \right] + \mathcal{O}(z_n^2). \tag{46}$$

We close this section by the following general remarks. As we observe in the study of the above toy models, the series solution (21) may be used to obtain a perturbative expansion for the pseudo-metric operator η. In general, depending on the details of the model under study, one may or may not have access to a dimensionless perturbation parameter. Typical examples for which this occurs are the imaginary cubic potential and the single imaginary delta-function potential (38). In this case, as explained in Ref. 9, the truncation of the perturbative expansion of $\eta(x,y)$ generally yields a reliable result only within a sufficiently small region in the x-y plane. Furthermore, one expects that for sufficiently small values of the perturbation parameter (the coupling constant ζ or ζ_n in the above examples) the perturbative corrections to a positive-definite metric operator such as $\eta=I$ leave this property intact.

V. CONCLUDING REMARKS

In this article, we have outlined a differential realization of the pseudo-Hermiticity condition that plays a central role in devising a unitary quantum theory based on quasi-Hermitian Hamiltonians of the standard form. The integral kernel $\eta(x,y)$ for the corresponding pseudo-metric operators η satisfies a linear partial differential equation. For systems having $\mathbb{R}$ as their configuration space this is nothing but a particular variable-mass Klein-Gordon equation. We have obtained a general series solution for this equation and demonstrated its application in treating the $\mathcal{PT}$-symmetric square well potential, an imaginary $\mathcal{PT}$-symmetric scattering potential, and a class of imaginary delta-function potentials. In particular, for the former two potentials, the approach presented here is by far more practical than the alternative approaches that use the spectral resolution of the metric operator. Another advantage of the former approach is that it is capable of producing the most general pseudo-metric operator. In particular, imposing the positive-definiteness condition (7), it yields the general form of the metric operators.

Our method is not only practically advantageous but also conceptually appealing. It furthers the analogy between QM and GR, for the differential pseudo-Hermiticity relation plays a similar role in QM as the Einstein's field equation does in GR [not to mention the curious fact that the field theoretic extension of the pseudo-Hermiticity relation (3) is a functional differential equation that has the same structure as the Wheeler-DeWitt equation of the conventional canonical quantum gravity]. Another valuable outcome of our method is a concrete characterization of the arbitrariness of the metric operator. Each choice of a metric operator defines a separate quantum system. One can pursue the prescription used in the so-called quasi-Hermitian quantum mechanics[1] to select an irreducible set of compatible quasi-Hermitian operators O_α and fix the metric operator η_+ (up to scale) through the requirement that O_α be η_+-pseudo-Hermitian. Alternatively, one can follow the approach of the so-called pseudo-Hermitian quantum mechanics,[3] choose η_+ directly, and construct the Hilbert space and observables of the theory accordingly.[4,5,7,9]

(Received 22 December 2005; accepted 16 May 2006; published online 12 July 2006)

We consider questions related to a quantization scheme in which a classical variable $f:\Omega\to\mathbb{R}$ on a phase space Ω is associated with a (preferably unique) semispectral measure E^f, such that the moment operators of E^f are required to be of the form $\Gamma(f^k)$, with Γ a suitable mapping from the set of classical variables to the set of (not necessarily bounded) operators in the Hilbert space of the quantum system. In particular, we investigate the situation where the map Γ is implemented by the operator integral with respect to some fixed positive operator measure. The phase space Ω is first taken to be an abstract measurable space, then a locally compact unimodular group, and finally $\mathbb{R}^2$, where we determine explicitly the relevant operators $\Gamma(f^k)$ for certain variables f, in the case where the quantization map Γ is implemented by a translation covariant positive operator measure. In addition, we consider the question under what conditions a positive operator measure is projection valued. © *2006 American Institute of Physics.*

I. INTRODUCTION

Quantization can be any procedure that associates a quantum mechanical observable to a given classical dynamical variable. The traditional way to realize a quantization is to assign to each classical variable a Hermitean (symmetric, or even essentially self-adjoint) operator that should describe the quantum observable. The question is how to modify the traditional scheme in order to fit it into the context of modern quantum mechanics.

We recall that, in this formulation, observables of a quantum system with a Hilbert space $\mathcal{H}$ are given as semispectral measures $E:\mathcal{B}(\mathbb{R})\to L(\mathcal{H})$ and states as positive trace one operators $T:\mathcal{H}\to\mathcal{H}$. The probability measure $X\mapsto \mathrm{Tr}[TE(X)]$ defined by a pair (E,T) is taken to describe the measurement outcome probabilities of the observable E in the state T. Here $\mathcal{B}(\mathbb{R})$ denotes the Borel σ-algebra of the real line $\mathbb{R}$, and $L(\mathcal{H})$ is the set of bounded operators on $\mathcal{H}$.

Classical variables can be represented by real valued measurable functions defined on some measurable space $(\Omega,\mathcal{A})$, which is the phase space of the classical system. The phase space can be taken to be, e.g., $\mathbb{R}^{2n}$, in which case the variables are Borel functions. In the conventional approach to quantization, we would have a map Γ from the set of real measurable functions to the set of all linear (not necessarily bounded) operators in a Hilbert space $\mathcal{H}$, and $\Gamma(f)$ would be the observable corresponding to the classical variable f (see, e.g., Refs. 9, 15, 28, 32, and 33).

We would like to modify this scheme so that we could assign a semispectral measure to the function f, instead of an operator. To do this, we still assume that we have a map Γ as above, but now we use all the operators $\Gamma(f^k)$, $k\in\mathbb{N}$, instead of just $\Gamma(f)$. (In this paper, $\mathbb{N}$ is the set of positive integers.) The idea is to consider the moment problem of finding the unique semispectral measure $E^f:\mathcal{B}(\mathbb{R})\to L(\mathcal{H})$ with the property that $\int x^k dE^f=\Gamma(f^k)$ for all $k\in\mathbb{N}$. Here $\int x^k dE^f$, the kth

moment of E^f, is the operator integral $L(x^k, E^f)$ of the function $x \mapsto x^k$ with respect to E^f; see the next section for its definition. So if Γ and f are such that there exists a unique solution E^f of the described moment problem, then the collection of the operators $\{\Gamma(f^k) | k \in \mathbb{N}\}$ is eligible to represent a quantization E^f of f. The motivation for this approach lies in the fact that then the moments of the measurement outcome probabilities of a quantum observable E^f correspond to those of the original classical variable f, which are simply the powers of its values.

One way to obtain a quantization map Γ is to use the operator integral with respect to some given positive operator measure E, i.e., define Γ to be the map $f \mapsto L(f, E)$. In this case, if we define E^f on the Borel sets of the real line by $B \mapsto E(f^{-1}(B))$, we have simply $L(x^k, E^f) = L(f^k, E)$, as is easily seen by using the definition of the next section and the usual change of variables in the integral with respect to a complex measure. So then E^f is a solution to the moment problem described above, which leaves us with the uniqueness question. Note that if we choose E to be a projection operator measure, we end up getting only spectral measures as the quantized observables, with all the operators $L(f^k, E)$ mutually commuting. We also remark that, in any case, all the observables obtained via this type of quantization are *functionally coexistent*,[26] so that they can be measured together in the sense of Ludwig (see Ref. 29, D.3.1, p. 153).

We mention that the approach described above is used, for instance, in Ref. 14 in the description of a quantum measurement. In a typical measurement situation, where one aims to measure a (traditional) quantum observable represented by a self-adjoint operator, one is actually measuring a noisy or unsharp version of that observable. The noisy version, represented by a semispectral measure, may agree with the observable intended to be measured, on the statistical level of expectations. The unsharpness of the measurement is reflected in the fact that the dispersion of the measurement statistics is actually greater than what would be obtained in the noiseless case. The observable, as represented by a semispectral measure, cannot be described using a single operator. Accordingly, in the approach of Ref. 14, each moment of the measurement outcome distribution is considered to be an average of a certain operator, called an "operational observable," and the collection of these operators then represents the measured observable. We want to point out that these operational observables are nothing more but the moment operators of the semispectral measure representing the observable. Note that these moments need not determine the semispectral measure uniquely. In certain special cases, however, they do,[12,13] and sometimes even the first moment is enough.[8,25]

The structure of this paper is as follows. In the Sec. II we give some results on the theory of operator integrals and give a simple characterization of the quantization maps that can be represented by an operator integral with respect to a positive operator measure. In Sec. III, we consider the operator integral with respect to covariant positive operator measures on a locally compact to pological group. Section IV is devoted to the quantizations obtained by using the covariant phase space observables in $\mathbb{R}^2$, and in Sec. V, we discuss the "optimal" choice for such a covariant observable, in view of quantization. In Sec. VI, we consider the question under what conditions a positive operator measure is a spectral one.

II. THE OPERATOR INTEGRAL

The basic tool in our quantization procedure is the operator integral. It associates a linear (not necessarily bounded) operator in the Hilbert space $\mathcal{H}$ of a quantum system to each complex measurable function on the phase space Ω. In this section we review the basic results concerning the theory of operator integrals and give some additional remarks in relation to quantization.

Let Ω be a nonempty set and $\mathcal{A}$ a σ-algebra of subsets of Ω. Let $\mathcal{H}$ be a complex Hilbert space and $L(\mathcal{H})$ the set of bounded operators on $\mathcal{H}$. Let $E: \mathcal{A} \to L(\mathcal{H})$ be a positive operator measure, i.e., a positive operator valued set function that is σ-additive with respect to weak operator topology. For each $\varphi, \psi \in \mathcal{H}$, let $E_{\psi,\varphi}$ denote the complex measure $B \mapsto \langle \psi | E(B) \varphi \rangle$. We recall that a normalized positive operator measure E is called a semispectral measure, and that a semispectral measure E is a spectral measure exactly when $E(A \cap B) = E(A)E(B)$ for all $A, B \in \mathcal{A}$. As mentioned in Sec. I, semispectral measures are also called observables.

Let $\mathcal{F}(\Omega,\mathcal{A})$, or $\mathcal{F}(\Omega)$ in brief, denote the set of all complex $\mathcal{A}$-measurable functions defined on Ω, and $\mathcal{O}(\mathcal{H})$ the set of all (not necessarily bounded) linear operators in $\mathcal{H}$. For $f\in\mathcal{F}(\Omega)$, define

$$D(f,E)=\{\varphi\in\mathcal{H}|f \text{ is } E_{\psi,\varphi}-\text{integrable for each } \psi\in\mathcal{H}\}$$

and

$$\tilde{D}(f,E)=\{\varphi\in\mathcal{H}||f|^2 \text{ is } E_{\varphi,\varphi}-\text{integrable}\}.$$

The following result was proved in Ref. 22. The operator $L(f,E)$ appearing in it is called *the operator integral of f with respect to E*.

Theorem 1:

(a) *The set $D(f,E)$ is a linear (not necessarily dense) subspace of $\mathcal{H}$, and there is a unique linear operator $L(f,E)=\int f dE$ on the domain $D(f,E)$ satisfying*

$$\langle\psi|L(f,E)\varphi\rangle=\int f dE_{\psi,\varphi}$$

for all $\psi\in\mathcal{H}$ and $\varphi\in D(f,E)$.

(b) *The set $\tilde{D}(f,E)$ is a subspace of $D(f,E)$.*

(c) *If f is real valued, $L(f,E)$ is a symmetric operator.*

(d) *While the inclusion $\tilde{D}(f,E)\subset D(f,E)$ may in general be proper, $\tilde{D}(f,E)=D(f,E)$ in the case where E is a spectral measure.*

Remark: Since the operator measure E is also strongly σ-additive, each set function $\mathcal{A}\ni B\mapsto E_\varphi:=E(B)\varphi\in\mathcal{H}$, for $\varphi\in\mathcal{H}$, is an $\mathcal{H}$-valued vector measure. The definition of the operator integral states that $D(f,E)$ is the set of those $\varphi\in\mathcal{H}$ for which f is integrable with respect to the vector measure E_φ in the sense of Ref. 20, p. 21, and $L(f,E)\varphi=\int f dE_\varphi$ for each $\varphi\in D(f,E)$. As pointed out in Ref. 20, p. 37, this definition of integrability is equivalent to that of Ref. 10, p. 323 (for proof, see Ref. 41, Corollary 3.6).

The vector measure approach provides an easy way to characterize the operator integral $L(f,E)$ by approximating f with bounded functions. For each $f\in\mathcal{F}(\Omega)$, and $n\in\mathbb{N}$, let $\tilde{f}_n$ be such that $\tilde{f}_n(x)=f(x)$ if $|f(x)|\leqslant n$, and $\tilde{f}_n(x)=0$ otherwise. It is a well-known fact that in the case where E is a spectral measure, we have

$$D(f,E)=\tilde{D}(f,E)=D^{f,E}:=\{\varphi\in\mathcal{H}|\lim_{n\to\infty}L(\tilde{f}_n,E)\varphi \text{ exists}\}.$$

In addition, $L(f,E)\varphi=\lim_{n\to\infty}L(\tilde{f}_n,E)\varphi$ for all $\varphi\in D^{f,E}$ (see, e.g., Ref. 11, p. 1196). In the case of a general positive operator measure E, this need not be true. For example, take a probability measure defined on the Borel sets of $\mathbb{R}$, such that it has a density that is an even function, and $\int_0^\infty x d\mu(x)=\infty$. Let E be the positive operator measure $B\mapsto\mu(B)I$, and $f(x)=x$. Now f is not μ-integrable, so $D(f,E)=\{0\}$. But if $\varphi\in\mathcal{H}$, we have $\langle\psi|L(\tilde{f}_n,E)\varphi\rangle=\langle\psi|\varphi\rangle\int_{-n}^{n}x d\mu(x)=0$ for all $n\in\mathbb{N}$ and $\psi\in\mathcal{H}$ because the density of μ is even, so that $D^{f,E}=\mathcal{H}$.

Thus in the general case, the existence of the limit $\lim_{n\to\infty}L(\tilde{f}_n,E)\varphi$ does not guarantee that $\varphi\in D(f,E)$. However, the following result holds.

Proposition 1: Let $E:\mathcal{A}\to L(\mathcal{H})$ be a positive operator measure, and $f\in\mathcal{F}(\Omega)$. Then

$$D(f,E)=\{\varphi\in H|\lim_{n\to\infty}L(\chi_B\tilde{f}_n,E)\varphi \text{ exists for each } B\in\mathcal{A}\},$$

and $L(f,E)\varphi=\lim_{n\to\infty}L(\tilde{f}_n,E)\varphi$ for all $\varphi\in D(f,E)$.

Proof: Denote by D the right-hand side of the set equality appearing in the statement. Let $\varphi\in D$, and let $B\in\mathcal{A}$, with $\eta_B=\lim_{n\to\infty}L(\chi_B\tilde{f}_n,E)\varphi$. Since each $\tilde{f}_n$ is bounded, we can choose a

sequence of $\mathcal{A}$-simple functions g_n, such that $|g_n(x)-\tilde{f}_n(x)|\leq 1/n$ for each $n\in\mathbb{N}$ and $x\in\Omega$. Clearly the sequence (g_n) converges to f pointwise. Now

$$\|L(\chi_B g_n-\chi_B\tilde{f}_n,E)\varphi\|=\sup_{\|\psi\|\leq 1}\left|\int_B (g_n-\tilde{f}_n)dE_{\psi,\varphi}\right|\leq\frac{1}{n}\sup_{\|\psi\|\leq 1}|E_{\psi,\varphi}|(\Omega)\leq\frac{4}{n}\|E(\Omega)\|\|\varphi\|,$$

so that

$$\left\|\int_B g_n dE_\varphi-\eta_B\right\|\leq\frac{4}{n}\|E(\Omega)\|\|\varphi\|+\|L(\chi_B f_n,E)\varphi-\eta_B\|.$$

It follows that the sequence $(\int_B g_n dE_\varphi)$ of vectors converges for each $B\in\mathcal{A}$ (to η_B), so by the definition of Ref. 10, p. 323, f is integrable with respect to the vector measure E_φ, i.e. $\varphi\in D(f,E)$ (see the Remark following Theorem 1). Conversely, let $\varphi\in D(f,E)$. Since $D(f,E)=D(|f|,E)$ by definition, and for each $B\in\mathcal{A}$ the sequence $(\chi_B\tilde{f}_n)$ converges to $\chi_B f$ pointwise, with $|\chi_B\tilde{f}_n|\leq|\chi_B f|$, it follows e.g. from the dominated convergence theorem for the vector measure E_φ (see Ref. 10, p. 328) that

$$L(\chi_B f,E)\varphi=\int\chi_B f dE_\varphi=\lim_{n\to\infty}\int\chi_B\tilde{f}_n dE_\varphi=\lim_{n\to\infty}L(\chi_B\tilde{f}_n,E)\varphi$$

for each $B\in\mathcal{A}$. Thus $\varphi\in D$, and $L(f,E)\varphi=\lim_{n\to\infty}L(\tilde{f}_n,E)\varphi$. □

Remark:

(a) We now have the subspace inclusions $\tilde{D}(f,E)\subset D(f,E)\subset D^{f,E}$, with each of them possibly proper. In the case where E is a spectral measure, both inclusions are equalities.

(b) It is well known that in the case where E is a spectral measure, the domain $D(f,E)$ is dense. As seen before in Proposition 1, this need not be the case in general, so a question arises what is required for E and f to make $D(f,E)$ dense.

(c) Another difference to the spectral case is that for real valued $f\in\mathcal{F}(\Omega)$, the symmetric operator $L(f,E)$ is not necessarily self-adjoint (the adjoint need not even exist), and it seems to be difficult, in general, to determine when $L(f,E)$ might have self-adjoint extensions. In the case where f is positive and $D(f,E)$ dense, the positive symmetric operator $L(f,E)$ of course has its self-adjoint Friedrichs extension.

As noted in Sec. I, the starting point of our quantization scheme is a map Γ from real valued measurable functions to the set $\mathcal{O}(\mathcal{H})$. The following theorem characterizes those maps $\Gamma:\mathcal{F}(\Omega)\to\mathcal{O}(\mathcal{H})$, which are implemented by an operator integral. The corresponding result involving bounded functions is well known. Here the functions $\tilde{f}_n$ are defined for each f as in Proposition 1.

Theorem 2: *A map $\Gamma:\mathcal{F}(\Omega)\to\mathcal{O}(\mathcal{H})$ coincides with the map $f\mapsto L(f,E)$ for a (clearly unique) positive operator measure E if and only if the following conditions are satisfied.*

(i) Γ *restricted to bounded functions is a positive linear map with values in* $L(\mathcal{H})$;

(ii) *if (f_n) is an increasing sequence of positive $\mathcal{A}$-measurable functions converging pointwise to a bounded $f\in\mathcal{F}(\Omega)$, then* $\sup_{n\in\mathbb{N}}\langle\varphi|\Gamma(f_n)\varphi\rangle=\langle\varphi|\Gamma(f)\varphi\rangle$ *for each* $\varphi\in\mathcal{H}$;

(iii) *for each $f\in\mathcal{F}(\Omega)$, the domain $D(\Gamma(f))$ of $\Gamma(f)$ consists of those vectors $\varphi\in\mathcal{H}$ for which the sequence $(\Gamma(\chi_B\tilde{f}_n)\varphi)$ of vectors converges for each $B\in\mathcal{A}$.*

(iv) *for each $\varphi\in D(\Gamma(f))$, the sequence $(\Gamma(\tilde{f}_n)\varphi)$ converges to $\Gamma(f)\varphi$.*

Proof: Assume first that there is a positive operator measure E, such that $\Gamma(f)=L(f,E)$ for each f. The above properties follow easily: Property (i) is well known (see, e.g., Ref. 2, pp. 22-28), and (ii) follows from the monotone convergence theorem. Proposition 1 gives (iii) and (iv). Next assume that (i)-(iii) hold for a map $\Gamma:\mathcal{F}(\Omega)\to\mathcal{O}(\mathcal{H})$. By (i) the map $\mathcal{A}\ni B\mapsto E^\Gamma(B):=\Gamma(\chi_B)\in\mathcal{O}(\mathcal{H})$ is a positive operator valued additive set function. Since Γ is positive for bounded functions by (i), $\sup_{n\in\mathbb{N}}$ in condition of (ii) can be replaced by $\lim_{n\to\infty}$. This implies that each set function $B\mapsto\langle\varphi|E^\Gamma(B)\varphi\rangle$ is a positive measure, so that E^Γ is a positive operator measure. If f

$\in \mathcal{F}(\Omega)$ is a bounded positive function, we have $\langle\varphi|\Gamma(f)\varphi\rangle = \langle\varphi|L(f,E^\Gamma)\varphi\rangle$ for all $\varphi \in \mathcal{H}$, as is seen by approximating f with an increasing sequence of simple functions and using linearity, (ii), and the monotone convergence theorem. Hence, if $f \in \mathcal{F}(\Omega)$ is bounded, it follows by linearity and polarization that $\Gamma(f) = L(f,E^\Gamma)$. Now let $f \in \mathcal{F}(\Omega)$ be arbitrary. It follows by (iii) and Proposition 1 that $D(\Gamma(f)) = D(f,E^\Gamma)$, and (since each $\widetilde{f}_n$ is bounded), also

$$L(f,E^\Gamma)\varphi = \lim_{n\to\infty} L(\widetilde{f}_n,E^\Gamma)\varphi = \lim_{n\to\infty} \Gamma(\widetilde{f}_n)\varphi = \Gamma(f)\varphi$$

for all $\varphi \in D(\Gamma(f))$ [where (iv) is used], so $L(f,E^\Gamma) = \Gamma(f)$. □

Remark: In the quantization scheme described in Sec. I the classical variables were thought to be real valued. Obviously, the preceding Theorem holds also with $\mathcal{F}(\Omega)$ replaced by the set of real $\mathcal{A}$-measurable functions.

We end this section by discussing briefly a simple way of obtaining quantization maps without the use of positive operator measures. This approach is essentially the one frequently used in the conventional quantization (e.g., Weyl quantization): the operator corresponding to a given classical variable $f:\mathbb{R}^{2n}\to\mathbb{R}$ is obtained by integrating the variable with respect to some operator valued function defined on the phase space. The quantization of the variable then becomes a continuous distribution valued operator defined on some dense subspace of $L^2(\mathbb{R})$, which does not depend on the variable itself. In the case of Weyl quantization, for example, all the quantized operators are defined on a common domain (see, e.g., Refs. 9 and 36). However, to make the situation similar to that of the operator integral map considered above, we define the quantization map in the following simple way. The proof is a direct adaptation of the proof of Theorem 1 (a) (see Ref. 22). Note that it follows from (i) that the integrand in (ii) is $\mathcal{A}$-measurable. This is so because $\|\varphi\| = \sup\{|\langle\psi|\varphi\rangle| \,|\, \psi\in\mathcal{M}, \|\psi\|=1\}$ for any vector $\varphi\in\mathcal{H}$, where $\mathcal{M}$ is a fixed countable dense set in the separable Hilbert space $\mathcal{H}$. Hence the integral in (ii) is well defined.

Proposition 2: Let $(\Omega,\mathcal{A},\mu)$ *be a measure space*, $\mathcal{H}$ *a separable Hilbert space, and* $\Lambda:\Omega\to L(\mathcal{H})$ *a map with the following properties:*

(i) $\omega\mapsto\langle\psi|\Lambda(\omega)\varphi\rangle$ *is* $\mathcal{A}$*-measurable for all* $\psi,\varphi\in\mathcal{H}$;
(ii) $\int_B \|\Lambda(\omega)\varphi\| d\mu(\omega) < \infty$ *for each* $\varphi\in\mathcal{H}$ *and* $B\in\mathcal{A}$ *with* $\mu(B)<\infty$.

Then for each $\mathcal{A}$*-measurable function* $f:\Omega\to\mathbb{C}$, *there exists a linear operator* $\Gamma_\Lambda(f)$ *in* $\mathcal{H}$, *such that*

$$D(\Gamma_\Lambda(f)) = \{\varphi\in\mathcal{H} | f\langle\psi|\Lambda(\cdot)\varphi\rangle \text{ is } \mu-\text{integrable for each } \psi\in\mathcal{H}\},$$

and

$$\langle\psi|\Gamma_\Lambda(f)\varphi\rangle = \int f(x)\langle\psi|\Lambda(\omega)\varphi\rangle d\mu(\omega)\psi\in\mathcal{H}, \quad \varphi\in D(\Gamma_\Lambda(f)).$$

Proof: It is clear that $D(\Gamma_\Lambda(f))\subset\mathcal{H}$ is a vector subspace. Let (f_n) be a sequence of simple functions converging pointwise to f, with $|f_n|\leqslant|f|$ for all $n\in\mathbb{N}$. Since $|\langle\psi|\Lambda(\omega)\varphi\rangle| \leqslant \|\psi\|\|\Lambda(\omega)\varphi\|$ for each $\psi,\varphi\in\mathcal{H},\omega\in\Omega$, it follows from (ii) and (i) that for each $n\in\mathbb{N}$, we have $D(\Gamma_\Lambda(f_n))=\mathcal{H}$ and the linear functional $\psi\mapsto\int\overline{f_n(\omega)}\langle\psi|\Lambda(\omega)\varphi\rangle d\mu(\omega)$ is continuous for each $\varphi\in\mathcal{H}$. Hence, for each $n\in\mathbb{N}$ and $\varphi\in\mathcal{H}$, there is $\eta_n^\varphi\in\mathcal{H}$, such that

$$\langle\psi|\eta_n^\varphi\rangle = \int f_n(\omega)\langle\psi|\Lambda(\omega)\varphi\rangle d\mu(\omega)$$

for all $\psi\in\mathcal{H}$. Now, let $\varphi\in D(\Gamma_\Lambda(f))$. Since $|f_n|\leqslant|f|$ for all n, the dominated convergence theorem implies that the sequence $\langle\psi|\eta_n^\varphi\rangle$ converges for each $\psi\in\mathcal{H}$ to $\int f(\omega)\langle\psi|\Lambda(\omega)\varphi\rangle d\mu(\omega)$, so by the uniform boundedness theorem and the reflexivity of $\mathcal{H}$, there is $\Gamma_\Lambda(f)\varphi\in\mathcal{H}$, such that

$$\langle\psi|\Gamma_\Lambda(f)\varphi\rangle = \int f(\omega)\langle\psi|\Lambda(\omega)\varphi\rangle d\mu(\omega)$$

for all $\psi \in \mathcal{H}$. Clearly, the map $D(\Gamma_\Lambda(f)) \ni \varphi \mapsto \Gamma_\Lambda(f)\varphi \in \mathcal{H}$ is linear, so the proof is complete. □

Remark: Consider the situation where we have a locally compact unimodular topological group G, with a left Haar measure μ, and a strongly continuous projective unitary representation $U: G \to \mathcal{U}(\mathcal{H})$. Then, for any $A \in L(\mathcal{H})$, the map $\Lambda: G \to L(\mathcal{H})$, defined by $\Lambda(g) = U(g)AU(g)^*$, satisfies the conditions of the preceding Proposition, so we get the corresponding quantization map Γ_Λ. Notice that in the case where the representation is square integrable and A positive, the quantization map Γ_Λ can be represented by an operator integral if and only if A has finite trace. Namely, the case $\mathrm{Tr}[A] = \infty$ gives $D(\Gamma_\Lambda(\chi_G)) = \{0\}$ (see, e.g., Ref. 19, Lemma 2), while the case $\mathrm{Tr}[A] < \infty$ leads to the usual quantization map given by the operator integral with respect to a covariant positive operator measure (multiplied by some constant).

Consider the case where $G = \mathbb{R}^2$, $U(g) = U((q,p))$ are the Weyl operators, and A is the parity operator $L^2(\mathbb{R}) \ni \psi \mapsto \psi(-\cdot) \in L^2(\mathbb{R})$ (multiplied by a suitable constant). Now Γ_Λ is the Weyl quantization map. It is well known that for $f \in L^1(\mathbb{R}^2) \cup L^2(\mathbb{R}^2)$, the operator $\Gamma_\Lambda(f)$ is bounded. Moreover, if $f \in L^2(\mathbb{R}^2)$, then $\Gamma_\Lambda(f)$ is a Hilbert-Schmidt operator, and if f is a Schwartz function, then $\Gamma_\Lambda(f)$ is a trace class operator (see, e.g., Ref. 36). It is a well-known fact that the Weyl quantizations of the classical position and momentum variables are the position and momentum operators Q and P, in the "distributional" sense. Note, however, that the actual domains of Q and P are not given by the formula of the preceding theorem. For example, the characteristic function $\chi_{[-1,1]}$ is in the domain of Q, but the function $(q,p) \mapsto q\langle\chi_{[-1,1]}|\Lambda(q,p)\chi_{[-1,1]}\rangle$ is not (Lebesgue)-integrable, as is easily seen by calculating the explicit form of the function.

III. COVARIANT QUANTIZATION

We now take the set Ω of the preceding section to be a locally compact second countable unimodular topological group, henceforth denoted as G, and let $\mathcal{B}(G)$ denote the Borel σ-algebra of G. Fix λ to be a Haar measure in G. Let $\mathcal{T}(\mathcal{H})$ denote the Banach space of trace class operators on the Hilbert space $\mathcal{H}$, and let $\mathrm{Aut}(\mathcal{T}(\mathcal{H}))$ denote the set of linear, positive, trace norm preserving bijections from $\mathcal{T}(\mathcal{H})$ onto itself. We consider it equipped with the topology given by the functionals $\mathrm{Aut}(\mathcal{T}(\mathcal{H})) \ni \beta \mapsto \mathrm{Tr}[A\beta(T)] \in \mathbb{C}$, where $A \in L(\mathcal{H})$ and $T \in \mathcal{T}(\mathcal{H})$.

Assume further that there is a continuous group homomorphism $\beta: G \to \mathrm{Aut}(\mathcal{T}(\mathcal{H}))$ and a constant $d > 0$, satisfying

$$\int \mathrm{Tr}[P_1\beta(g)(P_2)]d\lambda = d \text{ for all one-dimensional projections } P_1, P_2 \text{ on } \mathcal{H}. \tag{1}$$

We now consider quantizations connected to the structure of G given by the homomorphism β, in the following sense: A map $\Gamma: \mathcal{F}(G) \to \mathcal{O}(\mathcal{H})$ with the property that $\Gamma(f) \in L(\mathcal{H})$ for all bounded functions $f \in \mathcal{F}(G)$ is said to be *β-covariant*, if $\beta(g)^*(\Gamma(f)) = \Gamma(f(g\cdot))$ for all $g \in G$ and all bounded functions $f \in \mathcal{F}(G)$.

If Γ is such that it can be represented by the operator integral with respect to an observable E (i.e., Γ satisfies the conditions of Theorem 2), then it is straightforward to verify that Γ is β-covariant if and only if the observable E is β-covariant in the following sense: An observable $E: \mathcal{B}(G) \to L(\mathcal{H})$ is said to be β-covariant if $\beta(g)^*(E(B)) = E(g^{-1}B)$ for all $g \in G$, $B \in \mathcal{B}(G)$.

Covariant observables are essential in quantum mechanics, and hence they have been studied quite extensively. The canonical examples of covariant observables are constructed, e.g., in Ref. 7, and there are (at least) two completely different ways to obtain their characterization: a direct approach,[16,19,38] which uses the theory of integration with respect to vector measures, and a group theoretical approach.[6] The most general of these characterizations is in Ref. 6. In our context of a unimodular group, the characterization is given by the following theorem.

Theorem 3: *Let T be a positive operator of trace one. Then there is a β-covariant observable*

$E^T:\mathcal{B}(G)\to L(\mathcal{H})$, *such that*

$$E^T(B)=d^{-1}\int_B \beta(g)(T)d\lambda(g) \tag{2}$$

in the ultraweak sense for each $B\in\mathcal{B}(G)$. *Conversely, assume that* $E:\mathcal{B}(G)\to L(\mathcal{H})$ *is a* β*-covariant observable. Then there is a unique positive operator* T *of trace one, such that* $E=E^T$.

If E is a β-covariant observable, we call the corresponding trace-one positive operator T the *generating operator* for E. Thus, for a β-covariant observable E, we have

$$D(f,E)=\{\varphi\in\mathcal{H}|g\mapsto f(g)\langle\psi|\beta(g)(T)\varphi\rangle \text{ is } \lambda\text{ - integrable for each } \psi\in\mathcal{H}\}$$

and

$$\langle\psi|L(f,E)\varphi\rangle=d^{-1}\int f(g)\langle\psi|\beta(g)(T)\varphi\rangle d\lambda(g)$$

for all $\varphi\in D(f,E)$ and $\psi\in\mathcal{H}$, where T is the generating operator for E.

According to the Wigner theorem, each $\beta(g)$ has the form $\beta(g)(T)=U(g)TU(g)^*$ for some unitary or antiunitary operator $U(g)$, which is unique up to a phase factor, so that $\beta(g)$ corresponds to the associated equivalence class of unitary operators (see, e.g., Ref. 5, p. 19 or Ref. 16, p. 22). It follows that, in the case where G is connected, the map $g\mapsto U(g)$ is a weakly (Borel) measurable projective unitary representation of G, where each $U(g)$ is chosen from the equivalence class corresponding to $\beta(g)$ by means of some (measurable) section (see Ref. 16, p. 23 and Ref. 5, pp. 30 and 100). Relation (1) gives the so-called square integrability condition

$$\int|\langle\psi|U(g)\varphi\rangle|^2d\lambda(g)=d$$

for all unit vectors $\psi,\varphi\in\mathcal{H}$. Clearly, for each $\varphi,\psi\in\mathcal{H}$ there is a $g\in G$ such that $\langle\psi|U(g)\varphi\rangle\neq 0$. This implies that the closed linear span of $\{U(g)\varphi|g\in G\}$ is dense in $\mathcal{H}$ for each $\varphi\in\mathcal{H}$, which means that the projective representation $g\mapsto U(g)$ is irreducible. The β-covariance condition for an observable E takes the form $U(g)^*E(B)U(g)=E(g^{-1}B)$ for all $g\in G$, $B\in\mathcal{B}(G)$.

Hence, we know that each covariant quantization map $\Gamma:\mathcal{F}(G)\to\mathcal{O}(\mathcal{H})$, which can be represented by an operator integral, is of the form $\Gamma=\Gamma^T:=L(\cdot,E^T)$ for some generating operator T. It is worth noting that in certain cases the observables produced by the quantization scheme associated with a map Γ^T are never spectral measures. Namely, the irreducibility of U implies the following, perhaps well-known result.

Proposition 3: Assume that G *is connected, and that the projective representation* U *associated with* β *is strongly continuous. Let* $T\in\mathcal{T}(\mathcal{H})$ *be positive and of trace one. Then the only projections in the range of* E^T *are* O *and* I.

Proof: First we notice that if $E^T(X)$ is a projection for some $X\in\mathcal{B}(G)$ and positive operator T of trace one, then there is a nonzero $\varphi\in\mathcal{H}$, such that $E^{|\varphi\rangle\langle\varphi|}(X)$ is a projection. Indeed, let T be a positive operator of trace one, $\lambda>0$ an eigenvalue of T (so that $\lambda\leqslant 1$), and $\varphi\in\mathcal{H}$ an associated eigenvector. Then we can decompose T as $T=\lambda|\varphi\rangle\langle\varphi|+(1-\lambda)T'$, where $|\varphi\rangle\langle\varphi|$ and T' are positive and of trace one, so we can write $E^T(X)=\lambda E^{|\varphi\rangle\langle\varphi|}(X)+(1-\lambda)E^{T'}(X)$. Since any projection is an extreme point of the convex set $\{A\in L(\mathcal{H})|0\leqslant A\leqslant I\}$ (see, e.g., Ref. 7, p. 19), it follows that if $E^T(X)$ is a projection, then $E^T(X)=E^{|\varphi\rangle\langle\varphi|}(X)$.

Hence, it suffices to show that for each unit vector $\eta\in\mathcal{H}$, the only projections in the range of $E^{|\eta\rangle\langle\eta|}$ are O and I. Denote $T=|\eta\rangle\langle\eta|$, and assume that there is a projection P in the range of E^T. Then $PE^T(B)=E^T(B)P$ for all $B\in\mathcal{B}(G)$.[27] Let $\varphi\in\mathcal{H}$. Now

$$\int_B \langle\varphi|P\beta(g)(T)\varphi\rangle d\lambda(g) = \int_B \langle\varphi|\beta(g)(T)P\varphi\rangle d\lambda(g)$$

for all $B \in \mathcal{B}(G)$. Since $g \mapsto \langle\varphi|(P\beta(g)(T) - \beta(g)(T)P)\varphi\rangle$ is continuous, it is thus zero for all $g \in G$. Hence, $P\beta(g)(T) = \beta(g)(T)P$ for all $g \in G$.

Let U_η denote the map $g \mapsto U(g)\eta$. We then have

$$P|U_\eta(g)\rangle\langle U_\eta(g)| = |U_\eta(g)\rangle\langle U_\eta(g)|P$$

for all $g \in G$.

It follows that for each $g \in G$, either $U_\eta(g) \in P(\mathcal{H})$ or $U_\eta(g) \in P(\mathcal{H})^\perp$. Let $f: G \to \{0,1\}$ be the function such that $f(g) = 0$ if $U_\eta(g) \in P(\mathcal{H})$ and $f(g) = 1$ if $U_\eta(g) \in P(\mathcal{H})^\perp$. Then f is continuous, when the set $\{0,1\}$ is equipped with the discrete topology. Indeed, let $g_0 \in G$. Since U_η is continuous, $W = U_\eta^{-1}(\{\varphi \in \mathcal{H} \,|\, \|U_\eta(g_0) - \varphi\| < \sqrt{2}\})$ is an open set in G containing g_0. Assume first that $f(g_0) = 0$. Since all vectors $U_\eta(g)$ are of unit length, it follows that $\|U_\eta(g) - U_\eta(g_0)\| = \sqrt{2}$ whenever $f(g) = 1$. Hence, $f(W) \subset \{0\}$. Similarly, if we assume that $f(g_0) = 1$, it follows that $f(W) \subset \{1\}$. This implies that f is continuous. Since G is connected, f cannot be a surjection, so either $U_\eta(g) \in P(\mathcal{H})$ for all $g \in G$, or $U_\eta(g) \in P(\mathcal{H})^\perp$ for all $g \in G$. But, due to the irreducibility of the projective representation U, the closed linear span of the set $\{U_\eta(g) \,|\, g \in G\}$ is dense in $\mathcal{H}$. This is clearly possible only if either $P = I$ or $P = O$. The proof is complete. □

The following observation is another consequence of the irreducibility of the projective representation associated with β. It uses a calculation similar to that appearing e.g. in Ref. 40, p. 40 in a different context. Part (a) is mentioned also in Ref. 39.

Proposition 4: Assume that G is connected and let U be the projective representation associated with β. Let $E: \mathcal{B}(G) \to L(\mathcal{H})$ be a β -covariant observable.

(a) *Assume that $f \in \mathcal{F}(G)$ is such that $\widetilde{D}(f,E) \subset \widetilde{D}(f(g\cdot),E)$* for all $g \in G$. *Then $U(g)\widetilde{D}(f,E) = \widetilde{D}(f,E)$ for all $g \in G$, and either $\widetilde{D}(f,E) = \{0\}$ or $\widetilde{D}(f,E)$ is dense.*

(b) *Assume that $f \in \mathcal{F}(G)$ is such that $D(f,E) \subset D(f(g\cdot),E)$ for all $g \in G$. Then $U(g)D(f,E) = D(f,E)$ for all $g \in G$, and either $D(f,E) = \{0\}$ or $D(f,E)$ is dense. Moreover,*

$$U(g)^* L(f,E) U(g) \subset L(f(g\,\cdot),E) \tag{3}$$

for all $g \in G$.

Proof: Let T be the positive trace one operator associated with E, so that

$$\widetilde{D}(f,E) = \{\varphi \in \mathcal{H} | g \mapsto |f(g)|^2 \langle\varphi|U(g)TU(g)^*\varphi\rangle \text{ is } \lambda\text{-integrable}\},$$

$$D(f,E) = \{\varphi \in \mathcal{H} | g \mapsto |f(g)||\langle\psi|U(g)TU(g)^*\varphi\rangle| \text{ is } \lambda\text{-integrable for all } \psi \in \mathcal{H}\}.$$

For all $h, g \in G$, we have $U(h)^*U(g) = c(g,h)U(h^{-1}g)$, where $(h,g) \mapsto c(h,g)$ is some torus valued function, so that $U(g)^*U(h) = [U(h)^*U(g)]^* = c(g,h)^{-1}U(h^{-1}g)^*$, and hence

$$U(h)^*U(g)TU(g)^*U(h) = U(h^{-1}g)TU(h^{-1}g)^*. \tag{4}$$

(a) Let $\varphi \in \widetilde{D}(f,E)$, and $h \in G$. By the left invariance of the Haar measure and (4), we have

$$\begin{aligned}\int |f(g)|^2 \langle U(h)\varphi|U(g)TU(g)^*U(h)\varphi\rangle d\lambda(g) &= \int |f(g)|^2 \langle\varphi|U(h^{-1}g)TU(h^{-1}g)^*\varphi\rangle d\lambda(g) \\ &= \int |f(hg)|^2 \langle\varphi|U(g)TU(g)^*\varphi\rangle d\lambda(g),\end{aligned}$$

with all the integrands positive. Since $\varphi \in \widetilde{D}(f(h\cdot),E)$ by assumption, the last integral is finite, so $U(h)\varphi \in \widetilde{D}(f,E)$. Thus $\widetilde{D}(f,E)$ is an invariant subspace of the projective represen-

tation U, implying that the closure $\overline{\tilde{D}(f,E)}$ is a closed invariant subspace of U. It follows from the irreducibility of U that $\tilde{D}(f,E)$ is either trivial or dense. The fact that $U(h)\tilde{D}(f,E)=\tilde{D}(f,E)$ follows because we have $U(h^{-1})=c'(h)U(h)^*$ for some torus valued function c'. The proof of (a) is complete.

(b) Let $h\in G$, $\varphi\in D(f,E)$, and $\psi\in\mathcal{H}$. Then by using (4) and the assumption, we get

$$\begin{aligned}\int |f(g)||\langle\psi|U(g)TU(g)^*U(h)\varphi\rangle|d\lambda(g) &= \int |f(g)||\langle U(h)U(h)^*\psi|U(g)TU(g)^*U(h)\varphi\rangle|d\lambda(g)\\ &= \int |f(g)||\langle U(h)^*\psi|U(h^{-1}g)TU(h^{-1}g)^*\varphi\rangle|d\lambda(g)\\ &= \int |f(hg)||\langle U(h)^*\psi|U(g)TU(g)^*\varphi\rangle|d\lambda(g)<\infty,\end{aligned}$$

so that $U(h)\varphi\in D(f,E)$. Thus $D(f,E)$ is an invariant subspace for U, and hence $D(f,E)$ is either trivial or dense. The fact that $U(h)D(f,E)=D(f,E)$ follows for the same reason as the corresponding one in (a).

Let $h\in G$. By repeating the preceding calculation without the absolute value signs, we get

$$\langle\psi|L(f,E)U(h)\varphi\rangle=\langle U(h)^*\psi|L(f(h\cdot),E)\varphi\rangle=\langle\psi|U(h)L(f(h\cdot),E)\varphi\rangle$$

for each $\psi\in\mathcal{H}$ and $\varphi\in U(h)^*D(f,E)=D(f,E)\subset D(f(h\cdot),E)$, so that (3) holds. □

Remark:

(a) If we assume $D(f,E)=D(f(g\cdot),E)$ for all $g\in G$, then Proposition 4 (b) gives the strict operator equality $U(g)^*L(f,E)U(g)=L(f(g\cdot),E)$ for each $g\in G$, with dense domain $D(f,E)$. This resembles the covariance condition for the observable E.

(b) Since each $E_{\psi,\varphi}$ is a finite measure, it is clear that the conditions of Proposition 4 (a) and (b) are satisfied, e.g., by all functions $f\in\mathcal{F}(G)$ with the property that for each $h\in G$ there are nonnegative constants K_h and M_h, such that $|f(hg)|\leqslant K_h|f(g)|+M_h$ for almost all $g\in G$. In the case where $G=\mathbb{R}^{2n}$ (see the beginning of the next section), all polynomials of the form $\mathbb{R}^{2n}\ni(x_1,\ldots,x_{2n})\mapsto p(x_i)\in\mathbb{R}$, where $p:\mathbb{R}\to\mathbb{R}$ is a polynomial and $i=1,\ldots,2n$, are like this.

IV. PHASE SPACE QUANTIZATION ON $\mathbb{R}^2$

Consider the special case where $G=\mathbb{R}^2$, with λ the Lebesgue measure. Fix $\{|n\rangle|n\geq 0\}$ to be an orthonormal basis of $\mathcal{H}$, and let $U:L^2(\mathbb{R})\to\mathcal{H}$ be the unitary operator that maps the nth Hermite function h_n to $|n\rangle$. Define $W(q,p)=UW_0(q,p)U^{-1}$, where $(W_0(q,p)f)(t)=e^{i1/2qp}e^{ipt}f(t+q)$, and $\beta:\mathbb{R}^2\to\mathrm{Aut}(\mathcal{T}(\mathcal{H}))$ by $\beta(q,p)(T)=W(-q,p)TW(-q,p)^*$. Now β is a continuous group homomorphism, satisfying (1), with $d=2\pi$, and λ the Lebesgue measure of $\mathbb{R}^2$. Let $A_\pm$ be the ladder operators associated with the basis $\{|n\rangle\}$, and define Q and P to be the closures of the operators $1/\sqrt{2}(A_++A_-)$ and $1/\sqrt{2}i(A_+-A_-)$, respectively. Then $A_+=A_-^*$, and Q and P are unitarily equivalent to the position and momentum operators in $L^2(\mathbb{R})$ via U. Let N denote the self-adjoint operator A_+A_-.

According to the general result described above, each positive operator T of trace one generates the map $f\mapsto L(f,E^T)$, where

$$E^T(B)=d^{-1}\int_B\beta(q,p)(T)d\lambda(q,p).$$

The generating operators T of the form $T=\Sigma_n w_n|n\rangle\langle n|$, where $\Sigma_n w_n=1$, and $w_n\geqslant 0$ for each n, have a special significance, as they are the ones for which E^T is covariant with respect to the phase shifts also, i.e.,

$$e^{i\theta N}E^T([0,\infty)\times B)e^{-i\theta N}=E^T([0,\infty)\times(B+\theta))$$

for all $\theta\in[0,2\pi)$ and $B\in B([0,2\pi))$, where $\mathbb{R}^2=[0,\infty)\times[0,2\pi)$ and the sum $B+\theta$ is understood modulo 2π. (cf. Ref. 23).

Since $(q,p)\mapsto W(q,p)$ is a strongly continuous projective representation, and $\mathbb{R}^2$ is connected, Proposition 3 tells us that the range of E^T does not contain nontrivial projections. In particular, the corresponding quantization scheme cannot then produce spectral measures.

In this section, we inspect the possibility of applying the quantization scheme described earlier to the classical position and momentum variables, using the quantization map $\Gamma^T=L(\cdot,E^T)$ with various generating operators T. For each $k\in\mathbb{N}$, let x^k and y^k denote the functions $(q,p)\mapsto q^k$ and $(q,p)\mapsto p^k$.

The essential question is whether the operator measures $B\mapsto E^T(B\times\mathbb{R})$ and $B\mapsto E^T(\mathbb{R}\times B)$ are uniquely determined by their respective moment operator sets $\{\Gamma^T(x^k)\,|\,k\in\mathbb{N}\}$ and $\{\Gamma^T(y^k)\,|\,k\in\mathbb{N}\}$. It is known that this is indeed the case when T is a number state $|n\rangle\langle n|$, $n\geq 0$ (see Ref. 13). In that case, the operator sets $\{\Gamma^T(x^k)\,|\,k\in\mathbb{N}\}$ and $\{\Gamma^T(y^k)\,|\,k\in\mathbb{N}\}$ are eligible to represent the quantizations of x and y, respectively. As is well known, the associated quantum mechanical observables are unsharp position and momentum observables.

Our goal here is to explicitly determine the operators $\Gamma^T(x^k)$ and $\Gamma^T(y^k)$ for certain generating operators T.

To begin with, we consider the square integrability domains. According to Proposition 4 and the associated Remark, these sets are either dense or trivial. The following two Propositions specify them completely.

Proposition 5: Let $k\in\mathbb{N}$, let $\eta\in\mathcal{H}$ be a unit vector, and denote $u=U^{-1}\eta\in L^2(\mathbb{R})$.

(a) *$\widetilde{D}(x^k,E^{|\eta\rangle\langle\eta|})\neq\{0\}$ if and only if $\eta\in D(Q^k)$, and in this case, $\widetilde{D}(x^k,E^{|\eta\rangle\langle\eta|})=D(Q^k)$.*

(b) *The statement of (a) holds true, if "x" and "Q" are replaced by "y" and "P."*

Proof: Let $0\neq\varphi\in\mathcal{H}$ and $f=U^{-1}\varphi\in L^2(\mathbb{R})$. We get

$$\begin{aligned}\int_{\mathbb{R}^2}q^{2k}dE^{|\eta\rangle\langle\eta|}_{\varphi,\varphi}(q,p)&=\frac{1}{2\pi}\int q^{2k}\left(\int|\langle\varphi|W(-q,p)|\eta\rangle|^2dp\right)dq=\int q^{2k}\left(\int|F(\bar{u}(\cdot-q)f)(p)|^2dp\right)dq\\&=\int q^{2k}\left(\int|u(t-q)|^2|f(t)|^2dt\right)dq=\int\left(\int q^{2k}|u(t-q)|^2|f(t)|^2dq\right)dt\\&=\int\int(t-q)^{2k}|u(q)|^2|f(t)|^2dqdt,\end{aligned}$$

where Lemma 2 of Ref. 18, the unitarity of the Fourier-Plancherel operator, and Fubini's theorem have been used. (Since all the functions and measures involved are positive, the calculation is valid regardless of whether the integrals are finite or not.)

Now the last integral is finite if and only if φ and η are both in $D(Q^k)$. This is seen as follows.

Assume first that the last integral is finite. Then it follows from Fubini's theorem that $t\mapsto(t-q)^{2k}|f(t)|^2|u(q)|^2$ is integrable for almost all q, and $q\mapsto(t-q)^{2k}|u(q)|^2|f(t)|^2$ is integrable for almost all t. Thus $t\mapsto t^{2k}|f(t)|^2$ and $q\mapsto q^{2k}|u(q)|^2$ are integrable. (The fact that $t\mapsto t^{2k}|f(t)|^2$ is integrable is seen as follows: Take $q\in\mathbb{R}$, such that $|u(q)|^2>0$ and $t\mapsto(t-q)^{2k}|f(t)|^2|u(q)|^2$ is integrable. This is possible, since $\|\eta\|>0$, which implies that $|u(q)|^2>0$ in some non-null set. Then use the fact that there exist positive constants A,B,M, such that $At^{2k}\leq(t-q)^{2k}\leq Bt^{2k}$ for $|t|\geq M$. The fact that $q\mapsto q^{2k}|u(q)|^2$ is integrable follows similarly, since we assumed that also $\|\varphi\|>0$.) Thus f and u are in the domain of the kth power of the position operator in $L^2(\mathbb{R})$, so $\varphi,\eta\in D(Q^k)$.

Conversely, assume that $\varphi,\eta\in D(Q^k)$, so that $t\mapsto t^{2k}|f(t)|^2$ and $q\mapsto q^{2k}|u(q)|^2$ are integrable. Hence also $t\mapsto|t^l\|f(t)|^2$ and $q\mapsto|q^l\|u(q)|^2$ are integrable for all $l\leq 2k$, implying that $(t,q)\mapsto(t-q)^{2k}|u(q)|^2|f(t)|^2$ is integrable over $\mathbb{R}^2$. Thus the last integral of the above calculation is finite.

We conclude that $\widetilde{D}(x^k,E^{|\eta\rangle\langle\eta|})\neq\{0\}$ if and only if $\eta\in D(Q^k)$, and in this case, $\widetilde{D}(x^k,E^{|\eta\rangle\langle\eta|})=D(Q^k)$.

The result concerning $\widetilde{D}(y^k, E^{|\eta\rangle\langle\eta|})$ is obtained in an analogous manner by using the calculation

$$\begin{aligned}\int_{\mathbb{R}^2} p^{2k} dE^{|\eta\rangle\langle\eta|}_{\varphi,\varphi}(q,p) &= \frac{1}{2\pi}\int p^{2k}\left(\int |\langle\varphi|W(-q,p)|\eta\rangle|^2 dq\right)dp \\ &= \int p^{2k}\left(\int |F^{-1}(\overline{Fu}(\cdot - p)Ff)(q)|^2 dq\right)dp \\ &= \int p^{2k}\left(\int |Fu(t-p)|^2 |Ff(t)|^2 dx\right)dp \\ &= \int \left(\int p^{2k}|Fu(t-p)|^2 |Ff(t)|^2 dp\right)dt \\ &= \int\int (t-p)^{2k}|Fu(p)|^2|Ff(t)|^2 dp dt,\end{aligned}$$

as well as the fact that $P = UF^{-1}U^{-1}QUFU^{-1}$.

Now we consider the case of an arbitrary positive operator T of trace one. The following elementary fact is needed. The proof is included for the reader's convenience.

Lemma 1: Let T be a positive operator of trace one. Let (η_n) *be an orthonormal sequence and* (w_n) a sequence of nonnegative numbers, such that $T = \Sigma_n w_n |\eta_n\rangle\langle\eta_n|$. *Let A be a closed operator. Then*

$$\sum_{n=1}^{\infty} w_n \|A\eta_n\|^2 < \infty,$$

if and only if $A\sqrt{T}$ *is a Hilbert-Schmidt operator. [Here we have denoted* $\|A\eta_n\| = \infty$ *whenever* $\eta_n \notin D(A)$, *and used the convention* $0\cdot\infty = 0$.*] In particular, the convergence of the series is not dependent on the representation of T in terms of* (η_n) *and* (w_n).

Proof: Let $S = \Sigma_{n=1}^{\infty} w_n \|A\eta_n\|^2 (\leqslant \infty)$. Assume first that $S < \infty$, so that, in particular, $\eta_n \in D(A)$ for all those $n \in \mathbb{N}$ for which $w_n > 0$. Let $\varphi \in \mathcal{H}$. Since the series $\sqrt{T} = \Sigma_n \sqrt{w_n} |\eta_n\rangle\langle\eta_n|$ converges in the operator norm, the vector series $\Sigma_n \sqrt{w_n}\langle\eta_n|\varphi\rangle\eta_n$ converges to $\sqrt{T}\varphi$ in the norm of $\mathcal{H}$. Since (η_n) is orthonormal, the Cauchy-Schwartz inequality gives

$$\sum_n \sqrt{w_n}|\langle\eta_n|\varphi\rangle| \|A\eta_n\| \leqslant \sqrt{S}\|\varphi\| < \infty,$$

so also the series $\Sigma_n \sqrt{w_n}\langle\eta_n|\varphi\rangle A\eta_n$ converges in norm. Since A is closed, it follows that $\sqrt{T}\varphi \in D(A)$ and $A\sqrt{T}\varphi$ equals the sum of the latter series. In particular, $D(A\sqrt{T}) = \mathcal{H}$. Now the previous inequality shows that $\|A\sqrt{T}\varphi\| \leqslant \sqrt{S}\|\varphi\|$, so $A\sqrt{T}$ is bounded. Clearly $\Sigma_{\xi\in K}\|A\sqrt{T}\xi\|^2 = S < \infty$ if K is an orthonormal basis of H, which includes all the η_n, so $A\sqrt{T}$ is Hilbert-Schmidt.

Assume then that $A\sqrt{T}$ is a Hilbert-Schmidt operator. Now $\eta_n = w_n^{-1/2}\sqrt{T}\eta_n \in D(A)$ if $w_n > 0$, and $S = \Sigma_{\xi\in K}\|A\sqrt{T}\xi\|^2 < \infty$, where $\mathcal{K}$ is an orthonormal basis including all the η_n. □

Proposition 6:

(a) *Let* $k \in \mathbb{N}$. *Then* $\widetilde{D}(x^k, E^T) \neq \{0\}$ *if and only if* $Q^k\sqrt{T}$ *is a Hilbert-Schmidt operator, and in that case,* $\widetilde{D}(x^k, E^T) = D(Q^k)$.

(b) *The statement in* (*a*) *holds true, if* "*x*" *and* "*Q*" *are replaced by* "*y*" *and* "*P*."

Proof: Write T in the form $T = \Sigma_{n=1}^{\infty} w_n |\eta_n\rangle\langle\eta_n|$, where $\Sigma_n w_n = 1$, $t_n \geqslant 0$, and (η_n) is an orthonormal sequence in $\mathcal{H}$. The series converges in the trace norm, as well as in the operator norm.

For each $\varphi \in \mathcal{H}$, let $A^{\eta}_{\varphi,\varphi}$ be the density function of the positive measure $E^{|\eta\rangle\langle\eta|}_{\varphi,\varphi}$. Since the density function of the measure $E^T_{\varphi,\varphi}$ is $\Sigma_n w_n A^{\eta_n}_{\varphi,\varphi}$, we have $\varphi \in \widetilde{D}(x^k, E^T)$ if and only if the function

$x^{2k}\Sigma_n w_n A^{\eta_n}_{\varphi,\varphi}$ is integrable over $\mathbb{R}^2$. In view of the Proposition 5, it is therefore clear that $\tilde{D}(x^k,E^T)\neq\{0\}$ only if $\eta_n\in D(Q^k)$ for all those $n\in\mathbb{N}$ for which $w_n>0$, and that in any case, $\tilde{D}(x^k,E^T)\subset D(Q^k)$.

Assume now that $\eta_n\in D(Q^k)$ for all $n\in\mathbb{N}$ with $w_n>0$, and $0\neq\varphi\in D(Q^k)$. Let $u_n=U^{-1}\eta_n$ for each n. The monotone convergence theorem and the proof of Proposition 5 imply that

$$\int x^{2k}dE^T_{\varphi,\varphi}=\sum_n w_n\int x^{2k}dE^{|\eta_n\rangle\langle\eta_n|}_{\varphi,\varphi}=\int\int\sum_n (t-q)^{2k}w_n|u_n(q)|^2|(U^{-1}\varphi)(t)|^2dtdq$$

(regardless of whether the series converges or not). Now if the above integral is finite [i.e., $\varphi\in\tilde{D}(x^k,E^T)$], then Fubini's theorem gives that $q\mapsto(t-q)^{2k}|(U^{-1}\varphi)(t)|^2\Sigma_n w_n|u_n(q)|^2$ is integrable for almost all t, so by the argument similar to that used in the proof of the preceding Proposition, it follows that $\Sigma_n w_n\|Q^k\eta_n\|^2=\int\Sigma_n w_n q^{2k}|u_n(q)|^2dq<\infty$. On the other hand, if $\Sigma_n w_n\|Q^k\eta_n\|^2<\infty$, then each function $q\mapsto\Sigma_n w_n q^l|u_n(q)|^2$, with $l\leqslant 2k$ is integrable, so that $(q,t)\mapsto\Sigma_n(t-q)^{2k}w_n|u_n(q)|^2|(U^{-1}\varphi)(t)|^2$ is integrable over $\mathbb{R}^2$. [Note that since we assumed that $\varphi\in D(Q^k)$, the function $t\mapsto t^l|(U^{-1}\varphi)(t)|^2$ is integrable for each $l\leqslant 2k$.] Thus $\int x^{2k}dE^T_{\varphi,\varphi}<\infty$, so $\varphi\in\tilde{D}(x^k,E^T)$.

We have proved that $\tilde{D}(x^k,E^T)\neq\{0\}$ if and only if $\eta_n\in D(Q^k)$ for all $n\in\mathbb{N}$ with $w_n>0$, and

$$\sum_{n=1}^{\infty} w_n\|Q^k\eta_n\|^2<\infty$$

[where it is understood that $\|Q^k\eta_n\|=\infty$ if $\eta_n\notin D(Q^k)$ and we use the convention $0\cdot\infty=\infty$]. Since Q^k is closed, (a) follows from the preceding Lemma. The statement of (b) is proved similarly, since

$$\int x^{2k}dE^T_{\varphi,\varphi}=\int\int\sum_n w_n(t-p)^{2k}|Fu_n(p)|^2|FU^{-1}\varphi(t)|^2dpdt,$$

$P=UF^{-1}U^{-1}QUFU^{-1}$, and P^k is also closed. The proof is complete. □

Now we proceed to determine the operators $L(x^k,E^T)$ and $L(y^k,E^T)$ for $T=\Sigma_n w_n|\eta_n\rangle\langle\eta_n|$ satisfying the condition of the preceding Proposition.

Theorem 4:

(a) *Assume that T satisfies the condition of the previous Proposition* (*a*). *Then* $L(x^k,E^T)=\Sigma_{l=0}^k s^Q_{kl}Q^l$, *where* $s^Q_{kl}=\binom{k}{l}(-1)^{k-l}\operatorname{Tr}[Q^{k-l}T]$, *with each* $Q^{k-l}T$ *a trace class operator*.

(b) *The statement in* (*a*) *holds true, if* "(*a*)," "*x*," *and* "*Q*" *are replaced by* "(*b*)," "*y*," *and* "*P*."

Proof: Assume first that $T=|\eta\rangle\langle\eta|$ for $\eta\in D(Q^k)$. Denote $u=U^{-1}\eta\in L^2(\mathbb{R})$. Define a polynomial $p^\eta:\mathbb{R}\to\mathbb{R}$ by

$$p^\eta(t)=\langle\eta|(t-Q)^k\eta\rangle=\sum_{l=0}^{k}\binom{k}{l}(-1)^{k-l}\langle\eta|Q^{k-l}\eta\rangle t^l.$$

Since p^η is a polynomial of order k, the operator $p^\eta(Q)$ is self-adjoint, and has the domain $D(Q^k)$. Thus by Proposition 5 we have $D(p^\eta(Q))=D(Q^k)=\tilde{D}(x^k,E^{|\eta\rangle\langle\eta|})$.

Let $\varphi\in\tilde{D}(x^k,E^{|\eta\rangle\langle\eta|})\subset D(x^k,E^{|\eta\rangle\langle\eta|})$, and $\psi\in\mathcal{H}$. Let $f=U^{-1}\varphi$, $g=U^{-1}\psi$. Since the function

$$(q,p)\mapsto q^k\langle\psi|W(-q,p)|\eta\rangle\overline{\langle\varphi|W(-q,p)|\eta\rangle}$$

is integrable over $\mathbb{R}^2$ [by the definition of $D(x^k,E^{|\eta\rangle\langle\eta|})$], we get

$$\langle\psi|L(x^k,E^{|\eta\rangle\langle\eta|})\varphi\rangle = \int_{\mathbb{R}^2} q^k dE^{|\eta\rangle\langle\eta|}_{\psi,\varphi}(q,p) = \frac{1}{2\pi}\int q^k\left(\int \langle\psi|W(-q,p)|\eta\rangle\overline{\langle\varphi|W(-q,p)|\eta\rangle}dp\right)dq$$

$$= \int q^k\left(\int \overline{F(\bar{u}(\cdot-q)g)(p)}F(\bar{u}(\cdot-q)f)(p)dp\right)dq$$

$$= \int q^k\left(\int \overline{u(t-q)g(t)}u(t-q)f(t)dt\right)dq = \int\left(\int q^k|u(t-q)|^2dq\right)\overline{g(t)}f(t)dt$$

$$= \int\left(\int (t-q)^k|u(q)|^2dq\right)\overline{g(t)}f(t)dt,$$

$$= \int \langle\eta|(t-Q)^k|\eta\rangle\overline{g(t)}f(t)dt = \langle\psi|p^\eta(Q)\varphi\rangle.$$

The fifth equality follows from Fubini's theorem, since $(q,t)\mapsto q^k|u(t-q)|^2\overline{g(t)}f(t)$ is integrable [because of the Cauchy-Schwarz inequality and the square integrability of the maps $(q,t)\mapsto|u(t-q)g(t)|$ and $(q,t)\mapsto|q^ku(t-q)f(t)|$, the latter being a consequence of the proof of Proposition 5.] It follows that $p^\eta(Q)\subset L(x^k,E^{|\eta\rangle\langle\eta|})$.

The equality $p^\eta(Q)=L(x^k,E^{|\eta\rangle\langle\eta|})$ follows from the fact that being self-adjoint, the operator $p^\eta(Q)$ cannot have a proper symmetric extension.

Now we take $T=\Sigma_n w_n|\eta_n\rangle\langle\eta_n|$ under the condition of the preceding Proposition, so that $\tilde{D}(x^k,E^T)=D(Q^k)=\tilde{D}(x^k,E^{|\eta\rangle\langle\eta|})$ for each n. Let $\varphi\in D(Q^k)$ and $\psi\in\mathcal{H}$, and f,g be as before.

According to Proposition 1 of Ref. 18, we have

$$\langle\psi|L(x^k,E^T)\varphi\rangle = \sum_{n=1}^{\infty} w_n\langle\psi|L(x^k,E^{|\eta_n\rangle\langle\eta_n|})\varphi\rangle$$

$$= \sum_{n=1}^{\infty} w_n\langle\psi|p^{\eta_n}(Q)\varphi\rangle = \sum_{n=1}^{\infty} w_n\sum_{l=0}^{k}\binom{k}{l}(-1)^{k-l}\langle\eta_n|Q^{k-l}\eta_n\rangle\langle\psi|Q^l\varphi\rangle.$$

Since

$$\|Q^{k-l}\eta_n\|^2 = \int q^{2(k-l)}|(U^{-1}\eta_n)(q)|^2dq \leqslant 1+\int q^{2k}|(U^{-1}\eta_n)(q)|^2dq = 1+\|Q^k\eta_n\|,$$

it follows from the preceding Lemma that also each $Q^{k-l}\sqrt{T}$ is defined in all of $\mathcal{H}$ and is a Hilbert-Schmidt operator. Thus each $Q^{k-l}T=Q^{k-l}\sqrt{T}\sqrt{T}$ is defined in all of $\mathcal{H}$ and is a bounded operator of trace class. Thus the series $\Sigma_n w_n\langle\eta_n|Q^{k-l}\eta_n\rangle$ converges (clearly to $\mathrm{Tr}\,[Q^{k-l}T]$) for each l, so

$$\langle\psi|L(x^k,E^T)\varphi\rangle = \sum_{l=0}^{k} s^Q_{kl}\langle\psi|Q^l\varphi\rangle.$$

Since φ was arbitrarily chosen from the set $\tilde{D}(x^k,E^T)=D(Q^k)$ and the operator $\Sigma_{l=0}^k s^Q_{kl}Q^l$ is self-adjoint, we conclude that $L(x^k,E^T)=\Sigma_{l=0}^k s^Q_{kl}Q^l$, and the proof of (a) is complete.

Statement (b) is proved similarly by using the unitary equivalence of Q and P. □

Remark: As mentioned at the beginning of the section, the uniqueness of the operator measure that gives the moment operators of Theorem 4, is verified only in the case where $T=|n\rangle\langle n|$ for some n. The uniqueness question in the general case remains open.

We close this section with a remark on another application of our quantization scheme. Consider the function $h(q,p)=\frac{1}{2}(q^2+p^2)$, i.e., the classical oscillator energy variable. It is known that for each $n\in\mathbb{N}$, the operators $\Gamma^{|n\rangle\langle n|}(h^k)$, $k\in\mathbb{N}$, are the moment operators of the polar margin of the phase space observable $E^{|n\rangle\langle n|}$, and that the marginal observable is uniquely determined by

its moments.[12] Thus a quantization of h is given by the set $\{\Gamma^{|n\rangle\langle n|}(h^k)\,|\,k\in\mathbb{N}\}$ of operators. These operators were determined explicitly in Ref. 22; they are certain polynomials of the usual oscillator Hamiltonian $\frac{1}{2}(Q^2+P^2)$. The quantized oscillator energy observable is the unsharp number observable (see Ref. 4, p. 90).

V. OPTIMAL PHASE SPACE QUANTIZATION IN $\mathbb{R}^2$

Consider the situation of the previous section. At least in the case where $T=|n\rangle\langle n|$, the quantizations of the position and momentum variables x and y corresponding to the covariant quantization map $\Gamma^T=L(\cdot,E^T)$ are the Cartesian margins of E^T, or, equivalently, the sets of the operators $\{\Gamma^T(x^k)\,|\,k\in\mathbb{N}\}$ and $\{\Gamma^T(y^k)\,|\,k\in\mathbb{N}\}$. If the margins were projection valued, the quantization of, e.g., x would just be the spectral measure of $L(x,E^T)$, with each operator $L(x^k,E^T)$ equal to the corresponding power of $L(x,E^T)$. Although this is not the case, we can still try to find those generating operators T for which the situation would be in some sense close to this ideal situation, where only the first power of x is needed to determine its quantization.

First, we can find the generating operators T that give $L(x,E^T)=Q$ and $L(y,E^T)=P$, so as to make the operators $\Gamma^T(x)$ and $\Gamma^T(y)$ equal to the actual position and momentum operators. In view of Theorem 4, we know that the square integrability domains of $L(x,E^T)$ and $L(y,E^T)$ are nontrivial if and only if $Q\sqrt{T}$ and $P\sqrt{T}$ are Hilbert-Schmidt operators. In that case we have

$$L(x,E^T)=Q-\mathrm{Tr}\,[QT]I,$$

$$L(y,E^T)=P-\mathrm{Tr}\,[PT]I.$$

So if we assume that the square integrability domains of $L(x,E^T)$ and $L(y,E^T)$ are nontrivial, we have $L(x,E^T)=Q$ and $L(y,E^T)=P$ exactly when T is such that $\mathrm{Tr}\,[QT]=\mathrm{Tr}\,[PT]=0$. This occurs, for example, if we choose T to be a mixture of number states, i.e., $T=\Sigma_n w_n|n\rangle\langle n|$. Then the above Hilbert-Schmidt conditions take the form $\Sigma_n w_n n<\infty$.[18]

Consider next the operators $\Gamma^T(x^2)$ and $\Gamma^T(y^2)$. According to Theorem 4, they are given by

$$L(x^2,E^T)=Q^2-2\mathrm{Tr}\,[QT]Q+\mathrm{Tr}\,[Q^2T]I,$$

$$L(y^2,E^T)=P^2-2\mathrm{Tr}\,[PT]P+\mathrm{Tr}\,[P^2T]I,$$

provided that $Q^2\sqrt{T}$ and $P^2\sqrt{T}$ are Hilbert-Schmidt operators [or, equivalently, that $\tilde{D}(x^2,E^T)$ and $\tilde{D}(y^2,E^T)$ are nontrivial]. In order to make the situation close to the spectral measure case, we would like to minimize the "noise" operators $R^T(x)=L(x^2,E^T)^2-L(x,E^T)^2$ and $R^T(y)=L(y^2,E^T)^2-L(y,E^T)^2$. Now

$$R^T(x)=(\mathrm{Tr}\,[Q^2T]-\mathrm{Tr}\,[QT]^2)I=\mathrm{Var}(Q,T)I,$$

$$R^T(y)=(\mathrm{Tr}\,[P^2T]-\mathrm{Tr}\,[PT]^2)I=\mathrm{Var}(P,T)I,$$

on the domains $D(Q^2)$ and $D(P^2)$, respectively, where, e.g., $\mathrm{Var}(Q,T)$ denotes the variance of the probability measure $p_T^Q:=\mathrm{Tr}\,[TE^Q(\cdot)]$, with E^Q the spectral measure of Q. The last equalities are obtained as follows: Let $T=\Sigma_n w_n|\eta_n\rangle\langle\eta_n|$, $p_T^Q=\mathrm{Tr}\,[TE^Q(\cdot)]$, and $p_n^Q=\langle\eta_n|E^Q(\cdot)\,\eta_n\rangle$, where E^Q is the spectral measure of Q. Now $p_T^Q=\Sigma_n w_n p_n^Q$, with the series converging absolutely in the total variation norm, so we have (by, e.g., Lemma 1 of Ref. 18) that

$$\mathrm{Tr}\,[Q^2T]-\mathrm{Tr}\,[QT]^2=\sum_n w_n\langle\eta_n|Q^2\eta_n\rangle-\left(\sum_n w_n\langle\eta_n|Q\eta_n\rangle\right)^2$$
$$=\sum_n w_n\int x^2dp_n^Q-\left(\sum_n w_n\int xdp_n^Q\right)^2=\int x^2dp_T^Q-\left(\int xdp_T^Q\right)^2.$$

Therefore, $R^T(x)=\mathrm{Var}(Q,T)$. The result $R^T(y)=\mathrm{Var}(P,T)I$ follows similarly. Since $\mathrm{Var}(Q,T)$ and $\mathrm{Var}(P,T)$ are always positive, we see explicitly that $R^T(x)$ and $R^T(y)$ are never zero.

As is well known, the generating operator T can be chosen so that, e.g., $R^T(x)=\mathrm{Var}(Q,T)I$ is arbitrarily small [in the sense that $\|R^T(x)\|=\mathrm{Var}(Q,T)$ is such], but then $R^T(y)$ becomes large, because of the inequality $\mathrm{Var}(Q,T)\mathrm{Var}(P,T)\geqslant\frac{1}{4}$. The product $R^T(x)R^T(y)$ can reach its lower bound $\frac{1}{4}$ only in the case where T is a vector state of minimal uncertainty. If we assume that $\mathrm{Tr}\,[QT]=0=\mathrm{Tr}\,[PT]$ as discussed before, the operators T that give $R^T(x)R^T(y)=\frac{1}{4}$ are of the form $T=|\eta\rangle\langle\eta|$, with

$$(U^{-1}\eta)(t)=(\sqrt{\pi}\Delta q)^{-1/2}e^{-[t^2/4(\Delta q)^2]},$$

where $\Delta q>0$ [in fact, $(\Delta q)^2=\mathrm{Var}(Q,|\eta\rangle\langle\eta|)$ (Ref. 35, p. 92)]. Moreover, we could require that $R^T(x)=R^T(y)$, so as to make the situation symmetric between x and y. This leaves us with only one generating operator, namely $T=|0\rangle\langle 0|$. Note that this choice indeed gives a quantization of position and momentum, for the associated operator measure is uniquely determined by its moment operators (see Remark of Theorem 4).

VI. WHEN IS A POSITIVE OPERATOR MEASURE PROJECTION VALUED?

Let $E:\mathcal{B}(\mathbb{R})\to L(\mathcal{H})$ be a positive operator measure. If E is a spectral measure, the first moment $L(x,E)$ is always self-adjoint on the domain $\widetilde{D}(x,E)$, and $\int x^2dE_{\varphi,\varphi}=\|L(x,E)\varphi\|^2$ for all $\varphi\in\widetilde{D}(x,E)$. In the case of a general positive operator measure, this need not be true, as the above case of the Cartesian margins of the phase space observable E^T demonstrates. It turns out that this condition is sufficient for a positive operator E to be a spectral measure. This is explained in Ref. 1, p. 130, but the (sketch of) proof given there does not contain certain details, and so we give a (slightly different) proof here as part (b) of the following Proposition.

An adaptation of the steps leading to the result in Ref. 31, p. 466 gives part (a) of the following Proposition. For each $k\in\mathbb{N}$, we let $\widetilde{L}(x^k,E)$ denote the restriction of $L(x^k,E)$ to $\widetilde{D}(x^k,E)$.

Proposition 7: Let $E:\mathcal{B}(\mathbb{R})\to L(\mathcal{H})$ be a positive operator measure, such that

$$\int x^2dE_{\varphi,\varphi}=\|L(x,E)\varphi\|^2$$

for all $\varphi\in\widetilde{D}(x,E)$.

(a) $\widetilde{L}(x^n,E)=\widetilde{L}(x,E)^n$ *for all* $n\in\mathbb{N}$.

(b) If $\widetilde{L}(x,E)$ *is assumed to be self-adjoint, then E is projection valued.*

Proof: Let $P:\mathcal{B}(\mathbb{R})\to\mathcal{K}$ be a Naimark dilation of E into a spectral measure acting on a Hilbert space $\mathcal{K}$. Let $V:\mathcal{H}\to\mathcal{K}$ be the associated isometric map, so that $E(B)=V^*P(B)V$ for all $B\in\mathcal{B}(\mathbb{R})$. Denote by $P_{\mathcal{H}}$ the projection VV^*, acting on $\mathcal{K}$ with $\mathcal{V}\mathcal{H}$ as its range. (Note that V^*V is the identity operator of $\mathcal{H}$.) Now $\widetilde{L}(x^k,E)=V^*L(x^k,P)V$ for each $k\in\mathbb{N}$ (see Ref. 24). Since P is a spectral measure, we thus have

$$\widetilde{L}(x^k,E)=V^*A^kV \tag{5}$$

for all $k\in\mathbb{N}$, where $A=L(x,P)$. Denote $E_1=\widetilde{L}(x,E)$. We prove by induction that for each $n\in\mathbb{N}$,

$$\widetilde{D}(x^n,E) = D(E_1^n), \quad \text{and } A^n V\varphi = VE_1^n\varphi \text{ for all } \varphi \in \widetilde{D}(x^n,E). \tag{6}$$

Take first $n=1$, and let $\varphi \in \widetilde{D}(x,E)=D(E_1)=D(AV)$. Since the measures $E_{\varphi,\varphi}$ and $P_{V\varphi,V\varphi}$ are the same, and P is a spectral measure, the assumption implies that

$$\|AV\varphi\|^2 = \int x^2 dP_{V\varphi,V\varphi} = \int x^2 dE_{\varphi,\varphi} = \|E_1\varphi\|^2.$$

Using (5) and the fact that V is isometric, we thus get

$$\|AV\varphi\|^2 = \|E_1\varphi\|^2 = \|V^*AV\varphi\|^2 = \|P_H AV\varphi\|^2.$$

Since P_H is a projection, this means that

$$AV\varphi = P_{\mathcal{H}}AV\varphi = VE_1\varphi \text{ for all } \varphi \in \widetilde{D}(x,E) = D(E_1), \tag{7}$$

i.e., (6) holds for $n=1$. Now let $k \in \mathbb{N}$, $k>1$, and assume that (6) holds for $n=k-1$. Let $\varphi \in \widetilde{D}(x^k,E)$. By (5), this implies that $V\varphi \in D(A^k)$, so that $AV\varphi \in D(A^{k-1})$. Since $\varphi \in \widetilde{D}(x^k,E) \subset \widetilde{D}(x,E)$, it thus follows from (7) that $V(E_1\varphi)=AV\varphi \in D(A^{k-1})$, so (5) and the induction assumption give $E_1\varphi \in \widetilde{D}(x^{k-1},E)=D(E_1^{k-1})$. Hence, $\varphi \in D(E_1^k)$. Conversely, if $\varphi \in D(E_1^k)$, then $\varphi \in \widetilde{D}(x,E)=D(AV)$ and $E_1\varphi \in D(E_1^{k-1})=\widetilde{D}(x^{k-1},E)$, so $AV\varphi=V(E_1\varphi) \in D(A^{k-1})$ by (7) and (5), implying that $V\varphi \in D(A^k)$, i.e., $\varphi \in \widetilde{D}(x^k,E)$. Thus, $\widetilde{D}(x^k,E)=D(E_1^k)$. Let φ be in this set. Since now $E_1\varphi \in D(E_1^{k-1})$, the induction assumption [along with the fact that $AV\varphi=V(E_1\varphi)$] gives

$$A^k V\varphi = A^{k-1}(AV\varphi) = A^{k-1}V(E_1\varphi) = VE_1^{k-1}(E_1\varphi) = VE_1^k\varphi,$$

completing the induction proof of (6).

Let $n \in \mathbb{N}$. Now (5) and (6) give $\widetilde{L}(x^n,E)\varphi=V^*A^nV\varphi=V^*VE_1^n\varphi=E_1^n\varphi$ for all $\varphi \in \widetilde{D}(x^n,E) =D(E_1^n)$, so $\widetilde{L}(x^n,E)=\widetilde{L}(x,E)^n$. This proves (a).

If we assume that $\widetilde{L}(x,E)$ is selfadjoint, it follows from (7) that $P_{\mathcal{H}}D(A) \subset D(A)$. This fact is proved in Ref. 34, but we include the proof here for the reader's convenience. To that end, let $\psi \in D(A)$, and let $\varphi \in D(E_1)$ be arbitrary. Using (7), we get

$$\langle E_1\varphi | V^*\psi\rangle = \langle VE_1\varphi|\psi\rangle = \langle AV\varphi|\psi\rangle = \langle \varphi|V^*A\psi\rangle,$$

which implies that $V^*\psi \in D(E_1^*)$. Since E_1 is self-adjoint, $V^*\psi \in D(E_1)$, so $P_{\mathcal{H}}\psi=V(V^*\psi) \in VD(E_1)$. But $VD(E_1)$ is contained in $D(A)$, because $D(E_1)=D(AV)$. Thus $P_{\mathcal{H}}\psi \in D(A)$, proving the fact $P_{\mathcal{H}}D(A) \subset D(A)$. In addition, the above calculation shows that $V^*D(A) \subset D(E_1)$, and $E_1V^*\psi=E_1^*(V^*\psi)=V^*A\psi$ for all $\psi \in D(A)$. Combining this with (7), we get

$$P_{\mathcal{H}}A\psi = VV^*A\psi = V(E_1V^*\psi) = VE_1(V^*\psi) = AV(V^*\psi) = AP_{\mathcal{H}}\psi$$

for all $\psi \in D(A)$. Consequently, $P_{\mathcal{H}}A \subset AP_{\mathcal{H}}$. Since A is self-adjoint, this implies that $P_{\mathcal{H}}$ commutes with all the spectral projections $P(B)$ (Ref. 31, pp. 301 and 320). It follows that each $E(B)$ is a projection (Ref. 27, Corollary 2.2.2.), so the proof is complete. □

Remark: As mentioned before, the result appearing in part (b) of the above Proposition can be found in the classic book of Akhiezer and Glazman.[1] The result seems to be somewhat well known (see, e.g., Refs. 30 and 37 both of which refer to the works of Akhiezer and Glazman). However, the fact is given in a much later work[21] without reference to Ref. 1 (though we have not been able to convince ourselves of their argumentation), and Werner (Ref. 39, p. 796) only mentions that it holds for normalized compactly supported operator measures. Moreover, Ingarden (Ref. 17, p. 87) says that all the semispectral measures with the same self-adjoint first moment A have variances greater than or equal to that of the spectral measure of A. Part (b) of the above Proposition gives more—it asserts that the minimum variance occurs *only* in the case of the spectral measure of A.

We note also that the proof given in Ref. 17, p. 87 considers only compactly supported semispectral measures, and contains no reference to Ref. 1.

Now we get the following characterization for projection valued measures.

Theorem 5: *Let $E:\mathcal{B}(\mathbb{R})\to L(\mathcal{H})$ be a positive normalized operator measure, such that $\widetilde{L}(x,E)$ is self-adjoint. Then the following conditions are equivalent.*

(i) *E is a spectral measure*;
(ii) $L(x^2,E)=L(x,E)^2$;
(iii) $\int x^2 dE_{\varphi,\varphi}=\|L(x,E)\varphi\|^2$ *for all* $\varphi\in\widetilde{D}(x,E)$.

Proof. Since $\widetilde{L}(x,E)$ is self-adjoint, it coincides with its symmetric extension $L(x,E)$.

Assume that (i) holds. Then $\widetilde{L}(x^2,E)=\widetilde{L}(x,E)^2$ by a standard result of spectral theory. Since E is projection valued, we have also $\widetilde{L}(x^2,E)=L(x^2,E)$, so (ii) holds.

Assume (ii). Then we have

$$\int x^2 dE_{\varphi,\varphi}=\|L(x,E)\varphi\|^2 \tag{8}$$

for all $\varphi\in D(x^2,E)$. In order to get (iii), we have to establish this identity for vectors in the larger set $D(x,E)=\widetilde{D}(x,E)$. Let $\varphi\in\widetilde{D}(x,E)=D(x,E)$. Since $L(x,E)=\widetilde{L}(x,E)$ is self-adjoint, the closure of the restriction of $L(x,E)$ to the domain of $L(x,E)^2$ is $L(x,E)$ itself (Ref. 11, p. 1245). Therefore, by (ii), we can pick a sequence (φ_n) of vectors in $D(x^2,E)$, converging to φ, such that $(L(x,E)\varphi_n)$ converges to $L(x,E)\varphi$. Since $\varphi_n\in D(x^2,E)$ for each n, (8) gives that

$$\lim_n \int x^2 dE_{\varphi_n,\varphi_n}=\lim_n \|L(x,E)\varphi_n\|^2=\|L(x,E)\varphi\|^2.$$

Since $|E_{\varphi_n,\varphi_n}(B)-E_{\varphi,\varphi}(B)|\leqslant(\|\varphi_n\|+\|\varphi\|)\|E(\mathbb{R})\|\,\|\varphi_n-\varphi\|$ for all $n\in\mathbb{N}$ and $B\in\mathcal{B}(\mathbb{R})$, the sequence $(E_{\varphi,\varphi}(B))$ converges to $E_{\varphi,\varphi}(B)$ uniformly for $B\in\mathcal{B}(\mathbb{R})$, so the sequence $(E_{\varphi,\varphi})$ of positive measures converges to $E_{\varphi,\varphi}$ in the total variation norm (Ref. 10, p. 97). It follows by Ref. 22, Lemma A.5 that

$$\int x^2 dE_{\varphi,\varphi}\leqslant\|L(x,E)\varphi\|^2,\varphi\in D(x,E). \tag{9}$$

It follows, e.g., from the proof of Lemma A.2 of Ref. 22 (see Ref. 3, p. 65) that $\|L(x,E)\varphi\|^2\leqslant\int x^2 dE_{\varphi,\varphi}$ for all $\varphi\in D(x,E)$. Combining this with (9), we get (iii).

Because (iii) implies (i) by the preceding Proposition, the proof is complete. □

A "state property system" is the mathematical structure which models an arbitrary physical system by means of its set of states, its set of properties, and a relation of "actuality of a certain property for a certain state." We work out a new axiomatization for standard quantum mechanics, starting with the basic notion of state property system, and making use of a generalization of the standard quantum mechanical notion of "superposition" for state property systems. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2217807]

I. INTRODUCTION

In standard quantum mechanics a state $p_{\bar{c}}$ of a quantum entity S is represented by the one-dimensional subspace or the ray $\bar{c}$ of a separable complex Hilbert space $\mathcal{H}$. An experiment e_A testing an observable A is represented by a self-adjoint operator $\mathcal{A}$ on $\mathcal{H}$, and the set of outcomes of this experiment e_A is the spectrum $\mathrm{spec}(\mathcal{A})$ of this self-adjoint operator $\mathcal{A}$. Measurable subsets $B \subset \mathrm{spec}(\mathcal{A})$ represent the events (in the sense of probability theory) of outcomes. The interaction of the experiment e_A with the physical entity being in state $p_{\bar{c}}$ is described in the following way: (1) the probability for a specific event $B \subset \mathrm{spec}(\mathcal{A})$ to occur if the entity is in a specific state $p_{\bar{c}}$ is given by $\langle c, P_B(c)\rangle$, where P_B is the spectral projection corresponding to B, c is the unit vector in the ray $\bar{c}$ representing state $p_{\bar{c}}$, and $\langle,\rangle$ is the in-product in the Hilbert space $\mathcal{H}$; (2) if the outcome is contained in B, the state $p_{\bar{c}}$ is changed to $p_{\bar{d}}$ where $\bar{d}$ is the ray generated by $P_B(c)$.

Hence in standard quantum mechanics the states and experiments are represented by means of mathematical entities of a complex Hilbert space. The crucial role that is played by this complex Hilbert space is very much *ad hoc*, in the sense that there are no physically plausible reasons why the Hilbert space structure should be at the origin of both the structure of the state space, as well as the structure of the experiments.

This initiated the search for an axiomatic theory for quantum mechanics where the Hilbert space structure would be derived from more general and physically more plausible axioms. The area of forming physical models in the field of quantum mechanics is very large, and often involves philosophical problems of physics. Let us mention some of the most well known axiomatic approaches: the algebraic approach,[1–3] where the basic notions are observables, the convexity approach,[4–8] where the basic notion is the convex set of states, the empirical logic approach,[9–13] where the authors start with primitive notions of an operation or a test, and the quantum logic approach,[14–20] which starts with the set of experimental propositions.

Due to the original focus[14] on the collection of "experimental propositions" of a physical entity—with the conviction that such an experimental proposition would be a good basic concept—most of the later axiomatics were constructed taking as their basic concept the set $\mathcal{L}$ of experimental propositions concerning an entity S. The first breakthrough came with a theorem of

[a)]Electronic mail: diraerts@vub.ac.be
[b)]Electronic mail: pulmann@mat.savba.sk

Constantin Piron, who proved that if $\mathcal{L}$ is a complete [axiom 1], orthocomplemented [axiom 2] atomic [axiom 3] lattice, which is weakly modular [axiom 4] and satisfies the covering law [axiom 5], then each irreducible component of the lattice $\mathcal{L}$ can be represented as the lattice of all "biorthogonal" subspaces of a vector space V over a division ring K (with some other properties satisfied that we shall not explicitly address here).[17] Such a vector space is called an "orthomodular space" and also sometimes a "generalized Hilbert space." It can be proven that an infinite dimensional orthomodular space over a division ring which is the real or complex numbers, or the quaternions, is a Hilbert space. For a long time there did not even exist any other example of an infinite dimensional orthomodular space. The search for a further characterization of the real, complex, quaternionic Hilbert space started (see, e.g., Ref. 21). Then Hans Keller constructed a nonclassical orthomodular space,[22] and recently Maria Pia Solèr proved that any orthomodular space that contains an infinite orthonormal sequence is a real, complex, or quaternionic Hilbert space.[23,24] It is under investigation in which way this result of Solèr can be used to formulate new physically plausible axioms.[24–27]

The axiomatic approach, apart from delivering an axiomatic foundation for quantum mechanics, has been used fruitfully to study concrete problems in quantum mechanics. As an example we mention the problem of the description of joint quantum entities, and the problems of entanglement, nonlocality, and appearance of the complex numbers in quantum mechanics. Most recently this problem has been studied within the axiomatic approach with very interesting results.[28–34]

Next to the idea of finding axioms that introduce the Hilbert space structure step by step was the attempt to determine the basic notions for the axiomatics in a physically clear and operational way. "Operationality" means that the axioms should be introduced in such a way that they can be related to "real physical operations" that can be performed in the laboratory.

The approaches that have tried to formulate quantum mechanics operationally are the Geneva-Brussels approach,[17,18,35–41] the Amherst approach,[9–13] and the Marburg approach.[42,43] In the present article we elaborate further on the Geneva-Brussels approach. In the last versions of the formalism that were presented in this approach the power of making a good distinction between the mathematical aspects of the formalism and its physical foundations had been identified.[44,45] Let us explain more concretely what we mean. In the older founding papers of the Geneva-Brussels approach,[35–41] although the physical foundation of the formalism is defined in a clear way, and the resulting mathematical structures are treated rigorously, it is not always clear what are the "purely mathematical" properties of the structures that are at the origin of the results. That is the reason that in more recent work on the formalism we have made an attempt to divide up the physical foundation and the resulting mathematical structure as much as possible. We first explain in which way certain aspects of the mathematical structure arise from the physical foundation, but then, in a second step, define these aspects in a strictly mathematical way, such that propositions and theorems can be proven, "only" using the mathematical structure without physical interpretation. Afterwards, the results of these propositions and theorems can then be interpreted in a physical way again. This not only opens the way for mathematicians to start working on the structures, but also lends a greater axiomatic strength to the whole approach on the fundamental level. More concretely, it is the mathematical structure of a "state property system" that has been identified to be the proper mathematical structure of the Geneva-Brussels approach, i.e., the structure used to describe a physical entity by means of its states and properties.[44–46] This step turned out to be fruitful from the start, since we could prove that a state property system as a mathematical structure is isomorphic to a closure space.[44–46] This means that the mathematics of closure spaces can be translated to the mathematics of state property systems, and in this sense becomes relevant for the foundations of quantum mechanics. The step of dividing up the mathematics from the physics in a systematic way also led to a scheme to derive the morphisms for the structures that we consider from a covariance principle rooted in the relation of a subentity to the entity of which it is a subentity.[45,46] This paved the way to a categorical study of the mathematical structures involved.

Not only was it possible to connect with a state property system a closure space in an

isomorphic way, but, after we had introduced the morphisms starting from a merological covariance principle, it was possible to prove that the category of state property systems and their morphisms, that we have named **SP**, is equivalent to the category of closure spaces and continuous functions, denoted by **Cls**.[45,46] More specifically we could prove that SP is the amnestic modification of **Cls**.[47]

It could be proven that some of the axioms of axiomatic quantum mechanics[17,36,37] correspond to separation properties of the corresponding closure spaces.[48] More concretely, the axiom of state determination in a state property system[44] is equivalent to the T_0 separation axiom of the corresponding closure space,[48,49] and the axiom of atomicity in a state property system[44] is equivalent to the T_1 separation axiom of the corresponding closure space.[50,51] More recently it has been shown that "classical properties"[36,38,40,41] of the state property system correspond to clopen (open and closed) sets of the closure space,[52–54] and, explicitly making use of the categorical equivalence, a decomposition theorem for a state property system into its nonclassical components can be proved that corresponds to the decomposition of the corresponding closure space into its connected components.[52,53,57]

In the present article we put forward a new axiomatization for standard quantum mechanics, starting with the basic notion of "state property system," and founded on the concept of "superposition," that started in the quantum logic approach and was developed in Ref. 55. The general reason for introducing the new axiomatization is to put under one roof the Geneva-Brussels approach in its recent form and the quantum logic approach and to combine the algebraic approach and the probabilistic approach. We also wish to find out how the recent development in projective geometry (see Ref. 56) can be reflected in the axiomatization. A more specific reason for this new axiomatization is to take it as a mathematical basis for further research into the problem of the description of joint quantum systems. Both authors have done extensive research on the problem of the description of joint quantum systems.[57–60,37,61–65] One of the hard problems is that all types of product constructions on the level of the quantum logic structure give rise to a situation where the joint quantum entity only has product states of the subentities. On the level of the Hilbert space, the joint system of two quantum systems is described by means of the tensor product of the Hilbert spaces of the subsystems, and in this case there is an abundance of nonproduct states, giving rise to the well-known phenomenon of quantum entanglement. We plan to study the still open problem of coupled physical systems with entanglement, by investigating in which way we can introduce "superpositions between product states" by means of the notion of superposition which we introduced in this axiomatization on the level of the quantum logic.

The notion of a superposition of states was introduced by Varadarajan[66] for states as probability measures on quantum logics, i.e., orthomodular lattices. In the same sense it is also used in Ref. 55. In the present paper, we use a more general frame of a state property system to introduce the notion of superposition. We use superpositions to create two kinds of closure operations. The first one, together with a few simple additional axioms, enables us to associate the structure of a projective geometry with our state property system. A very useful tool here is the material presented in the recent book by Faure and Frölicher.[56] The first of our closure operations based on superposition leads to the formation of subspaces of a projective geometry. The second of our closure operations enables us to characterize closed subspaces of the projective geometry. Probabilities enter into play in order to introduce orthocomplementation on a subset $\mathcal{L}_0$ of the lattice $\mathcal{L}$, and we show that $\mathcal{L}_0$ can be organized into a σ- orthomodular poset with an order determining set of probability measures, which are supported by elements of the set Σ. The set $\mathcal{L}_0$ may be interpreted as a set of measurable properties, and may depend on the present state of knowledge and experimental techniques. In the following parts of the article, conditions are found under which the orthocomplementation can be extended to the whole $\mathcal{L}$, and $\mathcal{L}$ then becomes a complete, atomistic, orthocomplemented lattice. Moreover, $\mathcal{L}$ can be related with the closed subspaces of the projective geometry via the so-called Cartan map. The notion of "superposition principle" is introduced to obtain irreducibility of the projective geometry. More generally, sectors are introduced as the minimal subspaces in which the superposition principle holds, and their topological characterization as clopen subspaces is derived. In the following the classical properties (or the

superselection rules) are specified, and it is shown that they correspond exactly to the central elements of the lattice $\mathcal{L}$. In the following, we study conditions under which our projective geometry may admit some deeper properties, described in Ref. 56, such as the Mackey property or to become an orthogeometry. Although not all of our axioms have a physical meaning, we try to specify simple axioms which enable us to obtain different stages of the projective geometry. Eventually we find conditions under which a vector space can be associated with our state property system, and we finish with an analogue of the famous Piron theorem.

II. STATE PROPERTY SYSTEMS AND SUPERPOSITION

Definition 1:[44–46] *We say that* $(\Sigma,\mathcal{L},\xi)$ *is a state-property system if* $(\Sigma,<)$ *is a preordered set,* $(\mathcal{L},<,\wedge,\vee)$ *is a complete lattice with the greatest element I and the smallest element* 0, *and* ξ *is a function*

$$\xi:\Sigma\to\mathcal{P}(\mathcal{L}) \tag{1}$$

such that for $p\in\Sigma$ *and* $(a_i)_i\subseteq\mathcal{L}$, *we have*

$$I\in\xi(p), \tag{2}$$

$$0\notin\xi(p), \tag{3}$$

$$a_i\in\xi(p)\ \forall\, i\Leftrightarrow\wedge_i a_i\in\xi(p)\ (\textit{for an arbitrary set of indices}) \tag{4}$$

and for $p,q\in\Sigma$ *and* $a,b\in\mathcal{L}$ *we have*

$$p<q\Leftrightarrow\xi(q)\subseteq\xi(p), \tag{5}$$

$$a\leqslant b\Leftrightarrow\ \forall\, r\in\Sigma:a\in\xi(r)\Rightarrow b\in\xi(r). \tag{6}$$

Elements of Σ are called *states*, elements of $\mathcal{L}$ are called *properties*.

Let $(\Sigma,\mathcal{L},\xi)$ be a state-property system. For $S\subset\Sigma$ define $S\mapsto\lambda(S)$ as follows. First define, for any $p,q\in\Sigma$,

$$\lambda\{p,q\}:=\{s\in\Sigma:a\in\xi(p)\cap\xi(q)\Rightarrow a\in\xi(s)\}. \tag{7}$$

We will say that a subset $S\subseteq\Sigma$ is λ-*closed* if for any $p,q\in S$ we have $\lambda\{p,q\}\subset S$. Denote by $\mathcal{L}(\Sigma)$ the set of all λ-closed subsets. For any $P\subset\Sigma$, define

$$\lambda(P):=\ \cap\{G:G\in\mathcal{L}(\Sigma),P\subset G\}. \tag{8}$$

That is, $\lambda(P)$ is the intersection of all λ-closed subsets of Σ that contain P.

Lemma 1: (i) *For every subset* $P\subseteq\Sigma$, $\lambda(P)\in\mathcal{L}(\Sigma)$. (ii) *A subset* $S\subseteq\Sigma$ *is* λ-*closed if and only if* $S=\lambda(S)$.

Proof: (i) Let $p,q\in\lambda(P)$, then $p,q\in G$ for every $P\subseteq G\in\mathcal{L}(\Sigma)$. Therefore $\lambda\{p,q\}\subseteq G$ for every such G, and consequently $\lambda\{p,q\}\subseteq\lambda(P)$.

(ii) If $S=\lambda(S)$, then $S\in\mathcal{L}(\Sigma)$ by (i). If S is λ-closed, then clearly, S is the smallest λ-closed subset of Σ containing S, hence $\lambda(S)=S$. □

That is,

$$\mathcal{L}(\Sigma)=\{S\subset\Sigma:S=\lambda(S)\}. \tag{9}$$

Proof of the following statement is immediate.

Lemma 2: The mapping $\lambda:P\mapsto\lambda(P)$ *satisfies the following properties:*

(C1) $P\subseteq\lambda(P)$,
(C2) $P_1\subseteq\lambda(P_2)\Rightarrow\lambda(P_1)\subseteq\lambda(P_2)$.

We recall that a map $C:\mathcal{P}(X)\to\mathcal{P}(X)$ satisfying conditions (C1) and (C2) is a *closure operator* on the set X (Ref. 56, Definition 3.1.1). Consequently, λ is a closure operator on the set Σ.

According to Ref. 56, Remark 3.1.2, the following conditions are satisfied:

(1^0) $\lambda(A\cup B)=\lambda(\lambda(A)\cup B)=\lambda(\lambda(A)\cup\lambda(B))$,
(2^0) $\lambda(A\cap B)\subseteq\lambda(\lambda(A)\cap B)\subseteq\lambda(A)\cap\lambda(B)$.

More generally,

(3^0) $\lambda(\cup\mathcal{A})=\lambda(\cup\lambda(\mathcal{A}))$,
(4^0) $\lambda(\cap\mathcal{A})\subseteq\cap\lambda(\mathcal{A})$,

where $\mathcal{A}\subseteq\mathcal{P}(\Sigma)$ is an arbitrary subset and $\lambda(\mathcal{A})$ denotes the set $\{\lambda(A):A\in\mathcal{A}\}$.

Recall that a system $\mathcal{S}$ of sets is an *intersection system* if $\mathcal{A}\subseteq\mathcal{S}$ implies $\cap\mathcal{A}\in\mathcal{S}$. By [Ref. 56, Proposition 3.1.4], $\mathcal{L}(\Sigma)$ is an intersection system.

Definition 2: We say that a state-property system $(\Sigma,\mathcal{L},\xi)$ *satisfies property*

(A) *if there are at least two distinct states* $r,s\in\Sigma$ *and for all* $p,q\in\Sigma$, $\xi(p)\subset\xi(q)\Rightarrow p=q$.

Property (A) implies that $\xi:\Sigma\to\mathcal{P}(\mathcal{L})$ is injective. By Ref. 46, Proposition 14, the pre-order $<$ on Σ defined by (5) of Definition 1 is a partial order. Property (A) implies that Σ has only a trivial order $p<q$ iff $p=q$.

Recall that a closure operator C on a set X is called *simple* if it satisfies the additional axiom:

(C5) $C(\emptyset)=\emptyset$ and $C(x)=\{x\}$ for every $x\in X$.

(We write $C(x)$ instead of $C(\{x\})$). If X contains at least two different points, then the second property in (C5) implies the first one. Indeed, $\emptyset\subset\{x\},\emptyset\subset\{y\}$ implies $C(\emptyset)\subset C(x)\cap C(y)=\{x\}\cap\{y\}=\emptyset$.

Lemma 3: Let $(\Sigma,\mathcal{L},\xi)$ *be a state-property system such that there are at least two different states* $p,q\in\Sigma$. *Then the closure operator* λ *is simple if and only if property* (A) *of Definition 2 holds*.

Proof: If (A) holds, then for every $p\in\Sigma$,

$$\lambda\{p\}=\{s\in\Sigma:a\in\xi(p)\Rightarrow a\in\xi(s)\}=\{s\in\Sigma:\xi(p)\subset\xi(s)\}=\{p\}.$$

If $\lambda(\emptyset)$ contains r, then $\lambda(\emptyset)\subseteq\lambda(q)=\{q\}$ implies $r\in\{q\}$, hence $r=q$ for all q, a contradiction.

Conversely, if λ is simple and $\xi(p)\subseteq\xi(q)$ for $p\neq q$, then

$$\lambda(p)=\{s\in\Sigma:\xi(p)\subseteq\xi(s)\}\ni q$$

contradicting $\lambda(p)=\{p\}$. □

Proposition 1: Let $(\Sigma,\mathcal{L},\xi)$ *be a state property system satisfying* (A). *Then* $\mathcal{L}$ *is a complete atomistic lattice with the lattice operations*

$$\wedge S_\alpha=\cap S_\alpha,\quad \vee S_\alpha=\lambda(\cup S_\alpha).$$

Proof: Follows by Ref. 56, Proposition 3.1.4. □

In what follows, we introduce the notion of a superposition of states in analogy with Ref. 19.

Definition 3: A state $p\in\Sigma$ *is a superposition of a set of states* S, $S\subseteq\Sigma$, *if for each* $a\in\mathcal{L}$, $a\in\xi(s)$ *for all* $s\in S$ *implies* $a\in\xi(p)$, *i.e., if* $\cap_{s\in S}\xi(s)\subseteq\xi(p)$.

For $S\subseteq\Sigma$, *define*

$$\bar{S}=\left\{p\in\Sigma:\bigcap_{s\in S}\xi(s)\subseteq\xi(p)\right\}. \tag{10}$$

That is, $\bar{S}$ is the set of all superpositions of states in S. Obviously, for arbitrary $p,q\in\Sigma$,

$$\{p,q\}^-=\lambda\{p,q\}. \tag{11}$$

Definition 4: A state $p \in \Sigma$ is a minimal superposition of a subset $S \subseteq \Sigma$ if

(i) $p \in \bar{S}$,

(ii) $p \notin \bar{Q}$ *for any proper subset* $Q \subseteq S$.

For example, if (A) holds, then $s \in \{p,q\}^-$ is a minimal superposition iff $s \neq p$, $s \neq q$.

Definition 5: Let $(\Sigma, \mathcal{L}, \xi)$ be a state-property system.

(1) *We will say that a minimal superposition principle* (MSP) *holds for $(\Sigma, \mathcal{L}, \xi)$ if for every subset $S \subseteq \Sigma$ and for every minimal superposition p of S,*

$$\{S_1 \cup p\}^- \cap \bar{S}_2 \neq \emptyset \tag{12}$$

whenever S_1, S_2 are proper subsets of S such that $S_1 \cap S_2 = \emptyset$ and $S_1 \cup S_2 = S$.

(2) *We will say that a finite MSP* (f-MSP) *holds for $(\Sigma, \mathcal{L}, \xi)$ if* (12) *holds for every finite subset $S \subseteq \Sigma$.*

(3) *We will say that an n-MSP holds for $(\Sigma, \mathcal{L}, \xi)$ if* (12) *holds for every subset $S \subseteq \Sigma$ with the cardinality at most n.*

For example, the 3-MSP holds for a state-property system $(\Sigma, \mathcal{L}, \xi)$ iff for every $p,q,r,s \in \Sigma$ (not necessarily all different), if $p \in \{q,r,s\}^-$ is a minimal superposition, then $\{p,q\}^- \cap \{r,s\}^- \neq \emptyset$ and $\{p,q,r\}^- \cap \{s\}^- \neq \emptyset$. Clearly, MSP implies f-MSP, which in turn implies n-MSP for every $n \in \mathbb{N}$. Observe also that if (A) holds, then 2-MSP is the following exchange property: if $r \in \{p,q\}^-$ and $r \neq p,q$, then $p \in \{r,q\}^-$.

Theorem 1: *Let $(\Sigma, \mathcal{L}, \xi)$ be a state-property system with properties* (A) *and* 3-MSP. *Then the operator $*: \Sigma \times \Sigma \to \mathcal{P}(\Sigma)$ defined by $p*q = \lambda\{p,q\}$ has the following properties*:

(P1) $p*p = \{p\}$,

(P2) $p \in p*q$ *for all* $p,q \in \Sigma$,

(P3) $p \in q*r$ *and* $r \in s*t$ *and* $p \neq s$ *imply* $(p*s) \cap (q*t) \neq \emptyset$

That is, the system $(\Sigma, *)$ is a projective geometry.[56]

Proof: (P1) By (A), $\lambda\{p,p\} = \{p\}$.

(P2) Clearly, $p*q = \lambda\{p,q\} \supseteq \{p\}$.

(P3) From $p \in \{q,r\}^-$ and $r \in \{s,t\}^-$ we obtain $p \in \{q,s,t\}^-$. If $p \in q*s$, respectively, $p \in s*t$, then either $p = q$, respectively, $p = t$, or 2-MSP implies that $q \in p*s$, respectively, $t \in p*s$. In every case, (P3) is satisfied. It remains the case that either $p \in q*t$ or p is a minimal superposition of $\{q,s,t\}$. In the first case, $p \in (p*s) \cap (q*t)$ holds by (P2). In the second case the statement follows by 3-MSP. □

By Ref. 56, Definition 2.3.1, the λ-closed subsets of Σ coincide, under the suppositions of Theorem 1, with the subspaces of the projective geometry $(\Sigma, *)$ associated with $(\Sigma, \mathcal{L}, \xi)$. Consequently, we have the following.

Theorem 2: *Let $(\Sigma, \mathcal{L}, \xi)$ be a state-property system satisfying conditions* (A) *and* 3-MSP. *Then $\mathcal{L}(\Sigma)$ is a projective lattice, i.e., a complete atomistic meet-continuous modular lattice.*

Therefore we will call the elements of $\mathcal{L}(\Sigma)$ the *subspaces* of Σ. From the next theorem we can derive what properties satisfy the closure operator λ on the system $(\Sigma, *)$ with $p*q = \lambda\{p,q\}$. (We write $\lambda(x)$ instead of $\lambda(\{x\})$ and $\lambda(A \cup x)$ instead of $\lambda(A \cup \{x\})$.)

Theorem 3: *Let $(\Sigma, \mathcal{L}, \xi)$ be a state-property system such that $(\Sigma, *)$ with $p*q = \lambda\{p,q\}$ is a projective geometry, i.e., properties* (P1), (P2), *and* (P3) *are satisfied. Then the closure operator λ satisfies the following conditions*:

(C3) $x \in \lambda(A)$ *implies* $x \in \lambda(B)$ *for some finite subset* $B \subseteq A$, *i.e.*, λ *is finitary.*

(C4) $x \notin \lambda(A)$ *and* $x \in \lambda(A \cup y)$ *imply* $y \in \lambda(A \cup x)$, *i.e.*, λ *satisfies the exchange property.*

(C5) $\lambda(\emptyset) = \emptyset$ *and* $\lambda(x) = \{x\}$, *i.e.*, λ *is simple.*

(C6) $\lambda(A \cup B) = \cup\{\lambda\{x,y\} : x \in \lambda(A)$ *and* $y \in \lambda(B)\}$ *for every* $A, B \subseteq \Sigma$.

Proof: See Ref. 56, Theorem 3.3.4. □

Notice that (C6) is called a *projective law*. According to Ref. 56, Lemma 3.3.2, if a closure operator $C:\mathcal{P}(X)\to\mathcal{P}(X)$ satisfies the projective law, then for any nonempty subset $A\subseteq X$ and any $b\in X$ one has

(C7) $C(A\cup b)=\cup\{C(x,b):x\in C(A)\}$.

Moreover, the converse holds provided the closure operator C satisfies (C3), i.e., is finitary. The following proposition follows by Ref. 56, Proposition 3.3.4.

Proposition 2: Let the closure operator $\lambda:\mathcal{P}(\Sigma)\to\mathcal{P}(\Sigma)$ *satisfy properties* (C4), (C5), *and* (C7). *The couple* $(\Sigma,*)$ *where* $p*q=\lambda\{p,q\}$ *is a projective geometry*.

Now we will study connections between the mappings $A\mapsto\lambda(A)$ and $A\mapsto\bar{A}$, $A\subseteq\Sigma$. First we prove the following properties of $A\mapsto\bar{A}$.

Lemma 4: Let $(\Sigma,\mathcal{A},\xi)$ *be a state-property system. The operator* $A\mapsto\bar{A}$ *satisfies the following properties for every* $A,B\subseteq\Sigma$.

(i) $A\subseteq\bar{A}$.

(ii) $A\subseteq\bar{B}\Rightarrow\bar{A}\subseteq\bar{B}$.

(iii) $\bar{A}\in\mathcal{L}(\Sigma)$.

Proof: (i) Follows directly from the definition.

(ii) Let $p\in\bar{A}$, i.e., $\cap_{s\in A}\xi(s)\subseteq\xi(p)$. $A\subseteq\bar{B}$ implies that for every $s\in A$, $\cap_{q\in B}\xi(q)\subseteq\xi(s)$, so that $\cap_{q\in B}\xi(q)\subseteq\cap_{s\in A}\xi(s)\subseteq\xi(p)$. Hence $p\in\bar{B}$, and so $\bar{A}\subseteq\bar{B}$.

(iii) From $\lambda\{p,q\}=\{p,q\}^-\subseteq\bar{A}$ for every $p,q\in A$ we see that $\bar{A}$ is λ-closed, i.e., $\bar{A}=\lambda(\bar{A})$. □

Observe that (i) and (ii) in Lemma 4 coincide with the properties (C1) and (C2), respectively, so that $A\mapsto\bar{A}$ is a closure operator. Let us denote by $\mathcal{F}(\Sigma)$ the set of superposition-closed subsets of Σ, that is,

$$\mathcal{F}(\Sigma):=\{S\subset\Sigma:\bar{S}=S\}. \tag{13}$$

Proposition 3: Let $(\Sigma,\mathcal{L},\xi)$ *be a state property system satisfying condition* (A). *Then the set* $\mathcal{F}(\Sigma)$ *is a complete atomistic lattice. Moreover, if* $S_i\in\mathcal{F}(\Sigma),i\in I$, *for any index set* I, *then* $\wedge_{i\in I}S_i=\cap_{i\in I}S_i$, *and* $\vee_{i\in I}S_i=(\cup_{i\in I}S_i)^-$.

Proof: If $S\subset\Sigma$, $S=\emptyset$ or $S=\{s\}$, then $S=\bar{S}$ by condition (A). So one-element sets belong to $\mathcal{F}(\Sigma)$ which are atoms in $\mathcal{F}(\Sigma)$. From the properties of closure operators (Ref. 56, Proposition 3.1.4), we get $\wedge_{i\in I}S_i=\cap_{i\in I}S_i$, and $\vee_{i\in I}S_i=(\cup_{i\in I}S_i)^-$. □

Theorem 4: *Let* $(\Sigma,\mathcal{L},\xi)$ *be a state-property system such that condition* (A) *is satisfied.*

(i) *If* 3-MSP *holds, then for every* $p,q,s\in\Sigma$,

$$\{p,q,s\}^-=\lambda\{p,q,s\}. \tag{14}$$

(ii) *If* f-MSP *holds, then for every finite subset* $A=\{s_1,s_2,\ldots,s_n\}\subseteq\Sigma$,

$$\lambda(A)=\bar{A}. \tag{15}$$

Proof: (i) For every $p,q\in\Sigma$, $\lambda\{p,q\}=\{p,q\}^-$, and by Lemma 4(iii), $\lambda\{p,q,s\}\subseteq\{p,q,s\}^-$ for every $p,q,s\in\Sigma$. To prove the converse inclusion, let $t\in\{p,q,s\}^-$. If $t\in\{p,q\}^-$, then $t\in\lambda\{p,q\}\subseteq\lambda\{p,q,s\}$. Hence we may assume that t is a minimal superposition. Then by 3-MSP, there is $r\in\{p,t\}^-\cap\{q,s\}^-$. By 2-MSP, $t\in\lambda\{r,p\}\subseteq\lambda\{p,q,s\}$. This implies that $\{p,q,s\}^-\subseteq\lambda\{p,q,s\}$.

(ii) We will proceed by induction. For $n=2$, the statement holds. Assume that the statement holds for every $k\leqslant n$, $k,n\in\mathbb{N}$. Let $A=\{s_1,s_2\ldots,s_n,s_{n+1}\}$, and assume that $t\in\bar{A}$ is a minimal superposition. By f-MSP and induction hypothesis, there is $r\in\{t,s_{n+1}\}^-\cap\{s_1,\ldots,s_n\}^-\subseteq\lambda\{s_1,\ldots,s_n\}$. Now $t\in\lambda\{r,s_{n+1}\}\subseteq\lambda((\lambda\{s_1,\ldots,s_n\}\cup s_{n+1})\subseteq\lambda(A)$. If t is not a

minimal superposition, there is a subset $B \subseteq A$ such that $t \in \bar{B} = \lambda(B) \subseteq \lambda(A)$ by induction hypothesis. Hence $\bar{A} \subseteq \lambda(A)$. The converse holds by Lemma 4(iii). □

III. PROBABILITY MEASURES AND ORTHOCOMPLEMENTATION

Let $(\Sigma, \mathcal{L}, \xi)$ be a state-property system. Let there be a subset $\mathcal{L}_0 \subset \mathcal{L}$ such that $\mathcal{L}_0$ contains 0 and 1, and let there be a mapping $\mu: \Sigma \times \mathcal{L}_0 \to [0,1]$, $(p,a) \mapsto \mu_p(a)$, where $[0,1]$ is the unit interval of the reals, such that

(Oi) $\mu_p(a)=1$ iff $a \in \xi(p)$ $(a \in \mathcal{L}_0)$,
(Oii) $a \leqslant b$ implies $\mu_p(a) \leqslant \mu_p(b)$ $(a,b \in \mathcal{L}_0)$,
(Oiii) If $(a_i)_{i=1}^{\infty} \subset \mathcal{L}_0$ is a sequence such that for all i,j, and every $p \in \Sigma$,

$$\mu_p(a_i) + \mu_p(a_j) \leqslant 1,$$

then there is $b \in \mathcal{L}_0$ such that

$$\mu_p(b) + \sum_{i=1}^{\infty} \mu_p(a_i) = 1.$$

Clearly, $\mu_p(I)=1$ and $\mu_p(0)=0$ for all $p \in \Sigma$. Define a relation $\perp \subset \mathcal{L}_0 \times \mathcal{L}_0$ by setting $a \perp b$ iff $\mu_p(a)+\mu_p(b) \leqslant 1$ for all $p \in \Sigma$. We will say that a and b are *orthogonal* if $a \perp b$.

Lemma 5: Let $(\mathcal{L}, \Sigma, \xi)$ be a state-property system. Let $\mathcal{L}_0 \subset \mathcal{L}$ and $\mu: \Sigma \times \mathcal{L}_0 \to [0,1]$ satisfy the assumptions (Oi)–(Oiii). *Then*

(i) *$\mu_p(a) \leqslant \mu_p(b)$ for every $p \in \Sigma$ implies $a \leqslant b$.*
(ii) *$\mu_p(a) = \mu_p(b)$ for all $p \in \Sigma$ if and only if $a=b$.*
(iii) *For every $a \in \mathcal{L}_0$ there is a unique element $a' \in \mathcal{L}_0$ such that $\mu_p(a)+\mu_p(a')=1$ for all $p \in \Sigma$. Moreover, the mapping $a \mapsto a'$ is an orthocomplementation in $\mathcal{L}_0$, i.e.,* (1) *$a \leqslant b \Rightarrow b' \leqslant a'$,* (2) *$a'' := (a')' = a$,* (3) *$a \vee_0 a' = I$, $a \wedge_0 a' = 0$, where $\vee_0$ and $\wedge_0$ denote the supremum and infimum in $\mathcal{L}_0$, respectively.*
(iv) *For every sequence $(a_i)_{i=1}^{\infty}$ of mutually orthogonal elements in $\mathcal{L}_0$, their supremum $a = \vee_{0\, i=1}^{\infty} a_i$ exists in $\mathcal{L}_0$, and coincides with the supremum of $(a_i)_{i=1}^{\infty}$ in $\mathcal{L}$.*

Proof: (i) If $\mu_p(a) \leqslant \mu_p(b)$ for every $p \in \Sigma$, then $\mu_p(a)=1 \Rightarrow \mu_p(b)=1$, hence by (Oi), $a \in \xi(p) \Rightarrow b \in \xi(p)$, which implies $a \leqslant b$.

(ii) Follows by (Oii) and (i).

(iii) Let $a \in \mathcal{L}_0$, and consider the sequence $(a_i)_{i=1}^{\infty}$ where $a_1=a$, $a_i=0$, $i=2,3,\ldots$. By (Oiii), there is $b \in \mathcal{L}_0$ such that $\mu_p(b)+\mu_p(a)=1$ for all $p \in \Sigma$, i.e., $\mu_p(b)=1-\mu_p(a)$ for all $p \in \Sigma$. Hence we may put $a'=b$. By (ii), a' is uniquely defined. Now we prove that $a \mapsto a'$ is an orthocomplementation.

(1) $a \leqslant b \Rightarrow \mu_p(a) \leqslant \mu_p(b)$ for all $p \in \Sigma$, which implies $\mu_p(b')=1-\mu_p(b) \leqslant 1-\mu_p(a)=\mu_p(a')$ for all $p \in \Sigma$, which by (ii) entails $b' \leqslant a'$.

(2) $\mu_p((a')')=1-\mu_p(a')=1-(1-\mu_p(a))=\mu_p(a)$ for all $p \in \Sigma$, which entails $a''=a$.

(3) Let $c \in \mathcal{L}_0$ be such that $a \geqslant c, a' \geqslant c$. From $\mu_p(a)+\mu_p(a')=1$ and $\mu_p(a)=1$ iff $a \in \xi(p)$, it follows that $a \in \xi(p) \Rightarrow a' \notin \xi(p)$, and vice versa. Hence $a \in \xi(p)$ and $a' \in \xi(p)$ happen for no $p \in \Sigma$, which entails, by Definition 1, that $a \wedge a' = 0$ in $\mathcal{L}$. Since $0 \in \mathcal{L}_0$, the infimum of a and a' in $\mathcal{L}_0$ is 0.

Properties (1) and (2) imply de Morgan laws in $\mathcal{L}_0$: $a \vee_0 b$ exists, then $(a \vee_0 b)' = a' \wedge_0 b'$, and $(a \wedge_0 b)' = a' \vee_0 b'$ in the sense that if one side exists, so does the other, and they are equal. Therefore for every $a \in \mathcal{L}_0$, $a' \wedge_0 a'' = 0$ implies $(a' \wedge_0 a'')' = a \vee_0 a' = I$.

(iv) Let $(a_i)_{i=1}^{\infty}$ be a sequence of pairwise orthogonal elements of $\mathcal{L}_0$. Let b be the element from (Oiii). Put $a := b'$, then for every $p \in \Sigma$ we have $\mu_p(a) = \Sigma_{i=1}^{\infty} \mu_p(a_i)$. It follows that $\mu_p(a_i) \leqslant \mu_p(a)$ for all $i \in \mathbb{N}$, and for all $p \in \Sigma$. Hence a is an upper bound of $a_i, i=1,2,\ldots$. Let $c \in \mathcal{L}_0$ be

any other upper bound of $a_i, i=1,2,\ldots$. Then $a_i \leqslant c$ for all $i$implies that $c', a_1, a_2, \ldots$ are mutually orthogonal. By (Oiii), there is an element $d \in \mathcal{L}_0$ such that for every $p \in \Sigma$,

$$\mu_p(d) = \mu_p(c') + \sum_{i=1}^{\infty} \mu_p(a_i) = \mu_p(c') + \mu_p(a).$$

From this we obtain $\mu_p(c) = \mu_p(d') + \mu_p(a)$, which entails by (i) that $a \leqslant c$.

Let u be the supremum of $(a_i)_{i=1}^{\infty}$. The we have $\forall p \in \Sigma$, $u \in \xi(p)$ if and only if $a_i \in \xi(p)$ for some i. But then $u \in \xi(p)$ if and only if $a \in \xi(p)$, which entails that $u=a$. □

We will say that a set $\mathcal{F}$ of functions $f: L \to [0,1]$ defined on a partially ordered set L is *order determining* if $a \leqslant b \Leftrightarrow \forall f \in \mathcal{F}, f(a) \leqslant f(b)$.

Theorem 5: *Let* $(\mathcal{L}, \Sigma, \xi)$ *be a state-property system,* $\mathcal{L}_0 \subseteq \mathcal{L}$, *and let* $\mathcal{M} := \{\mu: \Sigma \times \mathcal{L}_0 \to [0,1]\}$ *satisfy conditions* (Oi)–(Oiii). *Then the set* L_0 *is a* σ*-orthomodular poset and the set* $\mathcal{M}$ *is order determining for* L_0. *Moreover, for every* $a \in L_0$, $a \neq 0$, *there is* $p \in \Sigma$ *such that* $\mu_p(a)=1$.

Proof: By definition, the set $\mathcal{L}_0$ with the ordering inherited from $\mathcal{L}$ is a partially ordered set. By Lemma 5, $\mathcal{L}_0$ is an orthocomplemented set such that the supremum of every pairwise orthogonal sequence exists in $\mathcal{L}_0$. Moreover, $\mathcal{M}$ is ordering for $\mathcal{L}_0$. Assume $a \leqslant b$, $a, b \in \mathcal{L}_0$. Then $\forall p \in \Sigma$, $\mu_p(a) \leqslant \mu_p(b)$ implies $\mu_p(a) + \mu_p(b') \leqslant 1$, so that $a \vee b'$ exists in $\mathcal{L}_0$ and $\mu_p(a \vee b') = \mu_p(a) + \mu_p(b')$ for all $p \in \Sigma$, which entails that $\mu_p(b) = \mu_p(a) + \mu_p(a' \wedge b)$ for all $p \in \Sigma$, hence $\mu_p(b) = \mu_p(a \vee (a' \wedge b))$ for all $p \in \Sigma$, so by Lemma 5(ii), $b = a \vee (a' \wedge b)$, which is the orthomodular law. Hence $\mathcal{L}_0$ is a σ-orthocomplete orthomodular poset.

Let $a \in \mathcal{L}$, $a \neq 0$, and assume that $\forall p \in \Sigma$, $a \notin \xi(p)$. Then the implication

$$\forall r \in \Sigma: a \in \xi(r) \Rightarrow 0 \in \xi(r)$$

holds, which by (5) of Definition 1 means that $a=0$, a contradiction. If $0 \neq a \in \mathcal{L}_0$, then $a \in \xi(p)$ for at least one $p \in \Sigma$ means that $\mu_p(a)=1$. □

From now on, we will write $(\Sigma, \mathcal{L}, \mathcal{L}_0, \xi)$ to denote a state property system for which there is $\mathcal{L}_0 \subset \mathcal{L}$ with a system of functions $\mu_s, s \in \Sigma$ such that conditions (Oi), (Oii), and (Oiii) are satisfied.

Definition 6: Let $(\Sigma, \mathcal{L}, \mathcal{L}_0, \xi)$ *be given. We will say that* μ_p *has a support* (*in* $\mathcal{L}_0$) *if there is an element* $b \in \mathcal{L}$ $(b \in \mathcal{L}_0)$ *such that* $\forall a \in \mathcal{L}_0$, $\mu_p(a)=1$ *iff* $b \leqslant a$.

Clearly, if a support exists, it is unique.

Proposition 4: Let $(\Sigma, \mathcal{L}, \xi)$ *be a state property system, satisfying condition* (A). *For* $p \in \Sigma$, *let* $a_p := \wedge\{a: a \in \xi(p)\}$. *Then* $a_p, p \in \Sigma$, *coincide with the atoms in* $\mathcal{L}$. *Moreover,* $a \in \xi(p)$ *if and only if* $a_p \leqslant a$.

Proof: Observe that condition (A) also implies condition

(A′) for all $p \in \Sigma$, the element $a_p = \wedge\{a: a \in \xi(p)\} \neq 0$.

Indeed, by Definition 1, $\wedge\{a: a \in \xi(p)\} \in \xi(p)$, and $0 \notin \xi(p)$. Hence $a_p \in \xi(p)$, and clearly, a_p is the smallest element in $\xi(p)$. Assume that $a_p \in \xi(r)$, $r \in \Sigma$. Now $a_p \leqslant a$ for all $a \in \xi(p)$ implies that $a \in \xi(r)$ for all $a \in \xi(p)$, hence $\xi(p) \subset \xi(r)$. By condition (A) then $p=r$.

Assume $b \leqslant a_p$, $b \neq 0$, then $\exists r, b \in \xi(r)$ and we have

$$\forall r \in \Sigma, b \in \xi(r) \Rightarrow a_p \in \xi(r) \Rightarrow a \in \xi(r) \; \forall \, a \in \xi(p),$$

$$\xi(p) \subset \xi(r) \Rightarrow p = r \Rightarrow b \in \xi(p) \Rightarrow a_p \leqslant b.$$

This proves that a_p is an atom in $\mathcal{L}$.

Now let a be an atom of $\mathcal{L}$. Then there is $r \in \Sigma$ with $a \in \xi(r)$, hence $a_r \leqslant a$. Since a_r is an atom, $a_r = a$. □

Notice that under conditions of Proposition 4, the element a_p is a support of μ_p.

Theorem 6: *Under the suppositions of* Proposition 4, $\mathcal{L}$ *is an atomistic lattice.*

Proof: Let $b \in \mathcal{L}$, put $c = \vee\{a_s: b \in \xi(s)\}$. Then clearly $c \leqslant b$, and if $b \in \xi(p)$, then $a_p \leqslant c$ im-

plies $c \in \xi(p)$, therefore $b=c$. □

Theorem 7: *Let* $(\Sigma, \mathcal{L}, \mathcal{L}_0, \xi)$ *be a state property system satisfying condition* (A) *and*

(B) *For every* $s \in \Sigma$, a_s *belongs to* $\mathcal{L}_0$.
(C) *For every* $b \in \mathcal{L}$, $b = \wedge\{a'_s : b \leqslant a'_s\}$.

Then $\mathcal{L}$ *with the mapping* $b' := \vee\{a_s : b \leqslant a'_s\}$ *is a complete, atomistic, orthocomplemented lattice.*

Proof: Owing to Theorem 6, it suffices to prove that $\mathcal{L}$ is orthocomplemented. (i) If $b \leqslant c$, then $\{a_s : c \leqslant a'_s\} \subset \{a_s : b \leqslant a'_s\}$, which by (C) implies $c' \leqslant b'$. (ii) From $b' \leqslant a'_s$ iff $a_s \leqslant b$ we obtain that $(b')' = \vee\{a_s : b' \leqslant a'_s\} = \vee\{a_s : a_s \leqslant b\} = b$. It remains to prove that $b \wedge b' = 0$. Assume that $a_s \leqslant b, a_s \leqslant b'$. By (i) and (ii), $a_s \leqslant b \leqslant a'_s$, which contradicts (B), so $b \wedge b' = 0$. By duality we get $b \vee b' = I$. □

Definition 7: Let $(\Sigma, \mathcal{L}, \mathcal{L}_0, \xi)$ *be given. We will say that* p *is orthogonal to* q, $p, q \in \Sigma$, *if there is* $a \in \mathcal{L}_0$ *such that* $\mu_p(a) = 1$ *and* $\mu_q(a) = 0$ (*equivalently*, $p \perp q$ *if* $a \in \xi(p)$, $a' \in \xi(q)$). *If* p *is orthogonal to* q *we will write* $p \perp q$.

It is obvious that the relation $\perp$ is symmetric and antireflexive. For $T \subset \Sigma$, we put $T' = \{p \in \Sigma : p \perp T\}$, where $p \perp T$ means that $p \perp t$ for all $t \in T$. Clearly, $\emptyset' = \Sigma$, $T \subseteq T''$ and $T_1 \subset T_2$ implies $T'_1 \supset T'_2 \forall T_1, T_2 \subset \Sigma$. If $s, p \in \Sigma$ have supports in $\mathcal{L}_0$, then $s \perp p$ if and only if their supports are orthogonal.

Denote by $\bar{T}^0$ the set of all $s \in \Sigma$ such that $\forall a \in \mathcal{L}_0$, $a \in \xi(t) \forall t \in T \Rightarrow a \in \xi(s)$. That is, $\bar{T}^0$ is the set of all superpositions of $T \subset \Sigma$ with respect to $\mathcal{L}_0$. Equivalently, $\bar{T}^0 = \{s \in \Sigma : \forall a \in \mathcal{L}_0, a_t \leqslant a \Rightarrow a_s \leqslant a\}$. Clearly, $\bar{T} \subset \bar{T}^0$.

Proposition 5: Let $(\Sigma, \mathcal{L}, \mathcal{L}_0, \xi)$ *be a state property system satisfying conditions* (A), (B), (C). *Then for every* $T \subset \Sigma$, $\bar{T} = \bar{T}^0$.

Proof: It suffices to prove that $\bar{T}^0 \subset \bar{T}$. We have $s \in \bar{T}^0$ iff $\forall a \in \mathcal{L}_0$, $a_t \leqslant a \forall t \in T \Rightarrow a_s \leqslant a$. Let us take $b \in \mathcal{L}$, and assume that $a_t \leqslant b \forall t \in T$. By property (C), $b = \wedge\{a'_r : b \leqslant a'_r\}$, which yields $a_t \leqslant a'_r$ for all $t \in T$ and r such that $b \leqslant a'_r$. From $s \in \bar{T}^0$we obtain that $a_s \leqslant a'_r$ for all corresponding r, and therefore $a_s \leqslant \wedge\{a'_r : b \leqslant a'_r\} = b$. In other words, $\vee_{t \in T} \xi(t) \subset \xi(s)$, hence $s \in \bar{T}$. □

Proposition 6: Let $(\Sigma, \mathcal{L}, \mathcal{L}_0, \xi)$. *Suppose that* (A), (B) *are satisfied. Then for any* $T \subset \Sigma$ *we have* $T'' = \bar{T}^0$.

Proof: We follow the proof of Ref. 55, Proposition 3.3.15. We will identify μ_s with $s \in \Sigma$ and write $T(a) = k$ if $\mu_t(a) = k \forall t \in T$. First we show that $T' = \emptyset$ if and only if $\{a \in \mathcal{L}_0 : T(a) = 1\} = \{1\}$. Assume that $T' = \emptyset$ and let $a \in \mathcal{L}_0$ be such that $a \neq 1$ and $T(a) = 1$. Since $a' \neq 0$, there is $p \in \Sigma$ such that $p(a') = 1$. But then $p(a) = 0$, so that $a \in T'$, a contradiction. Now assume that $\{a \in \mathcal{L}_0 : T(a) = 1\} = \{1\}$ and also that $p \in T'$. Then for the supports we have $a_p \perp a_t \forall t \in T$. Hence $t(a'_p) = 1$ for all $t \in T$, which is again a contradiction.

To prove the equality $T'' = \bar{T}^0$, assume first that $T' = \emptyset$. We have already proved that then $\{a \in \mathcal{L}_0 : T(a) = 1\} = \{1\}$, which implies $\bar{T}^0 = \Sigma = T''$.

Assume that $T' \neq \emptyset$ and also that $p \in \bar{T}^0$. We will show that $p \in T''$. Assume that $q \in T'$, then $a_q \perp a_t \forall t \in T$, and hence $T(a'_q) = 1$. This implies $a'_q \in \cap_{t \in T} \xi(t)$, which implies that $a'_q \in \xi(p)$. This implies $q \perp p$, which implies that $\bar{T}^0 \subset T''$.

Assume that $p \in T''$ and also that $T(a) = 1$ for some $a \in \mathcal{L}_0$. Without loss of generality we may assume that $a \neq 1$. We have $a_q \leqslant a'$ iff $q(a') = 1$. But $q(a') = 1$ implies that $q \in T'$. This means that $q \perp p$, and so $a_p \perp a_q$ for all q such that $q(a') = 1$. Hence $a_q \leqslant a'$ implies $a_q \leqslant a'_p$, so that $a' \leqslant a'_p$, so that $p(a) = 1$. This shows that $p \in \bar{T}^0$ and this completes the proof. □

As a corollary of Propositions 5 and 6, we obtain the following.

Corollary 1: Let $(\Sigma, \mathcal{L}, \mathcal{L}_0 \xi)$ *be a state property system satisfying* (A), (B), (C). *Then for every* $T \subset \Sigma$, $\bar{T} = T''$.

Theorem 8: *Let* $(\Sigma, \mathcal{L}, \mathcal{L}_0, \xi)$ *be a state property system satisfying* (A), (B). *Define* $\mathcal{F}^0(\Sigma) := \{S \subset \Sigma : S = \bar{S}^0\}$. *Then the mapping* $S \mapsto S'$ *is an orthocomplementation on* $\mathcal{F}^0(\Sigma)$. *Consequently,* $\mathcal{F}^0(\Sigma)$ *is a complete, atomistic, orthocomplemented lattice. If also* (C) *holds, then* $S \mapsto S'$ *is an orthocomplementation on* $\mathcal{F}(\Sigma)$, *and* $\mathcal{F}(\Sigma)$ *is a complete, atomistic, orthocomplemented lattice.*

Proof: It is easy to check that $S \mapsto \bar{S}^0$ is a closure operation, and hence $\mathcal{F}^0(\Sigma)$ is a complete lattice with lattice operations $S \wedge T = S \cap T$ and $S \vee T = (S \cup T)^{-0}$. Owing to property (A), $\mathcal{F}^0(\Sigma)$ is atomistic. To prove orthocomplementation, observe that $S \subset T \Rightarrow T' \subset S'$ and $S \wedge S' = \emptyset$ follow directly from the definition of the mapping $S \mapsto S'$. Property $S'' = S$ for $S \in \mathcal{F}^0(\Sigma)$ follows from Proposition 6. The remaining statement follows from Corollary 1. □

Definition 8: Suppose that $(\Sigma, \mathcal{L}, \xi)$ *is a state property system. The map* $\kappa: \mathcal{L} \to \mathcal{P}(\Sigma)$ *defined by*

$$\kappa(a) = \{p \in \Sigma : a \in \xi(p)\} \tag{16}$$

is called the Cartan map.

According to Ref. 46, Proposition 5, $\kappa: \mathcal{L} \to (\kappa(\mathcal{L}), \subset, \cap)$ has the following properties:

$$\kappa(1) = \Sigma, \tag{17}$$

$$\kappa(0) = \emptyset, \tag{18}$$

$$a \leqslant b \Leftrightarrow \kappa(a) \subset \kappa(b), \tag{19}$$

$$\kappa\left(\bigwedge_i a_i\right) = \bigcap_i \kappa(a_i). \tag{20}$$

That is, κ is an isomorphism of complete lattices. Moreover, by Ref. 46, Theorem 2, $\{\kappa(a) : a \in \mathcal{L}\}$ is an intersection system. Consequently, the operator $\mathrm{cl}: Y \mapsto \cap\{\kappa(a) : Y \subset \kappa(a)\}$ is a closure operator.[56]

The next lemma shows that $\kappa(a)$ is closed under superpositions.

Lemma 6: Let $(\Sigma, \mathcal{L}, \xi)$ *be a state property system. For all* $a \in \mathcal{L}$, $\kappa(a) \in \mathcal{F}(\Sigma)$.

Proof: For every $a \in \mathcal{L}$ we have $\kappa(a) \subset \kappa(a)^-$. Observe that $p \in \kappa(a) \Leftrightarrow a \in \xi(p)$. Let $s \in \bar{\kappa}(a)$, then $\cap_{p \in \kappa(a)} \xi(p) \subset \xi(s)$ implies $a \in \xi(s)$, which means that $s \in \kappa(a)$. □

Proposition 7: Let $(\Sigma, \mathcal{L}, \xi)$ *be a state property system such that condition* (A) *is satisfied. Then* $\kappa(\mathcal{L})$ *and* $\mathcal{F}(\Sigma)$ *are isomorphic as complete atomistic lattices*.

Proof: By Lemma 6, the range of κ is in $\mathcal{F}(\Sigma)$. By Ref. 46, Proposition 5, $\kappa(\mathcal{L})$ and $\mathcal{F}(\Sigma)$ are isomorphic as complete lattices. Let $a \in \mathcal{L}$ be an atom. By definition, $\kappa(a) = \{p \in \Sigma : a \in \xi(p)\}$. By (A), $a \in \xi(p)$ iff $a_p \leqslant a$, hence $a_p = a$ because a is an atom. By (A) we may conclude that $\kappa(a) = \{p\}$. □

Theorem 9: *Let* $(\Sigma, \mathcal{L}, \mathcal{L}_0, \xi)$ *be a state property system satisfying* (A), (B). *Then the mapping* $\kappa: \mathcal{L}_0 \to \mathcal{F}(\Sigma)$, $a \mapsto \kappa(a)$ *has the following properties*:

(i) *If* $a \wedge b$ *exists in* $\mathcal{L}_0$, *then* $\kappa(a \wedge b) = \kappa(a) \wedge \kappa(b)$.
(ii) *For all* $a \in \mathcal{L}_0$, $\kappa(a') = \kappa(a)'$.

Consequently, $\kappa(\mathcal{L}_0)$ *and* $\mathcal{L}_0$ *are isomorphic as atomistic* σ*-orthomodular posets*.

If also condition (C) *is satisfied*, *then* $\kappa(\mathcal{L})$ *and* $\mathcal{F}(\Sigma)$ *are isomorphic as complete*, *atomistic orthocomplemented lattices*.

Proof: (i) Suppose that $a \wedge b$ exists in $\mathcal{L}_0$. Obviously, $\kappa(a \wedge b) \leqslant \kappa(a) \wedge \kappa(b)$. Suppose that $s \in \kappa(a) \wedge \kappa(b) = \kappa(a) \cap \kappa(b)$. This gives $a, b \in \xi(s)$, hence $a_s \leqslant a, a_s \leqslant b$, consequently $a_s \leqslant a \wedge b$, i.e., $s \in \kappa(a \wedge b)$.

(ii) Assume that $p \in \kappa(a)'$, where $a \in \mathcal{L}_0$ with $0 < a < 1$. Then $p \perp q$ for all $q \in \kappa(a)$. It follows that $\forall q \in \kappa(a)$, $a_q \leqslant a'_p$. Hence $a_p \leqslant (\vee_{q \in \kappa(a)} a_q)' = a'$. This proves $\kappa(a)' \leqslant \kappa(a')$.

Now let $p \in \kappa(a')$, then $a_p \leqslant a' = (\vee\{a_q : a_q \leqslant a\})'$, hence $a_p \leqslant a'_q$ for all $q \in \kappa(a)$, which entails $p \in \kappa(a)'$.

The rest follows by Proposition 7. □

IV. SUPERPOSITION PRINCIPLE AND SECTORS

Let $(\mathcal{L},\Sigma,\xi)$ be a state property system such that property (A) and 3-MSP are satisfied. By Theorem 1, $(\Sigma,*)$, where $p*s=\lambda\{p,s\}=\{p,s\}^-$ is a projective geometry.

Definition 9: We will say that a superposition principle (SP, *for short*) *is satisfied in* $(\mathcal{L},\Sigma,\xi)$, *if for every* $p,q\in\Sigma$, $p\neq q$, *there is* $r\in\{p,q\}^-$ *such that* $r\neq p,r\neq q$.

The following statement is straightforward.

Theorem 10: *Let* $(\mathcal{L},\Sigma,\xi)$ *be a state property system such that* (A), 3-MSP *and* SP *are satisfied. The* $(\Sigma,*)$ *is an irreducible projective geometry*.

The notion of a sector was introduced in Ref. 67 (see also Ref. 55, Definition 3.2.7). Roughly speaking, a sector is a maximal λ-closed subset of Σ in which SP holds.

Definition 10: A nonempty subset $S\subset\Sigma$ *is called a sector if the following conditions hold*:

(i) $S\in\mathcal{L}(\Sigma)$;
(ii) *for any two different* $p,q\in S$ *we can find* $r\in\{p,q\}^-$ *distinct from* p *and* q;
(iii) *if* $q\in\Sigma\backslash S$, *then* $\{p,q\}^-=\{p,q\}$ *for every* $p\in S$.

A basic property of sectors is the following.

Lemma 7: If S,P *are sectors, then either* $S=P$ *or* $S\cap P=\emptyset$.

Proof: Assume that $S\neq P$. Then there is $q\in S\backslash P$ (or $q\in P\backslash S$), and by (ii) of Definition 10, $\{s,q\}^-\neq\{s,q\}$ whenever $s\in S\cap P$, while by (iii) of Definition 10, $\{s,q\}^-=\{s,q\}$. This contradiction implies that $S\cap P=\emptyset$. □

Theorem 11:[55] *Let* $(\mathcal{L},\Sigma,\xi)$ *be a state property system such that* (A) *and* 3-MSP *are satisfied. Then* Σ *can be written as a set theoretical union of sectors*.

Proof: Let us define a binary relation $\approx$ on Σ as follows: (i) for every $s\in\Sigma$, $s\approx s$, (ii) for distinct $s,t\in\Sigma$, $s\approx t$ if there is $r\in\{s,t\}^-$, $r\neq s,r\neq t$. We will prove that $\approx$ is an equivalence relation. Reflexivity and symmetry are clear from the definition. To prove transitivity, assume that $p\approx r$ and $r\approx s$. With no loss of generality, we may assume that p,r,s are mutually different. Let $x\in\{p,r\}^-\backslash\{p,r\}$, $y\in\{r,s\}^-\backslash\{r,s\}$. By 2-MSP we have $\{p,r\}^-=\{p,x\}^-=\{r,x\}^-$, $\{r,s\}^-=\{r,y\}^-=\{s,y\}^-$. Moreover, $r\in\{x,p\}^-$ implies $y\in\{x,p,s\}^-=\lambda\{x,p,s\}\subset S$ by 3-MSP. If $y\in\{p,s\}^-$ and $y\neq p$, then y is a minimal superposition of $\{p,s\}$, and hence $p\approx s$. If $y=p$, then $p\in\{r,s\}^-$ implies $r\in\{s,p\}^-$, hence $p\approx s$. If $y=x$, then $\{r,x\}^-=\{r,y\}^-$implies $\{p,r\}^-=\{r,s\}^-$, $p\in\{r,s\}^-$, hence $r\in\{s,p\}^-$ and $p\approx s$. Finally, if y is a minimal superposition, then $\{y,x\}^-\cap\{p,s\}^-\neq\emptyset$ implies that $p\approx s$.

Let $\hat{s}$ denote the equivalence class containing $s\in\Sigma$. We may write $\Sigma=\cup\{\hat{s}:s\in\Sigma\}$. It can be easily seen that $\hat{s}$ is a sector for every $s\in\Sigma$. □

Sectors can be characterized by the closure operator λ as follows.

Theorem 12: *Let* $(\mathcal{L},\Sigma,\xi)$ *be a state property system such that* (A) *and* 3-MSP *are satisfied. Let* $\Sigma=\cup_i S_i$, *where* $S_i\in\mathcal{L}(\Sigma)$ *and* (SP) *is satisfied on* S_i, $\forall i$. *Then* S_i *are sectors if and only if they are* λ*-clopen sets*.

Proof: By Theorem 11, Σ can covered by sectors, which are λ-closed. Let S be a sector. To prove that S is clopen, it suffices to prove that $\Sigma\backslash S$ is λ-closed. Assume that $p,q\in\Sigma\backslash S$ and let r be a minimal superposition of p,q. If $r\in S$, then by 2-MSP, $p\in\lambda\{r,q\}$. Since $r\in S$ and $q\notin S$, and S is a sector, we have $\lambda\{r,q\}=\{r,q\}$, which is a contradiction. Therefore $r\in\Sigma\backslash S$. This proves that sectors are λ-clopen sets.

Conversely, let S be a λ-clopen set such that SP is satisfied on S. Then conditions (i) and (ii) of Definition 10 are satisfied. To prove (iii), assume that $p\in S,q\notin S$, and $r\in\{p,q\}^-$, $r\neq p,q$, then either $r\in S$ or $r\notin S$. If $r\in S$, we get $q\in\{r,p\}^-$, which contradicts the supposition that S is λ-closed. If $r\notin S$, we get $p\in\{r,q\}^-$, which contradicts the supposition that S is open. It follows that $\{p,q\}^-=\{p,q\}$, hence S is a sector. □

Definition 11: We say that an element $a\in\mathcal{L}$ *is classical* (*or a superselection rule*) *if there is an element* $a'\in\mathcal{L}$ *such that for every* $s\in\Sigma$, $a\in\xi(s)\Leftrightarrow a'\notin\xi(s)$.

Clearly, 0 and 1 are classical elements.

Theorem 13: *Let $a \in \mathcal{L}$ be a classical element. Then $\kappa(a)=\{s \in \Sigma : a \in \xi(s)\}$ is a clopen set in $\mathcal{F}(\Sigma)$.*

Proof: We have $\Sigma=\{s:a \in \xi(s)\} \cup \{s:a' \in \xi(s)\}$. By symmetry, it suffices to prove that $S := \{s:a \in \xi(s)\}$ belongs to $\mathcal{F}(\Sigma)$. It easily follows from the fact that $r \in \bar{S}$ iff $\cap\{\xi(s):s \in S\} \subset \xi(r)$, which entails that if $a \in \xi(s)\, \forall\, s \in S$, then $a \in \xi(r)$, hence $r \in S$. □

From the fact that $\mathcal{F}(\Sigma) \subset \mathcal{L}(\Sigma)$, we obtain that $\kappa(a)$ is clopen also in $\mathcal{L}(\Sigma)$.

We recall that an element z in a lattice L with 0 and 1 is *central* when there exist two lattices L_1 and L_2 and an isomorphism between L and the direct product $L_1 \times L_2$ such that z corresponds to the element $(1_1, 0_2) \in L_1 \times L_2$. [cf., e.g., Ref. 68, Definition (4.12).] Evidently 0 and 1 are central elements.

Lemma 8: [Reference 68, Theorem (4.13)] *An element z of a lattice L with* 0 *and* 1 *is central if and only if there is an element z' in L such that*

$$a = (a \wedge z) \vee (a \wedge z') = (a \vee z) \wedge (a \vee z') \text{ for every } a \in L. \tag{21}$$

If L is orthocomplemented, then z is central if and only if the first equality in (21) *is satisfied for every $a \in L$* ([Ref. 68, Lemma (29.9)]).

Theorem 14: *Let $(\mathcal{L}, \mathcal{L}_0, \Sigma, \xi)$ be a state-property system such that conditions* (A), (B), (C) *are satisfied. Then an element $c \in \mathcal{L}$ is central if and only if c is classical.*

Proof: If properties (A), (B), (C) are satisfied, then $\mathcal{L}$ is a complete, atomistic, orthocomplemented lattice, and $\kappa: \mathcal{L} \to \mathcal{F}(\Sigma)$ is an isomorphism (Theorem 9).

Let c be a central element of L, then by (21), for every atom $a \in \mathcal{L}$, $a=(a \wedge c) \vee (a \wedge c')$, hence either $a=a \wedge c$, or $a=a \wedge c'$. By Proposition 7, $\kappa(a)=\{s\}$ for some $s \in \Sigma$. Moreover, $\kappa(a) = \kappa(a \wedge c) \vee \kappa(a \wedge c')$, hence either $\kappa(a \wedge c)=\{s\}$, or $\kappa(a \wedge c')=\{s\}$, that is, either $c \in \xi(s)$ or $c' \in \xi(s)$. This entails that c is classical.

Conversely, if c is classical, i.e., for every $s \in \Sigma$, either $s \in \kappa(c)$ or $s \in \kappa(c')$, then for every $a \in \mathcal{L}$,

$$\begin{aligned} a &= \vee\{a_s : s \in \kappa(a)\} = \vee\{a_s : s \in \kappa(a) \cap \kappa(c)\} \vee \vee\{a_s : s \in \kappa(a) \cap \kappa(c')\} \\ &= \vee\{a_s : s \in \kappa(a \wedge c)\} \vee \vee\{a_s : s \in \kappa(a \wedge c')\}, \end{aligned}$$

and consequently, $a=(a \wedge c) \vee (a \wedge c')$. By Lemma 8, c is central element of $\mathcal{L}$. □

V. CLOSED SUBSPACES AND MACKEY PROPERTY

Throughout this section we will use the following notations:

$$\text{For any } A, B \in \mathcal{L}(\Sigma), A \sqcup B := \lambda(A \cup B). \tag{22}$$

$$\text{For any } A, B \in \mathcal{F}(\Sigma), A \vee B := (A \cup B)^{-}. \tag{23}$$

For infima in both $\mathcal{L}(\Sigma)$, $\mathcal{F}(\Sigma)$ we use the same notation $A \wedge B (= A \cap B)$.

In Ref. 56, the following definitions were introduced, and the equivalence of the following three categories was proved.

Definition 12: A Mackey geometry is a projective geometry G together with a subset $\mathcal{S}$ of subspaces of G satisfying the following axioms:

(i) *$\mathcal{A} \subseteq \mathcal{S}$ implies $\cap \mathcal{A} \in \mathcal{S}$ (hence $\mathcal{S}$ is an intersection system)*,
(ii) *$\emptyset \in \mathcal{S}$*,
(iii) *if $E \in \mathcal{S}$, then $a \vee E \in \mathcal{S}$ for every $a \in G$.*

The elements of $\mathcal{S}$ are called the closed subspaces of G. An isomorphism of Mackey geometries is an isomorphism of projective geometries $g: G_1 \to G_2$ satisfying $S \in \mathcal{S}_1$ iff $g(E) \in \mathcal{S}_2$ (where E is any subspace of G_1).

Definition 13: A Mackey lattice is a projective lattice L together with an operator $x \to c(x)$

satisfying the following axioms:

(i) $x \leqslant c(x)$ *for every* $x \in L$,
(ii) $x \leqslant c(y)$ *implies* $c(x) \leqslant c(y)$,
(iii) $c(0)=0$,
(iv) *if* $x=c(x)$, *the* $a \vee x = c(a \vee x)$ *for every atom* a *in* L.

An element $x \in L$ *is closed if* $x=c(x)$. *An isomorphism of Mackey lattices is an isomorphism of* (*projective*) *lattices* $h: L_1 \to L_2$ *satisfying* $h(c_1(x))=c_2(h(x))$ *for every element* $x \in L_1$.

For any lattice L we shall denote by A_L the set of all atoms of L. We say that a lattice L has the *intersection property* (cf. [Ref. 56, Definition 2.5.1]) if one has

$$a,b \in A_L, a \neq b, x \in L \text{ and } a \leqslant b \vee x \Rightarrow \exists\, c \in A_L \text{ with } c \leqslant (a \vee b) \wedge x. \tag{24}$$

If L is an atomistic lattice, the following conditions are equivalent:

(1) L is upper and lower semimodular. A lattice L is called *upper semimodular* if $u \wedge v \lessdot v$ implies $u \lessdot u \vee v$, and L is *lower semimodular* if $u \lessdot u \vee v$ implies $u \wedge v \lessdot v$. Here $a \lessdot b$ means that b covers a.
(2) L has the covering property. A lattice L has the *covering property* if for $x \in L$ and any atom $a \in L$ one has, $a \wedge x = 0 \Rightarrow x \lessdot a \vee x$.
(3) L has the intersection property.

Moreover, the implications $1 \Rightarrow 2 \Rightarrow 3$ hold for any lattice.

Definition 14: An intersection lattice is a complete atomistic lattice C having the intersection property. (*Equivalently*, *C is both upper and lower semimodular.*)

Let L_1 and L_2 be Mackey lattices. We say that a morphism $f: L_1 \to L_2$ is *continuous* if

$$f(c_1(x)) \leqslant c_2(f(x)) \text{ for every } x \in L_1. \tag{25}$$

Theorem 15: [Reference 56, Theorem 13.3.8] *The categories of Mackey geometries*, *of Mackey lattices and of intersection lattices are equivalent. This means that one has a functor* $\mathcal{L}$ *from Mackey geometries to Mackey lattices*, *a functor* $\mathcal{C}$ *from Mackey lattices to intersection lattices*, *a functor* $\mathcal{G}$ *from intersection lattices to Mackey geometries*, *and natural isomorphisms* $G \cong \mathcal{G}(\mathcal{C}(\mathcal{L}(G)))$, $L \cong \mathcal{L}(\mathcal{G}(\mathcal{C}(L)))$ *and* $C \cong \mathcal{C}(\mathcal{L}(\mathcal{G}(C)))$.

In our setting, we obtain the following result.

Theorem 16: *Let* $(\mathcal{L}, \mathcal{L}_0, \Sigma, \xi)$ *satisfy properties* (A), (B), (C) *and* 3-MSP. *Then* $\mathcal{L}(\Sigma)$ *with the closure operation* $c(A)=\bar{A}$, $A \in \mathcal{L}(\Sigma)$, *is a Mackey lattice*.

Proof: (cf. Ref. 55, Proposition 3.3.18). Properties (i)–(iii) of Definition 13 are clear. We have to prove only property (iv).

By Theorem 8, $\mathcal{F}(\Sigma)$ is a complete, atomistic, orthocomplemented lattice with the orthocomplementation $S \mapsto S'$. We will use the fact that $\mathcal{L}(\Sigma) \supset \mathcal{F}(\Sigma)$, and $\mathcal{L}(\Sigma)$ is modular (Theorem 2). We must show that if $S \in \mathcal{F}(\Sigma)$ and $p \in \Sigma \backslash S$, $p \vee S = p \sqcup S$. Modularity of $\mathcal{L}(\Sigma)$ implies that $S \prec S \sqcup p$ (that is, $S \sqcup p$ covers S). Dually, $(S \sqcup p)' = S' \wedge \{p\}' \prec S'$. Then there is an atom $q \in \Sigma$ such that $(S \sqcup \{p\})' \sqcup \{q\} = S'$. Then $((S \sqcup \{p\})' \sqcup \{q\})' = S'' = S \prec (S \sqcup \{p\})''$. This entails $(S \sqcup \{p\})'' = S \vee \{p\} = S \sqcup \{p\}$. □

Corollary 2: If $(\mathcal{L}, \mathcal{L}_0, \Sigma, \xi)$ *satisfy properties* (A), (B), (C) *then for every* $S \in \mathcal{F}(\Sigma)$ *and a finite dimensional element* $P=\{p_1, \ldots, p_n\}^-$, *we have* $S \vee P = S \sqcup P$.

In accordance with Theorems 15 and 16, if a state property system $(\mathcal{L}, \Sigma, \xi)$ satisfies conditions (A), (B), (C) and 3-MSP, we may consider Σ with elements of $\mathcal{F}$ as closed subspaces as Mackey geometry, $\mathcal{L}(\Sigma)$ with the operator $S \to \bar{S}$ as a Mackey lattice, and $\mathcal{F}(\Sigma)$) as intersection lattice. Indeed, by Theorem 16, $\mathcal{L}(\Sigma)$ with the operation $S \mapsto \bar{S}$ is a Mackey lattice. By Ref. 56, Proposition 13.2.7, the set $\mathcal{F}(\Sigma)$ is an intersection lattice for the induced order. The infimum of any subset $\mathcal{A} \subset \mathcal{F}(\Sigma)$ is the element $\wedge \mathcal{A}$ and the supremum is $\vee \mathcal{A} = (\sqcup \mathcal{A})^-$. Moreover, the atoms of $\mathcal{F}(\Sigma)$are the atoms of $\mathcal{L}(\Sigma)$, that is, elements of Σ. Further, $\mathcal{F}(\Sigma)$ being an intersection lattice, the set of all atoms Σ of $\mathcal{F}(\Sigma)$ is a projective geometry (cf. Ref. 56, 2.5.7 and Theorem 1), and the set

of closure subspaces coincides with the sets $\{F \subset \Sigma : F \in \mathcal{F}(\Sigma)\}$ as closed subspaces. Owing the isomorphism between $\mathcal{F}(\Sigma)$ and $\mathcal{L}$, the lattice $\mathcal{L}$ can be considered as an intersection lattice with the atoms $\{a_s \in L : s \in \Sigma\}$.

In the sequel, we will need the following definition.

Definition 15: [Reference 56, Definition 13.4.6] *A Mackey lattice L is called regular if for every closed element $x \in L$ and every atom $a \not\leqslant x$, there exists a closed coatom $h \in L$ such that $x \leqslant h$ and $a \not\leqslant h$.*

VI. ORTHOGEOMETRIES, ORTHOLATTICES AND ORTHOSYSTEMS

Definition 16: [Reference 56, Definition 14.1.1] *An orthogeometry is a projective geometry with a relation $\perp$, called orthogonality, which satisfies the following axioms*:

(1) (O_1) *$a \perp b$ implies $b \perp a$,*
(2) (O_2) *if $a \perp p$, $b \perp p$ and $c \in a * b$, then $c \perp p$,*
(3) (O_3) *if $a, b, c \in G$ and $b \neq c$, then there is $p \in b * c$ with $p \perp a$,*
(4) (O_4) *for every $a \in G$ there exists $b \in G$ with $a \not\perp b$.*

An isomorphism of orthogeometries is an isomorphism of projective geometries $g : G_1 \to G_2$ satisfying $a \perp b$ iff $ga \perp gb$.

For any subset $A \subseteq G$ the *orthogonal set* $A^{\perp} := \{x \in G : x \perp a$ for every $a \in A\}$ is a subspace of G by condition (O_2). A point a of an orthogeometry G is called a *null point* if $a \in a^{\perp}$. The geometry is called *non-null* if it contains a non-null point and *pure* if every point is non-null [Ref. 56, Definition 14.1.7].

Definition 17: An ortholattice (please do not mistake it with orthocomplemented lattice, which is sometimes also called ortholattice) *is a projective lattice together with an operator $x \mapsto x^{\perp}$ which satisfies the following conditions*:

(1) $x \leqslant x^{\perp\perp}$ *for every* $x \in L$,
(2) $x \leqslant y$ *implies* $y^{\perp} \leqslant x^{\perp}$,
(3) $0^{\perp\perp} = 0$,
(4) *if* $x = x^{\perp\perp}$, *then* $a \vee x = (a \vee x)^{\perp\perp}$ *for every atom* $a \in L$.

An isomorphism of ortholattices is an isomorphism of lattices $f : L_1 \to L_2$ such that $f(x^{\perp}) = (fx)^{\perp}$ for every element $x \in L_1$.

Proposition 8: If L is an ortholattice, then L together with the operator $c(x) := x^{\perp\perp}$ is a regular Mackey lattice.

Definition 18: An orthosystem is an intersection lattice C together with an operator $x \mapsto x'$ satisfying the following conditions:

(1) $x = x''$ *for every* $x \in C$,
(2) $x \leqslant y$ *implies* $y' \leqslant x'$.

An isomorphism of orthosystems is an isomorphism of lattices $h : C_1 \to C_2$ such that $h(x') = (hx)'$ for every $x \in C_1$.

By Ref. 56, Remark 14.2.7, instead of an intersection lattice it is enough to require that C is a complete atomistic lattice satisfying the exchange property.

In Ref. 56, it is proved that there is a triple correspondence between orthogeometries and ortholattices and orthosystems [Ref. 56, Proposition 14.2.11]. We summarize the results in the next theorem.

Theorem 17:

(1) *If L is an orthogeometry, then the projective lattice $\mathcal{L}(G)$ together with the operator $E \mapsto E^{\perp}$ is an ortholattice* [Ref. 56, Proposition 14.2.5].
(2) *Let L be an ortholattice. Denote by $\mathcal{C}(L)$ the set of all closed element $x = x^{\perp\perp}$ of L. Then $\mathcal{C}(L)$ together with the operator $x \mapsto x^{\perp}$ is an orthosystem* (*for the induced order*) [Ref. 56, Proposition 14.2.8].

(3) *Let C be an orthosystem. Then the projective geometry* $\mathcal{G}(C)$ *consisting of the set* A_C *of all atoms of C and the operator* $*$, $a*b=\{c\in A_C: c\leqslant a\vee b\}$, *together with the relation* $a\perp b$ *iff* $a\leqslant b'$, *is an orthogeometry* [Ref. 56, Proposition 14.2.9].

Theorem 18: *Let* $(\mathcal{L},\mathcal{L}_0,\Sigma,\xi)$ *satisfy properties* (A), (B), (C) *and* 3-MSP. *Then* $\mathcal{F}(\Sigma)$ *is an orthosystem*.

Proof: By Theorems 16 and 15, $\mathcal{F}(\Sigma)$ is an intersection lattice. By Theorem 8, the mapping $S\mapsto S'$ is an orthocomplementation on $\mathcal{F}(\Sigma)$, which implies the desired result. □

Remark 1: If $(\mathcal{L},\mathcal{L}_0,\Sigma,\xi)$ *satisfies properties* (A), (B), (C) *and* 3-MSP *then, according to* Theorem 17, (Σ,λ) *is an orthogeometry and* $\mathcal{L}(\Sigma)$ *with the closed subspaces* $\mathcal{F}(\Sigma)$ *is an orthomodular lattice. Moreover, since* $\bar{S}=S''$, *in accordance with* Ref. 56, Proposition 14.2.4, $\mathcal{F}(\Sigma)$ *is a regular Mackey lattice*.

VII. REPRESENTATIONS IN VECTOR SPACES

Let V be any vector space over a field K. We emphasize that the dimension of V is arbitrary (possibly infinite) and K is allowed to be a skew field (often called division ring).

Proposition 9: [Reference 56, Proposition 2.1.6]. *Let V be any vector space. On* $V^*:=V\backslash\{0\}$ *one defines a binary relation as follows*: $x\sim y$ *iff* x,y *if* x,y *are linearly dependent. Since this is an equivalence relation, the quotient set* $\mathcal{P}(V):=V^*/\sim$ *is well defined and becomes a projective geometry if for any elements* $X,Y,Z\in\mathcal{P}(V)$ *one defines* $\ell(X,Y,Z)$ *iff* X,Y,Z *have linearly dependent representatives* x,y,z.

Theorem 19: *Let G be an irreducible projective geometry containing at least four independent points. Then there exists a (left) vector space V over a field K such that G is isomorphic to* $\mathcal{P}(V)$.

Definition 19: [Reference 56, Definition 14.1.5] *Let V be a vector space over K. A map*: $\Phi: V\times V\to K$ *is called a reflexive (or also symmetric) sesquilinear form if there exists an anti-isomorphism of fields* $\sigma: K\to K$ *such that the following axioms are satisfied:*

(1) $\Phi(x_1+x_2,y)=\Phi(x_1,y)+\Phi(x_2,y)$ *and* $\Phi(\lambda x,y)=\lambda.\Phi(x,y)$,
(2) $\Phi(x,y_1+y_2)=\Phi(x,y_1)+\Phi(x,y_2)$ *and* $\Phi(x,\mu y)=\Phi(x,y).\sigma(\mu)$;
(4) $\Phi(x,y)=0$ *iff* $\Phi(y,x)=0$.

A map $\Phi: V\times V\to K$ *is called a Hermitian form if there exists an involution* $\sigma: K\to K$, *i.e., an anti-isomorphism of order 2, such that the following axioms are satisfied*:

(1) $\Phi(x-1+x_2,y)=\Phi(x_1,y)+\phi(x_2,y)$ *and* $Phi(\lambda x,y)=\lambda.\Phi(x,y)$,
(4) $\Phi(x,y)=\sigma(\Phi(y,x))$ *for all* $x,y\in V$.

Obviously, these two axioms imply both (2) *and* (3). *Finally, we recall that the form* Φ *is nonsingular if* $\Phi(x,y)=0$ *for all* $y\in V$ *implies* $x=0$.

Proposition 10: [Ref. 56, Proposition 14.1.6] *If* $\Phi: V\times V\to K$ *is a nonsingular reflexive sesquilinear form, then the projective geometry* $\mathcal{P}(V)$ *together with the relation* $\perp$ *defined by* $[x]\perp[y]$ *iff* $\Phi(x,y)=0$ *is an orthogeometry.*

Definition 20: A point a of an orthogeometry G is called a null point if $a\in a^{\perp}$. *The orthogeometry is called non-null if it contains a non-null point and pure if every point is non-null.*

Let V be a pre-Hilbertian space over $\mathbb{R},\mathbb{C},\mathbb{H}$, then trivially the associated orthogeometry $\mathcal{P}(V)$ is pure.

Theorem 20: [Reference 56, Theorem 14.1.8] *Let V be a vector space of dimension* $\geqslant 3$ *over a field K, and suppose that* $\mathcal{P}(V)$ *together with the relation* $\perp$ *is an orthogeometry. Then there exists a nonsingular reflexive sesquilinear form* $\Phi: V\times V\to K$ *which induces the orthogonality* $\perp$ *in the sense of Proposition 10. Moreover, if* $\mathcal{P}(V)$ *is non-null, then* $\perp$ *can be induced by a (non-singular) Hermitian form.*

We call states $S:=\{s_1,\ldots,s_n\}$ in Σ *independent* if $\forall i$, $s_i\notin\lambda(S\backslash s_i)$.

Theorem 21: *Let* $(\mathcal{L},\Sigma,\xi)$ *be a state property system such that conditions* (A), SP, 3-MSP *are*

satisfied. Assume that there exist at least four independent states in Σ. *Then there is a field K and a vector space V over K such that the set* $\mathcal{L}(\Sigma)$ *of all linear subspaces of* Σ *is isomorphic to the lattice* $\mathcal{L}(V)$ *of all linear subspaces of V*.

Theorem 22: *Let* $(\mathcal{L},\Sigma,\xi)$ *be a state property system such that conditions* (A), (B),(C), SP, 3-MSP *are satisfied. Assume that there exist at least four independent states in* Σ. *Then there exists a field K, an involutive ant-automorphism* $^*:K\to K$, *a vector space V over K and a Hermitian form* $f:V\times V\to K$ *such that* $\mathcal{F}(\Sigma)$ *is orthoisomorphic to the set* $\mathcal{L}_f(V)$ *of all closed subspaces of V*.

JOURNAL OF MATHEMATICAL PHYSICS **47**, 072106 (2006)

On the ground state energy for a magnetic Schrödinger operator and the effect of the DeGennes boundary condition

Ayman Kachmar[a)]
Département de Mathématiques, Université Paris-Sud, Bât. 425, F-91405 Orsay, France

(Received 3 March 2006; accepted 5 June 2006; published online 28 July 2006)

Motivated by the Ginzburg-Landau theory of superconductivity, we estimate in the semiclassical limit the ground state energy of a magnetic Schrödinger operator with De Gennes boundary condition and we study the localization of the ground states. We exhibit cases when the De Gennes boundary condition has strong effects on this localization. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2218980]

I. INTRODUCTION

Let $\Omega \subset \mathbb{R}^2$ be an open bounded domain with regular boundary. Let us consider a cylindrical superconducting sample of cross section Ω. The superconducting properties are described by the minimizers (ψ,A) of the Ginzburg-Landau functional (cf. Refs. 1–3):

$$\mathcal{G}(\psi,A)=\int_{\Omega}\left\{|(\nabla-i\sigma\kappa A)\psi|^2+\sigma^2\kappa^2|\mathrm{curl}\,A-1|^2+\frac{\kappa^2}{2}(|\psi|^2-1)^2\right\}\mathrm{d}x+\int_{\partial\Omega}\tilde{\gamma}|\psi(x)|^2\mathrm{d}u_{|\partial\Omega}(x), \tag{1.1}$$

which is defined for pairs $(\psi,A)\in H^1(\Omega;\mathbb{C})\times H^1(\Omega;\mathbb{R}^2)$. The parameter κ is a characteristic of the material. A material is said to be of type I if κ is sufficiently small and it is said to be of type II when κ is large. The parameter σ is the intensity of the applied magnetic field which is supposed to be constant and perpendicular to Ω. For a minimizer (ψ,A) of the energy $\mathcal{G}$, the function ψ is called the order parameter and $|\psi|^2$ measures the density of superconducting Cooper electron pairs; the vector field A is called the magnetic potential and curl A is the induced magnetic field. Note that the order parameter ψ satisfies the following boundary condition proposed by De Gennes:[1]

$$\nu\cdot(\nabla-i\sigma\kappa A)\psi+\tilde{\gamma}\psi=0, \tag{1.2}$$

where ν is the unit outward normal of $\partial\Omega$ and $\tilde{\gamma}\in\mathbb{R}$ is called in the physical literature the De Gennes parameter. Note that the boundary condition (1.2) was initially introduced in the theory of PDE by Robin.

The physicist De Gennes[1] introduced the parameter $\tilde{\gamma}$ in order to model interfaces between superconductors and normal materials. In that context, $\tilde{\gamma}$ is taken to be a nonzero positive constant and $1/\tilde{\gamma}$ (called the extrapolation length) usually measures the penetration of the superconducting Cooper electron pairs in the normal material. The size of $\tilde{\gamma}$ depends on the nature of the material adjacent to the superconductor and it ranges from $\tilde{\gamma}=0$ (interfaces with insulators) to $\tilde{\gamma}=+\infty$ (interfaces with magnetic and ferromagnetic materials). Experiments show that for superconductors adjacent to ferromagnetic materials, the order parameter ψ vanishes at the boundary[4] and the boundary condition (1.2) is changed to the Dirichlet boundary condition. Negative values of $\tilde{\gamma}$

[a)]Also at: Université Libanaise, Département de mathématique, Hedeth, Beyrouth, Liban. Electronic mail: ayman.kachmar@math.u-psud.fr

were also considered in the physical literature.[5] It is suggested that negative values of $\tilde{\gamma}$ would be useful for modeling the situation when a superconductor is adjacent to another superconductor of higher transition temperature.

Suppose that we have a type II superconductor (i.e., κ is large). The functional $\mathcal{G}$ has a critical point of the type $(0,A)$. Such a critical point is called a normal state. It is then natural to study whether a normal state is a local minimum of $\mathcal{G}$ in the presence of a strong applied magnetic field. The Hessian of $\mathcal{G}$ near a normal state is given by

$$(\phi,B)\mapsto 2\left[\int_\Omega (|(\nabla-i\sigma\kappa A)\phi|^2-\kappa^2|\phi|^2)\mathrm{d}x+\int_{\partial\Omega}\tilde{\gamma}|\phi|^2\mathrm{d}\mu_{|_{\partial\Omega}}(x)+(\sigma\kappa)^2\int_\Omega|\mathrm{curl}\,B|^2\mathrm{d}x\right].$$

By defining the change of parameter $h=1/\sigma\kappa$, we then have to study as $h\to 0$ the positivity of the quadratic form:

$$H^1(\Omega)\ni u\mapsto\|(h\nabla-iA)u\|^2_{L^2(\Omega)}+h^2\int_{\partial\Omega}\tilde{\gamma}|u|^2\mathrm{d}\mu_{|_{\partial\Omega}}(x)-(\kappa h)^2\|u\|^2_{L^2(\Omega)}.$$

The semiclassical limit $h\to 0$ is now equivalent to a large field limit $\sigma\to+\infty$. In order to study the influence of the size of $\tilde{\gamma}$, it seems reasonable to suppose that $\tilde{\gamma}$ is depending on h. Also, due to the possibility of having different materials exterior to Ω together with possible lack of symmetry in the geometry of Ω, it seems also convenient to take $\tilde{\gamma}$ as a function of the boundary. Thus, given a vector field $A\in C^\infty(\bar{\Omega};\mathbb{R}^2)$, a regular real valued function $\gamma\in C^\infty(\partial\Omega;\mathbb{R})$, and a number $\alpha>0$, let us define the quadratic form:

$$H^1(\Omega)\ni u\mapsto q^{\alpha,\gamma}_{h,A,\Omega}(u)=\|(h\nabla-iA)u\|^2_{L^2(\Omega)}+h^{1+\alpha}\int_{\partial\Omega}\gamma(x)|u(x)|^2\mathrm{d}\mu_{|_{\partial\Omega}}(x). \tag{1.3}$$

Observing that $q^{\alpha,\gamma}_{h,A,\Omega}$ is semibounded, we consider the self-adjoint operator associated to $q^{\alpha,\gamma}_{h,A,\Omega}$ by Friedrich's theorem. This is the magnetic Schrödinger operator $P^{\alpha,\gamma}_{h,A,\Omega}$ with domain $D(P^{\alpha,\gamma}_{h,A,\Omega})$ defined by

$$P^{\alpha,\gamma}_{h,A,\Omega}=-(h\nabla-iA)^2,$$

$$D(P^{\alpha,\gamma}_{h,A,\Omega})=\{u\in H^2(\Omega);\ \nu\cdot(h\nabla-iA)u_{|_{\partial\Omega}}+h^\alpha\gamma u_{|_{\partial\Omega}}=0\}. \tag{1.4}$$

We denote by $\mu^{(1)}(\alpha,\gamma,h)$ the ground state energy of $P^{\alpha,\gamma}_{h,A,\Omega}$ which is defined using the min-max principle by

$$\mu^{(1)}(\alpha,\gamma,h):=\inf_{u\in H^1(\Omega),u\neq 0}\frac{q^{\alpha,\gamma}_{h,A,\Omega}(u)}{\|u\|^2_{L^2(\Omega)}}. \tag{1.5}$$

Let us also recall that this eigenvalue problem is gauge invariant.

In the case when $\gamma\equiv 0$ (which corresponds to a superconductor surrounded by the vacuum), a lot of papers are devoted to the estimate in a semiclassical regime of the ground state energy of $P^{\alpha,\gamma}_{h,A,\Omega}$. We would like to mention here the works of Baumann-Phillips-Tang,[6] Bernoff-Sternberg,[7] del Pino-Felmer-Sternberg,[8] Helffer-Mohamed,[9] Helffer-Morame,[10] and the recent work of Fournais-Helffer.[11] The special case when $\alpha=1$ and γ is a positive constant was considered by Lu-Pan.[12,13] It was shown that in this case the effect of the De Gennes parameter γ is weak in the sense that the limit $\lim_{h\to 0}[\mu^{(1)}(1,\gamma,h)]/h$ is the same as in the case $\gamma=0$. This regime is therefore not sufficient to recover all the physically interesting cases considered in Refs. 4 and 5. It is the object of this paper to establish the results announced in Ref. 14 and to analyze (for all values of α) the influence of the boundary term in (1.3) on the localization of the ground state energy of the operator $P^{\alpha,\gamma}_{h,A,\Omega}$.

Following the technique of Helffer-Morame,[10] we have to understand the model case of the half-plane when the magnetic field and the function γ are both constant. Consider the magnetic potential:

$$A_0(x_1,x_2)=\tfrac{1}{2}(-x_2,x_1),\quad \forall\,(x_1,x_2)\in\mathbb{R}\times\mathbb{R}_+. \tag{1.6}$$

Notice that $\operatorname{curl} A_0=1$. Let us define the function

$$\mathbb{R}\ni\gamma\mapsto\Theta(\gamma),$$

where

$$\Theta(\gamma):=\inf_{u\in H^1_{A_0}(\mathbb{R}\times\mathbb{R}_+),u\neq 0}\frac{\|(\nabla-iA_0)u\|^2_{L^2(\mathbb{R}\times\mathbb{R}_+)}+\gamma\displaystyle\int_{\mathbb{R}}|u(x_1,0)|^2\mathrm{d}x_1}{\|u\|^2_{L^2(\mathbb{R}\times\mathbb{R}_+)}}, \tag{1.7}$$

and

$$H^1_{A_0}(\mathbb{R}\times\mathbb{R}_+)=\{u\in L^2(\mathbb{R}\times\mathbb{R}_+);\ (\nabla-iA_0)u\in L^2(\mathbb{R}\times\mathbb{R}_+)\}. \tag{1.8}$$

Note that $\Theta(\gamma)$ is the bottom of the spectrum of the operator $P^{\alpha,\gamma}_{h,A_0,\Omega}$ with $h=1$ and $\Omega=\mathbb{R}\times\mathbb{R}_+$. We shall see that $\Theta(\gamma)<1$ (cf. Theorem II.2). If $\gamma=0$, we write:

$$\Theta_0:=\Theta(0). \tag{1.9}$$

It is Θ_0 which appears in the analysis for the Neumann problem.[6–13] Actually, we are interested in the bottom of the spectrum of the operator $P^{\alpha,\gamma}_{h,A_0,\mathbb{R}\times\mathbb{R}_+}$ but a scaling argument gives us

$$\forall h\in\mathbb{R}_+,\quad \forall\,\alpha,\gamma\in\mathbb{R},\quad \inf\operatorname{Sp}(P^{\alpha,\gamma}_{h,A_0,\mathbb{R}\times\mathbb{R}_+})=h\Theta(h^{\alpha-1/2}\gamma). \tag{1.10}$$

The semiclassical analysis of the half-plane model depends then on the sign of both $\alpha-\frac{1}{2}$ and γ. We have then to investigate the asymptotic behavior of $\Theta(\gamma)$ when $\gamma\to 0$ and when $\gamma\to\pm\infty$. This will be the object of study in Sec. II.

Now we state our main results.

Theorem I.1: *Suppose that $\Omega\subset\mathbb{R}^2$ is open, bounded, connected, and having a smooth boundary. Suppose moreover that the magnetic field is constant* $\operatorname{curl} A=1$. *Then, for $\alpha>0$ and $\gamma\in C^\infty(\partial\Omega;\mathbb{R})$, the ground state energy of the operator $P^{\alpha,\gamma}_{h,A,\Omega}$ satisfies*

$$\mu^{(1)}(\alpha,\gamma,h)=h\Theta(h^{\alpha-1/2}\gamma_0)(1+o(1))\quad (h\to 0), \tag{1.11}$$

where $\gamma_0:=\min_{x\in\partial\Omega}\gamma(x)$.

Theorem I.1 gives a first term approximation of $\mu^{(1)}(\alpha,\gamma,h)$. The asymptotics (1.11) is valid without the need for any nondegeneracy hypothesis on the set of minima of γ, and holds for the function γ being constant as well. Let us remark that the asymptotics (1.11) depends strongly on α. In particular, when $\alpha=\frac{1}{2}$, we get

$$\lim_{h\to 0}\frac{\mu^{(1)}(\alpha,\gamma,h)}{h}=\Theta(\gamma_0)<1,$$

and if $\gamma_0=0$ or if $\alpha>\frac{1}{2}$, then (cf. Proposition II.5):

$$\lim_{h\to 0}\frac{\mu^{(1)}(\alpha,\gamma,h)}{h}=\Theta_0<1.$$

When $\alpha<\frac{1}{2}$, it is the sign of γ_0 that affects the asymptotics. Actually, if $\gamma_0<0$ we have (cf. Proposition II.8)

$$\lim_{h\to 0}\frac{\mu^{(1)}(\alpha,\gamma,h)}{h^{2\alpha}}=-\gamma_0^2,$$

and if $\gamma_0>0$, we have (cf. (2.46))

$$\lim_{h\to 0}\frac{\mu^{(1)}(\alpha,\gamma,h)}{h}=1,$$

which is the same behavior as that for the Dirichlet problem.[10] This last regime ($0<\alpha<\frac{1}{2}$ and $\gamma_0>0$) is in accordance with the physical observations in Ref. 4.

In the next theorem, we give a two-term asymptotics of $\mu^{(1)}(\alpha,\gamma,h)$ when $\alpha\in]\frac{1}{2},1[$.

Theorem I.2: *Suppose in addition to the hypotheses of Theorem I.1 that* $\frac{1}{2}<\alpha<1$ *and that the function* γ *is nonconstant. Then we have the following asymptotic expansion as* h *tends to* 0:

$$\mu^{(1)}(\alpha,\gamma,h)=h\Theta_0+6M_3\gamma_0 h^{\alpha+1/2}+\mathcal{O}(h^{\inf(3/2,2\alpha)}),\tag{1.12}$$

where M_3 *is a strictly positive universal constant.*

The constant M_3 satisfies $\Theta'(0)=6M_3$ and it will be defined precisely in Sec. II, see however (2.25) and (2.27). Compared with the result obtained in Ref. 10, the second term in the two-term asymptotics of $\mu^{(1)}(\alpha,\gamma,h)$ when $\gamma=0$ is of order $h^{3/2}$, whereas it is of order $h^{\alpha+1/2}$ in the regime considered in Theorem I.2. Let us mention also that in Ref. 11, the authors obtain (when $\gamma=0$) a complete asymptotic expansion under a generic hypothesis on the scalar curvature of $\partial\Omega$. It seems that a complete asymptotic expansion could be obtained in the regime of Theorem I.2 but under the following generic hypothesis over γ:

(1) γ has a finite number of minima;
(2) all the minima of γ are nondegenerate.

We leave this point hoping to analyze it in a future work.

Next we turn to the question of the localization of the ground states. Let $u_{\alpha,\gamma,h}$ be a ground state of the operator $P_{h,A,\Omega}^{\alpha,\gamma}$. We say that $u_{\alpha,\gamma,h}$ is exponentially localized as h tends to 0 near a closed set $\mathcal{B}$ in $\bar{\Omega}$ if there exists $\beta>0$, and for each neighborhood $\mathcal{V}$ of $\mathcal{B}$, there exist positive constants h_0, δ and C such that

$$\|u_{\alpha,\gamma,h}\|_{L^2(\Omega\setminus\mathcal{V})}\leqslant C\exp\left(-\frac{\delta}{h^\beta}\right)\|u_{\alpha,\gamma,h}\|_{L^2(\Omega)},\quad\forall\, h\in]0,h_0].\tag{1.13}$$

In the next theorem we describe some effect of γ on the localization of the ground states of the operator $P_{h,A,\Omega}^{\alpha,\gamma}$.

Theorem I.3: *Under the hypotheses of Theorem I.1, if* $\gamma_0\leqslant 0$ *or* $\frac{1}{2}\leqslant\alpha<1$, *a ground state of the operator* $P_{h,A,\Omega}^{\alpha,\gamma}$ *is exponentially localized as* h *tends to* 0 *near the boundary points where* γ *is minimum.*

More precisely, (1.13) *is satisfied with* $\beta=1-\alpha$ *if* $\gamma_0<0$, $\beta=(1-\alpha)/2$ *if* $\frac{1}{2}<\alpha<1$, *and* $\beta=1/2$ *otherwise.*

In the special case $\alpha=1$, the scalar curvature κ_r and the function γ affects the asymptotic expansion of the ground state energy to the same order.

Theorem I.4: *Suppose in addition to the hypotheses of Theorem I.1 that* $\alpha=1$. *Then we have the following asymptotic expansion as* h *tends to* 0:

$$\mu^{(1)}(\alpha,\gamma,h)=h\Theta_0-2M_3(\kappa_r-3\gamma)_{\max}h^{3/2}+\mathcal{O}(h^{13/8}),\tag{1.14}$$

and a ground state $u_{\alpha,\gamma,h}$ *of the operator* $P_{h,A,\Omega}^{1,\gamma}$ *is localized near the boundary points where the function* $\kappa_r-3\gamma$ *is maximal.*

More precisely, (1.13) *is satisfied with* $\beta=1/4$.

If γ is constant, the remainder in (1.14) is better and of order $\mathcal{O}(h^{5/3})$. When $\gamma\equiv 0$ we recover in the above theorem the result of Helffer-Morame.[10] Let us mention that the expansion (1.14) is

announced by Pan[25] in the particular case when γ is a positive constant. As in Ref. 11, we believe that an asymptotic expansion with higher terms could be obtained under a generic hypothesis on the function $\kappa_r - 3\gamma$.

In the next theorem, we study the case when the function γ is constant and we find that only the scalar curvature plays a role.

Theorem I.5: *Suppose in addition to the hypotheses of Theorem I.1 that the function γ is constant and that $\alpha \geqslant \frac{1}{2}$. There exists a constant $M_3(\alpha,\gamma) > 0$ such that we have the following asymptotic expansion as h tends to* 0:

$$\mu^{(1)}(\alpha,\gamma,h) = h\Theta(h^{\alpha-1/2}\gamma) - 2M_3(\alpha,\gamma)(\kappa_r)_{\max}h^{3/2} + o(h^{3/2}). \tag{1.15}$$

Moreover, a ground state of the operator $P^{\alpha,\gamma}_{h,A,\Omega}$ is localized as h tends to 0 *near the boundary points where the scalar curvature is maximal, and* (1.13) *is satisfied with $\beta = 1/4$.*

When $\alpha > \frac{1}{2}$, the constant $M_3(\alpha,\gamma)$ is equal to the universal constant M_3. When $\alpha = \frac{1}{2}$, we have $M_3(\frac{1}{2},\gamma) = M_3(\gamma)$, where the constant $M_3(\gamma)$ will be defined in Sec. II cf. (2.24).

This paper is organized in the following way. In Sec. II, we link the analysis of the half-plane model operator to that of a one-dimensional operator. We get in particular the existence of a number $\xi(\gamma) > 0$ such that $\Theta(\gamma)$ is the lowest eigenvalue of the operator $-\partial_t^2 + (t-\xi(\gamma))^2$. Let φ_γ be an eigenfunction associated to $\Theta(\gamma)$. We establish the regularity of $\Theta(\gamma)$ and φ_γ as functions of γ, the asymptotic behavior of $\Theta(\gamma)$ as $\gamma \to \pm\infty$, and uniform estimates with respect to γ describing the exponential decay of φ_γ at infinity.

In Sec. III, we use the eigenfunction φ_γ to construct a test function inspired by Refs. 7 and 10 and we obtain an upper bound for $\mu^{(1)}(\alpha,\gamma,h)$. We then carry out a similar analysis to that in Ref. 10 and we use the results of Sec. II to prove Theorem I.1.

In Sec. IV, we show how to get the localization of the ground states using Agmon's technique.[15] Finally, in Sec. V, the analysis of a one-dimensional family of operators on a weighted L^2-space appears (cf. (5.21)). It is the same family of operators appearing in Ref. 10 (Sec. 11) but with a different boundary condition this time. This analysis permits us to derive two-term asymptotics of the ground state energy showing the influence of the scalar curvature. We finish then the proofs of Theorems I.2, I.3, I.4, and I.5.

II. THE MODEL OPERATOR

Given $\gamma \in \mathbb{R}$, let us consider the quadratic form:

$$H^1_{A_0}(\mathbb{R}\times\mathbb{R}_+) \ni u \mapsto q[\gamma](u) = \|(\nabla - iA_0)u\|^2_{L^2(\mathbb{R}\times\mathbb{R}_+)} + \gamma\int_{\mathbb{R}} |u(x_1,0)|^2 \mathrm{d}x_1. \tag{2.1}$$

The magnetic potential A_0 and the form domain $H^1_{A_0}(\mathbb{R}\times\mathbb{R}_+)$ are defined, respectively, in (1.6) and (1.8). Observing that the quadratic form $q[\gamma]$ is bounded from below, we can associate to $q[\gamma]$, by taking the Friedrichs extension, a unique self-adjoint operator $P[\gamma]$ on $L^2(\mathbb{R}\times\mathbb{R}_+)$. The min-max principle gives that the bottom of the spectrum of $P[\gamma]$ is equal to $\Theta(\gamma)$ (cf. (1.7)).

A. Link with a one-dimensional operator

By a change of gauge and a partial Fourier transformation with respect to the first variable, we obtain that the spectral analysis of the operator $P[\gamma]$ will be deduced from that of the ξ-family of one dimensional operators:

$$H[\gamma,\xi] = -\frac{\mathrm{d}^2}{\mathrm{d}t^2} + (t-\xi)^2, \tag{2.2}$$

with domain

$$D(H[\gamma,\xi]) = \{u \in B^2(\mathbb{R}_+);\ u'(0) = \gamma u(0)\}, \tag{2.3}$$

where, for a given integer k, the space $B^k(\mathbb{R}_+)$ is defined by

$$B^k(\mathbb{R}_+) = \{u \in H^k(\mathbb{R}_+);\ t^k u \in L^2(\mathbb{R}_+)\}. \tag{2.4}$$

Note that the operator $H[\gamma,\xi]$ has compact resolvent and hence the spectrum is discrete. We denote by $\mu^{(1)}(\gamma,\xi)$ the first eigenvalue of $H[\gamma,\xi]$. The min-max principle gives

$$\mu^{(1)}(\gamma,\xi) = \inf_{u\in B^1(\mathbb{R}_+),u\neq 0} \frac{q[\gamma,\xi](u)}{\|u\|^2_{L^2(\mathbb{R}_+)}},$$

where $q[\gamma,\xi]$ is the quadratic form associated to $H[\gamma,\xi]$:

$$q[\gamma,\xi](u) = \int_{\mathbb{R}_+} (|u'(t)|^2 + |(t-\xi)u(t)|^2)\mathrm{d}t + \gamma|u(0)|^2. \tag{2.5}$$

A spectral analysis using the separation of variables (cf. Ref. 16) gives us

$$\Theta(\gamma) = \inf_{\xi\in R} \mu^{(1)}(\gamma,\xi). \tag{2.6}$$

In the following lemma, we collect some useful estimates of $\mu^{(1)}(\gamma,\xi)$.

Lemma II.1: Given $\epsilon \in]0,1[$, *we have*

$$\mu^{(1)}(\gamma,\xi) \geqslant (1-\epsilon)\mu^{(1)}(0,\xi) - \frac{(\gamma_-)^2}{\epsilon}, \quad \forall\ \gamma,\xi \in \mathbb{R}, \tag{2.7}$$

where $\gamma_- = \max(-\gamma,0)$.

Moreover, given $\gamma \in \mathbb{R}$, *we have*

$$\lim_{\xi\to-\infty} \mu^{(1)}(\gamma,\xi) = +\infty, \quad \lim_{\xi\to+\infty} \mu^{(1)}(\gamma,\xi) = 1. \tag{2.8}$$

Proof: Using the density of $C_0^\infty(\overline{\mathbb{R}_+})$ in $H^1(\mathbb{R}_+)$, we get for any $u \in H^1(\mathbb{R}_+)$:

$$|u(0)|^2 = -2\int_0^\infty u(t)u'(t)\mathrm{d}t. \tag{2.9}$$

By the Cauchy-Schwarz inequality, we get for any $\alpha>0$:

$$|u(0)|^2 \leqslant \alpha\|u\|^2_{L^2(\mathbb{R}_+)} + \frac{1}{\alpha}\|u'\|^2_{L^2(\mathbb{R}_+)}.$$

Taking $\alpha = \epsilon/\gamma$ (with $\gamma<0$), we get

$$q[\gamma,\xi](u) \geqslant (1-\epsilon)q[0,\xi](u) - \frac{(\gamma_-)^2}{\epsilon}\|u\|^2_{L^2(\mathbb{R}_+)}, \quad \forall\ u \in B^1(\mathbb{R}_+). \tag{2.10}$$

The min-max principle now gives (2.7).

Notice that (2.8) is valid for $\gamma=0$ (Ref. 10). So the limit as $\xi\to-\infty$ in (2.8) is now a consequence of the estimate (2.7). For the reader's convenience, let us give for nonzero γ a proof for the limit as $\xi\to+\infty$ in (2.8). Let us denote by $\mu^D(\xi)$ the first eigenvalue of the Dirichlet realization of the harmonic oscillator $-\partial_t^2+(t-\xi)^2$ on $\mathbb{R}_+$. We have by the min-max principle:

$$\mu^{(1)}(0,\xi) + \gamma|\varphi_{\gamma,\xi}(0)|^2 \leqslant \mu^{(1)}(\gamma,\xi) \leqslant \mu^D(\xi), \tag{2.11}$$

where $\varphi_{\gamma,\xi}$ is the L^2-normalized eigenfunction associated to $\mu^{(1)}(\gamma,\xi)$. Let us notice also that[10,16] $\lim_{\xi\to+\infty}\mu^D(\xi)=1$. So, if we know that $\lim_{\xi\to+\infty}|\varphi_{\gamma,\xi}(0)|^2=0$, then (2.11) is sufficient to deduce the

limit as $\xi \to +\infty$ in (2.8). Thus, it remains for us to prove the following claim:

Given $\epsilon \in \,]0,1[$ and $\gamma \in \mathbb{R}$, there exists a constant $C > 0$ such that

$$\forall\, \xi \in [C, +\infty[, \quad |\varphi_{\gamma,\xi}(0)|^2 \leqslant Ce^{-\epsilon\xi/2}. \tag{2.12}$$

Let us mention that the decay in (2.12) is not optimal.[17,18] We prove (2.12) using Agmon type estimates.[15] Let Φ be a regular function with compact support. An integration by parts gives the following identity:

$$q[\gamma,\xi](e^{\Phi}\varphi_{\gamma,\xi}) = \mu^{(1)}(\gamma,\xi)\|e^{\Phi}\varphi_{\gamma,\xi}\|^2_{L^2(\mathbb{R}_+)} + \|\Phi' e^{\Phi}\varphi_{\gamma,\xi}\|^2_{L^2(\mathbb{R}_+)}. \tag{2.13}$$

Using the estimate (2.10) (with $\epsilon = 1/2$) together with the fact that $\mu^D(\xi)$ is bounded for $\xi \in \mathbb{R}_+$, we can rewrite (2.13) in the form:

$$\tfrac{1}{2}(\|(e^{\Phi}\varphi_{\gamma,\xi})'\|^2_{L^2(\mathbb{R}_+)} + \|(t-\xi)e^{\Phi}\varphi_{\gamma,\xi}\|^2_{L^2(\mathbb{R}_+)}) \leqslant \widetilde{C}\|e^{\Phi}\varphi_{\gamma,\xi}\|^2_{L^2(\mathbb{R}_+)} + \|\Phi' e^{\Phi}\varphi_{\gamma,\xi}\|^2_{L^2(\mathbb{R}_+)}, \tag{2.14}$$

for some constant $\widetilde{C} > 0$. We choose now Φ as

$$\Phi(t) := \begin{cases} \epsilon\xi\dfrac{(t-1)^2}{2} & \text{if } 0 \leqslant t \leqslant 1 \\ 0 & \text{if } t \geqslant 1. \end{cases}$$

Under this choice of Φ, we can get a sufficiently large constant $C > 0$ such that, for $\xi \in [C, +\infty[$, we can rewrite (2.14) in the form:

$$\|e^{\Phi}\varphi_{\gamma,\xi}\|_{H^1(\Omega)} \leqslant C.$$

Using the Sobolev imbedding $H^1(\mathbb{R}_+) \hookrightarrow L^\infty(\mathbb{R}_+)$, this last estimate is sufficient to deduce (2.12). □

Following the analysis of Dauge-Helffer,[19] we have now the following result.

Theorem II.2: *For each* $\gamma \in \mathbb{R}$, $\Theta(\gamma) < 1$ *and the function* $\mathbb{R} \ni \xi \mapsto \mu^{(1)}(\gamma,\xi)$ *attains its minimum at a unique positive point* $\xi(\gamma)$ *that satisfies*

$$\xi(\gamma)^2 = \Theta(\gamma) + \gamma^2. \tag{2.15}$$

Proof: Let us notice that by Kato's theory (Ref. 20), the maps

$$\xi \mapsto \mu^{(1)}(\gamma,\xi), \quad \xi \mapsto \varphi_{\gamma,\xi} \in L^2(\mathbb{R}_+)$$

are analytic. Here we recall that $\varphi_{\gamma,\xi}$ is the unique strictly positive and L^2-normalized eigenfunction associated to $\mu^{(1)}(\gamma,\xi)$. Let us consider $\tau > 0$. Note that

$$\mu^{(1)}(\gamma,\xi+\tau)\varphi_{\gamma,\xi+\tau}(t+\tau) = H[\gamma,\xi](\varphi_{\gamma,\xi+\tau}(t+\tau)), \quad \forall\, t \in \mathbb{R}_+.$$

Taking the scalar product with $\varphi_{\gamma,\xi}$ and then integrating by parts, we get

$$(\mu^{(1)}(\gamma,\xi+\tau) - \mu^{(1)}(\gamma,\xi))\int_{\mathbb{R}_+} \varphi_{\gamma,\xi+\tau}(t+\tau)\varphi_{\gamma,\xi}(t)\mathrm{d}t = \varphi'_{\gamma,\xi+\tau}(\tau)\varphi_{\gamma,\xi}(0) - \gamma\varphi_{\gamma,\xi+\tau}(\tau)\varphi_{\gamma,\xi}(0). \tag{2.16}$$

Recall that we have the boundary conditions

$$\varphi'_{\gamma,\xi+\tau}(0) = \gamma\varphi_{\gamma,\xi+\tau}(0), \quad \varphi'_{\gamma,\xi}(0) = \gamma\varphi_{\gamma,\xi}(0).$$

Then we can rewrite (2.16) as

$$\frac{\mu^{(1)}(\gamma,\xi+\tau)-\mu^{(1)}(\gamma,\xi)}{\tau}\int_{\mathbb{R}_+}\varphi_{\gamma,\xi+\tau}(t+\tau)\varphi_{\gamma,\xi}(t)\mathrm{d}t$$
$$=\left[\frac{\varphi'_{\gamma,\xi+\tau}(\tau)-\varphi'_{\gamma,\xi+\tau}(0)}{\tau}-\gamma\frac{\varphi_{\gamma,\xi+\tau}(\tau)-\varphi_{\gamma,\xi+\tau}(0)}{\tau}\right]\cdot\varphi_{\gamma,\xi}(0).$$

By taking the limit as $\tau\to 0$, we get

$$\partial_\xi\mu^{(1)}(\gamma,\xi)=(\varphi''_{\gamma,\xi}(0)-\gamma\varphi'_{\gamma,\xi}(0))\varphi_{\gamma,\xi}(0).$$

Finally, we make the substitutions

$$\varphi''_{\gamma,\xi}(0)=(\xi^2-\mu^{(1)}(\gamma,\xi))\varphi_{\gamma,\xi}(0),\quad \varphi'_{\gamma,\xi}(0)=\gamma\varphi_{\gamma,\xi}(0),$$

and we get the following formula,

$$\partial_\xi\mu^{(1)}(\gamma,\xi)=(\xi^2-\mu^{(1)}(\gamma,\xi)-\gamma^2)|\varphi_{\gamma,\xi}(0)|^2, \tag{2.17}$$

called usually the *F*-formula (cf. Refs. 19 and 21). Using (2.7) and (2.8), we get

$$\partial_\xi\mu^{(1)}(\gamma,\xi)_{|_{\xi=0}}<0,\quad \partial_\xi\mu^{(1)}(\gamma,\xi)_{|_{\xi=\eta}}>0,$$

for a sufficiently large $\eta>0$. This gives the existence of a positive critical point of $\mu^{(1)}(\gamma,\xi)$. Let us notice now that for any critical point ξ_c of $\mu^{(1)}(\gamma,\xi)$, we have

$$\partial^2_\xi\mu^{(1)}(\gamma,\xi)_{|_{\xi=\xi_c}}=2\xi_c|\varphi_{\gamma,\xi}(0)|^2.$$

This shows that any negative critical point is a global maximum and any positive critical point is a global minimum of $\mu^{(1)}(\gamma,\xi)$. Coming back to (2.8), $\lim_{\xi\to-\infty}\mu^{(1)}(\gamma,\xi)=+\infty$, and thus there does not exist any negative critical points. Therefore, the minimum of $\xi\mapsto\mu^{(1)}(\gamma,\xi)$ is attained at a unique point $\xi(\gamma)>0$ and the function $\xi\mapsto\mu^{(1)}(\gamma,\xi)$ is strictly increasing on $[\xi(\gamma),+\infty[$. This proves in particular (recalling (2.6)):

$$\Theta(\gamma)=\mu^{(1)}(\gamma,\xi(\gamma))<1.$$

□

In the sequel, we denote by φ_γ the unique strictly positive and L^2-normalized eigenfunction associated to the eigenvalue $\Theta(\gamma)$, and by $H[\gamma]$ the operator $H[\gamma,\xi(\gamma)]$:

$$\varphi_\gamma=\varphi_{\gamma,\xi(\gamma)},\quad H[\gamma]=H[\gamma,\xi(\gamma)]. \tag{2.18}$$

In the next lemma, we collect various useful relations satisfied by the eigenfunction φ_γ. These relations are similar to those given in Appendix A of Ref. 10.

Lemma II.3: For each $\gamma\in\mathbb{R}$, *the following relations hold:*

$$\int_{\mathbb{R}_+}(t-\xi(\gamma))|\varphi_\gamma(t)|^2\mathrm{d}t=0, \tag{2.19}$$

$$\int_{\mathbb{R}_+}(t-\xi(\gamma))^2|\varphi_\gamma(t)|^2\mathrm{d}t=\frac{\Theta(\gamma)}{2}-\frac{\gamma}{4}|\varphi_\gamma(0)|^2, \tag{2.20}$$

$$\int_{\mathbb{R}_+}(t-\xi(\gamma))^3|\varphi_\gamma(t)|^2\mathrm{d}t=\frac{1}{6}[1-2(\gamma\xi(\gamma))^2]|\varphi_\gamma(0)|^2. \tag{2.21}$$

Proof: We follow the calculations done in Bernoff-Sternberg.[7] Let us consider the differential operator:

$$L = -\partial_t^2 + (t - \xi(\gamma))^2 - \Theta(\gamma).$$

Note that for any polynomial p, we have the following identity:

$$L(2p\varphi_\gamma - p'\varphi_\gamma) = (p^{(3)} - 4[(t - \xi(\gamma) - \Theta(\gamma)]p' - 4(t - \xi(\gamma))p)\varphi_\gamma. \tag{2.22}$$

Let $v = 2p\varphi_\gamma - p'\varphi'_\gamma$. Integrating by parts we obtain

$$\int_0^{+\infty} \varphi_\gamma(t)(Lv)(t)\mathrm{d}t = (v'(0) - \gamma v(0))\varphi_\gamma(0). \tag{2.23}$$

Taking $p=1$, we get

$$-4\int_0^{+\infty} (t - \xi(\gamma))|\varphi_\gamma(t)|^2\mathrm{d}t = 2(\xi(\gamma)^2 - \gamma^2 - \Theta(\gamma))|\varphi_\gamma(0)|^2.$$

Recalling (2.15), the above formula proves (2.19).

We prove (2.20) by taking $p=(t-\xi(\gamma))$. To prove (2.21), we take $p=(t-\xi(\gamma))^2$. Note that we have in this case

$$v'(0) - \gamma v(0) = 2(2(\gamma\xi(\gamma))^2 - 1)\varphi_\gamma(0).$$

We get now from (2.22) and (2.23)

$$-12\int_0^{+\infty} (t - \xi(\gamma))^3|\varphi_\gamma(t)|^2\mathrm{d}t = 2(2(\gamma\xi(\gamma))^2 - 1)|\varphi_\gamma(0)|^2.$$

This proves (2.21). □

For $\gamma \in \mathbb{R}$, let us define the parameter

$$M_3(\gamma) = \tfrac{1}{6}(1 + (\gamma\xi(\gamma))^2)|\varphi_\gamma(0)|^2, \tag{2.24}$$

and when $\gamma=0$, we write $M_3 := M_3(0)$. Note that (2.21) gives

$$M_3 = \int_{\mathbb{R}_+} (t - \xi_0)^3|\varphi_0(t)|^2\mathrm{d}t, \tag{2.25}$$

where $\xi_0 := \xi(0)$. The constant M_3 is the universal constant appearing in Theorems I.2, I.4, and the parameter $M_3(\gamma)$ appears as $M_3\left(\frac{1}{2}, \gamma\right)$ in Theorem I.5.

B. Regularity

We discuss now the regularity of the functions $\gamma \to \Theta(\gamma) \in \mathbb{R}$ and $\gamma \mapsto \varphi_\gamma \in L^2(\mathbb{R}_+)$. It seems for us that Kato's theory (cf. Ref. 20) does not apply in this context at least for the reason that we do not know *a priori* whether the expression of the operator

$$H[\gamma] = -\frac{\mathrm{d}^2}{\mathrm{d}t^2} + (t - \xi(\gamma))^2$$

depends analytically on γ. Inspired by Bonnaillie,[22] we use a modification of Grushin's method[23] and we get the following proposition.

Proposition II.4. The functions $\mathbb{R} \ni \gamma \mapsto \Theta(\gamma) \in \mathbb{R}$ *and* $\mathbb{R} \ni \gamma \mapsto \varphi_\gamma \in L^2(\mathbb{R}_+)$ *are* C^∞.

Moreover, the function $\mathbb{R} \ni \gamma \mapsto \varphi_\gamma \in L^\infty(\mathbb{R}_+)$ *is locally Lipschitz.*

The specific difficulty in proving Proposition II.4 comes from the fact that both the expression and the domain of the operator $H[\gamma]$ depend on γ. To work with an operator with a fixed domain, we consider a cut-off χ that is equal to 1 on $[0, 1]$ and we apply the invertible transformation

$\varphi \mapsto \widetilde{\varphi} = e^{-\gamma t \chi(t)} \varphi$ that transforms the boundary condition $\varphi'(0) = \gamma \varphi(0)$ to the usual Neumann boundary condition $\widetilde{\varphi}'(0) = 0$ and leaves the spectrum invariant (cf. Proof of Proposition II.7).

In the next proposition we determine $\Theta'(\gamma)$. This is a first step in the proof of Proposition II.4.

Proposition II.5: The function $\gamma \mapsto \Theta(\gamma)$ is of class C^1 and satisfies

$$\Theta'(\gamma) = |\varphi_\gamma(0)|^2. \tag{2.26}$$

In particular, we have

$$\Theta'(0) = 6M_3. \tag{2.27}$$

Remark II.6: Using Formula (2.15) we get also that the function $\gamma \mapsto \xi(\gamma)$ is of class C^1.

Proof of Proposition II.5: Let τ be a real number. We shall define the following trial function:

$$u = e^{\pi t}(\varphi_\gamma + \tau u_1),$$

where

$$u_1 = (H[\gamma] - \Theta(\gamma))^{-1}\{|\varphi_\gamma(0)|^2 \varphi_\gamma + 2\varphi_\gamma' + 2(\xi(\gamma + \tau) - \xi(\gamma))(t - \xi(\gamma))\varphi_\gamma\}.$$

By standard Fredholm theory, the operator $(H[\gamma] - \Theta(\gamma))^{-1}$ is defined on the orthogonal space of φ_γ and has values in $D(H[\gamma])$. Hence, the function u_1 is well defined, thanks to (2.19), and the function u satisfies the boundary condition $u'(0) = (\gamma + \tau)u(0)$. When τ is sufficiently small, it is a result of the exponential decay of φ_γ at $+\infty$ (cf. Propositions II.9 and II.10) and standard elliptic estimates that $u \in B^2(\mathbb{R}_+)$. Therefore, $u \in D(H[\gamma + \tau])$, and we have

$$H[\gamma + \tau](u) = e^{\pi t}(-\partial_t^2 + (t - \xi(\gamma + \tau))^2 - 2\tau\partial_t - \tau^2)(\varphi_\gamma + \tau u_1). \tag{2.28}$$

Using the decomposition:

$$H[\gamma + \tau] = H[\gamma] - 2(\xi(\gamma + \tau) - \xi(\gamma))(t - \xi(\gamma)) + (\xi(\gamma + \tau) - \xi(\gamma))^2,$$

we can rewrite (2.28) as

$$(H[\gamma + \tau] - \Theta(\gamma) - |\varphi_\gamma(0)|^2 \tau)(u) = \tau^2 e^{\pi t}(\Theta(\gamma) + |\varphi_\gamma(0)|^2)u_1 + (\xi(\gamma + \tau) - \xi(\gamma))^2 u. \tag{2.29}$$

We make the following claim:

$$\forall\, \gamma \in \mathbb{R}, \quad \exists\, C > 0, \quad \forall\, \tau \in [-1, 1], \quad |\xi(\gamma + \tau) - \xi(\gamma)| \leqslant C|\tau|. \tag{2.30}$$

Therefore, thanks to (2.29) and (2.30), there exist constants $\widetilde{C}, \tau_0 > 0$ such that, for all $\tau \in [-\tau_0, \tau_0]$, we have

$$\|(H[\gamma + \tau] - \Theta(\gamma) - |\varphi_\gamma(0)|^2 \tau)u\|_{L^2(\mathbb{R}_+)} \leqslant \widetilde{C}\tau^2 \|u\|_{L^2(\mathbb{R}_+)}.$$

We now get by the spectral theorem the existence of an eigenvalue $\widetilde{\Theta}(\gamma + \tau)$ of the operator $H[\gamma + \tau]$ that satisfies the following estimate:

$$|\widetilde{\Theta}(\gamma + \tau) - \Theta(\gamma) - |\varphi_\gamma(0)|^2 \tau| \leqslant \widetilde{C}\tau^2, \quad \forall\, \tau \in [-\tau_0, \tau_0]. \tag{2.31}$$

We make now another claim:

$$\forall\, \gamma \in \mathbb{R}, \quad \exists\, C_1 > 0, \quad \forall\, \tau \in [-1, 1], \quad |\mu^{(2)}(\gamma + \tau, \xi(\gamma + \tau)) - \mu^{(2)}(\gamma, \xi(\gamma))| \leqslant C|\tau|, \tag{2.32}$$

where for $(\eta, \xi) \in \mathbb{R} \times \mathbb{R}$, $\mu^{(2)}(\eta, \xi)$ denotes the second eigenvalue of the operator $H[\eta, \xi]$. Under the above claim, the estimate (2.31) gives

$$\widetilde{\Theta}(\gamma+\tau)=\Theta(\gamma+\tau),\quad \forall\,\tau\in[-\tau_0,\tau_0].$$

Consequently, we get that $\Theta(\gamma)$ is differentiable and satisfies formula (2.26). We make now a final claim:

$$\text{The function } \gamma\mapsto|\varphi_\gamma(0)|^2 \text{ is locally Lipschitz.} \tag{2.33}$$

To achieve the proof of the theorem, we only need to prove (2.30), (2.32), and (2.33).

Proof of (2.30): As we have the formula (2.15), it is sufficient to prove

$$\forall\,\gamma\in\mathbb{R},\quad \exists\,C>0,\quad \forall\,\tau\in[-1,1],\quad |\Theta(\gamma+\tau)-\Theta(\gamma)|\leqslant C|\tau|. \tag{2.34}$$

The min-max principle gives

$$\mu^{(1)}(\gamma,\xi)+\tau|\varphi_{\gamma+\tau,\xi}(0)|^2\leqslant\mu^{(1)}(\gamma+\tau,\xi)\leqslant\mu^{(1)}(\gamma,\xi)+\tau|\varphi_{\gamma,\xi}(0)|^2,\quad \forall\,\xi\in\mathbb{R}. \tag{2.35}$$

Thus, given an eigenfunction φ of $H[\gamma,\xi]$, we need to estimate $|\varphi(0)|^2$. Let $u\in D(H[\gamma])$. Using (2.9) we get

$$|u(0)|^2\leqslant 2\|u\|_{L^2(\mathbb{R}_+)}\|u'\|_{L^2(\mathbb{R}_+)}. \tag{2.36}$$

We use now (2.10) (with $\epsilon=1/2$) to obtain

$$\|u'\|^2_{L^2(\mathbb{R}_+)}\leqslant 2q[\gamma,\xi](u)+(\gamma_-)^2\|u\|^2_{L^2(\mathbb{R}_+)}. \tag{2.37}$$

Combining (2.36) and (2.37), we get after an integration by parts and the application of the Cauchy-Schwarz inequality,

$$|u(0)|^2\leqslant 2\|H[\gamma,\xi]u\|_{L^2(\mathbb{R}_+)}\|u\|_{L^2(\mathbb{R}_+)}+(\gamma_-)^2\|u\|^2_{L^2(\mathbb{R}_+)},\quad \forall\,u\in D(H[\gamma]). \tag{2.38}$$

Let $M:=\sup_{\tau\in[-1,1]}\xi(\gamma+\tau)$. Let us show that $M<+\infty$. Actually, the min-max principle gives

$$\mu^{(1)}(\gamma-1,\xi)\leqslant\mu^{(1)}(\gamma+\tau,\xi)\leqslant\mu^{(1)}(\gamma+1,\xi),\quad \forall\,\tau\in[-1,1],\quad \forall\,\xi\in\mathbb{R}.$$

Recalling (2.6), we obtain $\Theta(\gamma-1)\leqslant\sup_{\tau\in[-1,1]}\Theta(\gamma+\tau)\leqslant\Theta(\gamma+1)$. Formula (2.15) now gives $M<+\infty$. Therefore, (2.38) gives

$$|\varphi_{\gamma,\xi}(0)|^2\leqslant C,\quad |\varphi_{\gamma+\tau,\xi}(0)|^2\leqslant C,\quad \forall\,\tau\in[-1,1],\quad \forall\,\xi\in[-M,M],$$

for some constant $C>0$. Consequently (2.35) yields the estimate

$$\mu^{(1)}(\gamma,\xi)-C\tau_-\leqslant\mu^{(1)}(\gamma+\tau,\xi)\leqslant\mu^{(1)}(\gamma,\xi)+C\tau_+,\quad \forall\,\xi\in[-M,M].$$

Minimizing with respect to ξ, we get (2.34), thanks to Theorem II.2.

Proof of (2.32): Let $u\in B^1(\mathbb{R}_+)$. We shall compare $q[\gamma+\tau,\xi(\gamma+\tau)](u)$ and $q[\gamma,\xi(\gamma)](u)$. In fact, we have

$$q[\gamma+\tau,\xi(\gamma+\tau)][u]=q[\gamma,\xi(\gamma)](u)-2(\xi(\gamma+\tau)-\xi(\gamma))\int_0^{+\infty}(t-\xi(\gamma))|u(t)|^2\mathrm{d}t+(\xi(\gamma+\tau)$$

$$-\xi(\gamma))^2\int_0^{+\infty}|u(t)|^2\mathrm{d}t+\tau|u(0)|^2,$$

where, combining (2.36) and (2.37),

$$|u(0)|^2\leqslant 2q[\gamma,\xi](u)+(\gamma_-)^2\|u\|^2_{L^2(\mathbb{R}_+)}.$$

The Cauchy-Schwarz inequality gives

$$2\left|\int_0^{+\infty}(t-\xi(\gamma))|u(t)|^2\mathrm{d}t\right| \leqslant \int_0^{+\infty}|(t-\xi(\gamma))u(t)|^2\mathrm{d}t+\int_0^{+\infty}|u(t)|^2\mathrm{d}t.$$

Using (2.30), we get a constant $C>0$ such that, for all $\tau\in[-1,1]$, we have

$$(1-C\tau_-)q[\gamma,\xi(\gamma)](u)-C\tau_-\|u\|^2_{L^2(\mathbb{R}_+)}\leqslant q[\gamma,\xi(\gamma+\tau)](u)\leqslant(1+C\tau_+)q[\gamma,\xi(\gamma)](u)+C\tau_+\|u\|^2_{L^2(\mathbb{R}_+)}.$$

The min-max principle now proves the claim.

Proof of (2.33): Let $u=\varphi_\gamma(t)-e^{-\pi}\varphi_{\gamma+\tau}(t)$. It is sufficient to prove that

$$|u(0)|^2\leqslant C|\tau|,\quad \forall\ \tau\in[-\tau_0,\tau_0], \tag{2.39}$$

for constants $C,\tau_0>0$. Using (2.38), we have to estimate $\|u\|_{L^2(\mathbb{R}_+)}$ and $\|H[\gamma,\xi]u\|_{L^2(\mathbb{R}_+)}$. Let $f=(H[\gamma]-\Theta(\gamma))u$. Then:

$$f=(\Theta(\gamma)-\Theta(\gamma+\tau))u+w,$$

where

$$w(t)=e^{-\pi}(-2\tau\partial_t+2(\xi(\gamma+\tau)-\xi(\gamma))(t-\xi(\gamma))-(\xi(\gamma+\tau)-\xi(\gamma))^2+\tau^2)\varphi_\gamma(t).$$

Therefore, thanks to (2.30) and (2.34), we have

$$\|f\|_{L^2(\mathbb{R}_+)}\leqslant C|\tau|,\quad \forall\ \tau\in[-\tau_0,\tau_0]. \tag{2.40}$$

Noticing that, after an integration by parts, $\langle f,\varphi_\gamma\rangle_{L^2(\mathbb{R}_+)}=0$, we write

$$u=(H[\gamma]-\Theta(\gamma))^{-1}f.$$

It is a standard result that the operator norm of $(H[\gamma]-\Theta(\gamma))^{-1}$ is bounded on the orthogonal space of φ_γ and is estimated by the inverse of the gap between the first two eigenvalues of $H[\gamma]$. Therefore, thanks to (2.40), we get that $\|u\|_{L^2(\mathbb{R}_+)}\leqslant\widetilde{C}|\tau|$ for some constant $\widetilde{C}>0$. Plugging this estimate together with (2.40) in (2.38), we get (2.39). □

In the next proposition we have a regularity result with respect to the two variables (γ,ξ).

Proposition II.7: The functions $(\gamma,\xi)\mapsto\mu^{(1)}(\gamma,\xi)$ *and* $(\gamma,\xi)\mapsto\varphi_{\gamma,\xi}$ *are of class* C^∞ *in* $\mathbb{R}^2$. *Moreover, we have*

$$\partial_\gamma\mu^{(1)}(\gamma,\xi)=|\varphi_{\gamma,\xi}(0)|^2. \tag{2.41}$$

Using Proposition II.5 and Remark II.6, Proposition II.7 is sufficient for achieving the proof of Proposition II.4.

Proof of Proposition II.7: In order to reduce the problem to a problem of an operator with a fixed domain, we define the bounded operator $V[\gamma]$ on $L^2(\mathbb{R}_+)$ by

$$V[\gamma]u=e^{\gamma\chi(t)t}u,\quad \forall\ u\in L^2(\mathbb{R}_+).$$

We then define the operator $\widetilde{H}[\gamma,\xi]$ by

$$D(\widetilde{H}[\gamma,\xi])=\{u\in B^2(\mathbb{R}_+);u'(0)=0\},$$

$$\widetilde{H}[\gamma,\xi]=V[-\gamma]H[\gamma,\xi]V[\gamma].$$

Note that the domain of $\widetilde{H}[\gamma,\xi]$ is independent of γ and ξ. Note also that $\widetilde{H}[\gamma,\xi]$ is not self-adjoint but it has the same spectrum as $H[\gamma,\xi]$. A fundamental state of $\widetilde{H}[\gamma,\xi]$ is given by

$$\tilde{\varphi}_{\gamma,\xi}(t) = V[-\gamma]\varphi_{\gamma,\xi}(t).$$

We denote by $\varphi^*_{\gamma,\xi}$ the orthogonal projector on $\varphi_{\gamma,\xi}$. Let us consider a point (γ_0, ξ_0). We define the operator $M_0 : D(\tilde{H}[\gamma,\xi]) \times \mathbb{C} \to L^2(\mathbb{R}_+) \times \mathbb{C}$ by

$$M_0 := \begin{pmatrix} \tilde{H}[\gamma_0,\xi_0] - \mu_0 & \tilde{\varphi}_0 \\ \varphi_0^* & 0 \end{pmatrix},$$

where $\mu_0 = \mu^{(1)}(\gamma_0, \xi_0)$ and $\varphi_0 = \varphi_{\gamma_0,\xi_0}$.

The operator M_0 is invertible and its inverse R_0 is given by

$$R_0 = \begin{pmatrix} E_0 & E_0^+ \\ E_0^- & E_0^{+-} \end{pmatrix},$$

where the coefficients of R_0 are

$$E_0 = V[-\gamma_0]\tilde{R}[\gamma_0,\xi_0]V[\gamma_0], \tag{2.42}$$

$$E_0^+ = V[-\gamma_0]\varphi_0, \tag{2.43}$$

$$E_0^- = \varphi_0^* V[\gamma_0], \tag{2.44}$$

$$E_0^{+-} = 0. \tag{2.45}$$

The operator $\tilde{R}[\gamma_0,\xi_0]$ is the regularized resolvent which is equal to 0 on $\mathbb{R}\cdot\varphi_0$ and to $(H[\gamma_0,\xi_0]-\mu_0)^{-1}$ on $\varphi_0^\perp$.

Now we define, in a neighborhood of (γ_0, ξ_0, μ_0), the operator $M(\gamma,\xi,\mu)$ by

$$M(\gamma,\xi,\mu) = \begin{pmatrix} \tilde{H}[\gamma,\xi] - \mu & \tilde{\varphi}_0 \\ \varphi_0^* & 0 \end{pmatrix}.$$

The operator $M(\gamma,\xi,\mu)$ is also invertible in a neighborhood of (γ_0,ξ_0,μ_0) and we denote its inverse by

$$R(\gamma,\xi,\mu) = \begin{pmatrix} E(\gamma,\xi,\mu) & E^+(\gamma,\xi,\mu) \\ E^-(\gamma,\xi,\mu) & E^{+-}(\gamma,\xi,\mu) \end{pmatrix}.$$

It is then standard to prove the following two points (cf. Ref. 18 for details):

- The coefficients of $R(\gamma,\xi,\mu)$ are C^∞ in a neighborhood of (γ_0,ξ_0,μ_0).
- A number μ is an eigenvalue of $H[\gamma,\xi]$ if and only if $E^{+-}(\gamma,\xi,\mu)=0$.

Moreover, in a neighborhood of (γ_0,ξ_0,μ_0), if μ is an eigenvalue of $H[\gamma,\xi]$, then $V[\gamma]E^+(\gamma,\xi,\mu)$ is a corresponding eigenfunction.

Thus, in a neighborhood of (γ_0,ξ_0), the eigenvalues of the operator $H[\gamma,\xi]$ are given by the solutions of the equation $E^{+-}(\gamma,\xi,\mu)=0$. By viewing the operator $M(\gamma,\xi,\mu)$ as a perturbation of M_0, we can calculate the coefficients of $R(\gamma,\xi,\mu)$ and we obtain that

$$\partial_\mu E^{+-}(\gamma_0,\xi_0,\mu_0) = 1.$$

As the function $E^{+-}(\gamma,\xi,\mu)$ is of class C^∞, we can apply the implicit function theorem and get the existence of a number $\eta>0$ and a function μ of class C^∞ such that

$$\forall (\gamma,\xi) \in]\gamma_0-\eta,\gamma_0+\eta[\times]\xi_0-\eta,\xi_0+\eta[, \quad \forall\, \mu \in]\mu_0-\eta,\mu_0+\eta[,$$

$$E^{+-}(\gamma,\xi,\mu)=0 \Leftrightarrow \mu=\mu(\gamma,\xi).$$

This proves that the functions $(\gamma,\xi)\mapsto\mu^{(1)}(\gamma,\xi)$ and $(\gamma,\xi)\mapsto\varphi_{\gamma,\xi}$ are of class C^∞. □

C. Asymptotic behavior

The asymptotic behavior at $\pm\infty$ of the eigenvalue $\Theta(\gamma)$ with respect to the parameter γ is given in the following proposition.

Proposition II.8: There exist constants $C_0,\gamma_0>0$ such that the eigenvalue $\Theta(\gamma)$ satisfies

$$1-C_0\gamma\exp(-\gamma^2)\leqslant\Theta(\gamma)<1,\quad\forall\ \gamma\in[\gamma_0,+\infty[, \tag{2.46}$$

and

$$-\gamma^2\leqslant\Theta(\gamma)\leqslant-\gamma^2+\frac{1}{4\gamma^2},\quad\forall\ \gamma\in]-\infty,0[. \tag{2.47}$$

Proof: We prove the estimate (2.46). Note that by the min-max principle and Theorem II.2 we get for any $\gamma>0$:

$$\mu^{(1)}(0,\xi(\gamma))\leqslant\Theta(\gamma)<1. \tag{2.48}$$

The following estimate for the Neumann problem is obtained by Bolley-Helffer[17] (formula (A18):

$$|\mu^{(1)}(0,\xi)-1|\leqslant C\xi\exp-\xi^2,\quad\forall\ \xi\in[A,+\infty[,$$

where $C,A>0$ are constants independent of ξ. Recalling (2.15), the last estimate gives

$$|\mu^{(1)}(0,\xi(\gamma))-1|\leqslant C_0\gamma\exp-\gamma^2,\quad\forall\ \gamma\in[\gamma_0,+\infty[,$$

where $\gamma_0=\max(\sqrt{A},1)$ and $C_0=2C$. Upon substitution in (2.48), we arrive at the estimate (2.46).

The relation (2.15) gives the lower bound $\Theta(\gamma)\geqslant-\gamma^2$. To get the upper bound in (2.47), we use the function $e^{\gamma t}$ (with $\gamma<0$) as a trial function for the quadratic form defining $H[\gamma,0]$, this which gives

$$\frac{q[\gamma,0](e^{\gamma t})}{\|e^{\gamma t}\|^2_{L^2(\mathbb{R}_+)}}\leqslant-\gamma^2+\frac{1}{4\gamma^2},\quad\forall\ \gamma\in]-\infty,0[.$$

Therefore, we get by the min-max principle that $\mu^{(1)}(\gamma,0)\leqslant-\gamma^2+1/4\gamma^2$. Recalling (2.6), we get the upper bound in(2.47).

D. Exponential decay of the ground state

Using Agmon's technique (cf. Ref. 15), we get the following decay result for the eigenfunction φ_γ.

Proposition II.9: For each $\epsilon\in]0,1[$ there is a positive constant C_ϵ such that, for all $\gamma\in\mathbb{R}$, we have the following estimate for the eigenfunction φ_γ:

$$\left\|\exp\left(\epsilon\frac{(t-\xi(\gamma))^2}{2}\right)\varphi_\gamma\right\|_{H^1(\{t\in\mathbb{R}_+;(t-\xi(\gamma))\geqslant C_\epsilon\})}\leqslant C_\epsilon(1+\gamma_-+\gamma_-^2), \tag{2.49}$$

where we use the notation $\gamma_-=\max(-\gamma,0)$.

Proof: Let us consider a function $\Phi\in H^1(\mathbb{R}_+)$. Given an integer $N\in\mathbb{N}$, an integration by parts gives the following identity:

$$\int_0^N [|(e^{\Phi}\varphi_\gamma)'|^2 + |(t-\xi(\gamma))e^{\Phi}\varphi_\gamma|^2]\mathrm{d}t + \gamma|e^{\Phi(0)}\varphi_\gamma(0)|^2 - \varphi'_\gamma(N)e^{2\Phi(N)}\varphi_\gamma(N) = \Theta(\gamma)\|e^{\Phi}\varphi_\gamma\|^2_{L^2([0,N])} + \|\Phi' e^{\Phi}\varphi_\gamma\|^2_{L^2([0,N])}. \tag{2.50}$$

Let us recall that the eigenfunction φ_γ is strictly positive. It results then from the eigenvalue equation satisfied by φ_γ:

$$\varphi''_\gamma(t) = ((t-\xi(\gamma))^2 - \Theta(\gamma))\varphi_\gamma(t) > 0, \quad \forall\, t \in]\sqrt{\Theta(\gamma)} + \xi(\gamma), +\infty[.$$

Therefore, the function φ'_γ is increasing on $]\sqrt{\Theta(\gamma)}+\xi(\gamma), +\infty[$. On the other hand, as $\varphi_\gamma \in H^2(\mathbb{R}_+)$, the Sobolev imbedding theorem gives $\lim_{t\to+\infty}\varphi'_\gamma(t)=0$. Thus, combining with the monotonicity of φ'_γ, we get finally that

$$\varphi'_\gamma(t) < 0, \quad \forall\, t \in \sqrt{\Theta(\gamma)} + \xi(\gamma), +\infty[.$$

Taking $N > \sqrt{\Theta(\gamma)}+\xi(\gamma)$ and recalling that $\Theta(\gamma)<1$, the identity (2.50) yields the estimate:

$$\int_0^N [|(e^{\Phi}\varphi_\gamma)'|^2 + |(t-\xi(\gamma))e^{\Phi}\varphi_\gamma|^2]\mathrm{d}t + \gamma|e^{\Phi(0)}\varphi_\gamma(0)|^2 \leqslant \|e^{\Phi}\varphi_\gamma\|^2_{L^2([0,N])} + \|\Phi' e^{\Phi}\varphi_\gamma\|^2_{L^2([0,N])}. \tag{2.51}$$

To estimate the boundary term in (2.51), we recall that (2.38) (with $u=\varphi_\gamma$ and $\xi=\xi(\gamma)$) gives

$$|\varphi_\gamma(0)|^2 \leqslant 2 + (\gamma_-)^2.$$

Therefore, the estimate (2.51) becomes

$$\int_0^N [|(e^{\Phi}\varphi_\gamma)'|^2 + ((t-\xi(\gamma))^2 - |\Phi'|^2 - 1)|e^{\Phi}\varphi_\gamma|^2]\mathrm{d}t \leqslant \gamma_-\sqrt{2+(\gamma_-)^2}e^{2\Phi(0)}. \tag{2.52}$$

Now we take Φ as

$$\Phi(t) = \epsilon\frac{(t-\xi(\gamma))^2}{2}.$$

We can then rewrite (2.52) as

$$\int_{t\in[0,N],(t-\xi(\gamma))\geqslant a_\epsilon} [|(e^{\Phi}\varphi_\gamma)'|^2 + |e^{\Phi}\varphi_\gamma|^2]\mathrm{d}t \leqslant \gamma_-\sqrt{2+(\gamma_-)^2}e^{\epsilon\xi(\gamma)} + e^{\epsilon a_\epsilon}, \tag{2.53}$$

where $a_\epsilon > 0$ satisfies

$$a_\epsilon^2 - \epsilon^2 a_\epsilon - 1 \geqslant 1.$$

Notice that the first term on the right hand side of (2.53) is effective only if $\gamma<0$. Coming back to the regularity of the function $\Theta(\gamma)$, the decay of $\Theta(\gamma)$ in (2.47) and the relation (2.15), we get that the function $\xi(\gamma)$ is bounded for $\gamma<0$. Let us now take

$$C_0 = \sup_{\gamma<0}\xi(\gamma), \quad C_\epsilon = \max(a_\epsilon, e^{\epsilon C_0}, e^{\epsilon a_\epsilon}).$$

The estimate (2.53) reads now as

$$\int_{t\in[0,N],(t-\xi(\gamma))\geqslant C_\epsilon} [|(e^{\Phi}\varphi_\gamma)'|^2+|e^{\Phi}\varphi_\gamma|^2]\mathrm{d}t \leqslant C_\epsilon(1+\gamma_-+(\gamma_-)^2).$$

Noticing that the above estimate is uniform with respect to N, we get (2.49) upon passing to the limit $N\to+\infty$.

Let us now recall that the regularized resolvent $\widetilde{R}[\gamma]$ is the bounded operator defined on $L^2(\mathbb{R}_+)$ by

$$\widetilde{R}[\gamma]\phi=\begin{cases}0, & \phi\|\varphi_\gamma,\\ (H[\gamma]-\Theta(\gamma))^{-1}\phi, & \phi\perp\varphi_\gamma,\end{cases} \tag{2.54}$$

and extended by linearity. Again, using the Agmon's technique, we get that this regularized resolvent is uniformly continuous in suitable weighted spaces.

Proposition II.10: For each $\delta\in]0,1[$ *and* $\eta_0>0$, *there exist positive constants* C_0,t_0 *such that*

$$\forall\,\gamma\in[-\eta_0,\eta_0],\quad \forall\,u\in L^2(\mathbb{R}_+;e^{\delta(t-\xi(\gamma))}\mathrm{d}t),\quad u\perp\varphi_\gamma,$$

we have

$$\|e^{\delta(t-\xi(\gamma))}\widetilde{R}[\gamma]u\|_{H^1([t_0,+\infty[)}\leqslant C_0\|e^{\delta(t-\xi(\gamma))}u\|_{L^2(\mathbb{R}_+)}. \tag{2.55}$$

III. PROOF OF THEOREM I.1

In this section we prove Theorem I.1 by comparing with the basic model introduced in the preceding section. We introduce a coordinate system (s,t) near the boundary $\partial\Omega$ where t measures the distance to $\partial\Omega$ and s measures the distance in $\partial\Omega$ (cf. the Appendix).

Proposition III.1 (Upper bound): Under the hypothesis of Theorem I.1, there exist positive constants C and h_0 *such that,* $\forall h\in]0,h_0]$, *we have*

$$\mu^{(1)}(\alpha,\gamma,h)\leqslant h\Theta(h^{\alpha-1/2}(\gamma_0+Ch^{1/2}))+Ch^{3/2}. \tag{3.1}$$

Proof: We start with the easy case when $\alpha<\frac{1}{2}$ and $\gamma_0>0$. Notice that in this case, given a constant $C>0$, formula (2.46) gives the existence of $h_0>0$ such that

$$|\Theta(h^{\alpha-1/2}(\gamma_0+Ch^{1/2}))-1|\leqslant\exp(-h^{2\alpha-1}),\quad \forall\,h\in]0,h_0]. \tag{3.2}$$

By comparing with the Dirichlet realization, the min-max principle gives

$$\mu^{(1)}(\alpha,\gamma,h)\leqslant\lambda^{(1)}(h),$$

where $\lambda^{(1)}(h)$ is the first eigenvalue of the Dirichlet realization (on Ω) of $-(h\nabla-iA)^2$. Using the following upper bound for $\lambda^{(1)}(h)$ (cf. Ref. 9):

$$\lambda^{(1)}(h)\leqslant h+Ch^{3/2},\quad \forall\,h\in]0,1],$$

together with (3.2), we get (3.1).

We suppose now that $\gamma_0\leqslant 0$ if $\alpha<\frac{1}{2}$. Consider a point $x_0\in\partial\Omega$ such that $\gamma(x_0)=\gamma_0$. We suppose that $x_0=0$ in the coordinate system (s,t) near the boundary (cf. the Appendix). Using this coordinate system we construct a trial function $u_{h,\alpha}$ supported in the rectangle $K_h=]-h^{1/4},h^{1/4}[\times[0,t_0[$ following the idea of Helffer-Morame[10] and Bernoff-Sternberg.[7] Since x_0 is a minimum of γ, Taylor's formula up to the first order gives the existence of positive constants C_1,h_0 such that

$$\forall\,h\in]0,h_0],\quad |\gamma(s)-\gamma_0|\leqslant C_1h^{1/2}\quad \text{in }]-h^{1/2},h^{1/2}[.$$

Thus, given a trial function u supported in K_h, we have the following estimate:

$$q^{\alpha,\gamma}_{h,A,\Omega}(u) \leqslant q^{\alpha,\tilde{\gamma}_0}_{h,A,\Omega}(u), \quad \forall\, h \in]0,h_0], \tag{3.3}$$

where $\tilde{\gamma}_0 = \gamma_0 + C_1 h^{1/2}$. So it is enough to work with $q^{\alpha,\tilde{\gamma}_0}_{h,A,\Omega}$.

We introduce $\eta = h^{\alpha-1/2}\tilde{\gamma}_0$ and we choose now the following trial function:

$$u_{h,\alpha} = a^{-1/2} \exp\left(-i\frac{\xi(\eta)s}{h^{1/2}}\right) v_{h,\alpha}, \tag{3.4}$$

where $a(s,t) = 1 - t\kappa_r(s)$ and

$$v_{h,\alpha} = h^{-3/8}\varphi_\eta(h^{-1/2}t)\chi(t) \times f(h^{-1/4}s). \tag{3.5}$$

The function χ is a cut-off equal to 1 in a compact interval $[0, t_0/2]$ and the function $f \in C_0^\infty(]-1/2, 1/2[;\mathbb{R})$ is chosen such that $\|f\|_{L^2(\mathbb{R})} = 1$.

Note that the decay of φ_η in Proposition II.9 gives:[1] For every $\delta > 0$ and $k \in \mathbb{N}$, there exist positive constants $C_{k,\delta}$ and h_0 such that,

$$\int_{\mathbb{R}_+} t^k |\varphi_\eta(t)|^2 \mathrm{d}t \leqslant C_{k,\delta} h^{-\delta k}, \quad \forall\, h \in]0,h_0]. \tag{3.6}$$

We work with the choice of gauge given in Proposition A2. Using formula (A3), we can write

$$\begin{aligned} q^{\alpha,\tilde{\gamma}_0}_{h,A,\Omega}(u_{h,\alpha}) = &\int_{-|\partial\Omega|/2}^{|\partial\Omega|/2} \int_0^{t_0} \left[|h\partial_t v_{h,\alpha}|^2 + a^{-2} \left| \left(h^{1/2}\xi(\eta) - t\left(1 - \frac{t}{2}\kappa_r(s)\right)\right) v_{h,\alpha} \right|^2 \right] \mathrm{d}s\mathrm{d}t \\ &+ h^{3/2}\eta \int_{-|\partial\Omega|/2}^{|\partial\Omega|/2} |v_{h,\alpha}(s,0)|^2 \mathrm{d}s + h^2 \int_{-|\partial\Omega|/2}^{|\partial\Omega|/2} \int_0^{t_0} [|(\partial_t a^{-1/2}) v_{h,\alpha}|^2 + 2a^{-1/2}(\partial_t a^{-1/2}) \\ &\times (\partial_t v_{h,\alpha}) v_{h,\alpha} + a^{-2} |\partial_s v_{h,\alpha}|^2] a \mathrm{d}s\mathrm{d}t. \end{aligned} \tag{3.7}$$

Recalling the expression of $v_{h,\alpha}$ (cf.(3.5)), we can replace the function χ by 1 getting an exponentially small error on the right-hand side of (3.7), thanks to the decay of φ_η in Proposition II.9. After a change of variables and using the decay of φ_η in (3.6), the leading order term on the right-hand side of (3.7) is equal to

$$h\left(\int_0^{+\infty} [|\varphi_\eta'(t)|^2 + |(t - \xi(\eta))\varphi_\eta|^2 \mathrm{d}t] \mathrm{d}t + \eta |\varphi_\eta(0)|^2 \right),$$

and the error is of order $\mathcal{O}(h^{3/2})$. Therefore, we get constants $C, h_0 > 0$ such that

$$|q^{\alpha,\tilde{\gamma}_0}_{h,A,\Omega}(u_{h,\alpha}) - h\Theta(\eta)| \leqslant Ch^{3/2}, \quad \forall\, h \in]0,h_0].$$

Using formula (A4) and the decay of φ_η (Proposition II. 9), we obtain that the L^2 norm of $u_{h,\alpha}$ is exponentially close to 1 as $h \to 0$. The application of the min-max principle permits one now to prove (3.1).

Remark III.2: In the regime $\alpha \in]\frac{1}{2}, 1[$, *we have, thanks to Proposition II.5:*

$$\Theta(h^{\alpha-1/2}\gamma_0) = \Theta_0 + 6M_3 h^{\alpha-1/2} + \mathcal{O}(h^{2\alpha-1}).$$

Substituting the above expansion in the upper bound (3.1), we get the following upper bound for the eigenvalue $\mu^{(1)}(\alpha,\gamma,h)$,

$$\mu^{(1)}(\alpha,\gamma,h) \leqslant h\Theta_0 + 6M_3\gamma_0 h^{\alpha+1/2} + \mathcal{O}(h^{\inf(3/2,2\alpha)}).$$

We shall prove that this upper bound is actually an asymptotic expansion of $\mu^{(1)}(\alpha,\gamma,h)$ *as* h

[1] Actually we shall need this decay only when $\alpha < 1/2$ and $\gamma_0 < 0$.

tends 0 (see Remark V.11).

Proposition III.3 (Lower bound): Under the hypothesis of Theorem I.1, there exist positive constants C, C' and h_0 such that, $\forall h \in]0, h_0]$, we have

$$\mu^{(1)}(\alpha, \gamma, h) \geqslant h\Theta(h^{\alpha-1/2}\gamma_0(1 + C'h^{1/4})) - Ch^{5/4}. \tag{3.8}$$

Proof: We follow the technique of Ref. 10 and we localize by means of a partition of unity to compare with the model operators in $\mathbb{R}^2$ and $\mathbb{R} \times \mathbb{R}_+$. Let us explain the heuristic idea. A partition of unity permits one to estimate the quadratic form $q^{\alpha,\gamma}_{h,A,\Omega}$ locally in small subsets of Ω. Near the boundary, we obtain after a transformation of coordinates that the expression of $q^{\alpha,\gamma}_{h,A,\Omega}$ is to leading order asymptotics as that of the half-plane model. In the interior of Ω, the expression of the quadratic form is actually like that of the entire-plane model.

Let us introduce a partition of unity (χ_j) of $\mathbb{R}^2$ that satisfies

$$\sum_j |\chi_j|^2 = 1, \quad \sum_j |\nabla \chi_j|^2 < +\infty, \quad \text{supp}\, \chi_j \subset D(z_j, 1),$$

where for $z \in \mathbb{R}^2$ and $r > 0$, we denote by $D(z, r)$ the disk of center z and radius r.

We introduce now the scaled partition of unity:

$$\chi^h_j(z) := \chi_j(\epsilon_0 h^\rho z), \quad \forall\, z \in \mathbb{R}^2,$$

where ϵ_0 and ρ are two positive numbers to be chosen suitably. Note that (χ^h_j) now satisfies

$$\sum_j |\chi^h_j|^2 = 1, \tag{3.9}$$

$$\sum_j |\nabla \chi^h_j|^2 \leqslant C\epsilon_0^{-2} h^{-2\rho}, \tag{3.10}$$

$$\text{supp}\, \chi^h_j \subset Q^h_j := D(z^h_j, \epsilon_0 h^\rho), \tag{3.11}$$

where C is a positive constant. We can also suppose that

$$\text{either supp}\, \chi^h_j \cap \partial\Omega = \emptyset \ \text{ or } z^h_j \in \partial\Omega. \tag{3.12}$$

Note that the alternative in (3.12) permits us to write the sum in (3.9) under the form:

$$\sum = \sum_{\text{int}} + \sum_{\text{bnd}},$$

where the summation over "int" means that the support of χ^h_j does not meet the boundary while that over "bnd" means the converse.

We have now the following decomposition formula:

$$q^{\alpha,\gamma}_{h,A}(u) = \sum_j q^{\alpha,\gamma}_{h,A}(\chi^h_j u) - h^2 \sum_j \| |\nabla \chi^h_j| u\|^2, \quad \forall\, u \in H^1(\Omega), \tag{3.13}$$

usually called the IMS formula (cf. Ref. 24). We have now to bound from below each of the terms on the right-hand side of (3.13). Note that (3.10) permits one to estimate the contribution of the last term in (3.13):

$$h^2 \sum_j \| |\nabla \chi^h_j| u\|^2 \leqslant C\epsilon_0^{-2} h^{2-2\rho} \|u\|^2, \quad \forall\, u \in H^1(\Omega). \tag{3.14}$$

If χ^h_j is supported in Ω, then we have

$$q_{h,A}^{\alpha,\gamma}(\chi_j^h u) = \int_{\mathbb{R}^2} |(h\nabla - iA)\chi_j^h u|^2 \mathrm{d}x.$$

Since the lowest eigenvalue of the Schrödinger operator with constant magnetic field in $\mathbb{R}^2$ is equal to h, we get

$$q_{h,A}^{\alpha,\gamma}(\chi_j^h u) \geqslant h\int_{\Omega} |\chi_j^h u|^2 \mathrm{d}x, \quad \forall\, u \in H^1(\Omega). \tag{3.15}$$

We now have to estimate $q_{h,A,\Omega}^{\alpha,\gamma}(\chi_j^h u)$ when χ_j^h meets the boundary. It is in this case that we see the effect of the boundary condition. We shall do that by writing $q_{h,A,\Omega}^{\alpha,\gamma}(\chi_j^h u)$ in the boundary coordinates. Note that, thanks to Proposition A.1, there exists a positive constant C_1 independent of h and j such that

$$\int_{\Omega} |(h\nabla - iA)\chi_j^h u|^2 \mathrm{d}x \geqslant (1 - C_1\epsilon_0 h^{\rho})\int_{\mathbb{R}\times\mathbb{R}_+} |(h\nabla - i\widetilde{A})\chi_j^h u|^2 \mathrm{d}s\mathrm{d}t, \quad \forall\, u \in H^1(\Omega), \tag{3.16}$$

where $\widetilde{A}$ is the vector field associated to A by (A2).

By a gauge transformation, we get a new magnetic potential $\widetilde{A}_{\mathrm{new},j}$ satisfying

$$\widetilde{A}_{\mathrm{new},j} = \widetilde{A} - \nabla\phi_j^h,$$

$$\widetilde{A}_{\mathrm{new},j}(z_j^h) = 0,$$

$$|\widetilde{A}_{\mathrm{new},j}(w) - \widetilde{A}_{\mathrm{lin}}^j(w)| \leqslant C|w|^2, \quad w = (s,t), \tag{3.17}$$

where $A_{\mathrm{lin}}^j := \frac{1}{2}(-t,s)$ is the linear magnetic potential and $C>0$ is a constant independent of h and j.

Given $\theta>0$ and any function v of support in $\mathbb{R}\times\mathbb{R}_+$, we get by the Cauchy-Schwarz inequality,

$$\left|\int_{\mathbb{R}\times\mathbb{R}_+} (h\nabla - i\widetilde{A}_{\mathrm{new},j})v \cdot \overline{(\widetilde{A}_{\mathrm{new},j} - \widetilde{A}_{\mathrm{lin}}^j)v}\mathrm{d}s\mathrm{d}t\right| \leqslant h^{2\theta}\int_{\mathbb{R}\times\mathbb{R}_+} |(h\nabla - i\widetilde{A}_{\mathrm{new},j})v|^2 + h^{-2\theta}\int_{\mathbb{R}\times\mathbb{R}_+} |(\widetilde{A}_{\mathrm{new},j} - \widetilde{A}_{\mathrm{lin}}^j)v|^2.$$

Writing $\widetilde{A}_{\mathrm{new},j} = \widetilde{A}_{\mathrm{lin}}^j + (\widetilde{A}_{\mathrm{new},j} - \widetilde{A}_{\mathrm{lin}}^j)$ and using (3.17), we get a positive constant $\widetilde{C}$ independent of h and j such that

$$\int_{\mathbb{R}\times\mathbb{R}_+} |(h\nabla - i\widetilde{A}_{\mathrm{new},j})v|^2 \mathrm{d}s\mathrm{d}t \geqslant (1 - h^{2\theta})\int_{\mathbb{R}\times\mathbb{R}_+} |(h\nabla - i\widetilde{A}_{\mathrm{lin}}^j)v|^2 \mathrm{d}s\mathrm{d}t - \widetilde{C}h^{-2\theta}\||w|^2\chi_j^h u\|^2. \tag{3.18}$$

Let us recall that $\chi_j^h u$ is supported in the disk $D(z_j^h, \epsilon_0 h^{\rho})$. Upon noticing that

$$\int_{\mathbb{R}\times\mathbb{R}_+} |(h\nabla - i\widetilde{A})\chi_j^h u|^2 \mathrm{d}s\mathrm{d}t = \int_{\mathbb{R}\times\mathbb{R}_+} \left|(h\nabla - i\widetilde{A}_{\mathrm{new},j})\exp\left(-i\frac{\phi_j^h}{h}\right)\chi_j^h u\right|^2 \mathrm{d}s\mathrm{d}t,$$

we get by combining (3.18) (with $v = \exp(-i(\phi_j^h/h))\chi_j^h u$) together with (3.16), a constant $C_2>0$ such that

$$\int_{\mathbb{R}\times\mathbb{R}_+} |(h\nabla - iA)\chi_j^h u|^2 \mathrm{d}x \geqslant (1 - C_2\epsilon_0 h^\rho - C_2 h^{2\theta}) \int_{\mathbb{R}\times\mathbb{R}_+} \left| (h\nabla - i\widetilde{A}_{\mathrm{lin}}^j)\exp\left(-i\frac{\phi_j^h}{h}\right)\chi_j^h u \right|^2 \mathrm{d}s\mathrm{d}t$$
$$- C_2\epsilon_0 h^{4\rho-2\theta} \int_{\mathbb{R}\times\mathbb{R}_+} |\chi_j^h u|^2 \mathrm{d}s\mathrm{d}t. \tag{3.19}$$

Notice also (possibly changing C_2) we have in $D(z_j^h, \epsilon_0 h^\rho)$,

$$\gamma(x) \geqslant \gamma(z_j^h) - C_2\epsilon_0 h^\rho.$$

Then, by putting,

$$\widetilde{\gamma}_j = \frac{\gamma(z_j^h) - C_2\epsilon_0 h^\rho}{1 - C_2 h^{2\theta} - C_2\epsilon_0 h^\rho},$$

the estimate (3.19) reads finally

$$q_{h,A,\Omega}^{\alpha,\gamma}(\chi_j^h u) \geqslant (1 - C_2\epsilon_0 h^\rho - C_2 h^{2\theta}) q_{h,\widetilde{A}_{\mathrm{lin}}^j,\mathbb{R}\times\mathbb{R}_+}^{\alpha,\widetilde{\gamma}_j}\left(\exp\left(-i\frac{\phi_j^h}{h}\right)\chi_j^h u\right) - C_2\epsilon_0^2 h^{4\rho-2\theta}\|\chi_j^h u\|^2. \tag{3.20}$$

Note that this permits one to compare with the half-plane model operator and to get finally the energy estimate (cf. (1.10)):

$$q_{h,A,\Omega}^{\alpha,\gamma}(\chi_j^h u) \geqslant \{(1 - C_2\epsilon_0 h^\rho - C_2 h^{2\theta})h\Theta(h^{\alpha-1/2}\widetilde{\gamma}_j) - C_2\epsilon_0^2 h^{4\rho-2\theta}\}\|\chi_j^h u\|_{L^2(\Omega)}^2. \tag{3.21}$$

We now substitute the estimates (3.8), (3.14), and (3.15), in (3.13) and get finally

$$q_{h,A,\Omega}^{\alpha,\gamma}(u) \geqslant h\sum_{\mathrm{int}} \int_\Omega |\chi_j^h u|^2 \mathrm{d}x + h\sum_{\mathrm{bnd}} \Theta(h^{\alpha-1/2}\widetilde{\gamma}_j) \int_\Omega |\chi_j^h u|^2 \mathrm{d}x - C(h^{4\rho-2\theta} + \epsilon_0^{-2}h^{2-2\rho} + h^{1+\rho} + h^{1+2\theta})$$
$$\times \|u\|^2, \quad \forall\, u \in H^1(\Omega). \tag{3.22}$$

As γ_0 is the minimum of γ, we can replace (3.20) by the estimate

$$q_{h,A,\Omega}^{\alpha,\gamma}(\chi_j^h u) \geqslant (1 - C_2\epsilon_0 h^\rho - C_2 h^{2\theta}) q_{h,\widetilde{A}_{\mathrm{lin}}^j,\mathbb{R}\times\mathbb{R}_+}^{\alpha,\widetilde{\gamma}_0}\left(\exp\left(-i\frac{\phi_j^h}{h}\right)\chi_j^h u\right) - C_2\epsilon_0^2 h^{4\rho-2\theta}\|\chi_j^h u\|^2, \tag{3.23}$$

where $\widetilde{\gamma}_0$ is defined by

$$\widetilde{\gamma}_0 := \frac{\gamma_0}{1 - C_2 h^{2\theta} - C_2\epsilon_0 h^\rho}.$$

We then get instead of (3.22):

$$q_{h,A,\Omega}^{\alpha,\gamma}(u) \geqslant h\sum_{\mathrm{int}} \int_\Omega |\chi_j^h u|^2 \mathrm{d}x + h\Theta(h^{\alpha-1/2}\widetilde{\gamma}_0)\sum_{\mathrm{bnd}} \int_\Omega |\chi_j^h u|^2 \mathrm{d}x - C(h^{4\rho-2\theta} + \epsilon_0^{-2}h^{2-2\rho} + h^{1+\rho} + h^{1+2\theta})$$
$$\times \|u\|^2, \quad \forall\, u \in H^1(\Omega). \tag{3.24}$$

The advantage of (3.22) is that it gives a lower bound of the quadratic form $q_{h,A,\Omega}^{\alpha,\gamma}$ in terms of a potential, see however Sec. IV.

We choose now $\epsilon_0 = 1$, and we optimize by taking $2-2\rho = 1+\rho = 4\rho-2\theta$ (i.e., $\rho = 3/8$ and $\theta = 1/8$) in (3.24). We obtain then (3.8) by applying the min-max principle. □

Proof of Theorem I.1: The proof follows in principle from Propositions III.1 and III.3. Actually, in the regime $\alpha<\frac{1}{2}$, we use further Proposition II.8, while in the regime $\alpha\geqslant\frac{1}{2}$, we use the continuity of the function $\Theta(\gamma)$ (Proposition II.4). □

IV. LOCALIZATION OF THE GROUND STATE

We work in this section under the hypotheses of Theorem I.3. Due to Theorem I.1 we have in this case that

$$\lim_{h\to 0}\frac{\mu^{(1)}(\alpha,\gamma,h)}{h}<1. \tag{4.1}$$

Then this gives, by following the same lines of the proof of Theorem 6.3 in Ref. 10, the following proposition.

Theorem IV.1: *Under the hypotheses of Theorem I.3, there exist positive constants* δ, C, h_0 *such that, for all* $h\in\,]0,h_0]$, *a ground state* $u_{\alpha,\gamma,h}$ *of the operator* $P^{\alpha,\gamma}_{h,A,\Omega}$ *satisfies*

$$\left\|\exp\left(\frac{\delta d(x,\partial\Omega)}{h^{\beta}}\right)u_{\alpha,\gamma,h}\right\|_{L^2(\Omega)}\leqslant C\|u_{\alpha,\gamma,h}\|_{L^2(\Omega)}, \tag{4.2}$$

and

$$\left\|\exp\left(\frac{\delta d(x,\partial\Omega)}{h^{\beta}}\right)u_{\alpha,\gamma,h}\right\|_{H^1(\Omega)}\leqslant Ch^{-\min(1/2,\beta)}\|u_{\alpha,\gamma,h}\|_{L^2(\Omega)}, \tag{4.3}$$

where $\beta=1-\alpha$ *if* $\gamma_0<0$ *and* $\alpha<\frac{1}{2}$, *and* $\beta=1/2$ *otherwise.*

Proof: Integrating by parts, we get for any Lipschitz function Φ:

$$q^{\alpha,\gamma}_{h,A,\Omega}\left(\exp\left(\frac{\Phi}{h^{\beta}}\right)u_{\alpha,\gamma,h}\right)=\mu^{(1)}(\alpha,\gamma,h)\left\|\exp\left(\frac{\Phi}{h^{\beta}}\right)u_{\alpha,\gamma,h}\right\|^2_{L^2(\Omega)}+h^{2-2\beta}\left\||\nabla\Phi|\exp\left(\frac{\Phi}{h^{\beta}}\right)u_{\alpha,\gamma,h}\right\|^2_{L^2(\Omega)}. \tag{4.4}$$

Let $u=\exp(\Phi/h^{\beta})u_{\alpha,\gamma,h}$. Using the lower bound for $q^{\alpha,\gamma}_{h,A,\Omega}(u)$ in (3.24) together with the upper bound for $\mu^{(1)}(\alpha,\gamma,h)$ in (3.1), we get from (4.4):

$$\sum_{\text{int}}\int_{\Omega}(1-\Theta(h^{\alpha-1/2}(\gamma_0+Ch^{1/2}))-C\epsilon_0^{-2}h^{1-2\rho}-Ch^{4\rho-2\theta-1}-Ch^{\min(\rho,2\theta)}-h^{1-2\beta}|\nabla\Phi|^2)\times|\chi_j^h u|^2\mathrm{d}x$$

$$\leqslant\sum_{\text{bnd}}\int_{\Omega}(\Theta(h^{\alpha-1/2}\tilde{\gamma}_0)-\Theta(h^{\alpha-1/2}(\gamma_0+Ch^{1/2}))+h^{\min(4\rho-2\theta-1,1-2\rho)}+h^{1-2\beta}|\nabla\Phi|^2)\times|\chi_j^h u|^2\mathrm{d}x.$$

We choose $\rho=\beta$ so that each χ_j^h is supported in a disk of radius $\epsilon_0 h^{\beta}$. We choose also $\theta>0$ such that $4\rho-2\theta-1>0$ and we define the function Φ by

$$\Phi(x)=\delta\max(\mathrm{dist}(x,\partial\Omega);\epsilon_0 h^{\beta}),$$

where δ is a positive constant to be chosen appropriately. Note that $1-\Theta(h^{\alpha-1/2}\tilde{\gamma}_0)$ decays in the following way:

$$\exists\, C_0,h_0>0\text{s.t.},\quad \forall\, h\in\,]0,h_0],$$

$$1-\Theta(h^{\alpha-1/2}\tilde{\gamma}_0)\geqslant C_0h^{2\alpha-1}\quad\text{if }\gamma_0<0\text{ and }\alpha<\frac{1}{2},$$

$$1-\Theta(h^{\alpha-1/2}\widetilde{\gamma}_0)\geqslant C_0 \quad \text{otherwise}.$$

Thus we can choose ϵ_0 and δ small enough, so that we get finally the following decay:

$$\sum_{\text{int}}\int_\Omega\left|\chi_j^h\exp\frac{\Phi}{h^\beta}u_{\alpha,\gamma,h}\right|^2\mathrm{d}x\leqslant C\int_\Omega|u_{\alpha,\gamma,h}|^2\mathrm{d}x.$$

This actually permits one to conclude (4.2) and, thanks to (4.4),

$$q_{h,A,\Omega}^{\alpha,\gamma}\left(\exp\frac{\delta d(x,\partial\Omega)}{h^\beta}u_{\alpha,\gamma,h}\right)\leqslant Ch^{\min(2-2\beta,1)}\left\|\exp\frac{\delta d(x,\partial\Omega)}{h^\beta}u_{\alpha,\gamma,h}\right\|^2_{L^2(\Omega)}. \tag{4.5}$$

For a function $u\in H^1(\Omega)$, let $\widetilde{u}(s,t)$ be defined by means of boundary coordinates (s,t) and equal to the restriction of u in Ω_{t_0} (cf. the Appendix). Notice that

$$|\widetilde{u}(s,0)|^2=-2\int_0^\infty\{\partial_t(\chi(t)\widetilde{u}(s,t))\}\chi(t)\widetilde{u}(s,t)\mathrm{d}t,$$

where χ is the same cut-off introduced in (3.5). Integrating the above identity with respect to the variable s then applying a Cauchy-Schwarz inequality, we get after a change of variables the following interpolation inequality:

$$\|u\|^2_{L^2(\partial\Omega)}\leqslant C\|u\|_{L^2(\Omega)}\times\|u\|_{H^1(\Omega)},$$

where C is a positive constant depending only on Ω.

Applying again a Cauchy-Schwarz inequality, the preceding estimate gives

$$\|(h\nabla-iA)u\|^2_{L^2(\Omega)}\leqslant 2q_{h,A,\Omega}^{\alpha,\gamma}(u)+Ch\|u\|^2_{L^2(\Omega)},\quad \forall\, u\in H^1(\Omega).$$

In particular, for $u=\exp\left(\frac{\delta d(x,\partial\Omega)}{h^\beta}\right)u_{\alpha,\gamma,h}$, we get (4.3), thanks to (4.2) and (4.5). □

We study now the decay near the boundary. Let us consider a number $\beta>0$ and a Lipschitz function Φ_0 defined in $\bar{\Omega}$. The function Φ_0 and the number β will be chosen later in an appropriate manner. Choosing $\rho=\frac{3}{8}$, $\theta=\frac{1}{8}$, and ϵ_0 large enough, the energy estimate (3.22) together with the upper bound (3.1) give the existence of a positive constant C such that

$$\begin{aligned}0\geqslant h\sum_{\text{int}}\int_\Omega&(1-\Theta(h^{\alpha-1/2}\widetilde{\gamma}_0)-Ch^{1/4}-h^{1-2\beta}|\nabla\Phi_0|^2)\left|\exp\left(\frac{\Phi_0}{h^\beta}\right)\chi_j^h u_{\alpha,\gamma,h}\right|^2\mathrm{d}x\\&+h\sum_{\text{bnd}}\int_\Omega[(\Theta(h^{\alpha-1/2}\widetilde{\gamma}(x))-\Theta(h^{\alpha-1/2}\widetilde{\gamma}_0))-Ch^{1/4}-h^{1-2\beta}|\nabla\Phi_0|^2]\left|\exp\left(\frac{\Phi_0}{h^\beta}\right)\chi_j^h u_{\alpha,\gamma,h}\right|^2\mathrm{d}x,\end{aligned}$$

where $\widetilde{\gamma}_0=\gamma_0+Ch^{1/2}$. The function γ is extended to a small boundary sheath by means of boundary coordinates in the following way:

$$\gamma(x)=\gamma(s(x)),\quad \forall\, x\in\Omega_{t_0}.$$

In the case $\alpha<\frac{1}{2}$ and $\gamma_0=0$, thanks to Proposition II.8, the difference between $\Theta(h^{\alpha-1/2}\widetilde{\gamma}(x))$ and $\Theta(h^{\alpha-1/2}\widetilde{\gamma}_0)$ decays in the following way:

$$\forall\,\varepsilon>0,\quad \exists\, C_\varepsilon>0,\quad \forall\, x\in(\gamma-\gamma_0)^{-1}([\epsilon,+\infty[),\quad \Theta(h^{\alpha-1/2}\widetilde{\gamma}(x))-\Theta(h^{\alpha-1/2}\widetilde{\gamma}_0)>C_\varepsilon.$$

In the case $\alpha<\frac{1}{2}$ and $\gamma_0<0$, we have a stronger decay:

$$\forall\,\varepsilon>0,\quad \exists\, C_\varepsilon>0,\quad \forall\, x\in(\gamma-\gamma_0)^{-1}([\epsilon,+\infty[),$$

$$\Theta(h^{\alpha-1/2}\tilde{\gamma}(x)) - \Theta(h^{\alpha-1/2}\tilde{\gamma}_0) > C_\varepsilon h^{1-2\alpha}.$$

So by taking Φ_0 in the form:

$$\Phi_0(x) = \delta\chi(\mathrm{dist}(x,\partial\Omega))\mathrm{dist}(x,\{x \in \partial\Omega; \gamma(x) = \gamma_0\}),$$

with δ an appropriate positive constant and χ is the same as in (3.5), we get for each $\epsilon > 0$ the following decay near the boundary:

$$\int_{\mathrm{dist}(x,\partial\Omega)<t_0} \left| \exp \frac{\Phi_0}{h^\beta} u_{\alpha,\gamma,h} \right|^2 \mathrm{d}x \leqslant C_\epsilon \exp \frac{\epsilon}{h^\beta} \|u_{\alpha,\gamma,h}\|^2, \quad \forall\, h \in]0,h_\epsilon], \tag{4.6}$$

with $\beta = 1-\alpha$ if $\gamma_0 < 0$ and $\alpha < \frac{1}{2}$, and $\beta = \frac{1}{2}$ otherwise. This gives finally the decay in Theorem I.3.

For the critical case $\alpha = \frac{1}{2}$ and γ_0 arbitrary, we define the function Φ_0 by

$$\Phi_0(x) = \delta\chi(\mathrm{dist}(x,\partial\Omega))\mathrm{dist}_{\mathrm{agm}}(x,\{x \in \partial\Omega; \gamma(x) = \gamma_0\}),$$

where $\mathrm{dist}_{\mathrm{agm}}$ is the Agmon distance associated to the metric $(\Theta(\gamma(x)) - \Theta(\gamma_0))_+$. We obtain then a similar decay result to (4.6).

In the case when $\alpha > \frac{1}{2}$, we need a finer energy estimate than (3.22), see however Remark V.11.

V. TWO-TERM ASYMPTOTICS

In this section we suppose in addition to the hypotheses of Theorem II.1 that $\alpha \geqslant \frac{1}{2}$. We give two-term asymptotic expansions for the ground state energy showing the influence of the scalar curvature and we finish the proofs of the remaining theorems announced in Sec. I.

A. Upper bound

We construct a trial function defined by means of boundary coordinates (s,t) near a point $z_0 \in \partial\Omega$. We suppose that $z_0 = 0$ in the coordinate system (s,t) and we denote by $\kappa_0 = \kappa_r(0)$, $a_0 = 1 - t\kappa_0$ and $\eta(z_0) = h^{\alpha-1/2}\gamma(z_0)$. We then define the trial function:

$$u_h = \exp\left(-i\frac{\xi(\eta(z_0))s}{h^{1/2}}\right) v_h(s,t), \tag{5.1}$$

with

$$v_h(s,t) = h^{-5/16} a_0^{-1/2}(t) \varphi_{\eta(z_0)}(h^{-1/2}t)\chi(t) \cdot f(h^{-1/8}s), \tag{5.2}$$

and where the functions χ and f are as in (3.5).

We continue now to work in the spirit of Ref. 10. We work with the gauge given in Proposition A.2. An explicit calculation, thanks to the decay of $\varphi_{\eta(z_0)}$ (Proposition II.9), gives the following lemma.

Lemma V.1: With the above notations, for each $\alpha \in \left[\frac{1}{2}, 1\right]$ *and* $\gamma \in C^\infty(\partial\Omega;\mathbb{R})$, *there exist positive constants* C, h_0 *such that,* $\forall h \in]0,h_0]$, *we have the following estimate:*

$$\left| q_{h,A,\Omega}^{\alpha,\gamma(z_0)}(u_h) - \int_{\mathbb{R}_+} H^h(U^h\varphi_{\eta(z_0)}) \times (U^h\varphi_{\eta(z_0)})\mathrm{d}t \right| \leqslant Ch^{13/8}, \tag{5.3}$$

where the operators H^h *and* U^h *are defined, respectively, by*

$$H^h = a_0^{-2}\left(t\left(1 - t\frac{\kappa_0}{2}\right) - h^{1/2}\xi(\eta(z_0))\right)^2 - h^2 a_0^{-1}\partial_t(a_0\partial_t),$$

$$(U^h g)(t) = h^{-1/4} g(h^{-1/2}t), \quad \forall\, g \in L^2(\mathbb{R}_+).$$

Proof: Note that in the support of u_h we have[2]

$$a = a_0 + \mathcal{O}(h^{5/8}), \quad \widetilde{A}_1 = -t\left(1 - \frac{t}{2}\kappa_0\right) + \mathcal{O}(h^{9/8}).$$

Then, thanks to formula (A3) (also cf. (3.7)) and the decay of $\varphi_{\eta(z_0)}$ (Proposition II.9), we get modulo $\mathcal{O}(h^{13/8})$:

$$q^{\alpha,\gamma(z_0)}_{h,A,\Omega}(u_h) = \int_{\mathbb{R}\times\mathbb{R}_+} a_0\left\{|h\partial_t v_h|^2 + a_0^{-2}\left|\left(t\left(1-\frac{t}{2}\kappa_0\right) - h^{1/2}\xi(\eta(z_0))\right)v_h\right|^2\right\}\mathrm{d}s\mathrm{d}t$$
$$+ h^{3/2}\eta(z_0)\int_{\mathbb{R}} |v_h(s,0)|^2. \tag{5.4}$$

Integrating with respect to s, the right-hand side above is equal to

$$h^{-1/2}\int_{\mathbb{R}} a_0\left\{h^2|\partial_t(a_0^{-1/2}\varphi_{\eta(z_0)}(h^{-1/2}t)\chi(t))|^2 + a_0^{-3}\left|\left(t\left(1-\frac{t}{2}\kappa_0\right) - h^{1/2}\xi(\eta(z_0))\right)\varphi_{\eta(z_0)}\right.\right.$$
$$\left.\left.\times(h^{-1/2}t)\chi(t)\right|^2\right\}\mathrm{d}s\mathrm{d}t + h\,\eta(z_0)|\varphi_{\eta(z_0)}(0)|^2.$$

We can replace the function χ in the above expression by 1 getting an exponentially small error, thanks to Proposition II.9. Thus, modulo a small exponential error, we rewrite the above expression as

$$\int_{\mathbb{R}}\left\{h^2 a_0|\partial_t(U^h\varphi_{\eta(z_0)})|^2 + a_0^{-2}\left|\left(t\left(1-\frac{t}{2}\kappa_0\right) - h^{1/2}\xi(\eta(z_0))\right)(U^h\varphi_{\eta(z_0)})\right|^2\right\}\mathrm{d}s\mathrm{d}t$$
$$+ h^{3/2}\eta(z_0)|(U^h\varphi_{\eta(z_0)})(0)|^2.$$

Notice that we have the boundary condition $(U^h\varphi_{\eta(z_0)})'(0) = h^{-1/2}\eta(z_0)(U^h\varphi_{\eta(z_0)})(0)$. Therefore, integrating by parts, the above expression is equal to $\int_{\mathbb{R}_+} H^h(U^h\varphi_{\eta(z_0)})\times(U^h\varphi_{\eta(z_0)})\mathrm{d}t$. Upon substituting in (5.3), this finishes the proof of the lemma. □

Similar computations also give the following lemma.

Lemma V.2: Under the hypotheses of Lemma V.1, there exist positive constants C, h_0 such that, $\forall h \in]0, h_0]$, we have

$$\|(H^h - H_0^h - H_1^h)U^h\varphi_{\eta(z_0)}\|_{L^2(\mathbb{R}_+)} \leqslant Ch^2, \tag{5.5}$$

where the operators H_0^h and H_1^h are defined, respectively, by

$$H_0^h = -h^2\partial_t^2 + (t - h^{1/2}\xi(\eta(z_0)))^2,$$

$$H_1^h = 2t\kappa_0(t - h^{1/2}\xi(\eta(z_0)))^2 - \kappa_0 t^2(t - h^{1/2}\xi(\eta(z_0))) + h^2\kappa_0\partial_t.$$

Let us denote by (cf. (2.24) and (2.25)):

$$M_3\left(\tfrac{1}{2}, \gamma(z_0)\right) = M_3(\gamma(z_0)), \quad M_3(\alpha, \gamma(z_0)) = M_3 \quad \text{for } \alpha > \tfrac{1}{2}.$$

The next lemma permits us to conclude an upper bound for the eigenvalue $\mu^{(1)}(\alpha, \gamma, h)$.

Lemma V.3: Under the above notations, there exist positive constants C, h_0 such that, when $h \in]0, h_0]$, we have the following estimate:

[2]Actually, if z_0 is a point of maximum of κ_r, the remainder is better and of order $\mathcal{O}(h^{3/4})$ for the first term. Consequently, we obtain (5.4) modulo an error of order $\mathcal{O}(h^{7/4})$.

$$|q^{\alpha,\gamma}_{h,A,\Omega}(u_h) - \{\Theta(\eta(z_0)) - 2M_3(\alpha,\gamma(z_0))\kappa_0 h^{3/2}\}\|u_h\|^2_{L^2(\Omega)}| \leqslant Ch^{\epsilon_\alpha},$$

where $\epsilon_\alpha = \inf(13/8, 2\alpha + \frac{1}{2})$ *for* $\alpha > \frac{1}{2}$ *and* $\epsilon_{1/2} = 13/8$.

Proof: Notice that in the support of u_h we have $\gamma(z) = \gamma(z_0) + \mathcal{O}(h^{1/8})$. Then this gives

$$q^{\alpha,\gamma}_{h,A,\Omega}(u_h) - q^{\alpha,\gamma(z_0)}_{h,A,\Omega}(u_h) = \mathcal{O}(h^{9/8+\alpha}).$$

In view of Lemmas V.1 and V.2, we get the following estimate:

$$\left| q^{\alpha,\gamma}_{h,A,\Omega}(u_h) - \int_{\mathbb{R}_+} (H^h_1 + H^h_0)(U^h \varphi_{\eta(z_0)}) \times U^h \varphi_{\eta(z_0)} dt \right| \leqslant Ch^{13/8}. \tag{5.6}$$

We note also that we have the following relations:

$$(U^h)^\star H^h_0 U^h = h\{-\partial_t^2 + (t - \xi(\eta(z_0)))^2\}, \tag{5.7}$$

$$(U^h)^\star H^h_1 U^h = \kappa_0 h^{3/2} H_1, \tag{5.8}$$

where the operator H_1 is defined by

$$H_1 = (t - \xi(\eta(z_0)))^3 - \xi(\eta(z_0))^2 (t - \xi(\eta(z_0))) + \partial_t.$$

By defining $K_3(\alpha,h) := \int_{\mathbb{R}_+} H_1 \varphi_{\eta(z_0)} \cdot \varphi_{\eta(z_0)} \mathrm{d}t$, the estimate (5.6) reads as

$$|q^{\alpha,\gamma}_{h,A,\Omega}(u_h) - \{h\Theta(\eta(z_0)) + K_3(\alpha,h)\kappa_0 h^{3/2}\}| \leqslant Ch^{13/8}. \tag{5.9}$$

Now, for $\alpha = \frac{1}{2}$, we get by using (2.3) that $K_3(\frac{1}{2},h) = -2M_3(\frac{1}{2},\gamma(z_0))$. For $\alpha > \frac{1}{2}$, thanks to Propositions II.4 and II.5, we get that

$$K_3(\alpha,h) = -2M_3 + \mathcal{O}(h^{2\alpha-1}).$$

Finally, the decay of $\varphi_{\eta(z_0)}$ in Proposition II.9 gives that $\|u_h\|_{L^2(\Omega)}$ is exponentially close to 1. This achieves the proof of the lemma. □

The min-max principle gives now, thanks to Lemma V.3, an upper bound for $\mu^{(1)}(\alpha,\gamma,h)$. Under the hypothesis of Theorem I.4, we take z_0 such that

$$(\kappa_r - 3\gamma)(z_0) = (\kappa_r - 3\gamma)_{\max}$$

and we use the expansion (cf. (2.27)):

$$\Theta(\eta(z_0)) = \Theta_0 + 6M_3\gamma(z_0)h^{1/2} + \mathcal{O}(h).$$

Therefore, (5.9) gives the following upper bound:

$$\mu^{(1)}(1,\gamma,h) \leqslant h\Theta_0 - 2M_3(\kappa_r - 3\gamma)_{\max} h^{3/2} + \mathcal{O}(h^{13/8}). \tag{5.10}$$

Under the hypothesis of Theorem 1.5, we choose z_0 such that $\kappa_r(z_0) = (\kappa_r)_{\max}$.

B. Lower bound

As in the proof of Proposition III.3, we consider a standard scaled partition of unity[3] $(\chi_{j,h^{1/6}})_{j\in\mathbb{Z}^2}$ of $\mathbb{R}^2$ that satisfies

$$\sum_{j\in J} |\chi_{j,h^{1/6}}(z)|^2 = 1, \quad \sum_{j\in J} |\nabla\chi_{j,h^{1/6}}(z)|^2 \leqslant Ch^{-1/3}, \tag{5.11}$$

[3]We take a partition of unity associated to squares instead of discs.

$$\operatorname{supp} \chi_{j,h^{1/6}} \subset jh^{1/6} + [-h^{1/6}, h^{1/6}]^2. \tag{5.12}$$

We define the following set of indices:

$$J^1_{\tau(h)} := \{j \in \mathbb{Z}^2; \operatorname{supp} \chi_{j,h^{1/6}} \cap \Omega \neq \phi, \operatorname{dist}(\operatorname{supp} \chi_{j,h^{1/6}}, \partial\Omega) \leqslant \tau(h)\},$$

where the number $\tau(h)$ is defined by

$$\tau(h) = h^\delta \quad \text{with } \tfrac{1}{6} \leqslant \delta \leqslant \tfrac{1}{2}, \tag{5.13}$$

and the number δ will be chosen in a suitable manner.

We consider also another scaled partition of unity in $\mathbb{R}$:

$$\psi^2_{0,\tau(h)}(t) + \psi^2_{1,\tau(h)}(t) = 1, \quad |\psi'_{j,\tau(h)}(t)| \leqslant acC\tau(h), \quad j = 0,1, \tag{5.14}$$

$$\operatorname{supp} \psi_{0,\tau(h)} \subset \left[\frac{\tau(h)}{20}, +\infty[, \operatorname{supp}\psi_{1,\tau(h)} \subset]-\infty, \frac{\tau(h)}{10} \right]. \tag{5.15}$$

Note that, for each $j \in J^1_{\tau(h)}$, the function $\psi_{1,\tau(h)}(t)\chi_{j,h^{1/6}}(s,t)$ could be interpreted, by means of boundary coordinates, as a function in $\bar{\Omega}$. Moreover, each $\psi_{1,\tau(h)}(t)\chi_{j,h^{1/6}}(s,t)$ is supported in a rectangle

$$K(j,h) =]-h^{1/6} + s_j, s_j + h^{1/6}[\times [0, h^\delta[$$

near $\partial\Omega$. The role of δ is then to control the size of the width of each rectangle $K(j,h)$. Due to the exponential decay of a ground state away from the boundary (Theorem IV.1), we get the following lemma.

Lemma V.4: Suppose that $\alpha > \frac{1}{2}$. With the above notations, an L^2-normalized ground state $u_{\alpha,\gamma,h}$ of the operator $P^{\alpha,\gamma}_{h,A,\Omega}$ satisfies

$$\left| \sum_{j \in J^1_{\tau(h)}} q^{\alpha,\gamma}_{h,A,\Omega}(\chi_{j,h^{1/6}}\psi_{1,\tau(h)}u_{\gamma,h}) - \mu^{(1)}(\alpha,\gamma,h) \right| \leqslant Ch^{5/3}. \tag{5.16}$$

The proof of (5.16) follows the same lines of that in Ref. 10 (Formulas (10.4), (10.5) and (10.6)).

For each $j \in J^1_{\tau(h)}$, we define a unique point $z_j \in \partial\Omega$ by the relation $s(z_j) = s_j$. We denote then by $\kappa_j = \kappa_r(z_j)$, $a_j(t) = 1 - \kappa_j t$, $A^j(t) = -t(1 - t/2\kappa_j)$, and $\gamma_j = \gamma(z_j)$.

We consider now the k-family of one-dimensional differential operators:

$$H_{h,j,k} = -h^2 a_j^{-1}\partial_t(a_j\partial_t) + (1 + 2\kappa_j t)(hk - A^j)^2, \tag{5.17}$$

where k is a real parameter. We denote by $H^{\alpha,\gamma,D}_{h,j,k}$ the self-adjoint realization on $L^2(]0,h^\delta[; a_j(t)dt)$ of $H_{h,j,k}$ whose domain is given by

$$D(H^{\gamma,D}_{h,j,k}) = \{v \in H^2(]0,h^\delta[); v'(0) = h^\alpha\tilde{\gamma}_j v(0), v(h^\delta) = 0\}. \tag{5.18}$$

The parameter $\tilde{\gamma}_j$ is defined by

$$\tilde{\gamma}_j = \gamma_j + \varepsilon(h),$$

where $\varepsilon(h) = 0$ if the function γ is constant; if γ is not constant, then there are constants $C, h_0 > 0$ such that

$$|\varepsilon(h)| \leqslant Ch^{1/6}, \quad \forall\, h \in]0,h_0].$$

We now introduce

$$\mu_1^j(\alpha,\gamma,h) := \inf_{k\in\mathbb{R}} \inf \mathrm{Sp}(H_{h,j,k}^{\gamma,D}). \tag{5.19}$$

We have now the following lemma:

Lemma V.5: For each $\alpha \in \left[\frac{1}{2}, +\infty\right[$, *we have under the above notations:*

$$\mu^{(1)}(\alpha,\gamma,h) \geqslant \Big(\inf_{j\in J^1_{\tau(h)}} \mu_1^j(\alpha,\gamma,h)\Big) + \mathcal{O}(h^{5/3}). \tag{5.20}$$

Again the proof follows the same lines of Ref. 10 (Sec. 11), but let us explain briefly the main steps. We express each term $q^{\alpha,\gamma}_{h,A,\Omega}(\psi_{1,\tau(h)}\chi_{j,h^{1/6}}u_{\alpha,\gamma,h})$ in boundary coordinates. We work with the local choice of gauge given in Proposition A.2. We expand now all terms by Taylor's formula near $(s_j,0)$. After controlling the remainder terms, thanks to the exponential decay of the ground states away from the boundary, we apply a partial Fourier transformation in the tangential variable s and we get finally the result of the lemma.

We now have to find, uniformly over $k\in\mathbb{R}$, a lower bound for the first eigenvalue $\mu_1^j(k;\alpha,\gamma,h)$ of the operator $H^{\alpha,\gamma,D}_{h,j,k}$. Putting $\beta=\kappa_j$, $\xi=-h^{1/2}k$, and $\eta=\tilde{\gamma}_j$, we get by a scaling argument

$$\mu_1^j(k;\alpha,\gamma,h) = h\mu_1(H^{\alpha,\eta,D}_{h,\beta,\xi}),$$

where $\mu_1(H^{\alpha,\eta,D}_{h,\beta,\xi})$ is the first eigenvalue of the one-dimensional operator:

$$H^{\alpha,\eta,D}_{h,\beta,\xi} = -\partial_t^2 + (t-\xi)^2 + \beta h^{1/2}(1-\beta h^{1/2}t)^{-1}\partial_t + 2\beta h^{1/2}t\left(t-\xi-\beta h^{1/2}\frac{t^2}{2}\right)^2 - \beta h^{1/2}t^2(t-\xi) + \beta^2 h\frac{t^4}{4}, \tag{5.21}$$

whose domain is defined by

$$D(H^{\alpha,\eta,D}_{h,\beta,\xi}) = \{u\in H^2(]0,h^{\delta-1/2}[); u'(0) = h^{\alpha-1/2}\eta u(0), u(h^{\delta-1/2}) = 0\}.$$

We have then to find (when $\eta,\beta\in\,]-M,M[$ and M a given positive constant), uniformly with respect to $\xi\in\mathbb{R}$, a lower bound for the eigenvalue $\mu_1(H^{\alpha,\eta,D}_{h,\beta,\xi})$. The min-max principle gives the following preliminary localization of the spectrum of the operator $H^{\alpha,\eta,D}_{h,\beta,\xi}$:

Lemma V.6: For each $M>0$ *and* $\alpha\in\left[\frac{1}{2},+\infty\right[$, *there exist positive constants* C, h_0 *such that*

$$\forall\ \eta,\beta\in\,]-M,M[, \quad \forall\ \xi\in\mathbb{R}, \quad \forall\ h\in\,]0,h_0],$$

we have

$$|\mu_j(H^{\alpha,\eta,D}_{h,\beta,\xi}) - \mu_j(H^{\alpha,\eta,D}_{0,\xi})| \leqslant Ch^{2\delta-1/2}(1+\mu_j(H^{\alpha,\eta,D}_{0,\xi})), \tag{5.22}$$

where, for an operator T *having a compact resolvent,* $\mu_j(T)$ *denotes the increasing sequence of eigenvalues of* T.

Remark V.7: Note that the min-max principle gives now that

$$\mu_j(H^{\alpha,\eta,D}_{0,\xi}) \geqslant \mu^{(j)}(h^{\alpha-1/2}\eta,\xi),$$

where, for $\tilde{\eta}\in\mathbb{R}$, $\mu^{(j)}(\tilde{\eta},\xi)$ *is the increasing sequence of eigenvalues of the operator* $H[\eta,\xi]$ *introduced in* (2.2).

The following lemma deals with the case when ξ is not localized very close to $\xi(h^{\alpha-1/2}\eta)$.

Lemma V.8: Suppose that $\delta\in\,]1/4,1/2[$. *For each* $\alpha\geqslant\frac{1}{2}$, *there exists* $\rho\in\,]0,\delta-\frac{1}{4}]$, *and for each* $M>0$, *there exist positive constants* $\zeta, h_0>0$ *such that*

$$\forall\ \eta,\beta\in\,]-M,M[, \quad \forall\ \xi \text{ such that } |\xi-\xi(h^{\alpha-1/2}\eta)|\geqslant\zeta h^{\rho}, \quad \forall\ h\in\,]0,h_0],$$

we have

$$\mu_1(H^{\alpha,\eta,D}_{h,\beta,\xi}) \geqslant \Theta(h^{\alpha-1/2}\eta) + h^{2\rho}. \tag{5.23}$$

Proof: It is sufficient to obtain (5.23) for $\mu^{(1)}(h^{\alpha-1/2}\eta,\xi)$, thanks to Lemma V.6 and Remark V.7. We start with the case when $\alpha=\frac{1}{2}$ and $\eta\in\,]-M,M[$. Writing Taylors formula up to the second order for the function $\xi\mapsto\mu^{(1)}(\eta,\xi)$, we get positive constants θ, C_1 such that when $|\xi-\xi(\eta)| \leqslant \theta$, we have

$$\mu^{(1)}(\eta,\xi) \geqslant \Theta(\eta) + C_1|\xi-\xi(\eta)|^2.$$

Then by taking ζ such that $C_1\zeta>\zeta_0$, where $\zeta_0>1$ is a constant to be chosen appropriately, we get when $\zeta h^\rho \leqslant |\xi-\xi(\eta)| \leqslant \theta$,

$$\mu^{(1)}(\eta,\xi) \geqslant \Theta(\eta) + \zeta_0 h^{2\rho},$$

where ρ is also a positive constant to be chosen later. When $|\xi-\xi(\eta)|>\theta$, we get a positive constant ϵ_θ such that

$$\mu^{(1)}(\eta,\xi) \geqslant \Theta(\eta) + \epsilon_\theta.$$

Then by choosing h_0 such that $\zeta_0 h_0^\rho < \epsilon_\theta$, we get for $|\xi-\xi(\eta)| \geqslant \zeta h^\rho$ and $h\in\,]0,h_0]$:

$$\mu^{(1)}(\eta,\xi) \geqslant \Theta(\eta) + \zeta_0 h^{2\rho}. \tag{5.24}$$

We treat now the case when $\alpha>1/2$. Note that the min-max principle gives uniformly for all $\xi \in \mathbb{R}$ and $\eta\in\,]-M,M[$,

$$\mu^{(1)}(h^{\alpha-1/2}\eta,\xi) \geqslant (1 - C\eta_- h^{\alpha-1/2})\mu^{(1)}(0,\xi).$$

Then using (5.24) for $\eta=0$ and $\rho=\inf\left(\delta-\frac{1}{4}, \alpha-\frac{1}{2}\right)$, we can choose ζ_0 large enough so that we have for $|\xi-\xi_0| \geqslant \zeta h^\rho$:

$$\mu^{(1)}(h^{\alpha-1/2}\eta,\xi) \geqslant \Theta(h^{\alpha-1/2}\eta) + \frac{\zeta_0}{2}h^\rho.$$

To finish the proof, we replace ξ_0 by $\xi(h^{\alpha-1/2}\eta)$ getting an error of order $\mathcal{O}(h^{\alpha-1/2})$. □

Now we deal with the case when $|\xi-\xi(h^{\alpha-1/2}\eta)| < \zeta h^\rho$. Let $\tilde{\eta}=h^{\alpha-1/2}\eta$. We look for a formal solution $(\mu, f^{\alpha,\eta}_{h,\beta,\xi})$ of the spectral problem

$$H^{\alpha,\eta}_{h,\beta,\xi} f^{\alpha,\eta}_{h,\beta,\xi} = \mu f^{\alpha,\eta}_{h,\beta,\xi}, \quad (f^{\alpha,\eta}_{h,\beta,\xi})'(0) = h^{\alpha-1/2} f^{\alpha,\eta}_{h,\beta,\xi}(0), \tag{5.25}$$

in the form:

$$\mu = d_0 + d_1(\xi-\xi(\tilde{\eta})) + d_2(\xi-\xi(\tilde{\eta}))^2 + d_3 h^{1/2}, \tag{5.26}$$

$$f^{\alpha,\eta}_{h,\beta,\xi} = u_0 + (\xi-\xi(\tilde{\eta}))u_1 + (\xi-\xi(\tilde{\eta}))^2 u_2 + h^{1/2}u_3, \tag{5.27}$$

where the coefficients d_0,d_1,d_2,d_3 and the functions u_0,u_1,u_2,u_3 are to be determined. We expand the operator $H^{\alpha,\eta,D}_{h,\beta,\xi}$ in powers of $(\xi-\xi(\tilde{\eta}))$ and then we identify the coefficients of the terms of orders $(\xi-\xi(\tilde{\eta}))^j$ $(j=0,1,2)$ and $h^{1/2}$. We then obtain for the coefficients:

$$d_0 = \Theta(\tilde{\eta}), \quad u_0 = \varphi_{\tilde{\eta}},$$

$$d_1 = 0, \quad u_1 = 2\widetilde{R}[\tilde{\eta}]\{(t-\xi(\tilde{\eta}))\varphi_{\tilde{\eta}}\},$$

$$d_2 =: d_2(\alpha,\eta) = 1 - 2\int_{\mathbb{R}_+} (t-\xi(\tilde{\eta}))\varphi_{\tilde{\eta}} u_1 \mathrm{d}t,$$

$$u_2 = \widetilde{R}[\widetilde{\eta}]\{4(t-\xi(\widetilde{\eta}))\widetilde{R}[\widetilde{\eta}][(t-\xi(\widetilde{\eta}))\varphi_{\widetilde{\eta}}] - d_2\},$$

$$d_3 =: d_3(\alpha,\eta) = \beta\int_{\mathbb{R}_+} \varphi_{\widetilde{\eta}}\{\partial_t + (t-\xi(\widetilde{\eta}))^3\}\varphi_{\widetilde{\eta}}\mathrm{d}t,$$

$$u_3 = -\widetilde{R}[\widetilde{\eta}][\beta(\partial_t + (t-\xi(\widetilde{\eta}))^3 - \xi(\widetilde{\eta})^2(t-\xi(\widetilde{\eta}))) - d_3]u_0. \tag{5.28}$$

Using the function $\chi(t/h^{\delta-1/2})f^{\alpha,\eta}_{h,\beta,\xi}$ (where χ is the same as in (3.5)) as a quasimode, we get by the spectral theorem, thanks to the decay results in Propositions II.9 and II.10 and to the localization of the spectrum in Lemma V.6, the following lemma.

Lemma V.9: Suppose that $\delta \in]\frac{1}{4},\frac{1}{2}[$. *For each* $M>0$ *and* $\alpha \in [\frac{1}{2},1]$, *there exist positive constants* $C>0, h_0$ *such that*

$$\forall\ \eta,\beta \in]-M,M[, \quad \forall\ \xi \text{ such that } |\xi-\xi(\widetilde{\eta})| \leqslant \zeta h^{\rho}, \quad \forall\ h \in]0,h_0],$$

we have

$$|\mu_1(H^{\alpha,\eta,D}_{h,\beta,\xi}) - \{\Theta(\widetilde{\eta}) + d_2(\alpha,\eta)(\xi-\xi(\widetilde{\eta}))^2 + d_3(\alpha,\eta)h^{1/2}\}| \leqslant C[h^{1/2}|\xi-\xi(\widetilde{\eta})| + h^{\delta+1/2}], \tag{5.29}$$

where $d_2(\alpha,\eta)$ *and* $d_3(\alpha,\eta)$ *are defined by (5.28)).* Hence we have obtained by this analysis a lower bound for the first eigenvalue $\mu^{(1)}(\alpha,\gamma,h)$. We complete the picture by showing that the term $d_2(\alpha,\eta)$ is positive.

Lemma V.10: For each $\alpha \in [\frac{1}{2},+\infty[$ *and* $M>0$, *there exists a positive constant* h_0 *such that*

$$d_2(\alpha,\eta) > 0, \quad \forall\ h \in]0,h_0], \quad \forall\ \eta \in]-M,M[.$$

Proof: It is actually sufficient to prove the conclusion of the lemma when $\alpha=\frac{1}{2}$. If $\alpha>\frac{1}{2}$, we replace $d_2(\alpha,\eta)$ by its approximation up to the first order, thanks to Proposition II.4, and we obtain that

$$d_2(\alpha,\eta) = d_2\left(\tfrac{1}{2},0\right) + \mathcal{O}(h^{\alpha-1/2}),$$

which gives the lemma. For the particular case $\alpha=\frac{1}{2}$, we show that

$$d_2\left(\tfrac{1}{2},\eta\right) = \tfrac{1}{2}(\partial^2_{\xi}\mu^{(1)}(\eta,\cdot))(\xi(\eta))$$

which is strictly positive. □

We are now able to conclude the asymptotics given in Theorems I.4 and I.5. First we choose $\delta=\frac{5}{12}$. When $\alpha>\frac{1}{2}$ we replace $\Theta(\widetilde{\eta})$ and d_3 by their approximations up to the second and first orders, respectively, thanks to Propositions II.5 and II.4. For $\alpha=\frac{1}{2}$ we get by (2.21) that d_3 is indeed equal to $-2M_3(\frac{1}{2},\gamma)$.

Remark V.11: When $\alpha \in]\frac{1}{2},1[$ *and when the function* γ *is not constant, we get from the above analysis that the upper bound in Remark III.2 is indeed an asymptotic expansion, and we achieve therefore the proof of Theorem I.2.*

We get also that the quadratic form $q^{\alpha,\gamma}_{h,A,\Omega}$ *can be bounded from below by means of a potential* W:

$$q^{\alpha,\gamma}_{h,A,\Omega}(u) \geqslant \int_{\Omega} W(x)|u(x)|^2\mathrm{d}x, \quad \forall\ u \in H^1(\Omega),$$

where W *is defined for some positive constant* C_0 *by*

$$W(x) = \begin{cases} h & \text{if } \operatorname{dist}(x,\partial\Omega) > h^{1/6} \\ h\Theta_0 + 6M_3\gamma(x)h^{\alpha+1/2} - C_0 h^{\inf(3/2,2\alpha)} & \text{if } \operatorname{dist}(x,\partial\Omega) < h^{1/6}. \end{cases}$$

Then, as in Sec. IV, we get by Agmon's technique that a ground state decays exponentially away from the boundary points where γ is minimum and hence we have completed the proof of Theorem I.3.

Remark V.12: Note also that the above analysis permits, under the hypotheses of Theorems I.4 and I.5, to bound the quadratic form $q^{\alpha,\gamma}_{h,A,\Omega}$ from below using a potential W defined either by means of the function $\kappa_r - 3\gamma$ (when $\alpha=1$) or by the scalar curvature κ_r (when γ is constant). Then, by using Agmon's technique, we finish the proofs of Theorems I.4 and I.5.

VI. CONCLUSION

The systematic analysis in the spirit of Ref. 10 has allowed us to understand the role of the boundary condition imposed by De Gennes. We have extended in Theorems I.4 and I.5 the expansion announced by Pan[25] in the particular case when $\alpha=1$ and γ is a positive constant. However, there is a specific difficulty when γ is negative. We have not been able to obtain the localization of the ground state when $\alpha<1/2$ and $\gamma_0>0$. This is strongly related to the question of the localization of the ground state of the Dirichlet realization of the Schrödinger operator with constant magnetic field which is open. Finally, in the spirit of Refs. 12, 26, and 27, we hope to apply this analysis to the onset of superconductivity and to complete the analysis of Ref. 28 (cf. Ref. 18).

ACKNOWLEDGMENTS

I am deeply grateful to Professor B. Helffer for the constant attention to this work, his help, advice, and comments. I would also like to thank S. Fournais for his attentive reading and suggestions, and the referee for his valuable comments which improved the presentation of the paper. I acknowledge the ESI at Vienna where I found good conditions to prepare part of this work and the ESF which had supported the visit under the SPECT program. This work has been carried out with the financial support of the *Agence Universitaire de la Francophonie* (AUF).

APPENDIX: COORDINATES NEAR THE BOUNDARY

We recall in this appendix well-known coordinates that straighten a portion of the boundary $\partial\Omega$. Let $s \in]-|\partial\Omega|/2, |\partial\Omega|/2] \mapsto M(s) \in \partial\Omega$ be a regular parametrization of $\partial\Omega$. For each $x \in \Omega$ and $\epsilon > 0$ we denote by

$$t(x) = \operatorname{dist}(x,\partial\Omega) \quad \text{and } \Omega_\epsilon = \{x \in \bar{\Omega}; \operatorname{dist}(x,\partial\Omega) < \epsilon\}.$$

Then there exists a positive constant $t_0 > 0$ depending on Ω such that, for each $x \in \Omega_{t_0}$, we can define the coordinates $(s(x), t(x))$ by

$$t(x) = |x - M(s(x))|,$$

and such that the transformation

$$\psi : \Omega_{t_0} \ni x \mapsto (s(x), t(x)) \in \mathbb{S}^1_{|\partial\Omega|/2\pi} \times [0, t_0[$$

is a diffeomorphisim. The Jacobian of this coordinate transformation is given by

$$a(s,t) = \det(D\psi) = 1 - t\kappa_r(s). \tag{A1}$$

To a vector field $A = (A_1, A_2) \in C^\infty(\bar{\Omega}; \mathbb{R}^2)$, we associate the vector field $\tilde{A} = (\tilde{A}_1, \tilde{A}_2) \in C^\infty(\mathbb{S}^1_{|\partial\Omega|/2\pi} \times [0, t_0[)$ by the following relation:

$$\tilde{A}_1 \mathrm{d}s + \tilde{A}_2 \mathrm{d}t = A_1 \mathrm{d}x_1 + A_2 \mathrm{d}x_2. \tag{A2}$$

We get then the following change of variable formulas.

Proposition A.1: Let $u \in H^1(\Omega)$ be supported in Ω_{t_0}. Then we have

$$\int_{\Omega_{t_0}} |(h\nabla - iA)u|^2 \mathrm{d}x = \int_{\mathrm{S}^1_{|\partial\Omega|/2\pi}\times[0,t_0[} [|(h\partial_t - i\tilde{A}_2)v|^2 + a^{-2}|(h\partial_s - i\tilde{A}_1)v|^2] a \mathrm{d}s\mathrm{d}t \tag{A3}$$

and

$$\int_{\Omega_{t_0}} |u(x)|^2 \mathrm{d}x = \int_{\mathrm{S}^1_{|\partial\Omega|/2\pi}\times[0,\epsilon_0[} |v(s,t)|^2 a \mathrm{d}s\mathrm{d}t, \tag{A4}$$

where $v(s,t) = u(\psi^{-1}(s,t))$.

We also have the relation

$$(\partial_{x_1} A_2 - \partial_{x_2} A_1)\mathrm{d}x_1 \wedge \mathrm{d}x_2 = (\partial_s \tilde{A}_2 - \partial_t \tilde{A}_1) a^{-1} \mathrm{d}s \wedge \mathrm{d}t,$$

which gives

$$\mathrm{curl}\,\tilde{A} = (1 - t\kappa_r(s))\mathrm{curl}\,A.$$

We give in the next proposition a standard choice of gauge.

Proposition A.2: Consider a vector field $A = (A_1, A_2) \in C^\infty(\bar{\Omega}; \mathbb{R}^2)$ such that $\mathrm{curl}\,A = 1$. *For each point $x_0 \in \partial\Omega$, there exists a neighborhood $\mathcal{V}_{x_0} \subset \Omega_{t_0}$ of x_0 and a smooth real-valued function ϕ_{x_0} such the vector field $A_{\mathrm{new}} := A - \nabla\phi_{x_0}$ satisfies*

$$\tilde{A}^1_{\mathrm{new}} = -t\left(1 - \frac{t}{2}\kappa_r(s)\right) \quad \textit{and } \tilde{A}^2_{\mathrm{new}} = 0 \quad \textit{in } \mathcal{V}_{x_0}, \tag{A5}$$

with $\tilde{A}_{\mathrm{new}} = (\tilde{A}^1_{\mathrm{new}}, \tilde{A}^2_{\mathrm{new}})$.

(Received 25 December 2005; accepted 11 May 2006; published online 17 July 2006)

In this work, we study the complex bosonic matter coupled to the SU(N_c) gauge fields on a cylinder, which has a circular space part. We extend the ideas used for fermions on a cylinder in [S. G. Rajeev and Guruswamy, Mod. Phys. Lett. A **7**, 3783 (1992)] to this case. Here, the normal ordering rule for bosonic bilinears is found. In the large-N_c limit, we can reformulate the whole problem in terms of a set of basic mesonic operators. The full equations of motion satisfied by these mesonic variables are too complicated. An approximation method, which is a kind of linearization, is suggested for this problem. © *2006 American Institute of Physics.*

I. INTRODUCTION

Calculation of the bound states from first principles in QCD is a very challenging problem. The perturbative approach is not sufficient to understand this problem. There are various interesting ideas in this direction, but the most promising one seems to be the large-N_c limit, which is first suggested by 't Hooft[1] and elaborated more by Migdal[2,3] and Witten.[4] 't Hooft applied the large-N_c limit to 1+1 dimensional QCD and found his celebrated equation for the mesonic spectrum.[5] Soon after this is generalized by Shei and Tsao to the scalar matter.[6] The same problem is also solved in the Hamiltonian formalism in Ref. 7. The generalized QCD, where the fermionic and bosonic matter fields present together, is solved by Aoki in Ref. 8 following 't Hooft's original approach.

In Ref. 9 Rajeev took a fresh look at the large-N_c limit of 1+1 dimensional QCD and has shown that this is indeed a classical theory which has the restricted Grassmanian as its phase space (see Ref. 10 for a nice review). The linearized equations for the mesonic bilinears are shown to agree with the 't Hooft equation. Being a nonlinear theory it admits also large deviations from the vacuum and they may be taken as the baryons. Krishnaswami gave a detailed study of these solutions in his thesis and showed that the minimum of the baryon mass in this theory goes to zero as the mass of the fermion goes to zero, contrary to what is believed to happen in 3+1 dimensions.[11] An extension of these ideas to bosonic matter is done in Ref. 12 and the linearized equations are shown to agree with what is found by Shei and Tsao. The method proposed in Ref. 9 also can be applied to SO(N_c) gauge theories,[13] the phase space there is an infinite dimensional version of the Siegel disk.

In all these problems the gauge theory sector is not dynamical and only generates a potential between the quarks. When we study the pure Yang-Mills on a cylinder, which has a circular spatial geometry, there is a global degree of freedom left out after the gauge equivalent configurations are removed. Therefore it is natural to try to add only a global degree of freedom to the gauge sector when it is coupled to matter for simplicity, by studying the same problem on a cylinder, which has

[a)]Electronic mail: turgutte@boun.edu.tr

a circle for the space part. This is perhaps the least complicated problem, but as we will see, the resulting theory is much more complex, and we are far from understanding it.

The literature on the pure Yang-Mills theory on such nontrivial spaces is large, we mention just a few of them closely related to our approach taken here, there is an extensive review by Moore *et al.*[14] where further references can be found. The solution of pure Yang-Mills theory on the cylinder is given by Rajeev in Ref. 15, there it is found that this system is equivalent to a particle moving on the group manifold. The Hamiltonian is the quadratic Casimir of the group, the global gauge invariance left out, forces one to restrict the Hilbert space of the theory to the character functions. The key to reduction is accomplished by the Wilson loop operator along the circle. Later, the nonrelativistic matter coupled to the gauge fields is worked out in a geometric setting using the Wilson loop operator to reduce the redundant gauge degrees of freedom in Ref. 16. The large-N_c limit of pure Yang-Mills is understood from different points of views in Refs. 17–20 (see for more the review in Ref. 14). The matter coupled to gauge fields on a cylinder was studied by other authors as well, in Langmann and Semenoff[21] the theory is constructed using the free vacuum and some ideas are suggested to study the spectrum. This problem is studied in Refs. 22 and 23, using again a large-N_c approximation in the path integral perspective. For large values of the radius, the authors give a formula for the eigenvalues of the Hamiltonian. In all these approaches the splitting of the true degrees of freedom of the gauge fields and the matter fields is not so clear. In Ref. 24, Rajeev and Guruswamy reduced the fermionic matter interacting with the gauge fields on the cylinder to matter coupled to quantum mechanics on the tangent bundle of the symmetry group. Again, only global degrees of freedom are left after the removal of gauge equivalent configurations from the gauge fields via the Wilson loop operator (the holonomy along the circle).

Here, we will study non-Abelian gauge theory coupled to scalars in the fundamental representation in $1+1$ dimensions. To decouple the gauge theory sector from the kinetic part of the bosons and reducing the gauge theory sector to its true degrees of freedom, we will use the same method suggested in Ref. 24. There are two essential points, first is the decoupling of the kinetic part of the bosons and gauge fields, since when we have coupling between the leading kinetic parts, the vacuum will change in an uncontrollable way. To start quantizing the fields, we should find the correct vacuum. The second point is the reduction of the gauge fields to their true degrees of freedom *without performing any gauge fixing*. The fermionic problem is more realistic, yet it is interesting to work out the same approach in the bosonic case. In Ref. 24, only the Hamiltonian of the theory is written in this coordinate system and no attempt is made to write down a large-N_c theory. There are some complications coming from the boundary conditions in the case of fermions, it seems to us that they are harder to resolve than the ones in the bosonic theory. In the bosonic theory, as we will see, it is more difficult to find the normal ordering prescription. In a separate section this is developed, which we believe could be useful in other contexts as well.

Following Ref. 24, we will perform our analysis in a coordinate system different from the Cartesian (x,t) coordinates used to solve pure Yang-Mills theory in Ref. 15. We construct a kind of light-cone formalism such that the new coordinates (u,x) are

$$u = t + |x|. \tag{1}$$

Then,

$$\mathrm{d}t = \mathrm{d}u - \mathrm{sgn}(x)\mathrm{d}x. \tag{2}$$

The metric is

$$\mathrm{d}s^2 = \mathrm{d}t \otimes \mathrm{d}t - \mathrm{d}x \otimes \mathrm{d}x = \mathrm{d}u \otimes \mathrm{d}u - \mathrm{sgn}(x)\mathrm{d}u \otimes \mathrm{d}x - \mathrm{sgn}(x)\mathrm{d}x \otimes \mathrm{d}u. \tag{3}$$

Thus the metric tensor becomes

$$\eta_{\mu\nu}=\begin{pmatrix}1 & -\operatorname{sgn}(x)\\ -\operatorname{sgn}(x) & 0\end{pmatrix},\quad \eta^{\mu\nu}=\begin{pmatrix}0 & -\operatorname{sgn}(x)\\ -\operatorname{sgn}(x) & -1\end{pmatrix}. \tag{4}$$

The points (u,x) and $(u,x+2L)$ are the same on the cylinder. These light-cone coordinates avoid the quadratic energy term appearing in the mass shell condition of the Cartesian coordinates,

$$p_0^2-p_1^2=m^2. \tag{5}$$

In Ref. 24, it is noticed that the ordinary light-cone method is not suitable for the elimination of the redundant gauge theory degrees of freedom, but in this coordinate system it can be done in a clever way. For this purpose, *we will use u as our evolution variable*. In this special light-cone coordinate system the mass-shell condition is

$$-2\operatorname{sgn}(x)p_xp_u-p_x^2=m^2 \tag{6}$$

from which we obtain a unique solution for p_u,

$$p_u=-\frac{1}{2}\left(\frac{m^2}{p_x}+p_x\right)\operatorname{sgn}(x). \tag{7}$$

This is important, since it suggests that in second quantization the positive and negative energies will be determined by the sign of $p_x\operatorname{sgn}(x)$. This is essentially correct, the operator that we will find has this as its leading symbol.

II. BOSONS IN THE FUNDAMENTAL REPRESENTATION

The action of the complex bosons in two dimensions interacting with an SU(N_c) gauge field can be written as

$$S=\int \mathrm{d}u\,\mathrm{d}x\sqrt{-\eta}\left[\frac{1}{2}(D_\mu\phi)^\dagger D^\mu\phi-\frac{1}{2}m^2\phi^\dagger\phi+\frac{1}{4g^2}\operatorname{Tr}F^{\mu\nu}F_{\mu\nu}\right], \tag{8}$$

where $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu+[A_\mu,A_\nu]$. Here $D_\mu=\partial_\mu+A_\mu$, where A_μ is the gauge potential, D_μ is the covariant derivative. We choose A_μ to be anti-Hermitian with

$$A_\mu=A_\mu^a t^a, \tag{9}$$

$$\operatorname{Tr}(t^at^b)=-\delta^{ab}, \tag{10}$$

where t^a are the generators of the Lie algebra. If we express this in terms of components in the new system of coordinates, we find

$$S=\int \mathrm{d}u\,\mathrm{d}x\left[-\frac{1}{2}\operatorname{sgn}(x)D_u\phi^\dagger D_x\phi-\frac{1}{2}\operatorname{sgn}(x)D_x\phi^\dagger D_u\phi\right]+\int \mathrm{d}u\,\mathrm{d}x\left[-\frac{1}{2}D_x\phi^\dagger D_x\phi-\frac{1}{2}m^2\phi^\dagger\phi\right]$$
$$+\int \mathrm{d}u\,\mathrm{d}x\left[-\frac{1}{g^2}\operatorname{Tr}E(\partial_uA_x-\partial_xA_u+[A_u,A_x])+\frac{1}{2g^2}\operatorname{Tr}E^2\right], \tag{11}$$

where

$$E=\partial_uA_x-\partial_xA_u+[A_u,A_x]. \tag{12}$$

Here we split the E^2 term, namely,

$$\frac{1}{4g^2}\operatorname{Tr}F^{\mu\nu}F_{\mu\nu}=-\frac{1}{2g^2}\operatorname{Tr}E^2=\frac{1}{2g^2}\operatorname{Tr}E^2-\frac{1}{g^2}\operatorname{Tr}E^2, \tag{13}$$

and insert the definition of E in terms of gauge fields in the second part to get

$$-\frac{1}{g^2}\,\mathrm{Tr}\,E(\partial_u A_x-\partial_x A_u+[A_u,A_x]). \tag{14}$$

If we write the action explicitly,

$$\begin{aligned}S=&-\int \mathrm{d}u\,\mathrm{d}x\frac{1}{2}\mathrm{sgn}(x)(\partial_u\phi^\dagger-\phi^\dagger A_u)(\partial_x\phi+A_x\phi)-\int \mathrm{d}u\,\mathrm{d}x\frac{1}{2}\mathrm{sgn}(x)(\partial_x\phi^\dagger-\phi^\dagger A_x)(\partial_u\phi+A_u\phi)\\&-\int \mathrm{d}u\,\mathrm{d}x\left[\frac{1}{2}(\partial_x\phi^\dagger-\phi^\dagger A_x)(\partial_x\phi+A_x\phi)\right]-\int \mathrm{d}u\,\mathrm{d}x\frac{1}{2}m^2\phi^\dagger\phi-\int \mathrm{d}u\,\mathrm{d}x\left[\frac{1}{g^2}\,\mathrm{Tr}\,E(\partial_u A_x-\partial_x A_u\right.\\&\left.+[A_u,A_x])+\frac{1}{2g^2}\,\mathrm{Tr}\,E^2\right].\end{aligned}$$

Now, following Ref. 24, we will define a variable $h(u,x)$ to eliminate the Yang-Mills field *without imposing any gauge condition*:

$$\frac{\partial h}{\partial x}+A_x h=0, \tag{15}$$

$$h(u,-L)=1. \tag{16}$$

The solution is represented as a path ordered exponential

$$h(u,x)=P[e^{\int_{-L}^{x}\mathrm{d}y\,A_x(u,y)}]. \tag{17}$$

The Wilson loop is then given by

$$q=h^{-1}(u,L). \tag{18}$$

We will define new field variables such that

$$\phi=h\tilde{\phi},$$

$$A_u=h\tilde{A}_u h^{-1},$$

$$E=h\tilde{E}h^{-1}. \tag{19}$$

Our aim is to decouple the leading bosonic action from the gauge fields and reduce the gauge field sector to its true dynamical degrees of freedom.

Since we are on a cylinder with $(u,x)\sim(u,x+2L)$, the fields are periodic with period $2L$. Thus

$$\phi(L)=\phi(-L),$$

$$\phi^\dagger(L)=\phi^\dagger(-L),$$

$$E(L)=E(-L). \tag{20}$$

In terms of the new variables, we have

$$\tilde{\phi}(L)=q\tilde{\phi}(-L),$$

$$\tilde{\phi}^\dagger(L)=\tilde{\phi}^\dagger(-L)q^{-1},$$

$$\tilde{E}(L) = q\tilde{E}(-L)q^{-1}. \tag{21}$$

We see that now we are dealing with a complicated boundary condition. We will define $E(-L)=e$. When we insert the new definitions of our variables, we find

$$S = \int \mathrm{d}u\,\mathrm{d}x\left[-\frac{1}{2}\mathrm{sgn}(x)(\partial_u\tilde{\phi}^\dagger\partial_x\tilde{\phi} + \partial_x\tilde{\phi}^\dagger\partial_u\tilde{\phi})\right] - \int \mathrm{d}u\,\mathrm{d}x\frac{1}{2}\mathrm{sgn}(x)[\partial_x\tilde{\phi}^\dagger(\tilde{A}_u + h^{-1}\partial_u h)\tilde{\phi} - \tilde{\phi}^\dagger(\tilde{A}_u + h^{-1}\partial_u h)\partial_x\tilde{\phi}] - \int \mathrm{d}u\,\mathrm{d}x\frac{1}{2}m^2\tilde{\phi}^\dagger\tilde{\phi} - \int \mathrm{d}u\,\mathrm{d}x\frac{1}{g^2}\,\mathrm{Tr}[h\tilde{E}h^{-1}(\partial_u A_x - \{\partial_x A_u + [A_u,A_x]\})] + \int \mathrm{d}u\,\mathrm{d}x\frac{1}{2g^2}\,\mathrm{Tr}[(\tilde{E}^2)]. \tag{22}$$

We used the definition of h to simplify the above expression. Let us now work on the combination below,

$$\partial_x A_u + [A_u,A_x]. \tag{23}$$

We insert identities on both sides in the form of hh^{-1} and use Eq. (15). We see that this term is the expansion of

$$h(\partial_x\tilde{A}_u)h^{-1}. \tag{24}$$

Thus

$$\partial_u A_x - \{\partial_x A_u + [A_u,A_x]\} = hh^{-1}\partial_u A_x hh^{-1} - h(\partial_x\tilde{A}_u)h^{-1}. \tag{25}$$

By using the relation below that can also be derived from (15),

$$h^{-1}(\partial_u A_x)h = -\partial_x(h^{-1}\partial_u h). \tag{26}$$

Equation (25) becomes

$$-h\partial_x(h^{-1}\partial_u h)h^{-1} - h\partial_x(h^{-1}A_u h)h^{-1} = -h\partial_x(h^{-1}\partial_u h + \tilde{A}_u)h^{-1}. \tag{27}$$

As we can see now, it is better to introduce a new variable A via

$$A = \tilde{A}_u + h^{-1}\partial_u h. \tag{28}$$

Let us write down the Yang-Mills part of our action,

$$-\frac{1}{g^2}\int \mathrm{d}u\,\mathrm{d}x\,\mathrm{Tr}[h\tilde{E}h^{-1}(\partial_u A_x - \{\partial_x A_u + [A_u,A_x]\})] = -\frac{1}{g^2}\int \mathrm{d}u\,\mathrm{d}x\,\mathrm{Tr}[-\tilde{E}\partial_x(h^{-1}\partial_u h + \tilde{A}_u)], \tag{29}$$

and express this in terms of total derivatives,

$$-\frac{1}{g^2}\int \mathrm{d}u\,\mathrm{d}x\,\mathrm{Tr}[-\partial_x(\tilde{E}h^{-1}\partial_u h) + (\partial_x\tilde{E})h^{-1}\partial_u h - \partial_x(\tilde{E}\tilde{A}_u) + (\partial_x\tilde{E})\tilde{A}_u] = \frac{1}{g^2}\int \mathrm{d}u\int_{-L}^{L}\mathrm{d}x\,\mathrm{Tr}[\partial_x(\tilde{E}h^{-1}\partial_u h)] - \frac{1}{g^2}\int \mathrm{d}u\,\mathrm{d}x\,\mathrm{Tr}[(\partial_x\tilde{E})[\tilde{A}_u + h^{-1}\partial_u h]].$$

Here the third term vanished, since the fields cancel out at the boundaries. The total derivative can be expanded as

$$\frac{1}{g^2}\int \mathrm{d}u\ \mathrm{Tr}[\tilde{E}(L)h^{-1}(L)\partial_u h(L) - \tilde{E}(-L)h^{-1}\partial_u h(-L)] - \frac{1}{g^2}\int \mathrm{d}u\ \mathrm{d}x\ \mathrm{Tr}[(\partial_x \tilde{E})A]. \tag{30}$$

In this expression $\partial_u h(-L)$ gives zero, we insert our boundary conditions; $h^{-1}(L)=q$, or $h(L)=q^{-1}$, obtaining

$$\frac{1}{g^2}\int \mathrm{d}u\ \mathrm{Tr}[q\tilde{E}(-L)q^{-1}q\partial_u q^{-1}] - \frac{1}{g^2}\int \mathrm{d}u\ \mathrm{d}x\ \mathrm{Tr}[(\partial_x \tilde{E})A]. \tag{31}$$

So the pure gauge theory part of our equation has become

$$-\frac{1}{g^2}\int \mathrm{d}u\ \mathrm{Tr}[q^{-1}\partial_u q e] - \frac{1}{g^2}\int \mathrm{d}u\ \mathrm{d}x\ \mathrm{Tr}[(\partial_x \tilde{E})A] + \frac{1}{2g^2}\int \mathrm{d}u\ \mathrm{d}x\ \mathrm{Tr}\,\tilde{E}^2. \tag{32}$$

Having derived the gauge field interaction part in terms of the new variables we can now go back to (22),

$$\begin{aligned} S = &\int \mathrm{d}u\ \mathrm{d}x\left[-\frac{1}{2}\mathrm{sgn}(x)[(\partial_u \tilde{\phi}^\dagger)(\partial_x \tilde{\phi}) + (\partial_x \tilde{\phi}^\dagger)(\partial_u \tilde{\phi})]\right] + \int \mathrm{d}u\ \mathrm{d}x\left[-\frac{1}{2}\mathrm{sgn}(x)[(\partial_x \tilde{\phi}^\dagger)A\tilde{\phi}\right. \\ &\left. - \tilde{\phi}^\dagger A(\partial_x \tilde{\phi})]\right] - \int \mathrm{d}u\ \mathrm{d}x\frac{1}{2}(\partial_x \tilde{\phi}^\dagger)(\partial_x \tilde{\phi}) - \int \mathrm{d}u\ \mathrm{d}x\frac{1}{2}m^2\tilde{\phi}^\dagger\tilde{\phi} - \int \mathrm{d}u\ \mathrm{d}x\left[\frac{1}{g^2}\mathrm{Tr}(\partial_x \tilde{E})A\right. \\ &\left. - \frac{1}{2g^2}\mathrm{Tr}\,\tilde{E}^2\right] - \frac{1}{g^2}\int \mathrm{d}u\ \mathrm{Tr}(q^{-1}\partial_u q e). \end{aligned} \tag{33}$$

We see now that A does not have a time derivative in the action, so it is just a Lagrange multiplier imposing a constraint and can be eliminated. Varying the action with respect to A we obtain a constraint,

$$\frac{1}{g^2}\partial_x \tilde{E}^b \delta A^a\ \mathrm{Tr}[t^b t^a] = -\frac{1}{2}\mathrm{sgn}(x)(\partial_x \tilde{\phi}^\dagger t^a \tilde{\phi} - \tilde{\phi}^\dagger t^a \partial_x \tilde{\phi})\delta A^a. \tag{34}$$

Thus the constraint becomes

$$-\frac{1}{g^2}\partial_x \tilde{E}^a = -\frac{1}{2}\mathrm{sgn}(x)\{(t^a)^\alpha{}_\beta[\tilde{\phi}^\beta(\partial_x \tilde{\phi}^\dagger)_\alpha - (\partial_x \tilde{\phi})^\beta \tilde{\phi}^\dagger_\alpha]\}. \tag{35}$$

In matrix form,

$$\tilde{E} = e - \frac{g^2}{2}\int_{-L}^{x} \mathrm{d}y\ \mathrm{sgn}(y)\{\tilde{\phi}(\partial_y \tilde{\phi}^\dagger) - (\partial_y \tilde{\phi})\tilde{\phi}^\dagger\}. \tag{36}$$

Thus the *classical* action is reduced to

$$\begin{aligned} S = &-\frac{1}{2}\int \mathrm{d}u\ \mathrm{d}x\ \mathrm{sgn}(x)[(\partial_u \tilde{\phi}^\dagger)(\partial_x \tilde{\phi}) + (\partial_x \tilde{\phi}^\dagger)(\partial_u \tilde{\phi})] - \int \mathrm{d}u\ \mathrm{d}x\frac{1}{2}(\partial_x \tilde{\phi}^\dagger)(\partial_x \tilde{\phi}) - \frac{1}{2}\int \mathrm{d}u\ \mathrm{d}x\ m^2\tilde{\phi}^\dagger\tilde{\phi} \\ &+ \frac{1}{2g^2}\int \mathrm{d}u\ \mathrm{d}x\ \mathrm{Tr}\left[e - \frac{g^2}{2}\int_{-L}^{x}\mathrm{d}y\ \mathrm{sgn}(y)\{\tilde{\phi}(\partial_y \tilde{\phi}^\dagger) - (\partial_y \tilde{\phi})\tilde{\phi}^\dagger\}\right]^2 - \frac{1}{g^2}\int \mathrm{d}u\ \mathrm{Tr}(q^{-1}\partial_u q e). \end{aligned} \tag{37}$$

Here, we see that the action has three parts, the first part consists of (dressed) bosons, the last term represents the true dynamical degrees of freedom for the gauge fields and the rest is the coupling of these two separate systems. There is only a global gauge freedom left, as we will see coming from the constraint equation. We can now start from the beginning and quantize these dynamical systems. The quantized bosonic field will not be related to the original bosonic fields in a simple way, in some sense they are dressed by the gauge fields.

The advantage of the light-cone systems is clear, the action is first order in the time variable u, thus we are already in the Hamiltonian picture. When we write this action in the form

$$S = \int \mathrm{d}u\, \bar{w}^i \omega_{ij} \dot{w}^j - \int \mathrm{d}u\, H \tag{38}$$

we can read off the Hamiltonian as

$$H = \int \mathrm{d}x \frac{1}{2}(\partial_x \tilde{\phi}^\dagger)(\partial_x \tilde{\phi}) + \int \mathrm{d}x \frac{1}{2} m^2 \tilde{\phi}^\dagger \tilde{\phi} - \frac{1}{2g^2} \int \mathrm{d}x\, \mathrm{Tr}\Bigg[e - \frac{g^2}{2} \int_{-L}^{x} \mathrm{d}y\, \mathrm{sgn}(y) \{ \tilde{\phi}(\partial_y \tilde{\phi}^\dagger) - (\partial_y \tilde{\phi}) \tilde{\phi}^\dagger \} \Bigg]^2, \tag{39}$$

the rest belonging to the symplectic part.

In the Hamiltonian formulation, the reduced gauge field theory part becomes the motion on the cotangent bundle of the Lie group SU(N). The geometric meaning of this symplectic form is well described in Ref. 25. This is the same result for the pure Yang-Mills on a cylinder first worked out by Rajeev[15] using the Cartesian coordinates. To help the reader we present a simple derivation of this in the appendix. Here, we state the result,

$$\{q^\alpha{}_\beta, q^\lambda{}_\sigma\} = 0,$$

$$\{\mathrm{Tr}\, \Lambda e, q^\alpha{}_\beta\} = g^2 (q\Lambda)^\alpha{}_\beta,$$

$$\{\mathrm{Tr}\, \Lambda_1 e, \mathrm{Tr}\, \Lambda_2 e\} = g^2 \mathrm{Tr}[\Lambda_1, \Lambda_2] e. \tag{40}$$

We can quantize by Dirac's rule of replacing the Poisson brackets by the commutators, and there is a natural representation of this on the space of square integrable functions on the Lie group SU(N). We set the Hilbert space to be $L^2(\mathrm{SU}(N))$, and

$$(\hat{q}^\alpha{}_\beta f)(q) = q^\alpha{}_\beta f(q), \quad (\mathrm{Tr}\, \Lambda \hat{e} f)(q) = i g^2 \mathcal{L}_\Lambda f(q). \tag{41}$$

One should further assume an ordering rule for the product of operators, one typically takes the Weyl (symmetric) ordering. The solution for the pure gauge theory on a circle can now be given easily, $\mathrm{Tr}\, e^2$ is proportional to the quadratic Casimir on the group. The boundary condition $\tilde{E}(L) = q\tilde{E}(-L)q^{-l}$ becomes

$$[\hat{e} - \hat{q}\hat{e}\hat{q}^{-1}] f(q) = 0, \tag{42}$$

as a result of nondynamical nature of A. Exponentiation of this constraint to the group will give us

$$f(sqs^{-1}) = f(q) \quad \text{for all} \quad s \in \mathrm{SU}(N), \tag{43}$$

and for all wave functions $f(q)$. Indeed the quadratic Casimir leaves this constraint invariant, hence we can reduce the dynamics onto this subspace. The energy eigenvalues are the values of the quadratic Casimir on all the irreducible representations. The eigenfunctions are the characters of the irreducible representations (see Rajeev[15]). It is known from the Peter-Weyl theorem that the characters form an orthonormal complete set in the above subspace.

In the next section we will focus on the quantization of the boson fields, since this will require a rethinking of the usual canonical quantization. What we need is the normal ordering prescription of the bosonic theory, we will give the answer formally, we are not able to compute the resulting integral kernel exactly at the moment.

III. QUANTIZATION AND THE NORMAL ORDERING FOR BOSONS

Looking back to our action in Eq. (37), we take the symplectic form of the field theory part as

$$-\frac{1}{2}\int \mathrm{d}u\,\mathrm{d}x\,\mathrm{sgn}(x)[(\partial_u\tilde{\phi}^\dagger)(\partial_x\tilde{\phi})+(\partial_x\tilde{\phi}^\dagger)(\partial_u\tilde{\phi})]. \tag{44}$$

Varying with respect to $\tilde{\phi}^\dagger$, we get

$$-\frac{1}{2}\int \mathrm{d}u\,\mathrm{d}x\,\mathrm{sgn}(x)[(\partial_u\delta\tilde{\phi}^\dagger)(\partial_x\tilde{\phi})+(\partial_x\delta\tilde{\phi}^\dagger)(\partial_u\tilde{\phi})]. \tag{45}$$

Integrating by parts in the first term gives

$$-\frac{1}{2}\int \mathrm{d}u\,\mathrm{d}x\,\mathrm{sgn}(x)[\partial_u(\delta\tilde{\phi}^\dagger\partial_x\tilde{\phi})-\delta\tilde{\phi}^\dagger\partial_u\partial_x\tilde{\phi}+(\partial_x\delta\tilde{\phi}^\dagger)(\partial_u\tilde{\phi})]. \tag{46}$$

The first term drops out since $\delta\tilde{\phi}^\dagger$ is zero at the boundaries $\pm\infty$ of the time coordinate. The same cannot be applied to the x coordinate due to the boundary conditions stated in Eq. (21). Thus we obtain

$$-\frac{1}{2}\int \mathrm{d}u\,\mathrm{d}x[\delta\tilde{\phi}^\dagger(\overleftarrow{\partial}_x\,\mathrm{sgn}(x)-\mathrm{sgn}(x)\overrightarrow{\partial}_x)\partial_u\tilde{\phi}]. \tag{47}$$

The term in parentheses gives the symplectic form. Its inverse can be written formally as

$$(\omega^{-1})^\alpha{}_\beta = 2(\mathrm{sgn}\,\overrightarrow{\partial}_x-\overleftarrow{\partial}_x\,\mathrm{sgn})^{-1}\delta^\alpha{}_\beta, \tag{48}$$

where sgn is defined as

$$\langle x|\mathrm{sgn}|y\rangle = \mathrm{sgn}(x)\,\delta(x-y). \tag{49}$$

We have the previously stated boundary conditions.

To second quantize the theory one must know the annihilation and creation operators. Once we find these operators, we will introduce the normal ordering procedure to make sure that the products of the fields at the same point are well defined.

Apart from the coupling with the gauge field, our problem is like the harmonic oscillator. First we will focus on a finite dimensional problem with constant symplectic and quadratic form.

We are going to make the quantization as in a real vector space. *We can do this since in our case the symplectic and quadratic forms are real operators and the real and imaginary parts of the complex vectors decouple*. We can see this easily by taking our complex fields as

$$\phi = a + ib. \tag{50}$$

Our action has the form

$$\int \mathrm{d}u\frac{1}{2}(\phi^\dagger\omega\dot{\phi}-\phi^\dagger Q\phi) \tag{51}$$

and it can be rewritten by using the antisymmetry of ω and the symmetry of Q,

$$\int \mathrm{d}u\frac{1}{2}[a^\dagger\omega\dot{a}-a^\dagger Qa+b^\dagger\omega\dot{b}-b^\dagger Qb]. \tag{52}$$

Since a and b commute, if we quantize these fields, the normal ordering of ϕ can now be defined in a simple way,

$$:\phi^\dagger\phi: = :(a+ib)^\dagger(a+ib): = :a^\dagger a: + :b^\dagger b: + i[a^\dagger b - b^\dagger a]. \tag{53}$$

At the end, we will subtract twice the commutator of the annihilation and creation operators from the normal ordered product, to get the correct vacuum energy.

For simplicity we work with a finite dimensional (real valued) system, which has coordinates x^i, in our application the indices $(i,j,k,l,\ldots)$ will refer to both a set of continuous indices and a set of discrete indices. To start quantization, the first step is to look at the equations of motion

$$\dot{x}^i = (\omega^{-1})^{ij}Q_{jk}x^k. \tag{54}$$

The next step is to complexify the underlying vector space to get the oscillatory solutions. Indeed the oscillatory solutions are related to a complex structure. (This is not the original complex structure in our complex case.) This quantization method is worked out using the ideas of Rajeev and Bowick in Ref. 26.

The polar decomposition of the operator $\omega^{-1}Q$ will reveal a complex structure J and a positive symmetric operator K. As a result the equations of motion become

$$\dot{x}^i = J^i_k K^k_l x^l, \tag{55}$$

where

$$J^\tau J = 1. \tag{56}$$

Here the transpose is not the usual one but instead it is defined with respect to the metric defined by the quadratic form, Q as

$$J^\tau = Q^{-1}J^T Q. \tag{57}$$

We have,

$$K^\tau = K, \quad K \geq 0. \tag{58}$$

It will be useful to define a new variable as

$$\tilde{\omega} = \omega^{-1}Q. \tag{59}$$

We can see that this operator is antisymmetric in the metric defined by the quadratic form, that is

$$\tilde{\omega}^\tau = -\tilde{\omega}, \tag{60}$$

since,

$$(\omega^{-1}Q)^\tau = Q^{-1}(\omega^{-1}Q)^T Q = Q^{-1}Q^T(\omega^{-1})^T Q = Q^{-1}Q(-\omega^{-1})Q = -\omega^{-1}Q. \tag{61}$$

If we use Eq. (60), we can solve for K and J in terms of $\tilde{\omega}$, giving

$$K = (-\tilde{\omega}^2)^{1/2}, \quad J = (-\tilde{\omega}^2)^{-1/2}\tilde{\omega}. \tag{62}$$

One can check that

$$J^\tau = -(-\tilde{\omega}^2)^{-1/2}\tilde{\omega} = -J, \quad \text{thus,} \quad J^2 = -1. \tag{63}$$

So, *J defines a complex structure*. What follows after the construction of the complex structure is to project the coordinates into $\pm i$ eigenspaces to obtain complex coordinates. But it would be instructive to stop at this point and apply this procedure to the well-known real scalar field in the usual coordinate system. For simplicity we will call this familiar quantization as the Klein-Gordon field. The Hamiltonian of a Klein-Gordon field on $\mathbb{R}^3$ can be written as follows:

$$H = \int d^3x[\pi^2 + (\nabla\phi)^2 + m^2\phi^2]. \tag{64}$$

By partial integration we get the quadratic form

$$H = \int d^3x[\pi^2 + \phi(-\nabla^2 + m^2)\phi] \tag{65}$$

$$= \int d^3x[\Phi^T Q \Phi]. \tag{66}$$

Here we use a two component representation such that

$$\Phi = \begin{pmatrix} \phi \\ \partial_t \phi \end{pmatrix}. \tag{67}$$

We can read off the quadratic form as

$$Q = \begin{pmatrix} (-\nabla^2 + m^2) & 0 \\ 0 & 1 \end{pmatrix}. \tag{68}$$

The symplectic form is

$$\omega = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{69}$$

Thus

$$\tilde{\omega} = \omega^{-1}Q = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} (-\nabla^2 + m^2) & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ (-\nabla^2 + m^2) & 0 \end{pmatrix}. \tag{70}$$

One can easily show that the transpose is

$$\tilde{\omega}^\tau = \begin{pmatrix} 0 & 1 \\ (-\nabla^2 + m^2) & 0 \end{pmatrix}. \tag{71}$$

We can now calculate the complex structure J for the Klein-Gordon field easily,

$$J = (\tilde{\omega}^\tau\tilde{\omega})^{-1/2}\tilde{\omega} = \begin{pmatrix} (-\nabla^2 + m^2)^{-1/2} & 0 \\ 0 & (-\nabla^2 + m^2)^{-1/2} \end{pmatrix}\begin{pmatrix} 0 & -1 \\ (-\nabla^2 + m^2) & 0 \end{pmatrix}$$
$$= \begin{pmatrix} 0 & -(-\nabla^2 + m^2)^{-1/2} \\ (-\nabla^2 + m^2)^{1/2} & 0 \end{pmatrix}. \tag{72}$$

At this point we go back to our main line of discussion. We will now project our coordinates into $\pm i$ eigenspaces to obtain complex coordinates. Let us point out that, there is always a basis $\{e_\alpha\}$, and a dual basis $\{e^{*\alpha}\}$ for which

$$J(e^{*\alpha}) = e^{*\alpha+n},$$

$$J(e^{*\alpha+n}) = -e^{*\alpha}, \tag{73}$$

where $\alpha = 1, 2, \ldots, n$, since J is a complex structure[27] (note that these indices have nothing to do with our previous use of color indices, they are just used to denote these special basis elements in the vector space). We may define the coordinates through

$$x^j = e^{*j}(x), \tag{74}$$

where x is a vector in our space. This can easily be verified, by looking at

$$e^{*j}(x) = e^{*j}(x^k e_k), \tag{75}$$

since the dual product gives a delta, $e^{*j}(e_k) = \delta^j_k$. If we do not think about a basis, symbolically we can write the projections as

$$x^j = \tfrac{1}{2}(1 + iJ)^j_s x^s + \tfrac{1}{2}(1 - iJ)^j_s x^s. \tag{76}$$

We can verify that

$$\left[\tfrac{1}{2}(1 \pm iJ)\right]^2 = \tfrac{1}{2}(1 \pm iJ) \tag{77}$$

and

$$(1 + iJ)(1 - iJ) = 0. \tag{78}$$

Here the first part is the projection into the $+i$ eigenspace and the second is into $-i$. Let us make a choice from the linearly independent dual basis elements as

$$\overline{f}^{*\alpha} = \tfrac{1}{2}(1 + iJ)(e^{*\alpha}) \sim \overline{z}^{\alpha},$$

$$f^{*\alpha} = \tfrac{1}{2}(1 - iJ)(e^{*\alpha}) \sim z^{\alpha}, \tag{79}$$

where $\alpha = 1, 2, \ldots, n$.

So we think of dual basis as if they are the coordinates, this simplifies our writing. Now we should compute the Poisson brackets of these projected coordinates. We expect to have nonzero Poisson bracket only for z, $\overline{z}$ term. Let us first check that the others give zero,

$$\left\{\tfrac{1}{2}(\delta^i_k + iJ^i_k)x^k, \tfrac{1}{2}(\delta^j_l + iJ^j_l)x^l\right\} = \tfrac{1}{4}[\{x^i, x^j\} + iJ^i_k\{x^k, x^j\} + iJ^j_l\{x^i, x^l\} - J^i_k J^j_l\{x^k, x^l\}] = \tfrac{1}{4}[(\omega^{-1})^{ij} + iJ^i_k(\omega^{-1})^{kj} + iJ^j_l(\omega^{-1})^{il} - J^i_k J^j_l(\omega^{-1})^{kl}] = \tfrac{1}{4}[(\omega^{-1})^{ij} + iJ^i_k J^k_r K^{rj} - iJ^j_l J^l_r K^{ri} - J^i_k J^j_l J^k_s K^{sl}].$$

Here $K^{ij} = K^i_s (Q^{-1})^{sj}$ and we used the equality of $\omega^{-1}Q$ to JK,

$$\left\{\tfrac{1}{2}(\delta^i_k + iJ^i_k)x^k, \tfrac{1}{2}(\delta^j_l + iJ^j_l)x^l\right\} = \tfrac{1}{4}[(\omega^{-1})^{ij} - i\delta^i_r K^{rj} + i\delta^j_r K^{ri} + J^j_l \delta^i_s K^{sl}] = \tfrac{1}{4}[(\omega^{-1})^{ij} - iK^{ij} + iK^{ji} + J^j_l K^{il}]$$
$$= \tfrac{1}{4}[(\omega^{-1})^{ij} + (\omega^{-1})^{ji}] = 0,$$

where we used the symmetry property of K and antisymmetry of ω.

In the same manner,

$$\left\{\tfrac{1}{2}(\delta^i_k - iJ^i_k)x^k, \tfrac{1}{2}(\delta^j_l - iJ^j_l)x^l\right\} = 0.$$

Now we can compute $\{\overline{z}, z\}$ combinations,

$$\left\{\tfrac{1}{2}(\delta^i_k + iJ^i_k)x^k, \tfrac{1}{2}(\delta^j_l - iJ^j_l)x^l\right\} = \tfrac{1}{4}[\{x^i, x^j\} + iJ^i_k\{x^k, x^j\} - iJ^j_l\{x^i, x^l\} + J^i_k J^j_l\{x^k, x^l\}] = \tfrac{1}{4}[(\omega^{-1})^{ij} + iJ^i_k(\omega^{-1})^{kj} - iJ^j_l(\omega^{-1})^{il} + J^i_k J^j_l(\omega^{-1})^{kl}] = \tfrac{1}{4}[(\omega^{-1})^{ij} + iJ^i_k J^k_r K^{rj} + iJ^j_l J^l_r K^{ri} + J^i_k J^j_l J^k_s K^{sl}]$$
$$= \tfrac{1}{4}[(\omega^{-1})^{ij} - i\delta^i_r K^{rj} - i\delta^j_r K^{ri} - J^j_l \delta^i_s K^{sl}] = \tfrac{1}{4}[2(\omega^{-1})^{ij} - 2iK^{ij}]$$
$$= \tfrac{1}{2}[(\omega^{-1})^{ij} - iK^{ij}] = \tfrac{1}{2}[J^i_s K^{sj} - iK^{ij}] = \tfrac{1}{2}(-i)[\delta^i_s + iJ^i_s]K^{sj}.$$

Alternatively we could switch the indices of the symplectic form in the middle step above, to get

$$\left\{\tfrac{1}{2}(\delta^i_k + iJ^i_k)x^k, \tfrac{1}{2}(\delta^j_l - iJ^j_l)x^l\right\} = \tfrac{1}{2}[-(\omega^{-1})^{ji} - iK^{ij}] = \tfrac{1}{2}(-i)[\delta^i_s - iJ^j_s]K^{si}. \tag{80}$$

Now we note that,

$$\tfrac{1}{2}(-i)[\delta^i_s + iJ^i_s]K^{sj} = \tfrac{1}{2}[-(\omega^{-1})^{ji} - iK^{ij}] = \tfrac{1}{2}(-i)[\delta^j_s - iJ^j_s]K^{si}. \tag{81}$$

We use the fact that the operator acting on K is the projection operator $(1+iJ)$. Now we have

$$(-i)\tfrac{1}{2}[\delta^i_s + iJ^i_s]\tfrac{1}{2}[\delta^s_{s'} + iJ^s_{s'}]K^{s'j} = (-i)\tfrac{1}{2}[\delta^i_s + iJ^i_s]K^{sj}. \tag{82}$$

From the equality of this to the above expressions we write

$$\left\{\tfrac{1}{2}(1+iJ)^i_l x^l, \tfrac{1}{2}(1-iJ)^j_k x^k\right\} = (-i)\tfrac{1}{2}[\delta^i_s + iJ^i_s]\tfrac{1}{2}[\delta^j_{s'} - iJ^j_{s'}]K^{s's}. \tag{83}$$

Indeed the meaning of this equation is clear if we construct a Hermitian product, using our original real inner product as

$$\left[\tfrac{1}{2}(1+iJ)e^{*\alpha}\right](x)\left[\tfrac{1}{2}(1-iJ)e^{*\beta}\right](x)K(e_\alpha, e_\beta)$$

$$= \left[\tfrac{1}{2}(x^\alpha + ix^{\alpha+n})\tfrac{1}{2}(x^\beta - ix^{\beta+n})\right]K(e_\alpha, e_\beta) = H(x,x), \tag{84}$$

or in a dual manner

$$\left[\tfrac{1}{2}(1-iJ)e^{*i}\right](e_s)\left[\tfrac{1}{2}(1+iJ)e^{*j}\right](e_{s'})K(e^{*s}, e^{*s'})$$

$$= e^{*i}\left[\tfrac{1}{2}(1+iJ)e_s\right]e^{*j}\left[\tfrac{1}{2}(1-iJ)e_{s'}\right]K(e^{*s}, e^{*s'}). \tag{85}$$

In a compact form using $x_i e^{*i} = x^*$ this could be expressed as

$$x^*\left[\tfrac{1}{2}(1+iJ)e_s\right]x^*\left[\tfrac{1}{2}(1-iJ)e_{s'}\right]K(e^{*s}, e^{*s'}). \tag{86}$$

If we now use our special basis, $\{e_\alpha\}$, we get

$$= \tfrac{1}{4}x^*(e_\alpha - ie_{\alpha+n})x^*(e_\beta + ie_{\beta+n})K(e^{*\alpha}, e^{*\beta})$$
$$= \tfrac{1}{4}(x_\alpha - ix_{\alpha+n})(x_\beta + ix_{\beta+n})K(e^{*\alpha}, e^{*\beta}) = H(x^*, x^*). \tag{87}$$

So, if we specialize to our choice of coordinates, $(z^\alpha, \bar{z}^\alpha)$, the expression on the right-hand side in Eq. (84) is indeed a Hermitian inner product. We will denote this Hermitian form as $H_{\alpha\underline{\beta}}$ and it has the symmetry

$$\overline{H_{\alpha\underline{\beta}}} = H_{\beta\underline{\alpha}}. \tag{88}$$

We will find the creation and annihilation operators in terms of our special choice of coordinates. By (76),

$$\tfrac{1}{2}(1+iJ)e^{*\alpha} + \tfrac{1}{2}(1-iJ)e^{*\alpha} = e^{*\alpha}. \tag{89}$$

The same is true for the second half, so

$$\tfrac{1}{2}(1+iJ)e^{*\alpha+n} + \tfrac{1}{2}(1-iJ)e^{*\alpha+n} = e^{*\alpha+n}. \tag{90}$$

We can extract the J from the $e^{*\alpha+n}$ term to get $e^{*\alpha}$ and act to the left to obtain

$$\tfrac{1}{2}(J+iJ^2)e^{*\alpha} + \tfrac{1}{2}(J-iJ^2)e^{*\alpha} = e^{*\alpha}. \tag{91}$$

Then we see that,

$$\tfrac{1}{2}(J-i)e^{*\alpha} + \tfrac{1}{2}(J+i)e^{*\alpha} = e^{*\alpha+n}. \tag{92}$$

Hence,

$$(-i)\left[\tfrac{1}{2}(1+iJ)e^{*\alpha}-\tfrac{1}{2}(1-iJ)e^{*\alpha}\right]=e^{*\alpha+n}. \tag{93}$$

Thus, we have the usual relation, such that

$$z^{\alpha}+\bar{z}^{\alpha}=x^{\alpha}, \tag{94}$$

$$(-i)(z^{\alpha}-\bar{z}^{\alpha})=x^{\alpha+n}. \tag{95}$$

Let us assume that we have made this special choice of basis and found

$$\{\bar{z}^{\alpha},z^{\beta}\}=(-i)H^{\underline{\alpha}\beta}. \tag{96}$$

Now we use the Dirac quantization rule and set

$$[a^{\alpha},a^{\dagger\beta}]=H^{\underline{\alpha}\beta}, \tag{97}$$

and we assume there is a vacuum state satisfying,

$$a^{\alpha}|0\rangle=0. \tag{98}$$

It is possible to further diagonalize the Hermitian form $H^{\underline{\alpha}\beta}$, without mixing z and $\bar{z}$ coordinates, they will be the independent excitations, which could be identified as the "particles" of the theory. We will not need this in our work, so not to complicate our notation further we ignore this step. Equation (97) creates a Fock space with positive norm elements as can easily be checked,

$$|\lambda\rangle=\lambda_{\alpha}a^{\dagger\alpha}|0\rangle, \tag{99}$$

$$\langle\lambda|\lambda\rangle=\lambda^{*}_{\underline{\beta}}\lambda_{\alpha}H^{\underline{\beta}\alpha}>0. \tag{100}$$

We will demonstrate in an alternative way that these commutation relations can be realized by operators acting on a Hilbert space and a^{α} and $a^{\dagger\alpha}$ are Hermitian conjugates under the inner product of our Hilbert space. For two functions $f(z^{\alpha})$ and $g(z^{\alpha})$, we define an inner product,

$$\langle f|g\rangle=\int\Pi_{\alpha}\,\mathrm{d}z^{\alpha}\,\mathrm{d}\bar{z}^{\underline{\alpha}}\,e^{-z^{\beta}(H^{-1})_{\beta\underline{\alpha}}\bar{z}^{\underline{\alpha}}}f(z)g(z). \tag{101}$$

The completion of holomorphic functions in this inner product defines our Hilbert space. Then we define,

$$a^{\alpha}=H^{\underline{\alpha}\beta}\frac{\partial}{\partial z^{\beta}},\quad a^{\dagger\beta}=z^{\beta}, \tag{102}$$

which clearly satisfies our commutation relations. A calculation reveals that

$$\langle f|H^{\underline{\gamma\lambda}}\partial_{\lambda}g\rangle=\langle z^{\gamma}f|g\rangle. \tag{103}$$

As a result we have the desired equality

$$\langle f|a^{\dagger\gamma}g\rangle=\langle a^{\gamma}f|g\rangle. \tag{104}$$

We have a well-defined normal ordering rule

$$:a^{\alpha}a^{\dagger\beta}:=a^{\dagger\beta}a^{\alpha}, \tag{105}$$

and no change for all the other combinations.

In general it will not be practical to switch to this special basis, but $\frac{1}{2}(1-iJ)$, $\frac{1}{2}(1+iJ)$ terms are, respectively, projections onto these subspaces and normal ordering brings a negative commutator at the end, so

$$\left[\tfrac{1}{2}(\widehat{(1+iJ)}x)^i, \tfrac{1}{2}(\widehat{(1-iJ)}x)^j\right] = i\tfrac{1}{2}[(\omega^{-1})^{ij} - iK^{ij}] = \tfrac{1}{2}[i(\omega^{-1})^{ij} + K^{ij}]. \tag{106}$$

So we can use this idea to set a normal ordering rule as

$$:\hat{x}^i\hat{x}^j: = \hat{x}^i\hat{x}^j - \tfrac{1}{2}[i(\omega^{-1})^{ij} + K^{ij}]. \tag{107}$$

The discussion on projections imply that there is no reason to look for two different relations, our projections have all the desired properties. (So the net result will be the above commutator relations.)

For complex coordinates as in our case, we can thus postulate the normal ordering with twice the commutator taken out. However, we note a subtle point, what we call as the symplectic structure and the quadratic form are not the same as in the complex case, there is a factor of 2. Thus, when we multiply the above subtracted term by a factor of 2, we should then covert back to the symplectic form and the quadratic form used in the complex case, this means that the factor of 2 disappears again, and we end up with

$$:\hat{\bar{w}}^i\hat{w}^j: = \hat{\bar{w}}^i\hat{w}^j - \tfrac{1}{2}[i(\omega^{-1})^{ij} + K^{ij}]. \tag{108}$$

It should be noted that in this equation the indices are assigned to a discrete set, and *from now on, we will use continuous indices as well as discrete ones; the continuous indices will be shown explicitly in parentheses or as bra-kets and* α, β, γ, *etc, will imply only discrete color degrees of freedom*.

If we go back to our example of Klein-Gordon field we can state our normal ordering as

$$:\Phi(x)\Phi(y): = \Phi(x)\Phi(y) - \tfrac{1}{2}[i(\omega^{-1})(x,y) + KQ^{-1}(x,y)] \tag{109}$$

$$\begin{aligned}=&\begin{pmatrix}\phi(x)\phi(y) & \phi(x)\pi(y)\\ \pi(x)\phi(y) & \phi(x)\phi(y)\end{pmatrix} - \frac{1}{2}\begin{pmatrix}0 & -i\delta(x-y)\\ i\delta(x-y) & 0\end{pmatrix}\\ &-\frac{1}{2}\begin{pmatrix}\langle x|(-\nabla^2+m^2)^{-1/2}|y\rangle & 0\\ 0 & \langle x|(-\nabla^2+m^2)^{\frac{1}{2}}|y\rangle\end{pmatrix}\end{aligned} \tag{110}$$

$$= \begin{pmatrix}\phi(x)\phi(y) & \phi(x)\pi(y)\\ \pi(x)\phi(y) & \phi(x)\phi(y)\end{pmatrix} \tag{111}$$

$$-\frac{1}{2}\begin{pmatrix}\langle x|(-\nabla^2+m^2)^{-1/2}|y\rangle & -i\delta(x-y)\\ i\delta(x-y) & \langle x|(-\nabla^2+m^2)^{\frac{1}{2}}|y\rangle\end{pmatrix}. \tag{112}$$

Let us now write the normal ordering rule in our theory using the formalism developed above,

$$:\phi^\dagger_\alpha(x)\phi^\beta(y): = \phi^\dagger_\alpha(x)\phi^\beta(y) - \tfrac{1}{2}[i(\omega^{-1})^\alpha{}_\beta(x,y) + K^\alpha{}_\beta(x,y)], \tag{113}$$

where

$$(\omega^{-1})^\gamma{}_\beta(x,y) = 2\langle x|(-\overleftarrow{\partial}\,\mathrm{sgn} + \mathrm{sgn}\,\overrightarrow{\partial})^{-1}|y\rangle\delta^\gamma{}_\beta. \tag{114}$$

Here sgn is

$$\langle x|\mathrm{sgn}|y\rangle = \mathrm{sgn}(x)\,\delta(x-y). \tag{115}$$

The system is diagonal in the color indices, hence we can write it as it is

$$K^\alpha{}_\beta(x,y) = \langle x|([-(\omega^{-1}Q)^2]^{1/2})^\alpha{}_\beta|y\rangle. \tag{116}$$

There is no difference between upper and lower color indices for our purposes here. Thus

$$K^{\alpha}{}_{\beta}(x,y) = \langle x|(-[(-\overleftarrow{\partial}\,\mathrm{sgn} + \mathrm{sgn}\,\overrightarrow{\partial})^{-1}(-\partial_x^2 + m^2)]^2)^{1/2}|y\rangle \delta^{\alpha}{}_{\beta}. \tag{117}$$

Then, transforming our expression $K^i_j Q^{js}$ to the infinite dimensional case only for the continuous indices, this becomes

$$K^{\alpha}{}_{\beta} = 2(-[(-\overleftarrow{\partial}\,\mathrm{sgn} + \mathrm{sgn}\,\overrightarrow{\partial})^{-1}(-\partial^2 + m^2)]^2)^{1/2}(-\partial^2 + m^2)^{-1}\delta^{\alpha}{}_{\beta}. \tag{118}$$

We *keep the color index* down in general, since from the group theory point of view the fields have special color indices attached to them. (The operator above has a kernel which should perhaps best be written as $K^{\alpha(x,y)}_{\beta}$, but to keep the notation simple we will keep the usual writing style for the kernels.) It is not so simple to evaluate these expressions. Only as symbols of operators we have some chance. We will not attack this question in the present work. From now on we will denote the colorless part of the subtraction in the normal ordering as the vacuum expectation value $V(x,y)$,

$$V(x,y) \equiv \langle x|(-[(-\overleftarrow{\partial}\,\mathrm{sgn} + \mathrm{sgn}\,\overrightarrow{\partial})^{-1}(-\partial^2 + m^2)]^2)^{1/2}(-\partial^2 + m^2)^{-1}|y\rangle + i\langle x|(-\overleftarrow{\partial}\,\mathrm{sgn} + \mathrm{sgn}\,\overrightarrow{\partial})^{-1}|y\rangle.$$

As mentioned, this is defined as a pseudodifferential operator. And of course after quantization we maintain the commutation relations for the bosons,

$$[\tilde{\phi}^{\alpha}(x), \tilde{\phi}^{\dagger}_{\beta}(y)] = i\omega^{-1}(x,y)\delta^{\alpha}{}_{\beta}, \tag{119}$$

where

$$\omega^{-1}(x,y) = \langle x|2(-\overleftarrow{\partial}\,\mathrm{sgn} + \mathrm{sgn}\,\overrightarrow{\partial})^{-1}|y\rangle. \tag{120}$$

IV. GAUGE INVARIANCE CONSTRAINT

When we quantize the theory, we get a normal ordered version of (36), since we have products of the fields at the same point. Thus a reduction at the quantum level should read

$$\hat{E} = \hat{e} - \frac{g^2}{2}\int_{-L}^{x} \mathrm{d}y\ \mathrm{sgn}(y){:}\{\tilde{\phi}(\partial_y\tilde{\phi}^{\dagger}) - (\partial_y\tilde{\phi})\tilde{\phi}^{\dagger}\}{:}\ . \tag{121}$$

With this expression our *quantum* Hamiltonian can be written as

$$\hat{H} = \frac{1}{2}\int \mathrm{d}x{:}(\partial_x\tilde{\phi}^{\dagger})(\partial_x\tilde{\phi}){:} + \frac{1}{2}\int \mathrm{d}x{:}m^2\tilde{\phi}^{\dagger}\tilde{\phi}{:} - \frac{1}{2g^2}\int \mathrm{d}x\ \mathrm{Tr}\left[\hat{e} - \frac{g^2}{2}\int_{-L}^{x}\mathrm{d}y\ \mathrm{sgn}(y){:}\{\tilde{\phi}(\partial_y\tilde{\phi}^{\dagger}) - (\partial_y\tilde{\phi})\tilde{\phi}^{\dagger}\}{:}\right]^2 \tag{122}$$

If we express our previous boundary condition (21), $\tilde{E}(+L) = q\tilde{E}(-L)q^{-1}$ we end up with a constraint,

$$\hat{e} - \frac{g^2}{2}\int_{-L}^{L}\mathrm{d}y\ \mathrm{sgn}(y){:}\{\tilde{\phi}(\partial_y\tilde{\phi}^{\dagger}) - (\partial_y\tilde{\phi})\tilde{\phi}^{\dagger}\} := \hat{q}\hat{e}\hat{q}^{-1}. \tag{123}$$

(For simplicity we are not using any ordering rule for $\hat{q}\hat{e}\hat{q}^{-1}$, we can take it as Weyl ordered, and the result will not change.) This is a too strong condition in the quantum theory. We should impose this constraint on physical states. Its meaning is clear if we define a global color operator as

$$\hat{Q} = \hat{e} - \hat{q}\hat{e}\hat{q}^{-1} - \frac{g^2}{2}\int_{-L}^{L}\mathrm{d}y\ \mathrm{sgn}(y){:}\{\tilde{\phi}(\partial_y\tilde{\phi}^{\dagger}) - (\partial_y\tilde{\phi})\tilde{\phi}^{\dagger}\}{:}\ , \tag{124}$$

which gives zero acting on any color invariant physical state.

Shortly we will demonstrate that $\hat{Q}$ truly generates global gauge transformations. Therefore the constraint tells us to restrict our theory to the color invariant sector. It is not difficult to form the simplest mesonic variable, i.e., a color invariant physical state, in the fundamental representation. We can check that the combination below is a gauge invariant state,

$$\phi^{\dagger}(x)P\{e^{\int_x^y A_x\,\mathrm{d}z}\}\phi(y). \tag{125}$$

Here the fields at these points are brought to the same point by parallel transport operator. When we transform the fields according to Eq. (19) we obtain

$$(\tilde{\phi}^{\dagger}(x)P\{e^{\int_{-L}^{x} A_x\,\mathrm{d}z}\})P\{e^{\int_x^y A_x\,\mathrm{d}z}\}(P\{e^{-\int_{-L}^{y} A_x\,\mathrm{d}z}\}\tilde{\phi}(y)). \tag{126}$$

The path ordered exponentials add up to one due to the boundary conditions of the Wilson loop in (16). We could as well construct a more general state by having several loops such as

$$\phi^{\dagger}(x)P\{e^{\int_x^{y+2KL} A_x\,\mathrm{d}z}\}\phi(y). \tag{127}$$

So the more general expression for the mesonic variable is as follows:

$$\tilde{\phi}_{\alpha}^{\dagger}(x)(q^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y). \tag{128}$$

We should normal order this at the quantum level. The normal ordered versions of these should be the general "mesonic" observables. Nevertheless, we will need even a more general expression for possible observables in our work, as we will see later on.

Now that we have constructed a color invariant physical state we should show that it commutes with our color operator. Typical color invariant state can be constructed through the products of such mesonic states on the vacuum. If we write the quantum constraint as

$$\mathrm{Tr}\,\Lambda\hat{Q}|\text{physical state}\rangle = 0, \tag{129}$$

where Λ is an element of the Lie algebra, after commuting through various mesonic operators eventually $\mathrm{Tr}\,\Lambda\hat{Q}$ acts on the vacuum and that gives zero as desired. So let us take a closer look at the commutator,

$$[\mathrm{Tr}\,\Lambda\hat{Q},{:}\tilde{\phi}_{\alpha}^{\dagger}(z)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(w){:}]. \tag{130}$$

First note that

$$\begin{aligned}
&\frac{g^2}{2}\int_{-L}^{L}\mathrm{d}y\;\Lambda^{\alpha}{}_{\beta}{:}\tilde{\phi}_{\alpha}^{\dagger}(y)(-\overleftarrow{\partial}_y\,\mathrm{sgn}(y)+\mathrm{sgn}(y)\overrightarrow{\partial}_y)\tilde{\phi}^{\beta}(y){:}\\
&\quad=\frac{g^2}{2}\int_{-L}^{L}\int_{-L}^{L}\mathrm{d}y\,\mathrm{d}y'\;\Lambda^{\alpha}{}_{\beta}{:}\tilde{\phi}_{\alpha}^{\dagger}(y')\langle y'|(-\overleftarrow{\partial}\,\mathrm{sgn}+\mathrm{sgn}\,\overrightarrow{\partial})|y\rangle\tilde{\phi}^{\beta}(y){:}\\
&\quad=g^2\int_{-L}^{L}\int_{-L}^{L}\mathrm{d}y\,\mathrm{d}y'\;\Lambda^{\alpha}{}_{\beta}{:}\tilde{\phi}_{\alpha}^{\dagger}(y')\omega(y',y)\tilde{\phi}^{\beta}(y){:}
\end{aligned}$$

Now it is a simple matter to check that,

$$\begin{aligned}
&[\mathrm{Tr}\,\Lambda\hat{e}-\mathrm{Tr}(\Lambda\hat{q}\hat{e}\hat{q}^{-1}),{:}\tilde{\phi}^{\dagger}\hat{q}^K\tilde{\phi}{:}]\\
&\quad=ig^2\sum_R{:}\tilde{\phi}^{\dagger}\hat{q}^R(\hat{q}\Lambda)\hat{q}^{K-R-1}\tilde{\phi}{:}-ig^2\sum_R{:}\tilde{\phi}^{\dagger}\hat{q}^R(\hat{q}\hat{q}^{-1}\Lambda\hat{q})\hat{q}^{K-R-1}\tilde{\phi}{:}\\
&\quad=-ig^2{:}\tilde{\phi}_{\alpha}^{\dagger}(z)[\Lambda,\hat{q}^K]^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(w){:}\;,
\end{aligned}$$

here the last commutator only refers to the color indices. We can now go back and find the action of the bosonic part on mesonic operators,

$$\begin{aligned}
&\left[g^2 \int_{-L}^{L} \int_{-L}^{L} \mathrm{d}y\, \mathrm{d}y'\ \Lambda^{\alpha}{}_{\beta} (: \tilde{\phi}^{\dagger}_{\alpha}(y') \omega(y',y) \tilde{\phi}^{\beta}(y):), : \tilde{\phi}^{\dagger}_{\sigma}(z) (\hat{q}^K)^{\sigma}{}_{\tau} \tilde{\phi}^{\tau}(w): \right] \\
&\quad = i g^2 \int_{-L}^{L} \int_{-L}^{L} \mathrm{d}y\, \mathrm{d}y'\ \Lambda^{\alpha}{}_{\beta} \tilde{\phi}^{\dagger}_{\alpha}(y') \omega(y',y) \omega^{-1}(y,z) \delta^{\beta}{}_{\sigma} (\hat{q}^K)^{\sigma}{}_{\tau} \tilde{\phi}^{\tau}(w) \\
&\qquad + i g^2 \int_{-L}^{L} \int_{-L}^{L} \mathrm{d}y\, \mathrm{d}y'\ \Lambda^{\alpha}{}_{\beta} \omega(y',y) \omega^{-1}(y',\omega) \delta^{\tau}{}_{\alpha} \tilde{\phi}^{\dagger}_{\sigma}(z) (\hat{q}^K)^{\sigma}{}_{\tau} \tilde{\phi}^{\beta}(y) \\
&\quad = i g^2 : \tilde{\phi}^{\dagger}_{\alpha}(z) \Lambda^{\alpha}{}_{\beta} (\hat{q}^K)^{\beta}{}_{\sigma} \tilde{\phi}^{\sigma}(w): - i g^2 : \tilde{\phi}^{\dagger}_{\alpha}(z) (\hat{q}^K)^{\alpha}{}_{\beta} \Lambda^{\beta}{}_{\tau} \tilde{\phi}^{\tau}(w): \\
&\qquad - i V(z,w) \delta^{\sigma}{}_{\alpha} \Lambda^{\alpha}{}_{\beta} (\hat{q}^K)^{\beta}{}_{\sigma} + i V(z,w) \delta^{\tau}{}_{\alpha} \Lambda^{\beta}{}_{\tau} (\hat{q}^K)^{\alpha}{}_{\beta} \\
&\quad = + i g^2 : \tilde{\phi}^{\dagger}_{\alpha}(z) \Lambda^{\alpha}{}_{\beta} (\hat{q}^K)^{\beta}{}_{\sigma} \tilde{\phi}^{\sigma}(w): - i g^2 : \tilde{\phi}^{\dagger}_{\alpha}(z) (\hat{q}^K)^{\alpha}{}_{\beta} \Lambda^{\beta}{}_{\sigma} \tilde{\phi}^{\sigma}(w): \\
&\quad = i g^2 : \tilde{\phi}^{\dagger}_{\alpha}(z) [\Lambda, \hat{q}^K]^{\alpha}{}_{\beta} \tilde{\phi}^{\beta}(w): .
\end{aligned}$$

We may need to deal with even more general operators of the form

$$: \tilde{\phi}^{\dagger}(z) \hat{q}^{K_1} \hat{e}^{S_1} \hat{q}^{K_2} \cdots \tilde{\phi}(w): \tag{131}$$

as we will discuss later on. The operator $\mathrm{Tr}\, \Lambda \hat{Q}$ still generates global color transformations on these operators. To show this it is enough to look at the action of $\mathrm{Tr}\, \Lambda \hat{Q}$ on $\hat{e}^{\alpha}_{\beta}$,

$$\begin{aligned}
[\mathrm{Tr}\, \Lambda \hat{Q}, \hat{e}^{\alpha}_{\beta}] &= [\mathrm{Tr}\, \Lambda \hat{e} - \mathrm{Tr}\, \Lambda \hat{q} \hat{e} \hat{q}^{-1}, \hat{e}^{\alpha}{}_{\beta}] = - i g^2 [\Lambda, \hat{e}]^{\alpha}{}_{\beta} + [(\Lambda \hat{q})^{\lambda}{}_{\sigma}, \hat{e}^{\alpha}{}_{\beta}] (\hat{e} \hat{q})^{\tau}{}_{\lambda} \\
&\quad + (\Lambda \hat{q})^{\lambda}{}_{\sigma} [\hat{e}^{\sigma}{}_{\tau}, \hat{e}^{\alpha}{}_{\beta}] (\hat{q}^{-1})^{\tau}{}_{\lambda} + (\Lambda \hat{q} \hat{e})^{\lambda}{}_{\tau} [(\hat{q}^{-1})^{\tau}{}_{\lambda}, \hat{e}^{\alpha}{}_{\beta}] \\
&= - i g^2 [\Lambda, \hat{e}]^{\alpha}{}_{\beta} - i g^2 \Lambda^{\lambda}{}_{\mu} (\hat{q}^{\mu}{}_{\beta} \delta^{\alpha}{}_{\sigma}) \hat{e}^{\sigma}{}_{\tau} (\hat{q}^{-1})^{\tau}{}_{\lambda} \\
&\quad + i g^2 (\Lambda \hat{q})^{\lambda}{}_{\sigma} (\hat{e}^{\alpha}{}_{\tau} \delta^{\sigma}{}_{\beta} - \hat{e}^{\sigma}{}_{\beta} \delta^{\alpha}{}_{\tau}) (\hat{q}^{-1})^{\alpha}{}_{\lambda} + i g^2 (\Lambda \hat{q} \hat{e})^{\lambda}{}_{\tau} (\hat{q}^{-1})^{\tau}{}_{\mu} \hat{q}^{\mu}{}_{\beta} \delta^{\alpha}{}_{\nu} (\hat{q}^{-1})^{\nu}{}_{\sigma} \\
&= - i g^2 [\Lambda, \hat{e}]^{\alpha}{}_{\beta}.
\end{aligned}$$

(As the reader can verify, the Weyl ordering will not change this result.) This proves that the color operator acts as desired.

V. THE LARGE N_c LIMIT

The basic idea of large N_c limit is to write everything in terms of color invariant observables. In the limit of large N_c, only the color invariant operators survive and the expectation values of color invariant operators split as a product up to order $1/N_c$ corrections, so

$$\langle AB \rangle = \langle A \rangle \langle B \rangle + O\left(\frac{1}{N_c} \right). \tag{132}$$

The equation above implies that the set of color invariant operators becomes classical as N_c goes to infinity. Thus all color invariant operators should be representable as classical observables in the large N_c limit. This is an idea of Migdal,[2] see also Witten.[28] A nice review of how one should think of it as a classical limit is presented in Ref. 29.

We had found the color invariant physical states to be of the form in Eq. (128). A more general expression would be of the form

$$: \tilde{\phi}^{\dagger}_{\alpha}(x) [\hat{q}^{K_1} \hat{e}^{S_1} \hat{q}^{K_2} \hat{e}^{S_2} \cdots \hat{q}^{K_m}]^{\alpha}{}_{\beta} \tilde{\phi}_{\beta}(y): . \tag{133}$$

In the large N_c limit there should be classical observables defined to be

$$N(x,y|K_1,S_1,\cdots,K_m)=\lim_{N_c\to\infty}\frac{1}{N_c}:\tilde{\phi}^{\dagger}_{\alpha}(x)[\hat{q}^{K_1}\hat{e}^{S_1}\hat{q}^{K_2}\hat{e}^{S_2}\cdots\hat{q}^{K_m}]^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y):. \tag{134}$$

We note that its complex conjugate is not an independent variable, but satisfies the relation

$$N^{*}(x,y|K_1,S_1,\cdots,K_m)=\lim_{N_c\to\infty}\frac{1}{N_c}(:\tilde{\phi}^{\dagger}_{\alpha}(x)[\hat{q}^{K_1}\hat{e}^{S_1}\hat{q}^{K_2}\hat{e}^{S_2}\cdots\hat{q}^{K_m}]^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y))^{\dagger}: \tag{135}$$

$$=N(y,x|-K_m,S_{n-1},\ldots,-K_1)(-1)^{S_1+\ldots+S_m}, \tag{136}$$

since, we keep

$$(\hat{e}^{\alpha}{}_{\beta})^{\dagger}=-\hat{e}^{\beta}{}_{\alpha}\quad\text{and}\quad(\hat{q}^{\alpha}{}_{\beta})^{\dagger}=(\hat{q}^{-1})^{\beta}{}_{\alpha} \tag{137}$$

(where † refers to the quantum mechanical Hermitian conjugate). Moreover, we may keep the tracelessness condition of $\hat{e}$ acting on the physical states, $\mathrm{Tr}\,\hat{e}\,|\text{physical}>=0$. When we apply our dynamical boundary conditions, namely

$$\tilde{\phi}(L)=\hat{q}^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(-L), \tag{138}$$

the N observable satisfies the relation

$$:\tilde{\phi}^{\dagger}_{\alpha}(x)[\hat{q}^{K_1}\hat{e}^{S_1}\hat{q}^{K_2}\hat{e}^{S_2}\cdots\hat{q}^{K_m}]^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(L):=:\tilde{\phi}^{\dagger}_{\alpha}(x)[\hat{q}^{K_1}\hat{e}^{S_1}\hat{q}^{K_2}\hat{e}^{S_2}\cdots\hat{q}^{K_m+1}]^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(-L):. \tag{139}$$

In the large N_c limit this condition should be postulated as

$$N(x,L|K_1,S_1,\ldots,K_m)=N(x,-L|K_1,S_1,\ldots,K_m+1). \tag{140}$$

We also define

$$Q(K)=\lim_{N_c\to\infty}\frac{1}{N_c}\,\mathrm{Tr}\,\hat{q}^{K}, \tag{141}$$

and in general more complex variables

$$Q(K_1,S_1,\ldots,K_r,S_r)=\lim_{N_c\to\infty}\frac{1}{N_c}\,\mathrm{Tr}(\hat{q}^{K_1}\hat{e}^{S_1}\cdots\hat{q}^{K_r}\hat{e}^{S_r}). \tag{142}$$

We believe that only the simpler variables will be essential to get the mesonic spectrum of the theory but in principle we have all these observables in our theory. These observables satisfy similar conjugation conditions.

VI. CONSTRAINTS OF THE LARGE-N_c THEORY

Color invariance implies a constraint on the bilinears of the theory, due to our requirement

$$\mathrm{Tr}\,\Lambda\hat{Q}|\text{physical}\rangle=0. \tag{143}$$

We note the following interesting observation about the infinite dimensional trace of the basic variables,

$$g^2\int_{-L}^{L}\int_{-L}^{L}\mathrm{d}x\,\mathrm{d}y\;\omega(y,x):\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^{K})^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y):=(\hat{q}^{K})^{\alpha}{}_{\beta}[\hat{e}^{\beta}{}_{\alpha}-(\hat{q}\hat{e}\hat{q}^{-1})^{\beta}{}_{\alpha}]=[\mathrm{Tr}(\hat{q}^{K}\hat{e})-\mathrm{Tr}(\hat{q}^{K+1}\hat{e}\hat{q}^{-1})]. \tag{144}$$

Let us reorder the last term as

$$\hat{q}^{\lambda}{}_{\sigma}(\hat{q}^K)^{\sigma}{}_{\mu}\hat{e}^{\mu}{}_{\nu}(\hat{q}^{-1})^{\nu}{}_{\lambda} = (\hat{q}^K)^{\sigma}{}_{\mu}(\hat{e}^{\mu}{}_{\nu}\hat{q}^{\lambda}{}_{\sigma}(q^{-1})^{\nu}{}_{\lambda} - [e^{\mu}{}_{\nu}, q^{\lambda}{}_{\sigma}])(q^{-1})^{\nu}{}_{\lambda} = (\hat{q}^K)^{\sigma}{}_{\mu}\hat{e}^{\mu}{}_{\nu}\delta^{\nu}{}_{\sigma} - ig^2\delta^{\mu}{}_{\sigma}\delta^{\lambda}{}_{\lambda}(\hat{q}^K)^{\sigma}{}_{\mu}$$
$$= \mathrm{Tr}(\hat{q}^K\hat{e}) - ig^2N_c\,\mathrm{Tr}\,\hat{q}^K.$$

Hence we get,

$$g^2\int_{-L}^{L}\int_{-L}^{L}\mathrm{d}x\,\mathrm{d}y\;\omega(y,x):\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y) = (\hat{q}^K)^{\alpha}{}_{\beta}[\hat{e}^{\beta}{}_{\alpha} - (\hat{q}\hat{e}\hat{q}^{-1})^{\beta}{}_{\alpha}] = ig^2\,\mathrm{Tr}(\hat{q}^K), \quad (145)$$

or in the large-N_c limit,

$$\lim_{N_c\to\infty}\frac{1}{N_c}\int \mathrm{d}x\,\mathrm{d}y\;\omega(y,x)N(x,y|K) = iQ(K). \quad (146)$$

This is an extra condition on the infinite dimensional trace,

$$\lim_{N_c\to\infty}\frac{1}{N_c}\,\mathrm{tr}(\omega\mathbf{N}(K)) = iQ(K). \quad (147)$$

(Note that this condition tells us what should be the leading divergence of the trace of this operator.)

Let us now look for another relation satisfied by the basic "mesonic" observables, so we compute the following product:

$$\int_{-L}^{L}\mathrm{d}y\,\mathrm{d}y':\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y'):\omega(y',y):\tilde{\phi}^{\dagger}_{\lambda}(y)(\hat{q}^L)^{\lambda}{}_{\sigma}\tilde{\phi}^{\sigma}(z):. \quad (148)$$

For simplicity of writing we will drop the limits of the integrals. We expand the normal orderings by subtracting the vacuum energies

$$\int \mathrm{d}y\,\mathrm{d}y'[\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y') - V(x,y')\mathrm{Tr}(\hat{q}^K)]\omega(y',y)[\tilde{\phi}^{\dagger}_{\lambda}(y)(\hat{q}^K)^{\lambda}{}_{\sigma}\tilde{\phi}^{\sigma}(z) - V(y,z)\mathrm{Tr}(\hat{q}^L)]. \quad (149)$$

Collecting the cross terms, and keeping the first term as it is, and normal ordering the other terms again we get, apart from the first term,

$$-\int \mathrm{d}y\,\mathrm{d}y'(\mathrm{Tr}\,\hat{q}^K)V(x,y')\omega(y',y):\tilde{\phi}^{\dagger}_{\lambda}(y)(\hat{q}^L)^{\lambda}{}_{\sigma}\tilde{\phi}^{\sigma}(z):-\int \mathrm{d}y\,\mathrm{d}y'(\mathrm{Tr}\,\hat{q}^L)V(y,z)\omega(y',y):\tilde{\phi}^{\dagger}_{\alpha}(x)$$
$$\times(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y'):-\int \mathrm{d}y\,\mathrm{d}y'(\mathrm{Tr}\,\hat{q}^L)(\mathrm{Tr}\,\hat{q}^K)V(x,y')\omega(y',y)V(y,z). \quad (150)$$

We will keep this term as it is, what we extract from the first term at the end will be added to this part. Now let us look at the other product coming from (149),

$$\int \mathrm{d}y\,\mathrm{d}y'\,\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y')\omega(y',y)\tilde{\phi}^{\dagger}_{\lambda}(y)(\hat{q}^L)^{\lambda}{}_{\sigma}\tilde{\phi}^{\sigma}(z). \quad (151)$$

Here we will change the order of $\tilde{\phi}^{\dagger}_{\lambda}(y)$ and $\tilde{\phi}^{\sigma}(z)$ inserting their commutation relations which brings the symplectic form as

$$\int \mathrm{d}y\,\mathrm{d}y'\;\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y')\omega(y',y)[\tilde{\phi}^{\sigma}(z)\tilde{\phi}^{\dagger}_{\lambda}(y) + i\omega^{-1}(y,z)\delta^{\sigma}{}_{\lambda}](\hat{q}^L)^{\lambda}{}_{\sigma}. \quad (152)$$

Hence,

$$\int \mathrm{d}y\ \mathrm{d}y'\ \tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(y')\omega(y',y)\tilde{\phi}^{\sigma}(z)\tilde{\phi}^{\dagger}_{\lambda}(y)(\hat{q}^L)^{\lambda}{}_{\sigma} + i\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(z)\mathrm{Tr}(\hat{q}^L). \quad (153)$$

Now the first term in the above expression is

$$\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}(\hat{q}^L)^{\lambda}{}_{\sigma}\tilde{\phi}^{\sigma}(z)\int \mathrm{d}y\ \mathrm{d}y'\ \tilde{\phi}^{\beta}(y')\omega(y',y)\tilde{\phi}^{\dagger}_{\lambda}(y). \quad (154)$$

The integral part is converted to normal ordering as

$$\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}(\hat{q}^L)^{\lambda}{}_{\sigma}\tilde{\phi}^{\sigma}(z)\Bigg[\int \mathrm{d}y\ \mathrm{d}y' {:}\tilde{\phi}^{\beta}(y')\omega(y',y)\tilde{\phi}^{\dagger}_{\lambda}(y){:} + \int \mathrm{d}y\ \mathrm{d}y'\,\delta^{\beta}{}_{\lambda}V(y,y')\omega(y',y)$$
$$- i\int \mathrm{d}y\ \mathrm{d}y'\,\omega(y,y')\omega^{-1}(y',y)\delta^{\beta}{}_{\lambda}\Bigg]. \quad (155)$$

The vacuum energy term gives $\mathrm{tr}(V\omega)$, an infinite dimensional trace, and there is another term $\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}(\hat{q}^L)^{\beta}{}_{\sigma}\tilde{\phi}^{\sigma}(z)$. Both of them are of smaller order in $1/N_c$. The last term is also of smaller order in $1/N_c$. Thus we drop these terms as $N_c\to\infty$. The first term in (155) satisfies the following on color invariant states as a result of vanishing color operator on such states;

$$\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}(\hat{q}^L)^{\lambda}{}_{\sigma}\tilde{\phi}^{\sigma}(z)\Bigg[-\frac{1}{g^2}(\hat{q}\hat{e}\hat{q}^{-1})^{\beta}{}_{\lambda}+\frac{1}{g^2}\hat{e}^{\beta}{}_{\lambda}\Bigg]. \quad (156)$$

To set the color indices in the right order we should commute $\hat{e}$ terms with $\hat{q}^L$ terms, which gives us,

$$\frac{1}{\tilde{g}^2}\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K\hat{e}\hat{q}^L)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(z) - \frac{1}{\tilde{g}^2}\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^{K+1}\hat{e}\hat{q}^{L-1})^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(z) - \frac{1}{\tilde{g}^2}\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\sigma}(z)([\hat{e}^{\beta}_{\lambda},(\hat{q}^L)^{\lambda}{}_{\sigma}]$$
$$-[(\hat{q}\hat{e}\hat{q}^{-1})^{\beta}{}_{\sigma},(\hat{q}^L)^{\lambda}{}_{\sigma}]).$$

Here, $1/g^2$ eats up one of the $1/N_c$ terms via $g^2N_c=\tilde{g}^2$ as $N_c\to\infty$. Now let us normal order these terms again and simplify the commutators by a similar method to finally obtain

$$\frac{1}{\tilde{g}^2}\Bigg({:}\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K\hat{e}\hat{q}^L)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(z){:} - {:}\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^{K+1}\hat{e}\hat{q}^{L-1})^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(z){:} - V(x,z)(\mathrm{Tr}(\hat{q}^{K+1}\hat{e}\hat{q}^{L-1}) - \mathrm{Tr}(\hat{q}^K\hat{e}\hat{q}^L))$$
$$- {:}\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\sigma}(z){:}\delta^{\beta}{}_{\sigma}(ig^2N_c)\frac{1}{N_c}\,\mathrm{Tr}\,\hat{q}^L + {:}\tilde{\phi}^{\dagger}_{\alpha}(x)(\hat{q}^K)^{\alpha}{}_{\beta}\tilde{\phi}^{\sigma}(z){:}(\hat{q}^L)^{\beta}{}_{\sigma}(ig^2N_c)$$
$$- ig^2V(x,z)(\mathrm{Tr}\,\hat{q}^K\,\mathrm{Tr}\,\hat{q}^L - N_c\,\mathrm{Tr}(\hat{q}^{K+L}))\Bigg).$$

We can use a further simplification,

$$\mathrm{Tr}(\hat{q}^{K+1}\hat{e}\hat{q}^{L-1}) - \mathrm{Tr}(\hat{q}^K\hat{e}\hat{q}^L) = -ig^2\,\mathrm{Tr}\,\hat{q}^K\,\mathrm{Tr}\,\hat{q}^L. \quad (157)$$

We divide the full expression by $1/N_c^2$ and find in terms of the large-N_c variables,

$$-iN(x,z|K)Q(L) + iN(x,z|K+L) + \frac{1}{\tilde{g}^2}[N(x,z|K,1,L) - N(x,z|K+1,1,L-1)] + iV(x,z)Q(K+L). \quad (158)$$

Here, we recall that

$$N(x,z|K,1,L) = \lim_{N_c\to\infty}\frac{1}{N_c}:\tilde{\phi}^{\dagger}_{\alpha}(x)(q^K\hat{e}q^L)^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(z):\ ,$$

$$N(x,z|K+1,1,L-1) = \lim_{N_c\to\infty}\frac{1}{N_c}:\tilde{\phi}^{\dagger}_{\alpha}(x)(q^{K+1}\hat{e}q^{L-1})^{\alpha}{}_{\beta}\tilde{\phi}^{\beta}(z):\ .$$

The final result will then be, in terms of the large-N_c variables,

$$\begin{aligned}
&\int \mathrm{d}y'\ \mathrm{d}y\ N(x,y'|K)\omega(y',y)N(y,z|L) + Q(K)\int \mathrm{d}y'\ \mathrm{d}y\ V(x,y')\omega(y',y)N(y,z|L)\\
&\quad + Q(L)\int \mathrm{d}y'\ \mathrm{d}y\ N(x,y'|k)\omega(y',y)V(y,z) + Q(K)Q(L)\int \mathrm{d}y'\ \mathrm{d}y\ V(x,y')\omega(y',y)V(y,z)\\
&= iN(x,z|K+L) + \frac{1}{\tilde{g}^2}[N(x,z|K,1,L) - N(x,z|K+1,1,L-1)] + iV(x,z)Q(K)Q(L)\\
&\quad + iV(x,z)Q(K+L).
\end{aligned}$$

We see that the constraint does not define a familiar algebra (in its present form). There are similar constraints for other variables as well, but they are more complicated to derive although the essential steps are the same. We believe that if we could understand the above sector of this large-N_c theory, a significant part of the mesonic excitations would be understood. This constraint can be put in a more elegant form by assuming that there is an operator $\mathbf{N}$ which satisfies

$$\langle x|\mathbf{N}(K)|y\rangle = N(x,y|K), \tag{159}$$

then, we can write it as a matrix equation,

$$\begin{aligned}
&\mathbf{N}(K)\omega\mathbf{N}(L) + Q(K)V\omega\mathbf{N}(L) + Q(L)\mathbf{N}(K)\omega V + Q(K)Q(L)V\omega V = i\mathbf{N}(K+L)\\
&\quad + \frac{1}{\tilde{g}^2}[\mathbf{N}(K,1,L) - \mathbf{N}(K+1,1,L-1)] + iVQ(K+L) + iVQ(K)Q(L).
\end{aligned} \tag{160}$$

We recall our discussion in the third section, using its original notation (now j,k,l refer only to the continuous indices), that

$$\begin{aligned}
(V\omega)^k{}_l &= \frac{1}{2}[i(\omega^{-1})^{kj} + (KQ^{-1})^{kj}]\omega_{jl} = \frac{1}{2}[i\delta^k{}_l + ([-(\omega^{-1}Q)^2]^{1/2})^k{}_j(Q^{-1}\omega)^j_l]\\
&= \frac{i}{2}\delta^k{}_l + \frac{1}{2}([-(\omega^{-1}Q)^2]^{1/2})^k{}_j[(\omega^{-1}Q)^{-1}]^j{}_l = \frac{1}{2}[i\delta^k{}_l + i[\mathrm{sgn}(i\omega^{-1}Q)]^k{}_l].
\end{aligned} \tag{161}$$

Here the operator $\omega^{-1}Q$ is an antisymmetric matrix, since the usual sign function is defined for Hermitian operators we introduce an extra $i=\sqrt{-1}$ and pull out a factor of i. We also recall that

$$K^{\tau} = Q^{-1}K^TQ = K, \tag{162}$$

which can be written as

$$(KQ^{-1})^T = KQ^{-1}. \tag{163}$$

Now we note the following:

$$\begin{aligned}
\omega_{kj}V^{jl} &= -\tfrac{1}{2}\omega_{jk}[-i\omega^{lj} + (KQ^{-1})^{lj}] = i\tfrac{1}{2}\delta^k{}_l - \tfrac{1}{2}([-(\omega^{-1}Q)^2]^{1/2})^k{}_j[(\omega^{-1}Q)^{-1}]^j{}_l\\
&= i\tfrac{1}{2}\delta^k{}_l - i\tfrac{1}{2}[\mathrm{sgn}(i\omega^{-1}Q)]^k{}_l.
\end{aligned} \tag{164}$$

Hence, by using $\tilde{\omega}=\omega^{-1}Q$, we get

$$\mathbf{N}(K)\omega\,\mathbf{N}(L) + iQ(K)\tfrac{1}{2}[1+\mathrm{sgn}(i\tilde{\omega})]\mathbf{N}(L)$$
$$+ iQ(L)\mathbf{N}(K)\tfrac{1}{2}[1-\mathrm{sgn}(i\tilde{\omega})]$$
$$- Q(K)Q(L)\tfrac{1}{4}[1+\mathrm{sgn}(i\tilde{\omega})]\omega^{-1}[1-\mathrm{sgn}(i\tilde{\omega})] = i\mathbf{N}(K+L) + \frac{1}{\tilde{g}^2}[\mathbf{N}(K,1,L) - \mathbf{N}(K+1,1,L-1)]$$
$$+ iVQ(K+L) + iVQ(K)Q(L). \tag{165}$$

Let us note that the above constraint is invariant under the complex conjugation, or using the matrix form, under the Hermitian conjugation. To check that one should take the Hermitian conjugation and use the constraint equation for the combination $-\mathbf{N}(-K)\omega\mathbf{N}(-L)$, then the two results actually agree.

VII. THE EQUATIONS OF MOTION

The next stage is to write the equations of motion for the simple mesonic variables, to accomplish this we preserve the Heisenberg equations of motion,

$$\frac{\partial N(x,y|K)}{\partial u} = -iN_c\left[N(x,y|K), \frac{H}{N_c}\right], \tag{166}$$

and we take the limit $N_c \to \infty$. Since the Hamiltonian contains various types of observables, we need to know the Poisson brackets among these variables. To calculate the equations of motion it is enough to know these Poisson brackets. The algebraic structure of these Poisson brackets, or the structure of all the Poisson brackets, may actually help us solve the problem. At the moment the calculations are too complex, and a direct attack to the equations of motion as in Refs. 9, 10, and 12 seems to be intractable. It is perhaps much better to look for a variational ansatz as in Ref. 11.

After some computations we can write down the Hamiltonian in a completely well-defined manner. The expression below unfortunately hides the analogies with the usual $\mathbf{R}^{1+1}$ case. As we will see there is a better way to write it which reflects this resemblance,

$$\frac{H}{N_C} = \frac{1}{2}\int \lim_{y\to x} \mathrm{d}x(-\partial_y^2 N(x,y)) + \frac{1}{2}\int \mathrm{d}x\, m^2 N(x,x) - \frac{L}{\tilde{g}^2}\mathrm{Tr}\, e^2$$
$$+ \frac{1}{2}\int \mathrm{d}x \int_{-L}^{x} \mathrm{d}y\ \mathrm{sgn}(y) \lim_{z\to y}[\partial_z N(z,y|0,1,0) - \partial_z N(y,z|0,1,0)]$$
$$- \frac{\tilde{g}^2}{8}\int \mathrm{d}x \int_{-L}^{x} \mathrm{d}y\ \mathrm{sgn}(y) \int_{-L}^{x} \mathrm{d}y'\ \mathrm{sgn}(y') \lim_{z\to y} \lim_{w\to y'} [\partial_w N(w,y)\partial_z N(z,y') - N(y',y)\partial_z\partial_w N(z,w)$$
$$- \partial_z\partial_w N(w,z)N(y,y') + \partial_z N(y',z)\partial_w N(y,w) + \partial_w N(w,y)\partial_z V(z,y') + \partial_z N(z,y')\partial_w V(w,y)$$
$$- N(y',y)\partial_z\partial_w V(z,w) - \partial_z\partial_w N(z,w)V(y',y) - \partial_z\partial_w N(w,z)V(y,y') - N(y,y')\partial_z\partial_w V(w,z)$$
$$+ \partial_z N(y',z)\partial_w V(y,w) + \partial_w N(y,w)\partial_z V(y',z) + i\partial_z N(z,y')\partial_w\omega^{-1}(y,w) - i\partial_z\partial_w N(z,w)\omega^{-1}(y,y')$$
$$- iN(y,y')\partial_z\partial_w\omega^{-1}(z,w) + i\partial_w N(y,w)\partial_z\omega^{-1}(z,y')]. \tag{167}$$

The above form shows that everything in the Hamiltonian is well defined. However, from a conceptual point of view there is a better way to write the Hamiltonian. After some algebra, we can get to the following form:

$$\frac{H}{N_C}=\frac{1}{2}\int_{-L}^{L}\mathrm{d}x'\,\mathrm{d}y'(N\omega)(x',y')\tilde{\omega}(y',x')-\frac{L}{\tilde{g}^2}\mathrm{Tr}\,e^2+\int_{-L}^{L}\mathrm{d}x'\,\mathrm{d}y'(N(0,1,0)\omega)(y',y')\theta(x'-y')$$
$$-\frac{\tilde{g}^2}{2}\int_{-L}^{L}\mathrm{d}x'\,\mathrm{d}y'\,G(x',y')(N\omega)(x',y')(N\omega)(y',x')-\frac{i\tilde{g}^2}{2}\int_{-L}^{L}\mathrm{d}x'\,\mathrm{d}y'G(x',y')$$
$$\times(N\omega)(x',y')\mathrm{sgn}(i\tilde{\omega})(y',x'),\tag{168}$$

where $\theta(x-y)$ denotes the usual step function and we also introduce the Green's function

$$G(y,z)=\frac{L}{2}-\frac{1}{2}(y+z)-\frac{1}{2}|y-z|.\tag{169}$$

For simplicity we write $\mathbf{N}\omega$ in place of $\mathbf{N}(0)\omega$, but the two will be used interchangeably.

To find the equations of motion for the basic large-N_c variables we will first calculate the Poisson brackets among various terms. These Poisson brackets along with the constraints satisfied by these variables, define the underlying classical phase space of the large-N_c theory. Since there is an infinite chain of operators we should compute the most general combinations. However, the Hamiltonian contains only a certain set of these terms and we believe the essentials of the dynamics is contained in the simple mesonic variables $N(x,y|K)$, so we restrict our computations to these variables. In fact, the above form of the Hamiltonian naturally suggests $(\mathbf{N}\omega)=(\mathbf{N}\omega)(x,y)$ as our basic variable, so we will write all the relations in terms of these variables (for simplicity when we use the explicit matrix elements we will not use the boldface notation). Poisson brackets below define an infinite dimensional algebra, a natural question is to ask what kind of algebra this is. Moreover, what should be the underlying symmetry principle, which in some sense will replace the gauge invariance principle in this classical system (see Ref. 30 for a study of these type of algebras)? All these questions are left unanswered here, we hope to return to them in a later work. We first state the commutators between the simple mesonic operators then write down the resulting Poisson brackets,

$$\begin{aligned}[(N(K)\omega)(x,y),(N(K')\omega)(x',y')]=&\frac{i}{N_c}\delta(y'-x)(N(K+K')\omega)(x',y)\\&-\frac{\mathrm{i}}{N_c}\delta(y-x')(N(K+K')\omega)(x,y')\\&-\frac{1}{2N_c}\delta(y'-x)\mathrm{sgn}(i\tilde{\omega})(x',y)Q(K+K')\\&+\frac{1}{2N_c}\delta(y-x')\mathrm{sgn}(i\tilde{\omega})(x,y')Q(K+K').\end{aligned}\tag{170}$$

Multiplying this by $-iN_c$ and taking the limit as $N_c\to\infty$ we postulate the Poisson brackets,

$$\begin{aligned}\{(N(K)\omega)(x,y),(N(K')\omega)(x',y')\}=&[\delta(y'-x)(N(K+K')\omega)(x',y)-\delta(y-x')(N(K+K')\omega)(x,y')]\\&+\frac{i}{2}\delta(y'-x)\mathrm{sgn}(i\tilde{\omega})(x',y)-\delta(y-x')\mathrm{sgn}(i\tilde{\omega})(x,y')Q(K+K').\end{aligned}\tag{171}$$

This is essentially the $U(\infty)$ Lie algebra, graded by $\mathbf{Z}$, and has a central extension determined by the operator $\mathrm{sgn}(i\tilde{\omega})$. If we switch to a basis where the operator is diagonal, we will find that it is the same central extension, apart from the $\mathbf{Z}$ grading, as before in Ref. 9. The next commutator we need is

$$\left[\frac{1}{\tilde{g}^2}\mathrm{Tr}\, e^2,(N(K)\omega)(x,y)\right]=\frac{2i}{N_C}\sum_{k=0}^{K}(N(k,1,K-k)\omega)(x,y)-\frac{2i}{N_C}(N(0,1,K)\omega)(x,y)$$
$$-\frac{K\tilde{g}^2}{N_C}(N(K)\omega)(x,y). \tag{172}$$

As a result we postulate the Poisson bracket, and we define a special variable, $C(2)=(1/\tilde{g}^2)Q(0,2)=(1/\tilde{g}^2)\mathrm{Tr}\,\hat{e}^2$,

$$\{C(2),(N(K)\omega)(x,y)\}=2\sum_{k=0}^{K}(N(k,1,K-k)\omega)(x,y)-2(N(0,1,K)\omega)(x,y)+iK\tilde{g}^2(N(K)\omega)(x,y). \tag{173}$$

The last commutator is the most complicated one, after a long computation we have,

$$\begin{aligned}[(N(K)\omega)(x,y),(N(0,1,0)\omega)(x',y')]=&-\frac{i\tilde{g}^2}{N_C}\sum_{k=0}^{K}[(N(K-k)\omega)(x,y')(N(k)\omega)(x',y)\\
&+(N(k)\omega)(x',y)(V\omega)(x,y')Q(K-k)\\
&+(V\omega)(x',y)Q(k)(N(K-k)\omega)(x,y')\\
&+(V\omega)(x',y)Q(k)(V\omega)(xy')Q(K-k)]\\
&+\frac{i\tilde{g}^2}{N_C}[(N(K)\omega)(x',y)(N\omega)(x,y')\\
&+(N(K)\omega)(x',y)(V\omega)(x,y')\\
&+(V\omega)(x',y)Q(K)(N\omega)(x,y')\\
&+(V\omega)(x',y)Q(K)(V\omega)(x,y')]\\
&-\frac{i}{N_C}[\delta(x'-y)(N(K,1,0)\omega)(x,y')\\
&-\delta(y'-x)(N(0,K,1)\omega)(x',y)]\\
&-\frac{i}{N_C}[\delta(x'-y)(V\omega)(x,y')Q(K,1,0)\\
&-\delta(y'-x)(V\omega)(x',y)Q(0,1,K)]\\
&+\frac{K\tilde{g}^2}{N_C^2}\delta(x'-y')[(N(K)\omega)(x,y)\\
&+(V\omega)(x,y)Q(K)]\\
&+\frac{iK\tilde{g}^2}{N_C^2}[(V\omega)(x',y')(N(K)\omega)(x,y)\\
&+(V\omega)(x,y)(N(K)\omega)(x',y')]\\
&+\frac{iK\tilde{g}^2}{N_C^2}(V\omega)(x',y')(V\omega)(x,y)Q(K).\end{aligned} \tag{174}$$

We take the large-N_c limit and drop terms of smaller order to finally postulate,

$$\{(N(K)\omega)(x,y),(N(0,1,0)\omega)(x',y')\} = -\tilde{g}^2\sum_{k=0}^{K}[(N(K-k)\omega)(x,y')(N(K)\omega)(x',y) + (N(k)\omega)(x',y)$$
$$\times(V\omega)(x,y')Q(K-k) + (V\omega)(x',y)Q(k)(N(K-k)\omega)(x,y')$$
$$+ (V\omega)(x',y)Q(k)(V\omega)(x,y')Q(K-k)] + \tilde{g}^2[(N\omega)(x,y')$$
$$\times(N(K)\omega)(x',y) + (N(K)\omega)(x',y)(V\omega)(x,y')$$
$$+ (V\omega)(x',y)Q(K)(N\omega)(x,y') + (V\omega)(x',y)Q(K)(V\omega)(x,y')]$$
$$+ [\delta(y'-x)(N(0,K,1)\omega)(x',y) - \delta(x'-y)$$
$$\times(N(K,1,0)\omega)(x,y')] + [\delta(y'-x)(V\omega)(x',y)Q(0,1,K)$$
$$- \delta(x'-y)(V\omega)(x,y')Q(K,1,0). \tag{175}$$

In principle we can compute now the equations of motion for the simple mesonic variables, via

$$\frac{\partial N(x,y|K)}{\partial u} = \{N(x,y|K),H_c\}, \tag{176}$$

where H_c denotes the limit of H/N_c as $N_c\to\infty$. However, the answer given in the appendix is not at all easy to work with. In the next section we search for a linear approximation.

VIII. LINEARIZATION

A casual look at the Poisson brackets and the Hamiltonian tells us that the equations are very complicated in the general case, and various terms are coupled. An approximation which keeps the nonperturbative aspects of the theory is needed. One possibility is to again look at a linearized version of these equations. This is a good approximation as we know from the previous work in Ref. 9. It seems natural to assume that the operators with various powers of $\hat{q}$ inserted should be the excited states (see also the nonrelativistic version in Ref. 16). In fact we expect that the operators of the form $N(x,y|K_1,S_1,K_2,S_2..)$ become less and less important when we study states close to the ground state. Of course it is possible that the theory readjusts itself further away from these naive expectations to a more complicated ground state. This can only be answered by a more careful study of the system. It is likely that a variational estimate will be more powerful to settle such questions. From a group theory point of view we cannot neglect products of $Q(K)$'s with themselves, but we will neglect the products of $N(x,y|K)$ with $Q(K)$ variables. This means that our basic variables are of order $\hbar$ fluctuations, or even smaller. Let us first rewrite the constraint for $\mathbf{N}(K)\omega$,

$$\mathbf{N}(K)\omega\mathbf{N}(L)\omega + i\left[\frac{1}{2}Q(K)(\mathbf{N}(L)\omega) + \frac{1}{2}Q(L)(\mathbf{N}(K)\omega) - \mathbf{N}(K+L)\omega\right] + i\frac{1}{2}[Q(K)\mathrm{sgn}(i\tilde{\omega})\mathbf{N}(L)\omega$$
$$+ Q(L)\mathbf{N}(K)\omega\,\mathrm{sgn}(i\tilde{\omega})] - \frac{1}{2}[1+\mathrm{sgn}(i\tilde{\omega})]Q(K+L) = \frac{1}{\tilde{g}^2}[\mathbf{N}(K,1,L)\omega - \mathbf{N}(K+1,1,L-1)\omega]. \tag{177}$$

If we set here $K=L=0$, we get a constraint equation which is

$$\mathbf{N}(0)\omega\mathbf{N}(0)\omega + i\frac{1}{2}[\mathrm{sgn}(i\tilde{\omega})\mathbf{N}(0)\omega + \mathbf{N}(0)\omega\,\mathrm{sgn}(i\tilde{\omega})] - \frac{1}{2}[1+\mathrm{sgn}(i\tilde{\omega})]$$
$$= \frac{1}{\tilde{g}^2}[\mathbf{N}(0,1,0)\omega - \mathbf{N}(1,1,-1)\omega]. \tag{178}$$

This looks very much like the constraints found before in Refs. 10 and 12 apart from terms with $\hat{e}$ in them and also a vacuum correction term. There, the constraint was used to throw away certain

momentum components of the basic variables, here we will use this to eliminate the variable $\mathbf{N}(0,1,0)$ as we will see. The linearized equations of motion will then be

$$\begin{aligned}\frac{\partial}{\partial u}(N\omega)(x,y) = \{(N\omega)(x,y), H_C\} &= -\frac{1}{2}[N\omega,\tilde{\omega}](x,y)\\ &+ \int \mathrm{d}x'\,\mathrm{d}y'\ \theta(x',y')[\delta(y',x)(N(0,1,0)\omega)(y',y) - \delta(y,y')(N(0,1,0)\omega)(x,y')]\\ &+ \frac{i\tilde{g}^2}{2}\int \mathrm{d}x'[G(x,x')\{\mathrm{sgn}(i\tilde{\omega})(x',y),(N\omega)(x,x')\}_+\\ &- G(y,x')\{\mathrm{sgn}(i\tilde{\omega})(x,x'),(N\omega)(x',y)\}_+ - G(x,x')(N\omega)(x',y)\mathrm{sgn}(i\tilde{\omega})(x,x')\\ &+ G(y,x')(N\omega)(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y)]\\ &+ \frac{\tilde{g}^2}{4}\int \mathrm{d}x'[G(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y)\mathrm{sgn}(i\tilde{\omega})(x,x')\\ &- G(y,x')\mathrm{sgn}(i\tilde{\omega})(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y)] \end{aligned} \tag{179}$$

in which $Q(0,1,0)=0$ is imposed (because $\mathrm{Tr}\,\hat{e}=0$ on physical states). We also used $\{.,.\}_+$ to denote symmetrized product. If we now assume that $N(x,y|1,1,-1)$ is of smaller order in comparison to the other terms, we can eliminate $N(x,y|0,1,0)$ in favor of $N(x,y|0)$ in the above constraint and plug it into the equations of motion. This gives us

$$\begin{aligned}\{(N(0)\omega)(x,y), H_c\} &= -\frac{1}{2}[\mathbf{N}(0)\omega,\tilde{\omega}](x,y)\\ &+ \frac{\tilde{g}^2}{2}(y-x)[i[\mathbf{N}(0)\omega,\mathrm{sgn}(i\tilde{\omega})]_+(x,y) - [1+\mathrm{sgn}(i\tilde{\omega})](x,y)]\\ &+ \tilde{g}^2\frac{i}{2}\int \mathrm{d}x'[G(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y)(N(0)\omega)(x,x')\\ &- G(y,x')\mathrm{sgn}(i\tilde{\omega})(x,x')(N(0)\omega)(x',y)]\\ &+ \tilde{g}^2\frac{1}{2}\int \mathrm{d}x'[G(x',x) - G(y,x')]\mathrm{sgn}(i\tilde{\omega})(x',y)\mathrm{sgn}(i\tilde{\omega})(x,x'). \end{aligned} \tag{180}$$

It can further be simplified and we reach to,

$$\begin{aligned}\frac{\partial(N(0)\omega)(x,y)}{\partial u} &= \{(N(0)\omega)(x,y), H_c\}\\ &= -\frac{1}{2}[\mathbf{N}(0)\omega,\tilde{\omega}](x,y) + \frac{\tilde{g}^2}{2}(y-x)[i[\mathbf{N}(0)\omega,\mathrm{sgn}(i\tilde{\omega})]_+(x,y) - \mathrm{sgn}(i\tilde{\omega})(x,y)]\\ &+ \tilde{g}^2\frac{i}{2}\int \mathrm{d}x'[G(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y)(N(0)\omega)(x,x')\\ &- G(y,x')\mathrm{sgn}(i\tilde{\omega})(x,x')(N(0)\omega)(x',y)]\\ &+ \tilde{g}^2\frac{1}{4}\int \mathrm{d}x'[|x'-x| - |y-x'|]\mathrm{sgn}(i\tilde{\omega})(x',y)\mathrm{sgn}(i\tilde{\omega})(x,x'). \end{aligned} \tag{181}$$

We can reorganize this equation into,

$$\frac{\partial(N(0)\omega)(x,y)}{\partial u} = \{(N(0)\omega)(x,y), H_c\}$$

$$= -\frac{1}{2}[\mathbf{N}(0)\omega, \tilde{\omega}](x,y) + \frac{\tilde{g}^2}{2} i(y-x)[\mathbf{N}(0)\omega, \mathrm{sgn}(i\tilde{\omega})]_+(x,y)$$

$$+ \tilde{g}^2 \frac{i}{2} \int \mathrm{d}x' [G(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y)(N(0)\omega)(x,x')$$

$$- G(y,x')\mathrm{sgn}(i\tilde{\omega})(x,x')(N(0)\omega)(x',y)]$$

$$+ \tilde{g}^2 \frac{1}{2} \int_x^y \mathrm{d}x' \left[x' - \frac{1}{2}(x+y) \right] \mathrm{sgn}(i\tilde{\omega})(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y) - \frac{\tilde{g}^2}{2}(y-x)\mathrm{sgn}(i\tilde{\omega})(x,y). \tag{182}$$

Here we face a problem, $\mathbf{N}\omega=0$ is not a solution, so it suggests that the true ground state of the theory is not the naive vacuum but has changed due to the interactions. It is also possible that this is the result of our approximations. This is hard to say at our present level of understanding. The inhomogeneous terms are proportional to the coupling constant, as it becomes weaker and weaker we should approach to the true vacuum. If we set $\tilde{g}=0$, the naive vacuum $N\omega=0$, indeed solves the time independent equations. (There are examples of this type of phenomena, in the Lee model, the coupling of the bosonic fields to a quantum mechanical system leads to a drastic change in the ground state of the system.) It is also possible to think of these inhomogeneous terms as if they were multiplied by some powers of $\hbar$ which allows one to get an idea about in which orders in $\hbar$ these terms make contributions to the naive vacuum of the theory due to the interactions. If one keeps in mind that there are $\hbar$'s both in the commutators of the bosonic sector and in the commutators of the gauge sector, more careful analysis shows that the first term in Eq. (182) is zeroth order in $\hbar$ as expected. Moreover the second, third, and fourth terms are the first order terms in $\hbar$ and the order of the last two terms is two in $\hbar$. The solutions of the equations of motion will not give us the invariant mass, the energy is not a relativistic invariant. We need to find the operator of the field momentum and look for the correct combinations of the simultaneous eigenvalues to determine the mass spectrum. All these can best be done in a variational setting. In Refs. 9 and 12, the ordinary momentum was used to diagonalize all the operators. A natural ansatz for the basic mesonic variables would be of the form $(N\omega)(x,y)=\xi(x-y)e^{iP(x+y)/2}$. The leading symbol of $\mathrm{sgn}(i\tilde{\omega})$ is given by $\mathrm{sgn}\left(\frac{1}{2}(x+y)\right)\mathrm{sgn}(p)$, this is expected and such a symbol expansion may be useful to understand this problem as an alternative. Our elimination method may not be the best approach, it may be better to develop a new kind of symbol calculus by combining the collective field approach of the papers[31,32] with bilinear methods. We hope to return to these issues in a later work.

ACKNOWLEDGMENTS

One of the authors (O.T.T.) would like to thank Rajeev for various discussions on gauge theories. The authors also would like to thank C. Saclioglu, M. Arik, T. Rador, M. Mungan, and A. Kaya for reading the paper. The research of one of the authors (O.T.T.) is partially supported by the Turkish Academy of Sciences, Young Investigator Award, OTT/TUBA-GEBIP/2002–1–18.

APPENDIX A: POISSON BRACKETS OF THE GAUGE SECTOR

In this section, in order to evaluate the Poisson brackets of the gauge sector, the suggestion given in Ref. 28 is followed. The variation of the action for the gauge sector can be given by

$$\delta S = \int \mathrm{d}u\ \delta x^{A\mu}{}_{\nu}\Omega^{AB\nu}{}_{\mu}{}^{\lambda}{}_{\sigma}\dot{x}^{B\sigma}{}_{\lambda} - \int \mathrm{d}u\ \delta H = \int \mathrm{d}u\ \delta x^{A\mu}{}_{\nu}\Omega^{AB\nu}{}_{\mu}{}^{\lambda}{}_{\sigma}\dot{x}^{B\sigma}{}_{\lambda} - \int \mathrm{d}u\ \delta x^{A\mu}{}_{\nu}Q^{AB\nu}{}_{\mu}{}^{\lambda}{}_{\sigma}x^{B\sigma}{}_{\lambda}. \tag{A1}$$

For simplicity δH is given as a quadratic form, its explicit form is not needed here. The indices A,B belong to the coordinates (e,q) and run from (1,2). On top of it, the μ,ν indices refer to matrix form of the Lie algebra. The equations of motion gives

$$\dot{x}^{A\mu}{}_{\nu} = (\Omega^{-1})^{AB\mu}{}_{\nu}{}^{\sigma}{}_{\lambda}Q^{BC\lambda}{}_{\sigma}{}^{\kappa}{}_{\tau}x^{C\tau}{}_{\kappa}. \tag{A2}$$

Since

$$\dot{x}^{A\mu}{}_{\nu} = \{x^{A\mu}{}_{\nu}, x^{B\sigma}{}_{\lambda}\}Q^{BC\lambda}{}_{\sigma}{}^{\kappa}{}_{\tau}x^{C\tau}{}_{\kappa}, \tag{A3}$$

the Poisson brackets can be read off directly from the expression. The variation of the action should be expressed in terms of a set of independent variables ξ, v, e and their variations $\delta\xi, \delta e$ on the group manifold. The variables $\delta\xi$ and v are given by

$$\delta\xi = q^{-1}\delta q,$$

$$v = q^{-1}\dot{q}. \tag{A4}$$

To obtain the Poisson brackets, a variation is made in the action

$$\delta S = -\frac{1}{g^2}\int \mathrm{d}u\ \mathrm{Tr}\ \delta(q^{-1}\dot{q}e). \tag{A5}$$

This variation can be expressed in terms of our proper variables after an integration by parts as

$$\delta S = -\frac{1}{g^2}\int \mathrm{d}u\ \mathrm{Tr}(-\delta\xi v e + \delta\xi e v - \delta\xi\dot{e} + \delta e v) \tag{A6}$$

in which there is no contribution coming from a boundary term since the variation of q at the boundaries gives zero. Equation (A6) can be written in terms of explicit indices

$$\delta S = -\frac{1}{g^2}\int \mathrm{d}u(-\delta\xi^{\mu}{}_{\nu}v^{\nu}{}_{\sigma}e^{\sigma}{}_{\mu} + \delta\xi^{\mu}{}_{\nu}e^{\nu}{}_{\sigma}v^{\sigma}{}_{\mu} - \delta\xi^{\mu}{}_{\nu}e^{\nu}{}_{\mu} + \delta e^{\mu}{}_{\nu}v^{\nu}{}_{\mu}). \tag{A7}$$

After some rearrangements of the indices, Eq. (A7) is given by

$$\delta S = -\frac{1}{g^2}\int \mathrm{d}u[\delta\xi^{\mu}{}_{\nu}(\delta^{\kappa}{}_{\mu}e^{\nu}{}_{\sigma} - \delta^{\nu}{}_{\sigma}e^{\kappa}{}_{\mu})v^{\sigma}{}_{\kappa} - \delta^{\kappa}{}_{\mu}\delta^{\nu}{}_{\sigma}(\delta e^{\mu}{}_{\nu}v^{\sigma}{}_{\kappa} - \delta\xi^{\mu}{}_{\nu}\dot{e}^{\sigma}{}_{\kappa})]. \tag{A8}$$

It is possible to write this variation in a more compact form as

$$\delta S = -\frac{1}{g^2}\int \mathrm{d}u(\delta\xi^{\mu}{}_{\nu} - \delta e^{\mu}{}_{\nu})\begin{pmatrix} A^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} & -\delta^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} \\ \delta^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} & 0 \end{pmatrix}\begin{pmatrix} v^{\sigma}{}_{\kappa} \\ \dot{e}^{\sigma}{}_{\kappa} \end{pmatrix} \tag{A9}$$

in which

$$A^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} = \delta^{\kappa}{}_{\mu}e^{\nu}{}_{\sigma} - \delta^{\nu}{}_{\sigma}e^{\kappa}{}_{\mu},$$

$$\delta^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} = \delta^{\kappa}{}_{\mu}\delta^{\nu}{}_{\sigma}. \tag{A10}$$

The symplectic form can, therefore, be given by a matrix as

$$\Omega^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} = -\frac{1}{g^2}\begin{pmatrix} A^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} & -\delta^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} \\ \delta^{\nu}{}_{\mu}{}^{\kappa}{}_{\sigma} & 0 \end{pmatrix}, \tag{A11}$$

and its inverse is also given by

$$(\Omega^{-1})^{\sigma}{}_{\kappa}{}^{\rho}{}_{\tau} = -g^2\begin{pmatrix} 0 & \delta^{\sigma}{}_{\kappa}{}^{\rho}{}_{\tau} \\ -\delta^{\sigma}{}_{\kappa}{}^{\rho}{}_{\tau} & A^{\sigma}{}_{\kappa}{}^{\rho}{}_{\tau} \end{pmatrix}. \tag{A12}$$

The equations of motion for ξ and e are expressed in terms of the Poisson brackets by

$$v^{\sigma}{}_{\kappa} = \{\xi^{\sigma}{}_{\kappa}, \xi^{\rho}{}_{\tau}\}\frac{\partial H}{\partial \xi^{\rho}{}_{\tau}} + \{\xi^{\sigma}{}_{\kappa}, e^{\rho}{}_{\tau}\}\frac{\partial H}{\partial e^{\rho}{}_{\tau}},$$

$$\dot{e}^{\sigma}{}_{\kappa} = \{e^{\sigma}{}_{\kappa}, \xi^{\rho}{}_{\tau}\}\frac{\partial H}{\partial \xi^{\rho}{}_{\tau}} + \{e^{\sigma}{}_{\kappa}, e^{\rho}{}_{\tau}\}\frac{\partial H}{\partial e^{\rho}{}_{\tau}}. \tag{A13}$$

Thus the Poisson brackets can be read off with the assistance of Eqs. (A12) and (A13) as follows:

$$\{\xi^{\sigma}{}_{\kappa}, e^{\rho}{}_{\tau}\} = -g^2\delta^{\sigma}{}_{\kappa}{}^{\rho}{}_{\tau} = -g^2\delta^{\sigma}{}_{\tau}\delta^{\rho}{}_{\kappa}, \tag{A14}$$

$$\{e^{\sigma}{}_{\kappa}, e^{\rho}{}_{\tau}\} = -g^2 A^{\sigma}{}_{\kappa}{}^{\rho}{}_{\tau} = g^2(\delta^{\sigma}{}_{\tau}e^{\rho}{}_{\kappa} - \delta^{\rho}{}_{\kappa}e^{\sigma}{}_{\tau}). \tag{A15}$$

A Poisson bracket between the variables q and e can be introduced by passing q^{-1} in the definition of v to the other side as q in the equation of motion for ξ. This is allowed since the Poisson bracket between the variables ξ themselves is zero. One can therefore end up with

$$\{e^{\mu}{}_{\nu}, q^{\sigma}{}_{\kappa}\} = g^2\delta^{\mu}{}_{\kappa}q^{\sigma}{}_{\nu}. \tag{A16}$$

Contracting e by an element of the Lie algebra, namely Λ, the Poisson brackets can be set in a form as below,

$$\{\mathrm{Tr}\,\Lambda e, q^{\sigma}{}_{\kappa}\} = g^2(g\Lambda)^{\sigma}{}_{\kappa},$$

$$\{\mathrm{Tr}\,\Lambda^1 e, \mathrm{Tr}\,\Lambda^2 e\} = g^2\,\mathrm{Tr}[\Lambda^1, \Lambda^2]e. \tag{A17}$$

There is a natural geometric interpretation for this symplectic structure. It is indeed the canonical form on T^*G; the cotangent bundle on G (see Ref. 25 for a good exposition).

APPENDIX B: THE FULL EQUATIONS OF MOTION

A long and tedious calculation will reveal the full equations of motion for the simple mesonic variables. We give the answer below without any details. One should subtract divergence coming from the renormal ordering of the Hamiltonian, this is not a simple task. We plan to come back to these issues in a later presentation,

$$\begin{aligned}\frac{\partial}{\partial u}(N(K)\omega)(x,y) = \{(N(K)\omega)(x,y), H_C\} = &-\frac{1}{2}[N(K)\omega, \tilde{\omega}](x,y) + i\tilde{g}^2 KL(N(K)\omega)(x,y) \\ &+ 2L\sum_{k=0}^{K} N(k,1,K-k)\omega(x,y) - 2L(N(0,1,K)\omega)(x,y) \\ &- \tilde{g}^2\sum_{k=0}^{K}\int \mathrm{d}x'\,\mathrm{d}y'\,\theta(x',y')[(N(K-k)\omega)(x,y')(N(k)\omega)(y',y) \\ &+ (V\omega)(x,y')Q(K-k)(N(k)\omega)(y',y) + (N(K-k)\omega)(x,y')(V\omega)(y',y)Q(k)\end{aligned}$$

$$
\begin{aligned}
&+ (V\omega)(x,y')(V\omega)(y',y)Q(K-k)Q(k)] \\
&+ \tilde{g}^2 \int \mathrm{d}x'\,\mathrm{d}y'\;\theta(x',y')[(N\omega)(x,y')(N(K)\omega)(y',y) + (V\omega)(x,y') \\
&\times (N(K)\omega)(y',y) + (N\omega)(x,y')(V\omega)(y',y)Q(K) + (V\omega)(x,y')(V\omega)(y',y)Q(K)] \\
&+ \int \mathrm{d}x'\,\mathrm{d}y'\;\theta(x',y')[\delta(y',x)(N(0,1,K)\omega)(y',y) - \delta(y,y')(N(K,1,0)\omega)(x,y')] \\
&+ \int \mathrm{d}x'\,\mathrm{d}y'\;\theta(x',y')[\delta(y',x)(V\omega)(y',y)Q(0,1,K) - \delta(y,y') \\
&\times (V\omega)(x,y')Q(K,1,0)] - \frac{\tilde{g}^2}{2}\int \mathrm{d}x'[G(x,x')\{(N(K)\omega)(x'y),(N\omega)(x,x')\}_+ \\
&- G(y,x')\{(N(K)\omega)(x,x'),(N\omega)(x',y)\}_+] \\
&+ \frac{i\tilde{g}^2}{2}\int \mathrm{d}x'[G(x,x')\{\mathrm{sgn}(i\tilde{\omega})(x',y),(N\omega)(x,x')\}_+Q(K) - G(y,x') \\
&\times \{\mathrm{sgn}(i\tilde{\omega})(x,x'),(N\omega)(x',y)\}_+Q(K) - G(x,x')(N(K)\omega)(x',y)\mathrm{sgn}(i\tilde{\omega})(x,x') \\
&+ G(y,x')(N(K)\omega)(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y)] \\
&+ \frac{\tilde{g}^2}{4}\int \mathrm{d}x'[G(x,x')\mathrm{sgn}(i\tilde{\omega})(x',y)Q(K)\mathrm{sgn}(i\tilde{\omega})(x,x') \\
&- G(y,x')\mathrm{sgn}(i\tilde{\omega})(x,x')Q(K)\mathrm{sgn}(i\tilde{\omega})(x',y). \qquad \text{(B1)}

(Received 16 January 2006; accepted 21 February 2006; published online 18 July 2006)

In a recent paper we have presented results for a set of massive scalar one-loop master integrals needed in the NNLO parton model description of the hadroproduction of heavy flavors. The one-loop integrals were evaluated in $n=4-2\varepsilon$ dimension and the results were presented in terms of a Laurent series expansion up to $\mathcal{O}(\varepsilon^2)$. We found that some of the ε^2 coefficients contain a new class of functions which we termed the L functions. The L functions are defined in terms of one-dimensional integrals involving products of logarithm and dilogarithm functions. In this paper we derive a complete set of algebraic relations that allow one to convert the L functions of our previous approach to a sum of classical and multiple polylogarithms. Using these results we are now able to present the ε^2 coefficients of the one-loop master integrals in terms of classical and multiple polylogarithms.
 [DOI: 10.1063/1.2190336]

I. INTRODUCTION

Recently, we have calculated the complete set of massive one-loop master integrals[1] needed in the calculation of the next-to-next-to-leading order (NNLO) parton model corrections to the hadroproduction of heavy flavors.[2] We used Feynman parametrization to evaluate the one-loop master integrals in $n=4-2\varepsilon$ dimensions. We obtained the coefficients of the Laurent series expansion of the relevant scalar integrals in terms of the parameter ε up to $\mathcal{O}(\varepsilon^2)$ as needed for the NNLO calculation. We found that the real parts of some of the ε^2 coefficients contain a new class of functions which can be written in terms of one-dimensional integral representations involving products of log and dilog functions. These so-called single and triple index L functions cannot be expressed in terms of classical polylogaritms but can be seen to belong to a generalization of the classical polylogarithms which are called multiple polylogarithms.

Functions analogous to the triple index functions $L_{\sigma_1\sigma_2\sigma_3}$ also arise in the approach of Ref. 3 when one analytically continues their $\mathcal{O}(\varepsilon^2)$ integral representation for a general vertex function. Methods differing from ours have been used for the derivation of master N-point integrals such as the differential equations method[4] or the nested sum method.[5] Depending on the number of scales involved, the results include multiple polylogarithms[6] and/or harmonic[7] or two-dimensional harmonic[8] polylogarithms. The latter functions all are subsets of multiple polylogarithms. Present-

ing our results in terms of multiple polylogarithms will facilitate a comparison with the results of possible rederivations of the scalar one-loop integrals using other methods. It is very likely that future results of multiloop calculations will be presented in terms of multiple polylogarithms or their subclasses. Alongside with this the necessary tools will be developed to deal with multiple polylogarithms, be it analytically or numerically. In fact, recently a computer code has been written for the numerical evaluation of the multiple polylogarithms.[9] It is therefore timely that we express the results of Ref. 1 also in terms of multiple polylogarithms.

It is a purpose of this paper to show that the single and triple index L functions introduced in Ref. 1 can all be related to multiple polylogarithms. This is done in explicit form. We are thus able to present our results for the scalar massive one-loop master integrals in terms of multiple polylogarithms and classical polylogarithms.[10] In Sec. II we recapitulate material on the definition of the single and triple index L functions as they arise in the approach of Ref. 1. Simple symmetry relations allow one to restrict the discussion to the triple index L functions L_{-++} and L_{+++}, and to the single index L function L_{+}. In Sec. II we also recapitulate the definition of multiple polylogarithms. In the subsequent sections we will write down the formulas needed to transform the L functions to multiple polylogarithms for general arguments. The general formulas are not always applicable when the arguments take special values as they do in the massive one-loop calculation. For these special values one must carefully discuss the limiting behavior of the general formulas. In Sec. III A we derive the general formula which relates the L_{-++} functions to the set of multiple polylogarithms. Section III B considers special cases of the general relation. Similarly, Sec. IV A gives general relations which allow one to express the L_{+++} functions in terms of multiple polylogarithms. In Sec. IV B we discuss special cases for the arguments of the L_{+++} functions. Sections V A and V B repeat the discussion for the single index L_{+} functions. Finally, Sec. VI presents our conclusions.

As remarked on before, the L functions appear only in the real parts of some of the $\mathcal{O}(\varepsilon^2)$ coefficient functions of the masive one-loop integrals. In the notation of Ref. 1 these are the three-point coefficient functions $\mathrm{Re}\, C_1^{(2)}$, $\mathrm{Re}\, C_2^{(2)}$, and $\mathrm{Re}\, C_5^{(2)}$, and the four-point coefficient functions $\mathrm{Re}\, D_1^{(2)}$, $\mathrm{Re}\, D_2^{(2)}$, and $\mathrm{Re}\, D_3^{(2)}$. For the sake of brevity we have decided to present multiple polylogarithm results in this paper only for the four-point coefficient function $\mathrm{Re}\, D_1^{(2)}$. This result is listed in the Appendix. The corresponding results for the other five coefficient functions are readily available in electronic form.[11]

II. BASIC FEATURES

In order to make the paper self-contained, we write down a number of basic definitions for the L functions and the multiple polylogarithms in this section, as well as some symmetry properties and domains of definitions for the single and triple index L functions. These will be of help when presenting the subsequent material.

The definition for the L functions is as follows:[1]

$$L_{\sigma_1\sigma_2\sigma_3}(\alpha_1,\alpha_2,\alpha_3,\alpha_4)=\int_0^1 \mathrm{d}y \frac{\ln(\alpha_1+\sigma_1 y)\ln(\alpha_2+\sigma_2 y)\ln(\alpha_3+\sigma_3 y)}{\alpha_4+y} \tag{1}$$

and

$$L_{\sigma_1}(\alpha_1,\alpha_2,\alpha_3,\alpha_4)=\int_0^1 \mathrm{d}y \frac{\ln(\alpha_1+\sigma_1 y)Li_2(\alpha_2+\alpha_3 y)}{\alpha_4+y}. \tag{2}$$

Here the σ_i $(i=1,2,3)$ take the values ± 1 and the α_j's are either integers $\{1,0,-1\}$ or else kinematical variables. We want to emphasize that the numerical evaluation of the L functions is straightforward.

The L functions possess simple symmetry properties as follows. One notices that a change of the integration variable $y \to 1-y$ results in the identity

$$L_{\sigma_1}(\alpha_1,\alpha_2,\alpha_3,\alpha_4) = -L_{-\sigma_1}(\alpha_1+\sigma_1,\alpha_2+\alpha_3,-\alpha_3,-\alpha_4-1) \tag{3}$$

which implies that L_- can always be related to L_+, and vice versa. We have thus written our results for the three-point and four-point functions in Ref. 1 only in terms of the L_+ functions.

Turning to the triple index L function one notices that $L_{\sigma_1\sigma_2\sigma_3}(\alpha_1,\alpha_2,\alpha_3,\alpha_4)$ is symmetric under permutations of any two pairs of indices and arguments $\{\sigma_i,\alpha_i\}$ and $\{\sigma_j,\alpha_j\}$ for $(i\neq j)$. The same change of variables as above $y\to 1-y$ results in

$$L_{\sigma_1\sigma_2\sigma_3}(\alpha_1,\alpha_2,\alpha_3,\alpha_4) = -L_{-\sigma_1-\sigma_2-\sigma_3}(\alpha_1+\sigma_1,\alpha_2+\sigma_2,\alpha_3+\sigma_3,-\alpha_4-1). \tag{4}$$

Therefore, from the eight functions L_{---}, L_{--+}, L_{-+-}, L_{+--}, L_{-++}, L_{+-+}, L_{++-}, and L_{+++} only two are independent. We have chosen to write our results in terms of L_{-++} and L_{+++}.

The domains of definition of the functions L_{+++}, L_{-++}, and L_+ that follow from the requirement that these functions take real values can be read off from the defining relations Eqs. (1) and (2) considering the arguments of the log and dilog functions in the integrands, as well as from ensuring that the denominator of Eqs. (1) and (2) does not change sign on the integration path. One has

$$L_{+++}(\alpha_1,\alpha_2,\alpha_3,\alpha_4): \quad \alpha_1>0,\alpha_2>0,\alpha_3>0,\alpha_4<-1 \text{ or } \alpha_4>0;$$

$$L_{-++}(\alpha_1,\alpha_2,\alpha_3,\alpha_4): \quad \alpha_1>1,\alpha_2>0,\alpha_3>0,\alpha_4<-1 \text{ or } \alpha_4>0;$$

$$L_{+}(\alpha_1,\alpha_2,\alpha_3,\alpha_4): \quad \alpha_1>0,\alpha_2\leqslant 1,\alpha_2+\alpha_3\leqslant 1,\alpha_3\neq 0,\alpha_4<-1 \text{ or } \alpha_4>0. \tag{5}$$

Looking at the definition of the triple index L function in (1) one concludes that the boundary points $\alpha_1=0$ and/or $\alpha_2=0$ and/or $\alpha_3=0$ can be included in the domain of the definition for L_{+++}. The same holds true for $\alpha_1=1$ and/or $\alpha_2=0$ and/or $\alpha_3=0$ for L_{-++}. Also, from the definition of the single index function L_+ in (2) one concludes that the boundary point $\alpha_1=0$ can be added to its domain of definition.

The points $\alpha_4=\{-1,0\}$ can also be included in the domain if the values taken by the other parameters α_i guarantee the convergence of the integral. We mention that for all of our purposes the conditions (5), with the boundary points included, are satisfied, e.g., our results for the integrals are real. Nevertheless, it is of course always possible to analytically continue the parameters to the complex plane.

There are some further relations for the L functions which result from applying integration-by-parts identities. They are not listed here but can be found in Appendix C of Ref. 1. They have been used to reduce the set of L functions occurring in the master integrals to a subset of L functions having real values in physical phase space.[1]

Multiple polylogarithms are defined as a limit of Z sums,[6] e.g.,

$$Li_{m_k,\ldots,m_1}(x_k,\ldots,x_1) = \lim_{n_1\to\infty} \sum_{n_1>n_2\ldots>n_k>0} \frac{x_1^{n_1}x_2^{n_2}\cdots x_k^{n_k}}{n_1^{m_1}n_2^{m_2}\cdots n_k^{m_k}}. \tag{6}$$

The number $w=m_1+\cdots+m_k$ is called the weight and k is called the depth of the multiple polylogarithm. The power series (6) is convergent for $|x_i|<1$, and can be analytically continued via the iterated integral representation:

$$Li_{m_k,\ldots,m_1}(x_k,\ldots,x_1) = \int_0^{x_1x_2\cdots x_k} \left(\frac{dt}{t}\circ\right)^{m_1-1} \frac{dt}{x_2x_3\cdots x_k-t}\circ \left(\frac{dt}{t}\circ\right)^{m_2-1} \frac{dt}{x_3\cdots x_k-t}\circ\cdots\circ\left(\frac{dt}{t}\circ\right)^{m_k-1}\frac{dt}{1-t}, \tag{7}$$

where the following notation is used for the iterated integrals:

$$\int_0^\lambda \frac{\mathrm{d}t}{a_n - t} \circ \cdots \circ \frac{\mathrm{d}t}{a_1 - t} = \int_0^\lambda \frac{\mathrm{d}t_n}{a_n - t_n} \int_0^{t_n} \frac{\mathrm{d}t_{n-1}}{a_{n-1} - t_{n-1}} \times \cdots \times \int_0^{t_2} \frac{\mathrm{d}t_1}{a_1 - t_1}. \tag{8}$$

III. TRANSFORMATION OF L_{-++} TO MULTIPLE POLYLOGARITHMS

In this section we will show that all our L_{-++} functions can be expressed in terms of multiple polylogarithms.

A. General case for the L_{-++} function

We begin with the L_{-++} function Eq. (1),

$$L_{-++}(\alpha_1, \alpha_2, \alpha_3, \alpha_4) = \int_0^1 \mathrm{d}y \frac{\ln(\alpha_1 - y)\ln(\alpha_2 + y)\ln(\alpha_3 + y)}{\alpha_4 + y}. \tag{9}$$

After changing the integration variable $y = \alpha_1 t$ one gets

$$\begin{aligned}
&\int_0^{1/\alpha_1} \mathrm{d}t \frac{\ln(\alpha_1 - \alpha_1 t)\ln(\alpha_2 + \alpha_1 t)\ln(\alpha_3 + \alpha_1 t)}{\frac{\alpha_4}{\alpha_1} + t} \\
&= \int_0^{1/\alpha_1} \mathrm{d}t \frac{\ln \alpha_1 \ln(\alpha_2 + \alpha_1 t)\ln(\alpha_3 + \alpha_1 t)}{\frac{\alpha_4}{\alpha_1} + t} \\
&\quad + \int_0^{1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)\left[\ln \alpha_1 + \ln\left(\frac{\alpha_2}{\alpha_1} + t\right)\right]\left[\ln \alpha_1 + \ln\left(\frac{\alpha_3}{\alpha_1} + t\right)\right]}{\frac{\alpha_4}{\alpha_1} + t} \\
&= \ln \alpha_1 \int_0^1 \mathrm{d}y \frac{\ln(\alpha_2 + y)\ln(\alpha_3 + y)}{\alpha_4 + y} + \ln^2 \alpha_1 \int_0^{1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)}{\frac{\alpha_4}{\alpha_1} + t} \\
&\quad + \ln \alpha_1 \int_0^{1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)\ln\left(\frac{\alpha_2}{\alpha_1} + t\right)}{\frac{\alpha_4}{\alpha_1} + t} + \ln \alpha_1 \int_0^{1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)\ln\left(\frac{\alpha_3}{\alpha_1} + t\right)}{\frac{\alpha_4}{\alpha_1} + t} \\
&\quad + \int_0^{1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)\ln\left(\frac{\alpha_2}{\alpha_1} + t\right)\ln\left(\frac{\alpha_3}{\alpha_1} + t\right)}{\frac{\alpha_4}{\alpha_1} + t}.
\end{aligned} \tag{10}$$

With the help of (7) the integral in the second term of the last equation of (10) can be written as

$$\int_0^{1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)}{\frac{\alpha_4}{\alpha_1} + t} = \int_0^{1/\alpha_1} \frac{\mathrm{d}t_1}{-\frac{\alpha_4}{\alpha_1} - t_1} \int_0^{t_1} \frac{\mathrm{d}t_2}{1 - t_2} = Li_{1,1}\left(-\frac{\alpha_4}{\alpha_1}, -\frac{1}{\alpha_4}\right). \tag{11}$$

The third and fourth terms of the last equation in (10) contain integrals of the form

$$\int_0^{t_m} \mathrm{d}t \frac{\ln(1-t)\ln(\beta_1+t)}{\beta_2+t}. \tag{12}$$

To express such integrals in terms of multiple polylogarithms one proceeds as follows:

$$\begin{aligned}
-Li_{1,1,1}\left(-\beta_2, \frac{\beta_1}{\beta_2}, \frac{-t_m}{\beta_1}\right) &= \int_0^{t_m} \frac{\mathrm{d}t_2}{\beta_1+t_2} \int_0^{t_2} \mathrm{d}t_1 \frac{\ln(1-t_1)}{\beta_2+t_1} = \int_0^{t_m} \mathrm{d}t_1 \frac{\ln(1-t_1)}{\beta_2+t_1} \int_{t_1}^{t_m} \frac{\mathrm{d}t_2}{\beta_1+t_2} \\
&= \ln(\beta_1+t_m) \int_0^{t_m} \mathrm{d}t_1 \frac{\ln(1-t_1)}{\beta_2+t_1} - \int_0^{t_m} \mathrm{d}t_1 \frac{\ln(1-t_1)\ln(\beta_1+t_1)}{\beta_2+t_1} \\
&= \ln(\beta_1+t_m) Li_{1,1}\left(-\beta_2, \frac{-t_m}{\beta_2}\right) - \int_0^{t_m} \mathrm{d}t_1 \frac{\ln(1-t_1)\ln(\beta_1+t_1)}{\beta_2+t_1}.
\end{aligned} \tag{13}$$

In the first line of (13) we have changed the order of integration in the two-dimensional integral. We shall frequently use this trick further on. From Eq. (13) one immediately concludes that

$$\int_0^{t_m} \mathrm{d}t \frac{\ln(1-t)\ln(\beta_1+t)}{\beta_2+t} = Li_{1,1,1}\left(-\beta_2, \frac{\beta_1}{\beta_2}, \frac{-t_m}{\beta_1}\right) + \ln(\beta_1+t_m) Li_{1,1}\left(-\beta_2, \frac{-t_m}{\beta_2}\right). \tag{14}$$

Let us now turn to the more involved integral [first term of Eq. (12)]

$$\begin{aligned}
\int_0^1 \mathrm{d}y \frac{\ln(\alpha_2+y)\ln(\alpha_3+y)}{\alpha_4+y} &\overset{y\to-\alpha_2 t}{=} -\int_0^{-1/\alpha_2} \mathrm{d}t \frac{[\ln\alpha_2+\ln(1-t)]\ln(\alpha_3-\alpha_2 t)}{\frac{\alpha_4}{\alpha_2}-t} \\
&= -\ln\alpha_2 \int_0^{-1/\alpha_2} \mathrm{d}t \frac{\ln(\alpha_3-\alpha_2 t)}{\frac{\alpha_4}{\alpha_2}-t} \\
&\quad - \int_0^{-1/\alpha_2} \mathrm{d}t \frac{\ln(1-t)\left[\ln\alpha_2+\ln\left(\frac{\alpha_3}{\alpha_2}-t\right)\right]}{\frac{\alpha_4}{\alpha_2}-t} \\
&= +\ln\alpha_2 \int_0^1 \mathrm{d}y \frac{\ln(\alpha_3+y)}{\alpha_4+y} - \ln\alpha_2 \int_0^{-1/\alpha_2} \mathrm{d}t \frac{\ln(1-t)}{\frac{\alpha_4}{\alpha_2}-t} \\
&\quad - \int_0^{-1/\alpha_2} \mathrm{d}t \frac{\ln(1-t)\ln\left(\frac{\alpha_3}{\alpha_2}-t\right)}{\frac{\alpha_4}{\alpha_2}-t}.
\end{aligned} \tag{15}$$

The integral in the first term can be expressed as

$$\int_0^1 \mathrm{d}y \frac{\ln(\alpha_3+y)}{\alpha_4+y} \overset{y\to-\alpha_3 t}{=} -\int_0^{-1/\alpha_3} \mathrm{d}t \frac{[\ln\alpha_3+\ln(1-t)]}{\frac{\alpha_4}{\alpha_3}-t} = \ln\alpha_3 \ln\left(\frac{\alpha_4+1}{\alpha_4}\right) + Li_{1,1}\left(\frac{\alpha_4}{\alpha_3}, -\frac{1}{\alpha_3}\right). \tag{16}$$

The integral in the second term can be written as

$$\int_0^{-1/\alpha_2} \mathrm{d}t \frac{\ln(1-t)}{\frac{\alpha_4}{\alpha_2}-t} = -Li_{1,1}\left(\frac{\alpha_4}{\alpha_2},-\frac{1}{\alpha_2}\right). \tag{17}$$

The term from the last line of Eq. (15) has a form which is an analog of the integral (12) and can be calculated in a similar way,

$$\int_0^{t_m} \mathrm{d}t \frac{\ln(1-t)\ln(\beta_1-t)}{\beta_2-t} = Li_{1,1,1}\left(\beta_2,\frac{\beta_1}{\beta_2},\frac{t_m}{\beta_1}\right) + \ln(\beta_1-t_m)Li_{1,1}\left(\beta_2,\frac{t_m}{\beta_2}\right). \tag{18}$$

Combining the Eqs. (16)–(18) we arrive at the result for Eq. (15),

$$\begin{aligned}\int_0^1 \mathrm{d}y \frac{\ln(\alpha_2+y)\ln(\alpha_3+y)}{\alpha_4+y} &= Li_{1,1,1}\left(\frac{\alpha_4}{\alpha_2},\frac{\alpha_3}{\alpha_4},-\frac{1}{\alpha_3}\right) + \ln\,\alpha_2 Li_{1,1}\left(\frac{\alpha_4}{\alpha_3},-\frac{1}{\alpha_4}\right)\\ &\quad + \ln(1+\alpha_3)Li_{1,1}\left(\frac{\alpha_4}{\alpha_2},-\frac{1}{\alpha_4}\right) + \ln\,\alpha_2\,\ln\,\alpha_3\,\ln\left(\frac{\alpha_4+1}{\alpha_4}\right).\end{aligned} \tag{19}$$

Because the initial integrand is symmetric under the exchange of the parameters α_2 and α_3, the rhs of (19) can be rewritten in a symmetric form if desired.

We are now left with the fifth term in (10). The fifth term is an integral of the type

$$\int_0^{t_m} \mathrm{d}t \frac{\ln(1-t)\ln(\gamma_1+t)\ln(\gamma_2+t)}{\gamma_3+t}. \tag{20}$$

In order to express such integrals in terms of multiple polylogarithms one can perform the following chain of transformations resulting in a multiple polylogarithm of weight four:

$$\begin{aligned}-Li_{1,1,1,1}\left(-\gamma_3,\frac{\gamma_2}{\gamma_3},\frac{\gamma_1}{\gamma_2},\frac{-t_m}{\gamma_1}\right) &= \int_0^{t_m}\frac{\mathrm{d}t_4}{\gamma_1+t_4}\int_0^{t_4}\frac{\mathrm{d}t_3}{\gamma_2+t_3}\int_0^{t_3}\frac{\mathrm{d}t_2}{\gamma_3+t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{1-t_1}\\ &= -\int_0^{t_m}\frac{\mathrm{d}t_4}{\gamma_1+t_4}\int_0^{t_4}\frac{\mathrm{d}t_3}{\gamma_2+t_3}\int_0^{t_3}\mathrm{d}t_2\frac{\ln(1-t_2)}{\gamma_3+t_2}\\ &= -\int_0^{t_m}\frac{\mathrm{d}t_4}{\gamma_1+t_4}\int_0^{t_4}\mathrm{d}t_2\frac{\ln(1-t_2)}{\gamma_3+t_2}\int_{t_2}^{t_4}\frac{\mathrm{d}t_3}{\gamma_2+t_3}\\ &= -\int_0^{t_m}\mathrm{d}t_4\frac{\ln(\gamma_2+t_4)}{\gamma_1+t_4}\int_0^{t_4}\mathrm{d}t_2\frac{\ln(1-t_2)}{\gamma_3+t_2}\\ &\quad +\int_0^{t_m}\frac{\mathrm{d}t_4}{\gamma_1+t_4}\int_0^{t_4}\mathrm{d}t_2\frac{\ln(1-t_2)\ln(\gamma_2+t_2)}{\gamma_3+t_2}\\ &= -I'(t_m)+\int_0^{t_m}\mathrm{d}t_2\frac{\ln(1-t_2)\ln(\gamma_2+t_2)}{\gamma_3+t_2}\int_{t_2}^{t_m}\frac{\mathrm{d}t_4}{\gamma_1+t_4}\\ &= -I'(t_m)+I''(t_m)-\int_0^{t_m}\mathrm{d}t_2\frac{\ln(\gamma_1+t_2)\ln(\gamma_2+t_2)\ln(1-t_2)}{\gamma_3+t_2},\end{aligned} \tag{21}$$

where we have introduced the notation

$$I'(t_m) = \int_0^{t_m}\mathrm{d}t_4\frac{\ln(\gamma_2+t_4)}{\gamma_1+t_4}\int_0^{t_4}\mathrm{d}t_2\frac{\ln(1-t_2)}{\gamma_3+t_2},$$

$$I''(t_m) = \ln(\gamma_1 + t_m) \int_0^{t_m} \mathrm{d}t_2 \frac{\ln(1-t_2)\ln(\gamma_2 + t_2)}{\gamma_3 + t_2}. \tag{22}$$

The third term on the last line of (21) is exactly the integral of the required type Eq. (20).

The integral in $I''(t_m)$ has the form of (14). For the integral $I'(t_m)$ we write

$$I'(t_m) = \int_0^{t_m} \mathrm{d}t_4 \frac{\ln(\gamma_2 + t_4)}{\gamma_1 + t_4} \int_0^{t_4} \mathrm{d}t_2 \frac{\ln(1-t_2)}{\gamma_3 + t_2} = \int_0^{t_m} \mathrm{d}t_4 \frac{\ln(\gamma_2 + t_4)}{\gamma_1 + t_4} Li_{1,1}\left(-\gamma_3, \frac{-t_4}{\gamma_3}\right). \tag{23}$$

On the other hand, one has

$$\begin{aligned} Li_{1,1,1,1}\left(-\gamma_3, \frac{\gamma_1}{\gamma_3}, \frac{\gamma_2}{\gamma_1}, \frac{-t_m}{\gamma_2}\right) &= \int_0^{t_m} \frac{\mathrm{d}t_2}{\gamma_2 + t_2} \int_0^{t_2} \frac{\mathrm{d}t_1}{\gamma_1 + t_1} Li_{1,1}\left(-\gamma_3, \frac{-t_1}{\gamma_3}\right) \\ &= \int_0^{t_m} \frac{\mathrm{d}t_1}{\gamma_1 + t_1} Li_{1,1}\left(-\gamma_3, \frac{-t_1}{\gamma_3}\right) \int_{t_1}^{t_m} \frac{\mathrm{d}t_2}{\gamma_2 + t_2} \\ &= \ln(\gamma_2 + t_m) \int_0^{t_m} \frac{\mathrm{d}t_1}{\gamma_1 + t_1} Li_{1,1}\left(-\gamma_3, \frac{-t_1}{\gamma_3}\right) \\ &\quad - \int_0^{t_m} \mathrm{d}t_1 \frac{\ln(\gamma_2 + t_1)}{\gamma_1 + t_1} Li_{1,1}\left(-\gamma_3, \frac{-t_1}{\gamma_3}\right) \\ &= -\ln(\gamma_2 + t_m) Li_{1,1,1}\left(-\gamma_3, \frac{\gamma_1}{\gamma_3}, \frac{-t_m}{\gamma_1}\right) - I'(t_m). \end{aligned} \tag{24}$$

One then concludes that

$$I'(t_m) = -Li_{1,1,1,1}\left(-\gamma_3, \frac{\gamma_1}{\gamma_3}, \frac{\gamma_2}{\gamma_1}, \frac{-t_m}{\gamma_2}\right) - \ln(\gamma_2 + t_m) Li_{1,1,1}\left(-\gamma_3, \frac{\gamma_1}{\gamma_3}, \frac{-t_m}{\gamma_1}\right). \tag{25}$$

Finally, substituting $I'(t_m)$ and $I''(t_m)$ into Eq. (21) we write down the result for the integral of the required type Eq. (20),

$$\begin{aligned} &\int_0^{t_m} \mathrm{d}t \frac{\ln(1-t)\ln(\gamma_1 + t)\ln(\gamma_2 + t)}{\gamma_3 + t} \\ &\quad = \ln(\gamma_1 + t_m)\ln(\gamma_2 + t_m) Li_{1,1}\left(-\gamma_3, \frac{-t_m}{\gamma_3}\right) + \ln(\gamma_2 + t_m) Li_{1,1,1}\left(-\gamma_3, \frac{\gamma_1}{\gamma_3}, \frac{-t_m}{\gamma_1}\right) \\ &\qquad + \ln(\gamma_1 + t_m) Li_{1,1,1}\left(-\gamma_3, \frac{\gamma_2}{\gamma_3}, \frac{-t_m}{\gamma_2}\right) \\ &\qquad + Li_{1,1,1,1}\left(-\gamma_3, \frac{\gamma_2}{\gamma_3}, \frac{\gamma_1}{\gamma_2}, \frac{-t_m}{\gamma_1}\right) + Li_{1,1,1,1}\left(-\gamma_3, \frac{\gamma_1}{\gamma_3}, \frac{\gamma_2}{\gamma_1}, \frac{-t_m}{\gamma_2}\right). \end{aligned} \tag{26}$$

We are now in the position to collect all required contributions to express the L_{-++} function in terms of multiple polylogarithms. Taking into account Eqs. (11), (14), (19), and (26) and we obtain

$$
\begin{aligned}
L_{-++}(\alpha_1,\alpha_2,\alpha_3,\alpha_4) = {} & Li_{1,1,1,1}\left(-\frac{\alpha_4}{\alpha_1},\frac{\alpha_2}{\alpha_4},\frac{\alpha_3}{\alpha_2},-\frac{1}{\alpha_3}\right) + Li_{1,1,1,1}\left(-\frac{\alpha_4}{\alpha_1},\frac{\alpha_3}{\alpha_4},\frac{\alpha_2}{\alpha_3},-\frac{1}{\alpha_2}\right) \\
& + \ln\,\alpha_1 Li_{1,1,1}\left(\frac{\alpha_4}{\alpha_2},\frac{\alpha_3}{\alpha_4},-\frac{1}{\alpha_3}\right) + \ln(1+\alpha_2) Li_{1,1,1}\left(-\frac{\alpha_4}{\alpha_1},\frac{\alpha_3}{\alpha_4},-\frac{1}{\alpha_3}\right) \\
& + \ln(1+\alpha_3) Li_{1,1,1}\left(-\frac{\alpha_4}{\alpha_1},\frac{\alpha_2}{\alpha_4},-\frac{1}{\alpha_2}\right) + \ln\,\alpha_1\,\ln\,\alpha_2 Li_{1,1}\left(\frac{\alpha_4}{\alpha_3},-\frac{1}{\alpha_4}\right) \\
& + \ln\,\alpha_1\,\ln(1+\alpha_3) Li_{1,1}\left(\frac{\alpha_4}{\alpha_2},-\frac{1}{\alpha_4}\right) + \ln(1+\alpha_2)\ln(1+\alpha_3) Li_{1,1}\left(-\frac{\alpha_4}{\alpha_1},-\frac{1}{\alpha_4}\right) \\
& + \ln\,\alpha_1\,\ln\,\alpha_2\,\ln\,\alpha_3\,\ln\left(\frac{\alpha_4+1}{\alpha_4}\right). \qquad (27)
\end{aligned}
$$

Some remarks are in order at this place. The final formula (27) contains multiple polylogarithms up to weight four. All multiple polylogarithms up to weight three can be expressed in terms of logarithms and clasical polylogarithms Li_2 and Li_3. This fact is used by us when we reexpress our results for the massive scalar integrals in terms of multiple polylogarithms, i.e., our final results will contain only multiple polylogarithms of weight four. For the variables α_i the conditions (5) are assumed. But in the results for the massive scalar integrals there are also cases when $\alpha_1=1$ and/or $\alpha_2=0$ and/or $\alpha_3=0$ and/or $\alpha_4=\{-1,0\}$. In such cases the general formula (27) is no longer valid and these cases must be studied separately.

B. Special cases for the L_{-++} function

In the Laurent series expansion of the massive scalar one-loop integrals one encounters special values of the arguments α_i for which the general formula Eq. (27) no longer applies. This is quite obvious from the list of special cases discussed in the following.

1. $\alpha_1=1$, $\alpha_4=0$

In such case one can make use of Eq. (26). One should find the limit of the expression on the right-hand side for $t_m=1$, $\gamma_3\to 0$. One obtains

$$
\begin{aligned}
\int_0^1 \mathrm{d}t \frac{\ln(1-t)\ln(\gamma_1+t)\ln(\gamma_2+t)}{t} = \lim_{\gamma_3\to 0}\Bigg\{ & \ln(\gamma_1+1)\ln(\gamma_2+1)\int_0^1 \frac{\mathrm{d}t_2}{-\gamma_3-t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{1-t_1} \\
& + \ln(\gamma_2+1)\int_0^1 \frac{\mathrm{d}t_3}{-\gamma_1-t_3}\int_0^{t_3}\frac{\mathrm{d}t_2}{-\gamma_3-t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{1-t_1} \\
& + \ln(\gamma_1+1)\int_0^1 \frac{\mathrm{d}t_3}{-\gamma_2-t_3}\int_0^{t_3}\frac{\mathrm{d}t_2}{-\gamma_3-t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{1-t_1} \\
& + \int_0^1 \frac{\mathrm{d}t_4}{-\gamma_1-t_3}\int_0^{t_4}\frac{\mathrm{d}t_3}{-\gamma_2-t_3}\int_0^{t_3}\frac{\mathrm{d}t_2}{-\gamma_3-t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{1-t_1} \\
& + \int_0^1 \frac{\mathrm{d}t_4}{-\gamma_2-t_3}\int_0^{t_4}\frac{\mathrm{d}t_3}{-\gamma_1-t_3}\int_0^{t_3}\frac{\mathrm{d}t_2}{-\gamma_3-t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{1-t_1}\Bigg\} \\
= {} & -\ln(\gamma_1+1)\ln(\gamma_2+1)\int_0^1 \frac{\mathrm{d}t_2}{t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{1-t_1} \\
& - \ln(\gamma_2+1)\int_0^1 \frac{\mathrm{d}t_3}{-\gamma_1-t_3}\int_0^{t_3}\frac{\mathrm{d}t_2}{t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{1-t_1}
\end{aligned}
$$

$$
\begin{aligned}
&- \ln(\gamma_1+1)\int_0^1 \frac{dt_3}{-\gamma_2-t_3}\int_0^{t_3}\frac{dt_2}{t_2}\int_0^{t_2}\frac{dt_1}{1-t_1}\\
&-\int_0^1 \frac{dt_4}{-\gamma_1-t_3}\int_0^{t_4}\frac{dt_3}{-\gamma_2-t_3}\int_0^{t_3}\frac{dt_2}{t_2}\int_0^{t_2}\frac{dt_1}{1-t_1}\\
&-\int_0^1 \frac{dt_4}{-\gamma_2-t_3}\int_0^{t_4}\frac{dt_3}{-\gamma_1-t_3}\int_0^{t_3}\frac{dt_2}{t_2}\int_0^{t_2}\frac{dt_1}{1-t_1}. \qquad (28)
\end{aligned}
$$

In order to get the expression under the sign of the limit in Eq. (28) one applies the definition (7) for the multiple polylogarithms in Eq. (26). Using the same definition for the final multidimensional integrals in (28) and making the change $\gamma_1\to\alpha_2$, $\gamma_2\to\alpha_3$ one finally arrives at the result for the case $\alpha_1=1$ and $\alpha_4=0$,

$$
\begin{aligned}
L_{-++}(1,\alpha_2,\alpha_3,0) &= -Li_{2,1,1}\left(-\alpha_3,\frac{\alpha_2}{\alpha_3},-\frac{1}{\alpha_2}\right)-Li_{2,1,1}\left(-\alpha_2,\frac{\alpha_3}{\alpha_2},-\frac{1}{\alpha_3}\right)-\ln(\alpha_3+1)Li_{2,1}\left(-\alpha_2,-\frac{1}{\alpha_2}\right)\\
&\quad -\ln(\alpha_2+1)Li_{2,1}\left(-\alpha_3,-\frac{1}{\alpha_3}\right)-\ln(\alpha_2+1)\ln(\alpha_3+1)\zeta(2). \qquad (29)
\end{aligned}
$$

2. $\alpha_1=1$, $\alpha_2=\alpha_3=0$

For these values of the parameters α_i one has an integral of the very simple form

$$
L_{-++}(1,0,0,\alpha_4)=\int_0^1 dy\frac{\ln(1-y)\ln^2 y}{\alpha_4+y}.
$$

After a change of variable $y\to 1-t$ one gets

$$
\begin{aligned}
\int_0^1 dt\frac{\ln t\ln^2(1-t)}{\alpha_4+1-t} &= -\int_0^1 dt_1\frac{\ln^2(1-t_1)}{\alpha_4+1-t_1}\int_{t_1}^1\frac{dt_2}{t_2}\\
&= -\int_0^1\frac{dt_2}{t_2}\int_0^{t_2}dt_1\frac{\ln^2(1-t_1)}{\alpha_4+1-t_1}\\
&= -2\int_0^1\frac{dt_2}{t_2}\int_0^{t_2}\frac{dt_1}{\alpha_4+1-t_1}\int_0^{t_1}\frac{dt_3}{1-t_3}\int_0^{t_3}\frac{dt_4}{1-t_4}. \qquad (30)
\end{aligned}
$$

Applying the definition (7) one obtains

$$
L_{-++}(1,0,0,\alpha_4)=-2Li_{1,1,2}\left(1,\alpha_4+1,\frac{1}{\alpha_4+1}\right). \qquad (31)
$$

3. $\alpha_1=1$, $\alpha_2=0$ (and $\alpha_4=-1$)

We shall again find the limit of the rhs of (26) for $t_m=1$ and $\gamma_1\to 0$. The first and the third terms are equal to 0 because of the limit $\lim_{\gamma_1\to 0}\ln(\gamma_1+1)=0$. The other terms transform into

$$
\lim_{\gamma_1\to 0} Li_{1,1,1}\left(-\gamma_3,\frac{\gamma_1}{\gamma_3},\frac{-1}{\gamma_1}\right)=-Li_{1,2}\left(-\gamma_3,-\frac{1}{\gamma_3}\right),
$$

$$
\lim_{\gamma_1\to 0} Li_{1,1,1,1}\left(-\gamma_3,\frac{\gamma_2}{\gamma_3},\frac{\gamma_1}{\gamma_2},\frac{-t_m}{\gamma_1}\right)=-Li_{1,1,2}\left(-\gamma_3,\frac{\gamma_2}{\gamma_3},\frac{-1}{\gamma_2}\right),
$$

$$\lim_{\gamma_1\to 0} Li_{1,1,1,1}\left(-\gamma_3,\frac{\gamma_1}{\gamma_3},\frac{\gamma_2}{\gamma_1},\frac{-t_m}{\gamma_2}\right)=-Li_{1,2,1}\left(-\gamma_3,\frac{\gamma_2}{\gamma_3},\frac{-1}{\gamma_2}\right).$$

Finally we write

$$L_{-++}(1,0,\alpha_3,\alpha_4)=-Li_{1,1,2}\left(-\alpha_4,\frac{\alpha_3}{\alpha_4},\frac{-1}{\alpha_3}\right)-Li_{1,2,1}\left(-\alpha_4,\frac{\alpha_3}{\alpha_4},\frac{-1}{\alpha_3}\right)-\ln(\alpha_3+1)Li_{1,2}\left(-\alpha_4,-\frac{1}{\alpha_4}\right). \tag{32}$$

For the special case $\alpha_4=-1$ one gets

$$L_{-++}(1,0,\alpha_3,-1)=-Li_{1,1,2}\left(1,-\alpha_3,\frac{-1}{\alpha_3}\right)-Li_{1,2,1}\left(1,-\alpha_3,\frac{-1}{\alpha_3}\right)-\ln(\alpha_3+1)\zeta(3). \tag{33}$$

4. $\alpha_2=\alpha_3=0$ (and $\alpha_4=-1$)

In this case one proceeds along the following lines:

$$\begin{aligned}
L_{-++}(\alpha_1,0,0,\alpha_4)&=\int_0^1 dy\frac{\ln(\alpha_1-y)\ln^2 y}{\alpha_4+y}\overset{y\to 1-t}{=}\int_0^1 dt\frac{\ln(\alpha_1-1+t)\ln^2(1-t)}{\alpha_4+1-t}\\
&=-\int_0^1 dt_1\frac{\ln^2(1-t_1)}{-\alpha_4-1+t_1}\int_{-\alpha_1+2}^{t_1}\frac{dt_2}{\alpha_1-1+t_2}\\
&=-\int_0^1 dt_1\frac{\ln^2(1-t_1)}{-\alpha_4-1+t_1}\left\{\int_1^{t_1}+\int_{-\alpha_1+2}^1\right\}\frac{dt_2}{\alpha_1-1+t_2}\\
&=\int_0^1\frac{dt_2}{\alpha_1-1+t_2}\int_0^{t_2}dt_1\frac{\ln^2(1-t_1)}{-\alpha_4-1+t_1}-\ln\alpha_1\int_0^1 dt_1\frac{\ln^2(1-t_1)}{-\alpha_4-1+t_1}\\
&=2\int_0^1\frac{dt_2}{\alpha_1-1+t_2}\int_0^{t_2}\frac{dt_1}{-\alpha_4-1+t_1}\int_0^{t_1}\frac{dt_3}{1-t_3}\int_0^{t_3}\frac{dt_4}{1-t_4}-2\ln\alpha_1 Li_3\left(-\frac{1}{\alpha_4}\right).
\end{aligned} \tag{34}$$

Using the definition (7) we arrive at the result

$$L_{-++}(\alpha_1,0,0,\alpha_4)=2Li_{1,1,1,1}\left(1,\alpha_4+1,\frac{1-\alpha_1}{\alpha_4+1},\frac{1}{1-\alpha_1}\right)-2\ln\alpha_1 Li_3\left(-\frac{1}{\alpha_4}\right). \tag{35}$$

For the case $\alpha_4=-1$ one obtains

$$L_{-++}(\alpha_1,0,0,-1)=-2Li_{1,2,1}\left(1,1-\alpha_1,\frac{1}{1-\alpha_1}\right)-2\ln\alpha_1\zeta(3). \tag{36}$$

5. $\alpha_2=0$ (and $\alpha_4=-1$)

For this integral we change the integration variable $y\to 1-t$,

$$\int_0^1 \mathrm{d}y \frac{\ln(\alpha_1 - y)\ln y \ln(\alpha_3 + y)}{\alpha_4 + y} = \int_0^1 \mathrm{d}t \frac{\ln(1-t)\ln(\alpha_1 - 1 + t)\ln(\alpha_3 + 1 - t)}{\alpha_4 + 1 - t}$$
$$= \int_0^1 \mathrm{d}t \frac{\ln(1-t)\ln(\gamma_1 + t)\ln(\gamma_2 - t)}{\gamma_3 - t}. \tag{37}$$

One notes that the last integral is an analog of the integral in Eq. (26). The calculation proceeds in a similar way,

$$\begin{aligned}
&- Li_{1,1,1,1}\left(\gamma_3, \frac{\gamma_2}{\gamma_3}, -\frac{\gamma_1}{\gamma_2}, -\frac{1}{\gamma_1}\right) \\
&= \int_0^1 \frac{\mathrm{d}t_4}{\gamma_1 + t_4} \int_0^{t_4} \frac{\mathrm{d}t_3}{\gamma_2 - t_3} \int_0^{t_3} \frac{\mathrm{d}t_2}{\gamma_3 - t_2} \int_0^{t_2} \frac{\mathrm{d}t_1}{1 - t_1} \\
&= -\int_0^{t_m} \frac{\mathrm{d}t_4}{\gamma_1 + t_4} \int_0^{t_4} \frac{\mathrm{d}t_3}{\gamma_2 - t_3} \int_0^{t_3} \mathrm{d}t_2 \frac{\ln(1-t_2)}{\gamma_3 - t_2} = -\int_0^{t_m} \frac{\mathrm{d}t_4}{\gamma_1 + t_4} \int_0^{t_4} \mathrm{d}t_2 \frac{\ln(1-t_2)}{\gamma_3 - t_2} \int_{t_2}^{t_4} \frac{\mathrm{d}t_3}{\gamma_2 - t_3} \\
&= \int_0^1 \mathrm{d}t_4 \frac{\ln(\gamma_2 - t_4)}{\gamma_1 + t_4} \int_0^{t_4} \mathrm{d}t_2 \frac{\ln(1-t_2)}{\gamma_3 - t_2} - \int_0^1 \frac{\mathrm{d}t_4}{\gamma_1 + t_4} \int_0^{t_4} \mathrm{d}t_2 \frac{\ln(1-t_2)\ln(\gamma_2 - t_2)}{\gamma_3 - t_2} \\
&= Y'(1) - \int_0^1 \mathrm{d}t_2 \frac{\ln(1-t_2)\ln(\gamma_2 - t_2)}{\gamma_3 - t_2} \int_{t_2}^1 \frac{\mathrm{d}t_4}{\gamma_1 + t_4} \\
&= Y'(1) - \ln(\gamma_1 + 1) \int_0^1 \mathrm{d}t_2 \frac{\ln(1-t_2)\ln(\gamma_2 - t_2)}{\gamma_3 - t_2} + \int_0^1 \mathrm{d}t_2 \frac{\ln(1-t_2)\ln(\gamma_1 + t_2)\ln(\gamma_2 - t_2)}{\gamma_3 - t_2} \\
&= Y'(1) - Y''(1) + \int_0^1 \mathrm{d}t_2 \frac{\ln(1-t_2)\ln(\gamma_1 + t_2)\ln(\gamma_2 - t_2)}{\gamma_3 - t_2},
\end{aligned} \tag{38}$$

where we have introduced the notation

$$Y'(t_m) = \int_0^{t_m} \mathrm{d}t_4 \frac{\ln(\gamma_2 - t_4)}{\gamma_1 + t_4} \int_0^{t_4} \mathrm{d}t_2 \frac{\ln(1-t_2)}{\gamma_3 - t_2},$$

$$Y''(t_m) = \ln(\gamma_1 + t_m) \int_0^{t_m} \mathrm{d}t_2 \frac{\ln(1-t_2)\ln(\gamma_2 - t_2)}{\gamma_3 - t_2}. \tag{39}$$

The last term in (38) is the required integral. The expansion of the integral $Y'(t_m)$ in terms of multiple polylogarithms is similar to the evaluation of $I'(t_m)$ in Eq. (22). The result of the calculation is

$$Y'(t_m) = Li_{1,1,1,1}\left(\gamma_3, -\frac{\gamma_1}{\gamma_3}, -\frac{\gamma_2}{\gamma_1}, \frac{t_m}{\gamma_2}\right) + \ln(\gamma_2 - t_m) Li_{1,1,1}\left(\gamma_3, -\frac{\gamma_1}{\gamma_3}, -\frac{t_m}{\gamma_1}\right). \tag{40}$$

For the calculation of $Y''(t_m)$ one can make use of (18). Finally using Eqs. (38) and (40) one arrives at the result

$$\int_0^1 \mathrm{d}t \frac{\ln(1-t)\ln(\gamma_1+t)\ln(\gamma_2-t)}{\gamma_3-t} = -Li_{1,1,1,1}\left(\gamma_3,-\frac{\gamma_1}{\gamma_3},-\frac{\gamma_2}{\gamma_1},\frac{1}{\gamma_2}\right)$$
$$-Li_{1,1,1,1}\left(\gamma_3,\frac{\gamma_2}{\gamma_3},-\frac{\gamma_1}{\gamma_2},-\frac{1}{\gamma_1}\right)-\ln(\gamma_1+1)Li_{1,1,1}\left(\gamma_3,\frac{\gamma_2}{\gamma_3},\frac{1}{\gamma_2}\right)$$
$$-\ln(\gamma_2-1)Li_{1,1,1}\left(\gamma_3,-\frac{\gamma_1}{\gamma_3},-\frac{1}{\gamma_1}\right)$$
$$-\ln(\gamma_1+1)\ln(\gamma_2-1)Li_{1,1}\left(\gamma_3,\frac{1}{\gamma_3}\right). \tag{41}$$

To obtain the formula for the L function with $\alpha_2=0$ we must only change γ_1, γ_2, and γ_3 to α_1-1, α_3+1, and α_4+1 according to Eq. (37):

$$L_{-++}(\alpha_1,0,\alpha_3,\alpha_4)=\int_0^1 \mathrm{d}y \frac{\ln(\alpha_1-y)\ln y\ln(\alpha_3+y)}{\alpha_4+y} = -Li_{1,1,1,1}\left(1+\alpha_4,\frac{1-\alpha_1}{1+\alpha_4},\frac{1+\alpha_3}{1-\alpha_1},\frac{1}{1+\alpha_3}\right)$$
$$-Li_{1,1,1,1}\left(1+\alpha_4,\frac{1+\alpha_3}{1+\alpha_4},\frac{1-\alpha_1}{1+\alpha_3},\frac{1}{1-\alpha_1}\right)-\ln\alpha_1 Li_{1,1,1}\left(1+\alpha_4,\frac{1+\alpha_3}{1+\alpha_4},\frac{1}{1+\alpha_3}\right)$$
$$-\ln\alpha_3 Li_{1,1,1}\left(1+\alpha_4,\frac{1-\alpha_1}{1+\alpha_4},\frac{1}{1-\alpha_1}\right)-\ln\alpha_1\ln\alpha_3 Li_{1,1}\left(1+\alpha_4,\frac{1}{1+\alpha_4}\right). \tag{42}$$

For the case $\alpha_4=-1$ we calculate the limit of the rhs of (42) for $\alpha_4\to-1$ and obtain

$$L_{-++}(\alpha_1,0,\alpha_3,-1)=Li_{2,1,1}\left(1-\alpha_1,\frac{1+\alpha_3}{1-\alpha_1},\frac{1}{1+\alpha_3}\right)$$
$$+Li_{2,1,1}\left(1+\alpha_3,\frac{1-\alpha_1}{1+\alpha_3},\frac{1}{1-\alpha_1}\right)+\ln\alpha_1 Li_{2,1}\left(1+\alpha_3,\frac{1}{1+\alpha_3}\right)$$
$$+\ln\alpha_3 Li_{2,1}\left(1-\alpha_1,\frac{1}{1-\alpha_1}\right)+\ln\alpha_1\ln\alpha_3\zeta(2). \tag{43}$$

IV. TRANSFORMATION OF L_{+++} TO MULTIPLE POLYLOGARITHMS

In this section we will show that all our L_{+++} functions can be expressed in terms of multiple polylogarithms.

A. General case for the L_{+++} function

We now proceed with the transformation of the triple index function L_{+++}

$$L_{+++}(\alpha_1,\alpha_2,\alpha_3,\alpha_4)=\int_0^1 \mathrm{d}y \frac{\ln(\alpha_1+y)\ln(\alpha_2+y)\ln(\alpha_3+y)}{\alpha_4+y}. \tag{44}$$

After changing the integration variable $y=-\alpha_1 t$ we obtain

$$
\begin{aligned}
&-\int_0^{-1/\alpha_1} \mathrm{d}t \frac{\ln(\alpha_1-\alpha_1 t)\ln(\alpha_2-\alpha_1 t)\ln(\alpha_3-\alpha_1 t)}{\frac{\alpha_4}{\alpha_1}-t} \\
&\quad = -\int_0^{-1/\alpha_1} \mathrm{d}t \frac{\ln\alpha_1 \ln(\alpha_2-\alpha_1 t)\ln(\alpha_3+\alpha_1 t)}{\frac{\alpha_4}{\alpha_1}-t} \\
&\qquad -\int_0^{-1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)\left[\ln\alpha_1+\ln\left(\frac{\alpha_2}{\alpha_1}-t\right)\right]\left[\ln\alpha_1+\ln\left(\frac{\alpha_3}{\alpha_1}-t\right)\right]}{\frac{\alpha_4}{\alpha_1}-t} \\
&\quad = \ln\alpha_1 \int_0^1 \mathrm{d}y \frac{\ln(\alpha_2+y)\ln(\alpha_3+y)}{\alpha_4+y} - \ln^2\alpha_1 \int_0^{-1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)}{\frac{\alpha_4}{\alpha_1}-t} \\
&\qquad -\ln\alpha_1 \int_0^{-1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)\ln\left(\frac{\alpha_2}{\alpha_1}-t\right)}{\frac{\alpha_4}{\alpha_1}-t} - \ln\alpha_1 \int_0^{-1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)\ln\left(\frac{\alpha_3}{\alpha_1}-t\right)}{\frac{\alpha_4}{\alpha_1}-t} \\
&\qquad -\int_0^{-1/\alpha_1} \mathrm{d}t \frac{\ln(1-t)\ln\left(\frac{\alpha_2}{\alpha_1}-t\right)\ln\left(\frac{\alpha_3}{\alpha_1}-t\right)}{\frac{\alpha_4}{\alpha_1}-t}.
\end{aligned} \tag{45}
$$

The first integral on the rhs of (45) has been calculated in Eq. (19). For the second integral one makes use of the formula (17) (the only change is $\alpha_2 \to \alpha_1$). For the evaluation of the third and fourth integrals one uses Eq. (18). We are left with the most complicated fifth integral. Let us consider an integral of the type

$$
\int_0^{t_m} \mathrm{d}t \frac{\ln(1-t)\ln(\gamma_1-t)\ln(\gamma_2-t)}{\gamma_3-t}. \tag{46}
$$

This integral is an analog of the integral in Eq. (26). The calculation proceeds in a similar way. One obtains the result

$$
\begin{aligned}
\int_0^{t_m} \mathrm{d}t \frac{\ln(1-t)\ln(\gamma_1-t)\ln(\gamma_2-t)}{\gamma_3-t} &= -\ln(\gamma_1-t_m)\ln(\gamma_2-t_m) Li_{1,1}\left(\gamma_3, \frac{t_m}{\gamma_3}\right) \\
&\quad -\ln(\gamma_2-t_m) Li_{1,1,1}\left(\gamma_3, \frac{\gamma_1}{\gamma_3}, \frac{t_m}{\gamma_1}\right) \\
&\quad -\ln(\gamma_1-t_m) Li_{1,1,1}\left(\gamma_3, \frac{\gamma_2}{\gamma_3}, \frac{t_m}{\gamma_2}\right) - Li_{1,1,1,1}\left(\gamma_3, \frac{\gamma_2}{\gamma_3}, \frac{\gamma_1}{\gamma_2}, \frac{t_m}{\gamma_1}\right) \\
&\quad - Li_{1,1,1,1}\left(\gamma_3, \frac{\gamma_1}{\gamma_3}, \frac{\gamma_2}{\gamma_1}, \frac{t_m}{\gamma_2}\right).
\end{aligned} \tag{47}
$$

Taking into account everything mentioned above for Eq. (45) we arrive at the final result for the L_{+++} function,

$$
\begin{aligned}
L_{+++}(\alpha_1,\alpha_2,\alpha_3,\alpha_4) &= Li_{1,1,1,1}\left(\frac{\alpha_4}{\alpha_1},\frac{\alpha_2}{\alpha_4},\frac{\alpha_3}{\alpha_2},-\frac{1}{\alpha_3}\right)+Li_{1,1,1,1}\left(\frac{\alpha_4}{\alpha_1},\frac{\alpha_3}{\alpha_4},\frac{\alpha_2}{\alpha_3},-\frac{1}{\alpha_2}\right)\\
&\quad+\ln\alpha_1 Li_{1,1,1}\left(\frac{\alpha_4}{\alpha_2},\frac{\alpha_3}{\alpha_4},-\frac{1}{\alpha_3}\right)+\ln(1+\alpha_2)Li_{1,1,1}\left(\frac{\alpha_4}{\alpha_1},\frac{\alpha_3}{\alpha_4},-\frac{1}{\alpha_3}\right)\\
&\quad+\ln(1+\alpha_3)Li_{1,1,1}\left(\frac{\alpha_4}{\alpha_1},\frac{\alpha_2}{\alpha_4},-\frac{1}{\alpha_2}\right)+\ln\alpha_1\ln\alpha_2 Li_{1,1}\left(\frac{\alpha_4}{\alpha_3},-\frac{1}{\alpha_4}\right)\\
&\quad+\ln\alpha_1\ln(1+\alpha_3)Li_{1,1}\left(\frac{\alpha_4}{\alpha_2},-\frac{1}{\alpha_4}\right)+\ln(1+\alpha_2)\ln(1+\alpha_3)Li_{1,1}\left(\frac{\alpha_4}{\alpha_1},-\frac{1}{\alpha_4}\right)\\
&\quad+\ln\alpha_1\ln\alpha_2\ln\alpha_3\ln\left(\frac{\alpha_4+1}{\alpha_4}\right). \qquad (48)
\end{aligned}
$$

For this equation the conditions (5) are assumed. We emphasize that the arguments of L_{+++} functions occurring in the actual calculation of the massive scalar one-loop integrals are not of the most general type as assumed in the derivation of (48). We have nevertheless included a discussion of the general case because Eq. (48) may be useful in other applications. In the results for the massive scalar integrals one has only the special cases where $\alpha_1=\alpha_2$ or $\alpha_1=\alpha_3$ as well as the cases $\alpha_1=0$ and/or $\alpha_2=0$ and/or $\alpha_3=0$ and/or $\alpha_4=\{-1,0\}$. If some α's coincide with each other Eq. (48) becomes simpler. In this case one can also make use of symmetry properties to obtain simpler relations between the L_{+++} functions and multiple polylogarithms. For the cases $\alpha_1=0$ and/or $\alpha_2=0$ and/or $\alpha_3=0$ and/or $\alpha_4=\{-1,0\}$ the general formula (48) is no longer valid and these cases must be studied separately.

B. Special cases for the L_{+++} function

In the Laurent series expansion of the massive scalar one-loop integrals the following special cases for the α_i are present.

1. $\alpha_1=\alpha_2$ or $\alpha_1=\alpha_3$

As it was stated in Sec. II the L_{+++} function is symmetric under the permutations $\alpha_i\leftrightarrow\alpha_j$. Therefore, it suffices to consider the case $\alpha_1=\alpha_2$.

We must evaluate the integral

$$
L_{+++}(\alpha_1,\alpha_1,\alpha_3,\alpha_4)=\int_0^1 dy\frac{\ln^2(\alpha_1+y)\ln(\alpha_3+y)}{\alpha_4+y}. \qquad (49)
$$

This integral can be expressed in different ways. First of all one can directly use Eq. (48) replacing α_2 by α_1. The second possibility is to use symmetry properties. One takes into account the rhs of Eq. (48) and notes that the part with multiple polylogarithms of weight four is symmetric under the exchange $\alpha_2\leftrightarrow\alpha_3$. It allows one to reduce the number of the multiple polylogarithms from two to one. First we apply Eq. (48) for the case $\alpha_2=\alpha_3$ replacing α_3 by α_2. Second we change $\alpha_1\rightarrow\alpha_3$ and $\alpha_2\rightarrow\alpha_1$. After these transformations one obtains the following result:

$$
\begin{aligned}
L_{+++}(\alpha_1,\alpha_1,\alpha_3,\alpha_4) &= \int_0^1 dy\frac{\ln^2(\alpha_1+y)\ln(\alpha_3+y)}{\alpha_4+y}\\
&= +2Li_{1,1,1,1}\left(\frac{\alpha_4}{\alpha_3},\frac{\alpha_1}{\alpha_4},1,-\frac{1}{\alpha_1}\right)+\ln\alpha_3 Li_{1,1,1}\left(\frac{\alpha_4}{\alpha_1},\frac{\alpha_1}{\alpha_4},-\frac{1}{\alpha_1}\right)\\
&\quad+2\ln(1+\alpha_1)Li_{1,1,1}\left(\frac{\alpha_4}{\alpha_3},\frac{\alpha_1}{\alpha_4},-\frac{1}{\alpha_1}\right)+\ln\alpha_3[\ln(\alpha_1+1)+\ln\alpha_1]Li_{1,1}\left(\frac{\alpha_4}{\alpha_1},-\frac{1}{\alpha_4}\right)
\end{aligned}
$$

$$+\ln^2(1+\alpha_1)Li_{1,1}\left(\frac{\alpha_4}{\alpha_3},-\frac{1}{\alpha_4}\right)+\ln^2\alpha_1\ln\alpha_3\ln\left(\frac{\alpha_4+1}{\alpha_4}\right). \tag{50}$$

There is also the third possibility to express $L_{+++}(\alpha_1,\alpha_1,\alpha_3,\alpha_4)$ in terms of multiple polylogarithms:

$$\begin{aligned}
&\int_0^1 \mathrm{d}y\frac{\ln^2(\alpha_1+y)\ln(\alpha_3+y)}{\alpha_4+y}\\
&\overset{y\to-\alpha_1 t}{=} -\int_0^{-1/\alpha_1}\mathrm{d}t\frac{\ln^2(\alpha_1-\alpha_1 t)\ln(\alpha_3-\alpha_1 t)}{\frac{\alpha_4}{\alpha_1}-t}\\
&=-\int_0^{-1/\alpha_1}\mathrm{d}t\frac{[\ln^2\alpha_1+2\ln\alpha_1\ln(1-t)+\ln^2(1-t)]\left[\ln\alpha_1+\ln\left(\frac{\alpha_3}{\alpha_1}-t\right)\right]}{\frac{\alpha_4}{\alpha_1}-t}\\
&=+\ln^3\alpha_1\int_0^1\frac{\mathrm{d}y}{\alpha_4+y}+\ln^2\alpha_1\int_0^1\mathrm{d}y\frac{\ln(\alpha_3+y)}{\alpha_4+y}-2\ln^2\alpha_1\int_0^{-1/\alpha_1}\mathrm{d}t\frac{\ln(1-t)}{\frac{\alpha_4}{\alpha_1}-t}\\
&\quad-\ln\alpha_1\int_0^{-1/\alpha_1}\mathrm{d}t\frac{\ln^2(1-t)}{\frac{\alpha_4}{\alpha_1}-t}-2\ln\alpha_1\int_0^{-1/\alpha_1}\mathrm{d}t\frac{\ln(1-t)\ln\left(\frac{\alpha_3}{\alpha_1}-t\right)}{\frac{\alpha_4}{\alpha_1}-t}\\
&\quad-\int_0^{-1/\alpha_1}\mathrm{d}t\frac{\ln^2(1-t)\ln\left(\frac{\alpha_3}{\alpha_1}-t\right)}{\frac{\alpha_4}{\alpha_1}-t}.
\end{aligned} \tag{51}$$

The first term can be integrated immediately. For the second and third term one uses Eq. (16) and Eq. (17), respectively. The integral of the fourth term can be rewritten as

$$\int_0^{-1/\alpha_1}\mathrm{d}t\frac{\ln^2(1-t)}{\frac{\alpha_4}{\alpha_1}-t}=2\int_0^{-1/\alpha_1}\frac{\mathrm{d}t_1}{\frac{\alpha_4}{\alpha_1}-t_1}\int_0^{t_1}\frac{\mathrm{d}t_2}{1-t_2}\int_0^{t_2}\frac{\mathrm{d}t_3}{1-t_3}=2Li_{1,1,1}\left(1,\frac{\alpha_4}{\alpha_1},\frac{-1}{\alpha_4}\right). \tag{52}$$

The fifth term is calculable with Eq. (14). To integrate the last term one first evaluates the following integral:

$$\begin{aligned}
\int_0^{t_m}\mathrm{d}t\frac{\ln^2(1-t)\ln(\beta_1-t)}{\beta_2-t}&=-\int_0^{t_m}\mathrm{d}t_1\frac{\ln^2(1-t_1)}{\beta_2-t_1}\left\{\int_{t_m}^{t_1}+\int_{\beta_1-1}^{t_m}\right\}\frac{\mathrm{d}t_2}{\beta_1-t_2}\\
&=\int_0^{t_m}\frac{\mathrm{d}t_2}{\beta_1-t_2}\int_0^{t_2}\mathrm{d}t_1\frac{\ln^2(1-t_1)}{\beta_2-t_1}+\ln(\beta_1-t_m)\int_0^{t_m}\mathrm{d}t\frac{\ln^2(1-t)}{\beta_2-t}\\
&=2Li_{1,1,1,1}\left(1,\beta_2,\frac{\beta_1}{\beta_2},\frac{t_m}{\beta_1}\right)+2\ln(\beta_1-t_m)Li_{1,1,1}\left(1,\beta_2,\frac{t_m}{\beta_2}\right).
\end{aligned} \tag{53}$$

Then to calculate the last term of Eq. (51) one only has to change β_1, β_2, and t_m by the corresponding combinations of α_i. Finally we arrive at the result for the $L_{+++}(\alpha_1,\alpha_1,\alpha_3,\alpha_4)$ function,

$$L_{+++}(\alpha_1,\alpha_1,\alpha_3,\alpha_4) = -2Li_{1,1,1,1}\left(1,\frac{\alpha_4}{\alpha_1},\frac{\alpha_3}{\alpha_4},-\frac{1}{\alpha_3}\right) - 2\ln(\alpha_3+1)Li_{1,1,1}\left(1,\frac{\alpha_4}{\alpha_1},-\frac{1}{\alpha_4}\right)$$
$$+ 2\ln\alpha_1 Li_{1,1,1}\left(\frac{\alpha_4}{\alpha_1},\frac{\alpha_3}{\alpha_4},-\frac{1}{\alpha_3}\right) + 2\ln\alpha_1\ln(\alpha_3+1)Li_{1,1}\left(\frac{\alpha_4}{\alpha_1},-\frac{1}{\alpha_4}\right)$$
$$+ \ln^2\alpha_1 Li_{1,1}\left(\frac{\alpha_4}{\alpha_3},-\frac{1}{\alpha_4}\right) + \ln^2\alpha_1\ln\alpha_3\ln\left(\frac{\alpha_4+1}{\alpha_4}\right). \tag{54}$$

This is the third possibility to express $L_{+++}(\alpha_1,\alpha_1,\alpha_3,\alpha_4)$ function in terms of multiple polylogaritms. Each of the Eqs. (50) and (54) contains only one multiple polylogarithm of weight four and they are both equally acceptable from this point of view. One has a free choice to apply any of these equations for the required L functions. The situation with the $L_{+++}(\alpha_1,\alpha_1,\alpha_3,\alpha_4)$ function is an example of the statement that the expansion of the L functions in terms of multiple polylogarithms is not unique.

2. $\alpha_1=0$ (or $\alpha_2=0$ or $\alpha_3=0$)

For this integral we change the integration variable $y\to 1-t$,

$$L_{+++}(0,\alpha_2,\alpha_3,\alpha_4) = \int_0^1 dy\frac{\ln y\ln(\alpha_2+y)\ln(\alpha_3+y)}{\alpha_4+y} = \int_0^1 dt\frac{\ln(1-t)\ln(\alpha_2+1-t)\ln(\alpha_3+1-t)}{\alpha_4+1-t} \tag{55}$$

and using Eq. (48) we arrive at the result

$$L_{+++}(0,\alpha_2,\alpha_3,\alpha_4) = -Li_{1,1,1,1}\left(1+\alpha_4,\frac{1+\alpha_2}{1+\alpha_4},\frac{1+\alpha_3}{1+\alpha_2},\frac{1}{1+\alpha_3}\right)$$
$$- Li_{1,1,1,1}\left(1+\alpha_4,\frac{1+\alpha_3}{1+\alpha_4},\frac{1+\alpha_2}{1+\alpha_3},\frac{1}{1+\alpha_2}\right)$$
$$- \ln\alpha_2 Li_{1,1,1}\left(1+\alpha_4,\frac{1+\alpha_3}{1+\alpha_4},\frac{1}{1+\alpha_3}\right) - \ln\alpha_3 Li_{1,1,1}\left(1+\alpha_4,\frac{1+\alpha_2}{1+\alpha_4},\frac{1}{1+\alpha_2}\right)$$
$$- \ln\alpha_2\ln\alpha_3 Li_{1,1}\left(1+\alpha_4,\frac{1}{1+\alpha_4}\right). \tag{56}$$

3. $\alpha_1=\alpha_2=0$

To calculate this integral we again change the integration variable $y\to 1-t$,

$$L_{+++}(0,0,\alpha_3,\alpha_4) = \int_0^1 dy\frac{\ln^2 y\ln(\alpha_3+y)}{\alpha_4+y} = \int_0^1 dt\frac{\ln^2(1-t)\ln(\alpha_3+1-t)}{\alpha_4+1-t}. \tag{57}$$

For the last integral we use Eq. (53). An additional simplification can be done if one notes that

$$Li_{1,1,1}\left(1,\alpha_4+1,\frac{1}{\alpha_4+1}\right) = -Li_3\left(-\frac{1}{\alpha_4}\right). \tag{58}$$

Finally one has

$$L_{+++}(0,0,\alpha_3,\alpha_4) = 2Li_{1,1,1,1}\left(1,\alpha_4+1,\frac{\alpha_3+1}{\alpha_4+1},\frac{1}{\alpha_3+1}\right) - 2\ln\alpha_3 Li_3\left(-\frac{1}{\alpha_4}\right). \tag{59}$$

4. $\alpha_1=\alpha_2=0$, $\alpha_4=-1$ (or $\alpha_2=\alpha_3=0$, $\alpha_4=-1$)

In this case one should calculate the limit of the rhs of (59) for $t_m=1$ and $\alpha_4\to-1$. After this procedure one obtains

$$L_{+++}(0,0,\alpha_3,-1)=-2Li_{1,2,1}\left(1,\alpha_3+1,\frac{1}{\alpha_3+1}\right)-2\ln\alpha_3\zeta(3). \tag{60}$$

For the case $\alpha_2=\alpha_3=0$ and $\alpha_4=-1$ one can use the same formula. The only change is $\alpha_3\to\alpha_1$.

5. $\alpha_1=0$, $\alpha_4=-1$

To obtain the solution for these values of the α_i we must find the limit of the rhs of (56) for $\alpha_4\to-1$. After taking the limit one arrives at the result

$$\begin{aligned}L_{+++}(0,\alpha_2,\alpha_3,-1)=&+Li_{2,1,1}\left(1+\alpha_2,\frac{1+\alpha_3}{1+\alpha_2},\frac{1}{1+\alpha_3}\right)+Li_{2,1,1}\left(1+\alpha_3,\frac{1+\alpha_2}{1+\alpha_3},\frac{1}{1+\alpha_2}\right)\\&+\ln\alpha_2 Li_{2,1}\left(1+\alpha_3,\frac{1}{1+\alpha_3}\right)+\ln\alpha_3 Li_{2,1}\left(1+\alpha_2,\frac{1}{1+\alpha_2}\right)+\ln\alpha_2\ln\alpha_3\zeta(2).\end{aligned} \tag{61}$$

V. TRANSFORMATION OF L_+ TO MULTIPLE POLYLOGARITHMS

In this section we will show that all our L_+ functions can be expressed in terms of multiple polylogarithms.

A. General case for the L_+ function

Here we derive the general formula for the single index L_+ function Eq. (2),

$$L_+(\alpha_1,\alpha_2,\alpha_3,\alpha_4)=\int_0^1 dy\frac{\ln(\alpha_1+y)}{\alpha_4+y}Li_2(\alpha_2+\alpha_3 y). \tag{62}$$

After changing the integration variable $y\to(t-\alpha_2)/\alpha_3$ one gets

$$L_+=\int_{\alpha_2}^{\alpha_2+\alpha_3}\frac{dt}{\alpha_3}\frac{\ln\left(\alpha_1+\dfrac{t-\alpha_2}{\alpha_3}\right)}{\alpha_4+\dfrac{t-\alpha_2}{\alpha_3}}Li_2(t)=\int_{\alpha_2}^{\alpha_2+\alpha_3}dt\frac{-\ln\alpha_3+\ln(\alpha_1\alpha_3-\alpha_2+t)}{\alpha_3\alpha_4-\alpha_2+t}Li_2(t). \tag{63}$$

The integration interval can be split into two pieces, $[\alpha_2,0]$ and $[0,\alpha_2+\alpha_3]$. One can then write L_+ as a sum of four terms,

$$L_+=-\ln\alpha_3\left\{\int_0^{\alpha_2+\alpha_3}-\int_0^{\alpha_2}\right\}\frac{dt}{\gamma+t}Li_2(t)+\left\{\int_0^{\alpha_2+\alpha_3}-\int_0^{\alpha_2}\right\}dt\frac{\ln(\alpha+t)}{\gamma+t}Li_2(t), \tag{64}$$

where we have introduced the notation

$$\alpha=\alpha_1\alpha_3-\alpha_2,\quad \gamma=\alpha_3\alpha_4-\alpha_2. \tag{65}$$

Looking at Eq. (64) it is clear that there are only two different types of integrals to be dealt with,

$$\int_0^{t_m} \frac{\mathrm{d}t}{\gamma+t} Li_2(t) \quad \text{and} \quad \int_0^{t_m} \mathrm{d}t \frac{\ln(\alpha+t)}{\gamma+t} Li_2(t). \tag{66}$$

The upper limits are $t_m=\alpha_2+\alpha_3$ or $t_m=\alpha_2$. The first integral can be evaluated analytically in terms of standard logarithms and classical polylogarithms up to Li_3. However, the same integral can also be expressed in terms of multiple polylogarithms via the integral representation (7), e.g.,

$$\int_0^{t_m} \frac{\mathrm{d}t}{\gamma+t} Li_2(t) = \int_0^{t_m} \frac{\mathrm{d}t_1}{\gamma+t_1} \int_0^{t_1} \frac{\mathrm{d}t_2}{t_2} \int_0^{t_2} \frac{\mathrm{d}t_3}{1-t_3} = -Li_{2,1}\left(-\gamma, \frac{-t_m}{\gamma}\right). \tag{67}$$

We now deal with the second integral in (66). Consider the following multiple polylogarithm of weight four:

$$\begin{aligned} Li_{2,1,1}\left(-\gamma, \frac{\alpha}{\gamma}, \frac{t_m}{-\alpha}\right) &= \int_0^{t_m} \frac{\mathrm{d}t_2}{-\alpha-t_2} \int_0^{t_2} \frac{\mathrm{d}t_1}{-\gamma-t_1} Li_2(t_1) = \int_0^{t_m} \frac{\mathrm{d}t_1}{\gamma+t_1} Li_2(t_1) \int_{t_1}^{t_m} \frac{\mathrm{d}t_2}{\alpha+t_2} \\ &= \int_0^{t_m} \frac{\mathrm{d}t_1}{\gamma+t_1} Li_2(t_1) \ln(\alpha+t_m) - \int_0^{t_m} \frac{\mathrm{d}t_1}{\gamma+t_1} Li_2(t_1) \ln(\alpha+t_1). \end{aligned} \tag{68}$$

In the first step we have used the usual trick to change the order of integration. As already noted before [see Eq. (67)] the first term on the second line can be expressed through a multiple polylogarithm of weight three. Thus one has

$$\int_0^{t_m} \mathrm{d}t \frac{\ln(\alpha+t)}{\gamma+t} Li_2(t) = -Li_{2,1,1}\left(-\gamma, \frac{\alpha}{\gamma}, \frac{t_m}{-\alpha}\right) - Li_{2,1}\left(-\gamma, \frac{-t_m}{\gamma}\right) \ln(\alpha+t_m). \tag{69}$$

Finally, substituting Eqs. (67) and (69) into Eq. (64) we arrive at the desired relation

$$\begin{aligned} L_+(\alpha_1,\alpha_2,\alpha_3,\alpha_4) = {} & Li_{2,1,1}\left(\alpha_2-\alpha_3\alpha_4, \frac{\alpha_2-\alpha_1\alpha_3}{\alpha_2-\alpha_3\alpha_4}, \frac{\alpha_2}{\alpha_2-\alpha_1\alpha_3}\right) \\ & - Li_{2,1,1}\left(\alpha_2-\alpha_3\alpha_4, \frac{\alpha_2-\alpha_1\alpha_3}{\alpha_2-\alpha_3\alpha_4}, \frac{\alpha_2+\alpha_3}{\alpha_2-\alpha_1\alpha_3}\right) \\ & + \ln\alpha_1 Li_{2,1}\left(\alpha_2-\alpha_3\alpha_4, \frac{\alpha_2}{\alpha_2-\alpha_3\alpha_4}\right) \\ & - \ln(\alpha_1+1) Li_{2,1}\left(\alpha_2-\alpha_3\alpha_4, \frac{\alpha_2+\alpha_3}{\alpha_2-\alpha_3\alpha_4}\right). \end{aligned} \tag{70}$$

We should note that, similar to Eq. (27), the conditions (5) are assumed for the variables α_i. Also, one cannot directly use Eq. (70) if $\alpha_2-\alpha_3\alpha_4=0$ or $\alpha_2-\alpha_1\alpha_3=0$. However, in the results for the massive scalar integrals precisely these special cases appear, as well as the cases where $\alpha_1=0$ and/or $\alpha_2=0$ and/or $\alpha_3=0$ and/or $\alpha_4=\{-1,0\}$. In such cases the general formula (70) is no longer valid and these cases must be studied separately.

B. Special cases for the L_+ function

In the Laurent series expansion of the massive scalar one-loop integrals the following special cases appear for the arguments of the L_+ functions:

1. $\alpha_2-\alpha_3\alpha_4=0$ (or $\alpha_2-\alpha_1\alpha_3=0$)

In this case one must find the limit of the rhs of Eq. (70) for $\alpha_2 \to \alpha_3\alpha_4$. First we rewrite the rhs of Eq. (70) in terms of multidimensional integrals via the definition (7). Second we replace α_2 by $\alpha_3\alpha_4$. We finally again use the definition (7) to obtain the result

$$L_+(\alpha_1,\alpha_3\alpha_4,\alpha_3,\alpha_4) = -Li_{3,1}\left(\alpha_3(\alpha_4-\alpha_1),\frac{\alpha_4}{\alpha_4-\alpha_1}\right)+Li_{3,1}\left(\alpha_3(\alpha_4-\alpha_1),\frac{\alpha_4+1}{\alpha_4-\alpha_1}\right)$$
$$-\ln\alpha_1 Li_3(\alpha_3\alpha_4)+\ln(\alpha_1+1)Li_3(\alpha_3(\alpha_4+1)). \tag{71}$$

When $\alpha_2-\alpha_1\alpha_3=0$ one must find the limit of the rhs of Eq. (70) for $\alpha_2\to\alpha_1\alpha_3$. We again rewrite the rhs of Eq. (70) in terms of multidimensional integrals. We then replace α_2 by $\alpha_1\alpha_3$ and use the definition (7). We arrive at the result

$$L_+(\alpha_1,\alpha_1\alpha_3,\alpha_3,\alpha_4) = -Li_{2,2}\left(\alpha_3(\alpha_1-\alpha_4),\frac{\alpha_1}{\alpha_1-\alpha_4}\right)+Li_{2,2}\left(\alpha_3(\alpha_1-\alpha_4),\frac{\alpha_1+1}{\alpha_1-\alpha_4}\right)$$
$$+\ln\alpha_1 Li_{2,1}\left(\alpha_3(\alpha_1-\alpha_4),\frac{\alpha_1}{\alpha_1-\alpha_4}\right)-\ln(\alpha_1+1)Li_{2,1}\left(\alpha_3(\alpha_1-\alpha_4),\frac{\alpha_1+1}{\alpha_1-\alpha_4}\right). \tag{72}$$

2. $\alpha_1=0$

Unfortunately in this case one cannot use Eq. (70) for $\alpha_1=0$ because one is immediately faced with the problem of a logarithmic infinity. One must find another algorithm to express the $L_+(0,\alpha_2,\alpha_3,\alpha_4)$ function in terms of multiple polylogarithms. After changing the integration variable $y\to 1-t$ one gets

$$\int_0^1 dy\frac{\ln y}{\alpha_4+y}Li_2(\alpha_2+\alpha_3 y) = \int_0^1 dt\frac{\ln(1-t)}{\alpha_4+1-t}Li_2(\alpha_2+\alpha_3-\alpha_3 t)$$
$$=\int_0^1 dt_1\frac{\ln(1-t_1)}{\alpha_4+1-t_1}\int_{\alpha_2/\alpha_3+1}^{t_1} dt_2\frac{\ln(1-\alpha_2-\alpha_3+\alpha_3 t_2)}{\frac{\alpha_2}{\alpha_3}+1-t_2}$$
$$=\int_0^1 dt_1\frac{\ln(1-t_1)}{\alpha_4+1-t_1}\left\{\int_1^{t_1}+\int_{\alpha_2/\alpha_3+1}^1\right\}dt_2\frac{\ln(1-\alpha_2-\alpha_3+\alpha_3 t_2)}{\frac{\alpha_2}{\alpha_3}+1-t_2}$$
$$=-\int_0^1 dt_2\frac{\ln(1-\alpha_2-\alpha_3+\alpha_3 t_2)}{\frac{\alpha_2}{\alpha_3}+1-t_2}\int_0^{t_2} dt_1\frac{\ln(1-t_1)}{\alpha_4+1-t_1}$$
$$-Li_2(\alpha_2)Li_{1,1}\left(\alpha_4+1,\frac{1}{\alpha_4+1}\right). \tag{73}$$

The last integral is an analog of $I'(t_m)$ in Eq. (22). First one notes that

$$\int_0^{t_2} dt_1\frac{\ln(1-t_1)}{\alpha_4+1-t_1} = -Li_{1,1}\left(\alpha_4+1,\frac{t_1}{\alpha_4+1}\right). \tag{74}$$

Then one considers the following chain of transformations:

$$\int_0^1 \frac{dt_2}{1-\alpha_2-\alpha_3+\alpha_3 t_2}\int_0^{t_2}\frac{dt_1}{\frac{\alpha_2}{\alpha_3}+1-t_1}Li_{1,1}\left(\alpha_4+1,\frac{t_1}{\alpha_4+1}\right)$$
$$=\int_0^1 \frac{dt_1}{\frac{\alpha_2}{\alpha_3}+1-t_1}Li_{1,1}\left(\alpha_4+1,\frac{t_1}{\alpha_4+1}\right)\int_{t_1}^1\frac{dt_2}{1-\alpha_2-\alpha_3+\alpha_3 t_2}$$
$$=\frac{1}{\alpha_3}\ln(1-\alpha_2)\int_0^1\frac{dt_1}{\frac{\alpha_2}{\alpha_3}+1-t_1}Li_{1,1}\left(\alpha_4+1,\frac{t_1}{\alpha_4+1}\right)$$
$$-\frac{1}{\alpha_3}\int_0^1 dt_1\frac{\ln(1-\alpha_2-\alpha_3+\alpha_3 t_1)}{\frac{\alpha_2}{\alpha_3}+1-t_1}Li_{1,1}\left(\alpha_4+1,\frac{t_1}{\alpha_4+1}\right). \tag{75}$$

Using Eq. (74) we see that the last integral is exactly the integral required in Eq. (73). The initial integral of Eq. (75) and the first integral of the rhs of Eq. (75) can be expressed in terms of multiple polylogarithms due to the definition (7). Finally for the $L_+(0,\alpha_2,\alpha_3,\alpha_4)$ function we obtain

$$L_+(0,\alpha_2,\alpha_3,\alpha_4)=Li_{1,1,1,1}\left(\alpha_4+1,\frac{\alpha_2+\alpha_3}{\alpha_3(\alpha_4+1)},\frac{\alpha_2+\alpha_3-1}{\alpha_2+\alpha_3},\frac{\alpha_3}{\alpha_2+\alpha_3-1}\right)$$
$$+\ln(1-\alpha_2)Li_{1,1,1}\left(\alpha_4+1,\frac{\alpha_2+\alpha_3}{\alpha_3(\alpha_4+1)},\frac{\alpha_3}{\alpha_2+\alpha_3}\right)-Li_2(\alpha_2)Li_{1,1}\left(\alpha_4+1,\frac{1}{\alpha_4+1}\right). \tag{76}$$

3. $\alpha_1=0$, $\alpha_4=-1$

For these values of the α_i one uses Eq. (76) to calculate the limit of the rhs for $\alpha_4\to-1$. One arrives at the result

$$L_+(0,\alpha_2,\alpha_3,-1)=-Li_{2,1,1}\left(\frac{\alpha_2+\alpha_3}{\alpha_3},\frac{\alpha_2+\alpha_3-1}{\alpha_2+\alpha_3},\frac{\alpha_3}{\alpha_2+\alpha_3-1}\right)-\ln(1-\alpha_2)Li_{2,1}\left(\frac{\alpha_2+\alpha_3}{\alpha_3},\frac{\alpha_3}{\alpha_2+\alpha_3}\right)$$
$$+Li_2(\alpha_2)\zeta(2). \tag{77}$$

4. $\alpha_1=0$, $\alpha_2+\alpha_3=1$ (and $\alpha_4=-1$)

If one takes a look at Eq. (76) one realizes that there is a problem if $\alpha_2+\alpha_4=1$. To express the L_+ function for this configuration of the α_i the limit of the rhs of (76) for $\alpha_2\to1-\alpha_3$ must be found. The result is

$$L_+(0,1-\alpha_3,\alpha_3,\alpha_4)=-Li_{1,1,2}\left(\alpha_4+1,\frac{1}{\alpha_3(\alpha_4+1)},\alpha_3\right)+\ln\alpha_3 Li_{1,1,1}\left(\alpha_4+1,\frac{1}{\alpha_3(\alpha_4+1)},\alpha_3\right)$$
$$-Li_2(1-\alpha_3)Li_{1,1}\left(\alpha_4+1,\frac{1}{\alpha_4+1}\right). \tag{78}$$

For the case $\alpha_1=0$, $\alpha_2+\alpha_3=1$, and $\alpha_4=-1$ one must find in addition the limit for $\alpha_4\to-1$. One arrives at the result

$$L_+(0,1-\alpha_3,\alpha_3,-1)=Li_{2,2}\left(\frac{1}{\alpha_3},\alpha_3\right)-\ln\alpha_3 Li_{2,1}\left(\frac{1}{\alpha_3},\alpha_3\right)+\zeta(2)Li_2(1-\alpha_3). \tag{79}$$

5. $\alpha_1=0,\ \alpha_2=-\alpha_3$

To obtain the result for this case one must calculate the limit of the rhs of (76) for $\alpha_3\to-\alpha_2$. After taking the limit one has

$$L_+(0,\alpha_2,-\alpha_2,\alpha_4)=-Li_{1,1,2}\left(\frac{\alpha_2}{\alpha_2-1},-\alpha_4,-\frac{1}{\alpha_4}\right)+\ln(1-\alpha_2)Li_{1,2}\left(-\alpha_4,-\frac{1}{\alpha_4}\right)+Li_2(\alpha_2)Li_2\left(-\frac{1}{\alpha_4}\right). \tag{80}$$

6. $\alpha_1=0,\ \alpha_2=0$

For this case one can directly use Eq. (76),

$$L_+(0,0,\alpha_3,\alpha_4)=Li_{1,1,1,1}\left(\alpha_4+1,\frac{1}{\alpha_4+1},\frac{\alpha_3-1}{\alpha_3},\frac{\alpha_3}{\alpha_3-1}\right). \tag{81}$$

But there is also another very simple possibility. We first change the integration variable $y\to t/\alpha_3$,

$$\begin{aligned}\int_0^1 \mathrm{d}y\frac{\ln y}{\alpha_4+y}Li_2(\alpha_3 y)&=\int_0^{\alpha_3}\mathrm{d}t\frac{\ln(t/\alpha_3)}{\alpha_3\alpha_4+t}Li_2(t)\\&=\int_0^{\alpha_3}\frac{\mathrm{d}t_1}{\alpha_3\alpha_4+t_1}Li_2(t_1)\int_{\alpha_3}^{t_1}\frac{\mathrm{d}t_2}{t_2}\\&=-\int_0^{\alpha_3}\frac{\mathrm{d}t_2}{t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{\alpha_3\alpha_4+t_1}Li_2(t_1)\\&=\int_0^{\alpha_3}\frac{\mathrm{d}t_2}{t_2}\int_0^{t_2}\frac{\mathrm{d}t_1}{-\alpha_3\alpha_4+t_1}\int_0^{t_1}\frac{\mathrm{d}t_3}{t_3}\int_0^{t_3}\frac{\mathrm{d}t_4}{1-t_4}.\end{aligned} \tag{82}$$

Now using the definition (7) we obtain the result

$$L_+(0,0,\alpha_3,\alpha_4)=Li_{2,2}\left(-\alpha_3\alpha_4,\frac{-1}{\alpha_4}\right). \tag{83}$$

The reader has a free choice to use either formula (83) or (85). Both equations contain multiple polylogarithms of weight four. The depth of the multiple polylogarithm in Eq. (83) is two against four in Eq. (81). For $\alpha_4=-1$ Eq. (83) can be directly used. However, in the case of Eq. (81) one must first calculate the limit for $\alpha_4\to-1$.

7. $\alpha_1=0,\ \alpha_2=1$

Unfortunately, in this case one cannot use Eq. (76) because of the term $\ln(1-\alpha_2)$. To express this L_+ function in terms of multiple polylogarithms we first make use of a standard relation between dilogs with arguments x and $1-x$ for the function Li_2 under the sign of the integral:

$$\int_0^1 \mathrm{d}y \frac{\ln y}{\alpha_4+y} Li_2(1+\alpha_3 y) = \int_0^1 \mathrm{d}y \frac{\ln y}{\alpha_4+y}[\zeta(2) - \ln(-\alpha_3 y)\ln(1+\alpha_3 y) - Li_2(-\alpha_3 y)]$$
$$= \zeta(2)\int_0^1 \mathrm{d}y \frac{\ln y}{\alpha_4+y} - \int_0^1 \mathrm{d}y \frac{\ln y}{\alpha_4+y} Li_2(-\alpha_3 y)$$
$$- \int_0^1 \mathrm{d}y \frac{\ln y[\ln(-\alpha_3)+\ln y]\ln(1+\alpha_3 y)}{\alpha_4+y}$$
$$= \zeta(2) Li_2\left(-\frac{1}{\alpha_4}\right) - Li_{1,1,1,1}\left(\alpha_4+1, \frac{1}{\alpha_4+1}, \frac{\alpha_3+1}{\alpha_3}, \frac{\alpha_3}{\alpha_3+1}\right)$$
$$- \ln(-\alpha_3)\int_0^1 \mathrm{d}y \frac{\ln y \ln(1+\alpha_3 y)}{\alpha_4+y} - \int_0^1 \mathrm{d}y \frac{\ln^2 y \ln(1+\alpha_3 y)}{\alpha_4+y}, \tag{84}$$

where the $Li_{1,1,1,1}$ function was obtained with the help of Eq. (81). To obtain the last integral in Eq. (84) one proceeds as follows:

$$\int_0^1 \mathrm{d}y \frac{\ln^2 y \ln(1+\alpha_3 y)}{\alpha_4+y} \overset{y\to 1-t}{=} \int_0^1 \mathrm{d}t \frac{\ln^2(1-t)\ln(1+\alpha_3-\alpha_3 t)}{\alpha_4+1-t}$$
$$= \int_0^1 \mathrm{d}t_1 \frac{\ln^2(1-t_1)}{\alpha_4+1-t_1}\int_1^{t_1} \frac{-\alpha_3 \mathrm{d}t_2}{1+\alpha_3-\alpha_3 t_2}$$
$$= \int_0^1 \frac{\mathrm{d}t_2}{\frac{1}{\alpha_3}+1-t_2}\int_0^{t_2} \mathrm{d}t_1 \frac{\ln^2(1-t_1)}{\alpha_4+1-t_1}$$
$$= 2\int_0^1 \frac{\mathrm{d}t_2}{\frac{1}{\alpha_3}+1-t_2}\int_0^{t_2} \frac{\mathrm{d}t_1}{\alpha_4+1-t_1}\int_0^{t_1} \frac{\mathrm{d}t_3}{1-t_3}\int_0^{t_3} \frac{\mathrm{d}t_4}{1-t_4}$$
$$= 2Li_{1,1,1,1}\left(1, \alpha_4+1, \frac{\alpha_3+1}{\alpha_3(\alpha_4+1)}, \frac{\alpha_3}{\alpha_3+1}\right). \tag{85}$$

Similarly one can evaluate the remaining integral

$$\int_0^1 \mathrm{d}y \frac{\ln y \ln(1+\alpha_3 y)}{\alpha_4+y} = -Li_{1,1,1}\left(\alpha_4+1, \frac{\alpha_3+1}{\alpha_3(\alpha_4+1)}, \frac{\alpha_3}{\alpha_3+1}\right). \tag{86}$$

Now combining Eqs. (84)–(86) one arrives at the result

$$L_+(0,1,\alpha_3,\alpha_4) = -2Li_{1,1,1,1}\left(1, \alpha_4+1, \frac{\alpha_3+1}{\alpha_3(\alpha_4+1)}, \frac{\alpha_3}{\alpha_3+1}\right)$$
$$- Li_{1,1,1,1}\left(\alpha_4+1, \frac{1}{\alpha_4+1}, \frac{\alpha_3+1}{\alpha_3}, \frac{\alpha_3}{\alpha_3+1}\right)$$
$$+ \ln(-\alpha_3) Li_{1,1,1}\left(\alpha_4+1, \frac{\alpha_3+1}{\alpha_3(\alpha_4+1)}, \frac{\alpha_3}{\alpha_3+1}\right) + \zeta(2) Li_2\left(-\frac{1}{\alpha_4}\right). \tag{87}$$

8. $\alpha_1=0$, $\alpha_2=-\alpha_3=1$

For these values of the α_i we must find the limit of the rhs of Eq. (87) for $\alpha_3\to-1$. After taking the limit we obtain

$$L_+(0,1,-1,\alpha_4)=Li_{1,1,2}\left(\alpha_4+1,\frac{1}{\alpha_4+1},1\right)+2Li_{1,1,2}\left(1,\alpha_4+1,\frac{1}{\alpha_4+1}\right)+\zeta(2)Li_2\left(-\frac{1}{\alpha_4}\right). \tag{88}$$

VI. CONCLUSIONS

We have presented all the necessary relations to transform the L functions [as defined in Eqs. (1) and (2)] that occur in our $\mathcal{O}(\varepsilon^2)$ results[1] for the Laurent series expansion of massive scalar one-loop integrals to multiple polylogarithms. We have used these relations to transform our results on massive one-loop integrals involving L functions to corresponding results involving multiple polylogarithms. The multiple polylogarithms results are readily available in electronic form.[11]

Despite of the fact that the relations between the L functions and the multiple polylogarithms have been derived having the massive scalar one-loop integrals in mind they can also be used in a more general setting. In fact, any definite integral given by

$$\int_A^B \frac{\ln(a_1+b_1x)\ln(a_2+b_2x)\ln(a_3+b_3x)\mathrm{d}x}{a_4+b_4x} \quad \text{or} \quad \int_A^B \frac{\ln(a_1+b_1x)Li_2(a_2+b_2x)\mathrm{d}x}{a_3+b_3x}$$

can be written in terms of multiple polylogarithms with the help of the relations presented in this paper. It is worthwhile to mention that all the equations presented in the present paper have been also checked numerically.

We have found several examples where the representation of the L functions in terms of multiple polylogarithms is not unique. This reflects the fact that multiple polylogarithms obey quasishuffle and shuffle Hopf algebras and hence satisfy numerous identities as is the case for the classical polylogarithms. More information about identities between multiple polylogarithms can be found, e.g., in Refs. 5 and 9 and references therein.

For future parton model applications of our results numerical efficiency is an important issue. We are presently writing numerical $C++$ codes to compare the numerical efficiency of the two representations in terms of L functions and multiple polylogarithms.

APPENDIX

In this Appendix we consider as an example the real part of the $\mathcal{O}(\varepsilon^2)$ coefficient $\mathrm{Re}\,D_1^{(2)}$ of the Laurent series expansion of the massive box D_1 with three massive propagators. Using the rules written down in the main text of this paper we have expressed the corresponding results of Ref. 1 involving L functions in terms of multiple polylogarithms. The L function structure of $\mathrm{Re}\,D_1^{(2)}$ in Ref. 1 is sufficiently rich to provide an illustration of the corresponding complexity in terms of multiple polylogarithms when transforming to the latter representation. We mention that all multiple polylogarithms up to weight three have been reexpressed in terms of classical polylogarithms. We then used automatic program codes to simplify the classical polylogarithms as much as possible, as was also done in Ref. 1.

We use the notation and the conventions of Ref. 1. In brief, we use the Mandelstam-type variables

$$s \equiv (p_1+p_2)^2, \quad t \equiv T-m^2 \equiv (p_1-p_3)^2-m^2, \quad u \equiv U-m^2 \equiv (p_2-p_3)^2-m^2 \tag{A1}$$

for the $2\to 2$ partonic process $a(p_1)+b(p_2)\to Q(p_3)+\overline{Q}(p_4)$ with $p_1^2=p_2^2=0$ and $p_3^2=p_4^2=m^2$. We also introduce the abbreviations ($\beta=\sqrt{1-4m^2/s}$)

$$z_3 \equiv (s+2t+s\beta)/2, \quad z_4 \equiv (s+2t-s\beta)/2,$$

$$z_5 \equiv (2m^2+t+t\beta)/2, \quad z_6 \equiv (2m^2+t-t\beta)/2,$$

$$l_s \equiv \ln\frac{s}{m^2}, \quad l_t \equiv \ln\frac{-t}{m^2}, \quad l_T \equiv \ln\frac{-T}{m^2}, \quad l_x \equiv \ln x,$$

$$l_\beta \equiv \ln\beta, \quad l_{z3} \equiv \ln\frac{z_3}{m^2}, \quad l_{z4} \equiv \ln\frac{-z_4}{m^2}. \tag{A2}$$

One finds

$$\begin{aligned}
\mathrm{Re}\, D_1^{(2)} = \frac{1}{st\beta}\Bigg[\frac{1}{192}\{&-109l_s^4+240l_t^4+32l_T^3l_x+264l_T^2l_x^2-200l_Tl_x^3-177l_x^4-96l_T^2l_xl_{z3}+192l_Tl_x^2l_{z3}\\

\end{aligned}
$$

At the very end of the expression one finds an explicit imaginary part. Since the whole expression must be real this clearly indicates that the same imaginary contribution with opposite sign must be contained in multiple polylogarithms, e.g., some of them are sitting on branch cuts. This is in fact true for the multiple polylogarithms

$$
Li_{3,1}\left(-\frac{m^2xz_3}{sT\beta},\frac{-T}{m^2x}\right),\quad Li_{3,1}\left(-\frac{m^2xz_3}{sT\beta},\frac{2T}{t(1-\beta)}\right),
$$

$$
Li_{2,1,1}\left(-\frac{m^2xz_3}{sT\beta},-\frac{sT\beta}{m^2xz_3},\frac{z_3}{s\beta}\right),\quad Li_{2,1,1}\left(-\frac{m^2xz_3}{sT\beta},-\frac{sT\beta}{m^2xz_3},-\frac{z_6}{t\beta}\right).
$$

Indeed, one finds that the imaginary contributions cancel out when one numerically evaluates the result.

As regards the length the representations of $\mathrm{Re}\, D_1^{(2)}$ in terms of L functions in Ref. 1 and in terms of multiple polylogarithms are of similar size. The representation in terms of L functions contains 43 different L function expressions against 59 different multiple polylogarithm expressions.

(Received 5 April 2006; accepted 17 May 2006; published online 13 July 2006)

We treat the problem of a Michelson interferometer in the field of a plane gravitational wave in the framework of general relativity. The arms of the interferometer are regarded as the world lines of the light beams, whose motion is determined by the Hamilton-Jacobi equation for a massless particle. In the case of a weak monochromatic wave we find that the formula for the delay of a light beam agrees with the result obtained by solving the linearized coupled Einstein-Maxwell equations. We also calculate this delay in the next (quadratic) approximation. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2212670]

I. INTRODUCTION

The subject of this work is to investigate the behavior of a Michelson interferometer in the presence of a plane gravitational wave. Sources of gravitational waves include the collapse of massive stars in supernova explosions, and the coalescence of stars in binary systems containing a neutron star and/or a black hole. The large distances from these objects allow us to assume that the gravitational waves detected on the Earth may be regarded as plane waves.

Gravitational waves were predicted by Einstein in his general theory of relativity[1,2] as perturbations of the space-time metric that propagate at the speed of light. Plane gravitational waves were considered first by Rosen,[3] Taub,[4] and McVittie,[5] and their work seemed to indicate that such waves may not physically exist. However, Bondi, Pirani, and Robinson[6–8] proved that this conclusion was wrong, and that these waves not only exist but also carry energy. Exact solutions of the Einstein equations, which describe plane gravitational waves, have also been developed in Refs. 9 and 10. In 1975, Hulse and Taylor[11] found indirect proof for the existence of gravitational waves by observing the pulsar PSR 1913+16. They noticed that the orbital parameters of this pulsar were changing according to a model assuming that such a system radiates gravitational waves.[12,13] This discovery was awarded with the Nobel Prize in physics in 1993.

Research on the possibility of detecting gravitational waves was started in the 1960s by Weber,[14] who constructed the first resonant-mass antenna. His results claiming the discovery of gravitational waves[15] could not be confirmed by other groups who built similar detectors. In the 1970s, another method of detection was suggested using laser interferometry.[16–19] Current and planned ground-based laser interferometric detectors include AIGO (Australia),[20] GEO 600 (Germany/UK),[21] LIGO (USA),[22] TAMA 300 (Japan),[23] and VIRGO (France/Italy).[24] The first search for signals from neutron stars in LIGO and GEO 600 data did not find direct evidence for gravitational waves,[25] but gave upper limits on the strength of periodic gravitational radiation.[26] In 2011, ESA and NASA plan to launch LISA,[27] a space project that will be able to make observations in a low-frequency band that is not achievable by ground-based observatories. A bibliography on gravitational-wave theory and experiment through 1999 is listed in Ref. 28.

Since the search for gravitational waves is mainly based on interferometry, we consider a Michelson interferometer in the presence of a plane gravitational wave. The effect of such a wave

a)Electronic mail: nipoplaw@indiana.edu

on a light beam, using the linearized coupled Einstein-Maxwell equations, was studied in Refs. 29 and 30. However, these equations in the quadratic approximation may lead to quite lengthy expressions. Instead, we can treat the light beam as photons whose motion is determined by the geodesic equations for a massless particle.

The equations of motion for a particle in the metric of a strong gravitational wave[13] were derived by Ebner,[31] and all seven integrals of motion can be found in the literature, e.g., Ref. 32. A simple model of a Michelson interferometer in the field of such a wave, based on the above equations of motion, was proposed by Bażański.[33] Here, we generalize this model to the second (quadratic) approximation. For simplicity, we consider a monochromatic plane gravitational wave whose direction is parallel to one arm of the interferometer and perpendicular to the other. Since the energy of gravitational waves contains the factor G/c^5, the amplitude for such waves is very small. Therefore, second-order effects in gravitational-wave detection are irrelevant experimentally, although it might be interesting to explore them.

This paper is organized as follows. In Sec. II we introduce a plane gravitational wave and review the equations of motion for a test particle. In Sec. III we study the behavior of a Michelson interferometer under the action of this wave in the first (linear) approximation. In Sec. IV we proceed to the second approximation. The results are summarized in Sec. V. For the metric tensor and the curvature tensor we use the conventions of Ref. 13.

II. MOTION OF A PARTICLE IN THE FIELD OF A PLANE GRAVITATIONAL WAVE

In this section we derive the motion of a test particle in the presence of a plane gravitational wave[31,33] using the relativistic Hamilton-Jacobi equation. Let us consider the metric tensor whose components are functions of only one variable u, $g_{ab}=g_{ab}(u)$. In this case, it can be shown[13] that the space-time interval in vacuum is of the form

$$ds^2 = dudv + g_{ab}(u)dx^a dx^b, \tag{1}$$

where the letters a,b refer to the coordinates 2,3. For a plane wave propagating in the direction of the x axis we have $u=ct-x$ and $v=ct+x$. If the interval is given by Eq. (1), then all components of the Ricci tensor identically vanish except $R_{uu}=-\frac{1}{2}\dot{\kappa}^a_a-\frac{1}{4}\kappa^a_b\kappa^b_a$, where $\kappa_{ab}=\dot{g}_{ab}$, and the dot denotes differentiation with respect to u. Thus, the Einstein field equations in the case of a plane gravitational wave reduce to one equation, $R_{uu}=0$.

The Hamilton-Jacobi equation for a particle with mass m moving in the gravitational field described by the metric in (1) is given by

$$4\frac{\partial S}{\partial u}\frac{\partial S}{\partial v}+g^{ab}\frac{\partial S}{\partial x^a}\frac{\partial S}{\partial x^b}=m^2c^2, \tag{2}$$

where $S=S(u,v,x^a)$ is a principal function. We seek a solution of (2) in the form $S=\tilde{S}(u)+\frac{1}{2}Bv+p_{0a}x^a$, where $B=p_0+p_x=\text{const}$ and $p_{0a}=\text{const}$. For a timelike geodesic line we have $B>0$. We obtain the principal function given by

$$S=\frac{1}{2B}[(m^2c^2u-G^{ab}(u,0)p_{0a}p_{0b})]+\frac{1}{2}Bv+p_{0a}x^a, \tag{3}$$

where we define

$$G^{ab}(p,q)=\int_q^{q+p} g^{ab}(u)du. \tag{4}$$

The components of four-momentum are given by the derivatives of a principal function, $p_i=\partial S/\partial x^i$. The world line of a particle is determined by Jacobi's theorem, $\partial S/\partial\alpha^k=\beta^k$, where α^k are the constants in the principal function (3), and β^k are new constants. Introducing a finite interval s as a parameter such that $mc(dx^a/ds)=g^{ab}(\partial S/\partial x^b)$ yields $u=(B/mc)(s-s_0)+u_0$. The equations of

motion for a massive particle in the field of a plane gravitational wave in terms of s are (in agreement with Ref. 31)

$$ct(s) = ct(s_0) + \frac{1}{2}\left(\frac{B}{mc} + \frac{mc}{B}\right)(s - s_0) - \frac{1}{2B^2}G^{ab}\left(\frac{B}{mc}(s - s_0), ct(s_0) - x(s_0)\right)p_{0a}p_{0b},$$

$$x(s) = x(s_0) + \frac{1}{2}\left(\frac{mc}{B} - \frac{B}{mc}\right)(s - s_0) - \frac{1}{2B^2}G^{ab}\left(\frac{B}{mc}(s - s_0), ct(s_0) - x(s_0)\right)p_{0a}p_{0b},$$

$$x^a(s) = x^a(s_0) + \frac{1}{B}G^{ab}\left(\frac{B}{mc}(s - s_0), ct(s_0) - x(s_0)\right)p_{0b}. \tag{5}$$

In a similar manner, we can determine the equations of null geodesic lines in the presence of a plane gravitational wave. The Hamilton-Jacobi equation in this case is equivalent to the eikonal equation,

$$4\frac{\partial\Psi}{\partial u}\frac{\partial\Psi}{\partial v} + g^{ab}\frac{\partial\Psi}{\partial x^a}\frac{\partial\Psi}{\partial x^b} = 0, \tag{6}$$

and its solution is of the form $\Psi = \tilde{\Psi}(u) + \frac{1}{2}Cv + k_{0a}x^a$, where $C = k_0 + k_x = \text{const}$ and $k_{0a} = \text{const}$. Consequently we find

$$\Psi = -\frac{1}{C}G^{ab}(u,0)k_{0a}k_{0b} + \frac{1}{2}Cv + k_{0a}x^a, \tag{7}$$

with G^{ab} defined in (4). The components of the four-dimensional wave vector are given by the derivatives of the eikonal, $k_i = \partial\Psi/\partial x^i$. A world line for a massless particle is again determined from Jacobi's theorem.

Let us define the affine parameter π such that $dx^a/d\pi = g^{ab}(\partial\Psi/\partial x^b)$ from which we find $u = C(\pi - \pi_0) + u_0$. As a result, we obtain the null geodesic lines:

$$ct(\pi) = ct(\pi_0) + \frac{1}{2}C(\pi - \pi_0) - \frac{1}{2C^2}G^{ab}(C(\pi - \pi_0), \quad ct(\pi_0) - x(\pi_0))k_{0a}k_{0b},$$

$$x(\pi) = x(\pi_0) - \frac{1}{2}C(\pi - \pi_0) - \frac{1}{2C^2}G^{ab}(C(\pi - \pi_0), \quad ct(\pi_0) - x(\pi_0))k_{0a}k_{0b},$$

$$x^a(\pi) = x^a(\pi_0) + \frac{1}{C}G^{ab}(C(\pi - \pi_0) \quad , ct(\pi_0) - x(\tau_0))k_{0b}, \tag{8}$$

where $G^{ab}(p,q)$ were defined in (4). Formulas (4) are satisfied for all null geodesics, except the curve for which $C = 0$. This condition represents a light beam moving parallel to a gravitational wave. In this case, $k_a = 0$ for an arbitrary π, and the solution is

$$ct = A(\pi - \pi_0) + ct_0, \quad x = A(\pi - \pi_0) + x_0, \quad x^a = x_0^a, \tag{9}$$

where A is a constant.

III. A MICHELSON INTERFEROMETER IN THE PRESENCE OF A PLANE GRAVITATIONAL WAVE

Using the equations of motion for a light beam in the field of a plane gravitational wave, Eqs. (8) and (9), we will show how to build a simple model of a Michelson interferometer.[33] Let us consider three observers at rest:

$$1.\quad ct = s - s_0,\quad x = 0,\quad y = 0,\quad z = 0,$$

$$2.\quad ct = s - s_0,\quad x = l_\parallel,\quad y = 0,\quad z = 0,$$

$$3.\quad ct = s - s_0,\quad x = 0,\quad y = l_\perp,\quad z = 0. \tag{10}$$

Let a light beam leave the world point (0,0,0,0) in the direction of a plane wave, and arrive at the point $(\tilde{s}_1 - s_0, l_\parallel, 0, 0)$. In this case Eqs. (9) lead to

$$\tilde{s}_1 - s_0 = A(\tilde{\pi}_1 - \tilde{\pi}_0),\quad l_\parallel = A(\tilde{\pi}_1 - \tilde{\pi}_0), \tag{11}$$

which gives $\tilde{s}_1 - s_0 = l_\parallel$. Then, let this light beam leave the point $(\tilde{s}_1 - s_0, l_\parallel, 0, 0)$ and arrive at the point $(\tilde{s}_2 - s_0, 0, 0, 0)$ (return to the initial space point). Consequently, the equations of motion (8) are

$$\tilde{s}_2 - \tilde{s}_1 = \frac{1}{2}C(\tilde{\pi}_2 - \tilde{\pi}_1) - \frac{1}{C^2}G^{ab}(C(\tilde{s}_2 - \tilde{s}_1), \tilde{s}_1 - l_\parallel)k_{0a}k_{0b},$$

$$-l_\parallel = -\frac{1}{2}C(\tilde{s}_2 - \tilde{s}_1) - \frac{1}{2C^2}G^{ab}(C(\tilde{s}_2 - \tilde{s}_1), \tilde{s}_1 - l_\parallel)k_{0a}k_{0b},$$

$$0 = \frac{1}{C}G^{ab}(C(\tilde{s}_2 - \tilde{s}_1), \tilde{s}_1 - l_\parallel)k_{0b}. \tag{12}$$

Therefore $\tilde{s}_2 - s_0 = 2l_\parallel$.

Next, let us consider a light beam leaving the point (0,0,0,0) in the direction perpendicular to that of the gravitational wave, and arriving at $(s_1 - s_0, 0, l_\perp, 0)$. In this case Eqs. (8) give

$$s_1 - s_0 = \frac{1}{2}C(\pi_1 - \pi_0) - \frac{1}{2C^2}G^{ab}_{\rightarrow}k_{0a}k_{0b},\quad l_\perp = \frac{1}{C}G^{2b}_{\rightarrow}k_{0b},$$

$$0 = -\frac{1}{2}C(\pi - \pi_0) - \frac{1}{2C^2}G^{ab}_{\rightarrow}k_{0a}k_{0b},\quad 0 = \frac{1}{C}G^{3b}_{\rightarrow}k_{0b}, \tag{13}$$

where $G^{ab}_{\rightarrow} = G^{ab}(C(\pi_1 - \pi_0), s_0) = \int_{s_0}^{s_1} g^{ab}(u)du$. We obtain the equation for s_1:

$$s_1 - s_0 = -\frac{l_\perp^2 G^{33}_{\rightarrow}}{\Delta_{\rightarrow}}, \tag{14}$$

where $\Delta_{\rightarrow} = G^{22}_{\rightarrow}G^{33}_{\rightarrow} - (G^{23}_{\rightarrow})^2$.

Then, let the same light beam go from the point $(s_1, 0, l_\perp, 0)$ to the initial space point $(s_2, 0, 0, 0)$. The equations of motion are (with different constants of motion)

$$s_2 - s_1 = \frac{1}{2}C(\pi_2 - \pi_1) - \frac{1}{2C^2}G^{ab}_{\leftarrow}k_{0a}k_{0b},\quad -l_\perp = -\frac{1}{C}G^{2b}_{\leftarrow}k_{0b},$$

$$0 = -\frac{1}{2}C(\pi_2 - \pi_1) - \frac{1}{2C'^2}G^{ab}_{\leftarrow}k_{0a}k_{0b},\quad 0 = \frac{1}{C}G^{3b}_{\leftarrow}k_{0b}, \tag{15}$$

where $G^{ab}_{\leftarrow} = G^{ab}(C(\pi_2 - \pi_1), s_1) = \int_{s_1}^{s_2} g^{ab}(u)du$. In a similar manner we obtain

$$s_2 - s_1 = -\frac{l_\perp^2 G_{\leftarrow}^{33}}{\Delta_{\leftarrow}}, \tag{16}$$

where $\Delta_{\leftarrow} = G_{\leftarrow}^{22} G_{\leftarrow}^{33} - (G_{\leftarrow}^{23})^2$.

A weak plane gravitational wave in metric (1) can be described by the two-dimensional metric tensor

$$g_{ab} = \begin{bmatrix} -1 + f(u) & h(u) \\ h(u) & -1 - f(u) \end{bmatrix}, \tag{17}$$

where $f(u)$ and $h(u)$ are small quantities. [If we neglect terms quadratic and smaller in f and h, then the metric tensor (17) identically satisfies the field equation $R_{uu}=0$.] The two possible polarizations correspond to setting either quantity to zero. Let us consider a polarization such that $h(u)=0$ and denote it by h_+. From this we find $\Delta_{\rightarrow} = (s_1 - s_0)^2 + O(A^2)$, where A is the amplitude of the gravitational wave. We can linearize Eq. (14), omitting terms quadratic and smaller in A:

$$s_1 - s_0 = -\frac{l_\perp^2}{(s_1 - s_0)^2}\left(-(s_1 - s_0) + \int_{s_0}^{s_1} f(u)du \right). \tag{18}$$

The analogous expression can be derived for Eq. (16).

Let us assume that a plane gravitational wave is monochromatic with wavelength λ, $f(u) = A\cos(2\pi u/\lambda)$. We seek the solution of Eq. (18) in the form $s_1 - s_0 = l_\perp + \Delta s_{\rightarrow}$, where $\Delta s_{\rightarrow}$ is a small quantity on the order of A. Keeping only linear terms in $\Delta s_{\rightarrow}$ we find

$$\Delta s_{\rightarrow} = -\frac{A\lambda}{2\pi} \sin\frac{\pi l_\perp}{\lambda} \cos\frac{2\pi(s_0 + l_\perp/2)}{\lambda}. \tag{19}$$

Similarly, for the returning beam we have $s_2 - s_1 = l_\perp + \Delta s_{\leftarrow}$, where

$$\Delta s_{\leftarrow} = -\frac{A\lambda}{2\pi} \sin\frac{\pi l_\perp}{\lambda} \cos\frac{2\pi(s_0 + 3l_\perp/2)}{\lambda}, \tag{20}$$

where we used $s_1 - s_0 = l_\perp$ since this term is on the order of A. Finally, the total delay of the light beam moving perpendicular to the gravitational wave, relative to the parallel beam, is given by

$$\Delta s = \Delta s_{\rightarrow} + \Delta s_{\leftarrow} = -\frac{A\lambda}{2\pi} \sin\frac{2\pi l_\perp}{\lambda} \cos\frac{2\pi(s_0 + l_\perp)}{\lambda}. \tag{21}$$

The other polarization (denoted by $h_\times$) is described by the metric tensor

$$g_{ab} = \begin{bmatrix} -1 & h(u) \\ h(u) & -1 \end{bmatrix}. \tag{22}$$

In this case, Eq. (14) reduces to $s_1 - s_0 = l_\perp$, whereas for the returning beam we find $s_2 - s_1 = l_\perp$. For this polarization there is no delay.

Equation (21) is what experimentalists use to detect gravitational waves.[28,34] Its relation to incoming gravitational waves with arbitrary propagation directions and polarization states can be found in the literature, e.g., Ref. 29. This equation agrees with the corresponding expression in Ref. 30 if we set the departure moment $s_0=0$ and use the relation $\Delta s = (c/\omega)\Delta\phi$, where ω is the light beam frequency and $\Delta\phi$ denotes the phase shift. Therefore, treating light as massless particles in the field of a weak gravitational wave and solving the linearized coupled Einstein-Maxwell equations lead to the same result.

The delay of a light beam depends on the quantity s_0, which corresponds to the moment when the beam leaves the start point [the time dependence of the gravitational field is fixed by the form of $f(u)$]. If the wavelength of a monochromatic gravitational wave is small compared to the size of the interferometer, we can average this delay over s_0: $\langle \Delta s \rangle = (1/\lambda)\int_0^\lambda \Delta s(s_0) ds_0$. The physical rea-

son for averaging arises from the fact that we do not know when the front of a gravitational wave hits the point of the departure of the beam. However, as for each periodic function, such an expression vanishes and is of no interest.

IV. LIGHT BEAM DELAY IN THE SECOND APPROXIMATION

In this section we will generalize the results of the preceding section and consider quadratic terms. Let the two-dimensional metric tensor g_{ab} of a weak gravitational wave be given by

$$g_{ab}=\begin{bmatrix} -1+f^{(1)} & h^{(1)} \\ h^{(1)} & -1+g^{(1)} \end{bmatrix}, \tag{23}$$

where $f^{(1)}$, $g^{(1)}$, $h^{(1)}$ are small quantities on the same order. In the linear approximation $f^{(1)}+g^{(1)}=O(A^2)$, where A is the amplitude of such a wave on the order of $f^{(1)}$. Therefore, without loss of generality we may assume $f^{(1)}+g^{(1)}=g^{(2)}$. The field equation is obtained from $R_{uu}=0$:

$$\frac{1}{2}(\dot{f}^{(1)2}+2f^{(1)}\ddot{f}^{(1)}+\ddot{g}^{(2)}+\dot{h}^{(1)2}+2h^{(1)}\ddot{h}^{(1)})=0, \tag{24}$$

which gives $g^{(2)}$ as a function of $f^{(1)}$ and $h^{(1)}$.

If we consider a polarization h_+ with $h^{(1)}=0$ and put $s_1-s_0=l_\perp$ in terms on the order of A^2, then Eq. (14) becomes

$$(s_1-s_0)^3-l_\perp^2(s_1-s_0)+l_\perp^2\int_{s_0}^{s_1}(f^{(1)}+f^{(1)2})du-l_\perp\left(\int_{s_0}^{s_1}f^{(1)}du\right)^2=0, \tag{25}$$

Note that this equation does not contain the quantity $g^{(2)}$. Let us apply the above results to the case of a monochromatic plane wave, $f^{(1)}=A\cos(2\pi u/\lambda)$. For such a wave, Eq. (24) leads to $g^{(2)}=(4\pi^2A^2/\lambda^2)[3\cos^2(2\pi u/\lambda)-1]$, and this quantity clearly is not a periodic function of u. [We could assume $f^{(1)}+g^{(1)}=f^{(2)}$, but then Eq. (25) would contain the nonperiodic function $f^{(2)}$. Thus, it would be impossible to average the light beam delay over s_0 (the moment when the beam leaves the start point) independently of the initial conditions.] We seek the solution in the form $s_1-s_0=l_\perp+\Delta s_\rightarrow$, where $\Delta s_\rightarrow$ is again a small quantity on the same order as A. Thus, up to quadratic terms in $\Delta s_\rightarrow$ we obtain

$$\begin{aligned}\Delta s_\rightarrow=&-\frac{A\lambda}{2\pi}\sin\frac{\pi l_\perp}{\lambda}\cos\frac{\pi}{\lambda}(2s_0+l_\perp)-\frac{A^2\lambda}{16\pi}\sin\frac{2\pi l_\perp}{\lambda}\cos\frac{2\pi}{\lambda}(2s_0+l_\perp)-\frac{A^2l_\perp}{4}\\&+\frac{A^2\lambda^2}{8\pi^2l_\perp}\left(\sin\frac{\pi l_\perp}{\lambda}\cos\frac{\pi}{\lambda}(2s_0+l_\perp)\right)^2+\frac{A^2\lambda}{4\pi}\sin\frac{\pi l_\perp}{\lambda}\cos\frac{\pi}{\lambda}(2s_0+l_\perp)\cos\frac{2\pi}{\lambda}(s_0+l_\perp).\end{aligned} \tag{26}$$

The above expression contains the quadratic corrections to Eq. (19). The mean value of this quantity over the moment of the departure of the beam s_0, $\langle\Delta s_\rightarrow\rangle=(1/\lambda)\int_0^\lambda\Delta s_\rightarrow(s_0)ds_0$, is now different from zero:

$$\langle\Delta s_\rightarrow\rangle=\frac{A^2\lambda^2}{16\pi^2l_\perp}\sin^2\frac{\pi l_\perp}{\lambda}-\frac{A^2l_\perp}{4}+\frac{A^2\lambda}{16\pi}\sin\frac{2\pi l_\perp}{\lambda}. \tag{27}$$

We remind that the moment s_0 is relative to the instant when a front of the gravitational wave in question hits the departure point, and we average with respect to s_0 since we do not know the value of this quantity.

For the returning beam we must replace s_1 with s_2 and s_0 with s_1 (since the beam departs from the reflection point right after it arrives there), which gives $s_2-s_1=l_\perp+\Delta s_\leftarrow$, where $\Delta s_\leftarrow$ is described by Eq. (26) in which s_0 is replaced with $s_0+l_\perp+\Delta s_\rightarrow$. The result is

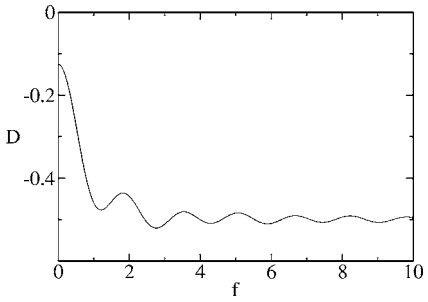

FIG. 1. The normalized average light beam delay D as a function of the normalized wave frequency f for the polarization h_+.

$$\langle \Delta s_{\leftarrow} \rangle = \langle \Delta s_{\rightarrow} \rangle - \frac{A^2 \lambda}{4\pi} \sin^2 \frac{\pi l_\perp}{\lambda} \sin \frac{2\pi l_\perp}{\lambda}. \tag{28}$$

Therefore, the total average delay of the light beam is given by

$$\langle \Delta s \rangle = \frac{A^2 \lambda^2}{8\pi^2 l_\perp} \sin^2 \frac{\pi l_\perp}{\lambda} - \frac{A^2 l_\perp}{2} + \frac{A^2 \lambda}{8\pi} \sin \frac{2\pi l_\perp}{\lambda} - \frac{A^2 \lambda}{4\pi} \sin^2 \frac{\pi l_\perp}{\lambda} \sin \frac{2\pi l_\perp}{\lambda}. \tag{29}$$

We observe that $\langle \Delta s \rangle$ is negative for all values of λ. If $l_\parallel = l_\perp$, then the light beam moving perpendicular to the direction of a gravitational wave lags (on average with respect to the departure moment s_0) behind the one which moves parallel, provided both beams left the light source at the same time. The dependence of the quantity $D = \langle \Delta s \rangle / A^2 l_\perp$ on the variable $f = \pi l_\perp / \lambda$ is shown in Fig. 1.

Now we consider the other polarization $h_\times$ for which $f^{(1)} = 0$. Equation (25) is replaced by

$$(s_1 - s_0)^3 - l_\perp^2 (s_1 - s_0) + l_\perp^2 \int_{s_0}^{s_1} (h^{(1)2}) du - l_\perp \left(\int_{s_0}^{s_1} h^{(1)} du \right)^2 = 0. \tag{30}$$

For a monochromatic plane wave, $h^{(1)} = A \cos(2\pi u / \lambda)$, instead of Eq. (26) we find

$$\Delta s_{\rightarrow} = \frac{A^2 \lambda^2}{2\pi^2 l_\perp} \left(\sin \frac{\pi l_\perp}{\lambda} \cos \frac{\pi}{\lambda} (2s_0 + l_\perp) \right)^2 - \frac{A^2 l_\perp}{4} - \frac{A^2 \lambda}{16\pi} \sin \frac{2\pi l_\perp}{\lambda} \cos \frac{2\pi}{\lambda} (2s_0 + l_\perp). \tag{31}$$

The returning beam again satisfies formula (28). Averaging over the departure moment s_0 gives

$$\langle \Delta s \rangle = \frac{A^2 \lambda^2}{2\pi^2 l_\perp} \sin^2 \frac{\pi l_\perp}{\lambda} - \frac{A^2 l_\perp}{2} - \frac{A^2 \lambda}{4\pi} \sin^2 \frac{\pi l_\perp}{\lambda} \sin \frac{2\pi l_\perp}{\lambda}. \tag{32}$$

We see that $\langle \Delta s \rangle$ is negative for all values of the length of a gravitational wave, and tends asymptotically to zero as $\lambda \to \infty$. In Fig. 2 we show the function $D(f)$. Note that for both polarizations $D \to 1/2$ as $\lambda \to 0$.

From Figs. 1 and 2 we conclude that a one-to-one relation between the average light beam delay and the wavelength exists only for waves longer than $\sim \pi l_\perp$. Moreover, the precision of the measurement of the delay is proportional to the length of the arms of the interferometer. Therefore, if we try to increase the precision by increasing this length, we end up with decrease of the range of waves measurable in this way.

V. SUMMARY

In this work we showed that the time delay of a light beam in a Michelson interferometer, obtained by treating light as massless particles moving on geodesics, agrees with the corresponding solution of the linearized coupled Einstein-Maxwell equations. We also calculated this delay in

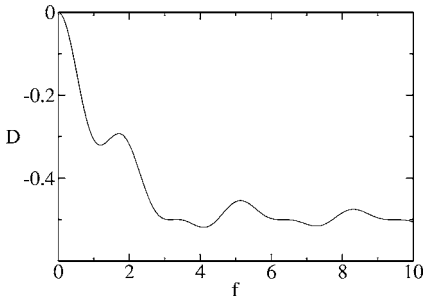

FIG. 2. The normalized average light beam delay D as a function of the normalized wave frequency f for the polarization $h_\times$.

the second (quadratic) approximation. We considered the simple case of a plane wave with the direction parallel to one arm of the interferometer, and treated the two polarizations separately. However, in reality, one should expect a broad spectrum of frequencies and a combination of both polarizations.

Averaging the light beam delay Δs over the moment of the departure of the beam s_0 would make sense if either wavelength λ is much smaller than the arm length $l_\perp$ or we measure $\langle \Delta s \rangle$ many times. Since we excluded the former, this method would not work in the case of supernova explosions that radiate significantly for a few seconds only. Instead, the presented model could be used (in principle) for continuous sources of gravitational waves such as stellar binaries containing a neutron star. As we stated in Sec. I, second-order effects in gravitational-wave detection are extremely small and thus irrelevant experimentally. However, they might be of some academic interest.

ACKNOWLEDGMENT

The author would like to express his gratitude to Professor S. L. Bażański for supervision of the M.S. thesis on which this paper is based (Faculty of Physics, University of Warsaw, Poland, 1999).

The orbital precession around oblate spheroids

J. M. C. Montanus[a)]
Bunuellaan 16, 1325 PL, Almere, The Netherlands

(Received 7 May 2006; accepted 21 May 2006; published online 20 July 2006)

An exact series will be given for the gravitational potential generated by an oblate gravitating source. To this end the corresponding Epstein-Hubbell type elliptic integral is evaluated. The procedure is based on the Legendre polynomial expansion method and on combinatorial techniques. The result is of interest for gravitational models based on the linearity of the gravitational potential. The series approximation for such potentials is of use for the analysis of orbital motions around a nonspherical source. It can be considered advantageous that the analysis is purely algebraic. Numerical approximations are not required. As an important example, the expression for the orbital precession will be derived for an object orbiting around an oblate homogeneous spheroid. © *2006 American Institute of Physics.*

I. INTRODUCTION

The basis of the analysis will be the well known expression for the gravitational potential for a point source: $\phi=GM/c^2r$. In this expression M is the mass, G is the gravitational constant, c is the velocity of light, and r is the distance with respect to the point source. One can think of a gravitating body as a collection of point sources. For a linear gravity theory the potential of the complete body simply is the sum over all the point sources: $\phi=\Sigma_i GM_i/c^2r_i$. Wherever possible, it is customary to take the continuum limit and perform the integration. As is known, for a spherical source the result of the integration will also be of the form $\phi=GM/c^2r$, where now M is the mass of the sphere and r is the distance with respect to the center of the sphere. This means that general relativity happens to be linear for the spherical situation. For nonspherical bodies the procedure of adding potentials is valid in the Newtonian limit of general relativity or in a linear gravitation theory. In the latter case the integration will lead to a series expansion for the potential of a nonspherical source.

In Sec. II the series expansion will be derived for the gravitational potential for an oblate spheroid. As a part of the analysis an Epstein-Hubbell type integral has to be solved. The evaluation of the Epstein-Hubbell elliptic type integral originates from 1963.[1] Ever since, various solution methods have been constructed for all kinds of generalizations of the Epstein-Hubbell elliptic integral.[2–4] For the evaluation of the integral under concern, use will be made of the Legendre polynomial expansion method in the same way as it recently has been used for disk galaxies.[5]

In Sec. III a new model for gravitation will be mentioned briefly. The new model describes gravitation in a flat Euclidean spacetime.[6,7] It has the advantage that it is a linear gravitation theory. The new model for gravitation is part of a larger theory.[8–10] According to this theory physics takes place in a Euclidean geometry. The results of the theory are compatible with the results of the theory of relativity. One of the differences with the theory of relativity is that proper time is taken as the fourth dimension. If one wishes, one can regard this fourth dimension as a hidden dimension. Recently, a model for elementary particles in a Eucldean geometry has been proposed on the basis of such a hidden dimension.[11] The results obtained in Sec. II will be applied

[a)]Electronic mail: hans.montanus@wxs.nl

to the new model for gravitation. Although the analysis holds for all kinds of motion, we will focus our attention to the precession of elliptic orbits. A general expression for the orbital precession will be given, with the potential unspecified. The substitution of the potential for a spherical source leads to the correct prediction for the precession of Mercury. In a recent paper the orbital precession has been derived in a pure algebraic manner for the bipole.[12] To significant order the latter equals the prediction as it results from the general theory of relativity and numerical calculations. Because of the novelty of the present theory, the algebraic result will be recalled briefly. It also illustrates that a linear gravitation theory leads to the same result as the general theory of relativity.

In Sec. IV we will consider an oblate spheroid as the source of gravitation. The exact series for the potential will be derived by means of an appropriate integration method. Finally, the exact series for the orbital precession will be given.

In Sec. V the results will be discussed briefly.

II. THE EPSTEIN-HUBBELL INTEGRAL FOR GRAVITATION

We start considering homogeneous disk sources. These disk sources have a cylindrical shape with radius R and thickness S. For convenience, the disk is taken in the $z=0$ or $\theta=0$ plane with the center of the disk in the origin. For such a disk source the potential is given by

$$\phi = \frac{4G\rho}{c^2}\int_0^{S/2}\int_0^{\pi}\int_0^{R} uk\,dk\,d\varphi\,dz, \tag{1}$$

with $u=1/\sqrt{k^2-2kr\cos\varphi+r^2+z^2}$. In this expression ρ is the homogeneous density and k, φ, z are the cylindrical coordinates in the interior of disk.[5] To be specific, φ is the azimuthal angle, z is the height and k is the radial distance in the $z=0$ plane with respect to the center of the disk. The elliptic integral (1) is known as an Epstein-Hubbell type integral. The integral can be evaluated exactly by expanding the function u in terms of Legendre polynomials. First, the function u is written as a Taylor series with respect to k:

$$u = \sum_{n=0}^{\infty} \frac{u^{(n)}(0)k^n}{n!}, \tag{2}$$

where $u^{(n)}(0)$ stands for the nth derivative of u with respect to k and evaluated at $k=0$. In addition, a function v is defined as follows: $v=r\cos\varphi-k$. The functions u and v have the following property: $u^{(1)}=u^3v$ and $v^{(1)}=-1$. By means of this property one finds for the higher order derivatives with respect to k:

$$u^{(n)}(0) = n!\,w^{-(n+1)/2}P_n(w^{-1/2}r\cos\varphi). \tag{3}$$

In the latter equation $w:=r^2+z^2$ and the P_n are the Legendre polynomials: $P_n(x)=(1/2^n)(1/n!)\times(d^n/dx^n)(x^2-1)^n$. Substituting the power series (2) into the equation (1), we obtain for the potential:

$$\phi(r) = \frac{4G\rho}{c^2}\sum_{n=0}^{\infty}\int_0^{R} k^{n+1}\,dk\int_0^{S/2} w^{-(n+1)/2}\int_0^{\pi} P_n(w^{-1/2}r\cos\varphi)d\varphi\,dz. \tag{4}$$

Since the integral vanishes for odd n, the integration over k yields

$$\phi(r) = \frac{4G\rho}{c^2}\sum_{n=0}^{\infty}\frac{1}{2t+2}R^{2t+2}\int_0^{S/2} w^{-(n+1)/2}\int_0^{\pi} P_n(w^{-1/2}r\cos\varphi)d\varphi\,dz. \tag{5}$$

This integral can be evaluated exactly in a systematic way.[5] For the derivative of the gravitational potential with respect to r, the result is

$$d_r\phi = -\frac{GM}{c^2 r^2}\sum_{t=0}^{\infty} A_t B_t(\lambda) C_t(\lambda)\left(\frac{R}{r}\right)^{2t}, \tag{6}$$

where d_r stands for the derivative with respect to r, $M=\pi R^2 S\rho$ is the mass of the disk and where the coefficients A, B, and C are given by

$$A_t = \frac{1}{2^{4t}}\cdot\frac{2t+1}{t+1}\cdot\left(\tfrac{2t}{t}\right)^2, \tag{7}$$

$$B_t(\lambda) = (1+\lambda^2)^{-2t-1/2}, \tag{8}$$

$$C_t(\lambda) = \sum_{i=0}^{t} d_{ti}\lambda^{2i} \tag{9}$$

with

$$d_{ti} = \binom{2t}{t}^{-1}\sum_{j=0}^{i}\frac{(-1)^j(2t+2j)!}{(2j+1)!\,(t+j)!\,(t-i)!\,(i-j)!}. \tag{10}$$

Here λ is defined as $\lambda := S/2r$. In case the distance r with respect to the center of the disk is larger than the size of the disk (either S or R) the derivative of the potential can also be written in an alternative way. That is, expanding the $B_t(\lambda)$, writing λ as $\sigma R/r$ and recollecting equal powers of R/r, we obtain

$$d_r\phi = -\frac{GM}{c^2 r^2}\sum_{t=0}^{\infty} A_t C_{t+1}(\sigma)\left(\frac{R}{r}\right)^{2t}, \tag{11}$$

where $\sigma = S/2R$ is the oblateness of the disk. Explicitly it reads to sixth order as

$$d_r\phi = -\frac{GM}{c^2 r^2}\left[1+\frac{3}{8}\left(1-\frac{4}{3}\sigma^2\right)\left(\frac{R}{r}\right)^2+\frac{15}{64}\left(1-4\sigma^2+\frac{8}{5}\sigma^4\right)\left(\frac{R}{r}\right)^4+\frac{175}{1024}\left(1-8\sigma^2+\frac{48}{5}\sigma^4-\frac{64}{35}\sigma^6\right)\times\left(\frac{R}{r}\right)^6+\ldots\right]. \tag{12}$$

The power series for the derivative of the potential for the disk will serve as the building block for the derivative of the potential for the oblate spheroid. In order to build a general function for an oblate spheroid out of the function for a disk one needs a suitable integration procedure.

First of all, it will be assumed that the cross section of the oblate spheroid through the origin is an ellipse. In analogy with the oblateness of a disk, the oblateness of the ellipse (or the oblateness of the spheroid) is defined as the semiminor axis divided by the semimajor axis: $\sigma = L\sqrt{1-\epsilon^2}/L$ or $\sigma^2 = 1-\epsilon^2$, where ϵ is the eccentricity of the ellipse. In the sequel we will not work with the eccentricity of the elliptic cross section just in order to avoid confusion with the eccentricity of the elliptic orbit. That is, the oblateness of the spheroid will be characterized solely by the oblateness σ. The symbol ϵ will be strictly reserved for the eccentricity of the orbit.

Now we consider a cylinder with radius q inside the spheroid, $q<R$ such that it precisely touches the surface of the spheroid. The cross section then is a rectangle with sizes $2q$ and $2h$, where the h and q are related according to the elliptic shape: $h=\sigma\sqrt{R^2-q^2}$. The value h is with respect to the equatorial plane, thus half the height of the cylinder. We can imagine the spheroid to be build of these cylinders. That is, we start with a cylinder with small radius q_0 and corresponding height $2h_0$ in the middle of the spheroid. Around it one can think a cylindrical tube with inner radius q_0, outer radius q_1, and height $2h_1$. Outside that tube is a next tube with inner radius q_1, outer radius q_2 and height $2h_2$ and so on until the last tube with outer radius equal to R and

height equal to 0. Tube number i with outer radius q_i and height $2h_i$ can be regarded as a cylinder with radius q_i and height $2h_i$ minus a cylinder with radius q_{i-1} and height $2h_i$. The calculation of the influence of a spheroid then is a matter of counting up the influence of all the tubes. For a general function F, this is

$$F = F(q_0,h_0) + F(q_1,h_1) - F(q_0,h_1) + \cdots + F(q_i,h_i) - F(q_{i-1},h_i) + \cdots . \tag{13}$$

Using

$$F(q_i,h_i) - F(q_{i-1},h_i) \approx (q_i - q_{i-1}) \cdot \left(\frac{\partial F}{\partial q}\right), \tag{14}$$

and taking the continuum limit yields the following expression for F:

$$F = \int_0^R \left(\frac{\partial F}{\partial q}\right) dq. \tag{15}$$

Alternatively, we first calculate the partial derivative of F with respect to q and then we substitute the function $h(q)$ for h and perform the integration.

The method will be illustrated by the simple case of the calculation of the mass of a homogeneous spheroid. We start with the mass of a homogeneous cylinder with density ρ, radius q and height $2h$: $2\rho\pi q^2 h$. The partial derivative with respect to q yields $4\rho\pi qh$. Now we substitute $h = \sigma\sqrt{R^2-q^2}$ in the integral for the mass of the spheroid:

$$M = 4\pi\rho\sigma R^3 \int_0^1 x\sqrt{1-x^2}\,dx. \tag{16}$$

An evaluation of the integral yields the correct value for the mass of an oblate spheroid: $M = \frac{4}{3}\pi\rho\sigma R^3$. Now we turn to the calculation of the derivative of the potential for an oblate spheroid. According to Eqs. (6) and (11) the derivative of the potential of a homogeneous cylinder with radius q and thickness $2h$ is given by

$$d_r\phi = -\frac{2\rho\pi q^2 hG}{c^2 r^2} \sum_{t=0}^{\infty} A_t B_t\left(\frac{h}{r}\right) C_t\left(\frac{h}{r}\right)\left(\frac{q}{r}\right)^{2t} \tag{17}$$

and

$$d_r\phi = -\frac{2\rho\pi q^2 hG}{c^2 r^2} \sum_{t=0}^{\infty} A_t C_{t+1}(\sigma)\left(\frac{q}{r}\right)^{2t}, \tag{18}$$

respectively. It does not matter which one we take, since they are identical. As for the mass, we take the partial derivative with respect to q, substitute the expression $\sigma\sqrt{R^2-q^2}$ for h, evaluate the integral Eq. (15), and collect equal powers of $R/2r$. After some elaboration we arrive at the following result:

$$d_r\phi = -\frac{3GM}{c^2 r^2}\left[\frac{1}{3} + \frac{2}{5}(1-\sigma^2)\left(\frac{R}{2r}\right)^2 + \frac{6}{7}(1-\sigma^2)^2\left(\frac{R}{2r}\right)^4 + \frac{20}{9}(1-\sigma^2)^3\left(\frac{R}{2r}\right)^6 + \frac{70}{11}(1-\sigma^2)^4\left(\frac{R}{2r}\right)^8 + \cdots\right], \tag{19}$$

where M is the mass of the spheroid. The latter can also be written as

$$d_r\phi = -\frac{GM}{c^2r^2}\sum_{t=0}^{\infty}\frac{3}{2t+3}\binom{2t}{t}\left(\frac{\alpha}{2}\right)^{2t}, \tag{20}$$

where the quantity α is defined as $\alpha := \sqrt{1-\sigma^2}R/r$. These expressions are identical to the power series of the following function:

$$d_r\phi = \frac{3GM}{2c^2r^2}\left(\frac{\sqrt{1-\alpha^2}}{\alpha^2} - \frac{\arcsin\alpha}{\alpha^3}\right). \tag{21}$$

Note that for a perfect sphere, $\sigma=1$, the latter expressions are reduced to $d_r\phi=-GM/c^2r^2$, exactly as required.

III. GENERAL DIFFERENTIAL EQUATION FOR ORBITAL MOTION

The theory of relativity is based on a Minkowskian geometry and in case of gravitational interactions even on curved spacetime. Recently, there has been proposed an alternative based on a Euclidean geometry.[8–14] Gravitational dynamics does not require an interpretation in terms of a curvature of spacetime.[6–8] According to this new model the proper time of an object is taken as its fourth coordinate: $x_4c := \tau$. As a consequence one obtains a circular spacetime diagram where distances are measured with the flat Euclidean metric: $ds^2=dx^2+dy^2+dz^2+c^2\,d\tau^2$, even in the presence of gravitation. The Schwarzschild counterpart of the Lagrangian for gravitational dynamics in a flat Euclidean spacetime is given by

$$L = m[e^{2\phi}(c\dot{\tau})^2 + e^{4\phi}(\dot{x}^2+\dot{y}^2+\dot{z}^2)], \tag{22}$$

where the overdot represents the derivative with respect to the global time t. In case of a spherical source the latter reads in polar coordinates

$$L = m[e^{2\mu/r}(c\dot{\tau})^2 + e^{4\mu/r}(\dot{r}^2+r^2\omega^2)], \tag{23}$$

where $\mu=GM/c^2$ is half the Schwarzschild radius. It leads to the correct prediction for the deflection of light and the orbital precession of Mercury.[8] Also, the prediction for the orbital precession around the bipole is in excellent agreement with the prediction of general relativity.[12] The new model leads in a straightforward manner to an algebraic expression for the relationship between the precession around the bipole and the distance between the two spheres who constitute the bipole.[12] In contrast, in the general theory of relativity one has to resort to numerical solutions.[15] Both solutions are identical to significant order. The advantage of the new gravitation theory is that it is a linear theory. For two or more spherical bodies, one can add the potentials of all the individual spheres. For bodies with non-spherical shape one can integrate over the volume precisely as we did in the previous section for an oblate spheroid. For the analysis of the orbital motion one has to substitute the resulting potential in the Lagrangian (22). However, one can avoid labor if one first derives the general differential equation for the orbital motion with an unspecified potential and substitutes the expression for the potential afterward. Since we restrict ourselves to motions in the $z=0$ plane, the orbital motion will be derived from the following Lagrangian:

$$L = m[e^{2\phi}(c\dot{\tau})^2 + e^{4\phi}(\dot{r}^2+r^2\omega^2)]. \tag{24}$$

The corresponding Euler-Lagrange equations of motion are

$$me^{4\phi}r^2\omega = A, \tag{25}$$

$$me^{2\phi}c\dot{\tau} = B \tag{26}$$

and

$$m^2c^2 = m^2e^{2\phi}(c\dot{\tau})^2 + m^2e^{4\phi}(\dot{r}^2 + r^2\omega^2). \tag{27}$$

Substituting the Eqs. (25) and (26) into the Eq. (27) and changing coordinates to $u := 1/r$, we obtain

$$m^2c^2 = e^{-2\phi}B^2 + e^{-4\phi}A^2(u'^2 + u^2). \tag{28}$$

The prime denotes the derivative with respect to the orbital angle φ. The derivative with respect to φ followed by the resubstitution of the Eq. (28) gives

$$(d_u\phi)^{-1}e^{-2\phi}A^2(u'' + u) + B^2 - 2e^{2\phi}m^2c^2 = 0, \tag{29}$$

where d_u stands for the derivative with respect to u.

An elliptic orbit without a precession is described as follows:

$$u = \frac{(1 + \epsilon\cos\varphi)}{L(1 - \epsilon^2)}, \tag{30}$$

where ϵ is the eccentricity of the orbit, L is the semimajor axis of the orbit and u is the inverse distance: $u = 1/r$. The equation (30) satisfies the zeroth order equation,

$$u'' + u = \frac{1}{L(1 - \epsilon^2)}. \tag{31}$$

Now we take the derivative of Eq. (29) with respect to φ and substitute the zeroth order equation (31). The result is

$$u''' + u'\left(1 + \frac{2r + r^2\, d_r^2\phi(d_r\phi)^{-1} + 2r^2\, d_r\phi}{L(1 - \epsilon^2)} - \frac{4r^2(d_r\phi)^2m^2c^2}{A^2}\right) = 0. \tag{32}$$

In this expression a factor $e^{4\phi}$ has been set equal to unity in the last term between the brackets, since the difference is of insignificant order. The Eq. (32) is the general differential equation for elliptic orbital motion.

IV. THE ORBITAL PRECESSION FOR OBLATE SPHEROIDS

For elliptic orbits with a precession one cannot neglect the second and last term between the brackets in the differential equation (32). To evaluate these terms we first will substitute the value for A. The constant A is determined by looking for its value at the perihelion.[6] It suffices to substitute the lowest order value for A in the differential equation. In the present analysis the plane of the orbit equals the equatorial plane of the source. For bodies like disks, spheres, and spheroids, the lowest order value for A then reads as

$$A^2 = \mu m^2c^2L(1 - \epsilon^2). \tag{33}$$

With the substitution of this expression for A, the differential equation for u is reduced to

$$u''' + u'\left(1 + \frac{2r + r^2d_r^2\phi(d_r\phi)^{-1} + 2r^2d_r\phi}{L(1 - \epsilon^2)} - \frac{4r^4(d_r\phi)^2}{\mu L(1 - \epsilon^2)}\right) = 0. \tag{34}$$

Now we can substitute the expression (19) for $d_r\phi$. The result is

$$u''' + u'\left(1 - \frac{K}{L(1 - \epsilon^2)}\right), \tag{35}$$

where K stands for the following power series:

$$K = 6\mu + \frac{3r+5\mu}{5}(1-\sigma^2)\left(\frac{R}{r}\right)^2 + \frac{324r+1377\mu}{700}(1-\sigma^2)^2\left(\frac{R}{r}\right)^4 + \frac{8184r+29975\mu}{21\,000}(1-\sigma^2)^3\left(\frac{R}{r}\right)^6 + \frac{7\,390\,528r+23\,695\,625\mu}{21\,560\,000}(1-\sigma^2)^4\left(\frac{R}{r}\right)^8 + \cdots . \tag{36}$$

From a practical point of view we will not consider motions in the vicinity of an extremely dense source. That is, we will restrict ourselves to the situation where $\mu \ll r$. When terms of order μ/r are neglected, the quantity K is reduced to

$$K = 6\mu + \frac{3r}{5}(1-\sigma^2)\left(\frac{R}{r}\right)^2 + \frac{81r}{175}(1-\sigma^2)^2\left(\frac{R}{r}\right)^4 + \frac{341r}{875}(1-\sigma^2)^3\left(\frac{R}{r}\right)^6 + \frac{115\,477r}{336\,875}(1-\sigma^2)^4\left(\frac{R}{r}\right)^8 + \cdots . \tag{37}$$

The latter can be written a little bit more elegantly as follows:

$$K = 6\mu + r\left[3\left(\frac{\alpha^2}{5}\right) + \frac{81}{7}\left(\frac{\alpha^2}{5}\right)^2 + \frac{341}{7}\left(\frac{\alpha^2}{5}\right)^3 + \frac{115\,477}{539}\left(\frac{\alpha^2}{5}\right)^4 + \frac{6\,776\,661}{7007}\left(\frac{\alpha^2}{5}\right)^5 + \frac{59\,419\,831}{13\,377}\left(\frac{\alpha^2}{5}\right)^6 + \frac{7\,380\,857\,431}{357\,357}\left(\frac{\alpha^2}{5}\right)^7 + \cdots\right]. \tag{38}$$

Here and in the sequel, $\alpha = \sqrt{1-\sigma^2}$. As can be inferred from Eq. (21) the latter is a power series of the following function:

$$K = 6\mu - r\left(\frac{\alpha^3 + 3\sqrt{1-\alpha^2}\arcsin\alpha - 3\alpha}{\alpha^3 + \sqrt{1-\alpha^2}\arcsin\alpha - \alpha}\right). \tag{39}$$

According to the averaging method, we approximate K by its average value $\langle K\rangle$:

$$\langle K\rangle \approx = \frac{1}{T}\int_0^T K(t)dt, \tag{40}$$

where T is the period of a revolution. Since $\langle K\rangle$ is independent of $u = 1/r$, an approximate solution for the differential equation (35) can be found. It reads as

$$u(\varphi) = \frac{1+\epsilon\cos[(1-p/2\pi)\varphi]}{L(1-\epsilon^2)}, \tag{41}$$

where the precession per revolution p is given by

$$p = \frac{\pi\langle K\rangle}{L(1-\epsilon^2)}. \tag{42}$$

When the source of gravitation is a perfect sphere, $\sigma = 1$, $\alpha = 0$, $\langle K\rangle = K = 6\mu$, the precession reads as

$$p = \frac{6\pi\mu}{L(1-\epsilon^2)}, \tag{43}$$

precisely in agreement with the prediction from the general theory of relativity. When the source of gravitation is an oblate spheroid, $\sigma < 1$, or a prolate spheroid, $\sigma > 1$, the precession will, in general, differ from the expression (43). For this situation there are two ways to proceed with the analysis of the precession.

One way is to keep the orbit fixed and to vary the radius R of the source. This is appropriate when $R \ll L$. For this situation it suffices to consider terms up to order R^2/r^2:

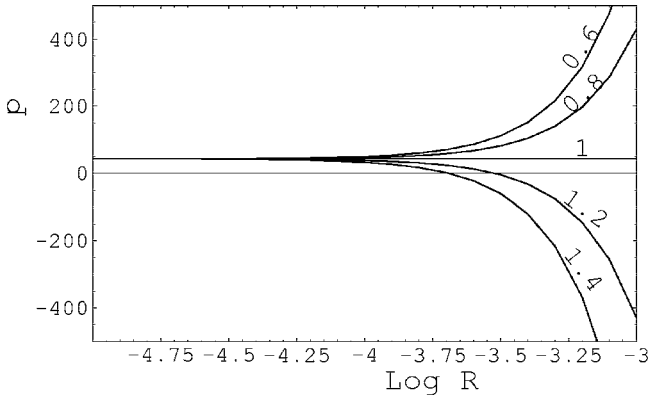

FIG. 1. The orbital precession against the radius of the spheroid for the values 0.6, 0.8, 1.0, 1.2, and 1.4 of the oblateness σ.

$$K \approx 6\mu + \frac{3}{5}\frac{R^2(1-\sigma^2)}{r}. \tag{44}$$

Substitution of the average value $1/L$ for $u=1/r$ gives

$$\langle K \rangle \approx 6\mu + \frac{3}{5}\frac{R^2(1-\sigma^2)}{L}. \tag{45}$$

The expression for the precession (in radians per revolution) then is reduced to

$$p \approx \frac{6\pi\mu}{L(1-\epsilon^2)}\left(1 + \frac{R^2(1-\sigma^2)}{10\mu L}\right). \tag{46}$$

In order to make a comparison, we imagine that Mercury is orbiting around the spheroid. That is, we substitute the values for L and ϵ as they hold for Mercury and the value for μ as it holds for the Sun. The relationship between the radius R (in astronomical units) and the precession p (in arcseconds per century) is then given by

$$p \approx 43'' \cdot \left[1 + (1-\sigma^2) \cdot \left(\frac{R}{2\times 10^{-4}}\right)^2\right]. \tag{47}$$

Figure 1 illustrates the latter relationship between R in astronomical units and the orbital precession p (in arcseconds per century) for various values of σ.

The other way is to keep the radius R of the spheroid fixed and to vary the radius r of the orbit. This seems appropriate when the radius of the orbit does not differ very much from the radius of the spheroid. For this situation we have to use the full equation (38). The averaging method will then give rise to all kinds of powers of $\sqrt{(1-\epsilon^2)}$ in the expression for $\langle K \rangle$. Since we are mainly interested in the consequences of the oblateness of the spheroid, the eccentricity of the orbit will be neglected for convenience. The precession (in radians per revolution) then is given by

$$p = \frac{6\pi\mu}{r} - \pi\left(\frac{\alpha^3 + 3\sqrt{1-\alpha^2}\arcsin\alpha - 3\alpha}{\alpha^3 + \sqrt{1-\alpha^2}\arcsin\alpha - \alpha}\right). \tag{48}$$

In order to make a comparison, we let the spheroid have a mass and radius identical to the Sun. It is obvious to regard the radius of the orbit in units of the Sun radius: $r=xR$. Since we vary the radius of the orbit, also the period of the orbit varies. To obtain the precession per second we have to take the precession per revolution times the number of revolutions per second. The latter, of

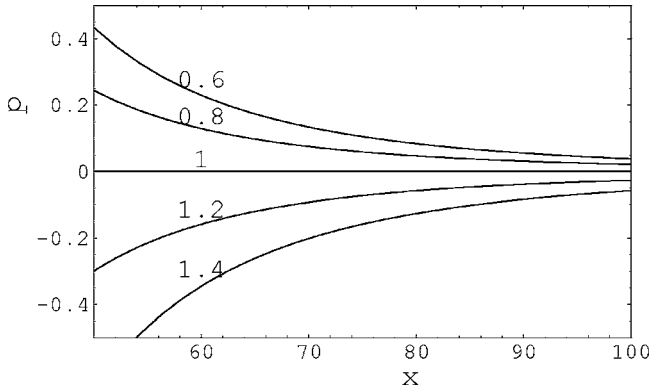

FIG. 2. The orbital precession against the relative radius of the orbit for the values 0.6, 0.8, 1.0, 1.2, and 1.4 of the oblateness σ.

course, is equal to $1/T$ where $T=2\pi\frac{r}{c}\sqrt{r/\mu}$ is the well known expression for the period of the orbit. For the precession in radians per second we then obtain

$$p = 3c\sqrt{\frac{\mu^3}{x^5R^5}} - \frac{c}{2}\sqrt{\frac{\mu}{x^3R^3}}\left(\frac{\alpha^3 + 3\sqrt{1-\alpha^2}\arcsin\alpha - 3\alpha}{\alpha^3 + \sqrt{1-\alpha^2}\arcsin\alpha - \alpha}\right). \tag{49}$$

If we substitute the values for R and μ as they hold for the Sun. The relationship between the relative orbit radius x (in sun radii) and the precession p (in radians per century) is then given by

$$p \approx \frac{13}{\sqrt{x^5}} - \frac{1\times 10^6}{\sqrt{x^3}}\left(\frac{\alpha^3 + 3\sqrt{1-\alpha^2}\arcsin\alpha - 3\alpha}{\alpha^3 + \sqrt{1-\alpha^2}\arcsin\alpha - \alpha}\right). \tag{50}$$

Figure 2 illustrates the relationship between the value x and the orbital precession for various values of σ.

It also is illustrative to consider the situation for a fixed radius of the spheroid at a fixed orbital radius (say the radius of Mercury) and to vary solely the oblateness of the spheroid. Substituting the values for R and μ as they hold for the Sun and of the value for r as it holds for Mercury, we obtain for the precession of the orbit in arcseconds per century:

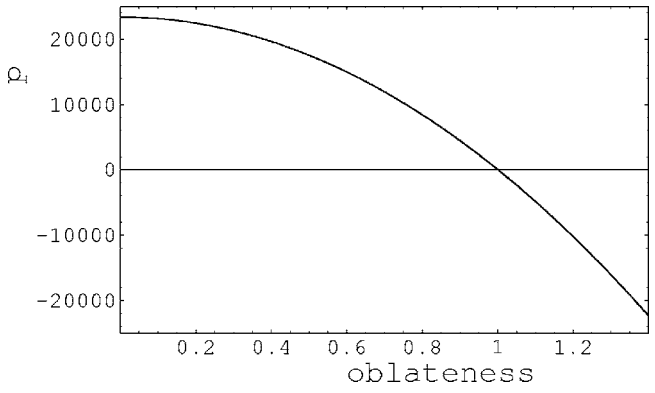

FIG. 3. The orbital precession against the oblateness σ of the gravitational source.

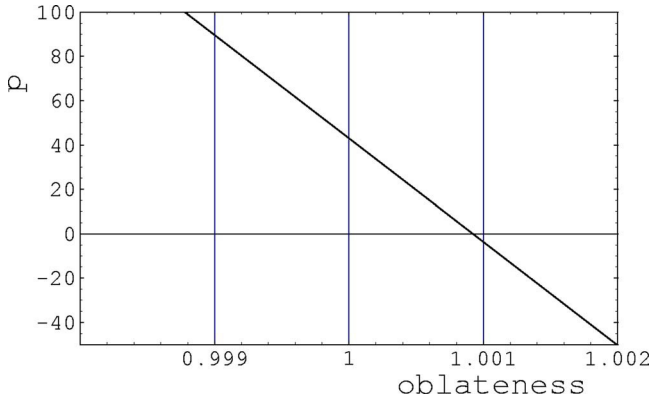

FIG. 4. (Color online) The orbital precession against the oblateness σ for a nearly spherical gravitational source.

$$p \approx 43 - 2.7 \times 10^8 \left(\frac{\lambda^3 + 3\sqrt{1-\lambda^2}\arcsin\lambda - 3\lambda}{\lambda^3 + \sqrt{1-\lambda^2}\arcsin\lambda - \lambda} \right), \tag{51}$$

where $\lambda \approx 0.012\sqrt{1-\sigma^2}$. As can be inferred from Eq. (47) the latter expression is approximately equal to

$$p \approx 43[1 + 550 \cdot (1-\sigma^2)]. \tag{52}$$

In Fig. 3 the precession (in arcseconds per century) is plotted against the oblateness of the spheroid. We see that the precession reaches a maximum value of about 23500 arcseconds per century when $\sigma=0$. That is, if the Sun would be a perfectly flat disk, Mercury would orbit around it with a precession of about 6.5° per century. For the details of the precession around a nearly spherical gravitational source, we have to zoom in at $\sigma \approx 1$. This is done in Fig. 4. We see that for $\sigma=1$ the precession is about 43 arcseconds per century. For the Sun, $\sigma \approx 0.999\,991$. Since the difference with respect to unity is so small, the contribution of the oblateness of the Sun to the precession of Mercury is less than half an arcsecond per century. We also see that the precession decreases for increasing σ. The precession of Mercury would be zero in case of a prolate Sun with $\sigma \approx 1.000\,92$. For larger values the precession rapidly falls off.

V. DISCUSSION OF THE RESULTS

We showed how the Epstein-Hubbell type integral for the gravitational potential for a disk can be evaluated by means of Legendre polynomials. By means of integration by parts one can obtain the expression for the gravitational potential for a spheroid. The method can be applied to gravitational theories based on a linear potential. In the present alternative model the linearity for gravitation is restored. In contrast to general relativity, it is based on a flat and Euclidean spacetime. Nevertheless, it leads to the same prediction for gravitational time dilation, gravitational lensing, and the orbital precession around a point source or a bipole as the general theory of relativity. In this paper we applied the method for the analysis of the orbital precession around an oblate spheroid. Obviously the new model allows for the analysis of gravitational motion in situations that are difficult to solve within the general theory of relativity. The precession of orbits around an oblate spheroid source is derived algebraically. To my knowledge, such a result has never been obtained with the general theory of relativity.

The paper might be of value for mathematicians interested in the mathematical correspondence between two different models for gravitation as well as for mathematicians interested in the applications of Epstein-Hubbell integrals.

The path topology and the causal completion

Do-Hyung Kim[a)]
Department of Mathematics, Korea Advanced Institute of Science and Technology, 373-1, Kusong-Dong, Yusong-Gu, Taejon, 305-701, Korea

(Received 3 February 2006; accepted 6 June 2006; published online 24 July 2006)

It is shown that the path topology of Hawking, King, and McCarthy can be extended to the causal completion of a globally hyperbolic Lorentzian manifold. The suggested topology $\mathcal{T}$ is defined only in terms of chronological structures and $\mathcal{T}$ is finer than the extended Alexandrov topology. It is also shown that a $\mathcal{T}$-homeomorphism induces a conformal isomorphism and a homeomorphism in the extended Alexandrov topology. © *2006 American Institute of Physics.*

I. INTRODUCTION

In the sense that the Lorentzian geometry gives mathematical tools and models to Einsten's general relativity, a causality is one of the major areas of the Lorentzian geometry. By a causality, we refer to the general question of which points in a space-time can be joined by causal curves. Relativistically, this is the question of which events can influence a given event. In a particular space-time, a causality may be trivial, but under fairly mild conditions it is closely related to fundamental geometrical properties. For example, it is well known that the Alexandrov topology $\mathcal{A}$ agrees with the given manifold topology $\mathcal{M}$ if and only if the strong causality condition holds.[1]

In connection with this, in 1964, Zeeman[2] has shown that the causal structure of Minkowski space already implies its linear structure. Also, in 1967, he proposed a new topology on Minkowski space that describes timelike and spacelike directions separately. Zeeman's idea on the new topology of Minkowski space was motivated by the fact that Euclidean space is locally isotropic whereas Minkowski space is not; every point has its associated light cone separating spacelike vectors from timelike vectors.

In 1976, Hawking, King, and McCarthy[3] took Zeeman's idea and they proposed a new topology $\mathcal{P}$, called the path topology, on a space-time which is strongly causal. They have shown that $\mathcal{P}$ has several advantages: $\mathcal{P}$ is defined only in terms of timelike curves and a $\mathcal{P}$-continuous curve has a very close relation to timelike curves. One of the advantages of $\mathcal{P}$ is that a $\mathcal{P}$-homeomorphism naturally induces a conformal diffeomorphism and thus $\mathcal{P}$ determines the causal, differential, and conformal structure of the manifold. However, there is a certain disadvantage on $\mathcal{P}$ in the sense that the manifold topology $\mathcal{M}$ is used implicitly in the definition of $\mathcal{P}$.

In 1991, Fullwood[4] proposed a new topology $\tilde{\mathcal{P}}$ defined only in terms of causal structures on the Lorentzian manifold in which the chronological condition is satisfied. He also proved that $\tilde{\mathcal{P}}$ is equivalent to the path topology if and only if the distinguishing condition holds. Thus if the distinguishing condition holds, $\tilde{\mathcal{P}}$ determines the causal, differential, and conformal structure of the manifold. Not only extending the path topology, he has shown that the topology $\tilde{\mathcal{P}}$ can be defined in terms of timelike sequences and its causal limits, which will be used in this paper.

A causal boundary was introduced by the need to control singular points effectively. In 1972, Geroch, Kronheimer, and Penrose[5] constructed the causal boundary of a strongly causal space-

[a)]Electronic mail: mathph@kaist.ac.kr

time. Whereas they constructed the causal boundary only from the properties of a space-time itself, the causal relation cannot be extended to boundary points and the identification rule cannot be given explicitly by the Hausdorff condition of the topology.

In 1974, Budic and Sachs (BS)[6] proposed a new causal boundary construction, ∂M, which states that in a causally continuous space-time, the Hausdorff condition can be naturally satisfied and the causal relation can be extended to the ideal boundary. The topology of the BS-causal completion was defined in terms of the causal relation and is called the extended Alexandrov topology, denoted by $\bar{\mathcal{A}}$. The fact that the BS-causal completion $\bar{M}$ is Hausdorff and is itself an abstract causal set suggests that the Fullwood's method can be applied to the BS-causal completion.

In this paper, it is shown that the path topology can be defined on the BS-causal completion if the manifold is globally hyperbolic. The new topology $\mathcal{T}$ is shown to be finer than the Extended Alexandrov topology $\bar{\mathcal{A}}$ and the inclusion map $i:(M,\tilde{\mathcal{P}})\hookrightarrow(\bar{M},\mathcal{T})$ is shown to be a dense imbedding. Also, it is shown that a $\mathcal{T}$-homeomorphism induces a conformal isomorphism and thus $\mathcal{T}$ determines the causal, differential, and conformal structure of the manifold.

As noted by several authors, in a sense, the structure of a causal boundary determines its inner structure: (1) M is globally hyperbolic if and only if $I^{\pm}(x)=\emptyset$ for $x\in\partial M$; (2) if ∂M is spacelike, then $\bar{M}$ is geodesically connected. Furthermore, Penrose has shown that the strong cosmic censorship is equivalent to $I^{\pm}(x)=\emptyset$ for $x\in\partial M$, which is equivalent to the condition that the space-time be globally hyperbolic. When we consider the fact that the BS-causal completion contains all the singular points of our space-time, the fact that a $\mathcal{T}$-homeomorphism on the BS-causal completion induces a conformal diffeomorphism on M tells us that singularities have deep effects on the structure of our space-time.

II. THE PATH TOPOLOGY

Let M be a time-oriented space-time, that is, M is a connected C^{∞} Hausdorff manifold with a countable basis, a Lorentz metric g of signature $(-,+,+,+)$, and a time orientation

A smooth future-directed curve in M is a smooth curve whose tangent vector is never vanishing, future directed nonspacelike, which means the tangent is always timelike or lightlike. If the tangent is always timelike the curve is said to be a timelike curve. If there is a future-directed timelike curve from x to y, we write $x\ll y$. When there is a future-directed curve from x to y, or when $x=y$, we write $x\leqslant y$. The chronological future $I^{+}(x)$ and the chronological past $I^{-}(x)$ are defined by $I^{+}(x)=\{y\,|\,x\ll y\}$ and $I^{-}(x)=\{y\,|\,y\ll x\}$. When S is a subset of M, one defines $I^{+}(S)=\{y\,|\,s\ll y$ for some $s\in S\}$. The causal future of a point x is defined by $J^{+}(x)=\{y\,|\,x\leqslant y\}$. Furthermore, one may define $J^{-}(x)=\{y\,|\,y\leqslant x\}$, $J^{+}(S)=\{y\,|\,s\leqslant y$ for some $s\in S\}$ and $J^{-}(S)=\{y\,|\,y\leqslant s$ for some $s\in S\}$. $I^{+}(p,N)$ is the set of points that can be reached by a smooth future-directed timelike curve from p in N. $I^{-}(p,N)$ is the dual to the past. $J^{+}(p,N)$ and $J^{-}(p,N)$ allow nonspacelike curves in similar definition to $I^{+}(p,N)$ and $I^{-}(p,N)$.

Throughout this paper, we denote the manifold topology of M by $\mathcal{M}$. It is well known that $I^{+}(p)$ and $I^{-}(p)$ is always $\mathcal{M}$-open and so $I^{+}(p)\cap I^{-}(q)$ is $\mathcal{M}$-open for any pair of points in M. The Alexandrov topology, $\mathcal{A}$, is the topology obtained by taking the set of the form $I^{+}(p)\cap I^{-}(q)$ as a basis. Then the following is a well-known fact.

Theorem 1: *The following are equivalent.*

(1) *The Alexandrov topology $\mathcal{A}$ agrees with the manifold topology $\mathcal{M}$.*
(2) *The strong causality condition holds on M.*
(3) *The Alexandrov topology is Hausdorff.*

Hawking, King, and McCarthy[3] defined that a set $E\subset M$ is $\mathcal{P}$-open if and only if for every timelike curve γ, there is an $O\in\mathcal{M}$ such that $E\cap\gamma=O\cap\gamma$. Then as can easily be shown, $\mathcal{P}$ is finer than $\mathcal{M}$, and we can prove the following.

Proposition 2.1: Let $\gamma:I\to M$ be a curve. If γ is $\mathcal{P}$-continuous, then γ is $\mathcal{M}$-continuous. If γ is timelike, then γ is $\mathcal{P}$-continuous.

Hawking, King, and McCarthy[3] have also shown that the sets of the form $I^+(p,U)\cup I^-(p,U)\cup\{p\}$ form a basis for $\mathcal{P}$ where U is a convex normal neighborhood. Thus we get the following.

Proposition 2: For any $\mathcal{P}$-open neighborhood U of $p\in M$, there is future (past, respectively)-directed timelike curve in U with p its future (past, respectively) end point.

Fullwood[4] defined the $\widetilde{\mathcal{P}}$-topology by taking the sets of the form $[I^+(p)\cap I^-(q)]\cup[I^+(q)\cap I^-(r)]\cup\{q\}$, for $p\ll q\ll r$, as a basis and has shown that $\mathcal{P}=\widetilde{\mathcal{P}}$ if and only if the distinguishing condition holds on M.

Fullwood has shown that the path topology can be obtained in a different manner described as follows. A sequence $\{x_i\}$ of points in M is said to be monotonic timelike if either $x_i\ll x_{i+1}$ or $x_{i+1}\ll x_i$ for each i. A sequence $\{x_i\}$ is said to be causally convergent to $x\in M$ if either $I^-(x)=\cup I^-(x_j)$ for each subsequence of $\{x_i\}$ or $I^+(x)=\cup I^+(x_j)$ for each subsequence of $\{x_i\}$. By the above definition for a sequential convergence, Fullwood defined a set $E\subset M$ to be $\mathcal{P}'$-closed if every monotonic timelike sequence in E that causally converges has a limit in E. Fullwood has proven that, actually, $\mathcal{P}'=\widetilde{\mathcal{P}}$. Since we assume that M is globally hyperbolic throughout in this paper, we do not distinguish $\mathcal{P}$, $\widetilde{\mathcal{P}}$, and $\mathcal{P}'$ and call the equivalent topology as the path topology.

One of the most notable properties of the path topology is that the topology itself determines the causal structure of the space-time. This stems from the fact that the construction of the path topology uses the timelike curve. It thus seems that many calculations involving the causal, differential structure may be made purely topological. We state some of the properties of the $\mathcal{P}$-homeomorphism between Lorentzian manifolds.

Proposition 2.3: A $\mathcal{P}$-homeomorphism is a C^∞ diffeomorphism.

Theorem 2.2: *A $\mathcal{P}$-homeomorphism h is a smooth conformal diffeomorphism and the group of $\mathcal{P}$-homeomorphisms of M coincides with the group of conformal diffeomorphisms of M.*

III. THE BS CAUSAL BOUNDARY

Given an open set $U\subseteq M$, the chronological common past $\downarrow U$ and the common future $\uparrow U$ are defined by $\downarrow U=I^-(\{x|x\ll y \text{ for all } y\in U\})$ and $\uparrow U=I^+(\{x|y\ll x \text{ for all } y\in U\})$, respectively.

A set P is called a past set if $P=I^-(S)$ for some subset S of M. A past set is always open since $I^-(x)$ is open for each $x\in M$. A nonempty past set P is called indecomposable if whenever Q_1 and Q_2 are past sets with $P=Q_1\cup Q_2$, then either $P=Q_1$ or $P=Q_2$. If an indecomposable past set (IP) P is of the form $I^-(x)$ for some $x\in M$, we say that P is a proper indecomposable past set (PIP). If an IP Q cannot be represented by the form $I^-(x)$ for any $x\in M$, we say that Q is a terminal indecomposable past set (TIP). Geroch, Kronheimer, and Penrose[5] have shown that an IP P is a PIP $I^-(x)$ if and only if $P=I^-(\gamma)$ for some timelike curve γ whose end point is x. They have also shown that an IP Q is a TIP if and only if Q can be represented by the form $Q=I^-(\gamma)$ for some inextendible timelike curve γ.[5] Future sets and indecomposable future sets are defined similarly.

Let $\hat{M}$ denote the collection of all indecomposable past sets of M and let $\check{M}$ denote the collection of all indecomposable future sets of M. It is not hard to show that either $\hat{M}\cap\check{M}=\varnothing$ or $\hat{M}\cap\check{M}=\{M\}$.[6] For most space-times, $\hat{M}\cap\check{M}=\varnothing$. Whenever $\hat{M}\cap\check{M}=\{M\}$, we will make a distinction between M considered as an indecomposable past set and M considered as an indecomposable future set.

If $A\in\hat{M}$ and $B\in\check{M}$ are such that $B=\uparrow A$ and $A=\downarrow B$, the pair (A,B) is called a hull pair. An equivalence relation may be defined on the collection $\hat{M}\cup\check{M}$. If $A,B\in\hat{M}\cup\check{M}$ and either (A,B) or (B,A) is a hull pair, we write $A\sim B$. Furthermore, let $A\sim A$ if $A\in\hat{M}$ and $A\sim A$ if $A\in\check{M}$. When M is in both $\hat{M}$ and $\check{M}$, M considered as a past set is not equivalent to M considered as a future set. Budic and Sachs have investigated this equivalence relation. Each equivalence class has at most two elements. The completion $\bar{M}$ is defined to be the set of equivalence classes of $\hat{M}\cup\check{M}$.[6]

In a causally continuous space-time, for each $x\in M$, we have $I^-(x)\in\hat{M}$, $I^+(x)\in\check{M}$ and $(I^-(x),I^+(x))$ is a hull pair. Thus, each point x of M corresponds to exactly one point in $\hat{M}\cup\check{M}/$

$\sim$, and we have an injection $M \hookrightarrow \hat{M} \cup \check{M}/\sim$. The causal completion $\bar{M}$ of the causally continuous space-time M is therefore defined to be $\hat{M} \cup \check{M}/\sim$. Technically, this definition is not the one given by Budic and Sachs, however, they remark that their definition is essentially the same as $\hat{M} \cap \check{M}/\sim$. Our definition is clearly invariant under reversal of time orientation.

Define a map $I: M \to \bar{M}$ by letting $I(x)$ be the equivalence class represented by $I^-(x)$. Since M is distinguishing, this is a one-to-one map into the set $\bar{M}$. The boundary ∂M of M may be defined as $\partial M = \bar{M} - I(M)$. A boundary point of M is represented by an indecomposable subset of M which is not of the form $I^-(x)$ or $I^+(x)$ for any $x \in M$. The map $I: M \to \bar{M}$ will be used to identify M as a subset of $\bar{M}$.

Budic and Sachs defined the causality on $\bar{M}$ by defining relations $\ll$ and $\leqslant$ on $\hat{M} \cup \check{M}$ as in the table to follow. For example, if $(P,Q) \in \hat{M} \times \hat{M}$, $(P,F) \in \hat{M} \times \check{M}$ and $(F,P) \in \check{M} \times \hat{M}$, the table indicates that $P \geqslant Q$ iff $P \supseteq Q$; $P \gg Q$ iff $P \cup (\uparrow Q) \neq \emptyset$; $P \geqslant F$ iff there is a hull pair $(\hat{L}, \check{L})$ such that $P \supseteq \hat{L}$ and $\check{L} \subseteq F$, etc.

	$\cdot \geqslant \cdot$	$\cdot \gg \cdot$
$\hat{M} \times \hat{M}$	$\cdot \supseteq \cdot$	$\cdot \cap (\uparrow \cdot) \neq \emptyset$
$\check{M} \times \check{M}$	$\cdot \subseteq \cdot$	$(\downarrow \cdot) \cap \cdot \neq \emptyset$
$\hat{M} \times \check{M}$	$\cdot \supseteq \hat{L}$ and $\check{L} \subseteq \cdot$	$\cdot \cap \cdot \neq \emptyset$
$\check{M} \times \hat{M}$	$\cdot \subseteq \check{L}$ and $\hat{L} \supseteq \cdot$	$(\downarrow \cdot) \cap (\uparrow \cdot) \neq \emptyset$

The relations $\geqslant$ and $\gg$ may be considered to be defined on $\hat{M} \cup \check{M}/\sim$. If $p, q \in \bar{M}$ and some representative in the equivalence class of p is in the causal future of some representative of q according to the table, then this same relation holds for any representatives of p and any representatives of q. The chronological past of q and causal past of q are defined, respectively, by $\underline{I}^-(q) = \{p \in \bar{M} \,|\, q \gg p\}$ and $\underline{J}^-(q) = \{p \in \bar{M} \,|\, q \geqslant p\}$. The set $\underline{I}^+(q)$ and $\underline{J}^+(q)$ are defined dually.

The extended Alexandrov topology $\bar{A}$ is defined on $\bar{M}$ by taking the smallest topology such that for all $q \in \bar{M}$ each of the following four subsets of $\bar{M}$ is open:

$$\underline{I}^+(q), \quad \underline{I}^-(q), \quad \bar{M} - \underline{J}^-(q), \quad \bar{M} - \underline{J}^+(q).$$

Budic and Sachs[6] have shown that, if the manifold M is causally continuous, the causal completion $\bar{M}$ becomes a causal space which is Hausdorff with respect to the extended Alexandrov topology.

For the following sections, we state some results concerning the extended Alexandrov topology $\bar{\mathcal{A}}$.

Definition: Let $\mathcal{T}$ be a topology on a topological space M and $\gamma: (a,b) \to (M, \mathcal{T})$ be a $\mathcal{T}$-continuous curve. Then $p \in M$ is called a $\mathcal{T}$ end point of γ if for every $\mathcal{T}$-open neighborhood U of p, there exists t_0 such that $\gamma(t) \in U$ for all $t \geqslant t_0$.

A curve is called inextendible, if it does not have an end point in M.

Theorem 3.1: *Let $\gamma: I \to M$ be a timelike curve. Then $I^-(\gamma) \in \partial M$ is the unique $\bar{\mathcal{A}}$ end point in $\bar{M}$.*

Proof: If γ is extendible, see theorem 2.3 in Ref. 5. If γ is inextendible, see Ref. 7. □

IV. THE PATH TOPOLOGY ON THE CAUSAL COMPLETION AND ITS PROPERTIES

Throughout this paper, all the concerned manifolds are always assumed to be globally hyperbolic.

Definition: A sequence $\{x_i\}$ in $\bar{M}$ is timelike if either $x_i \ll x_{i+1}$ or $x_{i+1} \ll x_i$. A timelike sequence $\{x_i\}$ satisfying $x_i \ll x_{i+1}$ ($x_{i+1} \ll x_i$, respectively) is called an increasing (decreasing, respectively)

sequence. A timelike sequence $\{x_i\}$ converges to x if either $\cup I^-(x_i)=I^-(x)$ when $\{x_i\}$ is increasing, or $\cup I^+(x_i)=I^+(x)$ when $\{x_i\}$ is decreasing.

Since we assume that M is globally hyperbolic, we have $I^\pm(x)=\emptyset$ for all $x\in\partial M$.[6] Thus, only the first term in every timelike sequence can be in ∂M.

Proposition 4.1: For increasing timelike sequence $\{x_i\}$, $\cup I^-(x_i)$ *is an indecomposable past set.*

Proof: (This proposition is due to Geroch, Kronheimer, and Penrose[5]) Assume not. Then there exist past sets Q and R such that $\cup I^-(x_i)=Q\cup R$. We must show that $Q\subset R$ or $R\subset Q$. Suppose that there exists $q\in Q-R$ and $r\in R-Q$. Then there exist i_0 and j_0 such that $q\ll x_{i_0}$ and $r\ll x_{j_0}$. Setting $k_0=\max\{i_0,j_0\}$, we have $q\ll x_{k_0}$ and $r\ll x_{k_0}$. If $x_{k_0}\in Q$, then both q and r are in Q since Q is a past set. If $x_{k_0}\in R$, then both q and r are in R since R is a past set. This is a contradiction. Thus, $\cup I^-(x_i)$ is an indecomposable past set. □

From the above proposition, we can easily see that for any increasing timelike sequence $\{x_i\}$, we have a timelike curve γ such that $\cup I^-(x_i)=I^-(\gamma)$. If this timelike curve has an end point x in M with respect to the $\bar{\mathcal{M}}$-topology, then it is also an end point with respect to the $\mathcal{A}$-topology and we have $\cup I^-(x_i)=I^-(x)$. If γ is inextendible, then it is known that $I^-(\gamma)$ is also an end point of γ with respect to the $\bar{\mathcal{A}}$-topology.[7] Thus we can conclude that for any increasing timelike sequence $\{x_i\}$, the corresponding timelike curve has an $\bar{\mathcal{A}}$ end point x in $\bar{M}$ and it is the unique limit of the sequence. Since $I^+(x_i)\cap I^-(\gamma)\neq\emptyset$, we also have $x_i\ll x$ for each i.

Now we define a new topology $\mathcal{T}$ on $\bar{M}$ as follows.

Definition: $U\subset\bar{M}$ is $\mathcal{T}$-closed if every timelike sequence that converges has a limit in U and $V\subset\bar{M}$ is $\mathcal{T}$-open if its complement is $\mathcal{T}$-closed.

Proposition 4.2: The above defines a new topology $\mathcal{T}$ *on* $\bar{M}$.

Proof: (i) Trivially, $\emptyset$ and $\bar{M}$ is closed and so $\emptyset$ and $\bar{M}$ are in $\mathcal{T}$.

(ii) Almost trivially, arbitrary intersection of $\mathcal{T}$-closed sets is also $\mathcal{T}$-closed.

(iii) Now we show that $A\cup B$ is closed when A and B are closed.

Let $\{x_i\}$ be an increasing timelike sequence in $A\cup B$ that converges to x, i.e., $\cup I^-(x_i)=I^-(x)$. If one of A or B contains all but finitely many terms of $\{x_i\}$, then it is trivial since both A and B are closed. Now, we assume that both A and B contain infinitely many terms of $\{x_i\}$. If we break $\{x_i\}$ into $\{y_j\}$ and $\{z_k\}$ such that $y_j\in A$ and $z_k\in B$, then we have $\cup I^-(x_i)=[\cup I^-(y_j)]\cup[\cup I^-(z_k)]$. Since both $\cup I^-(y_j)$ and $\cup I^-(z_k)$ are past sets and $\cup I^-(x_i)$ is an indecomposable past set, without loss of generality, we can have $I^-(x)=\cup I^-(x_i)=\cup I^-(y_j)$, i.e., y_j converges to x. Since $y_j\in B$ and B is closed, we must have $x\in B$, i.e., $x\in A\cup B$. □

In Sec. II, we have seen that the path topology $\mathcal{P}$ is finer than the manifold topology $\mathcal{M}$. We have the same result on the causal completion.

Proposition 4.3: The topology $\mathcal{T}$ *on* $\bar{M}$ *is finer than the extended Alexandrov topology* $\mathcal{A}$ *on* $\bar{M}$.

Proof: Since $I^\pm(y)$ and $\bar{M}-J^\pm(y)$ form a sub-basis of $\bar{\mathcal{A}}$, any $\bar{\mathcal{A}}$-closed subset of $\bar{M}$ can be expressed as an intersection of sets of the form $\bar{M}-I^\pm(y)$ and $J^\pm(y)$. So it is sufficient to show that the above four basic closed subsets are $\mathcal{T}$-closed. In the following four cases, we assume that $\{x_i\}$ is an increasing timelike sequence that $\mathcal{T}$-converges to x (i.e., $\cup I^-(x_i)=I^-(x)$).

(i) Let $\{x_i\}\subset\bar{M}-I^+(y)$.

Assume that $x\notin\bar{M}-I^+(y)$. Then $I^-(x)\cap I^+(y)\neq\emptyset$ and $[\cup I^-(x_i)]\cap I^+(y)\neq\emptyset$. Thus, $I^-(x_i)\cap I^+(y)\neq\emptyset$ for some i. This implies that $x_i\in I^+(y)$ for some i, which contradicts to $x_i\in\bar{M}-I^+(y)$. Thus, $x\in\bar{M}-I^+(y)$ and $\bar{M}-I^+(y)$ is $\mathcal{T}$-closed.

(ii) Let $\{x_i\}\subset\bar{M}-I^-(y)$.

Assume that $x\notin\bar{M}-I^-(y)$. Then $\cup I^-(x_i)=I^-(x)\subset I^-(y)$ and $x_i\ll y$ for some i. This implies that $x_i\in I^-(y)$ which contradicts to $x_i\in\bar{M}-I^-(y)$. Thus, $x\in\bar{M}-I^-(y)$ and $\bar{M}-I^-(y)$ is $\mathcal{T}$-closed.

(iii) Let $\{x_i\}\subset J^+(y)$.

Since $\cup I^-(x_i)=I^-(x)$, we have $x_i\ll x$ for each i by the remark following Proposition 4.1. Thus $y\leqslant x_i\ll x$. In other words, $x\in J^+(y)$ and $J^+(y)$ is $\mathcal{T}$-closed.

(iv) Let $\{x_i\}\subset J^-(y)$.

Since $x_i \leqslant y$, we have $I^-(x_i) \subset I^-(y)$ for each i. Thus, $\cup I^-(x_i) \subset I^-(y)$ and so $I^-(x) \subset I^-(y)$. So we can conclude that $x \in \overline{I^-(x)} \subset \overline{I^-(y)} = J^-(y)$. Thus, $J^-(y)$ is $\mathcal{T}$-closed. □

Since $\mathcal{T}$ is finer than $\bar{\mathcal{A}}$ and $\bar{\mathcal{A}}$ is Hausdorff, we can conclude that $\mathcal{T}$ is a Hausdorff topology on $\bar{M}$.

Proposition 4.4: Let $\gamma:(a,b)\to(\bar{M},\mathcal{T})$ be a curve. Assume that for any sequence $t_i \in (a,b)$ satisfying $t_i \to b$, we have $\gamma(t_i) \to p$ in $\mathcal{T}$-topology. Then $p \in \bar{M}$ is the $\mathcal{T}$ end point of γ.

Proof: Assume there exists a $\mathcal{T}$-open neighborhood U of p such that for any $t_i \in (a,b)$ we can choose $t \geqslant t_i$ such that $\gamma(t) \notin U$. If we let $t_i = b - 1/i$, then $t_i \to b$ and we can choose $s_i \geqslant t_i$ such that $\gamma(s_i) \notin U$. Clearly, $s_i \to b$ but $\gamma(s_i) p$ in $\mathcal{T}$-topology. This is a contradiction. □

We know that any timelike curve $\gamma:(a,b)\to M$ has an end point $I^-(\gamma)$ in $\bar{\mathcal{A}}$-topology. If $t_i \in (a,b)$ is a sequence such that $t_i \to b$, then we have $I^-(\gamma) = \cup I^-(\gamma(t_i))$. Thus, $\gamma(t_i) \to I^-(\gamma)$ in $\mathcal{T}$-topology. By the previous proposition, we have the following.

Corollary: $I^-(\gamma)$ is also an end point of a timelike curve $\gamma:(a,b)\to M$ in $\mathcal{T}$-topology.

Though $\mathcal{T}$ is finer than $\bar{\mathcal{A}}$, we can say that the two topologies $\mathcal{T}$ and $\bar{\mathcal{A}}$ share the same properties in the timelike directions in a sense, by the above corollary.

Let us assume that we have two topologies T_1 and T_2 on M. Then we can consider two sequential convergences with respect to T_1- and T_2-topologies and it is easy to show the following.

Lemma 4.1: Let T_1 and T_2 be two topologies defined on M and x_i be a sequence of points in M. Then ⌜$x_i \to x$ in $T_1 \Rightarrow x_i \to x$ in T_2⌟ if and only if ⌜A is T_2-closed $\Rightarrow A$ is T_1-closed⌟.

Proof: ⇒; Let A be T_2 closed and $\{x_i\} \subset A$ be such that $x_i \to x$ in T_1. Then, $x_i \to x$ in T_2. Since A is T_2-closed, we have $x \in A$ and so A is also T_1-closed.

⇐; Let U be a T_2-neighborhood of x. Then, since U is T_1-open and $x_i \to x$ in T_1, we have $x_i \in U$ for all but finitely many. Thus we have $x_i \to x$ in T_2 □

The construction of $\mathcal{T}$-topology on the causal completion extends the $\tilde{\mathcal{P}}$-topology on M by use of the sequential convergence. By the above lemma, the relation of $\mathcal{T}$ and $\tilde{\mathcal{P}}$ can be given.

Proposition 4.5: The inclusion map $i:(M,\tilde{\mathcal{P}})\hookrightarrow(\bar{M},\mathcal{T})$ is a dense imbedding.

Proof: The imbeddedness follows from the construction of $\mathcal{T}$ and the previous lemma. Let $p \in \partial M$, U be a $\mathcal{T}$-open neighborhood of p and assume that $U \cap M = \emptyset$. Then $\bar{M} - U$ is $\mathcal{T}$-closed and so it must contain all limits of convergent timelike sequence $\{x_i\}$. Since $p \in \partial M$, there exists a timelike sequence $\{x_i\}$ such that $x_i \to p$ with $x_i \in M = M - U$. Since $p \in U$, it is a contradiction. Thus, M with $\tilde{\mathcal{P}}$ topology is dense in $\bar{M}$ with $\mathcal{T}$-topology. □

V. THE PATH TOPOLOGY HOMEOMORPHISM

Definition: A bijection $f:\bar{M}\to\bar{N}$ is a chronological isomorphism if $x \ll y \Leftrightarrow f(x) \ll f(y)$ and antichronological isomorphism if $x \ll y \Leftrightarrow f(y) \ll f(x)$. Likewise, a bijection $f:\bar{M}\to\bar{N}$ is a causal isomorphism if $x \leqslant y \Leftrightarrow f(x) \leqslant f(y)$ and anticausal isomorphism if $x \leqslant y \Leftrightarrow f(y) \leqslant f(x)$. A bijection $f:\bar{M}\to\bar{N}$ is a conformal isomorphism if f is both (anti-) chronological isomorphism and (anti-) causal isomorphism.

In a Lorentzian manifold, it is known that the causal isomorphism and the chronological isomorphism are equivalent.[4]

The topology $\mathcal{T}$ is defined only in terms of chronological relations and so any chronological isomorphism $f:\bar{M}\to\bar{N}$ induces a $\mathcal{T}$-homeomorphism. The chronological isomorphism has the same effects on the $\bar{\mathcal{A}}$-topology.

Proposition 5.1: If M and N are globally hyperbolic and $f:\bar{M}\to\bar{N}$ is either a chronological isomorphism or an antichronological isomorphism, then f is an $\bar{\mathcal{A}}$-homeomorphism.

Proof: We show that the above statement holds in the case of a chronological isomorphism. The case of an antichronological isomorphism can be shown by the similar argument. Let $x \in \partial M$. Without loss of generality, we can assume that $I^+(x) = \emptyset$ since M is globally hyperbolic. Since f is a chronological isomorphism, $I^+(f(x)) = \emptyset$ and $f(x) \in \partial N$. Thus $f(\partial M) \subset \partial N$. Since f^{-1} is

also a chronological isomorphism, we have $f(\partial M)=\partial N$. Thus f induces a chronological isomorphism $f|_M: M \to N$ and $f|_M$ is also a causal isomorphism by Theorem 6.3 of Ref. 4. This implies that $f|_M$ is a conformal isomorphism between M and N. Since the BS-causal boundary and its topology $\bar{\mathcal{A}}$ is constructed only in terms of the causal and chronological relations, we can conclude that f is an $\bar{\mathcal{A}}$-homeomorphism. □

Theorem 5.1: *If $f: \bar{M} \to \bar{N}$ is a $\mathcal{T}$-homeomorphism, then f is either a chronological isomorphism or an antichronological isomorphism.*

Proof: First, we show that $f(\partial M) \subset \partial N$. Let us assume not. Then there are $p \in \partial M$ and $q \in N$ with $f(p)=q$. Since $i: (M, \tilde{\mathcal{P}}) \hookrightarrow (\bar{M}, \mathcal{T})$ is an imbedding, we can choose $\mathcal{T}$-neighborhoods U of p and V of q such that $V \subset N$ and $f: U \to V$ is a $\mathcal{T}$-homeomorphism. Then $f: U - \partial M \to V - f(\partial M)$ is $\tilde{\mathcal{P}}$-homeomorphism since $i: (M, \tilde{\mathcal{P}}) \hookrightarrow (\bar{M}, \mathcal{T})$ is an imbedding. Since M is globally hyperbolic, ∂M is $\mathcal{T}$-closed in $\bar{M}$ and thus $f(\partial M)$ is $\mathcal{T}$-closed in $\bar{N}$. Thus, $V - f(\partial M)$ is $\tilde{\mathcal{P}}$-open in N and so we can choose future-directed timelike curve γ_1 and past-directed timelike curve γ_2 in $V - f(\partial M)$ with q their common end point. Since $f^{-1}: V - f(\partial M) \to U - \partial M$ is a $\tilde{\mathcal{P}}$-homeomorphism, one of $f^{-1} \circ \gamma_1$ and $f^{-1} \circ \gamma_2$ is past-directed with p its end point. Since M is globally hyperbolic, it is a contradiction. Thus we have shown that $f(\partial M) \subset \partial N$. Likewise, since $f^{-1}: \bar{N} \to \bar{M}$ is also a $\mathcal{T}$-homeomorphism, we have $f^{-1}(\partial N) \subset \partial M$ and so we get $f(\partial M)=\partial N$. Therefore, we can conclude that a $\mathcal{T}$-homeomorphism $f: \bar{M} \to \bar{N}$ induces a $\tilde{\mathcal{P}}$-homeomorphism $f|_M: M \to N$. This implies that $f|_M: M \to N$ is either a chronological isomorphism or an antichronological isomorphism by Theorem 2 of Ref. 4. Without loss of generality, we assume that $f|_M: M \to N$ is a chronological isomorphism. It remains to show that $x \ll y$ implies that $f(x) \ll f(y)$ when either x or y is in ∂M. In either case, there exists a future-directed timelike curve from x to y. Since $f|M$ is a conformal diffeomorphism, $f \circ \gamma$ is a future-directed timelike cuve from $f(x)$ to $f(y)$. Thus $f(x) \ll f(y)$. □

As stated above, the causal isomorphism between Lorentzian manifolds is equivalent to the chronological isomorphism. Thus any $\mathcal{T}$-homeomorphism $f: \bar{M} \to \bar{N}$ induces a causal isomorphism $f|_M: M \to N$ and so we have shown the following theorem.

Theorem 5.2: *If $f: \bar{M} \to \bar{N}$ is a $\mathcal{T}$-homeomorphism, then f is a conformal isomorphism.*

Whereas $\mathcal{T}$ is finer than $\bar{\mathcal{A}}$, by combining proposition 5.1 and theorem 5.1, we have the following theorem.

Theorem 5.3: *A $\mathcal{T}$-homeomorphism induces an $\bar{\mathcal{A}}$-homeomorphism.*

We know that if $f: M \to N$ is a $\tilde{\mathcal{P}}$-homeomorphism, then f is a conformal isomorphism. If, in addition, both M and N are strongly causal, the manifold topologies are the same as the Alexandrov topologies since the Alexandrov topology is defined only in terms of a chronological relation. In other words, a $\tilde{\mathcal{P}}$-homeomorphism induces an $\mathcal{M}$-homeomorphism. By the above theorem, this is indeed the case in the path topology of the BS-causal completion. Thus, we know that, in this sense, the extended Alexandrov topology is natural to the causal completion.

VI. DISCUSSION

If two space-times are chronologically isomorphic or causally isomorphic, then, clearly their causal boundaries have the same structures. Conversely, what can be said about the structures of two space-times if their causal boundaries have the same structure? Considering the fact that the causal boundary contains all the past and the future end points of all the inextendible causal curves in our space-time, we can say that, in a sense, the causal boundary contains all the information of the initial and the final states of our space-time. This is similar to the situation of the initial value problems or the boundary value problems of differential equation theories. Therefore, we may expect that the causal boundary determines the inner structure of our space-time to some extent.

In fact, the study of this paper was motivated by the question: To what extent does the structure of the causal boundary determine the inner causal structure of our space-time. If we keep this in mind, it is natural to ask the following: If $f: \partial M \to \partial N$ is a $\mathcal{T}$-homeomorphism, what is the relation, if any, between the structures of M and N?

(Received 30 August 2005; accepted 5 June 2006; published online 25 July 2006)

We study the behavior of relativistic quantum particles in the space-times generated by a rotating massive body and a moving mass current, in the weak field approximation. We solve the Dirac equation in these gravitational fields and calculate the currents associated with the particles. It is shown that these solutions and the currents depend on the angular momentum and on the velocity of the sources, in the cases of a massive rotating body and a moving mass current, respectively. These effects may be looked upon as a gravitational analog of the Aharonov-Bohm effect. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2218671]

I. INTRODUCTION

The study of relativistic quantum systems under the influence of gravitational fields goes back to the pioneering works by Fock[1] and Schrödinger,[2] when the generalization of quantum mechanics to curved spaces has been discussed, motivated by the idea of constructing a theory combining quantum physics and general relativity. Along this line of research the hydrogen atom, for example, has been studied in particular curved space-times.[3,4] These investigations showed that the energy levels of an atom placed in a gravitational field is shifted as a result of the interaction of the atom with the space-time curvature.[4–6] These shifts of the atomic levels depend on the Riemann curvature tensor at the position of the atom and can be used in principle to measure or put an upper limit on the curvature of space-time at the position of the atom.

In a metric theory of gravitation, a gravitational field is related to a nonvanishing Riemann curvature tensor. However, the presence of localized curvature can produce effects on the geodesic motion and parallel transport in regions where the curvature vanishes. The best known example of this nonlocal (global) effect is provided when a particle is transported along a closed curve which encircles an idealized cosmic string.[7] In this case, the string is noticed at all. This situation corresponds to the gravitational analog[8] of the electromagnetic Aharonov-Bohm effect.[9] These effects are of global origin rather than local. It is worth calling attention to the fact that different from the electromagnetic Aharonov-Bohm effect which is essentially a quantum effect, the gravitational analog appears also at a purely classical context.

We also have an analog of the gravitational Aharonov-Bohm effect when particles are constrained to move in a region where the Riemann curvature does not vanish, but does not depend on certain parameters such as the angular momentum, as in the case of a weak gravitational field arising from a rotating cylindrical shell[10] which we will consider. In this situation, we can have

[a)]Electronic mail: gmarques@df.ufpb.edu.br
[b)]Electronic mail: valdir@fisica.ufpb.br

gravitational nonlocal effects associated with this parameter. A similar situation occurs when we have a gravitational field generated by a slowly moving mass current.[11] In this case, the Riemann curvature tensor does not depend on the velocity of the source, but we have a nonlocal effect on the quantum system due to this parameter.

The existence of a gravitational analog of the electromagnetic Aharonov-Bohm effect was first pointed out at the end of the 1960s.[12–16] Studies concerning this subject were reported by many authors from that time up to now.[17,18]

The aim of this paper is to investigate the behavior of relativistic particles placed in the gravitational field generated by a slowly rotating cylindrical shell[10] and by a slowly moving mass current.[11] The gravitational effects are taken into account in the weak field approximation in which case the curvature does not depend on the angular momentum or on the velocity of the sources.

This paper is organized follows. In Sec. II, we introduce the gravitational fields to be considered, namely, the gravitational field generated by a rotating cylindrical shell and by a slowly moving massive current. In Sec. III, we obtain the solution of the Dirac equation and determine the associated current. In Sec. IV, we do the same as the previous section, but now in the space-time generated by a moving mass current. Finally, in Sec. IV, we conclude with some remarks.

II. WEAK GRAVITATIONAL FIELDS

In this section, we will present the space-times generated by an infinitely long and thin cylindrical shell of matter which rotates slowly and by a cylindrical distribution of matter with uniform density along the z axis, which moves slowly with velocity v in the z direction.

First, let us consider the space-time generated by an infinitely long, infinitely thin massive cylindrical shell rotating slowly around its axis. In the weak field approximation the metric reads[10]

$$ds^2 = -\left(1 - \frac{a(\rho)}{2}\right)dt^2 + \left(1 + \frac{a(\rho)}{2}\right)(d\rho^2 + \rho^2 d\varphi^2 + dz^2) + 2b dt d\varphi, \tag{1}$$

where

$$a(\rho) = -8\mu\Theta(\rho - \rho_0)\ln\left(\frac{\rho}{\rho_0}\right) \tag{2}$$

and

$$b(\rho) = 4\mu\omega\rho_0\left[\frac{\rho^2}{\rho_0^2}\Theta(\rho_0 - \rho) + \Theta(\rho - \rho_0)\right], \tag{3}$$

with $\Theta(x)$ being the unit step function.

The metric given by Eq. (1) is characterized by two parameters, namely, the linear mass density μ and the linear angular momentum density $j = \mu\omega\rho_0$, with ρ_0 and ω being the radius of the cylinder and the angular velocity of the source, respectively. This approximate solution is justified in a domain in which the Newtonian potential generated by the thin massive cylindrical shell is much less than the unity which means that $|a(\rho)| \ll 1$ and when $b(\rho)^2 \sim 0$. The term with $b(\rho)$, in this metric, being proportional to j is completely due to the rotation of the cylindrical shell.

In the weak field approximation, the Riemann curvature tensor outside the rotating shell is completely determined by the function $a(\rho)$ only, if we neglect terms containing $b(\rho)a(\rho)$, $|a(\rho)|^2$, or $b(\rho)^2$, which is justified by the fact that $|a(\rho)| \ll 1$ and we are considering that the source rotates slowly around the z axis, which means that $b(\rho)^2 \sim 0$, as already stated. Thus, due to these considerations, the angular momentum is not present in the curvature, in this approximation. The contribution of the term with $b(\rho)$ is concentrated on the shell itself. This means that, in the weak field approximation, the local effects of curvature connected with the rotation of the cylindrical shell are absent outside it. In this background space-time a study concerning the gravitational Aharonov-Bohm effect has been done.[10,19]

The other space-time we will consider is generated by a cylindrical distribution of matter with uniform density along the z axis, which moves slowly with velocity v in the z direction. In the weak field approximation, the line element given by[11]

$$ds^2 = -(1-\Phi(\rho))dt^2 + (1+\Phi(\rho))(d\rho^2 + \rho^2 d\varphi^2 + dz^2) - 4v\Phi(\rho)dzdt, \tag{4}$$

where $\Phi(\rho)$ represents the Newtonian potential produced by this source and satisfies the condition $\Phi(\rho)^2 \approx 0$.

For this space-time, the curvature outside the distribution of matter does not depend on its velocity, in the weak field approximation. This means that for the weak gravitational field associated with slowly moving mass currents, the local effects of the curvature associated with the velocity of the source are absent outside it. In this space-time we also have a manifestation of the Aharonov-Bohm effect.[11,20]

III. RELATIVISTIC QUANTUM SYSTEM IN THE SPACE-TIME OF A SLOWLY ROTATING CYLINDRICAL SHELL

In this section we will consider a massive spinor particle in the space-time of a slowly rotating cylindrical shell. This particle obeys the covariant Dirac equation in a curved space-time, for a massive spinor field Ψ, which is given by

$$[i\gamma^\mu(x)\partial_\mu - i\gamma^\mu(x)\Gamma_\mu(x) - m]\Psi(x) = 0, \tag{5}$$

where $\gamma^\mu(x)$ are the generalized Dirac matrices and are given in terms of the standard flat space Dirac matrices $\gamma^{(a)}$ as

$$\gamma^\mu(x) = e^\mu_{(a)}(x)\gamma^{(a)}, \tag{6}$$

where $e^\mu_{(a)}(x)$ are tetrad components defined by

$$e^\mu_{(a)} e^\nu_{(b)} \eta^{(a)(b)} = g^{\mu\nu}. \tag{7}$$

Here and in what follows Greek indices are connected with tensor world indices (coordinate basis system) and Latin indices denote Lorentz indices which are connected with a local Minkowski coordinate system (tetrads).

The product $\gamma^\mu\Gamma_\mu$ that appears in Eq. (5) can be written as[21]

$$\gamma^\mu(x)\Gamma_\mu(x) = \gamma^{(a)}(A_{(a)}(x) + i\gamma^{(5)}B(x)), \tag{8}$$

with $\gamma^{(5)} = i\gamma^{(0)}\gamma^{(1)}\gamma^{(2)}\gamma^{(3)}$ and $A_{(a)}$ and $B_{(a)}$ given by

$$A_{(a)} = \tfrac{1}{2}(\partial_\mu e^\mu_{(a)} + e^\rho_{(a)}\Gamma^\mu_{\rho\mu}) \tag{9}$$

and

$$B_{(a)} = \tfrac{1}{2}\epsilon_{(a)(b)(c)(d)} e^{(b)\mu} e^{(c)\nu} \partial_\mu e^{(d)}_\nu, \tag{10}$$

where $\epsilon_{(a)(b)(c)(d)}$ is the completely antisymmetric fourth-order unit tensor and the Christoffel symbols $\Gamma^\mu_{\rho\mu}$ are given by $\Gamma^\mu_{\rho\mu} = (1/\sqrt{-g})(\partial/\partial x^\rho)(\sqrt{-g})$.

In order to write the Dirac equation in the space-time generated by a rotating cylindrical shell let us choose the following set of tetrads:

$$e^{\mu}_{(a)} = \begin{pmatrix} 1+\frac{a(\rho)}{4} & 0 & \frac{b}{\rho} & 0 \\ 0 & 1-\frac{a(\rho)}{4} & 0 & 0 \\ 0 & 0 & \frac{1-\frac{a(\rho)}{4}}{\rho} & 0 \\ 0 & 0 & 0 & 1-\frac{a(\rho)}{4} \end{pmatrix}. \tag{11}$$

Calculating the expresssions for $A(a)$ and $B(a)$ given by Eqs. (9) and (10), respectively, and substituting these results into Eq. (8), we get the following result:

$$\gamma^{\mu}\Gamma_{\mu} = \frac{1}{2\rho}\left(1+\frac{a(\rho)}{2}\right)\gamma^{(1)}. \tag{12}$$

Using the set of tetrads in (11), we obtain that the generalized matrices $\gamma^{\mu}(x)$, are given by

$$\begin{aligned} \gamma^{0}(x) &= \left(1+\frac{a(\rho)}{4}\right)\gamma^{(0)}, \\ \gamma^{1}(x) &= \left(1-\frac{a(\rho)}{4}\right)\gamma^{(1)}, \\ \gamma^{2}(x) &= \frac{1}{\rho}\left(1-\frac{a(\rho)}{4}\right)\gamma^{(2)}, \\ \gamma^{3}(x) &= \left(1-\frac{a(\rho)}{4}\right)\gamma^{(3)}. \end{aligned} \tag{13}$$

Thus, substituting Eqs. (12) and (13) into the Dirac equation in the curved space-time given by (5), and considering that the particle is restricted to move in a narrow region such that $a(\rho)$ is approximately constant and equal to a_1, we will get

$$\begin{aligned} &\left[i\left(1+\frac{a_1}{4}\right)\partial_t - m\right]\Psi_2 - \frac{b}{\rho}\partial_t\Psi_3 + i\left(1-\frac{a_1}{4}\right)\partial_\rho\Psi_3 - \frac{1}{\rho}\left(1-\frac{a_1}{4}\right)\partial_\varphi\Psi_3 \\ &\quad - i\left(1-\frac{a_1}{4}\right)\partial_z\Psi_3 + i\frac{1}{2\rho}\left(1-\frac{a_1}{4}\right)\Psi_4 = 0, \end{aligned}$$

$$\begin{aligned} &\left[i\left(1+\frac{a_1}{4}\right)\partial_t - m\right]\Psi_1 + \frac{b}{\rho}\partial_t\Psi_4 + i\left(1-\frac{a_1}{4}\right)\partial_\rho\Psi_4 - \frac{1}{\rho}\left(1-\frac{a_1}{4}\right)\partial_\varphi\Psi_4 \\ &\quad - i\left(1-\frac{a_1}{4}\right)\partial_z\Psi_3 + i\frac{1}{2\rho}\left(1-\frac{a_1}{4}\right)\Psi_4 = 0, \end{aligned}$$

$$\left[-i\left(1+\frac{a_1}{4}\right)\partial_t+m\right]\Psi_3-\frac{b}{\rho}\partial_t\Psi_2-i\left(1-\frac{a_1}{4}\right)\partial_\rho\Psi_2-\frac{1}{\rho}\left(1-\frac{a_1}{4}\right)\partial_\varphi\Psi_2$$
$$+i\left(1-\frac{a_1}{4}\right)\partial_z\Psi_1+i\frac{1}{2\rho}\left(1-\frac{a_1}{4}\right)\Psi_2=0,$$

and

$$\left[-i\left(1+\frac{a_1}{4}\right)\partial_t+m\right]\Psi_4+\frac{b}{\rho}\partial_t\Psi_1-i\left(1-\frac{a_1}{4}\right)\partial_\rho\Psi_1-\frac{1}{\rho}\left(1-\frac{a_1}{4}\right)\partial_\varphi\Psi_1$$
$$-i\left(1-\frac{a_1}{4}\right)\partial_z\Psi_1-i\frac{1}{2\rho}\left(1-\frac{a_1}{4}\right)\Psi_1=0, \tag{14}$$

where $\Psi_1,\Psi_2,\Psi_3,\Psi_4$ are the components of the four spinor

$$\Psi=\begin{pmatrix}\Psi_1\\ \Psi_2\\ \Psi_3\\ \Psi_4\end{pmatrix} \tag{15}$$

and we have used the standard representation of the Dirac matrices $\gamma^{(a)}$.

To solve the set of equations given in (14), let us choose

$$\Psi_1=\sqrt{E+m}e^{-iEt+il\varphi+ikz}u_1(\rho), \tag{16}$$

$$\Psi_2=\sqrt{E-m}e^{-iEt+i(l+1)\varphi+ikz}u_1(\rho), \tag{17}$$

and consider $\Psi_1=\Psi_3$, $\Psi_2=\Psi_4$, reducing this problem to a two-dimensional one. Thus, the set of equations in (14) turns into the following pair of equations for $u_1(\rho)$ and $u_2(\rho)$:

$$\left[\frac{\mathrm{d}^2}{\mathrm{d}\rho^2}+\frac{1}{\rho}\frac{\mathrm{d}}{\mathrm{d}\rho}+\frac{1}{\rho^2}(l+2bE)^2+\left(1-\frac{a_1}{2}\right)(E^2-m^2)\right]u_1(\rho)=0 \tag{18}$$

and

$$\left[\frac{\mathrm{d}^2}{\mathrm{d}\rho^2}+\frac{1}{\rho}\frac{\mathrm{d}}{\mathrm{d}\rho}-\frac{1}{\rho^2}(l+2bE+1)^2+\left(1-\frac{a_1}{2}\right)(E^2-m^2)\right]u_2(\rho)=0, \tag{19}$$

whose solutions are given by

$$u_i=C_{i,l}^{(1)}J_{v+i-1}(k\rho)+C_{i,l}^{(2)}N_{v+i-1}(k\rho), \tag{20}$$

where $i=1,2$, $k^2=(1-a_1/2)(E^2-m^2)$, $v=l+2bE$ and $C_{i,l}^{(1)}$, $C_{i,l}^{(2)}$ are constant spinors. The functions $J_{v+i-1}(k\rho)$ and $N_{v+i-1}(k\rho)$ are Bessel functions of first and second kind, respectively.

The results obtained show us that there exist a dependence with the angular momentum of the source, although this quantity does not have any influence on the curvature, in the limit of weak field we are considering.

To calculate the probability current and exhibit explicitly the influence of the spin on the trajactories of the particle, let us write the Dirac probability current in the Gordon decomposition form which is given by

$$j^{\mu}=\frac{1}{2m}\partial_{\mu}(\overline{\Psi}\sigma^{\mu\lambda}\Psi)+\frac{i}{4m}g^{\mu\lambda}[\overline{\Psi}\partial_{\lambda}\Psi-(\partial_{\lambda}\overline{\Psi})\Psi]+\frac{i}{4m}\overline{\Psi}([\partial_{\lambda}\gamma^{\mu},\gamma^{\mu}]+[\gamma^{\mu},\partial_{\lambda}\gamma^{\mu}])\Psi$$
$$+\frac{i}{2m}\overline{\Psi}[\gamma^{\lambda}\Gamma_{\lambda},\gamma^{\mu}]\Psi. \tag{21}$$

In order to calculate the current associated with a particle in this space-time, we need the following relations:

$$\sigma^{01}=i\gamma^{(0)}\gamma^{(1)}+\frac{ib}{\rho}\gamma^{(2)}\gamma^{(1)},$$

$$\sigma^{02}=\frac{i}{\rho}\gamma^{(0)}\gamma^{(2)}+\frac{ib}{\rho^{2}}\gamma^{(2)}\gamma^{(2)},$$

$$\sigma^{03}=i\gamma^{(0)}\gamma^{(3)}+\frac{ib}{\rho}\gamma^{(2)}\gamma^{(3)},$$

$$\sigma^{12}=i\gamma^{(1)}\gamma^{(0)}+\frac{ib}{\rho}\gamma^{(1)}\gamma^{(2)},$$

$$\sigma^{13}=i\gamma^{(1)}\gamma^{(3)},$$

$$\sigma^{23}=i\left(1-\frac{a(\rho)}{2}\right)\gamma^{(1)}\gamma^{(3)},$$

$$[\gamma^{\lambda}\Gamma_{\lambda},\gamma^{0}]=\frac{1}{\rho}\left(1+\frac{a(\rho)}{2}\right)\gamma^{(1)}\gamma^{(0)}+\frac{b}{\rho^{2}}\gamma^{(1)}\gamma^{(2)},$$

$$[\gamma^{\lambda}\Gamma_{\lambda},\gamma^{1}]=0,$$

$$[\gamma^{\lambda}\Gamma_{\lambda},\gamma^{2}]=\frac{2}{\rho^{2}}\gamma^{(1)}\gamma^{(2)},$$

$$[\gamma^{\lambda}\Gamma_{\lambda},\gamma^{3}]=\frac{2}{\rho}\gamma^{(1)}\gamma^{(3)}. \tag{22}$$

Substituting the set of equations (22) into Eq. (21), we obtain the result

$$j_{t}=\vec{\nabla}\cdot\vec{P}-\frac{2b}{\rho}\left[\frac{1}{\rho}M_{z}-(\vec{\nabla}\times\vec{M})_{\varphi}\right]+\rho_{\mathrm{conv}},$$

$$j_{\rho}=-\partial_{t}P_{\rho}+(\vec{\nabla}\times\vec{M})_{\rho}-\frac{2b}{\rho}\partial_{t}M_{z}+j_{\rho,\mathrm{conv}},$$

$$j_{\varphi}=-\partial_{t}P_{\varphi}+(\vec{\nabla}\times\vec{M})_{\varphi}-\frac{1}{\rho}M_{z}+j_{\varphi,\mathrm{conv}}, \tag{23}$$

$$j_z = -\partial_t P_z + (\vec{\nabla} \times \vec{M})_z - \frac{2b}{\rho}\partial_t M_\rho + j_{z,\mathrm{conv}},$$

where the convective part (subscript conv) is derived from $(i/4m)g^{\mu\lambda}[\overline{\Psi}\partial_\lambda\Psi - (\partial_\lambda\overline{\Psi})\Psi]$. The components of the polarization densities are given by

$$P_\rho = \frac{i}{2M}\overline{\Psi}\gamma_{(0)}\gamma_{(\rho)}\Psi,$$

$$P_\varphi = \frac{i}{2M}\overline{\Psi}\gamma_{(0)}\gamma_{(\varphi)}\Psi, \tag{24}$$

$$P_z = \frac{i}{2M}\overline{\Psi}\gamma_{(0)}\gamma_{(z)}\Psi,$$

where $\gamma_\rho = \gamma_1 \cos\varphi + \gamma_2 \sin\varphi$ and $\gamma_\varphi = \gamma_1 \sin\varphi + \gamma_2 \cos\varphi$.

The components of the magnetization current density vector, $\vec{M}$, are

$$M_\rho = \frac{i}{4M}\overline{\Psi}[\gamma_{(\varphi)}, \gamma_{(z)}]\Psi,$$

$$M_\varphi = \frac{i}{4M}\overline{\Psi}[\gamma_{(z)}, \gamma_{(\rho)}]\Psi, \tag{25}$$

$$M_z = \frac{i}{4M}\overline{\Psi}[\gamma_{(\rho)}, \gamma_{(\varphi)}]\Psi.$$

These results show us that the current also depends on the angular moment of the source, as well as on the Newtonian potential, $a(\rho)$, in the region where the particle is living.

It is worth calling attention to the fact that the Riemann curvature tensor, in this case, does not vanish, but does not depend on the angular momentum, and the solution and the current depend on the angular momentum of the source. This is a manifestation of the global features of the space-time generated by a rotating cylindrical shell, in the weak field approximation, and represents a gravitational analog of the Aharonov-Bohm effect.

IV. RELATIVISTIC QUANTUM SYSTEM IN THE SPACE-TIME OF A MOVING MASS CURRENT

In this section, we will consider a massive spinor particle in the weak gravitational field due to a moving mass current which moves slowly with velocity, v, in the z direction.

In order to solve the Dirac equation for a massive particle, given by Eq. (5), in this space-time given by the line element (4), let us choose the following set of tetrads:

$$e^{\mu}_{(a)} = \begin{pmatrix} 1+\frac{\Phi(\rho)}{2} & 0 & 0 & -2v\Phi(\rho) \\ 0 & 1-\frac{\Phi(\rho)}{2} & 0 & 0 \\ 0 & 0 & \frac{1-\frac{\Phi(\rho)}{2}}{\rho} & 0 \\ 0 & 0 & 0 & 1-\frac{\Phi(\rho)}{2} \end{pmatrix}. \tag{26}$$

In this space-time, the product $\gamma^{\mu}\Gamma_{\mu}$ that appears in the Dirac equation is given by

$$\gamma^{\mu}\Gamma_{\mu} = \gamma^{(a)}A_{(a)} = \frac{1}{2\rho}\left(1-\frac{\Phi}{2}\right)\gamma^{(1)}. \tag{27}$$

In this case, the generalized $\gamma^{\mu}(x)$ matrices are expressed in terms of the Dirac matrices as

$$\begin{aligned} \gamma^{0}(x) &= \left(1+\frac{\Phi(\rho)}{2}\right)\gamma^{(0)} - 2v\Phi(\rho)\gamma^{(3)}, \\ \gamma^{1}(x) &= \left(1-\frac{\Phi(\rho)}{2}\right)\gamma^{(1)}, \\ \gamma^{2}(x) &= \frac{1}{\rho}\left(1-\frac{\Phi(\rho)}{2}\right)\gamma^{(2)}, \\ \gamma^{3}(x) &= \left(1-\frac{\Phi(\rho)}{2}\right)\gamma^{(3)}. \end{aligned} \tag{28}$$

Substituting Eqs. (27) and (28) into (5), we obtain the following result for the Dirac equation in this space-time:

$$(AE-m)R_1 - (Bk+i\overline{v}E)aR_1 + \left(iB\frac{\mathrm{d}}{\mathrm{d}\rho} + \frac{iBl}{\rho} + \frac{iB}{2\rho}\right)R_2 = 0, \tag{29}$$

$$(AE-m)R_2 - (Bk+i\overline{v}E)R_2 + \left(iB\frac{\mathrm{d}}{\mathrm{d}\rho} - \frac{ilB}{\rho} + \frac{iB}{2\rho}\right)R_1 = 0, \tag{30}$$

$$-(AE+m)aR_1 + (Bk+i\overline{v}E)R_1 - \left(iB\frac{\mathrm{d}}{\mathrm{d}\rho} + \frac{ilB}{\rho} + \frac{iB}{2\rho}\right)R_2 = 0, \tag{31}$$

$$-(AE+m)bR_2 + (Bk-i\overline{v}E)R_2 + \left(-iB\frac{\mathrm{d}}{\mathrm{d}\rho} + \frac{ilB}{\rho} - \frac{iB}{2\rho}\right)R_1 = 0, \tag{32}$$

where $A=1+\Phi_1/2$, $B=1-\Phi_1/2$, and $\overline{v}=2v\Phi_1$, and we have considered that the components of the spinor, Ψ_j, solution of the Dirac equation can be written as

$$\Psi_j = e^{-iEt}e^{i(l\varphi+kz)}R_j(\rho), \quad j=1,2,3,4 \tag{33}$$

with $R_3=R_1$ e $R_4=R_2$.

Combining Eqs. (29)–(32), we obtain the following equations for $R_1(\rho)$ and $R_2(\rho)$,

$$B^2\frac{d^2R_1}{dr^2}+\frac{B^2}{\rho}\left(l+\frac{1}{2}\right)\frac{dR_1}{dr}+\left\{\frac{B^2}{\rho^2}\left[l(l+1)+\frac{1}{4}-\frac{1}{2B}\right]+pq\right\}R_1=0 \tag{34}$$

and

$$B^2\frac{d^2R_2}{dr^2}+\frac{B^2}{\rho}\left(l-\frac{1}{2}\right)\frac{dR_2}{dr}+\left\{\frac{B^2}{\rho^2}\left[l(l+1)-\frac{1}{4}-\frac{1}{2B}\right]-p'q'\right\}R_2=0, \tag{35}$$

where

$$p=AE-m-(Bk+i\overline{v}\overline{E}),$$

$$q=AE-m-(Bk+i\overline{v}\overline{E}),$$

$$p'=\overline{v}\overline{E}+Bk-(AE+m),$$

$$q'=\overline{v}\overline{E}+Bk+(AE+m).$$

The solutions of (34) and (35) are given by

$$R_1(\rho)=C_1\rho^{(1/2-u/2B)}J_\nu\left(\sqrt{\frac{\tau}{B}}\rho\right)+C_2\rho^{(1/2-u/2B)}J_\nu\left(\sqrt{\frac{\tau}{B}}\rho\right) \tag{36}$$

and

$$R_2(\rho)=C_1'\rho^{(1/2-u/2B)}J_{\overline{\nu}}\left(\sqrt{\frac{\overline{\tau}}{B}}\rho\right)+C_2'\rho^{(1/2-u/2B)}N_{\overline{\nu}}\left(\sqrt{\frac{\overline{\tau}}{B}}\rho\right), \tag{37}$$

where

$$\nu=\frac{1}{2}\sqrt{\frac{B^2-2uB+u^2-4\omega^2B}{B^2}},$$

$$\overline{\nu}=\frac{1}{2}\sqrt{\frac{B^2-2\overline{u}B+\overline{u^2}-4\overline{\omega^2}B}{B^2}},$$

$$\omega=B^2\left[l(l-1)+\frac{1}{4}-\frac{1}{2B}\right],$$

$$\tau=pq,$$

$$\overline{u}=-B^2\left(\frac{1}{2}-l\right),$$

$$u=B^2\left(l+\frac{1}{2}\right),$$

$$\overline{\omega}=-B^2\left(l+\frac{1}{4}\right),$$

$$\overline{\tau} = p'q'.$$

Note that these solutions depend on the velocity of the source. In this case the Riemann tensor does not depend on the velocity of the source, and therefore, the obtained result means that the dependence of the solution with the velocity is of purely global origin.

The current can be computed using Eq. (21). To this we will use the following expressions:

$$\sigma^{01} = i[\gamma^{(0)}\gamma^{(1)} - 2v\Phi\gamma^{(3)}\gamma^{(1)}],$$

$$\sigma^{02} = \frac{i}{\rho}[\gamma^{(0)}\gamma^{(2)} - 2v\Phi\gamma^{(3)}\gamma^{(2)}],$$

$$\sigma^{03} = i[\gamma^{(0)}\gamma^{(3)} - 2v\Phi\gamma^{(3)}\gamma^{(3)}],$$

$$\sigma^{12} = \frac{i}{\rho}\gamma^{(1)}\gamma^{(2)}, \tag{38}$$

$$\sigma^{13} = i\gamma^{(1)}\gamma^{(3)},$$

$$\sigma^{32} = \frac{i(1-\Phi)}{\rho}\gamma^{(3)}\gamma^{(2)},$$

$$[\gamma^{\lambda}\Gamma_{\lambda}, \gamma^{0}] = \frac{2}{\rho}\gamma^{(1)}\gamma^{(0)} - \frac{4v\Phi}{\rho}\gamma^{(1)}\gamma^{(3)}, \tag{39}$$

$$[\gamma^{\lambda}\Gamma_{\lambda}, \gamma^{1}] = 0, \tag{40}$$

$$[\gamma^{\lambda}\Gamma_{\lambda}, \gamma^{2}] = \frac{2(1-\Phi)}{\rho}\gamma^{(1)}\gamma^{(3)}. \tag{41}$$

Substituting these results into Eq. (22), we get

$$j_t = \vec{\nabla}\cdot\vec{P} - \frac{2v}{\rho^2}M_{\varphi} + \rho_{\mathrm{conv}},$$

$$j_{\rho} = -\partial_t P_{\rho} + (\vec{\nabla}\times\vec{M})_{\rho} - \frac{2v}{\rho}\partial_t M_{\rho} + j_{\rho,\mathrm{conv}},$$

$$j_{\varphi} = -\partial_t P_{\varphi} + (\vec{\nabla}\times\vec{M})_{\varphi} + j_{\varphi,\mathrm{conv}},$$

$$j_z = -\partial_t P_z + (\vec{\nabla}\times\vec{M})_z - \frac{2v}{\rho}\partial_t M_{\rho} + j_{z,\mathrm{conv}},$$

where the components polarization and magnetization vectors, $\vec{P}$ and $\vec{M}$, respectively, are given by

$$P_{\rho} = \frac{i}{2M}\overline{\Psi}\gamma_{(0)}\gamma_{(\rho)}\Psi,$$

$$P_{\varphi} = \frac{i}{2M}\overline{\Psi}\gamma_{(0)}\gamma_{(\varphi)}\Psi,$$

$$P_{z} = \frac{i}{2M}\overline{\Psi}\gamma_{(0)}\gamma_{(z)}\Psi,$$

$$M_{\rho} = \frac{i}{4M}\overline{\Psi}[\gamma_{(\theta)}, \gamma_{(z)}]\Psi,$$

$$M_{\varphi} = \frac{i}{4M}\overline{\Psi}[\gamma_{(z)}, \gamma_{(\rho)}]\Psi,$$

$$M_{z} = \frac{i}{4M}\overline{\Psi}[\gamma_{(\rho)}, \gamma_{(\varphi)}]\Psi.$$

From the obtained results, we conclude that the solution of the Dirac equation, as well as the current associated with the particle, depend on the velocity of the source, which does not have any influence on the curvature, in the weak field approximation. This is a manifestation of an analog of the electromagnetic Aharonov-Bohm effect, but in the present case in the context of the gravitational field.

V. CONCLUDING REMARKS

The obtained results show us that the solutions of the Dirac equation and the associated probability currents depend on the angular momentum and on the velocity. The parameters determine the gravitational fields we have considered, namely, the gravitational fields generated by a slowly rotating cylindrical shell and by a slowly moving mass current.

It is worth calling attention to the fact that in the region of motion of the massive spinor-1/2 particle, the Riemann curvature, in the weak field approximation, does not depend on the angular momentum or on the velocity of the source, respectively, for the rotating cylindrical shell and the moving mass current, but the solutions and probability currents for both cases do depend on these quantities. This result means that even in the situation in which the particle is constrained to move in a region where the Riemann curvature does not depend on the angular, or on the velocity of the source, it exhibits a gravitational effect associated with these quantities. This dependence on parameters which do not have any influence on the Riemann curvature tensor, in the weak field approximation, is a manifestation of a global phenomenon associated with these gravitational fields, which is called gravitational Aharonov-Bohm effect.

Poincaré-Birkhoff periodic orbits for mechanical Hamiltonian systems on $T^*\mathbb{T}^n$

Olga Bernardi[a] and Franco Cardin[b]
Dipartimento di Matematica Pura ed Applicata, Università degli Studi di Padova, Via Belzoni 7, 35131 Padova, Italy

(Received 19 October 2005; accepted 16 May 2006; published online 11 July 2006)

Here, a version of the Arnol'd conjecture, first studied by Conley and Zehnder, giving a generalization of the Poincaré-Birkhoff last geometrical theorem, is proved inside Viterbo's framework of the generating functions quadratic at infinity. We give brief overviews of some tools that are often utilized in symplectic topology. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2211930]

I. INTRODUCTION

Henri Poincaré has been the main pioneer of the modern dynamical systems theory. Among the large multitude of his contributes, he formulated what is now called "Poincaré's last geometrical theorem" in order to schematize a crucial class of problems related to the search of period solutions in Hamiltonian dynamics:

{P} *Any area preserving diffeomorphism of the annulus* $A=\{(x,y)\in\mathbb{R}^2: a\leqslant x^2+y^2\leqslant b\}$ *into itself, uniformly rotating the two boundary circles of radius a and b in opposite directions, admits at least two geometrically distinct fixed points.*

The first rigorous proof of this statement was given in the 1920s by Birkhoff by means of a technique that seems not easily extendible to greater dimensional systems. In a following paper,[4] he remarked on the power of "maximum-minimum considerations" in the existence of periodic orbits. Nowadays, theseaspects are well ruled in the Lusternik-Schnirelman setting: in this framework, one can select minimax critical values (connected to periodic orbits) of suitable generating functions—quadratic at infinity (see below).

In the 1960s, in a series of papers Arnol'd proposed his celebrated conjecture (see Ref. 1):

{A} *Any Hamiltonian diffeomorphism of a compact symplectic manifold* (M,ω) *possesses at least many fixed points as a function* $f: M\to\mathbb{R}$ *on* M *possesses critical points.*

This new and intriguing topological question has been answered by Conley and Zehnder,[10] in the case where $M=\mathbb{T}^{2n}$; in that same paper they also proved that

{C-Z} *For a Hamiltonian* $H:\mathbb{R}\times T^*\mathbb{T}^n\to\mathbb{R}$, *such that for* $|p|\geqslant C$ *the related vector field* X_H *is p-linear and independent of* $q\in\mathbb{T}^n$ *and* $t\in\mathbb{R}$, *the time-one flow* ϕ_H^1 *of* X_H *admits at least many fixed points as a function* $f:\mathbb{T}^n\to\mathbb{R}$ *on* $\mathbb{T}^n$ *possesses critical points.*

It is interesting to note that this last statement, directly descending from Poincaré's last geometrical theorem, in a sense comes back to the original setting of analytical mechanics in which it arose. E.g., the above Hamiltonians are at once interpreted as describing a physical landscape in which a number of particles does interact among them only under a suitable energy threshold (low energy scattering):

$$H(q,p)=1/2|p|^2+f(q,p),\quad q\in\mathbb{T}^n,\quad f\in O(1).$$

[a]Electronic mail: obern@math.unipd.it
[b]Electronic mail: cardin@math.unipd.it

Incidentally, we can note that this is quite near to a typical Hamiltonian setting of Nekhoroshev perturbation theory: $H(q,p)=1/2|p|^2+\varepsilon f(q,p)$.

Conley and Zehnder introduced a sort of Liapunov-Schmidt reduction technique, now known as *Amann-Conley-Zehnder reduction*, based on a suitable Fourier cutoff on the loop space and giving, at last, a finite dimensional variational problem. Later, Chaperon (see Ref. 5) proposed his new ingenious *broken geodesics reduction*, showing it is not indispensable to start from the infinite dimensional formulation of the problem. In both cases, the estimates on fixed points of ϕ_H^1 are proved using the isolated invariant sets and the Morse index, as presented by Conley.[9]

More recently, Golé[12,13] gave an alternative proof of the statement {C-Z}, extending $\mathbb{T}^n$ to any compact manifold and using a variation of Chaperon's argument. The finite variational problem that in such a way he obtained was solved by utilizing techniques based on the Conley index and further results on it by Floer. Furthermore, the author pointed out that his function, defining the above finite variational problem, was not a generating function quadratic at infinity, an essential property in order to agreeably apply the Lusternik-Schnirelman theory.

Nowadays, a short and nice proof of this theorem can be built up using the fine papers[6,7] by Chaperon.

After the impressive paper,[22] there exists a rather common growing prejudgment that the framework of the generating function quadratics at infinity and the Lusternik-Schnirelman theory should be the right environment to better understand many actual aspects of symplectic topology, as in the Arnol'd conjecture (see Ref. 15, p. 216).

In this paper, by assuming this point of view, we restart from the original statement {C-Z}, for $\mathbb{T}^n$. In genuine framework of the generating function quadratics at infinity, and then using the now classical results of Chaperon, Chekanov, Laudenbach, and Sikorav and Viterbo, we propose a finite variational problem consisting of a generating function quadratic at infinity: a suitable application of the Lusternik-Schnirelman theory in the degenerate case, and the Morse theory in the nondegenerate one, produces the expected result. By making this goal, we give brief overviews on some of the tools used here, and that are often involved in symplectic topology.

II. PRELIMINARIES

A. Generating functions

Let N be a compact manifold and $L\subset T^*N$ a Lagrangian submanifold. If $L=\mathrm{im}(df)=L_f$, where $f:N\to\mathbb{R}$ is a C^2 function, then the set $\mathrm{crit}(f)$ of the critical points of f coincides with the intersection of L_f with the zero section $0_N\subset T^*N$:

$$\mathrm{crit}(f)=L_f\cap 0_N.$$

In the more general case, Lagrangian submanifolds do not have the above graph structure L_f, and a classical argument by Maslov and Hörmander shows that, at least locally, every Lagrangian submanifold is described by some generating function like $S:N\times\mathbb{R}^k\to\mathbb{R}$, $(x,\xi)\mapsto S(x,\xi)$, in the following way:

$$L_S:=\left\{\left(x,\frac{\partial S}{\partial x}(x,\xi)\right):\frac{\partial S}{\partial \xi}(x,\xi)=0\right\},$$

where 0 is a regular value of the map $(x,\xi)\mapsto \partial S/\partial\xi(x,\xi)$.

Some authors (e.g., Benenti, Tulczyjew, and Weinstein) say that in this case the generating function S is a *Morse family*. In order to apply the calculus of variations to generating functions, one needs a condition implying the existence of critical points. In particular, the following class of generating functions has been decisive in many issues:

Definition 2.1: A generating function $S:N\times\mathbb{R}^k\to\mathbb{R}$ is quadratic at infinity (GFQI) if for $|\xi|>C$

$$S(x,\xi)=\xi^T Q\xi, \tag{1}$$

where $\xi^T Q \xi$ is a nondegenerate quadratic form.

In the literature (see, e.g., Refs. 16 and 23) two main operations on the generating functions that leave the corresponding Lagrangian submanifolds invariant are known. Lemmas 2 and 3 below recollect these facts. The globalization was realized by Viterbo (see Ref. 21).

Lemma 2.2: Let $S: N \times \mathbb{R}^k \to \mathbb{R}$ be a GFQI and $N \times \mathbb{R}^k \ni (x, \xi) \mapsto (x, \phi(x, \xi)) \in N \times \mathbb{R}^k$ a map such that, $\forall x \in N$,

$$\mathbb{R}^k \ni \xi \mapsto \phi(x, \xi) \in \mathbb{R}^k$$

is a diffeomorphism. Then $S_1(x, \xi) := S(x, \phi(x, \xi))$ generates the same Lagrangian submanifold: $L_{S_1} = L_S$.

Proof: Since ϕ is a diffeomorphism, $\partial S_1 / \partial \xi = \partial S / \partial \xi \partial \phi / \partial \xi = 0$ if and only if $\partial S / \partial \xi = 0$. Moreover, $\partial S_1 / \partial x = \partial S / \partial x + \partial S / \partial \xi \partial \phi / \partial x$ and it is immediately verified that 0 is a regular value for $\partial S_1 / \partial \xi(x, \xi)$. □

Lemma 2.3: Let $S: N \times \mathbb{R}^k \to \mathbb{R}$ be a GFQI. Then

$$S_1(x, \xi, \eta) := S(x, \xi) + \eta^T B \eta,$$

where $\eta \in \mathbb{R}^l$ and $\eta^T B \eta$ is a nondegenerate quadratic form, generates the same Lagrangian submanifold: $L_{S_1} = L_S$.

Proof. $\partial S_1 / \partial \xi(x, \xi, \eta) = 0$ if and only if $\partial S / \partial \xi(x, \xi) = 0$. Moreover, $\partial S_1 / \partial \eta(x, \xi, \eta) = 0$ if and only if $B\eta = 0$, that is $\eta = 0$. Thus

$$\left. \frac{\partial S_1}{\partial x} \right|_{\partial S_1 / \partial \xi = 0, \partial S_1 / \partial \eta = 0} = \left. \frac{\partial S}{\partial x} \right|_{\partial S / \partial \xi = 0}.$$

□

Finally, as a third—although trivial—invariant operation, we observe that by adding to a generating function S any arbitrary constant $c \in \mathbb{R}$, the described Lagrangian submanifold is invariant: $L_{S+c} = L_S$. Problems 1 and 2 below have been crucial in the global theory of Lagrangian submanifolds and their parameterizations.

1. When does a Lagrangian submanifold $L \subset T^*N$ admit a FGQI?
2. If L admits a GFQI, when can we state the uniqueness of it (up to the operations described above)?

The following theorem (see Ref. 18) partially answers the first question.

Theorem 2.4: *(Chaperon-Chekanov-Laudenbach-Sikorav) Let 0_N be the zero section of T^*N and $(\phi_t)_{t \in [0,1]}$ a Hamiltonian isotopy. Then the Lagrangian submanifold $\phi_1(0_N)$ admits a GFQI.*

The answer to the second problem is due to Viterbo:

Theorem 2.5: *(Viterbo) Let 0_N be the zero section of T^*N and $(\phi_t)_{t \in [0,1]}$ a Hamiltonian isotopy. Then the Lagrangian submanifold $\phi_1(0_N)$ admits a unique (up to the operations described above) GFQI.*

The theorems above (see also Ref. 20) still hold in T^*R^n, provided that $(\phi_t)_{t \in [0,1]}$ is a flow of a compactly supported Hamiltonian vector field.

B. Lusternik-Schnirelman theory

Let $f: N \to \mathbb{R}$ be a C^2 function. We shall assume that either N is compact or f satisfies the Palais-Smale (PS) condition:

(PS) Any sequence $\{x_n\}$ such that $\nabla f(x_n) \to 0$ and $f(x_n)$ is bounded, admits a converging subsequence.

We recall now some results of the Lusternik-Schnirelman theory, which allow us to associate critical values of f to nonvanishing relative cohomology classes and to give a lower bound to the number of critical points of f in terms of the topological complexity of N.

Let us define the sublevel sets

$$N^\nu := \{x \in N : f(x) \leqslant \nu\}. \tag{2}$$

(PS) condition guarantees the well-defined gradient vector field ∇f, whose flow realizes a diffeomorphism between N^μ and N^ν whenever no critical values exist in $[\mu, \nu]$:

Proposition 2.6: Let $\mu < \nu$. If f has no critical points in $N^\nu \backslash N^\mu$, then $H^*(N^\nu, N^\mu) = 0$.

Thus if $H^*(N^\nu, N^\mu) \neq 0$, then in $N^\nu \backslash N^\mu$ there exists at least one critical point of f, with critical value in $[\mu, \nu]$. For $\lambda \in [\mu, \nu]$, let $i_\lambda : N^\lambda N^\nu$ be the inclusion.

Definition 2.7: For every $u \in H^*(N^\nu, N^\mu)$, $u \neq 0$, we define:

$$c(u,f) =: \inf\{\lambda \in [\mu, \nu] : i_\lambda^* u \neq 0\},$$

where

$$i_\lambda^* : H^*(N^\nu, N^\mu) \to H^*(N^\lambda, N^\mu)$$

denotes the pull-back of the inclusion.

This Definition provides a tool to detect critical values, indeed:

Theorem 2.8. *$c(u,f)$ is a critical value of f.*

The main result of this construction consists of the following.

Theorem 2.9. (*Cohomological Lusternik-Schnirelman theory*) *Let $0 \neq u \in H^*(N^\nu, N^\mu)$* and *$v \in H^*(N^\nu) \backslash H^0(N^\nu)$.*

1.

$$c(u \wedge v, f) \geqslant c(u,f). \tag{3}$$

2. *If (3) is an equality ($c(u \wedge v, f) = c(u,f) =: c$), set $K_c = \{x : df(x) = 0, f(x) = c\}$, then, for every neighborhood U of K_c, v is not vanishing in $H^*(U)$, and the common critical level contains infinitely many critical points.*

Corollary 2.10: Let N be a compact manifold. The function $f : N \to \mathbb{R}$ has at least a number of critical points equal to the cup-length of N:

$$\mathrm{cl}(N) := \max\{k : \exists\, v_1, \ldots, v_{k-1} \in H^*(N) \setminus H^0(N) \text{ s . t . } v_1 \wedge \ldots \wedge v_{k-1} \neq 0\}. \tag{4}$$

Proof: Apply Theorem 2.9 with $\mu < \inf f$, $\sup f < \nu$, and $u = 1 \in H^*(N, \emptyset) = H^*(N)$. □

By Corollary 2.11 below, we verify that the preceding estimate on the number of critical points of f still holds in the noncompact case whenever GFQI f are taken into account.

Corollary 2.11: Let N be a compact manifold and $f : N \times \mathbb{R}^n \to \mathbb{R}$ be a GFQI, $f(x, \xi) = Q(\xi)$ out of a compact set in the parameters ξ. Then, for $c > 0$ large enough, there exist $0 \neq u \in H^*(f^c, f^{-c})$ and $v_1, \ldots, v_{k-1}$ as in (4) such that

$$u \wedge p^* v_1 \wedge \ldots \wedge p^* v_{k-1} \neq 0,$$

where $p : N \times \mathbb{R}^n \to N$ is the canonical projection. Consequently, the GFQI $f : N \times \mathbb{R}^n \to \mathbb{R}$ has at least cl(N) *critical points.*

Proof: Let us first observe that for $c > 0$ large enough, the sublevel sets of f are invariant from a homotopical point of view: $f^{\pm c} = N \times Q^{\pm c}$, and $f^{\pm \bar{c}}$ retracts on $f^{\pm c}$ for any $\bar{c} > c$. Let $A := Q^{-(c+\varepsilon)}$, $\varepsilon > 0$ small. Then the isomorphisms below (the first one by excision and the second one by retraction) hold:

$$H^*(Q^c, Q^{-c}) \cong H^*(Q^c \setminus \mathring{A}, Q^{-c} \setminus \mathring{A}) \cong H^*(D^i, \partial D^i),$$

where i is the index of the quadratic form Q and D^i denotes the disk (of radius $\sqrt{c}$) in $\mathbb{R}^i$. Consequently

$$H^h(Q^c,Q^{-c}) \cong H^h(D^i,\partial D^i) = \begin{cases} 0 & \text{if } h \neq i \\ \alpha\mathbb{R} & \text{if } h = i \end{cases}.$$

To conclude in the noncompact case $N\times\mathbb{R}^n$, by the Künneth isomorphism

$$H^*(N) \cong H_c^{*+i}(N\times\mathbb{R}^i)$$

and the homotopy argument

$$H_c^*(N\times\mathbb{R}^i) \cong H^*(N\times D^i, N\times\partial D^i),$$

the following isomorphism,

$$H^*(N) \ni v \mapsto q^*\alpha\wedge p^*v \in H^{*+i}(N\times D^i, N\times\partial D^i),$$

holds, where $p:N\times\mathbb{R}^n\to N$, $q=(q_1,q_2):(N\times D^i,N\times\partial D^i)\to(D^i,\partial D^i)$ are the standard projections. Now we apply Theorem 2.9 with $u=q^*\alpha$; since $q^*\alpha\wedge p^*v_1\wedge\ldots\wedge p^*v_{k-1}=q^*\alpha\wedge p^*(v_1\wedge\ldots\wedge v_{k-1})\neq 0$ whenever $v_1\wedge\ldots v_{k-1}\neq 0$, then the number of critical points of the GFQI $f:N\times\mathbb{R}^n\to\mathbb{R}$ is at least $\mathrm{cl}(N)$. □

III. THE HAMILTONIAN SETTING

Let $T^*\mathbb{R}^n\equiv\mathbb{R}^{2n}=\{(q,p):q\in\mathbb{R}^n,p\in\mathbb{R}^n\}$ be endowed with the standard symplectic form $\omega=dp\wedge dq=\Sigma_{i=1}^n dp_i\wedge dq^i$.

On $(\mathbb{R}^{2n},\omega)$ we consider the-time-dependent globally Hamiltonian vector field X_H given by

$$H(t,q,p) \in C^2(\mathbb{R}\times\mathbb{R}^{2n};\mathbb{R}),$$

periodic in q of period 2π and

$$H(t,q,p) = \frac{1}{2}|p|^2 \text{ if } |p| \geqslant C > 0. \tag{5}$$

Our aim is to draw a new proof of a popular version, due to Arnol'd, of Poincaré's last geometrical theorem (see Refs. 6, 7, 10, and 12) inside Viterbo's framework of symplectic topology.[22]

A. Properties of flows on the cotangent of the torus

In connection with the above Hamiltonian H, let (here, as in other analogous circumstances, we mean $\phi_H^t:=\phi_H^{t,0}$) ϕ_H^t be the flow of the Hamiltonian vector field X_H, $\omega(X_H,\eta)=-dH(\eta)$, so that $X_H=J\nabla H$, where J is the symplectic $2n$-matrix. The n-torus is denoted by $\mathbb{T}^n=\mathbb{R}^n/2\pi\mathbb{Z}^n$. Therefore a Hamiltonian $\bar{H}$ and the related flow $\phi_{\bar{H}}^t$ are well defined on $T^*\mathbb{T}^n$ (see Corollary 3.2 below):

$$\begin{array}{ccc} \mathbb{R}\times T^*\mathbb{R}^n & \xrightarrow{H} & \mathbb{R} \\ {\scriptstyle \mathrm{id}\times\pi}\downarrow & & \downarrow{\scriptstyle id_{\mathbb{R}}} \\ \mathbb{R}\times T^*\mathbb{T}^n & \xrightarrow[\bar{H}]{} & \mathbb{R} \end{array} \qquad \begin{array}{ccc} T^*\mathbb{R}^n & \xrightarrow{\phi_H^t} & T^*\mathbb{R}^n \\ {\scriptstyle \pi}\downarrow & & \downarrow{\scriptstyle \pi} \\ T^*\mathbb{T}^n & \xrightarrow[\phi_{\bar{H}}^t]{} & T^*\mathbb{T}^n \end{array}$$

It is standard matter to see that

Proposition 3.1: The flow ϕ_H^t associated to H satisfies

$$(\phi_H^t)_q(q+2\pi k,p) = (\phi_H^t)_q(q,p) + 2\pi k,$$

$$(\phi_H^t)_p(q+2\pi k,p) = (\phi_H^t)_p(q,p),$$

$\forall k\in\mathbb{R}^n$ *and* $\forall(q,p)\in\mathbb{R}^{2n}$.

We denote by $[q] \in \mathbb{T}^n := \mathbb{R}^n / 2\pi\mathbb{Z}^n$ the class of $q \in \mathbb{R}^n$. From the above deductions it follows that

Corollary 3.2: The flow of $X_{\bar{H}}$ is

$$\phi^t_{X_{\bar{H}}}([q],p) = ([\phi^t_{X_H,q}(q,p)], \phi^t_{X_H,p}(q,p)). \tag{6}$$

B. The splitting $H=H_0+f$

We remind that the Hamiltonian H coincides with $\frac{1}{2}|p|^2$ if $|p| \geqslant C > 0$. Consequently, outside of this compact set (in the p variables) the flow associated to the Hamiltonian H reduces to

$$\mathbb{R}^n \times \{p : |p| \geqslant C\} \to \mathbb{R}^n \times \{p : |p| \geqslant C\},$$

$$(q,p) \mapsto \phi^t_H(q,p) = (q + tp, p).$$

We split H as the sum of the Hamiltonian $H_0 := \frac{1}{2}|p|^2$ and a Hamiltonian f, hence necessarily compactly supported in the p variables,

$$H = H_0 + f : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R},$$

$$(t,q,p) \mapsto H(t,q,p) = H_0(p) + f(t,q,p).$$

Denoting by ϕ^t_0 the flow related to H_0, we define the Hamiltonian K as the pull-back of f with respect to ϕ^t_0:

$$K : \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R},$$

$$K := (\phi^t_0)^* f, \quad \text{i.e.,} \quad K(t,q,p) = H(t, q + tp, p) - \frac{|p|^2}{2}.$$

This Hamiltonian K, which is compactly supported in the p variables like f, will be essential in the following sections. We indicate now ϕ^t_K, the flow of K, and write down the following proposition, which is, essentially, a result of Hamilton[14] (see also Ref. 11).

Proposition 3.3: Let ϕ^t_H, ϕ^t_0, and ϕ^t_K be the flows of $H=H_0+(H-H_0)$, H_0, and $K=(\phi^t_0)^*(H-H_0)$, respectively. We have

$$\phi^t_H(q,p) = \phi^t_0 \circ \phi^t_K(q,p),$$

$\forall (q,p) \in \mathbb{R}^n \times \mathbb{R}^n$ *and* $\forall t \in \mathbb{R}$.

We recall some technical premises to the proof of this fact.

Definition 3.4: (Push-forward) Let N be a manifold and ρ a diffeomorphism of N into itself,

$$N \overset{\rho}{\to} N,$$

$$x \mapsto y = \rho(x).$$

The push-forward ρ_* of a vector field X is defined as follows:

$$\rho_* X(y) := d\rho(\rho^{-1}(y)) X(\rho^{-1}(y)).$$

(Below, we will use this definition with $N=T^*R^n$ and $\rho=\phi^t_0$.) The following Lemma is a central result of the canonical transformations theory.

Lemma 3.5: Let M be a manifold and ρ a symplectic diffeomorphism of T^*M into itself, then, for every Hamiltonian function $L : T^*M \to R$,

$$\rho_* X_L = X_{\rho_* L} = X_{L\circ\rho^{-1}}.$$

Proof.

$$\begin{aligned}\frac{d}{dt}(\phi_0^t \circ \phi_K^t)(q,p) &= X_{H_0}(\phi_0^t \circ \phi_K^t(q,p)) + d\phi_0^t(\phi_K^t(q,p))X_K(\phi_K^t(q,p)) = X_{H_0}(\phi_0^t \circ \phi_K^t(q,p)) \\ &\quad + d\phi_0^t(\phi_0^{-t} \circ \phi_0^t \circ \phi_K^t(q,p))X_K(\phi_0^{-t} \circ \phi_0^t \circ \phi_K^t(q,p)) \\ &= X_{H_0}(\phi_0^t \circ \phi_K^t(q,p)) + (\phi_0^t)_* X_K(\phi_0^t \circ \phi_K^t(q,p)) \\ &= [X_{H_0} + X_{(\phi_0^t)_* K}](\phi_0^t \circ \phi_K^t(q,p)) = X_{H_0+f}(\phi_0^t \circ \phi_K^t(q,p)) \\ &= X_H(\phi_0^t \circ \phi_K^t(q,p)).\end{aligned}$$

□

C. The "graph" and the "cotangent" structures of R^{4n}

We introduce now the linear symplectic isomorphism h, from the "graph" structure to the "cotangent" structure:

$$h:(T^*\mathbb{R}^n \times T^*\mathbb{R}^n, \omega_{\mathbb{R}^n} \ominus \omega_{\mathbb{R}^n}) \to (T^*(T^*\mathbb{R}^n), \omega_{\mathbb{R}^{2n}}),$$

$$(q,p,Q,P) \mapsto (q,P,p-P,Q+P-q). \tag{7}$$

The following Lagrangian submanifold F of $(T^*\mathbb{R}^n \times T^*\mathbb{R}^n, \omega_{\mathbb{R}^n} \ominus \omega_{\mathbb{R}^n})$,

$$F := \{(q,p,q-p,p):(q,p) \in T^*\mathbb{R}^n\}, \tag{8}$$

is mapped by h to the zero section $0_{\mathbb{R}^{2n}}$: $h(F) = 0_{\mathbb{R}^{2n}} \subset \mathbb{R}^{4n}$.

Since we are looking for fixed points of ϕ_H^1, we denote by Γ_H and Γ_K the graphs of ϕ_H^1 and ϕ_K^1 in $(T^*\mathbb{R}^n \times T^*\mathbb{R}^n, \omega_{\mathbb{R}^n} \ominus \omega_{\mathbb{R}^n})$, respectively, and by Δ the diagonal of $T^*\mathbb{R}^n \times T^*\mathbb{R}^n = \mathbb{R}^{4n}$. It comes out that

$$(\bar{q},\bar{p}) \in T^*\mathbb{R}^n \text{ is a fixed point of } \phi_H^1,$$

that is, by Proposition 3.3,

$$(\bar{q},\bar{p},(\phi_0^1 \circ \phi_K^1)_q(\bar{q},\bar{p}),(\phi_0^1 \circ \phi_K^1)_p(\bar{q},\bar{p})) \in \Gamma_H \cap \Delta,$$

if and only if, setting

$$\hat{\phi}_0^{-1}(q,p,Q,P) := id_{R^{2n}} \times \phi_0^{-1}(q,p,Q,P) = (q,p,Q-P,P),$$

and using F in (8),

$$(\bar{q},\bar{p},(\phi_K^1)_q(\bar{q},\bar{p}),(\phi_K^1)_p(\bar{q},\bar{p})) \in \hat{\phi}_0^{-1}(\Gamma_H) \cap \hat{\phi}_0^{-1}(\Delta) = \Gamma_K \cap F,$$

if and only if, using h,

$$h(\bar{q},\bar{p},(\phi_K^1)_q(\bar{q},\bar{p}),(\phi_K^1)_p(\bar{q},\bar{p})) \in h(\Gamma_K) \cap h(F) = h(\Gamma_K) \cap 0_{\mathbb{R}^{2n}}.$$

Thus, we claim that the periodic time-one solutions, corresponding to fixed points of ϕ_H^1, are caught by the critical points of a (possible) generating function for $h(\Gamma_K)$. Furthermore, they are contained in the region $\mathbb{T}^n \times \{p:|p|<C\}$. In fact, on $\mathbb{T}^n \times \{p:|p| \geqslant C\}$ the Hamiltonian system is trivially integrable and in such a case the tori $\mathbb{T}^n \times \{p\}$ are invariant under the flow $\phi_H^t:(q,p) \mapsto (q+tp,p)$. Consequently, the nontrivial periodic solutions of ϕ_H^1, corresponding precisely to the fixed points of ϕ_H^1, must lie in $\mathbb{T}^n \times \{p:|p|<C\}$ and are contractible loops on $\mathbb{T}^n$.

IV. EXISTENCE FOR GENERATING FUNCTIONS

Our original problem has been translated into the investigation of $h(\Gamma_K) \cap 0_{\mathbb{R}^{2n}}$. The Lagrangian submanifold $h(\Gamma_K)$,

$$h(\Gamma_K) = \{(q,(\phi_K^1)_p(q,p),p-(\phi_K^1)_p(q,p),(\phi_K^1)_p(q,p)+(\phi_K^1)_q(q,p)-q),$$

$$\forall\,(q,p) \in T^*\mathbb{R}^n\} \subset (T^*\mathbb{R}^{2n},\omega_{\mathbb{R}^{2n}}),$$

in a neighborhood of infinity (in the p variables) results:

$$h(\Gamma_K) = \{(q,p,0,p),\ \forall\, q \in \mathbb{R}^n,\ \forall\, p \in \mathbb{R}^n : |p| \geqslant C\}.$$

In this section we study its structure, proving that it is the image [through a suitable symplectic isomorphism ψ of $(T^*\mathbb{R}^{2n},\omega_{\mathbb{R}^{2n}})$] of another Lagrangian submanifold, denoted by $\bar{h}(\Gamma_K)$, which is isotopic to the zero section of $T^*\mathbb{R}^{2n}$, so that it admits a GFQI (Theorem 2.4). This is crucial in order to gain the existence of a generating function for $h(\Gamma_K)$. In fact, by means of a natural composition of the above generating functions for $\bar{h}(\Gamma_K)$ and for ψ, we will be able to construct a GFQI for $h(\Gamma_K)$.

A. The factorization of the map *h*

We introduce the following linear two maps $\bar{h}$ (introduced by Sikorav in Ref. 19 and used by Viterbo in Ref. 22) and ψ:

$$\bar{h}:(T^*\mathbb{R}^n \times T^*\mathbb{R}^n, \omega_{\mathbb{R}^n} \ominus \omega_{\mathbb{R}^n}) \to (T^*(T^*\mathbb{R}^n),\omega_{\mathbb{R}^{2n}}), \tag{9}$$

$$(q,p,Q,P) \mapsto \left(\frac{q+Q}{2},\frac{p+P}{2},p-P,Q-q\right),$$

$$\psi:(T^*(T^*\mathbb{R}^n) = T^*\mathbb{R}^{2n},\omega_{\mathbb{R}^{2n}}) \to (T^*(T^*\mathbb{R}^n) = T^*\mathbb{R}^{2n},\omega_{\mathbb{R}^{2n}}),$$

$$(q,p,Q,P) =: (x_0,y_0) \mapsto (x_1,y_1) =: \left(\frac{2q-P}{2},\frac{2p-Q}{2},Q,\frac{2P+2p-Q}{2}\right). \tag{10}$$

It results in the following well-defined map on the quotient tori structures:

$$\tilde{\psi}:T^*(T^*\mathbb{T}^n) \to T^*(T^*\mathbb{T}^n),$$

$$([q],p,Q,P) \mapsto \left(\left[\frac{2q-P}{2}\right],\frac{2p-Q}{2},Q,\frac{2P+2p-Q}{2}\right),$$

and the following diagram is commutative:

$$\begin{array}{ccc} T^*(T^*\mathbb{R}^n) & \xrightarrow{\psi} & T^*(T^*\mathbb{R}^n) \\ \pi \downarrow & & \downarrow \pi \\ T^*(T^*\mathbb{T}^n) & \xrightarrow[\tilde{\psi}]{} & T^*(T^*\mathbb{T}^n) \end{array}$$

It is standard matter to see that the maps ψ and $\bar{h}$ are symplectic isomorphisms and it is easy to check that the factorization $h=\psi\circ\bar{h}$ holds:

$$\begin{array}{ccc} T^*\mathbb{R}^n \times T^*\mathbb{R}^n & \xrightarrow{h} & T^*(T^*\mathbb{R}^n) \\ & \searrow^{\bar{h}} & \uparrow \psi \\ & & T^*(T^*\mathbb{R}^n) \end{array}$$

B. The Lagrangian submanifold $\bar{h}(\Gamma_K)$

This section is devoted to the proof of the following

Proposition 4.1: The Lagrangian submanifold $\bar{h}(\Gamma_K)\subset(T^*\mathbb{R}^{2n},\omega_{\mathbb{R}^{2n}})$ *admits a GFQI,* $S_1(q,p;\xi)$, 2π*-periodic in the* q *variables.*

Proof: We observe that like H also the Hamiltonian K is periodic of the 2π-period in the q variables.:

$$K(t,q+2\pi k,p)=H(t,q+2\pi k+tp,p)-\frac{|p|^2}{2}=H(t,q+tp,p)-\frac{|p|^2}{2}=K(t,q,p),$$

$\forall t\in R$, $\forall(q,p)\in R^{2n}$, and $\forall k\in Z^n$. Moreover, the flow $\phi_K^t=\phi_0^{-t}\circ\phi_H^t$ inherits from the flow ϕ_H^t (see Proposition 3.3) the following properties:

$$(\phi_K^t)_q(q+2\pi k,p)=(\phi_K^t)_q(q,p)+2\pi k,$$

$$(\phi_K^t)_p(q+2\pi k,p)=(\phi_K^t)_p(q,p),$$

$\forall(q,p)\in\mathbb{R}^{2n}$, $\forall k\in\mathbb{Z}^n$.

Consequently, for all fixed $t\in\mathbb{R}$ a flow $\tilde{\phi}_K^{t,0}$ in $T^*\mathbb{T}^n$ are well-defined results, in particular, the following definition it is independent of the choice of q in the class $[q]$:

$$\tilde{\phi}_K^{t,0}([q],p)=((\tilde{\phi}_K^{t,0})_q([q],p),(\tilde{\phi}_K^{t,0})_p([q],p)):=([(\phi_K^t)_q(q,p)],(\phi_K^t)_p(q,p)),$$

$$\begin{array}{ccc} T^*\mathbb{R}^n & \xrightarrow{\phi_K^t} & T^*\mathbb{R}^n \\ \pi \downarrow & & \downarrow \pi \\ T^*\mathbb{T}^n & \xrightarrow[\tilde{\phi}_K^{t,0}]{} & T^*\mathbb{T}^n \end{array}$$

Here we mean $\pi:(q,p)\to([q],p)$.

Similarly to Γ_K, we indicate by $\tilde{\Gamma}_K$ the graph of $\tilde{\phi}_K^{1,0}$:

$$\tilde{\Gamma}_K\subset(T^*\mathbb{T}^n\times T^*\mathbb{T}^n,\omega_{\mathbb{T}^n}\ominus\omega_{\mathbb{T}^n}).$$

The Lagrangian submanifold $\bar{h}(\Gamma_K)$,

$$\bar{h}(\Gamma_K) = \left\{ \left(\frac{q + (\phi_K^1)_q(q,p)}{2}, \frac{p + (\phi_K^1)_p(q,p)}{2}, p - (\phi_K^1)_p(q,p), (\phi_K^1)_q(q,p) - q \right), \forall\, (q,p) \in T^*\mathbb{R}^n \right\} \subset (T^*\mathbb{R}^{2n}, \omega_{\mathbb{R}^{2n}}),$$

in a neighborhood of infinity (in the p variables) results:

$$\bar{h}(\Gamma_K) = \{(q,p,0,0),\ \forall\, q \in \mathbb{R}^n,\ \forall\, p \in \mathbb{R}^n : |p| \geqslant C\}.$$

It is easy to verify that if $(q,p,Q,P) \in \bar{h}(\Gamma_K)$, then $\forall k \in \mathbb{Z}^n (q + 2\pi k, p, Q, P) \in \bar{h}(\Gamma_K)$. Therefore the Lagrangian submanifold $\bar{h}(\Gamma_K) \subset (T^*\mathbb{R}^{2n}, \omega_{\mathbb{R}^{2n}})$ has a natural inclusion into $(T^*(T^n \times R^n), \omega_{T^n \times R^n})$. Now, we prove that $\bar{h}(\Gamma_K)$ coincides, up to the symplectic morphism $\tilde{h}$ below from $\tilde{\Gamma}_K$ to $T^*(\mathbb{T}^n \times \mathbb{R}^n)$, with the image of the zero section $\mathbb{T}^n \times \mathbb{R}^n$ through $\tilde{\phi}_K^{1,0}$. In order to see this, we introduce the following well-defined (independent of the choice of q in $[q]$) [We note that, unlike the map $\bar{h}$, it does not exist a natural definition of $\tilde{h}$ from $T^*\mathbb{T}^n \times T^*\mathbb{T}^n$ in $T^*(\mathbb{T}^n \times \mathbb{R}^n)$, since it is essential the property: $(\phi_K^1)_q(q + 2\pi k, p) = (\phi_K^1)_q(q,p) + 2\pi k$.] map

$$\tilde{h} : \tilde{\Gamma}_K \to T^*(\mathbb{T}^n \times \mathbb{R}^n),$$

$$([q], p, [(\phi_K^1)_q(q,p)], (\phi_K^1)_p(q,p)) \mapsto \left(\left[\frac{q + (\phi_K^1)_q(q,p)}{2} \right], \frac{p + (\phi_K^1)_p(q,p)}{2}, p - (\phi_K^1)_p(q,p), (\phi_K^1)_q(q,p) - q \right).$$

Therefore the following commutative diagram results:

$$\begin{array}{ccc} \Gamma_K & \xrightarrow{\bar{h}} & T^*\mathbb{R}^{2n} \\ \pi_1 \downarrow & & \downarrow \pi_2 \\ \tilde{\Gamma}_K & \xrightarrow[\tilde{h}]{} & T^*(\mathbb{T}^n \times \mathbb{R}^n) \end{array}$$

here we mean $\pi_1 : (q,p,Q,P) \to ([q],p,[Q],P)$, $\pi_2 : (q,p,Q,P) \to ([q],p,Q,P)$.

Thus we have proved that $\bar{h}(\Gamma_K)$ results, up to the symplectic diffeomorphism $\tilde{h}$, the image of the zero section $\mathbb{T}^n \times \mathbb{R}^n$ through $\tilde{\phi}_K^{1,0}$. On the other hand, the manifold $\tilde{h}(\tilde{\Gamma}_K)$ is essentially the image of the zero section $\mathbb{T}^n \times \mathbb{R}^n$ through $\tilde{\phi}_K^{1,0}$. In such a hypothesis (see Theorem 2.4) the manifold $\tilde{h}(\tilde{\Gamma}_K)$ admits a GFQI, say, $s([q],p,\xi)$. Then a GFQI for $\bar{h}(\Gamma_K)$, say, $S_1(q,p,\xi)$, can be obtained extending periodically (in the q variables) $s([q],p,\xi)$. □

C. A generating function for $h(\Gamma_K)$

In this section we build (see Lemma 4.2 below) a generating function for the linear symplectomorphism ψ. Combining it with the one above (see Proposition 4.1), we will state the existence of a generating function for $h(\Gamma_K)$ (see Proposition 4.3).

The following composition rule is popular in symplectic geometry and mechanics (see, e.g., Refs. 2 and 3), and it has been handled by Laudenbach and Sikorav in meaningful problems in symplectic topology (see Ref. 18).

Lemma 4.2: The linear symplectomorphism ψ [see (10)] admits the generating function $S_2(x_0, x_1)$:

$$S_2(x_0,x_1)=\frac{1}{2}\left\langle x_0,\begin{pmatrix}0&-2\\-2&0\end{pmatrix}x_0\right\rangle-\left\langle x_0,\begin{pmatrix}0&-2\\-2&0\end{pmatrix}x_1\right\rangle+\frac{1}{2}\left\langle x_1,\begin{pmatrix}0&-2\\-2&1\end{pmatrix}x_1\right\rangle.$$

(See also Ref. 17, p. 280).

Proof: Recalling the map ψ in (10), we proceed to verify by direct computation:

$$-\frac{\partial S_2}{\partial x_0}(x_0,x_1)\Big|_{x_0=(q,p),x_1=(2q-P/2,2p-Q/2)}=-\begin{pmatrix}0&-2\\-2&0\end{pmatrix}\begin{pmatrix}q\\p\end{pmatrix}+\begin{pmatrix}0&-2\\-2&0\end{pmatrix}\begin{pmatrix}\frac{2q-P}{2}\\\frac{2p-Q}{2}\end{pmatrix}$$
$$=(2p,2q)+(Q-2p,P-2q)=(Q,P)=y_0,$$

$$\frac{\partial S_2}{\partial x_1}(x_0,x_1)\Big|_{x_0=(q,p),x_1=(2q-P/2,2p-Q/2)}=-(q,p)\begin{pmatrix}0&-2\\-2&0\end{pmatrix}+\begin{pmatrix}0&-2\\-2&1\end{pmatrix}\begin{pmatrix}\frac{2q-P}{2}\\\frac{2p-Q}{2}\end{pmatrix}$$
$$=(2p,2q)+\left(Q-2p,P-2q+\frac{2p-Q}{2}\right)$$
$$=\left(Q,\frac{2P+2p-Q}{2}\right)=y_1.$$

□

We can now prove the following.

Proposition 4.3: The Lagrangian submanifold $h(\Gamma_K)$ admits the generating function $S(x_1;x_0,\xi)$:

$$S(x_1;x_0,\xi)=S_1(x_0,\xi)+S_2(x_0,x_1).$$

Remark: Note that the variables x_0 now are interpreted as auxiliary parameters, at the same level of ξ.

Proof: The symplectomorphism ψ is generated by $S_2(x_0,x_1)$, that is,

$$\psi(x_0,y_0)=(x_1,y_1)\text{iff}\begin{cases}y_0=-\dfrac{\partial S_2}{\partial x_0}(x_0,x_1)\\ y_1=\dfrac{\partial S_2}{\partial x_1}(x_0,x_1)\end{cases},$$

$$\frac{\partial S}{\partial x_0}(x_1;x_0,\xi)=0\ \text{means}\ \frac{\partial S_1}{\partial x_0}(x_0,\xi)+\frac{\partial S_2}{\partial x_0}(x_0,x_1)=0,\quad \text{that is,}\ y_0=\frac{\partial S_1}{\partial x_0}(x_0,\xi).$$

Furthermore,

$$\frac{\partial S}{\partial \xi}(x_1;x_0,\xi)=0\quad\text{iff}\ \frac{\partial S_1}{\partial \xi}(x_0,\xi)=0.$$

Therefore the Lagrangian submanifold generated by $S(x_1;x_0,\xi)$ results:

$$\left\{(x_1,y_1)=\left(x_1,\frac{\partial S}{\partial x_1}(x_1;x_0,\xi)\right):\frac{\partial S}{\partial x_0}(x_1;x_0,\xi)=0,\frac{\partial S}{\partial \xi}(x_1;x_0,\xi)=0\right\}$$
$$=\left\{(x_1,y_1)=\left(x_1,\frac{\partial S}{\partial x_1}(x_1;x_0,\xi)\right):y_0=\frac{\partial S_1}{\partial x_0}(x_0,\xi),\frac{\partial S_1}{\partial \xi}(x_0,\xi)=0\right\}$$
$$=\left\{(x_1,y_1)=\left(x_1,\frac{\partial S_2}{\partial x_1}(x_0,x_1)\right):y_0=\frac{\partial S_1}{\partial x_0}(x_0,\xi),\frac{\partial S_1}{\partial \xi}(x_0,\xi)=0\right\}$$
$$=\{(x_1,y_1):(x_1,y_1)=\psi(x_0,y_0)\ \text{with}\ (x_0,y_0)\in\bar{h}(\Gamma_K)\}=\psi(\bar{h}(\Gamma_K))=h(\Gamma_K).$$

D. The quadratic at infinity property

We are ready to look for fixed points of ϕ_H^1, that is, to estimate

$$\#(h(\Gamma_K)\cap 0_{\mathbb{R}^{2n}}).$$

These intersection points are exactly the critical points, with respect to all the variables, of the generating function S for $h(\Gamma_K)$. More precisely, by Proposition 4.4 below, we show that they are essentially (that is to say, up to periodicity) the critical points for a GFQI f defined on a domain contracting to the torus $\mathbb{T}^n$: this is crucial in order to gain, in the Lusternik-Schnirelman format, a lower bound estimate of the number of fixed points of ϕ_H^1.

Although in the previous section we managed with a formal expression of S_2, by a straightforward computation we easily find out the simplified structure [here, for opportunity, we write $S_2(q_0,p_0,\dots)$ instead of $S_2(q,p,\dots)$] of it:

$$S_2(x_0,x_1)=S_2(q_0,p_0,q_1,p_1)=2(p_0-p_1)\cdot(q_1-q_0)+\frac{p_1^2}{2}.$$

Proposition 4.4: The fixed points of ϕ_H^1 correspond to the critical points of the GFQI:

$$f:\mathbb{T}^n\times\mathbb{R}^{3n+k}\to\mathbb{R},$$

$$([q_1],p_1,v,p_0,\xi)\overset{f}{\mapsto}S_1([q_1-v],p_0+p_1,\xi)+2p_0\cdot v+\frac{p_1^2}{2}. \tag{11}$$

Proof: Using the notation $x_1=(q_1,p_1)$ and $x_0=(q_0,p_0)$ we can rewrite S as

$$S:\mathbb{R}^{4n+k}\to\mathbb{R},$$

$$(q_1,p_1,q_0,p_0,\xi)\mapsto S_1(q_0,p_0,\xi)+2(p_0-p_1)\cdot(q_1-q_0)+\frac{p_1^2}{2}.$$

There is an evident invariance property:

$$S(q_1+2\pi k,p_1,q_0+2\pi k,p_0,\xi)=S(q_1,p_1;q_0,p_0,\xi),$$

$\forall(q_1,p_1,q_0,p_0,\xi)\in\mathbb{R}^{4n+k}$, and $\forall k\in\mathbb{Z}^n$. This fact is the same as saying that S is constant over the fibers of the surjective map Π below, thus it results in the following well-defined real-valued function $\tilde{S}$:

$$\begin{array}{ccc}\mathbb{R}^{4n+k} & \xrightarrow{\ S\ } & \mathbb{R}\\ \Pi\downarrow & \nearrow_{\tilde{S}} & \\ \mathbb{T}^n\times\mathbb{R}^{3n+k} & & \end{array} \tag{12}$$

$$\begin{array}{ccc} (q_1,p_1,q_0,p_0,\xi) & \xrightarrow{\;S\;} & \mathbb{R} \\ \Pi\downarrow & \nearrow_{\widetilde{S}} & \\ ([q_1],p_1,q_1-q_0,p_0,\xi) & & \end{array} \tag{13}$$

$$\Pi^{-1}([q_1],p_1,v,p_0,\xi)=\{(q_1+2\pi k,p_1,q_1-v+2\pi k,p_1,\xi):k\in\mathbb{Z}^n\}, \tag{14}$$

$$\widetilde{S}:\mathbb{T}^n\times\mathbb{R}^{3n+k}\to\mathbb{R},$$

$$([q_1],p_1,v,p_0,\xi)\mapsto S_1([q_1-v],p_0,\xi)+2(p_0-p_1)\cdot v+\frac{p_1^2}{2}, \tag{15}$$

satisfying the property

$$\widetilde{S}\circ\Pi=S. \tag{16}$$

Furthermore, since $d\widetilde{S}(y)_{|y=\Pi(x)}\circ d\Pi(x)=dS(x)$, we have that ($rk d\Pi=\max$): $\Pi^{-1}(\mathrm{Crit}(\widetilde{S}))=\mathrm{Crit}(S)$. Now $S_1([q_1-v],p_0+p_1,\xi)$ coincides for $|\xi|>C$ with a nondegenerate quadratic form $(A\xi,\xi)$, then for $|p_1|,|v|,|p_0|,|\xi|>C$ and for any fixed $[q_1]\in\mathbb{T}^n$, $f([q_1],p_1,v,p_0,\xi)=Q(p_1,v,p_0,\xi)$ where $Q(p_1,v,p_0,\xi)$ is the nondegenerate quadratic form

$$Q(p_1,v,p_0,\xi):=\begin{pmatrix} \frac{1}{2} & -1 & 0 & 0 \\ -1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & A \end{pmatrix}\begin{pmatrix} p_1 \\ v \\ p_0 \\ \xi \end{pmatrix}\begin{pmatrix} p_1 \\ v \\ p_0 \\ \xi \end{pmatrix}.$$

Therefore f is a GFQI. □

E. Fixed points: Degenerate case

We conclude this section with the estimate in the possible degenerate case, first proved by Conley and Zehnder,[10] of which we propose a proof based on the quadratic at infinity property of the generating function f.

Theorem 4.5: *Let ϕ_H^1 be the time-one map of a time-dependent Hamiltonian $H:\mathbb{R}\times\mathbb{R}^{2n}\to\mathbb{R}$ satisfying*

$$H(t,q+2\pi k,p)=H(t,q,p),\quad \forall\,(t,q,p)\in\mathbb{R}\times\mathbb{R}^{2n},\quad \forall\,k\in\mathbb{Z}^n,$$

and

$$H(t,q,p)=\frac{1}{2}|p|^2 \text{ if } |p|\geqslant C>0.$$

Then ϕ_H^1 has at least $n+1$ fixed points and they correspond to homotopically trivial closed orbits of the Hamiltonian flow.

Proof: Fixed points of ϕ_H^1 correspond to critical points of f (see Proposition 4.4). Moreover, via the Lusternik-Schnirelman theory (see Theorem 2.9), critical values of f can be detected involving nonvanishing relative cohomology classes in $H^*(f^c,f^{-c})$. As a consequence, and since $f:\mathbb{T}^n\times\mathbb{R}^{3n+k}\to\mathbb{R}$ is a GFQI, Corollary 2.11 does work, so that we obtain the well-known estimate

$$\#\mathrm{fix}(\phi_H^1) = \#\,\mathrm{crit}(f) \geqslant \mathrm{cl}(\mathbb{T}^n) = n+1.$$

□

V. FIXED POINTS: NONDEGENERATE CASE

Whenever all the fixed points of ϕ_H^1 are *a priori* nondegenerate, so that the corresponding critical points of f are also nondegenerate, it happens that the GFQI f becomes also a so-called Morse function, and in this case we achieve a rather better estimate.

Definition 5.1: Let N be a smooth manifold. A fixed point $x \in N$ of a diffeomorphism $\Phi: N \to N$ is said to be nondegenerate if the graph of Φ intersects the diagonal of $N \times N$ transversally at (x,x), that is,

$$\det(d\Phi(x) - \mathbb{I}) \neq 0.$$

The notion of nondegeneracy for fixed points of diffeomorphisms corresponds to the notion of nondegeneracy for critical points of functions, originally due to Morse.

Definition 5.2: Let N be a smooth manifold and $f: N \to \mathbb{R}$ be a C^2 function. A critical point x for f, $\nabla f(x)=0$, is said to be nondegenerate if the Hessian $\partial^2 f/\partial x^i \partial x^j(x)$ of f at x is nondegenerate.

(Recall that the Hessian of a scalar function f at its critical points is a well-defined tensorial object.) Starting from the study of the sublevel sets N^ν [see (2)], where ν is not a critical value of f, Morse proved the following famous lower bound on the number of critical points of f.

Theorem 5.3: *(Morse inequality) Let N be a compact manifold and $f: N \to \mathbb{R}$ be a Morse function. Then*

$$\mathrm{crit}(f) \geqslant \sum_{k=0}^{\dim N} H^k(N) =: \sum_{k=0}^{\dim N} b_k(N),$$

where the values $b_k(N)$ are called the Betti numbers of N.

As in the degenerate case, the preceding estimate still holds when $f: N \times \mathbb{R}^n \to \mathbb{R}$ is a GFQI (see, for example, Ref. 8):

Theorem 5.4: *Let N be compact manifold and $f: N \times \mathbb{R}^n \to \mathbb{R}$ be A GFQI. If all the critical points of f are nondegenerate, then*

$$\mathrm{crit}(f) \geqslant \sum_{k=0}^{\dim N} b_k(N).$$

The expected estimate on the number of nondegenerate fixed points for the Hamiltonian flow ϕ_H^1 is a straight consequence of Theorem 5.4.

Theorem 5.5: *Same hypothesis of Theorem 4.5. Then ϕ_H^1 has at least 2^n nondegenerate fixed points and they correspond to homotopically trivial closed orbits of the Hamiltonian flow.*

Proof: Nondegenerate fixed points of ϕ_H^1 correspond (via the diffeomorphisms h and ψ) to transversal intersections between $h(\Gamma_K)$ and $0_{R^{2n}}$. We observe now that the Lagrangian submanifold $h(\Gamma_K)$ intersects transversally $0_{R^{2n}}$ in the point $(\bar{q},\bar{p},\bar{u}) := (\bar{x},\bar{u}) \in h(\Gamma_K)$ if

$$\det\left(\frac{\partial^2 S}{\partial x^i \partial x^j}\right)(\bar{x},\bar{u}) \neq 0. \tag{17}$$

Moreover, since the point $(\bar{x},\bar{u}) \in h(\Gamma_K)$, the transversality condition guarantees that

$$\mathrm{rk}\left(\frac{\partial^2 S}{\partial x^i \partial u^j}, \frac{\partial^2 S}{\partial u^i \partial u^j}\right)(\bar{x},\bar{u}) = \max. \tag{18}$$

Then, from conditions (17) and (18), we conclude that the nondegenerate fixed points of ϕ_H^1 correspond exactly to the nondegenerate critical points of S, which are essentially (that is up to

periodicity) the nondegenerate critical points of f. Now $f:\mathbb{T}^n\times\mathbb{R}^{3n+k}\to\mathbb{R}$ is a GFQI, then, as a consequence of Theorem 5.4, we obtain

$$\#\text{non deg} - \text{fix}(\phi_H^1) = \#\text{non deg} - \text{crit}(f) \geqslant 2^n.$$

We consider a class of ordinary differential equations describing one-dimensional analytic systems with a quasiperiodic forcing term and in the presence of damping. In the limit of large damping, under some generic nondegeneracy condition on the force, there are quasiperiodic solutions which have the same frequency vector as the forcing term. We prove that such solutions are Borel summable at the origin when the frequency vector is either any one-dimensional number or a two-dimensional vector such that the ratio of its components is an irrational number of constant type. In the first case the proof given simplifies that provided in a previous work of ours. We also show that in any dimension d, for the existence of a quasiperiodic solution with the same frequency vector as the forcing term, the standard Diophantine condition can be weakened into the Bryuno condition. In all cases, under a suitable positivity condition, the quasiperiodic solution is proved to describe a local attractor. © *2006 American Institute of Physics.*

I. INTRODUCTION

In this paper we pursue the study started in Refs. 6 and 2. We consider one-dimensional systems with a quasiperiodic forcing term in the presence of strong damping, described by ordinary differential equations of the form

$$\varepsilon\ddot{x} + \dot{x} + \varepsilon g(x) = \varepsilon f(\boldsymbol{\omega} t), \tag{1.1}$$

where $\boldsymbol{\omega} \in \mathbb{R}^d$ is the frequency vector, $g(x)$ and $f(\boldsymbol{\psi})$ are functions analytic in their arguments, with f quasiperiodic, i.e.,

$$f(\boldsymbol{\psi}) = \sum_{\boldsymbol{\nu} \in \mathbb{Z}^d} e^{i\boldsymbol{\nu}\cdot\boldsymbol{\psi}} f_{\boldsymbol{\nu}}, \tag{1.2}$$

with average $\langle f \rangle = f_0$, and $\varepsilon > 0$ is a real parameter, physically representing the inverse of the damping coefficient. With $\cdot$ we are denoting the scalar product in $\mathbb{R}^d$. A Diophantine condition is assumed on $\boldsymbol{\omega}$ for $d > 1$, that is

$$|\boldsymbol{\omega}\cdot\boldsymbol{\nu}| \geqslant C_0 |\boldsymbol{\nu}|^{-\tau} \quad \forall\, \boldsymbol{\nu} \in \mathbb{Z}^d \setminus \{\mathbf{0}\}, \tag{1.3}$$

where $|\boldsymbol{\nu}| = |\boldsymbol{\nu}|_1 \equiv |\nu_1| + \cdots + |\nu_d|$, and C_0 and τ are positive constants. The set of vectors satisfying the condition (1.3) is nonvoid for $\tau \geqslant d-1$ and is of full measure for $\tau > d-1$. For $d=1$ we denote

[a)]Electronic mail: gentile@mat.uniroma3.it
[b)]Electronic mail: m.bartuccelli@surrey.ac.uk
[c)]Electronic mail: j.deane@surrey.ac.uk

the vectors without boldface; in that case ω will be called the frequency number.

In Ref. 6 we show that, under the nondegeneracy condition

$$\exists c_0 \in \mathbb{R} \quad \text{such that } g(c_0) = f_0 \text{ and } g'(c_0) \neq 0, \tag{1.4}$$

the system (1.1) admits a quasiperiodic solution $x(t;\varepsilon)$ with the same frequency vector as the forcing. Such a solution can be obtained by a suitable summation of the formal power series

$$x_0(t;\varepsilon) := \sum_{k=0}^{\infty} \varepsilon^k x^{(k)}(t), \quad x^{(k)}(t) = \sum_{\boldsymbol{\nu} \in \mathbb{Z}^d} e^{i\boldsymbol{\nu}\cdot\boldsymbol{\omega}t} x_{\boldsymbol{\nu}}^{(k)}, \tag{1.5}$$

which solves the equations of motion order by order. For $d=1$ (periodic forcing) the series (1.4) is Borel summable in ε. In Ref. 2 we also show that if $g'(c_0)>0$, for any d such a solution is locally an attractor. In some cases, for instance if $g(x)=x^{2p+1}$, $p \in \mathbb{N}$, and $f_0>0$, the attractor is global.

In this paper we first give a different (simpler) proof of Borel summability in the periodic case (Sec. II), then we prove that the formal series for the solution turns out to be Borel summable also for $d=2$ and $\tau=1$ (Sec. III); this corresponds to frequency vectors with components such that their ratios are irrational numbers of constant type (i.e., numbers with bounded partial quotients in their continued fraction expansion). The proof does not rely on Nevanlinna-type theorems,[7,8] but consists in checking directly that the conditions for the formal series of the solution to be Borel summable are satisfied, and follows the same strategy introduced in Ref. 4 to investigate Borel summability of lower-dimensional tori.

Finally in Sec. IV we show how to relax the Diophantine condition. We show that, in order to have the same results on existence and attractivity of the quasiperiodic solution, one can take $\boldsymbol{\omega}$ to be a Bryuno vector, that is one can assume that, by defining

$$B(\boldsymbol{\omega}) = \sum_{n=0}^{\infty} \frac{1}{2^n} \log \frac{1}{\alpha_n(\boldsymbol{\omega})}, \quad \alpha_n(\boldsymbol{\omega}) = \inf_{|\boldsymbol{\nu}| \leq 2^n} |\boldsymbol{\omega}\cdot\boldsymbol{\nu}|, \tag{1.6}$$

then $\boldsymbol{\omega}$ satisfies the Bryuno condition $B(\boldsymbol{\omega})<\infty$. More formal statements will be given in the next sections.

II. BOREL SUMMABILITY FOR $d=1$

First of all let us recall the definition of Borel summability.[8] Let $f(\varepsilon)=\Sigma_{n=1}^{\infty} a_n \varepsilon^n$ be a formal power series (which means that the sequence $\{a_n\}_{n=1}^{\infty}$ is well defined). We say that $f(\varepsilon)$ is *Borel summable* if

(1) $B(p) := \Sigma_{n=1}^{\infty} a_n p^n/n!$ converges in some circle $|p|<\delta$,
(2) $B(p)$ has an analytic continuation to a neighborhood of the positive real axis, and
(3) $g(\varepsilon)=\int_0^{\infty} e^{-p/\varepsilon} B(p) \mathrm{d}p$ converges for some $\varepsilon>0$.

Then the function $B(p)$ is called the *Borel transform* of $f(\varepsilon)$, and $g(\varepsilon)$ is the *Borel sum* of $f(\varepsilon)$. Moreover if the integral defining $g(\varepsilon)$ converges for some $\varepsilon_0>0$ then it converges in the circle $\mathrm{Re}\ \varepsilon^{-1} > \mathrm{Re}\ \varepsilon_0^{-1}$. A function which admits the formal power series expansion $f(\varepsilon)$ is called Borel summable if $f(\varepsilon)$ is Borel summable; in that case the function equals the Borel sum $g(\varepsilon)$.

Theorem 2.1: *Consider the system (1.1) for $d=1$, and assume that the nondegeneracy condition (1.4) is fulfilled. There exists $\varepsilon_0>0$ such that for $|\varepsilon|<\varepsilon_0$ there is a periodic solution $x(t;\varepsilon)$ which has the same frequency number as the forcing term and is Borel summable in ε at the origin. If $g'(c_0)>0$ such a solution describes a local attractor.*

Proof: We consider explicitly the case $g(x)=x^2$ in (1.1), which corresponds to the varactor equation extensively studied in Refs. 6, 1, and 2; the general case can be easily dealt with by reasoning as in Sec. VII of Ref. 6. In Ref. 6 we proved that the formal power series (1.5) is well defined and that to any order k one has

$$|x_\nu^{(k)}| \leqslant A_1 \varepsilon_2^{-k} k!, \quad |x^{(k)}(t)| \leqslant A_1 \varepsilon_2^{-k} k!, \tag{2.1}$$

for suitable constants A_1 and ε_2 [cf. formula (4.5) in Ref. 6]. This means that the first condition, in the definition of Borel summability, is satisfied, with $\delta = \varepsilon_2$.

In Ref. 6 we also proved that the formal power series can be summed, and gives a function

$$x(t;\varepsilon) = \sum_{k=0}^{\infty} \sum_{\nu \in \mathbb{Z}} e^{i\omega\nu t} x_\nu^{[k]}, \tag{2.2}$$

which is real-analytic and periodic in t, and analytic in ε in a suitable domain tangent to the imaginary axis at the origin. The coefficients $x_\nu^{[k]}$ can be written as

$$x_\nu^{[k]} = \sum_{\theta \in \mathcal{T}_{k,\nu}} \mathrm{Val}(\theta), \quad \mathrm{Val}(\theta) = \left(\prod_{\ell \in L(\theta)} g_\ell \right) \left(\prod_{v \in E(\theta) \cup V(\theta)} F_v \right), \tag{2.3}$$

where the symbols are defined as in Sec. V of Ref. 6. We briefly recall the basic definitions and notations, with the purpose of making self-consistent the discussion; reference should be made to Ref. 6 for further details.

A tree θ is a graph, that is a connected set of points and lines, with no cycle, such that all the lines are oriented toward a unique point (root) which has only one incident line (root line). All the points in a tree except the root are denoted nodes. The orientation of the lines in a tree induces a partial ordering relation ($\leqslant$) between the nodes. Given two nodes v and w, we shall write $w \leqslant v$ every time v is along the path (of lines) which connects w to the root. We call $E(\theta)$ the set of endpoints in θ, that is the nodes which have no entering line. The endpoints can be represented either as white bullets or as black bullets; we denote with $E_W(\theta)$ and $E_B(\theta)$ the set of white bullets and the set of black bullets, respectively. With each endpoint v we associate a mode label $\nu_v \in \mathbb{Z}$, such that $\nu_v = 0$ if $v \in E_W(\theta)$ and $\nu_v \neq 0$ if $v \in E_B(\theta)$. We denote with $L(\theta)$ the set of lines in θ. Since ℓ is uniquely identified with the point v which it leaves, we may write $\ell = \ell_v$. With each line ℓ we associate a momentum label $\nu_\ell \in \mathbb{Z}$. The modes of the endpoints and and the momenta of the lines are related as follows: if $\ell = \ell_v$ one has

$$\nu_\ell = \sum_{i=1}^{s_v} \nu_{\ell_i} = \sum_{w \in E_B(\theta): w \leqslant v} \nu_w, \tag{2.4}$$

where s_v denotes the number of lines entering v [one has $s_v = 2$ if $g(x) = x^2$ in (1.1), otherwise $s_v \geqslant 2$], and $\ell_1, \ldots, \ell_{s_v}$ are the lines entering v. We denote by $V(\theta)$ the set of vertices in θ, that is the set of points which have at least one entering line. We set $V_0(\theta) = \{v \in V(\theta) : \nu_{\ell_v} = 0\}$. We call *equivalent* two trees which can be transformed into each other by continuously deforming the lines in such a way that they do not cross each other. Let $\mathcal{T}_{k,\nu}$ be the set of inequivalent trees of order k and total momentum ν, that is the set of inequivalent trees θ such that $|V(\theta)| + |E_B(\theta)| = k$ and the momentum of the root line is ν. We associate with each line ℓ a *propagator*

$$g_\ell = \begin{cases} 1/((i\omega\nu_\ell)(1 + i\varepsilon\omega\nu_\ell)), & \nu_\ell \neq 0, \\ 1, & \nu_\ell = 0, \end{cases} \tag{2.5}$$

with each vertex v a node factor

$$F_v = \begin{cases} -\varepsilon, & v \notin V_0(\theta), \\ -1/2c_0, & v \in V_0(\theta), \end{cases} \tag{2.6}$$

and with each endpoint v a node factor

$$F_v = \begin{cases} c_0, & v \in E_W(\theta), \\ \varepsilon f_{\nu_v}, & v \in E_B(\theta). \end{cases} \tag{2.7}$$

Then (2.3) says that each coefficient $x_\nu^{[k]}$ is given by the sum over all trees of order k and total momentum ν of the corresponding values.

It is more convenient to slightly change the definition of node factors and propagators, by associating the factor ε with the propagator g_ℓ of the line ℓ coming out from v and not with v itself. In this way the propagator of any line with ℓ momentum $\nu_\ell \neq 0$ is

$$g_\ell = g(\omega\nu_\ell;\varepsilon), \quad g(x;\varepsilon) = \frac{\varepsilon}{ix(1+i\varepsilon x)}, \tag{2.8}$$

and the only dependence on ε in $\mathrm{Val}(\theta)$ is through the product of propagators with nonvanishing momentum. [Note that $g(x;\varepsilon)$ in (2.8) has a completely different meaning with respect to the function $g(x)$ appearing in (1.1). The same *caveat* applies to the propagators $g^{[n]}(x;\varepsilon)$ in Sec. III.]

The function (2.8) is Borel summable, and its Borel transform is easily computed to be

$$g_B(x;p) = \frac{e^{-ipx}}{ix} \Rightarrow |g_B(x;p)| \leqslant \frac{e^{|\mathrm{Im}\, p||x|}}{|x|}. \tag{2.9}$$

Moreover $g_B(x;p)$ is an entire function in p, and the integral $\int_0^\infty e^{-p/\varepsilon} g_B(x;p)\mathrm{d}p$ converges (absolutely) for all $\varepsilon > 0$.

For any tree $\theta \in \mathcal{T}_{k,\nu}$ the Borel transform of $\mathrm{Val}(\theta)$ is given by a constant times the Borel transform of the product of the propagators with nonzero momentum. One has

$$(\mathrm{Val}(\theta))_B(p) = \left(\prod_{\ell \in L_0(\theta)} g_\ell\right)\left(\prod_{v \in E(\theta)\cup V(\theta)} F_v\right)\left(\left(\prod_{\ell \in L_2(\theta)} g_\ell\right)_B(p)\right), \tag{2.10}$$

where we have called $L_0(\theta)$ is the set of lines in $L(\theta)$ with zero momentum, and we have set $L_2(\theta) = L(\theta)\setminus L_0(\theta)$ (cf. Sec. IV of Ref. 6). The Borel transform appearing in (2.10) equals the convolution of the Borel transforms of the propagators with nonzero momentum, so that it can be bounded as

$$\left|\left(\prod_{\ell \in L_2(\theta)} g_\ell\right)_B(p)\right| \leqslant \prod_{\ell \in L_2(\theta)}{}^{*} |g_B(\omega\nu_\ell;p)| \leqslant \left(\prod_{\ell \in L_2(\theta)} \frac{1}{|\omega\nu_\ell|}\right) \frac{|p|^{k-1}}{(k-1)!} \exp\left(|\mathrm{Im}\, p| \max_{\ell \in L_2(\theta)} |\omega\nu_\ell|\right), \tag{2.11}$$

where Π^* denotes the convolution product, and $|\omega| < |\omega\nu_\ell| < |\omega| \Sigma_{v \in E_B(\theta)} |\nu_v|$; cf. Remarks (4) to (6) after Definition 1 in Ref. 3 for properties of the Borel transforms we are using here.

Therefore, for p in any strip $\Sigma_\sigma = \{p \in \mathbb{C} : |\mathrm{Im}\, p| < \sigma\}$ of the real axis, we have

$$\left|\prod_{v \in E_B(\theta)} F_v\right| \exp\left(|\mathrm{Im}\, p| \max_{\ell \in L_2(\theta)} |\omega\nu_\ell|\right) \leqslant F^{|E_B(\theta)|} \prod_{v \in E_B(\theta)} e^{-\xi|\nu_v|/2}, \tag{2.12}$$

provided $|\omega|\sigma < \xi/2$, and summability over the Fourier labels in (2.3) is assured. The sum over k in (2.2) produces a quantity bounded proportionally to the exponential $e^{\Gamma|p|}$, for some positive constant Γ. A comparison with Ref. 6 shows that $\Gamma = 1/\varepsilon_0$, where ε_0 is the same as in the statement of the theorem. In particular the Borel transform $x_B(t;p)$ of the series (2.2) turns out to have an analytic continuation to the strip Σ_σ, and admits there the bound $|x_B(t;p)| \leqslant Ce^{\Gamma|p|}$, for a suitable constant C. Hence the integral

$$g(t;\varepsilon) := \int_0^\infty e^{-p/\varepsilon} x_B(t;p)\mathrm{d}p \tag{2.13}$$

absolutely converges provided $0<\varepsilon<\varepsilon_0$. So also the last two conditions for the formal series of $x(t;\varepsilon)$ to be Borel summable are satisfied.

That the solution $x(t;\varepsilon)$ describes a local attractor, under the further condition $g'(c_0)>0$, follows from the analysis performed in Ref. 2. ■

Note that, because of the analyticity properties of $x_B(t;p)$, it follows, as a consequence of Nevanlinna's theorem,[8] that the function defined by the integral (2.13) is analytic in the circle $C_R=\{\varepsilon\in\mathbb{C}:\mathrm{Re}\,\varepsilon^{-1}>R^{-1}\}$, with $R=\varepsilon_0$, and satisfies the bound

$$g(t;\varepsilon)=\sum_{k=0}^{N-1}\varepsilon^k x^{(k)}(t)+\mathfrak{R}_N(\varepsilon),\quad |\mathfrak{R}_N(\varepsilon)|\leqslant AB^N N!|\varepsilon|^N, \tag{2.14}$$

with constants A and B independent of N. This is consistent with Proposition 5.3 of Ref. 6.

III. BOREL SUMMABILITY FOR $d=2$ AND $\tau=1$

In the case of quasiperiodic forcing terms for $d=2$ we obtain the following result.

Theorem 3.1: *Consider the system (1.1) for* $d=2$, *and assume that* $\boldsymbol{\omega}$ *satisfies the Diophantine condition (1.3)* with $\tau=1$ *and that the nondegeneracy condition (1.4) is fulfilled. There exists* $\varepsilon_0>0$ *such that for* $|\varepsilon|<\varepsilon_0$ *there is a quasiperiodic solution* $x(t;\varepsilon)$ *which has the same frequency vector as the forcing term and is Borel summable at the origin. If* $g'(c_0)>0$ *such a solution describes a local attractor.*

Proof: Again we discuss explicitly the case $g(x)=x^2$ in (1.1). Let ψ be a nondecreasing C^∞ function defined in $\mathbb{R}_+$, such that

$$\psi(u)=\begin{cases}1 & \text{for } u\geqslant 1,\\ 0 & \text{for } u\leqslant 1/2,\end{cases} \tag{3.1}$$

and set $\chi(u):=1-\psi(u)$. Define, for all $n\in\mathbb{Z}_+$, $\chi_n(u):=\chi(2^nC_0^{-1}u/4)$ and $\psi_n(u):=\psi(2^nC_0^{-1}u/4)$.

With each line ℓ with zero momentum we associate a scale label $n_\ell=-1$, while with each line with nonzero momentum we associate (arbitrarily) a scale label $n_\ell\in\mathbb{Z}_+=\{0\}\cup\mathbb{N}$. Then we can define cluster and self-energy clusters as in Refs. 4 and 6. A cluster T on scale n is a maximal set of points and lines connecting them such that all the lines have scales $n'\leqslant n$ and there is at least one line with scale n. The lines entering the cluster T and the possible line coming out from it (unique if existing at all) are called the external lines of the cluster T. Given a cluster T on scale n, we shall denote by $n_T=n$ the scale of the cluster; we call $V(T)$, $E(T)$, $E_W(T)$, $E_B(T)$, and $L(T)$ the set of vertices, of endpoints, of white endpoints, of black endpoints, and of lines of T, respectively. We call self-energy cluster any cluster T such that T has only one entering line ℓ_T^2 and one exiting line ℓ_T^1, and one has $\Sigma_{v\in E_B(T)}\boldsymbol{\nu}_v=\mathbf{0}$. With each line ℓ with momentum $\boldsymbol{\nu}_\ell$ and scale n_ℓ we associate a renormalized propagator $g_\ell=g^{[n_\ell]}(\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell;\varepsilon)$, still to be defined. On the contrary the node factors are defined as in the previous case (with the only trivial difference that now $\boldsymbol{\nu}_v$, replacing ν_v, is a d-dimensional vector).

Define the self-energy value $\mathcal{V}_T(\boldsymbol{\omega}\cdot\boldsymbol{\nu};\varepsilon)$ in terms of the renormalized propagators and node factors as

$$\mathcal{V}_T(\boldsymbol{\omega}\cdot\boldsymbol{\nu};\varepsilon)=\left(\prod_{\ell\in L(T)} g^{[n_\ell]}(\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell;\varepsilon)\right)\left(\prod_{v\in E(T)\cup V(T)} F_v\right), \tag{3.2}$$

where $\boldsymbol{\nu}$ is the momentum of both the external lines of T.

We proceed as in Sec. VI of Ref. 6, with the only two differences that we perform a preliminary summation by including the contribution $-2\varepsilon c_0$ (arising from the self-energy graphs on scale

-1) into the propagator $g^{[0]}(x;\varepsilon)$, and—as in the periodic case of Sec. II—we associate the factors ε to the propagators with nonzero momentum. Therefore we define [see the comment after (2.8) in Sec. II]

$$g^{[0]}(x;\varepsilon)=\frac{\varepsilon\psi_0(|x|)}{ix(1+i\varepsilon x)-2\varepsilon c_0},\quad M^{[0]}(x;\varepsilon)=\varepsilon\sum_{k=1}^{\infty}\sum_{T\in\mathcal{S}^{\mathcal{R}}_{k,0}}\mathcal{V}_T(x;\varepsilon),\tag{3.3}$$

whereas the propagators on scale $n\geqslant 1$ are defined as in Ref. 6, again with a factor ε appearing in the numerator of the propagators with nonzero momentum; this means that one has

$$\begin{aligned}&g^{[n]}(x;\varepsilon)=\frac{\varepsilon\chi_0(|x|)\cdots\chi_{n-1}(|x|)\psi_n(|x|)}{ix(1+i\varepsilon x)-\mathcal{M}^{[n-1]}(x;\varepsilon)},\\&\mathcal{M}^{[n]}(x;\varepsilon)=\sum_{p=1}^{n}\chi_0(|x|)\cdots\chi_{p-1}(|x|)\chi_n(|x|)M^{[p]}(x;\varepsilon),\quad M^{[n]}(x;\varepsilon)=\varepsilon\sum_{k=1}^{\infty}\sum_{T\in\mathcal{S}^{\mathcal{R}}_{k,n}}\mathcal{V}_T(x;\varepsilon),\end{aligned}\tag{3.4}$$

where the set of renormalized self-energy clusters $\mathcal{S}^{\mathcal{R}}_{k,n}$ is defined and the set of self-energy clusters T on scale $n_T=n$ and of order k [that is with $|V(T)|+|E_B(T)|=k$]. With respect to Refs. 6 and 4 a further factor ε appears in $M^{[n]}(x;\varepsilon)$, $n\geqslant 0$, simply because there is one such factor per node (vertex or endpoint) with exiting line carrying a nonzero momentum—cf. Sec. 6 in Ref. 4—and we are associating the factors ε with the lines instead of the nodes.

An easy computation gives, for the Borel transform of $g^{[0]}(x;\varepsilon)$,

$$g^{[0]}_B(x;p)=\frac{\psi_0(|x|)}{ix}\exp\left(-ip\left(x-2\frac{c_0}{x}\right)\right)\Rightarrow|g^{[0]}_B(x;p)|\leqslant\frac{1}{|x|}e^{(|x|+2|c_0|/|x|)|\mathrm{Im}\,p|}.\tag{3.5}$$

If we set, for $n\geqslant 0$,

$$\tilde{g}^{[n]}(x;\varepsilon)=\frac{\varepsilon}{ix(1+i\varepsilon x)-\mathcal{M}^{[n-1]}(x;\varepsilon)}\qquad\forall\,|x|\leqslant 2^{-(n-1)}C_0,\tag{3.6}$$

and define $M^{[n]}(x;\varepsilon)=\mathcal{M}^{[n]}(x;\varepsilon)-\mathcal{M}^{[n-1]}(x;\varepsilon)$, we obtain the recursive equations

$$(\tilde{g}^{[n]}(x;\varepsilon))^{-1}=(\tilde{g}^{[n-1]}(x;\varepsilon))^{-1}-\chi_0(|x|)\cdots\chi_{n-1}(|x|)\varepsilon^{-1}M^{[n-1]}(x;\varepsilon),\quad n\geqslant 1.\tag{3.7}$$

By using these equations we can prove inductively the bound

$$|\tilde{g}^{[n]}_B(x;p)|\leqslant\frac{K_0}{|x|}e^{(c_n+c'_n|x|^{-1/2})|p|+\kappa_0|\mathrm{Im}\,p|(d_n|x|+d'_n|x|^{-1})},\tag{3.8}$$

where K_0 and κ_0 are two constants, and the sequences $\{c_n\}_{n=0}^{\infty}$, $\{c'_n\}_{n=0}^{\infty}$, $\{d_n\}_{n=0}^{\infty}$, $\{d'_n\}_{n=0}^{\infty}$ are to be found.

The proof proceeds as in Appendix A1 of Ref. 3. Set $x_\ell=\boldsymbol{\omega}\cdot\boldsymbol{\nu}_\ell$, and call $L_0(T)$ and $L_2(T)$ the set of lines in $L(T)$ with zero momentum and the set $L_2(T)=L(T)\setminus L_0(T)$, respectively. First we use the inductive bound to obtain

$$\left|\left(\frac{M^{[N]}(x;\varepsilon)}{\varepsilon}\right)_B\right| \leqslant \sum_{k=2}^{\infty} \sum_{T\in\mathcal{S}^{\mathcal{R}}_{k,N-1}} \left(\prod_{\ell\in L_0(T)} |g_\ell|\right)\left(\prod_{v\in E(T)\cup V(T)} |F_v|\right)$$
$$\times \left(\prod_{\ell\in L_2(T)} {}^{*}\frac{K_0}{|x_\ell|} e^{(c_{n_\ell}+c'_{n_\ell}|x_\ell|^{-1/2})|p|+\kappa_0(d_{n_\ell}|x_\ell|+d'_{n_\ell}|x_\ell|^{-1})|\mathrm{Im}\, p|}\right)$$
$$\leqslant \left(\prod_{v\in E_B(\theta)} e^{-\xi|\nu_v|}\right)\sum_{k=2}^{\infty}\Gamma^k\frac{|p|^{k-2}}{(k-2)!}e^{(c_{N-1}+c'_{N-1}2^{N/2})|p|+\kappa_0 d'_{N-1}2^N|\mathrm{Im}\, p|}, \tag{3.9}$$

where $D_0=\Gamma^2$, $r_N=\Gamma+c_{N-1}+\Gamma_0 c'_{N-1}2^{N/2}$, for some N-independent constant Γ_0. The bound in the last line of (3.9) has been obtained by using part of the exponential decay (say one-fourth) of the node factors associated with the endpoints to control the exponent $\kappa_0 d_{N-1}\max_{\ell\in L_2(T)}|x_\ell|$, provided $d_{N-1}<d$ for some N-independent constant d and $|\mathrm{Im}\, p|\leqslant\sigma$, with σ small enough, more precisely $\kappa_0\sigma d|\omega|<\xi/4$.

By explicitly performing the sum over k we obtain from (3.6),

$$\left|\left(\frac{M^{[N]}(x;\varepsilon)}{\varepsilon}\right)_B\right| \leqslant D_0 e^{r_N|p|}e^{-\xi_0 2^N}, \tag{3.10}$$

where we have used the bound $\Sigma_{\nu\in E_B(T)}|\boldsymbol{\nu}_v|\geqslant\Gamma_1 2^N$, for a suitable constant Γ_1—see formula (7.12) of Ref. 4—and again part of the exponential decay (say another one-fourth) of the node factors associated with the endpoints to control the exponent $\kappa_0 d'_{N-1}2^N|\mathrm{Im}\, p|$, provided again $d'_{N-1}<d'$ for some N-independent constant d' and $\kappa_0 d'\sigma<\xi\Gamma_1/4$; in particular one finds $\xi_0=\Gamma_1\xi/4$.

Then, by using (3.10) and, once more, the inductive bound, we obtain from (3.7),

$$|\tilde{g}^{[N]}_B(x,p)| \leqslant \frac{K_0}{|x|}e^{(c_{N-1}+c'_{N-1}|x|^{-1/2})|p|+\kappa_0(d_{N-1}|x|+d'_{N-1}|x|^{-1})|\mathrm{Im}\, p|} * \sum_{k=0}^{\infty}\left((D_0 e^{-r_N|p|}e^{-\xi_0 2^N})\right.$$
$$\left. * \left(\frac{K_0}{|x|}e^{(c_{N-1}+c'_{N-1}|x|^{-1/2})|p|+\kappa_0(d_{N-1}|x|+d'_{N-1}|x|^{-1})|\mathrm{Im}\, p|}\right)\right)^{*k}, \tag{3.11}$$

with $a^{*k}=a*a*\cdots*a$ (k times). This gives

$$|\tilde{g}^{[N]}_B(x,p)| \leqslant \frac{K_0}{|x|}\sum_{k=0}^{\infty}\frac{1}{(2k)!}\left(\frac{K_0|p|^2}{|x|}D_0 e^{-\xi_0 2^N}\right)^K e^{(r_N+c'_{N-1}|x|^{-1/2})|p|+\kappa_0(d_N|x|+d'_N|x|^{-1})|\mathrm{Im}\, p|}, \tag{3.12}$$

which implies the bound (3.5) for $n=N$, with $c_N=r_N=\Gamma+c_{N-1}+\Gamma_0 c'_{N-1}2^{N/2}$, $c'_N=c'_{N-1}+\sqrt{K_0 D_0 e^{-\xi_0 2^N}}$, $d_N=d_{N-1}$ and $d'_N=d'_{N-1}$. In particular one has $d_N=d=1$ and $d_{N'}=d'=2|c_0|$, so that there exists a constant $c>0$ such that $\max\{c_n 2^{-n/2}, c'_n, d_n, d_{n'}\}\leqslant c$ for all $n\geqslant 0$.

The bounds (3.8) for the Borel transforms of the propagators can be used to obtain a bound on the Borel transform $x_B(t;p)$ of $x(t;\varepsilon)$. We omit the details, which can be derived exactly as in Appendix A1 of Ref. 3. Eventually one finds the bound

$$|x_B(t;p)| \leqslant C_1 e^{C_2|p|^2}, \tag{3.13}$$

for suitable constants C_1 and C_2. Again, the bound (3.13) and the analyticity properties of $x_B(t;p)$ implies that $x(t;\varepsilon)$ is Borel summable, and it can be written for $\varepsilon>0$ as

$$x(t;\varepsilon)=\int_0^\infty e^{-p/\varepsilon}x_B(t;p)\mathrm{d}p, \tag{3.14}$$

in terms of its Borel transform.

As in the case $d=1$ the last statement of the theorem has been proved in Ref. 2. ■

In the general case $g(x) \neq x^2$ in (1.1) the quantity $2c_0$ must be replaced with $g'(c_0)$, with $g'(c_0) \neq 0$ by hypothesis. Then the discussion proceeds as in Sec. VII of Ref. 6.

Note also that in the case $d=2$ and $\tau=1$ the Borel transform is still defined in a strip around the real axis, but it does not satisfy any more an exponential bound like in the case $d=1$ (at least the argument given above does not provide an estimate of this kind). Thus, we cannot apply Nevanlinna's theorem to prove Borel summability.[7,8]

IV. BRYUNO FREQUENCY VECTORS

Let $\boldsymbol{\omega} \in \mathbb{R}^d$ be a Bryuno vector. This means that $B(\boldsymbol{\omega}) < \infty$, with $B(\boldsymbol{\omega})$ defined in (1.6).

Theorem 4.1: *Consider the system (1.1) for any $d \geqslant 2$, and assume that $\boldsymbol{\omega}$ satisfies the Bryuno condition $B(\omega) < \infty$ and that the nondegeneracy condition (1.4) is fulfilled. There exists $\varepsilon_0 > 0$ such that for all real $|\varepsilon| < \varepsilon_0$ there is a quasiperiodic solution with frequency vector $\boldsymbol{\omega}$. If $g'(c_0) > 0$ such a solution describes a local attractor.*

For simplicity's sake we discuss the case $g(x)=x^2$ and $\varepsilon \in \mathbb{R}$, but the analysis can be easily generalized to any analytic function g [provided the nondegeneracy condition (1.4) is satisfied]. Furthermore the solution can be showed to extend to a function analytic in ε in the domain $\mathcal{C}_R$ defined in Sec. VI of Ref. 6 (cf. Fig. 16 in Ref. 6).

Let $\psi(x)$ be the nondecreasing C^∞ function defined in (3.1) and set $\chi(x) := 1 - \psi(x)$. Define, for all $n \in \mathbb{Z}_+$, $\chi_n(x) := \chi(\alpha_n^{-1}(\boldsymbol{\omega})x/4)$ and $\psi_n(x) := \psi(\alpha_n^{-1}(\boldsymbol{\omega})x/4)$.

Set $g^{[-1]}(x;\varepsilon)=1$ and $M^{[-1]}(x;\varepsilon)=0$, and define iteratively $g^{[n]}(x;\varepsilon)$ and $M^{[n]}(x;\varepsilon)$ as done in the case of Diophantine vectors. This means that for $n=0$ we can define $g^{[0]}(x;\varepsilon)$ and $M^{[0]}(x;\varepsilon)$ as in (3.3), while for $n \geqslant 1$ we define

$$g^{[n]}(x;\varepsilon) = \frac{\varepsilon \chi_0(|x|) \cdots \chi_{n-1}(|x|)\psi_n(|x|)}{ix(1+i\varepsilon x) - \mathcal{M}^{[n-1]}(x;\varepsilon)},$$
$$\mathcal{M}^{[n]}(x;\varepsilon) = \sum_{p=0}^{n} \chi_0(|x|) \cdots \chi_p(|x|) M^{[p]}(x;\varepsilon), \quad M^{[n]}(x;\varepsilon) = \varepsilon \sum_{k=1}^{\infty} \sum_{T \in \mathcal{S}_{k,n}^{\mathcal{R}}} \mathcal{V}_T(x;\varepsilon), \tag{4.1}$$

where $\mathcal{S}_{k,n}^{\mathcal{R}}$ is the set of renormalized self-energy clusters T on scale n and of order k, and the self-energy value $\mathcal{V}_T(x;\varepsilon)$ is defined as in (3.2). Note that we are using the same definitions of Sec. III, in particular we are associating the factors ε with the propagators rather than with the nodes (contrary to what done in Ref. 6). So far the only difference with respect to the case of the standard Diophantine condition concerns the multiscale decomposition: the factors $2^n C_0^{-1}$ appearing in χ_n and ψ_n are substituted with $\alpha_n^{-1}(\omega)$.

Lemma 4.2: Assume that the renormalized propagators up to scale $n-1$ can be bounded as

$$|g^{[n_\ell]}(\boldsymbol{\omega} \cdot \boldsymbol{\nu}_\ell; \varepsilon)| \leqslant C^{-1} \alpha_{n_\ell}^{-\beta}(\boldsymbol{\omega}) \tag{4.2}$$

for some positive constants β and C. Then for all $p \leqslant n-1$ the number $N_p(\theta)$ of lines on scale p in any renormalized tree θ and the number $N_p(T)$ of lines on scale p in any renormalised self-energy cluster T are bounded both by

$$N_p(\theta) \leqslant K 2^{-p} \sum_{v \in E_B(\theta)} |\boldsymbol{\nu}_v|, \quad N_p(T) \leqslant K 2^{-p} \sum_{v \in E_B(T)} |\boldsymbol{\nu}_v|, \tag{4.3}$$

for some positive constant K. If $|\varepsilon| < \varepsilon_0$, with ε_0 small enough, then for all $p \leqslant n-1$ one has

$$|M^{[p]}(x;\varepsilon)| \leqslant D_1 |\varepsilon|^2 e^{-D_2 2^p}, \quad |\partial_x M^{[p]}(x;\varepsilon)| \leqslant D_1 |\varepsilon|^2 e^{-D_2 2^p}, \tag{4.4}$$

for some positive constants D_1 and D_2. Only the constant D_1 depends on β. The constant ε_0 can be written as $\varepsilon_0 = C_1 \alpha_{n_0}^{\beta}$, with $n_0(\boldsymbol{\omega}, \beta)$ such that

$$K\beta \sum_{n=n_0+1}^{\infty} \frac{1}{2^n} \log \frac{1}{\alpha_n(\boldsymbol{\omega})} \leqslant \frac{\xi}{4}, \tag{4.5}$$

and C_1 *a positive constant dependending on* C *but not on* β.

Proof: The lemma can be proved by reasoning as in Refs. 4 and 5. We simply sketch the proof, and omit the details. First of all note that, if we define $n(\boldsymbol{\nu})=\{n \in \mathbb{Z}_+ : 2^{n-1} < |\boldsymbol{\nu}| \leqslant 2^n\}$ then one has $|\boldsymbol{\omega}\cdot\boldsymbol{\nu}| \geqslant \alpha_{n(\boldsymbol{\nu})}(\boldsymbol{\omega})$. Moreover $n' > n$ implies $\alpha_{n'}(\boldsymbol{\omega}) \leqslant \alpha_n(\boldsymbol{\omega})$, and $\alpha_{n'}(\boldsymbol{\omega}) < \alpha_n(\boldsymbol{\omega})$ implies $n' > n$. Set $M(\theta)=\Sigma_{v \in E_B(\theta)}|\boldsymbol{\nu}_v|$ and $M(T)=\Sigma_{v \in E_B(T)}|\boldsymbol{\nu}_v|$. The bound on $N_p(\theta)$ is obtained by proving by induction on the order of the renormalized tree that if $N_p(\theta) \neq 0$ then $N_p(\theta) \leqslant 22^{-p}M(\theta) - 1$ Then, given a renormalized self-energy cluster $T \in \mathcal{S}^{\mathcal{R}}_{k,n}$, one proves first that $M(T) > 2^{n-1}$, hence, again by induction, that if $N_p(T) \neq 0$ then $N_p(T) \leqslant 22^{-p}M(T) - 1$. Therefore (4.3) is proved. An important property is that if a cluster T has two external lines, with momenta $\boldsymbol{\nu}$ and $\boldsymbol{\nu}'$, respectively, with $\boldsymbol{\nu} \neq \boldsymbol{\nu}'$, both on scales greater or equal to n, so that $|\boldsymbol{\omega}\cdot\boldsymbol{\nu}| \leqslant \alpha_{n-1}(\boldsymbol{\omega})/4$ and $|\boldsymbol{\omega}\cdot\boldsymbol{\nu}| \leqslant \alpha_{n-1}(\boldsymbol{\omega})/4$, then one has $|\boldsymbol{\omega}\cdot(\boldsymbol{\nu}-\boldsymbol{\nu}')| < \alpha_{n-1}(\boldsymbol{\omega})$, hence $n(\boldsymbol{\nu}-\boldsymbol{\nu}') \geqslant n$, so that $M(T) \geqslant |\boldsymbol{\nu} - \boldsymbol{\nu}'| > 2^{n-1}$. For details we refer to Ref. 5.

The bounds (4.4) are obtained by exploiting the just mentioned bound on $M(T)$ and half the exponential decay factors $e^{-\xi|\boldsymbol{\nu}_v|}$ associated with the vertices and endpoints internal to T to derive the factors $e^{-D_2 2^p}$, with D_2 independent of β, and by using the fact that any self-energy cluster T contributing to $M^{[p]}(x;\varepsilon)$ must be of order at least 2 to derive the factors $|\varepsilon|^2$.

Then for any $n_0 \in \mathbb{N}$ and for any tree θ, we can bound each propagator on scale up to n_0 with $C^{-1}\alpha_{n_0}^{-\beta}(\boldsymbol{\omega})$ and the product of propagators on scale greater than n_0 with

$$\prod_{n=n_0+1} (C^{-1}\alpha_n^{-\beta}(\boldsymbol{\omega}))^{N_n(\theta)} = C^{-\Sigma_{n=n_0+1}^{\infty} N_n(\theta)} \exp\left(\beta M(\theta) \sum_{n=n_0+1}^{\infty} \frac{1}{2^n} \log \frac{1}{\alpha_n(\boldsymbol{\omega})} \right), \tag{4.6}$$

so that, by choosing n_0 according to (4.5), the last exponential in (4.6) is controlled by half the exponential decay factor $e^{-\xi M(T)}$ arising from the node factors. Then the sum of the values of all trees of order k is bounded by $(C^{-1}C'\alpha_{n_0}^{-\beta})^k$, for a suitable constant C'—taking into account all the constants other than C and the sums over the trees. Hence also the assertion about the dependence of ε_0 on $\alpha_{n_0}(\boldsymbol{\omega})$ follows, and the proof of the lemma is complete. ■

As in Ref. 6, to prove existence of the quasiperiodic solution we need the following result, which together with Lemma 4.2 provides the proof of Theorem 4.1.

Lemma 4.3: For real ε *small enough the renormalized propagators satisfy the bounds (4.2) with* $\beta=1$. *For* ε *in the domain* $\mathcal{C}_R$ *in Fig.* 16 *of Ref.* 6 *they satisfy the bounds (4.2) with* $\beta=2$.

Proof: The proof can be carried out exactly as in Ref. 6. Indeed it is enough to show that the propagators $g^{[n]}(x;\varepsilon)$ can be bounded proportionally to $|x|^{-\beta}$, for ε small enough in a suitable domain, and this follows from Lemmata 6.2 to 6.5 of Ref. 6, independently on the particular Diophantine condition assumed on $\boldsymbol{\omega}$. ■

The proof of the theorem is completed if we show that the quasiperiodic solution is a local attractor if $g'(c_0) > 0$. But this can be proved as in the case of Diophantine frequency vectors, by reasoning as in Ref. 2: indeed the only property that we need for the argument given in Ref. 2 to work is the existence of the quasiperiodic solution.

(Received 11 January 2006; accepted 2 June 2006; published online 19 July 2006)

We study the long-time behavior of solutions to the Korteweg-de Vries-type equation $\partial_t u=-\partial_x(\partial_x^2 u+f(u)-b(t,x)u)$, with initial conditions close to a stable, $b=0$ solitary wave. The coefficient b is a bounded and slowly varying function, and f is a nonlinearity. For a restricted class of nonlinearities, we prove that for long time intervals, such solutions have the form of the solitary wave, whose center and scale evolve according to a certain dynamical law involving the function $b(t,x)$, plus an $H^1(\mathbb{R})$-small fluctuation. The result is stronger than those previously obtained for general nonlinearities f. © *2006 American Institute of Physics.*

I. INTRODUCTION

We study the long-time behavior of solutions to a class Korteweg-de Vries-type equations, with an additional term $b(t,x)u$. These equations, hereafter referred to as the bKdV, are of the form

$$\partial_t u = -\partial_x(\partial_x^2 u + f(u) - b(t,x)u), \tag{1}$$

where $b(t,x)$ is a real valued function and f is a nonlinearity. We formulate conditions on the nonlinearity in Sec. II. Our class includes, in particular, $f(u)=u^3$, corresponding to the modified KdV (mKdV). When $b=0$, Eq. (1) reduces to the generalized Korteweg-de Vries equation (GKdV)

$$\partial_t u = -\partial_x(\partial_x^2 u + f(u)). \tag{2}$$

A remarkable property of the GKdV is the existence of spatially localized solitary (or traveling) waves, i.e., solutions of the form $u=Q_c(x-a-ct)$, where $a\in\mathbb{R}$ and c in some interval I. When $f(u)=u^p$ and $p\geq 2$, solitary waves are explicitly computed to be

$$Q_c(x) = c^{1/(p-1)}Q(c^{1/2}x),$$

where

$$Q(x) = \left(\frac{p+1}{2}\right)^{1/(p-1)}\left(\operatorname{sech}\left(\frac{p-1}{2}x\right)\right)^{2/(p-1)}.$$

It is generally believed that an arbitrary, say $H^1(\mathbb{R})$, solution to Eq. (2) eventually breaks up into a collection of solitary waves and radiation. A discussion of this phenomenon for the generalized KdV appears in Bona.[12] For the general, but integrable, case, see Deift and Zhou.[19]

[a)]This paper is part of the first author's Ph.D. thesis.

The GKdV arises in different branches of science and engineering. In particular, the mKdV equation, to which our results apply, is fundamental in many areas of applied mathematics ranging from traffic flow to plasma physics (see Refs. 16, 32, 33, and 35), and arises from an approximation of more complicated systems. The effects of higher order processes can often be collected into a term of the form $b(t,x)u$. Our main result stated at the end of the next section gives, for long time, an explicit, leading order description of a solution to the bKdV initially close to a solitary wave solution of the GKdV.

We assume that the coefficient b and nonlinearity f are such that (1) has global solutions for $H^1(\mathbb{R})$ data and that (1) with $b=0$ possesses solitary wave solutions. Precise conditions will be formulated in the next section. Here we mention that the literature regarding well-posedness of the KdV [$b=0$, $f(u)=u^2$] is extensive and well developed. The Miura transform (see Ref. 34) then gives well-posedness results for the mKdV. Bona and Smith[10] proved global well-posedness of the KdV in $H^2(\mathbb{R})$. See also Ref. 28. Kenig, Ponce, and Vega[30] have proved local well-posedness in $H^s(\mathbb{R})$ for $s\geq -\frac{3}{4}$, and similar results are available for the generalized KdV [$b=0$, monomial nonlinearity $f(u)=u^p$ with $p=2,3,4$].[29] In particular, local well-posedness for the mKdV in $H^s(\mathbb{R})$ with $s\geq \frac{1}{4}$ and global well-posedness for $s\geq 1$ are known. More recently, results extending local well-posedness in negative index Sobolev spaces to global well-posedness have been proven.[17,18] There is little literature on global well-posedness of the bKdV in energy space, however, under a smallness assumption on the coefficient b, Dejak and Sigal[20] proved global well-posedness in $H^1(\mathbb{R})$ of the bKdV with $f(u)=u^p$, $p=2,3,4$. They used results of Ref. 29, and perturbation and energy arguments.

Soliton solutions of the KdV equation are known to be orbitally stable. Although the linearized analysis of Jeffrey and Kakutani[26] suggested orbital stability, the first nonlinear stability result was given by Benjamin.[2] He assumed smooth solutions and used Lyapunov stability and spectral theory to prove his results. Bona[4] later corrected and improved Benjamin's result to solutions in $H^2(\mathbb{R})$. Weinstein[46] used variational methods, avoiding the use of an explicit spectral representation, and extended the orbital stability result to the GKdV. More recently, Grillakis, Satah, and Strauss[24] extended the Lyapunov method to abstract Hamiltonian systems with symmetry. Numerical simulations of soliton dynamics for the KdV were performed by Bona *et al.* See Refs. 6–9.

The long-time dynamics of the bKdV was first studied in Ref. 20. For nonlinear Schrödinger and Hartree equations, long-time dynamics of solitary waves were studied by Bronski and Jerrard,[13] Fröhlich, Tsai, and Yau,[22] Keraani,[31] and Fröhlich and co-workers.[21,27]. For related results and techniques for the nonlinear Schrödinger equations, see also Refs. 14, 15, 23, 39–41, and 43–45.

In this paper we show that for long time intervals [$t\leq \mathrm{O}(|\partial_x b|^{-1})$], the solution of the bKdV initially close to a soliton $Q_{c_0}(x-a_0)$ remains close to a moving soliton $Q_{c(t)}(x-a(t))$ whose center $a(t)$ and shape parameter $c(t)$ satisfy a certain dynamical system. Although the class of nonlinearities consider in this paper is smaller than that of Ref. 20, we obtain more precise dynamical equations for the soliton parameters that are valid for longer time intervals, and hence obtain a better description of solutions to the bKdV. Moreover, our proof is simpler than that of Ref. 20. In our approach, we use the fact that the bKdV is a (nonautonomous if b depends on time) Hamiltonian system. As in Ref. 20, we construct a Hamiltonian reduction of this original, infinite dimensional dynamical system to a two-dimensional dynamical system on a manifold of soliton configurations. The analysis of the bKdV with general nonlinearity immediately runs into the problem that the natural symplectic form ω is not defined on the tangent space of the soliton manifold. However, we show that there is a class of nonlinearities for which the symplectic form is well defined on the tangent space. This is the class of nonlinearities considered in this paper.

II. PRELIMINARIES, ASSUMPTIONS, MAIN RESULTS

The bKdV can be written in Hamiltonian form as

$$\partial_t u = \partial_x H_b'(u), \tag{3}$$

where H_b' is the $L^2(\mathbb{R})$ function corresponding to the Fréchet derivative ∂H_b in the $L^2(\mathbb{R})$ pairing. Here the Hamiltonian H_b is

$$H_b(u) := \int_{-\infty}^{\infty} \frac{1}{2}(\partial_x u)^2 - F(u) + \frac{1}{2}b(t,x)u^2 dx,$$

where the function F is the antiderivative of f with $F(0)=0$. The operator ∂_x is the anti-self-adjoint operator (symplectic operator) generating the Poisson bracket

$$\{G_1, G_2\} := \frac{1}{2}\int_{-\infty}^{\infty} G_1'(u)\partial_x G_2'(u) - G_2'(u)\partial_x G_1'(u)dx,$$

defined for any G_1, G_2 such that $G_1', G_2' \in H^{1/2}(\mathbb{R})$. The corresponding symplectic form is

$$\omega(v_1, v_2) := \frac{1}{2}\int_{-\infty}^{\infty} v_1(x)\partial_x^{-1} v_2(x) - v_2(x)\partial_x^{-1} v_1(x)dx,$$

defined for any $v_1, v_2 \in L^1(\mathbb{R})$. Here the operator ∂_x^{-1} is defined as

$$\partial_x^{-1} v(x) := \int_{-\infty}^{x} v(y)dy.$$

Note that $\partial_x^{-1}\cdot\partial_x = I$ and, on the space $\{u \in L^2(\mathbb{R}) \,|\, \int_{-\infty}^{\infty} u dx = 0\}$, ∂_x^{-1} is formally anti-self-adjoint with inverse ∂_x. Hence, if $\int_{-\infty}^{\infty} v_1(x)dx = 0$, then $\omega(v_1, v_2) = \int_{-\infty}^{\infty} v_1(x)\partial_x^{-1} v_2(x)dx$.

Note that if b depends on time t, then Eq. (3) is nonautonomous. It is, however, in the form of a conservation law, and hence the integral of the solution u is conserved provided u and its derivatives decay to zero at infinity:

$$\frac{d}{dt}\int_{-\infty}^{\infty} u dx = 0.$$

There are also conserved quantities associated to symmetries of (1) when $b=0$. The simplest such corresponds to time translation invariance and is the Hamiltonian itself. This is also true if b is nonzero but time independent. If the potential $b=0$, then (1) is also spatially translation invariant. Noether's theorem then implies that the flow preserves the momentum

$$P(u) := \frac{1}{2}\|u\|_{L^2}^2.$$

In general, when $b \neq 0$, the temporal and spatial translation symmetries are broken, and hence the Hamiltonian and momentum are no longer conserved. Instead, one has the relations

$$\frac{d}{dt}H_b(u) = \frac{1}{2}\int_{-\infty}^{\infty} (\partial_t b)u^2 dx, \tag{4}$$

$$\frac{d}{dt}P(u) = \frac{1}{2}\int_{-\infty}^{\infty} b' u^2 dx, \tag{5}$$

where $b'(t,x) := \partial_x b(t,x)$. For later use, we also state the relation

$$\frac{d}{dt}\frac{1}{2}\int_{-\infty}^{\infty} bu^2 dx = \int_{-\infty}^{\infty} \frac{1}{2}u^2\partial_t b + b'\left(uf(u) - \frac{3}{2}(\partial_x u)^2 - F(u)\right) - b''u\partial_x u dx. \tag{6}$$

Assuming (1) is well-posed in $H^2(\mathbb{R})$, the above equalities are obtained after multiple integration by parts. Then, by density of $H^2(\mathbb{R})$ in $H^1(\mathbb{R})$, the equalities continue to hold for solutions in $H^1(\mathbb{R})$. To avoid these technical details, we assume the Hamiltonian flow on $H^1(\mathbb{R})$ enjoys (4)–(6).

Consider the GKdV, i.e., Eq. (2). Under certain conditions on f, this equation has traveling wave solutions of the form $Q_c(x-ct)$, where Q_c is a positive $H^2(\mathbb{R})$ function. Substituting $u = Q_c(x-ct)$ into the GKdV gives the scalar field equation

$$-\partial_x^2 Q_c + cQ_c - f(Q_c) = 0. \tag{7}$$

The existence of solutions to this equation has been studied by numerous authors. See Refs. 3, 5, and 42. In particular, Berestyki and Lions[3] give sufficient and necessary conditions for a positive and smooth solution Q_c to exist. We assume $g := -cu + f(u)$ satisfies the following conditions:

1. g is locally Lipschitz and $g(0)=0$;
2. $x^* := \inf\{x>0 \,|\, \int_0^x g(y)dy\}$ exists with $x^*>0$ and $g(x^*)>0$; and
3. $\lim_{s\to 0}[g(s)/s] \le -m < 0$.

Then, as shown by Berestycki and Lions, (7) has a unique (modulo translations) solution $Q_c \in C^2$ for c in some interval, which is positive, even (when centered at the origin), and with Q_c, $\partial_x Q_c$, and $\partial_x^2 Q_c$ exponentially decaying to zero at infinity ($\partial_x Q_c < 0$ for $x>0$). Furthermore, if f is C^2, then the implicit function theorem implies that Q_c is C^2 with respect to the parameter c on some interval $I_0 \subset \mathbb{R}_+$. We assume that $x^m \partial_c^n Q_c \in L^1(\mathbb{R})$ for $n=1,2, m=0,1,2$ so that integrals containing $\partial_c^n Q_c$ are continuous and differentiable with respect to c. We also make the assumption that

$$\int_{-\infty}^{\infty} \partial_c Q_c dx = 0 \tag{8}$$

for all $c \in I$. This implies that

$$\int_{-\infty}^{x} \partial_c Q_c(z)dz, \int_{-\infty}^{x} \partial_c^2 Q_c(z)dz \in L^2(\mathbb{R}). \tag{9}$$

To see this, use the isometry property of the Fourier transform and the decay properties of $\partial_c Q_c$. The above requirements of Q_c are implicit assumptions on the nonlinearity f and are true when $f(u)=u^3$. Assumption (8) is a very important and restrictive requirement; it does not hold when $f(x)=x^p$ and $p \neq 3$. For the case where (8) does not hold, see Ref. 20.

The solitary waves Q_c are orbitally stable if $\delta'(c)>0$, where $\delta(c)=P(Q_c)$ [to avoid potential confusion, we remark that the quantity $\delta(c)$ is often written as $d'(c)$ in the literature]. See Weinstein,[46] for the first proof for general nonlinearities. Moreover, in Ref. 24, Grillakis, Shatah, and Strauss proved that $\delta'(c)>0$ is a necessary and sufficient condition for Q_c to be orbitally stable. Bona, Souganidis, and Strauss[11] also gave stability results for KdV-type equations and Albert, Bona, and Henry[1] gave an instability result. The first proof of asymptotic stability for the KdV was given by Pego and Weinstein.[36] In this paper, we assume that Q_c is orbitally stable for all c in some compact interval $I \subset I_0$, or equivalently that $\delta'(c)>0$ on I. For $f(u)=u^p$, we have

$$\delta'(c) = \frac{5-p}{4(p-1)}\|Q_{c=1}\|_{L^2}^2 c^{\{(7-3p)/[2(p-1)]\}},$$

which implies the well-known stability criterion $p<5$ corresponding to subcritical power nonlinearities.

The scalar field equation (7) for the solitary wave can be viewed as a Euler-Lagrange equation for the extremals of the Hamiltonian $H_{b=0}$ subject to constant momentum $P(u)$. Moreover, Q_c is a stable solitary wave if and only if it is a minimizer of $H_{b=0}$ subject to constant momentum P. Thus, if c is the Lagrange multiplier associated to the momentum constraint, then Q_c is an extremal of

$$\Lambda_{ca}(u) := H_{b=0}(u) + cP(u) = \int_{-\infty}^{\infty} \frac{1}{2}(\partial_x u)^2 + \frac{1}{2}cu^2 - F(u)dx, \tag{10}$$

and hence $\Lambda'_{ca}(Q_c)=0$.

The functional Λ_{ca} is translationally invariant. Therefore, $Q_{ca}(x) := Q_c(x-a)$ is also an extremal of Λ_{ca}, and $Q_c(x-ct-a)$ is a solitary wave solution of (1) with $b=0$. All such solutions form the two-dimensional manifold of solitary waves

$$M_s := \{Q_{ca} | c \in I, a \in \mathbb{R}\},$$

with tangent space $T_{Q_{ca}}M_s$ spanned by the vectors

$$\zeta^{tr}_{ca} := \partial_a Q_{ca} = -\partial_x Q_{ca} \quad \text{and} \quad \zeta^{n}_{ca} := \partial_c Q_{ca}, \tag{11}$$

which we call the translation and normalization vectors. Notice that the two tangent vectors are orthogonal in $L^2(\mathbb{R})$.

In addition to the requirement on b that (1) is globally well posed, we assume the potential b is bounded, twice differentiable, and small in the sense that

$$|\partial_t^n \partial_x^m b| \le \epsilon_a \epsilon_t^n \epsilon_x^m, \tag{12}$$

for $n=0,1$, $m=0,1,2$, and $n+m\le 2$. The positive constants ϵ_a, ϵ_x, and ϵ_t are amplitude, length, and time scales of the function b. We assume all are less than or equal to one.

Lastly, we make some explicit assumptions on the local nonlinearity f. We require the nonlinearity to be k times continuously differentiable, $f(0)=f'(0)=0$. These assumptions ensure the Hamiltonian is finite on the space $H^1(\mathbb{R})$ and, since Q_c decays exponentially (see Ref. 3), both $f(Q_c)$ and $f'(Q_c)$ have exponential decay.

We are ready to state our main result. Recall that $I_0 \subset \mathbb{R}_+$ is an interval where Q_c is twice continuously differentiable.

Theorem 2.1: *Let the above assumptions hold and assume $\delta'(c)>0$ for all c in a compact interval $I \subset I_0$. Assume $\epsilon_a \le 1$. Then, if $\epsilon_x \le 1$, ϵ_0 and ϵ_t are small enough ($\ll \inf_I \delta'^2$), there is a positive constant C such that the solution to* (1) *with an initial condition u_0 satisfying $\inf_{Q_{ca}\in M_s} \|u_0 - Q_{ca}\|_{H^1} \le \epsilon_0$ can be written as*

$$u(x,t) = Q_{c(t)}(x - a(t)) + \xi(x,t),$$

where $\|\xi(t)\|_{H^1} = O(\epsilon_0 + (\epsilon_a \epsilon_x \epsilon_0)^{1/2} + \epsilon_x + \epsilon_t)$ for all times $t \le C(\epsilon_a \epsilon_x)^{-1}$. Moreover, during this time interval the parameters $a(t)$ and $c(t)$ satisfy the equations

$$\begin{pmatrix} \dot{a} \\ \dot{c} \end{pmatrix} = \begin{pmatrix} c - b(a) \\ 0 \end{pmatrix} + b'(a)\frac{\delta(c)}{\delta'(c)}\begin{pmatrix} 0 \\ 1 \end{pmatrix} + O((\epsilon_0 + \epsilon_x + \epsilon_t)^2 + (\epsilon_a \epsilon_x \epsilon_0)^{1/2}(\epsilon_x + \epsilon_t + \epsilon_0)),$$

where c is assumed to lie in the compact interval I.

Sketch of Proof and Paper Organization. To realize the Hamiltonian reduction we decompose functions in a neighborhood of the soliton manifold M_s as

$$u = Q_{ca} + \xi,$$

with ξ symplectically orthogonal to $T_{Q_{ca}}M_s$, i.e., $\xi \perp \partial_x^{-1} T_{Q_{ca}} M_s$. We show that there is an $\epsilon_0 = \mathrm{O}(\inf_I \delta'^2) > 0$ such that if the solution u satisfies the estimate $\inf_{Q_{ca}} \|u - Q_{ca}\|_{H^1} < \epsilon_0$, then there are unique C^1 functions $a(u)$ and $c(u)$ such that $u = Q_{c(u)a(u)} + \xi$ with $\xi \perp \partial_x^{-1} T_{Q_{ca}} M_s$.

With the knowledge that the symplectic decomposition exists, we substitute $u = Q_{ca} + \xi$ into the bKdV (1) and split the resulting equation according to the decomposition

$$L^2(\mathbb{R}) = \partial_x^{-1} T_{Q_{ca}} M_s \oplus (\partial_x^{-1} T_{Q_{ca}} M_s)^{\perp}$$

to obtain equations for the parameters c and a, and an equation for the (infinite dimensional) fluctuation ξ. In Sec. IV we isolate the leading order terms in the equations for a and c and estimate the remainder, including all terms containing ξ. In Secs. VI and VII, we establish spectral properties and a lower bound of the Hessian Λ''_{ca} on the space $(\partial_x^{-1} T_{Q_{ca}} M_s)^{\perp}$.

The proof that $\|\xi\|_{H^1}$ is sufficiently small is the final ingredient in the proof of the main theorem. The remaining sections concentrate on proving this crucial result. We employ a Lyapunov method and in Sec. V we construct the Lyapunov function Γ_c and prove an estimate on its time derivative. This estimate is later time maximized over an interval $[0,T]$, and integrated to obtain an upper bound on Γ_c involving the time T and the norms of ξ. We combine this upper bound with the lower bound on Γ_c following from the results of Sec. VII, and obtain an inequality involving $\|\xi\|_{H^1}$. In Sec. VIII we solve the inequality to find an upper bound on $\|\xi\|_{H^1}$ provided $\|\xi(0)\|_{H^1}$ is small enough. We substitute this bound into the bound appearing in the dynamical equation for a and c, and take $\epsilon_a \epsilon_x$and ϵ_0 small enough so that all intermediate results hold to complete the proof. □

III. MODULATION OF SOLUTIONS

As stated in the previous section, we begin the proof by decomposing the solution of (1) into a modulated solitary wave and a fluctuation ξ:

$$u(x,t) = Q_{c(t)a(t)}(x) + \xi(x,t), \tag{13}$$

with a, c, and ξ fixed by the orthogonality condition

$$\xi \perp \partial_x^{-1} T_{Q_{ca}} M_s, \tag{14}$$

where

$$\partial_x^{-1} : g \to \int_{-\infty}^{x} g(z)dz.$$

Note that $\partial_x^{-1} T_{Q_{ca}} M_s$ is a subset of $L^2(\mathbb{R})$ [see (9)].

The existence and uniqueness of parameters a and c such that $\xi = u - Q_{ca}$ satisfies (14) follows from the next lemma concerning a restriction of ∂_x^{-1} and the implicit function theorem. The restriction K of ∂_x^{-1} to the tangent space $T_{Q_{ca}} M_s$ is defined by the equation $KP_T = P_T \partial_x^{-1} P_T$, where P_T is the orthogonal projection onto $T_{Q_{ca}} M_s$. In the natural basis $\{\zeta_{ca}^{tr}, \zeta_{ca}^{n}\}$ of the tangent space $T_{Q_{ca}} M_s$, the matrix representation of K is $N^{-1}\Omega_{ca}$, where

$$N := \begin{pmatrix} \|\zeta_{ca}^{tr}\|_{L^2}^2 & 0 \\ 0 & \|\zeta_{ca}^{n}\|_{L^2}^2 \end{pmatrix}$$

and

$$\Omega_{ca} := \begin{pmatrix} \langle \zeta_{ca}^{tr}, \partial_x^{-1} \zeta_{ca}^{tr} \rangle & \langle \zeta_{ca}^{n}, \partial_x^{-1} \zeta_{ca}^{tr} \rangle \\ \langle \zeta_{ca}^{tr}, \partial_x^{-1} \zeta_{ca}^{n} \rangle & \langle \zeta_{ca}^{n}, \partial_x^{-1} \zeta_{ca}^{n} \rangle \end{pmatrix}. \tag{15}$$

Recall that $\delta(c) = \frac{1}{2}\|Q_c\|_{L^2}^2$.

Lemma 3.1: If $\delta'(c)>0$ on the compact interval $I\subset R_+$, then the matrix Ω_{ca} is invertible for all $c\in I$, and

$$\Omega_{ca}^{-1}=\frac{1}{\delta'(c)}\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}. \tag{16}$$

Clearly, $\|\Omega_{ca}^{-1}\|\leq\lfloor\delta'\rfloor^{-1}$, where $\lfloor\delta'\rfloor:=\inf_I\delta'(c)$.

Proof: The lemma follows from the relations $\langle\zeta_{ca}^{tr},\partial_x^{-1}\zeta_{ca}^{tr}\rangle=0$, $\langle\zeta_{ca}^{n},\partial_x^{-1}\zeta_{ca}^{n}\rangle=0$, and $\langle\zeta_{ca}^{tr},\partial_x^{-1}\zeta_{ca}^{n}\rangle=\langle\zeta_{ca}^{n},Q_c\rangle=\delta'(c)$. □

Given $\varepsilon>0$, define the tubular neighborhood

$$U_\varepsilon:=\left\{u\in L^2(\mathbb{R})\,\middle|\,\inf_{(c,a)\in I\times R}\|u-Q_{ca}\|_{L^2}<\varepsilon\right\}$$

of the solitary wave manifold M_s in $L^2(\mathbb{R})$.

Proposition 3.2: Let $I\subset\mathbb{R}_+$ be a compact interval such that $c\mapsto Q_{ca}$ is $C^1(I)$. Then there exists a positive number $\varepsilon_*=\varepsilon_*(I)=\mathrm{O}(\lfloor\delta'\rfloor^2)$ dependent on I and unique C^1 functions $a:U_{\varepsilon_*}\to\mathbb{R}$ and $c:U_{\varepsilon_*}\to I$, such that

$$\langle Q_{c(u)a(u)}-u,\partial_x^{-1}\zeta_{c(u)a(u)}^{tr}\rangle=0\quad\text{and}\quad\langle Q_{c(u)a(u)}-u,\partial_x^{-1}\zeta_{c(u)a(u)}^{n}\rangle=0$$

for all $u\in U_{\varepsilon_*}$. Moreover, there is a positive real number $C=C(I)$ such that

$$\|u-Q_{c(u)a(u)}\|_{H^1}\leq C\inf_{Q_{ca}\in M_s}\|u-Q_{ca}\|_{H^1} \tag{17}$$

for all $u\in U_{\varepsilon_*}\cap H^1(\mathbb{R})$.

Proof: Let $\mu:=(\mu^1,\mu^2)^T\in\mathbb{R}\times I$ and define $G:\mathbb{R}\times I\times H^1(\mathbb{R})\to\mathbb{R}^2$ as

$$G{:}(\mu,u)\to\begin{pmatrix}\langle Q_{ca}-u,\Omega_{ca}\zeta_{ca}^{tr}\rangle\\ \langle Q_{ca}-u,\Omega_{ca}\zeta_{ca}^{n}\rangle\end{pmatrix},$$

where $a=\mu^1$ and $c=\mu^2$. The proposition is equivalent to solving $G(g(u),u)=0$ for a C^1 function g. Let $\mu_0=(ac)^T$. If G is C^1, $G(\mu_0,Q_{ca})=0$, and $\partial_\mu F(\mu_0,Q_{ca})$ is invertible, then the implicit function theorem asserts the existence of an open ball $B_\varepsilon(Q_{ca})$ of radius ε with center Q_{ca}, and a unique function $g_{Q_{ca}}:B_\varepsilon(Q_{ca})\to\mathbb{R}\times I$, such that $G(g_{Q_{ca}}(u),u)=0$ for all $u\in B_\varepsilon(Q_{ca})$.The first two conditions are trivial, and the third follows from Lemma 3.1 since $\partial_\mu G(\mu_0,Q_{ca})=\Omega_{ca}$. The radius ε depends on the parameters c and a, however, since $\lfloor\delta'\rfloor:=\inf_I\delta'(c)>0$, we can choose a smaller ball radius ε_* of order $\lfloor\delta'\rfloor^2$ that works for all $a\in\mathbb{R}$ and $c\in I$. For details, see the proof of the decomposition theorem in Ref. 20. We define $U_{\varepsilon_*}=\cup\{B_{\varepsilon_*}(Q_{ca})\,|\,a\in\mathbb{R},c\in I\}$ and past the C^1 functions $g_{Q_{ca}}$ together into a C^1 function $g_I:U_{\varepsilon_*}\to\mathbb{R}\times I$. This proves existence of the required C^1 functions $a(u)$ and $c(u)$. Uniqueness follows from the uniqueness of the functions $g_{Q_{ca}}$.

Let $u\in U_{\varepsilon_*}$, $c\in I$, and $a\in\mathbb{R}$, and consider the equation

$$u-Q_{c(u)a(u)}=u-Q_{ca}+Q_{ca}-Q_{c(u)a(u)}.$$

Clearly, inequality (17) will follow if $\|Q_{ca}-Q_{c(u)a(u)}\|_{H^1}\leq C\|u-Q_{ca}\|_{H^1}$ for some positive constant C. Since the derivatives ∂_cQ_{ca} and ∂_aQ_{ca} are uniformly bounded in $H^1(\mathbb{R})$ over $\mathbb{R}\times I$, the mean value theorem gives that $\|Q_{ca}-Q_{c(u)a(u)}\|_{H^1}\leq C\|(c,a)^T-(c(u),a(u))^T\|$, where the constant C does not depend on c, a. The relations $g_I(Q_{ca})=(c,a)^T$ and $g_I(u)=(c(u),a(u))^T$ then imply $\|Q_{ca}-Q_{c(u)a(u)}\|_{H^1}\leq C\|g_I(Q_{ca})-g_I(u)\|$. Again, we appeal to the mean value theorem and use the properties of Ω_{ca} and that $\partial_ug_I=\partial_\mu G^{-1}\partial_uG$ is uniformly bounded in the parameters c and a to obtain (17). The last equation is obtained by implicitly differentiating $G(g_I(u),u)=0$ with respect to u.□

IV. EVOLUTION EQUATIONS FOR PARAMETERS ξ, a, AND c

In Sec. III we proved that if u remains close enough to the solitary wave manifold M_s, then we can write a solution u to (1) uniquely as a sum of a modulated solitary wave Q_{ca} and a fluctuation ξ satisfying the orthogonality condition (14). Thus, as u evolves according to the initial value problem (1), the parameters $a(t)$ and $c(t)$ trace out a path in $\mathbb{R}^2$. The goal of this section is to derive the dynamical equations for the parameters a and c, and the fluctuation ξ. We obtain such equations by substituting the decomposition $u=Q_{ca}+\xi$ into (1) and then projecting the resulting equation onto appropriate directions, with the intent of using the orthogonality condition on ξ.

From now on, u is the solution of (1) with initial condition u_0 satisfying $\epsilon_0 := \inf_{Q_{ca}\in M_s}\|u_0 - Q_{ca}\|_{H^1} < \varepsilon_*$, and $T_0=T_0(u_0)$ is the maximal time such that $u(t)\in U_{\varepsilon_*}$ for $0\le t\le T_0$. Then, for $0\le t\le T_0$, u can be decomposed as in (13) and (14).

Proposition 4.1: Assume $\delta'(c)\neq 0$. *Say* $u=Q_{ca}+\xi$ *is a solution to* (1), *where* ξ *satisfies* (14). *Then, if* $\|\xi\|_{H^1}$ *is small enough,* $\epsilon_x\le 1$, *and* $c\in I$,

$$\begin{pmatrix}\dot a\\ \dot c\end{pmatrix} = \begin{pmatrix} c-b(t,a)\\ 0\end{pmatrix} + b'(t,a)\frac{\delta(c)}{\delta'(c)}\begin{pmatrix}0\\1\end{pmatrix} + Z(a,c,\xi), \tag{18}$$

where $Z(a,c,\xi)=\mathrm{O}(\epsilon_a\epsilon_x^2+\epsilon_a\epsilon_x\|\xi\|_{H^1}+\|\xi\|_{H^1}^2)$.

Proof: Recall that the solitary wave Q_{ca} is an extremal of the functional Λ_{ca}. To use this fact we rearrange definition (10) of Λ_{ca} to write the Hamiltonian H_b as

$$H_b(u) = \Lambda_{ca}(u) - cP(u) + \frac{1}{2}\int_{-\infty}^{\infty} bu^2(x)dx,$$

where for notational simplicity we have suppressed the space and time dependency of b. Substituting $Q_{ca}+\xi$ for u in (3) and using the above expression for H_b gives the equation

$$\dot a\zeta_{ca}^{tr} + \dot c\zeta_{ca}^{n} + \dot\xi = \partial_x\Lambda_{ca}'(Q_{ca}+\xi) - c\partial_x[Q_{ca}+\xi] + \partial_x[(Q_{ca}+\xi)b],$$

where the dots indicate time differentiation. Let $\mathcal{L}_Q := \Lambda_{ca}''(Q_{ca})$,

$$\delta b := b(t,x) - b(t,a),$$

and

$$\delta^2 b := b(t,x) - b(t,a) - b'(t,a)(x-a).$$

Taylor expanding $\Lambda_{ca}'(Q_{ca}+\xi)$ to linear order in ξ, using that Q_{ca} is an extremal of Λ_{ca} and the relation $\zeta_{ca}^{tr}=-\partial_x Q_{ca}$ gives that

$$\begin{aligned}\dot\xi = {}& \partial_x[(\mathcal{L}_Q+\delta b + b(a)-c)\xi] + \partial_x N_{ca}'(\xi) - [\dot a - c + b(a)]\zeta_{ca}^{tr} - \dot c\zeta_{ca}^{n} + b'(a)\partial_x[(x-a)Q_{ca}]\\ & + \partial_x[\delta^2 bQ_{ca}].\end{aligned} \tag{19}$$

The nonlinear terms have been collected into $N_{ca}'(\xi)$ given by (A1) in the Appendix.

Define the vectors $\zeta_1 := \zeta_{ca}^{tr}$ and $\zeta_2 := \zeta_{ca}^{n}$. Projecting (19) onto $\partial_x^{-1}\zeta_i$ for $i=1,2$ and using the antisymmetry of ∂_x gives the two equations

$$\begin{aligned}&[\dot a - c + b(a)][\langle\zeta_{ca}^{tr},\partial_x^{-1}\zeta_i\rangle + \langle\xi,\zeta_i\rangle] + \dot c\langle\zeta_{ca}^{n},\partial_x^{-1}\zeta_i\rangle + \langle\dot\xi,\partial_x^{-1}\zeta_i\rangle - \dot a\langle\xi,\zeta_i\rangle\\ &\quad = -b'(t,a)\langle(x-a)Q_{ca},\zeta_i\rangle - \langle\delta^2 bQ_{ca},\zeta_i\rangle - \langle\delta b\xi,\zeta_i\rangle - \langle N_{ca}'(\xi),\zeta_i\rangle - \langle L_Q\xi,\zeta_i\rangle.\end{aligned} \tag{20}$$

We can replace the term containing $\dot\xi$ since the time derivative of the orthogonality condition $\langle\xi,\partial_x^{-1}\zeta_i\rangle=0$ implies $\langle\dot\xi,\partial_x^{-1}\zeta_i\rangle=\dot a\langle\xi,\zeta_i\rangle-\dot c\langle\xi,\partial_c\partial_x^{-1}\zeta_i\rangle$. Note that we have used the relation $\partial_a\zeta_i = -\partial_x\zeta_i$. Thus, in matrix form, (20) becomes

$$(I+B)\Omega_{ca}\begin{pmatrix}\dot{a}-c+b(t,a)\\ \dot{c}\end{pmatrix}=X+Y, \tag{21}$$

where

$$X:=-b'(t,a)\delta(c)\begin{pmatrix}1\\0\end{pmatrix}-\begin{pmatrix}\langle\delta^2 bQ_{ca},\zeta_{ca}^{tr}\rangle\\ \langle\delta^2 bQ_{ca},\zeta_{ca}^{n}\rangle\end{pmatrix},$$

$$Y:=-\begin{pmatrix}\langle\delta b\xi,\zeta_{ca}^{tr}\rangle+\langle N'_{ca}(\xi),\zeta_{ca}^{tr}\rangle+\langle L_Q\xi,\zeta_{ca}^{tr}\rangle\\ \langle\delta b\xi,\zeta_{ca}^{n}\rangle+\langle N'_{ca}(\xi),\zeta_{ca}^{n}\rangle+\langle L_Q\xi,\zeta_{ca}^{n}\rangle\end{pmatrix},$$

and

$$B:=\begin{pmatrix}\langle\xi,\zeta_{ca}^{tr}\rangle & \langle\xi,\zeta_{ca}^{n}\rangle\\ \langle\xi,\zeta_{ca}^{n}\rangle & -\langle\xi,\partial_c\partial_x^{-1}\zeta_{ca}^{n}\rangle\end{pmatrix}\Omega_{ca}^{-1}.$$

We have explicitly computed $\langle(x-a)Q_{ca},\zeta_i\rangle$ to obtain the above expression for X.

We now estimate the error terms and solve for $\dot{a}$ and $\dot{c}$. The assumption on the potential implies the bounds

$$|\delta b|\le\epsilon_a\epsilon_x(x-a)\quad\text{and}\quad|\delta^2 b|\le\epsilon_a\epsilon_x^2(x-a)^2. \tag{22}$$

Thus, Hölder's inequality and exponential decay of Q_{ca} imply

$$X=-b'(t,a)\delta(c)\begin{pmatrix}1\\0\end{pmatrix}+\mathrm{O}(\epsilon_a\epsilon_x^2)=\mathrm{O}(\epsilon_a\epsilon_x). \tag{23}$$

Similarly, exponential decay of ζ_{ca}^{tr} and ζ_{ca}^{n} implies $\langle\delta b\xi,\zeta_i\rangle=\mathrm{O}(\epsilon_a\epsilon_x\|\xi\|_{H^1})$. The linear term $\langle\mathcal{L}_Q\xi,\zeta_i\rangle$ is zero since $\mathcal{L}_Q\zeta_{ca}^{tr}=0$, $\mathcal{L}_Q\zeta_{ca}^{n}=-Q_{ca}$, and $\xi\perp\partial_x^{-1}\zeta_{ca}^{tr}=-Q_{ca}$. Lastly, $\langle N'_{ca}(\xi),\zeta_i\rangle\le C\|\xi\|_{H^1}^2$ by the first estimate in Lemma A.A.1. Combining the above estimates gives the bound

$$\|Y\|=\mathrm{O}\Big(\epsilon_a\epsilon_x\|\xi\|_{H^1}+\big\|\xi\big\|_{H^1}^2\Big).$$

By the second inclusion of (9), $\partial_c\partial_x^{-1}\zeta_{ca}^{n}\in L^2(\mathbb{R})$. Hölder's inequality then implies $\|B\|=\mathrm{O}(\|\xi\|_{H^1})$. Thus, if $\|\xi\|_{H^1}$ is sufficiently small, say so that $\|B\|\le 1/2$, then $I+B$ is invertible and $\|(I+B)^{-1}\|\le 2$. Acting on Eq. (21) by $(I+B)^{-1}=I-B(I+B)^{-1}$ and then Ω_{ca}^{-1} gives the equation

$$\begin{pmatrix}\dot{a}-c+V(a)\\ \dot{c}\end{pmatrix}=\Omega_{ca}^{-1}[X+B(I-B)^{-1}X+(I-B)^{-1}Y].$$

Using the above estimates of $\|B\|$, $\|(I-B)^{-1}\|$, $\|X\|$, and $\|Y\|$ implies

$$\begin{pmatrix}\dot{a}-c+V(a)\\ \dot{c}\end{pmatrix}=\Omega_{ca}^{-1}X+\mathrm{O}(\epsilon_a\epsilon_x\|\xi\|_{H^1}+\|\xi\|_{H^1}^2).$$

Replacing X by (23) completes the proof. □

V. THE LYAPUNOV FUNCTIONAL

In the last section we derived dynamical equations for the modulation parameters. These equations contain the $H^1(\mathbb{R})$ norm of the fluctuation. In this section we begin to prove a bound on ξ. Recall that the latter bound is needed to ensure that u remains close to the manifold of solitary waves M_s for a long time.

We employ a Lyapunov argument with a Lyapunov function

$$\Gamma_c(t) := \Lambda_{ca}(Q_{ca}+\xi) - \Lambda_{ca}(Q_{ca}) + b'(a)\langle (x-a)Q_{ca}, \xi\rangle. \tag{24}$$

Remark: If $f(u)=u^3$, the last term in the Lyapunov functional is not needed; however, apart from computational complexity, there is no disadvantage in using the above function for this special case as well.

Lemma 5.1: Say $u=Q_{ca}+\xi$ *is a solution to* (1), *where* ξ *satisfies* (14). *Say* $\epsilon_a \le 1$. *If* $\delta'(c)>0$, *and* ϵ_x *and* $\|\xi\|_{H^1}$ *are less than 1, with* $\|\xi\|_{H^1}$ *small enough, then*

$$\frac{d}{dt}\Gamma_c(t) = \mathrm{O}(\epsilon_a^2\epsilon_x^3 + (\epsilon_a\epsilon_x\epsilon_t + \epsilon_a\epsilon_x^2)\|\xi\|_{H^1}) + \mathrm{O}(\epsilon_a\epsilon_x\|\xi\|_{H^1}^2 + \|\xi\|_{H^1}^4). \tag{25}$$

Proof: Suppressing explicit dependence on x and t, we have by definition

$$\Lambda_{ca}(u) := H_b(u) - \frac{1}{2}\int_{-\infty}^{\infty} u^2 b dx + cP(u).$$

Thus, relations (4)–(6) imply that the time derivative of Λ_{ca} along the solution u is

$$\frac{d}{dt}\Lambda_{ca}(u) = \int_{-\infty}^{\infty} \frac{1}{2}\dot{c}u^2 + b'\left[\frac{1}{2}cu^2 - uf(u) + \frac{3}{2}(\partial_x u)^2 + F(u)\right] + b''u\partial_x u dx.$$

Substituting $Q_{ca}+\xi$ for u, manipulating the result using antisymmetry of ∂_x, and collecting appropriate terms into $b'(a)\langle \mathcal{L}_Q\xi, \partial_x((x-a)Q_{ca})\rangle$, $\langle N'_{ca}(\xi), \partial_x[\delta b(Q_{ca}+\xi)]\rangle$, and $\langle \Lambda'_{ca}(Q_{ca}), \partial_x(\delta b(Q_{ca}+\xi))\rangle$ gives the relation

$$\begin{aligned}\frac{d}{dt}[\Lambda_{ca}(Q_{ca}+\xi) - \Lambda_{ca}(Q_{ca})] &= b'(a)\langle \mathcal{L}_Q\xi, \partial_x((x-a)Q_{ca})\rangle + \dot{c}\langle Q_{ca}, \xi\rangle \\ &+ \dot{c}\frac{1}{2}\|\xi\|_{L^2}^2 + \langle \mathcal{L}_Q\xi, \partial_x(\delta^2 b Q_{ca})\rangle + c\frac{1}{2}\langle b'\xi, \xi\rangle + \frac{3}{2}\langle b'\partial_x\xi, \partial_x\xi\rangle \\ &- \langle f'(Q_{ca})\xi, \partial_x(\delta b\xi)\rangle + \langle N'_{ca}(\xi), \partial_x[\delta b(Q_{ca}+\xi)]\rangle \\ &+ \langle b''\xi, \partial_x\xi\rangle + \langle \Lambda'_{ca}(Q_{ca}), \partial_x[\delta b(Q_{ca}+\xi)]\rangle.\end{aligned}$$

The last term is zero because $\Lambda'_{ca}(Q_{ca})=0$ and since $\xi \perp Q_{ca}$, the quantity $\dot{c}\langle \xi, Q_{ca}\rangle$ is also zero. We use Lemma A.1, assumptions (12) on the potential, estimates (22), and

$$|\partial_x\delta^2 b| \le \epsilon_a\epsilon_x^2(x-a)$$

to estimate the size of the time derivative of $\Lambda_{ca}(Q_{ca}+\xi)-\Lambda_{ca}(Q_{ca})$. We also use that Q_{ca}, $\partial_x Q_{ca}$, $\partial_x^2 Q_{ca}$, and $f'(Q_{ca})$ are exponentially decaying. When $\epsilon_x \le 1$, higher order terms like $\langle b''\xi, \partial_x\xi\rangle$ are bounded above by lower order terms like $\langle b'\xi, \xi\rangle$. Similarly, if $\|\xi\|_{H^1} \le 1$, then $\epsilon_a\epsilon_x\|\xi\|_{H^1}^2 \le \epsilon_a\epsilon_x\|\xi\|_{H^1}$. This procedure gives the estimate

$$\begin{aligned}\frac{d}{dt}[\Lambda_{ca}(Q_{ca}+\xi) - \Lambda_{ca}(Q_{ca})] &= b'(a)\langle \xi, \mathcal{L}_Q\partial_x((x-a)Q_{ca})\rangle \\ &+ \langle N'_{ca}(\xi), \delta b\partial_x\xi\rangle + \mathrm{O}(\|\dot{c}\|\|\xi\|_{H^1}^2 + \epsilon_a\epsilon_x^2\|\xi\|_{H^1} + \epsilon_a\epsilon_x\|\xi\|_{H^1}^2).\end{aligned}$$

Applying the chain rule to the integrand of

$$\int_{-\infty}^{\infty} \partial_x \left[\left(F(Q_{ca}+\xi) - F(Q_{ca}) - f(Q_{ca})\xi - \frac{1}{2} f'(Q_{ca})\xi^2 \right) \delta b \right] dx = 0$$

and using the definition of $N'_{ca}(\xi)$ gives that

$$\langle N'_{ca}(\xi), \delta b \partial_x \xi \rangle = \left\langle N'_{ca}(\xi) + \frac{1}{2} f''(Q_c)\xi^2, \delta b \partial_x Q_c \right\rangle$$

$$- \int_{-\infty}^{\infty} \left((F(Q_{ca})+\xi) - F(Q_{ca}) - f(Q_{ca})\xi - \frac{1}{2} f'(Q_{ca})\xi^2 \right) b' dx.$$

The second estimate and the proof of the third estimate of Lemma A.1 of the Appendix then imply the bound $\langle N'_{ca}(\xi), \delta b \partial_x \xi \rangle = \mathrm{O}(\epsilon_a \epsilon_x \|\xi\|_{H^1}^3)$. Thus, since $\epsilon_a \epsilon_x \|\xi\|_{H^1}^3 \le \epsilon_a \epsilon_x \|\xi\|_{H^1}^2$ when $\|\xi\|_{H^1} \le 1$, we have

$$\frac{d}{dt}[\Lambda_{ca}(Q_{ca}+\xi) - \Lambda_{ca}(Q_{ca})] = b'(a)\langle \xi, \mathcal{L}_Q \partial_x((x-a)Q_{ca})\rangle + \mathrm{O}\left(\|\dot{c}\| \|\xi\|_{H^1}^2 + \epsilon_a \epsilon_x^2 \left\|\xi\right\|_{H^1} + \epsilon_a \epsilon_x \|\xi\|_{H^1}^2 \right). \tag{26}$$

When $f(u)=u^3$, $\langle \xi, L_Q \partial_x((x-a)Q_{ca})\rangle = 0$ since $\zeta^n_{ca} = \partial_x[(x-a)Q_{ca}]$. In this special case the above estimate is sufficient for our purposes, but in general we need to use the corrected Lyapunov functional. When $\xi \in C(\mathbb{R}, H^1(\mathbb{R})) \cap C^1(\mathbb{R}, H^{-2}(\mathbb{R}))$, $b'(a)\langle \xi, (x-a)Q_{ca}\rangle$ is continuously differentiable with respect to time;

$$\frac{d}{dt}[b'(a)\langle \xi, (x-a)Q_{ca}\rangle] = \partial_t b' \langle \xi, (x-a)Q_{ca}\rangle + b'(a)\langle \dot{\xi}, (x-a)Q_{ca}\rangle + \dot{c} b'(a)\langle \xi, (x-a)\zeta^n_{ca}\rangle + \dot{a} b'(a)$$
$$\times \langle \xi, (x-a)\zeta^{tr}_{ca}\rangle + \dot{a} b''(a)\langle \xi, (x-a)Q_{ca}\rangle,$$

where $\langle \xi, Q_{ca}\rangle = 0$ has been used to simplify the derivative. Substituting for $\partial_t \xi$ using (19) gives

$$\begin{aligned}
\frac{d}{dt}[b'(a)\langle \xi, (x-a)Q_{ca}\rangle] = & - b'(a)\langle \xi, \mathcal{L}_Q \partial_x((x-a)Q_{ca})\rangle - [\dot{a} - c + b(a)] b'(a) \frac{1}{2} \|Q_{ca}\|_{L^2}^2 \\
& + \partial_t b' \langle \xi, (x-a)Q_{ca}\rangle + [\dot{a} - c + b(a)] b'(a) \langle \partial_x \xi, (x-a)Q_{ca}\rangle \\
& + [\dot{a} - c + b(a)] b''(a) \langle \xi, (x-a)Q_{ca}\rangle + \dot{c} b'(a) \langle \xi, (x-a)\zeta^n_{ca}\rangle - b'(a) \\
& \times \langle \xi, \delta b \partial_x((x-a)Q_{ca})\rangle \\
& - b'(a)\langle N'_{ca}(\xi), \partial_x((x-a)Q_{ca})\rangle - b'(a)\langle \delta^2 b Q_{ca}, \partial_x((x-a)Q_{ca})\rangle \\
& + [c - b(a)] b''(a) \langle \xi, (x-a)Q_{ca}\rangle.
\end{aligned}$$

We estimate using the same assumptions used to derive (26). If $\|\xi\|_{H^1}$ and ϵ_x are less than 1, then

$$\begin{aligned}
\frac{d}{dt}[b'(a)\langle \xi, (x-a)Q_{ca}\rangle] = & - b'(a)\langle \xi, \mathcal{L}_Q \partial_x((x-a)Q_{ca})\rangle + \mathrm{O}(|\dot{a} - c + b(a)| \epsilon_a \epsilon_x + |\dot{c}| \epsilon_a \epsilon_x \|\xi\|_{H^1}) \\
& + \mathrm{O}(\epsilon_a^2 \epsilon_x^3 + ((1+\epsilon_a)\epsilon_x^2 + \epsilon_x \epsilon_t)\epsilon_a \|\xi\|_{H^1} + \epsilon_a \epsilon_x \|\xi\|_{H^1}^2).
\end{aligned}$$

Adding the above expression to (26) gives an upper bound containing $|\dot{c}|$ and $|\dot{a} - c + b(a)|$. Replacing these quantities using the bounds

$$|\dot{c}| = \mathrm{O}\left(\epsilon_a \epsilon_x + \epsilon_a \epsilon_x \|\xi\|_{H^1} + \|\xi\|_{H^1}^2 \right)$$

and

$$|\dot{a} - c + b(a)| = \mathrm{O}(\epsilon_a \epsilon_x^2 + \epsilon_a \epsilon_x \|\xi\|_{H^1} + \|\xi\|_{H^1}^2)$$

from Proposition 4.1, and bounding higher order terms by lower order terms gives (25). To use the above bounds on $|\dot{c}|$ and $|\dot{a}-c+b(a)|$ we must assume $\|\xi\|_{H^1}$ is small enough so that Proposition 4.1 holds. □

VI. SPECTRAL PROPERTIES OF THE HESSIAN $\mathcal{L}_Q$

The Hessian $\partial^2 \Lambda_{ca}$ at Q_{ca} in the $L^2(\mathbb{R})$ pairing is computed to be the unbounded operator

$$\mathcal{L}_Q := -\partial_x^2 + c - f'(Q_{ca}), \tag{27}$$

defined on $L^2(\mathbb{R})$ with domain $H^2(\mathbb{R})$. We extend this operator to the corresponding complex spaces.

Proposition 6.1: The self-adjoint operator $\mathcal{L}_Q$ has the following properties.

1. $\mathcal{L}_Q \zeta_{ca}^{tr} = 0$ *and* $\mathcal{L}_Q \zeta_{ca}^{n} = -Q_{ca}$.
2. *All eigenvalues of* $\mathcal{L}_Q$ *are simple, and* Null $\mathcal{L}_Q = \mathrm{Span}\{\zeta_{ca}^{tr}\}$.
3. $\mathcal{L}_Q$ *has exactly one negative eigenvalue.*
4. *The essential spectrum is* $[c, \infty) \subset \mathbb{R}_+$.
5. $\mathcal{L}_Q$ *has a finite number of eigenvalues in* $(-\infty, c)$.

Proof: Recall that the vectors $\zeta_{ca}^{tr} := -\partial_x Q_{ca}$ and $\zeta_{ca}^{n} := \partial_c Q_{ca}$ are in the Sobolev space $H^2(\mathbb{R})$. Thus, relations $\mathcal{L}_Q \zeta_{ca}^{tr} = 0$ and $\mathcal{L}_Q \zeta_{ca}^{n} = -Q_{ca}$ make sense, and are obtained by differentiating $\Lambda_{ca}'(Q_{ca}) = 0$ with respect to a and c. The first relation above proves that ζ_{ca}^{tr} is a null vector.

Say ζ, $\eta \in H^2(\mathbb{R})$ are linearly independent eigenvectors of $\mathcal{L}_Q$ with the same eigenvalue. Then, since $\mathcal{L}_Q$ is a second-order linear differential operator without a first-order derivative, the Wronskian

$$W(\eta, \zeta) = \zeta \partial_x \eta - \eta \partial_x \zeta$$

is a nonzero constant. With η and ζ both in $H^2(\mathbb{R})$, however, the limit $\lim_{x \to \infty} W(\eta, \zeta)$ is zero. This contradicts the nonvanishing of the Wronskian, and hence all eigenvalues of $\mathcal{L}_Q$ are simple and, in particular, Null $\mathcal{L}_Q = \mathrm{Span}\{\zeta_{ca}^{tr}\}$.

Next we prove that the operator $\mathcal{L}_Q$ has exactly one negative eigenvalue using the Sturm-Liouville theory on an infinite interval. Recall that the solitary wave $Q_{ca}(x)$ is a differentiable function, symmetric about $x = a$ and monotonically decreasing if $x > a$. This implies that the null vector ζ_{ca}^{tr}, or, equivalently, the derivative of Q_{ca} with respect to x, has exactly one root at $x = a$. Therefore, by the Sturm-Liouville theory, zero is the second eigenvalue and there is exactly one negative eigenvalue.

We use standard methods to compute the essential spectrum. Since the function $f'(Q_{ca}(x))$ is continuous and decays to zero at infinity, the bottom of the essential spectrum begins at $\lim_{x \to \infty}(c - f'(Q_{ca}(x))) = c$ and extends to infinity: $\sigma_{ess}(\mathcal{L}_Q) = [c, \infty)$. Furthermore, the bottom of the essential spectrum is not an accumulation point of the discrete spectrum since $f'(Q_{ca}(x))$ decays faster than x^{-2} at infinity. Hence, there is at most a finite number of eigenvalues in the interval $(-\infty, c)$. For details, see Refs. 25, 37, and 38. □

VII. STRICT POSITIVITY OF THE HESSIAN

In this section we prove strict positivity of the Hessian $\mathcal{L}_Q$ on the orthogonal complement to the two-dimensional space

$$\partial_x^{-1} T_{Q_{ca}} M_s = \mathrm{Span}\{Q_{ca}, \partial_x^{-1} \zeta_{ca}^{n}\}.$$

This result is a crucial ingredient needed to prove the bound on the fluctuation ξ.

Proposition 7.1: Assume $\delta'(c)>0$ *on* $I\subset\mathbb{R}_+$. *If* $\xi\perp\partial_x^{-1}T_{Q_{ca}}M_s$, *then there is a positive constant* ρ *such that* $\langle\mathcal{L}_Q\xi,\xi\rangle\geq\rho\|\xi\|_{H^1}^2$.

Proof: Define $X:=\{\xi\in H^1(\mathbb{R})\,|\,\xi\perp\partial_x^{-1}T_{Q_{ca}}M_s,\|\xi\|_{L^2}=1\}$. By the max-min principle, $\inf_{X\cap H^2(\mathbb{R})}\times\langle\mathcal{L}_Q\xi,\xi\rangle$ is attained or is equal to inf $\sigma_{ess}(\mathcal{L}_Q)=c$. If the latter holds, the proof is complete. In the former case, let η be the minimizer.

We claim the set of vectors $\{\zeta_{ca}^{tr},\zeta_{ca}^{n},\eta\}$ is a linearly independent set. If they were dependent, then, since ζ_{ca}^{tr} and ζ_{ca}^{n} are orthogonal, there are nonzero constants α and β such that $\eta=\alpha\zeta_{ca}^{tr}+\beta\zeta_{ca}^{n}$. Projecting this equation onto $\partial_x^{-1}\zeta_{ca}^{tr}$ and $\partial_x^{-1}\zeta_{ca}^{n}$ gives the equations $\beta\delta'(c)=0$ and $\alpha\delta'(c)=0$. Thus, the assumption $\delta'(c)>0$ implies $\eta=0$, a contradiction since the zero function does not lie in the set X.Note that in deriving $\alpha\delta'(c)=0$ we have used that ∂_x^{-1} is antisymmetric on the span of ζ_{ca}^{n} since $\partial_x^{-1}\zeta_{ca}^{n}\in L^2(\mathbb{R})$.

By the min-max principle, if

$$\lambda_3:=\inf\{\max\{\langle\mathcal{L}_Q\xi,\xi\rangle|\xi\in V,\|\xi\|_{L^2}=1\}|V\subset H^2(\mathbb{R}),\dim V=3\}$$
$$\leq\max\{\langle\mathcal{L}_Q\xi,\xi\rangle|\xi\in\mathrm{Span}\{\zeta_{ca}^{tr},\zeta_{ca}^{n},\eta\}\}$$

is below the essential spectrum, then it is the third eigenvalue counting multiplicity. Let $\xi=\alpha\eta+\beta\zeta_{ca}^{tr}+\gamma\zeta_{ca}^{n}$, where α, β, and γ are arbitrary apart from satisfying $\|\xi\|_{L^2}=1$. Thus, since the third eigenvalue of $\mathcal{L}_Q$ is positive (see Sec. VI),

$$0<\langle\mathcal{L}_Q\xi,\xi\rangle=\alpha^2\langle\mathcal{L}_Q\eta,\eta\rangle-\gamma^2\delta'(c)\leq\alpha^2\langle\mathcal{L}_Q\eta,\eta\rangle,$$

and hence $\langle\mathcal{L}_Q\eta,\eta\rangle>0$. The function $\sigma(c)=\langle\mathcal{L}_Q\eta,\eta\rangle$ is continuous since both $\partial_x^{-1}\zeta_{ca}^{tr}$ and $\partial_x^{-1}\zeta_{ca}^{n}$ are continuous in $L^2(\mathbb{R})$ as functions of c. Set $\varrho=\inf_I\sigma(c)$.

We now improve the result to an $H^1(\mathbb{R})$ norm. If we define the constant $K(I):=\sup_I\|c-f'(Q_{ca})\|_\infty$, then $\langle\mathcal{L}_Q\xi,\xi\rangle\geq\|\partial_x\xi\|_{L^2}^2-K(I)\|\xi\|_{L^2}^2$. Adding to this bound the factor $(K+1)/\varrho$ of the lower bound $\langle\mathcal{L}_Q\xi,\xi\rangle\geq\varrho\|\xi\|_{L^2}^2$ derived above completes the proof. □

VIII. BOUND ON THE FLUCTUATION

We are now ready to prove the bound on the fluctuation.

Proposition 8.1: Say $\epsilon_a\leq1$. *Then, for small enough* $\epsilon_x\leq1$ *and initial fluctuation* $\|\xi\|_{H^1}\leq1$, *there exists a constant* C *such that the bound*

$$\|\xi(t)\|_{H^1}=\mathrm{O}(\epsilon_0+(\epsilon_a\epsilon_x\epsilon_0)^{1/2}+\epsilon_x+\epsilon_t)$$

holds for all times $t\leq T=C(\epsilon_a\epsilon_x)^{-1}$.

Proof: Lemma 5.1 implies

$$\left|\frac{d}{dt}\Gamma_c(t)\right|\leq C(\epsilon_a^2\epsilon_x^3+(\epsilon_a\epsilon_x\epsilon_t+\epsilon_a\epsilon_x^2)\|\xi\|_T+\epsilon_a\epsilon_x\|\xi\|_T^2+\|\xi\|_T^4)$$

for some constant $C>0$ where $\|\xi\|_T:=\sup_{0\leq t\leq T}\|\xi\|_{H^1}$. Integrating over $[0,T]$ gives an upper bound on $\Gamma_c(T)$. A lower bound is obtained by expanding $\Lambda_{ca}(Q_{ca}+\xi)$ to quadratic order, then using Proposition 7.1, the third estimate of Lemma A.1, and $V'(a)\langle\xi,(x-a)Q_{ca}\rangle=\mathrm{O}(\epsilon_a\epsilon_x\|\xi\|_{H^1})$. We obtain, after setting all nonessential constants to one,

$$\|\xi\|_T^2-\|\xi\|_T^3-\epsilon_a\epsilon_x\|\xi\|_T\leq\Gamma_c(T)$$

$$\leq|\Gamma_c(0)|+(\epsilon_a^2\epsilon_x^3+(\epsilon_a\epsilon_x\epsilon_t+\epsilon_a\epsilon_x^2)\|\xi\|_T+\epsilon_a\epsilon_x\|\xi\|_T^2+\|\xi\|_T^4)T$$

for all $T>0$. Take $T=\mathrm{O}((\epsilon_a\epsilon_x)^{-1})$. Then, under the smallness assumption $\|\xi\|_{H^1}\ll(\epsilon_a\epsilon_x)^{1/2}$,

$$\|\xi\|_{H^1} = \mathrm{O}(|\Gamma_c(0)|^{1/2} + \epsilon_x + \epsilon_t).$$

The initial value of the Lyapunov functional $\Gamma_c(0)$ can be bounded by the $H^1(\mathbb{R})$ norm of the initial fluctuation $\|\xi(0)\|_{H^1} \leq C\epsilon_0$ (recall that $\epsilon_0 := \inf_{Q_{ca} \in M_s} \|u_0 - Q_{ca}\|_{H^1}$). Indeed, Taylor expanding $\Lambda_{ca}(Q_{ca}+\xi)$ to second order in ξ and using the third estimate in Lemma A.1 gives $|\Gamma_c(0)| = \mathrm{O}(\epsilon_0^2 + \epsilon_a\epsilon_x\epsilon_0)$ if $\epsilon_0 \ll 1$. To complete the proof we take ϵ_x and ϵ_0 small enough so that $\|\xi(t)\|_{H^1}$ is sufficiently small for Lemma 5.1 to hold. □

We now prove the main theorem.

Proof of Theorem 1: By our choice $\epsilon_0 < \varepsilon_*$, there is a (maximal) time T_0 such that the solution u in (1) is in U_{ε_*} for time $t \leq T_0$. Hence decomposition (13) with (14), and Proposition 8.1 are valid for the solution u over this time and imply the statements of the main theorem. In particular,

$$\|\xi(t)\|_{H^1} = \mathrm{O}(\epsilon_0 + (\epsilon_a\epsilon_x\epsilon_0)^{1/2} + \epsilon_x + \epsilon_t)$$

for times $t \leq \min\{T_0, T\}$. Taking $\epsilon_0 + (\epsilon_a\epsilon_x\epsilon_0)^{1/2} + \epsilon_x + \epsilon_t \ll \varepsilon_*$, we must have $t \leq T$ by maximality of the time T_0. □

APPENDIX: ESTIMATES OF NONLINEAR REMAINDERS

Define

$$N_{ca}(\xi) := -\int_{-\infty}^{\infty} F(Q_c + \xi) - F(Q_c) - F'(Q_c)\xi - \frac{1}{2}F''(Q_c)\xi^2 dx$$

and

$$N'_{ca}(\xi) := -(f(Q_c + \xi) - f(Q_c) - f'(Q_c)\xi). \tag{A1}$$

Note that $N'_{ca}(\xi) = \partial_\xi N_{ca}(\xi)$ under the $L^2(\mathbb{R})$ pairing.

Lemma A.1: If $\|\xi\|_{H^1} \leq 1$ *and* $f \in C^k(\mathbb{R})$ *for some* $k \geq 3$, *then there are positive constant* C_1, C_2, *and* C_3 *such that*

1. $\|N'_{ca}(\xi)\|_{L^2} \leq C_1\|\xi\|_{H^1}^2$,
2. $\|N'_{ca}(\xi) + \frac{1}{2}f''(Q_{ca})\xi^2\|_{L^2} \leq C_2\|\xi\|_{H^1}^3$,
3. $|N_{ca}(\xi)| \leq C_3\|\xi\|_{H^1}^3$.

Proof: Taylor's remainder theorem implies

$$N'_{ca}(\xi) = -\sum_{n=2}^{k-1} \frac{1}{n!} f^{(n)}(Q_{ca})\xi^n - R(Q_{ca}, \xi),$$

where, since $\|\xi\|_{H^1} \leq 1$, $|R(Q_{ca}, \xi)| \leq C|\xi|^k$. Recall that Q_{ca} is continuous and decays exponentially to zero. Together with the assumption that $f \in C^k(\mathbb{R})$, this implies $f^{(n)}(Q_{ca}) \in L^\infty(\mathbb{R})$ for $2 \leq n \leq k-1$. Thus, after pulling out the largest constant,

$$\|N'_{ca}(\xi)\|_{L^2} \leq C \sum_{n=2}^{k} \|\xi^n\|_{L^2}.$$

To obtain item 1 we use the bound $\|\xi^n\|_{L^2} \leq C\|\xi\|_{H^1}^n$, which is obtained from the inequality $\|\xi\|_{L^\infty} \leq C\|\xi\|_{H^1}$ and the assumption that $\|\xi\|_{H^1} \leq 1$.

Clearly, a slight modification of the above proof gives items 2 and 3. For the latter we use that the assumptions on f imply $F \in C^{k+1}(\mathbb{R})$ with $F^{(k+1)} \in L^\infty(\mathbb{R})$. □

Eigenvalue problems and their application to the wavelet method of chaotic control

Jonq Juang[a] and Chin-Lung Li
Department of Applied Mathematics, National Chiao Tung University, Hsin Chu, Taiwan, R.O.C.

(Received 5 January 2006; accepted 5 June 2006; published online 31 July 2006)

Controlling chaos via wavelet transform was recently proposed by Wei, Zhan, and Lai [Phys. Rev. Lett. **89**, 284103 (2002)]. It was reported there that by modifying a tiny fraction of the wavelet subspace of a coupling matrix, the transverse stability of the synchronous manifold of a coupled chaotic system could be dramatically enhanced. The stability of chaotic synchronization is actually controlled by the second largest eigenvalue $\lambda_1(\alpha,\beta)$ of the (wavelet) transformed coupling matrix $C(\alpha,\beta)$ for each α and β. Here β is a mixed boundary constant and α is a scalar factor. In particular, $\beta=1$ (respectively, 0) gives the nearest neighbor coupling with periodic (respectively, Neumann) boundary conditions. The first, rigorous work to understand the eigenvalues of $C(\alpha,1)$ was provided by Shieh *et al.* [J. Math. Phys. (to be published)]. The purpose of this paper is twofold. First, we apply a different approach to obtain the explicit formulas for the eigenvalues of $C(\alpha,1)$ and $C(\alpha,0)$. This, in turn, yields some new information concerning $\lambda_1(\alpha,1)$. Second, we shed some light on the question whether the wavelet method works for general coupling schemes. In particular, we show that the wavelet method is also good for the nearest neighbor coupling with Neumann boundary conditions. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2218674]

I. INTRODUCTION

Chaotic synchronization (Refs. 1, 8, 12–14, and references cited therein) is a fundamental phenomenon in physical systems with dissipation. It was first observed in Ref. 8 for identical master-slave Lorenz equations. This phenomenon was later observed in many different fields—physics, electrical engineering, biology, laser systems, etc. Experimental observations show that chaotic subsystems in a lattice manifest synchronized chaotic behavior in time provided they are coupled with a dissipative coupling and its coupling strength is greater than some critical value. Specifically, let there be N nodes (oscillators). Assume $\mathbf{u}_i$ is the m-dimensional vector of dynamical variables of the ith node. Let the isolated (uncoupling) dynamics be $\dot{\mathbf{u}}_i=f(\mathbf{u}_i)$ for each node. We assume that $\mathbf{u}_i$ has a chaotic dynamics in the sense that its largest Lyapunov exponent is positive. Let h: $\mathbb{R}^m\to\mathbb{R}^m$ be an arbitrary function describing the coupling within the components of each node. Thus, the dynamics of the ith node are

$$\dot{\mathbf{u}}_i = f(\mathbf{u}_i) + \epsilon\sum_{j=1}^{N} a_{ij}h(\mathbf{u}_j), \quad i=1,2,\ldots,N, \tag{1.1a}$$

where ϵ is a coupling strength. Here sum $\Sigma_{j=1}^{N}a_{ij}=0$. Let $\mathbf{u}=(\mathbf{u}_1,\mathbf{u}_2,\ldots,\mathbf{u}_N)^T$, $F(\mathbf{u})=(f(\mathbf{u}_1),f(\mathbf{u}_2),\ldots,f(\mathbf{u}_N))^T$, $H(\mathbf{u})=(h(\mathbf{u}_1),h(\mathbf{u}_2),\ldots,h(\mathbf{u}_N))^T$, and $A=(a_{ij})$. We may write (1.1a) as

$$\dot{\mathbf{u}} = F(\mathbf{u}) + \epsilon A\times H(\mathbf{u}). \tag{1.1b}$$

[a]Electronic mail: jjuang@math.nctu.edu.tw

Here $\times$ is the direct product of two matrices B and C defined as follows. Let $B=(b_{ij})_{k_1\times k_2}$ be a $k_1\times k_2$ matrix and $C=(C_{ij})_{k_2\times k_3}$ be a $k_2\times k_3$ block matrix, where each of C_{ij}, $1\leqslant i\leqslant k_2$, $1\leqslant j\leqslant k_3$, is a $k_4\times k_5$ matrix. Then

$$B\times C=\left(\sum_{l=1}^{k_2} b_{il}C_{lj}\right)_{k_1\times k_3}.$$

Many coupling schemes are covered by Eq. (1.1b). For example, if the Lorenz system is used and the coupling is through its three components x, y, and z, then the function h is just the matrix

$$I_3=\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix}. \tag{1.2}$$

The choice of A will provide the connectivity of nodes. For instance, the nearest neighbor coupling with mixed boundary conditions is given as follows:

$$A=A(\beta)=\begin{pmatrix}-1-\beta&1&0&\cdots&\cdots&\beta\\1&-2&1&\cdots&\cdots&0\\0&1&-2&1&\cdots&0\\\vdots&\ddots&\ddots&\ddots&&\vdots\\\vdots&&\ddots&\ddots&\ddots&\vdots\\\beta&0&\cdots&\cdots&1&-1-\beta\end{pmatrix}_{N\times N}. \tag{1.3}$$

Note that $\beta=1$ corresponds to periodic boundary conditions, while $\beta=0$ is associated with Neumann boundary conditions. The synchronous manifold of the chaotic system (1.1) can be studied by setting $\mathbf{u}_1(t)=\mathbf{u}_2(t)=\cdots=\mathbf{u}_N(t)=\mathbf{s}(t)$. Here the chaotic solution $\mathbf{s}(t)$ satisfies the single oscillator equation $d\mathbf{s}/dt=f[\mathbf{s}(t)]$. The stability property of the synchronous manifold can then be studied in the space of difference variables $\delta\mathbf{u}_i(t)=\mathbf{u}_i(t)-\mathbf{s}(t)$, which are governed by[7,10]

$$\frac{d\delta\mathbf{u}}{dt}=(I_N\times DF+\epsilon A\times DH)\delta\mathbf{u}, \tag{1.4a}$$

where $DH=dH(\mathbf{u})/d\mathbf{u}$, and $\delta\mathbf{u}=(\delta\mathbf{u}_1,\delta\mathbf{u}_2,\ldots,\delta\mathbf{u}_N)^T$. When H is just a matrix E, $DH=E$. The first term in (1.4a) is block diagonal. The second term can be treated by diagonalizing A. The transformation which does this does not affect the first term, since it acts only on the identity matrix I_N. This leaves us with a block diagonalized variational equation with each block having the form[7]

$$\delta\dot{\mathbf{u}}_i=[DF+\epsilon\lambda_i DH]\delta\mathbf{u}_i, \tag{1.4b}$$

where λ_i is an eigenvalue of A, $i=0,1,\cdots,N-1$. The Jacobian functions DF and DH are the same for each block, since they are evaluated on the synchronized state. It then follows from (1.4b) that the largest eigenvalue λ_0 of A being equal to 0 governs the motion on the synchronized manifold, and all of other eigenvalues $\lambda_i(i\neq 0)$ control the transverse stability[9] of the chaotic synchronous state. The stability condition is then given by $L_{\max}+\epsilon\lambda_1\leqslant 0$, where $L_{\max}>0$ is the largest Lyapunov exponent of a single chaotic oscillator. As a consequence, the second largest eigenvalue λ_1 is dominant in controlling the stability of chaotic synchronization, and the critical strength ϵ_c can be determined in term of λ_1,

$$\epsilon_c=\frac{I_{\max}}{-\lambda_1}. \tag{1.4c}$$

Note that the eigenvalues of $A=A(1)$ are given by $\lambda_i=-4\sin^2(\pi i/N)$, $i=0,1,\ldots,N-1$. In general, a larger number of nodes gives a smaller nonzero eigenvalue λ_1 in magnitude, and, hence,

a larger ϵ_c. As a consequence, controlling chaos is apparently of great interest and importance.[4–7,11,12] In Ref. 11, a new efficient strategy for controlling nonlinear dynamics was presented. To be self-contained, we briefly describe such procedures. Let

$$A = \begin{pmatrix} A_{11} & \cdots & A_{1n} \\ \vdots & \ddots & \vdots \\ A_{n1} & \cdots & A_{nn} \end{pmatrix}_{n\times n}, \tag{1.5a}$$

be a matrix with the dimension of each block matrix A_{kl} being $2^i \times 2^i$. By an i-scale wavelet operator W,[2,11] the matrix A is transformed into $W(A)$ of the form

$$W(A) = \begin{pmatrix} \tilde{A}_{11} & \cdots & \tilde{A}_{1n} \\ \vdots & \ddots & \vdots \\ \tilde{A}_{n1} & \cdots & \tilde{A}_{nn} \end{pmatrix}_{n\times n}, \tag{1.5b}$$

where each entry of $\tilde{A}_{kl}$ is the average of entries of A_{kl}, $1 \leqslant k, l \leqslant n$.

For a given matrix, the above wavelet transform allows a perfect reconstruction (inverse wavelet transform), by which there is nothing to gain: $A = W^{-1}(W(A))$. In Ref. 11, a simple operator O_k is introduced to attain a desirable coupling matrix. That is,

$$C = W^{-1}(O_k(W(A))) = A + (k-1)W(A) =: A + \alpha W(A), \tag{1.5c}$$

where O_k is the multiplication of a scalar factor K on each block matrix $\tilde{A}_{kl}$. After such reconstruction, the critical strength ϵ_c is again determined in terms of the second largest eigenvalue of C. A numerical simulation of a coupled system of 512 Lorenz oscillators in Ref. 11 shows that with $h = I_3$ and $A = A(1)$, the critical coupling strength ϵ_c decreases linearly with respect to the increase of α up to a critical value α_c. The smallest ϵ_c is about 6, which is about 10^3 times smaller than the original critical coupling strength, indicating the efficiency of the proposed approach.

To verify this phenomenon mathematically, we first consider the coupling matrix $A = A(\beta)$, as given in (1.3). Let $n = N/2^i \in \mathbb{N}$, where i is a fixed positive integer. We then write A into an $n \times n$ block matrix of the form

$$A = A(\beta) = \begin{pmatrix} A_1(\beta) & A_2(1) & 0 & . & . & 0 & A_2^T(\beta) \\ A_2^T(1) & A_1(1) & A_2(1) & . & . & 0 & 0 \\ 0 & . & . & . & & & . \\ . & & . & . & . & & . \\ . & & & . & . & . & 0 \\ 0 & 0 & . & . & A_2^T(1) & A_1(1) & A_2(1) \\ A_2(\beta) & 0 & . & . & 0 & A_2^T(1) & \bar{A}_1(\beta) \end{pmatrix}_{n\times n}, \tag{1.6a}$$

where

$$A_1(\beta) = \begin{pmatrix} -1-\beta & 1 & & & \\ 1 & -2 & 1 & & \mathbf{0} \\ & . & . & . & \\ & & . & . & . \\ & \mathbf{0} & & . & . & 1 \\ & & & & 1 & -2 \end{pmatrix}_{2^i\times 2^i},$$

$$\bar{A}_1(\beta) = \begin{pmatrix} -2 & 1 & & & \\ 1 & -2 & 1 & & \mathbf{0} \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & \\ & \mathbf{0} & & \ddots & 1 \\ & & & 1 & -1-\beta \end{pmatrix}_{2^i \times 2^i}, \tag{1.6b}$$

and

$$A_2(\beta) = \begin{pmatrix} 0 & \cdots & \cdots & \cdots & 0 \\ \vdots & & & & \vdots \\ \vdots & & & & \vdots \\ 0 & & & & 0 \\ \beta & 0 & \cdots & \cdots & 0 \end{pmatrix}_{2^i \times 2^i}. \tag{1.6c}$$

Then the newly transformed coupling matrix $C=C(\alpha,\beta)$ can be written as

$$\begin{aligned} &C(\alpha,\beta) \\ &= \begin{pmatrix} A_1(\beta)+\tilde{A}_1(\beta) & A_2(1)+\tilde{A}_2(1) & 0 & \cdots & 0 & A_2^T(\beta)+\tilde{A}_2^T(\beta) \\ A_2^T(1)+\tilde{A}_2^T(1) & A_1(1)+\tilde{A}_1(1) & A_2(1)+\tilde{A}_2(1) & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & A_2^T(1)+\tilde{A}_2^T(1) & A_1(1)+\tilde{A}_1(1) & A_2(1)+\tilde{A}_2(1) \\ A_2(\beta)+\tilde{A}_2(\beta) & 0 & \cdots & 0 & A_2^T(1)+\tilde{A}_2^T(1) & \tilde{\bar{A}}_1(\beta)+\tilde{\bar{A}}_1(\beta) \end{pmatrix} \\ &=: \begin{pmatrix} C_1(\beta) & C_2(1) & 0 & \cdots & 0 & C_2^T(\beta) \\ C_2^T(1) & C_1(1) & C_2(1) & 0 & \cdots & 0 \\ 0 & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & C_2^T(1) & C_1(1) & C_2(1) \\ C_2(\beta) & 0 & \cdots & 0 & C_2^T(1) & \bar{C}_1(\beta) \end{pmatrix}. \end{aligned} \tag{1.7}$$

Here for any matrix B of dimension $2^i \times 2^i$, the kl entry $(\tilde{B})_{kl}$ of $\tilde{B}$ is defined to be

$$(\tilde{B})_{kl} = \frac{\alpha}{2^{2i}} \sum_{l=1}^{2^i} \sum_{k=1}^{2^i} (B)_{kl}.$$

Here α is a scalar factor. The matrix $C(\alpha,\beta)$ carries a new relationship among the coupled oscillators, which might not be as simple as the original matrix A. Nevertheless, the stability of the synchronous states can be determined by matrix $C(\alpha,\beta)$, whose eigenvalues $\lambda_i(\alpha,\beta)$ $(i=0,1,2,\cdots,N-1)$ determine the synchronous stability of the coupled chaotic system. The following theorem of Shieh *et al.*[9] showed, indeed, the dramatic reduction in the critical coupling strength can be achieved with the periodic boundary conditions. We summarize their main results in the following.

Theorem 1.1: *Let $N\times N$, $N=8k$, $k\in N$, be the dimension of the matrix $C(\alpha,1)$. Let the dimension of each block matrix in $C(\alpha,1)$ be $2^i\times 2^i$. Then the following assertions hold.*

(i) $\rho_i := 2\cos(\pi/2^i)-2$ *is an eigenvalue of* $C(\alpha,1)$.

(ii) *The second eigenvalue* $\lambda_1(\alpha,1)$ *of* $C(\alpha,1)$ *is decreasing in* α. *Moreover,* $\lambda_1(\alpha,1)=\rho_i$ *when-*

ever $\alpha \geqslant -2^i \rho_i / 4 \sin^2(2^i \pi / N)$.

Note that $C(\alpha,1)$ is a block circulant matrix (see e.g., Ref. 3). A classical result of a block circulant matrix states that its eigenvalues exactly consist of those of certain linear combinations of its block matrices (see, e.g., Theorem 5.6.4 of Ref. 3). The proof of Theorem 1.1 was then reduced to working on the eigenvalues of those linear combinations of block matrices of $C(\alpha,1)$. Note that $C(\alpha,\beta)$, $\beta \neq 1$ are not block circulant matrix. The objective of the present work is to present another approach to study the eigenvalues of $C(\alpha,\beta)$. Specifically, we use this new method to study two coupling schemes, the nearest neighbor coupling with periodic boundary conditions and the nearest neighbor coupling with Neumann boundary conditions. To simplify our calculation, we consider only the case $i=1$. In both coupling schemes, we are able to obtain, respectively, exact form of eigenvalues $\lambda_m^{\pm}(\alpha,\beta)$ of its corresponding matrix $C(\alpha,\beta)$, see (2.16) and (3.9). Here $\beta=0$ or 1. For each α and β, let $\lambda_1(\alpha,\beta)$ be the second largest eigenvalue of $C(\alpha,\beta)$. We prove that for N being a multiple of 4, then

$$\lambda_1(\alpha,1) = \begin{cases} \lambda_1^+(\alpha,1), & 0 \leqslant \alpha \leqslant \dfrac{1}{\sin^2 \dfrac{z}{n}} \\ \lambda_{n/2}^+(\alpha,1) = -2, & \alpha \geqslant \dfrac{1}{\sin^2 \dfrac{\pi}{n}}. \end{cases}$$

Let $N=2n$ be an even number which is not multiple of 4. We show that $\lambda_1(\alpha,1)=\lambda_{[n/2]}^+(\alpha,1)$ for α sufficiently large, where $[n/2]$=the largest positive integer that is less than or equal to $n/2$. Moreover, we prove that for such N that $\lambda_1(\alpha,1)<-2$, whenever $\alpha>1/\sin^2(\pi/n)$. With those results above, we get considerably more information than those obtained in Ref. 9. Among other, such result suggests that if the number N of oscillators is even but not a multiple of 4, then the wavelet method works even better. Specifically, it is better in the sense that the corresponding second largest eigenvalue $\lambda_1(\alpha,1)$ is further away from 0, and, hence, gives even smaller critical length. Our second main result is concerned with $\lambda_1(\alpha,0)$ of $C(\alpha,0)$, which corresponds to the nearest neighbor coupling with Neumann boundary conditions. We show that for all even number N its second largest eigenvalue $\lambda_1(\alpha,0)$ for each α behaves like its periodic counterpart for which its corresponding N is a multiple of 4.

II. PERIODIC BOUNDARY CONDITIONS

Here, we consider the nearest neighbor coupling with periodic boundary conditions. The resulting coupling matrix $A(1)$ is given as in (1.6). Let the dimension of $A_1(1)$, $A_2(1)$, and $\bar{A}_1(1)$ be 2×2. Then

$$A_1(1) = \begin{pmatrix} -2 & 1 \\ 1 & -2 \end{pmatrix} = \bar{A}_1(1), \quad A_2(1) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \tag{2.1a}$$

$$\tilde{A}_1(1) = \alpha \begin{pmatrix} -\frac{1}{2} & -\frac{1}{2} \\ -\frac{1}{2} & -\frac{1}{2} \end{pmatrix} = \tilde{\bar{A}}_1(1), \quad \tilde{A}_2(1) = \alpha \begin{pmatrix} \frac{1}{4} & \frac{1}{4} \\ \frac{1}{4} & \frac{1}{4} \end{pmatrix}. \tag{2.1b}$$

Then $C_i(1)=A_i(1)+\tilde{A}_i(1)$, i=1,2, $\bar{C}_1(1)=\bar{A}_1(1)+\tilde{\bar{A}}_1(1)$. Thus,

$$C_1(1)=\begin{pmatrix} -\frac{1}{2}(4+\alpha) & \frac{1}{2}(2-\alpha) \\ \frac{1}{2}(2-\alpha) & -\frac{1}{2}(4+\alpha) \end{pmatrix}=\bar{C}_1(1), \quad C_2(1)=\begin{pmatrix} \frac{\alpha}{4} & \frac{\alpha}{4} \\ \frac{1}{4}(4+\alpha) & \frac{\alpha}{4} \end{pmatrix}. \tag{2.1c}$$

We begin by identifying some trivial eigenvalues of $C(\alpha,1)$.

Proposition 2.1: For each α, 0 *and* -4 *are eigenvalues of* $C(\alpha,1)$. *If, in addition,* $n/2(>1)$ *is a positive integer, then* -2 *is also an eigenvalue of* $C(\alpha,1)$ *for any* α.

Proof: Let $C(\alpha,1)+4I=(\mathbf{c}_1,\mathbf{c}_2,\ldots,\mathbf{c}_N)$, where $\mathbf{c}_i$, $1\leqslant i\leqslant N$, are column vectors. Then $\Sigma_{j=1}^{N}(-1)^{j+1}\mathbf{c}_j=0$. Thus -4 is an eigenvalue of $C(\alpha,1)$ for each $\alpha>0$. Let $C(\alpha,1)+2I=(\mathbf{c}_1,\mathbf{c}_2,\ldots,\mathbf{c}_N)$. If $N=2n(>4)$ is a multiple of four, then $\Sigma_{j=1}^{N}\delta(j)\mathbf{c}_j=0$, where

$$\delta(j)=\begin{cases} 1 & \text{if } j=4k \text{ or } 4k+1 \text{ for some } k \\ -1 & \text{if } j=4k+2 \text{ or } 4k+3 \text{ for some } k. \end{cases}$$

Thus, -2 is an eigenvalue of $C(\alpha,1)$ for each α with such N. □

Writing the corresponding eigenvalue problem $C(\alpha,1)\mathbf{b}=\lambda\mathbf{b}$, where $\mathbf{b}=(\mathbf{b}_1,\mathbf{b}_2,\ldots,\mathbf{b}_n)^T$ and $\mathbf{b}_i\in\mathbb{C}^2$, in block component form, we have

$$C_2^T(1)\mathbf{b}_{i-1}+C_1(1)\mathbf{b}_i+C_2(1)\mathbf{b}_{i+1}=\lambda\mathbf{b}_i, \quad 1\leqslant i\leqslant n. \tag{2.2a}$$

Periodic boundary conditions would yield that

$$C_2^T(1)\mathbf{b}_0+C_1(1)\mathbf{b}_1+C_2(1)\mathbf{b}_2=\lambda\mathbf{b}_1=C_1(1)\mathbf{b}_1+C_2(1)\mathbf{b}_2+C_2^T(1)\mathbf{b}_n$$

and

$$C_2^T(1)\mathbf{b}_{n-1}+C_1(1)\mathbf{b}_n+C_2(1)\mathbf{b}_{n+1}=\lambda\mathbf{b}_n=C_2(1)\mathbf{b}_1+C_2^T(1)\mathbf{b}_{n-1}+\bar{C}_1(1)\mathbf{b}_n,$$

or, equivalently,

$$\mathbf{b}_0=\mathbf{b}_n, \tag{2.2b}$$

$$\mathbf{b}_1=\mathbf{b}_{n+1}. \tag{2.2c}$$

To study the block difference equation (2.2), we first seek to find the solution $\mathbf{b}_i$ of the form

$$\mathbf{b}_i=\delta^i\begin{pmatrix} 1 \\ \nu \end{pmatrix}. \tag{2.3}$$

Substituting (2.3) into (2.2a), we get

$$[C_2^T(1)+\delta(C_1(1)-\lambda I)+\delta^2C_2(1)]\begin{pmatrix} 1 \\ \nu \end{pmatrix}=0. \tag{2.4}$$

To have a nontrivial solution $\binom{1}{\nu}$ to Eq. (2.4), we need to have

$$\det[C_2^T(1)+\delta(C_1(1)-\lambda I)+\delta^2C_2(1)]=0, \tag{2.5a}$$

or, equivalently,

$$\alpha\delta^4+(4\alpha+4+2\alpha\lambda)\delta^3-(8+10\alpha+16\lambda+4\alpha\lambda+4\lambda^2)\delta^2+(4\alpha+4+2\alpha\lambda)\delta+\alpha=0. \tag{2.5b}$$

Equation (2.5b) is to be called the characteristic equation of the block difference equation (2.2a). To study the property of Eq. (2.5b), we need the following proposition.

Proposition 2.2: Let D_1, D_2, and D_3 *be* 2×2 *matrices. Suppose* $D_1=D_3^T$ *and* $D_2=D_2^T$. *Let* x_1,

x_2, x_3, and x_4 be roots of $\det[D_1+xD_2+x^2D_3]=0$, *where* $x\in\mathbb{C}$. *Then we may renumber the subscripts if necessary so that*

$$x_1x_2=1=x_3x_4. \tag{2.6a}$$

If, in addition, diagonal elements of D_1 and D_2, respectively, are both equal, then

$$y_1y_2=1=y_3y_4. \tag{2.6b}$$

Here $\binom{1}{y_i}$, $i=1,2,3,4$, *are vectors satisfying*

$$[D_1+x_iD_2+x_i^2D_3]\begin{pmatrix}1\\ y_i\end{pmatrix}=0. \tag{2.6c}$$

Proof: If D_1, D_2, and D_3 are as assumed, then

$$\det[D_1+xD_2+x^2D_3]=ax^4+bx^3+cx^2+bx+a \tag{2.7}$$

for some constants $a\neq 0$, b, and c. Letting $y=x+1/x$, then (2.7) can be written as $\alpha y^2+\beta y+\gamma$, where α, β, and γ depend on the constants a, b, and c. Thus $\det[D_1+xD_2+x^2D_3]=0$ is equivalent to $x^2-\lambda_{\pm}x+1=0$, where $\lambda_{\pm}$ are the roots $a_1y^2+b_1y+c_1=0$. Consequently, $x_1x_2=1=x_3x_4$.

Letting $D_1=\left(\begin{smallmatrix}a_1 & b_1\\ c_1 & a_1\end{smallmatrix}\right)=D_3^T$ and $D_2=\left(\begin{smallmatrix}a_2 & b_2\\ b_2 & a_2\end{smallmatrix}\right)$, we write (2.6c) in component form,

$$(a_1+y_ib_1)+(a_2+y_ib_2)x_i+(a_1+y_ic_1)x_i^2=0,\quad i=1,2,3,4, \tag{2.8a}$$

$$(c_1+y_ia_1)+(b_2+y_ia_2)x_i+(b_1+y_ia_1)x_i^2=0,\quad i=1,2,3,4, \tag{2.8b}$$

For $i=1$, (2.8a) is equal to

$$(a_1+y_1b_1)+(a_2+y_1b_2)\frac{1}{x_2}+(a_1+y_1c_1)\frac{1}{x_2^2}=0$$

or

$$(a_1+y_1c_1)+(a_2+y_1b_2)x_2+(a_1+y_1b_1)x_2^2=0$$

or

$$\left(c_1+\frac{1}{y_1}a_1\right)+\left(b_2+\frac{1}{y_1}a_2\right)x_2+\left(b_1+\frac{1}{y_1}a_1\right)x_2^2=0. \tag{2.8c}$$

Using Eqs. (2.8c) and (2.8b) with $i=2$, and the uniqueness of y_i, $i=1,2,3,4$, we conclude that $y_1y_2=1$. Similarly, $y_3y_4=1$. We just complete the proof of the proposition. □

We are now in a position to further study Eq. (2.5). We assume, momentarily, that Eq. (2.5) has four distinct roots δ_1, δ_2, δ_3, and δ_4. The general solutions to (2.2a) can then be written as

$$\mathbf{b}_i=c_1\delta_1^i\begin{pmatrix}1\\ \nu_1\end{pmatrix}+c_2\delta_2^i\begin{pmatrix}1\\ \nu_2\end{pmatrix}+c_3\delta_3^i\begin{pmatrix}1\\ \nu_3\end{pmatrix}+c_4\delta_4^i\begin{pmatrix}1\\ \nu_4\end{pmatrix}. \tag{2.9}$$

Here ν_i, $i=1,2,3,4$, are some constants depending on δ_i.

Applying (2.9) to boundary conditions (2.2b) and (2.2c), we get

$$c_1(\delta_1^n-1)\begin{pmatrix}1\\ \nu_1\end{pmatrix}+c_2(\delta_2^n-1)\begin{pmatrix}1\\ \nu_2\end{pmatrix}+c_3(\delta_3^n-1)\begin{pmatrix}1\\ \nu_3\end{pmatrix}+c_4(\delta_4^n-1)\begin{pmatrix}1\\ \nu_4\end{pmatrix}=0 \tag{2.10a}$$

and

$$c_1\delta_1(\delta_1^n-1)\begin{pmatrix}1\\ \nu_1\end{pmatrix}+c_2\delta_2(\delta_2^n-1)\begin{pmatrix}1\\ \nu_2\end{pmatrix}+c_3\delta_3(\delta_3^n-1)\begin{pmatrix}1\\ \nu_3\end{pmatrix}+c_4\delta_4(\delta_4^n-1)\begin{pmatrix}1\\ \nu_4\end{pmatrix}=0. \tag{2.10b}$$

Writing (2.10) in matrix form, we have

$$\begin{pmatrix}1 & 1 & 1 & 1\\ \nu_1 & \nu_2 & \nu_3 & \nu_4\\ \delta_1 & \delta_2 & \delta_3 & \delta_4\\ \nu_1\delta_1 & \nu_2\delta_2 & \nu_3\delta_3 & \nu_4\delta_4\end{pmatrix}\mathrm{diag}(\delta_1^n-1,\delta_2^n-1,\delta_3^n-1,\delta_4^n-1)\begin{pmatrix}c_1\\ c_2\\ c_3\\ c_4\end{pmatrix}=0. \tag{2.11}$$

Now if, $\mathrm{diag}(\delta_1^n-1,\delta_2^n-1,\delta_3^n-1,\delta_4^n-1)$ is singular, then Eq. (2.9) has nontrivial solutions c_i, $i=1,2,3,4$. Note that $\mathrm{diag}(\delta_1^n-1,\delta_2^n-1,\delta_3^n-1,\delta_4^n-1)$ is singular if and only if δ_i, $i=1,2,3,4$, satisfy

$$\delta^n=1 \tag{2.12}$$

and (2.5b). To solve the system of equations (2.12) and (2.5b), we first note that

$$\delta_m=e^{i2m\pi/n},\quad 0\leqslant m\leqslant n-1, \tag{2.13}$$

are roots of Eq. (2.12). Substituting (2.13) and (2.5b), we get that the imaginary part of the resulting equation is

$$\left[-4\sin\frac{4m\pi}{n}\right]\lambda^2+\left[2\alpha\sin\frac{6m\pi}{n}-(4\alpha+16)\sin\frac{4m\pi}{n}+2\alpha\sin\frac{2m\pi}{n}\right]\lambda$$
$$+\left[\alpha\sin\frac{8m\pi}{n}+4(1+\alpha)\sin\frac{6m\pi}{n}-(8+10\alpha)\sin\frac{4m\pi}{n}+4(1+\alpha)\sin\frac{2m\pi}{n}\right]=0. \tag{2.14}$$

Before we proceed to compute the real part of the resulting equation, we need the following lemma.

Lemma 2.1: Let a, b, and c be any complex number, then

$$\cos 2\theta(\sin 4\theta+a\sin 3\theta+b\sin 2\theta+a\sin\theta)=\sin 2\theta(\cos 4\theta+a\cos 3\theta+b\cos 2\theta+a\cos\theta+1). \tag{2.15}$$

Since the proof of the lemma is straightforward, we will skip it.

Using (2.14) and (2.15), we see immediately that the real part of (2.5b) with $\delta=e^{i2m\pi/n}$ is a constant multiple $\sin/\cos(4m\pi/n)/(4m\pi/n)$ of its imaginary part. We next show that (2.14) is indeed the characteristic equation of the matrix $C(\alpha,1)$.

Theorem 2.1: *Let $N\times N$, $N=2k$, $k\in N$, be the dimension of the matrix $C(\alpha,1)$. Let dimension of each block matrix in $C(\alpha,1)$ be 2×2. Then the eigenvalues $\lambda_m^{\pm}(\alpha,1)$ of $C(\alpha,1)$ are of the following form:*

$$\lambda_m^{\pm}(\alpha,1)=\frac{1}{2}\left(\alpha\cos\frac{2m\pi}{n}-\alpha-4\right)\pm\frac{1}{2}\left[\left(\alpha\cos\frac{2m\pi}{n}-\alpha-4\right)^2+4\left(\alpha\cos^2\frac{2m\pi}{n}\right.\right.$$
$$\left.\left.+2(\alpha+1)\cos\frac{2m\pi}{n}-2-3\alpha\right)\right]^{1/2}=:\check{\lambda}_m(\alpha,1)\pm\hat{\lambda}_m(\alpha,1),\quad m=0,1,\ldots,n-1. \tag{2.16}$$

Proof: Solving (2.14), we get (2.16). Using Proposition 2.2, we see that if $\delta=1$ or -1 is a root of Eq. (2.5b), then the multiplicity of $\delta=1$ or -1 is both two. Thus, we have only proved the

following. (i) If $n/2$ is not a positive integer, then for each α, $\lambda_m^{\pm}(\alpha,1)$, $m=1,2,\ldots,n-1$, are eigenvalues of $C(\alpha,1)$. (ii) If $n/2$ is a positive integer, then for each α, $\lambda_m^{\pm}(\alpha,1)$, $m=1,2,\ldots,n/2-1,n/2+1,\ldots,n-1$, are eigenvalues of $C(\alpha,1)$. To complete the proof of the theorem, it remains to show that for each α, $\lambda_0^{\pm}(\alpha,1)(=0,-4)$ are eigenvalues of $C(\alpha,1)$ for each α and that if, additionally, $n/2>1$ is a positive integer, then for each α, $\lambda_{n/2}^{\pm}(\alpha,1)(=-2,-2-2\alpha)$ are also eigenvalues of $C(\alpha,1)$. Using Proposition 2.1, we only need to show that $-2-2\alpha=(\lambda_{n/2}^{-}(\alpha,1))$ is an eigenvalue of $C(\alpha,1)$ for fixed α. To this end, we see that

$$\textit{trace of } C(\alpha,1) = -n(\alpha+4). \tag{2.17}$$

Let $N=2n>4$ be a multiple of four, then

$$\lambda_{n/2}^{+}(\alpha,1)+\left(\sum_{j=1,j\neq n/2}^{n}\lambda_j^{\pm}(\alpha,1)\right)+\lambda_0^{\pm}(\alpha,1) = -2-(n-2)(\alpha+4)-4. \tag{2.18}$$

Using (2.17) and (2.18), we have that the remaining eigenvalue of $C(\alpha,1)$ for each α is $-2-2\alpha$, which is equal to $\lambda_{n/2}^{-}(\alpha,1)$. We thus complete the proof of the theorem. □

Proposition 2.3: For all $\alpha>0$, we have that $\hat{\lambda}_m(\alpha,1)>0$, $\check{\lambda}_m(\alpha,1)<0$ and $\lambda_m^{\pm}(\alpha,1)\leqslant 0$.

Proof: Obviously, $\check{\lambda}_m(\alpha,1)<0$. Now, letting $t=\cos(2m\pi/n)$, we have that

$$4(\hat{\lambda}_m(\alpha,1))^2=(t-1)^2\alpha^2+4(t^2-1)\alpha+8(1+t)=((t-1)\alpha+2(t+1))^2+4(1-t^2)>0$$

for any $\alpha>0$. Thus $\hat{\lambda}_m(\alpha,1)>0$. To prove the last assertion of the proposition, we note, via (2.16), that

$$0>4\left(\alpha\cos^2\frac{2m\pi}{n}+2(\alpha+1)\cos\frac{2m\pi}{n}-2-3\alpha\right)=:l.$$

Thus,

$$2\lambda_m^{\pm}(\alpha,1)=2\check{\lambda}_m(\alpha,1)\pm(4\check{\lambda}_m^2(\alpha,1)+l)^{1/2}\leqslant 0.$$

We just complete the proof of the proposition. □

Proposition 2.4: If $n/2$ is not a positive integer, then the eigencurves $\lambda_m^{\pm}(\alpha,1)$, $m=1,2,\ldots,n-1$, are strictly decreasing in $\alpha\in(0,\infty)$. If $n/2(>1)$ is a positive integer, then $\lambda_m^{\pm}(\alpha,1)$, $m=1,2,\ldots,n/2-1,n/2+1,\ldots,n-1$, and $\lambda_{n/2}^{-}(\alpha,1)$ are strictly decreasing in $\alpha\in(0,\infty)$.

Proof: Letting $t=\cos(2m\pi/n)$, we write (2.16) as

$$\begin{aligned}\lambda_m^{\pm}(\alpha,1)&=\tfrac{1}{2}\{\alpha(t-1)-4\pm[(t-1)^2\alpha^2+4(t^2-1)\alpha+8(1+t)]^{1/2}\}\\&=:\tfrac{1}{2}\{\alpha(t-1)-4\pm(t_\alpha)^{1/2}\}=:\lambda_t^{\pm}(\alpha).\end{aligned} \tag{2.19}$$

Then

$$2\frac{d\lambda_m^{\pm}(\alpha,1)}{d\alpha}=(t-1)\left(1\pm\frac{(t-1)\alpha+2(t+1)}{\sqrt{t_\alpha}}\right).$$

A direct computation would yield that

$$t_\alpha\geqslant((t-1)\alpha+2(t+1))^2.$$

Thus, $d\lambda_m^{\pm}(\alpha,1)/d\alpha\leqslant 0$. The equality holds only if $t=1$ or $t=-1$ for λ_m^{+}. □

Proposition 2.5: (i) In the $\alpha-\lambda$ plane, $\lambda_t^{\lambda}(\alpha,1)$ interest with $\lambda=-2+k$ at $\alpha_{t,k}$, where

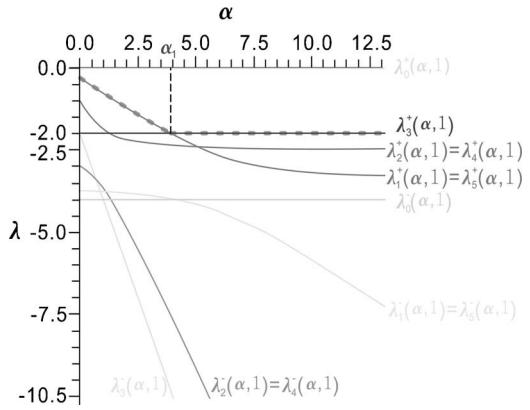

FIG. 1. The curves $\lambda_m^{\pm}(\alpha,1)$ with $N=2n=12$ are provided. As predicted in Theorem 2.2–(i), $\lambda(\alpha,1)$ turns flat after α_1.

$$\alpha_{t,k}=\frac{2(1+t)-k^2}{(1-t)(1+t+k)}. \tag{2.20}$$

(ii) For $-1\leqslant t<1$, $\lim_{\alpha\to\infty}\lambda_t^+(\alpha,1)=-(t+3)$.

Proof: Solving equation $-2+k=\lambda_t^+(\alpha,1)$, we easily get that $\alpha_{t,k}$ are as asserted. Rewriting $\lambda_t^+(\alpha,1)$ as

$$\lambda_t^+(\alpha,1)=\frac{-2\alpha(t-1)(t+3)+4(1-t)}{\alpha(t-1)-4-\sqrt{t_\alpha}},$$

we see that $\lim_{\alpha\to\infty}\lambda_t^+(\alpha,1)=-(t+3)$ for $-1\leqslant t<1$. □

Theorem 2.2: *Let N be any positive even integer. The dimension of each block matrix in* $C(\alpha,1)$ *is* 2×2. *Then (i) suppose N is a multiple of four and* $N>4$. *For each* $\alpha>0$, *let* $\lambda(\alpha,1)$ *be the second largest eigenvalue of* $C(\alpha,1)$. *Then* $\lambda(\alpha,1)=\lambda_1^+(\alpha,1)$, *for* $0\leqslant\alpha\leqslant 1/\sin^2(\pi/n):=\alpha_1$; *and* $\lambda(\alpha,1)=\lambda_{n/2}^+(\alpha,1)=-2$ *for all* $\alpha\in[\alpha_1,\infty)$. *See Fig. 1.*

(ii) Suppose N is not a multiple of four. Then there exists a $\tilde{\alpha}_c$ *such that* $\lambda(\alpha,1)=\lambda_{[n/2]}^+(\alpha)$ *for all* $\alpha\geqslant\tilde{\alpha}_c$. *Here* $[n/2]$=*the largest positive integer that is less than or equal to* $n/2$. *Moreover,* $\lambda(\alpha,1)<-2$ *whenever* $\alpha>\alpha_1$. *See Fig. 2.*

Proof: For $\alpha_{t,k}$ to be positive, we must have

$$2(1+t)>k^2. \tag{2.21}$$

Now,

$$(1-t)^2(1+t+k)^2\frac{\mathrm{d}\alpha_{t,k}}{\mathrm{d}t}=2(t+1)^2-k^3+4k-2tk^2>(1+t)k^2-k^3+4k-2tk^2$$
$$=-k(k^2+(t-1)k-4)=-k(k-t_+)(k-t_-),$$

where $t_\pm=(1-t\pm\sqrt{16+(1-t)^2})/2$. Note that we have used (2.21) to justify the above inequality. Moreover $t_-<0$ and $t_+\geqslant 2$. Thus, $\mathrm{d}\alpha_{t,k}/\mathrm{d}t>0$ whenever $\lambda=-2+k$, $0\leqslant k<2$, and $\lambda=\lambda_t^+(\alpha,1)$ have the intersections intersect at the positive $\alpha_{t,k}$. Upon using Proposition 2.4, we conclude that for $0\leqslant m\leqslant n-1$, the portion of the graphs of $\lambda_m^+(\alpha,1)$ lying above the line $\lambda=-2$ do not intersect each other. Thus, $\lambda(\alpha,1)$ is as asserted.

By Proposition 2.5(ii), we have that

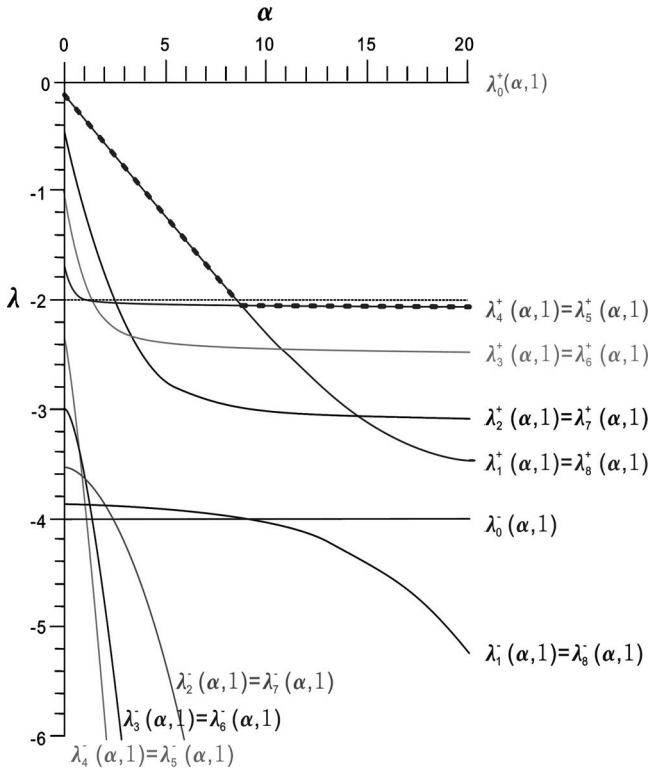

FIG. 2. The curves $\lambda_m^{\pm}(\alpha,1)$ with $N=2n=18$ are provided. As predicted in Theorem 2.2–(ii), $\lambda(\alpha,1)$ lies below -2 eventually.

$$\lim_{\alpha\to\infty}\lambda_m^+(\alpha,1)=-\left(\cos\frac{2m\pi}{n}+3\right)=:\lambda_m^\infty=\lambda_t^\infty.$$

Then $\lambda_m^\infty, 0<m\leqslant n-1$, have a maximum at $m=[n/2]$. Thus, there exists a $\tilde{\alpha}_c$ such that $\lambda(\alpha,1)=\lambda_{[n/2]}^+(\alpha,1)$ for all $\alpha\geqslant\tilde{\alpha}_c$. The last assertion of the theorem follows from Proposition 2.5-(i) and Proposition 2.1. □

Remark 2.1: (i) Since $\lambda_t^+(\alpha,1)$ is increasing in t and λ_t^∞ is decreasing in t, the eigencurves $\lambda_m^+(\alpha,1)$, $0<m\leqslant[n/2]$ must be crossing each other.

(ii) The first column in Table I contains the values of $\lambda_m^{\pm}(1,1)$, $m=0,1,\ldots,5$, while the second column contains the eigenvalues of $C(1,1)$ obtained by using MATHEMATICA. As indicated, the $C(1,1)$ and $C(5,1)$ obtained by both methods are identical. The values $\lambda_m^{\pm}(3,1)$, $m=0,1,\ldots,8$, in the first and third columns of Table II are computed by MAPLE, while those in the second and fourth columns are computed by MATLAB. Some discrepancies between the values in the respective columns occur due to the round-off errors.

(iii) Figure 1 illustrates the graph of $\lambda_m^{\pm}(\alpha,1)$, $m=0,1,\ldots,5$, with $n=6$. The dotted part of the curve is $\lambda(\alpha,1)$. Figure 2 gives the same information with $n=9$.

(iv) We conclude, via the last assertion of Theorem 2.1, that the wavelet approach works even better when N is an even number but not a multiple of four. Indeed, in such case, it synchronizes faster when α is chosen to be the critical value $\tilde{\alpha}_c$.

III. NEUMANN BOUNDARY CONDITIONS

Here, we consider the nearest neighbor coupling with Neumann boundary conditions. The resulting coupling matrix A is then $A(0)$, given as in (1.6a). With $i=1$, we have

TABLE I. The first and third columns contain the values computed by using formulas $\lambda_m^{\pm}(\alpha,1)$ as given in (2.16). The values in the second and fourth columns are eigenvalues of $C(\alpha,1)$ obtained by using MATHEMATICA.

$n=6$

$\lambda_7^-(3,1)\approx-4.2268$	-4.2265	$\lambda_7^-(10,1)\approx-9.2505$	-9.2495
$\lambda_8^-(3,1)\approx-3.9051$	-3.9052	$\lambda_8^-(10,1)\approx-4.0458$	-4.0465

$$A_1(0)=\begin{pmatrix}-1 & 1\\ 1 & -2\end{pmatrix},\quad \bar{A}_1(0)=\begin{pmatrix}-2 & 1\\ 1 & -1\end{pmatrix},\quad A_2(1)=\begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix},$$

$$A_1(1)=\begin{pmatrix}-2 & 1\\ 1 & -2\end{pmatrix},\quad A_2(0)=\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix},\quad \tilde{A}_2(0)=\alpha\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix},$$

$$\tilde{A}_1(0)=\alpha\begin{pmatrix}-\frac{1}{4} & -\frac{1}{4}\\ -\frac{1}{4} & -\frac{1}{4}\end{pmatrix}=\tilde{\bar{A}}_1(0),\quad \tilde{A}_2(1)=\alpha\begin{pmatrix}\frac{1}{4} & \frac{1}{4}\\ \frac{1}{4} & \frac{1}{4}\end{pmatrix},$$

and

$$\tilde{A}_1(1)=\alpha\begin{pmatrix}-\frac{1}{2} & -\frac{1}{2}\\ -\frac{1}{2} & -\frac{1}{2}\end{pmatrix} \tag{3.1}$$

A direct calculation would yield that

$$C_2(0)=\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix},$$

$$C_1(0)=\begin{pmatrix}-\frac{1}{4}(4+\alpha) & \frac{1}{4}(4-\alpha)\\ \frac{1}{4}(4-\alpha) & -\frac{1}{4}(8+\alpha)\end{pmatrix},\quad C_2(1)=\begin{pmatrix}\frac{\alpha}{4} & \frac{\alpha}{4}\\ \frac{1}{4}(\alpha+4) & \frac{\alpha}{4}\end{pmatrix},$$

$$C_1(1)=\begin{pmatrix}-\frac{1}{2}(4+\alpha) & \frac{1}{2}(2-\alpha)\\ \frac{1}{2}(2-\alpha) & -\frac{1}{2}(4+\alpha)\end{pmatrix},\quad \bar{C}_1(0)=\begin{pmatrix}-\frac{1}{4}(8+\alpha) & \frac{1}{4}(4-\alpha)\\ \frac{1}{4}(4-\alpha) & -\frac{1}{4}(4+\alpha)\end{pmatrix}. \tag{3.2}$$

As in the case of periodic boundary conditions, the eigenvalue problem $C(\alpha,0)\mathbf{b}=\lambda\mathbf{b}$, where $\mathbf{b}=(\mathbf{b}_1,\mathbf{b}_2,\ldots,\mathbf{b}_n)^T$, $\mathbf{b}_i\in\mathbb{C}^2$, can be formed as block difference equation

$$C_2^T(1)\mathbf{b}_{i-1}+C_1(1)\mathbf{b}_i+C_2(1)\mathbf{b}_{i+1}=\lambda\mathbf{b}_i,\quad 1\leqslant i\leqslant n. \tag{3.3}$$

With Neumann boundary conditions, $\mathbf{b}_0$, and $\mathbf{b}_{n+1}$ must satisfy

$$C_1(0)\mathbf{b}_1+C_2(1)\mathbf{b}_2=\lambda\mathbf{b}_1=C_2^T(1)\mathbf{b}_0+C_1(1)\mathbf{b}_1+C_2(1)\mathbf{b}_2 \tag{3.4a}$$

and

$$C_2^T(1)\mathbf{b}_{n-1}+\bar{C}_1(0)\mathbf{b}_n=\lambda\mathbf{b}_n=C_2^T(1)\mathbf{b}_{n-1}+C_1(1)\mathbf{b}_n+C_2(1)\mathbf{b}_{n+1}. \tag{3.4b}$$

Solving (3.4a) and (3.4b), respectively, we get

$$\mathbf{b}_0=(C_2^T(1))^{-1}(C_1(0)-C_1(1))\mathbf{b}_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}\mathbf{b}_1 \tag{3.5a}$$

and

TABLE III. The first and third columns contain the values computed by using formulas $\lambda_m^{\pm}(\alpha,0)$ as given in (3.9). The values in the second and fourth columns are eigenvalues of $C(\alpha,1)$ obtained by using MATHEMATICA.

$n=3$			
$\lambda_m^{\pm}(2,0)$	Eigenvalues of $C(2,0)$	$\lambda_m^{\pm}(5,0)$	Eigenvalues of $C(5,0)$
$\lambda_0^{+}(2,0)=0$	0	$\lambda_0^{+}(5,0)=0$	0
$\lambda_1^{+}(2,0)=-\frac{5}{2}+\frac{1}{2}\sqrt{7}$	$-\frac{5}{2}+\frac{1}{2}\sqrt{7}$	$\lambda_1^{+}(5,0)=-\frac{13}{4}+\frac{1}{4}\sqrt{13}$	$-\frac{13}{4}+\frac{1}{4}\sqrt{13}$
$\lambda_2^{+}(2,0)=-\frac{7}{2}+\frac{1}{2}\sqrt{7}$	$-\frac{7}{2}+\frac{1}{2}\sqrt{7}$	$\lambda_2^{+}(5,0)=-\frac{23}{4}+\frac{1}{4}\sqrt{181}$	$-\frac{23}{4}+\frac{1}{4}\sqrt{181}$
$\lambda_3^{+}(2,0)=-2$	-2	$\lambda_3^{+}(5,0)=-2$	-2
$\lambda_1^{-}(2,0)=-\frac{5}{2}-\frac{1}{2}\sqrt{7}$	$-\frac{5}{2}-\frac{1}{2}\sqrt{7}$	$\lambda_1^{-}(5,0)=-\frac{13}{4}-\frac{1}{4}\sqrt{13}$	$-\frac{13}{4}-\frac{1}{4}\sqrt{13}$
$\lambda_2^{-}(2,0)=-\frac{7}{2}-\frac{1}{2}\sqrt{7}$	$-\frac{7}{2}-\frac{1}{2}\sqrt{7}$	$\lambda_2^{-}(5,0)=-\frac{23}{4}-\frac{1}{4}\sqrt{181}$	$-\frac{23}{4}-\frac{1}{4}\sqrt{181}$

$$\mathbf{b}_{n+1} = C_2(1)^{-1}(\bar{C}_1(0) - C_1(1))\mathbf{b}_n = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\mathbf{b}_n. \tag{3.5b}$$

We then see that the characteristic equation of the block difference equation (3.3) is

$$\det[C_2^T(1) + \delta(C_1(1) - \lambda I) + \delta^2 C_2] = 0. \tag{3.6a}$$

Here δ is such that $\mathbf{b}_i = \delta^i\binom{1}{\nu}$, where ν is a constant depending on δ. Expanding the determinant in (3.6a), we get

$$\alpha\delta^4 + 2(2\alpha + 2 + \lambda\alpha)\delta^3 - 2(4 + 5\alpha + 2(\alpha + 4)\lambda + 2\lambda^2)\delta^2 + 2(2\alpha + 2 + \lambda\alpha)\delta + \alpha = 0. \tag{3.6b}$$

We assume, momentarily, that Eq. (3.6b) has four distinct roots δ_1, δ_2, δ_3, and δ_4. The general solutions to (3.3) can then be written as

$$\mathbf{b}_i = \sum_{j=1}^{4} c_j \delta_j^i \begin{pmatrix} 1 \\ \nu_j \end{pmatrix}. \tag{3.7}$$

Substituting (3.7) into boundary conditions (3.5), we get

$$\begin{pmatrix} \delta_1\nu_1 - 1 & \delta_2\nu_2 - 1 & \delta_3\nu_3 - 1 & \delta_4\nu_4 - 1 \\ \delta_1 - \nu_1 & \delta_2 - \nu_2 & \delta_3 - \nu_3 & \delta_4 - \nu_4 \\ \delta_1^n(\delta_1\nu_1 - 1) & \delta_2^n(\delta_2\nu_2 - 1) & \delta_3^n(\delta_3\nu_3 - 1) & \delta_4^n(\delta_4\nu_4 - 1) \\ \delta_1^n(\delta_1 - \nu_1) & \delta_2^n(\delta_2 - \nu_2) & \delta_3^n(\delta_3 - \nu_3) & \delta_4^n(\delta_4 - \nu_4) \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \end{pmatrix} =: D\mathbf{c} = 0, \tag{3.8}$$

where $\mathbf{c} = (c_1, c_2, c_3, c_4)^T$. We are now in a position to simplify $\det D$,

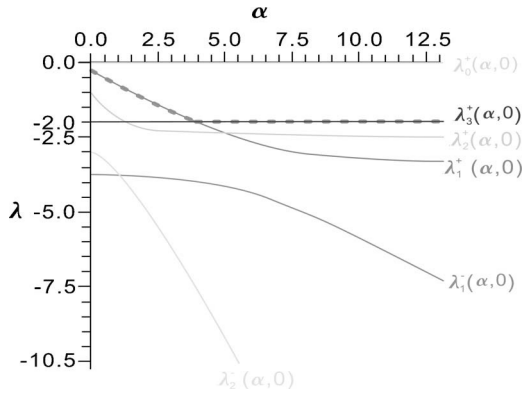

FIG. 3. The curves $\lambda_m^{\pm}(\alpha,0)$ with $N=2n=6$ are provided. As predicted in Theorem 3.2, $\lambda(\alpha,0)$ turns flat after $\bar{\alpha}_1$.

$$\det D=(\delta_2\nu_2)(\delta_4\nu_4)\begin{vmatrix} \delta_1\nu_1-1 & 1-\delta_1\nu_1 & \delta_3\nu_3-1 & 1-\delta_3\nu_3 \\ \delta_1-\nu_1 & \nu_1-\delta_1 & \delta_3-\nu_3 & \nu_3-\delta_3 \\ \delta_1^n(\delta_1\nu_1-1) & \delta_2^n(1-\delta_1\nu_1) & \delta_3^n(\delta_3\nu_3-1) & \delta_4^n(1-\delta_3\nu_3) \\ \delta_1^n(\delta_1-\nu_1) & \delta_2^n(\delta_1-\nu_1) & \delta_3^n(\delta_3-\nu_3) & \delta_4^n(\delta_3-\nu_3) \end{vmatrix}$$

$$=(\delta_2\nu_2)(\delta_4\nu_4)(\delta_1^n-\delta_2^n)(\delta_3^n-\delta_4^n)\begin{vmatrix} 0 & 1-\delta_1\nu_1 & 0 & 1-\delta_3\nu_3 \\ 0 & \nu_1-\delta_1 & 0 & \nu_3-\delta_3 \\ \delta_1\nu_1-1 & \delta_2^n(1-\delta_1\nu_1) & \delta_3\nu_3-1 & \delta_4^n(1-\delta_3\nu_3) \\ \delta_1-\nu_1 & \delta_2^n(\nu_1-\delta_1) & \delta_3-\nu_3 & \delta_4^n(\nu_3-\delta_3) \end{vmatrix}$$

$$=(\delta_2\nu_2)(\delta_4\nu_4)(\delta_1^n-\delta_2^n)(\delta_3^n-\delta_4^n)\Bigg\{[(\delta_1\nu_1-1)(\nu_3-\delta_3)+(\delta_1-\nu_1)(\delta_3\nu_3-1)] \times\begin{vmatrix} 1-\delta_1\nu_1 & 1-\delta_3\nu_3 \\ \nu_1-\delta_1 & \nu_3-\delta_3 \end{vmatrix}\Bigg\}.$$

Therefore, $\det D$ being equal to zero amounts to $\delta_i^{2n}=1$ for $i=1,2,3,4$.

To get the characteristic equation of $C(\alpha,0)$, we need to solve $\delta^{2n}=1$ and Eq. (3.6b). This leads to the following theorem.

Theorem 3.1: *Let N be any positive even integer. The dimension of each block matrix in $C(\alpha,0)$ is 2×2. Let $\lambda_m^{\pm}(\alpha,0)$ be defined as follows:*

$$\lambda_m^{\pm}(\alpha,0)=\frac{1}{2}\left(\alpha\cos\frac{m\pi}{n}-\alpha-4\right)\pm\frac{1}{2}\Bigg[\left(\alpha\cos\frac{m\pi}{n}-\alpha-4\right)^2+4\Bigg(\alpha\cos^2\frac{m\pi}{n}+2(\alpha+1) \times\cos\frac{m\pi}{n}-2-3\alpha\Bigg)\Bigg]^{1/2}. \tag{3.9}$$

Then $\lambda_m^{\pm}(\alpha,0)$, $m=1,2,\ldots,n-1$, $\lambda_0^+(\alpha,0)=0$ and $\lambda_n^+(\alpha,0)=-2$ are eigenvalues of $C(\alpha,0)$ for each $\alpha>0$.

Proof: Substituting $\delta=e^{im\pi/n}$, $0\leqslant m\leqslant n-1$, into (3.6b), we get (3.9). Clearly, if $\delta\neq 1$ or -1, or equivalently, $\cos(m\pi/n)\neq 1$ or -1, then $\lambda_m^{\pm}(\alpha,0)$, $m=1,2,\ldots,n-1$, are eigencurves of $C(\alpha,0)$. Since $0=\lambda_0^+(\alpha,0)$ is an eigenvalue of $C(\alpha,0)$ for all α, we only need to show that $\lambda_n^+(\alpha,0)$ is, indeed, the eigenvalue of $C(\alpha,0)$ for each α. To this end, we see that $\operatorname{trace}(C(\alpha,0))=-(n-2)(\alpha+4)-6-\alpha$. However, $\lambda_0^+(\alpha,0)+\sum_{j=1}^{n-1}\lambda_j^{\pm}(\alpha,0)=-(n-1)(\alpha+4)=:k$. Thus, $\operatorname{trace}(C(\alpha,0))-k=-2=\lambda_n^+(\alpha,0)$. We just complete the proof of the theorem. □

Remark 3.1: (i) Letting $t=\cos(m\pi/n)$, $\lambda_m^{\pm}(\alpha,0)=\lambda_t^{\pm}(\alpha,0)$ and treating t as a real parameter, we see that for fixed $\alpha>0$, the eigenvalues of C with periodic boundary conditions and Neumann

boundary conditions, respectively, lie on the curve $\lambda_t^{\pm}(\alpha,0)$ in $t-\lambda$ plane.

(ii) Note that $\lambda_m^{\pm}(\alpha,0)=\lambda_{2n-m}^{\pm}(\alpha,0)$.

Theorem 3.2: *For each* α, *let* $\lambda(\alpha,0)$ *be the second largest eigenvalue of* $C(\alpha,0)$. *Then* $\lambda(\alpha,0)=\lambda_1^{+}(\alpha,0)$, *for* $0\leqslant\alpha\leqslant 1/\sin^2(\pi/2n)=:\bar{\alpha}_1$; *and* $\lambda(\alpha,0)=\lambda_n^{+}(\alpha,0)=-2$ *for all* $\alpha\in[\bar{\alpha}_1,\infty)$.

We skip the proof of theorem due to its similarity with that of Theorem 2.1 (ii).

Remark 3.2: Table III and Fig. 3 illustrate, again, the accuracy of our theorems.

(Received 25 February 2006; accepted 24 March 2006; published online 24 July 2006)

We present a complete derivation of the formula of Smythe [Phys. Rev. **72**, 1066 (1947)] giving the electromagnetic field diffracted by an aperture created in a perfectly conducting plane surface. The reasoning, valid for any excitating field and any hole shape, makes use only of the free scalar Green function for the Helmoltz equation without any reference to a Green dyadic formalism. We compare our proof with the one previously given by Jackson and connect our reasoning to the general Huygens Fresnel theorem. © *2006 American Institute of Physics.*

I. INTRODUCTION

Diffraction of electromagnetic waves by an aperture in a perfect metallic plane is not only a mathematical problem of fundamental interest but is connected to many applications in the microwave domain (for example, in waveguides and in cavity resonators[1]) as well as in the optical regime where it is involved in many optical arrangements.[2] The fundamental importance of this phenomenon in near-field optics has been pointed out as early as in 1928 by Synge[3] in his prophetic paper and is currently involved in modern near-field scanning optical microscopy (NSOM).[4]

In the domain of applicability of NSOM where distances and dimensions are smaller than or close to the wavelength of light, we need to know the exact structure of the electromagnetic field, and we cannot in general consider the usual approximations involved in Kirchhoff's theory for a scalar wave.[5–7] In this context, one of the most cited approaches is the one given by Bethe[8] in 1944 and corrected by Bouwkamp.[9,10] It gives the electromagnetic field diffracted by a small circular aperture in a perfect metallic plane in the limit where the optical wavelength is much larger than the aperture. Less known is the more general formula of Smythe[11,12] which expresses in a formal way the Huygens Fresnel principle for any kind of aperture in a metallic screen. Even if this formula is not an explicit solution for the general diffraction problem, it constitutes an integral equation which can be used in a self consistent way in perturbative or numerical calculations of the diffracted field.[13,14] Further efforts have been made by Smythe[11,12] himself in order to justify his formula by means of some arrangements of current sheets fitting the aperture. This method essentially consists of transforming the problem of diffraction by a hole into a physically different one in order to guess the correct integral equation for the original problem. However, if this physical reasoning proves the consistency of the proposed solution with Maxwell equations and boundary conditions for the field, it is not directly connected to the rigorous electromagnetic formulation of the Huygens Fresnel principle obtained by Stratton and Chu.[15] Such a connection is expected naturally because these two formulations of diffraction must be equivalent here.

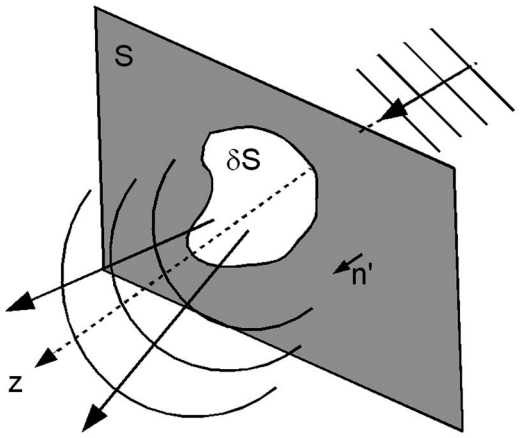

FIG. 1. The problem of diffraction in electromagnetism. The incoming wave comes from the $z<0$ half-space and is diffracted by the aperture δS located in the plane screen S at $z=0$. The unit vector $\vec{n}'=\hat{z}$ used in the text is represented.

Jackson,[16] in the first edition of his textbook on electrodynamics, developed a complete proof of the Smythe formula starting from the Stratton and Chu formula [Eq. (3) of the present paper]. Nevertheless, like in the original paper of Smythe, Jackson transforms the problem into a physically different one in order to guess the correct result. The result is then subjected to the same remarks as above for Smythe's approach. Other justifications of Smythe results are based on the use of the Babinet theorem or of the Green dyadic method. The latter, which uses a tensorial Green function instead of a scalar one like in Kirchhoff's or Stratton and Chu's theories, gives us the most direct justification for Smythe approach in terms of the Huygens Fresnel principle. However, this proof is for the moment not directly connected to the Stratton and Chu approach. It is the aim of this paper to establish such a link.

The paper is organized as follows. We give in Sec. II a description of the general theory of diffraction of electromagnetic waves by an aperture in a screen. In Sec. III, we exploit precedent works by Jackson[16,17] and Levine and Schwinger[18] to justify directly and rigorously the Smythe formula using the Stratton Chu theorem without relying on any ingenious physical "trick." Section IV deals with a vectorial justification of Smythe's approach. The consistency between the various theoretical treatments of diffraction by an aperture in a metallic screen is stressed in Sec. V which also compares our treatment with that obtained within the Green dyadic formalism.[19,20] Our conclusions appear in Sec. VI.

II. THE DIFFRACTION PROBLEM IN ELECTROMAGNETISM

The first coherent theory of diffraction was elaborated by Kirchhoff (1882) on the basis of the Huygens Fresnel principle.[2,21] The method of integral equations allows one to write a solution $\psi(\vec{r})e^{-i\omega t}$ of the Helmholtz propagation equation $[\nabla^2+k^2]\psi(\vec{r})=0$ $(k=\omega/c)$ using the "free" scalar Green function $G(\vec{r},\vec{r}')=e^{ikR}/4\pi R$ which is a solution of the equation $[\nabla^2+k^2]G(\vec{r},\vec{r}')=-\delta^3(\vec{r}-\vec{r}')$.

If, as schematized in Fig. 1, we consider now an aperture δS made in a two-dimensional infinite screen S and illuminated by incident radiation, we can express the field ψ existing at each observation point located behind the screen (i.e., for $z>0$) by the Kirchhoff formula

$$\psi(\vec{r}) = \int_S [\psi(\vec{r}')\vec{n}'\cdot\vec{\nabla}'G(\vec{r},\vec{r}') - G(\vec{r},\vec{r}')\vec{n}'\cdot\vec{\nabla}'\psi(\vec{r}')]\mathrm{d}S', \tag{1}$$

where the normal unit vector $\vec{n}'$ is oriented into the diffraction half-space.

In a problem of diffraction, we usually impose the additional first Kirchhoff "shadow" approximation $\psi(\vec{r}')=\partial_{n'}\psi(\vec{r}')=0$ which is valid on the unilluminated side of the screen. This per-

mits one to restrict the integral in (1) to the region of the aperture only, which is very useful in some approximations or iterative resolutions. Nevertheless, this intuitive hypothesis has some fundamental inconsistencies because, following a theorem due to Poincaré,[21] a field satisfying the shadow approximation on a finite domain must vanish everywhere.

A classic solution proposed by Rayleigh[22] and Sommerfeld[23] to circumvent this difficulty consists in replacing the free Green function by the Dirichlet G_D or the Neumann G_N Green functions[16] satisfying $\partial_{n'}G_N(\vec{r},\vec{r}')=0$ and $G_D(\vec{r},\vec{r}')=0$ for all points $\vec{r}'$ on S. We can then rigorously reduce the integral to the region of the aperture depending on the nature of the boundary problem. For example, if we impose $\psi=0$ on the screen, we can then write

$$\psi(\vec{r}) = \int_{\text{Aperture}} \psi(\vec{r}')\partial_{n'}G_D(\vec{r},\vec{r}')\mathrm{d}S'. \tag{2}$$

In principle, it could be possible to generalize the preceding methods to the different Cartesian components ψ_α of the electromagnetic field using equations of the form $\psi_\alpha=\int_S[\psi_\alpha\partial_{n'}G - G\partial_{n'}\psi_\alpha]\mathrm{d}S'$. Nevertheless, as pointed out by Stratton, Chu and others,[24–26]the Maxwell equations couple the field components between them and the consistency of these relations must be controlled *a posteriori* if we use an integral equation like Eq. (1) either in an exact or approximative treatment of diffraction. In addition, because the boundary conditions imposed by Maxwell's equations connect the tangential and the normal components of the field on the screen surface, it is not at all trivial to reduce the integral to the region of the aperture directly using Eq. (1).

Due to the uniqueness theorem, such possible reduction of the integral appearing in the Huygens Fresnel principle is expected in the case of a perfectly conducting metallic screen. Indeed, following this uniqueness theorem, the field in the diffracted space must depend only on the tangential electric field on the screen and aperture surface. Because the tangential electric field vanishes on the screen, the integral must depend only on the tangential field at the opening. Numerous authors, especially Stratton and Chu[15] as well as Schelkunoff,[27,28] have discussed a vectorial integral equation satisfying Maxwell's equations automatically. We can effectively write

$$\vec{E}(\vec{x}) = \int_S [ik(\vec{n}'\times\vec{B})G + (\vec{n}'\times\vec{E})\times\vec{\nabla}'G + (\vec{n}'\cdot\vec{E})\vec{\nabla}'G]\mathrm{d}S', \tag{3}$$

hereafter referred to as the Stratton-Chu equation. A similar expression holds for the magnetic field by means of the substitution $\vec{E}\to\vec{B}$ and $\vec{B}\to-\vec{E}$.

It is important to note that Eq. (3) is over-determined although it depends explicitly on the tangential and normal components of the electromagnetic field defined on S. Indeed, due to the equivalence principle of Love and Schelkunoff[24,27,29] and to the uniqueness theorem, we expect that the "most adapted" integral equations depend only on $\vec{n}'\times\vec{E}$ *or* $\vec{n}'\times\vec{B}$ on S. In addition, unlike in the scalar case, we cannot directly reduce the surface integral to the region of the aperture just by choosing an adapted Dirichlet or Neumann Green function. It seems then necessary to apply once again the shadow approximation of Kirchhoff in order to simplify the integration despite the inconsistency of the method. As in the Poincaré theorem, some problems appear here because we need to add a nonphysical contour integral associated with a magnetic line charge in Eq. (3) (or to an electric line charge in the equivalent formula for $\vec{B}$) in order to satisfy Maxwell's equations and to compensate for the arbitrary change imposed to the integration domain.[32] Furthermore, in this Kirchhoff Kottler[26] theory, the introduction of contour integrals induces a logarithmic divergence of the energy at the rim of the aperture, a fact which is forbidden in a diffraction problem.

The particular case of the diffraction by an aperture in a planar screen constitutes an exception in the sense that a rigorous integral equation had been anticipated by Schelkunoff[27] and Bethe[8] for a subwavelength circular aperture and generalized by Smythe[11,12] for any kind of aperture. The integral equation is

$$\vec{E}(\vec{x}) = \frac{1}{2\pi}\vec{\nabla} \times \left(\int_{\text{Aperture}} (\hat{z} \times \vec{E}) \frac{e^{ikR}}{R} \mathrm{d}S' \right). \tag{4}$$

For some applications, it is important to note that in the short wavelength limit ($\lambda \ll$ aperture typical radius) for which the electromagnetic field in the aperture can be identified with the incident plane wave $\vec{B}_i = \hat{z} \times \vec{E}_i$ (first Kirchhoff approximation), the formula of Stratton Chu limited to the aperture domain and the exact solution of Smythe give approximately the same result. Indeed, within the Fraunhofer approximation, Eq. (4) reads

$$\vec{E} \simeq \frac{ike^{ikr}}{r} \hat{r} \times \int_{\text{Aperture}} \left[\frac{\hat{z} \times \vec{E}_i}{2\pi} e^{-ik\hat{\mathbf{r}} \cdot \vec{x}'} \right] \mathrm{d}S', \tag{5}$$

whereas Eq. (3) reduces to

$$\vec{E} \simeq \frac{ike^{ikr}}{r} \frac{\hat{r} + \hat{z}}{2} \times \int_{\text{Aperture}} \left[\frac{\hat{z} \times \vec{E}_i}{2\pi} e^{-ik\hat{\mathbf{r}} \cdot \vec{x}'} \right] \mathrm{d}S'. \tag{6}$$

Both equations are identical in the practical limit of small diffraction angles, i.e., close to the normal axis z going through the aperture. Equation (5) is correct for a subwavelength aperture only because we cannot identify the field in the aperture with the incident one. We can see that the asymptotic diffracted field for $z > 0$ is equivalent to the one produced by an effective magnetic dipole

$$\vec{M}_{\text{eff}} = \int_{\text{Aperture}} \left[\frac{\vec{n}' \times \vec{E}}{2\pi i k} \right] \mathrm{d}S', \tag{7}$$

and by an effective electric dipole

$$\vec{P}_{\text{eff}} = \frac{\hat{z}}{4\pi} \int_{\text{Aperture}} (\vec{x}' \cdot \vec{E}) \mathrm{d}S'. \tag{8}$$

These formula are fundamental in the context of NSOM because they give us the Bethe Bouwkamp[8–10,16] dipoles which, in the particular case of a circular aperture of radius a, are

$$\vec{P}_{\text{eff}} = \frac{a^3}{3\pi} \vec{E}_{\perp}^{(0)}, \quad \vec{M}_{\text{eff}} = -\frac{2a^3}{3\pi} \vec{B}_{\parallel}^{(0)}. \tag{9}$$

$\vec{E}_{\perp}^{(0)}$ and $\vec{B}_{\parallel}^{(0)}$ are, respectively, the locally uniform normal electric field and tangential magnetic field existing in the aperture zone in the absence of the opening (in $z = 0^-$).

III. GREEN DYADIC JUSTIFICATION OF THE SMYTHE FORMULA

The so-called Smythe formula Eq. (4) is generally obtained on the basis of different principles such as the Babinet principle or the equivalence theorem (see Schelkunoff,[27] Bouwkamp,[30] Jackson[17]). In particular, the equivalence theorem shows that the solution of Smythe for $z > 0$ is identical to the one obtained by considering a virtual surface magnetic-current density given by $\vec{J}_s^m = -c\hat{z} \times \vec{E}/(2\pi)$. All these derivations are self consistent if we consider the very fact that the guessed results fulfill Maxwell equations. Then, the uniqueness theorem ensures that the result is the only one possible. Nevertheless, as already noted, the calculation is not direct and not necessarily connected to the Stratton and Chu formalism. A classical calculation due to Schwinger and Levine[19,20] shows, however, that it is possible to rigourously and directly obtain this equation using the tensorial, or dyadic, Green function formalism. Such an electric dyadic Green function[31] $\overleftrightarrow{G}$, which is solution of the equation

$$\vec{\nabla}\times\left(\vec{\nabla}\times\overleftrightarrow{G}_e(\vec{r},\vec{r}')\right)=k^2\overleftrightarrow{G}_e(\vec{r},\vec{r}')+\overleftrightarrow{\delta}\delta^3(\vec{r}-\vec{r}') \tag{10}$$

(with $\overleftrightarrow{\delta}=\Sigma_i\hat{x}_i\hat{x}_i$) satisfying the condition $\vec{\nabla}\cdot\overleftrightarrow{G}_e=-(1/k^2)\vec{\nabla}\delta^3(\vec{r}-\vec{r}')$, can be used to write the integral equation

$$\vec{E}(\vec{r})=\int_S[\left(\vec{n}'\times\vec{E}\right)\cdot\vec{\nabla}'\times\overleftrightarrow{G}-ik\vec{B}\cdot\left(\vec{n}'\times\overleftrightarrow{G}_e\right)]dS' \tag{11}$$

which is defined on the same surface as previously. By imposing the dyadic Dirichlet condition $\vec{n}'\times\overleftrightarrow{G}_e=0$ on S, we can obtain the relation

$$\vec{E}(\vec{r})=\int_{\text{Aperture}}[(\vec{n}'\times\vec{E})\cdot\vec{\nabla}'\times\overleftrightarrow{G}_e]\text{d}S' \tag{12}$$

which depends only on the tangential electric field at the aperture. This is in perfect agreement with the equivalence principle and the uniqueness theorem.

Following Ref. 31, the total Green function $\overleftrightarrow{G}_e$ for the plane can be deduced from the "free" dyadic

$$\overleftrightarrow{G}_e^0(\vec{r},\vec{r}')=\left(\overleftrightarrow{\delta}+\frac{1}{k^2}\vec{\nabla}\vec{\nabla}\right)\frac{e^{ikR}}{4\pi R} \tag{13}$$

[with $R=\sqrt{(x-x')^2+(y-y')^2+(z-z')^2}$] by using the image method. We have

$$\overleftrightarrow{G}_e(\vec{r},\vec{r}')=\left(\overleftrightarrow{\delta}-\frac{1}{k^2}\vec{\nabla}\vec{\nabla}'\right)G_D(\vec{r},\vec{r}')+2\hat{z}\hat{z}\frac{e^{ikR'}}{4\pi R'}, \tag{14}$$

where $G_D=(e^{ikR}/R-e^{ikR'}/R')/4\pi$ is the scalar Dirichlet Green function for the plane screen, and $R'=\sqrt{(x-x')^2+(y-y')^2+(z+z')^2}$. Inserting this Green function into Eq. (12) gives us directly Eq. (4). It is interesting to observe that with the Green dyadic method, we can recover the formula of Smythe by using a magnetic current distribution located in front of a metallic plane or, equivalently, by using a double layer of magnetic currents propagating in the same direction.[13]

In theory, both approaches based either on the scalar Green functions or on the dyadic Green functions are equivalent. In practice however, the difficulties related to the Stratton Chu formula Eq. (3) have imposed the Green dyadic method. An illustration of this statement is that the dyadic formalism has been extensively used in the context of the electromagnetic theory of NSOM.[33–36]

IV. VECTORIAL JUSTIFICATION OF THE SMYTHE FORMULA

We propose now a justification of Eq. (4) based on the Stratton Chu formula Eq. (3). This derivation will directly reveal the equivalence of the scalar and dyadic approaches in the particular case of a planar screen with an aperture. Let the surface S of equation $z=0$ be an infinite, perfectly conducting metallic screen containing an aperture covering the surface δS. By the definition of diffraction, we can always separate the total electric (magnetic) field $\vec{E}$ ($\vec{E}$) into an incident field $\vec{E}^i$ ($\vec{B}^i$) existing independently of the presence of the screen, and into a diffracted field $\vec{E}'$ ($\vec{B}'$) produced by the surface charge and current densities $\rho_s',\vec{J}_s'$ located on the metal.

We have $\vec{B}'=\vec{\nabla}\times\vec{A}'$ and $\vec{E}'=-\vec{\nabla}\Phi'+ik\vec{A}'$ where potentials are expressed in a Lorentz gauge

$$\vec{A}'(\vec{r})=\int_{\text{Screen}}\text{d}S'\left[\frac{\vec{J}_s'}{c}(\vec{r}')\frac{e^{iKR}}{R}\right], \tag{15}$$

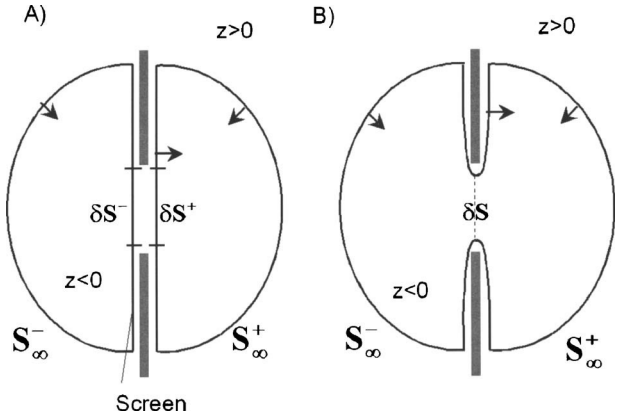

FIG. 2. The two surfaces of integration for the application of the vectorial Kirchhoff theorem.

$$\Phi'(\vec{r}) = \int_{\text{Screen}} dS' \left[\rho_s'(\vec{r}') \frac{e^{iKR}}{R} \right],$$

with $R = \|\vec{r} - \vec{r}'\|$ (we omit here the time dependent factor $e^{-i\omega t}$). Because these potentials are even functions of z we then have the following symmetries:

$$\begin{aligned} &E_x',\ E_y',\ B_z' \text{ are even in } z, \\ &E_z',\ B_x',\ B_y' \text{ are odd in } z. \end{aligned} \tag{16}$$

These symmetries already used by Jackson[16,17] imply in particular $E_z' = B_y' = B_x' = 0$ at the aperture. Therefore, the field is a discontinuous function through the metal.

Let us now consider an observation point **x** located in the half-space $z > 0$. We can apply the vectorial Green theorem on a closed integration surface made up of a half-sphere S_∞^+ "at infinity" and of the S^+ plane ($z = 0^+$) as seen in Fig. 2(A). This surface S^+ can itself be decomposed into an aperture region δS^+ and into a screen region $(S - \delta S)^+$.

We have then

$$\begin{aligned} \vec{E}'(\vec{x}) = &\int_{(S-\delta S)^+} [ik(\vec{n}' \times \vec{B}')G + (\vec{n}' \times \vec{E}') \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}')\vec{\nabla}' G] dS' + \int_{\delta S^+} [(\vec{n}' \times \vec{E}') \\ &\times \vec{\nabla}' G] dS' + \int_{S_\infty^+} [ik(\vec{n}' \times \vec{B}')G + (\vec{n}' \times \vec{E}') \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}')\vec{\nabla}' G] dS', \end{aligned} \tag{17}$$

where the unit vector $\vec{n}'$ lies on S^+ and is oriented in the positive z direction: $\vec{n}' = \hat{z}$. Similarly we can consider the surface of integration represented in Fig. 2(B). We obtain an integration on the S_∞^+, S_∞^- surfaces and on $(S - \delta S)^+$ and $(S - \delta S)^-$ surfaces. Such integration surfaces have already been used by Schwinger and Levine in the context of diffraction by a scalar wave.[18] Here, due to the symmetries given by Eq. (16), we deduce

$$\begin{aligned} \vec{E}'(\vec{x}) = 2&\int_{(S-\delta S)^+} [ik(\vec{n}' \times \vec{B}')G + (\vec{n}' \cdot \vec{E}')\vec{\nabla}' G] dS' + \int_{S_\infty^-} [ik(\vec{n}' \times \vec{B}')G + (\vec{n}' \times \vec{E}') \times \vec{\nabla}' G \\ &+ (\vec{n}' \cdot \vec{E}')\vec{\nabla}' G] dS' + \int_{S_\infty^+} [ik(\vec{n}' \times \vec{B}')G + (\vec{n}' \times \vec{E}') \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}')\vec{\nabla}' G] dS' \end{aligned} \tag{18}$$

with $\vec{n}' = \hat{z}$ on the $(S - \delta S)^+$ surface. After identification of Eq. (17) and (18), we obtain

$$\vec{E}'(\vec{x}) = 2\int_{S^+} [(\vec{n}' \times \vec{E}') \times \vec{\nabla}' G]\mathrm{d}S' - \int_{S_\infty^-} [ik(\vec{n}' \times \vec{B}')G + (\vec{n}' \times \vec{E}') \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}')\vec{\nabla}' G]\mathrm{d}S'$$

$$+ \int_{S_\infty^+} [ik(\vec{n}' \times \vec{B}')G + (\vec{n}' \times \vec{E}') \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}')\vec{\nabla}' G]\mathrm{d}S'. \tag{19}$$

In order to simplify this formula, it is important to note that the fields $\vec{E}'$, $\vec{B}'$ located on $S_\infty^\pm$ are the reflected fields $\vec{E}^r$, $\vec{B}^r$ which could be produced by the complete metallic screen $z=0$ submitted to the same incident field in the absence of the aperture.

Because this field compensates for the incident field for $z>0$, we have $\vec{E}^r=-\vec{E}^i$, $\vec{B}^r=-\vec{B}^i$ in this half-space. As a consequence, the integral on S_∞^+ in Eq. (19) can be written $-\vec{E}^i(\vec{x})$ $+\int_{S^+}[ik(\vec{n}' \times \vec{B}^i)G + (\vec{n}' \times \vec{E}^i) \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}^i)\vec{\nabla}' G]\mathrm{d}S'$, which is a direct application of the Green theorem for an observation point located on the closed surface composed of S_∞^+ and S^+.

Injecting this last result into Eq. (19) and after subtracting and adding $2\int_{S^+}[(\vec{n}' \times \vec{E}^i)$ $\times \vec{\nabla}' G]\mathrm{d}S'$, we finally obtain $\vec{E}'=\vec{E}^{(1)}+\vec{E}^{(2)}$ where

$$\vec{E}^{(1)}(\vec{x}) = 2\int_{S^+} [(\vec{n}' \times \vec{E}) \times \vec{\nabla}' G]\mathrm{d}S' - \vec{E}^i(\vec{x})\mathrm{d}S' \tag{20}$$

and

$$\vec{E}^{(2)}(\vec{x}) = -\int_{S_\infty^-} [ik(\vec{n}' \times \vec{B}^r)G + (\vec{n}' \times \vec{E}^r) \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}^r)\vec{\nabla}' G]\mathrm{d}S'$$

$$+ \int_{S^+} [ik(\vec{n}' \times \vec{B}^i)G - (\vec{n}' \times \vec{E}^i) \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}^i)\vec{\nabla}' G]\mathrm{d}S'. \tag{21}$$

Because of Eq. (16), we also have

$$E^r_{x,y}(x,y,z) = -E^i_{x,y}(x,y,-z),$$

$$B^r_z(x,y,z) = -B^i_z(x,y,-z),$$

and

$$\begin{aligned} B^r_{x,y}(x,y,z) &= B^i_{x,y}(x,y,-z), \\ E^r_z(x,y,z) &= E^i_z(x,y,-z) \end{aligned} \tag{22}$$

for $z<0$. Using the fact that the integral on S^+ can be written as an integral on S^-: $\int_{S^+}\{\vec{E}^i,\vec{B}^i\}$ $=-\int_{S^-}\{\vec{E}^i,\vec{B}^i\}$, and using Eq. (22), the last two integrals in Eq. (21) can be transformed into $\int_{S^-+S_\infty^-}[ik(\vec{n}' \times \vec{B}^r)G + (\vec{n}' \times \vec{E}^r) \times \vec{\nabla}' G + (\vec{n}' \cdot \vec{E}^r)\vec{\nabla}' G]\mathrm{d}S'$. Because the observation point is outside of the closed surface composed of S_∞^- and of S^-, $\vec{E}^{(2)}(\vec{x})$ is zero. Regrouping all terms, the total electric field in the half-plane $z>0$ is finally given by the Smythe formula

$$\vec{E}(\vec{x}) = 2\int_{\delta S^+} [(\vec{n}' \times \vec{E}) \times \vec{\nabla}' G]\mathrm{d}S' = \frac{1}{2\pi}\vec{\nabla} \times \left(\int_{\text{Aperture}} (\hat{z} \times \vec{E})\frac{e^{ikR}}{R}\mathrm{d}S' \right), \tag{23}$$

where we have applied Maxwell's boundary conditions that annihilate the tangential component of the total electric field on a perfect metal. An equivalent derivation in the $z<0$ half-space gives

$$\vec{E}(\vec{x}) = \vec{E}^0(\vec{x}) + 2\int_{\delta S^-} [(\vec{n}' \times \vec{E}) \times \vec{\nabla}' G] \mathrm{d}S' = \vec{E}^0(\vec{x}) - \frac{1}{2\pi}\vec{\nabla} \times \left(\int_{\text{Aperture}} (\hat{z} \times \vec{\nabla}) \frac{e^{ikR}}{R} \mathrm{d}S' \right), \tag{24}$$

where $\vec{E}^0 = \vec{E}^i + \vec{E}^r$ is now the total electric field existing in the $z<0$ domain for the problem without aperture.

V. CONSISTENCY BETWEEN VARIOUS APPROACHES

As written in the introduction, the proof given by Jackson[16] of the Smythe equation is connected to the theory of vectorial diffraction Eq. (3). In order to solve the problem, Jackson used a volume looking like a flat pancake limited by the two S^+ and S^- surfaces, and he applied Eq. (3) to this boundary. Then, in agreement with Smythe, Jackson imagined a double current sheet such that the surface current on the two S^+ and S^- layers at any point of a given area fitting the aperture are equal and opposite. With such a distribution, it is possible to reduce the integral of Eq. (3) to the one given by the formula of Smythe, Eq. (23). Such a formula is then the correct one to describe the diffraction problem by an aperture in agreement with the uniqueness theorem.

Our justification of the Smythe theorem is more direct because it uses only the Huygens Fresnel theorem without applying the intuitive trick of a virtual surface current distribution associated with a different physical situation (double layer of electric current, or layer of magnetic current confined to the aperture zone). Our result is in fact the direct generalization of a method used by the authors for a scalar wave ψ. Using two different surface integrations, as the ones used in this paper, we are indeed able to prove directly the Rayleigh-Sommerfeld theorem given by Eq. (2). This scalar reasoning, which is similar to the one presented before, is given in the Appendix. It can be observed that the scalar result makes only use of the Green function in vacuum G in order to justify the result obtained with the Dirichlet one G_D. Similarly, our derivation of the Smythe formula uses the scalar Green function in order to justify the result obtained with the "Dirichlet" dyadic Green function. Then, the two reasonings presented in this paper for an electromagnetic and a scalar wave show the primacy of the Huygens-Fresnel theorem given by Eq. (1) for the scalar wave and by Eq. (3) for the electromagnetic field, respectively.

A few further remarks here are relevant: First, the mathematical results described here constitute a justification of the physical "trick" introduced by Smythe and Jackson. However more work must be done in order to see if the method based on scalar Green functions could be extended to other geometries. Second, the Smythe formula allows one to express the electromagnetic field radiated by the aperture (far-field) as a function of the near-field existing in the aperture plane. This method could thus be useful for calculating the field generated by a NSOM aperture if we know the optical near-field (computed, for example, by using numerical methods discussed in Refs. 33–36).

VI. CONCLUSION

In this paper, we have justified the vectorial formula of Smythe expressing the diffracted field produced by an opening created in a perfectly metallic screen. Our justification is based only on the Huygens principle for electromagnetic wave and on the specifical nature of boundary conditions for the Maxwell field. This proof differs from the ones presented in the literature because it does not use the concept of current sheets introduced by Smythe and Jackson. The demonstration uses only the scalar Green function in free space and does not consider Dirichlet or Neumann boundary conditions as involved in the Green dyadic method.

APPENDIX

Let $\Psi(\vec{r})$ be a scalar wave solution of the Helmoltz equation for the problem of diffraction by an opening δS in a plane screen S. In order to define completely the problem, we must impose boundary conditions on the screen surface. Here, we choose $\Psi(\vec{r})|_{S-\delta S}=0$ for any point on the

screen (Dirichlet problem). The Neumann problem can be treated in a similar way. For such a problem, we can in principle always divide the field into an incident one, called $\Psi_{\text{inc}}(\vec{r})$ and existing independently of any screen, and into a scattered field $\Psi'(\vec{r})$, produced by sources in the screen. The problem cannot be solved without postulating some properties of the sources. A way to do this is to introduce a source term $J(\vec{r})$ in the second member of the Helmoltz equation such that this term goes to zero rapidly outside of the pancake volume occupied by the screen. Then, we have $[\nabla^2+k^2]\Psi(\vec{r})=-J(\vec{r})$. Imposing Sommerfeld's radiation condition at infinity gives us the solution

$$\Psi'(\vec{r}) = \int_{\text{pancake}} J(\vec{r}')G(\vec{r},\vec{r}')d^3\vec{r}'. \tag{A1}$$

We deduce the important fact that this potential $\Psi'(\vec{r})$ must be an even function of z. This is consistent with the Kirchhoff formula applied on the surface of Fig. 1(B). Imposing the condition $\Psi'(x,y,z)=\Psi'(x,y,-z)$ implies

$$\Psi(\vec{r}) = -\int_{(S-\delta S)} G(\vec{r},\vec{r}')\hat{z}\cdot\vec{\nabla}'\Psi'(\vec{r}')\mathrm{d}S' \tag{A2}$$

which defines the source term $J_S(x,y)$ (surface density) by $J_S(x,y)=-\lim_{z\to 0^+}\hat{z}\cdot\vec{\nabla}\Psi'(x,y,z)$. It is worth noting that the even character of Ψ' and the field continuity in the aperture impose $\hat{z}\cdot\vec{\nabla}\Psi'(x,y,z=0)$ in the opening. In order to complete the problem, we must define the reflected field $\Psi^r(\vec{r})$ produced by the sources when the plane screen contains no aperture. Since for $z>0$ there is no field, we must choose $\Psi^r(x,y,z)=-\Psi^i(x,y,z)$ in this half-plane. The requirement that the source field is an even function of z imposes $\Psi^r(x,y,z)=-\Psi^i(x,y,-z)$ for $z<0$. In this form, the problem is similar to the one described by Bouwkamp[10] and it can be solved. The rest of the reasoning is similar to the one given for the Smythe formula. Identifying the Kirchhoff integral on the two different surfaces represented in Figs. 2(A) and 2(B), we obtain

$$\Psi'(\vec{r}) = 2\int_{S^+}\Psi'(\vec{r}')\hat{z}\cdot\vec{\nabla}'G(\vec{r},\vec{r}')\mathrm{d}S' + \left(\int_{S_\infty^+} - \int_{S_\infty^-}\right)[\Psi'(\vec{r}')\vec{n}'\cdot\vec{\nabla}'G(\vec{r},\vec{r}') - G(\vec{r},\vec{r}')\vec{n}'\cdot\vec{\nabla}'\Psi'(\vec{r}')]\mathrm{d}S'. \tag{A3}$$

As for the Smythe formula, we can use the symmetry properties of the field as well as its asymptotic behavior at infinity to transform Eq. (A3) into

$$\Psi(\vec{r}) = 2\int_{\delta S^+}\Psi(\vec{r}')\hat{z}\cdot\vec{\nabla}'G(\vec{r},\vec{r}')\mathrm{d}S' \tag{A4}$$

which is equivalent to the Rayleigh-Sommerfeld result given by Eq. (2).

(Received 31 March 2006; accepted 2 June 2006; published online 24 July 2006)

We extend the work of Mello *et al.* based on Cabbibo and Ferrari concerning the description of electromagnetism with two gauge fields from a variational principle, i.e., an action. We provide a systematic independent derivation of the allowed actions that have only one magnetic and one electric physical field and are invariant under the discrete symmetries P and T. We conclude that neither the Lagrangian, nor the Hamiltonian, are invariant under the electromagnetic duality rotations. This agrees with the weak-strong coupling mixing characteristic of the duality due to the Dirac quantization condition providing a natural way to differentiate dual theories related by the duality rotations (the energy is not invariant). Also, the standard electromagnetic duality rotations considered in this work violate both P and T by inducing Hopf terms (theta terms) for each sector and a mixed Maxwell term. The canonical structure of the theory is briefly addressed and the magnetic gauge sector is interpreted as a ghost sector. © *2006 American Institute of Physics.*

I. INTRODUCTION AND DISCUSSION OF RESULTS

The seminal works of Dirac[1] introduced the famous charge quantization relation $eg=n$ that is obtained in the presence of both electric and magnetic poles (charges). The existence of both electric and magnetic charges raised the problem of a variational description of electromagnetism from an action that could actually contain explicitly both types of charges. Also, it is widely accepted that in order to achieve that goal one must consider a description in terms of gauge fields that minimally couple to both currents, so necessarily we need to consider the existence of two distinct gauge fields: A that couples to ordinary electric currents and C that couples to the magnetic current.[2–6] One possible approach first considered by Cabbibo and Ferrari[2] is to consider two physical gauge fields A and C. Although this approach preserves both time-space isotropy and Lorentz invariance has the drawback of the inexistence of experimental observable effects of the second gauge field. Another approach has been to consider mechanisms that, starting from a theory with two gauge fields, give us only one physical gauge field, either by considering solutions (constraints) for the second gauge field[3–6] (this approach has the drawback of not preserving space isotropy or not preserving Lorentz invariance) or by considering a very massive second gauge field.[7] Yet another very simple approach is to consider electromagnetism as an effective theory of an extended theory with two gauge fields such that one gauge field is fixed by the second gauge field obeying the equations of motion.[8] In Mello *et al.*,[9] for the first time an explicit action is built for electromagnetism with two gauge fields based on the work of Cabbibo and Ferrari.[2] In here we build a similar lower order action with two gauge fields A and C of the gauge group $U(1)\times U(1)$. In order to accomplish it, we take an independent approach of the original work[9] by studying in detail and systematically the desired properties of such an action. First, we note that

[a)]Electronic mail: pcastelo@catastropha.org

due to the different nature of A and C under the discrete symmetries of parity P and time inversion T,[10,11] standard electromagnetic duality[10,12] violates P and T symmetries. So it is desirable that under an electromagnetic duality transformation our action gains terms that explicitly violate these symmetries. This argument is not completely closed once there are ways of implementing duality rotations that preserve P and T symmetries.[13,14] Second, we demand that there is only one electric and one magnetic physical field. Implicitly this assumption means that the group charge flux of each of the $U(1)$'s is of the same nature of the topological flux of the other $U(1)$ group. The action suggested coincides (up to a sign choice) with the one of Ref. 9 and consists of two Maxwell terms with an opposite relative sign, one for each of the gauge fields and a topological cross Hopf term that mixes both gauge sectors allowing for the desired characteristics,

$$S^{\hat{\epsilon}}_{\mathrm{Max}\_} = -\int_M \left[\frac{\sqrt{-g}}{4e^2} F_{\mu\nu}F^{\mu\nu} - \frac{\sqrt{-g}}{4g^2} G_{\mu\nu}G^{\mu\nu} - \frac{\hat{\epsilon}}{4eg}\epsilon^{\mu\nu\rho\delta}F_{\mu\nu}G_{\rho\delta} + \frac{1}{e}(A_\mu - \hat{\epsilon}\tilde{C}_\mu)J^\mu_e - \frac{1}{g}(\hat{\epsilon}C_\mu + \tilde{A}_\mu)J^\mu_g \right],$$

with $\hat{\epsilon} = \pm 1$ corresponding to the two physical fields,

$$E^i = \frac{1}{e}F^{0i} - \frac{\hat{\epsilon}}{2g}\epsilon^{0ijk}G_{jk},$$

$$B^i = \frac{\hat{\epsilon}}{g}G^{0i} + \frac{1}{2e}\epsilon^{0ijk}F_{jk}.$$

However, the Maxwell terms of each of the gauge sectors have an opposite sign; this has no consequences at the classical level, but at the quantum level allows negative energy solutions that clearly violate causality. There are two approaches to overcome this problem. We can consider the C field to be a ghost; this means that upon quantization it has the opposite spin-statistics relations than the one of standard fields and therefore it has anticommutation relations,[15] such kinds of theories both with a matter and a ghost sector were introduced in cosmology by Linde.[16] Alternatively, we can consider some mechanism that allows for a classical treatment of the C field, as examples we have in cosmology the Phantom matter models,[17] and a dynamical symmetry breaking mechanism[8] that allows an effective electric description of the theory. Also compatible with this last mechanism, we can give a vacuum-expectation value to the C field that renders an effective Proca mass to the standard photon, the A field.[18,19]

II. ELECTROMAGNETIC DUALITY

The study of theories with two gauge fields were first considered by Cabbibo and Ferrari.[2] More recently, several studies addressed electromagnetic duality with two gauge fields, namely in Ref. 11 an explicit electromagnetic duality in terms of the gauge fields is presented. Here we review these results.

A. The original duality

The generalized Maxwell equations with both Electric and Magnetic currents[10] read as

$$\boldsymbol{\nabla}\cdot\mathbf{E} = \rho_e,$$

$$\boldsymbol{\nabla}\cdot\mathbf{B} = \rho_g,$$

$$\dot{\mathbf{B}} + \boldsymbol{\nabla}\times\mathbf{E} = -\mathbf{J}_g,$$

$$\dot{\mathbf{E}} - \boldsymbol{\nabla} \times \mathbf{B} = -\mathbf{J}_e. \tag{1}$$

This equation obeys the well known electromagnetic duality that rotates the electric and magnetic fields and currents,[12]

$$\mathbf{E} \to \cos(\theta)\mathbf{E} + \sin(\theta)\mathbf{B},$$

$$\mathbf{B} \to -\sin(\theta)\mathbf{E} + \cos(\theta)\mathbf{B},$$

$$J_e \to \cos(\theta)J_e + \sin(\theta)J_g,$$

$$J_g \to -\sin(\theta)J_e + \cos(\theta)J_g, \tag{2}$$

where $J=(\rho,\mathbf{J})$ stand for the four-vector current densities.

B. Duality with two gauge fields

In order to build an action for electromagnetism with magnetic monopoles it is necessary to consider two $U(1)$ gauge fields that minimally couple to the external electric and magnetic current densities. By introducing gauge fields one is led to the question whether the above duality can be extended to a duality of gauge fields instead of the electric and magnetic fields (i.e., the gauge field connections). By considering that both gauge fields have true physical degrees of freedom it is possible to elevate the duality to a transformation of those gauge fields, as has been shown in Ref. 11. In Ref. 11 the electric and magnetic fields are defined as

$$E^i = \frac{1}{2e}F^{0i} - \frac{1}{4g}\epsilon^{ijk}G_{jk},$$

$$B^i = \frac{1}{2g}G^{0i} + \frac{1}{4e}\epsilon^{ijk}F_{jk}, \tag{3}$$

where $F=dA$ and $G=dC$ are the gauge connections of the gauge fields A and C. In Sec. III B we will properly discuss the physical field definitions; for the time being we use these definitions, which can be found in the literature. The electromagnetic duality reads now as

$$\frac{1}{e}F^{0i} - \frac{1}{2g}\epsilon^{ijk}G_{jk} \to \cos(\theta)\left(\frac{1}{e}F^{0i} - \frac{1}{2g}\epsilon^{ijk}G_{jk}\right) + \sin(\theta)\left(\frac{1}{g}G^{0i} + \frac{1}{2e}\epsilon^{ijk}F_{jk}\right),$$

$$\frac{1}{g}G^{0i} + \frac{1}{2e}\epsilon^{ijk}F_{jk} \to -\sin(\theta)\left(\frac{1}{e}F^{0i} - \frac{1}{2g}\epsilon^{ijk}G_{jk}\right) + \cos(\theta)\left(\frac{1}{g}G^{0i} + \frac{1}{2e}\epsilon^{ijk}F_{jk}\right). \tag{4}$$

There are two ways to implement these transformations, either in terms of each of the $U(1)$ gauge sectors independently or mixing both gauge sectors. If we consider each sector independently, we obtain the standard electromagnetic transformations for each of the connections F and G,

$$F^{0i} \to \cos(\theta)F^{0i} + \sin(\theta)\frac{1}{2}\epsilon^{ijk}F_{jk},$$

$$F_{jk} \to \sin(\theta)\frac{1}{2}\epsilon_{ijk}F^{0i} + \cos(\theta)F_{jk},$$

$$G^{0i} \to \cos(\theta) G^{0i} + \sin(\theta) \frac{1}{2} \epsilon^{ijk} G_{jk},$$

$$G_{jk} \to \sin(\theta) \frac{1}{2} \epsilon^{ijk} G^{0i} + \cos(\theta) G_{jk}. \tag{5}$$

These transformations are not compatible with a transformation of the gauge fields because the $(0i)$ components transform differently from the components (ij).

If we consider mixing between both sectors, we can rewrite the electromagnetic duality in terms of the gauge fields or respective connections,[11]

$$F \to \cos(\theta) F + \sin(\theta) \frac{e}{g} G,$$

$$G \to -\sin(\theta) \frac{g}{e} F + \cos(\theta) G,$$

$$A \to \cos(\theta) A + \sin(\theta) \frac{e}{g} C,$$

$$C \to -\sin(\theta) \frac{g}{e} A + \cos(\theta) C. \tag{6}$$

There is a very simple argument to choose the second kind of duality (6) and exclude the possibility of the transformations (5). Let us consider the Lorentz gauge (or Lorentz condition) for both gauge fields $\partial_\mu A^\mu = \partial_\mu C^\mu = 0$ and assume regular gauge fields (meaning without discontinuities) such that the Bianchi identities are obeyed as $\epsilon^{\mu\nu\rho\delta} \partial_\nu \partial_\rho A_\delta = \epsilon^{\mu\nu\rho\delta} \partial_\nu \partial_\rho C_\delta = 0$. Then the Maxwell equations (1) read simply[11] as

$$\Delta A^\mu = J_e^\mu,$$

$$\Delta C^\mu = J_g^\mu, \tag{7}$$

where the Laplacian is $\Delta = \partial_\mu \partial^\mu$. Taking into account the duality transformations for the current densities expressed in (2), we conclude straight away that only (6) correctly transform the Maxwell equations for these particular *standard* conditions. Here, particular means that the gauge choice is not unique, we could have some other gauge fixing prescription and generally we can have discontinuities on the gauge fields such that the Bianchi identity is not obeyed everywhere. As an example, there are cases of the Dirac string[1] or equivalently the nontrivial fiber bundle of Wu and Yang.[20] However, regular gauge fields describe most of the physical applications and must therefore be a possible choice. There is, however, a serious problem concerning these equations; the two $U(1)$ gauge fields are completely decoupled and we obtain two different interactions corresponding to each of the gauge fields instead of only one, as in standard electromagnetism. Our main aim in the remainder of this work is how to obtain one only interaction described by two physical gauge fields.

So we have reviewed how to elevate electromagnetic duality of the Maxwell equations in terms of the electric and magnetic fields to a electromagnetic duality in terms of the gauge fields. Next, we will briefly describe how the discrete symmetries act on the several fields and how electromagnetic duality breaks parity and time inversion.

C. Discrete symmetries: *P* and *T* violation

We proceed to resume the known results for parity P and time inversion T for the electromagnetic physical quantities. The remaining discrete symmetry is Charge Conjugation C and plays no role in the following discussion.

Parity (P) stands for the inversion of spatial coordinates and time inversion (T) stands for the inversion of the time coordinate. Under these discrete symmetries the fields and current densities transform as[10]

$$
\begin{aligned}
&P: \quad x^i \to -x^i, \quad T: \quad t \to -t,\\
&E^i \to -E^i, \quad E^i \to +E^i,\\
&B^i \to +B^i, \quad B^i \to -B^i,\\
&\rho_e \to +\rho_e, \quad \rho_e \to +\rho_e,\\
&J_e^i \to -J_e^i, \quad J_e^i \to -J_e^i,\\
&\rho_g \to -\rho_g, \quad \rho_g \to -\rho_g,\\
&J_g^i \to +J_g, \quad J_g^i \to +J_g.
\end{aligned} \tag{8}
$$

Electric and magnetic fields transform differently under P and T being, respectively, vectors and pseudovectors. Accordingly, also the electric and magnetic currents have the same properties.[10] Then necessarily the gauge fields A and C also have to transform accordingly as vectors and pseudovectors.[11] The most straightforward way to show this is by considering an action for electromagnetism such that the electric and magnetic current densities are minimally coupled to the gauge fields A and C, respectively (we will return to this discussion later). Demanding invariance of the action under P and T imposes the gauge field C to transform as a pseudovector. We note that the field definitions (3) agree with these results. Then for the two gauge fields and respective gauge connections we have the discrete transformations

$$
\begin{aligned}
&P: \quad A^0 \to +A^0, \quad T: \quad A^0 \to +A^0,\\
&A^i \to -A^i, \quad A^i \to -A^i,\\
&C^0 \to -C^0, \quad C^0 \to -C^0,\\
&C^i \to +C^i, \quad C^i \to +C^i,\\
&F^{0i} \to -F^{0i}, \quad F^{0i} \to +F^{0i},\\
&F^{ij} \to +F^{ij}, \quad F^{ij} \to -F^{ij},\\
&G^{0i} \to +G^{0i}, \quad G^{0i} \to -G^{0i},\\
&G^{ij} \to -G^{ij}, \quad G^{ij} \to +G^{ij}.
\end{aligned} \tag{9}
$$

We want now to show that neither P nor T are maintained by the standard duality rotations (2) or equivalently (6). Here we consider duality as a global transformation independent of space-time

coordinates such that the angle θ is an exterior parameter to the theory used in the redefinition of the fields. Therefore it does not depend on the space-time coordinates and transform as a scalar with respect to the discrete symmetries P and T.

We can see explicitly that the duality transformations mix vector with pseudovectors such that

$$P: \quad \tilde{\mathbf{E}} = \cos(\theta)\mathbf{E} + \sin(\theta)\mathbf{B} \rightarrow -\cos(\theta)\mathbf{E} + \sin(\theta)\mathbf{B}$$

$$\tilde{\mathbf{B}} = -\sin(\theta)\mathbf{E} + \cos(\theta)\mathbf{B} \rightarrow \sin(\theta)\mathbf{E} + \cos(\theta)\mathbf{B}. \tag{10}$$

Clearly $\tilde{\mathbf{E}}$ and $\tilde{\mathbf{B}}$ are not transformed to $-\tilde{\mathbf{E}}$ and $\tilde{\mathbf{B}}$ under parity, as they should. The same argument follows for T:

$$T: \quad \tilde{\mathbf{E}} = \cos(\theta)\mathbf{E} + \sin(\theta)\mathbf{B} \rightarrow \cos(\theta)\mathbf{E} - \sin(\theta)\mathbf{B},$$

$$\tilde{\mathbf{B}} = -\sin(\theta)\mathbf{E} + \cos(\theta)\mathbf{B} \rightarrow -\sin(\theta)\mathbf{E} - \cos(\theta)\mathbf{B}, \tag{11}$$

and the redefined fields do not transform correctly under T. The current duality transformations (2) behave in the same way.

Charge conjugation C is not a space-time symmetry; it exchanges particles with antiparticles. At the classical level this is simply equivalent to change the sign of the current densities and it is preserved by electromagnetic duality.

So, to summarize, at the level of single fields, the electromagnetic duality preserves C, PT, and CPT while it violates P, T, CP, and CT.

The issue of P and T violation by the existence of dyons with both electric and magnetic charge can be found in Ref. 10. As for P and T, the violation by electromagnetic duality is discussed in Ref. 13. The argument is generic and applicable to the original duality transformations (2) independently of considering a gauge field description of electromagnetism. Also, we point out that upon redefinition of the fields one may as well redefine P and T, but in order to do so one would be changing the space-time interpretation of the discrete symmetries and necessarily redefining the action of the Lorentz group. This could be interpreted then as an extended duality of space-time. An alternative interesting construction is to consider θ to be a pseudoscalar;[13] in this way we manage to obtain a duality that preserves the discrete symmetries. Also, it is possible to gauge the duality by considering $\theta = \theta(x)$ to be an additional gauge parameter[14,21] [in this work the duality rotations constitute one further distinct $U(1)$ group].

Here we are considering θ to be a parameter exterior to the theory that transforms as a scalar, then, although the discrete symmetries violations are not explicit in the equations of motion, at the level of the action (a Lagrangian formulation of the theory) they will be explicit. As we will see in detail electromagnetic duality induces P and T violating terms.

In addition, we will demand that there is only one electric and one magnetic physical gauge fields. This requirement is going to reduce the allowed actions.

III. GAUGE SECTOR

In this section we will build a $U(1) \times U(1)$ gauge action such that the physical electric and magnetic fields are identified with the definitions (3). In order to do so, one expects that the group charge flux of each of the $U(1)$'s is coupled to the topological charge flux of the other $U(1)$. It is also desirable that a classical description of electromagnetism preserves both parity P and time inversion T (see, for instance Ref. 10 for a discussion on this topic). So, we are further demanding our action to be invariant under these discrete symmetries. In addition, and from the discussion on the last section, we expect that under an electromagnetic rotation our action explicitly gains terms that violate P and T. This will be the case.

A. Possible actions

Let us consider all the possible lower order terms that are Lorentz and gauge invariant. First, we list the lower order terms containing the gauge connections F and G that are invariant under P and T,

$$\mathcal{L}_{\text{Maxwell}_{FF}} = -\frac{1}{4e^2}F_{\mu\nu}F^{\mu\nu},$$

$$\mathcal{L}_{\text{Maxwell}_{GG}} = -\frac{1}{4g^2}G_{\mu\nu}G^{\mu\nu},$$

$$\mathcal{L}_{\text{Hopf}_{FG}} = -\frac{1}{4eg}\epsilon^{\mu\nu\rho\delta}F_{\mu\nu}G_{\rho\delta}. \tag{12}$$

The last term is a cross Hopf term (or theta term). To show that it is invariant let us rewrite the expression as $\mathcal{L}_{\text{Hopf}}=2\epsilon^{0ijk}(F_{0i}G_{jk}+G_{0i}F_{jk})$; then we see from (9) that F_{0i} and G_{0i} always transform in the same way as G_{jk} and F_{jk} (respectively) such that $\mathcal{L}_{\text{Hopf}_{FG}}$ is invariant under any of the discrete symmetries P and T.

The remaining possible lower order terms that are Lorentz and gauge invariant are not invariant under P and T. They are the cross Maxwell term and the usual Hopf (or theta) terms for each of the gauge sectors,

$$\mathcal{L}_{\text{Maxwell}_{FG}} = -\frac{1}{4eg}F_{\mu\nu}G^{\mu\nu},$$

$$\mathcal{L}_{\text{Hopf}_{FF}} = -\frac{1}{4e^2}\epsilon^{\mu\nu\rho\delta}F_{\mu\nu}F_{\rho\delta},$$

$$\mathcal{L}_{\text{Hopf}_{GG}} = -\frac{1}{4g^2}\epsilon^{\mu\nu\rho\delta}G_{\mu\nu}G_{\rho\delta}. \tag{13}$$

To show that they are not invariant under P and T, we note that, from Eq. (9), (F_{0i},F_{ij}) and (G_{0i},G_{ij}) transform in the opposite way under P and T such that the cross Maxwell term transforms as $\mathcal{L}_{\text{Maxwell}_{FG}}\rightarrow-\mathcal{L}_{\text{Maxwell}_{FG}}$. Concerning the Hopf terms, we note that F_{0i} and G_{0i} transform in the opposite way than F_{ij} and G_{ij} (respectively) under P and T such that $\mathcal{L}_{\text{Hopf}_{FF}}\rightarrow-\mathcal{L}_{\text{Hopf}_{FF}}$ and $\mathcal{L}_{\text{Hopf}_{GG}}\rightarrow-\mathcal{L}_{\text{Hopf}_{GG}}$. This is a known feature of such terms that have been extensively studied to explain the CP violation, both in Abelian and non-Abelian gauge theories (see, for instance Refs. 15 and 22 and references therein).

We have listed all the possible lower order candidate terms to build our action. We also need to study how these several candidate terms behave under electromagnetic duality:

$$\mathcal{L}_{\text{Maxwell}_{FF}} \rightarrow \cos^2(\theta)\mathcal{L}_{\text{Maxwell}_{FF}} + \sin^2(\theta)\mathcal{L}_{\text{Maxwell}_{GG}} + 2\cos(\theta)\sin(\theta)\mathcal{L}_{\text{Maxwell}_{FG}},$$

$$\mathcal{L}_{\text{Maxwell}_{GG}} \rightarrow \sin^2(\theta)\mathcal{L}_{\text{Maxwell}_{FF}} + \cos^2(\theta)\mathcal{L}_{\text{Maxwell}_{GG}} - 2\cos(\theta)\sin(\theta)\mathcal{L}_{\text{Maxwell}_{FG}},$$

$$\mathcal{L}_{\text{Hopf}_{FG}} \rightarrow \sin\theta\cos\theta(\mathcal{L}_{\text{Hopf}_{GG}} - \mathcal{L}_{\text{Hopf}_{FF}}) + (\cos^2\theta - \sin^2\theta)\mathcal{L}_{\text{Hopf}_{FG}},$$

$$\mathcal{L}_{\text{Maxwell}_{FG}} \rightarrow \sin\theta\cos\theta(\mathcal{L}_{\text{Maxwell}_{GG}} - \mathcal{L}_{\text{Maxwell}_{FF}}) + (\cos^2\theta - \sin^2\theta)\mathcal{L}_{\text{Maxwell}_{FG}},$$

$$\mathcal{L}_{\mathrm{Hopf}_{FF}} \to \cos^2(\theta)\mathcal{L}_{\mathrm{Hopf}_{FF}} + \sin^2(\theta)\mathcal{L}_{\mathrm{Hopf}_{GG}} + 2\cos(\theta)\sin(\theta)\mathcal{L}_{\mathrm{Hopf}_{FG}},$$

$$\mathcal{L}_{\mathrm{Hopf}_{GG}} \to \sin^2(\theta)\mathcal{L}_{\mathrm{Hopf}_{FF}} + \cos^2(\theta)\mathcal{L}_{\mathrm{Hopf}_{GG}} - 2\cos(\theta)\sin(\theta)\mathcal{L}_{\mathrm{Hopf}_{FG}}. \tag{14}$$

We are now ready to build an action that describes an electromagnetism with two gauge fields. Demanding the action to be P and T invariant, we are left only with the terms listed in (12). So we conclude that the most standard action that explicitly depends on two gauge fields must be a combination of $\mathcal{L}_{\mathrm{Maxwell}_{FF}}$ and $\mathcal{L}_{\mathrm{Maxwell}_{GG}}$. We will call this action the minimal action,[13,23,24]

$$S_{\mathrm{Min}_+} = -\int_M \sqrt{-g}\left[\frac{1}{4e^2}F_{\mu\nu}F^{\mu\nu} + \frac{1}{4g^2}G_{\mu\nu}G^{\mu\nu}\right], \tag{15}$$

$$S_{\mathrm{Min}_-} = -\int_M \sqrt{-g}\left[\frac{1}{4e^2}F_{\mu\nu}F^{\mu\nu} - \frac{1}{4g^2}G_{\mu\nu}G^{\mu\nu}\right]. \tag{16}$$

We note that from the electric and magnetic fields definition (3) both Maxwell terms must have the same numerical factor (up to the relative sign). The standard would be to consider both with the same sign in order to have the same quantum structure in both sectors, however, for completeness we consider both cases. These actions imply the existence of two electric and two magnetic fields as we will discuss in detail in Sec. III B. Instead, we expect to have only one electric and one magnetic field such that the group charge flux of one $U(1)$ is of the same nature of the flux of the topological charge of the other $U(1)$, as implied by the field definitions (3). As a *weaker* but valid argument, we note that the pure gauge sectors are completely decoupled, *a priori* one would expect that some sort of mixing (meaning coupling) between the two sectors exist that, at least, accomplishes the coupling of topological flux with group charge fluxes. We consider these argument as a drawback of the minimal actions.

From the above arguments we are further considering the remaining allowed term that preserves T and P, the cross Hopf term. We call these actions the maximal actions,

$$S^{\hat{\epsilon}}_{\mathrm{Max}_+} = -\int_M \left[\frac{\sqrt{-g}}{4e^2}F_{\mu\nu}F^{\mu\nu} + \frac{\sqrt{-g}}{4g^2}G_{\mu\nu}G^{\mu\nu} - \frac{\hat{\epsilon}}{4eg}\epsilon^{\mu\nu\rho\delta}F_{\mu\nu}G_{\rho\delta}\right], \tag{17}$$

$$S^{\hat{\epsilon}}_{\mathrm{Max}_-} = -\int_M \left[\frac{\sqrt{-g}}{4e^2}F_{\mu\nu}F^{\mu\nu} - \frac{\sqrt{-g}}{4g^2}G_{\mu\nu}G^{\mu\nu} - \frac{\hat{\epsilon}}{4eg}\epsilon^{\mu\nu\rho\delta}F_{\mu\nu}G_{\rho\delta}\right]. \tag{18}$$

The cross Hopf term couples the flux of the group charges (F^{0i} and G^{0i}) with the flux of the topological charge (G_{ij} and F_{ij}, respectively) of the two different $U(1)$'s. As we are going to show in Sec. III B, the only action that can be defined using only one electric and one magnetic field is $S^{\hat{\epsilon}}_{\mathrm{Max}_-}$, as given by (18). $\hat{\epsilon}=\pm 1$ sets the relative sign of the Hopf term and will be relevant in the definition of the physical fields, as we will show in detail.

We also note that when both Maxwell terms have the same sign the minimal action S_{Min_+}, as given by (15), is invariant under electromagnetic duality, so for an action of this form we have elevated the duality to a symmetry.[14,21] Also, the respective Hamiltonian will be duality invariant. However, this is not necessarily a good feature. As we already pointed out, the standard duality does not preserve either P or T, and this fact is not explicit on the action S_{Min_-}; neither can be on a duality invariant action. This argument is not completely close because one can consider the duality angle parameter θ to be a pseudoscalar.[13] However, another physical argument is that due to the Dirac quantization condition[1] ($eg=n$) we have that the A field obeys a weak coupling regime while the C field obeys a strong coupling regime. Then we expect that the energy (Hamiltonian) not to be conserved under a duality rotation. For these reasons a duality symmetric action does not look like a good choice. The remaining actions, the maximal actions (18) and (17) and

the minimal action (16), are not invariant under duality, but they are P and T invariant. Furthermore, a duality transformation does not preserve P and T invariance, as can explicitly be seen from (14). This is actually a good feature; duality explicitly breaks P and T at the level of the action, as expected from (10) and (11), and the respective Hamiltonians are not invariant under duality.

Finally, as we show in detail in the next subsection, only $S^{\hat{\epsilon}}_{\mathrm{Max\_}}$ is compatible with the existence of only one electric and one magnetic physical field.

B. Physical electric and magnetic fields

Due to the fact that a second gauge field C has been introduced, we now have twice the degrees of freedom than the usual electromagnetism. Accordingly, we expect to have as well a new interaction such that generally we have two *electric fields* and two *magnetic fields*. From a theoretical point of view this is standard; each of the gauge fields carry a different kind of interaction. Nevertheless, we are led to the question of whether both definitions are physical fields or not. Here we will show that for both the minimal actions (15) and (16) and the maximal action (17) we have indeed four physical fields (two electric and two magnetic), while for the maximal action (18) we have only two physical fields (one electric and one magnetic).

Let us consider the generic definitions of electric and magnetic fields corresponding to the gauge fields A and C,

$$E^i_A = \frac{1}{e}F^{0i}, \quad E^i_C = -\frac{1}{2g}\epsilon^{ijk}G_{jk},$$

$$B^i_A = \frac{1}{2e}\epsilon^{ijk}F_{jk}, \quad B^i_C = \frac{1}{g}G^{0i}. \tag{19}$$

We note that the definitions of electric and magnetic fields for C are reversed to the ones of the A field and for reasons that will become clear in the remainder of this section we consider a minus sign in the definition of $\mathbf{E_C}$. Both in order to define the electric and magnetic fields accordingly to (3) and to preserve the properties of the fields in relation to the discrete symmetries, i.e., the electric field is a vector and the magnetic field is a pseudovector. Then we take the following linear combinations of the above definitions (19):

$$E^i_+ = \frac{1}{2}(E^i_A + E^i_C) = +\frac{1}{2e}F^{0i} - \frac{1}{4g}\epsilon^{ijk}G_{jk},$$

$$B^i_+ = \frac{1}{2}(B^i_A + B^i_C) = +\frac{1}{2g}G^{0i} + \frac{1}{4e}\epsilon^{ijk}F_{jk},$$

$$E^i_- = \frac{1}{2}(E^i_A - E^i_C) = +\frac{1}{2e}F^{0i} + \frac{1}{4g}\epsilon^{ijk}G_{jk},$$

$$B^i_- = \frac{1}{2}(B^i_A - B^i_C) = -\frac{1}{2g}G^{0i} + \frac{1}{4e}\epsilon^{ijk}F_{jk}. \tag{20}$$

To consider these combinations is the approach of several authors that consider only $\mathbf{E}_+$ and $\mathbf{B}_+$ as physical fields.[11,23] As already explained in the Introduction, the main motivation is to achieve a generalized description of electromagnetism with both electric and magnetic particles.[2] Also, these combinations are used to implement an explicit electromagnetic duality between the two sectors in terms of two distinct gauge fields, as we explained in Sec. II.

For what follows we will need the identities

$$\frac{1}{2e^2}F^{0i}F_{0i}=\frac{1}{2}(E_+^i+E_-^i)(E_+^i+E_-^i)=\frac{1}{2}(+E_+^iE_+^i+E_-^iE_-^i+2E_+^iE_-^i),$$

$$\frac{1}{4e^2}F^{ij}F_{ij}=-\frac{1}{2}(B_+^i+B_-^i)(B_+^i+B_-^i)=\frac{1}{2}(-B_+^iB_+^i-B_-^iB_-^i-2B_+^iB_-^i),$$

$$\frac{1}{2g^2}G^{0i}G_{0i}=\frac{1}{2}(B_+^i-B_-^i)(B_+^i-B_-^i)=\frac{1}{2}(+B_+^iB_+^i+B_-^iB_-^i-2B_+^iB_-^i),$$

$$\frac{1}{4g^2}G^{ij}G_{ij}=-\frac{1}{2}(-E_+^i+E_-^i)(-E_+^i+E_-^i)=\frac{1}{2}(-E_+^iE_+^i-E_-^iE_-^i+2E_+^iE_-^i),$$

$$\frac{1}{2eg}\epsilon^{0ijk}F_{0i}G_{jk}=(E_+^i+E_-^i)(-E_+^i+E_-^i)=-E_+^iE_+^i+E_-^iE_-^i,$$

$$\frac{1}{2eg}\epsilon^{0ijk}G_{0i}F_{jk}=(B_+^i+B_-^i)(B_+^i-B_-^i)=+B_+^iB_+^i-B_-^iB_-^i, \tag{21}$$

where the minus sign and the factor of 2 in the second and fourth lines are due to the contraction of the indices of the antisymmetric tensor, i.e., $\epsilon^{0jki}\epsilon_{0jk}^{\ \ \ i'}=-2\delta^{ii'}$.

Let us consider both the minimal actions (15) and (16) and the maximal actions (17) and (18) and rewrite the respective Lagrangians in terms of the above combinations (20) using the identities (21). We obtain that

$$\mathcal{L}_{\mathrm{Min}_+}=-2(E_+^iE_-^i-B_+^iB_-^i),$$

$$\mathcal{L}_{\mathrm{Min}_-}=-(E_+^iE_+^i+E_-^iE_-^i-B_+^iB_+^i-B_-^iB_-^i),$$

$$\mathcal{L}^{\hat{\epsilon}}_{\mathrm{Max}_+}=-2(E_+^iE_-^i-B_+^iB_-^i)-\hat{\epsilon}(E_+^iE_+^i-E_-^iE_-^i-B_+^iB_+^i+B_-^iB_-^i),$$

$$\mathcal{L}^{\hat{\epsilon}}_{\mathrm{Max}_-}=-2(E_{\hat{\epsilon}}^iE_{\hat{\epsilon}}^i-B_{\hat{\epsilon}}^iB_{\hat{\epsilon}}^i). \tag{22}$$

Here we use the usual convention in classical electrodynamics;[10] we sum over repeated indices i that are considered always upstairs such that the metric is no longer explicit; because $E^i=-E_i$ we have that $\mathbf{E}^2=-E^iE_i=E^iE^i\geqslant 0$. The indices of the electric and magnetic fields correspond to $\pm$ depending, respectively, on what choice of $\hat{\epsilon}=\pm 1$ is taken.

We readily conclude that the only action that can be written in terms of only two fields ($\mathbf{E}_+$ and $\mathbf{B}_+$ for $\hat{\epsilon}=+1$ or $\mathbf{E}_-$ and $\mathbf{B}_-$ for $\hat{\epsilon}=-1$) is the maximal action (18). This is only possible if the cross Hopf term is present and the two Maxwell terms have opposite signs. We also note that the choice of $\hat{\epsilon}$ is relevant to the physical field definitions.

As a worm up for what follows, we can argue that, after our field redefinition (20), the form of the maximal Lagrangian $\mathcal{L}^{\hat{\epsilon}}_{\mathrm{Max}_-}$, as given in the last line of (22), is essentially the same as the one of standard electromagnetism, therefore we have a very strong indication that, for this Lagrangian, the physical fields are

$$E^i = \frac{1}{e}F^{0i} - \frac{\hat{\epsilon}}{2g}\epsilon^{0ijk}G_{jk},$$

$$B^i = \frac{\hat{\epsilon}}{g}G^{0i} + \frac{1}{2e}\epsilon^{0ijk}F_{jk}. \tag{23}$$

This is only possible for the maximal Lagrangian $\mathcal{L}^{\hat{\epsilon}}_{\mathrm{Max\_}}$.

To show that this is indeed the case, we will formalize this argument and analyze the four possible actions. Let us compute the equations of motion for the actions and check which fields appear in them. We will properly discuss how to couple each type of current density to both the gauge fields in the next section; for the moment being let us assume the standard minimal coupling,

$$S_{\mathrm{Sources,Min}_{\pm}} = -\frac{1}{e}\int A_\mu J_e^\mu \pm \frac{1}{g}\int C_\mu J_g^\mu, \tag{24}$$

where the $\pm$ correspond to the relative sign between the Maxwell terms.

For the minimal actions we have that the equations of motion are

$$\begin{cases} \frac{1}{e}\partial_\mu F^{\mu\nu} = J_e^\mu \\ \frac{1}{g}\partial_\mu G^{\mu\nu} = J_g^\mu \end{cases} \Leftrightarrow \begin{cases} \boldsymbol{\nabla}\cdot\mathbf{E}_A = \rho_e, \\ \boldsymbol{\nabla}\cdot\mathbf{B}_C = \rho_g, \\ \dot{\mathbf{B}}_C + \boldsymbol{\nabla}\times\mathbf{E}_C = -\mathbf{J}_g, \\ \dot{\mathbf{E}}_A - \boldsymbol{\nabla}\times\mathbf{B}_A = -\mathbf{J}_e. \end{cases} \tag{25}$$

The electric and magnetic equations are completely decoupled, and we have two electric and two magnetic fields. Also, in addition to this equation, we have the Bianchi identities for each gauge field. There is a way to couple both sectors by using nonhomogeneous Bianchi identities; for that consider nonregular gauge fields such that we have the respective Bianchi identities $dF = *\tilde{J}_g$ and $dG = *\tilde{J}_e$. Then by an appropriate combination of the equations of motion with the Bianchi identities we obtain $d(*F - G) = *J_e - *\tilde{J}_e$ and $d(F + *G) = *J_g + *\tilde{J}_g$ that correspond to the generalized Maxwell equations (1) with the current densities changed from $J_e \to J_e - \tilde{J}_e$ and $J_g \to J_g + \tilde{J}_g$. Here $*$ denotes the usual Hodge duality operation and we used form notation for compactness. There are two drawbacks for this approach: first the current densities are no longer the ones that minimally couple to the gauge fields at the level of the action and, second, the identification of the topological charge fluxes with the group charge fluxes of different gauge groups is imposed (by hand) not emerging naturally from the action. These problems are solved by using the maximal action with opposite signs for the Maxwell terms as given by (18).

In order to analyze the maximal action (18), we note that the above procedure of the redefinition of fields (20) and rewriting the Lagrangians in terms of the redefined fields (22) is equivalent to rewriting the Lagrangian in terms of the new 2-form *gauge connections*[13]

$$(\mathcal{F}^{\hat{\epsilon}}_{+})^{\mu\nu} = \frac{1}{2}(F + \hat{\epsilon} * G)^{(\mu\nu)} = \frac{1}{2e}F^{\mu\nu} + \frac{\hat{\epsilon}}{4g}\epsilon^{\mu\nu\rho\delta}G_{\rho\delta},$$

$$(\mathcal{F}^{\hat{\epsilon}}_{-})^{\mu\nu} = \frac{1}{2}(F - \hat{\epsilon} * G)^{(\mu\nu)} = \frac{1}{2e}F^{\mu\nu} - \frac{\hat{\epsilon}}{4g}\epsilon^{\mu\nu\rho\delta}G_{\rho\delta}, \tag{26}$$

or their Hodge duals

$$(\mathcal{G}_{+}^{\hat{\epsilon}})^{\mu\nu} = - * (\mathcal{F}_{-}^{\hat{\epsilon}})^{(\mu\nu)} = \frac{\hat{\epsilon}}{2g} G^{\mu\nu} + \frac{1}{4g} \epsilon^{\mu\nu\rho\delta} F_{\rho\delta},$$

$$(\mathcal{G}_{-}^{\hat{\epsilon}})^{\mu\nu} = - * (\mathcal{F}_{+}^{\hat{\epsilon}})^{(\mu\nu)} = \frac{\hat{\epsilon}}{2e} G^{\mu\nu} - \frac{1}{4g} \epsilon^{\mu\nu\rho\delta} F_{\rho\delta}. \tag{27}$$

Then the maximal Lagrangian (18) is rewritten in both equivalent expressions as

$$\mathcal{L}_{\mathrm{Max}_{-}}^{\hat{\epsilon}} = - (\mathcal{F}_{+}^{\hat{\epsilon}})^{\mu\nu} (\mathcal{F}_{+}^{\hat{\epsilon}})_{\mu\nu} = + (\mathcal{G}_{-}^{\hat{\epsilon}})^{\mu\nu} (\mathcal{G}_{-}^{\hat{\epsilon}})_{\mu\nu}, \tag{28}$$

where we used the Hodge duality property $**G=-G$ for 2-forms G in Lorentzian four dimensional (4D) manifolds. This is basically the reason why in (19) we defined $E_C^i = -\epsilon^{ijk} G^{jk}$ with a minus sign.[11,23] We note that these two ways of rewriting are algebraically equivalent. However, physically they have an important meaning, we can have both an electric and a magnetic description of the theory. This is seen in the equations of motion. Upon variation of the maximal action with respect to A and C, we obtain

$$\partial_\mu (\mathcal{F}_{+}^{\hat{\epsilon}})^{\mu\nu} = J_e^\nu,$$

$$\partial_\mu (\mathcal{G}_{-}^{\hat{\epsilon}})^{\mu\nu} = \hat{\epsilon} J_g^\nu, \tag{29}$$

which indeed correspond to the generalized Maxwell equations (1) and are expressed only in terms of the fields **E** and **B**, as given by (23). So these must be the physical fields! This is only possible for the maximal action. As for $\mathcal{L}_{\mathrm{Max}_{+}}^{\hat{\epsilon}}$ corresponding to the action (17), this construction is not possible; we obtain that

$$\mathcal{L}_{\mathrm{Max}_{+}}^{\hat{\epsilon}} = - \frac{1}{2} (\mathcal{F}_{+}^{\hat{\epsilon}})^{\mu\nu} (\mathcal{F}_{+}^{\hat{\epsilon}})_{\mu\nu} + \frac{1}{2} (\mathcal{F}_{-}^{\hat{\epsilon}})^{\mu\nu} (\mathcal{F}_{-}^{\hat{\epsilon}})_{\mu\nu} - (\mathcal{F}_{+}^{\hat{\epsilon}})^{\mu\nu} (\mathcal{F}_{-}^{\hat{\epsilon}})_{\mu\nu} \tag{30}$$

such that we need two distinct *gauge connections* in order to define it, hence, as expected, four physical fields.

One must be careful with the way we couple the source to both gauge fields depending on the choice of $\hat{\epsilon}$ due to the definitions of the physical fields and the current sign in the second line of (29). We will discuss this issue in detail in Sec. IV.

There is a subtlety here. The reader may by now be recalling the Bianchi identities (or homogeneity conditions for Abelian gauge fields) on the gauge connection and claiming that as usual for topological terms, the variation

$$\delta \mathcal{L}_{\mathrm{Hopf}_{FG}} = \frac{1}{2eg} \epsilon^{\mu\nu\delta\rho} (\partial_\nu G_{\delta\rho}\, \delta A_\mu + \partial_\nu F_{\delta\rho}\, \delta C_\mu) \tag{31}$$

should be always null and does not contribute to the equations of motion. This is true for regular fields, however, as already mentioned in the first section and in the analysis of the minimal actions, if nonregular gauge fields are allowed, then this contribution to the equations of motion is not null everywhere and must be taken into account, and (29) are actually the correct ones. By discontinuities we mean that $\partial_\mu \partial_\nu C \neq \partial_\nu \partial_\mu C$. Allowing for corrections to the Bianchi identities allows for the inclusion of magnetic charge in standard electromagnetism [with only one $U(1)$ gauge field] and is in the basis of the original construction that originates the Dirac string[1] or the equivalent nontrivial fiberbundle of Wu and Yang.[20] We present this argument only to show that algebraically (29) are correct, we do not need to *necessarily* have these discontinuities to describe both electric and magnetic charge as long as we work with two distinct gauge fields. However, we show in Ref. 8 that in order to have effective theories obtained from the maximal action only with one gauge field, we still have discontinuities, but the discontinuities will be present on the extra field (instead of the physical field of the effective theory as in Refs. 1 and 20).

An important result here is that for the maximal action the topological fluxes of one $U(1)$ are identified with the charge fluxes of the other $U(1)$ as desired for the existence of only one electric and one magnetic physical field. We must stress that this does not imply that we are constraining the fundamental fields A and C; we are maintaining the same degrees of freedom. We have four physical degrees of freedom (two for each of the gauge fields A and C) that are still maintained in the electric and magnetic fields (again two for each of the fields E and B). In standard electromagnetism with only one gauge field there is only two degrees of freedom. The interpretation in terms of the fields is quite interesting. For each of the $U(1)$ fields the two physical degrees of freedom correspond to the transverse modes while the longitudinal modes are not physical and do not constitute physical degrees of freedom. When combining the gauge connections as in (26) the degrees of freedom of the second gauge field C are combined with the degrees of freedom of the original gauge field A in such a way that they play the role of two Longitudinal modes of the gauge field A; simply, we have now two longitudinal modes instead of a single one, as is usual in theories with massive photons. These degrees of freedom constitute here physical degrees of freedom and are due to the inclusion of a second $U(1)$ gauge group.

Our discussion would not be complete without discussing the canonical variables. We do so next and also discuss briefly the expression for the Hamiltonians corresponding to the minimal and maximal actions.

C. Canonical variables and Hamiltonian formulation

The canonical momenta for the minimal actions (15) and (16) are

$$\pi^i_{A,\mathrm{Min}} = \frac{1}{e^2}F^{0i} = \frac{1}{e}E^i_A,$$

$$\pi^i_{C,\mathrm{Min}_\pm} = \pm\frac{1}{g^2}G^{0i} = \pm\frac{1}{g}B^i_C, \tag{32}$$

where the $\pm$ refers respectively to $\mathcal{L}_{\mathrm{Min}_+}$ (the $+$ sign) and $\mathcal{L}_{\mathrm{Min}_-}$ (the $-$ sign). This means that the canonical momenta are each of the $U(1)$ group charge fluxes. The Hamiltonian depends on both gauge sectors, but each of them are completely decoupled,

$$\mathcal{H}_{\mathrm{Min}_\pm} = \frac{1}{2}\left(e^2\pi^i_{A,\mathrm{Min}}\pi^i_{A,\mathrm{Min}} + \frac{1}{2e^2}F_{ij}F_{ij}\right) \pm \frac{1}{2}\left(g^2\pi^i_{C,\mathrm{Min}_\pm}\pi^i_{C,\mathrm{Min}_\pm} + \frac{1}{2g^2}G_{ij}G_{ij}\right), \tag{33}$$

such that the Hilbert space factorizes into states carrying charge fluxes of both gauge sectors. The topological charge fluxes are present only trough the potential $F_{ij}F_{ij}$ and $G_{ij}G_{ij}$, as in standard electromagnetism. So basically we have two distinct copies of standard electromagnetism and no interaction terms between the two sectors.

The canonical momenta for the maximal action (17) and (18) are

$$(\pi^{\hat{\epsilon}}_{A,\mathrm{Max}_\pm})^i = \frac{1}{e^2}F^{0i} \pm \frac{\epsilon}{2eg}\epsilon^{ijk}G_{jk} = +\frac{2}{e}E^i_{(\pm\hat{\epsilon})},$$

$$(\pi^{\hat{\epsilon}}_{C,\mathrm{Max}_\pm})^i = \pm\frac{1}{g^2}G^{0i} - \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}F_{jk} = -\frac{2\hat{\epsilon}}{g}B^i_\pm, \tag{34}$$

where the $\pm$ refers, respectively, to $\mathcal{L}_{\mathrm{Max}_+}$ (the $+$ sign) and $\mathcal{L}_{\mathrm{Max}_-}$ (the $-$ sign). In the electric field the subscript $(\pm\hat{\epsilon})$ means the product of ± 1 by $\hat{\epsilon}$. The canonical momenta coincide up to constants with the physical electric and magnetic fields, this is a good indication that, indeed, also at the quantum level, we can have the correct identifications between group charge and topological charge fluxes from the opposite $U(1)$'s.

After a straightforward computation, we obtain the following Hamiltonians:

$$\mathcal{H}^{\hat{\epsilon}}_{\mathrm{Max}_+} = +\frac{e^2}{2}\left(\pi^i_{A,\mathrm{Max}_+} + \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}G_{jk}\right)\left(\pi^i_{A,\mathrm{Max}_+} - \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}G_{jk}\right)$$
$$+\frac{g^2}{2}\left(\pi^i_{C,\mathrm{Max}_+} + \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}F_{jk}\right)\left(\pi^i_{C,\mathrm{Max}_+} - \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}F_{jk}\right)$$
$$+\frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}(\pi^i_{A,\mathrm{Max}_+}G_{jk} + \pi^i_{C,\mathrm{Max}_+}F_{jk}) - \frac{3}{4e^2}F_{ij}F_{ij} + \frac{5}{4g^2}G_{ij}G_{ij} \tag{35}$$

and

$$\mathcal{H}^{\hat{\epsilon}}_{\mathrm{Max}_-} = +\frac{e^2}{2}\left(\pi^i_{A,\mathrm{Max}_-} + \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}G_{jk}\right)\left(\pi^i_{A,\mathrm{Max}_-} - \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}G_{jk}\right)$$
$$-\frac{g^2}{2}\left(\pi^i_{C,\mathrm{Max}_-} + \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}F_{jk}\right)\left(\pi^i_{C,\mathrm{Max}_-} - \frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}F_{jk}\right)$$
$$+\frac{\hat{\epsilon}}{2eg}\epsilon^{ijk}(\pi^i_{A,\mathrm{Max}_-}G_{jk} - \pi^i_{C,\mathrm{Max}_-}F_{jk}) + \frac{5}{4e^2}F_{ij}F_{ij} - \frac{5}{4g^2}G_{ij}G_{ij}. \tag{36}$$

The first lines of both these equations are interpreted as usual with $a^i_+a^i_-$, where $a_\pm$ are creation and annihilation operators of electric excitations and the second lines correspond to $b^i_+b^i_-$, where $b_\pm$ are creation and annihilation operators of magnetic excitations. The third lines contain a generalized *angular momenta* term between the two gauge sectors and the potentials $F_{ij}F_{ij}$ and $G_{ij}G_{ij}$. We note that the potential terms have nonstandard factors and opposite signs in both Hamiltonians. In particular, the factors for the potentials in $\mathcal{H}^{\hat{\epsilon}}_{\mathrm{Max}_+}$, as given in (35), have different weights (i.e., besides, the opposite sign has different numerical factors independent of the coupling constants) while they have the same numerical weight for $\mathcal{H}^{\hat{\epsilon}}_{\mathrm{Max}_-}$, as given in (36). This is also a good indication that the Maximal action (18) is the correct one since there is no reason for the potentials $F_{ij}F_{ij}$ and $G_{ij}G_{ij}$ having different numerical weights (beside the coupling constants).

The Hilbert space is not generally factorizable, the states should only be factorizable for states that have null eigenvalues of the generalized angular momenta.

The main problem in quantizing this theory is that the $b^i_+b^i_-$ has the opposite sign (than the standard fields) and, using the usual commutation relations for the C field, makes the existence of negative energy states possible. In order to solve this issue the standard way out is to consider anticommutation relations for the C gauge sector.[15] In this case we are in the presence of a ghost field,[16] not a standard boson. An alternative approach is to consider some mechanism that allows us to quantize only the electric sector, as done in.[26] As such examples we have Phantom matter in cosmology,[17] where such fields are considered at classical level (i.e., we may consider them to be a collective field, meaning a statistical effective field) in inflationary models. Also, we can consider a dynamical symmetry breaking mechanism;[8] a possible application is considered in Refs. 18 and 19 as a way to generate a Proca mass for the usual photon.

We are not discussing any further the quantization procedure here.

IV. INCLUSION OF CURRENT DENSITIES

Here, we analyze in detail the current densities coupling to both the gauge fields for the Maximal action (18) and accordingly derive the Lorentz force with both gauge fields.

A. Current coupling terms

Concerning the inclusion of currents, let us consider the standard action,

$$S^{\hat{\epsilon}}_{\text{Sources,Max\_}} = -\int_M \left[\frac{1}{e}A_\mu J^\mu_e - \frac{\hat{\epsilon}}{g}C_\mu J^\mu_g\right], \tag{37}$$

where $\hat{\epsilon}$ correctly sets the current sign in the generalized Maxwell equations (29). This action is both P and T invariant but it is not invariant under electromagnetic duality rotation. Under a duality rotation we effectively couple each current density with both gauge fields obtaining violating terms.

From the discussion of the last section we concluded that the physical electric and magnetic fields are given by (23). So each of the currents need to couple in some way to both $U(1)$ gauge fields. The question is how to do it maintaining P and T symmetries and having the variation of the action with respect to space-time coordinates holding the Lorentz force defined in terms of the fields (3). We note that (37) is not enough since it holds that we would have two Lorentz forces, one for each $U(1)$ in terms of the decoupled fields as given in (19).

The way out is to consider the dual fields $\tilde{A}$ and $\tilde{C}$ defined in terms of the original gauge fields by the differential equations

$$\begin{cases} \tilde{F} = *F \\ \tilde{G} = *G \end{cases} \Leftrightarrow \begin{cases} d\tilde{A} = *dA \\ d\tilde{C} = *dC \end{cases}, \tag{38}$$

where again $*$ denotes the Hodge duality operation. We note that the dual fields have only longitudinal modes, so by dual we mean that we are exchanging transverse modes in A and C by longitudinal modes in $\tilde{A}$ and $\tilde{C}$. So the extra action for the current densities read as

$$S_{\text{Dual Sources,Max\_}} = +\int_M \left[\frac{\hat{\epsilon}}{g}\tilde{C}_\mu J^\mu_e + \frac{1}{e}\tilde{A}_\mu J^\mu_g\right]. \tag{39}$$

Both terms are P and T invariant because $\tilde{A}$ and $\tilde{C}$ are, respectively, a pseudovector and a vector due to (38). Again, the sign choice is not arbitrary, we already fixed it in order to obtain the correct Lorentz forces. Electromagnetic duality couples both current densities with both gauge fields $\tilde{A}$ and $\tilde{C}$ such that it induces P and T violating terms. For this action we indeed have that the group charges of each $U(1)$ (given by the J's) are coupled to the topological charges of the other $U(1)$ (in terms of $\tilde{A}$ and $\tilde{C}$). This is what is expressed in the definition of the dual fields as given by (38). Also, there are a couple of very important points we must address. These terms do not contribute to the equations of motion of the gauge fields. The reason is that due to (38) we exchange transverse with longitudinal modes in the definitions of $\tilde{A}$ and $\tilde{C}$ and that the current densities only carry transverse modes. Let us be more precise: the variation of a term $\tilde{A}_\mu X^\mu$ reads as

$$\frac{\delta\tilde{A}_\mu}{\delta A_\nu}X^\mu = \left(\frac{\delta\tilde{F}_{\alpha\beta}}{\delta\tilde{A}_\mu}\right)^{-1}\frac{\delta\tilde{F}_{\alpha\beta}}{\delta F_{\delta\rho}}\frac{\delta F_{\delta\rho}}{\delta A_\nu}X^\mu = 8\epsilon_\mu{}^\nu{}_\alpha{}^\beta(\partial_\alpha)^{-1}\,\partial_\beta X^\mu. \tag{40}$$

Now, considering the gauge invariance condition (continuity condition) for current densities $d*J=\partial_\mu J^\mu=0$, we obtain that the currents are given in terms of a regular antisymmetric 2-tensor ϕ (a 2-form) as

$$J^\mu = \epsilon^{\mu\delta\rho\lambda}\,\partial_\delta\phi_{\rho\lambda} + c^\mu, \tag{41}$$

where c_μ is a constant. This same result is already expressed in Refs. 25 and 26. We note that the above expression is obtained from the Hodge decomposition of the current densities $J=d\varphi + *\,d\phi+c$. Then, replacing this expression for $X=J$ in the above action variation (40), we have the

derivatives in μ and δ contracted with the antisymmetric tensor. Therefore we obtain a null variation. We note that although we may generally consider nonregular fields, we cannot consider nonregular current densities; the continuity equation for currents $\partial_\mu J^\mu=0$ is demanded everywhere for gauge invariance, while for the gauge fields F and G are gauge invariant independently of A and C being regular or not (as long as the gauge transformation parameter is regular and well understood). The second point to stress is that for regular gauge fields this term is a total derivative, however, for nonregular gauge fields it is not. So by admitting the existence of nonregular gauge fields, the term is present in the action and cannot be integrated to the boundary.

To clarify we give an explicit example. Let us rewrite the first term of the above expression (39) in terms of ϕ as given in (41) as

$$S_\phi=-\frac{\hat{\epsilon}}{g}\int_M G_{\mu\nu}\phi^{\mu\nu}, \tag{42}$$

being, as usual, $G_{\mu\nu}=\partial_\mu C_\nu-\partial_\nu C_\mu$. One can notice that for regular fields we would integrate by parts, obtaining $S_\phi=-\hat{\epsilon}/g\int_M C_\mu\,\partial_\nu\phi^{\mu\nu}=0$ because $\partial_\nu\phi^{\mu\nu}=0$. However, take as an example of a nonregular gauge field $C_1=H[x_2]$, and all the remaining components null, $C_0=C_2=C_3=0$. Here $H(x)$ is the Heaviside function (also known as a unit step function). Then the above action reads as

$$S_\phi=-\frac{\hat{\epsilon}}{g}\int_M \delta(x_2)\phi^{21}=-\frac{\hat{\epsilon}}{g}\int dt\,dx^1\,dx^3\,dx^4\,\phi^{21}\neq 0. \tag{43}$$

Clearly we are not allowed to integrate by parts for nonregular gauge fields. However, when computing the equations of motion for S_ϕ we obtain upon a functional derivation on C_μ the null contribution for the equations of motion $\partial_\nu\phi^{\mu\nu}=0$, as desired.

As a last remark, we note that adding a current carrying both electric and magnetic charges (corresponding to a dyon) we obtain an explicit P and T violation,

$$S_{\text{Mix Sources}}=-\int_M\left(\frac{1}{e}A_\mu-\frac{1}{g}C_\mu\right)J^\mu_{eg}. \tag{44}$$

This violation is independent of electromagnetic duality by the simple fact that J_{eg} must be a combination both of a vector and a pseudovector. So we are assuming that we have no dyons, meaning particles with both electric and magnetic charge. If they do exist then P and T are not valid symmetries.[10]

In the next subsection we derive the Lorentz force, checking that we actually have the usual expression but with the electric and magnetic fields defined as in (3).

B. Lorentz force and the physical fields

In order to derive the Lorentz force, consider the Lagrangian for a relativistic classical electron with charge $-e$ described by the current density $J^\mu_e=-e(1,\dot{\mathbf{x}})$,

$$\mathcal{L}_{\text{Lorentz-e}}=-m\gamma^{-1}-\left(\frac{1}{e}A_\mu-\frac{\hat{\epsilon}}{g}\tilde{C}_\mu\right)J^\mu_e, \tag{45}$$

where the first term accounts for the rest mass and, as usual, $\gamma^{-1}=\sqrt{1-\dot{x}^2}$. We have set $c=1$. Varying this action with respect to the coordinates x_i is equivalent to the Euler-Lagrange equations, and we obtain after a straightforward computation that

$$\frac{dp^i}{dt}=+e\left[\left(\frac{1}{e}F^{0i}-\frac{\hat{\epsilon}}{g}\tilde{G}^{0i}\right)+\dot{x}_j\left(\frac{1}{e}F^{ij}-\frac{\hat{\epsilon}}{g}\tilde{G}^{ij}\right)\right]=+e[E^i+\epsilon^{ijk}\dot{x}_jB_k], \tag{46}$$

where we used the definition of the dual fields $\tilde{G}$ as given in (38), and E^i and B_i are given by (23).

If instead we consider the Lagrangian for a relativistic classical magnetic monopole with charge $+g$ and current given by $J_g^\mu = +g(1, \dot{\mathbf{x}})$, we obtain

$$\mathcal{L}_{\text{Lorentz-g}} = -m\gamma^{-1} + \left(\frac{\hat{\epsilon}}{g}C_\mu + \frac{1}{e}\tilde{A}_\mu\right)J_g^\mu. \tag{47}$$

Then we obtain

$$\frac{dp^i}{dt} = +g\left[\left(\frac{\hat{\epsilon}}{g}G^{0i} + \frac{\hat{\epsilon}}{g}\tilde{F}^{0i}\right) + \dot{x}_j\left(\frac{\hat{\epsilon}}{g}G^{ij} + \frac{1}{e}\tilde{F}^{ij}\right)\right] = +g[B^i - \epsilon^{ijk}\dot{x}_j E_k], \tag{48}$$

where again we used the definition of the dual fields $\tilde{F}$ as given in (38), and E^i and B_i are given by (23). We note that here we considered a positive magnetic charge with rest energy positive; for that reason we obtain a plus sign in the definition of the Lorentz force.

We note that both Lorentz forces are duality invariant.[13]

We solve a physically significant extension of a classic problem in the theory of diffusion, namely the Ornstein-Uhlenbeck process [Ornstein and Uhlenbeck, Phys. Rev. **36**, 823 (1930)]. Our generalized Ornstein-Uhlenbeck systems include a force which depends upon the position of the particle, as well as upon time. They exhibit anomalous diffusion at short times, and non-Maxwellian velocity distributions in equilibrium. Two approaches are used. Some statistics are obtained from a closed-form expression for the propagator of the Fokker-Planck equation for the case where the particle is initially at rest. In the general case we use spectral decomposition of a Fokker-Planck equation, employing nonlinear creation and annihilation operators to generate the spectrum which consists of two staggered ladders. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2206878]

I. INTRODUCTION

This paper introduces a physically important extension of a classic problem in the theory of diffusion, namely the Ornstein-Uhlenbeck process.[1] Our results are obtained by spectral decomposition of a linear operator. The spectrum of this operator consists of two ladders of eigenvalues with, respectively, odd and even parity. The ladders of eigenvalues are staggered, that is the odd-even step is different from the even-odd step (see Fig. 1). The corresponding eigenfunctions are generated by a raising operator. A concise account of our work on these staggered ladder spectra appeared earlier.[2] In the following we show how the results summarized in Ref. 2 were obtained. We also derive new results, not included in our earlier report: a closed-form solution for example, and the generalization of our previous results to a continuous family of diffusion processes.

A. The Ornstein-Uhlenbeck process

Before we discuss our extension of the Ornstein-Uhlenbeck process, we describe its usual form.[1] This considers a particle of momentum p subjected to a rapidly fluctuating random force $f(t)$ and subject to a drag force $-\gamma p$, so that the equation of motion is

$$\dot{p} = -\gamma p + f(t). \tag{1}$$

The random force has statistics $\langle f(t)\rangle = 0$, $\langle f(t)f(t')\rangle = C(t-t')$ (angular brackets denote ensemble averages throughout). If the correlation time τ of $f(t)$ is sufficiently short ($\gamma\tau \ll 1$), the equation of motion may be approximated by a Langevin equation:

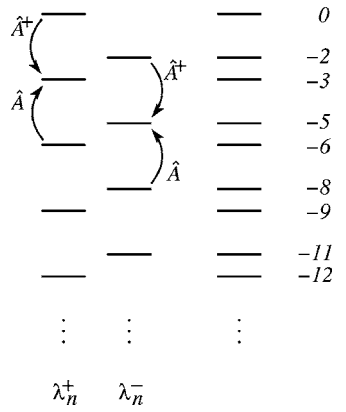

FIG. 1. The spectrum of $\hat{H}$ consists of two equally spaced (ladder) spectra λ_n^- and λ_n^+ which are "staggered" (that is, they are interleaved with uneven spacings). $\hat{A}$ and $\hat{A}^+$ do not change the parity of the eigenfunctions.

$$\mathrm{d}p = -\gamma p \mathrm{d}t + \mathrm{d}w, \tag{2}$$

where the Brownian increment $\mathrm{d}w$ has statistics $\langle \mathrm{d}w \rangle = 0$ and $\langle \mathrm{d}w^2 \rangle = 2D_0 \mathrm{d}t$. The diffusion constant is

$$D_0 = \frac{1}{2}\int_{-\infty}^{\infty} \mathrm{d}t \, \langle f(t) f(0) \rangle. \tag{3}$$

This problem is discussed in many textbooks (for example, Ref. 3).

B. Generalized Ornstein-Uhlenbeck processes

Our extension arises when the force depends upon position as well as time. We consider the case where the fluctuations of the force on the particle are mainly a consequence of the spatial, rather the temporal, fluctuations of the force $f(x,t)$. A consequence of this difference is that the impulse δw supplied to the particle in a short time δt depends upon the momentum of the particle. If the particle is at position x_0 at time t_0, this impulse is

$$\delta w = \int_{t_0}^{t_0+\delta t} \mathrm{d}t \, f(x_0 + p(t-t_0)/m, t) + O(\delta t^2). \tag{4}$$

In particular, the impulse approaches zero as the speed $|p|/m$ of the particle increases, because the motion of the particle effects an average over the spatial fluctuations of the force. This can be seen clearly by considering the second moment of δw. We assume that the force $f(x,t)$ has the following statistics:

$$\langle f(x,t) \rangle = 0, \quad \langle f(x,t) f(x',t') \rangle = C(x-x', t-t'). \tag{5}$$

The spatial and temporal correlation scales of the random force $f(x,t)$ are ξ and τ, respectively. We consider the case where (for most of the time) the momentum of the particle is large compared to $p_0 = m\xi/\tau$, then the force experienced by the particle decorrelates much more rapidly than the force experienced by a stationary particle. If δt is large compared to τ but small compared to $1/\gamma$, we can estimate the variance of the impulse $\langle \delta w^2 \rangle = 2D(p)\delta t$ as follows (due to translational invariance, we consider without loss of generality a particle which starts from position $x = 0$ at time $t = 0$):

$$\langle \delta w^2 \rangle = \int_0^{\delta t} \mathrm{d}t_1 \int_0^{\delta t} \mathrm{d}t_2 \, \langle f(pt_1/m,t_1) f(pt_2/m,t_2) \rangle = \delta t \int_{-\infty}^{\infty} \mathrm{d}t \; C(pt/m,t) + O(\tau^2). \tag{6}$$

We define the momentum diffusion constant by writing $\langle \delta w^2 \rangle = 2D(p)\,\delta t + O(\delta t^2)$, and find

$$D(p) = \frac{1}{2} \int_{-\infty}^{\infty} \mathrm{d}t \; C(pt/m,t). \tag{7}$$

When $p \ll p_0$ we recover $D(p) = D_0$. When $p \gg p_0$, we can approximate (7) to obtain

$$D(p) = \frac{D_1 p_0}{|p|} + O(p^{-2}), \quad D_1 = \frac{m}{2p_0} \int_{-\infty}^{\infty} \mathrm{d}X \; C(X,0). \tag{8}$$

When the force is the gradient of a potential $V(x,t)$ with a correlation function having continuous derivatives, we find that D_1 is zero. This case is discussed in Sec. VIII, where it is shown that $D(p) \sim |p|^{-3}$ provided the correlation function of $V(x,t)$ is sufficiently differentiable. Another variation, also discussed in Sec. VIII, arises when the correlation function of the force exhibits a discontinuity at $t=0$ [as when the potential $V(x,t)$ is itself generated by an Ornstein-Uhlenbeck process]. In this case $D(p) \sim |p|^{-2}$, and other exponents are also possible. We therefore consider a general situation where $D(p) \sim |p|^{-\zeta}$ and give exact results for the case

$$D(p) = D_\zeta (p_0/|p|)^\zeta \tag{9}$$

with $\zeta \geqslant 0$. We analyze the dynamics by solving a Fokker-Planck equation which determines the probability density for the Langevin process in which the momentum has diffusion constant given by (9). We discuss the form of this Fokker-Planck equation in Sec. II; the remainder of this introduction will set our work in context with earlier research on related topics.

C. Earlier work

The motion of a damped particle subjected to a force fluctuating in both space and time was first studied by Deutsch,[4] who addressed an entirely different aspect of the problem. Deutsch considered the case where the momentum of the particle remains small compared to p_0, and posed the question of whether particles aggregate. He discovered that there is a phase transition between coalescing and noncoalescing trajectories. (Two of the authors of the present paper subsequently solved Deutsch's one-dimensional model exactly,[5] and results for two and three spatial dimensions are discussed in Refs. 6 and 7). All of these papers only considered cases where $p \ll p_0$.

Sturrock[8] analyzed the motion of a particle subjected to a spatially varying force field without damping. He introduced the concept of a momentum diffusion constant which varies as a function of the momentum: that is, he considered the same problem as is addressed in the present paper, but in the limit of damping constant $\gamma = 0$. Subsequently Golubovic, Feng, and Zeng[9] identified the importance of the relation $D(p) \sim |p|^{-3}$ (in the case of a potential force), and discussed the nature of the Fokker-Planck equation and its solution in the case where $\gamma = 0$. It was argued that the particle exhibits anomalous diffusion and solution for the propagator of the Fokker-Planck equation with initial value $p = 0$ was proposed. Later Rosenbluth[10] pointed to an error in the evaluation of this propagator. The results of Refs. 8–10 were applied to the stochastic acceleration[11] of particles in plasmas, and subsequent contributions have concentrated on refining models for the calculation of $D(p)$ (see, for example, Refs. 12 and 13).

In the following we analyze the problem with the damping term, proportional to γ, included. Surprisingly, we find that this more general problem is more tractable: we are able, for example, to obtain precise results concerning the problems considered in Refs. 9 and 10 by taking, in our solutions, the limit $\gamma \to 0$.

There is a large literature devoted to the motion of particles advected in random velocity fields (corresponding to the large-γ limit of the model we study). In the case where the velocity field is independent of time, subdiffusive motion is typically found.[14,15] The advection of tracers in a

turbulent fluid is described by models with rapidly fluctuating velocity fields.[16] In our problem the inertia of the particles plays an important role. Particles suspended in a turbulent fluid can show surprising clustering properties when inertia effects are significant. These were first proposed by Maxey;[17] the current state of knowledge is summarized in Ref. 7. In cases where the random force results from motion of the surrounding fluid, it is not possible for the condition $p \gg p_0$ to be realized.[7]

Although our generalized Ornstein-Uhlenbeck process exhibits anomalous diffusion (at short times), this is not a result of power-law distributions that are built into the model. This distinguishes it from the anomalous diffusion of Levy flights or walks, reviewed in Ref. 18, which are a consequence of power-law distributions of the step lengths or waiting times for random jumps. Our model is thus distinct from the 'fractional Ornstein-Uhlenbeck process' described in Ref. 18.

Finally, we remark that a brief summary of many of the results of this paper has already been published.[2] The closed-form solution of Sec. III, the Wentzel-Kramers-Brillouin (WKB) analysis, and most of the results for general values of ζ were not discussed in Ref 2.

D. Description of our results and outline of this paper

In order to simplify the presentation, we describe in detail only our results for the case $\zeta=1$, corresponding to a generic random force. Corresponding expressions for general values of ζ are obtained using the same method, and we quote the most important results for general values of ζ in Sec. VIII at the end of the paper.

In Sec. II, the Fokker-Planck equation for the generalized Ornstein-Uhlenbeck processes is described. In Sec. III we briefly discuss a particular closed-form solution, which enables us to determine the steady state momentum distribution (which is non-Maxwellian) and some statistics, such as the time evolution of the variance of the momentum. The results of Sec. III are not sufficient to enable all statistics to be calculated, and in the general case we obtain statistics via a spectral decomposition of the Fokker-Planck equation. Section IV discusses this spectral decomposition. We transform the Fokker-Planck operator into a Hermitean operator and determine the eigenvalues and eigenvectors of this "Hamiltonian" operator by generating them using a new type of raising and lowering operators, which are nonlinear second-order differential operators. We show that the resulting spectrum is a ladder spectrum, consisting of separate ladders for the odd and even parity states. These are staggered: the odd-even separation differs from even-odd. Section V contains calculations of the matrix elements needed for computing correlation functions and expectation values. In Sec. VI we summarize our results on diffusion and anomalous diffusion for generic random forcing.

Section VII discusses a technical issue concerning our evaluation of the spectrum. When the index of the eigenvalue is large, it is possible to apply standard WKB approximation methods everywhere except in the vicinity of a singularity of the Hamiltonian. We show that the singularity introduces phase shifts which explain the staggered-ladder structure of the spectrum.

Finally, in Sec. VIII we explain in more detail how other values of ζ can arise and summarize our results for general ζ.

II. FOKKER-PLANCK EQUATIONS

We consider a particle with equations of motion

$$\dot{x} = p/m, \quad \dot{p} = -\gamma p + f(x,t) \tag{10}$$

where the force $f(x,t)$ is random, with statistics given by Eq. (5). In the limit as the correlation time τ of the force approaches zero, the equation of motion of the momentum may be approximated by a Langevin equation, (2), where the random increment $\mathrm{d}w$ has second moment $\langle \mathrm{d}w^2 \rangle = 2D(p)\mathrm{d}t$ with $D(p)$ given by (7). This Langevin equation for the stochastic evolution of $p(t)$ corresponds to a Fokker-Planck equation (generalized diffusion equation) for the probability density of the momentum, $P(p,t)$. Using standard results,[3] the Fokker-Planck equation is

$$\frac{\partial P}{\partial t} = -\frac{\partial}{\partial p}(v(p)P) + \frac{\partial^2}{\partial^2 p}(D(p)P), \tag{11}$$

where

$$v(p) = \frac{\langle \mathrm{d}p \rangle}{\mathrm{d}t}, \quad D(p) = \frac{\langle \mathrm{d}p^2 \rangle}{2\mathrm{d}t}. \tag{12}$$

Note that we can replace dp by dw in the expression for $D(p)$, because the neglected terms are of higher order in dt, and that $D(p)$ has already been obtained in Eq. (7). In order to determine the correct form of the Fokker-Planck equation it remains to determine $\langle \mathrm{d}p \rangle = -\gamma p\, \mathrm{d}t + \langle \mathrm{d}w \rangle$.

Expanding the impulse (4) about a reference trajectory $x(t) = pt/m$, and using the fact that $\langle f(x,t) \rangle = 0$, we obtain

$$\langle \delta w \rangle = \frac{1}{m} \int_0^{\delta t} \mathrm{d}t_1 \int_0^{t_1} \mathrm{d}t_2 \int_0^{t_2} \mathrm{d}t_3 \exp[-\gamma(t_2 - t_3)] \left\langle \frac{\partial f}{\partial x}(pt_1/m, t_1) f(pt_3/m, t_3) \right\rangle. \tag{13}$$

Note that throughout the three-dimensional region of integration, we have $0 \leqslant t_3 \leqslant t_2 \leqslant t_1 \leqslant \delta t$, and the short correlation time implies that the integrand is negligible unless $|t_1 - t_3| < \tau$. The integrand is therefore significant along a line rather than a surface, because t_2 must lie between t_1 and t_3. The integral is therefore $O(\delta t)$, rather than $O(\delta t^2)$ which would obtain if the integrand were significant on a surface. We replace the factor $\exp[-\gamma(t_2 - t_3)]$ by unity because $\gamma\tau \ll 1$, and the other factor is negligible when $|t_2 - t_3| > \tau$. The integral over t_2 then gives simply $t_1 - t_3$. Writing $t = t_1 - t_3$, in the limit $\gamma\tau \ll 1$, the result is therefore

$$\langle \delta w \rangle = \frac{\delta t}{2m} \int_{-\infty}^{\infty} \mathrm{d}t\, t \left\langle \frac{\partial f}{\partial x}(0,0) f(pt/m, t) \right\rangle = \delta t\, \frac{\mathrm{d}}{\mathrm{d}p} D(p). \tag{14}$$

This implies

$$v(p) = -\gamma p + \frac{\mathrm{d}}{\mathrm{d}p} D(p). \tag{15}$$

Rosenbluth[10] has pointed out that this relation can also be obtained as a consequence of applying the principle of detailed balance.

With (7) and (15), the following Fokker-Planck equation obtains:

$$\frac{\partial P}{\partial t} = \frac{\partial}{\partial p}\left(\gamma p + D(p) \frac{\partial}{\partial p} \right) P. \tag{16}$$

Sturrock[8] introduced a related Fokker-Planck equation (without the damping term) and also gave an expression for $D(p)$ analogous to Eq. (7).

In the following we discuss our solution of (16) with $D(p)$ given by Eq. (9), for the particular case of generic random forcing (corresponding to $\zeta = 1$). Results for other values of ζ are obtained in an analogous fashion. The general case is briefly described in Sec. VIII.

III. A PARTICULAR CLOSED-FORM SOLUTION

In this section we introduce a particular solution of the Fokker-Planck equation (16) with $D(p)$ given by (9). We restrict ourselves to the case of generic random forcing (corresponding to $\zeta = 1$):

$$\frac{\partial P}{\partial t} = \frac{\partial}{\partial p}\left(\gamma p + D_1 \frac{p_0}{|p|} \frac{\partial}{\partial p} \right) P. \tag{17}$$

Consider the distribution $P(p,t)$ of momentum p for particles initially at rest. It satisfies the initial condition $P(p,0)=\delta(p)$ where $\delta(p)$ is the Dirac δ-function. For this particular initial condition, we have found the following closed-form solution of (17):

$$P(p,t)=\frac{1}{2\Gamma(4/3)}\frac{\gamma^{1/3}}{[3p_0D_1(1-e^{-3\gamma t})]^{1/3}}\exp\left[-\frac{\gamma|p|^3}{3p_0D_1(1-e^{-3\gamma t})}\right]. \tag{18}$$

Equation (18) determines how the moments of momentum grow for a particle initially at rest:

$$\langle p^{2l}(t)\rangle=\left(\frac{3D_1p_0}{\gamma}\right)^{2/3}\frac{\Gamma((2l+1)/3)}{\Gamma(1/3)}(1-e^{-3\gamma t})^{2l/3} \tag{19}$$

for positive integers l. This result is consistent with the result obtained in Ref. 2 [Eq. (8) in that paper]. In the limit of small times (19) gives rise to anomalous diffusion

$$\langle p^{2l}(t)\rangle\sim t^{2l/3}. \tag{20}$$

At large times ($\gamma t\gg 1$), by contrast, we obtain a stationary non-Maxwellian momentum distribution

$$P_0(p)=\frac{1}{2\Gamma(4/3)}\frac{\gamma^{1/3}}{(3p_0D_1)^{1/3}}\exp[-\gamma|p|^3/(3p_0D_1)]. \tag{21}$$

The particular solution (18) generalizes in a natural way to other values of ζ.

However, in order to determine the momentum correlation function and the spatial diffusion properties, the particular solution (18) is not sufficient, the general solution for arbitrary initial condition is required. We have not been able to obtain the general solution to (16) in closed form. Therefore, we determine it using spectral decomposition: we construct the eigenvalues λ_n and eigenfunctions ψ_n of a Hermitian operator $\hat{H}$ corresponding to the Fokker-Planck equation (17). We identify raising and lowering operators $\hat{A}^+$ and $\hat{A}$ which map one eigenfunction to another with, respectively, two more or two fewer nodes. We use these to obtain the spectrum and eigenfunctions of $\hat{H}$ which in turn allow us to construct the propagator, expectation values, and correlation functions. This approach is described in Secs. IV and V.

IV. SPECTRAL DECOMPOSITION

Introducing dimensionless variables ($t'=\gamma t$ and $p=zp_0[D_1/(\gamma p_0^2)]^{1/3}$) we write (17) as

$$\frac{\partial P}{\partial t'}=\frac{\partial}{\partial z}\left(z+\frac{1}{|z|}\frac{\partial}{\partial z}\right)P\equiv\hat{F}P. \tag{22}$$

It is convenient to transform the Fokker-Planck operator $\hat{F}$ to a Hermitian form which we shall refer to as the Hamiltonian operator:

$$\hat{H}=P_0^{-1/2}\hat{F}P_0^{1/2}=\frac{1}{2}-\frac{|z|^3}{4}+\frac{\partial}{\partial z}\frac{1}{|z|}\frac{\partial}{\partial z}. \tag{23}$$

Here $P_0(z)\propto\exp(-|z|^3/3)$ is the stationary solution (21) satisfying $\hat{F}P_0=0$. We solve the diffusion problem by constructing the eigenfunctions of the Hamiltonian operator. In the following we make use of Dirac notation[19] of quantum mechanics to write the equations in a compact form and to emphasize their structure.

The eigenfunctions of the Fokker-Planck equation (16) are alternately even and odd functions, defined on the interval $(-\infty,\infty)$. The operator $\hat{H}$, describing the limiting case of this Fokker-Planck operator, is singular at $z=0$. We identify two eigenfunctions of $\hat{H}$ by inspection, $\psi_0^+(z)=\mathcal{C}_0^+\exp(-|z|^3/6)$ which has eigenvalue $\lambda_0^+=0$ and $\psi_0^-(z)=\mathcal{C}_0^-z|z|\exp(-|z|^3/6)$ with eigenvalue λ_0^-

$=-2$. These eigenfunctions are of even and odd parity, respectively (zero and one node, respectively). Our approach to determining the full spectrum is to define a raising operator $\hat{A}^+$ which maps any eigenfunction $\psi_n^{\pm}(z)$ to its successor with the same parity, $\psi_{n+1}^{\pm}(z)$, having two additional nodes.

A. Algebra of raising and lowering operators

We write

$$\hat{H} = \hat{a}^- |z|^{-1} \hat{a}^+. \tag{24}$$

Here $a^{\pm} = (\partial_z \pm z|z|/2)$. We introduce the operators

$$\hat{A} = \hat{a}^+ |z|^{-1} \hat{a}^+ \quad \text{and} \quad \hat{A}^+ = \hat{a}^- |z|^{-1} \hat{a}^- \tag{25}$$

as well as

$$\hat{G} = \hat{a}^+ |z|^{-1} \hat{a}^-. \tag{26}$$

Note that $\hat{A}^+$ is the Hermitian conjugate of $\hat{A}$. The commutator of $\hat{A}$ and $\hat{A}^+$ is

$$[\hat{A}, \hat{A}^+] = -3(\hat{H} + \hat{G}). \tag{27}$$

Note also that $\hat{H} - \hat{G} = \hat{I}$ (where $\hat{I}$ is the identity operator).

1. Eigenvalues

It can be verified that

$$[\hat{H}, \hat{A}] = 3\hat{A} \quad \text{and} \quad [\hat{H}, \hat{A}^+] = -3\hat{A}^+. \tag{28}$$

These expressions show that the action of $\hat{A}$ and $\hat{A}^+$ on any eigenfunction is to produce another eigenfunction with eigenvalue increased or decreased by three, or else to produce a function which is identically zero. The operator $\hat{A}^+$ adds two nodes, and repeated action of $\hat{A}^+$ on $\psi_0^+(z)$ and $\psi_0^-(z)$ therefore exhausts the set of eigenfunctions. Together with $\lambda_0^+ = 0$ and $\lambda_0^- = -2$ this establishes that the spectrum of $\hat{H}$ is (see Fig. 1)

$$\lambda_n^+ = -3n \quad \text{and} \quad \lambda_n^- = -3n - 2 \quad n = 0, \ldots, \infty. \tag{29}$$

2. Eigenfunctions

We represent the eigenfunctions by of $\hat{H}$ by kets $|\psi_n^-\rangle$ and $|\psi_n^+\rangle$. The actions of $\hat{A}$ and $\hat{A}^+$ are

$$\hat{A}^+ |\psi_n^{\pm}\rangle = C_{n+1}^{\pm} |\psi_{n+1}^{\pm}\rangle \quad \text{and} \quad \hat{A} |\psi_n^{\pm}\rangle = C_n^{\pm} |\psi_{n-1}^{\pm}\rangle. \tag{30}$$

The normalization factor C_{n+1}^- is determined as follows:

$$1 = \langle \psi_{n+1}^- | \psi_{n+1}^- \rangle = (C_{n+1}^-)^{-2} \langle \psi_n^- | \hat{A} \hat{A}^+ | \psi_n^- \rangle = (C_{n+1}^-)^{-2} \langle \psi_n^- | [\hat{A}, \hat{A}^+] + \hat{A}^+ \hat{A} | \psi_n^- \rangle. \tag{31}$$

It follows

$$(C_{n+1}^-)^2 = (3(-2\lambda_n^- + 1) + (C_n^-)^2). \tag{32}$$

By recursion we obtain

$$C_n^- = [3n(3n+2)]^{1/2}. \tag{33}$$

This determines the normalization of the states $(\hat{A}^+)^n|\psi_0^-\rangle$,

$$|\psi_n^-\rangle = N_n^-(\hat{A}^+)^n|\psi_0^-\rangle \tag{34}$$

with

$$N_n^- = \left(\prod_{k=1}^{n} 3k(3k+2)\right)^{-1/2} N_0^-. \tag{35}$$

For the positive-parity states we proceed in a similar fashion and obtain

$$C_n^+ = [3n(3n-2)]^{1/2}. \tag{36}$$

This implies

$$|\psi_n^+\rangle = N_n^+(\hat{A}^+)^n|\psi_0^+\rangle \tag{37}$$

with

$$N_n^+ = \left(\prod_{k=1}^{n} 3k(3k-2)\right)^{-1/2} N_0^+. \tag{38}$$

The operators $\hat{A}^+$ and $\hat{A}$ differ from the usual examples of raising and lowering operators in that they are of second order in $\mathrm{d}/\mathrm{d}z$, whereas other examples of raising and lowering operators are of first order in the derivative. The difference is associated with the fact that the spectrum is a staggered ladder: only states of the same parity have equal spacing, so that the raising and lowering operators must preserve the odd-even parity. This suggests replacing a first-order operator which increases the quantum number (total number of nodes) by one with a second-order operator which increases the quantum number by two, preserving parity.

There is an alternative approach to generating the eigenfunctions of $\hat{H}$. This equation falls into one of the classes considered in Ref. 20, and we have written down first-order operators which map one eigenfunction into another. However, these operators are themselves functions of the quantum number n, making the algebra cumbersome. The approach is briefly described in the next section.

B. Schrödinger factorization

Consider the eigenvalue problem

$$\hat{H}|\psi\rangle = \lambda|\psi\rangle \tag{39}$$

with Hamiltonian (23). For $z>0$ it can be transformed by the variable change $x=z^3$:

$$\left[(3x)^2\frac{\mathrm{d}^2}{\mathrm{d}x^2} + 3x\frac{\mathrm{d}}{\mathrm{d}x} - x\left(\frac{1}{4}x + \lambda - \frac{1}{2}\right)\right]\psi(x) = 0. \tag{40}$$

Equation (40) is a Fuchsian linear differential equation with regular singular points of rank less than or equal to two. Equation (40) can therefore be factorized using a generalized Schrödinger factorization scheme (see Ref. 20 for a review of this method).

Applying this scheme we have obtained raising and lowering operators generating the spectrum (29). The raising operator acting on $\psi_n^\pm$ is given by

$$T_{\pm,n+1} = -3x\frac{\mathrm{d}}{\mathrm{d}x} + \frac{x}{2} - 3(n+\delta_\pm) \tag{41}$$

with $\delta_+ = 1/3$ and $\delta_- = 1$. The lowering operator acting on $\psi_n^\pm$ is

$$\tilde{T}_{\pm,n} = -3x\frac{\mathrm{d}}{\mathrm{d}x} - \frac{1}{2}x + 3(n+\eta_\pm) \tag{42}$$

with $\eta_+ = 0$ and $\eta_- = 2/3$. Note that the Hermitian conjugates of $T_{\pm,n+1}$ and $\tilde{T}_{\pm,n}$ are

$$(T_{\pm,n+1})^+ = -\tilde{T}_{\pm,n+1} + 3, \tag{43}$$

$$(\tilde{T}_{\pm,n})^+ = -T_{\pm,n} + 3. \tag{44}$$

The raising and lowering operators satisfy

$$T_{\pm,n+1}|\psi_n^\pm\rangle = C_{n+1}^\pm|\psi_{n+1}^\pm\rangle \quad \text{and} \quad \tilde{T}_{\pm,n}|\psi_n^\pm\rangle = C_n^\pm|\psi_{n-1}^\pm\rangle \tag{45}$$

with $C_n^\pm$ given by (33) and (36), generating the spectrum (29). The operators differ from $\hat{A}$ and $\hat{A}^+$ introduced in Sec. IV in that they are of first order in $\mathrm{d}/\mathrm{d}x$, and in that they depend on the state they are applied to.

V. CORRELATION FUNCTIONS AND MATRIX ELEMENTS

A. Correlation functions

The required solutions of the Fokker-Planck equation may be expressed in terms of the propagator $K(y,z,t)$ which is the probability density for the scaled momentum to reach z after time t, starting from y. It satisfies the Fokker-Planck equation $\partial_{t'}K = \hat{F}K$ and can be expressed in terms of the eigenvalues λ_n^σ and eigenfunctions $\phi_n^\sigma(z) = P_0^{-1/2}(z)\psi_n^\sigma(z)$ of $\hat{F}$:

$$K(y,z;t') = \sum_{n\sigma} a_n^\sigma(y)\phi_n^\sigma(z)\exp(\lambda_n^\sigma t') \tag{46}$$

for $t' > 0$. The expansion coefficients $a_n^\sigma(y)$ are determined by the initial condition $K(y,z;0) = \delta(z-y)$, namely $a_n^\sigma(y) = P_0^{-1/2}\psi_n^\sigma(y)$. In terms of the eigenfunctions of $\hat{H}$ we have (for $t' > 0$)

$$K(y,z;t') = \sum_{n\sigma} P_0^{-1/2}(y)\psi_n^\sigma(y)P_0^{1/2}(z)\psi_n^\sigma(z)\exp(\lambda_n^\sigma t'). \tag{47}$$

Equilibrium correlation functions of an observable $O(z)$ are given by

$$\langle O(z_0)O(z_{t'})\rangle_{\mathrm{eq.}} = \int_{-\infty}^{\infty}\mathrm{d}z\int_{-\infty}^{\infty}\mathrm{d}y\, O(z)O(y)K(y,z;t')P_0(y). \tag{48}$$

Since $P_0^{1/2}(y) = \psi_0^+(y)$ this corresponds to

$$\langle O(z_0)O(z_{t'})\rangle_{\mathrm{eq.}} = \sum_{n\sigma}|\langle\psi_0^+|\hat{O}|\psi_n^\sigma\rangle|^2\exp(\lambda_n^\sigma t') \tag{49}$$

for $t' > 0$. The momentum correlation function in equilibrium, for instance, is

$$\langle p_{t'}p_0\rangle_{\mathrm{eq.}} = p_0^2\left(\frac{D_1}{\gamma p_0^2}\right)^{2/3}\sum_n\langle\psi_0^+|\hat{z}|\psi_n^-\rangle^2\exp(\lambda_n^- t') \tag{50}$$

for $t' > 0$, which requires the evaluation of matrix elements $\langle\psi_0^+|\hat{z}|\psi_n^-\rangle$.

Consider on the other hand the time-dependence of $\langle x^2(t)\rangle$, with particles initially at rest at the origin. We need to evaluate

$$\langle x^2(t)\rangle = \frac{1}{m^2}\int_0^t \mathrm{d}t_1 \int_0^t \mathrm{d}t_2 \,\langle p_{t_1} p_{t_2}\rangle. \tag{51}$$

In dimensionless variables this corresponds to

$$\langle x^2(t)\rangle = \frac{1}{\gamma^2}\left(\frac{p_0 D_1}{\gamma}\right)^{2/3} \frac{1}{m^2}\int_0^{t'} \mathrm{d}t_1' \int_0^{t'} \mathrm{d}t_2' \,\langle z_{t_1'} z_{t_2'}\rangle. \tag{52}$$

The required correlation function is (assuming $t_2' > t_1' > 0$)

$$\begin{aligned}\langle z_{t_2'} z_{t_1'}\rangle &= \int_{-\infty}^{\infty} \mathrm{d}z_1 \int_{-\infty}^{\infty} \mathrm{d}z_2 \, z_1 z_2 K(z_1, z_2; t_2' - t_1') K(0, z_1; t_1') \\ &= \sum_{n,m} \frac{\psi_m^+(0)}{\psi_0^+(0)} \langle \psi_0^+ | \hat{z} | \psi_n^- \rangle \langle \psi_n^- | \hat{z} | \psi_m^+ \rangle \exp[\lambda_n^-(t_2' - t_1') + \lambda_m^+ t_1'].\end{aligned} \tag{53}$$

In order to evaluate (53), the ratios of wave-function amplitudes $\psi_m^+(0)/\psi_0^+(0)$ are required in addition to matrix elements of $\hat{z}$. The matrix elements $\langle \psi_n^- | \hat{z} | \psi_m^+ \rangle$ are determined in Sec. V B, while the ratios of eigenfunctions are calculated in Sec. V C.

B. Matrix elements $\langle \psi_m^+ | \hat{z} | \psi_n^- \rangle$

To evaluate the matrix elements $Z_{mn} = \langle \psi_m^+ | \hat{z} | \psi_n^- \rangle$ we proceed in three steps: we first evaluate Z_{0n}, in a second step the matrix elements Z_{mn} are related to $Z_{0,n-m}$ for $m \leqslant n$. Third, Z_{mn} is evaluated for $m > n$.

1. Matrix elements $\langle \psi_0^+ | \hat{z} | \psi_n^- \rangle$

Consider first $Z_{0n} = \langle \psi_0^+ | \hat{z} | \psi_n^- \rangle$. These matrix elements are obtained by recursion. To evaluate

$$Z_{0,n+1} = \langle \psi_0^+ | \hat{z} \hat{A}^+ | \psi_n^- \rangle / C_{n+1}^- \tag{54}$$

we write $\hat{z}\hat{A}^+ = \hat{z}\hat{G} + \hat{z}(\hat{A}^+ - \hat{G}) = \hat{z}(\hat{H} - \hat{I}) + \hat{z}(\hat{A}^+ - \hat{G})$. It follows

$$\langle \psi_0^+ | \hat{z} \hat{A}^+ | \psi_n^- \rangle = (\lambda_n^- - 1) Z_{0n} + \langle \psi_0^+ | \hat{z}(\hat{A}^+ - \hat{G}) | \psi_n^- \rangle. \tag{55}$$

Using $(\hat{A}^+ - \hat{G}) = -\hat{z}\hat{a}^-$ and $[\hat{z}^2, \hat{a}^-] = -2\hat{z}$ we obtain

$$\langle \psi_0^+ | \hat{z} \hat{A}^+ | \psi_n^- \rangle = (\lambda_n^- + 1) Z_{0n}. \tag{56}$$

This corresponds to the recursion

$$Z_{0n} = (-1)^n \frac{\prod_{k=0}^{n-1} (3k+1)}{\sqrt{\prod_{k=0}^{n-1} 3(k+1)(3k+5)}} Z_{00}. \tag{57}$$

With $Z_{00} = 3^{-5/12}\sqrt{\pi}/\Gamma(2/3)$ (found by direct evaluation of an integral) we obtain

$$Z_{0n} = (-1)^n \frac{3^{-5/12}}{\sqrt{2\pi}} \sqrt{\Gamma(2/3)} \frac{\Gamma(n + 1/3)}{\sqrt{\Gamma(n+1)\Gamma(n+5/3)}}. \tag{58}$$

2. Matrix elements $\langle\psi_m^+|\hat{z}|\psi_n^-\rangle$ for $m\leqslant n$

Consider now the case $m\leqslant n$. Let

$$J_{mn}=\langle\psi_0^+|\hat{A}^m\hat{z}(\hat{A}^+)^n|\psi_0^-\rangle=\langle\psi_0^+|\hat{A}^m[\hat{z},\hat{A}^+](\hat{A}^+)^{n-1}|\psi_0^-\rangle+\langle\psi_0^+|\hat{A}^m\hat{A}^+\hat{z}(\hat{A}^+)^{n-1}|\psi_0^-\rangle.$$

We use $[\hat{z},\hat{A}^+]=-(|\hat{z}|^{-1}\hat{a}^-+\hat{a}^-|\hat{z}|^{-1})$ to write

$$\begin{aligned}J_{mn}&=-\langle\psi_0^+|\hat{A}^m|\hat{z}|^{-1}\hat{a}^-(\hat{A}^+)^{n-1}|\psi_0^-\rangle-\langle\psi_0^+|\hat{A}^m\hat{a}^-|\hat{z}|^{-1}(\hat{A}^+)^{n-1}|\psi_0^-\rangle+\langle\psi_0^+|\hat{A}^m\hat{A}^+\hat{z}(\hat{A}^+)^{n-1}|\psi_0^-\rangle\\&=J_{mn}^{(1)}+J_{mn}^{(2)}+J_{mn}^{(3)}\end{aligned}\tag{59}$$

and evaluate the three terms separately. The third one gives

$$J_{mn}^{(3)}=\langle\psi_0^+|\hat{A}^m\hat{A}^+\hat{z}(\hat{A}^+)^{n-1}|\psi_0^-\rangle=(C_m^+)^2\langle\psi_0^+|\hat{A}^{m-1}\hat{z}(\hat{A}^+)^{n-1}|\psi_0^-\rangle=(C_m^+)^2J_{m-1n-1}.\tag{60}$$

Consider next the first term: $\hat{A}^m|\hat{z}|^{-1}\hat{a}^-(\hat{A}^+)^{n-1}=\hat{A}^{m-1}\hat{a}^+|\hat{z}|^{-1}\hat{a}^+|\hat{z}|^{-1}\hat{a}^-(\hat{A}^+)^{n-1}=\hat{A}^{m-1}\hat{a}^+|\hat{z}|^{-1}\hat{G}(\hat{A}^+)^{n-1}$, and thus

$$\langle\psi_0^+|\hat{A}^m|\hat{z}|^{-1}\hat{a}^-(\hat{A}^+)^{n-1}|\psi_0^-\rangle=(\lambda_{n-1}^--1)\langle\psi_0^+|\hat{A}^{m-1}\hat{a}^+|\hat{z}|^{-1}(\hat{A}^+)^{n-1}|\psi_0^-\rangle.\tag{61}$$

Using $\hat{A}^{m-1}\hat{a}^+|\hat{z}|^{-1}(\hat{A}^+)^{n-1}=\hat{A}^{m-1}\hat{a}^+|\hat{z}|^{-1}\hat{a}^-|\hat{z}|^{-1}\hat{a}^-(\hat{A}^+)^{n-2}=\hat{A}^{m-1}\hat{G}|\hat{z}|^{-1}\hat{a}^-\hat{A}^{+n-2}$ we obtain the recursion

$$J_{mn}^{(1)}=(\lambda_{n-1}^--1)(\lambda_{m-1}^+-1)J_{m-1n-1}^{(1)}=3n(3m-2)J_{m-1n-1}^{(1)}.\tag{62}$$

Now consider $J_{mn}^{(2)}$. Using $\hat{a}^-|\hat{z}|^{-1}(\hat{A}^+)^{n-1}=\hat{A}^+|\hat{z}|^{-1}\hat{a}^-\hat{A}^{+n-2}$ it follows

$$J_{mn}^{(2)}=(C_m^+)^2J_{m-1n-1}^{(1)}.\tag{63}$$

This implies

$$J_{mn}^{(2)}=\frac{(C_m^+)^2}{(\lambda_{n-1}^--1)(\lambda_{m-1}^+-1)}J_{mn}^{(1)}=\frac{m}{n}J_{mn}^{(1)}.\tag{64}$$

Note also that $J_{0n}^{(3)}=0$, as well as $J_{0n}^{(2)}=0$. This gives $J_{0n}^{(1)}=J_{0n}$ [consistent with (64)]. We obtain

$$J_{mn}^{(1)}=\prod_{k=1}^{m}3(n-m+k)(3k-2)J_{0n-m},\tag{65}$$

which results in

$$J_{mn}^{(1)}=(-1)^{m+n}\frac{\Gamma(2/3)3^{m+n+5/6}}{6\pi}\frac{\Gamma(n+1)\Gamma(m+1/3)\Gamma(n-m+1/3)}{\Gamma(n-m+1)}.\tag{66}$$

Equation (66) allows us to write down an inhomogeneous recursion for J_{mn}:

$$J_{mn}=3m(3m-2)J_{m-1n-1}+(1+m/n)J_{mn}^{(1)},\tag{67}$$

where the inhomogeneous term is given by (66). Iterating this recursion we obtain

$$J_{mn}=\sum_{l=0}^{m}\left(\prod_{k=l+1}^{m}3k(3k-2)\right)\left(1+\frac{l}{n-m+l}\right)J_{ln-m+l}^{(1)},\tag{68}$$

which results in

$$J_{mn} = (-1)^{m-n} \frac{3^{m+n+1}\Gamma(2/3)^2}{4\pi^2}(m+n+1)\frac{\Gamma(n+1)\Gamma(m+1/3)\Gamma(n-m+1/3)}{\Gamma(n-m+2)}J_{00}. \tag{69}$$

This determines J_{mn} for $n \geqslant m$.

3. Matrix elements $\langle \psi_m^+ | \hat{z} | \psi_n^- \rangle$ for $m > n$

For $m > n$ we use instead

$$J_{mn} = \langle \psi_0^+ | \hat{A}^m \hat{z} \hat{A}^{+n} | \psi_0^- \rangle = \langle \psi_0^+ | \hat{A}^{m-1} [\hat{A}, \hat{z}] \hat{A}^{+n} | \psi_0^- \rangle + \langle \psi_0^+ | \hat{A}^{m-1} \hat{z} \hat{A} (\hat{A}^+)^n | \psi_0^- \rangle \tag{70}$$

and proceed as before. We find that $J_{mn}=0$ for $m > n+1$. For $m=n+1$ we obtain

$$\begin{aligned} J_{n+1n} &= \langle \psi_0^+ | \hat{A}^n |\hat{z}|^{-1} \hat{a}^+ (\hat{A}^+)^n | \psi_0^- \rangle + \langle \psi_0^+ | \hat{A}^n \hat{a}^+ |\hat{z}|^{-1} (\hat{A}^+)^n | \psi_0^- \rangle + \langle \psi_0^+ | \hat{A}^n |\hat{z}| \hat{A} (\hat{A}^+)^n | \psi_0^- \rangle \\ &= \tilde{J}^{(1)}_{n+1n} + \tilde{J}^{(2)}_{n+1n} + \tilde{J}^{(3)}_{n+1n}. \end{aligned} \tag{71}$$

Consider first $\tilde{J}^{(3)}_{n+1n}$:

$$\tilde{J}^{(3)}_{n+1n} = (C_n^-)^2 \tilde{J}^{(3)}_{nn-1} = 3n(3n+2)\tilde{J}^{(3)}_{nn-1}. \tag{72}$$

Second, using $\hat{A}^n |\hat{z}|^{-1} \hat{a}^+ (\hat{A}^+)^n = \hat{A}^{n-1} \hat{a}^+ |\hat{z}|^{-1} \hat{A} (\hat{A}^+)^n$ we determine $\tilde{J}^{(1)}_{n+1n}$:

$$\tilde{J}^{(1)}_{n+1n} = (C_n^-)^2 \tilde{J}^{(2)}_{nn-1} = 3n(3n+2)\tilde{J}^{(2)}_{nn-1}. \tag{73}$$

Third,

$$\tilde{J}^{(2)}_{n+1n} = (\lambda_n^+ - 1)(\lambda_{n-1}^- - 1)\tilde{J}^{(2)}_{nn-1} = (3n+1)3nJ^{(2)}_{nn-1}. \tag{74}$$

We deduce that

$$\tilde{J}^{(1)}_{n+1n} = \frac{3n+2}{3n+1}\tilde{J}^{(2)}_{n+1n} \tag{75}$$

and obtain the recursion

$$J_{n+1n} = \tilde{J}^{(1)}_{n+1n} + \tilde{J}^{(2)}_{n+1n} + \tilde{J}^{(3)}_{n+1n} = 3n(3n+2)J_{nn-1} + \left(1 + \frac{3n+2}{3n+1}\right)\tilde{J}^{(2)}_{n+1n}. \tag{76}$$

Iterating (74) we obtain

$$\tilde{J}^{(2)}_{n+1n} = \left(\prod_{k=1}^{n} 3k(3k+1)\right)\tilde{J}^{(2)}_{10} = \frac{3\sqrt{3}}{2\pi} 9^n \Gamma(2/3)\Gamma(n+1)\Gamma(n+4/3)J_{00} \tag{77}$$

and thus from (76)

$$J_{n+1n} = \frac{\sqrt{3}}{2\pi} 9^n \Gamma(2/3)\Gamma(2+n)\Gamma(n+4/3)J_{00}. \tag{78}$$

Comparing this result to (69) we find that (69) gives the correct result for $m=n+1$, although it was derived assuming $m \leqslant n$. Normalizing to obtain Z_{mn} our final result is

$$Z_{mn} = (-1)^{m-n}\frac{3^{5/6}}{6\pi}(m+n+1)\Gamma(2/3)\frac{\sqrt{\Gamma(n+1)\Gamma(m+1/3)}}{\sqrt{\Gamma(m+1)\Gamma(n+5/3)}}\frac{\Gamma(n-m+1/3)}{\Gamma(n-m+2)} \tag{79}$$

for $n \geqslant m-1$ and zero otherwise.

C. Ratios of eigenfunctions

In this section we show how to evaluate $\psi_n^+(0)/\psi_0^+(0)$. For $z>0$, the eigenfunctions $\psi_n^+(z)$ are of the form $N_n^+ g_n(z)\exp(-z^3/6)$, where $g_n(z)$ is polynomial in z^3, of the form

$$g_n(z) = g_n^{(0)} + g_n^{(1)} z^3 + \cdots . \tag{80}$$

We determine how $\hat{A}^+$ and $\hat{H}$ act on these polynomials. To this end we define

$$\hat{A}'^+ = e^{z^3/6}\hat{A}^+ e^{-z^3/6} = (\partial_z - z^2)z^{-1}(\partial_z - z^2), \tag{81}$$

$$\hat{H}' = e^{z^3/6}\hat{H}e^{-z^3/6} = (\partial_z - z^2)z^{-1}\partial_z. \tag{82}$$

This implies

$$\hat{A}'^+ - \hat{H}' = -(\partial_z - z^2)z = z^3 - z\partial_z - 1 \tag{83}$$

and thus

$$(\hat{A}'^+ - \hat{H}')g_n = -g_n^{(0)} + O(z^3). \tag{84}$$

Using $\lambda_n^+ = -3n$ we obtain

$$\hat{H}' g_n = -3n g_n^{(0)} + O(z^3) \tag{85}$$

from the eigenvalue equation. Taking (84) and (85) together we have

$$\hat{A}'^+ g_n = -(3n+1) g_n^{(0)} + O(z^3). \tag{86}$$

Equation (86) implies

$$g_{n+1}^{(0)} = -(3n+1) g_n^{(0)}. \tag{87}$$

With (30) it follows

$$\psi_{n+1}^+(0) = N_{n+1}^+ g_{n+1}^{(0)} = -(3n+1)N_{n+1}^+/N_n^+ \psi_n^+(0) = -\sqrt{\frac{3n+1}{3(n+1)}}\psi_n^+(0). \tag{88}$$

Our final result for the ratio of wave-function amplitudes is therefore

$$\psi_n^+(0)/\psi_0^+(0) = (-1)^n \sqrt{\frac{\sqrt{3}\Gamma(2/3)}{2\pi}\frac{\Gamma(n+1/3)}{\Gamma(n+1)}}. \tag{89}$$

VI. EQUILIBRIUM CORRELATIONS, DIFFUSION, AND ANOMALOUS DIFFUSION

In the following the momentum correlation function in equilibrium and the time dependence of $\langle x^2(t)\rangle$ are determined.

A. Momentum correlation function in equilibrium

The correlation function of momentum in equilibrium is obtained from (49). We have

$$\langle p_{t'} p_0 \rangle_{\text{eq.}} = p_0^2 \left(\frac{D_1}{\gamma p_0^2}\right)^{2/3} \sum_n Z_{0n}^2 \exp(\lambda_n^- t'). \tag{90}$$

Using (79) we obtain

$$\langle p_t p_0 \rangle_{\text{eq.}} = \frac{\Gamma(4/3)}{3^{1/3}\Gamma(5/3)} \left(\frac{p_0 D_1}{\gamma} \right)^{2/3} e^{-2\gamma t} F_{21}\left(\frac{1}{3}, \frac{1}{3}; \frac{5}{3}; e^{-3\gamma t} \right) \tag{91}$$

for $t>0$. Here F_{21} is a hypergeometric function.[21] It follows that $\langle p_t p_0 \rangle_{\text{eq.}}$ decays as $\exp(-2\gamma t)$ at large times as opposed to $\exp(-\gamma t)$ in the Ornstein-Uhlenbeck process.

B. Diffusion at long times

We now turn to $\langle x^2(t) \rangle$. This expectation value is calculated using Eqs. (52), (53), (79), and (89). We have

$$\langle x^2(t) \rangle = \left(\frac{p_0 D_1}{\gamma} \right)^{2/3} \frac{1}{m^2 \gamma^2} \sum_{k=0}^{\infty} \sum_{l=k-1}^{\infty} \frac{\psi_k^+(0)}{\psi_0^+(0)} Z_{0l} Z_{kl} T_{kl} \tag{92}$$

with

$$T_{kl}(t') = \int_0^{t'} \mathrm{d}t_1' \int_{t_1'}^{t'} \mathrm{d}t_2' \, e^{\lambda_l^-(t_2'-t_1')+\lambda_k^+ t_1'} + \int_0^{t'} \mathrm{d}t_1' \int_0^{t_1'} \mathrm{d}t_2' \, e^{\lambda_l^-(t_1'-t_2')+\lambda_k^+ t_2'} = 2\frac{\lambda_k^+(1-e^{\lambda_l^- t'}) - \lambda_l^-(1-e^{\lambda_k^+ t'})}{\lambda_l^- \lambda_k^+ (\lambda_k^+ - \lambda_l^-)}. \tag{93}$$

We define

$$A_{kl} \equiv \frac{\psi_k^+(0)}{\psi_0^+(0)} Z_{0l} Z_{kl} = \frac{3^{2/3}\Gamma(2/3)^2}{12\pi^2} \frac{(k+l+1)\Gamma(k+1/3)\Gamma(l+1/3)\Gamma(l-k+1/3)}{\Gamma(k+1)\Gamma(l+5/3)\Gamma(l-k+2)} \tag{94}$$

for $k \geqslant l-1$ and zero otherwise. In order to determine $\langle x^2(t) \rangle$, the sum

$$S(t') = \sum_{kl} A_{kl} T_{kl}(t') \tag{95}$$

is required. Note that $A_{kl}=0$ for $k<l-1$. Consider the behavior of (95) at large values of t'. We write the $k=0$ term separately

$$T_{0l} = -\frac{2t'}{\lambda_l^-} + \frac{2}{\lambda_l^{-2}}(e^{\lambda_l^- t'} - 1). \tag{96}$$

This gives

$$\langle x^2(t) \rangle = 2\mathcal{D}_x t + \left(\frac{p_0 D_1}{\gamma} \right)^{2/3} \frac{1}{m^2\gamma^2} \sum_{l=0}^{\infty} Z_{0l}^2 \frac{2}{\lambda_l^{-2}} (e^{\lambda_l^- t'} - 1) + \left(\frac{p_0 D_1}{\gamma} \right)^{2/3} \frac{1}{m^2\gamma^2} \sum_{k=1}^{\infty} \sum_{l=k-1}^{\infty} \frac{\psi_k^+(0)}{\psi_0^+(0)} Z_{0l} Z_{kl} T_{kl}(t'). \tag{97}$$

At large t' the secular term dominates and diffusion is thus recovered. The diffusion constant is obtained as[2]

$$\mathcal{D}_x = \frac{(p_0 D_1)^{2/3}}{m^2 \gamma^{5/3}} \frac{\pi 3^{-5/6}}{2\Gamma(2/3)^2} F_{32}\left(\frac{1}{3}, \frac{1}{3}, \frac{2}{3}; \frac{5}{3}, \frac{5}{3}; 1 \right). \tag{98}$$

C. Anomalous diffusion at short times

Next we consider short times. In order to evaluate (95) at small values of t', we replace the sums in (95) by integrals:

$$S(t') = \int_0^\infty \mathrm{d}l \int_0^l \mathrm{d}k\, T(k,l,t)A(k,l). \tag{99}$$

In order to evaluate (99) we use the asymptotic form of the coefficients A_{kl}:

$$A(k,l) \sim \frac{3^{2/3}\Gamma(2/3)^2}{12\pi^2}\frac{k+l}{k^{2/3}l^{4/3}(l-k)^{5/3}}. \tag{100}$$

The coefficients $A(k,l)$ exhibit nonintegrable divergence $k \to l$. In view of this divergence we make use of a sum rule of the A_{kl}:

$$\sum_{k=0}^{l+1} A_{kl} = 0. \tag{101}$$

It can be derived by considering

$$\sum_{k=0}^{l+1} \psi_k^+(z)\langle\psi_k^+|\hat{z}|\psi_l^-\rangle = \sum_{k=0}^{\infty} \psi_k^+(z)\langle\psi_k^+|\hat{z}|\psi_l^-\rangle = \sum_{k=0}^{\infty} \langle z|\psi_k^+\rangle\langle\psi_k^+|\hat{z}|\psi_l^-\rangle = \langle z|\hat{z}|\psi_l^-\rangle, \tag{102}$$

which vanishes for $z=0$. Replacing sums by integrals the sum rule amounts to

$$\int_0^l \mathrm{d}k\, A(k,l) = 0. \tag{103}$$

Equation (103) allows us to write

$$S(t') = \int_0^\infty \mathrm{d}l \int_0^l \mathrm{d}k\, [T(k,l;t') - \lim_{k\to l} T(k,l;t')]A(k,l). \tag{104}$$

We find that the divergence of $A(k,l)$ is reduced to an integrable divergence by the fact that $T(k,l;t) - \lim_{k\to l} T(k,l;t) = O(k-l)$. Approximately, $T(k,l;t)$ is given by

$$T(k,l;t) = -2\frac{3k[1-\exp(-3lt)] - 3l[1-\exp(-3kt)]}{27lk(l-k)}. \tag{105}$$

Changing the integration variables in (104) to $x=3lt$ and $xy=3kt$, we have $k=xy/(3t)$ and $l=x/(3t)$, and

$$A(x,y,t) = \frac{3^{10/3}\Gamma(2/3)^2}{12\pi^2}t^{8/3}x^{-8/3}\frac{1+y}{y^{2/3}(1-y)^{5/3}}. \tag{106}$$

The Jacobian of the transformation is $J=x/(9t^2)$. In the new variables,

$$T(x,y;t) = -2\frac{t^2}{x}\left[\frac{a(x)-a(xy)}{1-y}\right] \tag{107}$$

where

$$a(x) = [1-\exp(-x)]/x. \tag{108}$$

Using

$$\lim_{y\to 1} T(x,y;t) = -2\frac{t^2}{x}\left[\frac{\partial}{\partial y}a(xy)\right]\Bigg|_{y=1} = -2\frac{t^2}{x}xa'(x) \tag{109}$$

we finally obtain

$$T(k,l;t) - \lim_{k\to l} T(k,l;t) = -2\frac{t^2}{x}\left[\frac{a(x)-a(xy)}{1-y} - xa'(x)\right]. \tag{110}$$

This gives

$$S(t) = -C\,t^{8/3}\int_0^\infty \mathrm{d}x\, x^{-8/3}\int_0^1 \mathrm{d}y\left[\frac{a(x)-a(xy)}{1-y} - xa'(x)\right]\frac{1+y}{y^{2/3}(1-y)^{5/3}} \tag{111}$$

with $C=3^{1/3}\Gamma(2/3)^2/(2\pi^2)$. Equation (111) implies anomalous spatial diffusion at short times:

$$\langle x^2(t)\rangle = \mathcal{C}_x(p_0D_1)^{2/3}m^{-2}t^{8/3} \tag{112}$$

with

$$\mathcal{C}_x = -C\int_0^\infty \mathrm{d}x\, x^{-8/3}\int_0^1 \mathrm{d}y\left[\frac{a(x)-a(xy)}{1-y} - xa'(x)\right]\frac{1+y}{y^{2/3}(1-y)^{5/3}}. \tag{113}$$

This anomalous diffusion is analogous to that described by Golubovic, Feng, and Zeng[9] in the case where there is no damping (they considered the case where $\zeta=3$ in their paper). Our results give the prefactor as well as the scaling behavior. It is noteworthy that we are able to solve the problem discussed in Ref. 9 by solving a more complex set of equations exactly, and taking a limit.

In Ref. 2, Fig. 2b shows plots of Eqs. (97) and (112) in comparison with numerical simulations of the equations of motion (10), exhibiting anomalous spatial diffusion at short times, and a crossover to diffusion at long times.

VII. WKB ANALYSIS

The staggered ladder spectrum discussed in Sec. IV is surprising, especially in view of the fact that for large quantum number n we expect that the eigenfunctions of the Hamiltonian (23) might be obtained by WKB theory. In this section we show how to determine the spectrum (29) of $\hat{H}$ using asymptotic WKB analysis. We show how phase shifts associated with the singularity at $z=0$ of the Hamiltonian (23) are the source of the staggered spectrum. It turns out that the WKB procedure gives rise to the exact eigenvalues.

In dimensionless coordinates, the classical Hamilton function corresponding to (23) is

$$H_{\mathrm{cl}} = \frac{1}{2} - \frac{z^3}{4} - p^2/z. \tag{114}$$

Solving $H_{\mathrm{cl}}=\lambda$ for p we obtain $p(z,\lambda)=\pm\frac{1}{2}\sqrt{(2-4\lambda)z-z^4}$, while the velocity is

$$\dot{z} = \partial H_{\mathrm{cl}}/\partial p = -2p/z. \tag{115}$$

The classical trajectories are figure-of-eight orbits, illustrated in Fig. 2.

The WKB wave function is of the form

$$f(z) = [z/p(z,\lambda)]^{1/2}\exp\left(\pm\mathrm{i}\int^z \mathrm{d}z p(z,\lambda)\right). \tag{116}$$

The phase of the wave function can be determined as follows. We discuss separately the behaviors of the wave function at the origin $z_0=0$ and in the vicinity of the regular turning point $z_{\mathrm{t.p.}}=(2-4\lambda)^{1/3}$. In the latter case, the wave function at $z<z_{\mathrm{t.p.}}$ connected with the turning point is

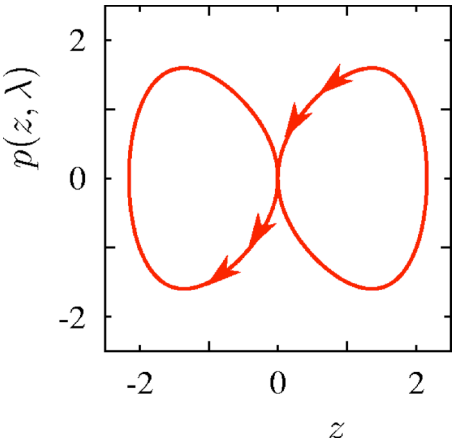

FIG. 2. (Color online) The trajectories of the classical Hamiltonian (114) are figure-of-eight orbits.

$$f_{\text{t.p.}}(z) = C_{\text{t.p.}}[z/p(z,\lambda)]^{1/2} \sin\left(\int_z^{z_{\text{t.p.}}} \mathrm{d}z\, p(z,\lambda) + \frac{\pi}{4} \right). \tag{117}$$

Consider now the behavior of the wave function near the origin. The Hamiltonian has a singularity at $z=0$. We find an exact solution of the equation when $\gamma=0$. This equation has a continuous spectrum, but we identify solutions $f_+(z)$ and $f_-(z)$ which correspond, respectively, to even and odd solutions of the full equation for $\gamma>0$ (with discrete spectrum). Close to $z=0$, the damping term in the Hamiltonian is negligible, and for $z>0$ the eigenfunctions resemble solutions of the equation

$$\partial_z z^{-1} \partial_z f(z) = -\Lambda f(z) \tag{118}$$

where $\Lambda(=-\lambda)$ is a positive constant. Write $f=F'$, and find that

$$\frac{\partial}{\partial z}\left(\frac{F'' + \Lambda z F}{z} \right) = 0 \tag{119}$$

so that $F''+\Lambda zF=Cz$ for some constant C. Thus we find $G(z)=F(z)-C/\Lambda$ satisfies $G''+z\Lambda G=0$, which has solution $G(z)=\mathrm{Ai}(-\Lambda^{1/3}z)$, and a similar solution constructed from $\mathrm{Bi}(x)$ [here $\mathrm{Ai}(y)$ and $\mathrm{Bi}(y)$ are Airy Ai and Bi functions[21]]. The general solution is

$$f(z) = A_1 \mathrm{Ai}'(-\Lambda^{1/3}z) + A_2 \mathrm{Bi}'(-\Lambda^{1/3}z). \tag{120}$$

We must find solutions of this form which resemble the behavior of the eigenfunctions of the equation with $\gamma>0$ which obey the boundary conditions

$$\frac{\mathrm{d}^2 f_+(0)}{\mathrm{d}z^2} = 0 \text{ and } f_-(0) = 0. \tag{121}$$

The functions Ai' and Bi' have the following forms in the neighborhood of $z=0$

$$\mathrm{Ai}'(y) = c_1\left(\frac{y^2}{2} + \mathcal{O}(y^5) \right) - c_2\left(1 + \frac{y^3}{3} + \mathcal{O}(y^6) \right), \tag{122}$$

$$\mathrm{Bi}'(y) = \sqrt{3}c_1\left(\frac{y^2}{2} + \mathcal{O}(y^5)\right) + \sqrt{3}c_2\left(1 + \frac{y^3}{3} + \mathcal{O}(y^6)\right) \tag{123}$$

with $y=-\Lambda^{1/3}z$, $c_1=3^{-2/3}/\Gamma(2/3)$, and $c_2=3^{-1/3}/\Gamma(1/3)$. So the positive-parity solution corresponds to the choice

$$A_1^+ = -\sqrt{3} \text{ and } A_2^+ = 1 \tag{124}$$

while

$$A_1^- = \sqrt{3} \text{ and } A_2^- = 1. \tag{125}$$

At large values of y the corresponding wave functions are of the form

$$f_\pm(y) \sim (-y)^{1/4} \sin\left(\frac{2}{3}(-y)^{3/2} + \frac{\pi}{4} \pm \frac{\pi}{3}\right). \tag{126}$$

Noting that, near $z=0$, $\int_0^z \mathrm{d}z p(z,\lambda)=(2/3)(-y)^{3/2}$ and $(z/p(z,\lambda))^{1/2} \propto (-y)^{1/4}$, the solution coming from the origin is

$$f_{O,\pm}(z) = C_{O,\pm}[z/p(z,\lambda)]^{1/2} \sin\left(\int_0^z \mathrm{d}z'\, p(z',\lambda) + \frac{\pi}{4} \pm \frac{\pi}{3}\right). \tag{127}$$

The forms (117) and (127) should be smoothly connected for $0<z<z_{\mathrm{t.p.}}$. This requires

$$\int_0^{z_{\mathrm{t.p.}}} \mathrm{d}z\, p(z,\lambda) + \frac{\pi}{2} \pm \frac{\pi}{3} = (n+1)\pi, \tag{128}$$

for $n=0,1,\ldots$ together with $C_{\mathrm{t.p.}}=(-1)^n C_{O,\pm}$. Writing

$$S(\lambda) = \int_0^{z_{\mathrm{t.p.}}} \mathrm{d}z\, p(z,\lambda) = \frac{\pi}{12}(-4\lambda + 2), \tag{129}$$

we find the quantization condition

$$S(\lambda_\pm) = \left(n + \tfrac{1}{2} \mp \tfrac{1}{3}\right)\pi. \tag{130}$$

Using (129) the quantization condition takes the form

$$\lambda = \begin{cases} -3n & \text{even parity} \\ -3n-2 & \text{odd parity}, \end{cases} \tag{131}$$

which corresponds exactly to the spectrum (29) obtained by algebraically diagonalizing $\hat{H}$.

VIII. RESULTS FOR OTHER VALUES OF ζ

Up to now we have only considered the case of generic random forcing [where the constant D_1 in Eq. (8) is not zero], corresponding to the case $\zeta=1$ in Eq. (9). In this section we explain two cases where other values of ζ arise and briefly describe results for arbitrary positive values of ζ, analogous to the results obtained in Sec. VI.

First consider the case where the force is the gradient of a potential, $f(x,t)=\partial V(x,t)/\partial x$. We assume that the potential has mean value zero and correlation function $\mathcal{C}(X,T)=\langle V(x+X,t+T)V(x,t)\rangle$. Assuming that $\mathcal{C}(X,T)$ is sufficiently differentiable at $T=0$, the diffusion constant is

$$D(p) = \frac{1}{2}\int_{-\infty}^{\infty} \mathrm{d}t \left\langle \frac{\partial V}{\partial x}(pt/m,t)\frac{\partial V}{\partial x}(0,0) \right\rangle = \frac{-m}{2|p|}\int_{-\infty}^{\infty} \mathrm{d}X \frac{\partial^2 \mathcal{C}}{\partial X^2}(X,mX/p)$$
$$= \frac{-m}{2|p|}\int_{-\infty}^{\infty} \mathrm{d}X \left[\frac{\partial^2 \mathcal{C}}{\partial x^2}(X,0) + \frac{mX}{p}\frac{\partial^3 \mathcal{C}}{\partial^2 X \partial T}(X,0) + \frac{m^2X^2}{2p^2}\frac{\partial^4 \mathcal{C}}{\partial^2 X \partial^2 T}(X,0) + O(X^3) \right]. \quad (132)$$

Integration by parts shows that the integral over the first term of the expansion is zero, and the integral over the second term is zero by symmetry. The leading-order contribution in $|p|^{-1}$ comes from the third term. Integrating this term by parts twice gives

$$D(p) \sim \frac{-m^3}{2|p|^3}\int_{-\infty}^{\infty} \mathrm{d}X \frac{\partial^2 \mathcal{C}}{\partial T^2}(X,0). \quad (133)$$

Thus in the case of a potential force with a sufficiently smooth correlation function we have $\zeta = 3$.

An exceptional case which is worthy of comment is when the potential $V(x,t)$ is itself generated from a set of Ornstein-Uhlenbeck processes $A_j(t)$ by writing $V(x,t)=\Sigma_j A_j(t)\Phi_j(x)$, where the $\Phi_j(x)$ are elements of some suitable set of basis functions. In this case the correlation function of $V(x,t)$ is of the form $c(x)\exp(-\gamma|t|)$ [for some function $c(x)$]. Then the second term in the expansion on the final line of Eq. (132) does not vanish by symmetry and we find $D(p) \propto |p|^{-2}$, that is $\zeta=2$.

For general positive values of ζ the Hamiltonian (22) is replaced by

$$\hat{H} = \frac{1}{2} - \frac{1}{4}|z|^{2+\zeta} + \frac{\partial}{\partial z}\frac{1}{|z|^{\zeta}}\frac{\partial}{\partial z}. \quad (134)$$

Its ground state

$$\lambda_0^+ = 0 \text{ and } \psi_0^+(z) = \mathcal{C}_0^+ e^{-|z|^{\zeta+2}/(4+2\zeta)} \quad (135)$$

and first excited state

$$\lambda_0^- = -1-\zeta \text{ and } \psi_0^-(z) = \mathcal{C}_0^- z|z|^{\zeta} e^{-|z|^{\zeta+2}/(4+2\zeta)} \quad (136)$$

are found by inspection. Raising and lowering operators can be introduced in a manner analogous to Eqs. (24)–(26). We write

$$\hat{H} = \hat{a}^-|z|^{-\zeta}\hat{a}^+ \quad (137)$$

with $\hat{a}^{\pm}=\partial_z \pm z|z|^{\zeta}/2$. The operators

$$\hat{A} = \hat{a}^+|z|^{-\zeta}\hat{a}^+ \text{ and } \hat{A}^+ = \hat{a}^-|z|^{-\zeta}\hat{a}^- \quad (138)$$

satisfy

$$[\hat{H},\hat{A}] = (2+\zeta)\hat{A} \text{ and } [\hat{H},\hat{A}^+] = -(2+\zeta)\hat{A}^+ \quad (139)$$

and act as lowering and raising operators. For the spectrum of $\hat{H}$ we obtain

$$\lambda_n^+ = -(2+\zeta)n \text{ and } \lambda_n^- = -(2+\zeta)n - 1 - \zeta. \quad (140)$$

These expressions replace (29). Note also that the commutator of $\hat{A}$ and $\hat{A}^+$ is

$$[\hat{A},\hat{A}^+] = -(2+\zeta)(\hat{H}+\hat{G}) \quad (141)$$

where $\hat{G}=\hat{a}^+|z|^{-\zeta}\hat{a}^-$ and $\hat{H}-\hat{G}=\hat{I}$. The normalization of the eigenstates

$$\hat{A}^+|\psi_n^-\rangle = C_{n+1}^-|\psi_{n+1}^-\rangle, \tag{142}$$

$$\hat{A}|\psi_n^-\rangle = C_n^-|\psi_{n-1}^-\rangle \tag{143}$$

is determined as in Sec. IV A 2. We obtain

$$(C_{n+1}^-)^2 = (2+\zeta)(n+1)[(2+\zeta)n+3+2\zeta] \tag{144}$$

and

$$(C_{n+1}^+)^2 = (2+\zeta)(n+1)[(2+\zeta)n+1]. \tag{145}$$

The results of Sec. V for the matrix elements $Z_{mn}=\langle\psi_m^-|\hat{z}|\psi_n\rangle$ and for $\psi_n^+(0)/\psi_0^+(0)$ generalize as follows:

$$Z_{mn} = (-1)^{n-m}\frac{(2+\zeta)^{-(1+\zeta)/(2+\zeta)}}{\Gamma\left(\frac{\zeta}{2+\zeta}\right)}(m+n+1)\frac{\Gamma\left(\frac{\zeta}{2+\zeta}-m+n\right)\sqrt{\Gamma(n+1)\Gamma\left(\frac{1}{2+\zeta}+m\right)}}{\Gamma(2-m+n)\sqrt{\Gamma\left(\frac{3+2\zeta}{2+\zeta}+n\right)\Gamma(m+1)}}, \tag{146}$$

$$\psi_n^+(0)/\psi_0^+(0) = (-1)^n\sqrt{\frac{\Gamma[((2+\zeta)n+1)/(2+\zeta)]}{\Gamma(n+1)\Gamma(1/(2+\zeta))}}. \tag{147}$$

This allows us to obtain, for example, the diffusion constant

$$\mathcal{D}_x = \frac{1}{m^2}\left(\frac{p_0^{2\zeta}D_\zeta^2}{\gamma^{4+\zeta}}\right)^{1/(2+\zeta)}\frac{(2+\zeta)^{-(4+3\zeta)/(2+\zeta)}\pi F_{32}\left(\frac{\zeta}{2+\zeta},\frac{\zeta}{2+\zeta},\frac{1+\zeta}{2+\zeta};\frac{3+2\zeta}{2+\zeta},\frac{3+2\zeta}{2+\zeta};1\right)}{\sin\left(\frac{\pi}{2+\zeta}\right)\Gamma\left(\frac{3+2\zeta}{2+\zeta}\right)^2} \tag{148}$$

describing the dynamics at large times. Upon substituting $\zeta=0$, Eq. (148) reproduces the standard Ornstein-Uhlenbeck result, and it gives (98) for $\zeta=1$.

For the short-time anomalous diffusion we obtain

$$\langle x^2(t)\rangle = \mathcal{C}_x((p_0^\zeta D_\zeta)^{2/(2+\zeta)}m^{-2})t^{(6+2\zeta)/(2+\zeta)} \tag{149}$$

with

$$\mathcal{C}_x = -C\int_0^\infty \mathrm{d}x\, x^{-(6+2\zeta)/(2+\zeta)}\int_0^1 \mathrm{d}y\left[\frac{a(x)-a(xy)}{1-y}-xa'(x)\right]\frac{1+y}{y^{(1+\zeta)/(2+\zeta)}(1-y)^{(4+\zeta)/(2+\zeta)}}, \tag{150}$$

where $a(x)$ is the same as in (113), and

$$C = \frac{2(2+\zeta)^{-2\zeta/(2+\zeta)}}{\Gamma\left(\frac{\zeta}{2+\zeta}\right)^2}. \tag{151}$$

This reproduces (112) for $\zeta=1$ and concludes our summary of results for other than generic random forcing.

Heat equilibrium distribution in a turbulent flow

Z. Haba[a)]

(Received 11 January 2006; accepted 1 June 2006; published online 24 July 2006)

We consider a shear flow of a scale invariant Gaussian random velocity field that does not depend on the coordinates in the direction of the flow. We investigate a heat advection coming from a Gaussian random homogeneous source. We discuss a relaxation at large time of a temperature distribution determined by the forced advection-diffusion equation. We represent the temperature correlation functions by means of the Feynman-Kac formula. Jensen inequalities are applied for lower and upper bounds on the correlation functions. We show that at finite time there is no velocity dependence of long range temperature correlations (low momentum asymptotics) in the direction of the flow but the equilibrium heat distribution has large distance correlations (low momentum behavior) with an index depending on the scaling index of the random flow and of the index of the random forcing. If the velocity has correlations growing with the distance (a turbulent flow), then the large distance correlations depend in a crucial way on the scaling index of the turbulent flow. In such a case the correlations increase in the direction of the flow and decrease in the direction perpendicular to the flow, making the stream of heat more coherent. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2217808]

I. INTRODUCTION

We investigate a heat advection in a random flow that is supposed to be "turbulent." The turbulence is a complex phenomenon that is difficult to define in precise mathematical terms. The complexity of turbulence can be related to its dependence on the length scale relevant for undergoing experiments. In this paper we apply only some aspects of the turbulent flow: randomness of the velocity field, its self-similarity, and long range correlations. The appearance of the turbulence should have an impact on transport phenomena described by an advection-diffusion equation of a passive scalar.[1] Such an equation can describe transport of heat, a mass, or some impurities. We are interested in the equilibrium distribution of solutions of the random advection-diffusion equation. The equilibrium is possible only under an external forcing (a heat source). We are interested in the equilibrium distribution at all scales. Such an equilibrium will depend on the forcing. The universality is possible only in the inertial range[2–4] where the external forcing should not be relevant (see Ref. 5 for some recent shear flow experiments). Although the precise equilibrium distribution depends on the form of the forcing. the asymptotic behavior of correlation functions depends solely on the asymptotic behavior of the random forcing. We investigate the way the long range correlations of the fluid velocity influence the long range correlations of the temperature.

We assume that there is a distinguished direction of the fluid velocity $\mathbf{V}$. We make a decomposition $X=(\mathbf{x},\mathbf{z})\in R^D$ with $\mathbf{x}\in R^d$ and $\mathbf{z}\in R^{D-d}$; $\mathbf{V}(\tau,\mathbf{x})$ depends only on $\mathbf{x}\in R^d$ and has nonvanishing components only in R^{D-d} (in such a case it automatically satisfies $\nabla\mathbf{V}=0$; for physical applications $D=3$ and $d=2$ or $d=1$). As a typical example we could consider a fluid flow $V_z(x,y)$ in the direction of the z axis, which does not depend on z. We can impose such an anisotropy of

a)Electronic mail: zhab@ift.uni.wroc.pl

the flow by an external force $\mathbf{R}$, which depends only on $\mathbf{x}$ and has nonzero components solely in the $\mathbf{z}$ direction. So, we consider the Navier-Stokes equation with such a random force $\mathbf{R}$:

$$\partial_t \mathbf{V} + \mathbf{V} \nabla \mathbf{V} - \nu \Delta \mathbf{V} = \mathbf{R}.$$

The $(0, \mathbf{V}(\mathbf{x}))$ solution of the Navier-Stokes equation is the solution of the linear equation (for the $\mathbf{z}$ component)

$$\partial_t \mathbf{V} - \nu \Delta_{\mathbf{x}} \mathbf{V} = \mathbf{R}$$

(together with a zero solution for the $\mathbf{x}$ component). By properly choosing the external force $\mathbf{R}$ we can simulate a large class of $\mathbf{x}$-dependent flows.

In Secs. II and III we discuss the advection-diffusion equation, the random velocity, and a random forcing. The advection-diffusion equation can be solved by means of the Feynman-Kac formula. The Feynman-Kac solution has already been discussed by other authors.[6,7] These authors have been interested in the asymptotic behavior of the advection-diffusion equation without forcing. Our main interest (Secs. IV and V) is in the asymptotic behavior for large time and distances of correlation functions of the temperature field resulting from the advection-diffusion equation with forcing describing the heat injection. First, in Sec. III we simulate forcing by a constant gradient term in the temperature. We obtain a simple soluble model of advection illustrating some general features. In general, we can obtain some lower and upper bounds on the correlation functions by means of the Jensen inequalities (Sec. V). For the sake of simplicity we concentrate on the two-point correlations. In Sec. VI we show how our methods can be extended to multipoint correlations. We obtain asymptotic behavior of the Fourier transform of the correlation functions for small and large momenta. We compare our methods and results (in Secs. IV–VI and in Appendix B) with an exactly soluble model of Kraichnan[4,8,9] (defined by a velocity field, which is a white noise in time). The random advection is closely connected with diffusion. In fact, under some natural assumptions random advection enforces diffusion[10–12] and vice versa the diffusion can be expressed as a white noise advection.[13] However, when we choose no diffusion (zero molecular diffusivity) in the initial equation of advection describing the temperature evolution, then we obtain a model of advection (discussed in Appendix A) as a limit of the solution of the random advection-diffusion equation. The limit of zero molecular diffusivity has been discussed earlier in Refs. 14 and 15.

In the text some positive constants arise (denoted usually as K, c_1, etc.) that are not described at each case and are not related one to another.

II. THE ADVECTION-DIFFUSION EQUATION

We consider the advection in a random velocity field $\mathbf{V}$ (described in Sec. I) forced by a random source f:

$$\partial_\tau \theta_\tau + \mathbf{V} \nabla \theta_\tau - \frac{\mu^2}{2} \Delta \theta_\tau = f, \tag{1}$$

where μ^2 is the molecular diffusivity. If the random velocity $\mathbf{V}$ has singular correlation functions at small time, then Eq. (1) needs a careful interpretation. If the singularity of the velocity's covariance is of the form $\delta(t-t')D(\mathbf{x}-\mathbf{x}')$, then there are two standard interpretations, either Ito or Stratonovitch.[16,17] The difference between them in Eq. (1) is $1/2 D(\mathbf{0}) \nabla^2_{\mathbf{z}} \theta$. Hence, choosing one of them will change only the diffusion constant. We choose the Stratonovitch interpretation throughout the paper and also in Appendix B.

First, let us consider $\mathbf{V}=0$ and $f=0$. Let N be a (deterministic) solution of the heat equation

$$\partial_\tau N_\tau - \frac{\mu^2}{2} \Delta N_\tau = 0. \tag{2}$$

We expand θ around the solution N of the diffusion equation

$$\theta = T + N$$

(if the mean value of $\mathbf{V}$ is zero, then T describes fluctuations of the temperature). From Eq. (1)

$$\partial_\tau T_\tau + \mathbf{V}\nabla T_\tau - \frac{\mu^2}{2}\Delta T_\tau = F, \tag{3}$$

where

$$F = f - \mathbf{V}\nabla N_\tau.$$

As the simplest example of a physical relevance we consider the mean gradient[18,19]

$$N = -\mathbf{gX}, \tag{4}$$

where $\mathbf{g}$ is a constant vector. The mean gradient is a stationary solution of the heat equation between two planes kept at fixed temperatures. For such a static solution

$$F = f + \mathbf{Vg}. \tag{5}$$

We can see that even if $f=0$ then F is nontrivial. This is a frequent realization of an advection in experiments.[20,21] In such a case the source F has the same distribution as the velocity. A constant mean gradient distinguishes a direction in space. It breaks the rotational symmetry. As a model we could consider $\mathbf{g}=(0,0,g_z)$ and $\mathbf{V}=(0,0,V_z)$.

We define the spectral measure ρ of the temperature T, which is directly measurable in experiments[22]

$$\langle T_\tau(\mathbf{x},\mathbf{z})T_\tau(\mathbf{x}',\mathbf{z}')\rangle - \langle T_\tau(\mathbf{x},\mathbf{z})\rangle\langle T_\tau(\mathbf{x}',\mathbf{z}')\rangle = \int d\mathbf{k}d\mathbf{p}\,\exp(i\mathbf{k}(\mathbf{x}-\mathbf{x}') + i\mathbf{p}(\mathbf{z}-\mathbf{z}'))\rho_\tau(\mathbf{k},\mathbf{p}). \tag{6}$$

We have

$$\int d\mathbf{x}(\langle \tilde{\mathrm{T}}_\tau(\mathbf{x},\mathbf{p})\tilde{\mathrm{T}}_\tau(\mathbf{x}',\mathbf{p}')\rangle - \langle \tilde{\mathrm{T}}_\tau(\mathbf{x},\mathbf{p})\rangle\langle \tilde{\mathrm{T}}_\tau(\mathbf{x}',\mathbf{p}')\rangle) = \delta(\mathbf{p}+\mathbf{p}')\rho_\tau(0,\mathbf{p}) \tag{7}$$

and

$$\langle \tilde{\mathrm{T}}_\tau(\mathbf{x},\mathbf{p})\tilde{\mathrm{T}}_\tau(\mathbf{x},\mathbf{p}')\rangle - \langle \tilde{\mathrm{T}}_\tau(\mathbf{x},\mathbf{p})\rangle\langle \tilde{\mathrm{T}}_\tau(\mathbf{x},\mathbf{p})\rangle = \delta(\mathbf{p}+\mathbf{p}')\int d\mathbf{k}\rho_\tau(\mathbf{k},\mathbf{p}),$$

$$\langle T_\tau(\mathbf{x},\mathbf{z})T_\tau(\mathbf{x},\mathbf{z})\rangle - \langle T_\tau(\mathbf{x},\mathbf{z})\rangle\langle T_\tau(\mathbf{x},\mathbf{z})\rangle = \int d\mathbf{p}\int d\mathbf{k}\rho_\tau(\mathbf{k},\mathbf{p}).$$

When the spectral function has singularities at low momenta, then the Fourier transform in Eq. (6) may need a careful definition in the sense of generalized functions. Instead of the correlation functions of $T_\tau(\mathbf{x},\mathbf{y})$, we could consider the structure functions

$$\mathcal{G}_\tau^{(2n)}(\mathbf{x},\mathbf{z}) = \langle (T_\tau(0,0) - \langle T_\tau(0,0)\rangle - T_\tau(\mathbf{x},\mathbf{z}) + \langle T_\tau(\mathbf{x},\mathbf{z})\rangle)^{2n}\rangle.$$

For $n=1$ we have

$$\mathcal{G}_\tau^{(2)}(\mathbf{x},\mathbf{z}) = 2\int d\mathbf{k}d\mathbf{p}\rho_\tau(\mathbf{k},\mathbf{p})(1-\exp(i\mathbf{kx}+i\mathbf{p}z)).$$

$\mathcal{G}_\tau^{(2)}$ scales in the same way as $\langle TT\rangle$ but has better infrared behavior. The structure functions $\mathcal{G}^{(2n)}$ are expressed by the correlation functions of the Fourier transforms of T_τ.

It can be seen that the spectral measure ρ of the temperature T depends on the spectral measure of the source f and the scaling properties of the random velocity field.

III. GAUSSIAN MODEL OF THE SHEAR FLOW

We decompose the fluid velocity

$$\mathbf{V} = \mathbf{U} + \mathbf{v}$$

into the mean value $\mathbf{U}$ and random fluctuations $\mathbf{v}$. We assume that the velocity $\mathbf{v}$ is a Gaussian Euclidean R^d invariant random field with the mean zero and the covariance

$$\langle v_j(s,\mathbf{x})v_k(s',\mathbf{x}')\rangle = G_{jk}(s-s',\mathbf{x},\mathbf{x}'), \tag{8}$$

where $j,k=d+1,\ldots,D$. For the sake of simplicity of the arguments we shall sometimes separate the time dependence, choosing G of the product form ΓD. If G is a decaying function of the distance $|\mathbf{x}-\mathbf{x}'|$ then a model of the vector field $\mathbf{v}$ can be determined by a translation invariant G, e.g.,

$$G_{jk}(s-s',\mathbf{x},\mathbf{x}') \equiv \delta_{jk}\Gamma(s-s')D(\mathbf{x}-\mathbf{x}') = \delta_{jk}\Gamma(s-s')\int d\mathbf{p}\,\exp(i\mathbf{p}(\mathbf{x}-\mathbf{x}'))\tilde{D}(\mathbf{p}), \tag{9}$$

where $\tilde{D}$ is a locally integrable function.

In a description of the turbulence we consider growing long range correlations. In such a case G cannot be translation invariant. We consider a model with Euclidean R^d invariant correlation functions of $\mathbf{v}(\mathbf{x})-\mathbf{v}(\mathbf{x}')$. Then

$$G_{jk}(s-s',\mathbf{x},\mathbf{x}') = \delta_{jk}\Gamma(s-s')(|\mathbf{x}|^{2\beta}+|\mathbf{x}'|^{2\beta}-|\mathbf{x}-\mathbf{x}'|^{2\beta}). \tag{10}$$

This G is positive definite if Γ is positive definite and $0<\beta<1$ [the covariance (10) determines Levy's model[23] of the Brownian motion depending on d parameters]. When $2\beta<2$ then the vector field $\mathbf{v}(\mathbf{x})$ does not satisfy the Lipschitz condition. In such a case we could expect difficulties with the uniqueness of the flow and the uniqueness of the solution of Eq. (1) at $\mu=0$. Fortunately, a definition of the unique solution of Eq. (1) in a weak probabilistic sense is possible[24,25] even without the Lipschitz condition.

The source f is an independent Gaussian field with the covariance

$$\langle f(s,\mathbf{x},\mathbf{z})f(s',\mathbf{x}',\mathbf{z}')\rangle = M(s-s',\mathbf{x}-\mathbf{x}',\mathbf{z}-\mathbf{z}'). \tag{11}$$

We take the Fourier transform of Eq. (3) in the $\mathbf{z}$ variable. Then, this equation reads

$$\partial_\tau \tilde{T}_\tau(\mathbf{x},\mathbf{p}) + \left(i\mathbf{p}\mathbf{V}(\tau,\mathbf{x}) + \frac{\mu^2\mathbf{p}^2}{2} - \frac{\mu^2}{2}\Delta_{\mathbf{x}}\right)\tilde{T}_\tau(\mathbf{x},\mathbf{p}) = \tilde{F}(\tau,\mathbf{x},\mathbf{p}). \tag{12}$$

We apply the Feynman-Kac formula[17] in order to express the solution of Eq. (12) with the initial condition $T_0 \in L^2(dX)$ in the form (the uniqueness of the solution is discussed in Refs. 24 and 25)

$$\tilde{T}_\tau(\mathbf{x},\mathbf{p}) = \exp\left(-\frac{\mu^2\mathbf{p}^2\tau}{2}\right)E\left[\exp(-i\mathbf{p}\int_0^\tau \mathbf{V}(\tau-s,\mathbf{x}+\mu\mathbf{b}(s))ds)\tilde{T}_0(\mathbf{x}+\mu\mathbf{b}(\tau),\mathbf{p})\right] + \int_0^\tau dt\exp\left(-\frac{\mu^2\mathbf{p}^2(\tau-t)}{2}\right)E\left[\exp\left(-i\mathbf{p}\int_0^{\tau-t}\mathbf{V}(\tau-s,\mathbf{x}+\mu\mathbf{b}(s))ds\right)\times\tilde{F}(t,\mathbf{x}+\mu\mathbf{b}(\tau-t),\mathbf{p})\right]. \quad (13)$$

In Eq. (13) b_j $(j=1,2,\ldots,d)$ is the Brownian motion defined as the Gaussian process with the covariance[17]

$$E[b_j(s)b_k(t)] = \delta_{jk}\min(s,t).$$

We are interested in the equilibrium distribution of T_τ, i.e., in the limit $\tau\to\infty$. When $\tau\to\infty$ and $T_0 \in L^2(dX)$, then the first term in Eq. (13) is vanishing. For this reason we may set $T_0=0$ from the beginning. The stationary solutions N being harmonic functions are not square integrable in R^D. Admitting such functions as initial conditions, we could regain the solution N from Eq. (13) (with $F=0$). In particular, the mean gradient (4) comes from a generalized function $\tilde{T}_0$ with its support concentrated at $\mathbf{p}=0$.

Before discussing more general correlations let us consider the constant mean gradient [Eqs. (4) and (5)] with $f=0$ and $F=\mathbf{g}V$. Then, from Eq. (13) (with $T_0=0$),

$$\tilde{T}_t(\mathbf{x},\mathbf{p}) = \delta(\mathbf{p})E\left[\int_0^\tau dt\mathbf{g}\mathbf{V}(t,\mathbf{x}+\mu\mathbf{b}(\tau-t))\right]. \quad (14)$$

We shall see that some properties of the general advection (3) appear already at the level of the simple model (14). It follows from Eq. (14) that

$$\langle T_\tau(\mathbf{X})\rangle = \delta(\mathbf{p})E\left[\int_0^\tau dt\mathbf{g}\mathbf{U}(t,\mathbf{x}+\mu\mathbf{b}(\tau-t))\right]$$

and

$$\langle\tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle - \langle\tilde{T}_\tau(\mathbf{x},\mathbf{p})\rangle\langle\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle = \delta(\mathbf{p})\delta(\mathbf{p}')\int_0^\tau dt\int_0^\tau dt' E[\mathbf{g}G(t-t',\mathbf{x}-\mathbf{x}'+\mu\mathbf{b}(\tau-t) - \mu\mathbf{b}'(\tau-t'))\mathbf{g}].$$

We calculate the integral over time. First, if the covariance G is time independent (a steady flow), then

$$\langle T_\tau(\mathbf{x},\mathbf{z})T_\tau(\mathbf{x}',\mathbf{z}')\rangle - \langle T_\tau(\mathbf{X})\rangle\langle T_\tau(\mathbf{X}')\rangle = 4\mu^{-4}\int d\mathbf{k}\exp(i\mathbf{k}(\mathbf{x}-\mathbf{x}'))\mathbf{g}\tilde{G}(\mathbf{k})\mathbf{g}|\mathbf{k}|^{-4}\left(1-\exp\left(-\frac{\mu^2}{2}\mathbf{k}^2\tau\right)\right)^2. \quad (15)$$

Next, let us consider

$$G(t-t',\mathbf{x}-\mathbf{x}') = \delta(t-t')D(\mathbf{x}-\mathbf{x}'). \quad (16)$$

The covariance (16) does not have any physical foundations but the virtue of the assumption (16) is the solubility of the model (3) (Ref. 8) (the Kraichnan model) in the sense that one can obtain a closed set of partial differential equations for the correlation functions (see Appendix B). In our simplified version (14)

$$\langle T_\tau(\mathbf{x},\mathbf{z})T_\tau(\mathbf{x}',\mathbf{z}')\rangle - \langle T_\tau(\mathbf{X})\rangle\langle T_\tau(\mathbf{X}')\rangle = \mu^{-2}\int d\mathbf{k}\exp(i\mathbf{k}(\mathbf{x}-\mathbf{x}'))\mathbf{g}\tilde{D}(\mathbf{k})\mathbf{g}|\mathbf{k}|^{-2}(1-\exp(-\mu^2\mathbf{k}^2\tau)). \tag{17}$$

If the **v** correlations are growing as in Eq. (10), then expression (17) can be infrared divergent (especially at $\tau=\infty$). In such a case we should rather consider

$$\langle (T_\tau(\mathbf{0},\mathbf{0}) - \langle T_\tau(\mathbf{0},\mathbf{0})\rangle - T_\tau(\mathbf{x},\mathbf{z}) + \langle T_\tau(\mathbf{x},\mathbf{z})\rangle)^2\rangle$$
$$= 8\mu^{-4}\int d\mathbf{k}(1-\exp(i\mathbf{k}\mathbf{x}))\tilde{G}(\mathbf{k})|\mathbf{k}|^{-4}\left(1-\exp\left(-\frac{\mu^2}{2}\mathbf{k}^2\tau\right)\right)^2. \tag{18}$$

In general, let

$$G(t-t',\mathbf{x}-\mathbf{x}) = \int d\omega d\mathbf{k}\tilde{G}(\omega,\mathbf{k})\exp(i\omega(t-t') + i\mathbf{k}(\mathbf{x}-\mathbf{x}')), \tag{19}$$

then

$$\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle - \langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\rangle\langle \tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle$$
$$= \delta(\mathbf{p})\delta(\mathbf{p}')\int_0^\tau dt\int_0^\tau dt'\int d\mathbf{k}\mathbf{g}\tilde{G}(t-t',\mathbf{k})\mathbf{g}\exp\left(i\mathbf{k}(\mathbf{x}-\mathbf{x}') - \frac{1}{2}\mu^2\mathbf{k}^2(2\tau-t-t')\right).$$

After the time integration

$$\langle T_\tau(\mathbf{x},\mathbf{z})T_\tau(\mathbf{x}',\mathbf{z}')\rangle - \langle T_\tau(X)\rangle\langle T_\tau(X')\rangle$$
$$= \int d\mathbf{k}d\omega\exp(i\mathbf{k}(\mathbf{x}-\mathbf{x}'))\mathbf{g}\tilde{G}(\omega,\mathbf{k})\mathbf{g}\left(\frac{1}{4}\mu^4|\mathbf{k}|^4+\omega^2\right)^{-1}\left|1-\exp\left(-\frac{1}{2}\mu^2\mathbf{k}^2\tau - i\omega\tau\right)\right|^2. \tag{20}$$

We assume that G is scale invariant:

$$G(ct,\lambda\mathbf{x}) = c^{-\alpha}\lambda^{-2\gamma}G(t,\mathbf{x}) \tag{21}$$

[$\alpha+\gamma<1$ if the time integral in Eq. (14) is to be finite]. This assumption has simple consequences for heat transport. It may not be exact in mathematical models. As an example, for the shear flow solution of the Navier-Stokes equation discussed in Sec. I, if $C_{jl}(\omega,\mathbf{k})$ is the spectral function of the force distribution **R**, then the spectral function of the stationary velocity distribution (obtained as a solution of the Navier-Stokes equation with the initial condition at t_0 and then letting $t_0\to -\infty$) is

$$\tilde{G}_{jl}(\omega,\mathbf{k}) = C_{jl}(\omega,\mathbf{k})\left(\left(\frac{\nu}{2}\mathbf{k}^2\right)+\omega^2\right)^{-1}. \tag{22}$$

We must choose a specific C in order to obtain a scale invariant $\tilde{G}$.

We can see from Eqs. (15)–(20) that at finite τ the large distance behavior of the temperature correlations is the same as that of the velocity correlations because the behavior of ρ_τ for small momenta does not change. However, if $\langle \mathbf{v}(\mathbf{x})\mathbf{v}(0)\rangle \simeq |\mathbf{x}|^{2\beta}$, then at $\tau=\infty$ for a steady flow we obtain in Eq. (18)

$$\langle (T_\infty(\mathbf{x},\mathbf{z}) - \langle T_\infty(\mathbf{x},\mathbf{z})\rangle - T_\infty(\mathbf{0},\mathbf{0}) + \langle T_\infty(\mathbf{0},\mathbf{0})\rangle)^2\rangle \simeq |\mathbf{x}|^{2\beta+4},$$

and for the Kraichnan model[8]

$$\langle (T_\infty(\mathbf{x},\mathbf{z}) - \langle T_\infty(\mathbf{x},\mathbf{z})\rangle - T_\infty(\mathbf{0},\mathbf{0}) + \langle T_\infty(\mathbf{0},\mathbf{0})\rangle)^2\rangle \simeq |\mathbf{x}|^{2\beta+2}$$

in Eq. (17). For a general time-dependent $G(t,\mathbf{x})$ of the form (19), we shall have the $|\mathbf{x}|^{2\beta-2\alpha+4}$ behavior of the structure functions $S_\infty^{(2)}$ in Eq. (20) if G scales as in Eq. (21) ($\gamma=-\beta$). We can establish the behavior for large $\mathbf{x}-\mathbf{x}'$ by means of a change of variables in the integrals (15)–(20), $\mathbf{k}=\tilde{\mathbf{k}}|\mathbf{x}-\mathbf{x}'|^{-1}$ and $\omega=\tilde{\omega}|\mathbf{x}-\mathbf{x}'|^{-2}$ and an estimate of the remainder. Note that the long range correlations of the velocity field ($\gamma<0$) lead to an increase of the temperature correlations.

IV. GAUSSIAN WHITE NOISE SOURCE

In this section we consider $F=f$ as a Gaussian random field independent of $\mathbf{v}$. Estimates on the equilibrium distribution are simplified if the sources at different times are independent:

$$M(t-t',\mathbf{x}-\mathbf{x}',\mathbf{z}-\mathbf{z}') = \delta(t-t')m(\mathbf{x}-\mathbf{x}',\mathbf{z}-\mathbf{z}'). \tag{23}$$

We assume the form (23) of M as a technical simplification. This is a mathematical idealization still justified by an application of physical sources of heat (as heat injections are independent at each time).

For a lower bound we need an assumption that the dependence on $\mathbf{x}-\mathbf{x}'$ is of the form of the Laplace transform (such an assumption includes the scale invariant distributions m, which do not increase at large distances) either in the form

$$\begin{aligned} m(\mathbf{x}-\mathbf{x}',\mathbf{z}-\mathbf{z}') &\equiv m_1(\mathbf{x}-\mathbf{x}')m_0(\mathbf{z}-\mathbf{z}') = \int d\mathbf{k}d\mathbf{p}\,\exp(i\mathbf{k}(\mathbf{x}-\mathbf{x}')+i\mathbf{p}(\mathbf{z}-\mathbf{z}'))\tilde{m}_1(\mathbf{k})\tilde{m}_0(\mathbf{p}) \\ &= \int_0^\infty da\,\nu_1(a)\exp(-a|\mathbf{x}-\mathbf{x}'|^2)m_0(\mathbf{z}-\mathbf{z}') \end{aligned} \tag{24}$$

or in the Euclidean invariant way

$$\begin{aligned} m(\mathbf{x}-\mathbf{x}',\mathbf{z}-\mathbf{z}') &= \int_0^\infty da\,\nu(a)\exp(-a(|\mathbf{x}-\mathbf{x}'|^2+|\mathbf{z}-\mathbf{z}'|^2)) \\ &\equiv \int_0^\infty da \int d\mathbf{p}\,\exp(i\mathbf{p}(\mathbf{z}-\mathbf{z}'))\exp(-a|\mathbf{x}-\mathbf{x}'|^2)\nu(a,\mathbf{p}). \end{aligned} \tag{25}$$

In Eqs. (24) and (25) ν_1 and ν are non-negative functions.

$\mathbf{v}$ in Eq. (13) enters T_τ in the form

$$\exp(i\mathbf{v}(\mathbf{J})),$$

where

$$\mathbf{v}(\mathbf{J}) = \int d\mathbf{u}\int_0^\tau ds\mathbf{v}(s,\mathbf{u})\mathbf{J}(s,\mathbf{u})$$

with

$$\mathbf{J}(s,\mathbf{u}) = -\theta(s)\mathbf{p}\,\delta(\mathbf{u}-\mathbf{x}-\mu\mathbf{b}(\tau-s)).$$

It follows that the expected values of n products of T_τ are expressed by

$$\langle \exp(i\mathbf{v}(\mathbf{J}_n))\rangle = S(\mathbf{J}_n),$$

where $S(\mathbf{J})$ is the characteristic function of the random field $\mathbf{v}$. For a Gaussian random field,

$$S(\mathbf{J}) = \exp\left(-\frac{1}{2}\mathbf{J}G\mathbf{J}\right). \tag{26}$$

Let us note that because of the translation invariance in the $\mathbf{z}$ variable of the source f, we have a conservation of momenta

$$\langle \tilde{T}_\tau(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\tau(\mathbf{x}_n,\mathbf{p}_n)\rangle = \delta(\mathbf{p}_1+\cdots+\mathbf{p}_n)\mathcal{H} \tag{27}$$

The correlation functions (27) are expressed by the characteristic function (26) with $\mathbf{J}_n$ satisfying the condition (for $n>1$)

$$\int \mathbf{J}_n(s,\mathbf{u})d\mathbf{u} = 0. \tag{28}$$

It follows that in the Gaussian case with the covariance (10) the part of G that is not translation invariant does not contribute to the correlation functions.

We calculate the equal time expectation values of T_τ [Eq. (13) with the zero initial condition] under the assumption that the random fields f and $\mathbf{v}$ are independent:

$$\begin{aligned}&\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle \\ &\quad = \delta(\mathbf{p}+\mathbf{p}')\int_0^\tau dt\,\exp(-\mu^2\mathbf{p}^2(\tau-t)) \\ &\qquad \times E\left[\exp\left(-i\mathbf{p}\int_0^{\tau-t}\mathbf{U}(\tau-s,\mathbf{x}+\mu\mathbf{b}(s))ds\right)\tilde{m}(\mathbf{x}-\mathbf{x}'+\mu\mathbf{b}(\tau-t)-\mu\mathbf{b}'(\tau-t),\mathbf{p})S(\mathbf{J}_2)\right],\end{aligned} \tag{29}$$

where

$$\mathbf{J}_2(\mathbf{u}) = \mathbf{p}\,\theta(s)\,\delta(\mathbf{u}-\mathbf{x}-\mathbf{b}(\tau-s)) - \mathbf{p}\,\theta(s)\,\delta(\mathbf{u}-\mathbf{x}'-\mathbf{b}'(\tau-s)).$$

For the Gaussian field (26)

$$\begin{aligned}S(\mathbf{J}_2) = \exp\Bigg(&-\frac{1}{2}\int_0^{\tau-t}\int_0^{\tau-t} dsds'\mathbf{p}G_0(s-s',\mu\mathbf{b}(s)-\mu\mathbf{b}(s'))\mathbf{p} \\ &-\frac{1}{2}\int_0^{\tau-t}\int_0^{\tau-t} dsds'\mathbf{p}G_0(s-s',\mu\mathbf{b}'(s)-\mu\mathbf{b}'(s'))\mathbf{p} \\ &+\int_0^{\tau-t}\int_0^{\tau-t} dsds'\mathbf{p}G_0(s-s',\mathbf{x}-\mathbf{x}'+\mu\mathbf{b}(s)-\mu\mathbf{b}'(s'))\mathbf{p}\Bigg),\end{aligned} \tag{30}$$

where G_0 is the translation invariant part of G. If

$$|\tilde{m}(\mathbf{x},\mathbf{p})| \leq K|\tilde{m}_0|(\mathbf{p}), \tag{31}$$

then from $|S(\mathbf{J})|\leq 1$ there follows the bound

$$|\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle| \leq K\delta(\mathbf{p}+\mathbf{p}')|\tilde{m}_0|(\mathbf{p})\mu^{-2}\mathbf{p}^{-2}(1-\exp(-\mu^2\mathbf{p}^2\tau)). \tag{32}$$

For a small $\mathbf{p}$ and a finite τ the correlations (32) are bounded by $\tau|\tilde{m}_0|(\mathbf{p})$ whereas at $\tau=\infty$ by $|\tilde{m}_0|(\mathbf{p})\mathbf{p}^{-2}$.

Next, we apply the scale invariance of the Brownian motion

$$\mathbf{b}(at) = \sqrt{a}\mathbf{b}(t) \tag{33}$$

in Eq. (29). We write $s=(\tau-t)\sigma$. Then, using the scaling properties (21) and (33) and denoting by G_0 the translation invariant part of G we can rewrite Eqs. (29) and (30) in the form

$$\begin{aligned}\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle = \delta(\mathbf{p}+\mathbf{p}')\int_0^\tau dt\,\exp(-\mu^2\mathbf{p}^2(\tau-t))\\ \times E\Bigg[\exp\Bigg(-i\mathbf{p}\int_0^{\tau-t}\mathbf{U}(\tau-s,\mathbf{x}+\mu\mathbf{b}(s))ds\Bigg)\tilde{m}(\mathbf{x}-\mathbf{x}'+\mu\sqrt{\tau-t}\mathbf{b}(1)\\ -\mu\sqrt{\tau-t}\mathbf{b}'(1),\mathbf{p})\\ \times\exp\Bigg(-\frac{1}{2}(\tau-t)^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma'\mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{b}(\sigma)-\mu\mathbf{b}(\sigma'))\mathbf{p}\\ -\frac{1}{2}(\tau-t)^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma'\mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{b}'(\sigma)-\mu\mathbf{b}'(\sigma'))\mathbf{p}\\ +(\tau-t)^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma'\mathbf{p}G_0(\sigma-\sigma',(\tau-t)^{-1/2}(\mathbf{x}-\mathbf{x}')\\ +\mu\mathbf{b}(\sigma)-\mu\mathbf{b}'(\sigma'))\mathbf{p}\Bigg)\Bigg].\end{aligned} \tag{34}$$

For the Kraichnan model[8] $\Gamma(s-s\prime)=\delta(s-s\prime)$ in Eqs. (9) and (10), then $\alpha=1$ in Eq. (22) and formula (34) reads

$$\begin{aligned}\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle = \delta(\mathbf{p}+\mathbf{p}')\int_0^\tau dt\,\exp(-\mu^2\mathbf{p}^2(\tau-t))\\ \times E\Bigg[\exp\Bigg(-i\mathbf{p}\int_0^{\tau-t}\mathbf{U}(\tau-s,\mathbf{x}+\mu\mathbf{b}(s))ds\Bigg)\tilde{m}(\mathbf{x}-\mathbf{x}'+\mu\sqrt{\tau-t}\mathbf{b}(1)\\ -\mu\sqrt{\tau-t}\mathbf{b}'(1),\mathbf{p})\\ \times\exp\Bigg(-(\tau-t)^{1-\gamma}\mathbf{p}D(0)\mathbf{p}+(\tau-t)^{1-\gamma}\int_0^1 d\sigma\mathbf{p}D((\tau-t)^{-1/2}(\mathbf{x}-\mathbf{x}')\\ +\mu\mathbf{b}(\sigma)-\mu\mathbf{b}'(\sigma))\mathbf{p}\Bigg)\Bigg].\end{aligned} \tag{35}$$

V. JENSEN INEQUALITIES FOR THE TEMPERATURE CORRELATIONS

We are going to estimate the spectral measure (6) and (7) by an application of the Jensen inequality. We can obtain an upper bound on the correlation functions by applying the Jensen inequality $[\int d\nu \exp f \geqslant \exp(\int d\nu f)$ if $\int d\nu=1]$ (Ref. 26) to the time integral in Eqs. (29) and (30):

$$|\langle\widetilde{T}_\tau(\mathbf{x},\mathbf{p})\widetilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle| \leqslant 2\delta(\mathbf{p}+\mathbf{p}')\int_0^\tau dr\int_0^1 d\sigma\int_0^\sigma d\sigma'\,\exp(-\mu^2\mathbf{p}^2 r)E\Big[|\widetilde{m}(\mathbf{x}-\mathbf{x}'+\mu\sqrt{r}\mathbf{b}(1)$$
$$-\mu\sqrt{r}\mathbf{b}'(1),\mathbf{p})|\times\exp\Big(-\frac{1}{2}r^{2-\alpha-\gamma}\mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{b}(\sigma)-\mu\mathbf{b}(\sigma'))\mathbf{p}$$
$$-\frac{1}{2}r^{2-\alpha-\gamma}\mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{b}'(\sigma)-\mu\mathbf{b}'(\sigma'))\mathbf{p}$$
$$+r^{2-\alpha-\gamma}\mathbf{p}G_0(\sigma-\sigma',r^{-1/2}(\mathbf{x}-\mathbf{x}')+\mu\mathbf{b}(\sigma)-\mu\mathbf{b}'(\sigma'))\mathbf{p}\Big)\Big]. \tag{36}$$

Let $p(s,\mathbf{u};t,\mathbf{w})$ be the transition function for the Brownian motion to pass from $\mathbf{u}$ at time s to $\mathbf{w}$ at time t. Then, the expectation value (36) reads

$$|\langle\widetilde{T}_\tau(\mathbf{x},\mathbf{p})\widetilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle|$$
$$\leqslant 2\delta(\mathbf{p}+\mathbf{p}')\int d\mathbf{u}d\mathbf{u}'d\mathbf{w}d\mathbf{w}'\int_0^\tau dr\int_0^1 d\sigma\int_0^\sigma d\sigma'\,\exp(-\mu^2\mathbf{p}^2 r)$$
$$\times p(0,\mathbf{0};\sigma',\mathbf{u})p(\sigma',\mathbf{u};\sigma,\mathbf{w})p(\sigma,\mathbf{w};1,\mathbf{z})p(0,\mathbf{0};\sigma',\mathbf{u}')p(\sigma',\mathbf{u}';\sigma,\mathbf{w}')p(\sigma,\mathbf{w}';1,\mathbf{z}')$$
$$\times|\widetilde{m}(\mathbf{x}-\mathbf{x}'+\mu\sqrt{r}\mathbf{z}-\mu\sqrt{r}\mathbf{z}',\mathbf{p})|\times\exp\Big(-\frac{1}{2}r^{2-\alpha-\gamma}\mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{w}-\mu\mathbf{u})\mathbf{p}$$
$$-\frac{1}{2}r^{2-\alpha-\gamma}\mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{w}'-\mu\mathbf{u}')\mathbf{p}+\frac{1}{2}r^{2-\alpha-\gamma}\mathbf{p}G_0(\sigma-\sigma',r^{-1/2}(\mathbf{x}-\mathbf{x}')+\mu\mathbf{w}-\mu\mathbf{u}')\mathbf{p}$$
$$+\frac{1}{2}r^{2-\alpha-\gamma}\mathbf{p}G_0(\sigma-\sigma',r^{-1/2}(\mathbf{x}-\mathbf{x}')+\mu\mathbf{w}'-\mu\mathbf{u})\mathbf{p}\Big). \tag{37}$$

Till now we have kept the mean velocity $\mathbf{U}$ as an arbitrary nonzero function. We can obtain a lower bound only if

$$\mathbf{U}=0.$$

As claimed by some authors (see, e.g., the standard textbook[27]) the mean velocity does not play any essential role in turbulence. So, setting it equal to zero we do not lose much. Moreover, for the lower bound we must assume m of the form (24) [or (25)] with $\widetilde{m}_0(\mathbf{p})\geqslant 0$. Then, we can apply the Jensen inequality to the expectation value over the Brownian motion

$$\langle\widetilde{T}_\tau(\mathbf{x},\mathbf{p})\widetilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle \geqslant \delta(\mathbf{p}+\mathbf{p}')\int_0^\tau dr\,\exp(-\mu^2\mathbf{p}^2 r)\int_0^\infty da\,\nu_1(a)$$
$$\times\widetilde{m}_0(\mathbf{p})\exp E\Big[-\frac{1}{2}r^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma'\mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{b}(\sigma)-\mu\mathbf{b}(\sigma'))\mathbf{p}$$
$$-\frac{1}{2}r^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma'\mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{b}'(\sigma)-\mu\mathbf{b}'(\sigma'))\mathbf{p}$$
$$+r^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma'\mathbf{p}G_0(\sigma-\sigma',r^{-1/2}(\mathbf{x}-\mathbf{x}')+\mu\mathbf{b}(\sigma)-\mu\mathbf{b}'(\sigma'))\mathbf{p}$$
$$-a|\mathbf{x}-\mathbf{x}'+\mu\sqrt{r}\mathbf{b}(1)-\mu\sqrt{r}\mathbf{b}'(1)|^2\Big]. \tag{38}$$

For m of the form (25) the inequality (38) reads

$$\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle \geqslant \delta(\mathbf{p}+\mathbf{p}')\int_0^\tau dr\,\exp(-\mu^2\mathbf{p}^2 r)\int_0^\infty da\,\nu(a,\mathbf{p})$$
$$\times \exp E\Bigg[-\frac{1}{2}r^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma' \mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{b}(\sigma)-\mu\mathbf{b}(\sigma'))\mathbf{p}$$
$$-\frac{1}{2}r^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma' \mathbf{p}G_0(\sigma-\sigma',\mu\mathbf{b}'(\sigma)-\mu\mathbf{b}'(\sigma'))\mathbf{p}$$
$$+r^{2-\alpha-\gamma}\int_0^1\int_0^1 d\sigma d\sigma' \mathbf{p}G_0(\sigma-\sigma',r^{-1/2}(\mathbf{x}-\mathbf{x}')+\mu\mathbf{b}(\sigma)-\mu\mathbf{b}'(\sigma'))\mathbf{p}$$
$$-a|\mathbf{x}-\mathbf{x}'+\mu\sqrt{r}\mathbf{b}(1)-\mu\sqrt{r}\mathbf{b}'(1)|^2\Bigg]. \tag{39}$$

The correlation functions (36)–(39) in general will essentially depend on the source distribution m. We consider m such that (i) m_1 is bounded from above by a constant [Eq. (31)] and, in addition, (ii) $m_1(\mathbf{x})$ is decreasing like a power 2Ω of $|\mathbf{x}|$. From Eq. (32) it follows that under the assumption (31) the limit $\tau\to\infty$ exists. We wish to estimate the correlation functions at $\tau=\infty$ under various conditions on $m_1(\mathbf{x})$. Using the inequality (for $A\geqslant 0$)

$$2\exp(-\mu^2\mathbf{p}^2 r - A(\mathbf{x}-\mathbf{x}',\mathbf{b})r^{2-\alpha-\gamma}\mathbf{p}^2) \leqslant \exp(-\mu^2\mathbf{p}^2 r)+\exp(-A(\mathbf{x}-\mathbf{x}',\mathbf{b})r^{2-\alpha-\gamma}\mathbf{p}^2),$$

and a change of variables in the r integral in Eqs. (36) and (37), $r=t|\mathbf{p}|^{-(2/2-\alpha-\gamma)}$, we obtain [when m_1 is a bounded function (31)]

$$\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x},\mathbf{p}')\rangle \leqslant \delta(\mathbf{p}+\mathbf{p}')|\tilde{m}_0|(\mathbf{p})\left(c_1\theta\left(|\mathbf{p}|-\frac{1}{\mu}\right)|\mathbf{p}|^{-2}+c_2\theta\left(\frac{1}{\mu}-|\mathbf{p}|\right)|\mathbf{p}|^{-(2/2-\alpha-\gamma)}\right), \tag{40}$$

where on the right-hand side (rhs) of Eq. (36), after an integral over r (which can be performed by a change of variables), we obtain a function $|A(\mathbf{x}-\mathbf{x}',\mathbf{b})|^{-(1/2-\alpha-\gamma)}$ (where $\mathbf{b}$ depends on σ and $\sigma\prime$) whose expectation value is expressed by the rhs of Eq. (37). This is an integrable function of $\mathbf{u},\mathbf{w},\mathbf{z},\mathbf{u}',\mathbf{w}'$, and $\mathbf{z}'$. Hence, the integral can be bounded by a constant c_2. Under a stronger assumption that

$$\int d\mathbf{x} m_1(\mathbf{x}) < \infty \tag{41}$$

from Eq. (37) we obtain in a similar way the bound

$$\int d\mathbf{x}\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x}',\mathbf{p}')\rangle \leqslant \delta(\mathbf{p}+\mathbf{p}')|\tilde{m}_0|(\mathbf{p})\left(c_3\theta\left(|\mathbf{p}|-\frac{1}{\mu}\right)|\mathbf{p}|^{-2}+c_4\theta\left(\frac{1}{\mu}-|\mathbf{p}|\right)|\mathbf{p}|^{-(2/2-\alpha-\gamma)}\right). \tag{42}$$

This is a bound on the spectral measure on the rhs of Eq. (7).

We wish to estimate the dependence of the correlation functions (34) on $\mathbf{x}-\mathbf{x}'$ in a more explicit form. Note that if the velocity correlations are defined by Eq. (9), where $\tilde{D}(\mathbf{k})$ is an integrable function, then on the basis of the Lebesgue lemma G is vanishing at large $|\mathbf{x}-\mathbf{x}'|$. In such a case the term depending on $\mathbf{x}-\mathbf{x}'$ in the exponential on the rhs of Eq. (34) can be neglected. If m is in addition a slowly varying function of $\mathbf{x}-\mathbf{x}'$ then

$$\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle \simeq \langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x},\mathbf{p}')\rangle. \tag{43}$$

A discussion of the turbulent flow (10) remains. We are unable to prove precise upper bounds for large $|\mathbf{x}-\mathbf{x}'|$ and general β. However, if $0<2\beta<1$ and $d=1$ then $g(\mathbf{x})=-|\mathbf{x}|^{2\beta}$ is a convex function[26]

$$g\left(\frac{1}{2}(\mathbf{x}+\mathbf{y})\right) \leqslant \frac{1}{2}g(\mathbf{x}) + \frac{1}{2}g(\mathbf{y}).$$

As a consequence,

$$\exp(-r^{2-\alpha+\beta}\mathbf{p}^2\Gamma(\sigma-\sigma')|r^{-1/2}(\mathbf{x}-\mathbf{x}') + \mu\mathbf{b}(\sigma) - \mu\mathbf{b}'(\sigma')|^{2\beta})$$
$$\leqslant \exp\left(-\frac{1}{2}r^{2-\alpha+\beta}\mathbf{p}^2\Gamma(\sigma-\sigma')(|2r^{-1/2}(\mathbf{x}-\mathbf{x}')|^{2\beta} + |2\mu\mathbf{b}(\sigma) - 2\mu\mathbf{b}'(\sigma')|^{2\beta})\right).$$

Hence, under the assumption (31) (after the r integration) the inequalities (36) and (37) at $\tau=\infty$ for $0<2\beta<1$ read

$$\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x}',\mathbf{p}')\rangle \leqslant K|\mathbf{p}|^{-(2/2-\alpha)}|\tilde{m}_0|(\mathbf{p})|\mathbf{x}-\mathbf{x}'|^{-(2\beta/2-\alpha)}. \tag{44}$$

We expect the inequality (44) to hold true in general [under the assumption (31)] for large $|\mathbf{x}-\mathbf{x}'|$ because we obtain such a behavior of the two-point function if in a formal way we take the limit $|\mathbf{x}-\mathbf{x}'|\to\infty$ in Eq. (34), neglecting terms of order $|\mathbf{x}-\mathbf{x}'|^{-1}$.

We discuss now the Jensen inequality (38) for the lower bound. It is sufficient to calculate the expectation value in the exponential (38). First, in the Kraichnan model (35) for the term $-W$ in the exponential appearing in Eq. (38), we obtain

$$\exp(-W(\mathbf{x}-\mathbf{x}')) = \exp\left(-r^{1-\gamma}\int d\mathbf{k}\mathbf{p}\tilde{D}(\mathbf{k})\mathbf{p}\right.$$
$$\left.\times(1-\mu^{-2}\mathbf{k}^{-2}\exp(i\mathbf{k}r^{-1/2}(\mathbf{x}-\mathbf{x}'))(1-\exp(-\mu^2\mathbf{k}^2)))\right). \tag{45}$$

It is easy to see that

$$\exp(-W(0)) = \exp\left(-r^{1-\gamma}\int d\mathbf{k}\mathbf{p}\tilde{D}(\mathbf{k})\mathbf{p}\times(1-\mu^{-2}\mathbf{k}^{-2}(1-\exp(-\mu^2\mathbf{k}^2)))\right) \geqslant \exp(-cr^{1-\gamma}\mathbf{p}^2) \tag{46}$$

under the assumptions that $\mathbf{p}\tilde{D}\mathbf{p} \geqslant |\tilde{D}|\mathbf{p}^2$, $\int d\mathbf{k}|\tilde{D}|(\mathbf{k})\theta(|\mathbf{k}|-(1/\mu))<\infty$, and

$$\int d\mathbf{k}|\tilde{D}|(\mathbf{k})\mathbf{k}^2\theta\left(\frac{1}{\mu}-|\mathbf{k}|\right) < \infty.$$

In such a case we can take the limit $\tau\to\infty$. In this limit

$$\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x},\mathbf{p}')\rangle \geqslant \delta(\mathbf{p}+\mathbf{p}')\tilde{m}_0(\mathbf{p})\int_0^\infty dr\int da\,\nu_1(a)\exp(-\mu^2\mathbf{p}^2r - c\mathbf{p}^2r^{1-\gamma} - 2a\mu^2r)$$
$$= \tilde{m}_0(\mathbf{p})\,\delta(\mathbf{p}+\mathbf{p}')\int_0^\infty dr m_1(\mu\sqrt{2r})\exp(-\mu^2\mathbf{p}^2r - c\mathbf{p}^2r^{1-\gamma}). \tag{47}$$

The behavior of the integral (47) depends on the behavior of the source correlations m_1 as a function of $|\mathbf{x}-\mathbf{x}'|$. If

$$m_1(\mu\sqrt{2r}) \geqslant K, \tag{48}$$

then

$$(\tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x},\mathbf{p}')) \geqslant \delta(\mathbf{p}+\mathbf{p}')\tilde{m}_0(\mathbf{p})\left(c_5\theta\left(|\mathbf{p}|-\frac{1}{\mu}\right)|\mathbf{p}|^{-2}+c_6\theta\left(\frac{1}{\mu}-|\mathbf{p}|\right)|\mathbf{p}|^{-(2/1-\gamma)}\right). \tag{49}$$

This lower bound coincides with the upper bound (40) (where $\alpha=1$). If m_1 satisfies a stronger condition ($\Omega<1$)

$$m_1(|\mathbf{x}|) \geqslant K|\mathbf{x}|^{-2\Omega} \tag{50}$$

[$\Omega\geqslant 0$ if it is to be of the form (24), i.e., $\nu_1(a)\geqslant Ka^{\Omega-1}$], then

$$\langle\tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x},\mathbf{p}')\rangle \geqslant \delta(\mathbf{p}+\mathbf{p}')\tilde{m}_0(\mathbf{p})\left(c_7\theta\left(|\mathbf{p}|-\frac{1}{\mu}\right)|\mathbf{p}|^{-2+2\Omega}+c_8\theta\left(\frac{1}{\mu}-|\mathbf{p}|\right)|\mathbf{p}|^{-[(2-2\Omega)/(1-\gamma)]}\right). \tag{51}$$

The inequality (51) results from the following estimate (for $\alpha+\gamma<1$):

$$\begin{aligned}\int_0^\infty drr^{-\Omega}\exp(-\mu^2\mathbf{p}^2r-c\mathbf{p}^2r^{2-\alpha-\gamma}) &= \int_0^1 drr^{-\Omega}\exp(-\mu^2\mathbf{p}^2r-c\mathbf{p}^2r^{2-\alpha-\gamma})\\ &\quad+\int_1^\infty drr^{-\Omega}\exp(-\mu^2\mathbf{p}^2r-c\mathbf{p}^2r^{2-\alpha-\gamma})\\ &\geqslant \int_0^1 drr^{-\Omega}\exp(-(\mu^2\mathbf{p}^2+c\mathbf{p}^2)r)\\ &\quad+\int_1^\infty drr^{-\Omega}\exp(-(\mu^2\mathbf{p}^2+c\mathbf{p}^2)r^{2-\alpha-\gamma})\\ &= |\mathbf{p}|^{-2+2\Omega}\int_0^{\mathbf{p}^2} t^{-\Omega}\exp(-(\mu^2+c)t)dt\\ &\quad+|\mathbf{p}|^{-[(2-2\Omega)/(2-\alpha-\gamma)]}\int_{a(\mathbf{p})}^\infty t^{-\Omega}\exp(-(\mu^2+c)t^{2-\alpha-\gamma})dt,\end{aligned} \tag{52}$$

where $a(\mathbf{p})=|\mathbf{p}|^{2/(2-\alpha-\gamma)}$ and $\alpha=1$ in application to Eq. (47).

Next, we wish to estimate the behavior of the temperature correlations at large $\mathbf{x}-\mathbf{x}'$ in the turbulent case (10) when $\gamma=-\beta<0$ [if $\gamma>0$ and m_1 is a bounded function then the temperature correlations are bounded from below and from above as functions of $\mathbf{x}-\mathbf{x}'$, Eq. (43)]. First, we consider the Kraichnan model (35) [$\Gamma(s-s')=\delta(s-s')$ in Eq. (10)] with the mean velocity $\mathbf{U}=0$ and

$$\tilde{D}(\mathbf{k}) \simeq |\mathbf{k}|^{-d+2\gamma}. \tag{53}$$

The integral in Eq. (45) is convergent for large $\mathbf{k}$ if $\gamma<0$ and for small $\mathbf{k}$ if $-\gamma<1$. We consider the model (10) with $0<\beta=-\gamma<1$. Let us change the integration variable in Eq. (45):

$$\mathbf{k} = |\mathbf{x}-\mathbf{x}'|^{-1}\sqrt{r}\mathbf{q}. \tag{54}$$

Then, after an estimate of the remainder,

$$\exp(-W(\mathbf{x}-\mathbf{x}')) \geqslant \exp(-cr\mathbf{p}^2|\mathbf{x}-\mathbf{x}'|^{2\beta}). \tag{55}$$

As a consequence,

$$\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle \geqslant \delta(\mathbf{p}+\mathbf{p}')\tilde{m}_0(\mathbf{p})(\mu^2\mathbf{p}^2+c\mathbf{p}^2|\mathbf{x}-\mathbf{x}'|^{2\beta})^{-1}(1-\exp(-\tau(\mu^2\mathbf{p}^2+c\mathbf{p}^2|\mathbf{x}-\mathbf{x}'|^{2\beta}))).$$

Hence, for large $|\mathbf{x}-\mathbf{x}\prime|$ we obtain

$$\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x}',\mathbf{p}')\rangle \geqslant \delta(\mathbf{p}+\mathbf{p}')\tilde{m}_0(\mathbf{p})c^{-1}\mathbf{p}^{-2}|\mathbf{x}-\mathbf{x}'|^{-2\beta}. \tag{56}$$

This lower bound for the Kraichnan model is the same as the upper bound (44) (here $\alpha=1$). Let us calculate the expectation value in the exponential of Eq. (38) (denoted by $-W$) for the general G of Eq. (19):

$$\begin{aligned} W(\mathbf{x}-\mathbf{x}') = r^{2-\alpha-\gamma}\int d\omega d\mathbf{k}\mathbf{p}\tilde{G}(\omega,\mathbf{k})\mathbf{p} \\ \times\left(2\left(\frac{1}{2}\mu^2\mathbf{k}^2-i\omega\right)^{-1}\left(1-\left(\frac{1}{2}\mu^2\mathbf{k}^2-i\omega\right)^{-1}\left(1-\exp\left(-\frac{1}{2}\mu^2\mathbf{k}^2+i\omega\right)\right)\right)\right) \\ -\left(\frac{1}{4}\mu^4|\mathbf{k}|^4+\omega^2\right)^{-1}\exp(i\mathbf{k}r^{-1/2}(\mathbf{x}-\mathbf{x}'))\left|1-\exp\left(-\frac{1}{2}\mu^2\mathbf{k}^2+i\omega\right)\right|^2\Bigg). \end{aligned} \tag{57}$$

We estimate this integral at $\mathbf{x}=\mathbf{x}\prime$ first. Similarly, as in Eq. (46), the scale invariance (21) leads to

$$W(\mathbf{0}) \geqslant cr^{2-\alpha-\gamma}\mathbf{p}^2 \tag{58}$$

if

$$\int d\mathbf{k}d\omega\tilde{G}(\omega,\mathbf{k})\left(\frac{1}{2}\mu^2\mathbf{k}^2-i\omega\right)^{-1}\theta\left(|\mathbf{k}|-\frac{1}{\mu}\right)<\infty$$

and

$$\int\int d\mathbf{k}d\omega\tilde{G}(\omega,\mathbf{k})\left(\frac{1}{4}\mu^4|\mathbf{k}|^4+\omega^2\right)^{1/2}\theta\left(\frac{1}{\mu}-|\mathbf{k}|\right)<\infty.$$

Hence, under the assumption (50), on the basis of the inequalities (52) and (58), we have the lower bound [generalizing that of Eq. (51) to $\alpha\neq 1$]

$$\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x},\mathbf{p}')\rangle \geqslant \delta(\mathbf{p}+\mathbf{p}')\tilde{m}_0(\mathbf{p})\left(c\,\theta\left(|\mathbf{p}|-\frac{1}{\mu}\right)|\mathbf{p}|^{-2+2\Omega}+c'\,\theta\left(\frac{1}{\mu}-|\mathbf{p}|\right)|\mathbf{p}|^{-[(2-2\Omega)/(2-\alpha-\gamma)]}\right) \tag{59}$$

[at $\Omega=0$ this lower bound coincides with the upper bound (40)]. Next, if $|\mathbf{x}-\mathbf{x}'|$ is large, then for $0<-\gamma=\beta<1$ we obtain from Eqs. (21) and (57) the lower bound

$$\exp(-W(\mathbf{x}-\mathbf{x}')) \geqslant \exp(-c\mathbf{p}^2r^{2-\alpha}|\mathbf{x}-\mathbf{x}'|^{2\beta}),$$

where the form of the rhs comes from a change of variables $\mathbf{k}=\mathbf{k}\prime|\mathbf{x}-\mathbf{x}'|^{-1}$ and $\omega=\omega'|\mathbf{x}-\mathbf{x}\prime|^{-2}$ and an estimate of the remainder in Eq. (57).

If we restrict ourselves to G of the form (10) and $2\beta\geqslant 1$, then we can derive a more precise lower bound for $\exp(-W)$ with an application of the Hölder inequality

$$|\mathbf{x}+\mathbf{y}|^{2\beta} \leqslant 2^{2\beta-1}(|\mathbf{x}|^{2\beta}+|\mathbf{y}|^{2\beta}).$$

From Eq. (38) and the Hölder inequality we obtain, after an elementary calculation of the expectation value over the Brownian paths,

$$\exp(-W(\mathbf{x}-\mathbf{x}')) \geqslant \exp(-Cr^{2-\alpha-\gamma}\mathbf{p}^2 - cr^{2-\alpha}|\mathbf{x}-\mathbf{x}'|^{2\beta}\mathbf{p}^2). \tag{60}$$

Hence, after a calculation of the expectation value in the exponential in Eq. (38), the remaining r and the a integrals [from the representation (24)] in the correlation function (38) read

$$\int_0^\infty dr \int da\,\nu_1(a)\exp(-W-a|\mathbf{x}-\mathbf{x}'|^2-2\mu^2 ra) \geqslant \frac{1}{2}\int_0^\infty dr \int da\,\nu_1(a)\exp(-W-a|\mathbf{x}-\mathbf{x}'|^2) + \frac{1}{2}\int_0^\infty dr \int da\,\nu_1(a)\exp(-W-2\mu^2 ra),$$

where $\exp(-W)$ is lower bounded by Eq. (60). An easy estimate of this integral leads to the following inequality for large $\mathbf{x}-\mathbf{x}'$:

$$\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x}',\mathbf{p}')\rangle \geqslant \delta(\mathbf{p}+\mathbf{p}')\tilde{m}_0(\mathbf{p})(K_1|\mathbf{p}|^{-[(2-2\Omega)/(2-\alpha)]}|\mathbf{x}-\mathbf{x}'|^{-2\sigma} + K_2|\mathbf{p}|^{-2/(2-\alpha)}|\mathbf{x}-\mathbf{x}'|^{-[2\beta/(2-\alpha)]-2\Omega}), \tag{61}$$

where

$$\sigma = \frac{\beta(1-\Omega)}{2-\alpha}. \tag{62}$$

For $0<2\beta<1$ this lower bound coincides with the upper bound (44) (derived for $\Omega=0$). We expect that Eq. (61) gives the asymptotic behavior of the two-point correlation function for any $0<2\beta<2$ because such a behavior is a consequence of a formal exchange of the limit $|\mathbf{x}-\mathbf{x}'| \to \infty$ with the integral over t and the expectation value over the Brownian motion in Eq. (34).

The lower bound (59) for small $\mathbf{p}$ is obtained by neglecting the $|\mathbf{x}-\mathbf{x}'|$-dependent term on the rhs of Eq. (60). We can see from Eq. (59) that if $\tilde{m}_0(\mathbf{p}) \simeq |\mathbf{p}|^{-\nu}$ and $m_1(\mathbf{k}) \simeq |\mathbf{k}|^{-d+2\Omega}$ then the $\langle \tilde{T}\tilde{T}\rangle$ correlations behave as $|\mathbf{p}|^{-2-\nu+2\Omega}$ for large momenta (short distances in the $\mathbf{z}$ direction), whereas the low momentum behavior (large distance) is $|\mathbf{p}|^{-\nu-[(2-2\Omega)/(2-\alpha-\gamma)]}$. These estimates show the effect of the random flow on the temperature correlations in the $\mathbf{z}$ direction. The effect on the temperature correlations in the $\mathbf{x}$ direction is described by the lower bound (61) and the upper bound (44). Again the decay of temperature correlations is determined by scaling indices of the velocity and source correlations.

VI. HIGHER ORDER CORRELATION FUNCTIONS

Let us consider the multipoint correlation functions

$$\langle \tilde{T}_\tau(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\tau(\mathbf{x}_{2n},\mathbf{p}_{2n})\rangle = \sum_{\text{pairs}} \int_0^\tau dt_1\cdots dt_{2n} \prod_{(j,k)} \delta(\mathbf{p}_j+\mathbf{p}_k)\delta(t_j-t_k)\exp\left(-\frac{1}{2}\mu^2\sum_j \mathbf{p}_j^2(\tau-t_j)\right) \times E\left[\prod_{(j,k)} \tilde{m}(\mathbf{x}_j-\mathbf{x}_k+\mu\mathbf{b}_j(\tau-t_j)-\mu\mathbf{b}_k(\tau-t_k),\mathbf{p}_j) \times \exp\left(-\frac{1}{2}\sum_{il}\int_0^{\tau-t_i}\int_0^{\tau-t_l} ds\,ds'\,\mathbf{p}_i G_0(s-s',\mathbf{x}_i-\mathbf{x}_l+\mu\mathbf{b}_i(s) - \mu\mathbf{b}_l(s'))\mathbf{p}_l\right)\right], \tag{63}$$

where the sum is over all pairings in accordance with the Gaussian combinatorics. From (63) we have

$$|\langle \tilde{T}_\tau(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\tau(\mathbf{x}_{2n},\mathbf{p}_{2n})\rangle| \leqslant \sum_{\text{pairs}} \int_0^t dt_1\cdots dt_{2n} \times \prod_{(j,k)} \delta(\mathbf{p}_j+\mathbf{p}_k)\delta(t_j-t_k)\exp\left(-\frac{1}{2}\mu^2\sum_j \mathbf{p}_j^2(\tau-t_j)\right)$$
$$\times E\left[\prod_{(j,k)} |\tilde{m}(\mathbf{x}_j-\mathbf{x}_k+\mu\mathbf{b}_j(\tau-t_j)-\mu\mathbf{b}_k(\tau-t_k),\mathbf{p}_j)|\right] < \infty.$$

Hence, the equilibrium limit $\tau\to\infty$ exists.

If m is either of the form (24) or (25) then we can apply the Jensen inequality to the expectation value in the form $E[\exp f]\geqslant \exp E[f]$. We obtain an analogue of the lower bound (38). For the upper bound we apply the Jensen inequality to the time integral

$$\exp\left(-\frac{1}{2}\int_0^\tau\int_0^\tau dsds' \int\int J_k(s)J_l(s')\langle v_k(s)v_l(s')\rangle\right)$$
$$\leqslant \tau^{-2}\int_0^\tau\int_0^\tau dsds' \exp\left(-\frac{\tau^2}{2}\int\int J_k(s)J_l(s')\langle v_k(s)v_l(s')\rangle\right), \tag{64}$$

where

$$\mathbf{J}(s,\mathbf{u}) = -\theta(s)\sum_{k=1}^{2n}\mathbf{p}_k\delta(\mathbf{u}-\mathbf{x}_k-\mu\mathbf{b}_k(\tau-s))$$

and the additional integral in Eq. (64) is over the spatial variable $\mathbf{u}$.

We can repeat the basic estimates concerning the behavior for low $\mathbf{z}$ momenta and large $\mathbf{x}$ distances by means of the methods applied for the two-point correlations. First, by means of the Jensen inequalities, we reduce the estimates of the expectation values to finite dimensional integrals. From the Jensen inequalities we can see that the correlation functions are bounded in τ when $\tau\to\infty$. Next, the results concerning the scaling behavior for $2n$-point functions can be obtained by an introduction of spherical coordinates in the $dt_1\cdots dt_n$ integral in Eq. (63). Then, the correlation functions scale in a simple way with respect to the temporal radius r. Let us explain such estimates in more detail for $n=2$. Then,

$$\langle \tilde{T}_\tau(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\tau(\mathbf{x}_4,\mathbf{p}_4)\rangle = \delta(\mathbf{p}_1+\mathbf{p}_3)\delta(\mathbf{p}_2+\mathbf{p}_4)\times\int_0^\tau dt_1\int_0^\tau dt_2\exp(-\mu^2\mathbf{p}_1^2(\tau-t_1)-\mu^2\mathbf{p}_2^2(\tau-t_2))$$
$$\times E\Bigg[\tilde{m}(\mathbf{x}_1-\mathbf{x}_3+\mu\mathbf{b}_1(\tau-t_1)-\mu\mathbf{b}_3(\tau-t_1),\mathbf{p}_1)\times\tilde{m}(\mathbf{x}_2-\mathbf{x}_4+\mu\mathbf{b}_2(\tau$$
$$-t_2)-\mu\mathbf{b}_4(\tau-t_2),\mathbf{p}_2)\times\exp\Bigg(-\sum_{j=1,2}\int_0^{\tau-t_j}\int_0^{\tau-t_j}dtdt'\mathbf{p}_jG_0(t-t',\mu\mathbf{b}_j(t)$$
$$-\mu\mathbf{b}_j(t'))\mathbf{p}_j+\sum_{j<k}\int_0^{\tau-t_j}\int_0^{\tau-t_k}dtdt'\mathbf{p}_jG_0(t-t',\mathbf{x}_j-\mathbf{x}_k+\mu\mathbf{b}_j(t)$$
$$-\mu\mathbf{b}_k(t'))\mathbf{p}_k\Bigg)\Bigg]+\text{permut.}, \tag{65}$$

where the sum is over permutations of the numbers from 1 to 4 in accordance with the Gaussian combinatorics; in the sum in the exponential we set $t_1=t_3$ and $t_2=t_4$. Let $\tau-t_1=r\cos\theta$, $\tau-t_2=r\sin\theta$, $t=r\sigma\cos\theta$, and $t'=r\sigma'\sin\theta$. In such a case r scales in the exponential in the same way as in Eqs. (37) and (38). The integral $dt_1dt_2=drrd\theta$ adds an additional power of r. Under the assumption (31) the small $\mathbf{p}$ behavior of the correlation functions (65) at $\tau=\infty$ is determined by the integral

$$|\langle \tilde{T}_\infty(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\infty(\mathbf{x}_4,\mathbf{p}_4)\rangle| \simeq |\tilde{m}_0|(\mathbf{p}_1)|\tilde{m}_0|(\mathbf{p}_2)\int_0^\infty drrE\left[\exp\left(-r^{2-\alpha-\gamma}\sum_{jk}\mathbf{p}_jG_0\mathbf{p}_k\right)\right] + \text{permut.}$$
$$\simeq |\tilde{m}_0|(\mathbf{p}_1)|\tilde{m}_0|(\mathbf{p}_2)E\left[\left|\sum_{jk}\mathbf{p}_jG_0\mathbf{p}_k\right|^{-[2/(2-\alpha-\gamma)]}\right] + \text{permut.} \quad (66)$$

For large distances, $\gamma=-\beta<0$ and G of Eq. (10), we can expand the dependence on the Brownian motion in Eq. (66) in powers of $\mu|\mathbf{x}_j-\mathbf{x}_k|^{-1}$. The leading order reads

$$|\langle \tilde{T}_\infty(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\infty(\mathbf{x}_4,\mathbf{p}_4)\rangle| \simeq |\tilde{m}_0|(\mathbf{p}_1)|\tilde{m}_0|(\mathbf{p}_2)\left|\sum_{jk}\mathbf{p}_j\mathbf{p}_k|\mathbf{x}_j-\mathbf{x}_k|^{2\beta}\right|^{-[2/(2-\alpha)]} + \text{permut.} \quad (67)$$

Note that the power describing the low $\mathbf{p}$ behavior in Eq. (66) and large $\mathbf{x}$ behavior in Eq. (67) is twice as big as that for the two-point function (34) and (40) indicating the asymptotic scale invariance of the temperature $\tilde{T}_\infty(\mathbf{x},\mathbf{p})$ at low momenta or large distances. This property can be extended to the $2n$ correlation functions where the scaling index is proportional to n as a consequence of the drr^{n-1} time integral in the spherical time coordinates. Such a behavior of the integrals suggests that if the velocities and the sources are scale invariant then the temperatures scale at large distances with the scale dimension determined by the two-point function.

VII. DISCUSSION

The power-law behavior of turbulent velocity correlation functions and passive scalar correlation functions in a homogeneous isotropic turbulent flow has been widely discussed in the literature since the basic papers of Kolmogorov[2] followed by Obukhov,[28] Corrsin,[29] and Batchelor[30] (concerning the scalar advection). The universal Kolmogorov 5/3 law for spectral velocity distribution as well as passive scalar distribution is derived by means of dimensional arguments (independent of any dynamical model). A statistical homogeneity and isotropy of the turbulence at a microscale in a sufficiently large space interval (called the "inertial range") is at the basis of the Kolmogorov theory. Under these assumptions the velocity (or passive scalar) correlation functions are universal, i.e., independent of the source distribution m. An experimental verification is not simple. Turbulent flows are usually nonhomogeneous and nonisotropic at a macro scale. However, if a flow satisfying Kolmogorov assumptions is created, then the spectral Kolmogorov law is satisfied in the inertial range.[31] Nevertheless, it is common for flows in nature that Kolmogorov assumptions are not satisfied (for some studies of such turbulent flows, see Refs. 32 and 33). Even if the velocity is satisfying the Kolmogorov law, the analogous Obukhov law for ρ may fail.[32–34] As the authors in Ref. 32 point out, some problems with the verification of Kolmogorov's theory concern a construction of a flow that would be homogeneous and isotropic in a sufficiently large inertial range (usually boundary conditions or sources violate a global symmetry). They suggest a study of nonisotropic flows.

An investigation of a general class of dynamical models of randomly forced Navier-Stokes and passive scalar equations is still beyond the reach of analytical as well as numerical methods. Substantial progress has been achieved in the white noise randomly forced passive scalar (Kraichnan model).[4,8,9] However, the white noise distribution of velocities is quite unrealistic. Our main motivation in these studies was a derivation of the scaling behavior for velocities that are not of the white noise type. A passive scalar in a shear flow independent of the coordinates in the direction of the flow was studied before in Refs. 6 and 7. However, these authors were interested in the anomalous free decay of solutions of the advection-diffusion equation.

Our results predict a power law of the passive scalar correlations in nonisotropic flows. The results depend on the source distribution m because the source f is present at any scale. We do not specify any inertial range in our model. In general, the correlations must depend on the source (for a discussion of random forcing, see Ref. 35). This can be seen from the detailed calculations in Refs. 36 and 37 performed in the isotropic Kraichnan model (white noise in time).[4,8,9] The two-

point passive scalar correlations depend explicitly on the source and on the molecular diffusivity μ^2. Only in a proper limit of the source covariance m and $\mu\to 0$ does the universal scaling law come out.

Before we summarize our results let us begin with simple models. First, consider a pure diffusion corresponding to $\mathbf{V}=0$. Then

$$\langle \tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle = 2\delta(\mathbf{p}+\mathbf{p}')\int_0^\tau dr\,\exp(-\mu^2\mathbf{p}^2 r)\times E[\tilde{m}(\mathbf{x}-\mathbf{x}'+\mu\sqrt{r}\mathbf{b}(1)-\mu\sqrt{r}\mathbf{b}'(1),\mathbf{p})]$$

$$= 2\delta(\mathbf{p}+\mathbf{p}')(2\pi)^{-D+d}\int_0^\tau dr\,\exp(-\mu^2\mathbf{p}^2 r)$$

$$\times\int d\mathbf{u}d\mathbf{w}\,\exp\left(-\frac{\mathbf{u}^2}{2}-\frac{\mathbf{w}^2}{2}\right)[\tilde{m}(\mathbf{x}-\mathbf{x}'+\mu\sqrt{r}\mathbf{u}-\mu\sqrt{r}\mathbf{w},\mathbf{p})]$$

$$= \mu^{-2}\delta(\mathbf{p}+\mathbf{p}')\int d\mathbf{k}\,\exp(i\mathbf{k}(\mathbf{x}-\mathbf{x}'))\tilde{m}_1(\mathbf{k})\tilde{m}_0(\mathbf{p})(\mathbf{p}^2+\mathbf{k}^2)^{-1}$$

$$\times(1-\exp(-\mu^2(\mathbf{p}^2+\mathbf{k}^2)\tau)).$$

In the limit $\tau\to\infty$

$$\langle T_\infty(\mathbf{x},\mathbf{z})T_\infty(\mathbf{x}',\mathbf{z}')\rangle = \mu^{-2}\int d\mathbf{k}d\mathbf{p}\,\exp(i\mathbf{k}(\mathbf{x}-\mathbf{x}'))\exp(i\mathbf{p}(\mathbf{z}-\mathbf{z}'))\tilde{m}(\mathbf{k},\mathbf{p})(\mathbf{p}^2+\mathbf{k}^2)^{-1}. \quad (68)$$

Hence

$$\rho_\infty(\mathbf{k},\mathbf{p}) = \mu^{-2}(\mathbf{p}^2+\mathbf{k}^2)^{-1}\tilde{m}_1(\mathbf{k})\tilde{m}_0(\mathbf{p}). \quad (69)$$

Let us note that the behavior of the temperature correlations changes abruptly for large $|\mathbf{z}-\mathbf{z}'|$ at $\tau=\infty$ in this simple model. At finite τ it is the same as that of the source (say $|\mathbf{z}-\mathbf{z}'|^{-d+\nu}$) whereas at $\tau=\infty$ it becomes $|\mathbf{z}-\mathbf{z}'|^{-d+\nu+2}$. However, it can be seen from Eq. (68) that after the limit $\tau\to\infty$, the limit $\mu\to 0$ does not exist in the model without the advection. If we first take $\mu\to 0$ then the subsequent limit $\tau\to\infty$ is linearly divergent in τ. The strong μ dependence of the asymptotic behavior means that this parameter sets a scale on time and space that determines different scaling behavior. In Appendix A we show that the limits $\mu\to 0$ and $\tau\to\infty$ can be interchanged in the model with a random advection. The correlation functions $\mathcal{S}^{(2n)}$ in a nonisotropic Kraichnan model are discussed in Appendix B. The correlation functions $\mathcal{S}^{(2n)}(\mathbf{x}_1,\mathbf{p}_1,\ldots,\mathbf{x}_{2n},\mathbf{p}_{2n})$ can be calculated exactly in the limit $\mu\to 0$ [Eq. (86)]. They show no anomalous scaling (encountered in the isotropic model[4,8]) as long as the points $\mathbf{x}_j$ are different. The scaling behavior can change after a transformation to the configuration space (the Fourier transform does not exist in the usual sense).

Let us compare the two-point temperature correlation function (68) with the one in a random flow, which is bounded in space and time, i.e., $G=\langle\mathbf{vv}\rangle\simeq$ const. Under the assumption (31) we obtain

$$\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x}',\mathbf{p}')\rangle \simeq K\delta(\mathbf{p}+\mathbf{p}')\tilde{m}_0(\mathbf{p})\int_0^\infty dr\,\exp(-\mu^2\mathbf{p}^2 r - c\mathbf{p}^2 r^2). \quad (70)$$

The integral (70) behaves as $\tilde{m}_0(\mathbf{p})\mathbf{p}^{-2}$ for large $\mathbf{p}$ and as $\tilde{m}_0(\mathbf{p})|\mathbf{p}|^{-1}$ for a small $\mathbf{p}$ in agreement with Eq. (59) for $\Omega=\alpha=\gamma=0$. Our results of Secs. IV and V give an extension of the simple observations on the temperature correlation functions derived in this section for a pure diffusion and for an advection by a uniformly bounded random flow.

In our model (defined by the assumption that the velocity does not depend on coordinates in the direction of the flow) the spectral distribution in the corresponding momentum is proportional to the source distribution $\tilde{m}$, as can be seen from Eq. (34). We could consider a source f with the covariance $m(\mathbf{x},\mathbf{z})$, which (approximately in a certain range as in Refs. 36 and 37) is independent

of $\mathbf{x}$. In such a case the spectral equilibrium distribution (6) for a pure diffusion $\rho_\infty(\mathbf{k},\mathbf{p})$ (67) is $\delta(\mathbf{k})\tilde{m}_0(\mathbf{p})\mathbf{p}^{-2}$, where the $\mathbf{p}^{-2}$ behavior comes from the molecular diffusivity. The temperature correlations remain independent of $\mathbf{x}$ and the limit $\mu\to 0$ does not exist. A random advection is changing the behavior of temperature correlations in $\mathbf{x}$ as well as in $\mathbf{p}$. This change involves a nonperturbative mechanism that could not be seen in an expansion in $\mathbf{V}$. It comes from an exponential of G in Eq. (34). In particular, a steady flow bounded in $\mathbf{x}$ gives $\rho_\infty(\mathbf{k},\mathbf{p})=\delta(\mathbf{k})|\mathbf{p}|^{-1}$ for $|\mathbf{p}|\ll 1/\mu$, whereas for the random velocity growing in space with the index β [Eq. (10)] we have for a small $\mathbf{k}$ the behavior $\rho_\infty(\mathbf{k},\mathbf{p})\simeq|\mathbf{k}|^{-d+[2\beta/(2-\alpha)]}$, as follows from Eq. (61).

In experiments ($D=3$) we could create an anisotropic flow with the Kolmogorov index (10) $\beta=1/3$ in $d=2$ or $d=1$. In such a case we obtain definite predictions concerning the temperature distribution. This will be $|\mathbf{x}-\mathbf{x}'|^{-2/3}|\mathbf{z}-\mathbf{z}'|^{\nu}$ where

$$\nu=\frac{2}{2-\alpha}-(D-d),$$

and $D-d$ is either 1 or 2, and there is a restriction $\alpha-\beta<1$ coming from the requirement of the integrability of the expression in the exponential of (34).

In general, we can see from Eqs. (40), (42), (44), (59), and (61) that the turbulent behavior $\gamma=-\beta<0$ of the velocity field will (in comparison to pure diffusion) decrease the temperature correlations in the direction orthogonal to the flow and increase the correlations (at the fixed α)in the direction of the flow. These effects contribute to the more coherent heat distribution in a turbulent stream.

APPENDIX A: THE LIMIT $\mu\to 0$

If there is no diffusion ($\mu=0$), then our formulas in Secs. IV–VI at finite τ remain valid but need some interpretation. There is no expectation value over the Brownian motion. In such a case, in some formulas [as in Eqs. (34) and (35)] $\gamma=0$. Let us consider as an example the formula (34) at $\mu=0$:

$$\begin{aligned}\langle\tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle=\delta(\mathbf{p}+\mathbf{p}')\tilde{m}(\mathbf{x}-\mathbf{x}',\mathbf{p})\int_0^\tau dt\exp\left(-i\mathbf{p}\int_0^{\tau-t}ds\mathbf{U}(\tau-s,\mathbf{x})\right)\\ \times\exp\left(-(\tau-t)^{2-\alpha}\int_0^1\int_0^1 d\sigma d\sigma'\mathbf{p}G_0(\sigma-\sigma',0)\mathbf{p}\right.\\ \left.+(\tau-t)^{2-\alpha}\int_0^1\int_0^1 d\sigma d\sigma'\mathbf{p}G_0(\sigma-\sigma',\mathbf{x}-\mathbf{x}')\mathbf{p}\right).\end{aligned}\tag{71}$$

For the Kraichnan model[8] (35) the formula (71) reads (with the Stratonovitch interpretation of the gradient term; see the discussion at the beginning of Sec. II)

$$\begin{aligned}\langle\tilde{T}_\tau(\mathbf{x},\mathbf{p})\tilde{T}_\tau(\mathbf{x}',\mathbf{p}')\rangle=\delta(\mathbf{p}+\mathbf{p}')\tilde{m}(\mathbf{x}-\mathbf{x}',\mathbf{p})\int_0^\tau dt\exp\left(-i\mathbf{p}\int_0^{\tau-t}\mathbf{U}(\tau-s,\mathbf{x})ds\right)\\ \times\exp(-(\tau-t)\mathbf{p}D_0(0)\mathbf{p}+(\tau-t)\mathbf{p}D_0(\mathbf{x}-\mathbf{x}')\mathbf{p}).\end{aligned}\tag{72}$$

In the limit $\tau\to\infty$ and for $\mathbf{U}=0$ we can calculate the integral over time in Eq. (71) with the result

$$\langle \tilde{T}_\infty(\mathbf{x},\mathbf{p})\tilde{T}_\infty(\mathbf{x}',\mathbf{p}')\rangle = C\delta(\mathbf{p}+\mathbf{p}')\tilde{m}(\mathbf{x}-\mathbf{x}',\mathbf{p})\Bigg(\int_0^1\int_0^1 d\sigma d\sigma' \mathbf{p}G_0(\sigma-\sigma',0)\mathbf{p} - \int_0^1\int_0^1 d\sigma d\sigma' \mathbf{p}G_0(\sigma-\sigma',\mathbf{x}-\mathbf{x}')\mathbf{p}\Bigg)^{-[1/(2-\alpha)]}, \tag{73}$$

in agreement with the bounds (56) and (61). We can also calculate the higher order correlation functions. As an example, the four-point function (65) reads

$$\langle \tilde{T}_\tau(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\tau(\mathbf{x}_4,\mathbf{p}_4)\rangle = \delta(\mathbf{p}_2+\mathbf{p}_4)\delta(\mathbf{p}_1+\mathbf{p}_3)\tilde{m}(\mathbf{x}_1-\mathbf{x}_3,\mathbf{p}_1)\tilde{m}(\mathbf{x}_2-\mathbf{x}_4,\mathbf{p}_2) \times \int_0^\tau dt_1\int_0^\tau dt_2 \exp\Bigg(-\sum_{j=1,2}\int_0^{\tau-t_j}\int_0^{\tau-t_j} dtdt'\mathbf{p}_j G_0(t-t',0)\mathbf{p}_j + \sum_{j<k}\int_0^{\tau-t_j}\int_0^{\tau-t_k} dtdt'\mathbf{p}_j G_0(t-t',\mathbf{x}_j-\mathbf{x}_k)\mathbf{p}_k\Bigg) + \text{permut.}$$

We can obtain detailed estimates of the time integrals for any α. In some special cases the integrals can be explicitly calculated. In Appendix B we give the formula [Eq. (88)] for the Kraichnan model ($\alpha=1$). For a steady flow [$\Gamma(s)=1$ in Eq. (10), $\alpha=0$] at $\tau=\infty$ the integration over t_j gives

$$\langle \tilde{T}_\infty(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\infty(\mathbf{x}_4,\mathbf{p}_4)\rangle = \delta(\mathbf{p}_2+\mathbf{p}_4)\delta(\mathbf{p}_1+\mathbf{p}_3)\tilde{m}(\mathbf{x}_1-\mathbf{x}_3,\mathbf{p}_1)\tilde{m}(\mathbf{x}_2-\mathbf{x}_4,\mathbf{p}_2) \times (4\mathbf{p}_1^2\mathbf{p}_2^2 D_0(\mathbf{x}_1-\mathbf{x}_3)D_0(\mathbf{x}_2-\mathbf{x}_4) - (\mathbf{p}_1\mathbf{p}_2)^2(D_0(\mathbf{x}_1-\mathbf{x}_4)+D_0(\mathbf{x}_2-\mathbf{x}_3) + D_0(\mathbf{x}_1-\mathbf{x}_2)+D_0(\mathbf{x}_3-\mathbf{x}_4))^2)^{-1/2} + \text{permut.}, \tag{74}$$

where $D_0(\mathbf{x}_j-\mathbf{x}_k)=-|\mathbf{x}_j-\mathbf{x}_k|^{2\beta}$ in the model (10).

APPENDIX B: THE KRAICHNAN MODEL

If $\Gamma(t-t')=\delta(t-t')$, then we obtain a closed set of equations for the correlation functions

$$\mathcal{S}_\tau^{(n)}(\mathbf{x}_1,\ldots,\mathbf{x}_n;\mathbf{p}_1,\ldots,\mathbf{p}_n) = \langle \tilde{T}_\tau(\mathbf{x}_1,\mathbf{p}_1)\cdots\tilde{T}_\tau(\mathbf{x}_n,\mathbf{p}_n)\rangle. \tag{75}$$

These equations have been derived by Kraichnan[8] for velocities depending on all coordinates. In our simplified model (9) and (10) they read (the odd order correlation functions are zero)

$$\partial_\tau \mathcal{S}_\tau^{(2n)} = \frac{1}{2}\mu^2\sum_{j=1}^{j=2n}\Delta_j\mathcal{S}_\tau^{(2n)} - \frac{1}{2}(\mu^2+D_0(\mathbf{0}))\sum_{j=1}^{j=2n}\mathbf{p}_j^2\mathcal{S}_\tau^{(2n)} + \sum_{\langle j,k\rangle}\mathbf{p}_j D_0(\mathbf{x}_j-\mathbf{x}_k)\mathbf{p}_k\mathcal{S}_\tau^{(2n)} + \sum_{\langle j,k\rangle}\delta(\mathbf{p}_j+\mathbf{p}_k)\tilde{m}(\mathbf{x}_j-\mathbf{x}_k,\mathbf{p}_j)\mathcal{S}_\tau^{(2n-2)}(jk) \equiv \mathcal{M}\mathcal{S}_\tau^{(2n)} + \mathcal{R}\mathcal{S}_\tau^{(2n-2)}, \tag{76}$$

where D_0 is the translation invariant part of D and $\mathcal{S}(jk)$ means that the coordinates $\mathbf{x}_j$ and $\mathbf{x}_k$ are lacking in $\mathcal{S}$. The term $D(\mathbf{0})$ (adding to μ^2) comes from the Stratonovitch interpretation of Eq. (1). The solution of Eq. (76) reads

$$\mathcal{S}_\tau^{(2n)} = \exp(\tau\mathcal{M})S_0^{(2n)} + \int_0^\tau dt\,\exp((\tau-t)\mathcal{M})\mathcal{R}\mathcal{S}_t^{(2n-2)}. \tag{77}$$

If the operator $\mathcal{M}$ is strictly negative in the space $L^2(R^{2dn})$, then the limit $\tau\to\infty$ exists and does not depend on the initial condition $\mathcal{S}_0^{(2n)}$.

We can express the solution of Eq. (76) by means of the Feynman-Kac formula for the heat kernel

$$(\exp(r\mathcal{M})g)(\mathbf{x}_1, \ldots, \mathbf{x}_{2n}) = E\left[\exp\left(\int_0^r ds W(\mathbf{b}(s))\right) g(\mathbf{x}_1 + \mu\mathbf{b}_1(r), \ldots, \mathbf{x}_{2n} + \mu\mathbf{b}_{2n}(r))\right], \tag{78}$$

where

$$W(s) = -\frac{1}{2}(\mu^2 + D_0(0)) \sum_{j=1}^{j=2n} \mathbf{p}_j^2 + \sum_{\langle j,k\rangle} \mathbf{p}_j D_0(\mathbf{x}_j + \mu\mathbf{b}_j(s) - \mathbf{x}_k - \mu\mathbf{b}_k(s))\mathbf{p}_k. \tag{79}$$

We obtain an upper bound on the correlation functions (78) from the Jensen inequality as applied to the time integral

$$((\exp r\mathcal{M})g)(\mathbf{x}_1, \ldots, \mathbf{x}_{2n}) \leqslant \frac{1}{r}\int_0^r ds E[\exp(rW(\mathbf{b}(s)))|g|(\mathbf{x}_1 + \mu\mathbf{b}_1(r), \ldots, \mathbf{x}_{2n} + \mu\mathbf{b}_{2n}(r))]. \tag{80}$$

If $g = \exp h$ [or a superposition with positive coefficients of such functions as in Eq. (25)], then we have the lower bound from the Jensen inequality as applied to the expectation value

$$(\exp(r\mathcal{M})\exp h)(\mathbf{x}_1, \ldots, \mathbf{x}_{2n}) \geqslant \exp E\left[\int_0^r ds W(\mathbf{b}(s)) + h(\mathbf{x}_1 + \mu\mathbf{b}_1(r), \ldots, \mathbf{x}_{2n} + \mu\mathbf{b}_{2n}(r))\right]. \tag{81}$$

As an example, the formula for the two-point function (in the limit $\tau \to \infty$) with the velocity correlations defined by Eq. (10) reads

$$\mathcal{S}_\infty^{(2)}(\mathbf{x}_1, \mathbf{x}_2, \mathbf{p}_1, \mathbf{p}_2) = \delta(\mathbf{p}_1 + \mathbf{p}_2)\int_0^\infty dr \exp(-r\mu^2\mathbf{p}_1^2) \times E\left[\exp\left(-\mathbf{p}_1^2\int_0^r ds|\mathbf{x}_1 - \mathbf{x}_2 + \mu\mathbf{b}_1(s) - \mu\mathbf{b}_2(s)|^{2\beta}\right)\tilde{m}(\mathbf{x}_1 + \mu\mathbf{b}_1(r) - \mathbf{x}_2 - \mu\mathbf{b}_2(r), \mathbf{p}_1)\right]. \tag{82}$$

Then, the resulting correlation functions are controlled from below and from above by the Jensen inequalities. For the lower bound (81) we obtain an explicit formula [using the representation (24) for m_1]

$$\mathcal{S}_\infty^{(2)}(\mathbf{x}_1, \mathbf{x}_2, \mathbf{p}_1, \mathbf{p}_2) \geqslant \delta(\mathbf{p}_1 + \mathbf{p}_2)\tilde{m}_0(\mathbf{p}) \int d\nu_1(a) \int_0^\infty dr \exp(-r\mu^2\mathbf{p}_1^2) \times \exp(-\mathbf{p}^2 r^{\beta+1} h(r^{-1/2}|\mathbf{x}_1 - \mathbf{x}_2|) - a|\mathbf{x}_1 - \mathbf{x}_2|^2 - 2\mu^2 ra), \tag{83}$$

where

$$h(\rho) = K\rho^{2(1+\beta)}\int_0^{\rho^{-2}} d\lambda \int_0^\infty db b^{-1-\beta}\left(1 - (1 + 2\mu^2\lambda b)^{-d/2}\exp\left(-\frac{b}{2(1 + 2\mu^2 b\lambda)}\right)\right); \tag{84}$$

here K is a positive constant. From Eq. (84) it can easily be seen that for large $\mathbf{x} - \mathbf{x}'$ [small ρ in Eq. (84)] the r integrand in Eq. (83) behaves as

$$\exp(-Kr\mathbf{p}^2|\mathbf{x}_1 - \mathbf{x}_2|^{2\beta} - a|\mathbf{x}_1 - \mathbf{x}_2|^2 - 2\mu^2 ra)$$

[as shown in another way in Eq. (60); here $\alpha = 1$], leading as a consequence to the estimate (61) for the correlation functions. We can continue the Jensen inequalities for higher correlation functions because it follows from Eqs. (77) and (78) that the correlation functions are again in the form of superpositions of exponentials.

For lower order correlations a direct study of the differential equation (76) can be equally efficient. As an example, if $D=3$ and $d=2$, then Eq. (76) at $\tau=\infty$ [with the velocity covariance (10)] reads (here $\rho=|\mathbf{x}_1-\mathbf{x}_2|$)

$$\left(\mu^2\frac{1}{\rho}\partial_\rho\rho\partial_\rho-\mu^2p^2-p^2\rho^{2\beta}\right)T_\infty^{(2)}(\rho,p;\mu)=\tilde{m}(\rho,p), \tag{85}$$

where we defined

$$\mathcal{S}^{(2)}(\rho,p_1,p_2;\mu)=\delta(p_1+p_2)\mathcal{T}^{(2)}(\rho,p_1;\mu).$$

In contradistinction to the spherically symmetric case,[8] Eq. (85) is not explicitly soluble but its asymptotic solution (61) is easy to obtain. This asymptotic behavior is the same as the limit $\mu=0$ of the solution (85):

$$\mathcal{T}_\infty^{(2)}(\rho,p;0)=-p^{-2}\rho^{-2\beta}\tilde{m}(\rho,p). \tag{86}$$

In general, from Eq. (76), the limit $\mu=0$ can be obtained inductively:

$$\mathcal{S}_\infty^{(2n)}(\mathbf{x}_1,\ldots,\mathbf{x}_{2n};\mathbf{p}_1,\ldots,\mathbf{p}_{2n};0)=\left(\frac{1}{2}D_0(\mathbf{0})\sum_{j=1}^{j=2n}\mathbf{p}_j^2-\sum_{\langle j,k\rangle}\mathbf{p}_jD_0(\mathbf{x}_j-\mathbf{x}_k)\mathbf{p}_k\right)^{-1}$$
$$\times\sum_{\langle i,l\rangle}\delta(\mathbf{p}_i+\mathbf{p}_l)\tilde{m}(\mathbf{x}_i-\mathbf{x}_l,\mathbf{p}_i)\mathcal{S}_\infty^{(2n-2)}(il;0). \tag{87}$$

The formulas for the asymptotic behavior (61) ($\alpha=1$) and (66) ($\alpha=1$, $\gamma=0$) agree with the exact solution (87). For $n=1$ the solution (82) takes the form (86), whereas for $n=2$ we have

$$\mathcal{S}_\infty^{(4)}(\mathbf{x}_1,\ldots,\mathbf{x}_4;\mathbf{p}_1,\ldots,\mathbf{p}_4;0)=\left(\frac{1}{2}D_0(\mathbf{0})\sum_{j=1}^{j=4}\mathbf{p}_j^2-\sum_{\langle j,k\rangle}\mathbf{p}_jD_0(\mathbf{x}_j-\mathbf{x}_k)\mathbf{p}_k\right)^{-1}$$
$$\times(\delta(\mathbf{p}_1+\mathbf{p}_2)\delta(\mathbf{p}_3+\mathbf{p}_4)(\mathbf{p}_1D_0(\mathbf{0})\mathbf{p}_1-\mathbf{p}_1D_0(\mathbf{x}_1-\mathbf{x}_2)\mathbf{p}_1)^{-1}$$
$$\times\tilde{m}(\mathbf{x}_1-\mathbf{x}_2,\mathbf{p}_1)\tilde{m}(\mathbf{x}_3-\mathbf{x}_4,\mathbf{p}_3)+\text{permut.}). \tag{88}$$

For the scale invariant random velocity field (10), $D_0(\mathbf{0})=0$ and $D_0(\mathbf{x}_j-\mathbf{x}_k)=-|\mathbf{x}_j-\mathbf{x}_k|^{2\beta}$. It follows from Eqs. (87) and (88) that the temperature correlation functions are scale invariant under scale transformations of the coordinates $\mathbf{x}_j$ as well as $\mathbf{p}_j$. When $\mu=0$, then the correlation functions $\mathcal{S}_\infty^{(2n)}$ are singular at coinciding points (the limit $\mu\to0$ has been studied earlier by other methods in Refs. 14 and 15). The bound (40) is valid for $\mu>0$.

Before the thermodynamic limit, macroscopic averages need not commute for a quantum system. As a consequence, aspects of macroscopic fluctuations or of constrained equilibrium require a careful analysis, when dealing with several observables. We propose an implementation of ideas that go back to John von Neumann's writing about the macroscopic measurement. We apply our scheme to the relation between macroscopic autonomy and an *H*-theorem, and to the problem of equivalence of ensembles. In particular, we show how the latter is related to the asymptotic equipartition theorem. The main point of departure is an expression of a law of large numbers for a sequence of states that start to concentrate, as the size of the system gets larger, on the macroscopic values for the different macroscopic observables. Deviations from that law are governed by the entropy. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2217810]

I. INTRODUCTION

"It is a fundamental fact with macroscopic measurements that everything which is measurable at all, is also simultaneously measurable, i.e. that all questions which can be answered separately can also be answered simultaneously." That statement by von Neumann enters his introduction to the macroscopic measurement.[16] He then continues to discuss in more detail how that view could possibly be reconciled with the non-simultaneous-measurability of quantum mechanical quantities. The main qualitative suggestion by von Neumann is to consider, for a set of noncommuting operators $A,B,\ldots$ a corresponding set of *mutually commuting* operators $A',B',\ldots$ which are each, in a sense, good approximations, $A'\approx A, B'\approx B,\ldots$. The whole question is: *in exactly what sense?* Especially in statistical mechanics, one is interested in fluctuations of macroscopic quantities or in the restriction of certain ensembles by further macroscopic constraints which only make sense for finite systems. In these cases, general constructions of a common subspace of observables become very relevant. Interestingly, at the end of his discussion on the macroscopic measurement,[16] von Neumann turns to the quantum *H*-theorem and to the relation between entropy and macroscopic measurement. He refers to the then recent work of Pauli,[13,15] who by using "disorder assumptions" or what we could call today, a classical Markov approximation, obtained a general argument for the *H*-theorem.

In the present paper, we are dealing exactly with the problems above and as discussed in Chapter V.4 of Ref. 16. While it is indeed true that averages of the form $A=(a_1+\cdots+a_N)/N, B=(b_1+\cdots+b_N)/N$, for which all commutators $[a_i,b_j]=0$ for $i\neq j$, have their commutator $[A,B]=O(1/N)$ going to zero (in the appropriate norm, corresponding to $[a_i,b_i]=O(1)$) as $N\uparrow+\infty$, it is not true in general that

$$\lim_{N\to+\infty}\frac{1}{N}\log \mathrm{Tr}[e^{NA}e^{NB}]\stackrel{?}{=}\lim_{N\to+\infty}\frac{1}{N}\log \mathrm{Tr}[e^{NA+NB}].$$

These generating functions are obviously important in fluctuation theory, such as in the problem of large deviations for quantum systems.[12] It is still very much an open question to discuss the joint large deviations of quantum observables, or even to extend the Laplace-Varadhan formula to applications in quantum spin systems. The situation is better for questions about normal fluctuations and the central limit theorem, for which the so-called fluctuation algebra provides a nice framework, see, e.g., Ref. 8. There the pioneering work of André Verbeure will continue to inspire coming generations who are challenged by the features of noncommutativity in quantum mechanics.

These issues are also important for the question of convergence to equilibrium. For example, one would like to specify or to condition on various macroscopic values when starting off the system. Under these constrained equilibria not only the initial energy but also, e.g., the initial magnetization or particle density, etc., are known, and simultaneously installed. As with the large deviation question above, we enter here again in the question of equivalence of ensembles but we are touching also a variety of problems that deal with nonequilibrium aspects. The very definition of configurational entropy as related to the size of the macroscopic subspace has to be rethought when the macroscopic variables get their representation as noncommuting operators. One could again argue that all these problems vanish in the macroscopic limit, but the question (indeed) arises before the limit, for very large but finite N where one can still speak about finite dimensional subspaces or use arguments like the Liouville-von Neumann theorem.

In the following, there are three sections. In Sec. II we write about quantum macrostates and about how to define the macroscopic entropy associated to values of several noncommuting observables. As in the classical case, there is the Gibbs equilibrium entropy. The statistical interpretation, going back to Boltzmann for classical physics, is however not immediately clear in a quantum context. We will define various quantum H-functions. Second, in Sec. III, we turn to the equivalence of ensembles. The main result there is to give a counting interpretation to the thermodynamic equilibrium entropy. In that light we discuss quantum aspects of large deviation theory. Finally, in Sec. IV, we study the relation between macroscopic autonomy and the second law, as done before in Ref. 5 for classical dynamical systems. We prove that if the macroscopic observables give rise to a first-order autonomous equation, then the H-function, defined on the macroscopic values, is monotone. That is further illustrated using a quantum version of the Kac ring model.

II. QUANTUM MACROSTATES AND ENTROPY

Having in mind a macroscopically large closed quantum dynamical system, we consider a sequence $\mathcal{H}=(\mathcal{H}^N)_{N\uparrow+\infty}$ of finite-dimensional Hilbert spaces with the index N labeling different finitely extended approximations, and playing the role of the volume or the particle number, for instance. On each space $\mathcal{H}^N$ we have the standard trace Tr^N. Macrostates are usually identified with subspaces of the Hilbert spaces or, equivalently, with the projections on these subspaces. For any collection $(X_k^N)_{k=1}^n$ of mutually commuting self-adjoint operators there is a projection-valued measure (Q^N) on $\mathbb{R}^n$ such that for any function $F\in C(\mathbb{R}^n)$,

$$F(X_1^N,\ldots,X_n^N)=\int_{\mathbb{R}^n}Q^N(\mathrm{d}z)F(z).$$

A macrostate corresponding to the respective values $x=(x_1,x_2,\ldots,x_n)$ is then represented by the projection

$$Q^{N,\delta}(x) = \int_{\times_k(x_k-\delta,x_k+\delta)} Q^N(\mathrm{d}z)$$

for small enough $\delta>0$. Furthermore, the Boltzmann H-function, in the classical case counting the cardinality of macrostates, is there defined as

$$H^{N,\delta}(x) = \frac{1}{N}\log \mathrm{Tr}^N[Q^{N,\delta}(x)]$$

with possible further limits $N\uparrow+\infty$, $\delta\downarrow 0$. However, a less trivial problem that we want to address here, emerges if the observables (X_k^N) chosen to describe the system on a macroscopic scale do not mutually commute.

Consider a family of sequences of self-adjoint observables $(X_k^N)_{N\uparrow+\infty,k\in K}$ where K is some index set, and let each sequence be uniformly bounded, $\sup_N\|X_k^N\|<+\infty$, $k\in K$. We call these observables macroscopic, having in mind mainly averages of local observables but that will not always be used explicitly in what follows; it will however serve to make the assumptions plausible.

In what follows, we define concentrating states as sequences of states for which the observables X_k^N assume sharp values. Those concentrating states will be labeled by possible "outcomes" of the observables X_k^N; for these values we write $x=(x_k)_{k\in K}$ where each $x_k\in\mathbb{R}$.

A. Microcanonical setup

1. Concentrating sequences

A sequence $(P^N)_{N\uparrow+\infty}$ of projections is called concentrating at x whenever

$$\lim_{N\uparrow+\infty} \mathrm{tr}^N(F(X_k^N)|P^N) = F(x_k) \tag{2.1}$$

for all $F\in C(\mathbb{R})$ and $k\in K$; we have used the notation

$$\mathrm{tr}^N(\cdot|P^N) = \frac{\mathrm{Tr}^N(P^N\cdot P^N)}{\mathrm{Tr}^N(P^N)} = \frac{\mathrm{Tr}^N(P^N\cdot)}{\mathrm{Tr}^N(P^N)} \tag{2.2}$$

for the normalized trace state on $P^N\mathcal{H}^N$. To indicate that a sequence of projections is concentrating at x we use the shorthand $P^N\overset{\mathrm{mc}}{\longrightarrow}x$.

2. Noncommutative functions

The previous lines, in formula (2.1), consider functions of a single observable. By properly defining the joint functions of two or more operators that do not mutually commute, the concentration property extends as follows.

Let $\mathcal{I}_K$ denote the set of all finite sequences from K, and consider all maps $G:\mathcal{I}_K\to\mathbb{C}$ such that

$$\sum_{m\geqslant 0}\sum_{(k_1,\ldots,k_m)\in\mathcal{I}_K} |G(k_1,\ldots,k_m)|\prod_{i=1}^{m} r_{k_i} < \infty \tag{2.3}$$

for some fixed $r_k>\sup_N\|X_k^N\|, k\in K$. Slightly abusing the notation, we also write

$$G(X^N) = \sum_{m\geqslant 0}\sum_{(k_1,\ldots,k_m)\in\mathcal{I}_K} G(k_1,\ldots,k_m)X_{k_1}^N\cdots X_{k_m}^N \tag{2.4}$$

defined as norm-convergent series. We write $\mathcal{F}$ to denote the algebra of all these maps G, defining noncommutative "analytic" functions on the multidisc with radii $(r_k), k\in K$.

Proposition 2.1: Assume that $P^N\overset{\mathrm{mc}}{\longrightarrow}x$. *Then, for all* $G\in\mathcal{F}$,

$$\lim_{N\uparrow+\infty} \mathrm{tr}^N[G(X^N)|P^N] = G(x). \tag{2.5}$$

Remark 2.2: In particular, the limit expectations on the left-hand side of (2.5) coincide for all classically equivalent noncommutative functions. As example, for any complex parameters $\lambda_k, k \in R$ with R a finite subset of K and for $P^N \overset{\mathrm{mc}}{\to} x$,

$$\lim_{N\uparrow+\infty} \mathrm{tr}^N(e^{\sum_{k\in R}\lambda_k(X_k^N - x_k)}|P^N) = \lim_{N\uparrow+\infty} \mathrm{tr}^N\left(\prod_{k\in R} e^{\lambda_k(X_k^N - x_k)}|P^N\right) = 1$$

no matter in what order the last product is actually performed.

Proof of Proposition 2.1: For any monomial $G(X^N) = X_{k_1}^N \cdots X_{k_m}^N$, $m \geqslant 1$, we prove the statement of the proposition by induction, as follows. Using the shorthands $Y^N = X_{k_1}^N \cdots X_{k_{m-1}}^N$ and $y = x_{k_1} \cdots x_{k_{m-1}}$, the induction hypothesis reads $\lim_{N\uparrow+\infty} \mathrm{tr}^N(Y^N|P^N) = y$ and we get

$$|\mathrm{tr}^N(Y^N X_{k_m}^N - y x_{k_m}|P^N)|$$

$$= |\mathrm{tr}^N(Y^N(X_{k_m}^N - x_{k_m})|P^N) + x_{k_m}\mathrm{tr}^N(Y^N - y|P^N)|$$

$$\leqslant \|Y^N\|\{\mathrm{tr}^N((X_{k_m}^N - x_{k_m})^2|P^N)\}^{\frac{1}{2}} + |x_{k_m}||\mathrm{tr}^N(Y^N - y|P^N)| \to 0$$

since $P^N \overset{\mathrm{mc}}{\to} x$ and (Y^N) are uniformly bounded. That readily extends to all noncommutative polynomials by linearity, and finally to all uniform limits of the polynomials by a standard continuity argument. □

3. H-function

Only the concentrating sequences of projections on the subspaces of the largest dimension become candidates for noncommutative variants of macrostates associated with $x = (x_k)_{k\in K}$, and that maximal dimension yields the (generalization of) Boltzmann's H-function. More precisely, to any macroscopic value $x = (x_k)_{k\in K}$ we assign

$$H^{\mathrm{mc}}(x) = \limsup_{P^N \overset{\mathrm{mc}}{\to} x} \frac{1}{N} \log \mathrm{Tr}^N[P^N], \tag{2.6}$$

where $\limsup_{P^N \overset{\mathrm{mc}}{\to} x} = \sup_{P^N \overset{\mathrm{mc}}{\to} x} \limsup_{N\uparrow+\infty}$ is the maximal limit point over all sequences of projections concentrating at x. By construction, $H^{\mathrm{mc}}(x) \in \{-\infty\} \cup [0, +\infty]$ and we write Ω to denote the set of all $x \in \mathbb{R}^K$ for which $H^{\mathrm{mc}}(x) \geqslant 0$; these are all admissible macroscopic configurations. Slightly abusing the notation, any sequence $P^N \overset{\mathrm{mc}}{\to} x$, $x \in \Omega$ such that $\limsup_N (1/N)\log \mathrm{Tr}^N[P^N] = H^{\mathrm{mc}}(x)$, will be called a microcanonical macrostate at x.

4. Example

Take a spin system of N spin-1/2 particles for which the magnetization in the α-direction, $\alpha = 1, 2, 3$, is given by

$$X_\alpha^N = \frac{1}{N}\sum_{i=1}^N \sigma_i^\alpha \tag{2.7}$$

in terms of (copies of) the Pauli matrices σ^α.

Let δ_N be a sequence of positive real numbers such that $\delta_N \downarrow 0$ as $N \uparrow +\infty$. For $\vec{m} = (m_1, m_2, m_3) \in [-1,1]^3$, let $\vec{e} \| \vec{m}$ be a unit vector for which $\vec{m} = m\vec{e}$ with $m \geqslant 0$. Consider $Y^N(\vec{m}) = \Sigma_{\alpha=1}^3 m_\alpha X_\alpha^N$ and its spectral projection $Q^N(\vec{m})$ on $[m-\delta_N, m+\delta_N]$. One easily checks that if $N^{1/2}\delta_N \uparrow +\infty$, then $(Q^N(\vec{m}))_N$ is a microcanonical macrostate at $\vec{m}$, and

$$H^{\mathrm{mc}}(\vec{m}) = \begin{cases} -\dfrac{1-m}{2}\log\dfrac{1-m}{2} - \dfrac{1+m}{2}\log\dfrac{1+m}{2} & \text{for } m \leqslant 1 \\ -\infty & \text{otherwise.} \end{cases}$$

B. Canonical setup

The concept of macrostates as above and associated with projections on certain subspaces on which the selected macroscopic observables take sharp values is physically natural and restores the interpretation of "counting microstates." Yet, sometimes it is not very suitable for computations. Instead, at least when modeling thermal equilibrium, one usually prefers canonical or grand-canonical ensembles, and one relies on certain equivalence of all these ensembles.

1. Concentrating states

For building the ensembles of quantum statistical mechanics, one does not immediately encounter the problem of noncommutativity. One requires a certain value for a number of macroscopic observables and one constructs the density matrix that maximizes the von Neumann entropy.

We write $\omega^N \overset{1}{\longrightarrow} x$ for a sequence of states (ω^N) on $\mathcal{H}^N$ whenever $\lim_{N\uparrow+\infty} \omega^N(X_k^N) = x_k$ (convergence in mean).

That construction and that of the concentrating sequences of projections of Sec. II A 1 still has other variants. We say that a sequence of states (ω^N) is concentrating at x and we write $\omega^N \to x$, when

$$\lim_{N\uparrow+\infty} \omega^N(G(X^N)) = G(x) \tag{2.8}$$

for all $G \in \mathcal{F}$. The considerations of Proposition 2.1 apply also here and one can equivalently replace the set of all noncommutative analytic functions with functions of a single variable.

2. Gibbs-von Neumann entropy

The counting entropy of Boltzmann extends to general states such as the von Neumann entropy which is the quantum variant of the Gibbs formula, both being related to the relative entropy defined with respect to a trace reference state. Analogous to (2.6), we define

$$H^{\mathrm{can}}(x) = \limsup_{\omega^N \to x} \frac{1}{N}\mathcal{H}(\omega^N), \tag{2.9}$$

where $\mathcal{H}(\omega^N) \geqslant 0$ is, upon identifying the density matrix σ^N for which $\omega^N(\cdot) = \mathrm{Tr}^N(\sigma^N \cdot)$,

$$\mathcal{H}(\omega^N) = -\mathrm{Tr}[\sigma^N \log \sigma^N]. \tag{2.10}$$

Second, we consider

$$H_1^{\mathrm{can}}(x) = \limsup_{\omega^N \overset{1}{\to} x} \frac{1}{N} \mathcal{H}(\omega^N). \tag{2.11}$$

Obviously, H_1^{can} is the analog of the canonical entropy in thermostatics and the easiest to compute, see also under Sec. II B 3. To emphasize that, we call any sequence of states (ω^N), $\omega^N \overset{1}{\to} x$ such that $\limsup_N (1/N)\mathcal{H}(\omega^N) = H_1^{\mathrm{can}}(x)$ a canonical macrostate at x.

Another generalization of the H-function is obtained when replacing the trace state (corresponding to the counting) with a more general reference state $\rho = (\rho^N)_N$. In that case we consider the H-function as derived from the relative entropy, and differing from the above-used convention by the sign and an additive constant:

$$H_1^{\mathrm{can}}(x|\rho) = \liminf_{\omega^N \overset{1}{\to} x} \frac{1}{N} \mathcal{H}(\omega^N|\rho^N). \tag{2.12}$$

Here, defining σ^N and σ_0^N as the density matrices such that $\omega^N(\cdot) = \mathrm{Tr}[\sigma^N \cdot]$ and $\rho^N(\cdot) = \mathrm{Tr}[\sigma_0^N \cdot]$,

$$\mathcal{H}(\omega^N|\rho^N) = \mathrm{Tr}[\sigma^N(\log \sigma^N - \log \sigma_0^N)]. \tag{2.13}$$

Remark that this last generalization enables one to cross the border between closed and open thermodynamic systems. Here, the state (ρ^N) can be chosen as a nontrivial stationary state for an open system, and the above-defined H-function $H_1^{\mathrm{can}}(x|\rho)$ may lose natural counting and thermodynamic interpretations. Nevertheless, its monotonicity properties under dynamics satisfying suitable conditions justify this generalization, see Sec. IV.

3. Canonical macrostates

The advantage of the canonical formulation of the variational problem for the H-function as in (2.11) is that it can often be solved in a very explicit way. A class of general and well-known examples of canonical macrostates have the following Gibbsian form.[3]

If $\lambda = (\lambda_1, \ldots, \lambda_n)$ are such that the sequence of states (ω_λ^N), $\omega_\lambda^N(\cdot) = \mathrm{Tr}^N(\sigma_\lambda^N \cdot)$ defined by

$$\sigma_\lambda^N = \frac{1}{\mathcal{Z}_\lambda^N} e^{N\Sigma_k \lambda_k X_k^N}, \quad \mathcal{Z}_\lambda^N = \mathrm{Tr}^N\left(e^{N\Sigma_k \lambda_k X_k^N}\right) \tag{2.14}$$

satisfies $\lim_{N\uparrow+\infty} \omega_\lambda^N(X_k^N) = x_k$, $k = 1, \ldots, n$, then (ω_λ^N) is a canonical macrostate at x, and

$$H_1^{\mathrm{can}}(x) = \limsup_N \frac{1}{N} \log \mathcal{Z}_\lambda^N - \sum_k \lambda_k x_k. \tag{2.15}$$

III. EQUIVALENCE OF ENSEMBLES

A basic intuition of statistical mechanics is that adding those many new concentrating states in the variational problem, as done in Sec. II B, does not actually change the value of the H-function. In the same manner of speaking, one would like to understand the definitions (2.9) and (2.11) in counting-terms. In what sense do these entropies represent a dimension (the size) of a (microscopic) subspace?

Trivially, $H^{\mathrm{mc}} \leqslant H^{\mathrm{can}} \leqslant H_1^{\mathrm{can}}$, and $H^{\mathrm{can}}(x) = H_1^{\mathrm{can}}(x)$ iff some canonical macrostate $\omega^N \overset{1}{\to} x$ is actually concentrating at x, $\omega^N \to x$. We give general conditions under which the full equality can be proven. We have again a sequence of observables X_k^N with spectral measure given by the projections $Q_k^N(\mathrm{d}z), k \in K$.

Theorem 3.1: *Assume that for a sequence of density matrices* $\sigma^N > 0$, *the corresponding* $(\omega^N)_N$ *is a canonical macrostate at x and that the following two conditions are verified*:

(i) (Exponential concentration property.)

For every $\delta>0$ *and* $k\in K$ *there are* $C_k(\delta)>0$ *and* $N_k(\delta)$ *so that*

$$\int_{x_k-\delta}^{x_k+\delta}\omega^N(Q_k^N(\mathrm{d}z))\geqslant 1-e^{-C_k(\delta)N} \tag{3.1}$$

for all $N>N_k(\delta)$.

(ii) (Asymptotic equipartition property.)

For all $\delta>0$,

$$\lim_{N\uparrow+\infty}\frac{1}{N}\log\int_{-\delta}^{\delta}\omega^N(\tilde{Q}^N(\mathrm{d}z))=0, \tag{3.2}$$

where $\tilde{Q}^N$ *denotes the projection operator-valued measure of the operator* $(1/N)(\log\sigma^N-\omega^N(\log\sigma^N))$.

Then, $H^{\mathrm{mc}}(x)=H^{\mathrm{can}}(x)=H_1^{\mathrm{can}}(x)\geqslant 0$.

Theorem 3.1 evidently expresses that the microcanonical and the canonical ensembles are equivalent. Results of that kind are well-known in the literature, see e.g., Ref. 14 or 7. An example of a similar type of reasoning for the quantum case is given in Ref. 11. Theorem 3.1 is, however, slightly different from these results in the following aspects,

(1) When considering the quantum microcanonical ensemble, one usually starts out with spectral projections P^N associated with one macroscopic observable. That at least is the approach in Ref. 11 and it is also sketched at the very beginning of Sec. II. Our approach is, however, not limited to one macroscopic observable. Indeed, remember that the $(X_k^N)_k$ need not commute (Sec. II A).

(2) Results on equivalence of ensembles, including those contained in, e.g., Refs. 14, 7, and 11 are mostly dealing solely with translation-invariant lattice spin systems. We do not have that limitation here; instead we have the assumptions (3.2) and (3.1).

(3) Even within the context of translation-invariant lattice spin systems, the results in Refs. 14, 7, and 11 do not yield Theorem 3.1. In these references the microcanonical state is defined as the average of projections P^N, translated over all lattice vectors. That lattice average is translation-invariant by construction (and hence technically easier to handle), but of course it is itself not longer a projection and hence it is not a microcanonical state in the sense of the present paper.

Remarks on the conditions of Theorem 3.1: Whether one can prove the assumptions of Theorem 3.1, depends heavily on the particular model.

The exponential concentration property (3.1) is not trivial even for quantum lattice spin systems, and not even in their one-phase region. Let us mention one criterion under which (3.1) can be checked, which indicates its deep relation to the problem of quantum large deviations. Consider the generating functions

$$\psi_k(t)=\lim_{N\uparrow+\infty}\frac{1}{N}\log\omega^N(e^{tNX_k^N}),\quad k\in K. \tag{3.3}$$

Their existence together with their differentiability at $t=0$ imply by an exponential Chebyshev inequality that ω^N exponentially concentrates at $x=(\psi_k'(0);k\in K)$. However, to our knowledge, the differentiability of $\psi_k(t)$ has only been proven so far for lattice averages over local observables for quantum spin lattice systems in a "high-temperature regime," see Ref. 12, Theorem 2.15 and Remark 7.13, where a cluster expansion technique has been used. The existence of the generating functions (3.3) has also been studied in Ref. 10.

The asymptotic equipartition property (3.2) is easier. The terminology, originally in information theory, comes from its immediate consequence (3.7) below, where P^N projects on a "high

probability" region: as in the classical case, the Gibbs-von Neumann entropy measures in some sense the size of the space of "sufficiently probable" microstates. For (3.2) it is enough to prove that the state ω^N is concentrating for the observable

$$A^N = \frac{1}{N} \log \sigma^N. \tag{3.4}$$

Explicitly, it is enough to show that for all $F \in C(\mathbb{R})$,

$$\lim_{N\uparrow+\infty} [\omega^N(F(A^N)) - F(\omega^N(A^N))] = 0. \tag{3.5}$$

In particular, if (ω^N), $\omega^N = \omega_\lambda^N$ is given by formula (2.14), a sufficient condition for the asymptotic equipartition property to be satisfied is that the pressure $p(\lambda)$ defined as

$$p(\lambda) = \lim_{N\uparrow+\infty} \frac{1}{N} \log \mathcal{Z}_\lambda^N \tag{3.6}$$

exists and is continuously differentiable at $\lambda = \lambda(x)$.

Remark that for ergodic states of spin lattice systems, the asymptotic equipartition as expressed by (3.2) and (3.7) follows from the quantum Shannon-McMillan theorem, see Ref. 2, and the references therein. An interesting variant of that result, which touches the problem of quantum large deviations, is the quantum Sanov theorem, proven for i.i.d. processes in Ref. 1. In contrast, our result focuses on the intimate relation of the asymptotic equipartition property to the problem of equivalence of ensembles in the noncommutative context, and Theorem 3.1 formulates sufficient conditions under which such an equivalence follows. An advantage of this approach is that it is not restricted to the framework of spin lattice models with its underlying quasilocal structure.

As $H^{\mathrm{mc}} \leqslant H^{\mathrm{can}} \leqslant H_1^{\mathrm{can}}$, we only need to establish that there is a concentrating sequence of projections for which its H-function equals the Gibbs-von Neumann entropy. Hence, the proof of Theorem 3.1 follows from the following lemma:

Lemma 3.2: If a sequence of states (ω^N) *satisfies conditions* (*i*) *and* (*ii*) *of Theorem 3.1*, *then there exists a sequence of projections* (P^N) *exponentially concentrating at x and satisfying*

$$\lim_{N\uparrow+\infty} \frac{1}{N} (\log \mathrm{Tr}^N(P^N) - \mathcal{H}(\omega^N)) = 0. \tag{3.7}$$

Proof: There exists a sequence $\delta_N \downarrow 0$ such that when substituted for δ, (3.2) is still satisfied. Take such a sequence and define $P^N = \int_{-\delta_N}^{\delta_N} \mathrm{d}\tilde{Q}^N(z)$. By construction,

$$e^{N(h_N - \delta_N)} P^N \leqslant (\sigma^N)^{-1} P^N \leqslant e^{N(h_N + \delta_N)} P^N \tag{3.8}$$

for any $N = 1, 2, \ldots$, with the shorthand $h_N = (1/N)\mathcal{H}(\omega^N)$. That yields the inequalities

$$\mathrm{Tr}^N(P^N) = \omega^N((\sigma^N)^{-1} P^N) \leqslant e^{N(h_N + \delta_N)} \omega^N(P^N) \tag{3.9}$$

and

$$\mathrm{Tr}^N(P^N) \geqslant e^{N(h_N - \delta_N)} \omega^N(P^N). \tag{3.10}$$

Using that $\lim_{N\uparrow+\infty} (1/N) \log \omega^N(P^N) = 0$ proves (3.7).

To see that (P^N) is exponentially concentrating at x, observe that for all $Y^N \geqslant 0$,

$$\begin{aligned} \omega^N(Y^N) &= \mathrm{Tr}^N((\sigma^N)^{1/2} Y^N (\sigma^N)^{1/2}) \geqslant \mathrm{Tr}^N(P^N (\sigma^N)^{1/2} Y^N (\sigma^N)^{1/2} P^N) \\ &= \mathrm{Tr}^N((Y^N)^{1/2} P^N \sigma^N (Y^N)^{1/2}) \\ &\geqslant e^{N(h_N - \delta_N)} \mathrm{Tr}^N(P^N) \mathrm{tr}^N(Y^N | P^N) \geqslant e^{-2N\delta_N} \omega^N(P^N) \mathrm{tr}^N(Y^N | P^N), \end{aligned} \tag{3.11}$$

where we used inequalities (3.8)–(3.10). By the exponential concentration property of (ω^N), inequality (3.1), for all $k \in K$, $\epsilon > 0$, and $N > N_k(\epsilon)$,

$$\int_{\mathbb{R}\setminus(x_k-\epsilon,x_k+\epsilon)} \mathrm{tr}^N(\mathrm{d}Q_k^N(z)|P^N) \leqslant e^{-(C_k(\epsilon)-2\delta_N)N}(\omega^N(P^N))^{-1}. \tag{3.12}$$

Choose $N_k'(\epsilon)$ such that $\delta_N \leqslant C_k(\epsilon)/8$ and $(1/N)\log \omega^N(P^N) \geqslant -C_k(\epsilon)/4$ for all $N > N_k'(\epsilon)$. Then (3.12) $\leqslant \exp[-C_k(\epsilon)N/2]$ for all $N > \max\{N_k(\epsilon), N_k'(\epsilon)\}$. □

IV. *H*-THEOREM FROM MACROSCOPIC AUTONOMY

When speaking about an *H*-theorem or about the monotonicity of entropy one often refers, and even more so for a quantum setup, to the fact that the relative entropy verifies the contraction inequality

$$\mathcal{H}(\omega^N\tau^N|\rho^N\tau^N) \leqslant \mathcal{H}(\omega^N|\rho^N) \tag{4.1}$$

for all states ω^N, ρ^N on $\mathcal{H}^N$ and for all completely positive maps τ^N on $\mathcal{B}(\mathcal{H}^N)$. That is true classically, quantum mechanically and for all small or large N. When the reference state ρ^N is invariant under τ^N, (4.1) yields the contractivity of the relative entropy with respect to ρ^N. However tempting, such inequalities should not be confused with second law or with *H*-theorems; note in particular that $\mathcal{H}(\omega^N)$ defined in (2.10) is constant whenever τ^N is an automorphism: $\mathcal{H}(\omega^N\tau^N) = \mathcal{H}(\omega^N)$.

In contrast, an *H*-theorem refers to the (usually strict) monotonicity of a quantity on the macroscopic trajectories as obtained from a microscopically defined dynamics. Such a quantity is often directly related to the fluctuations in a large system and its extremal value corresponds to the equilibrium or, more generally, to a stationary state.

In the previous section we have obtained how to represent a macroscopic state and constructed a candidate *H*-function. Imagine now a time-evolution for the macroscopic values, always referring to the same set of (possibly noncommuting macroscopic) observables X_k^N. To prove an *H*-theorem, we need basically two assumptions: macroscopic autonomy and the semigroup property, or that there is a first-order autonomous equation for the macroscopic values. A classical version of this study and more details can be found in Ref. 5.

A. Microcanonical setup

Assume a family of automorphisms $\tau_{t,s}^N$ is given as acting on the observables from $\mathcal{B}(\mathcal{H}^N)$ and satisfying

$$\tau_{t,s}^N = \tau_{t,u}^N \tau_{u,s}^N, \quad t \geqslant u \geqslant s. \tag{4.2}$$

It follows that the trace Tr^N is invariant for $\tau_{t,s}^N$.

Recall that $\Omega \subset \mathbb{R}^K$ is the set of all admissible macroscopic configurations, $H^{\mathrm{mc}}(x) \geqslant 0$. On this space we want to study the emergent macroscopic dynamics.

Autonomy condition. There are maps $(\phi_{t,s})_{t \geqslant s \geqslant 0}$ on Ω and there is a microcanonical macrostate (P^N), $P^N = P^N(x)$ for each $x \in \Omega$, such that for all $G \in \mathcal{F}$ and $t \geqslant s \geqslant 0$,

$$\lim_{N\uparrow+\infty} \mathrm{tr}^N(\tau_{t,s}^N G(X^N)|P^N) = G(\phi_{t,s}x). \tag{4.3}$$

Semigroup property. The maps are required to satisfy the semigroup condition,

$$\phi_{t,u}\phi_{u,s} = \phi_{t,s} \tag{4.4}$$

for all $t \geqslant u \geqslant s \geqslant 0$.

Theorem 4.1: *Assume that the autonomy condition* (4.3) *and the semigroup condition* (4.4) *are both satisfied. Then, for every* $x \in \Omega$, $H^{\mathrm{mc}}(x_t)$ *is nondecreasing in* $t \geqslant 0$ with $x_t = \phi_{t,0}x$.

Proof: Given $x \in \Omega$, fix a microcanonical macrostate $P^N \overset{\text{mc}}{\to} x$ and $t \geq s \geq 0$. Using that $(\tau^N_{t,s})^{-1}$ is an automorphism and $\mathrm{Tr}^N((\tau^N_{t,s})^{-1}\cdot) = \mathrm{Tr}^N(\cdot)$, the identity

$$\mathrm{tr}^N(\tau^N_{t,s} G(X^N)|P^N) = \frac{\mathrm{Tr}^N(G(X^N)(\tau^N_{t,s})^{-1}P^N)}{\mathrm{Tr}^N((\tau^N_{t,s})^{-1}P^N)} = \mathrm{tr}^N(G(X^N)|(\tau^N_{t,s})^{-1}P^N)$$

yields $(\tau^N_{t,s})^{-1}P^N \overset{\text{mc}}{\to} \phi_{t,s}x$ due to autonomy condition (4.3). Hence,

$$H^{\text{mc}}(\phi_{t,s}x) \geq \limsup_{N\uparrow+\infty} \frac{1}{N} \log \mathrm{Tr}^N((\tau^N_{t,s})^{-1}P^N) = H^{\text{mc}}(x).$$

In particular, one has that $x_s = \phi_{s,0}x \in \Omega$. The statement then follows by the semigroup property (4.3):

$$H^{\text{mc}}(x_t) = H^{\text{mc}}(\phi_{t,0}x) = H^{\text{mc}}(\phi_{t,s}x_s) \geq H^{\text{mc}}(x_s).$$

□

It is important to realize that a macroscopic dynamics, even autonomous in the sense of (4.3), need not satisfy the semigroup property (4.1). In that case one actually does not expect the H-function to be monotone; see Ref. 4 and below for an example. As obvious from the proof, without that semigroup property of $(\phi_{t,s})$, (4.3) only implies $H(x_t) \geq H(x)$, $t \geq 0$. Or, in a bit more generality, it implies that for all $s \geq 0$ and $x \in \Omega$ the macrotrajectory $(x_t)_{t\geq s}$, $x_t = \phi_{t,s}(x)$ satisfies $H(x_t) \geq H(x_s)$ for all $t \geq s$.

Remark that while the set of projections is invariant under the automorphisms $(\tau^N_{t,s})$, this is not true any longer for more general microscopic dynamics defined as completely positive maps, and describing possibly an open dynamical system interacting with its environment. In the latter case the proof of Theorem 4.1 does not go through and one has to allow for macrostates described via more general states, as in Sec. II B. The revision of the argument for the H-theorem within the canonical setup is done in the next section.

B. Canonical setup

We have completely positive maps $(\tau^N_{t,s})_{t\geq s\geq 0}$ on $\mathcal{B}(\mathcal{H}^N)$ satisfying

$$\tau^N_{t,s} = \tau^N_{t,u}\tau^N_{u,s}, \quad t \geq u \geq s \geq 0 \tag{4.5}$$

and leaving invariant the state ρ^N; they represent the microscopic dynamics. The macroscopic dynamics is again given by maps $\phi_{t,s}$.

As a variant of autonomy condition (4.3), we assume that the maps $\phi_{t,s}$ are reproduced along the time-evolution in the mean. Namely, see definition (2.12), for every $x \in \Omega_1(\rho) = \{x; H_1^{\text{can}}(x|\rho) < \infty\}$ we ask that a canonical macrostate $\omega^N \overset{1}{\to} x$ exists such that, for all $t \geq s \geq 0$,

$$\phi_{t,s}x = \lim_{N\uparrow+\infty} \omega^N(\tau^N_{t,s}X^N). \tag{4.6}$$

At the same time, we still assume the semigroup condition (4.4).

Theorem 4.2: *Under conditions* (4.6) and (4.4), *the function* $H_1^{\text{can}}(\phi_{t,0}x|\rho)$ *is nonincreasing in* $t \geq 0$ *for all* $x \in \Omega_1(\rho)$.

Proof: If $\omega^N \overset{1}{\to} x$ is a canonical macrostate at x then, by the monotonicity of the relative entropy,

$$H_1^{\text{can}}(x|\rho) = \liminf_{N\uparrow+\infty} \frac{1}{N}\mathcal{H}(\omega^N|\rho^N) \geq \liminf_{N\uparrow+\infty} \frac{1}{N}\mathcal{H}(\omega^N\tau^N_{t,s}|\rho^N).$$

On the other hand, by (4.6), the sequence $(\omega^N\tau^N_{t,s})$ is concentrating in the mean at $\phi_{t,s}(x)$, yielding

$$H_1^{\mathrm{can}}(x|\rho) \geqslant H_1^{\mathrm{can}}(\phi_{t,s}x|\rho).$$

Using (4.4), the proof is now finished as in Theorem 4.1. □

C. Example: The quantum Kac model

A popular toy model to illustrate and to discuss essential features of relaxation to equilibrium has been introduced by Mark Kac.[9] Here we review an extension that can be called a quantum Kac model, we described it extensively in Ref. 4, to learn only later that essentially the same model was considered by Max Dresden and Frank Feiock in Ref. 6. However, there is an interesting difference in interpretation to which we return at the end of the section.

At each site of a ring with N sites there is a quantum bit $\psi_i \in \mathbb{C}^2$ and a classical binary variable $\xi_i = \pm 1$ (which we also consider to be embedded in $\mathbb{C}^2$). The microstates are thus represented as vectors $(\psi;\xi)=(\psi_1,\ldots,\psi_N;\xi_1,\ldots,\xi_N)$, being elements of the Hilbert space $\mathcal{H}^N=\mathbb{C}^{2N}\otimes\mathbb{C}^{2N}$. The time is discrete and at each step two operations are performed: a right shift, denoted below by S^N and a local scattering or update V^N. The unitary dynamics is given as

$$U^N = S^N V^N, \quad U_t^N = (U^N)^t \quad \text{for } t \in \mathbb{N} \tag{4.7}$$

with the shift

$$S^N(\psi;\xi) = (\psi_N, \psi_1, \ldots, \psi_{N-1};\xi) \tag{4.8}$$

and the scattering

$$V^N(\psi;\xi) = \left(\frac{1-\xi_1}{2}V_1\psi_1 + \frac{1+\xi_1}{2}\psi_1, \ldots, \frac{1-\xi_N}{2}V_N\psi_N + \frac{1+\xi_N}{2}\psi_N;\xi\right) \tag{4.9}$$

extended to an operator on $\mathcal{H}^N$ by linearity. Here, V is a unitary 2×2 matrix and V_i its copy at site $i=1,\ldots,N$.

We consider the family of macroscopic observables

$$X_0^N = \frac{1}{N}\sum_{i=1}^N \xi_i, \quad X_\alpha^N = \frac{1}{N}\sum_{i=1}^N \sigma_i^\alpha, \quad \alpha = 1,2,3,$$

where $\sigma_i^1, \sigma_i^2, \sigma_i^3$ are the Pauli matrices acting at site i and embedded to operators on $\mathcal{H}^N$. We fix macroscopic values $x=(\mu,m_1,m_2,m_3)\in[-1,+1]^4$ and we construct a microcanonical macrostate (P^N) in x in the following way.

Let δ_N be a positive sequence in $\mathbb{R}$ such that $\delta_N \downarrow 0$ and $N^{1/2}\delta_N \uparrow +\infty$ as $N\uparrow+\infty$. For $\mu\in[-1,1]$, let $Q_0^N(\mu)$ be the spectral projection associated to X_0^N, on the interval $[\mu-\delta_N,\mu+\delta_N]$. For $\vec{m}=(m_1,m_2,m_3)\in[-1,1]^3$, we already constructed a microcanonical macrostate $Q^N(\vec{m})$ in Sec. II A 4. Obviously, $Q_0^N(\mu)$ and $Q^N(\vec{m})$ commute and the product $P^N=Q_0^N(\mu)Q^N(\vec{m})$ is a projection. It is easy to check that P^N is a microcanonical macrostate at $x=(\mu,\vec{m})$.

The construction of the canonical macrostate is standard along the lines of Sec. II B 3. The corresponding H-functions are manifestly equal:

$$H^{\mathrm{mc}}(x) = H_1^{\mathrm{can}}(x) = \eta\left(\frac{1+m}{2}\right) + \eta\left(\frac{1-m}{2}\right) + \eta\left(\frac{1+\mu}{2}\right) + \eta\left(\frac{1-\mu}{2}\right) \tag{4.10}$$

with $\eta(x)=-x\log x$ for $x\in(0,1]$ and $\eta(0)=0$, otherwise $\eta(x)=-\infty$.

We now come to the conditions of Theorem 4.1. The construction of the macroscopic dynamics and the proof of its autonomy was essentially done in Ref. 4. The macroscopic equation $\xi_t=\xi$ is obvious and the equation for $\vec{m}_t$ can be written, associating $\vec{m}_t$ with the reduced 2×2 density matrix $\nu_t=(1+\vec{m}_t\cdot\vec{\sigma})/2$, in the form $\nu_t=\Lambda_\mu^t\nu$, $t=0,1,\ldots$, where $\Lambda_\mu^t=(\Lambda_\mu)^t$ and

$$\Lambda_\mu(\nu) = \frac{1-\mu}{2} V\nu V^* + \frac{1+\mu}{2}\nu. \tag{4.11}$$

The semigroup condition (4.4) is then also automatically checked.

In order to understand better the necessity of the semigroup property for an H-theorem to be true, compare the above with another choice of macroscopic variables. Assume we had started out with

$$X_0^N = \frac{1}{N}\sum_{i=1}^N \xi_i, \quad X_1^N = \frac{1}{N}\sum_{i=1}^N \sigma_i^1$$

as the only macroscopic variables, as was done in Ref. 6. A microcanonical macrostate can again be easily constructed by setting $Q_0^N(\mu)$ the spectral projection associated to X_0^N on the interval $[\mu-\delta_N, \mu+\delta_N]$ and $Q_1^N(\vec{m})$ the spectral projection for X_1^N on $[\mu-\delta_N, \mu+\delta_N]$, and finally $P^N = Q_0^N(\mu)Q_1^N(\vec{m})$ as before. The sequence (P^N) defines a microcanonical macrostate at $(\mu, \vec{m})$ and the autonomy condition (4.3) is satisfied. However, the macroscopic evolution does not satisfy the semigroup property (4.4) and, in agreement with that, the corresponding H-functions are not monotonous in time (see Ref. 4).

ACKNOWLEDGMENT

Uniqueness of solutions to the helically reduced wave equation with Sommerfeld boundary conditions

C. G. Torre[a)]
Department of Physics, Utah State University, Logan, Utah 84322-4415

(Received 28 March 2006; accepted 12 May 2006; published online 10 July 2006)

We consider the helical reduction of the wave equation with an arbitrary source on $(n+1)$-dimensional Minkowski space, $n \geqslant 2$. The reduced equation is of mixed elliptic-hyperbolic type on $\mathbf{R}^n$. We obtain a uniqueness theorem for solutions on a domain consisting of an n-dimensional ball B centered on the reduction of the axis of helical symmetry and satisfying ingoing or outgoing Sommerfeld conditions on $\partial B \approx S^{n-1}$. Nonlinear generalizations of such boundary value problems (with $n=3$) arise in the intermediate phase of binary inspiral in general relativity. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2212667]

I. INTRODUCTION

Recent approaches to the quasistationary approximation of the intermediate phase of binary inspiral in general relativity have led to the consideration of reductions of the Einstein equations by a helical Killing vector field (see Refs. 1–3 and references therein). To date, model problems have been analyzed consisting of helical reductions of linear and nonlinear wave equations in $(3+1)$-dimensional Minkowski space–time with various sources using Sommerfeld conditions on a spherical boundary.[1] These helically reduced equations have the challenging feature of being of mixed elliptic-hyperbolic type on their three-dimensional domain. More precisely, they are elliptic in an inner cylindrical region surrounding the sources and hyperbolic outside this cylindrical region. There appear to be no general theorems to handle existence and uniqueness of solutions to partial differential equations of mixed type. Results tend to be specific to individual equations or limited classes of equations, and even then the equations which have been most studied are defined in two dimensions.[4] From the investigations of Ref. 1 it appears that the boundary value problem arising from helical reduction of (linear and nonlinear) wave equations using Sommerfeld conditions on an exterior boundary is well-posed. Solutions have been constructed and appear to be unique. This is somewhat remarkable since the boundary intersects both the hyperbolic and elliptic domains. In particular, one might not expect a single (Sommerfeld) condition on a closed boundary to enforce uniqueness of solutions.[1]

Some light was shed on this issue by the work of Ref. 5, where the helical reduction of the $(2+1)$-dimensional wave equation was shown to define a symmetric-positive system on an annular region in $\mathbf{R}^2$ such that the Sommerfeld boundary value problem was well-posed—solutions exist and, in particular, are unique. Unfortunately, it is not known how to generalize these results (i.e., symmetric positivity of the reduced equation) to higher dimensions. Moreover, the helical reduction of the $(2+1)$-dimensional wave equation leads to a boundary value problem on a two-dimensional region with an outer circular boundary which need never intersect the circle of degeneracy of the symbol of the reduced partial differential equation. In higher dimensions, the spherical outer boundary necessarily intersects the "light cylinder" where the symbol is degenerate so the boundary conditions *must* be imposed both in the elliptic and in the hyperbolic regions. (Unless, of course, the boundary is completely contained in the elliptic region, which is not of physical interest and which, in any case, leads to a standard elliptic boundary value problem). This

[a)]Electronic mail: torre@cc.usu.edu

makes the problem qualitatively different in the physical $(3+1)$ space–time dimensions (and in higher dimensions).

Thus, it is of interest both from mathematical physics and gravitational physics viewpoints to better understand the nature of boundary value problems arising from helical reduction of wave equations. Here we shall provide a uniqueness theorem for the helical reduction of the $(n+1)$-dimensional wave equation with arbitrary sources and with Sommerfeld boundary conditions. The proof is remarkably elementary and employs an approach used by Protter to study a generalization of the Tricomi problem.[6]

II. THE HELICALLY REDUCED WAVE EQUATION

We will be considering the helical reduction of the wave equation with an arbitrary source on $(n+1)$-dimensional Minkowski space, with $n \geqslant 2$. The space-time manifold is $N=\mathbf{R}^{n+1}$ with metric

$$\eta = -dt \otimes dt + dx \otimes dx + dy \otimes dy + \delta_{ij} dz^i \otimes dz^j, \tag{2.1}$$

where Latin indices $i,j=1,2,\ldots,n-2$. The wave equation for $\Psi: N \to \mathbf{R}$ with a prescribed source $F: N \to \mathbf{R}$ is

$$-\Psi_{tt} + \Psi_{xx} + \Psi_{yy} + \delta^{ij}\Psi_{ij} = F. \tag{2.2}$$

Note we use the notation where subscripts on a function indicate partial derivatives. The helical reduction is accomplished by assuming the source and solutions are invariant with respect to the isometry group (G) generated by

$$K = \partial_t + \Omega(x\partial_y - y\partial_x), \quad \Omega = \text{const.}, \tag{2.3}$$

which is equivalent to

$$\mathcal{L}_K F = \mathcal{L}_K \Psi = 0. \tag{2.4}$$

In cylindrical coordinates (t,ρ,ϕ,z^i), the metric and Killing vector field are

$$\eta = -dt \otimes dt + d\rho \otimes d\rho + \rho^2 d\phi \otimes d\phi + \delta_{ij} dz^i \otimes dz^j, \tag{2.5}$$

$$K = \partial_t + \Omega \partial_\phi, \tag{2.6}$$

the wave equation is

$$-\Psi_{tt} + \frac{1}{\rho}\partial_\rho(\rho\Psi_\rho) + \frac{1}{\rho^2}\Psi_{\phi\phi} + \delta^{ij}\Psi_{ij} = F, \tag{2.7}$$

and the invariance condition (2.4) is

$$\Psi_t = -\Omega\Psi_\phi, \quad F_t = -\Omega F_\phi. \tag{2.8}$$

Introducing $\varphi = \phi - \Omega t$, (2.8) means there exists functions u and f such that

$$\Psi(t,\rho,\phi,z^i) = u(\rho,\varphi,z^i), \quad F(t,\rho,\phi,z^i) = f(\rho,\varphi,z^i). \tag{2.9}$$

We then get the reduced equation defining helically invariant solutions to (2.2)

$$\frac{1}{\rho}\partial_\rho(\rho u_\rho) + \frac{\chi(\rho)}{\rho^2}u_{\varphi\varphi} + \delta^{ij}u_{ij} = f, \tag{2.10}$$

where

$$\chi(\rho) = 1 - \Omega^2\rho^2. \tag{2.11}$$

The locus of points where $\chi(\rho)=0$ is the "light cylinder". Inside the light cylinder ($\rho<1/\Omega$) Eq. (2.10) is elliptic and outside the light cylinder ($\rho>1/\Omega$) Eq. (2.10) is hyperbolic.

A useful geometric interpretation of this reduction is as follows. The set of orbits of the group generated by K defines a manifold $M=N/G\approx\mathbf{R}^n$. The functions (ρ,φ,z^i) are G-invariant and define cylindrical coordinates on M. In these coordinates the projection $\pi:N\to M$ is simply

$$\pi(t,x,y,z^i)=(\rho,\varphi,z^i), \tag{2.12}$$

and satisfies $\pi_* K=0$. The G-invariant functions F and Ψ on N correspond to functions f and u on M, respectively, via

$$F=\pi^* f, \quad \Psi=\pi^* u. \tag{2.13}$$

The inverse metric on N is given by

$$\eta^\sharp=-\partial_t\otimes\partial_t+\partial_\rho\otimes\partial_\rho+\frac{1}{\rho^2}\partial_\phi\otimes\partial_\phi+\delta^{ij}\partial_i\otimes\partial_j. \tag{2.14}$$

Being G-invariant, $\eta^\sharp$ projects to a tensor field q on M. Using (2.12),

$$q=\pi_*\eta^\sharp=\partial_\rho\otimes\partial_\rho+\frac{\chi(\rho)}{\rho^2}\partial_\varphi\otimes\partial_\varphi+\delta^{ij}\partial_i\otimes\partial_j. \tag{2.15}$$

This tensor field is well-defined everywhere on M, but it does not determine a metric on M because q has no inverse on the light cylinder. While the metric on N does not induce a metric on M, the metric volume form ϵ on N does define a volume form ν on M as follows. Define

$$\omega=K\rightharpoonup\epsilon, \tag{2.16}$$

which satisfies

$$L_K\omega=0, \quad K\rightharpoonup\omega=0. \tag{2.17}$$

Consequently, ω is the pull-back by π of a volume form ν on M. It is easy to check that

$$\nu=\rho d\rho\wedge d\varphi\wedge dz^1\wedge\cdots\wedge dz^{n-2}. \tag{2.18}$$

The volume form ν defines a scalar density of weight 1, $\sigma=\rho$, on M.

We will use Greek indices to label tensor fields on M. Introduce a torsion-free derivative operator ∇_α. The reduced equation (2.10) is equivalent to

$$\frac{1}{\sigma}\nabla_\alpha(\sigma q^{\alpha\beta}\nabla_\beta u)=f. \tag{2.19}$$

To see this, we first note that because of the density weights (2.19) is in fact independent of the choice of torsion-free derivative ∇_α. Using the cylindrical coordinate derivative operator, $\nabla_\alpha=\partial_\alpha$, in (2.19) we obtain (2.10). For what follows we rewrite (2.19) as

$$\nabla_\alpha(h^{\alpha\beta}\nabla_\beta u)=\partial_\alpha(h^{\alpha\beta}u_\beta)=\tilde{f}, \tag{2.20}$$

where $\tilde{f}=\sigma f$ is a scalar density of weight 1 and $h^{\alpha\beta}=\sigma q^{\alpha\beta}$ is a tensor density of weight 1 given by

$$h^{\rho\rho}=\rho, \quad h^{ij}=\rho\delta^{ij}, \quad h^{\varphi\varphi}=\frac{1}{\rho}\chi=\frac{1}{\rho}-\Omega^2\rho. \tag{2.21}$$

III. ENERGY INTEGRAL

The key ingredient in our uniqueness theorem is the following generalized energy integral. Fix a domain $B \subset M$ and define

$$E[u] = \int_B [(au + b^\gamma u_\gamma)\partial_\alpha(h^{\alpha\beta}u_\beta)], \tag{3.1}$$

where a and $b^\alpha\partial_\alpha$ are a function and vector field to be specified later. The integrand involving a can be written as

$$au\partial_\alpha(h^{\alpha\beta}u_\beta) = \frac{1}{2}\partial_\alpha(h^{\alpha\beta}a_\beta)u^2 - ah^{\alpha\beta}u_\alpha u_\beta + \partial_\alpha\left[auh^{\alpha\beta}u_\beta - \frac{1}{2}h^{\alpha\beta}a_\beta u^2\right]. \tag{3.2}$$

The integrand involving b^γ can be written as

$$b^\gamma u_\gamma\partial_\alpha(h^{\alpha\beta}u_\beta) = \frac{1}{2}\partial_\gamma(h^{\alpha\beta}b^\gamma)u_\alpha u_\beta - b^\gamma_{,\alpha}h^{\alpha\beta}u_\gamma u_\beta + \partial_\alpha\left[b^\gamma u_\gamma h^{\alpha\beta}u_\beta - \frac{1}{2}b^\alpha h^{\beta\gamma}u_\gamma u_\beta\right]. \tag{3.3}$$

Again, while these expressions use the coordinate derivative, they are in fact independent of the choice of torsion-free derivative operator. The divergences integrate to the boundary and we have

$$\begin{aligned} E[u] = &\int_B \left\{\frac{1}{2}\partial_\alpha(h^{\alpha\beta}a_\beta)u^2 - ah^{\alpha\beta}u_\alpha u_\beta + \frac{1}{2}\partial_\gamma(h^{\alpha\beta}b^\gamma)u_\alpha u_\beta - b^\gamma_{,\alpha}h^{\alpha\beta}u_\gamma u_\beta\right\} \\ &+ \int_{\partial B} n_\alpha\left\{(au + b^\gamma u_\gamma)h^{\alpha\beta}u_\beta - \frac{1}{2}h^{\alpha\beta}a_\beta u^2 - \frac{1}{2}b^\alpha h^{\beta\gamma}u_\gamma u_\beta\right\}. \end{aligned} \tag{3.4}$$

If there were a metric on B, n_α could be defined in terms of the unit normal to the boundary and the metric-induced volume element of the boundary. Without a metric n_α is still defined, of course, but its definition is necessarily more involved. We give the definition in the Appendix.

IV. UNIQUENESS THEOREM

We are now ready to formulate the boundary value problem of interest. We consider solutions to Eq. (2.20) on a ball of radius R,

$$B = \{(\rho, \varphi, z^i) | 0 \leqslant \rho^2 + \delta_{ij}z^i z^j \leqslant R^2\}. \tag{4.1}$$

The boundary ∂B is the sphere S^{n-1} of radius R. Using (A7), we have in spherical coordinates $(r, \theta_1, \ldots, \theta_{n-1})$,

$$n_\alpha dx^\alpha = dr. \tag{4.2}$$

We impose Sommerfeld-type conditions on ∂B of the type used in Ref. 1. These take the form (in cylindrical coordinates)

$$\frac{1}{R}(\rho u_\rho + z^i u_i) \pm \Omega\partial_\varphi u = \tau, \quad \text{on } \partial B, \tag{4.3}$$

where we have included a function $\tau: \mathbf{S}^n \to \mathbf{R}$ to allow for nonradiative (e.g., monopole) contributions to u (see Remark (ii) below). These boundary conditions can be understood as follows. Sommerfeld conditions for Ψ are, strictly speaking, decay conditions on $\Psi_r \mp \Psi_t$ at spatial infinity in N, where r denotes the spatial radius at fixed t in N (see, e.g., Ref. 7 for a discussion of Sommerfeld conditions). These conditions select ingoing/outgoing radiation. At a finite radius—necessary for numerical computations—one imposes conditions of the form

$$\Psi_r \mp \Psi_t = \tau, \quad \text{on } \partial B. \tag{4.4}$$

Applying the helical symmetry reduction the conditions (4.4) reduce to (4.3).

Remark: (i) If $R > 1/\Omega$ the boundary passes through both the elliptic and hyperbolic domains. (ii) The functions τ and $\tilde{f}$ cannot be specified independently. Using (4.3) the integral of (2.20) over B implies

$$\int_B \tilde{f} = \int_{\partial B} \sigma\tau. \tag{4.5}$$

Since (2.20) and the boundary conditions (4.3) only involve derivatives of u, solutions to these equations can only be unique up to an additive constant. In fact, this is the only freedom in the solution. Our main result is the following.

Theorem: *Given* Ω, $\tilde{f}: B \to \mathbf{R}$, *and* $\tau: \partial B \to \mathbf{R}$, *any two solutions to* (2.20) *on B with boundary conditions* (4.3) *differ at most by a constant.*

Proof: Consider the difference of two solutions, $u = u_1 - u_2$; u satisfies (2.20) and (4.3) with $\tilde{f} = 0$ and $\tau = 0$, respectively. Consequently, $E[u] = 0$ for any choices of the function a and vector field $b = b^\alpha \partial_\alpha$. We choose these as

$$a = -1, \quad b = \frac{2}{1-n}[\rho\partial_\rho + z^i\partial_i \pm R\Omega\partial_\varphi]. \tag{4.6}$$

Note that

$$b^\alpha u_\alpha = 0, \quad \text{on } \partial B. \tag{4.7}$$

A straightforward computation, using (4.3) with $\tau = 0$ in the boundary integral, then gives

$$0 = \int_B \left\{ \left(\frac{1}{n-1}\right)\sigma\left[(u_\rho^2 + \delta^{ij}u_i u_j) + \left(\frac{1}{\rho^2} + \Omega^2\right)u_\varphi^2 \right] \right\} + \int_{\partial B} \left(\frac{1}{n-1}\right)\sigma\frac{R}{\rho^2}\{(z^i z^j + \rho^2\delta^{ij})u_i u_j + (1 + \Omega^2\delta_{ij}z^i z^j)u_\varphi^2 \pm 2R\Omega z^i u_i u_\varphi\}. \tag{4.8}$$

The volume integrand (in the first integral) is manifestly non-negative for $n \geqslant 2$. We now show that the boundary integrand (in the second integral) is also non-negative.

We first note that the boundary integrand is invariant under orthogonal transformations of the z^i. Thus, given any point (ρ, φ, z^i), we can rotate the z^i axes such that $z^i = (z, 0, 0, \ldots, 0)$, where $z^2 = \delta_{ij}z^i z^j$. The boundary integrand at the given point is then

$$\begin{aligned}
&\left(\frac{1}{n-1}\right)\sigma\frac{R}{\rho^2}\{(z^i z^j + \rho^2\delta^{ij})u_i u_j + (1 + \Omega^2\delta_{ij}z^i z^j)u_\varphi^2 \pm 2R\Omega z^i u_i u_\varphi\} \\
&= \left(\frac{1}{n-1}\right)\sigma\frac{R}{\rho^2}\{z^2 u_1^2 + \rho^2\delta^{ij}u_i u_j + (1 + \Omega^2 z^2)u_\varphi^2 \pm 2R\Omega z u_1 u_\varphi\} \\
&\geqslant \left(\frac{1}{n-1}\right)\sigma\frac{R}{\rho^2}\{u_\varphi^2 + (Ru_1 \pm \Omega z u_\varphi)^2\} \geqslant 0.
\end{aligned} \tag{4.9}$$

Because both integrands in (4.8) are non-negative they must each vanish. From the volume integrand it follows immediately that

$$u_\alpha = 0. \tag{4.10}$$

□

APPENDIX: THE DIVERGENCE THEOREM WITHOUT A METRIC

Consider an n-dimensional orientable manifold M, a torsion-free derivative operator ∇_α on M, and a vector density of weight 1, V^α. Given $B \subset M$, Stokes theorem implies an identity of the form

$$\int_B \nabla_\alpha V^\alpha = \int_{\partial B} n_\alpha V^\alpha. \tag{A1}$$

Normally this divergence theorem is proved using a metric on M. However, this is not necessary. Here, we shall give a version of the divergence theorem and, in particular, give a formula for n_α without using a metric.

The manifold M, being orientable, comes equipped with a nowhere vanishing n-form density of weight minus 1, denoted by $\eta_{\alpha_1,\ldots,\alpha_n}$, and a totally antisymmetric contravariant tensor density of weight 1, $\tilde{\eta}^{\alpha_1,\ldots,\alpha_n}$, such that

$$\tilde{\eta}^{\alpha_1,\ldots,\alpha_n}\eta_{\beta_1,\ldots,\beta_n} = n!\,\delta^{[\alpha_1}_{\beta_1}\cdots\delta^{\alpha_n]}_{\beta_n}. \tag{A2}$$

Both $\eta_{\alpha_1,\ldots,\alpha_n}$ and $\tilde{\eta}^{\alpha_1,\ldots,\alpha_n}$ are constant for any choice of ∇_u.

The boundary ∂B is an oriented submanifold in M embedded by $i: S \to M$, i.e., $\partial B = i(S)$. S is equipped with an $(n-1)$-form density of weight minus 1, $\xi_{a_1,\ldots,a_{n-1}}$, and a skew, contravariant rank $(n-1)$ tensor density of weight 1, $\tilde{\xi}^{a_1,\ldots,a_{n-1}}$, satisfying

$$\tilde{\xi}^{a_1,\ldots,a_{n-1}}\xi_{b_1,\ldots,b_{n-1}} = (n-1)!\,\delta^{[a_1}_{b_1}\cdots\delta^{a_{n-1}]}_{b_{n-1}}. \tag{A3}$$

(In this appendix only we use Latin indices to denote tensors on S.)

To apply Stokes theorem we define an $(n-1)$-form

$$\omega_{\alpha_1,\ldots,\alpha_{n-1}} = V^\beta \eta_{\beta\alpha_1,\ldots,\alpha_{n-1}}. \tag{A4}$$

We then have (using differential form notation)

$$\int_B \nabla_\alpha V^\alpha = \int_B d\omega = \int_{\partial B} \omega = \int_S \frac{1}{(n-1)!}\xi^{a_1,\ldots,a_{n-1}}(i^*\omega)_{a_1,\ldots,a_{n-1}}. \tag{A5}$$

Now, at points of ∂B we can write

$$\xi^{a_1,\ldots,a_{n-1}}(i^*\omega)_{a_1,\ldots,a_{n-1}} = (i_*\xi)^{\alpha_1,\ldots,\alpha_{n-1}}\omega_{\alpha_1,\ldots,\alpha_{n-1}} = (i_*\xi)^{\alpha_1,\ldots,\alpha_{n-1}}\eta_{\beta\alpha_1,\ldots,\alpha_{n-1}}V^\beta. \tag{A6}$$

Thus we have

$$n_\beta = \frac{1}{(n-1)!}(i_*\xi)^{\alpha_1,\ldots,\alpha_{n-1}}\eta_{\beta\alpha_1,\ldots,\alpha_{n-1}}. \tag{A7}$$

An alternative approach to the integral over B in (A1) is to note that it is independent of the choice of ∇_α. If we fix a Riemannian metric $g_{\alpha\beta}$ on M, and use the metric-compatible derivative operator, we have available the more traditional form of the divergence theorem,

$$\int_B \nabla_\alpha V^\alpha = \int_{\partial B} \sqrt{\gamma}\hat{n}_\alpha W^\alpha, \tag{A8}$$

where

$$W^{\alpha} = \frac{1}{\sqrt{g}} V^{\alpha}, \tag{A9}$$

$\hat{n}_{\alpha}$ is the outwardly oriented unit normal to ∂B, and $\sqrt{\gamma}$ is the induced volume element on ∂B. The result (A8) is, of course, equivalent to the manifestly metric independent result (A5) above, as can be verified by using the identity

$$\hat{n}_{\beta} = \frac{1}{(n-1)!} \frac{\sqrt{g}}{\sqrt{\gamma}} (i_{*}\xi)^{\alpha_1,\ldots,\alpha_{n-1}} \eta_{\beta\alpha_1,\ldots,\alpha_{n-1}}. \tag{A10}$$

Feynman path integral of Riemann type

Kiyoko Furuya[a)]
Department of Mathematics, Ochanomizu University, 2-1-1 Otsuka-Bunkyo-ku, Tokyo, Japan

(Received 7 February 2006; accepted 21 May 2006; published online 14 July 2006)

In this paper, we shall define a kind of operator-valued integration and define the Feynman path integrals of Riemann integral type. It seems that it is one of the best possible conditions of the existence of the path integrals of Riemann integral type for the Schrödinger equation with singular potentials. Our class of potentials is wide enough: the real measurable potential U should be continuous except for a closed set of measure zero. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2213788]

I. INTRODUCTION

Heuristic Feynman path integrals have played a remarkable role in various aspects of quantum physics. But rigorous mathematical treatment of this integral is not enough. It is well known that Feynman path integrals for Schrödinger equations are not represented by scalar-valued measure (see Ref. 9).

In this paper, we discuss a kind of operator-valued integration and define the path integral of Riemann type, analogously to Riemann integration of scalar functions. So our integration is different from the one of Nelson's (see Ichinose,[5] Nelson,[9] and Takeo[11]).

We shall show that the solution to the Schrödinger equation in $\mathbb{R}^N (N \geqslant 2)$,

$$\frac{\partial}{\partial t}u(t,x) = i\Delta u(t,x) - iU(t,x)u(t,x), \quad u(0,x) = \varphi(x), \quad \varphi \in L^2(\mathbb{R}^N;\mathbb{C}) \tag{1}$$

is written as the path integral

$$u(t,x) = \int_{\Omega_{[0,t]}} e^{-i\int_0^t U(\tau,\gamma(\tau))\mathrm{d}\tau}\varphi(\gamma(0))\mathrm{d}\mu(\gamma), \quad \varphi \in L^2(\mathbb{R}^N;\mathbb{C}) \tag{2}$$

of Riemann type. Here we denote by γ a path on $\mathbb{R}^N$, that is, $\gamma \in \Omega_{[0,t]} \equiv \Pi_{\alpha\in[0,t]}\mathbb{R}^N_\alpha$ ($\mathbb{R}^N_\alpha$=a copy of $\mathbb{R}^N$): $\gamma=(x_\alpha \in \mathbb{R}^N)_{\alpha\in[0,t]}$ (or $\gamma(\alpha)=x_\alpha$).

We study the conditions to define the path integrals of Riemann integral type for Schrödinger equation with singular potentials. Our class of potentials is wide enough: the real valued measurable potential U should be locally essentially bounded except a closed set of measure zero.

The paper of Nelson[9] is concerned with the Schrödinger operator $i[(1/2m)\Delta - V(x)]$, except for a set $\mathcal{N}$ of m with measure 0 and he assumes that V is continuous on the complement of a closed set F of capacity 0. In this paper Nelson mentions that "*The restriction to almost every real value of the mass parameter is an unsatisfactory feature of the theory*" (Ref. 9, p. 335). As Johnson and Lapidus point out that it is a serious weakness (Ref. 6, p. 295). Notice that we have no restriction of this type.

This paper is organized as follows: In Sec. II we state some fact about abstract evolution equations that will be used later. The main purpose of Sec. III is to provide basic notions of path integral of Riemann type. The concepts of path integral of Riemann type are introduced in Sec.

a)Electronic mail: furuya@math.ocha.ac.jp

III A. In Sec. III B we discuss the relationship between the iteration integral and the multiple integral. Section III C deals with sufficient conditions for μ^Q-integrability on $\mathbb{R}^N$. In Sec. IV we investigate the integrability for potentials with singularity. Integration on bounded domain treated in Sec. IV A. The goal of Sec. IV B is to provide strong integrability for non-negative potentials with singularity. Section IV C deals with the integrability for more general real potentials with singularity (see Refs. 7 and 8).

II. ABSTRACT EVOLUTION EQUATION

We begin by introducing the following class of functions.

Definition 1: The space of functions f in $L^\infty(\mathbb{R}^N;\mathbb{C})$ *such that f is uniformly continuous on* $\mathbb{R}^N$ *will be denoted* $C_\infty(\mathbb{R}^N;\mathbb{C})$ *where* $L^\infty(\mathbb{R}^N;\mathbb{C})$ *consisting of all essentially bounded functions on* $\mathbb{R}^N$.

Equation (1) is written as an evolution equation

$$\frac{d}{\mathrm{d}t}u(t) - (A + V(t))u(t), \quad u(0) = \varphi, \tag{3}$$

where $A=i\Delta$ and $V(t)=-iU(t,\cdot)$ is a $C_\infty(\mathbb{R}^N;\mathbb{C})$-valued function.

The associate semigroup with $V\equiv 0$ is written as $\{S_t\}$. More precisely, $\{S_t|-\infty<t<\infty\}\subset L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))$ is a group of unitary operators, where $L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))$ is the space of all bounded linear operators from $L^2(\mathbb{R}^N;\mathbb{C})$ to $L^2(\mathbb{R}^N;\mathbb{C})$.

Let m be a natural number and $\theta=t/m$, $s_0=0$, $s_{j+1}=s_j+\theta$, for $j=0,\ldots,m-1$, $s_m=t$. The subject of this section is that the solution $u(t)$ to the equation (3) is approximated as

$$u(t,x) \sim \left(\prod_{j=1}^{m} S_\theta e^{V(\tau_j,x)\theta}\right)\varphi(x), \quad s_{j-1} \leqslant \tau_j < s_j, \quad j = 1,\ldots,m. \tag{4}$$

We wish to provide some background in abstract evolution equation theory. Let $H=(H,\|\cdot\|)$ be a Hilbert space. Here $\|\cdot\|$ is a norm of H.

We consider the following abstract evolution equation in H:

$$\frac{d}{\mathrm{d}t}u(t) = (A + B(t))u(t), \quad u(0) = \varphi \in H, \tag{5}$$

where A is the generator of a semigroup of unitary operators and $B(t)$ is a bounded linear operator for any $t>0$.

Definition 2: A function u which is differentiable almost everywhere on $[0,T]$ *such that* $\mathrm{d}u/\mathrm{d}t \in L^1(0,T;H)$ *is called a strong solution of the initial value problem* (5) *if* $u(0)=\varphi$ *and* $(d/\mathrm{d}t)u(t)=(A+B(t))u(t)$ *a.e. on* $[0,T]$.

Lemma 1: The strong solution to

$$\frac{d}{\mathrm{d}t}u(t) = (A + B(t))u(t), \quad u(0) = \varphi \in D(A), \tag{6}$$

is given by

$$u(t) = e^{tA}u(0) + \int_0^t e^{(t-s)A}B(s)u(s)\mathrm{d}s, \tag{7}$$

if $B(t)$ *is an* $L(D(A),D(A))$*-valued continuous function. Here* $D(A)$ *is the domain of A equipped with the graph norm* $\|f\|_{D(A)}=(\|f\|^2+\|Af\|^2)^{1/2}$.

Definition 3: The solution to the integral equation (7) *is called the mild solution to the evolution equation* (6), *if it uniquely exists.*

Lemma 2: The mild solution to (6) *uniquely exists if* $B(t)$ *is an* $L(H,H)$*-valued continuous function.*

From Eq. (7) we have

$$u(t+\theta) = e^{\theta A}u(t) + \int_0^\theta e^{(\theta-s)A}B(t+s)u(t+s)\mathrm{d}s. \tag{8}$$

In general $e^{A+B} \neq e^A e^B$. This is because A and B need not commute. Therefore we shall approximate $u(t+\theta)$ by $e^{\theta A}e^{\theta B(t)}u(t)$.

Lemma 3: Let $T>0$ and $B(t)$ be a $L(H,H)$-valued continuous function. Then we have for each $\varepsilon>0$, there exists $\theta_0>0$ such that

$$\|\varepsilon^{\theta A}e^{\theta B(t)}u(t) - u(t+\theta)\| < \theta\varepsilon \quad \textit{for } 0<\theta\leqslant\theta_0 \textit{ and } 0\leqslant t\leqslant T. \tag{9}$$

Proof: Note that the set $\mathcal{C}=\{u(t)\,|\,0\leqslant t\leqslant T\}$ is compact. Since $B(t)$, $u(t)$, and e^{tA} are continuous in t, we may assume for each $\varepsilon_1>0$, there exists $\theta_1>0$ such that

$$\|(B(t)-B(t+s))u(t)\| < \varepsilon_1, \quad \|B(t+s)(u(t)-u(t+s))\| < \varepsilon_1, \quad \|(e^{\theta A}-e^{sA})B(t)u(t)\| < \varepsilon_1$$

$$\textit{for } 0\leqslant s,\theta\leqslant\theta_1, \textit{ and } 0\leqslant t\leqslant T.$$

Since $B(t)$ is linear bounded operator, there exists $M>0$ such that

$$e^{sB(t)}u(t) = (1+sB(t))u(t) + s^2\eta \textit{ for } \|\eta\| < M.$$

Hence by (8), for any $\varepsilon>0$ it follows that

$$\begin{aligned}
\|e^{\theta A}e^{\theta B(t)}u(t) - u(t+\theta)\| &= \left\| e^{\theta A}e^{\theta B(t)}u(t) - e^{\theta A}u(t) - \int_0^\theta e^{(\theta-s)A}B(t+s)u(t+s)\mathrm{d}s \right\| \\
&= \left\| \theta e^{\theta A}B(t)u(t) + \theta^2 e^{\theta A}\eta - \int_0^\theta e^{(\theta-s)A}B(t+s)u(t+s)\mathrm{d}s \right\| \\
&= \left\| \theta^2 e^{\theta A}\eta + \int_0^\theta (e^{\theta A}-e^{(\theta-s)A})B(t)u(t)\mathrm{d}s \right. \\
&\quad + \int_0^\theta e^{(\theta-s)A}(B(t)-B(t+s))u(t)\mathrm{d}s \\
&\quad \left. + \int_0^\theta e^{(\theta-s)A}B(t+s)(u(t)-u(t+s))\mathrm{d}s \right\| \\
&\leqslant \|\theta^2\eta\| + \left\| \int_0^\theta (e^{\theta A}-e^{(\theta-s)A})B(t)u(t)\mathrm{d}s \right\| \\
&\quad + \left\| \int_0^\theta e^{(\theta-s)A}(B(t)-B(t+s))u(t)\mathrm{d}s \right\| \\
&\quad + \left\| \int_0^\theta e^{(\theta-s)A}B(t+s)(u(t)-u(t+s))\mathrm{d}s \right\| \\
&< \theta^2 M + \theta\varepsilon_1 + \theta\varepsilon_1 + \theta\varepsilon_1 < 4\theta\varepsilon_1 = \theta\varepsilon \quad \textit{for } 0\leqslant\theta\leqslant\min\{\theta_1,\varepsilon_1/M\} \\
&= \theta_0, \quad \textit{and } \varepsilon_1 = \varepsilon/4.
\end{aligned}$$

We turn now to the solution $u(t)$ to Eq. (3). □

Lemma 4: Let $u(t)$ be the solution to the equation (3). *If $V(t)$ is an $L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))$-valued continuous function, then it holds that*

$$u(t,x)=\lim_{\theta\to 0}\left(\prod_{j=1}^{m}S_\theta e^{\theta V(\tau_j)}\right)\varphi(x)\quad \text{for } s_{j-1}\leqslant\tau_j<s_j,\quad \text{and } \theta=t/m. \tag{10}$$

Proof: Set $u_k=(\Pi_{j=1}^{k}S_\theta e^{\theta V(s_j-1)})\varphi$ and $B=\sup_{0\leqslant s\leqslant t}\|V(s)\|_{L^\infty}$.

Given $\varepsilon>0$ it follows from (3) that

$$\begin{aligned}\|u_{k+1}-u(s_{k+1})\|&=\|e^{\theta A}e^{\theta V(s_k)}u_k-u(s_k+\theta)\|\leqslant e^{\theta\|V(s_k)\|_{L^\infty}}\|u_k-u(s_k)\|+\|e^{\theta A}e^{\theta V(s_k)}u(s_k)-u(s_k+\theta)\|\\&\leqslant e^{\theta\|V(s_k)\|_{L^\infty}}\|u_k-u(s_k)\|+\theta\varepsilon\leqslant e^{\theta\|V(s_k)\|_{L^\infty}}\{e^{\theta\|V(s_{k-1})\|_{L^\infty}}\|u_{k-1}-u(s_{k-1})\|+\theta\varepsilon\}+\theta\varepsilon\\&\leqslant\cdots\leqslant e^{k\theta B}k\theta\varepsilon\leqslant e^{tB}t\varepsilon\quad \text{for } k=1,\ldots,m-1.\end{aligned}$$

Since $\varepsilon>0$ is arbitrary the proof is complete. □

III. PATH INTEGRAL OF RIEMANN TYPE

A. Operator-valued integral of Riemann type

In this section we express the operator $S_te^V:\varphi\mapsto S_t(e^V\varphi)$ as the integral of $e^V\varphi$ by $\mathrm{d}S_t$. We denote by $\mathbb{Z}$ the set of integers. We consider a division of $\mathbb{R}^N$,

$$\bigcup_{k\in\mathbb{Z}^N}I_k^h=\mathbb{R}^N,\quad I_k^h=[hk_1,hk_1+h)\times\cdots\times[hk_N,hk_N+h),\quad k=(k_1,\ldots,k_N),\quad k_j\in\mathbb{Z}.$$

A function e^V in $L^\infty(\mathbb{R}^N;\mathbb{C})$ is considered as an operator in $L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))$:

$$e^V:L^2(\mathbb{R}^N;\mathbb{C})\ni\varphi\mapsto e^V\varphi\in L^2(\mathbb{R}^N;\mathbb{C}).$$

For simplicity we denote $L^\infty=L^\infty(\mathbb{R}^N;\mathbb{C})$. This implies the following estimates:

$$\begin{aligned}&\|e^{V(x)}\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))}\leqslant\|e^{V(x)}\|_{L^\infty},\\&\|S_te^{V(x)}\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))}\leqslant\|e^{V(x)}\|_{L^\infty}\leqslant e^{\|V(x)\|_{L^\infty}},\\&\|S_te^{\theta V(x)}\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))}\leqslant(1+\theta\|V(x)\|_{L^\infty})e^{\theta\|V(x)\|_{L^\infty}},\\&\|S_t(e^{\theta V(x)}-1)\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))}\leqslant\theta\|V(x)\|_{L^\infty}e^{\theta\|V(x)\|_{L^\infty}}.\end{aligned}\tag{11}$$

The characteristic function $\chi(I_k^h)$ of I_k^h is at the same time an operator in

$$L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C})):(\chi(I_k^h)\cdot\varphi)(x)\equiv\chi(I_k^h)(x)\cdot\varphi(x)=\begin{cases}\varphi(x) & \text{for } x\in I_k^h,\\ 0 & \text{for } x\notin I_k^h.\end{cases}$$

Note that $\varphi(x)=\Sigma_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)\varphi(x)$. We denote

$$\Delta_k^hS_t=S_t\chi(I_k^h)\in L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C})):\varphi\to S_t(\chi(I_k^h)\varphi). \tag{12}$$

Lemma 5: If e^V in $C_\infty(\mathbb{R}^N;\mathbb{C})$ then the sum $S_te^V=\Sigma_{k\in\mathbb{Z}^N}\Delta_k^hS_te^V$ is unconditionally strongly convergent. That is, for any φ in $L^2(\mathbb{R}^N;\mathbb{C})$, $\Sigma_{k\in\mathbb{Z}^N}\Delta_k^hS_te^V\varphi$ strongly converges independent of the order of the sum.

Proof: The lemma follows from the unconditional strong convergence of $\varphi=\Sigma_{k\in\mathbb{Z}^N}\chi(I_k^h)\varphi$ or $e^V\varphi=\Sigma_{k\in\mathbb{Z}^N}\chi(I_k^h)(e^V\varphi)$. In fact we get

$$\text{if } \chi(I_k^h)\varphi \perp \chi(I_{k'}^h)\varphi \text{ for } k \neq k' \text{ then } S_t\chi(I_k^h)\varphi \perp S_t\chi(I_{k'}^h 0)\varphi \text{ for } k \neq k',$$

since S_t is unitary. Therefore

$$\text{if } \mathbb{Z}_1 \subset \mathbb{Z}_2 \subset \mathbb{Z}^N \text{ then } \left\| S_t e^V - \sum_{k\in\mathbb{Z}_1} \Delta_k^h S_t e^V \right\| \geqslant \left\| S_t e^V - \sum_{k\in\mathbb{Z}_2} \Delta_k^h S_t e^V \right\|.$$

□

Definition 4: For $h>0$ and $k \in \mathbb{Z}^N$, let an element $x_h^k \in I_k^h$ be fixed. $\Sigma_k \Delta_k^h S_t e^{V(x_h^k)}$ is called the Riemann sum. $\lim_{h\to 0}\Sigma_k \Delta_k^h S_t e^{V(x_h^k)}$ is called the Riemann integral of $e^{V(x)}$ by $\mathrm{d}S_t(x)$ and denoted by

$$R-\int_{\mathbb{R}^N} \mathrm{d}S_t(x)e^{V(x)} = \int_{\mathbb{R}^N} S_t(\mathrm{d}x)e^{V(x)} = \lim_{h\to 0} \sum_{k\in\mathbb{Z}^N} \Delta_k^h S_t e^{V(x_h^k)} \in L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C})). \quad (13)$$

$\mathrm{d}S_t$ is finitely additive and may be called an operator-valued "Riemann measure."

B. Iterated integral and multiple integral

From the definition of Riemann integral, we obtain that

$$\prod_{j=1}^m S_\theta e^{\theta V(\tau_j,x)}\varphi = R-\int_{\mathbb{R}^N} dS_\theta(x)e^{\theta V(\tau_m,x)}\cdots R-\int_{\mathbb{R}^N} dS_\theta(x)e^{\theta V(\tau_1,x)}\varphi,$$

with $\theta=t/m$. This is the iterated integral. We shall express this by the multiple integral.

We denote by $C([0,t],C_\infty(\mathbb{R}^N;\mathbb{C}))$ the space of continuous functions on $[0,t]$ with values in $C_\infty(\mathbb{R}^N;\mathbb{C})$. Note that for all $V \in C([0,t],C_\infty(\mathbb{R}^N;\mathbb{C}))$ and for each $\varepsilon>0$, there exists $\delta>0$ such that

$$\begin{gathered} |V(s,x)-V(s',x')|<\varepsilon, \quad |e^{\theta V(s,x)}-e^{\theta V(s',x')}|<\varepsilon\theta, \\ \text{for } |s-s'|\leqslant\delta, \quad |x-x'|<\delta, \quad \text{and } 0\leqslant\theta\leqslant 1. \end{gathered} \quad (14)$$

Lemma 6: Let $\mathcal{C}$ be a compact subset of $L^2(\mathbb{R}^N;\mathbb{C})$. Let A^j and A_n^j be operators in $L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))$ for $1\leqslant j\leqslant m$.

Then for each $\varepsilon>0$, there exists $n_0>1$ such that for all $n\geqslant n_0$, (a) if

$$\|A_n^j - A^j\|_{L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))} < \varepsilon$$

then

$$\left\| \prod_{j=1}^m A_n^j - \prod_{j=1}^m A^j \right\|_{L^2(\mathbb{R}^N;\mathbb{C})} < \varepsilon m M^{m-1}, \quad (15)$$

(b) if

$$\sup_{\varphi\in\mathcal{C}_j} \|(A_n^j - A^j)\varphi\|_{L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))} < \varepsilon, \quad \textit{for all } \mathcal{C}_j\textit{:compact}$$

then

$$\sup_{\varphi\in\mathcal{C}} \left\| \left(\prod_{j=1}^m A_n^j - \prod_{j=1}^m A^j \right)\varphi \right\|_{L^2(\mathbb{R}^N;\mathbb{C})} < \varepsilon m M^{m-1}. \quad (16)$$

Here we write $\Pi_{j=1}^m A^j = A^m\cdots A^1$ and

$$M = \max\{1, \sup(\|A_n^j\|_{L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))}, \|A^j\|_{L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))}; n\in\mathbb{N}, j=1,\ldots,m)\}.$$

Proof: In this proof for simplicity we denote $\|\cdot\|=\|\cdot\|_{L(L^2(\mathbb{R}^N;\mathbb{C}),L^2(\mathbb{R}^N;\mathbb{C}))}$. Note that for each $\varepsilon>0$, there exists n_0 such that $\|A_n^j-A^j\|<\varepsilon$ for all $n\geqslant n_0$, and $j=1,\ldots,m$. We have

$$\prod_{j=1}^{m}A_n^j-\prod_{j=1}^{m}A^j=\left(\prod_{j=2}^{m}A_n^j\right)(A_n^1-A^1)+\sum_{k=2}^{m-1}\left(\left(\prod_{j=k+1}^{m}A_n^j\right)(A_n^k-A^k)\prod_{j=1}^{k-1}A^j\right)+(A_n^m-A^m)\prod_{j=1}^{m-1}A^j.$$

Then from (3.2), we obtain

$$\begin{aligned}\left\|\prod_{j=1}^{m}A_n^j-\prod_{j=1}^{m}A^j\right\|&\leqslant\left\|\left(\prod_{j=2}^{m}A_n^j\right)(A_n^1-A^1)+\sum_{k=2}^{m-1}\left(\left(\prod_{j=k+1}^{m}A_n^j\right)(A_n^k-A^k)\prod_{j=1}^{k-1}A^j\right)+(A_n^m-A^m)\prod_{j=1}^{m-1}A^j\right\|\\&\leqslant\left(\prod_{j=2}^{m}\|A_n^j\|\right)\|A_n^1-A^1\|+\sum_{k=2}^{m-1}\left(\left(\prod_{j=k+1}^{m}\|A_n^j\|\right)\|A_n^k-A^k\|\prod_{j=1}^{k-1}\|A^j\|\right)\\&\quad+\|A_n^m-A^m\|\prod_{j=1}^{m-1}\|A^j\|<\varepsilon mM^{m-1}\ \textit{for any}\ n\geqslant n_0.\end{aligned}$$

Set $\mathcal{C}_1=\mathcal{C}$ and $\mathcal{C}_k=(\Pi_{j=1}^{k-1}A^j)\mathcal{C}$ for $k>1$. Each $\mathcal{C}_k$ is compact, since it is the continuous image of the compact set $\mathcal{C}$. From the right-hand side of (16) we have for each $\varepsilon>0$ that there exists n_0 such that $\sup_{\phi\in\mathcal{C}_k}\|(A_n^k-A^k)\phi\|<\varepsilon$ for all $n\geqslant n_0$ and $j=1,\ldots,m$.

Hence

$$\begin{aligned}&\sup_{\varphi\in\mathcal{C}}\left\|\left(\prod_{j=1}^{m}A_n^j-\prod_{j=1}^{m}A^j\right)\varphi\right\|\\&\quad=\sup_{\varphi\in\mathcal{C}}\left\|\left(\left(\prod_{j=2}^{m}A_n^j\right)(A_n^1-A^1)+\sum_{k=2}^{m-1}\left(\left(\prod_{j=k+1}^{m}A_n^j\right)(A_n^k-A^k)\prod_{j=1}^{k-1}A^j\right)+(A_n^m-A^m)\prod_{j=1}^{m-1}A^j\right)\varphi\right\|\\&\quad\leqslant\sup_{\varphi\in\mathcal{C}_m}\left\|\left(\prod_{j=2}^{m}A_n^j\right)(A_n^1-A^1)\varphi\right\|+\sum_{k=2}^{m-1}\sup_{\varphi\in\mathcal{C}_k}\left\|\left(\prod_{j=k+1}^{m}A_n^j\right)(A_n^k-A^k)\prod_{j=1}^{k-1}A^j\varphi\right\|\\&\quad\quad+\sup_{\varphi\in\mathcal{C}}\left\|(A_n^m-A^m)\prod_{j=1}^{m-1}A^j\varphi\right\|\leqslant\left(\prod_{j=2}^{m}\|A_n^j\|\right)\sup_{\varphi\in\mathcal{C}_1}\|(A_n^1-A^1)\varphi\|\\&\quad\quad+\sum_{k=2}^{m-1}\left(\left(\prod_{j=k+1}^{m}\|A_n^j\|\right)\sup_{\phi\in\mathcal{C}_k}\|(A_n^k-A^k)\phi\|\right)\\&\quad\quad+\sup_{\phi\in\mathcal{C}_m}\|(A_n^m-A^m)\phi\|<\varepsilon mM^{m-1}.\end{aligned}$$

□

Lemma 7: Let V in $C([0,t],C_\infty(\mathbb{R}^N;\mathbb{C}))$. *Then we have*

$$\prod_{j=1}^{m}S_\theta e^{\theta V(\tau_j,\cdot)}\varphi=\lim_{h\to0}\prod_{j=1}^{m}S_\theta\sum_k\chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)}\varphi\quad\textit{for}\ x_h^k\in I_k^h\quad\textit{with}\ \theta=t/m.\tag{17}$$

Proof: From (14) we recall for each $\varepsilon>0$, there exists $h>0$ such that $|e^{V(\tau_j,x)\theta}-e^{V(\tau_j,x_h^k)\theta}|<\varepsilon\theta$ for all x in I_k^h and for all k in $\mathbb{Z}^N$. Then we have

$$\left\| e^{\theta V(\tau_j,\cdot)}\varphi - \sum_{k\in\mathbb{Z}^N} \chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)}\varphi \right\| \leqslant \left\| \sum_{k\in\mathbb{Z}^N} \chi(I_k^h)(\cdot)(e^{\theta V(\tau_j,\cdot)} - e^{\theta V(\tau_j,x_h^k)}) \right\|_{L^\infty} \|\varphi\| < \varepsilon\theta\|\varphi\|$$

$$\text{for all } \varphi \in L^2(\mathbb{R}^N;\mathbb{C}).$$

This means

$$\left\| e^{\theta V(\tau_j,\cdot)}\varphi - \sum_{k\in\mathbb{Z}^N} \chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)} \right\|_{L^\infty} < \varepsilon\theta.$$

From (11) we have

$$\|S_\theta e^{\theta V(\tau_j,\cdot)}\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))} \leqslant e_{L^\infty}^{\theta\|V(\tau_j,\cdot)\|},$$

$$\left\| S_\theta \sum_{k\in\mathbb{Z}^N} \chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)} \right\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))} \leqslant e_{L^\infty}^{\theta\|V(\tau_j,\cdot)\|} + \varepsilon h,$$

$$\left\| S_\theta e^{\theta V(\tau_j,\cdot)} - S_\theta \sum_{k\in\mathbb{Z}^N} \chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)} \right\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))} < \varepsilon\theta. \tag{18}$$

Hence from Lemma 6 we obtain that

$$\begin{aligned} &\left\| \prod_{j=1}^m S_\theta e^{\theta V(\tau_j,\cdot)} - \prod_{j=1}^m S_\theta \sum_{k\in\mathbb{Z}^N} \chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)} \right\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))} < \varepsilon\theta m e^{t\|V\|_{L^\infty}} = \varepsilon t e^{t\|V\|_{L^\infty}}, \\ &\left\| \prod_{j=1}^m S_\theta e^{\theta V(\tau_j,\cdot)}\varphi - \prod_{j=1}^m S_\theta \sum_{k\in\mathbb{Z}^N} \chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)}\varphi \right\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))} < \varepsilon t e^{t\|V\|_{L^\infty}}\|\varphi\|. \end{aligned} \tag{19}$$

This means (17). □

Denote $\kappa=(k(1),\ldots,k(m)) \in \mathbb{Z}^{N\times m}$ where $k(j)=(k_1(j),\ldots,k_N(j)) \in \mathbb{Z}^N$.

Note that $\Delta_{k(j)}^h S_\theta$ and $e^{\theta V(\tau_j,x_h^{k(j)})}$ commute since each $e^{\theta V(\tau_j,x_h^{k(j)})}$ is a constant function. Thus we have

$$\begin{aligned} \prod_{j=1}^m S_\theta \sum_{k\in\mathbb{Z}^N} \chi(I_{k(j)}^h)e^{\theta V(\tau_j,x_h^k)} &= \sum_{\kappa\in\mathbb{Z}^{N\times m}} \prod_{j=1}^m (S_\theta \chi(I_{k(j)}^h)e^{\theta V(\tau_j,x_h^{k(j)})}) = \sum_{\kappa\in\mathbb{Z}^{N\times m}} \prod_{j=1}^m (\Delta_{k(j)}^h S_\theta e^{\theta V(\tau_i,x_h^{k(j)})}) \\ &= \sum_{\kappa\in\mathbb{Z}^{N\times m}} \prod_{j=1}^m (\Delta_{k(j)}^h S_\theta) e^{\sum_{l=1}^m \theta V(\tau_l,x_h^{k(l)})}, \end{aligned} \tag{20}$$

since the sum $\Sigma_{k\in\mathbb{Z}^N}\chi(I_k^h)e^{\theta V(\tau_j,x_h^k)}$ is unconditionally convergent. The multiple integral is defined as follows.

Definition 5: The multiple integral of $\exp(\Sigma_{l=1}^m \theta V(\tau,\gamma(\tau_l)))$ *is defined by*

$$\begin{aligned} R - \int \cdots \int \mathrm{d}S_\theta(\gamma(\tau_1)) \cdots \mathrm{d}S_\theta(\gamma(\tau_m)) e^{\Sigma_{l=1}^m \theta V(\tau,\gamma(\tau_l))} \\ = \lim_{h\to 0} \sum_{\kappa\in\mathbb{Z}^{Nm}} \prod_{j=1}^m (\Delta_{k(j)}^h S_\theta) e^{\Sigma_{l=1}^m \theta V(\tau_l,x_h^{k(l)})} \quad \text{with } \theta = t/m. \end{aligned} \tag{21}$$

Let $h\to 0$ in (20) and we get the following lemma by (19), (13), and (17).

Lemma 8: Let $V \in C([0,\mathfrak{t}],C_\infty(\mathbb{R}^N;\mathbb{C}))$. *Then we have*

$$\prod_{j=1}^{m} S_\theta e^{\theta V(\tau_j,x)} = R - \int \cdots \int \mathrm{d}S_\theta(\gamma(\tau_1)) \cdots \mathrm{d}S_\theta(\gamma(\tau_m)) e^{\sum_{j=1}^{m} \theta V(\tau,\gamma(\tau_j))},$$

where $\gamma(\tau_j)$ *runs over* $\mathbb{R}^N$ *for each* j *and*

$$\int \mathrm{d}S_\theta(\gamma(\tau_j)) e^{\theta V(\tau,\gamma(\tau_j))} \quad \textit{means} \int_{\mathbb{R}^N} \mathrm{d}S_\theta(x) e^{\theta V(\tau_j,x)}.$$

Roughly speaking,

$$\prod_{j=1}^{m} \Delta^h_{k(j)} S_\theta \sim \prod_{j=1}^{m} \mathrm{d}S_\theta(\gamma(\tau_j)) \quad \text{for } \gamma \in \Omega_{[0,t]}, \quad \gamma(\tau_j) \in I^h_{k(j)} \text{ as } h \to 0.$$

C. Path integral of Riemann type

Now we define the path integral of the Riemann type.

Definition 6: The Riemann type path integral of $F(V;t,\gamma) = e^{\int_0^t V(\tau,\gamma(\tau))\mathrm{d}\tau}$ *is defined by*

$$R - \int_{\Omega_{[0,t]}} e^{\int_0^t V(\tau,\gamma(\tau))\mathrm{d}\tau} \varphi \, \mathrm{d}\mu^Q(\gamma) = \lim_{m\to\infty} \lim_{h\to 0} \sum_{\kappa \in \mathbb{Z}^{N_m}} \prod_{j=1}^{m} \Delta^h_{k(j)} S_\theta e^{\sum \theta V(\tau_j, x_h^{k(j)})} \varphi,$$

$$= \lim_{m\to\infty} \lim_{h\to 0} \sum_{\kappa \in \mathbb{Z}^{N_m}} \Delta^h_k S_\theta e^{\sum \theta V(\tau_j, x_h^{k(j)})} \varphi, \tag{22}$$

where $\Delta^h_\kappa S_\theta = \Pi_{j=1}^m \Delta^h_{k(j)} S_\theta$ *with* $\theta = t/m$.

Thus from Definition 5, Lemma 8, and Definition 6 we obtain that

$$R - \int_{\Omega_{[0,t]}} e^{\int_0^t V(\tau,\gamma(\tau))\mathrm{d}\tau} \varphi d\mu^Q(\gamma) = \lim_{m\to\infty} R - \int \cdots \int \mathrm{d}S_\theta(\gamma(\tau_1)) \cdots \mathrm{d}S_\theta(\gamma(\tau_m)) e^{\sum_{j=1}^{m} \theta V(\tau_j,\gamma(\tau_j))} \varphi$$

$$= \lim_{m\to\infty} \left(\prod_{j=1}^{m} S_\theta e^{\theta V(\tau_j,x)} \varphi \right).$$

Remark: In general we have not defined the function $F(V;t,\gamma) = e^{\int_0^t V(\tau,\gamma(\tau))\mathrm{d}\tau}$, nor the (generalized) measure μ^Q. Since $F(V;t,\gamma)$ might not exist for a path γ. Nevertheless the path integral (22) is defined for some V.

A sufficient (but not necessary) condition for a function $F(V;t,\gamma)$ to be μ^Q-integrable is given in our next theorem.

Theorem 1: *Let* $V \in C([0,\mathfrak{t}], C_\infty(\mathbb{R}^N;\mathbb{C}))$. *Then the function* $F(V;t,\gamma) = e^{\int_0^t V(\tau,\gamma(\tau))\mathrm{d}\tau}$ *is* μ^Q*-integrable.*

That is,

$$R - \int_{\Omega_{[0,t]}} e^{\int_0^t V(\tau,\gamma(\tau))\mathrm{d}\tau} \varphi(\gamma(0)) \mathrm{d}\mu^Q(\gamma) = \lim_{m\to\infty} \left(\prod_{j=1}^{m} S_\theta e^{\theta V(\tau_j,x)} \right) \varphi(x) \quad \textit{with } \theta = t/m \tag{23}$$

exists.

Proof: From (22) of Definition 6 it suffices to show $\lim_{m\to\infty} \Pi_{j=1}^m S_\theta e^{\theta V(\tau_j,x)}$ exists.

For each $\varepsilon > 0$, there exists $m \in \mathbb{N}$ such that $\| e^{\theta' V(\tau,x)} - e^{\theta' V(\sigma,x)} \|_{L^\infty} \leqslant \varepsilon \theta'$ for $|\tau - \sigma| \leqslant \theta = t/m$ and $0 < \theta' \leqslant \theta$. Hence

$$\|S_{\theta'}e^{\theta' V(\tau,x)} - S_{\theta'}e^{\theta' V(\sigma,x)}\|_{L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))} \leqslant \varepsilon\theta' e^{\theta'\|V\|_{L^\infty}}. \tag{24}$$

We divide each time interval $[s_j, s_{j+1}]$. Let m' be a natural number and $\theta' = \theta/m'$, $\sigma_{j0} = s_j$, $\sigma_{jj'} = s_j + \theta'$, $\sigma_{jm'} = s_{j+1}$ for $j' = 0, \ldots, m'-1$.

By Lemma 6 and (24) we have

$$\left\| S_\theta e^{\theta V(\tau_j,x)} - \prod_{j'=1}^{m'} S_{\theta'}e^{\theta' V(\sigma_{jj'},x)} \right\| = \left\| \prod_{j'=1}^{m'} S_{\theta'}e^{\theta' V(\tau_j,x)} - \prod_{j'=1}^{m'} S_{\theta'}e^{\theta' V(\sigma_{jj'},x)} \right\|$$
$$\leqslant \varepsilon m'\theta'(e^{\theta'\|V\|_{L^\infty}})^{m-1} \leqslant \varepsilon\theta e^{\theta\|V\|_{L^\infty}}.$$

In the same way as above we have

$$\left\| \prod_{j=1}^{m} S_\theta e^{\theta V(\tau_j,x)} - \prod_{j=1}^{m}\prod_{j'=1}^{m'} S_{\theta'}e^{\theta' V(\sigma_{jj'},x)} \right\| \leqslant \varepsilon\theta e^{\theta\|V\|_{L^\infty}} m(e^{\theta\|V\|_{L^\infty}})^{m-1} \leqslant \varepsilon t e^{t\|V\|_{L^\infty}}, \tag{25}$$

and the proof is complete. □

A direct consequence of Theorem 1 is the following theorem.

Theorem 2: *Let a real function U in $C([0,t], C_\infty(\mathbb{R}^N;\mathbb{C}))$. Then the mild solution to the Schrödinger equation (1) is expressed as the Riemann type integral*

$$u(t,x) = R - \int_{\Omega_{[0,t]}} e^{-i\int_0^t U(\tau,\gamma(\tau))\mathrm{d}\tau}\varphi(\gamma(0))\mathrm{d}\mu^Q(\gamma). \tag{26}$$

IV. INTEGRABLE FUNCTIONS

In this section we study the Schrödinger equations with singular potentials.

A. Integration on a bounded domain

Let subset D of $\mathbb{R}^N$ be a bounded open domain with smooth boundary and V be a continuous function on $\bar{D}$. Denote

$$\Omega_{[0,t]}(D) = \prod_{\alpha\in[0,t]} D_\alpha,$$

where D_α=a copy of $D=\{\gamma|\,\gamma(s)\in\bar{D}, \forall s\in[0,t]\}$.

We consider the integration on $\Omega_{[0,t]}(D)$.

The family of solutions to the Schrödinger equation in D with Dirichlet boundary condition

$$\frac{\partial}{\partial t}u(t,x) = i\Delta u(t,x), \quad u(t,x)\big|_{x\in\partial D} = 0, \quad u(0,x) = \varphi(x)\big|_{x\in D} \tag{27}$$

is written as $u(t)=S_t\varphi$ by a group $\{S_t|-\infty<t<\infty\}$ of unitary operators.

Let

$$\bigcup_{k\in\mathbb{Z}^N} I_k^h(D) = D, \quad I_k^h(D) = D\cap([hk_1, hk_1+h)\times\cdots\times[hk_N, hk_N+h)), \quad k=(k_1,\ldots,k_N), \quad k_j\in\mathbb{Z}.$$

Definition 7: If the Riemann sum $\Sigma_{k\in\mathbb{Z}^N}\mu(I_k^h(D))(\cdot)e^{V(x_h^k)}$ converges as $h\to 0$ independently of the choice of $\{I_k^h(D)\}$ and $\{x_h^k\}$, the function $e^{V(x)}$ is said to be Riemann integrable, where $\mu(I_k^h(D))$ is the volume of $I_k^h(D)$.

If the function $G(x)=e^{-iU(x)}$, $U(x)\in\mathbb{R}$, is a scalar valued Riemann integrable in a bounded domain D, the operator-valued integral $R-\int_D \mathrm{d}S_t(x)e^{V(x)}=\lim_{h\to 0}\Sigma_{k\in\mathbb{Z}^N}\Delta_k^h S_t e^{V(x_h^k)}$ also exists. Moreover the multiple integral exists.

As is well known, a bounded function on a bounded domain is Riemann integrable if and only if the set of discontinuous points is of measure zero. In our case, we have the following.

Lemma 9: A function $G(x)=e^{-iU(x)}$, $U(x)\in\mathbb{R}$ for a bounded function U, is Riemann integrable in a bounded domain D if and only if the set of discontinuous points of U is of measure zero.

Let $\mathcal{N}_{V(t)}(D)=\{x\in\bar{D}\,|\,V(t)$ is not continuous at$\}$ and $\mathcal{N}_V(D)=\cup_{t\in[0,T]}\mathcal{N}_{V(t)}(D)$.

Our next theorem is analogous to Theorem 1.

Theorem 3: *If a function V in $C([0,T];L^\infty(\mathbb{R}^n;\mathbb{C}))$ and for any t in $[0,T]V(t)$ is Riemann integrable on $\bar{D}$ and $\mathcal{N}_V(D)$ is a closed set of measure zero, then the function $e^{\int_0^t V(\tau,\gamma(\tau))\mathrm{d}\tau}$ is μ^Q-integrable on $\Omega_{[0,t]}(D)$. That is,*

$$R-\int_{\Omega_{[0,t]}(D)} e^{\int_0^t V(\tau,\gamma(\tau))\mathrm{d}\tau}\varphi(\gamma(0))\mathrm{d}\mu^Q(\gamma)=\lim_{m\to\infty}\prod_{j=1}^{m} S_\theta e^{\theta V(\tau_j,x)}\varphi(x),\quad x\in\text{a.e. } D \text{ with } \theta=t/m \tag{28}$$

exists.

Proof: Note that $\mathcal{N}_{V(t)}(D)$ is of measure zero since $V(t)$ is Riemann integrable on $\bar{D}$. Therefore we have for each $\varepsilon>0$ there exist open sets $J_j(D)\subset D(j=1,\ldots,n)$ such that $\cup_{j=1}^n J_j(D)\supset\mathcal{N}_V(D)$ and $\Sigma_{j=1}^n\mu(J_j(D))<\varepsilon^2$. Set $J(\varepsilon)=^{\mathrm{def}}\cup_{j=1}^n J_j(D)$. Since $\bar{D}\backslash J(\varepsilon\theta)$ is compact,V is uniformly continuous on $[0,T]\times\{\bar{D}\backslash J(\varepsilon\theta)\}$.

For each V and for each $\varepsilon>0$, there exists $\delta>0$, such that

$$|V(s,x)-V(s',x')|<\varepsilon,\quad |e^{\theta V(s,x)}-e^{\theta V(s',x')}|<\varepsilon\theta$$

for

$$|s-s'|<\delta,\quad s,s'\in[0,T],\quad |x-x'|<\delta,\quad x,x'\in\bar{D}\setminus J(\varepsilon\theta),\quad 0\leqslant\theta\leqslant 1. \tag{29}$$

If necessary we take finer division, we assume that $J(\varepsilon\theta)\cap[I_k^h(D)]^o=\emptyset$ for all $k\in\mathbb{Z}_1$, $J(\varepsilon\theta)\supset I_k^h(D)$ for all $k\in\mathbb{Z}_2$, $\mathbb{Z}^N=\mathbb{Z}_1\cup\mathbb{Z}_2$ and $\mathbb{Z}_1\cap\mathbb{Z}_2=\emptyset$. Here A^o is the interior of A. Thus we have

$$\begin{aligned}
&\left\|e^{\theta V(\tau_j,\cdot)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)}\right\|_{L(L^2(D;\mathbb{C});L^2(D;\mathbb{C}))}\\
&\quad=\sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left\|\left(e^{\theta V(\tau_j,\cdot)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(\cdot)e^{\theta V(\tau_j,x_h^k)}\right)\varphi\right\|_{L^2(D;\mathbb{C})}\\
&\quad=\sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left(\int_D\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)\right.\\
&\qquad\left.\times\overline{\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)}\mathrm{d}x\right)^{1/2}\\
&\quad=\sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left(\left(\int_{D\backslash J(\varepsilon\theta)}+\int_{J(\varepsilon\theta)}\right)\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)\right.\\
&\qquad\left.\times\overline{\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)}\mathrm{d}x\right)^{1/2}
\end{aligned}$$

$$\leqslant \sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left(\int_{D\setminus J(\varepsilon\theta)}\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)\right.$$
$$\left.\times\overline{\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)}\mathrm{d}x\right)^{1/2}$$
$$+\sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left(\int_{J(\varepsilon\theta)}\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)\right.$$
$$\left.\times\overline{\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)}\mathrm{d}x\right)^{1/2}$$
$$=\mathrm{I}+\mathrm{II}$$

since $\sqrt{A+B}\leqslant\sqrt{A}+\sqrt{B}$ for $A\geqslant 0$, $B\geqslant 0$.

From (29) it follows that

$$\mathrm{I}=\sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left(\int_{D\setminus J(\varepsilon\theta)}\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)\right.$$
$$\left.\times\overline{\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)}\mathrm{d}x\right)^{1/2}\leqslant\varepsilon\theta\sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left(\int_D\varphi(x)\overline{\varphi(x)}\mathrm{d}x\right)^{1/2}=\varepsilon\theta.$$

By the definition of $J(\varepsilon\theta)$, we have

$$\mathrm{II}=\sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left(\int_{J(\varepsilon\theta)}\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)\right.$$
$$\left.\times\overline{\left(e^{\theta V(\tau_j,x)}-\sum_{k\in\mathbb{Z}^N}\chi(I_k^h)(x)e^{\theta V(\tau_j,x_h^k)}\right)\varphi(x)}\mathrm{d}x\right)^{1/2}\leqslant 2e^{\|V\|_\infty}\sup_{\|\varphi\|_{L^2(D;\mathbb{C})}=1}\left(\int_{J(\varepsilon\theta)}\varphi(x)\overline{\varphi(x)}\mathrm{d}x\right)^{1/2}$$
$$\leqslant 2e^{\|V\|_\infty}\|\varphi\|_{L^2(D;\mathbb{C})}\mu(J(\varepsilon\theta))^{1/2}<2\varepsilon\theta e^{\|V\|_\infty}.$$

So the rest of the proof is obtained in a way similar to that of Theorem 1. □

B. Strong integrability for non-negative potentials with singularity

For simplicity we shall discuss the time-independent case. We use the following notations:

$$\mathcal{N}=\text{a fixed closed subset of } \mathbb{R}^N \text{ of measure } 0, \tag{30}$$

$$C(\mathbb{R}^N\setminus\mathcal{N},\mathbb{R}^+)=\{U\in C(\mathbb{R}^N\setminus\mathcal{N},\mathbb{R})\,|\,U(x)\geqslant 0,\ \text{for all } x\in\mathbb{R}^N\}. \tag{31}$$

In this section we consider the integrability of the function $e^{-i\int_0^t U(\gamma(s))\mathrm{d}s}$ for a function $U\in C(\mathbb{R}^N\setminus\mathcal{N},\mathbb{R}^+)$. Let $D_n=\{x\in\mathbb{R}^N\,|\,n>U(x)\}$ for $n\in\mathbb{N}$. $\{D_n\}_{n=1}^\infty$ is an increasing sequence such that $\bar{D}_n\subset D_{n+1}$ and $\cup_{n=1}^\infty D_n=\mathbb{R}^N\setminus\mathcal{N}$. Here D_n is a finite sum of E_k^n for $k\in\mathbb{N}$ and each E_k^n is a bounded open connected set with smooth boundary.

For $U\in C(\mathbb{R}^N\setminus\mathcal{N},\mathbb{R}^+)$ we define a sequence of functions U_n such that

$$U_n(x)=\min\{n,U(x)\}\quad\text{for } n\in\mathbb{N}.$$

Lemma 10: Let U in $C(\mathbb{R}^N\setminus\mathcal{N},\mathbb{R}^+)$. Then $e^{-i\int_0^t U_n(\gamma(s))\mathrm{d}s}$ is Riemann integrable.

Proof: From Theorem 3 we obtain this lemma. □

We denote that

$$T_n(t)\phi = \int_{\Omega_{[0,t]}(D_n)} e^{-i\int_0^t U_n(\gamma(s))\mathrm{d}s}\phi \,\mathrm{d}\mu^Q \quad \text{for } \phi \in L^2(\mathbb{R}^N;\mathbb{C}).$$

When a function U is not bounded the Riemann integral of $e^{-i\int_0^t U(\gamma(s))\mathrm{d}s}$ does not exist for U in $C(\mathbb{R}^N\backslash\mathcal{N},\mathbb{R}^+)$. Therefore we introduce the definition of improper Riemann integration with respect to μ^Q.

Definition 8: For a function $U \in C(\mathbb{R}^N\backslash\mathcal{N},\mathbb{R}^+)$, the function $e^{-i\int_0^t U(\gamma(s))\mathrm{d}s}$ is said to be improper Riemann integrable by μ^Q if

$$\lim_{n\to\infty} R - \int_{\Omega_{[0,t]}(D_n)} e^{-i\int_0^t U_n(\gamma(s))\mathrm{d}s}\phi \,\mathrm{d}\mu^Q$$

exists for any $\phi \in L^2(\mathbb{R}^N;\mathbb{C})$ independently of the choice of $\{D_n\}$.

The main result of this section is the following theorem.

Theorem 4: *Let a function U in $C(\mathbb{R}^N\backslash\mathcal{N},\mathbb{R}^+)$. Then the function $F(-iU;t,\gamma) = e^{-i\int_0^t U(\gamma(s))\mathrm{d}s}$ is improper Riemann integrable by μ^Q.*

For the proof of this theorem we shall use the subdifferential of convex functionals.

Denote $H_R^1 = H^1(\mathbb{R}^N;\mathbb{R})$ and $H_R^2 = H^2(\mathbb{R}^N;\mathbb{R})$, where $H^1(\mathbb{R}^N;\mathbb{R})$ is the first Sovolev space on $\mathbb{R}^N$ and $H_R^2 = H^2(\mathbb{R}^N;\mathbb{R})$ is the second Sovolev space on $\mathbb{R}^N$. The subdifferential of a lower semicontinuous convex functional $\Psi: L^2(\mathbb{R}^N;\mathbb{R}) \to (-\infty,\infty]$ is defined as

$$\partial\Psi: \psi \mapsto \{\phi \in L^2(\mathbb{R}^N;\mathbb{R}) \,|\, \Psi(\varphi) \geqslant \Psi(\psi) + \langle \phi, \varphi - \psi\rangle \text{ for all } \varphi \in L^2(\mathbb{R}^N;\mathbb{R})\}. \tag{32}$$

For the basic property of lower semicontinuous convex functionals and their subdifferentials, we refer to the book[1] by Brézis.

For $U \in C(\mathbb{R}^N\backslash\mathcal{N},\mathbb{R}^+)$, the functional $\|\sqrt{U}\phi\|^2$ is lower semicontinuous and convex.

$H_1^0(\Omega)$ denote the first Sobolev space defined as the closure of the space of test functions on the open set $\Omega \subset \mathbb{R}^N$ with respect to the Hilbert norm $(\|\cdot\|_2^2 + \|\nabla\cdot\|_2^2)^{1/2}$.

Lemma 11: Let φ_1 and φ_2 be properly lower semicontinuous and convex such that $D(\varphi_1) \cap D(\varphi_2) \neq \emptyset$ where $D(\varphi_1)$ and $D(\varphi_2)$ are effective domain. Then $\varphi_1 + \varphi_2$ is properly lower semicontinuous and convex and $\partial\varphi_1 + \partial\varphi_2 \subset \partial(\varphi_1 + \varphi_2)$. Moreover $\partial\varphi_1 + \partial\varphi_2$ is maximal monotone if and only if $\partial\varphi_1 + \partial\varphi_2 = \partial(\varphi_1 + \varphi_2)$.

Lemma 12: Each functional $\Psi_n(\phi) \equiv \frac{1}{2}(\|(-\Delta)^{1/2}\phi\|^2 + \|\sqrt{U_n}\phi\|^2)$ or $\Psi(\phi) \equiv \frac{1}{2}(\|(-\Delta)^{1/2}\phi\|^2 + \|\sqrt{U}\phi\|^2)$, is lower semicontinuous and convex. Its effective domain is

$$D(\Psi_n)(\equiv\{f \in L^2(\mathbb{R}^N;\mathbb{R}) \,|\, \Psi_n(f) < \infty\}) = H_R^1 \text{ or } D(\Psi) = D((-\Delta)^{1/2}) \cap D(\sqrt{U}).$$

Roughly speaking, $\Psi(\phi)$ is a closed extension of $\langle -\Delta\phi + U\phi, \phi\rangle$.

Lemma 13: The resolvent $\phi_n = (I + \partial\Psi_n)^{-1}\varphi_0$ of the subdifferential $\partial\Psi_n$ is given by the projection of φ_0 to B_n where $B_n = \{\phi \in L^2(\mathbb{R}^N;\mathbb{R}) \,|\, \Psi_n(\phi) \leqslant \Psi_n(\phi_n)\}$:

$$\mathrm{proj}_{B_n}\varphi_0 = (I + \partial\Psi_n)^{-1}\varphi_0. \tag{33}$$

Proof: Since B_n is closed convex, the projection $\mathrm{proj}_{B_n}\varphi_0$, $\|\varphi_0 - \mathrm{proj}_{B_n}\varphi_0\| = \inf\{\|\varphi_0 - \phi\| \,|\, \phi \in B_n\}$, uniquely exists. Using $\partial\Psi_n(\phi_n) = \varphi_0 - \phi_n$ and (32) we have

$$\Psi_n(\phi) \geqslant \Psi_n(\phi_n) + \langle \partial\Psi_n(\phi_n), \phi - \phi_n\rangle = \Psi_n(\phi_n) + \langle \varphi_0 - \phi_n, \phi - \phi_n\rangle, \quad \text{for all } \phi \in L^2(\mathbb{R}^N;\mathbb{R}).$$

This implies $\langle \varphi_0 - \phi_n, \phi - \phi_n\rangle \leqslant 0$, for all $\phi \in B_n$, since $\Psi_n(\phi) \leqslant \Psi_n(\phi_n)$ if $\phi \in B_n$. Thus we have

$$\begin{aligned}\|\varphi_0 - \phi\|^2 &= \|(\varphi_0 - \phi_n) - (\phi - \phi_n)\|^2 = \|\varphi_0 - \phi_n\|^2 - 2\langle \varphi_0 - \phi_n, \phi - \phi_n\rangle + \|\phi - \phi_n\|^2 \geqslant \|\varphi_0 - \phi_n\|^2 \\ &\quad + \|\phi - \phi_n\|^2 \\ &\geqslant \|\varphi_0 - \phi_n\|^2 \quad \text{for all } \phi \in B_n. \end{aligned} \tag{34}$$

The relation $\|\varphi_0-\phi\|^2 \geqslant \|\varphi_0-\phi_n\|^2$, for all $\phi \in B_n$, $\phi_n \in B_n$ means $\phi_n = \mathrm{proj}_{B_n}\varphi_0$. □

Lemma 14: The resolvent $(I+\partial\Psi_n)^{-1}$ *strongly converges to the resolvent* $(I+\partial\Psi)^{-1}$,

$$(I+\partial\Psi)^{-1}\varphi_0 = \lim_{n\to\infty}(I+\partial\Psi_n)^{-1}\varphi_0 \quad \textit{for any } \varphi_0 \in L^2(\mathbb{R}^N;\mathbb{R}). \tag{35}$$

Proof: Denote $B \equiv \{\phi \in L^2 \,|\, \Psi(\phi) \leqslant \Psi((I+\partial\Psi)^{-1}\varphi_0)\}$, $\phi_n = (I+\partial\Psi_n)^{-1}\varphi_0$ and $\phi_m = (I+\partial\Psi_m)^{-1}\varphi_0$. By virtue of Lemma 13 $\phi_n = \mathrm{proj}_{B_n}\varphi_0$ and $\phi_m = \mathrm{proj}_{B_m}\varphi_0$. Since effective domain $D(\Psi_n) \subset D(\Psi)$ implies $\Psi_n \downarrow \Psi$, we have $B_m \uparrow \cup_{n=1}^{\infty} B_n$ and $B = \cup B_n$. For $n > m$ we have $B_n \supset B_m$ and

$$\|\varphi_0-\phi_n\| = \|\varphi_0-\mathrm{proj}_{B_n}\varphi_0\| \leqslant \|\varphi_0-\mathrm{proj}_{B_m}\varphi_0\| = \|\varphi_0-\phi_m\|,$$

since $\phi_m \in (B_m \subset) B_n$. $\{\|\varphi_0-\phi_m\|\}_{m\in\mathbb{N}}$ is a non-negative decreasing sequence. Hence $\|\varphi_0-\phi_m\| - \|\varphi_0-\phi_n\|$ converges to 0 as $n \geqslant m$ tends to infinity. From (34) it follows that

$$\|\varphi_0-\phi_m\|^2 \geqslant \|\varphi_0-\phi_n\|^2 + \|\phi_m-\phi_n\|^2 \quad \text{for all } \phi_m \in B_m.$$

We have

$$\|\mathrm{proj}_{B_m}\varphi_0 - \mathrm{proj}_{B_n}\varphi_0\| = \|\phi_m-\phi_n\| \leqslant \|\varphi_0-\phi_m\|^2 - \|\varphi_0-\phi_n\|^2 \downarrow 0 \quad \text{as } n,m \to \infty.$$

Therefore we obtain (35). □

Proposition 1: $-\partial\Psi$ *generates a* C_0*-semigroup, hence it is a linear operator and* $R(I+\partial\Psi) = L^2(\mathbb{R}^N;\mathbb{R})$. *Here* $R(A)$ *is a range of the operator* A.

Proof: Since $R((I+\partial\Psi)^{-1})$ is dense in $L^2(\mathbb{R}^N;\mathbb{R})$, $-\partial\Psi$ generates a C_0-semigroup. Because of the maximal monotonicity of $\partial\Psi$, we have $R(I+\partial\Psi) = L^2(\mathbb{R}^N;\mathbb{R})$. □

Proposition 2: Let $S(t)$ *and* $S_n(t)$ *be the semigroups generated by infinitesimal generator* $-\partial\Psi$ *and* $-\partial\Psi_n$, *respectively. Then we obtain the following equation:*

$$\lim_{n\to\infty} S_n(t)\varphi = S(t)\varphi \quad \textit{for all } \varphi \in L^2(\mathbb{R}^N;\mathbb{R}). \tag{36}$$

Proof: We obtain (36) by using (35) and Trotter-Kato theorem (see Ref. 12). □

Let $\partial\widetilde{\Psi}$ and $\partial\widetilde{\Psi}_n : L^2(\mathbb{R}^N;\mathbb{C}) \to L^2(\mathbb{R}^N;\mathbb{C})$ be the complex extension of $\partial\Psi$ and $\partial\Psi_n : L^2(\mathbb{R}^N;\mathbb{R}) \to L^2(\mathbb{R}^N;\mathbb{R})$, respectively. From Proposition 1, $R(I+\partial\Psi) = L^2(\mathbb{R}^N;\mathbb{R})$. Hence we obtain $R(I+\partial\widetilde{\Psi}) = L^2(\mathbb{R}^N;\mathbb{C})$.

Lemma 15: The operator $\partial\widetilde{\Psi}$ *is a self-adjoint positive operator.*

Proof: If a symmetric operator T satisfies $R(I+T) = L^2(\mathbb{R}^N;\mathbb{C})$, then it is self-adjoint. The positivity of $\partial\widetilde{\Psi}$ is evident, since $\langle\partial\Psi(\phi),\phi\rangle \geqslant 0$ for all $\phi \in L^2(\mathbb{R}^N;\mathbb{R})$. □

Theorem 5 (Stone): *A is the infinitesimal generator of a* C_0 *group of unitary operator on a Hilbert space H if and only if iA is self-adjoint.*

Theorem 6: *If a function U in* $C(\mathbb{R}^N \backslash \mathcal{N}, \mathbb{R}^+)$ *then the Schrödinger equation*

$$\frac{d}{dt}u(t) = -i\partial\widetilde{\Psi}(u(t)) \quad (\equiv i(\Delta - U)u(t))$$

has a unique solution. Moreover the semigroup $\{T(t)\}$ *of solution family is unitary..*

Proof: Since $\partial\widetilde{\Psi} \equiv -(\Delta - U)$ is self-adjoint, $-i\partial\widetilde{\Psi} \equiv i(\Delta - U)$ generates a semigroup of unitary operators by virtue of Stone's theorem. □

Definition 9: Let A be the linear operator in complex Hilbert space $H = (H, \|\cdot\|)$.

(a) *The operator A is called monotone if and only if*

$$\mathrm{Re}(x,Ax) \geqslant 0 \quad \textit{for all } x \in D(A).$$

(b) *The operator A is called maximal monotone if and only if any monotone extension of A coincides with A.*

Lemma 16: Let $-A$ be a maximal monotone operator. Then

$$\|A(I-A)^{-1}\| \leqslant 1.$$

Proof: The monotonicity of $-A$ implies

$$\|Ay\|^2 \leqslant \|y\|^2 + 2\,\mathrm{Re}(-Ay,y) + \|Ay\|^2 = \|(I-A)y\|^2.$$

Let $y=(I-A)x$. Then we have

$$\|A(I-A)^{-1}x\| \leqslant \|(I-A)(I-A)^{-1}x\| = \|x\|.$$

□

Lemma 17: Let $-A$ and $-A_n$ be maximal monotone operators. Then $(I-(1+\alpha)A)^{-1}$ and $(I-(1+\alpha)A_n)^{-1}$ are bounded operators for $|\alpha|<1$.

Moreover if

$$\lim_{n\to\infty}(I-A_n)^{-1}\varphi = (I-A)^{-1}\varphi \quad \textit{for all } \varphi \in H,$$

then we have

$$\lim_{n\to\infty}(I-(1+\alpha)A_n)^{-1}\varphi = (I-(1+\alpha)A)^{-1}\varphi \quad \textit{for all } \varphi \in H.$$

Proof: From Lemma 16 we have $\|A_n(I-A_n)^{-1}\| \leqslant 1$.

Therefore,

$$I-(1+\alpha)A_n = (I-A_n)(I-\alpha A_n(I-A_n)^{-1}) \text{ and } |\alpha|<1$$

implies

$$(I-(1+\alpha)A_n)^{-1} = (I-\alpha A_n(I-A_n)^{-1})^{-1}(I-A_n)^{-1} = \left(\sum_{k=0}^{\infty}\alpha^k(A_n(I-A_n)^{-1})^k\right)(I-A_n)^{-1}$$
$$= \left(\sum_{k=0}^{K}\alpha^k(A_n(I-A_n)^{-1})^k\right)(I-A_n)^{-1} + \left(\sum_{k=K+1}^{\infty}\alpha^k(A_n(I-A_n)^{-1})^k\right)(I-A_n)^{-1}.$$

Since for any fixed K, we obtain that

$$\lim_{n\to\infty}\left(\sum_{k=0}^{K}\alpha^k(A_n(I-A_n)^{-1})^k\right)(I-A_n)^{-1} = \left(\sum_{k=0}^{K}\alpha^k(A(I-A)^{-1})^k\right)(I-A)^{-1}$$

and the monotonicity of A_n and Lemma 16 we have

$$\left\|\left(\sum_{k=K+1}^{\infty}\alpha^k(A_n(I-A_n)^{-1})^k\right)(I-A_n)^{-1}\right\| \leqslant \left(\sum_{k=K+1}^{\infty}|\alpha^k|\|(A_n(I-A_n)^{-1})\|^k\right)\|(I-A_n)^{-1}\|$$
$$\leqslant \sum_{k=K+1}^{\infty}|\alpha|^k = \frac{|\alpha|^{K+2}}{1-|\alpha|}.$$

For any $\varepsilon>0$ there exists $K\in\mathbb{N}$ such that $|\alpha|^{K+2}/(1-|\alpha|)<\varepsilon$. Then the proof is complete. □

Lemma 18: Let $-A$ and $-A_n$ be self-adjoint positive operators.

If $(I-e^{i\theta}A)^{-1}$ and $(I-e^{i\theta}A_n)^{-1}$ are bounded operators for $0\leqslant\theta\leqslant\pi/2$ and

$$\lim_{n\to\infty}(I-A_n)^{-1}\varphi = (I-A)^{-1}\varphi \quad \textit{for all } \varphi \in H,$$

then

$$\lim_{n\to\infty}(I-iA_n)^{-1}\varphi=(I-iA)^{-1}\varphi \quad \textit{for all } \varphi\in H.$$

Proof: By using Lemma 17 we get

$$\lim_{n\to\infty}\left(I-\frac{1+i}{\sqrt{2}}A_n\right)^{-1}\varphi=\left(I-\frac{1+i}{\sqrt{2}}A\right)^{-1}\varphi \quad \textit{for all } \varphi\in H, \tag{37}$$

since $|\alpha|<1$ for $\alpha=[(1+i)/\sqrt{2}]-1$. Note that $-[(1+i)/\sqrt{2}]A_n$ and $-[(1+i)/\sqrt{2}]A$ are maximal monotone. By virtue of Lemma 17 and

$$(1+\alpha)\frac{1+i}{\sqrt{2}}=\left(\frac{1+i}{\sqrt{2}}\right)^2=i$$

we have

$$\lim_{n\to\infty}(I-iA_n)^{-1}\varphi=(I-iA)^{-1}\varphi \quad \textit{for all } \varphi\in H.$$

□

Remark: $(-i+c)A$ and $(-i+c)iA_n$ are not maximal monotone operators for any $c>0$.

Proposition 3: Let $T(t)$ and $T_n(t)$ be the semigroups generated by infinitesimal generator $-i\partial\Psi$ and $-i\partial\tilde{\Psi}_n$, respectively. Then it follows that

$$\lim_{n\to\infty}T_n(t)\phi=T(t)\phi \quad \textit{for all } \phi\in L^2(\mathbb{R}^N;\mathbb{C}).$$

Proof: Denote $A=-i\partial\tilde{\Psi}$ and $A_n=-i\partial\tilde{\Psi}_n$. Fix $\phi\in L^2(\mathbb{R}^N;\mathbb{C})$ and an interval $0\leqslant t\leqslant T$. We consider

$$\begin{aligned}\|(T_n(t)-T(t))(I-A)^{-1}\phi\| &\leqslant \|T_n(t)((I-A)^{-1}-(I-A_n)^{-1})\phi\|+\|(I-A_n)^{-1}(T_n(t)-T(t))\phi\| \\ &\quad +\|((I-A)^{-1}-(I-A_n)^{-1})T(t)\phi\|=I_1+I_2+I_3.\end{aligned} \tag{38}$$

Since $\|T_n(t)\|$ is bounded for $0\leqslant t\leqslant \mathfrak{t}$ it follows from Lemma 18 that $I_1\to 0$ as $n\to\infty$ uniformly on $[0,\mathfrak{t}]$. The rest of the proof is obtained in a way similar to that of Pazy (Ref. 9, Chap. 3, Theorem 4.2). □.

Proof of the Theorem 4: From Proposition 3, it follows that $\lim_{n\to\infty}R-\int_{\Omega_{[0,t]}}e^{-i\int_0^t U_n(\gamma(s))\mathrm{d}s}\phi\,\mathrm{d}\mu^Q=\lim_{n\to\infty}T_n(t)\phi$ uniquely exists.

Therefore from Definition 7 we obtain that $e^{-i\int_0^t U(\gamma(s))\mathrm{d}s}$ is Riemann integrable by μ^Q. □

Corollary 1: Let a function $U\in C(\mathbb{R}^N\backslash\mathcal{N},\mathbb{R})$ and there exist $m\in\mathbb{R}$ such that $U(x)\geqslant m$ for any $x\in\mathbb{R}^N\backslash\mathcal{N}$. Then the function $F(-iU;t,\gamma)=e^{-i\int_0^t U(\gamma(s))\mathrm{d}s}$ is improper Riemann integrable by μ^Q.

For a time dependent case we give the following theorem.

Theorem 7: *Let $U(t,\cdot)$ be a $C(\mathbb{R}^N;\mathbb{R})\cap L^\infty(\mathbb{R}^N;\mathbb{R})$-valued function and be continuous in t on every compact set $\subset\mathbb{R}$. Then the function $F(-iU;t,\gamma)=e^{-i\int_0^t U(s,\gamma(s))\mathrm{d}s}$ is Riemann integrable by μ^Q.*

Proof: For a fixed t, the integrability follows from the integrability of $U+\|U\|_\infty$. We recall $U+\|U\|_\infty$ is non-negative. Since $V(t)=-iU(t,x)$ is a $L(L^2(\mathbb{R}^N;\mathbb{C});L^2(\mathbb{R}^N;\mathbb{C}))$-valued strongly continuous function, we get the result by virtue of Lemma 4. □

C. Weak integrability for real potentials with singularity

In this section we study about more general potentials. We consider the following equation:

$$\frac{\partial}{\partial t}u(t,x)=i\Delta u(t,x)-iU(x)u(t,x), \quad u(0,x)=\varphi(x), \quad \varphi\in H^2(\mathbb{R}^N;\mathbb{C}). \tag{39}$$

Recall that we set

$$\mathcal{N} = \text{a fixed closed subset of } \mathbb{R}^N \text{ of measure } 0. \tag{40}$$

Let $\mathcal{D}=\{D\}$ be the maximum family such that each element $D \subset \bar{D} \subset \mathbb{R}^N \backslash \mathcal{N}$ is a finite union of connected bounded open sets. The family $\mathcal{D}=\{D\}$ satisfies $\cup_{D\in\mathcal{D}} D = \mathbb{R}^N \backslash \mathcal{N}$.

We denote the restriction of f to D by $f|_D$, or simply, by f_D. We use the following notation:

$$L^\infty_{\mathrm{loc}}(\mathbb{R}^N \backslash \mathcal{N}, \mathbb{R}) = \{f | f(x) \in \mathbb{R},\ f|_D \in\ L^\infty(D;\mathbb{R})),\ \forall\, D \in \mathcal{D}\}. \tag{41}$$

Let U in $L^\infty_{\mathrm{loc}}(\mathbb{R}^N \backslash \mathcal{N}, \mathbb{R})$. We assume for any neighborhood of any point of $\mathcal{N}, U$ is not essentially bounded.

First we cite a result of Kōmura.[7] Let

$$B(n) = \{x \in \mathbb{R}^N | n > U(x) > -n\}, \quad n = 1,2,3, \ldots\ . \tag{42}$$

We have $B(m) \supset B(n)$ for $m > n$ and from the assumption that

$$\text{for any } D \text{ in } \mathcal{D}, \text{ there exists } B(n) \text{ such that } D \subset \bar{D} \subset B(n). \tag{43}$$

[Strictly speaking, $\bar{D} \backslash B(n)$ is a null set.]

We denote

$$U_n(x) = \min\{n, \max\{-n, U(x)\}\}, \quad n \in \mathbb{N}.$$

Thus U_n in $L^\infty(\mathbb{R}^N;\mathbb{R})$.

For U in $L^\infty_{\mathrm{loc}}(\mathbb{R}^N \backslash \mathcal{N}, \mathbb{R})$ we consider the approximate equation

$$\frac{d}{dt} u_n(t) = A_n u_n(t), \quad \text{where } A_n = i(\Delta - U_n). \tag{44}$$

In this case the operator $-iA_n$ is essentially self-adjoint and hence the semigroup $\{T_n(t)\}$ of the family of solutions to (44) is a group of unitary operators: $\|T_n(t)\varphi\| = \|\varphi\|, -\infty < t < \infty$ for all $\varphi \in L^2(\mathbb{R}^N;\mathbb{C})$.

Theorem 8 (Kōmura): *For any U in $L^\infty_{\mathrm{loc}}(\mathbb{R}^N \backslash \mathcal{N};\mathbb{R})$, there exists a closed extension of $(i\Delta - iU)|_{C_0^\infty(\mathbb{R}^N \backslash \mathcal{N})}$ in $L^2(\mathbb{R}^N;\mathbb{C}) \to L^2(\mathbb{R}^N;\mathbb{C})$ which generates a contraction C_0-semigroup $\{T(t) | t \geqslant 0\}$ such that*

$$T(t)\varphi = w - \lim_{n\to\infty} T_n(t)\varphi, \quad \forall\ \varphi \in L^2(\mathbb{R}^N;\mathbb{C}), \tag{45}$$

where $T_n(t)\varphi$ is the solution to

$$\frac{d}{dt} u_n(t) = A_n u_n(t), \quad \textit{where } A_n = i(\Delta - U_n) \tag{46}$$

and $w-\lim$ means the weak convergence.

Definition 10: For a function U in $C(\mathbb{R}^n \backslash \mathcal{N};\mathbb{R})$, the function $e^{-i\int_0^t U(\gamma(s))\mathrm{d}s}$ is said to be weakly Riemann integrable by μ^Q if

$$w - \lim_{m,n\to\infty} R - \int_{\Omega_{[0,t]}(D_{m,n})} e^{-i\int_0^t U_{m,n}(\gamma(s))\mathrm{d}s} \phi \, \mathrm{d}\mu^Q$$

exists for any ϕ in $L^2(\mathbb{R}^N;\mathbb{C})$ independently of the choice of $\{D_{m,n}\}$.

Now we return to (39). Let U in $C(\mathbb{R}^N \backslash \mathcal{N}, \mathbb{R})$. In order to use the previous theorem we define a sequence of functions $U_{m,n}$ and $D_{m,n}$ such that

$$U_{m,n}(x) = \min\{m, \max\{-n, U(x)\}\}, \quad m,n = 1,2,3, \ldots\ ,$$

$$D_{m,n} = \{x \in \mathbb{R}^N | m > U(x) > -n\}, \quad m,n = 1,2,3, \ldots .$$

By virtue of Corollary 1 the solution $u_{m,n}$ to the Schrödinger equation in $\mathbb{R}^N$,

$$\frac{\partial}{\partial t}u_{m,n}(t,x) = i\Delta u_{m,n}(t,x) - iU_{m,n}(x)u_{m,n}(t,x),$$
$$u_{m,n}(0,x) = \varphi(x), \quad \varphi \in L^2(\mathbb{R}^N;\mathbb{C}), \tag{47}$$

exists.

Theorem 9: *For any U in $L^\infty_{\mathrm{loc}}(\mathbb{R}^N\backslash\mathcal{N};\mathbb{R})$, there exists a closed extension of $i(\Delta - U)|_{C_0^\infty(\mathbb{R}^N\backslash\mathcal{N})}$ in $L^2(\mathbb{R}^N;\mathbb{C}) \to L^2(\mathbb{R}^N;\mathbb{C})$ which generates a contraction C_0-semigroup $\{T(t)|t \geqslant 0\}$ such that*

$$T(t)\varphi = w - \lim_{n\to\infty} T_{m,n}(t)\varphi, \quad \forall\, \varphi \in L^2(\mathbb{R}^N;\mathbb{C}), \tag{48}$$

where $T_{m,n}(t)\varphi$ is the solution to

$$\frac{d}{\mathrm{d}t}u_{m,n}(t) = A_{m,n}u_{m,n}(t), \quad \text{where } A_{m,n} = i(\Delta - U_{m,n}) \tag{49}$$

and $w-\lim$ means the weak convergence.

Proof: Let $U^+_{m,n}(x) = \max\{0, U_{m,n}(x)\}$ and $U^-_{m,n}(x) = \max\{0, -U_{m,n}(x)\}$. Then $U_{m,n}(x) = U^+_{m,n}(x) - U^-_{m,n}(x)$. Note the following:

(a) In the case that there exists $M \geqslant 0$ such that $U^+_{m,n}(x) \leqslant M$ for $x \in D_{m,n}$ and $m,n \in \mathbb{N}$, there exists $n_0 \in \mathbb{N}$ such that $D_{m,n} \subset B(n)$ for any $n \geqslant n_0 \geqslant M$.
(b) In the case that there exists $M \geqslant 0$ such that $U^-_{m,n}(x) \leqslant M$ for $x \in D_{m,n}$ and $m,n \in \mathbb{N}$, there exists $m_0 \in \mathbb{N}$ such that $D_{m,n} \subset B(m)$ for any $m \geqslant m_0 \geqslant M$.
(c) In another case we obtain that

$$\max\{B(n),B(m)\} \supset D_{m,n} \supset \min\{B(n),B(m)\}, \quad m,n \in \mathbb{N}.$$

Note that

$$D = \bigcup_{n,m=1}^{\infty} D_{m,n}.$$

Therefore from the result of Theorem 8 we obtain the consequence. □

Note that $\{T_t\}$ is independent of the choice of $\{D_{m,n}\}$.

We conclude this section with a condition for $F(-iU;t,\gamma)$ to be weakly Riemann integrable. (See Refs. 2–4 and 10).

Theorem 10: *Let the associated scalar function $G(x) = e^{-iU(x)}$ be the Riemann integrable on any bounded domain in $\mathbb{R}^N$. Then the function $F(-iU;t,\gamma) = e^{-i\int U(\gamma(s))\mathrm{d}s}$ is weakly Riemann integrable.*

Proof: Let $D \subset \mathbb{R}^N$ be a bounded domain. As is well known, $\int_D G(x)\mathrm{d}x$ is Riemann integrable if and only if $G(x)$ is continuous except a closed set $\mathcal{N}_G(D)$ of measure zero, since $G(x)$ is bounded. Hence $U(x) = i\log G(x)$ is continuous except a closed set $\mathcal{N}_G = \cup_D \mathcal{N}_G(D)$. In this case $F(-iU;t,\gamma)$ is weakly Riemann integrable. □

Corollary 2: Let U be continuous and real valued function on the complement of $\mathcal{N}$. Then the function $F(-iU;t,\gamma) = e^{-i\int_0^t U(\gamma(s))\mathrm{d}s}$ is weakly Riemann integrable.

(Received 17 January 2006; accepted 1 June 2006; published online 19 July 2006)

We construct an explicit example of dimensional reduction of the free massless Dirac operator with an internal SU(3) symmetry, defined on a 12-dimensional manifold that is the total space of a principal SU(3)-bundle over a four-dimensional (nonflat) pseudo-Riemannian manifold. Upon dimensional reduction the free 12-dimensional Dirac equation is transformed into a rather nontrivial four-dimensional one: a pair of massive Lorentz spinor SU(3)-octets interacting with an SU(3)-gauge field with a source term depending on the curvature tensor of the gauge field. The SU(3) group is complicated enough to illustrate features of the general case. It should not be confused with the color SU(3) of quantum chromodynamics where the fundamental spinors, the quark fields, are SU(3) triplets rather than octets. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2217811]

I. INTRODUCTION

It is well known that when we look for a solution with some symmetry, we can reduce the number of variables and thus simplify the problem of solving differential equations. The Schwarzschild solution of the nonlinear Hilbert-Einstein equation is a typical example. A point of view, different from this calculational aspect of symmetry, is essential for the so-called "Kaluza-Klein approach." It is observed in the pioneer work of Kaluza (1921, English translation in Ref. 1) that there is one-to-one correspondence between the U(1)-invariant metrics on a five-dimensional manifold and the triples [metric on four-dimensional manifold, linear connection with structure group U(1) (electromagnetic potential), scalar field]. The scalar curvature of five-dimensional U(1)-invariant metric is equivalent to the Einstein-Maxwell action for the mentioned fields. This action describes the really observed interaction between gravity and electromagnetic field. This demonstrates the general idea: We consider a "simple" field and "simple" equations but in a "multidimensional" universe. Imposing some symmetry conditions, after dimensional reduction we obtain a set of fields with different nature involved in complicated differential equations. Our hope is that the fields and differential equations, obtained in this way, may describe a real process, and that this investigation may be a step to the unification of different interactions in nature. The natural generalizations of the Kaluza-Klein ansatz are considered in the literature: the group of symmetry G is arbitrary, the group G acts on a manifold as on a total space of a principal bundle, and the group G acts on a manifold with one type orbits. See, for example, Ref. 2.

In this paper the starting point is the free Dirac operator with an SU(3) symmetry defined on a twelve-dimensional Minkowski space that is interpreted as an SU(3) principal bundle over four-dimensional Minkowski space. Should we interpret the outcome in physical terms we should relate the structure group with the "flavor SU(3)" of the quark model, identifying the resulting

[a)]Electronic mail: pnikolov@phys.uni-sofia.bg
[b)]Electronic mail: gergana@inrne.bas.bg

SU(3)-octets Dirac particles with observed baryons. Such an interpretation would again be a nonstandard one however since, unlike the flavor SU(3) of the standard model, our structure group appears as a local gauge group in four-space-time. We prefer, in fact, to view the present paper as a mathematical model illustrating some surprising features of dimensional reduction.

Our purpose is to consider the simplest possible case because then the arising structures after dimensional reduction are imperative. The initial manifold, denoted by E in the text, is the 12-dimensional total space of a principal SU(3) bundle, which admits a real spinor bundle with standard fiber $\mathbb{R}^{64}$. In the real case, the spinor connection is uniquely defined if it is compatible with the Levi-Civita connection of the metric on E. For physical reasons we consider a complex spinor bundle, a complexification of the real-valued one. The spinor connection is also considered as a complexification of the real one. Thus we avoid the necessity to fix a connection with structure group U(1). Further, when we fix the SU(3)-action on spinor fields we choose the trivial lifting. And thus we avoid some additional terms in the reduced Dirac operator. Also the scalar field in the Kaluza-Klein ansatz is taken to be constant—the Killing metric in the Lie algebra of SU(3). In this way, in the reduced Dirac operator there are only structures whose presence is necessary. We also point out the steps in which, imposing the symmetry, the new structures arise (the gauge field with structure group $G=\mathrm{SU}(3)$, its curvature tensor, the Clifford algebra for a four-dimensional manifold, the four-dimensional Dirac operator, the spinor octets, the mass term etc.).

We choose the group of symmetry to be SU(3) acting freely on the 12D manifold because of its connection to the standard model and because we wanted the arising after the reduction gauge field to have structure group SU(3). In the same way one can obtain the dimensional reduction of Dirac operator when the symmetry group is an arbitrary connected Lie group acting freely on the multidimensional manifold.

The article is organized as follows.

In Sec. II the necessary constructions from differential geometry and the algebraic origin of the Kaluza-Klein ansatz are presented. We give the coordinate expression of the Levi-Civita connection for the metric in nonholonomic basis. These formulas are applied to the canonical basis of the SU(3)-invariant metric on E. This basis determines a horizontal subbundle $T^h(E)\hookrightarrow T(E)$. The subbundle $T^h(E)$ is invariant under the action of SU(3) and defines a linear connection [gauge field with structure group SU(3)]. The components of the Levi-Civita connection for the SU(3)-invariant metric are calculated and they contain components of the gauge field and its stress tensor [Eq. (16)].

In Sec. III the Dirac operator for the SU(3)-invariant metric (the Kaluza-Klein ansatz) is considered. The crucial moment here is that the sum $T(E)=T^h(E)\oplus T^v(E)$ is orthogonal with respect to the SU(3)-invariant metric. According to the classifying theorem for Clifford algebras, the Clifford algebra $\mathrm{Cl}(T_z(E),g(x))\approx M_{64}(\mathbb{R})$ is realized as a tensor product of the Clifford algebras of $T^h_z(E)$ and $T^v_z(E)$. So the standard fiber $\mathbb{C}^{64}$ of the spinor bundle on E takes the structure of tensor product $\mathbb{C}^4\otimes\mathbb{C}^{16}$.

In Sec. IV we give the dimensional reduction of the Dirac operator for the SU(3)-invariant metric. We introduce an action of SU(3) on the spinor bundle, compatible with the action of SU(3) on $T(E)$. This condition of compatibility does not fix uniquely the action of SU(3) on the spinors. So we choose, as we mentioned above, the simplest case in which the lifting of the SU(3) action on E to the total space of the spinor bundle is trivial in the canonical basis.

In Sec. V we list the steps in the procedure of dimensional reduction where the new structures presented in the reduced Dirac operator arise.

II. BASIC CONSTRUCTIONS AND NOTATIONS

Let E be a smooth manifold, g a metric on E (with arbitrary signature), and ∇ the corresponding Levi-Civita connection. Let $\{\mathbf{h}_\mu\}$ be a (local) nonholonomic basis of $T(E)$ and $\{\mathbf{h}^\mu\}$ the corresponding dual basis on $T^*(E)$. In this basis we have the following notation:

$$\nabla(\mathbf{h}_\beta) = \Gamma^\rho_{\alpha\beta}\mathbf{h}^\alpha \otimes \mathbf{h}_\rho, \quad \nabla_{\mathbf{h}_\alpha}(\mathbf{h}_\beta) = \nabla_\alpha(\mathbf{h}_\beta) = \Gamma^\rho_{\alpha\beta}\mathbf{h}_\rho,$$

$$[\mathbf{h}_\alpha, \mathbf{h}_\beta] = C^\rho_{\alpha\beta}\mathbf{h}_\rho, \quad g(\mathbf{h}_\alpha, \mathbf{h}_\beta) = g_{\alpha\beta},$$

$$g(\nabla_\alpha(\mathbf{h}_\beta), \mathbf{h}_\gamma) = \Gamma^\rho_{\alpha\beta}g_{\rho\gamma} = \Gamma_{\alpha\beta\gamma}, \quad g([\mathbf{h}_\alpha, \mathbf{h}_\beta], \mathbf{h}_\gamma) = C^\rho_{\alpha\beta}g_{\rho\gamma} = C_{\alpha\beta\gamma}.$$

The condition $\nabla(g)=0$ and the requirement for the vanishing of the torsion reads:

$$\begin{aligned} &\mathbf{h}_\rho(g_{\mu\nu}) = g(\nabla_\rho(\mathbf{h}_\mu), \mathbf{h}_\nu) + g(\mathbf{h}_\mu, \nabla_\rho(\mathbf{h}_\nu)) \Rightarrow \Gamma_{\rho\mu\nu} + \Gamma_{\rho\nu\mu} = \mathbf{h}_\rho(g_{\mu\nu}), \\ &\nabla_\mu(\mathbf{h}_\nu) - \nabla_\nu(\mathbf{h}_\mu) = [\mathbf{h}_\mu, \mathbf{h}_\nu] \Rightarrow \Gamma_{\mu\nu\rho} - \Gamma_{\nu\mu\rho} = C_{\mu\nu\rho}, \end{aligned} \tag{1}$$

and from here it follows that

$$2\Gamma_{\alpha\beta\gamma} = C_{\alpha\beta\gamma} + C_{\gamma\beta\alpha} + C_{\alpha\gamma\beta} + \mathbf{h}_\alpha(g_{\beta\gamma}) + \mathbf{h}_\beta(g_{\alpha\gamma}) - \mathbf{h}_\gamma(g_{\alpha\beta}). \tag{2}$$

We follow the classical construction of the generalized Kaluza-Klein ansatz. The point structure of the ansatz is the description of the metric on the vector space L, which is the middle term in the short exact sequence:

$$0 \to L_0 \overset{i}{\to} L \overset{j}{\to} L_1 \to 0. \tag{3}$$

We realize this in coordinates by choosing a basis $\{\mathbf{h}\}=\{\mathbf{f},\mathbf{e}\}$ in L; $\mathbf{h}_\mu=\mathbf{f}_\mu$, $\mu=1,2,\ldots,m=\dim(L_1)$, $\mathbf{h}_k=\mathbf{e}_k$, $k=m+1,\ldots,m+n, n=\dim(L_0)$. The vector space $L_0=\mathrm{span}(\mathbf{e}_1,\ldots,\mathbf{e}_n)$, and the vector space L_1 is identified with $\mathrm{span}(\mathbf{f}_1,\ldots,\mathbf{f}_m)$ and $i(\mathbf{e}_k)=\mathbf{e}_k$; $j(\mathbf{e}_k)=\mathbf{0}$, $j(\mathbf{f}_\mu)=\mathbf{f}_\mu$. Every splitting of the exact sequence (3) is given by a linear map $S: L_1 \to L$ with the property $j\circ S=\mathbf{1}$, i.e., is given by defining the vectors:

$$\hat{\mathbf{f}}_\mu = S(\mathbf{f}_\mu) = \mathbf{f}_\mu - A^k_\mu \mathbf{e}_k. \tag{4}$$

In these formulas we have summation over repeated indices. Here the matrix A^k_μ is arbitrary. Every metric g_L on L, for which the restriction on $i(L_0)$ is nondegenerate is uniquely determinate by the conditions:

$$\begin{aligned} &g_L(\hat{\mathbf{f}}_\mu, \hat{\mathbf{f}}_\nu) = g_{\mu\nu}, \\ &g_L(\hat{\mathbf{f}}_\mu, \mathbf{e}_k) = 0, \\ &g_L(\mathbf{e}_k, \mathbf{e}_l) = g_{0kl}, \end{aligned} \tag{5}$$

where g_{0kl} and $g_{\mu\nu}$ are metrics on L_0 and L_1. In this manner we have one-to-one correspondence between the metrics on L, non degenerated on L_0 and the triples {metric on L_1, metric on L_0, splitting of (3)}.

In the basis $\{\mathbf{f}_\mu, \mathbf{e}_k\}$ the metric, defined by Eq. (5) has components:

$$\{g_L\} = \begin{pmatrix} g_{\mu\nu} + A_\mu{}^i A_\nu{}^j g_{0ij} & A_\mu{}^i g_{0il} \\ g_{0ki}A^i_\nu & g_{0kl} \end{pmatrix}. \tag{6}$$

The above construction is the algebraic origin of the Kaluza-Klein ansatz. In the case of the general Kaluza-Klein ansatz this construction arises in the tangent space of each point of the manifold where the group of symmetry acts. More precisely, let (E,p,M) be a principal bundle with structure group $G=\mathrm{SU}(3)$. We assume for simplicity that the principal bundle is trivial and the manifold M is isomorphic to $\mathbb{R}^4$ as a topological manifold. We take a global trivialization $E=M\times\mathrm{SU}(3)$ and the right group action is $R_{\mathbf{g}}(\mathbf{x},\mathbf{z})=(\mathbf{x},\mathbf{zg})$ where $(\mathbf{x},\mathbf{z})\in M\times\mathrm{SU}(3)$ and $\mathbf{g}$

$\in \mathrm{SU}(3)$. We also fix coordinates on the total space E, $(x^\mu, z^k)=(x,z)$, $\mu=1,2,3,4$, $k=5,\ldots,12$, $p(x^\mu,z^k)=(x^\mu)$. Because of the assumed triviality of M the coordinates x^μ are global. Let $T^v(E)\hookrightarrow T(E)$ be the vertical subbundle, $\mathbf{f}_\mu$ the nonholonomic basis of $T(M)$, $\mathbf{e}_k$ the fundamental fields on E corresponding to a basis $\hat{\mathbf{e}}_5,\ldots,\hat{\mathbf{e}}_{12}$ of the Lie algebra $su(3)$. The fields $\mathbf{f}_\mu,\mathbf{e}_k$ form a nonholonomic basis on $TE=T(M\times \mathrm{SU}(3))$, and have the form

$$\mathbf{f}_\mu = f_\mu^\nu(x)\frac{\partial}{\partial x^\nu}, \quad \mathbf{e}_k = e_k^l(z)\frac{\partial}{\partial z^l}. \tag{7}$$

The natural exact sequence

$$0 \to T^v(E) \to T(E) \to p^*(T(M)) \to 0 \tag{8}$$

realizes the exact sequence (3) at the tangent space of each point of the manifold E. Here $p^*(T(M))$ is the pull back of the tangent bundle of M (see Ref. 3). Each metric g_E on E can be written in the form:

$$\{g_E(x,z)\} = \begin{pmatrix} g_{\mu\nu}(x,z) + A_\mu{}^i(x,z)A_\nu{}^j(x,z)g_{0ij}(x,z) & A_\mu{}^i(x,z)g_{0il}(x,z) \\ g_{0ki}(x,z)A_\nu^i(x,z) & g_{0kl}(x,z) \end{pmatrix}, \tag{9}$$

where $g_{\mu\nu}(x,z)=g_E(x,z)(\mathbf{f}_\mu(x),\mathbf{f}_\nu(x))$, $g_{0kl}(x,z)=g_E(x,z)(\mathbf{e}_k(z),\mathbf{e}_l(z))$. The vector fields $\hat{\mathbf{f}}_\mu(x,z) = \mathbf{f}_\mu(x)-A_\mu^k(x,z)\mathbf{e}_k(z)$ span a horizontal subbundle $T^h(E)\hookrightarrow T(E)$ orthogonal to $T^v(E)$ with respect to the metric (9). The ansatz (9) is convenient to describe the metrics on E invariant under the action of the group $G=\mathrm{SU}(3)$. The invariant metrics g on E have the form

$$\{g_E(x,z)\} = \begin{pmatrix} g_{\mu\nu}(x) + A_\mu{}^i(x)A_\nu{}^j(x)g_{0ij}(x) & A_\mu{}^i(x)g_{0il}(x) \\ g_{0ki}(x)A_\nu^i(x) & g_{0kl}(x) \end{pmatrix}. \tag{10}$$

This is the Kaluza-Klein ansatz in our case. In this formula $g_{\mu\nu}(x)=g(\mathbf{f}_\mu,\mathbf{f}_\nu)(x)$ is an arbitrary metric on M. Because $\mathbf{f}_\mu$ is a nonholonomic basis on M, without loss of generality we can think that $g_{\mu\nu}$ is in canonical form, i.e. $\mathbf{f}_\mu$ are tetrada. This will be used in our calculation later. $g_{0kl}(x)$ at each point $x\in M$ is invariant metric on the Lie algebra $su(3)$, i.e., g_0 is a field defined on M taking values in the set of invariant metrics on the Lie algebra $su(3)$. The vector fields $\hat{\mathbf{f}}_\mu(x,z) = \mathbf{f}_\mu(x)-A_\mu^k(x)\mathbf{e}_k(z)$ span orthogonal horizontal subbundle $T^h(E)$ which is invariant under the action of the structure group of the principal bundle $G=\mathrm{SU}(3)$. So $A_\mu^k(x)$ define a linear connection in the principal bundle with a structure group $G=\mathrm{SU}(3)$. A classical result is that there is one-to-one correspondence between the G-invariant metrics on E and the triples {metric on M, linear connection with values in the Lie algebra of G, "scalar field"}. In the basis $\{\hat{\mathbf{f}}_\mu,\mathbf{e}_k\}$ for the metric (10) we have

$$\begin{gathered} g_E(\hat{\mathbf{f}}_\mu(x),\hat{\mathbf{f}}_\nu(x)) = g(\mathbf{f}_\mu(x),\mathbf{f}_\nu(x)) = g_{\mu\nu}(x), \\ g_E(\hat{\mathbf{f}}_\mu(x),\mathbf{e}_k(x)) = 0, \\ g_E(\mathbf{e}_k(z),\mathbf{e}_l(z)) = g_{0kl}(x). \end{gathered} \tag{11}$$

The next step is to construct the Dirac operator on E corresponding to the metric (10). To calculate the Levi-Civita connection (2) of the metric (10) we have to introduce the commutator coefficients for the basis $\{\mathbf{f}_\mu,\mathbf{e}_k\}$:

$$[\mathbf{f}_\mu,\mathbf{f}_\nu](x) = C_{\mu\nu}^\rho(x)\mathbf{f}_\rho(x),$$

$$[\mathbf{f}_\mu,\mathbf{e}_k] = \left[f_\mu^\nu(x)\frac{\partial}{\partial x^\nu}, e_k^l(z)\frac{\partial}{\partial z^l}\right] = 0,$$

$$[\mathbf{e}_k,\mathbf{e}_l](z)=t_{kl}^m\mathbf{e}_m(z). \tag{12}$$

Here $C_{\mu\nu}^\rho(x)$ are determined by the choice of the nonholonomic basis $\mathbf{f}_\mu$ in $T(M)$, t_{kl}^m are the structure constants of the Lie algebra $su(3)$ for the basis $\hat{\mathbf{e}}_5,\ldots,\hat{\mathbf{e}}_{12}$. The non-holonomic basis $\{\hat{\mathbf{f}}_\mu,\mathbf{e}_k\}$, because of (11), is convenient for the construction of the Dirac operator. By means of (12) and (4) we calculate

$$\begin{gathered}[\hat{\mathbf{f}}_\mu,\hat{\mathbf{f}}_\nu](x,z)=C_{\mu\nu}^\rho(x)\hat{\mathbf{f}}_\rho(x)-F_{\mu\nu}^k(x)\mathbf{e}_k(z),\\ [\hat{\mathbf{f}}_\mu,\mathbf{e}_k](x,z)=-A_\mu^l(x)t_{lk}^m\mathbf{e}_m(z),\\ [\mathbf{e}_k,\mathbf{e}_l](z)=t_{kl}^m\mathbf{e}_m.\end{gathered} \tag{13}$$

Here

$$F_{\mu\nu}^m=\mathbf{f}_\mu(A_\nu^m)-\mathbf{f}_\nu(A_\mu^m)+t_{\mu\nu}^\rho A_\rho^m-C_{\mu\nu}^\rho A_\rho^m \tag{14}$$

is the curvature tensor of the linear connection, determined by the one-form $A_\mu=A_\mu^m a_m$. Then the coefficients $C_{\alpha\beta\gamma}$ in (2) for the basis $\{\hat{\mathbf{f}}_\mu,\mathbf{e}_k\}$ are

$$\begin{gathered}C_{\mu\nu\rho}=g([\mathbf{f}_\mu,\mathbf{f}_\nu],\mathbf{f}_\rho)=C_{\mu\nu}^\sigma g_{\sigma\rho},\quad C_{\mu\nu k}=-g_{0kl}F_{\mu\nu}^l=-F_{\mu\nu k},\\ C_{\mu k\nu}=-C_{k\mu\nu}=0,\quad C_{\mu kl}=-A_\mu^k t_{mkl}=-C_{k\mu l},\\ C_{kl\mu}=0,\quad C_{klm}=t_{klm},\end{gathered} \tag{15}$$

where $t_{mkl}=g_{0li}t_{mk}^i$. From (2) we obtain the components of Levi-Civita connection in the basis $\{\hat{\mathbf{f}}_\mu,\mathbf{e}_k\}$:

$$\begin{gathered}\Gamma_{\mu\nu\rho}^E=\Gamma_{\mu\nu\rho},\quad \Gamma_{\mu\nu k}^E=-\tfrac{1}{2}F_{\mu\nu k},\\ \Gamma_{\mu k\nu}^E=\tfrac{1}{2}F_{\mu\nu k},\quad \Gamma_{\mu kl}^E=\tfrac{1}{2}A_\mu^m(t_{mlk}-t_{mkl})+\tfrac{1}{2}\mathbf{f}_\mu(g_{0kl}),\\ \Gamma_{k\mu\nu}^E=\tfrac{1}{2}F_{\mu\nu k},\quad \Gamma_{k\mu l}^E=\tfrac{1}{2}A_\mu^m(t_{mkl}+t_{mlk})+\tfrac{1}{2}\mathbf{f}_\mu(g_{0kl}),\\ \Gamma_{kl\mu}^E=-\tfrac{1}{2}A_\mu^m(t_{mkl}+t_{mlk})+\tfrac{1}{2}\mathbf{f}_\mu(g_{0kl}),\quad \Gamma_{klm}^E=\tfrac{1}{2}(t_{klm}+t_{mlk}+t_{mkl}).\end{gathered} \tag{16}$$

In these formulas $\Gamma_{\mu\nu}^\rho$ are the components of the Levi-Civita connection in the basis $\{\mathbf{f}_\mu\}$ for the metric g on M.

III. DIRAC OPERATOR FOR THE KALUZA-KLEIN METRIC

To describe the Dirac operator for the Kaluza-Klein metric (10) we need some preliminary constructions. Let L be a real vector space and η a metric on L of type (p,q); $\eta=\mathrm{diag}(-1,\ldots,-1,1,\ldots,1)$, $\{\text{number of }(1)\}=p$, $\{\text{number of }(1)\}=q$, $p+q=\dim(L)$. We denote by ϑ the canonical embedding

$$\vartheta:L\to \mathrm{Cl}(\eta) \tag{17}$$

of the vector space L into the corresponding Clifford algebra.[4,5] $\vartheta(\mathbf{x})^2=\eta(\mathbf{x},\mathbf{x})\mathbf{1},\mathbf{x}\in L$, where $\mathbf{1}$ is the unit of the algebra $\mathrm{Cl}(\eta)\equiv\mathrm{Cl}^{p,q}$. If $\mathbf{a}_1,\ldots,\mathbf{a}_n$ is an arbitrary basis of L, $\vartheta(\mathbf{a}_i)=\gamma_i$, $\gamma_i\gamma_j-\gamma_j\gamma_i=2\eta_{ij}\mathbf{1}$, $\eta_{ij}=\eta(\mathbf{a}_i,\mathbf{a}_j)$. If $\mathbf{a}_1,\ldots,\mathbf{a}_n$ is oriented orthonormal basis, the volume element $\omega=\gamma_1\ldots\gamma_n$ is uniquely determined and $\omega^2=\pm\mathbf{1}$. We will assume that L has fixed orientation. The symmetry of

the metric on L gives rise to some structures on the spinor bundle on L. In order to describe them we need some facts for the classificationof the Clifford algebras.

The first step in the classification and realizations of the Clifford algebras for arbitrary metric is the following statement:[4,5] If $(L_1 \oplus L_2, \eta_1 \oplus \eta_2)$ is an orthogonal direct sum of metric vector spaces (L_1, η_1) and (L_2, η_2) then $\mathrm{Cl}(\eta_1 \oplus \eta_2) = \mathrm{Cl}(\eta_1) \widehat{\otimes} \mathrm{Cl}(\eta_2)$, where $\widehat{\otimes}$ is the $\mathbb{Z}_2$-graded tensor product of the naturally $\mathbb{Z}_2$-graded Clifford algebras. In some exceptional cases the $\mathbb{Z}_2$-graded tensor product may be replaced with the usual tensor product. In our example is realized one of these exceptional cases.

Let $\dim(L) = p+q = 2k$ be even. We say that $\mathrm{Cl}(\eta) > 0$ or $\mathrm{Cl}(\eta) < 0$ if $\omega^2 = +1$ or $\omega^2 = -1$. Let (L_1, η_1) and (L_2, η_2) be vector spaces with metrics η_1 and η_2, and $(L_1 \oplus L_2, \eta_1 \oplus \eta_2)$ be an orthogonal direct sum. Then (see Ref. 4 and 5)

$$\begin{aligned} \mathrm{Cl}(\eta_1) > 0 \Rightarrow \mathrm{Cl}(\eta_1 \oplus \eta_2) = \mathrm{Cl}(\eta_1) \otimes \mathrm{Cl}(\eta_2), \\ \mathrm{Cl}(\eta_1) < 0 \Rightarrow \mathrm{Cl}(\eta_1 \oplus \eta_2) = \mathrm{Cl}(\eta_1) \otimes \mathrm{Cl}(-\eta_2). \end{aligned} \tag{18}$$

Let $\{\mathbf{a}_{1i}\}$, $\{\mathbf{a}_{2j}\}$ be bases in L_1 and L_2. The isomorphisms in (18) are given by

$$\begin{aligned} \gamma_{1i} \otimes \mathbf{1}_2 \mapsto \gamma_i = \vartheta(\mathbf{a}_{1i}, \mathbf{0}), \quad i = 1,2,\ldots,n_1 = \dim(L_1), \\ \omega_1 \otimes \gamma_{2j}, \mapsto \gamma_{n_1+j} = \vartheta(\mathbf{0}, \mathbf{a}_{2j}), \quad j = 1,2,\ldots,n_2 = \dim(L_2). \end{aligned} \tag{19}$$

These isomorphisms give the classification of the Clifford algebras.

For physical reasons we will consider complex spinor fields and we will need a complexification of the Clifford algebra:

$$\mathrm{Cl}^{p,q} \otimes \mathbb{C} = \mathrm{Cl}(L \otimes \mathbb{C}, \eta) = \mathrm{Cl}^n, \quad n = p+q. \tag{20}$$

It is known[4,5] that $\mathrm{Cl}^{2k} \approx M_{2^k}(\mathbb{C})$, $\mathrm{Cl}^{2k+1} \approx M_{2^k}(\mathbb{C}) \oplus M_{2^k}(\mathbb{C})$. In our case the Clifford algebra Cl^{12} is even and thus $\mathrm{Cl}^{12} \approx M_{64}(\mathbb{C})$ has only one simple module. We have the following isomorphisms:

$$\begin{aligned} \mathrm{Cl}^{1,3} \approx M_4(\mathbb{R}), \quad \mathrm{Cl}^{1,3} < 0 \\ \mathrm{Cl}^{0,8} = \mathrm{Cl}^{8,0} \approx M_{16}(\mathbb{R}), \quad \mathrm{Cl}^{0,8} > 0, \quad \mathrm{Cl}^{8,0} > 0. \end{aligned} \tag{21}$$

So we have

$$\mathrm{Cl}^{1,11} = \mathrm{Cl}^{1,3} \otimes \mathrm{Cl}^{8,0} \approx M_4(\mathbb{R}) \otimes M_{16}(\mathbb{R}). \tag{22}$$

Let (E,g) be an oriented even dimensional manifold with metric g, $\mathrm{sign}(g) = (p,q)$. This means that the tangent bundle over E has a cocycle $\psi_{\alpha\beta}(x) \in \mathrm{Aut}(\mathbb{R}^{2k}, \eta) = O(p,q)$. An element $A \in \mathrm{Aut}(\mathbb{R}^{2k}, \eta)$ uniquely determines an element $\widetilde{A} \in \mathrm{Aut}(\mathrm{Cl}^{p,q})$. So $\widetilde{\psi}(x) \in \mathrm{Aut}(\mathrm{Cl}^{p,q})$ is a cocycle which defines the Clifford bundle $\mathrm{Cl}(TE)$ over E. In this bundle the fiber $\mathrm{Cl}(TE)_x$ is the Clifford algebra for the vector space $(T_x(E), g(x))$. The standard fiber of the complex Clifford bundle $\mathrm{Cl}^{\mathbb{C}}(TE)$ is $\mathrm{Cl}^{2k} = M_{2^k}(\mathbb{C})$. A spin$^{\mathbb{C}}$ structure on E is equivalent to a bundle ζ of simple complex modules over the Clifford bundle $\mathrm{Cl}^{\mathbb{C}}(TE)$. We will point out some details in the construction of the complexified bundle ζ because they are important in our later study on the structures arising in ζ. Let $\widehat{L} = \vartheta(L) \hookrightarrow \mathrm{Cl}(\eta)$ be the image of the linear space L in the Clifford algebra. $\vartheta: L \to \widehat{L}$ is an isomorphism and we will identify L and $\widehat{L}$ by means of ϑ. The Clifford group $\mathcal{F}$ is defined by

$$\mathcal{F}^{p,q} = \{c \in \mathrm{Cl}^*(p,q) | c\widehat{L}c^{-1} \subset L\}, \tag{23}$$

where Cl^* is the set of invertible elements. In the complexified case we have similarly

$$\mathcal{F}^{2k} = \{c \in \mathrm{Cl}^{*2k} | c\hat{L}c^{-1} \subset L\}. \tag{24}$$

The linear map $j(c):\hat{L}\to\hat{L}$; $\mathbf{u}\to j(c)(\mathbf{u})=c\mathbf{u}c^{-1}$ is orthogonal and $j:\mathcal{F}\to O(p,q)$ is surjective and gives the exact sequence

$$1 \to \mathbb{C}^* \to \mathcal{F}^{2k} \overset{j^{\mathbb{C}}}{\to} O(p,q) \to \mathbf{1}. \tag{25}$$

And in the real case we have

$$1 \to \mathbb{R}^* \to \mathcal{F}^{p,q} \overset{j}{\to} O(p,q) \to \mathbf{1}. \tag{26}$$

A spin$^{\mathbb{C}}$ bundle ζ is a complex vector bundle on E and each fiber $\zeta_{(\mathbf{x},\mathbf{z})}, (\mathbf{x},\mathbf{z}) \in E = M \otimes G$, is a simple complex module over the algebra $\mathrm{Cl}(T_{(x,z)}E)$. Let $\psi_{\alpha\beta}(x) \in \mathrm{Aut}(\mathbb{R}^{2k}, \eta)$ be a cocycle of $T(E)$ and $\widetilde{\psi}_{\alpha\beta}(x) \in \mathrm{Aut}(\mathrm{Cl}^{2k})$ be the cocycle of $\mathrm{Cl}^{\mathbb{C}}(TE)$. Because the standard fiber of $\mathrm{Cl}(TE)$ is $\mathrm{Cl}^{2k} \approx M_{2^k}(\mathbb{C}) \approx \mathrm{Hom}(\mathbb{C}^{2^k}, \mathbb{C}^{2^k})$, and $\mathbb{C}^{2^k}$ (the standard fiber of the spinor bundle ζ)is the simple module of $M_{2^k}(\mathbb{C})$, the spin$^{\mathbb{C}}$ bundle has a cocycle $\varphi_{\alpha\beta}(x) \in \mathrm{Aut}(\mathbb{C}^{2^k}) \subset M_{2^k}(\mathbb{C}) \approx \mathrm{Cl}^{2k}$ of invertible elements $\varphi_{\alpha\beta} \in \mathcal{F}^{2k}$ and

$$j(\varphi_{\alpha\beta}(x)) = \psi_{\alpha\beta}(x). \tag{27}$$

In general, not every manifold admits a spin$^{\mathbb{C}}$ structure, and even if it admits there may exist different spin$^{\mathbb{C}}$ structures. In our example the base manifold has only one (up to isomorphism) spin$^{\mathbb{C}}$-structure.

The Dirac operator

$$D: C^{\infty}(\zeta) \to C^{\infty}(\zeta) \tag{28}$$

is determined by a linear connection on the spinor bundle and the requirement that its symbol $\sigma(D):T^*(E)\to\zeta^*\otimes\zeta$ be the unique irreducible representation of the Clifford algebra Cl^{2k} at each fiber (see Ref. 6).

In our example we choose E to be a total space of a principal SU(3) bundle over M and M to be isomorphic to $\mathbb{R}^4$ as a topological manifold. We also choose the metric on M to be $g_{\mu\nu} = \mathrm{diag}(-1,1,1,1)$, the basis $\{\mathbf{f}_{\mu}(\mathbf{x})\}$ to be a nonholonomic basis in $T(M)$, and the metric $g_{0kl}(x) = g_{0kl} = \mathrm{diag}(-1,\ldots,-1)$ to be the Killing metric on the Lie algebra $su(3)$. We consider the simplest case in which the "scalar fields" in Kaluza-Klein ansatz are constants.

Because of (11) the direct sum $T(E)=T^h(E)\oplus T^v(E)$ is orthogonal. And from (17)

$$\mathrm{Cl}(TE) = \mathrm{Cl}(T^hE) \otimes \mathrm{Cl}(T^vE), \tag{29}$$

i.e., the standard fiber of $\mathrm{Cl}(TE)$ is $\mathrm{Cl}^{1,3}\otimes\mathrm{Cl}^{0,8}$ in the real (Majorana) case and $\mathbb{C}^4\otimes\mathbb{C}^8$ in the complexified case. So the standard fiber of the spinor bundle ζ is isomorphic to $\mathbb{R}^4\otimes\mathbb{R}^{16}$ in the Majorana case and $\mathbb{C}^4\otimes\mathbb{C}^{16}$ in the complexified case. In the nonholonomic basis (7) of TE according to (19) we have

$$\begin{aligned} &\mathbf{f}_{\mu}(x) \mapsto \gamma_{\mu}\otimes\mathbf{1} \in \mathrm{Cl}(T^h_{(x,z)}E \oplus T^v_{(x,z)}E) = \mathrm{Cl}(T^h_{(x,z)}E, g) \otimes \mathrm{Cl}(T^h_{(x,z)}E, -g_0), \\ &\mathbf{e}_k(x) \mapsto \omega \otimes \gamma_k \in \mathrm{Cl}(T^h_{(x,z)}E \oplus T^v_{(x,z)}E) = \mathrm{Cl}(T^h_{(x,z)}E, g) \otimes \mathrm{Cl}(T^h_{(x,z)}E, -g_0). \end{aligned} \tag{30}$$

In the real case the Levi-Civita connection determines a unique connection on the Majorana spinor bundle. Let ∇ be the Levi-Civita connection for the metric g_E on E and $\mathbf{h}_{\alpha}$ be an orthonormal with respect of g_E nonholonomic basis of TE. If

$$\nabla_{\mathbf{h}_{\alpha}}(\mathbf{h}_{\beta}) \equiv \nabla_{\alpha}(\mathbf{h}_{\beta}) = \Gamma^{E\rho}_{\alpha\beta}\mathbf{h}_{\rho}, \tag{31}$$

then in the real case there is a unique corresponding connection on ζ,

$$\nabla_{\mathbf{h}_\alpha} = \mathbf{h}_\alpha + S_\alpha,$$

$$S_\alpha = -\tfrac{1}{4}\Gamma_\alpha^{E\rho\sigma}\gamma_\rho\gamma_\sigma = -\tfrac{1}{4}\Gamma_{\alpha\rho\sigma}\gamma^\rho\gamma^\sigma, \tag{32}$$

$$\Gamma_{\alpha\beta\sigma} = g^E_{\sigma\rho}\Gamma^\rho_{\alpha\beta}, \quad g^E_{\alpha\beta} = g^E(\mathbf{h}_\alpha, \mathbf{h}_\beta) = \text{const}.$$

If in the complexified case we want to have a soldering between the parallel transport in TE and ζ there remains freedom for the choice of the $U(1)$-connection. In our example we fix the complexification of (32). Then the Dirac operator reads:

$$D = \hat{\mathbf{h}}^\mu\nabla_\mu = g^{E\mu\beta}\hat{\mathbf{h}}_\beta\nabla_\mu = \gamma^{E\mu}(\mathbf{h}_\mu + S_\mu), \quad \hat{\mathbf{h}}^\mu = \vartheta(\mathbf{h}^\mu),$$
$$(D\psi)^a = \gamma^{E\mu}(\mathbf{h}_\mu(\psi^a) + S^a_{\mu b}\psi^b), \quad \psi \in C^\infty(\zeta^{\mathbb{C}}). \tag{33}$$

For the Kaluza-Klein metric we specify $g_{\mu\nu} = g(\mathbf{f}_\mu, \mathbf{f}_\nu) = \text{const} = \text{diag}(-1,1,1,1)$, $g_{0kl} = \text{const} = \text{diag}(-1,\ldots,-1)$. Because $\{\mathbf{f}_\mu\}$ is nonholonomic basis on $T(M)$, "tetrada," g can be an arbitrary metric on M. For simplicity we take the "scalar fields" g_{0kl} to be constant: the Killing form in the Lie algebra $su(3)$. In the global basis $\{\hat{\mathbf{f}}_\mu, \mathbf{e}_k\}$ the metric (10) has the form:

$$\{g^E\} = \begin{pmatrix} -1 & 0 & 0 & 0 & 0 & . & . & 0 \\ 0 & 1 & 0 & 0 & 0 & . & . & 0 \\ 0 & 0 & 1 & 0 & 0 & . & . & 0 \\ 0 & 0 & 0 & 1 & 0 & . & . & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ . & . & . & . & 0 & . & . & 0 \\ . & . & . & . & 0 & . & . & 0 \\ 0 & 0 & 0 & 0 & 0 & . & . & -1 \end{pmatrix}. \tag{34}$$

The coefficients of the Levi-Civita connection of the metric (34)

$$\begin{aligned}
\nabla_{\hat{\mathbf{f}}_\mu}(\hat{\mathbf{f}}_\nu) &= \Gamma^{E\rho}_{\mu\nu}\hat{\mathbf{f}}_\rho + \Gamma^{Ek}_{\mu\nu}\mathbf{e}_k; & \Gamma^E_{\mu\nu\rho} &= g_{\rho\sigma}\Gamma^{E\sigma}_{\mu\nu}, & \Gamma^E_{\mu\nu k} &= -g_{0ki}\Gamma^{Ei}_{\mu\nu},\\
\nabla_{\hat{\mathbf{f}}_\mu}(\mathbf{e}_k) &= \Gamma^{E\nu}_{\mu k}\hat{\mathbf{f}}_\nu + \Gamma^{El}_{\mu k}\mathbf{e}_l; & \Gamma^E_{\mu k\nu} &= g_{\nu\sigma}\Gamma^{E\sigma}_{\mu k}, & \Gamma^E_{\mu kl} &= -g_{0li}\Gamma^{Ei}_{\mu k},\\
\nabla_{\mathbf{e}_k}(\hat{\mathbf{f}}_\mu) &= \Gamma^{E\nu}_{k\mu}\hat{\mathbf{f}}_\nu + \Gamma^{El}_{k\mu}\mathbf{e}_l; & \Gamma^E_{k\mu\nu} &= g_{\nu\sigma}\Gamma^{E\sigma}_{k\mu}, & \Gamma^E_{k\mu l} &= -g_{0li}\Gamma^{Ei}_{k\mu},\\
\nabla_{\mathbf{e}_k}(\mathbf{e}_l) &= \Gamma^{E\mu}_{kl}\hat{\mathbf{f}}_\mu + \Gamma^{Em}_{kl}\mathbf{e}_m; & \Gamma^E_{kl\mu} &= g_{\mu\sigma}\Gamma^{E\sigma}_{kl}, & \Gamma^E_{klm} &= -g_{0mi}\Gamma^{Ei}_{kl}
\end{aligned} \tag{35}$$

are defined in the general case in (16). Because of the form of the metric in (34) the Clifford bundle $\text{Cl}(TE)$ has global generators:

$$\gamma^E_\mu = \gamma_\mu \otimes \mathbf{1}, \quad \mu = 1,2,3,4,$$
$$\gamma^E_k = \omega \otimes \gamma_k, \quad k = 5,\ldots,12, \tag{36}$$

where γ_μ are generators of $\text{Cl}^{1,3}$, γ_k are generators of $Cl^{0,8}$ (30), $\omega = \gamma_1\gamma_2\gamma_3\gamma_4$, $\omega^2 = -1$. After these specifications the Dirac operator (32) and (36) for the Kaluza-Klein metric (10) reads:

$$\begin{aligned}
D &= \gamma^{E\mu}\nabla_{\hat{\mathbf{f}}_\mu} + \gamma^{Ek}\nabla_{\mathbf{e}_k} = (\gamma^\mu \otimes \mathbf{1})(\hat{\mathbf{f}}_\mu + S_\mu) + (\omega \otimes \gamma^k)(\mathbf{e}_k + S_k)\\
&= (\gamma^\mu \otimes \mathbf{1})(\mathbf{f}_\mu - A^k_\mu\mathbf{e}_k) + (\omega \otimes \gamma^k)\mathbf{e}_k\\
&\quad + (\gamma^\mu \otimes \mathbf{1})\left(-\frac{1}{4}\right)(\Gamma^E_{\mu\nu\rho}\gamma^\nu\gamma^\rho \otimes \mathbf{1} + \Gamma^E_{\mu\nu k}(\gamma^\nu \otimes \mathbf{1})(\omega \otimes \gamma^k)
\end{aligned}$$

$$+\Gamma^E_{\mu k\nu}(\omega\otimes\gamma^k)(\gamma^\nu\otimes\mathbf{1})+\Gamma^E_{\mu kl}(\omega\otimes\gamma^k)(\omega\otimes\gamma^l))$$
$$+(\omega\otimes\gamma^k)\left(-\frac{1}{4}\right)(\Gamma^E_{k\mu\nu}\gamma^\mu\gamma^\nu\otimes\mathbf{1}+\Gamma^E_{k\mu l}(\gamma^\mu\otimes\mathbf{1})(\omega\otimes\gamma^l)$$
$$+\Gamma^E_{kl\mu}(\omega\otimes\gamma^l)(\gamma^\mu\otimes\mathbf{1})+\Gamma^E_{klm}(\omega\otimes\gamma^l)(\omega\otimes\gamma^m)). \tag{37}$$

Here $\gamma^\mu=g^{\mu\sigma}\gamma_\sigma$ and $\gamma^k=-g_0^{ki}\gamma_i$. Using (16) we obtain

$$D=(\gamma^\mu\otimes\mathbf{1})(\mathbf{f}_\mu-A^k_\mu\mathbf{e}_k)+(\omega\otimes\gamma^k)\mathbf{e}_k-\frac{1}{4}(\gamma^\mu\otimes\mathbf{1})\left(\Gamma_{\mu\nu\rho}\gamma^\nu\gamma^\rho\otimes\mathbf{1}+F_{\mu\nu k}\omega\gamma^\nu\right.$$
$$\left.\otimes\gamma^k-\frac{1}{2}A^m_\mu(t_{mlk}-t_{mkl})\mathbf{1}\otimes\gamma^k\gamma^l\right)-\frac{1}{4}(\omega\otimes\gamma^k)\left(\frac{1}{2}F_{\mu\nu k}\gamma^\mu\gamma^\nu\otimes\mathbf{1}-A^m_\mu(t_{mlk}+t_{mkl})\omega\gamma^\mu\right.$$
$$\left.\otimes\gamma^l-\frac{1}{2}(t_{klm}+t_{mlk}+t_{mkl})\mathbf{1}\otimes\gamma^l\gamma^m\right). \tag{38}$$

The Dirac operator (38) for the Kaluza-Klein metric (10) acts on spinor fields which have 64 components. Due to (30) the standard fiber of the complex spinor bundle is $\mathbb{C}^4\otimes\mathbb{C}^{16}$.

IV. DIMENSIONAL REDUCTION OF THE DIRAC OPERATOR

We need to specify the action of the symmetry group $G=\mathrm{SU}(3)$ on the spinor bundle. The action $R_g(x,z)=(x,zg)$ on the base $E=M\times\mathrm{SU}(3)$ of the spinor bundle ζ must be lifted to a bundle morphism action on the spinor bundle ζ. This lifting must be in agreement with the action of SU(3) on $T(E)$. More precisely, let $R_\mathbf{g}:(\mathbf{x},\mathbf{z})\to(\mathbf{x},\mathbf{zg})$ be the action of $\mathbf{g}\in G=\mathrm{SU}(3)$ on E. For the Kaluza-Klein metric (10) the tangent lifting $R^T_\mathbf{g}:T_{(\mathbf{x},\mathbf{z})}(E)\to T_{(\mathbf{x},\mathbf{zg})}(E)$ is an isometry. In our trivialization, in the basis $\{\hat{\mathbf{f}}_\mu,\mathbf{e}_k\}$ the tangent lifting $R^T_\mathbf{g}:\mathbb{R}^{12}\to\mathbb{R}^{12}$ is the identity. Let $\mathcal{F}:\mathbb{C}^4\otimes\mathbb{C}^{16}\to\mathbb{C}^4\otimes\mathbb{C}^{16}$be the lifting of the action $L_\mathbf{g}$ to the complexified spinor bundle $\zeta^\mathbb{C}$. $\mathcal{F}_\mathbf{g}$ must satisfy (in the same trivialization)

$$j^\mathbb{C}(\mathcal{F}_\mathbf{g})=R^T_\mathbf{g}=\mathbf{1} \tag{39}$$

with $j^\mathbb{C}$ given from (25). Our purpose is to construct explicitly the simplest example of the Dirac operator with SU(3) symmetry and its reduction to the Dirac operator acting on spinors over four-dimensional manifold. So we fix $\mathcal{F}_\mathbf{g}=\mathbf{1}$ and then the action of $G=\mathrm{SU}(3)$ on spinor fields, i.e., the sections on ζ, is

$$R_\mathbf{g}(\psi)^{\mu a}(\mathbf{x},\mathbf{z})=\psi^{\mu a}(\mathbf{x},\mathbf{zg}). \tag{40}$$

The Dirac operator (38) for the Kaluza-Klein metric (10) is SU(3)-invariant, when the action of SU(3) on spinor fields is specified as in (40). For the invariant spinor fields, from (40) we have

$$R_\mathbf{g}(\psi)^{\mu a}=\psi^{\mu a}\Rightarrow\psi^{\mu a}(\mathbf{x},\mathbf{zg})=\psi^{\mu a}(\mathbf{x},\mathbf{e})\equiv\psi^{\mu a}(\mathbf{x}). \tag{41}$$

The set of all invariant spinor fields $C^\infty(\zeta)_G$ is identified, due to (41), with $C^\infty(\zeta|_{M\times\{e\}})\equiv C^\infty(\zeta|_M)$. The dimensional reduction of the Dirac operator (38) is a restriction of (38) on the set of SU(3)-invariant spinor fields and we obtain the reduced Dirac operator D_r:

$$D_r:C^\infty(\zeta|_M)\to C^\infty(\zeta|_M). \tag{42}$$

To calculate D_r we have to put in (38) a SU(3) invariant spinor field. For invariant spinor fields $\psi^{\mu a}(\mathbf{x})$ we have from (41), $\mathbf{e}_k(\psi^{\mu a})=0$. For the reduced Dirac operator D_r we obtain

$$D_r = (\gamma^\mu \otimes \mathbf{1})\left(\mathbf{f}_\mu - \frac{1}{4}\Gamma_{\mu\nu\rho}(x)\gamma^\nu\gamma^\rho\right) - \frac{1}{8}F_{\mu\nu k}(x)\omega\gamma^\mu\gamma^\nu \otimes \gamma^k + \frac{1}{4}A^m_\mu(x)t_{mlk}\gamma^\mu \otimes \gamma^k\gamma^l + \frac{1}{4}t_{mlk}\omega \otimes \gamma^k\gamma^l\gamma^m, \tag{43}$$

where the coefficients t_{mlk} are totally antisymmetric in all indices. The reduced Dirac operator (43) acts on the sections $\psi \in C^\infty(\zeta|_M)$. The standard fiber is $\mathbb{C}^4 \otimes \mathbb{C}^{16}$. The bundle $\zeta|_M$ is canonically isomorphic to $\zeta^M \otimes \zeta^{\mathrm{SU}(3)}$:

$$\zeta|_M \approx \zeta^M \otimes \zeta^{\mathrm{SU}(3)}, \tag{44}$$

where ζ^M is the (complex) spinor bundle on M and $\zeta^{\mathrm{SU}(3)}$ is a vector bundle on M with standard fiber $\mathbb{C}^{16}$ considered as a simple module of the Clifford algebra $Cl^{0,8}$ corresponding to the Lie algebra $su(3)$ with the Killing metric g. $\{\mathbf{f}_\mu\}$ is a nonholonomic global basis of $T(M)$ and tetrada for the metric g. $\Gamma_{\mu\nu\rho}(x)$ are the components of the Levi-Civita connection of g in the basis $\{\mathbf{f}_\mu\}$ and $-\frac{1}{4}\Gamma_{\mu\nu\rho}(x)\gamma^\nu\gamma^\rho$ are the components of the spinor connection in ζ^M, so

$$D^M = (\gamma^\mu \otimes \mathbf{1})\left(\mathbf{f}_\mu - \frac{1}{4}\Gamma_{\mu\nu\rho}(x)\gamma^\nu\gamma^\rho\right) \tag{45}$$

is the Dirac operator for the metric g acting on spinor fields with isotopic indices. $A^m_\mu(x)$ is a gauge field with values in the Lie algebra $su(3)$ and $F_{\mu\nu k}(x)$ is its curvature tensor. We can write (45) in the form

$$D_r = (\gamma^\mu \otimes \mathbf{1})\left(\mathbf{f}_\mu - \frac{1}{4}\Gamma_{\mu\nu\rho}\gamma^\nu\gamma^\rho + \frac{1}{4}A^m_\mu t_{mkl}\mathbf{1} \otimes \gamma^k\gamma^l\right) - \frac{1}{8}F_{\mu\nu k}\omega\gamma^\mu\gamma^\nu \otimes \gamma^k + \omega \otimes \boldsymbol{\epsilon}, \tag{46}$$

where $\boldsymbol{\epsilon} = \frac{1}{4}t_{klm}\gamma^k\gamma^l\gamma^m$.

The interpretation of (46) is that the reduced free massless Dirac operator for the Kaluza-Klein metric acting on spinor fields with an "isotopic" index on M is equivalent to the usual Dirac operator in the presence of a gravitation field (the metric) and external gauge field with gauge group SU(3), source term depending on the curvature $F^k_{\mu\nu}$ and a mass term $\omega \otimes \boldsymbol{\epsilon}$.

The "isotopic" bundle $\zeta^{\mathrm{SU}(3)}$ in (44) has a standard fiber $\mathbb{C}^{16}$. $\mathbb{C}^{16}$ is the unique simple module of the Clifford algebra $\mathrm{Cl}(su(3), -g_0) = \mathrm{Cl}^{0,8} = M_{16}(\mathbb{R})$. The algebra $su(3)$, as a real vector space, is isomorphic to $\mathbb{R}^8$ and g_0 is the negative defined Killing metric. In the chosen basis $\{\hat{\mathbf{e}}_k\}$ of $su(3)$, $g_0 = \mathrm{diag}(-1, \ldots, -1)$. The group of symmetry of the Killing metric g_0 on $su(3)$ (considered as a vector space, isomorphic to $\mathbb{R}^8$) is $O(8)$. According to the standard procedure,[4,5] the Lie algebra $o(8)$has a complex spinor representation in $\mathbb{C}^{16}$, which is a direct sum of two irreducible representations and $\mathbb{C}^{16} = \mathbb{C}^8 \oplus \mathbb{C}^8$. These representations are realized on the eigenspaces of the operator $\omega_0 = \Pi_{k=4}^{12}\gamma^k$. Let $\rho: O(8) \to \mathrm{End}(\mathbb{C}^{16})$ be the spinor representation, $s \in o(8)$ and $s(\hat{\mathbf{e}}_i) = s^j_i\hat{\mathbf{e}}_j$. Then

$$\rho(s) = -\frac{1}{4}s_{ij}\gamma^j\gamma^j. \tag{47}$$

But the Lie algebra $su(3)$ has a natural adjoint representation: $b \in su(3), ad(b) \in End(su(3) \approx \mathbb{R}^6)$,

$$\mathrm{ad}(\hat{\mathbf{e}}_k)(\hat{\mathbf{e}}_i) = [\hat{\mathbf{e}}_k, \hat{\mathbf{e}}_i] = t^j_{ki}\hat{\mathbf{e}}_j. \tag{48}$$

The adjoint representation "ad" takes values in the Lie algebra $so(8)$, i.e. $\{t_k\} \in so(8)$. So we can take the composition of the two natural representations:

$$\rho \circ \mathrm{ad}: su(3) \to \mathrm{End}(\mathbb{C}^{16}) \tag{49}$$

$$(\rho \circ \mathrm{ad})(\hat{\mathbf{e}}_k) = -\frac{1}{4} t_{kij} \gamma^i \gamma^j.$$

This is a representation of $su(3)$ in $\mathbb{C}^{16}$ which is a direct sum of two eight-dimensional representations of $su(3)$. So the bundle $\zeta^{su(3)}$ on M is a Whitney sum of two eight-dimensional bundles. Due to this fact, the SU(3) invariant spinors, i.e., the sections $C^\infty(\zeta|_M) = C^\infty(\zeta^M \otimes \zeta^{\mathrm{SU}(3)})$ have the natural interpretation as two $su(3)$ spinor octets.

The main result of this paper is that the free massless SU(3)-invariant Dirac operator on the manifold E (the total space of principal SU(3)-bundle on four-dimensional manifold M) after dimensional reduction is equivalent to the Dirac operator on 4-dimensional manifold M, acting on two SU(3) spinor octets, in the presence of gravitational field, external SU(3) gauge field with a source depending on the curvature tensor of the SU(3) gauge field and mass term as it is in (46).

V. COMMENTS

One of the ideas of the "Kaluza-Klein approach" is that a collection of fields with different nature involved in complicated differential equations may be considered as "simple" differential equations for one-type field in a multidimensional case, but having some symmetry, and considered only on the invariant fields. In the spirit of this idea we comment here on the steps in the reduction procedure, where the structures of new type arise. In this example E is 12-dimensional manifold with trivial tangent bundle. For arbitrary metric g_E on E there is just one spinor structure and the spinor fields have 64-components. The group of symmetry $G = \mathrm{SU}(3)$ acts on E as on a total space of a principal bundle. This separate the vertical subbundle $T^v(E) \hookrightarrow T(E)$. The metric under consideration g_E determines a horizontal subbundle $T^h(E) \hookrightarrow T(E)$ as an orthogonal complement of $T^v(E)$. The metric g_E is G-invariant, so the horizontal subbundle $T^h(E)$ is G-invariant and is a linear connection with structure group $G = \mathrm{SU}(3)$. Further, the linear connection in the spinor bundle, coming from the Levi-Civita connection for g_E and needed for the Dirac operator, is expressed interms of this SU(3)-connection. This leads to the appearance of the SU(3) gauge field and its stress tensor. These are classical results for the Kaluza-Klein ansatz. The orthogonal splitting $T(E) = T^h(E) \oplus T^v(E)$ according to the classifying theorem for Clifford algebras leads to the representation (29) and to appearance of spinors on Four-dimensional base manifold after the reduction. The metric in the vertical subspace is the Killing metric. There is a natural adjoint representation of Lie algebra $su(3)$ on itself, orthogonal to the Killing metric and a natural representation of the orthogonal group of the Killing metric on corresponding 16-dimensional spinors. Due to the representations (29), this leads to the appearance of two SU(3) spinor octets after the reduction. Finally, the G-invariance of the spinor fields in the simple case that we consider leads to vanishing of the vertical derivatives and we obtain the reduced operator acting on the fields defined on the Four-dimensional base manifold.

(Received 5 August 2005; accepted 1 June 2006; published online 20 July 2006)

The relations between the different linear problems for Painlevé equations is an intriguing open problem. Here we consider our previously given second and fourth Painlevé hierarchies [Publ. Res. Inst. Math. Sci. (Kyoto) **37**, 327-347 (2001)], and show that they could alternatively have been derived using the linear problems of Jimbo and Miwa. That is, we give a gauge transformation of our linear problems for these two hierarchies which maps those of the second and fourth Painlevé equations themselves onto those of Jimbo and Miwa. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2217647]

I. INTRODUCTION

The discovery of the inverse monodromy transform[1–4] saw the inclusion of the six Painlevé equations amongst the panoply of integrable equations, i.e., of equations solvable using underlying linear problems. Recently, the question of obtaining linear problems for hierarchies of higher order analogues of the Painlevé equations has absorbed the attention of many authors. In particular, in a series of recent papers,[5–8] nonisospectral scattering problems have been used as a means of deriving new completely integrable hierarchies of partial differential equations (PDEs) in $2+1$ and $1+1$ dimensions, and, by reduction, new hierarchies of ordinary differential equations (ODEs), all together with corresponding underlying linear problems.

In Ref. 8 we presented a generalized nonisospectral dispersive water wave hierarchy in $2+1$ dimensions; amongst the reductions to ODEs of this hierarchy we obtained a generalized $P_{\mathrm{IV}}-P_{\mathrm{II}}$ hierarchy which includes as special cases both a hierarchy of ODEs having the fourth Painlevé equation (P_{IV}) as first member, and a hierarchy having the second Painlevé equation (P_{II}) as first member. We believe that the P_{II} hierarchy of Ref. 8 is not equivalent to the standard P_{II} hierarchy given in Refs. 9 and 1. We note in particular that for the first members of these two hierarchies, that is for P_{II} itself, there is no known gauge transformation between their respective linear problems (see the Appendix). We thus believe that both the P_{II} and P_{IV} hierarchies of Ref. 8 were previously unknown.

The aim of the present paper is to explore the relationship between the linear problems for the P_{II} and P_{IV} hierarchies presented in Ref. 8, and other linear problems for these hierarchies. We

[a)]Electronic mail: pilar.gordoa@urjc.es
[b)]Electronic mail: nalini@maths.usyd.edu.au
[c)]Electronic mail: andrew.pickering@urjc.es

give the important result that there exist gauge transformations which map the linear problems for these P_{II} and P_{IV} hierarchies onto two new sequences of linear problems, whose first members are the linear problems of P_{II} and P_{IV} given by Jimbo and Miwa.[3]

II. A SECOND PAINLEVÉ HIERARCHY

One of the hierarchies of ODEs obtained in Ref. 8, as a reduction of a (2+1)-dimensional nonisospectral hierarchy, can be expressed as

$$\mathcal{R}^n \mathbf{u}_x + \sum_{i=0}^{n-2} c_i \mathcal{R}^i \mathbf{u}_x + g_{n+1} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad n \geqslant 1, \tag{1}$$

where $g_{n+1}(\neq 0)$ and each of the c_i are constants. Here $\mathbf{u}=(u(x),v(x))^T$ and $\mathcal{R}$ is the recursion operator of the dispersive water wave hierarchy as given in Ref. 10,

$$\mathcal{R} = \frac{1}{2} \begin{pmatrix} \partial_x u \partial_x^{-1} - \partial_x & 2 \\ 2v + v_x \partial_x^{-1} & u + \partial_x \end{pmatrix}. \tag{2}$$

In Ref. 8, we also gave the following matrix linear problem for the hierarchy (1):

$$\boldsymbol{\Psi}_x = F \boldsymbol{\Psi}, \tag{3}$$

$$\left(\frac{1}{2} g_{n+1} \right) \boldsymbol{\Psi}_\lambda = H_n \boldsymbol{\Psi} = \left[\left(\lambda^n + \sum_{i=0}^{n-2} c_i \lambda^i \right) F + G_n + \sum_{i=1}^{n-2} c_i G_i \right] \boldsymbol{\Psi}, \tag{4}$$

where $\boldsymbol{\Psi}=(\psi_1,\psi_2)^T$ and the matrices F and G_i are given by

$$F = \begin{pmatrix} -\frac{1}{2}(2\lambda - u) & 1 \\ -v & \frac{1}{2}(2\lambda - u) \end{pmatrix}, \tag{5}$$

$$G_n = \begin{pmatrix} -\frac{1}{4}((2\lambda - u)P_n + P_{n,x}) & \frac{1}{2}P_n \\ \frac{1}{2}g_{n+1} + \frac{1}{2}\lambda^n u_x - \frac{1}{2}M_n & \frac{1}{4}((2\lambda - u)P_n + P_{n,x}) \\ -\frac{1}{4}((2\lambda - u)P_n + P_{n,x})_x - \frac{1}{2}vP_n & \end{pmatrix}, \tag{6}$$

and, for $i<n$,

$$G_i = \begin{pmatrix} -\frac{1}{4}((2\lambda - u)P_i + P_{i,x}) & \frac{1}{2}P_i \\ \frac{1}{2}\lambda^i u_x - \frac{1}{2}M_i & \frac{1}{4}((2\lambda - u)P_i + P_{i,x}) \\ -\frac{1}{4}((2\lambda - u)P_i + P_{i,x})_x - \frac{1}{2}vP_i & \end{pmatrix}. \tag{7}$$

In the above, M_i and P_i are given, respectively, by

$$\begin{pmatrix} M_n \\ N_n \end{pmatrix} = \mathcal{R}^n \mathbf{u}_x + g_{n+1} \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \tag{8}$$

$$\begin{pmatrix} M_i \\ N_i \end{pmatrix} = \mathcal{R}^i \mathbf{u}_x, \quad \text{for } i < n, \tag{9}$$

and

$$P_i = \partial_x^{-1} \sum_{j=0}^{i-1} \lambda^{i-1-j} M_j. \tag{10}$$

The compatibility condition of the matrix linear problem (3), (4) is Eq. (1).

Since each member of the dispersive water wave hierarchy is in conservation form, each component of our hierarchy (1) integrates immediately to give

$$\begin{pmatrix} \tilde{M}_n \\ \tilde{N}_n \end{pmatrix} \equiv \begin{pmatrix} \partial_x^{-1} & 0 \\ 0 & \partial_x^{-1} \end{pmatrix} \left[\mathcal{R}^n \mathbf{u}_x + \sum_{i=0}^{n-2} c_i \mathcal{R}^i \mathbf{u}_x \right] + \begin{pmatrix} g_{n+1} x \\ -\delta_n \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \tag{11}$$

where δ_n is one of the constants of integration; our assumption that $g_{n+1} \neq 0$ allows us to set the second constant of integration to zero without loss of generality. It is this hierarchy that is our P_{II} hierarchy; as we shall see, in the case $n=1$, this system of equations yields P_{II} itself. We note, however, that higher order members of this hierarchy are different from those of the P_{II} hierarchy presented in Refs. 9 and 1.

It is a simple matter to write down a linear problem whose compatibility condition gives the hierarchy (11) directly; this is given by the pair of equations

$$\boldsymbol{\Psi}_x = F \boldsymbol{\Psi}, \tag{12}$$

$$\boldsymbol{\Psi}_\lambda = K_n \boldsymbol{\Psi}, \tag{13}$$

where

$$K_n = \frac{1}{g_{n+1}} \left[2H_n + \begin{pmatrix} -\tilde{M}_n & 0 \\ 2\tilde{N}_n & \tilde{M}_n \end{pmatrix} \right] = \begin{pmatrix} (K_n)_{11} & (K_n)_{12} \\ (K_n)_{21} & (K_n)_{22} \end{pmatrix}. \tag{14}$$

Here we have added to H_n in the linear equation (4) a matrix whose entries (being the integrated equations themselves) are identically zero. This matrix is obtained by taking into account the dependence of H_n on the higher order derivatives u_{nx} and v_{nx}, as well as that of $\tilde{M}_n$ and $\tilde{N}_n$ on these derivatives: $\tilde{M}_n \sim (-\frac{1}{2})^n u_{nx}$, $\tilde{N}_n \sim (\frac{1}{2})^n v_{nx}$. The addition of this matrix to H_n in (4) is equivalent to substituting higher order derivatives in H_n in order to obtain as compatibility condition the integrated hierarchy (11) rather than the original hierarchy (1). The compatibility condition of the linear problem (12), (13) is

$$F_\lambda - K_{n,x} + [F, K_n] = R_1 \lambda + R_0 = 0, \tag{15}$$

where

$$(R_1)_{21} = \frac{4}{g_{n+1}} \tilde{N}_n, \quad (R_0)_{12} = \frac{2}{g_{n+1}} \tilde{M}_n, \tag{16}$$

all other $(R_1)_{ij}=0$, and all other $(R_0)_{ij}=0$ modulo $\tilde{M}_n=0$, $\tilde{N}_n=0$.

A. The relationship with the Jimbo-Miwa linear problem for the second Painlevé equation

Let us consider the linear problem for the hierarchy (11) given by the system of equations (12) and (13), where F and K_n are as above. We now consider the gauge transformation

$$\mathbf{\Psi} = M\mathbf{\Phi}, \tag{17}$$

where the matrix M is given by

$$M = \begin{pmatrix} e^{(1/2)s(x)} & 0 \\ 0 & e^{-(1/2)s(x)} \end{pmatrix}, \tag{18}$$

and where $s_x = u$. This maps the linear system (12) and (13) onto

$$\mathbf{\Phi}_x = A\mathbf{\Phi}, \tag{19}$$

$$\mathbf{\Phi}_\lambda = B_n\mathbf{\Phi}, \tag{20}$$

where (noting that $M_\lambda = 0$)

$$A = M^{-1}FM - M^{-1}M_x = \begin{pmatrix} -\lambda & \frac{w}{2} \\ -2\frac{v}{w} & \lambda \end{pmatrix}, \tag{21}$$

$$B_n = M^{-1}K_nM = \begin{pmatrix} (K_n)_{11} & \frac{w}{2}(K_n)_{12} \\ \frac{2}{w}(K_n)_{21} & (K_n)_{22} \end{pmatrix}, \tag{22}$$

and where we have introduced the auxiliary function $w = w(x)$ defined by $w = 2e^{-s}$, and which therefore satisfies the relation $w_x/w = -u$.

Thus we obtain a different sequence of linear problems (19), (20) for the P_{II} hierarchy (11): the first of these is, up to a trivial change of variables (see the next section), the linear problem for P_{II} given by Jimbo and Miwa.[3] We thus obtain the result that the P_{II} hierarchy obtained in Ref. 8 could also have been obtained by expanding in powers of λ (or $\mu = -2\lambda$; again, see the next section) in the Jimbo-Miwa linear problem for P_{II}, i.e., by using an Ablowitz-Kaup-Newell-Segur (AKNS) type approach[11] therein. We now illustrate this remark with some examples.

B. Examples

1. Example n=1

For the case $n = 1$ of the hierarchy (11) we have the system of equations

$$v + \tfrac{1}{2}(u^2 - u_x) + g_2 x = 0, \tag{23}$$

$$uv + \tfrac{1}{2}v_x - \delta_1 = 0. \tag{24}$$

This system is equivalent to the second order ODE,

$$u_{xx} = 2u^3 + 4g_2xu + 2(g_2 + 2\delta_1), \tag{25}$$

which for $g_2 \neq 0$ is just the second Painlevé equation P_{II}. We have the corresponding linear problem given by Eqs. (12) and (13), where

$$F = \begin{pmatrix} -\lambda + \frac{1}{2}u & 1 \\ -v & \lambda - \frac{1}{2}u \end{pmatrix}, \tag{26}$$

$$K_1 = \frac{1}{g_2}\sum_{j=0}^{2} K_{1,j}\lambda^j, \tag{27}$$

and where the matrices $K_{1,j}$ are given by

$$K_{1,2} = 2\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \quad K_{1,1} = 2\begin{pmatrix} 0 & 1 \\ -v & 0 \end{pmatrix}, \quad K_{1,0} = \begin{pmatrix} -v - g_2 x & u \\ uv - 2\delta_1 & v + g_2 x \end{pmatrix}. \tag{28}$$

After the gauge transformation (17) we obtain the linear problem (19), (20) with

$$A = \begin{pmatrix} -\lambda & \frac{w}{2} \\ -2\frac{v}{w} & \lambda \end{pmatrix}, \tag{29}$$

$$B_1 = \frac{1}{g_2}\sum_{j=0}^{2} B_{1,j}\lambda^j, \tag{30}$$

where each $B_{1,j} = M^{-1}K_{1,j}M$, and where w satisfies $w_x/w = -u$. This transformation leads to the introduction of factors $(w/2)$ and $(2/w)$ in the off-diagonal elements of the matrix B_1, as in (22).

If in the linear system (19), (20), with A and B_1 given as above, we set $\lambda = -(\mu/2)$, $v = z/2$, $g_2 = 1/4$, $u = y$ and $4\delta_1 = \alpha - \frac{1}{2}$, then we obtain the linear system for P_{II} as given by Jimbo and Miwa,[3] i.e.,

$$\mathbf{\Phi}_x = \tilde{A}\mathbf{\Phi}, \tag{31}$$

$$\mathbf{\Phi}_\mu = \tilde{B}_1\mathbf{\Phi} \tag{32}$$

with

$$\tilde{A} = \frac{1}{2}\begin{pmatrix} \mu & w \\ -2\frac{z}{w} & -\mu \end{pmatrix}, \tag{33}$$

$$\tilde{B}_1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\mu^2 + \begin{pmatrix} 0 & w \\ -2\frac{z}{w} & 0 \end{pmatrix}\mu + \begin{pmatrix} z + \frac{1}{2}x & -wy \\ \frac{2\alpha - 1 - 2zy}{w} & -z - \frac{1}{2}x \end{pmatrix}. \tag{34}$$

The compatibility condition of the latter gives $w_x = -yw$ and, after elimination of w, the system of equations

$$z_x = -2yz + \alpha - \tfrac{1}{2}, \tag{35}$$

$$y_x = y^2 + z + \frac{x}{2}. \tag{36}$$

These two equations imply that y satisfies P_{II}:

$$y_{xx} = 2y^3 + xy + \alpha. \tag{37}$$

2. Example n=2

In the case $n=2$ of the hierarchy (11) we have the system of equations

$$\frac{1}{4}(u_{xx} - 3uu_x + u^3 + 6uv) + c_0 u + g_3 x = 0, \tag{38}$$

$$\frac{1}{4}(v_{xx} + 3v^2 + 3uv_x + 3u^2 v) + c_0 v - \delta_2 = 0. \tag{39}$$

This system arises as the compatibility condition of the linear problem (12), (13) where F is given by (26) and K_2 by

$$K_2 = \frac{1}{g_3}\sum_{j=0}^{3} K_{2,j}\lambda^j, \tag{40}$$

where the matrices $K_{2,j}$ are as follows:

$$K_{2,3} = 2\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{41}$$

$$K_{2,2} = 2\begin{pmatrix} 0 & 1 \\ -v & 0 \end{pmatrix}, \tag{42}$$

$$K_{2,1} = \begin{pmatrix} -v - 2c_0 & u \\ -v_x - uv & v + 2c_0 \end{pmatrix}, \tag{43}$$

$$K_{2,0} = \begin{pmatrix} -\frac{1}{2}v_x - uv - g_3 x & \frac{1}{2}(u^2 - u_x) + v + 2c_0 \\ \frac{1}{2}(v^2 + uv_x - u_x v) + u^2 v - 2\delta_2 & \frac{1}{2}v_x + uv + g_3 x \end{pmatrix}. \tag{44}$$

After the gauge transformation (17) we obtain the linear problem (19), (20) with

$$A = \begin{pmatrix} -\lambda & \frac{w}{2} \\ -2\frac{v}{w} & \lambda \end{pmatrix}, \tag{45}$$

$$B_2 = \frac{1}{g_3}\sum_{j=0}^{3} B_{2,j}\lambda^j, \tag{46}$$

where as before each $B_{2,j} = M^{-1}K_{2,j}M$. We note that this particular member of our P_{II} hierarchy was also obtained by Kitaev[12] (see the Appendix).

3. Example n=3

In the case $n=3$ the system of equations (11) is

$$\frac{1}{8}(-u_{xxx}+6v^2+2v_{xx}+4uu_{xx}-6vu_x-6u^2u_x+3u_x^2+12u^2v+u^4)+c_1\left(v+\frac{1}{2}u^2-\frac{1}{2}u_x\right)+c_0u+g_4x=0, \tag{47}$$

$$\frac{1}{8}(v_{xxx}+6vv_x+2vu_{xx}+2u_xv_x+12v^2u+4u^3v+6u^2v_x+4uv_{xx})+c_1\left(uv+\frac{1}{2}v_x\right)+c_0v-\delta_3=0. \tag{48}$$

This system arises as the compatibility condition of the linear problem (12), (13), where F is given by (26) and K_3 by

$$K_3=\frac{1}{g_4}\sum_{j=0}^{4}K_{3,j}\lambda^j, \tag{49}$$

and where the matrices $K_{3,j}$ are

$$K_{3,4}=2\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix}, \tag{50}$$

$$K_{3,3}=2\begin{pmatrix}0 & 1\\ -v & 0\end{pmatrix}, \tag{51}$$

$$K_{3,2}=\begin{pmatrix}-v-2c_1 & u\\ -v_x-uv & v+2c_1\end{pmatrix}, \tag{52}$$

$$K_{3,1}=\begin{pmatrix}-\frac{1}{2}v_x-uv-2c_0 & \frac{1}{2}(u^2-u_x)+v+2c_1\\ -\frac{1}{2}(v_{xx}+2v^2+u^2v+2uv_x+u_xv) & \frac{1}{2}v_x+uv+2c_0\\ -2c_1v & \end{pmatrix}, \tag{53}$$

$$K_{3,0}=\begin{pmatrix}-\frac{1}{4}(v_{xx}+3v^2+3u^2v+3uv_x) & \frac{1}{4}(u_{xx}-3uu_x+6uv+u^3)\\ -c_1v-g_4x & +c_1u+2c_0\\ \frac{1}{4}(vu_{xx}+uv_{xx}+3u^2v_x-3uvu_x & \frac{1}{4}(v_{xx}+3v^2+3u^2v+3uv_x)\\ -u_xv_x+3u^3v+6uv^2) & +c_1v+g_4x\\ +c_1uv-2\delta_3 & \end{pmatrix}. \tag{54}$$

Again, after the gauge transformation (17) we obtain the linear problem (19), (20) with

$$A=\begin{pmatrix}-\lambda & \frac{w}{2}\\ -2\frac{v}{w} & \lambda\end{pmatrix}, \tag{55}$$

$$B_3 = \frac{1}{g_4}\sum_{j=0}^{4} B_{2,j}\lambda^j, \tag{56}$$

and where as before $B_{3,j}=M^{-1}K_{3,j}M$.

III. A FOURTH PAINLEVÉ HIERARCHY

We now consider the P_{IV} hierarchy which, together with its linear problem, we introduced in Ref. 8. Without any loss of generality we assume that our P_{IV} hierarchy is of the form

$$\mathcal{R}^n \mathbf{u}_x + \sum_{i=1}^{n-1} c_i \mathcal{R}^i \mathbf{u}_x + g_n \mathcal{R}\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}0\\0\end{pmatrix}, \quad n \geqslant 1, \tag{57}$$

where again $g_n(\neq 0)$ and c_i are constants, and where $\mathcal{R}$ is the recursion operator of the dispersive water wave hierarchy (2). Bäcklund transformations for this hierarchy have been given in Ref. 13. We also note that a detailed singularity analysis of the case $n=2$, which presented certain difficulties, was undertaken in Ref. 14. Here we concentrate on the linear problem for (57), whose matrix form is[8]

$$\mathbf{\Psi}_x = F\mathbf{\Psi}, \tag{58}$$

$$\left(\frac{1}{2}\lambda g_n\right)\mathbf{\Psi}_\lambda = H_n\mathbf{\Psi} = \left[\left(\lambda^n + \sum_{i=1}^{n-1} c_i\lambda^i\right)F + G_n + \sum_{i=1}^{n-1} c_i G_i\right]\mathbf{\Psi}, \tag{59}$$

where $\mathbf{\Psi}=(\psi_1,\psi_2)^T$ and the matrices F, G_n, and G_i for $i<n$, are given by

$$F = \begin{pmatrix} -\frac{1}{2}(2\lambda - u) & 1 \\ -v & \frac{1}{2}(2\lambda - u) \end{pmatrix}, \tag{60}$$

$$G_n = \begin{pmatrix} -\frac{1}{4}((2\lambda-u)P_n + P_{n,x}) & \frac{1}{2}P_n \\ \frac{1}{2}\lambda g_n + \frac{1}{2}\lambda^n u_x - \frac{1}{2}M_n & \frac{1}{4}((2\lambda-u)P_n + P_{n,x}) \\ -\frac{1}{4}((2\lambda-u)P_n + P_{n,x})_x - \frac{1}{2}vP_n & \end{pmatrix}, \tag{61}$$

where

$$\begin{pmatrix}M_n\\N_n\end{pmatrix} = \mathcal{R}^n\mathbf{u}_x + g_n\mathcal{R}\begin{pmatrix}1\\0\end{pmatrix}, \tag{62}$$

$$\begin{pmatrix}M_{n-1}\\N_{n-1}\end{pmatrix} = \mathcal{R}^{n-1}\mathbf{u}_x + g_n\begin{pmatrix}1\\0\end{pmatrix}, \tag{63}$$

$$\begin{pmatrix}M_j\\N_j\end{pmatrix} = \mathcal{R}^j\mathbf{u}_x, \quad \text{for } j < n-1, \tag{64}$$

and

$$P_n = \partial_x^{-1} \sum_{j=0}^{n-1} \lambda^{n-1-j} M_j; \tag{65}$$

and (for $i < n$)

$$G_i = \begin{pmatrix} -\frac{1}{4}((2\lambda - u)P_i + P_{i,x}) & \frac{1}{2}P_i \\ \frac{1}{2}\lambda^i u_x - \frac{1}{2}\widehat{M}_i & \frac{1}{4}((2\lambda - u)P_i + P_{i,x}) \\ -\frac{1}{4}((2\lambda - u)P_i + P_{i,x})_x - \frac{1}{2}vP_i & \end{pmatrix}, \tag{66}$$

where

$$\begin{pmatrix} \widehat{M}_i \\ \widehat{N}_i \end{pmatrix} = \mathcal{R}^i \mathbf{u}_x \tag{67}$$

and now

$$P_i = \partial_x^{-1} \sum_{j=0}^{i-1} \lambda^{i-1-j} \widehat{M}_j. \tag{68}$$

The compatibility condition of the matrix linear problem (58), (59) is Eq. (57).

Again, as in the case of the P_{II} hierarchy discussed in Sec. II, this hierarchy (57) can be integrated. The integrated version of this hierarchy was presented in Ref. 8 and its derivation was given in Ref. 15. A general statement of this integration process can be found in Ref. 16. The integrated form of (57), or equivalently of

$$B_2 \mathbf{K}_n[\mathbf{u}] = 0, \quad B_2 = \frac{1}{2}\begin{pmatrix} 2\partial_x & \partial_x u - \partial_x^2 \\ u\partial_x + \partial_x^2 & v\partial_x + \partial_x v \end{pmatrix}, \tag{69}$$

where

$$\mathbf{K}_n[\mathbf{u}] = \begin{pmatrix} K_n \\ L_n \end{pmatrix} = \mathbf{L}_n[\mathbf{u}] + \sum_{i=1}^{n-1} c_i \mathbf{L}_i[\mathbf{u}] + g_n \begin{pmatrix} 0 \\ x \end{pmatrix}, \tag{70}$$

is

$$\widetilde{M}_n \equiv L_{n,x} - 2K_n - uL_n - (g_n - 2\alpha_n) = 0, \tag{71}$$

$$\widetilde{N}_n \equiv K_{n,x} - \frac{\left(K_n + \frac{1}{2}g_n - \alpha_n\right)^2 - \frac{1}{4}\beta_n^2}{L_n} + vL_n = 0, \tag{72}$$

α_n and β_n^2 being the two arbitrary constants of integration.

A matrix linear problem whose compatibility condition is precisely the integrated hierarchy (71), (72) can easily be given. This can be done, in the same way as for the P_{II} hierarchy, by adding to H_n in the linear equation (59) a matrix whose entries (being the integrated equations themselves) are identically zero. This matrix is obtained by taking into account the dependence of H_n on the higher order derivatives u_{nx} and v_{nx}, as well as that of $\widetilde{M}_n$ and $\widetilde{N}_n$ on these derivatives: $\widetilde{M}_n \sim \left(-\frac{1}{2}\right)^{n-1} u_{nx}$, $\widetilde{N}_n \sim \left(\frac{1}{2}\right)^{n-1} v_{nx}$. We thus obtain the linear problem

$$\mathbf{\Psi}_x = F\mathbf{\Psi}, \tag{73}$$

$$\mathbf{\Psi}_\lambda = K_n\mathbf{\Psi}, \tag{74}$$

where the matrix K_n is given by

$$K_n = \frac{1}{\lambda g_n}\left[2H_n + \begin{pmatrix} \frac{1}{2}\tilde{M}_n & 0 \\ \tilde{N}_n & -\frac{1}{2}\tilde{M}_n \end{pmatrix}\right] = \begin{pmatrix} (K_n)_{11} & (K_n)_{12} \\ (K_n)_{21} & (K_n)_{22} \end{pmatrix}. \tag{75}$$

The compatibility condition of the linear problem (73), (74) is the integrated hierarchy (71), (72):

$$F_\lambda - K_{n,x} + [F,K_n] = S_0 + \frac{1}{\lambda}S_{-1} = 0, \tag{76}$$

where

$$(S_0)_{21} = \frac{2}{g_n}\tilde{N}_n, \quad (S_{-1})_{12} = -\frac{1}{g_n}\tilde{M}_n, \tag{77}$$

all other $(S_0)_{ij}=0$, and all other $(S_{-1})_{ij}=0$ modulo $\tilde{M}_n=0$, $\tilde{N}_n=0$.

A. The relationship with the Jimbo-Miwa linear problem for the fourth Painlevé equation

As for the P_{II} hierarchy discussed in Sec. II, we now consider a gauge transformation of the linear problem (73), (74): we set

$$\mathbf{\Psi} = M\mathbf{\Phi}, \tag{78}$$

where as before

$$M = \begin{pmatrix} e^{(1/2)s(x)} & 0 \\ 0 & e^{-(1/2)s(x)} \end{pmatrix} \tag{79}$$

and $s_x=u$. The linear system (73), (74) is then mapped to

$$\mathbf{\Phi}_x = A\mathbf{\Phi}, \tag{80}$$

$$\mathbf{\Phi}_\lambda = B_n\mathbf{\Phi}, \tag{81}$$

where A and B_n are now

$$A = M^{-1}FM - M^{-1}M_x = \begin{pmatrix} -\lambda & w \\ -\frac{v}{w} & \lambda \end{pmatrix}, \tag{82}$$

$$B_n = M^{-1}K_nM = \begin{pmatrix} (K_n)_{11} & w(K_n)_{12} \\ \frac{1}{w}(K_n)_{21} & (K_n)_{22} \end{pmatrix}, \tag{83}$$

and where we have introduced the auxiliary function $w=w(x)$ defined—differently from in Sec. II—by $w=e^{-s}$, and which therefore satisfies the relation $w_x/w=-u$.

We now consider some examples. In particular we will see how, using the above gauge transformation, the linear problem for the first nontrivial flow of our hierarchy is mapped onto the

linear problem for P_{IV} given by Jimbo and Miwa.[3] This then means that our P_{IV} hierarchy (71), (72) could alternatively have been obtained using an AKNS type approach in the Jimbo-Miwa linear problem for P_{IV}.

B. Examples

1. Example n=1

The first nontrivial flow of the hierarchy (71), (72) consists of the pair of equations

$$u_x = 2v + u^2 + g_1 x u - 2\alpha_1, \tag{84}$$

$$v_x = \frac{\left[v - \alpha_1 + \frac{1}{2}g_1\right]^2 - \frac{1}{4}\beta_1^2}{(u + g_1 x)} - v(u + g_1 x), \tag{85}$$

where α_1 and β_1 are two independent constants of integration. Eliminating v between these equations and performing the change of variables

$$u = y - g_1 x, \tag{86}$$

we obtain

$$y_{xx} = \frac{1}{2}\frac{y_x^2}{y} + \frac{3}{2}y^3 - 2g_1 x y^2 + 2[(g_1^2 x^2/4) - \alpha_1]y - \frac{1}{2}\frac{\beta_1^2}{y}. \tag{87}$$

Setting $g_1 = -2$, which can be done without loss of generality for $g_1 \neq 0$, gives

$$y_{xx} = \frac{1}{2}\frac{y_x^2}{y} + \frac{3}{2}y^3 + 4xy^2 + 2(x^2 - \alpha_1)y - \frac{1}{2}\frac{\beta_1^2}{y}, \tag{88}$$

i.e., P_{IV}. Corresponding to the system (84), (85) we have the linear problem given by Eqs. (73), (74) where

$$F = \begin{pmatrix} -\lambda + \frac{1}{2}u & 1 \\ -v & \lambda - \frac{1}{2}u \end{pmatrix}, \tag{89}$$

$$K_1 = \frac{1}{g_1}\sum_{j=-1}^{1} K_{1,j}\lambda^j, \tag{90}$$

with $K_{1,j}$ given by

$$K_{1,1} = 2\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{91}$$

$$K_{1,0} = \begin{pmatrix} -g_1 x & 2 \\ -2v & g_1 x \end{pmatrix}, \tag{92}$$

$$K_{1,-1}=\begin{pmatrix} -v-\frac{1}{2}g_1+\alpha_1 & u+g_1x \\ -\dfrac{\left[v-\alpha_1+\frac{1}{2}g_1\right]^2-\frac{1}{4}\beta_1^2}{(u+g_1x)} & v+\frac{1}{2}g_1-\alpha_1 \end{pmatrix}. \tag{93}$$

Our gauge transformation then yields the alternative linear problem (80), (81) with

$$A=\begin{pmatrix} -\lambda & w \\ -\dfrac{v}{w} & \lambda \end{pmatrix}, \tag{94}$$

$$B_1=\frac{1}{g_1}\sum_{j=-1}^{1} B_{1,j}\lambda^j, \tag{95}$$

where w satisfies $\frac{w_x}{w}=-u$ and each $B_{1,j}=M^{-1}K_{1,j}M$. This transformation leads to the introduction of factors w and $(1/w)$ in the off-diagonal elements of the matrix B_1, as in (83).

If in the linear system (80), (81), with A and B_1 given as above, we set $\lambda=-\mu$ and choose $g_1=-2$, make the transformation

$$u=y+2x, \tag{96}$$

$$v=-2z+2(\theta_0+\theta_\infty), \tag{97}$$

and redefine the parameters α_1 and β_1 as

$$\alpha_1=2\theta_\infty-1, \tag{98}$$

$$\beta_1^2=16\theta_0^2, \tag{99}$$

we obtain the linear problem

$$\mathbf{\Phi}_x=\widetilde{A}\mathbf{\Phi}, \tag{100}$$

$$\mathbf{\Phi}_\mu=\widetilde{B}_1\mathbf{\Phi}, \tag{101}$$

where

$$\widetilde{A}=\begin{pmatrix} \mu & w \\ \dfrac{2(z-\theta_0-\theta_\infty)}{w} & -\mu \end{pmatrix}, \tag{102}$$

$$\widetilde{B}_1=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\mu+\begin{pmatrix} x & w \\ \dfrac{2(z-\theta_0-\theta_\infty)}{w} & -x \end{pmatrix}+\begin{pmatrix} -z+\theta_0 & -\frac{1}{2}wy \\ \dfrac{2z(z-2\theta_0)}{wy} & z-\theta_0 \end{pmatrix}\frac{1}{\mu}, \tag{103}$$

and where we now have the relation $w_x/w=-y-2x$. The compatibility condition of this linear problem gives this last relation and, after elimination of w, the system of equations

$$z_x = -\frac{2}{y}z^2 - yz + \frac{4\theta_0}{y}z + (\theta_0 + \theta_\infty)y, \tag{104}$$

$$y_x = -4z + y^2 + 2xy + 4\theta_0, \tag{105}$$

which is of course equivalent to P_{IV}. The above linear problem is the linear problem for P_{IV} given by Jimbo and Miwa in Ref. 3.

2. Example n=2

As a further example we give here the results for the second member of our P_{IV} hierarchy (71), (72),

$$u_{xx} = 3uu_x - u^3 - 6uv - 2g_2xu + 2c_1(u_x - 2v - u^2) + 4\alpha_2, \tag{106}$$

$$v_{xx} = 2\left(\frac{\left[uv + \frac{1}{2}v_x + c_1v - \alpha_2 + \frac{1}{2}g_2\right]^2 - \frac{1}{4}\beta_2^2}{v + \frac{1}{2}u^2 - \frac{1}{2}u_x + g_2x + c_1u}\right) - 2(uv)_x - 2v\left(v + \frac{1}{2}u^2 - \frac{1}{2}u_x + g_2x\right) - 2c_1(v_x + uv), \tag{107}$$

where α_2 and β_2 are two independent constants of integration.

Corresponding to the system (106), (107) we have the linear problem given by Eqs. (73), (74) where

$$F = \begin{pmatrix} -\lambda + \frac{1}{2}u & 1 \\ -v & \lambda - \frac{1}{2}u \end{pmatrix}, \tag{108}$$

$$K_2 = \frac{1}{g_2}\sum_{j=-1}^{2} K_{2,j}\lambda^j, \tag{109}$$

with $K_{2,j}$ given by

$$K_{2,2} = 2\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{110}$$

$$K_{2,1} = \begin{pmatrix} -2c_1 & 2 \\ -2v & 2c_1 \end{pmatrix}, \tag{111}$$

$$K_{2,0} = \begin{pmatrix} -v - g_2x & u + 2c_1 \\ -v_x - uv - 2c_1v & v + g_2x \end{pmatrix}, \tag{112}$$

$$K_{2,-1}=\begin{pmatrix} -\frac{1}{2}(2uv+v_x) & \frac{1}{2}(2v+u^2-u_x) \\ -c_1v-\frac{1}{2}g_2+\alpha_2 & +c_1u+g_2x \\ -\dfrac{\left[uv+\frac{1}{2}v_x+c_1v-\alpha_2+\frac{1}{2}g_2\right]^2-\frac{1}{4}\beta_2^2}{v+\frac{1}{2}u^2-\frac{1}{2}u_x+g_2x+c_1u} & \frac{1}{2}(2uv+v_x) \\ & +c_1v+\frac{1}{2}g_2-\alpha_2 \end{pmatrix}. \tag{113}$$

Our gauge transformation then yields the alternative linear problem (80), (81), with

$$A=\begin{pmatrix} -\lambda & w \\ -\dfrac{v}{w} & \lambda \end{pmatrix}, \tag{114}$$

$$B_2=\frac{1}{g_2}\sum_{j=-1}^{2}B_{2,j}\lambda^j, \tag{115}$$

where w satisfies $w_x/w=-u$ and where each $B_{2,j}=M^{-1}K_{2,j}M$.

IV. CONCLUSIONS

We have studied in detail the P_{II} and P_{IV} hierarchies derived in Ref. 8. We have shown that the corresponding linear problems can be mapped on to alternative linear problems such that those for the first members of our hierarchies (i.e., for P_{II} and P_{IV} themselves) are precisely the linear problems given by Jimbo and Miwa.[3] This then means that our hierarchies could alternatively have been obtained by using an AKNS type approach, i.e., expanding in powers of λ, in the Jimbo-Miwa linear problems for P_{II} and P_{IV}. Our work here then raises the interesting problem of whether other Jimbo-Miwa linear problems can be used to obtain hierarchies based on Painlevé equations. This is a topic that we will pursue in subsequent studies.

The work of P.R.G. and A.P. is supported in part by the DGESYC under Contract No. BFM2002-02609 and that of A.P. by the Junta de Castilla y León under Contract No. SA011/04. P.R.G. currently holds a Ramón y Cajal research fellowship awarded by the Ministry of Science and Technology of Spain, which support is gratefully acknowledged. N.J.'s research is supported by Australian Research Council Discovery Grant No. DP0345505. P.R.G. and A.P. thank N.J. for her invitation to visit the University of Sydney in April-August 2005, where this work was completed, and everybody at the School of Mathematics in Sydney for their kind hospitality during their stay.

APPENDIX

In this Appendix we briefly consider the linear problems for P_{II} given in Refs. 1 and 3,

$$\mathbf{\Phi}_t=\mathcal{U}\mathbf{\Phi}, \quad \mathbf{\Phi}_\xi=\mathcal{V}\mathbf{\Phi}, \tag{A1}$$

which we take here in the forms presented in Ref. 17, i.e., respectively in the form of Ref. 1 with

$$\mathcal{U}=\begin{pmatrix} -i\xi & ip \\ -ip & i\xi \end{pmatrix}, \tag{A2}$$

$$\mathcal{V}=\begin{pmatrix} -i(4\xi^2+t+2p^2) & i(4p\xi-\beta/\xi)-2p_t \\ -i(4p\xi-\beta/\xi)-2p_t & i(4\xi^2+t+2p^2) \end{pmatrix}, \tag{A3}$$

or, corresponding to Ref. 3, with

$$\mathcal{U}=\begin{pmatrix} -i\xi & iq \\ -ir & i\xi \end{pmatrix}, \tag{A4}$$

$$\mathcal{V}=\begin{pmatrix} -i(4\xi^2+t+2qr) & 4iq\xi-2q_t \\ -4ir\xi-2r_t & i(4\xi^2+t+2qr) \end{pmatrix}. \tag{A5}$$

The compatibility condition of each of these linear problems yields P_{II} (in the case of (A4), (A5) after integrating twice). The linear problem (A1) with (A4), (A5) is put into standard Jimbo-Miwa form (31)–(34) by making the change of variables

$$q=-\frac{1}{2}i\gamma w, \quad r=-i\gamma\frac{z}{w}, \quad t=\frac{x}{\gamma}, \quad \xi=\frac{1}{2}i\gamma\mu, \tag{A6}$$

and using the relations

$$q_t=\frac{1}{2}i\gamma^2 wy, \quad r_t=-i\gamma^2\left(\frac{\alpha-(1/2)-zy}{w}\right), \tag{A7}$$

where $\gamma^3=-2$. This identification means that our P_{II} hierarchy described in Sec. II could also have been derived beginning with an AKNS type linear problem, which then explains why Kitaev obtained the second member of our hierarchy when seeking to isolate examples of higher order ODEs related to such a linear problem.[12]

It is argued in Ref. 17 that there is no elementary relation between the linear problems given by (A1) with (A2), (A3), and (A1) with (A4), (A5); for example, there is no gauge transformation mapping one into the other. However, while there is no known gauge transformation, we give a general linear problem which encapsulates both Lax pairs. Consider the linear problem (A1) with

$$\mathcal{U}=\begin{pmatrix} -i\xi & iq \\ -ir & i\xi \end{pmatrix}, \tag{A8}$$

$$\mathcal{V}=\begin{pmatrix} -i(4\xi^2+t+2qr) & i(4q\xi-\beta/\xi)-2q_t \\ -i(4r\xi-\beta/\xi)-2r_t & i(4\xi^2+t+2qr) \end{pmatrix}. \tag{A9}$$

The compatibility condition of this linear problem yields the three equations

$$q_{tt}=2q^2r+tq+\beta, \tag{A10}$$

$$r_{tt}=2qr^2+tr+\beta, \tag{A11}$$

$$\beta(q-r)=0, \tag{A12}$$

the third of which tells us that we must either have $q=r$ or $\beta=0$, corresponding to the choices (A2), (A3) and (A4), (A5), respectively. That is, the linear problems with (A2), (A3) and (A4), (A5) are in fact both special cases of (A8), (A9).

(Received 20 September 2005; accepted 1 June 2006; published online 21 July 2006)

We consider the deformations of Whitham systems including the "dispersion terms" and having the form of Dubrovin-Zhang deformations of Frobenius manifolds. The procedure is connected with the B. A. Dubrovin problem of deformations of Frobenius manifolds corresponding to the Whitham systems of integrable hierarchies. Under some nondegeneracy requirements we suggest a general scheme of the deformation of the hyperbolic Whitham systems using the initial nonlinear system. The general form of the deformed Whitham system coincides with the form of the "low-dispersion" asymptotic expansions used by B. A. Dubrovin and Y. Zhang in the theory of deformations of Frobenius manifolds. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2217648]

I. INTRODUCTION

The classical Whitham method[1–4] is connected with the slow modulations of the exact periodic or quasiperiodic solutions of nonlinear PDE's,

$$F^i(\boldsymbol{\varphi},\boldsymbol{\varphi}_t,\boldsymbol{\varphi}_x,\boldsymbol{\varphi}_{tt},\boldsymbol{\varphi}_{xt},\boldsymbol{\varphi}_{xx},\dots)=0,\quad i=1,\dots,n, \tag{1.1}$$

where $\boldsymbol{\varphi}=(\varphi^1,\dots,\varphi^n)$.

It is assumed that the system (1.1) admits the finite-parametric family of exact solutions

$$\varphi^i(x,t)=\boldsymbol{\Phi}^i(\mathbf{k}(\mathbf{U})x+\boldsymbol{\omega}(\mathbf{U})t+\boldsymbol{\theta}_0,\mathbf{U}), \tag{1.2}$$
